Results: MDs were confirmed in 38 (8.1%) patients (24 males/14 females). Presenting characteristics showed WBC>30x10^9/L in 30%, Rai stage III-IV in 13%, and LDH elevation in 23 % of patients. Immunophenotyping revealed CD38 positivity in only 4/38 patients. The most frequent aditional MDs were skin neoplasms in 9 (33.3%) patients comprising 5 cases of basocellular carcinoma, 2 of planocellular and 2 cases of melanoma. Other neoplasms were colorectal carcinoma in 6 (22.2%), prostatic cancer in 4 (14.8%), lung cancer in 3 (11.1%), bladder cancer in 2 (7.4%) and larynx cancer in 2 (7.4%) patients. There was gender related distribution of MDs with the most frequent breast carcinoma in females and prostatic carcinoma in males. Among males 3 patients had double MD, colorectal carcinoma associated with basocellular, prostatic and laryngeal cancer. Regarding females, the frequency of MDs were as following: breast carcinoma had 6 patients (42.8%), uterus and cervix carcinoma 3 (21.4%), colorectal carcinoma 2 (14.2%), kidney carcinoma 2 (14.2%) and gastric carcinoma 1 (7.1%). Diagnosis of pMD noticed in 17 patients (9 males/ 8 females). Among this patients the most frequent pMD was breast carcinoma (5 patients), and afterward colorectal carcinoma (4 patients). Initial treatment of pMD was only surgery in 8 patient, in 1 patients was combined with chemotherapy, in 3 with hormone therapy, and finally in 3 patient with radiotherapy. Single radiotherapy was performed in 2 patients. Median time for appearing CLL after diagnosis of primary MD was 5 years. Regarding OS of patients with CLL and previously diagnosed MDs, 5-years survival from pMD was 68% with median OS of 23 years. In 11 CLL patients (6 males/5 females) cMD was diagnosed and majority of them (90%) had stable CLL that didn`t require medical treatment. Regarding patients with cMD, none of 11 patients received any potentially mutagenic treatment previously. The OS of patients with cMDs was 75% in the first year, with slowly dropping up to 60% in the 5-years follow up. During CLL follow-up in 10 patients (9 males/1 females) was diagnosed .sMD, which was appeared most frequently in the first 4 years (80%). Previously 5 of them received chemotherapy (fludarabine based regimen). From the diagnosis of sMD, median OS was 12 months, with 5-years survival of only 25%.
Summary and Conclusions: CLL doesn't have more aggressive nature after

the treatment of previously diagnosed neoplasm and don't affect the OS. In patients with CLL and cMD the OS mainly depends on the behavior of concomitant malignancy. Finally, diagnosis of sMDs during CLL follow-up had an effect on patient`s inferior outcome.

E1069

MINIMAL RESIDUAL DISEASE IN HAIRY CELL LEUKEMIA: DOES IT MATTER?

A. Santos Carreira[1,*] R. Pinto[1], A. Carneiro[1], F. Príncipe[1], J.E. Guimarães[1]
[1]Hematology, Centro Hospitalar São João - Porto, Portugal, Porto, Portugal

Background: Hairy Cell Leukemia (HCL) is a fairly rare type of B-cell lymphoproliferative disorder. Its prognosis is good compared to most common types of leukemia but relapse remains a challenge. Minimal residual disease (MRD) assessment is routinely performed in most centers using different approaches, but its clinical usefulness is a matter of debate.
Aims: In an attempt to understand the impact of MRD evaluation in the natural history of the disease and relapse risk, we have retrospectively reviewed all patients with HCL diagnosed in our center and looked at how MRD measurements correlated with patient outcome.
Methods: MRD was assessed by flow cytometry expression of CD19, CD25, CD11c and CD103 as well as by marrow biopsy searching for minimal morphological and/or immunohistochemical evidence of disease. MRD implied that patients had achieved complete or partial remission (CR and PR, respectively) with the treatment provided. For flow cytometry MRD positivity, two cut-off values were defined: more than 0.3% or 0.01% of HCL clone. CR was defined as complete recovery of blood counts ie, hemoglobin>12g/dL in men and 11g/dL in women, neutrophils >1500/uL and platelets >100.000/uL (with exception to expected lymphopenia after chemotherapy courses), resolution of splenomegaly in case it was present at diagnosis and, if not absent, minimal morphological or immunohistochemical evidence of hairy cells in bone marrow biopsy. PR was defined as at least a 50% improvement in any of these parameters, without criteria meeting CR.
Results: We analysed data from 29 patients diagnosed between 1991 and 2013, median follow-up was 108 months (range: 23-259 months). Male prevailed (n=26). Median age at diagnosis was 54 years (range: 33-71). Most patients (89.7%) were treated with cladribine upfront (dose 0.14mg/kg x 5 days). 25 patients (86.2%) entered CR. All other 4 patients achieved PR with one cycle of cladribine. Flow cytometry MRD assessment and bone marrow histology were available in 17 and 14 patients, respectively. Median flow cytometry MRD positivity was 0.29% (range: 0-2.55%). Eight out of 17 patients had a HCL clone greater than 0.3% and MRD was negative (<0.01%) in 4 patients. Out of the 14 patients in whom MRD by histology was available, 6 proved to be positive. Median progression free survival (PFS) was 11.8 years (±11.6%). Relapse occurred in 12 patients (41.4%, n=12/29), of whom 2 had achieved PR: five patients had flow cytometry MRD >0.3%, 2 were negative for the test in question, whereas 4 had no MRD by histology. Moreover, we registered 6 relapses out of 13 patients who had a HCL clone greater than 0.01%, with the remainder maintaining CR (n=5/13) or PR (n=2/13). Of notice, we encountered only one relapse in 4 patients who had detectable MRD by both methods. We could not establish any correlation between relapse risk and MRD detection by any of the two methods used. Five-year PFS for patients with MRD >0,3% and <= 0,3% was 88.9%(±10.5%) and 62.5% (±17.1%), respectively (p=0.356). All but one patient (96.6%) continued alive at last follow-up.
Summary and Conclusions: HCL patients do not seem to behave differently in terms of relapse incidence, PFS or overall survival, in respect to the presence or not of MRD. Its assessment by flow cytometry and/or bone marrow histology did not prove to be clinical meaningful in our analysis. Currently, clinical surveillance and full blood count seem reasonable enough to accurately follow-up HCL patients. Furthermore, MRD assessments bear relevant economical costs and unnecessary stress to patients.

E1070

ONE OUT OF FOUR TREATMENT-NAÏVE CLL PATIENTS IN TAIWAN CARRY TP53 MUTATIONS: CLINICAL AND PATHOGENETIC IMPLICATIONS

S.J. Wu[1,*] C.T. Lin[1], A. Agathangelidis[2], L.I. Lin[1], P. Ghia[2], H.F. Tien[1]
[1]National Taiwan University Hospital, Taipei, Taiwan, ROC, [2]Università Vita-Salute San Raffaele, Milano, Italy

Background: Previous studies have shown significant differences between Taiwan and the West in terms of epidemiology and cytogenetic pattern of chronic lymphocytic leukemia (CLL). Recently, technology advances have led to the identification of previously unknown gene aberrations in CLL, some of which have been shown of clinical relevance. The comparison of these molecular genetic markers between Taiwan and the West may help clarifying the potential difference in the disease between these different ethnic groups.
Aims: The study aimed at establishing the molecular genetic profiles of CLL in the Taiwanese population and identifying the potential differences in this low-prevalence ethnic region.
Methods: In a cohort of 74 patients with newly diagnosed CLL at the National Taiwan University Hospital, we determined the usage and the mutational status of the Immunoglobulin Heavy chain variable (*IGHV*) genes and the presence of HCDR3 stereotypes, a frequent feature in western CLL. In addition, we also screened for the presence of mutations in the *TP53, NOTCH1, SF3B1, BIRC3, and MYD88,* genes recurrently mutated in CLL.
Results: In terms of *IGHV* gene usage, 56.4% of patients had somatic hypermutations and in 10.2% of patients the HCDR3 sequences belonged to the major stereotyped subsets, closely resembling the frequencies present in the western population. That notwithstanding, the commonly used *IGHV* genes in Taiwanese patients were different from those in Western patients as *IGHV3-07* and *IGHV3-23* were over-represented (18.4% and. 16.3%, respectively), whereas *IGHV4-34* and *IGHV4-39* were underrepresented, being absent in the current cohort. In terms of molecular genetics, the frequencies of *NOTCH1, SF3B1, BIRC3* and *MYD88* mutations were 9.7%, 9.7%, 1.6%, and 3.2%, respectively, similar to the data derived from the West. In clear contrast, the frequency of *TP53* mutation was significantly higher (24.2%) in Taiwanese CLL patients than in western populations (5-10%); such a higher frequency is compatible with the higher 17p deletion rate and inferior survival outcomes in Asian CLL patients reported previously. Similar to the data derived from the West, *TP53* mutation had a significant positive association with non-mutated *IgHV* (p=0.011), *TP53* and *SF3B1* mutations were closely associated with 17p deletion (p=0.010) and 11q deletion (p<0.001), respectively, and patients with *TP53*/17p deletion or *SF3B1* mutations had inferior overall survivals (p=0.007 and p<0.001, respectively).
Summary and Conclusions: The current study demonstrates a distinctly higher *TP53* mutation frequency that is in clear contrast with the features of CLL in the Western countries and might explain the overall inferior outcome of CLL in Taiwan, indicating a medical need for novel treatments in this region. The distinct usage of *IGHV* genes in this population may further suggest different pathogenetic mechanisms with distinct antigenic elements acting in the natural history of the disease that may predispose to genetic instability and the acquisition of dismal genetic lesions.

E1071

RETROSPECTIVE EVALUATION OF 83 PATIENTS WITH HAIRY CELL LEUKEMIA TREATED WITH 3 DIFFERENT TREATMENT MODALITIES IN THE LAST TWO DECADES: A SINGLE CENTER EXPERIENCE

S. Ongoren Aydin[1,*] A. E. Eskazan[1], S. Berk[1], I. Erdogan[1], F.F. Yalniz[1], T. Elverdi[1], A. Salihoglu[1], M.C. Ar[1], Z. Baslar[1], T. Soysal[1], B. Ferhanoglu[2], N. Tuzuner[3], Y. Aydin[1]
[1]Department of Internal Medicine, Division of Hematology, Istanbul University Cerrahpasa Faculty of Medicine, [2]Department of Internal Medicine, Division of Hematology, Koc University Faculty of Medicine, [3]Department of Pathology, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey

Background: Hairy cell leukemia (HCL) is a rare mature B-cell neoplasm. Various treatment modalities have been used, and until the introduction of cladribine (2-CdA), splenectomy and interferon-alpha (INF-α) were the formerly considered standard therapies for HCL, which led to clinical and hematologic responses. 2-CdA resulted in higher complete response (CR) rates and durable remissions, and became the standard treatment modalities in most of the patients.
Aims: The aim of this study was to retrospectively analyze the clinical outcome, treatment responses, toxicities and survival of HCL patients treated in our institution with 3 treatment modalities (splenectomy, INF-α, and 2-CdA) between 1991-2014.
Methods: Eighty-three patients with HCL were included this study. We analyzed the outcome of different treatment modalities as well as different lines of therapy among these patients. There were 12 patients with variant HCL (HCL-v). The response rates of the 3 first-line treatment options were evaluated. Patients were also divided into four subgroups according to the number of treatments they had received. Group 1 included patients who received first-line treatment. Group 2 consisted of patients who were treated with 2 lines of treatment; Group 3 had patients who underwent 3 lines; and Group 4 included patients with four lines of therapy. We used the criteria for response as described by the Consensus Resolution. CR and partial response (PR) together defined as overall response (OR), and any response other than a CR or PR was considered as no response (NR).
Results: Seventy-four patients (89%) were male, the median age was 49 years (range, 31-76 years), with a median follow-up duration of 54 months (range, 1-217 months). The median leukocyte counts of the HCL-v cases were 15.5 x 10^9/L and (range, 10.1-90.7 x 10^9/L). In 71 HCL cases, the median leukocyte count was 3.03 x 10^9/L (range, 0.5-9.4 x 10^9/L). The median hemoglobin level and platelet counts were 11 g/dL (range, 4-17 g/dL) and 51.5 x 10^9/L (range, 21-124 x 10^9/L), respectively. Splenomegaly was detected in 74% of the patients, with hepatomegaly and lymphadenopathy 37% and 35% of the cases, respectively. Seventy-three patients (88%) (Group 1) received 1st line treatment, and 2-CdA was administered in thirty-two (44%), twenty-one patients (29%) received INF-α and splenectomy was performed in 20 cases (27%) (Table 1). The OR rates among 2-CdA, INF-α and splenectomy as a 1st line

treatment option were 88%, 81% and 90%, respectively. Three patients (2-CdA in two, INF-α in one) died due to infection during treatment. None of the patients with splenectomy died due to post-operative complications. Twenty-nine patients (Group 2) required 2nd line treatment due to relapsed/refractory disease. Seventeen patients received INF-α, 10 patients received 2-CdA and two had splenectomy. Group 3 consisted of 9 patients, and 6 of them had INF-α, two were given 2-CdA and one patient received rituximab (RTX). As a 4th line of treatment one patient received RTX and one had fludarabine (Group 4) (Table 1). During the follow-up, 10 patients died mostly due to refractory disease and/or infections. Five patients were lost to follow-up. There were 64 infection episodes, and most common infections were bacterial infections (pneumonia in 12, tuberculosis in 8, febrile neutropenic episode in 7, soft tissue infection in 6, meningitis in one, and septic arthritis in one). Five patients had a secondary malignancy of which 3 had occurred before the diagnosis of HCL.

Table 1. Summary of the different treatment modalities. (2-CdA, cladribine; IFN-α, interferon-alpha).

Treatment	Group 1 (n=73)	Group 2 (n=29)	Group 3 (n=9)	Group 4 (n=2)
2-CdA	32	10	2	-
INF-α	21	17	6	-
Splenectomy	20	2	-	-
Rituximab	-	-	1	1
Fludarabine	-	-	-	1

Summary and Conclusions: These 3 treatment modalities were found to be comparable regarding efficacy when used in the 1st line setting. First line splenectomy was performed mostly prior to 2000, and nowadays 2-CdA and INF-α are usually chosen as the 1st line treatment in most of the patients. Infections were the most common complication which can be observed both prior to and during the treatment.

E1072

TWO DECADES OF SINGLE-CENTER EXPERIENCE REGARDING THE TREATMENT, PREDICTORS OF SURVIVAL AND CAUSES OF DEATH IN PATIENTS WITH HAIRY CELL LEUKEMIA

D. Lekovic[1,*] M. Gotic[1,2], N. Milic[2,3], M. Perunicic-Jovanovic[1], L. Jakovic[1], N. Kraguljac-Kurtovic[1], J. Bodrozic[1], M. Bogunovic[1], M. Todorovic[1,2], I. Elezovic[12], D. Tomin[1,2]B. Mihaljevic[1,2]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, [3]Institute for Medical Statistics, University of Belgrade, Belgrade, Serbia

Background: Treatment of hairy cell lekemia (HCL) is well established, however the predictors of survival and cause of death of these patients have not been evaluated. Also, occurence of second malignancies in HCL patients is matter of debate.
Aims: was to identify the parameters with an influence on survival as well as causes of death of HCL patients.
Methods: Study included 137 patients who HCL were diagnosed and treated at the Clinic for Hematology, CCS from January 1993 to December 2014. Eight patients were diagnosed as HCL variant. We analyzed only patients with classic HCL (129 pts) and their characteristics (age, gender, clinical and laboratory parameters, immunophenotypic expression of HCL cells in peripheral blood, histological characteristics of bone-marrow and type of therapy) as well as development of second malignancies in terms of survival.
Results: Median age at the time of diagnosis was 54 years (IQR 20), with dominance of male gender (82,9%). Regarding the therapy, one treatment-line (TL) received 67 patients (51.9%), 2 TL 34 patients (26.4%), 3 TL 10 patients (7.8%) and four or more TL 14 patients (10.9%) resulting in 80.5% of complete remissions (CR), 16.3% of partial remissions (PR) and 3.3% of non-response (NR). Four patients were followed up only, without any treatment (3%). Splenectomy was performed in 28 patients (21,7%). Purine analog (cladribine) received 106 pts (82.2%) resulting in 82,5% CR, 16.5% PR and 1% NR. Seven patients with relapse of HCL after multiple treatments with cladribine, received rituximab alone or in combination with cladribine resulting in 6 patients with CR and in 1 patient with PR. After the median follow up of 86 months, 36 deaths were documented (27.9.%). The 5- and 10- years OS was 90.2% and 70.9% respectively. Second malignancy during the follow-up of HCL developed 17 patients (13.3%). Solid tumors occurred in 13 patients while 4 patients developed second hematological malignancy. The causes of death in HCL patients were as follows: active HCL (9 patients; 25%), cardiovascular disease (11 patients with coronary disease, cardyomyopathy and heart failure; 30.6% and 4 patients with AIM; 11.1%), respiratory insufficiency (2 patients; 5.5%), second malignancy (6 patients with solid tumors; 16,8% and 2 patients with hematological malignancies; 5.5%) and concomitant diseases (2 patients with active HCL and solid tumor; 5.5%). The mean age of patients who died (63±10 years) was significantly higher than in living patients (50±11years) (p<0.001). In univariate Cox regression model unfavorable predictors of survival were: age>55y (p<0.001), hemoglobin level<100g/L (p=0.01), leukocyte count<2.8x10^9/L (p=0.001), sedimentation rate>30mm/h (p=0.011) and occurrence of second malignancy (p<0.001). Regarding the treatment, mortality of patients who did not receive cladribine was 74%, while of those who received cladribine was 18% (p<0.001).
Summary and Conclusions: The cladribine treatment is effective with the achievement of complete remission in over 80% of HCL patients. Patients with multiple relapses have benefit with rituximab treatment. Also, the long-term follow-up of HCL patients is important for evaluating the development of secondary malignancies which this study highlights as one of main causes of death in these patients.

LB2097

EVANS SYNDROME SECONDARY TO CHRONIC LYMPHOCYTIC LEUKAEMIA IS ASSOCIATED WITH ADVERSE BIOLOGICAL FEATURES AND OUTCOME

G. Carli[1,*] E. Falisi[1], O. Perbellini[2], E. Novella[1], I. Giaretta[1], I. Ferrarini[2], A. Sandini[3], A. Ambrosetti[2], F. Rodeghiero[1], C. Visco[1]
[1]Department of Cell Therapy and Hematology, San Bortolo Hospital, Vicenza, [2]Department of Medicine, Section of Hematology, University of Verona, Verona, [3]Department of Immunohematology, Genetics and Transfusional Medicine, San Bortolo Hospital, Vicenza, Italy

Background: Secondary Evans syndrome (ES) is characterised by simultaneous or sequential development of autoimmune haemolytic anaemia (AIHA) and immune thrombocytopenia (ITP), with a positive direct antiglobulin test in the presence of an underlying aetiology. ES secondary to chronic lymphocytic leukaemia (CLL) is an extremely rare occurrence, and its prevalence is unknown. Conversely, isolated AIHA and ITP are much more common in patients with CLL, occurring in 7-10% and 2-5% of patients, respectively.
Aims: Very few epidemiological and clinical data are available on ES secondary to CLL. In this study, we collected clinical and biological data of patients with ES secondary to CLL, and we compared them with patients developing isolated ITP or AIHA.
Methods: We analysed the records of consecutive patients with CLL diagnosed in two major Institutions from Veneto region between 2000 and 2014. All patients met the CLL diagnostic criteria of National Cancer Institute Working Group. To be included, patients with ES had to fulfill the international standardized criteria proposed both for ITP and AIHA.

Figure 1. Overall survival in patients with chronic lymphocytic leukaemia not developing autoimmune cytopenias (AIC) (740), compared to patients with isolated AIHA (63), isolated ITP (32) or Evans syndrome (25).

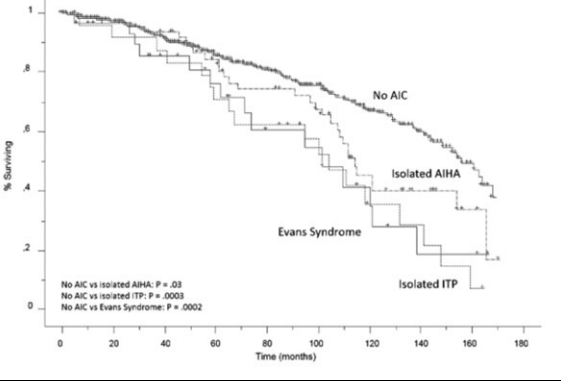

Figure 1.

Results: Overall, 860 patients with CLL were identified, and 25 (2.9%) developed ES. Additional 32 patients (3.7%) developed isolated ITP, and 63 isolated AIHA (7.3%). Demographic and clinical characteristics at CLL presentation (age, gender, Binet stage, median lymphocyte count) of patients developing either ES, ITP or AIHA were similar among the three groups, and not different from patients not developing autoimmune cytopenias (AIC). Of the three AIC, isolated ITP was more frequently diagnosed concurrently to CLL presentation (34% of patients developing this complication), as compared to ES (20%) or AIHA (13%). ZAP70 expression was high (cut-off 20%) in 79% of patients with ES, being significantly higher than in patients with no AIC (50%, p=0.01), but similar to patients with isolated AIHA or ITP. Immunoglobulin heavy chain variable region gene (*IGHV*) was un-mutated in 86% of patients with ES, which was statistically higher than in patients with no AIC (41%, p=0.001), but also compared to patients with ITP (60%, p=0.04) or AIHA (62%, p=0.04). Further-

more, del(17)(p13) and TP53 gene mutations were significantly more frequent in patients with ES (23% and 33% of tested patients, respectively) than in patients with no AIC (5% for both, p=0.003). In terms of overall survival (OS), patients developing ES had a significantly inferior OS than patients with no AIC (Figure 1), but similar to patients with isolated AIHA or ITP. No impact on OS was observed for patients with ES when divided according to time of onset of AIC (simultaneous ITP and AIHA, ITP before AIHA or vice versa). However, patients with ES diagnosed concurrently to CLL presentation had a significantly inferior OS compared to patients developing ES later in the course of disease (5 years OS 40% vs 74%, p=0.006). Treatment of ES was challenging, due to the quite high rate of primary resistant forms, and frequent recurrences, often requiring chemo-immunotherapy.

Summary/Conclusion: We showed that ES secondary to CLL is an infrequent but not so rare occurrence, that similarly to AIHA and ITP was significantly associated with unfavourable biological prognostic factors like ZAP70 expression, and un-mutated *IGVH* status. Furthermore, del(17)(p13) and TP53 gene mutations were highly prevalent among patients with ES. Consequently, patients with ES had poorer OS compared to patients not developing AIC, and OS was even poorer when ES occurred concurrently to CLL diagnosis.

Chronic myeloid leukemia - Biology

E1073

DETECTION OF BCR-ABL GENE MUTATIONS IN CHRONIC MYELOID LEUKEMIA USING SENSITIVE LOW-DENSITY MICROARRAY APPROACH

T. Nasedkina[1,2,*] A. Ikonnikova[1], Y. Yatsenko[1], V. Ovsepyan[3], O. Kremenetskaya[4]
[1]Engelhardt Institute of Molecular Biology, [2]Federal Scientific Clinical Center of Pediatric Hematology, Oncology and Immunology named after Dmitrii Rogachev, Moscow, [3]Kirov Scientific Research Institute of Hematology and Transfusiology, Kirov, [4]National Research Center for Hematology, Moscow, Russian Federation

Background: Chronic myeloid leukemia (CML) is a hematopoietic stem cell disease characterized by the Philadelphia (Ph) chromosome and BCR-ABL fusion gene coding for oncogenic tyrosine kinase. Imatinib mesylate, a tyrosine kinase inhibitor (TKI) is used as a first line therapy in newly diagnosed CML patients. However, imatinib resistance, usually due to BCR-ABL kinase domain point mutations, remains an important problem in treatment of CML patient. Different methods are used to analyze BCR-ABL point mutations, the common ones are direct sequencing and allele-specific polymerase chain reaction (AC-PCR). Direct sequencing is not very sensitive and can reveal 20-30% of mutant sequence in the background of wild-type DNA. AC-PCR is patient material and labour consuming while analysing a large number of point mutations.
Aims: Development of rapid and sensitive microarray-based approach for routine clinical diagnostics of BCR-ABL kinase domain point mutations.
Methods: A low-density microarray for the analysis of BCR-ABL point mutations has been designed and manufactured. Cytogenetically prepared fixed cells as well as fresh blood samples of CML patients were taken after informed consent. The procedure included RNA isolation and reverse transription-polymerase chain reaction (RT-PCR) followed by hybridization on microarray with immobilized probes able to discriminate between mutant and wild-type sequence. The amplified DNA was labelled via incorporation of fluorescent triphosphates in newly synthesized DNA strand. Fluorescent hybridization pattern was analyzed using portable laser detector. To increase the sensitivity of the assay locked nucleic acid (LNA) oligonucleotides were used to inhibit an amplification of wild-type DNA.
Results: Fifteen mutations associated with imatinib resistance in 85% of CML cases were included in the analysis: T315I, E255K, E255V, E255D, E255R, M351T, G250A, G250E, Y253H, Y253F, F359I, F359C, F359L, F359V, M244V. The microarray approach was validated using control CML samples with known mutations or synthesized mutant DNA matrice. In total, 62 CML patients were genotyped using the approach: 40 patients had chronic phase (CP) of the disease, 18 had accelarated phase (AP) and 4 patients had blast crisis (BC) manifestation. Mutations were found in 15% (6/40) of patients with CP, 72% (13/18) of patients with AP and 100% (4/4) of BC patients. Additionally, 2 of BC patients carried simultaneously 2 mutations. The following mutations have been found: T315I, E255K, E255V, E255D, M351T, G250A, G259E, Y253H, F359I, F359L, M244V. Most frequent mutations were T351I, M351T and M244V. The microarray genotyping data were confirmed by Sanger sequencing of selected samples. The sensitivity of the approach was experimentally tested. The method allowed detecting 2% of mutant DNA in the background of wild-type DNA. All CML patients carrying mutations developed imatinib resistance.
Summary and Conclusions: A low-density microarray-based approach has been developed to identify mutations in tyrosine-kinase domain of BCR-ABL gene, leading to resistance against target therapy with imatinib. The method includes RT-PCR following by allele-specific hybridization with immobilized oligonucleotide probes. Fifteen BCR-ABL mutations which determine 85% of imatinib resistant cases are included in the assay. The sensitivity of the method allows detecting at least 2% of cells carrying mutations among cells with wild-type BCR-ABL gene. The feasibility of the assay for routine clinical practice has been demonstrated by genotyping of CML samples.

E1074

ANTIPROLIFERATIVE AND APOPTOTIC EFFECTS OF PONATINIB AND ITS EFFECTS ON MACROMOLECULAR CHANGES IN IMATINIB-SENSITIVE AND RESISTANT CHRONIC MYELOID LEUKEMIA (CML) CELL LINES: A MECHANISTIC APPROACH

M. Kartal Yandim[1,*] C. Ceylan[2], E. Elmas[2], Y. Baran[1]
[1]Molecular Biology and Genetics, [2]Food Engineering, Izmir Institute of Technology, Izmir, Turkey

Background: Although effective treatment strategies have been invented for CML therapy, CML patients have still developed resistance against tyrosine kinase inhibitors used in the clinic. The most aggressive reason of resistance in CML therapy is T315I mutation. Frontline therapeutics, imatinib, nilotinib, and dasatinib cannot be effective in CML patients with T315I mutation. Ponatinib, approved in 2012 by FDA, is an effective inhibitor of BCR/ABL, even with

the mutation T315I. However, the exact mechanism of ponatinib in CML has been still unknown.
Aims: In this study, we aimed to examine apoptotic and antiproliferative effects of ponatinib, and also its effects on macromolecules in imatinib-sensitive K562 human CML cell lines and 3 μM-imatinib-resistant K562/IMA3 CML cell lines generated at our lab. In other words, we aimed to determine the potential mechanisms and structural metabolic changes activated by ponatinib-treatment in CML cell lines.
Methods: K562/IMA3 cells were previously generated by selecting them under increased concentrations of imatinib. The cells are resistant to 3 μM imatinib. Cytotoxic effects of ponatinib on K562 and K562/IMA3 cells were determined by MTT assay while apoptotic effects were assessed by examining the changes in caspase-3 enzyme activity, loss of mitochondrial membrane potential (MMP), and the localization of phosphatidylserine on the plasma membrane by Annexin-V staining. Cytostatic effects of ponatinib were determined by flow cytometry after propidium iodide staining. Changes in macromolecules were determined by Fourier Transform Infrared (FTIR) spectroscopy as the intensities of the secondary derivatives of the absorption bands.
Results: IC50 values of ponatinib for 72 h in K562 and K562/IMA3 cells were found 1,72 nM and 28,5 nM, respectively. In order to examine the apoptotic effects of ponatinib, K562 and K562/IMA3 cells were treated increasing concentrations of ponatinib (10-100 nM) for 72 h. Caspase-3 enzyme activity changed 1,82- to 2,38-fold; and 1- to 1,45-fold in K562 and K562/IMA3 cells, respectively, as compared to untreated controls. Ponatinib treatment also caused changes in MMP by 1,3- to 3,56-fold; and 1- to 6,6-fold in K562 and K562/IMA3 cells, respectively, as compared to untreated controls. Additionally, ponatinib increased apoptotic cell population 1,96- to 8,47-fold in K562 cells in response to 10-100 nM ponatinib; and also 7,75- and 9,64-fold in K562/IMA3 cells exposed to 50- and 100 nM ponatinib, respectively. Furthermore, cell cycle analyses revealed that ponatinib arrested K562 and K562/IMA3 cells at G1 phase, and it also arrested K562/IMA3 cells treated with the highest concentration at G2/M phase. Moreover, FTIR results showed that the transcription rate observed as 994/969 cm^{-1} ratio (RNA/DNA ratio) decreased 13.79% in K562/IMA3 cells. The glycogen/DNA ratio indicated by 1023/1021 cm^{-1} ratio decreased in K562 cells by 8.15% whereas it increased by 16.67% in K562/IMA3 cells. The intensity ratio of 1172/1011 cm^{-1} is accepted as the ratio of cholesterol esters/DNA and it decreased in both types of the cells. The order of the cellular DNA is expressed as 1069/1053 cm^{-1} decreased in K562 cells, whereas increased in K562/IMA3 cells.
Summary and Conclusions: Under the light of these results, ponatinib could affect strongly both imatinib-sensitive and resistant CML cells via cytotoxic, cytostatic, and apoptotic ways in a dose-dependent manner. Moreover, our results indicate that increasing concentrations of ponatinib causes significant structural and organizational changes in both imatinib-sensitive and -resistant K562 cells.

E1075

COMPARATIVE ANALYSIS OF BCR-ABL AND VEGFR2 INHIBITORY ACTIVITIES OF PONATINIB, AXITINIB, AND PF-114

J.M. Gozgit[1,*] F. Gonzalvez[1], Y. Song[1], T. Baker[1], V.M. Rivera[1]
[1]ARIAD Pharmaceuticals, Inc., Cambridge, United States

Background: Resistance to tyrosine kinase inhibitors (TKIs) in patients (pts) with chronic myeloid leukemia (CML) is frequently caused by mutations in the BCR-ABL kinase domain. The T315I gatekeeper mutation (BCR-ABL^{T315I}) confers uniform resistance to all approved TKIs except ponatinib, which has demonstrated deep and durable responses in heavily pretreated pts without or with BCR-ABL mutations, including T315I. However, at a starting dose of 45 mg, ponatinib treatment is also associated with an increased risk of arterial occlusive events. Ponatinib also inhibits a number of other kinases that may contribute to its adverse event profile, including VEGFR2. Recently, axitinib, a commercially available VEGFR2 inhibitor, was reported to have preclinical activity against BCR-ABL^{T315I}, and PF-114, a close analog of ponatinib, was reported to have T315I activity while exhibiting reduced inhibitory activity against VEGFR2.
Aims: To compare the anti-BCR-ABL and -VEGFR2 activities of axitinib and PF-114 to that of ponatinib, and where possible, relate these potencies to clinical PK parameters to address the potential for these compounds to be clinically effective.
Methods: The potencies of ponatinib, axitinib, and PF-114 were assessed using Ba/F3 cells whose viability was dependent on native BCR-ABL, BCR-ABL^{T315I}, or VEGFR2. IC_{50}s for ponatinib and axitinib were compared to "clinically effective" plasma concentrations (C_{eff}), which were derived using average steady-state levels in patients treated at recommended starting doses (C_{ave} 101 nM and 49 nM for 45 mg qd ponatinib and 5 mg bid axitinib, respectively), and corrected for the functional effects of protein binding that we measured *in vitro* (3.6-fold for ponatinib and 49-fold for axitinib). Analysis of crystal co-structures was used to assess detailed molecular ligand-protein interactions.
Results: Consistent with previously reported results, ponatinib potently inhibits the activity of native and T315I-mutant BCR-ABL, as well as VEGFR2, with IC_{50}s ≤5 nM (Table). These IC_{50}s are substantially below the C_{eff} of ponatinib in patients (28 nM). Axitinib is a similarly potent inhibitor of VEGFR2, with an IC_{50} (2 nM) that is close to its C_{eff} (1 nM). However, axitinib has substantially lower activity against T315I and native BCR-ABL (IC_{50}s 365 and 635 nM, respectively). PF-114 inhibits native BCR-ABL (13 nM), though less potently than ponatinib, and has substantially lower activity against not only VEGFR2, but also BCR-ABL^{T315I} (IC_{50}s 201 and 538 nM, respectively). A plausible explanation for this loss of potency is the introduction of an atom substitution into PF-114 that creates a repulsive molecular interaction with a conserved structural element in the hinge-binding region of the proteins.

Table: IC_{50} in Ba/F3 Cell Viability Assay (nM)

	Native BCR-ABL	BCR-ABL^{T315I}	VEGFR2
Ponatinib	1	5	3
Axitinib	635	365	2
PF-114	13	538	201

Summary and Conclusions: Neither axitinib nor PF-114 has a preclinical profile that would suggest greater potential clinical benefit than ponatinib. Concentrations of axitinib required to inhibit T315I and native BCR-ABL substantially exceed effective concentrations achievable in patients, and those required to inhibit its clinically validated target VEGFR2. In generating PF-114, structural modifications of ponatinib, designed to reduce its VEGFR2 activity, also result in reduced potency against native BCR-ABL, and especially against BCR-ABL^{T315I}. A dose ranging trial aimed at evaluating the benefit/risk of ponatinib treatment for patients with CML is planned.

E1076

CD26 ANTIGEN IS SPECIFIC FOR LEUKEMIC STEM CELLS IN CHRONIC MYELOID LEUKEMIA AND DISTINGUISHES PATIENT GROUPS WITH DIFFERENT RATIOS OF LEUKEMIC AND HEALTHY STEM CELLS

M. Culen[1,*] M. Borsky[2], V. Nemethova[2], J. Smejkal[2], T. Jurcek[2], D. Dvorakova[2], B. Weinbergerova[2], L. Semerad[2], D. Zackova[2], J. Mayer[2], Z. Racil[2]
[1]Faculty of Medicine, Masaryk University, [2]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic

Background: Putative leukemic stem cells (LSC) persist in chronic myeloid leukemia (CML) patients during treatment and constitute risk of relapse. To study LSC and develop a targeted therapy, it is necessary to define these cells. Herrmann *et al.* (Blood 2014) recently proposed that CML LSC are defined by expression of CD26. We therefore set to further confirm these results on a larger group of patients.
Aims: To analyze the stem cell population in a wider cohort of chronic phase CML patients based on CD26 expression and to analyze the disease burden in sorted CD26- and CD26+stem cells.
Methods: For 25 consecutive *de novo* patient samples, we FACS sorted CD45+34+38-/dim population into CD26- and CD26+cells fractions and analyzed the Ph burden in both fractions by FISH. Additionally, we re-analyzed the FACS data and CD26 expression on SC using a more stringent CD45+34+38- gate. Detection of BCR-ABL1 in sorted sub-fractions was performed using single-cell nested RT-PCR.

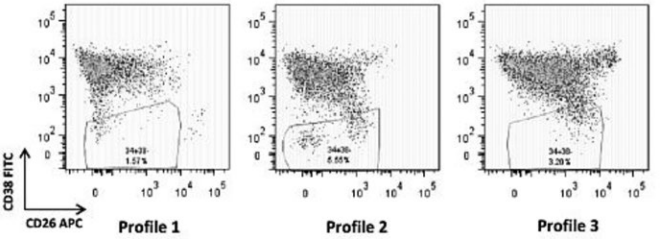

Figure 1.

