Results: Alloimmunization to HLA and to HPA was detected in 70% patients with AA and MDS, 35,5% patients suffering AML, and 15% patients with ALL. Antibody formation depends on disease's forms which range on alloimmunization frequency as follow: AA-AML-ALL. Parallel investigations of HLA antibody formation and HLA genotyping were carried out in 124 patients (39 AA+MDS, 36 ALL, and 49 AML) from whom only 48 made HLA antibodies (20 AA, 22 AML, and 6 ALL). Risk factors for anti-HLA antibody formation were established as HLA-DQB1*02 and HLA-DQB1*03:01 with closely linked genes of superfamily HLA-DRB3*01 (HLA-DRB1*03,-*11,-12,-*13,-*14): 18/20 AA and 13/22 AML patients with anti-HLA and 6/19 AA and 7/27 AML without anti-HLA were HLA-DQB1*03:01 positive (p<0,001 and 0,04 accordingly). Absolute marker of alloimmunization to HLA was haplotype HLA-DRB1*13:03,-DQB1*03:01: 5/20 patients with AA (p=0,047), 4/22 patients with AML (p=0,035) and 3/6 patients with ALL (p=0,01) were positive for this one. 10/22 AML patients with antibodies and 4/27 without those were HLA-DQB1*02 positive (p=0,027). Genes HLA-DRB1*15 and HLA-DQB1*06 had protective effect for anti-HLA antibody formation in AML patients: 13/27 patients without HLA antibodies and 3/22 with antibodies were HLA-DRB1*15 positive (p=0,015); according HLA-DQB1*06 the relation was as 19/27 and 7/22 (p=0,016). Parallel investigations of HPA antibody formation and HLA typing were carried out in 114 patients (46-AA+MDS, 56-ALL, and 12-AML) from whom only 33 made HPA antibodies. We could detect the antibody specifies in 24 patients. Haplotypes of predisposition for specific HPA antibodies formation were determined as follow: to anti-HPA-1b in HPA-1a/1a patients-HLA-DRB1*07:01,-DQB1*02; to anti-HPA-5b in HPA-5a/5a patients-HLA-DRB1*13:01,-DQB1*06 and HLA-DRB1*13:03,-DQB1*03:01, to anti-HPA-2b in HPA-2a/2a patients-HLA-DRB1*15,-DQB1*06:02/*06:14.
Summary and Conclusions: HLA tissue type profiles together with HPA typing will be informative in predicting the alloimmunization in multitransfused patients. It's very important in patients needed long term platelet transfusion support.

E1580

STUDY OF AN ALTERNATIVE PYROGEN TEST FOR BLOOD PRODUCTS USING MONOCYTE ACTIVATION TEST

J.H. Kim[1,*] C.-Y. Ahn[1]
[1]Blood Product Team, National Center for Lot Release, NIFDS, Ministry of Food and Drug Safety, Cheongju-si, Chungcheongbuk-do, Korea, Republic of

Background: Blood product such as plasma derivatives is a drug manufactured by separating plasma protein components. For example, human serum albumin, immunoglobulin, coagulation factor etc. are plasma-derived preparations. Currently the rabbit pyrogen test is practiced for national lot release of final blood derived products. However, the replacement of rabbit test needs to be considered due to the high consumption of animals and ethical issues. While it costs many lives of rabbits, it does not line with the international trend which argues for minimization of animal testing, also represented as 3R. There also has been a need of replacement due to its impossibility in quantification of pyrogen, and also to its sensitivity to condition of animals and technique of examinant.. In this study, we established an assay method of alternative pyrogen test for final blood derived products using monocyte activation test as a quality control.
Aims: The aim of our study was to develop an alternative *in vitro* pyrogen test for final blood derived products.
Methods: Three organizations including MFDS collaborated for this joint research about monocyte activation test. We established the assay protocol of monocyte activation test according to the EP 2.6.30. In this research, human cryopreserved blood was used as a cell source of human monocyte and fever inducing cytokines were measured by ELISA method to determine the pyrogenisity of the samples. Three organizations shared the established protocol

and conducted the monocyte activation test for WHO-endotoxin international standard and representative non-endotoxin pyrogenes from gram positive bacteria, fungi. And then we also applied the assay method to final plasma derived preparations. We confirmed the possibility to replace of the rabbit pyrogen test by conducting the preliminary test.
Results: As a result, we established conditions and test method of monocyte activation test for endotoxin and non-endotoxin pyrogen standards. And we confirmed that not only endotoxin from gram negative bacteria but also non-endotoxin pyrogenes from other origins were detected by monocyte activation test using human cryopreserved blood and cytokine IL-1beta, IL-6 and TNF-alpha ELISA kit. In addition, we conducted monocyte activation test (MAT) based on human fever reaction to study on the possibility of its application to final blood products. Furthermore, data showing that MAT is capable of covering the total pyrogens and applicable to blood derived products.
Summary and Conclusions: By this study of alternative pyrogen test, especially monocyte activation test for national lot release of complete blood products, we predicted substitutability of the rabbit pyrogen test. The results of the research will be used as baseline data for introduction of *in vitro* pyrogen test which is mainly inspected for safety of blood product, and will also contribute to blood product quality improvement. However, further study is needed to confirm that the developed method can be used as an official quality control test.

E1581

INFILTRATION OF PLATELET RICH PLASMA OBTAINED IN OPEN SYSTEM IN PATIENTS WITH EPICONDILITIS

A. García Raso[1,*] A. Fernandez Bravo[2], S. Sanchez[3], T. Arquero[3], B. Gutierrez[2], E. Fontoira[4], M.V. Rodriguez[3], G. Bermejo[2], C. Fernandez[2], P. Llamas [3]
[1]Hematolgy, Health Care Institute Fundación Jiménez Díaz, [2]Rehabilitation, [3]Hematolgy, [4]Radiology, Fundacion Jimenez Diaz University Hospital, Madrid, Spain

Background: There is evidence that the infiltration of PRP improves function and pain in patients with chronic epicondylitis and is an alternative before considering surgical treatment.
Aims: To assess the efficacy and safety of treatment with platelet-rich plasma obtained in an open system in a group of patients with epicondylitis.
Methods: We included patients with a diagnosis of chronic epicondylitis (>6 months) with persistent pain despite proper rehabilitation treatment. All patients had rehabilitation; patients with persistent symptoms after four months were referred to the Interventional Rehabilitation Unit. A shoulder ultrasound was ordered to all patients, to exclude major elbow tendon ruptures and determine the degree of damage. They were evaluated according to the DASH scale before and after infiltration to estimate the results objectively. The infiltration was performed with ultrasound control. PRP was obtained from 12x3ml tubes of PB with 3.2% sodium citrate. Additionally, we obtained blood samples from each patient to carry out serology (HBsAg, anti-HIV type 1 and 2, HCV S, techniques HCV genomic nucleic acid amplification, syphilis, ABO group, regular antibodies). The samples were processed using a two sequential centrifugation, keeping them at room temperature. All manipulations were performed under sterile conditions in laminar flow cabin within a C/D room. The samples were processed immediately after extraction in the Blood Bank.
Results: To date, 12 patients have been treated with PRP. They received a minimum of 1 and a maximum of 3 infiltrations. All patients showed tendon thickening, decreased echogenicity and neovascularization in the ultrasound. In 6 cases intrasubstance rupture was found and one patient had microcalcifications. 9 patients had symptoms improvement (considered as a reduction of at least 25% in the DASH scale), that is 75% of the treated patients. In these 9 patients ultrasound improvement was documented 4 months after the end of the PRP treatment.Only one patient had a minor complication: a presyncopal episode after infiltration without hemodynamic instability. There are no other adverse reactions or complications associated with PRP treatment in the 12 month follow-up.

Figure 1.

Summary and Conclusions: Infiltration with PRP in patients with epicondylitis refractory to conservative treatment is safe and effective and can be considered as an option prior to surgery. In our patients signs of clinical and ultrasound improvement (tendon regeneration mediated by the PRP) was found one month after the first infiltration. Obtaining PRP in an open system has proved safe in the treatment of these patients.

LB2084

PREVALENCE AND TRENDS OF HBV, HCV, AND HIV SEROLOGICAL AND NAT MARKERS AND PROFILES IN SAUDI BLOOD DONORS

W. Elbjeirami[*] H. Al-Jedani[1], N. Arsheed[1], N. Elnagdi[1], H. Abou Eisha[1], A. Abdulwahab[2], N. Abd Alltif[1], E. Hezam[1], F. Al-Allaf[1]
[1]Laboratory and Blood Bank, [2]Hematology Department, King Abdullah Medical City, MAKKAH 21955, Saudi Arabia

Background: Epidemiologic studies on the prevalence of transfusion-transmitted infections (TTIs) in Saudi Arabia (SA) regions are limited.
Aims: This study investigated prevalence of HBV, HCV, and HIV using both serological and nucleic acid testing (NAT) methods to determine temporal and geographic trends among blood donors in Makkah. Our secondary objective was to realize the most suitable NAT format, without compromising sensitivity of NAT results by using individualized or mini-pool testing.
Methods: Serologic and NAT screening records of 22,963 blood donors from January 2011 to December 2014 were evaluated for HBsAg, Anti-HBc, Anti-HCV, Anti-HIV, HBV-DNA, HCV-RNA, and HIV-RNA. Prevalence rates were calculated for TTIs per hundred donations and additional analysis was conducted to examine donor profiles associated with positive serologic and NAT results. Known viral loads (<20 IU/ml for each HBV and HCV and <50 copies/ml HIV) diluted in negative plasma at 1:2, 1:4, 1:6, and 1:8 were evaluated by NAT screening.
Results: The overall serological prevalence of HBs-Ag, anti-HBc, anti-HCV, and anti-HIV were 0.7, 6.7, 0.44, and 0.07%, while molecular HBV-DNA, HCV-RNA, and HIV-RNA overall prevalence were 0.72, 0.05, and 0.03% respectively. There was a gradual decline in percentage of infected donor blood based on combined serological and/or NAT screening from 8.3% in 2011 to 6.8% in 2014 with an overall 7.4% (n=1,689) infected by one or more TTI during the period under study. The prevalence of HBV, HCV and HIV was unevenly distributed among different regions in SA. Analysis of donor serologic and molecular profiles revealed solitary anti-HBc- positive was the highest (6%) donor profile followed by anti-HBc-positive/HbsAg-positive/HBV-DNA positive donor profile at 0.6%, and solitary anti-HCV at 0.4%. Simulation of mini-pool NAT format by dilution of known viral loads at 1:6, resulted in 70% reduction in HBV detection, 50% for HCV, and 40% for HIV.
Summary and Conclusions: This is the first study to provide current data collectively comparing prevalence and trends of HBV, HCV, and HIV serologic and nucleic acid markers amongst Saudi blood donors. Makkah boasts one of the lowest TTIs prevalence in SA and to surrounding countries. The majority of seropositive and NAT-reactive blood donors are in a state of acute, chronic or resolved HBV infection. Individual donor NAT is the ideal methodology that should be applied in SA where diluted samples could compromise clinical sensitivity and blood safety.

LB2093

PLASMA EXCHANGE FOR ACUTE HUMORAL REJECTION OF RENAL ALLOGRAFT AFTER ABO-MATCH KIDNEY TRANSPLANTATION: 5-YEAR EXPERIENCE IN A UNIVERSITY HOSPITAL

I. Parra Salinas[1,*] V. González Rodríguez[1], A. Gutiérrez Dalmau[2], J. Gimeno Lozano[1], J. A. Gracia[1], P. Delgado Beltran[1], J. A. Garcia-Erce[3]
[1]Dept. of Hematology and Hemotherapy, [2]Dept. of Nephrology, Miguel Servet Universitary Hospital, Zaragoza, [3]Dept. of Hematology and Hemotherapy, San Jorge Hospital, Huesca, Spain

Background: Acute humoral rejection (AHR) of renal allograft after ABO-match Kidney Transplantation (KT) is one of the main causes of acute graft dysfunction and had a high risk of allograft loss. This entity often pose challenge to nephrologists and hematologists during practice.
Aims: To analyze the safety and effectiveness of plasma exchange (PE) in patients with AHR in our department.
Methods: Retrospective review of PE procedures carried out over 5 years (2008-2012) in patients with AHR. We collected clinical and analytical data and defined *response* as a reduction greater than 25% from nadir initial values of serum creatinine (SC), *Stable graft function* as decrease of less than 25% or increase over 25% of nadir initial values of SC and *no response* as a rise greater than 25% of values. *Early response*: response with 3 or less procedures of PE. *Graft failure*: restarting of hemodialysis.
Results: 15 patients (8♀y 7♂), median age: 44,64 (29-76) *y-o*. Median time between KT and AHR: 10,8 (0,57-148,7) months. Five patients had also histological findings of Acute Cellular Rejection (n=3), Chronic Humoral Rejection (*n=2*) and Tubular Acute Necrosis (*n=1*). Treatments before PE: monoclonal antibody anti-cd20 in 3 cases (in one case with MTPD bolus). Simultaneous treatments: none (*n=1*), IVIG (*n=1*); IVIG with MTPD bolus (*n=2*); IVIG with anti-cd20 (*n=6*), IVIG, MTPD and anti-cd20 (*n=4*); IVIG, anti-cd20 and Bortezomib (*n=1*). Median procedures done on each patient: 6 (5-12). During this period time 109 procedures were performed, we observed 7 sessions (6,4%) with technique-related adverse events, none of them was severe. One patient achieved *Response* and eleven *Stable graft function*. These 12 patients had the highest values of serum creatinine before PE (3,5 mg/dL *vs* 2,2 mg/dL, *p=0,041*) and a late development of AHR (38,3 *vs* 4,7 months after KT,

p=0,035). Variables related with better responses were, initial hypertension (*p=0,046*) and immunosuppressive *therapy* before PE (*p=0,024*). At the end of follow up, eight sustained graft function. Five patients reached *early response*. These patients were mainly women (57,1%), all of them had hypertension and more than 2 antibodies (see Table) in the immunohematological study before PE. At the end of follow up, three of them sustained graft function. After PE, all patients had immunosuppressive *therapy* (Tacrolimus, MF and Prednisone) and in one case, there was necessary to add a dose of anti-cd20. Only in two cases, antibodies turned negative after PE (1 for Class I and 1 for Class II). Random urine Protein/Creatinine ratio was normal in all patients before and after PE. There were no important differences between values of white blood cells, hemoglobin, platelet count, pH or albumin before and after PE. During 2,7 (0,21 - 6,24) years of follow up, three patients died (1 of unknown cause and 2 of infectious cause), one of them with functional graft. One out of 12 patients alive, had been transplanted for a second time (32 months after PE completion), and 33,3% had graft failure. Other abbreviations used (alphabetical order): Abs: Antibodies, DSA: Donor specific antibodies, IGIV: Intravenous Immunoglobulin, MF: Mycophenolate, MTPD: Methylprednisolone.

Table 1. Immunohematological study previous and after plasma exchange (PE).

Immunohematological study previous and after Plasma Exchange (PE)

	Previous PE			After PE		
	Abs Anti Class I	Abs Anti Class II	Abs Anti-MICA	Abs Anti Class I	Abs Anti Class II	Abs Anti-MICA
Global series						
Positive	10	11	4	9	11	4
DSA	6	4				
No DSA	4	7				
Negative	5	4	11	6	3	10
No data	0	0	0	0	1	1
Patients with response	7 (3 DSA)	9 (2 DSA)	2	6	9 No data: 1	2 No data: 1
Patients with early response	5 (2 DSA)	5 (1 DSA)	2	4	5	2

Abs: antibodies. DSA: Donor specific antibodies. MICA: Major-histocompatibility-complex class I-related chain A antigens.

Summary and Conclusions: Eighty percent of our series achieved response and 33% of them in an early way. These results are maintained long-term. Therefore, although AHR is a serious complication for transplant recipients, PE improve results regards renal graft survival, and is a safe therapeutic method. In addition, we observed that there is no correlation between response and the presence of antibodies in the immunohematological study.

GENE THERAPY USING TRAIL-SECRETING HUMAN ADIPOSE TISSUE DERIVED MESENCHYMAL STEM CELLS (AD-MSCS) AGAINST LEUKEMIA

S. Solali[1,*] S. Kaviani[2], M. soleimani[2]
[1]Tabriz University of Medical Science, Tabriz, [2]Tarbiat Modares University, Tehran, Iran

Background: Mesenchymal Stem Cells (MSCs) are a group of adult stem cells naturally found in the body. These cells were reported from many sources. Bone marrow and adipose tissue are two main sources of human MSCs. MSCs have attracted considerable attention in the fields of cell and Gene Therapy due to their intrinsic characteristics and ability to differentiate into multiple lineages. Whereas BM has been the first recognized source of MSC, adipose tissue represents a valid reservoir of mesenchymal progenitors. Adipose tissue can be obtained in relevant amount and easily processed to release large numbers of adipose-derived MSC (AD-MSC). These cells may offer efficient tools for cell-based Gene Therapy approaches.
Aims: In this study, we evaluated whether AD-MSC could deliver TRAIL for leukemic cells treatment and induce apoptosis in leukemic cells.
Methods: Human AD-MSCs were isolated, characterized and transduced with a lentiviral vector encoding secretory tumor necrosis factor-related apoptosis-inducing ligand (TRAIL). TRAIL protein production verified by western blotting. TRAIL-ADMSCs were Co-cultured with HL-60 and AML-M3 patients MNCs. Apoptosis induction was studied by flow cytometry using annexin-FITC. We also studied MSCs migration potential by Trans-Well method.
Results: In coculture experiment of TRAIL secreting MSCs with leukemic cells we observed TRAIL-AD-MSC targeted HL-60 cells and AML-M3 mononuclear cells (MNCs). We observed significant apoptosis inducing potential by TRAIL-ADMSC in HL-60 cells and AML patients' mononuclear cells (MNCs) compared to control once (P<0.05). Maximum apoptosis induction in HL-60 cells was 25% which shows most of these cells have resistance to TRAIL induced cell death. Whatever in patients MNCs maximum induction of apoptosis was 45%. *in vitro* coculture experiments on Trans-well plate's migration assays showed that HL-60 cells culture but not FBS lacked growth media, supported the migration of hMSCs and enhanced their migration (P<0.05).
Summary and Conclusions: We found that stably TRAIL transduced ADMSCs could serve as constant source of TRAIL production. However this treatment modality didn't completely induced apoptosis in all HL-60 or MNCs nevertheless it indicate needs for finding cotreatments appropriate to type of resistance mechanism. We also observed that leukemic cells are able to production and releasing cytokines which cause migration of AD-MSCs toward leukemic cells and also AD-MSCs have relevant receptors on the cell surface to respond such cytokines. In conclusion these results suggest that human AD-MSCs have potential use as effective delivery vehicles for therapeutic genes in the treatment of hematologic malignancies.

PB1585

PEDIATRIC TEL-AML1-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS SHOW INCREASED MN1 EXPRESSION

M. D. Yener[1,*] M. Numata[2], S.S. Ekmekçi[3], M. Aydın[3], G. Grosveld[2], U. Özbek[3], Ç. Güleç[4], S. Anak[4], S. Karaman[4], G. Öztürk[5], M. Akbıyık[5], A. Kandilci[1]
[1]Molecular Biology and Genetics, Gebze Technical University, Gebze, Kocaeli, Turkey, [2]Genetics, St. Jude Children's Research Hospital, Memphis, United States, [3]Department of Genetics, Institute for Experimental Medicine, [4]Pediatric Hematology Division, Istanbul Medical Faculty, [5]Medical Park Hospitals, İstanbul, Turkey

Background: The *MN1* (Meningioma 1) gene is overexpressed in certain subtypes of acute myeloid leukemia (AML), including patients carrying translocations inv(16)(CBFB-MYH11) and t(8;21)(AML1-ETO) which target the core-binding factor (CBF) transcription factor complex. In consistence, ectopic *MN1* expression in mouse bone marrow (BM) cells cultured under myeloid conditions results in increased myeloid colony forming activity and myeloid leukemia. Despite this growing body of evidence describing *MN1's* involvement in AML development, it is unknown if *MN1* also plays a role in the pathogenesis of lymphoblastic leukemia.
Aims: We aimed to determine expression level of *MN1* in pediatric B-ALL as well as effect of ectopic *MN1* expression on primary mouse Pro B/pre B-cells *in vitro*.
Methods: Engogenous *MN1* expression in BM samples of 73 pediatric B-ALL patients and healthy controls (n=9), as well as in FACS isolated primary mouse pro B/pre B-cells, were analyzed using RT-qPCR. *MN1* was overexpressed in mouse pro B/pre B-cells using retrovirus and followed by methocult assays.
Results: Here we showed that compared with control BM, *MN1* expression was increased (2-fold or more) in 29 out of 73 (40%) pediatric B-ALL patient BM. Additional analysis of *MN1* expression in sub-groups within our cohort carrying different chromosome translocations showed that carriers of t(12;21)(TEL-AML1) (n=27), targeting CBF, expressed significantly more *MN1* than both healthy controls (P=0.02) and the group carrying the t(9;22)(BCR-ABL) (n=9) (P=0.001). In addition, there was a trend of increased *MN1* expression in TEL-AML1^{positive} patients (18 out of 27) as compared with patients that are negative for this translocation (n=30). Retroviral *MN1* overexpression increased the colony forming activity of mouse Pro B/Pre B cells *in vitro*.
Summary and Conclusions: Our results suggest that deregulated *MN1* expression contributes to the pathogenesis of pediatric B-ALL. Further investigation into the clinical and biological significance of elevated *MN1* expression in TEL-AML1^{positive} leukemia might provide insight into additional molecular mechanisms contributing to B-ALL and may lead to improved treatment options for patients.

PB1586

SCREENING FOR VARIATIONS IN EXONS 9, 10 AND 12 OF CD22 GENE IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

D. Aslar[1,*] D.F. Akın[1], M. Mumcuoglu[1], U. Ezer[2], E. Kurekci[2], N. Akar[3]
[1]Lösante Cancer Research and Genetics Laboratory, [2]Lösante Hospital, [3]TOBB ETU Hospital, Ankara, Turkey

Background: CD22, a B cell specific transmembrane protein, have commonly seen in hematological malignancies and plays a role in B cell survival, proliferation, and differentiation via B-cell receptor (BCR). BCR is an inhibitory co-receptor of B cells and B cell precursors that acts as a negative regulator of multiple signal transduction pathways critical for B cells. CD22 signaling is mediated through interactions with kinases and phosphatases which connect the cytoplasmic domain via phosphorylated tyrosine residues that locate within TAM and TIM motifs. CD22 protein SHP-1 (Src homology 2 domain-containing tyrosine phosphatase) function deficient mice showed disruption of the SHP-1 signaling network that can result in defective maturation in development of B-cell lymphoproliferative state and apoptosis. Studies of human CD22 demonstrated that its variations could cause CD22 molecule with inadequate functional and disturbance of mRNA expression. CD22 is expressed in 90% of chronic lymphoblastic leukemia patients, in 60-70% of B cell lymphoma patients, in 100% of hairy cell leukemia patients, in 96% of childhood acute lymphoblastic leukemia patients. Precursor B Cell Acute Lymphoblastic Leukemia (precursor B-ALL) the largest subset of acute lymphoblastic leukemia (ALL), is the most common form of childhood cancer. B cell expression of CD22 makes this a great target for the treatment of leukemia. CD22 that is located on chromosome 19q24 contains 14 exons. Studies by using DNA sequencing method were detected several homozygous mutations (transversions/transitions, deletions, and insertions) between exon 12 and intron 13 in CD22 gene and this region was called "mutational hotspot".

Tabella 1. Charcaterization of the variants in CD22 gene.

rs Number	Nucleotide Change	Localization	Amino acid change
Novel	T 2199 G	Intron 10	-
rs4805119	A2538G	Intron 12	-
rs4805120	A2646G	Intron 12	-
rs10413526	C2642G	Intron 12	-
rs10406539	G2557A	Intron 12	-
rs10413500	C2612G	Intron 12	-
rs10406069	G2318A	Exon 12	Gly-Asp

Aims: In this study we aimed to screen exon 9, 10 and 12 of CD22 gene that is mutational hotspot region in children with precursor B-ALL and to find possible genetic variations for molecular hematological analysis in childhood ALL.
Methods: In this study we aimed to screen exon 9, 10 and 12 of CD22 gene that is mutational hotspot region in children with precursor B-ALL and to find possible genetic variations for molecular hematological analysis in childhood ALL. Study population consisted of 115 patients aged between 1 and 15 years who were admitted to Lösante Hospital with the diagnosis of precursor B-ALL. Blood samples were collected with EDTA-containing tubes and DNA was extracted from peripheral blood and bone marrow leukocytes with MagNA Pure automatic DNA isolation instrument (Roche Diagnostics, Manheim, Germany). Amplification of gene was performed by PCR and all samples were screened

for the variants by SSCP. Samples showing band shifts were directly sequenced on an automated sequencer (Beckman Coulter, USA).
Results: We detected 7 variants in CD22 gene in our study population. There were no variants at exon 9. We report a novel mutation at exon 10 of CD22 (T2199G). The most of CD22 variants were described in exon 12; intron A2538G (rs4805119), intron A2646G (rs4805120), intron C2642G (rs10413526); intron G2557A (rs10406539); intron C2612G (rs10413500); exon G2318A (rs10406069). Table 1 shows summary of CD22 variant profiles.
Summary and Conclusions: The detected variants in this study seem to be the first screening results of studied gene in childhood precursor B-ALL patients in our country. Identified variants in the CD22 exons encoding the cytoplasmic domain could disturb mRNA stability and splicing mechanism of gene. Thus, a truncated CD22 protein or reduced expression levels of an intact protein might lead to development of leukemia. These results need to be confirmed by further exons on a larger number of patients.

PB1587

COMPARISON OF THE IMMUNOPHENOTYPE OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA AT DIAGNOSIS AND RELAPSE

E. Zengin[1,*] S. Aylan Gelen[1], S. Çakı Kılıç[1], U. Demirsoy[1], M. Karadoğan[1], G. Gacar[2], G. Beyazıt[2], N. Sarper[1]
[1]Pediatric Hematology, [2]Stem Cell and Gene Therapies Research/Aplied Center, Kocaeli University, Kocaeli, Turkey

Background: Lineage switch was reported in relapsed acute leukemia.
Aims: Leukemia-associated immunophenotypes in patients with acute lymphoblastic leukemia (ALL) at diagnosis and relapse were investigated.
Methods: The immunophenotype of leukemia cells from 28 relapsed patients at diagnosis and relapse was detected by four-color flow cytometry (FCM). Isolated testicular relapse was excluded. Antibodies used in the panel were CD2, CD3, cyCD3, CD5, CD7, CD13, CD14, CD15, CD33, CD10, CD19, CD20, CD22, cyCD79a, CD34, CD117, MPO, TdT, glicophorin A, CD41 and HLA-DR. The classification was according to the European group for the immunologic group. Cut-off for positive antigens was ≥20%.
Results: Mean age at the diagnosis was 7.57±4.32 years and 71.43% (n=20) of the patients were male. Median time from diagnosis to relapse was 25 months (6 -138 months). According to BFM criteria 11, 9 and 8 patients had very early, early and late relapse, respectively. Sites of relapse were isolated bone marrow in 19, bone marrow and testis in 5, bone marrow and central nervous system (CNS) in 3 and isolated CNS in 1 patient. At presentation precursor B-ALL, T-ALL, and mix lineage leukemia was detected in 21, 3 and 4 patients respectively. Immunophenotypic switch occurred in 28.57% (n=8) of the relapsed patients (two patients from precursor B-ALL to T-ALL, three patients from precursor B-ALL to mix lineage leukemia, one patient from precursor B-ALL to AML-M5; and of the two patients with mix lineage leukemia one switched to precursor B-ALL and the other to T-ALL). There was no relation between immunophenotypic switch and site and time of relapse. HLA-DR expression decreased at relapse (50.99±32.01% at diagnosis, 38.67±27.4% at relapse, P=0.029). However, CD33 and TdT expression increased at relapse (CD33 from 34.02±32.26% to 58.05±31.28% and TdT from19.83±24.84% to 44.0934.86±%; p values were 0.006 and 0.031, respectively.
Summary and Conclusions: There are many hypotheses in lineage switch as physiological plasticity of the original clone or emerging of a new clone or expansion of secondary clone after eradication of the dominant clone by chemotherapy. In the present study, immunophenotypic switch was detected about one fourth of the patients at relapse. In addition, there were significant differences in the expression levels of HLA-DR, CD33 and TdT. Their clinical implications require further study.

FREQUENCY OF COPY NUMBER ABNORMALITIES IN COMMON GENES ASSOCIATED WITH BCP-ALL CYTOGENETIC SUBTYPES IN BRAZILIAN CHILDREN

T.C. Barbosa[1,*] C.F.G. Andrade[1], E.T.P. Granado[1], I. M.Q. Magalhaes[2], G.R. Neves[3], A. Gadelha[4], G.*e.g.* Filho[5], M.S. Souza[6], R. Melaragno[7], M. Emerenciano[1], M.S. Pombo-de-Oliveira[1]
[1]Pediatric Hematology-Oncology Program, Instituto Nacional de Câncer, INCA-RJ, Brazil, Rio de Janeiro, [2]Hospital da Criança José Alencar, Brasília, [3]Hospital Sarina Rolin, São Paulo, [4]Hospital Napoleão Laureano, [5]Instituto de Hematologia da Paraíba, João Pessoa, [6]Hospital Regional de Mato Grosso do Sul, Campo Grande, [7]Hospital Santa Marcelina, São Paulo, Brazil

Background: Copy number alterations (CNAs) in genes committed to B-cell precursors have been associated with poor survival in subgroups of B-cell precursor acute lymphoblastic leukemia (BCP-ALL).
Aims: Therefore, the aim of this study was to determine the frequency of gene deletions and the significance of copy number alterations in *IKZF1*, *CDKN2A/B*, *PAX5*, *EBF1*, *ETV6*, *BTG1*, *RB1*, *CSF2RA*, *IL3RA* and *CRLF2* within a cohort of Brazilian pediatric BCP-ALL patients.
Methods: Bone marrow and peripheral blood aspirates samples from 274 BCP-ALL patients were analyzed prior to any oncological treatment (period 2004-2011). The inclusion criteria were the quality of the frozen diagnostic material, having at least 30% blast cells, patients with ≤18 years old at the time of BCP-ALL diagnosis. The exclusion criteria were acute leukemia in children with Down syndrome, samples collected in heparin, and DNA of insufficient quality. DNA was analyzed by the SALSA multiplex ligation-dependent probe amplification (MLPA) kit (P335-A4). *IKZF1* deletion results were confirmed using a P202 *IKZF1* SALSA MLPA kit. The age at diagnosis and white blood cell (WBC) count were the criteria for assigning prognostic risk of ALL, according to the National Cancer Institute (NCI). The disease risk associated with CNA occurrence across overall and subgroups of patients was determined by calculating odds ratios (ORs) with a 95% confidence interval (CI). Overall survival (OS) was defined as the time from diagnosis to last event (death or alive). The OS analysis were obtained by the Kaplan-Meier method and log-rank test.
Results: Deletions/amplifications in at least one gene were identified in 83% of the total series. In children older than two years, there was a predominance of CNAs involving deletions in *IKZF1*, *CDKN2A* and *CDKN2B*, whereas *IL3RA* and *CSF2RA* had deletions that were found more frequently in infants ($P<0.05$). Multiple gene deletions occurred in the same patients. Sixty-three patients had both *CDKN2A* and *CDKN2B* deletions ($P<0.01$). Deletions of *CDKN2A* and *CDKN2B* also coincided significantly with deletions in *PAX5* ($P<0.01$) and *IKZF1* ($P<0.05$). *IKZF1* deletions were also found concomitantly with *BTG1* and *EBF1* deletions ($P<0.05$ and $P<0.01$, respectively). *ETV6* deletions overlapped with *PAX5*, *BTG1*, *EBF1* ($P<0.01$) and *CRLF2* deletions ($P<0.05$). Based on the cytogenetic subgroups, favorable cytogenetic subgroups (*i.e. ETV6-RUNX1* and hyperdiploiy) showed more deletions than other subgroups, specifically *ETV6* deletions ($P<0.05$). *TCF3-PBX1* was frequently deleted in *RB1*, and an absence of deletions was observed in *IKZF1* and genes localized to the *PAR1* region. *IKZF1* deletions ($P=0.01$, 30.2 months, 95% CI 8.5-52.0) and *RB1* deletions ($P<0.01$, 16.8 months, 95% CI 0.0-46.1) confered poorer OS to standard risk patients.
Summary and Conclusions: The results corroborate previous genome-wide data and are an important validation of the impact of *IKZF1* deletions in the prognosis of BCP-ALL. The obtained results emphasize the need for including screening of submicroscopic alterations as additional markers for risk stratification, especially in standard risk patients.

PB158

PROGNOSTIC VALUE OF GLUCOCORTICOID RECEPTOR GENE POLYMORPHISMS AND MRNA EXPRESSION IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA.

A. Bedewy[1,*] S. Elmaghraby[1], W. Elbendary[2]
[1]Hematology, Alexandria University, Alexandria, [2]Clinical Pathology, Military Medical Academy, Cairo, Egypt

Background: Therapeutic protocols used in adult acute lymphoblastic leukemia (ALL) are widely variable. However, glucocorticoids (GC) are essential components in its treatment. The antineoplastic actions of glucocorticoids can be partially attributed to glucocorticoid-induced apoptosis.
Aims: The aim of this study was to evaluate the distribution of the 3 prominent glucocorticoid receptor gene polymorphic variants (*Bcl*I, *N363S*, and ER22/23EK) among controls and Philadelphia-negative adult ALL patients. In addition, we aimed to investigate the association between glucocotiocid receptor mRNA isoforms expressions and the response to induction chemotherapy in the studied patients.
Methods: Fifty-two adults with newly diagnosed Philadelphia-negative ALL, aged 18 to 75 years and 30 healthy control subjects were enrolled in this study. Genotyping of *Bcl*I, *N363S*, and *ER22/23EK* polymorphisms was carried out by polymerase chain reaction restriction fragment–length polymorphism. Glucocotiocid receptor mRNA isoforms expressions were assayed by quantitative real time PCR.
Results: Fifty-two newly diagnosed Philadelphia-negative adult ALL patients were enrolled with a median age of 34 years (range 18-75). They were 35 (67.3%) males and 17 (32.7%) females. The incidences of *BclI, N363S*, and *ER22/23EK* polymorphic variants were 44.2%, 5.8% and 1.9% among patients and were 33.3%, 6.7% and 6.7% among controls, respectively with no statistically significant difference. The allelic frequencies of the mutant allele of *Bcl*I, *N363S*, and *ER22/23EK* polymorphisms in patients were 0.15, 0.02, and 0.004, respectively. The different genotypes of the polymorphisms were not related to glucocorticoid resistance. No association was found between the studied parameters and the expression of beta glucocorticoid receptor (GR) isoform. The alpha GR expression was associated with complete remission (P=0.03). Compared to GC sensitive patients, the expression of gamma GR mRNA was significantly higher in GC resistant patients (P=0.032). Moreover, the expression of gamma GR mRNA was significantly higher in non-responders *versus* responder patients(P=0.019).
Summary and Conclusions: The *BclI* polymorphic variants of the GR gene are the most frequent compared to *N363S* and *ER22/23EK* polymorphisms in Philadelphia-negative adult ALL patients. Polymorphisms of the GR gene were not associated with the sensitivity to glucocorticoids. Higher alpha GR and

lower gamma GR expressions were associated with achievement of complete remission while higher expression of gamma isoform was associated with glucocorticoid resistance. Our data suggest that pretreatment glucocorticoid receptor isoforms expression levels can be useful in predicting response to glucocorticoids and in anticipating achievement of complete remission in Philadelphia-negative adult ALL patients.

PB1590

EFFECTS OF SIRT6 INHIBITORS ON ACUTE LYMPHOBLASTIC T CELL LEUKEMIA

S. Boero[1,*] A. Poggi[2], A. Nencioni[1]
[1]Dipartimento di Medicina Interna e Specialità Mediche DIMI, Università degli Studi di Genova, [2]2Unit of Molecular Oncology and Angiogenesis, IRCCS AOU San Martino-IST, Genoa, Italy

Background: Sirtuins are NAD(+)-dependent deacetylases with documented roles in gene expression, metabolic pathways, apoptosis, cell survival, DNA repair, development, inflammation, and healthy aging. SIRT6 is a sirtuin family member which has been implicated in the control of glucose uptake and metabolism, cell metabolism, genomic stability and DNA repair, and in inflammation. Aside for the observation that SIRT6 chromosomal locus is a region prone to chromosomal breaks in human acute myeloid leukemia, no data are available concerning the possible involvement of SIRT6 in leukemogenesis.
Aims: Herein, we have selected a series of novel and specific quinazolinedione small molecules SIRT6 inhibitors named S602, S603, and S610 and we have analyzed their *in vitro* effects on the T-ALL cell line Jurkat upon stimulation with anti-CD3/CD28 antibodies coated immunomagnetic beads to mimic tumor microenvironment signaling of the T-ALL cells.
Methods: After 24, 48 and 72 hours of stimulation in presence or absence of SIRT6 inhibitors we performed: a) a viability test with propidium iodide to determine whether these inhibitors affect cell survival; b) an assay for evaluating the content of ATP to determine whether the inhibitors alter the mitochondrial metabolic activity and therefore proliferation; c) an ELISA for TNF-α released on harvested supernatants
Results: We found that none of these inhibitors induced cell death or inhibited cell proliferation at concentrations raging between 10 and 100 μM. On the contrary, a strong and concentration dependent inhibition of TNFα production triggered by CD3 and CD28 co-engagement was observed. Notably, a marked reduction in intracellular ATP levels in Jurkat cells treated with the SIRT6 inhibitors could also be detected after a 72 h incubation.
Finally, SIRT6 inhibition resulted in a decrease in TNFα production in Jurkat cells line triggered through CD3 and CD28 co-engagement
Summary and Conclusions: Altogether, these findings suggest that inhibitors of SIRT6 can selectively affect the synthesis of ATP and thus the metabolic state of T-ALL cells. These inhibitors could be an useful tool when used together with pro-apoptotic anti-blastic drugs because of their complementation activity, affecting different molecular targets that are relevant for T-ALL cell growth.
In addition, TNFα production inhibition is expected to favorably affect the tumor microenvironment and to reduce invalidating systemic manifestations of disease, such as fever and cachexia, which typically worsen the clinical outcome of T-ALL patients.

PB1591

ROLE OF FLOW-CYTOMETRIC IMMUNOPHENOTYPING IN PREDICTION OF BCR/ABL GENE REARRANGEMENT IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

F. Corrente[1,*] S. Bellesi[1], E. Metafuni[1], P. L. Puggioni[1], S. Marietti[1], A.M. Ciminello[1], T. Za[1], L. Laurenti[1], F. Sora'[1], S. Giammarco[1], L. Pagano[1], S. Sica[1], V. De Stefano[1], P. Chiusolo[1]
[1]Hematology, Policlinico A. Gemelli UCSC, Rome, Italy

Background: Among B-cell precursor acute lymphoblastic leukemia (B-ALL), t(9;22) (q34;q11) responsible for BCR/ABL fusion transcripts is the most common cytogenetic abnormality that occurs in around 20-30% of adult patients (pts). BCR/ABL-positive (BCR/ABL+) B-ALL has been typically associated with high expression of myeloid antigen such as CD13, CD33, CD66c. We analyzed 44 adult patients with B-ALL diagnosed in our center from December 2004 to December 2013, with a median age of 46 ys (range 13-78), 23 males and 21 females.
Aims: The purpose of this study was to establish by immunophenotyping which combination of antigens was most predictive for BCR/ABL gene rearrangement.
Methods: Flow-cytometric data were acquired by immunophenotypic B-ALL definition panels performed using FACSCanto cytometer and BDFACSCanto software. Arbitrary cutoff of 20% analyzed events that were brighter than the control stain, was required for an antigen to be considered positive. Levels of BCR-ABL fusion transcript were quantified in RT-PCR assay. Comparison between two groups were performed using the Mann–Whitney *U* (MWW) and Chi-square tests (CSQ) or Fisher exact test (FET) for continuous and dichotomic variables, respectively. Measure of association was expressed by Odds Ratio (OR). Cut-off value for the marker was selected using receiver operating curves (ROC). Multivariate analysis was performed using Logistic Regression (LR). P values lower than 0.05 were considered statistically significant (SPSS 15.0 version).
Results: BCR/ABL transcript was identified in 21 pts (47.7%). CD10 and CD34 was positive in the totality of BCR/ABL+ cases. BCR/ABL+ pts exhibited a greater median percentage of CD10 (96.8% vs 88.6%, MWW, P=0.030) and CD34 (98.3% vs 92.3%, MWW, P=0.013) expressions, but a lower median percentage of CD38 expression (92.6% vs 99.0%, MWW, P=0.001) than pts with BCR/ABL-. Considering Median Fluorescence Intensity (MFI), BCR/ABL+ cases presented a higher CD10 MFI (median of MFI, 11295 vs 1972, MWW, P=0.001) and a lower CD38 MFI (median of MFI, 919 vs 6747, MWW, P=0.006) than their counterpart. No significant difference were observed in CD34 MFI values comparison. By calculating ROC, the best cut-off for CD10 MFI was 5159 (AUC=0.787, 95% CI: from 0.65 to 0.92) and for CD38 MFI was 6284 (AUC=0.750, 95% CI: from 0.60 to 0.90). These cut-off values provided a sensitivity of 80% and a specificity of 74% for CD10 and a sensitivity of 83% and a specificity of 54% for CD38. Categorized CD10 MFI and CD38 MFI presented a strong association with BCR/ABL rearrangement [CSQ, P<0.001, OR 12.75 (95% CI: from 3.06 to 53.19); P=0.010, OR 0.14 (95% CI: from 0.03 to 0.59), respectively]. CD66c positivity was more frequent in BCR/ABL+ pts than in the others (81% vs 45%, FET, P=0.016). The co-expression of CD66c with CD13 or CD33 was more frequently present in BCR/ABL+ pts (44% and 39%, respectively) than in BCR/ABL- (13% and 6%, respectively)(FET, P=0.04). The sensitivity and the specificity of CD66c as sole marker were 81% and 55%, respectively. In opposite, the co-expression of CD66c/CD13 or CD66c/CD33 showed a lower sensitivity (44% and 39%, respectively) and a greater specificity (88% and 94%, respectively). Multivariate analysis in which categorized CD10 MFI was combined with categorized CD38 MFI and CD66c expression showed that CD10 was an independent predictor for the presence of BCR/ABL rearrangement (LR, P=0.003).
Summary and Conclusions: We suggest a screening panel predictive for BCR/ABL rearrangement in B-ALL by using the combination of CD38, CD10, CD34, CD66c, CD13 and CD33 expressions.

PB1592

EVALUATION OF MULTIPLEX LIGATION DEPENDENT PROBE AMPLIFICATION FOR IDENTIFICATION OF ACUTE LYMPHOBLASTIC LEUKEMIA WITH AN INTRACHROMOSOMAL AMPLIFICATION OF CHROMOSOME 21 IN A BRAZILIAN POPULATION

G. Fuka[1,*] T.M. Farias-Vieira[1], L. Hummel[1], C.B. Blunck [1], J.C. Santoro[1], E. Terra-Granado[1], T. Conceição Barbosa[1], M. Emerenciano[1], M.S. Pombo-de-Oliveira[1]
[1]Instituto Nacional de Câncer (INCA), Rio de Janeiro, Brazil

Background: An intrachromosomal amplification of chromosome 21 (iAMP21) defines a unique subgroup of B-cell precursor acute lymphoblastic leukemia (BCP-ALL). The finding of three or more extra copies of the *RUNX1* gene by fluorescence *in situ* hybridization (FISH) is internationally used to define of an iAMP21. Recently, genomic profiling of chromosome 21 has been suggested for assisting the identification of an iAMP21.
Aims: In this work, we aimed to test the multiplex ligation-dependent probe amplification (MLPA) SALSA P327-A1 probe set for evaluating copy number alterations (CNA) on chromosome 21.
Methods: A series of consecutive diagnostic samples from Brazilian childhood BCP-ALL patients collected between the years 2002 to 2012 were selected according to availability of material of good quality providing that bone marrow aspirates harbored at least 30% of blast cells. The MLPA SALSA P327-A1 probe set was employed to detect an iAMP21 (MRC Holland, Amsterdam, The Netherlands). Test fragments of the P327-A1 probe set were designed to detect CNA of 24 genes distributed from centromeric to telomeric regions (q11.2-q22.3, 14.668-46.356) of chromosome 21. Relative copy numbers were obtained after normalization of peaks against cord blood derived controls. Relative peak heights between 0.75 and 1.3 were considered normal, while those below 0.75 and above 1.3 indicated losses or gains of genomic material, respectively. FISH was performed using the "LPH012 *TEL/AML1* Translocation, Dual Fusion Probe", designed to detect the *ETV6/RUNX1* fusion gene. Cases were considered positive for an iAMP21 when ≥5 *RUNX1* FISH signals were observed in at least 7% of metaphase nuclei (standard deviation +/- 2%).
Results: In 74 out of 368 BCP-ALL patients, gain of genetic material on chromosome 21 was detected. MLPA peak profiles segregated patients into three groups by hierarchical clustering. Next, patient material was subjected to FISH. Cells with ≥5 *RUNX1* FISH signals (n=9) were considered as "true iAMP21". By contrast those with 3-4 *RUNX1* signals (n=35) or a normal *RUNX1* FISH pattern (n=6) probably acquired additional copies of an intact chromosome 21, even though not detectable by FISH in all cases. Peak ratios of *RUNX1* and *DYRK1A* genes, located within the common region of amplification (CRA), were in "true iAMP21" patients higher, an opposite pattern was observed for telomeric *SNF1LK* and *TFF1* genes. Since we observed variations in MLPA peak heights between different patients, the correlation between *RUNX1, DYRK1A, ETS2* and *ERG* gene load and expression was tested. For illustration we stepwise

arranged cases from the lowest to the highest MLPA peak ratios and depicted corresponding delta CT (threshold cycle) values. Positive correlation between the MLPA peak ratios and CT values were observed, since those patients with high MLPA peak ratios were the ones with low gene expression. This observation particularly held true for the genes *RUNX1, DYRK1A,* and *ERG*.
Summary and Conclusions: Altogether, we confirmed that aberrations on chromosome 21 represent a high level of complexity and individuality and provided evidence for the existence of gene regulatory mechanisms that might modulate the expression of amplified genes. In BCP ALL with an iAMP21 we consider MLPA tests highly desirable for data replication of array based comparative genomic hybridization analyzes. MLPA profiles of high peak ratios of CRA genes might be especially helpful in case identification whenever metaphase nuclei for FISH are not available. However, we want to stress that a precise separation of BCP-ALL with an iAMP21 from hyperdiploid ALL with additional copies of chromosome 21 is still under revision. Control fragments binding on chromosomes that are usually over represented should be included in next generation MLPA probe sets.

PB1593

CIRCADIAN RHYTHM OF MELATONIN IS PRESERVED AT DIAGNOSIS AND DURING TREATMENT IN PEDIATRIC PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

A. Vlachou[1,*] A. Kattamis[1], D. Perrea[2], I. Papassotiriou[3], N. Tourkantoni[1], S. Polychronopoulou[4]
[1]Division of Pediatric Hematology-Oncology, First Department of Pediatrics, University of Athens, [2]Laboratory for experimental surgery and surgical research N.S Christeas, University of Athens, [3]Department of Clinical Biochemistry, [4]Department of Pediatric Hematology-Oncology, Aghia Sophia Childrens Hospital, Athens, Greece

Background: Melatonin, the main hormone secreted by the pineal gland in the human brain, has a strong impact on the sleep-wake cycle and is considered to be the general moderator of circadian rhythm and through this of several biological functions. It has also been shown to neutralize a number of free radicals and to enhance the activity of several antioxidative enzymes. Patients with acute lymphocytic leukemia (ALL) show significantly deranged oxidation homeostasis due to both the leukemic burden and the therapy. Alterations of circadian rhythm of melatonin secretion on these patients either at diagnosis or during therapy could enhance oxidative stress or affect bioavailability and efficacy of therapeutic agents.
Aims: Aim of the present study was to elucidate whether melatonin maintains its diurnal variation among pediatric patients with ALL from diagnosis and throughout their treatment. Additionally, correlation of melatonin's level with the oxidative/antioxidant status of these patients was also evaluated.
Methods: Twelve patients (median age 6.5 years old) with intermediate risk B-ALL, treated according to BFM-ALL95 protocol, were included in this study. Morning (10 am) and night (10 pm) samples were collected from each patient at 7 different time points, with a median follow up time being 8 months. More precisely, blood samples were collected at the time of diagnosis, at the end of the first part of Induction, at the beginning and at the middle of Consolidation and Reinduction cycles and before starting Maintenance therapy. Melatonin levels were measured in serum by an Enzyme Linked Immunofluorescent Assay (ELISA). Total oxidative stress was estimated by colorimetric assay by measuring the total quantity of lipid peroxides present in serum. Total antioxidative serum capacity was estimated by photometric assay by adding a specific quantity of hydrogen peroxide in the sample and then measuring the remaining amount, not neutralized by the natural antioxidants in the serum.
Results: Melatonin's secretion retained its circadian rhythmicity with higher levels (9.72±7.39 pg/mL) at night and lower during the day (8.1±6.19 pg/mL) throughout the study (P<0.05). In this respect, intrapatient AM and PM levels, as well as their difference were stable. Total Oxidative Capacity showed an inverse circadian rhythm pattern with higher levels measured in the morning (612.79±329.56 μmol/L) and lower in the night (531.50 ±321.75 μmol/L) samples (P<0.001). Of note the highest levels of oxidative stress (913.30 ±277.26 μmol/L) were measured at the time of diagnosis (P<0.001). This was the time point with the lowest, though not statistically significant, melatonin concentration. Moreover, morning levels of melatonin correlated with the oxidative *versus* anti-oxidative ratio (r 0.23, P<0.05).
Summary and Conclusions: This study depicts, for the first time to our knowledge in the literature, the daily variations of melatonin and oxidative stress in pediatric patients with ALL. Our results showed that melatonin levels maintain their circadian rhythm in our pediatric patients with ALL, both at diagnosis and throughout treatment. Furthermore, we portrayed that oxidative capacity exhibited a similar inverse circadian rhythm, also retained throughout the study. However, oxidative status presented significant fluctuations between distinct measurements, probably related to leukemic burden and the type and intensity of therapy. The above data are of significant importance as many physiological processes, like hormonal secretion and pharmacodynamics, are affected by the body's circadian rhythms.

PB1594

IMPLEMENTATION OF 8 COLORS MULTIPARAMETRIC FLOW CYTOMETRY (8-MFC) IN THE DIAGNOSIS AND MONITORING OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN A SINGLE CENTER

A. Alonso[1,*] M. Camós[2], S. Rives[1], A. Català[1], R. Berrueco[1], A. Ruiz-LLobet[1] M. Mesegue[2], M. Trabazo[1], R. Malatesta[2], N. Vega-Garcia[2], M. Torrebadell[2]
[1]Pediatric Hematology. Department of Hematology and Oncology, [2]Hematology Laboratory, Hospital Sant Joan de Déu, Fundació Sant Joan de Déu, University of Barcelona., Barcelona, Spain

Background: ALL is the most common childhood malignancy and the leading cause of pediatric cancer-related mortality. Minimal residual disease (MRD) is a powerful predictor of outcome in childhood ALL and allows stratification of patients into prognostic risk subgroups and the application of risk-directed therapy. MRD assessment is routinely performed by flow cytometry and quantitative real-time polymerase chain reaction (qRT-PCR).
Aims: the aim of our study was to implement 8-MFC to diagnose ALL and monitor MRD using EuroFlow Consortium approach and evaluate its correlation with molecular techniques.
Methods: a descriptive study of childhood ALL diagnosed in a single center between September 2013 and February 2015 and treated according to Spanish Pediatric Hemato-Oncology Society SEHOP-PETHEMA-2013 protocol. The initial diagnosis was established with the monoclonal antibodies panels proposed by the EuroFlow Group. Detection of MRD was based on leukemia-associated immunophenotype (LAIP) observed at diagnosis. Fusion genes ETV6-RUNX1, TCF3-PBX1 and BCR-ABL1 were analyzed by qRT-PCR following the guidelines of the Europe Against Cancer program.
Results: twenty-six patients were included (17 males, median age 6.5 years, range 1.1-16.7 years). Twenty-one cases were B-cell precursor ALL (B-pre-ALL) in common stage (CD10+) and 5 patients had T-cell ALL in cortical (CD1a+) stage. The most frequent LAIPs identified in B-pre-ALL were cross-lineage antigen expression (studying CD13, CD15, CD123 and CD66) and asynchronous antigen expression. ETV6-RUNX1 rearrangement was detected in six patients and TCF3-PBX1 rearrangement was observed in three cases. All patients had a good response to prednisone at day +8 and the evaluation on day +15 by morphology showed persistent disease (≥5% blasts) in 4 B-pre-ALL cases. At the end of induction IA all patients (24 cases evaluated) achieved morphologic remission (<5% blasts). The MRD by 8-MCF on day +15 was negative (<0.01%) in 8/26 cases (5 B-pre-ALL and 3 T-ALL), on day +33 in 21/24 cases and on day +78 in all cases (18 cases evaluated). Two follow-up samples were not evaluable by qRT-PCR analysis. The MRD study by qRT-PCR was concordant with the 8-MFC in 17/19 samples. In a patient with TCF3-PBX1 rearrangement the MRD on day +33 was negative by 8-MCF but positive by qRT-PCR (ratio TCF3-PBX1/ABLx10[4] 3 copies) but the assessment on day +78 was negative in both. In addition, a patient with ETV6-RUNX1 rearrangement had a negative MRD on day +33 by 8-MCF but qRT-PCR still detected a very low number of copies (ratio ETV6-RUNX1/ABLx10[4] 4.9 copies). The evaluation on day +78 for this patient is still pending.
Summary and Conclusions: implementation of MFC-8 has optimized the diagnosis and monitoring of MRD using less amount of sample for the analysis, representing a significant improvement in pediatric care. Furthermore, a good correlation of the MFC-8 MRD levels with molecular results was observed (89.5% of cases), suggesting a good complementarity of both techniques. Thus, MFC-8 confirms as a simple, fast and very useful tool to diagnose and follow MRD with high sensitivity in pediatric ALL patients.

PB1595

ABERRANT BAFF-R EXPRESSION AFFECTS APOPTOSIS RATE OF B LYMPHOBLASTS AFTER CORTICOSTEROID TREATMENT

E. Sevdali[1], M. Zamanakou[1], A. Germenis[1], M. Speletas[1,*]
[1]Department of Immunology and Histocompatibility, University of Thessaly, School of Health Sciences, Faculty of Medicine, Larissa, Greece

Background: BAFF and APRIL play crucial role in the survival, maturation and homeostasis of peripheral B-cells through their interactions with BAFF-R, TACI and BCMA receptors. While the BAFF/APRIL cytokine axis lacks functional roles in early stages of normal B cell development, recent evidence indicates that malignant lymphoblasts aberrantly express receptors of the BAFF-system (predominantly BAFF-R), suggesting a new role for these molecules in acute lymphoblastic leukemia (ALL) biology.
Aims: The **aim** of this study was to uncover any possible effect of BAFFR aberrant expression on the *in vitro* survival capacity of malignant lymphoblasts after treatment with conventional chemotherapeutic drugs.
Methods: Two ALL cell lines were included in the study: the pre-B-ALL cell line 697, expressing BAFF-R and carrying the E2A-PBX1 chromosomal translocation and the T- ALL Jurkat cell line, characterized by the absence of expression of any BAFF/APRIL receptor (served also as a negative control). Cells have been treated in the presence of chemotherapeutic agents that are currently being used in ALL therapeutic protocols (aracytine and dexamethasone). The hypotoxic dose of these drugs (aracytine: 0.08-40.0 μg/mL, dexametha-

sone: 0.01-200.0 μg/mL) was determined by evaluating the apoptosis rate of cells with flow cytometry, using an Annexin V-FITC/7-AAD kit (Beckman-Coulter), according to the manusfacturer's instructions. In order to determine if the presence of BAFF could affect the survival of ALL cell lines, cells have been treated with exogenous BAFF (5 ng/mL-800 ng/mL), in combination or not with one of the above agents.
Results: Dexamethazone induced apoptosis of both cell lines in a dose-dependent manner. Interestingly enough, exogenous BAFF significantly increased the dexamethasone-induced apoptosis of 697 cells; this effect was also obvious in the lowest dose of BAFF (5ng/mL). As expected, exogenous BAFF did not affect the rate of dexamethasone-induced apoptosis in Jurkat cells, which did not express BAFF-R. Concerning aracytine, treatment of both cell lines with BAFF did not alter the apoptosis rate caused by the drug itself.
Summary and Conclusions: The aberrant expression of BAFFR might play a crucial role in ALL biology and treatment.

Acute lymphoblastic leukemia - Clinical

THE EFFECT OF PROLIFERATION INHIBITION AND APOPTOSIS OF BRD4 INHIBITORS JQ1 ON PH POSITIVE ACUTE LYMPHOCYTIC LEUKEMIA CELL AND ITS MECHANISM

M. LiangMing[1,*] W. XiaoZhen[1], W. Tao[1]
[1]Hematology, Shan Xi Da Yi Hospital, Taiyuan, China

Background: It has been widely demonstrated that BRD4 knockdown or inhibition by JQ1 is associated with c-MYC downregulation and antileukemic activity. leading to suppression of the transcriptional program linked to proliferation and survival.
Aims: We evaluated the effect of proliferation inhibition and apoptosis of brd4 inhibitor JQ1 on Ph positive acute lymphocytic leukemia(Ph+ ALL) cell and its mechanism.
Methods: different concentrations of JQ1 are used on SUP-B15 cell and proliferation inhibition level were detected by MTT assaythe cell apoptosis rate were determined by flow cytometry(FCM) the expressions of BCR – ABLmRNA brd4mRNA mycmRNA P53mRNA were detected by real-time fluorescent quantitative PCR(RT-PCR).
Results: different concentrations of JQ1 can all inhibit SUP-B15 cell proliferation, inducing cell apoptosis apoptosis rate was significantly increased compared to control group, and depend of time and dose. half inhibitory concentration of 72h is about 1.0 umol/L.At the same time□JQ1 can down regulation BCR-ABLmRNA,brd4 mRNA, myc mRNA transcription levels, and up regulation the transcription level of p53mRNA.
Summary and Conclusions: JQ1 as brd4 inhibitor can down regulation the expression of brd4, thus affecting its downstream gene myc and p53, at the same time it can changeover the express of BCR-ABL,further achieve inhibition of cell proliferation, inducing cell apoptosis.

PB1597

THE EFFECTS OF JQ1 ON SUP-B15 CELL NOTCH1 PATHWAY AND ITS MECHANISMS

M. Liangming[1,*] W. Yan[1], W. Tao[1]
[1]Hematology, Shan Xi Da Yi Hospital, Taiyuan, China

Background: Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL) has a poor prognosis. Advances of treatment due to the tyrosine kinase inhibitor imatinib have improved the cure rates.
Aims: The study was aimed to investigate the inducing effect of JQ1 on the apoptosis of Ph(+) human ALL Cell(SUP-B15),and whether the regulation of Notch1 pathway involved in the effect of JQ1 on SUP-B15 cells.
Methods: The SUP-B15 cell were treated with different concentrations of JQ1 for different time.The cell proliferation was analyzed with cytotoxicity test(MTT method).Cell cycle was detected by fluorescence microscopy and flow cytometry. The expression of Notch1 pathway was detected by real-time quantitative PCR by MSI2□Notch1□Hes1mRNA.
Results: The results indicated that JQ1 could significantly inhibite the viability of SUP-B15 cells treated with 0-4μmol/L in does-and time-dependent manner.JQ1 could induce S cycle arrest in does-dependent manner which was statistical different from the control at the same time ($P<0.05$).MIS2 Notch1 Hes1mRNA expression was down-regulated by JQ1 which was statistical different from the control($P<0.05$)
Summary and Conclusions: It is concluded that JQ1 could potently inhibit the growth and proliferation of SUP-B15 cells and the Notch1 pathway might be one of the important apoptosis mechanisms in Ph(+) ALL cells induced by JQ1.

IS BERLIN-FRANKFURT-MUNSTER (BFM) REGIMEN FEASIBLE FOR TREATMENT OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: RETROSPECTIVE ANALYSIS OF OUTCOME OF ADULT ALL TREATED WITH BFM AND HPER-CVAD PROTOCOLS

I. Alacacioglu[1,*] S. solmaz[1], H. Ozsan[1], B. PAyzin[2], G. Sevindik[1], C. Acar[1], A. Katgi[1], F. Ozdemirkan[2], O. Piskin[1], M. A. Ozcan[1], B. Undar[1], F. Demirkan[1]
[1]Hematology, Dokuz Eylul University Faculty of Medicine, [2]Hematology, Katip Celebi Universty Ataturk Research And Training Hospital, Izmir, Turkey

Background: Multiple induction regimens have been developed for adult patients with acute lymphoblastic leukemia (ALL). But none have been directly compared in a prospective randomized trial.
Aims: In this report, we want to evaluate outcome of our adult ALL patients treated with BFM-like and Hyper-CVAD protocols retrospectively and also evaluate the feasibility of BFM protocol in adult patients in case of efficacy and tolerability.

Methods: In this study, we want to evaluate outcome of our 50 adult ALL patients treated with Berlin-Frankfurt-Munster (BFM) (20 patients) and Hyper-CVAD (30 patients) protocols between march 2006 and october 2012.
Results: The median age was 25 years in BFM, 30.5 years in Hyper-CVAD group with M/F ratio 15/5 and 17/13 respectively. 45% of patients in BFM group and 30.3% of patients in Hyper-CVAD group were under age of 25. The majority of cases were B cell in origin (80% in BFM, 70% Hyper-CVAD group). Complete remission after induction therapy was achieved in 95% and 96% of the patients, respectively. Median follow-up time was 37 months. Five-year survival rate was higher in BFM group with respect to Hyper-CVAD group (59%x 34%). There were also no complication which can cause a delay during Hyper-CVAD regimen. Both chemotherapy were well tolerated. None of patients died due to drug related toxicity. Only mild liver enzyme elevations were seen as toxicity in BFM which didn't cause any delay in therapy.
Summary and Conclusions: BFM regimen seems to be feasible for adult patients with ALL in case of tolerability and efficacy especially in young adults.

THE RESULTS OF BFM 95 PROTOCOL IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE CENTER EXPERIENCE FROM TURKEY

U. Ezer[1,*] M. Ozturk[1], F. Sirin[1], N. Sonmez[1], S. Tasdelen[1], D. Aksen Ezer[1], E. Akkaya[1], D.F. Akin[1], M. Mumcuoglu[1], A. E. Kurekci[1]
[1]Losev Losante Hematology Hospital, ANKARA, Turkey

Background: In the past, acute lymphoblastic leukemia (ALL) treatment success was 20-30%. But in the last three decades this rate has been increased by over 80%. This success achieved by contemporary protocols, improvements in the infrastructures, supportive treatments, and social and psychological supports. Over the last decade, our country has reached the same success level as other developed countries. ALL BFM 95 protocol is commonly used for pediatric ALL in European countries and also in Turkey.

Table 1. Demographic characteristics and treatment results of the 147 children receiving ALL-BMF-95 protocol.

Age (years)	5.3 (1-14)

SR: standard risk; IR: intermediate risk; HR: high risk; EFS: event-free survival; OS: overall survival; BM: bone marrow

Aims: We would like to present our results of 147 pediatric ALL patients who were treated with this protocol in our hospital within a 10-year period.
Methods: One hundred and forty-seven children with acute lymphoblastic leukemia (ages 1-14) who were treated with ALL BFM 95 protocol in the Lösante Hospital between the years 2000 to 2009 were reviewed. The risk groups were defined by the age and leukocyte count at diagnosis, steroid response of 8th day, bone marrow aspiration results of 15th and 33th day and cytogenetics/genetic alterations.
Results: Demographic characteristics, distribution of risk groups and survival rates for children with ALL receiving ALL BFM 95 protocol are shown in Table 1. The standard risk group showed excellent results with a rate of 100% for both EFS and OS. The rates of EFS and OS for B-cell ALL are around 90% when the SR and IR groups were taken together whereas they were 55.88% and 58.82 for HR group. The event free survival (EFS) and overall survival rate (OS) for 123 patients with B-cell phenotype were 82.25% and 83.1%, respectively. The rates of OS of T-cell IR and HR groups were 86.66% and 50%, respectively. Twenty-four patients with T-cell phenotype achieved 73.91% five-year OS and 69.56% EFS rate. Overall, five-year survival rate of 147 patients who received treatment in our center was 81% and event-free survival rate was 77% that is comparable to published results so far. Regarding the white blood cell count (WBC), the rates EFS and OS are higher in patients with low WBC (<20 000/μL). During high dose corticosteroid treatment, 8 patients showed hypertension and six patients showed hyperglycemia. Later on, patients who showed hyperglycemia diagnosed with diabetes mellitus and insulin treatment was initiated. One patient developed aseptic necrosis on femur two years after chemotherapy. PRES Syndrome was seen in two patients. Regarding the distribution of the patients included in the risk groups, we found that number of our patients in SR group were lower (19% *vs* 35%), equal in IR group (51% *vs* 53%), and higher in HR group (30% *vs* 12%). This result may be due to referred patients diagnosed with ALL to our center from other medical centers. We proudly observed that the rates for EFS and OS in our ALL-BFM 95 SR group were 100%. This excellent outcome could be explained by successful planning of the current chemotherapy protocol by BFM group and implementation of appropriate supportive treatments. Additionally, our treatment results of other risk groups suggest that our success rates are comparable to the results of centers using ALL-BFM 95 protocol in European countries and our country.
Summary and Conclusions: We are pleased to know that ALL-BFM 95 protocol improved survival in childhood ALL. However, the development of new strategies is still necessary in order to prevent relapses and to improve survival.

PB1600

NO ADVANTAGE OF ALLOGENEIC STEM CELL TRANSPLANTATION OVER MAINTENANCE CHEMOTHERAPY AS POST-REMISSION THERAPY IN ADULT PATIENTS WITH B-ACUTE LYMPHOBLASTIC LEUKEMIA IN OUR CENTRE

M. Alpoim[1,*] G. Brás[1], R. Pinto[1], A. Carneiro[1], F. Príncipe[1], J.E. Guimarães[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar de São João, Porto, Portugal

Background: The optimal post-remission therapy for adult acute lymphoblastic leukemia (ALL) patients is not well established. Although allogeneic stem cell transplantation (allo-SCT) has been used in adult ALL for more than 20 years, its role remains controversial as demonstrated by conflicting results in many studies.
Aims: Compare allo-SCT vs maintenance chemotherapy as post-remission therapy in adult B-ALL patients.
Methods: We retrospectively analyzed 64 patients with *de novo* B-ALL in a single centre from 2006 to 2014.
Results: The median age at diagnosis was 47 years [17-70], 25(39.1%) patients with ≤40 years. The median white blood count (WBC) was $9x10^9$/L [1.0-254] and 17(26.6%) patients had hyperleucocytosis (>$30x10^9$/L). Forty (62.5%) cases corresponded to common-B ALL, 20 (31.3%) to a pre-B ALL and 4 (6.2%) were pro-B ALL. Thirty-three (51.6%) patients had an unfavorable karyotype: t(9,22) in 31 (48.4%) patients, t(4,11) in 1 (1.6%) and hypodiploidy in 1 (1.6%) patient. Thirty-four (53.1%) patients received remission induction therapy with the HOVON 100 ALL/EORTC 06083 protocol (nonexperimental arm), 24 (37.5%) with the Hyper-CVAD protocol and 6 (9.4%) with CLG/EORTC 58951 protocol. In cases of Philadelphia chromosome–positive (Ph+) ALL, all patients received tyrosine kinase inhibitors (TKI) (in addition to multiagent chemotherapy). Sixty-two (96.9%) patients achieved complete remission (CR) after either one (90.6%, n=58) or two (6.3%, n=4) courses of induction therapy. Four patients (6.25%) died during consolidation treatment (2 related to toxicity of chemotherapy and 2 due to early relapse). Among 58 (90.6%) patients who completed consolidation therapy, 30 (51.7%, n=30/58) received allo-SCT (matched related donor, n= 23 and unrelated donor, n=7) and 28 (48.3%, n=28/58) were treated with maintenance chemotherapy. In patients receiving allo-SCT, 12 (40%, n=12/30) had ≤40 years and 19 (63.3%, n=19/30) were Ph+ ALL. The mortality rate in patients submitted to allo-SCT was 56.7% (n=17/30) and the majority (52.9%, n=9/17) of patients died in CR. In patients treated with maintenance chemotherapy, the mortality rate was 42.9% (n=12/28) and the main (75% n=9/12) cause of death was disease relapse.
The median follow-up was 27 months [1-108]. The disease-free survival (DFS) and overall survival (OS) rates at 3 years of the all cohort were 41.1% (+/-6.7%) and 48.4% (+/-6.7%), respectively. Comparing Hyper-CVAD protocol with HOVON 100 ALL/EORTC 06083 protocol, no differences statistically significant were found for RC vs NR (P=0.270), DFS (P=0.741) or OS (P=0.411). According to allo-SCT vs maintenance chemotherapy comparisons, no significant differences were observed for DFS (P=0.167) and OS (P=0.259) even including only Ph+ ALL patients in the analysis (DFS for Ph+ ALL allo-SCT vs Ph+ ALL chemotherapy-P=0.539; OS for Ph+ ALL allo-SCT vs Ph+ ALL chemotherapy-P=0.857). Additionally, when patients with ≤40 years were analyzed as a separate group, we failed to observe any statistical difference between the two post-remission therapies in terms of DFS (P=0.575) and OS (P=0.780).
Summary and Conclusions: Our study does not demonstrate any advantage for allo-SCT compared with maintenance chemotherapy as post-remission

therapy in adult B-ALL even in those patients with Ph+ or ≤40 years. In our analysis the non-relapse treatment-related mortality in patients submitted to allo-SCT was very significant. Although our series was small, it represents the results of daily clinical practice, where graft-*versus*-host-disease and serious infections are major challenges.

PB1601

A PEDIATRIC TREATMENT REGIMEN FOR PHILADELPHIA NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA IN ADOLESCENTS AND YOUNG ADULTS IS FEASIBLE IN THE REAL-LIFE SETTING – SAFETY ANALYSIS IN A SINGLE-CENTER SERIES

M. Koehler[1,*] F. Gonçalves[1], J. Lobato[1], J. Desterro[1], M. D. J. Frade[1], A. Nunes[1], M. Gomes da Silva[1]
[1]Hematologia, Instituto Português de Oncologia de Lisboa, Francisco Gentil, Lisboa, Portugal

Background: There is considerable evidence that pediatric (PED), high intensity chemotherapy protocols may improve clinical outcome in adolescents and young adults (AYA) with Acute Lymphoblastic Leukemia (ALL). Toxicity, which is more frequent and severe in older patients (pts), is a key issue, limiting the potential benefits and becoming more evident outside clinical trials.
Aims: We evaluated the feasibility and safety of a PED regimen – the Dana-Farber Cancer Institute Consortium Protocol (DFCI) 05-01-in Ph- AYA ALL pts receiving treatment (Tx) in an adult Hematology reference center.
Methods: We conducted a retrospective analysis of all adverse events (AE) occurring during the DFCI 05-01 regimen in a series of consecutive AYA pts treated at our institution, with a focus on Grade 3-5 CTCAE toxicities and special interest side effects with at least a possible relationship to Tx.

Table 1.

Characteristics	Total N (%)	With Thrombotic event N (%)	Without thrombotic event N (%)	P
Patients	31 (100)	10 (32)	21 (68)	
Male/Female	12/19	4/6	8/13	NS
Age in years: median (range)	34 (17-56)	34 (25-47)	32 (17-56)	NS
Largest mass diameter in mm: median (range)	98 (50-150)	78 (50-150)	106 (58-150)	NS
Extranodal involvement	8 (27)	2 (20)	6 (28.5)	NS
SVCS	16 (52)	5 (50)	11 (52)	NS
Complete response after first line treatment	23 (74)	7 (70)	16 (76)	NS
4-year Overall survival: % (IC95%)	80 (64 - 96)	83 (53-100)	78 (59-97)	NS
4- year Progression-Free Survival: % (IC 95%)	71 (54 - 88)	85 (59 - 100)	64 (43 - 85)	NS

NS: No statistically significant.

Results: 22 Ph- ALL pts (median age 18 yo, range 15-42, 68.2% males), diagnosed between 2007 and 2014, were treated according to the DFCI 05-01 protocol. 54.6% were<20 yo, 13.6% 20-29 yo, and 31.8% were 30-42 yo. B-ALL was diagnosed in 11 (50%), T-ALL in 8 (36.4%), and T Lymphoblastic Lymphoma in 3 (13.6%). Only 1 case had detectable blast cells in diagnostic spinal tap (<5/ul). At the end of induction (IND) 20 (91%) pts achieved CR, 2 had refractory disease, being excluded from the analysis after this point, and 4 B-ALL cases had high MRD levels (≥0.001) assessed by RQ-PCR. Based on cytogenetics and molecular response at day 32, 7 (31.8%) pts moved to the very high-risk group and received intensified Tx according to protocol. 2 relapses occurred before maintenance and 2 pts died of refractory disease shortly after starting salvage regimens. 2 Tx-related deaths were observed. With a median follow up of 37 months, 16 pts (72.7%) are alive in CR1: 5 completed the protocol, 8 had an allogeneic stem-cell transplant after Consolidation II, and 3 are still under Tx. Table1 depicts the grade 3-5 toxicities and asparaginase (ASP) specific related toxicities observed during a median of 11 months of Tx per pt. No deaths were observed during IND and infectious complications were the most frequent AE: 9 pts (40.9%) developed febrile neutropenia with 7 confirmed bacteremias. Overall, infections were the most relevant reported AE during Tx, with 2 grade 5 events. 2 episodes of reversible AKD (not requiring renal-replacement therapy) during high dose MTX Tx were seen. 10/14 evaluable pts (71.4%) who initiated the 30-week ASP course were able to receive 26 or more IM *E. coli* ASP equivalent doses, with one of the ASP formulations – native *E. coli* ASP, PEG-L-ASP, or *Erwinia* L-ASP. 4 musculoskeletal AEs were observed, including 3 cases of avascular necrosis, and 1 bone fracture, possibly related to corticosteroid therapy.
Summary and Conclusions: Increased toxicity in AYA is the limiting factor for the use of intensified therapeutic regimens in ALL. We did not observe unexpected grade 3-4 AE, nor an unacceptable high incidence of these events, compared to literature. Tx-related mortality was also equivalent (9%). In this series ASP tolerance was acceptable: the incidence of major ASP-related toxicities was similar to older children, with a proportion of pts completing at least 26 weeks of high-dose ASP only slightly lower than described in PED populations (71.4% VS 88%). The application of tolerable, PED protocols may improve the outcome of adult ALL.

PB1602

THE EFFECTS OF THIOPURINE METHYLTRANSFERASE POLYMORPHYSMS (TPMT*2, TPMT*3B, TPMT*3C, TPMT*3A) AND ITS CYTOPLASMIC ENZYME LEVELS ON MYELOSUPPRESSION IN CHILDREN WITH ALL TREATED WITH 6-MERCAPTOPURINE.

Y. Mortazavi[1,*] M. Jafarian[2], S. Alavi[3], M. Hedayati[4]
[1]Pathology, [2]Molecular Medicine and Genetics, Zanjan University of Medical sciences, Zanjan, [3]Pediatric congenital hematologic disorders research center, Shahid Beheshti University of Medical Sciences, [4]Hematology, Tehran Mofid Hospital, Tehran, Iran

Background: Thiopurine Methyltransferase (TPMT) prevents the toxic effects of thiopurine drugs such as 6-mercaptopurine and neutralizes its side effects such as myelosuppression. This enzyme methylates toxic metabolites and leads to their inactivation.
Aims: The aim of this study was to evaluate *TPMT* gene polymorphisms (*TPMT*2, TPMT*3B, TPMT*3C, TPMT*3A)* and detection its cytoplasmic enzyme levels and myelosuppression and hepatotoxicity effects *in* children with acute lymphoblastic leukemia (ALL) treated with 6-MP.
Methods: 98 patients with standard risk paediatric ALL in maintenance phase were selected. PCR-RFLP method was performed to detect mutations in exon7 (460G>A; *TPMT*3B*), and in exon 10 (719A>G; *TPMT*3C*). *TPMT*2* (238G>C) allele, in exon 5 was analyzed by allele-specific PCR method. Exons 7 and 10 in 19 patients and exone 5 of 2 patients were also sequenced to confirm the results obtained by PCR-RFLP and AS-PCR methods. The enzyme level of 70/98 patients was assessed by ELISA. Then Correlation between genotype, phenotype and side effects such as myelosuppression and hepatotoxicity was analyzed by statistical methods.
Results: Frequency of *TPMT*1*3B* genotype was 1.1% and the frequency of *TPMT*3B* allele variant was 0.71%. No allele variant was detected in *TPMT*2* and *TPMT*3C,*3A, *4, *7, *8, *10* (4 allele variants *(TPMT *4, *7, *8, *10*) were analyzed by sequencing). The concentration of enzyme was low in 8 (11.4%) individuals. There was no meaningful association between phenotype and genotype of TPMT enzyme. A significant correlation was found between low concentration of TPMT enzyme and myelossuppresion *(P=0.04*, leucopenia*, P=0.02* neutropenia *)*. There was no statistical difference between low and normal concentration of TPMT enzyme and hepatotoxicity *(P=0.12)*.
Summary and Conclusions: The results of this study showed that there is a relationship between low enzyme concentration and myelosuppression in some patients who were treated with 6-MP. Therefore, to avoid some side effects of 6-MP such as myelosuppression, studying common and rare *TPMT* gene variant as well as measurement of TPMT enzyme level is recommended.

PB1603

MULTICOLOR FLOW-CITOMETRY IS A CHEAP AND RELIABLE PREDICTOR OF RELAPSE RISK IN ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS, RETROSPECTIVE DATA FROM REAL LIFE EXPERIENCE.

F. Guolo[1,*] P. Minetto[1], G. Pastori[1], D. Guardo[1], L. Giannoni[1], A. Kunkl[2], M. Clavio[1], N. Colombo[1], R. Grasso[1], F. Ballerini[1], M. Miglino[1], R. M. Lemoli[1], M. Gobbi[1]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Department of Pathological Anatomy, IRCCS AOU San Martino-IST, Genoa, Italy

Background: Many studies have shown the prognostic value of minimal residual disease (MRD) evaluation in Acute Lymphoblastic Leukemia (ALL). Nowadays, most of the modern therapeutic protocols include risk-oriented and MRD-driven consolidation program. MRD is usually evaluated by multicolor-flow cytometry (MFC) and RQ-PCR for VDJ rearrangements. The latter method is significantly more sensible but is quite expensive and complex, and usually requires a great amount of time. MFC is cheaper and quicker, and it is currently applied in most induction protocols, where is performed at fixed timepoints. However, few data are available on MFC MRD value outside clinical trials, where often response assessment timing greatly varies between different induction schedules and different patients.
Aims: The aim of the present study is to evaluate if MFC-MRD maintains prognostic significance in the real life therapeutic experience, outside clinical trials and with different induction schedules.
Methods: We retrospectively analyzed outcome of 132 consecutive ALL patients, treated in our centre in the last 10 years. Median age was 44.5 years (range 15-82 years). Induction regimens included Hyper-CVAD, standard three or four drug induction, with or without L-Asparaginase, and TKI with or without chemotherapy for Philadelphia positive ALL. Relapse-free survival (RFS) was calculated from the time of diagnosis until last follow-up or documented leukemic relapse. Patients were censored upon allogeneic transplantation.

MFC MRD levels were evaluated on bone marrow samples after first induction cycle, at a median of 36 days after diagnosis (range 28-52). A positive MFC MRD was defined by the presence of no less than 25 clustered leukemic cells/10^5 total events (threshold of $2.5x10^{-4}$ residual leukemic cells) at four-color flow-cytometry.
Results: Sixteen patients (12,1%) died during induction, mainly because of infectious events. Of remaining 116 patients, 101 (84%) achieved complete remission (CR). None of the analyzed variables significantly influenced CR probability. After a median follow-up of 58 months, 63 relapses were observed. The probability of disease relapse was significantly increased by leukocytosis at diagnosis, omission of L-Asparaginase and MFC MRD positivity after first cycle (P=0.003, P=0.047, P=0.048, respectively, Fig.1). Specifically, relapse rate in MFC MRD negative patients were very low (5/25 MFC-MRD negative patients, 25%), when compared to the whole cohort. MFC value resulted independent from ALL lineage, induction schedule, sex and age. High dose Methotrexate administration conferred a borderline advantage on RFS (P=0.066). Multivariate RFS analysis disclosed low WBC count and inclusion of L-Asparaginase as the strongest predictor of longer RFS, however without reaching statistical significance (P=0.061).

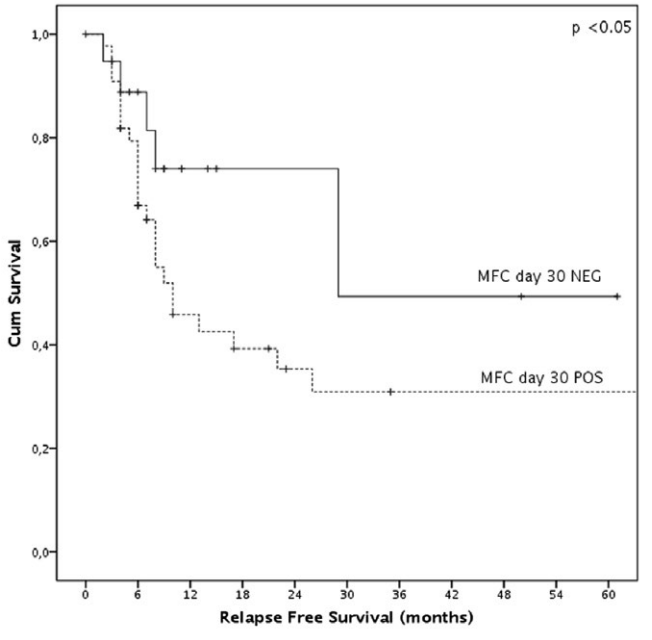

Figure 1. RFS according to MFC MRD.

Summary and Conclusions: Risk adapted consolidation and transplant timing has recently shown high efficacy in many MRD-driven clinical trial. Our data confirm that evaluation of MRD by MFC on bone marrow samples is a cheap, relatively simple and a reliable predictor of relapse risk, even outside clinical trials. Basing on those findings, MFC MRD evaluation could be a valid surrogate of RQ-PCR for VDJ rearrangement, with potential clinical utility especially in those setting where access to expensive molecular techniques is difficult, allowing to apply risk adapted consolidation even if molecular MRD methodic are not available.

PB1604

PREGNANCY IS NOT AN EXCLUSION CRITERIA FOR THE TREATMENT ACCORDING TO THE ADULTS ACUTE LYMPHOBLASTIC LEUKEMIA PROTOCOL ALL-2009: RESULTS OF THE RUSSIAN ALL STUDY GROUP (RALL)

V. Troitskaya[1,*] E. Parovichnikova[1], A. Sokolov[1], S. Makhinya[2], G. Galstyan[3], G. Kliasova[2], A. Zvereva[4], Z. Fidarova[1], O. Gavrilina[1], A. Sidorova[1], S. Novikov[3], T. Kaporskaya[5], V. Lapin[6], O. Latyshkevich[4], V. Savchenko[2]
[1]Department of Hematological Oncology and BMT, [2]National Research Center for Hematology, Moscow, Russian Federation, [3]Department of anesthesiology and Intensive therapy, National Research Center for Hematology, [4]Centre of Family Planning and Reproduction, Moscow, [5]Irkutsk Clinical Regional Hospital, Irkutsk, [6]Yaroslavl regional hospital, Yaroslavl, Russian Federation

Background: Acute lymphoblastic leukemia ALL accounts for about a third of acute leukemias diagnosed during pregnancy. Pregnancy is a common exclusion criteria for any clinical trial. RALL study group decided to include the pregnant women with ALL in the multicenter clinical trial ALL-2009 (ClinicalTrials.gov public site; NCT01193933). The protocol is based on non-intensive but non-interruptive treatment.
Aims: To evaluate efficacy and toxicity the ALL-2009 protocol for pregnant women with ALL.
Methods: From Jan 2009, till Dec 2014, 30 centers enrolled 263 Ph-negative ALL pts, among whom there were 13 pregnant women (3-in 1st; 3- in the 2nd and 7-in 3rd trimester of pregnancy) from 3 hematological centers. The median age was 28 (18-32) years. B-cell ALL was diagnosed in 6 (46%) and T-cell ALL-7 (54%) patients. 10 patients (77%) were attributed to a high-risk, 3 (23%)-to a standard risk group. The treatment according the protocol ALL-2009 was carried out without deviations except the shift of L-asparaginase for later phases of treatment (after delivery) and applying intrathecal injections without methotrexate for those in whom chemotherapy was started during pregnancy. Medical abortion was performed in 3 patients at the 1st trimester (10-11 weeks of gestation) during the prephase (7 days with prednisolone 60 mg/m^2). 3 patients at 36-40 weeks of gestation were delivered before treatment and prephase was initiated after 2-3 days after delivery. All others (n=7) were started with chemotherapy during pregnancy (at 16, 19, 25, 28, 29, 31 and 34 weeks of gestation).
Results: All pregnant women were refractory to prednisolone defined by more than 25% of bone marrow blasts after 7 days of prephase. So dexamethasone was used for all further treatment. One patient is on the induction now, so CR rate was evaluated in 12. CR was achieved in 10 of 12 (83,3%), in 7 after the 1st phase and in 3 – after the 2nd induction phase. 2 patients had refractory ALL and died from the disease. There were no differences in the frequency of infections, duration of neutropenia, transfusion support during induction in comparison with common ALL pts. In 3 pts of those who were treated during pregnancy delivery was carried out after the 1st induction phase, in 2 – during the 2nd phase, in 1 – after the 2nd phase. Gestational age at delivery was 34 weeks (33-39 weeks). At time of delivery 4 pts were and 2 were not in CR. One pregnant woman is still on the induction treatment. The median interval between the last administration of cytostatic drugs and delivery was 6 days (1-20 days). The median time from delivery to continuation of chemotherapy was 16 days (11-44 days). Chemotherapy duration during pregnancy constituted 5-9 weeks. Totally 9 children were born at a median gestation time – 36 weeks (33-40). All are alive at a median 9 months (8-60 mo) and healthy. Allo-HSCT was performed in 2 pts, auto-HSCT-2. There were 2 relapses and 1 death in CR. The OS and DFS constituted 62% and 53% at 3 years, and these results did not differ from the other pts treated according ALL-2009 protocol (60% and 57%, respectively).
Summary and Conclusions: Our data demonstrate that ALL in pregnant women is characterized by higher frequency of T-cell phenotype and high risk disease, most cases occurred in the 2nd and 3rd trimester, CR rate is 83%. All born children are well. Long-term survival does not differ from that of the other patients on this protocol. So pregnancy should not be considered as an exclusion criteria for our protocol that is non-intensive, non-interruptive and easily reproducible.

PB1605

FOURTEEN YEARS EXPERIENCE WITH THE EORTC 58951 PROTOCOL FOR THE TREATMENT OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA IN THE SOUTH OF TUNISIA

M. Medhaffar[1,*] I. F[1], B. A. I[1], H. S[1], J. I[2], S. I[3], G. M[1], K. O[1], B. H[1], K. F[1], E. M[1],
[1]Hematology, Hedi Chaker Hospital, [2]Hematology, Habib Bourguiba Hospital, [3]Hematology, Institut Pasteur, Sfax, Tunisia

Background: Childhood acute lymphoblastic leukemia (ALL) is an hematologic malignancies with high rate of cure. We report the experience of the department of clinical hematology of Sfax for the treatment of childhood ALL with the EORTC 58951 protocol.
Aims: we report the results of fourteen years treatment of childhood acute lymphoblastic leukemia with the EORTC 58951 Protocol
Methods: From January 2000 to December 2013, we retrospectively studied the outcome of all childhood ALL treated with the EORTC 58951 pediatric protocol. For those patients we studied the leukemia characteristics (sex ratio, white blood cell counts WBC, blast's phenotype, cytogenetic abnormalities) and response to treatment: response to prophase, remission rate, risk group stratification, treatment related mortality (TRM) (induction and post induction death) and survival (overall survival OS, event free survival EFS and disease free survival DFS: calculated for patients in complete remission). We complete the analysis by a comparison between two periods P1 and P2 (P1: 2000-2006 and P2: 2007-2013).
Results: From January 2000 to December 2013, 160 children were treated with the EORTC 58951 protocol. Median age was 6 years (range: 13 months to 15 years). Sex ratio M/F was 1.4. WBC counts less than 10 G/l, from 10 to 100 G/L and more than 100 G/L were observed respectively in 42, 42 and 16% of cases. The blast's phenotype was B in 70% and T in 30%. Cytogenetic abnormalities were noted in 48% of cases. A good response to prophase was noted in 84% and complete remission in 97% of cases. The EORTC risk group stratification was Low Risk (LR) in 6.5%, Average Risk1 (AR1) in 45%, Average Risk2 (AR2) in 25.5% and Very High Risk (VHR) in 23%. TRM was 9%: induction rate death was 7% and post-induction rate death was 2%. Seven patients from VHR group with familial donor underwent allograft. The relapse rate was 23% of all patients in remission; 10% for LR group, 22% for AR1 group, 17% for AR2 group and 37.5% for VHR group. At 5 years of follow up, OS, EFS and DFS were 67, 64 and 74% respectively. We compared two periods, we noted less TRM and less relapse in P2 with respectively (2% vs 14%) and (19% vs

28%), so we have a good survival at 5 years in P2 (OS: 75% vs 58%, EFS: 73% vs 55% DFS: 79% vs 68%).
Summary and Conclusions: Childhood ALL in our institut were characterized by a poor presentation at diagnosis: male sex, leucocytosis more than 100 G/L, T phenotype and bad response to prophase are frequent compared to the occident reports. EFS are acceptable in our study but still less than observed in literature (85-90%). We have noted an improvement in the survival rates during the second period P2 this could be explained by improved support treatment

PB1606

WHAT IF YOU FAIL? IMPACT OF UNSUCCESSFUL CYTOGENETIC ANALYSIS ON TREATMENT OUTCOMES IN ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): A TERTIARY CARE SINGLE CENTRE ANALYSIS FROM INDIA

C. Philip[1,*] M. J. John[1], A. Mathew[1], S. Singh[1]
[1]Clinical Haematology, Haemato-Oncology and Bone Marrow (Stem Cell) Transplantation, Christian Medical College & Hospital, Ludhiana, India

Background: Cytogenetic findings are important in predicting prognosis; and are an obligatory tool in stratifying patients for treatment assignment in ALL. The large studies in ALL have reported between 10-30% of cytogenetic failure. The impact of cytogenetic failure on treatment outcomes in this group with ALL has not been sufficiently explored.
Aims: To determine the differences in clinical features and treatment outcomes in patients with ALL based on the success of karyotype analyses.
Methods: We undertook a retrospective study to evaluate the impact of cytogenetic failure on treatment outcomes in patients with a diagnosis of ALL (Burkitt-excluded) treated at our tertiary care center from January 2009 till December 2014. Cytogenetic failure was used to define analyses that could not be performed in the laboratory due to no mitoses or non-informative morphology. Risk stratification and treatment was based on the BFM95 protocol for patients' ≤15 years and GMALL in the older patients. Standard of care diagnostic tests and supportive care was administered to all patients. The cytogenetic data was retrieved from the original reports of the laboratory performing the analyses at our centre. Only cytogenetic studies sent to the laboratory were included for analyses. Clinical details were ascertained through patient admission records and discharge cards. The collected data was analyzed using SPSS.

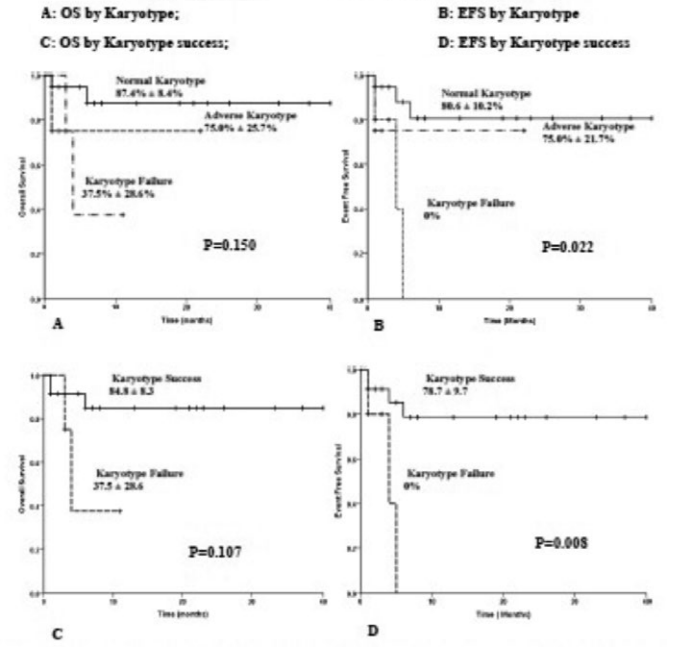

Figure 1.

Table 1. Socio-demographic characters, clinical features and laboratory parameters in newly diagnosed patients (N=54).

Variable	Cytogenetic Success (N=26) n (%)/Median (Range)/Mean ±SD	Cytogenetic failure (N=7) n (%)/Median (Range)/Mean ±SD	P value
Age (years)	16 (2-65)	17(11-30)	0.604
Sex (male)	16 (61.5)	3 (42.5)	0.203
ALL type (B-ALL)	20 (76.9)	3 (42.9)	0.092
Philadelphia (positive)	5 (20.8)	0 (0)	0.252
Steroid response (day8)	17 (89.5)	2 (40.0)	0.044
Post Induction Marrow (remission)	16 (80)	2 (50)	0.232
Infection in induction	7 (26.9)	1(14.3)	0.469
Treatment duration (Induction)	28 (27-41)	29 (28-35)	0.278
Haemoglobin (g/L)	82.0(24.0-137.0)	73.0 52.0-153.0)	0.706
WBC count (x10 ^{9}/ L)	68.2 (0.6-360.0)	33.2 (0.2-124.0)	0.327
Platelet count (x10 ^{9}/ L)	43(5.4-344.0)	84 (3.0-307.0)	0.589
Absolute Blast count(x10 ^{9}/ L)	24.1(0.12-229.4)	26.5(0-111.6)	0.912

Results: A total of 76 admitted patients were diagnosed with ALL. Of these 54 (71.1%) continued with treatment. Bone marrow was sent for cytogenetic analyses in 33 of these patients. There were no significant differences observed in terms of socio-demographic and baseline laboratory parameters among the two groups based on the success of cytogenetic analyses (table1).The Event Free Survival (EFS) and Overall Survival (OS) were lesser in patients with cytogenetic failure than in those who had a successful karyotype analyses (Figure 1). With a mean follow up of 32 months, the EFS at one year in those with cytogenetic failure was significantly lower than those with a successful karyotype analyses (P=0.008). When compared against the outcomes of patients with adverse karyotype (t (9; 22) or >3 abnormalities), those with cytogenetic failure had a significantly lower EFS (P=0.022).
Summary and Conclusions: Risk stratification in ALL has not defined the optimal strategy in patients with cytogenetic failure. Unsuccessful cytogenetics likely predicts a poor outcome. This needs to be further explored by facilitating the inclusion of these patients as a group in clinical trials.

PB1607

THE FREE RADICAL OXIDATION ROLE IN THE DEVELOPMENT OF ANTHRACYCLINE-INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE LEUKEMIA IN THE PRESENCE OF CONCOMITANT ISCHEMIC HEART DISEASE

T. Lymanets[1,*] I. Skrypnyk[1], G. Maslova[1],
[1]Chair of Internal Medicine #1, Ukrainian Medical Stomatological Academy, Poltava, Ukraine

Background: Anthracycline antibiotics (AA) are included into the most modern acute leukemia (AL) treatment regimens. The AA assignment in polychemotherapy (PCT) programs contributes to the clinical-hematological remission percentage growth, and the improvement of pts survival. However, the formation of anthracycline-induced cardiotoxic effects can be significant limiting factor of PCT full dose conducting, which certainly leads to reduced effectiveness of anticancer therapy. In this aspect particularly important becomes the assessment of the heart tissue injuries potential risks. The incidence of cardiotoxicity depends on the cumulative dose (CD) of AA. The generally toxic AA CD is 550 mg/m^2 for doxorubicin. An additional risk factor for anthracycline cardiotoxicity is considered to be the concomitant ischemic heart disease (IHD). The imbalance between generation and inactivation mechanisms of aggressive free radicals as a risk factor of heart tissue AA-induced injury in patients with AL with concomitant ischemic heart disease remain insufficiently studied.
Aims: To assess the prooxidant-antioxidant imbalance status in patients with AL in the dynamics of AA treatment taking into account concomitant IHD.
Methods: The study involved 41 patients with acute leukemia (acute lymphoblastic leukemia-13 pts, acute myeloid leukemia-28 pts), aged 16–72 years, 23 (56%) men and 18 (44%) women, which PCT included AA. Patients were divided into two groups according to the presence of concomitant IHD: I (n=24) – without concomitant IHD; II (n=17) – with the concomitant IHD. The general condition assessment of pts of the both groups was performed twice: before specific therapy and after reaching AA cumulative dose from 100 to 200 mg/m^2. The POL processes activity was determined by the malondialdehyde (MDA) level, the antioxidant protection (AOP) – the serum catalase concentration.
Results: Before treatment in patients of group I without concomitant IHD the MDA concentration in serum exceeded the upper limit of normal in 1.2 times, the catalase level – in 1.1 times. In patients of group II with concomitant IHD the MDA level was increased in 1.46 times with the simultaneous tendency to reduce the catalase concentration in serum compared to normal, indicating that the exhaustion of antioxidant protection on the IHD background. Upon reaching the AA CD of 100-200 mg/m^2 MDA concentration in serum was in 1.54 times higher in pts of group II compared with pts of group I (4.81±0.38 mmol/l vs 3.12±0.28 mmol/l; P<0.05). Simultaneously, with the presence of concomitant IHD in pts of group II the catalase level in serum was in 2.1 times lower in comparison with pts of group I (72.5±8.7 mkkat/l vs 33.8±3.2 mkkat/l; P<0.05).
Summary and Conclusions: Therefore, concomitant ischemic heart disease in patients with AL during the treatment AA is an additional risk factor for cardiotoxicity, due to exhaustion antioxidant protection system and deepening imbalance between the formation and inactivation of free radicals.

PB1608

OUTCOME OF ADOLESCENTS AND YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH PEDIATRIC PROTOCOL: 62 CASES

F. I[1,*] M. Medhaffar[1], B. A. I[1], H. S[1], K. O[1], B. H[1], K. F[1], E. M[1]
[1]Hematology, Hedi Chaker Hospital, Sfax, Tunisia

Background: Several retrospective studies have confirmed that adolescents and young adults (AyA) with acute lymphoblastic leukemia (ALL) treated with pediatric protocols have better outcomes than similarly aged patients treated with adult protocols. We reported results and feasibility of a pediatric-based protocol (EORTC 58951) in adolescents and young adults.

Aims: Pediatrics protocols improve the outcome of adiolescents and adults acute lymphoblastic leukemia
Methods: From January 2000 to December 2013, 62 patients aged 16 to 30 years with newly diagnosed ALL were treated, in the department of clinical hematology of Hedi Chaker Hospital, according to the pediatric protocol EORTC 58951. Further leukemia characteristics (Sex, White Blood cell count, Blasts phenotype, Cytogenetic results), we studied the protocol results: response to prophase, risk group stratification (average: AR1 and AR2, very high: VHR), treatment related mortality (TRM), remission rate, relapse rate and 5 years survivals (overall OS, event free EFS and relapse free survival RFS).
Results: Sixty two AyA ALL were treated with the pediatric protocol. The patients were 38 males and 24 females (SR=1.58). 34% had a WBC>100 G/l. A T blast phenotype was noted in 53% of cases. Nineteen patients (30.5%) had poor response to pophase. Fifty two patients (86%) received AR2 (52%) or VHR (34%) arm induction. Fifty seven patients (97%) achieved CR. Two patients failed to achieve complete respond after 2 courses of chemotherapy. Induction death was noted in 8%. Consolidation death was noted in 17%. Relapse was observed in 25%. Five years OS, EFS and RFS were respectively 48, 48.5 and 65%.
Summary and Conclusions: This study showed that pediatric protocol can offer good results concerning CR and DFS to adolescent and young adult ALL. However OS and EFS, sure better than adult ALL treated during the same period by adult protocol (OS= 14%, EFS=14% and DFS= 40%) was not satisfactory because the high toxic mortality rate.

PB1609

HIGH RISK CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA GROUP TREATED WITH THE EORTC58951 PROTOCOL: RESULTS AND OUTCOME

M. Medhaffar[1,*] F. I[1], G. M[1], K. O[1], B. H[1], K. F[1], B. A. I[1], H. S[1], E. M[1]
[1]Hematology, Hedi Chaker Hospital, Sfax, Tunisia

Background: More than 80% of children with acute lymphoblastic leukemia (ALL) can be cured, but subsets of patients have significantly worse outcomes. In this study we analyzed the clinical, biological features and therapeutic results of patients treated with high risk group of the EORTC protocol.
Aims: Report the outcome of high risk childhood acute lymphoblastic leukemia group
Methods: From January 2000 to December 2013, 160 patients with ALL aged less than 16 years were treated by the EORTC protocol in the Hematologic department of Hedi Chaker Hospital, from those 37 patients were treated by high risk group (VHR). The VHR group includes patients with poor prednisone response at day 8 (more than 1000 blasts/mm^3 on the blood smear), those with defavorable cytogenetic abnormalities (t (9,22), t (4,11)...) and those with complete remission after two courses of chemotherapy. From those patients we analyzed the clinical and biological features (Age, sex, blood count, cytogenetic abnormalities and blasts phenotypes) and therapeutic results (remission rate, rate relapse, overall survival (OS), event free survival (EFS) and disease free survival (DFS) at 5 years follow up).
Results: In our study, thirty seven children were treated with VHR group of the EORTC protocol (23%). The median age of patients was 9 years (ranged 2-15 years). Sex ratio H/F=1,64. The median WBC count at diagnosis was 55.8 G/L (ranged from 2 to 400 G/L). There were 51% with B-cell ALL and 49% with T-cell ALL. Cortico-resistance was the only high risk factor in 23 patients, absence the remission after induction in 8 patients and only cytogenetic abnormalities in 4 patients. The cortico-resistance at day 8 was observed in 65% of patients. Five children (13.5%) were treatment failure after two courses of chemotherapy. The complete remission was obtained in 32 children (86%), among them 12 relapsed (37.5%). The post induction death was noted in 2 patients. Only 7 patients (16%) underwent allograft from familial donor. At 5 years follow-up, the OS, EFS and DFS were respectively 46%, 43% and 54%.
Summary and Conclusions: The frequency of high risk group in our study is more than those observed in the literature (12 to 16%). The poor 5 years survivals (OS=46%, EFS=43%) are related to the high rate of relapse. Improvement of outcome can be obtained by enlargement of donor source: unrelated and cord blood.

PB1610

CLINICAL CHARACTERISTICS AND CYTOGENETIC ABNORMALITIES OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS: SINGLE INSTITUTE EXPERIENCE FROM SAUDI ARABIA

N. Alkhayat[1,*] G. Elyamany[2], Y. Elborai[1,3], O. Alsharif[1], M. Awad[2], O. Alsuhaibani[2], I. Ben-Abdallah Bouhajar[2], E. Al Mussaed[4], M. ALshahrani[1]
[1]Pediatric Hem/Onc and BMT Department, [2]Pathology and Laboratory Medicine, Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [3]Pediatric Hem/Onc and BMT Department, National Cancer Institute, Cairo University, Cairo, Egypt, [4]Department of Basic Science, Princess Nourah Bint Abdulrahman University College of Medicine, Riyadh, Saudi Arabia

Background: Childhood Acute Lymphoblastic Leukemia are generally characterized by recurrent molecular and cytogenetic abnormalities; the identification of those abnormalities is clinically important because they are considered significant risk-stratifying markers.
Aims: Currently, no sufficient data exist regarding cytogenetic abnormalities and treatment outcome in Saudi pediatric ALL patients. Ninety-two cases of childhood ALL were examined to determine cytogenetic profile, and did correlations to other biologic factors.
Methods: Patients. From 2004 to 2014, we reviewed all cases with established diagnosis of childhood ALL. Of the 92 patients, 82 were B-lineage ALL, and 10 T-cell ALL. All patients were treated by UKALL 2003 protocol and risk stratified according previously published criteria. Cytogenetic Analysis. Chromosome banding analysis and fluorescence *in situ* hybridization (FISH) were used to detect genetic aberrations. Analysis of *FLT3* mutations. Bone marrow or blood samples were screened for *FLT3* mutations (internal tandem duplications, ITDs and point mutations, D835) using polymerase chain reaction methods (PCR).
Results: Figure 1 and Table 1. Summarize patient's characteristics and patient's outcome. Cytogenetic analysis showed chromosomal anomalies in 59 out of 92 cases with overall incidence 64.1%.The most frequent chromosomal anomalies in ALL were trisomy 21, t(9;22), and t(12;21). Our data are in accordance with those published showed that *FLT3* mutations not common in ALL patients (4.7%) and have no prognostic relevance in pediatric ALL patients while t(9;22) and MLL gene rearrangements were signs of a bad prognosis in childhood ALL, with high rate of relapse, shorter overall survival; (P=0.031) and event-free survival (EFS) was also worse(P=0.040**)** compared to standard risk group.

Tabella 1. Cytogentic abnormalities detected in our study.

Available for Karyotype	28 normal 11 abnormal
Available for Fish	n=83
t (9;22)	10 (12%)
t (12;21)	8 (9.6%)
MLL	6 (7.2%)
MYC	2 (2.4%)
t (1;19)	1 (1.2%)
+21	11 (13.3%)
Del 12p	5 (6%)
+6	1 (1.2%)
+9	3 (4.6%)
+8	1 (1.2%)
-19	1 (1.2%)
Hyperdiploid	6 (7.3%)
Pseudotriploidy	2 (3.1%)
Tetraploidy	1 (1.5

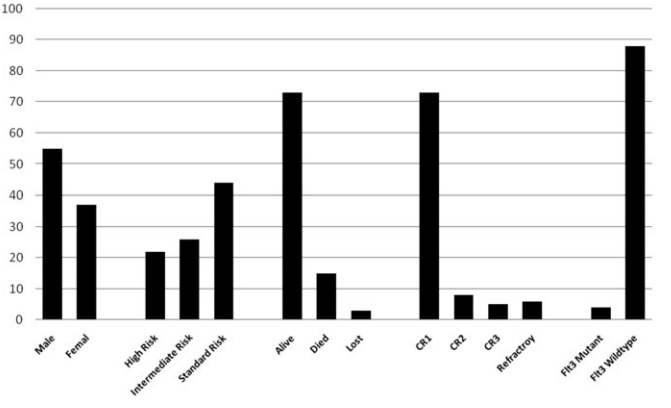

Figure 1. Patient characteristics and *FLT3* mutations.

Summary and Conclusions: Our data are in accordance with those published and confirm that the frequency of cytogenetic abnormalities and their prognostic relevant were comparable to those reported in the literature. FLT3 mutations not common among Saudi ALL and occur in low percentage and had no prognostic relevance as in AML and did not affect clinical outcome.

PB1611

IMPACT OF DURATION TO COMPLETE INDUCTION IN ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE CENTER EXPERIENCE FROM INDIA

C. Philip[1,*] M. J. John[1], A. Mathew[1], S. Singh[1]
[1]Clinical Haematology, Haemato-Oncology and Bone Marrow (Stem Cell) Transplantation, Christian Medical College & Hospital, Ludhiana, India

Background: The improvement in event free survival in Acute Lymphoblastic leukemia(ALL) corresponds to advances in chemotherapy and supportive care. However despite these breakthroughs, the intensity of the chemotherapy predisposes patients to cytopenias and infections. These result in a break from the protocol and delay in induction completion. In a resource restricted setting where a major constraint to therapy remains the cost, it is important to analyze the factors to optimize treatment. The impact of duration to complete the initial intensive induction on survival needs analysis.
Aims: To evaluate the clinical characteristics and outcome of patients with a diagnosis of ALL (Burkitt- excluded) admitted at our tertiary care center.
Methods: We undertook a retrospective study on patients with ALL (Burkitt-excluded) admitted at our tertiary care center. Induction chemotherapy consisted of standard induction as in the BFM95 protocol for patients' ≤15 years and GMALL in the older patients. In addition to the chemotherapy; standard of care diagnostic tests and supportive care was administered to the patients. The data was retrieved from the patient admission records and discharge cards. The collected data was analyzed using SPSS.
Results: A total of 76 admitted patients were diagnosed with ALL during this period. Of these 54 (71.1%) continued with treatment (Fig 1A). The median age of newly diagnosed patients was 20 years (range: 1-65) and there were 53 (69.7%) males. In the treated patients, B-ALL was seen in 37(68.5%).The other baseline features are as depicted in Table1. The mean duration of induction chemotherapy was 30.4(± 5.3) days. A microbiologically documented infection was seen in 11(20.4%) and the induction was delayed more than the mean duration in 14 (37.8%). With a mean follow up of 15 months, the Event Free survival at one year in those with delay in completion of induction was 68.2%±15.4 and not statistically significant from those without a delay (Fig 1B). A similar conclusion was seen in the pediatric subgroup analysis (Data not shown).

Table 1. Descriptive baseline demogrphic characteristics in newly diagnosed patients with ALL.

Variable	PATIENTS (N=74)** n (%)/ Median (Range)/Mean (±SD)
Age (years)	20 (1-65)
Sex (Male)	53 (69.7)
Decision to continue treatment (Yes)	54 (71.1)
ALL subtype (B-ALL) n=54	37 (68.5)
Philadelphia positive (yes) n=37	6 (16.2)
Duration of induction	30.4 (± 5.3)
Haemogram N=43	
Haemoglobin (g/L)	79.6 (±32.5)
White blood cell count (x10 ^{9}/ L)	10.2 (0.2-360.0)
Platelet count (x10 ^{9}/ L)	38.0 (3.0-398.0)
Blasts in bone marrow (%)	82.2 (±19.6)
**(% derived from n)	

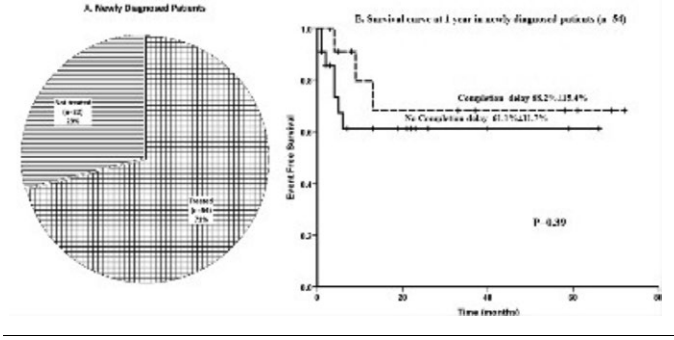

Figure 1. Newly diagno

Summary and Conclusions: In conclusion there are challenges in the management of ALL in India. One fourth of the patients decline treatment in view of financial constraints. In those who proceed with induction, there occurs a delay in one third. These delays do not appear to impact the event free survival in ALL. More analysis of prevalent practices will help tailor therapy in resource restricted settings.

PB1612

COST EFFECTIVE APPROACH IN FLOWCYTOMETRY BASED IMMUNOPHENOTYPE OF ACUTE LYMPHOBLASTIC LEUKEMIA. A TERTIARY CENTRE EXPERIENCE FROM AIIMS, NEW DELHI, INDIA

P. Tanwar[1,*] A.R. Singh[1], R. Gupta[1] S. Bakhshi[2], I. Kumar[2]
[1]Laboratory Oncology Unit, Dr B.R.A.Institute Rotary Cancer Hospital, [2]Medical Oncology, Dr B.R.A.Institute Rotary Cancer Hospital, all India Institute of Medical Sciences, New Delhi, India

Background: The diagnosis of acute lymphoblastic leukemia is based on morphology, cytochemistry, cytogenetics and immunophenotyping. In an under resource setting and sparsely insurance covered nation like India, the cost of investigation and treatment is one of the major barrier between disease and its curative management. With primary objective of establishing, the cost effective diagnostic panels without compromising the quality, we used primary screening antibodies panel comprising of major pan-lineage markers. This was followed by extensive secondary antibodies panel comprising of more lineage specific markers to reach a final diagnosis. In this study, we evaluated, the cost effective role of five-color primary screening antibodies to reach to the final conclusive diagnosis without compromising the quality of analysis.
Aims: Evaluation of the cost effective role of five-color primary screening antibodies panel in flowcytometry based immunophenotyping of Acute Lymphoblastic Leukemia.
Methods: A total of 234 newly diagnosed cases of Acute Leukemia from Jan 2013 to Jan 2015 were included in this study. All these cases were stratified to their respective lineages with the panel of primary screening antibodies comprising of cytoplasmic myeloperoxidase (MPO), cytoplasmic 79a (c79a), CD34, cytoplasmic CD3 (c3) and CD45.Once the lineage has been screened, then extensive secondary panel of antibodies with more specific marker of B-cell, T-cell and myeloid lineage were used to conclude for final diagnosis
Results: Of all the cases (234) evaluated 206(88%) were successfully identified on primary screening panel only, 28/234(17%) cases failed to show any specific lineage in primary screening panel. These 28 cases included 23/187(12%) B-ALL and 5/47(10%) cases of T-ALL
Summary and Conclusions: The five-color primary screening antibodies panel was very cost effective in identifying correct lineages in majority *i.e.* 88% of all cases. The absence of lineage specific marker was the most common reason for failure of the predictive power of the primary panel

PB1613

OVERALL-SURVIVAL, DISEASE-FREE SURVIVAL AND COMPLETE RESPONSE RATE IN ACUTE LYMPHOBLASTIC LEUKEMIA IN ADULTS IN COLOMBIA

E. Castillo[1,*] A. M. Castellanos[2], M. E. Pierre[3], J. Prada-Arismendy[4]
[1]Hematology and Oncology Unit, Hospital Manuel Uribe Angel, Envigado, [2]Hematology and Oncology Department, Fundación Cardio-Infantil, [3]Hematology and Oncology Department, Hospital Militar Central, Bogotá, [4]Grupo de Investigación e Innovación Biomédica, Instituto Tecnológico Metropolitano, Medellín, Colombia

Background: The ASR incidence of acute lymphoblastic leukemia (ALL) in U.S. is 1.6 cases per 100,000, with 6,050 de novo cases per year and 1,440 deaths estimated during 2012. ALL accounts for 80% of all acute leukemias in children, with 3-years overall-survival (OS) around 80%. In adults, ALL is responsible of 20% of acute leukemias, with 3-year OS around 40%. In Colombia, the statistics are poor. Globocan and National Cancer Institute of Colombia estimated approximately 2,500 cases of leukemias in 2012, with an ASR incidence of 6.3 per 100,000 and an ASR mortality of 4.8 per 100,000. Taking into account these dates, approximately 73% of patients diagnosed with any kind of leukemia in Colombia die. Treatment response rates and OS data in Colombia are even scarcer; the study of the National Cancer Institute found a complete response (CR) rate of 64% and 3 years OS of 0%.
Aims: To determine the CR rate to treatment, disease-free survival (DFS) and (OS) in adults with ALL treated with different chemotherapy protocols in Hospital Militar Central (HMC) (Bogotá, Colombia) between 2006-2012.
Methods: A retrospective study was made on newly diagnosed ALL patients who came to HMC from January 2006 to December 2012. Descriptive statistics and cross-tabulation were used to describe patient characteristics. Mann-Whitney analyses were used to determine between-group differences. OS and DFS were analyzed with Kaplan- Meier method.
Results: Thirty-four patients older than 15 years were diagnosed with de novo ALL. Mean age was 28.5 years-old; 55.9% of cases had between 15 to 24 years-old. 23.5% of patients were older than 35 years- old, of which 25% had t(9;22). Mean leukocyte count was 38,490/uL (1500-367.000/uL). Anemia was present in 86.7% and 20.6% of patients had normal platelet count.
Twenty-six patients (76.5%) showed B-cell lineage, while T-cell lineage was found in 5 cases (14.7%). Ten patients (38.5%) with B-cell lineage had leukocyte count ≥ 30,000/µL (avg. 82,318/µL). All patients with T-cell lineage had leukocyte count less than 100,000/µL (avg. 17,536/µL). Karyotype was normal in 22 cases (64.7%). 80% of patients with abnormal karyotype had t(9;22), of which 66.7% had hyperleucocytosis. Twenty patients (58.8%) were at high risk for systemic relapse, (presence of one or more of the following: hyperleucocytosis ≥ 30,000/ul in B-cell phenotype, hyperleucocytosis ≥100.000/uL in T-cell phenotype, age ≥ 35 years, CD20 positivity >20% and t(9;22). The other molecular risk factors are not available in Colombia. The most frequent chemotherapy protocol used was GMALL (35%) followed by FRALLE 93 (29%). Two patients (5.9%) died during induction phase. Twenty-eight cases (82.3%) entered CR after induction therapy. Minimal residual disease was evaluated by flow cytometry in 17 patients (60.7%), being positive in 10 (58.8%) and negative in 7 (41.2%). From 28 patients who entered CR after induction therapy, 9 cases relapsed; 88.9% of relapses occurred during first 12 months. Mean time to relapse was 7.4 months. All patients who relapsed received second-line protocol

(R HyperCvad, HyperCvad, BFM Retz, IDA-FLAG and ALL R3) and only 3 responded (42.8%). OS and DFS at the first year was 92% and 84.8%, respectively. The OS and DFS to 3 years was 29.5% and 32.4%, respectively.
Summary and Conclusions: Comparing data previously obtained by National Cancer Institute between 2001-2005, this study shows improved CR rates and OS in ALL in Colombia during recent years. However these data are still less favorable than those obtained in studies from developed countries.

SUPPRESSION OF ADRENAL AXIS FUNCTION AFTER HIGH-DOSE STEROID THERAPY FOR CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA IN IRAN

S. Ansari[1,*] M. Sabzechian[2], A. Kiumarsi[1], T. Rostami[1], F. Rouhani[3]
[1]Hematology, Iran University, [2]Hematology, Baghiyatollah University, [3]Iran University, Tehran, Iran

Background: A 4 weeks course of high-dose glucocorticoids (GCs) may cause prolonged adrenal suppression even after a 9 days tapering phase.
Aims:.In this study, adrenal function and signs and symptoms of adrenal insufficiency were prospectively assessed in children with acute lymphoblastic leukemia (ALL) after induction treatment with high-dose prednisone.
Methods: In 42 children with newly diagnosed ALL, a baseline serum cortisol level was assessed and after receiving a 28 days of high dose prednisone according to the BFM 2009 protocol ad a 9 days tapering phase, serum cortisol level was assessed again and thosel was normal underwent low-dose adrenocorticotropic hormone (LDACTH) stimulation 24 h after the last tapered steroid dose. Signs and symptoms of adrenal insufficiency were recorded during the observation period. All patients except one who was excluded had normal basal cortisol values at diagnosis.
Results: Twenty-four hours after last GC dose, morning cortisol was reduced in 15 (36.5%) patients. LDACTH testing showed adrenal suppression in 17 (41.4%) patients.
Summary and Conclusions: High-dose GC therapy in ALL children may cause adrenal suppression even after a tapering phase. Laboratory monitoring of cortisol levels and steroid coverage during stress episodes may be indicated.

PB1615

EVALUATION OF BONE MINERAL DENSITY IN YOUNG ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS: A SINGLE CENTER EGYPTIAN EXPERIENCE

G. Elgohary[1,*] I. Asfour[1], N. Moustafa[1], H. Abdelbary[1], H. Dief[1], M. Refaee[1], M. Tolba[1]
[1]Adult Haematology, Ain Shams University, Cairo, Egypt

Background: Bone health and the loss of bone density are important clinical concerns for patients with cancer who may be at risk for primary osteoporosis because of aging and other risk factors. They may have the added risk for cancer treatment-induced bone loss (CTIBL), which also could be termed secondary osteoporosis related to therapy and cancer as in acute lymphoblastic leukemia (ALL).
Aims: To assess bone mineral density in young adult patients with ALL at presentation and after induction therapy, to determine whether disease and/or chemotherapy can affect bone density
Methods: 25 Adult patients aged 20-45 years, with newly diagnosed ALL, presenting to Ain Shams University hospitals were recruited to this cross-sectional prospective study if they were eligible for induction therapy.All patients were evaluated according to published international guidelines for assessment of new acute leukemia patients. In addition, bone mineral density (BMD) was evaluated by using dual-energy X-ray absorptiometry (DXA) for all studied subjects at presentation and at D28 for evaluable patients. Measurements were performed at the lumbar spine (L2 to L4) and the left femoral neck using a Lunar DPX-L scanner. Bone mineral density was expressed in grams per square centimeter (g/cm2). Lumbar spine and femoral neck BMD was evaluated in all patients at diagnosis and after receiving induction chemotherapy. T-score was used to describe BMD (normal, osteopenia or osteoporosis) according to WHO classification.All patients except those who had mature B cell ALL received induction according to Holtzer protocol, while Patient with mature B-cell ALL received hyperCVAD chemotherapy (cycle A).
Results: 25 patients with newly diagnosis of ALL were recruited into this prospective study. Mean age was 30.32 (20-45 years), male: female ratio was 3:2. Presenting features include anemia (80%), bleeding tendency (52%), fever (52%) and hyperleucocytosis (32%). Extra medullary infiltration was detected in 3 patients, testis (n=1) and Central nervous system (n= 2).Sixteen patients (64%) had Pre-B ALL, one patient (4%) had Pro-B ALL, two patients (8%) had mature B ALL and six patients (24%) had T ALL. Clonal chromosomal abnormalities was detected in 4 patients (complex chromosomal abnormalities in one patient and t (9; 22) in 3 patients). 21 were evaluable at day +28. Seventeen patients (68%) were in complete remission and four patients (16%) had refractor leukemia.None of the patients had osteoporosis either in the pre or post treatment evaluation (T-score<-2.5). Seven patient (28%) fulfilled the WHO criteria for osteopenia in the lumbar spine at diagnosis (T- score -1 to -2.5). At post-treatment evaluation, ten patients (40%) were found to have osteopenia as assessed at the lumbar spine. Yet the difference in bone density at the lumbar spine did not reach statistical significance (p-value >0.05). There was statistically significant reduction in the BMD at the left femoral neck, in the post treatment evaluation as compared to the pre treatment evaluation, with p-value<0.001.We have tried to correlate the bone density (BMD,T score, Z score) in femoral neck to several clinical variables in a multivariate analysis (age, sex, extra medullary disease, and Ph chromosome). However, we did not find any statistically significant correlation with any of the previous factors.

Table 1. Bone mineral density BMD pre- and post tratment values at the lumber spine and the left femor neck.

Left Femur Bone Density			Paired Differences		t-test	
	Mean	±SD	Mean	±SD	t	p-value
Lt.femoral BMD pre treatment	1.33	0.15	0.11	0.10	5.384	**<0.001**
Lt.femoral BMD - post treatment	1.22	0.14				
Lt.femoral T score pre treatment	2.25	0.96	0.81	0.68	5.441	**<0.001**
Lt.femoral T score post treatment	1.44	1.05				
Lt.femoral Z score pre treatment	2.02	0.99	0.77	0.69	5.107	**<0.001**
Lt.femoral Z score post treatment	1.25	1.10				
Lumbar spine BMD pre-treatment	1.14	0.10	0.057	0.231	1.134	0.270
Lumbar spine BMD post-treatment	1.08	0.26				
Lumbar spine T score pre-treatment	-0.50	0.77	0.205	0.765	1.227	0.234
Lumbar spine T score post-treatment	-0.70	1.18				
Lumbar spine Z score pre-treatment	-0.92	0.86	0.005	0.762	0.029	0.977
Lumbar spine Z score post-treatment	-0.92	1.18				

Summary and Conclusions: Skeletal morbidity, characterized by bone pain, osteonecrosis, fractures, loss of mobility, bone deformation, or osteopenia, is frequently encountered in patients affected by ALL. Clinically important sites for evaluation of osteopenia/ osteoporosis in adult are the lumbar spine (L2-L4), and femoral neck. Larger sized studies are required to draw more firm conclusions and to design screening and prophylactic programs.

PB1616

ANALYSIS OF THE EFFICACY OF CCLG-ALL2008 PROTOCOL ON THE ADOLESCENTS AND YOUNG PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

Y. Lang[1], C. Wang[2], S.J. Gao[2], Y.H. Tan[2,*]
[1]Dermatology Department, [2]Tumor Center, First Hospital of Jilin University, Changchun, China

Background: Acute lymphocytic leukemia is a kind of heterogeneous disease, the prognosis of the pediatric patients was significantly better than that of adults. Adolescent and young adult (AYA) patients could adopt pediatric or adult chemotherapy regimens. In recent years, some studies showed pediatric like regimens could improve the prognosis of AYA ALL patients.
Aims: Analysis of efficacy and safety of the pediatric ALL chemotherapy regimen CCLG-ALL2008 on adolescents and young ALL.
Methods: 15 to 30 years old ALL patients treated with CCLG-ALL 2008 regimen from January 2008 to December 2013 in our cancer center was retrospectively analyzed. CR rate on day 14 and day 28, relapse-free survival, overall survival and the relativity between the clinical characteristics and RFS were analyzed. The chemotherapy related toxicity was assessed with WHO criteria. The informed consents of each patient was obtained before the treatments.
Results: 21 cases of adolescent ALL included 13 males and 8 females were analyzed, with a median age of 18 years old and 18 cases with median-risk and 3 cases with high-risk according to regimen CCLG-ALL2008. 14 days CR rate was 90.5% and 28 day CR rate was 100%, median CR time were 14 days (14 to 28d), median cytogenetic remission time was 2 months, 17 patients reached molecular biology remission with a median time of one month. Three cases relapsed and 1 patient was lost in follow-up, five cases underwent hematopoietic stem cell transplantation. 2-year OS rate was 100.0% and 2-

year RFS rate was 66.6%; Univariate and multivariate analysis showed that the presence of extramedullary infiltration was unfavorable factors of 2-year RFS. Neutropenia was observed in 17 patients (81%), neutropenia fever occurred in 12 cases (57.1%) and were documented with infection, including 2 (9.5%) pneumonia and 5 sepsis (23.8%). 4 degree of thrombocytopenia occurred in 13 patients (61.9%) and coagulation abnormalities occurred in 16 patients (76.2%), Non-fatal bleeding occurred. 1-2 grade toxicity occurrence rates in heart, liver and kidney and gastrointestinal were 33.3%, 61.9%, 23.8% and 71.4% respectively.
Summary and Conclusions: The regimen of CCLG-ALL2008 has obtained good curative efficacy in AYA ALL patients, and the toxicity was easily tolerated.

PB1617

EVALUATION OF ENDOCRINE LATE COMPLICATIONS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA SURVIVORS

C. Bayram[1,*] N. Yarali[1], A. Fettah[1], F. Demirel[2], A. Kara[1], B. Tunc[1],
[1]Pediatric Hematology, [2]Pediatric Endocrinology, Ankara Children's Hematology and Oncology Hospital, Ankara, Turkey

Background: Improvement in long-term survival in patients with acute childhood leukemia has led to the need for monitorization of chemotherapy related morbidity and mortality.
Aims: This study aimed to evaluate long-term endocrine compliations in acute lymphoblastic leukemia survivors.
Methods: Sixty patients diagnosed with acute lymphoblastic leukemia between December 2003 and May 2009 at Pediatric Hematology Clinic, Ankara Children's Hematology and Oncology Education and Research Hospital, who were in remission for at least two years, were evaluated retrospectively for endocrine complications.
Results: There were 31 male and 29 female patients, while 55 of them were diagnosed with precursor B-cell ALL and 5 of them with T-cell ALL. Median age of the patients at the time of diagnosis, at the time of chemotherapy completion and at the time of study was 5 years (range:3-7,8 years), 8 years (6,2-10,8 years) and 11.7 years (range: 10-14.9 years), respectively and median duration of remission was 4 years (range: 2.5-5 years). At least one complication was observed in 81,6% of patients. Vitamin D insufficiency / deficiency (46,6%), overweight / obesity (33,3%) and dyslipidemia (23,3%) were the most three frequent endocrine complications. Other complications seen in our patients were hyperparathyroidism secondary to vitamin D deficiency (15%), insulin resistance (11,7%), hypertension (8,3%), failure to thrive (6,7%), thyroid function abnormality (5%), precocious puberty (3,3%) and decreased bone mineral density (1,7%), respectively. There were no statistically significant correlation between endocrine complications and age, sex and radiotherapy.
Summary and Conclusions: A high frequency of endocrine complications were observed in the current study. It is estimated that about two-thirds of cancer survivors will experience at least one late adverse effects and more than 40% may have a severe, disabling or life-threatening condition or may die 30 years after cancer is diagnosed as a result of their cancer and it's therapy. The high frequency of late effects necessitates long-term surveillance of this population to better understand the incidence of late-occurring events and defining high-risk features that can facilitate developing intervention strategies for early detection and prevention.

ANALYSIS OF THERAPY RESULTS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKAEMIA. A SINGLE CENTER EXPERIENCE IN TURKEY

T. Patiroglu[1,1,*] M. A. Ozdemir[1], E. Unal[1], K. Degirmenci[1], M. Karakukcu[1]
[1]Pediatric Hematology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Prognosis of children with acute lymphoblastic leukemia (ALL) which the most common cancer in childhood, has improved in the last years.
Aims:
Analysis of treatment outcome and identification of prognostic factors in children treated for acute lymphoblastic leukaemia (ALL).
Methods: The patients diagnosed for ALL in our Hospital of Kayseri-Turkey between 2000-2014 were evaluated retrospectively. Children were treated according to the protocol of BFM-90 (Berlin-Frankfurt-Münster). Patients were classified into standart-risk (SR), medium-risk (MR) and high-risk (HR) group according to initial leukaemic burden, early treatment response, genotype of leukemia.
Results: A total number of 341 children aged 4 monts -17 years (median age 5.45 years) were diagnosed for ALL in our Hospital of Kayseri-Turkey between 2000-2014. Children were treated according to the protocol of BFM-90 (Berlin-Frankfurt-Münster).Duration of the chemotherapy was two years. Treatment results were evaluated in 341 children. With a median follow-up of 7 years, event-free-survival (EFS) was 85.4% and overall survival 86.4%. Relapse was diagnosed in 14.6% of the patients.
Summary and Conclusions: Large progress has been made in the treatment of acute lymphoblastic leukaemia of childhood and adolescence over the analyzed period of 14 years. Our results for children with acute lymphoblastic leukaemia are similar to the results in the other BFM study-Group.

PB1619

IS CD45 EXPRESSION LEVEL RELATED TO HIGH RISK DEFINITION IN CHILDHOOD PEDIATRIC B ALL?

D. Albayrak[1,*] C. Albayrak[2]
[1]Pediatric Hematology Department, Samsun 19May University Faculty Of Medicine, [2]Pediatric Hematology Department, Samsun Ondokuz Mayis University Faculty Of Medicine, Samsun, Turkey

Background: Two report shows CD45 brightnes of childhood ALL blast is associated with poor prognosis. Borowitz et al showed that bright CD45 expression was associated with a poor prognosis in BCP-ALL patients treated according to theprotocols of the Pediatric Oncology Groupstudy group and Cario et al also in ALL-BFM-2000 protocol.
Aims: In the present study, we assessed the relation of brightness of CD45 expression in pediatric ALL patients treated according to he ALL-IC-BFM 2009 protocol.
Methods: The brightness of CD45 expression was compared in ten patients of high risk group and ten patient of standart and intermediate groups. In the ALL-IC BFM 2009 trial, the high-risk group was defined by poor prednisone response on treatment day 8, FCM blast ratio >%10 at day 15 and BCR-ABL OR MLL positivity. The brightness of CD45 expression was evaluated as mean flouresence index (MFI).
Results: CD45 MFI was 710,2 for blast, 13784,6 for normal lymphocytes, 0,056 for blast/lymphocytes in hr group, CD45 MFI was 590 for blast, 7904,4 for normal lymphocytes, 0,082 fr blast/lymphocytes in hr group. The differenceb between groups was not significantly different.
Summary/Conclusion: In conclusion, the CD45 brightnes of childhood BCP-ALL did nod have any additional contribution to high risk stratification. This result is different from previous reports. New reports is required to solve this debate.

PB1620

T315I CLONE SELECTION IN A PHI+ ALL PATIENT UNDER MAINTENANCE PONATINIB

J. Noetzli[1,*] M. Gavillet[1], S. Masouridi-Levrat[2], A. Priovolos Hughes[1], C. Abbal[3], O. Spertini[1]
[1]Hematology, CHUV, Lausanne, [2]Hematology, HUG, Geneva, [3]LCH, CHUV, Lausanne, Switzerland

Background: Ponatinib is a third generation tyrosine kinase inhibitor (TKI) approved for the treatment of chronic myeloid leukemia (CML) or Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL) with T315I or resistant/intolerant to other TKIs. Serious vascular adverse events have been reported at the dosage of 45 mg once daily suggesting that a reduction in the dosage of ponatinib may be advisable.
Aims: We present here the case of a Ph+ ALL in 2nd relapse who achieved a molecular remission with ponatinib 30 mg/day. To decrease the risk of vascular complications, ponatinib dosage was reduced to 15 mg/day during maintenance therapy. We examined whether this ponatinib dosage is sufficient to prevent molecular relapse.

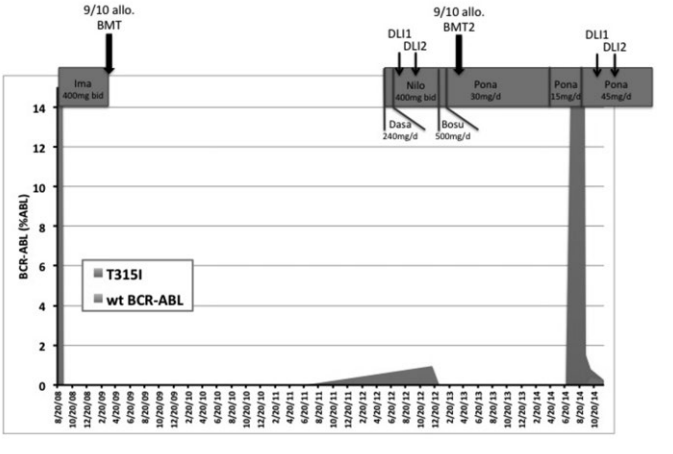

Figure 1.

Methods: Residual disease was measured by RQ-PCR and BCR-ABL mutations were detected by Sanger sequencing.
Results: This 39-year-old patient was diagnosed in 2008 with a Ph+ ALL (Figure 1). He was first treated with imatinib (GRAALL/GRAAPH 2005 trial) and

then successively with dasatinib, nilotinib and bosutinib because of intolerance or resistance and finally with ponatinib. Due to liver toxicity, ponatinib was given at 30 mg/day as maintenance therapy. One year after the second transplant, while the patient was still in CR, an unexpected high rate of ponatinib-induced vascular events was reported. According to recommendations made for CML in major molecular response, the maintenance therapy was reduced to 15 mg/day. Six months later, a molecular relapse was identified in bone marrow and Sanger sequencing revealed a T315I mutation in BCR-ABL kinase domain (KD). The patient was treated with steroids, a single dose of vincristine (1,4 mg/m^2) and ponatinib 45mg once daily. Fifteen days later, MBCR-ABL level was reduced by 1 log and sequencing showed the concomitant presence of wild-type and T315I BCR-ABL KD. Donor lymphocyte infusions were started. Three months later, the MBCR-ABL/ABL ratio was 0,025%. Presently, 6 months after the 2nd relapse, the patient is in complete molecular remission, without graft *versus* host disease.
Summary/Conclusion: We report here the clinical course of a Ph+ ALL patient who was treated with ponatinib 15mg/day, as maintenance therapy, and developed a BCR-ABL T315I mutation leading to leukemia molecular relapse. This clonal evolution was reversed, without adverse effects, by increasing ponatinib dosage to 45mg/day suggesting that ponatinib dose reduction may not be appropriate in Ph+ALL maintenance therapy.

PB1621

A RETROSPECTIVE ANALYSIS OF COMPLICATIONS OBSERVED IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA DURING CHEMOTHERAPY
A. Canbolat Ayhan[1,*] C. Timur[1], O. Kalaycık[1], A. Yoruk[1]
[1]Pediatric Hematology, Medeniyet University Goztepe Education And Research Hospital, Istanbul, Turkey

Background: ALL is the most common cancer in the paediatric age group. In recent years, through the use of intensive chemotherapy together with improved supportive care, the 5-year survival rate has increased above 85%. Despite this high survival rate, completing the entire therapy regimen is challenging because of the severe complications that interrupt the chemotherapeutic process. A minor proportion of patients can be expected to complete chemotherapy without experiencing serious complications during chemotherapy.
Aims: We aimed to evaluate the complications that we observed in children with acute lymphoblastic leukaemia (ALL) during the remission induction, consolidation, and reinduction phases of chemotherapy retrospectively.
Methods: We analysed the clinical records of 128 patients with ALL who were diagnosed and treated in the Department of Pediatric Hematology of Istanbul Medeniyet University Goztepe Training Hospital between August 2009 and April 2014.
Results: Of these documented complications, 53.05% were in males, 46.95% in females; 32.26% were in standard-risk, 45.52% in medium-risk, 22.22% in high-risk group of patients. Common documented events were pneumonia (25%), therapy-induced hyperglycemia (16.40%) therapy-related hepatitis (15.62%), generalized tonic-clonic seizures (14.84%), anaphylaxis to asparaginase (14.06%), hypertension (13.28%), varicella zoster infection (13.28%), renal tubulopathy (12.5%). Time of complications was induction phase in 32.62%, consolidation in 19.35%, HR blocks in 18.28%, reinduction 29.75% during the phases. Mortality rate due to complications was 13.28%.
Summary and Conclusions: Therapy-related complications can limit the survival rates in children with ALL. To minimize the treatment burden, even very rare complications must be considered and treated promptly with a multidisciplinary approach.

BONE MARROW MESENCHYMAL STROMAL PRECURSOR CELLS FROM ACUTE MYELOID LEUKEMIA PATIENTS ARE DAMAGED BY LEUKEMIC CELLS AND THE PROCEDURE OF ALLOGENEIC BONE MARROW TRANSPLANTATION
T. Sorokina[1,*] N. Petinati[2], I. Shipounova[2], A. Bigildeev[2], N. Drize[2], L. Kuzmina[1], E. Parovichnikova[1], V. Savchenko[3]
[1]High dose chemotherapy, depressions of hematopoiesis and bone marrow transplantation dept., [2]Physiology of Hematopoiesis laboratory, [3]General director, National Research Center for Hematology, Moscow, Russian Federation

Background: Leukemic cells and high dose chemotherapy affect both hematopoietic and stromal precursor cells. Changes in the hematopoiesis occurring in acute myeloid leukemia (AML) are well characterized, however, the mechanisms of alterations in stromal microenvironment during the debut of AML and pre-transplantational conditioning are still obscure.
Aims: This study aimed to analyze the alterations in the characteristics of human multipotent mesenchymal stromal cells (MSC) and their more differentiated progeny – fibroblastic colony forming units (CFU-F) derived from the bone marrow (BM) of AML patients.
Methods: 18 newly diagnosed and 20 patients who underwent allogeneic bone marrow transplantation (alloBMT) were included in the study after informed consent. BM was aspirated prior to any treatment in the newly diagnosed group, before the conditioning and at 6 time points during 1st year after alloBMT in the corresponding group. MSC were cultured in aMEM with 10% fetal calf serum. Cumulative MSC production was counted after 3 passages. CFU-F concentration was analyzed in standard conditions. The relative expression level (REL) of different genes was measured by TaqMan RQ-PCR. As a control MSC and CFU-F from 88 healthy donors were used.
Results: The CFU-F concentration in the BM of newly diagnosed AML patients was 1/3 of the donor's (8.7±3.7 *versus* 25.8±3 per 10^6 nucleated cells, P=0.0008). There were no correlation between CFU-F concentration and blast count in the patients BM samples. So the decrease in CFU-F concentration could not be explained by mere substitution of stromal cells by blasts, but rather it reflects the action of leukemic cells on the stromal microenvironment. In the remission BM CFU-F concentration restored (26.7±7.2 per 10^6 BM nucleated cells). After the alloBMT CFU-F concentration in patients' BM decreased 3-9 fold during the next year of observation. The decrease at each time point was highly significant comparing to donors. Similar picture was observed in MSC features. Cumulative cell production in cultures of newly diagnosed AML patients was half to donor's (5.03±0.8x10^6 *versus* 7.6±0.8x10^6, P=0.07). MSC from the BM of patients before alloBMT were also slightly and insignificantly lower than from healthy donors (5.9±1x10^6). In patients after alloBMT cumulative MSC production decreased 1.3-5.2 fold during the next year. The decrease at almost each time point was significant comparing to donors. Gene expression analysis revealed that in MSC of new diagnosed patients the expression of FGF2 and VEGFA significantly decreased, while REL of CSF1, FGFR1, JAG1, PPARG, PDGFRA and PDGFRB-increased. In remission REL of FGF2 and LIF were twice as high as donor's, after alloBMT the expression of FGF2 was mainly elevated. However, REL of CSF1, PDGFB, VEGF and VCAM1 was significantly decreased at the most time points after alloBMT. It seems that expression profile of MSC at manifestation of AML reverses in the remission but still does not achieve normal levels.
Summary and Conclusions: During the AML development leukemic cells alter the stromal precursor cells leading to the decrease in their proliferative ability, in the level of expression of some regulatory genes and in the number of CFU-F in the BM. Chemotherapy used for induction the remission restores the stromal precursor cells incompletely. Conditioning regiments used for the alloBMT significantly damage both types of studied stromal precursors, and the effect lasted at least for 1 year. Thus, both AML cells and chemotherapeutic treatment affect BM hematopoietic microenvironment.

CHARACTERIZATION OF KMT2A (MLL) CHROMOSOMAL BREAKPOINTS
L. Zejskova[1,*] R. Plachy[1], T. Jancuskova[1], D. Hardekopf[1], J. Stika[1], M. Ondrackova[1], N. Kosyakova[2], T. Liehr[2], A. Zavrelova[3], P. Zak[3], V. Petecukova[4], J. Novak[4], T. Kozak[4], S. Pekova[1]
[1]Laboratory synlab genetics s.r.o., Synlab Genetics s.r.o., Prague, Czech Republic, [2]Institute of Human Genetics, Jena University Hospital, Jena, Germany, [3]4th Department of Internal Medicine-Hematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, [4]Internal Clinic of Hematology, University Hospital Kralovske Vinohrady, Prague, Czech Republic
Background: The *KMT2A* gene (*MLL*, mixed lineage leukemia) is located at chromosome region 11q23. Chromosomal rearrangements involving the human *MLL* gene are associated with development of childhood, adult and therapy-related acute leukemia. The presence of certain *MLL* rearrangements is an

independent prognostic factor and patients are usually treated according to high-risk protocols. Minimal residual disease (MRD) detection provides an objective assessment of treatment response and enables risk stratification of patients. However, MRD assays using *MLL* fusion transcripts as molecular markers usually do not provide sufficiently sensitive detection of residual leukemic cells.

Aims: Identification of the unique chromosomal breakpoints of the *MLL* gene, which is necessary for the design of a quantitative real-time PCR (qPCR) DNA-based MRD assay.

Methods: For the identification of patient-specific *MLL* breakpoint sequences we used two different technical approaches. The first approach was long-range PCR followed by sequencing of the PCR products. The second approach included a combination of conventional chromosome microdissection, amplification of the microdissected material, next-generation sequencing, long-range PCR and sequencing of the final PCR products. Patient-specific sequences of the chromosomal breakpoint were used to develop MRD assays and enabled us to perform sensitive monitoring of MRD using qPCR in six acute leukemia patients.

Results: We identified unique breakpoint sequences in five patients with acute myeloid leukemia and one patient with acute lymphoblastic leukemia at the time of diagnosis. Using first approach (*i.e.* long-range PCR followed by sequencing of the PCR products) we detected *MLL/AF6*, *MLL/AF9* (two patients) and *MLL/ELL*. A combination of conventional chromosome microdissection, amplification of the microdissected material, next-generation sequencing, long-range PCR and sequencing of the PCR products was used for identification of *MLL/AF10* and *MLL/AF4* breakpoints. Identification of unique breakpoint sequences was followed by the design of sufficiently sensitive qPCR MRD assays. The MRD levels of residual leukemic cells correlated with clinical outcome.

Summary and Conclusions: *MLL* breakpoints could be identified by various methods (*e.g.* inverse PCR, panhandle PCR). Our results show other approaches for identification of unique *MLL* breakpoint sequences, which can be utilized for the design of the leukemia-specific assay for DNA-based MRD monitoring in patients with acute leukemia.

MUTATIONAL PROFILE STUDY OF ADULT DE NOVO ACUTE MYELOID LEUKEMIA BY HIGH-DEPTH NEXT GENERATION SEQUENCING (NGS)

E. Onecha[1,*] I. Rapado[1], S. Barrio[1], N. Castro[2], R. Alonso[2], J.M. Sanchez[2], P. Martinez-Sanchez[2], J. Martinez Lopez[2, 3], R. Ayala[2,3]
[1]Hematologia Traslacional-Biologia Molecular, [2]Servicio De Hematologia, Hospital Universitario 12 De Octubre, [3]Universidad Complutense De Madrid, Madrid, Spain

Background: AML is a highly heterogeneous pathology with a variety of subtypes stratified function of cytogenetic and molecular markers. To date, the major prognosis criteria is cytogenetics, however the 40-50% of *de novo* patients have normal karyotype. Recent sequencing techniques such as NGS allow us to identify the mutational profile, to decide the diagnosis and risk stratification of patients and to personalize therapy.

Aims: To identify the mutational profile of AML and to correlate with the patient's survival data.

Methods: A cohort of 65 AML patients who were treated with intensive chemotherapy was selected. Mediam age at diagnosis was 52 years (range: 18-79), male:female ratio 30:35; 53 patients had de novo AML, 10 s-AML following MDS or MPN, and 2 t-AML; median leukocytes was $36.8x10^9/L$. Cytogenetic results were available in 64 cases and categorized according to MRC (Blood 2010): favorable in 6 (9.4%), intermediate in 44 (68.8%), and adverse in 14 (21.9%). We performed targeted gene sequencing by NGS (*Ion Torrent Proton System–Life Technologies*) using a panel of 33 genes implicated in leukemia prognosis; in addition, FLT3 internal tandem duplication (ITD) was detected by GENSCAN and NPM1 mutation was detected by qPCR.
The discrete variables of patients with and without analyzed gene mutations were compared using the X^2 test. Kaplan-Meier survival curves and Long-rank test were used for estimation of survival and difference between groups

Results: On average, 90,8% of the target sequence showed a mean depth coverage around 1300. We discovered 140 non-synonymous mutations which 118 were somatic single nucleotide variants (SNVs) and 22 small insertions and deletions (Indels) in coding regions. No mutations were detected in 5 samples, 14 samples presented 1 mutation, and the others 46 samples present 2 or more mutations. TET2 was the most frequently mutated gene (33,8%), followed by DNMT3A (26,2%), NPM1 (26,2%), FLT3 (21,5%), NRAS (20%), FLT3-ITD (18,5%), KMT2A (16,9%), IDH2 (13,8%), RUNX1 (13,8%), EPOR (12,8%), KRAS (12,8%), ASXL1 (9,2%), IDH1 (9,2%) and the others genes had a frequency below 8%. Mutations in ASXL1 (P=0.005), KRAS (P=0.033), JAK2 (P=0.061) and ZRSF2 (P=0.019) were associated with secondary AML. DNMT3A (P<0.001) and ZRSF2 (P=0.005) mutations with NPM1 mutations. DNMT3A and ETV6 mutations with FLT3 ITD AML (P=0.041 and 0.029 respectively). AML patients who present TP53 or TET2 mutations showed a statistically non-significant correlation with death (P=0.103 and 0.062 respectively), in contrast IDH2 mutations were more frequent among alive patients (P=0.061). RUNX1 mutations were associated with female gender (P=0.023), and these and TP53 mutations were associated with refractoriness (P=0.009 and P=0.001, respectively). EZH2 and TET2 mutations were associated to AML patients >55yrs (P=0.011 and 0.025 respectively). In contrast to KRAS mutations that were detected mainly in patients<55yrs (P=0.090). Median RFS was significantly longer in female (28.5 vs 10.8months, P=0.017) and also in patients<55 years (18.9 vs 10.8 months, P=0.026). Median OS was significantly longer in patients<55 years (18.9 vs 11.8 months, P=0.038). No significant differences in RFS in function of analyzed gene mutations were found, but we observed that the median OS was significantly shorter in mutated TET2 patients (8.4 vs 18.8 months, P=0.049).

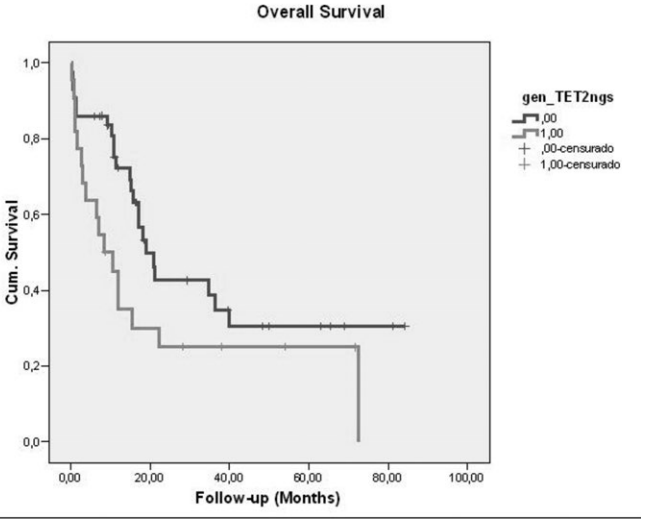

Figure 1.

Summary and Conclusions: NGS is a useful technique to classify groups in AML with biological and prognosis implications. These results support the role of TET2 as an important poor prognostic biomarker in AML. This study was funded by Instituto Carlos III (PI13/02387)

CD81 AS NEW POTENTIAL MARKER IN ACUTE MYELOID LEUKEMIA

S. Guihard[1,*] T. Boyer[2], C. Roumier[2], P. Peyrouze[1], F. Gonzales[1], C. Preudhomme[2], C. Roche-Lestienne[3], M. Cheok[1]
[1]UMR-S1172, [2]Hematology institute, Centre de Biologie-Pathologie Pierre-Marie Degand, [3]Genetic institute, Jeanne de Flandre Hospital, Lille, France

Background: AML is a heterogeneous disease at both the phenotypic and molecular level with a variety of distinct genetic alterations giving rise to the disease. This heterogeneity extends to the leukemic stem cell (LSC), with this dynamic compartment evolving to overcome various selection pressures imposed upon it during disease progression. Since LSC are thought to be resistant to current chemotherapeutic regimens and mediate disease relapse, their study may have profound clinical implications. Various markers have been described to characterize the LSC. CD81 antigen belongs to the tetraspanin family (33 members in mammals) which are cell surface transmembrane proteins and may be involved in the re-entry of hematopoietic stem cells into quiescence.

Aims: In this project, we plan to investigate the role of CD81 in the heterogeneity of AML, its potential to induce tumor dormancy and if this is characterized by resistance to chemotherapy.

Methods: In order, to study CD81 expression on primary leukemic blasts, we designed a MFC panel (CD36, CD81, CD33, CD90, CD123, CD34, CD38, CD45).Cell surface marker expression was measured in fresh or thawed bone marrow samples from adult patients with AML at diagnosis (n=122) or at relapse (n=10) using the above mentioned panel. This is a retrospective study to test the prognostic value of CD81, in comparison with other markers of LSC/HSC, for survival (overall survival, event free survival, relapse free survival). AML was diagnosed between 2010 and 2013 at the CHRU of Lille. To further study the function of CD81, we will use AMLxenografts. Blasts obtained from newly diagnosed AML, were FACS sorted based upon high CD45 intensity and were then directly injected into NSG mice. After engraftment, the mice were sacrificed, and the bone marrow and spleen were analyzed by flow cytometry. Serial engraftment is performed by injecting one part of the blast cells into a subsequent NSG mouse.

Results: We performed the analysis on 122 diagnosis bone marrow samples and we found that 35% of the samples were positive for CD81 expression. Classification by CD81 expression predicts OS and EFS in AML (EFS: P=0.012; OS: P=0.0066). 23 primary AMLs have been injected and 8 of them produced

serial engraftments. Yet, we did not find any difference in phenotype between the AMLxenografts and the AML diagnosis. However, the phenotype of the blasts differ between bone marrow and spleen (P= 0.027).
Summary and Conclusions: Our preliminary results show that CD81 may have an important role in AML as their expression on blast cells predicts worse clinical outcome (OS and EFS) in this pathology. Furthermore, we have put in place and phenotypically validated AMLxenografts, and we will be able to study the functional role of CD81 in AML in the near future. Nevertheless, the impact ofxenografts in general and in particular with regard to CD81 on prognosis will be studied once we have sufficient follow-up time and numbers of patients analyzed and injected into NSG mice.

DEOXYCYTIDINE KINASE IS DOWN-REGULATED UNDER HYPOXIC CONDITIONS AND CONFERS RESISTANCE AGAINST CYTARABINE IN ACUTE MYELOID LEUKEMIA

N. Degwert[1,*] E. Latuske[1], G. Vohwinkel[1], M. Klokow[1], H. Stamm[1], C. Bokemeyer[1], W. Fiedler[1], J. Wellbrock[1]
[1]Hematology and Oncology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Leukemia initiating cells reside within specialized niches in the bone marrow where they undergo complex interactions with different stromal cell types. The bone marrow niche is characterized by a low oxygen tension resulting in high expression of hypoxia-inducible factor 1 alpha (HIF-1α). Expression of HIF-1α has been shown to represent a negative prognostic factor in acute myeloid leukemia (AML).
Aims: In the current study, we investigated the impact of hypoxic *versus* normoxic conditions on the sensitivity of AML cell lines and primary AML blasts to cytarabine.
Methods: AML cell lines HL60, Kasumi-1, MOLM-13, OCI-AML5, MV4-11 and KG-1 as well as primary blasts from AML patients were cultured under normoxic and hypoxic conditions (oxygen content of 20% vs. 6%, respectively). After an adaptation period of three days, cells were plated for proliferation and colony formation assays to investigate the susceptibility to cytarabine (Cell Pharm GmbH, Bad Vilbel, Germany). Proliferation and colony formation was determined after 3 and 7 days of cytarabine treatment, respectively. Using quantitative RT-PCR analysis, we investigated the mRNA expression of deoxycytidine kinase in AML cells cultured under normoxic vs. hypoxic conditions for 3 days. AML cells under hypoxic conditions were additionally treated with the HIF-1α inhibitor BAY87-2243 (Selleckchem, Houston, TX).
Results: AML cells cultured under 6% oxygen were significantly more resistant to cytarabine compared to cells cultured under normoxic conditions in proliferation assays. HL60 cells were the most susceptible cells to the drug-induced growth inhibition under hypoxic conditions for cytarabine concentrations between 10 nM and 1000 nM. Although less pronounced, Kasumi-1, MOLM-13, OCI-AML5 and MV4-11, also showed the hypoxia-induced resistance to cytarabine. Only in KG-1 cells, no significant differences in growth inhibition could be detected under normoxic vs. hypoxic conditions. Furthermore, increased sensitivity to cytarabine under normoxia could also be observed in primary AML samples (n=5). Response to cytarabine under normoxic vs. hypoxic conditions was also analyzed by colony formation assays for several AML cell lines using cytarabine concentrations ranging from 25 nM to 100 nM. Colony numbers at day 7 of cytarabine treatment were significantly higher at 6% oxygen than at normoxia. Interestingly upon cultivation under hypoxia, the expression of the cytarabine-activating enzyme deoxycytidine kinase was down-regulated in all analyzed AML cell lines and primary AML samples representing a possible mechanism for resistance to chemotherapy. Furthermore, the down-regulation of deoxycytidine kinase could directly be associated with HIF-1α as treatment with its inhibitor BAY87-2243 hampered the down-regulation of deoxycytidine kinase expression under hypoxic conditions.
Summary and Conclusions: In conclusion, our data reveal that the hypoxia-induced down-regulation of deoxycytidine kinase might represent one mechanism of drug resistance to cytarabine in acute myeloid leukemia.

MUTATED REGIONS OF NUCLEOPHOSMIN 1 ELICIT CD8+ T-CELL RESPONSES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

A. Sun[1,*] Z. Cheng[1], G. Chen[1], X. Yang[1], D. Wu[1]
[1]1the First Affiliated Hospital Of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Stimulating lymphocytes from healthy donors by DCs loaded with NPM1^{mut}peptides *in vitro* in order to induce specific cellular immune responses against the peptides.
Aims: Detecting the NPM1^{mut} peptide specific T-cell in peripheral blood of patients with NPM1^{mut} positive acute myeloid leukemia (AML), to provide a theoretical basis for immune therapy of AML.
Methods: 1. newly diagnosed patients of AML underwent gene mutations screening routinely. 2. peripheral blood mononuclear cells (PBMCs) were isolatedfrom healthy donors with HLA-A* 0201 or A*1101 and NPM1^{mut} positive AML patients in complete remission. 3. Inducing differentiation of PBMCs into DCs. 4. Generation of NPM1-specific cytotoxic T cells. 5. ELISPOT analysis and intracellular staining.
Results: 1. In the Han Chinese population, the most common alleles of HLA-A loci were A* 1101, A*2402, and A*0201 allele. 2. Through prediction of the aforementioned software, HLA-A*0201 restricted wild type NPM1 amino acid sequences (DLWQWRKSL), mutated NPM1-A/D amino acid sequences (AIQDLCLAV), and HLA-A*1101 restricted mutated NPM1-A/D amino acid sequences (AVEEVSLRK) were synthesized. There were no proper epitopes for either HLA-A*1101 restricted wild type NPM1 protein or HLA-A*2402 restricted wild type and mutated NPM1 protein. 3. Expression of surface antigens of DCs on day 7 were as follows: CD14(2.6%), CD80(43.4%), CD83(7.8%), CD86(99.9%), HLA-DR(67.1%), which was consistent with DCs phenotype.
4. About 10 days after DCs were co-incubated with their own PBMCs, the number of lymphocytes increased significantly, especially in the NPM1^{mut} peptide pulsed group. On day 7 of co-incubation, ELISPOT analysis results of all samples were negative. However, 3 cases' ELISPOT results were positive for the mutated peptide holes on day 14, in contrast, the results of the wild type peptide holes were negative. The NPM1^{mut} peptide-specific T lymphocytes positive rate [=(average number of spots in mutated peptide holes-the average number of spots in negative control holes)/total lymphocytes per hole] was about 1/2500. Intracellular staining showed that in the aforementioned 3 cases, the proportion of $CD8^{+}IFN\text{-}\gamma^{+}$ cells of the mutant peptide group was higher than either the wild type peptide group or negative control group, but there was no difference between the later two groups. 5. 6 peripheral blood samples of patients with NPM1^{mut+}AML were performed ELISPOT analysis, with only 1 case (16.7%) showing a approaching positive result.
Summary and Conclusions: NPM1^{mut} peptide pulsed DCs can stimulate their own PBMCs from healthy donors *in vitro* to produce mutated NPM1 specific T lymphocytes, and it is expected to be used as immune therapy of AML. The mutated NPM1 specific CTL in NPM1^{mut+}AML patients are almost undetectable that indicates immune system have been comprised because of chemotherapy and disease, and can not responses to antigens efficiently. Perhaps AML patients can accept CTL transfusion from their relatives. Our study provide an experimental basis for cellular immunotherapy of AML.

PB1628

PHENOTYPIC AND FUNCTIONAL ANALYSIS OF BONE MARROW MESENCHYMAL STEM CELLS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

M. Al Bagami[1,2,*] I. Marcq[1], H. Ouled Haddou[1], V. Debuysscher[1], M.N. Lacassagne[2], L. Garcon[1,3], H. Bouhlal[1,2], J.P. Marolleau[1,2]
[1]EA 4666, Lymphocyte Normal/Pathologique et Cancers CURS, CHU Sud, [2]Service Hématologie clinque-Thérapie cellulaire, CHU Sud, [3]Hématologie, CHU Sud, Amiens, France

Background: Mesenchymal stem cells MSC are main cells found in bone marrow BM microenvironment. They play a major role in hematopoietic stem cell HSC niche. These niches support acute myeloid leukaemia AML cells proliferation and differentiation.Many studies showed the protection of AML cells from chemotherapy induced apoptosis by BM microenvironment. The mechanism of this protection is still unclear.
Aims: Our present work is to compare the phenotype and functional properties of AML BM-MSCs to normal MSCs from BM to identify new mechanisms could help to improve the treatment of AML.
Methods: MSC were obtained from the BM of patients with AML and healthy donors (n=5 per group). Following parameters were used for: cell morphology, cell proliferation test, cell cycle, immunophenotype, differentiation capacity into osteoblastic and adipogenic lineages. Gene expression profile was determined by Q-PCR.
Results: 4/5 of AML BM-MSC have heterogenous morphology and 1/5 has homogenous fusiform, fibroblast-like appearance. AML BM-MSC show, significantly (P<0.05), low proliferative ability than normal BM-MSC, which induces an increase of doubling time (62,8-/ + 7h and 44,5-/ + 8h for AML and normal BM-MSC, respectively; P<0,01). The analysis of cell cycle show that the number of cells in AML BM-MSC cultures in G2/M phase, significantly P<0.05, reduced by 50% compared to normal BM-MSC cultures. However, Both of Normal and AML BM-MSC have similar immunophenotype profile (positive: CD90, CD73, CD105, CD166 and CD146; negative: HLA-DR, CD34, CD45). Both of cell types have a potential to differentiate into osteoblastic and adipogenic lineages showed by specific stains. This result was confirmed by the expression levels of Runx2, BMP2 and ALP Alkaline phosphatase (osteoblasts); and PPAR-γ2 (adipocytes). However, expression of these genes in osteoblasts derived from AML BM-MSC remains, significantly P<0.01, lower than the expression in osteoblasts obtained in normal BM-MSC differentiated cells.
Summary and Conclusions: The proliferative capacity of MSC obtained from the BM of patients with AML are limited and have a heterogenous morphology although the expression of phenotypic markers remains unchanged compared to normal BM-MSC. More significantly, the capacity to differentiate into

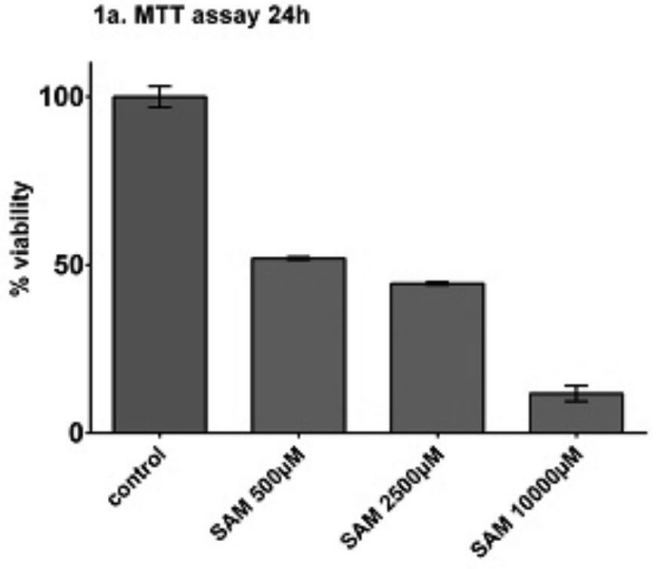
osteoblasts is reduced in AML BM-MSC. This result suggest that, the bone quality obtained by AML BM-MSC is affected. Therefore, there is an influence on the endosteal microenvironment and that could affect the behavior of CD34 HSC in the endosteal niche.

PB1629

EVIDENCES OF A DNMT3A DEPENDENT CYTOSTATIC EFFECT OF S-ADENOSYLMETHIONINE ON OCI-AML3 CELLS

K.A. von Hohenstaufen[1,*] B. De Servi[2], M. Meloni[2]
[1]Liber Augustalis, Independent Biomedical Research Association, [2]Vitroscreen, *in vitro* Research Laboratory, Milan, Italy

Background: AML with mutated NPM1 and its cell line OCI-AML3 carry the NPM1 mutation A and the heterozygous R882C mutation of the DNA (cytosine-5-)-4 methyltransferase 3 alpha (DNMT3A). The mutant DNMT3A protein exerts a dominant negative inhibition on the wild type protein resulting in focal hypomethylation. Of note, AML with mutated NPM1 harbors a distinct methylation profile among AML subtypes. S-adenosylmethionine (SAM) is a universal methyl donor and a coenzyme of DNMT3A. SAM has been used in the clinical practice as an antidepressant drug with very limited side effects. There are growing evidences of the antineoplastic activity of SAM *in vitro* and in murine models of solid cancers. Recently, the combination of SAM with demethylating agents showed an interesting *in vitro* synergistic cytotoxicity on breast cancer cells.



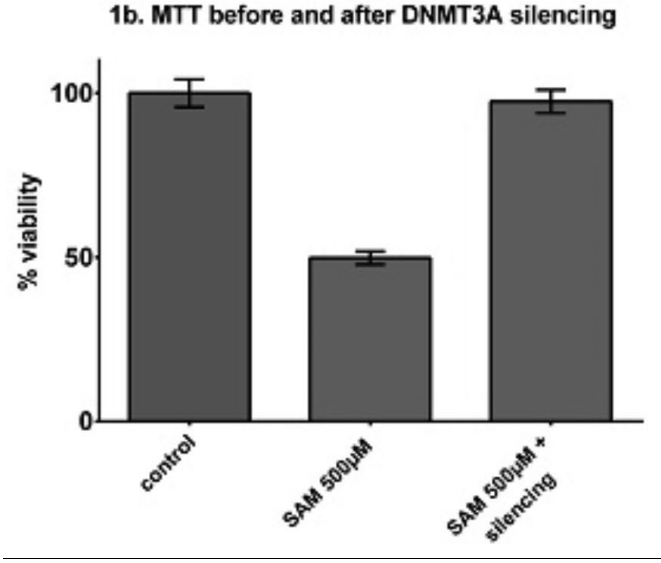


Figure 1.

Aims: To explore the effect of SAM on OCI-AML3 cells and its dependence on DNMT3A activity.
Methods: We used the MTT assay to test the cytostatic effect of SAM iodide (Sigma-Aldrich, St. Louis -MO) on OCI-AML3 cells (DSMZ Leibniz Institut, Braunschweig -Germany). The cells were treated with SAM for 24h. Untreated and treated cells were tested in triplicate for each SAM concentration. Results were expressed as percentage of cells viability compared to the control (*i.e.* OCI-AML3 untreated cells). The Apoptosis assays were performed after 24h and 72h of SAM treatment using the Tali® Apoptosis Assay Kit–Annexin V Alexa Fluor®488/Propidium Iodide (Invitrogen, Carlsbad, CA) for cells staining, and the Tali Image Based Cytometer (Invitrogen) for cells counting. In order to verify if the observed effect was mediated by DNMT3A, we repeated the MTT assay after DNMT3A silencing with a predesigned SiRNA directed against DNMT3A (SiRNA ID HSS176224, life technologies). Transfection was performed on triplicates cultures with lipofectamine RNAiMax (Invitrogen) and transfection efficiency calculated by BLOCK-IT AlexaFluor Red Fluorescent Oligo (Ambion-life Technologies). DNMT3A knock-down was verified by RTPCR (TaqMan Applied Biosystem ABI7500; Taqman primer/probes for DNMT3A, Hs01027166_m1).
Results: A significant dose dependent reduction of the cells viability was evident for SAM concentrations equal or superior to 500µM, with an IC50 of 500µM (Figure 1a). Since a Cmax of 211µM (SD 94) after single intravenous infusion of SAM was previously reported in healthy volunteers, we tested SAM concentations close to 211µM, and observed a significant reduction of the cells viability with SAM 200µM (62,74% viable cells) and SAM 300µM (53.32% viable cells), (data not shown). The apoptosis assay at 24h and 72h of SAM treatment, showed no significant increase in the amount of apoptotic cells, (data not shown), however a dose dependent decrease of the percentages of living cells was observed which was considered congruent with the results of the MTT tests. The MTT assay was repeated testing at the same time DNMT3A silenced and non-silenced OCI-AML3 cells. SiRNA transfection efficiency was 80%. Gene knock-down was confirmed by a DNMT3A expression of 39% compared to the non-silenced cells. In the MTT assay with SAM 500 µM (24h) the non-silenced cells showed a significant reduction of the cell viability (49,8% viable cells), while no effect was observed in the DNMT3A silenced cells (97,5% viable cells) (Fgure 1b).
Summary/Conclusion: SAM shows *in vitro* cytostatic activity on OCI-AML3 cells, at concentrations close to the blood concentrations achievable in humans. These preliminary results are in line with other studies using similar SAM concentrations in solid tumors cell lines. The MTT assay performed after DNMT3A knock-down demonstrated that the cytostatic effect of SAM on OCI-AML3 cells is specifically mediated by DNMT3A. This finding suggests that modulating the activity of DNMT3A with supraphysiological concentrations of its substrate can induce cell growth inhibition in AML cells with heterozygous DNMT3A mutation. SAM should be further investigated as a potential antileukemic compound in AML with NPM1 and DNMT3A mutations.

PB1630

CLINICAL SIGNIFICANCE OF DIFFERENT GATA-2 MUTATION TYPE IN ACUTE MYELOID LEUKEMIA

S. Zhang[1,*]
[1]Hematology, Ruijin Hospital of Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Cytogenetic and gene abnormalities are considered to be the most important prognostic factors of acute myeloid leukemia(AML) patients. Gene mutations such as internal tandem duplications (ITDs) or tyrosine kinase domain (TKD) of FMS-like tyrosine kinase 3 (FLT3), C-KIT, neuroblastoma RAS viral oncogene homolog gene (NRAS) have been considered to belong to class involving signal transduction, nucleophosmin gene (NPM1), the CCAAT/enhancer binding protein α gene (CEBPA) or the mixed-lineage leukemia (MLL)gene, which can be affected either through chromosomal translocation or via an intragenic partial tandem duplications (PTDs) to form a fusion gene to class those causing impaired differentiation. GATA-2 is a zinc-finger(ZF) transcription factor and play important roles in hematopoiesis in many cell lineages.
Aims: To evaluate the prognostic value of GATA-2 mutation in acute myeloid leukemia (AML) patients, we performed sequence analysis to see if GATA-2 mutation play important role in AML leukemogenesis.
Methods: We performed sequence analysis to detect GATA-2 mutation in 135 AML patients. We also performed luciferase assay and Western-Blot assay to analyze the biological function of mutant GATA-2.
Results: A total of 5 (3.7%) different *GATA-2* mutations were detected in 135 patients. The mutation types of *GATA-2* were *GATA-2* W10C(tgg>tgt, Trp→Cys), *GATA-2* S277N(agc>aac, Ser→Asn), *GATA-2* P304H(cct>cat, Pro→His), *GATA-2* R362Q(cga>caa, Arg→Gln), *GATA-2* V369A(gtc>gcc, Val→Ala). Luciferase assay showed the transcription activity of GATA-2 G320D was significantly lower than that of wt GATA-2(P<0.05), whereas the activity of GATA-2 P304H and GATA-2 R362Q was slightly lower than wtGATA-2 (*P*>0.05). The result of Western-Blot showed that the expression of GATA-2 protein in GATA-2 P304H(*P*=0.002) was significantly higher while GATA-2 R362Q or GATA-2 G320D mutants was lower than wt GATA-2 (*P*=0.02 and *P*=0.004, respectively).
Summary and Conclusions: GATA-2 mutation is a rare mutation in AML patients. The mutations located in zinc-finger domain may contribute to AML leukemogenesis.

PB1631

DETECTION OF TET2, KRAS, AND CBL VARIANTS BY NEXT GENERATION SEQUENCING IN CHILDHOOD ACUTE MYELOID LEUKEMIA

D.F. Akın[1,*] D. Aslar[1], M. Mumcuoglu[1], U. Ezer[2], M. Bahce[3], E. Kurekci[2], N. Akar[4]

[1]Lösante Hospital Cancer Research and Genetics Laboratory, [2]Lösante Hospital, [3]Gene-Lab Genetic Diseases Diagnosis Center, Ankara, Turkey, Gene-Lab Genetic Diseases Diagnosis Center, [4]TOBB-ETU Hospital, Ankara, Turkey

Background: Acute myeloid leukemia (AML) is a heterogeneous clonal neoplasm characterized by accumulated genetic aberrations, which result in enhanced proliferation, block in differentiation, increased survival of the leukemic blast cells and variable response to therapy. During the past decades, a number of recurrent cytogenetic and molecular genetic abnormalities have been identified in AML such as t(8;21), inv(16), FLT3, NPM1, CEBPA, Ten-Eleven-Translocation 2 (TET2), Kirsten rat sarcoma viral oncogene homolog (KRAS), and Casitas B-cell lymphoma (CBL). Mutations in TET2 gene could contribute to leukemogenesis by altering epigenetic regulation of transcription via DNA methylation. The incidence of TET2 mutations is approximately 10-20% in AML. RAS mutations, especially KRAS, represent about 90% of cancer-associated mutations. RAS proteins play a major role in cell signaling pathway of cell proliferation, differentiation, and survival. KRAS mutations are the most frequently seen and found in 10-15% of these patients. *CBL* is a mammalian gene encoding the protein CBL which is an E3 ubiquitin-protein ligase involved in cell signaling and protein ubiquitination. These mutations have also been observed in 1% of AML.

Aims: In this study, we aimed to screen whole TET2, (KRAS) and (CBL) genes by using Next generation sequencing (NGS) analysis to find new possible genetic markers in children with AML.
Methods: Study population consisted of eight patients aged between 1 and 15 years who were admitted to Lösante Hospital for Children with leukemia with the diagnosis of AML. The Patient characteristics of the cases are shown in Table 1. Blood samples were collected with EDTA-containing tubes and DNA was extracted from peripheral blood and bone marrow leukocytes with MagNA Pure automatic DNA isolation instrument (Roche Diagnostics, Manheim, Germany). We utilized NGS to study three candidate genes at *TET2, KRAS* and *CBL*. All coding exons of *TET2* (exons 3 and 11) were presented by 27 amplicons. Beside, two primer pairs were amplified known mutational hotspot regions to describe the RING finger domain and linker sequence for *CBL* (exons 8 and 9) and *KRAS* (exons 2 and 3).
Results: We detected 16 variants in *TET2*, 2 variants both *KRAS* and *CBL*. The most of *TET2* variants were described in the largest exon 3 and 11; 1842 G>- (6/8 patients, 75%) and 1088 C>T (5/8, 62,5%) variants, 5162 T>G(5/8, 62,5%) in exon 3 and exon 11 of *TET2*, respectively. 310 A>C (7/8 87,5%) variation was the highest among the variants in intron 2 of *KRAS*. 1347 T>- in exon 8 of *CBL* was detected 6/8 patients (75%).Table 1 summarizes the association of patients' characteristics and variants of *TET2, KRAS* and *CBL* profiles.
Summary and Conclusions: In this study, we screened the mutations of *TET2, KRAS* and *CBL* genes in pediatric AML patients. We used an amplicon based sequencing method to find possible new genetic markers for leukemia diagnosis. *TET2, KRAS* and *CBL* genes were selected based on recent studies on genetic abnormalities in AML and other hematologic malignancies. In 8 patients, we report novel mutations at *TET2* and *CBL* genes. Seven of 16 substitutions were missense mutations in the exon and UTR regions. These mutations may result in truncated translation of protein. In conclusion, we found that *TET2* mutations are more frequent than *KRAS,* and *CBL* mutations in pediatric AML in this study. The usage of NGS to search for *TET2, KRAS,* and *CBL* mutations might be fruitful, however, these results need to be confirmed by further studies on a larger number of patients.

PB1632

IMPACT OF LEUKEMIA STEM CELL FREQUENCY AT DIAGNOSIS ON SURVIVAL IN ADULT ACUTE MYELOID LEUKEMIA PATIENTS

A. Kamel[1,*] N. El-Sharkawy[1], E. Kandeel[1], M. Hanafy[1], M. Samra[2]

[1]Clinical Pathology, [2]Medical Oncology, NCI, Cairo University, Cairo, Egypt

Background: Acute myeloid leukemia (AML) is a heterogeneous disorder with treatment results much inferior to acute lymphoblastic leukemia. Treatment failure is largely attributed to the persistence of leukemia stem cells (LSCs) which are less accessible and hence less responsive to chemotherapeutics. The classical LSC phenotype is CD34+/CD38-; however LSCs express other markers especially CD123 and CD133 which may be even earlier than CD34. We hypothesized that CD123 and CD133 may be better markers of LSCs and that higher frequency of LSCs at diagnosis may be associated with shorter survival.
Aims: To evaluate CD123 and CD133 as LSC markers as compared to the standard CD34+/CD38- and to study the impact of LSCs frequency at diagnosis on overall survival (OS) and disease free survival (DFS) in adult AML as well as correlate the LCS frequency with other findings at diagnosis.
Methods: The study was performed on 84 newly diagnosed AML patients including 51 Males and 33 females with an age range of 18-70 with a median of 31.5 years. Two 4 color panels of monoclonal antibodies were used: CD45/CD34/CD38/Cd123 and CD45/CD133/CD90/Cd33 and analyzed on Navios Coulter Flow Cytometer. Cell populations with different surface markers were calculated using the prism function of the soft ware. Results were correlated to other parameters at diagnosis. The median value for each marker alone and in different combinations (panels) was used to divide the cohort into high and low expressers. Patients were treated by (3+7) protocol; they were followed up for a period of 0.2-24 with a median of 5.5 months and evaluated for OS and DFS. The study was performed according to the guidelines of Helsinki declaration for studies performed on human beings and approved by the Institution Review Board (IRB) of the National Cancer Institute, Cairo University. An informed signed consent was obtained from all study subjects before enrollment.
Results: Single markers or panels expression were not correlated to age, gender, percentage PB or BM blasts, Hb level, TLC or platelet count**.**
Among the studied single markers CD123 and CD133 high expression was associated with shorter OS (P=<0.001 and<0.006 respectively) and DFS (P=<0.001). Among the panels, CD123+/CD34+/CD38- was the best discriminator for OS (P=0.005) followed by CD123+/CD34- /CD38+ (P=0.025) and CD34+/CD38- (P=0.025). For DFS CD123+/CD34+/CD38- and CD123+/CD34- /CD38+ were both associated with shorter DFS (P=<0.001); CD34+/CD38- population level at diagnosis had no significant impact on DFS.
Summary and Conclusions: The classical phenotype of CD34+/CD38- is not inclusive; LSC may be present among CD34- and/or CD38+ populations. CD123 and CD133 are sensitive markers, even better than CD34+/CD38-, for the detection of LSC. Higher frequency of leukemia stem cells at diagnosis is associated with shorter OS and DFS.

PB1633

NOVEL TETRACYCLINE TIGECYCLINE EFFECTS ON HEMATOLOGICAL MALIGNANCIES VIA CASPASE 3,9 PATHWAY AND NFKB PATHWAY

H. Shigemi[1,*] T. Yamauchi[1], Y. Tanaka[2], I. Sakamaki[1], M. Ohkura[1], H. Naiki[3], H. Iwasaki[4], T. Ueda[1]

[1]Hematology and Oncology, [2]Molecular and Biochemistry, [3]Molecular Pathology, [4]Infectious Disease, University of Fukui, Faculty of Medical Science, Fukui, Japan

Background: Novel tetracycline derivative tigecycline has an antibiotic effect against a wide range of microorganisms including an activity in multi-resistant drug infections and modulates the production of cytokines and chemokines. FDA approved it for the treatment of complicated infections in 2005. Besides it might affect hematological malignancies. Skrtic *et al.* reported tigecycline's anti-leukemia activity in TEX cell lines and M9-ENL-1 cell lines. The phase I clinical trial has undergone in USA.
Aims: We examined the anti-leukemic effect and elucidated the mechanism of tigecycline. Furthermore, we confirmed tigecycline is also effective on cytarabine resistant (AraC-R) HL60 cell line and clofarabine resistant (CAFdA-R) HL60 cell line. Two cell lines showed 200-fold and 100-fold resistant to parental HL60 cells, respectively.
Methods: To assess the effects of tigecycline on cell viability in acute myeloid

leukemia HL60 cell line, acute lymphocytic leukemia CEM cell line, multiple myeloma U266 cell line and chronic myeloid leukemia K562 cell line, XTT assay was performed. Annexin-PI assay, sub G1 analysis in cell cycle were performed using by flowcytometry in HL60 and CEM cell line. Apoptosis related protein (caspase 3, 8, 9, Bax, Bad, Bclxl, Bcl2) and the phosphorylation of IKKα/β, NFκB were detected by Western Blotting. The effectiveness of tigecycline on AraC-R HL60 cell line and CAFdA-R HL60 cell line, those have been established in our laboratory, were evaluated. Sensitivities on Bcl2 inhibitor (ABT737) and NFkB inhibitor (BAY11-7821) in HL60, CEM, AraC-R HL60 and CAFdA-R HL60 cells, were also examined.

Results: 1) The cell viability was measured at 72 hours by XTT assay. The values of Inhibition Concentration 50% (IC_{50}) of tigecycline in HL60, CEM, K562 and U266 cells were 5.0μM, 2.5μM, 2.7μM and 21.2μM respectively. It was shown that tigecycline was cytotoxic to leukemic cells. 2) Tigecycline induced apoptosis in a dose- and time- dependent manner. In addition, sub G1 analysis showed that tigecycline suppressed S phase in cell cycle. 3) Tigecycline suppressed the expression Bcl2 in a time-dependent manner and inhibited the phosphorylation of NFκB in HL60 cells and CEM cells. Tigecycline activated caspase3, 9. 4) We examined the effectiveness of tigecycline on AraC-R HL60 cells and CAFdA-R HL60 cells. The values of IC_{50} of tigecycline were 6.7 μM (AraC-R) and 2.0 μM (CAFdA-R). ABT737 and BAY11-7821 displayed more effective on resistant cells compared to HL60 parental cells. The values of IC_{50} of ABT737 were 881nM (Parental), 73.3nM (AraC-R), 68.4nM (CAFdA-R). Those of BAY11-7821 were 2.4 μM (Parental), 1.1 μM (AraC-R), 1.5 μM (CAFdA-R).

Summary and Conclusions: Tigecycline showed an anti-leukemic effect on HL60, CEM and K562 cell lines. Tigecycline is presently used for the treatment of certain infections. Pharmacological concentration of tigecycline is useful for treatment of cancer and leukemia. Targeting caspase3, 9 pathway and NFκB pathway, tigecycline induced apoptosis. Furthermore, tigecycline were cytotoxic to both resistant cells. That means tigecycline could be used as the new strategy for treating the recurrent and resistant leukemia. ABT737 and BAY11-7821 also could be new agents, however, they have not been approved for the clinical use. Interestingly, ABT737 showed collateral sensitivity to the resistant cells. Tigecycline mechanically has both effects on leukemic cells. In short, tigecycline might give a marked improvement in anti-leukemic chemotherapy.

PB1634

GENE EXPRESION MARKERS PANEL IN POSTTRANSPLANT RELAPSES EVALUATION

A. Shakirova[1,*] I. Barkhatov[1], O. Shakirova[2], O. Smykova[1], V. Teplyashina[3], Y. Gudozhnikova[3], S. Bondarenko[1], L. Zubarovskaya[1], B. Afanasyev[1]
[1]R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University of St.Petersburg, [2]St.Petersburg State Polytechnic University, St.Petersburg, Russian Federation, [3]R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, St.Petersburg State Polytechnic University, St.Petersburg, Russian Federation

Background: It is known that up to 50 percent of cases of acute myeloid leukemia (AML) does not have informative genetic markers. At the same time, the studies of donor chimerism do not fully indicate the degree of tumor cells elimination and not always allows to estimate the risk of post-transplant relapse. Thus, finding of universal markers allowing for adequate therapy in post-transplant period, is quite important. *WT1, BAALC, EVI1* and *PRAME* gene expression analysis is one of the possible approaches is this field.

Aims: Evaluation of WT1, BAALC, EVI1, PRAME gene expression markers significance in assessment of posttransplant relapse likelihood of acute myeloid leukemia.

Methods: Our study included 63 patients with AML (1 to 60 years old) (M0-2pts, M1-11pts, M2-13pts, M3-2pts, M4-21pts, M5-11pts, M6-1pt, M7-2pts) who underwent allogeneic transplantation of hematopoietic stem cells (allo-HSCT). In 24 patients myeloablative conditioning regimen were used, 39 – received reduced toxicity protocols. Assessing the levels of *WT1, BAALC, EVI1, PRAME* gene expression and the level of chimeric transcripts was performed by means of RQ-PCR with normalization for ABL gene expression. For the donor chimerism monitoring a panel of STR-markers was used.

Results: As based on gene expression in healthy donors, we have established cut-off overexpression (gene exp. / *ABL* exp. X100) values for the genes: *WT1* – 250, *EVI1*-10, *BAALC* – 20, *PRAME*-200. For the present patient setting, we found no statistically significant differences in *WT1, BAALC, EVI1, PRAME* genes expression between the patients with different FAB variants of AML. However we were able to identify a trend to higher values of *PRAME* and *BAALC* gene expression in patients with M1 variant, and *WT1* gene values among patients with M4 variant of AML. In patients who underwent transplantation in relapse state, we have noted a significant overexpression of *EVI1* (P=0.006), *WT1* (P<0.001), *BAALC* (P<0.001). A similar trend was observed for *PRAME* gene (P=0.08). *EVI1* gene overexpression was revealed for 6 patients (33%), *WT1* in 13 cases (72%), *BAALC* in 10 patients (55%) and *PRAME* in 4 patients (22%). When comparing the data on chimeric transcripts expression, we detected a correlation between expression levels of the studied genes and chimeric transcripts (*PML-RARa* and *RUNX1-RUNX1T1*, P<0.05) as well as with donor chimerism levels. At the same time, we did not find this relationship, when comparing with data about of expression of a *CBFB-MYH11* chimeric gene. When evaluating the test sensitivity and specificity analysis we revealed a bellow-cutoff value of the expressed genes in presence of the chimeric transcript less than 2%.

Summary and Conclusions: Evaluation of universal gene marker expression is an attractive approach for assessing efficiency of therapy in patients with AML. Thus, their use in early diagnostics of relapse in post-transplant period is quite promising. However, due to low specificity caused by basal expression in normal cells, futrher application of these markers is limited, when detecting minimal residual disease levels.

PB1635

PROGNOSTIC VALUE OF HEMATOGONES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA IN FIRST COMPLETE REMISSION

M. Hassanein[1,*] R. Haggag[1], S.M. El Shorbagy [1], H. F.Ebian[2]
[1]Medical Oncology, [2]Clinical Pathology, Zagazig University, Zagazig, Egypt

Background: Hematogons (HGs) are normal bone marrow cells; that may reflect the quality of the bone marrow response to chemotherapy. Many studies have focused on the role of HGs in acute leukemia.

Aims: In our study, we investigated the prognostic value of HGs expression in patients with AML in first complete remission.

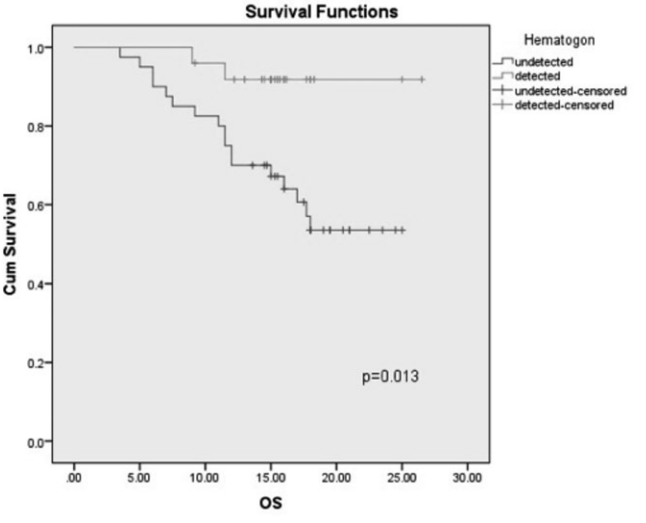

Figure 1. Overall-survival according to HGs status.

Methods: A total of 65 patients with non- promyelocytic AML, in first complete remission were enrolled in this study, and four color flow cytometry was used to quantify Hematogones. We identify the HGs detectable group as those who had more than or equal to 0.01% HGs in bone marrow aspirated sample.

Results: HGs were detectable in 25 patients' marrow samples, and they were significantly associated with cytogenetic risk (P=0.01). After a median follow-up of 17.6 months, patients with detectable HGs had better DFS and OS than those with undetectable levels (P=0.013 and<0.001; respectively) and only 3 patients with detectable HGs in marrow remission samples experience relapse. On multivariate analysis, the HG ≥0.01% is an independent predictive value for DFS (P< 0,0001), and OS (P<0,007), but number of chemotherapy cycles to achieve CR and poor cytogenetic had significant prognostic effect on DFS but not on OS.

Summary and Conclusions: we can concluded that AML patients in first complete remission with HGs ≥0.01% have better DFS and OS.

PB1636

THE MICROARRAY GENE PROFILING ANALYSIS OF ACUTE PROMYELOCYTIC LEUKEMIA CELLS IN RESPONSE TO FISETIN AND HESPERETIN

A. Adan Gökbulut[1,*] Y. Baran[1]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, İzmir, Turkey

Background: Flavonoids are reported to prevent the initiation, promotion and progression of cancer by making changes in various signaling pathways. Although several treatment options exist for acute promyelocytic leukemia (APL), it is not cured effectively due to the development of drug resistance and intolerance and its heterogenic nature. Thus, it is important to develop novel natural treatment approaches in order to improve outcome. Fisetin and hes-

peretin, bioactive flavonoids, found in fruits and vegetables have been reported to be promising novel antioxidants with their potentials as chemopreventive/chemotherapeutic agents in several cancer types such colon, breast and prostate cancers. However, there is no information about the precise mechanisms by which fisetin and hesperetin exert their antileukemic effects.
Aims: We intented to explain the molecular mechanisms and global gene expression patterns modulated by fisetin and hesperetin using genome-wide microarray analysis in APL cells.
Methods: Illumina Human HT-12v4 beadchip microarrays (San Diego, CA) were used to assess global gene expression. Poly-A tail mRNA isolated from fisetin and hesperetin treated HL60 APL cells was converted to biotin labelled c-RNA. The data obtained after hybridization of c-RNA to beadchips was analyzed using Illumina GenomeStudio software to cluster genes. The list of differentially expressed genes constrained by p-value<0.05 and at least 2.0 fold change was obtained. Affected genetic networks were determined by using the Kyoto Encyclopedia of Genes and Genomes (KEGG) and Ingenuity Pathway Analysis (IPA).
Results: A total of 54 and 1608 genes were significantly regulated (P<0.05) in 20 and 50 μM fisetin treated HL60 cells, respectively. Fold change analysis displayed that TXNIP, TFPI, miRNA1974, ID1 and ID3, HSPA1B and IDH1 were altered genes in both 20 and 50 μM fisetin-treated HL60 cells. On the other hand, MAP3K1, Caspase 4 and LASS6 were the examples of upregulated genes while LONP1, STAT5A and STAT3 and JAK1 were some of specifically downregulated genes in 50 μM fisetin treated HL60 cells. KEGG and IPA analysis displayed that MAPK, JAK/STAT and PI3K/AKT signaling pathways and ID signaling pathway were examples of the most altered networks. Moreover, HL60 cells treated with 100 and 150 μM hesperetin changed the expression of 130 and 691 genes (P<0.05), respectively. SASH1, MT1F and SPRR2D were common upregulated genes while TUBB1, ID3, ID1, NMU, FGFR3 and S100P were common dowregulated genes in both 100 and 150 μM hesperetin treated HL60 cells based on fold change analysis. Futhermore, 150 μM hesperetin induced more genes that were either upregulated or downregulated as compared to 100 μM hesperetin. TXNIP, MT1A, MAP3K1 and SPRR2F were some of upregulated genes while RPS25, C-MYC, TUBA1C were the examples of downregulated genes. ID signaling pathway, translation-, gluconeogenesis- and mitosis-related networks, TGF-β and MAPK pathways were the affected signaling networks based on KEGG and IPA analysis.
Summary and Conclusions: Our data show that fisetin and hesperetin trigger growth inhibitory and apoptotic effects by modulating the expression of genes involved in cellular processes. The genetic networks identified in this study enlight some important biological pathways that are altered by fisetin and hesperetin while giving a list of candidate genes that could be targeted for APL therapy. In conclusion, we determined the molecular mechanisms by which fisetin and hesperetin exert pleiotropic effects on APL cells.

PB1637

CHARACTERISTICS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES WITH MONOSOMAL KARYOTYPE

I. Kostroma[1,*] S. Gritcaev[1], I. Martinkevitch[2], Z. Chubukina[3], L. Martinenko[2], M. Ivanova[2], N. Potichonova[4], K. Abdulkadyrov[1]
[1]Hematological clinic, [2]Cytogenetic laboratory, [3]Immunological laboratory, [4]Clinico-morphological laboratory, Russian Institute of Hematology and Transfusiology, St.Petersburg, Russian Federation

Background: It has been shown previously that monosomal karyotype (MK) is associated with bad prognosis in patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). At the same time there are ambiguous data about relationship of MK with other clinical and biological features of AML and MDS.
Aims: To characterize clinical, morphological and cytogenetic signs of AML and MDS patients that are associated with MK.
Methods: A retrospective analysis of 44 patients with AML and 33 patients with MDS was done. To diagnose AML and MDS the criteria of WHO classification was used. Karyotype was studied by standard method. The cases with t(8;21), t(15;17), and inv(16) were excluded from the analyses.
Results: The median age of AML and MDS patients was 64 (17-84) y and 63 y (28-81), accordingly. Number of patients with therapy-related AML and MDS was 11.4% and 12.1%, accordingly. In the MDS group there were 3 (9.1%) patients without excess of bone marrow (BM) blasts and 30 patients had ≥5% BM blasts. So the ratio was 1:10. The most frequent monosomies were -5, -7, and -18 regardless of the diseases. The number of monosomies in individual patients was ranged from 1 till 7. In the AML group the number of cases with ≥3 monosomies was more frequent event in patients ≥60 y than in patients<60 y: 46.4% vs 18.7%; P=0.02. There was correlation between the number of monosomies and AML patients' age: r=0.308; P<0.05. Specific CD expression different from the typical myeloid blasts' phenotype was not found. Median overall survival (OS) of AML and MDS patients were 6 and 8 months, accordingly. Nevertheless there were some long-liver patients: 4 with AML (12-171 mo) and 2 with MDS (20, 38 mo). Three of the AML patients were treated with chemotherapy only and the period of follow-up without relapse were 52, 119 and 171 months. Their karyotype did not characterize by any iterant chromosomal aberration. AlloSCT was realized to the fourth AML patient. Long-liver MDS patients had variant without excess of BM blasts and died after AML transformation or pancytopenia's intensification.
Summary and Conclusions: Monosomal karyotype is the cytogenetic finding that is not associated with patients' age, negative influence of the previous therapy or specific CD expression on the BM blast. But it may be more often event in the group of advanced MDS. AML patients with monosomal karyotype have to be treated aggressively as there is a chance of long relapse-free and OS after standard intensive chemotherapy.