Results: We FACS sorted CD26- and 26+SC populations and analyzed the percentage of Ph+cells in both fractions by FISH. This showed 96.2±9.3% (mean±SD) Ph+cells in the supposed CD26+LSC fraction, and 40,0±42,0% (mean±SD) Ph+cells in the CD26- fraction, regarded as HSC, which, however, did not correspond with the results by Herrmann *et al.* We suspected that the Ph positivity in CD26- fraction originated from cells with slightly higher CD38 expression (thus being CD38dim non-SC), included in the sorting to provide enough cells for FISH analysis. Therefore, we performed a re-analysis of all our FACS data with more stringent CD38- gate and re-analyzed the CD26 expression in the pure CD38- SC population. This revealed three clear CD26 SC expression profiles among the patients: 1 – dominant CD26- population; 2 – equal CD26- and +populations; 3 – missing CD26- population. The re-analysis results therefore supported our previous theory; where, for example, the patients analyzed with almost 100 % FISH Ph+cells in sorted CD26- fraction had no or very few (0-11%) HSC after the re-analysis (Profile 3). This confirmed that the FISH positivity in sorted CD26- fraction originated from the CD38dim/26- non-stem cells and proved the concept that CD26 expression

reflects Ph positivity only in the true hematopoietic CD34+38- compartment. To provide a further proof, we analyzed 3 samples using a nested RT-PCR protocol for single cell analysis. Here, we sorted 3-5 consecutive sub-fractions (each constituting 5-20 cells) for both CD26- and +populations, ranging from most CD38neg to CD38dim. CD26+population proved positive in all sub-fractions, whereas in CD26- population, a weak BCR-ABL1 positivity could be detected only for sub-fractions previously defined for re-analysis as CD38dim.
Summary and Conclusions: We have confirmed that CD26 based differentiation of CML HSC and LSC (CD45+34+38-) is applicable irrespective of CD26 expression profiles, showing different HSC/LSC ratios, and proved the concept that CD26 expression reflects Ph positivity only in strictly gated true hematopoietic CD34+38- compartment. The results also show that simultaneous sorting of pure CD26+LSC and CD26- HSC fractions from one patient will often be unfeasible due to low cell number in either population. These findings extend our knowledge on SC in CML and are important for further study and eradication attempts of LSC.

E1077

SPHINGOSINE-1-PHOSPHATE RECEPTOR 2/GQ/PHOSPHOLIPASE C AXIS IS A NOVEL MECHANISM TO OVERCOME NILOTINIB RESISTANCE IN T315I MUTATION EXPRESSING 32DCL3 MURINE CELLS

A. Adan Gökbulut[1,*] B. Ogretmen[2], Y. Baran[1]
[1]Molecular Biology and Genetics, İzmir Institute of Technology, İzmir, Turkey, [2]Department of Biochemistry and Molecular Biology, Medical University of South Carolina, Charleston, United States

Background: Chronic myeloid leukemia is characterized by the Philadelphia chromosome (Ph), encoding chimeric BCR-ABL with constitutive tyrosine kinase activity. Although tyrosine kinase inhibitors (TKIs) provide great success in the treatment, the development of resistance against TKIs is a main problem in CML patients. Despite the expression of mutant forms of BCR-ABL such as T315 mutation is a common reason for the development of nilotinib resistance, the alterations in sphingolipid signaling pathway is an alternative significant BCR-ABL1-dependent resistance mechanism. Some sphingolipid members such as ceramide have apoptotic effects while others like sphingosine-1 phosphate (S1P) cause the development of drug resistance and induce cell growth. Recently, we showed that sphingosine kinase-1 (SK-1)/sphingosine-1 phosphate (S1P)/ sphingosine-1 phosphate receptor 2 (S1P2)-mediated drug resistance is related to inhibition of protein phosphatase 2A (PP2A), causing increased stability of BCR-ABL1 (Salas *et al*. Blood 2011) However, specific signaling cascade involved in this process remains unkown.
Aims: Determine the details of S1P2/PP2A mediated-TKI resistance in a mechanistic manner by identifying intermediate players between S1P2 and PP2A.
Methods: BCR-ABL1 expressing 32Dcl3 cells, 32D-p210$^{Bcr-Abl}$(wt) and 32D-p210$^{Bcr-Abl}$(T315I) were used. The antiproliferative effects of nilotinib, SK-1 inhibitor (PF-543), S1P2 inhibitor (JTE-013), phospholipase C inhibitor (U-73122) and nilotinib/PF-543 and nilotinib/JTE-013 combinations on wt and resistant cells were determined by MTT assay. Isobologram analysis was performed using CompuSyn program. The mRNA and protein levels of BCR-ABL1, SK-1 and S1P2 were checked by qRT-PCR and western blotting. Resistant cells were also transfected with Gq peptide. The effect of U-73122/okadaic acid (PP2A inhibitor) and Gq peptide/ okadaic acid combinations on BCR-ABL1 levels were evaluated by western blot.
Results: Vector transfected control cells do not give any response to nilotinib while IC_{50} values were 8 and >500 nM for wt and resistant cells, respectively. IC_{50} values for JTE-013 were calculated as 20 and 40 μM while that for PF-543 were 8 and 30 μM, respectively. Nilotinib/PF-543 and nilotinib/JTE-013 combination studies showed strong synergistic effects on both cell types as indicated by MTT assay and isobologram results. Although there is no significant changes in BCR-ABL1 levels for wt and resistant cells, SK-1 and S1P2 levels increased in resistant cells. Combination studies caused significant decreases in BCR-ABL1 protein levels in resistant cells comparing to untreated control, PF-543 or JTE-013 alone treatments. Overall, these data suggest that nilotinib resistance is not related to BCR-ABL1 overexpression, but related to SK-1/S1P2 axis. Although U-73122 and Gq peptide treatments decreased BCR-ABL1 protein, their combination with okadaic acid restored BCR-ABL1 protein levels. Therefore, SK-1/S1P2-mediated nilotinib resistance could be overcome by activating PP2A through the inhibition of Gq and phospholipase C, which are the newly identified players in this signaling.
Summary and Conclusions: Our data suggest that BCR-ABL1 levels decreased by activating PP2A via Gq and phopholipase C inhibition, which is a novel mechanism reported for the first time. This proposed mechanism of nilotinib resistance could be a potential novel therapeutic target to overcome nilotinib resistance.

Background: The mechanism of action of imatinib is known to involve the Fas-mediated apoptosis pathway. Consequntly inter-individual variations in this apoptosis pathway might be associated with imatinib response or resistance.
Aims: This study attempted to focus on 8 genotypes in the apoptosis pathway including *FAS* (rs1800682, rs2229521, rs2234767 and rs2234978), *FASLG* (rs763110), *CASP10* (rs13006529), and *APAF1* (rs1439123, rs2288713) and analyzed their association with treatment outcomes including molecular response with 4.5 log reduction (MR4.5), following imatinib therapy in 187 Korean CML patients.
Methods: Candidate genotypes were selected as non-synonymous SNPs in exon regions with a minor allele frequency over 0.01 or based on the literature review. The candidate SNPs were primarily evaluated for adequacy of Hardy-Weinberg Equilibrium (HWE) using the Chi-square test. HWE and genotype frequencies were calculated using Haploview software version 4.2 (Broad Institute, Cambridge, MA). For validation of the genetic effect, we performed internal validation using a bootstrap algorithm.
Results: The GG/GA genotype in *FAS* (rs2234767) showed a higher rate of MR4.5 than the AA genotype (at 5 years 59.7% *vs* 37.4%, p=0.013). Using a bootstrap procedure for internal validation we confirmed that FAS (rs2234767) correlates with MR4.5 (p=0.050). Multivariate analysis confirmed that the *FAS* genotype (rs2234767) is an independent surrogate for MR4.5 (p=0.019, HR 0.43, 95% CI [0.22-0.87]).
Summary and Conclusions: In conclusion, the Fas/FasL signaling pathway may represent the major pathway that mediates apoptosis in CML treated with imatinib. SNP markers in the apoptosis pathway including *FAS* genotype (rs2234767) can be potential surrogates for predicting deeper molecular response after imatinib therapy.

THE ROLE OF MICRORNAS IN RESPONSE TO NEW TARGETED THERAPIES IN CHRONIC MYELOID LEUKEMIA

S. Veiga[1], A. Pires[1], R. Alves[1,2,3], S. Fernandes[1,4], P. Matafome[5], R. Seiça[5], A.C. Gonçalves[1,2,3], A.B. Sarmento Ribeiro[1,2,3,6,7,*]
[1]Applied Molecular Biology and University Clinic of Hematology, [2]CIMAGO - Center of Investigation on Environment Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, [3]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, [4]Department of Biology, University of Aveiro, Aveiro, [5]Laboratory of Physiology, Institute of Biomedical Imaging and Life Sciences (IBILI), Faculty of Medicine, University of Coimbra, [6]7Center for Neuroscience and Cell Biology and Institute for Biomedical Imaging and Life Sciences (CNC.IBILI), University of Coimbra, [7]Clinical Hematology, Centro Hospitalar Universitário de Coimbra (CHUC), Coimbra, Portugal

Background: Imatinib is, at present, the first-choice treatment for chronic myeloid leukemia (CML) patients. Despite the impressive success of treatment obtained with this drug, some patients show incomplete response or resistance to Imatinib. The BCR-ABL oncoprotein, resulting from the *BCR-ABL* fusion gene, characteristic of CML, is able to activate multiple signaling pathways, including the NF-kB, mTOR and the proteasome pathways, which may provide new therapeutic targeted alternatives in cases of resistance to Imatinib. Furthermore, the altered expression of microRNAs, small RNA molecules that regulate gene expression, may influence the sensitivity and/or acquisition of resistance to therapy.
Aims: Our goal was to evaluate the influence of the expression levels of miR-21, miR-125b, and miR-155 in CML cell lines sensitive and resistant to Imatinib, as well as the therapeutic potential of new drugs such as Bortezomib, Parthenolide, and Everolimus.
Methods: In this work we used two CML cell lines, one sensitive to Imatinib (K562 cells) and another resistant to Imatinib (K562 RC cells). Cell viability was assessed by rezasurine assay and cell death by flow cytometry (annexin V and propidium iodide) and through optic microscopy (May-Grünwald-Giemsa staining). The expression of BAX, BCL-2, phosphorylated NF-kB, ubiquitin conjugates, and cell cycle analysis was performed by flow cytometry. The expression levels of AKT and AKT activation were analyzed by Western Blot. MiRNAs expression was performed by qRT-PCR using commercial kits.
Results: Initially we observed that K562 RC cells had increased expression of miR-21 and miR-125b as well as decreased expression of miR-155 in relation to K562 cells. Bortezomib, Parthenolide and Everolimus were able to induce a

decrease in cell viability in a time-, dose- and -dependent manner. Parthenolide and Bortezomib induce a stronger cytotoxic effect on K562 cells resistant to Imatinib, while Everolimus shows a higher cytotoxic effect on K562 cells sensitive to Imatinib. These results may be related to the differential expression of miRNAs observed in the cell lines. These compounds induce cell death predominantly by apoptosis and also induce cell cycle arrest. Furthermore, Bortezomib induced a decrease in NF-κB levels and an increase in ubiquitin levels in both cell lines and may represent a possible therapeutic alternative for CML patients resistant to Imatinib. Moreover, it was found that Parthenolide influences NF-κB levels in a dose and cell type-dependent manner, since small doses induce a decrease of NF-κB in Imatinib-sensitive cells, while high doses induce a decrease of NF-κB in the resistant cell line and an increase in the sensitive cell line. Additionally, it was also observed that treatment with these compounds was also able to modulate miRNAs expression levels, which can influence therapy response.

Summary and Conclusions: In summary, miR-21, miR-125b and miR-155 expression levels could provide new biomarkers predictive of response to TKI and/or new targeted drugs such as Bortezomib, Parthenolide and Everolimus in CML. Moreover, these drugs may be new therapeutic approaches in CML, specially Bortezomib and Parthenolide, namely as an alternative therapy in CML patients with resistance to Imatinib. *This work was supported by CIMAGO and R. Alves is supported by the FCT fellowship FRH/BD/51994/2012.*

E1080

A STUDY OF CELL CYCLE KINETICS AND OF KU80 EXPRESSION AS A MARKER OF GENETIC INSTABILITY IN BONE MARROW MESENCHYMAL STEM CELLS OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA

V. Papadopoulou[1,*] I. Anagnostopoulos[1], D. Koumpi[1], C. Peste[1], D. Dimitroulis[2], A. Galanopoulos[3], M. Sofotasiou[1], A. Pouli[4], P. Tsaftaridis[5], P. Zervakis[1], P. Diamantopoulos[1], N. Viniou[1]
[1]1st Department of Internal Medicine, Hematology Unit, University of Athens, [2]2nd Department of Surgery, Laiko Hospital, University of Athens, [3]General Hospital ''G.Gennimatas'', [4]''Agios Savvas'' Hospital, [5]Hematology Clinic, University of Athens, Athens, Greece

Background: In chronic myeloid leukemia (CML), there is a well-characterized lesion of the haemopoietic stem cell; however, mechanisms underlying disease initiation and progression are unclear. Therefore, the role of bone marrow (BM) stromal cells in disease pathogenesis merits further investigation. In myelodysplastic syndromes, BM mesenchymal stem cells (MSCs) were shown to have a proliferation defect in comparison to BM MSCs of healthy individuals.
Aims: We first examined BM MSCs of CML for cytogenetic abnormalities. We then studied kinetics of BM MSCs from CML patients and compared them to those of BM MSCs from healthy controls. We also measured expression of the Ku80 protein, a protein involved in non-homologous end joining of double strand DNA breaks, as a marker of genetic instability. We compared Ku80 expression among BM MSCs of CML patients, adipose tissue (healthy tissue) MSCs of CML patients and BM MSCs of healthy individuals.
Methods: Samples of seven (7) CML patients (6 diagnosed in chronic phase and 1 in blast crisis) were collected before onset of therapy, along with samples of 4 healthy controls. MSCs were isolated from the mononuclear cell fraction of BM or adipose tissue via a limited number of passages, removing non-adherent-to-plastic cells. Purity of MSCs from haemopoietic cell contaminants (>94%) was confirmed by flow cytometry; mesenchymal stem cells were positive for CD90, CD73 and CD105 and negative for CD34, CD45 and CD14. Karyotyping was performed in BM MSCs of CML patients. BrdU and 7-AAD staining of BM MSCs to detect S-phase and apoptotic cells, respectively, was performed via standard protocols and stained cell populations were analyzed with flow cytometry. Cell lysates of BM and adipose tissue MSCs were used in standard SDS electrophoresis. Western blotting with the use of Ku80 and actin antibodies was performed.
Results: Karyotypes of BM MSCs of CML patients were normal. Percentage of S-phase cells and apoptotic cells was compared between patient BM MSCs (20,4% S-phase, 2,7% apoptosis) and control BM MSCs (19,3% S-phase, 4,6% apoptosis). Mean values (t-test) did not have a statistically significant difference (p=0,88% for S-phase percentage and p=0,92% for apoptosis). The ratio of expression Ku80/actin, calculated by densitometry of Western blotting bands, did not differ to a statistically significant degree among: patient BM MSCs, adipose tissue MSCs and control BM MSCs (one-way ANOVA for 3 groups, p=0,28).
Summary and Conclusions: Bone marrow mesenchymal stem cells in CML are known to lack the BCR-ABL fusion gene, but their properties and possible contribution to disease pathogenesis have not been thoroughly researched. This is the first study of kinetics of BM MSCs in CML in the literature. We have shown that BM MSCs display a normal karyotype and have a proliferative and apoptotic potential equivalent to MSCs of healthy individuals. We have additionally shown that expression of Ku80, a marker of genetic instability (double strand DNA breaks), does not significantly differ between BM MSCs of patients and those of adipose tissue MSCs or MSCs of healthy donors. Further research is warranted on properties of MSCs in CML, also assessing whether these properties can be exploited in bone marrow transplantation strategies.

E1081

BCR-ABL EXPRESSION IS REDUCED IN THE PRIMITIVE PRECURSOR FRACTION FROM CML TKI-TREATED PATIENTS.

M.S. Ruiz[1,*] S. Baffa Trasci[1], B. Moiraghi[2], M. Pérez[3], R. Burgos[4], C. Foncuberta[4], A. Vitriu[4], C. Pavlovsky[5], J. Mordoh[1], I. Larripa[6], J.C. Sánchez Ávalos[4], M. Bianchini[1]
[1]Centro de Investigaciones Oncologicas - Fundacion Cancer, [2]Hospital J.M. Ramos Mejía, Ciudad Autonoma de Buenos Aires, [3]Hospital Interzonal General de Agudos Prof. "Dr. Rodolfo Rossi", La Plata, [4]Instituto Alexander Fleming, [5]Fundaleu, [6]IMEX-CONICET, Ciudad Autonoma de Buenos Aires, Argentina

Background: Insensitivity to imatinib is a property exhibited by a population of leukemic rare, primitive stem cells that are present in most chronic myeloid leukemia (CML) patients, even in those with sustained undetectable molecular residual disease (UMRD). It remains unclear whether such patients are definitively cured or whether leukemic stem cells (LSCs) that persist in their bone marrow represent a risk of disease recurrence. This suggests that the characterization of LSCs by functional assays could be of interest in clinical practice.
Aims: To evaluate the burden of LSCs in TKI-treated patients.
Methods: We evaluated the presence of LSCs in patients with CML at different levels of molecular response induced by imatinib or nilotinib, and patients naïve of treatment. All patients gave their informed consent. Bone marrow-derived $CD34^+$cells were used as initiators for 2-week CFU-C and 6-week long-term culture-initiating cell (LTC-IC) assays. Their phenotype was defined using RT-qPCR on individual (8-10 colonies per patient) and pooled colonies (24-30 colonies per patient).
Results: In samples from newly diagnosed patients, BCR-ABL mRNA expression was measured in individual colonies from CFU-C assays (mean %BCR-ABL/ABL=24.0, SD=7.3, n=4). However, in LTC-IC assays, BCR-ABL mRNA only became detectable when measured in pools of 3-15 colonies (mean %BCR-ABL/ABL =6.6%, SD=9.6, n=3). BCR-ABL mRNA levels were highly variable in LTC-IC-derived pooled CFU-Cs, but still lower than in 2-week CFU-Cs (ANOVA, $p<0.05$) (Figure 1a). In patients under TKIs treatment, BCR-ABL transcripts were only detectable in LTC-IC-derived pooled CFU-Cs from patients with a high burden of disease (n=7, %BCR-ABL/ABL in peripheral blood=1.1-7.7%), whereas no BCR-ABL transcripts were detected either in individual colonies from patients with a high burden of disease, nor in individual or pooled colonies from patients with deeper responses (n=5). We observed a tendency of reduction in BCR-ABL/ABL ratios in LTC-IC-derived CFU-Cs in accordance with a reduction in disease burden, measured at peripheral blood and in response to TKIs treatment (Figure 1b). On the other hand, the number of colonies (expressed as the square root of no. colonies per 1,000 initiating cells) obtained in LTC-IC assays was higher in patients showing a deep molecular response (defined as at least $MR^{4.0}$) than for patients with a high burden of disease (at diagnose or with at least BCR-ABL/ABL of 1%) (ANOVA, $p<0.01$).

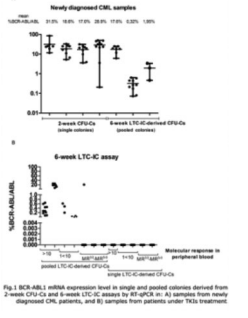

Figure 1.

Summary and Conclusions: We observed a reduction in BCR-ABL/ABL ratios in LTC-IC-derived pooled colonies compared to CFU-Cs in newly diagnosed patients. Given that these patients have not received any TKI treatment, this seems to be an intrinsic characteristic of primitive precursors, unrelated to exposure to TKI selective pressure. On the other hand, as the burden of disease was reduced by TKI treatment, lower BCR-ABL/ABL ratios were detected in the primitive fraction, suggesting that the ability to detect rare residual LSCs in TKI-treated patients will be limited by BCR-ABL expression levels. Despite that measuring on pooled colonies may be masking a dilution effect, the same tendency has been reported for HSCs and progenitor fractions isolated by sorting (Kumari et al, Blood 2012, 119:530-539), further suggesting that LSCs are not oncogene-addicted. Therefore, the results obtained in this work support the hypothesis that evaluation of minimal residual disease in candidates for discontinuation studies would benefit from the measurement of Ph^+primitive precursors cells at DNA level, so as to accurately assess LSCs persistence.

E1082

TRIM32 E3 LIGASE AS A TARGET IN CHRONIC MYELOID LEUKAEMIA

C.K. Johnston[1,*] L.J. Crawford[1], K.M. Clarke[1], A.E. Irvine[1]

[1]CCRCB, Queen's University Belfast, Belfast, United Kingdom

Background: Chronic myeloid leukaemia (CML) is a clonal myeloproliferative disorder characterised by the presence of the BCR-ABL fusion gene. The gold standard treatment for CML is the tyrosine kinase inhibitor (TKI) imatinib. Although imatinib and second generation TKIs induce durable responses, TKI resistance is a major issue and additional therapeutic options are still required. Proteasome inhibitors have shown efficacy in the treatment of haematological malignancies which has validated the ubiquitin proteasome system (UPS) as a therapeutic target; there is now interest in targeting of specific components of the UPS, such as E3 ligases and deubiquitinating enzymes. We have shown previously that the proteasome inhibitors, bortezomib and carfilzomib, potently induce apoptosis in imatinib-sensitive and -resistant CML cell lines and primary CD34+CML cells, suggesting that CML cells may be sensitive to targeting of other UPS components. Gene expression profiling of CML CD34+cells compared to normal CD34+cells using UPS-specific microarrays (PIQOR) identified that the E3 ligase TRIM32 was overexpressed in CML (p=0.02). TRIM32 is a member of the TRIM family of RBCC proteins; it contains a RING finger domain, one or two B-boxes, and a predicted coiled-coil domain. Studies have shown TRIM32 to be involved in the ubiquitination and degradation of the tumour suppressor proteins abelson interactor (ABI)-2 and p53.
Aims: The aim of this study was to examine the expression of TRIM32 in CML cell lines and investigate its effects on ABI-2 and p53.
Methods: TRIM32 expression in KCL22 and LAMA84 imatinib sensitive and resistant CML cell lines was analysed by qPCR and Western Blotting. ShRNA-mediated gene knockdown was used to analyse the effects of TRIM32 on cell viability (*CellTiter-Glo*®) and cell cycle (flow cytometry analysis of propidium iodide stained cells). Following knockdown, qPCR and western blotting were used to validate the change in TRIM32 expression. Effects of TRIM32 knockdown on ABI-2 and p53 were analysed by Western Blotting.
Results: Increased expression of TRIM32 was validated at both the gene and protein level in CML cell lines compared to normal cells. Following knockdown of TRIM32 expression with shRNA, a 14.8±8.8% decrease in cell viability was determined with a statistically significant decrease (p= *0.009*) observed in KCL22-sensitive cells. This decrease in cell viability was associated with an increase in the subG0 population in each CML cell line. TRIM32 knockdown resulted in an increase in ABI-2 and an increase in p53 protein levels. Furthermore we show that combining knockdown of TRIM32 with imatinib and nilotinib treatment increases the sensitivity of CML cell lines to theTKIs.
Summary and Conclusions: In this study we demonstrate that TRIM32 is overexpressed in CML cells at both the RNA and protein levels. Knockdown of TRIM32 results in decreased cell viability and increased apoptosis. This was associated with an increase in expression of the tumour suppressors ABI-2 and p53. TRIM32 knockdown also increased sensitivity of CML cells to TKIs. Loss of ABI-2 has been previously shown to contribute to BCR-ABL+leukaemia progression and suppression of p53 has been seen to enhance survival and proliferation of CML. These studies suggest that TRIM32 may be a relevant therapeutic target in CML and further study is warranted.

E1083

SELECTION OF RUNX1-MUTATED CLONE ASSOCIATED WITH RELAPSE AND BLAST CRISIS IN CHRONIC MYELOID LEUKEMIA PATIENT AFTER ALLO-HSCT AS REVEALED BY TARGETED ENRICHMENT AND DEEP SEQUENCING

I. Solarska[1,*] M. Machnicki[1,2], P. Stawinski[3], B. Pienkowska-Grela[4], B. Nasilowska-Adamska[5], I. Seferynska[6], R. Ploski[3], T. Stoklosa[1]
[1]Immunology, The Medical University of Warsaw, [2]Postgraduate School of Molecular Medicine, [3]Medical Genetics, The Medical University of Warsaw, [4]Cytogenetics, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, [5]Stem Cell Transplantation, [6]Hematology, Institute of Hematology and Blood Transfusion, Warsaw, Poland

Background: Advanced phase of chronic myeloid leukemia called blastic phase or blast crisis (CML-BC) is incurable, despite success of targeted therapy for the chronic phase CML (CML-CP). CML-BC is characterized by successive increase in amount of blast cells in blood and bone marrow but pathogenesis is still poorly understood. Majority of genomic studies are focused on detecting clonal abnormalities, which arise during the progression of the disease and are present only in advanced phase of the disease. However, recent findings revealed, that in addition to the t(9;22) translocation, CML-CP at diagnosis may already harbor a variety of sporadic genetic aberrations affecting the prognosis and treatment.
Aims: We aimed at employing targeted deep-sequencing strategy to dissect the underlying genetic cause of clonal evolution and rapid progression to CML-BC in a patient who relapsed after allogeneic haematopoietic stem cell transplantation (HSCT), developed lymphoid CML-BCs and died within 18 months.
Methods: Targeted enrichment strategy (NimbleGene SeqCap EZ Choice custom gene panel comprising almost 1000 genes) was applied followed by massive-parallel sequencing using the Illumina HiSeq1500 system and chemistry. The data were processed by the CASAVA. Reads were mapped to the reference genome (hg19 build) using Burrows-Wheeler Aligner 6.2 and processed using Genome Analysis Toolkit. The detected variants were annotated using Annovar. Alignments were viewed with Integrative Genomics Viewer.
Results: Female patient (30-yrs old) was diagnosed with CML in 12/2005 (low Sokal and Hasford score and no detectable clonal cytogenetic abnormalities (CCA) additional to Philadelphia chromosome). Within 6 months from the diagnosis patient underwent allo-HSCT and achieved 100% chimerism and complete cytogenetic remission (CCyR) but not a major molecular response (MMR). After 4 months, patient relapsed with lymphoid BC with no detectable *BCR/ABL1* mutation at that time. Despite intensive chemotherapy and imatinib patient developed within few months 2nd BC and Y253H mutation in *BCR-ABL1* was detected. Then dasatinib was added to chemotherapy and patient obtained partial remission. Unfortunately, 14 months after transplantation patient developed 3rd BC with detectable *BCR-ABL1* T315I mutation and died. Since there were no CCA detected at any time point, we screened four sequential DNA samples (peripheral blood leukocytes): one from the time of diagnosis and three samples from three consecutive BCs with targeted deep sequencing. We detected a nonsense R320* *RUNX1* mutation, resulting in carboxyl-terminal truncated RUNX1 protein in all 4 samples. Importantly, this mutation was already present in the diagnostic sample, although the prevalence of mutated clone was low (1%). In the BC samples *RUNX1*mut. clone rised and ranged between 90% to 50% of CML blasts (Figure 1). We have also confirmed both *BCR-ABL1* mutations previously detected with standard sequencing. Interestingly appearance of T315 clone in the 3rd BC was associated with lower frequency of *RUNX1* mutated clone (Figure1). No *BCR-ABL1* gene mutation was detected by NGS sequencing in diagnostic sample nor in the 1st BC. Additionally, missense mutation in *ASXL1* (Q1102N) was detected in all samples, consistent with observation in acute myeloid leukemia (AML),where mutations in *ASXL1* frequently co-occurs with *RUNX1*.

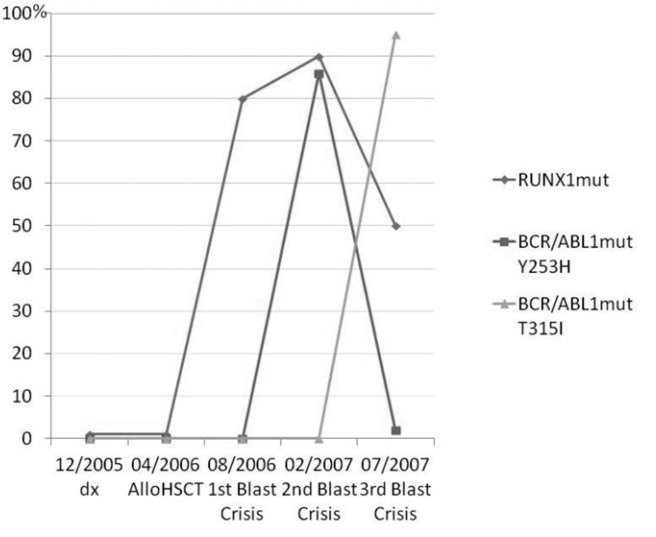

Figure 1. Frequency of RUNX1-mutated and BCR-ABL1-mutated clones during progression and subsequent CML-BCs.

Summary and Conclusions: Deregulation of RUNX1 transcription factor by chromosomal translocation or mutation are common events in haematological malignancies, especially in AML. In CML-BC *RUNX1* mutations have been reported in few studies. We have shown that *RUNX1* mutation may be already present in CML -CP at diagnosis and may potentially occur as a pre-leukemic event prior to t(9;22) translocation (as also recently described by Schmidt *et al.*, Leukemia 2014; 28(12); 2292-9). Genetic screening of a large cohort of patients at diagnosis may answer if presence of CML cells with *RUNX1* mutation at diagnosis confers a negative prognostic factor.

E1084

NANOPORE SEQUENCING TO RAPIDLY CHARACTERISE LEUKEMIA-SPECIFIC GENOMIC TRANSLOCATION BREAKPOINTS

A. Chase[1,2,*] M. Lyon[3], J. Score[1,2], C. Mattocks[1,2], N.C. Cross[1,2]
[1]School of Medicine, University of Southampton, Southampton, [2]Wessex Regional Genetics Laboratory, Salisbury Hospital, Salisbury, [3]Institute of Medical Genetics, University Hospital of Wales, Cardiff, United Kingdom

Background: The identification of leukemia associated fusion genes is critical for the correct diagnosis, choice of therapy and molecular monitoring of hematological malignancies. Although usually inferred by cytogenetic analysis, the precise identification of fusion genes typically requires specific PCR amplification from cDNA and careful positioning of primers to enable detection of all possible mRNA variants. Identification of gene fusions from genomic DNA is

technically much more demanding since for many genes the breakpoints are dispersed over large regions, for example >100kb in the case of *ABL1*. Nevertheless, the identification of genomic breakpoints provides some potential advantages, for example patient-specific molecular monitoring using genomic DNA enables the cellular burden of residual disease to be estimated much more accurately than RT-PCR based methods. Furthermore, genomic DNA assays facilitate much more sensitive detection of residual disease. We have previously described long range PCRs (up to 10 kb) that amplify genomic breakpoints of two fusions, *BCR-ABL1* and *FIP1L1-PDGFRA*, with subsequent breakpoint identification by more focused PCR and Sanger sequencing. It is expected that new sequencing technologies will simplify this process, ideally allowing *ab initio* identification of any fusion gene present from genomic DNA. The Oxford Nanopore MinION is a miniature sensing system currently adapted for DNA single molecule sequence analysis. A DNA strand passes through a nanopore which registers a change in current allowing determination of nucleotide sequence. The MinION device is currently being made available by Oxford Nanopore though an early access program.
Aims: To assess Nanopore technology for sequencing long range PCR products to identify precise translocation breakpoints.
Methods: Long range PCR products encompassing genomic fusions were amplified from *BCR-ABL1* (n=4) and *FIP1L1-PDGFRA* (n=5) positive samples. PCR products were processed according to the Oxford Nanopore genomic DNA protocol which involves end repair, dA-tailing, ligation of adapter, HP motor and tether. *FIP1L1-PDGFRA* fragments were sequenced using R6 flow cell chemistry and *BCR-ABL1* fragments using R7 chemistry. Samples were run sequentially with washing between samples. Reads were aligned to the reference genome and split at their 'soft' or 'hard' clip sites using an in-house programme. The resulting daughter reads were subjected to another round of alignment in order to finely map fusion breakpoints.
Results: A median of 40 reads (range 7 - 458) passing internal quality control were obtained per sample, of these 26% (11%>100%) were 2D reads *i.e.* were read in both directions and therefore of higher quality. Median read length of 2D reads was 2980bp (range 318-7729) and consistent with PCR fragment sizes. Only 2D reads were considered in subsequent analyses. During the initial alignment phase 61% (33-100%) aligned to within 50bp of one of the amplification primer sequences. The location of the breakpoints determined by Nanopore sequencing were fully concordant with breakpoints determined by focused PCR and Sanger sequencing in five samples, the remainder had insufficient read depth.
Summary and Conclusions: We conclude that LR-PCR and Nanopore sequencing provides a rapid approach to characterize genomic breakpoints in leukemia. Nanopore technology is rapidly improving and recent developments promise improved accuracy, particularly for 2D reads.

THE STUDY OF FUNCTIONAL ACTIVITY OF CD34 CELLS IN CML PATIENTS WITH DIFFERENT RESPONSE TO IMATINIB THERAPY

T. Perekhrestenko[1,*] I. Sviezhentseva[2], A. Gordienko[1], D. Bilko[2], N. Tretyak[1], I. Dyagil[3]
[1]blood disease, State Institution «Institute of Hematology and Transfusiology of NAMS of Ukraine», [2]1Centre for Molecular and Cell Research of National University of "Kyiv-Mohyla Academy", [3]blood disease, State Institution «National Research Center for Radiation Medicine of NAMS of Ukraine», Kyiv, Ukraine, Kyiv, Ukraine

Background: It is believed that the reason of the leukemic clone cell resistance to treatment with tyrosine kinase inhibitors in CML patients is mutations in the genome of an early bone marrow progenitor cells that are CD34-positive. Such cells, regardless of treatment, acquire ability to proliferation and differentiation. This leads to the re-expansion of the CD34-positive cells.
Aims: was to determine the features of CD34 antigen expression in bone marrow (BM) and peripheral blood (PB) in CML patients with different response to imatinib therapy using the results of hematopoietic cells culturing and the data of flow cytometry.
Methods: We studied the BM samples of 41 CML patients in chronic phase of disease treated with imatinib for at least 12 months. To determine the functional activity of hematopoietic cells of patients *in vitro* culturing of BM mononuclear cells in semisolid agar ("Difco", USA). To assess the phenotypic characteristics of hematopoietic cells of patients the method of direct cytometry was used. For this purpose, BM mononuclear cells were stained with monoclonal antibodies (Becton Dickinson, USA).
Results: The results of cultivation suggest that in patients with an optimal response to imatinib therapy the number of colonies was 1.8 times lower than the number of those in the group of patients with suboptimal response to therapy. In turn, in patients with failure of imatinib therapy the number of colonies was the highest and was 2.1 times higher than the patients with optimal response. In the case of clusters was recorded tendency to increase this indicator in patients with suboptimal response and treatment failure. In addition, the patients with inefficiency and suboptimal response to imatinib therapy had the significantly higher proliferative potential than in patients with optimal response. This may indicate that early progenitor cells dominated the more differentiated cells which form clusters in the culture. In turn, in the BM of patients who have increasing numbers of leukemic clone cells proliferation processes dominate over the processes of differentiation that may be the cause of the increase of the number of colonies in semisolid agar *in vitro.* The results of cytometry analysis showed that in patients with the acquisition of resistance to imatinib the number of $CD34^+$cells increases in the BM and PB. It should be noted, in patients with different response to therapy the number of CD34 antigen in BM and PB was significantly different. This may indicate that during the progression of CML and during the acquisition of resistance to the drug by leukemic clone cells the pool of early progenitor cells not only expands, but also, due to the weakening of contacts between the cells of the microenvironment and leukemic clone cells, the early progenitor cells fall in blood flow in large numbers, promoting a poorly differentiated hematopoietic cells in PB of patients. A correlation analysis was conducted to identify the correspondence between the number of CD34 cells in the BM and in PB of patients treated with imatinib. These results indicate a direct correlation between the number of colonies and clusters in semisolid agar *in vitro* and the number of CD34 cells in the patient BM (R=0,83 and R=0,58, $p<0.05$).
Summary and Conclusions: Thus, the number of CD34 cells in the BM of patients increases with the acquisition of leukemic clone cells resistance to imatinib. The correlation between the number of CD34 cells and the number of cell aggregates in semisolid agar *in vitro*, which may be predictive method for determining the future course of CML, shows the prognostic value of method for determining the CD34 cells in the BM of patients; and a parallel increase of their number in PB will allow to develop express methods for the detection of individual patient response to imatinib therapy.

TYROSINE KINASE INHIBITOR THERAPY INDUCES ALTERATIONS OF CD137 AND CD137L EXPRESSION IN CHRONIC MYELOID LEUKEMIA PATIENTS

P. Rodrigues Santos[1,2,*], P. Couceiro[2], F. Coirada[1], J. Almeida[2], D. Queirós[2], D. Gomes-Silva[3], V. Alves[1], L. Růžičková[4], P. Freitas-Tavares[4], M. Santos-Rosa[1]
[1]Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, [2]Lab Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, [3]Lab Imunologia e Oncologia, Faculdade de Medicina da Universidade de Coimbra, [4]Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: CD137 (4-1BB, TNFRSF9) is a member of the TNFR superfamily that provides expansion and survival signals to T cells. In addition to the ability to costimulate T cells, CD137 ligand (CD137L) also signals back into antigen presenting cells, promoting their activation and differentiation. Recently, CD137 has been proposed as a therapeutic target to improve and sustain anticancer immune response. Expression of CD137 or CD137L was described in T leukemia and B lymphoma activated cell lines, respectively, and soluble CD137L has been found in sera of leukemia patients. However, the role of these costimulatory molecules in hematologic malignancies is still unknown.
Aims: The aim of the present study was to evaluate CD137/CD137L role in Chronic Myeloid Leukemia (CML) patients treated with tyrosine kinase inhibitors (TKI).
Methods: In this study, approved by the Hospital and University Center of Coimbra ethics committee, peripheral blood mononuclear cells from 60 patients with CML, treated with imatinib mesylate and 39 blood donors were analyzed for membrane expression (CD137 and CD137L) and intracellular cytokine (IFNγ and TNFα) content in T (CD3+, CD4/CD8), B (CD19) and NK (CD3-CD56+) cells using flow cytometry. *In vitro* 4-hours stimulation with LPS or PMA/ionomycin was performed in order to evaluate the impact on CD137/CD137L expression. Soluble CD137 was analyzed by ELISA in patients sera and supernatants of stimulation experiments. Gene expression profiling for cytokines (IFNG, IL1B, IL2, IL4, IL6, IL10, IL12, TNFA, TGFB), granules (perforin, granzyme and granulysin), caspases (CASP3 and CASP9) and reference genes (ATP5B, SDHA and UBC) was performed for all samples. Additionally, miRNA profiling was performed by RT-qPCR.
Results: Soluble CD137 was significantly increased in sera and supernatants of *in vitro* stimulated PBMCs from CML patients. CD137 and CD137L were found in T (CD4 and CD8), B and NK cells from CML patients. CD137 was mainly expressed in CD8+T cells and CD137L was significantly detected in CD4+T cells, but was also found in B and NK cells. Expression of CD137 and CD137L positively correlated with TKI dose. These results were accompanied by the increased production of IFN-γ. Gene expression of IFN-γ, granzyme B and perforin was found to be upregulated in TKI-treated patients, compared to TKI-*naïve* patients and healthy controls. Analysis of miRNAs that were predicted as targeting TNFRSF9 and TNFSF9, revealed a significant increase of hsa-mir-886-3p. The analysis of miRNAs associated with CD137 signaling pathway and the induction of IFN-g via the ADAP-CBM signaling module (Lck, Fyn, ADAP, CARMA/CARD11, Bcl-10, MALT1, c-Jun and IFN-γ) showed no correlation in TKI treated CML patients.
Summary and Conclusions: Taking together, our results suggest that CD137/CD137L signaling should be further investigated in CML patients undergoing TKI therapy to improve and sustain anticancer immune response.
Financial Support: *FEDER (Programa Operacional Factores de Competitivi-*

dade – COMPETE) and FCT (Fundação para a Ciência e a Tecnologia) through project PEst-C/SAU/LA0001/2013-2014.

E1087

METABOLIC CHARACTERISTICS OF IMATINIB RESISTANT CHRONIC MYELOID LEUKEMIA WITH T315I MUTATION

J.Y. Heo[1,*] J. Han[1], M.J. Ryu[1], Y. Jang[1], S.J. Kim[1], J. Kim[1], M.J. Lee[1], G.R. Kweon[1]
[1]Biochemistry, Chungnam National University School of Medicine, Deajeon, Korea, Republic Of

Background: Imatinib resistant chronic myeloid leukemia (CML) cells made by treatment of low dose imatinib in long period has known metabolic phenotypes as more glycolysis and fatty acid synthesis compared with imatinib sensitive cells. But metabolic characteristics of T315I mutant CML cells which accounts for ~20% of the total burden in CML patients remains unknown.
Aims: Differenced metabolic characteristics of T315I mutant in CML cells could provide opportunity as therapeutic target. Two human CML cell lines, KBM5 (imatinib-sensitive) and KBM5-T315I (imatinib-resistant) were analyzed to assess metabolic phenotypes, including cell proliferation, oxygen consumption, lactate production and redox state.
Methods: Metabolic phenotype between KBM5 and KBM5-T315I without imatinib has been identified as the therapeutic target by molecular biologic methods including measurement of cell viability, western blot and realtime-PCR.
Results: Unlike previously reported imatinib resistant cells, we found that genetically mutated T315I cells showed decreased cell proliferation rate, lactate production, fatty acid synthesis and Glucose-6-phosphate dehydrogenase (G6PD), which is enzyme in the pentose phosphate pathway by maintaining the level of the co-enzyme nicotinamide adenine dinucleotide phosphate (NADPH), compared with KBM5 without imatinib. This result correlated with decrease of cellular reactive oxygen species (ROS) and mRNA expression of ROS scavengers, including SOD1, 2, catalase and enzymes related gulutathione, which is an important antioxidant. Although basal mitochondrial oxygen consumption had no difference between KBM5 and KBM5-T315I, mitochondrial maximal capacity and Isocitrate dehydrogenase 2 (IDH2) was higher in T315I mutant.
Summary and Conclusions: Thus, we described changed specific metabolic markers in T315I mutant in CML. Differenced metabolic characteristics of T315I mutant might be considered for finding therapeutic target of imatinib resistance.

E1088

MISSPLICED GSK3B TRANSCRIPT IS UNIVERSALLY EXPRESSED AND CANNOT BE USED TO PREDICT BLAST CRISIS TRANSFORMATION IN CHRONIC MYELOID LEUKAEMIA

L. Wang[1,2,*] G. Austin[2], R. Clark[2]
[1]Department of Haematology, Royal Liverpool University Hospital, [2]Section of Haematology, Department of Molecular ans Clinical Cancer Medicine,, University of Liverpool, Liverpool, United Kingdom

Background: GSK3β (glycogen synthase kinase 3β) has been shown to be misspliced in its kinase domain in granulocyte/macrophage precursors (GMP) in blast crisis (BC) samples of chronic myeloid leukaemia (CML). The misspliced GSK3β could enhance β-catenin expression and self-renewal ability of CML BC progenitors. Moreover it was also demonstrated that the misspliced GSK3β was not detected by sequencing in more primitive CML blasts or normal samples.
Aims: Here we investigated the presence of the misspliced form of GSK3β transcript in a broader population of peripheral blood white cell samples from CML chronic phase (CP), blast crisis (BC), *de novo* Ph+acute leukaemia, healthy volunteers and *in vitro* immortalised cell lines.
Methods: Peripheral blood white blood cells were separated and RNA was extracted and cDNA synthesised. Long range RT-PCR was performed to amplify the full length of the GSK3β coding region. Nested PCR steps were subsequently used to amplify exons 1-6 and exons 5-12. In addition, nested PCR steps were performed to amplify exons 6-10 and exons 10-12. PCR products were then run on an agarose gel. Products on the agarose from selected samples were purified from the gel and cloned into p-GEMTeasy vector to be sequenced. Allele specific real-time RT-PCR primers were designed to quantify the transcript level of misspliced GSK3β (exon 8 and 9 deleted). The specificity of the allele specific PCR primers were confirmed by PCR product direct sequencing using both forward and reverse primers. The misspliced GSK3β transcript levels were normalised to the levels of dominant GSK3β transcripts (GSK3β with exon 9 deleted). The misspliced GSK3β to dominant GSK3β transcript ratio in KYO-1 cells was considered as an arbitrary unit of 1.0.
Results: It was found the misspliced GSK3β transcripts could be detected in CML CP (6/12), BC (12/13), *de novo* Ph+acute leukaemia (7/9), the CML cell lines KYO-1, LAMA84, the T cell leukaemia line Jurkat, and the hepatoma cell line HepG2. The dominant GSK3β transcript in all samples tested was GSK3β with exon 9 deleted. It was showed by using allele specific real-time RT-PCR that CD34+cells separated from newly diagnosed CP CML had greater levels of misspliced GSK3β than matched mononuclear cells (n=6, p=0.028, Wilcoxon signed-rank test). For 9 cases of CML who had transformed to BC, the misspliced GSK3β levels at BC stage were greater than those at the CP stage (p=0.008, Wilcoxon signed-rank test). However no significant difference was found between CML CP (n=50), CML BC (n=34) and *de novo* Ph+acute leukaemia (n=15). Furthermore, at diagnosis of CP (prior to imatinib treatment), there was no significant difference in misspliced GSK3β levels between patients who achieved complete cytogenetic response after 12 months treatment (n=26), those who had no cytogenetic response (n=23) and those who subsequently progressed to BC (n=6).
Summary and Conclusions: The misspliced GSK3β transcript can be detected at various levels in a wide range of cells from CML CP, CML BC and healthy volunteers. Transcript levels of the misspliced GSK3β do not appear to be useful as a prognostic marker to predict the progression of CML.

E1089

DISCOVERING ALTERNATIVE TARGETS IN CHRONIC MYELOID LEUKEMIA (CML): DETERMINATION OF EXPRESSION LEVELS OF BIOACTIVE SPHINGOLIPID GENES IN NEWLY DIAGNOSED AND DRUG-RESISTANT CML PATIENTS

M. Kartal Yandim[1,*] I. Kozanoglu[2], H. Ozdogu[2], O. Piskin[3], M.A. Ozcan[3], G. Saydam[4], F. Sahin[4], F. Avcu[5], A.U. Ural[6], A. Unal[7], Y. Baran[1]
[1]Molecular Biology and Genetics, Izmir Institute of Technology, Izmir, [2]Hematology, Baskent University, Adana, [3]Hematology, Dokuz Eylul University, [4]Hematology, Ege University, Izmir, [5]Hematology, Gulhane Military Medical Academy, [6]Hematology, Bayındır Hospital, Ankara, [7]Hematology, Erciyes University, Kayseri, Turkey

Background: Bioactive sphingolipids, found in cellular membranes, are important molecules that have vital roles affecting several cellular events such as proliferation, apoptosis, senescence, cell cycle arrest, angiogenesis, and transformation. Ceramide, the central molecule of bioactive sphingolipid metabolism, is synthesized *de novo* by the activity of ceramide synthases (CERS1-6), whereas clearence of ceramide is carried out by the activity of glucosylceramide synthase (GCS) and sphingosine kinase 1 (SK1). While ceramide is a powerful pro-apoptotic molecule, glucosylceramide generated from ceramide via GCS, and S1P generated from ceramide via SK1 are powerful anti-apoptotic molecules. Previous studies from our lab revealed that increased ceramide or decreased GCS and SK1 levels in tyrosine kinase inhibitor (TKI)- sensitive and –resistant CML cell lines result in trigger of apoptotic pathways while increased intracellular GCS and SK1 levels trigger the pathways related to cell survival. Additionally, for the first time, we revealed that sensitivity of CML cell lines against TKIs can be increased via targeting bioactive sphingolipids. So far, there is no study about the roles of bioactive sphingolipids in CML patient samples.
Aims: In this study, our goal was to determine the potential relation between bioactive sphingolipids and disease progression in CML patients newly diagnosed, TKI-treated and shown hematological response (HR), and also TKI-resistant. Our additional goal was to confirm our previous data obtained in CML cell lines.
Methods: Bone marrows were harvested from CML patients with different disease profiles, and mononuclear cells were isolated by lysis buffer. cDNA was synthesized by reverse transcription from RNAs isolated from the cells. Expression levels of CERS1, -2, -3, -4, -5, and -6, GCS, SK1, and BCR/ABL genes were analyzed via quantitative real-time PCR. In this study, totally 66 CML patients including 33 newly diagnosed, 14 imatinib-treated, 2 nilotinib-treated, 3 dasatinib-treated, 6 imatinib-resistant, 1 nilotinib-resistant, 1 dasatinib-resistant, 1 dasatinib&nilotinib-resistant, 2 imatinib&nilotinib-resistant, and 3 blastic phase were involved.
Results: Our results revealed that expression levels of CERS1-6 genes were higher in the patients treated with TKIs and shown HR than the patients newly diagnosed or TKI-resistant. GCS and SK1 expression levels were markedly greater in TKI-resistant patients than that of newly diagnosed or TKI-treated and shown HR. Moreover, comparison of the expression levels of the genes mentioned above in bone marrow samples harvested from the particular patients at once in six months periods showed that while CERS1, -2, -3, and -6 expressions increased, GCS and SK1 expressions decreased by the time in the patients treated with TKIs and shown HR. Additionally, GCS and SK1 expressions were found increased, whereas expression levels of CERS genes decreased in the patients developing TKI-resistance.
Summary and Conclusions: The results of this study revealed for the first time that there might be a strong relation between TKI-sensitivity or resistance and the expression levels of bioactive sphingolipid genes in CML patients. More importantly, our results demonstrated that expression levels of bioactive sphingolipid synthesis genes might be decisive markers for predicting TKI-resistance as well as novel targets for more effective therapy in CML patients. Our project was supported by The Scientific and Technological Research Council of Turkey with the Project number 111S392.

Chronic myeloid leukemia - Clinical

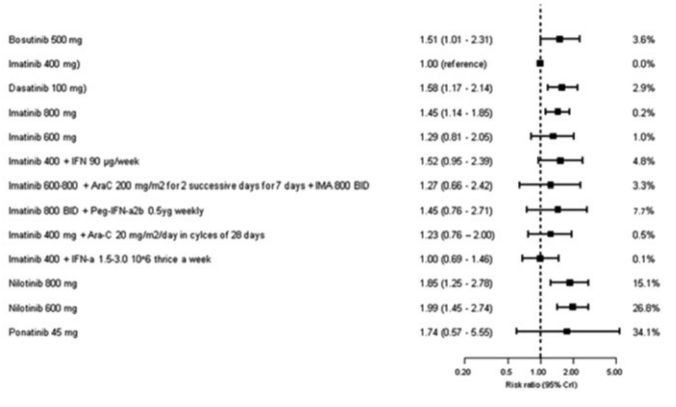
E1090

COMPARISON OF TYROSINE-KINASE INHIBITORS AS FIRST-LINE TREATMENT FOR CHRONIC MYELOID LEUKEMIA: RESULTS OF A NETWORK META-ANALYSIS INCLUDING 6314 PATIENTS

N. Skoetz[1,*] M. Rancea[1], S. Trelle[2], E. Nüesch[2], A. Engert[3], K.A. Kreuzer[3]
[1]Cochrane Haematological Malignancies Group; Department I Of Internal Medicine, University Hospital of Cologne, Cologne, Germany, [2]Department of Clinical Research, CTU Bern and Institute of Social and Preventive Medicine,, University of Bern, Bern, Switzerland, [3]Department I Of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: The best treatment strategy for patients with chronic myeloid leukemia (CML) is still a matter of debate. Since the introduction of the BCR-ABL tyrosine-kinase inhibitor (TKI) imatinib in 1998, CML patients have experienced a significant improvement in overall survival. Prior to the usage of TKIs, the 10-year survival rate was 20%, therefore imatinib 400 mg nowadays is recommended as standard treatment. Currently, published evidence of second generation TKIs also recommends dasatinib and nilotinib as first-line therapy. However, direct head-to-head comparisons of second generation TKIs, which are important for a clinical decision-making, are lacking.
Aims: To assess the benefits and risks of different initial treatment strategies with TKIs for patients with CML in chronic phase and to provide patients and physicians with a high-level evidence for treatment decisions.
Methods: Data sources: We developed sensitive search strategies for CENTRAL, MEDLINE, and conference proceedings (searched from 1990 to 12/2014). Study selection and data extraction: Randomized controlled trials that evaluated in at least one arm a regimen including a TKI as first-line therapy in patients with CML in chronic phase. Two authors independently assessed studies for eligibility. We extracted data and assessed quality of trials in duplicate. The primary outcome was major molecular response (MMR). Secondary outcomes included complete cytogenetic response (CCyR), overall survival and adverse events. Data synthesis: Effect measures were risk ratios (RR) for complete MMR, CCyR and adverse events, and hazard ratios (HR) for OS. We pooled data using network meta-analysis. Direct comparisons within trials were combined with indirect evidence from other trials by using a Bayesian random-effects model. We evaluated both, the full network including all trials reporting the outcome and a core network including only those regimens that were evaluated in at least two trials. Results are reported relative to imatinib 400 mg with a RR <1 and HR >1 indicating superiority of imatinib 400mg. This project was funded by the Federal Ministry of Education and Research, grant number: 01KG1112.
Results: The systematic search resulted in a database including 1,114 potentially important references. Of those, 16 final RCTs from 209 publications were identified and included into the network-analysis. These trials assessed the effects of 14 various treatment arms and 18 comparisons for 6,314 patients with CML. Nilotinib was associated with the highest chance to be best (41.9%) in terms of MMR at 12 months (nilotinib 600 mg RR 1.99, 95%>credibility interval (CrI) 1.45 to 2.74 and nilotinib 800 mg RR 1.85, 95%>CrI 1.24 to 2.78, respectively) in the full network meta-analysis (see figure 1). This effect is even more pronounced in the core network with a probability to be best of 83.1%. Dasatinib 100 mg (RR 1.58, 95% CrI 1.16 to 2.13) and imatinib 800 mg (RR 1.45, 95% CrI 1.13 to 1.85) might be superior to imatinib 400 mg as well. All other treatment strategies and the results for CCyR showed no statistically significant difference to imatinib 400 mg. There are few events for OS, and thus results are not conclusive (*i.e.* wide 95% CrI). Results regarding adverse events will be reported in due course. Between-trial heterogeneity was negligible in all three analyses (tau-square 0.01, 0.02, and 0.05, respectively).

Table 1.



Summary and Conclusions: The comparison of different first-line treatment strategies for CML patients in this network meta-analysis shows a significant and relevant nilotinib advantage over standard imatinib 400 mg treatment. This analysis provides the currently best available evidence of different initial treatment strategies for chronic phase CML patients and therefore adds valid and important information for both, patients and physicians. However, some of the regimens were only evaluated in one trial with a limited number of patients, leading to imprecise results.

E1091

PREDICTIVE FACTORS FOR TREATMENT-FREE REMISSION IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH IMATINIB-TREATED, UNDETECTABLE MOLECULAR RESIDUAL DISEASE: RESULTS FROM THE KID STUDY

Background: Since the recent several reports have shown that imatinib (IM) discontinuation can be employed in patients who had enough IM therapy and undetectable molecular residual disease (UMRD) durations prior to IM discontinuation, treatment-free remission (TFR) has emerged as a goal in chronic myeloid leukemia (CML) treatment. Although UMRD with a sensitivity of 4.5 log for at least 2 years is required for a trial of TFR and factors associated with a higher rate of sustained UMRD after IM cessation have found, precise identification of the minimum requirement for a safer, successful TFR and the underlying mechanism of sustained UMRD thus remains elusive. In addition, the possibility of the second attempt to discontinue IM in patients with second sustained UMRD who experienced loss of MMR after first IM discontinuation was suggested.
Aims: The aim of this study is to identify predictors for safer, successful IM discontinuation and to explore additional contributing factors for sustained molecular responses.
Methods: CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction for at least 2 years were eligible for Korean Imatinib Discontinuation (KID) study. In this analysis, the patients with at least 6 months of follow-up were included, with the exception of the patients who received IM for post-transplant relapse. In case of relapse, defined as loss of MMR on 2 consecutive assessments, IM therapy was re-introduced. If the patients re-achieved and maintained second UMRD for at least 2 years, second IM discontinuation was allowed.
Results: A total of 92 patients (52 females, 40 males) with follow-up of ≥6 months were analyzed, with a median age of 49 years (range, 21-77). After a median follow-up of 20.2 (range, 6.6-52.1) months after IM discontinuation, 46 patients (50%) lost UMRD. Of the 46 patients who lost UMRD but not MMR exhibited different patterns of BCR-ABL1 kinetics; 7 patients spontaneously re-achieved UMRD and 2 patients showed fluctuation of BCR-ABL1 transcript under the level of 0.1% on IS, while the other 37 patients lost MMR by 2 consecutive analyses. Probabilities for sustained MMR at 12 months and 24 months were 61.7% and 58.3%, respectively. All 37 patients who lost MMR were re-treated with IM therapy for a median of 12.3 months (range, 0.3-41.4 months). Among them, 30 patients re-achieved MMR at a median of 4.2 months (range, 0.5-11.1 months) after resuming IM therapy. In the univariate analysis, positivity of digital PCR at screening, IM duration and UMRD duration before IM discontinuation, and aggravation or newly development of musculoskeletal pain had a higher probability of sustained MMR. In addition, three patients who re-achieved and maintained second UMRD for 23.9, 25.3, and 25.3 months, respectively entered into the second IM discontinuation, among whom 2 patients re-lost MMR after 2 months and 1 patients sustained MMR during 6 months.
Summary and Conclusions: Our data suggest the predictive factors for sustained MMR which may provide additional information to guide clinical decisions on the TFR study and the possibility of the second attempt to discontinue IM. Overall, positivity of digital PCR at screening, both UMRD and IM duration, and

IM withdrawal symptom were predictive factors for successful IM-off. Further studies on underlying mechanisms about immunological control, minimal residual leukemia and stem cell biology during TKI-off study should be conducted.

E1092

SUPERIORITY OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION TO NILOTINIB & DASATINIB FOR ADULT PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA IN THE ACCELERATED PHASE

L. Xu[1,*] H.L. Zhu[2], J.D. Hu[3], D.P. Wu[4], H. Jiang[5], Q. Jiang[5], X.J. Huang[5]
[1]department of Hematology, Peking University People's Hospital, Peking University Institute of Hematology, Beijing, [2]Hematology, West china hospital, Sichuan University, Chengdu, [3]Hemotology, Fujian Medical University Union hospital, Fujian Institute of Hematology, Fuzhou, [4]The first affil hospital, Sochoow University, Suzhou, [5]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: In the tyrosine kinase inhibitor (TKI) era, imatinib is often the first-line therapy for chronic myeloid leukemia (CML) patients in either the chronic or the accelerated phases. However, even though second-generation TKIs (TKI_2) including dasatinib and nilotinib are appropriate options for patients with disease progression to the accelerated phase following imatinib therapy, allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative therapy. Nevertheless, the second-generation TKIs (TKI_2) including nilotinib and dasatinib can induce a faster and stronger molecular response and may achieve better OS and PFS than first-generation TKIs. Meanwhile, great progression has been achieved in human leukocyte antigen (HLA)-mismatched/haploidentical HSCT recently, the clinical results of which are comparable to that of matched sibling HSCT. Now, almost every patient can have a donor. We recently reported that haploidentical HSCT affords a 4-year OS rate of 73.3% for CML in AP. However, the efficacy of TKI_2 has not been compared with that of HSCT.
Aims: This study retrospectively analyzed the data from the Chinese CML alliance database to compare the efficacy of TKI_2 and HSCT for the treatment of CML in AP.
Methods: This study retrospectively analyzed the efficacy of TKI_2 and HSCT for the treatment of CML in the accelerated phase. Ninety-three CML patients registered in the Chinese CML alliance database from February 2001 to February 2014 were enrolled. Patients were divided into the TKI_2 (n=33) and allo-HSCT (n=60) groups. Twenty-six patients toke Nilotinib as initial TKI_2, 7 patients toke Dasatinib as initial TKI_2. Eleven patients exchanged to the alternative TKI_2 after failure to one TKI_2. Sixty patients received HSCT; 22 (36.7%), 35 (58.3%), and 3 (10%) patients underwent allo-HSCT from an HLA-matched sibling donor, HLA mismatched/haploidentical donor and unrelated donor respectively.
Results: All patients in HSCT group engrafted. Overall, 69.7% of patients had hematological response, 48.5% had cytogeneic response, 45.5% had MMR. to at least one of TKI2.. Sity (100%) patients achieved CHR and cytogenetic response in HSCT group patients. The 5-year overall survival rate was significantly lower in the TKI_2 group than the allo-HSCT group (42.9% vs. 86.4%, P=0.002). The 5-year event-free survival rate was significantly lower in TKI_2 group than the allo-HSCT group (14.3% vs. 76.1%, $P<0.001$). The 5-year progression-free survival rate was significantly lower in the TKI_2 group than the allo-HSCT group (28.6% vs.78.1%, P <0.001). Multivariate analysis showed that male sex and TKI_2 therapy were predictors of poor OS, while hemoglobin <100 g/L and TKI_2 therapy were predictors of poor EFS and PFS.
Summary and Conclusions: These results indicate allo-HSCT may be superior to nilotinib and dasatinib for adults CML patients in the accelerated phase. Prospective trial is needed in the future.

Background: Medication non-adherence (MNA) to tyrosine kinase inhibitors (TKIs) occurs in around 30% of chronic myeloid leukemia (CML) patients. Electronically measured MNA to TKIs is associated with less favorable outcomes. There are no proven strategies for improving adherence or identifying patients at risk for non-adherence in CML. Modifiable risk factors for non-adherence may guide intervention development yet have mainly been studied for imatinib alone, based primarily on adherence measured by pharmacy refill records, pill counts and subjective measures such as collateral and self-reports. Electronically measured adherence to imatinib was reported primarily in the landmark study by Marin *et al*, while electronically measured adherence to nilotinib and dasatinib has not yet been reported.
Aims: (1) To determine the period prevalence of electronically-assessed MNA to TKIs; (2) To assess which factors are associated with MNA to TKIs.
Methods: We used baseline data of the TAKE-IT study (NCT01768689), a prospective Israeli multicenter (N=4) pre-post adherence intervention study in CML. A convenience sample of 56 adults with chronic phase CML receiving imatinib, nilotinib or dasatinib, for ≥3 months before study inclusion were included. Sample characteristics were as follows: median age, 60.5 [IQR 19] years; prior disease duration, 43 [IQR 81] months; current TKI treatment duration, 34 [IQR 61] months; line of TKI treatment: 1st=62.5%, 2nd=28.5%, 3rd=9%; type of TKI: imatinib 59%, nilotinib 18%, dasatinib 23%; optimal response at baseline according to the ELN(2013) guidelines, 93%; membership in a CML advocates (support) group, 50%. Period prevalence of TKIs adherence was assessed using electronic monitoring during a 3 month period and expressed as a percentage of the prescribed doses taken over 3 months. Selected socio-demographic, patient, treatment, condition and healthcare system-related (according to WHO taxonomy) risk factors of TKI MNA were assessed (For overview see Table 1). Simple linear regression was used to identify risk factors associated with TKIs MNA. Statistical significance was set at p<0.05.
Results: Median period prevalence of TKI adherence was 97.7% (IQR: 6.6%; range: 48%>100%). We found the following *sociodemographic factors*, *i.e.* younger age, Arab ethnicity (perhaps reflecting health inequalities), living alone; *patient related factor*, *i.e.* non-membership in a CML advocates group; *condition related factor*, *i.e.* prolonged duration of CML; *treatment related factors*, *i.e.* advanced line of treatment, Nilotinib treatment; and *healthcare system factor*, *i.e.* study center, to be significant predictors of TKI MNA (see Table 1).

Table 1.

Risk factor evaluated for TKI non-adherence	WHO taxonomy of adherence risk factors	p-value for association with TKI non-adherence* in CML (univariate analysis)

Table 1: Risk factors of electronically measured non-adherence to tyrosine kinase inhibitor treatment in chronic myeloid leukemia

* Electronically measured adherence over a 3 month period.
[+] Modifiable risk factor.
[@] Non-modifiable risk factor.
CML, chronic myeloid leukemia; TKI, tyrosine kinase inhibitor

Summary and Conclusions: TKI adherence was high yet showed large variability. We identified several multi-level risk factors of TKI MNA, most of them congruent with the chronic care literature. Half of the risk-factors identified are modifiable and can thus guide intervention development in the future, optimally targeting the different domains of the WHO taxonomy. Of special interest is decreased adherence with Nilotinib, taken twice daily while fasting, as opposed to imatinib and dasatinib. This may be a proxy for increased treatment complexity, or for non-adherent patients receiving advanced lines of treatment due MNA-driven failure of 1st line treatment. This must be taken in the context of conflicting findings from previous studies comparing adherence between various TKIs. Study center may be a proxy for practice patterns or differences in case mix treated. Non-membership in a patient's advocate group as risk factor for MNA is an interesting novel finding. Such groups might provide informational

and other types of social support favoring adherence. In conclusion, our study quantifies MNA to different TKI regimens and provides guidance for identifying patients at risk, as well as ideas regarding which factors could be targeted for intervention.

E1094

A CRITICAL COMPARISON OF SOKAL, EURO, AND EUTOS RISK SCORES IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS

Background: In the era of molecular hematology, the prognosis of BCR-ABL+chronic myeloid leukemia (CML) is still based on three prognostic systems including few clinical and hematological variables: age, platelet count, blast cells, eosinophils, basophils (percentage in peripheral blood) and spleen size (assessed by manual palpation; maximum distance in cm from costal margin). The three prognostic systems are the Sokal score (Sokal et al, Blood 1984;63:789-799), the EURO score (Hasford et al, J Natl Cancer Inst 1998;90:850-858), and the EUTOS score (Hasford et al, Blood 2011;118:686-692), based on the analysis of international, multicentric series of newly diagnosed, chronic phase (CP) CML patients, treated with conventional chemotherapy (Sokal), interferon-alfa (IFNa)-based regimes (EURO), or imatinib-based regimes (EUTOS), respectively.
Aims: In all the main studies exploring the efficacy of tyrosine-kinase inhibitors (TKIs), at least one of these scores has been used: all three scores were able to predict the response and/or the outcome, but the three scores are different, and there is no agreement on which score may be more useful and should be adopted. The aim of our analysis was to identify which score has been more frequently used and which one is able to give more consistent results.
Methods: We reviewed the most relevant reports of the 13 important clinical studies, published in peer-reviewed journals between 2003 and 2014. Moreover, we analyzed 559 patients enrolled within 3 multicentric prospective studies conducted by the GIMEMA CML WP (NCT00514488, NCT00510926, observational trial CML023).

UK Spirit	142	Das 100	2 years	nr	.11	2 years	88,87%	.35

Legend: nr = not reported; ns = not significant; L = low, I = intermediate, H = high

Results: The Sokal score was used in 12 studies, the EURO score in 2 studies, the EUTOS score in 4 studies (Table 1). The results are difficult to interpret, because sometimes only the p-values for differences (not the response rates), and sometimes only the response rates (not the p-value) were reported. The relationship between the risk and survival was analyzed in few studies: the Sokal score was able to predict the survival in three studies (Hammersmith, Czeck registry and Swedish registry), the EURO in only one study (Swedish registry), and the EUTOS in no studies. Therefore, we tested all three scores in 559 newly diagnosed CP-CML patients who were enrolled in GIMEMA studies with imatinib front-line. No score was able to predict the early molecular response. The complete cytogenetic response (CCyR) and the major molecular response (MMR) rates by 1 year were better predicted by Sokal (p=.006 and. 001) and EURO (p=.002 and .002) scores than by EUTOS score (p=.009 and .010). The rate of deep molecular response ($MR^{4.0}$) by 6 years was better predicted by Sokal score (p<.001) than by EURO (p=.019) or EUTOS (p=.031) score. The 6-year overall survival was better predicted by Sokal (p=.002) and EURO (p=.003) score than by EUTOS score (p=.160).
Summary and Conclusions: There are no studies supporting the superiority of any risk score over the others. The EUTOS score could be the first choice because based on TKIs-treated patients. However, the Sokal score may still be considered the reference risk score, because it has been validated in many more independent studies, with more consistent results. All the three scores could be refined introducing other biological variables (*i.e.* clonal chromosome abnormalities in Ph+cells). However, more progress in CML biology is needed to move from the era of clinical/hematologic prognosis to an era of molecular-based prognosis.

E1095

SWITCHING TO NILOTINIB IS ASSOCIATED WITH DEEPER MOLECULAR RESPONSES IN CHRONIC MYELOID LEUKEMIA CHRONIC PHASE WITH MAJOR MOLECULAR RESPONSES ON IMATINIB; STAT1 TRIAL IN JAPAN

N. Takahashi[1,*] C. Nakaseko[2], K. Nishiwaki[3], H. Ogasawara[4], H. Wakita[5], O.B.O. STAT study group[6]

[1]Hematology, AKITA UNIV., Akita, [2]Hematology, Chiba University, Chiba, [3]Oncology and Hematology, Jikei University Kashiwa Hospital, Kashiwa, [4]Internal Medicine, Odate Municipal General Hospital, Odate, [5]Hematology, Narita Red Cross Hospital, Narita, [6]STAT, study group, Japan

Background: Nilotinib is a second-generation tyrosine kinase inhibitor (TKI) that exhibits significant efficacy as first- or second-line treatment in patients with chronic myeloid leukemia (CML). Superior rates of deeper molecular responses were achieved with nilotinib vs. imatinib in patients newly diagnosed with CML in chronic phase (CML-CP) in the ENESTnd trial. In addition, the 24-month analysis of the ENESTcmr study demonstrated that switching to nilotinib after a minimum of 2 years on imatinib led to increased rates of deeper molecular responses vs. remaining on imatinib. Significantly more patients treated with nilotinib achieved undetectable BCR-ABL1 by 24-month (32.7% on nilotinib vs. 16.5% on imatinib; P =0.005).
Aims: To evaluate the efficacy of nilotinib in patients with CML-CP who have achieved a major molecular response (MMR) with imatinib.
Methods: Patients with CML-CP who had achieved MMR but still had persistent BCR-ABL positivity by real-time quantitative polymerase chain reaction (RQ-PCR) on imatinib were eligible. Nilotinib will be taken twice daily (600 mg/day) for 2 years. Thirty-five institutions in STAT study group participated. The study was conducted in accordance with the principles of the Declaration of Helsinki. Informed consent was written by all patients according to institutional guidelines. The study was approved by all institutional review boards and registered with ClinicalTrials.gov (number UMIN000005903). The primary objected of this multicenter phase II, single-treatment arm, open-label clinical study was to identify the MR4.5 rate at 24 months after the initiation of nilotinib treatment. The molecular response was evaluated according to the International Scale [IS] RQ-PCR upon study entry and every 3 months thereafter. IS RQ-PCR was performed in a central laboratory using a Molecular MD One-Step qRT-PCR BCR-ABL kit (BML Inc., Kawagoe, Japan). At least 32,000 control gene (ABL) were required for scoring deep molecular responses.

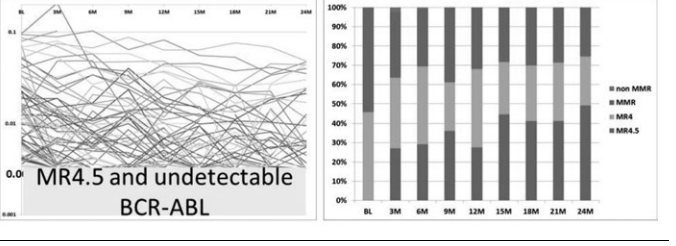

Figure 1-2.

Results: Between July, 2011 and December, 2012, 80 Japanese patients were recruited, and 74 patients were evaluated in the study. The median age was 54.5 years. The ratio of men to women was 52:22. The median duration of CML in patients was 68.9 months. The median duration of imatinib treatment was 66.0 months. All patients showed MMR at the time of entry into the study and the median time to MMR on imatinib therapy was 20.2 months. The proportion of patients achieving deeper molecular responses (MR4, MR4.5)

increased over time (Figure 1). The rates of MR4 in the evaluable patients were 69% and 73% at 12 and 24 months, respectively, and the rates of MR4.5 were 28% and 49% at 12 and 24 months, respectively (Figure 2).
Summary and Conclusions: Switching to nilotinib led to deeper molecular responses in patients with minimal residual disease on long-term imatinib therapy. The results of our study suggest that switching to the more potent, selective tyrosine kinase inhibitor nilotinib is beneficial in patients with minimal residual disease after long-term imatinib therapy. Achievement of MR4.5 after switching to nilotinib may enable a greater proportion of CML-CP patients to be eligible for future discontinuation studies.

E1096

THE LYMPHOCYTE DYNAMICS PREDICTS THE BETTER RESPONSE FOR DASATINIB TREATMENT IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE

Background: Currently, as a second generation tyrosine kinase inhibitor, dasatinib is one of the key treatment options for chronic myeloid leukemia (CML) patients. Increase in lymphocyte counts, especially in the large-granular lymphocytes (LGLs), has been well investigated in patients treated with dasatinib as a second line therapy, suggesting the correlation of increased LGL number with the favorable outcome. However, lymphocyte dynamics in CML patients treated with dasatinib as a first line therapy has yet to be clarified.
Aims: Elucidate the association between the lymphocyte dynamics after dasatinib introduction and a favorable treatment response in newly diagnosed patients with CML in chronic phase (CML-CP).
Methods: An open-label, multicenter, prospective clinical trial; D-First study (ClinicalTrials.gov NCT01464411), enrolling patients with newly diagnosed CML-CP was implemented to receive dasatinib 100mg/day. All patients were followed-up for at least 18 months. BCR-ABL1 transcripts were quantified at 1, 3, 6, 9, 12, 15, and 18 months after initiation of dasatinib in all but one, harboring the atypical undetectable BCR-ABL1 transcript. A deep molecular response (DMR) was defined as BCR-ABL1 IS <0.01%. The incidence of lymphocytosis was diagnosed if the number of peripheral blood (PB) lymphocyte counts exceeded 3,600/μL on two occasions or more, after at least 4 weeks of dasatinib initiation. Flow cytometry analysis was performed on each PB sample to examine the phenotype of lymphocyte fractions.
Results: Of the 52 patients registered to the D-First study, 14 patients developed lymphocytosis and 29 patients achieved DMR by 18 months. The median time from dasatinib induction to the first incidence of lymphocytosis was 7 months (range 1 – 16). The majorities of increased lymphocytes were morphological LGLs and were highly differentiated CD56+CD57+natural killer cells (NK) or cytotoxic T lymphocytes (CTL) in most cases. Cumulative DMR rates by 18 months were not significantly different between patients with lymphocytosis and those without (50% *vs* 62%, P=0.53). However, total lymphocyte counts at 1 month were significantly higher in patients with DMR by 18 months compared to those without DMR (median 1,709/μL vs. 1,118/μL; P=0.018). Furthermore, NK and CTL counts were significantly higher in patients with DMR compared to those without DMR (P=0.009 for NK and P=0.005 for CTL). Using the receiver operating characteristic curve, the optimal threshold in total lymphocyte, NK and CTL values at 1 month were calculated, indicating moderate correlations (area under the curves were 0.70 in total lymphocyte, 0.72 in NK and 0.74 in CTL) with the highest Youden's index at 1,583/μL, 467/μL and 367/μL, respectively. When the patients were divided into 2 groups according to those calculated thresholds, the cumulative DMR rates were significantly better in higher value group compared to lower value groups (P=0.03 in total lymphocyte, Figure 1 upper left; P=0.013 in NK, Figure 1 upper right and P=0.007 in CTL, Figure 1 lower left). In contrast, regulatory T cell (Treg) counts were significantly lower at 12 and 15 months in patients achieved DMR.