PB1638

MORPHOFUNCTIONAL STATE OF U-937 TREATED WITH PROTEIN KINASES INHIBITOR MALEIMIDE DERIVATIVE IN COMBINATION WITH PHORBOL-12-MYRISTATE-13-ACETATE

I. Byelinska[1,*] L. Garmanchuk[2], V. Rybalchenko[1]
[1]Research sector "Membranology and Cytology", ESC "Institute of biology", [2]Biochemistry, ESC "Institute of biology", Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Background: Maleimide derivative (MI-1, 1-(4-Cl-benzyl)-3-Cl-4-(CF_3-phenylamino)-1H-pyrrole-2,5-dione synthesized in Taras Shevchenko National University of Kyiv, Ukraine) is a competitive inhibitor of PDK1, VEGF16, SW-620) *in vitro* and in vivo decreases the number of colon tumors and normalizes an increased number of monocytes and platelets in blood of rat with 1,2-dimethylhydrazine-induced colon carcinogenesis. MI-1 inhibits proliferation and mitotic activity, activates apoptosis, causes shift of cells from G_2/M+S to Go/G_1 stage of human monocytic cells U-937.
Aims: The aim of this study was to investigate the effects of MI-1 on the morphofunctional state of U-937 in combination with agonist protein kinase C phorbol-13-miristat-13-acetat.
Methods: Cells U-937 were incubated (5% CO_2, 100 humidity, 37 ºC) in 96 well plates in RPMI-1640 («Sigma», USA) with 10% FBS («Sigma»), 2 mM Glutamine and 40 μg/mL gentamicin. MI-1 at final concentration of 0.008 mM or 0.016 mM in combination with 100 nM phorbol-12-myristate-13-acetate (PMA) were added to cell cultures and incubated for 24 or 48 hours. The number of live and dead cells was calculated in hemocytometer with 0.1% trypan blue staining. Percent of apoptotic, mitotic or necrotic cells was calculated per 1000 cells in cytospin prepared specimens after Pappenheim's stained. SPSS 16.0 One-Way ANOVA followed by Hochberg and DunnettT3 tests were used. Mean and SD are presented.
Results: MI-1 at 0.008 mM with 100 nM PMA tended to reduce proliferation of U937 by 22% (0,67±0,18; P=0.064), at 0.016 mM and PMA reduced proliferation by 35% (0,56±0,12; P=0.004) in comparison with PMA only (PMA-control 0,86±0,13) after 24 hours exposure. Number of dead cells didn't differ between the indicated groups (0,08±0,03, P=0.944; 0,12±0,03, P=0,12 vs. PMA-control 0,07±0,05). Extension of treatment for 48 hours with 0.008 mM of MI-1 and PMA reduced proliferation by 40% (0,57±0,13; P<0.001), with 0.016 mM-by 62% (0,36±0,09; P<0.001) vs. PMA-control (0,95±0,13). Number of dead cells at 0.008 mM of MI-1 (0,08±0,04; P=0.94) didn't differ from the control (0,10±0,04), at 0.016 mM-increased (0,32±0,09; P=0.008). MI-1 at 0.008 mM and PMA tended to increase by 26% (2,57±0,32%; P=0.245) and at 0.016 mM increased the number of apoptotic cells in 8,5 times (17,17±2,52%, P=0.018) vs. PMA only (2,03±0,31%). The number of apoptotic cells was increased after 48 hours exposure of MI-1 and PMA (10,17±0,15%, P=0.001; 10,73±0,64%, P<0.001 respectively) vs. PMA-control (2,00±0,53%).MI-1 at both investigated concentration with PMA decreased the number of mitotic cells (1,90±0,10%, P=0.005; 1,60±0,10%, P=0.001 respectively) vs. PMA-control (2,50±0,10%) after 24 hours exposure. 48 hours exposure of MI-1 at 0.008 mM and PMA reduced by 20% (1,07±0,15% P=0.526), at 0,016 mM-by 47% of the mitotic cells (0,70±0,10%, P=0.125) vs. PMA-control (1,33±0,31%). The number of necrotic cells after 24 exposure of MI-1 at 0.008 mM and PMA (2,63±0,15%, P=0.001) lower from the PMA-control (5,10±0,36) and tended to reduce at 0.016 mM (4,27±0,31%, P=0.060) but after 48 hours exposure tended to increase (1,90±0,36% P=0.592, 2,17±0,40% P=0.060) vs. PMA (0,87±0,31%).
Summary and Conclusions: MI-1 in combination with PMA reinforces oppression proliferation activity of U-937, reduces mitotic activity and activates apoptosis through inhibiting of VEGFR-, EGFR- and of non-receptor PDK1-, Src- and Syk- kinases that are involved in hematopoiesis.

Acute myeloid leukemia - Clinical

CLINICAL CHARACTERISTICS OF PATIENTS AFFECTED BY ACUTE MYELOID LEUKEMIA RESISTANT TO PRIMARY INDUCTION CHEMOTERAPY: AN ANALYSIS OF 385 CASES FROM A SINGLE INSTITUTION

S. D'Ardia[1,*] E. Messa[2], B. Allione[1], E. Audisio[1], S. Aydin[1], A. Castiglione[3], G. Ciccone[3], C. Frairia[1], E. Maffini[4], B. Nicolino[1], U. Vitolo[1]
[1]Hematology, Città della salute e della Scienza, Torino, [2]Internal medicine, Carmagnola Hospital, Carmagnola (Torino), [3]Statistic Department, [4]Hematology, Torino University, Torino, Italy

Background: patients (pts) affected by acute myeloid leukemia (AML) resistant to a first line treatment are a relatively small group with a very poor prognosis. There are few data about clinical and molecular features predictive of primary induction failure (PIF) at baseline. Ravandi observed in a series of 1597 AML patients that higher age, unfavourable cytogenetic, high white blood cells (WBC) count at presentation were associated with PIF while they failed to identify any association with molecular abnormalities such as FLT3 mutations.
Aims: aim of our work was to evaluate clinical and molecular features of PIF AML patients at baseline in order to identify any possible clinical characteristics predictive of PIF.
Methods: Clinical and molecular data at baseline of 385 pts affected by AML fit for standard chemotherapy from 2000 to 2013 were collected in a prospective manner in our institution. The distribution of patients' characteristics were summarized using percentiles, for continuous variables, and percentages and frequencies for categorical variables. In order to test difference in distribution of patients' characteristics according to PIF we performed the Wilcoxon rank sum test for continuous variables and the χ^2 test for categorical variables. We performed a logistic regression analysis to identify risk factors associated of failure to achieve complete remission after induction treatment.
Results: 104 (27%) out of 450 pts resulted refractory to the first line treatment. Clinical characteristics at baseline were as follows: median age 58 (± 19) years, 207 out of 385 pts were male. 25,8% of patients who achieved complete remission showed organomegalies *versus* 28,6% of PIF pts. High WBC count at presentation was evident in 22% of PIF *versus* 23,9% of controls. Median platelets count at presentation was similar in the two subgroups: 60 in controls *versus* 48 in PIF pts. Cytogenetic risk was as follows: 9% of controls and 2,3% of PIF pts were low risk, 23,8% of controls and 39,1% of PIF patients were high risk, the remaining pts were intermediate risk. The majority of the pts (64%) were treated by standard dose anthracycline based induction regimen, while 26% were treated by fludarabine based regimen and 10% were treated by high dose chemotherapy. At univariate analysis age, unfavourable cytogenetic risk and fludarabine based regimen were predictive factors of induction failure (OR 1,02, 2.05 and 1,77 respectively with 1,01-1,04, 1,22-3,45 and 1,09-2,87 95% CI) while NPM mutated status, high dose ARA-C regimen and favourable cytogenetic risk were associated with complete remission (OR 0,33, 0,4 and 0,23 with 0,1-1,07, 0,17-0,99 and 0,05-1,02 95% CI). We failed to identify a statistically significant association with WBC, platelets count and FLT3 status and PIF status.
Summary and Conclusions: In our experience the only predictive factors of PIF in adults affected by AML are higher age and unfavourable cytogenetic at baseline. Flt3 status is confirmed not to be a molecular marker of treatment failure while NPM mutation seems to have a positive predictive value but the data need to be confirmed in a larger series of cases. Even if our study is only observational, our data showed that pts treated by conditioning regimen based on high dose ARA-C showed a better outcome than pts who underwent fludarabine based induction chemotherapy. Further studies are needed in order to identify more clinical and biological factors predictive of primary treatment failure at baseline.

PB1640

EFFICACY OF DECITABINE IN 10-DAY REGIMEN IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA INELIGIBLE FOR INTENSIVE CHEMOTHERAPY

B. Moreno De Gusmao[1,*] I. Esteves[1], M. Petrolli[1], J. Hyppolito[1], F. Santos[1], F. Ferreira[1], G. Perini[1], R. Helman[1], N. Hamerschlak[1]
[1]Department of Hematology, Hospital Israelita Albert Einstein, São Paulo, Brazil

Background: Currently the hypomethylating agents (azacitidine, decitabine) are safe and effective alternative treatment for patients with acute myeloid leukemia (AML) that do not fit for intensive chemotherapy treatments. Several studies have been described the modification of the treatment regimen with hypomethylating agentes. We analyzed the effectiveness of decitabine in patients with acute leukemia not eligible for intensive therapy.
Aims: The objective of this study is to analyze the safety and efficacy of using decitabine in 10-day regimen.
Methods: We reviewed 11 patients with AML treated with DEC between June 2010 and January 2015. The schedule was DEC 20 mg/m2x 10 days in induction therapy. Patients who achieved remission cytological (defined as<5% blasts in the bone marrow aspirate) received consolidation therapy with DEC 20 mg/m2x 5 days until progression and the remaining patients received a re-induction before start consolidation therapy.
Results: 36.4% were de novo AML 63.6% were secondary AML (2 myelofibrosis, 4 MDS and CMML 1). All patients were male with a median age of 82 years old (range 69-86) and 36.4% patients had cytogenetic abnormalities in diagnosis according to European Leukemia Net (ELN): 6 patients were favorable risk, intermediate risk 1 and 3 high-risk. 54.5% patients had>30% blasts and 45.4% received treatment previously. 91% of patients had some comorbidities. A median of 6 cycles (range 1-10) were administered in total 57 cycles of decitabine. All patients had adverse effects during treatment, the most frequent febrile neutropenia (63%) and there was an early death (<8 weeks) associated with liver failure in a patient previously diagnosed. According to ELN, with induction in 10 days, we had a global response rate of 72.7% (2 CR with cytogenetic remission; 2 CR, 4 CR with incomplete hematologic recovery, 1 PR and 3 patients with refractory disease. Secondary AML, transfusion dependence and number of blasts>30% at diagnosis, had no effect on treatment response induction. In our study 6 patients died because disease progression infection. Median follow-up of 340 days (range 148- 1506 days) with OS of 63% in 1-year and 45.5% during the follow up with a DFS of 45.5%.
Summary and Conclusions: In our experience, decitabine in 10-day regimen in elderly patients is safe and very effective, even in poor prognosis patients.

PB1641

INTENSITY OF CHEMOTHERAPY INFLUENCING AN OVERALL SURVIVAL OF PATIENTS WITH ACUTE MYELOID LEUKEMIA OLDER THAN 70 YEARS

I. Djunic[1,*] M. Virijevic[1], N. Suvajdzic-Vukovic[2], A. Novkovic[3], M. Mitrovic[4], N. Colovic[2], A. Vidovic[2], D. Tomin[2]
[1]Department of acute leukemias, Clinic for Hematology, Clinical Center of Serbia, [2]Department of acute leukemias, Clinic For Hematology, Clinical Center of Serbia, Medical Faculty of Belgrade University, [3]Clinical Hospital Center "Zemun", [4]Clinic For Hematology, Clinical Center of Serbia, Medical Faculty of Belgrade University, Belgrade, Serbia

Background: Acute myeloid leukemia (AML) is common disease in people aged >70 years. While the best management of AML is based mainly on intensive chemotherapy (CT) in younger patients, are still remains a matter of controversies in the elderly. In elderly AML patients, intensive CT is often poorly tolerated and gives scanty results.
Aims: The aim of this study was to identify the patients with AML not eligible for CT and who could be suitable only for supportive care.
Methods: This single-center study involved 68 patients aged >70 years (range 71-85) with nonpromyelocytic AML during follow-up of 5 years. Patients were treated by three type of therapeutic regimen with various intensity: CT (induction therapy with daunorubicin 30 mg/m^2 on day 1 and 3 and cytarabine 100 mg/m^2 given for 5 days; or mitoxantrone 10 mg/m2 and etopozide 100 mg/m2 given for 5 days), paliative therapy (Hydroxiurea, Etoposide or 6-mercaptopurine per os) and supportive therapy (transfusions). Comorbidities were evaluated by using the hematopoetic cell transplantation-specific comorbidity index (HCT-CI). Performance status (PS) was evaluated by Eastern Cooperative Oncology Group (ECOG), ranged 0-4. Cytogenetic risk group was assessed by recomandation of Europian LeukemiaNet (ELN). The following parameters were estimated as risk factors for treatmement with CT: age >75 years, leukocytopenia (white blood count<4x10^9/L), thrombocytopenia (platelet count<50x 10^9/L), higher absolute peripheral blasts (>5x 10^9/L), ECOC PS (<2 vs ≥ 2), ELN cytogenetic risk group, and HCT-CI (<3 vs ≥ 3). Risk factors were identified using the univariate and multivariate analysis.
Results: In this group of patients, 16 pts treated with CT, 24 pts treated with palliative and 28 pts with supportive therapy. In group of patients treated with CT, univariate analysis showed that the following risk factors were significant for OS: leukocytopenia (P=0.039), thrombocytopenia (P=0.043), higher absolute peripheral blasts (P=0.002), ECOG PS ≥ 2 (P<0.001) and HCT-CI ≥ 3 (P< 0.001). Multivariate analysis indicated HCT-CI ≥ 3 as the most important risk factor for poor OS of patients treated with CT: P<0.001, relative risk (RR)=3.689; 95% confidental interval (CI)=1.817-7.489. Patients with leukcytopenia and HCT-CI ≥ 3 were separated in single group and in this group (17 pts) most benefit for OS had patients treated only with supportive therapy: P=0.043, RR=0.382, CI=0.131-1.115.
Summary and Conclusions: Elderly AML patients with cytopenia and comorbidities are not suitable for intensive CT. In these patients supportive care need to be concidere as a choise of therapy because the intensive CT has a poor influence on its OS.

PB1642

MYELOID SARCOMA: CLINICAL FEATURES AND OUTCOMES AFTER INTENSIVE TREATMENT, TEN YEARS EXPERIENCE AT A SINGLE CENTRE.

F. Pavesi[1,*] M.G. Carrabba[1], C. Messina[1], M. Ponzoni[2], R. Milani[3], P. Ronchi[3], L. Vago[1], E. Sala[1], B. Gentner[1], M. Tassara[3], S. Marktel[1], M. Morelli[1], M.T. Lupo-Stanghellini[1], J. Peccatori[1], C. Corti[1], F. Ciceri[1], M. Bernardi[1],

[1]Onco-Ematology, Unit of Hematology and Bone Marrow Transplantation, [2]Pathology Unit, [3]Immuno-hematology and Transfusion Medicine, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: Myeloid Sarcoma (MS) is a rare neoplasm composed of immature myeloid cells potentially occurring in any extramedullary organ, most commonly in the lymph node and soft tissues. MS develops before, concurrently or after the diagnosis of acute myeloid leukemia (AML), but can rarely occur without bone marrow infiltration by leukemia. MS is associated with poor outcome. The rarity of this presentation has been an obstacle to characterize its clinical features and prognosis.
Aims: The aim of the study was to analyze characteristics, treatments and overall survival of all patients presenting with MS.
Methods: We retrospectively reviewed medical record of patients who presented with MS to our institute from 2004 through 2015. In total 28 patients with MS were identified.
Results: Thirteen patients had a MS at disease onset, 2 as primary sarcoma and 11 associated with AML, 15 developed MS at relapse of AML, 9 patients had only extramedullary relapse (EM), 6 also bone marrow involvement (table 1). The median age of patients at MS presentation was 45 years (range 22-76). The most commonly involved site for patients with MS at disease onset was abdomen (gastrointestinal tract and kidney.) Six out of 13 patients had cytogenetic abnormalities involving chromosomes 8, 21, 16, Y; karyotype was normal in 3/13 and complex in 2/13. Cytogenetic was not available in 2/13 cases. Eleven out of 13 patients with MS at diagnosis received allogeneic stem cells transplantation (alloSCT) as post-remission treatment and 2 patients were treated with palliative chemotherapy due to old age. After a median follow-up of 560 days (range 108-3715) 8/13 patients (61%) are alive and 6/13 (46%) are disease free. Among the 15 patients who have developed a MS at AML relapse the most frequent location was paravertebral (table 1) The median age at presentation was 46 years (range 22-65). Seven out of 13 available cytogenetic analysis were normal, 5 complex and 1 was t(8;21) plus delY. The median time from AML diagnosis to EM relapse was 657 days (range 308-2312) and in 14/15 cases EM occurred after alloSCT, with a median time to relapse of 444 days (range 254-3195). Salvage treatment of these patients: 6 alloSCT, 3 immunotherapy, 4 chemotherapy, 2 palliative radiotherapy. At last follow up three out of 15 patients (20%) are alive and in complete remission from AML and MS (median follow-up was 350 days, range 39-1847).

Table 1. Sites of Myeloid Sarcoma.

sites of MS	MS at disease onset	MS at relapse of AML
mediastinic	1	
addomen	5	2
paravertebral	1	4
mammary	1	1
nodes	1	
multiple (at least 3 sites)	3	3
retrorbital	1	
nasopharynx		1
mucosal		1
testis		1
bone		2

Summary and Conclusions: With this study we provide a single institution experience of MS management and outcome. Our Institution is a referral centre for alloSCT thus explaining the high rate of alloSCT in this series. Our data support alloSCT as part of first line treatment of MS after chemotherapy. EM relapse of AML after first line therapy has a poor prognosis even after intensive treatment. The high rate of EM relapse after alloSCT (14/15) suggests that MS may represent a form of post alloSCT AML immune escape not necessary related to sarcomatous presentation at onset. Larger multicenter studies are needed to better and more fully assess outcomes of these patients.

PB1643

PRELIMINARY RESULTS OF ACUTE LEUKEMIA EPIDEMIOLOGICAL ESTIMATIONS BASED ON CLINICAL REGISTIRY DATA IN RUSSIA

Z. Akhmerzaeva[1,*] S. Kulikov[2], M. Rusinov[2], L. Gavrilova[3], E. Zotina[4], A. Pristupa[5], N. Vopilina[6], E. Borisenkova[7], E. Parovichnikova[8]
[1]Acute leukemia department, [2]Biostatistic department, National Research Center For Hematology, Moscow, [3]Hematological Department, Saransk Clinical Hospital, Saransk, [4]Hematological Department, Kirov Clinical Hospital, Kirov, [5]Hematological Department, Ryazan's Clinical Hospital, Ryazan, [6]Hematological department, Tambov regional clinical hospital, Tambov, [7]Hematological department, Kaluga regional clinical hospital, Kaluga, [8]BMT department, National Research Center For Hematology, Moscow, Russian Federation

Background: The incidence of acute leukemia (AL) in US and European countries is about 5 per 100000 according data from cancer registries. Russian Federal Cancer Register reported AL incidence rate across the country as about 3 per 100000. Russian Hematology Society in 2013 initiated the AL population based registry study in which participated 8 regions of Russia Federation. The primary goal was to pre-registry patients for clinical studies, and secondary-to evaluate the epidemiology of AL. 5 regions were included into analysis of epidemiology statistics. The criteria were the fullness and reliability of AL cases registration. Also, only regions with one big hematological center accumulating all AL cases were chosen. All new cases were recorded on-line into special Web based data capture system.

Table 1.

	Adult population (10^6)			Registered cases			Duration of registration (y)	Crude incidence		
Region	All	M	F	All	M	F		All	M	F
Kirov	1.15	0.52	0.63	41	19	22	1.96	1.82	1.87	1.78
Mordovia	0.72	0.33	0.40	44	20	24	1.88	3.24	3.26	3.22
Ryazan	1.01	0.45	0.56	37	23	14	1.48	2.48	3.45	1.69
Kaluga	0.88	0.39	0.48	19	13	6	0.87	2.50	3.80	1.44
Tambov	0.95	0.43	0.52	27	19	8	1.56	1.82	2.85	0.98

Aims: To evaluate the age-gender specific incidence, profile and other epidemiologic characteristics AL in Russian regions.
Methods: The registry was started at 1st April of 2013 and is ongoing.
Results: 169 new ALL cases from Kirov, Ryazan, Kaluga, Tambov regions and Mordovia republic (4,7 M of population) were included into analysis. The distribution by AL subtypes was following: AML-109 (74,6%), ALL - 31 (21,2%), APL-5 (3,4%), other-1 (0,7%). Median age was for AML-59 (17-85), ALL - 38 (18-80), APL 54 (38-60) years. Gender female/male proportions in AML were – 18/13, in ALL - 54/55, in APL - 4/1. 105 (62,5%) patients are alive; 58(34,5%)-died, 5 (3%) were withdrawn. The incidence rate estimates by region are listed in Table1. Two regions (Kirov region and Mordovia) with longest duration of registration were taken for age specific incidence calculations. Incidence of AL by age is following: in 15-19 age group – 0.90; in 20-39 age group – 1.13; in 40-59 age group – 2.45; in 60-79 age group – 3.54; in 80-99 age group – 2.18. Total crude incidence in this two regions is 2.09, standardized by WHO population – 1.87.
Summary and Conclusions: The first estimations of AL epidemiology in selected Russian regions was made based on direct registration data from hematological centers. The incidence rate estimations are less than expected. Some explanations may be: incomplete registration of cases, under -diagnostics of AL, non-admission of AL patients to hematological center.

PB1644

AML-PATIENTS FROM A SOCIALLY DISADVANTAGED ENVIRONMENT SHOW POORER THERAPEUTIC OUTCOME

A. Kaifie[1,*] T. Lunau[2], N. Dragano[2], E. Jost[1], T. H. Brummendorf[1], S. Wilop[1], M. Crysandt[1]
[1]Department for Hematology, Oncology, Hemostaseology and SCT, Medical Faculty, RWTH Aachen University, Aachen, [2]Institute for Medical Sociology, Medical Faculty, University of Dusseldorf, Dusseldorf, Germany

Background: The socioeconomic status (SES) is strongly associated with the development and clinical course of several malignant and non-malignant diseases. Only few studies examined the clinical outcome of AML patients in relation to indicators of the social environment at their area of residence, showing divergent country-specific results. So far, no evaluation of area level social differences for survival in AML-patients has been conducted in Germany.
Aims: The aim of the study was to investigate if the social environment in the area of residence is related to complete remission and overall survival of individual AML-patients in the city of Aachen.
Methods: All patients who were treated with a confirmed diagnosis of AML from 1996-2014 at the University Hospital in Aachen were assessed retrospec-

tively (n=139). Clinical and prognostic parameters like age at diagnosis, sex, cytogenetic risk group, primary or secondary AML, curative or palliative intention of treatment were recorded. Patients were assigned to geographical areas using administrative area codes. We classified the social status at the area of residence using area-specific socioeconomic indicators (*e.g.* proportion of unemployed, crime rate). Based on this index we divided the sample into patients living in high or medium SES areas and those living in low SES areas. Survival analyses were performed using Kaplan-Meier estimator and Log-rank test. Furthermore univariate and multivariate Cox-regression analyses were conducted.

Results: First of all, the distribution of prognostic factors (age at diagnosis, cytogenetic risk group, therapeutic intention) was assessed for the two social environments. No significant differences were detected. Survival analyses for all patients and defined subgroups (stratified by age and therapeutic intention) were performed. Younger patients (≤65 years) who received induction therapy with a curative intention showed a significant difference in overall survival (P=0.0084) between the two social spaces (Figure 1).

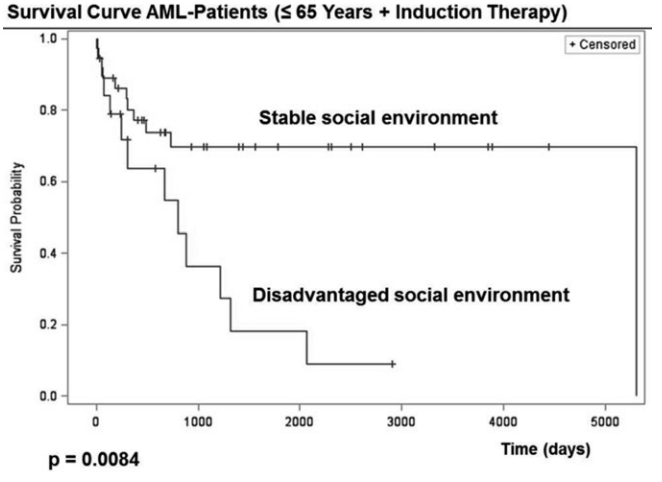

Figure 1.

In the assessment of the clinical course, patients from a social disadvantaged environment reached significantly less often a complete remission (23.1% vs. 12%, P=0.0039).

Summary and Conclusions: Similar to several solid tumors the socioeconomic environment in the area of residence was significantly related to the clinical course in younger patients with AML. A detailed evaluation of the underlying mechanisms is needed for the improvement of this unsatisfactory situation. As these are findings from analyses not specified in advance confirmation with independent data is needed.

PB1645

FAVORABLE EFFECT OF PRIMING WITH GEANULOCYTE COLONY-STIMULATING FACTOR IN REMISSION INDUCTION OF HYPOCELLULAR ACUTE MYLOID LEUKEMIA

N. Colovic[1,*] Y. Palibrk[1], G. Jankovic[1], M. Colovic[1]
[1]Internal medicine, Medical Faculty University Belgrade, Belgrade, Serbia

Background: The hypocellular variant of acute leukemia is very rare atypical leukemia which mainly occurs in older patients. It ussually has a myeloid phenotype. Survey of Pub Med have shown that there are no guidelines in the world literature for the treatment of such subtype of AML. The effect of G-CSF priming has not been investigated as a key constituent of remission induction chemotherapy in this cohort of patients. We point out the need for such contribution of world centers to show the best way for good outcome of these rare subtype of acute myloid leukemia.

Aims: The aim was to evaluate the results of treatment with different protocols.

Material and methods. We retrospectively analyzed all hypocellular acute myeloid leukemias which were treated in ten years period, between january 1990 and december 2010 at the Clinic of Hematology, Clinical Center Belgrade. All diagnostic criteria were met: pancytopenia with blasts in peripheral blood, less than 20% of bone marrow cellularity and more than 20% of blastas in bone marrow which were myeloperoxidase positive responding to myelod phenotype. There were 30 patients, 18male 12female. The median age of the patients was 58,9 years (ranging from 32-76 years) and median cellularity of bone marrow of this group of patients was 16%. Only one patient had myelodysplastic syndrome as antecedent disorder. No one of presented patients received prior chemoradiotherapy for non-hematopoietic neoplasms.

Results: All patients at presentation had leucopenia ranging from 0.3-2.0 (with SD 0.4). The distribution according to FAB Classification were as follows: 5 patients(pts) had M0 (16%), 11 pts M1 (36%), 6 M2 (20%), M4 1pts(3%), M5a 2 pts(6%) and M7 1 pts (3%) and 4 patients had unclassified acute myeloid leukemia. The ECOG performance status was: 17 patients had favorable performance status (1 PS was in 4 pts and 2 in 13 pts – 56,6%), status 3 in 8 (26,6 %) and 4 in 5 (1.3%). Sixteen patients had a normal diploid karyotype (or –Y in one), in seven patients cytogenetic analyses were inadequate, in four patients it was not done, in one 47XY, der(13)/46,XY, and another 46,XX, t(8;20) ad finally 46,XX,add(9)(p24)[6]/46,XX[14] was found. AML M1 was the most common subtype. Followed by M2 and M5a. Twelve patients received priming with G-CSF followed by standard 3+7 regimen, 5 patients GCSF plus small doses of cytosine arabinoside, 8 patients only support and 5 patients hydoxiurea. Thirteen patients (43%) achieved a complete remission, 11 treated with G-CSF followed by standard induction chemotherapy and 2 patients treated with GCSF and low doses of cytosine arabinoside. Disease free survival was from 4 months to 72 months (median 14 months). On multivariate analysis overall survival, remission duration and event free survival were comparable to other patients with acute myeloid leukemia.

Summary and Conclusions: This report describes a cohort of patients with hypocellular AML characterized by prominent cytopenias, older age, low bone marrow cellularity, cytogenetic findings and distribution of morphologic subtypes similar to normocellular AML. We found that patients treated with priming G-CSF achieved the best CR rate and OS which were statistically significantly longer(Log rank P<0.0001) (P<0.008) then the rest of the cohort patients.

PB1646

MOLECULAR ANALYSIS OF FUSION POINTS AND RELATIVE EXPRESSION OF MEIS1, EVI1, HOXA5 AND FLT3 IN MLL-MLLT10 HARBORING AML PATIENTS

S. Burillo-Sanz[1], R. Morales-Camacho[2], M. T. Vargas[2], T. Caballero-Velazquez[2], I. Perez de Soto[2], A. Rodriguez[3], E. Carrillo[2], C. Prats-Martín[2], R. Bernal[2], J. A. Perez-Simon[2], *J. R. Garcia-Lozano[1]
[1]Inmunology, [2]Hematology, HUV del Rocio, [3]Hematology, HUV del Rocio y HUV Macarena, Sevilla, Spain

Background: A frequently occurring chromosomal aberration in acute myeloblastic leukemia (AML) is a translocation involving the mixed lineage leukemia (*MLL*) gene at 11q23 with one of more than 70 partner genes described to date. Although, in general, *MLL* rearrangements are related with a poor outcome, there are great differences based only on the translocation partner of *MLL*. Up to 15% of all *MLL* rearrangements in AML are due to *MLLT10* fusions. *MLL*-rearrangements result in an upregulation of *HOX* transcription factor genes. Moreover, *EVI1* and *MEIS1* upregulation are significantly associated to a poor prognosis in AML and not all *MLL*-rearranged leukemia cases overexpress these genes.

Aims: In this work we report on the molecular analysis and gene expression profiling for *MLL-MLLT10* AML.

Methods: *MLL* gene fusion was detected by cytogenetics; FISH with LSI *MLL* dual color, Break Apart probe, and WCP 10 and 11 probes; reverse transcription PCR (RT-PCR) and sequencing. Gene expression was analyzed by real-time PCR in a reaction with specific primers and SybrGreen. Relative quantification was performed by 2^{-DDCt} method. We include analysis of two *MLL-MLLT10* harboring leukemias of the FAB-M5 subtype. Both patients obtain complete remission (CR) with positive MRD and disease relapse 4 months after diagnosis. Patient 1 die 3 months after transplantation and second one is currently receiving rescue chemotherapy.

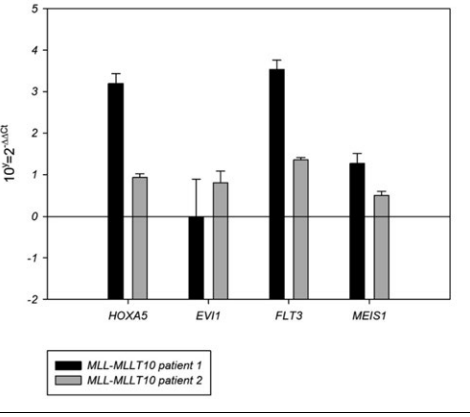

Figure 1. Gene upregulation in MLL-MLLT10 harboring AML.

Results: Patient 1 cytogenetic analysis revealed 46,XY,del(10)(p12),add(11)(q23)[20]. FISH analysis using *MLL* locus specific probe showed a 73% of an uncertain pattern with two nearby split signals. Metaphase FISH with WCP confirmed that chromosome 10 material was present at 11q and that the chromosome 11 material had not been transferred elsewhere in the genome. Patient 2 presented a 46,XX[20], and the same *MLL* FISH pattern that patient 1. Molecular analysis for the *MLL-MLLT10* fusion demonstration was performed based

on the presence of NG2 by flow cytometric analysis and a FISH pattern suggesting a gene insertion in 11q23. The cDNA was used in multiplex PCR reactions for detection of the MLL-MLLT10 fusion, and PCR product was sequenced. In patient 1, a mRNA fusion between exon 7 of 5' MLL mRNA and exon 15 of 3' MLLT10 mRNA was detected, with frame conservation and the whole sequence of both exons (GenBank ID: KF778381). The breakpoint described here is unusual in 10;11 rearrangements and the same fusion at mRNA level was previously described in only one case. In the second case, the same RT-PCR analysis revealed an mRNA fusion between exon 8 of 5' MLL mRNA and exon 16 of 3' MLLT10 mRNA. This MLL-MLLT10 fusion was first described in patient C from Chaplin, *et al.* 1995. Gene expression analysis showed overexpression of *HOXA5, FLT3* and *MEIS1* in both cases but *EVI1* was only overexpressed in patient 1.
Summary and Conclusions: Molecular studies are required for *MLL-MLLT10* detection in cryptic rearrangements and, as illustrated in this work, for the identification of new *MLL-MLLT10* fusion points. Gene expression analysis shows overexpression of *MEIS1* in both *MLL-MLLT10* patients, previously related to poor outcome, and *EVI1* only in patient 1.

PB1647

PREVALENCE AND PROGNOSTIC IMPACT OF IDH1 AND IDH2 MUTATIONS AMONG CYTOGENETICALLY NORMAL AML EGYPTIAN PATIENTS

S. Aref[1], M. El-Ghonemy[1], M. El Baiomy[2,*]
[1]Hematology Unit, Clinical pathology Department, [2]Medical Oncology and Hematology Unit, Oncology Center Mansoura University, Mansoura, Egypt

Background: Acute myeloid leukemia (AML) is a clonal malignant disease of haematopoietic tissue caused by somatic mutations in genes that control normal cell proliferation and differentiation.The molecular genetic alterations is one of the most important prognostic factors that have been identified in AML and the role of this genetic alterations has been emphasized by the 2008 revised WHO classification of AML like FLT3, NPM1, and CEBPA. The isocitrate dehydrogenases (IDHs) are enzymes that catalyze oxidative decarboxylation of isocitrate into ketoglutarate by using NAD or NADP as a cofactor to yield NADH or NADPH, respectively.
Aims: This study aimed to evaluate the clinical impact and prognostic relevance of IDH1 and IDH2 mutations among cytogenetically normal AML patients.
Methods: Two hundred and eleven patients were assessed for the presence of IDH1 and IDH2 mutations by sequencing.
Results: IDH1 mutation was detected in 18 out of 211 AML patients (8.5%) and IDH2 mutation was detected in 22 out of 211 AML patients (10.4%). The IDH1 mutant cases were more older age, female, with high platelet count (P 0.01), high bone marrow blast cells count (P 0.002) and the NPM1 mutation was more common in wild *versus* mutated groups (81.1% vs 18.9% respectively with P<0.001). The IDH2 mutation was more common in older age, normal karyotyping (P 0.001), with low WBCs count (P 0.003) and high platelets count (P<0.001). The induction of remission rate wasn't significantly associated with neither IDH1 nor IDH2 mutation status. Patients with mutant IDH1 showed poor OS *versus* patients with wild type (6 vs 9 months respectively; P 0.07), however there was no statistically significant relation between IDH2 mutation and OS. In this study, there was 24 patients with CN-AML patients (ie: NPM1 mutation and without FLT3 mutation), IDH1 mutation in this group showed significantly shorter overall survival *versus* patients with IDH1 wild (5 vs 13 months respectively; P 0.02).
Summary and Conclusions: IDH1 and IDH2 mutations occur in 8.5% and 10.4% respectively in AML patients which is a minor subset of the newly diagnosed cases and these mutations have an association with molecular and cytogenetic status. We recommend molecular testing for *IDH1* and *IDH2* mutations to confirm the role of these mutations as novel genetic markers in risk stratification of AML patients in a larger study.

PB1648

ACUTE ANTHRACYCLINE CARDIOTOXICITY IN ACUTE MYELOID LEUKEMIA DURING INDUCTION CHEMOTHERAPY: ROLE OF ECHOCARDIOGRAPHY

M. Aggarwal[1,*] P. Mishra[1], A. Saxena[2], S. Gupta[2], S. Tyagi[1]
[1]Hematology, [2]Cardiology, All India Institute Of Medical Sciences, New Delhi, India, New Delhi, India

Background: Anthracyclines are used in induction treatment of acute myeloid leukemia**.** However, they cause dose-dependent cardiac dysfunction through generation of reactive oxygen species, mediated by topoisomerase -IIb in cardiomyocytes and forming complexes with intracellular iron, leading to lipid peroxidation and DNA damage. Due to low potential for regeneration in cardiac myocytes, these changes are likely irreversible. Early detection of cardiotoxicity is important before changes become clinically overt. Left ventricular ejection fraction (LVEF) has been the main indicator of cardiac dysfunction but impairment in LVEF is detected only after considerable myocyte loss has occurred. So, more sensitive tools to detect these alterations are warranted.
Aims: To study acute cardiac toxicity of anthracycline in acute myeloid leukemia (AML) patients by serial echocardiographic parameters during induction chemotherapy.
Methods: The prospective study included newly diagnosed AML patients. Patients with history of previous anthracycline exposure were excluded. AML induction therapy consisted of daunorubicin 60 mg/m^2/day for 3 days and cytarabine 100 mg/m^2/day for 7 days. All patients were assessed by echocardiography at start and end of induction chemotherapy and after 3 days of daunorubicin. Parameters on M mode, Doppler and tissue Dopper modes at mitral valve (lateral) and septum were recorded.

Table 1.

				P value		
Parameter	Baseline(B) Mean+SD (n= 32)	Mid (M) Mean+SD (n= 29)	Post (P) Mean+SD (n=16)	B vs M	B vs P	M vs P
E vel (cm/s)	94.7+20.7	83.4+21.0	73.4+19.5	0.2	0.02	0.6
A vel (cm/s)	63.5+19.2	57.1+20.1	67.1+17.6	0.09	0.9	0.5
E/A	1.6+0.6	1.6+0.6	1.1+0.4	0.6	0.4	0.2
Sm (lateral)(cm/s)	11.6+2.4	10.6+2.6	10.4+2.3	0.7	0.1	0.9
Sm (septal)(cm/s)	8.9+1.4	8.6+1.6	8.3+1.5	0.9	0.9	0.9
Em (lateral)(cm/s)	16.4+4.6	14.4+3.8	12.9+4.1	0.6	0.002	0.2
Em (septal)(cm/s)	11.4+3.5	9.6+2.8	9.1+2.5	0.5	0.04	0.9
Am (lateral)(cm/s)	8.9+2.6	7.7+2.2	6.7+2.0	0.4	0.001	0.2
Am (septal)(cm/s)	8.5+2.4	8.0+1.9	7.8+2.1	0.9	0.4	0.9
LVEF (%)	65.2+5.9	63.7+7.1	63.6+9.0	0.2	0.5	0.9

Results: A total of 32 patients of AML were enrolled with median age of 21 years (range 7-57 years) and 18 males (56.2%). Median leucocyte count was 6300/uL (range 300-380,000). 16 patients (50%) had fungal infection during induction and 14 patients expired (44%). Cardiac chamber dimensions were not altered during induction. Doppler parameters: E velocity decreased in AML patients (P value 0.023). A velocity did not changed significantly. E/Ashowed overall decreasing trend (P value 0.09). Tissue Doppler parameters: Em lateral decreased (P value 0.005) in AML patients. Em septal decreased from baseline to post chemotherapy echo (P value 0.04). Am lateral dropped from baseline to post chemotherapy echo in AML patients (P value 0.001). Sm lateral and septal were not altered significantly. Isovolumetric contraction time was significantly increased from baseline to post chemotherapy echo (P value 0.019). Ejection fraction did not show significant changes during induction.
Summary and Conclusions: Significant changes occur in various Doppler and tissue doppler parameters during induction chemotherapy reflecting underlying diastolic dysfunction due to anthracycline induced cardiotoxicity. Ejection fraction is relatively insensitive tool to ascertain these early changes. It is suggested that these patients be followed up with repeated ECHO to find improvement or worsening of these changes before any overt clinical symptoms due to heart failure develop. Early interventions can be planned before overt heart failure in consultation with cardiologists especially while planning treatment for patients with relapsed disease or transplantation.

PB1649

ELLIPTICINES DRIVE LEUKAEMIA CELL DEATH VIA MITOCHONDRIAL ROS

e.g. Russell[1,*] E.C. O'Sullivan[2], F.O. McCarthy[2], T.G. Cotter[1]
[1]School of Biochemistry and Cell Biology, [2]Department of Chemistry, University College Cork, Cork, Ireland

Background: Ellipticine is an anticancer agent which induces cell death by multiple mechanisms of action[1]. Unfortunately, this compound and its analogues have limited solubility and have been associated with several toxic effects which has hampered their clinical development. A panel of novel ellipticine isomers was designed and synthesised with the aim of evaluating their cytotoxic effects[2]. A preliminary NCI 60-cell screen demonstrated that these compounds display promising anti-tumour activity across a number of different cancer cell types, particularly leukaemia cell lines.
Aims: We examined the effect of these derivatives in detail on the acute myeloid leukaemia (AML) cell line, MV4-11. The most cytotoxic compound, 7-formyl-10-methylisoellipticine was identified from this panel. The mechanism by which this compound induces its cytotoxic effects was investigated.
Methods: Cell cycle was monitored by flow cytometry. Cell number and viability was measured by dye exclusion. Confocal microscopy was used to visualise compound accumulation. Protein levels were evaluated by Western blotting. Reactive oxygen species (ROS) levels were measured by flow cytometry using the ROS probes dihydroethidium and MitoSOX.
Results: Cell cycle analyses revealed that the compounds had a range of distinctive cell cycle effects[3]. 7-formyl-10-methylisoellipticine showed the most promise with respect to cytotoxic activity. We demonstrated that this compound killed cells by apoptosis which is mediated by an induction of reactive oxygen species (ROS). In a cell, mitochondria and NAPDH oxidase (NOX) are the

major sources of ROS. Previous research in our laboratory has shown that NOX derived ROS is critical for cell survival[4]. ROS inhibitors were employed to reveal the origin of the ROS. Our study suggests that the compound generates ROS in mitochondria which ultimately leads to its cytotoxic effect. Interestingly synergistic effects are seen when 7-formyl-10-methylisoellipticine is used in combination with a NOX inhibitor as well as the clinically used AML chemotherapeutic, daunorubicin.

Summary and Conclusions: This study provides detailed cellular information on the potential use of isoellipticines as chemotherapeutic agents. By probing the mechanism of action of this novel compound class we have uncovered a potential clinical application in the field of adjuvant therapy. We are currently investigating the effects of the compound in a pre-clinical AML mouse model.

TREATMENT OUTCOME OF CHILDREN WITH DE NOVO AML GROUPED BASED ON RISK FEATURES AND TREATMENT RESPONSE

K.H. Yoo[1,*] Y.B. Choi[1], K.W. Sung[1], H.H. Koo[1], J.W. Lee[2], N.G. Chung[2], B. Cho[2], H.K. Kim[2], H.J. Baek[3], H. Kook[3]
[1]Pediatrics, Samsung Medical Center, SUNGKYUNKWAN University School of Medicine, [2]Pediatrics, The Catholic University of Korea College of Medicine, Seoul, [3]Pediatrics, Chonnam National University Hwasun Hospital, Gwangju, Korea, Republic Of

Background: Approximately 80-100 children are newly diagnosed as AML in Korea. The survival rate of pediatric AML has improved due to intensified well-designed chemotherapy, better supportive care, risk-based treatment adaptation and allogeneic HSCT. However, relapse still remains the leading cause of events, which accounts for 30 to 40%. Because pediatric AML is a heterogeneous disease and only some subgroup of patients benefits from allogeneic transplantation in 1st CR, risk-adapted treatment strategy is needed.

Aims: This multicenter pilot study was aimed to evaluate the feasibility of new treatment protocol based on risk stratification for newly diagnosed pediatric de novo acute myeloid leukemia (AML).

Methods: Patients with acute promyelocytic leukemia and AML of Down syndrome were excluded. Risk features were defined as follows: 1) low risk features (LRF): inv(16)/t(16;16), t(8;21) without c-kit mutation, or with normal karyotype in the presence of NPM1 or CEBPA mutation without FLT3/ITD mutation; 2) high risk features (HRF): -5, 5q-, -7, 3q abnormalities, t(8;16), t(6;9), t(16;21), t(6;11), t(10;11), AMKL without t(1;22), complex karyotype, or FLT3/ITD mutation; 3) standard risk features (SRF): all the others. A new chemotherapy regimen was developed which consisted of 2 induction and 4 consolidation cycles. Treatment responses were determined according to the marrow response at the end of each induction as good response (CR-CR), delayed response-1 (PR [blast 5~15%]-CR), delayed response-2 (NR [blast>15%]-CR), refractory (PR/NR-PR/NR), and early relapse. Patients were allocated into either favorable (FG), intermediate (IG), or poor (PG) prognostic group considering both risk features and treatment response. Patients in FG were not allocated to transplantation.

Results: Fifty-seven patients were enrolled. There were 13 patients (22.8%) with LRF, 22 (38.6%) with SRF, and 22 (38.6%) with HRF. The overall CR rate following 2 cycles of induction was 87.5%. One patient (1.8%) died during induction therapy. Eight patients relapsed of whom 6 were in PG, 1 in IG, and 1 in FG. Twenty-three patients underwent allo-HSCT. With a median follow-up of 13 mo, the estimated 2-y overall survival and event-free survival of all patients were 91% and 71%, respectively.

Summary and Conclusions: Although follow-up duration is short, our new treatment protocol based on risk stratification seems effective.

PB1651

PROGNOSTIC SIGNIFICANCE OF INTRACELLULAR SURVIVIN IN MYELOID BLAST CELLS AS AN INHIBITOR OF APOPTOSIS IN EGYPTIAN ADULT ACUTE MYELOID LEUKEMIA (AML) PATIENTS

M.O. Azzazi[1,*] M. Mattar[2], S. Ezz El-Arab[1], H. Hegab[1], R. Ibrahim[1], W. Elsalakawy[1], N.N. mostafa[1], M. Shazly[1]
[1]hematology and BMT., Ain Shams University, [2]hematology and BMT., Cairo University, Cairo, Egypt

Background: The balance between cell death and cell viability is important in tissue homeostasis. Abnormalities in the control of apoptosis play an important role in tumorigenesis (Altieri Cancer 2013). Survivin is one of eight members of the inhibitor of apoptosis protein family (IAP) that, regulates, integrates cell division and suppresses apoptosis. Over expression of several IAPs has been detected in various hematological malignancies, including acute leukemias, myelodysplastic syndrome, chronic myeloid leukemia, and many types of lymphoid malignancies, such as chronic lymphocytic leukemia and diffuse large B-cell lymphoma. Many publications revealed significant correlation between a high level of IAPs, especially of XIAP and survivin, and tumor progression contributing to leukemogenesis due to deregulated apoptosis. The expression of survivin may be a general feature of cancer and alone or with other antiapoptosis genes such as Bcl-2, survivin may extend the viability of transformed cells and regulate their susceptibility / resistance to apoptosis-based therapy. For this reason survivin may provide an ideal therapeutic target for its selective expression in neoplasia. Survivin shuttles between the nucleus and the cytoplasm, it effectively inhibits apoptosis, by binding to second mitochondrial activator of caspase.Expressed during embryonic development and by many cancer cell types,but not in the differentiated normal tissue,survivin is implicated in control of cell survival and regulation of mitosis in cancer(Coumar *et al*. Cancer 0013).

Aims: To assess expression of survivin in Egyptian AML patients, and its correlation to outcome, impact on progression, and survival.

Methods: 120 adult Egyptian patients with AML (52 females and 68 males) were recruited and followed up for 2 years, (mean age:42.1±13.1years), 16 patients had AML-M0, 32 AML- M1,32 AML- M2, 12 AML- M3, 16 AML -M4 and 12 AML-M5 (FAB classification). A control group of 60 age and sex matched normal healthy volunteers was included.All enrolled patients were treated according to our unit ongoing induction and consolidation regimens(NCCN guidelines). Patients were followed up for two year and outcome was designated as either favorable or unfavorable.Detection of intracellular Survivin antigen in myeloid blast cells was done by flow cytometry on bone marrow samples at D0, D28 and then every 6 month (Kim et al Ann Lab Med 2013).

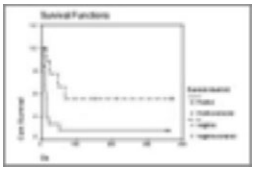

Figure 1.

Results: Survivin expression was higher in AML patients at D0 and D28 compared to healthy controls (P=0.001),highest survivin level were seen in AML M5 (FAB subtypes) followed by AML M4,then by AML M1, AML M0, AML M3 and AML M2 subtype. A statistically significant positive correlation was found between age of patient at diagnosis and Survivin expression, also between survivin level at D0 and at D28 among responders patients (P=0.001), also between D0-survivin level of AML patients with favorable response compared to patients with unfavorable response (P=0.005), survivin expression positively correlated with CD15, CD14 and CD11c expression. No statistically significant correlations were found between survivin expression and sex, or with results of cytogenetic studies,nor with AML FAB subtypes. There was statistically significant negative correlation between survivin level and with Complete remission (CR),overall survival (OS) Figure -1. EFS, and PFS. CR and post induction response to chemotherapy occured in patients with negative survivin expression more than in patients with positive survivin expression (P=0.005),and after 2 year follow up patients with positive survivin expression relapsed more (P=0.015).

Summary and Conclusions: Survivin is important factors involved in control of apoptosis in malignant cells. Survivin expression was found to be higher in elderly AML patients compared to younger patients group, A statistically significant negative correlation was detected between survivin level at D0 and CR,OS,EFS, and PFS. Being preferentially and highly expressed in cancer cells, with little expression in normal tissues,makes it an attractive therapeutic target to inhibit cancer growth by inhibiting extrinsic and intrinsic apoptotic pathways and confers resistance to apoptosis by directly suppressing caspase activity.

PB1652

EVALUATION OF MINIMAL RESIDUAL DISEASE IN ACUTE MYELOID LEUKEMIA WITH NPM1 MARKER

N. Alizadghandforoush[1,*] F. Nadali[2], S. Rostami[1], B. Chahardouli[1], H. Ghadimi[1], A. Ghasemi[1], K. Alimoghaddam[1], A. Ghavamzadeh[1]
[1]Hematology, Oncology, and Stem Cell Transplantation Research Center, Tehran University of Medical Sciences, [2] Hematology, School of Allied Medical Sciences, Tehran university of Medical Sciences, Tehran, Iran

Background: Minimal residual disease (MRD) tests provide early identification of hematologic relapse and timely management of acute myeloid leukemia(AML)patients. Approximately 50% of AML patients do not have clonal chromosomal aberrations and categorize as a cytogenetically normal acute

myeloid leukemia (CN-AML). Molecular markers are useful in the dissection of this heterogeneous group of AML patients into prognostically different subgroups. About 60% of adult CN-AML have a mutationin exon 12 of the NPM1 gene. This mutation is specific for malignant clone and potentially is a good marker of MRD.
Aims: In this retrospective study, we set up a NPM1quantitative test and then AML patients carrying $NPM1^{mut}$ were followed up for MRD monitoring.
Methods: In this study, we prepared plasmids containing a cDNA fragment of the NPM1 and ABL genes by PCR cloning. ABL served as a control to compensate for variations in the quality of the RNA and for differences in the efficiency of the reverse transcription reaction the plasmids were used to construct standard curves quantitation of each of the target and control genes. Eleven patients were analyzed using established method. Serial PB /and or BM samples (71 samples) were taken in1-3 month intervals (mean 1.5-month intervals) and median follow up duration after chemotherapy was 11 months (5- 28.5 months).
Results: In this study, we developed RNA-based RQ-PCR to quantitation of NPM1 mutation A with sensitivity of $10^{(-5)}$. NPM^{mut} transcript levels were expressed as a percentage ratio of NPM^{mut} to ABL transcripts. The percent of NPM^{mut}/ ABL level showed a range between 132 and 757 with a median of 383.5 in samples at diagnosis. The median NPM^{mut} transcript level log reduction was 3 log.Relapse occurred in 45% of patients (5 cases), All cases at diagnosis demonstrated the same mutation at relapse. In patients who experienced relapse, Log reduction levels of NPM1 mRNA transcript after therapy were 4(2 patients),3(two patients) and 1 log(1 patient). Totaly NPM^{mut} level showed less than 5 log reduction in all of them, Whereas this reduction was 5-6 log in other patients.
Summary and Conclusions: Despite the limitations of this study in terms of sample size and duration of follow up, it showed the accuracy of set up for detection of mutation and this marker has worth for following up at different stages of disease. Because of high frequency, stability, specificity to abnormal clone and high sensitivity, NPM1 is a suitable marker for monitoring of NPMc+ AML patients.

PB1653

DECITABINE AS THE FIRST-LINE TREATMENT FOR ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA; A SINGLE CENTER EXPERIENCE IN KOREA

J. Lee[1,*], H. Park[1], H. Cho[1], J. Jang[1], S. J. Kim[1], Y. Kim[1], J.S. Kim[1], J.W. Cheong[1], Y.H. Min[1]
[1]Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Decitabine, a DNA hypomethylating agent, was approved by the European Union for the treatment of elderly patients with acute myeloid leukemia (AML) who are not candidates for standard induction chemotherapy in 2012, but the role of decitabine for remission induction is still controversial. Recently, Korean Food and Drug Administration also approved decitabine as the first-line treatment for as same indication as of EU.
Aims: Through this study, we want to share our recent experience of decitabine for the treatment of elderly AML patients.
Methods: Among patients who were diagnosed with AML except acute promyelocytic leukemia from Jan. 2014 at Severance hospital in Korea, 16 patients treated with decitabine as the first-line therapy for remission induction were evaluated retrospectively. All patients were treated with at least one course of decitaibine at an initial dose of 20 mg/m^2 intravenously daily for 5 days in 28-day cycles. Patients showing complete response (CR) or partial response (PR) could continue to decitabine therapy, and those showing no response (NR) or loss of response (LOR) could be considered treatment failure and received second-line treatment.
Results: The median age of total patients was 73.5 (range, 68-82) years, with 9 patients 65–74 years and 7 over 75 years. Cytogenetic risk assignment based on the National Comprehensive Cancer Network criteria was favorable in 3 patients (18.8%), normal karyotype or other intermediate-risk in 11 (68.8%), poor-risk in 1 (6.3%) and unknown in one. The median follow-up duration after diagnosis was 138 (range, 39-310) days. Median and mean number of cycle was 3 and 3.75 (range, 1-8), respectively, and 2 patients received total 8 cycles. Fifteen (93.8%) patients completed the second cycle, and 9 were evaluated for response. CR was achieved in 2 patients (22.2%) after the second cycle and in additional 2 patients after the fourth cycle, for an overall response rate (ORR) of 33.3%. LOR was shown in 2 patients. Eight patients discontinued decitabine treatment due to NR or LOS in 5 (62.5%) and side effects in 3 (37.5%). Grade 3-4 febrile neutropenia was developed in 7 (43.8%), grade 2-3 fatigues in 3 (18.8%), and grade 3-4 heart failure in 1 (6.25%). The estimated median overall survival (OS) was 302 (95% CI, 83.5-520.5) days. The pretreatment characteristics that differed significantly between responders and non-responders was age (P=0.042) and serum ferritin level (P=0.016). Age and serum ferritin level were younger and lower in responder than in non-responder.
Summary and Conclusions: In our experience, 5-day decitabine treatment has efficacy in elderly patients with AML considered unfit for conventional chemotherapy with 33.3% of CR rate and 10 months of median OS. Further study will be objected to discover good clinical determinants and biomarker to select patients who may drive greater benefit from decitabine.

PB1654

THE EFFECT OF SERUM IRON TESTS AND IRON OVERLOAD ON TRANSPLANTATION-RELATED COMPLICATIONS AND PROGNOSIS IN ACUTE LEUKEMIA

U.Y. Malkan[1], G. Gunes[1], H. Demiroglu[1,*], H. Goker[1], I. Haznedaroglu[1], S. Etgul[1], T. Aslan[1], S. Balaban[1], O. Ozcebe[1], N. Sayinalp[1], S. Aksu[1], Y. Buyukasik[1]
[1]Department of Internal Medicine, Division of Hematology, Hacettepe University, School of Medicine, Ankara, Turkey

Background: Many studies have investigated impacts of serum iron parameters and/or radiological evidence of systemic iron overload on stem cell transplantation in acute leukemia.Some of them aimed to discover if iron overload might have any detrimental effect on the transplantation. On the other hand some other studies were interested in negative prognostic sign of hyperferritinemia irrespective of body iron status. Unfortunately, some of the studies evaluating iron overload in transplant setting did not precisely show the patients with iron overload, mainly due to inadequacy of radiological methods in relatively mild hemosiderosis and ignoring consideration of transferrin saturation along with hyperferritinemia for elimination of non-iron overload etiologies of hyperferritinemia.
Aims: Herein, we aimed to investigate the the effect of serum iron tests and iron overload on transplantation related complications and prognosis in acute leukemia with adequate methodology.
Methods: Patients who undergone allogeneic stem cell transplantation for acute leukemia in Hacettepe University Medical School Department of Hematology were screened retrospectively in order to find cases with serum iron tests within 9 months before transplant. Serum iron (SI), total iron binding capacity (TIBC) and ferritin levels had been measured. Transferrin saturation was calculated by dividing serum iron level to TIBC.
Results: There were 84 patients suitable for inclusion. Important baseline characteristics and rates of the endpoints are presented in Figure 1. When various ferritin plus TS cut-off values presented in Table 1 were investigated for a possible relationship with major transplant results only ferritin>2000 + TS>45% was found to have an association with VOD at borderline significance (P=0.067) (Table 1).

Table 1. The relationship between iron overload and major transplant results

	Ferritin >2000 and TS >45%P value		
	Yes	No	
aGVHD	2	12	0.410
cGVHD	3	11	0.813
VOD	2	12	0,067
OS	69.6±12.5	69.5±7.3	0,603
DFS	61.5±13.4	62.5±7.2	0.729

Table 2. Baseline characteristics and rates of the endpints.

Age (Range)	35 (17-66)
Gender (M/F)	47/37
Type of transplant (Myeloablative/Non-myeloablative)	17/67
Iron, ug/dl	82 (25-277)
TIBC, µg/dl	260 (81-418)
TS, %	34 (7-98)
TS > 45% (Yes/No)	22/40
TS > 60% (Yes/No)	17/45
Ferritin, ng/ml	1104 (12-15000)
Ferritin > 500 and TS > 45% (Yes/No)	39/45
Ferritin > 1000 and TS > 45% (Yes/No)	29/55
Ferritin > 1500 and TS > 45% (Yes/No)	19/65
Ferritin > 2000 and TS > 45% (Yes/No)	14/70
Ferritin > 2500 and TS > 45% (Yes/No)	0/84
aGVHD (Yes/No)	17/70
cGVHD (Yes/No)	19/68
VOD (Yes/No)	4/80
DFS (% at 5 years)	%49.8
OS (% at 5 years)	%51.7

Summary and Conclusions: There are many studies reporting about the impact of iron overload on stem cell transplantation. Unfortunately only ferritin level was used to detect iron overload in these studies. There are many conditions associated with increased serum ferritin level (eg. Inflammation, infection, macrophage activation, liver injury, etc...) Therefore an increased ferritin level should not be considered as iron overload by itself. The laboratory sign of iron overload is ferritin elevation in the presence of an increased transferring saturation.Iron overload was investigated by radiological tests in some studies. Although this method is an optimal one in apparent iron overload, it might miss iron overload in early stages. There are some studies which investigated the association between iron overload and post-transplant prognosis using an acceptable method to define iron overload. Some of them found a relationship between iron overload and post-transplant survival. On the other hand some others did not. Interestingly the relationship between iron overload and VOD, probably the most expected specific transplant complication in patients with liver injury, was not reported in any of these studies considered to have adequate methodologies for detection of iron overload. In conclusion, we observed a possible relationship between iron overload and post-transplant venoocclusive disease. We did not confirm other post-transplant complications reported in the literature. It must be noticed that although many studies intended to investigate the relationship between iron status and transplant outcomes, only a few of them really looked for the effect of iron overload.

Aggressive Non-Hodgkin lymphoma - Clinical

PB1655

IS THERE A PLACE FOR TOTAL TUMOR RESECTION OF PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA IN PATIENTS WITH GOOD PERFORMANCE STATUS?

J. Jelicic[1,*] M. Todorovic[1], D. Antic[1], J. Bila[1], B. Andjelic[1], V. Djurasinovic[1], A. Sretenovic[1], V. Vukovic[1], M. Smiljanic[1], B. Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, Belgrade, Serbia

Background: The outcome of the patients with primary diffuse large B cell lymphoma of central nervous system (PCNSL) still remains poor. The prognostic value of available prognostic scores need to be validated as well as the surgical approach since the improvements made in the field of neurosurgery.
Aims: The aim of this study was to evaluate treatment approach and the validity of the International Extranodal Lymphoma Study Group (IELSG) score of the patients with PCNSL.
Methods: This study involves 30 patients (13 males/17females) with a median age of 53.5 years (range 29-72 years). The patients presented usually with more than two different symptoms which mostly reflected tumor location, and were as following: headache (13 patients), hemiparesis (13 patients), neuropsychiatric (11 patients), dysarthria (8 patients), nausea and vomiting (5 patients), visual symptoms and vertigo (5 patients), and other symptoms occasionally. Five patients (16.7%) had B symptoms, 5 patients (16.7%) had bone marrow infiltration and 13 patients (43.3%) had deep tumor location. According to the Eastern Cooperative Group performance status (ECOG), 9 patients (30%) had ECOG 1–2 and 21 patients (70%) had ECOG 3–4. Regarding the International Prognostic Index (IPI), low score was present in 44.4% of patients, low intermediate in 26%, high-intermediate in 22.2% and 7.4% of patients had high IPI score. The prevalence of the IELSG score was as following: low score had 17.4% of patients, intermediate had 65.2% and 17.4% had high IELSG score. Treatment options included total tumor resection in 13 patients (43.3%), partial tumor resection in 10 patients (33.3%) and biopsy only in 7 patients (23.3%). A customized de Angelis protocol based on high doze methotrexate with/without whole brain irradiation was applied in all patients.
Results: The median overall survival (OS) was 41 months. Median event free survival was 36 months. Overall treatment response was achieved in 22 patients (73.4%), 8 patients (26.6%) had primary resistant disease with lethal outcome within 5 months. Statistical analyzes showed that the patients with ECOG≥3 had worst prognosis than the patients with ECOG 1–2 (Log Rank $\chi^2$11.722, p<0.01). Median OS in the group of patients with ECOG 1-2 was 62 months and 23 months in the group of patients with ECOG 3-4 (95% CI 3.118-42.882). The IPI didn`t show prognostic significance in the patients with PCNSL (Log Rank χ^2 0.274, P=0.601), however the IELSG score significantly predicted survival in these patients (Log Rank χ^2 12.755, P<0.01). The patients who underwent an open surgery with total tumor reduction had significantly longer OS (median 62 months) in comparison to the patients who had partial tumor reduction or biopsy only (Log Rank χ^2 5.692, P=0.017) and whose median OS was 23 months (95% CI 1.634-44.366).
Summary and Conclusions: Despite that total tumor resection is not standard procedure in the patients with PCNSL, according to our data, it should be considered in patients with good performance status and surgically accessible lesions for resection. The IELSG score should be used as prognostic index in patients with PCNSL.

UNRECOGNIZED RENAL INSUFFICIENCY AMONG NON-HODGKIN LYMPHOMA PATIENTS TREATED WITH R-CHOP: EVALUATION OF PREVALENCE, CHARACTERISTICS AND EFFECT ON REGIMEN RELATED TOXICITY

A. Leader[1,2,3,*] S. Kaptzon[2], M. Maor[2], G. Itchaki[1,3], O. Cohen[2], L. Vidal[1,3], A. Gafter Gvili[1,3], E. Joffe[1,3], M. Lishner[2,3]
[1]Institute of Hematology, Davidoff Cancer Center, Beilinson Hospital, Rabin Medical Center, Petah Tikva, [2]Department of Medicine A, Meir Medical Center, Kfar Saba, [3]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel

Background: Estimated glomerular filtration rate (eGFR) is more accurate than serum creatinine (SCR) in assessing renal function. The IRMA study demonstrated a 50% prevalence of decreased eGFR despite normal SCR, coined as “unrecognized renal insufficiency (RI)”, among patients with solid malignancies. Unrecognized RI potentially may have an impact on treatment toxicity. In a recent study, breast cancer patients with unrecognized RI receiving cyclophosphamide and doxorubicin had an adjusted OR of 3.56 for regimen-

related toxicity. However, little is known regarding its prevalence and clinical implications in hematologic malignancies.
Aims: To determine the prevalence of unrecognized RI and its association with treatment toxicity in non-Hodgkin lymphoma (NHL) patients treated with rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone (R-CHOP).
Methods: Patients ≥ 18 years with normal pre-treatment SCR (<1.3 mg/dl) and NHL treated with R-CHOP every 21 days at our institute's hemato-oncology unit (1/1/2005 – 31/8/2013) were included in this retrospective cohort. Patients who had previous chemotherapy or total bilirubin ≥ 3mg/dl were excluded. The eGFR was calculated from pre-treatment SCR, using Cockcroft-Gault (primary analysis), aMDRD and CKD-EPI equations. Joint primary outcomes were neutropenic fever and premature treatment termination, while dose reduction after cycle 1 (>20%), dose delay (≥7 days), any hospital admission and death, were secondary outcomes. Rates of treatment toxicities were compared between eGFR groups as defined by NKF-KDOQI and KDIGO guidelines, using Kendall's Tau.

Table 1. Baseline characteristics of study partecipants with a comparison between e GFR groups (based on Cockcroft Gault formula).

		All patients* (N=94)	eGFR ≥ 90* (N=28)**	eGFR 60-89* (N=31)**	eGFR 30-59* (N=35)**	p value***
Age (yrs, median[min;max])		67.0 [36.0;87.0]	55.5 [36.0;85.0]	64.0 [36.0;85.0]	77.0 [38.0;87.0]	0.134

Diabetes mellitus		19 (20.2%)	6 (21.4%)	7 (22.6%)	6 (17.1%)	0.85

* eGFR units: ml/min/ 1.73 m2

** N (% of total number of patients in same eGFR group), unless specified otherwise

*** p value for difference between the eGFR groups, in univariate analysis

****Indolent lymphomas: Follicular lymphoma (n=11), Marginal cell lymphoma (N=1), Mucosa-associated lymphoid tissue lymphoma (N=2), small lymphocytic lymphoma (N=3) ; Aggressive lymphoma: Diffuse large B-cell lymphoma (N=74), Mantle cell lymphoma (N=2)

BMI, body mass index; eGFR, estimated glomerular filtration rate; GCSF, granulocyte colony stimulating factor; NHL, non-hodgkins lymphoma

Results: 94 patients fulfilled the study criteria, reaching the planned sample size. Seventy percent had unrecognized RI distributed evenly among CKD stage 2 and 3. CHOP dose reduction ≥10% from cycle 1 was associated with lower eGFR groups (57% of patients with CKD3 vs 7% in CKD1), as was lower BMI. These were the only statistically significant differences in patient characteristics between CKD stages (Table 1). Patients with CKD 3 were older than patients in CKD 2 and CKD 1, although the difference was not statistically significant (P=0.134). There was no difference in rates of neutropenic fever (overall 29.8%, P=0.68) or other regimen-related toxicities between eGFR groups. Premature treatment discontinuation was most frequent in the lowest eGFR group (P=0.03) in univariate analysis using Cockcroft Gault equation (but not with aMDRD OR EPI_CKD), but lost statistical significance after multivariate analysis. Thirty percent of patients had baseline dose reductions ≥ 10%. They were older (P<0.001) and with a lower eGFR (70% vs 22.7% CKD3, P<0.001), but had similar outcomes.
Summary and Conclusions: Most NHL patients treated with R-CHOP have unrecognized RI. The absence of an association between eGFR and treatment toxicity among these patients is in contrast to findings from solid malignancies. This may indicate that relatively subtle changes in renal excretion of cyclophosphamide do not carry clinical significance in this potent multidrug regimen. This could also be a false negative result, reflecting the much more common preplanned dose reductions in older patients with lower eGFR. Thus, in this population, unrecognized RI is common and had no effect on treatment toxicity when chemotherapy doses were reduced in older patients with lower eGFR, at the hematologist's discretion. Further research is needed to determine whether lower eGFR is indeed associated with treatment toxicity in a large cohort of older patients receiving full R-CHOP dose intensity, or whether it is merely a marker of older and frailer NHL patients with normal SCR.

PB1658

OCCURRENCE OF DERMOPATHY BY TREATMENT WITH ANTI-CCR4 ANTIBODIES FOR ADULT T-CELL LEUKEMIA

G. Eguchi[1,*] S.I. Kawaguchi[1], A. Konishi[1], K. Yamamoto[1], T. Yamaguchi[1], Y. Maeda[1]
[1]Hematology, National Hospital Organization Osaka Minami Medical Center, Kawachinagano, Japan

Background: Human T-cell leukemia virus type I (HTLV-I) is a human retrovirus that is an etiologic agent of adult T-cell leukemia/lymphoma (ATL/ATLL). The poor outcome of adult ATL is mainly because of an intrinsic resistance of the leukemic cells to conventional or high doses of chemotherapy and severe immunosuppression. The CC-chemokine receptor 4 (CCR4) is expressed in almost ATLL cells. Thus, anti-CCR4 antibodies can be used as a treatment strategy for ATLL. Mogamulizumab (MOG), which is a defucosylated anti-CCR4 monoclonal antibody, showed good results even in patients with recurrent ATLL in phase I or II studies. MOG has strong antibody-dependent cellular cytotoxicity (ADCC). The common adverse events in the phase II study were infusion reaction and skin rashes. In our study, MOG inhibited the growth of ATL cells and induced remission. CCR4 is expressed not only in ATL cells but also in non-ATL regulatory T cells (Treg). After treatment with MOG, the population of Treg decreased significantly, which boosted the antitumor activity. MOG treatment was associated with the risk of viral infection as an opportunistic infection and skin disturbance (dermopathy).
Aims: In this study, we observed the effects of MOG as CCR4-specific ADCC against CCR4-positive ATL cells. At the same time, frequency of opportunistic viral infection including active CMV infection and severe skin disturbance (dermopathy) have been observed.
Methods: Patients were eligible for enrollment in the study if they were at least 18 years of age, had previously untreated ATL, and recorded a World Health Organization (WHO) performance status (PS) of 0-3. Fourteen patients diagnosed with acute type ATL were selected for this study. In the present study, we treated 14 patients with ATL who were resistant to chemotherapy using MOG monotherapy.
Results: All patients showed CR with a marked decrease in the number of ATL cells. These results suggested that MOG was effective in chemotherapy-resistant ATL patients. No rearrangement of TCRαβ gene was observed, which indicated molecular CR. Skin disturbance (dermopathy) was found 9 cases of 14 ATL patients treated with MOG monotherapy. The skin rash spread throughout her body with bulla and skin biopsy was performed, and diagnosed as Stevens–Johnson syndrome (SJS)(Figure) in 2 patients of them. Administration of steroid and intravenous immunoglobulin was performed, and SJS gradually improved. Further, in other patients, grade 2 and 3 dermopathy was found, and the patients were treated with glucocorticoid steroid. CMV infection was detected using C7-HRP methods. CMV infection was diagnosed in 5 patients of 14 MOG treated ATL patinets. One of the patients died because of severe CMV infection despite of adequate treatment
Summary and Conclusions: Thus, physicians should be aware of CMV infection and development of immunocompromised condition after MOG monotherapy. In that case, specific anti-CMV treatment for CMV reactivation should be recommended. Moreover, We have to find out the skin rash as soon as possible after treatment with MOG and it should be recommended quick administration with glucocorticoid. Further study for the dermopathy should be considered.

PB1659

THE ROLE OF PROGNOSTIC AND COMORBIDITY INDEXES IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH IMMUNOCHEMOTHERAPY

J. Jelicic[1,*] M. Todorovic[1], D. Antic[1], J. Bila[1], B. Andjelic[1], D. Stanisavljevic[2], V. Djurasinovic[1], A. Sretenovic[1], V. Vukovic[1], M. Smiljanic[1], I. Petkovic[3], I. Vrbic[3], B. Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, [2]Department of statistics, Faculty of Medicine, Belgrade, [3]Hospital of Knez Selo, Clinical Center of Nis, Nis, Serbia

Background: The influence of comorbidities in patients with diffuse large B-cell lymphoma (DLBCL) in the rituximab era has been modestly investigated. Different comorbidity scoring systems are available for cancer patients.
Aims: In order to evaluate the impact of comorbidities on the overall survival (OS) we have performed retrospective analyses of clinical records of the patients with DLBCL treated with R-CHOP, R-EPOCH and R-CVP protocol. The following comorbidity scores were used: Cumulative Illness Rating Scale (CIRS), Charlson Comorbidity Index (CCI), age adjusted CCI (aaCCI) and Hematopoietic-Cell-Transplantation Comorbidity Index (HCT-CI)
Methods: A total of 378 patients (195 female/183 male) were included in the study. Median age was 58 years (range 18-80). Elderly population (70 years and older) represented 20.2% of analyzed group. According to the Ann Arbor classification, stage I, II, III and IV had 51patients (13.5%), 129 (34.1%), 72 (19%) and 129 (33.3%), respectively. Bulky disease was present in 88 patients (23.3%) and B symptoms in 248 patients (65.6%). Regarding Eastern Coop-

erative Group (ECOG) performance status (PS), 23.7% of patients had ECOG PS ≥ 2. The most frequent extranodal localization were bone marrow (27.2% of patients) and gastrointestinal tract (28.8% of patients). Revised International Prognostic Index (R-IPI) was represented as low score in 70 patients (18.5%), intermediate in 203 (53.7%) and high in 105 (27.8%). Approximately 55% of patients didn`t have any comorbidity. Regarding comorbidity indexes (CI), CIRS ≥ 17 had 4% of patients (minimal score was 14), CCI ≥ 3 had 3.2%, aaCCI ≥ 5 had 34.1%, and HCT-CI ≥ 2 had 31.2% of patients. The patients were treated with R-EPOCH protocol (13 patients, 34.4%), R-CVP (22 patients, 5.8%), and R-CHOP (343 patients, 90.7%).

Results: Complete and partial remission were achieved in 334 (88.4%) of patients and 44 patients (12.6%) had primary resistant disease. The prognostic value of R-IPI was highly statistically significant (Log Rank χ^2 53.569, P<0.01). The patients with ECOG PS ≥ 2 had poorer outcome than the patients in good PS (Log Rank χ^2 33.075, P<0.01). In patients with CIRS ≥ 17 median OS was 30 months (95% CI 10.147-49.859) comparing to the patients with CIRS 14-16 whose median OS was not reached (Log Rank χ^2 10.046, P<0.01). The patients with CCI ≥ 3 had poorer outcome (median OS of 24 months, 95% CI 0.00-50.877) than the patients with CCI 0-2 (Log Rank χ^2 12.659, P<0.01). The patients with HCT-CI≥2 had significantly poorer outcome than the patients with low CI (Log Rank χ^2 8.041, P<0.01). OS in patients with HCT-CI≥2 after 1, 2 and 5 years was 69%, 63% and 49% respectively, and 89%, 81% and 72% for those with HCT-CI 0-1. The patients treated with R-CHOP and R-EPOCH protocol had statistically significant better OS than the patients treated with R-CVP protocol (Log Rank χ^2 8.754, P<0.01). Multivariant analysis (CIRS, CCI, aaCCI, HCT-CI, therapeutic approach, R-IPI) revealed that the most predictable factor for OS was R-IPI (P<0.0001).

Summary and Conclusions: Comorbidities are an independent prognostic parameters for worse OS in patients with DLBCL treated with immunochemotherapy. Omission of the antracyclines due to the frailty, older age or high comorbidity score leads to significantly poorer outcome. Finally, in the rituximab era prognosis is appreciably influenced with the value of initial R-IPI.

PB1660

THE COMBINATION OF IFOSFAMIDE, CARBOPLATIN AND ETOPOSIDE (ICE) WITH OR WITHOUT RITUXIMAB IS SAFE AND EFFECTIVE SALVAGE THERAPY FOR ELDERLY PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

N. Sarid[1,*] E. Joffe[1], L. Gibstein[1], I. Avivi[1], A. Polliack[1], C. Perry[1], Y. Herishanu[1]
[1]Hematology, Tel Aviv Sourasky Medical Center, tel aviv, Israel

Background: Elderly patients are under-represented in clinical trials, especially in studies evaluating intensive salvage combinations for relapsed or refractory diffuse large B-cell lymphoma (DLBCL). Yet, the risk of developing non-hodgkin lymphomas increases with age, with approximately 50% of patients are diagnosed above the age of 65 years. This leads to uncertainty regarding the risks and benefits of these treatments, and can have a substantial impact on treatment decisions.

Aims: To evaluate a 10-year single-center experience and results of therapy using the ifosfamide, carboplatin and etoposide±rituximab (ICE±R) as a salvage regimen in elderly patients with DLBCL.

Methods: This a retrospective single-center study evaluating the efficacy and tolerability of ICE±R regimen used for the treatment of elderly patients (>70 years) with relapsed or refractory DLBCL. The ICE±R regimen consisted of etoposide (100 mg/m^2) on day 1-3, carboplatin (dose=5x [25+creatinine clearance], capped at 800mg) and ifosfamide (5000 mg/m^2, mixed with an equal dose of MESNA administrated by continuous infusion over 24 hours) on day 2±rituximab (375 mg/m^2) given on day 0, as reported previously.

Data were collected from medical records. Adverse events (AEs) graded according to the Common Terminology Criteria for Adverse Events version 4.0. Disease response was defined according to the revised response criteria for malignant lymphoma. Clinical endpoints were defined according FDA guidance. The study was approved by the local institutional Helsinki ethics committee.

Results: Between October 2003 and June 2014, a total of 32 patients (21 women and 11 men) with DLBCL older than 70 years, were treated in our institute with the ICE±R regimen. Median age of the entire cohort was 75.6 years (range 70.6-87.1). Most of the patients had an Ann Arbor stage IV disease (56%, n=18), an intermediate-high to high sIPI (63%, n=20), a low Carlson comorbidity index (0-1 in 81%, n=26), and an excellent ECOG score (0-1 in all cases). In 27 patients (84%) the dosage of the chemotherapy was reduced, with a median dose reduction of 25% (range 0-50%). ICE±R was administered in all, except one case, as an in-patient therapy and all received G-CSF as primary prophylaxis. The overall response rate observed was 53.1% with a complete response of 40.6%. After median follow-up of 12 months, the median progression free survival (PFS) and overall survival (OS) were 3.9 months and 17.0 months, respectively. Patients who responded to ICE±R (including cases followed by autologous stem-cell transplantation) achieved median PFS of 47.2 months and OS of 78.9 months. Previous response to first-line therapy appeared to be the strongest predictor of response, PFS and OS to second-line treatment. Following treatment with ICE±R, an attempt to harvest peripheral blood stem cells was performed in 8 patients. Harvesting was successful in seven patients (>2.5x10^6 of CD34 cells/Kg) of which six (19%) proceeded to autologous stem-cell transplantation (ASCT). Patients ineligible for ASCT that responded to ICE±R (n=11) were treated with extended cycles of ICE±R (median of 4 cycles per patient), and achieved median PFS of 18.9 months and OS of 21.7 months. ICE±R was generally well tolerated and major toxicity related mostly to hematological adverse events.

Summary and Conclusions: ICE±R is a safe regimen and achieves high response rates in elderly patients with relapsed or refractory DLBCL. Response to first-line therapy is the strongest predictor of response to ICE±R. Patients with chemosensitive disease, who are not transplant-eligible, should be considered for extended treatment with this regimen.

PB1661

SUBCUTANEOUS PANNICULITIS-LIKE T-CELL LYMPHOMA: CLINICAL CHARACTERISTICS AND SURVIVAL STUDY OF 21 THAI PATIENTS IN A SINGLE INSTITUTION

J. Julamanee[1,*] K. Kayasut[2], A. Lekhakula[1]
[1]Department of Internal Medicine, [2]Department of Pathology, Prince of Songkla University, Songkhla, Thailand

Background: Subcutaneous panniculitis-like T-cell lymphoma (SPTCL) is a rare lymphoma subtype which is commonly associated with hemophagocytic syndrome (HPS) and had an aggressive clinical course. The incidence of SPTCL is high in Asian countries including Thailand. Due to the rarity of the disease, there are limited data on the clinical characteristics and optimal therapeutic approaches of this entity.

Aims: The aim of this study was to characterize the clinical features, treatment outcomes, and survival of SPTCL in Thai patients at a single institution.

Methods: Twenty-one patients diagnosed as SPTCL according to WHO classification 2008 were enrolled from January 2001 to December 2014 in Songklanagarind Hospital. All tissue specimens were reviewed by hematopathologist. The demographic, clinical, treatment, and outcomes data were collected for analyses.

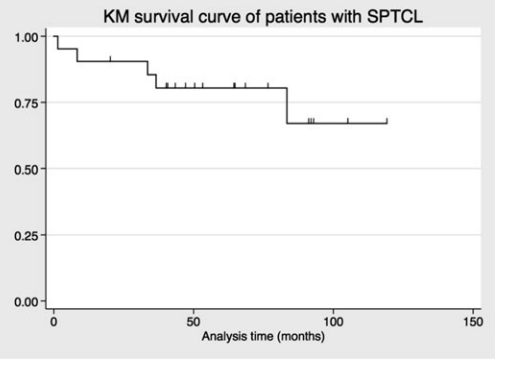

Figure 1.

Results: The median age was 33 years (range 22-64 years) and 12 patients were female. Lesions usually presented as multifocal subcutaneous nodules or masses in 90%, commonly at lower extremities and trunk. Nine patients had extra-cutaneous manifestations. The common sites of involvement were liver, spleen, and lymph nodes. None of the patients had HPS in this study. Most patients had a good ECOG performance score (90%) and low prognostic scores (IPI low to low-intermediate in 71% and PIT score 0-1 in 90%). Fifty-seven percent of the patients had limited stage of disease. B symptoms occurred in 57% and elevated LDH level in 86%. Nineteen (90%) patients were treated with chemotherapy, CHOP chemotherapy was used in 85%. Only one patient was treated with radiotherapy. Of the 20 patients evaluated, the overall response rate was 85% with 75% complete remission. Nevertheless, progressive disease occurred in 8 patients, including 5 patients who had obtained complete remission. With median follow-up time of 52 months, the median OS and RFS were unreached. The 5-year OS and RFS were 80% and 68%, respectively. No significant prognostic factors were identified in this study.

Summary and Conclusions: SPTCL frequently affected young females. Lesions typically presented as multifocal subcutaneous nodules or masses on trunk and lower extremities. Patients responded well to CHOP chemotherapy with long-term survival outcomes.

PB1662

CLINICAL FEATURES AND TREATMENT OUTCOMES IN NON-HODGKIN'S LYMPHOMA IN CHILDHOOD: 24 YEARS EXPERIENCE OF A SINGLE CENTER

F. Akici[1,*] D. Tugcu[1], G. Aydogan[1], Z. Salcioglu[1], H. Sayilan Sen[1], A. Akcay[1], A. Kiyak[1], M. Gokce[1], S. Sander[2], O. Dogan[3]

[1]Pediatric Hematology-Oncology Clinic, [2]Pediatric Surgery Clinic, Kanuni Sultan Suleyman Training and Research Hospital, [3]Division of Pathology, Istanbul Medical Faculty, İstanbul, Turkey

Background: Non-Hodgkin's lymphomas (NHL) of childhood and adolescence are a heterogeneous group of malign diseases originating from the lymphoid cells. NHL usually responds to the polychemotherapy and survival rates in NHL have increased significantly in the last decades.
Aims: This study aims was to evaluate and compare the demographic data and treatment results of childrens with NHL treated and therapeutic efficacy of modified NHL German Berlin Frankfurt Munster (BFM) protocols in our center retrospectively.
Methods: 115 children (79 male, 36 female) from January 1990 to September 2014, new diagnosed with NHL were enrolled to the study. The patients were stratified by risk factors and treated either with a modified B-nonB NHL BFM-90 (before 2004) or BFM-95 (after 2004) protocols. (Until September 1993, lymphoblastıc patients recived LSAL2, non lymphoblastıc NHL patients recived COMP) and the use of 1 or 3 g/m2 of methotrexate instead of 5 g/m2/24 h was the only important modification in BFM-90 protocol.
Results: Demographic results: the median age 7 years(range: 3-14.5years) were treated in the center with median 81 months follow-up. Histopathologic subtypes were:24 lymphoblastıc, 11 anaplastic large cell, 80 nonlymphoblastic Burkitt/diffüz B cell. 3 patients (3%) were in stage I, 19 patients (17%) in stage II, 64 (56%) in stage III, and 29(24%) in stage IV. The most common initial primary tumor location sites were abdomen (58%), head and neck (18%) and thorax (15%).The median LDH level at diagnosis was 790U/L(224-10300). Treatment results: 32 patients (24 progressive disease, 6 toxicity, 2 seconder neoplasm)died.7 patients were follow-up. The 10-year overall survival (OS) for all patients was 72%, and event-free survival (EFS) was 67% respectively. 10 year survival was 100,89,76,51% in stage I,II,III, and IV. The 10-year OS rates in modified BFM-90 and in BFM-95 protocols were 66% and 84%; the 10-year EFS rates in these 2 protocols were 60% and 84%, respectively (P=0.061 for OS, P=0.049 for EFS).Survival rates were significantly higher in patients receiving modified BFM regimen, than in ones COMP and LSA2L2
Summary and Conclusions: Survival rates in the whole group are in parallel with advances attained in the world in NHL.The significantly higher survival rates achieved in patients with advanced stage non lymphoblastic patients receiving modified BFM(1 g/m2MTX) may be due to the decreased toxicity seen in this group and to the advences in supportive care in the last decade.

PB1663

FAVORABLE PROGNOSTIC PARAMETERS IN TREATMENT OF AIDS RELATED LYMPHOMA PATIENTS; TEN YEAR SINGLE CENTRE EXPERIENCE

B. Mihaljevic[1,2], M. Smiljanic[1,*] D. Jeftovic[2,3], J. Ranin[2,3], D. Salemovic[3], M. Todorovic[1,2], J. Bila[1,2], B. Andjelic[1,2], V. Djurasinovic[1], A. Sretenovic[1], V. Vukovic[1], J. Jelicic[1], D. Antic[1,2],
[1]Lymphomas, Clinic of Hematology Clinical Centre of Serbia, [2]Faculty of Medicine, Belgrade University, [3]AIDS Department of the Institute for Infectious and Tropical Disease, Clinical Center of Serbia, Belgrade, Serbia

Background: AIDS-related lymphomas (ARL) are frequent complication of HIV infection, due to progressive CD4+ T-lymphocytes depletion and subsequent immune impairment. HIV-positive patients (pts) have up to 200-fold increased incidence for non-Hodgkin lymphomas (NHLs). Most ARLs are aggressive forms of B-NHLs. Usually pts presents with advanced disease, and prognosis is generally poor. Previous studies reported International prognostic Index score (IPI) ≤2 as significant predictive factor for overall survival (OS). Current standard in ARL patient's treatment is concomitant combined antiretroviral therapy (ART) and chemotherapy.
Aims: The aims of this study were to detect prognostic factors and estimate benefit of concomitant ART and chemotherapy for ARL patients OS.
Methods: We enrolled 37 ARL patients in our study. All were treated at the Clinical Centre of Serbia, Belgrade in period 2004-2014. Thirty-two pts had an aggressive NHL. Indolent NHL and Hodgkin disease were diagnosed in 2 cases each, unclassified lymphoma in 1 case. Concomitant ART (same in all cases) and chemotherapy was applied in 30 cases, chemotherapy only in 4, neither ART nor chemotherapy in 3 cases.
Results: We found that use of concomitant ART and chemotherapy (P=.009, DF=1), IPI risk score ≤2 (P=.031, DF=1) and LDH level ≤400IU (P=.028, DF=1) were significant for OS (10 months, 2-102). Same parameters were confirmed as positive OS predictors in univariate survival analysis (P=.020, 95.0%CI for RR 0.141-0.847; P=.046, RR 1.013-4.813; P=.097, RR 0.875-4.25 respectively). In multivariate analysis concomitant ART and chemotherapy remained significant for OS (P=.012, RR 0.120-0.774).
Summary and Conclusions: Our results suggested necessity for prompt use of concomitant ART and chemotherapy in ARL treatment, in order to improve OS. Most ARLs are very aggressive, both in terms of histology and clinical course, but pts without advanced disease seems to have better OS rate when treated this way.

PB1664

TOXICITY AND EFFICACY OF LMBA-02 PROTOCOL IN THE TREATMENT OF BURKITT'S LYMPHOMA AMONG THE MOROCCAN ADULT POPULATION

S. Regragui[1,*] S. Jennane[1], S. Amelal[1], K. Doghmi[1], M. Mikdame[1]
[1]Clinical hematology, Militarian Hospital of Rabat, Rabat, Morocco

Background: The geographical position of Morocco, straddling Europe and sub-Saharan Africa gives the Burkitt lymphoma equitable distribution between the endemic and the sporadic form.
Aims: The objective of this study is to evaluate the toxicity and the efficacy of LMBA02 Protocol on the Moroccan population.
Methods: This is a retrospective study including all patients managed in our training for Burkitt's lymphoma and treated using the LMBA02-Mabthera protocol.
Results: A total of 18 patients were included. The median age was 44 years, with a range of 16-70 years. The rate of men was more likely higher than women with a sex ratio [M/F] of 1.6. Diagnosis delay was 3 months average. At diagnosis, 39% of patients had abdominal localization, 33.3% had a mandibular one, 16.6% had a neurological localization and 11% had a marrow infiltration. Two patients (11%) were infected with human immunodeficiency virus. 39% were in stage III and 39% in stage IV Murphy. 50% of patients had systemic symptoms. All patients were treated according to the protocol LMBA02- Mabthera. The overall response rate (OR) was 83.2% with a complete response rate (CR) of 66.6% and a partial response (PR) to 16.6%. The treatment-related mortality (TRM) was 16.6%. The overall survival rate was 62% at 6 months, 50% at 1 year and 36% at 2 years; when analyzing it in terms of age, there is a 2-year survival of 75% among patients under 40 years and 14% in patients over 40 years (P<0.05). The main causes of death are dominated by treatment-related toxicity (37.5%), resistance to first-line treatment (37.5%) and relapse of the disease (25%). Both mortality risk factors are age and cure spacing due to the toxicity of treatment.
Summary and Conclusions: Despite its effectiveness, the treatment-related mortality of LMBA02-Mabthera protocol in patients over 40 years is considered high.

PB1665

ALLOGENEIC STEM-CELL TRANSPLANTATION FOR ADVANCED MYCOSIS FUNGOIDES/SEZARY SYNDROME

E. Atilla[1,*] P. Ataca[1], S. Civriz Bozdag[1], S.K. Toprak[1], M. Kurt Yuksel[1], P. Topcuoglu[1], B.N. Akay[2], H. Sanli[2], G. Gurman[1], M. Ozcan[1]
[1]Hematology, [2]Dermatology, Ankara University School of Medicine, Ankara, Turkey

Background: T-cell lymphomas are heterogeneous group of diseases that account for<10% of non-Hodgkin lymphomas. The prognosis for patients with most forms of T-cell lymphoma is generally poor. Mycosis fungoides (MF) and Sezary Syndrome (SS) are cutaneous T cell lymphomas. Several studies have suggested that allogeneic hematopoietic stem cell transplantation (HSCT) may improve survival in advanced MF and SS.
Aims: We aim to present the outcome of our patients with MF or SS who underwent HSCT
Methods: We retrospectively evaluated totally 8 patients, 5 advanced stage MF and 3 SS who underwent peripheral HSCT rescue at Ankara University Department of Hematology from Oct 2012 to Oct 2014. Three MF patients had large cell transformation at pre-transplantation period. All of the patients received at least three lines of therapy prior to HSCT (Table). Two out of 8 patients were transplanted from unrelated HLA one antigen or allele mismatch donors whereas other 6 patients had fully matched siblings. All of the patients had refractory disease prior to HSCT, 6 of 8 patients received reduced intensity conditioning regimen (Fludarabine-Cyclophosphamide-TBI +/-ATG) while 2 patients received myeloablative conditioning regimens including Cyclophosphamide plus total body irradiation. Peripheral blood was the stem cell source in all the patients. For graft-*versus* host disease prophylaxis, patients received cyclosporine plus methotrexate or mycophenolate mofetil except one patient in whom metal-prednisolone was used due to renal toxicity.

Table 1. Patient characteristics.

Patient	Age/Sex	Disease	Disease onset to HSCT (years)	Clinical Stage	Diseases tatus at HSCT	Largecell transformation	Number of priortreatments	HSCT/HLA mismatch	Conditioning Regimen (MA/RIC)	Acute GVHD / Grade	Chronic GVHD/ location	GVHD prophylaxis	Engraftment ANC >0.5X10..4/ (Day)	Outcome
1	53/M	MF	11	T4N2M1 B0 IVB	Active disease	-	4	U-PBSCT (9/10)	RIC (Flu+Cy+TBI+ATG)	+/2	NA	CSA+MMF	9	Ex,fungal infection,23 th day posttransplant
2	50/M	MF	2	T4N2M0 B2 IVA1	Active disease	+	8	R-PBSCT (10/10)	RIC (Flu+Cy+TBI)	+/3	Limited	CSA+MMF	Never below	Relapsedafter 10 months, ECP
3	61/M	MF	4	T3N1M0 B0 IIB	Active disease	+	4	U-PBSCT (9/10)	RIC (Flu+Cy+TBI+ATG)	+/2	Extensive	CSA+MMF	12	VGPR (8months)
4	55/M	SS	3	T4N2M0 B1 IIIB	Active disease	-	3	R-PBSCT (10/10)	RIC (Flu+Cy+TBI+ATG)	0	-	CSA+MMF	11	Relapsed after 4months
5	56/F	MF	3	T4N1M0 B0 IIIA	Active disease	+	5	R-PBSCT (10/10)	MA (Cy+TBI)	+/2	-	CSA+MTX	16	Relapsed 4 months
6	50/F	SS	1	T4N2M0 B2 IVA1	Active disease	-	6	R-PBSCT (10/10)	RIC (Flu+Cy+TBI)	NA	-	CSA (bac)+MMF+PREDNOL	No	Ex, fungalinfection, 16th daypostransplant
7	49/M	MF	4	T4N0M0 B0 IIIA	Active disease	-	7	R-PBSCT (10/10)	RIC (Flu+Cy+TBI)	0	-	CSA+MTX	14	Ex, acinetobacter sepsis 16th day posttransplant
8	49/M	SS	3	T4N2M0 B1IIIB	Active disease	-	3	R-PBSCT (10/10)	MA (Cy+TBI)	0	Limited	CSA+MMF	22	CR (24 months)

Results: The median age of the group was 59 years (range 49-61). The median time from diagnosis to HSCT was 3 years (range 1-11 years). The Sorror HCT-CI scores prior to HSCT were listed as: 2/8 score of 0, 3/8 score of 1, 3/8 score of 2. The patients achieved engraftment at a median of 12 days after HSCT (range 0-22). We evaluated the disease response in only 6 patients because two patients died of the early transplant-related mortality in 16th day of the transplantation due to fungal or Acinetobacter infection. Disease responses after the transplantation could evaluated in only six patients as follows: 2 complete remissions, 2 very good partial remission (VGPR), and 2 minimal responses. We obtained complete remission in one patients with VGPR after developing acute GvHD. Acute GvHD developed in 57.1% of the patients (4/7). Chronic GvHD was detected in 3 out of 5 patients surviving longer than 100 days after the transplantation. Early transplant-related mortality was seen in 25%. Our follow-up was changing between 16 days and 769 days. The possibility of two-year progression free and overall survival was 37.5%±1.7% and 62.5%±1.7%, respectively.
Summary and Conclusions: Our results in a small patient group suggest that allo-HSCT is an effective treatment in the patients with advanced stage refractory MF/SS.

PB1666

INCIDENCE OF THROMBOTIC EVENTS IN PRIMARY MEDIASTINAL B-CELL LYMPHOMA AND ITS INFLUENCE ON THE OUTCOME OF THESE PATIENTS: EXPERIENCE OF SINGLE CENTER

J. Hidalgo[1,*], C. Carpio[1], B. Merchan[1], J. Castellví[2], O. Salamero[1], P. Abrisqueta[1], A. López[1], F. Bosch[1]
[1]Hematology, [2]Pathology, University Hospital Vall d'Hebron, Barcelona, Spain

Background: Primary Mediastinal B cell Lymphoma (PMBL) is a lymphoid neoplasm that accounts for 2% to 4% of non-Hodgkin lymphomas (NHL). Because of its particular features (fibrosis, large mediastinal mass, pericardial and/or pleural effusion) is included in the Large B-cell lymphomas (LBCL) with special features category. PMBL presents usually with superior vena cava syndrome (SVCS) and thrombotic events of the mediastinal circulation although the real prevalence of these events have not been accurately reported in the literature.
Aims: The main objective of the study was to determine the incidence of these thrombotic events and how this complication influences the outcome of patients diagnosed with PMBL.
Methods: Thirty-one patients consecutively diagnosed with PMBL in a single center between 1995 and 2014 were included. After reviewing the pathology, the demographic and clinical characteristics of the series were recorded and evaluated, paying particular attention to the thrombotic events.

Table 1.

Characteristics	Total N (%)	With Thrombotic event N (%)	Without thrombotic event N (%)	P
Patients	31 (100)	10 (32)	21 (68)	
Male/Female	12/19	4/6	8/13	NS
Age in years: median (range)	34 (17-56)	34 (25-47)	32 (17-56)	NS
Largest mass diameter in mm: median (range)	98 (50-150)	78 (50-150)	106 (58-150)	NS
Extranodal involvement	8 (27)	2 (20)	6 (28.5)	NS
SVCS	16 (52)	5 (50)	11 (52)	NS
Complete response after first line treatment	23 (74)	7 (70)	16 (76)	NS
4-year Overall survival: % (IC95%)	80 (64 - 96)	83 (53-100)	78 (59-97)	NS
4- year Progression-Free Survival: % (IC 95%)	71 (54 - 88)	85 (59 - 100)	64 (43 - 85)	NS

NS: No statistically significant.

Results: The median age at diagnosis was 34 years (range: 17 to 56) and 61% were female. The median of the largest diameter of the mediastinal mass was 98 mm (range: 50-150 mm), 26% had extranodal involvement (most frequently associated with adjacent structures) and 52% had SVCS. Ten patients (32%) had thrombotic events, 90% detected at diagnosis. There were no differences between the clinical characteristics (sex, age, larger diameter of the mediastinal mass, SVCS presence or extranodal involvement) between patients with or without thrombotic events. With a median follow-up of 71 months (range: 1-183) we did not find any difference between patients with or without thrombotic events regarding the response to therapy and the outcome (PFS and OS), Table 1.
Summary and Conclusions: The prevalence of thrombotic events in PMBL reported in our study is higher than the one described in other types of lymphomas. Nevertheless, response to therapy and outcome seems not to be influenced by this complication.

PB1667

ALCOHOL INTAKE AND SMOKING HABITS HAVE NO MAJOR IMPACT ON THE SHORT TERM SURVIVAL IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

P. Svenssen Munksgaard[1,*], T. Christoffer El-Galaly[1], E. Bekric[2], C. Brieghel Mortensen[3], K. Buchardi Jensen[4], M. Bøgsted[5], M. Dahl Bendtsen[5], M. Tang Severinsen[1]
[1]Department of hematology, Aalborg University Hospital, Aalborg, [2]Department of hematology, Odense University Hospital, Odense, [3]Department of hematology, Copenhagen University Hospital, Copenhagen, [4]Department of hematology, Holstebro Hospital, Holstebro, [5]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark

Background: Individual lifestyle factors such as smoking and alcohol intake are common in the Western world and modify the risk of several cancer types, including non-Hodgkin lymphoma (NHL). However, less is known about the impact of these lifestyle factors on survival once the lymphoma has arisen.
Aims: To examine the prognostic impact of smoking and alcohol intake on overall survival (OS) in patients with newly diagnosed DLBCL treated with immunochemotherapy.
Methods: This retrospective study included adult patients with newly diagnosed DLBCL seen at the hematology centers of Aalborg (2003-2010), Holstebro (2006-2012), Odense (2006-2012), and Copenhagen (Rigshospitalet, 2010-2012). All patients had been treated with R-CHOP/CHOP-like regimens. Patient lists were obtained from the Danish Lymphoma registry (LYFO). The LYFO contains detailed information on a wide range of clinico-pathological features as well as complete follow-up data. Medical records were retrieved and reviewed for information on smoking habits, alcohol consumption, and comorbidities. Overall survival (OS) estimates were made using the Kaplan-Meier method. The impact of lifestyle and comorbidity on OS was evaluated with simple and multiple Cox models with inclusion of the standard international prognostic index (IPI) risk groups and comorbidities.
Results: A total of 502 DLBCL patients had available information on smoking and alcohol intake and were included in the present study. Patients were categorized as low-risk (26%), low-intermediate (24%), intermediate-high (26%) and high risk (18%), according to the IPI. Never smokers accounted for 43% of the patients, former smokers 31%, and current smokers 26%. A low alcohol intake (<3 standard drinks per week) was noted in 33% of the patients, a moderate intake (3-14 standard drinks per week) in 55%, and heavy drinking (>14 standard drinks per week) in 11%. The Table shows the impact of lifestyle on outcome. In male patients, both current and former smoking were associated with a lower 3-year OS. Smoking habits did not influence survival in female patients. However, the associations between smoking and OS were attenuated after adjusting for comorbidities, which suggest that the effects of smoking were at least partially mediated by excess comorbidity in these patients. Participants with a moderate alcohol intake had the highest 3-years OS (71%), whereas heavy drinkers had the lowest 3-years OS (60%), but alcohol consumption did not have impact on survival in univariate or multivariate Cox analyses.

Table 1.

	3-year OS (95% CI)			Crude HR (95%CI)			Adjusted HR (95%CI)*		
	All	Men	Women	All	Men	Women	All	Men	Women
Never smokers	73% [66-78]	73% [63-81]	72% [62-79]	1 (ref)	1 (ref)	1 (ref)	1 (ref)	1 (ref)	1 (ref)
Former smokers	66% [57-74]	60% [48-70]	77% [62-86]	1.23 [0.83-1.81]	1.47 [0.88-2.46]	0.84 [0.42-1.68]	1.12 [0.75-1.67]	1.13 [0.66-1.95]	0.83 [0.41-1.67]
Current smokers	66% [57-73]	60% [47-70]	75% [61-85]	1.27 [0.85-1.90]	1.66 [0.96-2.86]	0.85 [0.42-1.68]	1.09 [0.70-1.68]	1.34 [0.74-2.41]	0.80 [0.40-1.59]
Low alcohol intake	67% [58-74]	60% [47-71]	73% [61-82]	1 (ref)	1 (ref)	1 (ref)	1 (ref)	1 (ref)	1 (ref)
Moderate alcohol intake	71% [65-76]	70% [62-77]	72% [63-80]	0.92 [0.64-1.32]	0.77[0.48-1.24]	1.10 [0.64-1.90]	0.91 [0.62-1.32]	0.70 [0.42-1.18]	1.06 [0.61-1.87]
Heavy drinkers	60% [43-74]	51% [31-67]	-	1.07 [0.62-1.84]	1.13 [0.62-2.07]	-	0.91 [0.51-1.61]	0.94 [0.49-1.79]	-

*Adjustment for IPI score and comorbidity

Summary and Conclusions: Overall, smoking habits and alcohol intake had no significant impact on the short term survival in this large cohort of uniformly treated DLBCL patients. However, current and former smoking were associated with a strong trend toward inferior OS, which is possibly mediated by excess comorbidity in this subset of patients.

PB1668

UPFRONT AUTOLOGOUS STEM CELL TRANSPLANTATION OVERCOMES A NEGATIVE IMPACT OF MALE GENDER IN HIGH-RISK DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS TREATED WITH R-CHOP

H. Cho[1,*], H. Chung[1], S.J. Kim[1], H. Park[1], J.Y. Lee[1], J.E. Jang[1], Y. Kim[1], J.W. Cheong[1], Y.H. Min[1], J.S. Kim[1]

[1]Severance Hospital, Seoul, Korea, Republic Of

Background: Combining rituximab to combination chemotherapy (R-CHOP) has significantly improved overall survival (OS) of patients with diffuse large B-cell lymphoma (DLBCL), but high-risk patients stratified according to the international prognostic index (IPI), non-germinal center B cells (non-GCB) subtype, and male patients have shown inferior treatment outcomes. Although the first-line treatment of patients with DLBCL is R-CHOP irrespective of the risk-group, there have been few studies evaluating the role of upfront ASCT as consolidative treatment strategy for high-risk DLBCL patients.
Aims: To investigate the role of upfront ASCT as consolidation after R-CHOP chemotherapy according to the gender in newly diagnosed advanced stage DLBCL patients.
Methods: We performed a multicenter retrospective analysis of 204 newly diagnosed DLBCL patients between January 2008 and December 2013. Patients who were younger than 65 years of age with advanced stage (Ann Arbor stage III or IV) and elevated serum lactate dehydrogenase were included. All the patients completed 4 to 8 cycles of planned R-CHOP chemotherapy and achieved at least PR after completion of planned R-CHOP chemotherapy.
Results: The median age at diagnosis was 50 (range 22-64) years and 111 (54.4%) patients were male. Median follow-up for surviving patients was 42 (range 4-115) months. Seventy-five (36.8%) patients underwent upfront ASCT as consolidation. Fifteen (11.6%) patients in the non-ASCT group (n=129) underwent ASCT after relapse. The 3-year OS and PFS rate for all patients were 78.8% and 68.4%, respectively. In multivariate analysis, non-CR after R-CHOP chemotherapy and non-upfront ASCT was associated with shorter OS (hazard ratio (HR) 2.57; 95% CI 1.34-4.95; P=0.005 and HR 2.97; 95% CI 1.38-6.40; P=0.005, respectively). Non-ASCT was also associated with shorter PFS in multivariate analysis (HR 2.26; 95% CI 1.25-4.07; P=0.014). Among the male patients, upfront ASCT showed superior OS and PFS compared to the non-ASCT group (P=0.016 and P=0.024, respectively). GCB subtype compared to the non-GCB subtype showed better PFS in male patients (*P*=0.026), but there were no difference in OS and PFS in male patients who received upfront ASCT. In female patients, non-CR after completion of chemotherapy was associated with shorter OS on multivariate analysis (P=0.024). However, survival differences in OS and PFS according to the disease status after the completion of chemotherapy were not observed in female patients who received upfront ASCT.

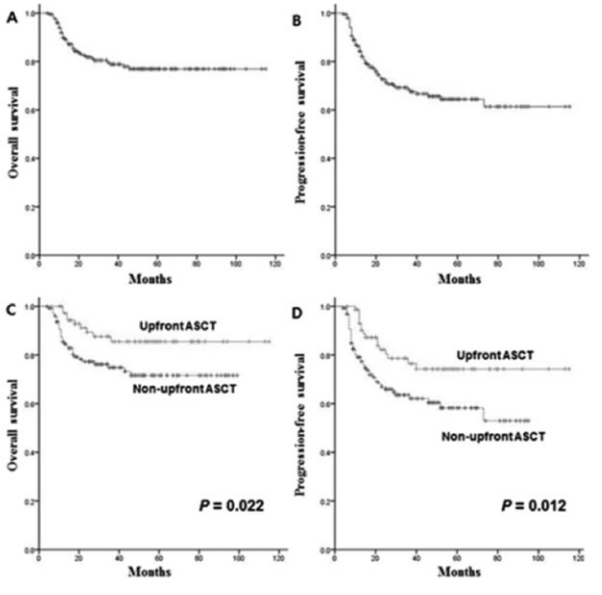

Figure 1.

Summary and Conclusions: Upfront ASCT as consolidation after R-CHOP chemotherapy overcomes a negative impact of male gender and non-GCB subtype in male patients with high-risk DLBCL. Among female patients with high risk DLBCL, upfront ASCT after R-CHOP chemotherapy may overcome a negative impact of non-CR response to initial therapy. Additional data comparing with new regimens such as additional use of rituximab are necessary to find out the exact role of upfront ASCT.

PB1669

HIGH NEUTROPHIL LYMPHOCYTE RATIO AT DIAGNOSIS IDENTIFIES DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS WITH POOR CLINICAL OUTCOME

B. Spassov[1,*] G. Balatzenko[2], D. Vassileva[3], G. Mihaylov[1], S. Toshkov[2], M. Guenova[4]
[1]Department of Clinical Hematology, [2]Laboratory of Cytogenetics and Molecular Biology, [3]Laboratory of Nuclear Medicine, [4]Laboratory of Hematopathology and Immunology, National Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common type of non-Hodgkin lymphoma (NHL) and is a biologically heterogeneous disease. At present, the stratification of DLBCL patients is performed by the revised international prognostic index (R-IPI). However, some preliminary data suggest the important role of inflammation in cancer biology. It has been assumed that systemic inflammatory response has prognostic significance in a wide range of different cancer types including NHL. The neutrophil to lymphocyte ratio (NLR) in the peripheral blood has been proposed as a prognostic factor in cancer patients. However data regarding the prognostic significance of NLR in DLBCL patients is quite limited.
Aims: To evaluate the prognostic significance of baseline NLR in a cohort of newly diagnosed DLBCL patients treated with chemoimmunotherapy.
Methods: Data from 254 DLBCL patients, at a median age of 58.6 years (range, 19-82 years), diagnosed between 2007 and 2014, were evaluated retrospectively. The patients were treated with R-CHOP. The NLR cutoff value for survival analysis determined by receiver operation characteristics (ROC) curve in the whole patients' cohort was 3,01. The prognostic influence of the NLR and other factors including age, lactate dehydrogenase (LDH), β_2 microglobulin (β_2 M), R-IPI and Ann Arbor stage at diagnosis on 5-year overall- (OS) and disease-free (DFS) survival was studied by Kaplan–Meier curves. To evaluate the independent prognostic relevance of NLR, univariate and multivariate Cox regression models were applied.
Results: A significantly higher proportion of patients with NLR above 3,01 had elevated levels of LDH and β_2 M (64% vs 28.8% and 75% vs 53.1%, respectively), advanced disease stage (III – IV) (48.2% vs 31.1%), high risk (R-IPI 3-5) disease (9.3% vs 32.2%) in comparison to patients with NLR below the cutoff value. Patients with high NLR at diagnosis experienced an inferior 5-year OS (38.5% vs 74.4%, P<0.001) and 5-year DFS (61.8% vs 77.7%, P<0.001). By multivariate analysis, an independent significant association between high NLR and poor clinical outcome in terms of OS (harard ratio [HR]=1.99, 95% confidence interval [CI], 1.07-3.71, P=0.03) and DFS (HR=2.58, 95% CI, 1.04-6.43, P=0.04) was identified.
Summary and Conclusions: Our data suggest that NLR at diagnosis provides useful independent prognostic information to assess clinical outcomes in DLBCL patients treated with R-CHOP. Further studies are required to confirm these results.

PB1670

COMBINATION OF CHEMOTHERAPY AND RADIATION IMPROVE THE PROGNOSIS OF PRIMARY DIFFUSE LARGE B-CELL LYMPHOMA OF THE TONSIL

S.N. Lim[1,*] H.J. Shin[2], C. Suh[3], S.I. Lee[4], W.S. Kim[5], W.S. Lee[6], H.J. Kim[7], C.W. Choi[8], J.S. Kim[9]
[1]Internal Medicine, Inje University College of Medicine Haeundae Paik Hospital, [2]Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan, [3]Department of Oncology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, [4]Internal Medicine, Dankook University Medical College, Dankook University Hospital, Cheonan, [5]Internal Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, [6]Internal Medicine, Inje University College of Medicine, Busan Paik Hospital, Busan, [7]Internal Medicine, Hallym University College of Medicine, Hallym University Sacred Heart Hospital, Anyang, [8]Internal Medicine, Korea University College of Medicine, Korea University Guro Hospital, [9]Internal Medicine, Yonsei University College of Medicine, Severance Hospital, Seoul, Korea, Republic Of

Background: Non-Hodgkin lymphoma of the Waldeyer's ring is a relatively rare entity and the tonsil is the most frequently involved site. The majority of tonsil lymphomas are of B-cell origin and the most common histological type is diffuse large B-cell lymphoma (DLBCL). Treatment approaches that have used include chemotherapy (CTx) alone, radiation (RT) alone, and combination of both.
Aims: We reviewed our data and evaluate treatment outcome of patient with primary diffuse large B-cell lymphoma of the tonsil.
Methods: Retrospective review of 114 stage I-II DLBCL patients treated with curative intent between 1995 and 2010. Forty-five (39.5%) patients had stage I disease and systemic symptoms (B-symptoms) were present in only 7 (6%) patients. Seventy-two (65.5%) patients were treated with CTx alone, whereas the remaining 38 (34.5%) received treatment with a combination of CTx and RT. Chemotherapy was CHOP-based, with R-CHOP in 80 patients (70%). Median involved-field RT dose was 3,960 cGy, with 96% receiving more than 3,000 cGy.
Results: The median age was 59 years and the majority of patients (61%) were males. Low risk disease: low to low intermediate by International prognostic index (IPI) was 97.3% and only 10 (8.8%) patients had high serum lactate dehydrogenase (LDH) level. Overall CR rate was 73.5% and seven (13.5%) of the patients who had achieved CR had recurred. The median follow up was 28 months (34 months for CHOP-treated, 23 months for R-CHOP). Disease-free survival (DFS) and overall survival (OS) were 43.9% and 42.5%, respectively. Significant prognostic factors included: age ≥60 year-old (OS: 93.1% vs. 74.1%, *P*=0.011; DFS: 83.3% vs. 80.6%, *P*=0.160), LDH >upper normal limit (OS:

88.2% vs. 72.9%, *P*=0.003; DFS: 86.8% vs.20.0%, *P*<0.001), IPI>0 (OS: 90.0% vs. 55.9%, *P*=0.007; DFS: 86.5% vs. 64.0%, *P*=0.034) and combination of CTx and RT (OS: 79.6% vs. 48.2%, *P*=0.025; DFS: 72.6% vs. 48.5%, *P*=0.038). Germinal center (GC) and non-GC phenotype were not predictors of outcome in localized primary DLBCL of the tonsil. Combination chemotherapy-treated patients with rituximab did not show a significantly better OS and DFS than the combination chemotherapy-treated patients without rituximab. On multivariate analysis; LDH >upper normal limit (DFS: hazard ratio [HR], 14.958; 95% CI, 2.474-90.432, *P*=0.003; OS: HR, 9.341; 95% CI, 1.635-53.361, *P*=0.012), and combination of CTx and RT (DFS: HR, 0.088: 95% CI, 0.009-0.834, P=0.034; OS: HR, 0.112; 95% CI, 0.014-0.918, *P*=0.041), retained statistical significance.

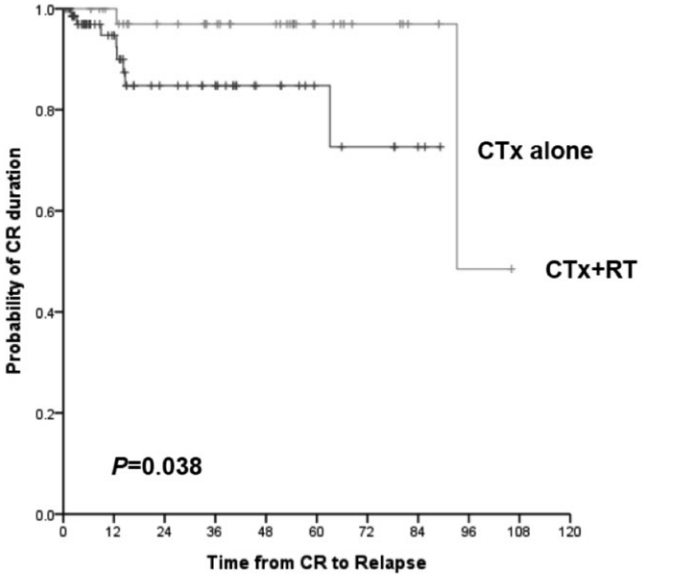

Figure 1.

Summary and Conclusions: The DFS and OS rates were significantly better for patients receiving combination of CTx and RT. A combined treatment, consisting of CTx and RT results in a satisfactory outcome in patients with localized primary DLBCL of tonsil.

PB1671

TREATING HIV-RELATED NON-HODGKIN LYMPHOMA IN SEVERELY IMMUNOCOMPROMISED PATIENTS, IN THE CART ERA. A SINGLE CENTER EXPERIENCE.

A. Re[1,*] S. Casari[2], C. Cattaneo[1], A. Peli[1], D. Dal Ceggio[1], F. Castelli[2], A. Scalzini[3], G. Rossi[1]
[1]Ematologia, [2]Clinica di Malattie Infettive e Tropicali, [3]Malattie Infettive 1, SPEDALI CIVILI DI BRESCIA, BRESCIA, Italy

Background: Low CD4+ lymphocyte count at diagnosis, in patients (pts) with HIV-related non-Hodgkin's lymphoma (NHL), is associated with poor clinical outcome, mainly due to low treatment tolerability. Severely immunocompromised pts are frequently excluded from clinical trials. Moreover, several authors claim that Rituximab should be held in pts with very low CD4 count due to the increased risk of infections
Aims: To define the outcome of severely immunocompromised HIV positive (+) pts with NHL in the real-life, in terms of possibility to receive treatment with curative intent, treatment-related mortality (TRM), complete remission (CR) rate and survival
Methods: All consecutive HIV pos pts diagnosed at our Institution from Jan 1997 to Dec 2013 (cART era) with aggressive systemic NHL and CD4+ lymphocyte count<100/mcl (CD4<100) at lymphoma diagnosis were considered. Histology included DLBCL, Burkitt, plasmablastic or other aggressive lymphomas. Pts'characteristics, treatment response and long-term outcome were compared with the concomitant series of HIV-related NHL pts with CD4+ lymphocyte count >100/mcl (CD4>100). Each pt was treated with standard state-of-the art in lymphoma and HIV care at the time of diagnosis, or enrolled in prospective trials. After 2001 all pts with CD20+ NHL received Rituximab combining chemotherapy (CT)
Results: Since 1985 to 2013 198 HIV pos pts were diagnosed at our Institution with NHL, 84 in the pre-cART era (1985-1996) and 114 in the cART era (1997-2013). The proportion of pts with CD4<100 during the cART era was 35% vs 63% in the pre-cART era (P=.0002). The clinical characteristics of the 2 groups (CD4>100 vs CD4<100) are shown in table 1. Significant differences included worse performance status (PS) and more pts with B symptoms in CD4<100 group and a greater proportion of pts on cART at NHL onset in CD4>100 group. The proportion of pts with CD4<100 we treated with curative intent was 63% vs 97% in pts with CD4>100 (P<0.0001). Pts were excluded from curative treatment for poor PS, major infections and/or severe comorbidities. After a follow-up of 60 ms (1-204), the 5y-overall survival (OS) of the 2 groups of pts was 31% (CD4<100) and 60% (CD4>100) (P=0.003). However, analysing pts who underwent CT, CR rate was similar (54% for CD4<100 and 64% in CD4>100; P=0.6). TRM was respectively 21% and 9% and included mainly infectious events. Overall, 14 pts (58%) died in CD4<100 (cause of death: NHL 7 pts,TRM 5,HCV cirrosis 1 and unknown 1) and 29 (41%) in CD4>100 group (NHL 19,TRM 6,lung cancer 1,car crush 1,suicide 1 and drug overdose 1). Response duration was not different (85% and 84% at 5 years). A trend towards worse OS and PFS were seen in pts treated with CD4<100 (38% vs 62% and 39% vs 52%) (P=NS). Fifteen pts with CD4<100 (DLBCL 11 and Burkitt 4) received Rituximab combining CT, while 6 pts (DLBCL 5 and Burkitt 1) did not. The CR rate for pts who received Rituximab was higher (60% vs 33%, P=NS) with similar TRM (20% vs 17%), and median OS and PFS of 19 vs 4.5 ms and 17 vs 4.5 ms (P=NS).
Summary and Conclusions: After the advent of cART the proportion of severely immunocompromised pts with HIV-related NHL has significantly decreased. In our single center experience, a substantial proportion of them could not receive adequate treatment and OS remained poor. However, if properly treated with standard immunochemotherapy, the CR rate was similar to pts with less immunocompromise, with chance of favourable long-term outcome. TRM was not negligible. Rituximab appears feasible in this setting and it seems to improve CR rate and possibility of long-term survival.

Table 1. Comparison between characteristcs of patients with CD4+ limphocyte count more or less than 100 at lymphoma diagnosis.

	CD4 < 100 pts 39	CD4 > 100 Pts 73	P
Histology: -BDLCL	25 (64%)	36 (49%)	0.1
- Burkitt	7 (18%)	18 (25%)	0.4
- Plasmablastic	2 (5%)	11 (15%)	0.2
- Others/NOS	5 (13%)	8 (11%)	1.0

CLINICAL OUTCOMES OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN PARTIAL RESPONSE AFTER FIRST-LINE R-CHOP CHEMOTHERAPY: THE PROGNOSTIC VALUE OF SECONDARY IPI

H. Lee[1,*] Y.R. Kim[2], S.J. Kim[2], Y. Park[3], H.S. Eom[1], S.Y. Oh[4], H.J. Kim[5], H.J. Kang[6], W.S. Lee[7], J.H. Moon[8], Y.W. Won[9], J.S. Kim[2]
[1]National Cancer Center, Goyang, [2]Yonsei University College of Medicine, [3]Korea University College of Medicine, Seoul, [4]Dong-A University College of Medicine, Busan, [5]Hallym University, Hallym University Sacred Heart Hospital, Anyang, [6]Korea Cancer Center Hospital, Korea Institute of Radiological and Medical Sciences, Seoul, [7]Inje University College of Medicine, Busan, [8]Kyungpook National University Hospital, Daegu, [9]Hanyang University College of Medicine, Seoul, Korea, Republic Of

Background: Rituximab in combination with cyclophosphamide, vincristine, doxorubicin and prednisolone (R-CHOP) has been a standard treatment for patients with diffuse large B cell lymphoma (DLBL). Although complete response (CR) rate is up to 60~70%, 10~20% patients remained in PR after R-CHOP. Patients with PR are relatively chemo-sensitive compared to primary refractory diseases, but predictive factors and treatment strategy for these patients are in controversy.
Aims: We investigated the characteristics and prognosis for the patients who achieved PR after the first-line R-CHOP to analyze the survival of these patients and to define the prognostic factors affecting the clinical outcome of this specific patient group.
Methods: We performed a retrospective multicenter study on behalf of the Consortium for Improving Survival of Lymphoma (CISL). Patients who achieved PR by Cheson response criteria, and who had available PET scans at the end of R-CHOP were enrolled. Clinical parameters before and after R-CHOP were obtained to evaluate whether the patients' dynamic condition after treatment could predict the outcome. For survival analysis, PFS2 (from the date PR was

documented to disease progression or death) and OS2 (from the date PR was documented to death) were used.
Results: A total of 88 patients were enrolled. Median age was 53.5 years (21-88), and the number of patients with initial stage III-IV was 64 (72.7%). The International Prognostic Index (IPI) score at diagnosis was >2 in 46 (52.3%). At the time of PR documentation, secondary IPI scores (IPI2) assessed after R-CHOP were 0 in 33 (37.5%), 1 in 27(30.7%), and >1 in 28 (31.8%). The Deauville scores of PET scans after R-CHOP were ≤2 in 24 (28.2%), 3 in 26 (30.6%), ≥ 4 in 35 (41.2%), and unknown in 3 cases. As a second-line treatment, local radiation to residual lesion without any systemic treatment was performed in 33 (38.6%) patients. Intensive chemotherapy such as salvage chemotherapy or upfront ASCT was performed in 42 (47.7%) patients. Four (4.5%) patients received less intensive therapy such as rituximab or other oral agents. With a median follow up of 47.8 months, 3-year PFS2 and OS2 rates were 57.9% and 68.1%. In the univariate analysis, age, bone marrow involvement, lymphopenia, and high IPI score at diagnosis were significantly associated with poor PFS2 and OS2. High IPI2 score (≥1) and the Deauville score (≥4) were significantly associated with worse PFS2 (P=0.001 and P=0.029, respectively). In the multivariate analysis, high IPI2 was an independent predictive factor for PFS2 (HR 2.40, 95% CI 1.08-5.269, P=0.031) after adjustment with initial IPI (P=0.163), bone marrow involvement (P=0.005), lymphopenia (P=0.124) at diagnosis and the Deauville score after R-CHOP (P=0.338). For overall survival, high IPI2 score was also associated with poor OS2 in univariate analysis (P=0.013), but not the Deauville score (P=0.134). Only the initial IPI score >2 (P=0.041) and bone marrow involvement at diagnosis (P=0.001) remained significant in the multivariate analysis model.

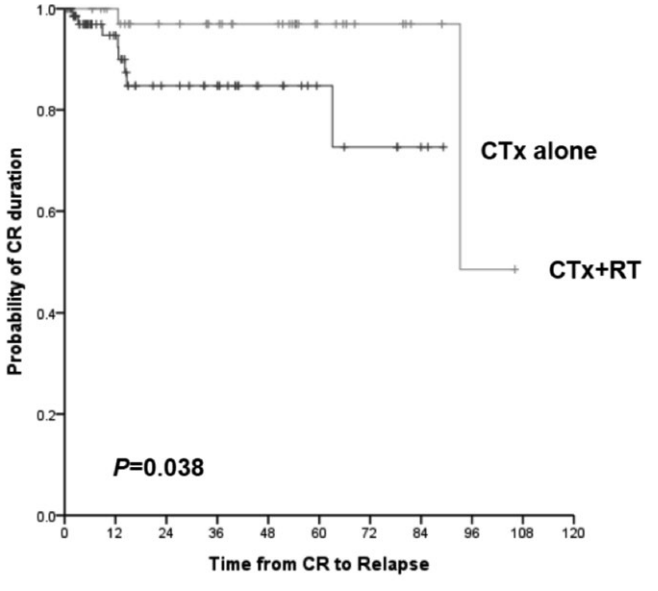

Figure 1.

Summary and Conclusions: IPI2 in patients with DLBL who achieved PR after R-CHOP was an important predictive factor for further survival outcomes. This suggests that the patient's condition and residual tumor burden might be helpful when we are planning the next treatment.

PB1673

SURVIVAL BENEFIT OF HEMATOPOIETIC STEM-CELL TRANSPLANTION FOR PTCLS: A RETROSPECTIVE COMPARISON STUDY BETWEEN CONVENTIONAL CHEMOTHERAPY AND STEM CELL TRANSPLANTATION FOR PTCLS FROM A CHINESE CENTER

H. Huang[1,*] Q. Wang[1], Z. Jin[1], D. Wu[1]
[1]The First Affiliated Hospital of Soochow University, Suzhou, China

Background: Peripheral T-cell lymphomas (PTCLs) are rare malignancies with poor outcome after conventional chemotherapy. The role of stem cell transplantion in the treatment of PTCLs is still unclear.
Aims: Here, we present the result of a comparison study between conventional chemotherapy and stem cell transplantation for PTCLs in our centre.
Methods: From July 2004 to July 2014, 104 cases were analyzed retrospectively, including age, IPI score and morbid state before transplantion. 52 patients underwent HSCT including angioimmunoblastic T-cell Imphoma (n=15), anaplastic large cell lymphoma (n=14), PTCL not specified (n=12), NK/T cell lymphoma (n=11). In this group, 43 patients were IPI≥3-4). Thirty-three patients (63.5%) received autologous stem-cell transplantion (autoSCT) and nineteen patients (36.5%) received allogeneic stem-cell transplantion (allo-SCT). Before stem-cell transplantation, 43 Patients were in complete remission (CR), 2 patients were in partial remission (PR), 7 patients were not-remission(NR). In conventional chemotherapy group, 52 patients (median age, 49.5 years, IPI≥3-4: 40 patients) only received conventional chemotherapy. Primary outcomes of progression-free survival (PFS), and overall survival (OS) rates were estimated by using the Kaplan-Meier method.
Results: After a median follow-up of 23.5 months, K-M analysis showed that the 5-year PFS for HSCT and chemotherapy were 60% and 30%(P=0.006), the 5-year OS were 65% and 33% (P=0.007) (Fig 1), respectively. These results suggested that frontline stem cell transplantation for high-risk PTCLs may improve treatment outcome. The 5-year PFS for autoHSCT and alloHSCT were 60% and 58%(P=0.074). The 5-year OS were 62% and 61% (P=0.074) (Fig 2). There were no significant survival differences between the auto-HSCT and allo-HSCT.

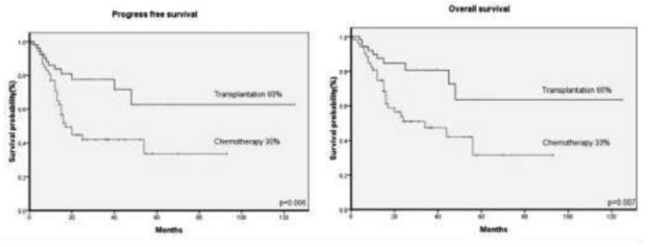

Figure 1. Progression-free survival an overall survival by transplantation and conventional chemotherapy for PTCLs.

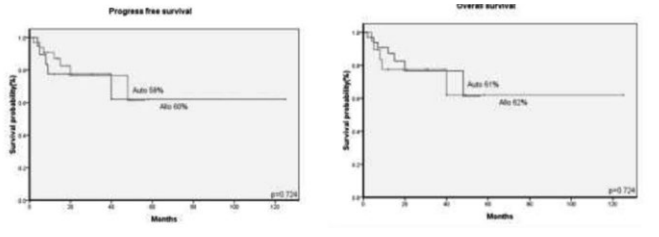

Figure 2. Progression-free survival an overall survival by auto-HSCT and allo-HSCT fot PTCLs.

Summary and Conclusions: The results of this retrospective study suggest that HSCT have great advantange copared to conventional chemtherapy on long-term survival in peripheral T-cell lymphomas. However, the resullt of auto-HSCT and allo-HSCT seems to have no difference. Therefore, autoHSCT should be considered to be the first -line therapy in peripheral T-cell lymphomas, especially for those patients with high risk factors.

PB1674

PERIPHERAL ABSOLUTE MONOCYTE AND LYMPHOCYTE COUNTS AT DIAGNOSIS PREDICT SURVIVAL IN PATIENTS WITH PRIMARY NODAL DIFFUSE LARGE B-CELL LYMPHOMA

B. Spassov[1,*] G. Balatzenko[2], D. Vassileva[3], S. Nikolov[4], G. Mihaylov[1], M. Guenova[5]
[1]Department of Clinical Hematology, [2]Laboratory of Cytogenetics and Molecular Biology, [3]Laboratory of Nuclear Medicine, [4]Clinical Laboratory, [5]Laboratory of Hematopathology and Immunology, National Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: Diffuse large B-cell lymphoma (DLBCL) is a biologically heterogeneous disease with primary nodal and extranodal origin. At present, the stratification of DLBCL patients is performed by the revised international prognostic index (R-IPI). However, some preliminary data suggest the important role of blood monocytes and lymphocytes in cancer biology. It has been assumed that baseline levels of peripheral absolute lymphocyte (ALC) and monocyte (AMC) counts have prognostic value in solid tumors. However, data regarding their impact on clinical outcomes of DLBCL patients are limited.
Aims: To evaluate the prognostic significance of baseline ALC and AMC in a cohort of newly diagnosed DLBCL patients treated with chemoimmunotherapy.
Methods: Data from 255 DLBCL patients, at a median age of 58.6 years (range, 19-82 years), diagnosed between 2007 and 2014, were evaluated retrospectively. Primary nodal and extranodal lymphoma were detected in 60.4% (154/255) and 39.6% (101/255), respectively. The patients were treated with R-CHOP. Values<1.0x 10^9/L for ALC and >0.8x 10^9/L for AMC were considered abnormal and applied to stratify patients in the present study. The prognostic influence of the ALC and AMC, and other factors including age, lactate dehydrogenase (LDH), β_2 microglobulin (β_2 M), R-IPI and Ann Arbor stage at diagnosis on 5-year overall- (OS) and disease-free (DFS) survival was studied by Kaplan–Meier curves. To evaluate the independent prognostic relevance of

ALC and AMC, univariate and multivariate Cox regression models were applied.
Results: The median ALC at diagnosis was 1.74x 10^9/L (range 0.28–7.16x 10^9/L) and abnormal ALC were detected in 16.8% (42/255) of the patients. A significantly higher proportion of patients with ALC<1.0x 10^9/L had elevated levels of LDH and β_2 M (76.2% vs 36.1% and 86.8% vs 57.6%, respectively), advanced disease stage (III – IV) (60.9% vs 34.9%), high risk (R-IPI 3-5) disease (43.9% vs 15.8%) in comparison to patients with ALC ≥ 1.0x 10^9/L. The median AMC at diagnosis was 0.59x 10^9/L (range 0.28–7.16x 10^9/L) and AMC >0.8x10^9/L were detected in 24.3% (62/255). Similarly, a significantly higher proportion of patients with abnormal AMC had elevated levels of LDH and β_2 M (59.7% vs 37.3% and 76% vs 60.1%, respectively), advanced disease stage (III – IV) (52.4% vs 34.9%), high risk (R-IPI 3-5) disease (36.8% vs 15.5%) in comparison to patients with AMC ≤0.8x 10^9/L. Patients with abnormal ALC at diagnosis experienced an inferior 5-year OS (18% vs 64.7%, P<0.001) and 5-year DFS (48.9% vs 78.2%, P<0.001). Patients with abnormal AMC at diagnosis experienced an inferior 5-year OS (60% vs 79.2%, P=0.002) and 5-year DFS (53.6% vs 80.4%, P=0.001). However, regarding nodal and extranodal origin of lymphoma the analysis revealed that only primary nodal DLBCL patients with abnormal baseline ALC and AMC experienced inferior 5-year OS and 5-year DFS. Moreover, an independent significant association between abnormal ALC and poor clinical outcome in terms of OS (hazard ratio (HR) 2.14, 95% confidence interval (CI) 1.13-4.06, P=0.019) and DFS (HR 5.88, 95% CI 2.00-17.25, P=0.001) was identified by multivariate analysis only in primary nodal DLBCL patients.
Summary and Conclusions: Our data suggest that ALC and AMC in peripheral blood at diagnosis predict survival in primary nodal DLBCL treated with R-CHOP. However only ALC is independent, poor prognostic factor for DFS and OS, and can be used in combination with other prognostic features to better predict the outcome of these patients.

PB1675

PROGNOSTIC FACTORS AND INTERNATIONAL PROGNOSTIC INDEX VARIANTS IN PATIENTS WITH B-LARGE CELL LYMPHOMA-AN OBSERVATIONAL STUDY OF KROHEM, THE CROATIAN COOPERATIVE GROUP FOR HEMATOLOGIC DISEASES

V. Periša[1,*] I. Aurer[2], D. Radić-Krišto[3], A. Duletić-Načinović[4], I. Radman[2], S. Bašić-Kinda[2], R. Ajduković[5], P. Gaćina[6], J. Jakelić-Piteša[7], S. Ostojić-Kolonić[3], V. Pejša[5], D. Nemet[2]
[1]Hematology, University Hospital Centre Osijek, Osijek, [2]Hematology, University Hospital Centre Zagreb, [3]Hematology, Clinical Hospital Merkur, Zagreb, [4]Hematology, University Hospital Centre Rijeka, Rijeka, [5]Hematology, Clinical Hospital Dubrava, [6]Hematology, University Hospital Centre Sestre Milosrdnice, Zagreb, [7]Hematology, University Hospital Centre Split, Split, Croatia

Background: B-large cell lymphoma (B-LCL) is the most common form of NHL. 5-year survival rates vary between 40 and >90% depending on prognostic factors but the importance of many of them is disputed. Those found most important and reproducible in the pre-rituximab era were included in the IPI. Since the original description, various variants of this index have been published.
Aims: To reassess the value of the IPI, revised IPI (R-IPI), age-adjusted IPI (aaIPI), stage-adjusted IPI and different possible clinical prognostic factors in an unselected population of patients with B-LCL receiving rituximab containing front-line therapy.
Methods: 371 patients diagnosed with B-LCL during 2007 and 2008 and treated with rituximab plus chemotherapy in 16 Croatian hematology departments were included in this study. Patients were registered at the time of treatment start, and data on demographics, clinical features and laboratory parameters collected. Follow-up was performed yearly. The study was approved by the Croatian Central Ethics' Committee. Prognostic values of IPI, R-IPI, aaIPI, stage-adjusted IPI, individual factors used in indices (age, PS, LDH, stage, number of extranodal organs involved), bulk, gender, anemia, bone marrow infiltration and the presence of B symptoms were evaluated with respect to overall survival (OS) and progression-free survival (PFS) were evaluated. Survival analyses were performed using the Kaplan-Meier method and comparisons using the log-rank test. Multivariate analysis is ongoing.
Results: 5-year OS and PFS of the whole cohort were 50% and 49.5%. Significant negative prognostic factors in univariate analyses for OS and PFS were: age>65, LDH high, PS>1, stage>2, Hb<120 g/l, male gender, bone marrow infiltration and presence of B symptoms. Number of involved extranodal sites and presence of bulky disease did not influence prognosis. Regarding prognostic indices, conventional IPI was most useful, distinguishing 4 categories with reasonable proportions of patients. R-IPI was less useful; the differences in PFS between the three prognostic categories were significant, but there was no difference in OS between patients with scores 0 and 1-2. aaIPI distinguished only two categories; patients with score 0 had excellent prognosis, while there was no difference in outcomes between those with scores 1 and 2-3. Stage adjusted IPI distinguished three prognostic groups, but very few patients had a score 0.
Summary and Conclusions: Our study suggests that conventional IPI remains the most useful prognostic index. Bulky disease does not seem to be of prognostic importance, probably because of widespread use of adjuvant radiotherapy to initial bulky sites after immunochemotherapy. As seen in some other studies, men have a worse prognosis, possibly related to differences in rituximab metabolism. Additional negative prognostic factors include anemia, B symptoms and bone marrow infiltration, possibly as markers of aggressive systemic disease.

PB1676

CLINICAL IMPACT OF EARLY RECOVERY OF POST-TRANSPLANT PERIPHERAL BLOOD ABSOLUTE LYMPHOCYTE COUNT ON THE OUTCOME OF FRONTLINE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR DIFFUSE LARGE B-CELL LYMPHOMA

Y. Kim[1,*] J.Y. Lee[1], H.S. Park[1], J. Jang[1], S.J. Kim[1], J.W. Cheong[1], Y.H. Min[1], J.S. Kim[1]
[1]Yonsei University Severance hospital, Seoul, Korea, Republic Of

Background: Several studies have shown that lymphopenia, which is considered a surrogate marker of immunological incompetence, has considered as an adverse prognostic factor in Non-Hodgkin`s lymphoma (NHL). Recently, it has been suggested that early recovery of an absolute lymphocyte count (ALC) at 2-3 weeks following therapy has been associated with superior progression-free survival (PFS) and overall survival (OS) in patients who received autologous stem cell transplantation (ASCT) for NHL,. However, the prognostic significance of early recovery of peripheral ALC following frontline ASCT in diffuse large B-cell lymphoma (DLBCL) remains unclear.
Aims: The purpose of this study was to investigate the prognostic role of early recovery of peripheral ALC after ASCT in patients with DLBCL who underwent frontline ASCT.
Methods: We retrospectively evaluated 51 patients who underwent ASCT for DLBCL at Yonsei University Severance Hospital between January 2006 and 2014. All patients were treated with R-CHOP (rituximab-cyclophosphamide, doxorubicin, vincristine, and prednisone) every 3 weeks for 3 to 8 cycles as first-line therapy and received frontline ASCT as consolidation. Most patients (n=40) received intravenous busulfan-based conditioning chemotherapy. The ALC at the time of D+14 after ASCT was obtained. Receiver operating characteristics (ROC) analysis was performed to determine the optimal cut-point for the ALC.

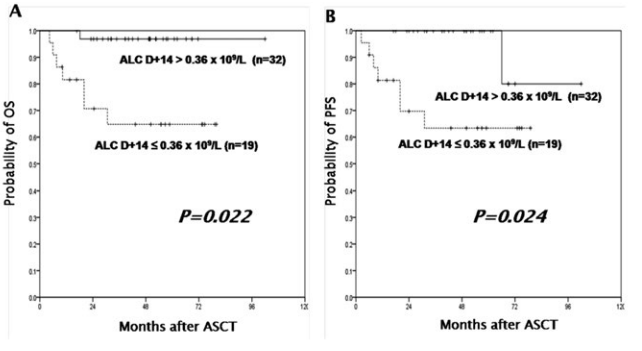

Figure 1.

Results: The study population included 51 patients with a median age of 53 years (range, 19-66 years). Fourty-six (90.2%) had stage IV disease according to the Ann Arbor staging system. Most patients (87.3%) were younger than 60 years. Thirty-five (68.8%) patients had B symptoms. International prognostic index (IPI) was low in 2 (4%), Low-intermediate in 15 (30%), high-intermediate in 25 (50%) and high in 8 (16%). Pre-transplant disease status was complete remission (CR) in 30 (58.8%) patients and partial remission (PR) in 21 (41.2%) patients. The median ALC at D+14 after ASCT was 0.43x 10^9/L (range, 0.03-1.57x 10^9/L). The ROC curve analysis identified 0.36x 10^9/L as the cutoff value of ALC at D+14 for predicting relapse with an area under curve of 0,759 (95% CI, 0.628-0.890, P=0.020). When comparing the baseline clinical characteristics of patients with an ALC at D+14 of ≤0.36x 10^9/L (low ALC group, n=19) and >0.36x 10^9/L (high ALC group, n=32), no significant difference was found between two groups, except for a female dominance and presence of B symptoms at diagnosis in the low ALC group. The median survival of patients following ASCT was 49.4 months (range, 4.4-101.9 months). In a univariate analysis from the time of ASCT, it appears that high ALC at D+14 was associated with a better OS (HR=0.083; 95% CI 0.010-0.694, P=0.022) and PFS (HR=0.086; 95%CI 0.010-0.720, P=0.024) and event-free survival (EFS) (HR=0.283; 95% CI 0.082-0.971, P=0.045). Multivariate analysis revealed that high ALC at D+14 was a good prognostic factor for OS (HR=0.086; 95%CI 0.008-0.979, P=0.048).
Summary and Conclusions: The early recovery of ALC at D+14 after ASCT can be regarded as a good prognostic marker in patients with DLBCL who underwent frontline ASCT.

PB1677

INVESTIGATION OF SEROUS EFFUSIONS WITH FLOW CYTOMETRY

O. Salim[1], U. Iltar[1,*] O. K. Yucel[1], R. Erdem[1], M. Ulubahsi[1], L. Undar[1]
[1]Hematology, AKDENIZ University, Antalya, Turkey

Background: In current clinical practice serous effusions are evaluated by cytopathologic, chemical and microbiologic examinations. As well as infections and inflammatory diseases, serous body fluids can also be observed in hematopoietic and solid neoplastic diseases. Flow cytometry(FC) is well established as a critical and quick diagnostik tool used routinely in the diagnosis of hematopoietic neoplasms by fine-needle aspiration and an alternative diagnostic method for the evaluation of serous body fluids.
Aims: The aim of this study was to investigate immunophenotypic analysis of serous body fluids by FC.
Methods: During the time period of 2010-2014, a total of 79 consecutive serous effusion specimens (45 pleural, 33 peritoneal, 1 pericardial) of 76 cases (40 female, 36 male, 24-84 years of age) were investigated with the six-color FC (FACSCanto II, BD Biosystems, San Jose, USA) in the Division of Hematology Laboratory at Akdeniz University Hospital. We retrospectively analyzed these datas.
Results: FC was positive for definitive immunophenotypic evidence of a hematopoietic malignancy in 3 of 45 pleural fluid specimens (Diffuse Large B-cell lymphoma(1 case), Burkitt's lymphoma(1 case), T-cell Acute Lymphoblastic Leukemia / Lymphoma(1 case)) and 3 of 33 peritoneal fluid specimens (T-cell prolymphocytic leukemia(1 case), diffuse large B-cell lymphoma(1 case), Burkitt's lymphoma(1 case)(Figure 1)). Subsequent tissue studies confirmed the diagnosis of a hematopoietic neoplasm in these seperate six cases.

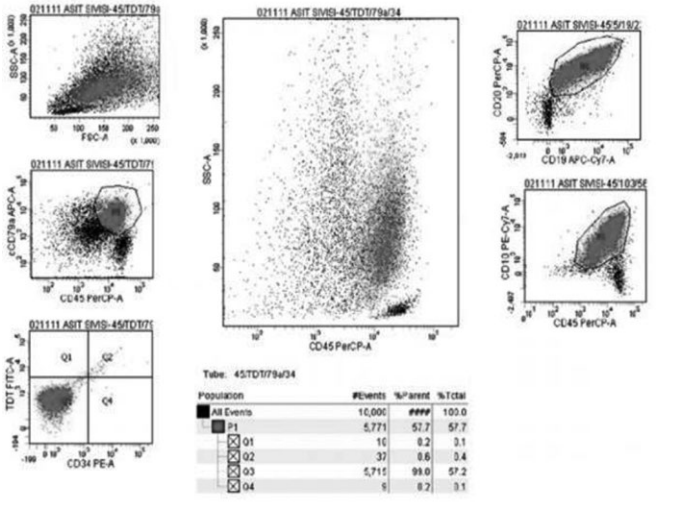

Figure 1.

Summary and Conclusions: Cytopathologic evaluation may lay long especially in the diagnosis of aggressive lymphomas which requires urgent evaluation and treatment. Immunophenotypic analysis of serous body fluids by FC can provide better access to early diagnosis and also accurate clinical staging.

PB1678

EVALUATION OF MINIMAL RESIDUAL DISEASE AND USAGE OF TARGETED THERAPY IN PEDIATRIC PATIENTS WITH ANAPLASTIC LARGE CEL LYMPHOMA

K. Katsibardi[1,*] A. Vlachou[1], N. Tourkantoni[1], E. Atmatzidou[1], S. Kostaridou[1], A. Kattamis[1]
[1]Hematology-Oncology Unit, 1st Department of Pediatrics, "Aghia Sofia" Children's Hospital, Athens, Greece

Background: Anaplastic large cell lymphoma (ALCL) is an aggressive T cell non-Hodgkin lymphoma, characterized by an increased risk of relapse. Its presentation maybe cutaneous or systemic. It is classified on the basis of the expression of anaplastic lymphoma kinase (ALK) protein, which carries the translocation t(2;5)(p23;q35) and results in the specific fusion gene Nucleophosmin (*NPM-ALK*). In 50% to 60% of patients with NPM-ALK–positive ALCL, *NPM-ALK*–expressing cells can be detected in peripheral blood and bone marrow samples by qualitative reverse-transcriptase polymerase chain reaction (RT-PCR). ALCL is designated by the uniform expression of CD30, making this surface antigen a target for immunotherapeutic approaches.
Aims: The purpose of the present report was the evaluation of minimal residual disease in children with ALCL and its usage in guiding treatment with targeted therapy, namely the anti-CD30 antibody-drug conjugate, Brentuximab vedotin.
Methods: RT-PCR for *NPM-ALK* was performed in bone marrow or peripheral blood samples in two pediatric patients with NPM-ALK–positive ALCL, at regular time points.
Results: The first patient is an 11-year-old girl with systemic NPM-ALK–positive (lymphadenopathy, skin, orbit and central nervous system involvement). She achieved remission and completed chemotherapy based on the AEIOP protocol. Three months after treatment completion she presented with disseminated relapse and required ventillatory support. She started targeted treatment with Brentuximab vedotin. She promptly responded to the treatment and she was able to be weaned off ventillatory support within 3 days after the infusion. The patient entered clinical and radiological remission (MRI and PET scan) with Brentuximab vedotin given at dose of 1.8 mg/kg IV every 3 weeks. She received a total of 6 cycles and subsequently underwent mega-therapy with autologous bone marrow transplantation rescue. Six months after transplantation, RT-PCR for *NPM-ALK* became positive, while the patient remained in clinical remission and the imaging examinations were negative for disease. Brentuximab vedotin was reinstituted and she entered molecular remission with negative minimal residual disease after the 5th cycle. The second patient is a 9-year-old boy with systemic NPM-ALK–positive ALCL, presenting with an abdominal primary mass. He completed chemotherapy and is monitored by radiological examinations and RT-PCR for *NPM-ALK* at regular time points. Minimal residual disease in this patient remains negative six months after the end of therapy.
Summary and Conclusions: Recent advances in the treatment of adult patients with NPM-ALK–positive ALCL have led to better follow up and expanded options of therapeutic modalities, especially for patients who relapse. Early detection of relapse by assessing minimal residual disease with molecular techniques seems to be superior to classical clinical risk features, identifying a high risk for overt relapse group of patients, which can be amenable by alternative therapeutic approaches. In conclusion, the potential use of minimal residual disease detection and second-line treatment like the novel antibody-drug conjugate, Brentuximab vedotin, warrant further evaluation for pediatric patients with CD30-expressing ALCL.

PB1679

PERFORMANCE OF THE NGS-BASED LYMPHOTRACK® IGK ASSAY: IDENTIFYING AND MONITORING CLONALITY IN LYMPHOPROLIFERATIVE DISEASE

Z. Xie[1,*] K. Hutt[1], W. Huang[1], M. Klass[1], J.E. Miller[1]
[1]Invivoscribe Technologies, Inc., San Diego, United States

Background: During B-cell development functional immunoglobulin genes are assembled from individual V, D, and J gene segments to generate V-D-J combinations of length and sequence that are unique for each cell. Rearrangements within IGH occur first, followed by IGK. Along with the Vk and Jk segments, there are other elements in the IGK loci that can be involved in recombination. The Kde can rearrange to Vk gene, but also to an isolated RSS in the Jk-Ck intron (INTR). If IGK rearrangements that produce functional IgH/IgK molecules are not successful, rearrangement proceeds within the other immunoglobulin light chain (IGL) locus. Leukemia and lymphomas originating from the malignant transformation of individual lymphoid cells generally share one or more of these cell specific or "clonal" gene rearrangements. Assays that identify clonal lymphocyte populations in clinical specimens are used on a routine basis to assist in the diagnosis of lymphoproliferative disease.
Currently, most IGK clonality assays use multiplex PCR followed by capillary electrophoresis. However, these methods often do not provide sufficient analytical sensitivity and are incapable of identifying the specific rearranged DNA sequence data required to track clones in follow up testing. The emergence of cost-effective, next-generation sequencing (NGS) platforms and development with associated bioinformatics tools have resulted in powerful new approaches for clonality detection and monitoring.
Aims: To establish the performance of a sensitive, robust and reliable NGS assay formatted for the Illumina® MiSeq instrument that includes the bioinformatics tools to identify clonal IGK gene rearrangements and the corresponding specific V-J DNA sequence information.
Methods: LymphoTrack® IGK Assay (Invivoscribe, Inc., San Diego, CA USA) uses a single PCR multiplex master mix to amplify each sample (24 indices,5 reactions each, are included in each kit).The amplicons were purified using the AMPureXP system and purified equimolar amounts of amplicons were pooled to generate a library. A portion of the library was sequenced on a MiSeq instrument using the MiSeq v2 Reagent kit (500 cycles). The MiSeq data was analyzed using LymphoTrack® bioinformatics software, which generated frequency distributions and identified the rearranged DNA sequences.
Results: Data generated with the LymphoTrack® IGK Assay and bioinformatics software identified clonality and corresponding DNA sequences of IGK Vk-Jk, Vk-Kde, and INTR-Kde gene rearrangements. The results obtained generally were concordant with results of testing with capillary electrophoresis. The assay demonstrated excellent linearity, sensitivity, and reproducibility using contrived samples. This assay was used to test genomic DNA from peripheral blood, bone marrow and FFPE specimens. In addition, this NGS testing approach identified the specific break point sequence of the INTR element.

Summary and Conclusions: A comprehensive NGS assay has been developed for the Illumina MiSeq platform that identifies clonal IGK Vk-Jk, Vk-Kde and INTR-Kde rearrangements and the associated specific DNA sequences. The assay can be used both to detect and monitor clonal populations.

PB1680

PRIMARY CENTRAL NERVOUS SYSTEM POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER (PTLD-CNS) IS AN EBV-RELATED DISEASE WITH GOOD RESPONSE TO ISS REDUCTION AND RADIOTHERAPY: SINGLE-CENTER STUDY OF 16 CASES

E.M. Cavalcante[1,*] G.F. Perini[1], J. Garibaldi Jr[1], A.M.D. Penna[1], J.C. Vargas[1], J.O.M. Pestana[2], O.C.G. Baiocchi[1]
[1]UNIFESP-Federal University Of São Paulo, [2]Hospital do Rim e Hipertensão, São Paulo, Brazil

Background: Post-transplant lymphoproliferative disorders are a heterogenous group of diseases occurring in the setting of post-transplant immunossupression. Clinically, extranodal involvement is common, and it occurs in the CNS in approximately 7-15% of cases. Most data on PTLD-CNS are based on case series/reports, with an exception of a multicenter study of 84 patients. In this group, PTLD-CNS showed to be a poor prognosis, late-ocurring EBV-associated disease. We retrospectively analyzed 16 cases of PTLD-CNS in Hospital do Rim, Sao Paulo, Brazil.
Aims: To analyze the cases of PTLD with CNS involvement diagnosed on our center over the past 17 years.
Methods: From 1998 to 2014, a total of 11,284 kidney transplants were performed at Hospital do Rim e Hipertensão/UNIFESP (Federal University of São Paulo). We retrospectively analyzed cases of PTLD with CNS involvement diagnosed over the past 17 years. Only confirmed cases of PTLD with available clinical and epidemiological data were included.
Results: From 1999 to 2014, a total of 20 patients were diagnosed with PTLD-CNS. Four patients were excluded from the analysis due to conflict data. Among 16 patients, the median age at time of diagnosis was 40, with a male:female ratio of 0,77:1. 56% of patients received ATG at the time of transplant. Regarding immunossupression (ISS), all patients received Prednisone, 37,5% received FK, 43,7% received MMF, and 56,2% received CSA. The median time of transplant to PTLD was 93 months, with 25% patients with polymorphic PTLD and 75% with monomorphic PTLD (DLBCL). Regarding EBV positivity, 14/16 were EBV+, with 1 EBV- and 1 inconclusive. All patients had ISS reduction, 43% of patients received brain radiotherapy. Only 1 patient received high dose Methotrexate. 75% of patients responded to treatment. No death related to lymphoma progression was observed: four patients died, all of them due to infectious complications, and none of them during therapy.
Summary and Conclusions: In our population, CNS-PTLD was an EBV-related disease with good response to ISS reduction and radiotherapy, with most patients achieving responses. No death due to disease progression was observed. Late effects of brain radiation, however, should be taken in account when deciding the best therapy for this rare complication of transplant.

CIRCUMCISION AND COMPLICATIONS IN ADOLESCENT AND ADULT PATIENTS WIITH HEMOPHILIA IN SOUTHERN PART OF TURKEY

I. Sasmaz[1,*] B. Antmen[1], B. Guvenc[2], B. Karagun[1], Y. Kilinc[1], A. Aridogan[3]
[1]Pediatric Hematology, [2]Hematology, [3]Urology, Çukurova University, Adana, Turkey

Background: Circumcision is the oldest and most frequent surgical procedure in the world and especially in Turkey as is seen in the other Islamic countries because of religious and traditional pressures. The world health organization defines an adolescent as any person between ages 10 and 19. The social pressures are very strong in adolescent patients and especially adult patients. In this study, we aim to report the experience of circumcision at Çukurova University in total 36 adolescent and adult patients with hemophilia between 1994 and 2013.
Aims: We retrospectively reviewed medical records of 33 hemophilia patients without inhibitors and 3 hemophilia patients with inhibitors who had been circumcised. Before the year 2000, factor concentrates were given before and after circumcision for 6-7 days. After 2000, we used fibrin glue together with factor concentrates for only 3 days. By-passing agents were used for circumcision in hemophilia patients with inhibitors.
Methods: We retrospectively reviewed medical records of 33 hemophilia patients without inhibitors and 3 hemophilia patients with inhibitors who had been circumcised. Before the year 2000, factor concentrates were given before and after circumcision for 6-7 days. After 2000, we used fibrin glue together with factor concentrates for only 3 days. By-passing agents were used for circumcision in hemophilia patients with inhibitors.
Results: 33 patients with hemophilia were circumcised in our centre under general anesthesia except for 3 patients who were given local anesthesia. Eight of 33 hemophilia patients (24,2%) without inhibitors had 5 mild and 3 moderate bleeding complications. A few patients had significant bleeding despite adequate factor replacement. Two of three hemophilia patients with inhibitors had 2 mild bleeding complications.
Summary and Conclusions: Our experience showed that circumcision for patients with hemophilia should be carefully performed by surgeons together with pediatric hematologist under appropriate conditions in hemophilia centers which has comprehensive coagulation lab.

PB1683

MONITORING OF TREATMENT WITH BYPASSING AGENTS IN PATIENTS WITH ACQUIRED AND CONGENITAL HAEMOPHILIA WITH INHIBITORS USING ROTEM: A SINGLE-CENTRE EXPERIENCE

A. Balta[1,*] M. Tornemo[1], V. Radulovic[1], F. Baghaei[1]
[1]Coagulation Department, SAHLGRENSKA University HOSPITAL, Gothenburg, Sweden

Background: Acquired and congenital haemophilia with inhibitor against FVIII or FIX are usually managed with bypassing agents, such as recombinant factor VIIa (rFVIIa) and activated prothrombin complex concentrates (APCC). To be able to evaluate and predict the clinical effects of treatment with bypassing agents, global coagulation assays could be useful monitoring tools. One of the currently leading candidate methods for this purpose is thromboelastography/rotational thromboelastometry (TEG/ROTEM).
Aims: Our purpose is to evaluate the changes in ROTEM parameters during treatment with bypassing agents and its correlation with the clinical effect.
Methods: In this retrospective study 11 haemophilia patients were included (age 5-85 years). Four (n:4) were patients with congenital severe haemophilia A with inhibitors and seven (n:7) were patients with acquired haemophilia A. Recorded total 15 bleeding episodes, acute or associated to surgical procedures and all of the patients treated with APCC. Monitoring of global hemostasis was performed with ROTEM assay, before and after bypassing agent administration.
Results: Excellent and good haemostatic effect was demonstrated in 87% of patients. One patient had adverse effect complicated with thrombosis. According to ROTEM analysis in NATEM the average of clotting time (CT) before and after APCC administration was 2110 sec and 888 sec respectively. Furthermore the clot stability was evaluated with maximum clotting firmness (MCF) parameter and that was 11 mm and 62 mm before and after APCC administration respectively.
Summary and Conclusions: The results of this single-centre report demonstrates, in a limited number of patients, improvement in ROTEM parameters (CT and MCF in NATEM) after APCC administration. In the most of the cases these results accompanied with good or excellent clinical response (87%) in

bypassing agent treatment. According to our data the ROTEM method could be a useful monitoring tool to predict the efficacy of treatment with bypassing agents in haemophilia patients with inhibitors. Undoubtedly further studies should be performed with adequate number of patients in order to reinforce our conclusion.

PB1684

RARE BLEEDING DISORDERS IN OMANI CHILDREN: A SINGLE CENTER EXPERIENCE

M. Elshinawy[1,2,*] A. Rawas[1], Y. Wali[1]
[1]Pediatric hematology, SQUH, Muscat, [2]Pediatrics, Faculty of Medicine, Alexandria University, Alexandria, Egypt, Oman

Background: Rare bleeding disorders (RBDs) are autosomal recessive heterogeneous group of inherited coagulation factor deficiencies, with a prevalence varying between 1:500,000 and 1:2,000,000. Remarkably, there is a paucity of data on RBDs from the Middle East. Despite education and social modernization, Oman still has a high prevalence of consanguineous marriage, reaching more than 50% of all registered marriages. Being mostly autosomal recessive, RBDs are expected to be relatively high in such community compared to western countries.
Aims: The aim of the current work is to study the demographic characteristics, clinical presentations and management of RBDs in Omani pediatric patients.
Methods: Retrospective data analysis of all children diagnosed with inherited coagulation factor deficiencies in Pediatric Hematology Unit, Sultan Qaboos Universsity Hospital, Muscat, Oman from January 2009 till December 2014.
Results: Deficiencies of fibrinogen, FV, FVII, FX and FXIII were diagnosed in 16 pediatric patients (7 males and 9 females), accounting for 9.5% (16/169) of all children with inherited coagulation factor deficiencies. The age ranged from 3 days to 6 years and consanguineous marriages were found in 13/16 cases (81.3%). The clinical spectrum varied from mild mucocutaneous bleeding to serious sight-threatening retrobulbar and intraocular hemorrhage with subsequent unilateral enucleation. As an initial presentation, intracranial hemorrhage occurred in 5/16 cases (31.3%). Two patients (12.5%) suffered from global developmental delay due to severe intracranial hemorrhage in early infancy. Four patients (3 with FV deficiency and 1 with FXIII deficiency) are on regular prophylaxis. The detailed demographic data, clinical presentations, complications and management of all patients are shown in Table 1.

Table 1. Demographic data and clinical characteristics of pediatric patients with rare bleeding disordes.

Data	Afibrinogenemia	Hypofibrinogenemia	FV def	FVII def	FX def	FXIII def
Number	3	4	4	3	1	1
M:F	1:2	1:3	1:1	1:2	1:0	1:0
Age range	3 d-6 m.	6-18 m.	2 m-6 y.	2-6 m.	9 m.	5 d.
Consanguinity %	100%	75%	75%	66.6%	100%	100%
Intracranial *	1	-	2	1	-	1
Umbilical stump*	2	1	-	-	-	-
Musculoskeletal*	-	-	1	1	-	-
Post circumcision*	1	1	-	-	1	-
Muco-cutaneous*	3	4	1	2	1	-
Intraocular*	1	-	-	-	-	-
Developmental delay	-	-	1	-	-	1
Treatment	Cryoppt	Cryoppt	FFP	rFVIIa	APCC	Cryoppt
Prophylaxis	-	-	3 cases	-	-	1 case

* bleeding site, def:deficiency, d: days, m: months, y: years, cryoppt: cryoprecipitate, APCC: Activated prothrombin complex concentrate, FFP: fresh frozen plasma, rFVIIa: recombinant activated FVII.

Summary and Conclusions: In conclusion, children with RBDs constitute almost one tenth of cases of hereditary coagulation factor deficiencies in our center. They have some unique features in terms of severity, clinical profile and the need for prophylaxis early in life. We recommend establishing a national/regional registry of RBDs in collaboration with other centres in Oman and the Middle East. This will serve to identify the epidemiology, clinical presentations, genotype-phenotype correlation and therapeutic options of such rare, yet significant disorders in this part of the world.

PB1685

COMBINED FV AND FVIII DEFICIENCY (F5F8D) IN A CHINESE FAMILY WITH A NOVEL MISSENSE MUTATION IN MCFD2 GENE

A. Wang[1,*] X. Liu[1], J. Wu[1], Z. Sun[1]
[1]Hematology, Anhui Provincial Hospital; Anhui Provincial Hemophilia Treatment Center, Hefei, China

Background: Mutations in LMAN1 or MCFD2 genes cause a rare autosomal recessive bleeding disorder, which was named combined FV and FVIII deficiency (F5F8D). Encoded proteins by MCFD2 and LMAN1 genes which may form a Ca2+-dependent cargo receptor complex have been confirmed to participate in the transport of FV and FVIII from the endoplasmic reticulum (ER) to the Golgi. We made a diagnosis F5F8D by findings of decreased FV and FVIII levels in a Chinese family.
Aims: Try to study the molecular mechanism of the disease and observe the clinical features and treatment in this family.
Methods: We do a molecular genetic analysis in the family. All the exons of LMAN1 and MCFD2 genes were PCR amplified and sequenced.
Results: We found a novel missense mutations p.Asp81Ala in MCFD2 gene in a Chinese family. The patient was homozygous missense mutation for Asp81Ala in exon 3 of MCFD2 gene, while his father and one of his sisters were heterozygous. LMAN1 gene in this family was revealed no additional mutations.
Summary and Conclusions: The presence of consanguineous marriage in the family played an important role in the cause of this disease. The Asp81 missense mutations reported in MCFD2 to date was carried out from the many patients, like Asp81Tyr and Asp81Asn, while the mutations 'Asp81Ala' have not previously been reported. Therefore, It seems likely that the mutation in the Asp 81 is a hot region, The Asp81 residue replacement by Ala most likely disrupts the MCFD2–LMAN1 cargo receptor complex.

PB1686

SURGICAL MANAGEMENT OF ELECTIVE SURGERY IN PATIENTS WITH MILD HAEMOPHILIA FROM A SINGLE INSTITUTION

L. Lacalle[1,*] N. Espinosa[1], A. Segura[1], J. M. Calvo[1], N. Fernandez[1], P. Delgado[1]
[1]HUMS, Zaragoza, Spain

Background: There is a spectrum of severity of haemophilia, defined as 'mild', 'moderate' or 'severe' according to the plasma levels of FVIII or FIX activity. Mild haemophilia may not be diagnosed until a minor surgery causes prolonged bleeding. Although general surgery in patients with 'mild' haemophilia has become more common, the surgical literature concerning these patiens remains limited.
Aims: The purpose of this single centre retrospective study was to investigate perioperative management and outcome of mild haemophiliac patients undergoing different surgical procedures.
Methods: For this study, we revised 12 mild hemophilia patients, who underwent 31 surgical procedures between 2008 and 2014 at our institution. Classification into minor/major surgery was carried out according to the BUPA system. We analized the hematologic diagnosis, type of surgery, genetic mutation linked to haemophilia, treatment undertaken to correct the bleeding disorders, the dose and duration of clotting factor administrated and post-surgical complications.
Results: We revised a total of 31 surgical procedures performed in 12 mild haemophilia patients, 9 Haemophilia A (HA) and 3 Haemophilia B (HB). Median age at surgery 37 years (range: 20-54). No patients received an anticoagulatory prophilaxys for perioperative management. Among this haemophiliac group, 5 patients (41.6%) were hepatitis C seropositive who did not receive antiretroviral therapy. We didn´t found any seropositive for HIV or other viral disease. Molecular study was available in 7 patients (6 HA and 1 HB). 6 patients showed missense mutations: exon 14 (p.Arg698Trp), Exon 7 (p.Val 266Ala), Exon 2 (c.6374G>A), exon 12 (p.Arg593Cys), Exon25 (p.Asp2267Gly) and Exon 3 (p.Asp82Glu) and exon 2 (c.6374G>A) in 1 HB patient. Data about surgery, pre and post procedure treatment are seen in Table 1, 23 (74.2%) were minor and 8 (25.9%) were major surgery. Loco-regional anaesthesia was performed in 22 (70.9%) procedures. 8 (66.7%) patients (6 HA/2 HB) underwent more than one surgical procedure. Pre and post-procedure dose of factor replacement treatment were adjusted according WFH guidelines. Plasma derived FVIII was employed in 2 patients during 4 procedures and recombinant FVIII or FIX were employed in 9 patients. Desmopressin alone and tranexamic acid alone were employed in 2 patients who underwent dental extraction (no wisdom tooth). Regarding minor procedures, 20 patients received Tranexamic Acid IV on postoperative days 1, 2 and 3. Before surgery, 1 patient who underwent 1 surgical procedure (dental extraction) showed a baseline factor level 5%>10%, 6 patients (12 procedures) showed factor levels 10%>20%, 5 patients levels 21%>30% (16 procedures) and 2 patients (2 procedures) 31%>40%. One HB patient (3.2% of all procedures) with a baseline factor level of 7.6% developed local bleeding after dental extraction although preoperative dose of recombinant FIX was administered, and he required one additional dose of recombinant FIX. No inhibitor development was observed.

Table 1.

SURGICAL PROCEDURES

Dental procedures	Dental implants Dental extractions	17 1
Orthopedic procedures	Arthroscopies Osteosynthesis Osteosynthesis material extraction	2 3 2
Urological surgery	Testicular torsion	1
Another surgeries	Inguinal repair Haematoma muscle drainage Fibroma extirpation Skin suture Foot surgery	1 1 1 1 1

Summary and Conclusions: Surgical procedures in patients with mild haemophilia can be performed with low hemorrhagic morbidity rates when there is good haematological support and appropriate hemostatic treatment. There was no association between the type of product used in perioperative period and inhibitor development in our group of patients. It is important that minor surgery should be scheduled to use desmopressin analogs +/- antifybrinolytics agents instead of recombinant clotting factor VIII/IX to minimize the risks of therapies and reduce overall treatment costs.

PB1687

CHANGES IN THE HEMOSTATIC SYSTEM IN PATIENTS WITH APLASTIC ANEMIA

V. Kobilyanskaya[1,*] S. Bessmeltsev[2], E. Shilova[2], T. Morozova[1]
[1]Hemostasiological Laboratory, [2]Hematological department, Russian Research Institute of Hematology and Transfusiology of the FMBA of Russia, St-Petersburg, Russian Federation

Background: Introduction. Since the first description by Paul Arliam acquired aplastic anemia (AA) over 100 years ago, but today this disease remains in the spotlight hematologists and physicians in adjacent fields. AA-a serious disease of the blood system, resulting from damage to the stem cells (precursors of all blood cells), resulting in a profound inhibition of normal hematopoiesis with the development of pancytopenia. One of the main clinical manifestations is hemorrhagic syndrome caused by thrombocytopenia. Moreover, the clinically significant hemorrhagic syndrome is observed usually only with severe thrombocytopenia. In connection with this, is of great interest the study of the compensating functions of the system of hemostasis in AA – patients.
Aims: The search for diagnostic markers hypercoagulation status in patients with AA.
Methods: The research material was venous blood 25 patients (17 men and 8 women, mean age 38±0,5), with a diagnosis of aplastic anemia". Plasma level of hemostasis was evaluated in the following coagulation tests: activated partial thromboplastin time (APTT), prothrombin time Quick (PT), thrombin time (TT), the concentration of fibrinogen (Fg), the activity of the factor VIII activity of antithrombin (AT). The control group consisted of 40 clinically healthy men and women of similar age.
Results: Compared to the normal performance of screening tests (APTT, PV, TV, FG) in 18 (72%) of 25 patients reported a significant increase in the activity of factor VIII, which is usually regarded as an indicator hypercoagulation state of hemostasis (189,8%±96,5% against normal value 119,0%±30.5%, P<0,001). However, in 8 (44%) of 18 patients with elevated factor VIII revealed reduced levels of antithrombin, which amounted to 68% (fluctuations from 74% to 62%). However, clinical manifestations hypercoagulation syndrome (thrombosis and thromboembolism) single patient not were observed.
Summary and Conclusions: Thus, in patients with AA showed increased activity of factor VIII and decreased levels of anti-thrombin. Whether these indicators markers hypercoagulation state, or is it a manifestation of compensatory functions, which prevent severe hemorrhagic complications in this category of patients. Research in this direction continues.

PB1688

FACTOR VII DEFICIENCY IN WEST ALGERIA

D. Benlaldj[1,*] M. Moueden[1], W. Homane[1], F. Seghier[1]
[1]HEMOBIOLOGIE, CHU ORAN, oran, Algeria

Background: Factor VII deficiency is one of the rare inherited bleeding disorders, the frequency is 1/500000. His molecular study is very interesting because of its rarity.
Aims: The objectif of this study was to describe the bleeding tendencies and the variation of factor VII level.
Methods: Retrospective study coducted for 7 years (2008 to 2014) in the west Algeria. 63 patients has been tested for diagnosis of rare bleeding disorder.
we use the assigned categories of clinical bleeding severity of European Network of Rare Bleeding Dsorders: 1. Asymptomatic (no document bleeding episodes). 2. Grade I bleeding (bleeding that occured after trauma or drug ingestion). 3. Grade II bleeding (spontaneous minor bleeding, bruising, ecchymosis, minor wounds, oral cavity bleeding, epistaxis and menorrhagia). 4. Grade III bleeding (spontaneous major bleeding, hematomas, hemarthrosis, central nervous system, gastrointestinal and umbilical cord bleeding).
Results: 18 patients (28.57%) diagnosed with factor VII deficiency, 06 patients have factor level<10% classified with severe form, 01 patients had factor level between 10 and 20% classified with moderate form and 11 patients have factor level >20%, according the classification of Europen Network of Rare Bleeding Disorders. Regarding the clinical severity 10 patients are asymptomatic (factor level >30%), 07 patients classified on grade II (factor level between 01 and 40%) and 01 patients on grade III (factor level<5%). The oral cavity bleeding (25%) and hematoma (17%) are the frequent bleeding symptom in our patients. The molecular study performed for 05 patients from the same family revealed a mutation c.430+78 G>A and polymorphism IVS7H7 in the homozygous state (02 patients), in the heterozygous state (03 patients).
Summary and Conclusions: Not corelation found between factor VII level and the clinical severety. This results are according the literature database.
The diagnosis of factor VII deficiency is depending the laboratory testing (level factor depending to the reagent) and the bleeding severety define the disease. The mutation c.430+78 G>A and polymorphism IVS7H7 are described in the literature and involved in the modulation rates of factor VII.

PB1689

ANGIODYSPLASIA IN A CHILD AS A CAUSE OF LOWER GASTROINTESTINAL BLEEDING FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION, WHICH WAS SUCCESSFULLY CONTROLLED BY ANGIOEMBOLIZATION

I. Eker[1,*] O. Gürsel[1], O. Babacan[1], O. Koç[2], M.S. Uğurel[3], A.E. Kürekçi[4]
[1]Pediatric Hematology, Gulhane Military Medical Faculty, [2]Pediatrics, [3]Radiology, [4]Pediatric Hematology, Gülhane Military Medical Faculty, Ankara, Turkey

Background: Gastrointestinal complications are common following hematopoietic stem cell transplantation (HSCT); however angiodysplasia is not well characterized in terms of its association with HSCT and only a few reports of angiodysplasia in transplant recipients are available, all of them are adults.
Aims: Here we report a 7 years old child with a massive lower gastrointestinal bleeding, caused by angiodysplasia (vascular ectasia) following HSCT. To our knowledge, this is the first reported pediatric case demonstrating the association of angiodysplasia with HSCT and successfully controlled by angioembolization.
Methods: The patient was a 6-year-old boy who underwent HSCT for relapsed acute lymphoblastic leukemia. He was in remission at the time of transplant. Preparative regimen consisted of 12 Gy total body irradiation and 60 mg/kg etoposide. He received $2{,}4x10^6$/kg CD34+ stem cells from his well-matched father (one antigen mismatched at HLA-C). Cyclosporin was administered for GVHD prophylaxis. Full engraftment was achieved with neutrophil, platelet and erythrocyte recovery being 13, 20 and 27 days respectively. On the 14th day of transplantation grade IV acute graft-*versus*-host disease (GVHD) was developed (skin stage III, liver and gastrointestinal tract stage IV). Skin manifestations were resolved, but liver and gastrointestinal GVHD went on depite prednisolone therapy and the increase of cyclosporin. However, thrombotic microangiopathy (TMA) was developed on the 19th day and resolution was not achieved despite the switch of cyclosporin to mycophenolate mofetil. He underwent therapeutic plasma exchange sessions on alternate days. The resolution was achieved after 14 sessions, liver GVHD was also resolved, but gastrointestinal symptoms went on with recurrent massive gastrointestinal bleeding despite therapies including octreotide, recombinant human coagulation Factor VIIa and third party mesenchymal stem cells. The localization of the gastrointestinal bleeding couldn't be identified despite nuclear medicine scan, endoscopy and colonoscopy. The localization of the bleeding couldn't be identified with transcatheter arteriography also, but there were seen angiodysplastic lakes in branchs of celiac, gastroduodenal and superior mesenteric artery (Figure1). With the suspicion of these lakes may be the origin of bleedings, superselective embolization was performed and gastrointestinal bleeding episodes were resolved completely without any complication. Occult gastrointestinal bleeing was also became negative after ten days of the embolization and he was discharged on the 130th day of HSCT.
Results: In the literature on the subject, it is observed that HSCT associated gastric vascular ectasias are with a prior TMA episode and suggested that local endothelial injury and subsequent local thrombosis in TMA may obstruct submucosal blood vessels and eventually lead to development of vascular ectasia. The fibrin thrombi and/or ectasia in mucosal vessels observed histologically in these patients supported their hypothesis
Summary and Conclusions: In conclusion, angiodysplasia is a rare but important cause of recurrent intestinal bleeding in children and should be kept in mind as a diagnostic possibility especially in HSCT patients who have a history of TMA. Early diagnosis of this rare lesion is important to avoid a possible fatal outcome and thus the physician should be aware of this lesion as a rare cause of intestinal bleeding in children.

PB1690

RELATION BETWEEN INHIBITOR PRODUCTION AND BCLI/INTRON 18 AND VNTR ST14 POLYMORPHISMS IN A IRANIAN POPULATION WITH HEMOPHILIA A

N.B. Mirbehbahani[1,*] A. Rashidbaghan[2], S. Livani[1], A. Khosravi[1]
[1]Golestan University of Medical Science, Gorgan, [2]2Medical Biology Research Center, Kermanshah University, Kermanshah, Iran

Background: According to several reports, 20-30% of severe hemophilia A and 1-3% of severe hemophilia B patients develop inhibitors. There is a collection of mutations related to production of inhibitor in hemophilia A.
Aims: In factor VIII gene that is associated hemophilia A, the most useful polymorphisms are bi-allelic that are formed by a single nucleotide substitution. Identifying these mutations can help to diagnosis the susceptible people for this disorder. Here, two of these mutations were studied in Iranian Hemophilia with inhibitor production.
Methods: We have 150 patients with hemophilia and rare bleeding disorders in our center. It was studied all of patients with hemophilia A from our center. Inhibitor was tested for all of them and cases with inhibitor >0.5 BU determined. 20 patients from 80 had inhibitor. BclI/intron 18 and VNTR st14 polymorphisms of factor VIII gene were analyzed in 20 patients of hemophilia A with inhibitor. DNA was extracted from whole blood. RFLP and usual PCR techniques were done for BclI/intron 18 and VNTR st14, respectively. Results: In this population, 55% had a restriction site on BclI. All of patients were homozygote for VNTR st14 and just one allele was observed.
Results: In this population, 55% had a restriction site on BclI. All of patients were homozygote for VNTR st14 and just one allele was observed.
Summary and Conclusions: The observed BclI/intron 18 was quite high in our cases in comparison other hemophilias without inhibitor. But, the heterozygosity rate for VNTR st14 was different in our study in comparison with other hemophilias without inhibitor. Therefore BclI/intron 18 can increase risk of production of inhibitor in Iranian population.

PB1691

SEQUENTIAL THERAPY WITH ACTIVATED PROTHROMBIN COMPLEX CONCENTRATES AND RECOMBINANT FVIIA IN PATIENTS WITH SEVERE HAEMOPHILIA A, INHIBITORS AND LIFE THREATENING BLEEDING

M. Mitrovic[1,2,*]P. Miljic[1,2], A. Darko[1,2], B. Jelena[1], L. Daniejla[1], I. Elezovic[1,2]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background: Haemophilia patients with inhibitors can develop bleeding episodes refractory to monotherapy with either recombinant factor VIIa (rFVIIa) or activated prothrombin complex concentrates (APCC). These bleeds are often very difficult to treat and can result in significant morbidity. For such patients, therapies with sequential administration of standard doses or concomitant administration of lower dose of rFVIIa and APCC have been suggested. However, treatment with a combination of these agents is not widely practiced.
Aims: To present our experience of sequential therapy with rFVIIa and APCC in patients with severe haemophilia A, inhibitors and life threatening bleeding.
Methods: We reviewed the medical records of all the inhibitor patients for whom sequential therapy was prescribed, defined as having received both APCC and rFVIIa within 6 h of each other.
Results: Case 1) A 19 year's old patient with sever haemophilia A and previously detected inhibitor (11 BU) developed intracranial hemorrhage. He was treated with rFVIIa in dose 90 µg/kg/2 h. Due to very bad venous access central venous catheter was inserted with rVIIa (120 µg/kg every 2 hours, 2 dose). Four hour after surgery massive neck oedema and breathless developed. CT scan showed diffuse large neck muscle and soft tissue hematoma. Therapy with APCC 100 U/kg/12h and rFVIIa 90 µg/kg every 2 to 3 hours resulted in bleeding control. After 12 h of sequential usage, therapy was continued with rFVIIa. Case 2) A 35 year's old patient with sever haemophilia A and previously detected inhibitor (220 BU) developed spontaneous mediastinal and pericardial bleeding, without sings of tamponade. He was treated with APCC 100 U/kg/12h. Two days after admission haemoglobin level decreased from 134 to 78 g/L. CT showed massive mediastinal bleeding complicated with pleural effusion. Therapy was continued with rFVIIa 90 µg/kg every 2 hours, APCC 100 U/kg/12 h and blood transfusion. After 24 h of sequential usage therapy was continued with APCC. Case 3) A 19 year's old patient with sever haemophilia A and previously detected inhibitor (20 BU) was prepared for tooth extraction with rFVIIa (90 µg/kg). Extraction was complicated with massive subconjuctival, infraorbital and buccal hematoma with difficult swallowing. Dose of rFVIIa was increased to 120 µg/kg every 2 hours, without effect. Sequential therapy with rFVIIa 90 µg/kg/2 hours and APCC 100 U/kg/12 h was continued and bleeding was stopped. After 24 h of sequential therapy treatment was continued with APCC. Symptoms and sings of thrombosis and disseminate intravascular coagulopathy, as well as d dimer elevation were not seen in our patient's during sequential therapy.
Summary and Conclusions: Our report confirms efficacy and the safety of short course sequential rFVIIa and APCC for the management of life threatening bleeding refractory to monotherapy with APCC or rFVIIa. However, controlled trials with a larger number of patients are required to further assess the safety, efficacy and cost benefit of this treatment.

PB1692

PREOPERATIVE SCREENING FOR BLEEDING DISORDERS: OUTCOME OF EVALUATION IN CHILDREN WITH ABNORMAL TESTS

A. Rajendran[1,*] J. Scott[2]
[1]Pediatric Hematology Oncology, Sri Ramachandra Medical College and Research Institute, [2]Pediatric Hematology Oncology, Sei Ramachandra Medical College and Research Institute, Chennai, India

Background: Children prior to invasive procedures undergo screening tests with platelet count and basic ciagulation studies like prothrombin time (PT), Partial Thromboplastin Time (PTT) to identity children with bleeding disorders
Aims: This study aims at studying the outcome of these children with abnormal screening tests or positive bleeding history
Methods: Case records of children who satisfy the inclusion criteria and evaluated in the last 5 years (2009-2014) were analyzed for the final diagnosis and surgery details.
Results: Twenty seven children were evaluated during this five years period due to abnormal screening tests or positive bleeding history. Twenty three children tested to have a bleeding disorder with variable severity. Three children did not have any bleeding disorder on evaluation. Two had positive lupus anticoagulant and therefore prolonged PTT. The above five children underwentrequired surgery without excess bleeds. Te diseases picked up during evaluation of children with abnormal screening tests or positive bleeding history were hemophilia (5), von Willebrand disease (type3>type1) (5), mild factor 7 deficiency, mild platelet function disorder(2), Bernard Soulier syndrome (2) and Glanzmann's thrombasthenia. One third of these cjildren underwent surgery with appropriate component replacement.
Summary and Conclusions: These inexpensive screening tests coupled with a good bleeding history is an essential tool to screen children for bleeding risk. This is especially important in children who would have never been challenged till date and this will definitely prevent critical bleeding which might be life threatening.

PB1693

SUBSTITUTION WITH RECOMBINANT ACTIVATED FACTOR VII (NOVOSEVEN) IN A PATIENT WITH CONGENITAL COMBINED DEFICIENCY OF FACTOR VII AND FACTOR X DURING SURGERY OF LUNG TUMOR-CASE REPORT

V. Milosevic[1,*] M. Mitrovic[1,2], P. Miljic[1,2], M. Jurisic[3,4], D. Subotic[2,5], I. Elezovic[1,2]
[1]Clinic of hematology Clinical Center of Serbia, [2]Faculty of Medicine University of Belgrade, [3]Clinic of Oral Surgery Clinical Center of Serbia, [4]Faculty of Dental University of Belgrade, [5]Clinic of Thoracic Surgery Clinical Center of Serbia, Belgrade, Serbia

Background: Combined deficiency of coagulation factors is considered as an extremely rare bleeding disorder (RBD) inherited in an autosomal recessive pattern. Combined FX et FVII deficiency appear also associated with coagulation-unrelated abnormalities (carotid body tumors, mitral valve prolapse, atrial septal defect, ventricular septal defect, thrombocytopenia absent radius- TAR syndrome, mental retardation, microcephaly and cleft palate).
Aims: The purpose of our case report was to evaluate therapy options for prevention of bleeding in patient with hereditary combined deficiency of FVII and FX who underwent surgery.
Methods: Application recombinant activated factor VII (NovoSeven) in patient with congenital combined deficiency of factor VII and factor X during surgery of lung tumor.
Results: A 19-year- old woman admited to the hospital due to preparation treatment before teeth extraction. Combined deficiency of factors VII and X has been diagnosed when she was 14 years old (27% FVII, FX 50%). In early childhood was noted the delay in physical development, with spastic paraparesis and brachydactyly on foot. Cytogentics analysis showed a normal female karyotype. Her sister also has a combined deficiency of FVII and FX with mental retardation. Patient had surgery operation of echinococcus cyst at age of 15 years, and teeth extraction on several occasions. Prior to teeth extraction patient received fresh frozen plasma (FFP), recombinant activated factor VII (rFVIIa) and antifibrinoyitic. Intervention proceeded without complications. Few months later, she was admited for teeth extraction (15 and 16) in general anesthesia, due to mental retardation. During the administration of FFP she developed severe allergic reactions with intensive urticaria, and anesthesiologist has not consented the intervention done. After 15 days the patient received rFVIIa 20µg/kg b.w. (2mg i.v.) and tranexamic acid imidiately before teeth extraction. It was performed without complications (25% FVII, FX 43% before therapy). Two days after the intervention, the patient had chast pain. ECG, cardiospecific enzymes and D-dimer were in the reference values. X-rays and CT of the chest showed a tumor in the left lung diameters 55x51x43 mm, which could corresponded as tumor or echinococcus cyst. In December 2014, underwent resection of lung tumor with preoperative application of rVIIa in a dose of

2 mg i.v (20µg/kg b.w) The therapy was continued at the same dose at 12 h following 5 days to remove the drain. The levels of FVII were from 80% to 130% during the treatment. Histopathology examination showed hamartoma. During and after the surgical intervention she had not unexpected bleeding complications.
Summary and Conclusions: Therapy options for prevention of bleeding in patients with hereditary combined deficiency of FVII and FX, who underwent surgery, can be concentrate of rFVIIa, in dosage 20µg/kg, as the treatment of choice.

PB1694

PREVELANCE OF H PYLORI INFECTION AND RISK OF GIT BLEEDING IN EGYPTIAN HAEMOPHILIC PATIENTS
N. El Husseiny[1,*] M. kassas[2], L. Issac[2]
[1]Heamatology Department, [2]Kaser El Eini University, Cairo, Egypt

Background: : H pyelori is endemic in Egypt and present a main cause of gastrointestinal bleeding.
Aims: Aim of this study was to evaluate the prevalence of Helicobacter pylori infection in hemophilic patients, and to assess its impact on gastrointestinal bleeding associated with this infection in such patients.
Methods: Methods: we prospectively investigated the prevalence of H. pylori infection in 40 Egyptian patients with hemophilia A,B and von Willebrand syndrome and 20 male subjects were included. Every patient and control subject in the study was tested one time for H. pylori stool antigen by ELISA. All patients and control subjects were tested for occult blood using Guaiac-based fecal occult blood test.
Results: Twenty eight out of 40 patients were H. pylori positive (70%); and 12 out of 20 control subjects were H. pylori positive (60%). The odds ratio is 1.55, 95% CI (0.6162 to 3.9269), Significance level P=0.3497. Among 28 H.pylori positive patients, 5 patients tested positive for occult blood (17.9%). Among the 12 H.pylori positive subjects in the control group, only one tested positive for occult blood (8.3%). Odds ratio for Occult bleeding in H pylori positive patients and control was 2.39: P=0.4504. None of the H. pylori negative patients or control subjects had a positive occult blood disease.
Summary and Conclusions: Conclusion: We concluded that in patients with hemophilia, H. pylori should be considered as an important cause of GI bleeding. The recurrence of the infection and GI bleeding can be prevented with eradication of H. pylori. Screening test for H. pylori would be needed in patients with hemophilia in endemic areas.

PB1695

HEMOPHILIC PSEUDOTUMOR OR TUMOR? DIAGNOSTICS AND TREATMENT CHALLENGES
M. Smiljanic[1,*] M. Mitrovic[2,3], D. Antic[1,3], I. Elezovic[2,3]
[1]Lymphomas/Department of hemostasis, [2]Department of hemostasis, Clinic of Hematology Clinical Centre of Serbia, [3]Faculty of Medicine, University of Belgrade, Serbia, Belgrade, Serbia

Background: Hemophilic pseudotumor is characterized by slowly expanding, encapsulated mass. It develops as a result of extra-articular musculoskeletal hemorrhage, in 1-2% of hemophiliacs. Hemophilia treatment has significantly improved, bringing the opportunity for age-related morbidities development, including malignancies. Sometimes after imaging diagnostics, surgery is necessary for differential diagnostics.
Aims: To present hemophiliac patient with large tumor mass, initially suspected for hemophilic pseudotumor. Pathohistological finding of tumor biopsy revealed HCC metastasis with HCV infection. We discuss treatment option for such patient.
Methods: Single case report.
Results: Hemophilia B with F IX 1% was diagnosed at the age of 15. Forty years later, our patient was diagnosed with HCV infection and he received subsequent antiviral therapy. After four years, following abdominal CT finding (liver necrotic lesions) and presence of elevated serum alpha-fetoprotein (AFP, 174 ng/mL), HCC diagnosis was established. Trans-arterial chemoembolization (TACE) was opted as treatment choice but prior to intervention, right forearm painful swelling occurred. Since MRI finding of right arm and shoulder showed large tumor mass in humeroscapular region with severe osteolytic lesions of the right humerus, hemophilic pseudotumor was highly suspected. F IX concentrate substitusion was applied but with no obvious therapy response. Subsequently, tumor biopsy was performed and it revealed HCC metastasis. PET scan finding confirmed this metastasis as solitary. Several treatment options were discussed. Since HCC is known to be poor radiotherapy responder, and it would only be applied to metastasis, we excluded this treatment. Second generation tyrosin kinases inhibitors that would have a certain degree of systemic effect were not available in our country. Radical surgery that included right hand amputation was also excluded, due to a very high perioperative risk and present comorbiditiy (Diabetes mellitus type 2). Patient was subsequently treated with palliative therapy. Five months later, lethal outcome occurred, after severe bleeding in humeroscapular region.
Summary and Conclusions: A leading cause for HCC in hemophilia is HCV chronic infection. Extra hepatic metastases occur in approximately half of HCC patients, and in our case tumor biopsy revealed very unusual HCC metastasis. If HCV infection is diagnosed it has to be treated. Due to the high risk for HCC in hemophilia, regular ultrasonography should be performed. When pseudotumor is suspected, HCC possibility should also be investigated. HCC should be surgically treated in its early stage.

PB1696

ASSESSMENT OF EFFICIENCY OF DIFFERENT PLASMA DERIVED FVIII CONCENTRATES IN BLEEDING CONTROL-HEMOPHILIA PATIENTS' PERSPECTIVE
J. Bodrozic[1,*] I. Elezovic[1], D. Antic[1], D. Lekovic[1], M. Mitrovic[1], P. Miljic[1]
[1]Clinic of Haematology, Clinical Center of Serbia, Belgrade, Serbia

Background: Patients in Serbia are usually switching between different plasma derived FVIII concentrates (pdFVIII), dependent on their market availability. We observed that some of the patients expressed a personal impression that there is a difference in efficiency of different factor concentrates in achievement of bleeding control.
Aims: To investigate is there any difference regarding efficiency in achievement bleeding control in hemophilia A patients between different pdFVIII concentrates, based on analysis of subjective assessments recorded in patients diaries
Methods: We extracted the data from a personal patient diary of eight adult patients, average age of 29, with severe form of hemophilia A about spontaneous joint bleeding episodes, while they were on a low dosage tertiary prophylaxis. Over a 4-year observation period from January 2010 to March 2014, our patients received, twice a week, the same dosage (15U/kg) of pdFVIII. During this time they switched between five different pdFVIII, dependent on the availability at that specific point of time. For every bleeding episode we recorded the type of pdFVIII applied, pain intensity, graded from 1 to 10, time necessary for the bleeding to stop measured in hours and overall subjective assessment of the therapy efficiency (OSA). OSA was graded from 1, meaning that patient considered therapy completely ineffective, to 10, meaning that bleeding stopped immediately after treatment.
Results: Eight patients received first plasma derived FVIII concentrate (pdFVIII1) during altogether 88 months, second (pdFVIII2) 83 months, third (pdFVIII3) 68, fourth (pdFVIII4) 79 and fifth (pdFVIII5) during 82 months. For pdFVIII1 average bleeding frequency per month was 0.53, for pdFVIII2 0.52, pdFVIII3 0.52, pdFVIII4 0.59, pdFVIII5 0.58. Mean time for bleeding to stop while using different pdFVIII was 6.15, 5.88, 6.08, 5.91, 6,02 hours. Average OSA was 6.0, 7.38, 6.67, 6.0, 6.9, for each pdFVIII respectively. In multivariate logistic regression analysis, OSA, was highly influenced by the time necessary for the bleeding to stop (OR=0,108 CI 0,068-0,147), but not with used pdFVIII concentrate.
Summary and Conclusions: According to our results, the type of pdFVIII applied didn't have any influence on OSA as well as the pain intensity. The OSA was dependent only on the length of bleeding episode.

PB1697

FACTOR XIII DEFICIENCY WITH INTRACRANIAL HEMORRHAGE
N. B. Mirbehbahani[1,*]
[1]Golestan University of Medical Science, Faculty of Medicine, Gorgan, Iran

Background: Congenital factor XIII (FXIII) deficiency is a rare autosomal recessive coagulation disorder. This congenital disorder is associated with poor wound healing, spontaneous abortion, life-long tendency towards spontaneous bleeding and a high risk of potentially life-threatening intracranial hemorrhage.
Aims: Routine prophilaxis with FXIII concentrate is recommended in all individuals with FXIII levels of<1 IU/dl from the time of diagnosis and in some severely affected patients with FXIII levels of 1-4 IU/dl.Therefore reliable assays for FXIII are necessary not only for the diagnosis of deficiency state but also to guide prophilaxis and replacement therapy in patients during times of increased risk. In Iran, ureaclot lysis test (FXIII screen) is the most available test and reliable assays are not accessible because of limitations of laboratory equipment. Hence, we recommended prophilaxis in any cases with abnormal FXIII screen and history of intracranial hemorrhage.
Methods: In here, it is reported the clinical course and outcome of 38-month old boy with intracranial hemorrhage that successfully managed and received prophilaxy with fibrogammin® P. He had a history of recurrent spontaneous bleeding or bleeding after trauma in extremities from birth. He admitted at 27 month of age in hospital due to gluteous hematoma after muscle injection. He was tested for PLT, PT, PTT, INR, fibrinogen (clauss method) and FXIII screen (ureaclot lysis test). He had abnormal FXIII screen test and other tests were normal. He managed with fresh froze plasma before diagnosis and recommended for on demand therapy after diagnosis
Results: He admitted at 30 months of age due to headache and vomiting. Brain CT scan revealed intracranial hemorrhage. He was treated with fibrogammin® P. The prophylactic substitution therapy with fibrogammin® P 20 IU/kg every 4 weeks performed and he is free from bleeding episodes. Nugent *et al*, 2012, studied on 41 patients with congenital FXIII deficiency. Fibrogammin® P was administrated

intravenously at an initial dose of 40 IU/kg every 4 weeks, with dosing adjusted to maintain a trough FXIII activity level of 5-20%. No spontaneous bleeding episodes requiring FXIII treatment were reported during the study.
Summary and Conclusions: According to inaccessibility to reliable assays of FXIII in Iran we recommended prophilaxy with fibrogammin® P in all cases with intracranial hemorrhage.

PB1698

FACTOR II DEFICIENCY IN WEST OF ALGERIA : SINGLE CENTER EXPERIENCE

M. amine[1,*] H. wassila[1], B. Driss[1], S. fatima[1]
[1]pharmacy oran, hemobiology service, Oran, Algeria

Background: Factor II deficiency is one of the rare inherited bleeding disorders the frequency in world is 1/ $2*10^6$. But in algeria there is high consanguinity rates have increased the number of patients with Rare Bleeding Disorders (RBDs)
Aims: It was established a clinical and biological classification of patients with rare deficiency disorders. It was explored the relationship between coagulation factor activity level and bleeding severity for this patients.
Methods: A retrospective study conduct from 2008 to 2014. It was concerned 63 patients with a mean age 29 years (range1 year to 73 years) and Sex ratio ♂/♀=1.17. We use assigned categories of clinical bleeding severity of The European Network of Rare Bleeding Disorders (EN-RBD): 1. Asymptomatic : No documented bleeding episodes. 2. Grade I : bleeding Bleeding that occurred after trauma or drug ingestion (antiplatelet or anticoagulant therapy). 3. Grade II : Spontaneous minor bleeding:bruising, ecchymosis, minor wounds, oral cavity bleeding, epistaxis and menorrhagia. 4.Grade III : bleeding Spontaneous major bleeding: hematomas*, hemarthrosis, central nervous system,gastrointestinal and umbilical cord bleeding.
Results: 06 patients (09.5%) of RBDs were diagnosed with Factor II deficiency, Clinical bleeding showed that the most common symptoms in patients with FII deficiency were oral cavity bleeding(34%), followed by hematomas(17%), epistaxis (17%) .
Summary and Conclusions: Any association between bleeding manifestations and residual FII coagulant activity in plasma was found, but is very difficult to ascertain this association because the small number of reported cases. However, 03 patients with FII coagulant activity<10% reported to be associated with severe bleeding manifestations grade II and III.and a weak direct correlation between laboratory severity and the age at first bleed was noted.