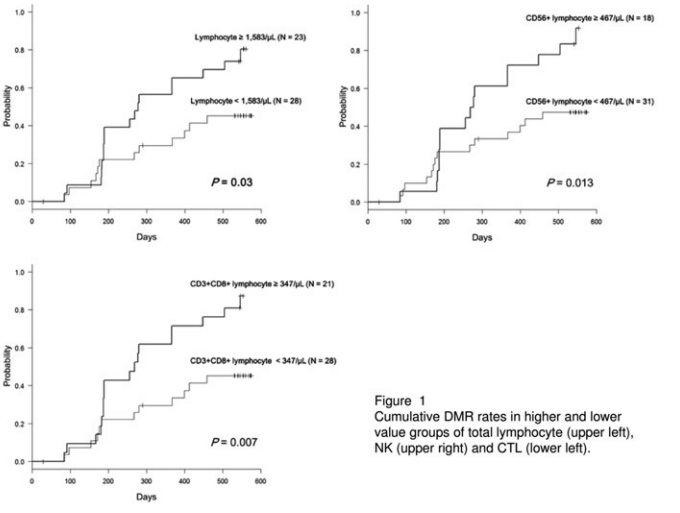

Figure 1
Cumulative DMR rates in higher and lower value groups of total lymphocyte (upper left), NK (upper right) and CTL (lower left).

Figure 1.

Summary and Conclusions: Increased counts of total lymphocyte, NK and CTL at 1 month after the initiation of dasatinib predicted better DMR rate in newly-diagnosed CML-CP patients. Treg inhibition was also obvious in patients with DMR at later time points, suggesting the dual effects of dasatinib on immune system through the cytotoxic lymphocytes activation and Treg deregulation in different periods.

E1097

EVALUATION OF A QUANTITATIVE MULTIPLEX BCR-ABL1 ASSAY ALIGNED DIRECTLY TO THE WHO PRIMARY STANDARD REFERENCE MATERIALS TO REPORT EXPRESSION ON THE INTERNATIONAL SCALE

J.M. Cayuela[1], C. Maute[1], G. Armstrong[2], J. Brown[2,*]
[1]Laboratory of Hematology, University Hospital Saint-Louis, Paris, France, [2]Asuragen, Austin, United States

Background: Detection of BCR-ABL1 e13a2 or e14a2 transcripts (major breakpoint, M-BCR) of translocation t(9;22) (also known as the Philadelphia chromosome) is important in CML monitoring tumor burden. The International Scale (IS) was established to standardize reporting relative to a common baseline. As newer TKI therapies create deeper responses, analytical sensitivity has become a critical topic in investigations into TKI discontinuation, where researchers require an assay that calls a molecular response (MR) of ≥4.5 logs below baseline (*i.e.* MR4.5 or 0.0032%IS).
Aims: Asuragen has developed a multiplexed RT-qPCR assay for the simultaneous amplification and detection of two BCR-ABL1 fusion transcripts (e13a2 and e14a2) and ABL1 (an endogenous control) using total RNA extracted from human leukocytes. We evaluated the assay's ability to meet current performance requirements for ease of use, sensitivity, and traceability to a higher order standard reference material.
Methods: We tested whether this prototype BCR-ABL1 fusion quantification assay could be an alternative to current clinical diagnostic tools for monitoring CML patients for minimal residual disease. We compared patient test results obtained with the Asuragen assay to our current clinical laboratory developed test (LDT) to define correlation and concordance between the two methods. Clinical and cell line RNA samples were used to study additional performance characteristics of the Asuragen assay, including sensitivity (7-member human RNA panel over 3 days), specificity (cell line RNAs and *in vitro* transcripts), linearity (7-point human RNA dilution), precision (3-member human RNA panel over 5 days), and clinical accuracy (20 human RNA specimens over 2 runs, assessed against the LDT). EDTA blood-based RNA specimens were evaluated for purity ($OD_{260/280}$ >1.6) and concentration (100-500 ng/uL). Asuragen's BCR-ABL1 assay included all required RT and qPCR reagents in the kit. The RT and qPCR were performed and analyzed on the ABI 7500 Fast Dx with software version 1.4. RNA was provided as 7 different blends of BCR-ABL1 and ABL1 Armored RNA Quant® (ARQ) standards and controls to calibrate and control the system. A single four-point standard curve using ARQ blends mimicked the WHO Primary BCR-ABL1 reference materials. Assay-specific software was used to automatically generate results reported in MR and %IS values.
Results: We found positivity in samples ≤MR4.5 (≥0.0032%IS) with human CML positive RNA, indicating good analytical sensitivity. Despite deep analytical sensitivity, the system maintains analytical specificity (non-M-BCR, non-CML, and non-leukemic specimens produce true negative results). Linearity was

demonstrated from LOQ to <MR1 (>10%IS). Technical replicates yielded acceptable precision, including good %CV around the key clinical decision points of 0.1%IS (MR3, MMR) and 10%IS (MR1, near PCyR). The Asuragen assay showed good intra-laboratory correlation. Moreover, using assay comparison criteria proposed by Müller *et al.* (Leukemia 2009), the Asuragen assay was considered comparable to our current LDT, suggesting good clinical accuracy (when treating the prior result in the LDT as truth).

Summary and Conclusions: The BCR-ABL1-targeting prototype improves workflow with its streamlined reagent formulation, all inclusive contents, and multiplex assay format. It facilitates assessment on the IS without conversion (through integrated ARQ materials traceable to the WHO Primary reference set), and generates results sufficient for studies in deep molecular responses.

E1098

IMATINIB TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS IN EARLY AND LATE CHRONIC PHASE: CURRENT INCIDENCE OF CYTOGENETIC REMISSION AND A VERY LONG-TERM AN INTENTION-TO-TREAT ANALYSIS

O. Shukhov[1,*] E. Chelysheva[1], G. Gusarova[1], O. Lazareva[1], A. Turkina[1]
[1]Scientific and Advisory Department of Chemotherapy of Myeloproliferative Neoplasms, Federal State Budgetary Institution Hematology Research Center of Health Ministry of Russian Federation, Moscow, Russian Federation

Background: Imatinib (IM) is remarkably effective in treating newly diagnosed patients with chronic myeloid leukemia (CML) in chronic phase (CP). The long term outcome is extremely important to assess the treatment efficacy and stability. To date, most of the available data come from studies in which some of the patients were censored for diverse reasons. In the IRIS trial, at 8 year, 55% of patients were still on IM and the overall survival (OS) was 85%. Other published reports have shorter follow-up.
Aims: To evaluate the results of long term treatment in CML patients in a setting where all events were recorded.
Methods: A total of 235 adult patients with CML in CP started IM from July 2000 till April 2007. Early CP was in patients with <1 year of pretreatment before IM**.** At the time of therapy initiation 37% (86/235) patients were in early CP. Common (ComCI) and current (CCI) cumulative incidences of complete cytogenetic response (CCyR), progression-free survival (PFS) and overall survival (OS) were evaluated.
Results: Baseline demographics characteristics: median age: 42 years (extremes 18-66 years); male sex: 49%; high Sokal, high Euro and high EUTOS scores: 16%, 7% and 6%, respectively; clonal chromosomal abnormalities (CCA) in Ph+cells: 7%. Median follow-up: 123 (9-162) months; still on IM treatment: 54%; switched to TKI2: 34%; alive: 81%. The reasons for IM discontinuation were: lack of efficacy (31%), death (12%), toxicity and other reasons (4%); 4% of patients were lost to follow-up. ComCI of CCyR in early CP and late CP was 89% and 77%, respectively (p<0,0001). The CCI of CCyR in early CP was higher than in late CP at all observation time. Switching to TKI2 allowed to increase CCI in all group after 5 years therapy. The 12-year OS for early CP and late CP was 90% and 74%, respectively (p=0,017); the 12-year PFS for early CP and late CP was 94% and 77%, respectively (p=0,006).

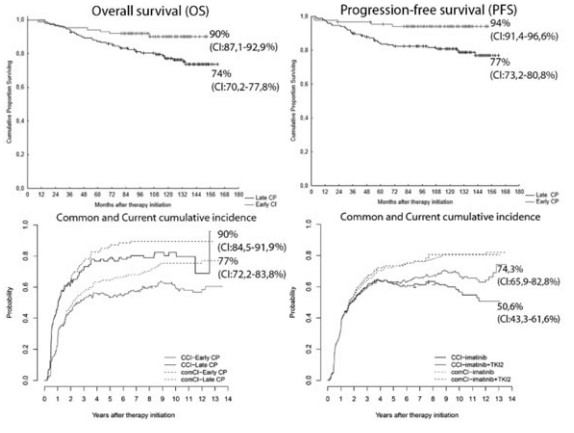

Figure 1.

Summary and Conclusions: The available data on the very long-term outcome of newly diagnosed CP CML patients treated frontline with IM are limited to a company sponsored study (IRIS study). Until now, there are no available data on the very long-term outcome of late CP CML patients treated with IM. This study provided an unbiased overview of the long-term IM therapeutic effects in early and late CP CML. IM more effective in early CP then in late CP CML. Achieving and maintaining CCyR correlated with disease duration before IM initiation. Switching to TKI2 allows to increase achieving and maintaining CCyR in early and late CP CML

E1099

CARDIOVASCULAR (CV)-RELATED HOSPITALIZATION IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) IN SIMPLICITY, A PROSPECTIVE OBSERVATIONAL STUDY

R. Paquette[1,*] M. Mauro[2], B. Simonsson[3], E. Abruzzese[4], D. Andorksy[5], R. Hansen[6], M. Subar[7], M. Turner[8], T. Zyczynski[7], H. Mohamed[7], S.L. Goldberg[9]
[1]UCLA Medical Center, California, [2]Memorial Sloan-Kettering Cancer Center, New York, United States, [3]Uppsala Universitet, Upsala, Sweden, [4]S. Eugenio Hospital, Rome, Italy, [5]Rocky Mountain Cancer Centers, Colorado, United States, [6]Privat Practice for Hematologa and Oncology, Kaiserslautern, Germany, [7]Bristol-Myers Squibb Co, Princeton, [8]ICON Plc, San Diego, [9]John Theurer Cancer Center, Hackensack University Medical Center, New Jersey, United States

Background: SIMPLICITY is an ongoing observational study of CP-CML patients (pts) designed to understand the use of first-line (1L) imatinib (IM), dasatinib (DAS) or nilotinib (NIL) in the United States (US) and Europe (Eu) outside clinical trials (NCT01244750). Previous SIMPLICITY data (ASH 2013) showed pts had 3.3 (±2.8) comorbidities (mean±standard deviation [SD]) at start of 1L tyrosine kinase inhibitor (TKI; N=949); ≥1 baseline comorbidity reported in >75% of pts, with >3 comorbidities in majority. 40.6% had cardiovascular (CV) comorbidities at start of 1L TKI. Baseline comorbidity did not affect initial TKI selection, although cautions regarding risks for specific adverse events (*e.g.* cardiac and pulmonary) have been described for individual TKIs in pts with pre-existing conditions.
Aims: This analysis focuses on the frequency of CV-related hospitalizations in SIMPLICITY pts and describes these events by 1L TKI and TKI received at time of hospitalization. Demographics and clinical characteristics of hospitalized pts are compared with the total SIMPLICITY population.
Methods: SIMPLICITY includes three prospective pt cohorts treated with IM, DAS or NIL as 1L therapy since 2010 and a historical cohort treated with IM since 2008. Among hospitalizations reported through 22 Sept 2014, CV-related hospitalizations were identified using preferred MedDRA terms in the CV category. Based on events reported, events were categorized: valvular disease; arrhythmia; cardiac failure; cardiac ischemic disease; and pericardial disorder. TKI exposure was calculated from total duration on specified TKI regardless of initial TKI.
Results: 1460 pts were enrolled prospectively on IM (n=415), DAS (n=416) or NIL (n=376), and data collected retrospectively for IM (n=253). Over half of pts were male (54.7%) and over half were from the US (66.7%). Median age (interquartile range [IQR]) at 1L TKI was 56.0 (45.0–67.0) years and 31% of pts were ≥65 years. Overall, 329 pts (22.5%) were hospitalized and 46 pts (3.2%) had CV hospitalizations (retrospective IM: n=21; prospective IM: n=6; DAS: n=8; NIL: n=11). Multiple CV hospitalizations were reported in 21.7% of CV hospitalized pts. Of pts with CV hospitalizations, median (IQR) age at 1L TKI was 70.8 (57.1–74.8) years; 60.9% were ≥65 years. Most pts were male (60.9%) and from the US (82.6%); 62% were on 1L TKI at first admission. Median follow-up from start of TKI to hospitalization was 370 days (retrospective IM, 484; prospective IM, 847; DAS, 105; NIL, 239 days) compared with 29.3 months for the total SIMPLICITY population. Most frequent causes of CV hospitalization were cardiac ischemic disease (34.6%), arrhythmia (30.8%) and cardiac failure (26.9%).The rate of CV hospital admissions per 100 pt years exposure was 1.46 for all hospitalized pts and was highest in the NIL-treated cohort (NIL: 2.61 compared with 0.77 [retrospective IM], 1.15 [prospective IM] and 1.15 [DAS]). The mean (±SD) duration of hospitalization was 5.9 (±7.2) days.
Summary and Conclusions: In SIMPLICITY, few patients overall were hospitalized for CV-related events. Pts with CV-related hospitalizations were older than the total SIMPLICITY population. The highest rate of CV hospitalizations per 100 pt years was in NIL-treated pts, while the observed rates for DAS and IM patients appeared similar. Analysis of pre-existing CV co-morbidities in hospitalized patients will be described.

E1100

ESTIMATED GLOMERULAR FILTRATION RATES OF CHRONIC MYELOID LEUKEMIA (CML) PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS (TKIS) IN DASATINIB TRIALS: DASISION (CA180-056), CA180-034, AND CA180-035

J. Cortes[1,*] A. Hochhaus[2], N. Shah[3], H. Kantarjian[1], J. Preston[4], G. Saglio[5]
[1]University of Texas MD Anderson Cancer Center, Houston, TX, United States, [2]Universitätsklinikum Jena, Jena, Germany, [3]University of San Francisco School of Medicine, San Francisco, CA, [4]Bristol-Myers Squibb, Princeton, NJ, United States, [5]University of Turin, Turin, Italy

Background: As the survival of patients with CML has increased with the introduction of BCR-ABL-targeted TKIs, more attention is being paid to the potential long-term effects of chronic treatment. There is evidence that suggests individual TKIs may affect metabolic pathways such as glucose control, lipid levels, and thyroid function (Breccia 2014, *Leuk Res*). In addition, imatinib has been associated in two single center studies with decreased estimated glomerular filtration rate (eGFR) over time, not reported with either dasatinib or nilotinib

(Marcolino 2011, *Ann Oncol*; Yilmaz 2013, *Blood*, abstr 1488).
Aims: The objective of this analysis was to evaluate the long-term effects of BCR-ABL-targeted TKIs on renal function in patients from three dasatinib phase 3 clinical trials: newly diagnosed patients with CML in chronic phase (CP) from DASISION, imatinib-intolerant or -resistant CML-CP patients from CA180-034, and imatinib-intolerant or -resistant patients with CML in accelerated/blast phase (AP/BP) or Ph+acute lymphoblastic leukemia (ALL) from CA180-035.
Methods: This pooled trial analysis was conducted using final data reports from each study: 5-year data from patients treated with first-line dasatinib 100 mg once daily (QD) or imatinib 400 mg QD in DASISION (NCT00481247; N=519), 7-year data from patients treated with second-line dasatinib 100 mg QD/50 mg twice daily (BID)/140 mg QD/70 mg BID in CA180-034 (NCT00123474; N=670), and 5-year data from patients treated with dasatinib 140 mg QD/70 mg BID in CA180-035 (NCT00123487; N=609). Modification of Diet in Renal Disease (MDRD) values for eGFR were calculated for patients aged ≥18 years using the formula: eGFR (mL/min/1.73 m²)=175 x (serum creatinine)$^{-1.154}$ x (age)$^{-0.203}$x (0.742 if female) x (1.212 if African American).
Results: In DASISION, newly diagnosed patients started on imatinib and dasatinib had a similar mean eGFR at baseline (89 mL/min/1.73 m^2). The mean eGFR with imatinib dropped approximately 9 mL/min/1.73 m² within the first 2 weeks of treatment, and then stabilized over the remaining length of the analysis (Figure 1). Conversely, there was a small increase in mean eGFR with dasatinib at early time points that then returned to baseline levels for the remainder of the analysis. In patients from CA180-034 and CA180-035 previously treated with imatinib, the baseline mean eGFR (79 mL/min/1.73 m^2 for dasatinib 100 mg QD in CA180-034 and 82 mL/min/1.73 m^2 for dasatinib 140mg QD in CA180-035) was lower than that observed in DASISION (89 mL/min/1.73 m^2). There was no difference in mean eGFR over time across all dasatinib doses tested in patients from CA180-034. In CA180-035, where all patients had advanced CML or ALL, a decrease in eGFR of approximately 10 mL/min/1.73 m^2 in the year following dasatinib initiation was observed without any long-term changes.

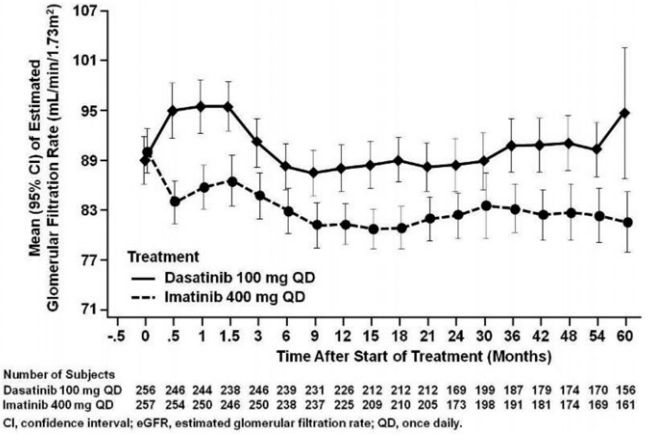

Figure 1. eGFR Over Time After the Start of Treatment in DASISION.

Summary and Conclusions: The renal profile of newly diagnosed CML patients or imatinib-intolerant/resistant CML or Ph+ALL patients did not worsen with long-term dasatinib treatment, regardless of CML phase. In DASISION, the mean eGFR with imatinib decreased soon after treatment initiation to a level consistent with the National Kidney Foundation (NKF) chronic kidney disease stage 2 (NKF Guidelines, 2002). Further analyses are ongoing to determine if there are any subpopulations of CML patients at risk, or other confounding factors, for developing renal dysfunction on TKIs.

Background: Nilotinib (NIL) elicits rapid, deep MR as first- or second-line treatment of patients (pts) with CML in chronic phase. However, the best treatment for pts with suboptimal MR to first-line imatinib (IM) is not yet known. *BIM* polymorphisms (eg, *BIM* deletion [del] polymorphism at intron 2 or a single nucleotide polymorphism [SNP; C465C>T at *BIM* exon 5]) reduce rates of MR and increase the frequency of newly detected *BCR-ABL1* mutations with IM treatment, but little is known about how *BIM* affects pts receiving NIL.
Aims: SENSOR (NCT0104387) evaluated the efficacy and safety of switch to NIL in Japanese pts with suboptimal MR (per 2009 European LeukemiaNet criteria) to first-line IM. Here, we present final 24-mo data and results from a *BIM* polymorphisms substudy.
Methods: In this multicenter study conducted in Japan, pts with suboptimal MR to frontline IM (complete cytogenetic response but not major molecular response [MMR] after ≥18 mo of IM) received open-label NIL 400 mg twice daily for up to 24 mo. Laboratory tests were performed centrally. *BCR-ABL1* transcript levels (using the International Scale with *ABL1* as a control gene) were assessed each mo (mo 1-3) and every 3 mo thereafter. *BCR-ABL1* mutation status was assessed by direct sequencing at baseline and retrospectively analyzed at all these time points in pts without mutations detected. *BIM* polymorphisms were evaluated using a validated assay during or after treatment. Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method.

Table 1.

Results: Of 45 pts enrolled in the main study (Dec 2009-Feb 2012), 6 pts discontinued (3 had adverse events [AEs], 1 had disease progression, and 2 withdrew consent). Median treatment duration was 22.1 mo (range, 0.1-22.7 mo). Rates of MMR, MR^4, and MR$^{4.5}$at 24 mo were 66.7% (95% CI, 51.0%–80.0%), 11.1% (95% CI, 3.7%–24.1%), and 6.7% (95% CI, 1.4%–18.3%), respectively. The cumulative incidence of MMR, MR^4, and MR$^{4.5}$by 24 mo was 75.6%, 13.3%, and 6.7%, respectively. Only 1 pt progressed or died; this pt had a newly detected T315I mutation, progressed to blast crisis at 5.4 mo, and died at 9.4 mo. Estimated 24-mo PFS and OS were 97.8% (95% CI, 85.3%–99.7%) and 97.8% (95% CI, 85.3%–99.7%), respectively. Of 40 pts evaluated for *BIM*

polymorphisms, 3 pts (7.5%) were heterozygous (hetero) for the *BIM* del, 10 pts (25.0%) had the C/T SNP, and 12 pts (30.0%) were hetero for the *BIM* del and/or had the C/T SNP. Pts achieved MMR and acquired *BCR-ABL1* point mutations or splicing abnormalities regardless of polymorphism status, but no pts with these *BIM* polymorphisms achieved MR^4 or $MR^{4.5}$(Table). Headache (28.9%) and rash (26.7%) were the most common drug-related nonhematologic AEs. The most common new or worsening laboratory abnormalities were increased bilirubin (95.6%) and increased alanine aminotransferase (80.0%). New or worsening hematologic abnormalities were decreased lymphocytes (53.3%) and decreased hemoglobin (31.1%).

Summary and Conclusions: Upon switch to NIL, 66.7% of pts achieved MMR at 24 mo, and 75.6% achieved MMR by 24 mo. Safety results were consistent with those from other NIL studies. Pts achieved MMR regardless of *BIM* polymorphism status, but no pts with *BIM* polymorphisms achieved deeper MR. Larger studies are required to determine how polymorphism of *BCL-2*-related genes, including *BIM*, may affect clinical response to NIL in pts with CML.

E1102

EFFICACY OF NILOTINIB VS HIGH-DOSE IMATINIB VS SUSTAINING STANDARD-DOSE IMATINIB IN EARLY CHRONIC PHASE CML PATIENTS WHO HAVE SUBOPTIMAL MOLECULAR RESPONSE TO FRONTLINE IMATINIB

S.Y. Choi[1,*] S.E. Lee[2], S.H. Kim[1], R. Woodman[3], T. Szczudlo[3], S. Jootar[4], H.J. Kim[5], S.K. Sohn[6], J.S. Park[7], S.H. Kim[8], D.Y. Zang[9], S.J. Oh[10], D.W. Kim[11]

Background: In chronic myeloid leukemia (CML), achievement of optimal responses by time point has improved long-term outcomes. In IRIS study, patients who achieved major molecular response (MMR) at 18 months had event-free survival (EFS) benefit, compared to those who achieved complete cytogenetic response (CCyR) without MMR. However, the best treatment for these patients is still not confirmed. By the previous studies, sustaining standard-dose of imatinib (IM) is expected to yield less than 20 percent of additive MMR.

Aims: In this study, we investigated the efficacy of nilotinib (NIL) versus high-dose IM versus sustaining standard-dose IM for CCyR patients with suboptimal molecular response to frontline IM therapy.

Methods: Early chronic phase (CP) CML patients who have achieved CCyR but no MMR after at least 18 months and up to 24 months (18 to 24 months) on first-line IM therapy at a daily dose of 400 mg were divided into 3 treatment groups; NIL 400mg BID (800 mg/day; group 1) *vs* IM 400 mg BID (800 mg/day; group 2) *vs* IM 400mg QD (400mg/day; group 3). Group 1 and 2 patients were selected in RE-NICE multicenter study and group 3 patients were selected with the same inclusion criteria of RE-NICE. The efficacy endpoints are MMR rate by 12 months and MMR rate and undetectable molecular residual disease (UMRD) rates by 36 months. Safety profiles of each group were compared. Patients showing lack of response (lack of complete hematologic response (CHR) at 6 months, increasing WBC, no major cytogenetic response (MCyR) at 24 months), loss of response (loss of CHR or MCyR) or intolerance to treatment were allowed to switch to other treatment.

Results: With a data cut-off date of 12 Jan 2015, a total of 84 patients were evaluated; 29 patients in NIL group (group 1), 29 patients in high-dose IM group (group 2) and 26 patients in standard-dose IM group (group 3). With a median follow-up of 36 months (range, 1-63), all patients in group 1 remained in nilotinib treatment, 18 patients in group 2 switched to NIL 400mg BID due to intolerance (n=4) and lack of response (no MMR; n=14). In group 3, with a median follow-up of 13 months (range, 1-130), 16 patients switched to other treatment due to intolerance (n=5) and lack of response (no MMR; n=10, treatment failure; n=1) and 1 patient loss of follow-up after 9 months follow-up. Up to now, three patients lost CCyR (1 in group 1, 1 in group 2 and 1 in group 3). With an initial treatment 10 in 29 (35%), 8 in 29 (28%) and 5 in 26 (19%) patients achieved MMR by 12 months, and 20 in 29 (69%), 10 in 29 (34%) and 10 in 26 (38%) patients achieved MMR by 36 months in group 1, group 2 and group 3 respectively. Overall, 3 patients in group 1 (3/29, 10%) achieved confirmed UMRD. Overall 3 years probability of MMR was higher in group 1 than the other two groups (81.0% *vs* 64.6% *vs* 64.0%, group 1, 2, 3 respectively, group 1 *vs* 2, P=0.098, group 1 *vs* 3, P=0.020, group 2 *vs* 3, P=0.443). Compare to other groups, the patients in group 2 showed higher toxicities, such as leukopenia, anemia, thrombocytopenia, edema, fatigue, dyspnea and hypophosphatemia.

Summary and Conclusions: Nilotinib 400mg twice daily treatment showed better efficacy than high-dose or same standard-dose imatinib for the treatment of patients who have suboptimal molecular response to initial standard-dose imatinib. Additionally, a switch to nilotinib in suboptimal molecular responder to imatinib would also be preferable option in terms of tolerability. Updated data with longer follow-up duration will be presented in the meeting.

E1103

OUTCOMES OF CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WITH 10%≤AND >10% BCR-ABL1 (IS) TRANSCRIPT LEVELS AFTER 3 MONTHS OF GENERIC IMATINIB TREATMENT

Z. Baslar[1] A. E. Eskazan[1,*] M. Ayer[2], B. Kantarcioglu[3], N. Demirel[3], D. Aydin[3], F. Aydinli[4], O. Yokus[4], S. Sadri[1], I. Erdogan[1], S. Berk[1], F.F. Yalniz[1], T. Elverdi[1], A. Salihoglu[1], M.C. Ar[1], S. Ongoren Aydin[1], Y. Aydin[1], N. Tuzuner[5], U. Ozbek[6], T. Soysal[1]

[1]Department of Internal Medicine, Division of Hematology, Istanbul University Cerrahpasa Faculty of Medicine, [2]Department of Hematology, Haseki Training and Research Hospital, [3]Department of Hematology, Okmeydani Training and Research Hospital, [4]Department of Hematology, Istanbul Training and Research Hospital, [5]Department of Pathology, Istanbul University Cerrahpasa Faculty of Medicine, [6]Department of Genetics, Istanbul University, Institute of Experimental Medicine (DETAE), Istanbul, Turkey

Background: The molecular response at 3 months of tyrosine kinase inhibitor (TKI) therapy for patients with chronic myeloid leukemia (CML) has prognostic significance and, a *BCR-ABL1* transcript level >10% on the international reporting scale (IS) at 3 months is associated with inferior outcomes. This finding was confirmed by many groups with the original imatinib (OI) (Glivec®; Novartis, East Hanover, NJ, USA), but never been tested for generic imatinib (GI). GI was first introduced in Turkey in August 2012, and afterwards most of the patients with chronic phase CML (CML-CP) were administered up-front GI according to the reimbursement policy in Turkey.

Aims: The first aim of this study was to evaluate the *BCR-ABL1 (IS)* transcript levels at 3 months of GI treatment, and to demonstrate whether early molecular response (EMR) had a prognostic impact on outcome among CML-CP patients who receive GI in the first-line setting. The second aim was to compare these findings to that of OI, in order to determine whether there was any difference between group of patients receiving these two imatinibs.

Methods: The testing for *BCR-ABL1 (IS)* was available in our institute after January 2010, so the study cohort consisted of 90 CML-CP patients who were diagnosed between 2010 and 2014. Patients' demographics, Sokal risk scores and follow-up periods were retrospectively noted from the patients' files. Imatinib response was evaluated according to the criteria recommended by the European LeukaemiaNet (ELN). The cumulative major MR (MMR) and complete cytogenetic response (CCyR) rates were calculated. Patients were divided into two groups according to imatinib they consume; patients receiving OI were Group A, and GI were Group B. Also these groups were further divided into two regarding the *BCR-ABL1 (IS)* transcript levels at 3 months of imatinib as 10%≤and >10%.

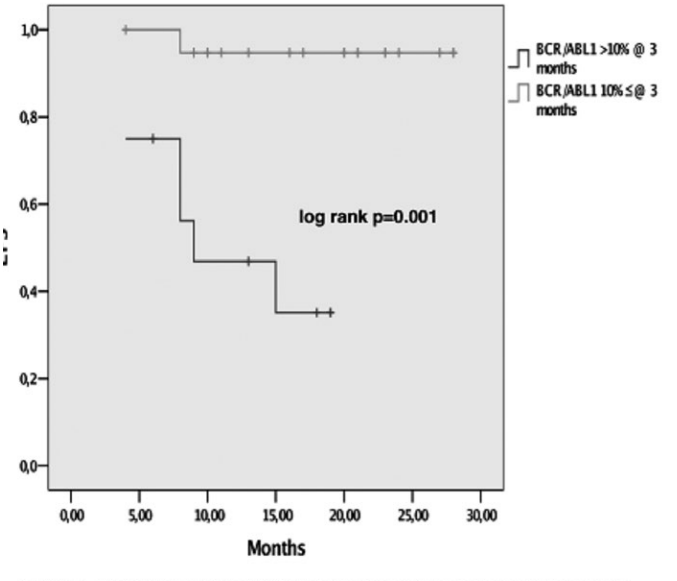

Figure 1. Event-free survival (EFS) difference between patients receiving generic imatinib with 10%≤ and >10% BCR-ABL1 (IS) transcript levels at 3 months

Figure 1.

Results: There were 47 patients in Group A and forty-three in Group B. The two groups were equally balanced regarding age, gender and Sokal risk scores

(Table 1). But patients in Group A had significantly longer median follow-up than patients in Group B (32.5 months vs. 13 months, *p<0.001*). *BCR-ABL1 (IS)* transcript levels at 3 months were available in 43 patients in Group A and thirty-two in Group B. There were 31 patients in Group A with a *BCR-ABL1 (IS)* transcript level 10%≤at 3 months whereas twelve patients had *BCR-ABL1 (IS)* transcript levels >10%. In Group B, 20 patients had a *BCR-ABL1 (IS)* transcript level 10%≤at 3 months and twelve had *BCR-ABL1 (IS)* transcript levels >10% (Table 1). The cumulative CCyR and MMR rates in patients with *BCR-ABL1 (IS)* level 10%≤at 3 months were significantly superior than patients with *BCR-ABL1 (IS)* level >10% both in Group A and B (Table 1). Also there were significantly more patients switching to 2nd generation TKIs (2GTKIs) due to resistance in both groups among patients with a *BCR-ABL1 (IS)* level >10% at 3 months (Table 1). Two groups did not significantly differ regarding cumulative CCyR and MMR rates as well as the number of patients with *BCR-ABL1 (IS)* levels 10%≤and >10%. In Group B, among patients with *BCR-ABL1 (IS)* levels 10%≤at 3 months (n=20), sixteen had MMR but the remaining 4 patients had a median follow-up of 8 months (range, 4-9 months) and 3 of them had CCyR and one had partial CyR. Among patients receiving GI, event-free survival (EFS) was significantly superior in patients with *BCR-ABL1 (IS)* level 10%≤at 3 months than patients with *BCR-ABL1 (IS)* level >10% (p=0.001) (Figure 1).

Table 1.

Table 1. Patient characteristics and treatment outcomes. (F, female; M, male, MMR, major molecular response; CCyR, complete cytogenetic response; PCyR, partial cytogenetic response; CHR, complete hematologic response; 2GTKI, second generation tyrosine kinase inhibitor) *Forty-three patients in Group A and 32 in Group B had a *BCR/ABL1* transcript level available at 3 months. ΦThe remaining 4 patients had a median follow-up of 8 months (range, 4-9 months) and 3 of them had CCyR and one had PCyR.

	Patients on front-line original imatinib Group A (n=47)			Patients on front-line generic imatinib Group B (n=43)			p value
Gender, n (M/F)	29/18			30/13			0.673
Median age, years (range)	42 (16-83)			46 (17-75)			0.411
Sokal risk score, low/intermediate/high (%)	54/33/13			41/38/21			0.388
Median follow-up, months (range)	32.5 (5-58)			13 (3-29)			<0.001
Patients with optimal response, n (%)	40 (85)			37 (80)			0.673
	*BCR/ABL1 (IS) at 3 months**			*BCR/ABL1 (IS) at 3 months**			
	10%≤, n 31	>10%, n 12	p value	10%≤, n 20	>10%, n 12	p value	
Cumulative CCyR rate, n (%)	30 (97)**	7 (64)***	0.001	19 (95)**	4 (34)***	<0.001	**0.150 ***0.229
Cumulative MMR rate, n (%)	30 (97)**	5 (45)***	<0.001	16 (80)+**	2 (17)***	0.001	**0.955 ***0.187
# of patients need to switch to 2GTKIs due to resistance, n	NA°	4°°	0.001	1°	5°°	0.011	°0.123 °°0.680

Summary and Conclusions: *BCR-ABL1 (IS)* transcript levels 10%≤at 3 months in CML-CP patients receiving generics had superior outcomes in terms of cumulative CCyR and MMR rates as well as EFS when compared to patients with *BCR-ABL1 (IS)* level >10%. And these findings were consistent with the literature displaying similar results in patients receiving Glivec.

E1104

PONATINIB EFFICACY AND SAFETY IN PATIENTS WITH A HISTORY OF STEM CELL TRANSPLANTATION (SCT) IN THE PACE TRIAL

F.E. Nicolini[1,*] D.J. DeAngelo[2], E. Abruzzese[3], J.F. Apperley[4], T.L. Holyoake[5], R.A. Larson[6], S. Lustgarten[7], V.M. Rivera[7], T. Clackson[7], M.G. Conlan[7], F.G. Haluska[7], M. Talpaz[8], J.E. Cortes[9]
[1]Centre Hospitalier Lyon Sud, Pierre Bénite, France, [2]Dana-Farber Cancer Institute, Boston, United States, [3]S Eugenio Hospital, Tor Vergata University, Rome, Italy, [4]Centre for Haematology, Imperial College London, London, [5]Paul O'Gorman Leukaemia Research Centre, Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom, [6]University of Chicago, Chicago, [7]ARIAD Pharmaceuticals, Inc., Cambridge, [8]Comprehensive Cancer Center, University of Michigan, Ann Arbor, [9]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Ponatinib is a potent oral BCR-ABL tyrosine kinase inhibitor (TKI) approved for patients with refractory chronic myeloid leukemia (CML) or Philadelphia chromosome–positive acute lymphoblastic leukemia (Ph+ALL) and those with the T315I mutation in BCR-ABL1.
Aims: This retrospective analysis describes the efficacy and safety of ponatinib (starting dose 45 mg once daily) in patients with a history of SCT prior to enrollment in the ongoing phase 2 PACE trial.
Methods: Patients with CML or Ph+ALL who were resistant or intolerant to dasatinib or nilotinib or who had the T315I mutation were enrolled in PACE (NCT01207440). All patients gave informed consent. The PACE trial excluded patients who underwent SCT <60 days before the first ponatinib dose, patients with evidence of ongoing graft-versus-host disease (GVHD), and patients who had GVHD requiring immunosuppressive therapy. Of 449 patients, 40 (9%) had a history of SCT.
Results: Of 40 patients with a history of SCT, 12 (30%) had chronic-phase (CP)-CML, 8 (20%) had accelerated-phase (AP)-CML, 11 (28%) had blast-phase (BP)-CML, and 9 (23%) had Ph+ALL at study entry (PACE enrollment). Median age was 48.5 years and median time since diagnosis was 3.8 years at the time of the first dose. Most patients (73%) had received ≥3 TKIs, either before or after SCT, prior to ponatinib treatment. Twelve patients (30%) had T315I detected at baseline (1 CP-CML, 2 AP-CML, 5 BP-CML, and 4 Ph+ALL patients). Twenty-five patients (63%) had an SCT ≤2 years (but ≥60 days) before starting ponatinib, and 15 (38%) had an SCT >5 years before starting ponatinib. Patients may have received intervening therapy between SCT and ponatinib. As of 6 October 2014, median follow-up for these 40 patients was 12.6 months after start of ponatinib; median duration of ponatinib treatment was 5.9 months. Median dose intensity was 39.9 mg/d and 45% of patients had their dose reduced. The primary endpoint in CP-CML (major cytogenetic response by 12 months) was achieved by 4 (33%) of 12 CP-CML patients. The primary endpoint in AP-CML, BP-CML, and Ph+ALL (major hematologic response by 6 months) was achieved by 3 (38%) of 8 AP-CML patients, 3 (27%) of 11 BP-CML patients, and 2 (22%) of 9 Ph+ALL patients. Major molecular response at any time was achieved in 1 (8%) of 12 CP-CML patients, 1 (13%) of 8 AP-CML patients, 2 (18%) of 11 BP-CML patients, and 1 (11%) of 9 Ph+ALL patients. Vascular adverse events occurred in 6 (15%) of 40 patients and included myocardial infarction (n=2), pulmonary embolism (n=2), angina pectoris (n=1), cerebral ischemia (n=1), coronary artery disease (n=1), portal vein thrombosis (n=1), superficial thrombophlebitis (n=1), and transient ischemic attack (n=1). Additional data regarding SCT and other treatments before ponatinib will be presented.
Summary and Conclusions: Ponatinib treatment induced responses in a substantial proportion of heavily pretreated Ph+patients with a history of SCT. Vascular adverse events were observed in 15% of patients. Benefits and risks should be considered when using ponatinib in patients with a history of SCT.

E1105

LONG-TERM BOSUTINIB FOR PHILADELPHIA CHROMOSOME–POSITIVE (PH+) ADVANCED CHRONIC MYELOID LEUKEMIA (CML) AFTER PRIOR TYROSINE KINASE INHIBITOR FAILURE

C. Gambacorti-Passerini[1,*] H.M. Kantarjian[2], D.W. Kim[3], H.J. Khoury[4], J.H. Lipton[5], T.H. Brümmendorf[6], K. Noonan[7], E. Matczak[8], E. Leip[9], J.E. Cortes[2]
[1]University of Milano-Bicocca, Monza, Italy, [2]University of Texas MD Anderson Cancer Center, Houston, TX, United States, [3]Seoul St. Mary's Hospital, Seoul, Korea, Republic Of, [4]Winship Cancer Institute of Emory University, Atlanta, GA, United States, [5]Princess Margaret Cancer Centre, Toronto, ON, Canada, [6]Universitätsklinikum RWTH Aachen, Aachen, Germany, [7]Pfizer Inc, Groton, CT, [8]Pfizer Inc, New York, NY, [9]Pfizer Inc, Cambridge, MA, United States

Background: Advanced (ADV) Ph+CML patients (pts) have worse outcomes *vs* chronic CML pts.
Aims: In this first report of bosutinib (BOS) activity in this cohort as fully enrolled, we evaluate long-term efficacy and safety of BOS in ADV pts ≥4 y *vs* ≥1 y from last enrolled pt.
Methods: Ongoing phase 1/2 BOS study in 79 accelerated phase (AP) and 64 blast phase (BP) pts with prior tyrosine kinase inhibitor (TKI) failure. Informed consent was obtained from all pts.

Table 1.

Newly Occurring AEs*								
	Year 1		Year 2		Year 3		Year 4	
n	AP N=79	BP N=64	AP N=34	BP N=5	AP N=19	BP N=3	AP N=15	BP N=2
Diarrhea	67	41	0	0	0	0	0	0
Cardiac	12	7	1	1	1	1	2	0
Vascular	4	7	4	0	1	0	1	0
*Not experienced by same patient previously (denominator=patients on treatment each y [1 y = 52 wk])								

Results: For AP and BP pts, 18% and 3% remained on BOS at 4 y (vs 48%; 13% at 1 y; 1 y=48 wk); 57% and 28% newly attained or maintained baseline overall hematologic response (OHR) by 4 y (most by 12 mo); 40% and 37% attained/maintained major cytogenetic response (MCyR) by 4 y (most by 12 mo). Kaplan-Meier probabilities of maintaining OHR in responders at 4 *vs* 1 y were 49% *vs* 78% (AP) and 19% *vs* 28% (BP); Kaplan-Meier MCyR probabilities at 4 *vs* 1 y were 49% *vs* 65% (AP) and 21% *vs* 21% (BP). AP and BP pts were treated for median 10.2 (range, 0.1–88.6); 2.8 (0.03–55.9) months. Most common AEs were gastrointestinal (AP, 96%; BP, 83%), primarily diarrhea (85%; 64%), which was typically low grade (grade 1/2: 96%; 93%), transient (median duration/any grade AE: 2 [range, 1–910] d; 2 [1–211] d); no pt discontinued due to this AE. Newly occurring AEs arose mostly in y1; new cardiac/vascular AEs occurring in y4 were pericardial effusion, sinus bradycardia/1st degree atrioventricular block (same pt), and hypertension (all n=1); those in y1 (>2 pts either cohort) were pericardial effusion (AP, n=4; BP, n=1), tachycardia (n=2; n=4), hypertension (n=3; n=2; Table). Serious AEs occurred in 56% AP and 58% BP pts, most commonly pneumonia (n=9; n=5). 11 AP and 13 BP pts died within 30 d of last dose; 2 BOS-related (AP). Treatment discontinuations were mostly due to progressive disease (AP, ≤1/>1 y,

n=10/13; BP, n=29/3) and AEs in AP (n=16/5); death (n=6/0) and symptomatic deterioration (n=6/0) in BP.
Summary and Conclusions: Durable response was seen in ~50% AP responders (~25% BP responders at y1, for whom BOS may be bridge to transplant); toxicity was manageable with long-term treatment.

E1106

PATIENT CHARACTERISTICS AND ADVERSE EVENTS (AES) OF TYROSINE KINASE INHIBITORS (TKIS) FOR THE TREATMENT OF CHRONIC MYELOID LEUKEMIA (CML) IN REAL WORLD SETTINGS

S.L. Goldberg[1,*] Y. Su[2], D. Frame[3], M. Ryan[3], W.D. Irish[3], C. Gunnarsson[3], M. Woloj[2], R. Ferdinand[4], M. Shapiro[5]
[1]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, NJ, [2]Pfizer, Inc., New York, NY, [3]CTI Clinical Trials and Consulting, Cincinnati, OH, United States, [4]Pfizer, Ltd., London, United Kingdom, [5]Pfizer, Inc., Cambridge, MA, United States

Background: The growing number of TKIs available for CML increases complexity in choosing therapy in non-research settings.
Aims: This study aims to determine patient (pt) characteristics & emergent AEs that might underlie treatment choices.
Methods: TKI treatment episodes for adult CML pts from 1/2008 - 7/2014 were identified in the MarketScan Commercial, Medicaid, and Medicare supplemental databases. Pts were required to have ≥6 mos of enrollment prior to each TKI episode and ≥1 pharmacy or medical claims for one of the TKIs on or after the first CML diagnosis date. Analyses were retrospective and descriptive. Charlson comorbidity index (CCI) and frequency of other key comorbid conditions prior to each TKI episode were used to characterize patient baseline status (BL). Corresponding treatment-emergent events were captured using the same diagnosis or treatment codes indicative of the conditions. Vascular occlusive (VO) conditions include one or more of the following: myocardial infarction, congestive heart failure (CHF), thrombotic events, acute coronary syndrome, peripheral vascular, cerebrovascular, or coronary artery diseases. Median duration of treatment was assessed using the Kaplan-Meier method.
Results: 4,166 TKI treatment episodes for CML were identified. Median follow up was 13 months. Imatinib (IM) was most commonly used 1st line, dasatinib (DAS) and nilotinib (NIL) 2nd line, and bosutinib (BOS) and ponatinib (PON) 3rd line. BOS pts had the most previous TKI episodes and were furthest from initial diagnosis. They were the oldest, had the highest CCI, the most histories of VO conditions, kidney diseases, and pleural effusion at baseline, but the lowest rates of serious emergent AEs and discontinuation. With younger age and lower CCI, PON pts had the highest incidences of treatment emergent VO events and fluid retention, with the shortest treatment duration and highest rates of discontinuation.

Table 1.

	IM n=1,898	DAS n=1,180	NIL n=953	BOS n=87	PON n=48
Age (median)	55	52	53	56	51.5
# Prior TKIs (mean)	0.8	1.2	1.2	2.4	2.0
Time since initial diagnosis (median mos)	9	10	11	25	18
CCI (mean)	5.5	5.0	5.4	6.2	5.4
BL /emergent AE (%)					
VO conditions	31/5	30/6	31/5	43/5	40/15
CHF	11/3	10/4	14/3	23/1	15/6
Dysrhythmias	19/4	18/6	24/9	39/5	35/8
Fluid retention	16/6	17/6	18/5	36/3	33/10
Renal diseases	13/4	11/4	16/3	20/3	19/6
Diabetes	24/6	24/4	23/5	23/2	25/4
Pleural effusion	7/3	10/8	14/4	33/1	29/2
COPD	22/4	22/6	23/3	26/2	23/0
Abdominal pain	32/7	36/7	37/9	45/2	46/10
Diarrhea	14/6	16/5	17/3	24/13	31/8
Treatment Duration (median mos)	16	17	15	13	5
Discontinuation (%)	27	19	24	15	29

Summary and Conclusions: BOS appeared to be associated with lower risks of serious AEs compared to other TKIs and suited to elderly pts with high orbidities. It will be important to confirm the findings with larger sample sizes.

E1107

THE EFFECT OF NILOTINIB IN CHRONIC MYELOID LEUKEMIA TREATMENT DOSE ON FERTILITY AND TERATOGENICITY IN A HEALTHY MOUSE MODEL

G. Cengiz Seval[1,*] S. Ozkavukcu[2], M. Seval[3], C. Celik Ozenci[4], N. Kuscu[4], M. Ayli[5]
[1]Hematology, Yildirim Beyazit University Yenimahalle Education and Research Hospital, [2]Center of Assisted Reproduction/Depatment of Obstetrics and Gynecology, [3]Depatment of Obstetrics and Gynecology, Ankara University School of Medicine, Ankara, [4]Department of Histology and Embryology, Akdeniz University School of Medicine, Antalya, [5]Hematology, Ufuk University School of Medicine, Ankara, Turkey

Background: Chronic myeloid leukemia (CML) is a hematopoietic pluripotent stem cell disease where myeloid cells lead to uncontrolled proliferation. Current treatment of Ph (+) CML is based on the inhibition of tyrosine kinase inhibitors (TKI), especially second-generation drugs. Majority of CML patients are male and 46% of them are between 20 and 64 years of age. Therefore, it is conceivable that inhibition of c-kit or PDGFR by TKI may have deleterious effects on spermatogenesis or folliculogenesis, resulting in male or female subfertility. In the first part of this study we showed the suppression of folliculogenesis and prevention of spermatogenesis during the long-term nilotinib treatment.
Aims: The aim of this part of our study is to determine the effect of nilotinib on fertility and teratogenicity that is used routinely to treat CML.
Methods: Here we present the results of testicular and ovarian changes after nilotinib administration to five- week old male and female C57bl6 mice. Mice received 0.4 mg of nilotinib per day dissolved in the drinking water for 2 months. Control group received only drinking water. Treatment dose was determined according to the clinical studies regarding the plasma concentrations (20 mg/kg, orally).
Results: There were no differences in the fertility and live birth index, the sex ratio or the frequency of survival to the time of weaning and also no evidence of teratogenicity in the fetuses. Low birth weight fetuses were seen in the nilotinib receiving female group whether the interruption of the drug during the pregnancy. The pregnancy rates of the couples according to the case of the using nilotinib or not were shown in Table 1. The pregnancy rates were reduced to 75% in the case of male mice used nilotinib; to 60% in the case of female mice used nilotinib; and finally to 25% in the case of both female and male mice used nilotinib in the cohort.

Table 1. The pregnancy rates of the couples

Pregnancy Rate	Nilotinib Female (n=12)	Control Female (n=12)
Nilotinib Male (n=12)	25%	75%
Control Male (n=12)	60%	100%

Summary and Conclusions: Although our results indicate that mice achieved the pregnancy whether they used nilotinib, the pregnancy rates reduced significantly compared to the control group in the study, especially if both female and male mice used nilotinib together. According to limited information, the potential consequences of the drug on developing fetus is still matter of debate, all female mice have given birth to healthy baby in our study. In the third part of our ongoing study, we are investigating the long-term effect of nilotinib on baby mice.

E1108

DYNAMICS OF RESPONSE AND IMPACT OF SOKAL SCORE IN 3 MONTHS MOLECULAR "WARNING" CML PATIENTS. A RETROSPECTIVE STUDY OF GRUPPO TRIVENETO LMC

G. Binotto[1,*] M. Tiribelli[2], M. Bonifacio[3], E. Maino[4], E. Calistri[5], I. Gianesello[1], R. Bertorelle[6], F. Gherlinzoni[5], A. Ambrosetti[3], R. Fanin[2], G. Semenzato[1]

Immunologia e Diagnostica Molecolare Oncologica, Ist. Oncologico Veneto, Padova, Italy

Background: Response to TKI is considered the strongest predictor of long-term outcome in CML patients. As known, effective treatment overcomes the negative impact of most prognostic factors, including Sokal score. Different studies have demonstrated that early molecular response is strictly correlated with outcome: infact, missing the 10% BCR-ABL landmark at 3 months predicts inferior long-term survival.
Aims: We investigated the dynamics of 3 months molecular "warning" CML patients at 6 and 12 months landmarks; secondly, we sought to evaluate the impact of Sokal score in the context of this unfavourable group
Methods: A total of 51 patients with BCR-ABL levels >10% at 3 months were identified for the analysis from a cohort of 350 consecutive CML patients treated with front-line standard dose imatinib (400 mg daily). "Optimal", "warning" and "failure" responses were stated according to ELN2013 recommendations. Complete cytogenetic response (CCyR) was defined as 0% Ph+metaphases; major molecular response (MMR) was defined as BCR-ABL <0.1%IS. TTF was measured from the start of imatinib to the date of any of the following events: progression to accelerated or blastic phase, death for any cause at any time, primary or secondary hematologic, cytogenetic or molecular resistance leading to imatinib discontinuation. PFS was measured from the start of imatinib to the date of progression to accelerated or blastic phase or death for any cause at any time. Survival probabilities were estimated by the Kaplan-Meier method and compared by log rank test; differences among variables were evaluated

by the Fisher's exact test or by Cochran–Mantel–Haenszel test
Results: The median age of patients was 56 years (range 25–81), with 33 males and 18 females. The median follow-up was 45.3 months (range 7–110). The distribution of patiens according to the Sokal score was: 11 (21.6%) in the low risk, 24 (47.1%) in the intermediate and 16 (31.4%) in the high risk group, respectively. At 6 months, only 3 of 40 evaluable patients, 1 in each group (11.1%, 5% and 9% respectively), improved their 3 months molecular response, achieving an optimal response. 20 failures, defined as more than 10%IS BCR-ABL transcript level, were recorded (1, 11 and 8 in low, intermediate and high risk group respectively, P=0.008 comparing low *vs* other risk groups). At 12 months, 21 of 25 evaluable patients were considered failures; only 1 patient gained an optimal response. 27.2%, 50% and 50% of low, intermediate and high Sokal score patients failed to achieve a CCyR at any time (P=0.047), while 72.7%, 45.8% and 31.3% of patients obtained a MMR (P=0.104), respectively. Median time to CCyR and MMR was 12, 12.5, 24.5 months (P=0.21), and 30, 25 and 22 months (P=0.21) for low, intermediate and high risk group responding patients. Imatinib discontinuation rate, albeit remarkable in all Sokal groups, was not significantly different (66.7% *vs* 78.3% *vs* 93.8% respectively, P=0.22), as well as PFS (P=0.349), TTF (P=0.321) and OS (P=0.812). 9.1%, 12.5% and 25% of low, intermediate and high Sokal risk patients progressed to AP/BC phase, respectively.
Summary and Conclusions: These data suggest that although non-low Sokal score CML patients may experience a higher probability of early failure, long term outcomes of molecular "warning" patients seem not to be significantly influenced by Sokal risk. Therefore, 3-months BCR-ABL transcript level higher than 10% IS appears to overcome non only the negative, but also the positive prognostic impact of Sokal score. These observations warrant further confirmation in larger studies.

E1109

EVALUATION OF A CENTRALIZED MOLECULAR MONITORING OF CHRONIC MYELOID LEUKEMIA THERAPY IN SOUTH KOREA

Background: For the treatment of chronic myeloid leukemia (CML), higher efficacy of tyrosine kinase inhibitors (TKI) has required accurate molecular monitoring by standardized real-time quantitative polymerase chain reaction (RQ-PCR). Although the standardization of RQ-PCR test has become particularly important to increase the accuracy, each participating laboratory should establish a laboratory-specific conversion factor through regular exchange of a series of samples. However the process is very complicated and periodic validation is needed to keep the stabilization of original conversion factors of laboratories. Otherwise the measurement of *BCR-ABL1* transcript by single standardized laboratory can reduce many unnecessary processes and is able to increase accuracy of result.
Aims: In this study, we evaluated the Korean centralized RQ-PCR program and the result of molecular monitoring of CML patients in routine clinical practice.
Methods: Twenty four Korean university hospitals were agreed on a centralized assay performing in the Catholic University of Korea and the program was started in October, 2012. EDTA tubes containing peripheral blood were shipped to central laboratory within 24 hours and standardized RQ-PCR assays were performed. To validate the result, we analyzed *BCR-ABL1* transcript level and compared with *ABL1* copy number for quality control of each samples.
Results: Between October 2012 and November 2014, a total of 4,638 samples from 1,545 CML patients were tested to measure the ratio of *BCR-ABL1* to *ABL1* transcript level in international scale (IS). The *ABL1* copy number was more than 100,000 copies in 3,770/4,638 (81.3%), 32,000 and 100,000 copies in 784 (16.9%), 10,000 and 32,000 in 43 (0.9%), and less than 10,000 copies in 41 (0.9%) samples. Of 1,203 patients who were tested more than 2 times, 1,094 (90.9%) had appropriate copies of *ABL1* for defining MR of each patient. However, 109 (9.1%) in undetectable level were less than 100,000 ABL1 copies which is inappropriate copies of *ABL1* for defining $MR^{5.0}$. Of 1,545 patients, 1,064 (69%) had $MR^{3.0}$. Among them, 515 (33.1%) and 514 (33%) were in $MR^{4.5}$and $MR^{5.0}$ respectively. Of patients achieving at least $MR^{3.0}$, 98% (n=1,043) and 87% (n=925) of patients had ≥32,000 and ≥100,000 *ABL1* copies respectively, and these were in the minimal requirement of *ABL1* copy number for defining $MR^{4.5}$and $MR^{5.0}$.

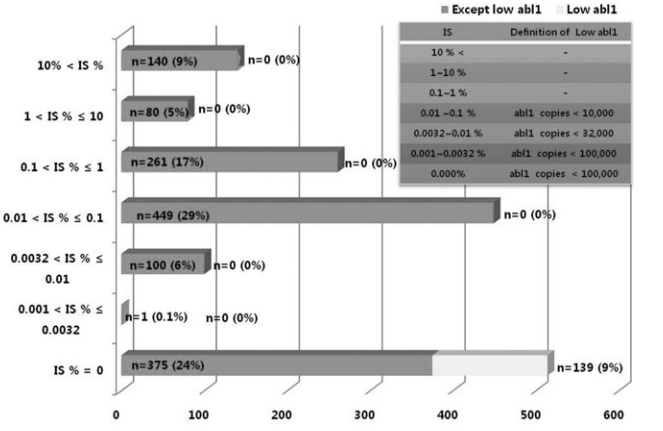

Figure 1. Molecular response and Quality of RQ-PCR assay measuring by *ABL1* copy number (n=1,545).

Summary and Conclusions: Molecular monitoring using a centralization program of *BCR–ABL1* assay may provide stable and qualified results. Through this program, more than 98%of samples met the minimum requirement of ABL1 copy numbers for at least $MR^{4.5}$sensitivity and it can support for TFR studies in the future.

E1110

PREDICTIVE FACTORS TO ACHIEVE DEEP MOLECULAR RESPONSE AND LONG-TERM OUTCOMES IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS. A SINGLE CENTER EXPERIENCE IN ARGENTINA

M.J. Mela Osorio[1,*] I. Giere[2], I. Fernandez[1], M.A. Pavlovsky[1], G. Remaggi[1], F. Sackmann Massa[1], D. Intile[3], C. Pavlovsky[1]
[1]Hematology, [2]Molecular Biology, [3]Statistics, Fundación para Combatir la Leucemia (FUNDALEU), Ciudad Autónoma de Buenos Aires, Argentina

Background: Few data is available about long-term follow-up treatment and outcomes with Tyrosine Kinase Inhibitors (TKI) in South American patients (pts). Response to TKI is known as the most important predictor of outcome in Chronic Myeloid Leukemia (CML). Early achievement of responses has also been determined by many authors as predictor of long-term outcomes. However, major molecular response (MMR) is not a failure criterion at any time point.
Aims: To identify predictive factors for achievement of deep molecular response (MR) and improvement of failure-free survival (FFS). Secondary objective was to determine whether late MMR acquirement impacts on FFS.
Methods: Pts were treated with various TKI modalities between 2000 and 2014. Cytogenetic analyses were performed with standard G-banding. Molecular diagnostics for residual BCR-ABL transcripts followed the procedures and definitions of Cross et al; and were performed in a standardized and accredited laboratory. Confirmed $MR^{4.0}$was defined as ≥4.0 log reduction of BCR-ABL (detection ≤0.01%) on the international scale and determined by Rq-PCR in two consecutive analyses. Overall survival (OS) was defined as the time between diagnosis and death from any cause. FFS accounts for failure to achieve response as defined by ELN, lost of complete cytogenetic response (CCyR), accelerated phase and blast crisis. Adherence monitoring was assessed by treating physician and reported in medical record.

Results: Of 119 pts with diagnosed chronic phase CML, median age was 48 years (range, 16-82), 52% were males. The percentage of pts with low Sokal risk score were 82%, 25% of pts had been previously treated with interferon. Median follow-up was 89 months (mo) (range, 3-306). A total of 103 pts were treated with 1st line imatinib (IM) 400mg daily and constitute the basis of the analysis. The proportion of pts treated with IM who achieved CCyR or BCR-ABL <1% within 6 mo and MMR within 12 mo was 84% and 38% respectively. Median-time to achieve MMR and $MR^{4.0}$was 2.6 and 3.6 years respectively. At 60 mo, FFS was 91% and OS 98%. Pts still on initial IM were 79% after 8 years. By logistic regression analysis CCyR/BCR-ABL <1% within 6 mo, MMR within 12 mo and adherence resulted independent predictors for achieving $MR^{4.0}$ (*OR, 95%CI* and *p value* are detailed in Table 1). In pts who acquired CCyR/BCR-ABL <1% within 6 mo, MMR within 12, 24 mo and adherence >90%, FFS at 60 mo was higher than those who did not (Table 1). The sub-analysis determined that pts ≤30 years had lower adherence than older pts (76% *vs* 94% *p.* 0.02).

Table 1. Predictors of Deep Molecular Response and FFS analysis in Pts With CML treated With IM.

Variables	n (%)	Univariate analysis		Multivariate analysis		Univariate analysis	
		MR 4.0 (%)	p Value	OR	95% CI	5-yr FFS (%)	p Value
Within 6 mo							
CCyR/BCR-ABL < 1%	78 (84)	77	0.003	5.6	(1.6-19)	95	0.001
No CCyR	15 (16)	40				71	
Within 12 mo							
MMR	31 (38)	84	0.006	5.3	(1.4-21)	100	0.01
No MMR	50 (62)	54				82	
Within 24 mo							
MMR	54 (64)	80	0.03	2.5	(0.9-7.2)	100	0.006
No MMR	31 (36)	58				75	
Adherence							
> 90%	86 (91)	78	0.003	7.0	(1.3-37)	92	0.00001
< 90%	9 (9)	33				79	

Responses at each time point were compared using χ^2 test or Fisher exact test, as appropriate. Multivariate models (logistic regression) were performed, considering MR4.0 as dependent variable and CCyR/BCR-ABL < 1% within 6 mo, MMR within 12 mo, MMR within 24 mo and adherence as predictive variables. Failure-Free Survival (FFS) was estimated using the Kaplan-Meier method and compared by log-rank test.

Summary and Conclusions: In our long-term follow-up population, CCyR/BCR-ABL <1% within 6 mo, MMR within 12 mo and adherence constitute early independent predictors for achievement of deep MR consistent with the published literature. Although good responses are obtained with IM, some pts still progress, this is the reason why it is necessary to identify those who will relapse so as to consider a change in treatment to another TKI at a convenient time point. Better results in terms of FFS were observed for pts who acquired CCyR/BCR-ABL <1% within 6 mo, MMR within 12 mo and adherence >90%. Nevertheless MMR within 24 mo does not seem to affect long-term outcomes and further investigations, in a larger pt population, are needed to determine when MMR must be considered a failure criterion. In terms of adherence, young adults are particularly at risk and a new strategy may be needed in this special subgroup of pts. Lack of adherence can prevent the long-term molecular objective of treatment. These results emphasize the validity, feasibility and harmonization of molecular monitoring and treatment of CML worldwide.

E1111

NEW TOOL FOR MONITORING MOLECULAR RESPONSE IN CHRONIC MYELOID LEUKEMIA

T. Badar[1,*] H. Kantarjian[1], E. Jabbour[1], G. Borthakur[1], N. Daver[1], X. Huang[1], B. Alvarez[1], B. Austermiller[2], T. Morrison[3], J. Cortes[1]
[1]Leukemia, University of Texas MD Anderson Cancer Center, Houston, [2]Accugenomics, Wilmington,NC, [3]Accugenomics, Wilmington, NC, United States

Background: Chronic myeloid leukemia (CML) treatment monitoring using PCR based peripheral blood testing provides improved test sensitivity over cytology but suffers from inadequate standardization due to variation inherent in the existing PCR methodologies. Standardized Nucleic Acid Quantification BCR-ABL (SNAQ-BCRABL) is a novel competitive template based peripheral blood b2a2/b3a2 transcript abundance method. It uses mixtures of b2a2 or b3a2 and GusB competitive templates and melting curve analysis to provide desired quality controls to correct for procedural variation.
Aims: A pilot study was conducted in CML patients to evaluate the imprecision and linearity of two established real-time qPCR laboratory developed test (LDT) and SNAQ for monitoring BCR-ABL.
Methods: Thirty six CML patients treated at our institution were enrolled in this pilot study. Their peripheral blood sample were analyzed at MD Anderson Molecular Diagnostic Laboratory and Cancer Genetics Institute for BCR-ABL by LDT (L1 and L2) and SNAQ (S1 and S2) test respectively. The LDT methods used TaqMan real-time assays to quantify BCR-ABL and ABL targets in cDNA synthesized from WBC RNA isolated from the blood specimens. The SNAQ method likewise used cDNA synthesized from WBC, but differs at the PCR step by the addition of known quantities of competitive templates (b2a2 or b3a2 and GusB) to the cDNA prior to PCR amplification and melting curve analysis. AccuGenomics's SNAQ software imports the melting curve data, performs quality control and curve fitting analysis to generate a BCR-ABL report. The LDT methods report %BCR-ABL/ABL results using International Standard, and the SNAQ results were reported as %BCR-ABL/GusB.
Results: Each test result (n= 36) was ranked against all the other samples tested by the same method. The Pearson correlation between SNAQ and LDT was met with correlations of 0.96, 0.96, 0.97 and 0.94 with L1 x S1, L1 x S2, L2 x S1 and L2 x S2 respectively. ANOVA of log %BCR-ABL interlaboratory results indicated a significant difference between LDT methods ($p<0.0000001$), but not with the SNAQ methods between labs ($p=0.98$) (Figure1A). Imprecision was estimated using the Bland-Altman method and the plot indicated that sample results from L2 had 1 outlier, which was excluded from analysis. All three L1 difference plots (Figure1B & C) had a significant trend ($p<0.007$), requiring regression correction prior to estimating variation. The linear regression analysis, indicated L2 LDT was a large source of method bias.Post hoc analysis of method agreement showed the SNAQ method did not generate any outliers and had a 95% limit of agreement of ±3-fold between laboratories, whereas L1 and L2 LDT method had significant differences despite reporting in international scale, with 95% limit of agreement of 2 to 20-fold.

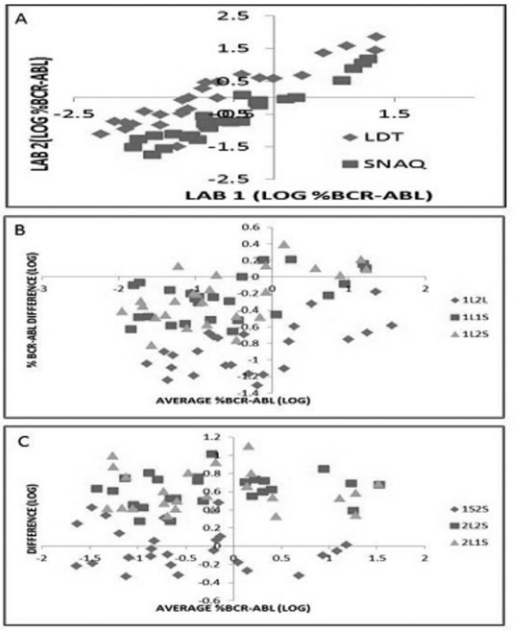

Figure 1.

Summary and Conclusions: In this pilot study, SNAQ methodology performed well suggesting it might be able to overcome some of the limitations encountered by some of the LDT currently in clinical practice. Additional studies with more patients and correlation with clinical outcomes are required to confirm this observation.

E1112

MULTICENTER STUDY OF COMORBIDITY IN CANARIAN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

M. Saez-Perdomo[1,*] J. Viedma[1], C. Bilbao-Sieyro[1], N. Herranz[2], J.D. González San Miguel[3], H. Luzardo[1], G. Brito[4], N. Navarro[5], M. Tapia[6], A. Ruano[7], M.T. Gómez-Casares[1]
[1]Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, [2]Hospital Ntra Sra de la Candelaria, Santa Cruz de Tenerife, [3]Hospital Universitario Insular, Las Palmas de Gran Canaria, [4]Hospital Clínico Universitario de Tenerife, Santa Cruz de Tenerife, [5]Hospital José Molina Orosa, Arrecife, [6]Hospital General de la Palma, Santa Cruz de La Palma, [7]Hospital Ntra Sra de Guadalupe, San Sebastián de la Gomera, Spain

Background: In February of 2009 the Canarian registry of chronic myeloid leukemias (CML) was created in order get a better insight of treatment response, behavior and outcome in our region. For that purpose data from patients treated in the 7 hospitals of the Canary Islands was collected.
Aims: The purpose of the study was to investigate the cardiovascular risk associated with the use of Tyrosine Kinase Inhibitors (TKI) in the CML treatment.
Methods: Since 2009**,** 127 patients have been included. The series consisted of 65 (51.18%) males and 62 (48.8%) females with a mean age at diagnosis of 54.64±16.37. 75 patients (59%) received Imatinib, 37 (29%) received Nilotinib and 15 (12%) Dasatinib. We analyzed cardiovascular risk factors such as hypertension (HTA), diabetes (DM), body mass index (BMI) and smoking. We estimated the Framingham risk score (FRS) and researched the series retrospectively for atherosclerotic events.
Results: Among risk factors to be considered in our series, we revealed that 55 patients (43.31%) were receiving concomitant drugs for hypertension, 34 patients (26.77%) had a concomitant DM, and 9 patients (7.09%) were smok-

ers. According to WHO classification, 12 patients were classified as normal weight (BMI<25), 32 patients were overweight (BMI 26≤30), 36 were obese (BMI>30) and 47 unclassified because we couldn't retrieve the BMI for the whole series. At time of diagnosis 87 patients (68.5%) were classified as low risk FRS category (<10% chance of suffering an atherosclerotic event), 19 patients (14.96%) as intermediate risk (10-20%) and 21 patients (16.54%) as high risk (>20%). There were 9 patients (7.09%) who presented an atherosclerotic event after treatment with a TKI of which 1 patient used Dasatinib (1/15) (Cerebrovascular accident), 4 used Imatinib (6.67%) (2 aortic stenosis, 1 aortic aneurism with bypass and 1 peripheral arteryoclusive disease (PAOD) with ischemic ulceration) and 4 used Nilotinib (10.81%) (1 anterior ischemic optic neuropathy, 1 intermittent claudication, 1 aortic stenosis accompanied with intermittent claudication and 1 toe amputation). There was no significant difference in the incidence of the atherosclerotic events between Imatinib and Nilotinib. Dasatinib patients were excluded due to the small series. The 9 patients with atherosclerotic events had high blood pressure levels, 2 of them had the hypertension under contol and the rest (7 patients) had an uncontrolled hypertension. There was a significant difference in incidence of the events between patients with low risk FRS category (33.33%) and intermediate-high risk FRS (66.66%) regardless the treatment (p=0.025). There was no significant difference in patients with imatinib between low risk FRS (57.33%) and intermediate-high risk FRS (42.67%), where 2 of the patients having atherosclerotic events were classified as low risk FRS and the other 2 were classified as high risk FRS. But in patients with nilotinib is a significant difference between patients classified as low risk FRS (64.86%) and intermediate-high risk FRS (35.10%) (p=0.005), where the 4 patients presenting atherosclerotic events were classified as high risk FRS.

Summary and Conclusions: Atherosclerotic risk factors in patients with CML should be considered before the treatment with TKIs. Those patients with high risk factors to which is decided treatment with Nilotinib despite the risk score should also be closely monitored.

E1113

THE RATE OF BCR-ABL DECLINE AS AN OPTIMIZED PREDICTOR OF OUTCOME FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE ON TREATMENT WITH TYROSINE KINASE INHIBITORS

M. Fominykh[1,*] V. Shuvaev[1], I. Martynkevich[1], G. Tsaur[2,3], N. Bederak[4], E. Chelysheva[5], O. Shukhov[5], A. Abdullaev[5], V. Udaleva[1], R. Golovchenko[1], I. Zotova[1], D. Shikhbabaeva[1], L. Polushkina[1], E. Petrova[1], M. Ivanova[1], L. Martynenko[1], E. Kleina[1], N. Cybakova[1], A. Turkina[5], K. Abdulkadyrov[1]

[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, [2]Regional Children's Hospital N 1, [3]Research Institute of Medical Cell Technologies, [4]Municipal City Hospital N 7, Ekaterinburg, [5]Hematology Research Center, Moscow, Russian Federation

Background: About 70% of chronic myeloid leukemia (CML) patients achieved early molecular response (*BCR-ABL*^{IS} ≤10% at 3-months) that led to 5-years overall survival close to 95%. Nonetheless, CML patients remain heterogeneous group and several studies in recent years were aimed to personalize treatment based on individual patients' characteristics. Our group previously put forward a hypothesis about the prognostic value of individual *BCR-ABL* decline rate in the first three months of CML therapy[1,2]. The ratio *BCR-ABL* at 3 months to baseline had chosen as 0.1 as best cut-off value (sensitivity 83.33, CI 62.6-95.3; specificity 66.67, CI 34.9-90.1) to predict MMR at 12 months.

Aims: The aims of this study were to validate our prognostic method in larger group of patients.

Methods: Fifty-five patients (median age, 52 years; range 19-84; 24 male and 31 female) with chronic phase CML were included in the study. Distribution of Sokal risk groups were as follows low-30 / intermediate-15 / high-10. Six patients had EUTOS high-risk. Forty-two patients started treatment with Imatinib 400 mg/day, 12 patients started with Nilotinib 600 mg/day and 1 patient started with Dasatinib 100 mg/day. Median *BCR-ABL*^{IS} transcript levels was 41.38% at diagnosis, range 3.39-3185.36%. The ratio of *BCR-ABL* levels at 3 months to baseline for each patient was calculated. In addition, we calculated ratio of *BCR-ABL* levels at 3 months to *BCR-ABL* levels at 1 month for 13 patients. Comparison was made of the predictive sensitivity to achieve early molecular response at 3 months (10% by IS). We estimated relative risk (RR) the probability of achieving MMR, depending on the method of stratification of patients. Statistical analysis was conducted with Fisher exact test.

Results: Twenty-six out of 34 patients (76.5%) with ratio of *BCR-ABL* levels at 3 months to baseline below than 0.1 achieved MMR at 12 months, while only 9 of 21 patients (42.9%) with ratio more than 0.1 had optimal response (RR=0.41 (0.20 – 0.84); p=0.03). Ratio of *BCR-ABL* levels at 3 months to 1 month also showed good results with the same (0.1) cut-off value – 5 out of 6 patients (83.3%) with ratio *BCR-ABL* at 3 months to 1 month below than 0.1 achieved MMR, while only 1 patient (14.3%) with ratio more than 0.1 achieved optimal response (RR=0.19 (0.03 – 1.19); p=0.05). Application of early molecular response at 3 months (10% by IS) yielded worse discrimination results: 34 of 47 (72.3%) patients with *BCR-ABL* level ≤10% at 3 months had achieved MMR at 12 months, whereas 2 of 8 (25%) patients with *BCR-ABL*>10% had MMR at 1 year (RR=0.96 (0.62 – 1.49); p=0.78). Moreover, application of our ratio cut-off value among patients with *BCR-ABL* level ≤10% at 3 months allowed us to revealed additional 6 high-risk patients have not reached MMR at 1 year of therapy, Figure1.

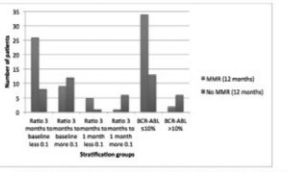

Figure 1. The patient numbers of achieving MMR at 12 months of therapy in various stratification groups.

Figure 1.

Summary and Conclusions: Our study demonstrated that the individual *BCR-ABL* decline rates from baseline to 3 months and to 1 month might be useful prognostic markers that allowed detecting more patients at risk who had no MMR at 1 year of treatment with using *ABL* as control gene. Also, the study showed that the individual ratio of *BCR-ABL* levels might be studied as more predictive landmark for change of TKI treatment even among patients that have *BCR-ABL* levels ≤10% at 3 months.