PB1699

RESISTANT THROMBOSIS WITH STANDARD HEPARIN TREATMENT: ANTI-THROMBIN III DEFICIENCY

Y. Altuner Torun[1,*] M. C. Serbetci[2], G. Poyrazoglu[3]
[1]Pediatric hematology, [2]Pediatrics, [3]Pediatric neurology, Kayseri education and research hospital, Kayseri, Turkey

Background: Sinus vein thrombosis is a type of stroke anda multifactorial disease that usually manifested by non-specific symptoms in children.In most cases there is an underlying prothrombotic risk factors or a combination of many clinical reasons. The prevalence of antithrombin III deficiency in patients with thrombosis incidence is 0.02%, as this rate in normal populations is 1%.In this article, we will discuss a case with antithrombin III deficiency that he do not receive the standard heparin treatment. A twenty years old male patient with sudden onset of headache, dizziness, nausea and vomiting was admitted to our clinic.His physical examination and vital findings were stable. His cranial MRI showed thrombosis of superior sagittal sinus and the left transverse and sigmoid sinuses.Clexane(enoxaparin) started 2x1 mg/kg/daily and contunied for 15 days.There was not any recanalization in the thrombosis veins on his repeated cranial MRI after the 15 days treatment.The patient's anti-thrombin III activity was 34.8% as other normal thrombophilia tests. Antithrombin III deficiency was diagnosed. Coumadin(warfarin) treatment was started due to ineffective low molecular weight heparins. The possibility of antithrombin III deficiency should be considered when a low molecular weight heparin therapy is not effective in the follow up patients with the diagnosis of thrombosis. Sinus vein thrombosis is a type of stroke anda multifactorial disease that usually manifested by non-specific symptoms in children.In most cases there is an underlying prothrombotic risk factors or a combination of many clinical reasons.
Aims: The prevalence of antithrombin III deficiency in patients with thrombosis incidence is 0.02%, as this rate in normal populations is 1%.In this article, we will discuss a case with antithrombin III deficiency that he do not receive the standard heparin treatment.

LUPUS ANTICOAGULANT-HYPOPROTHROMBINEMIA SYNDROME IN A 7-YEAR OLD GIRL: A CASE REPORT

T. Patiroglu[1,*] E. Yılmaz[1], E. Unal[1], M. Karakukcu[1], M.A. Ozdemir[1]
[1]Pediatric Hematology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Lupus anticogulant (LA) can be associated with bleeding as a consequence of hypoprothrombinemia.
Aims: We present the report of a patient with hemorrhagic symptoms in combination of hypoprothrombinemia and LA.
Methods: A 7 year-old girl was admitted with epistaxis for 5 days. On physical examination, she had scleral icterus, echimosis and hepatomegaly. The complete blood count was normal expect hemoglobin of 47 g/l. The coagulation screening showed a prolonged prothrombin time (PT) (60.8 s) and activated partial thromboplastin time (aPTT) (118.6 s). Although a packed fresh frozen plasma was administered to the patient, the prolonge of PT and aPTT continued. Therefore, the mixing study was performed but both PT and aPTT did not improve.
Results: Factor assay revealed a low prothrombin level (4,46%). The lupus anticoagulant and anti nuclear antibody were found positivity but anti DS-DNA was negativity in advanced laboratory examination of patient respectively. Further evaluation revealed the presence of immunoglobulin (Ig) G an M anticardiolipin antibodies, IgG and IgM anti-β-2-glycoprotein antibodies, IgG and IgM anti phosphotydilserin antibodies. After 5 days of mega dose methylprednisolone (30 mg/kg/d) was administered to the patient, PT(13.6 s) and a PTT (38.4 s) were measured normal and directly Coombs test was found negatively. Therefore, mega dose methylprednisolone treatment was stopped. One month after stopping of the treatment with mega dose methylprednisolone she had again both prolonged PT and aPTT, and the positivity of directly Coombs test. In this period, it was revealed the presence of immunoglobulin (Ig) G an M anticardiolipin antibodies, IgG and IgM anti-β-2-glycoprotein antibodies, IgG and IgM anti phosphotydilserin antibodies. Hence, the patient re-treated with steroid. Her family asked the follow-up in another hospital.
Summary and Conclusions: The low dose immunosuppresive treatment in the patients with LA and hypoprothrombinemia is necessary to continue for the long time.

PB1701

NEW BIRTHS OF CHILDREN WITH HEMOPHILIA: REPORT FROM A SINGLE CENTER

M. Economou[1,*] A. Teli[1], V. Gourtsa[1], G. Lakkaki[1], S. Vakalopoulou[2], V. Garipidou[2]
[1]First Department of Pediatrics, [2]Hematology Department, Second Propedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Great progress has been reported during recent years on prenatal diagnosis of several congenital diseases, including hemophilia. In addition, pre-implantation techniques have enabled couples at risk to give birth to healthy babies. In Greece, genetic counseling is offered in specialized centers to all women carriers of hemophilia who opt to seek advice.
Aims: The aim of the present study was to report on new births of hemophilic children in Central-Northern Greece during the last 5 years (January 2010-December 2014).
Methods: Patient records of the Pediatric and Adolescent Center for Hemorrhagic Diseases were retrispecively studied. The Center is one of the 2 pediatric hemophilia centers in Greece, following all patients aged under 18 years, living in the area of Northern and in parts of Central Greece. New births in the given 5 year period were recorded, as well as data regarding age of diagnosis, disease severity, family history and prenatal counseling.
Results: During the study period 12 new patients with hemophilia A were born, 8/11 with severe hemophilia, 2/11 with moderate hemophilia and 2/11 with the mild form of the disease. Overall, 8/11 had a positive and 3/11 a negative family history. In none of the cases was prenatal screening performed, even though 6/8 cases with a known family history were associated with severe hemophilia and in one case death due to the disease in a very young age was reported. Mean age of diagnosis in the a positive history group was 9.8 months (3 days – 3 years), while in 3/8 cases bleeding episodes preceded laboratory investigation. In the negative family history group diagnosis was reported at an earlier mean age (8.5 months, 7 months-12 months), in all cases diagnosis following

a bleed. In one of the 3 patients with a negative family history, the mother was pregnant to a second baby-also a hemophiliac- when she was informed of the diagnosis of the first child, but the family did not opt for prenatal screening.
Summary and Conclusions: New births of hemophilia are still recorded, even in cases with known-even severe-family history. This could be attributed to the knowledge of progress in the management of hemophilic children, as well as to religious issues. Weaknesses in the health system's provision of information regarding availability of prenatal counseling cannot be ruled out.

PB1702

SUCCESSFUL ABDOMINAL OPERATION WITHOUT REPLACEMENT THERAPY IN A PATIENT WITH COMBINED FV AND FVIII DEFICIENCY DUE TO NOVEL HOMOZYGOUS MUTATION IN LMAN1

A. Wang[1,*] X. Liu[1], J. Wu[1], Z. Sun[1]
[1]Hematology, Anhui Provincial Hospital; Anhui Provincial Hemophilia Treatment Center, Hefei, China

Background: Surgical operations in congenital coagulation factor deficiencies' patients will increase risk of perioperative bleeding if without adequate replacement therapy. After adequate replacement therapy, patients with hemophilias can have successful experience of surgical operation. Patient with congenital combined FV and FVIII deficiency (F5F8D) can also have successful percutaneous coronary intervention after replacement therapy. There are rare reports about successful surgical operations in patients with F5F8D without adequate replacement therapy.
Aims: We reported that a patient with combined FV and FVIII deficiency had successful abdominal operation without replacement therapy and analyzed the molecular mechanism of the disease for the patient.
Methods: Before the diagnosis of the combined FV and FVIII deficiency, a 35 years old female patient was admitted for abdominal operation due to hydrosalpinx and chocolate cyst of ovary. We do a molecular genetic analysis in the family. Peripheral blood DNA was extracted. All the exons of LMAN1 and MCFD2 genes were PCR amplified and sequenced.
Results: Although with prolong activated partial thromboplastin time and prothrombin time, the patient underwent successful abdominal operation without replacement therapy. She tolerated well for abdominal operation therapy without increase risk of perioperative bleeding. Molecular analysis showed that the patient has a novel homozygous deletion mutation in exon 12 of LMAN1 (1456delGTG).
Summary and Conclusions: Our results suggest that a F5F8D patient with homozygous deletion mutation in exon 12 of LMAN1(1456delGTG) can safely undergo abdominal operation therapy for hydrosalpinx and chocolate cyst of ovary without fresh frozen plama and recombinant FVIII replacement therapy.

PB1703

SERUM FERRITIN IN PATIENTS WITH APLASTIC ANEMIA RECEIVING COMBINED IMMUNOSUPPRESSIVE THERAPY.

Z. Fidarova[1,*] E. Mikhaylova[1], V. Dvirnyk[1], V. Troitskaya[1], E. Parovichnikova[1], V. Savchenko[1]
[1]chemotherapy of hemoblastoses and bone marrow transplantation, Research Center of Hematology of Russian Ministry of Health, Moscow, Russian Federation

Background: Iron metabolism disorders in patients with AA are not only related to disease pathogenesis but to regular red blood cells (RBC) transfusions.
Aims: Analyze iron parameters before immunosupressive therapy, in time of it (meaning RBC transfusions dependence retained) and in remission phase.
Methods: A total of 85 patients from 18 to 65 years old were enrolled: 41 males and 44 females at age from 18 to 65 years old. Patients were followed up from 1 month to 3 years. Severe forms of AA were detected in 59 patients, non-severe in 26 pts. All patients received immunosupressive therapy (ATG + cyclosporine). Serum ferritin level (SF) was applied as the main iron overload (IOL) indicator (N 11-160 ng/mL). Depending on obtained results all patients were divided into 3 groups. Group 1 patients had SF evaluation prior to combined immunosupressive therapy (n=47), these patients were split into subgroups 1A and 1B: 1A subgroup patients (n=16) received<20 transfusions in 1-4 months prior to the study, 1B subgroup patients (n=31) received >20 transfusions in 2-19 months prior to the study. Group 2 patients (n=20) retained long term RBC transfusion dependence in spite of continued immunosupressive therapy. Group 3 patients (n=20) demonstrated good immunosuppressive therapy response, therefore developed significant hematological improvement and became transfusion independent.
Results: In patients of 1A subgroup SF median was 303 ng/mL (range 40-1483 ng/mL), in 1B Group-722 ng/mL (range 105-4950 ng/mL) with significant difference between SF levels received (P=0.025). Group 2 patients had SF median of 1018 ng/mL (range 250-6300 ng/mL), and Group 3 patients were notable for lower SF levels with SF median of 480 ng/mL (range 15-1500 ng/mL). Significant differences recorded when comparing Group 1 SF levels of and Group 2 patients data (P=0.004) as well as Group 2 and Group 3 patients SF levels (P=0.014).
Summary and Conclusions: It was discovered that iron metabolism disorders have been detected in almost all AA patients prior to immunosupressive therapy start and then progressed in time of ongoing RBC transfusions. Notable high SF levels of maintained for a long time after patients became transfusion independent. These data suggest chelation therapy is valuable not only for transfusion dependent AA patients but may also be useful in remission patients with retained laboratory signs of iron overload.

PB1704

DIAGNOSTIC, THERAPEUTIC AND EVOLUTIVE ASPECTS OF ACQUIRED APLASTIC ANEMIA: ABOUT A RETROSPECTIVE STUDY OF 107 CASES

F. Kallel[1,*] H. Bellaaj[1], C. Maha[1], G. Manel[1], S. Mseddi[1], H. Rekik[2], M. Mdhaffar[1], O. Kassar[1], M. Elloumi[1]
[1]Hematology Department Sfax Hospital, 2centre De Transfusion Sanguine, Faculté De Médecine De Sfax Unité De Recherche, Sfax, Tunisia

Background: The acquired aplastic anemia (AAA) is a rare but serious and severe disease. Evolution could be fatal by medullary isuffisance 's complications.
Aims: We found it useful to carry out a retrospective study over a period of 16 years and to analyze the diagnostic, therapeutic and evolutive characteristics of myelosuppression in southern Tunisia.
Methods: Our study is retrospective, it has enrolled the acquired aplastic anemia patients diagnosed and monitored in the hematology department of Sfax hospital over 16 years from january 1998 to december 2013. 107 cases were collected.The date of point was fixed to January 2015. The etiological diagnosis contained a careful history, a study of medullary and constitutional karyotype, a search for HPN clone, viral serology....overall survival was carried out according to Kaplan Meier method.
Results: 107 cases of acquired aplastic anemia were collected, they were 60 men and 47 women with a median age of 27 years (range 2-81 years). The circumstances of discovery were hemorrhagic syndrome, anemic syndrome and fever respectively in 7%,% and11% of cases. Our patient's distribution according to Camitta) score showed 38% AAA moderate, 31% severe AAA and 31% very severe AAA. The etiological investigation has revealed negative in 85 patients (79%) and labeled idiopathic. It showed a toxic agents or viral infections as in postseronegative hepatitis respectively in 7% and 11% of patients. Two patients have had AM / HPN.In addition to symptomatic treatment, specific treatment concerned 99 patients. It involved the allogenic bone marrow (allo-

graft), ciclo associated with SAL, ciclo only and androgen.The therapeutic results according to the used therapeutics are detailed in the following table.

Table 1.

therapy	Patients number	Death rates(%)	5years Overall survival	Terapeutic response(%)
Allogeneic bone marrow	33	15	80	RC=79 RP=6
SAL Ciclo	10	20	71	RC=40 RP=40
Ciclo	40	67	40	RC=25 RP=8
androgens	6	50	50	RC=33 RP=17
Total	99	37	60	RC=52 RP=11

Summary and Conclusions: The acquired aplastic anemia is a rare and serious disease. It is a therapeutic emergency requiring a carefull etiological investigation and early management with effective therapeutic.

PB1705

CONTRIBUTION OF FLOW CYTOMETRY IN THE BALANCE SHEET OF ACQUIRED APLASTIC ANEMIA

M. Charfi[1,*] H. Bellaaj[1], F. Kallel[1], M. Ghorbel[1], H. Rekik[2], M. Mdhaffar[1], O. kassar[1], M. Elloumi[1]
[1]Hematology, Hedi Chaker Hospital, [2]Hematology, Regional Center of Blood Transfusion, Sfax, Tunisia

Background: Flow cytometric immunophenotyping has become the gold standard for the diagnosis and monitoring of Paroxysmal hemoglobinuria(PNH). PNH results from acquired somatic mutation of the phosphatidylinositol glycan complementation class A (PIG-A) gene, leading to partial or complete absence of the glycosylphosphatidylinositol (GPI) anchor that is responsible for linking a large number of proteins to the cell membrane.
Aims: The aim of our work is to detect and quantify by flow cytometry (FC) PNH clones in aplastic anemia (AA) patients.
Methods: From January 2001 to december 2013,we have evaluated 103 patients with aplastic anemia. The presence of a PNH clone was assayed by peripheral blood flow cytometry on granulocytes(CD16) and monocytes(CD14). The diagnosis of PNH was retained by the presence of a deficit clone greater than or equal to 50% of white blood cells. The PNH clone is considered small if >5%, and major if >30%.
Results: Among all AA patients, 15% patients had the PNH clone. Ham's test was performed in ¾ of cases. Anemia was present in all patients with PNH-AA syndrome. Among them,80% had severe aplastic anemia. Bone marrow transplantation (BMT) concened 21% of patients with PNH-AA syndrome. three patients with PNH-AA syndrome died by severe thrombotic accident, progression to acute leukemia and severe anemia.

Table 1.

	Patients number	Percentage
Major HPN clone	5	5%
Small HPN clone	10	10%
No clone HPN	88	85%
Total	103	100%

Summary and Conclusions: The flow cytometry on granulocytes is a useful method to diagnose and characterize PNH. This test is good for early detection of PNH clones in AA patients at initial diagnosis. PNH clone search using specific erythroid markers (CD 55 and CD59) should improve the specificity of our results.

PB1706

CLINICAL MANIFESTATIONS AND TREATMENT OUTCOME OF FANCONI ANEMIA: RESULTS OF A SINGLE CENTER

B. Koc[1], N. Ozdemir[1,*] B.S. Koc[1], G. Dikme[1], H. Apak[1], T. Celkan[1]
[1]Pediatric Hematology Oncology, ISTANBUL University, Cerrahpasa Medical-Faculty, Istanbul, Turkey

Background: Fanconi anemia is an inherited disease characterized by congenital malformations, pancytopenia, cancer predisposition, and sensitivity to cross-linking agents. The molecular diagnosis of Fanconi anemia is relatively complex for several aspects including genetic heterogeneity.
Aims: The aim of this study is to characterize clinical manifestations and treatment of Turkish patients with Fanconi anemia (FA) at our center.
Methods: The medical records of 16 FA patients diagnosed at Istanbul University, Cerrahpasa Medical Faculty from 2006 to 2014 were retrospectively reviewed.
Results: The median age at diagnosis was 6,5 years (6 months-12 years). Nine of them were male and 7 of them were female (M/F:). Two of them were brother and sister. All patients showed evidence of marrow failure and one or more physical stigmata. Most common findings were cafe-u-lait, hypopigmented lesions, thumb anomaly and renal anomalies. Chromosome breakage tests were positive in 12 out of 12 available patients and 2 of them had mosaism in the chromosome breakage tests. The median follow-up duration was 63 (7-112) months. None of the patients underwent stem cell transplantations (SCTs). All patients were alive by the end of the study. None of the patients developed leukemia. Androgens were used in 7 patients for treatment. Two of the patients received erythrocyte suspension and 1 of them received thrombocyte suspension.
Summary and Conclusions: We provide information of FA patients at our center. A nation-wide FA registry that includes information of the genotypes of is required to further characterize ethnic differences and provide the best standard of care for FA patients.

PB1707

CHRONIC LIVER DISEASE WITH HYPERSPLENISM PRESENTING AS PANCYTOPENIA

H. Ryu[1,*] J.Y. Moon[1], Y.S. Choi[1], I.C. Song[1], D.Y. Jo[1]
[1]Department of Internal Medicine, School of Medicine, Chungnam National University, Daejeon, Korea, Republic Of

Background: Hypersplenism is one cause of pancytopenia. Chronic viral hepatitis and liver cirrhosis are prevalent in Asian populations and often result in splenomegaly and hypersplenism.
Aims: In this study, we reviewed and analysed the diagnostic process of chronic liver disease associated with hypersplenism initially presenting as pancytopenia.
Methods: Patients with chronic liver disease with hypersplenism who initially presented with bicytopenia or pancytopenia from January 2002 to December 2013 at Chungnam National University Hospital were enrolled. The patients' characteristics and laboratory investigation findings at the time of diagnosis were analysed retrospectively.
Results: Nineteen patients with a median age of 61.5 years (range, 43–77 years) were enrolled, accounting for about 3% of patients presenting with bicytopenia or pancytopenia during the study period. All patients were first seen by a haematologist. In 12 patients (63.2%), bicytopenia or pancytopenia was incidentally found during a health check-up at a local clinic. A history of liver disease was limited to six patients (31.6%), and one patient (5.3%) was a carrier of the hepatitis B virus. Hepatitis B surface antigen and anti-hepatitis C antibody were detected in four (21.1%) and seven (36.9%) patients, respectively. Eighteen (94.7%) patients exhibited one or more abnormalities among the aspartate transaminase level, alanine transaminase level, alkaline phosphatase level, total bilirubin level, albumin level, and prothrombin time. All patients exhibited hepatic dysfunction and splenomegaly on Tc-99m phytate liver scintigraphy; therefore, all were diagnosed with liver cirrhosis accompanied by hypersplenism. The causes of the cirrhosis were hepatitis B in four patients (20.0%), hepatitis C in seven (36.9%), alcohol consumption in two (10.5%), chronic heart failure in one (5.3%), and an autoimmune disorder in one (5.3%). No clear aetiology was found in four (20.0%) patients. Of 15 patients with liver cirrhosis who underwent a bone marrow study, 2 (13.3%) were confirmed to have aplastic anaemia in addition to hypersplenism. Myelodysplastic syndrome and megakaryocytic hyperplasia were reported in three (20.0%) and two (13.3%) patients, respectively, and were later confirmed to be reactive changes of hypersplenism.
Summary and Conclusions: Chronic liver disease accompanied by splenomegaly and hypersplenism should be highly suspected when bicytopenia/pancytopenia and abnormalities in chemistry coexist in the same patient, even in those with no history of liver disease or who are negative for viral hepatitis markers. The Tc-99m liver scan is a simple but highly efficient investigational tool for these patients.

IMPLEMENTATION OF MINIMAL RESIDUAL DISEASE IN CHRONIC LYMPHOCYTIC LEUKEMIA ON REUNION ISLAND

I. Kittler[1,*] R. Letestu[2], P. Zunic[3], A. Clabé[4]
[1]Laboratoire HLA, CHU de La Réunion, Saint-Denis, Réunion, [2]Laboratoire d'hématologie, Hôpital Avicenne, Paris, [3]Hémato-oncologie, CHU de La Réunion, Saint-Pierre, France, [4]Laboratoire d'hématologie, CHU de La Réunion, Saint-Pierre, Réunion

Background: Emerging data strongly indicate that quantification of Minimal Residual Disease (MRD) in Chronic Lymphocytic Leukemia (CLL) appears to be a powerful predictor of progression-free and overall survival, regardless of the clinical response, type of therapy and known biological markers. Two methods are currently available for assessing complete remission according to the international consensus and IWCLL guidelines, *i.e.* allowing to detect one malignant cell in 10.000 leukocytes. These approaches are either based on specific immunoglobulin heavy chain rearrangement in each clone (RQ-ASO IgH-PCR) or on the unique immunophenotype profile of CLL cells using multiparameter flow cytometry.
Aims: Our aim was to assess complete remission in CLL on Reunion Island. The assay had to be not as complex, expensive and time-consuming as previously published techniques. This study describes the different steps in implementing and optimising an eight-colour flow cytometry MRD assay in peripheral blood.
Methods: Our work is based on an antibody panel designed by the ERIC expert group (www.ericll.org) including the following combination: CD81/CD79b/CD22/CD19/CD43/CD20/CD5/CD3. The malignant clone is identified among normal B cells thanks to 15 scattergrammes combining six CLL highly characteristic markers. Tumor cells typically express CD5, dim CD22, dim CD20, dim or negative CD79b, CD43, dim or negative CD81. In order to reach a higher specificity and sensibility for detection of CLL cells, we have been working on three different approaches: modification of sample preparation procedure, introduction of a new brilliant fluorochrome for the violet laser line and optimisation of data analysis strategy. Once the implementation of the assay had been carried out, we studied performance criteria according to learned societies, considering clinical relevance and practical feasibility.
Results: After modifying the eight-colour protocol, we achieved a precise estimation of the number of total leukocytes events by excluding unlysed cells (SSC/CD43 dot plot), erythrocytes debris (CD81/CD19 dot plot) and doublets (FSC-A/FSC-H dot plot). This new gating algorithm allows us to calculate the number of CLL cells events as a percentage of total leukocytes, according to international guidelines. The intersection of 16 regions of interest contribute further to clearly define the CLL population by minimizing the error of inclusion risk. Analysis of ten healthy donor blood has been carried on to assess the limit of detection, which is 5.3. The application of this new data analysis strategy achieves a sensitivity of $5x10^{-6}$ after acquiring one million leukocytes. Performance criteria proved mostly satisfying: imprecision, accuracy, carryover and specimen stability meet the standards we set.
Summary and Conclusions: We have developed on Reunion Island a flow cytometric technique reliable and sensitive enough to detect the presence of less than one CLL cell in 100.000 leukocyte. This 8-colour assay reduces subjectivity, sample requirements and time taken for acquisition and analysis, compared with 4 and 6-color assays. It also presents the advantage of requiring less specialized equipment and being not as expensive as the sensitive PCR methods.

PB1709

THE EFFECT OF THE RETINOIC ACID DERIVATIVE, ACITRETIN, ON CHRONIC LYMPHOCYTIC LEUKEMIA CELL VIABILITY, MIGRATION AND APOPTOSIS.

S. Elsir Mohammed[1,*] B. Hennessy[2], J. Quinn[3], P. Thornton[1], O. Aslan[2], A. Eustace[2], P. Murphy[3]
[1]Haematology, [2]Molecular Medicine, Royal College Of Surgeons OF Ireland, [3]Haematology, Beaumont Hospital, DUBLIN, Ireland

Background: Retinoids modulate the activity of a large number of genes through binding to the retinoic acid receptor (RAR/RXR) resulting in a variety of molecular and biochemical consequences. The role of retinoids in different malignancies has been extensively explored. However little is known about their effect on lymphoid malignancies.
Acitretin is a synthetic retinoid which has been shown to induce cell differentiation, and apoptosis in squamous cell carcinoma, where it was shown to induce apoptosis of malignant squamous cells without effecting normal epithelial cells.
Aims: We aimed to investigate the effects of Acitretin on the CLL like cell line MEC-1 and on primary CLL cells.
Methods: Peripheral blood samples were obtained from 28 CLL patients who gave written informed consent (14 treatment naïve, 14 with relapsed disease). The CLL like cell line MEC-1 was obtained and experiments were performed on these and on primary CLL cells, freshly isolated from whole blood using a density centrifugation technique. Viability assays were performed using the Celltitre96 AquousOne® MTS assay. Migration assays were performed on the Boyden chamber platform where migration of acitretin treated cells toward the chemokine CXCL12 was compared to untreated controls. Apoptosis was measured using FACS analysis of CLL cells treated with 10microM Acitretin for 24 and 72hrs. Treated cells and vehicle controls were labelled with Annexin 5 and Propidium Iodide to detect early apoptotic cells and dead cells.
Results: Acitretin significantly reduced proliferation of MEC-1 cells at drug concentrations of up to 25μM (28.6% mean reduction, P=0.0002).
Acitretin reduced the proportion of viable CLL cells in 5 out of 7 patients as compared to control in cells from treatment Naïve patients (18% mean reduction, P=0.0001), at drug concentrations up to 20 μM. Furthermore, one clinic patient with early stage CLL was commenced on acitretin for control of squamous cell carcinoma of the skin. His lymphocytosis was found to have resolved 3 weeks into treatment. His lymphocyte count continued to be normal 1 year into follow up. However, acitretin had no effect on viability of cells from relapsed patients. Acitretin also had a variable effect on cell migration whereby it reduced the ability of cells to migrate towards the chemokine CXCL12 in 2 out of 5 patient samples and did not appear to effect migration of the cells in 3 patient samples. Acitretin does not appear to significantly affect the rate of early apoptosis in the primary cells as measured by the proportion of Annexin V/Propidium Iodide labelled cells. Future analysis of additional primay cell lines will further substantiate these results.
Summary and Conclusions: The retinoid derivative acitretin reduced the proliferation rate of MEC-1 cells and the viability of primary CLL cells from treatment Naïve patients *in vitro*, but had a variable effect on cell migration and did not appear to effect early apoptosis.
Our findings show a potential effect of retinoids in early CLL however the mechanism and clinical significance needs to be further defined.

PB1710

MIMICKING THE TUMOR MICROENVIRONMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA *IN VITRO* CRITICALLY DEPENDS ON THE TYPE OF B CELL RECEPTOR STIMULATION

A. Rombout[1,*] S. Lust[2], F. Offner[2], E. Naessens[1], B. Verhasselt[1], J. Philippé[1]
[1]Department of Clinical Chemistry, Microbiology and Immunology, [2]Department of Internal Medicine, Ghent University, Ghent, Belgium

Background: The B cell receptor (BCR) plays a key role in the crosstalk between chronic lymphocytic leukemia (CLL) cells and the tissue microenvironment, which favors disease progression by promoting proliferation and drug resistance. In these protective niches in the bone marrow and secondary lymphoid organs, the BCR becomes activated and sets a signaling cascade in motion that contributes to the survival and expansion of the malignant clone. *In vitro* studies of this crosstalk investigating downstream signaling and functional effects of BCR ligation often report contradictory results, in part due to the lack of a standardized protocol for BCR stimulation in CLL.
Aims: Our aim was to define a biologically relevant and robust *in vitro* stimulation method with regard to cellular phenotypic and transcriptional responses.
Methods: We evaluated mRNA (*MYC, FOS, LPL*) and protein (CD54, CD19, CD62L, CD184) expression of genes modulated by BCR triggering in *IGHV* mutated and unmutated CLL cells, after stimulation using soluble or immobilized anti-IgM antibodies from different brands.
Results: The effect of BCR stimulation on gene and protein expression was comparable in all CLL patients, irrespective of *IGHV* mutation status, as previously reported by us. However, immobilized anti-IgM stimulation elicited clear and robust changes in gene and protein expression, whereas the response to soluble anti-IgM was far less obvious.
Summary and Conclusions: These results show that the method of BCR stimulation is of major importance regarding responsiveness of CLL cells in the context of the tumor microenvironment, while genetic differences in the BCR pathway are less critical.

PB1711

ANALYSIS OF MONOCYTES SUBPOPULATIONS WITH CYTODIFF™* IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

S. Lugovskaya[1], E. Sukhacheva[2,*] F. Dukov[1], E. Naumova[1], M. Pochtar[1], V. Dolgov[1]
[1]Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation, [2]Beckman Coulter Eurocenter, Nyon, Switzerland

Background: During last decade 3 sub-populations of monocytes have been described in the human blood: classical, intermediate and non-classical monocytes, which can be differentiated with flow cytometry based on the expression of CD14 and CD16. The involvement of monocyte subpopulations in different pathological processes also was described, including sepsis, HIV infection,

tuberculosis and cardiovascular disorders. Very limited information available about monocyte sub-populations in Chronic Lymphocytic Leukemia (CLL), but according to literature they seem to be important for tumor progression and immune suppression in CLL.
Aims: The aim of our study was to compare CD-16 negative and CD16-positive monocytes in CLL patients and in normal individuals. Also we aimed to compare the groups of CLL patients with bad and good prognosis.
Methods: 58 patients with confirmed diagnosis of CLL were included in the study at the time of diagnosis. The comparison group included 307 blood donors. EDTA-anticoagulated blood sample were analyzed with CytoDiff™* panel according to the recommendation of the supplier. The CytoDiff™* panel is a 5-color / 6-marker reagent that provides an extended 18-part white blood cell differential from whole blood specimens by flow cytometry (Beckman Coulter). Among other WBC sub-populations, CytoDiff™* is able to provide the count of CD16-positive and CD16-negative monocytes (@M+ and @M-) in peripheral blood. The expression of CD38 on lymphocytes was used as prognostic marker for CLL patients.
Results: The absolute number of classical CD16-negative monocytes (@M-) was similar in donors and in CLL patients (503 cells/mcl vs 510 cells/mcl respectively). When compared to normal individuals, patients with CLL were characterized by higher absolute count of CD16-positive monocytes (@M-, 40 cells/mcl vs 30 cells/mcl, P=0.0007), higher proportion of CD16-positive monocytes among all monocytes (@M+/Total Mono; 8.8% vs 5.8%, P<0.0001) and lower proportion of CD16-negative monocytes among all monocytes ((@M-/Total Mono; 94.2% vs 91.3%, P<0.0001). Within the group of 58 CLL patients we identified patients with unfavorable prognosis (n=16) based on the CD38 expression (>6%). In patients with bad prognosis CytoDiff™* results revealed higher proportional (0.24% vs 0.175%, P=0.1346) and absolute (63 cells/mcl vs 38 cells/mcl, P=0.166) count of CD16-positive monocytes, but the difference did not reach the statistical significance.
Summary and Conclusions: CytoDiff™* analysis is very efficient tool to monitor the monocyte subpopulations in various pathologies, including CLL. The exact role of CD16-positive monocytes in CLL and their significance remain to be investigated on a larger cohort of patients. *Not available in the United States and other geographies. For research use only. Not for use in diagnostic procedures. @-Research Use Only (RUO) parameters

ASSOCIATION OF CD38, ZAP-70, CD49D AND CXCR4 EXPRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA
I. Milosevic[1,2,*] S. Popovic[2], A. Savic[2], I. Urosevic[2], N. Rajic[2], D. Agic[2], I. Savic[2]
[1]Department for internal medicine, Medical faculty of Novi Sad, [2]Clinic for hematology, Clinical Center of Vojvodina, Novi Sad, Serbia

Background: Chronic lymphocytic leukemia is disease with very heterogeneous clinical course, some patients have long survival without treatment, while others have short survival in spite of intensive treatment. Therefore is important to predict clinical outcome at the time of diagnosis and to plan adequate therapy. Classic prognostic parameters is based on tumor size and are not valid for prognosis in the early clinical stages. CD38, ZAP-70, CD49d and CXCR4 are involved in cell signalization and interactions with microenvironment. This molecules conduct proliferative and anti-apoptotic signals and contribute to the development of the disease and resistance to treatment. Expression of CD38, ZAP-70, CD49d and CXCR4 correlates with active subpopulation of leukemic clone and can predict course of the chronic lymphocytic leukemia at the time of diagnosis.
Aims: Aim of the study was to determine if there is a correlation of CD38, ZAP-70, CD49d and CXCR4 expression in chronic lymphocytic leukemia and if there is a correlation between expression of these antigens with clinical and laboratory parameters.
Methods: 40 patients with chronic lymphocytic leukemia was analysed before treatment. Expression of CD38, ZAP-70, CD49d and CXCR4 was detected by immunocytochemical staining. Correlation of expression of the CD38, ZAP-70, CD49d, CXCR4, and correlation between expression of these antigens and clinical and laboratory parameters were tested with standard statistical methods.
Results: Median age of patients was 61,8 years; 14 patients were in Binet stage A, 14 in Binet stage B and 12 in Binet stage C. Median total lymphocyte count was 38,8x10.9/l. Among all patients, CD38 positive were 45%, ZAP-70 positive 55%, CD49d positive 52,5% and mean percent of CXCR4 positive cells was 57,2% cells. There were statistically significant correlations between CD38 and ZAP-70 positivity, CD38 and CD49d positivity, and ZAP-70 and CD49d positivity. There were also correlation between percentage of cells which express CD38, ZAP-70 and CD49d, and correlation between percentage of cells which express CD49d and CXCR4. Expression of ZAP-70 correlate with advanced clinical stage and hepatomegaly, expression of CD49d with hepatomegaly, and expression of CD38 with number of lymph nodes and splenomegaly.
Summary and Conclusions: In our study, expression of CD49d in chronic lymphocytic leukemia cells strongly correlates with expression of CD38 and ZAP-70, and CD49d expression correlates with CXCR4 expression, suggesting cooperation of these molecules in leukemic cell functions.

Chronic lymphocytic leukemia and related disorders - Clinical

CHROMOSOMAL ABERRATIONS BY FLUORESCENCE IN SITU HYBRIDIZATION IN JAPANESE CHRONIC LYMPHOCYTIC LEUKEMIA: CLLRSG-01 STUDY.
J. Takizawa[1,*] S. Aoki[2], R. Suzuki[3], N. Nakamura[4], K. Ohshima[5], K. Izutsu[6], A. Utsunomiya[7], J. Suzumiya[3]
[1]Hematology, Endocrinology and Metabolism, Niigata University Faculty of Medicine, [2]Clinical Oncology, Niigata University of Pharmacy and Applied Life Sciences, Niigata, [3]Cancer Center, Shimane University Hospital, Izumo, [4]Pathology, Tokai University, Isehara, [5]Pathology, Kurume University, Kurume, [6]Hematology, Toranomon Hospital, Tokyo, [7]Hematology, Imamura Bun-in Hospital, Kagoshima, Japan

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in Western countries but is very rare in Asian countries, including Japan. There are few reports about immunophenotypes, chromosome aberrations and mutations of immunoglobulin heavy chain gene variable region (IGVH) in Japanese CLL patients.
Aims: Hence we have conducted a nationwide registry study (CLLRSG-01) from January 2011 to clarify the characteristics of Japanese CLL patinets. We present here the interim results of prospective study.
Methods: Seventy-five untreated patients with indolent B-cell neoplasms met the inclusion criteria: (i) absolute lymphocyte counts of 5000/ul or more in the peripheral blood; or (ii) abnormal lymphocytes of 20% or more in the peripheral blood. The morphological examination was carried out according to the WHO classification by diagnostic committee. “Atypical CLL” was determined according to the morphology by the FAB classification, but this term does not mean atypical expression of surface immunophenotype. Immunophenotyping was performed using flow cytometry with a panel of antibodies including CD5, CD19, CD20, CD21, CD22, CD23, CD38, CD69, FMC7 and ZAP-70. The immunophenotypic score was calculated based on the CLL scoring system proposed by Matutes *et al.* We investigated del(13q14), del(11q22), del(17p13), and trisomy 12 using interphase fluorescence *in situ* hybridization (FISH). Cases with mantle cell lymphoma were excluded by FISH with t(11;14) probe and/or the overexpression of CCDN1 by immunostaining.
Results: According to the morphologic review of peripheral blood smear, 41 patients (55%) were classified as typical CLL, 12 (16%) as atypical CLL and 22 (29%) as other indolent B-cell tumors (others) including 8 hairy cell leukemia. The immunophenotypic profile demonstrated that the frequency of expression of CD5, CD21, CD23 and CD69 in CLL (typical and atypical) group was higher than that of others. The Matutes’ CLL scoring system showed that 27 patients (51%) with CLL had higher values (5 or 4) whereas 21 patients (95%) with others had lower score values (0-3) (P=0.004). There was no significant difference between the typical and atypical CLL in this scoring system. Of the 75 patients analyzed by FISH, 44 (59%) had at least one aberration. The most frequent abnormality was del(13q14)(37%), followed by trisomy 12 (23%), del(11q22)(7%), and del(17p13)(7%). Del(17p13) was not detected in patients with CLL, but was detected in 5 patients (23%) with others. Among CLL patients, atypical morphology was shown to correlate with ZAP-70 expression and trisomy 12 by FISH analysis in comparison with typical CLLs.
Summary and Conclusions: The present study demonstrated immunophenotypic and cytogenetic characteristics of CLL in Japan. Our results have shown that Japanese CLL has atypical immunophenotypes and similar chromosomal aberrations as those in Western countries. Our results should be confirmed by further Japanese and Western collaborative study.

AUTOIMMUNE HAEMOLYTIC ANAEMIA DURING BENDAMUSTINE TREATMENT IN CLL PATIENTS
F. Autore[1], I. Innocenti[1], G. D’Arena[2], M. Coscia[3], P. Mondello[4], R. Pasquale[1], S. Sica[1], L. Laurenti[1,*]
[1]Catholic University of the Sacre Heart, Rome, [2]IRCCS Centro di Riferimento Oncologico della Basilicata, Rionero In Vulture, [3]University of Turin, Torino, [4]University of Messina, Messina, Italy

Background: Immune dysregulation with autoimmune phenomena, especially autoimmune haemolytic anaemia (AIHA), is a common complication over the lifetime of CLL patients. Therapy-related haemolysis in CLL was first described in 1966 in patients treated with radiotherapy or alkylating agents. Drug-induced haemolytic anaemia mostly related to the use of fludarabine has been often reported, even if the use of monoclonal antibody with chemotherapeutic agents could reduce the incidence of haemolytic episodes. Bendamustine is an alkylating agent composed by benzimidazole ring which is similar to some purine analogs; for these reasons the haemolysis generated by bendamustine should be similar to that induced by fludarabine. To date, this complication was rarely reported in association with bendamustine.

Aims: We reported the experience of 4 Italian haematological centres focusing on AIHA during treatment with bendamustine plus rituximab (BR) in patients affected by CLL.
Methods: We included in the study all CLL patients who underwent BR treatment as front-line or successive treatment for progressive disease. All patients who experienced AIHA during or after BR treatment were described. AIHA was diagnosed as reduction of haemoglobin level with positivity of haemolysis tests.
Results: One hundred-thirty CLL patients were treated with BR in our four centres. Of these, 61 patients were treated for progressive CLL as first-line therapy and 69 patients as second-line therapy. No patient experienced autoimmune phenomena when bendamustine was used with rituximab as part of front-line therapy. On the opposite in CLL patients treated with BR as second-line therapy, 5 episodes of AIHA were reported as shown in Figure 1. The prevalence of bendamustine related AIHA in patients who underwent to BR treatment as second line therapy was 7.2%. Three of five patients who experienced AIHA had positive DAT, AIHA or immunological autoantibodies at the onset of CLL. Three cases used fludarabine based regimens as front-line therapy. Three of five patients developed DAT positive AIHA; low median lymphocytes count (1000/mmc) and the use of rituximab could justified DAT negative AIHA in two patients. The onset of AIHA was observed during the BR treatment in 4 patients and at the end of planned therapy in 1 patient. The course of AIHA was mild, it responded to steroid or rituximab therapy and it was solved in a few days.

Table 1. Characteristics and biological profile of AIHA/CLL patients.

Patient number	1	2	3	4	5
Sex/Age	F/58	F/62	M/68	F/64	F/63
Binet/Rai stage	B/II	B/II	B/II	B/II	C/III
Zap-70/CD38	neg/pos	pos/pos	neg/pos	neg/neg	n.a/n.a.
IgVH	unmutated	unmutated	unmutated	unmutated	mutated
FISH	del13/del11	del13	del13	del17	del11/+12
First-line treatment	BR	CtxR	FCR	FCR	FCR
Autoimmunity at first-line treatment	AIHA thyroiditis	DAT+ thyroiditis	DAT+ thyroiditis	DAT-	DAT-
Response to 1st line	PR	PR	CR	SD	CR
Type of treatment prior AIHA	BR	BR	BR	BR	BR
Time of insurgence of AIHA respect bendamustine	30 days after the end of therapy	After 4th cycle	After 2nd cycle	After 3rd cycle	After 4th cycle
Type and specificity of DAT	4+/-	2+/ IgG	4+/-	neg	neg
Lymphocyte count at AIHA (mmc)	550	2510	1000	680	2500
Minimum Hb level during AIHA gr/dL	7.7	7.5	5.4	9.4	8.5
Type of therapy for AIHA	steroid	steroid	R-CVP	Rituximab	steroid

Summary and Conclusions: All 5 patients experienced bendamustine related AIHA during or after BR treatment as second line chemotherapy. Our experience confirms the literature data in which 9 of 10 cases of bendamustine related AIHA in CLL patients reported, appeared after second or further treatment. Patients who experienced previous autoimmune phenomena or underwent fludarabine as front-line therapy, probably for its similitude in the drug structure to bendamustine, showed an increase risk of AIHA. AIHA is probably due to depletion of CD4 cells which can lead to failure to control auto-reactive T-cells that are free to create autoimmunity. The course of bendamustine related AIHA was mild, it could be quickly solved in a few days with the use of immunosuppressive agents as steroid or monoclonal antibodies. In conclusion BR is safe and effective regimen in CLL patients, a care observation should be taken in patients in which BR was used as second or further line therapy. Previous autoimmune phenomena, prior use of fludarabine and CD4 depletion could explain the increased incidence of bendamustine related AIHA.

PB1715

SIMILAR EPIDEMIOLOGICAL TRENDS OF LYMPHOID MALIGNANCIES AND THEIR RESPECTIVE PRECURSOR LESIONS IN TAIWAN

P.Y. Hsieh[1,*] S.C. Lin[1], C.T. Lin[2], C. Fazi[3], S.J. Wu[2], P. Ghia[3], C.S. Chuang[4]
[1]Far Eastern Memorial Hospital, New Taipei City, [2]National Taiwan University Hospital, Taipei, Taiwan, ROC, [3]Università Vita-Salute San Raffaele, Milano, Italy, [4]Chi-Mei Hospital, Tainan, Taiwan, ROC

Background: Based on epidemiological studies, it is well known that Taiwan differs from the Western countries in terms of incidence of lymphoid malignancies with follicular lymphoma (FL), multiple myeloma (MM), and chronic lymphocytic leukemia (CLL) being much less prevalent The respective incidence rates are around one-fourth, one-third, and one-sixth of the one in the US. For these reasons, it is of interest to evaluate whether also their respective precursor conditions, *i.e.*, circulating t(14;18)-*IGH*/*BCL2* translocation, monoclonal gammopathy of unknown significance (MGUS), and monoclonal B-cell lymphocytosis (MBL) are also less common in Taiwan.
Aims: To know the epidemiology of the preursor conditions of lymphoid malignancies in Taiwan.
Methods: We screened 300 healthy Taiwanese individuals with the median age of 43 (range 23~73) for the presence of *IGH*/*BCL2* translocation in peripheral blood mononuclear cells by polymerase chain reaction. In another cohort of 302 healthy individuals with the median age of 53 (range 23-79), the screening for the appearance of MGUS by serum immunofixation and MBL by flow cytometry were done. The results were compared to the data from Western cohorts.
Results: In line with the epidemiological findings on the actual diseases, the prevalence rates of all three precursor conditions appear significantly lower in the Taiwanese population with 10.7% (32/300) of the cases positive for circulating *IGH*/*BCL-2* translocations, 1.3% (4/302) positive for MGUS, and 1.3% (4/302) positive for MBL, as compared with the frequencies of more than 50% for circulating *IGH*/*BCL-2* translocation, 3~5% for MGUS, and 3.5~7% for MBL in the Western populations. The differences, however, were similar to those observed for the incidence rates of FL, MM, and CLL, respectively, between Taiwan and the West. For MGUS and MBL, the numbers of positive cases were too small for analyses in terms of age. In the case of circulating *IGH*/*BCL2* translocations, the prevalence in the healthy population was higher in middle-aged to older people than in young adults (6.3% in the 3rd decade, 6.6% in the 4th decade, 13.8% in the 5th decade and 10.6% in the 6th decade), similar to the age-distribution pattern of FL.
Summary and Conclusions: The present study demonstrates lower rates for pre-neoplastic conditions in the Taiwanese population, *i.e.* of the presence of the circulating t(14;18)-*IGH*/*BCL2* translocations, MGUS, and MBL that is in line with the known lower frequency of their respective lymphoid neoplasms as compared to Western populations. These results confirm the role of the precursor conditions during the natural history of the actual diseases and the pre-neoplastic nature of these manifestations. Unraveling the molecular and genetic features of circulating *IGH*/*BCL2* translocations, MGUS, and MBL in healthy Taiwanese population will be key to understand the pathogenetic mechanisms responsible for the lower frequencies of FL, MM, and CLL as compared to the Western populations.

PROGNOSTIC TESTING PATTERNS IN PATIENTS (PTS) WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) TREATED IN US PRACTICES FROM THE CONNECT® CLL REGISTRY

A. Mato[1], C.R. Flowers[2], C.M. Farber[3], M.A. Weiss[4], T.J. Kipps[5], M.F. Kozloff[6], C. Nabhan[7,*] I.W. Flinn[8], D.L. Grinblatt[9], N. Lamanna[10], K. Sullivan[11], P. Kiselev[12], E.D. Flick[13], K.A. Foon[12] A.S. Swern[12], J.P. Sharman[14]
[1]Center for Chronic Lymphocytic Leukemia, University of Pennsylvania, Philadelphia, [2]Emory University, Atlanta, [3]Morristown Memorial Hospital, Carol G. Simon Cancer Center, Morristown, [4]Thomas Jefferson University, Philadelphia, [5]Division of Hematology-Oncology and Central Office of CLL Research Consortium, Moores Cancer Center, University of California San Diego, La Jolla, [6]Section of Oncology/Hematology, Ingalls Hospital, Harvey, [7]The University of Chicago, Chicago, [8]Sarah Cannon Research Institute, Tennessee Oncology PLLC, Nashville, [9]NorthShore University HealthSystem, Evanston, [10]Leukemia Service, Hematologic Malignancies Section, Department of Medicine, New York-Presbyterian/Columbia University Medical Center, New York, [11]Celgene Corporation, Overland Park, [12]Celgene Corporation, Summit, [13]Celgene Corporation, San Francisco, [14]Willamette Valley Cancer Institute, US Oncology, Springfield, United States

Background: Genetic aberrations detected by fluorescence *in situ* hybridization (FISH) and cytogenetic (CG) testing provide important prognostic information for CLL pts. The identification of genetic abnormalities has particular relevance in choosing immunochemo- or kinase inhibitor therapies, allogeneic stem cell transplantation, or clinical trials for CLL pts.
Aims: To analyze factors influencing decisions to perform FISH or CG testing in CLL pts.

Table 1.

MV analysis: Predictors of FISH/CG		
Time point/Practice setting	**Covariate**	**OR 95% CI**
LOT1 All sites	Academic center vs. community/government center	1.76 1.03–2.99
	White vs. other ethnicity	1.90 1.13–3.17
	Private insurance vs. other	1.44 1.08–1.92
LOT1 Community-Government sites	White vs. other ethnicity	2.40 1.26–4.58
	Age ≤ 75 vs. > 75	1.44 1.01–2.05
	RAI stage ≥ 2 vs. 1	1.52 1.07–2.14
LOT≥2 All sites	White vs other ethnicity	0.34 0.17–0.68
	Age ≤ 75 vs. > 75	1.45 1.01–2.07
LOT≥2 Community- Government sites	White vs other ethnicity	0.41 0.16–1.04
	Age ≤ 75 vs. > 75	1.65 1.05–2.61
	RAI stage ≥ 2 vs. 1	1.74 1.12–2.71

Methods: Connect® CLL is a large, prospective, longitudinal, multicenter, observational registry of 1494 CLL pts at 179 community (1311 pts), 17 academic (155 pts), and 3 government (28 pts) sites. Pts were enrolled within 2 months of initiating any line of CLL-directed therapy (LOT). Univariate (UV) and multivariate (MV) logistic regression analyses were conducted to identify characteristics associated with a decision to perform genetic testing at LOT 1 and at LOT ≥ 2.
Results: Baseline characteristics for the cohort were as follows: 63.8% of pts were male and the median age was 69 years (range 22–99). The median time from diagnosis to inclusion in the registry was 3.7 years (range 0–32) and 92.7% of pts had an ECOG PS score of ≤1. FISH or CG was performed at study enrollment in 861/1494 (58%) pts (36% CG, 49% FISH, 28% both). 65% of 889 pts were tested for FISH/CG prior to LOT1, 50% of 260 in LOT2, 45% of 345 in LOT≥3. Of 861 pts tested at enrollment, 29% had FISH/CG retested with a subsequent LOT. In UV analyses (14 predictors), FISH/CG were more often performed at academic sites (p 0.005), in pts age ≤75 (p 0.0002), at enrollment at LOT1 vs. LOT ≥2 (P<0.0001), in private insurance pts (p 0.002) and Rai stage ≥2 (P<0.0001). Table 1 describes independent predictors of performing genetic FISH/CG testing stratified by LOT (LOT1 vs. LOT≥2) and practice setting (all practice settings vs. community-government settings only).
Summary and Conclusions: Our results indicate that only a fraction of CLL pts are tested/re-tested for genetic alterations by FISH/CG. Given the significance of identifying del17p or complex CG in selecting each LOT, these results indicate a need for increased awareness of the importance of this testing in clinical practice.

PB1717

VALUE OF CIRCULATING GALECTIN-3 FOR PROGNOSIS OF CARDIOVASCULAR EVENTS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA IN REMISSION

B. Samura[1,*]
[1]Zaporizhzhia Regional Clinical Hospital, Zaporizhzhia, Ukraine

Background: Perivascular leukocyte infiltrates and endothelial damage are vital in the development of chronic lymphocytic leukemia. As cell-to-cell interactions are critical in the processes of chronic lymphocytic leukemia, galectin-3 have become of interest as novel regulators of inflammation. Galectin-3 is produced by activated macrophages and it is predominantly expressed in subclinical atherosclerosis, unstable and stable coronary artery disease, heart failure. Therefore, galectin-3 is not only key player in inflammation and as well as in tumor progression by displaying intracellular and extracellular activities. However, the predictive role of galectin-3 in stable patients with chronic lymphocytic leukemia in remission is not understood.
Aims: Evaluate the prognostic value of circulating galectin-3 for cumulative survival in patients with chronic lymphocytic leukemia in remission.
Methods: One hundred fifty six out subjects with chronic lymphocytic leukemia in full or partial remission were enrolled in the study. Diagnosis and staging of chronic lymphocytic leukemia were defined by current clinical practice guidelines. All subjects gave their written informed consent to participation in the study. Observation period was up to 12 months. Blood samples for biomarkers measurements were collected. ELISA method for measurements of circulating level of galectin-3 was used. Hemodynamic evaluation was performed by transthoracic echocardiography. Echocardiography in B-mode was performed accordingly to Recommendation of American Society of Echocardiography on the scanner "MyLab 50" (Italy) using a transducer with a frequency of 2.5-3.5 MHz.
Results: Two hundred sixteen cumulative clinical events occurred in 51 patients (32,7%) within the follow-up, with their distribution being as follows: 7 deaths, 122 cardiac arrhythmias, 16 cardiac ischemic events, 3 strokes, 30 chronic heart failures and 38 hospital admissions for cardiovascular reasons. Medians of circulating levels of galectin-3 in free-events subject cohort and subjects cohort with cardiovascular events were 5,16 ng/mL (95% confidence interval [CI]=4,74-5,56 ng/mL) and 16,40 ng/mL (95% CI=14,80-18,01 ng/mL) (P<0.001). In multivariate logistic regression circulating VE-catherin independently predicted cumulative cardiovascular events (odds ratio [OR]=1,13; 95% CI=1,07–1,25; P=0.003) within 12 months of observation period. Results of the study showed that exaggerated circulating level of galectin-3 in patients with chronic lymphocytic leukemia in remission may consider biomarker with power predictive value for cardiovascular events whether for tumor progression did not. Probably it may be related with small size of the study or short-term period of the observation. However, association of galectin-3 with tumor progression was not found. Author think that it is needed more studies with higher statistical power to be recognized prognostic potential of Gal-3 in two directions: cardiovascular outcomes and tumor progression.
Summary and Conclusions: Among patients with chronic lymphocytic leukemia in remission increased circulating galectin-3 associates with increased cumulative cardiovascular events within 12 months.

PB1718

EFFICACY AND TOLERABILITY OF PENTOSTATIN CYCLOPHOSFAMIDE RITUXIMAB (PCR) REGIMEN IN ELDERLY, "SLOW-GO" CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS. A MONOCENTRIC EXPERIENCE

S. De Lorenzo[1,*] M. Barone[1], F. Rivellini[1], C. Califano[1], V. Belsito Petrizzi[1], M. Langella[1], C. Ingenito[1], P. De Prisco[1], A. Campana[1], V. Iovino[1], C. Trezza[1], A.M. D'Arco[1]
[1]U.O. Oncoematologia, Ospedale A.Tortora, Pagani, Italy

Background: Chronic lymphocytic leukemia (CLL) is the most common adult leukemia and primarily affects the elderly. Treatment of CLL has evolved significantly in recent years. There is currently no standard of care for patients with CLL older than 70 years or patients with co-morbidities and an impaired physical condition ("Slow go"). These patients may be offered a mild chemotherapy regimen: chlorambucil or dose-reduced fludarabine or bendamustine. Dose-modified combination regimens such as Fludarabine, Cyclophosphamide, Rituximab (FCR)-Lite seem to deliver the FCR therapy with a lower toxicity, but this combination still has to be tested on a large scale, in less fit patients. Similarly, the use of pentostatin, cyclophospamide, rituximab (PCR) was investigated to achieve a reduced toxicity, with promising results, both in pretreated CLL patients than in frontline.
Aims: Starting in December 2010, we selected elderly patients with "slow-go" CLL to evaluate efficacy and safety of PCR regimen in this subset.
Methods: To date, we observed 16 cases of "slow-go" elderly CLL, most were high risk patients. They were treated with PCR regimen consisting of pentostatin (P:2mg/m^2), cyclophospamide (C:600 mg/m^2) and rituximab (R:375 mg/m^2) on day 1 (21-day cycles). Dose 1 of R was given on day 8 (Cycle 1) and was increased to 500 mg/m^2, from cycle 2. The dose of pentostatin was increased to 4 mg/m2, from cycle 3, in the absence of grade III-IV hematologic toxicity. This PCR regimen was given on a 21-day, 6-cycle schedule. Support from granulocyte colony-stimulating growth factor was provided, as required. Patients received prophylaxis with cotrimoxazole and lamivudine (as required).
Results: 13 patients (82%) were treated in frontline and 3 patients (18%) at relapse. The median age was 73 years and 88% were 70 years older. 69% (RAI stages 3-4) and 100% (Binet B-C). Cytogenetics showed Trisomy 12 (31%) and 13q14 deletion (19%). No other cytogenetic abnormalities were detected. IgV_H status resulted "unmutated" in 81% of cases. All patients had comorbidities and 87% had a Creatinìne Clearance (CrCl)<70 ml/min. The overall response rate (ORR) on the whole population was 88%, complete response (CR):25%, partial response (PR):63%. The ORR in frontline was 85%, CR(31%), PR(54%). All patients completed the planned six courses of PCR, without dose reductions or delayed. Toxicities were: grade III-IV neutropenia (18%) and anemia (6%); grade II thrombocytopenia (18%), grade II nausea (31%), grade II constipation (6%), grade II hypertransaminasemia (6%). We didn't observe severe or prolonged infections or other toxicities. There were no significant differences in the number of cycles administered, need for dose reductions, grade 3-4 toxicities in patients with CrCl<70 ml/min. At a median follow-up of 29 months (range: 6-44), the median progression free survival (mPFS) was 17.6 months (range: 3-42), 75% of patients are alive, 3 patients (25%) died for cardiovascular disease, respectively after 6, 12 and 12 months and 1 patient for severe pneumonia after 3 months from the end of therapy.
Summary and Conclusions: Therapeutic strategies for "slow-go" patients with CLL are still lacking, especially for elderly patients. In previous studies, PCR regimen demonstrated activity, both in frontline and at relapse. Moreover, PCR seems feasible and safe because loaded from toxicities less than FCR regimen. In our experience, PCR was well tolerated in elderly and "slow-go" CLL, also in patients with CrCl<70 ml/min. Then, PCR may be a treatment option in this subset of patients.

PB1719

IMMUNE THROMBOCYTOPENIA IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

K. Alexandrova[1,*] M. Velizarova[2], E. Hadjiev[3], A. Stanchev[4], D. Popova[5]
[1]Department of medical oncology, Gustave Russy Cancer Campus, University Hospital, Paris, France, [2]University Hospital Alexandrovska, Sofia, Bulgaria, [3]Clinic of Hematology, University Hospital Alexandrovska, Sofia, Bulgaria, [4]The Royal Oldham Hospital, Oldham, United Kingdom, [5]Military Medical Academy, Sofia, Bulgaria

Background: Chronic Lymphocytic leukemia (CLL) is sometimes associated with autoimmune cytopenia: autoimmune hemolytic anemia (5-25% of cases) and immune thrombocytopenia (1-8% of cases)]. The effect of immune thrombocytopenia (ITP) on the clinical outcome and survival of patients with CLL is controversial.
Aims: The aim of the study was to correlate of ITP-CLL evidence with biological features, phenotypic and cytogenetic abnormalities and disease outcome in patients with B-CLL.
Methods: We studied 175 patients with B-cell CLL. All patients were diagnosed according to the revised criteria of the National Cancer Institute-sponsored Working Group (NCI-WG) on Chronic Lymphocytic Leukemia (CLL) and were classified according to the Rai staging system. Twelve of them (6.9%) were with immune thrombocytopenia (IT). The diagnosis of immune thrombocytopenia was based on the presence on unexplained fall in platelet count to<100x10^9/L and on more than two indirect parameters: evidence of normal

bone marrow function (normal or increased megakaryocytes in bone marrow), no splenomegaly and no chemotherapy within the last month. The patients with thrombocytopenia due to bone marrow suppression (lymphocytes over 80% in bone marrow) were excluded from this analysis.
Results: Among clinical and biological variables, neither age, gender, tumor mass nor Rai stages at CLL diagnosis were significantly associated with ITP development. The ITP occurrence was significantly associated with ZAP-70 positivity (7/12; 58.3%). In contrast ZAP-70 was found in 44 of 119 B-CLL cases (27%, P=0.028). CD38 and P53 expressions was significantly higher (75% and 41.7%, respectively; P=0.038 and P=0.013, respectively) than in CLL without ITP (44% and 11.2%). Based on available FISH data, we found that among 12 cases with deletion of (11)(q22-23) region only one (9%) developed ITP. There was no statistical significance (p>0.05) between ITP development and cytogenetic deletion (13)(q14). The median overall survival of CLL-ITP patients was significantly shorter -68.6 months (95% CI: 49.5-87.6 months) than the patients without ITP -111 months (95% CI: 104.7-117.4 months; P=0.016) and overall survival dropped rapidly and was in stable rate after 12 months since the diagnosis. ITP cases had an increased risk of disease progression and mortality risk over 3 fold above the patients without ITP (P<0.001, P<0.05, respectively). CLL-ITP patients showed shorter median free of treatment period-2.08 months (95% CI 0-5.99), compared to CLL without ITP-45.10 (95%CI 36.50-53.70).
Summary and Conclusions: ITP-CLL is associated with a higher frequency of poor prognostic markers such CD38, ZAP-70 and P53 expressions and shortened free of treatment period and overall survival.

PB1720

IMPACT OF CLINICAL AND BIOLOGICAL VARIABLES ON TIME TO FIRST TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA
A. Giordano[1,*] P. Curci[1], R. Rizzi[1], T. Perrone[1], A. Cimmino[2], A. Mestice[1], G. Nardelli[1], B. Daraia[1], V. P. Gagliardi[1], F. Albano[1], G. Specchia[1]
[1]Hematology with Transplantation, [2]Anatomic Pathology, University, Bari, Italy

Background: Chronic lymphocytic leukemia (CLL) is a heterogeneous disease with variable outcome. The identification of factors that could predict the clinical course of CLL is a crucial objective. Recently, prognostic models involving a set of clinical and biological risk factors have been proposed to evaluate the association with the time before initiating treatment and the prognosis for patients with CLL.
Aims: In our study we investigated time to first treatment (TFT), measured as the time elapsed between diagnosis and first treatment, and its relation with clinical and biological parameters and overall survival.
Methods: We retrospectively evaluated patients (pts) with de novo CLL treated at the University Hospital of Bari (Italy) between April 2006 and February 2013. At diagnosis pts were studied for clinical characteristics and biological prognostic factors: age, β-2 microglobulin, absolute lymphocyte count, sex, Rai stage, number of lymph node groups involved, pattern of bone marrow involvement, splenomegaly, mutational status of the immunoglobulin heavy chain gene variable region (IGVH), cytogenetic abnormalities detected by FISH. Median time to first treatment was calculated for all pts, divided into two groups according to Median time to first treatment. The first group included pts treated within 40 months from diagnosis; the second group pts treated after 40 months from diagnosis. Univariate analyses of each group were performed to evaluate the correlation between the clinical variables and time to treatment. In addition, overall survival was calculated and compared in the two groups.
Results: In total, 69 pts were included; 42 in the group of pts treated within 40 months from diagnosis, and 27 in the group treated after 40 months.
Statistically significant differences were seen between the 2 groups regarding the pattern of bone marrow involvement (diffuse *versus* other patterns of marrow involvement; P=0.05), number of lymph node groups involved, (one *versus* more than one; P=0.01); mutational status of the immunoglobulin heavy chain gene variable region (IGVH) (mutated *versus* unmutated; P =0.05), cytogenetic abnormalities by FISH (21 pts with 13q14 in the group of TFT >40 months and 2 in the group of TFT<40 months; P:0.01). No statistically significant difference was seen among the other clinical variables and TFT. Moreover, comparing the OS of the group with TFT >40 months with OS of the group with TFT<40 months, statistically significant difference was observed (P:0.01).
Summary and Conclusions: In our study the pattern of bone marrow involvement, the number of lymph node groups involved, the mutational status of the immunoglobulin heavy chain gene variable region and the cytogenetic abnormalities could help to recognize at diagnosis a subset of patients that may show rapid evolution to progressive disease. Multicentric studies and larger cohorts of patients are warranted to confirm these preliminary data.

PB1721

INCIDENCE OF SECOND CANCER IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA: 19 YEARS EXPERIENCE FROM SINGLE CENTRE.
O. Seimeni[1,*] S. Koumas[1], C. Prokopiou[1], N. Neokleous[1], F. Tsolakis[1]
[1]hematology, Limassol General Hopsital, Limassol, Cyprus

Background: Patients with chronic lymphocytic leukaemia (CLL) have a higher incidence of second malignancies than the general population.
Aims: Our study aims to present the incidence in our population and predicting whether stage and previous chemotherapies could have a negative impact on the number of second cancer in patients of CLL at our Hospital.
Methods: We retrospective evaluated 178 patients of CLL registered at General Hospital of Limassol, in Cyprus over a period of 19 years (1995-2014). A second malignancy was defined as another malignancy at the time of diagnosis or during follow up.

Table 1. Results of study in parathensis there is the report of deaths related to second cancer (dead patients w/o cancer+dead patients with cancer).

		Early stage	Advanced stage
Patients	178	141	37
male	103	78	25
therapy		*22*	*10*
2nd cancer		*4*	*4*
death		*13 (11+2)*	*4 (3+1)*
w/o therapy		*56*	*15*
2nd cancer		*7*	*4*
death		*7 (3+4)*	*4 (2+2)*
Female	75	63	12
therapy		*13*	*4*
2nd cancer		*0*	*0*
death		*6 (6+0)*	*3 (3+0)*
w/o therapy		*50*	*8*
2nd cancer		*8*	*0*
death		*5 (3+2)*	*0*

Results: There were 178 patients, 75 females and 103 males. The average age, was 67 years (34-94 years). The common presenting features were lymphocytosis 86%, lymphadenopathy 82%, splenomegaly 20%, and hepatomegaly 7%. Analysing data for all the patients, at diagnosis, 79% were early stage, (Rai stage 0- 46,3%, Rai stage I- 14,7%, Rai stage II-18%) and 21% of cases were in advanced stage, (Rai stage III- 18,6%, Rai stage IV-2,4%). Twenty seven percent of patients received treatment at presentation or at disease progression, including chlorambucil, fludarabine, rituximab and bendamustine based regimens. During the follow up, we noticed 27 cancers, including two haematological malignancies along with cancer of breast, uterus, lung, prostate, colon, skin, pancreas renal and larynx. We also found two high grade transformation (Richter syndrome), two cases of prostate infiltration and one case of breast infiltration by chronic lymphocytic leukaemia (Table I). Median time between CLL and second cancer diagnosis was 5.01 years (0-16 years). According to correlation analysis, neither advanced stage nor previous chemotherapies influenced with statistical significance the incidence of second malignancy in patients with CLL in our Hospital. Moreover the second tumour did not predisposed shortness of patient's survival and chemotherapy has no impact in the time of cancer diagnosis.
Summary and Conclusions: The incidence of second cancer is 15,3% in our population. Advanced stage and previous chemotherapies have none impact in this incidence and did not influenced the survival of the patient, comparing with the survival of the non-cancer patients. Unfortunately, the majority of our patients has diagnosed before the facility for molecular and cytogenetic analysis became feasible in Cyprus, that didn't let us to include modern prognostic factors in our study.

PB1722

HYPOGAMMAGLOBULINEMIA AND INFECTIOUS EVENTS IN CHRONIC LYMPHOCYTIC LEUKEMIA
M.J. Mendes[1,*] G. Ferreira[1], H. Saturnino[1], J.C. Almeida[1], L.F. Araújo[1], M. Duarte[1], M.L. Ribeiro[1]
[1]Hematology, CHUC, Coimbra, Portugal

Background: Infections are a major cause of morbidity and mortality in Chronic Lymphocytic Leukemia (CLL), related to humoral and cellular immune deregulations due to the disease itself and enhanced by immunosuppression associated to treatments. Hypogammaglobulinemia is the most common chronic immune defect in CLL, related to duration and stage of the disease, and correlates with the frequency and severity of infections observed in these patients.
Aims: Analyze and compare the frequency and type of infectious episodes requiring hospital admission in a population of patients diagnosed with CLL, with and without hypogammaglobulinemia.

Methods: Retrospective analyses of the clinical files of patients with CLL diagnosed between January 2004 and August 2014.
Results: Between January 2004 and August 2014, 151 patients were diagnosed with CLL. Twenty-five patients (16.6%) developed hypogammaglobulinemia, 6 at the time of diagnosis. The mean time from diagnosis of CLL to the development of hypogammaglobulinemia in the remaining patients was 38.2 months (min=4; max=97). Patients with a serum IGg<5g/L and recurrent or severe infections received IVIg replacement therapy. In the group with hypogammaglobulinemia (n=25), the median age at diagnosis was 71 years (min=50; max=88); 14 men (56%) and 11 women (44%). The initial staging (Rai) was 0 in 11 patients (44%), I in 8 patients (32%), III in 3 patients (12%) and IV in 3 patients (12%). The initial approach was watchful waiting in 16 patients (64%), with 9 patients (36%) requiring treatment. Sixteen patients (64%) required hospital admission related to infectious intercurrences, with 25.6 days as mean time of hospitalization (min=1; max=133). The total number of documented infections was 47 (mean of 3 episodes/patient; min=1; max=9): upper and lower respiratory tract infection in 14 patients (87.5%), urinary tract infection in 6 patients (37.5%); gastroenteritis, lower and upper limb cellulitis, oral candidiasis and febrile neutropenia in 2 patients each (12.5%). One patient developed cryptococcal meningitis and one patient developed septicemia. In the group without hypogammaglobulinemia (n=126), the median age at diagnosis was 70 years (min=37; max=93); 73 men (58%) and 53 women (42%). The initial staging was 0 in 90 patients (71.4%), I in 24 patients (19%), III in 6 patients (4.8%) and IV in 7 patients (5.6%). The initial approach was watchful waiting in 113 patients (89.7%) and treatment in 13 patients (10.3%). Twenty-two patients (17.4%) required hospital admission due to infectious events, with a mean time of 15.55 days (min=1; max=69) and a total number of 37 infections (mean of 1.7 episodes; min=1; max=5): upper and lower respiratory tract infection in 12 patients (54.5%), urinary tract infection in 6 patients (27.3%); gastroenteritis, septicemia and cellulitis in 3 patients each (13.6%); febrile neutropenia in 2 patients (9.1%). One patient developed a rickettsia infection.
Summary and Conclusions: The two groups were similar in terms of age and sex distribution. The proportion of patients staged III and IV was higher in the group with hypogammaglobulinemia. The percentage of patients with infectious events requiring hospital admission was significantly higher in the group with hypogammaglobulinemia (64% vs 17.4%). Fungal infections were only present in the group with hypogammaglobulinemia. A higher number of infectious events in this group required a longer time of hospital admission, reflecting their severity. Therefore, it is important to monitor immunoglobulin levels and to administer immunoglobulin replacement therapy in these patients.

PB1723

CUMULATIVE ILLNESS RATING SCALE (CIRS) – AN INDEPENDENT PROGNOSTIC PARAMETER FOR CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS' PRETREATMENT STRATIFICATION

V. Vukovic[1,*] D. Antic[1,2], M. Todorovic[1,2], J. Bila[1,2], B. Andjelic[1,2], V. Djurasinovic[1], A. Sretenovic[1], J. Jelicic[1], B. Mihaljevic[1,2]
[1]Lymphoma center, Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: Most of data about the clinical outcome of patients with chronic lymphocytic leukemia (CLL) come from patients participating in clinical trials. Such trials typically have strict eligibility criteria based on performance status and organ function. Little is known about the organ function of unselected patients (*i.e.*, regardless of whether they are eligible for trials). Adult comorbidity evaluation-27 (ACE-27), Cumulative Illness Rating Scale (CIRS) and hematopoietic cell transplantation comorbidity index (HCT-CI) are comorbidity indexes that take concurrent presence of nonmalignant diseases into account when explaining survival. They differ in both the number and categorization of comorbidities.
Aims: We investigated the prognostic significance of three comorbidity indexes in adition to standard prognostic tools in a sample of 74 patients with CLL.
Methods: We retrospectively evaluated the impact of ACE-27, CIRS and HCT-CI in a cohort of 74 adult patients with chronic lymphocytic leukemia (HLL) treated with Fludarabine-Cyclophosphamide combination. Also we tested impact of standard prognostic tool available in daily practice as age, gender, Rai/Binet clinical stage, LDH level, type of bone marrow infiltration and CD38 expression. Patient and survival data were acquired from inpatient hospital records. Cox hazard regression model was used to analyze overall survival according to standard prognostic factors and comorbidities classified by the ACE-27, CIRS and HCT-CI.
Results: Median follow up of our group was was 5 years (60 months) while median overall and progression free survival was 72 and 32.5 months, respectively. We found a significant association between CIRS and bone marrow infiltration pattern and overall survival (P=0.037; RR=2.0; 95%CI for RR 1.1-4.0 for CIRS>15 and P=0.014; RR=2.3; 95%CI for RR 1.2-4.5 for diffuse type of bone marrow infiltration). Other two comorbidity indexes – ACE-27 and HCT-CI and standard prognostic factors did not outperform the survival model, while in multivariate analysis CIRS>15 and diffuse type of marrow infiltration remained the most important predictors of overall survival (P=0,009 and P=0,004, respectively). We developed a new scoring system based on the CIRS score value and bone marrow infiltration pattern. Patients with CIRS≤15 and without diffuse type of marrow infiltration were of low risk (score 0), patients with CIRS>15 or diffuse bone marrow infiltration pattern corresponded with intermediate risk (score 1), while patients with both CIRS>15 and diffuse type of bone marrow infiltration represented high risk group (score 2). Median overall survival for patients with score 0, 1 and 2 was 96, 82 and 34 months, respectively, which makes this new score a good predictor of mortality among patients with chronic lymphocytic leukemia (P<0.001; RR=2.6; 95%CI for RR 1.5-4.5).

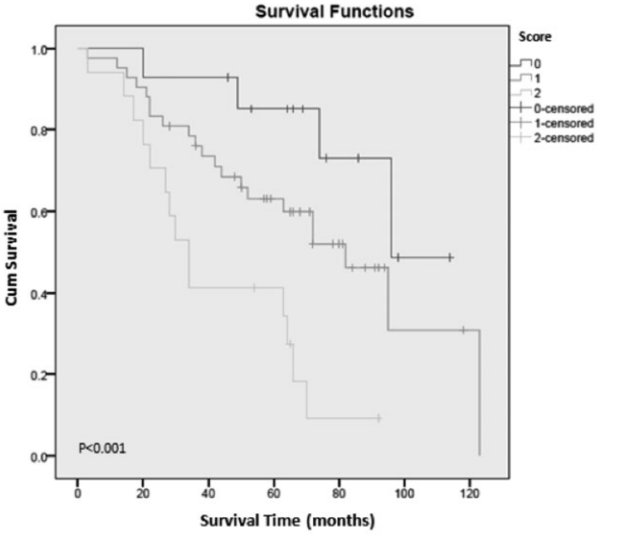

Figure 1.

Summary and Conclusions: In our group of adult CLL patients the overall survival is associated with the presence of comorbidities defined by the CIRS index. CIRS and type of bone marrow infiltration present a superior comorbidity risk-adjustment model for CLL survival prediction.

Carlo" Hospital, Potenza, [6]Laboratory of Preclinical and Translational Research, IRCCS Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, [7]Allergology Unit, "S. Maria della Speranza" Hospital, Battipaglia, [8]Hematology Chair, Catholic University of Sacred Heart, Rome, [9]Pharmacology Department, University of Salerno, Salerno, [10]Scientific Direction, IRCCS Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, Italy

Background: The anti-CD20 monoclonal antibody rituximab is approved for the treatment of non-Hodgkin's lymphomas (NHL) and chronic lymphocytic leukemia (CLL). Infusional side effects are commonly seen during rituximab administration, mostly in the first cycle and in patients with high tumor load. Severe adverse events (SAE) may also occur, following which the drug needs to be definitively stopped in some cases. Very recently, Norin et al, have reported data of a Swedish national observational study focusing on SAE occurring in patients with CLL who underwent rituximab treatment (Leuk Res, 2015). These Authors evaluated 96 patients and found that 58% of them experienced at least one adverse drug reaction (ADR) during the first cycle. Only 5 patients (5%), however, reported grade ≥ 3 ADRs, with one grade 4 reactions. Only 2 patients had a leukocyte count >50.000/mL and no correlation between leukocyte count and ADR grade was found.
Aims: Starting in October, 2014, we are conducting a retrospective Italian multicenter study aiming to evaluate the incidence of side effects in patients treated in the last 5 years at our Institutions with rituximab for their hematologic malignancies or autoimmune disorders. We choose to focus on ADRs occurred in CLL patients aiming to evaluate the incidence of infusional side effects and, possibly, its correlation with clinico-biological features evaluated immediately before to start therapy.
Methods: To date, 130 patients have been evaluated: 60 with CLL, 34 with non-Hodgkin's diffuse large B-cell lymphomas, 33 with non-Hodgkin's indolent lymphomas, 1 with Hodgkin's lymphomas with lymphocyte predominance, and 2 with autoimmune disorders (1 immune thrombocytopenia and 1 acquired hemo-

philia A). Sixty patients with immunologically typical CLL were evaluated (40 were male and 20 female; mean age was 66,4 years, range 46-86; 1 patient with Rai stage 1; 29 patients stage 2; 17 stage 3; and 13 stage 4). Rituximab was given as first line treatment and variously combined with different drugs, the most used being fludarabine, cyclophosphamide, chlorambucil and bendamustine.
Results: Twenty-three patients (38%) experienced an adverse event during the first infusion of rituximab, while 37 patients (62%) did not. Overall, 13 patients (57%) had grade 1, 7 (30%) grade 2, 1 (4%) grade 3, and 2 (9%) grade 4 ADRs, according to National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE). No correlation was found with age, gender, concomitant presence of an autoimmune hemolytic anemia, spleen and lymph node involvement, platelet count, and type of associated-chemotherapy. Degree of bone marrow infiltration (p 0.03) and the concomitant infusion of rituximab plus chemotherapy with respect to a delayed administration (p 0.007) were significantly associated with the occurrence of ADRs. Quite surprisingly, patients with more elevated hemoglobin levels (p 0.02) and those with lower peripheral lymphocyte counts (p 0.03) displayed a greater risk to develop ADRs; these last patients also showed more severe ADRs. Most of side effects were easily managed. In the majority of cases rituximab was temporarily stopped, while steroids and anti-histaminic drugs were given. The monoclonal antibody was then safely re-started with a less rapid infusion. Only one patient definitively stopped rituximab treatment, due to grade 4 ADR (shock and dyspnea).
Summary and Conclusions: Overall, in our multicenter experience, side effects after rituximab were commonly seen in CLL patients during the first infusion. However, they were mostly limited to grade 1 and 2 (mild-moderate) and were easily managed. Rituximab was generally re-administered during the same course of the treatment. Only very few patients experienced severe infusion-related ADRs and rarely the monoclonal antibody had to be definitively stopped. Clinico-biological variables, including pharmacogenomic parameters, that could be useful in predicting the development of infusional side-effects are warranted in order to identify patients at higher risk for ADR and to develop appropriate preventing therapies.

PB1725

EPIDEMIOLOGY OF CHRONIC LYMPHOCYTIC LEUKEMIA ON REUNION ISLAND

I. Kittler[1,*] P. Zunic[2], R. Letestu[3], A. Clabé[4]
[1]Laboratoire HLA, CHU de La Réunion, Saint Denis, [2]Hémato-oncologie, CHU de La Réunion, Saint-Pierre, Réunion, [3]Laboratoire d'hématologie, Hôpital Avicenne, Paris, France, [4]Laboratoire d'hématologie, CHU de La Réunion, Saint-Pierre, Réunion

Background: Chronic Lymphocytic Leukemia (CLL) is the most common type of leukemia diagnosed in the Western world. The causes of its occurrence remain unclear: environmental factors are involved, such as farming related and chemical exposures. Family history of any hematological malignancy may also increase risk of CLL. Reunion Island is an 874.000 inhabitants tropical French overseas department located in the southwestern Indian Ocean. Because of its insularity and the significant interbreeding population, this territory lends itself to genetic peculiarities. The fraction of people of each ethnicity is not known exactly. A 2002 regional report estimated the distribution of different ethnic groups as 33% Persons of mixed race, 27% Caucasians, 20% Indians, 17% Africans and 3% Chinese.
Aims: In the absence of previous epidemiological study, we conducted a comprehensive review of epidemiological, prognostic and therapeutic characteristics of CLL Reunionese patients over a period of ten years, between 2004 and 2013.
Methods: Inclusion criteria were as follows: any French patient having a permanent residence on Reunion Island and matching the NCI/WG diagnosis criteria for the 2004-2008 period, or the IWCLL diagnosis criteria for the 2009-2013 period. Monoclonal B-cell lymphocytosis as well as small lymphocytic lymphomas were not included in the study. Variables analyzed were age at diagnosis of CLL, sex, prognostic markers (ZAP-70, lymphocyte doubling time, B2-microglobulin, and where available del (17p13)), stage at diagnosis and treatment intervention.
Results: A total of 134 cases of CLL were identified in this study. The age-standardized incidence rate was 1.23 per 100.000 with a male/female sex ratio of 1.98:1. Median age at diagnosis is 63 (range, 38-93 years). 37.3% of patients were under 60 years. A majority of CLL diagnosis (86.3%) were discovered incidentally after a blood cell count is performed for another reason. More patients were at early stage (Binet A) *versus* advanced (Binet B or C) at the time of CLL diagnosis (77% *versus* 23%). Median absolute lymphocyte count at diagnosis was 11.7 G/L. When treatment was indicated (30%), 2/3 patients (12%) received immunochemotherapy as first-line treatment. The median time to treatment was 21.9 months. The overall survival at 5 years is 85%.
Summary and Conclusions: All CLL diagnosis in Reunion Island are carried out *a priori* in one of the two Hospital Centers existing on the island, which are the only facilities able to perform blood lymphocytic immunophenotyping by flow cytometry. The French National Network of Registers FRANCIM analyses together CLL and small lymphocytic leukemia: the 2012 incidence rate on the whole French territory is estimated at 4.4 and 2.2, in men and women respectively, per 100,000. CLL incidence seems twice to three times lower on Reunion Island. Despite a comparison bias between national and Reunionese statistics, the difference appears significate. This Reunionese peculiarity might be explained either by genetic factors related to a highly mixed population, or by environmental factors. Another hypothesis which might explain the low CLL incidence would be an under-use of public and private medical facilities by the Reunionese, in particular elderly people. Besides, sharing between Binet classification stages is the same as the one reported in the literature. No significant differences were identified in overall survival compared with European CLL patients. The low CLL incidence observed on Reunion Island is probably due to multiple factors and requires further investigations. The determination of each patient's ethnic origin shall highlight a possible under-representation of one or several population categories.

PB1726

SECONDARY MALIGNANCIES AFTER FCR AND FC TREATMENT IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA. A SINGLE CENTER STUDY.

T. Byalik[1,*] O. Timofeeva[1], Y. Ryabukhina[1], V. Larionova[1], E. Osmanov[1]
[1]Oncohematology, N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: The combination of fludarabine, cyclophosphamide and rituximab (FCR) improved response rates and prolonged both overall survival (OS) and progression-free survival (PFS). On the basis of CLL8 trial FCR has become the standard treatment for fit patients with CLL.
Aims: In this report we presents of follow up results of FCR and FC therapy and adverse events as secondary malignancies.
Methods: 117 patients (50 previously untreated and 67 with relapsed and refractory) received six courses of FCR or FC. Median age was 56,5 (range 28-73) for FCR group and 57 (range 38-76) for FC group. 52 patients were in Binet stage B and 15 in stage C for FCR group, 38 patients were in Binet stage B and 12 in stage C for FC group. OR was 91% with CR rate 57% for FCR group, 86% and 50% for FC group.
Results: At follow up period 120 months median overall survival in FCR group was 61,3 month, in FC group – 44,6 months, in previously untreated FCR group median OS was 89 months and OS was not reached for previously untreated FC group, progression-free survival were 42,4 months for previously untreated FCR group and 24,4 month for previously untreated FC group (P=0,01). Infection complications III-IV grade were appeared in 15 patients: 4 (6%) for FCR group and 11 (22%) for FC group. 5 patients died due to infection: 2 patients in FCR group (2,9%) and 3 patients in FC group (6%). Secondary malignancies were occurred at 10 patients (8,5%): 6 patients in FCR group (8,9%) and 4 – in FC group (8%). Of these 10 patients, 5 patients (4,2%) had a solid tumor (lung, bladder, colon), 1patient (0,8%) had a melanoma, 4 patients (3,4%) had a Richter transformation.
Summary and Conclusions: FCR chemoimmunotherapy is highly effective in patients with CLL. The frequency of secondary malignancies was 8,5%.

PB1727

IBRUTINIB IN CHRONIC LYMPHOCYTIC LEUKAEMIA: A SINGLE CENTRE EXPERIENCE

J. Russell[1,*] C. Gomez[2], K. Bowles[3], G. Turner[3], S. Sadullah[2]
[1]Department of Medicine, Norfolk and Norwich University Hospital, Norwich, [2]Department of Haematology, James Paget University Hospital, Gorleston, [3]Department of Haematology, Norfolk and Norwich University Hospital, Norwich, United Kingdom

Background: Ibrutinib, a first-in-class Bruton's Tyrosine Kinase inhibitor, was available to National Health Service patients with relapsed/refractory Chronic Lymphocytic Leukaemia (CLL) through a Named Patient Supply (NPS) program from April to September 2014, funded by Janssen Pharmaceuticals. Approximately 600 patients with CLL were enrolled in the United Kingdom (UK). The James Paget University Hospital treated 23 patients with CLL through the NPS (including 10 patients from the Norfolk and Norwich University Hospital).
Aims: To evaluate the therapeutic response to ibrutinib in the clinical setting compared to clinical trial data.
Methods: Therapeutic response was assessed in October 2014 using clinical and laboratory data. The patient group was 65.2% male, with a median age of 74 years (range 45–89) and a median of 3 prior lines of therapy (range 1-6). Cytogenetic analysis was available for 20 (87%) patients. Five (25%) patients had 17p deletion, four (20%) had 13q deletion, three (15%) had trisomy 12p, two (10%) had 11q deletion, and six (30%) had no detectable abnormalities. Five patients were excluded from the analysis, including four who had received less than eight weeks of treatment and one who had withdrawn from the NPS early.
Results: Out of 18 patients, comprising a total of 242 drug-weeks, there was one (5.6%) Clinical Complete Response (CR), four (22.2%) Partial Responses (PR), nine (50%) Partial Responses with Lymphocytosis (PR+L), two (11.1%) with Stable Disease (SD), one (5.6%) with Disease Progression (DP) and histological transformation, and one (5.6%) death from sepsis. The Overall Response Rate (including PR+L patients) was 78%. Notably, both the patient

in Clinical CR and the patient with histological transformation had 17p deletion. Common side-effects included diarrhoea (16.7%), upper respiratory tract infections (11.1%), low platelet counts (<30x10^9/L in 5.6%), and lymphocytosis (>two-fold increase in 22.2%). None were treatment-limiting.
Summary and Conclusions: These encouraging early results must be interpreted cautiously, but they suggest that Ibrutinib has similar efficacy and side-effect profiles in the clinical setting as it does in clinical trials.

Chronic myeloid leukemia - Biology

PB1728

COMBINED EFFECTS OF PI3K INHIBITOR, COPANLISIB WITH ABL TYROSINE KINASE INHIBITORS IN PH-POSITIVE LEUKEMIA CELLS
S. Okabe[1,*] T. Tauchi[1], Y. Tanaka[1], S. Katagiri[1], K. Ohyashiki[1]
[1]Department of Hematology, TOKYO MEDICAL University, Shinjuku-Ku, Japan

Background: ABL tyrosine kinase inhibitor (TKI), imatinib and second-generation ABL TKIs, nilotinib and dasatinib have demonstrated the potency against chronic myeloid leukemia (CML) patients. However, resistance to ABL TKI can develop in CML patients due to BCR-ABL point mutations. Moreover, ABL TKIs cannot eradicate leukemia stem cells (LSCs), thus, TKIs do not appear to lead to a cure the diseases. Therefore, new approach against BCR-ABL mutant cells and LSCs may improve the outcome of BCR-ABL-positive leukemia patients. Phosphoinositide 3-kinase (PI3K) pathway regulates cell metabolism, proliferation and survival. Furthermore, aberrant activation of PI3K signaling pathway has been shown to be important in initiation maintenance of human cancers. Copanlisib, also known as BAY80-6946 is a potent pan-class I PI3K inhibitor against PI3Kα and PI3Kδ with potential anti-neoplastic activity. Copanlisib is being investigated in a pivotal phase 2 clinical trial against hematological malignancies such as malignant lymphoma.
Aims: We hypothesized that targeting PI3K, in combination with ABL TKI, would result in enhanced therapeutic activity in Philadelphia chromosome (Ph)-positive leukemia cells including T315I mutation and ABL TKI resistant.
Methods: We investigated the combination therapy with a copanlisib and an ABL TKIs (imatinib, nilotinib and ponatinib) by using the BCR-ABL positive cell line, K562, murine Ba/F3 cell line which was transfected with T315I mutant, nilotinib resistant K562, ponatinib resistant Ba/F3 cells and primary samples.
Results: 72 h treatment of copanlisib exhibits cell growth inhibition against K562 cells in a dose dependent manner. The treatment of imatinib, nilotinib and ponatinib exhibits cell growth inhibition partially against K562 cells in the presence of feeder cell line, HS-5. We found that mRNA of PI3K subunit, p110δ is significantly increased after a co-culture with HS-5 in K562 and primary CD34 positive CML samples. We examined the intracellular signaling after treatment of copanlisib. High concentration of copanlisib reduced the phosphorylation of BCR-ABL, Crk-L and S6 ribosomal protein. Activity of poly (ADP-ribose) polymerase (PARP) was increased. Phosphorylation of BCR-ABL, Crk-L and S6 ribosomal protein was reduced after imatinib and copanlisib treatment. We investigated the copanlisib activity against T315I positive cells. Copanlisib potently induced cell growth inhibition of Ba/F3 T315I cells. Combined treatment of Ba/F3 T315I cells with ponatinib and copanlisib caused significantly more cytotoxicity than each drug alone. Phosphorylation of BCR-ABL and Crk-L was reduced and cleaved PARP was increased after ponatinib and copanlisib treatment. To assess the activity of copanlisib and ponatinib, we performed to test on CML tumor formation in mice. We injected nude mice subcutaneously with Ba/F3 T315I mutant cells. A dose of 20 mg/kg/day p.o of ponatinib and 6 mg/kg/three times per week i.p of copanlisib inhibited tumor growth and reduced tumor volume compared with control mice. We examined the intracellular signaling of tumor model. Phosphorylation of Crk-L and S6 ribosomal protein was reduced and cleaved PARP was increased. Treatments were well tolerated with no animal health concerns observed. We also found that the treatment of copanlisib exhibits cell growth inhibition against Ba/F3 ponatinib resistant cells, K562 nilotinib resistant cells and primary samples.
Summary and Conclusions: Our preclinical results indicated that administration of the PI3K inhibitor, copanlisib may be a powerful strategy against ABL TKI resistant cells and enhance cytotoxic effects of ABL TKI against those Ph-positive leukemia cells.

PB1729

DISTINCT ASSOCIATIONS BETWEEN UGT1A1 GENE PROMOTER POLYMORPHISM AND HYPERBILIRUBINEMIA IN CML PATIENTS TREATED WITH NILOTINIB AND RADOTINIB
S. Kim[1,*] S.Y. Choi [1], S.E. Lee[2], H.L. Yoo[1], Y.J. Oh[1], M.Y. Lee[1], E.J. Jang[1], M.Y. Choi[1], M.M. Jang[1], D.W. Kim[1,2]
[1]Cancer Research Institute, The Catholic University of Korea, [2]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Second-generation BCR-ABL tyrosine kinase inhibitors (2nd generation TKIs) including nilotinib (NIL) and radotinib (RAD) are approved for the treatment of newly diagnosed and other TKI failed chronic myeloid leukemia (CML). Uridine diphosphate glucuronosyltransferase 1A1 (UGT1A1) gene promoter polymorphism, distinct number of TA repeats in promoter, has been reported for an association with hyperbilirubinemia on nilotinib therapy (Singer *et al. Leukemia (2007) 21, 2311–2315*). However, the distribution of UGT1A1 $(TA)_7$ repeat polymorphism differs greatly between Caucasians and Japanese,

namely, the frequency of UGT1A1(TA)$_7$ repeat polymorphism is high in Caucasians, whereas it is low in Asians (Beutler *et al. Proc. Natl. Acad. Sci. USA 95 (1998)* 95, 8170–8174).
Aims: The aim of this study was to investigate the association between UGT1A1 gene promoter polymorphism and hyperbilirubinemia in Korean CML patients treated with NIL and RAD as a frontline therapy.
Methods: A total of 94 newly diagnosed chronic phase CML patients who treated with frontline NIL (n=42) and RAD (n=52) was screened for UGT1A1 promoter polymorphism genotype analysis. We used the High Pure PCR Template Preparation Kit (Roche, Germany) to prepare genomic DNA from whole blood and genotyped by direct sequencing of the 253- to 255-bp fragments produced by PCR.
Results: The (TA)$_6$/(TA)$_6$ homozygote and (TA)$_6$/(TA)$_7$ heterozygote were seen in all genotyped population and frequency of (TA)$_6$/(TA)$_6$ homozygote was 77.7% (73/94) in our patients. (TA)$_6$ /(TA)$_6$ homozygote predominated with 78.9% of the alleles in the RAD group and 76.2% in the NIL group. Relative risk for each genotype presented in Table 1, with hyperbilirubinemia defined as CTCAE grade 2 or greater observed at any post-baseline point. The relative risks for 6/6 genotype *versus* 6/7 genotype was 3.9 with 95% CIs of (0.7, 20.3) in the RAD group compared with 10.5 (2.0, 54.3) in the NIL group and NIL group showed significantly high association with UGT1A1 gene promoter polymorphism (P<0.05).

Table 1. Relative risk calculations prevalcence of hyperbilirubinemia.

	Radotinib				Nilotinib		
	Max grade≤1	Max grade≥2	Total		Max grade≤1	Max grade≥2	Total
(TA)6/(TA)6	19	22	41	(TA)6/(TA)6	28	4	32
	46.34%	53.66%			87.50%	12.50%	
(TA)6/(TA)7	2	9	11	(TA)6/(TA)7	4	6	10
	18.18%	81.82%			40.00%	60.00%	
Total	21	31	52	Total	32	10	42
Relative risk=3.9, 95% CI of (0.7, 20.3)				*Relative risk=10.5, 95% CI of (2.0, 54.3)*			

Abbreviation: CI, confidence interval.

Summary and Conclusions: This finding suggests that UGT1A1 gene promoter polymorphism may be an important determinant of hyperbilirubinemia in CML patients with NIL therapy, but not in RAD. However other mechanisms should be explored in patients who have significant hyperbilirubinemia with RAD therapy. Updated data with longer follow-up duration will be presented in the meeting

PB1730

IMPACT OF MULTIDRUG RESISTANCE GENE 1 (MDR1) C3435T POLYMORPHISM ON CHRONIC MYELOID LEUKEMIA RESPONSE TO TYROSINE KINASE INHIBITORS
Y. Elnahass[1,*] M. mattar[2], H. El Leithy[2]
[1]Clinical Pathology, National Cancer Institute, [2]Cinical hematology, School of Medicine, Cairo, Egypt

Background: Single nucleotide polymorphisms (SNPs) of multiple drug resistance (*MDR1*) gene are associated with altered P-glycoprotein (p-gp) activity and contribute to resistance to tyrosine kinase inhibitors (TKIs) in chronic myeloid leukemia (CML).
Aims: We aimed to demonstrate the association between MDR1 gene C3435T polymorphism and molecular response in newly diagnosed chronic phase (CP) CML patients to standard dose upfront imatinib and nilotinib therapy.
Methods: MDR1 C3435T was genotyped using polymerase chain reaction Restriction Fragment Length Polymorphisms (PCR-RFLP) at diagnosis. BCR-ABL1 transcripts level was measured by Real Time Quantitative polymerase chain reaction (RQ-PCR) at diagnosis then every 3 months.
Results: This study included 74 Philadelphia (Ph') positive CP-CML patients; 38 males and 36 females. Median age at diagnosis was 38 years (18-78). Median BCR-ABL1 level was 101%. Forty patients received imatinib (54%) while 34 received nilotinib (46%). Optimal response at 12 month was 35% in the imatinib arm *versus* 80% in the nilotinib arm (P=0.001). The frequency of MDR1 SNP C3435T was 46%, 32% and 22% for CC, TT and CT genotypes, respectively. Optimal response at month 12 differed significantly between imatinib and nilotinib among patients with MDR1 C3435TT genotype (11% *versus* 83%, respectively, P=0.002) while less significant difference was found between the two drugs in CC and CT genotypes (35% vs. 75% and 60% vs. 83%, respectively, P=0.042 & P=0.588).
Summary and Conclusions: MDR1 C3435TT may be used as an additional criterion for initiating nilotinib instead of imatinib as front line therapy for CP-CML patients. We demonstrated the usefulness of MDR1 SNP polymorphism in the identification of CML patients who may or may not respond optimally to imatinib.

PB1731

DIFFERENTIAL EXPRESSION OF ABCF2 IN NEWLY DIAGNOSED AND DASATINIB-TREATED CHRONIC MYELOID LEUKEMIA PATIENTS
B. Ribeiro[1,*] R. Ferreira[1], R. Silveira[1], Â. Fachel[2], S. Verjovski-Almeida[2], B. Vergílio[1], D. Albuquerque[1], C. Souza[1], K. Pagnano[1]
[1]Hematology and Hemotherapy Center, University of Campinas-UNICAMP, Campinas, [2]Departamento de Bioquímica, Instituto de Química, Universidade de São Paulo, São Paulo, Brazil

Background: *ABCF2* was previously identified by our group as genes differentially expressed in CML patients which are resistant to imatinib, in samples collected before and after dasatinib treatment (responsive and resistant) in a microarrays analysis study (SILVEIRA, RA *et al. Hematology*;19(1):31-41,2014). *ABCF2* gene is a member of the ATP binding cassette (ABC) transporter family and although its function is not clear, studies with colorectal and breast cancer showed an association of low expression of *ABCF2* and poor prognosis and non-response to palliative chemotherapy. The role of *ABCF2* in CML pathogenesis is unknown.
Aims: The aim of this study was to analyse the expression profile of *ABCF2* in CML patients without previous treatment, in CML patients treated with dasatinib (after imatinib failure) and in healthy donors.
Methods: Total RNA extraction of mononuclear cells from peripheral blood, transcription to cDNA, and qPCR were performed to analyze differential gene expression. *ACTB* and *GAPDH* were used as endogenous control. *geNorm* program was used to estimate the gene expression in arbitrary units (A.U.). Results were expressed as median and compared using non-parametric tests (*Mann Whitney* or *Kruskal-Wallis*). We evaluated 13 healthy donors (control group) and 39 CML patients treated with dasatinib in second line after imatinib failure: 25 responsive to dasatinib, all with complete cytogenetic response (CCyR), 15 of them with major molecular response (MMR) and 14 patients resistant to dasatinib. We also analyzed 9 samples collected at CML diagnosis from the group that was responsive to dasatinib. Only one patient of this group had no sample available after dasatinib treatment.
Results: *ABCF2* expression was down-regulated in the newly diagnosed CML samples and in patients treated with dasatinib compared to control group (0.15 [0.05 – 0.91] *versus* (*vs.*) 0.35 [0.04 – 3.07] *versus* (*vs.*) 2.5 [0.61 – 4.84] P< 0.0001). There was no difference of expression between patients at diagnosis and patients treated with dasatinib (all patients) (*P*=0.09). However, *ABCF2* expression was significantly lower in CML dasatinib-resistant patients when compared to dasatinib-responsive patients with MMR (0.35 [0.05 – 2.21] *versus* (*vs.*) 1.19 [0.14 – 3.07] P=0.02). The expression of *ABCF2* was down-regulated in 8 CML patients at diagnosis and its expression increased after treatment with dasatinib in patients that achieved MMR (0.22 [0.06 – 0.91] *versus* (*vs.*) 1.20 (0.14 – 2.73] P=0.049).

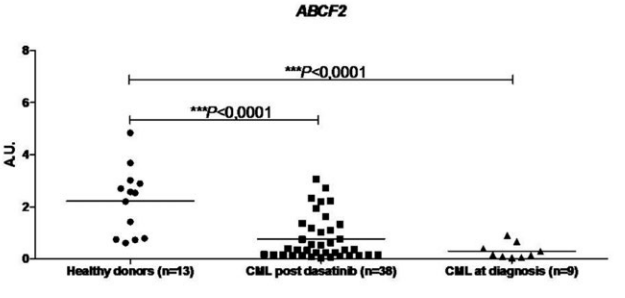

Figure 1.

Summary and Conclusions: *ABCF2* is down-regulated in newly diagnosed CML when compared to the healthy donors and to dasatinib treated patients. On the other hand, up-regulation of *ABCF2* was observed after treatment in patients which achieved MMR with dasatinib. *ABCF2* might be involved in mechanisms associated with the development of CML or resistance. Further studies are necessary to clarify the role of *ABCF2* in CML.

PB1732

DIDO 2 LOW EXPRESSION IN CML IS LINKED TO APOPTOSIS RESISTANCE
M. Coelho[1,*] A.P. Marsola[1], S. Burin[1], M. Rocha-Junior[1], A. Ferreira[1], S. Haddad[1], B. Simões[2], R. Panepucci[3], C. Martinez[4], F. Castro[1]
[1]Faculdade de Ciências Farmacêuticas de Ribeirão Preto-USP, [2]Faculdade de Medicina de Ribeirão Preto-USP, [3]Fundação Hemocentro de Ribeirão Preto, Ribeirão Preto, Brazil, [4]Centro Nacional de Biotecnologia-CSIC, Madrid, Spain

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neo-

plasm which patients are diagnosed by the *BCR-ABL1* oncogene presence. *BCR-ABL1* encodes Bcr-Abl, a tyrosine kinase protein responsible for CML pathogenesis and apoptosis impairment. CML patients are treated with tyrosine kinase inhibitors (TKI). However resistance to TKI have been described and can be associated with Bcr-Abl dependent and independent mechanisms. Therefore new therapeutic targets and CML pathogenesis, including the possible involvement of *DIDO*, should be investigated. *DIDO* is a gene that encodes transcription factors of apoptosis-inducing genes and has three different isoforms: *DIDO* 1, 2 and 3. In physiological conditions *DIDO* is present in small concentrations in cytoplasm, but during the process of apoptosis its protein expression rises and then it is translocated to the nucleus. Increased expression of *DIDO* is therefore associated with the induction of apoptosis process. In myeloproliferative diseases *DIDO* is defined as a tumor supressor gene. Expression changes of isoforms 2 and 3 were already described in the pathophysiology of myeloid neoplasms.
Aims: To evaluate the association between apoptosis resistance and Dido expression by the quantification of the expression of *DIDO* 1, 2 and 3 genes in CML patients in chronic and advanced phases and in healthy subjects.
Methods: 39 CML patients (median age = 45 years; 19 women and 20 men) and 16 controls (median age = 35 years; 10 women and 6 men) were studied. Peripheral blood mononuclear cells were isolated by Ficoll-Hypaque density gradient method and the mRNA was extracted by Trizol® method. The cDNA was synthesized by High Capacity cDNA Reverse Trasnscription® Kit in conventional PCR and gene expression analysis of isoforms 1, 2 and 3 of *DIDO* gene was performed by real-time PCR (Applied Biosystems 7500 Real Time PCR®). The results were expressed as relative units of expression. The gene expression comparison of *DIDO*1, 2 and 3 between health subjects and patients in different stages of the disease was assessed by Mann-Whitney statistical test.
Results: The *DIDO* 2 expression was lower in advanced stages (median=1.352 and P=0.0130) in comparison to controls (median=4.886 and P=0.0130). Comparison of isoforms 1 and 3 expression between CML patients and controls yielded no significant differences.
Summary and Conclusions: The results indicate that *DIDO* 2 low expression may be linked to apoptosis resistance in CML patients. In addition the results also suggest a different role for each of the three different gene isoforms in CML.

PB1733

DOWN-REGULATION OF MIR-203-B IN IMATINIB-RESISTANT CHRONIC MYELOID LEUKEMIA PATIENTS

N. Ryabchikova[1], G. Safuanova[1,*] I. Minniakhmetov[2], A. Karunas[2], B. Yalaev[2], E. Shut[2], R. Latypov[2], E. Khusnutdinova[2]
[1]Bashkir State Medical University, [2]IBG USC RAS, UFA, Russian Federation

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the expression of the BCR-ABL oncoprotein, which is essential for the pathogenesis of the disease. Imatinib, an ATP-competitive selective inhibitor of BCR-ABL, has unprecedented efficacy for the treatment of CML. Nevertheless resistance to imatinib is observed in over 30% cases of CML. Several cellular and genetic mechanisms of imatinib resistance have been proposed, including overexpression of the *BCR-ABL* gene, the tyrosine kinase domain mutations, pharmacokinetic and pharmacodynamic factors.
Aims: The purpose of this study was to investigate the mechanisms of resistance to imatinib in CML patients.
Methods: We have analyzed mRNA level of *BCR-ABL* gene by quantitative real time RT-PCR in 114 patients and have studied BCR-ABL mutations in patients with high level of expression of fusion gene. Mutation status was studied by direct sequencing of *BCR-ABL* cDNA samples.
Results: *BCR-ABL* mutations were founded in 16 (32%) patients with resistance to imatinib treatment. The mutation spectrum included four missense mutation: M351T (7 cases), T315I (4), T315I+M351T (2), M244V (1) and H396R (1). Next we conducted a search for microRNAs specifically targeting 3'UTR of BCR-ABL, using the miRBASE program to scan human genome (http://microrna.sanger.ac.uk/) and analyzed microRNAs expression profile. The down-regulation of miR-203-b (25-fold), mir-323 (4-fold) and miR-196-b (2-fold) in the group of patients with resistance was discovered.
Summary and Conclusions: In conclusion, our data showed that mutations in the BCR-ABL kinase domain may cause, or contribute to, resistance to tyrosine kinase inhibitors in CML patients, but resistance mechanisms might also be regulated by microRNAs.

PB1734

A GENOME-WIDE ANALYSES OF DIFFERENTIALLY EXPRESSED GENES AND RELATED NETWORKS AFFECTED BY FISETIN AND HESPERETIN IN CHRONIC MYELOID LEUKEMIA CELLS

A. Adan Gökbulut[1,*] Y. Baran[1]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, İzmir, Turkey

Background: Diet is an important determinant of cancer risk based on various epidemiologic and case control studies. Therefore, there is a great interest to investigate bioactive food components for their cancer preventive and therapeutic potentials. Fisetin and hesperetin are members of the flavonoid polyphenols, found in several plant species. They have a wide range of pharmacological properties including antioxidant, anti-inflammatory and anticancer effects. Their chemopreventive/chemotherapeutic potentials were investigated in several cancer types such as colon and prostate cancers, however, the exact mechanisms of fisetin and hesperetin actions are not known in CML.
Aims: We aimed at determining the underlying molecular mechanisms of fisetin and hesperetin induced growth inhibitory effects in K562 CML cells based on changes in global gene expression patterns using genome-wide microarray analysis.
Methods: Expression profiling is accomplished using the Human HT-12v4 beadchip microarrays (Illumina, Inc.). Total RNA isolated from fisetin and hesperetin treated K562 CML cells was converted to biotin labeled cRNA, which were hybridized to beadchips. The BeadChips were analyzed using Illumina's Genome Studio in order to cluster genes. We obtained the list of differentially expressed genes based on p-value<0.05 and at least 2.0 fold change. Affected genetic networks were determined by using the Kyoto Encyclopedia of Genes and Genomes (KEGG) and Ingenuity Pathway Analysis (IPA).
Results: A total of 553 and 1734 genes were significantl regulated (P<0.05) in 50 μM and 100 μM fisetin treated K562 cells, respectively. Both 50 and 100 μM fisetin treatment resulted in the upregulation of common genes such as NFKBIA, NOXA, p21 and GADD45B. We also found each fisetin concentration altered expression of specific genes. For instance, 50 μM fisetin upregulated NFKBIZ and GADD45A while 100 μM fisetin treatment resulted in the upregulation of CDKN2D/ p19, TXNIP and SMAD5. Furthermore, MYC, MYB, C-KIT, TUBA1A and TUBAL3 were some of common downregulated genes after 50 and 100 μM fisetin treatment. 100 μM fisetin also caused downregulation of important genes such as FOXK1, FOXA2 and BCL-XL. Apoptosis modulation, TP53 network, TNF-α, KIT receptor and JAK/STAT signaling, adhesion networks, growth hormone receptor signaling and angiogenesis were modulated networks. On the other hand, a total of 1659 and 1201 genes were significantly changed (P<0.05) in 100 and 150 μM hesperetin treated K562 cells, respectively. DUSP1, CDKN1A, GADD45B and BIM were the examples of common upregulated genes in 100 and 150 μM hesperetin treatment. On the other hand, 100 μM hesperetin also upregulated some other genes such as p27, CASP4, DUSP5 whereas 150 μM hesperetin upregulated MT1A, DUSP3 and NFKBIA. STAT5A, TUBA1A, MYB, KIT, EPCAM and PCNA were the examples of common downregulated genes in 100 and 150 μM hesperetin treatment. 100 μM hesperetin treatment also resulted in the downregulation of EEF1G, POLR2B and STAT3. Furthermore, 150 μM hesperetin treatment downregulated genes such as MCM10, ABCC4 and POLE2. Translation initiation and elongation networks, replication and trancription networks, EGF, JAK/STAT and KIT receptor signaling pathways, growth hormon receptor signaling and PI3K pathway were altered networks.
Summary and Conclusions: Fisetin and hesperetin trigger apoptosis and growth suppression via affecting various significant targets in K562 cells, which could open the usage of new strategies together with fisetin to overcome difficulties in CML treatment.

PB1735

A STATE OF THE ART CUSTOM "DUPLEXED" REAL TIME PCR ASSAY FOR MINIMAL RESIDUAL DISEASE MONITORING OF CHRONIC MYELOID LEUKEMIA USING LOCKED NUCLEIC ACID PROBES.

S.K. Joshi[1,*] P. Subramanian[1], S. Chaudhary[1], P. Tembhare[1], S. Gujral[1], S. Gaware[1], H. Doshi[1], N. Patkar[1]
[1]Hematopathology, Tata Memorial Centre, Kharghar, India

Background: In India treatment of Chronic Myeloid Leukemia (CML) is supported through an International Patient Assistance Program in which imatinib mesylate is provided to economically disadvantaged patients free of cost. As a result most of these patients opt for treatment and need regular molecular monitoring. However, commercial kits for BCR-ABL monitoring are cost prohibitive for our patients. It is also currently recommended to test for BCR-ABL copy numbers in triplicates to ensure making confident calls at low levels placing further economic strain in resource constrained settings especially if all quality control measures are to be followed. In that context it is required to develop cost effective BCRABL monitoring technologies. Globally, a majority of centres use the EAC protocol for CML, an assay that suffers from background noise. We addressed these problems by modifying the legacy real time PCR (qPCR) process. We cloned a duplex qPCR compatible plasmid that enables us to multiplex BCRABL and ABL reaction in a single well using FAM- black hole quencher1 (BHQ1) and HEX-BHQ1 probes modified with locked nucleic acids (LNA).
Aims: To develop a custom duplex PCR compatible plasmid and develop and standardize a LNA probe based assay for BCR-ABL and ABL.
Methods: A 1600bp amplicon from a newly diagnosed CML (E13A2) patient into a pJET1.2/blunt cloning vector. This was linearized and using Avogadro's number an estimate of copy numbers were arrived at and a standard curve was created. Accuracy of dilutions were confirmed by using Ipsogen's standards. Using Modified EAC protocol: BCR-ABL probe was truncated to 16

nucleic acids labelled with FAM and BHQ1 with three LNA modifications whereas the ABL probe was 19 nucleic acids (HEX and BHQ1) with 4 LNA modifications. Calibration to the WHO calibrator was done using a secondary standard (Asuragen Inc) to derive an international scale conversion factor. Assay precision was monitored using two levels of controls in the duplex assay (median NCN 0.1% and 0.05%). We compared the normalized copy number (NCN) derived from the duplex assay with the simplex assay in 87 samples of CML (NCN ranging from 0.002 to 108.5, median 0.14%).
Results: The plasmid was successfully cloned and confirmed by sanger sequencing. The duplex assay did not lead to loss of MMR in any patient also we did not face any issues with false positivity. We found a good correlation between the simplex and duplex assay (r^2=0.97). In all runs, slope was between -3.2 to -3.6, R^2>0.98. The international scale conversion factor was 0.79. Over 60 runs the BCRABL assay has a CV of 38.9% and 48.1% for high and low precision controls.
Summary and Conclusions: This assay has enabled us to maintain a high level of quality control (runs in triplicates, precision, no template as well as no reverse transcription controls) yet process 22 samples per run. As a result the cost of the assay is low. We would be happy to share this plasmid to other users from resource constrained setting such as ours. To the best of our knowledge, this is first paper to use LNA probes for CML minimal residual disease (MRD) monitoring. The use of a duplex PCR enables us to significantly decrease the cost of the assay ($5/patient) yet maintain a high standard of quality control.

PB1736

EXPRESSION LEVELS OF JAK/STAT SIGNALING GENES IN NEWLY DIAGNOSED, DRUG SENSITIVE AND RESISTANT CHRONIC MYELOID LEUKEMIA PATIENTS

Y. Kiraz[1,*] G. Saydam[2], F. Şahin[2], I. Kozanoğlu[3], H. Özdoğu [3], Ö. Pişkin[4], M.A. Özcan[4], F. Avcu[5], A. U. Ural[6], A. Ünal[7], Y. Baran[1]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, [2]Hematology, Ege University, İzmir, [3]Hematology, Baskent University, Adana Research and Application Hospital, Adana, [4]Hematology, Dokuz Eylul University, İzmir, [5]Hematology, Gülhane Military Medical School, [6]Hematology, Bayındır Hospital, Ankara, [7]Hematology, Erciyes University, Kayseri, Turkey

Background: Jak/STAT is a major intracellular signaling pathway that involved in immune response, cancer development (mostly leukemias) and hematopoiesis by stimulating cellular growth, proliferation and differentiation. This pathway relies on transmition of outside signals into the cells through cell membrane. The Jak/STAT mechanism composed of 2 main components including Janus kinase (Jak) and signal transducers and activators of transcription (STAT) proteins. Janus kinases, have four different types (Jak1, Jak2, Jak3 and Tyk2), found as an inactive form and associated with receptor protein on the cell membrane whereas there are seven types of STAT protein (STAT1, STAT2, STAT3, STAT4, STAT5A, STAT5B, STAT6) that are located in cytoplasm and activated by Jak kinases. The system is started with conformational change and trans-activation of Jak proteins by a signal from a number of cytokines. This activation is followed by STAT phosphorylation at tyrosine residue in transactivation domain of STAT protein. Phosphorylated STAT proteins become dimerized by interacting phosphotyrosine of one STAT and SH2 domain of another STAT, as a result, they either affect different pathways and cause signaling cascades or move into the nucleus and directy activate their target genes involved in proliferation, differentiation, cell growth, cell death or survival. Abnormal activation of Jak/STAT signaling pathway proteins are found in many types of hematological malignancies including AML, MDS, B-cell lymphomas and CML.
Aims: Despite high efficiency of tyrosine kinase inhibitors, the success of therapy is limited to multidrug resistance phenomenon. Recent developments in drug resistance mechanism in CML showed that many molecular interactions and signaling pathways are involved in mediating TKI resistance in patients. Jak/STAT signaling pathway is one of these pathways that have significant roles in various cellular mechanisms including leukemia initiation and drug resistance. The aim of this study is to examine the relationship between expression levels of Jak/STAT genes and clinical outcome of chronic myeloid leukemia (CML) patients who are newly diagnosed; treated with imatinib, nilotinib or dasatinib; responded positively to TKIs; imatinib, nilotinib or dasatinib resistant; or lost of their molecular response.
Methods: This study including 14 newly diagnosed CML patients, 5 patients who are CML diagnosed and treated with imatinib, 1 patient who positively responded to imatinib, 1 patient who lost molecular response, 1 imatinib resistant patient and 1 patient who has both imatinib and nilotinib resistance. Mononuclear cells were isolated from bone marrow samples of the patients and total RNAs were isolated, mRNAs were converted into cDNAs and expression levels of *JAK1-3, TYK2, STAT1-4, STAT5A-B* and *STAT6* genes were detected by Real-Time PCR.
Results: The results showed that expression levels of *Jak3, STAT1-4* and *STAT5A* genes had higher in TKI resistant patients, compared to other patient groups. Expression levels of *STAT5B, JAK1* and *JAK2* genes were higher in newly diagnosed and positively responded patients than in resistant patients while expression levels of *TYK2* was lower in imatinib-treated patients.
Summary and Conclusions: It was demonstrated for the first time that there is a relation between the clinical outcome of CML patients and expression levels of JAK-STAT genes that could make this signaling pathway a new target for more effective treatment of CML.

PLASMA AND LEUKOCYTE METABOLOMICS AND METABOLISATION STUDY OF PATIENTS WITH CHRONIC MYELOID LEUKAEMIA

R. Karlíková[1], K. Mičová[1], M. Hrdá[1], J. Široká[1], I. Vrobel[1], A. Gardlo[1], L. Najdekr[1], D. Friedecky[1,2,3,*] E. Faber[4], T. Adam[1,2,3]
[1]Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacký University in Olomouc, [2]Laboratory of Inherited Metabolic Disorders, Faculty of Medicine and Dentistry, Palacký University in Olomouc, University Hospital Olomouc, [3]Department of Clinical Chemistry, University Hospital Olomouc, [4]Department of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacký University in Olomouc, University Hospital Olomouc, Olomouc, Czech Republic

Background: Metabolomics refers to the interpretation of information-rich data with the aim to understand metabolic processes and to find changes in metabolite levels as a potential biomarkers of the disease. Due to drug metabolizing enzymes several bioactive or toxic metabolites of tyrosine kinase inhibitors are produced. Therefore determination of drug metabolites may have clinical relevance and could be helpful for treatment adjustment.
Aims: The first aim of this work was to examine the influence of tyrosine kinase inhibitors and hydroxyurea on the leukocyte and plasma metabolite profiles from patients with CML compared with healthy controls. The second aim of this work was profiling of imatinib metabolites in plasma from patients with chronic myeloid leukaemia.
Methods: Leukocytes and plasma samples from healthy controls (n=10), patients before treatment (n=9), treated with hydroxyurea (n=5), imatinib (n=24), dasatinib (n=8) and nilotinib (n=10) were prepared from whole blood and metabolites were extracted by the chloroform/methanol/water mixture. Analysis of 400 metabolites was performed using high performance liquid chromatography (Ultimate 3000, Dionex) coupled with tandem mass spectrometry (QTRAP 5500, AB Sciex). Metabolites were quantified using MultiQuant 3.0 software and statistically evaluated in R programme language with statistics packages. For metabolisation study plasma samples were taken from patients on treatment by imatinib (24h after dose of 400 mg). Separation of imatinib metabolites was performed on Phenomenex Kinetex C18 column using UltiMate 3000 RS (Thermo Scientific) liquid chromatography. For detection in full scan mode and MS^2 fragmentation experiments Orbitrap Elite mass spectrometer (Thermo Scientific) based on exact mass measurement was used. Data were evaluated using MetWorks 1.3 SP3 and Mass Frontier 7.0 software.
Results: Total 170 metabolites were identified on the basis of its transition and retention time in all leukocyte and plasma samples. Significant changes in metabolic pathways were found. Both unsupervised and supervised statistic methods (PCA, PLS-DA, OPLS-DA, cluster analysis) separated all the studied groups. In plasma samples more than 90 potential metabolites in concentration range of 4 orders of magnitude were found. All metabolites were identified by exact m/z values and confirmed by MS2 and MS3 exact m/z fragmentation experiments. Changes in profiles of several metabolisations between patients were followed.
Summary and Conclusions: In this study metabolome of human leukocytes and plasma was defined and changes of metabolite levels were observed in all groups of patients compared to healthy controls. High Resolution Mass spectrometry using Orbitrap principle is able to detect and confirm high as well as low intensive metabolites and its fragments. Tyrosine kinase inhibitor – Imatinib offers complex metabolite profile. It has diagnostic potential for individualized treatment of patients with adverse effects or resistance on treatment. The work was supported by grant of IGA Ministry of Health, Czech Republic NT12218-4/2011.

PB1738

TO THE DIFFERENTIAL DIAGNOSIS OF ACUTE MYELOBLASTIC LEUKEMIA AND CHRONIC MYELOID LEUKEMIA STARTED WITH BLAST CRISIS

T. Saralidze[1,*] T. Saralidze[2], T. Shvelidze[3], B. Metreveli[4]
[1] Faculty of Medicine, AIETI Medical School, [2]Department of Internal Medicine, Tbilisi State Medical University, [3]Clinical Laboratory, [4]Department of Gynecology, Medical Center "JUNONA", Tbilisi, Georgia

Background: Despite the achievements of modern medicine sometimes there is a problem to differentiate chronic myeloid leukemia (CML) started with blast crisis from acute myeloblastic leukemia (AML), especially in the cases of Ph chromosome negative or BCR-ABL1- negative cases. Even in the presence of this marker one should have taken in mind that there are cases of Ph + AML as well.
Aims: The aim of our study was to precise the diagnose in patients with blast cells in peripheral blood and prominent hepato- and splenomegaly suspicious

on CML and reveal additional criteria for the diagnosis of CML started with blast crisis.
Methods: To solve this problem we have used peripheral blood and bone marrow cell culture method worked out by us. This method supports propagation of blast cells specific for each form and variant of leukemia and enables to reveal the malignant clone according to morphocytochemical investigation or phenotyping *in vitro* proliferating cells (Shvelidze, Saralidze *et al.* Atlas of Hematology, 2013. http://www.e-bookland.ge/Books/medical/ATLAS-of-HEMATOLOGY). We investigated peripheral blood and bone marrow cell cultures of 5 patients with CML presented with blast crisis at the time of diagnosis, 8 patients with CML at chronic stage, 2 patients with CML in accelerated phase and 7 patients with AML (3 cases of AML without maturation and 4 cases of AML with maturation).
Results: Our studies showed that in all cases of AML proliferation of blast cells is confirmed by abundance of blast cells in cultures during 2 weeks of cultivation and appearance of maturation part of them up to promyelocytes and myelocytes and rarely to the band neutrophils in late cultures. On contrary, in the cases of CML presented with blast crisis as well as in the cases of CML at chronic stage, rapid maturation of blast cells up to band neutrophils is obvious from the beginning of cultivation. Just from the second day of cultivation in cultures of patients with CML disappearance of blast cells and abundance of band and segmented granulocytes, mainly neutrophilic, but eosinophilic and basophilic also are observed (Figure 1). It must be noticed that from 2 patients with CML in accelerated phase in one case majority of cells in culture were matured granulocytes, that is characteristic for CML, while in another case culture material was presented by abundance of immature myeloid cells – myeloblasts, promyelocytes and myelocytes and a few band and segmented granulocytes that pointed to tumor progression. In the last case treatment was not effective at all. Figure 1. Abundance of band neutrophils with ring nuclei. 2-day- bone marrow culture of a patient with CML started with blast crisis. Rapid maturation of blast cells up to band neutrophils *in vitro* enabled to diagnose CML. May-Grünwald –Giemsa stain. X 1000.

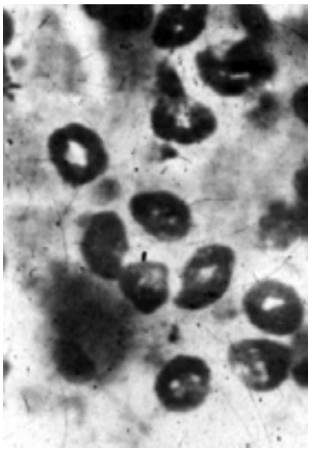

Figure 1.

Summary and Conclusions: Results of our study show that blood and bone marrow culture data of patients with CML can be successfully used as additional criteria for the differentiation of CML started with blast crisis from AML as far as in cultures of patients with AML abundant proliferation of blast cells is observed, whereas in the cases of CML started with blast crisis rapid maturation of blast cells up to band neutrophils from the beginning of cultivation is obvious. Abundance of immature cells in blood or bone marrow cultures of patients with CML points to tumor progression in spite of the clinical stage of disease and represents a bad prognostic marker. Cytochemical study or immunophenotyping of proliferated *in vitro* cells can help to determine the type of new proliferative clone.

PB1739

USEFULNESS OF THE TEMPUS™ BLOOD RNA STABILIZATION SYSTEM FOR OPTIMIZING RNA EXTRACTION METHOD FROM WHOLE BLOOD, MEASURING AND REPORTING ABL TRANSCRIPTS LEVELS IN CHRONIC MYELOID LEUKEMIA.

R. Lukackova[1,*] M. Eckertova[1], I. Hojsikova[1]
[1]Genetics, Medirex, Bratislava, Slovakia

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder of blood stem cells. More than 95% of patients with detected translocation t(9;22) is characterized by the fusion between exons e13 or e14 of *BCR* gene, which are located in major breakpoint cluster region (*M-bcr*) and exon a2 of *ABL* gene. These fusions are described as b2a2 (e13a2) and b3a2 (e14a2). Because patients treated with tyrosine kinase inhibitors achieve lower levels of detectable disease, quantification of *BCR-ABL* transcripts with quantitative RT-PCR has become an essential tool in chronic myeloid leukemia monitoring. Major molecular response (MMR; *i.e.*, a ≥3-log reduction in *BCR-ABL* transcript levels) is used in current treatment guidelines to assess prognosis. Recent evidence suggests that deeper molecular responses (≥4-log reductions in *BCR-ABL* transcript levels), particularly when attained early during treatment, may have even better correlation with long-term outcomes, including survival and disease progression. Therefore, quantitative measurement of *BCR-ABL* transcripts in blood and bone marrow both aids in the initial diagnosis of CML is essential for routine post-therapy minimal residual disease monitoring. Establishing methods for secure long-term storage of RNA is critical to realize MRD monitoring. We describe the results of RNA stability in the same set for whole blood RNA collecting in Tempus Blood RNA tubes and tubes with EDTA.
Aims: All the steps of the preanalytical phase (blood collection, conservation and procedures of isolation RNA) are influencing on the number of copies of the *ABL* control gene in the analysis of *BCR/ABL* transcripts. Our aim was to show the differences in the stability of the RNA using EDTA tubes and tubes with a special stabilizing solution Tempus (Tempus™ VACUETTE® Blood RNA Tube) for the collection of peripheral blood and bone marrow in CML.
Methods: Various kits for stabilizing the RNA at the time of blood collection were developed: Ambion RNA later (Applied Biosystems) and the new Tempus Blood RNA kit (Applied Biosystems). The Tempus Blood RNA kit (VACUETTE® Tempus™ Blood RNA Tube) uses tubes containing a proprietary blend of reagents based on a patented RNA stabilization technology. In order to evaluate the Tempus Blood RNA kit, it was compared to unstabilized EDTA blood protocol. The RNAs extracted by the different methods were assessed for quantity control gene (*ABL*) and fusion gene transcripts *BCR-ABL* by QRT-PCR. After extraction, both RNA purity were measured by using both, the ratio A260/280, no significant changes in these ratios were observed in either system. The integrity of RNA after extraction was confirmed using the Agilent 2100 Bioanalyzer and was indicated by the RIN.

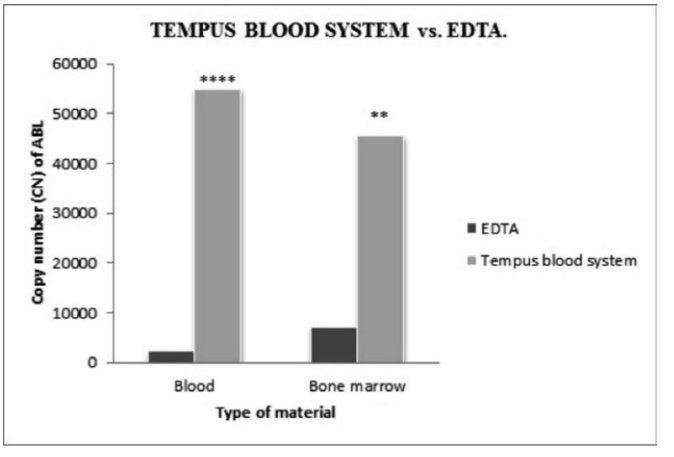

Figure 1.

Results: Our results strongly suggest the superiority of the stabilization system special tubes over the unstabilized EDTA blood. Tempus tubes are preventing the degradation of RNA at the time of the preanalytical phase during genetic analysis of CML patients. Using Tempus tubes we have achieved increased stability of RNA, which has a direct impact on increasing the number of copies of the *ABL* control gene (3-4 times) for the analysis of *BCR/ABL* and thus ultimately increases the sensitivity of QRT-PCR method. Tempus blood RNA systems have been shown to provide efficient stabilization of the blood RNA for several days at room temperature. Comparison of expression levels of *ABL control* gene in RNA (10 patients) extracted by EDTA or Tempus Blood RNA system. *ABL* expressions are expressed as copy number. P-value: in blood $P<0.0001$ and in bone marrow $P<0.0101$ (t-test).
Summary and Conclusions: In summary, molecular response measured by *BCR-ABL* QRT-PCR provides important prognostic information for the management of patients with CML treated with TKI therapies. The deeper molecular response (MR^4, $MR^{4.5}$, and MR^5) that is necessary to enroll a patient in a trial aiming at treatment-free remission (TFR).

PB1740

IMMUNE MONITORING OF THERAPEUTIC EFFICACY IN CHRONIC MYELOID LEUKEMIA

P. Rodrigues Santos[1,2,*] P. Couceiro[2], J. Almeida[2], A. Diniz[1], V. Alves[1], L. Růžičková[3], P. Freitas-Tavares[3], M. Santos-Rosa[1]
[1]Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, [2]Lab Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, [3]Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Different effects on the immune system are reported at the diag-

nosis and during therapy depending on Tyrosine Kinase Inhibitors (TKI) and interferon-alpha protocols. Some of these are dose-dependent effects. At present time, several clinical trials are establishing also the safety parameters for cessation of therapy in a selected group of Chronic Myeloid Leukemia (CML) patients. Although there is no consensus for laboratory evaluation of immune response for clinical trials, the Human Immunophenotyping Consortium (HIPC) aims at the standardization of protocols based on multicolor flow cytometry (Maecker *et al*. Nat Rev Immunol 2012).

Aims: The current study aimed at the evaluation of the immune status in treated CML patients to establish addtional efficacy parameters of different therapeutic strategies.

Methods: We used an extended 10-parameter panel for the analysis of T cells (Th1, Th2, Th17, Tregs), B cells (including plasmablasts), monocytes (classical and non-classical), dendritic cells (myeloid and plasmacytoid) and NK cells ($CD56^{bright}$ and $CD56^{dim}$) in CML immune monitoring. Additionally, activation and maturation profile, as well as memory status was investigated for T and B cells. Intracellular cytokine staining, phosphorylation studies, response to multiple stimuli and gene expression profiling of relevant sorted cells was also performed for evaluation of immune response in these patients. Deep analysis of specific subsets (NK, NKT and γδ T cells) and pathways (CD137, PD-1, CD96, CD226, TIGIT) were explored.

Results: Significant impact on NK cells, NKT and Th17 cells was observed in CML patients undergoing therapy with TKI. Maturation and activation status of different lymphocyte subsets was found affected by therapy. Optimal response was found associated to immune response robustness of CML patients.

Summary and Conclusions: In conclusion, CML successful treatment is highly influenced by the immune response and an immune-based monitoring could be an important tool in the near future.

Chronic myeloid leukemia - Clinical

PB1741

EARLY BCR-ABL REDUCTION IS PREDICTIVE OF BETTER EVENT FREE SURVIVAL IN CHRONIC MYELOID LEUKEMIA NEWLY DIAGNOSED PATIENTS TREATED WITH ANY TKIS

C. Fava[1,*] G. Rege-Cambrin[2], I. Dogliotti[1], E. Gottardi[1], P. Berchialla[3], B. Di Gioacchino[2], F. Crasto[1], R. Lorenzatti[1], A. Volpengo[1], F. Daraio[1], C. Fantino[1], G. Saglio[1]

[1]Department of Clinical and Biological Sciences, University of Turin, [2]Division of Internal Medicine and Haematology, AOU San Luigi, Orbassano, [3]Department of Clinical and Biological Sciences, University of Turin, Turin, Italy

Background: Treatment of chronic myeloid leukemia (CML) aims at obtaining optimal response, as defined by international recommendations. As more tirosine kinase inhibitors (TKIs) are now available, much attention has been paid to the identification of early prognostic markers during treatment. A strong predictive value has been observed for early molecular response, with BCR-ABL ratio ≤10% at 3 months (mos), and BCR-ABL ratio ≤1% at 6 mos, being predictive for overall survival and event-free survival (EFS). Recently, the velocity of early BCR-ABL transcript elimination, namely the halving time, has shown to represent an additional prognostic index.

Aims: To evaluate the prognostic significance of the 3 mos time-point in our population.

Methods: We retrospectively analyzed the population of CML-CP pts treated in our Division, selecting pts who had a quantitative molecular evaluation at 3 mos. EFS was estimated with Kaplan-Meier method. Log-rank test was used to identify significant differences between curves. ROC analysis was used to calculate the optimal halving time thresholds for discriminating between outcomes. ABL was used as control gene.

Table 1. Responses and events according to BCR-ABL transcripts at 3 months

	BCR-ABL >10% at 3 months (n=12)	BCR-ABL ≤10% at 3 months (n=38)	p-value*
BCR-ABL ≤1% at 6 months	42.9% (3/7)	80% (24/30)	0.07
BCR-ABL ≤0.1% at 12 months	0% (0/9)	50% (15/30)	0.007
MR≥ 4, last follow-up	17% (2/12)	50% (19/38)	0.05
Total Events	75% (9/12)	13% (5/38)	<0.001

*P-values were computed using Fisher's test.

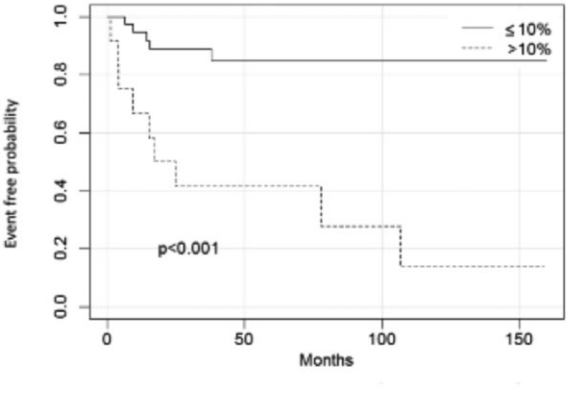

Figure 1. Event free survival by BCR-ABL levels at 3 months.

Results: 50 CML-CP pts, with a median follow-up of 57,5 mos (31-110.5) were analyzed. 36 pts (72%) were male, 14 (28%) female. Median age at diagnosis was 59 years. 33 pts were treated frontline with imatinib, 10 with nilotinib, 4 with dasatinib and 3 were enrolled in the GIMEMA rotational protocol nilo/ima. 76% of patients had a transcript ≤10% at 3 mos. 37 pts had the 6 mos evaluation and 39 pts had the 12 mos evaluation. 3/7 pts who had a transcript >10% at 3 mos had a transcript ≤1% at 6 mos (Table 1). None of the patients with a transcript >10% at 3 mos achieved an MR3 at 12 mos, compared to 50% in the other group (P=0.007). 14/50 pts had an event, defined as lack or loss of optimal response as per ELN recommendations, with a statistically significant difference among groups (94.6% in the group with 3 mos BCR-ABL >10% vs 66.7% in the group with BCR-ABL ≤10%, by 12 mos, P<0.001; 84.6% in the >10% group vs 41.7% in the ≤10% group, by the median time of follow-up, P<0.001) (Figure 1). No progressions occurred. 12 pts had to change drug because of an event (6 shifted to dasatinib, 6 to nilotinib), 3 for intolerance (1 shifted to dasatinib, 2 to nilotinib). Excluding these pts, in the group of pts >10% at 3 mos the probability of achieving a long-term MR4 was more than 60% lower compared to the other group [HR 0.36 95% CI (0.10;1.27)]. The halving time thresholds for discriminating between EFS was 25.5 days (specificity 84.8% and sensitivity of 83.3%; AUC 85.9%). None of the pts with a transcript >10% at 3 mos had a

halving time<25.5 days. Among pts with a transcript ≤10%, those with a halving time<25.5 days had an EFS of 93% vs 50% with a halving time >25.5 days (P =0.012). Those with a halving time<25.5 days had a reduction of risk of event of 92% (HR 0.08; 95% CI (0.02;035)). All pts were alive at the last follow-up.
Summary and Conclusions: Three different drugs, imatinib, dasatinib and nilotinib. are commercially available for frontline treatment of newly diagnosed CML. Clinicians are allowed to decide which of these therapies is most suitable for each pt, based on comorbidities, Sokal risk and age of the pt. Irrespective of the TKI used, the achievement of a BCR-ABL transcript ≤10% influences the outcome of the pts. Interestingly, we confirmed the importance of halving time in discriminating pts with the best outcome.

PB1742

GENERIC IMATINIB MESYLATE IS AS EFFECTIVE AS ORIGINAL GLIVEC IN THE MANAGEMENT OF CML

S. Aksu[1], S.H. Aktimur[2], D.Ç. Arica[3], H. Atay[2], O. Bektas[4], Y. Buyukasik[1], H. Demiroglu[1], E. Eliacik[1], M. Esme[5], H. Goker[1], A. Hacihanefioglu[6], S. Karakus[3], S. Kilickap[7], E. Koca[3], U.Y. Malkan[1], O.I. Ozcebe[1], N. Sayinalp[1], P. Tarkun[6], M. Turgut[2], I.C. Haznedaroglu[1]
[1]Hematology, Hacettepe University, Ankara, [2]Hematology, Ondokuz Mayıs University, Samsun, [3]Hematology, Başkent University, Ankara, [4]Hematology, Konya Research Hospital, Konya, [5]Internal Medicine, Hacettepe University, Ankara, [6]Hematology, Kocaeli University, Kocaeli, [7]Oncology, Hacettepe University, Ankara, Turkey

Background: Unsustainable drug prices in chronic myeloid leukemia (CML) and cancer may be causing harm to patients. Advocating for lower drug prices is a necessity to save the lives of patients who cannot afford them (Experts in CML. Blood. 2013; 121(22):4439-4442). The patent date of imatinib mesylate in USA has just expired in January 2015. Patent expiration dates for imatinib may be different in different countries/regions. In Turkey, generic imatinib preparations are currently present. The only concern for generic imatinib is its efficacy over the original drug, Glivec or Gleevec.
Aims: The aim of this multi-center study is to assess the efficacy of generic imatinib over Glivec in terms of hematological, cytogenetic, and molecular responses in CML.
Methods: This work is designed as multicenter and retrospective study

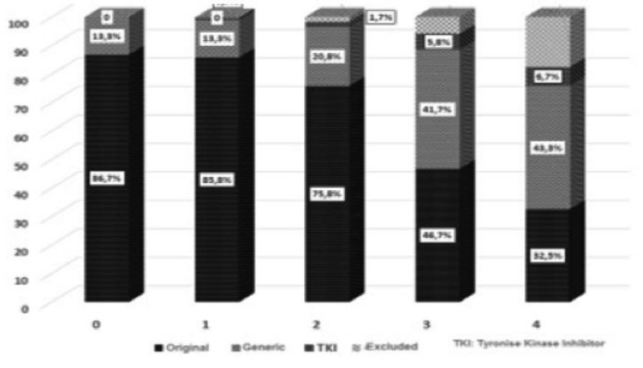

Figure 1. The ratio of drugs that were preferred by the clinicians for each evaluation.

Results: In this study, the retrospective data of 120 Turkish CML patients receiving imatinib from six different CML centers across Turkey were analyzed (68 females, 56.7%; 52 males, 43.3%). The mean age was 53 years (21-81). The most frequent ECOG performance status was "0" (65%). The distribution of genders between centers was similar. At the study onset, 86.7% of the patients (n=104) were using original molecules, and 13.3% of the patients (n=16) were using generic molecules. Original (86.7%), 16 generic imatinib mesylate. The patients were evaluated at 4 different time points for change of medication and efficacy. The mean period between each evaluation was 9 months. Initial evaluation showed that a patient who was using only original molecule, switched to second generation tyrosine kinase inhibitor (TKI) treatment. In this period, hematological response (HR) was observed in 99.2% of the patients, cytogenetic response (CR) was observed in 88.7% of the patients (47 of 53), and molecular response (MR) was observed in 75% of the patients. For each evaluation, the ratio of drugs that were preferred by the clinicians is shown in Figure 1. According to Figure 1, clinicians had a tendency to prefer generic molecules in each sequent visit, and this change rate was significant (P<0.001). The rate of using generic molecules was 13.3% in the initial evaluation, 20.8% in the second visit, 41.7% in the third visit, and 43.3% in the fourth visit. The rates of switching from original molecule to generic molecule, from original molecule to second generation TKI, and from generic molecule to second generation TKI are shown in Table 1. Accordingly, 11 patients, who were using original molecules during all cohort, switched to second generation TKI. On the other hand, only 1 patient, who was using generic molecules, switched to second generation TKI. Response to treatment is shown in Figure 2.

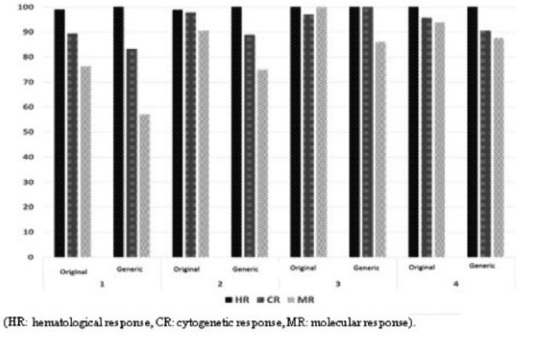

Figure 2. The ratio of CML treatment of the four evaluation points.

Table 1. The rates of switching from original molecule to generic molecule, from original molecule to second generation TKI, and from generic molecule to second generation TKI.

	Original → Generic		Original → Second generation TKI		Generic → Second generation TKI	
	n	%	n	%	n	%
First Visit	1/103	1,0	-	-	-	-
Second Visit	12/103	11,6	1/103	1,0	1/17	5,9
Third Visit	28/91	30,8	5/91	5,5	-	-
Fourth Visit	28/56	50,0	5/56	8,9	-	-

Summary and Conclusions: Therefore, we did not find any significant difference in HR, CR, and MR for original and generic drugs in each visit. Based on this data, generic imatinib mesylate is as effective as original Glivec in the management of CML.

PB1743

IMPACT OF TYROSINE KINASE INHIBITORS (TKIS) ON THE FERTILITY OF CHRONIC MYELOID LEUKEMIA PATIENTS (CML) IN A SINGLE CENTER IN ALGERIA

B. Yamina[1,*] T. Souad[1], A. Mohand Tayeb[1]
[1]Hematology, EHS ELCC CAC Faculty of Medicine, University Blida 1, Blida, Algeria

Background: TKIs have dramatically modified the outcome of CML patients giving opportunity to 10% of patients that are in age to procreate to have a parental project.TKIs stopping leads to the relapse. We count the event of pregnancy and its evolution among patients with CML at Chronic Phase treated with TKIs in the two sexes at Blida in Algeria.
Aims: To evaluate in the two sexes fertility of patients treated by tyrosine kinase inhibitors.
Methods: Of 231 CML patients treated by TKIs, 29 pregnancies were noted among 19 women; we analyze the time of exposure to the TKIs before and at the time of the pregnancy and the hematologic, cytogenetic and molecular status before and after the pregnancy.
Results: Pregnancy of the spouse: - Husbands treated by Imatinib (IM): 10 cases, median age=34 years; IM (400mg/d); median time of exposure (MTE)=23 months; No interruption of IM before the conception; 3 early abortions; 12 pregnancies carried out in the term; 12 alive new-born without malformation. - Husbands treated by Dasatinib: 2 Cases (100mg/d; MTE before the conception (BTC)=12 months, not treatment stopping before the design; 02 pregnancies carried out in the term; 2 alive new-born, no malformations.
- Husbands treated by Nilotinib: 1 case (800 mg/d), MTE BTC=12 months, no stop of TKI before the conception; 1 pregnancy carried out in the term; 1 new-born living any malformation. Pregnancies not planned in 0 3 women treated by Imatinib: median age=31 years; median time of impregnation BTC : 19 months (4, 24, 39); Cytogenetic profile: CCyR=2 patients, MMR: 1 pt; no treatment stopping before the conception; exposure time to the IM of 6, 8 and 12 weeks; Evolution of the pregnancy without incidents; childbirth at 35 weeks=2 pts, 1 Caesarian (after acceleration phase); 03 alive new-born of weight (2400-3500 gr) without malformations; Evolution of the CML: loss of the hematologic remission at 20 weeks=3 patients of which one acceleration, relayed by interferon; No breast feeding; resumption of IM=3 pts, one blast phase (AML5) treated by Nilotinib, which died after 12 months; 2 pts with HR and CCyR after 12 months of recovery. Pregnancies planned in 5 women treated by Imatinib: 4 (G0P0), 01 (G2P1); median age=29 years; sokal high=2 pts: Intermediary=3

pts; MTE BTC=48 months (30-60) with IM 400 mg/d; cytogenetic profile=5 CCyR, 2 MMR 4.5 and 2 MMR 4; stop of IM BTC =5 pts, from 01 to 05 months; 2 early abortions 1 month from stopping; 5 pregnancies 3 to 5 months after stopping IM; Evolution of the pregnancy: without incidents, of which one treated by interferon; Childbirth: in the term = 4 pts; 5 alive new-born (twin) without malformations; 1 in progress; breast feeding: 3 pts (1 month); Evolution of CML=CHR maintained at 37 weeks=4 patients, a loss of the CHR; resumption of IM=4 Pts, MMR in one pt after 12 months of recovery OS=75 months; 3 still of evaluation, OS=61 months (46-83). Pregnancy in woman treated by Dasatinib: 30 years, sokal: Intermediary; G0P0; MTE BTC: 18 months, Cytogenetics: CCyR; no treatment stopping before the conception; pregnancy not planned; exposure time: 4 weeks; lost of follow up until the childbirth, new-born alive without malformations, Evolution of the CML: loss of HR; Resumption of Dasatinib, HR after 2 months, CCyR after 3 months, OS=65 months

Summary and Conclusions: Infertility is not an side effect of the TKIs; the major molecular response made it possible to carry out a pregnancy without relay, a non-response requires a relay and exposes to the risks

PB1744

SECOND REPORT OF ARAB LEUKEMIA NET (ALN) REGISTRY FOR CML IN THE MIDDLE EAST &NORTH AFRICA REGION(AFME).PART II RESULTS OF ADDITIONAL CHROMOSOMAL ABNORMALITIES(ACAS) IN EGYPT, A MULTICENTER RESULTS.

M.O. Azzazi[1,*] M. Mattar[2], A. El Ghandour[3], M. El Sorady[3], S. Shehata[4], A. El Nahass[5], H. Hegab[1], R. Ibrahim [1], NN. Mostafa[1], H. Ellithy[2], M. Shazly[1]
[1]Hematology and BMT., Ain Shams University, [2]Hematology and BMT., Cairo university, Cairo, [3]hematology and BMT., Alexandria university, Alexandria, [4]Oncology and Haematology,, University of Assiut, Assiut, [5]Clinical Pathology., cairo university, Cairo, Egypt

Background: The first ALN report1 demonstrated that age-specific rates for CML in Egypt and Arab nations are lower by at least two decades compared to western populations1. Geographic and ethnic variations contribute to the variability of incidences among CML registries2. ACAs were reported in 5% of CML patients in chronic phase (CP). At diagnosis considered by ELN as a "warning" requiring careful patient monitoring, while ACAs emerging during treatment are considered by WHO classification as accelerated phase (AP) CML.ACAs influence response to Imatinib and outcome of TKI therapy. The occurrence of ACAs and additional mutations besides Ph chromosome(Ch) indicates that the leukemia has become at least partially BCR-ABL independent by secondary genetic acquisitions 2.Although the underlying mechanisms of resistance /disease progression are not fully understood for all ACAs, some are well identified as poor prognostic factors. such as the acquisition of additional Ph chromosome which might confer resistance via increasing the kinase activity of BCR-ABL3, the isochromosome 17q i(17q) which leads to inactivation of the tumor suppressor gene p53 and impedes the response to Imatinib via allowing the damaged cells to escape the DNA repair machinery of p53 and thus escape cell growth arrest or apoptosis, the extra 8 which is known to lead to c-Myc over expression that enhances the transformation of BCR-ABL positive cells or allows rapid growth of leukemic cells, and the extra 19 which might hinder Imatinib activity via hypermethylation / inactivation of neoplastic transformation silencing gene promoters such as ATG16L2 gene promoter4.

Aims: 1) To Release data of second ALN report concerning epidemiology of CML in Egypt, after enrolling 6 new centres,228 patients and adding ACAs to evaluate disease and clonal evolution. 2) Investigate the low mean age of CML in Egypt and the role of ACAs.

Methods: We analyzed data of 578 CML Egyptian patients (302 male and 276 female) followed-up for 5 years. Data were collected from 10 centers according to ELN2 and EUTOS recommendations2-3 by using a multicenter web based data registery portal, the ALN. (www.aln-afme.com). Chromosome banding analysis and FISH were performed according to the International System for Human Cytogenetic Nomenclature. we tested for ACAs defined as "major route" namely trisomy 8, duplication of Ph chromosome, i(17q), and trisomy 19.21.FISH was performed on at least 200 cells on bone marrow cells prepared according to cytogenetic techniques and by using DNA probes that hybridize at the BCR and ABL regions. RT-PCR, and real-time quantitative PCR were performed.

Results: Patients Median age was 43y, (40y for males, 41y for females), The age specific rates were highest for the age group of 30-35 years. Female patients presented with lower hemoglobin, higher platelet counts and smaller spleen size (P<0.0001). 98%of patients achieved CH respone,89% CYR,87% CYR,and 83% MMR. At diagnosis 87% patients were in CP-CML, 8.1% in AP and 4.9% in blastic phase. Sokal score: Low risk 57.8% Intermediate24.5% and High in 17.7%. EURO (Hasford) score (59% Low risk, 28.4% Intermediate risk and12.6% High risk). 42% of patients received first generation TKI, 54% second generation TKI, and 4% needed therapies plus TKI). Transplantation rate was 19%, PFS and OS were equal in female and male patients. ACAs were found in 62(11%) patients, they had lower cytogenetic and molecular response rates and longer response time to TKI and inferior outcome. ACAs were more frequent in younger, Imatinib resistant patients, and in blast phase. We identified loss of Y Ch in 18 patients (29%), trisomy 8 in 7 (11%), trisomy 19 in 12 (19%), i (17q) in 12(19%), other different single abnormalities in 8 patients (13%), complex karyotype with double ACAs in only 5 patient (8%).Four patient showed variant Ph Ch: t(9;22;22)(q34;q11;q11). Deletion of der(9) Ch in 17 cases (27%): (10 cases with loss of Y Ch, case with del(20)(q11q13), and 3 case with t(X;13)(q13;q32)). The cytogenetic and molecular response rates were uniformly lower in patients with ACAs, CCgR and MMR rates were significantly lower in patients with ACAs (68% vs 89% and 55% vs 86% respectively), responses were significantly slower in patients with ACAs, 54 patients presented with ACAs at diagnosis while 8 patients developed or acquired ACAs while on treatment.

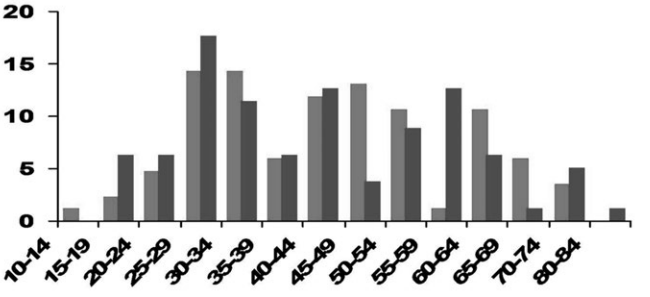

Figure 1.

Summary and Conclusions: The importance of ethnicity and gender differences in relation to disease incidence, and prognosis are major health policy focus2.To investigate the low mean age of CML in Egypt and evaluate role of ACAs on disease and clonal evolution, we analyzed CML data of 10 Medical Centers in Egypt. We identified 62(11%) cases with clonal ACAs. ACAs are more frequent in younger patients and adversely affected time and response rates to Imatinib treatment they were related to lower cytogenetic and molecular response rates and longer response time toTKI and inferior outcome and lower overall survival.

EXTREME THROMBOCYTOSIS IN CHRONIC MYELOID LEUKEMIA IN THE ERA OF TYROSINE KINASE INHIBITORS (TKIS)

F. Sorà[1,*] F. Autore[1], G. Alimena[2], M. Annunziata[3], P. Avanzini[4], M. Bocchia[5], M. Breccia[2], F. Celesti[6], P. Chiusolo[1], M. Crugnola[7], M. Endri[8], C. Fava[9], S. Galimberti[10], A. Gozzini[11], A. Iurlo[12], R. Latagliata[2], P. Musto[13], R. Porrini[14], P. Pregno[15], G. Rege Cambrin[9], S. Sica[1]
[1]Università Cattolica del Sacro Cuore-Policlinico A. Gemelli, [2]Università La Sapienza-Policlinico Umberto I, Roma, [3]Ospedale Cardarelli, Napoli, [4]Azienda Ospedaliera di Reggio Emilia, Reggio Emilia, [5]Policlinico Santa Maria alle Scotte, Siena, [6]Ospedale Belcolle di Viterbo, Viterbo, [7]Azienda Ospedaliero-Universitaria di Parma, Parma, [8]Ospedale Civile Pordenone, Pordenone, [9]Polo Universitario ASO S. Luigi Gonzaga, Orbassano, [10]Università di Pisa, Pisa, [11]Università di Firenze, Firenze, [12]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, [13]Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, [14]Azienda Ospedaliera Sant'Andrea, Roma, [15]Ospedale San Giovanni Battista, Torino, Italy

Background: Thrombocytosis is a common feature in chronic myeloproliferative disorders. The incidence of thrombocytosis in CML is reported to be around 30 to 50%. Extreme thrombocytosis defined as a platelet (PLT) count >1.000x 10^9/l is uncommon in CML as well as isolated thrombocytosis.

Aims: Our aim is to study the clinical management and the therapeutic response of CML with extreme thrombocytosis.

Methods: From January 2001 to January 2015, 1314 patients affected by CML were followed in 15 different Italian hematological centers. We diagnosed 78 CML with extreme thrombocytosis at onset (5.9%); we conducted the study on 70 pts who have at least 6 months of follow-up and were in chronic phase; 2 pts in blast phase and in accelerated phase were excluded from the analysis.

Results: Our patients were 48 females and 22 males with a median age of 59 years (range 18-84). At diagnosis, median hemoglobin level was 11.6 g/dl, median WBC 32.7x 10^9/l and PLT count 1.466x 10^9/l. The Sokal score was high in 44 (62.9%), intermediate in 21 (30%) and low in 5 (7.1%). According to Hasford score 47.5% pts resulted high, 30.5% intermediate, 22% high; Eutos score available in 48/70 pts was high in 13 (27.1%) and low in 35 (72.9%). Pts' characteristics are summarized in Figure 1. PCR analysis showed the presence of p210 in all cases and the absence of JAK2 V617F mutation in 28 out of 30 pts (42.9% of all the pts) who performed the test. At diagnosis we registered 5 thrombotic/hemorrhagic episodes: 1 superficial thrombosis, 1 subarachnoid hemorrhage, 1 metrorrhagia, 1 epistaxis and 1 purpura. None of the two JAK2 positive patients showed thrombotic/hemorrhagic episodes. All but six pts received initial treatment with hydroxyurea and allopurinol. One patient underwent PLT apheresis. PLT count was generally unresponsive to initial treatment. Upfront treatment was imatinib in 53 pts, nilotinib in 11 pts and dasatinib in 6

pts. PLT count normalization was rapidly achieved after introduction of TKIs. Hematological response was reached at a median of 1 month, complete cytogenetic response after a median of 3 months (range 3-36) in 62/65 evaluable pts, and major molecular response in 53 out of 64 evaluable pts after a median of 9 months (range 3-101). Of the 53 pts who started imatinib 7 pts shifted to nilotinib for resistance (3 primary and 4 secondary), 3 to dasatinib for primary resistance, 1 to ponatinib for primary resistance and 2 pts are not on TKI at this time for intolerance. Four of these pts dead for causes independent from CML (1 pt for myocardial infarction, 1 pt for GVHD post-transplantation and 2 pts for second tumor at 3, 9, 38 and 147 months respectively) and 3 pts were lost during follow-up. Three patients of the 11 who started nilotinib stopped treatment with TKIs for resistance or intolerance, 1 shifted to dasatinib for secondary resistance. Sixty-three patients (90%) are alive, 58 of them on TKIs (33 imatinib, 14 nilotinib, 10 dasatinib, 1 ponatinib) at a median follow up of 65 months (range 7-168).

Table 1. Characteristics of patients and laboratory findings.

Number of patients	70
Male/female	22/48
Median age	59 years (18-84)
Median hemoglobin	11.6 g/dl (7.3-16.3)
Median white blood cell count	32.700 x 10^9/l (3.800-390.000)
Median platelets count	1.466 x 10^9/l (1.020-4.849)
Sokal score: low	5/70 (7.1%)
Sokal score: intermediate	21/70 (30%)
Sokal score: high	44/70 (62.9%)

Summary and Conclusions: The prevalence of extreme thrombocytosis in CML is 5.9% in a large multicenter observational study. Cytoreduction with hydroxyurea was not able to achieve normalization of PLT count, however pts with extreme thrombocytosis were easily and rapidly managed by TKIs. CML pts with extreme thrombocytosis resulted similar to the CML population considering the response to TKIs and low number of thrombotic/hemorrhagic complications. Patients on at least major molecular response are 48 out of 55 evaluable (87.3%) at a median follow-up of 65 months.

PB1746

ELEVATED BLOOD PRESSURE (BP) AND ADVERSE EVENTS OF HYPERTENSION (HTN) IN PHASE 1, 2, AND 3 TRIALS OF PONATINIB IN LEUKEMIA

F. Guilhot[1,*] H.J. Khoury[2], M. Baccarani[3], A. Hochhaus[4], T.P. Hughes[5], J.H. Lipton [6], S. Lustgarten[7], K. Yanase[7], M.G. Conlan[7], J.E. Cortes[8], M.W. Deininger[9], H.M. Kantarjian[8], N.P. Shah[10], M. Talpaz[11], M.J. Mauro[12]
[1]Inserm CIC 1402, CHU de Poitiers, Poitiers, France, [2]Winship Cancer Institute of Emory University, Atlanta, United States, [3]University of Bologna, Bologna, Italy, [4]Jena University Hospital, Jena, Germany, [5]Institute of Medicine and Veterinary Science, Adelaide, Australia, [6]Princess Margaret Cancer Centre, Toronto, Canada, [7]ARIAD Pharmaceuticals, Inc., Cambridge, [8]The University of Texas MD Anderson Cancer Center, Houston, [9]Huntsman Cancer Institute, University of Utah, Salt Lake City, [10]University of California San Francisco, San Francisco, [11]Comprehensive Cancer Center, University of Michigan, Ann Arbor, [12]Memorial Sloan Kettering Cancer Center, New York, United States

Background: Ponatinib is a potent, multitargeted tyrosine kinase inhibitor with proven efficacy in resistant Philadelphia chromosome–positive (Ph+) leukemia.
Aims: This analysis reports elevated BP and adverse events of HTN in phase 1, 2, and 3 trials of ponatinib in patients with leukemia.
Methods: Ponatinib safety and efficacy were evaluated in patients with relapsed/refractory hematologic malignancies in the ongoing phase 1 trial, in heavily pretreated chronic myeloid leukemia (CML)/Ph+ acute lymphoblastic leukemia (ALL) patients in the ongoing PACE (phase 2) trial, and in newly diagnosed chronic-phase CML patients in the terminated EPIC (phase 3) trial of ponatinib vs imatinib. All patients gave informed consent. Phase 1 and EPIC, but not PACE, excluded patients with uncontrolled HTN (defined as untreated systolic/diastolic >150/>100 mm Hg in phase 1 and >140/>90 mm Hg in EPIC). Elevated BP was defined by the single highest BP measurement (systolic/diastolic): grade (G) 1/pre-HTN 120–139/80–89 mm Hg, G2 140–159/90–99 mm Hg, G3 ≥160/≥100 mm Hg. HTN adverse events were reported by investigators.
Results: Elevated BP was frequent at trial entry (Table 1). G1/G2–3 rates were 44%/42% in phase 1, 37%/47% in PACE, and 51%/19% with ponatinib vs 52%/12% with imatinib in EPIC. Any increase in BP grade from baseline was also frequent, with rates of 74% in phase 1, 68% in PACE, and 68% with ponatinib vs 51% with imatinib in EPIC. In PACE, estimated systolic/diastolic BP increases over time were low, at 2.3/0.7 mm Hg per year. HTN adverse events were reported in 38%, 28%, 18%, and 2% of patients in phase 1, PACE, and the EPIC ponatinib and EPIC imatinib arms, respectively. Hypertensive crisis was reported in 2 patients in PACE and in 2 patients in the EPIC ponatinib arm. HTN adverse events did not lead to discontinuation or death. Few patients had dose modifications for HTN adverse events (0% in phase 1, 5% in PACE, and 3% with ponatinib vs 0% with imatinib in EPIC). A retrospective multivariate analysis of pooled patients showed that HTN adverse events were significantly associated with ponatinib dose intensity.

Table 1. Baseline BP and Any Increase in BP Gradea on Study.

	Normal BP[b] at Baseline				G1 BP at Baseline			G2 BP at Baseline		G3 BP at Baseline
	n	Increase to G1	Increase to G2	Increase to G3	n	Increase to G2	Increase to G3	n	Increase to G3	n
Phase 1, N=81	11	18%	45%	27%	36	47%	39%	27	70%	7
PACE, N=449	70	34%	31%	23%	167	53%	35%	157	62%	55
EPIC/ponatinib, n=154	46	57%	22%	7%	78	51%	14%	30	50%	0
EPIC/imatinib, n=152	54	65%	13%	2%	79	35%	5%	12	17%	6

[a]Based on single highest BP measurement; [b]<120/<80 mm Hg. Baseline BP was missing for 1 patient in the EPIC imatinib arm.

Summary and Conclusions: Increase in BP was frequently observed in ponatinib trials, including in patients on imatinib. Rates of HTN adverse events were relatively lower and seen primarily with ponatinib. While associated with ponatinib dose intensity, HTN adverse events rarely led to change in leukemia therapy. Given BP variability, investigator reporting of HTN adverse events may be a more reliable indicator of clinically meaningful HTN.

PB1747

PATIENTS WHO DO NOT ACHIEVE STABLE UNDETECTABLE BCR-ABL1 AFTER LONG-TERM IMATINIB OBTAIN DEEP MOLECULAR RESPONSES AFTER SWITCHING TO DASATINIB

N. Takezako[1,*] C. Yoshida[2], M. Shiseki[3], T. Kumagai[4], K. Inokuchi[5], M. Takano[6], K. Nishiwaki[7], A. Ohwada[8], M. Yamamoto[9], Y. Kouzai[10], H. Sakamaki[11]

Background: Imatinib therapy has drastically changed the prognosis for patients with chronic myeloid leukemia (CML). Confirmed deep molecular response predicted significantly higher survival probabilities and no patient with confirmed deeper molecular response (*i.e.* $MR^{4.5}$) has experienced progression (Hehlmann R *et al. J Clin Oncol.* 2014). However, even after 8 years of imatinib administration, the cumulative incidence of ≥2 years of undetectable BCR-ABL1 (Stable $MR^{4.5}$) was 36.5% (Branford S *et al. Blood*. 2013). On the other hand, second generation tyrosine kinase inhibitor, nilotinib has been shown to be a more potent inhibitor of BCR-ABL than imatinib (Saglio G *et al. N Engl J.* 2010). Another study shows that patients with CML-CP with persistent minimal residual disease (MRD) on imatinib who switched to nilotinib experienced deeper confirmed molecular responses compared with those who remained on imatinib, and these responses were stable (Hughes P, *et al. Blood* 2014). Dasatinib, another second generation tyrosine kinase inhibitor also induces fast and deep cytogenetic and molecular responses that translate to better outcomes (Jabbour E *et al. Blood* 2014). However, it is not clear that dasatinib has a potential for achieving further molecular response after switching. Here, we conducted a multicenter, prospective 'CMR-CML' study and observed molecular response of CML-CP patients treated with dasatinib.
Aims: The primary endpoint of our study was complete molecular response (CMR) rate by 18 months after switching to dasatinib.
Methods: For the assessment of molecular response, a quantification of BCR-ABL transcripts by RQ-PCR analysis was applied. The analysis of BCR-ABL transcripts were performed at registration, 1, 3, 6, 9, 12, 15, and 18 months after switching to dasatinib. Measurement of BCR-ABL transcripts was performed as described previously (Yoshida C et.al. *Int J Clin Oncol.*2013). Undetectable level of BCR-ABL transcript (<50 copies/μgRNA), which is equivalent to 4.16-log reduction, was defined to be CMR in this study. Comparisons between the qualitative variables were carried out using the $\chi 2$ test. These sta-

tistical analyses were performed with the software package Stata version 11 (Stata Corp LP, College Station, TX, USA). For all analyses, the P values were 2-tailed, and a P value less than 0.05 was considered to be significant.

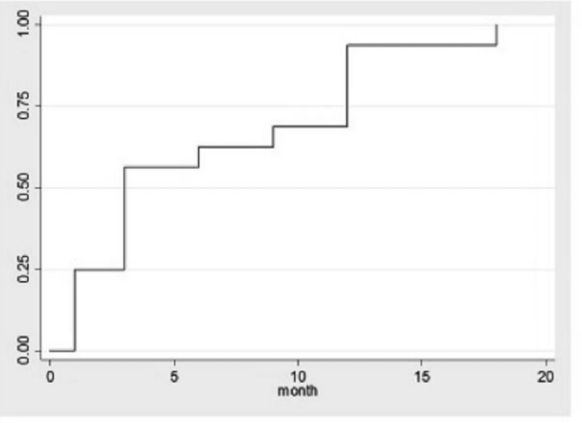

Figure 1.

Results: From August 6, 2011 to January 17, 2013, a total of 21 patients with CML-CP with persistent MRD after at least 2 years of imatinib therapy assigned in our study. Five patients were excluded because of several reasons. Finally, 16 patients were registered in this trial. The median age at registration was 50 years (range, 25-70 years), and 11 were men and 5 were women. All patients received a dosage of 100mg/day dasatinib once daily. All patients achieved CMR within 18 month. There were 4, 5, 1 patients obtained CMR by 1, 3, and 6 months respectively in 16 evaluable patients (Figure). Ten patients kept CMR at 16 month and 6 patients lost CMR (2 patients widowed this trial, 3 patients was suffered from recurrence). We investigated the possible associations between the achievement of early CMR and a number of baseline variables, including age, sex, lymphocyte count, International Scale (IS), and duration of imatinib therapy. There was higher cumulative incidence of CMR at 1 month when patients with a low IS at registration were compared with those with a high IS (0.013 vs 0.034 *P*=0.0201). Duration of imatinib therapy was significantly longer in patients who obtained CMR in 1 month (106±21 months vs 55±10 months *P*=0.0322). There was no difference in the frequency of female sex, age, lymphocyte count. Dasatinib therapy was well tolerable and toxicities were almost low grade. Non-hematological toxicities were liver dysfunction (grade 1 or 2, 43%), pleural effusion (grade 1 or 2, 37%), dyspnea (grade 1, 12%; grade 3, 6%), and gastrointestinal bleeding (grade 1, 12%). Hematological toxicities were anemia (grade 1or 2, 75%; grade 3, 12%), neutropenia (grade 1 or 2, 43%; grade 3, 6%), and thrombocytopenia (grade 1 or 2, 37%; grade 3, 12%).

Summary and Conclusions: This pilot study shows dasatinib has the ability to obtain further deep molecular response for the patients who do not achieve stable undetectable BCR-ABL1 after long-term imatinib therapy. Based on this study, randomized control study should be attempted in the future.

Medizinische Abteilung, LKH Klagenfurt, Klagenfurt, [26]UMIT University for Health Sciences, Medical Informatics and Technology, Hall, Austria

Background: Tyrosin kinase inhibitors (TKI) treatment in CML has is standard of care, however, its treatment goals have become more stringent are directed by response kinetics. Since standardized BCR-ABL transcript monitoring has been established the ELN recommendations guide treatment according to the achieved molecular response. Clinical trials have demonstrated the predictive value of early molecular response with respect to consecutively achieved deep responses which in turn would allow for about half of the patient to remain in treatment free remission. In addition, the duration of sustained deep molecular response has recently been shown to be associated with a lower relapse rate after treatment discontinuation. Although second generation TKIs (2G-TKIs) are of superior efficacy in inducing deep molecular response the majority of patients in routine care are still receiving imatinib.

Aims: Assessing the current status of treatment and response thereto is a prerequisite to ascertain a high quality of disease management and to guide physicians to future treatment options for their patients. This registry aims to reflect the real life situation of CML treatment in Austria.

Methods: The Austrian CML registry is a database project under the patronage of the ASHO approved by an ethics committee. It is focused on diagnostic parameters, *e.g.*, conventional cytogenetics and/or FISH, BCR-ABL transcript levels, blood counts, general laboratory parameters, CML phase, concomitant diseases, CML specific treatment and including stem cell transplantation and adverse effects. Participating centres can contribute patient data after having obtained written informed consent.

Results: We summarize the CML registry data as of March 2015 and focus on treatment response. The CML registry cohort comprised a total of 434 patients with a median number of 4581 follow-up visits. At diagnosis 87.9%, 8.3% and 0.7% of evaluable patients were in early, late and secondary phase, respectively, whereas only 2.1%, 0.7% and 0.2% were in accelerated phase, myeloid and lymphatic blast crisis, respectively. First line treatment was imatinib, nilotinib or dasatinib in 301, 21 and 8 evaluable cases, respectively. The majority of patients had an optimal response according to ELN criteria at the last evaluable follow up (Figure1). We will present the results of the currently running final update on the registry cohort.

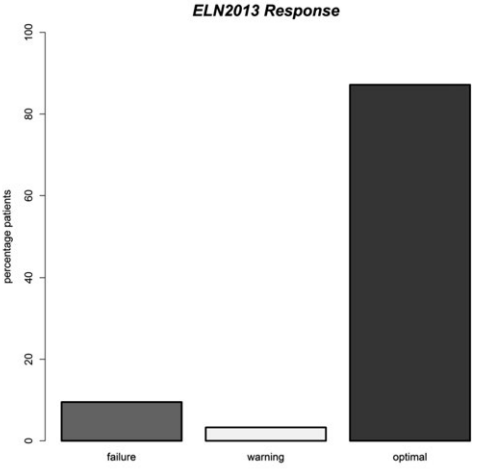

Figure 1.

Summary and Conclusions: The majority of patients fulfils the ELN 2013 criteria for optimal response. For years imatinib has been for years the mainstay of treatment and continues to be so. However, the use of 2G-TKIs has increased. The main focus of this registry for 2015 will be the percentage of patients reaching a sustained deep molecular response.

PB1749

UTILIZATION OF LABORATORY DATA TO QUANTIFY THE BCR-ABL1 TESTING LANDSCAPE IN USA

J. Clark[1,*] A. Jack[1], E. Aita[2], R. Keeling[1], M. Fe Paz[3]

[1]Labceutics, Belfast, United Kingdom, [2]Labceutics, New York, United States, [3]Labceutics, Madrid, Spain

Background: According to NCCN and ELN Guidelines, the monitoring of *BCR-ABL1* transcript levels is central to care of Chronic Myeloid Leukemia (CML) patients. Previous studies have shown that, in the US, a high proportion of CML patients do not receive the recommend frequency of BCR-ABL testing. Efforts have been made to standardize technical aspects of monitoring, but a large degree of variation remains in many other aspects of the BCR-ABL testing process, for example test requisition and result reporting. Therefore physicians are required to collect, assimilate and interpret a large amount of, often technical, information associated monitoring CML patients.

Aims: The aim of this study was to quantify the variation in the BCR-ABL testing

pathway, from test availability through to result reporting. An additional objective was to use a national database to analysis testing rates for CML patients.
Methods: Insurance claims data and independent information from clinical laboratories were used to map and evaluate the current US *BCR-ABL1* testing landscape. This study included analysis of test availability (including geographic reach), test request forms, turn around times (TAT), cost (as billed by the laboratory), methodology, sample reports and number of tests performed and billed.
Results: Between June 2013 and May 2014, *BCR-ABL1* testing was offered by 209 US clinical laboratories, of which, 137 laboratories conducted the testing in-house. The remaining 72 laboratories sent this testing to 26 laboratories, 22 of which were used by only a single referring laboratory. Geographic spread of the laboratories was not uniform, *e.g.* 16 laboratories in California whereas only one laboratory in each of 9 other states. 21% of laboratories stated they report on the International Scale (IS), with 77% not providing this critical information. Only 30% (6/20) of test request forms specified transcript types for which testing is available. TAT and cost varied from 2-14 working days and $187-$497 respectively. Only 22% (4/18) of laboratory reports included full test methodology details, graphical representation of historical results and clear interpretative comments in line with current NCCN guidelines. The testing frequency of CML patients was found to be<1 test per annum, much lower than current guidelines recommend.
Summary and Conclusions: Availability of quantitative *BCR-ABL1* testing appears to be adequate in the US, however, our data show that in those states with fewer laboratories offering BCR-ABL quantitation, a physician is less likely to have access to a laboratory offering testing on the International Scale. The heterogeneous landscape for *BCR-ABL1* testing is likely contributing to insufficiently-informed testing choices, testing frequency and, ultimately, treatment choices. The inadequate and inconsistent information available for physicians poses a barrier to supporting them in choice of testing laboratory and in determining actionable outcomes from patient test results. A more uniform and integrated approach is needed to better support physicians and to ensure optimal patient care.

PB1750

CORRELATION OF DASATINIB PHARMACOKINETICS WITH CLINICAL RESPONSE AND ADVERSE EVENTS IN NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA CHRONIC PHASE

A. Mita[1,*] M. Miura[2], T. Niioka[2], M. Abumiya[2], T. Kobayasi[1], S. Takahshi[1], Y. Kameoka[1], T. Yoshioka[1], N. Takahashi[1]
[1]Department of Hematology, Nephrology, and Rheumatology, Akita university graduate school of medicine, [2]Pharmacy, Akita university hospital, Akita, Japan

Background: The second-generation tyrosine kinase inhibitor (TKI) dasatinib is used as the first-line therapy for newly diagnosed chronic myeloid leukemia (CML). However, some patients fail to respond or become intolerant to dasatinib. Several studies have shown a relationship between pharmacokinetics of dasatinib and molecular responses or significant adverse events.
Aims: To investigate pharmacokinetics of dasatinib and to identify an influence of transporter gene polymorphisms on dasatinib treatment in newly diagnosed CML patients.
Methods: Fourteen patients treated with dasatinib from whom were obtained a total of 118 pharmacokinetic profiles were enrolled in this study. Dasatinib plasma concentrations from samples obtained just prior to and 1, 2, and 4 h after oral dasatinib administration were analyzed by liquid chromatography-tandem mass spectrometry. Genotyping of 10 single nucleotide polymorphisms (SNPs) in genes involved in dasatinib pharmacokinetics (*ABCG2, ABCB1, CYP3A5*3, SLC22A1, ABCC2*) was performed by PCR-RFLP. The study protocol was approved by the Ethics Committee of Akita University Hospital, and all recipients gave written informed consent.

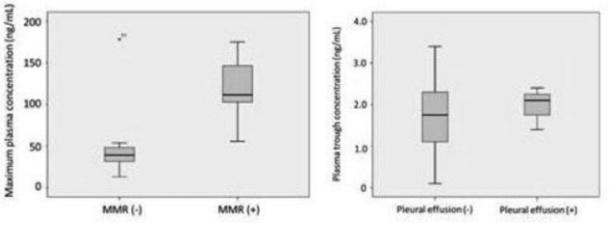

Figure 1.

Results: In this study, associations between dasatinib concentration, clinical response, adverse event, and 10 SNPs were investigated among newly diagnosed chronic phase CML patients. Seven patients achieved major molecular response (MMR) at 3 month and the other 7 patients did not. The plasma concentration at 2 h (C2h) or the maximum plasma concentration (Cmax) of dasatinib was significantly higher among patients with a MMR at 3 month than those without (*P*=0.051, *P*=0.035, Figure 1). Among 118 pharmacokinetics profiles, there were 8 adverse events of pleural effusion in 4 patients. Although there was not a significant difference in plasma trough concentration of dasatinib (C0h) between groups with pleural effusion and without (*P*=0.350), it was observed in patients with more than 1.4 ng/mL of C0h which could be translated into 2.8 nM (Figure 2). 5 patients have ABCG2 421C/C and 9 patients have ABCG2 421C/A. There were significant differences of plasma concentration at 2 h (C2h) after dasatinib administration between two groups (*P*=0.019). However, the other SNPs were not associated with dasatinib pharmacokinetics in this study.
Summary and Conclusions: Higher dasatinib C2h/max was associated with the likelihood of achieving a MMR at 3 month in our small CML patient cohort. Additionally, pleural effusion was not observed in patients with lower dasatinib trough concentration. Although a prospective study with a larger patient population is necessary to validate these findings, in addition to *BCR-ABL1* mutation analysis, our data indicate that clinical dasatinib blood-level testing may improve the efficacy and the safety of dasatinib therapy among newly diagnosed CML patients.

PB1751

«FLAG» REGIMEN IS EFFECTIVE FOR CHRONIC PHASE INDUCTION FOR CHRONIC MYELOID LEUKEMIA BLAST CRISIS.

E. Romanova[1,*] L. Girshova[1], E. Goryunova[1], N. Siordia[1], V. Ivanov[1], D. Motorin[1], E. Lomaia[1], A. Zaritskey[1]
[1]Hematology department, Federal North – West Medical Research Centre, St-Petersburg, Russian Federation

Background: Only hematopoetic stem cell transplantation (HSCT) should be curative in chronic myeloid leukemia blast crisis (CML BC). It seems that few patients obtain stable second chronic phase (CP) on monotherapy with tyrosin kinase inhibitors (TKI)and then might be switched to HSCT. We suggest that more patients may benefit with high doses of cytostatics in combination with TKIs.
Aims: To evaluate whether high doses of cytostatics in combination with TKIs may allow to obtain more stable response and switch more patients to HSCT.
Methods: We studied the results of different therapeutic approaches for CML BC in 19 patients (9 females and 10 males) with median age 43 years at the moment of the BC onset (range 21-63). CML was initiated in BC in 4 pts, whereas other pts develop BC on TKIs therapy. Median time from CML diagnosis was 44,5 mo (range from 1,7 to 139 mo). Type of BC was myeloid in 9, lymphoid in 7 and nondifferenciated in 3 pts. Pts were treated with FLAG based regimen+TKI (n=8), low dose chemo+TKIs or mono TKI (n=11). All pts obtained monoTKIs before FLAG regimen. The therapy was intensified due to lack or loose of second CP. 8 pts had SCT. Type of SCT was 4 unrelated alloSCT, 2 related alloSCT, 2 haploidentical SCT. 5 pts after FLAG and 3 pts after low dose chemo or monoTKIs undergo SCT.
Results: Second CP was obtained in 7/ 8(87.5%) patients after FLAG and only in 3/11 (27%) pts after low dose chemotherapy induction (P=0,02). Moreover 3 and 2 pts after FLAG induction have CCyR and MMR, accordingly. No pts on other therapies reach CCyR. 3 patients were undergone HSCT after 1 of FLAG course. Other patients received one or more FLAG consolidation. Consolidation did not lead to stable CP. All patients had rapid increase of blast count. There are no differences in duration of response in patients with low and high dose cytostatic therapy. The median time to HSCT from BC onset was 12 mo (range from 5,6 to 94 mo). The probability of survival is higher for transplanted patients vs not transplanted patients (25% vs 15%, p 0,014). 50% patients are alive after HSCT with median overall survival time after HSCT 14,5 mo (range from 4,4 to 38 mo). Median time to HSCT in alive and dead pts was 6,6 and 12,8 mo accordingly. There were no differences in overall survival after HSCT between treatment groups.
Summary and Conclusions: HSCT should be the goal of treatment strategy in BC CML. FLAG regimen in combination with TKIs is effective for CP induction and allow us to switch more pts to HSCT in compare with less aggressive strategies. Intensive chemo+TKIs may be able pts to reach CCyR or even MMR, but the responses are unstable and whether pts should obtained several courses of chemo for response deepening is questionable. It seems that pts should undergo HSCT as soon as possible after CP induction.

PB1752

FLOW CYTOMETRY-BASED ASSAY FOR DETECTION OF BCR-ABL FUSION PROTEIN IN BLOOD CELLS FROM CML PATIENTS

L. Löf[1,*] U. Strömberg[2], U. Landegren[3], M. Kamali-Moghaddam[3]
[1]Uppsala University, [2]University Hospital, [3]Departement of Immunolgy, Genetics and Pathology, Uppsala University, Uppsala, Sweden

Background: Chronic myeloid leukemia (CML) is currently diagnosed using RT-PCR and/or FISH to reveal the presence of the fusion mRNA transcripts for BCR-ABL, or of the characteristic Philadelphia chromosome. RT-PCR is also used to monitor the effects of treatment by sensitively measuring transcripts representing minimal residual disease (MRD). It has not been possibly to use flow cytometry to identify the neoplastic cells but such a method would be helpful in the workflow of a hematopathology lab.

Aims: We have now developed a method that successfully detects and enumerates cells harboring the fusion protein BCR-ABL by flow cytometry in CML patients.
Methods: The method uses the *in situ* proximity ligation assay (PLA) (Söderberg et al 2006, Leuchowius et al 2009), where two antibodies target the BCR and the ABL part, respectively, of the fusion protein. The antibodies are equipped with DNA oligonucleotides that – when brought in proximity – guide the formation of a circular DNA molecule as a template for localized DNA amplification through rolling circle amplification (RCA). Each RCA-product is then labeled with around 1,500 fluorophore-coupled DNA oligonucleotides, allowing cells to be detected by flow cytometry.
Results: The method has proven very sensitive, able to detect very low number of cells in patient samples, and it allows identification of patients in relapse at a very early state. We have analyzed 25 CML patient samples using PLA-based flow cytometry, and the results were compared to the routine RT-PCR analysis. More than 50% of the analyzed samples were positive for both methods, ranging from 75 IS% down to 0.03 IS% for the RT-PCR. Five of the samples were positive only in RT-PCR, while three were positive only in the PLA method.
Summary and Conclusions: Since the method is developed for readout with flow cytometry all the advantages with multicolor fluorescence analysis can be achieved simultaneously. In addation, the method allows for standard cytological markers to further characterize the malignant cells.

Abstract withdrawn

PB1754

LOW HEMOGLOBIN LEVELS AT DIAGNOSIS ARE ASSOCIATED WITH WORSE TREATMENT RESPONSES AND EVENT FREE SURVIVAL IN CHRONIC MYELOID LEUKEMIA PATIENTS IN CHRONIC PHASE RECEIVING TYROSINE KINASE INHIBITORS

P.S. Ko[1,*] Y.B. Yu[1], M.H. Hung[1], J.P. Gau[1], C.J. Liu[1], L.T. Hsiao[1], M.H. Chen[1], J.H. Liu[2], T.J. Chiou[3], C.Y. Liu[1], C.H. Tzeng[1]
[1]Division of Hematology and Oncology, Department of Medicine, [2]Division of Oncology, Department of Medicine, [3]Division of Transfusion Medicine, Department of Medicine, Taipei Veteran General Hospital, Taipei City, Taiwan, ROC

Background: SPECIAL;Despite progress in prognosis of patients with chronic myeloid leukemia in the era of tyrosine kinase inhibitors (TKI), values of current available three prognostic scoring systems, namely Sokal, Hasford and EUTOS scores, for predicting survival outcomes and treatment response remained inconclusive. Current Sokal and Hasford score developed in pre-TKI era and they both included many baseline clinical variables but without baseline hemoglobin levels, a seldomly discussed variable. The value of baseline hemoglobin levels for predicting treatment responses and survival outcomes might be worthy to be reevaluated.
Aims: This study aims to exam the role of hemoglobin level at diagnosis in association with survival outcomes and treatment responses in chronic myeloid leukemia patients in chronic phase (CML-CP) receiving frontline TKIs and to validate the three scoring systems.

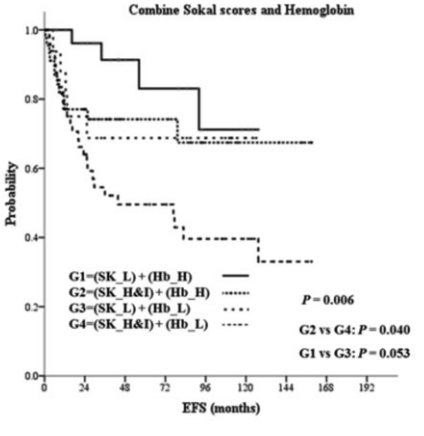

Figure 1.

Methods: SPECIAL;A total 172 consecutive patients with CML-CP patients were screened retrospectively from January 2001 to April 2014. Patients who previously recieved interferon-alpha or any chemotherapeutic agents or in combination with TKIs treatment, patients who were lost follow-up within 3 months of diagnosis, and patisnts who had no adequate data to calculate baseline risk socres were excluded. 143 patients were enrolled to further analysis after screening. The cut-offs of baseline hemoglobin level were defined as 12.3 mg/dl for male and 9.0 mg/dl for female sperately in consideration for gender difference in hemoglobin levels by adopting the receiver oprator characteristic (ROC) curve method.
Results: With a median follow-up of 54.0 months, 5-year overall survival (OS), progression-free survival (PFS), and event-free survival (EFS) were 87.5%, 85.9% and 66.8%. We found Sokal and Hasford, but not EUTOS score were predictive for difference in EFS and PFS; however, none of the three scoring systems were predictive for difference in OS. Lower baseline hemoglobin levels was an independent adverse factors for EFS (hazard ration 2.06; 95% confidence interval 1.12-3.78, P=0.019) and associated with worse treatment responses: the proportion of patients with lower *versus* higher hemoglobin levels achieving optimal responses were 52.2% vs 71.1% for 3-month early molecular response (P=0.021), 20.0% vs 51.4% for 6-month complete cytogenetic respone (P<0.001), and 18.0% vs 45.1% for 12-month major molecular response (P<0.001). Furthermore, combining hemogobin level and Sokal score further distinguised a population at risk for worse EFS and treatment responses.
Summary and Conclusions: The results highlights the need for revisiting tradition CML scoring systems in the TKI era and suggests baseline hemoglobin levels at diagnosis might be considered for new scoring systems.

Background: Nilotinib, a more potent and selective BCR-ABL-1 inhibitor than imatinib is approved by FDA and EMA for the treatment of newly-diagnosed Ph+ CML patients in the chronic phase (CML-CP).
Aims: The aim of the present study was to evaluate the efficacy and safety of nilotinib in a Turkish population of newly-diagnosed Ph+ CML-CP patients.
Methods: The study was a multicenter, open-label, single-arm phase II clinical trial. All patients were to be treated with nilotinib (AMN107, Tasigna®) 300 mg BID for 24 months.

Table 1. Baseline characteristics and molecular responses of the study patients.

Characteristics (n=96)	
Age, year (range)	46 (19-78)
Gender (Female/Male)	39 (40.6%)/57 (59.4%)
Palpable spleen size (baseline), cm	0.0 (0-17)
Leukocyte count, K/mm³	26.5 (1.7-289.4)
Platelet count(baseline), K/mm³	343.0 (75-1268)
Molecular response	
Cumulative MMR rate by 24th month (n=96)	77 (80.2)
Time to MMR (days) (n=77)	260.0±157.5
BCR-ABL level Month 3 (n=89)*	
<%10	77 (86.5)
≥%10	12 (13.5)

Data are expressed as median (minimum-maximum) or number (%) or mean±standard deviation, where appropriate.
MMR (Major molecular rate): BCR-ABL/control gene ratio of ≤%0.1 measured by RQ-PCR as %
* The number of patients who were still on treatment at 3rd month.

Results: As of April 30, 2014, of the 96 patients out of a total 112 enrolled that had 24 month follow-up, 77 completed active treatment period. General characteristics of the patients at baseline and molecular response by 24 months are presented in Table 1. Cumulative major molecular response rates at 3rd, 6th, 9th, 12th, 15th, 18th, 21st and 24th months were 23.4%, 47.9%, 56.4%, 61.7%, 71.9%, 79.2%, 82.2%, and 80.2%, respectively. For the assessment of deeper molecular responses (defined as transcript levels of BCR–ABL on the International Scale [BCR–ABLIS] ≤0.0032%]), complete molecular response with a 4·5 log reduction required at least 32000 control genes. According to this evaluation, within 24 months follow-up 19 patients achieved MR4.5 (19.7%) by 12 months whereas 45 patients achieved increased MR4.5 (46.8%) ratio by 24 months in out of 96 patients. Out of 96 patients, 39 patients had temporally or permanently discontinued treatment. Permanent discontinuation rate due to adverse event was 9.6% (9 patients) which was the most common reason among all patients (19.8%>19 patients) who permanently discontinued during 24 months. Thrombocytopenia was the most frequent (10.4%) AE, followed by hyperbilirubinemia (8.3%) and increased lipase level (7.3%). Despite published peripheral arterial occlusive disease (PAOD) reports related to nilotinib usage, there were no PAOD events reported at our cohort.
Summary and Conclusions: By 24 months, in Turkish patients with newly diagnosed CML, the cumulative MMR rate was 80.2%. Only one progression occurred, during the first year of therapy. Additionally results showing that 46.8% of these patients achieving MR4.5 by 2 years suggest that high efficacy was achieved with nilotinib, an approved first-line therapy for newly diagnosed chronic phase of CML (CP-CML) and can be an option for future candidate CML treatment regimen. Treatment free remission approach for the patients with sustainable responses during long term follow-up. This study contribute to well established nilotinib profile for chronic phase CML patients which is a licensed alternative for the treatment of newly diagnosed Ph+ CML-CP in Turkey.

PB1756

INCIDENCE OF SECOND NEOPLASMS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA ANALYSED IN THE FRAME OF INTERNATIONAL RESEARCH PROJECT EUTOS POPULATION BASED STUDY IN RUSSIAN FEDERATION

O.V. Lazareva[1,*] E. Chelysheva[1], I. Tischenko[2], M. Galayko[3], V. Pepelyaeva[4], S. Meresiy[5], G. Milutina[6], O. Senderova[7], A. Luchinin[8], L. Gavrilova[9], L. Avdeeva[10], S. M. Kulikov[2], A.G. Turkina[1]
[1]Scientific Advisory Department for chemotherapy of myeloproliferative disorders, [2]Department of Biomedical Statistics, Federal State Budgetary Institution Hematology Research Center, Ministry of Healthcare of Russian Federation, [3]Central Clinical Hospital №2 named after Semashko N.A, Russian Railways JSC, Moscow, [4]Regional Clinical Hospital, [5]Clinical state medical sanitary unit№ 1, Perm, [6]Regional Clinical Hospital, Bryansk, [7]Oblast Clinical Hospital, Irkutsk, [8]Research Institute of Hematology and Blood Transfusion, Kirov, [9]Republican Clinical Hospital №4, Saransk, [10]Regional Clinical Hospital, Chita, Russian Federation

Background: Success of tyrosine kinase inhibitors (TKIs) in chronic myeloid leukemia (CML) gives hope for a durable disease free survival. Therefore long-term effects of TKI treatment should be studied. A significant event for CML patients (pts) is the development of other tumors, second neoplasms (SN) which can be defined as prior malignancies (pM) if detected before CML diagnosis and second malignancies (sM) which occur after the CML diagnosis during TKI treatment.
Aims: To evaluate the incidence and variants of SN in CML pts treated in clinical practice in Russian Federation (RUS).
Methods: We included 199 CML pts from 7 centers of 6 administrative districts of RUS into RUS part of EUTOS PBS-study. The inclusion criteria were: Ph'/bcr-abl-positive CML diagnosed in 1.10.2009-31.12.2012 verified by cytogenetic/molecular data, age of pts ≥ 18 years (y). Median (Me) age was 50(18- 82)y, sex ratio M/F(%) was 100/99 (50/50)pts. At the time of diagnosis phases of CML were the following: chronic phase (CP) in 187(94%)pts, accelerated phase in 11 (5,5%) pts, blast crisis in 1(0,5%) pts. Me time from diagnosis to imatinib (IM) therapy was 0,6 (0,5-15) months (mo). Pretreatment before IM was the following: hydroxyurea in 99 (50%) pts; IFN-α in 2 (1%) pts. Me follow-up since the CML treatment start was 35.2 (0,5-85)mo (Me for n=192; 7pts were without TKI therapy).
Results: Total rate of sN was 7% (14 of 199 pts). Two of those cases were sM revealed at 22mo (Encephaloma) and 23mo (adenocarcinoma of the colon) after diagnosis of CML, respectively. These 2pts died due to progression of sM after 29 and 32 mo of CML diagnosis respectively. A pM before CML diagnosis was in 6% (12 of 199 pts). Their Me age was 69(33-73)yy, sex ratio (M/F) 4/8pts. The Me time from diagnosis of a pM to CML diagnosis was 61 (28-429) mo. The pMs were: breast cancer (4/12 of cases), cancer of uterus and ovaries (2/12 of cases), rectal cancer, tumor of the upper third of the shoulder, kidney cancer, prostate cancer, basal cell carcinoma of the eyelid, GIST. Me time of IM therapy was 36 (7- 49)mo. Most of the pts among 12 cases had good results of TKI therapy: 7pts achieved major (4/7) and complete molecular (3/7) response (Me 13 (extr.6–30) mo). Three out of 12 pts with pM in anamnesis died (2 pts not achieved even hematologic response). Pts with sM achieved complete and partial cytogenetic response to 12mo of IM therapy. Mortality in the whole group of 199pts was 15,6% (31cases) and 5 of them (2,5%pts) or 35% (5 of 14 pts) died due to SN progression: 3pts with sM+ 2pts with pM, all 5 were in CP CML.
Summary and Conclusions: Identified cases of SN and CML combination underline a need for understanding the relationship between CML, other malignancies and their therapy. Assosiation of sM annd CML needs deeper analysis during longer observation time.

PB1757

OUTCOME OF FRONTLINE TREATMENT WITH GENERIC IMATINIB ACCORDING TO ELN 2009 BASED NATIONAL GUIDELINES. EXPERIENCE FROM University CLINIC OF HEMATOLOGY, CLINICAL CENTER OF SERBIA, BELGRADE

A. Bogdanovic[1,*] V. Milosevic[2], D. Lekovic[2], V. Djordjevic[2], J. Jovanovic[2], M. Dencic Fekete[2]
[1]Outpatient&Diagnostic Dept, Clin Hematology CCS, Faculty of Medicine, Unv Belgrade, [2]Outpatient&Diagnostic Dept, Clinic of Hematology CCS, Belgrade, Serbia

Background: Serbia was the first country in Europe introduced generic imatinib (ANZOVIP®, Actavis). Lot of concerns and many issues were arisen by general and medical public, especially by patients knowing reports about treatment failures. All patients in Serbia were switched to the same drug together with newly diagnosed patients. To realize real efficiency of the drug, we made evaluation of newly diagnosed patients only.
Aims: Retrospective analysis of response to generic imatinib in frontline treatment.
Methods: As the largest institution, Clinic of Hematology CCS, we analyzed cohort of 49 patients with CML in chronic phase, frontline treated by generic imatinib from August 2012 to March 2014. All patients were treated according to ELN 2009 based National guidelines with regular cytogenetic follow up and molecular monitoring after 12 months (after CCgR). In all patients the follow up of treatment was at least 6 month.
Results: Our 49 patients, had median age of 47yrs ranging from 24 to 74yrs. There were 31 male and 18 female patients. In all patients CHR was achieved within 3 months of treatment. In 17 pts after their approval, we have performed early cytogenetic evaluation at 3 mths: 3/17 pts was without mitoses, 10/17 pts (58%) had Ph<35%, and 4 were non responders (Ph from 50-100%). According to our National guidelines evaluation at 6 and 12 months were performed. At 6 months, 23/49 pts achieved CCgR (46.9%), 38/49 (77.5%) was in majorCgR (ELN 2009 optimal), and 9/49 pts had insufficient response (no major CgR). At 12 mths similar evaluation revealed 26/49 pts achieving CCgR (53%), and ELN 2009 suboptimal response was noted in 7/49 pts (14.3%). Unfortunately we have also noted that some patients lost their previously achieved response after one year of treatment. Also 3 patients developed sudden blast phase. Taken together failure >12 mths was in 5+3 pts (16%). Besides 7 pts (14.3%) never achieved optimal response by 400mg imatinib up to one year of treatment. Seven patients (14.3%) were treated by imatinib escalation (800mg), and 4 achieved CCgR. 9 pts were treated with second line nilotinib (failure by ELN 2009) and 5 of them achieved secondary CCgR. From other four patients without optimal response to nilotinib, 3 of them were sent to BMT. Molecular evaluation was performed at M12 and M18 from start of the treatment. Due to technical reasons it was performed in more than half of the patients, 30 of 49 (61%), and optimal molecular response at M12 of M18 was achieved in 25 of 30 analyzed patients (at least MR3) but in 5 patients MR3 was not achieved even they are in continuous CCgR up to at M18.
Summary and Conclusions: Our pilot data are based on small number of patients from single center, but provided data that generic imatinib used in Serbia (ANZOVIP) is not much inferior to branded imatinib. Larger series of patients from whole Serbia (*e.g.* 90-100) will provide more accurate data about efficiency of generic imatinib in the first line treatment.

PB1758

THIRD-LINE TREATMENT WITH 2ND GENERATION TYROSINE KINASE INHIBITORS (TKIS) IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA WHO FAILED TWO PRIOR TKIS: A SINGLE CENTER EXPERIENCE OF 21 PATIENTS

A. Salihoglu[1], A. E. Eskazan[1,*] V. Suzan[2], S. Savci[2], I. Erdogan[1], S. Berk[1], F. F. Yalniz[1], T. Elverdi[1], M. C. Ar[1], S. Ongoren Aydin[1], Z. Baslar[1], Y. Aydin[1], N. Tuzuner[3], U. Ozbek[4], T. Soysal[1]
[1]Department of Internal Medicine, Division of Hematology, [2]Department of Internal Medicine, [3]Department of Pathology, Istanbul University Cerrahpasa Faculty of Medicine, [4]Department of Genetics, Istanbul University Institute of Experimental Medicine (DETAE), Istanbul, Turkey

Background: Although most of the chronic phase chroic myeloid leukemia (CML-CP) patients do well under imatinib (IM), some quit IM due to resistance and/or intolerance. 2nd generation tyrosine kinase inhibitors (2GTKIs) (dasatinib

(DAS) and nilotinib (NIL)) can be used in patients who have intolerance and resistance to IM, and approximately 50% of patients failing to respond to previous treatments may respond to 2GTKIs. Limited data is available, displaying the outcome of CML patients who failed two lines of TKI, and received 2GTKIs as a 3rd-line treatment option.
Aims: The aim of this study is to report our single center experience on CML patients who received 2GTKIs as a 3rd-line treatment option.
Methods: Two hundred and nine CML-CP patients who were diagnosed between 1999-2013 and received IM were evaluated. Patients' demographics, Sokal risk scores, treatment outcomes and durations, and the follow-up periods were noted from the patients' files retrospectively. Patient monitorization was performed according to European LeukemiaNet (ELN) recommendations, and in case of resistance, mutational analysis was performed. The cumulative incidence of major molecular response (MMR) and complete cytogenetic response (CCyR) rates during the follow-up periods were calculated. The choice of 2GTKIs depended on mutational status and comorbidities of the patient, and the disease phase at the time of the switch (*i.e.* in patients with blastic crisis (BC), DAS was the treatment choice). Also in Turkey DAS was in the market before NIL became available, so at that period of time, DAS was the only option for 2nd-line TKI treatment.

Table 1.

Table 1. Baseline characteristics and treatment outcomes of patients received 3rd-line 2GTKIs. (F, female; M, male, HU, hydroxyurea; IFN, interferon; Ara-C, cytarabine; IM, imatinib mesylate; MMR, major molecular response; CCyR, complete cytogenetic response; PCyR, partial cytogenetic response; CHR, complete hematologic response; DAS, dasatinib; NIL, nilotinib) *Patient had splenectomy prior to the diagnosis of CML so Sokal score could not be calculated. ϕPatient died after stem cell transplantation.

Patient #	Age, years/ Gender	Sokal Risk Score	Treatment prior to IM	Reason for stopping IM	Duration of IM treatment (months)	2nd-line treatment	Reason for stopping 2nd-line treatment	Duration of 2nd-line treatment (months)	3rd-line treatment	Duration of 3rd-line treatment (months)	Reason for stopping 3rd-line treatment	Best response under 3rd-line treatment	Follow-up duration (months)	Outcome

19	36/M	Low	None	Resistance	20	NIL	Resistance	19	DAS	7	Continued	CCyR	46	Alive
20	50/M	Low	None	Resistance	63	DAS	Resistance	12	NIL	22	Continued	MMR	97	Alive
21	53/M	High	HU	Resistance	123	NIL	Intolerance	5	DAS	1	Continued	CHR	129	Alive

Results: One hundred and twenty-two patients were male (58%), and the median age was 44 years (range, 18-92 years). The rates of low, intermediate and high Sokal risk scores were 44%, 39% and 17%, respectively. One hundred and seventy-eight patients (85%) were in early CP (ECP), whereas 31 (15%) were in late CP (LCP). One hundred and forty-four (68.9%) of the patients had only received IM as a TKI treatment, of which 129 (61.7%) were still on IM after a median follow-up of 86 months (range, 13-142 months) at the time of the analysis. The cumulative MMR and CCyR rates under IM were 73.6% and 79.9%, respectively. Sixty-five patients (31.1%) received 2GTKIs, of which 45 had DAS and twenty received NIL as 2nd-line treatment. One patient having an allogeneic hematopoietic stem cell transplantation (AHSCT) after IM failure received DAS for the post-transplant relapse. Among patients receiving DAS, BC was the reason for starting treatment in 5, and nine patients receiving 2nd-line DAS, and one patient receiving 2nd-line NIL died due to BC. Two patients underwent AHSCT after receiving 2nd-line DAS+chemotherapy, of which one died due to disease progression and the other one remained in remission. The cumulative MMR rates under 2nd-line DAS and NIL were 40% and 55%, respectively. Twenty-one patients (15 NIL and 6 DAS) received 2GTKIs as a 3rd-line treatment, and at the time of the analysis, 13 patients were still on treatment, five and 3 patients had to stop therapy due to intolerance and resistance, respectively. During the follow-up, four patients died (3 due to disease progression, and one after AHSCT) (Table 1). Eight patients had 3rd-line treatment for less than 6 months (median 2.5 months), and the remaining 13 had a median follow-up of 22 months under 3rd-line 2GTKIs. Ten patients achieved MMR after a median of 22.5 months (Table 1). Among patients who were refractory to 2nd-line treatment (n=10), only three had gained MMR and one achieved CCyR, whereas 7 of the remaining eleven had achieved and/or maintained MMR under 3rd-line 2GTKI treatment where switching from the 2nd-line treatment was due to intolerance.
Summary and Conclusions: 2GTKIs can be a reasonable choice for the 3rd-line treatment even in patients who are resistant to prior 2 lines of TKI treatment, especially when 3GTKIs are not available and AHSCT is not an option.

PB1759

PDGFRB SUSTAINS THE "WITHDRAWAL SYNDROME" AFTER IMATINIB DISCONTINUATION

S. Galimberti[1,*] G. Fontanelli[1], S. Barsotti[1], F. Ricci[1], F. Guerrini[2], E. Ciabatti[1], S. Grassi[1], C. Baratè[1]
[1]Clinical and experimental Medicine, [2]UO Hematology University of Pisa, Pisa, Italy

Background: The Swedish group reported that 30% of patients who stopped imatinib presented by the first 2 months musculoskeletal pains, localized to shoulders and hips or extremities, like a rheumatic polymyalgia (Richter J, JCO 32: 25 -2014). Some of these cases have been described as sensitive to paracetamol, whereas other patients need long-term treatment with corticosteroids.
Aims: The aim of this study was the strict molecular and clinical follow-up of patients who stopped imatinib for intolerance in order to do a precocious diagnosis and start an appropriate treatment for this "withdrawal syndrome".
Methods: Seven patients discontinued imatinib in 2014 at the Hematology Unit of the Pisa University; median age was 70 years (range 54-75); all patients received imatinib for more than 3 years, with a median time from diagnosis of 10 years. Initial Sokal risk score was low in 4 patients, intermediate in 2, and high in one patient; EUTOS score was low in all cases, except for one. All patients were in deep molecular response (at least MR4.5) from a minimum of 24 months at the moment of discontinuation. Treatment was interrupted because of non-hematological toxicities (PAOD, bleeding, alopecia, eyes, liver, skin toxicity). BCR-ABL1/ABL1 IS ratio was monitored by quantitative PCR every month. Reactive C protein, interleukin-2, interleukin-10, TNFa, PDGFb, VEGF, and interferong were measured in the plasma by ELISA.
Results: Two of our 7 patients developed the "withdrawal syndrome" after 2 and 3 weeks from the imatinib discontinuation, respectively. They presented muscolo-skeletal pains, localized to shoulders, arms and hip; these symptoms were graded as 2. The C-reactive protein serum level was normal in one case and only slightly increased in the other one; lactate dehydrogenase and protein electhrophoresis were normal in both cases. None of the 7 patients lost the deep molecular response during the follow-up (median 6 months, range 3-11 months). Interleukin-2, interleukin-10, TNFa, IFNg, and VEGF were in the normal range; interestingly, in both patients presenting the "withdrawal syndrome" PDGFRb resulted increased (2.5 fold higher than the highest value in the normal range). Both these patients did not respond to paracetamol 1g trice/day, thus corticosteroids were given (16 mg methyl-prednisolone per day), with tapering within 8 weeks up to 4 mg. Both patients showed a clear improvement within days; after 8 weeks steroid was discontinued, but symptoms, even if milder, reappeared. Both patients still receive 4 mg/day. PDGFb in this phase was still high, even if significantly reduced in respect of the onset of the syndrome.
Summary and Conclusions: Our study confirms, even if in a limited experience, the feasibility of the TKI discontinuation, but also the presence of the "withdrawal syndrome". It is well known that imatinib inhibits PDGFRb; PDGFRb has been also reported to contribute to synovitis by re-directing synovial fibroblasts toward a more aggressive phenotype (Rosengren S, 2010), and increased expression of PDGFb was also detected in the inflamed synovia, supporting its relevant role in the inflammatory processes (Reuterdhal C, 1991).
Consequently, we could hypothesize that the discontinuation of imatinib, stopping the PDGFRb inhibition, could activate the PDGF-mediated arthalgias.

PB1760

CROSSING OF BLOOD-PLACENTAL BARRIER BY TYROSINE KINASE INHIBITORS USED FOR TREATMENT OF CHRONIC MYELOID LEUKEMIA: THEORETICAL AND PRACTICAL ASPECTS

E. Chelysheva[1,*] A. Zeifman[2], G. Chilov[2], D. Guranda[3], S. Mordanov[4], K. Kazakbaeva[5], S. Saliev[5], E. Polushkina[6], A. Turkina[1]
[1]Scientivic Advisory Department of Chemotherapy of Myeloproliferative disorders, Federal State Funded Institution National Research Center for Hematology of the Ministry of HealthCare of the Russian Federation, [2]FSBI Institution of Organic Chemistry of Russian Science Academy named after N.D.Zelinsky, [3]Farm innovation technologies Ltd, Moscow, [4]FBEI HPE Rostov State Medical University of Healthcare Ministry of Russian Federation, Rostov, Russian Federation, [5]Research Institute of Hematology and Blood Transfusion MOH of Uzbekistan, Tashkent, Uzbekistan, [6]FSBI Scientific Center of Obstetrics, Gynecology and Perinatology of Healthcare Ministry named after V.I.Kulakov, Moscow, Russian Federation

Background: The issue of safe usage of tyrosine kinase inhibitors (TKIs) in chronic myeloid leukemia (CML) patients on late stages of pregnancy is unclear. TKI ability to cross the blood-placental barrier (BPB) in humans and association with the adverse effects is rarely evaluated in practice due to rareness of cases and ethical reasons. The obtained data are scarce. We hypothesized whether BPB crossing can be predicted by a model based on molecular physicochemical properties of available TKIs.
Aims: To compare the theoretical calculations of BPB crossing of TKIs used for CML treatment with the data obtained in practice and association with clinical outcomes.
Methods: The relative rate of TKIs penetration through BPB was evaluated by so called clearance index (CI) in comparison with antipyrine as free passive diffusion reference with CI=1. The CI of imatinib, nilotinib, dasatinib and bosutinib. was estimated using Quantitative Structure-Activity Relations (QSAR) approach (Hewitt et al, Environ Res, 2007) according to the equation (picture 1). Concentration of imatinib in available cases was simultaneously measured

at labour in blood plasma of mother, cord blood and homogenized placenta by HPLC-mass spectrometry technique. Information of therapy and pregnancy outcomes was taken from Russian CML pregnancy registry and local database of Uzbekistan.

Results: Calculated CI values for imatinib, nilotinib, dasatinib, bosutinib were 0,36, 0,33, 0,44 and 0,67 correspondingly showing moderate but not negligible rate of BPB transfer compared to antipyrine. In 3 of 17 women with CML who received TKI (15 imatinib, 2 nilotinib) since 2nd-3rd trimester (due to lack of response) imatinib concentration was measured. The fetal:maternal ratio ranged from 0,12 to 0,25 and imatinib concentration in placenta was higher than in maternal blood (Table 1). All 17 newborns had no birth abnormalities, low weight<2500 g was in 6 cases. In 5 of 6 cases infants were born preterm at week 35-37, their further development was normal.

Table 1. Concentration of imatinib measured at labour and fetal:maternal ratio.

ratio of case	Imatinib concentration, ng/ml maternal blood plasma	placenta	cord blood	fetal:maternal
1	896,5	ND	109,5	0,12
2	897,5	1095	226	0,25
3	520,6	702,10	115,5	0,22

$$CI=-0,00246TPSA+0,244\sum C_2H_5+0,139\sum Hal+0,569$$

TPSA -topological polar surface area of a TKI molecule
$\sum C_2H_5$ – number of ethyl groups
$\sum Hal$ – number of halogen atoms

Equation for prediction of clearance index of tyrosine kinase inhibitors (TKI)

Figure 1.

Summary and Conclusions: A simple QSAR model based on diffusion-like properties of TKIs used for CML treatment showed the moderate rate of BPB transfer compared to antipyrine. Data obtained at practice showed reduced level of imatinib in cord blood plasma and higher level in placenta compared to maternal blood. Factors which were not accounted in the theoretical model (active transportation mechanisms, extensive metabolic clearance at the fetal side) might specifically prevent TKIs from crossing BPB. Cases of preterm delivery with low weight of children in mothers who got TKIs during pregnancy need further evaluation.

PB1761

ACHIEVING EARLY OPTIMAL RESPONSE IS ASSOCIATED WITH BETTER HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB OR NILOTINIB AS FRONTLINE THERAPY

Q. Jiang[1,*] H.B. Wang[2], X.D. Mo[1], L. Yu[1], X.J. Huang[1]
[1]Peking University People's Hospital, [2]Peking University Clinical Research Institute, Beijing, China

Background: Tyrosine kinase inhibitors (TKIs) as the first-line therapy have improved the outcome of patients with chronic myeloid leukemia in chronic phase (CML-CP). Health-related quality of life (HRQoL) is becoming increasingly recognized as an important component of the management of CML.

Aims: To prospectively assess the HRQoL in newly-diagnosed patients with CML-CP treated with imatinib or nilotinib and to identify the factors associated with the HRQoL outcomes.

Methods: From June 2011 to July 2011, 59 newly-diagnosed patients with CML-CP from Peking University People's Hospital, who were enrolled in the ENESTchina trial, were randomly assigned to receive imatinib 400 mg daily (n=27) or nilotinib 300 mg BID (n=32). Response to first-line TKI therapy was assessed according to European LeukemiaNet 2013 recommendations for the management of CML. HRQoL was measured with the Short Form 36 Health Survey (SF-36) at baseline and every 3 months during the 3 years follow-up. Fisher Exact tests or chi-square tests were used to compare subjects treated with imatinib or nilotinib. The Kaplan-Meier method was used to assess statistical significance in the time-to-event analyses. The longitudinal change in HRQoL was further analyzed in a mixed model approach to linear regression for repeated measurements.

Results: Among the 59 patients (35 man and 22 women), the median age was 37 years (range, 18-74 years). Patients in the two treatment arms were comparable in terms of demographics (*e.g.* gender, age, education and house register), clinical characteristics (*e.g.* Sokal risk score and interval from diagnosis to treatment) and HRQoL scores at baseline. With a median follow-up of 37 months (range, 11-38 months), patients in the nilotinib arm had significant higher cumulative incidences of complete cytogenetic response (P=0.0077) and major molecular response (P=0.0248) compared with those in the imatinib arm. Higher proportions of optimal responses at 3 months (81.5% vs. 68.8%, P=0.263), 6 months (77.8% vs. 62.5%, P=0.204) and 12 months (51.9% vs. 37.5%, P=0.269) were also observed in the nilotinib arm, but without statistical significance. Patients in the two arms had similar rates of event-free survival (84.4% vs. 85.2%, P=0.958), progression-free survival (88. 9% vs. 87.5%, P=0.893) and overall survival (100% vs. 90.6%, P=0.199 at 3 years. Regarding HRQoL, although there was no difference on the SF-36 physical and mental assessments between patients in the two arms during the follow-up, role-physical functioning subscale was improved in patients treated with imatinib (P=0.0421) over time, furthermore, social functioning (P=0.0293) and mental component summary (P=0.0043) were improved in those treated with nilotinib. In total population, patient characteristics at baseline (including gender, age, education, house register and Sokal risk score), TKI used (imatinib vs. nilotinib) and early responses to TKI therapy (optimal response vs. non-optimal response) at 3, 6 and 12 months was analyzed in order to identify the independent factors affecting the HRQoL. Multivariable analyses by mixed model showed that patients with university graduate or above was associated with better vitality (P=0.0468), achieving optimal response at 3 months improved physical functioning dramatically (P<0.0001), and achieving optimal response at 6 months (P=0.0432) or 12 months (P=0.0483) improved social functioning remarkably.

Summary and Conclusions: Imatinib or nilotinib as the first-line therapy improved the HRQoL of CML-CP patients significantly, especially for those achieving optimal response at 3 months, 6 months or 12 months.

Background: Dasatinib has been recently licensed for first line treatment of patients with chronic myeloid leukemia (CML). However, very few data are available as to toxicity and efficacy of dasatinib in unselected elderly CML patients.

Aims: To address this issue, we revised a "real-life" cohort of 54 CML patients in chronic phase aged >65 years treated with frontline dasatinib in 24 Italian Centers from 6/2012 to 12/2014 focusing on toxicity and efficacy data.

Methods: The main clinical features of the patients at diagnosis were as follows: M/F 27/27, median age 75.4 years [interquartile range (IQR) 70.6 – 79.5), median Hb 12.3 g/dl (IQR 11.1 – 13.6), median WBC 51.5x 10^9/l (IQR 28.1 – 100.0), median PLTS 430x 10^9/l (IQR 233 – 770). According to Sokal risk classification, 2 patients (3.7%) were low risk, 32 (59.3%) intermediate risk, 15 (27.8%) high risk while 5 (9.2%) were not classificable. 30/54 patients (55.5%) had ≥ 2 comorbidities requiring concomitant therapies: according to ECOG scale, performance status at baseline was 0 – 1 in 46 patients (85.1%) and 2 in 8 patients (14.9%).

Results: Median interval from diagnosis to dasatinib start was 23 days (IQR 14 – 35). Dasatinib starting dose was 140 mg/day in 1 patient (1.8%), 100 mg/day in 40 patients (74.1%) and<100 mg/day in 13 patients (24.1%), respectively. After a median period of treatment of 13.7 months (IQR 6.4 – 20,6) all patients were evaluable for toxicity; on the whole, grade 3 – 4 hematological and extra-hematological toxicities were reported in 5 (9.2%) and 9 (16.6%) patients, respectively. Overall, 9 patients (16.6%) permanently discontinued dasatinib due to toxicity (2 patients in the first 3-month period of treatment and 7 beyond that period). Pleural effusions of all WHO grades occurred in 10 patients (18.5%): in 4 of them the pleural effusion occurred during the first 3-month period of treatment. As to treatment efficacy, 5 patients were considered too early to be evaluated (<3 months of treatment) and 49 were evaluable for cumulative response; on the whole, 45/49 patients (91.8%) achieved complete cytogenetic response (CCyR) and 33/49 (67.3%) also a major molecular

response (MMolR). Response to treatment at different time-points is shown on Table 1. After a median period of observation from dasatinib initiation of 15,5 months (IQR 9.2 – 24.7), only 1 patient died from unrelated cause (senectus) while in MMolR: cumulative event-free survival (EFS) at 12 months was 82.4% (95%CI 71.3 – 93.5).

Table 1.

	3rd month	6th month	12th month
Not evaluable:	12	15	16
Too early	5	6	16
Not performed	7	9	0
Evaluable	42	39	38
Discontinuation	2 (4.7%)	4 (10.2%)	7 (18.4%)
Less than CCyR	6 (14,3%)	2 (5.1%)	2 (5.2%)
CCyR only	21 (50.0%)	10 (25.7%)	9 (23.6%)
MMolR	13 (31.0%)	23 (59.0%)	20 (52.6%)

Summary and Conclusions: Present data shows that dasatinib could have a major role in the treatment of unselected patients aged >65 years; indeed, dasatinib seems very effective and has a favourable safety profile also in elderly subjects with comorbidities.

PB1763

QUALITY OF LIVE IN PATIENTS WITH CML: QUESTIONNAIRE BASED STUDY

K.H. Kim[1,*] D.Y. Kim[2], Y.K. Kim[3], S. Park[4], I. Kim[4], J.W. Cheong[5], J.O. Lee[6], C.W. Jung[7], S.K. Sohn[8]
[1]Soonchunhyang University Hospital, [2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, [3]Chonnam National University Medical School, Gwangju, [4]Seoul National University Hospital, [5]Yonsei University College of Medicine, Seoul, [6]Seoul National University Bundang Hospital, Seongnam, [7]Samsung Medical Center, Seoul, [8]Kyungpook National University Hospital, Daegu, Korea, Republic Of

Background: With imatinib therapy, the survival of patients with CML has improved dramatically. In recent years, second generation TKI (2G TKI) led to more increased responses. Despite the demonstrated superiority of efficacy and toxicities as previous treatments, several adverse events of TKIs remain. Because CML treatment is lifelong, it is important for patients to maintain adherent to treatment. Correlations between poor adherence to TKI treatment and adverse events and quality of life (QoL) have been demonstrated among CML patients in clinical settings. The FACT-leu is a validated tool that measures leukemia-specific and more general QoL concerns. However, there are few studies about QoL of CML patients in Korea.
Aims: Therefore, we evaluated the QoL of CML patients treated with TKIs.
Methods: The CML working party of the Korean society of Hematology was produced by the questionnaire included the questions of FACT-leu. We distributed the questionnaire over the online or offline. QoL of patients with CML was analyzed using these questionnaires.
Results: A total of 384 patients responded to the survey between March 2014 and June 2014. Patients with high compliance of TKI (taking 90% or more drugs) were 88.28% and lower compliance (taking 70% or less drugs) were 1.82%. In queries about poor adherence to TKI therapy, most common cause was forgetfulness (18.49%). FACT-Leu scale was higher in patients with 2G TKIs than imatinib (122.9±22.65 vs 116.0±25.00 (P=0.005)). Female, older patients showed meaningful worse QoL in FACT-leu scale.
Summary and Conclusions: In 2G TKI era, QoL of CML patients seemed that is better than before. Additional prospective studies are warranted using adequate measuring tool of QoL.

PB1764

SAFETY AND USEFULNESS OF REDUCING THE DOSE OF IMATINIB TO 300 MG IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS WITH SUSTAINED DEEP MOLECULAR RESPONSE.

S. Redondo Velao[1,*] I. Pérez Sánchez[1], C. Laperche[1], I. Buño[1], J.L. Díez-Martín[1], S. Osorio Prendes[1],
[1]Hematology, Gregorio Marañón Hospital, Madrid, Spain

Background: Tyrosine kinase inhibitors have dramatically changed the treatment of CML and nowadays most of the patients are able to achive sustained deep molecular responses in this setting. This scenario has led to an increasing interest on therapy discontinuation studies but this strategy is not recommended outside clinical trials
Aims: We have reduced the dose of Imatinib (IM) from the standard 400 to 300 mg/day, in some patients with deep and stable deep responses in order to improve tolerability and costs of the treatment. In this analysis we review whether this strategy was safe and clinically useful.
Methods: Patients with chronic phase CML that decreased IM 400 to 300 mg/day at least during 3 months and who had molecular responses analyzed before and after the change were retrospectively selected from our database. BCR-ABL ratio was measured by automated means (GeneXpert, Cepheid, CA, USA) according to the International-Scale. Hematological parameters such as hemoglobin level and mean corpuscular volume were also analyzed before and after the IM dose change. Data were analyzed using SPSS v11.0.

Table 1. Patient's responseti IM 300MG/DAY (N=13).

RESPONSE BEFORE DOSE REDUCTION	MONTHS IN UNDETECTABLE DEEP RESPONSE BEFORE DOSE REDUCTION	CAUSE FOR DOSE REDUCTION	IMPROVED TOXICITY	WORST RESPONSE AFTER DOSE REDUCTION	RESPONSE AT LAST FOLLOW UP	MONTHS WITH IM 300MG
≥RM4.5 with UD[a]	14	≥RM4.5 with UD	NA[c]	≥RM4.5 with UD	≥RM4.5 with UD	12
≥RM4.5 with UD	44	≥RM4.5 with UD	NA	≥RM4.5 with UD	≥RM4.5 with UD	4
≥RM4.5 with UD	12	≥RM4.5 with UD	NA	≥RM4.5 with UD	≥RM4.5 with UD	11
≥RM4.5 with UD	33	≥RM4.5 with UD	NA	≥RM4.5 with UD	≥RM4.5 with UD	5
≥RM4.5 with UD	26	≥RM4.5 with UD	NA	RM4with DD[b]	RM4and UD	19
≥RM4.5 with UD	17	≥RM4.5 with UD	NA	≥RM4.5 with UD	≥RM4.5 with UD	9
≥RM4.5 with UD	25	≥RM4.5 with UD	NA	≥RM4.5 with UD	RMC4.5	12
RM4 and UD[a]	15	Pancytopenia	YES	MMR	RM4and UD	50
RM4 and UD	0	Pancytopenia	YES	MMR	≥RM4.5 with UD	34
CCR[a]	0	Heart failure	YES	MMR	RM4with DD	24
MMR[a]	0	Neutropenia	YES	≥RM4.5 with UD	≥RM4.5 with UD	117
≥RM4.5 with UD	11	Neutropenia	YES	≥RM4.5 with UD	RM4and UD	30
RM4.5 with DD[a]	0	Limb Edema	YES	≥RM4.5 with UD	Exitus[a]	7

[a]≥RM4.5 with UD : At least RM4.5 and undetectable disease. [a]RM4 and UD: RM4 and undetectable disease. [a]CCR: Complete cytogenetic response. [a]MMR: Major molecular response. [a]RM4.5 with DD: RM4.5 with detectable disease. [a]RM4 with DD: RM4 with detectable disease. [c]NA=Not applicable. [a] Exitus= not CML related.

Results: A total of 13 patients (7 males, 6 females) with chronic-phase CML diagnosed between 1998 and 2012 were included in the present study. Median age at diagnosis was 67 years (range 23-78). According to Sokal score, 3 were high risk, 4 intermediate and 6 low; according to EURO score, 1 was high risk, 6 intermediate and 6 low; according to EUTOS score, all were low risk. First line treatment was IM 400 mg in 10 (76.9%), IM 600 mg in 1 (7.1%) and Interferon-alpha in 2 (16%). The reason for dose reduction was toxicity in 6 patients (46%): neutropenia (2), pancytopenia (2), limb edema (1) and heart failure (1). In all of them the adverse event improved after lowering the dose. All patients that reduced the dose due to toxicity were at least in CCR. In the other 7 patients (54%) the dose was reduced because of sustained deep response; RM4.5 or better and undetectable disease (≥RM4.5 with UD). Median time in ≥RM4.5 with UD, prior to dose reduction was 24.4 months (range 12-33; Table 1). Median time of treatment with 300 mg/day was 12 months (range 4-117). Comparing molecular response before dose reduction and at last follow up, 3 patients improved and 10 maintained it; if we compared molecular response before the dose reduction and the worst response during follow up, just 3 patients worsened (2 from RM4 and UD to MMR, and 1 from RM4.5 and UD to RM4 with detectable disease), but none of this changes were clinically relevant. The median hemoglobin increase was 1.2 g/dl (range 0.4-2.3; P=0,054). The median decrease in mean corpuscular volume was 3.7 fL (range 0.4-11.5; P=0,006) (Wilcoxon Test). With this univariate analysis we cannot rule out that other concurrent causes could contribute to this hematological change. Additionally, there was an economical benefit derived from the dose reduction, since 334 accumulated months of treatment with IM 300 mg/day, produced savings of 357.046 Euros (savings for 13 patients would be of 166.764 Euros per year). Out of the 13 patients, 12 continue with 300 mg, and one patient died due to causes not related to CML
Summary and Conclusions: In our experience IM dose reduction due to medical decision or toxicity in patients with sustained deep response has been safe, clinically useful and economically beneficial. This could be a useful strategy in some patients with deep responses until treatment discontinuation could be recommended in common clinical practice.

PB1765

INFLUENCE OF CYP3A5 AND SLCO1 ON IMATINIB RESPONSE AMONG EGYPTIAN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA.

S. Aref[1], M. El-Ghonemy[1], M. El Baiomy[2,*]
[1]Hematology Unit, Clinical pathology Department, [2]Medical Oncology and Hematology Unit, Oncology Center Mansoura University, Mansoura, Egypt

Background: Imatinib (IM) was approved as a molecular target drug that selec-

tively inhibits Bcr-Abl tyrosine kinase which causes Philadelphia-positive chronic myeloid leukemia (CML) and so far been the first-choice treatment in CML with excellent results. However, only a proportion of patients achieve major molecular response. Hence, the need to find whether there are some factors that affect the response to treatment is essential. Although IM pharmacokinetics is influenced by several enzymes and transporters, little is known about the role of pharmacogenetic variation in IM metabolism.
Aims: This study aimed to investigate the frequencies of mutational status of CYP3A5 and SLCO1 in CML patients undergoing imatinib treatment and to determine whether these two genes could predict the response to imatinib therapy in CML patients.
Methods: We investigated the mutational status of SLCO1 and CYP3A5 by Polymerase Chain Reaction followed by restricted fragment length polymorphism in 62 Philadelphia positive newly diagnosed Egyptian CML patients in chronic phase. All patients received imatinib therapy and were followed for at least one and half years. The response to imatinib therapy was evaluated by recording the hematological response, cytogenetic response at 6 month, and molecular response at 12 month of imatinib treatment according to the European Leukemia Net criteria.
Results: 11 patients were excluded from the study as they showed treatment failure to imatinib at 6 month of treatment so they were shifted to 2nd line TKIs. Six (54.5%) out of these 11 patients were mutant for CYP3A5 while five were wild, however four (36.3%) out of them were mutant for SLCO1 and seven patients were wild type. The remaining 51 patients who continued in the study showed that the mutant CYP3A5 was more common with low hemoglobin level (P 0.03) and low platelets count at diagnosis (P 0.001) however, there was no relation between SLCO1 mutational state and patients characteristics. Also there was no relation between mutational state of either CYP3A5 or SLCO1 with the sokal score of the patients at diagnosis. Patients with mutant CYP3A5 showed suboptimal cytogenetic response to imatinib at 6 month *versus* patients with wild type (P 0.07). At 12 month of imatinib treatment, 74.1% of patients with mutant CYP3A5 had no MMR *versus* 66.7% of patients with wild type had MMR (P 0.004). However there was no significant relation between mutational state of SLCO1 with neither cytogenetic response at 6 month nor molecular response at 12 month of imatinib treatment.
Summary and Conclusions: CYP3A5 mutant gene was associated with poor imatinib efficacy while the SLCO1 was not associated with the response to imatinib treatment in Egyptian patients with CML in chronic phase.

PB1766

IS GENERIC MESILATE OF IMATINIB LESS INFERIOR THAN GLIVEC? ANALISYS IN BRAZILIAN COHORT
P. Cappelletti[1,*] S. Bonecker[1], R. Bittencourt[1], J. Dobbin[2], A. Moellman[2], I. Zalcberg[1]
[1]Laboratory of Molecular Biology, Bone Marrow Transplant Center (CEMO), National Cancer Institute (INCA), [2]Hematology Service, INCA, RIO DE JANEIRO, Brazil

Background: The improvement of the treatment for LMC patients after the introduction of tyrosine kinase inhibitor (TKI) Imatinib (Glivec®, Novartis) speaks for itself. After the developed of Glivec, others TKIs became available on the market. These new drugs, however, come to market with prices to astronomical levels. The introduction of therapies with generic drugs is extremely relevant. In Brazil, mesilate of imatinib (IM) become available in a generic formulation (gIM) by January 2014 with a productive development partnership signed Farmanguinhos/FIOCRUZ, Vital Brazil Institute and Cristália Pharmaceutical Chemicals.
Aims: The objective of this study was analyzed our Brazilian CML patients cohort and evaluate the molecular response of these patients before and after the exchange of the drug (Glivec vs. gIM) and monitoring a small group of CML patients considering only gIM as first line therapy.
Methods: We analyzed and compared two different groups. The first one has 171 patients who start with Glivec as first line therapy and followed them between 2001 and 2014. All these patients switched to gIM in 2014. The second group has 11 patients who started the treatment with gIM in 2014. For those, the follow-up was 12 months.
Results: The median time follow-up for patients whom start Glivec was 5.4 years (1.1 – 13.8), while on the other group was 0.4 (0.3 – 1) years. We observed a slight predominance of female on the Glivec first line therapy cohort. Most of the patients (96.8%) were diagnosed in chronic phase in both group; 96.8% and 92.3% respectively. Considering the group who start with Glivec as front line therapy before switch to generic, 9.9% (17/171) of the patients lose MR during the treatment. One of them presented a L452I mutation. In spite of that, they still switch to gIM. Among 17 patients, 5 (29.4%) gain MR after switch to generic IM. At this time, these 17 patients are excluded from subsequent analyzes. After switch to gIM, 5.8% of the patients (9/154) lost MMR response or more. Three of them acquire a mutation, 1 patient at 7 months and the other 2 patients, 3 months after change the treatment: L273M, L387M and F359V. L387M mutation was already described as sensitive to IM. F359V-mutated cell lines demonstrated decreased sensitivity to imatinib compared with CML cell lines wild type. One patient present E453A mutation before change the drug. The median time to lose response was 7 months. Only 3.3% (5/154) of the patients gain MR after change to generic IM. We had 11 patients in our cohort who star the treatment with generic IM. Taking account the 3 months cutoff, 72.7% (8/11) of the patients presented levels ≤10% BCR-ABL1 transcripts and 5 of these 8 patients (62.5%; 5/8) achieved MMR at 12 months. None of them discontinuous the treatment.
Summary and Conclusions: In our patient cohort of "good responders", taking into account that all of the patients who had to switch to second generation TKIs were excluded from this study, the generics were at least non inferior to the original drug in terms of maintenance of response state, efficacy and tolerability when used in the upfront setting, as well as when used subsequently. Prospective studies are needed to address the effectiveness of generic IM in CML patients.

PB1767

A POSSIBLE CONNECTION BETWEEN CIRCULATING 25-HYDROXY VITAMIN D AND MOLECULAR RESPONSE IN CHRONIC MYELOID LEUKEMIA
F. Ozdemirkiran[1,*] G.G. Oruk[2], S. Aksun[3], M. Calan[4], A.F. Yılmaz[1], U.B. Korkmaz[5], N. Guner[1], K. Savasoglu[6], R. Sutcu[3], B.K. Payzin[1]
[1]Hematology, [2]Endocrinology, [3]Biochemistry, Izmir Katip Celebi University Ataturk Training and Research Hospital, [4]Endocrinology, Izmir Bozyaka Training and Research Hospital, [5]Internal Medicine, [6]Laboratory of Genetic, Izmir Katip Celebi University Ataturk Training and Research Hospital, Izmir, Turkey

Background: Vitamin D deficiency is a common problem all over the world. Growing evidence suggest that there is connection vitamin D and cardio-metabolic disease and cancer. Low-circulating 25-hydroxy vitamin D (25-OH-D) has been associated with various malignancies, although it remains unclear whether vitamin D deficiency exerts as a causal effect on the development of malignancies.
Aims: In this study we aim to evaluate whether there is link between circulating 25-OH-D levels and molecular response in chronic myeloid leukemia (CML)
Methods: Subjects : A total of 61 patients with CML (31 women, 30 men) were recruited in this cross-sectional study from hematology clinics of Katip Celebi University Ataturk Training and Research Hospital between June 2014 and September 2014.The study was approved by the human research ethics committee of the hospital and informed consent was obtained from all participants. Vitamin D status as defined; severe deficiency ≤10 ng/mL; deficiency 10-20 ng/mL; insufficiency 20-30 ng/mL; sufficiency ≥30 ng/mL (1). Treatment responses were evaluated according to the ELN recommendations. Statistical: All analyses were performed using the Statistical Package for the Social Sciences Software, version 18.0 (SPSS Inc., Chicago, USA). In view of the subjects number for each groups, patients were divided into two groups according to their vitamin D levels (group 1 ≤10 ng/mL, group 2 >10 ng/mL) and two groups were compared with clinic and laboratory feature using Mann-Whitney U test. Among the groups difference in gender distribution was analyzed byx2 analysis. To evaluate vitamin D levels on molecular response, we used binary logistic regression analysis. In the model, molecular response was defined as a dependent variable and subjects were categorized to their vitamin D levels; ≤10 ng/mL an >10 ng/mL and also which were added the analysis as a categorical variable. To clarify effect of potential confounders; sokal score, gender and type of treatment, we added these variables in the model as a consecutively. All reported confidence interval (CI) values are calculated at the 95% level. A two-sided p value of<0.05 was considered statistically significant.
Results: According to the vitamin D levels; 37 (60.7%) patients had ≤10 ng/mL, 19 (31.1%) patients had 10-20 ng/mL and 5 (8.2%) patients had 20-30 ng/mL. In our study population no subjects had sufficient vitamin D levels. In unadjusted logistic regression models, increased vitamin D levels were significantly associated with molecular response. After adjusting potential confounders, this association was slightly diminished but it is still remained
Summary and Conclusions: In present study, we demonstrated for the first time that lower circulating 25-OH-D levels were independently associated with molecular unresponsive in subjects with chronic myeloid leukemia after adjusting for potential confounders.There are some limitations to the current study. The size of study population was relatively small and the cross-sectional design of the study cannot prove causality. These findings are initial and provoking, but this association should be verified in another larger population using a prospective-cohort design. Taken together, our results indicate for the first time that decreased circulating 25-OH-D levels were associated with molecular unresponsive in patients with CML. 25-OH-D may contribute to molecular response in the patients

PB1768

ANALYSIS OF MINIMAL RESIDUAL DISEASE AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) FOR CHRONIC MYELOID LEUKEMIA (CML) BY REAL-TIME QPCR FOR BCR-ABL GENE AND ITS CORRELATION WITH RELAPSE
V. Funke[1,*] I. Menezes[1], D. Setubal[1], L. Medeiros[1], C. Bonamin[1], A.L. Mion[1], N. Farah[1], R. Pasquini[1]

[1]Hematology, Federal University of Parana, Curitiba, Brazil

Background: hronic myeloid leukemia (CML) is a clonal bone marrow disease characterized by the presence of the Philadelphia chromosome, resulting from translocation between chromosomes 9 and 22 producing the BCR-ABL hybrid gene., which encodes tyrosine kinase proteins and regulate cell growth. The development of targeted therapies for the treatment of this disease, such as imatinib mesylate, changed the landscape treatment of CML. Hematopoietic stem cells transplantation (HSCT) still remains the only curative modality of therapy. After HSCT, relapse can be observed even very late. The amount of leukemic cells in relapse (molecular, cytogenetic or hematologic) and relapse phase are the main prognostic factors found, and the response to the interventions (infusion of donor lymphocytes or imatinib mesylate) are best when relapse is identified early. The use of real-time PCR for the detection of BCR-ABL gene for monitoring of recurrence in patients after HSCT shows a good alternative of tracking disease, however cut-offs which would define relapse are not yet established in the literature. Besides, there have been recent changes in the PCR methodology including the padronization of an international scale, used as monitorization for TKI therapy. Few studies evaluated this method for monitoring patients after HSCT.
Aims: The main objective of this study is assessing the significance of the results of real-time PCR for quantification of BCR-ABL gene in patients previously diagnosed with CML who underwent HSCT. The intention is to analyze if the results of this test are reliable predictors of the risk of disease recurrence and what is the range of values that is considered at increased risk for relapse, which would allow early intervention.
Methods: We retrieved databases and records of 57 patients diagnosed with CML who were treated with HSCT from 2003 in the HC-UFPR. Type of relapse (hematology or cytogenetic) and correlation with BCR-ABL values obtained by real-time PCR, is the primary endpoint.
Results: We identified 57 patients which received HSCT from 2003-2014. All them had been molecularly monitored by Real Time Q-PCR and have more than one value measured. 21 patients had positive Q-PCR results. From those, 17 had persistent positive results, and 12 of them ultimately relapsed. Four patients had intermitent low values of BCR-ABL and so far no one of them relapsed. No patient with persistent negative brc-abl relapsed. IS ratio of patients who relapsed were significantly higher than those who didn't relapse, which had IS showing 2-3 log reduction. Patients with intermitent low values of BCR-ABL had IS showing 3 log reduction altenating with negative results.
Summary and Conclusions: Although there were changes in BRC-ABL techniques, real time Q PCR can be used for monitorization of relapse after transplant. Persistent positive results highly correlated with relapse within the present cohort of patients. However, low levels aternated with negative results did not resulted in a higher rate of relapse. Patients with persistent negative measuses did not relapse at all.

PB1769

MONITORING CLINICAL CARDIOLOGY WITH TRANSTHORACIC ECHOCARDIOGRAPHY AND ELECTROCARDIOGRAPHY IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS SECOND GENERATION

M. Ayala[1,*] I. Bonilla[2], J. Domínguez[3], X. Aquino[3], A. Flores[4],
[1]Hematology & BMT Unit, Hospital de Especialidades, CMN "La Raza", [2]Cardiology, Hospital de Especialidades, CMN "La Raza", IMSS, [3]Consulmed, [4]Signufarma, México, Mexico

Background: Long term prognosis of patients with chronic myeloid leukemia (CML) has significantly improved during the "age of tyrosine kinase inhibitors", though the occurrence of adverse events on medium and long term in patients with chronic comorbidities, of which cardiopulmonary and metabolic diseases must be routinely evaluated, has become a clinical concern albeit the cardiac safety profile has been prospectively investigated. During the phase II and III clinical trials of both first and second-line therapy, we reported our experience in cardiologic monitoring of patients with CML treated with second-generation TKI (nilotinib and dasatinib) on second-line therapy.
Aims: Identify clinical, electrocardiographic and transthoracic echocardiogram alterations in CML patients treated with nilotinib or dasatinib.
Methods: Clinical evaluation, electrocardiograms and transthoracic echocardiogram were performed to all CML patients on treatment with nilotinib or dasatinib during the period between October 2010 and January 2015, at the beginning of treatment and every 6 and 12 months after that according to the occurrence or not of abnormalities detected at baseline. The exclusion criteria were; clinically significant cardiac disease (congestive heart failure), left ventricular ejection fraction (LVEF) < 45%, past myocardial infarction or unstable angina (during the last 12 months), resting bradycardia (< 50 beats/min), left bundle branch block, ventricular bypass, acquired or congenital long QT syndrome (including family history), QTcF interval >450 msec, patients taking medications that could extend the QT interval and those who could not discontinue their treatment before initiating nilotinib or dasatinib. The doses used of tyrosine kinase inhibitors were 400 mg every 12 hours for nilotinib and 100 mg every 24 hours for dasatinib per os.

Results: Baseline characteristics and electrocardiogram and transthoracic echocardiogram abnormalities are shown on table 1, along with the identified changes in the monitoring during treatment of the clinical, electrocardiogram and transthoracic abnormalities recorded.

Table 1.

Baseline characteristics		
	Nilotinib 83 (100%)	Dasatinib 51 (100%)
Male, n	54 (55%)	29(57%)
Age, years median (range)	47.9 (17-79)	42
Older than 60 years	24 (29%)	7 (13.7%)
Congestive heart failure	2 (2.4%)	1 (1.9%)
Ischemic cardiac disease	1 (1.2%)	0 (0%)
Cardiopulmonary comorbidities	2 (5.40%)	2 (7.14%)
Systemic arterial hypertension	9 (11%)	3 (6%)
Type 2 diabetes mellitus	5 (6%)	4 (7.8%)
Hypercholesterolemia	0	0
Hypertriglyceridemia	0	1 (2%)
QTc higher than 480 ms	0 (0%)	0 (0%)
QTc higher than 500 ms	0 (0%)	0 (0%)
LV diastolic dysfunction	26(31.32%)	17 (33.33%)
LVEF higher than 55%	83 (100%)	48 (94.11%)
Pericarditis without effusion	10 (12%)	3 (6%)
PAH	3 (3.6%)	5 (10%)
PHA slight/mild/severe, n	2(2.4%)/1(1.2%)/0	3(6%)/1(2%)/1(2%)
Mitral minimum insufficiencies	4(5%)	1(2%)
Follow up monitoring		
	Nilotinib 56 (100%)	Dasatinib 46 (100%)
# follow up transthoracic echocardiogram	130 (1-8)	77 (2-6)
# follow up electrocardiograms	185 (1-6)	105 (2-7)
Congestive heart failure	2 (2.4%)	1 (1.9%)
Ischemic cardiac disease	1 (1.2%)	0 (0%)
Cardiopulmonary comorbidities	2 (5.40%)	2 (7.14%)
Systemic arterial hypertension	4 (7%)	3 (6%)
Type 2 diabetes mellitus	6 (11%)	3 (6%)
Hypercholesterolemia	7 (12.5%)	0
Hypertriglyceridemia	14 (25%)	1 (2%)
QTc higher than 480 ms	0 (0%)	0 (0%)
QTc higher than 500 ms	0 (0%)	0 (0%)
LV diastolic dysfunction	27 (48%)	7 (15%)
LVEF decrease FEVI (≥10%)/FEVI normal	4 (7%)	8 (17%)
PAH	6 (10.71%)	8 (16%)
PAH slight/mild/severe	2(3.5%)/3(5%)/1(1.8%)	4(8%)/2(4%)/2(4%)

Summary and Conclusions: The cardiac adverse events in patients with CML undergoing treatment with second-generation TKI are not common and may be related to factors independent from treatment like age, cardiopulmonary and metabolic comorbidities and pharmacological interactions. Treatment was discontinued on those patients with recurrent PAH on dasatinib dose adjustment, though there was a temporary suspension in one nilotinib patient due a severe PAH, extended QT syndrome was not observed in any of the patients, however 8 patients undergoing treatment with dasatinib (16%) showed PAH (2 severe, 2 mild, and 4 slight), 5 were temporary suspensions and 2 resulted in definitive suspensions due severe PAH; In our experience the results do not differ significantly from the international publications. To our knowledge is the first report to adverse events in México for PAH secondary to second-generation TKIs.

EVALUATION OF PLURIPOTENT MARKERS IN CELLS OBTAINED FROM DIFFERENT HUMAN HEMATOPOETIC SOURCES

D.D. Çelik[1,*] S. Kuruca[1], M. Aktan[2], Z. Çelebi[3]
[1]Department of Physiology, [2]Internal Medical Science, Demartment of Hematology, İstanbul University Faculte of Medicine, [3]Gynecology and Obstetrics, Zeynep Kamil Women and Children Diseases Training and Research Hospital, İstanbul, Turkey

Background: Clinical use of hematopoetic stem cells (HSC) is a developing field for treatment of most hemoglobinopaties, hereditary blood diseases and cancers. Even though use of HSC's are practical they are not as effective as pluripotent stem cells (PSC). In last years the thought of possible presence of PSCs in other adult tissues has become an attractive research area for search and isolate of PSCs from adult tissues.
Aims: In our study we refined cell populations using different isolation methods. Cells obtained from three different human hematopoetic sources and analysed for expression of pluripotent markers like NANOG, OCT3/4 and SSEA4.
Methods: Human peripheral blood (PB), apheresis material (AM) and cord blood (CB) were used as hematopoietic sourses. Two isolation method performed to all materials. 1) Total mononuclear cells obtained by eryhtrocyte lysis method. 2) MNC layer and erythrocyte layer were isolated with ficoll density gradient method. The presence of pluripotent markers such as NANOG, OCT3/4 and SSEA4 and their celullar location were detected with immunofluorescence staining in all three layers. Also western blotting method used for determinig NANOG and OCT3/4 protein expression.
Results: The results obtained from western blotting and immunofluorescence methods showed expression of NANOG, OCT3/4 and SSEA4 proteins in PB, AM and CB. And also immunofluorescence images demonstrated cytoplasmic and nuclear presence of these proteins. OCT3/4 protein of immunofluorescence determinations showed cytoplasmic locations in all layers. Futher investigations need to be done for enlighten this protein function in hematopoetic cells because OCT3/4 has different isoforms. NANOG protein showed cytoplasmic location in PB and AM, both cytoplasmic and nucleic location in CB. Western blotting results indicated that NANOG protein create a ladder pattern mostly cause of post-translational modifications. NANOG ladder pattern also changed between layers. These findings showed different layers had different post-translational modifications so different type of NANOG protein.
Summary and Conclusions: As a result, these findings showed that it is necessary to investigate the function of PSC markers in differentiated adult cells. Another conclusion is, among the lysis and ficoll density gradient method, lysis method has the highest cell recovery amount.Consequently, this study provided us new informations and viewpoints about expression of PSC markers in adult tissues.

PB1771

ALTERATIONS IN THE BONE MARROW MICROENVIRONMENT CAN ELICIT DEFECTIVE HEMATOPOIESIS: COMPARISON OF APLASTIC ANEMIA, CHRONIC MYELOID LEUKEMIA AND NORMAL BONE MARROW.

M. Park[1,*] C.J. Park[2], S. Jang[2], D.Y. Kim[3], J.H. Lee[3], J.H. Lee[3], K.H. Lee[3], Y.H. Lee[4]
[1]Department of Pediatrics, College of Medicine Chungbuk National University, Cheongju, [2]Department of Laboratory Medicine, [3]Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, [4]Department of Pediatrics, Hanyang University Medical Center, Hanyang University College of Medicine, Seoul, Korea, Republic Of

Background: Normal hematopoiesis involves complex interactions between hematopoietic cells and the bone marrow (BM) microenvironment. Examples of extremes at both ends of dysregulated hematopoiesis are BM failure in aplastic anemia (AA) and myeloproliferative disease such as chronic myeloid leukemia (CML). The specific causes of and mechanisms involved in dysregulated hematopoiesis are unknown.
Aims: To better understand the interactions between hematopoiesis and the BM microenvironment, we investigated changes in the hematopoietic stem cell (HSC) compartment and the BM microenvironment of patients with AA (n=10), CML in chronic phase (n=10) and normal marrow (n=10).
Methods: BM biopsy specimens were analyzed by semiquantitative immunohistochemistry (mean positive cell number/high power field) for osteopontin, osteonectin, osteocalcin, nestin, stromal-derived factor-1 (SDF-1) expression, and to identify endothelial cells, lymphocytes (CD3, CD4, CD8, CD20, CD56), macrophage (CD169), and HSCs (CD34, CD117).
Results: The lowest numbers of HSCs were in AA specimens, and the highest numbers were in CML specimens. The highest numbers of T and B lymphocytes were found in normal control specimens (P<0.01). Natural killer (NK) cells were occasionally observed in the AA specimens, but were absent from the CML and control specimens (P<0.01). Macrophages were absent from the CML specimens, whereas the number of macrophages (P<0.01) was highest in the AA specimens. There were significant differences between the stromal cell components of AA specimens and CML specimens. Numbers of cells positive for osteopontin (P<0.01), SDF-1 (P<0.01) and nestin (P<0.01) expression were higher in the AA than in the CML specimens. No nestin+ cells were observed in CML specimens. Numbers of cells positive for osteocalcin (P<0.01) and osteonectin (P=0.015) expression were higher in CML than in AA specimens. The highest numbers of endothelial cells were in CML specimens (P<0.01).

Table 1.

TABLE 1. Semiquantitative immunohistochemical analysis of bone marrow cells from patients with aplastic anemia, chronic myeloid leukemia and control

Antigen	AA	CML	Control	*P* value*
Hematopoietic stem cells				
CD34	1.36 ± 1.22	14.31 ± 15.44	9.49 ± 3.02	0.013
CD117	2.84 ± 2.06	34.00 ± 21.83	11.17 ± 4.25	<0.01
Lymphocytes and macrophages				
CD3	18.67 ± 12.88	26.28 ± 10.44	70.83 ± 30.70	<0.01
CD4	1.56 ± 1.25	0.74 ± 1.14	9.87 ± 3.65	<0.01
CD8	12.41 ± 9.79	16.96 ± 6.27	41.17 ± 14.11	<0.01
CD20	1.01 ± 1.07	0.00 ± 0.00	7.37 ± 4.98	<0.01
CD56	0.11 ± 0.12	0.00 ± 0.00	0.00 ± 0.00	<0.01
CD169	1.53 ± 0.96	0.00 ± 0.00	1.05 ± 1.07	<0.01
Stromal cell components				
Osteopontin	5.79 ± 2.08	0.10 ± 0.32	4.45 ± 1.11	<0.01
Osteocalcin	113.40 ± 88.54	261.70 ± 323.93	145.20 ± 149.28	0.275
Osteonectin	0.40 ± 0.17	2.13 ± 0.73	2.60 ± 1.10	<0.01
SDF-1	2.96 ± 2.76	0.43 ± 0.49	1.94 ± 0.47	<0.01
Nestin	8.04 ± 8.41	0.00 ± 0.00	3.62 ± 1.21	<0.01
Endothelial cells	39.20 ± 21.46	186.90 ± 140.95	18.00 ± 7.64	<0.01

Values are expressed as mean ± standard deviation.

*Analysis of variance (ANOVA) was used to test for differences between the 3 types of bone marrow specimens.

AA, aplastic anemia; CML, chronic myeloid leukemia; SDF-1, stromal-derived factor-1

Summary and Conclusions: The BM of AA patients demonstrated increased numbers of macrophages and NK cells, which could result in cytotoxic and/or immune-mediated marrow damage; or, alternatively, be a consequence of HSC injury. The BM of CML patients demonstrated decreased numbers of SDF-1-expressing and absence of nestin-expressing cells, which may result in reduced homing of HSCs and proliferation of malignant hematopoietic cells. There were significant differences between AA and CML specimens in the numbers of cells expressing osteoblast-derived extracellular proteins such as osteopontin, osteocalcin and osteonectin. Our findings suggest that changes in the components of the BM microenvironment might be related to defective hematopoiesis that may lead to BM failure and/or myeloproliferative disease.

PB1772

ENDOPLASMIC RETICULUM STRESS RESPONSE IN G6PC3 DEFICIENT WHITE BLOOD CELLS

R. Pittner[1,*] G. Kriván[2], Z. Lédeczi[1], T. Kardon[1]
[1]Medical Chemistry, Molecular Biology and Pathobiochemistry, Semmelweis University, [2]Pediatric Hematology and Stem Cell Transplantatio, Szent László Hospital, Budapest, Hungary

Background: Severe Congenital Neutropenia type 4 (SCN4) is a rare autosomal recessive disease due to mutations in the glucose-6-phosphatase beta (G6PC3) gene. G6PC3 is a typical metabolic enzyme in the endoplasmic reticulum (ER) suggested hydrolyzing glucose-6-phopshate (G6P) in glucose and phosphate. This enzyme catalyzes the final step of glycogenolysis in non gluconeogenic tissues like neutrophils. In the lumen of ER glucose-6-phosphate can be metabolized by hexose-6-phosphate dehydrogenase (H6PD) as well, which is responsible for ER redox homeostasis. The first diagnosed patient in our country has a non-sense mutation in the first exon at position W73Term causing a lack of G6PC3. Beyond severe inborn neutropenia and consequent inflammatory episodes the phenotype comprises other anomalies including congenital heart defects, urogenital anomalies prominent superficial veins, facial dysmorphism, growth and developmental delay.
Aims: The question arises as to what kind of disturbances can cause a defect of a metabolic enzyme leading to developmental malignancies-beyond affecting neutrophils? Since data are already presented in G6PC3 KO mice, we were interested in the differences or similarities between human and rodent WBC-s.
Methods: Whole blood from healthy and patient with SCN4 was collected and purified obtaining total white blood cell (WBC) fraction. Enzymatic and Western-blot measurements were made on these protein samples.

Results: Neutrophils from G6PC3-deficient WBC-s proved the lack of G6PC3 on Western blot, and also on the enzymatic level. Surprisingly we could not identify any metabolic aberrations in G6PC3-deficient WBC-s. G6PC3 deficient cells showed increased level of Grp78 and phosphorylated eIF2-α compared to the control one. Other ER stress enzymes are still under investigation. Interestingly H6PD was also decreased in the mutant cells vs. control cells.
Summary and Conclusions: Lack of G6P reduction or hydrolysis suggests that endoplasmic reticulum stress can be responsible for increased apoptosis in G6PC3-deficient neutrophils. However, the involvement of the PERK-eIF2α-ATF4 signaling pathway in SCN4 is still unclear, these alterations may at least in part be responsible for the phenotype of G6PC3 deficiency. Our results suggest that trying to maintain the ER redox environment with small molecules, like ascorbic acid, may help in neutrophil granulocyte surviving. We continue our investigations towards this direction. This work was supported by the Hungarian Scientific Research Fund OTKA 101226

PB1773

EXPANSION OF UMBILICAL CORD BLOOD HEMATOPOIETIC STEM CELLS ON BIOCOMPATIBLE NANOFIBER SCAFFOLDS USING CO-CULTRE SYSTEM WITH BONE MARROW DRIVED MESENCHYMAL STEM CELLS

M. Mokhtari[1,*] A. Atashi[2], M. Soleimani[3]
[1]PhD student of hematology, Department of hematology, Faculty of medical sciences, [2]Assistant professor of hematology, Department of hematology, Faculty of medical sciences, [3]Associate professor of hematology, Department of hematology, Faculty of medical sciences, Tarbiat Modares University, tehran, Iran

Background: Hematopoietic stem cell transplantation (HSCT) is a therapeutic approach in treatment of hematological malignancies and inability of the bone marrow. Umbilical cord blood (UCB) known as an alternative for hematopoietic progenitor/stem cells (HPSC) for in allogeneic transplantation. The advantage of this source of HPSC is the low aptness of GVHD due to low number of T lymphocytes. The main hindrance in application of HPSC derived from umbilical cord blood is the low number of stem cells in the cord blood. So, ex vivo expansion of HSCs is the useful approach to overcome this restriction.
Aims: The aim of using this systems is to produce appropriate amount of hematopoietic stem cells, which have the ability of transplantation and long term hematopoiesis.

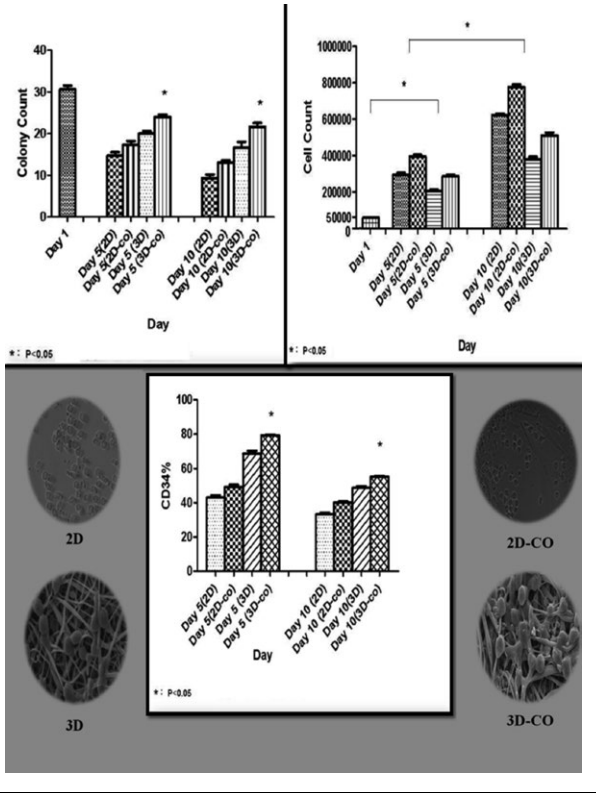

Figure 1.

Methods: The routine system of hematopoietic stem cells expansion is using expansion cytokine cocktail including, SCF, TPO and FLT3L in 2- Dimensional (2D) microenvironment. In this microenvironment cells only affected by cytokines and there is not any influence of cell – cell interactions. Synthetic biomaterials such as nanofibers based on Polyethersulfone(PES) is used to produce synthetic niches. These 3D structures leads to activation of adhesion, proliferation and differentiation of CD34+cells with highly similarity to bone marrow microenvironment. Considering the important role of mesenchymal cell lineages in the bone marrow hematopoietic stem cells fate through the production of secretory factors andcell-cell interactions, in this study we used mesenchymal stem cells seeded on the bottom surface of the nanofiber scaffolds to provide their supportive role in hematopoietic stem cell proliferation during the three-dimensional culture system.Accordingly, we set up four culture systems consist of two-dimensional (2D), three-dimensional (3D),two dimensional + co-cultured by mesenchymal stem cells (2D-CO) and three-dimensional + co-culture by mesenchymal stem cells(3D-CO). We sorted CD34+ cell by MACS technology and the cells were cultured in StemSpan serum-free medium containing SCF+TPO+Flt3L.
Results: The results of this study showed that coculture of HPSC with MSC in three dimensional scaffold could able to expand of CD34 cells with minimal differentiation in comparison to other systems.
Summary and Conclusions: Establishing a cell culture system with maximum similarity to the bone marrow microenvironment lead to improve culture conditions and proliferation of hematopoietic stem cells. this include three-dimensional (3D) nanofiber scaffold system and use of chemical molecules existing in matrix of bone marrow.also given important role of mesenchymal stem cells in fate of hematopoietic stem cells,using this cell resulted improved proliferation of hematopoietic stem cells.it is recommended to additional studies for more investigate the required characteristics of stem cells for bone marrow transplantation and evaluate enhanced abilities of this system.One of the challenges in this system is the harvesting hematopoietic stem cells amidst of of fiber scaffolds and mesenchymal stem cells.To overcome this problem, use of biodegradable fibers in future studies is recommended.

Abstract withdrawn

PB1775

EFFECTS OF STORAGE IN PARAMETERS OF FULL BLOOD COUNT (FBC)

D. Gunawardena[1,*] S. Jayaweera[2], D. Lokumarakkala[3], G. Madhubhashini[3]
[1]Heamatology, [2]Depertment of Allied Health Sciences, [3]Department of Allied Health Sciences, University of Sri Jayawardenapura, Colombo, Sri Lanka

Background: It is common knowledge that the FBC has to be analyzed as soon as possible to get an accurate result. However due to the heavy workload and the increase demand for FBC, a delay before analysis is seen many times. Therefore it is vital to know the storage effects that are likely to affect the FBC.
Aims: FBC is a laboratory test which is routinely done as one of the first steps in the diagnostic workup. There is often a post collection interval before analysis of results where external factors such as storage temperature, and the duration of sample storage can affect the results. This study analyses the storage effects of components of FBC at different temperatures over time.
Methods: A descriptive cross sectional study was conducted in the laboratory of CSTH. K_2EDTA blood samples were randomly taken from 102 apparently healthy individuals aged between 20-70 years. Baseline measurements were analyzed within 30 min of collection through a fully automated haematology analyzer Sysmex SX 500i. Samples were divided into 3 portions and each of them was kept at 4±2^{o}C, 23±2^{o}C and 31±2^{o}C up to 48hrs. All were repeatedly analyzed after 6hrs, 24hrs, and 48hrs. Statistical analysis was conducted using SPSS 17.O.
Results: Among parameters of the FBC, red cell count and haemoglobin were stable at 4^{0} C, 23±2^{o}C and 31±2^{o}C throughout the study (48 hrs).White blood cell count (WBC) was increased at 31±2^{o}C and 23±2^{o}C. Machine refused to read the differential count of some samples after 24hr of storage. Neutrophil and Basophil counts were significantly increased with time throughout the study in all temperatures. Storage caused a significant decline in platelet count and an increment in MPV at all temperatures after 6hr. (P<0.05). At 4^{0}C MCV and RDW were decreased whereas it was significantly increased at RT and 23±2^{o}C.
Summary and Conclusions: In order to prevent variability in FBC parameters, it is preferred to analyze the blood sample as soon as possible. For an accurate platelet count, samples should be analyzed within 6hr. Haemoglobin remains stable at any temperature even at 48 hr. Neutrophil count keeps increasing with storage time at different temperatures. Differential counts were rejected by the machine in most cases after 1day of storage.

Hodgkin lymphoma - Clinical

PB1776

CLINICAL OUTCOME OF VERY REFRACTORY HODGKIN'S LYMPHOMA

F. Gaudio[1,1,*] F.E. Laddaga[1], F.E. Laddaga[1], T. Perrone[1], T. Perrone[1], P. Pinto[1], M. Leo[1], C. Bitetto[1], M.S. De Candia[1], G. Ingravallo[2], P. Pedote[3], D. Pastore[1], G. Specchia[1]
[1]Hematology, University of Bari, [2]Patology, University of Bari, [3]Radiology, University of Bari, Bari, Italy

Background: Although Hodgkin's lymphoma (HL) is largely curable with first-line therapy, approximately one-third of patients will not have a complete response to frontline treatment or will subsequently relapse. Only in 50% of these patients will effective salvage be achieved with conventional therapies. The prognosis is particularly poor for those patients who are refractory or relapse following an autologous stem cell transplant (ASCT). Reduced-intensity conditioning (RIC) is increasingly used as a potentially curative option.
Aims: We performed a retrospective analysis of 25 adult patients (15 women/10 men) with HL, who relapsed within 12 months or had progressive disease after ASCT, in order to analyze clinical outcome.
Methods: Disease status at ASCT was complete remission in 7 patients (28%), sensitive disease in 14 (56%), and refractory disease in 4 (16%). Median time from ASCT to relapse was 7 months (range 0.5-11); 12 patients (48%) had stage 3-4 at relapse/progression. B symptoms were present in 40% of the patients, bulky disease in 20% and extranodal involvement in 56%. Treatments following relapse/progression were the standard BEACOPP regimen in 10 patients (40%), 2nd ASCT in 5 (20%), brentuximab vedotin without further therapy in 2 (8%) and RIC in 8 (32%); the therapeutic regimens used as a "bridge" to RIC were brentuximab vedotin in 6 (24%) and bendamustine in 2 (8%).
Results: Overall response rate was 64%, including 36% complete remission and 28% partial response. Progression occurred in 24% and 12% had stable disease. No difference in response rate was found among the treatment regimens. RIC was administered in 8 patients (4 in complete and 4 in partial remission). Estimated overall survival at 40 months was 72% for the whole population, 88% for patients who underwent RIC and 58% for those who did not. Estimated progression-free survival at 40 months was 50%; 62% for the RIC group and 42% for the non RIC group. After a median follow-up of 36 months (range 3-84), 18 of the 25 patients are alive (72%) and 11 (44%) still in complete remission (45% of them underwent RIC).
Summary and Conclusions: Patients with HL who fail ASCT have a very poor prognosis, and the goal of treatment should be to ultimately refer them to RIC. Even if several questions are still open, this approach should be proposed for these poor prognosis patients. Brentuximab vedotin is useful in order to reduce the disease burden before RIC.

PB1777

THERAPEUTIC RESULTS OF TUNISIAN NATIONAL HODGKIN LYMPHOMA PROTOCOL :MDH2008 UNICENTRIC EXPERIENCE ABOUT 71 PATIENTS

F. Kallel[1,*] S. Mseddi[1], C. Maha[1], B. Hatem[1], K. Olfa[1], H. Ben Salah[2], G. Manel[1], M. Moez[1], G. Lilia[2], F. Imen[1], B.A. Imen[1], E. Moez[1]
[1]Hematology department sfax hospital, [2]Radiotherapy SFAX Hospital, Faculté de Médecine de SFAX Unité de Recherche, SFAX, Tunisia

Background: Hodgkin lymphoma(HL) is a curable hemopathy. Several groups have established management protocols for this disease. The Tunisian group has adopted a third version of a national consensus: MDH2008
Aims: assessment of therapeutic response of hogkin lymphoma treated according the national protocol HL 2008.
Methods: Between Mai 2009 and decembre 2013,71 patients were enrolled in HL-2008 protocol (a third version of prospective trial) at the haematology department of Hedi Chaker hospital (Sfax). HL-2008 defined 5groups : G1 : favorable early stage, G2 : unfavorable early stage, G3 : advanced stage and localised stage with mediastinal bulk(MTI>0.35), G4 : early stage in elderly patients, G5 : advanced stage in elderly group. We recommanded 2 cycles ABVD+radiotherapy (IFRT) for G1, 4 cycles of ABVD + IFRT for G2, 8cycles of BEACOPP (4 escalated+ 4 baseline) for G3. Elderly groups recieved 6 and 8 cycles of ABVD for G4 and G5 resectively. Early assessment of response was recommanded after 2 cycles in each group and an escalation to BEACOPP-R took place if response was less than 75%. The date of point is in january 2015. Our study determine therapeutic response, the overall survival (OS), event free survival (EFS), relapse free survival (RFS) and factors forecast which influenced these survivals.
Results: Median age was 33 years (range16-82) with sex ratio=0.87. 62% of patients were treated in G3, 21% in G2, 7% in G5, 6% in G1 and 4% in G4. 86% of patients were in complete response after the first line therapy. 7% of patients were refractory. OS, EFS, RFS were respectively 91%, 82% and 92%. 5 relapse were noted. There were grade 3-4 hematological toxicities only in patients treated with BEACOPP. 3 toxic deaths were noted 1 with escalated BEACOPP and two with ABVD treating elderly(G5). In univariante study, chemosensivity (2cure) and therapeutic response at the end of treatment were 2 predictive prognostic factors for OS (P=0.01, P<0.001), EFS (P<0.001, P<0.001). Bulky mediastinal disease was a significant adverse prognostic factor for the EFS and the RFS (P=0.03, P=0.009).
Summary and Conclusions: Comparatively to the second version, intensive chemotherapy for unfavorable HL(advanced stage and bulky medaistinal disease with stage II), RFS and OS are better.

PB1778

SECOND NEOPLASMS IN LONG SURVIVORS OF HODGKIN'S LYMPHOMA: A RETROSPECTIVE ANALYSIS IN A SINGLE CENTER

B. Rosado[1,*] A. Garcia[1], J.A. Queizan[1], S. Valencia[1], C. Olivier[1], R. Fisac[1], C. Navarro[1], M. Vargas[2], J.M. Hernandez[1]
[1]Hematology, [2]Psychiatry, General Hospital of Segovia, Segovia, Spain

Background: Prolonged survival in patients with Hodgkin's Lymphoma (HL) seems to be associated with an increased risk of developing secondary malignancies.
Aims: Ours objectives were to describe and analyze incidence of secondary malignancies, to detect predictors and their overall survival.
Methods: Single-center retrospective analysis of patients diagnosed and treated for LH in the period 1975 to 2015, at the General Hospital of Segovia (Spain). Statistical analysis was performed using SPSS[a] (v.15).
Results: 101 patients were analyzed. Median age was 33 years [10-88]. 59.4% were male. 60% had an advanced stage at diagnosis (IIB-IV). The most common histology was nodular sclerosis (n=48). 82.2% patients had a favorable prognosis (Hasenclever ≤2). 87.1% patients were treated with chemotherapy (schedule ABVD the most used). 62.5% of patients received radiotherapy (RT) as first-line therapy. 10 patients only received RT as single therapy. The median follow-up was 88 months [0-422]. 16 second malignancies were detected. Median onset was 10 years [2-26]. Differences in median onset between hematologic malignancies and non-hematologic (4 vs16 years) were observed, but the difference was non stadistical significantly, perhaps due to small sample size. Comparing patients with secondary neoplasia against the global serie, only the stage (P=0.013) and number of deaths showed significant differences (P=0.005). Cumulative incidence (CI) was 35% at 300 months (CI in second malignancies is shown in Figure 1). The median overall survival stimated was 310 months in global serie (patients with second neoplasms: 300 months). Nowadays, 71 patients (70.3%) still alive, but only 6 affected by second neoplasia are alive.

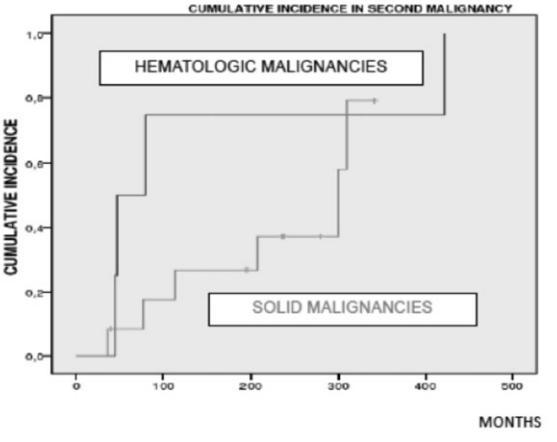

Figure 1.

Summary and Conclusions: HL is considered curable in a high percentage of patients, but carries a incidence of second malignancies in long survivors with an increased risk at 25 years of diagnosis, as happened in our series of a single center with median onset of 16 years. A previous publication (Kg, AK. Blood, 2014) describe an increased risk of hematologic neoplasia in patients who had received chemotherapy with alkylating agents type MOPP plus extensive radiotherapy later or with the combination chemotherapy (ABVD-MOPP). We found similar data in our serie featuring 2 cases who were treated with MOPP and mantle type RT, and other 2 with ABVD-MOPP. Another publication showed higher risk associated with BEACOPP schedule, results against to our findings: None of the 11 patients who received BEACOPP (standard or scalated) developed second neoplasia. In any case, the absence of these neoplasms along the track (last hematologic neoplasia in 1996), may be due to the change in therapeutic schemes and extent of RT (field involved vs extend field). Patients

who developed non-hematological malignancies, 8 were treated with RT (all type Mantle). Therapeutic schemes were different, but in those patients who did not receive RT, all except one received ABVD scheme, no differences in both arms. Appearance of secondary neoplasms in field radiation is to be expected, as shown in our serie; however, there is also an increased risk in patients treated with alkylating agents.
In our retrospective study of single center, stage at diagnosis proved to be a predictor factor of development of second neoplasia related with higher mortality. Therefore, our data resemble previously publications as increase in the CI throughout evolution. Secondary malignancies may be lower with actual therapeutic schemes although longer follow-up would be necessary.

PB1779

ENDOCRINOPATHIES AND SECOND MALIGNANCIES IN LYMPHOMA SURVIVORS: A SINGLE CENTRE EXPERIENCE

M.P. Simula[1,*] A.M. Mamusa[1], S. Usai[1], E. Angelucci[1]
[1]Struttura Complessa di Ematologia e Centro Trapianti. Ospedale Oncologico di Riferimento Regionale. Cagliari, Italia, ASL Cagliari, Cagliari, Italy

Background: Improvements in the treatment of both Hodgkin's and non Hodgkin's Lymphomas (HL and NHL) have resulted in an increasing number of long term survivors. But this patient's population is at high risk of developing serious late therapy related complications that can negatively affect their lives or lead them to an early death. The most common secondary diseases in the people cured from lymphomas are cardiovascular diseases, second malignancies (mainly solid tumours) and endocrinopathies that in the majority of the cases are thyroid dysfunctions.
Aims: In our institution the HL and aggressive NHL long term survivors are followed up in a dedicated clinic since September 2014. Here we report preliminary data on second malignancies and thyroid dysfunctions.
Methods: We have collected retrospective data on thyropathies and second tumours in 216 lymphoma survivors.
Results: We have analyzed data regarding 216 patients coming in our clinic from 15 September 2014 to 16 February 2015, 119 were affected by HL and 97 by NHL. One hundred fifteen are females, 101 males; median age at observation is 53 (range 22-89). All of them are in complete response for lymphoma for at least 5 years from the completions of curative therapy. Thirty patients (28 females and 2 males) had thyropathies (13.8%),namely hypothyroidism interesting 25 of them and multinodular goiter in 5 cases. Twenty six had a previous HL but only 4 developed endocrinopaties after a NHL. According to lymphoma therapies, 26 (24 HL and 2 NHL) of them had neck and/or mediastinal radiotherapy. They are the 26.5% of all receiving irradiation in the chest and neck; the other 4 did not had radiotherapy. Twenty four patients (11%) experienced a second cancer, 3 of them had 2 neoplasms, so we documented 27 second tumours. They were: 8 breast, 7 skin basocellular, 3 colon and sigma, 3 thyroid, 2 prostatic, 1 lung, 1 bladder carcinoma, 1 testis and 1 cutaneous appendages cancer. Regarding the previous therapies all but 2 the females with breast cancer had undergone to mediastinal radiotherapy; 5 out of 7 with cutaneous cancer developed the lesion in the sites of previous irradiation; 1 out of 3 with thyroid cancer had mantel radiotherapy, the one with lung cancer had MOPP chemotherapy and mantle radiotherapy; no one of the intestinal cancers had abdominal radiotherapy, the one with urinary cancer had abdominal radiotherapy and MOPP/ABVD regimen. Median age of breast cancer in our setting is 50.5 (range 38-70). The median time between diagnosis of lymphoma and diagnosis of second malignancy was 21 years (range 5-41).
Summary and Conclusions: Our data confirm the incidence of thyroid diseases in lymphoma survivors particularly in people with prior HL. In our Department we described also numerous cases of second neoplasms in the lymphoma survivors population. That outline the importance of a plan for early diagnosis of cancers in this setting of patients.

Indolent Non-Hodgkin lymphoma – Clinical

PB1780

CLINICAL AND OUTCOME IN PATIENTS WITH ALK POSITIVE AND NEGATIVE ANAPLASTIC LARGE-CELL LYMPHOMA

A. Ramirez-Ibarguen[1,*] B. Acosta-Maldonado[1], S. Rivas-Vera[1]
[1]Hematology, Instituto Nacional de Cancerologia, Mexico, Tlalpan, Mexico

Background: Anaplastic large-cell lymphoma (ALCL) accounts for approximately 3% of non-Hodgkin´s lymphomas (NHL). It is a peripheral T-cell lymphoma characterized by expression of CD30. Currently the WHO recognized two kinds of ALCL based on anaplastic lymphoma kinase (ALK) expression. In previous studies, ALK positive ALCL was associated with younger patients and a better prognosis. The International Peripheral T-Cell Lymphoma Project Study reported a 5 year overall survival of 70% and 49% in ALK positive and ALK negative ALCL respectively.
Aims: To study the clinical characteristics and outcomes of patients with systemic ALK-positive and negative ALCL in our population.
Methods: We retrospectively analyzed 39 consecutive cases of ALCL referred and treated at the Instituto Nacional de Cancerologia, México
Results: A total of 1951 charts of NHL patients from 2008 to 2013 were reviewed. ALCL was confirmed in 49 (2.5%). Ten patients had primary cutaneous anaplastic lymphoma, thus 39 patients were analyzed.
Twelve patients were ALK-positive (33%) and 27 (77%) Alk-negative. Median aged was 26 (17-48) vs 47 years (22-76) respectively (P=0.40). Clinical characteristics are shown in table 1. There were not significance differences between groups. Seventeen patients achieved a CR (44%), 3 (8%) partial responses, 5(13%) had refractory /relapsed disease and 14 patients (36%) could not be evaluated for response, 12 died before treatment completion. The median follow up was 39 months with an overall survival (OS) of 47%, median EFS was not reached. The multivariate analysis for OS in all group identified B2-microglobulin ≥2.7 mg/dL as the only prognosis factor (P=0.01). No difference in overall response, overall survival or event-free survival was found in relation with ALK status.

Table 1.

	ALCL ALK negative n(%)	ALCL ALK positive n(%)	p
Range, y			
<40	7 (29)	8 (67)	0.71
≥40	17 (71)	4 (33)	
Performance status 0-1	12 (52)	7 (70)	0.45
Ann Arbor stage III-IV	19 (83)	9 (75)	0.67
B symptoms	19 (83)	11 (92)	0.64
Bulky disease	9 (39)	6 (50)	0.53
Extranodal disease	11 (48)	5 (42)	0.72
Albumin ≤3.5 mg/dL	15 (65)	8 (89)	0.38
DHL elevated ≥213 UI/L	13 (56)	6 (67)	0.70
Hemoglobin ≤10 g/dL	4 (17)	3 (33)	0.37
Lymphocyte ≤1200 cel/mm3	15 (65)	7 (78)	0.68
2microglobulin ≥2.7 mg/dL	11 (50)	7 (78)	0.23
IPI score			0.56
Low/ Low-intermediate	9 (39)	5 (50)	
High-intermediate/ High	14 (61)	5 (50)	
Treatment			
CHOP	13 (72)	6 (54)	0.039
CHOEP	-	4 (36)	
Other	5 (28)	1 (9)	
Radiotherapy	6 (25)	7 (58)	0.050
Overall response (CR+PR)	10 (71.4)	8 (88.9)	0.61
Relapsed	7 (29)	2 (17)	0.68
3 years OS	49.5%	70%	0.38
10 months EFS	50%	80%	0.15

Summary and Conclusions: Interestingly, we found no difference in outcome between Alk positive and negative patients. There are controversial reports about the prognostic significance of ALK status in ALCL. Gascoyne and cols. reported a 5 years OS of 93% vs 37%. However a GELA study did not find such a difference, while an elevated B2-microglobulin was a poor prognostic factor (OS 84% vs 22%). We also found B2-microglobulin to be a significant prognosis factor.

PB1781

BENDAMUSTINE PLUS RITUXIMAB TREATMENT IN FIRST LINE/ RELAPSED HCL: A SINGLE CENTRE EXPERIENCE

M. Pelosini[1,*] R. Riccioni[1], E. Capochiani[1]
[1]Hematology, Ospedali Riuniti di Livorno, Livorno, Italy

Background: Hairy Cell Leukemia (HCL) is a low grade Non Hodgkin lym-

phoma that presents with cytopenia and splenomegaly. Diagnosis is confirmed by the presence of lymphocytes CD103, CD25, CD11c positive on bone marrow. Treatment is based of purine analogs with which patients reach an hematological response. However relapse still occurs suggesting the presence of residual disease. Recently it has been discovered the presence of B-RAF V600 mutation in HCL, and experience with B-RAF inhibitor had shown major responses. Bendamustine experience in hematologic neoplasms lead to clinical and long lasting response, especially in low grade lymphomas. The drugs acts as an alkylating agent but it shares some characteristic with purine analogs.
Aims: We previously observed its promising clinical activity with MRD eradication as well, here we report updated results.
Methods: We treated a total of 9 patients (2011-2014) with bendamustine (60-70 mg/ m^2 days 1,2) in association with rituximab (375 mg/m^2 day 3). Cycles were repeated every 28 days up to 6 cycles. Before and after treatment patients had an abdomen ultrasound and bone marrow evaluation. Complete response was considered absence of marrow involvement and splenomegaly post treatment. MRD was evaluated by cytometry or IgH rearrangement with Pcr techniques. Patients' characteristics are summarized in Table 1.
Results: Treatment was well tolerated in all patients, with neutropenia (grade 2) and skin toxicity (grade 2). One patient had to stop treatment due to pulmonary embolism. We did not observe any serious infective complication. Overall response rate (ORR) was 100% with 7/9 complete response (CR) and 2/9 partial response (all in patient with relapsed disease). After a median follow up 25,7 months patients are all alive without any relapse. In evaluable patients MRD eradication has been achieved in 5/9 cases Patients treated at diagnosis obtained 100% CR and were MRD negative.

Table 1.

Cases	Age	Sex	Previous Treatment	Status pre tp	N of tp	Toxicity/Grade	Response	MRD
Pt 1	46	M	Cladribrine-rituximab	1ST Relapse	4	-	CR	NEG 1
Pt 2	58	M	-	Diagnosis	4	-	CR	NEG 1
Pt 3	63	M	Cladribrine	1ST Relapse	4	-	CR	NEG 2
Pt 4	73	M	IFN-a, cladribine	2nd relapse	4	-	PR	POS
Pt 5	67	M	-	Diagnosis	5	Hematologic/II	CR	NEG 1
Pt 6	78	M	-	Diagnosis	6	Hematologic/II	CR	NEG 1
Pt 7	75	M	-	Diagnosis	6	-	CR	NEG 1
Pt 8	74	M	Splenectomy	1st relapse	6	SKIN,EP	PR	POS
Pt 9	54	M	Cladribine	1st relapse	6	-	CR	NA

1 Flow cytometry
2 IgH rearrangement with Pcr techniques

Summary and Conclusions: Here we confirmed our first report on bendamustine in HCL with a longer follow up and additional cases. Results are encouraging and this approach is well tolerated also in elderly patients. Data of bendamustine in HCL as first line therapy are not yet described in literature and in our experience results are at least comparable to those with purine analogs. First data on MRD are interesting as well. Future will bring B-RAF inhibitors which are not still available and with whom resistance has already been described, but in the in the meanwhile bendamustine could be suggested as a treatment option for HCL patients.

PB1782

EXPERIENCE WITH VEMURAFENIB IN THE TREATMENT OF HAIRY CELL LEUKEMIA

E. Sari[1,*] K. Baghy[2], I. Kovalszky[2], C. Bödör[2], H. Rajnai[2], J. Csomor[2], Z. Nagy[1], J. Demeter[1]
[1]1st Department of Internal Medicine, [2]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary

Background: Targeted inhibitory therapy with first line BRAF-inhibitors has been used successfully in HCL patients refractory to or relapsing following previous lines of therapy, including cladribine and rituximab. Careful selection of eligible patients is mandatory since vemurafenib might cause secondary skin malignancies, photosensitivity, QTc-prolongation, liver enzyme elevations and arthralgia. Nevertheless, vemurafenib treatment has the advantage of perfect oral bioavailability, possibility of outpatient treatment, and the lack of hematological toxicity.
Aims: Treatment of relapsed/refractory hairy cell leukemia patients is a challenging task. We report on our experience gained with vemurafenib, a treatment option targeting the disease-defining genetic event, the BRAF V600E mutation.
Methods: Since 2012 January, six out of our 75 hairy cell leukemia patients were found to be refractory to at least two or three lines of therapy or relapsed repeatedly following previous treatments and thus were candidates for vemurafenib treatment. The National Institute for Quality and Organizational Development in Healthcare and Medicines permitted the off label use of vemurafenib in each case. All patients were male, median age was 67 yrs (40-83). One patient was refractory to four previous lines of therapy, the other patients relapsed, on average three times (2-6), and were ineligible for cladribine treatment (4/6 patients) or had cladribine-intolerance (1/6). Before starting vemurafenib, every patient underwent a dermato-oncological and ophtalmological screening. Treatment was planned for 56 days with 240 mg BID regime. Three-four months after treatment splenic ultrasound and bone marrow biopsy were performed to assess the response.
Results: Treatment lasted for 56 days, starting dosage was 240 mg BID. Three of six patients had no complaints during therapy. In two cases asymptomatic and reversible indirect hyperbilirubinaemy was detected without any other clinical signs of hemolysis of hepatic transaminase elevation. Dosage modification (240 mg once a day) was indicated in a patient with reversible grade 1 toxicoderma. In one case treatment was interrupted arbitrarily by the patient after 14 days because of grade 3 arthralgia. In another patient vemurafenib was withhold for 10 days because of community acquired pneumonia. Treatment responses were as follows: partial remission in 4/6, minor response 1/6, and still not evaluable in a recently treated patient A 83 year old patient received vemurafenib treatment for only 10 days when he had to be hospitalised due to progressive cardiac decompensation anaemia, renal insufficiency and hyperuricaemy. The patient died a few days later due to cardiac cause, an autopsy report was not available. Interestingly, in an 80-ys-old patient vemurafenib treatment resulted in gradual and stable normalisation of blood counts while the degree of bone marrow infiltration decreased from the initial 90% only to 70% at three months after having finished therapy. With a median follow up time of 12 (1-22) months until now we observed no overt relapse in our HCL patients treated with vemurafenib.
Summary and Conclusions: Vemurafenib offers a feasible outpatient treatment option for relapsed/refractory patient without hematologic toxicity. Questions to be answered in prospective studies are the optimal dosage and duration of vemurafenib, retreatment and the possibility to combine treatment with a MEK inhibitor.

PB1783

PREVALENCE OF HEPATITIS B REACTIVATION IN PATIENTS WITH INDOLENT NON HODGKIN LYMPHOMA CD20+ DURING MAINTENANCE THERAPY WITH RITUXIMAB

G. Giagnuolo[1,*] M. Raimondo[1], C. Cimmino[1], R. Della Pepa[1], S. Luponio[1], G. Beneduce[1], C. Cerchione[1], M. Masarone[2], M. Persico[2], F. Pane[1], A. De Renzo[1]
[1]Hematology Division, Department of Biochemistry and Medical Biotechnology, university of Federico II, Naples, [2]Internal Medicine and Hepatology Unit, University of Salerno, Salerno, Italy

Background: Anti CD20 antibody (Rituximab) based chemotherapy regimens increase the HBV reactivation risk although sporadic HBV reactivation cases are reported in patients on maintenance with Rituximab single therapy. We evaluated how many reactivation occurred among patients Hepatitis B core antigen positive (HBcAb+) and Hepatitis B surface antigen negative (HBsAg-) who received maintenance therapy with Rituximab.
Aims: The aim of this study is to assess the prevalence of HBV reactivation among patients HBcAb+/HBsAg- during maintenance therapy with Rituximab.
Methods: Here we report our experience about 98 patients with indolent non Hodgkin Lymphoma CD20+ who received maintenance therapy with Rituximab (schedule: 375 mg/mq every 2 months for 2 years) from January 2007 to January 2015. Patients received different chemotherapy regimens during induction: 45% (44/98) with R-CHOP, 34% (33/98) with R-FN, 13% (13/98) R-Bendamustine, 3% (3/98) with R-Fludarabine, 3% (3/98) with R-Leukeran and 2% (2/98) with Rituximab monotherapy. We performed blood tests for HBV (HBsAg, HBsAb, HBeAg, HBeAb, HBcAb) in all patients before starting maintenance therapy and liver function tests before each administration of Rituximab. None of these patients received prophylactic therapy with antiviral drugs during induction and maintenance therapy.
Results: 32% of the patients (32/98) were HBcAb positive. 58% of the patient (57/98) completed therapy with Rituximab and 30% of them (17/57) were HBcAb positive; one of these patients occurred HBV reactivation. 42% of the patients (41/98) are still in maintenance therapy and 36% of them (15/41) were HBcAb positive with risk of HBV reactivation too.
Summary and Conclusions: In patients HBcAB+/HBsAg- treated with Rituximab in single therapy is indicated the prophylaxis with lamivudine. In our single centre experience HBcAB+/HBsAg- patients didn't received therapy with antiviral drugs during maintenance therapy with Rituximab; one of our patient occurred HBV reactivation. In terms of cost-benefit, we reported an advantage in the monitoring approach that was used in our patients in respect to universal prophylaxis with a total savings of about € 3.400,00 for each patient. More study are necessary to estabilish the clinical utility of prophylactic therapy with lamivudine during the maintenance therapy with Rituximab.

PB1784

ARE THE FOLLICULAR LYMPHOMAS CURABLE DISEASES? RETROSPECTIVE STUDY ON 146 PATIENTS WITH AT LEAST 10 YEARS OF OBSERVATION

L. Rigacci[1,*] F. Lancia[1], S. Kovalchuk[1], L. Mannelli[1], G. Benelli[1], B. Puccini[1], A. Bosi[1]
[1]Haematology, AOU Careggi, Firenze, Italy

Background: Follicular lymphomas are usually defined as incurable diseases with a natural history characterized by several relapses. This study was launched to evaluate how many patients, after a long observation period, don not relapse or do not experience a new chemotherapy treatment.
Aims: We aim to identify which clinical characteristics or therapeutical approaches are associated with this cohort of favourable patients.
Methods: All patients with histologically confirmed diagnosis of follicular lymphomas grade I-II or IIIa were selected from our data base starting from January 2000 untill December 2004 in such a way to have at least 10 years of observation for alive patients. We divided patients in two cohorts, cohort 1 with patients relapsed or progressed and cohort 2 with patients never relapsed or progressed.
Results: From January 2000 to December 2004, 146 patients were diagnosed and treated in our Institution. Thirteen patients were excluded from the analysis, 8 because of lost to the follow-up and 5 did not obtained at least a partial remission. Finally 133 patients were selected for the study. The median age at diagnosis was 61 years (range 30-87). Stage I-II in 47 patients, III-IV in 86. Bone marrow biopsy was positive in 87 patients, FLIPI 0-1 in 35, FLIPI 2 in 43, FLIPI 3 in 40 and FLIPI 4 in 15 patients. According to treatment 96 patients were treated with antracycline containing regimens, 24 with fludarabine containing regimens and 13 were observed or treated with radiotherapy. Rituximab was used in 92 patients, as sequential treatment in 70 or chemotherapy combined in 22; 41 patients did not use rituximab. Patients relapsed or progressed represent cohort 1 (85 patients) and those without relapse or progression represent cohort 2 (48 patients). The statistically significant differences between the two cohorts were: elderly patients (P 0.05), symptomatic patients (P 0.05), FLIPI and FLIPI2 high score (P 0.005), lack of complete remission (P 0.0000) all observed in cohort 1. The overall survival with a median period of observation of 115 months (range 2-185) was 71%, considering the two groups the overall survival in cohort 1 was 62% with a median of 142 months and it was 94% in cohort 2 with median not reached. In univariate analysis normal value of beta2 microglobulin (P 0.05) and the use of rituximab (P 0.01) were associated with a better overall survival; in multivariate analysis treatment with rituximab manteined a statistically significance.
Summary and Conclusions: In conclusion this retrospective monocentric study confirms that about one third of follicular lymphoma patients could be considered cured particularly if rituximab was used in the treatment. At the present time all patients with follicular lymphoma are treated with combined immuno-chemotherapy, moreover after induction therapy patients are started on manteinance. We can therefore hope for the future in an improvement of survival results.

PB1785

A RETROSPECTIVE ANALYSIS OF SPLENIC MARGINAL ZONE LYMPHOMA: PROGNOSTIC FACTORS, ROLE OF WATCH AND WAIT, AND THERAPEUTIC APPROACHES IN THE RITUXIMAB ERA

S. Perrone[1,*] G.M. D'Elia[1], G. Annechini[1], P. D'Urso[1], C. Stefanizzi[1], R. Foà[1], A. Pulsoni[1]
[1]Hematology, Department of Cellular Biotechnologies and Hematology., Sapienza University, Rome, Italy

Background: Splenic marginal zone lymphoma (SMZL) is an indolent lymphoma recognized as a distinct entity in the WHO classification. Arcaini's scoring system (Blood, 2006)-based on Hgb<12 g/dL, albumin<3.5 g/dL, elevated LDH-is useful to stratify patients prognostically. Given the lack of standard criteria guiding treatment initiation, the watch and wait (W&W) approach in asymptomatic patients is recommended. In symptomatic patients it has been suggested that, apart from splenectomy, rituximab +/- chemotherapy is the best option.
Aims: The aims of our study were to identify risk factors at diagnosis, to assess the progression rate within a W&W strategy, and to analyze the outcome of different therapies in the post-rituximab era.
Methods: : We retrospectively examined the clinical files of 83 patients with SMZL managed at our center in Rome between 2000 and 2013. Patients were stratified according to Arcaini's scoring system. Asymptomatic patients were managed with a W&W policy. Splenectomy was performed in 21 patients with a symptomatic spleen enlargement and limited bone marrow or nodal involvement. Patients not eligible for a splenectomy or with a more generalized disease were treated with chemotherapy alone (12) and, after its introduction, with rituximab + chemotherapy (R-chemo) (8).
Results: The median age at diagnosis was 66 years. The male/female ratio was 1.1. HCV antibodies were positive in 3.7% of cases. The 10-year overall survival was 93% (CI: 84.7-100%). Notably, no patient died of disease progression. The 5- and 10-year progression-free survival (PFS) were 77% and 62%, respectively. In univariate analysis, negative predictors of a worse PFS were splenomegaly (>18 cm) and bone marrow infiltration (>30%). Patients with a low Arcaini score had a better 5-year PFS (87%) than those with an intermediate (76%) or high (44%) risk score (P value=0.01). Fifty asymptomatic patients underwent a W&W program. The median PFS of this population was 45 months; at 10 years, 17% of patients are still on W&W (Figure 1). Sixty-five patients, either at diagnosis or after a W&W period, were treated; those treated with splenectomy or R-chemo first line had similar results, while those treated only with chemo had an inferior outcome. However, when analyzing separately patients with a score<1, splenectomy alone resulted in a highly significant PFS advantage compared to the other treatment approaches (Figure 2).

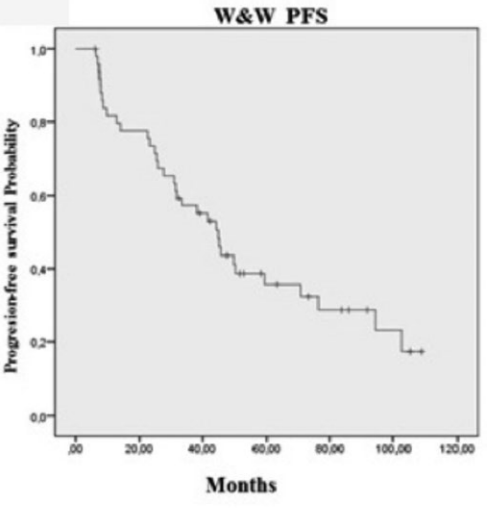

Figure 1.

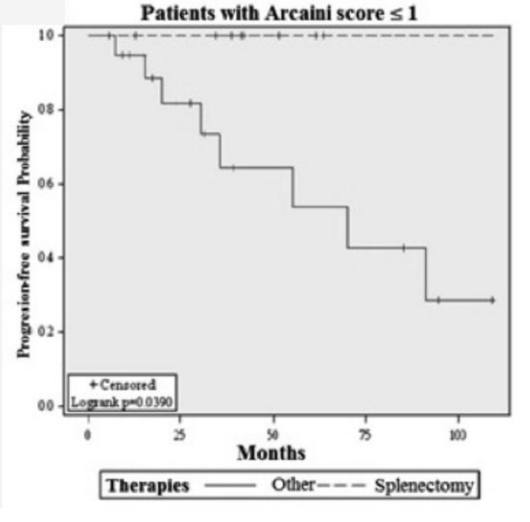

Figure 2.

Summary and Conclusions: This real-life single center study offers an insight into the natural history of indolent SMZL, confirming its very good prognosis. We found a negative prognostic impact of a marked splenomegaly and marrow infiltration. At variance from previous reports, we did not observe a high prevalence of HCV, especially as this is a Center/South-Italian case series. Moreover, we confirm that Arcaini's staging system, that defines 3 separate risk groups, is a powerful prognostic stratificator. The W&W approach allows a median PFS of 45 months, longer than that reported in follicular lymphoma patients. Finally, our data confirm the inferiority of chemotherapy alone against splenectomy and R-chemo. The subgroup of low risk patients treated only with splenectomy fared very well. For such patients, splenectomy could remain the best first-line approach even in the rituximab era. Prospective studies are needed to confirm these results.

PB1786

SINGLE-AGENT IBRUTINIB DEMONSTRATES LONG-TERM ACTIVITY AND SAFETY IN PATIENTS WITH RELAPSED/REFRACTORY WALDENSTRÖM'S MACROGLOBULINEMIA

R. R. Furman[1,*] E. Bilotti[2], T. Graef[2]
[1]Division of Hematology and Medical Oncology, Weill Cornell Medical College,

New York City, [2]Pharmacyclics, Inc., Sunnyvale, United States

Background: Bruton's tyrosine kinase (BTK) is an essential component of the B-cell receptor pathway and functions via the activation of downstream signals mediating B-cell growth, adhesion, and survival. Ibrutinib, a first-in-class, once-daily, oral, covalent inhibitor of BTK, has emerged as an attractive treatment option for patients with Waldenström's macroglobulinemia (WM). Recently, ibrutinib was approved by the FDA for the treatment of WM, representing the first FDA-approved agent in WM. The first-in-human trial of ibrutinib was an open-label, phase 1 study in patients with relapsed/refractory (R/R) B-cell malignancies including WM (Advani, *J Clin Oncol*. 2013) and demonstrated encouraging activity of ibrutinib (75% overall response rate) in WM, thus initiating further studies.
Aims: To report long-term activity and safety outcomes of ibrutinib in 4 patients with R/R WM who enrolled in this phase 1 study and then continued into an extension study.
Methods: All patients provided written informed consent before enrollment. Four patients with R/R, histologically confirmed WM and adequate hematologic, renal, and hepatic function received oral ibrutinib between 560 mg/day and 12.5 mg/kg/day until progressive disease or unacceptable toxicity. Patients were required to have IgM levels ≥1000 mg/dL with bone marrow infiltration. After 6 months of therapy, patients with objective response or stable disease were rolled over from the parent study (PCYC-04753) into the extension study (PCYC-1103-CA) at a fixed dose of ibrutinib 560 mg daily. Adverse events (AEs) were assessed by NCI CTCAE v3.0. In the 1103 study, only data on AEs grade ≥3, serious AEs (SAEs), and AEs leading to dose modification or discontinuation were captured. Disease response assessments included laboratory assessments (serum IgM) and radiographic imaging when applicable. Best clinical response was assessed per the 3rd International Workshop of WM (IWWM).
Results: Three of 4 WM patients achieved durable partial responses accompanied by ≥50% reductions from baseline in IgM levels (~80% to 90%), which reached a plateau after 1 year of therapy. Responses are ongoing after 4 years of therapy with no evidence of progression in other clinical features attributed to WM. Additional clinical improvements included sustained increases or stabilization in hemoglobin levels (without the use of erythropoietic growth factors or transfusion); reduction in lymphadenopathy (present in 3 of 4 patients at baseline); and improvement in hematocrit over time. Grade 3/4 AEs included neutropenia (1 patient) and thrombocytopenia (1 patient), and SAEs included febrile neutropenia (2 patients), pneumonia and pneumonitis (1 patient), and atrial fibrillation (1 patient). In addition, the same patient experienced a second episode of grade 2 atrial fibrillation (not an SAE), leading to dose modification to ibrutinib 420 mg daily. All grade 3/4 AEs and SAEs were resolved without sequelae and were assessed by the investigator as unrelated to ibrutinib.
Summary and Conclusions: This case series is the first to demonstrate extended activity and tolerability of ibrutinib in R/R WM, accompanied by early and rapid decline in IgM levels and increase in hemoglobin levels. Single-agent ibrutinib induced profound and durable responses, with a favorable safety profile, in this difficult-to-treat patient population—consistent with findings of a phase 2 trial (Treon, IWWM, 2014).

PB1787

BENDAMUSTINE IN ELDERLY PATIENTS WITH INDOLENT NON-HODGKIN'S LYMPHOMA: A REPORTED EXPERIENCE IN ROUTINE PRACTICE ON 76 PATIENTS

A. Razurel[1,*] S. Amorin[2], M. Tiv[3], M. Zine[2], L. Biard[3], S. Harel[2], P. Brice[3], I. Madelaine[1], C. Thieblemont[2]
[1]Pharmacy, [2]hemato-oncology, [3]Biostatistics and Medical Information, Saint-Louis Hospital, Paris, France

Background: The combination of bendamustine and rituximab (RB) has been shown to be an appropriate option for first line treatment or treatment for relapsed / refractory patients (pts) with indolent non-Hodgkin's lymphoma (NHL) and Chronic Lymphocytic Leukemia (CLL).
Aims: The objective of this retrospective study was to compare the toxicities of RB between pts<65y and ≥ 65y among pts with indolent NHL or CLL in relapse.
Methods: Analysis was performed retrospectively on pts treated with RB between January 2009 and December 2013 in relapse. The treatment consisted of rituximab (375 mg/m^2 D1) and bendamustine (90 mg/m^2 D1-2) every 28 days. Fisher and Wilcoxon tests were used, and the probability of adverse event (AE) during cure was compared according to the age in generalized linear mixed models.
Results: Among the 76 pts included, 41 pts (54%) were<65y (median age= 57y, range 33-64), and 35 pts (46%) ≥65y (median age= 74y, range 65-80). In the cohort of pts<65y, 33 pts presented with indolent NHL (24 FL, 6 MZL, 2 SLL, 1 tricholeucocyte), 7 pts CLL, 1 MCL. In pts ≥65y, 26 pts presented with indolent NHL (15 FL, 7 MZL, 3 SLL, 1 Waldenström), 8 pts CLL and 1 MCL. The PS was ≥2 in 18% of pts<65y vs 32% of pts ≥65y, with high LDH in 29% vs 53% of pts. The median number of prior treatments was 4 in<65y and 6 for ≥65y. Fifty-seven (75%) pts received at least 4 cycles of RB and 34 (45%) pts at least 4 cycles, corresponding to 344 cycles overall (179 (52%) in pts<65y and 165 (48%) in pts ≥ 65y). Eighty-six percent of pts had at least one AE during their treatment, wich was G3/4 in 47% of the pts. The occurrence of G1/4 AE per cycle was 51% in the whole cohort without significant difference between age groups (53% and 49%, respectively in pts<65y and pts ≥65y, P=0.65). Among them, AE was noticed grade (G) 3/4 in 50 cycles corresponding to 28 (16%) cycles in pts<65y and 22 (13%) in pts ≥65y (P=0.64). Hematotoxicity was present in 29 pts (70%)<65y and 27 pts (77%) ≥65y. Probability of hematotoxicity per cycle was 20% for<65y and 18% for ≥ 65y (P=0.70). Thrombocytopenia and neutropenia were the most frequent G3/4 hematotoxicity, occurring in 12% and 17% of the pts<65y and pts ≥65y respectively. Nausea affected 34% of pts<65y vs 43% pts ≥65y. Twenty-seven percent of pts<65y and 31% pts ≥65y developed infections. Pulmonary toxicities G1/4 with bronchitis were rare (3% per cycle) but significantly more frequent in pts ≥65y, 5% per cycle compared to pts<65y, 1% per cycle (P<0.036). A dose adjustment was required for 10 pts (24%)<65y related to thrombocytopenia in 7 pts; the same happened to 12 pts (34%) ≥65y, because of thrombocytopenia, deep neutropenia, cutaneous rash G3, maculopapular rash, severe sepsis or digestive disorder. Treatment was discontinued in 13 (32%) pts<65y (4 pancytopenia, 2 thrombocytopenia, neutropenia G4, 1 severe sepsis and 1 pneumonitis) and in 11 (31%) pts ≥65y (4 fever infections (bronchitis), 2 febrile aplasia, 1 cutaneous rash G3, 1 pancytopenia, 1 thrombocytopenia, 1 mucositis G3 and 1 gastrointestinal intolerance) (P=1).
Summary and Conclusions: The toxicities of RB combination and their probabilities do not differ significantly with the age, except for respiratory disorders. Bronchitis G1/2 appears to occur more frequently in pts ≥ 65y. This has to be noticed in the perspective of association of BR with new agents such tyrosine Kinase inhibitors that may increase this risk of pulmonary toxicity in elderly patients.

PB1788

INCIDENCE OF SECONDARY PRIMARY NEOPLASM IN A COHORT OF PATIENTS WITH FOLLICULAR LYMPHOMA. A SINGLE CENTER REPORT

M. M. Andrade Campos[1,*] E. Colorado Ledesma[2], N. Espinosa[3], P. Giraldo[4]
[1]Traslational Research Unit. CIBERER. IIS-A, Hematology. Miguel Servet University Hospital., [2]Hematology, [3]Miguel Servet University Hospital., [4]Traslational Research Unit. CIBERER., IIS-A. FEEHA, Zaragoza, Spain

Background: Follicular lymphoma (FL) account approximately one third of all non-Hodgkin lymphomas, it is know that primary affect males and white population; also is established that any patient diagnosed for a primary cancer have an increased risk to be diagnosed for a second primary neoplasm (SPN), respect to follicular lymphoma there are few reports about a 25% increased risk for all non-Hodgkin lymphomas not related with histologic subtype. Although is recognized that chemotherapy, radiotherapy and radioimmunotherapy (RIT) increased this risk; there are recent reports about the use of radioimmunotherapy with 90Y-Ibritumomab-Tiuxetan (90Y-IT) that show an increased risk for SPN. RIT is available in our center since 2005 and we have been accumulated a long experience. Considering this we analyze our data and compare the incidence of SPN in all patients with FL treated in our institution with different schedules including or not 90Y-IT.
Aims: To analyze the incidence of second primary neoplasm in FL patients diagnosed and treated in our center, searching for relationship with RIT
Methods: A chart review was carried using the registry of diagnosed patients, from the Department of Hematology, all consecutive patients diagnosed of Follicular lymphoma of any grade according to WHO since 2001 were included, a review of clinical records: demographic and clinical data, incidence of previous cancer and therapies, SPN (basocellular skin and *in situ* cervix carcinoma were excluded), number of chemotherapies, relapses, therapy with 90Y-IT, actual status and cause of dead were recorded.
Results: A total of 251 FL patients were registered, Male/female ratio: 107/144, mean age 59.9 years (15-86), Stage I: 7.2%, II: 11.0%, III: 24.1%, IV: 57.8%, FLIPI: Low-risk: 62.15%, Intermedium: 13.9%, High-risk: 10.3%. A 27.8% of patients receiving two or more chemotherapy schedules, 10,5% had underwent an auto-SCT. 100 patients (39.8%) received 90Y-IT (55 as a 2nd or 3rd line of therapy and 45 as a consolidation therapy). The mean follow-up for all patients is 108 months (median 49 m). Respect to incidence of neoplasms we found that 38 (15.1%) patients have a registry of at least 2 primary cancers, in 16 (42.1%) of them FL diagnosis were the second primary neoplasm. In the 22 patients who developed a SPN after FL diagnosis, 11 had been received two or more lines of therapies and 5 of them including RIT.
According to relationship with 90Y-IT, in 3 SPN were diagnosed before the use of RIT and in one at the same time of RIT, and in 8 patients the diagnosis of SPN occur after RIT at a mean time of 32.3 months. For all patients the SPN were recorded at a mean time of 24.5 months after FL diagnosis.
Summary and Conclusions: Even this work is a single institution reports, summarize relevant information outside clinical trials about the incidence of second primary neoplasm in one cohort of follicular lymphoma patients treated (100) or not (151) with 90Y-IT. In our experience 90Y-IT not increase significantly the risk of SPN. A more exhaustive analysis will be presented in case of acceptance.

PB1789

COMBINATION OF FLUDARABINE, MITOXANTRONE, DEXAMETHASONE AND RITUXIMAB (R-FND) IN THE TREATMENT OF INDOLENT NON-HODGKIN B CELL LYMPHOMA-RETROSPECTIVE STUDY OF 60 CHINESE PATIENTS

T. Chan[1,*] G. Harinder Singh[2], H. Yu Yan[1], T. Eric Wai Choi[2], K. Yok Lam[3]
[1]Department of Medicine, [2]Department of Medicine, [3]Medicine, Queen Mary Hospital, Hong Kong, Hong Kong

Background: Indolent non-Hodgkin B cell lymphomas (NHL) are a group of lymphoid malignancies that typically follows a protracted clinical course with frequent relapses. Although it is generally considered incurable, effective treatment regimens exist. The combination of fludarabine, mitoxantrone and dexamethasone (FND) resulted in high complete remission (CR) rate in the pre-rituximab era. Data are scarce on whether the addition of rituximab (R-FND) would result in a better CR rate or longer remission. Moreover, this combination has never been properly evaluated in Chinese patients, a population that reportedly has a much lower prevalence of indolent NHL.
Aims: To determine the efficacy of RFND regimen in indolent lymphomas in Chinese patients
Methods: Consecutive patients who are diagnosed with indolent NHL (follicular lymphoma, marginal zone lymphoma, lymphoplasmacytic lymphoma and low grade B cell lymphoproliferative disease (B-LPD) not otherwise classified) were recruited into this retrospective study from January 2012 to December 2014. The R-FND regimen (Rituximab 375mg/m^2 on D1, Fludarabine 40mg/m^2 daily D1-3, mitoxantrone 10mg/m^2 on D1 and dexamethasone 20mg daily D1-5) was used as frontline treatment in our institution. Baseline demographic data were collected. Response rate and toxicity of the regimen was evaluated. Overall survival and progression free survival was analyzed using Kaplan-Meier method.
Results: Sixty patients (29 men, 31 women) (follicular, N=22; marginal zone lymphoma, N=27; lymphoplasmacytic lymphoma, N=4; B-LPD not otherwise classified, N=7) at a median age of 61 years were treated, with R-FND given as frontline therapy in 50 patients and salvage therapy in 10 patients. Stage III/IV disease occurred in the majority of the cases (N=42, 70%). The median follow up time was 23 months. Complete remission (CR) was achieved in 49 out of 59 evaluated patients (83.1%), and partial remission (PR) in 8 patients (13.6%), giving an overall response rate (ORR) of 96.7%. The response was also durable, with a progression free survival at 2 years of 81.3%. The overall survival at 2 years was 93.4%. Haematological toxicities were the most common adverse effects, with grade III/IV anaemia, neutropenia and thrombocytopenia being 10%, 88% and 17% respectively. Clinically significant cytomegalovirus (CMV) reactivation occurred in 8 patients (13%) with 2 of them developing CMV retinitis.
Summary and Conclusions: R-FND is a highly effective regimen with high CR rate and long duration of remission. However, due care should be taken with respect to haematological toxicity.

PB1790

A MULTICENTER, RETROSPECTIVE ANALYSIS OF LOW-GRADE PRIMARY FOLLICULAR LYMPHOMA OF THE GASTROINTESTINAL TRACT: TREATMENT AND OUTCOME

J.Y. Lee[1,*] H. Cho[1], J.W. Cheong[1], Y.H. Min[1], S.I. Lee[2], C. Suh[3], Y. Park[4], D.H. Yang[5], J.S. Kim[1]
[1]Internal medicine, Severance hospital, Seoul, [2]Internal medicine, Dankook University College of Medicine, Cheonan, [3]Oncology, University of Ulsan College of Medicine, Asan Medical Center, [4]Internal medicine, Korea University College of Medicine, Seoul, [5]Hematology-Oncology, Chonnam National University Hwasun Hospital, Hwasun, Jeollanam-do, Korea, Republic Of

Background: Primary gastrointestinal (GI) follicular lymphoma (FL) has been regarded as a relatively rare malignant disease, accounting for 1-3.6% of primary non-Hodgkin lymphomas of the GI tract. The primary FL of the GI tract occurs most often in middle-aged adults with a 2:1 female predominance. The most frequent primary occurrence location is duodenum. The low-grade primary FL of the GI tract which is especially located at duodenum characterized as an indolent. Although the various therapeutic strategies have been developed for FL, there is no definite guideline for the treatment of low-grade primary FL of the GI tract.
Aims: In this study, we analyzed our experience of low-grade primary FL of the GI tract according to the treatments.
Methods: A total of 12 patients who diagnosed as a low-grade primary FL of the GI tract between June 2005 and June 2014 from 5 institutions in Korea were retrospectively analyzed. Low-grade primary FL of the GI tract was defined as Lugano stage I or II and WHO histologic grade 1 or 2. Endoscopy and immunohistochemical pathologic work-up were performed at diagnosis. The patients were classified according to the treatment strategies such as watch & wait group (n=4) and treatment group (n=8). Treatments included various chemotherapies (CTx) and radiotherapy (RTx).
Results: Median age was 44 years (range, 33-66) and a female predominance was observed (male:female=4:8). All patients had an Eastern Cooperative Oncology Group (ECOG) performance score of 0 or 1. The most common reason for initial evaluations of primary FL of the GI tract was health screening (n=10, 83.3%). Only two patients received initial evaluations due to GI symptoms. The small intestine, especially the 2nd or 3rd portion of duodenum was the most common primary site of involvement (n=8, 66.6%). There were similar clinical characteristics between the two groups. Exceptionally, white blood cell (WBC) count (P=0.024) at diagnosis was higher in the treatment group. The primary site of involvement was not different between the two groups. However, the only primary site of the watch & wait group was duodenum (n=4, 100%). In the watch & wait group, the maintenance of stable disease status was observed in all patients. However, one patient in the watch & wait group eventually received additional RTx after the initial observational period of 19.4 months according to the decision of the attending physician. In the treatment group, two patients received CTx such as CVP (cyclophosphamide, vincristine and prednisone, n=1) or CHOP (cyclophosphamide, doxorubicin, vincristine and prednisone, n=1) and six patients received RTx (median 3600 cGy, range, 2520-4140). These eight patients in the treatment group achieved complete remission (CR) after treatment, but one patient with low-grade primary FL of the rectum who received 6th cycles of CVP CTx relapsed at 30.5 months after achieving 1st CR. She received 4 cycles of weekly rituximab monotherapy and re-achieved CR. After a median follow-up of 33.1 months (range, 3.6 to 107.7 months), all 12 patients were alive.

Table 1. Clinical characteristics of primary follicular lymphoma of the GI tract.

Characteristics	Watch & Wait group	Treatment group	All patients	*P. value*
No. of patients, n (%)	4 (33.3%)	8 (66.7%)	12 (100%)	
Age, median (range), years	48 (46-54)	42 (33-66)	44 (33-66)	*0.471*
Gender, Male/Female, n (%)	1 (25.0%)/3 (75.0%)	3 (27.5%)/5 (62.5%)	4 (33.3%)/8 (66.7%)	*0.594*
WBC x 10^9/L, median (range)	5.61 (5.2-6.93)	6.90 (5.82-9.33)	6.80 (5.20-9.33)	*0.024*
Primary location of involvement				*0.460*
Duodenum, n (%)	4 (100%)	4 (50.0%)	8 (66.6%)	
Rectum, n (%)	0 (0%)	3 (27.5%)	3 (25.0%)	
Ampulla of vater, n (%)	0 (0%)	1 (12.5%)	1 (8.4%)	
Ann Arbor stage, IEA/IIEA, n (%)	4 (100%)/0 (0%)	7 (87.5%)/1 (12.5%)	11 (91.7%)/1 (8.3%)	*0.667*
Lugano stage, I/II, n (%)	4 (100%)/0 (0%)	7 (87.5%)/1 (12.5%)	11 (91.7%)/1 (8.3%)	*0.667*
1st line treatment				*0.002*
Watch & Wait, n (%)	4 (100%)	0 (0%)	4 (33.3%)	
Chemotherapy, n (%)	0 (0%)	2 (25.0%)	2 (16.7%)	
Radiotherapy, n (%)	0 (0%)	6 (75.0%)	6 (50.0%)	
Final follow-up status, CR/SD, n (%)	1 (25.0%)/3 (75.0%)	8 (100%)/0 (0%)	9 (75.0%)/3 (25.0%)	
Overall survival, median (range), months	13.5 (3.6-21.3)	46.6 (16.0-107.6)	33.1 (3.6-107.7)	

Summary and Conclusions: In this study, we confirmed that the watch & wait strategy was safe in low-grade primary FL of duodenum. In addition, radiation alone also was an appropriate strategy for the low-grade primary FL of the GI tract. However, close monitoring would be necessary for the patients with non-duodenal site of the low-grade primary FL. Further studies with more patients would be needed to confirm appropriate treatment strategies for the low-grade primary FL of the GI tract.

PB1791

RITUXIMAB INDUCES HYPOGAMMAGLOBULINEMIA IN PATIENTS WITH NON HODGKIN LYMPHOMA

R. Della Pepa[1,*] A. De Renzo[1], A. Pecoraro[2], S. Luponio[1], G. Giagnuolo[1], G. Beneduce[1], I. Migliaccio[1], M. Raimondo[1], N. Pugliese[1], D. Salvatore[1], C. Cimmino[1], F. Pane[1], G. Spadaro[2]
[1]Hematology, [2]Medical Translational Science, Federico II University, Naples, Italy

Background: Rituximab (R) is a monoclonal antibody that binds the CD20 antigen on all peripheral B cells. Its favorable toxicity profile and effectiveness have led to its wide use in induction and maintenance regimens for Non Hodgkin Lymphoma (NHL).
Aims: This retrospective single center study aimed to evaluate the hypogammaglobulinemia (hypoIg) associated with R use.
Methods: We performed serial quantitative serum immunoglobulin (SIg) concentration at the baseline, after chemotherapy, during and after R maintenance therapy.
IgG, IgA and IgM deficit were respectively defined by level below 700 mg/dL, 70 mg/dL and 40 mg/dL. Symptomatic patients were defined as having 2 or more non-neutropenic infections in a 6-month period after or during R.
Results: 123 patients with indolent NHL and SIgG studies were analyzed, 47,1% were relapsed or refractory. The median age of patients was 60 years (range: 28-80). The histologies included follicular lymphoma (FL) (n=77), small lymphocytic lymphoma (SLL) (n=14), marginal zone lymphoma (ML) (n=20), mantle cell lymphoma (MCL) (n=12). Patients received a median of 13 doses of R (range: 6-27). The median follow-up of surviving patients was 4,4 years. Before treatment with R, 11/123 (8,9%) had low SIgG levels (5 FL, 1 MCL, 4 SLL, 1ML) and 3/11 (27,2%) required, during R maintenance treatment, Intravenous Immunoglobulin (IVIG) administration. After R-chemotherapy, IgG deficiency appeared in 29/123 (28,4%), 2/29 needed IVIG. After or during R maintenance 25/123 (20,3%) showed IgG deficiency after a median of 9 R cumulative doses; the deficit occurred in the 80% (20/25) within the fourth R maintenance dose and in no one after the sixth R administration. In this category, 10/25 (40%) were symptomatic and 4/25 (16%) required IVIG. All 10 patients who needed IVIG showed at least two Ig isotypes deficiency.
Summary and Conclusions: We observed that R administration was associated with a high risk of hypoIg. In addition, we found that the number of R doses

correlated to the development of symptomatic hypoIg. Finally we observed that the risk of hypoIg increased in patients who received maintenance R. The decision to introduce therapy with IVIG in non-neutropenic patients was related to repeated episodes of infection. HypoIg often is underestimated also for the presence of confounding symptoms. Our study suggests that the baseline and periodic Ig monitoring should be considered in these patients subset.

PB1792

LONG TERM OUTCOME OF PATIENTS WITH GASTRIC MARGINAL ZONE LYMPHOMA RECEIVING FLUDARABINE, MITOXANTRONE AND RITUXIMAB AS FIRST-LINE TREATMENT

E. Cencini[1,2,*] A. Fabbri[2], G. Bartalucci[2], L. Schiattone[2], A. Gozzetti[2], F. Lauria[1], M. Bocchia[1,2]
[1]Hematology, University of Siena, [2]Hematology, Azienda ospedaliera universitaria senese, Siena, Italy

Background: Gastric mucosa-associated lymphoid tissue (MALT) B-cell lymphoma represents the most frequent localization of extranodal marginal-zone lymphoma (MZL), characterized by a well established association with *Helicobacter pylori* (HP) infection. The first-line treatment for HP positive patients is HP eradication therapy; however, there is no consensus on the standard management for patients with HP negative or persistent disease after HP eradication. Current approaches include radiation therapy, chemotherapy and immunotherapy with rituximab, either alone or in combination. Despite the activity of many alkylating agents and nucleoside analogues against MALT lymphoma, evidence about the superiority of a specific regimen toward others is still lacking.
Aims: in this study we have investigated long-term efficacy and safety of fludarabine and mitoxantrone in association with rituximab (R-FM) as first-line treatment for gastric MALT lymphoma with HP negative or persistent disease after HP eradication.
Methods: A cohort of 13 patients (M/F: 5/8; median age 65 yrs) diagnosed with gastric MALT lymphoma by gastroscopy biopsies and treated between August 2005 and March 2012 was retrospectively analyzed. All patients completed staging with whole body CT scan and bone marrow (BM) biopsy. Five patients had stage I disease, 7 stage II and 1 stage IV, HP was positive in 9/13 patients. Induction treatment consisted of fludarabine (25mg/m^2 i.v. on days 2 to 4), mitoxantrone (10mg/m^2 i.v. on day 2) and rituximab (375 mg/m^2 i.v. on day 1), administered for up to 6 cycles every 28 days. Final response assessment including esophagogastroduodenoscopy with random biopsies and CT scan was done 4-6 weeks after completion of therapy according to the 2007 Revised Response Criteria. During follow-up period CT scan was performed together with esophagogastroduodenoscopy every 6 months for the first 2 years (annually for stage I patients). Thereafter, endoscopy was performed annually until the 5th year, after this period the patients continued only clinical follow-up.
Results: All patients (13/13, 100%) achieved a complete remission (CR), a median of 4 cycles (range 3-6) of R-FM were given and all were evaluable for response and toxicity. Treatment-related toxicities were mainly hematologic, with grade 3-4 neutropenia observed in 11/13 patients (84.6%), grade 2 thrombocytopenia and anemia in 1 and 2 patients, respectively. All but one cases required secondary neutropenia prophylaxis with filgrastim, 1 patient had grade 3 febrile neutropenia. The same patient was hospitalized while on treatment because of non-neutropenic fever with detection of Candida Albicans by stool culture; 2 months later experienced CMV reactivation, too. Two patients developed prolonged pancytopenia, with slow recovery after about 12 months. Grade II nausea was documented in 4/13 patients, no other adverse events occurred. After a median follow-up of 60 months (range 24-110) all patients were alive, 1/13 had disease relapse after 8 months and received total gastrectomy; estimated 9-year progression-free survival and overall survival were 92.4% (Figure 1) and 100%, respectively.

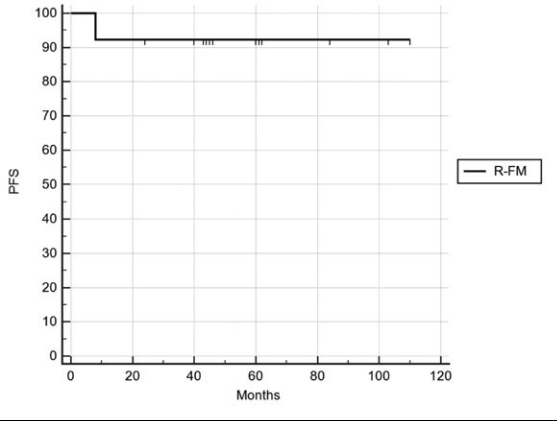

Figure 1.

Summary and Conclusions: This small series of homogeneously treated patients suggests R-FM regimen has a high long-term efficacy as frontline treatment for gastric MALT lymphoma. However, the high incidence of grade 3-4 hematological toxicity makes this treatment less safe compared to the previously published results of other regimens such as rituximab in combination with chlorambucil or bendamustine. It could remain a suitable option for patients with advanced-stage disease, while exluding stage I.

PB1793

THE ROLE OF FLOW CYTOMETRY IN THE DIAGNOSIS AND FOLLOW UP OF GASTRIC LNH

S. Luponio[1,*] A. De Renzo[1], M. Romano[2], A. Miranda[2], D. Sgambato[2], M. Raia[3], G. Scalia[3], R. Della Pepa[1], F. Pane[1], L. Del Vecchio[3]
[1]Division of hematology, university Federico II, [2]Department of Clinical and Experimental Internal Medicine, AOU, SUN, [3]Biotecnologie Avanzate, CEINGE, Naples, Italy

Background: The diagnosis of lymphoma is mainly based on morphology, but the diagnostic accuracy is greatly increased by the use of ancillary techniques like immunophenotyping, citogenetic and molecular tests. This multiparametric approach is recommended by WHO classification.
Aims: To evaluate the role of flow cytometry in the study of gastric biopsies with suspect of NHL. We have assessed the validity of integration of histological and cytometric assays to optimize diagnosis of lymphoproliferative diseases and to lower the number of inconclusive cases at histological exam. The aim of flow cytometry was to define lineage and clonality of lymphoid proliferation, thus giving a support to final assessment.
Methods: 27 patients with primary gastric lymphoma underwent, from January 2007 to June 2010, to double gastric biopsy at diagnosis or during follow up. Diagnosis was MALT in 15/27 (56%), DLBCL in 8/27 (30%) and other histological type in 4/27 (14%). Every patient underwent complete staging and the stage was I/E in 12/27 and II/E in 15/27. Therapy was antibiotic eradication of HP in 5/27 and chemo-immunotherapy in accordance with guidelines. Samples for histology were fixed with formalin and stained with HE, then tested by antibodies for CD3, CD5, CD10, CD20, CD21, CD23, CD30, CD38, CD43, CD45RO, CD79a, CiclinaD1, BCL-2, BCL-6, Ki67, EMA, κ e λ. Samples for flow cytometry were put in saline, sent to laboratory within thirty minutes and processed with standard methods. A cytometric pattern was defined as pathological if there was an evident atypical assempbly of B or T lymphoid antigens along with clonal restriction for Ig light chains or TCRVβ repertoire.
Results: We have carried out 36 biopsies in a population of 27 patients and we obtained a final diagnosis in all cases. Diagnosis was: NHL in 9/36 (8 MALT and 1 follicular lymphoma), plasmacytoma in 1/36, and benign conditions in the remaining 26/36. In all cases there was strict concordance between the two methods, but in one single cases positivity of flow cytometry led to histological revision and, finally, to full concordance.
Summary and Conclusions: This study demonstrated that flow cytometry is an easy and reliable diagnostic tool for gastric lymphoma: assumed that its goal is to assess lineage and clonality, it is fast, sensitive and specific. It is synergistic to histology, especially in difficult cases like biopsy performed during a revaluation after chemotherapy or antibiotic therapy, or reactive conditions where lymphoid infiltrates can mimic lymphoma. Histological diagnosis certainly remains the gold standard for lymphoma diagnosis but flow cytometric typing can usefully support histology to reach a correct diagnosis in 100% of cases.

PB1794

IMPROVED DETECTION OF CHLAMYDOPHILA PSITTACI DNA IN OCULAR ADNEXAL MALT LYMPHOMA WITH PCR OPTIMIZATION

C. Yoo[1,*] D.H. Yoon[1], J. Choi[2], Y.S. Park[2], C. Suh[1]
[1]Oncology, [2]Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: The pathogenic association between *Chlamydophila psittaci* (*Cp*) infection and ocular adnexal MALT lymphoma (OAML) has been suggested, but large geographic variation (0-87%) has been reported in the prevalence of Cp infection in patients with OAML. Although its cause has not been elucidated fully, this geographic discrepancy may be in part due to the methodological biases or suboptimal PCR.
Aims: Therefore, we examined the detection rates for *Cp* DNA in patients with OAML according to the different PCR condition.
Methods: Six OAML patients diagnosed between April 8, 2014 and August 11, 2014 were included in this study. DNA was extracted from paraffin-embedded tissues and touchdown enzyme time release (TETR)-PCR was performed to identify *Cp* DNA as previously reported (Madico *et al.*, J Clin Microbiol 2000;38:1085-93). Then, we performed TETR-PCR with modified annealing temperature (beginning at 67C vs 62C in original protocol) using same extracted DNA samples.
Results: Four (67%) patients were male and median age was 50 years (range, 41-77 years). The primary site of OAML was conjunctiva in 4 (67%) patients

and orbital soft tissue in 2 (33%) patients. At presentation, each 3 (50%) patients were diagnosed as stage I and IV, respectively. In initial TETR-PCR according to the original protocol, *Cp* DNA was detected in none of 6 patients. When TETR-PCR was performed with modification of annealing temperature, Cp DNA was identified in 4 (67%) patients. Direct sequencing could be performed in 3 of 4 positive cases, and specificity of amplified fragments was confirmed.
Summary and Conclusions: PCR optimization with modification of annealing temperature could improve the detection of *Cp* DNA in patients with OAML. Future prospective validation in a larger sample size is necessary.

PB1795

SYMPTOMATIC BONE INVOLVEMENT IN WALDENSTROMS MACROGLOBULINAEMIA

S. D'Sa[1,*] K. Rajesparan[2], J. Kothari[3], C. Yeomans[1], W.K. Wong[4], C. House[2]
[1]Cancer Division, [2]Radiology, UCLH NHS Foundation Trust, London, [3]Haematology, Oxford University Hospitals, Oxford, [4]Haematology, UCLH NHS Foundation Trust, London, United Kingdom

Background: Bone involvement by Waldenstroms macroglobulinaemia (WM) is very uncommon. The presence of bony lesions may point towards possible high-grade transformation, or the diagnosis of a different IgM paraprotein-producing disorder (*e.g.* IgM myeloma).
Aims: We describe symptomatic skeletal involvement in 4 cases of previously diagnosed WM patients and evaluate the diagnostic value of bone biopsy to allow tailored management decisions to be made.
Methods: Four patients with WM were evaluated when they developed progressive bony pain, using MRI, PET-CT and bone biopsy. An image-guided biopsy of affected bone was performed in each case and the results were correlated with their bone marrow histology and other clinical and laboratory data. Patient characteristics are shown below:

Table 1.

Patient ID	Age/ Sex	IPSSWM	ECOG	Isotype	Genetics	Time from diagnosis	Prior therapy
A	53/M	1	0	IgMk	N/A	New diagnosis	None
B	60/M	2	1	IgMk	N/A	2 years	DRC x 6 to VGPR
C	57/F	2	1	IgMk	L265P Glu343Valfs*2	1 year	DRC x 6 to MR
D	44/F	2	0	IgGK	L265P	3 years	DRC x 6 to PR

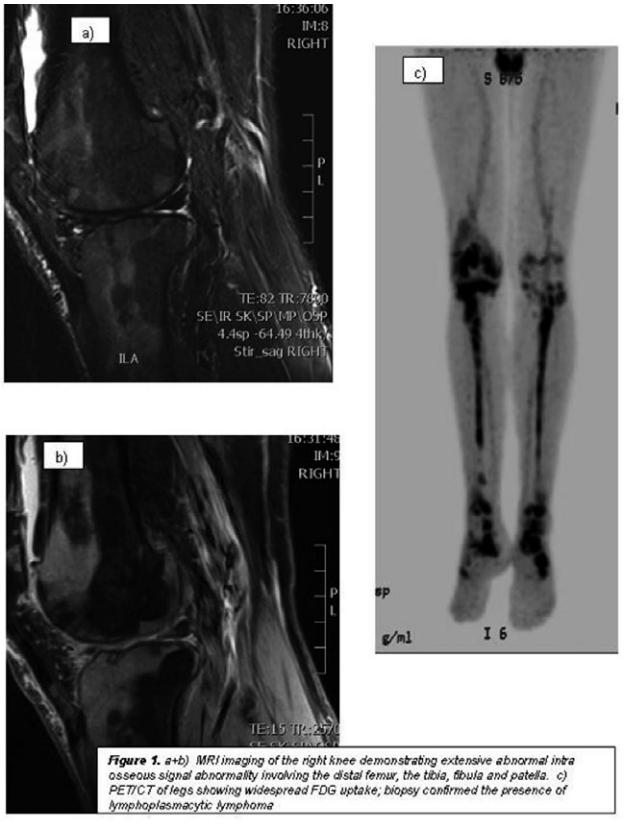

Figure 1. *a+b) MRI imaging of the right knee demonstrating extensive abnormal intra osseous signal abnormality involving the distal femur, the tibia, fibula and patella. c) PET/CT of legs showing widespread FDG uptake; biopsy confirmed the presence of lymphoplasmacytic lymphoma*

Figure 1.

Results: In all cases, patients were investigated due to unrelenting bone or joint pains, including shoulder & upper arm (24 months); knee (6 months); ankle and lower limb (6 months); knees (8 months) with limitation of movement and/or joint swelling. The bone disease was evident at the outset, at 12, 18 and 38 months from diagnosis respectively; 1 patient had newly diagnosed WM needing treatment, 2 had evidence of progressive disease 6 and 14 months post last treatment and the 4th patient had achieved a minor response to therapy at the time of bone disease. MRI scans demonstrated abnormal intraosseous signal characteristics in the affected bones in all cases which enhanced with contrast and showed low signal intensity on the T1 weighted sequences and areas of high signal intensity on the T2 weighted sequences. PET-CT scans were performed in 3 cases and showed patchy diffuse uptake correspomding with MRI signal abnormality in 2 cases, but no focal tracer uptake in the third case. There was no evidence of osteolysis on the CT component. Biopsy of affected bones demonstrated a heavy infiltrate (70-90%) of lymphoplasmacytic lymphoma with identical characteristics to the iliac crest biopsy. In all cases, the bones were diffusely infiltrated by CD20+ cells, with a scattering of CD138+ cells. There was no evidence of transformation to high grade disease in any case. Blood work showed a median Hb of 120 g/L, median platelets 270x 10^9/L, median M-protein of 17 g/L (range 5-22 g/L), raised alkaline phosphatase and LDH in 1 patient, and normocalcaemia in all. All 4 went on to receive chemoimmunotherapy (patient A also had radiotherapy to the humerus) which improved the bone symptoms in 2, but too early to assess in 2, and are alive with a median follow up is 7 months (range 1-20).
Summary and Conclusions: In our cohort of 4 patients who developed symptomatic bone disease there was appendicular skeletal infiltration by lymphoplasmacytic lymphoma; the possibility of skeletal disease in WM should be considered patients with bone or joint pain and the significance of bone disease in WM deserves further characterisation. Image-guided bone biopsy helps to confirm the diagnosis and rule out transformation to high grade lymphoma or an alternative diagnosis of IgM myeloma.

PB1796

BORID REGIMEN IN PATIENTS WITH MANTLE CELL LYMPHOMA

I. Erdogan[1], A. E. Eskazan[1,*] D. Cuhadar Ercelebi[2], S. Berk[1], F.F. Yalniz[1], T. Elverdi[1], A. Salihoglu[1], M.C. Ar[1], S. Ongoren Aydin[1], Z. Baslar[1], Y. Aydin[1], N. Tuzuner[3], T. Soysal[1],
[1]Department of Internal Medicine, Division of Hematology, [2]Department of Internal Medicine, [3]Department of Pathology, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Mantle cell lymphoma (MCL) is seen in predominantly elderly and male patients, and responsive to chemotherapy but usually remission periods are short. There is no standart treatment regimen but addition of rituximab to treatment protocols increased response rates. Bortezomib has been shown to have synergistic effect with rituximab and alternative combination regimens [eg. BORID (bortezomib-rituximab-dexamethasone)] have been implemented.
Aims: To evaluate the effect of BORID regimen to prognosis and survival in MCL.
Methods: We investigated 15 patients diagnosed MCL between 2001-2014 in our clinic and treated with BORID regimen during follow up because of relapsed disease. Demographic data collected from patient files retrospectively.

Table 1.

Rs: Response to treatment; PFS: Progression free survival; PR: Partial remission; CR: Complete remission; N: Non-responsive;

R: Rituximab; Len: Lenalidomide; Cyc: Cyclophosphamide; Chlr: Chlorambucil; B: Bendamustin; ARA-C: Cytosine arabinoside; ASCT: Autologous Stem Cell Transplantation; OS: Overall survival, Ib: Ibrutinib; RT: Radiotheraphy; R main: Rituximab maintenance

Results: 73% of patients were male, and the median age was 65 years (range, 46-73 years). All of the patients were in advanced stage (III-IV) at diagnosis and according to MIPI score all patients were high risk. Mean hemoglobin level was 10.7 g/dL (range, 6.2-14.8 g/dL). Mean leukocyte and lymphocyte counts were 8.900x 10^9/L (range, 2.79-561 x 10^9/L) and 2.2 x 10^9/L (0.7-522 x 10^9/L), respectively. LDH was normal in seven (47%) patients and high in 8. Ki-67 index was examined in 9 patients, and it was >%50 in 3. Median number of treatments prior to BORID was 2 (range, 1-5) and median BORID cycle was 3 (range, 1-6). Treatment regimens are listed in Table 1. BORID was discontinued after first cycle in 3 patients (20%) because of side effects; 1 patient had tumor lysis syndrome, 1 had elevated liver enzymes and 1 grade 4 polyneuropathy. Response rates for BORID were as follows: 1 patient was non-responsive and lost the follow-up after two cycles, 1 patient was partial responsive after 6 cycles and she received 12 courses of BORID totally, after all she had complete response. 1 patient lost the follow up after 3 cycles, 1 had tumour lysis syndrome and died after first course of BORID, 1 patient had progression and CNS involvement after 3 cycles, 1 patient had hepatotoxicity and lost the follow-up after first course, 2 patients had partial remission, 6 patients were non-responsive and one of them died because of pneumosepsis after second course of BORID, 1 patient had grade 4 polyneuropathy after first cycle but she remained progression free for 23 months. 4 patients received SCT (3 autologous, 1 autologous and allogeneic), and median survival was 41 months (range, 7-152 months).

Summary and Conclusions: Cure in MCL is not possible with current treatment strategies. Combination of bortezomib and rituximab may be appropriate treatment regimen in relapsed MCL especially for patients who are not candidate for SCT or with comorbidities, but to evaluate the efficacy and toxicity of BORID in relapsed MCL prospective studies are needed.

Infectious diseases, supportive care

PB1797

THE MANAGEMENT OF INVASIVE FUNGAL INFECTION WITH POSACONAZOLE ORAL SUSPENSION MAINTENANCE TREATMENT FOLLOWING INTRAVENOUS ANTIFUNGAL REGIMENS IN ROUTINE UK CLINICAL PRACTICE (MAINTAIN)

H. Ahir[1], C. Craddock[2,*]N. Duncan[3], C. Loughran[4], D. Cooper[5]
[1]Market Access, Merck Sharp & Dohme Limited, Hoddesdon, [2]Haemato-oncology, [3]Queen Elizabeth Hospital, Birmingham, [4]University Hospitals Leicester, Leicester, [5]Merck Sharp & Dohme Limited, Hoddesdon, United Kingdom

Background: There are limited data on the use of posaconazole oral suspension (POS) as a maintenance treatment for invasive fungal infection (IFI) following initial treatment with an intravenous (IV) antifungal agent/s.
Aims: To describe a population of patients who received POS following previous IV antifungal treatment for possible, probable, or proven IFI and describe the IV antifungal agents prescribed in those patients, prior to POS, the rationale for initiating POS maintenance therapy, and the dose and duration of POS received.
Methods: A retrospective analysis of 25 consecutive eligible adult patients who received oral POS following IV antifungal treatment was conducted in three hematology centers in the UK. Study data were obtained from hospital records, including patient case notes and hospital administrative and clinical databases. Data is presented as descriptive statistics.
Results: *Description of patient population:* The patient population reported in this analysis comprises 25 adults with a median age of 54 years (interquartile range [IQR]: 43-61 years), of whom 15 were male and 22 were defined as White British. The most common primary diagnosis was acute myeloid leukaemia (n=13). 7 patients had a previous IFI prior to the case under review; 7 had documented long-term immunosuppression, and 17 patients were stem cell transplant recipients. *Antifungal treatment:* 12 out of 25 patients received prophylaxis prior to this episode of IFI. All patients were given IV antifungal treatment prior to the initiation of oral POS maintenance treatment. The two most commonly prescribed IV antifungal treatments prior to POS initiation were either caspofungin or liposomal amphotericin B. The most common reasons for treatment initiation were; persistent temperature and suspicious CT result. For the majority of the patients who were subsequently prescribed POS the center attributed rationale for doing so, was to “facilitate hospital discharge” (n=16). All 25 patients received POS at the normal recommended dose; of the 19 patients with a recorded stop date, the median duration of POS therapy was 27 days (IQR: 15-87.5 days). Table 1 shows the mean number of diagnostic and monitoring tests of those patients that had the specified test.
Summary and Conclusions: This analysis suggests that in a UK patient population diagnosed with hematological malignancy and receiving treatment for an IFI, POS is frequently used following iv therapy, as a step-down treatment. Physicians most frequently stated that this treatment decision was to allow the early discharge of patients from hospital. The sample size although relatively small, has similar demographics to already published data. Use of POS, by allowing the discontinuation of iv therapy, may reduce the burden on hospital resources and may deliver considerable cost savings to the NHS by decreasing length of stay. Furthermore, other benefits may include allowing patients to receive treatment at home, in their preferred environment, where appropriate and also reduce the risk of nosocomial infections.

PB1798

IMMUNOLOGICAL MEMORY OF HEPATITIS B VACCINE IN CHILDREN WITH CANCER

M. Zakaria[1,*] A. Al Alakhras[1], M. Atfy[1], M. Al Amin[2], N. Abdallah[1]
[1]pediatrics, [2]Clinical pathology, zagazig university, zagazig, Egypt

Background: Children with cancer are at risk of severe infections especially who have not completed their primary immunizations. Immune competence decreases not only due to chemotherapy-induced neutropenia, but also due to the reduction of serum antibody titers gained from previous immunizations. Hepatitis B infection in cancer patients occurs as a result of recurrent blood transfusions and also due to suppressed immune system. The national immunization program plays an important role in decreasing subsequent hepatitis B infection in children with cancer, however, the efficacy of the immunization strategies employed is questionable.
Aims: We aimed at evaluating the acquired immunity from the routine hepatitis B vaccination in cancer patients after recovery of their immune system.
Methods: case control study was conducted on 22 patients with cancer(13 males,9 females, mean age 7.2±3.14 years) who were registered in and followed up at pediatric oncology unit of Zagazig university hospital and who completed their standard chemotherapy at least 6 months prior to the study. Twenty two age and sex matched healthy children were enrolled as a control group. Data abstraction form was designed to capture the appropriate information

from the individual medical records including full clinical, transfusion and laboratory data.. HBsAb and HBcAb concentrations were determined in the patients and healthy subjects serum by ELISA. HBs AB titer >10 mIU/mL was considered as baseline protective titer for preventing HBV infection.
Results: The frequency of non immune subjects in children with cancer was significantly higher than those in healthy children (P-value=0.001),where anti-HBs antibody titer was more than 10 mIU/mL in 54.5% of patients and less than 10 mIU/mL in 45.5% of patients. While in healthy controls, 90.9% had antibody titer more than10 mIU/mL and 9.1% had antibody titer less than 10mIU/mL. No significant relation was found between loss of immunity against HBV and age of patient, type of cancer and duration of chemotherapy.
Summary and Conclusions: Children with cancer who received chemotherapy are at increased risk for HBV infection. HBV revaccination should be considered at least six month post-intensive chemotherapy.larger studies still needed to confirm our finding.

PB1799

THE EVALUATION OF FEBRILE NEUTROPENIA EPISODES IN CHILDHOOD MALIGNANCY; SINGLE CENTER EXPERIENCE

E. Toret[1,*] T. Karapinar[1], I. Devrim[2], Y. Ay [1], B. Demirag[1], Y. Oymak[1], B. Gunes[1], M. Bulut[1], D. İnce[1], C. Vergin[1]
[1]pediatric hematology-oncology, [2]pediatric infectious diseases, Izmir Dr Behcet Uz hospital, Izmir, Turkey

Background: Febrile neutropenia (FN) is an oncologic emergency that may cause serious complications or death. Rapidly diagnosis and empirical antimicrobial therapy can decrease morbidity and mortality in FN. Agents for empirical therapy have choosen by clinicians must be bacterisidal, broad-spectrum and least toxic. Guidelines and current studies have anticipated about high risk factors and empirical therapy in FN.
Aims: To evaluation of febrile neutropenia episodes (FNEs) in our clinic is aimed in current study.
Methods: We retrospectively analyzed data of 131 FNEs of 48 patients who were admitted to the Pediatric Hematology and Oncology Department of Dr. Behçet Uz Children's Hospital, Izmir, Turkey between January 2012 and March2014.
Results: The median age at diagnosis of FNEs was 7.4years (3 months-17 years). Thirty-two of the 48 patients were male and 16 were female. The diagnosis were leukemia at 31, lymphoma at 2 and solid tumor at 15 of patients. Seventy-four per cent of 131 FNEs were determined in patients with leukemia. Focus of clinical infection were determined in 78% of episodes. The distribution of infection's focus were shown at figure 1. Thirty of FNEs (23%) were documented microbiologically and 60% of them were gram negative bacteria, 30% of them were gram positive bacteria and 10% of them were fungus. Empirical antibiotherapy was applied with monotherapy in 28% of episodes as monotherapy with piperacillin-tazobactam. Piperacillin-tazobactam was also used in 47% of FNEs as duotherapy with aminoglycosides. Other empirical antibitherapy choose were 16% meropenem and 9% cefoperasone-sulbactam. Empirical antifungal was applied in 10% of episodes. Modification of therapy was made as adding antibiotics in 37% (adding aminoglycoside or glycopeptide) or changing antibiotics in 22% (changing to meropeneme) of FNEs. Fourty-eight per cent of FNEs had got response with monotherapy or duotherapy like controlled fever with clinical stabilization. Fever control was provided in 72% of episodes in first 72 hours and also in 83% of episodes in 5 days. Two of 48 patients (4%) were died during neutropenic fever due to pneumonia.

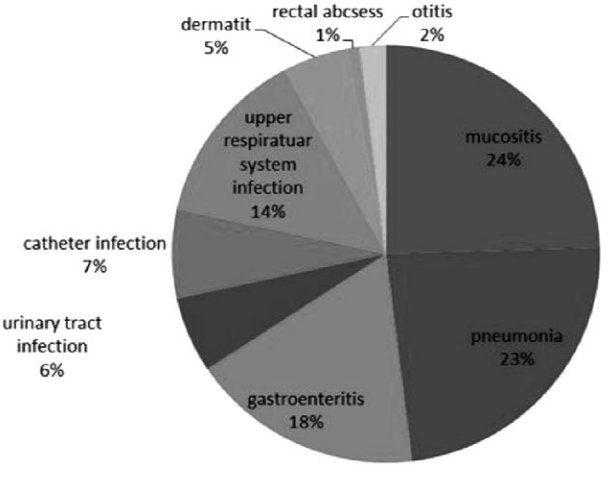

Figure 1. The distribution of infection's focus.

Summary and Conclusions: This study presents clinical findings of patients with FN in childhood malignancy at single center. FNEs were the most in leukemia than the other malignancy. In current study, we identified that we modificated to therapy in FNEs and this value is higher then expected. Even so, fever control rate of us was successfull in FNEs for initial 5 days. This study will contribute to rapidly and efficacious empirical therapy can decrease morbidity and mortality in FNEs.

PB1800

AFTER ADMISSION TO INTENSIVE CARE UNIT NON-TRANSPLANT PATIENTS WITH HAEMATOLOGIC MALIGNANCIES HAVE BETTER SURVIVAL OUTCOME THAN RECIPIENTS OF HAEMATOPOIETIC STEM CELL TRANSPLANTATION

T. Knight Asorey[1,*] Y. Corcía Palomo[2], J. Garnacho Montero[2], F. Márquez- Malaver[1], I. Montero Cuadrado[1], J. Falantes Gónzalez[1], R. Parody Porras[1], J. Gonzalez Campos[1], M. Martino Galiana[1], D. Gallo Cavero[1], L. Martín Villén[2], J. Pérez Simón[1,3] I. Espigado[1,3]
[1]Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocio- Virgen del Macarena, [2]Intensive Care Unit, Hospital Universitario Virgen del Rocio, [3]University of Seville and Instituto de Investigación Biomédica de Sevilla (IBiS), Sevilla, Spain

Background: Patients with haematological malignancies admitted to Intensive Care Units (ICU) have a high mortality rate and poor survival. Identifying predictors of mortality and survival may be useful for clinical decision making and can help to improve survival. The differences in mortality rate and survival outcomes between recipients of haemoipietic stem cell transplant (HSCT) and non-transplant haematologic patients have been poorly studied.
Aims: to compare survival rate after intensive care management between recipients of haematopoietic stem cell transplant and non-transplant patients with haematologic malignancies.
Methods: prospective observational study of all consecutive patients with haematologic malignancies admitted to the ICU. Patients have been undergone an HSCT or not. Period: December 2012 through April 2014. Variables that were analyzed included: demographics, haematological disease, stage of the haematological disease, main reason for admission into the ICU, critical score evaluation (APACHE II y SOFA), organ failure, organic support therapy, death rate in the ICU and in hospital during the following 28 days after admission. Comparisons of quantitative and qualitative variables between independent groups were analyzed by Student t-test, or Mann-Whitney U test for non-normally distributed variables, and chi-square test, Fisher's exact test in 2x2 tables, depending on sample size.
Results: 63 consecutive patients were included and their data analyzed. Twenty seven have undergone an HSCT and 36 did not. HSCT recipients tended to be younger [median age 51 (34-55) vs. 57 (43-66); P=0,01] and they were admitted to the ICU in a worst clinical condition [SOFA: 10 (8-14) vs. 8 (4-11); P=0,01] and APACHE II [26 (19-29) vs. 21 (16-28); P=0,3]. The most frequent cause of admission to the ICU was respiratory failure (77,8%), without differences between both groups (P=0,5). However, recipients of HSCT needed more frequently invasive mechanical ventilation (IMV; P=0,007) and suffered significantly more liver failure (77,8% vs. 30, 6%; P<0,001) and renal failure (85,2% vs. 44,4%, P<0,001). Haemodynamic failure was also more frequent in the HSCT recipients than in non-transplant patients (88, 9% vs. 63, 9%; P=0, 02). Hospital mortality rate 28 days after ICU admission of patients with HSCT was higher (92,6%) than for non-HSCT patients (44,4%; P<0,001). There were no significant differences between both groups in the rest of analyzed variables
Summary and Conclusions: recipients of an haemopoietic stem cell transplant have a significantly higher mortality rate and worst survival than non-transplant haematologic patients after intensive care admission. The causes for such an outcome could be the worst clinical condition at ICU admission, more need for invasive mechanical ventilation and higher rate of organ failure in HSCT recipients. Knowing the reasons for these differences merit further investigation and may help to improve survival of both settings of patients

PB1801

INVASIVE PULMONARY ASPERGILLOSIS IN ACUTE LEUKEMIA:ABOUT 57 CASES

O. Kassar[1,*] A. miled[1], M. ghorbel[1], H. bellaaj[1], H. fourati[2], W. ketata[3], M. mdhaffar[1], F. cheikhrouhou[4], S. hdijji[1], M. elloumi[1]
[1]hematology, [2]radiology, [3]pneumology, [4]Laboratory of Parasitological-Mycology, university sfax, sfax, Tunisia

Background: Invasive pulmonary aspergillosis (IPA) is a serious fungal infection and it's associated with high mortality.
Aims: In this study, we evaluate the incidence and treatment outcome of IPA in acute leukemia (AL).
Methods: Our retrospective study included patients with *novo* acute leukemia (ALL or AML) under which occurring IPA during chemotherapy following in department of Hematology CHU Hédi CHaker Sfax between January 2009 and December 2013. The treatment of acute leukemia is based in chemotherapy and /or corticosteroids, and it is done in conventional rooms.Invasive pulmonary aspergillosis was diagnosed based on the revised definitions of invasive fungal

disease from the EORTC/MSG clinical, microbiological and radiological criteria. Accordingly, the patients were diagnosed as having "proven," "probable," or "possible" IPA.For this, a Clinical data including clinical manifestations, diagnostic results, and treatment was collected for every patient.
Results: We analyzed 247 patients with acute leukemia. IPA was diagnosed in 57 patients.the incidence of IPA was 23% during 5 years. The average age was 29 years old (3-53 years old). All our patients had at least 3 criteria according to EORTC/MSG (neutropenia<500 / mm3 and prolonged, fever despite broad-spectrum antibiotics and immunosuppressive agents in the previous 30 days). The aspergillus antigenemia was positive in 26 patients (45%).The broncho-alveolar lavage (LBA) was done in 22 cases including (38%). For this, patients with aspergillosis were diagnosed with probable IPA in 45%, possible IPA in 46.5% and proven one in 5 cases (8.5%). All patients were treated with amphotericin B and relay by voriconazole. The Evolution was favorable in 28 cases (49%) with early deaths in 10 patients (18%). Twenty patients (35%) are alive with an average decline about 1 year.
Summary and Conclusions: The prevalence of the IPA in our series is higher than the literature (15%) because patients are treated in conventional rooms. The prevalence of proven IPA in our study is very low because of the difficulty of histological documentation (technic problem and deep thrombocytopenia). Wherever; the precocity of diagnosis by TDM imagery and the treatment with voriconazole have improved the mortality rate in our series.

PB1802

DIAGNOSTIC UTILITY OF ADDING SERUM GALACTOMANNAN TEST TO STANDARD TECHNIQUES OF DIAGNOSING INVASIVE FUNGAL INFECTION IN PATIENTS OF ACUTE LEUKEMIA WITH NEUTROPENIA
P.K. Singh[1,*] R. Maiwall[2], Y. Dabas[3], P.C. Misra[1], T. Seth[1], I. Xess[3], M. Mahapatra[1]
[1]Hematology, All India Institute of Medical Sciences, [2]Hepatology, Institute of Liver and Biliary Sciences, [3]Microbiology, All India Institute of Medical Sciences, New Delhi, India

Background: Invasive fungal infection (IFI) (esp. Invasive Aspergillosis) is very common in patients of acute leukemia undergoing induction chemotherapy. Case fatality rates are approximately 50-60% in various studies. It is usually diagnosed as probable case based on CT, as per EORTC/MSG criteria. Serial Galactomannan (GM) monitoring can be helpful in diagnosing IFI early.
Aims: To study the diagnostic & prognostic significance of weekly Serum Galactomannan level monitoring and the development of invasive fungal infection based on radiological imaging.
Methods: Prospective single centre cohort study which included 100 patients of acute leukemia with neutropenia. Weekly GM levels were done with CT chest done as and when clinically indicated. Results of GM levels were compared with CT positivity at any time point during the phase of neutropenia. GM levels were also assessed to predict the survival.
Results: Patients of acute leukemia with neutropenia (mean age 24 8 years, 62% males) were followed for a period of 1 month of which 37% patients expired with median day of expiry 40 days. ALL and AML patients were 34 and 66%, respectively with fever being most common (92%) presenting symptom. 49% patients had evidence of fungal pneumonia on the basis of CT chest with median day of positivity was 12 days (IQR 3-16 days). 74% patients had GM positive value at any time point out of which 20% had persistent GM index positive. Highest value of GM index was 0.701 at day 14 correlating with nadir ANC of 30/cumm at day 14. GM levels were positive in 43%, 63%, 69% and 54% patients at day 0, 7, 14 and 21, respectively. The median GM levels at day 7 (0.8 vs 0.4; P=0.001), 14 (0.87 vs 0.49; P=0.00) and 21 (0.92 vs 0.46; P=0.00) were higher in CT positive group as compared to CT negative group. There was a significant negative correlation between ANC and GM levels (P=0.007). High GM levels at day 7 (p value=0.018) and day 14 (p value<0.001) were predictor of development of invasive fungal infection on 1st or 2nd CT. Low GM levels at day 14 (1 vs 0.63; P<0.001) and post induction CR status (98% vs 8%; P<0.001) were significantly associated with better survival.
Summary and Conclusions: High GM levels at day 7 were predictor of development of invasive fungal infection on CT. High GM levels negatively correlates with the degree of neutropenia. Low GM levels at day 14 and post induction CR is associated with better survival.

PB1803

INFECTIOUS COMPLICATIONS AFTER AUTOLOGOUS HEMATOPOIETIC TRANSPLANTATION:EARLY AND LATE EVENTS
M. J. Requena[1,*] G. Amores[1], M. Diaz Goizueta[1], C. Payamps[1], N. Fontarigo[1], M. Berberana[1], P. Sanchez Godoy[1]
[1]Hematology, Hospital Severo Ochoa, Madrid, Spain

Background: Infectious complications occur in most patients receiving high dose therapy (HDT) and autologous stem cell transplantation (ASCT) both during neutropenia,related to the conditioning regimen and later on due to gradual immunological reconstitution of lymphoid and immune effector cells. Fatal infections are rare, but they represent a mayor cause of morbidity and treatment related mortality.
Aims: We retrospectively analyzed the incidence and type of infections (early:day (d) 0-100, late:from d 100) after ASCT for haematological malignancies at our hospital from January 2002 to February 2015.
Methods: We studied 103 ASCT performed to 98 patients: 62 males and 41 females;median age:55 years (23-69); the diagnosis were: 42.7% Multiple Myeloma, Non Hodgkin Lymphoma(follicular 10.67%,Large cell B diffuse 10.67%,T 5.8%,anaplastic 0.97%,plasmablastic 0.97%),Hodgkin Lymphoma 19.4%,amyloidosis 1.9%, acute myeloid leukaemia 5.8%, acute lymphoblastic leukaemia 0.97%. Conditioning regimens were:BEAM 19.4%, escalated CBV 28.1%,melfalan 41.7%,BUMEL 2.9%,BEA 5.8%,other 1.9%.
All patients received antibiotic and antiviral prophylaxis during conditioning and for at least 6 months.Vaccinations were administered as stated in EBMT guidelines.(one dose of polysaccharide pneumococcal vaccine at 7m).
Results: Early infections: 94.2% patients have febrile neutropenia; fever of unknown origin represented 44.3% of episodes, the documented infections were as follows:see table 1. We have a fatal sepsis caused by multirresistant pseudomonas aeruginosa.Mortality due to infection:1.03%. Late infections: 75 episodes were recorded in 43 patients. Mortality due to infection was 7.14%. The incidence of Herpes zoster reactivation was11.2% at 6m(3-48) postransplantation; 54.5% were receiving corticosteroids and 36.2% had relapsed. Urinary tract infections 12.2% at 57.5m(10-117). Bacterial Pneumonia:20.4% at 43m(4-78);50% received corticosteroids and 65% had relapsed. Influenzae pneumonia 2%at 27.5 m(14-41).Invasive fungal infections(aspergillus) pneumonia 3.1%: 2 probable,1 proven at 31.5m(4-59).Oropharyngeal candidiasis 3.1% at 45.5m (10-86). Pneumococcal infection: 8.2% at (45.5m (15-76):(5 invasive pneumococcal disease:1 arthritis, 3 bacteriemic pneumonia,1meningitis), 3 pneumonia; 2 patients have multiple episodes;mortality rate was 25%;50%of patients had progressed.and 62.5% received corticosteroids. Catheter related infections: 5.1% at 17m(4-46). Gastroenteritis 3.1%(1 campylobacter, 2 clostridium difficile) at 13m (7-23). 1(1.02%)episode of bacteriaemia by Listeria monocytogenes without focal infection at 8m. 1(1.02%)Visceral Leishmaniasis at 33m. Cryptosporidium infection 3.1% (1 systemic, 2 diarrhea) at 40.5m(8-73).

Table 1.

Microbiologically documented infection 37.1%)	Clinically documented infections (13.4%)
2 Herpes zoster	6 pneumonia
3 oral herpes simplex	1 maxilar sinusitis
3 UTI (urinary tract infection)Ecoli	
2 low respiratory tract: 1 Hemophilus influenzae ,1 Stenotrophomona maltophilla	1 otitis
3 oral candidiasis: 1 C.albicans,1 C.tropicalis	
1 Campylobacter gastroenteritis	5 enterocolitis
18 bacteriemia (50% gram positive)	
1 celulitis EColi	
2 candidemia (1 C.parapsilosis,1 C.tropicalis	
1 vulvar abcess Enterococo faecium	

Summary and Conclusions: Our incidence of infectious complications during neutropenia period is similar to that previously described in literature. The incidence of fungal infections is low. 43.8% of our patients suffered late infections and the mortality was 16.2%.Herpes zoster is an important cause of morbidity late after ASCT. Pneumococcal infections stand out due to its continuous occurrence late after transplantation and its high mortality; perhaps the use of the 13-valent pneumococcal conjugated vaccine could help to prevent it. Constant surveillance and prompt therapy must be held for infections, even late after autologous transplantation.

PB1804

RITUXIMAB-ASSOCIATED HEPATITIS B VIRUS (HBV) REACTIVATION IN LYMPHOPROLIFERATIVE DISEASES: CASE REPORTS
S. Bougherira[1,*] M.E.H. Meghadcha[2]
[1]hematology, [2]Infectious Disease, faculty of medecine, university hospital of Annaba, Annaba, Algeria

Background: Reactivation of hepatitis B virus (HBV) after rituximab-based chemotherapy regimens in patients with B chronic lymphoproliferative disorders is well-recognized as a potentially serious complication in HBV immune patients. It has been observed in patients positive for hepatitis B surface antigen (HBsAg) and in HBsAg negative patients who had HBV infection in the past.

The risk of HBV reactivation differs according to both the patient's HBV infection status prior to systemic chemotherapy and the degree of immunosuppression due to chemotherapy. The overall incidence of reactivation with use of rituximab is unclear, but ranges from 2% to 35% of patients.
Aims: To discuss the relationship between Rituximab-based therapy and B hepatitis reactivation, and to estabilish the management of hepatitis associated with the use of Rituximab, prevention and treatment.
Methods: We conducted a prospective study on nine patients with lymphoproliferive diseases, whom treated with Rituximab, in our institution from 2013 to 2014. Data were collected and analysed from medical records. We were focused on risk factors for HBV reactivation, clinical characteristics, biological data and management. Lymphoproliferative histologies were diffuse large B-cell lymphoma (n = 3), follicular lymphoma(n=1) CLL (n=2), mantle-cell lymphoma (n=1), and marginal zone lymphoma (n=2). All patients received Rituximab-containig chemotherapy: FCR (Fludarabine, Cyclophosphamide, Rituximab), and R-CHOP (Rituximab-Cyclophosphamide, Doxorubicine, Vincristine and Prednisone). Four patients were HBV positve; one of them was treated by pegylated Interferon and was completely recovered before starting Rituximab.
Results: The median age at diagnosis was 56 years (rang 37-72), and seven patients were male. HBV screening data were available for all patients at baseline. 4 patients were HBsAg positive, five of them were HBsAg negative. The time from last rituximab to reactivation was 3 months (range 0–12), HBV reactivation occured usually at the completion of chemotherapy (upper than 3 months after the last dose of Rituximab), for 3 patients in the periods between cycles (median occurrence was 17 days). Clinical manifestations of hepatitis B reactivation were variable and ranged from asymptomatic to acute hepatitis (2 patients). Serum transaminase (ALT, AST) levels were elevated, high total bilirubin and hepatitis serology tests revealed reappearance of HBsAg and hepatitis B e antigen (HBeAg), loss of anti-HBsAb, and positivity for hepatitis B virus (HBV) DNA (3 patients were HBV DNA negative). Lamivudine and entecavir (nucleoside analogues) were the most antiviral used for the treatment of HBV reactivation. Six patients were treated : 05 of them received Lamuvidine schudeled at 100 mg daily. Entecavir was prescribed for one patient who received previously Interferon. The remaining 3 (33% patients) were HBsAg negative and anti-HBsAb negative and anti-HBcAb positive, did not undego treatment and they were closely monitored for HBsAg, anti-HBsAb, HBV-DNA, and transaminase levels. The hepatitis flare was controlled (improvement of liver function tests, reduction of HBV DNA levels) and treatment was well tolerated. At the last follow-up, two patients died because of fulminant hepatitis and severe peumonia
Summary and Conclusions: Rituximab-based therapy may cause serious HBV-related complications and even death, by increasing the risk of HBV reactivation both in inactive carriers and those with resolved HBV. Baseline HBV serology is recommended for all patients receiving immuno-chemotherapy regimen, and HBsAg positive patients should receive anti-HBV prophylaxis to decrease virus reactivation and death rates.

PB1805

DIAGNOSTIC VALUE OF PLASMA LEVELS OF PRESEPSIN (SOLUBLE CD14-SUBTYPE) FOR FEBRILE NEUTROPENIA IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES

H. Koh[1,*] T. Katayama[1], M. Hashiba[2], A. Sato[2], M. Kuno[1], Y. Makuuchi[1], T. Takakuwa[1], H. Okamura[1], A. Hirose[1], M. Nakamae[1], M. Hino[1], H. Nakamae[1]
[1]Hematology, Graduate School of Medicine, Osaka City University, Osaka, [2]Development Research, Mochida Pharmaceutical Co., Ltd., Shizuoka, Japan

Background: Previous studies reported that procalcitonin (PCT), C-reactive protein (CRP) and cytokines such as interleukin (IL)-6 and IL-8 may be useful as biomarkers of bacterial infections in the management of febrile neutropenia (FN). CD14, one of the surface markers in monocytes/macrophages, is a lipopolysaccharide-binding protein complex receptor, and its fragment "presepsin (soluble CD14-subtype)" has recently been reported as a novel diagnostic biomarker of infection, especially sepsis (Endo S, *et al*. 2012). However, the superiority of this test in FN, compared with the other markers, is unknown.
Aims: The purpose of the study was to examine whether presepsin was a superior diagnostic marker for bacterial infections in comparison with PCT, CRP, IL-6 and IL-8.
Methods: We prospectively evaluated the utility of these biomarkers in patients with hematological disorders who developed FN during chemotherapy between Nov 2013 and Feb 2014. FN was defined as an axillary temperature ≥ 37.5 □ recorded once with a neutrophil count<500/μl or<1,000/μl with an expected decline to<500/μl. Patients were closely and frequently monitored to assess precisely differences in kinetics among these markers. Thus, blood samples for these measurements were collected simultaneously at the following time points: once before chemotherapy as a control, 3 times per week until onset of FN after chemotherapy, at onset of FN, at 8, 16, 24, 48 and 72 hours after the onset of FN, and every 48 hours after that until resolution of fever, in accordance with the protocol. Plasma presepsin was determined by the PATHFAST® Presepsin kit (LSI Medience Corporation, Japan). Serum levels of CRP, PCT and cytokines were measured by nephelometry, electrochemiluminescence immunoassay and the Bio-Plex Pro Cytokine Assay® system (Bio-Rad Laboratories, CA), respectively.
Results: A total of four patients aged 29–54 years were enrolled and four FN episodes were evaluable. The underlying diseases were acute leukemia in three patients and one case of non-Hodgkin's lymphoma. Concerning the cause of FN, Patient no.1 (P1), P2, P3 and P4 were finally diagnosed as having a fever of unknown origin, suspected drug fever, clinically documented local infection and Staphylococcus aureus bacteremia, respectively. The number of times each of these patients was sampled was 18, 17, 18 and 15 respectively. A result was considered to be positive if it met the following criteria: 314 pg/mL for presepsin, 0.30 mg/dl for CRP, 0.05 ng/mL for PCT, and the levels of the baseline controls sampled before chemotherapy for both IL-6 and IL-8, respectively. The presepsin peak levels from the onset of FN to 24 hours in P1, P2, P3 and P4 were 330, 148, 348 and 460 pg/mL, respectively. The corresponding levels of CRP, PCT, IL-6 and IL-8 in P1, P2, P3 and P4 were 1.8, 6.0, 11.9 and 4.9 mg/dl; 0.04, 0.34, 0.36 and 0.22 ng/mL; 14 (baseline, 27), 107 (23), 69 (25) and 24 (8.4) pg/mL; and 52 (62), 787 (58), 56 (150) and 26 (13) pg/mL, respectively. In P2, where no infection was suspected, presepsin was the only marker that did not increase. This suggests that presepsin might be useful to differentiate infectious from non-infectious causes of FN.
Summary and Conclusions: Our results suggest that presepsin may be more useful than CRP, PCT, IL-6 and IL-8 in the management of FN, especially when attempting to rule out the presence of serious bacterial infections.

PB1806

EFFECTIVENESS OF SUPPORTIVE THERAPY WITH LOW-DOSE LENOGRASTIM FOR B-CELL LYMPHOMAS

A. Nagata[1,*] N. Sekiguchi[1], M. Kurimoto[1], S. Noto[1], N. Takezako[1]
[1]hematology, Disaster Medical Center, Tachikawa, Japan

Background: To date, over 30 kinds of malignant lymphomas have been classified by the WHO classification. Although R-CHOP chemotherapy is currently considered the standard therapy for B cell lymphoma, the beneficial effects of G-CSF, namely, decreases in the number of neutrophils, the prevention of febrile neutropenia, and maintenance of the treatment interval, have also been reported. We performed R-CHOP therapy in our hospital between 2009 and 2014 and assessed its curative effects based on the number of neutrocytes when combined with three G-CSF agents (filgrastim, nartograstim, and lenograstim), which were used as supportive therapy in our hospital.
Aims: We would like to confirm whether the usage of G-CSFs which are filgrastim, nartograstim, and lenograstim is considered a safe supportive therapy for R-CHOP chemotherapy.
Methods: White blood cell counts were measured before administering G-CSF to a total of 177 patients scheduled for the next cycle of R-CHOP chemotherapy in our hospital between February 2009 and February 2014. The effectiveness and side effects of the 3 drugs were examined through analysis of variance.
Results: The median age of patients who underwent a total of 177 cycles of R-CHOP chemotherapy was 61 years old. The Filgrastim group was significantly older than the Nartograstim and Lenograstim groups (Filgrastim: 75±5 years old ($P=1.64\times10^6$), Nartograstim: 61±17 years old, Lenograstim: 58±12 years old). The proportion of females was high in the nartograstim group (P=0.004). No significant difference was observed the incidence of infiltration to the bone marrow between the Nartograstim and Lenograstim groups. LDH levels were significantly lower (LDH: 200±24mg/dL, P=0.036) in the Filgrastim group immediately prior to chemotherapy. Furthermore, white blood cell counts before the next course of chemotherapy were significantly lower in the Filgrastim group (WBC: 4352±1412/μL, P=0.006), whereas no significant difference were observed between the Nartograstim and Lenograstim groups.
Summary and Conclusions: It was difficult to directly compare filgrastim with the other 2 drugs due to the large number of elderly patients in the study hospital. On the other hand, no significant differences were observed in effectiveness between nartograstim and lenograstim and no influence was noted on the white blood cell count immediately prior to the next course of chemotherapy. We herein confirmed that no significant differences existed between the Nartograstim and Lenograstim groups; therefore, the usage of these agents is considered a safe supportive therapy for R-CHOP chemotherapy.

PB1807

INVASIVE FUNGAL INFECTION IN ACUTE LEUKEMIA PATIENTS-A SINGLE CENTER EXPERIENCE

A. Dascalescu[1,*] G. Butura[2], A. Dascalu[2], I. Antohe[1], C. Burcoveanu[2], C. Danaila[1],
[1]Hematology, University of Medicine and Pharmacy "Gr.T.Popa", [2]Hematology, Institutul Regional de Oncologie, Romania

Background: Invasive fungal infection (IFI) is one of the most severe complications that apppear in patients with acute leukemia. The outcome of the acute leukemia is significantly influenced by the presence of severe fungal infection during induction, consolidation or salvage therapy.
Aims: To evaluate the outcome of patients with proven or probable IFI at diagnosis or during therapy. We analyzed the risk factors for invasive fungal infection in our study group.

Methods: We evaluated 91 patients diagnosed with acute leukemia during a 2 year period between March 2012 and October 2014. Of the 91 patients included, 63% was diagnose with acute myeloid leukemia. Median age at diagnosis was 52 years old. The number of episodes of febrile neutropenia in all patients and the appearance of probable or confirmed invasive fungal infections in the course of these episodes was analyzed.
Results: In our cohort the incidence of IFI during 90 episodes of febrile neutropenia analyzed was 18,6%. More than 50% of invasive fungal infection appeared after induction chemotherapy and the median duration of neutropenia grade IV OMS at this patients was 22 days. Infection with Aspergillus spp. was the most frequent diagnosed fungal infection (14 patients). Invasive candidiasis was diagnosed in only 3 patients. The most common location was the lung. 2 patients were diagnosed with probable cerebral aspergillosis. Despite the good response of azole based therapy in majority of patients, 5 patients required second line of antifungal therapy and death appear in 4 patients with invasive fungal infection. In our study group the only risk factor which statistic significantly influenced IFI risk was duration of neutropenia more than 21 days (P=0,006).
Summary and Conclusions: IFI is an important cause of morbidity and mortality in patients diagnosed with acute leukemia. The high percentage of patients with invasive fungal infection after induction chemotherapy (9,9% in our study) with significantly delays in subsequent consolidation courses is a important issue. Correct assessment of the risk of infection in these patient populations associated with appropriate prophylactic measures can significantly reduce the risk of these forms of infection.

PB1808

INFECTION HISTORY MAY BE USED TO PREDICT OF BENEFIT OF IVIG THERAPY IN HYPOGAMMAGLOBULINAEMIC HAEMATOLOGY PATIENTS

L. Paxton[1], P. Crispin[1,2,*] C. Hawkins[1,3]
[1]Australian National University Medical School, Canberra, [2]Haematology, [3]Immunology, Canberra Hospital, WODEN, Australia

Background: Intravenous immunoglobulin (IVIg) has been shown to reduce the risk of infections in unselected patients with hypogammaglobulinemia secondary to hematological malignancies. It is not known whether a history of infections can predict benefit from IVIg and can therefore by used to select patients for therapy
Aims: To determine the risk of serious infections when selecting hematological patients for IVIg based on a history of infections and IgG levels.
Methods: A retrospective review of the rate of hospitalisation for infections before and during IVIg therapy in hematological malignancy patients selected for therapy on the basis of serious or recurrent infections was conducted. Results were compared with hypogammaglobulinemic haematology patients not selected for therapy. Characteristics of the groups were compared with Chi-squared tests and event rates expressed as rate ratios with estimated variance to determine 95% confidence limits.
Results: A total of 35 treated patients were treated with IVIg for 1194 months and had 776 months of observations prior to starting treatment. By comparison 57 patients with low IgG levels were identified with hypogammaglobulinemia (IgG<7g/L) who did not require IVIg, with the total observational period being 2587 months. The untreated group had fewer cases with severe hypogammaglobulinemia (51% v 77%, P<0.01) but were otherwise similarly matched for diagnosis, age and sex. The treated group showed a rate of hospitalisation for bacterial infection of 0.42 per patient year prior to treatment, reducing to 0.14 (relative risk 3.1 (1.6-5.9) for infection prior to treatment). The risk of infection prior to treatment also compared favourably to the 0.08 hospitalisation per patient year in those never treated (relative risk 5.5 (3.0-10)). An IgG level of<4g/L did not predict rates of infection compared with an IgG level >4g/L in either the untreated group or the treated group prior to the commencement of IVIg.
Summary and Conclusions: In this retrospective study, selecting hypogammaglobulinemic hematology patients to have IVIg given or withheld on the basis of a history of infections appears safe and effective.

PB1809

IMPACT OF POSACONAZOLE PROPHYLAXIS ON INVASIVE FUNGAL INFECTION, ASPERGILLUS GALACTOMANNAN AND PERSISTENT FEBRILE NEUTROPENIA DURING AML INDUCTION THERAPY: A SINGLE-CENTER, REAL-LIFE EXPERIENCE

V.S. Sampath[1,*] A. Tso Ching Yee[1], L.K. Lee[1], S.Z. Fong[1], P. Kuperan[1], Y.C. Lim[1], J. Rajendran[1], C.A. Gallardo[1], K.H. Ong[1]
[1]Haematology, Tan Tock Seng Hospital, Singapore, Singapore

Background: Posaconazole prophylaxis has been shown to prevent invasive fungal infection(IFI) in acute myeloid leukaemia (AML) patients during induction therapy. The role of serum aspergillus galactomannan(GM) in diagnosis of invasive fungal infection and the optimal management of persistent febrile neutropenia during posaconazole prophylaxis is less clear.
Aims: The aims of this study are to determine in patients having AML induction chemotherapy with posaconazole prophylaxis, the incidence of IFI, the role of GM in diagnosis and premptive antifungal treatment and the management of persistent febrile neutropenia for more than 96 hours despite broad-spectrum antibiotics.
Methods: We collected prospective data on 22 consecutive patients undergoing AML induction chemotherapy with posaconazole prophylaxis between August 2013 and November 2014. Induction chemotherapy comprised duanorubicin 45-90 mg/m^2 for 3 days and cytarabine 100 mg/m^2 for 7 days. Oral posaconazole was started on day 1 of chemotherapy. Patients not in complete remission received salvage reinduction chemotherapy. Serum posaconazole levels were not done. GM was performed once or twice weekly.Patients who had persistent febrile neutropenia for more than 96 hours despite broad spectrum antibiotics were investigated with computed tomography. Respiratory consult for broncho-alveolar lavage was discretionary. Empirical antifungal therapy was commenced if the patient was clinically unstable or had radiological findings of probable IFI.
Results: IFI(aspergillus flavus sinusitis) was diagnosed in 1 out of 22 patients (4.55%) during the first cycle of induction chemotherapy. Probable invasive pulmonary aspergillosis was diagnosed in one patient during salvage chemotherapy. Both infections were fatal. Both patients had radiological findings but negative serum GM levels and diarrhoea at the time of diagnosis. One patient had a single positive serum GM (GM index of 0.9) two weeks prior to the diagnosis of IFI but was deemed to be false-positive as he was afebrile and asymptomatic. Serum GM was done on 179 occasions but was positive only once (0.56%) which was deemed false-positive. Persistent febrile neutropenia for more than 96 hours despite broad spectrum antibiotics were seen in 17 patients (77.27%). Computed tomography showed radiological findings suggestive of chest infection in 9 patients (40.9%) and sinusitis in 3 patients (13.63%). Positive blood cultures were seen in 10 patients with febrile neutropenia (45.45%). 4 patients(18.19%) had antifungal treatment. BAL was performed in one patient and did not reveal any specific microbiology.
Summary and Conclusions: Posaconazole is effective antifungal prophylaxis in AML patients undergoing induction chemotherapy. Diarrhoea may impair posaconazole absorption and may have lead to invasive fungal infection in the two patients but posaconazole levels were not done. Therapeutic drug monitoring may be useful as IFI are uncommon with adequate levels. Serum GM is not useful in the diagnosis and initiation of preemptive antifungal therapy with posaconazole prophylaxis. Persistent febrile neutropenia should not be automatically an indication for empirical antifungal therapy in all patients. Individualised decision making is needed in this context. Assessment of serum posaconazole levels, computed tomography, broncho-alveolar lavage with BAL galactomannan and the clinical status of the patient may be the best approach to initiate antifungal therapy with posaconazole prophylaxis in persistent febrile neutropenia of unknown origin. Empirical antifungal therapy is an alternative option but may increase treatment cost and drug resistance. Invasive fungal infection in the setting of posaconazole prophylaxis is difficult to treat and often fatal.

PB1810

THE EPIDEMIOLOGY OF INVASIVE FUNGAL INFECTIONS INHEMATOLOGIC ADULT PATIENTS IN WROCLAW University HOSPITAL, POLAND

M. Biernat[1,2], D. Urbaniak-Kujda[1], K. Kapelko[1,*] U. Nawrot[3], M. Laszkowska[1], J. Dybko[1], T. Wróbel[1], K. Kuliczkowski[1]
[1]Department and Clinic of Haematology, Blood Neoplams and Bone Marrow Transplantation, [2]Department of Microbiology, [3]Department of Pharmaceutical Microbiology and Parasitology, Wroclaw Medical University, Wroclaw, Poland

Background: The invasive fungal infections (IFIs) are associated with a very high mortality in hematologic patients mainly because of asymptomatic course and delayed diagnosis.
Aims: The aim of the study was to analyze the clinical feature and outcome of invasive fungal infections in adult patients diagnosed and treated in Wroclaw Medical University.
Methods: The retrospective analysis of patients with hematologic malignancies and patients undergone hematopoietic stem cell transplant (HSCT), who were hospitalized in our hospital between January 2011 and December 2014, was performed. Proven, probable and possible IFIs were diagnosed according to the definitions of EORTC/IFICG. Galactomannan and mannan antigens were detected by ELISA whereas culture of pathogenic fungi was based on EUCAST recommendations.
Results: In analyzed period, invasive fungal infection was diagnosed in 55 patients, of which 34 (62%) was proven, 19(34,5%) probable, and 2(3,5%) possible. Aspergillosis was diagnosed in 50/55 patients, candidosis in 3/55 patients, mucormysosis in 1/55, and cryptococcosis in one patient (1/55). The major pathogens isolated form clinical specimens were: *Aspergillus fumigatus* (21/55,38.2%), *Aspergillus flavus* (2/55, 3.6%), *Aspergillus niger* (1/55, 1.8%), *Absidia* (1/55, 1.8%), *Mucor* (1/55, 1.8%), *Candida glabrata* (3/55, 5.5%). In two patients two different *Aspergillus spp*. (*A. fumigatus* and *A. flavus*) were identified from lower respiratory tract. The infection was mostly localized in lungs (48/55,87.2%), and central nervous system (4/55, 7.3%). Disseminated infection was noted in two patients (3/55, 5.5%). IFIs were most common in patients with acute myeloid leukemia (27/55, 49%) and patients undergone HSCT (8/55, 14.5%). The major risk factors in this patients were prolonged neutropenia and degree of immunosupression. A total of 39 patients (71%) died.

Summary and Conclusions: The most common pathogen of invasive fungal infection in the cohort of hematologic patients was *Aspergillus fumigatus*. Constant monitoring of the epidemiologic trends and insights in timing of fungal infections in this patients may help to improve the effective prevention and treatment strategies.

PB1811

A COMPARISON OF IMMATURE GRANULOCYTE (IG) PARAMETER BETWEEN A HEMATOLOGY ANALYZER AND MANUAL MICROSCOPY

P. Tsiatsiou[1,*] D. Lazaridou[1], E. Evaggelou[1], P. Mauroidaki[1], M.A. Fotiadou[1], T. Karamitopoulou[1], L. Skoura[1], A. Nikolaidou[1]
[1]Clinical Microbiology, AHEPA University Hospital, Thessaloniki, Greece

Background: Left shift in granulopoiesis, has been seen in cancer or infection. An accurate marker has been IG (immature granulocyte which includes promyelocytes, myelocytes and metamyelocytes), blasts and bands are excluded from the measurement. In the peripheral blood smear, the appearance of immature granulocytes (IG) is a common finding in infection, inflammation, hematologic malignancy disorders and other factors that stimulate the bone marrow such as Growth-Stimulating Factors (G-CSF). Also, increased granulation in neutrophils indicates serious infection or patients undergoing chemotherapy.
Aims: To compare the manual IG with the IG provided from an automated hematology analyzer.
Methods: A total of 143 unselected whole-blood samples were collected in tubes with K3-EDTA and were analysed in approximately 3 h of collection. Patients who had their blood counts monitored on a daily basis were excluded. The automated IG% results (a percent of the total white blood count) provided from the hematological analyzer (Sysmex-XE 5000) were divided into three groups IG<1 (61 samples), IG 1-10 (61 samples), IG >10 (21 samples) and compared to manual IG counts. The first two groups were similar in regard to sex (39 males-22 females) and age (8-86 years avg=59,4 years). In the third group there were 14 males and 7 females, the age was 18 to 88 years (avg=58,4 years). The peripheral blood smears, from flagged reported samples (Imm Gran), were stained with May-Grünwald- Giemsa by Sysmex SP-100 slide system. The immature granulocytes and granularity of the neutrophils, were generated by two expertised physicians. Mean value comparison using paired t-tests was used in order to examine the statistical significance among the groups. The significance level was defined as $P<0.05$. All statistical analysis was performed using SPSS 20 and Mc Excel 2010.
Results: In the first group with the automated IG<1, the manual IG count was zero, so there was an agreement between visual microscopy and SYSMEX XE-5000. In the second group there was also an agreement in comparison to the manual IG. The difference of the mean values of IG1-10 between the manual IG and the automated IG is not statistically significant (p-value >0,05) showing that there is no difference between the two methods. In the third group there was a difference. The manual IG percentage revealed a higher number of immature granulocytes than the automated IG. The difference between the microscopic and manual results increased with increasing levels of IG. In the third group, the number of specimen was very low so, in order to acquire reliable results, a larger number of samples should be generated.
Summary and Conclusions: Immature granulocytes (IG) are a predictive useful parameter for the presence of infection, sepsis, inflammation, treatment with oncolytic drugs or bone marrow activation. For blood samples whose IG was >1%, a microscopic examination should be operated. In addition, taking into consideration IG% as a marker, a serious number of spurious blood film reviews might be reduced and minimized. Also, the implication to shorter turn-around times would enhance the diagnostic effectiveness.

PB1812

VORICONAZOLE AND CASPOFUNGIN COMBINATION THERAPY IS EFFECTIVE AND SAFE FOR PROBABLE AND POSSIBLE INVASIVE PULMONARY FUNGAL INFECTION IN PEDIATRIC ACUTE LEUKEMIA

J.M. Lee[1,*] Y.T. Lim[1], K.H. Suh[1], S.Y. Kim[1], Y.K. Kim[2], C.H. Lee[2]
[1]Pediatrics, [2]Laboratory Medicine, College of Medicine, Yeungnam University, Daegu, Korea, Republic Of

Background: Aspergillus species have emerged as an important cause of life-threatening infections in immunocompromised patients. Despite timely diagnosis and appropriate antifungal therapy, clinical outcome might be disappointing, necessitating treatment with a combination of antifungal agent.
Aims: in this study, we report the efficacy of voriconazole and caspofungin in pediatric acute leukemia.
Methods: We identified 30 pediatric acute leukemia patients who received the combination of CAS and VRC for invasive fungal infection (IFI) from April, 2009 to May, 2013 in pediatric department of Yeungnam university hospital. Medical records of patients were reviewed and analyzed retrospectively. We analyzed data that included the following: Demographic characteristics, underlying disease and disease state, radiological findings and outcome in patients with IFI.
Results: Of the 30 consecutive patients who receive CAS and VRC during study period, 8 patients were not evaluable for the following reasons: pneumonia not attributed to fungus (n=3), non-infectious pulmonary infiltration (n=5). The study group comprised 11 boys and 11 girls, with mean age was 7 years (range, 0.8-13.3) years. Underlying diseases were acute lymphoblastic leukemia (ALL) in 11 of these patients, acute myeloid leukemia (AML) in 11 of patients. No patient had received hematopoietic stem cell transplantation nor immunosuppressive treatment at the onset of IFD. IFD were classified as probable in 9 (41%) and possible in 13 (59%) patients, respectively. All but 1 patients had received previous empirical antifungal monotherapy with conventional amphotericin B, liposomal amphotericin B and fluconazole (range 1-21 days) before start of VRC and CAS combination therapy. One patient had started *de novo* combination antifungal therapy. The median duration of VRC and CAS combination therapy was 45 (range, 5 – 99 days) days. Loading and maintenance dose of CAS were 63.1±7.7 mg/m^2 and 47.2±6.0 mg/m^2 respectively. Those of VRC were 5.9±0.5 mg/kg and 3.6±0.60 mg/kg respectively. The survival rate of 100 days after initiation of combination therapy is 90.9%. Twenty patient (90.9%) had response to combination therapy. (19 complete response and 1 partial response). Age, sex, underlying disease, disease state, treatment phase, oxygen and intravenous immunoglobulin therapy did not affect overall response and overall survival by univariate analysis. VRC and CAS combination therapy was well tolerated except for 2 patents. Two had mild increased in liver enzyme.

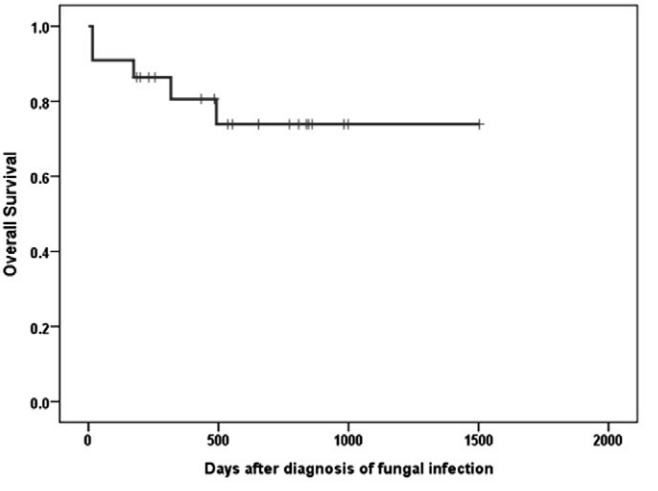

Figure 1.

Summary and Conclusions: Voriconazole and caspofungin combination therapy is effective and safe treatment for serious invasive pulmonary fungal infections in pediatric acute leukemia

PB1813

POSACONAZOLE AS PRIMARY PROPHYLAXIS REDUCES INVASIVE FUNGAL INFECTIONS IN AML PATIENTS: A SINGLE CENTRE MATCHED PAIRED ANALYSIS

P. Minetto[1,*] F. Guolo[1], G. Pastori[1], L. Giannoni[1], D. Guardo[1], D. Avenoso[1], M. Clavio[1], M. Miglino[1], R. M. Lemoli[1], M. Gobbi[1]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCSS AOU San Martino-IST, Genoa, Italy

Background: Prevention and prompt treatment of invasive fungal infections (IFI) in acute myeloid leukemia (AML) patients can improve overall survival by reducing infection-related mortality and allowing to receive full planned chemotherapy in a timely manner.
Aims: Since January 2013, AML patients undergoing intensive chemotherapy in our institute and potentially eligible for bone marrow transplantation received posaconazole (PSZ) as IFI prophylaxis. The aim of the present study was to evaluate tolerability and efficacy of PSZ and to optimize our clinical practice.
Methods: From January 2013 to October 2014, 35 patients treated for newly diagnosed AML in our institute received PSZ for antifungal prophylaxis.
Non promyelocytic AML patients received a fludarabine, cytarabine and idarubicin containing regimen (FLAI) as first line treatment. M3 AML patients were treated according to GIMEMA AIDA 2000 protocol.
PSZ was given at the standard dose of 200 mg for 3 times/day, concurrently with a fat snack or with at least 100 ml of an acidic drink. Because of unpredictable absorption rates PSZ serum levels (TDM) were assessed routinely according to a validated high-performance liquid chromato-graphic (HPLC) method as described. To detect factors affecting PSZ exposure we analyzed each period of hospitalization as a single independent event.
We retrospectively compared through a matched-paired analysis 22 non M3 AML patients treated with PSZ as IFI prophilaxys to a control historical series of 22 patients who had received fluconazole (FLC) or itraconazole (ITZ). Of 22 patients in PSZ cohort, 18 received subsequent induction cycle 2 and 6 received

consolidation therapy, therefore accounting for a total of 46 episodes of prolonged neutropenia. In FLC/ITZ arm 22 patients received cycle 2 and 6 received consolidation therapy, for a total of 50 episodes of prolonged neutropenia. Matching variables were sex, age, response to induction. Patients median age, sex and days of severe neutropenia were not significantly different between the two cohorts. The incidence of IFI and the days of empirical or targeted intravenous antifungal therapy were analyzed.
Results: PSZ showed a good tolerability profile with no serious adverse events clearly related to prophylaxis occurring. A median number of 3 TDM for each period of hospitalization was performed (range 2-6). The achievement of a plasmatic PSZ concentration >0,7 mcg/mL is considered optimal for prophylaxis efficacy; in 39/65 (60%) episodes of hospitalization and treatment, with at least two TDM, the threshold PSZ serum concentration was reached, with stable plasmatic levels. Median PSZ plasmatic value at first assessment was 0.73 mcg/mL (range 0.1-3.9). The strongest negative factors affecting PSZ absorption are the temporary discontinuation of prophylaxis and the concomitant assumption of proton pump inhibitors. No proven or probable IFI were observed in the PSZ cohort. Data coming out from the matched paired analysis demonstrated a significant reduction in IFI incidence in our institution: 0% in PSZ cohort Vs 12% (6 proven/probable IFI episodes over 50 severe neutropenic periods) in FLC/ITZ cohort (P<0.05). Mean days of targeted/empirical intravenous antifungal therapy for single patient in PSZ cohort was 0 days Vs 2.2 days in FLC/ITZ cohort (P<0.05).
Summary and Conclusions: Our clinical experience confirms the benefit and potential cost-effectiveness of primary prophylaxis with PSZ in AML patients receiving intensive treatment, as no patients in PSZ cohort experienced IFI nor received empirical intravenous antifungal therapy.

PB1814

IMPACT OF CHEMOTHERAPY REGIMENS WITH ESCALATED ANTHRACYCLINES ON INCIDENCE OF FEBRILE NEUTROPENIA IN PATIENTS WITH ACUTE MYELOID LEUKEMIA
I. Iskrou[1,*] I. Stoma[1], I. Lendzina[2]
[1]cells transplantation, [2]Hematological, City Clical Hospital №9, Minsk, Belarus

Background: Modern chemotherapy schemes of acute myeloid leukemia include remission of induction regimens with escalated doses of anthracyclines (escalated "7+3" regimen). Changes in incidence of febrile neutropenia are not clear in patients receiving remission induction regimen "7+3" with escalated anthracycline dose (90mg/m^2) comparing to standart "7+3" chemotherapy regimen(45mg/ m^2).
Aims: The aim of the study was to assess the influence of "7+3" chemotherapy regimen with escalated anthracyclines on incidence of febrile neutropenia in patients with acute myeloid leukemia comparing to standard "7+3" chemotherapy regimen.
Methods: 56 hospitalization episodes of patients with acute myeloid leukemia on chemotherapy from March 2013 to January 2014 were reviewed. Incidence of febrile neutropenia (fulfilled criteria of Freifeld *et al.*, 2011) was compared in the groups receiving standard "7+3" regimen and "7+3" with escalated anthracyclines. Groups were comparable by age and gender characteristics and adjusted for other possible confounders.
Results: No statistically significant difference in incidence of neutropenia in patients receiving the escalated "7+3" regimen comparing to the standard one was found (71% to 70% accordingly, P=1, exact Fisher's criterion).
Summary and Conclusions: Use of "7+3" chemotherapy regimen with escalated anthracycline dose in treatment of acute myeloid leukemia does not increase the risk for development of febrile neutropenia in patients.