IMATINIB TREATMENT DURATION EFFECT ON ESTIMATED GLOMERULAR FILTRATION RATE IN CHRONIC MYELOID LEUKEMIA PATIENTS

L. Růžičková[1,*] P. Freitas Tavares[1], P. Rodrigues Santos[2,3], P. Couceiro[3], L. Ribeiro[1]

[1]Hematologia, Centro Hospitalar e Universitário de Coimbra, [2]Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, [3]Lab Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, Coimbra, Portugal

Background: Imatinib (IM) represents an important therapeutic option in Chronic Myeloid Leukemia (CML). There are various clinical trials suggesting safe IM discontinuation in CML patients with sustained major molecular response (MMR), however, life-long therapy with IM is still the consensus recommendation. Therefore, there is increasing interest in identifying long-term therapy associated toxicity of this treatment. There is lack of evidence regarding the effect of long-term IM treatment on renal function.

Aims: To study the possible effect of IM therapy duration on renal function impairment.

Methods: We studied a group of 48 patients (25 men, 23 women), 47 in chronic phase (CP) CML, 40 (83%) of these patients with deep molecular response ($MR^{4.5}$), 1 patient with accelerated disease, receiving IM in the course of their disease. Exclusion criteria was chronic renal disease at baseline (estimated glomerular filtration rate (eGFR) ≤60 ml/min/1.73m^2). The median age was 51 (range 25-78) at the time when IM was started. The median duration of IM treatment was 76,8 months (4,2 – 149,6), median total follow-up was 84,1 months (4,2 – 152,6). 36 patients (75%) were previously treated with interferon (IFN), median duration of treatment 29,4 months (4,2-278,8). At present, 6 of these patients are receiving IFN together with IM treatment. Laboratory data (creatinine, urea) and eGFR using CKD-EPI equation were obtained periodically from the start of IM treatment. Clinical information about hypertension (HTA) and diabetes (DM), relevant for renal function assessment was collected.

Results: The mean baseline eGFR was 96,27±17 ml/min/1.73m^2, mean eGFR at last observation 77,55±25 ml/min/1.73m^2, mean decrease between the baseline and last eGFR 18,71 ml/min/1.73m^2. During the follow-up, 5 patients developed Acute kidney injury (AKI), defined as increase in creatinine ≥0,3mg/dl, all of them during the first month of IM treatment. There was the normalization of creatinine and eGFR values in only 2 of these patients. 10 patients developed chronic kidney disease, median age of this group was 64 (31-78), 1 patient was diabetic and 6 patients had history of HTA. eGFR decreased significantly with IM treatment duration (p<0,05). Age, HTA, DM or previous IFN treatment were not significantly related to eGFR decrease.

Summary and Conclusions: Although IM is well tolerated and highly efficient, its long-term effect on eGFR decrease and its mechanism are not well established. We proved that IM treatment duration may be associated with important eGFR decrease. Patients receiving IM should be monitored closely with regular eGFR calculation.

E1115

CHRONIC MYELOID LEUKEMIA: IS THE REAL PROGNOSIS OF NEWLY DIAGNOSED PATIENTS REALLY SO GOOD?

D. Zackova[1,2,*] Z. Racil[1,2], E. Janousova[3], D. Dvorakova[1], T. Jurcek[1], R. Minarik[1], J. Prochazkova[1], A. Oltova[1], B. Weinbergerova[1], L. Semerad[1], L. Pavlovska[3], L. Dusek[3], J. Mayer[12]
[1]Dpt. of Internal Medicine, Hematology and Oncology, University hospital Brno, [2]Faculty of Medicine, [3]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic

Background: Precise, mature data about real-world treatment efficacy in modern era of chronic myeloid leukemia (CML) are still missing. Moreover, true incidence of persistent side effects of tyrosine kinase inhibitors (TKI) is rarely reported in clinical trials.
Aims: To give a real picture of TKI treatment by analyzing detailed, prospective database of all consecutive CML cases.
Methods: Data regarding all patients treated in the academic institution with the catchment area of about 2 million people were analyzed according to the European LeukemiaNet recommendations (Guilhot, Blood 2012). Diagnostic and treatment protocols follow ELN and EUTOS recommendation/standardization. TKI side effects were assessed according to CTCAEv4.
Results: Two hundred and fourteen patients (median age 58 years, range 18-92; 53.7% of males) with newly diagnosed CML in 2005 – 2014 underwent the analysis: 194 patients (90.7%) in chronic phase (CP), 11 (5.1%) in accelerated phase, 8 (3.7%) in blast crisis, and in 1 (0.5%) case the phase was unknown. In total, 41 (19.2%) patients died during the follow-up (median 3.8 years, range 0.1-9.8): 22 patients due to CML activity, 13 patients due to causes probably not related to CML, and in 6 cases the reason was unknown. The first line therapy given to patients diagnosed in CP (Sokal high risk in 29.9%) was as follows: imatinib, N=152 (78.4%); nilotinib, N=24 (12.4%); dasatinib, N=6 (3.1%); other, N=7 (3.6%); none, N=5 (2.5%) due to death (N=3) and lost to follow-up (N=2) before the treatment start. The median follow-up of 182 patients in CP treated with 1st line TKI was 45.3 months (range, 5.2-115.8). Estimated cumulative incidences of complete cytogenetic responses and major molecular responses at 48 months were 92.2% and 89.2%, respectively. Estimated OS (defined as the time from the start of TKI therapy to the death, with no censoring at the time of therapy change) at 48 months was 89%. Estimated PFS, FFS, EFS, and ATFS at the same time point were 89.9%, 74.5%, 67.4%, and 66.7%, respectively. In total, 38.5% of patients permanently discontinued the first line TKI. The reasons for discontinuation in group treated with imatinib (N=61/152; 40.1%) were resistance in 32/61 patients (52.4%), intolerance (13/61; 21.3%), and other reasons (16/61; 26.2%; in 9 cases the reason was participation in discontinuation trials, and in 5 patients non-CML related deaths). Reasons for nilotinib discontinuation (6/24; 25%) were as follows: resistance (N=1), intolerance (N=3), and other (N=2). Subsequent therapy after imatinib discontinuation included dasatinib (N=19), nilotinib (N=16), and other (N=15). After cessation of nilotinib, patients were treated with dasatinib (N=2), imatinib (N=2), and other therapy (N=2). Analysis of imatinib and nilotinib clinical non-hematological toxicity incidence during the time revealed significant proportion of clinically relevant events of grade 2-4, and their persistence during the whole follow-up (Table 1).

Table 1. Incidence of clinical non-hematological toxicities during the time of imatinib and nilotinib first line therapy.

1st line imatinib (N=152)						
Grade	M0-3 N=152	M3-6 N=142	M6-12 N=135	M12-24 N=120	M24-48 N=97	M48+ N=58
1	71 (46.7%)	76 (53.5%)	68 (50.4%)	67 (55.8%)	48 (49.5%)	32 (55.2%)
2	19 (12.5%)	23 (16.2%)	23 (17.0%)	24 (20.0%)	27 (27.8%)	15 (25.9%)
3	15 (9.9%)	7 (4.9%)	5 (3.7%)	4 (3.3%)	8 (8.2%)	6 (10.3%)
4	-	1 (0.7%)	1 (0.7%)	-	-	-
Total	105 (69.1%)	107 (75.4%)	97 (71.9%)	95 (79.2%)	83 (85.6%)	53 (91.4%)
1st line nilotinib (N=24)						
Grade	M0-3 N=24	M3-6 N=24	M6-12 N=20	M12-24 N=12	M24-48 N=4	M48+ N=0
1	11 (45.8%)	14 (58.3%)	11 (55.0%)	1 (8.3%)	1 (25.0%)	-
2	3 (12.5%)	2 (8.3%)	4 (20.0%)	1 (8.3%)		-
3	2 (8.3%)	1 (4.2%)	1 (5.0%)	4 (33.3%)	1 (25.0%)	-
4	-	-	-	-	-	-
Total	16 (66.7%)	17 (70.8%)	16 (80.0%)	6 (50.0%)	2 (50.0%)	-

Summary and Conclusions: About 10% of CML patients is diagnosed in advanced disease and many newly diagnosed patients still die from leukemia. Moreover, more than one third of patients in CP have changed the first line therapy, mainly due to resistance, or intolerance. ATFS is a valuable parameter covering all situations of treatment change. In patients who continue on originally chosen TKI, there is the evidence of clinically relevant adverse events persistence in many of them, which can influence quality of life and can contribute to drug non-compliance. More detailed analysis will be presented.

E1116

SIGNIFICANCE OF ANEMIA IN PATIENTS WITH CML AT DIAGNOSIS AND DURING THE TREATMENT WITH IMATINIB OUTSIDE THE CLINICAL TRIALS: CAMELIA REGISTRY EXPERIENCE

E. Faber[1,*] J. Mužík[2], E. Janoušová[2], T. Dufková[2], P. Jindra[3], E. Cmunt[4], Z. Sninská[5], L. Demitrovičová[6], E. Mikušková[6], J. Chudej[7], I. Markuljak[8], S. Palášthy[9], N. Štecová[10], E. Tóthová[10], L. Dušek[2], K. Indrák[1]
[1]Department of Hemato-Oncology, Faculty Hospital Olomouc; Faculty of Medicine and Dentistry, Palacky University In Olomouc, Olomouc, [2]Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno, [3]Department of Hemato-Oncology, University Hospital, Pilsen, [4]Ist Internal Department, University Hospital, Prague, Czech Republic, [5]Institute of Hematology and Blood Transfusion, University Hospital, [6]Department of Hemato-Oncology, National Cancer Institute, Bratislava, [7]Department of Clinical Hematology, University Hospital, Martin, [8]Department of Clinical Hematology, University Hospital, Banská Bystrica, [9]Department of Clinical Hematology, University Hospital, Prešov, [10]Department of Clinical Hematology, University Hospital, Košice, Slovakia

Background: Attention of physicians caring for CML patients is seldom focused on anemia as it was not shown to be an independent prognostic factor and it may have different causes during the course of disease. The relevance of anemia in routine clinical setting outside the clinical trials has not been sufficiently covered.
Aims: To evaluate the prognostic and clinical importance of anemia in CML patients treated with imatinib using data from the international CML CAMELIA Registry.
Methods: Retrospective analysis of all files of CML patients treated with first-line imatinib in first chronic phase was performed. For the purpose of the study anemia was defined by hemoglobin level lower than 120g/l. Single center survey of quality of life using simple questionnaire in 32 CML patients with and 31 without anemia was performed. For statistical testing Mann-Whitney test and Fisher exact test, for survival analysis Kaplan-Meier method with log-rank test were used.
Results: Anemia was identified at diagnosis in 211 (45%) from the total cohort of 469 patients in first chronic phase of CML treated with imatinib. Anemia was not associated with initial cytogenetic findings (p=0.946) or age (p=0.125), but strong correlation was found with higher risk scores in all prognostic systems (Sokal, Hasford, EUTOS; p<0.001). Patients with anemia had significantly higher numbers of WBC (median=175.6 *vs* 48.0 p<0.001) and more frequent splenomegaly (p<0.001). Response to the treatment was similar: major molecular response was achieved in 72.5% and 68.7% of patients without and with anemia, respectively. However, when assessing overall survival with the endpoint death caused by CML, anemia was associated with worse outcome (log-rank test p=0.013). There were 23 deaths caused by CML among 31 dead patients with anemia (74.2%) but only 11 out of 28 deaths (39.3%) in the group of patients without anemia (p=0.009). During the treatment with imatinib anemia was identified in 91 (19.4%) patients at one or more occasions. There was no correlation with the anemia or risk scores at diagnosis. There was a trend towards association of anemia with age over 60 years (24.4% *vs* 16.9%; p=0.063). Anemia during the treatment was not associated with response to treatment, but has significant impact on quality of life: patients spent more time in bed (p=0.014), less time outside the flat or house (p<0.001), they suffered more from dyspnea (p=0.022) and there were trends for lower Karnofski score (p=0.057), unemployment (p=0.077) or sport capacity (p=0.079).
Summary and Conclusions: Anemia at diagnosis in CML patients from CAMELIA Registry was a frequent finding and was associated with the high-risk features. Despite the fact that response to treatment was not compromised with anemia at diagnosis, a significant association was found with CML-related death rate. During the treatment with imatinib, anemia was found in about 20% of patients, affected more frequently elderly patients and had negative impact on their quality of life.

E1117

EFFICACY AND SAFETY FOR DASATINIB IN EARLY CHRONIC PHASE CML PATIENTS WITH LATE SUBOPTIMAL RESPONSE TO FRONTLINE IMATINIB. PRELIMINARY RESULTS FROM DASAPOST STUDY

V. Garcia-Gutierrez[1,*] B. Colom[2], F. Sanchez-Guijo[3], R. Ayala[4], C. Boqué[5], C. Luis Felipe[6], B. Xicoy[7], I. Montero[8], C. Soto[9], R. de Paz[10], A. Kreutzman[2], C. Muñoz[2], J.L. Steegmann[11]
[1]Servicio de Hematología y Hemoterapia, Hospital Universitario Ramón y Cajal, [2]Servicio de Inmunología, Hospital Universitario de la Princesa, Madrid, [3]Servicio de Hematología y Hemoterapia, Hospital Universitario de Salamanca, Salamanca, [4]Servicio de Hematología y Hemoterapia, Hospital Universitario 12 de Octubre, Madrid, [5]Servicio de Hematología, Hospital Duran i Reynals, Barcelona, [6]Servicio de Hematología, Hospital Virgen de la Salud, Toledo, [7]Servicio de Hematología, Hospital Hospital Germans Trias i Pujol, Barcelona, [8]Servicio de Hematología, Hospital Universitario Virgen del Rocio, Sevilla, [9]Servicio de Hematología, Hospital Povisa, Vigo, [10]Servicio de Hematología, Hospital Universitario de la Paz, [11]Servicio de Hematología, Hospital Universitario de la Princesa, Madrid, Spain

Background: The additional benefit of achieving major molecular response (MMR) in patients with Complete Cytogenetic Response (CCyR) response is still under debate, and therefore, patients with CCgR without MMR after 12 months of treatment are considered as a "warning" by European LeukemiaNet (ELN) recommendations. Several clinical trials have shown how patients treated with imatinib front line and classified as late warning responders can benefit from treatment changed to nilotinib in terms of improving molecular response. However, there are no data regarding to treatment change to dasatinib in this group of patients
Aims: To evaluate the efficacy and safety of treatment change to dasatinib in patients treated with imatinib first line with late suboptimal response (patients with CCyR without MMR after at least 18 months of treatment) by the ELN 09 recommendations
Methods: We are presenting preliminary results of the first 18 patients enrolled in the phase II DASAPOST study (NCT01802450). Main inclusion criteria were patients treated with late suboptimal response by the ELN09 (CCyR without MMR after 18 months of treatment). Previous treatment with imatinib 600mg (but not 800mg) was allowed. Median exposure to imatinib before dasatinib was 5.1 years (1.8-12.2). Sokal risk groups % (L/I/H) was 22.5%, 55% and 22.5%. Median age was 56 years (34-77). Primary end point was the achievement of MMR after 6 months of dasatinib. Secondary endpoints were to assess the efficacy of dasatinib in terms of depth and kinetics of molecular response, as well as the relationship of response with lymphocyte alterations. Responses evaluations were performed following indications of the ELN. All BCR-ABL/ABL (IS) measurements were centralized in an EUTOS laboratory.
Results: Clinical: Eighteen patients have been enrolled in the study. Median follow up at data cut-off was 262 days (21-380). Three out of 18 (16%) patients had discontinued dasatinib due to side effects (pancreatitis, pleural effusion and low grade, persistent side effects (fever, arthralgias, anemia and asthenia). 16/18 patients have been evaluated at 3 months, 12 at 6 months and 6 at 12 months. Cumulative incidences by ITT of MMR calculated by competing risks by 3 and 6 months were 50 and 83%. However, for patients who reached the 6 months assessment frequencies of MMR and MR4.5 were 85% and 42% respectively. No patient have lost CCyR while 1 patient in MR4.5 lost MMR. 1 patient had reduced dasatinib dose to 70mg due to congestive heart failure (patient achieved and maintained undetectable molecular response). Immunological: Lymphocyte counts were done before and after dasatinib intake at baseline, at 3 and 6 months, observing an increment of counts post intake in most patients. At baseline the median increase post intake was 1,79 fold (0,98-3,2). There was no significant association between this increment and MMR at 3M (MMR at 6 months was not studied, as most patients obtained this response at that timepoint).
Summary and Conclusions: Our study shows, for the first time to our knowledge, that in patients treated with Imatinib and late suboptimal (warning) responses, switch to Dasatinib induced MMR in 83% of the patients, although 16% discontinued treatment because of toxicity. No association was found between lymphocyte "mobilization" post intake and response. Dasatinib appears to have a good benefit/ risk ratio in this type of patients. More details on the immunologic studies will be provided.

Co., Ltd., Yongin, [17]Department of Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: BCR-ABL1 tyrosine kinase inhibitors (TKIs) have been administered as fixed doses for adult patients with chronic myeloid leukemia (CML). However, due to the wide inter-individual variability in the pharmacokinetics of TKIs and increasing evidence supporting the relationship between drug exposure and the efficacy and toxicity of these agents, there may be potential benefits of TKI dose individualization based on body size. Radotinib is a selective second generation BCR-ABL1 TKI and a phase 2 study was previously conducted in patients with TKI failed CP CML.
Aims: Using the data from the phase 2 study, radotinib exposure-efficacy and -safety relationship analyses were conducted to explore the dosing methods that will potentially improve the efficacy and safety profiles of radotinib.
Methods: The efficacy and safety data were collected for 12 months after the initiation of radotinib therapy from a multi-center phase 2 study conducted in 77 CP CML patients resistant and/or intolerant to other TKIs. All patients received radotinib 400 mg twice daily until a dose-limiting toxicity (DLT) appeared, after which the dose was reduced to 300 mg twice daily. The relationships between the body weight-adjusted dose (Dose/wt) and the probability of achieving major cytogenetic response or experiencing DLT were explored using a logistic regression method. The analyses were repeated using body-surface-area-adjusted dose (Dose/BSA). Upon a stratification of the patients based on Dose/wt or Dose/BSA, time-to-first DLT curves were compared using a Kaplan-Meier method.
Results: *Efficacy.* No significant associations were found between radotinib Dose/wt or Dose/BSA and major cytogenetic response at Months 1, 3 and 6. *Safety.* Positive correlations were observed between radotinib Dose/wt and the probabilities of first DLT occurrence at Months 3 (p=0.002), 6 (p=0.003), 9 (p=0.004), and 12 (p=0.007). Similar positive correlations were observed for Dose/BSA. Statistically significant differences were evident in the Kaplan-Meier curves of DLT between various Dose/wt groups, particularly between the groups of Dose/wt <6 mg/kg and Dose/wt ≥6 mg/kg (p=0.008) with the median time to first DLT being 259 and 83 days, respectively. At the cut-off of 6 mg/kg, the patient weighs 66.7 kg. A 2-tier weight-based dosing method was recommended to reduce the probability of DLT: radotinib 300 mg or 400 mg twice daily for patients weighing ≤65 kg or >65 kg, respectively.
Summary and Conclusions: The probability of DLT increased without improvement in efficacy as the Dose/wt or Dose/BSA of radotinib increased. Therefore, a lower initial radotinib dose of 300 mg twice daily is recommended for CP CML patients weighing ≤65 kg. A randomized clinical trial would be needed to confirm the efficacy and safety of this alternative dosing regimen.

E1119

EFFICACY AND SAFETY OF DASATINIB VS. IMATINIB IN LATIN AMERICAN SUBPOPULATION FROM THE DASISION TRIAL IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA (CML) IN CHRONIC PHASE (CP)

A. Enrico[1,*] J. Milone[1], B. Moiraghi[2], L. Casanova[3,4], M.S. Undurraga[5], L. Enciso Olivera[6,7], E. Bullorsky[8], J. Navarro Cabrera[9], K. Pagnano[10], M. De Riz[11], C. Pavlovsky[12]
[1]Hospital Italiano La Plata, La Plata, [2]Hospital J. M. Ramos Mejía, CABA, Argentina, [3]Department of Medical Oncology, Instituto Nacional de Enfermedades Neoplásicas, [4]Department of Medical Oncology, Clínica Oncológica Miraflores, Lima, Peru, [5]Hospital del Salvador, Santiago, Chile, [6]Instituto Nacional de Cancerología Bogotá, [7]; Universidad Nacional de Colombia, Bogotá, Colombia, [8]Hospital Británico Buenos Aires, CABA, Argentina, [9]Hospital Nacional Edgardo Rebagliati Martins, Lima, Peru, [10]Hemocentro-Unicamp, Universidade Estadual de Campinas, Campinas-SP, Brazil, [11]Medical Department, Bristol-Myers Squibb, Buenos Aires, [12]FUNDALEU, CABA, Argentina

Background: Kantarjian *et al.* reported in the phase 3 DASISION TRIAL that 519 patients with newly diagnosed CML-CP from 108 centers in 26 countries were randomized to receive dasatinib (n=259) or imatinib (n=260). Of these, 23 % (120) were from the Latin America (LA) region (23 % Argentina, 9 % Chile, 3 % Colombia, 15 % Peru, 19 % Brazil and 30% Mexico).
Aims: The main objective was to evaluate if LA results from DASISION TRIAL can be considered similar to those obtained in the overall study.
Methods: DASISION (CA180-056; NCT00481247) is a signed IC 60 month-Open Label Multinational randomized phase 3 trial comparing dasatinib 100 mg QD versus imatinib 400 mg QD in patients with CML-CP diagnosed within 3 months who had not received previous treatment for CML. All exposure, safety, and efficacy results described here were analyzed on the 120 LA patients (all randomly assigned to receive dasatinib (n=63) or imatinib (n=57)) in comparison to the total patients treated (including Latin American patients), here referred to as "all randomized". The efficacy and safety were assessed by using data obtained during the initial 3 years period of the trial.
Statistical Methods: Comparison of the rates was performed for p=0.05 (two-tailed). Response (efficacy variables) and AEs rates were estimated with their 95% confidence intervals (CIs) when needed. The difference in rates between the 2 treatment groups was tested by using Pearson Chi square Test. PFS and OS by treatment group were estimated via the Kaplan-Meier product-limit method. Due to the fact that the 120 LA patients is a subset of the planned total enrolled population, every statistical analysis of LA was considered exploratory.
Results: Treatment was discontinued due to disease progression in 4,8 % and

7% of the cases, unacceptable toxicity in 3,2% and 8,8% of the cases in dasatinib and imatinib groups respectively. Baseline characteristics and demographics of LA patients were relatively well balanced between the two treatment groups and were similar to the overall study data with exception of baseline high Hasford risk score in LA patients that was higher in both (dasatinib and imatinib) treatment groups. At 36 months the rates of cumulative cCCyR, MMR and PFS, OS and AEs rates for patients in either arm in LA patients and in all randomized patients can be seen in Table below. AEs in LA and in all randomized patients will be described.

Table 1.

Rates (% of patients) of Efficacy Variables and Safety				
Variable	Latin America (LA)		DASISION TRIAL (All Patiens)	
	dasatinib (n=63)	imatinib (n=57)	dasatinib (n=259)	imatinib (n=260)
cCCyR within 12 months (a)	79.4	64.9	76.8	66.2 **
cCCyR within 24 months (a)	82.5	73.7	80.3	74.2
cCCyR within 36 months (a)	82.5	73.7	82.6	77.3
MMR within 12 months (b)	44.4	28.1	52.1	33.8 **
MMR within 24 months (b)	69.8	43.9 **	64.5	50.0 **
MMR within 36 months (b)	73.0	49.1 **	69.1	56.2 **
PFS within 36 months (c)	91.9	89.7	91.0	90.9
OS within 36 months (d)	91.9	92.7	93.7	93.2
DRAEs (e)	84.1	98.2	84.5	88.0
(a) confirmed Complete Cytogenetic Response; (b) Major Molecular Response; (c) Progression Free Survival; (d) Overall Survival; (e) Drug Related Adverse Events. dasatinib vs. imatinib: **: p < 0.01.				

(1) Kantarjian H, Shah N, Hochhaus A, et al. Dasatinib versus imatinib in newly diagnosed chronic-phase chronic myeloid leukemia. New England Journal of Medicine. June 2010; 362:2260-70.
(2) Kantarjian H, Shah N, Cortes J, et al. Dasatinib or imatinib in newly diagnosed chronic-phase chronic myeloid leukemia: 2-year follow-up from a randomized phase 3 trial (DASISION). February 2012;119:1123-1129.

Summary and Conclusions: The results reported here suggest that the efficacy profiles of dasatinib vs. imatinib in LA patients are similar to those seen in the analysis of all patients worldwide. Exploratory comparisons of efficacy in LA patients of dasatinib vs. imatinib arms yielded similar trends as observed in all patients, having numerically higher rates of cumulative long-term response rate values of cCCyR and MMR in dasatinib treatment Group. Both treatment groups also experienced high rate values of PFS and OS after a 3-year follow-up. Since small sample size in LA limits the strength of conclusions for efficacy and safety, further exploration is needed to confirm any potential differences compared with the total treated population in order to increase accuracy.

E1120

THE EFFICACY AND SAFETY OF GENERIC IMATINIB IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) AFTER SWITCHING FROM GLIVEC: UPDATED DATA FROM CERRAHPAŞA CML COHORT

T. Soysal[1], A.E. Eskazan[1,*] S. Sadri[1], I. Erdogan[1], S. Berk[1], F.F. Yalniz[1], T. Elverdi[1], A. Salihoglu[1], M.C. Ar[1], S. Ongoren Aydin[1], Z. Baslar[1], N. Tuzuner[2], U. Ozbek[3], Y. Aydin[1]

Background: Imatinib is the standart of care in patients with chronic myeloid leukemia (CML). Generic imatinib (GI) has been approved in the treatment of CML in many countries including Turkey. We previously published our experience regarding the efficacy and safety of GI in patients with CML who started tyrosine kinase inhibitor (TKI) treatment with original imatinib (OI) [Glivec] but then had to switch to GI due to reimbursement policy [Eskazan AE, *et al.* Leuk Lymphoma. 2014;55:2935-7]. Among our patient cohort, the efficacy and safety of GI were comparable to those of OI. However the median duration of GI exposure in that study was 12 months, shorter than the OI treatment duration prior to switching.
Aims: The aim of this study was to update the efficacy and safety data of GI among our chronic phase CML (CML-CP) patient cohort when used sequentially after OI treatment with an extended follow-up.
Methods: Our study cohort consisted of one hundred and forty-five patients with CML-CP who were followed under OI with a median of 55 months (Figure 1). Patients on OI first switched to GI due to reimbursement policy after August 2012, and 80 patients switched to GI whereas sixty preferred to receive OI and pay the price difference from their own pockets. After a median follow-up of 12 months, the data was first analyzed in October 2013, and the generics were found to be at least non-inferior to the OI regarding efficacy and tolerability when used subsequently [Eskazan AE, *et al.* Leuk Lymphoma. 2014;55:2935-7]. We updated the data of this study after an additional follow-up of 16 months in February 2015.
Results: Since the first analysis, 74 patients received GI with a median duration of 15.5 months, and there were four patients who switched to 2nd generation TKIs (2GTKIs) due to resistance and 4 patients were lost to follow-up. The median of GI exposure in these patients after the first switch was 27 months (range, 6-32 months). In the OI group, 60 patients received Glivec with a median of 61 months and 13 months after the first switch and the first analysis, respectively. There were 3 patients who switched to 2GTKIs (2 due to resistance, one due to grade IV hepatitis), one patient was lost to follow-up, and one patient quit OI due to a planned pregnancy. Twenty-seven patients receiving OI switched to GI during the follow-up after a median of 10 months, and at the time of the analysis, the study cohort consisted of 121 patients of which 28 were still on OI whereas ninety-three were receiving GI. All of these 121 patients had durable major molecular respose (MMR), and none of the 27 patients who switched from OI to GI lost their responses during the follow-up. There were no imatinib dose reductions due to toxicities in both arms, and 4 patients had non-hematological adverse events (AEs) (myalgia in 3 and gastrointestinal in one) in the GI group whereas in the OI group there were 3 patients (myalgia in 2 and one patient had both myalgia and hepatitis) with non-hematological AEs. Among the twenty-seven patients who switched from OI to GI, two had grade I myalgia after the switch.

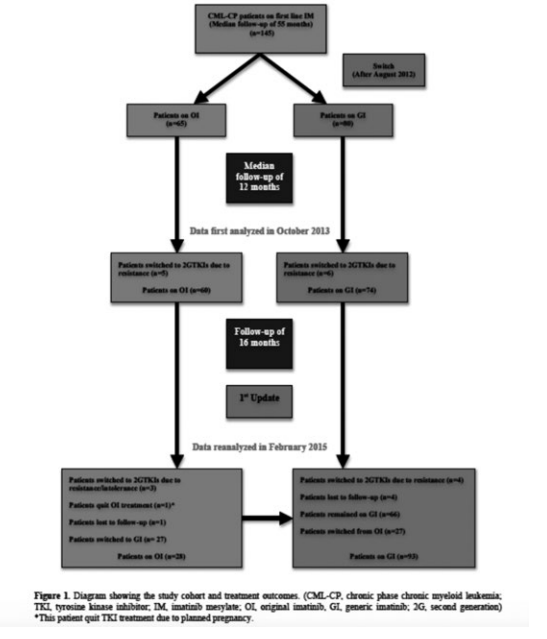

Figure 1. Diagram showing the study cohort and treatment outcomes. (CML-CP, chronic phase chronic myeloid leukemia; TKI, tyrosine kinase inhibitor; IM, imatinib mesylate; OI, original imatinib; GI, generic imatinib; 2G, second generation) *This patient quit TKI treatment due to planned pregnancy.

Figure 1.

Summary and Conclusions: With an extended follow-up, generics were still found to be comparable to Glivec regarding both efficacy and safety when used subsequently.

GENERIC IMATINIB IN NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA (CML) PATIENTS IN CHRONIC PHASE: UPDATED DATA FROM A TURKISH CML COHORT

A.E. Eskazan[1,*] M. Ayer[2], B. Kantarcioglu[3], N. Demirel[3], D. Aydin[3], F. Aydinli[4], O. Yokus[4], S. Sadri[1], I. Erdogan[1], S. Berk[1], F.F. Yalniz[1], T. Elverdi[1], A. Salihoglu[1], M.C. Ar[1], S. Ongoren Aydin[1], Z. Baslar[1], Y. Aydin[1], N. Tuzuner[5], U. Ozbek[6], T. Soysal[1]
[1]Department of Internal Medicine, Division of Hematology, Istanbul University Cerrahpasa Faculty of Medicine, [2]Department of Hematology, Haseki Training and Research Hospital, [3]Department of Hematology, Okmeydani Training and Research Hospital, [4]Department of Hematology, Istanbul Training and Research Hospital, [5]Department of Pathology, Istanbul University Cerrahpasa Faculty of Medicine, [6]Department of Genetics, Istanbul University, Institute of Experimental Medicine (DETAE), Istanbul, Turkey

Background: Generic imatinib (GI) has been approved in the treatment of patients with chronic myeloid leukemia (CML)in many countries including Turkey. Since there were limited data and some concerns about the efficacy of

generics, we previously published our experience regarding the efficacy and safety of GI when used in the up-front setting [Eskazan AE, *et al.* Br J Haematol. 2014;167:139-41]. Although the duration of GI exposure in this study was relatively short, the efficacy and safety of GI were at least non-inferior to those of original imatinib (OI) [Glivec].

Aims: The aim of this study was to update the efficacy and safety data of GI among our chronic phase CML (CML-CP) patient cohort in the frontline setting with a prolonged follow-up.

Methods: We first analyzed the data of CML-CP patients who received up-front Glivec and GI in February 2014 [Eskazan AE, *et al.* Br J Haematol. 2014;167:139-41] (Figure 1). There were 36 patients who started the tyrosine kinase inhibitor (TKI) treatment had with OI, and twenty-six with GI. After median follow-up of 8.5 months and 20 months of GI and OI, respectively, we did not find significant difference regarding efficacy and AEs between these 2 groups. During the follow-up, 8 patients switched from OI to GI due to reimbursement policy. We wanted to update the data of the initial cohort with an additional follow-up of 12 months, and we also recruited new patients to the study.

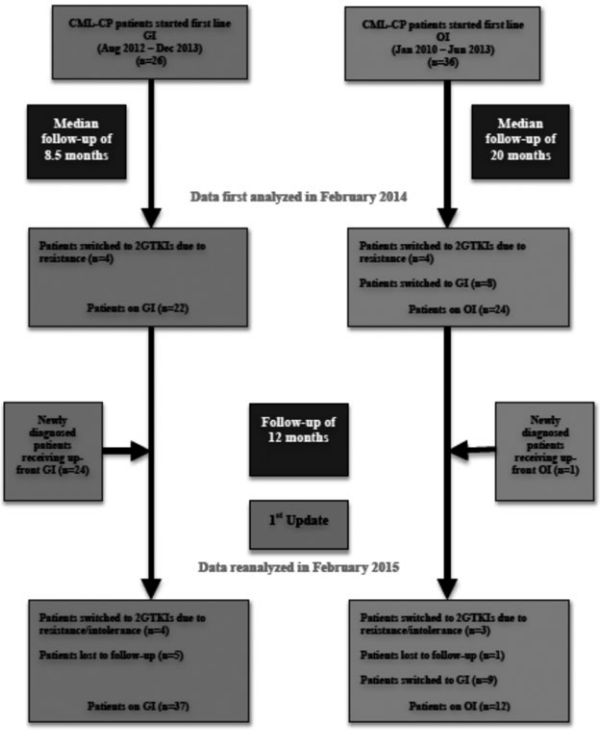

Figure 1. Diagram showing the study cohort and treatment outcomes. (CML-CP, chronic phase chronic myeloid leu TKI, tyrosine kinase inhibitor; IM, imatinib mesylate; OI, original imatinib, GI, generic imatinib; 2G, second generation

Figure 1.

Results: During the follow-up, 24 newly diagnosed patients were recruited in the GI group whereas one patient started receiving OI (Figure 1). Nine patients from the OI group switched to GI group due to reimbursement policy after a median follow up of 24 months (range, 11-45 months). They were all in major molecular response (MMR) at the time of the switch, and after a median of 7 months (range, 3-15 months) of GI expose, they all maintained their responses. In the GI group, 20 patients from the initial analysis were still receiving GI after a median of 20 months (range, 10-28 months), of which 15 had MMR, 4 had complete cytogenetic response (CCyR), and one had partial CyR. Among the 24 newly diagnosed patients receiving GI, sixteen (67%) were male, and the median age was 55 years. Low, intermediate and high Sokal risk score rates were 47%, 47% and 6%, respectively. The median duration of GI treatment was 8 months (range, 2-28). There were 11 patients with a follow-up of ≤6 months of which ten had complete hematologic response (CHR). Among the 8 patients with a follow-up of >6 and <12 months, 5 had CCyR and three had MMR. Five patients had a follow-up duration of ≥12 months (median, 22 months), and all of them were in MMR. During the follow-up, patients who needed to be switched to 2nd generation TKIs (2GTKIs) due to resistance in the GI and OI groups were 3 and two, respectively. When the two groups were compared regarding AEs, in the OI group the most common non-hematologic AEs (all grades) were myalgia (n=8) and peripheral edema (n=4). The most common hematologic AEs were thrombocytopenia (n=4) and neutropenia (n=1) observed among patients in the OI group. In the GI group, the most common non-hematologic AEs were peripheral edema (n=6), myalgia (n=5) and skin reactions (n=3). The most common hematologic AEs in the GI group were thrombocytopenia (n=3) and neutropenia (n=3). There was a patient in the GI group who was switched to a 2GTKI due to grade III skin reaction. Also one patient from the OI group switched to 2GTKI due to grade IV hepatitis. There were 5 patients in the GI group who were lost to follow-up, and one patient was lost to follow-up in the OI group. At the time of the analysis, after a median follow-up of 16 months (range, 3-28 months), there were 37 patients who were on up-front GI. Twelve patients who were still on frontline OI after a median follow-up of 31 months (range, 19-55 months) were all in MMR.

Summary and Conclusions: GI was still non-inferior to OI regarding efficacy and tolerability when used in the up-front setting among patients with CML-CP with an extended follow-up.

E1122

ANALYSIS OF THE RELATIONSHIP BETWEEN DOSE AND BCR-ABL HALVING TIME IN CP-CML PATIENTS TREATED WITH PONATINIB OR IMATINIB

J. Pritchard[1,*] S. Lustgarten[1], J.G. Hodgson[1], M. Baccarani[2], J.E. Cortes[3], M.W. Deininger[4], F. Guilhot[5], T.P. Hughes[6], N.P. Shah[7], M. Talpaz[8], M.C. Mueller[9], T. Clackson[1], F.G. Haluska[1], R. Knickerbocker[1], V.M. Rivera[1]
[1]ARIAD Pharmaceuticals, Inc., Cambridge, United States, [2]University of Bologna, Bologna, Italy, [3]The University of Texas MD Anderson Cancer Center, Houston, [4]Huntsman Cancer Institute, The University of Utah School of Medicine, Salt Lake City, United States, [5]CHU La Miletrie, Poitiers, France, [6]Centre for Cancer Biology, University of Adelaide, Adelaide, Australia, [7]University of California San Francisco, San Francisco, [8]University of Michigan, Ann Arbor, United States, [9]Universitätsmedizin Mannheim III. Med. Klinik, Mannheim, Germany

Background: Ponatinib is a potent pan-BCR-ABL tyrosine kinase inhibitor (TKI). The phase 2 PACE study demonstrated that ponatinib is highly active in heavily pretreated CP-CML patients, 58% of whom received ≥3 prior TKIs. Preliminary evidence in the phase 3 EPIC study suggests that ponatinib has improved efficacy over imatinib in newly diagnosed CP-CML, but with a higher rate of arterial occlusive events at the doses studied. Fixed starting doses of ponatinib (45 mg qd) and imatinib (400 mg qd) were used in these studies, but the allowance for treatment interruptions and dose reductions, coupled with frequent assessment of *BCR-ABL* levels, enabled high-resolution analysis of dose-response relationships.