PB1815

PREDICTORS OF OUTCOME AND SEVERITY IN ADULT FILIPINO PATIENTS WITH FEBRILE NEUTROPENIA
R.E. Villalobos[1,*] M.G. Yu[1], R. Berba[1]
[1]Department of Internal Medicine, Philippine General Hospital, Manila, Philippines

Background: Febrile neutropenia carries a significant mortality rate of 5-21.5%, warranting early recognition and institution of appropriate therapy. In the Philippines, there is a lack of studies on prognostic factors that predict poor outcome in patients with febrile neutropenia. It is important to identify these factors to recognize patients who will benefit from early aggressive therapy and closer monitoring.
Aims: The study aimed to describe the clinical, laboratory, and microbiologic profile of adult Filipino patients with febrile neutropenia, and to determine specific parameters that are potentially associated with severe outcomes, complications, and mortality.
Methods: This is a retrospective study of adult febrile neutropenia patients, regardless of cause, admitted at the Philippine General Hospital from January 2010-October 2014. Patients were described in terms of clinical, laboratory, and microbiologic presentation, and stratified according to the presence or absence of severe outcomes. Prognostic factors were then identified using univariate and multivariate logistic regression analysis.
Results: A total of 115 febrile episodes in 102 patients were identified. There was no difference in median age or gender ratio between the complicated and non-complicated groups; leukemia (48.7%) was the most common primary underlying disease in both groups. Most patients (50.43%) had infections of the respiratory tract, with Gram negative organisms predominating in the complicated group. The factors that significantly predicted poor outcome in the univariate analysis were non-treatment/relapse of the underlying disease (OR 2.28; 95% CI, 1.04-4.98; P=0.040), prolonged fever >7 days prior to admission (OR 3.24; 95% CI, 1.16-9.01; P=0.024), non-recovery from neutropenia (OR 2.17; 95% CI, 1.01-4.68; P=0.048), and severe thrombocytopenia<50,000/uL (OR 3.45; 95% CI, 1.52-7.84; P=0.003.) Meanwhile, completeness of antibiotic therapy significantly predicted a better outcome (OR 0.26; 95% CI 0.12-0.57; P=0.001.) Using the factors that reached significance in the univariate analysis, subsequent multivariate analysis yielded prolonged fever (OR 2.43; 95% CI, 0.77-7.74), isolation of a pathogen on cultures (OR 2.69; 95% CI, 1.04-6.98), and nadir absolute neutrophil count (ANC)<100 during admission (OR 1.96; 95% CI, 0.75-5.12) as significant predictors of poor outcome. The factors that significantly correlated with better outcome were granulocyte colony-stimulating factor (G-CSF) use (OR 0.31; 95% CI, 0.11-0.85) and completeness of antibiotic therapy (OR 0.26; 95% CI, 0.10-
Summary and Conclusions: Adult febrile neutropenia patients with prolonged fever >7 days prior to admission, known pathogen on cultures, and nadir ANC<100 during admission were at significant risk of developing worse outcomes, whereas those with G-CSF use and complete antibiotic therapy were significantly associated with better outcomes. These prognostic variables might be useful in identifying patients that need more intensive treatment and closer monitoring.

PB1816

CHEMOTHERAPY-INDUCED NEUTROPENIA AMONG PEDIATRIC CANCER PATIENTS IN EGYPT: RISKS AND CONSEQUENCES
T. Hassan[1,*] M. Badr[1], H. Sakr[1], M. Al Malky[1], W. Al-Saeed[1]
[1]pediatrics, Zagazig university, zagazig, Egypt

Background: Chemotherapy –induced neutropenia (CIN) is the major dose-limiting toxicity of systemic chemotherapy, and is associated with substantial morbidity, mortality and costs.
Aims: The aim of the current work was to identify risk factors that may predispose pediatric cancer patients, treated with myelo-suppressive chemotherapy, to CIN and associated sequels.
Methods: 113 neutropenia episodes were analyzed, risk factors for CIN were classified into; patient-specific, disease-specific and regimen specific while consequences associated with CIN were divided into infectious and dose modifying sequels. Both risks and consequences were analyzed to target high risk patients with appropriate preventive strategies.
Results: 28% of our patients presented with single neutropenia attack while 72% of them experienced recurrent attacks during their treatment cycles. Mean absolute neutrophil count (ANC) was 225.5±128.5 (10^9/L), ranged from 10-497(10^9/L) started at 14.2±16.3 days (ranged 2-100) after the onset of chemotherapy and resolved within 11.2±7.3 days either with (45.1%) or without (54.9%) granulocyte colony stimulating factor (G-CSF).No significant association could be found between any patient character or disease stage and the risk for CIN. However, certain malignancies (ALL, Neuroblastoma and Burkitt's lymphoma) and certain regimens (induction blocks for ALL, AML) had the worst myelotoxic effect with severe and prolonged neutropenia episodes. G-CSF significantly shortened the neutropenia episodes and enhanced bone marrow recovery. Febrile neutropenia was the leading complications among our cases (73.5%), associated with several documented infections particularly mucositis (54.9%), respiratory (45.1%), GIT (38.9%) and skin (23.9%) infections. 6% of our cases died of infection –related complications. Neutropenia was responsible for treatment discontinue (13.3%), dose delay (13.3%), and dose reduction (5.3%) of our patients. The mean cost for each episode in our service was 9386.5±6688.9 Egyptian pounds (L.E) which represented a significant burden on health care providers.
Summary and Conclusions: Although this study is preliminary survey with relatively small number of patients, our findings are relevant to clinical care of pediatric cancer patients in our region. Special attention to CIN prevention should be directed to hematologic malignancy cases especially at early cycles. Severe and prolonged neutropenia are life-threatening events that need aggressive management.

PB1817

MENTAL DISORDERS OBSERVED DURING THE APPLICATION OF VORICONAZOLE
D.E. Vybornykh[1,*] G. Klyasova[1], E. Mikhailova[1], L. Kuzmina[1], V. Troitskaya[1], O. Pokrovskaya[1], E. Urnova[1], M. Drokov[1], E. Parovichnikova[1]
[1]National Research Center for Hematology, Moscow, Russian Federation

Background: Among the side effects of the drugs from the group of antifungal agents voriconazole are the mental disorders by different psychopathological registers.
Aims: The aim was to study the typology of mental disorders and therapeutic approaches in the event of psychosis in patients with hematological diseases complicated by fungal infection, during the application of voriconazole.
Methods: There were studied 15 patients with various hematological diseases (AML, ALL, MM, AA) by the clinical method in the period from 2006 to 2014, in which observed the development of mental disorders during therapy with voriconazole in connection with invasive fungal infections (aspergillosis, candidiasis).
Results: Of the 15 patients, 11 demonstrated hallucinatory syndrome. Development hallucinosis in most cases within 1-2 days underwent almost stereotypical dynamics-the formation of psychopathological disorders began with demonstrations insomniac disorders (violation of falling asleep, frequent awakenings), joined by vivid nightmares with disturbing content, accrued unexplained anxiety, persistent daytime (4 patients of the 11 alarm combined with hypothymia (depressed mood). Then, against the clear consciousness and stored criticism, manifest verbal perceptual deception by type of acoasma (hiss, scratches) or elementary functional hallucinations (addressed to the patient isolated words or phrases arising on a background of real sounds of medical equipment or personnel speech), which gradually became more complicated. With closed eyes formed visual hallucinatory disorders that were in the nature of sensuous vividness, and were represented by a set of bright, moving images of people and (rarely) animals of normal size or reduced. It is noted high involvement of the patient in what is happening-"people" were talking among themselves and with the patient, "commented" his actions and thoughts. There was not noted the increasing of anxiety on the background of experienced by patients deceptions of perception. In 4 patients, hallucinatory disorders are not formed and mental disorders limited by insomniac, anxiety disorders and hypothymia and had more short-term character than in the previous group of patients. Described disorders in patients persisted for 6±2 days on average. Formation of described psychopathological disorders occurred on the background of significant somatogenic asthenia caused by severe hematologic malignancies and its complications (including infectious origin) and intoxication by chemotherapeutic agents. In the history of the patients showed no manifest psychopathological disorders. Treatment of mental disorders in the studied patients was phased. The aim of the first phase was psychosis reduction, the second – the support treatment to prevent relapse of psychotic disorders. Preference was given to intravenous administration of psychotropic drugs (in most cases – through a central venous catheter) that correspond to the guidelines for the management of patients with haematological diseases. In hallucinatory disorders the main therapeutic intervention focused on the first stage; the treatment have a short duration and include the use of butyrophenone antipsychotics (haloperidol 10 mg / day). In necessary of the rapid sedation or relief the anxiety/insomniac disorders diazepam was administered in therapeutic scheme (20 mg/day).
Summary and Conclusions: During the application of voriconazole the mental disorders may occur (most often formed hallucinatory syndrome) that require psychopharmacological correction.

Myelodysplastic syndromes - Biology

IN VITRO EVALUATION OF A BACTERIAL BIOLUMINESCENT REPORTER ASSAY FOR ASSESSMENT OF RESPONSE TO DECITABINE

A. Aruomaren[1,*] K. Page[1], C. Stratford-Smith[2], V. Salisbury[2], M. A. Smith[3], M. Ruddock[4], A. Martin[4], C. Reid[4], J. Lamont[4], H. Alloush[1], J. May[1], E. Anderson[1]
[1]Centre for Research in Biosciences, [2]University of the West of England, Bristol, [3]Royal Marsden NHS Foundation Trust, Surrey, [4]Randox Laboratories Ltd, Belfast, United Kingdom

Background: Decitabine (DAC) is a cytidine analogue and hypomethylating agent used in the management of patients with myelodysplastic syndrome (MDS) and increasingly in acute myeloid leukemia (AML). Cellular uptake via the hENT1 transporter and subsequent phosphorylation by deoxycytidine kinase (dCK) produces the active metabolite decitabine triphosphate (DAC-TP). DAC-TP is incorporated into DNA, where it covalently binds to and inactivates DNA methyltransferases (DNMTs), leading to hypomethylation and potential re-expression of silenced tumour suppressor genes. DAC is also known to have a direct cytotoxic effect on leukaemic cells. DAC has been compared extensively with the related compound azacytidine (AZA) clinically. Only 10-20% of intracellular AZA is converted to DAC-TP leading to hypomethylation, compared with 100% DAC-TP from DAC. Trials have shown AZA to be clinically favourable, indicating that a lower intracellular concentration of DAC-TP could be beneficial. Current opinion is that DAC may be useful following appearance of resistance to AZA. Therefore a tool that could assist in predicting individual patient benefit from treatment with DAC is needed, particularly considering associated costs to healthcare services for this drug (~$80,000 pa per patient).
Aims: This study aimed to assess the feasibility of detecting DAC and DAC-TP using a previously validated biosensor sensitive to the cytidine analogue cytosine arabinoside (ara-C) (Alloush *et al., Clin Chem.* 2010;56(12):1862-70). Biosensor HA-1 is a *cdd*-deficient, bioluminescent bacterium with inducible expression of human dCK that is specific for toxic analogues of cytidine. Biosensor HA-1 has been formulated into an assay capable of predicting response to treatment within 8-hours and is currently undergoing clinical evaluation for ara-C.
Methods: Direct application of DAC to biosensor HA-1 using a clinically relevant dosing range (0.1-10 mM) equivalent to 15-150 mg/m^2 resulted in a dose-dependent increase in light output, with maximum 2.6-fold increase over control. A concurrent decrease in bacterial growth was observed as previously noted with ara-C, confirming intercalation of bacterial DNA with DAC-TP. Direct comparison of DAC with ara-C demonstrated an equivalent response by biosensor HA-1 for both time to peak (5.25 hours) and scale of increase of light output
Results: Subsequently leukaemic cell lines, HL-60 and K562 were exposed to DAC (0-10 μM) to assess whether DAC uptake and metabolism to DAC-TP during the initial 1-hour post-dosing would predict cytotoxicity at 72 hours. Assessment of cytotoxicity of DAC performed following daily dosing of DAC (0.1 – 10 mM) on HL-60 and K562 cells over a 72-hour period indicated that HL-60 cells were more susceptible to DAC-induced cytotoxicity than K562 cells. Concurrent assessment of accumulation of parent DAC and DAC-TP using biosensor HA-1 indicated that K562 cells produced more DAC-TP than HL-60 cells in the initial 1-hour post-dosing with DAC (≥1 mM), implying that the cytotoxicity observed may be more related to accumulation of parent DAC than metabolite. Previous *in vitro* studies have observed that the IC_{50} concentration of DAC is associated with maximal hypomethylation, indicating that DAC-TP could be responsible for the suppression of proliferation observed
Summary and Conclusions: Studies are on-going in our laboratory to directly assess DAC-TP using biosensor HA-1 and compare with hypomethylation in cell lines and patient blasts to define the intracellular drug kinetics of DAC, and further dissect the role of parent drug and metabolite in DAC-mediated toxicity.

PB1819

LOW RPS14 EXPRESSION IN THE NON 5Q- MYELODYSPLASTIC SYNDROMES

S. Grassi[1], E. Ciabatti[1], M. Rousseau[2], F. Guerrini[1], N. Cecconi[1], G. Cervetti[1], P. Musto[3], F. La Rocca[4], D. Cilloni[5], V. Gaidano[5], I. Petrini[6], A. Poloni[7], G.A. Palumbo[8], S. Galimberti[1,*]
[1]Clinical and experimental Medicine, [2]UO Hematology University of Pisa, Pisa, [3]IRCCS-CROB, Rionero in Vulture, Italy, [4]Laboratory of Preclinical and Translational Research, IRCCS-CROB, Rionero in Vulture, [5]Oncology, Division of Hematology and Internal Medicine, Turin, [6]Department of Translational Medicine, Pisa, [7]Department of Clinical and Molecular science, Division of Hematology, Ancona, [8]Hematology-AOU "Policlinico-V.Emanuele, Catania, Italy

Background: The *RPS14* gene, located on chromosome 5 and involved in the ribosomal protein synthesis, has been reported as a causal factor in the 5q-syndrome, where its up-regulation during treatment with lenalidomide has been associated with best responses. *RPS14* expression in non-5q-MDS was reported in 53%>71% of cases. Interestingly, in low and intermediate-1 IPSS subgroups, patients with lower *RPS14* expression had longer OS.

Aims: The aim of this study was to assess the *RPS14* expression in a larger series of non-5q- MDS patients.
Methods: A total of 112 patients, 45% females and 55% males, with a median age of 71-year (range 19-89), were enrolled in 5 different Italian institutions from March 2010 to October 2014. Nine patients were affected by CMMoL; the prognosis of the remaining 103 cases was determined according to the IPSS in low (36%), intermediate-1 (31%), intermediate-2 (21%), and high risk (12%). About 40% of cases were affected by RCMD, 24% by RAEB-2, and 13% by RA. Twelve bone marrow samples from healthy donors have been used as normal references.
Results: In healthy donors, the mean *RPS14* expression was 0.94±0.26; in the whole MDS series, it was 0.57±0.42. In comparison with healthy controls, the 52% of MDS cases showed lower *RPS14* expression levels: 79% in the RA, 56% in the RAEB1, 44% in the RAEB-2, and 41% in the RCMD subgroups. When patients were stratified according to the IPSS, in the half of the low, intermediate-1 and intermediate-2 cases *RPS14* was under-expressed, opposite to one third of the high risk and 13% of the CMMoL patients only. No relationships with age or sex were observed. To evaluate if the haploinsufficiency would be responsible of the low expression of *RPS14* gene, we performed the copy number assay on 32 MDS, 15 healthy donors, and 3 patients with 5q- syndrome: in 91% of cases the copy number assay excluded the haploinsufficiency.
Summary and Conclusions: Our study showed in a large series of patients that a lower *RPS14* expression interests the half of the non-5q- cases, especially those affected by RA and at low and intermediate IPSS risk. Other authors previously reported that low expression of *RPS14* was not due to promoter hypermethylation. Here we demonstrated that also the haploinsufficience is not the cause of the *RPS14* low expression. Moreover, our findings suggest a possible role for lenalidomide in non-5q- MDS, especially in low risk patients.

PB1820

MOLECULAR MAPPING OF THE PDGFRB/SPTBN1 GENE FUSION TRANSCRIPT AS A RESULT OF THE T(2;5)(P16.2;Q33.1) IN AN IMATINIB MESYLATE-RESPONSIVE MDS

D. Koumbi[1,*] P. Kollia[2], S. Samara2[2], M. Psyllaki[3], V. Pappa[4], S. Zachaki[1], A. Daraki[1], M. Kalomoiraki[1], K. Manola[1], G. Pantelias[1], H. Papadaki[3], C. Sambani[1],
[1]Health Physics, Radiobiology & Cytogenetics, NCSR "Demokritos", [2]Department of Genetics and Biotechnology, Faculty of Biology, Athens, [3]Department of Hematology, University Hospital of Crete, Heraklion, [4]Hematology Unit, 2nd Dept. of Internal Medicine, Athens, Greece

Background: PDGFRB is a member of the tyrosine kinase family and PDGFRB gene rearrangements, already reported in myeloproliferative neoplasms (MPN), lead to its constitutive activation, ultimately affecting cell proliferation and migration. Patients with PDGFRB rearrangements respond to imatinib mesylate therapy. The t(2;5)(p16.2;q33.1) (PDGFRB/SPTBN1) has been reported only in one case of atypical MPN. SPTBN1 is a cytoskeletal protein with a role in mitotic spindle assembly.
Aims: The aim of the study was to fully characterize the partner fusion gene products formed as a result of the t(2;5)(p16.2;q33.1), encountered for the first time in a MDS patient.
Methods: A 78-years-old man presented for investigation of macrocytic anemia in 2012. Bone marrow smear showed mild dysplastic features in the granulocytic and megakaryocytic series. Bone marrow biopsy showed 60% cellularity and 4% CD34+ cells. The findings were consistent with MDS diagnosis. One year later, a new biopsy showed 23% CD34+ cells and dyserythropoiesis. The patient was administrated imatinib mesylate and since July 2014 has achieved hematological remission. Following karyotypic analysis on bone marrow cells, interphase and metaphase FISH studies with specific BAC probes (UCSC Genome Bioinformatics, Source Bioscience) were performed in order to refine the chromosome breakpoints and detect the partner genes. RP11-100O5/RP11-368O19 BAC probes encompassing the PDGFRB gene at 5q33.1 and RP11-423N19/RP11-1022E1 BAC probes flanking the SPTBN1 gene at 2p16.2, were fluorescently labeled by nick-translation and used as dual-color break-apart probes. For the molecular characterization of the partner genes, 5' rapid amplification of cDNA ends, followed by single step 5'RACE PCR was performed using a 5'Gene Racer primer (Life Technologies) and a reverse primer for PDGFRB exon 15. Second step PCR was carried out with a 5'Gene Racer nested primer and a reverse nested primer for PDGFRB exon 15. Following cloning, sequence analysis of the PCR products was conducted to fully characterize the fusion transcripts.
Results: At diagnosis the karyotype was: 46,XY,t(2;5)(p16;q33)[20]/46,XY[5]. iFISH detected PDGFRB and SPTBN1 gene rearrangements in 56% of the cells. Based on those results, the patient was administrated imatinib mesylate and has favorably responded thus far. Metaphase FISH revealed translocation of 5' PDGFRB at 2p16.2 and fusion with the 3' SPTBN1 onto derivative chromosome 2. Accordingly, the 5' of SPTBN1 was translocated at 5q33.1 and fused with the 3' PDGFRB onto derivative 5. For the molecular characterization of the fusion gene transcripts, cloning and sequencing of the 5'RACE PCR products, showed that SPTBN1 exons 1-3 were fused to PDGFRB exon 12 onto derivative chromosome 5.
Summary and Conclusions: Cytogenetics identified the PDGFRB/SPTBN1 fusion gene generated from the rare translocation t(2;5)(p16.2;q33.1). Thorough molecular mapping analyses revealed that the genomic breakpoints were located at exon 3 of SPTBN1 gene and exon 12 of PDGFRB gene, leading to a PDGFRB/SPTBN1 fusion transcript comprising exons 1-3 of SPTBN1 gene and exon 12 of PDGFRB gene onto derivative chromosome 5. Importantly, the involvement of tyrosine kinase gene PDGFRB in t(2;5), encountered for the first time in a MDS case, prompted the administration of a successfully tailored-based signal transduction therapy (imatinib mesylate) to the patient.

PB1821

EVALUATION OF P53 PROTEIN EXPRESSION IN MYELODYSPLASTIC PATIENTS: PROGNOSTIC IMPACT IN A SINGLE CENTRE EXPERIENCE

A. Ricco[1,*] A. napoli[2], P. carluccio[1], A.V. Russo Rossi[1], C. pasciolla[1], M. leo[1], A. franco[1], B. daraia[1], V. carluccio[1], A. cellamare[1], G. specchia[1],
[1]Department of Emergency and Transplantation, Hematology Section, [2]Department of Emergency and Transplantation, Pathology Section, University of Bari Medical School, Bari, Italy

Background: AML follwing MDS has a very poor outcome, so accurate prediction is essential, expecially in patients who could potentially be cured by stem cell transplantation. A strong association between p53 protein expression, the TP53 mutation and an adverse outcome has been reported in various hematologic malignancies including MDS. Strong nuclear staining of the p53 protein by immunhistochemistry (IHC) has been used as a surrogate marker for TP53 gene mutation in hematologic and other malignancies; a strong correlation of p53 nuclear expression with TP53 mutation has also been demonstrated.
Aims: To assess the role of p53 expression in MDS patients as a new prognostic tool, as well as its feasibility in routine clinical practice, we analyzed the prevalence of p53 expression in a cohort of 62 consecutive bone marrow (BM) biopsies from patients with MDS at diagnosis, and correlated our findings to other validated prognostic markers and clinical outcome
Methods: The DO-7 antibody (DakoCytomation, Denmark), which labels both wild and mutant-type p53 proteins, was used to detect p53 expression (a colorectal carcinoma positive control was included on each slide). Diagnosis according to the 2008 WHO Classification was: isolated del (5q) in 4 cases, RA in12, RARS in 5, RCMD in 8, RAEB-1 in 15, RAEB-2 in 18.
Results: Among patients with strong p53 immunostaining in ≥1% of BM cells, we found significant correlations with BM blasts (70% RAEB-1/2, vs 32% in negative cases). IPSS-R cytogenetic risk was int/poor/very poor in 36% of positive and 0% in negative IHC cases. IPSS score was int-2/high in 54% of patients with strong positivity vs 20% in negative cases. BM fibrosis was present in 70% of positive vs. 30% of negative IHC cases. Transfusion dependency was observed in 50% of patients with p53 strong expression vs. 20% of negative cases. Moreover, we found that strong p53nuclear expression was associated with a significantly worse outcome (87% disease progression plus leukemic evolution vs. 20% in negative cases) and shorter median OS (18 months vs. 35 in negative cases).
Summary and Conclusions: Our data indicate that IHC p53 protein expression, evaluated in bone marrow biopsies by a widely available method, is a highly predictive marker and thus a helpful tool in risk assessment and the decision making process in MDS.

PB1822

MYELODYSPLASTIC SYNDROMES: AN INTEGRATED WORKUP FOR A CORRECT DIAGNOSIS

E. Ciabatti[1,2,*]A. Valetto[3], V. Bertini[3], F. Guerrini[1], S. Grassi[1], M.I. Ferreri[3], A. Guazzelli[3], A. Azzarà[1], I. Petrini[4], P. Simi[3], M.R. Metelli[1], M. Petrini[1], S. Galimberti[1]
[1]Clinical and Experimental Medicine, Hematology, University of Pisa, Pisa, [2]GenOMec, University of Siena, Siena, [3]Medicine Laboratories, AOUP, Pisa, [4]Translational Research and New Technologies in Medicine, Oncology, University of Pisa, Pisa, Italy

Background: The diagnosis of MDS is determined by bone marrow's histology and is integrated by conventional cytogenetic (CC) analyses that, although, are unable to show chromosomal abnormalities in about 30% of cases. Array Comparative Genomic Hybridization (aCGH) detects copy number aberrations in half of MDS diploid by CC. Recently, *TET2, ASXL1, EZH2, CBL, IDH1/IDH2, DNMT3A,* and *UTX* mutations have been described in MDS.
Aims: Therefore, we evaluated the prognostic and predictive implications of FISH, aCGH and mutation assays when added to CC.
Methods: Fifty patients, 15 females and 35 males, with a median age of 72-year (range 39-88) were enrolled in a single institution (Hematology Unit, University of Pisa, Italy), between March 2013 and October 2014. Patients' prognosis was determined according to IPSS in low (42%), intermediate-1 (33%), intermediate-2 (17%) and high risk (8%). Samples were evaluated by CC including, conventional karyotyping and FISH for chromosome 5, 7, PDGFRA, and

PDGFRB. Moreover, aCGH was performed using SurePrint G3 Human CGH Microarray, 8x60K (Agilent), and mutations of TET2, TP53, ASXL1, and EZH2 were determined using qBiomarker somatic mutation PCR array (Qiagen).
Results: After FISH analysis, additional copy number losses of chromosome 3 and 5 were observed in 1 and 2 cases, respectively. According to aCGH, 20 patients (40%) showed copy number aberrations (Table). Seventeen patients had a mutation: 12 in TP53, 4 in ASXL1 and 1 in TET2 sequence.

Summary and Conclusions: 1) The study showed the reduction of CC failures (only 16%); 2) Because of FISH results, a patient received azacitidine and another one lenalidomide; 3) Three MDS patients with copy number aberrations detected exclusively by aCGH progressed in acute leukemia being lethal: one patient had copy number loss of chromosome 3, one had copy number losses of chromosomes 8 and Y and the last one had copy number loss of *ETV6* locus. 4) One patient with *TET2* mutation did not respond to the azacitidine. Three out of 4 patients with *ASXL1* mutation had a good response to epoietin. TP53 mutations were observed in 12 cases of which 2 developed acute leukemia, 2 were resistant, and 2 sensitive to epoetin. In conclusion, our results support the relevance of an integrated work-up for MDS and provide a preliminary estimation of copy number aberration and mutation frequencies. The prognostic role of aCGH and somatic mutations needs to be determined in properly sized series.

PB1823

CD38 EXPRESSION ON CD34+ BONE MARROW CELLS (BM) AS A TOOL IN LOW GRADE MYELODYSPLASTIC SYNDROMES (MDS)

R. Siguenza[1,1,*] M.H. Bañas[1], I. Casas[1], F. Ibañez[1], N. Bermejo[1], J.M. Bergua[1], M.J. Arcos[1], J. Prieto[1], M.L. Martin Mateos[1], C. Cabrera[1], F.D.A. Perez Leal[1]
[1]Hematología, Hospital San Pedro de Alcantara, Cáceres, Spain

Background: The diagnosis of MDS can be difficult, especially in the absence of markers of clonality. Flow cytometry (FCM) has tried to be a useful tool but the methods described so far are poorly standardized and time-consuming.
Aims: Recently, a study has shown that a reduced expression of CD38 in the CD34 + BM cells below a threshold value diagnosed low-grade MDS with high sensitivity and specificity, (Goardon et al, Haematologica, 2009, 94:. 1160-1163). Our aim was to test the effectiveness of this method.
Methods: We analyzed 140 BM samples sent to our laboratory between 2012-2015 with suspected MDS. The samples were processed within 24 hours of aspiration and were labeled with an antibody panel that included CD45-FITC, CD34-PE-Cy5 CD38 PE, CD10 PE-Cy7, CD117-APC and CD19-APCCy7. A sufficient number of nucleated cells was acquired on a FACSCanto (Becston Dickinson) flow cytometer and CD38 expression was analyzed in CD34 + myeloid and lymphoid blasts. The expression of CD38 was quantified as a ratio as the MFI of CD38 on CD34 + cells divided by the MFI of isotype control staining. The result was considered pathological below the threshold value described in the study (CD38 IMFR<110)
Results: Of the total of 140 patients, 71 patients were diagnosed with MDS using current WHO criteria (2008): 39 RCDM, 7 RCUD, 2 AR, 10 CMML, 3 RAEB-1, 7 RAEB-2, 1 RARS,1 5q-, 1 MDS / MPD. In them, the ratio CD38 IMFR gave altered in 46 (64.5%). (Media 95.2, range 10.3-314.1). 69 patients did not meet criteria for SMD, of which 61 (88.4% patients) had a normal ratio (mean 145.9, range: 63.8-808.8).
In our case, the test gave a sensitivity of 64.5% and a specificity of 88.4% in the diagnosis of MDS.
Summary and Conclusions: Our results confirm that CD38 expression is reduced in CD34 + cells from MDS patients and may be helpful in the diagnosis of low-grade MDS.

PB1824

COMPARISON BETWEEN CYTOMORPHOLOGY AND CYTOGENETIC ANALYSIS FOR THE DIAGNOSIS OF MYELODYSPLATIC SYNDROME IN COHORT OF 374 PATIENTS

E. Lestang[1,*] J. Delaunay[1], O. Theisen[2], Y. Le Bris[2], M. Eveillard[2], P. Peterlin[1], P. Chevallier[1], P. Moreau[1], C. Godon[2], M.C. Béné[2], S. Wuilleme[2],
[1]Service d'hématologie clinique, [2]Laboratoire d'hématologie, Hôtel Dieu, CHU de Nantes, Nantes, France

Background: Cytogenetic analysis is an essential step to establish the prognosis in patients with myelodysplastic syndrome (MDS). In our center, the investigation of cytopenia includes a systematic cytogenetic analysis.
Aims: The aim of this work was to compare the efficiency in first intention of bone marrow morphologic analysis to karyotype analysis to reach the diagnosis of myelodysplastic syndrome.
Methods: A monocentric cohort of patients investigated for one or more cytopenia(s) was analysed. Patients diagnosed with MDS with blasts excess, acute leukaemia, bone marrow localization of lymphoma or solid tumor were excluded. Blood, bone marrow smears morphology and karyotype were compared according to the final diagnosis (MDS, immune, metabolic, inflammatory, congenital cytopenia).
Results: Between 2010 and 2013, samples of 374 patients were analysed. Median age of the whole cohort was 66.8 y.o (1-91). 72% of patients had one cytopenia (mostly anaemia in 50%), 20% were bicytopenic and 8% were pancytopenic. Analysis of bone marrow smears revealed no dysplasia, a uni-or multi-lineage dysplasia or an abnormality of cellularity in respectively 53%, 42% and 5% of cases. Cytogenetic disclosed a normal karyotype in 84% and at least one abnormality in 16% of patients. Loss of Y chromosom, recurring abnormalities and del 5q were the most frequent karyotype abnormalities respectively 7%, 3,7%, 3%. The diagnostic of MDS was retained in 105 patients (29%) whereas 269 patients (71%) were classified as having a differential diagnosis of cytopenia (immune, metabolic, inflammatory, congenital). MDS subtypes were refractory anemia (49%), refractory cytopenias with multilineage dysplasia (20%), refractory cytopenia with unilineage dysplasia (17%), refractory neutropenia (1%), refractory thrombopenia (3%), del 5q syndrome (4%) and MDS-unclassified (6%). In group of MDS patients compared to non-MDS patients, blood test revealed a deeper anaemia (10.2 vs 11 g/dL, P< 0.0001), a higher mean corpuscular volume (94 vs 89 fL, P<0.0001), a higher red-cell distribution width (15.15 vs 13.8, P<0.0001). Then, bone marrow cytomorphology showed more often at least one lineage dysplasia 86.7% vs 30% without dysplasia (P<0.0001) and at least one karyotype abnormality in 32.6% vs 10% without abnormality (P<0.0001). Finally, table 1 summarizes sensitivity, specificity, positive predictive (PPV) and negative value (PNV) of morphological and cytogenetic analyses for the diagnosis of MDS

Table 1.

Table 1. Sensitivity, specificity, PPV, PNV of cytomorphology and cytogenetic analysis to confirm or exclude diagnosis of MDS

	Sensitivity %	Specificity %	PPV %	PNV %
DIAGNOSIS OF MDS				
BONE MARROW MORPHOLOGY				
Erythroid dysplasia (>20%)	59	79.5	52.3	83.3
CYTOGENETIC ANALYSIS				
Loss of Y chromosom	8.5	92.5	31	72
Other karyotype abnormalities	9.5	98.5	71.5	73.5
Defavorable karytoype	8.5	100	100	73.7
DIAGNOSIS of NON-MDS				
BONE MARROW MORPHOLOGY				
No dysplasia	86.6	68.7	52	92.9
CYTOGENETIC ANALYSIS				
No cytogenetic abnormality	32.4	90.3	56.6	77.39

Summary and Conclusions: For the diagnosis of myelodysplastic syndrome, cytomorphology of bone marrow is more sensitive but less specific than cytogenetics. Our results suggest that in case of cytopenia without blast excess or malignant infiltration, blood and bone marrow smears microscopic examination could be performed frontline and cytogenetic examination could be delayed at the time of morphology confirmation after 1 to 3 months.

Myelodysplastic syndromes – Clinical

PB1825

MYELODYSPLASTIC SYNDROMES IN PATIENTS AFFECTED BY AUTOIMMUNE DISEASES

C. Baldini[1], E. Elefante[1], E. Cioffi[1], F. Ferro[1], R. Vagelli[1], M. Rousseau[2], E. Ciabatti[2,3], R. Talarico[1], M. Mosca[1], S. Galimberti[2,*]
[1]Clinical and experimental Medicine, UO Rheumatology University of Pisa, [2]Clinical and experimental Medicine, UO Hematology University of Pisa, Pisa, [3]GenOMec, university of Siena, Italy

Background: Background: Several immunological abnormalities have been reported among patients affected by myelodysplastic syndromes (MDS). On the other hand, a relatively limited number of studies have explored the occurrence of MDS during the course of systemic autoimmune diseases (AD)
Aims: Aim of the study: to estimate characteristics and frequency of MDS among patients with systemic autoimmune diseases (AD).
Methods: Methods: A retrospective systematic search through the electronic health records of patients admitted at the Rheumatology University Medical Center from 2009 and 2014 who were concomitantly evaluated by the Division of Hematology was performed to select those patients with systemic AD and MDS. To refine the search the ICD-9-CM diagnosis code for MDS was utilized. Medical charts of eligible patients were retrieved and data were collected with regard to demographics, type of AD, AD duration, prior treatments, bone marrow biopsy, and cytogenetic profile. Categorical variables were compared using chi square test and Fisher's test; continuous variables were compared using Student's t-test. A 2-tailed value of $P<0.05$ was taken to indicate statistical significance.
Results: Results: Out of the medical records of 3800 patients, we identified 23 patients with AD and MDS. Patients' median age at the diagnosis of MDS was 65 years, with a 1.09:1 female to male ratio. Rheumatoid arthritis and seronegative arthritis were the most frequent underlying AD condition (7/23, 30%) followed by large and small vessel vasculitis (7/23, 30%), Systemic Lupus Erythematosus (3/23, 13%), Sjogren's syndrome and myositis (2/23, 8%). Moreover, one patient was affected by Systemic Sclerosis and one by Behçet's syndrome. Anemia (21/23, 91%) was the most common hematologic presenting abnormality, followed by thrombocytopenia (9/23, 39%) and neutropenia (8/23, 35%). Three patients out of 23 presented with a trilineage cytopenia (13%). In the majority of the patients the diagnosis of MDS was subsequent to that of AD, with a median period between the two diagnosis of 4 years. Prior to MDS diagnosis, about one third of the patients received cytotoxic drugs, among which MTX was the most commonly prescribed (5/23, 22%) followed by azathioprine and cyclophosphamide (2/23, 8%). Regarding MDS, the most common diagnosis was refractory anemia with excess of blasts (RAEB I and II) (4/16, 25%) followed by sideroblastic anemia (2/16, 12%) and refractory anemia (2/16, 12%). A progression to leukemia was documented in 2 patients.
Summary and Conclusions: Conclusions: Our study is limited by its retrospective design. However, our results documented that the frequency of MDS in AD is not negligible and might be suspected especially in older patients presenting with "unexplained" cytopenias.

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal stem cell disorders characterized by ineffective hematopoiesis, cytopenias and risk of progression to acute myeloid leukemia (AML).
Aims: The influence of serum ferritin concentration on survival and acute myeloid leukemia transformation in MDS patients remains controversial. The data for Central European population is scarce and so far there is no description for Poland. Aim of this study was to perform an retrospective analysis of relationship of ferritin concentration with red blood cell transfusion dependency, survival and acute myelogeneous leukemia transformation.
Methods: We retrospectively evaluated data of the 819 MDS patients (58% male; median age 70 years), included in the MDS Registry of the Polish Adult Leukemia Group (PALG). Analysis was performed for 190 patients diagnosed with MDS maximal 6 months before inclusion to registry in order to avoid selection bias (shorter survival of higher risk MDS patients).
Results: Patients with hyperferritinemia higher than 1000 ng/l *versus* patients with ferritin concentration lower than 1000 ng/l had median survival of 320 days vs 568 days respectively (p log-rank=0.014). It was shown that the following factors significantly worsened survival: ferritin concentration higher than 1000 ng/l (P=0.0023; HR=2.94), RBC-transfusions dependence (P=0.0033; HR 2.671), platelet transfusions dependence (P=0.0033; HR 2.671), hemoglobin concentration lower than 10 g/dl (P=0.0036; HR 2.97), platelet count lower than 10 G/l (P=0.0081 HR=5.04), acute leukemia transformation (P=0.0081; HR 1.968).
Summary and Conclusions: Taking into account relatively low number of patients in previous studies exploring the topic of hyperferritinemia in MDS patients, the study provides important insights.

PB1827

HIGH P53 PROTEIN EXPRESSION IS ASSOCIATED WITH WT1 MRNA LEVEL AND DISEASE STAGE PROGRESSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME.

E. Yamazaki[1,*] M. Enaka[2], S. Koyama[1], H. Takahashi[1], Y. Nakajima[1], T. Miyazaki[1], T. Tachibana[1], K. Ohashi[2], N. Tomita[1], Y. Ishigatsubo[1]
[1]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, [2]Department of Pathology, Yokohama City Univeresity Hospital, Yokohama, Japan

Background: Myelodysplastic syndrome (MDS) is a heterogeneous disease. Several clinical findings were reported as prognostic markers. Identification of p53-positive cells by immunohistochemistry in bone marrow (BM) was demonstrated to correlate with presence of TP53 mutations, indicative of poor prognosis. Wilms' tumor gene (WT1) mRNA expression was associated with the WHO classifications and risk evaluation of MDS. But there was no report about correlation between p53 expression and WT1 mRNA level.
Aims: We assessed BM biopsy specimens for p53 expression by immunohistochemistry in association with other clinical parameters including WT1 mRNA expression in adult MDS patients.
Methods: We performed a retrospective study involving 29 BM biopsy samples from 24 patients with MDS between 2013 and 2014. The percentage of p53 staining positive cells was assessed based on a total manual count of 1000 BM hematopoietic cells. Clinical parameters were corrected from patient medical charts.
Results: The study included 17 males and 7 females. The median age at procedure was 71 years (range, 28-84). Five patients received sequential BM biopsies when clinical findings changed. According to WHO 2008 classification of MDS, 14 specimens were RCMD, 3 were RCMD-RS, 6 were RAEB-1 and 6 were RAEB-2. The result of cytogenetic analysis of 26 samples, showed complex karyotypes with more than 3 abnormalities found in 7 samples including 4 of complex karyotype with -5/5q-, isolated del5q was not found in this cohort and 11 were normal karyotype. Nine patients (11 specimens) were treated with azacitidine after first biopsy. With the median post-procedure follow up of 5.7 months (1-23.3 months), leukemic transformation and death occurred in one patient (two specimens) and two patients (three specimens), respectively. Positive rate of p53 expression in BM was as follows;<1%, 5 specimens; 1-3%, 8; 3-5%, 4; 5-10%, 4; >10%, 8. In 5 patients with sequential biopsies, p53 expression level of first sample was lower than it of second sample except in one patient who received azacitidine treatment after first biopsy. WT1 mRNA

expression level in peripheral blood (PB) was as follows;<100 copies, 11; 101-1000copies, 8; >1000 copies, 6; 4 patients were not tested for WT1 mRNA level at the time of BM biopsy. Higher level of p53 expression was significantly associated with greater WT1 mRNA expression level in PB (r=0.40, P=0.05), complex cytogenetic abnormality (r=0.64, P<0.001), increasing with WHO2008 classification (r=0.68, P<0.001), IPSS (r=0.50, P=0.01), and IPSS-R (r=0.53, P=0.006). But it was not associated with percentage of CD34 positive cells in BM. In spite of short duration of follow-up time, high level of p53 expression was associated with overall survival (r=0.54, P=0.003).
Summary and Conclusions: High p53 protein expression in BM is associated with WT1 mRNA expression level and disease stage progression. It can be a predictor of survival in adult MDS.

PB1828

BONE MARROW OSTEOPONTIN AS A PROGNOSTIC FACTOR IN MYELODYSPLASTIC SYNDROME

S. Kim[1,*] Y.S. ji[1], J. Yun[1], H.J. Kim[2], K.H. Kim[3], H.J. Kim[1], S.C. Lee[2], S.B. Bae[2], C.K. Kim[1], N.S. Lee[3], K.T. Lee[2], S.K. Park[1], J.H. Won[3], D.S. Hong[1]
[1]Division of Hematology & Oncology, Soonchunhyang university hospital, Bucheon, [2]Division of Hematology & Oncology, Soonchunhyang university hospital, Cheonan, [3]Division of Hematology & Oncology, Soonchunhyang university hospital, Seoul, Korea, Republic Of

Background: Osteopontin, a glycophosphoprotein encoded by a single gene on chromosome 4q13, is expressed and secreted in numerous human cancers and plays a role in tumor progression and metastasis. Also, high osteopontin level is associated with shortened survival in hematologic malignancies. Bone marrow (BM) osteopontin levels are currently not reported, and relationship between BM osteopontin and the clinical course of disease has not been demonstrated in myelodysplastic syndrome (MDS).
Aims: The objectives of present study were to investigate 1) the prognostic value of BM osteopontin, 2) whether osteopontin level in response to chemotherapy can be used to predict therapeutic response in patients with newly diagnosed MDS.
Methods: From July 2012 to February 2014, 24 patients [12 with refractory cytopenia with multilineage dysplasia (RCMD) and 12 with refractory anemia with excess blasts (RAEB)] were enrolled. The RAEB patients were treated with hypomethylating agent, while RCMD patients received supportive care. The patients with RAEB were divided into three separate groups: in marrow complete remission (mCR), in progression of disease (PD), and in stable disease (SD) after chemotherapy. The levels of BM osteopontin were analyzed at the time of diagnosis from RCMD and RAEB patients, and after 3 cycles of hypomethylation chemotherapy from RAEB patients. The BM samples obtained at the time of diagnosis in RCMD patients, and at the time of diagnosis and after chemotherapy in RAEB patients.
Results: Osteopontin levels were significantly higher in the RAEB group compared to the RCMD group (120.62±20.42 vs. 62.62±7.40 ng/mL, respectively; P<0.001). Osteopontin levels did not change significantly with chemotherapy response (Figure 1).We analyzed the association between osteopontin levels at diagnosis and survival in RCMD and RAEB patients. RCMD patients were divided into two subgroups with high (≥ 63.1 ng/mL) and low (< 63.1 ng/mL) osteopontin levels at diagnosis. The osteopontin level had no significnat impact on survival among thess subgroups (P=0.157 for each variable; Figure 2). RAEB patients also were divided into two subgroups with high (≥ 115.3 ng/mL) and low (< 115.3 ng/mL) osteopontin levels. The low osteopontin level had a trend toward survival advantage (P=0.087 for each variable; Figure 3).

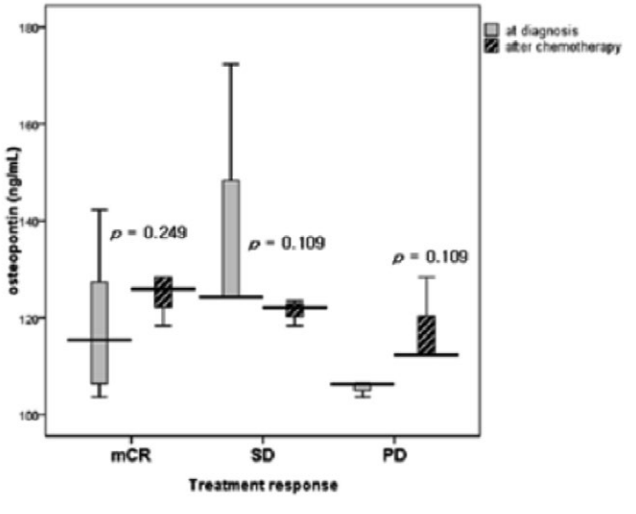

Figure 1. BM osteopontin level in response to chemotherapy in RAEB group.

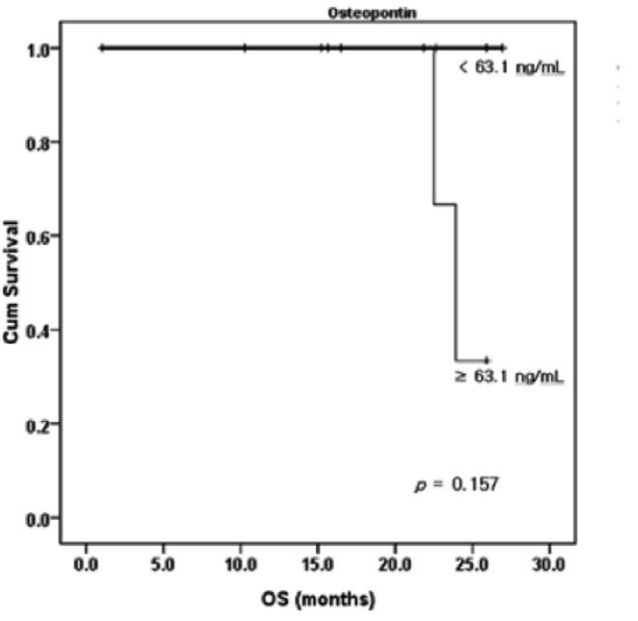

Figure 1. BM osteopontin level and survival in RCMD group. The patients were divided into two subgroups with high (≥63.1 ng/mL) and low (<63.1 ng/mL) osteopontin levels at diagnosis.

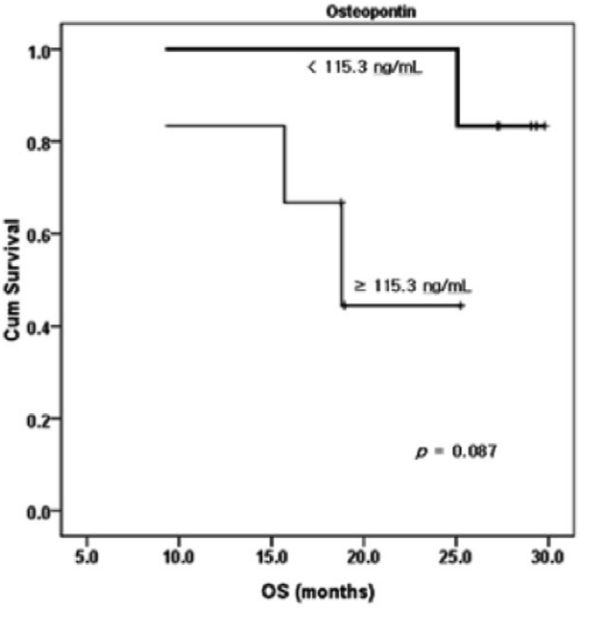

Figure 1. BM osteopontin level and survival in RAEB group. The patients were divided into two subgroups with high (≥115.3 ng/mL) and low (<115.3 ng/mL) osteopontin levels.

Summary and Conclusions: The present study demonstrated that RAEB patients have higher levels of marrow osteopontin than RCMD patients, and that these patients tend to show a shorter survival. In RAEB patients, the low osteopontin level had a trend toward survival advantage. Thus, these result may contribute to the understanding of the role of marrow osteopontin as the prognostic factor in MDS patients.

PB1829

HIPERFERRITINEMIA IN MYELODYSPLASTIC SYNDROME (MDS) PATIENTS - RETROSPECTIVE STUDY FROM A SINGLE CENTRE EXPERIENCE

M. Ionita[1,*] I. Ionita[1], L. Cheveresan[1], V. Todorescu[1], C. Ionita[1], D. Calamar[1], D. Oros[1], H. Ionita[1]
[1]Hematology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara, Romania

Background: Most myelodysplastic (MDS) patients have anemia and many of them require red blood cells (RBC) transfusions leading to iron overload. Hema-

tological improvement (HI) during iron chelation therapy (ICT) was first pointed out more than twenty years ago. This phenomenon seems to be more frequent after introduction of Deferasirox. The most simple test assessing iron overload is serum ferritin concentration.
Aims: Assessment of hyperferritinemia incidence in MDS patients at the moment of MDS diagnosis, and correlation between ferritin level and AML transformation in patients diagnosed with MDS.
Methods: The retrospective data collection from a single center experience (Department of Hematology County Hospital, Timisoara, Romania) between December 2003 and December 2012 included 121 patients (68 men and 53 women) with MDS. All the patients had complete blood count and serum ferritin level, and complete follow-up data.
Results: Ferritin level above 1000 ng/mL was found in 38 patients (31%) (Group 1) and ferritin level ≤1000 ng/mL in 83 patients (69%) (Group 2). Most patients with significant hiperferritinemia, were RBC transfusion dependent (81% of patients). Among patients with ferritin level ≤1000 ng/mL, 38% were RBC transfusion dependent. Serum hemoglobin concentration was lower in Group 1 patients in comparison with Group 2 patients (7,5 g/dL vs 9,4 g/dL, P<0,001). The most frequent MDS subtype in Group 1, were patients with refractory anemia (RA) (30%), compared with patients with ferritin ≤1000 ng/mL-15% (P<0,04). According to IPSS score, there were no differences between studied groups. Median follow up was 12 months. There was an improved overall survival (OS) in RBC transfusion independent patients compared to RBC transfusion dependent patients, but mean OS was not significantly statistically different in studied groups. No correlation was found between ferritin level and time to AML transformation.
Summary and Conclusions: Hiperferritinemia >1000 ng/mL does not influence survival and time to AML transformation in MDS patients. The most frequent MDS subtype in patients with ferritin level>1000 ng/mL was MDS RA. Among patients with ferritin level >1000 ng/mL, 81% were RBC dependent.

PB1830

EPIDEMIOLOGICAL, CLINICAL, THERAPEUTIC AND PROGNOSTIC FEATURES OF MYELODYSPLASTIC SYNDROM IN FARHAT HACHED HOSPITAL SOUSSE TUNISIA.

H. Rgaieg[1], K. Zahra[1,*] N. Ben Sayed[1], B. Achour[1], Y. Ben Youssef[1], M. Romdhani[1], M. Zaier[1], A. Khelif[1]
[1]hematology, Hopital Farhat Hached, SOUSSE, Tunisia

Background: The myelodysplastic syndrom (MDS) is a frequent entity in hematology. The clinical manifestations are characterized mainly by hemorrhagie, anemia or infection. An early diagnosis is essential in order to initiate an appropriate management to improve the prognosis of this affection.
Aims: The aim of our study is to report the epidemiological, clinical and therapeutic features of patients with MDS.
Methods: This retrospective analysis included 114 patients with MDS who were treated and followed between 2005 and 2013.
Results: The sex ratio was 1.The median age was71 years with a range from 11 to 99 years. Three patients had a family history of hematological diseases, and two had a personal history of neoplasia treated with chemotherapy and radiotherapy. The circumstances of discovery were an anemic syndrome, hemorrhagic syndrome and hemorrhagic syndrome in 68.7%, 5.2% and 2.6% of cases, respectively. The blood count showed anemia in 89.5% with VGM>100fl in 48.7% of cases, thrombocytopenia in 61.4% of cases, and leukopenia in 24.3% of cases. The myelogram showed dyserythropoiesis, dysgranulopoiesis, dysmegacaryopoiesis in 44.3%, 65,2% and 44.3% of cases, respectively. The karyotype was normal in 75.4% and abnormal in the remaining cases. According to the latest WHO classification, refractory anemia, sideroblastic anemia, refractory anemia with excess blasts, refractory anemia with excess blasts type 2, 5q- syndrome, refractory cytopenia with multi line and unclassifiable in 26.4%, 7%, 22.4%, 20%, 1.7%, 2.6%, and 20%, respectively. According to the IPSS, patients were classified very low risk, low risk, intermediate risk, high risk and very high risk in 10%, 36%, 30%, 17% and 7%, respectively. The management was symptomatic with red blood cell transfusions in 66% of cases, platelet transfusion in 56% of cases. The MDS was stable in 51% of cases and transformed into acute myeloid leukemia (AML) in 12, 3% of cases and only 5.26% of patients received chemotherapy. Only one patient aged 30years was underwent allograft of hematopoietic stem cell transplantation and two patients received revlemid. The overall survival at 2 years was 59% and 48% at 5 years.
Summary and Conclusions: Specific treatment for the kind of MDS should be started early in order to improve the management and prognosis of these patients.

PB1831

A MULTICENTRIC STUDY TO EVALUATE THE EFFICACY OF EPOIETIN ZETA (BIOSIMILAR OF EPO ALPHA) IN LOW RISK MYELODISPLASTIC PATIENTS

G.A. Palumbo[1,*] C. Vetro[1], C. Consoli[1], F. Dell'Aria[2], V. Di Giacomo[3], V. Di Martina[1], E. Schinocca[1], I. Amico[1], L. Tambè[1], P. Spina[1], S. Siragusa[2], D. Mannina[3], F. Di Raimondo[1]
[1]UO Ematologia, AOU "Policlinico-V.Emanuele", Catania, [2]UO Ematologia, AOU "Policlinico P.Giaccone", Palermo, [3]UO Ematologia, AO Papardo, Messina, Italy

Background: Erytropoietin (EPO) is a valuable option in the treatment of low risk myelodisplastic syndrome (MDS). Since the expiration of EPO alpha patent, epoietin biosimilars are becoming an increasingly important therapeutic option as anti-anemic drugs. Clinical efficacy and safety of biosimilar EPOs have been demonstrated in renal failure and chemotherapy anemias, but not in the treatment of myelodisplasic syndrome (MDS) patients.
Aims: Our study was designed to evaluate safety and efficacy of erythropoietin zeta (Retacrit, Hospira), a biosimilar of EPO alpha, to treat anemia of low risk MDS, such as low and Intermediate-1 (Int-1) patients according to International Prognostic Scoring System (IPSS).
Methods: We collected data from 32 MDS patients (14 males, 18 females), aged 58-84 (median 76.5), treated with EPO zeta in Sicily. According to WHO classification, 15 out of 32 subjects were diagnosed as refractory anemias (RA), 13/32 as refractory cytopenias with multilineage dysplasia (RCMD) and 4/32 as refractory anemias with excess blasts-1 (RAEB-1, bone marrow blasts<10%). Considering cytogenetic subgroups, karyotype was favourable in 28 out of 32 patients while was intermediate in the remaining 4. According to IPSS risk stratification, 17/32 patients were classified in the low risk group and 15/32 in the Int-1. Four patients were transfusion dependent before anti-anemia treatment with EPO. To start EPO treatment: 1) Emoglobin (Hb) had to be below 10 g/dl; 2) Serum iron, folate and B12 vitamin had to be in the in the normal range or corrected before therapy onset; 3) the maximum allowed transfusional need was of 3 units of packed red blood cells (PRBC) per month in the 90 preceding days; 4) serum EPO levels had to be below 500 UI/mL. Patients were treated with EPO zeta, 40.000 U s.c./week. After 8 weeks, whether there was no or suboptimal response (raise in Hb of less than 1.5 g/dl and/or no transfusion independence), EPO dose was raised to 80.000 U s.c./week. Treatment was continued for 24 weeks.
Results: Patients were considered as responders either when Hb levels raised of at least 1.5 g/dl from basal levels (and this data had to be confirmed in two consecutive evaluations) or when there was at least a 50% reduction of the trasfusional needs as evaluated before starting EPO. Responders were 23 out of 32 patients (71.9%); for 9/23 responders (39%) EPO dose had to be raised to 80.000 U/week to obtain the best results. No side effects greater than G1 according to WHO were reported in our cohort of patients during the 24 weeks treatment period.
Summary and Conclusions: In our series, efficacy of EPO zeta in low risk MDS patients was consistent with that reported in the literature using the originator EPO alpha in similar patient populations. Larger prospective randomized studies comparing originator and biosimilar EPOs will provide a definitive answer. However, biosimilar EPO zeta seems to be a good option to treat anemia in low risk MDS, thus saving resources considered its favourable pharmaco-economic profile.

PB1832

MANAGEMENT OF MYELODYPLASTIC SYNDROMES:EXPERIENCE OF MILITARIAN HOSPITAL OF RABAT MOROCCO

A. Sanae[1,*] J. selim[1], R. safae[1], D. kamal[1], M. Mohammed[1]
[1]clinical hematology, militarian hospital Mohammed V Rabat, Rabat, Morocco

Background: Myelodysplastic syndromes (MDS) are a disorder of hematopoietic stem cell that affects essentially old population.
Aims: In this study we aim to show characteristics of management of MDS in our department and give a small example about Moroccan way to treat them with a few resources.
Methods: This is a retrospective study including all patients managed in our training for MDS since 2006 to February 2015.
Results: A total of 78 patients were included. The median age was 65.94 years; the rate of men was more likely higher than women with a sex ratio [M/F] of 1.7. At diagnosis, the international prognosis scoring system (IPSS) was calculated for only 85, 89% (67 patients), 41.79% (28 patients) had low risque, 35.82%(24 patients) had intermediate 1 IPSS,14.92% (10 patients) intermediate 2,just five patients had a high risque with range of 7%.Reviesed IPSS(R-IPSS) was also calculated for only 61 patients (78%),9.8% had a very low R-IPSS,44.26% had low risque,29.5% had intermediate risque,10 patients had high (9%) and very high (6,55%) risque. Concerning management, we decided to wait and see for 41% of patients, 34.6% needed best supportive care, Erythropoietin was prescribed for 28% of our patients, 21.7% received Azacithidine, three of our patients had Hydroxyurea,one of them had Thalidomide, and only two of them have been selected to have an allo stem cell l transplantation. Overall Follow up is about 42 months. The overall survival rate was 77, 78% at 2 years, and 44, 44% at 5 years.
Summary and Conclusions: Despite our few resources our results are the same of most publications concerning survivals in MDS.

PB1833

THE MDS/MPN PATIENTS TREATED WITH 5-AZACITIDINE: A CLINICAL REAL LIFE EXPERIENCE

M. Riva[1,*] A. Molteni[1], L. Borin[2], M. Bernardi[3], A. Pellizzari[4], A. Freyrie[5], M. Della Porta[6], M. Nichelatti[1], E. Ravano[1], G. Quaresmini[7], J. Mariotti[8], D. Caramazza[9], M. Ubezio[6], S. Guarco[5], F. Gigli[10], R. Greco[1], R. Cairoli[1]
[1]Hematology, AO Niguarda Ca' Granda, Milan, [2]Hematology, Ospedale San Gerardo, Monza, [3]Hematology, Ospedale San Raffaele, Milan, [4]Hematology, Spedali Civili, Brescia, [5]Hematology, Ospedale Maggiore Policlinico, Milan, [6]Hematology, Policlinico San Matteo, Pavia, [7]Hematology, Ospedale Papa Giovanni XXIII, Bergamo, [8]Transfusion and Hematology, AO "Treviglio-Caravaggio", Treviglio, [9]Hematology, Ospedale di Circolo e Fondazione Macchi, Varese, [10]Hematology, Istituto Europeo di Oncologia, Milan, Italy

Background: The myelodysplastic/myeloproliferative disorders (MDS/MPN), according to the World Health Organization classification, include cases that have clinical, laboratory, and morphologic features intermediate between myelodysplastic syndrome (MDS) and myeloproliferative neoplasm (MPN). This is an infrequent entity and there is few data in the literature regarding treatment.
Aims: To evaluate the efficacy of 5-azacitidine (5-AZA) treatment in patients (pts) affected by MDS/MPN disorders.
Methods: A retrospective analysis of the MDS/MPN pts, into a large cohort of MDS or AML with blast<30% subjects, treated with 5-AZA in 10 centers in Lombardia region was performed. Response to therapy was considered evaluable if pts had reached, at the time of observation, at least 6 cycles of 5-AZA. The Kaplan Meier method was applied to evaluate the survival.
Results: From a population of 187 pts, data about 9 cases of MDS/MPN were carried out. Of these 4 were female and 5 male. Median age was 65 (range 23-81). Median bone marrow blasts was 5% (range 2-15); in two cases blasts were over 10%. In 3 pts Red Blood Cells transfusion dependence was present. In the other 6 cases median hemoglobin level was 10.2 g/dl (range 9-15). Only 1 patient had Platelet count (PLT) <10.000/mm^3, in 3 case PLT was <50.000/mm^3 and in 2 cases PLT was >300.000/mm^3. In 3 pts the Neutrophil count was ≥ 10.000/mm^3, in 1 case was<1500/mm^3. The median number of 5-AZA courses administered was 6 (range 5-20). A response to the treatment (including the cases of "stable disease" maintenance) was achieved in 5 cases on 7 evaluable. The median survival was 10 months (Figure 1).

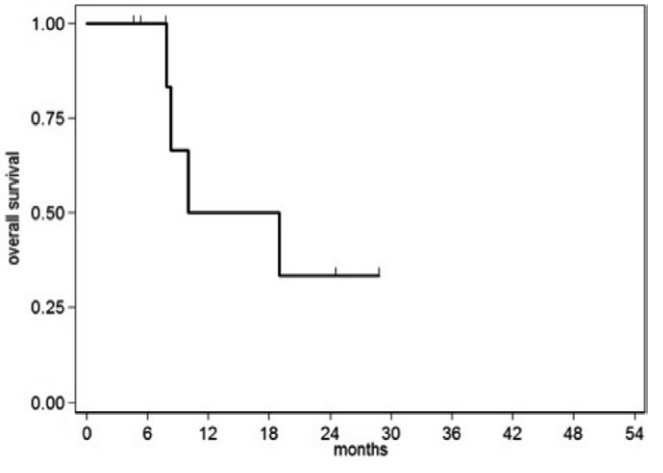

Figure 1.

Summary and Conclusions: This abstract is intended to be only a descriptive report of a disease entity rarely considered. The small sample size does not allow to draw any conclusion about the observed population. Nevertheless, the response rate to 5-AZA therapy seems to indicate a trend of efficacy and, therefore, the interest in collecting new data to make a significant analysis.

CHARACTERISTICS OF BLASTS IN THE PERIPHERAL BLOOD AND BONE MARROW SAMPLES OF THE PATIENTS WITH MDS TREATED WITH 5-AZACITADINE

H.T. Mya[1,*] L. Lopéz Anglada[1], J. Caballero[1], F. López Cadenas[1], J. Pérez Lopéz[1], M. Vidriales[1], A.M. Garcia-Sancho[1], N. Puig[1], J. Alonso[2], B. Albarrán[2], C. Olivier[3], J. Gonzalez Hurtado[4], M. Castellanos[5], M. Cañizo[1], M. Diez Campelo[1]
[1]Haematology, Hospital Universitario de Salamanca, Salamanca, [2]Haematology, Hospital Rio Carrión, Palencia, [3]Haematology, Hospital General de Segovia, Segovia, [4]Haematology, Hospital Virgen Del Puerto, Plasencia, [5]Haematology, Hospital Clinico de Valladolid, Valladolid, Spain

Background: Identification of the blast population in the patients with MDS has been improved in the recent years with the application of multiparametric flow cytometry (MFC).
Aims: The aim of our study was to fully characterize the blasts in the peripheral blood (PB) and bone marrow (BM) of the patients with MDS, by MFC before and after the treatment with 5-Azacitadine (5-AZA).
Methods: Patients with MDS, suitable for the treatment with 5-AZA were selected by the participating centers after the approval of the ethic committee. BM and PB samples were analyzed by BD FACSCanto flow cytometer before and after the treatment with 5-AZA. For each sample, detailed analysis with Euroflow leukemia orientation tube and acute myeloid leukaemia panels were performed (Table 1). A minimum of two million events were acquired. Infinicyt software version 1.8 (Euroflow member version) was used to analyze the acquired data files.
Results: Thirteen patients have consented to participate in the study from January 2011 to December 2014. Eight patients had normal cytogenetics and the remainder had one to three abnormal clones with del 5q, del 20q, trisomy 8 and del 11q. All patients had advanced MDS, either RAEB-1 or RAEB2 at 5-AZA treatment and received at least 3 cycles of 5-AZA before the reassessment.There were 13 pre and post 5-AZA BM samples and 8 pre and post 5-AZA PB samples. The pre 5-AZA blast count by flow cytometry ranged from 2.5 to 14% in the bone marrow and post 5-AZA blast count from 0.48% to 13%. By applying the Euroflow panels, the blast population with the same expression pattern as in the marrow was detected in the peripheral blood samples of all patients, with the lowest post treatment peripheral blood blast count being 0,02%. The blasts were uniformly positive for CD117, HLADR, dim CD45, CD13, CD33 and CD34 except one patient with negative CD34 expression. They did not express granulocytic or monocytic maturation markers in all patients, with MPO expression found only in 28% of the tested samples. Dim CD71 and dim CD123 expression was noted in ten patients whereas aberrant CD7 expression in three patients, CD56 in one patient and CD22 in one patient were noted. None of the patients had cCD3 or CD19 expression.

Table 1. Monoclonal antibodies used to analyze the blasts of in bone marrow and peripheral blood samples

Tubes	FITC	PE	PerCP5.5	PECy7	APC	APCH7	PB	PO
Tube 1	CD16	CD13	CD34	CD117	CD11b	CD10	HLA-DR	CD45
Tube 2	CD35	CD64	CD34	CD117	IREM-2	CD14	HLA-DR	CD45
Tube 3	CD36	CD105	CD34	CD117	CD71	CD33	HLA-DR	CD45
Tube 4	cTDT	CD56	CD34	CD117	CD7	CD19	HLA-DR	CD45
Tube 5	CD15	7.1	CD34	CD117	CD22	CD38	HLA-DR	CD45
Tube 6	CD42b/CD61	CD203c	CD34	CD117	CD123	CD4	HLA-DR	CD45
Tube 7	cMPO	cCD79b	CD34	CD19	CD7	cCD3	HLA-DR	CD45

Summary and Conclusions: The myeloblasts in the study patients demonstrated more immature immunophenotypic features with rare expression of maturation markers, consistent with the previous findings in advanced MDS. MFC can accurately identify the blast population of the same immunophenotypic features as that of the BM samples, in the PB samples at diagnosis and post treatment. Assessing the evolution of the characteristic blast population in the PB samples by multiparameter flow-cytometry may be an interesting and useful approach in the patients with MDS during the post-treatment period.

PB1835

SINGLE CENTRE SURVIVAL OUTCOMES IN THE TREATMENT OF INTERMEDIATE AND HIGH-RISK MYELODYSPLASTIC SYNDROME AND ACUTE MYELOID LEUKAEMIA WITH 5-AZACITIDINE

R. Stringer[1,*] D.T. Rider[2], D.J. Newman[2], D.R. Grace[2]
[1]Brighton and Sussex Medical School, Brighton, [2]East Sussex Healthcare NHS Trust, Eastbourne, United Kingdom

Background: The hypo-methylating agent, 5-azacitidine, is used to treat chronic myelomonocytic leukaemia (CMML), intermediate and high-risk myelodysplastic syndrome (MDS) and acute myeloid leukaemia (AML) with 20-30% blasts in patients unsuitable for high intensity treatment. Our centre is one of the largest users of azacitidine in the South East of England, reflecting the predominantly elderly population served.
Aims: To evaluate overall survival (OS) of patients treated with 5-azacitidine at our centre. Comparison of OS for MDS and AML groups and according to cytogenetic prognostication. Also to compare local prescribing practice with 2011 guidelines published by the National Institute for Clinical Excellence (NICE).
Methods: A retrospective analysis of medical records for all patients treated with four weekly cycles of 5-azacitidine (75mg/m^2) for 7 days. Patients were grouped according to diagnosis (MDS, CMML or AML) and cytogenetic classification as per the 5-group MDS Revised International Prognostic Scoring System (IPSS-R).
Results: Forty-two patients (*n*=19 AML, *n*=22 MDS, *n*=1 CMML) were identified from a 40 month observation period. Mean age was 71 (range 43-84). The median time from diagnosis to treatment was 17 days. The mean number of cycles received was 6 (range 1-23). Eighteen patients were diagnosed and received 5-azacitidine after treatment for a previous haematological malignancy: relapsed AML (*n*=7); transformed MDS (*n*=4); myeloproliferative disorder (*n*=3);

MDS following AML treatment (*n*=2); chronic lymphocytic leukaemia (*n*=1); myeloma (*n*=1). Kaplan-Meier analysis revealed an OS of 9.77 months for all 42 patients (95% CI 6.55-12.98). OS for MDS patients was 12.11 (CI 7.69-16.5). OS for MDS subgroups according to cytogenetic prognostic groups 'good', 'intermediate', 'very poor' and 'unknown' were 15.7 (*n*= 9, CI 7.7-23.7), 8.25 (*n*=4, CI 6.44-10.05), 3 (*n*=4, CI 0.23-5.77), and 10.6 (*n*=5, CI 2.48-18.72), months respectively. The 'good' cytogenetic group had significantly longer OS compared to 'bad' cytogenetics, P<0.001. OS for AML patients was 6.34 (CI 2.02-10.7) significantly worse when compared to all MDS patients, P=0.001. Twenty-nine patients (69%) met NICE approval criteria. Treatment outside the criteria was due to either no alternative available (9), instruction from regional transplant centre (3) or as part of a trial (1). Treatment within NICE recommendations showed significantly improved survival (P=0.001) with a mean of 13.27 months (CI 9.32-17.23) compared to 2.73 (CI 1.84-3.67).
Summary and Conclusions: Treatment with 5-azacitidine for AML and MDS gave OS of 12.11 and 6.34 months respectively in our elderly population with limited alternative therapeutic options. Favourable prognostic cytogenetics and treatment within national guidelines led to superior survival in this sample.

PB1836

PROGNOSIS IN MDS – CAN SERUM ERYTHROPOIETIN BE OF HELP?
R. Tenreiro[1,*] E. Cortesão[1], S. Ramos[1], M. Pereira[1], P. César[1], J. Carda[1], M. Gomes[1], L. Rito[1], E. Magalhães[1], A.C. Gonçalves[1], N. Costa e Silva[1], C. Geraldes[1], A.B. Sarmento Ribeiro[1], J. Nascimento Costa[1], L. Ribeiro[1]
[1]Clinical Hematology, Coimbra University Hospital Center, Coimbra, Portugal

Background: Myelodysplastic syndromes (MDS) are a heterogeneous entity characterized by dysplasia, hypercellular bone marrow, cytopenias and a risk of transformation to acute leukaemia (AL). Treatment is mainly based in the International Prognostic Scoring System (IPSS). In the last few years a lot has been written about MDS prognosis, with new scores for survival increasing in complexity making their use in everyday practice somewhat difficult. Although other prognostic factors, for instance, bone marrow fibrosis, LDH and β2-microglobulin elevation are readily available to clinical practice, others like gene mutations *TP53*, *EZH2*, *ETV6*, *RUNX1*, *NRAS*, *ASXL1*, *SRSF2*, *U2AF1* and *SF3B1* are not so easy to obtain. Two retrospective studies show a benefit in survival in patients treated with erythropoietin (Epo)±G-CSF, however without an impact on progression to AL.
Aims: We aimed to study the prognostic impact of serum Epo at diagnosis in a cohort of MDS patients.
Methods: We analyzed the records of 102 patients with *de novo* MDS between October 2009 and March 2014. Clinical and laboratorial data were collected and overall survival (OS) was estimated stratified according their serum Epo level: low vs normal vs<100 mUI/mL vs 100-500 mUI/mL vs ≥ 500 mUI/mL.
Results: The patients had median age of 74 years, with a Male:Female ratio of 0.8. According to the WHO classification, MDS subtypes where distributed as follows: Refractory Cytopenia with Multilineage Dysplasia (RCMD) (n=52), Refractory Cytopenia with Unilineage Dysplasia (RCUD) (n=12), Refractory Anemia with Excess Blasts (RAEB)-1 (n=8), (RAEB)-2 (n=8), Refractory Anemia with Ring Sideroblasts (RARS) (n=6), 5q- Syndrome (n=4) and Chronic Myelomonocytic Leukaemia (n=12). Thirty seven patients presented with low IPSS score, 39 with intermediate-1, 10 with intermediate-2 and 1 with high score. The mean erythropoietin was significantly lower in RCMD patients when compared to other MDS subtypes (P<0.05). Eleven patients (7 RAEB-2, 2 RCMD, 1 RAEB-1 and 1 CMML) progressed to AL. Their mean erythropoietin value was higher than in patients who did not evolve (P<0.05). We found that patients with elevated serum Epo had significantly lower survival rates than those with normal Epo levels (P=0.0336). The predictive value of serum Epo was maintained after Cox regression adjustment for LDH, age, IPSS, R-IPSS, hemoglobin, neutrophils, platelets, ferritin, β2-microglobulin and bone marrow blasts. In multivariate analysis, the independent survival predictors were serum Epo (P<0.001), ferritin (P<0.001), β2M (P=0.008) and marrow blast percentage (P<0.001).
Summary and Conclusions: In the present study, serum baseline erythropoietin was identified as in independent poor prognostic factor, with higher values in patients with progression to AL and decreased OS.

PB1837

CHRONIC MYELOMONOCYTIC LEUKEMIA IS CHARACTERIZED BY HYPOADIPONECTINEMIA AND HYPORESISTINEMIA INDEPENDENTLY FROM THE IGF-I SYSTEM: A CROSS-SECTIONAL STUDY
M. Dalamaga[1], A. Lekka[2,*], K. Karmaniolas[3], G. Sotiropoulos[2], J. Chamberland[4], M. Triantafilli[2], L. Tzianoumis[5], C. Mantzoros[4]
[1]Clinical Biochemistry, University of Athens, School of Medicine, Attikon General University Hospital, [2]Laboratory of Hematology, [3]Department of Internal Medicine, NIMTS Hospital, Athens, Greece, [4]Division of Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, [5]Hematologic Clinic, Ygeias Melathron, TYPET, Athens, Greece

Background: Accumulating evidence supports a role for obesity in the etiology of hematologic malignancies. Obesity may be also linked to chronic myelomonocytic leukemia (CMML), a hematologic malignancy combining proliferative and dysplastic characteristics, through altered adipokine secretion, one of which, adiponectin, presents a protective role in several malignancies, including leukemia and lymphoma.
Aims: In this cross-sectional study, we investigated the association of circulating adiponectin and resistin with CMML in relation to insulin-like growth factor-I (IGF-I), a hormonal system which is implicated in several human malignancies including leukemia.
Methods: Blood samples were collected from 14 cases with incident, histologically confirmed CMML and 70 healthy controls (1 patient *versus* 5 controls) who came for an annual check-up examination without any neoplastic and infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2004 and 2012. Informed consent was obtained from all participants. Serum adiponectin and resistin were determined respectively by radioimmunoassay (LINCO Research Institute, St Louis, MO). High molecular weight (HMW) adiponectin was measured using ELISA (ALPCO Diagnostics, Salem). IGF-I and IGFBP-3 concentrations were measured using an immunoradiometric assay kit (DSL, Webster, TX) The statistical analysis of the data was performed using IBM-SPSS® version 22 for Windows.
Results: CMML cases presented significantly higher height and weight than control subjects (P<0.001), while differences of body mass index (BMI) were only of borderline significance (P=0.10). Lower serum total or HMW adiponectin and/or resistin levels were independently associated with higher risk of CMML adjusting for age, gender, BMI and serum IGF-I levels (p≤0.05). In particular, CMML was characterized by hypoadiponectinemia (total adiponectin in CMML patients: 12.5±8.8 μg/dL *versus* controls: 16.3±7.9 μg/dL, P=0.05) and hyporesistinemia (resistin in CMML patients: 12.1±6.2 ng/mL *versus* controls: 21.9±32.7 ng/mL, P=0.013). Total adiponectin exhibited a positive correlation with HMW adiponectin both in CMML cases and controls (r=0.83, P<0.001; r=0.88, P<0.001, respectively). Although, total and HMW adiponectin were both significantly reduced in CMML, HMW did not offer any substantial additional predictive value over total adiponectin. Serum IGF-I was not significantly and independently associated with CMML in multivariable analysis adjusting for age, gender, date of diagnosis, BMI and history of lymphohematopoietic cancer (P=0.56).
Summary and Conclusions: Total and HMW adiponectin may present a protective role in CMML by suppressing proliferation of myeloid cell lineage, whereas resistin levels may be decreased via a compensatory mechanism due to an upregulation of other inflammatory factors etiologically and ontologically linked to CMML. Further studies are needed to confirm these associations and to explore the mechanisms underlying adiponectin's role in myelopoiesis and leukemogenesis.

PB1838

THE HETEROGENEITY OF MYELODYSPLASTIC SYNDROME WITH CHROMOSSOME 5 ABNORMALITIES: THE PROGNOSTIC IMPACT OF BLAST COUNT, KARYOTYPE, P53 PROTEIN EXPRESSION AND TRANSFUSION DEPENDENCY
G. Brás[1,*] A.R. Pereira[2], M. Alpoim[1], R. Pinto[1], E. Fonseca[3], F. Príncipe[1], J. Guimarães[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar de São João, Porto, [2]Escola de Ciências da Saúde, Universidade do Minho, Braga, [3]Serviço de Anatomia Patológica, Centro Hospitalar de São João, Porto, Portugal

Background: Deletion of the long arm of chromosome 5 [del(5q)] is the most prevalent cytogenetic abnormality in patients with Myelodysplastic Syndrome (MDS) and is frequently associated with good prognosis. However, MDS with del(5q) is a heterogeneous entity in terms of survival and/or progression to Acute Myeloid Leukemia (AML). The analysis of the proposed Revised International Prognostic Scoring System (R-IPSS) for MDS reinforces the importance of blast count, karyotype and number and degree of cytopenias to define high-risk subgroups with worse prognosis. More recently, the presence of TP53 mutation and/or high P53 protein expression by immunohistochemistry (IHC) has been proposed as additional markers of poorer outcome in MDS with chromosome 5 abnormalities.
Aims: Assess the prognostic impact of blast count, number of additional cytogenetic abnormalities, transfusion dependency and p53 IHC expression, in MDS with del(5q).
Methods: We retrospectively analyzed 18 patients diagnosed with MDS and del(5q) at our centre, between 2005-2014, in which a bone marrow histology was available. All patients were evaluated for R-IPSS, transfusion dependency and P53 protein expression by bone marrow IHC. A high blast count was defined by the presence of >5% of blasts cells in bone marrow smear. A high number of chromosome abnormalities was defined by >=2 abnormalities besides del(5q). A positive p53 IHC expression was defined by the presence of >5% p53 positive cells observed on the histology of bone marrow. Transfusion dependency was defined as no period of eight consecutive weeks without red blood cell (RBC) transfusions.
Results: The median of age was 69 (55-81) years and 11 (61%) patients were male. The MDS WHO-classification was: RCMD n=3 (16,7%), RAEB-1 n=3 (16,7%), RAEB-2 n=5 (27,8%) and MDS with isolated del(5q) n=7 (38,9%). In

terms of R-IPSS evaluation, patients were stratified as: Very Low n=1 (5,6%), Low n=6 (33,3%), Intermediate n=2 (11,1%), High n=2 (11,1%) and Very High n=7 (38,9%). For the relevant prognostic parameters analyzed, frequencies were: n=8 (44,4%) had >5% of blasts, n=4 (22,2%) had >=2 chromosome abnormalities besides del(5q), n=16 (88,9%) had transfusion dependency and n=9 (50%) had >5% of p53 IHC protein expression. Overall Survival (OS) and Progression to AML Free Survival (PFS) were significantly worse for patients with >5% of blast count (OS: 5 months vs 39 months, P<0.05; PFS: 5 months vs 32 months, p>0.05) and for those with >=2 chromosome abnormalities besides del(5q)(OS: 6 months vs 36 months, P<0.05; PFS: 5 months vs 29 months, P<0.05). Those differences were also observed in multivariate analysis (P<0.05). A trend towards a worse OS and PFS was observed for transfusion dependency (OS: 21 months vs 48 months, P=0.18; PFS: 17 months vs 44 months, P=0.12) and >5% of p53 IHC protein expression (OS: 19 months vs 30 months, P=0.37; PFS: 18 months vs 21 months, P=0.75).

Summary and Conclusions: The presence of a high blast count and other chromosome abnormalities besides del(5q) define subsets of worse prognosis in MDS with del(5q), despite of this being classically considered a chromosomal abnormality associated with good prognosis. There is also a trend for a poor prognosis in patients with transfusion dependency and positive p53 IHC protein expression. The absence of a statistical significant difference in OS and PFS for these patients subsets might be due to the low number of patients in this cohort.

PB1839

COMPLEX KARYOTYPE CHANGES ARE THE STRONGEST PREDICTOR OF OUTCOME OF ALLOGENEIC TRANSPLANTATION IN MYELODYSPLASTIC SYNDROME

J. Radocha[1], A. Zavrelova[1], P. Belohlavkova[1], M. Lanska[1], B. Visek[1], P. Zak[1,*]
[1]University Hospital Hradec Kralove, 4th Department of Medicine-Hematology, Hradec Kralove, Czech Republic

Background: Complex karyotype has been recently reported as one of the predictors of poor outcome of allogeneic transplantation in patients with myelodysplastic syndrome (MDS). Current opinions challange transplantation as a curative option in these patients.

Aims: To evaluate impact of complex karyotype changes of MDS in setting of allogeneic stem cell transplantation

Methods: We evaluated all consecutive patients with all stages of MDS transplanted at our center from 2007-2014. Patients parameters, demographic data, disease status, pretransplant remission status, type of transplantation and karyotype has been evaluated as possible factors influencing outcome of transplantation.

Results: Overall 22 patients (12 males, 10 females, median age 56 years, 32-66 years) were analysed. Disease status was as follows: 12/22 were MDS related AML, 4/22 RAEB-2, 3/22 RAEB-1 and 3/22 RA or RCMD. Majority of patients (20/22) underwent transplant from matched unrelated donor, 2/22 had sibling donor. Conditioning was intended myeloablative in 13/22 patients and reduced intensity in 9/22. 14 patients reached hematologic CR before transplant. Five (5/22) patients had complex karyotype changes. The median follow-up was 3 months. Median overall survival was not reached, survival at 5 years was 56%. The strongest predictors of outcome were: CR before transplant (median survival 4.5 months vs. not reached, P=0.0997, trend only), stage of the disease (AML and RAEB-2 vs. others, median survival 18 months vs. not reached, P=0.0361) and komplex karyotype changes (meadian survival 4.5 months *versus* not reached P=0.0044).

Summary and Conclusions: Complex karyotype changes, disease stage and remission status are probably the most singificant factors which influence the outcome of allogeneic transplantation in MDS. The possibility of transplant for these patients is a matter for debate since the outcome remains dismal.

PB1840

AZACITIDINE IN CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML): POSSIBILITY OF IMPROVED RESPONSE AND SURVIVAL

P. Niscola[1,*] A. Tendas[1], L. Cupelli[1], D. Piccioni[1], M. Giovannini[1], L. Scaramucci[1], E. Abruzzese[1], T. Caravita[1], T. Dentamaro[1], L. Morino[1], B. Neri[1], D. Renzi[1], A. Siniscalchi[1], M.M. Trawinska[1], P. de Fabritiis[1]
[1]Hematology, Sant'Eugenio Hospital, Rome, Italy

Background: CMML is a clonal disease characterized by high rate progression to AML. Treatment is not curative traditionally and allo-SCT remains the only option, although in a minority of patients. Recently, significant clinical benefits by hypomethylating agents have been reported.

Aims: To evaluate efficacy and toxicity of azacitidine on CMML.

Methods: Fourteen patients with a median age of 75 (60-85) and several comorbidities were evaluated; 5/14 (37%) aged >80 years. Median PS was 70% (range 50-90). According to WHO, 10, 2 and 2 patients presented CMML-2, CMML-1 with severe and symptomatic cytopenias and CMML-related AML with<30% BM blasts, respectively. Six patients had proliferative CMML, 7 were transfusion-dependent at the start of azacitidine and two had abnormal karyotype. Three patients had CMML secondary to low risk MDS; one patient presented a therapy-related CMML. Previous therapies were: intensive chemotherapy (1), ESA (6) and hydroxyurea (8); 4 patients were treatment-naïve. The interval between diagnosis and the start of azacitidine was 2 months (0.3 – 18) and the median number of courses was 12 (2-33). Treatment was well-tolerated and with no remarkable side effects. Responses were evaluated according to 2006 IWG.

Results: Thirteen patients were evaluable for response after the fourth cycle of azacitidine; the remaining patient developed AML after the second cycle of therapy. Five patients (36%) achieved CR and 6 (43%) PR with an ORR of 78%; two patients presented a primary failure to azacitidine. After a median follow-up of 19 months (5-46), 6 patients (3 in PR, 2 in CR and 1 with AML) are still alive, with an OS from CMML diagnosis and the start of azacitidine treatment of 25 and 17 months, respectively. Among responding patients, 1 is alive and well 120 days after unrelated allo-SCT. Six patients progressed to AML: 1 was primarily unresponsive to azacitidine and 5 progressed after 17 (5-40) months from the start of therapy. Among the 8 deceased patients, 5 died from AML progression and 3 because of complications related to pre-existing cardiac comorbidities (2 patients), or secondary lung cancer (1 patient).

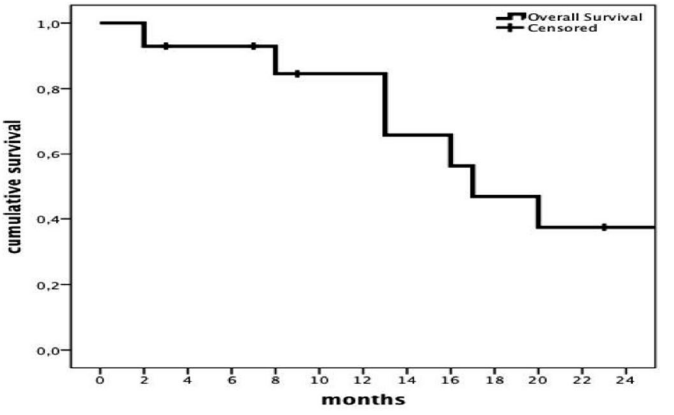

Figure 1. Overall survival from the start of azacitidine.

Summary and Conclusions: Despite the limited number of cases, the results are encouraging, considering age and the complexity of the patients. The ORR of 78% and the unfavorable prognosis of our comorbid patients reinforce the existing evidence, making azacitidine the most appropriate treatment of CMML in the real life setting.

PB1841

CIRCULATING TOTAL LEPTIN, LEPTIN RECEPTOR AND FREE LEPTIN INDEX LEVELS IN CHRONIC MYELOMONOCYTIC LEUKEMIA: A CROSS-SECTIONAL STUDY

M. Dalamaga[1,1], A. Lekka[2,*] M. Triantafilli[2], G. Sotiropoulos[2], J. Chamberland[3], K. Karmaniolas[4], L. Tzianoumis[5], C. Mantzoros[3]
[1]Clinical Biochemistry, University of Athens, School of Medicine, Attikon General University Hospital, [2]Laboratory of Hematology, NIMTS Hospital, Athens, Greece, [3]Division of Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States, [4]Department of Internal Medicine, NIMTS Hospital, [5]Hematologic Clinic, Ygeias Melathron, TYPET, Athens, Greece

Background: Recent evidence suggests that overweight/obesity may be implicated in the etiology of hematologic malignancies, including myelogenous leukemia and myelodysplastic syndromes. A strong asociation of overweight/obesity with insulin resistance, characterized by hyperinsulinemia, has been well documented. There is evidence that insulin resistance is implicated in several malignancies associated with excess body weight. Leptin and, particularly, free leptin, the biologically significant form of leptin, reflecting accurately the body fat mass, regulate glucose and lipid metabolism by ameliorating insulin sensitivity and decreasing intracellular lipids.

Aims: In this cross-sectional study, we investigated the potential association of leptin and free leptin with chronic myelomonocytic leukemia (CMML), a hematologic malignancy combining proliferative and dysplastic features, after adjusting for a potential confounding effect of age,gender, date of diagnosis (matching factors) a well as withbody mass index (BMI), family history of lymphohematopoietic cancer (LHC) and serum insulin.

Methods: Blood samples were collected from 14 cases with incident, histologically confirmed CMML and 70 healthy controls (in an analogy of one patient *versus* five healthy controls) who came for an annual check-up examination without any neoplastic and infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2004-2012. Informed consent was obtained from all study participants. Serum leptin and insulin were determined by radioimmunoassay (Linco Research Institute St Louis MO, and Milli-

pore Co Billerica, MA respectively). Serum leptin receptor levels (sOB-R) levels were measured using a commercially available ELISA (BioVendor R&D, Brno, Czech Republic). Free Leptin Index (FLI) was calculated as the ratio of leptin to sOBR. The statistical analysis of the data was performed using IBM-SPSS® version 22 for Windows.
Results: CMML cases presented significantly higher height and weight than control subjects (P<0.001), while differences of BMI were only of borderline significance (P=0.10). Serum insulin was significantly higher in cases than controls (P=0.05). CMML cases exhibited a significant total and free hypoleptinemia in comparison to controls (total leptin in patients with CMML: 13.2±16.3 ng/mL *versus* controls 24±21.1 ng/mL, P=0.005; FLI in patients with CMML: 0.81±1.6 *versus* controls: 2.84±5.4, P=0.04). Moreover, CMML cases exhibited significantly lower serum levels of sOB-R than controls (P=0.04). In multivariate analysis, subjects with total and free hypoleptinemia presented significantly higher odds for CMML after adjusting for age, gender, date of diagnosis, BMI, family history of LHC and serum insulin levels.
Summary and Conclusions: This study raises the hypothesis that leptin which reflects overall fat mass and insulin may be associated with CMML. Leptin's major physiological role is to signal inadequate rather than excess energy stores, and hypoleptinemia found in a small but significant percentage of obese humans is associated with hyperinsulinemia and impaired T-cell function. Further mechanistic, interventional and epidemiological studies are needed to confirm these findings and to explore whether leptin may mediate the effect of body fat distribution on insulin resistance and leukemogenesis risk.

PB1842

ASSOCIATION OF THYROID HORMONES AND AUTOIMMUNE THYROIDITIS WITH CHRONIC MYELOMONOCYTIC LEUKEMIA
M. Dalamaga[1], M. Triantafilli[2], G. Sotiropoulos[2], K. Karmaniolas[3], L. Tzianoumis[4], A. Lekka[2,*]
[1]Clinical Biochemistry, University of Athens, School of Medicine, Attikon General University Hospital, [2]Laboratory of Hematology, [3]Department of Internal Medicine, NIMTS Hospital, [4]Hematologic Clinic, Ygeias Melathron, TYPET, Athens, Greece

Background: Thyroid disease has been associated with increased incidence of leukemia, myelodysplastic syndrome (MDS) and lymphoma. No previous study has investigated whether thyroid disease and especially autoimmune thyroid disease (ATD) is associated with chronic myelomonocytic leukemia (CMML), a hematologic malignancy which has been classified as a subtype of MDS but was recently demonstrated to be a distinct entity combining proliferative and dysplastic features.
Aims: In this case-control study, we investigated the potential association of thyroid hormones and ATD with CMML.
Methods: Our study included 14 cases with incident histologically confirmed CMML and 70 controls (one patient *versus* five controls) who came for an annual check-up examination without any neoplastic and infectious conditions, matched on gender, age and year/month of diagnosis (±1 month) between 2004-2012. All participants were submitted to clinical and ultrasound thyroid evaluation. Informed consent was obtained from all study participants. Serum free T3 (fT3), free T4 (fT4), thyroid-stimulating hormone (TSH), thyroglobulin and thyroperoxidase antibodies (anti-TG and anti-TPO) were determined using electrochemiluminescence on Cobas e411 analyzer (Roche, Basel, Switzerland). The statistical analysis of the data was performed using IBM-SPSS® version 22 for Windows.
Results: Mean serum levels of fT3 and fT4 were significantly higher in CMML patients than in controls (fT3 in patients with CMML: 3.6±0.3 pg/mL *versus* controls: 2.9±0.42 pg/mL, P<0.001; fT4 in patients with CMML: 1.7±0.29 ng/dL *versus* controls: 1.4±0.28 ng/dL, P<0.001). The prevalence of anti-thyroid antibodies (anti-TG and anti-TPO Ab) was significantly higher in CMML patients than in controls (P<0.001). On the contrary, mean TSH serum levels were significantly lower in CMML patients than in controls (TSH in patients with CMML: 1.56±0.6 μIU/mL *versus* controls: 2.9±0.4 μIU/mL, P=0.001). The frequency of family history of thyroid disease (first degree relatives) in CMML patients was similar with that reported by controls (P=0.52). Finally, the prevalence of clinical thyroid disease-especially ATD-was higher in patients with CMML than in controls (P=0.06, though not statistically significant at α=0.05).
Summary and Conclusions: We have found biologically plausible and empirically strong evidence that thyroid hormones, thyroid disease and especially ATD may be associated with CMML. Further larger prospective studies are needed to confirm this association and explore underlying interactive mechanisms between thyroid hormones and thyroid autoimmunity with myelopoiesis and leukemogenesis.

PB1843

EFFICACY OF AZACITIDINE IN MDS AND AML WITH PROLIFERATIVE FEATURES
A. Almeida[1,*] F. Pierdomenico[1]
[1]IPO Lisboa, Lisbon, Portugal

Background: Azacitidine is a hypomethylating agent with demonstrated efficacy in high risk myelodysplastic syndromes (MDS), chronic myelomonocytic leukemia (CMML) and acute myeloid leukemia (AML). The trials that have led to its approval for these indications excluded patients with leucocytosis and most observational studies suggest that it is less efficacious in patients with proliferative disease.
Aims: We present a single-centre retrospective analysis of the efficacy of azacitidine in 18 with MDS, CMML and AML with proliferative features and compare these with a similar cohort of patients with non-proliferative disease.
Methods: Data was collected retrospectively from clinical files following ethical committee approval
Results: The cohort with proliferative disease, defined by a leukocytosis >13x10^9/L, had a median age at diagnosis of 67 years; 55% were men. WHO 2008 diagnosis was MDS in 2 patients, AML in 8 patients and CMML in 8 patients. At diagnosis, the median hemoglobin was 8.9 g/dL (range 6.5-13.0), median WBC was 34.7x10^9/L (range 12.7-95.0) and median platelet count 89x10^9/L (range 12-695). Bone marrow blast percentage was >10% in 72% of patients; median 19% (range 1.2-98) Karyotypes were normal in 44%, intermediate risk in 27% and poor risk in 29%. Azacitidine was used as single agent as first line therapy with no prior cytoreduction in all patients. Patients started treatment a median of 2.3 months following diagnosis. Marrow response was assessed after the 6th cycle. Treatment was continued until progression in all cases. A median number of 8 cycles were administered. Marrow assessments were available in 16 patients. Responses were documented in 6 patients, of which 1 was complete and 5 were partial. Stable disease at time of assessment was seen in 4 patients and progression in 6. Transfusion independence was achieved in 8 of 10 patients who were previously transfusion-dependent. Four patients only received 1 cycle of treatment due to progression in 3 and pneumonia in one. Normalization of WBC was achieved in all but the former 4 patients after a median of 2.3 cycles. All patients had died by the time of analysis, 16 due to progression, one due to pneumonia and one due to cerebral haemorrhage. Median overall survival was 15.85 months. The median survival of the comparator non-proliferative group was 11.58 months. This was not significantly different from that of the proliferative group (15.85 vs 11.58 months, respectively; log rank test: P=0.25).
Summary and Conclusions: These results support the use of azacitidine in patients with proliferative disease, increasing treatment options in these patients.

PB1844

CHARACTERISTICS, TREATMENT, OUTCOMES AND SURVIVAL OF IRISH PATIENTS WITH CHRONIC MYELOMONOCYTIC LEUKAEMIA (CMML)
S. Maung[1,*] C. Burke[2], J. Bains[2], M. Coyne[2], R. Desmond[2], J. McHugh[2], H. Enright[2]
[1]Haematology, Tallaght Hospital, Trinity College Medical School, Dublin, Ireland, [2]Haematology, Tallaght Hospital, Trinity College Medical School, Dublin, Ireland

Background: CMML is classified as a myelodysplastic/myeloproliferative neoplasm (2008, WHO). Compared with other haematological malignancies it is an uncommon disorder, and there are few large studies regarding outcome. Approximately 9.5% of patients registered with the Irish National Registry for Myelodysplastic Syndromes (MDS) between 2007 and 2014 had CMML.
Aims: We evaluated the treatment, outcome and survival for 29 Irish patients with CMML.
Methods: We evaluated presenting symptoms, diagnostic findings, cytogenetics and treatment received including blood transfusions, haematopoietic growth factors, hypomethylating agents, chemotherapy and transplantation.
Results: The median age at diagnosis was 75 years (range 56-89) with male: female ratio of 1.9:1. Nineteen patients (65.5%) were asymptomatic at presentation and 10(34.5%) had constitutional symptoms, bleeding, and/or splenomegaly. Apart from monocytosis in all patients, features at presentation included anaemia (65.5%), thrombocytopenia (55%), leukocytosis (45%), neutropenia (20.5%), raised LDH (68.9%) and splenomegaly (17%). Peripheral blasts were present in 5 patients, all of whom subsequently developed Acute Myeloid Leukaemia (AML). JAK2V617F mutation was negative in all patients tested (n=9). Seven patients (44%) had CMML-2 and 21(72.4%) CMML-1. Ninety three percent of patients had a hypercellular marrow. Evidence of dysplasia (93% dyserythropoiesis, 86% myeloid dysplasia, 72% megakaryocytic dysplasia) and increased reticulin fibrosis (73%) were noted. Only 7 patients (24.1%) had cytogenetic abnormalities, including trisomy 8 (n=2), t(8;21) (n=1), Monosomy 7 (n=1), trisomy 19 (n=2) and –Y (n=2). Seventeen patients (58.6%) received active management including Azacitidine (n=11), intensive AML-type induction therapy (n=2), allogeneic marrow transplant (n=1) and Hydroxycarbamide (n=6). Seven (24.1%) patients received transfusion support only. Erythropoietin was given in 7 patients (24.1%) and G-CSF in 2. Sixteen patients (55%) required transfusion at diagnosis. Twelve patients (72%) required red cells and 13(68%) required platelets during the course of illness. Eight of 11 patients treated with Azacitidine remained transfusion dependent. Median survival was 20 months (0-154 months). Transformation to AML was seen in 7 patients (24.1%). Survival for patients who received Azacitidine was 22 months

(11 to 154) with a median treatment cycles of 18 (3-33). One patient has been on Azacitidine for 7 years and remains alive 13 years after diagnosis. Median survival of patients who received Hydroxycarbamide and AML-type induction were 11.5 and 22 months respectively. Only one patient (with monosomy 7) received allogeneic transplantation but died 12 months later due to AML. Survival was 32 and 15 months respectively for patients with normal/ good risk karyotype and those with adverse cytogenetics and 18 months and 21 months respectively for those who received active management and those managed by best supportive care.
Summary and Conclusions: A significant number of CMML patients are diagnosed incidentally and the majority of patients are asymptomatic at diagnosis. The classical finding of splenomegaly is not always present. All male patients were anaemic at diagnosis. Adverse risk cytogenetics was less frequently encountered but indicated poor outcomes. Most patients were transfusion dependent and two thirds of patients were managed actively, mainly with Azacitidine.

PI3K GAMMA/DELTA AS A NOVEL TARGET FOR THE TREATMENT OF MULTIPLE MYELOMA

R. Piddock[1,*] G. Pillinger[1], M. Auger[2], S. Rushworth[1], K. Bowles[1,2]
[1]Norwich Medical School, University of East Anglia, [2]Norfolk and Norwich University Hospital Trust, Norwich, United Kingdom

Background: Inhibiting tumor proliferation by targeting specific tyrosine kinases has proved an effective and well tolerated strategy in a number of hematological malignancies. Phosphoinositide-3-kinases (PI3K) are an enzyme group that generates phosphatidylinositol 3, 4, 5-triphosphate which provides a membrane docking site for the tyrosine kinase AKT (also known as protein kinase B). The class 1 PI3K isoforms (p110α/β/γ/δ) are known to be involved in the carcinogenesis and chemotherapy resistance of many cancers types, with p110δ and p110γ specifically being enriched in the hematopoietic system. The aberrant activation of the PI3K-AKT pathway has previously been shown to be active in Multiple Myeloma (MM) where it functions as a pro-survival signaling pathway. IPI-145 (Duvelisib) is a PI3K p110δ and p110γ inhibitor which at 25mg twice a day dosing is reported to achieve a plasma steady-state concentration of 0.9 μM and plasma peak concentration (Cmax) of 2.4 μM.
Aims: Here we investigate the effects of IPI-145 on MM pro-survival signaling, proliferation and bone marrow stromal cell (BMSC) and SDF1 mediated plasma cell migration using drug concentrations achievable in vivo.
Methods: To investigate the role of PI3K p110δ and p110γ subunits in regulating MM survival and migration we used PI3K pharmacological inhibitor IPI-145 (PI3K δγ inhibitor) with LY295002 (Pan PI3K inhibitor) and CAL101/Idelalisib (PI3K p110δ inhibitor) as controls. CellTiter-Glo was used to measure survival and transwell permeable plates with 8.0μM pores for migration assays. Western blotting was used to examine the role of BMSC, SDF-1 and IL-6 in regulating AKT and MAPK activation in MM cells in response to PI3K δγ inhibition.
Results: The PI3K δγ inhibitor IPI-145 reduced survival of MM cells at 1uM. IPI-145 triggered cytoxicity was associated with pAKT inhibition. IPI-145 also inhibited MM cell growth in response to IL-6 and bone marrow stromal cell co-culture. Furthermore we found that IPI-145 inhibited the migration of MM cells responding to BMSC and SDF-1 stimulation. Finally, we report that IPI-145 can inhibit SDF-1 induced AKT phosphorylation and downstream signaling.
Summary and Conclusions: IPI-145 inhibits MM cell survival and migration at concentrations achievable in vivo. The results reported here provide a molecular mechanistic rationale for the clinical evaluation of IPI-145 in MM patients.

PB1846

BORTEZOMIB INHIBITS OSTEOCLASTOGENESIS AND MODULATE CHIT1 AND YKL40 EXPRESSION

D. Tibullo[1,*] M. Di Rosa[1], C. Giallongo[1], P. La Cava[1], N. Parrinello[2], A. Romano[1], C. Conticello[1], F. Puglisi[1], G. Sapienza[1], G. A. Palumbo[1], F. Di Raimondo[1]
[1]Division of Hematology, azienda ospedaliera universitaria policlinico Vittorio Emanuele, University of Catania, [2]Division of Hematology, azienda ospedaliera universitaria policlinico Vittorio Emanuele, azienda ospedaliera universitaria policlinico vittorio emanuele, Catania, Italy

Background: Osteolytic bone disease is a common manifestation of multiple myeloma (MM) that leads to progressive skeleton destruction and is the most severe cause of morbidity in MM patients. It results from increased osteolytic activity and decrease osteoblastic function. Activation of mammalian chitinases CHIT1 and YKL40 is associated with osteoclast (OCs) differentiation and bone digestion.
Aims: In the current study, we investigated the effect of two Bortezomib's concentration (BO) (2.5 nM and 5nM) on osteoclastogenesis by analyzing regulation of chitinase expression.
Methods: In order to obtained the OCs, the conditioned medium was supplemented with 25 ng/mL soluble rhRANK ligand (Peproteck, BDA, Italy) and 20 ng/mL rhM-CSF (Peproteck, BDA, Italy), for 21 days w/o Bortezomib (2.5nM or 5nM). The medium was replaced every 3 days. Cells and supernatants were harvested every 3 days for enzymatic assay, qRT-PCR, immunofluorescence and Western blotting. The supernatants were stored at − 20 °C. To confirm that macrophages achieved OCs differentiation, suitable markers were analyzed by qRT-PCR. Finally, in order to evaluate the ability of MM cell lines (U266) to digest bone, dentine discs were added to the wells before cell seeding. U266 cultured with conditioned medium (without BO) for 24 h were used as a control.
Results: OCs exposition to BO was able to inhibit the expression of different OCs markers such as RANK, CTSK, TRAP and MMP9. In addition BO-treatment reduced CHIT1 enzymatic activity and both CHIT1 and YKL40 mRNA expression levels and cytoplasmatic and secreted protein. Moreover,, immunofluorescence evaluation of mature OCs showed that BO was able to translocate YKL40 into the nucleus, while CHIT1 remained into the cytoplasm. Since MM

cell lines such as U266, SKM-M1 and MM1 showed high levels of CHIT1 activity, we analyzed bone resorption ability of U266 using dentin disc assay. After 3 days of incubation, we observed that U266 cells were able to form resorption pits on a dentin disc. Silencing the chitinase proteins in U266 cell line with specific siRNAs, resulted in pits number reduction on dentine discs
Summary and Conclusions: In conclusion we showed that BO decreases osteoclastogenesis and reduces bone resorption in OCs and U266 cell line by modulating the chitinases CHIT1 and YKL40. These results indicate that chitinases may be a therapeutic target for bone disease in MM patients.

PB1847

POLYMORPHISM WITHIN THE BFGF PROMOTER REGION IS ASSOCIATED WITH DISEASE PROGRESSION AND RESPONSE TO CHEMOTHERAPY IN PATIENTS WITH MULTIPLE MYELOMA

T. Wróbel[1,*] A. Butrym[1,2], P. Lacina[3], J. Rybka[1], K. Gembura[3], K. Bogunia-Kubik[3], G. Mazur[4]
[1]Dept. of Hematology, Blood Neoplasms and Bone Marrow Transplantation, [2]Dept. of Physiology, Wroclaw Medical University, [3]Laboratory of Clinical Immunogenetics and Pharmacogenetics,, L. Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, [4]Department of Internal, Occupational Diseases and Hypertension, Wroclaw Medical University, Wrocław, Poland

Background: Vascular endothelial growth factor (VEGF) and basic fibroblast growth factor (bFGF) play an important role in the initiation of angiogenesis.
Aims: We aimed to assess whether polymorphisms located within the genes coding for these key angiogenic activators (*VEGF* (rs3025039; C>T) and *bFGF* (rs308395, G>C)) contribute to disease susceptibility and/or progression in patients with multiple myeloma (MM) and response to chemotherapy.
Methods: For this purpose, 133 patients with MM and 122 healthy individuals were typed for the *VEGF* and *bFGF* alleles by PCR-RFLP technique.
Results: Patients and controls presented with similar distributions the *VEGF* and *bFGF* alleles and genotypes, thus none of the polymorphisms was associated with the risk of MM. However, it was observed that patients presented with stage I-II of the disease (according to the Durie-Salmon criteria) more frequently carried the *bFGF-923G* allele as compared to patients in stage III of MM (0.31 vs 0.16, P=0.052) and healthy controls (OR=2.010, P=0.040). Progression of the disease after first line chemotherapy was more frequent among patients carrying this allelic variant (6/32 vs 4/88, P=0.022).
Summary and Conclusions: Clinical course of disease in patients with multiple myeloma is associated with a polymorphism within the *bFGF* promoter region.

PLASMA CELLS CULTURE OPTIMIZATION FOR CYTOGENETIC STUDY IN MULTIPLE MYELOMA

M. Peris[1], C. Palacio[2], J. Hidalgo[3,*] M. Gironella[3], F. Bosch[3], M.R. Caballin[4], M. Ortega[1]
[1]Cytogenetic Laboratory, Department of Haematology, [2]Cytometry Laboratory, Department of Haematology, [3]Department of Haematology, Hospital Universitary Vall d'Hebron, [4]BAVE. Antropology Unity, University Autonoma of Barcelona.UAB, Barcelona, Spain

Background: Multiple myeloma (MM) is a malignant disease characterized by clonal proliferation of plasma cells (PC) and their accumulation in the bone marrow (BM). Cytogenetics alterations have a remarkable prognostic value in patients with MM. But the main limitation of the karyotype study is that PC have a low proliferative index, and conventional cytogenetics methods allow to detect chromosomal alterations in only 20-40% of cases at diagnosis. For this reason the eligible diagnostic technique is the iFISH in selected PC. Selected PC cytogenetics cultures studies are not found in the literature
Aims: To optimize the conventional cytogenetic study by the selection of PC
Methods: In 32 patients with PC neoplasms (19 MM at diagnosis, three MM after treatment, five MM at relapse, three smoldering MM (SMM) and two monoclonal gammopathy of undetermined significance (MGUS)) a PC negative selection with the commercial kit *RosetteSep® Human Multiple Myeloma Cell Enrichment Cocktail (Stemcell®)* and the culture (SCP) was performed. In parallel, a conventional culture (N-SCP) as a control was performed in 27 patients. To evaluate the technique efficiency, in both cultures, the%CP post-culture and the detection of chromosome alterations were compared
Results: It was observed that the PC negative selection prior to culture significantly increased the%CP post-culture (54% SCP *vs* 16.9% N-SCP) in all PC neoplasms (P=0.02) and significantly increased the detection of chromosome aberrations (75% SCP *vs* 37,5% N-SCP) (P=0.022). It was also confirmed the possibility to perform the iFISH technique in addition to karyotype and the increase in the percentage of interfasic nuclei with genetic alterations in SPC culture(71% SCP *vs* 16% N-SCP)
Summary and Conclusions: The PC selected culture is a viable, simple and effective technique that allows the conventional cytogenetic study with an increase of chromosomal aberrations detection in patients with PC neoplasms (75%) and also allows iFISH study

PB1849

THE ROLE OF FLT3-LIGANT IN THE PROGRESSION OF MULTIPLE MYELOMA: CORRELATION WITH ANGIOGENIC CYTOKINES.

M. Kokonozaki[1,*] M. Devetzoglou[2], G. Tsirakis[2], C. Vasilokonstantaki[2], I. Stagakis[2], F. Psarakis[2], E. Moraitaki[2], E. Nioti[2], M. Alexandrakis[2]
[1]Laboratory of Haematology, [2]PAGNI, heraklio crete, Greece

Background: Background.Multiple myeloma (MM) is a malignant proliferation of monoclonal plasma cells, resulting in a variety of clinical manifestations including osteolytic bone lesions, anemia, hypercalcemia and renal failure. Angiogenesis, the formation of new blood vessels from existing blood vessels,is an essential component in the growth and progression of MM. Fms-like tyrosine kinase 3 (Flt3) ligand (Flt3-L) is a potent hematopoietic cytokine that is probably involved in early B cell development and it is expressed by endothelial cells.
Aims: Aims. The aim of the present study was to evaluate serum levels of circulating FLT3-L in newly diagnosed MM patients and to estimate if there is any relationship between FLT3-L and known markers of angiogenesis such as,TNFa,HGF, and the expression of CD105 on endothelial cells.
Methods: Methods. We studied 56 newly diagnosed MM patients (26 female and 30 male with mean age 64.5±12.3 years), according to ISS.15 had stage-I disease,19 stage -II and 22 stage- III. We also studied 20 healthy persons as control group.TNFa,HGF and FLT3-L serum levels,were determinate by a solid-phase sandwich ELISA,using commercially available kits.CD105 expression was determinate by immunohistochemical methods.
Results: Results.FLT3-L,TNFa,HGF and expression of CD105 values,were significantly higher in MM patients compare to controls(P<0,001 in all cases),TNFa,FLT3-L,HGF and CD105 values,were also significantly higher with advancing disease stage(P<0,001 in all cases). We also found significant correlations between FLT3-L serum levels with expression of CD105 values (r=0,459,P<0,0001),TNFa (r=0,458,P<0,0001) and HGF (r=0,537,P<0,0001).
Summary and Conclusions: Conclusion. There is a growing evidence that FLT3-L has a significant role in the progression of MM.Serum levels of the angiogenic cytokines TNFa,HGF and the expression of CD105 wich reflect bone marrow neovascularisation,are increased in MM patients and correlated strongly with FLT3-L values this findings indicates that FLT3-L serum levels could be used as a potential tumor marker for disease severty and angiogenesis.

PB1850

SYNERGISTIC APOPTOTIC EFFECTS OF BORTEZOMIB AND METHYLSTAT ON DIFFERENT MULTIPLE MYELOMA CELL LINES

N. Kaci[1], Y. Kiraz[1,*] Y. Baran
[1]Molecular Biology and Genetics, İzmir Institute of Technology, İZMİR, Turkey

Background: Several treatment strategies are used for multiple myeloma (MM), because of the high heterogeneity of MM, it still remains an incurable disease and it gives different clinical response against the therapeutic agents and drugs. Bortezomib, proteasome inhibitor, is an anticancer agent used for the treatment of multiple myeloma while methylstat is a demethylase inhibitor having anticancer potential. Until now, the effects of methylstat have been reported in breast and oesophageal cancer types. However, there is no study on multiple myeloma cells (MM).
Aims: In this study, we investigated antiproliferative and apoptotic effects of methylstat alone or in combination with bortezomib on U266 and ARH77 cells. We also examined the genes involved in methylstat induced apoptosis.
Methods: Cytotoxic effects of bortezomib and methylstat on U266 and ARH77 cells were demonstrated by MTT cell proliferation assay. To understand the apoptotic effects of these agents, loss of mitochondrial membrane potential and changes in caspase-3 enzyme activity were investigated by using JC-1 dye based-method (Cayman Chemicals, USA) and caspase-3 colorimetric assay kit (BioVision Research Products, USA) while phosphatidylserine localization was investigated by Annexin V assay. Cell cycle analysis in response to Bortezomib and Methylstat alone or in their combination were measured by flow cytometry. Changes in expression profiles of 84 genes underlying apoptosis and cell cycle control, in response to Methylstat were determined by Human Cancer Pathway Finder RT^2 Profiler PCR Array System (SABiosciences Corporation, USA).
Results: There were dose- and time- dependent decreases in cell proliferation in response to bortezomib and methylstat based on the results of MTT assay. IC_{50} values were calculated from cell proliferation plots and found to be 41 nM and 19 nM for U266 and ARH77 cells in respons to bortezomib, respectively while they were 2.2 μM and 4.2 μM for U266 and ARH77 cells in response to methylstat, respectively. On the other hand, combination studies showed that IC_{50} values decreased as compared to bortezomib and methylstat alone and were calculated as 0.5 nM and 0.6 nM for U266 and ARH77 cells, respectively. To evaluate the apoptotic effects of agents, JC-1, caspase-3 and Annexin-V

analysis were performed. Combination of bortezomib with methylstat showed more effect on apoptosis as compared to any agent alone and untreated control group. Also, cell cycle analysis was performed to detect the DNA contents of cells. Combination of bortezomib and methylstat arrested cells at the S phase. The fraction of cells in S phase increased accordingly. Previous data demonstrated that combination of agents caused apoptosis and it could be cell cycle-dependent. Human Cancer Pathway Finder RT^2 Profiler PCR Array System results of this study had shown that 1.1 μM and 2.2 μM methylstat treatment caused upregulation of FASLG, NGFR, TNF, TNFRS10B and TNFRS1B apoptosis- triggering genes in U266 cells and BCL2L11, CSP7, TNFRSF21 and 2.1 μM and 4.2 μM methylstat treatment caused TNFSF8 apoptosis- triggering genes in ARH77 cells in a dose-dependent manner. Furthermore, there were significant decreases in the expression levels of AKT1, AVEN, BAG1 BCL2L2 and RELA anti-apoptotic genes in U266 cells and NFKB1 anti-apoptotic gene in ARH77 cells in response to increasing concentrations of methylstat.
Summary and Conclusions: In conclusion, all results showed that the effects of bortezomib in combination with methylstat on U266 and ARH77 MM cells had significant decreases in proliferation and triggered apoptosis. Lots of genes and pathway in the cell were affected by methylstat treatment so methylstat might be used as candidate agent for the treatment of MM after *in vivo* analyses.

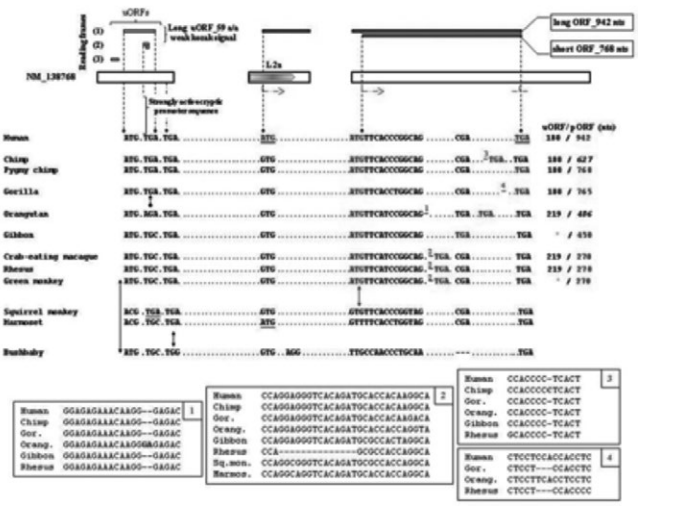
PB1851

MYELOMA OVEREXPRESSED (MYEOV) ONCOGENE: AN ANCIENT TRANSPOSABLE ELEMENT EXAPTATION EVENT ALLOWED FOR THE PRODUCTION OF A HUMAN-SPECIFIC PEPTIDE.

S. Papamichos[1,*] D. Margaritis[1], E. Spanoudakis[1], A. Christoforidou[1], Z. Bezirgiannidou[2], E. Vlachaki[3], S. Vakalopoulou[4], G. Koutra[5], S. Dapdapi[6], A. Rampotas[1], I. Kotsianidis[1]
[1]Department of Haematology, Medical School, Democritus University of Thrace, [2]Blood Transfusion Center, University Hospital of Alexandroupoli, Alexandroupolis, [3]Thalassaemia Unit, Hippokration General Regional Hospital, [4]Second Propedeutic Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, Thessaloniki, [5]Cardiac Intensive Care Unit, General Hospital of Kavala, Kavala, [6]Thalassaemia Unit, University Hospital of Alexandroupoli, Alexandroupolis, Greece

Background: It has formerly been suggested that the high incidence of cancer in human, as compared to non-human primates, could likely be related to maladaptations during the recent evolutionary past. *MYEOV*, an oncogene in multiple myeloma (MM), was recently characterized as a human-specific protein-coding gene of *de novo* origin from long non-coding RNA. In 2010, *MYEOV* expression was documented in primary MM cells and in purified plasma cells from patients with monoclonal gammopathy of undetermined significance however was scarcely detected in bone marrow plasma cells and was absent in normal plasmablasts or memory B cells. In addition, the gene was identified as causally involved in promoting MM cells propagation. *MYEOV* has the potential to encode for two protein isoforms, namely for a 313 amino acid peptide (MYEOV-313) and for a shorter one (MYEOV-255). Solid Western-blot assays support the production of both the proteins while MYEOV-313 expression has been validated in patients with MM. Both the peptides seem to be directed to the membrane nonetheless are of, yet, unknown function.
Aims: Illuminate, via *in silico* analysis, the evolutionary path leading to *MYEOV*. Highlight that a captivating exaptation event of an ancient transposable element (TE) significantly contributed to the creation of *MYEOV* gene structure.
Methods: BLASTN search against the GenBank human genomic database and BLASTP search against the GenBank nonredundant protein database were used to exclude *MYEOV* origination via gene duplication and to verify unambiguous *MYEOV* orthologs. *MYEOV* orthologs annotated in the respective databases from NCBI and Ensembl were identified by searching with the gene name. Whole-genome shotgun (WGS) sequence contigs, including within the DNA segments used to curate the reference genomic sequences of *MYEOV* orthologs, were downloaded from the NCBI Gene database. The WGS sequence contigs were used to build *MYEOV* locus alignment blocks between human and the 11 species with annotated orthologs, via BLASTN. Each alignment block was manually scrutinized for validating the primary open reading frame (ORF) of the annotated orthologs. Search for *MYEOV* upstream ORFs was performed with the ORF Finder program. *MYEOV* splice site analysis was performed with the Human Splicing Finder Version 2.4.1 program. *MYEOV* was scanned for the presence of TEs by Repeat Masker. *MYEOV* locus syntenic alignments of numerous Vertebrates were downloaded from the UCSC Genome Browser Database (UCSC GBD). The automated alignments were used to extract syntenic DNA segments in numerous mammals that flank MYEOV-313 start codon. The DNA segments extracted were scanned by RepeatMasker.
Results: *MYEOV* BLASTN search yields no significant similarity with any other coding sequence in the human genome. Syntenic alignments, extracted from the UCSC GBD, signify that the DNA segment where *MYEOV* locates emerged in Eutherian mammals. An important mutational event occurred in Catarrhini resulting in the *de novo* gain of a translatable ORF in a genomic region that seems noncoding in other species. That is the acquisition of a MYEOV-255 start codon. During evolution in the Catarrhini genome, *MYEOV* acquired a gradually elongated translatable ORF, a gradually shortened translation-regulatory upstream ORF, as well as introns and alternatively spliced mRNA variants. During Homo / Pan separation time, a momentous point mutation was introduced in human resulting in the acquisition of MYEOV-313 start codon. Accordingly, many of the automated annotations of *MYEOV* orthologs, provided by the NCBI and Ensembl automated pipelines, contain inaccuracies. MYEOV-313 start codon is included in a genomic region reported from RepeatMasker to match a TE of the L2 family. The RepeatMasker match appears degenerated however in-depth phylogenetic analysis verified the presence of the L2 repeat in syntenic DNA segments in many mammals.

Table 1.



Summary and Conclusions: *MYEOV* is a Primate Orphan Gene. MYEOV-255 is conserved in Hominines while MYEOV-313 represents a human-specific peptide. *MYEOV* was characterized as a human-specific *de novo* gene because the existence of two protein isoforms was not specifically addressed. MYEOV-313 start codon was evolutionary provided by a L2 TE. Could this rare exaptation event represent a human mal-adaptation, is a tantalizing possibility. Accordingly, MYEOV-313 biological role warrants further research, especially because targeting a human-specific peptide could theoretically cause less adverse effects than targeting components of evolutionary conserved signaling cascades.

PB1852

EXPRESSION OF MULTIDRUG RESISTANCE GENES IN PATIENTS WITH NEWLY DIAGNOSED AND REFRACTORY MULTIPLE MYELOMA

Y. Chernykh[1,*] A. Golenkov[1], S. Shushanov[2], E. Rybalkina[2], T. Mitina[1], E. Trifonova[1], L. Vysotskaya[1], E. Kataeva[1]
[1]The State Budgetary Healthcare Institution of Moscow Area "Moscow's regional research clinical institute n.a. M.F. Vladimirskiy", [2]FGBU Russian Cancer Research Center named after N. N. Blokhin Russian Academy of Medical Sciences, Moscow, Russian Federation

Background: The myeloma cells have the phenomenon of multidrug resistance (MDR), which reduces the effects of chemotherapy. The better understanding of the molecular genetic mechanisms of development of MDR may lead to the development of the individual criteria of prediction of response to cytotoxic treatment of patients with multiple myeloma.
Aims: To determine the expression of four genes associated with MDR, such as MDR1, MRP1, LRP, and BCRP in relation to treatment status. We studied the aspirate of bone marrow of patients with multiple myeloma before cytotoxic treatment and in the resistant group of patients.
Methods: The study included 33 patients (16 men and 17 women) with a diagnosis of multiple myeloma stage 3 by Durie-Salmon system. The age of the patients ranged from 50 to 78 years. 14 patients were investigated before the start of cytostatic treatment. In 19 patients the bone marrow studied after treatment alkylating-containing combinations at the time of registration of resistance to the given therapy. The mRNA expression of the genes was determined by semiquantitative RT-PCR (polymerase chain reaction with reverse transcription) in the mononuclear fraction of the bone marrow aspirate.
Results: Generally, the incidence of mRNA expression of the studied genes MDR in a group of untreated patients was high. The MDR 1 mRNA expression was detected in 93% (13/14) of the samples, the mRNA of the gene MRP 1 was detected in 79% (11/14). The BCRP mRNA expression was detected in 100% of the investigated samples. The expression of mRNA of the gene LRP was identified in 71% of the studied cases (10/14). In the group of patients after treatment the expression of mRNA of genes MDR1, MRP 1, BCRP was detected in 100% of cases, and the LRP mRNA levels detected in 16/19 (84%) of the samples. The expression level of mRNA of each of the tested MDR genes

in all studied patients was different. The average value of the expression a total of 4 MDR genes in the group of untreated patients was 3.5±0.72 points. In group of pretreated patients value of the expression has increased to 6.3± 0.54points (P=0.004).
Summary and Conclusions: The expression of mRNA of MDR MRP 1, MDR 1, BCRP, LRP was determined in patients with untreated multiple myeloma. The intensity of gene expression increases in resistant patients.

PB1853

IL-4 AND IL-6 GENE POLYMORPHISMS IN PATIENTS WITH MULTIPLE MYELOMA FROM THE NORTHWEST FEDERAL DISTRICT OF RUSSIA
A. Pavlova[1,*] I. Sokolova[1], L. Bubnova[1], S. Bessmeltsev[2], I. Pavlova[1]
[1]Immunohaematology laboratory, [2]Deputy director for science, Russian Institute of Haematology and Transfusion, Saint-Petersburg, Russian Federation

Background: It is a well known fact that interleukin 6 (IL-6) stimulates the proliferation of neoplastic plasma cells and acts as an osteoclast-activating factor (plays an important role in the development of the bone disease), whereas interleukin 4 (IL-4) suppresses growth of multiple myeloma (MM) by inhibiting the synthesis of IL-6. Single nucleotide polymorphisms (SNPs) in the regulatory regions of cytokine genes may affect on the transcription and production of the cytokines that can effect on the development of various diseases.
Aims: The aim of this study was to identify SNP in different regions of IL-6 (-174G/C, nt565G/A) and IL-4 (-1098T/G, -590T/C, -33T/C) genes associated with the development of MM among the residents of the Northwest Federal District of Russia as well as determination of the bone lesions severity.
Methods: We analysed 43 MM patients with the median age 69 years. Patients were divided into two groups depending on the detected changes in the bones: 1st group (19 patients)-with severe osteolytic bone lesions (III stage of the *Durie-Salmon staging* system); 2nd group (24 patients) – with manifestations of osteoporosis and isolated pockets of osteolytic bone lesions (II stage of the *Durie-Salmon staging* system). The control group consisted of 40 healthy unrelated Caucasoid blood donors (median age 54 years). All analysed people were from the Northwest Federal District of Russia (St-Petersburg). Genomic DNA was extracted from the peripheral blood and both IL-4 and IL-6 gene genotyping was performed by the use of PCR-SSP.
Results: Based on the genotyping results of IL-4 -1098T/G we found that in general cohort of patients with MM genotype frequencies were not significantly different from each other except for the IL-4 -1098GG genotype which was not detected in the group of healthy people but was registered in the group of patients with a frequency of 0.05. When we analysed data for IL-4 -590T/C the genotype frequency of IL-4 -590TC in patients was two times lower than in control group (0.25 vs. 0.53). Although genotype IL-4 -33TT in MM patients with manifestation of osteoporosis occurs three times often than in control group (0.33 vs. 0.10 respectively). Some differences in IL-6 -174GG genotype frequencies in patients with MM were observed: in a total group of patients-0.47 (0.53 in the 1st group and 0.42 in the 2nd group) against 0.13 in the control group. Conversely, the IL-6 -174GC genotype was more frequent in the group of donors than in the group of patients with severe osteolytic lesions (0.70 vs. 0.26 respectively). Similar pattern was observed for IL-6 nt565GA genotype-in control group this genotype was noticed more frequently (0.80) than in patients (from 0.26 in the 1st group and 0.42 in the 2nd group). However, IL-6 nt565GG genotype frequency was less common in healthy people compare to patients with MM (0.13 to 0.49 respectively). Finally, IL-6 nt565GG was significantly higher in patients with severe osteolytic bone lesions than in patients with symptoms of osteoporosis and in the control group (0.53 vs. 0.46 and 0.13 respectively).
Summary and Conclusions: Thus, our results allow to describe some genotypes as markers associated with the development of MM such as IL-4 -33TT, IL-6 -174GG and IL-6 nt565GG. Furthermore, IL-6 nt565GG genotype is associated with the development of severe osteolytic lesions in multiple myeloma.

Myeloma and other monoclonal gammopathies - Clinical

PB1854

HIGH LEVELS OF SERUM ANGIOGENIC GROWTH FACTORS AND MAST CELL DENSITY IN THE DEVELOPMENT OF MULTIPLE MYELOMA
R. Vyzoukaki[1,*] M. Devetzoglou[2], M. Kokonozaki[1], A. Papadopoulou[1], A. Boula[3], E. Nioti[1], A. Alegakis[4], M. Alexandrakis[5]
[1]Laboratory of Haematology, [2]Department of Haematology, University Hospital of Heraklion Crete, [3]Division of Haematology, Venizeleion Hospital of Heraklion Crete, [4]School of Medicine, University of Crete, [5]Laboratory of Haematology,Department of Haematology, University Hospital of Heraklion Crete, Heraklion, Greece

Background: Bone marrow angiogenesis is involved in the pathogenesis and progression of certain haematological malignancies, like multiple myeloma (MM). Increased mast cell density (MCD) in bone marrow (BM) produces various mediators promoting MM progression with multiple manners.
Aims: The purpose of this study was to evaluate the involvement of BM MCD, and angiogenic cytokines such as angiopoietin-2(angiop-2), angiogenin (ang) and metalloproteinase-9(MMP-9) in MM disease progression.
Methods: We studied 70 newly diagnosed MM patients, 38 males, 32 females, mean age 57±14,5 years.According to ISS 20 were in stage I, 28 in stage II and 22 in stage III. 20 age and sex matched healthy volunteers were used as control group. The immunohistochemical expression stage of mast cell thryptase was measured in BM biopsy samples in order to estimate MCD, while angiop-2, MMP-9 and ang values were measured in serum by a solid phase sandwich ELISA.
Results: There are significant differences in levels of MCD, Angiop-2 and ANG (P<0,001 for all cases) but no significant differences in MMP-9(P=0,538) between patients and controls. All of the measured parameters were also in parallel with ISS stage(P<0,001 for all cases). Moreover BM MCD correlated positively with angiop-2, MMP-9, and ang (P<0,0001 for all cases).
Summary and Conclusions: Mast cells are increased in MM BM and they participate in many aspects of the disease. They release various mediators, increasing directly and indirectly myeloma growth.It has been also established that disease progression in MM is accompanied by increased BM angiogenesis. Overall mast cells and angiogenic growth factors seem to be important factors in MM biology and disease progression.

PB1855

MAST CELL DENSITY AND CIRCULATING BIOMARKERS OF BONE DISEASE INCREASE SIMULTANEOUSLY WITH PROGRESSION OF HUMAN MULTIPLE MYELOMA
R. Vyzoukaki[1,*] M. Kokonozaki[1], P. Kanellou[2], K. Pappa[3], P. Spatharaki[1], S. Masud[1], D. Stafylaki[1], M. Tzardi[4], M. Alexandrakis[5]
[1]Laboratory of Haematology, [2]Department of Haematology, University Hospital of Heraklion Crete, [3]Department of Internal Medicine, Venizeleion Hospital of Heraklion, [4]Department of Pathology, [5]Laboratory of Haematology, Department of Haematology, University Hospital of Heraklion Crete, Heraklion, Greece

Background: Multiple myeloma (MM) is a neoplastic disorder characterized by clonal proliferation of plasma cells in the bone marrow. Many circulating biomarkers posses variable roles in the pathogenesis of bone disease causing bone distruction. Mast cells (MCs) can produce, store and release many kinds of chemical mediators with angiogenic properties. MCs accumulation has been associated with enhanced tumor growth.
Aims: The purpose of the study is to estimate the participation of RANK-ligand, matrix metalloproteinase 9 (MMP-9), N-terminal telopeptide (Ntx), carboxyterminal propeptide of type 1 collagen (*PICP*) and mast cell density(MCD) in the process of bone disease in MM patients.
Methods: We studied fifty-two newly diagnosed MM patients, 28 males, 24 females, mean age 64 years. The types of monoclonal proteins were 27 IgG, 18 IgA, 7 light chain, according to ISS:15were in stage I, 18 in stage II, 19 in stage III. Twenty age- and sex-matched healthy subjects were used as control group. We measured serum levels of sRANKL, MMP-9 and Ntx in urine samples by a solid-phase sandwich ELISA, and MCD in bone marrow biopsy samples by immunostaining. Radiographic examination including skull, pelvis, long bones and cervical, thoracic, and lumbar spine was carried out in all patients as a routine staging procedure.
Results: MCD, RANKL and Ntx were significant higher in untreated myeloma patients in comparison to healthy controls (P<0,001 for all cases). All values were increasing in parallel with ISS stage (P<0,001 for MCD, RANKL, MMP-9 and Ntx). There are significant correlations between MCD and MMP-9, RANKL and Ntx (P<0,001 for all cases). No correlation between MCD and PICP was found.
Summary and Conclusions: In conclusion, our results underline that MCD is an important factor responsible for the enhancement of bone involvement in MM. The positive correlation between MCD and circulatin biomarkers of bone

disease support the involvement of mast cells in the biology of myeloma cell growth. Moreover MCD could be used as a marker of disease activity.

PB1856

SUCCESSFUL TREATMENT OF PATIENTS WITH NEWLY DIAGNOSED/UNTREATED LIGHT CHAIN MULTIPLE MYELOMA WITH A COMBINATION OF BENDAMUSTINE; PREDNISONE AND BORTEZOMIB (BPV)

W. Poenisch[1,*] H. Mrachacz[1], N. Khoder[1], M. Plötze[1], B. Holzvogt[1], M. Andrea[1], T. Schliwa[1], S. Heyn[1], G. N. Franke[1], R. Krahl[1], M. Jentzsch[1], S. Leiblein[1], S. Schwind[1], V. Vucinic[1], D. Niederwieser[1]
[1]Hematology/Oncology, University of Leipzig, Leipzig, Germany

Background: Patients with light chain myeloma have frequently a light chain tubular cast nephropathy, which can lead to severe renal impairment.
Aims: Both bortezomib and bendamustine have been identified as quickly acting, effective and well tolerated drugs and might therefore constitute an adequate combination regimen for patients with newly diagnosed/untreated light chain multiple myeloma.
Methods: Between September 2009 and March 2014, 20 patients with newly diagnosed/untreated light chain multiple myeloma were treated with bendamustine 60mg/qm on days 1 and 2, bortezomib 1.3 mg/qm on days 1,4,8 and 11, and prednisone 100mg on days 1,2,4,8 and 11 once every 21 days. 5 patients (25%) had a moderate or severe renal dysfunction (eGFR 15–59ml/min) and 9 patients (45%) a renal failure/dialysis (eGFR<15ml/min).
Results: The median number of the BPV-treatment was 2 (1-5) cycles. 19 patients (95%) responded after at least one cycle of chemotherapy with 3sCR, 4nCR, 5VGPR, and 7PR. The myeloma light chains decreased rapidly, reaching the best response after the first cycle in 8 and after the second cycle in additional 9 patients. 16 patients discontinued therapy after median 2 cycles of BPV treatment to receive autologous (n=13) or autologous/allogeneic SCT (n=3). All together 10/14 patients with at least moderate renal failure improved their renal function (4CRrenal, 2PRrenal, 4MRrenal). 3 of the 6 dialysis-dependent patients became dialysis-independent.With a median follow up of 23 months of the surviving patients, median PFS and OS for patients at 24 months were 90% and 95%, respectively. The most common severe side effect was grade 3-4 leukocytopenia in 25% of the patients. Grade 3-4 thrombocytopenia was observed in 15% of the patients. Moderate to severe infection were seen in 4 patients.
Summary and Conclusions: We conclude that BPV is effective and well tolerated in patients with newly diagnosed/untreated light chain multiple myeloma.

PB1857

THE FREQUENCY OF CYTOGENETIC ABNORMALITIES AND THEIR IMPACT ON OVERALL SURVIVAL IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA.

A. Garifullin[1,*] S. Voloshin[1], I. Martynkevich[1], S. Bessmeltsev[1], L. Martynenko[1], E. Kleina[1], G. Salogub[2], E. Karyagina[3], A. Schmidt[1], A. Kuvshinov[1], K. Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, [2]Saint-Petersburg Pavlov State Medical University, [3]3City Hospital N15, Saint-Petersburg, Russian Federation

Background: Cytogenetic analyses, including fluorescence *in situ* hybridization (FISH) is integral part of stratification in patients with multiple myeloma on risk groups. Detection of specific abnormalities optimizes treatment strategy for life expectancy improvement. The impact of the mixed specific genetic aberrations on the overall survival (OS) is studied.
Aims: To estimate the OS in patients with multiple myeloma, according to risk stratification.
Methods: 133 patients were prospectively assessed (median age 61 years, range 26-93; male: female ratio – 1:1.27) with newly diagnosed multiple myeloma. Cytogenetic and FISH analyses were determined in all patients for search of genetic abnormalities. Cytogenetic studies were performed on bone marrow samples using standard GTG-method. Metaphase FISH analyses were performed according to the manufacturer's protocol with use of DNA probes: LSI 13(*RB1*)13q14, *IGH/CCND1*, *IGH/FGFR3*, LSI *TP53* (17q13.1) (Abbott). Stratification of patients was carried in risk groups according to the molecular classification mSMART 2.0 Patients with nonspecific genetic abnormalities were included in standard risk group. Patients with complex karyotype (3 and more chromosomal aberrations) and who has 2 specific chromosomal abnormalities were included in certain group-mixed specific genetic aberrations risk group.
Results: Genetic abnormalities in newly diagnosed multiple myeloma were detected in 49.5% (56/113). The occurrence frequency of t(11;14) was 26.5% (n=30), del(13q) – 22.1% (n=25), t(4;14) – 7.1% (n=8), del(17p) – 7.1% (n=8). 73/113 (64.4%) patients was in standard risk group, 17/113 (15,0%) – intermediate risk, 8/113 (7,1%) – high risk and 15/113 (13,3%) – with mixed specific genetic aberrations risk. 5-years OS in standard risk group was 70%, in intermediate risk-84% (*P=.42*), in high risk – 36.5% and in group with mixed specific genetic aberrations – 68.7% *(P=.036)*.

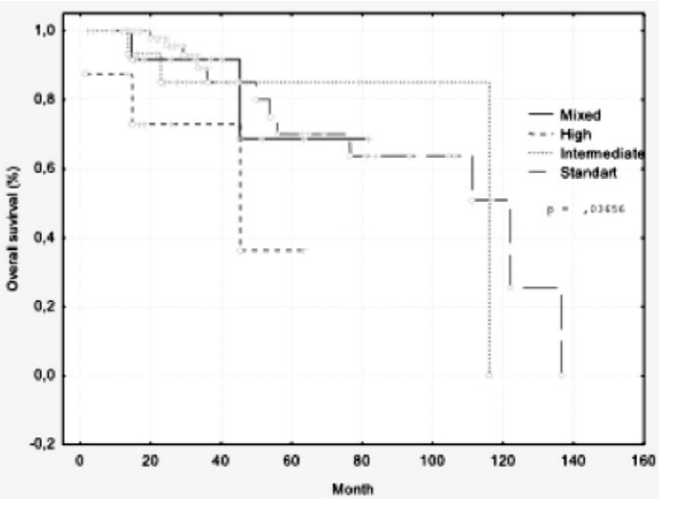


Figure 1.

Summary and Conclusions: Genetic abnormalities are important prognostic factors in patients with multiple myeloma. Identification of specific genetic markers, which included into high risk group, is a reason for search of optimal strategy of therapies. The obtained data need in further analysis taking into account age and variants of anti-myeloma therapies.

PB1858

THE DYNAMICS OF SERUM CROSSLAPS AND SCLEROSTIN LEVELS CORRELATES WITH TREATMENT RESPONSE IN MULTIPLE MYELOMA PATIENTS WITH THE PRESENCE OF MYELOMA BONE DISEASE

J. Minarik[1,*] Z. Hermanova[2], P. Petrova[3], P. Pusciznova[1], T. Pika[1], J. Bacovsky[1], J. Zapletalova[4], V. Scudla[1]
[1]Department of Hemato-oncology, [2]Department of Clinical Immunology, [3]Department of Clinical Biochemistry, [4]Department of Biophysics and Statistic, Faculty of Medicine and Dentistry, Palacky University and University Hospital Olomouc, Olomouc, Czech Republic

Background: We performed a prospective study in patients with multiple myeloma (MM) and monoclonal gammopathy of undetermined significance (MGUS) aimed at the behavior of 13 selected parameters of myeloma bone disease (MBD).
Aims: The aim of our study was to assess the behavior of selected parameters of MBD with respect to therapeutic response.
Methods: Altogether we assessed a cohort of 51 patients: 31 patients with newly diagnosed active MM who responded to treatment reaching at least partial remission (PR) after 4 cycles of chemotherapy, 10 patients with refractory MM (progression or not reaching PR after 4 months), and two control groups – 5 patients with smoldering MM and 5 individuals with MGUS. The selected parameters of MBD were as follows: serum calcium (Ca), phosphorus (P), procollagen-I N-terminal propeptide (PINP), carboxyterminal telopeptide of type I collagen (ICTP), cross linked C-telopeptide (CTX), osteocalcin (OC), parathormone (PTH), calcitonine (C), 25-hydroxyvitamin D (D2), 1,25 dihydroxyvitamin D (D3), bone fraction of alkaline phosphatase (bALP), sclerostin (Scl) and matrix metallopeptidase 9 (MMP9). In the whole cohort we performed the analysis of MBD parameters at the time of diagnosis (before start of chemotherapy in active MM) and after 4 months. We assessed the behavior of the parameters with respect to treatment response. The patients were treated using bortezomib or thalidomide based regimens. All patients with MBD received bisphosphonates and adequte calcium support. In patients undergoing autologous stem cell transplantation the follow-up results were acquired 4 months after the diagnosis but before the transplantion. For statistical estimation we used Wilcoxon pair test at $p < 0,05$, and McNemara test of symetry at $p < 0,05$.
Results: We detected significant decrease of CTX (M 0,649 vs. 0,413ug/l; P=0,014) and sclerostin (M 44,4 vs. 40,6pmol/l; P=0,030) together with significant increase of parathormone (M 26,0 vs. 60,0pmol/l; P=0,0005) after 4 months of therapy in patients responding to initial treatment. All the other assessed parameters were without significant change. In patients with refractory MM there was no significant change in any of the assessed parameters. Similarly, there was no significant change in any of the assessed parameters in the control groups, *i.e.* in patients with smoldering MM, and there was only boderline significant decrease of Ca (M 2,42 vs. 2,28 mmol/l; p =0,042) in MGUS individuals.
Summary and Conclusions: Despite appropriate anti-resorption therapy, there is no change in the parameters of MBD in patients with MM who failed to respond after 4 months of treatment. Patients who respond to therapy have significant decrease of sclerostin and CTX suggesting their auxiliary clinical potential in the assessment of bone turnover in MM patients. With support of NT14393.

Background: Prognosis of patients with multiple myeloma (MM) has improved with the use of novel agents in the past decade. The data on real-world safety of these agents is limited. Following its regulatory approval in 2010, lenalidomide is now commonly used in the relapsed/refractory multiple myeloma (RRMM) setting in Turkey.
Aims: This post-authorization observational study is designed to define the safety profile of lenalidomide + dexamethasone therapy under routine real-world clinical practice by characterizing and identifying the incidence of adverse events (AE) of special interest in RRMM patients in Turkey.
Methods: Patients aged ≥18 years with RRMM and started on lenalidomide + dexamethasone treatment were included in the study. Patients who had previously received lenalidomide and discontinued or who had a treatment interruption for ≥4 weeks were excluded from the study. Thromboprophylaxis was allowed but not required. AEs were graded according to NCI-CTCAE (version 4.03) grading.
Results: As of January 30, 2015, 119 patients across 24 institutions in Turkey were enrolled. Of those, results of 111 patients with available data are going to be presented in this early safety report. Median follow-up was 19.9 weeks (range, 1.4–56.4). Median age was 62 years (range, 29–85) and 56.8% were male. Among 98 of the patients whose ECOG status were recorded at entry, 81 (82.7%) had good performance status (ECOG score 0–1) and 17 (17.3%) had an ECOG score of 2–4. Median number of prior therapies was two (29.7% had one prior therapy, 53.2% had two prior therapies and 17.1% had ≥3 prior therapies). Fifty-four (48.6%) patients had received autologous stem cell transplantation. The overall incidence of peripheral neuropathy at the baseline was 30.6%. Starting dose of lenalidomide was 25 mg in 85 (76.6%) patients, while 15 mg, 10 mg, and 5 mg were the initial dose in 10 (9.0%), 11 (9.9%), and 5 (4.5%) patients, respectively. Dose modifications were required in 13 (11.7%) patients. Prophylaxis for thromboembolism was performed in total of 37 (33.3%) patients with aspirin (n=21), heparin (n=15) and warfarin (n=1). Overall, 46 Grade 3-4 AEs were observed in 41 (%36.9) patients and 70 (63.1%) patients were free of Grade 3-4 AEs. Grade 3–4 neutropenia, pneumonia, anemia, and thrombocytopenia developed in 8.1%, 5.4%, 3.6%, and 1.8% of patients, respectively. VTE was reported only in one patient (Grade 2). Among 111 patients, 69 (62.2%) are still receiving lenalidomide + dexamethasone while 42 (37.8%) patients discontinued treatment (AEs : 12 [10.8%], death: 10 [9.0%], progression: 6 [5.4%], and other reasons: 14 [%12.6]). No second primary malignancy was reported.
Summary and Conclusions: Early safety data confirmed known AEs of lenalidomide plus dexamethasone therapy in RRMM patients in Turkey. Longer-term follow-up of AEs in this study will provide better characterization of AEs.

PB1860

LIFE-THREATENING BOWEL PERFORATION WHILE ON THALIDOMIDE-BASED TRIPLET REGIMEN FOR MULTIPLE MYELOMA: A RETROSPECTIVE CASE SERIES

P. Sriskandarajah[1,*] F. Scott[1], S. Muthalali[1], J. Mercieca[1]
[1]Haematology, Epsom and St Helier Hospital, Carshalton, United Kingdom

Background: Thalidomide is an oral agent which has demonstrated significant anti-myeloma activity resulting in improved progression-free and overall survival rates in newly diagnosed multiple myeloma (MM) patients. The mechanisms of action of Thalidomide are complex and thought to include both antiangiogenic and immunomodulatory properties. However, as well as targeting neoplastic plasma cells, Thalidomide can affect other organ systems resulting in toxicities. These have been well documented and supportive measures are currently incorporated into our daily clinical practice to counteract these. However, there are other adverse effects which have been recorded as uncommon, including diverticular perforation. Recent figures have suggested that<1% patients treated between 2004-2012 reported this to the Food and Drugs Administration (FDA). However, contradictory to these findings, we have noticed an increasing number of patients within our trust presenting with this life-threatening complication. Furthermore, this complication has not been observed in patients receiving other types of anti-myeloma treatment, including Bortezomib, Lenalidomide and Bendamustine.
Aims: To study the association between Thalidomide and diverticular perforation in patients with Multiple Myeloma.
Methods: A retrospective case series was performed examining all MM patients who received Thalidomide, either as a single agent or in a combination regimen, between 1st January 2007 and 31st December 2014 at Epsom and St Helier Hospital. Patients who developed diverticular perforation while on Thalidomide were identified and further data collected. This included demographics, comorbidities, disease response (according to the International Myeloma Working Group Response Criteria), time interval between current cycle of treatment and diverticular perforation, and patient outcome.
Results: A total 118 patients received Thalidomide of which 6 (5%) developed diverticular perforation. Interestingly, 3 of these patients had presented in the last 12 months. The median age for this group was 69 years (range 56-86 years) with equivalent numbers of males and females. None of the patients were known to suffer with gastrointestinal disease, although one patient did have associated renal amyloidosis. All 6 patients received Thalidomide as part of a triplet regime with Dexamethasone and either Cyclophosphamide or Bortezomib for newly diagnosed multiple myeloma. The median number of cycles received was 4 (range 2.5 – 6) with 5 out of the 6 patients achieving a disease response. Response rates included 1 Complete Response (CR), 1 Very Good Partial Response (VGPR) and 3 PRs. Five patients received 100mg Thalidomide with 20mg Dexamethasone, while one patient was taking 200mg Thalidomide with 40mg Dexamethasone. All 6 patients were receiving thromboprophylaxis throughout their treatment. Median time to presentation with diverticular perforation was 24 days (range 14-37) from day one of their current cycle. At presentation the median nadir neutrophil count was $5.1x10^9$/L (range 1.1-$14.4x10^9$/L). All 6 patients were managed surgically with subsequent bowel biopsies confirming diverticulitis. Five patients made a good post-operative recovery and were discharged. Three later received further treatment of which one patient was rechallenged with Thalidomide while the other two patients received Bortezomib instead. Two patients did not receive further treatment and are currently under active surveillance.
Summary and Conclusions: Our case series demonstrates that Thalidomide-associated diverticular perforation is far more prevalent than previously reported. Given the increasing use of this drug caution should be exercised by clinicians, particularly in patients with a known background of diverticular disease. Further research to establish the molecular mechanism by which Thalidomide induces diverticular perforation should be performed.

PB1861

HYPERCOAGULABILITY AND ITS ASSOCIATION WITH METABOLIC AND PRO-INFLAMMATORY MARKERS OF CARDIOVASCULAR RISK IN PATIENTS WITH MULTIPLE MYELOMA

I. Dzis[1,*]
[1]Hematology, Institute Of Blood Pathology and Transfusion Medicine, Lviv, Ukraine

Background: Patients with multiple myeloma (MM) have an increased risk of thrombotic complications. The incidence of venous thromboembolism in patients with MM ranges from 3% to 10%. Hypercoagulability is one of prognostic biomarkers of venous and arterial thrombosis.
Aims: To identify associations between blood markers of coagulation activation, systemic inflammation, lipid and protein metabolism in patients with MM to elaorate prognostic markers of thrombotic events.
Methods: Our study involved 22 patients with MM, 14 men and 8 women aged 46-81 years, and a control group of 16 healthy people. Parameters of hemostasis, systemic inflammation, protein and lipid metabolism were studied. In statistics, Mann-Whitney test and Kendall's tau correlation were used. Medians and interquartile intervals were used to describe parametric data.
Results: In the group of patients with MM, markers of hypercoagulability, such as increased levels of fibrin monomer and D-dimer were found in 77.3% of cases. Frequencies of other cardiovascular risk factors were the following: overweight/obesity – 81.8%, hyperuricemia – 45.5%, atherogenic dyslipidemia with higher than optimal levels of low density lipoprotein cholesterol (LDL-Ch) and low levels of high density lipoprotein cholesterol – 68.2%, increased inflammatory markers CRP and IL-6 – 77.3%. There were significantly higher levels of fibrinogen – 5,35 (3,93-6,87) g/L vs 3,80 (3,49-4,40) g/L (P=0,005), fibrin monomer – 6 (4-10) mg/dL vs 3 (3-3,5) mg/dL (P=0,002) and D-dimer – 90,05

(32,9-487,8) ng/mL vs 21,55 (18,96-35,50) ng/mL (P<0,001) in comparison with the control group. Fibrinogen levels correlated positively with body mass index (BMI) (τ=0.63, p=0.001), levels of total cholesterol (τ=0.44, p=0.004), LDL-Ch (τ=0.42, p=0.006), albumin in percentage (τ=0.43, p=0.007), and correlated negatively with total protein (τ=-0.41, p=0.01) and M-protein levels (τ=-0.35, p=0.029). Fibrin monomer levels correlated positively with fibrinogen (τ=0.51, p=0.001), IL-6 (τ=0.51, p=0.001), triglycerides levels (τ=0.47, p=0.002), albumin in percentage (τ=0.38, p=0.018), and correlated negatively with M-protein (τ=-0.34, p=0.034) and IgA levels (τ=-0.56, p=0.034). D-dimer levels correlated positively with triglycerides levels (τ=0.32, p=0.035). Thus, in myeloma patients, increased BMI, systemic inflammation and atherogenic hyperlipidemia promotes hypercoagulability. Laboratory data of more severe disease stage according to parameters of protein metabolism were associated with less significant features of hypercoagulability.
Summary and Conclusions: To predict the risk of arterial and venous thrombosis in patients with MM it is advisable to determine BMI, blood levels of fibrinogen, fibrin monomer, D-dimer, CRP, IL-6, and lipid fractions.

PB1862

BORTEZOMIB IN THE FIRST-LINE TREATMENT OF MULTIPLE MYELOMA: THE EXPERIENCE OF A CENTER
M.J. Mendes[1,*] G. Ferreira[1], H. Saturnino[1], M. Duarte[1], J.C. Almeida[1], L.F. Araújo[1], M.L. Ribeiro[1]
[1]Hematology, CHUC, Coimbra, Portugal

Background: The therapeutic approach of Multiple Myeloma (MM) has been marked by two great advances: the possibility of hematopoietic stem cell transplantation in eligible patients and the use of new active drugs, such as Talidomide, Bortezomib and Lenalidomide.
Aims: Analyze the follow-up of a group of patients with MM submitted to regimens including Bortezomib in the first line, evaluate the response to the treatment, analyze the overall survival (OS), duration of response (DOR) and time to progression (TTP).
Methods: Retrospective analyses of the clinical files of patients with MM, diagnosed between January 2009 and December 2014, undergoing treatment with protocols including Bortezomib in the first line. Response criteria after treatment according to the International Myeloma Working Group (IMWG). Statistic analyses using SPSS 22.
Results: Between January 2009 and December 2014, 65 patients were diagnosed with MM, 34 of which (52,3%) were treated with first line Bortezomib (CyBorDexa in 29; BorDexa in 3; VMP in 2). The median number of cycles administered was 8,5. The median age at diagnosis was 65,6 years (min=42; max=79), 18 were females (52,9%) and 16 males (47,1%). The mean follow-up time was 1,9 years. At diagnosis 31 patients (91,2%) presented anemia, 24 bone disease (70,6%), 19 renal impairment (55,9%) and 11 hypercalcemia (32,4%). According to the ISS, 10 patients were low risk (ISS 1) (29,4%), 10 patients intermediate (ISS 2)(29,4%) and 14 high risk (ISS 3)(41,2%). Six patients were eligible for transplant consolidation (17,6%). In 5 patients disease progression occurred during treatment (14,7%) and 3 are still under treatment. Response after treatment completion was accessed in 26 patients: PR=13 patients (50%), CR=9 (36,4%), VGPR=3 (11,5%) and sCR=1 (3,9%). Eleven patients progressed (42,3%) with a median TTP of 15,81 months and mean DOR of 9,09 months, 2 of them had reached VGPR and 9 PR. Five patients died. The 5-year overall survival was 85,3%.
Summary and Conclusions: The use of Bortezomib in the regimens CyBorDexa, BorDexa and VMP was effective in the majority of the patients, with response rates and overall survival mimicking the literature. In 58,8% of patients the ISS risk was low and intermediate; all the high risk patients presented renal impairment. Most of the patients completed treatment, 29/34 with CyBorDexa protocol, 86,4% reaching PR or CR. Among the responding patients, 15 (57,7%) have not progressed after a mean follow up time of 14 months. Although being widely used for its good tolerance and low toxicity, in several studies the CyBorDexa protocol showed inferior results compared with other multiple-drug protocols, such as VTD (Bortezomib, Talidomide and Dexa) or VRD (Bortezomib, Lenalidomide and Dexa). Currently, ongoing clinical trials will hopefully define the new standard of care in Multiple Myeloma, namely for the transplant eligible patients.

PB1863

BORTEZOMIB, LENALIDOMIDE AND DEXAMETHASONE FOLLOWED BY AUTOLOGOUS TRANSPLANTATION AS FIRST LINE TREATMENT IN MULTIPLE MYELOMA. SINGLE CENTER EXPERIENCE
J.M. Arguinano[1,*] M. Zudaire[1], E. Pena[1], I. Aoiz[1], M. Hamdi[1], M. Mateos[1], M. Ardaiz[1], M. Viguria[1], M. Rodriguez Calvillo[1], A. Gorosquieta[1], M. Sanchez Anton[1], I. Quispe[1], P. Arregui[1], M. Montoya[1], P. Garcia Ramirez[1], M. Alvarellos[1]
[1]Hematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: A three drug induction regimen followed by autologous transplantation is considered the best approach in multiple myeloma patients who can endure that procedure. Despite scarce evidence available, the combination of lenalidomide, bortezomib and weekly dexamethasone (VRd) has been widely adopted, probably due to more favourable toxicity profile as compared to bortezomib, thalidomide and dexamethasone
Aims: To review our center's experience in using VRd protocol and autologous transplantation as first line therapy in multiple myeloma patients
Methods: Multiple myeloma was diagnosed according to IMWG criteria, as well as response assessment. All patients fit enough to undergo transplantation were treated with VRd combination, as previously described by Richardson et al, except for weekly administration of 40 mg dexamethasone. Four cycles were initially scheduled, but two additional cycles could be administered if less than partial response was achieved. Only patients with creatinine clearance below 50 mL/min were excluded. At least partial response was required to proceed to transplantation. Postransplant consolidation with two cycles of bortezomib and dexamethasone was administered in case of partial response, as well as lenalidomide maintenance in order to achieve complete response
Results: From April 2011 to February 2014 a total of 19 patients were treated according to this protocol. Median age at diagnosis was 58 years, ranging 32 to 70. ISS score was 1 in 7/19, 2 in 7/19 and 3 in 5/19. One patient required second line therapy due to lack of response to VRd induction, but proceeded to transplant once a partial response to DT-PACE was achieved. Other patient did not receive transplantation because of significant cardiac amyloid deposition. Stem cell mobilization yielded enough cells for the procedure in all patients despite lenalidomide usage. Responses after VRd induction therapy were complete response (CR) in 5/19, very good partial response (VGPR) in 4/19 and partial response (PR) in 10/19. A total of 18 transplantation procedures were performed, conditioned with melphalan 200 mg/m2 in 15 patients; the other 3 received 140 mg/m2 because of renal impairment (one patient) and poor tolerability to previous therapies (2 patients). Time to engraftment, infectious and non-infectious complications were similar to those previously reported. No deaths occurred during the procedure or immediately thereafter. Response after transplantation was CR in 13/18 (strict in 11/13), VGPR in 2/18 and PR in 3/18. Transplant upgraded the response in 9 out of 18 patients (50%). Only three patients required posttransplant consolidation and four received lenalidomide maintenance. After a median follow up of 28 months, a total of 11 patients (61%) have experienced relapse after a median of 18 months from start of treatment. Only 7 of them, (39%) have experienced clinical or paraprotein relapse requiring second line therapy. Median progression free survival is 22 months. No second neoplasms have been detected so far
Summary and Conclusions: VRd induction followed by autologous transplantation is a safe and effective therapy for newly diagnosed multiple myeloma. Half of the patients upgraded their response after transplantation, making it an essential part of therapy. Despite excellent responses achieved, relapse is still the main cause of failure

PB1864

BONE MARROW PLASMA CELLS ASSESSMENT AFTER INDUCTION THERAPY DOES NOT IMPACT ON PERIPHERAL BLOOD STEM CELLS MOBILIZATION IN MULTIPLE MYELOMA PATIENTS IN THE NOVEL AGENTS ERA
C. Nozzoli[1,*] E. Antonioli[1], M. Staderini[1], I. Donnini[1], F. Bacchiarri[1], S. Urbani[1], R. Saccardi[1], S. Guidi[1], A. Bosi[1]
[1]Hematology and stem cell transplant center, AOU CAREGGI, Florence, Italy

Background: Over the past 10 years, novel agents (NA), including immunomodulatory drugs and proteasome inhibitors, have been increasingly incorporated in front line multiple myeloma (MM) treatment. Induction with NA did not negatively affected the efficacy of stem cell harvest in some studies. Few data are available on the prognostic role of residual bone marrow plasma cells (BMPC) assessment on peripheral blood stem cell harvest after induction therapy with NA in MM patients undergoing autologous stem cell transplant (ASCT).
Aims: The aim of this retrospective single-center study was to determine the impact of BMPC, quantified before peripheral blood stem cell (PBSC) mobilization, on the efficacy of $CD34^+$ cells collection and number of leukapheresis.
Methods: This retrospective study concerned 132 newly diagnosed MM patients who underwent ASCT in the Hematology Unit in Florence from January 2006 to January 2015. Induction therapy included dexamethasone with thalidomide (TD) and/or bortezomib (VTD, VD). Patients who were refractory to induction therapy were excluded from the study. Bone marrow biopsy was performed before PBSC mobilization and residual plasma cells were evaluated after CD138, kappa and lambda immunostaining. All patients were mobilized with cyclophosphamide (EDX) 3 or 4 gr/m^2 followed by G-CSF 5-10 μg/kg daily subcutaneously from day 2 until the end of the collection procedure. Leukapheresis was scheduled to start on day 10 and be performed until at least 2.0×10^6 $CD34^+$ cells/kg were collected. Patients who failed G-CSF mobilization received plerixafor. $CD34^+$ cells counts were assayed using a single platform method. Statistical analisys was made by Mann-Whiney test.
Results: Median age was 59 (range, 37-68), 48 patients (37%) were females; 81 patients (61%) received VTD as induction therapy (3-7 cycles) while 39 (30%) received TD (3-8 cycles) and 12 (9%) received VD (4-6 cycles). After induction therapy 18 (14%) patients obtained a complete response, 62 (47%) had a very

good partial response, 49 (37%) a partial response, and 3 (2%) a minimal response. BM biopsy was performed in all patients: in 67 (51%) the BMPC were<5% of the total cellularity, whereas in 40 (30%) the BMPC were between 5% and 20% and in 25 (19%) the BMPC were over 20%. All patients proceeded to chemo-mobilization: 16 (12%) with EDX 3 gr/m^2 and 116 (88%) with EDX 4 gr/m^2. No grade ≥3 toxicities were recorded. In 98 patients (74%), the mean number of CD34$^+$ cells collected was 12.2×10^6/kg (range 2.8-57.2x10^6/kg) within 1 leukapheresis; 23 (17%) patients needed a second procedure to collect a mean CD34$^+$ cells count of 7.3×10^6/kg (range, 2.0-16.2x10^6/kg), whereas 7 patients (5%) required 3 or 4 procedures and collected 4.4×10^6/kg (range, 2.3-7.4x10^6/kg) (P=ns). A total of 4 (3%) patients, all females, aged 49-61 years (median age 60 years), received plerixafor. In 2 patients, the mean number of CD34$^+$ cells was 5.8x10^6/kg collected in 1 day, in 2 other patients leukapheresis was repeated 3 times to collect 6.9x10^6 cells/kg. The BMPC percentage was not significantly correlated with the mean CD34$^+$ cells counts or with the numbers of leukapheresis. The CD34$^+$ cells count was significantly higher in patients younger than 55 (n=47; mean 12.7×10^6/kg, range 4.9-36.8) than in the older patients (n=85; mean 9.6×10^6/kg, range 2.0-57.2) (P<0.001). Furthermore the mean CD34$^+$ cells count was significantly higher in patients treated with VTD (n=81; mean 11.8×10^6/kg, range 2.7-57.2) vs those treated with TD (n=39; mean 8.2× 10^6/Kg, range 2.0-21.2).

Summary and Conclusions: The residual BMPC percentage did not adversely impact on CD34$^+$ collection in our study. Younger age and VTD induction were associated with higher CD34$^+$ cells counts.

PB1865

CURRENT MANAGEMENT OF MULTIPLE MYELOMA TREATMENT IN SPAIN: MEETINGS OF EXPERTS FROM 41 HOSPITALS

M.V. Mateos[1,*] J. de la Rubia[2], J. Martínez[3], J.A. Pérez Simón[4], T. Garrido[5]
[1]H. Universitario Salamanca, Salamanca, [2]H. Dr. Peset, Valencia, [3]Hospital 12 de Octubre, Madrid, [4]Hospital Virgen del Rocío, Sevilla, [5]Amgen, S.A., Barcelona, Spain

Background: The outcome of patients with multiple myeloma (MM) has improved significantly due to the introduction of autologous hematopoietic stem cell transplant (ASCT) and, subsequently, with the introduction of new drugs. However, the optimal sequence of treatments is unknown and, in Spain, there are no national MM treatment guidelines.

Aims: The purpose of the expert meetings was to obtain updated information about the most commonly used treatment strategies in Spain outside clinical trials.

Methods: A total of 5 expert meetings attended by 43 hematologists were held in November-December 2014. The treatment algorithms published by Ludwig *et al.* (The Oncologist 2014) were used as the basis for the discussions. Information was obtained on the most commonly used treatments in 3 different scenarios: 1) front line in patients who are candidates for ASCT, 2) front line in patients who are not eligible for ASCT, and 3) first relapse.

Results: Most patients are not candidates for ASCT (50-70%). The most frequently used induction regimens before transplant (4-6 cycles) are triple therapies (86%), bortezomib/thalidomide/dexamethasone (VTD) being the most common (79%), followed by bortezomib/doxorubicin/dexamethasone (PAD) (36%), bortezomib/cyclophosphamide/dexamethasone (VCD)(32%), lenalidomide/bortezomib/dexamethasone (RVD)(14%), and cyclophosphamide/thalidomide/dexamethasone (CTD)(4%). When triple therapy cannot be used due to access restrictions or patient characteristics, bortezomib/dexamethasone (VD) is generally administered. Most centers (53%) do not administer consolidation after ASCT. If consolidation is administered, the regimen is usually the same as in induction. Maintenance treatment after transplant is used only in selected cases and centers and usually consists of lenalidomide for 2 years (47%)(exceptionally until progression), thalidomide for 1 year (26%) or bortezomib (21%). In non-transplant candidates, the front-line regimen most commonly administered is (VMP)(97%). Maintenance is not usually administered. After the first relapse, a second transplant is considered if the remission lasted ≥18 months and if patients have good performance status. Retreatment with the same initial regimen (20-60% cases) is reserved for patients with a treatment-free interval >12-18 months or in whom the progression-free survival is greater than the median for the regimen. Otherwise, physicians prioritize inclusion in clinical trials or treatments with authorized drugs with a different mechanism of action, such as lenalidomide and dexamethasone (50-60%). If no new drugs are used in induction (8%), bortezomib-based regimens are usually administered (77%).

Summary and Conclusions: Although there is considerable inter-center and inter-region variability in the treatment of MM in Spain, partly explained by different patient characteristics or restrictions on access to some drugs, pre-ASCT induction and front line treatments without ASCT are quite consistent. Following the first relapse, treatment is more variable and individualized.

PB1866

OUTCOME IMPROVEMENT IN IGD MULTIPLE MYELOMA WITH AGGRESSIVE CLINICAL FEATURES: IMPACT OF NOVEL DRUGS

L. Torti[1,*] S. Pulini[1], A.M. Morelli[1], F. Bacci[2], P. Di Bartolomeo[1]
[1]Department of Hematology, Transfusion Medicine and Biotechnology, Clinical Hematology, "Spirito Santo" Civic Hospital, Pescara, [2]Department of Hematology and Oncological Sciences, Section of Hematopathology, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy

Background: IgD Multiple Myeloma (MM) is one of the rarest type of MM, representing almost 2% of all myeloma cases. It has been reported a poorer outcome of this variant when compared with other subtypes, with an aggressive course, high incidence of bone complications, extramedullary disease and resistance to chemotherapy. These data come from small retrospective studies mainly before the introduction of bortezomib and immunomodulatory drugs.

Aims: We describe aggressive and unusual clinical course of IgD MM, with a good outcome after hematopoietic-stem-cell transplantation (HSCT) and "novel-agent" therapy.

Methods: We present four female patients with aggressive IgD MM diagnosed in our Department; they received chemotherapy with novel agents alone or followed by autologous hematopoietic stem cell transplantation (HSCT).

Results: Mean age was 56 yrs. All patients had multiple bone lesions, two of them a serum creatinine >2 mg/dl and hypercalcemia; two patients showed extramedullary involvement and multiple lymphadenopathy, two of them showed chromosomal abnormalities. Bone-marrow biopsy revealed more than 40% clonal plasma cells. Three women showed LDH superior to normal values. Three young patients underwent autologous HSCT upon conditioning chemotherapy with melphalan 200 mg/m^2: in two cases it was preceded by bortezomib-thalidomide based induction therapy; the third patient received VAD induction and she was treated with bortezomib for recurrent disease. The fourth older patient receveid melphalan, bortezomib and steroids based regimens. A relapse was observed in this patient with progressive paraplegia; MRI revaled an extramedullary tumour of 68x 57 mm extended from D5 to D7, with need of irradiation plan-treatment. Chemotherapy consisted of Lenalidomide and Dexamethasone. All these four patients presented an atypical clinical onset, but they all obtained a CR after treatment, which is still present after various months (median overall survival 55 months). Despite heterogeneity of the population studied, use of the novel drugs both in first line therapy and relapsing disease has been shown to achieve an improvement in overall survival.

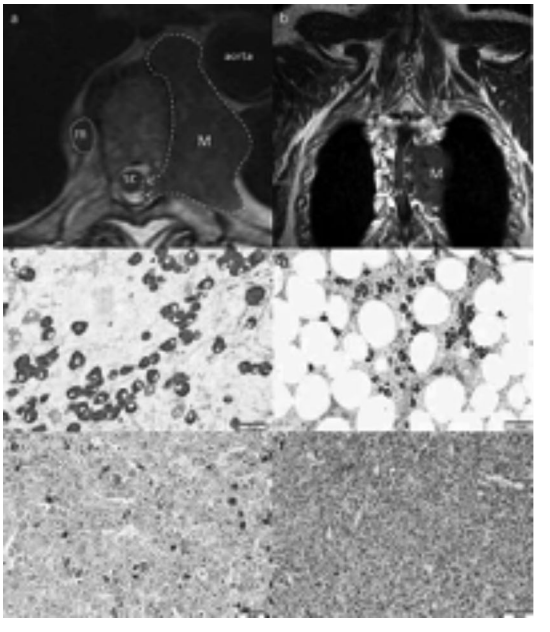

Figure 1.

Summary and Conclusions: The IgD MM is really different from IgG and IgA MM; it could be interesting to discover if the clinical picture and the course of illness could be somehow related to the class of M-component. IgD MM could be considered a different kind of neoplasia, with high kinetic proliferation rate and peculiar biologic aspects. Probably new cytogenetic aberrations, as presented in our population (trysomy of chromosome 5 and 9 in two patients) could explain this different biology and behavior. Nowadays IgD myeloma is still a challenging matter. Half of our patients with IgD MM presented extramedullary plasmacytoma, a rare and poorly understood entity. It is not known which mechanisms are involved in the hematogenous myeloma spread and how can myeloma cells growth and survival at extramedullary sites. Therefore in a patient with fever, lymphoadenopaties and high LDH levels we should consider this kind of aggressive myeloma as differential diagnosis with lymphoproliferative disorders. Nevertheless, after the introduction of different novel agents the clinical course and prognosis of IgD MM seems to have improved in particular with novel drugs in combination with autologous HSCT. All our patients are in CR after treatment and are currently being monitored at our centre. Our results were obtained in a few patients and an international collaborative trial is needed to confirm these findings.

PB1867

USE OF FLC AND HLC RATIOS FOR DIAGNOSIS AND MONITORING OF MONOCLONAL GAMMOPATHIES

A. Gagliardi[1,*] C. Carbone[2], A. Russo[2], R. Cuccurullo[1], A. Lucania[1], P. Della Cioppa[1], L. Mastrullo[1], C. Tommasino[2]
[1]ASL NA1 -Centro U.O.C. Ematologia Ospedale San Gennaro-NAPOLI, [2]ASL NA1 -Centro U.O.C. Patologia Clinica Ospedale San Gennaro-NAPOLI, Napoli, Italy

Background: Monoclonal Gammopathies are characterized by the presence of a serum monoclonal component (MC), either an intact immunoglobulin, a free light chain, or a combination of both. Measurement of FLC with Freelite® is standard practice and it is recommended by IMWG guidelines. Recently, Hevylite™ heavy light chains (HLC) assays were introduced to specifically target junctional epitopes between the heavy and light chains of intact immunoglobulins, allowing the independent quantification of the involved Monoclonal Component and uninvolved, polyclonal background.
Aims: In our Department we have used FLC and HLC for diagnosis and monitoring of Monoclonal Gammopathies, particularly in Multiple Myeloma patients this method is useful for monitoring of disease.
Methods: from January 2012 to March 2014 we collected 300 samples from 90 patients and assessed the diagnostic and monitoring performance of Hevylite® A and G assays in 7 transplanted patients, 17 non eligible patients and 18 relapsing patients, receiving a combination therapy with VTD; PAD; MPV or Len/Dexa. We selected 3 emblematic case studies
Results: Hevylite® absolute values and ratio demonstrated high sensitivity and specificity with respect to Freelite and serum protein electrophoresis, serum immunofixation. The combined use of Hevylite® A and G with Freelite® was particularly useful in dubious cases with more than one MC or with co-migrating components, and in the course of monitoring to assess the independent change of FLC and HLC, possibly reflecting the presence of clonal heterogeneity in our cohort.
Summary and Conclusions: Freelite and Hevylite are independent, useful markers to monitor the MC and to assess with greater specificity and sensibility the effect of therapy, thereby providing clinical support. More studies are needed to assess the prognostic potential of Hevylite in SMM and MGUS patients.

PB1868

IMPACT OF PG-SGA SCORE ON SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA

H.S. Kim[1,*] M.Y. Lee[1], J.Y. Lee[1], S.H. Lim[1], K. Kim[1], S. Kim[1]
[1]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

Background: Disease-related weight loss is relatively common in patients with newly diagnosed multiple myeloma, but there are limited data on the impact of nutritional status on survival.
Aims: Using the Patient-Generated Subjective Global Assessment (PG-SGA) score, we retrospectively explored the effect of malnutrition on the survival of multiple myeloma patients. We also investigated the relationship between PG-SGA score prior to chemotherapy and clinical manifestation, in patients with multiple myeloma.
Methods: Analysis was performed on a retrospectively assembled cohort of 216 multiple myeloma patients diagnosed between October 1, 2002, and October 31, 2013. A total of 216 myeloma patients were subdivided into three groups based on PG-SGA scores.
Results: Twenty-three percent (50/216) patients had a PG-SGA score 9 or over, indicating severe malnutrition requiring specialist nutrition intervention. BMI and serum LDH were independently associated with PG-SGA scores (P<0.05). The median survival times were not reached in nourished patients with PG-SGA score 0-3, 58.7 months in moderately malnourished patients with PG-SGA score 4-8 and 35.0 months in severely malnourished patients with PG-SGA score ≥9 (P=0.001). Multivariate analysis showed that PG-SGA score ≥9 patients compared with PG-SGA score 0-3 patients (HR 2.347, 95% confidence interval [CI] 1.271-4.334; P=0.006), International Staging System (ISS) stage III compared with ISS stage I (HR 2.360, 95% CI 1.271-4.379, P=0.007) and autologous stem cell transplantation (HR 0.388, 95% CI 0.248-0.606, P<0.001) were associated with overall survival.
Summary and Conclusions: In conclusion, higher PG-SGA score prior to chemotherapy was associated with reduced survival among patients with multiple myeloma. Nutritional evaluation should be integral part of the clinical assessment of MM patients and PG-SGA score would be an appropriate tool to evaluate nutritional status.

PB1869

BING NEEL SYNDROME, ABOUT A CASE REPORT AND REVIEW OF LITTÉRATURE

S. Bougherira[1,*]
[1]Hematology, faculty of medecine, university hospital of Annaba, Annaba, Algeria

Background: Waldenstrom's Macroglobulinaemia (WM) is is defined by the World Health Organization as an IgM secreting "lymphoplasmacytic lymphoma, characterized by BM infiltration, and occasionally lymph nodes and spleen.
The most frequent neurological complication of Waldenström's macroglobulinemia is IgM-mediated polyneuropathy. Direct tumor cell infiltration of the nervous system is extremely rare and better known as the "Bing and Neel Syndrome" (BNS), that was first described in 1936.
Aims: We describe a patient with a long history of WM presenting Bing and Neel syndrome revealed by convulsion.
Methods: 68-year-old man was followed up in our department since September 2002 for a typical WM. A first complete remission was obtained with CHOP. In March 2007, he relapsed, and a second complete remission was obtained with chlorambucil. FCR therapy regimen (fludarabine, cyclophosphamide and rituximab) was used on July 2011. In March 2014, the patient presented with persistant headaches, episods of convulsion, blurry vision and disorders of memory. Computerized tomography of the brain showed a tumor mass multifocal supratentorial with edema. Brain magnetic resonance imaging displayed pachymeningeal regions of enhancement with associated FLAIR hypertensity on T2-weighted sequences. Examination of the cerebrospinal fluid (CSF) showed a lymphocytic meningitis with an increase of the CSF protein, and a normal CSF glucose. The patient did not undergo biopsy. The staging including full body scan, bone marrow aspiration, and bone marrow biopsy was normal, no organomegaly, meaning stable WM. Our patient underwent successful treatment with MPV-A regimen chemotherapy of Methotrexate 3,5 g/m² D1/ Vincristine 1,4 mg/m² max 2,8 D1/Procarbazine 100 mg/m² D1to D7(cycles 1, 3, & 5)-5 cycles repeated every 15 days, at final a closing course with AraC 3g/m² D1 and D2 without radiation therapy.
Results: The evolution was characterized by disparition of clinical symptoms, a marked regression of lesions on MRI and normalization of CSF analysis. The patient is still alive with free-symptoms in December 2014, last scheduled visit.
Summary and Conclusions: BN syndrome is a very rare complication of WM that should be considered in patients with neurologic symptoms and a history of WM. A brain MRI and histologic analysis may be a good supportive tool to diagnose Bing-Neel syndrome.There is still no consensus on the treatmentstrategies to use in BNS.

PB1870

DAY-100 BONE MARROW TREPHINE FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA: HOW USEFUL ARE THE RESULTS?

B. Catherine[1], R. Byers[2], E. Rothwell[1], M. Saif[1], F. Dignan[1], J. Thachil[1,*] B. John[1], T. Eleni[1], R. Krishna[1]
[1]Haematology, [2]Histopathology, Manchester Royal Infirmary, Manchester, United Kingdom

Background: Bone marrow trephine samples are routinely assessed from patients following autologous stem cell transplantation (SCT) for Multiple Myeloma (MM) 100 days after the procedure
Aims: The aim of this study is to assess the clinical value of the day 100 trephine biopsy and to see if it offers additional information when compared to serological markers.
Methods: We analysed the pre-transplant and day 100 (d100) post-transplant bone marrow trephines for a series of consecutive patients (n=64) who underwent autologous stem cell transplant between June 2013 to August 2014. Only patients who had adequate pre- and post-transplant trephine biopsies taken were included in the study (n=46). Pre-transplant state was categorised as either complete response (CR) or as partial response (VGPR/PR groups) as defined by the International Myeloma Working Group (Uniform Response Criteria for MM). At d100 the bone marrow trephine results and corresponding serum paraprotein and light chain values were analysed. The concordance between these sets of results was determined
Results: Prior to transplant, 34 patients were in VGPR/PR and 12 in CR. Overall, the bone marrow trephines showed no change in 34/46 patients. There was an improvement in 11/46, while poor regeneration was noted in 1/46. In all patients with CR (n=12), there was no change in the d100 trephine results. However, paraprotein became detectable in 7/12. 5/12 remained in CR. In the VGPR/PR patients (n=34), d100 trephine showed no change in 22/34, 11/34 showed an improvement, 1/34 showed poor regeneration. Out of the 11 that showed improvement, 4/11 showed concordant improvement in the serum markers (paraprotein and/or light chain levels), 1/11 showed worsening of serum markers, 5/11 showed no change and 1/11 had no d100 serum markers available. In the VGPR/PR group, 2/34 had progressive disease according to serum markers; of these, one had no change in the trephine while the other showed improvement. 10/34 showed improvement in the serum markers; of these, 4/10 showed concordant improvement in the trephine samples. 21/34 showed no change in serum markers, of which 15/21 showed no change in the trephine, 5/21 showed improvement, 1/21 had poor regeneration. There were no d100 serum markers available for one patient. Overall, no progression was seen in all d100 trephines compared to pre-transplant sample, while progression was seen in 9/46 serum markers at d100 compared to the pre-transplant levels
Summary and Conclusions: Data from this study demonstrates that based on the bone marrow trephine results in isolation, patients who had received

SCT for MM did not require a change to clinical management. There was no progression noted in any d100 trephine biopsy sample, although 9/46 patients showed progression in serum markers. Although this study is too early to assess any longer-term predicative value of d100 marrow assessment, we would propose routine day 100 bone marrow trephine biopsies for MM patient's post autologous SCT contributes little additional clinical value and could be omitted with little risk to the patient. It may be more appropriate to follow up such patients using serum paraprotein and/or light chain levels alone.

PB1871

OUTCOME OF POMALIDOMIDE THERAPY IN RELAPSED / REFRACTORY MYELOMA: A UK MULTI-CENTRE EXPERIENCE

N. Maciocia[1,*] F. Sharpley[2], E. Belsham[3], H. Renshaw[4], S. Schey[4], S. Cheesman[1], A. Cerner[1], A. Rismani[1], S. D'sa[1], M. Streetly[5], B. Reuben[4], M. Jenner[3], K. Ramasamy[2], K. Yong[1], N. Rabin[1]
[1]Haematology, University College London Hospitals NHS Foundation Trust, London, [2]Haematology, Oxford University Hospitals NHS Trust, Oxford, [3]Haematology, University Hospital Southampton NHS Foundation Trust, Southampton, [4]Haematology, King's College Hospital NHS Foundation Trust, [5]Haematology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: Pomalidomide is licensed in Europe for patients with relapsed / refractory myeloma, who have received at least two prior therapies including lenalidomide and bortezomib and who have progressed on their last therapy. In the phase 3 NIMBUS study, pomalidomide and dexamethasone was associated with longer progression free (PFS, 4.0 vs 1.9 months) and overall survival (OS, 12.7 vs 8.1 months) compared to dexamethasone alone (San Miguel et al 2013).
Aims: To assess the clinical efficacy of pomalidomide in a real-world setting in several large treatment centres in the UK.
Methods: Patients had measurable disease (IMWG criteria) and received at least 1 cycle of pomalidomide with dexamethasone. Disease response was assessed as per IMWG and high risk disease defined as ISS II/III plus t(4;14) +/- del(17p) (IMWG criteria). PFS and OS were measured from start of pomalidomide therapy and estimated using Kaplan-Meier method.

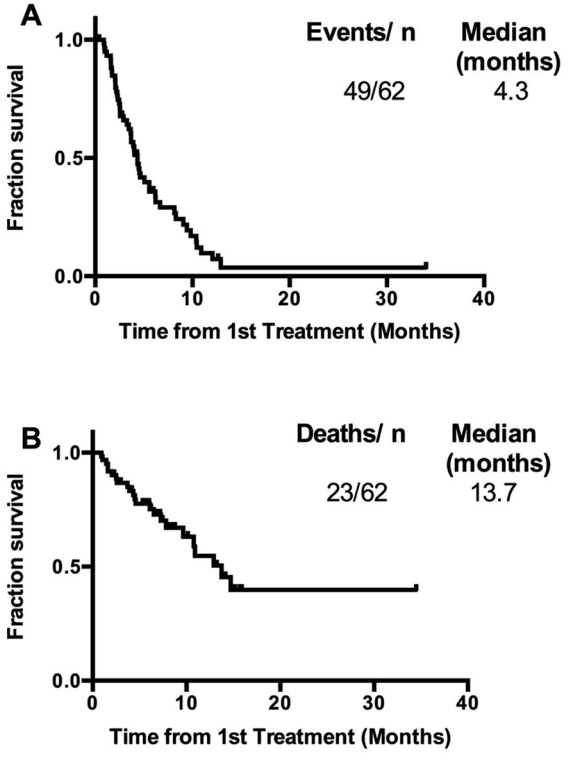

Figure 1. A) Progression-free survival and B) overall survival of all patients.

Results: Seventy-nine patients were identified, of whom 62 (78.5%) were suitable for inclusion in response analyses. All patients received pomalidomide (2-4mg days 1-21) with weekly dexamethasone, 30/79 (38%) received another agent(s) [clarithromycin (23), cyclophosphamide (9), carfilzomib (1), bortezomib (1)]. Patient characteristics were as follows: median age 67 years (range 40-89); isotypes were: 43 (55%) IgG, 19 (24%) IgA, 15 (19%) LC only. Median time from diagnosis was 4.9 years (range 0.5 to 18); median prior lines of therapy was 4 (range 1 to 8). Prior therapies included lenalidomide (100%), bortezomib (98%), thalidomide (84%), and autologous stem cell transplantation (61%). Seventy-three patients (92%) were refractory to their last therapy, and 58 (73%) were refractory to both bortezomib and lenalidomide. Median follow up was 6.4 months (0.92-34.5). Median number of cycles was 4 (range 1-32), and median daily dose was 4 mg. Fifteen patients (19%) had dose reductions. In those with a GFR<45ml/min at baseline, 50% (7/14) started at a dose<4mg. Overall response (≥ PR) was 53%, VGPR 5%, and at least stable disease was achieved in 58/62 (94%). PFS was 4.3 months (Figure 1A), and OS was 13.7 months (Figure 1B). Impaired renal function (GFR<45ml/min, 14 patients) did not appear to influence PFS (4.0 months vs 4.5 months, P=0.44), or OS (10.8 vs 13.7 months, P=0.80). High risk FISH was present in 11/40 (28%) patients, who had comparable outcomes to standard risk patients: PFS 3.6 months vs 4.5 months, (P=0.70) and OS 11.3 vs not reached (P=0.19). Inclusion of a third agent at start of therapy (14 patients) did not appear to confer benefit (PFS 4.3 vs 4.0 months, P=0.40, OS 7.8 vs 13.7 months P=0.37). In eight patients with biochemical or clinical progression on pomalidomide/dexamethasone, a third agent was added, and 7 achieved SD/PR. Grade 3/4 non-haematological toxicities occurred in 27/79 (34%) patients: pneumonia, 15 patients (19%) and neutropenic sepsis, 9 patients (11.4%) being the most common. Grade 3/4 neutropenia occurred in 28 patients (35%) and thrombocytopenia in 17 patients (22%).
Summary and Conclusions: Pomalidomide is an effective treatment in relapsed / refractory myeloma, with survival outcomes comparable to reported results from the phase 3 NIMBUS study. Impaired renal function and adverse genetics do not appear to influence outcomes. The addition of a third agent should be explored prospectively.

PB1872

THE IMMUNOPHENOTYPIC CHARACTERISTICS OF CD19 POSITIVE MYELOMA AND ITS PROGNOSTIC IMPACT

H.T. Mya[1,*] N. Puig[1], M.B. Vidriales[1], M. Díez-Campelo[1], J.J. Pérez Morán[1], J. Flores-Montero[2], A.M. Garcia-Sancho[1], N.C. Gutiérrez[1], M.V. Mateos[1], E. Ocio[1], M. Cañizo[1], A. Orfao[2], R. García Sanz[1]
[1]Haematology, Hospital Universitario de Salamanca, [2]Flow cytometry, Universidad de Salamanca, Salamanca, Spain

Background: Clonal plasma cells (CPCs) in multiple myeloma were usually characterized by negative CD19 expression by multiparametric flow cytometry (MFC). However, positive CD19 expression in CPCs was noted in some cases with the reported incidence ranging from 0 to 8%. Positive CD19 expression in CPCs could complicate the minimal residual disease (MRD) assessment by high sensitivity MFC as the majority of polyclonal plasma cells (PPCs) retained CD19 expression. In addition, CD19 positive myeloma patients were reported to have a poorer clinical outcome in the group of patients treated with induction chemotherapy followed by autologous stem cell transplantation.
Aims: We aimed to review the immunophenotypic features of CD19 positive myeloma patients in comparison with that of CD19 negative cases to determine specific immunophenotypes which could be useful for MRD assessment. The prognostic impact of positive CD19 expression on clinical outcome in patients treated with the regimens including novel therapies was also evaluated.

Table 1.

Table 1. Patients characteristics, clinical and biochemical profile

		CD19 positive	CD19 negative	p-value
Sex				
	Male (%)	4.90	95	0.79
	Female (%)	4	96	
Heavy Chain				
	Ig G (%)	6	94	0.921
	Ig A (%)	6.50	93.50	
Light Chain				
	Kappa (%)	5.20	94.80	0.867
	Lambda (%)	4.50	95.50	
ISS				
	1 (%)	4.80	95.20	0.934
	2(%)	6.10	93.90	
	3(%)	3.10	96.90	
FISH				
	Standard risk (%)	5.10	94.90	0.85
	High risk (%)	4.20	95.80	
Age (mean)		69.86	71	0.466
Creatinine (mean, mg/dl)		1.52	1.51	0.278
Bone disease				
	Yes (%)	4.1	95.9	0.373
	No (%)	8.1	919	
Hypercalcaemia				
	Yes (%)	10.7	89.3	0.08
	No (%)	2.9	97.1	
Haemoglobin (g/dl)		10.65	11.38	0.043
LDH (mean, U/L)		241	266	0.26
Albumin (mean, g/L)		3.49	3.69	0.221
B2 microglobulin (mean, mg/L)		4.34	5.61	0.494
Plasma cells count by flow cytometry in %		16.77	12.8	0.526
Plasma cell count by microscopy in %		38	28.96	0.520

Methods: A retrospective review of newly diagnosed myeloma patients in a single centre was performed for the period of Jan 2006 to Jan 2015. The clinical data was retrieved from the patient information system of the institution as well as by reviewing the clinical records. Multiparametric flow cytometry analysis was performed by BD FACSCalibur™ for four colour analysis and BD FACSCanto™ flow cytometer for eight colour analysis. CD19, CD45, CD38, CD138 and CD56 expression was determined for all patients and for those cases where eight colour analysis was applied, CD27, CD28, CD117 and CD81 expression was studied. All the FCS data was analysed using infinicyt software. Plasma cells were identified by primarily gating on CD38 and CD138 positive cells. Mean fluorescent intensity of CD19 expression on plasma cells was compared with that of B-lymphocytes to determine positive or negative expression. It was considered a positive expression if 20% of the CPCs were positive.
Results: A total of 157 newly diagnosed multiple myeloma patients were reviewed. The incidence of CD19 positive myeloma cases was 4.46%. Out of 7 patients who were CD19 positive, four patients had homogeneous strong positive expression while the remainder had heterogeneous dim positive expression. Baseline demographics of the patients, ISS, immunoglobulin subtypes and clinical parameters at presentation *i.e.* related organ and tissue impairment, LDH, albumin,beta2 microglobulin levels and cytogenetic risks were similar in both CD19 positive and CD19 negative myeloma patients (Table 1). CD56 expression was 100% and 74% positive in CD19 positive and negative myeloma patients respectively (P 0.12). There was a higher percentage of positive CD81 expression (80% vs. 37.3%, P 0.056) and higher percentage of negative CD27 expression (60% vs. 35.9%, P 0.276) in CD19 positive cases though it did not reach statistical significance. No statistically significant difference in overall survival was found with a median OS of 56 and 75 months for CD19 positive and negative cases respectively (P 0.847).
Summary and Conclusions: In our study, CD19 expression was associated with a 100% positive CD56 expression, a higher positive CD81 expression and a higher negative CD27 expression rate even though statistical significance was not reached due to few numbers of patients in the cohort. This could be a useful finding for MRD assessment of the patients as well as to differentiate CPCs from PPCs in MGUS or smoldering myeloma by MFC. In the current cohort, we did not demonstrate a poorer prognostic impact of CD19 positive expression. This could be explained by the difference in the treatment era of the study patients where almost all the patients eligible for treatment received one or more novel therapeutic agents, compared to previous cohorts. Prospective studies with larger cohorts may further elucidate the significance of CD19 positive myeloma.

PB1873

BURDEN OF MULTIPLE MYELOMA IN THE UNITED KINGDOM

M. Raluy-Callado[1,*] D. Lambrelli[1], E. Merinopoulou[1], S. Panjabi[2]
[1]Evidera, London, United Kingdom, [2]Onyx Pharmaceuticals Inc., an Amgen subsidiary, San Francisco, United States

Background: The introduction of novel agents for the treatment of multiple myeloma (MM) in recent years has been shown to lead in improvements in response and overall survival. However, real world evidence studies on the burden of disease are limited and outdated.
Aims: To describe patient characteristics of newly diagnosed MM patients in the United Kingdom (UK) and to assess disease burden in terms of healthcare resource use.
Methods: Retrospective primary care data from the Clinical Practice Research Datalink (CPRD) linked to the Hospital Episode Statistics (HES) was used. Adult patients with a first diagnosis of MM between Jan 2008-Dec 2012 were identified. Patient characteristics including comorbidities were described at date of diagnosis (index date). Disease-related symptoms, complications and adverse events were described during follow up, as well as primary and secondary care resources, including GP visits and hospitalisations.
Results: In the CPRD cohort, 1,457 newly diagnosed MM patients were identified and followed up on average for 2.1 years. Of those, 910 (62.5%) were linked to HES (CPRD-HES cohort). Mean age in the CPRD cohort was 71 years (SD: 11.6) and 54.8% were male. Body mass index (BMI) recorded in the 12 months prior diagnosis for 48.5% of the patients was on average 27, classifying them as obese or overweight. The most common comorbidities identified in whole medical history prior diagnosis were renal disease (25.5%), chronic pulmonary disease (19.6%), other malignancies excluding MM (17%) and diabetes without complications (13.1%). During the follow–up period, renal insufficiency was the most common disease symptom (annual incidence: 176.5 per 1,000 patients). Side effects including constipation, vomiting, diarrhoea, syncope, skin rash, and venous thromboembolism were observed at a rate greater than 10 per 100 patients in the first year after diagnosis. GP visits around diagnosis increased from a rate of 4.5 visits/patient (95% Poisson Confidence Intervals [CI]: 4.4-4.6) in 12 to 6 months prior to 8.4 (CI: 8.2-8.5) in the 6 months post diagnosis, and remained high for the entire follow up period (rate: 6.4; CI: 6.4-6.5). Demographic and clinical characteristics of the CPRD-HES cohort were comparable to the overall CPRD cohort; mean age at diagnosis was 71 years (SD: 11.7). A majority (86.6%) of patients in the CPRD-HES cohort incurred at least one hospitalisation post diagnosis (Figure 1). Most hospitalizations were day case admissions (85.6%), with inpatient admissions (14.4%) accounting for the remainder. On average, 4.4 day case admissions per patient per year (SD: 8.8) were encountered in the post-diagnosis period, while the average length of stay for inpatient admissions was 9.8 days (SD=11.85).

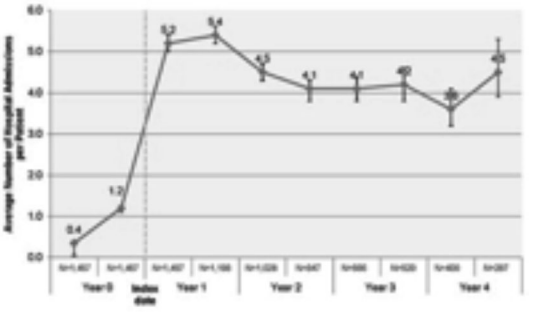

Figure 1. Average number of hospital admissions (inpatient and day cases) per patient during 6-month periods prior and post index date (Poisson CI)

Summary and Conclusions: Renal disease and respiratory conditions are common presenting comorbidities among MM patients. The management of disease symptoms, complications and adverse events as well as severe comorbidities leads to increased resource use in both primary and secondary care settings.

PB1874

TIME TO ONSET AND DURATION OF INDUCTION THERAPY AND ASSOCIATED FACTORS AMONG NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

A. Yusuf[1,2,*] T. Bovitz[1], T. Matlon[1], W. Werther[3], D. Felici[3], M. Mahue[3], K. Bridges[3], Y. Peng[1]
[1]Chronic Disease Research Group, [2]University of Minnesota, Minneapolis, [3]Onyx Pharmaceuticals Inc., an Amgen Subsidiary, South San Francisco, United States

Background: While early start of induction chemotherapy may improve treatment outcomes for patients with cancer, little is known about time to treatment onset and duration of induction therapy in newly diagnosed multiple myeloma (NDMM) patients.
Aims: We examined onset and duration of induction therapy and associated factors including age, gender, race, index year, stem cell therapy, and drug regimen in NDMM patients in the United States.
Methods: Using Medicare 20% data, we created a cohort of adult (≥18 years) NDMM patients (2008-2010) who initiated therapy with defined medications within 1 year of cancer diagnosis. Induction therapy regimens were categorized as bortezomib-based, immunomodulator (IMiD)-based, bortezomib-IMiD-based, or corticosteroid-based. Median number of days from diagnosis to therapy onset and of therapy duration were examined overall and for associated factors in a univariate approach using the Kruskal-Wallis test.

Table 1.