Aims: To inform design of trials to optimize ponatinib dose, here we use a novel approach, BARD (*BCR-ABL* Response-Dose association), to evaluate associations between ponatinib dose and changes in *BCR-ABL* levels across different lines of therapy.

Methods: *BCR-ABL* transcript levels were measured every 1-3 months in blood samples from CP-CML patients in the PACE (N=267) and EPIC (N=154 [ponatinib] and 152 [imatinib]) studies, which had median follow-ups of 34.2 and 5.1 months, respectively. The change in *BCR-ABL* levels (expressed as 1/doubling time [1/DT]) and average daily dose (based on patient daily dosing records) were calculated for every measurement interval (window). 1/DT values were analyzed for differences by t-test. An exponential growth/decay model was used to transform the average 1/DT values, to *BCR-ABL* halving times. We performed a series of analyses to demonstrate that including *BCR-ABL/ABL* transcript values >10% IS does not strongly affect our conclusions; we will present additional data using GUS to normalize the data.

Results: In newly diagnosed patients (EPIC), across all dose levels, BARD analysis showed that *BCR-ABL* halving times induced by ponatinib and imatinib were 13.8±1.2 and 27.1±2.4 days, respectively, consistent with the more rapid molecular responses observed in the ponatinib arm. Within windows that included only continuous dosing at starting dose levels, *BCR-ABL* halving times were significantly more rapid with 45 mg ponatinib than 400 mg imatinib ($p<0.0001$) (Table). Moreover, compared with 400 mg imatinib, *BCR-ABL* halving times were also more rapid when average ponatinib dose levels were <15 mg ($p>0.05$), 15 to <30 mg ($p<0.02$), and 30 to <45 mg ($p<0.0001$) (Table). In heavily pretreated patients (PACE), across a similar timeframe as EPIC, increased doses of ponatinib were also associated with a trend towards more rapid decreases in *BCR-ABL* levels, although the rate of decrease induced by 45 mg ponatinib (halving time 28.1±4.8 days) was reduced compared with that observed in newly diagnosed patients. Importantly, across the entire PACE study, average daily doses of ponatinib as low as 10 mg were associated with net decreases in *BCR-ABL* levels.

Table 1.

Table. *BCR-ABL* Response Dose Association (BARD) from EPIC

Drug	Dose range (mg)	Windows* (N)	*BCR-ABL* halving time (Days)
Ponatinib	<15	40	20.0 ±6.9
	15 to <30	60	16.6 ±3.4
	30 to <45	136	14.3 ±2.1
	45	184	12.0 ±1.3
Imatinib	400	374	24.9 ±2.3

*Number of *BCR-ABL* measurement intervals when average dose was within the indicated range

Summary and Conclusions: In newly diagnosed patients, ponatinib doses as low as 15 mg induced more rapid decreases in *BCR-ABL* levels than 400 mg imatinib. The magnitude of *BCR-ABL* decreases induced by ponatinib in heavily pretreated patients was reduced compared with newly diagnosed

patients; nonetheless, ponatinib doses as low as 10 mg were still associated with disease control overall. These analyses have helped inform the design of studies aimed at optimizing the benefit/risk of ponatinib treatment for patients with CML.

Gene therapy, cellular immunotherapy and vaccination

IL-10/IL-17 DOUBLE-PRODUCING T CELLS: NEW IMMUNOSUPPRESSIVE INSIGHT IN ACUTE MYELOID LEUKEMIA

S. Carloni[1,*] S. De Matteis[1], R. Napolitano[1], C. Papayannidis[2], V. Guadagnuolo[2], A. Lucchesi[3], P. Mariotti[2], G. Martinelli[2], G. Musuraca[3]
[1]Preclinical Hematolgy, IRCCS IRST (Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori), Meldola (FC), [2]Hematology and Oncological Sciences, L. and A. Seràgnoli, Bologna, [3]Hematology Unit, IRCCS IRST (Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori), Meldola (FC), Italy

Background: Acute myeloid leukemia (AML) is the most common form of acute leukemia in adults and current treatments remain unsatisfactory. Serious infections, resistance to therapy and relapses are the main causes of mortality among these patients. The high frequency and severity of infections, even before or during any chemotherapy, are probably due to a deep dysfunction of adaptive immunity directly induced by the disease. T helper 17 cells (Th17) play a key part in inflammatory response and autoimmune diseases, reducing or promoting tumor growth and protecting against bacterial and fungal pathogens. However, the role of Th17 cells in AML has not yet been clarified.
Aims: In our study we examine the relationship between Th17 cells, leukemic cells, infections and immunocompetence.
Methods: After obtaining the patient's informed consent, peripheral blood was collected from 30 newly diagnosed AML patients without infections and from 30 age-matched healthy volunteers (HV). Mononuclear cells (PBMCs) were separated by density gradient centrifugation and CD4+cells isolated by negative immunomagnetic depletion. Cells were cultured in complete medium, primed for 24 h with IL-6 and for 5 h with PMA and ionomycin. An unstimulated control was included for each experiment. After stimulation, cells were fixed, permeabilized and immunophenotyped for intracellular IFN-γ, IL-4 and IL-17A expression using the human TH1/TH2/TH17 phenotyping kit. For Treg analysis, naïve PBMCs were stained with anti-CD4 FITC, anti-CD25 APC-Cy7 and then fixed, permeabilized and stained with anti-FoxP3 APC. Appropriate isotype controls were included for each sample. For cytokine secretion analysis, stimulated CD4+cells were analyzed using human IL-17 and IL-10 secretion assay-detection kits. For co-culture assays, leukemic CD33+blast cells magnetically isolated from patients and allogeneic CD4+cells obtained from HV were co-seeded in 1:1, 1:5 and 1:10 ratios and stimulated as previously described. At the end of stimulation, T cell immunophenotypic and cytokine secretion analysis were performed. Naïve CD4+cells were also stimulated for 24 h with *C. Albicans* peptides, then depleted of IL-17-secreting cells and cultured for a further 24 h in complete medium supplemented with *C. Albicans* peptides. T cells were then analyzed for intracellular IFN-γ expression using the human TH1/TH2/TH17 phenotyping kit. A sample stimulated with *C. Albicans* for 48 h without depletion of IL-17-secreting cells was added as control.
Results: In AML patients, compared to HV, we observed a strong increase in Th17 cells that simultaneously released immunosuppressive IL-10, together with a reduced frequency in Th1 and Th2 cells. Through the culture of AML-derived CD4+cells with an infectious antigen (*C. Albicans*), we demonstrated that Th17 cells selectively determined an immunosuppressive state, in terms of a reduction in IFN-g production (Figure A). Moreover, all the changes observed in T cells, and in particular in Th17 cells, were induced *in vitro* by CD33+leukemic cells, as observed after co-cultures of healthy CD4+cells and AML peripheral blasts (Figure B) and confirmed by restoration of the healthy cytokine pattern after purification of patient T cells from CD33+cells.

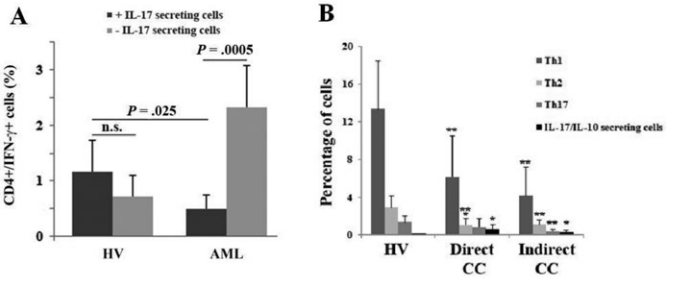

Figure 1.

Summary and Conclusions: Our results show that altered Th17 cells actively cause an immunosuppressive state in AML patients that may, considering the long life of these cells, persist long enough to promote infections and probably tumor escape. Th17 cells could thus represent a new target to improve AML immunotherapy.

E1124

HUMAN MEMORY-LIKE NATURAL KILLER CELLS ABLE TO KILL NEOPLASTIC CELLS AS A TOOL FOR A NOVEL APPROACH OF ANTI-TUMOR CELL THERAPY

M. Tanzi[1] F. Ferulli[1], I. Airoldi[2], I. Turin[1], E. Montini[1], A. Zorzoli[2], T. Mina[3], L. Rubert[3], M. Zecca[3], R. Maccario[4], D. Montagna[5,*]
[1]Laboratorio Immunologia e Trapianti, Fondazione IRCCS Pol San Matteo, Pavia, [2]Laboratorio Oncologia, Istituto Giannina Gaslini, Genova, [3]Unità di Onco-Ematologia Pediatrica, [4]Laboratorio Immunologia e Trapianti, Cell Factory, Fondazione IRCCS Pol San Matteo, [5]Laboratorio Immunologia e Trapianti, Fondazione IRCCS Pol San Matteo, Università di Pavia, Pavia, Italy

Background: Several strategies have been under investigation for enhancing antitumor activity in patients affected by a high risk solid or hematological malignancies. The poor prognosis of these patients and the need to sustain antitumor surveillance early after HSCT prompted the development of immune-based therapies including the use of natural killer (NK). Currently, strategies to prepare NK cell products include stimulation with IL-2 or other cytokines without any pre-activation. The efficacy of these approaches is restricted by short-term persistence and limited survival and effector function after adoptive transfer of the NK cells into a patient. Recent studies in mice have shown that *in vitro* activation with appropriate cytokines result in differentiation of long-lived NK lymphocytes with memory-like properties.
Aims: Aim of this study was to investigate optimal culture conditions to induce human memory-like NK cells both in autologous and allogeneic setting and to analyze their lytic capacity against tumor cells (TC) or leukemia blasts (LB) derived from onco-hematological patients.
Methods: The optimal culture conditions for *ex vivo* activation of human memory-like NK cells were established in allogeneic setting in 10 donors/recipients pairs, using NK cells derived from HSCT donors and tested against leukemia blasts (LB) derived from transplanted patients affected by acute myeloid or lymphatic leukemia. For induction of *memory like* NK cells, NK cells isolated from mononuclear cells of HSCT-donor by NK cell isolation Kit (Miltenyi Biotec) were pre-activated for 16 hours with different concentrations of IL-12/IL-15/IL-18, maintained in culture 7-10 days with IL-2 or IL-15 and then further activate or not prior cryopreservation and evaluation of cytotoxic activity. NK cells were alternatively activated overnight (ON) with IL-2 (control NK). During the various phases and at the end of culture cell recovery, NK receptors and anti-tumor cytotoxic activity of memory-like and control NK cells, were evaluated.
Results: Donor-derived NK *memory like* displayed high levels of cytotoxic activity against patients LB (mean: 53.7%, range 26-82 at effector:target ratio of 30:1), while the levels of lysis against patients' non malignant cells was always less than 10% at E:T ratio of 30:1. Interestingly, this approach of activation with IL-12/IL-15/IL-18 makes NK cells endowed of high levels of anti-tumor cytotoxic activity when compared with control NK cells activated ON with IL-2 alone (mean 25%, range 12-33 at E:T ratio of 30:1). A surface marker phenotype specific to memory-like NK cells has not yet been clearly identified in mice, while in humans few studies have established some correlation between surface phenotype of human NK-memory like and IFN-gamma production. In agreement with these studies we confirmed that human cytokine induced memory-like NK cells demonstrated increased expression of CD94, NKG2A, NKp46 and CD69 compared with control NK cells from the same donor. Preliminary experiments in murine model, obtained after transfer of *memory like* and control NK cells derived from two different HSCT donors, suggested that *memory like* NK cells persisted longer in the mice compared with control NK cells. However, these data have to be confirmed in a larger number of experiments, together with the ability of the transferred cells to maintain their anti-tumor activity. Further experiments are in progress to determine the possibility of *in vitro* inducing *memory like* NK cells, able to efficiently kill TC, in autologous setting, starting from NK cells isolated from patients affected by solid tumors.
Summary and Conclusions: In the present study, we identified human NK cells that exhibit enhanced anti-tumor cytotoxic activity after short-term pre-activation with IL-12/IL-15/IL-18, followed by 7-10 days of *in vitro* culture with IL-2 or IL-15 as compared with control NK cells. After confirmation that these cells can persist and maintain their effector functions *in vivo* in both autologous and allogeneic settings, this approach could be translated into future clinical trials of adoptive NK cell therapy for cancer patients.

E1125

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: REVIEW OF 28 CASES

L. Guerrero Fernández[1,*] D. Sánchez Argüello[1], D. Martínez Carballeira[2], C. Fernández Canal[1], C.V. Antuña Santurio[1], C. De Brabandere[1], A. Fernández González[1], R. Fernández Alvarez[1], C. Miguel Ruiz[3]
[1]Hematology, Hospital de Cabueñes, Gijon, [2]Hematology, Hospital Universitario Central de Asturias, Oviedo, [3]Pathology, Hospital de Cabueñes, Gijon, Spain

Background: Hemophagocytic syndrome (HLH) is characterized by prolonged and excessive activation of antigen-presenting cells (macrophages, histiocytes) and $CD8^+$T cells. This generates a severe hyperinflammatory condition and organ damage including fever, cytopenia, splenomegaly, coagulophaty and/or hypertrigliceridemia. HLH includes two different conditions: primary (or genetic HLH) and secondary (or adquired), caused by infections, malignancy or autoimmune disorders. Histiocyte Society criteria have been widely used for diagnosing HLH, however not all of them are usually present at the initial presentation. HLH is a life-threatening disease which must be suspected and treated as early as possible.
Aims: HLH is a rare and often fatal disease. Its incidence and main form of presentation are not yet well known. This study aimed to evaluated the etiology, clinical features and prognosis of HLH in our community.
Methods: A retrospective analysis was conducted through the medical files of all patients with diagnosis of HLH between 2004 and 2014 in two different hospitals. Clinical features, age, diagnostic criteria proposed by the Histiocyte Society, etiology, treatment and evolution were analyzed. In our study 7 out of 28 patients did not meet the requested criteria due to the rapidly fatal evolution of the disease.
Results: A total of 28 patients with a median age of 46.5 years were identified (0,2 – 84 years), 19 male and 9 female (ratio 2.1/1). 12 were infection associated forms, 7 malignancy related, 5 due to autoimmune diseases and 4 were of unknown etiology. Only secondary forms were analyzed. On the 21 patients who met the diagnostic criteria, the clinical manifestations were fever (100%), splenomegaly (66.6%), adenopathies (61.9%), ictericia (28.5%), edema (28.5%) and neurological manifestations (19%). The laboratory findings were hyperferritinemia (100%), cytopenias affecting two or more lines (90.5%), hypertriglyceridemia (66.6%), liver enzyme alteration (52.4%), hypofibrinogenemia (47.6%), coagulopathy (38%), hypoproteinemia (38%), and hyponatremia (28.5%). Hemophagocytosis was observed in 19 cases in bone marrow, only 1 case in the liver. The activity of natural killer lymphocytes was measured in 9 cases, and it was reduced in 5. Comparing the treatment regimens, 13 were treated according to protocol HLH-04, in 8 of the underlying disease, a supportive treatment was given to 7. The mortality due to HLH complications was 38% (8 patients), for non related complications 4.7% (3 patients). 52% experienced full recovery (11 patients).

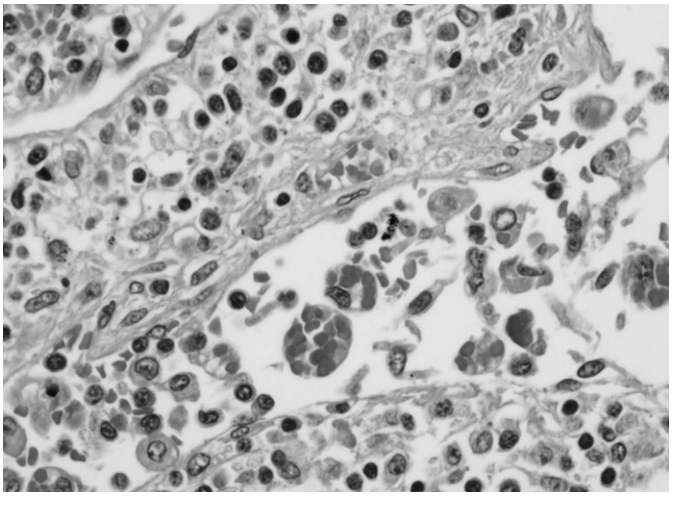

Figure 1.

Summary and Conclusions: The incidence of HLH in our population can be estimated between 2,1 and 2,8 cases /million. The majority were male (ratio 2.1/1). No primary forms were found in this analysis. The most common trigger was infection which is consistent with the studies found in the literature. Outstanding clinical manifestation were persistent fever and splenomegaly. Laboratory data indicated that the most prevalent abnormality were hyperferritinemia and cytopenia. The most used treatment regimen protocol was HLH-04 which obtained acceptable tolerance and results.

E1126

HLA-PARTIALLY MATCHED CELLULAR THERAPY (STEM-CELL MICROTRASPLANTATION) IN ACUTE MYELOID LEUKEMIA AND MYELODISPLASTIC SYNDROMES

M.E. Martinez-Muñoz[1,*] R. Fores[1], C. Regidor[1], J.L. Bueno[1], Y. Gutierrez[1], M. Garcia[1], G. Bautista[1], A. de Laiglesia[1], N. Dorado[1], J. Garcia-Marco[1], E. Ojeda[1], A. Morales[1], G. Anze[1], C. Vilches[1], R. de Pablo[1], R. Cabrera[1]
[1]Hospital Universitario Puerta de Hierro Majadahonda (Madrid), Majadahonda, Spain

Background: Non-engraftment alloreactive cellular therapy has been proposed as a treatment for acute myeloid leukaemia (AML). A host-*versus*-tumour effect induced by graft-rejection has been suggested.

Aims: To evaluate feasibility and safety of the microtransplantation in AML and myelodisplastic syndrome (MDS) and estimate response rate, infections incidence and the development of GVHD and alloreactivity.
Methods: We have performed 25 HLA-partially matched donor leukocyte infusions (PM-DLI) infusions in 9 elderly patients (64-72 years old) with AML (6), CMML (2) or RAEB (1) from 11 partially mismatched donors (9 haploidentical). One or two apheresis of related donor peripheral mononuclear cells were collected after G-CSF mobilization. The median number of MNC, CD34+, CD3+and NK cells infused per course were: $3.16x10^8$/kg (range 1.37-$5.51x10^8$/kg), $3.29x10^6$/kg (range1.42-$6.58x10^6$/kg), $1.15x10^8$/kg (range 0.35-$2.42x10^8$/kg), $0.94x10^7$/kg (range 0.50-$1.55x10^7$/kg), respectively. Patients received each PM-DLI following a conventional chemotherapy cycle (IA, HDAC, MEC) or hypomethylant agent course. All patients except one received at least two PM-DLI in each microtransplant. Expected NK cell alloreactivity, chimerism and minimal residual disease were analyzed.
Results: The procedure was well tolerated, with a mild and transient "haploimmunostorm syndrome" (fever, rash, diarrhea). Only the two patients with CMML received corticosteroid. One patient suffered from early infusional reaction that was resolved with support treatment. None of the patients showed acute or chronic graft-versus-host disease (GVHD) or donor engraftment in chimerism tests. No significant infections were observed. All AML/RAEB patients achieved complete remission (CR). Four patients relapsed at 7, 9, 10 and 15 months after the infusion; two of them achieved a second sustained complete remission with another PM-DLI from a different donor (one of them had developed anti-HLA antibodies). Currently, with a median follow-up of 11 months (range 1-25 months), six patients are alive and three died (one with CMML during the induction treatment and two due to leukemia progression).
Summary and Conclusions: Microtransplantation is a well tolerated procedure, infectious complications are insignificant and the remission rates are encouraging, in the absence of engraftment or GVHD. Patients can undergo a second microtransplantation from a different donor. Leukocyte infusions can be safely administered following a hypomethylant agent course instead of conventional chemotherapy. Despite of the promising results, larger patient cohorts are necessary to assess the efficacy of this novel therapeutic strategy for hematologic malignancies.

UNTOUCHED GMP-GRADE PURIFIED ENGINEERED IMMUNE CELLS

T. Straetemans[1], C. Grunder[1], S. Heijhuurs[1], S. Hol[1], I. Slaper-Cortenbach[2], H. Bonig[3], Z. Sebestyen[1], J. Kuball[1,*]
[1]Hematology / Laboratory of Translational Immunology, [2]Cell Therapy Facility, University Medical Center Utrecht, Utrecht, Netherlands, [3]Institute for Transfusion Medicine and Immunohematology, Johann-Wolfgang-Goethe University, Frankfurt, Germany

Background: Engineering T cells with receptors to re-direct the immune system against cancer has most recently been described as one of the scientific breakthroughs. However, a main challenge remains the GMP-grade purification of immune cells selectively expressing the introduced receptor in order to reduce potential side effects due to poorly or non-engineered immune cells.
Aims: By taking advantage of a model γδT cell receptor (TCR) naturally interfering with endogenous TCR expression we aimed to develop a GMP-grade method to obtain pure but untouched receptor engineered immune cells.
Methods: We designed the optimal retroviral expression cassette to achieve maximal interference with endogenous TCR chains. Following retroviral transduction, non-and poorly engineered immune cells were efficiently depleted with GMP-grade anti-αβTCR-beads. Next, the engineered immune cells were validated for TCR expression, function and potential allo-reactivity *in vitro* against a panel of tumor cell lines and primary tumors and in two humanized mouse models.
Results: The untouched enrichment of engineered immune cells translated into highly purified receptor engineered cells with strong anti-tumor reactivity both *in vitro* but also *in vivo* in two humanized mouse models. Importantly, this approach also eliminated residual allo-reactivity of engineered immune cells. Our data demonstrate that even with long-term suboptimal interference with endogenous TCR chains such as in resting cells, allo-reactivity remained absent and tumor control preserved.
Summary and Conclusions: All together, we present a novel GMP-grade enrichment method of untouched engineered immune cells, which is potentially applicable to all receptor-modified cells even if interference with endogenous TCR chains is far from complete.

E1129

EFFICIENT AND STABLE GENE TRANSFER INTO MESENCHYMAL STEM CELLS

A. Bigildeev[1,*] N. Sats[1], I. Shipounova[1], N. Petinati[1], V. Surin[2], K. Cornils[3], T. Aranyossy[3], B. Fehse[3], N. Drize[1]
[1]lab. physiology of hematopoiesis, [2]lab. genetic engineering, National Research Center for Hematology, Moscow, Russian Federation, [3]Research Dept. Cell and Gene Therapy, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Mesenchymal stem cells (MSC) are attractive tool for gene therapy due to their intrinsic properties. These cells produce long-living progeny, differentiate into all mesenchymal lineages, and are easy to manipulate *ex vivo*. Lentivectors have been shown to facilitate efficient transduction of rarely proliferating cells.
Aims: The aim of this study was to evaluate the efficiency and stability of MSC and progenitor-cell transduction by lentivectors *in vitro* and *in vivo*.
Methods: For in-vitro gene transfer, murine Dexter type long-term bone marrow cultures (LTBMC) were infected 2 weeks after initiation by either a standard LeGO-G2 vector (encoding eGFP gene under SFFV promoter) or a modified, promoter-deprived vector (LeGO-G2pd) that was in some experiments barcoded. The frequency of colony-forming unit fibroblast (CFU-F) was analyzed in adherent cell layers (ACL) of LTBMC 2 weeks after infection. ACL were trypsinized, and 500 cells/well were seeded in 96-well plates in aMEM with 20% FBS and 5 ng/ml bFGF. Infected LTBMC from each group were implanted under the renal capsules of syngeneic recipients for the hematopoietic ectopic foci formation. DNA was isolated from ACL, CFU-F, the inner cell mass of the foci and the corresponding bone shells. The percent of marked samples was assessed by PCR. For in-vivo gene transfer mice were injected with lentivirus intrafemorally. The percent of marked ACL, CFU-F and foci formed was calculated 2-6 months after injection of lentivirus.
Results: Results are shown in Table. The percentage of cells in ACL marked by lentivirus with eGFP expression was 17.6±5.9. About 25% of CFU-F from those ACL were eGFP positive. Over half of all ectopic foci and corresponding bone shells but only 5% of CFU-F from those foci were eGFP positive. Unlike in LTBMC no eGFP fluorescence was detected in ectopic foci and CFU-F derived from them. eGFP containing samples were revealed only by PCR. It has been suggested that eGFP itself is immunogenic *in vivo* and CFU-F expressing eGFP are eliminated by immune system of the recipients. So SFFV promoter was deleted from the vector and LTBMC were infected with viruses lacking eGFP expression. All bone shells developed from these implanted LTBMC were marked. The abrogation of eGFP expression led to the increase of marked CFU-F percentage within the ectopic foci up to 55%. The infection of LTBMC with barcoded library provided the information of individually marked CFU-F from infected ACL. Ectopic foci obtained from the infected LTBMC were also marked. As ectopic foci are formed only by true MSC able to self-renew the presence of foreign gene in the foci and CFU-F derived from them indicates the possibility to transfer the genes of interest into MSC. It is important for the gene not to be immunogenic. *in vivo* infection of MSC and CFU-F with vector w/o SFFV promoter was effective as over half of LTBMC and ectopic foci carried foreign gene.

Table 1.

Lentivector/method of infection	Percent of marked ACL	Percent of marked CFU-F from ACL	Percent of ectopic foci with marked bone shells	Percent of ectopic foci with marked cells	Percent of marked CFU-F in ectopic foci
eGFP/LTBMC infection	100	26.9±5.9	59.3±12.2	50.9±18.5	5.4±1.3
eGFP without promoter/LTBMC infection	100	4.0±1.8	100	33	55±5.6
eGFP without promoter/in vivo injection	55.7±24.1	4.3±1.4	57	14	6.4±1.8
Bar code/ LTBMC infection	100	60.9±5.2	75	74	0

Summary and Conclusions: Our data suggest that MSC and stromal precursor cells can be effectively and stably transduced *in vitro* and *in vivo* by lentivectors. The genes of interest should not be immunogenic. Thus MSC can be used as a reliable delivery system in gene therapy settings.

IDENTIFICATION OF PREDICTIVE MARKERS OF IMMUNO-SENESCENCE WITH FOCUS ON TUMOR SUPPRESSIVE GENES: HEALTHY DONORS VERSUS PATIENTS DIAGNOSED WITH A LYMPHOPROLIFERATIVE DISEASE

L. Dang[1], K. Willard-Gallo[2], H. Duvillier[1], J.N. Lodewyckx[1], S. Garaud[1], C. Gu[1], S. Catherine[3], D. Bron[1,*]
[1]Hematology, [2]Molecular Immunology, [3]Anatomo-pathology, Institut Jules Bordet (ULB), Bruxelles, Belgium

Background: Aging is associated with the functional alteration of multiple organs including our immune system, thus affecting immune surveillance that prevent the development of cancer. This is illustrated by the high median age of most of the malignant hemopathies (MDS: 75y, AML: 70y, MM: 70y, NHL: 67y, CLL: 72y). In addition, aging is affecting other mechanisms of natural protection against cancer, resulting in poor DNA repair, telomere shortening, chromosomal instability, altered intercellular communication, senescent environment and loss in apoptosis-regulating genes. However, little is known in terms of genetic or epigenetic modifications of tumor suppressive genes (TSG) in lymphocytes subsets.
Aims: 1.To identify predictive markers of immuno-senescence in T/B and NK lymphocytes subsets, in a population of elderly patients with or without lymphoproliferative diseases (LPD): 2.To study tumor suppressor genes expression

in lymphocytes subsets, according to age and diseases; 3.To Study the impact of these factors on therapeutic responses and overall survival.
Methods: Healthy donors belonging to different ages groups and patients with lymphoproliferative diseases (LPD) are recruited for immune status evaluation after signed informed consent forms accepted by our ERB. Lymphocytes subsets were analysed by flow cytometry (CD4, CD4RA, CD4RO, CD4/CD25/FOXP3, CD8, CD19, CD16, CD56, CD197, CD27) before any treatment. Each lymphocytes subset was isolated by the MASC isolation technology for further molecular investigations. Tumor suppressor genes (TP53, PRDM1 and others) were quantified by RT-PCR on each purified lymphocytes subset.
Results: 21 healthy donors and 17 LPD (CLL and NHL) are currently prospectively investigated and stratified according to ages and diseases. Absolute lymphocytes count was not significantly different among the different groups. In terms of innate immunity, we found a significant lower number of NK celles (CD56+) betwenn younger (<50y) and older (p=0 ,002) and between healthy donors and patients (p=0,001). The functional tests are still on going. The CD4+/CD8+T cells ratio was significantly increased in older patients (p=0,008). Among CD4+T cells, CD4 memory and particularly T cenral memory lymphocytes were significantly increased. CD3-/CD4+was also increaded. Quantitative RT PCR analysis demonstrated a significant reduction in the TP53 gen expression in all pruified lympocytes subgroups (CD4+, CD8+, CD19+, CD57+) when matched healthy donors (>50yr) was compared with LPD patients (p=0,02). Thiese TP53 values were inversely correlated with the expression of RPDM1 gene. Patients recruitment is still on going and follow-up is too short to answer the tihrd objective.
Summary and Conclusions: our preliminary observations in a small series of donors confirm that 1) both innate and adoptive immunities are affected by aging: 2) Immuno-senescence is even more pronounced in patients compared to matched healthy donors. The reason remains to be investigated. 3) down-regulation of tumor suppressor gene such as TP53 is present in all lymphocytes subsets and is correlated with aging.

E1131

CHRONIC EXPOSURE TO INTERFERON-ALPHA DRIVES MEDULLAR LYMPHOPOIESIS TOWARDS T CELL DIFFERENTIATION IN MICE
M. Di Scala[1,*] I. Gil-Fariña[1], L. Vanrell[1], R. Sánchez-Bayona[1], D. Alignani[2], C. Olagüe[1], A. Vales[1], P. Berraondo[1], J. Prieto[1], G. Gonzalez-Aseguinolaza[1]
[1]Gene Therapy, [2]Department of Instrumental Techniques-Cytometry Unit, CIMA, Pamplona, Spain

Background: Interferon-α (IFNα) is an antiviral, immunomodulatory and antiproliferative cytokine which is produced in response to a variety of infectious agents including viruses and bacteria. It constitutes a key component of natural immunity linking innate and adaptive immune responses. In line with these functions, IFNα has been utilized in the treatment of chronic viral infections and diverse neoplastic conditions including hematological malignancies and solid tumors. However, these activities are counterbalanced by the induction of peripheral pancytopenia, which frequently limits its clinical use.
Aims: Although a large amount of information exits about the beneficial and deleterious effects of IFNα the modulation of hematopoiesis by IFNα still remains poorly understood. This study aimed to investigate the consequences of long-term IFNα treatment on blood cell homeostasis using a gene therapy vector expressing this cytokine.
Methods: In this work, we analyzed the hematopoietic changes occurring in mice subjected to chronic IFNα exposure. This was achieved by transducing the liver of C57/BL6 mice with an intravenous injection of an adenoassociated vector encoding IFNα (AAV-IFNα) to obtain sustained high serum levels of the cytokine. Furthermore, the consequences of chronic IFNα exposure on lymphoid differentiation was assessed by transferring bone marrow cells from IFNα-treated mice to Rag-/- mice. To understand the way IFNα modulates the commitment of HSCs, we analysed by quantitative real time-PCR the expression levels of key transcription factors (TFs) involved in multipotent progenitors (MPPs) lineage specification in total bone marrow (BM) cells, in purify Lin-cKit+(LK) cells and in differentiated cells (Lin+).
Results: Chronic IFNα exposure by AAV-IFNα injection induces a dramatic change in the composition of the leukocyte population in the peripheral blood and in the bone marrow. Here we found that (long-term hematopoietic stem cells) LT-HSCs and (short-term) ST-HSCs are dramatically reduced in IFNα treated animals causing a progressive and lethal pancytopenia indicative of the exhaustion of the HSCs compartment. Moreover, long term IFNα treatment guides multipotent hematopoietic progenitor cells toward a T cell fate. IFNα directly downregulates both *in vivo* and *in vitro* the expression of B cell TFs in lymphocyte precursor cells and this effect alters the differentiation of these cells driving them to the production of T lymphocytes.
Summary and Conclusions: In conclusion, our results demonstrate that long-term exposure to IFNα exerts a complex impact on hematopoiesis, it compromises the stemness of hematopoietic stem cells (HSCs) but also redirects the function of the hematopoietic precursors cells triggering an unique genetic program in these cells favoring the generation of T cells while blocking the development of B cells.

REQUIREMENT FOR PHOSPHOLIPASE C GAMMA 1 (PLCG1) IN DEVELOPMENT AND MAINTENANCE OF HEMATOPOIETIC STEM- AND PROGENITOR CELLS
P. Arreba-Tutusaus[1,*] T. Schnoeder[1], T. Fischer[1], F.H. Heidel[1]
[1]Department of Hematology and Oncology, Otto-von-Guericke University, Magdeburg, Germany

Background: Hematopoietic stem cells (HSC) play a crucial role in the maintenance of hematopoiesis, balancing self-renewal capacity and differentiation potential to form more committed progenitor cells. HSC homeostasis is highly regulated by a complex network of signaling pathways and transcription factors. Phospholipase C gamma 1 (Plcg1) is known as a key regulator of calcium signaling which plays an important role in proliferation and differentiation of immune. Upon activation by receptor and non-receptor tyrosine kinases, such as T-cell receptor or JAK2, Plcg1 regulates the hydrolysis of phosphatidylinositol 4,5-biphosphate, leading to the activation of various downstream pathways. Several studies have reported Plcg1 to be essential for erythropoiesis during murine embryonic development as well as for granulopoiesis in zebrafish models. Recently, our group provided first evidence for Plcg1 regulating maturation of adult erythropoiesis. However, no previous study has investigated whether Plcg1 is required for development or maintenance of hematopoietic stem cells.
Aims: In this study we aim to investigate the functional role of Plcg1 signaling in fetal liver cells and adult hematopoietic stem- and progenitor cells using RNA interference technology.
Methods: Fetal liver cells (FLC) were isolated from embryos at stage E13.5 while adult immature hematopoietic cells (Lin-Sca1+KIT+CD48-CD150+) were sorted from 6-8 weeks C57/BL6 mice. Cells were transduced with either (non-targeting) control shRNA or two different validated shRNAs targeting Plcg1. All shRNAs were either GFP-labeled or selectable by puromycin. Colony-forming potential was measured in methylcellulose medium and immunephenotype was analyzed by flow cytometry. Functional potential of HSPCs was measured *in vivo* using a short-term colony-forming unit spleen assay (CFU-S12) as well as a long-term competitive repopulation assays. Engraftment capacity was measured by a homing assay.
Results: Following Plcg1 knockdown, colony-forming capacity was significantly reduced in fetal liver cells and adult HSC (when compared to non-targeting control). While fetal liver cells showed a significant erythroid maturation defect upon Plcg1 knockdown in our previously published data, hematopoietic stem cells revealed no maturation defect or lineage bias following inactivation of Plcg1. Immunophenotypic analysis of colonies confirmed presence of all lineages at reduced total numbers. To assess for HSC function we performed colony-forming spleen assay and competitive repopulation studies *in vivo*. Here, loss of Plcg1 affected the functional potential of HSCs and fetal liver cells with significant impairment of their colony-forming potential and repopulation capacity. This was indicated by a drop in whole bone marrow chimerism below 10% at week 16-20 post-transplantation. Again, lineage commitment was not affected, while a reduction in HSPC abundance was observed. Inactivation of Plcg1 did not affect homing of transplanted HSCs but effectively reduced proliferative potential.
Summary and Conclusions: Taken together, our data provide first evidence that Plcg1 is required for HSPC homeostasis, since its genetic inactivation negatively affects the functional capacity of HSCs. Ongoing experiments investigate the effects of Plcg1 on cell cycle activity and induction of apoptosis and, aim to establish a mechanistic model to explain the observed phenotype.