		Treatment onset		Treatment Duration	
	% of sample	Median(IQR)	P	Median(IQR)	P
Overall	100	26 (12-64)		195 (113-349)	
Age (years)					
18-64	8.1	25 (14-67)	0.7	187.5 (99-275)	0.2
65+	91.9	26 (12-64)		197 (114-358)	
Gender					
Male	44.8	25 (12-58)	0.5	201 (117-357.5)	0.3
Female	55.2	27 (13-68)		187 (106-343)	
Race					
White	78.9	25(12-64)	0.7	195 (113-357)	0.9
Black	15.8	27 (13-75)		201.5 (113-333)	
Other	5.3	30 (13-57)		185 (116-339)	
Index year					
2008	34.0	29(14-84)	<0.0001	187.5 (107-331)	0.06
2009	34.7	28 (14-72)		190 (112-329)	
2010	31.3	21 (10-42)		213.5 (117-366)	
Receipt of SCT					
No	93.6	26(12-65)	0.5	202 (114-366)	<0.0001
Yes	6.4	25(14-55)		162 (106-215)	
Regimen					
Bortezomib-based	25.2	21 (11-45)	<0.0001	203 (143-292)	<0.0001
IMiD-based	27.4	24 (13-50)		257 (151-366)	
Bortezomib-IMiD-based	9.2	20 (10-35)		258 (169-366)	
Corticosteroid-based	12.4	31 (11-108)		129 (91-276)	
Others	25.8	38 (15-114)		131 (91-366)	

Results: We identified 1455 NDMM patients**.** Overall, median (IQR) number of days to therapy onset from diagnosis and of therapy duration were 26 (12-64)

and 195 (113-349), respectively. Neither days to onset nor duration varied significantly by age, sex, or race. Days to onset decreased from 29 to 21 days from 2008 to 2010, respectively (P<0.0001), but therapy duration was similar across years ranging from 188 to 214 days (P=0.06). Although days to onset were similar for patients who did (25 days) and did not (26 days) receive stem cell therapy (SCT; P=0.52), median therapy duration was 25% longer at 202 days for those who did not (P<0.0001). Onset was more rapid (21, 24, and 20 vs. 31 days) and duration longer (203, 257, and 258 vs. 129 days) for patients treated with bortezomib-, IMiD-, and bortezomib-IMiD-based regimens compared to those treated with corticosteroid-based regimens, respectively. Duration of therapy was longer for patients who did not receive SCT compared to those who did for bortezomib-based (209 vs. 156 days), IMiD-based (284 vs. 124 days), and bortezomib-IMiD-based (291 vs. 142 days) regimens, respectively.
Summary and Conclusions: We observed differences in time to onset and duration of induction therapy by index year, SCT status, and choice of regimen, and found no racial or sex differences. The clinical implications of these findings are unknown. Further studies are warranted to better understand the observed differences.

PB1875

SALVAGE THERAPY WITH BORTEZOMIB AND DEXAMETHASONE IN VERY ELDERLY PATIENTS WITH RELAPSED REFRACTORY MULTIPLE MYELOMA

R. Castelli[1,*] G. Pantaleo[2], P. Gallipoli[3], P. Gallipoli[3], M. Arquati[4], M.A. Wu[4], G. Lambertenghi Deliliers[5], M. Cicardi[4]
[1]Hematology, 1 Department of Pathophysiology and Transplantation University of Milan, and Department of Haematology IRCCS Ca' Granda Policlinico, Milan, Italy, [2]2 UniSR-Social.Lab, Faculty of Psychology, Vita-Salute San Raffaele University of Milan, Italy, Milan, Italy, [3]Department of Haematology, Addenbrooke's Hospital, Cambridge University Hospitals NHS Trust, Cambridge, UK, Cambridge, United Kingdom, [4]4Department of Biomedical and Clinical Sciences Luigi Sacco, University of Milan, Luigi Sacco Hospital Milan, Milan, Italy, University of Milan, [5]Fondazione Matarelli Milan, Fondazione Matarelli, Milan, Italy

Background: Despite recent advances in therapy, multiple myeloma (MM) patients eventually relapse and become refractory to treatment with a median survival ranging from 6 to 9 months. Over the last decade, the introduction of new front-line agents, such as the immunomodulatory drugs (IMIDs) thalidomide and lenalidomide and the proteasome inhibitor, have led to an increase in survival in MM by achieving deeper levels of responses and prolonging the duration of remission. Bortezomib (bort)–dexamethasone (dex) is an effective therapy for relapsed/refractory (R/R) MM, but few data are available for elderly patients. Although MM affects people of all ages, more than 60% of MM patients are older than 70 years of age (median age at diagnosis 70 years), and the number of new patients is expected to double worldwide by 2030
Aims: To evaluate efficacy and toxicity of bort-dex treatment in elderly R/R MM patients.
Methods: From 2006 to 2015 we performed a retrospective, observational study to detect the efficacy and tolerability of bort-dex in a cohort of 81 elderly patients with R/R MM. Patients were treated with bortezomib at the dose of 1.3 mg/m^2 on days 1, 4, 8, 11 every 3 weeks up to 6–8 cycles alone or in association with dexamethasone at the dose of 20 mg on the day of bortezomib administration and on the subsequent day. Responses were assessed according to the International Myeloma Working Group (IMWG) criteria
Results: Median age of study population was 73 years (range 65-89 years). Fifty-three (65. 4%) of patients achieved at least a partial response, including 8 patients (11%) with Complete Response (CR) and 9 patients (12.5%) with very good partial response (VGPR). The median number of prior lines of therapy was 2. The median number of cycles of bort-dex was 6 (range 1-11). Thirty-nine patients (48%) received bortezomib intravenously, 42 (52%) received bortezomib subcutaneously. Fifty patients (61.7%) had received immunomodulatory drugs. The median duration of response, time to next therapy and treatment free intervals were 8, 11 and 5 months. The duration of response was significantly longer for patients achieving CR/VGPR than for those achieving PR (7.3 vs. 3.8 months, P=0.03). After a median follow up of 24 months, 78 patients showed disease progression and 70 patients died. Median Time to progression (TTP), progression free survival (PFS) and overall survival (OS) of the whole population were 8.9, 8.7 and 22 months respectively. The most relevant side effect was peripheral neuropathy (PN), occurring in 38 patients.
Summary and Conclusions: The depth of response to bortezomib and clinical benefit are known to be strictly related in younger MM R/R patients. Our data highlight that bort-dex is highly effective and tolerable in fit elderly patients, thus justifying the efforts to obtain deeper responses to therapy also in this subset of patients. However, awareness of the risk of short living haematological responses to bort-dex salvage therapy (both in young and in old patients) should lead to thorough evaluation about the need of a maintenance therapy with other agents such as lenalidomide or pomalidomide in order to achieve sustained responses.

PB1876

LEVELS OF UNINVOLVED IMMUNOGLOBULIN PREDICT CLINICAL STATUS AND PROGRESSION FREE SURVIVAL FOR MULTIPLE MYELOMA PATIENTS

J. Berenson[1,*] N. Harutyunyan[1], S. Vardanyan[1], M. Ghermezi[1], J. Gottlieb[1], A. Berenson[1], C. Andreu-Vieyra[2], M. Li[1], C. Wang[1], G. Tang[1], E. Sanchez[1], J. Ben-Zvi[1], G. Garzio[1], H. Chen[1]
[1]Institute for Myeloma & Bone Cancer Research, [2]Oncotherapeutics, West Hollywood, United States

Background: The levels of monoclonal immunoglobulins (M-Igs) are used to monitor multiple myeloma (MM). HevyLite® +(HLC) assays are able to discriminate between uninvolved and M-Ig levels.
Aims: We evaluated the levels of involved and uninvolved HLC, their ratios and differences and their relationship to outcomes among 189 MM patients.
Methods: Serum samples were analyzed using the HLC assays, and results were correlated with clinical status (complete response (CR), ≥ partial response (PR),<partial response, and progressive disease (PD)). Comparisons were made using student's t, Mann-Whitney, and Fisher's tests. PFS was calculated using Kaplan-Meier analysis. All tests were double-tailed and P-values determined.
Results: The patients were 62% IgG and 38% IgA with a median age of 66 years, β2 microglobulin 3.27 mg/L, albumin 3.8 g/dl, and median follow up of 72.5 months. Patients with PD had higher involved HLC levels, lower uninvolved HLC levels, higher ratios of involved/uninvolved HLCs and greater differences between them compared with patients with ≥ PR (all with P<0.0001). A higher proportion of patients in ≥ PR had normal uninvolved HLC levels than patients with<PR (P<0.0001). Additionally, patients in CR were more likely to have normal uninvolved HLC than those with below normal levels (P<0.0001). Similarly, patients in CR were more likely to have normal HLCs than in PR (P=0.0040). Patients with normal uninvolved HLCs showed a longer PFS (45 months) than those with less than normal levels (11 months; P=0.0019). Patients with normal involved HLC levels had longer PFS (33 months) than patients with involved HLC above the normal range (11 months; P=0.0405).
Summary and Conclusions: We show that involved/uninvolved HLC ratios, differences between them, involved and uninvolved HLC levels correlate with clinical status for MM patients. Patients with normal uninvolved levels or normal involved HLC levels have a longer PFS.

PB1877

SUBCUTANEOUS BORTEZOMIB IS AS EFFECTIVE AND LESS NEUROTOXIC THAN INTRAVENOUS BORTEZOMIB: ANKARA University EXPERIENCE

B. Ateşağağlu[1,*] P. Topçuoğlu[1], M. Merter[1], M. Sungurlu[1], Ö. Şener[2], M. Beksaç[1]
[1]Department Of Hematology, [2]Department Of Neurology, Ankara University, Ankara, Turkey

Background: Bortezomib is a proteasome inhibitor which has proven potent activity against malignant plasma cells.Peripheral polyneuropathy (PNP)is one of the most frequent, non-hematologic adverse effects (AE) of Bortezomib often requiring dose modification or discontinuation.
Aims: Although the initial report by Moreau et al demonstrating the advantages and safety of subcutaneous use which led to the approval,this route of application is not being widely used in Turkey.Here we aimed to present our experience on the incidence of Bortezomib induced neuropathy (BiN)comparing two approved routes of administration.
Methods: After 2012 s.c.administration has become an accepted approach in our clinic for patients presenting with BiNin addition to dose reduction as recommended in the package.Weekly administration is the second step that follows if PNP does not improve.After 2013 s.c.has become the preferred approach for NDMM too.We retrospectively analyzed 129 consecutive patients diagnosed with Multiple Myeloma at Ankara University School of Medicine Department of Hematology between 2008-2013 and had completed at least three cycles of a Bortezomib containing protocol either at diagnosis or at relapse. Hospital records were screened to evaluate the incidence ofBiN, dose adjustments arising from AEs of Bortezomib and outcome measures.We compared the frequencies of AEs and treatment outcomes between patients who started treatment with s.c.*versus* i.v.administration of Bortezomib.We also analyzed outcomes following conversion from iv to sc too.Statistical analysis were performed using the SPSS for Windows,Version 16.0
Results: Baseline demographics,disease characteristics or number of previous lines of therapy were similar between patients receiving s.c.or i.v. treatment (Table-1). *De novo* subcutaneous Bortezomibwas given to 58 patients during induction;16 patients converted from i.v.tos.c route following diagnosis of BiN(n:9) or due to change in adminstration policy(n:7).s.c.groupconsisted of 74 patients.55 Patients completed Bortezomib treatment only i.v.The median cumulative dose of Bortezomib was 15.6 (range 5.2-44.8) and 18.3 (range 5.2-62.4) mg/sq.m. among sc and iv groups (P=0.72).Neurologic adverse effects are summarized in Table-1.The median cumulative Bortezomib dose to onset of any grade of PN was 20.8 (range 3.9-41.6) and 20.8 (range 5.2-44.8)

mg/sq.m. to onset of PN with sc and iv group (P=0.69)respectively. Although statistically not significant dose reduction was required more often among patients in the iv group.Eight of the nine patients who converted to sc following onset of BiN had a improvement in symptoms with change in route and weekly administration.None of the patients experienced severe AEs related to s.c. administration or discontinued treatment. Rash at injection site was the most frequent AE which was lasting for 3 days maximum and easily tolerable.The progression-free survival (PFS) and OS between arms were also similar.

Table 1.

	Subcutaneous n=74	Intravenous n=55	P
Median age, range, years	57 (26-75)	57 (37-83)	0.41
Gender (M/F)	45/29	28/27	0.26

Autonomic neuropathy +/-	47 (66.1%)	44 (88%)	0.006
Polyneuropathy+/-	27 (36.4%)	30 (54.5%)	0.04
Median cumulative dose until PNP (mg/sq. m)	20.8(3.9-41.6)	20.8 (5.2-44.8)	0.69
Median cumulative dose (mg/sq. m)	15.6 (5.2-44.8)	18.3(5.2-62.4)	0.72
Dose reduction due to neurotoxicity	14 (19%)	17(31%)	0.12
Orthostatic hypotension	18 (25.7%)	13 (26%)	0.97
Gastointestinal symptoms Grade≥2	16(23%)	9 (18%)	0.52
Discontinuation due to toxicity*	4 (5,4%)	5 (9%)	0.41

Table 1 Clinical characteristics and comparision of neurological side effects
*among only s.c. route group

Summary and Conclusions: These results confirmed the safety and equal efficacy of sc Bortezomib compared to iv administration.Based on our results we recommend s.c. administration to avoid dose reduction requirement and discontinuation arising from neurotoxicity.

PB1878

CANCER-TESTIS ANTIGEN SLLP1 REPRESENTS A PROMISING TARGET FOR THE IMMUNOTHERAPY OF MULTIPLE MYELOMA

S. Yousef[1], J. Heise[2], N. Lajmi[2], T. Luetkens[1], N. Kröger[2], D. Atanackovic[1,*]
[1]University of Utah/Huntsman Cancer Institute, Salt Lake City, United States, [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Most patients with Multiple Myeloma (MM) will relapse after an initial response and eventually succumb to their disease. This is due to the persistence of chemotherapy-resistant tumor cells in the patients' bone marrow (BM) and immunotherapeutic approaches could contribute to eradicating these remaining cells. We evaluated SLLP1 as a potential immunotherapeutic target for MM.
Aims: Our goal was to evaluate cancer-testis antigen SLLP1 as a potential target for the immunotherapy of Multiple Myeloma.
Methods: We determined SLLP1 expression in myeloma cell lines and 394 BM samples from myeloma patients (n=177) and BM samples from healthy donors (n=11). 896 blood samples and 64 BM samples from myeloma patients (n=263) and blood from healthy donors (n=112) were analyzed for anti-SLLP1 antibodies. Seropositive patients were evaluated regarding SLLP1-specific T cells.
Results: Most cell lines showed SLLP1 RNA and protein expression while it was absent from normal BM. Of 177 patients 41% evidenced SLLP1 expression at least once during the course of their disease and 44% of newly diagnosed patients were SLLP1-positive. Expression of SLLP1 was associated with adverse cytogenetics and with negative prognostic factors including the patient's age, number of BM-infiltrating plasma cells, serum albumin, β_2-microglobulin, creatinine, and hemoglobin. Among patients treated with allogeneic stem cell transplantation those with SLLP1 expression showed a trend towards a reduced overall survival. Spontaneous anti-SLLP humoral immunity was detectable in 9.5% of patients but none of the seropositive patients evidenced SLLP1-specific T cells. However, antigen-specific T cells could readily be induced *in vitro* after stimulation with SLLP1.
Summary and Conclusions: SLLP1 represents a promising target for the immunotherapy of MM, in particular for the adoptive transfer of T cell receptor-transduced T cells.

PB1879

ASSESSMENT OF INDIVIDUAL THROMBOSIS RISK ON THE CAPRINI SCALE IN MULTIPLE MYELOMA PATIENTS UNDERGOING PERIPHERAL BLOOD STEM CELL MOBILIZATION.

E.S. Urnova[1,*] M. Gracheva[1], L. Mendeleeva[1], O. Pokrovskaya[1], L. Kuzmina[1], I. Tarandovskii[1], S. Vasiliev[1], E. Gemdzhian[1], M. Soloviev[1], M. Firsova[1], M. Nareyko[1], E. Parovichnikova[1], V. Savchenko[1]
[1]Hematology Research Center, Russian Ministry of Health, Moscow, Russian Federation

Background: Patients (pts) with multiple myeloma (MM) face an high risk of thrombosis. We are talking about pts-related, disease-related and therapy-related risk factors. Meanwhile no specific scale exists to assess the risk of thrombotic complications for MM pts. We suppose that the Caprini scale is the most comprehensive instrument for validation of individual risk factors and it can be used not only for surgery pts.
Aims: The study was aimed to investigate the blood coagulation status in MM pts depending on the individual risk assessment on the Caprini scale before and during peripheral blood stem cell (PBSC) mobilization.
Methods: The study's sample consisted of 30 pts-candidates for high dose chemotherapy. There were 19 males and 11 females at the age of 27 – 64 years (median 55). After bortezomib-containig induction therapy 7 of them achieved PR, 16 – VGPR and 7 – CR. PBSC mobilization was performed by using cyclophosphamide (CY, 4g/m^2) and granulocyte colony-stimulating factor (G-CSF, 5mcg/kg/day). According to the internal protocol all pts had prevention heparin-sulphate continuous infusion (in initial dose 500 IU/hour), starting the day before CY introduction and stopping the next day after finish last PBSC collection. All pts were assessed with Caprini model. Hemostasis analysis was performed 5 times and included validation the results of activated partial thromboplasin time (APTT, 25 – 38 sec) and concentration of D-dimer (0 – 500 mkg/l). Hypercoagulation was considered in cases when APTT<25 sec and D-dimer >500 mkg/l. And hypocoagulation was estimated by data APTT >38 sec. Statistical analysis was performed with SAS 9.1 (using the GLM procedure).

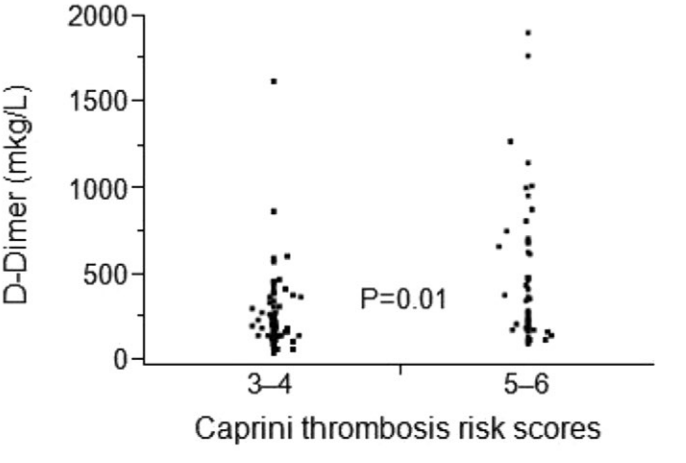

Figure 1.

Results: This group of pts had 3-6 (mean 4,4±0,96) scores on the Caprini scale. Initially (before heparin administration) APTT evaluation showed normal coagulation in 26 pts and hypocoagulation in 4 pts (mean 34 sec; 95% CI 32 – 36 sec). D-dimer was normal in 25 pts and increased in 4 cases (mean 309,8 mkg/l; 95% CI 170,0– 449,5 mkg/l). APTT had significantly (P<0,05) changed to hypocoagulability on the next day after starting thromboprophylaxis and in a state of agranulocytosis became 39 sec (95% CI 36 – 46 sec) and 40 sec (95% CI 36 – 50 sec) respectively. On the next day after CY infusion, APTT was statistically significantly decreased (P<0,05) reaching 34 sec (95% CI 32 – 37 sec). On the day of PBSC collection the mean APTT was 38 sec (95% CI 37 – 43 sec). Concentration of D-dimer was not modified in response to heparin or CY infusion or in a state of agranulocytosis and it icreased (P<0,05) reaching 476 mkg/l (95% CI 326-626 mkg/l) on the day of PBSC collection. Thrombotic complications were detected in 2 pts from a very high risk group (>5 score) on the Caprini scale. The analysis of our results showed statistically significant increase of (P=0,01) concentration of D-dimer in pts with the score of 5 or 6

compared pts with the score of 3 or 4 score (figure 1). Pts in CR demonstrated no significant difference in coagulation status compared to pts in VGPR or PR.
Summary and Conclusions: The possibility to use the Carpini scale to assess an individual risk of thrombotic complications for patients with MM has been confirmed clinically and by results of laboratory tests.

PB1880

REAL-WORLD CLINICAL CHARACTERISTICS AND TREATMENT PATTERNS IN US PATIENTS WITH RELAPSED/REFRACTORY (R/R) MULTIPLE MYELOMA (MM)

L. Viana Nicacio[1], G. Calkins[1], M. Curtis[1], J. Kohansimeh[1], F. P. Lindberg[1], K. Larrabee[1], A. Jaskiw[1], R. N. Feinstein[1], M. Terry[1], L. Plotkin[1], M. L. Palladino[1], A. Krishna[2,*], R. J. Green[1]
[1]Flatiron Health, New York, [2]Novartis Pharmaceuticals, East Hanover, United States

Background: The introduction of proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) has improved survival of patients (pts) with R/R MM. However, there is little real-world data on PI, IMiD, and autologous stem cell transplantation (ASCT) use.
Aims: The aim of this study was to describe recent US multiple myeloma treatment patterns through August 2014.
Methods: Pts with R/R MM were selected from a longitudinal, nationally-representative electronic medical record (EMR) database (Flatiron Health). MM diagnoses were confirmed by physician (MD) notes. Pts were required to progress after 1st line (1L), ≥ 1 visit after 2010, and ≥ 3 months follow-up post-progression. Data were integrated from structured and unstructured EMR sources: disease class from laboratory results and confirmed in MD notes and ASCT status from MD notes.
Results: We identified 607 pts with R/R MM (median age, 70 years; 32%<65 years). Most pts were male (57%), Caucasian (63%), and had IgG myeloma (66%). Of the 117 pts who received an ASCT, the most common 1L regimens were RVD 44%, VD 14%, RD 11%, and CyBorD 9%. In non-ASCT pts, the most common 1L regimens were VD 27%, RVD 16%, RD 14%, and CyBorD 7%. Overall, 29% of pts received both mechanisms of action (MOAs; PIs and IMiDs) in 1L. Of pts exposed to either a PI or IMiD in 1L who went on to receive 2L, 62% switched from PI to IMiD or IMiD to PI, and 30% continued with the same MOA. MOA switching was highest in ASCT pts who received 1L PI (73% received an IMiD in 2L, 23% continued on PI). By 3L, 79% of non-ASCT pts had been exposed to both MOAs vs. 96% in ASCT pts. Treatment utilization is shown in Table 1.

Table 1.

		Had Bortezomib, %			Had Carfilzomib, %			Had Lenalidomide, %			Had Pomalidomide, %			Had Thalidomide, %		
	Line number	1	2	3	1	2	3	1	2	3	1	2	3	1	2	3
All lines	ASCT	83	50	41	0	11	23	66	68	45	0	3	14	4	5	5
	No ASCT	69	56	36	0	6	23	35	49	43	0	2	9	8	6	4
Starting in 2013-2014	ASCT	72	45	36	0	16	29	61	54	33	0	5	16	0	4	7
	No ASCT	74	56	30	0	9	35	39	48	35	0	4	15	4	5	4

Summary and Conclusions: PIs and IMiDs are the most prevalent MOAs used in R/R MM in the US. Most patients receiving a single MOA in 1L go on to receive the other MOA in 2L, suggesting a perceived clinical benefit of switching MOA. Most patients have been exposed to both MOAs by 2L (67%) or 3L (83%), suggesting a possible need for treatment options with novel MOAs.

PB1881

REAL-WORLD BORTEZOMIB USAGE PATTERNS AMONG PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

G. Calkins[1], J. Kohansimeh[1], A. Krishna[2,*], R.J. Green[1], M. Curtis[1], F.P. Lindberg[1], A. Jaskiw[1], K. Larrabee[1], M. Terry[1], R.N. Feinstein[1], L. Plotkin[1], M.L. Palladino[1], L. Viana Nicacio[1]
[1]Flatiron Health, New York, [2]Novartis Pharmaceuticals, East Hanover, United States

Background: The 2012 FDA approval of subcutaneous (SC) bortezomib (BTZ) was based on non-inferior efficacy and reduced toxicity vs intravenous (IV) administration of BTZ. While differences in BTZ toxicity are attributed to route, dose, schedule, and duration, little is known about BTZ use in recent real-world practice in the US.
Aims: This study aimed to examine the real-world use of bortezomib in relapsed/refractory multiple myeloma patients in the US.
Methods: Patients (pts) with relapsed/refractory (R/R) multiple myeloma (MM) were selected from a longitudinal, nationally-representative electronic medical record (EMR) database (Flatiron Health). MM diagnoses were confirmed by physician (MD) notes. Pts were required to have disease progression following 1st line of therapy (LOT), ≥1 visit after 2010, and ≥3 months follow-up post-progression. Pt-level data were integrated from structured and unstructured EMR sources: transplant status abstracted from MD notes and IV/SC administration data merged with oral data from MD notes. We evaluated BTZ usage among these pts with R/R MM.
Results: We identified 607 pts with R/R MM; among these pts, 542 (89%) received BTZ. There were 830 LOTs containing BTZ. Initiation with SC vs IV BTZ increased over time (2011: 13% SC; 2012: 64% SC; 2013: 76% SC; 2014: 71% SC). Among BTZ initiations after 2012, 34% of those starting IV BTZ later switched to SC (7% of SC BTZ initiations later switched to IV). Across all BTZ initiations, 47% started at a schedule of >once per week (1×/wk); the rate was higher in earlier LOTs and transplant recipients (Table 1). BTZ initiations starting at 1x/wk were associated with longer duration (4.9 vs. 4.0 months, P=0.02), fewer dose reductions (26% vs. 40%, P<0.01) and similar cumulative total dose (median of 20.8 vs. 22.3 mg/m2, P=0.24) than BTZ initiations starting at >1x/wk.

Table 1.

Status	Line of Therapy	No. of Administrations in wk 1	% of Patient Starts
No transplant	1	1	45
		>1	55
	2	1	70
		>1	30
	3	1	70
		>1	30
Transplant	1	1	22
		>1	78
	2	1	56
		>1	44
	3	1	57
		>1	43

Summary and Conclusions: To our knowledge, this is the first real-world study evaluating evolving patterns of BTZ use in pts with R/R MM in the US. There was increased SC administration after 2012, longer duration of treatment among those starting at 1x/wk, and fewer dose reductions among those starting at 1x/wk; all which may be associated with toxicity management.

PB1882

RISK OF THROMBOTIC EVENTS IN PATIENTS WITH NEWLY DIAGNOSED (NDMM) AND RELAPSED REFRACTORY MULTIPLE MYELOMA (RRMM) TREATED WITH LENALIDOMIDE BASED THERAPY: A SINGLE CENTRE EXPERIENCE

J. George[1,*] A.J. Mahdi[1], H.I. Sati[1]
[1]Haematology, Singleton Hospital, ABMUHB, Swansea, United Kingdom

Background: Thrombotic events (TEs) are a known complication of lenalidomide (LEN) therapy in patients with multiple myeloma. Venous thromboprophylaxis has been recommended to reduce this risk. There is paucity of information regarding the risk of arterial TEs in this group of patients. Furthermore the difference in the risk and pattern of TEs between the NDMM and RRMM patients exposed to LEN therapy has not been assessed in clinical trials.
Aims: To compare the incidence and nature of arterial and venous TEs between NDMM and RRMM patients receiving LEN based therapy. Identification of patients at risk by correlation with thromboprophylactic measures, LEN dose, duration of treatment and additional anti-myeloma therapy.
Methods: We conducted a retrospective analysis of patients receiving LEN based therapy between September 2009 to January 2015 in Singleton Hospital, ABMUHB, UK. Patients were identified from our electronic prescribing system (ChemocareÓ) and correlated with clinical notes.
Results: A total of 81 patients were identified (NDMM: n=34; RRMM: n=47). The mean age at the start of treatment was 64.3 years (range 45-85 years) and 69.4 years (range 48-86 years) for NDMM and RRMM groups respectively. Thromboprophylactic measures were identified in 33 (97.1%) and 39 (83.0%) of NDMM and RRMM patients respectively. A total of 12 TEs were noted (NDMM: n=6, 17.6%; RRMM: n=6, 12.8%). Arterial TEs were noted in 3 patients (8.8%) of the NDMM group compared to only 1 (2.1%) patient in the RRMM group. The arterial TEs in the NDMM group were 2 TIA's and one popliteal artery thrombosis. One of the NDMM patients developed the arterial TIA whilst on LEN monotherapy in the absence of additional risk factors for arterial thrombosis. In the RRMM group, one patient who had a previous history of TIA, developed an ischaemic stroke resulting in dense hemiplegia despite dual antiplatelet therapy. There were 3 (8.8%) venous TEs (all below knee DVTs) in the NDMM group compared to 5 (10.6%) in the RRMM group (2 PEs, 2 proximal lower limb DVT and 1 distal DVT). The mean LEN dose of those having TEs was 22.5mg and 18.3mg in NDMM and RRMM groups respectively. The mean time to TEs was 3.0 months in NDMM patients and 5.8 months RRMM groups from the start of LEN therapy. All but one patient was on dexamethasone at the time of TE.
Summary and Conclusions: Our analysis confirms the thrombotic risk of LEN therapy both in NDMM and RRMM patients. There was a trend towards an increase in arterial TEs (8.8% vs 2.1%) in NDMM compared to RRMM patients. Hence LMWH in combination with anti-platelet therapy may be warranted in

NDMM patients. Larger prospective studies are required to define optimal strategies of TEs prophylaxis in patients with multiple myeloma receiving LEN therapy.

PB1883

PRESENTING FEATURES AT DIAGNOSIS OF MULTIPLE MYELOMA IN AN ISRAELI COHORT: PATIENTS YOUNGER THAN AGE 50 YEARS REPRESENT A SPECIAL GROUP WITH A HIGH FREQUENCY OF T (11; 14).

A. Duek[1,*] L. Trakhtenbrot[1], A. Avigdor[1], A. Nagler[1], M. Leiba[1]
[1]Hemato-Oncology, Sheba Medical Center, Ramat Gan, Israel

Background: Multiple myeloma is uncommon in persons younger than the age of 50. Conflicting reports have been published concerning the presenting features in this age group. The question regarding characteristics in presentation is clinically relevant since significant differences in biological features have been demonstrated in several malignancies.
Aims: We analyzed the presenting features of patients with multiple myeloma aged younger than 50 years currently treated in our center.
Methods: Patients fullfilling diagnostic criteria for multiple myeloma currently treated in our center and younger than the age of 50 were included for analysis. The following information was available: age, sex, date of birth, date of diagnosis, type, percentage of BM inflitration, FISH, serum levels of immunoglobulins free light chains, hemoglobin, creatinine, albumin,and b2 microglobulin,ISS stage, bone lytic lesions, proteinuria, and plasmocytoma
Results: Of the total of 23 patients studied, median age was 42 years (37.5-47), with 36.3% younger than 40. In accordance with previously published studies[1], the patients were more frequently male (81.8%), had favorable features such as low International Staging System (ISS) (78.6% ISS I-II) as well as relatively small frequency of adverse prognostic factors including hemoglobin <10gr/dL (33.3%), serum creatinine >2mg/dL (16.6%), albumin <3.5m/dL (44.4%), b2 microglobulin >3.5mg/dL (42.8%), and calcium >10mg/dL in only 27.7% of cases. However, most of the cases (71.42%) showed bone marrow plasma cell infiltration >30% and bone lytic lesions were present in 88.2% of cases. As usually described, the most common isotype was IgG (47.6%) while that of light chain myeloma was higher than frequently reported (40.9%). FISH analysis was available in 22 patients. Surprisingly, t (11; 14) was present in 13 cases (59.1%). This is significantly higher than the normally reported frequency of this translocation (15 to 20%) in myeloma patients[2-3] (binomial test with P<0.001, equal than 0.02, respectively). Patients carrying such abnormality were younger (mean age of 40 year vs. 46 year), had lower b2 microglobulin values (mean 3.1mg/dL vs 5.2mg/dL), lower serum FLC kappa (38.6 vs 150mg/dL), lambda (8.3 vs 47mg/dL), and FLC ratio (4.82 vs 24.75 mg/dl). Moreover, the group revealed more plasma cell infiltration (75% vs. 47.5%), higher proteinuria (2.9gr/day vs 0.19gr/day), and only 20% of these patients suffered from plasmocytomas. Patients younger than 40 did not show differences in any of parameters evaluated.
Summary and Conclusions: In summary, our cohort of young myeloma patients from a single center showed at presentation a less aggressive disease (low ISS stage, and low frequency of b2 microglobulin higher than 3.5mg/dL, hypercalcemia, anemia and renal failure), as previously suggested[1]. Interestingly, we found a higher frequency of t(11;14) by FISH analysis in this age group. The data may support the fact that t (11;14) is present at the earliest stage of plasma cell dyscrasias[4]. Further studies are needed to evaluate the different biological nature of Multiple Myeloma in this age group.

EPIDEMIOLOGIC AND CLINICAL CHARACTERISTICS OF MULTIPLE MYELOMA IN FIVE REGIONS OF RUSSIAN FEDERATION

L. Mendeleeva[1,*] M. Soloviev[1], O. Pokrovskaya[1], E. Volodicheva[2], L. Anchukova[3], S. Men'shakova[4], S. Osunihina[5], V. Voitsehovskiy[6], V. Savchenko[7]
[1]Bone Marrow Transplant Department, National Research Center for Hematology of Ministry of Healthcare Service Russian Federation, Moscow, [2]Hematology, Tula Regional Hospital, Tula, [3]Hematology, Vologda Regional Hospital, Vologda, [4]Hematology, Tver' Regional Hospital, Tver', [5]Hematology, Clinical Hospital №4 of Mordoviya Republic, Saransk, [6]Hematology, Amur regional hospital, Blagoveshensk, [7]National Research Center for Hematology of Ministry of Healthcare Service Russian Federation, Moscow, Russian Federation

Background: Multiple myeloma (MM) is an incurable hematological disease previously associated with poor prognosis and survival rates. MM accounts for 15% of all hematologic malignancies and 2% of all malignancies. In Europe it affects about 4 per 100 000 individuals each year. The total number of patients in Russian Federation is still unknown. Epidemiological cancer registries are institutions for the collection, storage, processing, analysis and interpretation of data on the incidence and prevalence of cancers within defined registration areas. The data from the cancer registries also forms an indispensable basis for further studies into the assessment of early detection measures and population-based care of tumour patients.
Aims: To define epidemiologic and clinical characteristics of MM in 5 different regions in Russian Federation.
Methods: 170 patients with multiple myeloma from 5 different regions of Russian Federation (Tul'skaya region, Vologodskaya region, Tverskaya region, Mordoviya republic and Amurskaya region) diagnosed from January 01, 2009 to January 01, 2012 were included in the study. Data regarding these patients were extracted from prospectively maintained databases and review of medical records. Follow-up information on these patients was collected prospectively and entered at the time of each visit. Response was defined according to IMWG criteria. Kaplan-Meier analysis was used for analyzing overall survival. The cut-off date for the interim analysis was January 22, 2014.
Results: Among 170 pts, there were 68 men and 102 women, aged from 42 to 86 years (median 61 year). 48,9% of pts were less than 60 years. There were 55% pts with myeloma G, 19% with myeloma A, 13% with light-chain myeloma, 1% with myeloma D, 3% with myeloma M, 2% with non-secretory myeloma, 5% pts with diclonaly myeloma and in 2% of pts the type of MM was not defined. 85 (50%) pts were in stage III, 77 (45%) pts were in stage II and only 8 (5%) of pts in stage I. At the time of diagnosis 36 (21%) pts had signs of renal failure (serum creatinine more 177 mmol/l). Information about treatment and treatment responses was available in 153 cases. 97% of pts proceeded induction therapy: 84% pts – bortezomib-containing treatment, 13%-conventional therapy and 3% refused of treatment. High-dose therapy with autologous stem cell transplantation was performed only in 14 cases due to remoteness from transplant centers. Overall response was achieved in 68% of pts, among them complete remission – in 26%. Absolute 5-year overall survival rate in our group was 37%±6,3% (median 41,7 months). No difference was seen in overall survival between men and women. There was a trend of increase of 3-year overall survival in pts diagnosed in 2011 in compare with pts diagnosed in 2009 (65,5% vs 46,4%). 71of 170 pts are still alive. The main reasons of deaths were disease progression (70%), concomitant illnesses (21%) and inflectional complications (5%).
Summary and Conclusions: Our study showed that the median of age of pts with newly diagnosed MM in Russian Federation is 10 years less than in Europe and USA. Absolute 5-year overall survival rate in our pts is 37% that is comparable with MM pts in Germany (39%).

PB1886

BENDAMUSTINE IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A REGIONAL REAL-LIFE EXPERIENCE

C. Cerchione[1,*] L. Catalano[1], A.E. Pareto[1], S. Basile[1], L. Marano[1], I. Peluso[1], L. Simeone[1], O. Vitagliano[1], S. Palmieri[2], S. Rocco[2], F. Ferrara[2], F. Pane[1]
[1]Hematology, AOU "Federico II", [2]Hematology, AORN "A.Cardarelli", Napoli, Italy

Background: Bendamustine is a bifunctional alkylating agent, with low toxicity, that produces both single- and double-strand breaks in DNA, and shows incomplete cross resistance with other alkylating drugs, proved to be effective either in relapsed or refractory and in new diagnosed MM as single agent or combined with steroid and has also additive/synergistic activity with bortezomib.
Aims: Here we evaluate the efficacy and tolerance of bendamustine in combination with bortezomib-dexamethasone in patients with relapsed and refractory multiple myeloma, whose prognosis is severe, so that there is a strong need for new options for the management of these patients. A retrospective analysis of patients with relapsed and refractory MM, who had received bendamustine as salvage therapy, has been performed.
Methods: 39 patients, 21 males, 18 females, with advanced multiple myeloma, treated with several lines of treatments, and refractory to all the lines previously performed, received a schedule Bendamustine-based. Median age at diagnosis was 57 years (r.36-82) while age at start of treatment was 62 years (r.37-83), and median number of prior lines of treatment was 6 (r.2-11). ISS was equally distributed, and cytogenetic characteristics were evaluable in 9 patients, only two of whom had cytogenetic abnormalities, and in particular one of them had del13q and in the other one was observed t(11;14). All the patients had previously been treated with schedule containing bortezomib and lenalidomide, while 90% of them had been treated with melphalan, 77% with cyclophosphamide and 34% with anthracyclines, and 30% had also received radiotherapy. 58% of patients had undergone at least to a single autologous stem cell transplantation. Last treatment before bendamustine was a bortezomib-based regimen in 39%, an IMIDs- based regimen in 49% (a combined bortezomib/IMIDs-based regimen in 27%), while 12% of patients had received other chemotherapies. All patients were relapsed and refractory to last therapies received.

Results: Only patients completing at least two courses of Bendamustine were considered for analysis. A total of 128 cycles was administered (median 3, range 2-9). Bendamustine was variously associated to bortezomib (66%), or IMIDs (25%) and only in 9% it was combined only with dexametasone. In our schedule, Bendamustine was given, at a median dose of 90 mg/sqm (range total dose : 120-180) on day +1 and +2 every 28 days. Median OS from diagnosis was 56.5 months (range 6-145), while median OS from start of Bendamustine was 6.5 months (range 2-30). 16/39 patients went in progressive disease during treatment, 2/39 patients died for other causes (one for cardiovascular disease and the other one had a gastric cancer). Grade 3 transfusion-dependent anemia occurred in 31% while in 46% grade 3 neutropenia occurred. No severe extrahematologic toxicity was observed, only grade 1 gastrointestinal side effect (nausea), treated by common antiemetic drugs. According to IMWG response criteria, after a median follow up of 6 months (r.2-30), 1 patient achieved a complete response, 1 patient achieved a VGPR and 21 out of 39 evaluable patients achieved a partial response after a median time of 2 months with an overall response rate of 59% and 12 patient were considered in stable disease, which can be considered an impressive result in this subset of patients. In particular, for 4 patients of this study, Bendamustine treatment was, after having achieved a PR, a bridge to second autologous stem cell transplantation, and for one patient a bridge to allogenic stem cell transplantation.
Summary and Conclusions: In conclusion, Bendamustine has shown significant efficacy in a particularly severe setting of patients, relapsed and refractory to almost all available therapeutic resources, and in particular cases it could be considered as a bridge to a second autologous or to allogeneic BMT.

PB1887

ROLE OF HEAVY/LIGHT CHAIN ASSAY, ALONE AND IN COMBINATION WITH FREE LIGHT CHAIN ASSAY AND MINIMAL RESIDUAL DISEASE, IN MYELOMA PATIENTS WHO ACHIEVE COMPLETE RESPONSE AFTER FIRST LINE TREATMENTS

F. D'Auria[1], T. Statuto[1], F. Larocca[2], V. Simeon[2], R. Guariglia[3], G. Pietrantuono[3], O. Villani[3], G. Mansueto[3], T. Izzo[3], C. Criscuolo[3], G. D'Arena[3], P. Musto[4,*]
[1]Laboratory of Clinical Research and Advanced Diagnostics, [2]Laboratory of Pre-Clinical and Translational Research, [3]Unit of Hematology and Stem Cell Transplantation, [4]Scientific Direction, IRCCS, Referral Cancer Center of Basilicata, Rionero In Vulture (Pz), Italy

Background: The International Myeloma Working Group (IMWG) guidelines recommend the use of protein electrophoresis, serum/urine immunofixation and free light chain (FLC) assay for assessing response to treatment in multiple myeloma (MM). In this setting, flow cytometry (FC) is emerging as a useful, though difficult to standardize, additional tool to detect minimal residual disease (MRD). Furthermore, the novel heavy/light chain (HLC) assay has recently become available to improve quantification of IgG and IgA MM isotypes.
Aims: To evaluate the effect of HLC ratio, FLC ratio and MRD on clinical outcome of MM patients achieving immunofixation negative complete response (CR) after first line therapy, according to IMWG criteria.
Methods: We followed a prospective cohort of 25 patients with MM (14 males, 11 females; median age 63.2, range 43-82; 14 IgG and 11 IgA) who had achieved CR after initial treatments including novel agents, with (n. 11) or without (n. 14) autologous stem cell transplantation (AuSCT). CR was identified after 6 induction cycles in patients not eligible for AuSCT and after AuSCT in those undergoing such a procedure. Sera samples were tested for HLC and FLC ratios by commercially available immunonephelometry kits, while bone marrow samples were analyzed by multiparametric FC for assessing MRD, using a home-made method based on a combination of CD138, CD38, CD56, CD19, CD45, CD20, and CD117 monoclonal antibodies. MRD was defined negative if< 10 neoplastic plasma cells were detected in a 100.000-event file. The Kaplan-Meier method was used to plot and calculate progression free survival (PFS) and overall survival (OS). Variables were analysed by log-rank test and p-value<0.05 was considered statistically significant.
Results: At CR detection time, 18 patients showed normal HLC ratio, 11 had normal FLC ratio (thus they were in "stringent" CR), and 13 had negative MRD. After a median follow-up of 42 months, 12 patients remain in CR and 13 have relapsed, 11 of whom are deceased. Overall, though neither HLC or FLC assays, nor MRD evaluation, alone or in different combinations, showed a statistically significant influence on the clinical outcome, a trend toward a better PFS (81% vs 50%) was observed in patients with sCR, particularly in those with IgA subtype (100% vs 35%), where normal HLC also identified a subgroup with more favorable outcome (PFS 67% vs 41%). Interestingly, PFS was lower in patients with both abnormal HLC and FLC ratios than in those with only abnormal FLC (40% vs 55%, respectively).
Summary and Conclusions: Our preliminary and still numerically limited experience suggests that HLC might have a prognostic role in patients with IgA MM in CR and might enhance the negative effect of abnormal FLC on PFS estimate. A larger number of patients and an extended follow-up are required for achieving more robust data.

PB1888

IMPACT OF INITIAL CHEMOTHERAPY RESPONSE AND PRETRANSPLANT DISEASE STATUS BEFORE AUTOLOGOUS TRANSPLANTATION ON SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA

F. Yalniz[1,*] T. Elverdi[1], E. Celik[1], S. Berk[1], I. Erdogan[1], A. Salihoglu[1], A.E. Eskazan[1], C. Ar[1], S. Aydin[1], Z. Baslar[1], Y. Aydin[1], T. Soysal[1]
[1]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: High dose chemotherapy with autologous stem cell transplantation (ASCT) has been considered the standard of care for multiple myeloma patients and has been shown to increase both overall survival (OS) and progression free survival (PFS). However, the significance of initial treatment response and the significance of pretransplant disease status are not clear whether the depth of response influences the OS or PFS.
Aims: In this retrospective study we aimed to evaluate the significance of initial chemotherapy response and pretransplant disease status on PFS and OS.
Methods: We identified 127 myeloma patients who underwent ASCT between 1997- 2014 at Istanbul University Cerrahpasa Medical Faculty. Five of them were excluded from the study due to missing first line response data. Remaining 122 were grouped according to the first line chemotherapy responses, as suboptimal and optimal. Standard International Myeloma Working Group criteria were used for classifying disease responses and defining progression of multiple myeloma. Suboptimal response to first line pretransplant therapy was defined as a failure to achieve at least a VGPR following the first line chemotherapy. Demographic variables and disease related variables were given in Table 1. PFS and OS of patients in the 2 study cohorts were compared using Logrank test (Table 3)
Results: 127 patients treated with high dose chemotherapy and ASCT between 1997-2014 were included in the study. Median follow up time is 56 months. Of these patients, 56% (n:68) failed to achieve an optimal response following the first line chemotherapy. Most of these patients received second line chemotherapy before proceeding to ASCT. Subsequent to additional chemotherapy, 37% (n:46) underwent ASCT. The overall survival of patients responded as CR or VGPR is 53 months.

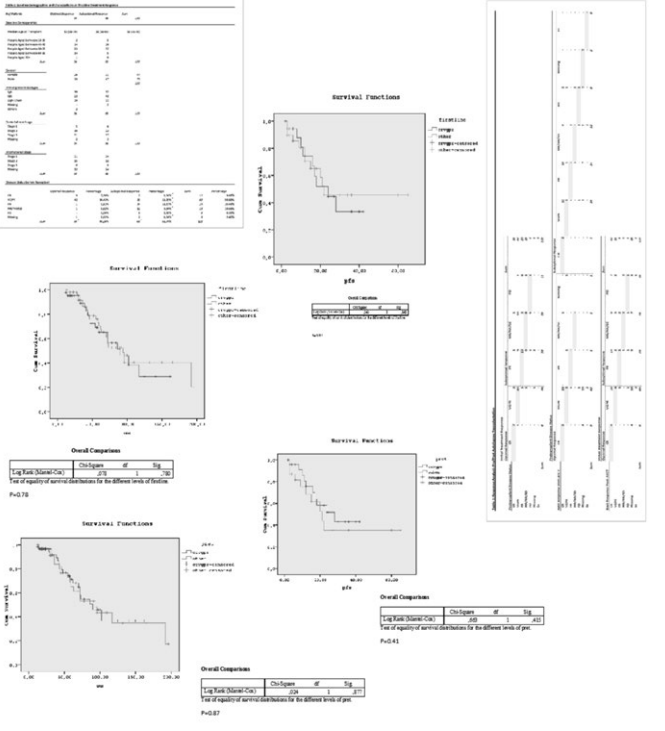

Figure 1.

Summary and Conclusions: In conclusion, for patients achieving less than a VGPR response following initial chemotherapy, additional chemotherapy improved depth of response, but was not associated with survival benefit. Furthermore we found no impact of initial treatment response on PFS and OS. This might be explained by the increased efficacy of new agents.

PB1889

NEUTROPHIL TO LYMPHOCYTE RATIO (NLR) IMPROVES THE RISK ASSESSMENT OF ISS STAGING IN NEWLY DIAGNOSED MM PATIENTS TREATED UPFRONT WITH NOVEL AGENTS

A. Romano[1,*] N. L. Parrinello[1], M. L. Consoli[1], S. Forte[1], C. Conticello[1],

A. Corso [2]A. Pompa [2]K. Noonan[3], I. Borrello[3], F. Di Raimondo[1],
[1]Division of Hematology, Azienda Policlinico-OVE, Catania, [2]Divisione di Ematologia, IRCCS FOndazione San Matteo, Pavia, Italy, [3]Department of Oncology, Johns Hopkins University, Baltimore, United States

Background: Recent reports identify the ratio between absolute neutrophils count (ANC) and absolute lymphocyte count (ALC), called NLR,as predictor of progression free survival (PFS) and overall survival (OS) in cancer patients.
Aims: We retrospectively tested NLR in a cohort of 309 newly diagnosed MM patients treated upfront with novel agents.
Methods: NLR was calculated using data obtained from the complete blood count (CBC). PFS and OS were evaluated.
Results: Median NLR was 1.9 (range 0.4-15.9). Higher NLR was not due to ISS stage, plasma cell infiltration or cytogenetics. The 5-year PFS and OS estimates were, respectively, 18.2% and 36.4% for patients with NLR ≥ 2 *versus* 25.5% and 66.6% in patients with NLR<2. NLR ≥ 2 reduced PFS for ISS stage I and OS significantly for stages I and III, but not stage II. Among younger patients (age<65 years, N=179), NLR ≥ 2 had a negative prognostic impact on both PFS and OS, in all ISS stages. By combining ISS stage and NLR in a model limited to young patients, we found that 19% of the patients were classified as very-low risk group, and 70% and 11% were in standard-risk and very-high risk groups, respectively. The 5-year estimates were 39.3%, 19.4% and 10.9% for PFS and 95.8%, 50.9% and 23.6% for OS for low, standard and high risk groups, respectively.
Summary and Conclusions: We found NLR as predictor of PFS and OS in MM patients treated upfront with novel agents. NLR can be combined with ISS staging system allowing a better identification of patients with dismal outcome.

PB1890

MULTIPLE MYELOMA IN ELDERLY AFRO-CARIBBEAN PATIENTS TREATED WITH MEPHALAN PREDNISONE AND THALIDOMIDE IN MARTINIQUE;A RETROSPECTIVE STUDY

A. Lok[1,*] J.C. Meniane[2], V. Vinh Hung[3], J. Baudin[4], C. Joachim[4], J. Macni[4], P. Escarmant[3], L. Majoubi[5], M. Razakanaivo[6], A. Brebion[2], P. Moreau[1]
[1]Hematology, CHU Nantes, Nantes, France, [2]Hematology, [3]Oncology, [4]AMREC, CHU Martinique, Fort de France, Martinique, [5]CHU Villejuif, Villejuif, France, [6]CHU Martinique, Fort de France, Martinique

Background: In African-Americans (AA), the incidence of multiple myeloma (MM) is twice as high as in Caucasians. Only few studies have focused on overall survival. A recent population-based study comparing white and AA subjects showed a better survival in AA patients over a entire study period ranging from 1973 to 2005. However, significant survival improvement after the current era of intensive treatment or new therapies was only seen among whites, with smaller, non-significant change seen among blacks.This study hypothesized that the disparities in improvement in outcome observed could be related to a lower response to new therapies in AA patients. In Martinique, a French overseas department, the vast majority of the population is of Afro-Caribbean origin.
Aims: Our aim was to assess the characteristics, progression-free (PFS) and overall survival (OS) of this ethnicity subgroup.
Methods: We conducted a retrospective study on transplant-ineligible patient, newly diagnosed with MM who were treated in the Hematology Department of Fort de France in Martinique between 2007 and 2012.

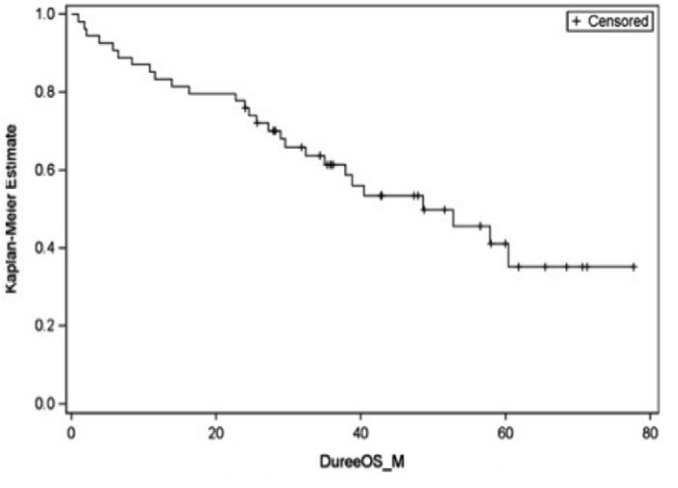

Figure 1.

Results: During this period, the Martinique Association for Epidemiological Research on Cancer revealed an incidence of 8/100,000 inhabitants per year. Fifty four patients were not eligible for autologous stem cell transplantation and had been treated with melphalan, prednisone and thalidomide as part of frontline therapy.The patients had a median age of 80 years, with ISS stage III documented in 48%. The overall response rate was 76%. With a median follow up of 35 months, PFS and OS were 28.9 months and 48.6 months.
Summary and Conclusions: Compared to metropolitan France, our results show a higher incidence and a similar outcome in this population, despite an advanced age and disease status at diagnosis. No data have been published focusing only on the outcome of AA or African-Caribbean elderly patients treated with combination therapies that include novel agents. Our study highlights findings which had so far not been described and do not support the hypothesis that AA patients had a lower response to new therapies.

PB1891

WALDENSTROM'S MACROGLOBULINEMIA EXPRESS B-CELL MATURATION ANTIGEN AND SERUM LEVELS CORRELATE WITH DISEASE STATUS AND CONVENTIONAL M-PROTEIN AND IGM LEVELS

J. Berenson[1,*] S. Vardanyan[1], E. Sanchez[1], M. Li[1], C. Wang[1], A. Gillespie[1], M. Spitzer[1], A. Shvartsur[1], N. Harutyunyan[1], G. Garzio[1], G. Tang[1], J. Said[2], H. Chen[1]
[1]Institute for Myeloma & Bone Cancer Research, West Hollywood, [2]Pathology and Laboratory Medicine, Geffen School of Medicine at the University of California at Los Angeles, Los Angeles, United States

Background: Waldenström's macroglobulinemia (WM) is an incurable B-cell lymphoplasmacytic lymphoma. B-cell maturation antigen (BCMA) is expressed on malignant B cells and we have previously shown that serum BCMA levels are elevated in multiple myeloma (MM) patients and correlate with disease status in multiple myeloma (MM) patients.
Aims: Our objective was to determine whether BCMA is present in WM; and, furthermore, whether its serum levels also correlate with disease status and track with conventional tumor markers for patients with WM.
Methods: Data was obtained on 20 WM patients who received treatment in a single clinic specializing in monoclonal gammopathies. Mann-Whitney analysis was used to measure statistical significance (P<0.05). Immunohistochemical staining and flow cytometric analysis was used to determine the expression of BCMA on WM cells.
Results: First, we found that BCMA is highly expressed on the surface of tumor cells from the bone marrow of WM patients using both immunohistochemical and flow cytometric analysis. Next, we compared serum BCMA levels from untreated WM patients (n=9) to healthy individuals (n=14), and the levels were markedly higher in WM patients (P<0.0001). Next, BCMA levels in WM patient sera were also correlated with disease status at the time during which the sample was collected. Serum from patients achieving ≥partial response (n=7) showed significantly lower levels of BCMA than samples from patients with stable disease (n=4) or progressive disease (n=7; P=0.003 and P=0.0003, respectively). Additionally, the BCMA levels of seven WM patients were correlated with the serum M-protein and IgM levels of these patients during the course of their therapy. Changes in serum BCMA levels correlated with changes in serum M-protein as well as IgM levels.
Summary and Conclusions: These results indicate that BCMA is present on the malignant cells from WM patients and serum levels of this protein can be used as a potential marker for tracking the course of their disease.

PB1892

EXTRA MEDULLARY RELAPSE AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION FOR MULTIPLE MYELOMA (MM)

L. Torjemane[1,*] M. Chelli[2], N. Abdejlil[1], I. Safra[3], H. Kaabi[4], A. Lakhal[5], R. El Fatmi[1], S. Ladeb[1], H. Slama[4], T. Ben Othman[1]
[1]Hematology, Centre National de Greffe de Moelle Osseuse de Tunis, Bab Saadoun, [2]Radiology, Institut Kassab de Tunis, [3]Hematology, Institut Pasteur de Tunis, Tunis, [4]Immunology, [5]Hematology, Centre National de Transfusion Sanguine de Tunisie, Bab Saadoun, Tunisia

Background: The role of allogeneic stem-cell transplantation (allo-SCT) in treatment of myeloma patients is still controversial. Allo-SCT consolidates treatment by virtue of its graft-*versus*-myeloma (GvM) effect and results in a higher rate of molecular remission and lower risk of relapse. However, in our experience we observed extra-medullary relapse (EMR) which can be reversed by new post-transplantation strategies.
Aims: The goal of our study is to evaluate the frequency, aspects and the prognosis of EMR after a tandem auto-allogeneic bone marrow transplantation (allo-BMT) for MM.
Methods: Our study is retrospective about 25 patients with MM who underwent allo-BMT between February 1998 and December 2013 in the "Centre National de Greffe de Moelle Osseuse de Tunis". The median age at transplant were 42 years (range; 31-49). Conditioning regimen were oral or IV Bu 14-Cy (n=23), Fludarabine-TBI (n=2). All patients received cyclosporine with methotrexate as graft-*versus*-host disease (GVHD) prophylaxis; one patient received in addition mycophenolate mofetil. Responses were assessed using the IMWG criteria. EM relapse was defined as the presence of plasmocytoma evidenced by medical imaging techniques and secreting the same monoclonal component while the myelogram is normal and hematopoiesis was of donor type.

Results: After allogeneic –BMT, eight patients (32%) are alive after a median follow up of 36 months (range 2- 168 months). Nine patients (36%) died from toxicity mainly related to GVHD and its complications. Eleven patients (44%) relapsed (n=9) or progressed (n=2) after ABMT. In eight patients (8/11; 72%), relapse was extra medullary with histological confirmation in 2 patients. Component monoclonal was IgG lambda (n=4), IgA lambda or kappa (n=2), IgG kappa (n=1) and light chains lambda (n=1). The median time between allogeneic- BMT and EM relapse was 29 months (range 3-132 months). The status of the disease before allograft was CR (n=4), PR (n=4). Six patients had a tumor mass adjacent to bone, 2 patients have soft tissue involvement or multiple organs involvement (pancreas, kidney and abdomen). There were no evidences of medullary involvement at the time of relapse. Molecular and cytogenetic chimerism was performed in 5 patients and they were of donor type. Seven patients were treated by chemotherapy (bortezomib or lenalidomid; n=4) and / or radiotherapy (n=6). Three patients from them (3/8; 37.5%) are alive after a median follow-up of 156 months (range; 132-168) with partial (n=1) or complete remission (n=2).
Summary and Conclusions: After allogeneic BMT, patients are at risk of TRM and extra medullary relapse. The effect GvM seems to be limited to the bone marrow. New treatments options (lenalidomide/bortezomib) in combination with radiotherapy seems controlling the disease.

PB1893

CLINICAL PROGNOSTIC FACTORS OF LONG TERM SURVIVAL IN MULTIPLE MYELOMA

A. Tsakiridou[1,*] P. Lampropoulou[1], A. Anastasiadis[1], G. Papageorgiou[1], D. Stoumbos[1], I. Patsias[1], C. Gekas[1], M. Kotsopoulou[1], P. Repousis[1], A. Megalakaki[1],
[1]Clinical Heamatology, Anticancer METAXA Hospital, PEIRAUS, Greece

Background: Multiple myeloma prognosis may correlate with the patient's clinical characteristics as well as biologic variables of the malignant clone.
In the mid 90's with the systematic use of high dose melphalan and ASCT the average survival rate was 3-4years,while after 2007 with the indroduction of immunomodulatory agents and proteasome inhibitors, life expectancy exceeded the limit of 7-8 years.At the same time the impact of the molecular features of the malignant cell in prognosis was strongly validated and acknowledged.
Aims: In this cohort we present patients diagnosed with multiple myeloma before 2006, who remain alive at least eight years after the initial diagnosis.The purpose of the study was to identify common clinical characteristics of favorable prognosis among long term survivors independently of cytogenetic or molecular abberations.
Methods: The present study included 26 patients(19males,7 females) diagnosed with multiple myeloma between 2000-2005 in our institution.The median age at the time of diagnosis was 57(44-75)yrs.Among the cases reported 10 were IgGk, 4 IgGλ,3IgAk, 3IgAλ,3 light chain(λ), 2 non secretory and one had tripple M-component(IgGk/IgAk/IgDk). The majority of patients (25/26) were eligible of treatment initiation according to the current criteria (presenting with CRAB).23 patiens were diagnosed with bone disease,14 had anemia,11 presented with renal insufficiency and 3 with hypercalcemia.In 6/26 patients MGUS preceeded the diagnosis for more than 12 months. At staging by Salmon Durie 15/26 were at stage III,6 at stage II,5 at stage I,while according to ISS 6/26 were at stage III.Classical cytogenetic analysis was performed in bone marrow speciments for 20/26 patients and all had a normal karyotype. 23/26 received VAD or VAD-Caelyx regiments.Two received melphalan -steroids combination and one bortezomib-steroids.Palliative radiotherapy was applied to all patients having bone disease (23/26).19/26 received high dose melphalan and autologous transplant while 5 of them were submitted to a second transplantation (tandem) and 15 reached complete remission after transplantation.22/26 followed a maintenance schedule with thalidomide.
Results: 15 out of 26 patients remain in complete remission 9-15 years after diagnosis,while 3 are alive with relapsed or progressive disease.8 patients died >8-14 years after diagnosis(7 died from disease complications and one from an irrelevant cause).Although no statistical analysis can be performed in this sample,two different subgroups are revealed:the first subgroup consists of 15 patients of younger age (median 54),no comorbidities,with bone disease as the main clinical feature,who were treated with high dose melphalan and ASCT and achieved CR according to the contemporary response criteria.The latter subgroup included 9 patients of older age with previous MGUS diagnosis (mostly IgGk),whose survival exceeded the average life expectancy.
Summary and Conclusions: A clinical profile of younger age,lower ISS, prolonged PFS is compatible with long term survival. ISS appears to have higher prognostic value than Salmon Durie.Even in the era of novel treatment agents clinical characteristics of the patient may indicate survival benefits although the use of cytogenetic or molecular analysis when available has become mandatory.

PB1894

THE ROLE OF THE UPTAKE PATTERN OF 18F-FDG PET/CT AND 99MTC-MIBI IN THE DIAGNOSTIC EVALUATION OF PATIENTS WITH MULTIPLE MYELOMA

I.G.H.L. Metze[1,*] R.J. Ferrari[2], G.B. Duarte[3], C. Mosci[2], C.D. Ramos[2]
[1]Internal Medicine, [2]Radiology, [3]Hematology/Hemotherapy Center, University of Campinas, Campinas, Brazil

Background: for staging of myeloma it is important not only to measure the total tumor mass but also to localize the lesions in order to treat special localizations
Aims: to compare the image patterns of ^{18}F-FDG positron emission computed tomography/ computed tomography (PET/CT) with those of ^{99m}Tc-MIBI single photon emission tomography/CT (SPECT/CT) at diagnosis in plasma cell neoplasms (MM) and evaluate the relation of this pattern with risk factors, therapy response and patients' progression-free survival (PFS).
Methods: Eighteen newly diagnosed MM patients were enrolled. PET/CT and SPECT/CT were included in the diagnostic work-up, reporting focal lesions and diffuse bone marrow involvement. One patient had a solitary plasmacytoma and was not evaluated for response. Patients gave informed consent.
Results: Eleven patients (61%) were male. Median age: 57 years (37-84); albumin 3.4 g/dL (2.16-4.2), beta-2-microglobulin: 4.2 mg/L (0.4-29.4), calcium 9.8 mg/dL (7.8-15), serum creatinine 0.85 mg/dL (0.6-2.4). No patient was on dialysis. According to ISS, 2 patients were stage I; 6 were stage II, and 10 were stage III. One case fulfilled criteria for plasma cell leukemia and 1 had a solitary plasmocytoma. Patients received CTD (12 patients); MPT (3 patients); CVD and Dexa-Tal (one case each). PET/CT and SPECT/CT, were concordant for presence (11) or absence (4) of a diffuse pattern. In the last ones, two showed positive foci in PET/CT. PET was able to detect >84 (extramedullary in six cases) while SPECT/CT detected only 10 focal lesions (extramedullary in one case). Intensity of ^{99m}Tc-MIBI uptake as well as the number of foci seen in PET/CT had an inverse correlation with hemoglobin values but not with ISS. A very good partial remission was seen in 5 patients and 2 had a complete remission. After a median follow-up of 12 months (1-19), 4 patients had progressed and 3 patients (17.6%) died during the follow-up. The 12 month progression free survival for diffuse pattern of PET/CT and SPECT/CT was not statistically different, although none of the patients with a negative SPECT/CT had progressed.
Summary and Conclusions: in this preliminary study, ^{18}F-FDG PET/CT detected more focal lesions (including extramedullary lesions) and ^{99m}Tc-MIBI was able to measure the intensity of diffuse BM involvement. Both techniques should be used together, especially in clinical studies, as they give complementary information. Concerning therapy response, the time of observation is rather short, and no relation with PFS and OS was found yet.

PB1895

BENDAMUSTINE-BASED THERAPY RELAPSE/REFRACTORY MULTIPLE MYELOMA PATIENTS: FIRST IMPRESSIONS IN RUSSIA

S. Voloshin[1], S. Bessmeltsev[1], T. Zagoskina[2], A. Garifullin[1,*] N. Kotova[3], E. Kariagina[4], K. Kaplanov[5], N. Medvedeva[3], A. Kuvshinov[1], L. Stelmashenko[1], K. Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, [2]2Kirov's Institute of Hematology and Transfusiology, Kirov, [3]3City Hospital Number 31, [4]4City Hospital Number 15, Saint-Petersburg, [5]5Volgograd Regional Clinical Oncology Dispensary Number 1, Volgograd, Russian Federation

Background: Relapsed and refractory (R/R) multiple myeloma (MM) constitutes a specific and unmet medical need. Median survival ranges from as little as 6 to 9 months, and responses to treatment are characteristically short. In patients with R/R MM after therapy of bortezomib and/or immunomodulators (IMiDs) a bendamustine-based treatment can be used as "salvage".
Aims: Examine efficiency of bendamustine-based chemotherapy in R/R MM patients.

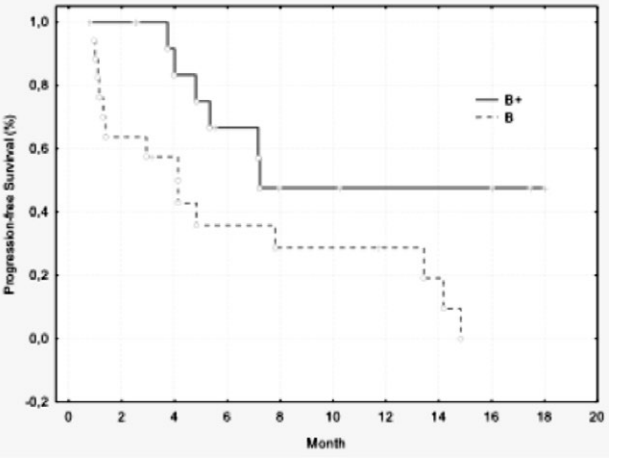

Figure 1.

Methods: In this retrospective analysis we have identified 32 patients with R/R MM by means of case research, who have been bendamustine-based treated at Hematological Clinics of Russian Federation since 2011. Median age was 67 years, the female/male ratio was 2.5:1. After in median 2 lines of prior therapy (range: 1-7) patients received in median 3 (range: 1-9) cycles of bendamustine-based therapy. Bendamustine dosage was 70-120 mg/m^2/day on days 1 and 2 of a each 28-day cycle until progressive disease or intolerability. Bendamustine was administered as monotherapy in 12% of patients, whereas 88% received concomitant steroids (group Bendamustine (B), n=17). Bendamustine with dexamethasone and bortezomib or IMiDs (BBD, BRD, BTD) was evaluated in 15 patients with R/R MM (group Bendamustine-plus (B+)). Primary end point was overall response rate (ORR). Secondary end points were time to progression (TTP), overall survival (OS), and toxicity.
Results: ORR in both group was 59.2%: 22.2% partial response (6.7% in group B vs. 41.7% in group B+, p<0.05), stable disease 37.0% (26.7% vs. 50.0%, accordingly, p>0.05). Median TTP was 9.7 months (4.1 mo in group B vs. 7.2 mo in group B+, p=0.02)) (pic). Median OS was 25.4 months in group B, but in group B+ median OS is not reached. Hematologic toxicity was in 25.0% of patients: grade 3/4 anemia was noted in 9.4%, grade 3/4 thrombocytopenia was noted in 6.3%, and grade 3/4 infections were noted in 21.9%.
Summary and Conclusions: Bendamustine-based therapy is active and well tolerated in patients with relapsed/refractory multiple myeloma.

PB1896

THE IMPORTANCE OF IMMUNOPHENOTYPIC COMPLETE REMISSION AFTER INDUCTION THERAPY IN PATIENTS WITH MULTIPLE MYELOMA ON PROGRESSION/RELAPSE FREE SURVIVAL

T. Zabranska[1,*] A. Jungova[1], P. Jindra[1]
[1]Department of Hematology and Oncology, Charles University Hospital in Pilsen, Pilsen, Czech Republic

Background: Multiple myeloma (MM) is a malignant, essentially incurable desease caused by malignant transformation of B-lymphocytes. Depth of achieved remission appears to correlate with the duration of desease control. Therefore there are cumulative data supporting the importance of the molecularly or imunophenotypically defined remission (absence of minimal residual disease-MRD). MRD in bone marrow may be detected by flow cytometry (with a threshold sensitivity at a level of 1x10-4). Immunophenotypic complete remission (iCR) is defined by fulfilling requirements of conventional CR along with negative test of free light chains in serum and absence of myeloma cells in the bone marrow by examination of at least 10□ cells using >4-color flow cytometry.
Aims: To verify the importance of iCR after induction therapy in patients with MM on progression/relapse free survival (PFS).
Methods: Retrospective analysis of 25 patients with MM consecutively diagnosed in 2010-2013, who achieved conventional CR after induction therapy and were examined by flow cytometry to evaluate eventual presence of MRD in bone marrow (according to EMN – European myeloma network).
Results: Our cohort of patients comprised 14 men and 11 women, the mean age was 60 years. Patients were treated with induction chemotherapy containing thalidomide in 12/25 (48%) and bortezomib in 13/25 (52%) and all patients subsequently received highdose chemoterapy (HD-Melphalan 200 mg/m2) supported by autologous stem-cell transplantation. A total of 8 patients (32%) in conventional CR after induction therapy achieved also iCR (the MRD-ve), while 17 patients (68%) had still by flow cytometry detectable MRD in bone marrow at a level of 1x10 to 1x10-2-4 (MRD +ve). Immunofenotypic data after autologous transplantation are not available. Between the two groups was no statistical difference in sex (P=0.34), cytogenetic risk group (P=0.63), or type of induction chemotherapy (P=0.73). The median PFS for MRD+ve was 23 months (12-48) and for MRD-ve 35 months (15-57), however difference in the median PFS between the two groups was not statistically significant (P=0.73).
Summary and Conclusions: Our data indicated a trend towards a longer PFS for patients MRD-ve, however absence of statistical signification may be caused by the relatively low number of patients and eventually by the efect of subsequent HD-chemotherapy. The study with longer follow-up of more patients with flow cytometry-monitoring in all stages of treatment (also after HD-Melphalan) is thus waranted.

PB1897

RAPID EFFICACY OF LENALIDOMIDE PLUS DEXAMETHASONE FOR POEMS SYNDROME: ASSESSMENT OF FOUR PATIENT'S CLINICAL OUTCOME

S. Kalayoglu-Besisik[1,*] M. Ayer[2], E. Osmanbaşoglu[3], E.S. Torun[1], O. Arslan[1], O. Dogan[4]
[1]Internal Medicine, Hematology, Istanbul University, Istanbul Medical Faculty, [2]Internal Medicine, Hematology, Istanbul Haseki education and research hospital, [3]Internal Medicine, Hematology, Bakırkoy Sadi Konuk education and research hospital, [4]Pathology, Istanbul University, Istanbul Medical Faculty, Istanbul, Turkey

Background: The POEMS syndrome (coined to refer to polyneuropathy; PNP), organomegaly, endocrinopathy, M protein, and skin changes) is a rare disorder and characterized by elevated vascular endothelial growth factor (VEGF) levels. The treatment for POEMS syndrome is mostly derived from regimens that have shown efficacy in other plasma cell dyscrasia, such as lenalidomide which reduces proinflammaotory and proangiogenic cytokines.
Aims: We report the efficay of a combination of lenalidomide and dexamethasone (Ld) in four patients with POEMS syndrome.
Methods: Four patients (M : F, 3 : 1)(age ranf-ge: 37-56 years) had been diagnosed as having POEMS syndrome. Serum VEGF level elevation could be documented only in one patient. The common main complain were fatique and weight loss which defined the reason that Internal Medicine speciaist were the first physicians. Two of the patients had severe PNP which inhibits normal daily activity and led to need assistance for walking. Two patients had severe extravascular volume overload as pleural effusion and ascite. As endocrinopathy, all of them had hypogonatorophic hypogonadism and hypocortisolemia among hypothyroidism and mild diabetes. Hyperpotasemia, mild increased serum creatinine level and hyponatremia were noted as biochemical changes. Only two patients had hyperpigmentation and acanthosis nigrigans. Treatment was started with lenalidomide (25mg, days 1-21) and dexamethasone (40mg weekly) following approvement for reimbursement. All patients received venous thrombosis prophylaxis.
Results: Massive ascite and also pleural effusion dramaticaly diminished and disappeared with the time. All of the patients put on weight and biochemistry was normalized. With intensive physical and occupational therapy, there was also steady improvement of the pateint's motor function. Two patients were agree to collect autologous peripheral blood stem cell harvesting but decide for delayed transplantation. One patient had needed radiotherapy for the pain related with bone lesions. The patient's serum free light chain ratio became normalized but M-protein was still detectable with immunfixatipn.
Summary and Conclusions: Our experience suggest that Ld therapy is not only realtively safe but also a promising option for POEMS syndrome.

PB1898

CASE REPORT: CEREBRAL LIGHT CHAIN DEPOSITION DISEASE (LCDD)

F.I. Ibañez Camacho[1,2,*] V. Cabanas-Perianes[1], J. Monserrat Coll[1,3], A. Rábano Gutiérrez[4], B. Cuartero-Perez[5], J. Ros De Sampedro[6], A. Sanchez Salinas[2], M. Blanquer Blanquer[2], M. Berenguer[2], J.M. Moraleda Jimenez[2,7]
[1]Hospital Universitario Virgen de la Arrixaca, Murcia, [2]Hematology, Hospital Universitario Virgen de la Arrixaca, [3]Hospital Virgen Arrixaca, Murcia, Murcia, [4]12Departamento de Neuropatología y Banco de Tejidos, Fundación Cien, Instituto de Salud Carlos III, Madrid, [5]Neurosurgery, Hospital Universitario Vigen de la Arrixaca, [6]Neurosurgey, Hospital Universitario Virgen de la Arrixaca, [7]Catedrático Facultad de Medicina, Universidad de Murcia, Murcia, Spain

Background: Light chain deposition disease (LCDD) is a rare monoclonal gammopathy characterized by the systemic deposition of non-amyloid immunoglobulin light chains causing a progressive accumulation of extracellular material with varying degrees of organ impairment. Although LCDD mainly affects the kidneys (it manifests as proteinuria and/or renal insufficiency) the involvement of other organs (*e.g.*, heart, central nervous system and peripheral nerves) is very common. We present the case of a patient with a newly diagnosed cerebral restricted λ LCDD.
Aims: We present the case of a patient with a newly diagnosed cerebral restricted λ LCDD.
Methods: A 49 -year-old female was admitted to our hospital with progressive loss of coordination in her right hand and some in her left leg for 3 months, associated with mayor depression, headaches and constitutional symptoms (asthenia, weight loss and anorexia). Clinical examination revealed a decrease in the strength and the sensitivity in the right hemisphere 4/5. Her complete blood count showed a mild anaemia (Hb 114 g/L) and trombocytopenia (122.000/uL) with total leukocyte in the normal range. Calcium was normal. Liver and renal function was also normal. Serum and urine protein electrophoresis did not reveal any monoclonal protein spike. Immunofixations were negative. Nephelometry was performed showing a decreased of IgA and IgM levels with a normal IgG. Serum λ free light chains were 6.98 mg/L with a normal or K/λ ratio (K/λ:). The MRI study was made to the patient in order to discard a central nervous system (CNS) neoplasm. The MRI revealed a space occupying diffuse lesion in left front parietal. Histological examination with hematoxylin and eosin of the resected tumor demostrated an amorphous eosinophilic deposits in white and grey matter of the brain without plasmacytic cells. These deposits were positive for λ-light chain antibody by immunohistochemistry. To rule out other plasma cell dyscrasias, bone marrow aspiration (BMA) and fine-needle aspiration of abdominal fat pad (FPFNA) were assessed. BMA showed a 3% of plasma cells (PC). Flow cytometry did not evidence monoclonal PC. FPFNA was negative to amyloid. With these data, Multiple Myeloma (MM) and Primary Systemic Amyloidosis (PSA) were discarded and the diagnosis of λ cerebral LCDD was made. The patient received conditioning regimen consisted of BEAM: BCNU 300 mg/m2 (d-6) cytosine arabinoside 200 mg/m2/d and VP-16 200 mg/m2/d (d-5 to d-2) and melphalan 200 mg/m2 (d-1) followed by autologous stem cell transplantation (ASCT). Currently (After 3 months of ASCT) the patient has been improved her strength and sensitivity.

Results: LCDD is a rare monoclonal gammopathy and it is less common involving CNS. As in other neurological disorders, the clinical presentation (epilepsy, cognitive impairments, hemiparesis,headaches.) depends mainly on the location of deposition and not on the histological finding. Although chemotherapy including an alkylating agent, radiotherapy or steroids have been reported in a few cases, the standard treatment has not yet been clearly established. ASCT has been reported as a feasible strategy in LCDD. We choised BEAM conditioning regimen in order to cross the blood-brain barrier. The median overall survival is approximately of 4 years. Prognostic factors for LCDD include age, presence of concomitant MM or PSA. Nowadays, there is not enough data about the management of brain LCDD and more information is needed describing the efficacy of the different treatments.
Summary and Conclusions: We choised BEAM conditioning regimen in order to cross the blood-brain barrier. The median overall survival is approximately of 4 years. Prognostic factors for LCDD include age, presence of concomitant MM or PSA. Nowadays, there is not enough data about the management of brain LCDD and more information is needed describing the efficacy of the different treatments.

PB1899

EXTRAMEDULLARY BREAST PLASMACYTOMA ACCIDENTALLY DIAGNOSED PRECEDING AGGRESSIVE SYSTEMIC RELAPSE: AN UNUSUAL AND RARE MANIFESTATION OF RECURRENCE OF MULTIPLE MYELOMA

L. Torti[1,*] S. Pulini[1,1], E. Sabattini[2], F. Bacci[2], A. M. Morelli[1], P. Di Bartolomeo[1]
[1]Department of Hematology, Transfusion Medicine and Biotechnology, Clinical Hematology, "Spirito Santo" Civic Hospital, Pescara, [2]Department of Hematology and Oncological Sciences, Section of Hematopathology, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy

Background: Extramedullary (EM) plasmacytoma is a plasma cell neoplasm of the soft tissues that may occur with or without bone marrow and systemic involvement. EM disease is an uncommon manifestation in Multiple Myeloma (MM) and can either accompany newly diagnosed disease or more frequently develop with relapse. It seems to have a different pathogenesis from the medullary involvement and represents an independent poor prognostic factor with high rate of mortality. Myeloma of the breast is a rare entity not completely understood, with only a few reported cases in the literature not providing any statistical information.
Aims: We present a patient with extramedullary breast plasmacytoma diagnosed incidentally during breast plastic surgery for long-term history of fibrocystic disease. This unexpected diagnosis was shortly thereafter followed by a severe systemic medullary and extramedullary recurrence, treated with chemotherapy and radiotherapy.
Methods: A 44 year-old woman was diagnosed with IgG lambda MM stage IIIA ISS3, showing deletion of 17 and 13 chromosome detected by FISH and without bone or EM lesions. She was affected by MGUS from 14 years and had undergone right nephrectomy for renal cancer five years before. VTD therapy was started (total 4 cycles) followed by double autologous HSCT obtaining a VGPR. She remained in remission of disease for 14 months until mastopexy breast surgery. Surprisingly the histopathological examination of the breast tissue was consistent with diagnosis of plasmacytoma. Strangely, both the ultrasound and the breast MRI showed no nodular areas. Molecular examination confirmed the presence of monoclonal lambda positive plasma cells achieved through analysis of the rearrangement of the immunoglobulin heavy chain genes by PCR.
Results: A subsequent disease restaging showed an unexpected massive skeletal bone marrow and extramedullary involvement. PET/CT revealed pathological accumulation in the femoral heads, left iliac bone, gluteal muscles, pelvis. X-rays demonstrated multiple lytic lesions of right and left humerus, pelvis and D2 vertebral wall. MRI showed massive effusion in the left iliac bone with multiple lytic lesions extending up to gluteal muscles. She presented high level of LDH and 30% of atypical bone marrow CD56 negative plasma cells. She underwent radiotherapy on her pelvis and was treated according with PAD regimen (4 cycles). Nowadays patient is currently undergoing therapy; autologous and allogenetic HSCT are being evaluated.
Summary and Conclusions: EM is prevalent in genomically defined high-risk MM with shorter overall survival. Some autopsy studies have shown extraskeletal involvement in approximately 50-70% of patients with MM. EM disease seems to be prevalent in patients treated with novel agents, although this finding is not confirmed and could be due to the increased survival of patients with new drugs. The mechanisms of extramedullary spread are poorly understood; a decreased expression of integrins and loss of CD56 have been described, which could cause disease dissemination. Several papers have described relapses of MM occurring from different subclones of plasma cells from those of initial diagnosis. Recently, it has been speculated the presence of Circulating Myeloma Tumor Cells (CTCs), that constitute a subpopulation of clonal plasma cells associated with aggressive disease. They are characterized by downregulation of adhesion molecules, might transit in the peripheral blood and colonize other sites during the patients' resting and remission period. One might ask some questions: some recurrent MM could be firstly an awakening of dormant MM circulating clones? Which are the mechanisms for hematogenous spread and EM involvement? These and others are unanswered questions; international collaborative trials are necessary to better understand EM dissemination and discover optimal treatment.

TAZ GENE FROM HIPPO PATHWAY IS OVEREXPRESSED IN POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA PATIENTS

M. Cacemiro[1,*] N. Nunes[1], R. Tognon[2], E. Souto[3], F. Traina[4], L. Pontes[4], L. Perobelli[3], P. Prata[4], B. Simões[4], F. Castro[1]
[1]Faculdade de Ciências Farmacêuticas de Ribeirão Preto-USP, Ribeirão Preto, [2]Universidade Federal de Juiz de Fora, Governador Valadares, [3]Hospital Estadual de Transplantes Euryclides Zerbini, São Paulo, [4]Faculdade de Medicina de Ribeirão Preto-USP, Ribeirão Preto, Brazil

Background: Polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibosis (MF) are myeloproliferative neoplasms (MPN) characterized by the increase of mature hematopoietic cells of one or more of the myeloid series proliferation. MPN may present theJAK2V617F mutation which occurs in 95% of PV patients and 50% of ET and MF patients. The JAK2V617F mutation constitutively active STAT3 transducer protein, which is related to apoptosis resistance and myeloproliferation in MNP. Although all the molecular knowlegde about MNP pathogenesis, these diseases do not have an efficient therapy. Thus, more studies related to MPN pathophysiology and description of new therapeutic targets, such as the molecules from Hippo pathway are relevant. The Hippo signaling pathway has been defined as a tumor suppressor pathway responsible for regulating the proliferation, differentiation and cell death. This pathway is composed of *MST1/2, WW45, Lats1/2, Mob1* and *YAP/TAZ* proteins present in mammals.
Aims: To compare the *TAZ* gene expression among PV, ET, MF patients and controls (CTRL) subjects.
Methods: The leukocytes were obtained from peripheral blood of 23 PV patients (median age=60 years; 13 men and 10 women), 21 ET patients (median age=62 years; 10 men and 11 women), 21 MF patients (median age=64 years; 16 men and 5 women) and 23 CTRL (median age=58 years; 6 men and 17 women). The leukocytes were separated by Voluven gradient method. The RNA were extracted by Trizol® method and the cDNA were synthesized using High Capacity cDNA reverse transcription kit®. The gene expression was assessed by a real time PCR and the results were expressed as relative units of expression (RUE).
Results: Moreover, in PV patients the *TAZ* expression is higher in those JAK2V617F-negative patients.
Summary and Conclusions: The results indicate that *TAZ* gene may contribute to PV and ET pathogenesis since *TAZ* is well known for their regulation by the Hippo pathway acting as a transcriptional co-activator inducing expression of cell-proliferative and anti-apoptotic genes via interactions with specific transcription factors. Supported by FAPESP process 2014/04234-9

PB1901

ABCB1 AND SLC22A1 MRNA EXPRESSIONS ARE INCREASED IN A HOMOZYGOUS JAK2V617F CELL LINE TREATED WITH JAK INHIBITOR

G.W. Gomes[1,*] F.A. de Castro[2], D.P.T. Nunes[1], L.T. de Lima[1], A.C. Rodrigues[3], R. Tognon Ribeiro[4], E.M. Guerra Shinohara[1]
[1]Departamento de Análises Clínicas e Toxicológicas, Faculdade de Ciências Farmacêuticas, Universidade de São Paulo, Sao Paulo, [2]Departamento de Análises Clínicas, Toxicológicas e Bromatológicas, Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Universidade de São Paulo, Ribeirao Preto, [3]Departamento de Farmacologia, Instituto de Ciências Biomédicas, Universidade de São Paulo, Sao Paulo, [4]Departamento de Farmácia, Faculdade de Farmácia, Universidade Federal de Juiz de Fora/Campus Avançado, Governador Valadares, Brazil

Background: Pharmacokinetics of many anticancer drugs is affected by drug transporters as ABCB1, ABCG2 and SLC22A1. These molecules are responsible for cell uptake (SLC22A1) or efflux (ABCB1 and ABCG2) of severalxenobiotics and are widely distributed in many tissues. Several studies have shown their role in resistance and toxicity to chemotherapeutic agents. Dysregulation of JAK-STAT pathway is considered a hallmark of myeloproliferative neoplasms (MPN), and disruption of this pathway may result from mutations such as $JAK2^{V617F}$. Therefore, therapies targeting the inhibition of JAK proteins have been developed. However, the impact of JAK-STAT pathway inhibition over ABCB1, ABCG2 and SLC22A1 gene expression in MPN cells has not been investigated yet.
Aims: To evaluate the effect of JAK-STAT pathway inhibition in the expression of drug transporters ABCB1, ABCG2 and SLC22A1 in $JAK2^{V617F}$ positive cell line HEL92.1.7.
Methods: Erythroleukemia homozygous $JAK2^{V617F}$ cell line HEL92.1.7 was treated with 1 µM of *JAK Inhibitor I* (Merck/Calbiochem, Darmstadt, Germany), an ATP-competitive inhibitor of JAK proteins, for 24h. Western blot was used for verifying JAK-STAT pathway inhibition by inactivation of STAT-5. Quantitative real time-PCR and flow cytometry analysis were used to assess *ABCB1*, *ABCG2* and *SLC22A1* mRNA and protein expression, respectively, in JAK inhibitor-treated cells and in vehicle-treated control cells.
Results: JAK-STAT pathway was inhibited by treatment with 1 µM of *JAK Inhibitor I* for 24h, confirmed by non-detection of phosphorylated STAT-5. *ABCB1* and *SLC22A1* mRNA expressions were increased after treatment (median of 1.58 and 1.64 fold change, respectively), however, no difference was observed between ABCB1, ABCG2 and SLC22A1 protein expression in cells treated with 1 µM of *JAK Inhibitor I* for 24h and controls (P>0.05 for all).
Summary and Conclusions: Our data suggest that JAK-STAT pathway inhibition could modulate mRNA expression of drug transporters ABCB1 and SLC22A1 in MPN cells. Further studies with longer periods of treatment may confirm this proposition and help to elucidate the effect of JAK-STAT pathway in ABCB1, ABCG2 and SLC22A1 protein expression.

PB1902

INCIDENCE OF CALR MUTATIONS IN COHORT OF MPD PATIENCE FROM RUSSIAN FEDERATION

P. Butylin[1,*] N. Matuhina[1], A. Silutina[1], N. Siordia[1], E. Lisina[2], O. Senderova[3], A. Zaritskey[1]
[1]Hematology Insitutte, North-West Federal medical research center (Almazov institute), Saint-Petersburg, [2]Hematology, Chuvash republic regional clinical hospital, Cheboksary, [3]Hematology, Irkutsk regional clinical hospital, Irkutsk, Russian Federation

Background: Since discovery of mutation in 9th exon of the CALR gene in 2013, molecular diagnostics of ET and PMF by analysis of JAK2V617F, CALR and MPL515L/K mutations became standard in many of the research centers in the world. In this study we are for the first time reporting incidence of abovementioned mutations in patients from Russian Federation.
Aims: This study aimed to reveal incidence of mutation in calreticulin encoding gene in patients with myeloproloferative deseases: PV, ET, PMF.
Methods: Patients: DNA from peripheral blood of 103 patients diagnosed with PV, ET, and PMF tested for the mutations. Patients group was sex balanced 54F/49M. Average age was 52 years. For JAK2V617F and MPL515L/K detection allele specific real-time PCR with specific primers set were used (Genotechnology, Russia). CALR mutations were detected by Sanger sequencing of the C-end coding region, as described earlier (1). 1. Nangalia J, *et al.*, Somatic CALR mutations in myeloproliferative neoplasms with nonmutated JAK2. N Engl J Med. 2013 Dec 19;369(25):2391-405.
Results: Results of patints test presented in table. We did not found any cases with simultaneous appearance of two mutations in one patient. PMF patient with MPL515L mutation also have co appearence of BCR-ABL chimera. Calreticulin mutations were mostly type1 -deletions of 52 bp (15 cases), type 2-insertions of 5bp (4 cases) and deletions other than 52bp (2 cases). CALR mutated patients were no younger than average – mean 57 years old (from 20 to 77). Also, we did not observe any significant correlation between type of the mutation and age/sex/complications.

Table 1.

	JAK2V617F	CALR	MPL	all negative
PV	25 (100%)	0	0	0
ET	12 (46%)	6 (23%)	1 (4%)	7 (27%)
PMF	28 (54%)	15 (29%)	1 (2%)	8 (15%)

Summary and Conclusions: Incidence of the JAK2V617F, CALR and MPL515l/L in studied patient group is similar to the one reported in European centers. We did not find correlation of CALR mutation status with younger age, as described previously. No thrombotic events were found in ET patients with CALR mutations.

PB1903

CALR GENE MUTATIONS IN MOROCCAN PATIENTS IN ESSENTIAL THROMBOCYTHEMIA: FIRST REPORT

M. Kerbout[1,*] E.M. Mahtat[2], S. Jennane[2], W. Smaili[3], A. Sefiani[3], K. Doghmi[4], M. Mikdame[5]
[1]Clinical HematologyDepartment, [2]Clinical Hematology, Military Hospital Mohammed V, [3]Département de Génétique Médicale,, Institut National d'Hygiène, [4]Clinical Hematology Department, Mlitary Hospital Mohammed V, [5]Clinical hematology department, Military Hospital Mohammed V, Rabat, Morocco

Background: Since 2005, the discovery of the somatic mutation V617F in exon 14 of the Janus Kinase 2 gene (JAK2) was the front-line molecular tool for the diagnosis of Myelproliferative neoplasms (MPN) of which essential thrombocythemia (ET). In addition, detection of genetic alteration in the 10th exon of the myeloproliferative leukemia gene (MPL) plays a significant role in the pathogenesis of ET. However, about 40% of patients did not carry any of these markers and the diagnosis of ET remained a major challenge. Towards the end of 2013, somatic mutations in the 9th exon of the gene encoding cal-

reticulin (CALR) were revealed to be responsible of MPN in around 80% of ET patients who don't carry the JAK2 or MPL mutations.
Aims: This discovery have improved and simplified the accuracy of diagnosis of patients with ET worldwide, and opened the door to a better understanding of the disease pathogenesis. In this study, we present the 1st mutational profiles in CALR gene assessed in Moroccan Patients.
Methods: 25 Moroccan patients from Clinical Hematology Department of the Military Hospital Mohammed V were reviewed for having ET. All patients had a CBC with elevated platelet count; We searched magakaryocytes proliferation at the bone marrow biopsy for only 8 patients. The bcr-abl transcript was negative for all patients. The mutational status for exon 10 of MPL gene has not been evaluated in any of our patients. We evaluate somatic mutation V617F in JAK2 gene and mutations in 9th exon of CALR.
Results: Patients ages were between 23 and 75 years, 13 of them were female. Discovery circumstances ranged from fortuitous discovery to thrombotic or hemorrhagic manifestations. Median platelet countat diagnosis was 1 027 578 /mm3. Molecular assessment of the somatic mutation V617F in JAK2 gene was positive in eight, negative in 13 patients, 4 patients were not evaluated. Among the 13 "JAK2 negative" patients mutations in 9th exon of CALR were evaluated in 11 patients and were detected in four of them (36.3%). All the variants found were insertion/deletion mutations; All mutations were found between positions 1142 and 1157 in the coding DNA sequence (cDNA). Patients with intermediate and high risk received therapy such as hydroxyurea (13 patients), anagrelide (2 patients), pipobroman (4 patients) to lower the platelet count.
Summary and Conclusions: CALR gene mutations discovery represented a major milestone in the diagnosis of ET that would be highly considered in the revision of the WHO classification of MPN. Up to date, comparative studies on the treatment of CALR mutated patients with ET were not yet reported and further studies should help to explore this area.

PB1904

ET BUT NOT PV ARE ASSOCIATED WITH POLYMORPHISM ARG399GLN XRCC1 IN PATIENTS OF THE KRASNOYARSK TERRITORY
A. Gorbenko[1,*] M. Stolyar[1,2], T. Subbotina[1,2], E. Vasiliev[3], I. Olkhovskiy[1,4]
[1]Krasnoyarsk Branch of the Federal State-Funded Institution «National Research Center for Hematology» of the Ministry of Healthcare of the Russian Federation, [2]Siberian Federal University, [3]Krasnoyarsk regional hospital, [4]Krasnoyarsk Scientific Center of the Siberian Branch of the Russian Academy of Sciences, Krasnoyarsk, Russian Federation

Background: The associations between the Arg399Gln polymorphism in X-ray repair cross-complementing gene 1 (XRCC1) gene and the risk of hematological malignancies have been extensively investigated. In the subgroup analysis by ethnicity and cancer types, significant association was found in Asians but not in Europeans (Du L e.a. 2015 PMID: 25619474). No data on any it association with Ph-negative myeloid neoplasms.
Aims: The purpose of this study was to evaluate the association between XRCC1 Arg399Gln and Ph-negative myeloid neoplasms risk in patients of the Krasnoyarsk Territory.
Methods: In this study was included 134 cases with ET -75 V617F JAK2 (+), 31 CALR(+) and 5 MPL(+), 91 patients was included with PV -79 V617F JAK2(+). The control group (n= 114) consisted of healthy individuals. The XRCC1 polymorphism was detected in DNA isolated from peripheral leucocytes using PCR-based Taqman assay using a "iQ iCycler" 5.0. We used two pairs of primers (F: GTA-AGG-AGT-GGG-TGC-TGG-ACT-GT; R: GTC-TGA-CTC-CCC-TCC-AGA-TTC-C) and two probes (A allele: FAM-CTG-CCC-TCC-CAG-AGG-TAA-GGC-CTC-BHQ1; G allele: HEX-CTG-CCC-TCC-CGG-AGG-TAA-GGC-C-BHQ1).
Results: Our data are shown in the table. The additive model of Arg399Gln was associated with Essential Thrombocytemia (ET) risk. Conversely, no statistical association was found with Polycythemia vera (PV).

Table 1.

	Arg/Arg	Arg/Gln	Gln/Gln	n
healthy	47%	41%	11%	114
PV	45%	47%	8%	91
ET	33%	52%	14%	134
	OR (95% CI)			p
ET vs healthy	0,56 (0,33-0,93)	1,56 (0,94-2,59)	1,31 (0,61-2,78)	< 0,05
ET vs PV	0,50 (0,20-1,23)	0,82 (0,48-1,40)	1,64 (0,95-2,84)	< 0,04

Summary and Conclusions: The differences were found in the association between the polymorphism PV and ET to suggest Arg allele of the Arg399Gln polymorphism prevents the loss of homozygosity typical to PV.

Myeloproliferative neoplasms - Clinical

PB1905

Abstract withdrawn

PB1906

A PRESENTING NEUTROPHIL COUNT MORE THAN 75% IS A PREDICTOR OF THROMBOSIS AT DIAGNOSIS BUT IS ASSOCIATED WITH LESS THROMBOSIS SUBSEQUENTLY IN PATIENTS WITH POLYCYTHAEMIA VERA
G. Kam[1,*] M. Kam[2], Z.Y. Myint[1], H. Than[1], G.C. Wong[1], A. L. Ang[1], R. Yiu[1], L.H. Lee[1], C. Chuah[1]
[1]Department of Haematology, [2]Division of Medicine, Singapore General Hospital, Singapore, Singapore

Background: Polycythaemia vera (PV) is a myeloproliferative neoplasm (MPN) characterised by elevated haemoglobin and thrombotic tendency. Leukocytosis has been demonstrated to be a risk factor for thrombosis in PV. However, the white cell subtype implicated in thrombosis in PV has not been evaluated.
Aims: In this study we examined the role of presenting neutrophil levels in PV patients with thrombosis.
Methods: We retrospectively reviewed the case records of 163 patients with PV for thrombotic events in our institution's MPN registry. This is an institutional review board approved registry that utilises REDCap, an electronic data capture tool for research studies. Thrombotic events considered were ischaemic heart disease, cerebrovascular accident, peripheral arterial disease, retinal artery occlusion, thrombosis of the splanchnic circulation and venous thromboembolism.
Results: Median age of diagnosis was 58years; 58.3% were male. 32 patients presented with a thrombotic event at diagnosis of PV. 12.5% of events were venous. Patients with a thrombosis at diagnosis were more likely to have risk factors for atherosclerotic disease (31.3% vs. 8.4%, P=0.012), have a higher presenting white cell count (15.2x 10^9/L vs. 13.6x 10^9/L, P=0.04) and to be treated with cytoreduction (90.6% vs. 71.8%, P=0.026). Patients with a thrombosis at diagnosis had a higher presenting neutrophil percentage of 82% (vs. 76.4%, P=0.002) and median absolute neutrophil count (ANC) (12.1x 10^9/L vs. 10.1x 10^9/L, P=0.017) than patients who did not. Based on receiver operating characteristic (ROC) analysis, a cut-off neutrophil percentage of 75% was derived for further analysis. 80.6% of patients who presented with thrombosis at diagnosis had a neutrophil count ≥ 75%, whereas 57.3% of those who did not, had a presenting neutrophil count ≥ 75% (P=0.016). On logistic regression, adjusting for gender, age ≥ 60 at diagnosis, prior thrombosis and presence of atherosclerotic disease risk factors, a presenting neutrophil percentage ≥ 75% (Odds ratio (OR) 3.36, 95% CI 1.25-9.03, P=0.016) and presence of atherosclerotic disease risk factors (OR 4.43, 95% CI 1.21-16.18, P=0.024) were predictors for thrombosis at diagnosis. Over a 5.4year median follow up, 31 thrombotic events occurred in 28 patients. Six patients who presented with thrombosis had subsequent events. Paradoxically, less patients who had a thrombotic event on follow up had a presenting neutrophil percentage ≥ 75% than patients who did not have thrombosis on follow up (34.6% vs 67.4%, p =0.002). Of patients who had a thrombosis after diagnosis, 57.1% were on cytoreduction compared to 74.8% of those who did not develop thrombosis (P=0.059). 10 and 20year thrombosis-free survivals were better in patients with presenting neutrophil percentage ≥ 75% than those with lower presenting neutrophil counts: 91.4% vs. 47.6% and 64.9% vs. 35.7% (P=0.001) respectively. On multivariate analysis, in a model including gender, age ≥ 60 at diagnosis, atherosclerotic disease risk factors, prior thrombosis, use of cytoreduction, thrombosis at diagnosis and presenting neutrophil ≥ 75%, a presenting neutrophil level ≥ 75% was significant (Hazard ratio 0.25, 95% CI 0.11-0.6, P=0.002).
Summary and Conclusions: More patients who presented with a thrombotic complication at diagnosis had a presenting neutrophil count ≥ 75%. A presenting neutrophil count ≥ 75% and presence of risk factors for atherosclerotic disease were predictors of thrombosis occurring at diagnosis. However, for follow up thrombotic events, a presenting neutrophil ≥ 75% was associated with less thrombosis.

PB1907

WT1 EXPRESSION IN PH-NEGATIVE MYELOPROLIFERATIVE DISEASES
N. Siordia[1,*] E. Lomaia[1], P. Butylin[1], N. Matyhina[1], K. Bogdanov[1], E. Lisina[1], A. Zaritskey[1]
[1]Hematology, Federal North-West Medical Research Centre, Saint-Petersburg, Russian Federation

Background: Expression of Wilms tumor antigen (WT1), which encodes a transcription factor, is significantly increased in tumor cells of the kidney, testes, ovaries, breast and certain hematological malignancies. WT1 is overexpressed in many patients with acute myeloid leukemia and in the absence of more specific molecular markers can be used for monitoring of minimal residual disease.

The rate and significance of WT1 overexpression in chronic myeloproliferative diseases (MPDs) currently remains unclear

Aims: The aim of this study was to evaluate the incidence of overexpression of WT1 gene in MPDs.

Methods: Peripheral blood samples from 52 (male n= 33, female n=19) patients with polycythemia vera (PV), essential thrombocythemia (ET) and primary or post-PV/post-ET myelofibrosis were evaluated for WT1 expression. Patients's characteristics at the time of evaluation is presented in the table 1. WT1 expression was performed by quantitative PCR, using a standard set ProfileQuant Wt1 kit, PCR analyzer «Rotor- Gene 6000". Normal reference range in peripheral blood considered is 0.00-50.00 WT1/10^4 ABL copies.

Results: WT1 overexpression was observed in 25/52 (48%) patients. It was found in all patients with myelofibrosis (primary or post-PV/post ET). No patients with PV or ET have WT1 overexpression. The mean level of WT1 gene expression was 714 WT1/10^4 ABL copies in MF (range, 171-6000), 4.0 WT1/10^4 ABL copies in PV (range 1.1-17), and 8.32 WT1/10^4 ABL copies in ET(range, 1.8-14). We did not find any significant correlation of WT1 expression level with either mutation status of Jak2, MPL and CALR genes or clinical data (age, gender, DIPSS risk groups, median time from MF diagnosis).

Table 1.

	PV n=16	ET n=11	PMF n=20	post-PV/post ET MF n=5	All MPDs n=52
Age, median (years)	50	50	65	60	60
JAK2V617F +	16 (100%)	9(82%)	8 (40%)	5 (100%)	38(78%)
MPL + in Jak2V617F negative pts	NA	0/2 (0%)	1/12 (8%)	NA	1/14 (7%)
CALR + in Jak2V617F negative pts	NA	2/2(100%)	7/12 (58%)	NA	9/14 (64%)

Summary and Conclusions: WT1 gene was overexpressed in all MF, including post-PV/post-ET cases, but was normal in PV and ET patients. It seems that WT1 gene overexpression could be potential marker for prediction of bone marrow fibrosis development in patients with PV/ET. Whether the level of expression of WT1 is correlated to grade of fibrosis is a subject of our investigation.

PB1908

MULTICENTER-RETROSPECTIVE ANALYSIS OF TURKISH PATIENTS WITH CHRONIC MYELOPROLIFERATIVE NEOPLASMS

G. Saydam[1,*] I.C. Haznedaroglu[2], N. Akad Soyer[3], D. Cekdemir[4], M. Yilmaz[5], A. Unal[6], O. Bilgir[7], O. Ilhan[8], F. Ozdemirkiran[7], F. Sahin[1]
[1]Hematology, Ege University Hospital Internal Medicine, Izmir, [2]Hematology, Hacettepe Univ, Ankara, [3]Hematology, Ege University Hospital Internal Medicine, Bornova, [4]Hematology, Sakarya EAH, Sakarya, [5]Hematology, Gaziantep Univ., Gaziantep, [6]Hematology, Erciyes Univ, Kayseri, [7]Hematology, Bozyaka EAH, Izmir, [8]Hematology, Ankara Univ., Ankara, Turkey

Background: Chronic Myeloproliferative neoplasms (CMPN) are Philadelphia-negative malignancies characterized by a clonal proliferation of one or several lineages. According to WHO classification, CMPNs include Polycythemia Vera (PV), Essential Thrombocythemia (ET) and Primary Myelofibrosis (PMF).

Aims: The aim of this report was to determine the demographic features, disease characteristics, JAK mutational status, treatment strategies, and survival rates of 708 patients with CMPN from 8 centers in Turkey.

Methods: Across all of Turkey, 8 centers were enrolled in the study. We retrospectively evaluated 708 patients' results with CMPN.

Results: The JAK2V617F mutation was found positive in 75.11% of patients with PV, in 51.5% of patients with ET and in 50.4% of patients with PMF. Thrombosis occurred in 20.65% of patients with PV, arterial in 21 (47.7%) cases and venous in 23 (52.2%). Thrombosis was observed in 15.12% of patients with ET, arterial in 30 (50.8%) cases, venous in 27(45.8%) and two (3.4%) patients suffered both arterial and venous thrombosis. Approximately ten percent of PMF patients suffered from thrombosis, arterial in 7 (6.7%) cases and venous in 3 (2.9%). Bleeding at diagnosis occurred in 7.5% of PV patients, in 9% of ET patients and in 10.4% of PMF patients. Six hundred and eight patients (85.9%) had a cytoreductive therapy. The most common used drug was hydroxyurea (75.1%). Hydroxyurea was used 79.3% of PV patients, 57.1% of PMF patients, and 77.7% of ET patients in the first-line treatment. Interferon was used 5.1% of PV patients, 1.9% of PMF patients, and 5.1% of ET patients. Cytoreductive therapy was changed in 198 (28% of all) patients. In the second-line treatment, the most common used drug was anagrelide (147 of 198 patients). Anti-platelet therapy was used in 553 (78.1%) patients. Splenectomy was performed in 10 (1.4%) patients. Eight PMF patients (1.1% of all CMPN patients) were treated with allogeneic stem cell transplantation. Progression to acute leukemia and secondary myelofibrosis were observed in 0.6% and 11.3% of all patients, respectively. The median follow- up was 38 months (0-322) and overall survival (OS) was 86.7% at 10 years in all patients. Among the 213 PV patients, the median follow- up was 3.5 months (0-322) and the OS was 89.7% at 10 years. In 390 ET patients, the median follow- up was 35 months (0-280) and the OS was 98.5% at 10 years. Among the 105 PMF patients, the median follow-up was 15.5 months (0-229) and the OS was 82.5% at 10 years.

Summary and Conclusions: Our patients results is compatible the literature except the frequency of JAK2V617F mutation in PV patients. Hydroxyurea was the most common used cytoreductive therapy in our country.

PB1909

INCREASED PLATELET COUNTS AT DISEASE DIAGNOSIS IS RELATED WITH EARLY INTRODUCTION OF CYTOREDUCTICTION AND REDUCED EVENT-FREE SURVIVAL IN YOUNG ADULT PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA.

E. Spanoudakis[1,*] C. Zagoridis[1], S. Guliamtzi[1], D. Margaritis[1], I. Kotsianidis[1], [1]Democritus University of Thrace, Alexandroupolis, Greece

Background: ET is not such an innocent disease in young adults. Most thrombotic events occur during diagnosis and almost half of the initially asymptomatic patients will have an event during the course of their disease

Aims: Herein, we analyzed retrospectively the medical records of 33 ET patients diagnosed below the age of 45 years and followed in a single institution from 1992 to 2014.

Methods: Management was left at the discretion of the treating physician but antithrombotic agents were used from disease diagnosis in all patients. Among 33 young adult patients 11 were males and 22 females. 18 patients were followed for a median period of 94,5 (range 45-178) months and left untreated and they were included in group A. While cytoreductive treatment was introduced in 15 patients included in group B. Among 15 treated patients cytoreduction was introduced from disease diagnosis in seven patients and in eight during the course of their disease after a median period on observation of 36 months (ranging from 6 to 168).

Results: We separated our patients into two groups according to the need to start any cytoreductive treatment and try to discover patient's characteristics at diagnosis that can predict the early use of cytoreductive treatment. Splenomegaly of any grade was palpated in 3/18 (16.5%) patients in group A and in 2/15(13%) in group B, P=0,796. Although hematocrit levels were equal between the two groups [42,7%(34,7-47,6) in group A and 40,7%(37,3-46) in group B, P=0,84] as were also and the leucocyte counts [7,85 (5,6-13,2) X 10^3 pcm in group A and 9,73 (4,7-11,7) X 10^3 in group B P=0,6], the median values of platelet counts at diagnosis was significantly higher in group B compared to group A [805(490-2300) X 10^9 pcm vs 604,5(490-921) X 10^9 pcm, P=0,012]. Fibrosis (grade I) at the initially performed bone marrow biopsy was met at higher percentages in patients allocated in group B 40% (6/15) in group B and11% (2/18) at group A, P=0,03. JAK2V617F was detected in 40% (6/15) in group B and 50% (9/18) in group A, P=1. According to the IPSET-thrombosis scoring system in group A most patients had low thrombotic risk 10/18, 7/18 had intermediate thrombotic risk and 1/18 had high thrombotic risk. In group B 7/15 had low thrombotic risk, 3/15 intermediate and 5/15 had high thrombotic risk. In the total cohort of 33 young ET patients platelet counts at disease diagnosis can predict reduced Event free Survival (EFS). As an event were considered thrombohemorhagic complications, development of myelofibrosis and the need to start cytoreductive treatment. 10 year EFS was for patients with platelet counts<600x 10^9 pcm 89% for platelet counts between 600-800 X 10^9 pcm 66% and for platelet counts>800 X 10^9 pcm was 22%, P=0.003, Kaplan-Mayer, LogRANK test. On the contrary the presence of grade-I fibrosis was not associated with reduced EFS.

Summary and Conclusions: In young ET patients increased platelet counts at disease diagnosis can predict an eventful disease journey with early need for the use of cytoreductive treatment and reduced EFS.

PB1910

INCIDENCE AND CLINICAL CORRELATION OF CALR MUTATIONS IN PATIENTS WITH JAK2/MPL NEGATIVE ESSENTIAL THROMBOCYTEMIA (ET) AND PRIMARY MYELOFIBROSIS (MF). A SINGLE INSTITUTION COHORT REVIEW.

H. Saturnino[1], M. Coucelo[1], M. Mendes[1,*] G. Ferreira[1], M. Duarte[1], L. Araujo[1], J. Almeida[1], M. Ribeiro[1], B. Celeste[1]
[1]Serviço de Hematologia, Centro Hospitalar Universitário de Coímbra, Coimbra, Portugal

Background: The recent description of *CALR* mutations occurring in ET and MF greatly contributed to the diagnostic evaluation of *ph-* Myeloprolyferative Neoplasms (MPN). The *CALR* gene encodes the endoplasmic reticulum Ca^{2++}-binding chaperone-Calreticulin. Exon 9 *CALR* somatic insertions and deletions have been reported and the most frequent variants are Type-1, 52-bp deletion (p.L367fs*46), and type-2, 5-bp TTGTC insertion (p.K385fs*47), representing

about 80% of the cases. These mutations have also been reported as favorable prognostic factor on ET thrombosis-free patients, particularly the type-1.
Aims: To evaluate *CALR, JAK2* and *MPL* mutations in a group of ET and MF patients and to correlate clinical and analytical data.
Methods: We actualized a retrospective analysis of 115 patients (pts) diagnosed MPN: 88 ET and 27 MF (according to WHO2008 criteria), with a mean follow-up time of 8 years (3 moths-31 years). *JAK2V617F* mutation was assessed by ASO-PCR and real-time quantitative PCR, mutations in exon 10 *MPL* and exon 9 *CALR* by PCR-sequencing in blood or bone marrow samples.
Results: In ET group (39males/49females), 59,1% (52) were *JAK2* positive; 20,5% (18) *CALR* 4,5% (4) *MPL* and 15,9% (14) were negative for *JAK2/CALR/MPL*- "triple negative". The *CALR* type-1 mutation was detected in 11/18, the type-2 in 6/18 and one patient harbored the p.K375Rfs*49 mutation. Comparing *JAK2*, *CALR* and triple negative pts, *CALR* had a male dominance and higher mean platelet (PLT) counts (P=0.02), *JAK2* pts had higher hemoglobin (Hb) levels (P=0.04) and triple negative pts presented at younger age (P=0.002). Analyzing the *CALR* subgroups, there is a trend to an older age and a higher PLT count in type-2 mutation group and an incremental difference on PLT counts comparing to *JAK2* (P<0.001). There were no differences in leukocyte (WBC), serum ferritin and erythropoietin levels. Regarding hematological response to cytoreduction we did not observe differences within *CALR* pts. Thrombosis occurred in 24/88 ET, 18 previously or at diagnosis; 21/52 *JAK2*: 2 of splanchnic veins both associated to prothrombotic factors (1 HTZ Factor V Leiden (*FVL*), 1 HTZ PRT20210G/A/FVL); 3/18 *CALR* all type-1 and 2 associated to prothrombotic factors *FVL* (1) and HTZ *PRT20210G/A* (1). One *CALR* (type-2) and 4 *JAK2* pts progressed to MF, one of them to AML. Eleven patients deceased: 6 *JAK2*, 3 *CALR (type-1)* and 2 triple negative. The MF pts (15M/12F) were 55,6% (15) *JAK2*, 33,3% (9) *CALR* : 6/9 type-1, 3/9 type-2; 7,4% (2) *MPL* and 3,7%(1) triple negative. About 70% of *JAK2* pts had an allelic burden >50%. We observed a higher WBC count in *JAK2* compared to *CALR* (P=0.04) and no differences in Hb, PLT, serum ferritin and EPO values. Thrombosis occurred in 3 JAK and 1 *CALR* type-1. There were 3 deaths 2 *JAK2* and 1 *CALR* type-1.
Summary and Conclusions: In this cohort of MPN, 58,2% (67/115) have *JAK2V617F* mutation, 23,5% (27/115) *CALR* and 5,2% (6/115) *MPL*. In 13,1% (15/115) we found no *JAK2/MPL/CALR* mutation. Exon 9 *CALR* mutations, the second most prevalent marker in ET pts, are associated to higher PLT counts and lower Hb levels comparing to *JAK2*. Comparing *CALR* subgroup, ET pts with type-1 mutations had more thrombotic events, most of them in association to prothrombothic factors while type-2 presented with higher PLT counts and only a type-2 pt progressed to MF. There were no differences in cytoreduction response. The impact of the different type of *CALR* mutations on natural history of ET and MF pts are not yet completely elucidated. Nevertheless, these mutations constitute a molecular marker of ph- NMP and offer an important tool in the diagnostic pathway ET and MF.

PB1911

CALRETICULIN V/S JAK2 MUTATION CHARACTERISTICS IN ESSENTIAL THROMBOCYTOSIS IN ASIAN AND NON-ASIAN POPULATION: A META-ANALYSIS

H.R. Kourie[1,*] L. Ameye[1], M. Paesmans[1], D. Bron[1]
[1]Jules Bordet Institute, Brussels, Belgium

Background: 2014 was marked in myeloproliferative neoplasms by the discovery of Calreticuline mutation in essential thrombocytosis and primary myelofibrosis. Many papers were published describing the clinical, biological and epidemiological characteristics of this mutation compared to JAK2 mutation in ET. A meta-analysis of these studies was necessary to confirm the different characteristics of this new mutation in Asian and non-Asian populations.
Aims: The aim of this study is to evaluate the epidemiological, clinical and biological characteristics of patients with essential thrombosis having JAK2 or Calreticuline mutation and to compare the particularity of these mutations in Asian and non-Asian population.
Methods: 8 studies published from December 2013 to October 2014 met the inclusion criteria of this meta-analysis: three of them in Asian population and five in non-Asian population. More than 2307 patients diagnosed having ET either with Calreticuline or JAK2 mutation were included. The epidemiological, clinical and biological characteristics of those patients at diagnosis (age, sex, hemoglobin level, white blood cells count, platelet counts, risk of thrombosis and hemorrhage, transformation to myelofibrosis or leukemia) were compared according to the positivity of JAK2 or Calreticuline mutation and to the race (Asian and non-Asian).
Results: The incidence of Calreticuline is 25% in ET patients in Asian and non-Asian subgroups. JAK 2 mutated ET patients are older than Calreticuline mutated patients with a mean difference of 6.9 years in all included patients, 5.3 years in Asians and 8.5 years in non-Asians. JAK2 mutated patients are less likely to be men when compared to calreticuline mutated patients in non-Asians with an OR =0.49; this OR was 1 in Asians. Hemoglobin level and white blood cell count was higher in JAK2 mutated patients compared to Calreticuline mutated patients in all sub-groups, while platelet count in JAK2 mutated patients was significantly lower. The risk of thrombosis was higher in JAK2 mutated patients compared to Calreticuline mutated patients at diagnosis and during the follow-up in all sub-populations with an OR>2 in all groups. The transformation to primary myelofibrosis was lower in JAK2 mutated patients, while there was no-significant difference in leukemia transformation, presence of splenomegaly at diagnosis and risk of hemorrhage.
Summary and Conclusions: With those specific characteristics, Calreticuline mutation will probably be added as diagnostic criteria of ET and will be considered a new prognostic factor affecting the treatment and the management of ET.

TWO NOVEL CALRETICULIN MUTATIONS IN A TURKISH PATIENT WITH PRIMARY MYELOFIBROSIS: C.1116DELA AND C.1120A>C

S. Güvenç[1,*] V.S. Hançer[2], N. Uslu[1], M. Arat[3], R. Küçükkaya[1]
[1]Hematology, [2]Molecular Biology and Genetics, Istanbul Bilim University, [3]Hematology, Florence Nightingale Hospitals, Istanbul, Turkey

Background: With the discovery of somatic frameshift mutations in exon 9 of the calreticulin (CALR) gene, approximately 90% of myeloproliferative neoplasm (MPN) patients have gained a chance of genetic diagnosis. *CALR* mutations were first identified exclusively in JAK2-MPL negative essential thrombocytemia (ET) and primary myelofibrosis (PMF) at a rate of 60-88%, accounting for 1/4 to 1/3 of all patients with ET and PMF. *CALR* mutations that reported in the literature, consist of somatic insertions, deletions or both which always leading to an one base pair shift in the open reading frame and produce a novel C-terminal amino acid sequence that impair the function of calreticulin. As of today, more than 50 different types of mutations have been reported. The 2 most common mutations accounting for 85% of mutated cases are either a 52-bp deletion (Type 1; c.1099_1150del; L367fs*46; 44%–53% of cases) or a 5-bp insertion (Type 2; c.1154_1155insTTGTC; K385fs*47;32%–42% of cases). The remaining 15% include various other infrequent mutations that are often unique or found in a few patients.
Aims: Here we present another two *CALR* mutations in one patient with PMF that is not reported before.
Patient: The patient is a 46 year old man who is suffered from low back pain that have started 6 months ago. MRI scan of lumbosacral region revealed sacroileitis at the left side and he referred to a rheumatologist for further investigations. Anemia (hgb 10,8 g/dl) and thrombocytosis (700x10^9/L) with high LDH level (351 U/l) were found in initial tests. The other tests for a possible rheumatologic disease including HLA-B27, were all negative and the patient was admitted to hematology clinic. Physical examination was almost normal with no sign of organomegaly. Spleen size was also normal in the abdominal ultrasound. Peripheral blood smear showed dacrocytes, occasional myelocytes (1%) and metamyelocytes (1%). Bone marrow biopsy showed diffuse, grade 3-4 reticulin fibrosis with atypical proliferation of megakaryocytes and increased cellularity consistent with PMF. BCR-ABL, JAK-2 V617F, and MPL 515L/K tests were found to be negative.
Methods: Genomic DNA was extracted from whole blood using a commercial kit (HibriGen Biotech R&D, Istanbul, Turkey). Exon 9 of the *CALR* gene was amplified using Forward ACAACTTCCTCATCACCAACG and Reverse GGCCTCAGTCCAGCCCTG primers. PCR reaction was performed using 2X PCR master mix (HibriGen Biotech R&D, Istanbul, Turkey), primers and 25-30 ng genomic DNA. Direct Sanger sequencing of amplified fragments were performed using BigDye Terminator Cycle Sequencing kit v3.1 and an ABI3130xl sequencer (Applied Biosystems, Foster City, CA, USA). Our results were evaluated using the BLAST (http://www.ncbi.nlm.nih.gov/BLAST) and SeqScape™ v2.0 (Applied Biosystems, Foster City, CA, USA) software packages. Mutation was confirmed on a second DNA sample isolated from a duplicate tube of blood followed by sequencing in both forward and reverse directions. All nucleotide numbers refer to the wild type cDNA sequence of *CALR* (NM_004343) as reported in Ensembl.
Results: Electropherogram of *CALR* exon 9 of the patient was shown in figure 1. Due to a 1bp deletion in codon 372 c.1116delA (D373fs*57) and c.1120 A>C, reading frame has changed in codon 373 and there after.

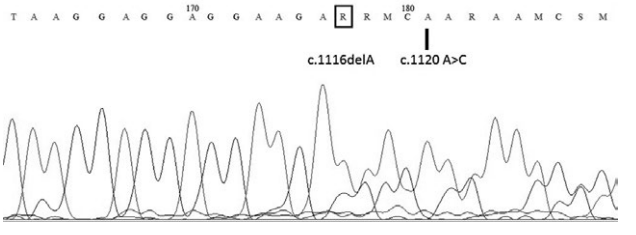

Figure 1.

Summary and Conclusions: To date 55 different CALR mutations have been described. Here we report two new *CALR* mutations [1bp deletion; c.1116delA (D373fs*57) and c.1120 A>C] in a same patient with PMF. These mutations have occured in exon 9 of the *CALR* gene, and changed the aminoacid sequence of C domain starting with aminoacid residue 372; which will interfere

with calcium binding capacity of the molecule. The identification of new *CALR* mutations will improve our understanding of the pathophysiology of MPN, and will help to find new theraupetic targets.

ESSENTIAL THROMBOCYTEMIA IN CHILDREN – CLINICAL, HEMATOLOGICAL, MOLECULAR AND THERAPEUTICAL ASPECTS – SINGLE CENTER EXPERIENCE

A. Colita[1,2,*], M. Asan[1], C. Dobrea[3], M. Dragomir[4], D. Coriu[5], C.V. Arion[6], A. Colita[7],
[1]Pediatric Hematology & BMT, Fundeni Clinical Institue, [2]Fundeni Pediatric Clinic, Carol Davila University of Medicine & Pharmacy, [3]Hematology, [4]Molecular Biology, Fundeni Clinical Institue, [5]Hematology, Carol Davila University of Medicine & Pharmacy, [6]Fundeni Pediatric Clinic, Fundeni Clinical Institue, [7]Hematology, Coltea Hospital, Bucharest, Romania

Background: Essential thrombocytemia (ET) is an extremely rare disease in children, with an incidence of 1-4 cases/10 million people/year. ET can be present as sporadic or familial disease and exclusion of secondary thrombocytemia is mandatory. There are few data about ET in children. Some studies showed a lower incidence of JAK2 mutation in children compared to adults.
Aims: The purpose of this study is to evaluate the clinical manifestations and follow-up of children with ET.
Methods: We performed a retrospective study of 5 children with ET, followed between 2008-2014 in the Fundeni Clinical Institute, Bucharest. Diagnosis consisted of: a) tests to exclude secondary thrombocytosis; b) tests to exclude other malignant thrombocytosis and c) specific tests: JAK2V617 PCR analysis, calreticulin, C-MPL, bone marrow examination, cytogenetic analysis. The WHO 2008 criteria for ET were used. Thrombopilia screening was performed with – PC, PS, AT, APC-R analysis; in case of positive screening for thrombophilia, PCR assay for MTHFR 677, FVL, FII was recommended.
Results: Five patients, 4F/1M were diagnosed with ET at ages 7- 15 years (median 8 years). One case was familial ET and 4 were sporadic ET. The platelet count at diagnosis was 700-2500x 10^9/L. Three cases showed extreme thrombocytemia (>900x109/L), 2 cases moderate thrombocytemia (700-900x10^9/L), one case with mild thrombocytemia (450-700x10^9/L). Clinical manifestations at diagnosis: 2 cases had cephaleea, 1 case cephaleea and severe abdominal pain, 1 with cerebral thrombotic event and hemiparesis and 1 asymptomatic case. Three out of 5 cases were JAK2 positive. BM biopsy revealed in all cases hypercellularity, giant megakaryocytes, absence of reticulin fibrosis. The karyoype was normal in all cases. One case was MTHFR heterozygote. Treatment consisted of α-Interferon followed by anagrelide, due to severe symptoms persistence, in a JAK2 negative case, first-line anagrelide in all 3 JAK2 positive cases and hematologic monitoring in the ET familial case. Anagrelide treatment reduced the platelet count in all cases, and controlled the symptoms, but 1out of 4 patients developed ischemic stroke despite treatment. No secondary effects were recorded.
Summary and Conclusions: We observed severe clinical symptoms in 4/5 pediatric ET cases. Some pediatric studies suggested that JAK2 positive cases have a severe course and could be considered distinct disorders. It is necessary to asses which child with ET really needs cytoreductive therapy, as already defined for adults.

PB1914

TYPE 1 CALR MUTATION IMPROVES DIAGNOSIS OF PREFIBROTIC IDIOPATHIC MYELOFIBROSIS (MF0)

B. Martino[1,*] C. Labate[2], D. Ielo[1], D. Rotilio[1], C. Mammì[2], C. Laganà[2], F. Ronco[1]
[1]Hematology, [2]Genetic, Ospedali Riuniti, Reggio Calabria, Italy

Background: CALR mutation discovery improves essential thrombocythemia (TE) and idiopathic myelofibrosis (MI) diagnosis. Over 36 CALR type mutations have been found, but only two types (type 1: del52bp and type 2: ins5bp) are present in 80% of the patients. It seems that type 1 mutation is frequently associated to fibrosis and that it has a worse impact on overall survival than type 2 mutation. Diagnosis of a prefibrotic state (MF0) presents histological diagnostic difficulties. MF0 has a worse prognostic impact than TE with regard to thrombotic risk, and a higher risk towards MI and acute leukemia evolution. For this reason a new type of identification of a group of patients is very useful.
Aims: The aim of this study was to evaluate CALR mutations in patients with MI and TE JAK2-negative and MPL-negative and the type of CALR mutations frequently associated to MF0.
Methods: We studied 47 patients CALR-positive, 21 with TE and 26 with MI. 12 out of 26 with MI were classified as MF0 on the basis of the histological examination of bone marrow biopsy. Debut features have been evaluated for WBC, Hb, PLT, LDH, peripheral CD34, spleen. Fragment analysis of PCR exone 9 CALR gene was performed.
Results: Type 1 mutation was present in 6 out of 21 patients (30%) with TE and in 19 out of 26 patients (73%) with MI. In the subgroup of MF0, 9 patients out of 12 (75%) were positive to del52bp. Conversely, type 2 mutation was present in 15 patients out of 21 (70%) with TE and in only 7 patients out of 26 (27%) with MI. Of the 12 patients with MF0, 3 patients (25%) were positive to ins5bp. Statistical analysis was negative for WBC, Hb, PLT, LDH, peripheral CD34 and spleen and not statistically significant between these 3 groups of patients.
Summary and Conclusions: It was recognized that CALR mutation has a better impact with respect to the complications of myeloproliferative neoplasm Ph1 negative. It is still unclear the role of del and ins mutations of CALR gene. In our experience, type 1 mutation is more representative in "fibrotic" phenotype as it is demonstrated the higher frequence of del 52bp in MF0 patients than in MI patients. This allowed us to better identify MF0 clinical features, in that a particular clinical attention for MF0 is required, being different from TE.
Keywords: MF0, CALR, CALR mutations, TE

TET2 MUTATIONS IN ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS

C. Turan[1], S. Güvenç[1,*] V. S. Hançer[2], F. Hindilerden[1], M. Arat[3], R. Küçükkaya[1],
[1]Hematology, [2]Molecular Biology and Genetics, Istanbul Bilim University, [3]Hematology, Florence Nightingale Hospitals, Istanbul, Turkey

Background: Myeloproliferative neoplasms other than CML are grouped as policytemia vera (PV), essential trombocythemia (ET) and primary myelofibrosis (PMF). By the identification of JAK2617f mutation in 2005; the explanation of the clonal proliferation in 90-95% of PV, 50% of ET and 50% of PMF have been possible. Thereafter JAK exon-12 mutations for PV and MPL mutations for ET and PMF have been defined. However the clonal proliferation in approximately half of the ET and PMF cases have been undetermined. One of the many mutations which could have a role in the pathogenesis is TET2 mutations. TET2 mutations were found positive in 15% of PV, 4-11% of ET and 19% of PMF patients. Some studies also showed that TET2 mutations have prognostic value.
Aims: Our aims are the determination and clinical relevance of TET2 mutations in patients with ET and PMF which are following in our clinic.
Methods: 35 ET ve 10 PMF patiens are included according to WHO criteria. Patients' demographic informations, clinical and laboratory findings were registered. DNAs were isolated from venous blood samplings and all exons of the TET2 gene were analyzed by Sanger based sequencing method. Informed consent was obtained from all patients. In addition to descriptive statistics, datas were evaluated for the comprasion of two groups with t test, chi-square test and Odds Ratio.
Results: TET2 mutations were found in 47,5% (16/35) of ET patients and 70% (7/10) of PMF patients. Six mutations were defined: I1762V, M1907T, L1721W, H1778A, C1298Y and Q1828X. Of these, L1721W and I1762V have possibility of being a genetic polymorphism. The frequency of TET2 mutation was not statistically different between sex and age. We demonstrated a correlation between initial spleen size and TET2 mutations for patients with ET (P=0.011). Increased bone marrow fibrosis is also found in bone marrow biopsy examination in TET2 mutation-positive ET patients (P=0,011). Furthermore, complications including arterial thrombosis and bleeding are found more frequent in TET2 mutations positive ET and PMF patients (for ET relatively OR:2,59, for PMF relatively OR:1,7, OR:1,6). Togetherness of JAK2V617F and TET2 mutations associates bigger spleen size (P=0,001) and increased risk of arterial thrombosis and bleeding in patients with ET and PMF (for ET, relatively OR:3,85, OR:2,8; for PMF, relatively OR:3,67, OR:3,67).
Summary and Conclusions: We herein found higher rates of TET2 mutations in patients with ET and PMF. Positivity of TET2 mutations are correlated with especially spleen size and the rate of fibrosis for patients with ET; and these mutations increase the risk of arterial thrombosis and bleeding. For patients with PMF, positivity of TET2 mutations increase spleen size and the risk of arterial thrombosis and bleeding. Togetherness of JAK2V617F and TET2 is associated with increased risk of complications. We conclude that to know the TET2 mutations in ET and PMF can give information about disease progression and complications thus may identify a high-risk subgroup of MPN patients.

PB1916

VORINOSTAT MAY OFFER LONG TERM CONTROL OF DISEASE IN THERAPY RESISTANT ESSENTIAL THROMBOCYTHAEMIA

S. Alimam[1,*] D. Radia[1], M.F. McMullin[2], H. Hasselbalch[3], C.L. Andersen[3], C. Harrison[1]
[1]Department of Haematology, Guy's & St Thomas' NHS Foundation Trust, London, [2]Department of Haematology, Belfast City Hosptial, Belfast, United Kingdom, [3]Department of Haematology, Roskilde University Hospital, Roskilde, Denmark

Background: Vorinostat, a histone deacetylase (HDAC) inhibitor has shown promise in a number of haematological malignancies including myeloma, lymphoma and myelodysplastic syndromes. Inhibition of histone deacetylases leads to arrest of tumor cell growth, differentiation and increased apoptotic cell death. The role of HDAC inhibitors in myeloproliferative neoplasms were described by Guerini *et al* (2008) who demonstrated the arrest of proliferation in polycythaemia vera (PV) and essential thrombocythaemia (ET) haemopoietic cells.

Aims: We describe our experience using Vorinostat as an alternative agent in therapy resistant ET.
Methods: A phase II study evaluating vorinostat in ET and PV reported early discontinuations due to adverse events, and poor tolerability (Andersen *et al* 2013). Two patients at our institution continued vorinostat in a compassionate use programme following this phase II study. We describe herein their on-going responses.
Results: Patient 1, a 54 years old male with *CALR* positive ET since 2001 complicated by a left internal capsule infarct, chronic kidney disease and leg ulcers whilst on hydroxycarbamide (HU). Despite dose escalation he was unresponsive to standard therapy with HU and anagrelide (ANA). On initiation of vorinostat 400 mg daily, his Haemoglobin (Hb) concentration was 103g/L (130 – 150g/L), leukocyte count 12.3x 10^9/L (4.0 – 11.0x 10^9/L), platelet count was 978x 10^9/L (150-400x 10^9/L), and creatinine was 151 umol/L (59-104 umol/L) (EGFR 42). Shortly following commencing on Vorinostat, there was a notable decline in his renal function to 201umol/L (EGFR to 29), thus a dose reduction to 300 mg daily was made with satisfactory control of platelet count. The only side effect he reported was dysgeusia, which did not impact on his activities of daily living. He has now been on Vorinostat for 51 months; over this time, the vorinostat dose was gradually reduced with overall stable platelet count control. His current maintenance dose is 100 mg/200 mg alternate days with a platelet count of 367x10^9/L at last clinic visit. Renal function has remained stable throughout therapy; the most recent creatinine level was 171umol/L (EGFR 36). The second patient, a 53 year old male also had CALR positive ET, diagnosed in 2004. He had a history of a previous cerebrovascular accident and was symptomatic from his ET; his main complaints were profound pruritus and fatigue. Both blood counts and symptoms were resistant to treatment with busulphan, HU, interferon and ANA. When vorinostat was initiated his Hb concentration was 128g/L, leukocyte count 5.3x10^9/L and an unstable platelet count that ranged between 315 – 947x10^9/L. To date the patient has been on vorinostat 52 months with minimal side effects. Vorinostat 300mg/400mg alternate days has reduced his symptom burden and maintained the platelet count below 800x 10^9/L with no thrombotic or haemorrhagic events. Renal function has remained stable; creatinine level on commencing therapy was 77umol/L (EGFR 92) increasing to 104umol/L (EGFR 64) at last clinical visit.
Summary and Conclusions: Although displaying two contrasting clinical courses on vorinostat, both patients have demonstrated a prolonged clinical response with symptom and platelet count control. Therefore, we conclude that vorinostat may offer selected patients resistant to standard therapy an alternative agent in ET when options are often extremely limited.

PB1917

UTILITY OF NEXT-GENERATION SEQUENCING FOR INTEGRATED MOLECULAR PROFILING OF PRIMARY MYELOFIBROSIS USING ION TORRENT PGM SYSTEM

V. Shivarov[1,*] M. Ivanova[2], E. Naumova[2]
[1]Laboratory of Clinical Immunology, Sofiamed University Hospital, [2]Department of Clinical Immunology, Medical University of Sofia, Sofia, Bulgaria

Background: In the last decade a number of genes have been reported to be recurrently associated with primary myelofiborsis (PMF). While some mutations such as *JAK2* V617F and *MPL* exon 10 mutations are easily detectable by conventional molecular genetics methods other mutations are more difficult for screening because of lower frequency and being scattered along large genomic ranges. On the other hand, newly developed approaches for next-generation sequencing (NGS) provide an affordable solution for targeted multiplex resequencing of up-to several hundreds of amplicons.
Aims: Here, we aimed at the development and validation of a novel custom panel for targeted resequencing of PMF samples using the Ion PGM™ System (Ion Torrent, USA).
Methods: We designed a pool of 424 primers for amplification of 212 amplicons covering 99.46% of the exonic regions of 9 human genes as follows: *ASXL1*, *EZH2*, *CALR*, *RUNX1*, *SETBP1*, *SF3B1*, *SRSF2*, *TET2* and *U2AF1*. Initial testing of the panel performance was done on Ion PGM™ machine using PGM™ 316 v2 chips on 8 DNA samples from PMF patients (6 males, 2 females, median age 61.5 years). Sequences alignment, variants calling and annotation were performed using Ion Reporter software.
Results: We identified a total of 22 nonsynonymos somatic coding variants in 7 out of 8 samples. The most frequently mutated gene was *TET2* (6 mutated samples out of 8). Two patients had mutations in *SRSF2*, and *CALR*, *EZH2* and *SETBP1* were found mutated in one sample each. No mutations in *RUNX1*, *SF3B1* and *U2AF1* were found. Overall, mutations rate was consistent with previous reports on PMF molecular profiling.
Summary and Conclusions: This small proof-of-concept study confirms the feasibility of Ion Torrent systems for resequencing of clinically relevant mutations in myeloid malignancies such as PMF. It can be particularly useful in cases without the most frequent clonal markers in PMF such as *JAK2*, *MPL* and *CALR* mutations.
Acknowledgements: The authors are thankful to Dr. Nina Petkova and Dr. Evgenii Hadzhiev for providing the clinical samples as part of the project ID_09_157 (National Science Fund, Bulgaria).

HYPEREOSINOPHILIA: A CENTER'S EXPERIENCE

I. Conde[1,*] D. Alves[1], S. Matos[2], B. Polo[1], E. Espada[1], A. Ferreira[1], S. Silva[1], I. Pereira[1], M. Neves[1], H. Martins[1], S. Mendes[1], J. Amaral[1], A. Alho[1], F. Velosa[1], S. Valle[1], C. Lopes[1], M.J. Costa[1], G. Esteves[1], C. Martins[1], F. Lourenço[1], R. Moreno[1], L. Guerra[1], J. Raposo[1], J. Alves do Carmo[1]
[1]Hematology and Bone Marrow Transplantation, Hospital de Santa Maria, [2]Genomed, Molecular Medicine Institute, Lisbon, Portugal

Background: Hypereosinophilias comprise a very heterogenous group of haematologic alterations. They are usually secondary to diseases affecting various organ systems, although they may also have clonal or idiopathic aetiologies. The differential diagnosis is crucial and has significant implications that affect the therapeutic decision. According to the World Health Organization Classification (WHO) 2008, clonal hypereosinophilias are included in lymphoid and myeloid neoplasms associated with eosinophilia and platelet-derived growth factor receptor alfa (PDGFRA), platelet-derived growth factor receptor beta (PDGFRB) or fibroblast growth factor receptor 1 (FGFR1) abnormalities. Screening for rearrangements of these genes to document clonal eosinophilias, in which the tyrosine kinase inhibitor Imatinib has demonstrated effectiveness as a first-line agent, is fundamental since the treatment of reactive hypereosinophilias and idiopathic Hypereosinophilic Syndrome (HS) is, respectively, that of the underlying condition and systemic corticosteroids.
Aims: Analysis of patients with peripheral blood (PB) or bone marrow (BM) hypereosinophilia screened for PDGFRA and PDGFRB gene rearrangements and evaluation of response to treatment.
Methods: Retrospective analysis of patients with PB (>1500/uL) or BM (>5%) hypereosinophilia screened for PDGFRA and PDGFRB gene rearrangements, between 2008 and 2014.
Results: PDGFRA and PDGFRB gene rearrangements were screened in 23 patients with hypereosinophilia: of these 12 had secondary aetiologies and 11 were primary. Of the secondary eosinophilias, 4 were due to parasitic infestation, 4 allergic, 2 lung diseases, 1 systemic mastocytosis and 1 T cell lymphoma. Of the primary eosinophilias (11): 4 patients had PDGFRA rearrangements, 2 of them associated with T-ALL; 2 had PDGFRB rearrangements; 3 had HS; 1 had chronic eosinophilic leukemia and 1 myeloproliferative neoplasm. Out of the 6 patients with PDGFRA or PDGFRB rearrangements, 1 died before starting treatment, 1 had no criteria for therapy iniciation and all 4 treated with Imatinib (100-400mg/day) had good tolerance and hematologic response with 2 achieving molecular response. The median eosinophil count at presentation was 1780/uL (Q1 382.5; Q2 1787.5).
Summary and Conclusions: Our data is in agreement with the literature regarding the incidence of primary hypereosinophilias and the therapeutic efficacy of Imatinib, with response rates >80%.
Disclosure of Interest: none declared

PB1919

HOW DIAGNOSTIC AND THERAPEUTIC APPROACHE CHANGED IN THE LAST DECADES IN THE PHILADELPHIA NEGATIVE MPN PATIENTS OF THE REGISTRO ITALIANO TROMBOCITEMIE (RIT)

L. Gugliotta[1,*] A. Iurlo[2], G. Gugliotta[1], A. Tieghi[3], A. Candoni[4], M. Lunghi[5], A. Dragani[6], E. Antonioli[7], P.R. Scalzulli[8], V. Martinelli[9], B. Martino[10], M.L. Randi[11], A. Background: The last decade starts for the patients with Philadelphia Neg-MPN after the JAK2 mutations discovery (2005), the Italian guidelines for Essential Thrombocythemia therapy (2004), and the WHO classification (2001)
Aims: To evaluate how the diagnostic and therapeutic approach changed in the clinical practice in the last decade.
Methods: The patients of the Registro Italiano Trombocitemie (RIT) diagnosed before and after 2005 were compared by considering demography, clinico-biological characteristics at diagnosis, and the initial treatment approach.
Results: The 2418 analyzed patients were diagnosed (PVSG or WHO criteria) before 2005 (Group I, n 1230, 51%) and after 2005 (Group II, n 1188, 49%). The patients of Group II, as compared with those of Group I, had at diagnosis older age (median 60 vs 55 y, p60 y in 50% vs 41%, P<0.001), higher rate of comorbidities (56% vs 49%, p 0.002), and lower median PLT count (748 vs 786x109/L, P< 0.001). No significant differences were found for gender (males 38% vs 38%), prior thrombosis (20% vs 20%), prior hemorrhage (4.9% vs 5.6%), CV general risk factors (71% vs 68%), symptoms (41% vs 41%), splenomegaly (25% vs 23%), hepatomegaly (22% vs 24%), WBC count (median 8.7 vs 8.5x109/L; >10x109/L 28% vs 27%), and HCT level (median in males 44.8% vs 44.1%; median in females 41.5% vs 41.0%). The bone marrow biopsy in the first year was performed more frequently (76% vs 67%, P<0.001). The test for JAK2 mutation was performed in 89% of Group II patients, and, a posteriori, in 72% of Group I patients (P<0.001). The patients of Group II had a higher rate of JAK2 V617F mutation (62% vs 56%, p 0.015), and of allele burden<25% (65% vs 51%, P<0.01). Moreover, the patients of Group II had a higher rate of standard high thrombotic risk (57% vs 49%, P<0.001).During the first year after diagnosis, an antiplatelet (+ or-cytoreductive) treatment (almost always low dose aspirin) was started more frequently in the Group II (65% vs 48%, P<0.001), particularly (P<0.001) in patients at low thrombotic risk (standard and IPSET-Th). Similarly, a cytoreductive (+ or-antiplatelet) treatment was started more frequently in the Group II (57% vs 50%, p 0.002), particularly (74% vs 68%, p 0.013) in patients with high thrombotic risk (standard and IPSET-Th). In the Group II, as compared with Group I, the rate of hydroxycarbamide use was higher for patients over 60 y (71% vs 63%, P<0.01) and lower for those below 40 y (8% vs 14%, P<0.05), while the rate of anagrelide use was higher for patients below 40 y (6.4% vs 2.7%, P<0.05).
Summary and Conclusions: The patients of the RIT diagnosed after 2005, compared with those diagnosed before, although were older, had more frequently a bone marrow biopsy at diagnosis. They had lower platelet count, higher rate of JAK2 V617F mutation, and higher rate of high thrombotic risk. No significant differences were found for gender, prior thrombosis, CV general risk factors, symptoms, splenomegaly, WBC count. During the 1st year, they were treated more frequently with antiplatelet drugs (particularly if at low thrombotic risk), and with cytoreductive drugs (particularly if at high thrombotic risk). The hydroxycarbamide use increased in older patients, while the anagrelide use increased in younger ones. In conclusion, in the real life of the RIT centers, a significant improvement of the diagnostic and therapeutic approach was documented in the last decade.

PB1920

ATHEROSCLEROSIS AND RELATED FACTORS IN PATIENTS WITH PHILADELPHIA-NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

M. Demir[1,*] E. Umit[1], S. Uyanik[1], V. Ermis[2], S. Tuncel[2], G. Pamuk[1]
[1]Hematology, [2]Radiology, Trakya University Faculty Of Medicine, Edirne Turkey, Edirne, Turkey

Background: Cardiovascular diseases,thrombohemorrhagic complications, bone marrow failure due to myelofibrosis and leukemic transformation are the major causes of mortality and morbidity in patients with Philadelphia negative chronic myeloproliferative neoplasms (MPNs). Chronic inflammation is also suggested to play a role in the development of atherosclerosis in this group of patients.
Aims: We aimed to evaluate the prevalance of subclinical atherosclerosis in patients with essential thrombocythemia and polistemia vera with the terms of conventional risk factors like lipid profile and carotid intima media thickness (CIMT).
Methods: 100 patients with Philadelphia negative chronic MPN and 50 age and gender matched healthy controls were enrolled in our study. We determined the lipid profile, fasting blood glucose, body mass index and CIMT of both groups.
Results: Mean age of patient group was 58.46 years (26-86 years). 44 were female (44%) and 56 were male (56%). In the control group, mean age was 58.68 years (37-67 years), 24 were female (48%) and 26 were male (52%). Duration of disease was 1 to 14 years (mean 5.81). In the medical history of patients venous thromboembolism was present in 10 patients (10%) and arterial thromboembolism was present in 28 patients (28%). 1 patient had diabetes (1%) and 34 patients had hypertension (34%). Levels of cholesterol, LDL, HDL, triglyceride, fasting blood glucose and body mass indexes were similar in both groups. Over 1 cm thickness was accepted as plaque. Plaque was observed on the right in 3 patients (%3) while on the left in 8 patients (%8). No patients had plaque on both carotid arteries. In the control group, 3 patient had plaque on the right carotid artery (6%) and 2 patient had on the left carotid artery (4%, total 10%). CIMT was related with age, disease duration, body mass index, levels of total cholesterol, LDL and absolute leucocyte count while not related with gender, fasting blood glucose, levels of HDL, triglyceride, hemoglobin, hematocrite and thrombocytes. Logistic regression analysis of age, disease duration and presence of plaque showed a relation with disease duration and presence of plaque (P=0.001). In patients with a history of arterial thrombosis, 6 had plaque (21.4%) while in patients with a history of venous thrombosis, 5 was observed to have plaque (50%), though no relation was observed with logistic regression analysis.
Summary and Conclusions: During the course of chronic MPNs, a chonic inflammatory process with thromboembolic complications is certain. Development of subclinical atherosclerosis is related with traditional risk factors like hypercholesterolemia as well as disease duration independent of age.

PB1921

RELATIONSHIP BETWEEN HUMAN PLATELET ANTIGEN-1 GENE POLYMORPHISM AND ASPIRINATED PLATELETS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

R. Cacciola[1,*] E. Gentilini Cacciola[2], A. Cipolla[2], M. Torre[2], E. Cacciola[2]
[1]Experimental and Clinical Medicine, [2]Institute of Haemostasis, Catania, Italy

Background: Essential thrombocythemia (ET) is a myeloid neoplasm characterized by platelet activation and thrombotic risk. Aspirin (ASA) is the standard therapy to prevent the thrombosis. It is reported that thrombocythaemic patients have ASA insentivity. It is debated if inherited thrombophilia induces the thrombocythemic platelet activation and, hence, the ASA platelet insensitivity.
Aims: Therefore, we evaluated human platelet antigen-1 (HPA-1) gene polymorphism, as thrombophilic molecular mutation associated with platelet hyperfunction, platelet count, b-thromboglobulin (b-TG) and platelet factor 4 (PF4), as markers of platelet activation, the platelet functional activity (PFA) as indicator of ASA platelet sensitivity and the maximum clot firmness (MCF), as indicator of aspirinated platelet contribution to clot firmness. We studied 48 patients (4 men, 8 women; mean age 51 years, range 32-70) with ET according to WHO criteria.
Methods: The mean duration of disease was 11 years. All patients were on ASA 100 mg once daily. Fifty subjects served as controls. The genotype HPA-1 was determined using a commercialized polymerase chain reaction kit with sequence-specific primers. Platelets were measured by automated analyzer. b-TG and PF4 were determined by ELISA. ASA platelet sensitivity and MCF were measured by Platelet Function Analyzer (PFA-100) and by ROTEM delta, respectively.
Results: Of 48 patients, 36 were HPA-1a/1a and 12 were HPA-1a/1b. The mean platelet count was 462±240x109/L. All patients had high b-TG and PF4 (244±15 IU/mL vs 20±11 IU/mL and 162±56 IU/mL vs 6±2 IU/mL, respectively) (P<.0001 and P<.0001, respectively), prolonged C/EPI closure time (CT, unit: s, n.v. 84-160 s) (252±48 s) and normal MCF (MCF, unit: mm, n.v. 50-72 mm) (71±2 mm).
Summary and Conclusions: These findings suggest that HPA-1 gene polymorphism does not inhibit aspirinated platelets sensitivity in patients with ET.

PB1922

BIOMARKERS FOR PREDICTION OF THROMBOSIS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA (ET)

M. Podolak-Dawidziak[1,*] I. Prajs[1], K. Kuliczkowski[1]
[1]Hematology and Bone Marrow Transplantation, Wroclaw Medical University, Wroclaw, Poland

Background: Arterial or venous thrombotic events occurs in 15% of essential thrombocythemia (ET) cases at presentation and in 10% to 20% during the disease course. The pathogenesis of thrombosis in ET is multifactorial and not yet clear. Prevention of thrombohaemorrhagic events is the important goal of the ET therapy.
Aims: The aim of this study was to examine biomarkers for prediction of possible prothrombotic condition in patients with essential thrombocythemia.
Methods: Diagnosis of ET based on the WHO criteria (2008). The study was approved by the Ethics Committee of the Medical University of Wroclaw and was performed in accordance with the Declaration of Helsinki. Each patient has been tested using Ceveron alpha (Technoclone) for fibrinogen (F) (Fibrynogen Reagent, Technoclone), factor VIII (Siemens test), D-dimer (Technoclone), pro-

tein C (PC) (TECHNOCHROM® Protein C, Technoclone), activated protein C resistance (APCR) (APC Restance Kit Technoclone), thrombin generation and microparticles (MPs) (TECHNOTHROMBIN® TGA (Technoclone). The activation markers thrombin-antithrombin complexes (TAT) and prothrombin fragment F_{1+2} (F1+F2) were determined by ELISA using kits from Enzygnost micro, Simens). Testing for the factor V Leiden mutation (FVL mutation) and prothrombin gene mutation was accomplished by the PCR on peripheral blood leukocyte DNA.
Materials: The study group consisted of 45 patients with ET (13 males and 32 females; mean age 61) and 45 healthy subjects (28 males and 17 females; mean age 62). The *JAK2V617F* mutation was present in 25 ET patients. Twenty-one patients experienced thrombotic events, 12 had arterial thrombosis (myocardial infarction in 6, TIA in 3, and peripheral arterial disease in 3 and 8 had deep venous thrombosis in 8 patients. Out of 45 ET patients 35 were treated with anagrelide and 8 with hydroxyurea.
Results: In ET patients the median level D-dimer was significantly higher compared to control (183.2 vs 18.5 ng/mL; P=0.00018), but not fibrinogen level, TAT, F1+F2, FVIII activity and protein C activity. Neither thrombin generation (TG) nor microparticles (MPs) were elevated in ET patients. Five of 45 ET patients had the activated protein C resistance (APCR), and in two of them the heterozygous type of FVL was confirmed. Prothrombin gene mutation was not present in the ET group.
Summary and Conclusions: Conclusions: D-dimer has been shown as a valuable biomarker for prediction of thrombotic events in patients with essential thrombocythemia, and the knowledge of carriership of FVLeiden can be used in the individual thrombosis risk assessment.

PB1923

CLINICOPATHOLOGIC CHARACTERISTICS OF UNCLASSIFIABLE MYELOPROLIFERATIVE NEOPLASMS

J. Huh[1,*] Y.C. Mun[2], C.M. Seon[2], W.S. Chung[1], H.J. Huh[3]
[1]Department of Laboratory Medicine, [2]Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, [3]Department of Laboratory Medicine, Dongguk University, Ilsan Medical Center, Ilsan, Korea, Republic Of

Background: According to WHO classification 2008, myeloproliferative neoplasm, unclassifiable (MPN-U) is defined as neoplasms that has MPN features but fails to meet the criteria of any specific MPN entities, or that has two or more characteristics of MPN entities. Accurate diagnosis of each MPN subgroup is important because each subgroup could show different clinical courses; leukemic transformation rate at 20 years is estimated at<10% for polycythemia vera (PV) and<5% for essential thrombocythemia (ET) and fibrotic transformation rates are slightly higher (Tefferi A. Am J Hematol 2015;90:162). The prognosis of primary myelofibrosis (PMF) is significantly poor, compared with those of PV or ET.
Aims: The clinicopathologic characteristics of MPN-U are needed to be cleared so that we could assign MPN-U to specific subtypes, if possible. The purpose of this study was to identify characteristics of laboratory findings, bone marrow pathology, genetic aberrations and clinical course in MPN-U.
Methods: The study group included 8 patients diagnosed as having MPN-U based on WHO 2008 criteria from 2000 to 2014. Median follow up period was 59 months (range 8-91 months). The mutation analysis of JAK2, MPL and CALR was performed by real time PCR or direct Sanger sequencing. Whole genome single nucleotide polymorphism array (SNP-A) (SNP 6.0, Affymetrix, CA) based karyotyping and target exome sequencing (Ion AmpliSeq Comprehensive Cancer panel, Life Technologies) were performed according to manufacturer's instructions.
Results: Five patients with thrombocytosis (450-991x10^6/L) and normal or mild leukocytosis(7.6-14.9x10^6/L) showed upper normal hemoglobin (16.1-17.4 g/dL in 2 men, 15.9-16.1 g/dL in 3 women), but, not met PV criteria of WHO 2008 (Hb >16.5 g/dL for women and 18.5 g/dL for men). Hypercellularity with trilineage proliferation for ages was found in 4 patients and megakaryocytic atypia was found in 1 patients. All patients showed normal karyotype and *JAK2 V617F* mutation. Of them, two patients showed one or more mutations in addition to *JAK2* : 1 patient had *JAK2, DNMT3A, and C-KIT*; 1 patient *JAK V617F* and *CSF1R*. In the other hand, a 73-year old female patient with high hemoglobin (Hb 16.3 g/dL) had neither *JAK2 V617F* nor *CALR* mutation and the laboratory findings were as follows; WBC 15x10^6/L, platelet 1,290x10^6/L, low levels of erythropoietin and panhyperplasia with megakaryocytic atypia. There was no one progression showing hemoglobin levels which met the criteria for typical PV during follow up period. Taken together, these patients didn't meet the hemoglobin criteria for PV, but we can't exclude the possibility of pre-PV phase. In two patients developed myelofibrosis, the initial laboratory findings met neither the criteria of PMF nor ET fully. One patient (55-year old female) developing myelofibrosis at 33 months after initial diagnosis showed *CALR* mutation and copy neutral-loss of heterozygosity of 19p13.3-p13.12 region (including *CALR* gene) by SNP-A based karyotyping. The other laboratory findings were as follows: Hb 13.8 g/dL, WBC 6x10^6/L, platelet 1,626x10^6/L, increased LDH, normocellularity for ages and megakaryocytic atypia. The other patient (62- year old female) developing myelofibrosis at 6 months showed dual mutations of *MPL* and *SF3B*1, Hb 13.0 g/dL, WBC 17x10^6/L, platelet 930x10^6/L, increased LDH, hypercellularity for ages, but not significant megakaryocytic atypia. These findings suggested that these two patients may be prefibrotic stage of PMF at initial diagnosis.
Summary and Conclusions: This study suggests that MPN-U could include pre-PV or prefibrotic-PMF. Therefore, the pathologists need to assign a more specific diagnosis in MPN-U and further follow up study is recommended to provide a more precise classification in MPN-U patients.

PB1924

IS THERE A ROLE FOR A NEW REGISTRY IN PV? EARLY ASSESMENT OF A NEW MPN REGISTRY IN HUNGARY

M. Egyed[1,*] P. Dombi[2], A. Illes[3], J. Demeter[4], L. Homor[5], M. Udvardy[3]
[1]Department of Hematology, Somogy County Kaposi Mor Teaching Hospital, Kaposvar, [2]Department of Hematology, Szent Borbala County Hospital, Tatabanya, [3]Department of Hematology, University of Debrecen Faculty of Medicine, Debrecen, [4]First Department of Internal Medicine, Division of Hematology, Semmelweis University of Budapest, [5]Faculty of Humanities and Social Sciences, Pazmany Peter Catholic University, Budapest, Hungary

Background: A new MPN registry,based on the database of available patient data and a disease specific questionnaire were conducted and used in several Hungarian hematology centers.
Aims: The aim of the survey was to collect data of Philadelphia negative MPN patients, in order to establish a Hungarian MPN registry.
Methods: There was close cooperationbetween hematologists and information technicians (IT) experts to create an easily evaluable questionnaire. Data of classical MPN patients were collected from Hungarian centers. The thrombotic risk and the risk adapted treatment characteristics were stratified according to the Landolfi criteria. In this review the data of 408 patients (57% male) registered as having PV,were analysed. The data entry (Table 1)started at 2014 and the centers entered their patients data, diagnosed between 1989-2014.
Results: There were 820 evaluable MPN patients till the initial assesment deadline(15th Feb 2015) In the 408 evaluable PV pts the average time from diagnosis was 7.6 years, and about 50% of them were diagnosed more than 5 years ago. The number of evaluable cumulative patient years was 3016.
Among the 408 PV patients there were 80%(327) JAK2 V617F positive,13%(52) of them were JAK2 V617F negative. JAK status was missing in 7%(29)of patients.The detailed analysis of the JAK negative group revealed that 6 of them had an elevated hemoglobin + 2 positive minor criteria, fulfilling the 2008 WHO criteria, therefore they had proven PV.The other 67 patients did not fulfill the WHO diagnostic criteria of PV,they were identified as …insufficient" and therefore their data have not been included into the present evaluation. According to the Landolfi thrombotic risk stratification there were 73 patients stratified as low/moderate risk. They have to be treated with phlebotomy and ASA only. 44 (60%) of them were treated with phlebotomy and only 25(34%) with ASA. 45(62%) of them were treated with cytoreductive drugs-mainly with hydroxyurea 36pts(49%), 1 with a JAK inhibitor,1 with anagrelide,and 1 with HU+anagrelide+ASA combination. Seven pts.(10%) received interferon-alfa. Among them 8 thrombotic events and no transformation was observed, thus, according to the Landolfi risk treatment criteria, patients in this group were overtreated. In the high /extremely high risk group there were 260 patients. 35% had thrombotic events prior to diagnosis. 32% had a thrombotic event after the diagnosis. Disease transformation has been found in 10% of the patients (MF 22 pts, AML 2 pts, lymphoproliferative neoplasia in two patients.) 6% of registered PV patients had bleeding episodes

Table 1: **PV patients, year of diagnosis**

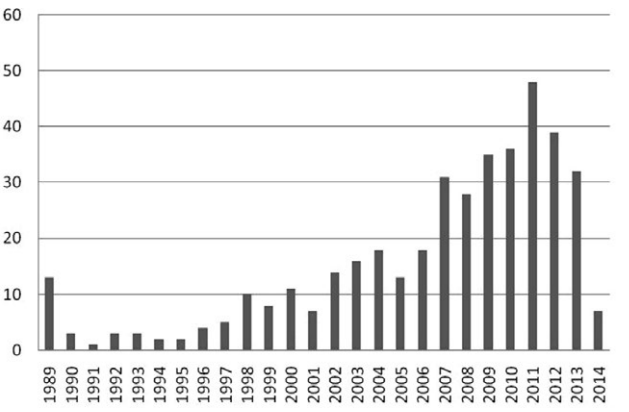

Figure 1.

Summary and Conclusions: The main aim of the questionnaire was to create a national registry of MPN patients and to help our colleagues how to stratify the thrombotic risk and to choose the proper treatment. To date it remains unanswered whether low risk patients need cytoreductive treatment to prevent

thrombotic events? Our data show an increase of thrombotic events in low risk patients treated with cytoreductive drugs (8 pts treated with cytoreductive drugs *versus* no patient treated with phlebotomy and ASA), thus arguing against treating these patients with cytoreductive drugs.Our results show the risk of thrombotic and hemorrhagic complications in PV to be comparable to published results. Based on our data we are convinced that the new national registry helps to give a good feedback about our diagnostic and treatment habits in PV.

PB1925

EARLY EXPERIENCE WITH THE ESTABLISHMENT OF A REGISTRY FOR PHILADELPHIA-NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS (MPN) IN HUNGARY

P. Dombi[1,*] M. Egyed[2], A. Illes[3], J. Demeter[4], L. Homor[5], M. Bodnar[6], L. Szerafin[7], Z. Simon[3], M. Udvardy[3]
[1]Department of Hematology, Szent Borbala County Hospital, Tatabanya, [2]Department of Hematology, Somogy County Kaposi Mor Teaching Hospital, Kaposvar, [3]Department of Hematology, University of Debrecen Faculty of Medicine, Debrecen, [4]First Department of Internal Medicine, Division of Hematology, Semmelweis University of Budapest, [5]Faculty of Humanities and Social Sciences, Pazmany Peter Catholic University, Budapest, [6]Department of Internal Medicine, Carolina Hospital, Mosonmagyarovar, [7]Department of Internal Medicine, Josa Andras County Hospital, Nyiregyhaza, Hungary

Background: Considering and realising the remarkable heterogeneity of MPN care in Hungary an MPN Working Group has been established in year 2012.
Aims: The Hungarian MPN Working Group created our MPN Registry in 2013, the aims were: (1) to gain epidemiological, diagnostic, therapeutic data, to follow up complications and disease transformations. (2) to investigate the adherence to the WHO/2008 diagnostic criteria and to the Landolfi therapeutic guidelines, to gain insight into vascular and haematological complications. (3)Try to identify crucial issues and possible gaps, and promote internationally accepted, standard care in MPN.
Methods: The basis of the Hungarian MPN registry was the former Regional Centre of the Hungarian Academy of Sciences, Veszprém. The questionnaire had been thoroughly updated regarding the 2008 WHO diagnostic criteria (morphology, mutations, etc.)with focus on complications, risk stratification and treatment. The electronic platform can be continuously updated as needed by our steering committee (new molecular results *e.g.* calreticulin mutations can be included). All haematologists using the system are entitled to initiate search and association analysis. Our MPN Registry is legally permitted by our authorities (ETT-TUKEB).
Results: During the two active years of the Hungarian MPN Registry 15 of our major or smaller haematological centers provided patient data, alltogether reaching the evaluable patient number of 820. Even if some major centers data are still missing probably our data are representative enough to characterize MPN patient care in our country. The most important data are summarised in Table. I. The complex multiparametric analysis of vascular events (venous, arterial, minor, major) correlation with haematocrit, cell counts (platelet, leukocyte, monocyte), Landolfi score, traditional vascular risk factors, treatment modalities will be presented in details. We detected some shortcomings regarding the diagnostic evaluation of some JAK2V617F negative PV and some myelofibrosis cases, this will be shown in a separate poster (M. Egyed *et al.*) Treatment modalities have been analysed in depth, both regarding treatment modalities (*i.e.* phlebotomy, ASA, cytoreductive drugs, interferons, JAK inhibitors,etc.) and in the context of cell counts, vascular complications and risk stratification. Even if the observation was short, we found interesting transformation patterns in PV (408 patients): myelofibrosis 22, MDS-AML in two patients, secondary lymphoproliferative disease in two patients.

Table 1.

Table 1: **Data of the registry for Philadelphia-negative chronic myeloproliferative neoplasms (MPN) in Hungary**

Diagnosis	Number of registered patiens	Gender female/male	JAK2 V617F positive *	JAK2 V617F negative *	Thrombotic event before diagnosis JAK2+/JAK2-	Vascular event during follow up JAK2+
PV	408	176/232	327	52	90/12	81
ET	337	229/108	218	103	42/21	27
MF	30	15/15	14	12		
Complex, overlap	45	28/17				

* Till the initial assesment deadline (15,Febr.2015) some data are missing

Summary and Conclusions: 1. We have created a national MPN Registry covering a large part of Hungary. The database is operational, online, user-friendly, easily adjustable to the new professional needs. It is convenient for complex search, correlation and other multiparametrical analysis. The data collected so far are in concert with the international epidemiological data. 2. In addition, it gives a valuable reflection on the adherence to the diagnostic and therapeutic standards, revealing some heterogenities. The Hungarian MPN Working Group decided to help small centers to render better diagnostic possibilities (rare genetic alterations and determination of von Hippel Lindau mutation). The Steering Committee tries to facilitate patient enrollment to new MPN drug multicenter trials, too. 3. The early results of our database clearly show that important correlations could be made or further confirmed regarding vascular events, cell counts, monocyte number, etc. In spite of the short observation period patients with non-myeloid transformation were also found deserving further attention.

Background: An increase of allele burden and development of homozygosity with the JAK2 gene V617F mutation is well-known in polycythemia vera (PV) patients (Vannucchi AM et al, Leukemia 2008). However, the homozygosity development of specific for PV mutations in JAK2 exon 12 has been much less studied.
Aims: The aim of this study was detection and quantification of JAK2 exon 12 allele burden in JAK2 V617F- negative PV patients using a pyrosequencing method.
Methods: The 10 DNA samples from JAK2 V617F- negative patients with confirmed clinical diagnosis and bone marrow morphological features have been selected. The informed consents from these patients were obtained. The nucleotide sequencing of the JAK2 exon 12 fragment was performed by pyrosequencing method as described in (Mironov K et al, Spravochnik zav clin lab, 2011). The routine sample preparation and PCR kits («AmpliSens», Russia) we used. Pyrosequencing was carried out with «PyroMark Q24» using «PyroMark Gold» kit («Qiagen», Germany). To verify the presence of mutations, the DNA sequences extracted from the clinical samples were cloned into pGem-T vector using standard protocol («Promega», USA), and obtained clones were sequenced using reagents and equipment of the «Applied Biosystems» (USA).
Results: Among 10 of JAK2 V617F-negative PV patients, a N542-E543del mutation of JAK2 in exon 12 has been detected in one 62-year old male patient. On the onset of the disease in July 2013 he had a pronounced plethoric syndrome, Hb 204 g/l, HCT 49.9%, RBC $6.43x10^{12}$/l, WBC $8.0x10^{9}$/l, PLT $250x10^{9}$/l. The level of JAK2 exon 12 N542-E543del allele burden was 19%. The patient was treated phlebotomy only and did not received any cytoreductive treatment during 18 months. After these 18 months, the patient characterized with presence of moderate splenomegaly, level of Hb 171 g/l, HCT 61.3%, RBC $9.03x10^{12}$/l, WBC $7.47x10^{9}$/l, PLT $500x10^{9}$/l. The level of JAK2 exon 12 N542-E543del allele burden was increased up to 68%.
Summary and Conclusions: A pyrosequencing with «PyroMark Q24» was able to identified mutations in JAK2 exon 12 and it demonstrated a possibility that N542-E543del mutation is evolving into homozygous form in the same manner as described for the JAK2 V617F mutation.

PB1927

SCREENING PCR FOR DETECTION OF CALR MUTATIONS IN PATIENTS WITH THROMBOCYTOSIS

J.H. Jeong[1], H.T. Lee[1], J.Y. Seo[1], P.W. Park[1], Y.H. Seo[1], K.H. Kim[1], M.J. Kim[1], J.H. Lee[2], J. Park[2], J.S. Hong[2], J.Y. Ahn[1,*]
[1]Laboratory Medicine, [2]Internal medicine, Gachon University Gil Medical Center, Incheon, Korea, Republic Of

Background: *JAK2* and *MPL* mutation play an important role in diagnosis of myeloid proliferative neoplasm (MPN). Another key marker in the molecular diagnosis of MPNs, mutations in *CALR*, was recently reported. Known mutations are all located at exon 9 and they are somatic mutations of deletion or insertions; the two commonest abnormalities account for 80-90% of *CALR* mutations, whereas lesions are highly heterogeneous in the remaining 10-20%.
Aims: Almost previous reports analyzed *CALR* mutations using Sanger sequencing. However, sequencing method can't be used easily in every laboratory condition. Authors want to make an easy system to detect *CALR* mutations which is available in small laboratory without sequencing machine. We investigated the screening PCR to detect *CALR* mutations in Korean patients with thrombocytosis and compared the results with Sanger sequencing.
Methods: Bone marrow DNA samples were obtained from 83 patients with thrombocytosis. Screening PCR primer sets were designed to detect the wild

type (product: 357 bp), type 1 mutation (product: 302 bp) and type 2 mutation (product: 262 bp) in one reaction (Figure 1). And Sanger sequencing was done in hot spot region.

Results: *JAK2V617F* was detected in 36 patients (33 ET, 1 PMF, 1 MPN, U, and 1 MDS/MPN, U) (Table 1). Two kinds of *CALR* mutation, type 1 (c.1092_1143del) and type 2 (c.1154_1155insTTGTC) were detected in 16 ET and 1 PMF patients. In ET group, mutational frequencies were 62.3% for *JAK2V617F* and, 30.2% for *CALR*, 5.7% for dual positive and 13.2% for dual negative. Among the ET patients without *JAK2V617F*, frequency of *CALR* mutation was 80%. The frequency of type 2 *CALR* mutation (8/16, 50.0%) was higher than type 1 (6/16, 37.5%). Interestingly, one patient with both mutations (1/16, 6.3%) was identified and novel mutation pattern (c.1123_1132delinsTGC) was detected by only Sanger sequencing. Any mutation was not detected in reactive disease group.

Table 1. The frequency of JAK2 and CALR mutations in different patient groups

Disease	ET	PMF	MDS/MPN, U	MPN, U	HES	Reactive	Total
	N=53	N=3	N=3	N=2	N=1	N=21	N=83
JAK2 mutation, N (%)	33 (62.3%)	1 (33.3%)	1 (33.3%)	1 (50.0%)	0 (0.0%)	0 (0.0%)	36 (43.4%)
CALR mutation, N (%)	16 (30.2%)*	1 (33.3%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	17 (20.5%)
Dual positive, N (%)	3 (5.7%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	3 (3.6%)
Dual negative, N (%)	7 (13.2%)	1 (33.3%)	2 (66.7%)	1 (50.0%)	1 (100.0%)	21 (100.0%)	34 (41.0%)
CALR mutation (%) in *JAK2* (-) patients	80%	50%					

**Type 1: 6 patients (37.5%); Type 2: 8 patients (50.0%); Type 1 & Type 2: 1 patient (6.3%) and novel mutation: 1 patient (6.3%)*

Abbreviation: ET; essential thrombocythemia, PMF; primary myelofibrosis, MDS/MPN,U; myelodysplastic syndrome/myeloproliferative neoplasm, unclassifiable, MPN,U; myeloproliferative neoplasm, unclassifiable, HES; hypereosonophilic syndrome, Reactive; reactive disease group with non-hematologic malignancy.

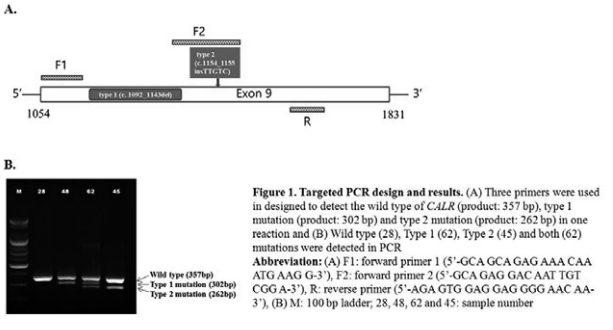

Figure 1. Targeted PCR design and results. (A) Three primers were used in designed to detect the wild type of *CALR* (product: 357 bp), type 1 mutation (product: 302 bp) and type 2 mutation (product: 262 bp) in one reaction and (B) Wild type (28), Type 1 (62), Type 2 (45) and both (62) mutations were detected in PCR
Abbreviation: (A) F1: forward primer 1 (5'-GCA GCA GAG AAA CAA ATG AAG G-3'), F2: forward primer 2 (5'-GCA GAG GAC AAT TGT CGG A-3'), R: reverse primer (5'-AGA GTG GAG GAG GGG AAC AA-3'), (B) M: 100 bp ladder; 28, 48, 62 and 45: sample number

Figure 1.

Summary and Conclusions: Screening PCR could detect the 94.1% (16/17) of mutation cases, and this method showed the concordant result with Sanger sequencing in the case of type 1 and type 2 mutations. One novel mutation was only identified with Sanger sequencing. Our system can't detect single base pair substitution or small base insertions like the mutation of this case; however, the frequency of these mutations is very rare. Therefore, this Screening PCR would be useful in small laboratory condition as a screening test for detection of *CALR* mutations.

PB1928

MYELOPROLIFERATIVE NEOPLASMS: TREATMENT APPROACH AND OUTCOMES, THE DREXEL University EXPERIENCE

S. Kaur[1,*]
[1]internal medicine, Drexel university/Hahnemann hospital, Philadelphia, United States

Background: Myeloproliferative neoplasms are a group of clonal disorders that arise from a transformation in a hematopoietic stem cell. These disorders consist of essential thrombocytosis (ET), primary myelofibrosis (PMF) and polycythemia vera (PCV). Several therapeutic agents have been used in the past to treat these disorders. Treatment strategies for these patients must consider the possibility of long-term survival, morbidity from thrombotic complications, transformation into myelofibrosis with myeloid metaplasia or acute myeloid leukemia, and the effect of specific therapies on the incidence of leukemic transformation and on pregnancy.

Aims: At Drexel University, a significant number of patients were treated with busulfan and were thought to have a more favorable clinical course and increased survival in comparison to other agents. In our study we analyzed the outcomes of patients treated in the practice of I. Brodsky Associates diagnosed with ET, PCV and PMF, who received a variety of treatment modalities, and compared their clinical courses to determine if there is a superior treatment.

Methods: This study is a retrospective cohort study in which we examined the medical records of patients treated for the diagnoses of ET, PCV and PMF at Hahnemann Hospital-Drexel University College Medicine in the practice of I. Brodsky Associates from January 1960 to December 2013. The following variables were measured and compared: age of the patient; sex of the patient; demographics; cytogenetics; family history; baseline hemoglobin level, hematocrit level, platelet count and WBC count; JAK 2 V617F mutation status; initial erythropoietin level, red cell mass, oxygen saturation, presence of splenomegaly and B12 level; Bone marrow biopsy results; thrombohemorrhagic complications; transformation to acute leukemia, progression to myelofibrosis and development of secondary malignancies; and treatment with busulfan, aspirin with or without clopidogrel, anegralide, hydroxyurea, and phlebotomy
Results: One hundred ninteen patients charts were reviewed. Twenty-four patients were given aspirin. One progressed to myelofibrosis (4%), seven patients were noted to have recurrent thrombotic episodes in the form of TIA, CVA, DVT/PE, and MI (29%). Thirty four patients were given Busulfan. Four patients progressed to myelofibrosis with MM (11%) and one patient progressed to CML (3%). Six patients were noted to have thrombotic events in the form of CVA, MI, subclavian vein thrombosis and carotid artery stenosis (17%). Twenty six patients were given hydroxyurea. One patient's course was complicated by Hodgkin's lymphoma (4%), four patients progressed to acute leukemic blast crises (15%), and three patients progressed to myelofibrosis (11%). Eight patients were noted to have multiple thrombotic events in the form of CVA, DVT, TIA, splenic vein thrombosis, and renal artery stenosis (31%). Twenty four patients were given Busulfan and Hydroxyurea together during their course of treatment. Fourteen patients were noted to have multiple thrombotic events in the form of PVT, SMV thrombosis, PE, TIA, Budd Chiari syndrome and LE arterial thrombosis (58%). Two patients progressed to CML blast crises (8%) and three patients developed myelofibrosis with MM (12%). Eleven patients were treated with only phlebotomy. Five patients progressed to myelofibrosis with MM (45%). Two patients were noted to have thrombotic events that included MI or TIA (18%)
Summary and Conclusions: Our study set out to discover if this unique treatment correlated with improved survival and less treatment toxicity. Busulfan and hydroxyurea given together proved to have the lowest rate of progression to leukemia and myelofibrosis when compared to other standard therapies. Patients treated with hydroxyurea and intermittent busulfan, were shown to have the best long-term outcomes. This suggests that physicians should include the use of busulfan in treating myeloproliferative neoplasms

PB1929

THROMBOTIC AND BLEEDING PROFILE IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA (ET)

F. Yus Cebrian[1,*] C. Coello de Portugal Casana[1], M. Tercero-Mora Rodriguez[1], N. Fernandez Mosteirin[2], G. Caballero Navarro[1], P. Delgado Beltran[1]
[1]Haematology, [2]Hospital Miguel Servet, zaragoza, Spain

Background: ET is a chronic myeloproliferative neoplasm, characterised by the presence of thrombohemorrhagic events (THE), the evolution to myelofibrosis and acute myeloid leukemia. The mutation of JAK2 exon 14 V617F is detected in 70% of the patients, and it is related to more THE and a higher number of leukocytes and platelets.
Aims: To analyze the thrombotic (T) and bleeding (B) clinical and analytical profile in patients with ET.
Methods: Clinical files of a sample of patients diagnosed of ET from 1990 to 2014 in our hospital, and that were evaluated in our center consultations for 12 months were reviewed. Demographic and analytical variables, type and THE's location, and the treatment received were analyzed.

Table 1.

		JAK 2		
		NEGATIVE	POSITIVE	NOT AVAILABLE

	YES	4	3	0
PRE DIAGNOSIS	NO	38	48	8
POST DIAGNOSIS	YES	7	2	0
	NO	35	49	8
ARTERIAL*				
PRE DIAGNOSIS		1	11	3
POST DIAGNOSIS		5	7	2
VENOUS*				
PRE DIAGNOSIS		2	4	2
POST DIAGNOSIS		0	2	0

Table 1. (*) Ratio arterial/venous 2,9

Results: 101 patients were valued, 34 ♂ (33.7%) and 67 ♀ (66.3%). *Mean age at diagnosis* 59.32 (♂ 56.53 and ♀ 60.73). A higher prevalence of male (38.2% *vs* 19.4%) was o*bserved in patients between 45 and 65 years,* in contrast to the group of ≥65 years where prevalence in women was higher (65,7% *vs* 52,9%).

39 events T in 35 patients, 29 arterial (74.3%) and 10 venous (25.7%) which is shown in the data table. T pre diagnosis: 6 in legs, 10 brain, 5 coronary, 1 thrombosis in lower cava, 1 central retinal vein, 78 without thrombosis. Post-diagnosis: 1 in legs, 5 brain, 9 coronary, 1 thrombosis in lower cava, 85 without thrombosis. 51 patients (50.5%) were JAK2 positive (+) and 24 of those presented T (61.5% of the total T), with regard to 7 in group JAK2 negative (-) (results were not available in 8 patients). 16 T (41.02%) were observed during the evolution of disease in 12 patients (11.9%), 4 of these patients didn´t received cytorreductive treatment, 14 antiplatelet therapy and 2 anticoagulantion. B was observed in 16 patients (5 JAK2 +/11 JAK2 -) mainly located in ORL mucous membranes and genitourinary. At diagnosis *no significant differences* were *observed* between hematologic values and development of T, however, patients who had developed B events had a higher platelet counts (>900x 10^9/L).
Summary and Conclusions: THE define the natural evolution of ET. B events, as shown in literature, are more frequent on mucous membranes levels and in patients with higher platelet counts. We observe a higher frequency of these events in patients JAK2-. A third of the patients developed T events in our series reaching values around 50% in JAK2+, with an incidence of arterial T similar to prospective studies. Despite antithrombotic prophylactic treatment after diagnosis and during the evolution of the disease, 10% of the patients developed T which suggests that a better stratification and control the T risk is needed.

PB1930

JAK-INHIBITORS COULD INDUCE HEPCIDIN DOWNREGULATION IN PATIENTS WITH MYELOFIBROSIS

R. Del Orbe Barreto[1,*] B. Arrizabalaga[1], L. Posada[1], M.I. Moreno[2], M.J. Moran[2]
[1]Hematology, Cruces University Hospital., Barakaldo, [2]Hematology, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Iron homeostasis is dysregulated in primary myelofibrosis (PMF), given the high prevalence of anemia, need for red blood cell (RBC) transfusions, and disease-associated inflammatory state. Recent data published by Pardanani *et al.* (Am. J. Hematol. 88:312–316, 2013) show that hepcidin levels in patients diagnosed with Myelofibrosis (MF) are considerably elevated (MF patients median 156,3 pg/mL, Healthy patients median 13,5 pg/mL) and are strongly correlated with serum ferritin levels and even increased hepcidin levels were associated with shortened survival.
Aims: To appraise serum hepcidin levels in MF patients treated with JAK inhibitors.
Methods: Plasma hepcidin levels were measured in six patients diagnosed with Myelofibrosis, all of them with intermediate-2 or high IPSS-risk, were on treatment with a JAK-1/JAK-2 inhibitor (Ruxolitinib) at least 6 months prior. All patients with transfusion dependence were receiving iron chelation therapy (except patient 1). The methodology for hepcidin measurement was DRG Hepcidin-25 (bioactive) ELISA kit. It is a solid phase enzyme-linked immunosorbent assay (ELISA) based on the principle of competitive binding (DRG Instruments GmbH, Germany). The microtiter wells are coated with a monoclonal (mouse) antibody directed towards an antigenic site of the hepcidin-25 molecule. Endogenous hepcidin-25 of a sample competes with a hepcidin-25-biotin conjugate for binding to the coated antibody. After incubation, the unbound conjugate is washed off and a streptavidin-peroxidase enzyme complex is added to each well. After incubation, unbound enzyme complex is washed off and substrate solution is added. The blue color development is stopped after a short incubation time, turning the color from blue to yellow. The absorbance of each well is determined at 450 nm with a microtiter plate reader. The intensity of color developed is reverse proportional to the concentration of hepcidin in the sample. A standard curve is calculated using a 4PL (4 Parameter Logistics) curve fit. The concentrations of the samples can be read directly from this standard curve. Data from serum ferritin level, transferrin saturation index and transfusion dependence was collected from their medical records.
Results: The results are summarized in the table.

Table 1.

	Serum Hepcidin	Serum Ferritin	Transferrin Saturation Index	Transfusion requirements
Patient 1+	94 ng/mL	8825 ng/mL	107.2%	4 units / month
Patient 2	12 ng/mL	223 ng/mL	45.4%	
Patient 3	40 ng/mL	1235 ng/mL	95.6%	3 units / month
Patient 4	24 ng/mL	116 ng/mL	20.9%	
Patient 5+	138 ng/mL	2091 ng/mL	60.4%	4 units / month
Patient 6	23 ng/mL	862 ng/mL	43.9%	

**median serum Hepcidin in control cohort: 9.8 ng/mL.*
+Dead.

Summary and Conclusions: In our cohort of patients diagnosed with Myelofibrosis we can observe elevated levels of hepcidin and its direct correlation with serum ferritin levels. In turn, we realize the hepcidin levels represent a negative prognostic factor in survival of these patients. Comparing hepcidin levels observed in our patients with the data published by Pardanani et al we can infer that Ruxolitinib plays a role in lowering serum hepcidin level.

PB1931

LEUKOCYTOSIS AS A RISK FACTOR FOR THROMBOTIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA (PH)-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

E. Simonovic[1,*] V. Colic[1]
[1]Internal, General Hospital Leskovac, Leskovac, Serbia

Background: Myeloproliferative neoplasms (MPNs) are a group of clonal hematopoietic stem cell malignancies, characterized by overgrowth of one or more blood lines with normal or nearly normal maturing of those cells in the bone marrow and extramedullary hematopoietic organs. MPNs are acquired prothrombogenic conditions. The mechanism of increased predisposition to thrombosis in myeloproliferative neoplasms is not clear enough. Elevated leukocyte count is an independent prognostic factor for the development of thrombosis. It is considered that activated neutrophils bind platelets influencing the increased expression of tissue factor and activation and damage of endothelial cells, especially in JAK2V617F-positive patients.
Aims: The aim of this paper is to monitor the leukocyte count as a potential risk factor for the development of thrombotic complications with patients with Philadelphia-negative Chronic Myeloproliferative Neoplasms.
Methods: During the five-year period we followed up the occurrence of thrombotic complications and the leukocyte count in 109 patients of both sexes aged between 30 and 78 years, with a diagnosis of Ph-myeloproliferative neoplasms. Patients were classified into the following groups: 1. Group with Polycythemia Vera (PV) (51); 2. Group with Essential Thrombocythemia (ET) (28); 3. Group with Idiopathic Myelofibrosis (IMF) (21); 4. Group with myeloproliferative neoplasm unclassified (MPNs) (29). We used methods of clinical, laboratory, ultrasound and CT scans.
Results: The leukocyte count ranged from 2,2-17,1x10^9/L. The highest leukocyte count was recorded in the group of patients with PV and MPNs ($P<0.001$) and the lowest in the group of patients with the IMF ($P<0.01$). Between the group of patients with PV and MPNs there were not any statistically significant differences noticed in the leukocyte count. The highest percentage of thrombotic complications (arterial and venous) is in a group of patients with ET and MPNs ($P<0.01$) and then in the group with PV ($P<0.05$). Thrombotic complications in those groups were more frequent in percentage with patients with leukocytosis, but statistical significance was found only in the group with MPNs.
Summary and Conclusions: Leukocytosis may be considered as a potential risk factor for thrombosis in patients with myeloproliferative neoplasms, especially with PV, ET and MPNs. It is necessary to continue follow-up of these patients and to increase the number of subjects as well. Follow-up of the patients with neoplasms unclassified is of special importance, which showed a high prevalence of leukocytosis and thrombotic complications, and all with the aim to continue their further differentiation.

PB1932

TREATMENT WITH RUXOLITINIB IN PATIENTS WITH PRIMARY OR SECONDARY MYELOFIBROSIS: SINGLE CENTER EXPERIENCE

D. Sotiropoulos[1,*] G. Papaioannou[1], M. Iskas[1], G. Karavalakis[1], Z. Bousiou[1], A. Athanasiadou[1], M. Gaitatzi[1], N. Stavroyianni[1], C. Lalayanni[1], T. Touloumenidou[1], V. Kalaitzidou[1], A. Anagnostopoulos[1]
[1]Hematology & HCT Unit, G. Papanikolaou Hospital of Thessaloniki, Thessaloniki, Greece

Background: Myelofibrosis is one of the classical Philadelphia negative myeloproliferative neoplasms (MPNs), either appearing de novo (primary MF[PMF]) or following a previous ET or PV (post-ET or post-PV MF). The disease is essentially the same. The therapeutic landscape of MF has changed with the introduction of JAK inhibitors.
Aims: To evaluate the efficacy and safety of ruxolitinib treatment in patients with MF.
Methods: Eighteen patients with MF (12 male and 6 female), median age 62.5 (33-75) years old were evaluated: 7 with PMF, 5 post PV, 3 post ET, 3 post MPN-U. Median follow up since ruxolitinib initiation was 4 (1-33) months, whereas total follow up since diagnosis was 5 (2-19) years. JAK2 mutational status was available in 14/18 patients, 12/14 being positive for the V617F mutation. Cytogenetic study was available in 12/18 patients, 8 of them having normal karyotype, 2 with deletion of long arm of chromosome 20 [del(20)(q13.1)], one with trisomy 8 and one with complex karyotype [48,XX,+8,+9,t(12:14)(q24.1:q24)]. According to dynamic international prognostic scoring system (DIPSS) upon ruxolitinib initiation, risk group was low in 2, intermediate-1 (int-1) in 4, intermediate-2 (int-2) in 7 and high in 5 patients.
Results: Spleen volume (SV) reduction was observed in 11/18 (61%) patients with a mean SV reduction of 33.7%. Constitutional symptoms subsided in all patients within 2 weeks of ruxolitinib initiation. Fifteen out eighteen patients had weight gain and quality of life improvement. Hematologic toxicity involving anemia and thrombocytopenia was observed in 6/18 (33%) and 2/18 (11%) patients respectively. Red cell transfusion was required in one patient. Dose adjustment with dosage de-escalation was required in 2 patients due to platelet count decrease or preexisting thrombocytopenia, while upgrading and dosage escalation in 3 patients was performed due to platelet count increase (6^{th}, 8^{th} and

12th week). Low dose hydroxyurea administration was continued as concomitant medication in post-PV and post-MPN-U MF patients.
Summary and Conclusions: JAK inhibitors, such as ruxolitinib, have significantly improved the treatment of MF. The clinical experience of the drug has shown that it is generally well tolerated. Long term effects and impact on disease natural history remain to be further studied through diligent monitoring.

Non-Hodgkin & Hodgkin lymphoma - Biology

PB1933

OUT OF EPIGENETIC CONTROL: REGULATION OF MIR23A~27A~24-2 IN B CELL NON-HODGKIN LYMPHOMA AND CLASSICAL HODGKIN LYMPHOMA

S. Eberth[1,*] N. Klytta[1], T. Lusansky[2], A. Rosenwald[3], R. Siebert[4], H. Drexler[2], H. Quentmeier[2]
[1]Junior Research Group Molecular Cancer Research, [2]Human and Animal Cell Lines, Leibniz-Institute DSMZ-German Collection of Microorganisms and Cell Cultures, Braunschweig, [3]Institute of Pathology, University of Würzburg, Würzburg, [4]Institute of Human Genetics, Christian-Albrechts University, Kiel, Germany

Background: Recent publications suggest an important role for microRNAs in B-cell differentiation, maturation and malignant transformation. Epigenetic and genetic alterations are supposed to contribute to the deregulation of microRNA expression in lymphoma.
Aims: We sought to identify microRNAs which are deregulated in B-cell lymphoma due to epigenetic alterations and aimed to test these for subtype-specific DNA methylation patterns.
Methods: Using a microRNA expression array, we screened for microRNAs inducible by the DNA demethylating agent 5-Aza-2'-deoxycytidine (Aza) in B cell non-Hodgkin lymphoma (B-NHL) cell lines. Putative Aza-induced microRNAs were shortlisted by harboring CpG islands in their 5'-region. Array data were validated with quantitative real-time PCR on the level of primary, precursor and mature microRNAs. To determine any correlation of DNA methylation and histone acetylation cell lines were treated with suberoylanilide hydroxamic acid (SAHA) or Trichostatin A (TSA) in combination with Aza. DNA methylation was analyzed by methylation specific PCR and bisulfite sequencing of respective CpG islands in a panel of B-NHL and classical Hodgkin lymphoma (cHL) cell lines together with primary B-NHL samples and healthy controls.
Results: Of the 872 microRNAs represented on the microarray 15 (1.7%) were induced >1.5-fold by Aza in follicular lymphoma (FL) cell line SC-1, 31 (3.6%) were activated in mantle cell lymphoma (MCL) cell line JEKO-1. Altogether 11/15 miRNAs are located downstream of a CpG island in SC-1 and 20/31 in JEKO-1, rendering them potentially susceptible to silencing via DNA methylation. Transcriptional validation of mature and precursor microRNAs identified the microRNA cluster MIR23A~27A~24-2 which was inducible by both DNA demethylating agents and histone deacetylase inhibitors. Analysis of MIR23A~27A~24-2 in a panel of B-NHL and cHL cell lines revealed that its expression was inversely correlated with the DNA methylation status of its 5'-region. Burkitt lymphoma (BL) and FL cell lines were methylated and mainly negative for miR-23a, miR-27a and miR-24 expression. In contrast, most MCL and all cHL cell lines analyzed expressed these microRNAs and were not methylated. Diffuse large B cell lymphoma (DLBCL) cell lines showed a more heterogeneous picture. Notably, these *in vitro* data are in accordance with the methylation status of the MIR23A~27A~24-2 5'-region in primary samples: 23/29 BL patient samples were methylated, compared to 4/10 DLBCL samples and only 1/9 MCL samples. Peripheral blood mononuclear cells and tonsils from three healthy controls were all methylated at the MIR23A~27A~24-2 5'-region, indicating that loss of epigenetic silencing might be the aberrant event in lymphomatous entities like MCL and cHL.
Summary and Conclusions: The microRNA cluster MIR23A~27A~24-2 is frequently downregulated due to DNA methylation in BL, FL, and some DLBCL, but is demethylated and highly expressed in MCL and cHL. Future investigations need to test the eligibility of this microRNA cluster as a potential diagnostic or prognostic biomarker in B-NHL and cHL.

PB1934

PRELIMINARY STUDY ON THE MECHANISM OF CCL5/RANTES IN DIABETIC PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

J. zhang[1,*] H. hu[1], F. he[1,2]
[1]Hematology, [2]Jinhua Hospital of Zhejiang University, jin hua, China

Background: The chemokine RANTES/CCL5 is an inducible, secreted inflammatory cytokine of small molecular weight, and has functions of chemotaxis and activation of T cells and mononuclear cell. The protein among them, containing 68 amino acid residues and its molecular weight being 8kd, is mainly formed by NK cells and T lymphocytes, and plays an important part in immunity to the tissue damage, infection and tumor.
Aims: The purpose of this experiment is to investigate the mechanism of chemokine CCL5 in diabetes mellitus with diffuse large B cell lymphoma (DLBCL), and to investigate the action of CCL5 gene from molecular level, cell level and animal level and partial molecular mechanism, in order to provide experimental data with reference value for the function mechanism of CCL5 in diabetes with DLBCL.
Methods: Normal human B cells and DLBCL cells were cultured *in vitro*, and

RT-PCR was used to detect the expression of CCL5 mRNA; human diffuse large B lymphoma cell lines and rat diffuse large B cell lymphoma cell lines A20 were cultured in two kinds of sugar concentration of 5mmol/L and 30mmol/L, RT-PCR was applied for the detection of the expression of CCL5 mRNA respectively; BALB/ c mice were intraperitoneal injected streptozotocin (STZ) of small dose to construct diabetic rats model, and cell lines with a stable low expression of CCL5 and high expression of CCL5 were established via lentiviral transfection technology. The three kinds of cell lines of low expression of CCL5, high expression of CCL5 and un-transfection were injected subcutaneously in the diabetic BALB/c mice and normal blood glucose BALB/c mice, then were observed about the rate and the time of tumor formation and tumor size and texture; the expression of CCL5 in each group was detected by tumor tissue routine HE staining and immunohistochemistry; peripheral blood from mice in each group was extracted to detect the expression of CCL5 in peripheral blood by ELISA.

Results: 1. DLBCL cell lines of Ly1, Ly8, Ly10 are cultured *in vitro*, the expression level of CCL mRNA in each group is higher than the normal B cell(P<0.05); 2. Glu30mmol/L cultivate human DLBCL cell strain Ly1, Ly8, Ly10 and mice DLBCL cell strain A20, after culturing for 2W, the CCL5mRNA are all higher than the one cultured by Glu5mmol/L P<0.05 ; 3. Through injecting the diabetic mice by lower expression CCL5, high expression CCL5, none transfection cell lines A20, the diabetic mice's tumor formation rate is A1: 93.3%; A2: 60%; A3: 66.6%, the tumor forming time are respectively A1: 7.0±0.85d; A2: 9.5±2.8d; A3: 9.0±1.8d. Higher than the normal blood sugar mice's tumor forming rate B1 20% B2: 20%; B3: 46.6%, the tumor forming time are respectively B1: 12±1.3d; B2: 14±2.5d; B3: 12 ±4.2d; 4. Using the immuno-histochemistry to detect the diabetic mice tumor forming tissue CCL5's expression, and the result is higher than the normal blood sugar mice's tumor tissue;5. The result of ELISA detecting the diabetes mice's CCL5 expression is higher than the mice with normal blood sugar in the peripheral blood.

Summary and Conclusions: 1. Human DLBCL cell strain's expression of CCL5mRNA are higher than the normal B cell; 2. High concentrated glucose cultivate human DLBCL cell strain and mice DLBCL cell strain's CCL5mRNA is higher than the low sugar cultivate one, this shows in the high glucose environment, the DLBCL tumor cell can produce more CCL5; 3. The high expression CCL5's cell strain is more easily to form tumor in the body than the low expression CCL5's cell strain, the tumor grow faster; and at the same condition, the diabetes mice are more easily to form the tumor than the normal mice; 4. The expression of CCL5 in the tumor forming tissue of the diabetic mice is higher than the tumor forming tissue of the normal mice; 5. The expression of CCL5 in the serum of the diabetic mice is higher than the normal mice.

Hospital N.S. de Sonsoles, [5]Hematologia, Hospital N.S. de Sonsoles, Ávila, Spain

Background: Hodgkin lymphoma (HL) is the most frequent cancer in adolescent and young adults (AYA). It is considered a curable tumor, but still many patients do not favorably respond or quickly relapse after responding to the current chemotherapy. Most widely used prognostic guides still fail to accurately identify those patients with very poor prognosis. Recently, microenvironment has been a main focus of interest for define risk and disease outcome. Few studies have analyzed the role of $CD4^+$ T-helper cells (THs) and macrophages. Results about cytotoxic T cells remain controversial.

Aims: To analyze the role of the amount of CD8 assessed by flow cytometry in the outcome of patients diagnosed of HL.

Methods: Fresh samples from lymph the node biopsy were obtained during diagnostic process in 80 patients. Single cell suspensions were prepared after homogenizing these samples. Immunophenotyping was made by flow cytometry with standard methods as a tool to help in the diagnosis, which was finally got by standard pathological methods. Clinical data were collected retrospectively from clinical courses and statistical comparisons were performed using SPSS 20.0.

Results: Ratio male/female was 52/46, and median age 37 year (12-85). Forty-six patients (60%) patients had advanced-stage disease (III, IV, B or Bulky disease). Histologic diagnoses were: nodular sclerosis n=58 (73%), mixed cellularity n=10 (12%), lymphocyte rich n=5 (6%), and lymphocyte depletion n=2 (3%), and finally nodular lymphocyte predominance n=5 (6%).The distribution of cases according to IPS prognosis was: good 16%, intermediate 49%, and poor 35%. Considering the total lymphocyte number, CD8+ T cells median value of was 15% (2-75). 76 patients received therapy with ABVD+/-radiotherapy (RT) and 2 with RT alone. With a median follow up of 5 years, freedom from treatment failure (FFTF) was longer for females (P=0.05), patients achieving complete response to 1st line therapy (P<0.001) and cases with >15% CD8+ cells (P=0.018). This superiority was maintained when only advanced-stage cases were evaluated (P=0,035), as well as in patients with Bulky disease, where all patients with >15% CD8+ remained free from treatment failure (P=0.08). In multivariate analysis, response to therapy and having >15% CD8+ were the parameters with independent statistically significance.

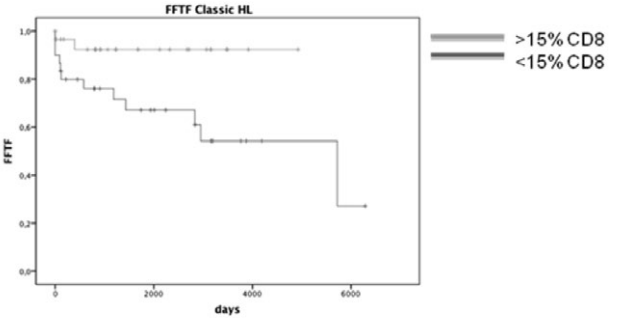

Figure 1.

Summary and Conclusions: An increased number of infiltrating CD8+ cells in the microenvironment of HRS cells assessed by FCM is associated with superior FFTF in classic HL and could be considered as a new biomarker for risk stratification. Prospective studies must be performed to confirm these results and further understanding of their role in microenvironment.

PB1936

ROLE OF HLA SPECIFICITIES IN FOLLICULAR LYMPHOMA

M. Alcoceba* [1,*] M. García-Álvarez* [1], S. Alonso-Álvarez* [1], I. Prieto-Conde[1], C. Jiménez[1], M. E. Sarasquete[1], M. C. Chillón[1], A. Balanzategui[1], R. Maldonado[1], M. Hernández-Ruano[1], A. Antón[1], R. Corral[1], N. Puig[1], A. Martín[1], M.B. Vidriales[1], N. Gutiérrez[1], M.D. Caballero[1], R. García-Sanz[1], L. Marín[1], M. González[1]
[1]Department of Hematology, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Follicular lymphoma (FL) is the most common indolent lymphoma, accounting for ~20-30% of all non-Hodgkin (NHL). It is an incurable disease with frequent relapses and shorter response to further treatments, developing drug resistance. Recently, using GWAS, polymorphisms in 6p21.3 region were related to susceptibility to develop NHL, including FL. The role of the HLA system in antigen presentation could be related to susceptibility and disease control. Previous studies show an association between HLA alleles and/or haplotypes and NHL. However, information regarding FL is little.

Aims: To analyze the role of HLA specificities in development and prognosis of FL.

Methods: A total of 149 consecutive patients from a single centre diagnosed of FL between 2000 and 2012 were included in the study. Grade 3b FL or those cases with DLBCL areas were not considered. Healthy donors (n=1940) from the CyL Bone Marrow Donors Registry as control group. HLA typing of class I (–A, –B y –C) and II (–DRB1 y –DQB1) at low resolution level were performed according to the EFI methodology. Allelic frequencies were estimated by direct counting. Phenotypic frequencies between groups were compared with the Fisher test, considering P<0.05 as statistical significant. P-value were corrected (Pc) according to the number of valid comparisons (Bonferroni correction). Survival analyses were carried out using Kaplan-Meier. Differences between curves were estimated using the log-rank test (SPSS 20.0).

Results: There were no statistical differences in specificities frequencies of HLA class I. However, a higher incidence of HLA-DRB1*01 was observed in patients than in donors (46% vs. 19,5%, P<0,0001, Pc<0,0013). The median follow-up of the series was of 75 months. A total of 82% of the patients received treatment for FL, 68% of them with Rituximab. Those patients receiving a CHOP-like plus Rituximab regimen and carrying the HLA-DRB1*13 had worse 10-year OFS (54% vs. 85%, P=0.05) compared with patients without this specificity.

Summary and Conclusions: The present study suggest an association between HLA-DRB1*01 and FL development, in line with previous studies. However, this study should be considered as preliminary, requiring higher sample size.

DIFFERENTIAL EXPRESSION OF ROBO1 IN MANTLE CELL LYMPHOMA, CHRONIC LYMPHOCYTIC LEUKEMIA AND ACUTE MYELOID LEUKEMIA.

A. Appe[1,*] M. Hansen[1], L.H. Ebbesen[1], A. Aggerholm[1], H. Bentzen[1], C.G. Nyvold[1]

[1]Hematology, R, Hemodiagnostic Laboratory, Aarhus C, Denmark

Background: Mantle Cell Lymphoma (MCL) is a B-cell neoplasm that represents 6%-9% of malignant lymphoma in Western Europe. MCL is characterized genetically by the translocation t(11;14) leading to overexpression of the cell cycle protein Cyclin D1 distinguishing MCL from other lymphomas. The outcome is extremely heterogeneous, supporting the need for new molecular markers to clarify the disease cause as well as assisting in diagnosis and prognosis. Chronic lymphocytic leukaemia (CLL) is the most common leukaemia of adults in Western countries. The mutational status of the IgH-V genes envisages here the prognosis along with mutations in a number of genes including *p53*, *notch1*, *sf3b1*, and *birc3*. Nevertheless, there is still a need for new markers for prediction of survival and treatment strategy in CLL. Recent next generation sequencing (NGS) studies have pinpointed a number of candidate genes that harbor mutations in clonal B cell neoplasms among others, the *ROBO1* gene (1). We likewise identified mutations in the ROBO genes in a pair of monozygotic twins with monoclonal B-cell disorders (2). The ROBO gene family consists of the genes *ROBO1-4* which encode single pass transmembrane proteins involved in neuronal migration across the midline and fetal brain development. These genes have previously been associated with several malignancies though only a single study, to our knowledge, -directly associated *ROBO1* with lymphomas (3).
Aims: The aim of this project is to investigate *ROBO1* as a new molecular target in patients suffering from MCL, CLL and acute myeloid leukemia (AML). We explored the mRNA expression patterns of the gene and compared the expression to a cohort of healthy individuals.
Methods: Blood samples from 20 patients with MCL, 20 patients with CLL and 20 patients with AML were collected at diagnosis. In addition blood samples from 20 healthy individuals were employed. The qPCR assay Hs00268049_m1 (Applied Biosystems, Foster City, CA, USA) targeting the specific ROBO1 mRNA was applied in triplicates on a MX3005 (Agilent Technologies, Santa Clare, CA, USA) and the quantitative range of the assays was determined. β-glucoronidase (GUS) and β-2-microglobulin (B2M) were employed as reference genes and the cell line K562 was used as positive control. ΔCq was calculated as Ave(Cq, target gene) – Ave(Cq, reference genes). The non-parametric Mann-Whitney U test was used to evaluate significant difference between the groups (Figure).
Results: We identified a significant difference between the expression of *ROBO1* in MCL *versus* healthy individuals (P=0.0002), between CLL and healthy individuals (p =<0.0001) and between AML and healthy individuals (p =<0.0001). Interestingly, three MCL patients displayed remarkably high expression of *ROBO1* compared to the rest of the cohort (Figure).

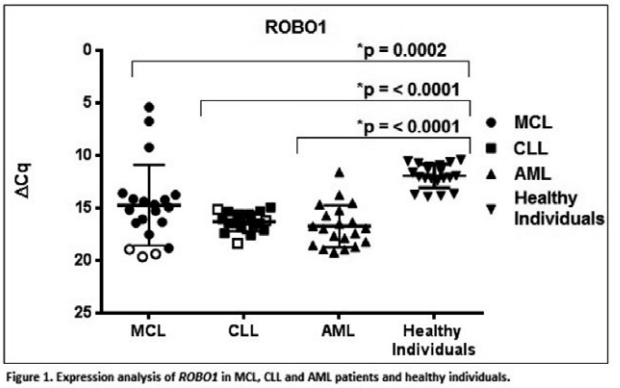

Figure 1. Expression analysis of *ROBO1* in MCL, CLL and AML patients and healthy individuals.

Figure 1.

Summary and Conclusions: Using a qPCR assay, specifically targeting *ROBO1* mRNA we found a significantly difference in the expression level in the MCL, CLL and AML cohorts compared to the healthy individuals. There has previously been a report on promoter methylation of *ROBO1* in MCL with impact on prognosis (3). Methylation of the promoter CpG islands could explain the significant difference in expression that we observed. However, whether the difference in expression of *ROBO1* solely derives from promoter methylation or is due to mutations in the gene needs to be further explored. Perspectives of using the expression profile of genes like *ROBO1* as additional tool for prognosis are interesting in these B-cell neoplasms with very heterogeneous outcome.

PB1938

CXCR4 WHIM-LIKE MUTATIONS ARE A RARE EVENT IN DIFFUSE LARGE B-CELL LYMPHOMA

M.C. Fernandez[1,*] B. Sánchez-González[2], S. Pairet[1], L. Camacho[1], M. Ferraro[2], L. Colomo[3], C. Besses[2], S. Serrano[3], A. Salar[2], B. Bellosillo[3]
[1]Grup de Recerca Clínica Aplicada en Neoplàsies Hematològiques, IMIM, [2]Servei d'Hematologia, [3]Servei de Patologia, Hospital del Mar, Barcelona, Spain

Background: *MYD88* p.L265P mutation has been recently reported to have predictive value for worse response and survival in diffuse large B-cell lymphoma (DLBCL). In lymphoplasmacytic lymphoma (LPL), that is characterized by a high presence of the *MYD88* p.L265P change, different mutations in the C terminus of the *CXCR4* gene have been lately described. These alterations, that affect almost a 30% of LPL cases, are similar to those found in the WHIM syndrome and virtually all of them coexist with the *MYD88* p.L265P alteration, modifying the clinical presentation and outcome of the disease.
Aims: To study the occurrence of *CXCR4* WHIM-like mutations in adult patients with DLBCL and their possible association with other frequent mutations affecting the *MYD88* (p.L265) and C*D79B* (p.Y196) genes.
Methods: We analysed the mutational status of *CXCR4 and CD79B* in a series of 101 DLBCL (19 of them harbouring the *MYD88* p.L265P mutation) diagnosed in our institution according to the WHO 2008 diagnostic criteria for lymphomas. DNA samples extracted from FFPE tissue were used and macrodissection was performed in those cases where tumoral tissue represented less than the 50% of the sample. The presence of the *MYD88* p.L265P mutation was assessed by allele-specific real time-PCR. The mutational status of *CXCR4* was determined by direct Sanger sequencing of the C terminus of the gene (aminoacidic positions Glu288 to Ser352, according to the NCBI reference sequence NM_003467.2). Mutations affecting the tyrosine 196 at the ITAM motif of *CD79B* were studied also by direct Sanger sequencing of the targeted region.
Results: A total of 101 DLBCL cases (54 male; 47 female) with a median age of 71 years (range 25-88) were included in the study. According to the Hans' immunochemistry-based algorithm, 48% of the cases were ABC-type and 52% were GCB-type. *CD79B* p.Y196 mutations were found in 10 patients. Consistently with previous studies, most of the cases of the *MYD88* p.L265P positive group (n=19) were ABC-type lymphomas (74%) and presented a primary extranodal origin (68.4%) besides of being more enriched in *CD79B* Y196 mutations than the *MYD88* wild-type group (36.8% vs 3.7%, *P*<0.001).
Only one case with a mutation in the *CXCR4* gene was detected in the *MYD88* p.L265P positive group (5.26%) whereas no *CXCR4* mutations were found within the *MYD88* wild-type cases. The alteration consisted in the c.C1000T heterozygous substitution, leading to a nonsense mutation at the arginine 334 (p.R334*) and coexisted with a mutation in the *CD79B* ITAM motif (p.Y196C). Noteworthy, this mutation represents a rare *CXCR4* WHIM-like alteration also in LPL, where the most frequent altered position is, by far, the serine 338. Regarding the clinical features of the mutated case, the patient was a 71 years old male that presented an ABC-DLBCL with primary testicular origin. After 26 months of follow-up, the patient has not presented monoclonal component, bone marrow affectation or any other meaningful alteration.
Summary and Conclusions: Our study shows that the *CXCR4* WHIM-like mutations are a rare event in DLBCL, even within those patients bearing the *MYD88* L265P mutation, despite the recently shown correlation between these two molecular alterations in patients with LPL. Although these findings require further validation in larger studies, these results suggest that the pathogenic events driven by the *MYD88* L265P mutation might differ among both diseases.

PB1939

THE B-CELL RECEPTOR PATHWAY IS HIGHLY ACTIVED IN CANINE DLBCL CELL LINE CLBL-1

A. Zoellner[1,2,*] B. Ruetgen[3], G. Hutter[2], Y. Zimmermann[2], M. Mohring[4], W. Hiddemann[1,2], J. Hirschberger[5], M. Dreyling[1,2]
[1]Internal Medicine III, Haematology and Oncology, LMU, [2]Clinical Cooperative Group Leukemia, Helmholtz Center Munich, Munich, Germany, [3]University of Veterinary Medicine, Vienna, Austria, [4]Nuclear medicine, Iniversity hospital Klinikum rechts der Isar, [5]Clinic of Small Animal Medicine, Centre for Clinical Veterinary Medicine, LMU, Munich, Germany

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of canine lymphoma and shows significant similarities in its clinical and biological presentation to human DLBCL. Since the majority of canine DLBCL appears to have genetic parallels to the human Activated B-Cell (ABC) subtype of DLBCL, analysis of the biology and evaluation of possible treatment targets in canine DLBCL could supply valuable insights about the disease.
Aims: Here we demonstrate the expression of hallmark kinases of the B-cell

receptor pathway in the canine DLBCL cell line CLBL-1. Further we investigated the treatment with B-cell receptor pathway interacting compounds such as BTK inhibitor Ibrutinib and PI3K inhibitor Idelalisib and substances lately known for their anti-lymphoid activity.
Methods: Established canine DLBCL (CLBL-1) and T-cell lymphoma (CL-1) cell lines were cultivated under standard conditions in RPMI and exposed to ascending doses of Idelalisib, Ibrutinib, Temsirolimus, BX-912, Ku-63764, Enzastaurin and Bortezomib. Cell proliferation was determined after 48 hours based on WST cell proliferation assay. Western blotting was performed after 24h. All experiments were performed at least in triplicates.
Results: In Western blot analysis kinases hallmarking the B-cell receptor- PI3K-AKT pathway (AKT, PDK, PI3K, mTOR) and their phosphorylated isoforms were detected in CLBL-1 cells. Furthermore untreated CLBL-1 cells expressed p42/44, p38, MEK, GSK alpha and GSK beta and their phosphorylated isoforms as well as the cyclins CDK2, CDK4, CDK7, CDK9 but no cyclin D1. Significantly, treatment with only 1,25nM Ibrutinib induced in WST analysis a growth reduction to 45%, with 1µM arresting growth thoroughly. The PI3K-delta inhibitor Idelalisib showed dose dependent effects: 0,6µM reduced cell growth to 41%, whereas 5µM reduced proliferation to 13%. The mTor inhibitor Temsirolimus showed high efficacy: 1,25nM Temsirolimus reduced cell proliferation to 38%, while the mtorc1/mtorc2 inhibitor Ku-63794 induced at the dose of 0,25µM a reduction to 49%. CLBL-1 was also sensitive towards other compounds with anti-lymphoid activity such as the PDK-1 inhibitor BX-912 (0,25µM; 20%), the PKC inhibitor Enzastaurin (1,25µM; 52%) and the proteasome inhibitor Bortezomib (5nM; 50%). To identify B-cell receptor pathway specific mechanisms the T-cell lymphoma cell line CL-1 was treated as control. Increasing doses of Ibrutinib, Idelalisib and Enzastaurin (up to 5µM) and Temsirolimus (up to 20nM) did not have significant effects.
Summary and Conclusions: The detected activated B-cell receptor pathway in CLBL-1 and the sensitivity towards small molecule inhibitors targeting this pathway indicates the similarity to human ABC DLBCL. This data strongly supports the relevance of canine DLBCL as model for its human counterpart.

CANCER-TESTIS GENES ARE EXPRESSED IN T-CELL LYMPHOMAS
V. Misyurin[1,*] A. Misyurin[1], A. Misyurina[2], E. Penskaja[2], N. Chernova[2], L. Gorenkova[2], D. Mar'in[2], L. Plastinina[2], L. Kesaeva[1], Y. Finashutina[1], N. Lyzhko[1], A. Ponomarjov[1], E. Sal'nik[1], S. Kravchenko[2], A. Baryshnikov[1]
[1]Federal State Budgetary Science Institution "N.N.Blokhin Russian Cancer Research Center", [2]National Research Center for Hematology, Moscow, Russian Federation

Background: Several types of T-cell lymphomas are characterized by a high risk of relapse after standard chemotherapy. It continues to be reasonable to investigate potential targets for immunotherapy in T-cell lymphomas. CTG are expressed in some hematologic malignancies. Nowadays there are a few information about the CTG expression in T-cell lymphomas.
Aims: To investigate the expression profile of CTG in T-cell lymphomas.
Methods: We used RQ PCR to evaluate mRNA expression of CTG's *HAGE*, *NY-ESO-1*, *MAGEA1*, *PASD1*, *SCP1*, *SEMG1*, *SPANXA1*, *SSX1* and *PRAME* relatively gene *Abl*. Systems of specific primers and fluorescent probes were used for each gene. mRNA has been extracted from peripheral blood (PB), marrow (BM) and lymph nodes (LN). mRNA has been extracted from 4 samples of LN, 4 PB and 5 BM of 6 patients with Angioimmunoblastic T-Cell Lymphoma (AITL); 2 samples of LN, 3 PB and 3 BM of 6 patients with T-cell lymphoma, not otherwise specified (PTL-NOS); 4 samples of LN, 5 PB and 3 BM of 5 patients with Anaplastic Large Cell Lymphoma ALK-positive (ALTCL ALK+); 2 samples of PB and 3 BM of 3 patients with Anaplastic Large Cell Lymphoma ALK-negative (ALTCL ALK-). Statistical analysis was carried out using χ^2.
Results: We observed the *PRAME* (in 1 of 4 cases) and *SSX1* (1/4) expression in LN of patients with AITL. *SCP1* (1/4), *SEMG1* (1/4) and *SSX1* (2/4) were expressed in PB of these patients. *SCP1* (1/5), *SEMG1* (1/5), *SPANXA1* (1/5) and *SSX1* (2/5) were expressed in BM of patients with AITL. We detected *GAGE* (1/2) *SEMG1* (1/2) *SSX1* (1/2) and *PRAME* (2/2) in LN, *GAGE* (1/3), *SEMG1* (1/3), *SSX1* (1/3) and *PRAME* (2/3) in PB of patients with PTL-NOS. It is interesting that *GAGE*, *SEMG1*, *SSX1* and *PRAME* were expressed together in LN and PB of one patient. There wasn't any CTG expression in BM of PTL-NOS patients. *PASD1* (1/4), *SCP1* (2/4) and *PRAME* (4/4) mRNA were expressed in LN; *NY-ESO-1* (1/5), *PASD1* (1/5), *SCP1* (1/5), *SEMG1* (2/5), *SPANXA1* (1/5) and *PRAME* (2/5) were expressed in PB, *GAGE* (1/3), *NY-ESO-1* (1/3), *PASD1* (1/3), *SCP1* (2/3), *SEMG1* (2/3), *SPANXA1* (1/3) and *PRAME* (1/3) were expressed in BM of ALTCL ALK+ patients. *SCP1* (1/2) and *SPANXA1* (1/2) were expressed in PB and *GAGE* (1/3), *SCP1* (1/3) and *SEMG1* (1/3). Expression of CTG occurred only in BM of patients with histologically proven tumor involvement. *PRAME* expression was observed in LN more frequently, than in PB (P=0,0841) and BM (P=0,0194). All other CTG were expressed with similar frequency in LN, PB and BM.
Summary and Conclusions: T-cell lymphomas have a different CTG expression profile. *PRAME* expression was predominantly observed in lymph nodes and could be considered like a potential target in relapsed or resistant cases of T-cell lymphomas.

PB1941

CD26 AND CD39 IN THE REGULATORY MICROENVIRONMENTS OF LYMPHOMA AFFECTED LYMPH NODES
R. Di Gaetano[1,*] V. Gasparetto[1], B. Callegari[1], M.A. De Benedetto[1], R. Sartori[1], E. Scarpa[1], N. Maschio[1], G. Tagariello[1]
[1]Haematology, Castelfranco Veneto Hospital, Castelfranco Veneto, Italy

Background: In previous reports we have described that lack of CD26 on the surface of activated $CD4^+$T ($CD38^+$) in the microenvironment of Hodgkin lymphoma (HL) suggest a T-reg immunosuppressive activity. Other studies have shown that low expression of CD26, associated with adenosine deaminase (ADA), and the presence of CD39, ectoenzyme associated with hydrolysis of extracellular ATP, might be responsible for the generation of adenosine recognized as a major mechanism of T-reg for the suppression of anti-tumor immune responses and for successful tumour escape.
Aims: Significant amount of non-clonal cells infiltrating HL is an excellent model to analyze the para-neoplastic cellular elements of the tumor microenvironment. The scope of this study was to perform lymphocyte immunophenotyping by flow cytometry (FC) from lymph node samples suspected of lymphoma with the scope of verify biomarkers of enzymatic activity favorable to the proliferation of neoplastic cells.
Methods: We have examined the relationship between the expression of CD26 and CD39 by FC on $CD4^+$T and measured its expression on $CD4^+$ T subset correlating to the CD26 and CD38 in 52 samples of lymph nodes (6 HL, 30 non Hodgkin lymphoma (NHL) and 16 non malignant nodes (BN).
Results: HL samples show statically differences compared to BN in the expression of CD26 (12% vs 42%; P<0,0002), CD38 (72% vs 20%; P<0,0005), CD39 (42% vs 14%; P<0,05). When compared to NHL there is a confirmation significance in CD26 (12% vs 37%; P<0,0007), in CD38 (72% vs 25%; P<0,0009) in contrast to CD39 (42% vs 26%; P<0,3). Among NHL cases, there were 6 relapses, that we have compared to HL: CD26 (42% vs 12; P<0,02); CD38 (23% vs 72%; P<0,04); CD39 (30% vs 42%;P<0,7).
Summary and Conclusions: Data confirm the activated profile ($CD38^+$) that distinguishes HL-infiltrating cells from NHL and BN. It is more evident in HL, but in NHL microenvironment there is a tendency to a reduction of the expression of CD26 on $CD4^+$T cells compared with BN; this, correlated with CD39 increase, might suggests an enzymatic activity with a significant adenosine accumulation in NHL too. Although the small size of the cohort, the pattern of relapsed seems similar to HL. This mimics the regulatory microenvironments that strengthens the neoplastic cells to manipulate its surrounding to avoid host immune attack suggesting a possible resistance to treatment.

PB1942

DETECTION OF MYD88 L265P IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA
A. Sidorova[1,*] E. Zvonkov[1], A. Sudarikov[1], N. Severina[1], N. Gabeeva[1], A. Kovrigina[1], V. Troitskaya[1], V. Savchenko[1]
[1]National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: The mutation of the myeloid differentiation primary response gene 88 (MYD88) at amino acid position 265 leading to a change from leucine to proline (L256P) is present in approximately one-third of patients (pts) with activated B-cell–like types of diffuse large B-cell lymphoma (ABC-DLBCL) and rarely occurs in pts with other subtypes of DLBCL. Considering the published data, patients with MYD88 DLBCL treated by standard chemotherapy (CHOP and CHOP-like regimens), was associated with an unfavorable outcome.
Aims: To identify the clinical and prognostic value of the MYD88 L256P mutation in pts with ABC-DLBCL who received treatment in the National Research Center for Hematology during 2008-2014.
Methods: Thirty-two newly diagnosed pts with ABC-DLBCL were selected for the study. The diagnosis of ABC-DLBCL was established according to the World Health Organization 2008 classification. DNA from 28 cryopreserved and 4 formalin-fixed paraffin-embedded tumor samples were available for our study. The screening for MYD88 L256P mutation was performed by Sanger sequencing and allele-specific PCR.
Results: Thirty-two pts with ABC-DLBCL (median age 54,5 years (range 18-74), 18 males and 14 females) were tested for MYD88 mutation. MYD88 L265P mutation was found in 28,2% (9/32) of pts. There was just a slight predominance of the female sex for MYD88 L265P positive group (5:4) as compared to MYD88 negative group (9:14). According to the Ann Arbor classification, approximately 55% pts had stage IV of the disease in both groups. Sixty-six percent of the pts with MYD88 mutated DLBCL were classified as the high risk group by the international prognostic index (IPI) vs 8 (34,8%) pts MYD88 unmutated DLBCL. In addition, 17 of 23 pts (73,9%) with MYD88 wild type DLBCL had elevated lactate dehydrogenase (LDH) levels *versus* 100% of pts with MYD88-positive DLBCL. Among MYD88 positive group 5/9 (55,6%) pts had extranodal lesions: central nervous system, skin, gastrointestinal tract, adrenal gland, bone and soft tissue, as compared to cases without MYD88 DLBCL 8/23 (34,8%). The clinical characterictics of the pts are summarized in Table 1. All pts received high-dose chemotherapy, 6/9 MYD88 mutated pts achieve complete remission after initial

treatment, one of them experienced disease relapse with nasopharynx, bone marrow, vertebral involvement 45 months after the diagnosis, median follow-up was 41 (range 11-83) months. Three pts had died of progressing lymphoma. Out of 23 pts with MYD88 wild type DLBCL, 17 pts achieved complete remission (median follow-up 54 months, range 11-90), 2 pts had early relapse and 4 pts were refractory. Overall survival (OS) was better in pts with MYD88 unmutated DLBCL than pts with MYD88 positive DLBCL (5-year *OS*, 72% vs 42%).

Table 1.

Patients Characteristics n=32 (%)		
	MYD88 mutation	**MYD88 WT**
Number of patients	9 (28,2)	23 (71,8)
Sex (male:female)	4:5	14:9
Age at diagnosis, years.		
Median	62	53
Range	18-70	23-74
Over 60years old	5 (55,6)	8 (34,8)
Serum LDG Level > normal	9 (100)	17 (73,9)
International Prognostic Index		
Low	-	4 (17,4)
Low-intermediate	2 (22,2)	6 (26)
High-intermediate	1 (11,1)	5 (21,8)
High	6 (66,7)	8 (34,8)
Lymph node involvement	4 (44,4)	15 (65,2)
Extranodal sites:	5 (55,6)	8 (34,8)
Gastrointestinal tract	1	2
Brain	1	2
Bone	1	-
Skin	1	2
Adrenal	1	-
Bone marrow	2 (22,2)	9 (39,1)
5-year OS rate	(42)	(72)

LDG: lactate dehydrogenase; OS: overall survival

Summary and Conclusions: Our study has demonstrated that the presence of MYD88 L256P mutation in pts with ABC-DLBCL is associated with worse OS probability. An analysis of treatment outcomes revealed no statistically significant differences in OS because of the small number of pts enrolled in study. MYD88 L265P DLBCL presented with higher number of extranodal involvement, IPI high risk and older age as compared to MYD88 wild type DLBCL. We plan to increase patient recruitment in our research, continue to analysis MYD88 mutation in ABC DLBCL and try to improve treatment strategy in patients with poor-prognosis DLBCL.

PB1943

T REGULATORY CELLS IN CHILDHOOD MALIGNANCIES

N. Katzilakis[1], G. Martimianaki[1], M. Stratigaki[1,*] E. Stiakaki[1]
[1]Pediatric Hematology-Oncology, University of Crete, University Hospital of Heraklion, Heraklion,Crete, Greece

Background: T regulatory cells (T regs) participate in the maintenance of immunological self-tolerance and according recent studies play an essential role for the control of antitumor immune responses. The utility of T regs as prognostic factors and targeted treatment strategies in different cancers is under immense investigation.
Aims: The study of T regulatory cells' subpopulations CD4+CD25high and CD4+CD25highFOXP3+ in the peripheral blood of children with malignancies (lymphomas and soft tissue sarcomas) at diagnosis, during therapy and after treatment completion as well as of children with autoimmune cytopenias.
Methods: Mononuclear cells were isolated from peripheral blood (PBMCs) of children with malignancies at diagnosis (Md, n=9), during therapy (T, n=8) and at the end of treatment (ET, n=26) as well as of children with autoimmune cytopenia (CP, n=6) by density gradient centrifugation. A multi-color flow cytometry panel was used for the validation of T reg subpopulations using CD4-PC5, CD25-PE and the intracellular FOXP3-FITC monoclonal antibodies. The panel for the estimation of CD4/CD8 ratio included CD45-PC7, CD3-FITC, CD4-PE and CD8-PC5.
Results: The findings of our study revealed that the levels of CD4+CD25high and CD4+CD25highFOXP3+ subpopulations of T regulatory cells were low at diagnosis of malignancies. According to our analysis an increase of CD4+CD25high and CD4+CD25highFOXP3+ levels (0.5±0.094 vs 1.08±0.187, P=0.015 and 0.390± 0.087 vs 0.84±0.173, P=0.049 respectively) were observed during treatment administration and a new reduction of the above subpopulations after treatment completion (1.08±0.187 vs 0.62±0.062, P=0.034 and 0.84±0.173 vs 0.46±0.063, P=0.031 respectively). T reg CD4+CD25high-FOXP3+ cells were also elevated during treatment compared to cytopenias (0.84±0.173 vs 0.36±0.065, P=0.041). No statistically significant differences were estimated from the comparison between the group of cytopenias and the diagnosis of malignancies as well as the end of treatment. In addition CD4/CD8 ratio was significantly higher at diagnosis of malignancies compared to treatment period and the end of treatment group (2.13±0.299 vs 1.29±0.207, P=0.043 and 2.13±0.299 vs 1.4±0.085, P=0.019 respectively).
Summary and Conclusions: In childhood malignancies studied the levels of T regulatory cells were estimated low at diagnosis and after treatment completion whereas were elevated under treatment as a result related to immunosuppression.

PB1944

ASSOCIATION OF SELECTED GENE POLYMORPHISMS WITH PROGNOSIS AND TREATMENT RESULTS IN FOLLICULAR LYMPHOMA PATIENTS

E. Tothova[1,*] A. Kafkova[2], L. Klimcakova[3], J. Duras[4], J. Salagovic[3], R. Hajek[5]
[1]Dpt of Clinical and Medical Biophysics, LF UPJS, [2]Dpt.of Hematology, HEMKO I.t.d, [3]Dpt of Medical Biology, LF UPJS, Kosice, Slovakia, [4]Dpt of Hematooncology, FNO and OU, [5]Dpt of Hematooncology, FNO and LF OU, Ostrava, Czech Republic

Background: Biological studies suggest that a host immunologic environment plays a major role in follicular lymphomagenesis, which is partly determined by host genetic background. Cytokines are key regulators of immune function and regulation, they are highly polymorphic, and have been implicated in lymphoma etiology and prognosis. To date, few studies addressing the association of polymorphisms with prognostic indicators and results of the treatment in follicular lymphoma have been carried out.
Aims: We analyzed the effect of polymorphisms of selected genes on some indicators of prognosis, response to treatment regimen and survival rate.
Methods: We genotyped 4 single nucleotide polymorphisms (SNPs) from 44 candidates' cytokine and immune genes in 64 follicular lymphoma patients who had participated in our study. Baseline clinical data and survival rates were obtained from cancer registry files. Genotyping of polymorphisms (IL2 rs 2069762, IL12B rs 3212227, FCGR2A rs 1801274, C1QA rs172378) was performed by the method of analysis of melting curve according to real time PCR by using Eco Real-Time PCR system. Statistical analysis was executed by using statistical software SPSS with the use of following tests: chi-kvadrat test, Fisher exact test, Kaplan-Meier analysis and Cox regres model. P=0.05 was considered as level of statistical significance. Following genetic models were tested: codominant, recessional and dominant.
Results: The median age at diagnosis was 53 years (range, 23–76), 41% men, 37% of patients were in high risk, 8 (12.5%) patients died during the follow-up, with a median follow-up of 59 months (range, 29 – 79 months) for surviving patients. The dominant genetic model, IL12B allele carriers rs 3212227G had achieved in comparison to TT homozygotes significantly more complete remissions after first-line treatment (95.5% vs 67.6%, P= 0.018, Fisher exact test). Other 3 polymorphisms were not associated with 1.line treatment (R-CVP, R-CHOP). Statistical significance limit was observed for the association with mortality rate for the recessional genetic model, while the carrier homozygotes CC polymorphism rs 2069762 IL2 showed a pattern of higher mortality rate, compared to carriers of allele A (40% vs. 12%, P=0.144). In the Kaplan-Meier survival analysis, we observed significantly shorter time for overall survival (OS) in the group CC homozygotes compared to carriers allele polymorphism IL2rs2069762 (34 vs 166 months; P<0.001); this difference between genotypes remained statistically significant after adjustment to age and sex in the Cox regression model (P=0005).
Summary and Conclusions: In summary, the results of the project have shown an association of several polymorphisms to response to treatment, mortality and survival rates. For the most important prognostic consider polymorphism IL12B rs3212227, where the G allele was associated with higher frequency of achieving complete remission in the group followed. Given the small number of patients in the study, for the final analysis and possible use of the results in practice it is necessary to evaluate larger population of patients with follicular lymphoma.

PB1945

BRAF-V600E AND P53 MUTATION AS A POTENTIAL PROGNOSTIC MARKERS OF REMISSION DURATION

I. Kryachok[1,*] T. Skrypets[1], O. Novosad[1], N. Khranovska[2], N. Svergun[2], O. Grabovoy[2], S. Antoniuk[2]
[1]Oncohematology, [2]Experimental oncology, National Cancer Institute, Kiev, Ukraine

Background: Langerhans Cell Histiocytosis (LCH) is an orphan disease of clonal dendritic cells which may affect any organ of the body.It is most often diagnosed in childhood, but can occur at any age. Clinically, LCH manifestations range from isolated bone lesions to multisystem disease, with outcomes ranging from spontaneous remission to progressionon therapy. Morphologically, LCH cells are for CD1a and/or CD207 (Langerin), S-100 positive. Recent identification of cancer-associated mutation BRAF V600E and p53 in LCH cases provided molecular evidence of the neoplastic nature of LCH.
Aims: To investigate the frequency of BRAF V600E and correlation with p53

mutations in histiocytosis, and it clinical significance as a potential biomarker of early relapse or refractory disease.
Methods: Formalin-fixed, paraffin embedded (FFPE) tissuegenotyped for BRAF-V600E mutations with allele-specific, real-time PCR assays and immunohistochemistry (IHC) with moAb p53 in order to study an expression of tumor protein p53.
Results: During last 5 years in our Institute we diagnosed 5 cases of LCH. All patients have multisystem LCH and were immunohistochemically positive for S-100, CD1a. Patients received the same therapy: 6 cycles of chemo according to LCH – 1 study protocol: etoposide – 150 mg/m^2 i.v. (day 1-3), methylprednisolone – 30 mg/kg i.v. (day1-3). We assessed BRAF-V600E status in FFPE samples from all 5 patients (4 men and 1 woman, age between 23-55 years old, median age 39 y.o). BRAF-V600E mutation was found only in one patient. P53 was found at the same patient with positive BRAF-V600E. Compared with patients in which mutation of BRAF-V600Eand p53 have not been identified, this patient demonstrated early relapse (in 6 months after treatment). Two patients without mutation had late relapse (in 46 and 24 months – median 35 months), 1 patient had transformation in Hodgkin's lymphoma (in 12 months) and 1 patient is still in remission (for 36 months).
Summary and Conclusions: BRAF V600E and p53 mutations were found in 1 out of 5 patients with LCH. This patient had short remission duration in comparison with patients without BRAF and p53 abnormalities. Probably BRAF and p53 could be considered as a potential prognostic markers of remission duration.

PB1946

LYMPHANGIOGENESIS AND ANGIOGENESIS IN DIFFUSE LARGE B-CELL LYMPHOMA: RELATIONSHIP WITH CLINICAL FEATURES AND TREATMENT OUTCOME

A. Korycka-Wolowiec[1,*] E. Ziolkowska[1], D. Jesionek-Kupnicka[2], A. Wosztyl[3], M. Danielewicz[4], T. Robak[1], D. Wolowiec[5]
[1]Department of Hematology, [2]Department of Pathology, Medical University of Lodz, Lodz, [3]Hematology Department, Holycross Cancer Center, Kielce, [4]Department of Patomorphology, Medical University of Lodz, Lodz, [5]Department of Hematology, Medical University of Wroclaw, Wroclaw, Poland

Background: Formation of new blood and lymphatic vessels, called angio- and lymphangiogenesis, is essential for the development and dissemination of malignant tumors, including diffuse large B-cell lymphomas (DLBCL). It was demonstrated that the main lymphangiogenesis-involved cytokines:VEGF-C,-D and their receptor VEGFR-3 are expressed in the majority of DLBCL cases. Our previous studies revealed that VEGF-D serum concentration has a negative impact on the overall survival of DLBCL patients, however the influence of lymphangiogenesis on the clinical picture and treatment outcome assessed directly by a mean vascular density (MVD) and mean lymphatic vessels density (LVD) has not been studied so far.
Aims: The aim of our study was to evaluate the angiogenesis and lymphangiogenesis in DLBCL lymph nodes in relationship to the clinical features and the serum VEGF-C,-D, VEGFR-3 and bFGF levels at diagnosis, in order to assess the predictive value of those cytokines as to the complete remission (CR) achievement after standard R-CHOP treatment.
Methods: The study was performed in 31 (21 M, 10 F) DLBCL patients NOS type, aged 26-84 yrs (mean 67,5±13,6) from the Holycross Cancer Center, Kielce, Poland. 14 patients were classified as GCB, and the remaining 17 were non-GCB. For each patient blood count, serum LDH activity, b-2microglobulin, albumin and CRP concentrations were determined. The clinical stage of the disease and the general condition were determined according to the Ann Arbor classification, ECOG and the IPI staging system. The patients received 6-8 courses of the standard 21-R-CHOP regimen, and 10 of them achieved CR, in one case no data on remission were not obtainable. The cytokines serum concentration was established by ELISA method. The angio- and lymphangiogenesis were assessed in the DLBCL lymph nodes by immunohistochemical staining with anti-CD34 and D2-40 (a marker of lymphatic endothelium) antibodies. MVD and LVD was estimated in three selected hot spots by two independent investigators. As a control, MVD and LVD in a group of 11 inflammatory lymph nodes were determined. Statistical analysis was performed using Mann-Whitney test and the Spearman rank correlation coefficient. The p value less than 0.05 was assumed as statistically significant.
Results: For the whole group of patients, the mean MVD and LVD were 126,7±51,1/mm^2 and 99,6±81.6/mm^2, respectively. For the reactive lymph nodes the respective values were 197.1±43,0/mm^2 and 84.4±19,2/mm^2. MVD was significantly higher in reactive than in neoplastic lymph nodes (P=0.002). There was also a significant difference in MVD between complete as opposed to not complete remission patients (144.0±37.6/mm^2 and 117.9±56.7/mm^2; P=0.03). We did not find any relationship between LVD and the clinical parameters studied. MVD displayed no relationship either with clinical features or with treatment issue. We also found no correlation between the cytokines serum concentration and the extent of either angiogenesis or lymphangiogenesis.
Summary and Conclusions: Although the extent of lymphangiogenesis seems to be similar in DLBCL and non-neoplastic lymph nodes, the LVD may be a negative predictive factor with regard to the treatment of DLBCL with R-CHOP immunochemotherapy. Although our results do not support the usefulness of serum concentration of VEGF-C, -D, VEGFR-3 and bFGF as surrogate markers of angiogenesis and lymphangiogenesis in DLBCL, further studies on this issue would be worthwhile. The work was supported from a grant of Medical University of Lodz (503/1-093-01/503-01).

OPTIMISATION OF RNA EXTRACTION AND RT-QPCR FOR THE QUANTIFICATION OF AID IN ARCHIVED FFPE BIOPSY SAMPLES: ONLY TWO SECTIONS OF 4 MM TISSUE ARE REQUIRED

O. Alishlash[1,*] A. Pettitt[1], S. Coupland[1], K. Lin[1]
[1]Department of Clinical and Molecular Cancer Medicine, University of Liverpool, Liverpool, United Kingdom

Background: Activation induced cytidine deaminase (AID) induces genomic alterations required for immunoglobulin SHM degradation and CSR in normal B cells. The mutagenic effects of AID may also contribute to genomic instability and adverse outcome in B-cell malignancies. We sought to address this question by measuring levels of AID mRNA and protein in formalin fixed paraffin embedded (FFPE) biopsy samples from patients with follicular lymphoma (FL). Since measuring specific mRNAs in FFPE samples is notoriously challenging owing to RNA
Aims: in this study, we aimed to first optimise the conditions for mRNA extraction, cDNA synthesis and qPCR amplification.
Methods: 8 FFPE tissue samples stored in a local FL tissue bank for 0.5 – 14 years were used for this optimisation. Using 2 sections of 4µm-thick tissue, we found that a better yield of RNA was obtained with the Qiagen RNeasy FFPE Kit as compared to the Promega ReliaPrep™ FFPE Total RNA Kit (2 µg vs 0.9 µg in average).
Results: The yield was further increased (65%) by modification of the deparafinization procedure. Using random primers for cDNA synthesis combined with a pair of qPCR primers targeting a 100-bp sequence spanning two exons, we found that AID mRNA was consistently and reproducibly detected in both recently obtained and old FFPE samples. Applying our method to artificially degraded RNA extracted from B-cell line cells, we found that AID mRNA levels were not changed when the RNA integrity number (RIN) varied between 2.1 and 10. Applying this criterion to archived FFPE samples from patients with FL that had been stored for between 0.5 and 5 years allowed us to successfully quantify AID mRNA levels in 33/56 (59%) cases. To validate our findings, levels of AID mRNA were compared to levels of AID protein detected in all of the 33 samples by IHC; a significant positive correlation (P<0.001) was observed.
Summary and Conclusions: In summary, we have shown that a sufficient quantity of mRNA for RT-qPCR can be extracted from only two sections of 4mm-thick FFPE tissue if an optimised protocol is applied. Our findings are relevant not only to the measurement of AID but to all situations where mRNA quantification is required and tissue availability is a limiting factor.

PB1948

TRANSAMINASES AND THE INFLUENCE OF SILYMARIN IN EPIRUBICIN CHEMOTHERAPY REGIMENS IN MICE

S. Alciona[1,2,*] H. Anca[3], M. Eftimie[4,5], C. Coralia[1,2]
[1]Hematology, Clinical emergency county hospital of arad, [2]Hematology, [3]histology, [4]gastroenterology, Vasile Goldis Western University of Arad, [5]gastroenterology, Clinical emergency county hospital of arad, arad, Romania

Background: Epirubicin is a chemotherapeutic drug used in the haematological malignancies regimens. Epirubicin forms a complex with DNA, with consequent inhibition of nucleic acid (DNA and RNA) and protein synthesis. Epirubicin is cytotoxic *in vitro* to a variety of established murine and human cell lines and primary cultures of human tumors. It is extensively and rapidly metabolized by the liver, one of the reported toxicities being the hepatotoxicity. Serum aminotransferase elevations occur in up to 40% of patients on antraciclin therapy. There are some natural compounds that have been investigated for their hepatoprotective effects.
Aims: The scope of this study was to evaluate the hepatotoxicity of epirubicin as seen through the elevation of transaminases and in parallel to evaluate the protective effect of silymarin in mice treated with epirubicin and silymarin.
Methods: The study included 6 mice experimental lots (first lot with no treatment, the second lot treated with epirubicin alone, the third and the forth lots treated with epirubicin and silymarin 50 and 100mg/day, the fifth and sixth lots treated with silymarin alone, 50 and 100mg/day).
Results: The results showed that in the epirubicin treated lot, the level of ASAT was increased compared to the lots treated with epirubicine and silymarine or silymarine alone (P=0,0111 for the lot treated with epirubicin and also 50mg silymarine/day, P= 0.0374 for the ot treated with epirubicin and also with 100mg silymarine/day). Concerning the ALAT, we haven't found any statistical significant results in the compared lots.
Summary and Conclusions: As a conclusion, silymarine could have a hepatic protective effect when taken in the same time with the epirubicin included regimens in mice.

Non-malignant hematopoietic disorders

ERYTHROPOIETIC RESPONSE TO A LIGAND TRAP OF ACTIVIN RECEPTOR II IN CULTURES FROM B-THALASSEMIA PATIENTS

S. Flotta[1,*] P. Delbini[1], G. Graziadei[1], A. Marcon[1], V. Sung[2], M.D. Cappellini[1,3]
[1]Internal Medicine Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [2]Celgene Corporation, San Francisco, United States, [3]Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milan, Italy

Background: The hallmark of β-thalassemias is ineffective erythropoiesis leading to anemia and tissue hypoxia. Activin has been shown to affect the erythropoiesis in the late-stage of maturation. Sotatercept [ACE-011; Celgene Corporation (Summit, NJ, USA)], a recombinant activin receptor type IIA ligand trap, binds with high affinity activin A/B and other members of the transforming growth factor β-superfamily**.** In animal models, RAP-011, a murine ortholog of ACE-011, reverses bone loss and increases hemoglobin and hematocrit by acting indirectly on the late stages of erythropoiesis and in a mouse model of β-thalassemia, RAP-011 was shown to improve anemia and the quality of erythroid cells.
Aims: The aim of our study is to further explore the molecular mechanisms underlying the effect of RAP-011 on erythropoiesis in erythroid progenitor cell cultures from β-thalassemia patients at different stages of differentiation and maturation.
Methods: $CD34^+$-enriched cells were isolated from peripheral blood of β-thalassemia patients and healthy donors by immunoselection. $CD34^+$ cells were cultured in the presence or absence of RAP-011 (50 and 100 μg/mL) for 14 days in two conditions: liquid standard cultures and HS5 stromal cell line co-cultured with $CD34^+$ cells. $CD34^+$ liquid cultures in medium from HS5 cells conditioned with RAP-011 (CM) were also set up. Conditioned medium was assayed for apoptosis activity and cytokine content by ELISA. In the co-cultures, the erythroid cells were rescued as non-adherent cells in supernatant (NAC), phase-bright cells adhering to the surface of HS5 cells (PBC) and phase-dim cells beneath the stromal cells (PDC). At day 14 erythroid cells were evaluated for cell number and viability, differentiation (Glycophorin/CD71/CD34) and gene expression profile.
Results: At day 14, there were no significant differences in cell number, viability and immunophenotype between untreated liquid cultures and those treated with RAP-011 (either derived from β-thalassemia and control subjects). In β-thalassemia co-cultures, no relevant differences in cell number and viability of the three cell fractions, in presence or absence of RAP-011 were observed; whereas the cell surface marker Glycophorin was more highly expressed in NAC (1.5-fold, $P<0.05$) and PDC (3.6-fold, $P<0.001$) treated with RAP-011 in comparison to untreated fractions. Similar results were observed in controls. In CM cultures, RAP-011-treated erythroid precursors from β-thalassemic patients expanded significantly compared to untreated cells (6.5-fold vs 3.1-fold). No significant differences were found in controls. High levels of anti-inflammatory, anti-apoptotic cytokines (SICAM-1, Bcl-2 and Bcl-xL) and factors that favour erythroid differentiation (MCP-1 and GRO-a) were detected in CM. At day 14 in presence of RAP-011, GATA1 expression increased ($P<0.005$) while GATA2 and α-globin expression decreased in erythroid thalassemic cells. In control subjects, no significant differences were observed. In β-thalassemic CM and co-cultures treated with RAP-011, GATA1 mRNA production was strongly induced ($P<0.001$), while the levels of GATA2 and α-globin mRNA were significantly lower ($P<0.005$). Similar results were observed in controls.
Summary and Conclusions: Our results suggest that RAP-011 didn't directly affect erythroid maturation, but probably acted through bone marrow-derived factors. Furthermore, RAP-011 seemed to recruit quiescent $CD34^+$ cells with more primitive properties (NAC and PDC), stimulating them to differentiate with an especially marked effect on erythroid maturation.

PB1950

DACRYOCYTES ARE A COMMON MORPHOLOGIC FEATURE OF AUTOIMMUNE AND MICROANGIOPATHIC HEMOLYTIC ANEMIA

C. Robier[1,*] D. Klescher[1], G. Reicht[2], O. Amouzadeh-Ghadikolai[3], F. Quehenberger[4], M. Neubauer[2]
[1]Central Laboratory, [2]Department of Internal Medicine, [3]Department of Psychiatry, Hospital of the Brothers of St. John of God, [4]Medical University of Graz, Graz, Austria

Background: Dacryocytes are teardrop- or pear-shaped erythrocytes which are usually found in peripheral blood smears of patients with primary or secondary myelofibrosis as well as infiltrative neoplastic disorders of the bone marrow. Such a teardrop poikilocytosis has rarely been observed in blood smears of patients with autoimmune (AIHA) and microangiopathic hemolytic anaemia (MAHA). The prevalence of dacryocytes in AIHA and MAHA has not been examined to date.
Aims: The aim of this study was to determine the prevalence of dacryocytes in peripheral blood films of patients with AIHA and MAHA.
Methods: We compared the dacryocyte counts in blood smears stained according to the May-Grünwald-Giemsa technique between 20 subjects with AIHA (n=9) and MAHA (n=11) with those from 21 controls having normal peripheral blood counts and lacking signs of hemolysis. The dacryocytes, defined as erythrocytes tapered to a point at one end, were counted as cells per 20 high power fields (HPF) at 630-fold magnification.
Results: In AIHA, MAHA and controls, dacryocytes were found in 89% (8/9), 91% (10/11) and 19% (4/21) of the blood smears, respectively. The medians and ranges of the dacryocyte counts per 20 HPF were 24 (0-89), 11 (0-50) and 0 (0-1). The rates of dacryocyte positivity and the dacryocyte counts between the samples of hemolytic anemias and controls differed statistically highly significant ($P<0.0001$).
Summary and Conclusions: The results of this study indicate that dacryocytes are commonly apparent in blood smears of patients with AIHA and MAHA. Knowledge of this frequent feature may be beneficial in clinical routine diagnosis.

SCREENING OF GAUCHER DISEASE TYPE 1 IN NON-ASHKENAZIC POPULATION – A PILOT PROJECT IN MORAVIAN-SLESIAN REGION

L. Stejskal[1,*] C. Bodzásová[1], E. Tothová[1,2]Z. Kučerová[1], J. Bizoňová[1], M. Janušková[1], J. Vaculova[3], Z. Zetková[4], N. Rytiková[5], M. Mičaníková[6], R. Hájek[1,2]
[1]Department of Haematooncology, University Hospital, [2]Faculty of Medicine, University of Ostrava, Ostrava, [3]Department of Haematology, Hospital in Frýdek Místek, Frýdek Místek, [4]Department of Clinical Haematology, Hospital in Nový Jičín, Nový Jičín, [5]Department of Haematology, Hospital in Krnov, Krnov, [6]Departement of Haematology, Multicipal Hospital in Ostrava, Ostrava, Czech Republic

Background: The patients with Gaucher disease (GD) type 1, although it is the most common lysosomal storage disease, have probably not met the primary care doctors not even once in 10 years. This may cause that GD patients have been passing through the years in a specialized clinic under different diagnosis and they are not being treated properly. With regard to the incidence of GD 1: 60000 in our Moravian-Silesian Region (with approx. 1,3 mil. people), should be 20 persons with GD type 1. But there was only one patient with GD in National Center for the treatment of GD in the Czech Republic till December 2013. Based on a successful pilot project of GD diagnosis that was solved by our colleagues in Italy, under the leadership of prof. Cappellini (*), we decided to implement similar in our conditions. *(*) Motta I. et al., A Multicenter Observational Study For Early Diagnosis Of Gaucher Disease In Patients With Splenomegaly and/Or Thrombocytopenia, Poster ASH 2013*
Aims: Our aim is to highlight this rare diagnosis, on which we should think more in the differential diagnosis of hepatosplenomegaly and thrombocytopenia, particularly in all the unclear cases.

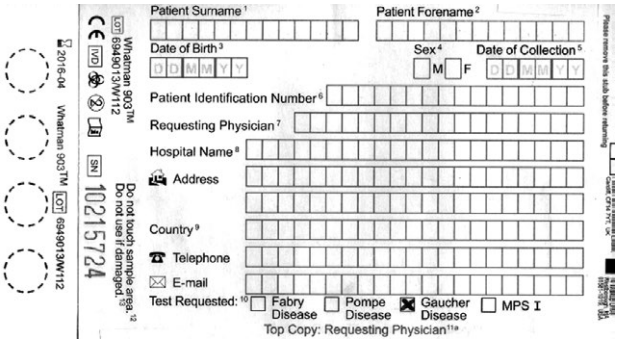

Figure 1.

Methods: We have used Dried Blood Spot (DBS) cards (attached) to detect beta-glucosidase enzyme activity in patients with splenomegaly (palpable spleen or ultrasound examination demonstrated over 12 cm) and/or thrombocytopenia (platelets below 130x 10/9/l). In the case of thrombocytopenia, at least 1 more condition must be met: the current anemia, MGUS or polyclonal gammopathy, bone pain history, or past history of splenectomy. We excluded individual with criteria: A) known hematological malignancy, B) proven cirrhosis of the liver or hemolytic anemia incl. hemoglobinopathy.
Results: For 10 months (from May 2014 to February 2015) we enrolled 15 patients (9 male, 6 female) from hematology clinics in Moravian-Silesian Region. The reasons for testing were: 27% (4/15) splenomegaly, 27% (4/15) thrombocytopenia and 46% (7/15) both of them. During this period all 15 DBS test were negative, none patient was diagnosed with GD.
Summary and Conclusions: We are continuing to search for the patients with GD to may put these patients the chance of timely and adequate treatment to prevent serious complications and restrictions on their quality of life.

PB1952

GAUCHER DISEASE LATE COMPLICATIONS IN AN ITALIAN FAMILY

C. Carbone[1,*]
[1]Hematology, Ospedali Civili Brescia, BRESCIA, Italy

Background: Gaucher disease is a genetic disorder, autosomal recessive, due to the lack of an enzyme in the metabolic pathway of phospholipids. The deficiency of glucocerebrosidase leads to accumulation of glucocerebroside in macrophages in the spleen, liver, bone marrow, bone, and other tissues/ organs. Its manifestations are still highly subject to different penetrance.
Aims: We know in Gaucher patients there is major incidence of neoplastic diseases and of Parkinson's disease.
Methods: We describe an Italian family, composed of 5 brothers, where we can observe all described complications.
Results: In this family only one member is healthy. The first brother, suffering from Gaucher (diagnosis 58 years old), never treated, at the age of 64 years developed acute lymphoblastic leukemia with a rearranged karyotype, was treated with supportive care and he died of infection after a few months in 2004. The sister, born in 1941, received diagnosis in 2004 with her brothers.She was already affected of a neurological form of juvenile-onset Parkinson's disease. Treated for about 2 years with enzyme replacement therapy, she manifested improvement in haematological parameters but simoultaneously she showed a rapid deterioration of psychophysical performance. Brother n° 3 (b. 1949) received the diagnosis of Gaucher disease in 2004. He was treated with enzyme, in 2011 he developed acute myeloid leukemia, and he died in 2012 after chemotherapy. The last brother, born 1952, is currently in treatment without complications, with stable disease.
Summary and Conclusions: The history of this family confirms the data of higher incidence of neoplasms and Parkinson's disease reported in the literature. It confirms, also, the reduced expectance of life of Gaucher patients.

PB1953

PRIMARY HEMOPHAGOCYTIC SYNDROME IN PEDIATRIC

S. guemghar[1,*] C. kaddache[1], F. sadaoui[1], H. mesbaiah[1], A. lamraoui[1]
[1]university of BLIDA, Clinical of pédiatric BLIDA, Blida, Algeria

Background: Hemophagocytic syndrome (HS) is a clinical-biological entity characterized by exaggerated and uncontrolled immune response. It can be primary or secondary. Serious illness that can develop life-threatening and imposing the initiation of urgent specific treatment. The existence of a family history, consanguinity and an early start is very suggestive of primitive forms and reports to various forms of immunodeficiencies. We relating 6 cases of primary HS hospitalized in our department over a 4 year period.
Aims: Records of patients with HS
Methods: Retrospective study from December 2009 to December 2014, 6 children with primary HS were collected, the diagnosis was made on the criteria of histiocyte society, 2007.
Results: There are 4 boys and 2 girls with an average age of 23 months (range 2 months-6 years). The clinical picture is dominated by fever and poor general condition (100% of cases), organomegaly (hepato splenomegaly) control tissue infiltration by histiocytes, was found in all cases. Neurological involvement is present in 3 patients. The pigmentation abnormality is found in 3 cases. Very contributive biology revealed a healthy cytopenia at least 2 bloodlines (100% of cases), fibrinogen is decreased in 83% of cases associated with a lower TP. Ferritin sensitive and specific test HS is greater than 500 microg / l in 5 cases. Medullary smear showed hemophagocytosis and confirms the diagnosis in all cases. Genetics is made in 3 cases. The underlying etiologies were: 3 cases of syndrome Chediak-Higashi (CHS), 2 cases of familial hemophagocytic lympho- histiocytosis probable, probable case of Purtilo syndrom type 2. These surges haemophagocytosis were triggered by EBV infection in 3 cases. The combination of corticosteroids and immunosuppressive have been established in all cases, and in 03 cases an anti CD20, no child has received marrow transplant. The evolution was fatal for 4 children in an array of multi-visceral failure (2 CHS and 2 family HLH). A case has developed autoimmune cytopenia.
Summary and Conclusions: Primary HS remains a serious disease with a poor prognosis, 70% mortality was observed in our series. Hope lies in the realization of a bone marrow transplant for our patients in Algeria

PB1954

CONTRIBUTION OF BLOOD SMEAR IN THE DIAGNOSIS OF STORAGE DISEASES: REPORT OF A CASE OF NIEMANN PICK'S DISEASE

N. Haddad[1,*] S. Guemghar[2], S. Bouchrit[2], A. Lamraoui[2], R. Belouni[1], C. Kaddache[2]
[1]central laboratory, [2]pediatric departement, BLIDA Hospital, Faculty of Medecine, BLIDA, Algeria

Background: Lysosomal storage diseases are rare constitutional diseases due to deficiency of a lysosomal protein that causes the blockage of a catabolic pathway of macromolecules. These conditions result in the accumulation of non-degraded metabolites in various tissues including the hematopoietic tissue. Their classification is based on the nature of the accumulated substance (mucopolysccharides, sphingolipids, neutral lipids, oligosaccharides...) and the protein in question anomaly. There are: the Gangliosidoses, Gaucher disease and Niemann-Pick disease. Niemann Pick's disease is associated with abnormal transport of cellular lipids inducing an accumulation of cholesterol and glycosphingolipids in the brain (type A +++) and other tissues. There are 3 types according to the presence (type A) or absence (type B), progressive presence (type C) neurological manifestations.
Aims: We report the case of a 50 days old infant hospitalized at the pediatric department for exploration of a fever in the long term with hepatosplenomegaly.
Methods: The blood count shows a bicytopenia: aplastic anemia hypochromic microcytic to 6 g / dL with moderate thrombocytopenia 118 G / L. The examination of the blood smear then highlights a population of abnormal lymphocytes containing large and multiple vacuoles. The anomaly appears vacuolated lymphocytes with enough evidence to we can assert its pathological nature and distinguish visible microvacuoles sometimes in normal lymphocytes.
Results: These clinical characteristics (hepato splenomegaly) and biological (presence of vacuolated lymphocytes) are evoke a lysosomal storage disease. Bone marrow smer confirms the pathological origin of these vacuoles and shows the presence of foam cells and bulky loads that oriented towards the diagnosis of the Niemann Pick's disease.
Summary and Conclusions: The storage diseases include the often poorly understood diseases. In this context, the detection of inconstant cytologic anomalies in blood and bone marrow smears, permitting a rapid screening, is an important step in the diagnostic approach.

PB1955

ETIOLOGICAL EVALUATION OF PATIENTS WITH VENOUS THROMBOEMBOLISM

E. Saribacak Can[1,*] H. Okutan[2]
[1]Hematology, Ankara Diskapi Yildirim Beyazit Training and Research Hospital, [2]Hematology, Ankara Diskapi Yildirim Beyazit Training and Research Hospital,, Ankara, Turkey

Background: Etiological Evaluation of Patients with Venous Thromboembolism.
Aims: Venous thromboembolism (VTE) is the common name for all pathological thrombosis in venous circulation. It commonly occurs deep veins of lower extremities; and more rarely in upper extremities, pelvis and in other veins. The most important component of VTE which poses a threat to life is pulmonary embolism. It is determined that pulmonary embolism is deadly disease, and 30% of the patients with pulmonary embolism die within the 30 days, and exactly the same proportion of patients (30%) die within following 8 years due to chronic complications such as recurrent attacks or pulmonary hypertension. Hospitalization is one of the most important factors which acutely trigger the pulmonary embolism. The purpose of this study is to perform etiological examination of the patients who apply to the department of hematology of our hospital and who are diagnosed with venous thromboembolism.
Methods: In this study, we prospectively evaluated the factors, which can play a role for etiology, in outpatients of our hospital, who were diagnosed with VTE and who received hospitalized treatment during 2009 – 2012.
Results: The patients with venous thromboembolism, 83 in total, ranged in age between 18 and 50 years with an average age of 38,1±10,1. 35 of the patients were men (42,2%) and 48 (57,8%) were women. According to the classification of thrombosis localization in the patients, pulmonary embolism was detected in 34 patients (41,0%), DVT in 29 patients (39%), SVT (sinus ven thrombosis) in 9 patients (10,8%), RVT (retinal ven thrombosis) in 7 patients (8,4%), and intraabdominal ven thrombosis in 4 patients (4,8%). In the classification of thrombosis localization of the patients with venous thrombosis according to the age groups, there was a statistically significant difference among the age groups in terms of pulmonary embolism (P=0,028), and localization of pulmonary embolism was more frequent in the age group of >40 compared to ≤30 (P=0,008). No statistically significant difference was determined among the age groups for the frequency of localization for DVT (P=0,325). There was a statistically significant difference among the age groups for sinus thrombosis (P=0,005), and frequency of sinus thrombosis was higher for the age groups of ≤30 and >40 compared to the age group of 31-40 (P=0,010 and P=0,017). When the findings were evaluated as normal/heterozygote+homozygote for FV Leiden, there was a statistically significant difference among the age groups (P=0,026), and the rates of heterozygote/homozygote was lower for the age groups of ≤30 and >40 compared to the age group of 31-40 (P=0,013 and P=0,035). No statistically significant difference was detected for prothrombin gene mutation (P=0,090). When inherited and acquired thrombophilia factors were studied in the patients with recurrent abortus history, FV Leiden heterozygote (16,7%) was determined in 8 patients, FV Leiden homozygote (6,3%) in 3 patients, prothrombin gene mutation heterozygote 1 (2,1%) in 1 patient, AT3 deficiency (2,1%) in 1 patient, high level of D-dimer (6,3%) in 3 patients, high level of fibrinogen (8,3%) in 4 patients, high level of homocysteine (8,3%) in 4 patients, ANA positive (8,3%) in 4 patients, AntiDsDNA positive (4,2%) in 2 patients, AKAIGM positive 4 (8,3%) in 4 patients, AKAIGG positive (4,2%) in 2 patients.

Summary and Conclusions: Venous thromboembolism is a frequently seen at the clinic practice with high mortality and morbidity. The patients must be evaluated with appropriate methods, and their diagnosis must be made at an early stage. Moreover, inherited and acquired risk factors must be systematically evaluated in an appropriate manner. This evaluation proposes anticoagulant therapy for risky cases and determines duration of the therapy.

PB1956

HEMATOLOGY MEETS ONCOLOGY: AN INTERESTING CASE OF SPLENOMEGALY AND CYTOPENIA AFTER SURGICAL RESECTION AND CHEMOTHERAPY FOR COLORECTAL CANCER

M. Haas[1,*] P. Rexrodt[2], H.J. Schlitt[3], U. Vehling-Kaiser[1]
[1]Practice for Hematology, Oncology and Palliative Care, [2]Practice for Radiology and Radiotherapy, Landshut, [3]Department of Surgery, University Hospital of Regensburg, Regensburg, Germany

Background: Hematology and oncology are increasingly becoming different specializations with own experts in their fields.
Aims: The current case from a rural oncologic practice in Germany shows an interesting cross-link between surgery, oncology and hematology.
Methods: A 38 year old woman underwent R0 resection of an adenocarcinoma of the ascending colon in 2001. Afterwards she was treated with 4 cycles of adjuvant chemotherapy with 5-fluorouracil/folinic acid/oxaliplatin. In 2005 recurrent disease with liver metastasis in the right liver lobe was diagnosed and was treated by a right hemihepatectomy. One year after the partial liver resection, a splenomegaly of 18cmx 5cm became evident, but did not cause any symptoms. The blood count then showed a slight tri-cytopenia with leucocytes 2.8 G/L, hemoglobin 11.3 g/dl and thrombocytes 85 G/L, which was interpreted as associated with previous chemotherapy. In frequent follow-up visits, there has been no sign of relapse of colorectal cancer up to now. The splenomegaly remained constant with recovered values for leucocytes and persistent thrombocytopenia around 100G/L. The patient was fully active without any problems due to splenomegaly. In 2013, the patient increasingly suffered from left-sided abdominal pain and fatigue, the spleen then was 20cm in size. Thrombocyte count had occasionally dropped below 50 G/L. Bone-marrow puncture was performed showing no signs of dysplastic syndrome or other malignancy. In August 2014, the spleen was 23 cm in longest diameter. A CT-scan showed signs of portal hypertension with pronounced collaterals, possibly due to constriction of the inferior vena cava and/or left hepatic vein, as a potential complication of the liver-resection in 2005. A gastroscopy confirmed oesophageal varices. The patient was transferred to a university hospital for further diagnostics and potential placement of a portosystemic shunt. Left hepatic vein stenosis could not be substantiated by venous catheter pressure measurements. As a definite reason for portal hypertension was not clear with no evidence for liver cirrhosis or fibrosis, the patient was advised for splenectomy for symptom relief.
Results: To avoid splenectomy, as preferred by the patient and the treating hemato-oncologist, the case was again discussed with the surgeon. It was concluded to initially perform a side-to-side spleno-renal shunt. After constructing the shunt, a significant reduction of blood-flow through the portal vein directly after surgery was observed. Only three months after the intervention, the spleen had shrunk from 24cm to 16cm accompanied by an increase in thrombocytes above 100 G/L and significant improvement of symptoms.
Summary and Conclusions: Splenectomy could finally be avoided and the patient showed a significant improvement in symptoms after construction of the shunt. The current case illustrates the necessity of close networking between different disciplines and especially the treating physicians in rural areas and specialists at highly specialized centers.

FLOW CYTOMETRY ANALYSIS OF BONE MARROW HEMATOPOIESIS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP)

G. Shubinsky[1,2,3,*] Y. Kapelushnik[2,4], A. Abu-Koider[4], O. Pikovsky[2,3], T. Gershberg[1], I. Dulman[1], I. Levi[2,3]
[1]Flow Cytometry Unit, Hematology Laboratory, Soroka University Medical Center, [2]Faculty of Health Sciences, Ben-Gurion University of the Negev, [3]Institute of Hematology, [4]Department of Pediatric Hemato-oncology, Soroka University Medical Center, Beer Sheva, Israel

Background: Immune thrombocytopenia (ITP) is a clinically and pathogenetically diverse autoimmune disorder resulted from antibody and/or T-cell mediated destruction of platelets and insufficient platelet production by immunologically affected megakaryocytes. The studies of bone marrow (BM) hematopoiesis in ITP show morphologically normal marrow with increased number of megakaryocytes in many patients. Abnormal levels of plasma thrombopoietin, interleukin 6 and some other hematopoietic cytokines were recently reported in patients with ITP, and these suggested a disorder of cytokine regulation with possible consequences for BM hematopoiesis. BM examination is usually unnecessary for patients with ITP, but flow cytometry (FC) study of BM is needed in some thrombocytopenic patients to exclude non-immune causes of cytopenia. The data of multi-parametric FC analysis in these patients represent a good opportunity to determine morphologically undetectable abnormalities in BM hematopoiesis at ITP.
Aims: The **aim** of current study was to examine hematopoiesis in patients with ITP by FC analysis of their BM.
Methods: FC records of eleven adult and seven pediatric patients with non-treated primary ITP from our database were enrolled for retrospective analysis. Different types of hematopoietic progenitor cells, B-lineage, myeloid and nucleated erythroid cells of different maturity were counted in BM of patients with ITP using several eight-color staining protocols and multi-parametric FC analysis. The data from ITP patients were compared with the data from hematologically normal adult (n=29) and pediatric (n=7) BM.
Results: Differential count of BM cells by FC detected the elevated numbers of total CD34+ hematopoietic progenitors, CD34+/cytoCD79a+/nuTdT+ B-lineage progenitors, CD34+/CD33+ committed myeloid progenitors and probable increase of early erythroid progenitors (erythroblasts) in adult patients with ITP when compared with normal adult BM and BM from patients with idiopathic cytopenia of undetermined significance as pathological control. FC showed an increased fraction of CD10+/CD20+/nuTdT- immature B cells and increase of total population of B cells in BM of adult patients with ITP. In contrast to adult patients, a reduced number of B cells was found in BM of pediatric patients with ITP, and it resulted from decrease of B-cell progenitors and immature B cells. FC revealed no other significant differences between BM of pediatric patients with ITP and age-related controls.
Summary and Conclusions: The present data suggest an acceleration of hematopoiesis in adult patients with ITP and address the question of its potential role in the pathogenesis of disease. Opposite changes in the composition of BM B cells in adults and children may reflect a different pathogenetic role of B cells and BM lymphopoiesis in the adult and pediatric ITP.

PB1958

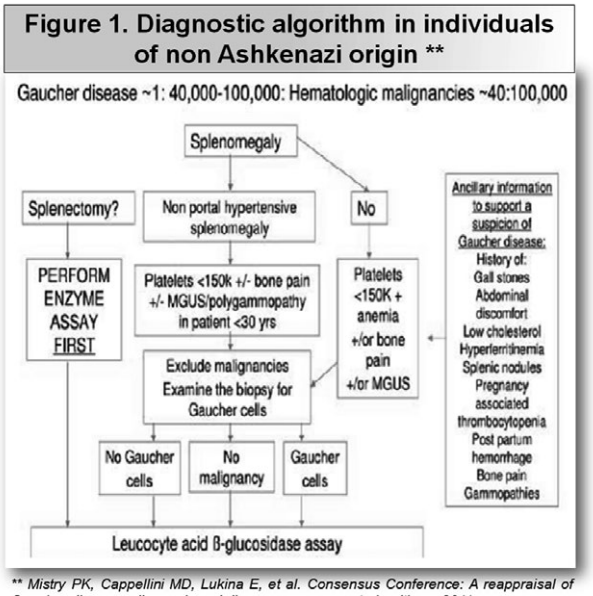
IDENTIFICATION OF INCIDENT CASES OF GAUCHER DISEASE IN PATIENTS CONSULTING FOR SPLENOMEGALY AND/OR THROMBOCYTOPENIA IN SPECIALIZED MEDICAL SERVICES IN COLOMBIA THROUGH THE USE OF A SELECTION ALGORITHM

J.N. Marun Chagin[1], G.J. Davd Tarud[1], Y.P. Jimenez[2], W.A. Barcenas Narvaez[2], R.D. Salazar[3], D.I. Molina[4], J.D. Villanueva[5], J.G. Duque[6,*] C. Mejia[7], A.C. Rubio Marin[6]
[1]Colombia, Cecac, [2]Colombia, Bonnadona, Barranquilla, [3]Colombia, Astorga, Medellin, [4]Colombia, IPS Medicos Internista de Caldas, Manizales, [5]Colombia, Caimed, Barranquilla, [6]Colombia, Caimed, [7]Colombia, Genzyme Colombia, Bogota, Colombia

Background: Gaucher disease (GD), categorized by its low frequency as rare disease is an autosomal recessive lysosomal storage disorder, characterized by deficiency of the enzyme acid beta-glucosidase. The prevalence is 1:40,000/100,000 live births in the general population and 1:500 live births among Ashkenazi Jewish (Grabowsky G.,2004). Data from the International Gaucher Registry (GR), 2010 have included 5828 patients, reporting that 15.6% (911) of the patients are from Latin America. GD has great variability in the severity and organ involvement, being usually of nonspecific clinical characteristics, leading to late diagnosis, with irreversible complications. Splenomegaly and thrombocytopenia are the two most common manifestations, revealed in 2008 on the GR, which reported 86% cases with moderate to severe splenomegaly and 60% thrombocytopenia at the time of diagnosis,

and these are the reasons why patients are referred in the first instance to hematology. Considering the diagnosis of GD after other diagnostic hypotheses have been ruled out. The consensus of international experts in the management of patients with GD, established a diagnostic algorithm that is specially intended for specialists (Mistry et al 2010). The diagnostic algorithms of straightforward implementation, to support medical specialties in Latin America for early diagnostic suspicion of GD is required.

Aims: To identify new cases of GD in a selected population referred to Hematology, Pediatric Hematology, Pediatrics, Genetics and Internal Medicine services with a history of splenomegaly and/or thrombocytopenia, which are parameters of the diagnostic algorithm for the general population, based on the recommendations of the article by Mistry, et al (Figure 1).



** Mistry PK, Cappellini MD, Lukina E, et al. Consensus Conference: A reappraisal of Gaucher disease - diagnosis and disease management algorithms. 2011.

Figure 1.

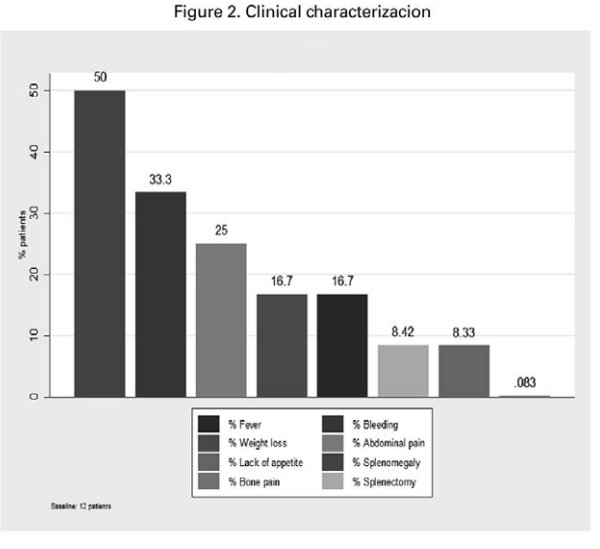


Figure 2.

Methods: Multicenter, descriptive study, in active recruitment process with non-probabilistic sampling by convenience. Currently, the study has 16 specialized medical centers in Hematology, Pediatrics and Internal Medicine in Colombia. Eligible patients are those with documented thrombocytopenia<150,000 mm3 according to Mistry algorithm, or splenomegaly defined as palpable spleen ≥1 cm below the costal rim or diagnosed by ultrasound, Nuclear Magnetic Resonance and Computed Tomography. Patients with prior diagnosis of GD, splenomegaly due to portal hypertension, documented hematologic malignancy or hemolytic anemia/ thalassemia were excluded. All patients were compiled information from their medical history and the determination of the activity of the enzyme beta-glucosidase, was performed. The study has an expected duration of 12 months of recruitment for each center.

Results: Since February 2014 (many of the patients were admitted in November and December), 27 patients have been recruited, of which analysis of enzymatic results report was obtained in 12 patients (7 women and 5 men) with median age of 9 years in a range of 1.33 to 79 years. All patients of non-Ashkenazi origin reported 50% of splenomegaly, among other symptoms and signs (Figure 2). It was recorded from the total sample analyzed, 91.7% of thrombocytopenia, and an enzymatic report of a patient with evidence of a positive correlation with chitotriosidase levels (Figure 3).

Figure 3. Laboratory report

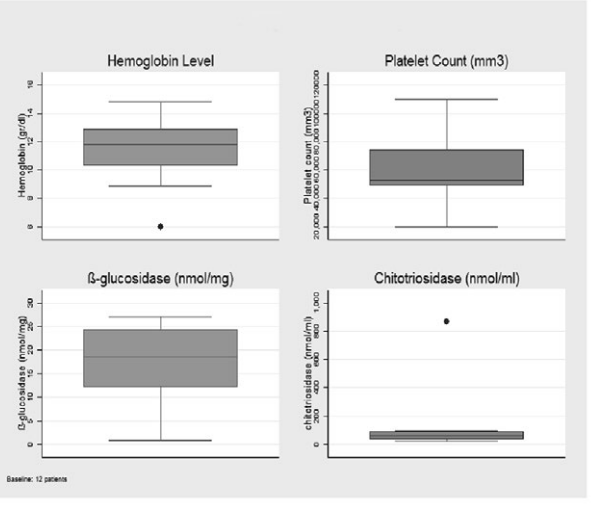

Figure 3.

Summary and Conclusions: The results of this study are in early stages of development, and its analysis is based on a limited sample. Nevertheless there is evidence that the algorithm offers support to specialists in our environment to detect new cases of GD. We will expect to recruit more patients and sites during year 2015 to provide more power to the results of this clinical study.

Acknowledgements: We thank Genzyme Colombia for financial support and CAIMED Colombia for coordination of the study.

PB1959

CORRELATION OF CLINICAL FEATURES AND OUTCOME IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA

S.J. Kim[1,2,*] H.S. Ahn[1,2], H.S. Choi[1]
[1]Pediatrics, Seoul National University Bundang Hospital, Seongnam, [2]Medicine, Seoul National University, Seoul, Korea, Republic Of

Background: Immune thrombocytopenia (ITP) is the most common cause of abrupt onset thrombocytopenia in an otherwise healthy child. Many efforts have been made to identify patients at risk of developing persistent or chronic ITP.

Aims: The aim of this research was to investigate the relationship of clinical features and outcome of patients receiving intravenous immunoglobulin (IVIG), with the intent of identifying prognostic factors.

Methods: During the period between January 2009 and July 2014, we retrospectively analyzed 94 children newly diagnosed with ITP who received IVIG treatment. Medical records of all patients were reviewed retrospectively. CBCs with differential counts were obtained at diagnosis, 1, 3, 6, and 12 months.

Results: Ninety four patients aged between 1.3 months and 15 years (median 27.3 months) were enrolled. Multivariate analysis showed that patient gender, age at diagnosis, history of viral infection or vaccination prior to disease onset and IVIG dosage was not statistically correlated with platelet recovery at 6 and 12 months. Also, hemoglobin count, total leukocyte count (TLC), absolute neutrophil count (ANC), and absolute lymphocyte count (ALC) at diagnosis was not correlated with patient outcome. However, early platelet count recovery of ≥ 100,000/μl at 1 and 3 months after IVIG treatment was significantly correlated with platelet recovery at 6 (P<0.001 and P<0.001, respectively) and 12 months (P=0.014 and P=0.019, respectively).

Summary and Conclusions: To date, there is no consensus regarding the management of acute ITP, however IVIG use to expedite the recovery of a platelet count adequate for hemostasis is commonly practiced for newly diagnosed ITP children. The results of this study indicate that early platelet count recovery was the only significant prognostic factor associated with a short disease duration and favorable outcome. Further investigation of a larger pool of patients is warranted to validate these findings and an understanding of the pathophysiological mechanism underlying this association is needed to properly identify prognostic factors of patients at risk of developing persistent or chronic ITP.

Key words: immune thrombocytopenia (ITP); children, prognostic factor, outcome.

PB1960

THERAPY WITH RITUXIMAB AND TPO-RA IN THE REAL-LIFE CLINICAL PRACTICE OF ITP

V. Rancitelli[1,*]
[1]Internal Medicine, University of Padua, Padova, Italy

Background: The classical therapeutic approach for Immune Thrombocytopenic Purpura (ITP), provides the use of corticosteroids and intravenous immunoglobulins (IVIg) as first line treatment and, in case of refractoriness, the splenectomy as second line therapy. Since more than ten years other two drug regimens with Rituximab and TPO-ra, are available for the ITP treatment but their precise location in the stages of the disease is still debated.
Aims: Goal of this study was to evaluate, retrospectively, the use and efficacy of Rituximab and TPO-ra in the real-life practice of ITP to define the best time for their use.
Methods: The response to Rituximab and TPO-ra was investigated in patients treated (21 and 15 ITP patients respevtively) between May 2004 and February 2015 at our ward. The response was evaluated in terms of efficacy (CR*= Complete Response >100 pltx 10^9L, PR= Partial Response >50 pltx 10^9L, MR= Minimal Response >30 pltx 10^9L, NR= None Response <30 pltx 10^9L or no change from the baseline platelet count) and duration (SR**= Sustained Response >6 months, PeR= Persistent Response >3 months, TR= Transitory Response <3 months).
Results: The results are summarized in Table 1 and Table 2. Overall response to Rituximab was 62% and to TPO-ra was 67%. The response rate in Rituximab group decreases significantly if it was used as second line of treatment (69%) rather than as third (23%) or fourth (8%) line. Our results don't show the same trend for the TPO-ra group where the response seems to be independent from the time of use and from the previous treatments (40% of rat response in second line; 40% in the third line; 20% in the fourth line).

Table 1. Efficacy and duration of the response

	Rituximab	TPO-ra
Total treated patients	21	15
Complete Response* (CR) n (%)	11 (52%)	10 (67%)
Partial Response (PR) n (%)	1 (5%)	0
Minimal Response (MR) n (%)	1 (5%)	0
Sustained Response (SR)** n (%)	6 (47% of responders)	6 (60% of responders)
Persistent Response (PeR) n (%)	5 (38% of responders)	3 (30% of responders)
Transitory Response (TR) n (%)	2 (15% of responders)	1 (10 % of responders)
None Response (NR) n (%)	8 (38%)	5 (33%)
Response Onset-time (weeks) Median (min; max)	2 (1; 8)	1 (1; 2)

Table 2. Relationship between response and previous treatments

	Rituximab		TPO-ra	
	Responders	Non-responders	Responders	Non-responders
Total patients n (%)	13 (100%)	8 (100%)	10 (100%)	50 (100%)
Second line n (%)	9 (69%)	5 (63%)	4 (40%)	1 (20%)
Third line n (%)	3 (23%)	3 (37%)	4 (40%)	1 (20%)
Fourth line n (%)	1 (8%)	0	2 (20%)	3 (60%)
Splenectomy n (%)	3 (23%)	4 (50%)	3 (30%)	2 (40%)
Plts (n x 10.9L) before treatment Median (min; max)	5 (1; 74)	12 (3; 50)	12 (1; 30)	4 (2; 5)

Summary and Conclusions: The overall response is than clearly higher when Rituximab was used in an early stage of ITP showing a marked trend to inefficacy in the chronic and multi-refractory phases. Actually we can't say the same thing for TPO-ra. Prospective and multicenter studies about the use of these drugs in acute ITP should be performed to validate these results.

PB1961

INCREASED PRODUCTION OF ROS BY PLATELETS IN EXPERIMENTAL CIRRHOSIS

P. Romecín D[1,*] N. Marin Atucha[1], D. Iyu[1], J.E. Millan[1], F. Garcia-Candel[2], E. Garcia[2], C. Ortiz[1], J. Garcia Estañ[1]
[1]Fisiología, Universidad de Murcia, [2]Hematology, Hospital Universitario Virgen de la Arrixaca-España, Murcia, Spain

Background: Despite the endogenous coagulopathy of cirrhosis, some patients experience venous thromboembolism. Previous studies in experimental cirrhosis by bile duct ligation (BDL) have shown a platelet hyperactivity, similar to humans with biliary cirrhosis disease (Clin.Sci., 2007,112(3):167-74). In these experiments we have found abnormal intracellular Ca^{2+} homeostasis and alterations in the metabolism of homocysteine (Hcy) that may contribute to those platelet alterations (J. Hepatology 2009, S280). The role of ROS in this platelet hyperactivity is not known.
Aims: Investigate agonist-induced production of ROS in platelets of bile duct ligated rats and the effects of chronic folic acid treatment (an essential cofactor in the metabolism of homocysteine (Hcy)).
Methods: Cirrhosis was induced in rats by bile duct ligation (BDL) and sham-operated rats were used as control. The experiments were performed after 21 days (without ascites) and 28 days (BDL group with ascites) after surgery. Platelet rich plasma aggregation in response to ADP (5μM) was analyzed using a lumiaggregometer. To analyze ROS, by fluorescence spectroscopy, platelet suspensions were washed and incubated with CM-H_2DCFDA acetyl ester and stimulated with thrombin (0.3U/mL), ADP (5μM) and homocysteine (Hcy, 50-200μM). In some experiments, sham and BDL rats were treated with folic acid (8 mg/Kg/day in drinking water).
Results: Platelet stimulation with thrombin and Hcy induced an increase in ROS production that was of greater magnitude in platelet from BDL rats than in control. Ascites reduced aggregation response and increased ROS production. Chronic treatment with folic acid decreased more platelet aggregation and ROS production in BDL than in control group.
Summary and Conclusions: Folic acid show antiaggregant actions in cirrhotic rats due in part to attenuation of a high ROS production and might be used for prevention of venous thromboembolism in liver cirrhosis. But, with proper control, due to the folic acid reduces platelet aggregation excessively in cirrhosis with ascites and can produce increased maintenance of gastrointestinal bleeding due to portal hypertension characteristic of this disease.

PB1962

STUDY OF IMMATURE PLATELET FRACTION AND POTENTIAL ROLE IN DIFFERENTIATING VARIOUS CAUSES OF THROMBOCYTOPENIA

A. Khuhapinant[1,*] E. Utchariyaprasit[1]
[1]Medicine, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Immature platelets are newly released reticulated platelets into circulation. They can be measured using a specifically designed automated hematology analyzer as immature platelet fraction (IPF). IPF was shown to be high in immune thrombocytopenic purpura (ITP) due to rapid clearance and enhanced production of platelet. In aplastic anemia (AA), IPF was lower because of low platelet production rate. Utilization of this parameter to differentiate causes of thrombocytopenia between underproduction and peripheral destruction has been proposed. There is no IPF data on other diseases with similar mechanisms such as hypersplenism, Evans syndrome (ES), thrombotic thrombocytopenic purpura (TTP), or chemotherapy-induced bone marrow suppression (CIBMS).
Aims: To measure IPF in healthy Thai volunteers, and patients with thrombocytopenia from various causes and to compare IPF from different thrombocytopenic mechanisms *i.e.* underproduction (AA, CIBMS) and peripheral destruction/ sequestration (ITP, TTP, ES, hypersplenism).
Methods: This was a prospective, cross-sectional, observational study. Each EDTA-anticoagulated blood from Thai healthy volunteers (NL; 51) and thrombocytopenic patients (67) (platelet count<150x 10^9/L) with known diagnosis of AA (14), CIBMS (22), ITP (20), TTP (2), ES (3) and hypersplenism (6) was analyzed by Sysmex XE-5000 for complete blood count, reticulocyte parameters (percentage, absolute count and fluorescent ratio), IPF, and mean platelet volume (MPV). Peripheral blood smears were simultaneously examined for RBC, WBC and platelet morphology. Clinical parameters were collected on fever, anemia, jaundice, bleeding status with/ without ecchymosis, and concurrent therapy for thrombocytopenia.
Results: Mean platelet number (x 10^9/L) for NL, AA, CIBMS, ITP, TTP, ES and hypersplenism were 277.25, 27.21, 35.55, 50.20, 54.50, 22.67, and 63, respectively. Negative correlation between platelet number and IPF value was shown in which the lowest median IPF (%) was found in NL (1.50; 0.6-4.5) compared among underproduction (2.95; 0.7-24.8) and peripheral destruction group (4.80; 0.2-25.7). In each underproduction subgroup, median IPFs (%) for AA and CIBMS were 4.25 (1.8-24.8) and 2.50 (0.7-15.5). In each peripheral destruction/ sequestration subgroup, median IPFs (%) were 5.45 (0.2-25.7), 4.90 (2.4-7.4), 8.90 (4.8-11.4), and 3.95 (1.3-17.2) for ITP, TTP, ES and hypersplenism, respectively. A cut-off absolute immature platelet count value of more than 1,000x 10^9/L was proposed to differentiate peripheral destruction from underproduction mechanism with sensitivity and specificity of 75.2% and 63.9%, respectively.
Summary and Conclusions: IPF is a simple, reliable parameter and can potentially be used to differentiate mechanisms causing thrombocytopenia. More beneficial roles of IPF are expected.

PB1963

PROPHYLAXIS OF FETO-MATERNAL ALLOIMMUNE THROMBOCYTOPENIA (FMAIT) WITH ENRICHED INTRAVENOUS IMMUNOGLOBULINS (IVIG) AND CORTICOTHERAPY

G. Dine[1,*] E. Nacoulma[1], S. Brahimi[1], N. Ali-Ammar[1], S. Misra[1], S. Vergnolle[1], Y. Rehn[1]
[1]Hematologie, Hopital des Hauts Clos, TROYES, France

Background: FMAIT can lead to serious complications such as intracranial hemorrhage. The current consensus is to initiate first line prophylactic treatment with IVIg and corticotherapy. We describe 2 cases of successful prophylactic treatment of FMAIT with enriched IVIg and corticotherapy. Infusion of enriched

IVIg is interesting to the quality of life in outpatient setting. Time of infusion is faster than standard IVIg.
Aims: Ms VH born in 1982 gave birth normally to a 2.130 g girl in 2005. In 2008 a second pregnancy was medically terminated during week 30 because of fetal hydrocephalus. The post expulsion evaluation identified FMAIT caused by incompatibility of parental HPA1 and HPA3 platelet groups and anti-platelet alloantibodies against HPA1a/a and HPA3a/a. In 2009 this woman begin a third pregnancy and was treated prophylatically with lyophilized IVIg (Tegeline 5%, 1 g/kg bodyweight) from the 16th week combined with Prednisolone (60 mg/day) from week 30. A healthy 2.070 g girl was delivered by caesarean section during week 33. This woman initiated 2 new pregnancies in 2011 and 2013 treated with prophylactic infusion of enriched IVIg (Privigen 10%, 1 g/kg bodyweight) from week 19 combined with Prednisolone (60 mg/day) started during week 32. In 2011 she gave birth by caesarean section at 37 weeks to a 3.370 g girl. In 2013 a scheduled caesarean section was performed on week 37 and a 2.460 g girl was born.
Methods: Ms SA born in 1973 is mother of 1 child with no reported clinical issues. During her second pregnancy in 2014, thrombocytopenia was observed at the 5th month with a maternal platelet count of 35 000/mm3. FMAIT is diagnosed with parental HPA5 incompatibility and anti-platelet alloantibodies against HPAa/b. Prophylactic treatment with enriched IVIg (Privigen 10%, 1 g/kg bodyweight) was started during week 18. Platelet count of 190 000/mm3 was observed 2 weeks after. Prednisolone (40 mg/day) was started during week 32. A caesarean section was performed on week 38 with birth of a 2. 800 g boy.
Results: Owing to the morbidity of FMAIT IVIg prophylactic treatment with corticotherapy is nowadays considered a standard approach. IVIg are generally intiated during weeks 16 – 18 of pregnancy and continued until planned caesarean section 2 – 4 weeks before the due date. The current consensus on the IVIg dose is 1 g/kg bodyweight per week. Corticotherapy is regularly combined with IVIg from week 30. Interest of enriched IVIg concerns particularly the quality of life of these patients.
Summary and Conclusions: To our knowledge this is the first report of FMAIT treatment with enriched IVIg preparation which was well tolerated and effective consistent with the profile of standard IVIg. Prophylactic treatment of FMAIT depends on identification of risk factors from previous pregnancies with diagnosis by laboratories experienced in biological platelet testing. Management must involve close multidisciplinary collaboration between obstetrics team and hematologists experienced in IVIg use. Surveillance mainly involves fetal echographic monitoring and maternal biological parameters follow-up. Based on our experience use of enriched IVIg in women at high risk of FMAIT is efficient and safe.

PB1964

BORTEZOMIB IN THE MANAGEMENT OF ACUTE TTP – DIFFICULTY IN MONITORING PROGRESS

R. Low[1,*] T. Dutt[2]
[1]Haematology, Royal liverpool Hospital, [2]University of Liverpool, Liverpool, United Kingdom

Background: Thrombotic Thrombocytopenic Purpura (TTP) is a rare but life threatening condition that has an untreated mortality of 90%. It is characterised by the presence of autoantibodies against the von Willebrand factor cleaving enzyme ADAMTS13.(1) Therapeutic plasma exchange (PLEX) remains the mainstay treatment – adjuvant immunosuppressant therapy with rituximab is also required in some patients.(2)
Aims: We report the case of an acute acquired TTP that did not respond to PLEX or rituximab however rapidly responded to the proteasome inhibitor, commonly used in multiple myeloma, bortezomib.
Methods: The case is of a 59 year old gentleman who presented with vomiting, progressive dizziness and double vision. Acute TTP was confirmed and the patient was commenced on once daily PLEX to which he had an inadequate response. He was subsequently initiated on twice daily PLEX and prescribed four doses of rituximab. Again only a partial response was observed, so based on case report data, a course of bortezomib was trialed alongside the twice daily PLEX.
Results: A relatively quick recovery in platelet count was observed, and although difficult to interpret the ADAMTS13 inhibitor titre and ADAMTS13 activity normalised. The patient was discharged 57 days post diagnosis and has remained stable since.
Summary and Conclusions: This case supports the use of bortezomib as an adjuvant therapy in the management of acute TTP where PLEX and rituximab have been ineffective. Flow cytometry conducted on this patient's bone marrow post-rituximab revealed a normal CD19 count supporting the failure of rituximab in this case. One potential reason that is important to consider, is that effect of twice daily plasma exchange on the pharmacokinetics of rituximab, evidence suggests peak plasma concentrations are difficult to achieve during PLEX.(3) The PLEX also made it difficult to monitor progress with bortezomib, as both ADAMST13 and its inhibitor titre were unreliable representations of disease activity.

PB1965

IMMUNE THROMBOCYTOPENIA: AN EGYPTIAN EXPERIENCE IN MANAGING ADULT PATIENTS WITH ITP

D. El Demerdash[1,*] M. Mattar[1], N. El Hussieny[1]
[1]Internal Medicine (Clinical Hematology Unit), Cairo University, Cairo, Egypt

Background: Idiopathic thrombocytopenic purpura (ITP) is a heterogeneous clinical disorder characterized by immune-mediated platelet destruction, it may present both as an acute, self-limiting condition and as a recurrent (chronic) form. The clinical differences between newly diagnosed and chronic ITP suggest the existence of different pathophysiological mechanisms in the two forms.
Aims: We aimed to study the clinical, laboratory parameters as well as response to therapy in Egyptian adults with ITP.
Methods: We investigated 108 Egyptian patients with immune thrombocytopenia who were registered in clinical hematology unit, internal medicine department, Cairo university, Egypt during period between 2013 and early 2015 through history, physical examination, laboratory tests including CBC, reticulocyte ounts, ESR, PTT, PT, virology markers; CMV IgM, EBV IgM, HCVAb, HBsAg and HBcAb, ANA, Lupus anticoagulant, anticardiolipine, H pylori antigen in stool and TSH and response to therapy including response to rituximab and thrompopoietin agents recently introduced as line of therapy in our center.
Results: We had investigated 108 ITP patients, Female (*n*;89) were 82% while male were 18%, The median age at the time of diagnosis was 30 years and its range was (14–70) years, Duration of disease ranged between (3 months-21 years) where the median duration was 2.5 years, 45% were newly diagnosed, 44% had chronic ITP and 10% had persistent ITP. Bleeding symptoms were present in 88% (the frequency of various bleeding symptoms were as follows: cutaneous bleeding 79%; gingival hemorrhage 33%; epistaxis 30.5%; vaginal bleeding 27.7%; melena 3.7%; hematuria 4.6%; 1.8% fresh bleeding per rectum and post-partum hemorrhage 0.9%), The median platelet count at the time of diagnosis was 15,000/ mm3 where 38.8% patients had a platelet count<10,000/mm3, ANA was positive in 13.8%, and anti-DNA was positive in 1.8% of ITP patients who had symptoms and signs fulfilling criteria to diagnose SLE. APL antibodies were positive in 4.8% who also had history either of thrombosis or abortion. HBsAg was negative in all studied patients where anti-HCV antibody was positive in 13.8% of patients, also 15.7% of our patients had positive H pylori antigen in stool with silent gastritis, 2.7% had positive anti EBV IgM with high titer and none of studied patients had positive anti CMV IgM. Regarding the thyroid functions 6.4% had abnormal functions where 3.7% of ITP patients had overt hypothyroidism. Also the onset of disease was related to pregnancy in 12% of ITP patients. Regarding Treatment and follow-up; There was an indication for treatment in 96% of patients, Of the 104 ITP patients who were given first-line therapy (corticosteroid 1mg/kg/day PO), there was complete response (CR) in 40.3% and 59.7% patients were nonresponsive to therapy. Patients who had failure of response to 1st line of therapy were given a 2nd line of therapy and the details of it were as follow (splenectomy was done in 16,1% and CR was 3%, 14% received rituximab and CR was 60%, 3% received (TPO) agonist; Eltombopag and CR was 100%, 45% received combined azathioprine and steroid therapy and CR was 64%, 4.8% received triple therapy in form of steroid, azathioprine and danazole where CR was 66%, 8.1% received vincristine and CR was 20% and 5 patients received anti H pylori triple therapy and CR was 20%)
Summary and Conclusions: Most ITP patients were females and investigating 2ry causes of ITP cases even when there is no clear symptoms of the 2ry cause is very important and may be a rising issues in future. Using another agents as 2nd line therapy rather than splenectomy they proved its value although it still need more time and number of ITP patients to prove its efficacy that's why our study still ongoing recruiting more chronic ITP patients to represent our single center Egyptian experience.

PB1966

MUTATION ANALYSIS AND CLINICAL SPECTRUM IN PATIENTS WITH BERNARD SOULIER SYNDROME: A SINGLE CENTER EXPERIENCE

H. Tokgoz[1,*] U. Caliskan[1], A. Pecci[2]
[1]Pediatric Hematology and Oncology, Necmettin Erbakan University Meram Medical Faculty, Konya, Turkey, [2]Dept of Internal Medicine, University of Pavia, Pavia, Italy

Background: Bernard Soulier Syndrome (BSS) is a rare inherited disorder of platelet function due to absence of obviously decreased expression of the platelet Gp Ib-V-IX receptor. This complex plays a critical role in hemostasis by initiating platelet adhesion and subsequent activation at the site of injured vessel. Due to rarity of disease, there are reports only a few cases about the relationship between phenotype and genotype.
Aims: We aimed to evaluate clinical and genetic characteristics of the patients with BSS diagnosed at our department.
Methods: Five patients with BSS diagnosed at department of Pediatric Hematology, Necmettin Erbakan University, Meram Medical Faculty, were enrolled the study. The diagnosis of patients was based on low platelet count, presence of giant platelets and aggregometric studies. Flow cytometry to assess the surface Gp Ib-V-IX complex showed reduced expression. Clinical manifestations and lab-

oratory investigations of the patients were evaluated. We also analyzed the coding regions of genes GpIBA (NM-ooo173,4), GpIBB (NM-000407.4_ and GpIX (NM-000174.3) using DNA samples of affected patients and their family members.
Results: Four of the patients have mutation in GpIBB gene. Two patients have c.233T>G (p.Leu78Arg) in GpIBB gene. Two patients have c.[470T>A(+)472_473del(CT)] (p.Leu157GlnfsX151) in GpIBB gene. One patient has c.1A>C in GpIA gene. Clinical and laboratory findings of the patients are summarized in table 1.

Table 1.

Table 1. Clinical and laboratory Characteristics of the patients with Bernard Soulier Syndrome

Patient no	1	2	3	4	5
Age (year)	29	28	8,5	11,5	24
Gender	female	female	female	female	female
Age at diagnosis (year)	2,5	2	0,5	8	2
Platelet count(x10^9/L)	44000	42000	40000	35000	45000
Mean platelet volume (fl)	16	15,2	11,8	11,2	12,1
Aggregation with Ristocetin	%0	%0	NA	Anormal	%2
CD42a	%0	%0	%0,03	%89 (CD42b %75)	NA
Mutation type	c.[470T>A(+)472_473del(CT)] (p.Leu157GlnfsX151)	c.[470T>A(+)472_473del(CT)] (p.Leu157GlnfsX151)	c.233T>G (p.Leu78Arg)	c.1A>C	c.233T>G (p.Leu78Arg)
Screened area	GpIBB	GpIBB	GpIBB	GpIBA	GpIBB
Bleeding phenotype	Menorhagia, epistaxis, gum bleeding, gastrointestinal system bleeding, splenic rupture	Menorhagia, epistaxis, gum bleeding	Epistaxis, gum bleeding, gastrointestinal system bleeding	Epistaxis, gastrointestinal system bleeding, ecchimousis	Menorrhagia, gum bleeding
History of surgery	Uterin polipectomy, tooth extraction	Uterin polipectomy	-	-	-

Summary and Conclusions: Patients with BSS often suffer from mucocutaneous bleedings. All of our cases are female. Menorrhagia is the major problem for girls at the age of menstruation. One patient, who carrying the mutation of c.[470T>A(+)472_473del(CT)] (p.Leu157GlnfsX151) at GpIBB gene, had experienced spontaneous splenic rupture and successfully treated with conservative approaches such as transfusion of erythrocyte and thrombocyte suspensions. Three different mutations were identified in 5 patients. All of them are previously described mutations. Larger collaborative studies are needed to describe relationship between clinical phenotype and genotype.

PB1967

THE EVALUATION OF OXIDATIVE STRESS IN CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP)

A.M. Gaman[1,2,*] M.A. Gaman[3]
[1]Hematology, Filantropia City Hospital, [2]Pathophysiology, University of Medicine and Pharmacy of Craiova, Craiova, [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background: Chronic Idiopathic Thrombocytopenic Purpura (ITP) is an autoimmune disease characterised by a low platelet count determined by an increased platelet destruction or a decreased platelet production. Oxidative stress, defined as an imbalance between the reactive oxygen species and the antioxidant defence system, plays an important role in the pathophysiology of autoimmune diseases determined by DNA, protein and lipid oxidation.
Aims: To evaluate if oxidative stress is involved in the pathogenesis of chronic ITP.
Methods: We studied 28 patients with chronic ITP hospitalized in the Clinic of Hematology of Craiova (Romania) between 2012 and 2014 (group A). The A group was compared to 30 healthy people who represented the control group (group B). Both free oxygen radicals and total antioxidant capacity were evaluated by FORT (Free Oxygen Radicals testing) and FORD (Free Oxygen Radical Defence) tests from a single drop of capillary blood, at the time of diagnosis, before the administration of any drug. The normal value of FORT was less than 2.3 mmol/L H_2O_2 and the normal value of FORD was in between 1.07-1.53 mmol/L. The statistical analysis was performed and a p value ≤0.001 was considered significant.
Results: A statistically significant difference was determined for both FORT and FORD levels between the two groups. The FORT and FORD levels were higher in group A compared with group B.
Summary and Conclusions: We believe that oxidative stress is involved in the pathophysiology of the chronic ITP. When free oxygen radicals become excessive and surpass the total antioxidant defence capacity, they are destructive and attack the fundamental cellular components such as proteins that may be highly immunogenic and induce autoantibody production which is involved in platelet destruction.

PB1968

EVALUATION OF A FLOW CYTOMETRIC PLATELET COUNT METHOD

M.N. Ben Naoum[1,*] H. Lazreg[1], A. Adda[1], M. Hamadi[1]
[1]Department of Hemobiology, Etablissement Hospitalier et Universitaire (EHU) ''1er Novembre 1954'', oran, Algeria

Background: The platelet count is an important orienting test for clinicians to diagnose various pathologies and in the therapeutic monitoring of patients, this is why the accuracy of the results is essential and any measurement faults may leads the clinician to errors in the diagnostic and the treatment.
Aims: We tried to use the high precision of flow cytometry in the platelet count. In this respect we adapted a simple method and tried it.
Methods: We compared the platelet count obtained by flow cytometry based on red blood cells/platelet ratio with 2 automated hematology analyzers. : one with impedance principle and another with optical principle. The flow cytometric count is performed after labeling platelets with specific monoclonal antibody (CD61), then the red cells/platelet events ratio is determined on a forward scatter/Fl1 cytogram and the platelet count is calculated from the number of red blood cells obtained precisely by an hematology analyzer. A total of 105 blood samples were analyzed including 3 levels quality control: 45 samples with a normal platelet count, 29 samples with a low platelet count and 31 samples with a high platelet count.
Results: The correlation of the results of the platelet count obtained by the 3 methods is excellent for samples with normal and low platelet count. However the impedance hematology analyzer shows less accuracy in the high platelet count samples. The stability of the flow cytometric platelet count over the time is good. The mean of the CV over the time is 08%, which is accepted in biological analysis.
Summary and Conclusions: Finally, we suggest using the flow cytometric platelet count as a gold standard since the other methods have a large margin of error and we need exactly results to manage thrombopenic patients.

PB1969

THE BURDEN OF GAUCHER DISEASE: A REVIEW OF THE LITERATURE

L. Nalysnyk[1,*] T. Eagleton[1], A. Hamed[1]
[1]Genzyme, a Sanofi company, Cambridge, United States

Background: Gaucher disease (GD) is a rare, genetic lysosomal storage disorder caused by a deficiency in the enzyme β-glucocerebrosidase. This enzymatic deficiency leads to progressive accumulation of the substrate glucosylceramide in organ tissues resulting in debilitating hematologic, visceral, and skeletal manifestations that span a wide spectrum of disease severity and adversely impact patients' quality of life. Glucosylceramide accumulation in macrophage lysosomes of the liver, spleen, and bone marrow leads to anemia, thrombocytopenia, hepatosplenomegaly, and bone disease as defining clinical signs. Three subtypes of GD are recognized: type 1 (GD1, non-neuropathic), type 2 (GD2, acute neuropathic), and type 3 (GD3, sub-acute/chronic neuropathic), with GD1 being most prevalent. Diagnosis of GD relies on clinical presentation, heightened diagnostic suspicion and exclusion of other hematologic diseases. Enzyme assay to measure deficiency of β-glucocerebrosidase in leukocytes is the definitive diagnostic test. However, owing to low disease awareness and symptoms that overlap with other diseases, diagnostic delay is common, which substantially impairs patient care.
Aims: To better understand the burden of GD, a comprehensive review of the published literature was conducted.
Methods: MEDLINE, EMBASE, CENTRAL, and conference proceedings literature sources published in English between January 1990 and February 2013 were searched for relevant publications. Eligible studies were primarily of observational design and examined the disease epidemiology, clinical and socioeconomic disease burden of GD and the impact of current treatment options.
Results: Overall, 2034 citations were identified through a systematic search of databases, conference abstracts, and manual searches of published reviews. Full text was reviewed in-depth for 177 relevant studies and a total of 97 publications were summarized. In the reviewed studies, the standardized incidence and prevalence of GD in the general population varies from 0.30 to 5.80 per 100,000 and 0.33 to 1.75 per 100,000, respectively, and GD1 is the predominant type in most regions. The risk of mortality is highest in GD patients who present younger than age 5 years and generally increases after age 55; the life expectancy is lower than the general population. Prior to treatment, anemia was present in 11–75% and thrombocytopenia in 20–62% of GD patients in the reviewed studies. Prevalence of splenomegaly and hepatomegaly varied widely among small samples of patients with untreated GD (15–96% and 10–86%), respectively. Bone pain and bone crises were reported frequently in studies of patients with untreated GD (8.0–64.2% and 3.4–24.2%), respectively. Parkinson's disease and cancer were frequently reported medically important comorbidities among patients with GD.
Summary and Conclusions: GD is a rare, chronic disease associated with significant disease burden to patients and their families. Signs and symptoms of Gaucher disease can be nonspecific and are often suggestive of hematologic abnormalities, including neoplasms. Disease awareness is of critical importance in facilitating clinical diagnosis and optimal management. Current treatment options for GD include enzyme replacement therapy or substrate reduction therapy. However, there are still medical unmet needs and further research is needed in this area.

PB1970

IMPACT OF THE ABNORMALITIES IN IMMUNOGLOBULIN LEVELS IN THE EGYPTIAN PATIENTS WITH ITP

T.E.E. Abouzeid[1,*] E. Azmy[1], M.S. Elghonemy[2], S. Aref[2], S. Abd Elaziz[2], A. Elsabaagh[3]
[1]Hematology, [2]Clinical pathology, [3]Micrbiology, Mansoura Oncology Center, Mansoura, Egypt

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune disorder that characterized mainly by a low platelet count and absence of any apparent initiating and/or underlying cause of the thrombocytopenia. ITP is associated with a loss of tolerance to platelet antigens and a phenotype of accelerated platelet destruction with impaired platelet production. Common variable immunodeficiency (CVID) is a mixed group of disorders characterized by decreasing the Immunoglobulins (Igs) and an increased susceptibility to repeated infections, autoimmunity and malignancies. Both ITP and autoimmune hemolytic anemia (AIHA) are autoimmune disorders which can be seen together with CVID.
Aims:. This study aimed to assess the immune system deregulation in the form of measuring the immunoglobulins (Igs) levels in patients diagnosed as ITP and correlates the relation of these levels to the initial platelet counts, severity of the disease, treatment response and clinical outcome.
Methods: Across-section study was done on 105 patients' age range from 10-61 years, with newly diagnosed ITP at the Oncology Center Mansoura University over the past 2 years.
Results: The patients with IgA level below or equal to median had good response to stander treatment (steroids, intravenous Ig (IVIG), or intravenous anti-D), while the patients with a higher IgA level than median showed excellent response with stander treatment (P=0.02). Subjects with High IgA levels associated with increased major bleeding but not platelet count. Low IgM levels associated with failure to response to stander treatment and platelet count but not major bleeding. Changes in IgG levels wasn't associated with either response to treatment nor bleeding tendency or platelet count.
Summary and Conclusions:. We recommend initial measure of immunoglobulin level in patients with ITP to help us in the treatment protocol for each patient.

UNMET NEED FOR TREATMENT RELAPSES IN MANTLE CELL LYMPHOMA: DECREASING INTERVALS BETWEEN SEQUENTIAL TREATMENT LINES IN THE US

S. Le Gouill[1,*] J.Y. Chen[2], D. Mahmoud[3], H.X. Hu[3], R.L. Wade[2]
[1]Haematology Department, CHU Nantes and UMR892 INSERM, Nantes, France, [2]Health Economics and Outcomes Research, IMS Health, Plymouth Meeting, [3]Global Market Access, Celgene Corporation, Summit, United States

Background: No large scale description of sequential treatment (tx) lines and time to the next treatment (TTNT) exists for mantle cell lymphoma (MCL).
Aims: This study evaluated first, second, and third tx lines (1L/2L/3L) and TTNT for US patients in the usual care setting.
Methods: MCL patients (pts) were identified from the IMS PharMetrics Plus database (>100 million US pts) having ≥2 medical claims (ICD-9-CM 200.4x) at least 30 days apart in 2008-2012 (the first diagnosis date as the index), no MCL claims in the 6 months pre-index and continuous enrollment in the health plans for ≥3 months post-index. The 1L therapy was defined as all MCL tx administered within 90 days of tx start. A new tx line was defined as addition of a new agent ≥90 days from tx start, or when tx was restarted following a 90 day gap in therapy. For ASCT pts, TTNT to 2L was the duration from ASCT procedure date to the start of subsequent tx; for non-ASCT patients and ASCT pts post-2L, TTNT was the time between the initiation of current line tx to the beginning of next line tx. Rituximab (R) monotherapy was not considered a new tx line when initiated within 12 months post any tx line.
Results: Of the 872 pts in the study, 172 (19.7%) received ASCT, 628 (72.0%) were males and mean age was 63.3 years. Comparison between transplanted and non-transplanted pts revealed ASCT pts were younger (median: 56.8 vs 64.9 years). Compared to non-transplanted pts, ASCT pts had also fewer comorbidities calculated by Charlson Comorbidity Index (mean: 1.63 vs 2.44). Within 1L, the majority (52.9%) of ASCT pts received tx regimens containing anthracycline + R, followed by regimens containing cyclophosphamide or vincristine +/- R (18.6%). The most frequent 1L tx regimens for non-ASCT pts were anthracycline +/- R (30.7%), R monotherapy (19.9%) and bendamustine +/- R (13.9%). The most common tx regimens in 2L contained R monotherapy (32.3%), bendamustine +/- R (21.9%), bortezomib +/- R (16.8%) and other chemotherapy +/- R (24.3%), and the most common regimens in 3L contained bendamustine +/- R (29.4%), R monotherapy (20.2%), bortezomib +/- R (14.3%), and other chemotherapy +/- R (23.5%). Of the pts not followed to TTNT (n=538), median follow-up time in days was 517 from the start of 1L tx, 304 from 2L tx, and 243 from 3L tx. The median TTNT to 2L was 349.5 days for pts who relapsed after ASCT (n=54) and 421.5 days for relapsed non-ASCT pts (n=280). For all relapsed/refractory pts, median TTNT was 403.5 days from 1L to 2L (334 pts); 272 days from 2L to 3L (119 pts), and 213 days from 3L to 4L (41 pts).
Summary and Conclusions: Within each tx line, there was substantial variation in treatment regimens. The decreasing interval from one line of therapy to the next line of therapy suggests that once patients relapse, they deteriorate at an increasing pace. Taken together, the current results suggest an unmet need exists for effective treatment of patients that relapse.

PB1972

A TRANSITION FROM USING "OFF-LINE" TO INTEGRATED PROCEDURES FOR PERFORMING EXTRACORPOREAL PHOTOPHERESIS: A COMPARISON OF COSTS AND EFFICIENCIES

N. Azar[1], M. Ouzegdouh[1], N. Goncalves[1], N. Mouayas[1], C. Cherat[1], M.J. Chollet[1], V. Leblond[1], J. A. Button[2], P.M. Button[2,*]
[1]Groupe Hospitalier, Pitié Salpêtrière, Paris, France, [2]ProcEx Solutions Ltd, Wales, United Kingdom

Background: The Hemobiotherapy Department at Pitié Salpêtrière Hospital has been providing extracorporeal photopheresis (ECP) procedures for patients presenting with graft *versus* host disease (GvHD) and cutaneous T-cell lymphoma (CTCL) since November 2011 and for lung transplant rejection patients since June 2013. Initially, an "off-line" system was used for all procedures, and in the first 12 months we carried out a total of 225 treatments. At the end of 2012 we commenced a transition from the off-line system to a Therakos integrated photopheresis system. In 2013 we carried out a total of 527 ECP procedures with 397 using the integrated system. At the start of 2014, the unit was thought to be close to capacity so we participated in a ProcEx Solutions workflow assessment where we successfully implemented improved ways of managing the increasing demand with the same number of nurses in the unit. Then, in 2014 we transitioned to performing all procedures using the integrated system and a total of 797 treatments were performed.
Aims: The aim of this study was to compare the cost and efficiency of performing ECP using the off-line system *versus* the Therakos integrated system.

Methods: An activity-based costing method was applied to provide an accurate and meaningful cost comparison between administration of ECP using the off-line method or the integrated system. This was important so as to not be misled by comparing the costs of off-line and integrated system procedural kits alone.
Results: The cost of performing ECP using the off-line system was more expensive than the Therakos integrated system (€1,429 vs €1,265) resulting in a cost avoidance of €131,242 for 2014 by performing all ECP treatments on the integrated system. Of note, the lymphocyte PHA and OKT3 inhibition tests mean scores were 99.2% (Integrated system) and 97.4% (off-line system), respectively. Off-line (Macopharma) Integrated (Therakos) Collection of leukocyte concentrate (PTC) €173.75 €1,009.20 Biologic analysis (patient) €59.00 €59.00 Biologic analysis (cell collection) €31.05 — Transportation of cells to CT area €7.76 — Irradiation of leukocyte concentrate €616.55 — Biologic analysis (irradiated cells) €76.00 — Transportation of cells to ward €7.76 — Injection (triple access) €12.00 — Personnel costs €108.00 €40.50 Bed retention cost/treatment (per hours used) €337.50 €156.00 Total cost €1,429.37 €1,264.70Number of treatments in 2014 797 Cost per treatment €1,429.37 €1,264.70 Total cost in 2014 €1,139,208 €1,007,966 Difference in cost (2014) €131,242.
Summary and Conclusions: The transition from off-line to the Therakos integrated system proved beneficial in terms of cost and ease of implementation. The integrated system has resulted in efficiency gains in terms of the number of patients who can be treated in a day with the same number of nurses being employed. For hospitals considering a transition from off-line methods where cost is a barrier, activity-based costing should be applied to gain an accurate understanding of the true situation. Also, reimbursement factors should be considered when making a judgement; the off-line system allows significantly fewer treatments, so reimbursement levels received by the treatment center will be substantially reduced.

PB1973

INNOVATION IN ONCOLOGY: WHY FOCUSING ONLY ON BREAKTHROUGH INNOVATION MAY BE COUNTER-PRODUCTIVE

C. Quinn[1,*] S. Palmer[2], J. Bruns[3], J. M. Borras[4], C. Grant[1], D. Sykes[1], S. Kaura[5]
[1]PRMA consulting Ltd, Fleet, [2]Centre for Health Economics, University of York, York, United Kingdom, [3]Deutsche Krebsgesellschaft, Berlin, Germany, [4]Department of Clinical Sciences, University of Barcelona, Barcelona, Spain, [5]Celgene Corporation, Summit, New Jersey, United States

Background: Innovative oncology products are routinely perceived to be those that offer a substantial increase in overall survival (OS), usually above a certain threshold. However, this growing emphasis on significant OS gain (breakthrough innovation), to the exclusion of other clinical and non-clinical gains, undervalues new products and may not capture aspects of treatment that are important to patients. Clinicians, patient groups, and manufacturers argue that progressive innovation in other domains needs to be considered and valued in regulatory and health technology assessment (HTA) decisions.
Aims: The aim of this paper is to bridge the perspectives on progressive innovation and the approaches taken to measure and value innovation among different stakeholders at all levels of drug approval, appraisal and access.
Methods: We conducted a targeted literature search for definitions of innovation in academic and grey literature, covering regulatory, HTA, and industry bodies. Current/proposed OS thresholds were applied to standard of care (SOC) therapies in colorectal cancer (CRC) and non-small cell lung cancer (NSCLC).
Results: The magnitude of OS benefit consistently emerges as key in the definition of innovation from policy (*e.g.*, England's Cancer Drugs Fund) and clinical (*e.g.*, American Society of Clinical Oncology [ASCO]) perspectives. Regulators and HTA agencies do not provide clear consistent definitions, however. Emphasis is increasingly on 'clinically meaningful' change in survival, expressed as minimum thresholds: OS gain >2.5months, HR>0.8; progression-free survival gain >3months, HR>0.5. Only one of six CRC products approved since 2000 met the OS threshold published by ASCO of three to five months (Ellis *et al*. 2014) whereas survival has doubled in that time. None of the products approved for NSCLC since 2005 met the OS threshold, for 3.25 to 4 months, while survival in patients receiving first-line treatment for advanced NSCLC has also doubled.
Summary and Conclusions: Innovation should not be defined solely on one-time large survival gains but should be evaluated according to the value provided to patients and health systems. Smaller sequential gains in clinical benefit and improvements in quality of life, safety, convenience, and system efficiency should be considered in assessing value and innovation. Products that have smaller outcome gains can be combined to provide an amplification of effectiveness. Similarly, small incremental advances can lead to significant improvemments over time. If the focus moves too far towards breakthrough innovation, these treatment opportunities will be lost. Progressive innovation in these aspects provides opportunities for immediate benefit, including survival until the next therapy is available, and may uncover new clinical pathways with significant cumulative benefit over time. Recognition of this 'option value' for future health and research advances is needed. Focussing only on breakthrough OS gains Regulatory and HTA agencies should balance clinical and economic gains and societal and patient preferences when evaluating innovation in a new therapy.

PB1974

IMPACT OF THE ECONOMIC CRISIS IN GREECE ON THE MANAGEMENT OF THALASSEMIA PATIENTS

A. Teli[1,*] V. Gourtsa[1], S. Theodoridou[2], M. Economou[1]
[1]First Department of Pediatrics, Aristotle University of Thessaloniki, [2]Hemoglobinopathy Prevention Unit, Hippokration General Hospital, Thessaloniki, Greece

Background: Economic crisis has had a major impact on public health in Greece during the last 5 years, negatively affecting both ability for health insurance coverage and availability of medical and laboratory services. As all patients suffering from chronic illnesses, thalassemia patients have had to live with and try to overcome relevant difficulties.
Aims: Purpose of the present retrospective study was to evaluate the impact of economic crisis on management of thalassemia patients for the 5 year crisis period (January 2010-December 2014) in a single pediatric institution.
Methods: A total of 17 multi-transfused pediatric patients participated in the study. Patient data assessed included annual heart and liver MRI T2* measurements, transfusion frequency, chelation therapy, as well as mean annual pre-transfusional hemoglobin and ferritin level. Changes in family working status of the patients as well as in insurance coverage ability were recorded.
Results: Mean study population age was 10.5 years (range 6.5-18 years), with a baseline mean pre-transfusional hemoglobin of 9.5g/dl, a mean ferritn value of 1380ng/mL, a mean heart T2* of 32m (20-58ms) and a mean liver T2* of 7.4ms (3.1-26ms). No significant change in pre-transfusional hemoglobin was recorded during the study period, as all patients continued their regular transfusion program. All patients continued chelation therapy during follow-up. Changes in chelation therapy during study period were only based on medical criteria and were not related to economic issues. With regards to ferritin levels, 13/17 patients showed an improvement, with an overall statistically significant improvement in the mean value at the end of study. As to iron concentration, 15/17 patients improved their liver measurements and 2/17 remained stable. Out of 17 patients, 8 improved their heart measurements, 2 remained stable and 8 showed decrease in heart values – however, in only one case did the measurement reach an abnormal value, consistent with mild heart siderosis. With regards to insurance ability, 3/17 patients lost coverage due to parents' unemployment, but Social Security provided free services, enabling patients to continue regular transfusions and chelation treatment.
Summary and Conclusions: Although Greece has seriously suffered during the last years because of the economic crisis, provision for health has managed to survive-at least for patients suffering from chronic illnesses, such as thalassemia.

PB1975

PREVALENCE OF TRANSFUSION TRANSMITTED INFECTIONS IN INDIVIDUALS WITH THALASSEMIA IN PAKISTANI POPULATION

H. Yasmeen[1,2,*] S. Hasnain[1,2]
[1]Department of Microbiology and Molecular Genetics, University of the Punjab, Lahore Pakistan, Lahore, [2]Department of Microbiology and Molecular Genetics, The Women University, Multan, Multan, Pakistan

Background: Individuals suffering from thalassemia requires regular transfusion in absence of expensive stem cell transplant treatment. However, repeated or frequent blood transfusion along with post transfusion hepatitis intensifies the severity of disease and it continues to be a problem in these high risked individuals.
Aims: Present study undertaken at multicenter of Pakistan aims to estimate the prevalence of blood transfusion transmitted infections (TTI) in individuals suffering from beta thalassemia.
Methods: In a cross-sectional study, after consents 350 individuals suffering from beta thalassemia excluding patients of any other blood disease were interviewed for different epidemiological parameters *e.g.* Gender, age, transfusion history, family and personal history from October 2012-December 2013. Haematological parameters such as RBC indices and quantification of haemoglobin were recorder retrospectively. Individuals were screened for transfusion transmitted infections (TTI) mainly anti-HIV, HBsAg and anti-HCV.
Results: Out of 300 thalassemic individuals 47% (142/350) were infected with TTI including 78 males and 64 females. The seroactivity for HCV was highest 93% (133/142) followed by for HBV 6.3% (9/142) and no seroactivity for HIV. Beta thalassemia major (>95%) was most common followed by thalassemia intermedia (<5%) and few structural variants (<1%) *e.g.* HbS and HbH. When compared to the normal age span, it was observed that only 3.14% (11/350) of the patients crossed the second decade of their life. Early onset disease (before 6 months) was more common (24%; 124/350) than the late onset *e.g.* above 36 months (06%; 21/350).
Summary and Conclusions: Short life span and high number of HCV/ HbBAg status depicts that in a country like Pakistan insufficient facilities, poor management and compromised socioeconomic status are deteriorating the disease

status. More multicenter studies covering cities from different regions of country are needed in developing preventive measurements at regional and national level.

PB1976

THE QUALITY OF LIFE OF ANEMIC PATIENTS WITH LYMPHOPROLIFERATIVE DISORDERS TREATED WITH RED BLOOD CELL TRANSFUSIONS AND ERYTHROPOIESIS-STIMULATING AGENTS

N. Romanenko[1,*] A. Romanenko[2], M. Zenina[1], N. Potikhonova[1], K. Abdulkadyrov[1]
[1]Clinical Hematology, Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, [2]Clinical Neurology, Children Hospital of St. Olga, Saint-Petersburg, Russian Federation

Background: Although haematological toxicities, such as anemia, are common in lymphoproliferative disorders (LPD), no clear consensus exists on the use and impact of Erythropoiesis-stimulating agents (ESA) and Red blood cells transfusions (RBCsT) on quality of life (QoL).
Aims: To assess alteration of QoL in anemic patients with LPD treated with RBCsT and ESA.
Methods: There were included 131 anemic patients with LPD (multiple myeloma, low-grade non-Hodgkin's lymphoma, chronic lymphocytic leukemia). Median age of patients was 67 years (range 24-85). All persons were divided into two groups: 1st group included patients (n=54) treated with RBCsT, 2nd (n=77) – treated with ESA. Posetive response for ESA considered as achievement of hemoglobine concentration 120 g/L or increase Hb ≥ 20 g/L. QoL was studied with Functional Assessment of Cancer Therapy Anemia subscale (FACT-An) and Fatigue subscale (FACT-F).
Results: In the 1st group of patients treated with RBCsT (in average 3.7±0.3 Units) concentration of Hb increased from 70.0±1.6 g/L to 93.1±1.2 g/L. Statistically significant improvement of their QoL was found in FACT-An subscale – from 41.1±2.0 (95% CI=37.1-45.0) to 34.2±2.1 (95% CI=30.0-38.3) points (P<0.001; n=54). Improvement of QoL was also found in FACT-F subscale – from 30.2±1.4 (95% CI=27.8-32.9) to 23.2±1.5 (95% CI=19.8-26.9) points (P<0.0001; n=54). In the 2nd group positive response for ESA-therapy was found in 52 (67.5%) out of 77 patients: 39 (50.6%) patients achieved the Hb concentration 120 g/L and 13 (16.9%) ones increased Hb more than 20 g/L. The patients with positive response increased the Hb concentration significantly from 88.4±1.4 g/L to 123.1±2.4 g/L (P<0.0001; n=52). We found out improvement of QoL in both subscale: in FACT-An – from 34.5±1.7 (95% CI=31.1-37.9) to 30.1±1.6 (95% CI=26.9-33.2) points (P<0.001; n=52) and in FACT-F – from 22.8±1.3 (95% CI=20.3-25.4) to 19.7±1.2 (95% CI=17.3-22.1) points (P=0.013; n=52).
Summary and Conclusions: Both RBCsT and ESA-therapy are able to increase Hb concentration considerably and improve QoL. However the RBCsT patients had more severe anemia and over a period of its correction the RBCsT patients's planned level of Hb was less than ESA-patietnts's one therefore their final QoL was less. So using the ESA-therapy can increase higher Hb concentration and improve QoL more than RBCsT. It's indicating importance of ESA-therapy not as alternative RBCsT method of anemia's correction but also as a way to prevent decreasing of the Hb induced by toxic effect of chemotherapy and as a method of anemia treatment with which a normal Hb level can be achieved.

PB1977

VITAMIN D DEFICIENCY IN SURVIVORS OF CHILDHOOD ACUTE LEUKEMIA

S. Tasdelen[1,*] M. Öztürk[2], F. Şirin[2], N. Sönmez[2], Y. Cıvır[1], Ü. Ezer[2], M. Mumcuoğlu[3], A. Kürekçi[2]
[1]Clinic laboratory, [2]Pediatric hematology/oncology, [3]Genetic laboratory, Lösante Hospital, Ankara, Turkey

Background: Vitamin D plays an important role in calcium and bone metabolism. It also exerts some biological effects in regulatory systems including host defense, inflammation and immunity. Vitamin D deficiency is to be a worldwide problem, especially in developing countries. Low serum levels of 25-hydroxy-vitamin D (25(OH)D) have been associated with a number of diseases like cardiovascular diseases, diabetes, cancer, and infections. However, recent studies demonstrated evidence for vitamin D in preventing the development of many diseases including cancer. 25(OH)D is formed by hydroxylation of cholecalciferol in microsomes of hepatocytes. The serum concentration of 25(OH)D is used to determine vitamin D status in the body.
Aims: The prevalence of subclinical vitamin D deficiency has been reported to be higher in adult survivors of childhood cancer (1). However, the data on this subject are scarce.In this study, we aimed to determine the frequency of vitamin D deficiency/insufficiency in acute leukemia patients who completed treatment.
Methods: Serum 25(OH)D levels of leukemia survivors were measured using liquid chromatography-mass spectrometry (LC-MS) technique who were followed-up at Late Effect Clinic in Lösante Hospital between January 2013 and December 2013. According to criteria published by Mısra M *et al.* the serum 25(OH)D levels<15-20 ng/mL is considered insufficiency, or deficiency if<15 ng/mL or severe deficiency if ≤10 ng/mL for children and adolescents (2,3). According to criteria published by Kuchuk NO *et al.* the serum level of 25(OH)D was considered insufficiency if the level was ≤30 ng/mL and deficiency<10 ng/mL for young adults. (3,4)
Results: Two hundred and forty-eight patients (113 female and 135 male) aged between 3 and 31 were recruited. Of these, 233 patients had acute lymphoblastic leukemia (ALL), 12 acute myeloid leukemia (AML), and 3 myelodysplastic syndrome (MDS).Treatment completion times were between 2 months and 17 years. The results of serum 25(OH)D levels in survivors of childhood leukemia are shown in Table 1. Overall, 95 children and adolescents (38.1%) had normal levels of 25(OH)D whereas only two young adults older than 21 years (10.5%) had normal levels.

Table 1. Distribution of 25-hydroxy-vitamin D Levels after Chemotherapy According to Age.

	<5age (n:4)	6-9age (n:82)	10-18age (n:113)	19-21age (n:30)	>21age (n:19)	Total (n:248)
Children and adolescents						
Normal (%)	4 (100)	34 (41.5)	51 (45.1)	6 (20.0)		95 (38.3)
Insufficiency (%)	None	22 (26.9)	28 (24.8)	7 (23.4)		57 (23.0)
Deficiency (%)	None	14 (17.0)	20 (17.7)	13 (43.3)		47 (19.0)
Severe deficiency (%)	None	12 (14.6)	14 (12.4)	4 (13.3)		30 (12.1)
Young adults						
Normal (%)					2 (10.5)	2 (0.81)
Insufficiency (%)					14 (73.7)	14 (5.64)
Deficiency (%)					3 (15.8)	3 (1.21)

Summary and Conclusions: The results of the current study showed that vitamin D insufficiency/deficiency is an important problem in survivors of leukemia even in a country which the rate of sunlight exposure is high. Studies in recent years, which show that vitamin D deficiency plays an important role in many diseases, including cancer, emphasize the importance of detection of the insufficiency/deficiency of Vitamin D and the necessity of the planning the corrective treatment. Vitamin D deficiency is a health problem that concerns all age groups. Vitamin D inadequacy is now an internationally recognized health problem and survivors of neoplastic diseases may be at even higher risk than healthy children, adolescents, and adults. Thus, the measurement of vitamin D level in survivors of neoplastic diseases seems mandatory during their follow-up.(3,5).

PB1978

THE RULE OF QUALITY OF LIFE QUESTIONNAIRE IN OLDER ADULTS PATIENTS WITH ACUTE MYELOID LEUKEMIA IN A MONOCENTRIC EXPERIENCE

C. Buquicchio[1,*] L. Ciuffreda[1], T. Santeramo[1], P. Mongelli[1], R. Miccolis[1], D. Diomede[1], G. De Sanris[1], G. Tarantini[1]
[1]Ematologia, Ospedale Dimiccoli, Barletta, Italy

Background: In older patients the concept of frailty is changing, infact actually it's necessary to analize not only the age and the comorbidities but also how the tumoral pathology involve and modify the performance status of the patient s(generally calculated by karnosky, IADL and ADL scale)
Aims: We investigated the value and utility of a simple and fast questionnaire about physical and mental quality of life (SF12 Standard V1) administered to a group of elderly consecutive patients with acute myeloid leukemia in our single center.
Methods: During the years 2013-2015 twenty consecutive patients with acute myeloid leukemia (AML) and age >65 years treated with hypomethylating agents (azacitidine 75mg/m2 for seven consecutive days each twenty-eight days) compiled a simple questionnaire(SF12 Standard V1) with twelve questions to determine and quantify the degree of physical and mental fitness/frailty at the onset of AML and during the treatment(each six months with a monitoring an year.
Results: We observed that the patients with higher score at the questionnaire (major impairments in physical activity and mental discomfort) had a poor outcome, while patients with lower score at AML onset or score improvement of 6th months questionnaire(during treatment) predicted longer overall survival (median 200 days *versus* 600 days;p0.03) and better response to therapy (overall response vs non response p0.04).
Summary and Conclusions: The quality of life questionnaire could help to have a more complete vision of the pathology in those vulnerable patients and to take therapeutic decision (non intensive care *versus* intensive care)considering the reversibility of frailty caused in part of the acute leukemia.Clinical trials are necessary to confirm the rule predictor of this quality of life questionnaire for overall survival and response to therapy in a large population of older AML patients.

PB1979

HALOPERIDOL CURES COGNITIVE DYSFUNCTION; THE MECHANISM OF ACTION IS EXPLAINED.

M. Van Hoef[1,*]
[1]Transplant Creations, Amsterdam, Netherlands

Background: Cognitive disorders occur in the course of life threatening situations such as deportation and diseases such as cancer and are often associated with acute stress and post traumatic stress disorders induced by the treatment received. A battery of function tests have been used to assess cognitive disorders but cure for these disorders is not known.
Aims: Cognitive dysfunction has been reported after cancer treatment and after hematopoietic stem cell transplantation. The observations in this case lecture how to proceed in patients with similar conditions in the treatment of cancer.
Methods: The subject experienced a life changing situation of major impact that induced a cognitive disorder, which expressed itselves in difficulty writing letters, documents and composing presentations; moreover she reported her capacity after deportation to be 10% of her former capacity (1). At a conference in 2013 a video was presented of a patient who had been treated for breast cancer who had the same cognitive disorder, being difficulty writing.
Results: Treatments that impact life drastically induce stress that may result in acute stress disorders, posttraumatic stress disorders and cognitive impairment. The subject was initially not treated and noticed slow improvement; however the old level of functioning was not reached and work finally resulted in burnout. Although time off work improved the status it was not until haloperidol was instated that she noticed improvement of writing skills after about three weeks of treatment. A few years later upon new exposure to stress she noticed a decrease in capacity that could not be overcome with rest and requested reinstatement of haloperidol. She reported recovery in about three weeks after start of therapy. The subject first received haloperidol at a dose of 5 mg/day which was too high and induced extrapyramidal side effects. The dose was reduced to 2 mg/day, which was well tolerated. Although the subject had been advised to take the drug life long she stopped after nine to ten months and remained well. The second time haloperidol was prescribed at 2 mg/day and well tolerated and the function recovered in about three weeks. The subject took the drug four months and alternated 2 mg and 1 mg every other day. Since stopping the subject's status has remained well.
Summary and Conclusions: Biochemical studies have demonstrated that stress increases dopamine turn over in the prefrontal cortex, which is associated with cognitive deficits (2). Haloperidol is a dopamine receptor antagonist and administration reverses cognitive impairment.Van Hoef MEHM. Successful treatment of stress induced cognitive impairment with haloperidol; evaluation also warranted in hematopoietic stem cell transplantation. The observations described hereabove warrant evaluation of haloperidol as treatment for cognitive disorders that may develop in the course of treatment for cancer; although these are generally attributed to chemotherapy, the mechanism of action may rather be attributable to stress induced biochemical changes in the brain. In prescription of the drug, doctors should inform the recipient what to expect from the drug, that treatment is temporary, that they can relapse and that at a dose of 2 mg/day driving capacity is affected.

PB1980

DEVELOPMENT OF A PROGRESS TEST BASED ON THE EHA CURRICULUM AND EHA CV PASSPORT, USED FOR YEARLY EVALUATION OF HEMATOLOGY RESIDENCY IN SWEDEN

J. Ungerstedt[1,*] A. Eriksson[2], E. Ölander[3], E. Bergfelt[2], M. Liljeholm[3], H. Lind Kristjanssdottir[1], T. Erger[1], D. Erixon[3], C. Isaksson[3], G. Birgegård[2]
[1]Department of Medicine, Karolinska Institute, Stockholm, [2]Department of Medical Sciences, Uppsala University, Uppsala, [3]Department of Medicine, Umeå University, Umeå, Sweden

Background: In Sweden, after 5.5 years of medical school and 18-21 months of general internship, you can pursue a residency in internal medicine and hematology, which takes an additional 6.5-7 years. The Swedish Hematology Association (SHA) [AE1] appointed a Work Unit (WU) of resident hematologists lead by two senior colleagues with a vast teaching experience, to develop a yearly progress test for evaluation of hematology residents in Sweden. The framework for the progress test was the EHA curriculum and EHA CV Passport, which divides the Hematology Specialty into eight large parts, with subunits to systematically cover the whole field of Hematology.
Aims: The aim for the WU was to develop a yearly MCQ based progress test, based on the eight parts of the EHA CV Passport, and to launch it among Swedish resident hematologists, with a questionnaire to fill out along with the assessment.
Methods: Individuals or groups of Swedish experts, *e.g.* the National Diagnostic Groups, were asked to produce a number of multiple choice (MCQ) questions. The questions were read, revised and sorted by the WU, after which 75 MCQ questions, covering the eight major fields of the EHA CV Passport, were selected. The test was available via the SHA homepage, www.sfhem.se for one week in October 2014, whereafter the test was removed and the answers posted online. Instructions were to complete the test within 2 hours, and when answers were available, sit down and discuss with a clinical mentor, and fill out an internet based questionnaire on your impressions of the MCQ test.
Results: Among 77 listed resident physicians in the SHA registry, 54 (70%) answered the questionnaire. Out of these, 83% had completed the test. All except one valued the subjective usefulness of the test to high/very high, and interestingly, 37 of 54 reported that their test result would contribute to them actively re-planning their education in some way, mostly by adding courses in specific subjects, or by increasing literature studies. 67% had not yet gone through the test with mentor, but almost all claimed that they would do so in the near future. There was an even spread in years of education, with 21 in the beginning, 10 in the middle, and 23 physicians at the end of their residency. All but two residents acknowledged that they would do the test again next time it is given, to assess progress on an individual level. Comments from residents were that the test was well received, the questions adequate to assess skills, and helpful to point out weaknesses to work on.
Summary and Conclusions: There is a need for continuous evaluation of acquired skills during residency. The Swedish MCQ progress test reflecting the EHA CV Passport was well received by the resident doctors and may be an appropriate tool for yearly progress evaluation.

PB1981

ANDRAL NETWORK: OPEN ACCESS SOLUTION FOR BEST CYTOLOGICAL EXPERTISE

V. Leymarie[1,2,*] F. Trimoreau[2], D. Lusina[3], J.M. Martelli[4], F. Delhommeau[5], A.C. Galoisy[6], F. Geneviève[7], J.F. Lesesve[8], O. Crepin[9], S. Daliphard[10], G. Flandrin[11], X. Troussard[12]
[1]Medical laboratory BIOSANTE19, Brive la Gaillarde, [2]Laboratory of Hematology, Dupuytren University Hospital, Limoges, [3]Laboratory of Hematology, Avicenne University Hospital, Bobigny, [4]Laboratory of Hematology, General Hospital, Melan-les-Mureaux, [5]Department of Hematology, Saint-Antoine University Hospital, Paris, [6]Laboratory of Hematology, Hautepierre University Hospital, Strasbourg, [7]Laboratory of Hematology, University Hospital, Angers, [8]Department of Hematology, University Hospital, Nancy, [9]Laboratory of Hematology, Local Hospital, Bethune, [10]Laboratory of Hematology, University Hospital, Rouen, [11]French Speaking Group of Hematology, Paris, [12]Laboratory of Hematology, Côte de Nacre University Hospital, Caen, France

Background: In hematology, the microscopic analysis of cellular morphology of blood, bone marrow, lymph node… samples remains the first important stage for diagnosis and patient follow-up. In our field, the application of information technology has allowed remarkable developments: iconographic databases, e-learning systems, automated systems of classification of blood cells, and cytological web-review of clinical protocols. However, the cytological diagnosis itself has yet to really benefit from the great possibilities offered by modern technology.
Aims: In this aim, the French speaking Group of Cellular Hematology in partnership with the College of Hematology established the open access solution of "tele-expertise" in cytology: the ANDRAL network.
ANDRAL proposes remote expert decision-making support in cytology: for any transmitted request for classification, an image file with a clinical/biological form is submitted. The network then allows remote classification and diagnosis to be obtained by opinion of two expert reviewers within 24h.
Methods: The ANDRAL network is accessible on www.gfhc-reseau-andral.fr. It is free and accessible to both hospital and the private biologists. ANDRAL is linked to a group of 45 international expert reviewers, who assure by paired review, continuous cytological care service. Globally, the system satisfies the strictest requirements regarding medical data exchange in terms of security, confidentiality, and sample/patient traceability.
Results: From October 2012 through August 2014, the network recorded more than 300 registrations with approximately 40% from private biologists, 60% from biologists practicing in a local or university hospital. 15% of the subscribers (n=42) practiced outside of France. Over the same period, more than 200 dossiers were submitted. 70% were de novo diagnoses; 15% were urgent requests. Image files were selections of images and rarely wide field images. The requests were variable ranging from benign to malignant pathologies and common occurrences to rare hemopathies. The average time of request management was 1h50min, and the time to obtain a classification was on average 6h00min. The ANDRAL network also features specific evaluation tools which allow for follow up activity and also allow the measure of the quality of service provided.
Summary and Conclusions: Today, the assessments and the perspectives offered by ANDRAL network are real and very encouraging. In term of assessments, the constant and rapid increase of membership, the incredible motivation of all the expert reviewers and the high quality of exchanges are highlights. Several developments are further committed: collaboration with other networks and other countries and the development of a permanent economically feasible medical model. For the hematologists involved in morphological diagnoses, the ANDRAL network is a working example of cooperative function of which the first results are very encouraging.

PB1982

PREVALENCE AND TREATMENT OF MANTLE CELL LYMPHOMA (MCL) IN GERMANY: AN ANALYSIS OF SICKNESS FUNDS

J. Tomeczkowski[1,*] M.K. Leisten[1], H. Metin[1], J. Fleischmann[1], C. Tapprich[1]
[1]Janssen-Cilag GmbH, Neuss, Germany

Background: No central registries for patients with mantle cell lymphoma (MCL) exist in Germany.
Aims: The objective of this analysis was to determine the number of patients with MCL diagnosed (with or without other diagnoses of cancer) and to characterize the types of treatment being utilized and care settings using sickness funds claim data.
Methods: This analysis evaluates data from 1,771,225 beneficiaries in 2012 from different statutory sick funds (SHI). MCL patients were identified by ICD-10 C83.1, oncological co-diagnoses by ICD-10 C00-79; D37-48 and chemotherapy by Anatomical Therapeutic Chemical (ATC) Code L01*, pharmacy number (PZN) 9999092 and/or operating and procedure code (OPS) 854*.
Results: 78 patients with a diagnosis of MCL (C83.1) could be identified (4/100.000). Overall gender ratio was 76.9% male and 23.1% female. Additional oncological diagnoses were found in 43.6% of patients. 20.7% had malignant neoplasms of ill-defined, other secondary and unspecified sites (C76-80), 17.2% had malignant neoplasms of digestive organs (C15-26), 13.8% had melanoma (C43-44), 10.3% had neoplasms of uncertain behavior, polycythemia vera and myelodysplastic syndromes (D37-48), 8.6% had malignant neoplasms of urinary tract (C64-68) and malignant neoplasms of lip, oral cavity and pharynx (C00-14) (multiple diagnoses possible). The outpatient diagnosis rate was 64.1%, inpatient rate 15.4% and in- and outpatient 20.5%. From a total of 78 patients 44 (56.4%) patients received chemotherapy (40 men [90.9%] and 4 women [9.1%]) in 2012. 25.0% of patients received both out- and in-patient treatment, 65.9% received out-patient treatment and 9.1% in-patient treatment. Identification of the administered substances was possible when ATC codes were reported. The most commonly used treatments were rituximab (34.7%), bendamustine (14.9%), cyclophosphamide (11.9%), vincristine (8.9%), doxorubicine (21.8%) and other treatments (21.8%) (multiple treatments possible).
Summary and Conclusions: Prevalence and gender ratio 3:1 was consistent with previously reported[1,2]. Most patients were diagnosed and treated as outpatients. Other oncological disorders are higher than in chronic lymphocytic leukemia[3]. About half of the patients were treated with chemotherapy within a year.

PB1983

THE SOUTHERN TRANSYLVANIA HEMATOLOGICAL PATIENTS' OPINION ON THE QUALITY OF MEDICAL CARE

R.-G. Mihaila[1,*] L. Mondoc[2], C. Salcudean[2], V. Baldovin[2], N.M. Stopici[2]
[1]Faculty of Medicine, Lucian Blaga University of Sibiu, [2]Emergency County Clinical Hospital Sibiu, Sibiu, Romania

Background: The interest about the opinion of our patients on various aspects of health management has become a constant in our work, helping us to improve our activity.
Aims: To find the opinion of our patients on the quality of medical care.
Methods: A transversal study was performed on a sample of 214 consecutive hospitalized patients in our Hematology department in January 2015 who responded to a questionnaire on the quality of medical care. The results were analyzed and they have allowed conclusions that we hope to have implications for clinical practice.
Results: The mean age of surveyed patients was 61,79+/-16,05 years. Distribution by gender: women 51,19%, men 48,81%. Most surveyed patients (92.8%) believe that regular consultations in hematology service is a useful opportunity for drug doses adjustment and early detection and treatment of possible recurrences. Most of them (84.14%) believe that the time interval between two successive control consultations is suitable and only 8.33% think it is too short. It is gratifying that all surveyed patients believe that the attitude of physicians towards them is polite and 94.04% of them think that nurses are polite, too. However, the lack of courtesy of nurses was observed by 5.95% of respondents. Most patients (83.33%) think that the time established by the doctor for patient consultation is long enough, 3.57% of them consider that it is too short. All surveyed patients said they had been informed by their doctor on the diagnosis of hematological disease,the therapeutic plan has been exposed to them, and they understand its necessity. Most patients (94.04%) are satisfied with the results of treatment, and the rest do not know. The possible adverse effects of transfusions were explained to 82.82% of them. A percentage of 13.64% of them said they did not receive such information, and 4.55%-did not remember about this. While 82.82% of them admited to having read and signed a transfusion consent before they were transfused, 15.91% of them said they did not remember hereof. A proportion of 83.33% of surveyed patients is satisfied with the conditions of hospitalization and 14.29% of them are not. A proportion of 11.9% of them would like the medical staff to offer more attention to them. If they had to decide again in what hematology department in the country to be hospitalized and treated, 100% of respondents would still come in Sibiu.
Summary and Conclusions: Although most patients are satisfied with the medical care they have expressed several opinions that may contribute to increase their quality: a more polite attitude of the nurses, more time dedicated by physicians for consultation, explaining the possible adverse effects of transfusion to all patients, additional efforts to improve the conditions of hospitalization, more attention offered to the patient and their needs, greater concern for the introduction of innovative therapies. The fact that, despite the reported imperfections, patients prefer to be hospitalized again in our service, means that the general opinion is favorable and that they trust the provided medical services, which are perfectible.

PB1984

LIPOSOMIAL IRON IMPROVES FATIGUE IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AS REFRACTORY ANEMIA. MULTICENTRIC STUDY.

G. Giordano[1,*] F. d'amico[2], A. commatteo[3], G. berardi[4], D. berardi[5], B. carabellese[6], R. gigli[3], M. magri[3], A. licianci[3], L. di marzio[3]
[1]medicine, Regional Hospital "A. Cardarelli", Campobasso, [2]Foundation "J. Paul II", campobaso, [3]Regional Hospital "A. Cardarelli", [4]family medicine, Campobasso, [5]University "La Sapienza", Rome, [6]nuclear medicine, Regional Hospital "A. Cardarelli", Campobasso, Italy

Background: Fatigue is the most invalidating symptom in neoplastic disease. Fatigue frequently is linked to an iron deficiency. In inflammatory diseases as myelodysplastic syndromes fatigue might be linked to a functional iron deficiency with elevated ferritin level and a saturation of total iron binding capacity<20%.
Aims: Aim of this study is to verify if liposomial iron support in myelodysplastic syndromes as refractory anemia improves fatigue perception in patients with a saturation of total iron binding capacity<20%.
Methods: Between june 2011and december2014,20patients affected by refractory anemia were studied. Median follow-up was12 months(R10-24).Patients were randomized1:1 to receive in groupA alpha erythropoietin 40000IUsc/week+calcium levofolinate7.5mg/day orally+Vitamin B12:400mg/day orally.In group B patient received liposomial iron14mg1 tablet orally/day+alpha erythropoietin 40000IUsc/week+calcium levofolinate7.5mg/day orally+Vitamin B12:400 mg/day orally.In group A median age was60 years(R65-70),M/F:8/2.In groupB median age was66 years(R60-75),M/F:6/4.Caryotype was normal in groupA andB patients.Median level of haemoglobin was 9 g/dl in group A(R8.5-11) and8.8g/dl(R8.5-11.5)in group B.Fatigue was measured with Modified Fatigue Impact Scale (FISC-Fisk 1994).
Results: Patients in group A reached a median hemoglobin level of11.5g/dl after 3 month of therapy and referred a median FISC score of74 (R65-80). Patients in group B reached a median hemoglobin level of12.5g/dl after 3 month of therapy and referred a median FISC score of54 (R42-68).
Summary and Conclusions: Liposomial iron support improves fatigue perception in patients with refractory anemia. This study needs confirmation on a lager cohort of patients.

MOLECULAR CHARACTERIZATION OF BETA GLOBIN GENE OF THALASSEMIA REVEALS NEW AND RARE MUTATIONS IN PAKISTANI POPULATION

H. Yasmeen[1,2,*] S. Hasnain[1,2], S. Toma[3], N. Killeen[3], L. Foroni[3,4]
[1]Department of Microbiology and Molecular Genetics, University of the Punjab, Lahore, [2]Department of Microbiology and Molecular Genetics, The Women University Multan, Multan, Pakistan, [3]Department of Medicine, Imperial College Healthcare NHS Trust, Hammersmith Hospital, [4]Centre for Haematology, Department of Medicine, Imperial College London, London, United Kingdom

Background: Imbalance in synthesis of α- or β- chains of hemoglobin results in thalassemia that has clinically diverse manifestations ranging from asymptomatic to regularly transfusion dependent individuals. More than 200 deletions or point mutations have been identified that impair transcription, processing, or translation of α- or β-globin mRNA. In Pakistan, a carrier rate of 5 to 7% demands communal preventive measures such as carrier identification, genetic counseling and prenatal diagnosis.
Aims: Present multicentre study undertaken in four cities of Pakistan examines the frequency and spectrum of alpha and beta thalassemia in Pakistani population.
Methods: 161 seronegative beta thalassemia patients, identified on the ground of haematological parameters, were screened for mutations of the Alpha (HBA2 and HBA1) and Beta (HBB) genes and G Gamma (HBG2) Globin gene XmnI polymorphism using a combination of Multiplex Gap PCR, Sanger sequencing and RFLP PCR.
Results: Among 16 mutations identified in the beta gene, HBB:c.27_28insG (p.Ser10Val) was the most prevalent. α-3.7 and α-4.2 deletions were also found in coinheritance with beta thalassemia mutations. Rare mutations such as HBB:c.-138C>T and HBB:c.315+1G>A were also identified. Interestingly, one novel mutation (HBB:c.-148T>A), two rare variants (HBB:c.332T>C (p.Leu111Pro) and HBB:c.92G>C (p.Arg31Thr) and a novel association (HBB:c.92G>C (p.Arg31Thr)/HBB:c.-92C>G) were also reported for the first time in our study in the Pakistani population. HBG2:c.-211C>T base-pair substitution (historically described as -158 Gγ XmnI polymorphism) was present in 36% of the patients analysed.
Summary and Conclusions: Such comprehensive studies revealing some rare mutations are essential for prenatal screening and control of this highly prevalent disease in Pakistani population along with nationwide awareness campaign.

HEME EXPORT AND HEME DEGRADATION DURING MURINE ERYTHROPIESIS

S. Petrillo[1,*] D. Chiabrando[1], S. Mercurio[1], L. De Franceschi[2], A. Camporeale[1], L. Silengo[1], F. Altruda[1], E. Tolosano[1]
[1]Department of Molecular Biotechnology and Health Sciences, University of Turin, Turin, [2]Department of Medicine, University of Verona, Verona, Italy

Background: Erythropoiesis is the biological process that consumes the highest amount of body iron for heme synthesis. Heme accumulation within differentiating erythroid cells is crucial for globin genes expression and hemoglobin production. Recently, a role for heme oxygenase (HO)-1and Feline Leukemia Virus subgroup C Receptor (Flvcr)-1 genes in the control of cytosolic heme during erythropoiesis has been reported. HO-1 is the inducible enzyme responsible for heme degradation. Flvcr1 gene encodes for two heme exporters, Flvcr1a and Flvcr1b, localized at the plasma and mitochondrial membrane, respectively. Flvcr1 plays a crucial role in erythropoiesis since loss of both *Flvcr1a* and *Flvcr1b* in mice and zebrafish results in anaemia. Moreover, we demonstrated that *Flvcr1b* is required along all phases of erythropoiesis while *Flvcr1a* is important for the expansion of committed erythroid precursors but dispensable for their differentiation.
Aims: The aim of this work was the elucidation of the interplay between heme export and heme degradation during erythropoiesis.
Methods: We isolated erythroid sub-population from murine bone marrow and analyse the expression of *Flvcr1* isoforms and HO-1. Moreover, we compared HO-1 level observed in wild-type mice to that of conditional knock-out mice that do not express *Flvcr1a* and *Flvcr1b* in bone marrow. The same analysis was performed on the fetal liver of mouse embryos carrying alleles that differentially affect *Flvcr1a* and *Flvcr1b* expression.
Results: Our data indicated different profiles of expression for HO-1, *Flvcr1a* and *Flvcr1b* during erythropoiesis. Moreover, when *Flvcr1a* or *Flvcr1b* were lost, HO-1 resulted up-regulated.
Summary and Conclusions: These results suggest that during erythroid differentiation, heme export and heme degradation control different pools of heme.

PB1988

HEME, INFLAMMATION AND PARKINSON'S DISEASE

R. Gozzelino[1,2,*]
[1]Chronic Diseases Research Center, Lisbon, [2]Instituto Gulbenkian de Ciência, Oeiras, Portugal

Background: Heme is a metallo-compound, essential for the survival of most organisms. However, the ability of the central iron (Fe) atom, contained within its protoporphyrin ring, to participate in the Fenton chemistry and generate highly reactive hydroxyl radicals renders heme potentially toxic. Under inflammatory conditions, the release of heme from hemoproteins leads to unfettered oxidative stress, a deleterious effect allowing this molecule to sensitize parenchyma cells to undergo programmed cell death. We previously demonstrated that heme critically contributes to the pathogenesis of immune-mediated inflammatory diseases, by promoting the activation of the c-Jun N-terminal kinase signaling transduction pathway in response to pro-inflammatory agonists released in the course of the infection. The deleterious effect of heme is associated to tissue damage and disease severity, as upon hemolysis its release into circulation dictates the outcome of infectious diseases.
Aims: As infectious and inflammatory diseases are often associated to a certain degree of vascular leakage, it is possible that under these conditions the cytotoxicity of heme may affect also organs of restricted accessibility, such as the brain, thus increasing the risk and severity of neurodegenerative diseases.
Methods: This hypothesis has been investigated in mice by assessing whether the peripheral exogenous administration of heme or the release of heme upon exposure to immune-mediated inflammatory diseases enhances the severity of Parkinson's disease.
Results: Preliminary data demonstrates that heme triggers neurodegeneration and enhances the susceptibility to Parkinson's disease.
Summary and Conclusions: The protective effect of heme scavengers and proteins counteracting the pro-oxidant reactivity of Fe in preventing the development of Parkinson's disease suggests that heme cytotoxicity may critically contribute to this disorder.

PB1989

GHRELIN GENE POLYMORPHISM IN IRON DEFICIENCY ANEMIA

E. Bahadir[1], S. Akarsu[2,*] E. Onalan Etem[3]
[1]University of Firat Faculty of Medicine, Department of Pediatrics, [2]University of Firat Faculty of Medicine, Department of Pediatric Hematology Oncology, [3]University of Firat Faculty of Medicine, Genetics, Elazig, Turkey

Background: Iron deficiency anemia (IDA) is the most common in infancy and childhood hematologic diseases. It is seen in all age groups. Nutrition plays an important role in the development of IDA which is the most common cause of nutritional anemia. In our country, IDA has been determined in 12.7% of children between 4-months and 18-years old. One of the clinical features of IDA is loss of appetite and nutrition plays a major rol in IDA. Ghrelin stimulates appetite and food intake. It is considered that appetite and eating behavior are controlled with complex mechanisms by certain areas located at hypothalamus in central nervous system (CNS). The neurons containing ghrelin involved in appetite were found at arcuate nucleus of hypothalamus. Ghrelin at this localization controlles food intake. In addition to becoming hunger hormone, ghrelin regulates eating behavior and weight balance. Also ghrelin, before and after fasting, controlles behavioral, metabolic and gastrointestinal adaptations. The significant positive correlation was found between body iron and ghrelin levels. Ghrelin levels progresively decrease from iron decrease to development of IDA.
Aims: The frequency of ghrelin gene polymorphism was aimed to be investigated in children diagnosed as IDA and healthy control group. In this way, we aimed to determine ghrelin gene polymorphism in healthy children of our society. It was aimed which determined polymorphisms are seen more frequently. Thus, we aimed to determine difference between the ratios of healthy children and children with IDA. Among children with the same nutrition manner, common living conditions, we aimed to answer question that the real reason of IDA development may be occurance of a polymorphism at ghrelin gene.
Methods: In our study, total 57 children with IDA, 27 female (47.4%) and 30 male (52.6%), and 57 healthy control group were assessed. -501 promoter, arg51Gln, Leu72Met, and Gln90Leu polymorphisms at ghrelin gene were studied in patients and contol group.
Results: In terms of -501 A/C polymorphism at ghrelin gene, A allele was found statistically significant in patients group (P<0.05). For promoter -501 A/C polymorphism, the frequencies of genotype was not different from the control group (P<0.05). When genotype and allele frequencies were compared with control group for Arg51Gln, Leu72Met and Gln90Leu polymorphisms, there is no statistically significant difference (P<0.05).
Summary and Conclusions: We suggest that ghrelin gene may play an important role in IDA immunogeneticy. Also we think that studies are needed to be

done in both Turkish population and other populations for the determiation of other polymorphisms in this gene which may contribute to this disease. To verify our data, the same polymorphisms should be futher investigated in patients with IDA in different populations by more futher studies. We suggest that increased promoter -501 variant frequency in ghrelin gene may be one of he mechanisms involved in etiopathogenesis of IDA.

PB1990

RESPONSIVENESS TO PARENTERAL IRON THERAPY IN THE DIFFERENTIAL DIAGNOSIS FROM UNEXPLAINED REFRACTORY IRON DEFICIENCY ANEMIA TO IRON-REFRACTORY IRON DEFICIENCY ANEMIA

M. Akin[1,*] H. Sarbay[2], S. Guler[2], C. Cicek[2], Y. Balci[2], A. Polat[2]
[1]Pediatric hematology, [2]Pamukkale University, denizli, Turkey

Background: We evaluated responsiveness to parenteral Iron therapy in the differential diagnosis from unexplained refractory iron deficiency anemia to iron-refractory iron deficiency anemia.
Aims: We evaluated responsiveness to parenteral Iron therapy in the differential diagnosis from unexplained refractory iron deficiency anemia to iron-refractory iron deficiency anemia.
Methods: This study analyzed responses to IV iron sucrose therapy given to 15 children with unexplained refractory IDA who were unresponsive to oral iron therapy.
Results: Ferritin, MCV, MCH and Hb values were normal range in 10 patients at 6 weeks following the first therapy. The increase in Hb, MCH, MCV, and ferritin values were ranging from 2.6 to 3.5g/dL, 1.7 to 4.2 pg, 2 to 9 fL and 13 to 25 ng/mL in table 1, respectively. In five patients, Hb, MCH and MCV mean (range) values [11.2 g/dL (11-12.2), 24.5 pg (24-25.6) and 67fL (65-70)] were nearly normal but ferritin mean (range) values [9.8 ng/mL (8-11)] were below normal. The increase in Hb, MCH, MCV and ferritin were ranging from 2.6 to 3.5g/dL,7 to 4.2 pg, 2 to 9 fL and 5 to 12 ng/mL, respectively. Children with IRIDA in previous our study, Hb, MCH, MCV and ferritin values increased 6 weeks after the first therapy. The increase in Hb was 0.8–2.7g/dL and that of MCH, MCV, and ferritin values were 1.7–4.2 pg, 2–9 fL, and 13–25 ng/mL, respectively.
Summary and Conclusions: Intravenous iron therapy increased rapidly blood parameters in children with unexplained refractory IDA. The hematologic response to IV iron therapy should be used differentiation from unexplained refractory IDA to IRIDA.

PB1991

PHENOTYPIC PROFILE OF PAROXYSMAL NOCTURNAL HÉMOGLOBINURIA CLONES BY FLOW CYTOMETRY IN BLIDA, ALGERIA.

O. Salima[1,*] T. Souad[1], A. Mohand Tayeb[1]
[1]Hematology, EHS ELCC CAC Faculty of Medicine, University Blida 1, Blida, Algeria

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, genetically acquired, life-threatening disease. We report 24 cases of PNH diagnosed and followed by flow cytometry (FC).
Aims: To evaluate the size of PNH clones and their clinical impact
Methods: The PNH clone was required in the event of bone marrow aplasia with or without hemolysis, of regenerative haemolytic anemia with negative direct Coombs test, in case of Myélodysplastic syndrome, in case of unexplained cytopenia and in thrombosis. The research of the clone by FC is carried out by analysis of the following monoclonal antibodies: Flear, CD59, CD14 with gating on the CD45, CD64 and on Glycophorin A; the clone was required on the red cells, neutrophil graulocytes (NG) and monocytes. We judged that the patients (pts) has a HPN clone when the deficit is >5% on at least two markers highlighted on two different lines. PNH clone was diagnosed among 151 pts since August 2009. A monitoring by CMF is ensured in the event of absence of deficit or a very moderate deficit or concerning only one line.
Results: On 151 analyzed cases, absence of HPN clone in 127 cases (84,2%); In 24 cases (15,8%), a deficit ≥ two markers in two lines or more was present. They are 10 women and 14 men; sex ratio=1,4, median age=41 years (21-58). PNH clone was found in bone marrow aplasia: 15/67 cases (22, 4%), hemolytic anemia with negative direct coombs: 2 /28 case (7,1%), other hemolysis : 2/11 cases (18%), thrombosis: 2 /21 (9,5%), bone marrow aplasia in pregnancy: 1/3 cases (33%), myelodysplastic syndrome : 02/14 cases (14.3%) and cytopénia: 0/6 cases. Types of HPN: type II: 2 cases (8,4%), type III: 16 (66%), mixed type: 6 cases (25%). The median rate of deficit of the CD59 on red cells=31.7% (5-72), of the CD59 on neutrophil granulocytes = 58,7% (7-99) and of Flear carried out in 11 cases=61.42% (6-98) and the deficit on the monocytes was required in 8 cases, the median rate of the deficit of CD14=77.7% (22-97) and of Flear (4 cases)=72,2% (19,4-92,1). In monitoring: appearance of the PNH clone in 1 case, increase in the size of clone in 4 cases, initially lower than 2%, and in a case the clone has doubled of size from 54% to 98% after 6 months and the patient developed a wide thrombosis. In 13 cases, a moderate deficit of a marker was noted on only one line.
Summary and Conclusions: In our study HPN clone was noted in 14% of the cases of MDS which joined the literature.
In the group where moderate deficit was observed, biological signs of hemolysis were absent; the indication of a follow-up of the size of HPN clone is then necessary and must include an assessment of hemolysis repeated with evaluation of the LDH; that is checked in our study since in 04 cases of increase size of the clone, a thrombosis occurred in one case.. B. Höchsmann showed after follow-up of 155 cases a significant increase of the clone in 28% of cases.
The application of FC, enabled us to make the diagnosis of PNH. Moreover it determined the phenotypic profile of PNH clones in our area and specified their size; it is also very useful for the follow-up of the patients. It remains a key examination in the diagnosis of the PNH and in some cases it will be necessary to repeat research of the clone after a first negative analysis in particular in the event of bone marrow aplasia and of hemolysis associated, and also in the event of small clone to follow its evolution.

PB1992

IRON AND TRANSFERRIN IN CHLDREN WITH SIDEROPENIC ANEMIA

V. Grajqevci-Uka[1,*] R. Macastena-Maxhuni[1], B. Abrashi[1], F. Selimi[1]
[1]hemato-oncology, university clinical centre kosova, prishtina, Kosovo

Background: Introduction: Sideropenia means lack of iron within the organism. As the result of the absence of the iron the synthesis of hemi decreases in hemoglobin. Sideropenic anemia is the most common anemia to children because of the specific metabolic needs associated with growth and development. Anemia as a lack of iron is charachteriszed by a defect in the synthesis of hemoglobin and as a result of that we end up to a reduction of the red blood cells (micro cells), and to a reduction of amount of hemoglobin (hypochromic).
Aims: The purpose of the paper: was the presentation of cases with sideropenic anemia to our patients.
Methods: Materials and methods: Within the study we had 200 children consisting of all age groups, hospitalized in the Pediatric Clinic, in hemato-oncology department. The diagnosis is done based on the past history, physical examination, and laboratory analysis. The test of iron and transferrin is done using the electronic modern method.
Results: Results: Regarding the age of children diagnosed with sideropenic anemia, the most endangered age group was 0-1 years where 113 cases or (56.1%) were diagnosed, whereas the ages with lower risk were ages 7-15 years which consisted of 18 cases or (5.6%). Further on, according to settlements, we did not have many differences. From villages we have had 109 cases (54.5%), while from the cities 91 cases (45.5%). Male children dominated by 107 cases (53.5%), whereas females consisted of 93 cases (46.5%). In terms of nutritional status, eutrophic children dominated by 131 cases (65.6%). Moreover, according to iron values of 1-2.9 micromoles/L have been presented 14 cases (70%), and of 6-10 micromoles/L 108 cases (54.0%) have been presented. By nominal values of UIBC transferrin have been 187 cases (93.5%), while those with higher values of TIBC consisted of 128 cases (64.8%).
Summary and Conclusions: Conclusion: Based on our data, it is obvious that sideropenic anemia is not rare to our children, however it tends to be quite frequent. A very important part to this disease we consider some factors such as: socio-economic low status, the low level of parental education, and the nutritional manner.

MULTI-PARAMETRIC CARDIAC MAGNETIC RESONANCE FOR PREDICTION OF CARDIAC COMPLICATIONS IN THALASSEMIA INTERMEDIA: A PROSPECTIVE MULTICENTER STUDY

A. Pepe[1,*] A. Meloni[1], P. Giuliano[2], F. Terrazzino[3], M. G. Neri[1], C. Gerardi[4], A. Pietrapertosa[5], G. Roccamo[6], A. Ciancio[7], V. Positano[1], N. Giunta[2]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]U.O. Cardiologia, [3]U.O.C. Radiologia, "ARNAS" Civico, Palermo, [4]Ospedale "Giovanni Paolo II" ASP Agrigento-Distretto di Sciacca, Sciacca (AG), [5]Servizio Regionale Talassemie, Policlinico di Bari, Bari, [6]Unità di Prevenzione e Cura delle Mictrocitemie, PO di S.Agata di Militello (ASP-ME), S.Agata di Militello (ME), [7] Day Hospital di Talassemia, Ospedale "Madonna delle Grazie", Matera, Italy

Background: Cardiovascular Magnetic Resonance (CMR) has an established role in managing and predicting prognosis of patients with Thalassemia Major (TM). Thalassemia Intermedia (TI) is a milder variant of beta-thalassemia showing a different clinical and prognostic profile; pulmonary hypertension (PH) is a more common complication in TI patients.
Aims: We prospectively determined the predictive value of CMR parameters, including measurement of right ventricular mass, for cardiac complications in TI.
Methods: We considered 342 TI patients enrolled in the Myocardial Iron Overload in Thalassemia network; about half of them (178/302, 58.9%) became transfusion-dependent in the adult age. Myocardial and liver iron overload were measured by T2* multiecho technique. Atrial dimensions, left and right ventricular mass and systolic function were quantified by cine SSFP images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.
Results: Twenty-three patients were excluded because a cardiac complication was present at the time of first CMR, so we prospectively followed 319 patients. All 319 patients were white, with a mean age at time of their first scan of 38.02±11.69 years and 165 (51.7%) of them were females. Mean follow-up time was 52.24±24.87 months (median 54.64 months). Cardiac events were recorded in 22 patients (6.9%): heart failure (HF) in 1 patient, arrhythmias in 12 patients, pulmonary hypertension (PH) in 7 patients and myocardial infarction (MI) in 2 patients. The mean time from the first MR scan to the development of a cardiac complication was 30.77±23.48 months and 8 (36.4%) cardiac events occurred within the first year of follow-up. Significant myocardial iron overload (global heart T2*<20 ms), ventricular dilation, right ventricular (RV) hypertrophy, myocardial fibrosis and atrial dilation were identified as univariate prognosticators. In the multivariate analysis the independent predictive factors were RV hypertrophy (HR=24.12, 95% CI=5.09-114.12, P<0.0001) and myocardial fibrosis by LGE (HR=6.59, 95% CI=1.33-32.67, P=0.021). The Figure displays the Kaplan–Meier curves showing the impact of each predictive factor on the development of cardiac complications. The log-rank test revealed a significant difference in the curves for each predictor factor (RV hypertrophy: P<0.0001 and myocardial fibrosis: P<0.0001).

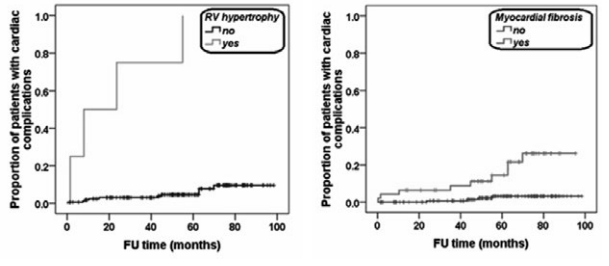

Figure 1.

Summary and Conclusions: For the first time we studied the prognostic value of right ventricular mass as part of multiparametric CMR imaging in a population of TI patients. Both RV hypertrophy and fibrosis detected by LGE were independent predictive factor for cardiac complications. Measurement of RV mass should be part of the multi-parametric CMR study of patient with thalassemia intermedia.

PB1994

A PROSPECTIVE MRI STUDY OF CARDIAC AND HEPATIC IRON AND CARDIAC FUNCTION IN NON-TRASFUSION-DEPENDENT THALASSEMIA INTERMEDIA PATIENTS TREATED WITH DESFERRIOXAMINE

Diagnostica per Immagini e Interventistica, Policlinico "Casilino", Roma, Italy

Background: In thalassemia intermedia (TI) patients no observational study prospectively evaluated in the real life the efficacy of the desferrioxamine (DFO) therapy in removing or preventing iron overload from the heart and the liver by T2* Magnetic Resonance Imaging (MRI).
Aims: The efficacy endpoint of this study is represented by the changes in cardiac T2* values, MRI LIC (liver iron concentration) values and biventricular function parameters in non-transfusion dependent (NTD) TI patients after 18 months of desferrioxamine therapy.
Methods: Among the 325 TI patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, we selected 129 TI patients NTD. We considered 29 patients who had been received DFO alone between the two MRI scans. Cardiac iron overload was assessed by the multislice multiecho T2* technique. Hepatic T2* values were assessed in a homogeneous tissue area and converted into LIC. Biventricular function parameters were quantified by cine SSFP sequences. Myocardial fibrosis was evaluated by late gadolinium enhancement (LGE) acquisitions.
Results: Mean age was 39.69±8.12 years and 14 (48.3%) patients were females. Patients started regular chelation therapy at a mean age of 21.92±15.89 years. The mean administered dosage of DFO via subcutaneous route was 38.46±10.27 mg/kg body weight on 3.32±1.54 days/week. The percentage of patients with excellent/good levels of compliance to the chelation treatment was 82.1%. At baseline only one patient showed cardiac iron overload (global heart T2*=15.23 ms) but he recovered at the FU (global heart T2*=26.93 ms). All patients without cardiac iron maintained the same status at the follow-up (FU). Eighteen patients (62.1%) had hepatic iron overload (MRI LIC ≥3 mg/g/dw) at the baseline. For this subgroup, the baseline and the FU LIC values were, respectively, 9.15±7.97 mg/g/dw and 7.41±6.28 mg/g/dw. The reduction in MRI LIC values was not significant (P=0.102). Out of the 11 patients with a baseline MRI LIC<3 mg/g/dw, only one (9.1%) showed hepatic iron at the FU. The Figure shows the evolution of different hepatic iron overload risk classes between the baseline and the FU. Due mainly to technical reasons, cardiac function was assessed at both baseline and FU MRIs in 24 patients. At baseline all patients had a normal LV ejection fraction (EF) and 4 of them showed a reduced LV ejection fraction (LVEF) at the FU. No patient had a pathological RV EF. No significant change between the two MRIs was detected in biventricular volume indexes, biventricular EFs and LV mass index. For 21 patients the presence of myocardial fibrosis was investigated at both baseline and FU MRIs, and this subgroup was considered. Three (14.3%) patients had myocardial fibrosis at the baseline, all with a non ischemic pattern. At the FU two new occurrences of non-ischemic myocardial fibrosis were detected.

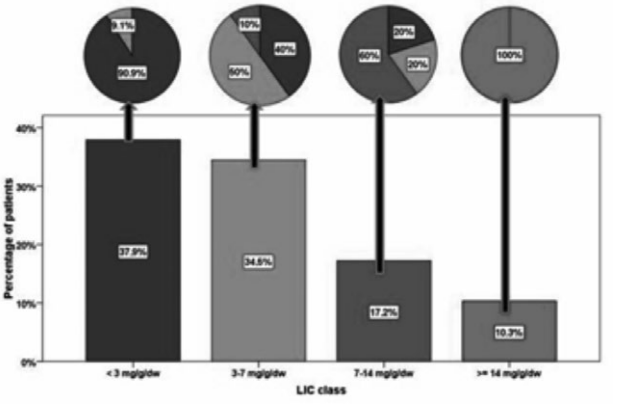

Figure 1.

Summary and Conclusions: In this small population of sporadically or non transfused TI patients, the DFO therapy showed 100% efficacy in maintaining a normal global heart T2* value. As regards as the hepatic iron overload, the DFO therapy did not prevent the transition to a worst class in 2 patients. Moreover, the DFO therapy did not prevent the worsening of the LV function and the occurrence of new myocardial fibrosis.

PB1995

THE ROLE OF NITRIC OXIDE IN SLEEP OF ADULTS PATIENTS WITH SICKLE CELL DISEASE

A.C. Cabanas-Pedro[1,*] S.S. Matsuda[1], S. Roizenblatt[2], M.G. Mouro[3], T.P. Biassi[1], J.R. Reinfelderon Jr[4], E.M.S. Higa[3], S. Tufik[4], M.S. Figueiredo[1]

[1]Clinical and Experimental Oncology, Hematology and Bloor Transfusion Division, [2]Department of Medicine, Internal Medicine Division, [3]Department of Medicine, Nephrology and Emergency Division, [4]Department of Psychobiology, UNIFESP/ Escola Paulista de Medicina, Sao Paulo, Brazil

Background: Nitric oxide (NO) is widely implicated in the modification of the sleep-wake states and, in obstructive sleep apnea, decreased NO levels have been implicated as possible mechanisms for development of cardiovascular diseases. Previous studies have shown that sleep disorders are prevalent in sickle cell disease (SCD) patients, and it is well known that NO plays a significant role in the pathophysiology of this disease.
Aims: The aim of the present study was to analyze the relationship between NO and sleep disorders in a group of SCD patients.
Methods: Steady-state adult patients with SCD followed at Ambulatory of Hereditary Anemias from Escola Paulista de Medicina/UNIFESP were invited to this study. Exclusion criteria were: chronic blood transfusion, pregnancy, and vaso-occlusive episodes and transfusion in the last three months. Sleep disorders were evaluated by standard overnight multichannel polysomnography (Somnologica, Embla™). NO plasma samples were determined by chemiluminescence using Model 280 Nitric Oxide Analyzer (NOA™) from Sievers Instruments, Inc. (Boulder, CO, USA). This study was approved by Ethical Committee, and all patients agreed to participate.
Results: 64 consecutive patients were enrolled, 33 (51.6%) males, with median (range) age of 28 (19–60) years. 42 (65.6%) had sickle cell anemia in use of hydroxyurea (SS-HU), 13 (20.3%) SS without HU, and 9 (14.1%) SC disease. The NO median concentration was 71.75 uM (40.5–243.5), with no difference among SS-HU, SS and SC patients (P=0.40). According with median level of NO, the patients were divided in two groups: G1 ≤71.75 and G2 >71.75uM. Among the sleep parameters analyzed, only two showed significant difference when compared G1 with G2: AHI – apnea-hypopnea index: 3.1(0–43.2) *vs.* 0.8 (0–10.4) (P=0.008), and DI – desaturation index: 5.1 (0–106.3) *vs.* 3.3 (0–29.9) (P=0.011). Considering the normal values of AHI and DI (≤5 and ≤10, respectively), we found association between lower levels of NO and AHI (OR=5.05, 95%CI: 1.25-20.43, P=0.03), and between lower levels of NO and DI (OR=3.81, 95% CI: 1.04–13.95, P=0.07).
Summary and Conclusions: Obstructive sleep apnea is, probably, the most known sleep-disordered breathing (SDB). It is a multifactorial process that leads not only to chronic intermittent hypoxia and sleep fragmentation, but also to increased cardiovascular morbidity. NO plays a contributory role in the pathophysiology of this process. Interestingly, SDB and SCD present many aspects in common, like chronic inflammatory status, endothelial dysfunction, and lower levels of NO. Moreover, SDB is prevalent in SCD and there is a relationship between NO level and SCD manifestations. The AHI and DI are important indexes related to SDB and risk of cardiovascular morbidity. The fact that we found both indexes altered in SCD, especially in patients with lower levels of NO, confirm that SCD patients suffered from sleep disturbances, and implies that NO is probably associated with it. This is one of the first studies about sleep disorders in adult patients with SCD, reinforcing the need of more studies in this field.

LESSONS FROM VERY SEVERE, REFRACTORY AND FATAL PRIMARY AUTOIMMUNE HAEMOLYTIC ANAEMIAS

W. Barcellini[1,*] B. Fattizzo[2], A. Zaninoni[3], F. Nesa[3], A. Zanella[3], A. Cortelezzi[4]
[1]U.O. Oncoematologia, Fondazione IRCCS Ospedale Maggiore Policlinico, [2]U.O. Oncoematologia, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, [3]UO Oncoematologia, Fondazione IRCCS Ospedale Maggiore Policlinico, [4]UO Oncoematologia, Fondazione IRCCS Ospedale Maggiore Policlinico e Università degli Studi, Milano, Italy

Background: Autoimmune haemolytic anaemia (AIHA), usually classified as warm (WAIHA), cold (CAD), mixed, and atypical forms, is a greatly heterogeneous condition both in terms of clinical presentation and response to treatment, varying from mild/fully compensated to very severe, life-threatening and fatal.
Aims: To describe acute and very severe cases of AIHA who displayed multidrug refractoriness and related complications.
Methods: 13 consecutive patients were identified among 157 primary AIHA followed from 1996 to 2014 at our institution. Patients were selected on the basis of very severe clinical presentation (Hb<6 g/dL, 51 cases) and requirement of at least 3 lines of therapy [steroids +/- IVIG, splenectomy, various immunesuppressants, plasma-exchange (PEX) and erythropoietin, 13/51].
Results: Table 1 shows the clinical characteristics of patients: 7 cases were direct antiglobulin test (DAT) positive with IgG+C antisera, 4 with IgG, and 1 with C; 1 case was DAT negative. All displayed marked intravascular haemolysis, 8 inadequate reticulocytosis, and 6 immune thrombocytopenia. Thrombotic events occurred in 8 patients (of whom 4 pulmonary embolism and 3 disseminated intravascular haemolysis) and acute renal failure in 3. All patients (but a Jehovah witness) received transfusions and steroids +/- intravenous immunoglobulins, 11 rituximab, 9 immunosuppressants, 5 PEX, 3 erythropoietin and 5 underwent splenectomy. Seven cases (54%) were fatal. In most cases death was due to infections and multiple organ failure, and was related with multi-treatment, particularly splenectomy, and with concomitant thrombocytopenia. Thrombotic complications were not fatal, and occurred more frequently in splenectomised cases.

Table 1.

	Date of diagnosis	DAT positivity	Hb g/dL	Ret 10^3 /mmc	LDH U/L	Treatment	Complications	Outcome (date last f-u or death)
Case 1 (F/ 31yrs)	1986	IgG	3.5	139	7665	Azathioprine, Splenectomy Vincristine, Cyclophosphamide	ITP, Gastro-intestinal bleeding Deep venous thrombosis Pulmonary embolism Acute renal failure, MOF	Death (May, 2014)
Case 2 (F/ 61 yrs)	May 2001	IgG+C	6.0	297	10404	Cyclophosphamide, Splenectomy Cyclosporine, Plasma exchange Rituximab, Vincristine	Pulmonary embolism Pneumonia	In follow-up, off therapy (Sept 2014)
Case 3 (M/ 50 yrs)	Nov 2004	IgG	5.2	500	12787	Cyclophosphamide, Azathioprine Rituximab, Splenectomy	ITP, Pneumonia Peritonitis Acute renal failure Sepsis/ARDS, MOF	Death (March 2006)
Case 4 (M/ 37 yrs)	Oct 2006	DAT-	5.4	200	839	Plasma-exchange, Cyclophosphamide, Rituximab	ITP Deep venous thrombosis	In follow-up off therapy (July 2014)
Case 5 (F/ 33 yrs)	Dec 2009	IgG+C	4.3	429	955	LD-Rituximab, Azathioprine Splenectomy	Sepsis,MOF	Death (April 2012)
Case 6 (F/ 46 yrs)	Sept 2009	IgG+C	4.9	157	1074	LD-Rituximab Cyclophosphamide Splenectomy	Pulmonary embolism Pneumonia	In follow up off therapy (Sept 2014)
Case 7 (F/ 46 yrs)	Dec 2010	IgG+C	5.9	114	835	Rituximab	ITP, Pneumonia HCV/toxic hepatitis MOF	Death (March 2013)
Case 8 (F/ 67 yrs)	Jan 2008	C3d	6	271	468	LD-Rituximab Cyclophosphamide, EPO	Pneumonia Pulmonary embolism	In follow-up off therapy (June 2014)
Case 9 (M/ 40 yrs)	Sept 2011	IgG+C	5	90	960	LD-Rituximab	ITP, Pneumonia Respiratory insufficiency	Death (April 2013)
Case 10 (F/ 73 yrs)	June 2011	IgG+C	2	58	703	Plasma-exchange, EPO	ITP, Pneumonia /Respiratory insufficiency Acute renal failure, DIC	Death (July 2014)*
Case 11 (F/ 18yrs)	April 2012	IgG	2.1	50	4000	Plasma-exchange, Rituximab Cyclophosphamide, EPO	Pneumonia, DIC	In follow-up off therapy (Sept 2014)
Case 12 (M/ 40 yrs)	Feb 2009	IgG	5.9	397	579	Cyclophosphamide, Rituximab	Osteonecrosis Septic arthritis Mastoiditis	In follow-up off therapy (Sept 2014)
Case 13 (M/ 66 yrs)	April 16, 2014	IgG+C	1.8	48	2200	Plasma-exchange, Rituximab	DIC, MOF	Death (April 23, 2014)

All patients were treated with steroids +/- IVIG. Bone Marrow evaluation and imaging studies excluded AIHA secondary to lymphoproliferative diseases in all patients. Autoimmunity profile was negative in cases 1, 2, 4, 6, 7, 9, 10, 11, 12, 13. In case 10 death was not related to AIHA

Summary and Conclusions: The challenging AIHA cases described showed a greatly unpredictable clinical course. Evans syndrome and previous splenectomy, particularly when performed after multiple immunosuppressive therapies, were associated with poor prognosis. Rituximab, when promptly administered, was effective in solving the clinical emergency in most cases unresponsive to steroids and transfusions. Plasma exchange and erythropoietin were valuable options. Above all, in very severe AIHAs a scrupulous and continuous attention by experienced clinicians is required in order to avoid a delay in potentially life-saving strategies.

PB1999

THE CORRELATION BETWEEN CAROTID ARTERY INTIMA MEDIA THICKNESS AND ANTIOXIDATIVE ENZYMES ACTIVITIES IN CHILDREN WITH IRON DEFICIENCY AND IRON DEFICIENCY ANEMIA

H. Aslaner[1], Y. Altuner Torun[2,*] C. Karakurkcu[3], A.B. Ergul[1]
[1]Pediatrics, [2]Pediatric Hematology, [3]Biochemistry, Kayseri Education and Research Hospital, Kayseri, Turkey

Background: Lipid peroxidation increased in iron defiency anemia (IDA) as a result of increase capasity of oxydant and also decreases of antioxydant capasity. Though there are many studies that damaged antioxydant activity affects atherogenonosus in IDA; there are not any studies over intima-media thickness of carotid artery (CIMT).
Aims: The aim of this study is to assess the antioxydant enzym activity in iron defiency (ID) without anemiea and thickness of carotid intima media as an early indicator of premature of atherosclerosis.
Methods: In this study, we searched for the relationship between carotid intima-media thickness and antioxidant enzyme activities in adolescents with iron deficiency or IDA. The study was performed on 71 children aged 11 to 17 years old including 25 children with ID, 25 children with IDA and 21 healthy children. Complete blood count, the serum levels of iron and iron binding capacity, ferritin, lipid profile, glutathione peroxidase, glutathione reductase, paraoxonase activity were carried out. The CIMT were assessed by using echocardiography. All blood tests and CIMT were reevaluated after three months oral ferric iron treatment in the group with iron deficiency anemia.
Results: We founded significantly lower paraoxonase activity in groups of iron deficiency and iron deficiency anemia (P<0.05), but there was not a difference between this two groups. In addition, glutathione peroxidase and reductase activities were similar (p>0.05). CIMT in ID and IDA were higher than the control group (P<0.05), but there was not a difference between this two groups. After the iron treatment, significantly increased PON, GSH-Px, GSH-R activities (P<0.05) and CIMT were decreased. It has been determined that a significant correlation between PON enzyme activity and levels of hemoglobin, serum

iron, ferritin, serum transferrin saturation. Moreover, there was an inverse correlation between carotid intima thickness and levels of hemoglobin, ferritin, and serum transferrin saturation. It was also revealed PON was negatively correlated with CIMT in IDA group (P<0.05, r: -0.410).

Table 1.

Table I. Corelation between PON and CIMT in ID, IDA, and control groups.

	ID	IDA	Control	*p* value
PON (U/L)	132±60[a]	105± 29[b]	209±38	p<0.05
CIMT(mm)	0.44±0.01[a]	0.44±0.01[b]	0.41±0.02	p<0.05

(a) There was a signicifant between ID and Control groups.
(b) There was a signicifant between IDA and control groups.

Table 2.

Table II. Corelation between PON and CIMT in pre and post treatment groups.

	Pre-treatment	Post-treatment	*p* value
PON(U/L)	105± 29	242± 77	*p*<0.05
CIMT(mm)	0.44±0.01	0.42±0.02	*p*<0.05

Summary and Conclusions: We think that impaired antioxydant capasity exist during iron defiency without anemia and this lead up to atherosclerosis. In addition, iron defiency even if not anemia should be treated to prevent prematüre aterosclerosis

PB2000

A COMMON GENETIC VARIANT OF THE TMPRSS6 GENE INFLUENCES THE SUSCEPTIBILITY TO IRON DEFICIENCY ANAEMIA IN PORTUGUESE WOMEN

L. Goncalves[1,*] A. Miranda[2], R. Faria[1], L. Correia[3], P. Faustino[1]
[1]Departamento de Genética Humana, Instituto Nacional de Saúde Doutor Ricardo Jorge (INSA), [2]Departamento de Promoção da Saúde, Instituto Nacional de Saude Doutor Ricardo Jorge, [3]Departamento de Bioquímica e Biologia Humana, Faculdade de Farmácia da Universidade de Lisboa, Lisboa, Portugal

Background: Anaemia is a worldwide blood disorder affecting about one-quarter of the world's population. Iron-deficiency anaemia (IDA) is the most common type of anaemia and is caused by inadequate iron availability for haemoglobin synthesis. The disorder development can be attributed to nutritional factors, namely to an iron deficiency diet. However, genetic variants may also be involved. Genome-wide association studies have suggested that common variants in the liver-expressed *TMPRSS6* gene might modulate haematological phenotype and iron status. This gene encodes for a membrane-bound serine protease, matriptase-2, that plays an essential role in down regulation hepcidin, the key regulator of iron homeostasis. One of the suggested genetic variant is the SNP rs855791 c.2207 C>T, p.Ala736Val.
Aims: The objective of this work was to evaluate whether the SNP rs855791 in *TMPRSS6* gene may influence IDA susceptibility in Portuguese women.
Methods: The SNP rs855791 (c.2207 C>T, p.V736A) was characterized at DNA level, using an *allele specific amplification* approach, in 25 Portuguese women presenting IDA (mean age=38 years) and in another 89 women without IDA, corresponding to the normal control group (mean age=39 years).
Results: We have found that the frequency of the three genotypes at SNP rs855791 is different between the two groups of women. The CC genotype frequency (736A) is lower in the IDA group than in controls and, inversely, the TT genotype frequency (736V) is higher; (P=0.037). Also, the TT genotype is associated with low haemoglobin level (P=0.036), serum iron (P=0.009) and transferrin saturation (P=0.015).
Summary and Conclusions: The genotype TT at SNP rs855791 within the gene *TMPRSS6* is associated with the lowest haemoglobin levels and serum iron parameters of the studied women. Moreover, it is more frequent in the IDA group. Therefore, we can conclude that this variant is a genetic risk factor to develop IDA, which corroborates results obtained by previous studies in other populations. So, this study has revealed that the *TMPRSS6* gene, besides its association with the rare iron deficiency iron refractory anaemia (IRIDA), has also an important role as genetic modifier of common iron-related disorders. The polymorphism p.Ala736Val effect is probably due to a partial impairment of matriptase-2 and, consequently, to an increased expression of hepcidin which perturbs iron absorption in the duodenum as well as iron recycling by macrophages. *Partially funded by FCT: PEst-OE/SAU/UI0009/2013 and Pest-OE/SAU/UI4013/2011.*

PB2001

LONG TERM FOLLOW-UP OF HYDROXYUREA IN SICKLE CELL DISEASE

B. Mohamed[1,*] B. Faiza[1], C.L.[1], K. MOURAD[1]
[1]Deprtement de Médecine, Faculté de Médecine. Unicersité Saad Dahleb, Blida, Algeria

Background: Hydroxyurea (HU) is considered to be the most successful drug therapy for severe sickle cell disease (SCD) and has many characteristics of an ideal drug for sickle cell anemia (SCA) and provides therapeutic benefit through multiple mechanisms of action. HU emerged as an important therapeutic option for children and adolescents with recurrent vaso-occlusive events and sustained long-term benefits were documented
Aims: To assess long term effects of hydroxyurea therapy in infants and adults with sickle cell disease (all types)
Methods: Since 2000, there were 54 SCD patients treated with HU, 39 SS 14S/βthal and 1 SC: Mean age at inclusion was 12+/-4.4 years (4 – 22 y), just 3 patients was aged above 40y at the inclusion, sex ratio: 29F/25M. Thirty night included for standard criteria (more than 3 severe crisis pain/year and/or recurrent acute chest syndrome >1 ACS/y) and 7 because of severe chronic anemia (baseline of hemoglobin lower than 6g/dL), 2 for complex red cell alloimmunization, 1 for delayed posttransfusional hemolysis, 1 invalidant priapism, 2 association with auto-immun disease(sarcoidosis, Systemic lupus erythematosus), 1 history of stroke with transfusional difficulties, 1 for nephropathy and renal failure (creatinine 18 mg/mL). 13 patients have been splenectomized before the inclusion; Avascular Necrosis of hips was noted in 5 patients. Ferritine in 27 patients polytransfused (more 20 blood units) was 3700 ng/mL. The median daily dose of HU was 18 mg/kg (14 to 22 mg/kg/d)
Results: After a follow-up of 9 years(5 to 14 years), we observed a significant decreased (P<0,0001) of severe and recurrent acute pain crisis (5,5→0,7/y) and Acute chest syndrome (1,5→0,3/y), need of blood transfusions (8→2/year), days of hospitalization (17→3/y). Sustained clinical benefits for the most patients received long-term HU treatment. Total hemoglobin increase was 1,1g/dl (0.5 à 2.5). In the subgroup of 7 patients treated for severe anemia, the mean hemoglobin level was 6.6±0.5 g/dL prior to HU and increased to 8.2±1.5 g/dL after 1 year of therapy. The iron chelation Deferroxamine (30mg/kg/j, 3j/7) and phlebotomy, performed in 11 patients when Hb level was upper 9g/dl). We noted some severe events: acute priapism in 4 patients (1 shunt cavernospongieux),4 hip osteonecrosis**.** We deplored 7 deaths: recidive of stroke (1), sepsis (1), ACS (2), progressive renal failure (1), acute hepatic sequestration (1), undetermined (1). Five were lost to follow-up after a median of 48 months. Very young patients treated have been associated with excellent growth and development. Sexual maturation, including menarche, has occurred without apparent delay. No severe side effect was related to HU treatment, which was discontinued in children mainly for transient neutropenia or thrombopenia, hypersplenism or acute splenic sequestration, followed by splenectomy(9 cases) or non-compliance (2 cases). Four women were pregnant after 8 years of HU. Long-term clinical benefits have also been observed wth improved quality of life. Ferritin levels were decreased with significant decline in group of patients treated with Deferroxamine and/or phlebotomy (3700→950 ng/mL).
Summary and Conclusions: Long-term exposure to HU seems associated with significantly reduced mortality, perhaps by reducing long-term end organ damage and does not appear to be associated with increased risk of secondary malignancies nor myelodysplasic syndrome. Our experience, mainly in children allows us to consider that this drug is a very potent therapeutic option for the management of severe forms of the disease, particularly in countries with limited blood supply. An updated national registry is highly needed to further assessment.

PB2002

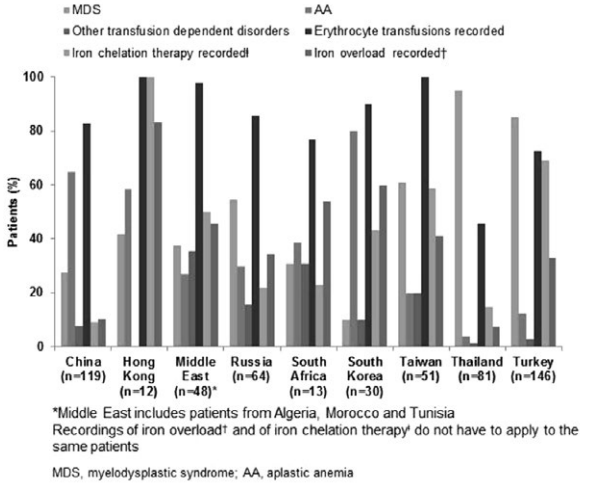
GEOGRAPHICAL DIFFERENCES IN IRON OVERLOAD AND IRON CHELATION PRACTICES IN ANEMIA PATIENTS: BASELINE RESULTS FROM THE TRANSFUSIONAL HEMOSIDEROSIS REGISTRY STUDY (TORS)

N. Siritanaratkul[1,*] J. W. Lee[2], M. Pehlivan[3], E. Volodicheva[4], Q. Jiang[5], F. Grifi[6], B.S. Ko[7], R. Wong[8], V. Louw[9], A. Khelif[10], A. El-Ali[11], A. Losco[11], O. Ilhan[12]
[1]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, [2]The Catholic University of Korea, Seoul, Korea, Democratic People's Republic Of, [3]Medical Faculty, Department of Hematology, Gaziantep University, Gaziantepet, Turkey, [4]Tula Regional Clinical Hospital, Tula, Russian Federation, [5]Peking University People's Hospital, Beijing, China, [6]Centre Hospitalier Universitaire Annaba, Annaba, Algeria, [7]National Taiwan University Hospital, Taipei, Taiwan, ROC, [8]The Chinese University of Hong Kong, Shatin, Hong Kong, [9]University of the Free State, Bloemfontein, South Africa, [10]Farhat Hached University Hospital, Sousse, Tunisia, [11]Novartis Pharma AG, Basel, Switzerland, [12]Department of Hematology, Ankara University School of Medicine, Ankara, Turkey

Background: Data describing transfusion practices and diagnoses of iron overload as well as iron chelation in patients with anemia across geographical regions are limited. A prospective epidemiological study may provide further insights into clinical practices for these conditions.
Aims: This prospective, multinational, non-interventional study, aimed to (1)

evaluate the differences in baseline characteristics among early diagnosed patients with anemia requiring chronic transfusion therapy; (2) assess the extent of iron overload and patterns of care surrounding the use of iron chelation therapy in different geographical regions.
Methods: Patients aged >2 years requiring chronic transfusion therapy with newly diagnosed anemias (<12 months from diagnosis), including thalassemia, low and intermediate-1 myelodysplastic syndromes (MDS), aplastic anemia (AA), Diamond-Blackfan anemia (DBA) and other transfusion-dependent anemias were enrolled. Patients were recruited from Turkey, Russia and South Africa as well as from countries within the Asia-Pacific and Middle East regions. Patients with secondary or therapy-related MDS; intermediate-2 or high-risk MDS; or acute leukemia were excluded. Patients were evaluated at baseline and at follow-up visits according to the standard practice for up to 3 years or until death. At baseline, patient demographics and details of iron overload and iron chelation therapy use were assessed. Transfusional hemosiderosis was defined as ≥1 serum ferritin measurement >1000 ng/mL after onset of transfusion therapy; or a liver iron concentration (LIC) >2 mg Fe/g dry weight; or if serum ferritin or LIC measurements were not available, evidence of ≥20 units of red blood cell transfusions.
Results: Of the 564 patients (including patients aged ≤18 years, n=57) recruited, majority had a diagnosis of MDS (58.5%, n=330), followed by AA (31.2%, n=176), other transfusion-dependent disorders (6.2%, n=35), β-thalassemia major (2.0%, n=11), β-thalassemia intermedia (1.1%, n=6), sickle cell anemia (0.5%, n=3) and DBA (0.4%, n=2). The mean age (±SD) of the patients was 51.9±23.87 years (range, 2-92); 49.5% (n=279) were male. At study entry, >70% of patients in all countries, except Thailand (45.7%), were receiving transfusion therapy. Overall, 29.4% (166/564) patients and 36.8% (21/57) pediatric patients were assessed as having iron overload during the study; extent of iron overload across countries varied and ranged from 7.4% (6/81) in Thailand to 83.3% (10/12) in Hong Kong. Patients receiving drug therapy only were less likely to be assessed for iron overload (1.2% [1/86]) than patients receiving erythrocyte transfusion (33.0% [33/100]) or erythrocyte transfusion and drug therapy (38.1% [131/344]). Overall, 39% of the population received iron chelation therapy and ranged from 9.2% (11/119) in China to 100.0% (12/12) in Hong Kong. Despite receiving iron chelation therapy, 56.4% (124/220 patients) were documented as having iron overload (Figure 1).

Figure 1- Geographical Differences in Diagnoses, Iron Overload, Erythrocyte Transfusions and Iron Chelation Use in Patients Included into the TORS



*Middle East includes patients from Algeria, Morocco and Tunisia
Recordings of iron overload† and of iron chelation therapy‡ do not have to apply to the same patients

MDS, myelodysplastic syndrome; AA, aplastic anemia

Figure 1.

Summary and Conclusions: In this large observational study, MDS was the most common disease type enrolled. Majority of patients received transfusion therapy across countries; consequently there was a proportion of patients that had iron overload. Despite a large percent of patients receiving transfusion therapy and having developed iron overload, there was a broad spectrum of iron chelation use. Notably, over half of patients still had iron overload despite receiving chelation therapy. Overall, these results suggest that iron overload management practices may still be suboptimal in many parts of the world. Further studies are required to clearly understand these geographical differences in management of transfusion–dependent anemias.

CHRONIC HCV INFECTION AND HEMOSIDEROSIS AMONG EGYPTIAN THALASSEMIA PATIENTS: THE ROLE OF HOMA INDEX

M. Hamdy[1,*] M. mokhles[2], D. fikry[3]
[1]pediatric hematology, cairo university, [2]internal medicine, national center for research, [3]clinical pathology, national research center, cairo, Egypt

Background: Hepatitis C virus (HCV) is a major cause of chronic hepatitis C (CHC) which increases the risk for insulin resistance, glucose intolerance and type 2 diabetes. Egypt has the highest reported rates of HCV infection especially among chronically transfused patients. Abnormal glucose tolerance is common in multitransfused thalassemia and is attributed to early impaired beta cells function with increasing insulin resistance (IR). The HOMA index (homeostasis model assessment) has been extensively used to investigate insulin resistance in CHC
Aims: to detect insulin resistance in transfusion dependent thalassemia major patients and to evaluate its possible link to chronic hepatitis and iron overload
Methods: : Fifty nine Egyptian thalassemia major patients were divided into hepatitis C (HCV) positive (group A; n= 39) and HCV negative thalassemics (group B; n=20) by HCV antibody and RNA. Thalassemia patients were compared to 20 age and sex matched HCV positive (non thalassemic) patients (group C). Blood samples were withdrawn from all patients for assessment of HOMA index, serum ferritin, AST and ALT
Results: : Abnormal HOMA test was evident in 30.8% (n=12) of group A and 40% (n=8) of the control group while none of group B had abnormal test. Significant results of HOMA-IR was observed between the three groups (P=0.029) and between group B and each of groups A and C (P= 0.012, 0.043 respectively) while no difference was observed between HCV positive thalassemics and control group (P=0.99) Positive correlation (P=0.038) was observed between HOMA- IR and AST but no correlation to age or serum ferritin level
Summary and Conclusions: Chronic Hepatitis in transfusion dependent thalassemia major patients is a major risk factor for insulin resistance in these patients

PB2004

MRI BRAIN IN YOUNG EGYPTIAN SICKLE CELL DISEASE PATIENTS: RELATION TO CEREBRAL BLOOD FLOW AND NEUROPSYCHOMETRIC EVALUATION

A.A.G. Tantawy[1,*] M.H. El Rakawy[2], S. A.Mohamed[2], A.A.Z. Dewedar[2], A.A.N.A. Aziz[2], S. Abdel Ghani[1]
[1]Pediatric Department, [2]Neuropsychiatry, Faculty of Medicine,Ain Shams University,Cairo,Egypt, Cairo, Egypt

Background: Stroke is an important and common complication of sickle cell disease (SCD), affecting children as well as adults.
Aims: To evaluate the prevalence of abnormal MRI brain in sickle cell disease (SCD) patients and its relation to transcranial Doppler findings and the results of neurosychometric evaluation
Methods: A cohort of 30 SCD patients aged less than 18 years were recruited from the Children's Hospital, Faculty of Medicine, Ain Shams University, Cairo, Egypt, examined in the steady state.Patients were subjected to full clinical and neurological examination and psychometric evaluation using Wechsler intelligence scale and Benton visual retention test, laboratory investigations including CBC,Hb electrophoresis,serum ferritin, MRI brain,transcranial Doppler ultrasonography for MCA,ACA,PCA,ICA,vertebral artery and basilar artery.
Results: The cohort included 12 males and 18 females, mean age 11+/-3.5 years., including 14 splenectomized patients. Abnormal MRI findings were present in 7/30 patients(23.3%), as tiny cortical infarctions in 5 patients (all were asymptomatic) and large infarctions in two patients (both had previous history of stroke). The presence of abnormal MRI was not related to age,sex,family history of SCD or stroke,neurological symptomatology,abnormal findings on neurological examination,or frequency of blood transfusion. Abnormal brain MRI was significantly related to frequency of sickling crises (P=0.002), surgical splenectomy (P=0.002), HDU therapy (P=0001), scholastic retardation (P=0.0001), impaired Penton visual perception (P=0.0001), impaired attention (P=0.001), impaired comprehension (P=0001), hematocrit value(P=0.001), HbS%(P=0.0001), HbF%(P=0.001), Total WBCs count(P=0.0001), absolute neutrophil count(P=0.0001), serum ferritin(P=0.0001).Abnormal MRI was related to cerebral blood flow in MCA (P=0001)and ICA (P=0001) but not related to cerebral blood flow in ACA,PCA, vertebral artery and basilar artery.
Summary and Conclusions: Conclusion: In patients with SCD,the neurologist should not only rely on standard neurological examination,but should add cerebral doppler and neuropsychometric assessment tools as soft signs to identify even minor MRI lesions and to identify the children at risk of stroke

PB2005

THE PREVALENCE OF ANEMIA, IRON DEFICIENCY AND IRON DEFICIENCY ANEMIA, AND THEIR ASSOCIATION WITH HEAVY METALS IN BLOOD AND NUTRITIONAL INTAKES IN KOREAN WOMEN AGED 10 YEARS OR OLDER

S.K. Kim[1,*] Y.J. Seo[2], D.H. Lee[2]
[1]Dept. of Pediatrics, [2]Department of Biomedical Sciences, Inha University Hospital, Incheon, Korea, Republic Of

Background: Anemia, iron deficiency (ID) and iron deficiency anemia (IDA) continue to be common disorders in the world.
Aims: This study was aimed at assessing the prevalence of anemia, ID and

IDA in apparently healthy Korean women aged 10 years or more. We also aimed at verifying an association of heavy metals in blood or nutritional intakes with ID and IDA.
Methods: We used the fifth Korea National Health and Nutrition Examination Survey (KNHANES V; 2010~2012) data by the Korea Centers for Disease Control and Prevention. This study was performed on 10,169 Korean women including 1,232 anemia, 2,030 ID and 690 IDA subjects. Prevalence and 95% confidence intervals (CI) were calculated using the SAS Survey Procedures. Logistic regression analyses were performed to identify significant factors that affect the risks of ID and IDA.
Results: The overall prevalence rate of anemia, ID and IDA was 12.4%, 23.11% and 7.7%, respectively, between 2010 and 2012 in Korean women. The most prevalent age groups for anemia were ≥ 70 (17.8%) and 19-49 years (15.0%). The women of 15-18 (36.5% for ID; 10.7% for IDA) and 19-49 years (32.7% for ID; 11.3% for IDA) were most prevalent for ID and IDA. The risks of ID and IDA conferred by the blood cadmium level were significant (OR=3.03, 95% CI=2.45-3.75, P<0.0001 for ID; OR=3.14, 95% CI=2.41-4.10, P<0.0001 for IDA). Vitamin D intake showed significant protective effects of ID and IDA (OR=0.96, 95% CI=0.94-0.98, P=0.0004 for ID; OR=0.94, 95% CI=0.91-0.98, P=0.0015 for IDA).
Summary and Conclusions: This study shows that the prevalence of anemia, ID and IDA was relatively high in late adolescents and reproductive ages, and there has been minimal improvement in the burden of anemia and IDA compared with the previous data. The cadmium in blood was found to increase the risk for ID and IDA, however, vitamin D intake contributed to prevent the risk for ID and IDA. Our findings indicate that systematic health systems between policymakers and specialists are needed to control anemia, ID and IDA.

PB2006

EFFICACY OF DEFERIPRONE IN THALASSEMIA: POSSIBLE ROLE OF UGT1A6 GENETIC POLYMORPHISM AND NON-GENETIC FACTORS
A.L. Ang[1,*] M. Hae Tha[1], Y. Zhao[2]
[1]Haematology, [2]Singapore General Hospital, Singapore, Singapore

Background: Deferiprone(DFP) is an oral iron chelator widely used in thalassemia(thal) patients(pts). It is mostly glucuronidated by liver UGT1A6 to an inactive metabolite before renally excreted. UGT1A6 polymorphism has been studied as a potential cause for variability in DFP's efficacy. No significant(sig) effect of UGT1A6 polymorphism was shown on the single-dose pharmacokinetics of DFP in healthy volunteers, while another study on β thal major pts treated with DFP showed an association of UGT1A6 single nucleotide polymorphism(SNP) 541A>G with lower ferritin. There are no studies on UGT1A6 polymorphism's association with MRI-T2*, which allows more specific measurement of DFP response by non-invasive liver and heart iron quantification.
Aims: Determine associations of UGT1A6 genetic polymorphism and other non-genetic factors with MRI-T2* responses to DFP in thal.
Methods: Thal pts(aged ≥18 years) who had ≥1 year of DFP and at least two MRI-T2* of ≥1 year apart for assessment of DFP response were enrolled after consenting for UGT1A6 DNA analysis. 3 common non-synonymous SNPs(19T>G, 541A>G, 552A>C) and 1 synonymous SNP(105C>T) of UGT1A6 were detected by sequencing PCR-amplified target DNA segments. Data on MRI-T2* response to DFP was retrospectively collected and analysed for associations with UGT1A6 SNPs/haplotypes and other non-genetic factors(gender, race, splenectomy, baseline cardiac/liver T2*, type of thal, transfusional iron load, DFP and concomitant deferoxamine(DFO) doses). Liver T2* was converted to liver iron concentration(LIC). Improvement in cardiac T2*(if baseline cardiac T2*<20ms) or LIC without discrepant changes in corresponding LIC or cardiac T2* were considered to have responded to DFP.

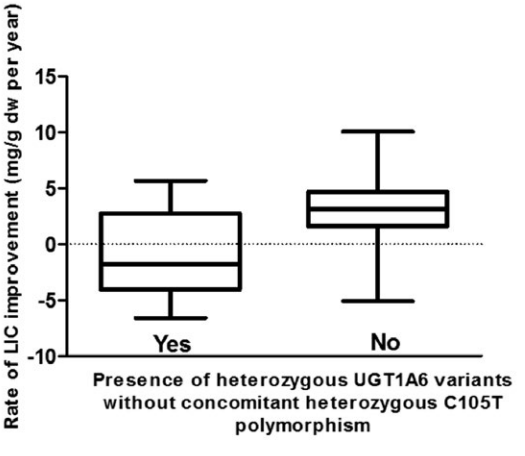

Figure 1.

Results: 32 pts(Chinese 56%, Malay 35%, Indian 3%, others 6%) were treated with median 6(1-11) years of DFP at median average dose of 68.2(24.4-93.3) mg/kg/day. 53% received concomitant DFO at median average dose of 23.1(11.4-40.6) mg/kg/day; 84% was regularly transfused, with median transfusional iron load of 0.4(0.1-0.6) mg/kg/day. Genotypic frequency was UGT1A6*1/*1: 75%, UGT*1/*2: 18.8%, UGT*1/*4: 6.2% (UGT1A6*1=wild type haplotype; UGT1A6*2=variant haplotype with SNPs 19T>G, 541A>G, 552A>C; UGT1A6*4=variant haplotype with SNPs 19T>G and 552A>C). In addition, 15.6% were heterozygous for 105C>T SNP. On multivariate analysis, splenectomy(OR 0.002, 95% CI[0.000, 0.697], P=0.04) and UGT1A6 variant haplotypes(*2 or *4) without concurrent 105C>T(OR 0.016, 95% CI[0.000, 0.766], P=0.03) independently associated with absent DFP response. The median rate of LIC improvement was 2.7(-12.0 to 10.1) mg/g dw per year after excluding 2 patients with discordant liver and cardiac T2* changes. On multivariate analysis, thal major(-2.8, 95% CI[-5.5, -0.04] mg/g dw per year, P<0.05) and UGT1A6 variant haplotypes without concurrent 105C>T (-4.8, 95% CI[-7.8, -1.7] mg/g dw per year, P<0.01) independently associated with poorer LIC improvement rate (see Figure). Other analysed factors did not have sig independent associations with DFP response and LIC improvement rate(P>0.15).
ISummary and Conclusions: Splenectomy decreases iron storage capacity, might lead to iron redistribution to other organs and poorer MRI-T2* responses to DFP. Thal majors had poorer DFP response than other types of thal likely due to higher body iron load. The poorer DFP response observed in our pts with UGT1A6 variant haplotypes (and no concurrent 105C>T) was contrary to expectations since recombinant UGT1A6 variants have slower *in vitro* DFP glucuronidation rates than wild type. One possibility is UGT1A6 variants have different in vivo activities on DFP since conflicting activities of recombinant and liver UGT1A6 allozymes are reported for other substrates. Concomitant 105C>T appeared to negate the adverse impact of UGT1A6 variants on DFP response in our pts. *in vitro*, this SNP increased mRNA stability despite no amino acid changes. This might influence mRNA or enzyme protein stability in vivo for heterozygotes of UGT1A6 variants, leading to changes in DFP metabolism and efficacy. More studies on UGT1A6 SNPs' clinical impact and interactions with other factors on DFP's efficacy are needed for better insights into individualisation of DFP therapy for thal.

CHARACTERISTICS OF FEBRILE CONVULSIONS OF PEDIATRICS RELATED TO IRON DEFICIENCY IN EAST DELTA OF EGYPT
M. Fathy[1], M. Zakria[1], N. Rafaat[2], S. Al Esh[3], U. El Safy[1,*]
[1]Pediatric Hematology and Oncology, [2]Biochemistry, [3]Clinical Pathology, Zagazig University, Zagazig, Egypt

Background: Iron is clearly important for brain development as well as for prevention of anemia, and more study is warranted to understand its role in these common neurodevelopmental disorders.Iron deficiency has also been associated with alterations in synaptic neurotransmitter systems including norepinephrine, dopamine, serotonin, glutamate and gamma-aminobutyric acid (GABA). Febrile seizures may reflect different facets of altered brain excitability that is enhanced by iron deficiency and also influenced by genetic factors.
Aims: To find the association between iron deficiency anemia and febrile convulsions among children aged 6 to 36 months presenting at Pediatric Hematology and Oncology out patients clinic of Zagazig university hospital- Zagazig city – Egypt, from January 20011 to December 20014..As well as to find characteristics of febrile convulsion with iron deficiency in Pediatrics.
Methods: A total of 200 patients fulfilled the study criteria of febrile seizure and 100 patients with any febrile illness without convulsion. These were divided into two groups with children having febrile seizures comprised the cases (Group I) while those having only febrile illness with no seizures comprised the controls (Group II). Both matched for age and gender. Workup for seizures [History and complete neurological and developmental examination.EEG and MRI according the need for each case] and iron deficiency anemia [CBC-Serum iron – Serum Ferritin- Total Protein Iron Binding Capacity – Serum Calcium ionized and total] were done and data was analyzed using SPSS version 10. According to iron deficiency, Group I had been subclassified into Group IA with iron deficiency and Group IB without iron deficiency. Any case with abnormal calcium level and those with MRI findings were excluded.
Results: A total of 24% of group I had iron deficiency (ID) and 16% had iron deficiency anemia (IDA), compared to 17% and 12% of controls respectively. There was significant decrease of Hb level, serum iron, serum ferritin and total iron binding capacity in children with febrile convulsion than that of controls. There was significant decrease age, HB conc, serum iron, ferritin and total protein iron binding capacity in group IA than group IB. One attack of febrile convulsion at presentation was significant higher in group IA than group IB. Duration of convulsion was significantly lower in group IA than group IB.
Summary and Conclusions: Serum Iron, Total Protein Iron binding capacity and Plasma ferritin level were significantly lower in cases as compared to controls suggesting that iron deficient children are more prone to febrile seizures. The characteristics of iron deficiency related febrile convulsions were young age [9-21 month], short duration [not exceed 3 minutes],usually first attack,high with non-breast fed baby.

PB2008

PREVALENCE AND CLINICAL SIGNIFICANCE OF XMNI ΓG-158 (C/T) POLYMORPHISM IN AN EGYPTIAN COHORT OF SICKLE CELL DISEASE PATIENTS

M. El-Ghamrawy[1,*] M. Khorshied[2], A. Tosson[3], N. Babiker[3]
[1]Pediatric Hematology, [2]Clinical & Chemical Pathology, [3]Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Sickle cell disease (SCD), well-known for its clinical and hematologic variability, comprises a heterogeneous group of hemoglobin genotypes where affected individuals have sickle hemoglobin (HbS). This considerable clinical heterogeneity among SCD patients is still not well understood. Genetic variants that modulate fetal hemoglobin (HbF) level have a strong impact on ameliorating the clinical phenotype.
Aims: The current study aimed to evaluate the prevalence of *Xmn*1 γ^G-158 (C/T) gene polymorphism in an Egyptian cohort of SCD patients and to investigate the possible association between this polymorphism and HbF level.
Methods: This case control study included 111 Egyptian SCD patients aged 1-21 years (mean age 11.08±5.5 years; 77 HbSS and 34 S/β thalassemia) and 100 age and gender matched unrelated healthy controls. All subjects were recruited only after informed consents were freely obtained from their guardians. Genotyping of *Xmn*1 γ^G-158 (C/T) polymorphism was performed by polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP) method.
Results: In our cohort, wild genotype *Xmn1* (-/-) was the most prevalent (91.9%), while polymorphic genotypes whether heterozygous or homozygous (-/+ and +/+) were detected in 8.1% of SCD patients; six (6/77-7.8%) were HbSS and three (3/34-8.8%) were S/β thalassemia. No statistically significant differences were detected between SCD patients and controls or between HbSS and S/ β-thalassemia patients regarding prevalence of Xmn1 polymorphic genotypes (P=0.50 and 0.73 respectively). Baseline hemoglobin, HbF level and mean corpuscular volume were significantly higher in patients harboring polymorphic genotypes (P=0.01, 0.001 and 0.04 respectively). We found no significant effect of γ^G-158 (C/T) polymorphism on age of first transfusion, vasoocclusive crisis frequency or transfusion frequency (P=0.067, 0.778 and 0.053 respectively). Although HbF level was significantly higher in patients with polymorphic genotypes (19.24±7.0 vs. 9.06±7.45, P<0.001), Xmn1 γ^G-158 (C/T) polymorphism did not seem to influence HbF levels in patients receiving hydroxycarbamide (P=0.68, 95% Confidence interval= 5.08-7.68). By multiple regression analysis, only baseline HbF correlated independently with elevation of HbF in response to hydroxycarbamide therapy (P<0.001, 95% Confidence interval=0.75-1.31).
Summary and Conclusions: Egyptian sickle patients have low frequency of *Xmn1* γ^G-158 (C/T) polymorphism. The presence of *Xmn1* γ^G-158 (C/T) polymorphism had positive influence on HbF level.

PB2009

ELECTIVE CHOLECYSTECTOMY IS ASSOCIATED WITH INCREASED MORBIDITY AND MORTALITY IN PATIENTS WITH SEVERE THALASSEMIA: A RETROSPECTIVE CASE CONTROL STUDY

A. Premawardhena[1,*] R. Fernando[1], S. Kumarage[2], N. Nishad[1], I. de Silva[3]
[1]Medicine, [2]Surgery, University of Kelaniya, [3]Hemals Thalassaemia Unit, Teaching Hospital Ragama, Ragama, Sri Lanka

Background: Haemoglobin disorders including thalassemia and sickle cell disease are often complicated with gall stone formation. The co-existence of Gilbert's syndrome together with these diseases further increases the risk of gall bladder disease. Some of these patients develop symptomatic disease which necessitates surgical intervention. At present the timing of cholecystectomy for thalassemia is no different from that of the general population with the exception of removal of the gall bladder at the time of splenectomy. This is no longer the case in sickle cell disease where, laparoscopic cholecystectomy is recommended even in asymptomatic patients. This practice however has not been extended to other types of haemoglobin disorders.
Aims: 1.To assess the perioperative complications of patients with thalassaemia during cholecytetomy and to compare it with non thalassaemics who undergo the procedure. 2. To see if there is enough evidence to recommend elective cholecystectomy for thalassaemics.
Methods: We retrospectively studied case notes of thalassemia patients who had cholecystectomy (cases) in two of the biggest thalassaemia centres in Sri Lanka and also of 62 non-thalassaemics (controls) with gall bladder disease who had been scheduled to have gall bladder surgery in the same hospitals and looked at their peri-operative complications.
Results: 98 out of 540 (18%) thalassaemics in the two centres had gall stones. Mean age of cases was 26.8 (SD 10.9) years and of controls 47.5 (SD 19.7) years. 19 (19%) thalassaemics with gall stones had undergone cholecystectomy. Ten patients had cholecystectomy simultaneously with splenectomy. The majority of non-thalassaemic "controls" had laparoscopic cholecystectomy 53/55 (96.3%) whilst the patients with thalassaemia were mostly operated with laparotomy 13/19 (68%). There was a significant excess complications occurring in both early (42.11 vs. 18.1%) and late (31.5 vs. 12.7%) phases in the thalassaemic patients compared with the controls.
Among the early complications, sepsis (10.5% vs. 1.8%) and liver abscess formation (5.2 vs. 0%) was significantly different in the groups, adversely affecting the thalassaemics. Recurrent abdominal pain was more common among the thalassaemics as a late complication (P<0.05). Six thalassaemic patients with gall stone disease died during this study, 5(5%) while awaiting surgery and 1(1%) after surgery. There were no deaths among the controls. Out of the deaths, 3 (50%) were directly attributable to gallstone disease. In all three septicemia precipitated heart failure. We found a significant increase of both early and late post-surgical complications in the thalassemia group and also increased mortality most of which was related to severe sepsis. Higher perioperative mortality and morbidity were seen among symptomatic thalassaemic patients with gall stone disease undergoing cholecystectomy. This seems to suggest a strong case for supporting elective cholecystectomy in thalassemics before they develop symptoms.
Summary and Conclusions: We suggest that laparoscopic elective cholecystectomy be considered for non-sickle, thalassemia patients too who have asymptomatic gall bladder disease, in an attempt to reduce this morbidity and mortality.

PB2010

EFFICACY AND SAFETY OF DEFERASIROX IN SINGLE VS DIVIDED DOSAGE IN THALASSEMIC CHILDREN.

S. Kakkar[1,*] P.P.C. Sobti[2], A. Kalra[3]
[1]Pediatrics, Hemato-oncology unit, Dayanand Medical College, Ludhiana, [2]Pediatrics, hemato-oncology unit, Christan Medical College, Ludhiana, [3]Pediatrics, Dayanand Medical College, Ludhiana, Ludhiana, India

Background: Iron chelation has improved the prognosis in thalassemia major. DFX had been the recent oral iron chelator in use. Dose-dependent effect of DFX had been observed in many studies. Initially it was used at 20 – 30 mg/kg/day but efficacy proved to be better when used at higher doses of 30 – 40 mg/kg/day with good tolerability. Ferritin levels tended to be high even on DFX (30 – 40 mg/kg/day) with good compliance, so safety and efficacy of higher doses (40 – 50 mg/kg/day) in once daily vs two daily doses needed to be compared.
Aims: To study the efficacy and safety of DFX (40-50 mg/kg/day) in single vs divided doses in thalassemic children
Methods: The prospective study was conducted in thalassemia ward of Department of Pediatrics, Dayanand Medical College and Hospital, Ludhiana from Jan 2013 to June 2014. Patients were randomly allocated in two groups, Group A & Group B. Both took DFX in doses of 40 – 50 mg/kg/day, group A once daily doses and group B in two divided doses. Efficacy was studied in terms of change in ferritin levels, cardiac & liver MRI T2 * values and LVEF. Safety profile was studied in terms of gastrointestinal side effects, rash and change in serum creatinine values, SGPT and GFR.
Results: Serum ferritin levels reduced in both the groups viz. Group A (2692.5±1232.35 ng/mL to 1959.5±696.19 ng/mL p value=0. 07), Group B (2766.2±897.51 to 2569.9±762.6 ng/mL ;p value=0.38) with significant difference between the two groups at the end of study (P=0.05).Liver MRI T2* values improved in group A (2.1±1.50 to 3.1±1.84 ms; P= 0.096)as compared to group B (2.8±1.84 to 2.2±2.71 ms; P=0.70). Mean LIC decreased in group A (17.4±7.83 mg/g dw to 12.4±8.05 mg/g/dw; P= 0.197) as compared to group B (15.3±10.42 mg/g dw to 22.1±11.93 mg/g/dw; P= 0.340).Overall mean cardiac MRI T2 * values decreased (30.5±10.30 ms to 24.5±4.94 ms; P=0.202) in group A and (31.7±14.78 ms to 20.5±11.78 ms; P=0.167) in group B but remained within normal limits. No change in LVEF was observed. No significant adverse effects were noted with 40–50 mg/kg/day dose of DFX. There was increase in liver transaminases (SGPT) levels (64.4±54.0 to 34.5±14.1 mg/dl in group A; P= 0.05) and (97.9±79.3 to 61.9±39.2 mg/dl ;P= 0.134) in group B
Summary and Conclusions: DFX is safe in higher dosages (40 – 50 mg/kg/day) and once daily dosage is more efficacious as compared to twice a day dosage schedule.

PB2011

MICROPARTICLE PROFILE DURING PAINFUL CRISIS AND NON-CRISIS PERIOD IN SICKLE CELL ANEMIA

A. Atmis[1], I. Sasmaz[1,*] B. Antmen[1], B. Karagun[1], Y. Kilinc[1]
[1]Pediatric Hematology, Çukurova University, Adana, Turkey

Background: Sickle cell anemia is a disease which is characterized with hemolytic anemia, hypercoagulopathy and painful crisis. Microparticles are 0,1-1 µm sized little membrane particles which are derived during activation or apoptotic phase of cell cycle. It is reported that microparticles are increased in many systemic disease including sickle cell anemia.
Aims: In this study we aimed to investigate the role of microparticles on clinical state and prognosis during crisis and non-crisis periods in sickle cell anemia patients.
Methods: Twenty nine patients, following by Çukurova University Department of Pediatric Hematology, are included in this study. Blood samples were collected in 26 of these patients in non-crisis period. Control group was formed

with 18 healthy children without any systemic disease. Complete blood count, hemoglobin electrophoresis and biochemical parameters were studied in both groups. Also patients' total microparticle levels, erythrocyte (CD235a), endothelia (CD106), monocyte (CD14) particle levels and tissue factor expressing (CD142) microparticle levels were studied by flow cytometry and whole data was statistically analyzed.
Results: Hemoglobin and hematocrit levels were significantly low in sickle cell anemia patients (P<0,001). Levels of HbS were significantly high during crisis period comparing with mean HbS levels during non-crisis period (P<0,001). Total microparticle levels were significantly high in sickle cell anemia patients with painful crisis comparing with control group (P<0,05). Erythrocyte and monocyte microparticle levels were significantly high in patients with painful crisis comparing with non-crisis periods (P<0,05). Endothelial and tissue factor expressing microparticle levels were high in patiens with crisis comparing to non-crisis period but this was not statistically significant (p>0,05). There was not any significant relation with microparticle levels and femur or humerus head avascular necrosis (p>0,05). There was not any significant relation with frequency of crisis and microparticle levels (p>0,05). Microparticle levels were low in patients whose were taking hydroxiurea treatment comparing with not taking hydroxiurea treatment but this was not statistically significant (p>0,05).
Summary and Conclusions: As a result we found high levels of total microparticle, erythrocyte and monocyte microparticles in sickle cell anemia patients during painful crisis period. These microparticles may be role in pathophysiological process of crises in SCA patient. We need further studies in order to understand the effect of microparticles on prognosis of sickle cell anemia.

PB2012

TRANSIENT RED CELL APLASIA "THE GIFT OF PROGRESS"
N. Vaynyuskaya[1,*]
[1]Hematological, State Children Hospital 1, Saint-Petersburg, Russian Federation

Background: "What we call progress is the replacement of one trouble to another",H.Ellis. Modern technologies that enabling blood transfusion even in utero, possibilities to identify new viruses and so on that is a background why doctors have to solve previously never-existing problems.Transient aplasia crisis is an often situation for the pediatric hematologist in Russia. It would seems strange, but we have decided to unite under this name two quite different nosological forms:hemolytic disease of the newborn,complicated with an absence of reticulocytosis, and transient erythroblastopenia of childhood.
Aims: To analyze the clinical features and management of aplasia crisis in children with hemolytic disease of newborns, complicated with an absence of reticulocytosis and children with transient erythroblastopenia.
Methods: There were reviewed medical histories of 62 patients (16 babies with hemolytic disease of the newborn, complicated absence of reticulocytosis, 46 children with transient erythroblastopenia of childhood). We have evaluated duration of hospitalization, number of transfusions,the connection of the disease with infection, therapeutic options. Period of evaluation was since 2009 to 2014 years.
Results: Children with hemolytic disease of the newborn were aged from 0 to 3. Children with transient erythroblastopenia of childhood were aged from 12 months to 5 years.The length of hospitalization of children ranged from 16 days to 35 days, the average was 24 days, and from 9 to 25 days on average 16 days, respectively.Children with hemolytic disease of the newborn were closely observed immediately after birth, and were admitted to hospital in adequate time. Only 12 of the 46 children with transient erythroblastopenia of childhood were applied to hospital immediately after infection. During the observation period the number of patients with transient erythroblastopenia of childhood increased from 7 (2009) to 15 (2014).Children with hemolytic disease of the newborn has increased from 3 (2009) to 5 (2014).6 children with hemolytic disease of the newborn required intrauterine transfusions, 9 children required exchange transfusion immediately after birth, 12 babies needed transfusion during the first month of life.There were 21 child with transient erythroblastopenia of childhood that required blood transfusions because of the hemic hypoxia signs.In 18 children with transient erythroblastopenia of childhood was verified acute viral infection (6 EBV,2 Parvovirus 19,4 CMV, 5 herpes virus type 6,1 herpes type 1).In children with hemolytic disease of the newborn, complicated by aplastic crisis, acute viral infections has not been found. Two children with severe long regenerating form of hemolytic disease of the newborn held a bone marrow biopsy, to 44 patients with erythroblastopenia was also made this study.According to the results of myelogram in all patients there was excluded systemic blood diseases. All patients with hemolytic disease of the newborn received drugs of erythropoietin from 5 to 15 injections depending on the severity of the condition. Reticulocytosis crisis was reached in an average of 4-5 injections. All patients with erythroblastopenia received B group vitamins, 16 children received a course of prednisolone. Children with erythroblastopenia had normalization of blood count at 12-25 day.
Summary and Conclusions: Transient aplasia crisis, that presented by normochromic aregenerating anemia, is severe, but in the modern world, treatable condition. Duration and severity of hemolytic disease of the newborn regenerating status is determined by prenatal transfusion therapy. Severity and length of transient erythroblastopenia of childhood is determined by the etiology of the infectious agent and the time of anemia status. Parvovirus B19 is not the only reason for the erythroblastopenia of childhood.Both of these diseases are relatively benign conditions, it can pass without trace, but in view of the high transfusion dependence it requires further study and observation. Regularly blood tests after birth and diseases can help to find this conditions earlier and to reduce transfusion rate.

IL28B GENE POLYMORPHISMS IN EGYPTIAN PEDIATRIC PATIENTS WITH SICKLE CELL DISEASE: PREVALENCE AND RELATION TO SPONTANEOUS CLEARANCE OF HCV
S. Mohammed Mousa[1], M. El-Ghamrawy[2,*] H. Gouda[1], M. Khorshied[1], D. Abd Elsalam Ahmed[1], H. Shiba[1]
[1]Clinical and Chemical Pathology, [2]Pediatric Hematology, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Egypt has the highest prevalence of hepatitis C virus (HCV) worldwide. Patients with sickle cell disease (SCD) are exposed to the risk of HCV infection. Genetic polymorphisms in IL28B gene have been associated with spontaneous HCV clearance.
Aims: To determine the prevalence of both HCV infection and IL28B gene polymorphisms among pediatric patients with SCD and to explore the relation between IL28B gene polymorphisms and spontaneous HCV clearance.
Methods: Seventy SCD patients were screened for HCV antibody. All patients were recruited only after informed consents were obtained freely from their guardians. Detection of IL28B polymorphisms (rs 12979860 SNP and rs 12980275 SNP) was done using Taqman QRT-PCR and sequence specific primers PCR respectively. HCV RNA was measured in sera of HCV positive patients using quantitative real time PCR.
Results: Sixteen patients (23%) were positive for HCV antibodies. Nine patients (56.3%) had undetectable HCV RNA in serum (spontaneously cleared) and 7 patients (43.8%) were not cleared. Genotypes CC/CT/TT of rs12979860 were found in 30 (42.9%), 29 (41.4%) and 11 (15.7%) while rs12980275 AA/AG/GG were found in 8 (11.4%), 59 (84.3%) and 3 (4.3%). There was no significant difference in the frequency of IL28B (rs 12979860) genotypes between HCV patients who cleared the virus and those with persistent viremia (P=0.388). In addition, frequency of IL28B (rs12980275) genotypes did not differ between the two groups (P=0.438).
Summary and Conclusions: Egyptian sickle cell disease patients have high prevalence of HCV. IL28B gene polymorphisms are not associated with spontaneous clearance of HCV in this cohort of Egyptian children with sickle cell disease.

PB2014

GLUCOSE PHOSPHATE ISOMERASE DEFICIENCY: CLINICAL AND MOLECULAR CHARACTERIZATION OF 10 CASES
E. Fermo[1,*] C. Vercellati[1], P. Bianchi[1], A.P. Marcello[1], S. Aytac[2], M. Cetin[2], A. Zaninoni[1], A. Zanella[1], W. Barcellini[1]
[1]UOS Fisiopatologia delle Anemie, UO Oncoematologia, fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milano, Italy, [2]Department of Pediatric Hematology, Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: Glucose-6-phosphate isomerase (GPI, EC 5.3.1.9) is a dimeric enzyme that catalyses the reversible isomerisation of glucose-6-phosphate (G6P) to fructose-6-phosphate (F6P), the second reaction step of glycolysis. GPI deficiency, transmitted as an autosomal recessive trait, is the second most common erythro-enzymopathy of anaerobic glycolysis, after pyruvate kinase. GPI deficient patients are affected by chronic non-spherocytic hemolytic anemia of variable severity; in rare cases mental retardation or neuromuscular symptoms have also been reported. The gene locus encoding GPI is located on chromosome 19q13.1 and contains 18 exons. So far about 60 cases of GPI deficiency have been described, and 35 mutations have been reported at the nucleotide level.
Aims: We report the clinical, haematological and molecular characteristics of 10 GPI deficient cases
Methods: 10 patients (6 males, 4 females) from 9 families, with a median age at admission of 7 yrs (range 1-51) were studied. Eight patients were of Italian origin and 2 were Turkish. Haematological parameters and red cell enzyme activity were determined according to standard methods. The entire coding region of the *GPI* gene was amplified by PCR and automatically sequenced.
Results: Main clinical and haematologic parameters and results of the molecular characterization are reported in Table 1. All patient displayed anaemia at birth or in the early infancy; neonatal jaundice was observed in 4 patients, 3 of whom required exchange transfusion. All patients needed blood transfusion in childhood: 3 regularly (every 4-8 weeks), the remaining occasionally in concomitance of haemolytic crises due to infections. Splenectomy, performed in 5 patients, did not lead to normalization of anaemia, only resulting in a slightly increase of Hb levels (0.5-1 g/dL) but it eliminated transfusion requirement;

bilirubin levels increased after splenectomy in 3 cases. No patient needed transfusions in adulthood; however, two underwent chelation therapy for iron overload. None showed neurological signs. Eleven different mutations were found in *GPI* gene, 4 of them never described before (c.311 G>A, c.307C>G, c.269T>C, c.1066G>A); all the new mutations affect highly conserved residues, were not detected in Ensembl and 1000 genomes database, and were predicted to have pathogenic effects by Polyphen, SIFT analysis. In particular, mutation Asp356Asn falls in a region involved in the sugar isomerase domain and dimer-dimer interface, and it is part of active site, further suggesting its drastic effect. In one patient we were unable to find the second mutation; however, the loss of heterozygosity at the cDNA level suggested the presence of a null mutation of the paternal GPI allele

Tx: transfusions: 1 = occasional, 2= regular until splenectromy, 3= regular; SF: Serum Ferritin, n.a.: not available;
*= during hemolytic crises. New mutations are reported in bold.

Summary and Conclusions: We characterized the largest series of GPI deficient patients so far reported. Patients present with moderate/severe anaemia that improve with aging. The study confirms the great heterogeneity of the molecular defect. Although neurological impairment is sometime reported in literature in GPI deficiency, none of the cases here described displayed extra-haematological symptoms.

PB2015

ASEMPTOMATIC NEPHROTOXICITY IN PATIENTS WITH TRANSFUSION DEPENDENT BETA THALASSEMIA

Z. Karakas[1,*] A. Annayev[1], A. Yalçıner[2], S. Emre[3]
[1]Pediatric Hematology/Oncology, Istanbul University, [2]Duzen Laboratory, [3]Pediatric Nephrology, Istanbul University, Istanbul, Turkey

Background: There is few information about nephrotoxicity than other organ damages in patients with transfusion-dependent Beta thalassemia(TDT). Creatinine levels are not sensitive indicators and do not change unless renal injury is significant. Cystatin C(Cys-C) is a marker to predict glomerular dysfunction with higher sensitivity and specificity than serum creatinine and creatinine clearance.
Aims: The aim of this study was to evaluate renal tubular and glomeruler functions with Glomerular Filtration Rate(GFR), Beta 2 microglobuline(B2 MG), mean fractional Na excretion (FENe) and cystatin C in patients with TDT.
Methods: Fifty patients with TDT who were being followed up at Istanbul University, Istanbul Medical Faculty, Thalassemia Center between January 2014 and May 2014, were included in this study after the approval of the ethical committee and informed consents were signed by patients. The mean age was 18.4±11.8 years (28 female and 22 male, age range:2-45 years). Thirty healthy volunteers with matched age and sex were also evaluated as the control group. Patients with known renal disease were excluded from our study. The patients were evaluated using GFR, FENe for glomerulopathy and serum Cys-C and urine β-2 MG for tubulopathy. These results were compared with the controls. Serum Cys-C and urine β-2 MG were measured by a latex particle-enhanced nephelometric immunoassay (DadeBehring, Liederbach, Germany).
Results: We studied 50 patients, all of them have normal GFR according to age.Thirty patients (60%) had at least one sign of glomerulopathy and tubulopaty. Twenty-seven of 50 patients (55%) had higher serum Cys-C values (mean : 0,75+0,12) compared with controls (mean:0,66+0,09), P<0.001) while no patient had increased levels of serum Cr according to age. There was a linear relationship between Cystatin C and GFR. When we evaluated the etiology of glomerulopathy and tubulopathy, we found that; there were no statistically significant differences between pretransfusion Hb, ferritin, liver iron overload, cardiac iron overload, and cystatin C, β-2 MG, FENe and GFR. Cystatin C increases with the age, the beta-2 MG and FENe does not change with age. 27 of 30 patients with renal injury (90%) had an increased Cys-C levels compared to the control group. Forty-two of 50 patients (84%) used Deferasirox (DFX), 8 (16%) used Deferipron (DFP). When patients were evaluated with respect to chelation they received, nephrotoxicity was determined in 22 of 42 patients using DFX (52%). Only FENe level in 2 of these patients, only Cys-C level in 11, both FENe and Cys-C levels in 2, both B2 MG and Cys-C levels in 4, all three parameters had increased in 3 of these patients. Nephrotoxicity was detected in 7 of 8 patients (85%) using DFP. Only Cys-C level increased in 4 of these patients (57%), only FENe level increased in 1, both B2 MG and Cys-C levels had increased in 2 of these patients. Also, Cys-C level increase was detected in one TDT patient who didn't receive any chelator yet. In patients receiving DFX, nephrotoxicity was more obvious and related with dosage.

11	DFP	7	65	3712	**27.6**	**25.6**	7.5	1.26	**<0.21**	0.64	2.9	17.0	166	No

Summary and Conclusions: Nephrotoxicity in thalassemia patients is reported with rate of 4-80% and is multifactorial, even if DFX receiving patients have more risk, all TDT patients should be evaluated with Cys-C for early identification of asymptomatic nephrotoxicity. We suggest intermitten evaluations (at least every 6 months) with Cys-C in addition to routine renal function tests to diagnose and prevent major renal injury in patients with TDT.

SPURIOUSLY LOW PULSE OXIMETRY SATURATION ASSOCIATED WITH HEMOGLOBIN SYDNEY IN A CHILD AND RELATIVES: IDENTIFICATION OF THIS UNSTABLE HEMOGLOBIN MAY AVOID UNNECESSARY TESTING AND HOSPITAL ADMISSIONS

S. Rives[1,*] A. Català[2], M. Fernández-Sevilla[3], R. Berrueco[2], M. Camós[4], M. Torrebadell[2], T. Toll[2], A. Alonso[2], M. Mesegué[2], M. Trabazo[1], V. Santa-María[2], A. Ruiz-Llobet[2], A. Blanco[5], D. Benéitez[6]
[1]Pediatric Hematology. Department of Hematology and Oncology, [2]Hospital Sant Joan de Déu de Barcelona. Fundació Sant Joan de Déu. Universitat de Barcelona, Barcelona, Spain, [3]Pediatric Department, [4]Hematology Laboratory, Hospital Sant Joan de Déu de Barcelona. Fundació Sant Joan de Déu. Universitat de Barcelona, [5]Hematology Molecular Genetics Department. Hematology Department, Hospital Vall d'Hebron, [6]Erythropathology Unit. Department of

Hematology, Hospital Vall d'Hebrón, Barcelona, Spain

Background: Pulse oximetry is a noninvasive method to measure hemoglobin oxygen saturation and is widely used in different medical settings. Very few variant hemoglobins have been associated with unexpectedly low SpO2. We describe a new family with the unstable hemoglobin Sydney associated to artifactually low SpO2, which, to our knowledge, has not been reported as a cause of this phenomenon. Identification of these rare hemoglobinopathies may avoid cardiac and pulmonary testing, unnecessary treatments and even hospital admissions.
Aims: To describe the association of Hemoglobin Sydney with artifactually low SpO2.
Methods: HPLC analysis with the VARIANT II equipment and CDM software (Bio-Rad) and acid and alcaline electrophoresis (HYDRASIS, SEBIA HISPANIA) were performed on the hemoglobin of the index case and his father. PCR amplification of the exons 1, 2, 3 and adjacent intronic regions was performed on the HBB gene (betha-hemoglobin gene) and sequence analysis of the amplified region.
Results: A 19-month-old male and his father had low pulse oxygen saturation measured by pulse oximetry (SpO2), which was not confirmed by arterial blood oxigen measurement (SaO2) in the child (index case). The child was referred by his primary care pediatrician to the Emergency ward because of bronchospasm that, in spite of salbutamol nebulizations and oxygen did not improve SpO2 (87%). He was admitted to the hospial ward and treated with salbutamol, corticosteroids and oxygen. A chest XR and cardiac ultrasound were performed which were normal. He had mild compensated hemolysis (hemoglobin 125g/L, VCM 94 fL, reticulocytes 4.5%, haptoglobin<40 mg/L. SaO2 was 96% (FiO2 21%) when SpO2 was 85%. The patient's father, grand-father and aunt had history of chronic hemolysis due to an unstable hemoglobin, not further characterized. The grand-father had a history of splenectomy. A hemoglobinopathy causing this falsely low SpO2 was suspected and confirmed. Both the patient and his father had anomalous hemoglobin peaks on HPLC that did not separate at all from HbA1 and DNA sequence analysis exhibited a mutation in heterozigosity in the HBB gene (Beta 87 (E11) Val>Ala) consistent with Sydney hemoglobin. The artifactuosly low SpO2 may be due to abnormal absorption peak measured by pulse oximeter.
Summary and Conclusions: Hemoglobin Sydney is a known unstable hemoglobin which can result in an artifactually low oxygen saturation measurement with pulse oximetry, previously not reported. To describe this association is important in order to avoid unnecessary tests in patients with this rare hemoglobinopathy.

FREQUENCY OF MUSCULOSKELETAL AND OTORHINOLARYNGOLOGIC MANIFESTATIONS IN CHILDREN WITH B- THALASSEMIA

A. Abo Elsoaud[1], M. Hesham[2], M. Beshir [2,*] D. Atta[1], W. Elsaeed[2], M. Mortada[1], H. Kelani[3], M. Hassan[3], N. Ezzeldin[1]
[1]Rheumatology department, [2]Pediatrics department, [3]E.N.T department, Faculty of Medicine, Zagazig University, Egypt, Zagazig, Egypt

Background: Beta-thalassaemias have a wide variety of musculoskeletal system manifestations. Spinal involvement related to disease course and treatment is common in patients with thalassemia syndromes. Also, a high frequency sensorineural hearing loss is observed in a large percentage of patients during intensive Desferrioxamine therapy.
Aims: To study the clinical and radiographic skeletal changes in transfusion-dependent beta-thalassaemia patients and to present a comprehensive overview of spinal involvement in those patients.
Methods: this cross sectional study was carried out on 240 patients with b-thalassemia major who came weekly for blood transfusion at the hematology outpatient clinic of Pediatric Department at Zagazig University hospital during a period from 2012-2013. In all patients studied, detailed history regarding musculoskeletal involvement was taken and locomotor examinations were performed. Also, preliminary auditory perceptual assessment of patient's voice and careful laryngeal examination. All patients underwent all routine laboratory investigations (CBC, Serum iron and ferritin, Liver and renal functions), Imaging study with standing anteroposterior and lateral X-rays of the spine,Ultra sonography on affected knee (s) joint, augmentation and documentation of the glottic picture and high-fidelity voice recording and acoustic analysis was done.
Results: locomotor system involvement was found in 56 patients (23.3%). Most frequent complaints were arthralgia and low back pain in 21.3% and 6.3% of patients respectively. Scoliosis was detected radiologically in 8 patients (3.3%). The most common curve pattern in thalassemia was the left lumbar (62.5%) followed by the right lumbar (37.5). Ultrasonography of affected knee (s) joint showed synovitis, effusions, signs of metaphysis dysplasia and increased power Doppler signals in (23.8%,14.3%,85.7%,19% respectively). There was mild to moderat laryngeal congestion nearly in all cases but the vocal fold mobility (crico-arytenoid joint) is not affected.
Summary and Conclusions: Patients with beta thalassemia have a variety of musculoskeletal problems and spinal involvement is common. Further studies will be needed to detect the risk factors involved in the development of these musculoskeletal problems.

PB2018

STUDY OF GROWTH DIFFERENTIATION FACTOR 15 IN EGYPTIAN PATIENTS WITH BETA THALASSEMIA

M. El Tagui[1], M. Hamdy[2,*] D. Mosallam[2], N. Sowelam[3]
[1]pediatric hematology, [2]pediatrics, [3]clinical pathology, cairo university, cairo, Egypt

Background: The thalassemia syndromes represent the most common causes of ineffective erythropoiesis. The increased but ineffective erythropoiesis resulting in tissue iron overload induces numerous endocrine diseases, hepatic cirrhosis, cardiac failure and even death. Growth Differentiation factor 15 (GDF-15) is a member of the transforming growth factor β super family. It was recently studied as a marker of ineffective erythropoiesis in different types of anemia.
Aims: Our objective was to study the serum level of GDF- 15 in β thalassemia major (TM) and thalassemia intermedia patients (TI) and to correlate it to the iron status and different clinical and laboratory parameters in these patients
Methods: twenty five thalassemia major patients (mean age of 12.08± 4.6 years) and 25 thalassemia intermedia patients (mean age of 9.3± 4.7 years) were randomly selected from the hematology clinic of the children hospital at Cairo University together with 30 age and sex matched healthy controls. All patients were subjected to thorough history taking and clinical exam. Blood samples were withdrawn for the assessment of complete blood count, liver function tests and serum ferritin. Estimation of GDF-15 level was done using ELISA technique.
Results: On comparing the level of GDF-15 among the 3 groups, it was significantly elevated in the TM group (8769.6±3560 pg/mL) *versus* the TI group (7090±3656 pg/mL); P< 0.05 and *versus* the control group (385.1±244); P< 0.05. GDF-15 showed positive correlation to the age of starting chelation among TM patients; P= 0.04 and negative correlation to the frequency of transfusion and hemoglobin level in the TI group; P= 0.001.
Summary and Conclusions: GDF-15 in our study represent a first step for its use as a biomarker in thalassemia patients. Future studies with large number of patients are needed to confirm this hypothesis.

PB2019

EFFECT OF IRON FORTIFIED FORMULA FEEDING IN THE SECOND 6 MONTHS OF LIFE ON IRON STATUS AND ZINC LEVELS

H. Apak[1], N. Ozdemir[1,*] G. Tuysuz[1], B. Kutlubay[1], E. Erginoz[2], M. Kucur[3]
[1]Pediatric Hematology Oncology, [2]Statistics, [3]Biochemistry, ISTANBUL University, CERRAHPASA MEDICAL FACULTY, Istanbul, Turkey

Background: Malnutrition, iron deficiency anemia, zinc deficiency and associated conditions are among the significant health problems of infancy especially in developing countries. The influence of nutrition types on iron deficiency has not been adequately studied.
Aims: The aim of this sudy is to investigate the relationship between iron status and zinc levels in infancy and type of milk consumed.
Methods: All infants were exclusively breatfed in the first 6 months life. All mothers were recommended to start complementary foods at 6 months of age. Infants, without a nutritional problem, weighing over 10th percentile and continue to be breastfed in addition to adequate complemantary foods were enrolled in the control group (n: 45), babies weighting over 3rd percentile, did not get adequate complementary foods and an iron fortifed formula was added to the diet were included in the study group (n: 39). All infants were followed-up monthly for 3 months. Hemoglobin, ferritin, iron, iron binding capacity and zinc levels were assessed in relation to the type of milk.
Results: Mean hemoglobin values were similiar in the two groups at the end of 3 months of follow-up. Mean ferritin values increased from 53,2±41,8 mg/L to 64,7±89,7 mg/L in the study group, while decreased from 42,8±34,0 mg/L to 34,6±29,3 mg/L in the control group. In the study group, significantly higher levels of ferritin were measured in the last assessment, compared to the control group. There was no difference in the zinc levels between breastfed and formulafed babies.
Summary and Conclusions: An increase in the iron stores of iron fortifed formula fed infants was observed during the follow-up period

PB2020

DO PANCREATIC FUNCTIONS PREDICT CARDIAC AND LIVER IRON LOADING IN TRANSFUSION-DEPENDENT BETA THALASSEMIA MAJOR PATIENTS USING CARDIOVASCULAR AND LIVER T2-STAR (T2*)MAGNETIC RESONANCE ?

G.M. Mokhtar[1], W.E. Ibrahim[1], N.S. Elbarbary[1,*] R.M. Matter[1], A.S. Ibrahim[2], S.M. Sayed[1]
[1]Ain Shams University,Pediatric Department, [2]Ain Shams University,Department of Clinical Radiology, Cairo, Egypt

Background: In Egypt, b-thalassemia is the most common genetically determined chronic hemolytic anemia. Regular and frequent red blood cell transfusions have significantly increased the life expectancy of patients with b-TM.

The transfusions reduce some of the consequences of anemia, such as growth deficit. However, when no appropriate chelation therapy is available, patients accumulate iron in the heart, liver, spleen, pancreas, and endocrine glands, leading to progressive organ dysfunction.
Aims: To assess the correlation between cardiac and hepatic T2*MRI findings with the endocrine and exocrine pancreatic functions in known β-TM patients.
Methods: A total of 44 children and adolescents β-TM patients and 44 healthy controls were investigated via: serum amylase, lipase, triglyceride index, oral glucose tolerance test, and T2* MRI to assess iron content in the heart and liver.
Results: Overt diabetes was found in 9.4% and 45.5% of patients had impaired fasting glucose. Median cardiac T2* was 22ms (12-31 ms) and LIC was 6ms (4-9 ms). CardiacT2* was less than 10ms in 21.4% indicating heavy load with iron in cardiac tissues. There is a significant decrease in serum amylase (87.5 vs. 63.5 IU/L, p =0.003) and lipase (94 vs.70 IU/L, P=0.056) among enrolled patients in comparison to control group. Thalassemic diabetic showed low serum amylase (32.5 vs. 59.5,P=0.0005),serum lipase (39.5 vs. 68, P=0.0007), low cardiac T2* was found (7 vs. 22 ms,p =0.0006) and low LIC (2 vs. 6ms,P=0.0006) than other β-TM patients without diabetes. Inverse correlation was found between triglyceride index with cardiac T2*(r= -0.376, P=0.014) and low LIC (r=-0.376, P=0.014 respectively) but not with serum lipase (r= -0.099,P=0.533), (r= -0.222,P=0.1570) and serum amylase (r =-0.191P=0.225), (r=-0.053 ,P= 0.738) respectively. In Egypt, β-thalassemia is the most common genetically determined chronic hemolytic anemia.
Summary and Conclusions: Follow up of thalassemic patients with impaired fasting glucose together with intensive chelation therapy may help to prevent the development of cardiac and hepatic siderosis.

PB2021

USEFULNESS OF DUAL-ENERGY CT FOR DETECTION OF LIVER IRON DEPOSITION IN TRANSFUSION-DEPENDENT PATIENTS

H. Kobayashi[1,*] N. Yoshimura[2], T. Kasami[1], T. Katagiri[1], H. Nemoto[1], K. Kawamoto[1], T. Ushiki[3], Y. Shibasaki[4], M. Moriyama[5], J. Takizawa[1], M. Narita[6], H. Sone[1], M. Masuko[4]
[1]Hematology, Endocrinology and Metabolism, [2]Radiology, Niigata University Faculty of Medicine, [3]Transfusion Medicine and Regenerative Medicine Bioscience Medical Research Center, [4]Stem Cell Transplantation, Niigata University Medical and Dental Hospital, [5]Medical Oncology, Niigata University Faculty of Medicine, [6]Hematology and Oncology, Graduate School of Health Sciences, Niigata, Japan

Background: Chronic red blood cell transfusions lead to iron overload, which has been implicated in the development of serious complications. Liver iron concentration (LIC) is considered an indicator of total body iron stores, and the measurement of T2* values by MRI represents a standard noninvasive technique to evaluate LIC. However, some limitations are associated with MRI, such as its high cost and the overestimation of LIC. Although the application of CT, which is easy to use and widely applied to measure LIC, needs to be considered, conventional single energy CT (SECT) also has limitations for the detection of LIC due to normal variations in CT attenuation, predominantly in patients with mild iron overload. Moreover, SECT fails to detect iron in fatty livers, which has an inverse effect on attenuation by lowering CT numbers. Dual-energy CT (DECT) is used to obtain additional information on tissue composition over that provided by SECT. This technique is based on substances showing different densities with two different energies, with each substance displaying its own energy-dependent change in CT attenuation. However, the role of DECT in the detection of LIC remains to be clarified.
Aims: The aim of this study was to examine whether DECT represented a novel and useful technique for the detection of LIC.
Methods: Eight transfusion-dependent patients underwent liver DECT using a dual-source 128-slice CT system, serum ferritin levels were measured, and liver MRI was performed. DECT images were acquired using a tube voltage pair of 140 kV and 80 kV or 140 kV and 100 kV, and the three-material decompositions of fat, soft tissue and iron. All patients provided informed consent. Patient 1 was a 54-year-old male with MDS (RCMD-RS). Patient 2 was a 66-year-old female with AML with MRC in 1st CR. Patient 3 was a 47-year-old female who had undergone renal transplantation for chronic renal failure. Patient 4 was a 65-year-old male with AML with MRC receiving iron chelation therapy. Patient 5 was a 47-year-old male with AML in 3rd CR. Patient 6 was a 52-year-old female with AA. Patient 7 was a 63-year-old male with AIHA. Patient 8 was a 56-year-old female with AML in 2nd CR. All patients had long transfusion histories and received red blood cell transfusions of at least more than 12 U.
Results: Serum ferritin levels in patients 1 to 8 were 961, 2168, 7875, 795, 1921, 5104, 2401, and 2916 ng/mL, respectively. Although patient 8 with fatty liver, which was confirmed by abdominal ultrasonography, showed hypodensity on SECT images, liver iron deposition was detected on DECT images. All patients showed diffuse severe hypointensity on MRI T2*-weighted images. Patients 1, 2, and 3 also showed severe diffuse iron deposition on DECT images. However, patients 4, 5, 6, and 8 showed mild focal iron deposition, while patient 7 did not show iron deposition on DECT images.
Summary and Conclusions: Our results suggest that DECT has the ability to detect liver iron deposition in transfusion-dependent patients more precisely than MRI. DECT may be a new tool that can overcome the limitations of MRI.

PB2022

INCIDENTAL DETECTION OF HAEMOGLOBIN VARIANTS DURING GLYCATED HEAMOGLOBIN ANALYSIS

E. Petridou[1], A. Kotanidou[1], A. Agorasti[1,*]
[1]Laboratory Haematology, General Hospital of Xanthi, Xanthi, Greece

Background: The presence of a haemoglobin variant (Hb variant) influences the glycated haemoglobin (HbA1c) analysis in a method-depending manner and may erroneously lead to underestimated HbA1c measurements by high performance liquid chromatography (HPLC).
Aims: The aim of this study is the retrospective registration of the cases of Hb variant detected during HbA1c analysis by HPLC, in order to reevaluate the use of this specific method.
Methods: All patients who had their HbA1c levels determined in our laboratory during the period of time from 01-01-2004 to 31-03-2013 were included in the study. The measurements of HbA1c were performed by automated reversed phase cation exchange HPLC on an ADAMS™ A1c HA-8160, ARKRAY® analyzer. All Hb variant cases found during routine HbA1c analysis and further identified with HPLC analyzer (HLC-723 G7 β-Thalassemia Mode, TOSOH®) were recorded. Only one HbA1c result per patient was included in the study.
Results: Out of a total of 12617 patients, 122 (54 men & 68 women) was found to have Hb variant. In particular, 83 patients (68,03%) had Hb-O Arab (1 homogyzous & 82 heterozygous), 36 patients (29,5%) had HbS (heterozygous), two patients (1,64) had HbJ (heterozygous) and one patient (0,82%) had HbD (heterozygous). The determination of HbA1c was impossible in the case of homozygous O-Arab (no s-A1c peak detected). In all cases, the presence of Hb variant was first diagnosed during the routine HbA1c analysis.
Summary and Conclusions: The analysis of HbA1c using the HPLC method is a simple and reliable screening test for Hb variant. The incidental finding of haemoglobinopathy is very important, because old people that usually suffer from diabetes mellitus, probably did not have previous haemoglobinopathy investigation. Furthermore, homozygous O-Arab and heterozygous HbS present a significant clinical importance. As the measurement of HbA1c can potentially be affected by the presence of a Hb variant, and in order to avoid mismanagement of diabetes mellitus (pre-diabetes, diagnosis, monitoring) in individuals with Hb variants, the visual inspection of chromatograms obtained from HPLC analysis for the detection of additional peaks is recommended. The laboratory should report the presence of Hb variant with the HbA1c result.

Stem cell transplantation - Clinical

PB2023

CHARACTERIZATION OF CHRONIC GRAFT-VERSUS-HOST-DISEASE IN MALIGNANT HEMATOLOGICAL DISORDERS AFTER USING G-CSF-PRIMED BONE MARROW AS A SOURCE OF HEMATOPOIETIC STEM CELLS FOR ALLOGENEIC TRANSPLANTATION

P. Guzman[1,*] E. Leon[1], M. Rivera[1], R. Terrazas[1], C. Balderas[1]
[1]Hematology-Oncology, Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Mexico, Mexico

Background: A major complication of allogeneic stem cell transplantation (allo-SCT) is chronic graft-*versus*-host disease (cGVHD). Risk factors for the development of cGVHD include prior acute GVHD, increasing patient age, and use of a parous female donor for a male recipient. GVHD is also associated with significant morbidity and mortality, commonly requiring long-term immunosuppressive therapy after allo-SCT. It has been documented that the use of G-CSF-primed bone marrow as a source of hematopoietic stem cells decreases the frequency and severity of cGVHD.
Aims: To describe the frequency and characteristics of cGVHD in 35 patients who underwent allogeneic, G-CSF-primed bone marrow transplantation, at INCMNSZ, from November 1998 to December 2014.
Methods: A retrospective analysis was performed in 35 patients who underwent allogeneic, G-CSF-primed bone marrow transplantation, describing the characteristics and outcome of 12 of them who developed cGVHD, using the Statistical Software Package SPSS v21.0.
Results: Twelve out of 35 patients who underwent allogeneic, G-CSF-primed bone marrow transplantation, from November 1998 to December 2014, developed cGVHD (34.2%). Median age was 33 years (range 16-49), and 60% were male. The patients had a following range of underlying diseases: acute lymphoblastic leukemia (LLA, n=4, 33.3%), myelodysplastic syndrome (n=5, 41.6%), chronic myeloid leukemia (CML, n=2, 16.6%), and acute myeloid leukemia (AML, n=1, 8.3%). Median infused CD34+ stem cell dose was 2.04x 10^6/kg. All patients received conditioning with busulphan and cyclophosphamide, and prophylactic immunosuppression with methotrexate (10 mg/m2 days 3, 6, and 11) and cyclosporine A (CsA 5mg/kg) for the first 4 months. The median interval from transplantation to occurrence of cGVHD was 275.3 (range, 101-1359) days. 83.3% of the patients had limited cGVHD (10/12). Among the risk factors associated with cGVHD we identified the following: five male patients were given grafts from female donors, 2 patients with CML developed cGVHD after donor lymphocyte infusion, three patients previously experienced acute GVHD, and only one patient had an antigen mismatch (9/10). In 11 patients (31.4%), hepatic dysfunction was consistent with elevation of transaminases and alkaline phosphatase. Nine patients developed skin involvement characterized by exanthema; 6 had mucous lesions: 2 patients lichen reticularis, 2 developed ulcers, and one leukoplakia. None of the patients had pulmonary or ophthalmic lesions. Initial treatment included steroids in all patients, without complete response and additional Immunosupressive therapy was prescribed including: CsA, sirolimus, mycophenolate mophetyl, cyclophosphamide, ruxolitinib, and imatinib. Median time of duration of immunosuppression therapy was 12.9 months (range, 3-41) with an overall response of 66% (8/12 patients). GVHD associated mortality occurred in one patient, and one patient was lost during follow up. At last follow up, the remaining 10 patients were alive and 8 were out of immunosuppressive therapy without evidence of GVHD.
Summary and Conclusions: Using G-CSF-primed bone marrow as a source of hematopoietic stem cells for allo-SCT is associated with a different pattern of cGVHD tissue impairment, characterized by skin and liver involvement, in most cases mild and limited. At least two immunosuppressive therapy approaches were needed to induce clinical remission. Further studies including a larger number of patients are required in order to validate this strategy.

PB2024

IMPACT OF PLATELETS ALLOIMMUNIZATION IN ALLOGRAFT

S. Astati[1,*] S. Maury[2], M. Mikdame[1]
[1]Service d'Hématologie Clinique,, Hôpital Militaire d'Instruction Mohammed V, Rabat, Maroc, Rabat, Morocco, [2]Service d'Hématologie Clinique et de thérapie cellulaire, Hôpital Henri Mondor, Créteil, France

Background: The prolonged thrombocytopenia after hematopoietic stem cell transplantation (HSCT) present factor of poor prognosis. There causes are varied and complex; whose platelet alloimmunization, which is responsible for refractoriness platelet transfusions.
Aims: The objective is to demonstrate the impact of mismatches between donor and recipient for human platelet antigens (HPA) on recovery of platelet counts after transplantation.
Methods: A retrospective analysis of 96 patients transplanted at the Department Hematology at Hospital Henri Mondor, Creteil, between January 2011 and December 2013 was performed. Only geno and pheno-identical HSCT are studies.
Results: We tested each of the four HPA systems (HPA1, HPA3, HPA5 and HPA15), the platelet recovery in recipients "aa" as they receive HSC donor "aa" or "ab or bb". We demonstrated no significant differences between groups with or no mismatch HPA, compared at 1, 3, 6, and 12 months after graft. While there was a trend (P=0.07) in HPA3 system at 24 months to transplant. In HPA5 system, the differences were in the expected direction without statistically significant.
Summary and Conclusions: It would be important to demonstrate the impact of mismatch HPA on platelet recovery in a most important sample of patients to prevent the onset of refractoriness to platelet transfusions in the course of allogeneic haematopoietic stem cell.

PB2025

CLINICAL IMPACT OF HEPATITIS B SURFACE ANTIGEN POSITIVITY IN PATIENTS UNDERGONE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

H.G. Yi[1,*] M.H. Lee[1], J. Hong[2], J. Park[2], J.H. Lee[2], S.H. Kim[3], S.K. Park[3], D.S. Hong[3], C.S. Kim[1]
[1]Internal medicine, Inha University, School of Medicine, [2]Internal medicine, Gachon University, School of Medicine, Incheon, [3]Internal medicine, Soonchunhyang University, School of Medicine, Bucheon, Korea, Republic Of

Background: Hepatitis B virus (HBV)-related events could increase in patients who have HBV before or after allogeneic hematopoietic stem cell transplantation (HSCT) due to their immunosuppressive status because of their primary diseases, conditioning regimens, immunosuppressive agents, and immature immune reconstruction. However, the consensus of the risk of HBV status and prophylactic or therapeutic strategies for these patients were not settled yet.
Aims: We intented to search the clinical impact of HBV surface antigen (HBS Ag) positivity in patients undergone allogeneic hematopoietic stem cell transplantation.
Methods: We reviewed clinical information of HBS Ag-positive patients who had been treated with allogeneic HSCT for various hematologic diseases to evaluate the influence of HBsAg positivity to the clinical outcomes. A total of 398 patients who had been treated with allogeneic HSCT between January 1998 and November 2014 in three domestic institutes of Korea were enrolled in this study.
Results: Eleven patients (2.8%) were HBsAg-positive among 398 patients treated with allogeneic HSCT. The diagnosis were acute myeloid leukemia (N=3), acute lymphoblastic leukemia (N=1), non-Hodgkin lymphoma (N=1), myelodysplastic syndrome (N=2), severe aplastic anemia (N=3), and acute biphenotypical leukemia (N=1). Ten patients were HBsAg-positive before HSCT, and one patient became seroreversion after HSCT due to HBsAg-positive donor. Seven patients (63.6%) were given prophylactic antiviral agents (lamivudine, N=4; entecarvir, N=3). Three patients (27.3%) experienced chronic active hepatitis (CAH) after HSCT, which was controlled well with antiviral agents. Of three CAH patients, two had not been give any HBV prophylaxis during HSCT. Sinusosidal obstruction syndrome (SOS) occurred in 3 patients (27.3%), and one died of SOS. Acute liver graft-*versus* host disease (GVHD) occurred in 4 patients (36.4%); and chronic liver GVHD did in 2 (18.2%). Interestingly, one patient whose donor had HBs antibody (HBsAb) lost HBsAg after HSCT.
Summary and Conclusions: HBsAg positivity could increase the risk of the incidence of chronic active hepatitis after allogeneic HSCT. However, it seems not to influence markedly to the overall clinical outcomes of HSCT including survival, SOS or liver GVHD. Loss of HBsAg might be expected if the donor has HBsAb. Further large-scaled studies designed to identify the risk of HBsAg positivity and the optimal strategy for HBsAg-positive patients is required.

THE ROLE OF HLA HIGH RESOLUTION TYPING IN UMBILICAL CORD BLOOD TRANSPLANTATION

A. Sun[1,*] S. Yang[1], J. He[1], C. Xu[1], H. Qiu[1], Z. Jin[1], X. Tang[1], C. Fu[1], X. Ma[1], D. Wu[1]
[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: 1s smdy was pur10sed to investigate me clillical value of HLA mtchjn2(10w and tligh I esolution)aJld its effect on outcome of the patients received umbilical cord blood_ransplantation(UCBT). This study was purposed to investigate the clillical value of HLA matching(low and high resolution) and its effect on outcome of the patients received umbilical cord blood transplantation(UCBT)
Aims: To analyze HLA matching(low or high resolution) on outcomes of umbilical cord blood transplantation(UCB) and the value of clinical application.
Methods: From October 2010 to July 2012,26 patients were selected umbilical cord blood transplantation in our hospital,in the absence of a suitable HLA-identical sibling donor or alternative donors.We examined the effects of HLA matching (low or high resolution) on engraftment of leading, engraftment,graft-*versus*-host disease (GVHD), infection and mortality.Performed mainly by

sequence-specific oligonucleotide probe (SSOP) methods, sequence-based typing (SBT) methods and high resolution sequence-specific primers(SSP) methods,retrospective HLA matching of cord blood,typed at high resolution for HLA-A,-B, -C, -DRB1, -DQ, and -DP and low resolution for HLA-A,B,DRB1.
Results: Compared single UBC units transplantation with double UBC units,the hematopoietic reconstitution rate was 88% vs 56%.The median total nucleated cells(TNC) of single and double cord blood was 5.5×107/kg, when TNC≥5×107/kg could promote neutrophil recoveries (P<0.05). The UBC units were a 6/10 HLA high resolution match or better with each other could promote UCB implantation advantaged P<0.05, accelerate platelet recovery P<0.05 and reduce more risk of acute GVHD (grade III -IV) P<0.05. There are different between the group 5-6/6 HLA low resolution and 3-4/6.but no statistical difference P>0.05.
Summary and Conclusions: The HLA High resolution typing can select the better UCB than HLA low-resoulution. It has important clinical value on promoting hematopoietic reconstitution and reducing complications after UCB transplation.

WHICH IS THE MOST ADOPTABLE PROGNOSTIC MODEL FOR DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH R-CHOP FOLLOWED BY AUTOLOGOUS TRANSPLANTATION?

M. Lee[1,*] S.Y. Kim[1], I. Kim[2], Y.K. Kim[3], J.A. Kim[4], Y.S. Kim[5], H.S. Lee[5], J. Park[6], S.J. Kim[7], H. Shim[8], H.S. Eom[9], B.B. Park[10], J. Lee[11], S.K. Park[12], J.W. Cheong[13], K.W. Park[14]
[1]Internal Medicine, Konkuk University Medical Center, [2]Internal Medicine, Seoul National University Hospital, Seoul, [3]Internal Medicine, Chonnam National University Hwasun Hospital, Hwasun, [4]Medicine, The Catholic University of Korea College of Medicine, Seoul, [5]Medicine, Kosin University Gospel Hospital, Busan, [6]Medicine, Gachon University Gil Hospital, Incheon, [7]Medicine, Samsung Medical Center, Seoul, [8]Medicine, Wonkwang University Hospital, Iksan, [9]Medicine, National Cancer Center, Ilsan, [10]Medicine, Hanyang University College of Medicine, Seoul, [11]Medicine, Daegu Fatima Hospital, Daegu, [12]Medicine, Soonchunhyang University Hospital, Bucheon, [13]Medicine, Yonsei University College of Medicine, Seoul, [14]Medicine, Dankook University Hospital, Cheonan, Korea, Republic Of

Background: The ideal prognostic model has not been developed for patients with diffuse large B cell lymphoma (DLBCL) treated with rituximab combined with the CHOP regimen (R-CHOP) followed by upfront autologous stem cell transplantation (Auto-SCT).
Aims: Among the currently adoptable prognostic models for DLBCL, we investigated to find out which one is the most adoptable one for DLBCL treated with R-CHOP followed by upfront Auto-SCT.
Methods: We retrospectively evaluated survival differences between the risk groups based on the International Prognostic Index (IPI), the age-adjusted IPI (aaIPI), the revised IPI (R-IPI) and the National Comprehensive Cancer Network IPI (NCCN-IPI) at diagnosis in 63 CD20-positive DLBCL patients treated with R-CHOP followed by upfront Auto-SCT.
Results: Patients had either stage I/II bulky disease (6.3%) or stage III/IV disease (93.7%). The median age at diagnosis was 50 years (range, 22-66 years). 37 of 63 patients (58.7%) belonged to the IPI high-intermediate or high risk group. 48 of 63 (76.2%) received 6 or more cycles of R-CHOP. The median time to transplantation was 7.2 months (range, 3.4-40.3 months). At the time of Auto-SCT, 74.6% and 25.4% of patients achieved complete (CR) and partial remission (PR) after R-CHOP, respectively. As a whole, the 5-year overall (OS) and progression-free survival (PFS) were 78.8% and 74.2%, respectively. The 5-year OS and PFS rates according to IPI, aaIPI, R-IPI, and NCCN-IPI did not differ in statistical significance between the risk groups of each prognostic model (*P* values for OS: 0.255, 0.185, 0.881, and 0.803, respectively; *P* values for PFS: 0.177, 0.832, 0.295, and 0.609, respectively).
Summary and Conclusions: There is no ideal prognostic model among the currently adoptable ones for CD20-positive DLBCL treated with R-CHOP followed by upfront Auto-SCT. A new prognostic model is necessary to identify those who will gain the maximum benefit from upfront Auto-SCT in the rituximab era.

PB2028

EAM (ETOPOSIDE, CYTARABINE, MELPHALAN) BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION IS SAFE AND EFFECTIVE FOR RESISTANT/RELAPSED HODGKIN LYMPHOMA PATIENTS

A. Bekadja[1,*] R. Bouhass[1], S. Osmani[1], M. Brahimi[1], S. Talhi[1], N. Yafour[1], A. Arabi[1],
[1]Hematology and cell therapy, University hospital Oran, Oran, Algeria

Background: High-dose chemotherapy (HDT) followed by autologous stem cell rescue has become the standard of care for patients with relapsed, chemosensitive Hodgkin lymphoma (HL). A BEAM regimen is widely used conditioning regimen for autologous stem cells transplant (ASCT) in patients with lymphoma because of its acceptable toxicity and high effectiveness. Adverse events associated with BEAM are related in part to BICNU.
Aims: On 2011-2012, we started a pilot study designed as follows: Etoposide 800 mg/m^2 J-5 to J-2, Cytarabine 1000 mg/m^2/12h, J-5 to J-2 and Melphalan 140 mg/m^2 J-1 as the conditioning regimen to ASCT for resistant/relapsed HL patientsto evaluate the safety and the efficacy of this regimen with high dose Cytarabine.
Methods: Seventeen patients, seven males and ten females, 17 to 51 years old (median, 28 years), with HL were consecutively treated in our center. Regarding the stage of disease, four patients were in early stage (I-II), thirteen in advanced stage (III-IV) and concerning their status at ASCT, thirteen were in complete remission, three in partial response and one presented a refractory disease. A median number of 3,73x10^6 CD34$^+$ cells/kg (range, 2, 97-6, 15) were re-infused.
Results: All patients had a full hematopoietic reconstitution. Median time to achieve neutrophils >500 /µl was 13 days (range: 9-19) and median time to achieve an unsupported platelet count >20,000/µl was16 days (range: 14-25). Toxicities included grade 4 hematologic in all patients, grade 3 mucositis in 4, grade 3 infectious in 2. Among 16 patients evaluable, fifteen patients (94%) achieved CR; one patient had progressive disease post-ASCT.Fivepatients died: one within the first 100 days that followed transplantation, one after progression of disease and three after relapse. After a median follow up of 37 months (2-45) (End point: 31/12/2014), the overall survival was 70% at 45 months, the DFS was 75% at 45 months and 12 patients are alive in continuous CR (80%).
Summary and Conclusions: In conclusion, this pilot studyof EAMas conditioning regimen seems to be safeand effective for heavily pre-treated Hodgkin lymphoma patients. Although these outcomes are encouraging, our results need to be confirmed by more other studies.

CLINICAL IMPLICATION OF ΓΔ+ T CELL RECOVERY AFTER AB+ T CELL DEPLETED HAPLOIDENTICAL HEMATOPOIETIC CELL TRANSPLANTATION IN CHILDREN WITH HEMATOLOGIC MALIGNANCY

J.K. Suh[1], J.J. Seo[1,*] S.W. Lee[1], K.N. Koh[1], Y.U. Cho[2], E.S. Choi[1], S. Jang[2], H.J. Im[1], C.J. Park[2]
[1]Pediatrics, [2]Laboratory medicine, ASAN MEDICAL CENTER, Seoul, Korea, Republic Of

Background: Human γ$^+$ T cells exhibit an ability to kill tumors but do not recognize major histocompatibility complex, thus have shown limited risk of graft-*versus*-host disease (GVHD).
Aims: The purpose of this study were to determine antitumor efficacy of γ$^+$ T cells in children with hematologic malignancy after αβ$^+$ T cell depleted haploidentical hematopoietic stem cell transplantation (haplo-HSCT).
Methods: Ten children (6 males, 4 females, median age 12.3 years) with hematologic malignancy received haplo-HSCT after *ex vivo* depletion of αβ$^+$ T cells between May 2012 and December 2013 at AMCCH. Of 10 patients, 1 had ETP-ALL in CR2 who relapsed after MSD-HCT, 1had MLL in relapse after 2 rounds of URD-HCT, 5 had AML [2 CR1, 2 CR2, 1 non-remission (NR)], 2 had JMML (1 CR1, 1 NR), and 2 had NHL (1 CR2 and 1 CR3) who relapsed after AUTO-HCT. The median number of CD34$^+$, αβ$^+$, γ$^+$ and CD3$^+$ cells infused was 10.6x 10^6/Kg, 6.3x 10^5/Kg, 2.1x 10^7/Kg and 22.9x 10^6/Kg, respectively. Proportion of TCR γ$^+$ T cells in T lymphocyte were analyzed by using Gallios flow cytometer™ (Beckman Coulter, Fullerton, CA, USA) after HSCT.
Results: All 10 patients engrafted and 1 patient experienced grade IV acute GVHD without treatment related mortality. At a median follow-up period of 387 days (range, 208-766), 5 patients (1 ETP-ALL, 1 MLL, 2 AML, 1 NHL) relapsed at the median 131 days (range, 42-234) after haplo-HSCT. The median dose of infused γδ$^+$ T cell for 5 patients without relapse and 5 with relapse were 2.2x 10^7/Kg and 1.8x 10^7/Kg. The median proportion of γ$^+$ T cells after HSCT was higher in non-relapsed patients than in relapsed patients. (69.4% vs 29.3% at 1 month, 44.2% vs 6.2% at 2 months and 36.8% vs 9.1% at 3 months post-transplant) At a median follow-up of 12 months probability of 1 year relapse-free survival was 48.0%, and probability of 1 year overall survival was 78.8%.
Summary and Conclusions: These findings suggest a correlation between an increase in the proportion of γ$^+$ T cells and improved relapse-free survival after αβ$^+$ T cell depleted haplo-HSCT. However, further studies including prospective large numbered trial are needed to confirm our results.

PB2030

EXTRACORPOREAL PHOTOPHERESIS AS A TREATMENT FOR ACUTE AND CHRONIC GRAFT VERSUS HOST DISEASE. A SINGLE CENTER EXPERIENCE IN SPAIN

J. Fonseca-Cipagauta[1,*] V. García Gutierrez[1], S. Pérez-Gala[2], P. Herrera-Puente[1], A. Chinea-Rodriguez[1], M. Calbacho-Robles[1], G. Moreno-Jiménez[1], M.C. Tenorio-Nuñez[1], A. Jiménez-Martín[1], N. Revilla-Calvo[1], I. Saavedra-Tapia[1], J. López-Jiménez[1]
[1]Haematology Department, [2]Dermatology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: Graft *versus* host disease (GvHD) is the most important cause

of mortality and morbidity in patients who have undergone allogeneic stem cell transplantation. Currently, high-dose steroid is the first line of therapy in this disease. Nevertheless, there are no guidelines or agreement about the second and subsequent lines of treatment, so this still remains a matter of discussion. Extracorporeal photopheresis (ECP) has shown to be an effective and safe option to treat GvHD.

Aims: To evaluate the efficacy and safety of ECP in GvHD treatment in our center.

Methods: Since 2011 we have treated with ECP (Therakos System) a total of 25 patients with acute GvHD (aGvHD) (group 1) (n=12) and chronic GvHD (cGvHD) (group 2) (n=13) with refractory disease to two or more previous lines of therapy. Patients in group 1 were treated with weekly cycles and response was evaluated at week 6-8 after treatment was started. Patients in group 2 were treated every 2 weeks and response was evaluated at month 3-4. In group 1 Complete Response (CR) was defined as resolution of all symptoms, Partial Response (PR) as improvement of at least one grade compared to baseline and, Non Response (NR) when patients did not accomplish any of the other definitions. In group 2 CR was defined as symptom resolution with immunosuppressant treatment discontinuation, PR as improvement of more than 50% over baseline and/or reduction of more than 50% in immunosuppressant treatment, Minimum Response (MR) as improvement less than 50% over baseline and/or immunosuppressant reduction between 25-50% and Progression (PG) as clinical worsening or new organ involvement. The Modified Glucksberg classification was used to stage aGvHD and the NIH criteria to stage cGvHD.

Results: GvHD staging was 16%, 42% and 42% for grade II, III and IV respectively in group 1 and 8%, 38% and 54% for mild, moderate and severe in group 2. Group 1 was treated with a median of 6 cycles (1-12) and group 2 with a median of 9 cycles (3-22). The responses in group 1 was CR= 25%, PR= 33% and NR= 42% and in group 2 was CR= 15%, PR= 54%, MR= 8% and PG= 23%. The mortality rate was 67% for group 1 and 54% for group 2. The main causes of mortality were infections (88% and 57% for group 1 and 2) and GvHD progression (12% and 29% for group 1 and 2). The only complication associated to ECP was catheter infection (2 cases).

Summary and Conclusions: In our experience, ECP has proven to be a safe and effective treatment for patients with aGvHD and cGvHD. Prospective studies are required to establish indications and treatment guidelines.

PB2031

EFFECT OF COMORBIDITIES ON HEMATOPOIETIC STEM CELL TRANSPLANTATION OUTCOME IN ADULT PATIENTS WITH DIFFERENT HEMATOLOGIC DIEASES :SINGLE CENTER EXPERIENCE IN EGYPT

A. El afifi[1], M. elzimaity[1], N. mostafa[1], M. M. Moussa[1,*] G. shams eldin[1], R. magdy[1], A. abdelaziz[2], N. shalaby[2], H. saber[1]
[1]Internal Medicine, Hematology and BMT unit, [2]clinical pathology, Ain Shams University, Cairo, Egypt

Background: Background Heamtopoeitic Stem cell transplantation (HSCT) is a procedure that can restore marrow function for patients who have had severe marrow injury, replacement of marrow by disease, or abnormalities of the immune system..It is either autologous or allogenic. It has become increasingly important to optimize pre-transplant risk assessment in order to improve HCT decision making and clinical trial assignments. Single-organ comorbidity involving liver, lung, heart, or kidney before HCT has been traditionally found to cause organ toxicity after HCT. The HCT-comorbidity index (HCT-CI) has provided better prediction of HCT-related morbidity and mortality than other non-HCT-specific indices

Aims: The aim of this work is to study the impact of various pretransplant comorbidities on outcome of patients who had undergone either-allogenic or autologous HSCT -in relation to treatment related mortality and disease related mortaliy with specific emphasis on overall survival.

Methods: A retrospective study was conducted at the bone marrow Transplantation Unit, of internal medicine department Ain Shams University on 119 patients who were transplanted either by autologous or allogenic HSCT (matched or mismatched related donor). All of them were aged >18ys.and had different types of hematologic diseases; the most frequent being AML(34.4%) followed by multiple myeloma(17.6%) then ALL(16.8%) and lymphoma (10.9%) whereas,aplastic anemia,MDS,CML and biphenotypic leukemia.collectively were20.1%.They were either in complete or partial remission according to the type of disease. They were categorized according to HCT-CI into mild score (0) 43 patients (36.2%), moderate score (1-2) 60 patients (50.4%) and severe score (≥3) 16 patients (13.4%). The study data were collected from medical notes, pathology reports and laboratory data.

Table 1.

Score	Median	SE	95% Confidence Interval	Log Rank	P-value
Mild	67.85	8.18	(51.82-83.88)	8.790	0.012 S
Moderate	62.06	7.14	(48.07-76.05)		
Severe	5.00	2.66	(0.00-10.21)		

Results: There was statistically significant relation between HCT-CI and overall survival (p 0.012), disease free survival (p 0.007), mortality(p 0.047). and the incidence of graft failure.(p 0.034). Comparison between different HCT-CI scores as regard overall survival (Kaplan- Maier curve): P<0.05S-

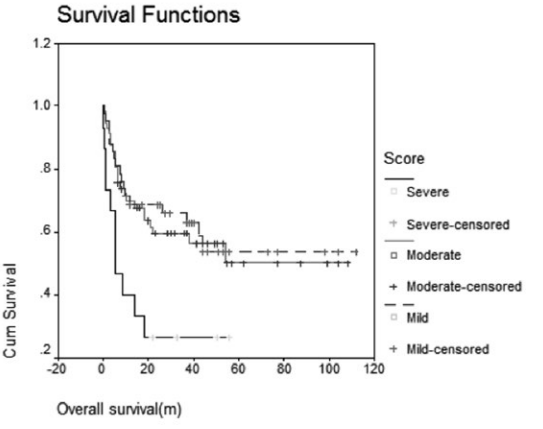

Figure 1.

Summary and Conclusions: In our study, we could conclude that the HCT-CI is a better predictor to detect the influence of comorbidity in patients with hematologic disorders on mortality, overall survival and disease free survival post HCT.

PB2032

ALLOGENEIC STEM CELL TRANSPLANTATION FOR MYELODYSPLASTIC SYNDROME

A. Sabrina[1,*] B. Malek[1], T. Amina[1], M. Farih[1], B. Rachida[1], R. Nadia[1], B. Mounira[1], A.O. Dina[1], B. Hanane[1], Z. Sara[1], M. Hanane[1], B. Fatiha[1], A.A. Nacera[1], T. Farida[1], A. Naima[1], B. Fateh[1], A.N. Redouane[1], H. Rose Marie[1]
[1]Pierre and Marie Curie Center, Algiers, Algeria

Background: Myelodysplastic syndromes (MDS) are clonal hematopoietic disorders characterized by ineffective hematopoiesis, marrow dysplasia with cytopenias, abnormal blasts and variable rates of transformation to acute myeloid leukemia (AML). Allogeneic hematopoietic stem cell transplantation (HSCT) currently is the only potentially curative therapy for MDS. However, since most patients with MDS are older than 60 years, few are candidates for myeloablative transplantation. We present in this study our experience in HSCT for MDS.

Aims: Between May 2001 to June 2014 (13 years period), twenty two pts with MDS underwent allogeneic HSCT with HLA- identical sibling donors. The median age of the pts is 35,5 years (11-58), the Sex ratio is 1,44 (13M/9F), according to WHO classification 2008 (RA : 01, RA with del 5q : 01, RA with ring sideroblasts: 01, refractory cytopenia with multilineage dysplasia: 07, RA with excess blasts-1: 07, RA with excess blasts-2 : 05), 20pts were transfusion-dependent before transplantation. Median time from diagnosis to allogeneic HSCT was 17, 2 months (7-52).

Methods: Myeloablative conditioning (MAC) was employed in 08pts and the reduced intensity conditioning (RIC) in 14pts. GVHD prophylaxis consisted of association of Cyclosporin and Methotrexate according to Seattle protocol. All pts received G-CSF mobilised peripheral blood stem cells, with a median CD34+ cell count : 5 ,8.10^6 /Kg (3,18-19,9). At 31 December 2014, a median time of follow-up is 41, 5 months (6-135).

Results: Neutropenia occured in all pts and the median duration of aplasia was 14 (7-23) days. Median time to achieve neutrophils count >0,5.10^9/l : 13,5days (11-23) and platelets >20.10⁹/l : 13 days (9-35). Twenty pts (90%) required red blood cells transfusions (9, 9 units/pt) and 20 pts (90%) needed platelet transfusions (6 units/pt). Acute GVHD was observed in 05 cases (22,7%) grade II-IV and chronic GVHD in 07 pts (31,8%) of whom 5 with an extensive form.One pt (4,5%) relapsed at 4 months. 12 pts (54,5%) are still alive in complete remission, 10 pts (45,5%) died (4 : early severe infection, 1 : VOD, 1 : MAT, 3 : acute GVHD, 1 after relapse). The overall survival (OS) and the Disease free survival (DFS) are respectively 52, 4% in all pts. The OS and DFS for RIC group are 53, 9%.

Summary and Conclusions: This study, after a long follow-up, suggests that allogeneic HSCT is the treatment of choice for pts with advanced stage MDS and pts with dependent transfusion. Relapse seems low (4,5%) in our study and no difference in term of OS between MAC and RIC group. The advantage of RIC is the possibility of HSCT for pts up to 60 years of age and older.

PB2033

HAPLOIDENTICAL PERIPHERAL BLOOD STEM CELL TRANSPLANTATION WITH POST-TRANSPLANTATION CYCLOPHOSPHAMIDE FOR HIGH RISK PEDIATRIC LEUKEMIA. EXCELLENT ENGRAFTMENT AND ENCOURAGING LEUKEMIA FREE SURVIVAL

A. Karduss-Urueta[1], G. Suarez[1,*] R. Perez[1], J. Betancurt[2], M. Ramirez[2], J.A. Jimenez[1], L.R. Gomez[1], P. Reyes[1], M. Gonzalez[1], A. Cardona[3], C.L. Hurtado[4], H. Deossa[4], C. Fernandez[4]
[1]Bone Marrow Transplantation, Instituto de Cancerologia-Clinica las Americas, [2]Critical Care Unit, Clinica Las Americas, [3]Research Unit, Instituto de Cancerologia, [4]Bone Marrow Transplantation, Clinica Las Americas, Medellin, Colombia

Background: T cell replete haploidentical stem cell transplantation with post-transplantation cyclophosphamide (PTCy) has shown encouraging results for the treatment of hematologic malignancies; its main advantage is that almost every patient will have a donor. But this technique has been explored mainly in adults and using bone marrow as a cellular source
Aims: To present our experience using T cell replete haploidentical peripheral blood stem cell transplantation (TCR-Haplo-PBSCT) with PTCy for high risk pediatric acute leukemia
Methods: Donors were mobilized with filgrastim 5 ucg/kg/BID for five days, the PBSC were collected with one large volume apheresis procedure. The conditioning consisted of fludarabine 150 mgs/m2, busulfan 4-8 mgs/kg and Total Body Irradiation 400 cGy (Flu Bu TBI) or fludarabine 150 mgs/m2, melfalan 100-140 mgs/m2 and TBI 200 cGy(Flu Mel TBI); on days +3 and +4 PTCy 50 mgs/kg/day was given followed by cyclosporin and mycophenolate starting day + 5. All patients received post transplant filgrastim beginning on d + 6.
Results: After a signed informed consent, 18 patients, were transplanted; median age was 11.5 years (range 6-16), 8 were girls, the diagnosis were: acute lymphoblastic leukemia 8 patients, acute myeloid leukemia 9 and blastic phase of chronic myeloid leukemia one. 22% were in CR1, 39% in CR2 and 39% in CR3 or with refractory disease. Flu Bu TBI conditioning was given in 14 cases while Flu Mel TBI in 4. A median of 10 million/kg of CD34+ cells were infused. The engraftment rate was 100%, median time to achieve 500 neutrophil or more was 15 days (range 14-20), 1 patient out of 18 died without platelet recovery, the remaining had a self- sustained platelet count of 20.000 or more at a median of 14 days (range 10-21). Chimerism at day + 100 was available in 14 cases, all of them had full donor hematopoiesis. The cumulative incidence of aGVHD II-III and extensive cGVHD was 37.5% and 27% respectively. The median follow-up is 13.5 months (range 1-24), 4 patients have died, the causes were; pneumonia (n:1) and relapse of leukemia(n:3), other 2 have relapsed but are alive receiving low intensity chemotherapy. The cumulative incidence of transplantation related mortality is 5.6% and the 2 years actuarial overall survival and event free survival are 79.8% and 58.7% respectively
Summary and Conclusions: The use of TCR-Haplo-PBSCT with PTCy for treating pediatric acute leukemia is promising; it is associated with low transplantation related mortality, very good engraftment rate, acceptable incidence of GVHD, despite the use of peripheral blood, and encouraging leukemia free survival. It deserve more studies

PB2034

HIGHER DOSE CD34+ CELLS AFFECT ABSOLUTE IMMATURE PLATELET COUNT BEFORE ENGRAFTMENT AND PLATELET COUNT AFTER ENGRAFTMENT IN CORD BLOOD TRANSPLANTATION: A SINGLE-INSTITUTIONAL STUDY

K.I. Iwama[1,*]
[1]Hematology, Tokyo Metropolitan Tama Medical Center, Fuchu-shi, Japan

Background: Platelet recover is important to successful allogeneic stem cell transplantation and platelet is the last to be regenerated in bone marrow after stem cell transplantation. Especially, platelet increase is far slower in cord blood transplant(CBT). Recent retrospective studies suggested CD34+ cell and total nucleated cell affect blood cell recover. However, the impact of CD34+ cells dose on each blood cell lineages is not be sufficiently investigated. In addition, these studies mainly focus on engraftment.
Aims: Therefore, we analyzed cases in our database to evaluate the impact of CD34+ cell and total nucleated cell on each blood cell lineages in consecutive patients who were treated with CBT and achieved platelet engraftment over the past 6 years at our institution in Tokyo, Japan.
Methods: We included 95 consecutive patients treated at our institution between April 2008 and May 2014. The study population consisted of 58 male and 37 female patients with a median age of 53 years old (range: 16-69). Patient in this cohort underwent CBT as a part of therapy for myeloid malignancies(N=52) and lymphoid malignancies (N=43). 38 patients were treated with Flu+Cy+TBI(2gy), and 29 patients were treated with Flu+Bu+TBI(2Gy), and 29 patients were treated with AraC+CY+TBI(12gy). All patients received calcineurin inhibitor plus MMF for GVHD prophylaxis. Due to the influence of blood transfusion on blood cell counts and overall estimation of each blood cell movement, each blood cell lineages, and absolute Immature platelet count(ABPC) were assessed by the 5-day moving average,and then we checked movement of the 5-day moving average between patients receiving higher doses of CD34+ cells and patients receiving lower. The 5-day moving average was calculated from the time of day4 after transplantation until day 100 or death from any cause or the date on which the patient was received next chemotherapy.
Results: Among 95 patient, 69 patieunt achieved platelet engraftment. The median CD34+ cells doses and total nucleated cells doses were 0.8*10^5/kg and 2.0*10^7/kg. Among patients' age, total cell count and CD34 cell count in donor cord blood and disease status and conditioning regimen, disease status and myeloablative regimen impacted on pletelet engraftment on multivariate analysis. But, as shown figure 1, the curve of ABPC in patients receiving higher doses of CD34+ cells is highter than the other from day +30 to day +50, and the curve of platlet counts in platelet patients receiving higher doses of CD34+ cells were raising after day +40. In patient who attained platelet engraftment, only age and CD34 cells affect over all survival rate.

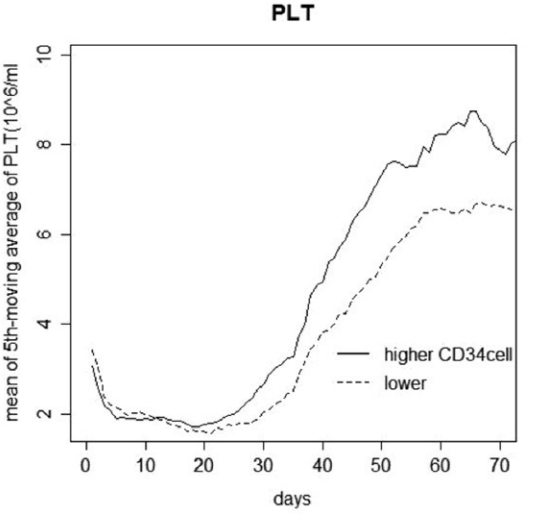

Figure 1.

Summary and Conclusions: The results of the present study highlighted the importance of CD34 cells on platelet recover and CD 34+ cell can be prognostic factor after engraftment in RIC-CBT.

PB2037

COMPARATIVE ANALYSIS OF FILGRASTIM, BIOSIMILAR FILGRASTIM AND LENOGRASTIM AS PERIPHERAL BLOOD CD34+ MOBILIZATION DRUG FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION

B. Soria[1,*] P. Ubierna[2], J. Rodríguez-López[1], A. Iglesias[1], J. Mesa[1], I. González-Perera[3], G. González-de-la-Fuente[3], M.T. Hernández-García[1], J.M. Raya[1]
[1]Hematology and Hemotherapy, Hospital Universitario de Canarias, [2]Hematology and Hemotherapy, Medicina-Universidad de La Laguna, [3]Pharmacy, Hospital Universitario de Canarias, La Laguna, Spain

Background: There are different strategies to mobilize peripheral blood CD34+ cells in oncohematologic patients that will receive an autologous stem cell transplantation (ASCT). As mobilizers drugs (G-CSF), in addition to the original filgrastim (Neupogen®) and lenograstim (Granocyte®), since 2012 we have a biosimilar filgrastim (Nivestim®).
Aims: Our objective was to compare the effectiveness and cost of these drugs in our hospital during the past six years.
Methods: We retrospectively analyzed patients undergoing peripheral blood CD34+ apheresis between January 2009 and December 2014. The collected data included: age, sex, disease (acute leukemia, plasma cell neoplasm, NHL, Hodgkin lymphoma and solid tumor), number of lines of prior chemotherapy, prior use of purine analogs or alkylating agents or radiotherapy, type of mobilization (G-CSF alone, associated with cyclophosphamide or mega-CHOP, or associated with disease-specific chemotherapy) days of administration and daily dose of G-CSF. As for the apheresis procedure: leukocytes, hematocrit,

platelets, percentage of mononucleated cells, percentage of CD34+ cells and CD34+ cells/μL in blood just before apheresis; total number of volemias and processed volume, total number of apheresis per mobilization, process time and obtained CD34+ cells (x10^6/Kg, target >2), and cost per total mobilization procedure. If ASCT was done, we also collected infused CD34+ cells, day to achieve a neutrophil count >500/μL and platelets >20,000/μL. For statistical analysis, SPSS was used.
Results: We studied 201 patients, mean age 50 years (range 2-71) and 64% males, and we used filgrastim in 85 cases, biosimilar 66 and lenograstim 50. There were no significant differences among the three groups for any of the analyzed variables, except for the total number of apheresis per mobilization (the lowest with biosimilar, 1.7, and the highest with filgrastim, 2.1; P=0.009), the number of lines of prior chemotherapy (biosimilar 1.4, lenograstim 1.5 and filgrastim 1.9; P=0.006) and the cost in euros per total mobilization procedure (biosimilar 200, lenograstim 531, and filgrastim 602; P<0.001). Average CD34+ cells in the final product was 6.7x 10^6/Kg (range 0.2 to 40.2) for mobilization and similar with all three drugs (P=0.38). In 25 cases (12%), CD34+<2x 10^6/Kg were obtained. ASCT was performed in 103 patients (51%) and no differences in infused CD34+ cells, days to achieve neutrophils >500/μL or platelets >20,000/μL (for the two last, average 11 and 17, respectively), were observed.
Summary and Conclusions: In our experience we found no differences between the three analyzed drugs in terms of number of CD34+ cells obtained at the final product of apheresis, or hematopoietic recovery after ASCT. However, for the biosimilar drug fewer apheresis for mobilization procedure were needed, and a significantly lower overall cost was observed.

PB2038

FROM HLA TYPING TO ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION: BARRIERS AND OUTCOME

L. El Halabi[1,*] R. shamieh[1], C. soussain[1], S. glaisner[1], S. malak[1]
[1]hematology, Rene Huguenin/Institut Curie, saint cloud, France

Background: Despite the advent of newer targeted and immune therapies, allogeneic hematopoietic cell transplantation (HCT) still offers an advantage in terms of disease free survival, overall survival and quality of life in appropriate settings.
Aims: Several studies have elucidated the heterogeneity in HCT practice among individual physicians, transplant centers and different countries. In our institution, we conducted a retrospective analysis describing and evaluating the outcome of patients for whom an allogeneic HCT was discussed or planned.
Methods: From 2007 till the end of 2014, an HLA typing was done for 156 patients treated for different hematological malignancies at Centre Rene Huguenin/ Institut Curie, France. We reviewed the files of these patients for the type of malignancy, the reason why HLA typing was done, the major barriers to allogeneic HCT and the different outcomes.

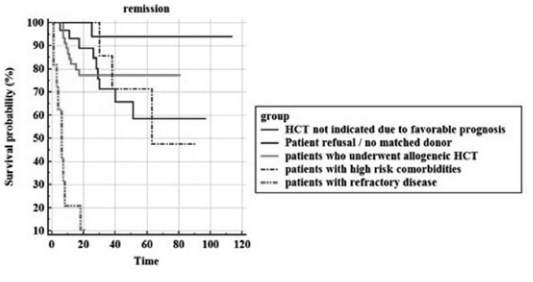

Figure 1.

Results: Among the 156 patients, 27.5% had acute myeloid leukemia, 5.8% acute lymphoblastic leukemia, 0.6% biphenotypic leukemia, 1.9% plasmacytic leukemia, 15.4% multiple myeloma, 7.1% hodgkin lymphoma, 16.1% non hodgkin lymphoma, 7.7% chronic lymphocytic leukemia, 12.8% myelodysplastic syndrome, 5.1% myeloproliferative neoplasms. Of these, 14.1% were typed before complete risk stratification of the disease, 37.2% for the presence of high risk factors (e.g karyotype, molecular markers, ...), 17.3% because their disease was refractory to primary treatment or had an early relapse, 30.8% for late and multiple relapses, and 0.6% upon patient's request. Fifty nine patients or 37.8% underwent allogeneic hematopoietic cell transplantation and 7.1% are currently being evaluated by the committee. The median age of the patients undergoing allogeneic HCT was 53 years (19-67years) and those for whom an HLA typing was done was 57 years (19-72years). Median time from HLA typing to HCT was 7 months ranging from 1 to 14 months. For the remaining patients, in 31.4% of the cases, allogeneic HCT was finally not indicated due to favorable prognosis, 25.6% didn't have a matched donor, 15.1% were ineligible because of refractory/resistant disease and 15.1% were also ineligible because of high risk comorbidities. In 10.5% of cases, the patients refused to undergo HCT and 2.3% were lost to follow up. In terms of outcome, the patients with no indication to HCT due to a favorable prognosis had a significantly better survival than all others. Patients ineligible to HCT with a refractory/resistant disease had the poorer outcome. The group of patients undergoing allogeneic HCT had a lower relapse rates (10.1%) compared to those who didn't have a matched donor or who refused transplantation (22.5%) but there was no significant difference in survival between these groups possibly due to a transplant related mortality of 20.4%.
Summary and Conclusions: In patients for whom HCT was discussed in our institution, a favorable prognosis was the main cause for not undergoing HCT. The major barriers were lack of matched donors, patient's refusal and significant comorbidities. Our results show that current risk stratification of the hematological malignancies correlates well with the patients outcome. Clear criteria for allogeneic HCT are still lacking especially with the advent of new targeted therapies and the persistence of a significant transplant related mortality and morbidity.

PB2039

HYPERBARIC CHAMBERS APPLICABLE IN THE TREATMENT OF HEMORRHAGIC CYSTITIS AFTER ALLOGENEIC STEM CELLS FROM UNRELATED DONORS.

D. Urbaniak-Kujda[1], J. Dybko[1], K. Kapelko[1,*] M. Biernat[1,2], M. Laszkowska[1], T. Wróbel[1], K. Kuliczkowski[1]
[1]Department and Clinic of Haematology, Blood Neoplams and Bone Marrow Transplantation, [2]Department of Microbiology, Wroclaw Medical University, Wroclaw, Poland

Background: Hemorrhagic cystitis (HC) is a diffuse inflammation of the bladder of an infectious or non-infectious etiology, causing bleeding of the bladder mucosa. Medications: (busulfan, endoxan, idarubicin, carboplatin), radiation, viruses, chemicals may be the cause of HC. HC occurs after approximately 35 days after stem cell/bone marrow transplantation and continues for approximately 23 days. Symptoms of cystitis may be caused by defect in the inflammatory response and increase the permeability of glycosaminoglycan layer, which covers the bladder mucosa, form a physiological barrier. There are no explicit guidelines defining appropriate treatment. Hyperbaric therapy (HBO) has been recognized clinically in the treatment of HC in the past 15 years. It is a non-invasive method involving the operation of 100% oxygen under increased pressure, which penetrates poorly perfused areas, patient exposure to 100% oxygen-saturated tissue oxygen efficiently.
Aims: We reviewed the records of 5 patients with HC who received hyperbaric oxygen as an adjunctive treatment.
Methods: We retrospectively analyzed the effectiveness of HOT in 5 patients in the years from 2012 to 2014. Among patients there were 3 men, aged from 31 to 41 years and 2 women aged from 40 to 43 years. Patients characteristics is shown in Table 1.

Table 1.

Patient No	Age yr	Sex	Diagnosis	Clinical status	Condidtioning regimen	Source for alloHSCT	GvHD prophylaxis
1	40	F	MDS	CR1	BuCyTym	PBSC, MUD	C, MTX, Gluc
2	41	M	AML	CR1	BuCyTym	PBSC, MUD	C, MTX, Gluc
3	39	M	ALL	CR1	TBI, CyTym	PBSC, MUD	C, MTX, Gluc
4	43	F	AML	CR1	BuCyTym	PBSC, MUD	C, MTX, Gluc
5	31	M	AML	CR1	BuCyTym	PBSC, MUD	C, MTX, Gluc

Abbreviations: C= cyclosporine, Tym= tymoglobuline, Gluc=glucocorticoids, MUD=matched unlrelated donor, MTX=methotrexate

Table 2.

Patient No	Onset days post BMT	Hematuria (grade)	Ultrasound	GvHD (type)	GvHD (grade)	Viruria	Antiviral treatment before HBO
1	14	2	Bladder wall thickening	Cutaneous And Gastrointestinal	III	BKV	Cidofovir
2	24	2	Normal	Cutaneous	II	ADV	Cidofovir
3	15	2	Bladder wall thickening	Cutaneous	II	BKV+ADV	Cidofovir+Rybavirin
4	11	3	Bladder wall thickening	Cutaneous	II	BKV+ADV	Cidofovir+Rybavirin
5	55	2	Not performed	None		ADV	Cidofovir

Results: Clinical presentations of 5 patients with haemorrhagic cystitis. The median time to onset of HC after allogeneic stem cell transplantation was 22 days (range, 11-55 days). In one patient, the symptoms did not appear until the day 55 after transplantation. Despite immunosuppressive therapy, all patients had macroscopic hematuria and GvHD. The BKV and ADV DNA were detected in urine and plasma samples in 2 patients, ADV DNA was detected in urine and plasma in 2 other patients, and in the one patient, BKV was detected in both samples, respectively. The patients were treated with HOT (2.5 atmospheres for 60 minutes, 5 days per week) after treatment failure of bladder drainage flow, hyaluronic acid administered intravesically, as well as antiviral treatment. All patients showed complete resolution of hematuria and eradicaton of the virus after a median of 13 sessions (range, 11-30) of HOT.
Summary and Conclusions: Hyperbaric oxygen therapy may be an alternative and promising therapy in the treatment of severe hemorrhagic cystitis.

PB2040

THE IMPACT OF INDUCTION THERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA ON TREATMENT OUTCOMES: A SINGLE CENTER EXPERIENCE

V.P. Pop[1,*] O.A. Rukavitsin[1], S.V. Shamansky[2]
[1]Federal State Budgetary Institution Main Military Clinical Hospital named after ac. N.N. Burdenko of the Ministry of Defense of the Russian Federation, [2]Federal State Budgetary Scientific Institution Russian Cancer Research Center named after N.N. Blokhin Russian Academy of Medical Sciences, Moscow, Russian Federation

Background: Treatment of symptomatic multiple myeloma (MM) in patients (pts) eligible for ASCT is a main approach, which can lead to a complete eradication of the tumor, improving or deepening of response, as well as increased survival rates.
Aims: The primary aim was to assess whether induction therapy and ASCT was associated with improved results on anti-tumor response and overall survival (OS). We also evaluated the impact of renal impairment and advanced stage of MM on OS in pts that underwent of ASCT.
Methods: The study included a cohort of pts with MM who underwent of ASCT for the period from 2001 to 2014. Induction therapy prior to ASCT included VAD-regimen and bortezomib-containing regimens with subsequent high-dose cyclophosphamide therapy. OS and progression free survival (PFS) estimated by the Kaplan-Meier method.
Results: The analyzed group consisted of 71pts with primary diagnosed MM (48 males/23 females; mean age 53.1 yrs (range 34-69). IgG MM was diagnosed in 39pts (55%), IgA MM in 13 (18%), Bence Jones myeloma in 16 (23%), primary plasma cell leukemia in 3pts (4%). In accordance with clinical stage, (Durie B.G.M. and Salmon S.E.) pts were distributed as follows: IA-2 (2.8%), IIA-23 (32.4%), IIB-2 (2.8%), IIIA-21 (29.6%), IIIB-22 (31%). Induction therapy was VAD in 28pts (39.4%), bortezomib (VDD, VD) in 40 pts (56.4%), and VAD-like and VD in 3 pts (4.2%). The median of follow-up was 26.7m (3.1-126.2m). The cohort studied performed 83 ASCT. 12pts received 2 ASCT including planned tandem ASCT (n=6) and 2nd ASCT due to progression (n=6). Before the 1st ASCT complete response (CR) was observed in 21pts (29.6%) including 8 stringent CR, which was preserved when restaging after 3m. We identified improving the quality of response from a very good partial response (VGPR) and partial response (PR) to CR in 16 (37.2%) of 43pts after ASCT. 5pts with stable disease (SD) reached VGPR and PR. Of the 2pts transplanted in early biochemical relapse, 1 was reached CR, and the 2nd developed clinical relapse. Before the 2nd planned tandem ASCT performed with an interval of 3m (2-5m), in 3 of 6pts were reported CR, which hasn't changed during 3m. Of the remaining 3pts the achieved VGPR and CR preserved in 2pts. VGPR and PR was noted before the 2nd ASCT after relapse/progression in 5pts; 3m later 1 patient achieved CR, and 4pts showed no change. A patient with signs of disease progression after the 2nd ASCT achieved SD. The impact of induction therapy (with or without bortezomib) did not affect the results of survival (P=0.57). Renal impairment and advanced stage of MM as a poor prognostic factors also had no effect on the survival rate after ASCT (P=0.1). PFS and OS after ASCT (n=71) was 19.6m and 45.2m, respectively. OS from the diagnosis of MM was 58.5m. OS after 1st-line therapy (n=62) was 69m compared to 29m after 2nd-line (n=9), P=0.02. Median PFS after the 1st and 2nd line therapy did not differ (P=0.14). OS was significantly greater in the group of pts with CR after induction therapy (n=21) than with PR (n=43): 94 m vs 43 m, P=0.04. PFS for pts with CR before transplantation also exceeded PFS in pts with PR (34m vs 16m, P=0.05).
Summary and Conclusions: The depth (degree) of response to induction therapy was positively associated with survival rates. ASCT followed by high-dose chemotherapy demonstrated improving responses in a substantial proportion of patients not only after the first ASCT but also after the second ASCT (tandem or due to relapse of MM), which confirms the important role of ASCT. No survival benefit was seen for patients treated with ASCT in different regimens of induction chemotherapy and if they have renal impairment.

PB2041

THE INFLUENCE OF HAPLOTYPE HLA-BW4 IN EVOLUTION AFTER HSCT

D. Bratu[1,*] I. Constantinescu[2], A. Moise[2]
[1]Haematology, [2]Immunogenetics, Clinical Institute Fundeni, Bucharest, Romania

Background: Continuing to study haplotypes of patients like ligands for inhibitories and activatories donors KIR allele in HSCT,it is an evidence that haplotypes can be protective or not against postHSCT complication,like ligand or not.
Aims: Haplotype HLA-BW4 is described in literature like,,bad,, haplotype.We try to demonstrate the influence of this haplotype at patients with acute leukemia after HSCT.
Methods: Eighteen pairs patients-donors are evaluated :patients with acute leukemia,lymphoblastic and non-lymphoblastic and their genoidentics donors.Eleven patients have HLA-BW4 haplotype,seven HLA-BW6(absence of HLA-BW4) Following the impact of inhibitory KIR3DL1 and activatory KIR3DS1 on survival and complication development,we proved the protective effect of absence of HLA-BW4 haplotype,HLA-BW6,respectively.The source of HSCT was PBSC.The method used was PCR-SSP (Innotrain DIAGNOSTIK GMBH,Dynal BIOTECH PEL-FREEZE)The complications like graft *versus* host disease acute and chronic,relapse,TMA and the recovery with leucocytes and thrombocytes are followed
Results: Absence of HLA-BW4 haplotype(HLA-BW6,respectively) is protective for both types of leukemia,the patients survival is 100% in presence of KIR3DS1(activatory allele) and with statistical significance (sig<0,05) and 83% in presence of KIR3DL1(inhibitory allele) Is protective against relapse, TMA, aGVHD, leucocytes and thromboytes recovery,with statistical significance in presence of KIR3DS4,and also in presence of KIR3DL1 is protective against aGVHD,TMA and relapse,also thrombocytes recovery,without statistical significance.
Summary and Conclusions: Absence of HLA-BW4 improve survival and protect against most complication at patients with acute leukemia and related donors with 100% allele match,in presence of both types of KIR alleles and confirme the "missing " ligand theory.

PB2042

MATCHED UNRELATED DONOR HAEMATOPOIETIC STEM CELL TRANSPLANTATION OFFERS LONG-TERM SURVIVAL IN ABOUT HALF OF ADULTS WITH HAEMATOLOGICAL MALIGNANCIES. THE GREEK EXPERIENCE.

D. Karakasis[1,*] I. Batsis[2], F. Panitsas[1], V. Pardalis[1], Z. Bousiou[2], E. Xenou[1], S. Karakatsanis[1], M. Linga[3], P. Kalogiannidis[2], A. Xirokosta[1], A. Kaisari[1], D. Mallouri[2], E. Triantafyllou[3], E. Giannaki[2], A. Loidoris[1], M. Bouzani[1], C. Smias[2], I. Markou[1], J. Apostolidis[1], S. Gigantes[1], A. Spyridonidis[3], I. Sakellari[2], I. Baltadakis[1], A. Anagnostopoulos[2], N. Harhalakis[1]
[1]BMT Unit, Evangelismos Hospital, Athens, [2]BMT Unit, Papanikolaou Hospital, Thessaloniki, [3]BMT Unit, University Hospital Patras, Patras, Greece

Background: Allogeneic haematopoietic stem cell transplants (HSCT) are steadily increasing in number due to the enhanced availability of matched unrelated donors (MUD) over the last decade. The results of MUD-HSCT have improved considerably, mainly due to the introduction of high-resolution molecular HLA typing for donor selection. Currently, more than 50% of allogeneic HSCT are done with MUD worldwide.
Aims: The aim of this study is to retrospectively analyze the outcomes in a cohort of adult patients, who underwent MUD-HSCT for hematological malignancies at three major transplant centers in Greece.
Methods: From 01/2001 until 12/2013, 331 patients (M/F: 197/134) underwent MUD-HSCT for acute myeloid leukemia (n= 148), acute lymphoblastic leukemia (n= 74), non-Hodgkin's lymphoma/chronic lymphocytic leukemia (n=28), myelodysplastic syndrome (n=26), chronic myeloid leukemia (n=21), Hodgkin's lymphoma (n=20), myelofibrosis (n=7), or other haematological malignancies (n=7). The median age of patients was 40 (range, 14-66) years. Median time from diagnosis to transplantation was 13 (range, 2-235) months. Disease Related Index (DRI) was low, intermediate or high/very high in 11%, 66% or 23% of cases, respectively. EBMT risk score was ≤3 in 38% and ≥4 in 62% of patients. The comorbidity-age index was ≤1 in 58.4%, and ≥2 in 41.6% of recipients. The conditioning regimen was myeloablative in 252 (76%) or reduced intensity in 79 (24%) of procedures. Peripheral blood was the source of graft in 92% of cases. Donor/recipient HLA allele match at HLA-A, -B, -C and -DRB1 loci was 8/8, 7/8 or<7/8 in 51%, 47% and 2% of cases, respectively. *in vivo* T cell depletion with antithymocyte globulin or alemtuzumab was performed in 58% of cases. The combination of tacrolimus and methotrexate was used for GvHD prophylaxis in 234 (71%) patients.
Results: Engraftment was achieved in 97% of patients. The incidence of acute and chronic GvHD was 42.5% and 55.5%, respectively. The cumulative incidence (CI) of treatment related mortality (TRM) was 26% and 33% at 1 and 3 years post transplant, respectively. CI of relapse was 25%. With a median follow-up of 36.5 months, 3-year event free survival (EFS) and overall survival (OS) were 44% and 47%, respectively. The major prognostic factors for OS in multivariate analysis were EBMT score (≥4 vs. ≤3, 37.4% vs. 64.1%, HR: 2.32, P<0.001), comorbidity-age index (≥2 vs. ≤1, 32.6% vs. 59.7%, HR 1.81, P<0.001), DRI (high/very high vs. intermediate/low, 26.3% vs. 54.3%, HR: 1.79, P<0.004) and HLA match (≤7/8 vs. 8/8, OS 40% vs. 56.1%, HR: 1.68, P<0.002).
Summary and Conclusions: MUD-HSCT is an effective therapeutic option for adults with haematological malignancies, and offers long-term survival in about half of them. Apart from age and comorbidities, the outcome greatly depends on HLA match and disease stage at transplant. Therefore, timely referral of patients for MUD-HSCT early in the course of disease may further improve the results.

PB2043

COMPARISON OF ORAL BUSULFAN (BU) AND INTRAVENOUS BU THERAPY FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR HEMATOLOGICAL MALIGNANCY IN CHILDREN AT A SINGLE INSTITUTION

K. Isobe[1,*] K. Koh[1], Y. Ikeda[1], C. Oyama[1], T. Aoki[1], Y. Kubota[1], M. Mori[1], Y. Arakawa[1], R. Hanada[1]
[1]Hematology / Oncology, Saitama Children's Medical Center, Saitama, Japan

Background: Busulfan (BU) is a frontline agent in the hematopoietic stem cell transplantation (HSCT); however, severe complications including sinusoid obstructive syndrome (SOS) have been reported, particularly with oral administration. Since intravenous BU (i.v. BU) was introduced in 2006, some reports have demonstrated i.v. BU reduces hepatic complication such as SOS and treatment related mortality in adults. However, there have been few studies in pediatric populations comparing i.v. BU and oral BU (p.o. BU).
Aims: The purpose of this study was to determine the efficacy and safety of i.v. BU in children.
Methods: We retrospectively analyzed 38 cases of hematological malignancy in which HSCT was performed with myeloablative dose of BU between January 2000 and March 2014.
Results: Twenty-six cases received p.o. BU and 12 cases received i.v. BU. The median age at HSCT was 5 years (range, 3months-17 years). The median overall follow up was 777.5 days (range,7 -4893 days), 1400 days (range, 7-4893 days) in the p.o. BU group, and 459.5 days (range, 33-2360 days) in the i.v. BU group. Diagnosis of hematological malignancies were as follows: 11 AML, 10 ALL (5 infan) and 5 others in the p.o. BU group, and 10 ALL (4 infant) and 2 others in the i.v. BU group. Disease status at HSCT with BU were as follows: 14 cases (36.8%) were CR1 overall, 11 cases (42.3%) in the p.o. BU group, and 3 cases (25%) in the i.v. BU group (P=0.32). Overall survival (OS) at 1 year was 52.5% overall, 56% in the p.o. BU group, and 50% in the i.v. BU group (P=0.83). Event free survival (EFS) was 35% overall, 42.8% in the p.o. BU group, and 33.3% in the i.v. BU group (P=0.35). Relapse rates at 1 year were 27.5% overall, 21.4% in the p.o. BU group, and 41.7% in the i.v. BU group. Non relapse mortality at 1 year was 26.3% over all, 26.9% in the p.o. BU group, and 25.0% in the i.v. BU group. SOS occurred in 6 cases (15.8%) overall, 4 (15.4%) in the p.o. BU group, and 2 (16.7%) in the i.v. BU group (P=0.92). Adverse events above grade 3 included pulmonary complications such as interstitial pneumonia is 3.8% (2/26) in the p.o. BU group, while 50% (6/12) in the i.v. BU group. We also analyzed OS and EFS, cumulative incidence of relapse, non-relapse mortality of patiens with no prior HSCT (n=23) in this cohort. There were no statistically significant differences in OS, EFS, cumulative incidence of relapse or non-relapse mortality between p.o. BU (n=16) and i.v. BU (n=7) among patients with no prior HSCT.

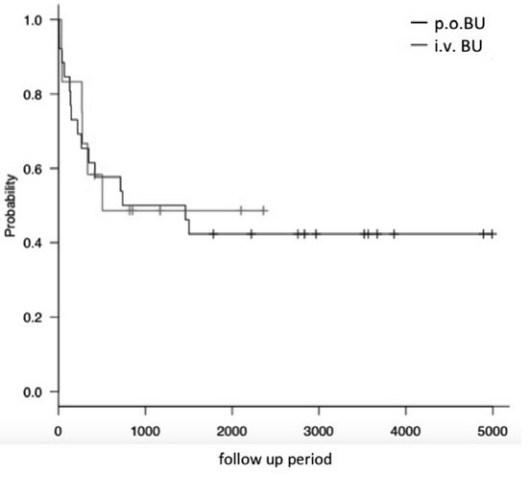

Figure 1.

Summary and Conclusions: In summary, our analysis demonstrated no difference in OS and EFS at 1 year or probability of SOS between myeloablative i.v. BU and p.o. BU doses for the treatment of hematological malignancies. Recent reports have demonstrated i.v. BU can improve the outcome following HSCT in adult. However, retrospective analysis of a large number of pediatric HSCT cases in Japan found no significant benefit of i.v. BU on the survival probability (M Kato *et al.*Biol Blood Marrow Transplant 2013; 19: 1690-1694). Our study corroborated these result; however, this was a retrospective study with different patients backgrounds. These are the major limitations of this study. In terms of adverse events, pulmonary complication was more frequent with i.v. BU than that with p.o. BU. This result may be due to the proportion of infantile cases at a high risk of pulmonaly complications with BU included in this study. Although i.v. BU is considered the gold-standard, i.v. BU does not confer benefit on survival probability and is still associated with severe complications including SOS and interstitial pneumonia. It is important that complications arising from the use of i.v. BU are fully elucidated by long term observational studies and the accumulation of evidence regarding the outcomes following i.v. BU use.

PB2044

THE NUMBER OF ANTI-MYELOMA DRUGS IN PRIOR TREATMENT REGIMENS DOES NOT NEGATIVELY AFFECT THE SUCCESS OF AUTOLOGOUS CD34+ HEMATOPOIETIC STEM CELL MOBILIZATION

M.I. Pereira[1,*] M. Santos[1], A.L. Pinto[1], L. Ruzickova[1], A. Roque[1], R. Tenreiro[1], D. Mota[1], A.S. Batista[1], A. Ribeiro[1], J.P. Carda[1], C. Geraldes[1], E. Cortesão[1], A. Espadana[1], L. Ribeiro[1],
[1]Clinical Hematology Department, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Post-induction Autologous Hematopoietic Stem Cell (HSC) Transplantation (aHSCT) remains the standard of care for multiple myeloma pts (MM) who are fit enough to tolerate it. Although treatment guidelines favour transplantation after induction, recent drug developments have lead to prolonged survivals and the ability to salvage patients who were not transplanted at diagnosis, and who now present at aHSCT Centers, referred from hospitals with differing practices regarding the timing for autologous HST and the protocols used. While it is known that prior treatment can adversely affect the success of HSC collection, consensus is lacking on whether this is only due to the myelotoxicity of the drugs used, or also to the type of regimen chosen.
Aims: We aim to clarify the influence of the type of prior antimyeloma regimens on the success of HSC collection in a real world sample of newly-diagnosed and previously treated patients (pts).
Methods: We analysed 96 MM pts undergoing their first aHCT. HSC collection success was evaluated by the number of peripheral blood autologous CD34+ cells ("PB CD34"), per kilogram, available for infusion at the first transplant ("Number of Cells").
Results: The median overall survival was 104.5 m after a median follow-up of 59.1 m. Overall, 68.8% of pts underwent their first aHSCT after 1st line therapy, 23.9% after 2nd line and the remaining 7.3% after 3rd line or greater. The mean Number of Cells infused was 3.4±1.9x10^6, 3.3±1.7, and 2.6±0.7, respectively, P=0.05. The regimens received prior to apheresis ranged from doublets up to seven-drug associations (VBMCP/VBAD), and included alkylator-, bortezomib, IMID- and anthracycline-based therapies. Considering pts undergoing aHSCT after 1st line, 40.9% were treated with doublets, 47.0% with triplets and 12.1% with associations of ≥4 antimyeloma agents. Pts receiving doublets were transplanted with a larger number of PB CD34 cells (4.1±2.6 vs 3.0±1.1x10^6, P<0.001), compared to pts receiving ≥3 drug-associations. Within the same cohort, the 57.6% who were treated with alkylator-based regimens were transplanted with a lower Number of Cells than pts treated with alkylator-free protocols (3.0±1.0 vs 4.1±2.6x10^6, P<0.001). In contrast, neither the presence of anthracyclines nor of bortezomib in the 1st line regimen influenced the success of apheresis; the 21.1% of pts treated with anthracycline-based regimens were infused with 4.1±1.7x10^6 cells vs 3.3±1.9 (P=NS) in pts without anthracyclines; the 74.2% of pts treated with bortezomib-based regimens received 3.4±2.0x10^6 cells vs 3.8±1.7 (P=NS) in pts without bortezomib. Only 7.6% of pts received one of the IMIDs at 1st line in our cohort, limiting our analysis. We found that 0% of doublet-regimens included alkylators, compared to 96.8% of triplets and 100% of ≥4 drugs (P<0.001). Taking this into account, after multivariate analysis the number of drugs used lost its predictive value, while only the presence of an alkylator maintained its effect over the success of HSC collection.
Summary and Conclusions: We found that the presence of an alkylator in the 1st line regimen negatively impacted HSC collection success, as expected from its myelotoxic effects. Neither the anthracyclines nor proteasome-inhibitors influenced the success of HSC collection. While there was a significant difference favouring the use of doublets prior to apheresis, this was due to the higher likelihood of the inclusion of an alkylator in higher-number drug-associations. Our results support the option of saving alkylators for advanced-lines of treatment, in pts who have not yet undergone HSC collection.

PB2045

HIGH INCIDENCE OF NEUROLOGICAL COMPLICATIONS IN SICKLE CELL DISEASE UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: EARLY DIAGNOSIS CAN CHANGE THE PROGNOSIS

R. Helman[1,2,*] J. Fernandes[1], M. Diniz[1], F. Kerbauy[1], L. Kerbauy[1], E. ChapChap[1], M. Brumati[1], N. Halley[1], A. Azambuja[1], J.M. Kutner[1], A. Ribeiro[1], N. Hamerschlak[1]
[1]Hematology, Hospital Israelita Albert Einstein, [2]Hematology, Santa Casa São Paulo, Sao Paulo, Brazil

Background: Hematopoietic stem cell transplantation (HSCT) was offered primarily as a therapeutic option for severe sickle cell disease in the context of myeloablative matched sibling donor transplants over the last two decades and helped to establish the benefits of transplantation for this disorder. In recent years, the transplant community has set out to explore ways to make stem-cell transplantation more available to patients with the disease, define indications and better timing, and offset toxicities with novel approaches to conditioning and better supportive care. In this context, neurological complication such as stroke and blood flow alterations in cerebral artery constitute the main indications of HSCT but neurological complications are the main causes of TRM in D+100 and is important to find ways to prevent this problem.
Aims: Describe early neurological complications in sickle cell patients undergoing related HSCT on single center and its following after the early diagnosis.
Methods: Seven patient undergone related HSCT for sickle disease from 2011 to 2013. All patients filled inclusion criteria in the study and signed agreement term. Seven HSCT were developed in the period, being four males. The aver-

age age was 13 years old (7-24). The HSCT indications were previous stroke, cerebral flow alteration on Doppler, acute chest syndrome and alloimunization. All patient were on blood transfusion therapy. The conditioning regimen was BuCy + ATG and the GVHD prophylaxis was MTX and CSA. Related donors were chosen with 10/10 HLA match and graft source marrow

Results: The median of the neutrophil engraftment was D+ 25 and the platelets engraftment was in D+60. Two patient died, one by intestinal and liver GVHD on D+120, and another with sagittal sinus thrombosis and hemorrhagic stroke on D+3. Other two patients showed PRES syndrome related to cyclosporine use. The patients showed generalized seizures with tomographic neurological alteration. After the imunossupressor change to tacrolimus and the change of Phenytoin to Lamotrigine, the patient had total resolution of neurological complications without development of neurological sequelae. Patients who used Lamotrigine since the beginning of the conditioning have not shown neurological alterations.

Summary and Conclusions: The PRES Syndrome and Stroke are two of the main causes of mortality related to the use of calcineurin inhibitors. Patients with sickle disease have shown endothelial and cerebral microcirculation changes, which made them highly susceptible to neurological complication. The control of blood pressure, maintenance of 50.000 platelets level and the use of Lamotrigine as prophylaxis of seizures seems to decrease the risk of neurological complications. Prospective studies with lamotrigine as primary prevention of PRES Syndrome must be performed. Patients with severe neurological alteration as vessels stenosis more than 90% and Moya-Moya Syndrome must be better evaluated before the conditioning because of high TRM risk.

PB2046

THE COMPARISON OF LENOGRASTIM AND FILGRASTIM IN ALLOGENEİC STEM CELL TRANSPLANTATİON: EFFECTS ON BONE MARROW STEM CELL PRİMİNG

A. Fettah[1,*] N. Özbek[1], F. Azik[1], B. Tavil[1], M. Ozguner[2], Z. Avcı[1], P. Isik[1], N. Yarali[1], D. Uckan[1], B. Tunc[1]
[1]Pediatric Hematology and Bone Marrow transplantation Unit, [2]Stem Cell Research Laboratory, Department of Pediatric Hematology, Ankara Children's Hematology and Oncology Research Hospital, Ankara, Turkey

Background: Hematopoietic stem cell transplantation from HLA-matched siblings improved long-term survival of the children with hematologic malignancies and bone marrow failure syndromes.Recombinant human granulocyte colony stimulating factor (G-CSF) is used to mobilize hematopoietic stem cells for allogeneic and autologous hematopoieitc stem cell transplantation.

Aims: In this study, we aimed to compare the efficacy profile of different G-CSF agents including biosimilar filgrastim (Leucostim®) and lenograstim (Granocyte®) on bone marrow stem cell mobilization in healthy donors

Methods: A total of 29 healthy donors were enrolled in the study and analysed retrospectively. Fifteen donors received biosimilar filgrastim and fourteen donors received lenograstim. The dose and duration of G-CSF treatment was 10 μcgr/kg/dose for 3 days and similar between two groups. Post-G-CSF white blood cells, harvested stem cell volume, number of total nucleated cells (TNC) and CD34+ cells, CFU-GM colony number has been compared between biosimilar filgrastim and lenograstim groups.

Results: There were 16 (55.2%) male and 13 (44.8%) female donors. The median age and body weight of donors was 12.5±10.2 years and 37.1±19.3 kg respectively. The median number of post G-CSF white blood cells ($x10^3$/μL) [32.6 (28-41.2) vs. 37.3 (25.7-40), P=0.663], harvested total stem cell volume (cc) [437 (385-850) vs. 643 (324-1018), P=0.694], number of total nucleated cells($x10^8$/recipient kg) [6.4 (5.1-8.7) vs. 7.1 (5.1-8.6), P=0.861], CD34+ cells (μL) in the harvested stem cell [183 (104-272) vs. 160 (93-259), P=0.801], number of CD34+ cells ($x10^6$/recipient kg) [3.1 (2.1-5.2) vs. 2.6 (2.3-5.5), P=0.930], CFU-GM colony number ($x10^4$/recipient kg) [13.2 (8-15.4) vs. 14.1 (9.8-25.6), P=0.538] were similar between filgrastim and lenograstim groups.

Summary and Conclusions: In conclusion, the current retrospective study shows that biosimilar filgrastim and lenograstim are similar in terms of efficacy for the mobilization of bone marrow hematopoietic stem cells in healthy donors.

PB2047

FACTORS RELATED TO THE FINAL NUMBER OF CD34+ CELLS OBTAINED BY APHERESIS FOR AUTOLOGOUS STEM CELL TRANSPLANTATION: EXPERIENCE IN 181 CONSECUTIVE PROCEDURES IN A SINGLE CENTER

B. Soria[1,*] A. Martín-Martín[1], J. Rodríguez-López[1], C. De Bonis[1], A. Iglesias[1], J. Mesa[1], M. Tapia[2], M.T. Hernández-García[1], J.M. Raya[1]
[1]Hematology and Hemotherapy, Hospital Universitario de Canarias, La Laguna, [2]Hematology and Hemotherapy, Hospital General de La Palma, Santa Cruz de La Palma, Spain

Background: The successful mobilization of hematopoietic progenitors (CD34+) for autologous stem cell transplantation has been associated with the number of cycles of previous chemotherapy (CT), recent administration of CT (<3 months), prior use of purine analogs or alkylating agents, radiotherapy, age, marrow involvement by the disease, and leukopenia or thrombocytopenia before mobilization.

Aims: Our objective was to analyze our experience on CD34+ cell collection by apheresis in the past 5 years, focusing in what factors are implicated in a better or worse final product.

Methods: We retrospectively analyzed all consecutive mobilization procedures performed in our department between 2009 and 2014. Analyzed data included: age, sex, underlying desease (acute leukemia, plasma cell neoplasm, small cell NHL, aggressive NHL, Hodgkin's lymphoma or solid neoplasm), type of used G-CSF (filgrastim, biosimilar filgrastim or lenograstim), type of mobilization (G-CSF alone, associated with cyclophosphamide or mega-CHOP CT, or disease-specific CT), number of previous CT lines, prior radiotherapy or purine analogs or alkylating agents, marrow involvement at diagnosis, percentage of CD34+ cells and CD34+ cells/μL in blood just before apheresis, and CD34+ cellsx 10^6/kg at the final product. For statistical analysis (SPSS adapted to Windows) we used the Pearson correlation coefficient, ANOVA and Tukey HSD test for multiple comparisons.

Results: We studied 181 patients, mean age 51 years (range 3-71) and 64% males. We found that the type of G-CSF, the number of previous lines, the use of purine analogs or alkylating drugs, and marrow involvement at diagnosis did not influence significantly in the final number of CD34+ cells obtained. In the other hand, we observed a tendency to a poorer final product in older patients (P=0.09) or when there was a history of radiotherapy (P=0.062). Significantly, the richest final product was achieved in patients with Hodgkin's disease compared with poorer in those affected of acute leukemia, plasma cell neoplasm or small cell NHL (P=0.012). Similarly, a higher number of CD34+ cells were collected in patients mobilized with disease-specific CT, compared with the other types of mobilizations (P=0.006). Finally, as expected, the pre-apheresis mononuclear cells and CD34+ cell percentages, and circulating CD34+ cells/μL, were directly related to the achieved final product (P=0.004, P<0.001 and P<0.001, respectively).

Summary and Conclusions: In our experience, the factors that most influenced the amount of CD34+ cells harvested by mobilization and apheresis, are the type of hematologic disease (from most to least favorable: Hodgkin's disease, solid tumors, aggressive NHL, small cell NHL, plasma cell neoplasms and acute leukemia) and type of mobilization scheme used (the best product was obtained with disease-specific CT, and worst with G-CSF alone). To a lesser extent, the patient's age and history of radiotherapy may also influence the final product.

PB2048

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION USING FLUDARABINE, MELPHALAN, TOTAL BODY IRRADIATION AS REDUCED-INTENSITY CONDITIONING REGIMEN FOR MYELOID MALIGNANCIES IN A SINGLE INSTITUTION.

T. Nemoto Anan[1,*] R. Watanabe[1], T. Tomikawa[1], M. Sagawa[1], T. Tabayashi[1], Y. Kimura[1], Y. Takahashi[1], M. Tokuhira[1], M. Kizaki[1]
[1]Department of Hematology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan

Background: Traditional transplant conditioning regimens have a limiting factor regarding co-morbidities or old age. Therefore, reduced intensity conditionig (RIC) regimens have been increasingly used since RIC regimens have lower rates of severe toxicity. Although RIC regimen for allogeneic hematopoietic transplants (allo-SCT) have become common usuful strategy for high risk myeloid malignancy, optimal conditioning regimen has not been established.

Aims: To define the role of RIC and MAC condition for patients with myeloid malignancy.

Methods: We retrospectively compared long-term outcomes of 38 consecutive transplants for adult patients with high-risk myeloid malignancy. Fifteen out of 38 patients who were older age (□55 year-old) or unfit received RIC regimen consisting of fludarabine (125mg/m2), melphalan (80mg/m2) and total body irradiation (TBI) (4Gy). Twenty-three patients received MAC regimens containing TBI (12Gy). All transplants received uniform strategy of graft *versus* host disease (GVHD) prophylaxis.

Results: All patients achieved engraftment in RIC comparing with 2 patients were engraftment failure in MAC. High level of treatment related toxicities was observed in patients with MAC rather than RIC. Compared with MAC, relapse rate was higher in RIC. Overall 2-year survival rate and relapse free survival were 42.3%, 36.7% in RIC and 43.5%, 39.1% in MAC respectively. Grade III to IV of acute GVHD were occured 6.6% in RIC and 30.4% in MAC, chronic GVHD were appeared 46.6% in RIC and 34.7% in MAC. In unitivariate analysis, good performance status (PS) and disease status CR, In multivariate analysis, disease status CR was the only prognostic variable for prolonged OS in high risk myeloid malignancy.

Summary and Conclusions: Our retrospective study, RIC was feasible and survival benefit was obtained in same level MAC. Lower tumor burden before transplantation but not conditioning intensity nor patient age intensity influenced longer survival. Although our study was small size of patient population, larger prospective randomized study should be required.

PB2049

EFFICACY OF COMPLEMENT MODULATING THERAPIES IN ALLOGENEIC STEM CELL TRANSPLANTATION ASSOCIATED THROMBOTIC MICROANGIOPATHY

I. Herraez[1,*] L. Bento[1], A. Sampol[1], A. Gutierrez[1], A. Novo[1], C. Ballester[1], L. Garcia[1], J. Besalduch[1]
[1]hematology, hospital son espases, palma de mallorca, Spain

Background: Thrombotic microangiopathy (TMA) is a rare but potentially devastating complication of allogeneic stem cell transplantation (allo-SCT). Its pathophysiology remains poorly understood. Mechanisms associated with TMA include loss of endothelial cell integrity induced by intensive conditioning regimens, immunosuppressive therapy, irradiation, infections or graft-*versus*-host-disease (GVHD). Management and treatment strategies of MAT remain challenging. Strategies as the discontinuation of calcineurin inhibitors or plasma exchange have limited efficacy. Eculizumab could be a promising complement targeting therapy for allo-SCT associated TMA.
Aims: To describe our experience with eculizumab in two cases of TA-TMA.
Methods: Post-allo-SCT TMA was diagnosed according to diagnostic criteria (International Working Group Definition for TMA (2007)). All patients received Tacrolimus (T) and Sirolimus (S) as immunosuppressive therapy. ADAMTS13 and serum C3 complement were analysed in all patients.
Results: 2 patients with TA-MAT are described: Case 1: 53 year old woman diagnosed with refractory Hodgkin Lymphoma who underwent allo-SCT from a sibling donor. TA-TMA was diagnosed on day +34 post-allo-SCT. This patient had a severe kidney injury and neurologic disfunction and the blood tests confirmed an overdose of inmunosupressives. TMA treatment consisted in S and T withdrawal and plasma exchange with no response. ADAMTS13 was normal and serum C3 level was low. Induction therapy with 4 doses of Eculizumab was initiated with resolution of renal function and improvement of hemolysis parameters. Due to the excellent response we did not complete the maintenance treatment. Case 2: 52 year old woman diagnosed with AREB-II who underwent allo-SCT from a sibling donor. TMA was diagnosed on day +26 post-allo-SCT. This patient had a severe kidney injury, alveolar hemorrhage and the blood tests confirmed an overdose of inmunosupressives. ADAMTS13 and C3 were normal. The TMA treatment consisted in S and T withdrawal and plasma exchange with no response. Finally, induction therapy with Eculizumab was initiated. The patient received only 1 dose when normal C3 was confirmed and also because of the good evolution of renal function and hemolytic parameters.
Summary and Conclusions: Allo-SCT associated TMA is an uncommon but devastating complication of HCT. The pathogenesis is unclear. Although T and S have been implicated as risk factors for TA-TMA, there is no solid evidence supporting the discontinuation or dose reduction of these medications. Recently, it has been observed that both the classical and alternative complement pathways may be involved in TA-TMA, supporting the potential use of complement modulating therapies as Eculizumab in patients at highest risk for the worse outcomes. It poses certain challenges such as the reported difficulty of achieving therapeutic levels in critically ill HSCT patients, limited availability in certain countries and significant cost associated with this therapy. We achieved good response with the use of Eculizumab in one patient who had serum C3 low levels. Novel TMA biomarkers, reflecting predisposition for injury to specific organs, need to be identified in order to aid earlier TA-TMA.

PB2050

PULMONARY FUNCTION TESTS (PFTS) PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANT AS PREDICTOR OF PULMONARY COMPLICATIONS AND SURVIVAL IN ADULTS WITH HEMATOLOGICAL MALIGNANCIES

O. Annibali[1,*] F. Chiodi[1], S. Scarlata[2], S. Santangelo[2], C. Sarlo[1], D. Armiento[1], E. Cerchiara[1], S. Ferraro[1], M. C. Tirindelli[1], R. Antonelli Incalzi[2], W. Arcese[3], G. Avvisati[1]
[1]Hematology Unit, [2] Geriatric Unit of Respiratory Pathophisiology, University Campus Bio-Medico Roma, [3]Hematology Unit, University Tor Vergata on behalf of Rome Transplant Network (RTN), Rome, Italy

Background: Autologous Stem Cell Transplantation (ASCT) represents a standard-of-care for Multiple Myeloma patients eligible to receive high-dose chemotherapy, Lymphoma patients undergoing second-line treatments and for a small proportion of Acute Leukemia patients. Although all canditates to an ASCT are carefully evaluated for their eligibility with a complete screening of clinical, laboratory, imaging and functional tests to check comorbidities, global organ function and infections, pulmonary and infective complications are a significant cause of morbidity and mortality after ASCT. However, the relationship between pre-transplant Pulmonary Function Tests (PFTs), development of post-ASCT complications and mortality is unknown.
Aims: The aim of this study was to evaluate the role of pre ASCT PFTs on post-ASCT complications and mortality
Methods: We collected data for 88 patients undergoing ASCT between March 2008 and February 2015 in our Institution. Complete PFTs were obtained in 62 patients (74% males; median age 57 yrs, range, 18-69): Multiple Myeloma n=44, Non-Hodgkin Lymphoma n=18, Hodgkin Lymphoma n=4, Acute Myeloid Leukemia n=1). ASCT was performed as first line treatment in 42 (67%) patients, after first relapse in 17 (28%) and as salvage treatment after ≥2 relapse in 3 (5%). Previous regimens including drugs known to induce pulmonary toxicity, such as bortezomib and bleomycin had been administered to 34/62 (55%) patients
Results: Of the 62 transplanted patients, 9 (13.4%) had abnormal PFTs at baseline (5 obstructive and 4 restrictive PFTs) and 19 (28.4%) had two or more major chronic comorbidities (metabolic and cardiovascular disease). Infective complications occurred in 40/62 (64.5%) and respiratory complications in 9/62 (14.5%) cases. After a median follow-up of 25 months (range, 4-111), 48 out of 62 patients (77,4%) are alive. Post-ASCT respiratory complications were significantly higher (97% vs 83%; P=0.05) in patients with reduced pre-ASCT FEV1.
Summary and Conclusions: To reduce the risk of respiratory complications after ASCT, these patients might benefit from the use of a reduced intensity conditioning.

PB2051

COMPLETE RESOLUTION OF EXTENSIVE CHRONIC GRAFT-VERSUS-HOST DISEASE WITH IBRUTINIB

R. Kamble[1,*] G. Obi[1], A. Schollof[1], G. Carrum[1]
[1]Hematology Oncology, CAGT Baylor College of Medicine and Houston Methodist Hospital, Houston, United States

Background: Chronic graft *versus* host disease (cGvHD) is mediated donor T cells. The role of B cells in the pathogenesis of cGvHD is increasingly recognized. Two murine studies have explored the role of ibrutinib in cGVHD-like syndromes, one in which there is T cell driven sclerodermatous cGvHD and a second in which there is Ab driven multiorgan system cGvHD that includes bronchiolitis obliterans.
Aims: We herein document a complete response of extensive chronic graft-*versus*-host disease (cGvHD) to a Bruton's tyrosine kinase (BTK) inhibitor, ibrutinib.
Methods: Following approval from Institute Review Board, patient disease and transplant related variables were studies in a single patient who received Ibrutinib for post- allogeneic transplant relapse of mantle cell lymphoma (MCL). NIH criteria for cGvHD diagnosis and staging were followed for disease assessment.
Results: A 41 years old female with primary refractory MCL underwent mismatched unrelated donor allogeneic hematopoietic stem cell transplantation in December 2011 (ablative conditioning with CY/TBI and alemtuzumab, graft=6.6x 106/kg CD-34+ cells, tacrolimus alone for GVHD prevention). Following engraftment on day 11, she developed grade III acute GvHD involving the skin and gut on day 17 of transplantation that persisted beyond 100 days post-transplant. Her cGvHD was treated with steroids, but remained active and extensive. Despite persistent cGvHD and 100% donor chimerism she relapsed in July 2012. Treatment with radiation, bendamustine and rituximab failed. By December 2013, the patient had extensive cGvHD manifesting as scleromatous skin thickening, oral ulcers and sclerosis of the buccal mucosa, ocular dryness and diarrhea, and was started on ibrutinib[1] 560 mg once daily for relapsed MCL. After 8 weeks of therapy, cGvHD had begun to improve. Oral steroids were reduced and ultimately stopped after 26 weeks of ibrutinib; after 30 weeks treatment all cGvHD manifestations resolved completely. A complete remission for MCL was documented at 8 weeks of ibrutinib initiation. Currently she continues to be on 560 mg daily ibrutinib without cGvHD exacerbation or MCL relapse for 22 weeks and 52 weeks, respectively.
Summary and Conclusions: Our report provides the evidence for BTK inhibition led complete cGvHD resolution and supports exploration of its role in future clinical trials.

Stem cell transplantation - Experimental

PB2052

RIC WITH BUSILVEX 4 DAYS OF ONCE-DAILY 100MG/M² WITH FLUDARABINE AND ANTITHYMOCYTE GLOBULINS PRIOR TO ALLOGENEIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH RISK HEMATOLOGICAL MALIGNANCIES.

J. Elcheikh[1,*] A. wanquet[1], R. crocchiolo[1], S. furst[1], A. granata[1], C. faucher[1], R. devillier[1], S. harbi[1], C. lemarie[1], B. calmels[1], R. bouabdallah[1], N. vey[1], P.J. weiller[1], C. chabannon[1], L. castagna[1], D. blaise[1]
[1]Transplantation, Institut Paoli Calmettes, Marseille, France

Background: The optimal intensity of myeloablation delivered as part of a reduced-intensity/toxicity conditioning (RIC/RTC) regimen to decrease the recurrence rate, without increasing non relapse mortality (NRM), remains to be established and the disease control remains a major challenge. The introduction of RTC regimens has allowed allogeneic hematopoietic cell transplantation to be performed in patients who were previously considered too old or otherwise unfit.
Aims: When busulfan Pharmacokinetic is not available the optimal dose is difficult to determine. In this perspective we made the hypothesis that decreasing the daily dose can be safer and efficient in high risk patients.
Methods: We studied the outcome of 27 patients (median age, 50 years; range, 21-65 years) with hematological malignancies were included. The conditioning regimen based on busulfan at a dose of 100 mg/m^2 /day intravenously for 4 days, fludarabine at a dose of 30 mg/m^2 /day for 5 days, and antithymocyte globulins at a dose of 2.5 mg/kg/day for 2 days. Patient, disease and transplant characteristics are shown in Table 1.

Table 1.

	N=27
Sex ratio M/F	15/12
Median age (years)	50
Age < 60years	25 (93%)
Donor	
Sibling	10(37%)
MUD	15(56%)
MMUD	2(7%)
Graft source	
PBSC	23(85%)
Bone marrow	3(11%)
PBSC+BM	1(4%)
Diagnostic	
AML	13(48%)
ALLB (Phi+/Phi-)	8 (30%) (6/2)
ALLT	2(7%)
CML	1(4%)
MDS	2(7%)

Results: No patients experienced graft rejection. The median HCT comorbidity index score was 2 (range, 0 to 5). With a median follow-up of 13 months (range, 3-16months), the cumulative incidences of grade 2 to 4 acute graft-*versus*-host disease (GVHD) and chronic GVHD (all grades) were 43% (95% CI, 26%>60%) and 44% (95% CI, 20%>68%), respectively. The Kaplan-Meier estimates of overall and disease-free survival at 1 year were 63% (95% confidence interval [95% CI], 42%>84%) and 49% (95% CI, 27%>71%), respectively. At 1 year, the cumulative incidence of recurrence/disease progression was 32% (95% CI, 12%>52%). Non relapse mortality (NRM) was 4% and 19% at day 100 and at 1 year respectively. Patient age, diagnosis, donor type, sex, presence of comorbidities, and the Hematopoietic cell transplantation-specific comorbidities index did not appear to have any statistically significant impact on NRM, recurrence/disease progression, disease-free survival, or overall survival.
Summary and Conclusions: This well-tolerated conditioning platform can lead to long-term disease control The RTC regimen used in the current study appeared to be safe, with a low NRM rate at 1 year noted among high-risk patients, and efficient disease control, warranting prospective phase 3 trials.

VENOUS THROMBOEMBOLISM (VTE) IN CHILDREN WITH CANCER AND HEMATOLOGICAL DISORDERS; 16 YEARS OF EXPERIENCE IN A GREEK CENTER

M. Ampatzidou[1,*] H. Pergantou[2], H. Platokouki[3], H. Papachristodoulou[1], V. Dendrinos[1], E. Rigatou[1], L. Petrikkos[1], V. Papadakis[1], S. Polychronopoulou[1]
[1]Department of Pediatric Hematology-Oncology, [2]Hemophilia Center and Hemostasis Unit, "Aghia Sophia" Children's Hospital, [3]"Aghia Sophia" Children's Hospital, Hemophilia Center and Hemostasis Unit, Athens, Greece

Background: Guidelines addressing the management of venous thromboembolism (VTE) in pediatric cancer and hematological patients remain heterogeneous while the identification of independent risk factors for VTE, represents a major challenge that may help in refining prevention and treatment strategies.
Aims: Our aim is to define characteristics, treatment and outcome of pediatric hematology-oncology pts with proven VTE and illustrate possible risk factors and genetic predisposition.
Methods: Data from all pts with benign or malignant hematological disorders and solid tumors consecutively diagnosed and treated at the Department of Pediatric Hematology-Oncology (N=532,1999-2014) have been retrospectively recorded and analysed. Pts with superficial thrombosis were excluded from the study.
Results: In our cohort, a total of 32 pts (median age 5.7 yrs, range 1.1-18.6) developed VTE with the following disease background: acute lymphoblastic leukemia(14), T-lymphoblastic lymphoma(2), RAEB-T/acute myeloid leukemia(1), nephroblastoma(3), neuroblastoma(3), hemophagocytic lymphohistiocytosis(1), autoimmune hemolytic anemia(2) and other rare solid tumors(6). In our cohort, 21 pts had high risk disease features and 6 pts presented with bulky mediastinum involvement. Median time of VTE occurrence from disease diagnosis was 129 days (range 0-4244). 25/32 pts developed DVT during the intensive chemotherapy regimen (16 not in CR). Most commonly used drugs within the last 30 days from DVT diagnosis were Asparaginase and steroids, followed by VCR, MTX, CPM and cisplatin. 13/32 pts had undergone major surgery and no pt received hormone therapy. In 26/32 pts CVL was placed; median time between CVL placement and VTE occurrence was 60 days (range 0-1352). VTE diagnosis was symptom-driven (n=16) or incidental finding (n=16); in 15 pts VTE was CVL-related (4 with infection) and 6 cases presented in tumor adjacent areas. The most common VTE sites were right atrial and jugular veins (16), subclavian veins and superior vena (2), kidney and inferior vena cava (6), pulmonary embolism (2), femoral and iliac vein (3), cerebral sinovenous thrombosis (5) [ischemic cerebral infracts, cavernous sinus (after XRT), upper sagittal and transverse sinus], with some patients presenting with multiple VTE sites. Additionally, 2 pts presented with VOD, as well. WBC or PLTs count at diagnosis did not have a statistically significant impact on the probability of VTE. Thrombophilia evaluation that was performed in 16/32 pts did not reveal an increased incidence of predisposing factors [factor G20210A variant homozygous or heterozygous (1/1), heterozygous MTHFR variant (8), elevated FVIII (7)]. Treatment consisted mainly of sc LMWHs as anticoagulation therapy in 28/32 pts. Median time of treatment duration was 6 months (range 3-12) and was guided by the continuing presence of CVL, CR status and until establishing vascular patency and stable imaging findings. Within a median follow-up time of 33.8 months (range 2.1-195.1) no VTE recurrence occurred while overall survival was 78.12% with morbidity not related to VTE.
Summary and Conclusions: In our study, VTE was not very common among our pediatric haematology-oncology pts and continuation of chemotherapy was feasible in all cases, with no VTE recurrence. Furthermore, thrombophilia evaluation neither revealed an increased incidence of predisposing factors nor altered our therapeutic decisions; thus, extensive baseline screening or DVT prophylaxis are not supported in pediatric pts who can be successfully diagnosed and treated with current recommendations.

PB2054

ARTERIAL ISCHEMIC DISEASE AND CONGENITAL THROMBOPHILIA TESTING IN YOUNG PATIENTS: DO OR NOT DO?

M.M. Moreno Vega[1,*] I. Balda Aguirre[1], T. Molero Labarta[1]
[1]Hematology, Universitary Hospital of Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: Cardiovascular disease (CVD) includes coronary, renal, cerebral and peripheral artery atherosclerosis and ischemia. It may be caused by several cardiovascular risk factors (CVRF), the most are acquired and modifiable like high blood pressure, smoking, diabetes, obesity or high blood cholesterol, and others unchangeable factors like age or family history of premature illness. Many researchs which have investigated association between congenital thrombophilia (CT) and CVD have obtained positive and negative results. In spite of the doubtful utility of CT analysis in these cases, it is not infrequent its request for young patients with CVD.
Aims: Our aim in this research is to assess CT prevalence in young patients (less or equal than 55 years old) with CVD and comparing to observed in patients with venous thrombotic disease with same age and that has been described in general population.
Methods: Sequential and retrospective analytical study of 149 patients (68 men and 81 women) ≤55 years old with arterial isqhemic event in different vascular areas whom were made CT analysis that included: Antithrombin (AT) and functional chromogenic Protein C (PrC), Functional coagulative Protein S (PrS) and immunological PrS; resistance to Activated Protein C and molecular analysis of factor V Leiden (FVL) and Prothrombin G20210A (FIIG20210A) by PCR. Data were taken from database of our Unit.
Results: Mean age at presentation was 42.9 years (18-55). Ischemic location was cerebral in 122 cases, 16 cardiac and 11 peripheral cases. Twelve patients (8%) presented postivie CT: six of them were heterozygous FIIG20210A mutation (4.02%), four heterozygous FVL mutation (2.6%) and one case was positive for type I PrS deficiency (0.67%); a patient presented double thrombophilia (FIIG20210a and PrS deficiency). Eight of twelve patients with TC (66,6%) presented some CVRF and the patient with double thrombophilia was taking oral contraceptives and she was obese, smoker, diabetic and hypertensive. Comparatively, CT prevalence in other previous research of ours about 253 young patients with venous thrombotic disease was 26.8%.
Summary and Conclusions: Congenital thrombophilia prevalence in young patients with CVD is not higher than in general population. Congenital thrombophilia positive result did not trigger any change in therapeutic attitude and it is the reason why its routing testing in arterial thrombosis cases presents little or no use.

PB2055

EFFICACY OF TREATMENT WITH ASPIRIN IN THE PREVENTION OF RECURRENT THROMBOTIC EVENTS

A. García Raso[1,*] M. Carolina[2], S. Monsalvo[3], R. Mata[3], R. Vidal[3], E. Askari[3], P. Llamas[1]
[1]Hematolgy, Health Care Institute Fundación Jiménez Díaz, [2]Hematolgy, Rey Juan Carlos University Hospital, [3]Hematolgy, Fundación Jimenez Diaz University Hospital, Madrid, Spain

Background: The risk of recurrent venous thromboembolism persists for several years after the interruption of anticoagulant treatment. The role of aspirin in the primary prevention of venous thromboembolism has been evaluated by different groups. In these studies, treatment with low-dose aspirin (100 mg / day) was associated with a reduced risk from 20-50%. The benefit of antiplatelet therapy for secondary prevention of VTE was evidenced by the results of WARFASA study.
Aims: To evaluate the efficacy of aspirin for the prevention of recurrent venous thromboembolism after treatment with vitamin K antagonists in an unselected group of patients with VTE.
Methods: 105 patients with VTE referred to the Hematology consultation during last year were included, the mean age of the group was 52.83±18.40 (63.8% were women, n=67). From each patient cardiovascular risk factors and the location of thrombosis were collected. Aspirin administration was decided depending on the presence of cardiovascular risk factors. Aspirin was prescribed in patients with 2 or more risk factors.

Figure 1: Distribution of patients depending on the location of thrombosis.

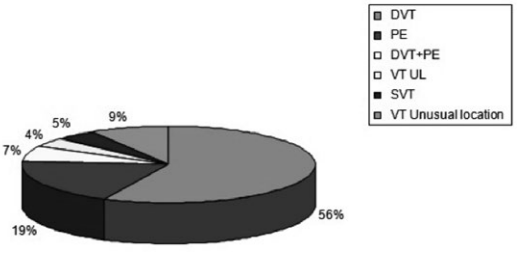

Figure 1.

Results: The characteristics of the population and the result of the comparison of both groups are shown in Table 1. The mean follow-up period after discontinuation of OAT was 35.96±19.49 months, after which 15 cases of recurrent thrombosis (14.3%) and 31 cases of post-thrombotic syndrome (29.5%) were diagnosed. Figure 1 shows the distribution of patients according to the location of the thrombosis. The mean duration of OAT was 12.63±9.79. 87.6% of patients (n=92) were treated with acenocoumarol and 12.4% were treated with LMWH (n=13). Finally, 49 patients were treated with low dose aspirin (46,7%). In this group 20.4% (n=10) patients had recurrent VTE, compared to the patients not prescribed with aspirine 8,9% (n=5) (P=ns). The number of PTS diagnosed was similar in both groups (26.8% (n=15) vs 32.7% (n=16); P=0.6577). VTE Aspirin No aspirin p Age 52,83±18,40 55,45 ±16,06

50,54±20,10 0,1735 Dyslipemia 32,7 (33) 41,7 (20) 24,5 (13) 0,1049 Smoke 24,8 (26) 18,4 (9) 30,4 (17) 0,2327 Obesity 15,2 (16) 16,3 (8) 14,3 (8) 0,9855 Hypertension 26,7 (28) 30,6(15) 23,2 (13) 0,5261 DM 3,8 (4) 6,1 (3) 1,8 (1) 0,3370 CVD 5,0 (5) 6,1 (3) 3,6 (2) 0,0491.

Summary and Conclusions: The results we obtained are consistent with those published in the WARFASA study, although we found no statistically significant difference in the recurrence rate. It would be interesting to extend this study including a larger population and review the selection criteria to choose patients who may benefit with aspirin treatment; and also a prospective analysis of the evolution of the patients treated with low-dose aspirin.

PB2056

RESISTANCE TO ACTIVATED PROTEIN C AS PATHOGENIC MECHANISM UNDERLYING THROMBOSIS ASSOCIATED WITH LUPUS ANTICOAGULANTS

V. Shmeleva[1,*] O. Matvienko[1], V. Kobilanskaya[1], S. Kapustin[2], Y. Namestnikov[1], L. Papayan[1]
[1]Laboratory of Blood Coagulation, [2]Laboratory of Biochemistry, Russian Research Institute of Haematology and Transfusion, St-Petersburg, Russian Federation

Background: Resistance to activated protein C (APCR) is associated with high risk of venous thromboembolism (VTE). After the factor V Leiden (FVL) mutation was found as the main cause of APCR little attention is paid to the role of acquired APCR. An acquired resistance to activated protein C has been previously shown in patients with antiphospholipid antibodies. The Calibrated Automated Thrombography (CAT) is now considered to reflect patients phenotype better than traditional coagulation tests. When thrombomodulin (TM) is used thrombin generation (TG) becomes sensitive to all disorders of the PC system.
Aims: Aim of our study was to evaluate the prevalence of acquired APCR and its reasons in patients with VTE manifestation under the age of 45 years.
Methods: The study involved 35 patients (M/F 15/20, mean age 37,0±9,0 yr) with early manifestation of VTE and 30 controls. All patients received vitamin K antagonists (VKA) treatment at least for 6 months, 18 of them were still on VKA. TG was measured according to Hemker *et al*. with fluorogenic assay, at 5 pM TF and 4 µM phospholipids in platelet poor plasma (PPP) with PPP plasma+/-TM reagent (Thrombinoscope BV, Maastricht, The Netherlands).
Results: Endogenous thrombin potential (ETP) and peak thrombin (PT) were markedly reduced in the presence of TM. None of the patients had increased ETP measured as values above 95th percentile in controls (*i.e.* >2114 nMmin in the absence of TM and >1433 nMmin in the presence of TM). Lupus anticoagulants (LA) were found in 5 patients. From parameters derived from the thrombin generation curves measured both with and without TM significant correlation with LA (P<0,05) was found for lag-time (R=0,45), ETP (R=-0,45) and PT (R=-0,44) both in presence and absence of TM. Normal ranges of ETP and PT inhibition calculated in controls were 21-62% and 14-51% respectively. Values below 21% for ↓ETP and/or 14% for ↓PT (*i.e*. APRC) were found in 20 (57%) of samples. In the studied group 100% of patients with FVL demonstrated APCR phenotype. So, in 50% of cases APCR was due to FVL mutation (10 patients, among them 2 patients with acquired protein C deficiency on VKA treatment). As for the rest 50% of detected APCR cases 25% (5 patients) were associated with LA, 10% (2 patients) with isolated increased FVIII activity, 10% (2 patients) with prothrombin G20210A mutation and increased FVIII activity. The reasons of APCR in the rest 5% of cases need further elucidation. APCR was found in 100% of LA samples. Importantly all these patients had protein C activity within the normal range. Abnormal PT inhibition seemed the most sensitive to detect APCR. Abnormal PT inhibition was found in all patients, contrary to ETP inhibition-50% cases with FVL and 75% with LA.
Summary and Conclusions: In conclusion LA was the most prevalent cause of acquired APCR in our patients. Beta2 glycoprotein I, anti-prothrombin antibodies and lupus anticoagulants previously demonstrated association with APCR, determined by classic activated partial thromboplastin time-based tests. We used a novel integrated approach with calibrated automated thrombography made in parallel with and without TM. This modification of the thrombin generation test allows effectively detecting APCR and LA even in patients on vitamin K antagonists treatment, that is very important for clinical practice. APCR in patients with lupus anticoagulants is strongly associated with thrombotic complications; it was demonstrated by CAT in all patients with VTE manifestation under the age of 45 years and LA laboratory phenotype. Acquired APCR could be the main pathogenic mechanism underlying thrombosis associated with LA.

PB2057

RELATIONSHIP BETWEEN ANTIPHOSPHOLIPID SYNDROME CLINICAL MANIFESTATIONS AND MULTIPLE POSITIVE ANTIPOSPHOLIPID ANTIBODIES

R. Siguenza[1,*] N. Bermejo[1], I. Casas[1], F. Ibañez[1], M.H. Bañas[1], J.M. Bergua[1], M.J. Arcos[1], J. Prieto[1], M.L. Martin Mateos[1], C. Cabrera[1], F.D.A. Perez Leal[1]
[1]Hematología, Hospital San Pedro de Alcantara, Cáceres, Spain

Background: The Antiphospholipid syndrome (APS) is characterized by the development of thrombosis and/or pregnancy complications in addition to the persistent presence of antiphospholipid antibodies (APLS): Lupus Anticoagulant, Anticardiolipin antibodies, Anti-beta 2 GP1 antibodies. At this moment, is not well known that risk factors could be associated to any clinical manifestations of APS.
Aims: We investigated if there are relationship between the different clinical manifestations of APS and the presence of cardiovascular risk factors, hereditary and acquired thrombophilia or multiple positive APLS.
Methods: Retrospective we investigated the relationship between clinical manifestations and the presence of cardiovascular risk factors, hereditary and acquired thrombophilia or the existence of multiple positive APLS in 65 patients consecutive diagnosed of APS in our hospital from 1 February 2000 to 31 January of 2015. The patients ages were between 21 to 88, gender 53.8% male and 46.2% females. 43 patients present cardiovascular risk factors (26 smokers 24 hypertension, 22 dyslipidemia, 3 Diabetes Mellitus), 21 patients with thrombophilia (8 hyperhomocysteinemie, 2 antithrombine deficiency, 3 protein S deficiency, 1 protein C deficiency, 4 FV Leiden mutations and 3 prothrombin G20210A mutation), 17 patients with triple APLS (TP) and 48 with one/double APLS (ODP). 37 patients presented venous thrombosis (22 deep vein thrombosis, 6 pulmonay embolism, 9 both), 15 patients with arterial thrombosis manifestations (2 arterial thrombosis, 3 myocardial infarction and arterial thrombosis, 10 cerebrovascular accident), 4 with pregnancy complications, and 9 with combined complications (arterial/venous thrombosis/pregnancy complications). The statistical analysis was performed with Chi2 test realized by JMP 9, being statistically significant P<0.05.
Results: We found statistically significant difference between the presence of TP and the development of arterial thrombosis (OR 0.16 y IC 95% 0.03 – 0.76 P=0.01).
Summary and Conclusions: Our data show an association between TP and development of arterial thrombosis in APS patients. We did not found association between one or multiple positivity on APLS and the other clinical manifestations of APS, and the presence or not of cardiovascular risk factor or thrombophilia with clinical manifestations of APS.

PB2058

THE INFLUENCE OF CYP2C9 AND VKORC1 GENE POLYMORPHISMS ON THE RESPONSE TO WARFARIN IN EGYPTIANS

A. Bedewy[1,*] S. Showeta[2], M. Hasan[2], L. Kandil[3]
[1]Hematology, alexandria university, [2]Biotechnology, Institute of Graduate Studies and Research, [3]Biochemisty, Pharos university, Alexandria, Egypt

Background: warfarin is the most commonly used drug for chronic prevention of thromboembolic events and stroke, it also ranks high among drugs that cause serious adverse events. The narrow therapeutic index coupled with substantial inter-individual variability in warfarin dose requirement puts patients at increased risk for hemorrhagic events, and the variability in dose requirements has been attributed to inter-individual differences in medical, personal, and genetic factor. Cytochrome P-450 2C9 is the principle enzyme that terminates the anticoagulant effect of warfarin by catalyzing the conversion of the pharmacologically more potent S-enantiomer to its inactive metabolites. Warfarin exerts its anticoagulant effect by reducing the regeneration of vitamin K from vitamin K epoxide in the vitamin K cycle, through inhibition of vitamin K epoxide reductase. This protein is encoded by the recently identified vitamin K epoxide reductase complex subunit 1 gene (*VKORC1*).
Aims: The current study aimed to investigate the pharmacogenetic effect of CYP2C9 and VKORC1 gene polymorphisms on the patients response to warfarin.
Methods: This study was carried out on 100 cases starting warfarin treatment. Informed consent was obtained from each subject or patient prior to participating in this work. The mean daily dose of warfarin (mg) was calculated from patient's medical records. For each patient,<10% variability in warfarin dose and a target international normalized ratio (INR) within the therapeutic target range (2–3) and for patients having valve replacement and recurrent pulmonary embolism target was (2.5-3.5), were required for at least 3 months for one of the following indications (Deep vein thrombosis, Pulmonary embolism, cerberovascular stroke and Myocardial infarction) prior to inclusion in the study. Molecular genetic study was performed to determine *CYP2C9**2, *CYP2C9* *3, and the *VKORC1* 1639G >A genetic polymorphisms. The genotypes were determined with the tetraprimer amplification refractory mutation system (T-ARMS) using specific outer and inner primers. Plasma warfarin determination was performed using rapid flouremetric assay.
Results: The median age of the studied cases as shown in table 1 was 49 years (range, 33–68).The males represented 56% of the cases while the females represented 44%. The body mass index of the patients ranged from 19.81 to 42.44. The plasma warfarin concentration ranged from 2.19-10.98 µg/mL with a median 3.52 µg/mL. The patients were stratified into three different groups based on their maintenance dose (>2.5 mg is the low dose group, ≤2.5 mg to 7 mg is the standard dose group and >7 is the high dose group). The INR ranged from 2 to 4 wth a Mean of 2.58±0.62(SD).The incidence of supratherpeutic INR was presented in 11% of the cases. Thromboembolic complications occurred to 7% of the cases. While 8% of the cases experienced

major bleeding. The majority of the patients receiving high maintenance dose (>7 mg/day) had combined *non VKORC1*2 and* homozygous wild-type *CYP2C9* (*CYP2C9*1*1*) alleles, representing 52.2% of the high dose group while the majority of the patients recieving low maintenance dose are carriers of the Variant (AG + AA)/ Wild (*1/*1) representing 55.6% of the low dose group.These results were statistically significant with p value<0.001. With respect to Incidence of supratherapeutic INR, a significantly increased risk occurred in patients carrying the CYP2C9 variant in the multivariate logistic regression model. Also with respect to thromboembolic complications and incidence of supratherapeutic INR, higher risk was observed in patients carrying combined VKORC1 Variant (AG + AA) and CYP2C9 Variant (*2/*3).
Summary and Conclusions: Data from our study suggest that together with clinical factors, VKORC1 and CYP2C9 polymorphisms are important contributors to warfarin dosing and may help predict adverse effects in Egyptian patients.

PB2059

ASSOCIATION OF FACTOR V LEIDEN G1691A AND PROTHROMBIN GENE G20210A MUTATION WITH ADVERSE PREGNANCY OUTCOMES
S. Asad[1,*] B. Moiz[1]
[1]Pathology and Microbiology-Section haematology, Aga Khan University Hospital, Karachi, Pakistan

Background: Familial defects and polymorphisms of clotting cascade proteins protein S, protein C, factor V Leiden G1691A and factor II G20210A are linked with increased risk of thromboembolism which is better known as *inherited thrombophilia*. Thrombophilia causes deep venous thrombosis, pulmonary embolism and is strongly associated with poor pregnancy outcomes. Pathophysiology of these outcomes is thought to involve thrombosis in uteroplacental blood flow hence, anticoagulation therapy can potentially improve obstetric outcome in females with thrombophilias. To date, there is limited data from this region on the role of these genetic abnormalities causing adverse pregnancy outcomes.
Aims: Determine the association of factor V Leiden G1691A and prothrombin gene G20210A mutation with adverse pregnancy outcomes.
Methods: It was a case control study, conducted at clinical laboratory, section of haematology, and PCR-RFLP technique is used at multi-disciplinary laboratory, Aga Khan University Hospital. Females with adverse pregnancy outcomes who came to obstetrical clinic were included in the study as cases. Adverse pregnancy outcomes included recurrent pregnancy loss (defined as >2 first trimester miscarriages or one or more second trimester miscarriage), severe pre-eclampsia, placental abruption, intrauterine growth restriction and still birth. Control samples are selected from females with ≥ 2 consecutive normal pregnancies. Calculated sample size is 172 which comprise of 86 cases and 86 controls.
Results: Overall mean age of all subjects was 28.5 years (±4.9). Mean age of cases was 29.3 (±5.17) years and of controls was 27.6 years (±4.5). 73 (84.8%) cases had recurrent pregnancy loss, 12 (13.9%) had pre-eclampsia, 8 (9.3%) had IUGR while placental abruption and still birth was present in 2 (2.3%) cases each. 10 (11.6%) cases had more than one adverse pregnancy outcomes. 19 (22.09%) cases had >4 pregnancy losses. Among cases, 40 (46.5%) females had previous live births and 9 (10.4%) were pregnant at the time of sample collection. Two cases with recurrent pregnancy loss (P=0.155 OR=0.49) showed heterozygous mutation of factor V Leiden G1691A and while no mutation identified in the control arm. Heterozygous prothrombin gene mutation was identified in one case with recurrent pregnancy loss (P= 0.316 OR=0.497) while none of the control exhibited this mutation.
Summary and Conclusions: This is a small sample sized study which does not support a significant association between inherited thrombophilia mutations and adverse pregnancy outcomes. The apparent lack of association may be reconciled by the low numbers of subjects recruited.

PB2060

LONG-TERM ANTICOAGULATION WITH DABIGATRAN IN PATIENTS WITH SEVERE LACTOSE INTOLERANCE
N. Bermejo[1,*] R. Sigüenza[1], F. Ibañez[1], M.H. Bañas[1], I. Casas[1], F.D.A. Perez Leal[1], J. Bergua[1]
[1]Hematology, Hospital San Pedro de Alcántara, Cáceres, Spain

Background: Chronic anticoagulation is realized mainly with vitamin K antagonists (VKA), but the use of VKA is problematic in patients with severe lactose intolerance. Dabigatran is currently the only available lactose-free oral anticoagulant, however its use in patients with lactose intolerance has not been described.
Aims: Evaluate long-term anticoagulation with dabigatran in patients suffering lactose intolerance.
Methods: We present two patients with severe lactose intolerance on long-term anticoagulation with VKA, that were transitioned from VKA to dabigatran because the treatment with VKA worsened symptoms of their lactose intolerance. Case 1. A 75-year-old female was diagnosed with nonvalvular atrial fibrillation. Long-term anticoagulation with VKA was started for stroke prevention. Two weeks later, the patient was admitted by recurrence of acute diarrhea in the setting of her lactose intolerance, well controlled so far. VKA was replaced by dabigatran and fifteen months later, she remains asymptomatic. Case 2. A 40-year-old female was diagnosed with antiphospholipid syndrome (APS) when she experienced a non provocated acute left upper extremity venous thrombosis. She was started on anticoagulation with VKA with an INR target of 2.5 and had no recurrence of thrombosis. However, VKA therapy was complicated by frequent episodes of diarrhea that the patient suffered from several years. She was evaluated by a gastroenterologist and was diagnosed with lactose intolerance. Due to progressive worsening gastrointestinal clinical despite a lactose free diet, three years later she was transitioned from VKA to dabigatran. One year later, she is asymptomatic and has not suffered thromboembolic recurrence. We present two patients with severe lactose intolerance on long-term anticoagulation with VKA, that were transitioned from VKA to dabigatran because the treatment with VKA worsened symptoms of their lactose intolerance. Case 1. A 75-year-old female was diagnosed with nonvalvular atrial fibrillation. Long-term anticoagulation with VKA was started for stroke prevention. Two weeks later, the patient was admitted by recurrence of acute diarrhea in the setting of her lactose intolerance, well controlled so far. VKA was replaced by dabigatran and fifteen months later, she remains asymptomatic. Case 2. A 40-year-old female was diagnosed with antiphospholipid syndrome (APS) when she experienced an unprovoked acute left upper extremity venous thrombosis. She was started on anticoagulation with VKA with an INR target of 2.5 and had no recurrence of thrombosis. However, VKA therapy was complicated by frequent episodes of diarrhea that the patient suffered from several years earlier. She was evaluated by a gastroenterologist and was diagnosed with lactose intolerance. Due to progressive worsening gastrointestinal clinical despite a lactose free diet, three years later she was transitioned from VKA to dabigatran. One year later, she is asymptomatic and has not suffered thromboembolic recurrence.
Results: Our patients with lactose intolerance on long-term anticoagulation with dabigatran have not experienced gastrointestinal symptoms or thromboembolic complications months after transitioning to dabigatran.
Summary and Conclusions: Switching from VKA to dabigatran for patients with lactose intolerance seemed clinically reasonable, but until results of prospective randomised trials are available, we recommend caution in using dabigatran in patients with APS.

PB2061

THE PENETRANT FEATURE OF VENOUS THROMBOEMBOLISM IN FAMILIES WITH INHERITED THROMBOPHILIA FROM NATURAL ANTICOAGULANT DEFICIENCY IN KOREA
Y.J. Jung[1,*] D.K. Kim[2], S.H. Kim[1], H.J. Kim[1]
[1]Department of Laboratory Medicine and Genetics, [2]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

Background: Inherited thrombophilia is a genetic predisposition to develop venous thromboembolism (VTE) from either deficiency of natural anticoagulants (NA) or increased procoagulant activity. Deficiencies of NA such as protein C (PC), protein S (PS) and antithrombin (AT) are relatively common in Asian populations. It has been acknowledged that the development of VTE is affected by various factors other than genetic predisposition such as environmental influences and other modifiers.
Aims: The purpose of this study was to investigate the penetrance of VTE in families with inherited thrombophilia from NA deficiency in Korea.
Methods: The authors reviewed the family history and family study results in a cohort of consecutive patients with VTE from genetically confirmed NA deficiency between January 2005 and December 2014 at a single tertiary institution in Seoul, Korea.
Results: A total of 87 probands were VTE patients with PC (N=44), PS (N=21), or AT (N=22) deficiency confirmed by molecular genetic tests (mean age: 40 years; 62 men and 25 women). The family history of the parents was available in 78 probands, and a positive VTE history was ascertained in 7 (9%). Family study was performed in both or either one of the parents in 10 probands, and 11 parents of either side (mean age: 55 years; 4 fathers and 7 mothers) were confirmed to have the same mutation as in the probands. Among them, 2 had a history of VTE (18%).
Summary and Conclusions: To our knowledge, this is the first study to investigate the family history of VTE in a large cohort of probands with genetically confirmed NA deficiency. The results demonstrated a low penetrance of VTE in the parents of the probands, even in genetically confirmed cases. The data suggested that the environmental factors (possibly generation-dependent) have implications for the index of suspicion in inherited thrombophilia and genetic counseling in VTE patients. A further study involving siblings of the probands is believed to better delineate the penetrance feature.

PB2062

A LOCAL PROCESS AND MANAGEMENT FOR HOSPITAL ASSOCIATED VENOUS THROMBOEMBOLISM EVENTS
S. Patel[1,*] S. Deplano[1], F. Matthey[1]

[1]Chelsea and Westminster NHS Foundation Trust, London, United Kingdom

Background: In 2005 a House of Commons Health Committee in England reported an estimated 25000 avoidable deaths occur annually in the UK from hospital associated venous thromboembolism (VTE)[1]. There is ongoing work in England to develop up-to-date and accurate statistics about incidence and death from hospital associated VTE although this is difficult due to often clinically silent nature of VTE and a decrease in post-mortems in recent years. Root cause analysis (RCA) is required for all confirmed cases of pulmonary embolism and deep vein thrombosis associated by patients in hospital, with an aim to reduce avoidable death, disability and chronic ill heath from VTE[2].
Aims: To implement a process for identification and management of hospital associated VTE events (HATs). To determine incidence of HATs and potentially preventable HATs. To identify contributory factors for potentially preventable HATs
Methods: Support from senior Executives were essential in prioritising VTE as a patient safety quality improvement objective. RCA tools were developed to explore the *how*, the *what*, and most importantly the *why* of HAT. RCA will identify contributory factors and inform an action plan developing solutions with monitoring to prevent reoccurrence. The VTE RCA team is multidisciplinary with Consultant Haematologist, Anticoagulation Pharmacist, lead clinician, clinical governance and radiology departments. Weekly imaging reports are sent by the radiology team. Reports are screened to identify new VTE diagnosis. Patient records are reviewed to establish whether the VTE event is hospital associated. Lead clinicians are requested to complete the RCA tool to determine whether the HAT was potentially preventable. An action plan is implemented to address contributory factors.
Results: From April 2014-January 2015, 6 potentially preventable HATs identified. Interventions to address contributory factors for HATs were: A 'Preventing Harm' group was introduced to investigate omitted doses of thromboprophylaxis, without clinical omission. An electronic report was created for 'prescribed but not given' medications, by ward. Agency nursing staff were given access to the electronic prescribing system to allow for documentation of medications given. VTE ward rounds introduced on medical, surgical and obstetric wards to review VTE risk assessment completion and accuracy, and whether thromboprophylaxis is appropriate. A summary report of findings/learning points is circulated to division. Risk assessment and guidance for patients with lower limb immobilisation was updated with appropriate management. Patient agreement to investigation or treatment consent form updated to include VTE as a significant, unavoidable or frequently occurring risk related to surgical procedures. WHO checklist updated to define if thromboprophylaxis is required and if prescribed. Educational support for accurate VTE risk assessments at booking appointments for antenatal women, to identify those at risk requiring antenatal thromboprophylaxis. Audits performed to assess whether patients receive verbal/written information on VTE prevention.
Summary and Conclusions: The VTE team implemented a robust and sustainable system for identifying and analysing HATs with feedback to departments. Successful interventions are embedded into clinical practice to reduce HATs. *Key messages:* Continuous VTE awareness, education and stewardship, Robust action plans to drive and excel performance, Real-time reporting, Maintain VTE momentum – cause some noise about VTE prevention.

PB2063

INHERITED AND AQUIRED THROMBOPHILLIAS IN WOMEN WITH RECCURENT PREGNANCY LOSS- OUR EXPERIENCE

E. Miljkovic[1,*] D. Markovic[1], M. Vucic[1]
[1]Clinical Center Nis, Nis, Serbia

Background: Inherited thrombophilias are the leading cause of maternal thromboembolism and are associated with an increased risk of certain adversy pregnancy outcomes including second and third trimester fetall loss, abruptions, severe intrauterine growth restriction and early onset severe preeclampsia. The antiphospholipid antibody syndrome (APS) is an acquired autoimmune thrombophyllia in which vascular thrombosis and/or reccurent pregnancy losses occur in patients having laboratory evidence for antibodies againts phospholipids or phospholipid-binding protein cofactors in their blood. Pregnant women with these highly thrombogenic conditions are at very high risk for both thromboembolism and adverse pregnancy outcomes.
Aims: Aim was to determine the presense of inherited or acquired thrombophillias in women with reccurent pregnancy losses (RPL).
Methods: Women with RPL were tested for heterozygosity for the factor V Leiden and prothrombin G 20210A mutations, homo and heterozygosity in the type 1 plasminogen activator inhibitor gene (PAI-1) and the thermolabile variant of the methylentetrahydrofolate reductase gene (MTHFR). They were also tested for deficiencies of protein C, protein S and antithrombin, as well as for antiphospholipid antibodies-anti beta 2 glycoprotein I antibodies, anticardiolipin antibodies and lupus anticoagulant assays.
Results: From January 2011 till January 2015 260 women were tested for the presense of inherited or acquired thrombophillias because of reccurent pregnancy loss or treatment of infertility. Median age of patients was 33.4 (19-45). Six women (2.3%) was negative for both inherited or APS and others (97.7%) were positive. Criteria for APS fullfilled 57 patinets (21.9%), 8 patients (3%) had only APS and 49 patients (97%) had APS with some of inherited thrombophillias. 246 patients (94.6%) were positive for one or more inherited thrombophillias. 99 patients (38.1%) were positive for one inherited thrombophillia: 4 (1.5%) for Factor V Leiden, 2 (0.7%) for prothrombin G 20210A, 47 (18%) for MTHFR and 46 (17.7%) for PAI-1. 133 patients (41.1%) were positive for 2, 13 patients (5%) for 3 inherited thrombophillias. 105 patients (40.3%) with low molecular weight heparin plus aspirin (LMWH/ASA) or ASA alone had successfully pregnancy outcome-live birth.
Summary and Conclusions: Some form of thrombophillia-inherited or acquired was found in most of tested women with reccurent pregnancy loss (97.6%) and 163 patients (62.7%) had more then one thrombophillia. With adequate anticoagulant therapy patients with these conditions had chance for successfully pregnancy outcome.

PB2064

INHERITED PROTHROMBOTIC RISK FACTORS IN CHILDREN WITH INTRACRANIAL VENOUS THROMBOSIS: SINGLE CENTER EXPERIENCE IN TURKEY

T. Patiroglu[1,*] G. Koç[2], M. Canpolat[3], E. Unal[1], S. Doğanay[2], M. Karakukcu[1], M.A. Ozdemir[1]
[1]Pediatric Hematology, [2]Pediatric Radiology, [3]Pediatric Neurology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Intracranial venous thrombosis (IVT) is a rare condition in childhood, with a wide variety of clinical features and etiologies.
Aims: We aimed to describe the inherited prothrombotic risk factors in children with IVT, confirmed by neuroimaging.
Methods: The retrospective study involved reviewing the records of patients who were admitted to our hospital during the years of 2010-2014. The patients diagnosed as having IVT, confirmed by neuroimaging were investigated for the common thrombophilia markers, such as protein C (PC), protein S (PS), antithrombin III (AT III), factor V G1691A and prothrombin 620210A mutations, methylenetetrahyrafolate reductase (MTHRF) C677T, and MTHFR A1298C genotypes.
Results: The clinical manifestations in 18 patients with IVT included headache, seizures, cranial nerve palsy, and hemiparesis. Transfer sinus thrombosis was the commonest site (50%) followed by diffuse sinus thrombosis (31.25%). Two patients had PC deficiency. Furthermore, one of them had homozygous MTHFR C677T genotype. No patient had PS and ATIII deficiencies, and prothrombin 620210A mutations. Eleven patients showed the MTHFR genotype (homozygous C677T, n=4, heterozygous C677T, n=5, heterozygous A1298 C, n=2); and 1 patient was carrier of heterozygous factor V mutation.
Summary and Conclusions: Early diagnosis by fast and safe radiological methods (neuroimaging of the brain), investigation of thrombophilia markers and the appropriate anti-clotting therapy in acute phase may prevent death due to IVT at the pediatric age.

PB2065

PAIN AS UNIQUE MANIFESTATION OF HIGH TITER ANTI-PF4/HEPARIN ANTIBODIES.

M. Nagy[1,*] L. Alberio[1]
[1]Hematology, CHUV, Lausanne, Switzerland

Background: A 68 years old male patient was addressed for hematological care in the context of polycythemia vera, a recent proximal deep vein thrombosis, and a newly diagnosed rectal tumor requiring resection. The patient had been known for polycythemia vera for 10 years, was treated by hydroxycarbamid and aspirin, and presented stable blood counts. A recently diagnosed left femoro-popliteal thrombosis had been treated by dalteparin. One week after the initiation of anticoagulation he signaled the apparition of extreme, burning pain in the distal region of the thrombosed leg and in the right hand, always starting 1 hour after each injection of dalteparin. The pain persisted for a couple of hours and was not responsive to anti-inflammatory and analgesic treatment. The switch of the low molecular weight heparin (LMWH) to nadroparin did not affect the pain. Clinical examination showed discrete lower limb edema predominantly in the affected side, without sign of ischemia. Imaging did not show an extension of the thrombosis. Discrete thrombocytopenia (137 G/l) was the only anomaly of blood count. Coagulation tests were normal.
Aims: To describe laboratory findings and clinical course of this unsusual case.
Methods: Because of the consistent temporal relation of the pain to the administration of LMWH and the slight degree of thrombocytopenia, anti-PF4/heparin antibodies were assessed. The IgG-monospecific ELISA was highly positive (OD 1.86; cut-off : 0.32). The HIPA test performed in a reference laboratory was negative even if the local ELISA was also highly positive.
Results: Nadroparin was immediately changed to fondaparinux, which allowed prompt and complete resolution of the pain. After one month of fondaparinux treatment a Doppler control of the thrombosis showed thrombus persistence without complete canalization. Blood counts showed discrete anemia and thrombocytosis, and the anti-PF4/heparin antibody level decreased to OD 1.45.

The rectal surgery was performed with no complication 36 hours after the last dose of fondaparinux and anticoagulation was resumed in the post-operative phase with argatroban followed by fondaparinux 3 days later. At last follow-up, 1 month after surgery the patient was still on fondaparinux, free of pain and the anti-PF4/antibody level had further decreased (OD 0.98).
Summary and Conclusions: Because of the temporal relation of the patient's symptoms with the administration of LMWH and the steady decline of anti-PF4/heparin antibodies after switch to fondaparinux, we consider this the first case report of high titer anti-PF4/heparin antibodies uniquely presenting with post-injection pain. We propose that clinicians should be aware that the presence of high titer anti-PF4/heparin antibodies might be related to otherwise unexplained pain after injection of low-molecular weight heparins. In our case, switch to a non-heparin based anticoagulation lead to an immediate disappearance of the post-injection pain.

Transfusion medicine

PB2066

PREVENTING UNNECESSARY TRANSFUSIONS DURING ELECTIVE PROCEDURES

A. Niblock[1,*] K. Donnelly[2], L. Henderson[3], A. Ruiz[2], J. McCormick[2]
[1]haematology, Belfast City Hospital, Belfast, [2]Altnagelvin Area Hospital, Londonderry, [3]Orthopaedics, Altnagelvin Area Hospital, Derry, United Kingdom

Background: In 2013 the UK chief medical officers iniative Patient Blood Management superseded Better Blood Transfusion. Patient Blood Management is a multidisciplinary, evidence-based approach to optimising the care of patients who might need blood transfusion. Patient Blood Management puts the patient at the heart of decisions made about blood transfusion to ensure they receive the best treatment and avoidable, inappropriate use of blood and blood components is reduced. Reduced blood usage will reduce demand, therefore less pressure on Northern Ireland Blood Transfusion Service. In turn will mean less shortages and more blood available for emergencies. If a transfusion is avoided then there is no risk of a transfusion reaction. Safest blood transfusion is the one not given.
Aims: Can blood transfusions be prevented during elective procedures?
Methods: A surgical list of all elective hip replacements was obtained between 01/09/2013 and 31/12/2013. Preoperative assessment including baseline haemoglobin was recorded. Post operative complications including haemoglobin drop and blood transfusions were looked at.
Results: 68 patients underwent elective hip replacements during this time. 5 patients underwent post operative blood transfusions 12/68 had pre operative haemoglobins<120g/l 56/68 had pre operative hb >120g/l 0% of patients with a pre operative hb >120g/l required a blood transfusion. 5/12 patients with a pre operative hb<120g/l required at least 1 unit of packed red cells post operatively.
Summary and Conclusions: All patients with a hb<120g/l at present are not being added to the elective hip replacement list until their anaemia is investigated and managed appropriately. General Practitioners received a letter indicating that the pre operative assessment has detected anaemia, also enclosed is guidelines regarding the investigation of anaemia. Once the patients anaemia has been treated or hb optimised the patient is returned to the waiting list.
The safest blood transfusion is the one not received.

PB2067

PROGRESSIVE DECLINE OF HBSAG SEROPREVALANCE IN BLOOD DONORS IN NORTHERN TURKEY: THE TWENTY ONE-YEAR EXPERIENCE

D. Albayrak[1,*] C. Albayrak[1]
[1]Pediatric Hematology Department, Samsun Ondokuz Mayis University Faculty of Medicine, Samsun, Turkey

Background: The high prevalence of HBV, HCV, HIV-1/2 and treponema pallidum carriers among blood donors has the unpleasant results for cost- effective, transfusion security and contagious disease.
Aims: The aim of this study was to determine the seroprevalence of HBV, HCV, HIV-1/2 and treponema pallidum in blood donors who applied to our Blood Bank in an twenty one –year period retrospectively.
Methods: The single donations and first time donation of repeat donors entered statistical analysis. HBsAg, anti-HCV treponema pallidum and anti-HIV-1/2 screening tests were performed using ELISA kits.
Results: Between 1994 and 2015, total 267,242 blood donation records at the Blood Banks of University were retrieved. Of them 206,027 were first time donors. HBV, HCV, HIV-1/2 and treponema pallidum seroprevalences among these first time donors were analyzed. The mean seroprevalence of HBsAg was 3.6% between 1994 and 2000 years. The rate of HBsAg positivity was unchanged in these seven years. But prevalence began to decrease in 2001. The positivity rates were 3.7% in 2000 and 3.1% in 2001. This difference was significant statistically. This declining continued progressively in later years and the rate dropped to 0.5% in 2014.
Summary and Conclusions: This retrospective study showed a significant and progressive decline in the HBsAg seropositivity while no apparent change were those of HCV, HIV and T. Pallidum among blood donors in Northern Turkey at last thirteen years. The drop in HBsAg seroprevalence is probably multifactorial such as public education activities and use of mandatory disposable injectors.