E1134

THE UTILITY OF FLUORESCENCE LIFETIME IMAGING IN ROUTINE BONE MARROW SMEARS
I. Lorand-Metze[1,*] A.P. Racanelli[2,3], C. Lenz Cesar[4,5], M.A. Falconi[6], K. Metze[2,7,8]
[1]Internal Medicine, [2]Laboratory of Analytical Cellular Pathology, [3]National Institute of Photonics applied to Cell Biology ,(INFABIC), [4]Institute of Physics, [5]National Institute of Photonics applied to Cell Biology ,(INFABIC, [6]Hematology/Hemotherapy Center, [7]Pathology, [8]National Intitute of Photonics applied to Cell biology (INFABIC), University of Campinas, Campinas, Brazil

Background: After excitation by a photon, a fluorophore will drop to the ground state with some delay, according to exponential decay rates. This delay is called lifetime. The new technique "fluorescence-lifetime imaging microscopy (FLIM)" creates the image contrast with the help of the fluorescence lifetime values (transformed in pseudo-colors) at each pixel of the two-dimensional microscopic image and does not use the local concentration of the fluorophores or the emitted spectrum. Now we can visualize microscopic structures based on differences of their fluorescence decay rates, which depend on the physicochemical properties of the molecules, even when fluorescence is emitted at the same wavelength. FLIM is a non-invasive technique, using low-potency lasers. Therefore

it has been widely used in experimental settings with cell cultures or small organisms. There are only very few reports on its application for diagnostic purposes in routinely collected samples, such as bone marrow smears.
Aims: The aim of this pilot study was to investigate the utility of the FLIM technique for diagnostic purposes in routinely collected bone marrow smears.
Methods: We used non-stained routine bone marrow smears of 15 patients after fixation with formaldehyde vapor. Images were obtained with a confocal Zeiss Upright LSM780-NLO microscope equipped with a 63x oil immersion objective and a HPM-100-40 Hybrid detector (Becker & Hickl), Image size was 512 x 512 pixels. The specimens were excited by a 405 nm pulsed diode laser (80 MHz). In order to create equivalent images of the cytologic smears, pseudo-colors were attributed to different lifetime ranges. Images were compared with the standard May-Grünwald-Giemsa (MGG) stained smears.
Results: In every case we obtained highly contrasted FLIM images, with clearly distinguishable cellular elements. Photobleaching was rare. The obtained chromatin textures were somehow similar to that of the MGG images and permitted to recognize the different types of hemopoietic cells. Erythrocytes were characterized by the short lifetimes of their hemoglobin component. Cytoplasm and the protein background showed intermediate lifetime values. Fluorescence lifetime of granulopoetic nuclei was considerably longer than in nuclei of erythroblasts. Leukemic blasts of several types of acute leukemia showed considerable variation, generally long lifetime values. In one case of Chediak-Higachi disease, the pathologic cytoplasmic granula were clearly distinguishable. Besides, in that case, intracytoplasmic bacteria could be identified, which were not well visible in the MGG stained smears.
Summary and Conclusions: The FLIM technique can be applied in routinely acquired diagnostic bone marrow smears. No staining is needed. The images are well contrasted, and permit proper identification of the cellular elements. Different lifetime values of nuclear chromatin distinguish erythropoetic and granulopoetic lineage, thus suggesting relevant physicochemical differences of the nuclear organization. Supported: FAPESP, CNPq

CORD BLOOD STEM CELLS BUT NOT ADULT STEM CELLS AFTER TRANSPLANTATION OVEREXPRESS STEMNESS AND REPROGRAMMING GENES PARTIALLY OVERLAPPING THE SIGNATURE OF INDUCED PLURIPOTENT STEM CELLS (IPS)

D. Cilloni[1,*] M. Podestà[2], J. Petiti[1], S. Carturan[1], A. Bertaina[3], F. Sabatini[2], V. Campia[1], V. Gaidano[1], P. Nicoli[1], M. Berger[4], F. Saglio[4], G. Bandini[5], F. Bonifazi[5], F. Fagioli[4], L. Moretta[6], F. Locatelli[3], F. Frassoni[2]
[1]Dept Of Clinical and Biological Sciences, University of Turin, Orbassano, [2]Stem Cell Laboratory, G.Gaslini Institute, Genova, [3]Ospedale Bambino Gesù, Rome, [4]Ospedale Regina Margherita, Turin, [5]Seragnoli Institute, Bologna, [6]G.Gaslini Institute, Genova, Italy

Background: Hematopoietic stem cells (HCT) undergo tremendous expansion and amplification during Hematopoietic Cell Transplant (HTC). To cope with this challenge, HSC must activate several genes including those responsible for self-renewal.
Aims: To prove or disprove whether HSC decline or not in their proliferative potentiality after HCT, we analyzed the expression of genes involved in self-renewal and reprogramming in CD34+cells obtained from bone marrow cells after the engraftment has been achieved.
Methods: Ninety-three genes, mainly involved in HSC regulation plus 30 gene involved in epigenetic regulation, were analyzed in CD34+cells isolated from: (i) Cord Blood (CB), (ii) normal Bone Marrow (BM), (iii) BM taken after umbilical CB Transplant (UCBT), BM taken from (iv) adult or (v) children transplanted with adult HSC. Expression data were compared among the five groups and further with those obtained from iPS (induced pluripotent stem cells).
Results: Among the 93 genes analyzed, the following genes: *DPPA2, LIN28, NANOG, NESTIN, OCT4, SOX1* and *SOX2* were found highly over-expressed in CD34+cells isolated after UCBT with respect to CB or BM CD34+cells. The level of expression of the above mentioned genes found in CD34+cells after UCBT was similar to iPS cells. However, relevant differences in the expression of several other genes were found between CD34+cells post-UCBT and iPS. For instance, PTEN expression was 2 logs higher in UCBT CD34+cells than in iPS. Protein analysis on CD34+cells confirmed the RNA data. Remarkably, over-expression of genes overexpressed in CD34+cells after UCBT was not observed in CD34+taken from BM after any other type of adult cell transplantation. Moreover, we found about 2 logs over-expression of genes involved in epigenetic control in CD34+cells taken from BM after UBCT when compared to native CB CD34+cells.
Summary and Conclusions: CD34+cells taken from BM after UCBT overexpress fundamental genes involved in self-renewal and somatic cell reprogramming thus, partially acquiring the signature of iPS. These features are unique since no other CD34+cell taken either from CB or adult BM or after any hematopoietic adult cell transplantation shows similar pattern of gene expression. These findings open new perspectives: (i) toward a better understanding of transplantation biology, (ii) toward governing gene expression in iPS to render them safer for therapeutic purposes; (iii) in designing new methods to expand HSC in more efficient and consistent manner.

E1136

STROMAL CELL-DERIVED FACTOR-1 PLAYS IMPORTANT ROLES IN THE REGULATION OF HUMAN EARLY B- AND T/NK-LINEAGE LYMPHOID DIFFERENTIATION IN DIFFERENT MANNERS

H. Minami[1,*] K. Ohishi[2], M. Masuya[1], N. Katayama[1]
[1]Hematology and Oncology, Mie University Graduate School of Medicine, [2]Blood Transfusion Service, Mie University Hospital, Mie University, Tsu city, Mie prefecture, Japan

Background: Stromal cell-derived factor-1 (SDF-1) is shown to be essential for B-lymphoid differentiation in mice. However, role for SDF-1 in human lymphopoiesis remains undefined. We previously reported that telomerized human stromal cells support the differentiation of human hematopoietic progenitors to $CD45RA^+CD7^+CD10^-$ T/NK- and $CD45RA^+CD7^-CD10^+CD19^+$B-lineage lymphoid precursors (Br J Haematol. 157:674-86, 2012). Because the stromal cells produced SDF-1, we examined a role of SDF-1 in human early lymphoid differentiation, using our coculture system.
Aims: In this study, we investigated whether and how SDF-1 regulates early lymphoid differentiation from human hematopoietic progenitors to $CD45RA^+CD7^+CD10^-$ and $CD45RA^+CD10^+CD19^+$lymphoid precursors in the presence of stromal cells.
Methods: $CD34^+lin^-CD45RA^-CD38^{lo}$ hematopoietic progenitors were purified from cord blood and cultured for 21 days either on *hTERT*-transduced human bone marrow stromal cells or with conditioned medium (CM) collected from cultures with stromal cells, in the presence of SCF, Flt3L, and TPO. To block the binding of SDF-1 to CXCR4 receptor, anti-CXCR4 blocking antibody (Ab) was added to the cultures. In some experiments, $CD34^+lin^-CD45RA^-CD38^{lo}$ cells were cultured with CM for 14 days and $CD45RA^+CD7^+CD10^-$ or $CD45RA^+CD7^-CD10^+$cells were isolated and incubated on stromal cells with anti-CXCR4 Ab or isotype control.
Results: In the cultures on stromal cells, anti-CXCR4 Ab significantly inhibited the generation of $CD45RA^+CD7^+$as well as $CD45RA^+CD10^+$lymphoid precursors from $CD34^+lin^-CD45RA^-CD38^{lo}$ hematopoietic progenitors. Anti-CXCR4 Ab predominantly inhibited B-lineage differentiation in the cultures with CM. We next examined the effect of anti-CXCR4 Ab on $CD45RA^+CD7^+CD10^-$ lymphoid precursors by culture on stromal cells. In control cultures, the number of $CD45RA^+CD14^-$ lymphoid cells including $CD10^+$cells increased during 10 days of cultures. However, in the presence of anti-CXCR4 Ab, the generation of $CD45RA^+CD14^-$ lymphoid cells including $CD10^+$cells from $CD45RA^+CD7^+CD10^-$ cells was suppressed, and few or no $CD45RA^+CD14^-$ cells were detected at day 10 after culture. Significant numbers of $CD14^+$monocytic cells were generated in both cultures. In the culture of $CD45RA^+CD7^-CD10^+$cells on stromal cells, anti-CXCR4 Ab inhibited their differentiation to $CD45RA^+CD10^+CD19^+$proB cells.
Summary and Conclusions: These data suggest that SDF-1 is important for B-lineage differentiation regardless of presence of stromal cells but critical for lymphoid differentiation from human early hematopoietic and $CD7^+$lymphoid precursors in contact with stromal cells. These findings indicate that SDF-1 plays key roles in early B- and T/NK-lineage lymphoid differentiation in different ways.

E1137

COMPARISON OF SELF-RENEWAL EXPRESSION IN STROMAL IN VITRO AND IN VIVO MICROENVIRONMENT MODELS – CRITICAL DIFFERENCES AND THEIR IMPACT ON HEMATOPOIETIC SUPPORT FUNCTIONS

G. Horne[1,*] V. Campbell[1], H. Wheadon[1], T. Holyoake[1], M. Copland[1]
[1]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, United Kingdom

Background: The intricate relationship between the bone marrow (BM) microenvironment and hematopoietic stem cells (HSCs), both normal and malignant, is well established. Recent evidence highlights the importance of the BM niche in governing stem cell behavior. Translational research is dependent on understanding this relationship, utilizing both 2D and 3D *in vitro* co-culture experiments aiming to recapitulate this environment prior to *in vivo* studies. The use of radiation and anti-proliferative agents on stromal cells is essential in long-term co-culture. The effects of these treatments on hematopoietic supportive function remain poorly understood.
Aims: (1) To define patterns of gene and protein expression of self-renewal pathway components in *in vitro* co-culture models, using mesenchymal stem cells (MSCs) and stromal cell lines; (2) To compare *in vitro* and *in vivo* models, using CD34+CML-engrafted NSG mice. We hypothesized that radiation, anti-proliferative agents and confluency changes would be integral in altering hematopoietic supportive function leading to incomparable results across models.
Methods: Human BM samples were collected from healthy donors and CML patients (n=13) following informed consent. An unselected population of mononuclear cells was isolated to allow expansion of MSCs by plastic adherence. MSC immunophenotype was confirmed as described (Mennan et al, 2013). Primary CD34+CML cells were transplanted into sublethally irradiated (2.5Gy) 8week old NSG mice (n=6). Mice were euthanized after 16weeks. Engraftment was assessed using anti-human CD45 FACS analysis. Sorted CD45+cells were evaluated for BCR-ABL translocation by FISH. *In vitro*, M210B4, SLSL and HS5

stromal cell lines were evaluated±irradiation (40Gy) or±mitomycin (10ng/mL); varying confluency states were assessed. Gene expression of self-renewal pathway components and downstream targets were analysed by Fluidigm qRT-PCR. Protein expression was studied by IF and western blot.
Results: Between experimental models, significant variation in expression of self-renewal pathway components was observed. Expression did not significantly vary between normal and CML MSCs. Ageing MSC passage altered these components, with upregulation in Notch (NOTCH2 p=0.0005, JAG1 p<0.0001, HES1 (ns)) between 4 subsequent passages. Unlike *in* vivo models, there is limited expression of NOTCH4. The Hedgehog (Hh) pathway increased with ageing MSC passage (SMO p=0.0002, GLI1 p=0.05). As expected, irradiation altered self-renewal expression in a time and cell-type dependent manner, with most variation in M210B4. There was progressive downregulation of Hh receptors, SMO (p=0.0005) and PTCH1 (ns). Within the Notch pathway, there was initial upregulation followed by significant downregulation, particularly in NOTCH2 (p=0.001). Ligands and downstream targets were unaffected. Mitomycin did not alter expression. Progressive confluency significantly increased NOTCH1-4 expression in SLSL (p=0.03). However, unaffected ligand and downstream targets suggested this was not due to cis-inhibition. Protein analysis confirmed significant changes. Expression of both Hh and Notch varied considerably from 2D *in vitro* models compared to *in vivo* murine models suggesting further analysis is required in CML co-culture models.
Summary and Conclusions: Our data highlights the diversity between *in vitro* co-culture models and the need to critically appraise these confounding factors when developing 3D models and interpreting results *in vivo*. This will allow for improved translation to clinical research.

E1138

BONE MARROW-DERIVED MSCS STIMULATED BY IFN-Γ INHIBITED THE GROWTH OF TOXOPLASMA GONDII VIA UP-REGULATION OF GBP1
A. Qin[1], D.H. Lai[2], Q. Liu[1,*]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Center for Parasitic Organisms, School of Life Sciences, Sun Yat-Sen University, Guangzhou, China

Background: Mesenchymal stromal cells (MSCs) are a heterogeneous cell population endowed with multi-lineage differentiation potential and extensive immunomodulatory properties. MSCs have been successfully used for prevention and treatment of immune disorders such as graft-versus-host disease. Emerging preclinical studies suggest that MSCs might also protect against infectious challenge. *Toxoplasma gondii* is an apicomplexan protozoan parasite with a broad host range that is capable of causing significant disease in humans and animals.
Aims: This study aimed to rule out the potential mechanism of human MSCs against *T. gondii*.
Methods: Human bone marrow-derived MSCs (hMSCs) were pretreated for 24h with a series of concentrations of IFN-γ and then infected with *T. gondii* strains of variant virulences (virulent RH/GFP and avirulent PLK/RED). RNA-seq and westernblots were used to analyze gene and protein expression patterns of hMSCs under IFN-γ-stimulated and unstimulated conditions. The intracellular parasites (with fluorescence labeled) were counted microscopically at multiple time points postinfection. The short hairpin RNA (shRNA) expression was used to generate RNAi of GBP-1, GBP-2 and GBP-5.
Results: Human MSCs stimulated with IFN-γ were capable to inhibit the growth of *T. gondii* (eg: at IFN-γ 10 ng/ml, the inhibition rates are 26.5% (RH/GFP) and 37.5% (PLK/RED) at 12 hr postinfection) in a dose-dependent manner. Compared with the unstimulated MSCs (controls), IFN-γ treatment groups of 5, 10, 20 ng/ml inhibited *T. gondii* (RH/GFP) growth by percent of 17.7±7.9, 26.5±6.2, 30.0±7.7 (mean±SD, n=4) at 12 hr postinfection and the inhibition rates are 48.5±9.1%, 66.5±8.0% and 68.5±6.1% at 24 hr postinfection, respectively. In the same concentrations of IFN-γ, the inhibition effect of MSCs on PLK/RED strain was stronger than that on RH/GFP strain. Furthermore, After 48 hr postinfection, the ratio between parasites per parasitophorous vacuole (PV) containing rosettes and single parasites in IFN-γ-stimulated MSCs was significantly reduced compared with that in the unstimulated MSCs (p<0.01, p<0.01, p<0.001 for RH/GFP at IFN-γ 5, 10, 20 ng/ml, respectively). We also observed that the resistance in hMSCs does not depend on IDO (p=0.59 for RH/GFP and p=0.45 for PLK/RED at IFN-γ 20ng/ml 24 hr postinfection). RNA-seq data showed that IFN-γ-inducible p65 guanylate-binding proteins (GBPs) might play pivotal roles in the inhibition of *T. gondii* growth. Reads per kilobase-pairs per million (RPKM) mean values of GBP1, 2, 5 in IFN-γ-stimulated MSCs are 1093.3, 443.3, 348.2, respectively. RNAi knockdown of GBP1 (but not GBP2, GBP5) in hMSCs resulted in significantly recovery of *T. gondii* growth from inhibition stimulated by IFN-γ at 24 hr postinfection (p<0.01 and p<0.01 for RH/GFP and PLK/RED at 20 ng/ml level of IFN-γ, compared to shRNA control).
Summary and Conclusions: Human MSCs pre-stimulated with IFN-γ inhibited the growth of *T. gondii* in a dose-dependent manner via up-regulation of GBP-1 expression.

Hodgkin lymphoma - Clinical

Background: Patients with Hodgkin lymphoma (HL) who progress after autologous hematopoietic stem cell transplantation (ASCT) have a dismal prognosis. Therapeutic efficacy of conventional chemoradiotherapy is of little benefit and only allogeneic stem cell transplantation (allo-SCT) is associated with prolonged progression free (PFS) and overall survival (OS) in a proportion of eligible patients. Monoclonal antibody drug conjugate Brentuximab Vedotin (BV) has recently received approval for patients with HL who relapsed after, or are not candidates for auto-SCT.
Aims: To retrospectively study the outcome of patients with HL who were treated with BV in Greece. The primary objective of our study was the estimation of overall response rate as well as the PFS and OS of patients treated with BV.
Methods: From June 2011 until August 2014, eighty patients with relapsed/refractory HL received treatment with BV in Greece. Forty-three males and 37 females with a median age of 32 years, range (18-77) were included in this retrospective analysis. The median time from diagnosis to treatment with BV was 35 months, range (5-245). Among the 80 patients, 61 (76%) received BV due to relapse/progression after auto-SCT, 2 (2.5%) after failing both auto- and allo-SCT, whereas 19 patients were treated with BV before auto-SCT, since they were considered non-eligible for the procedure due to advanced age or refractory disease. Fifty-four out of 80 (67%) patients had disease refractory to induction treatment. The median number of treatments administered before BV was 4, range (1-7). Refractoriness to treatment administered before BV was observed in 52 out of 80 (65%) patients. BV was administered at a dose of 1.8mg/kg every 3 weeks until disease progression or for a maximum of 16 cycles.
Results: At the time of this analysis, the median number of BV cycles administered was 6, range (1-6). Three patients died from progressive disease after cycle 1, and therefore they were excluded from statistical analysis. The best response achieved after BV was complete (CR) and partial remission (PR) in 14 (18%) and 31 (40%) patients, respectively. Nine (12%) patients had stable disease (SD), while 23 out of 77 (30%) patients progressed during treatment with BV. With a median follow up period of 9.5 months (range, 1-35) the median PFS and the median OS were 10.5 and 31 months respectively (Figure 1). In multivariate analysis: 1) refractoriness to treatment administered before BV was associated with significantly reduced probability of achieving response to BV [Odds Ratio=2.7, (95% CI 1.0 to 7.2), p=0.04], and 2) response to BV was associated with significantly increased PFS [HR=0,14, (95% CI, 0,06 to 0,29), p <0,0001] and OS [HR= 0,24, (95% CI, 0,07 to 0,77), p=0,017].

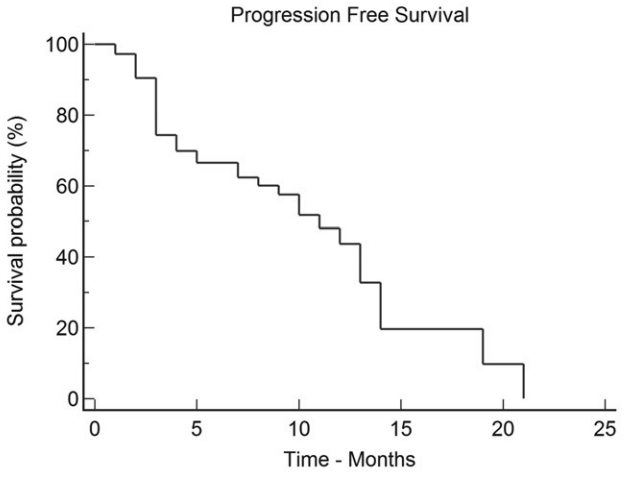

Figure 1.

Summary and Conclusions: To our knowledge, this study is the second largest study reported so far after the pivotal phase II trial which included 102 patients and resulted in the accelerated approval of BV. Although BV is a promising therapeutic option with an overall response rate of 58%, the median PFS is only 10 months when BV is administered as a single agent. The therapeutic efficacy of BV should be explored in different time settings such as, as salvage before auto-SCT or as maintenance after SCT in order to consolidate established responses.

E1140

EXPRESSION OF PD-I LIGANDS FOR CLASSICAL HODGKIN LYMPHOMA PROGNOSIS

I. Kryachok[1,*] N. Khranovska[2], O. Novosad[1], N. Svergun[2], T. Skrypets[1], T. Kadnikova[1], I. Tytorenko[1], O. Aleksik[1]
[1]Oncohematology, [2]Experimental oncology, National Cancer Institute, Kiev, Ukraine

Background: Classical Hodgkin lymphoma (cHL) is presente by some cancerous cells from germinal center B-cells and generality from non-malignant reactive cells. Clinical outcome of cHL could be directly depended on pathways between Hodgkin and Reed-Sternberg (HRS) cells and other cells in their microenvironment. There is still much to learn in significance of the microenvironment in cancerous tumors and cHL especially. So, the main purpose of study to evaluate importance of microenvironment expression.
Aims: To determine value of PD-L1 as a marker at prognosis and its association with clinical outcome in cHL patients.
Methods: 49 patients with cHL were included in the analysis with stages IIA – 23, IIB – 3, III-IV – 23. Patients were treated by ABVD or BEACOPP 14/esc as the first line therapyand radiotherapy by indications. cHL samples were received from lymph node biopsies. PD-L1, PD-L2 expression levels were analyzed using real-time RT-PCR.
Results: For 49 patients OR rate after the first-line therapy was 93.9 % (47/49) with a CR of 73.5 % (36/49) and PR – 22.4 % (11/49). Progression of the disease during the therapy was observed in 2 patients. Among the patients who achieved a CR during the follow up (median – 24 months; range 12–36) – 9 had relapses. PD-L1 positive were 73.5% (36/49) of cHL cases and 26.5 % (13/49) were PD-L1 negative. PD-L1 expression level was higher in nodular sclerosis cHL and advanced stages of disease (p=0.19). PD-L2 expression level was not associated with histological cHL variant, disease stage and clinical outcome. ROC analysis revealed that PD-L1 expression level in tumor is an important marker which is associated with clinical outcome of cHL patients (Se=87.5 %; Sp=64.5 %; AUC=0.75; p=0.002). High PD-L1 expression was associated with reduced progression-free survival (PFS) in cHL patients. The 2-year PFS rate for cHL patients with high PD-L1 expression was 47% compared to 95% for low or absent of PD-L1 expression.
Summary and Conclusions: PD-L1 showed promising activity as a marker at prognosis in patients with cHL. High expression of the PD-L1 is associated with unfarouble clinical outcome in cHL patients.

THE ARROVEN STUDY (MA25101): POST-AUTHORISATION OBSERVATIONAL SAFETY STUDY OF BRENTUXIMAB VEDOTIN IN RELAPSED/REFRACTORY HODGKIN LYMPHOMA AND SYSTEMIC ANAPLASTIC LARGE CELL LYMPHOMA

K. Linton[1,*] R. Ayto[2], F. d'Amore[3], M. Moestl[4], I. Chau[5], S. Paneesha[6], J. Kinley[7], D. Huebner[8], J. Porter[8], B. Exter[8], B. Wang[8], J. Tymoszczuk[8], A. Arumainathan[9]
[1]University of Manchester and The Christie NHS Foundation Trust, Manchester, [2]Northwick Park Hospital, London, United Kingdom, [3]Aarhus University Hospital, Aarhus, Denmark, [4]Hanusch Krankenhaus, Vienna, Austria, [5]Royal Marsden Hospital, Surrey, [6]Birmingham Heartlands Hospital, Birmingham, [7]Takeda Development Centre Europe Ltd, London, United Kingdom, [8]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited., Cambridge, United States, [9]Royal Liverpool University Hospital, Liverpool, United Kingdom

Background: Brentuximab vedotin, a CD30-targeted antibody-drug conjugate, has conditional approval in Europe for the treatment of adult patients with relapsed/refractory (R/R) CD30+Hodgkin lymphoma (HL), and systemic anaplastic large cell lymphoma (sALCL). The European Medicines Agency requires a post-authorisation safety study to further evaluate brentuximab vedotin's safety profile. ARROVEN is an ongoing, multi-centre, international, prospective, observational study of R/R CD30+HL and sALCL patients treated with brentuximab vedotin as part of routine clinical care. Currently available data will be presented.
Aims: To evaluate the occurrence of serious adverse events (SAEs) and AEs of special interest (AESI) in patients actively treated for R/R HL or sALCL with brentuximab vedotin in routine practice; and to identify and describe potential risk factors for peripheral neuropathy.
Methods: R/R CD30+HL or sALCL patients aged ≥18 years who are planned to start or recently commenced brentuximab vedotin as part of routine clinical care, are eligible. Data are extracted from information routinely recorded in the medical record and no study visits or examinations are required. Follow-up information and safety data are collected in conjunction with all routine visits, every 3 months until death, withdrawal of consent, or loss of follow-up. The frequency, intensity and relationship to treatment is evaluated for all SAEs and AESIs considered related to brentuximab vedotin; peripheral neuropathy, neutropenia, infections, hyperglycaemia, and hypersensitivity reactions.
Results: Between June 2013 and January 2015, 62 patients (mean age 47.6 years [range 19–82]) out of a target of 500 were enrolled across 21 sites; 39 (63%) had HL, and 18 (29%) had sALCL (5 [8%] unknown). Patients received a median of 4 treatment cycles (range 1–12). AEs were reported in 45 (73%) patients. The most common AEs (n≥4) were peripheral neuropathy (n=18), infections (n=14), neutropenia (n=13), hypersensitivity reactions, and lethargy (each n=4). There were no reported hyperglycaemia events. In the 18 patients with peripheral neuropathy, all 21 events reported were categorised as 'sensory, motor, or other'; peripheral neuropathy risk factors were not evaluable at the time of analayis. Grade ≥3 AEs were reported in 24 (39%) patients; grade ≥3 AEs in >1 patient were infections (n=8), neutropenia (n=6), and peripheral neuropathy (n=2). Seven (11%) patients reported grade 4 toxicities. These included infection (n=4), progression with sepsis (n=2), neutropenia (n=2), thrombocytopenia (n=1), and tumour lysis syndrome (n=1, sALCL patient). SAEs were reported in 21 (34%) patients. This included 11 patients with drug-related SAEs; the most common (n≥2) were infection (n=9), and peripheral neuropathy (n=4). No cases of progressive multifocal leukoencephalopathy, Stevens-Johnson syndrome, toxic epidermal necrolysis, or acute pancreatitis were reported. Two patients discontinued brentuximab vedotin, 1 due to grade 5 multi-organ failure during cycle 1, and 1 due to grade 3 left pleural effusion and grade 5 bronchopneumonia during cycle 4. There were 4 on-study deaths in total, due to pneumonia (n=3) and disease progression (n=1).
Summary and Conclusions: The severity and frequency of reported toxicities in R/R HL and sALCL patients treated with brentuximab vedotin are consistent with the known safety profile of brentuximab vedotin, and the pivotal phase 2 studies. These data indicate that brentuximab vedotin is manageable and tolerable in the conditionally approved indications.

E1142

BRENTUXIMAB VEDOTIN (BV) AN EFFECTIVE TREATMENT FOR TRANSPLANT INELIGIBLE PATIENTS WITH RELAPSED/REFRACTORY (R/R) HODGKIN LYMPHOMA (HL)

S. Viviani[1,*] A. Guidetti[1], S. Dalto[1], A. Dodero[1], L. Farina[1], S. Bolis[2], L. Rigacci[3], F. Zallio[4], A. Busca[5], B. Bruno[5], N. Mordini[6], G. Parvis[7], P. Corradini[1]
[1]Hematology and Pediatric Onco-Hematology, FONDAZIONE IRCCS ISTITUTO NAZIONALE DEI TUMORI, Milano, [2]Hematology, Azienda Ospedaliera San Gerardo-Monza, Monza, [3]Hematology Division, AOU Careggi, Firenze, [4]Hematology, Ospedale SS Antonio e Biagio, Alessandria, [5]Oncology and Hematology, AOU Città della Salute e della Scienza, Torino, [6]Hematology Department, Ospedale Santa Croce, Cuneo, [7]Hematology, Ospedale San Luigi, Orbassano, Italy

Background: Patients with R/R HL, who are refractory to ≥2 lines of salvage chemotherapy, are generally considered ineligible for ASCT and have a very dismal 2-year PFS. Furthermore, patients relapsing after ASCT need effective treatment to eventually proceed to alloSCT. BV is a safe and highly effective treatment in R/R HL after ASCT and 75% overall responses have been reported.
Aims: The aim of this retrospective study was to assess the efficacy of BV in

inducing remission and enable R/R HL patients to proceed to ASCT or alloSCT.
Methods: Patients with R/R CD30-positive HL, treated with BV between January 2011 and April 2014 for failure of at least two prior therapies, when ASCT was not considered a treatment option (Group A), or for failure following ASCT (Group B), were included in this retrospective analysis. BV was given at the standard dose of 1.8 mg/kg iv every 21 days in an outpatient setting. The primary endpoint of this study was to evaluate efficacy of BV to enable patients to proceed to ASCT or alloSCT. Secondary endpoints included BV toxicity, Progression-free Survival (PFS) and Overall Survival (OS).
Results: Twenty R/R HL patients for Group A (ASCT-ineligible) and 25 patients for Group B (ASCT failures) were identified. Main characteristics at start of BV were as follows:

Table 1.

Characteristics	Group A (n=20)	Group B (n=25)
Males/Females	9/11	9/16
Median age (range) yrs	38 (20-76)	39 (18-64)
B Symptoms	7	9
Stage III-IV	10	11
Extra ±nodal involvement	9	11
Bulky disease (>7 cm)	7	4
Median number prior regimens (range)	4 (2-12)	4 (2-9)
Refractory disease after frontline therapy	15	17

A median of 6 BV cycles (range, 3 to 19) were administered. Overall response rate in Group A and B was 75% and 64%, respectively; CR was documented in 8 patients (40%) in Group A and 5 patients (20%) in Group B. Best response was reported after a median of 3 cycles (range, 2-9). Three pts in Group A and one in Group B, achieving a negative PET scan, by continuing BV therapy, had PD and were considered transplant ineligible; one patient in Group B refused alloSCT. BV enabled 7 patients in Group A (achieving CR: 5, PR:1, SD:1) and 15 patients in Group B (achieving CR:3, PR: 8, SD:4) to receive a transplant procedure. Nine patients (20%) had grade ≥3 adverse events (2 sensory peripheral neuropathy, 1 pneumonia, 6 neutropenia), no patient discontinued treatment due to toxicity. After a median follow-up of 14 months (range, 1-36), median PFS was 5 months and median OS was still not reached. For patients achieving CR or PR after BV and receiving ASCT (n=5) or alloSCT (n=12), median PFS was 8 months. At 2 years OS was 70%, 53% and 60%, for Group A, Group B and the entire patient population, respectively.
Summary and Conclusions: These data confirm that BV is effective in heavily pretreated R/R transplant ineligible HL patients, who have generally limited conventional treatment options and a low median OS. BV may overcome chemorefractoriness and enable patients to receive ASCT or allo-SCT, by omitting the significant toxicity of multiagent chemotherapy regimens.

E1143

THE PROGNOSTIC SIGNIFICANCE OF ELEVATED LEVELS OF SERUM FERRITIN PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANT IN PATIENTS WITH HODGKIN LYMPHOMA

A.A. Borda[1,2,*] I. Cordoba[3], M. Osuna[1], C. Rosales[4], M. Rosales[4], V. Abello[4], J. Figueroa[4], L. Villamizar[4], A. Viilegas[4], H. Esguerra[4], E. Pedraza[4]
[1]RECLIN, Registro Colombiano de Linfomas, [2]Hematologia Unidad de trasplante de Médula Osea, [3]Hematologia, Clinica de marly, [4]Hematologia Unidad de trasplante de Médula Osea, Clinica Marly, Bogota, Colombia

Background: Some studies have shown that serum ferritin levels correlated with tumor mass and closely followed disease activity in patients with hematologic malignancies such as malignant lymphoma and acute leukemia. Studies have also shown that elevated serum ferritin levels in cancer patients are associated with a poor prognosis. Studies suggest that elevated pretransplantation serum ferritin levels are associated with increased mortality and a lower transplantation-related survival after allogeneic hematopoietic stem cell transplantation and after autologous hematopoietic stem cell transplantation (ASCT) for malignant lymphoma.
Aims: The aim of this study was to determine the relationship between pretransplantation ferritin levels and outcome following ASCT for Hodgkin lymphoma.
Methods: We performed a retrospective analysis the predictive value of pretransplantation serum ferritin (drawn within 60 days preceding transplant admission) of 136 consecutive adult patients who underwent ASCT for Hodgkin lymphoma (HL) at the Clinica Marly between January 1995 and December 2014, was available for 136 patients (64%) who form the patient population for this report. The normal range for ferritin in our laboratory is 10 to 500 ng/mL.
Results: The median pretransplantation ferritin for patients in this study was 658 ng/mL (range: 10 – 6352). Baseline ferritin 912 ng/mL as the cut off point that best correlated with poor survival. Univariable analysis demonstrated that number of prior chemotherapy regimens, disease status, and elevated ferritin were significantly associated with overall survival (OS). On multivariate analysis, a pre transplantation ferritin 912 ng/mL was associated with significantly lower overall (OS; P: 0.025) and Disease Free Survival (DFS ; P= 0.002). Ferritin 912 ng/mL was associated with a higher incidence of relapse (P=0.004) and relapse mortality (P= 0.001). The median follow-up for surviving patients is 44 months (range: 12 - 74). Multivariable analysis demonstrated that elevated ferritin (P= .0022, HR 1.78, 95% CI 1.35 – 2.26) and, number of prior chemotherapy regimens (P= 0.032, HR 1.63, 95% CI 1.12- 2.45) were significant adverse prognostic factors for OS. Elevated ferritin (P= .021, HR 1.60, 95% CI 1.08-2.38) and disease status (P= .003, HR 2.05, 95% CI 1.45-2.71) were also adverse factors for Disease Free Survival.
Summary and Conclusions: Elevated levels of serum ferritin of 912 ng/mL, number of prior chemotherapy regimens, disease status, may be an important marker for predicting poor survival outcomes following ASCT for Hodgkin lymphoma. The present study cannot distinguish between a causal relationship of elevated ferritin, through iron stores, on the malignancy and ferritin being a surrogate for extent or aggressiveness of malignancy. Our results indicate the need for studies designed to correlate an elevated ferritin with iron overload and survival outcomes.

E1144

AUTOMATED IMAGE ANALYSIS REVEALED A HIGH VARIABILITY OF CD30+HRS CELLS DENSITY IN CLASSICAL NODULAR SCLEROSIS HODGKIN LYMPHOMA

V. Prochazka[1,*] Z. Capkova[2], Z. Prouzova[3], T. Dyskova[2], T. Papajik[1], E. Kriegova[2]
[1]Dept. of Hemato-Oncology,, [2]Olgen research center, Dept. of Immunology, [3]Dept. of Clinical and Molecular Pathology, Faculty of Medicine and Dentistry, Palacky University Olomouc, Czech Republic., Olomouc, Czech Republic

Background: Hodgkin lymphoma, classic type (cHL) tissue is characterized by an extreme disproportion between tumor (Hodgkin-Reed-Sternberg, HRS) cells ranging from 0.1% to 10% and surrounding non-malignant microenvironment cells. Last years brought an explosion of novel information about close HRS-microenvironment cross-talk, which promotes a tumor growth. Numerous studies tested the predictive value of microenvironment cells density using immunohistochemistry (IHC) methods and many of them were focused on lymphoma-associated macrophages (LAM). High LAM density at time of diagnosis was found to be an inferior prognostic factor. However, no studies were performed on HRS cells density and HRS:LAM ratio analysis.
Aims: To assess an impact of HRS cells density and HRS:LAM relationship on disease development/prognosis in cHL, nodular sclerosis subtype using novel automated scanning system of the total tumor sample area.
Methods: We analyzed cHL tissues, obtained at time of diagnosis, in fourteen patients with intermediate and advanced stages (KS IIB-IV). Six patients represented a relapsed/refractory (RR) cohort, eight patients were selected as age-sex matched relapse-free (RF) controls. Paraffin-embedded biopsies were prepared from pre-selected high-quality diagnostic samples stained with hematoxylin-eosin for morphology analyses and using CD30 (HRS) and CD68 (LAM) for cell-density analyses. Tissue array analyses were performed using the TissueFAXS (TissueGnostics, Vienna, Austria) system that combines detailed morphologic information offered by microscopy with the scientific accuracy of multi-channel flow cytometry. Data were analyzed with TissueQuest software. Each sample was previewed by scanning software and only significant tumor tissue was manually gated for further analyses, excluding fibrotic (≥10 %), necrotic or residual lymphatic structures. This area was considered as a Total Tumor Sample (TTS) area.
Results: Mean TTS area covered 17.7±11.9 mm2 with mean total number of cells 457,257±397,599. The mean TTS was not different in RF (17.9 mm2) compared to RR cohort (19.2 mm2, p=0.86). There was a trend for higher cell density in RF compared to RR cases (27,679 *vs* 20,861 cells per mm2, p=0.09). Density of CD30+HRS cells was 2.4 fold higher in RF than in RR patients (429 *vs* 180 cells per mm2, p=0.055). Although mean density of CD68+LAM was comparable in RF and RR group (2,372 and 2,716 cells per mm2, respectively, p=0.66), a CD30:CD68 ratio was higher in RF (0.31) than in RR (0.07, p=0.044) patients. The number of LAM per one HRS cell was 33.1 in RR, whereas only 12.1 in RF group (p=0.10). Our data showed that automated analysis of a TTS area may overcome technical limitations caused by a tissue selection, heterogeneity in HRS and bystander cell distribution or tissue fibrosis/necrosis comparing to analysis of small tissue samples (2-3 mm2).
Summary and Conclusions: Cell distribution in cHL tissue is highly variable, automated analysis of may bring more accurate cell-density results with lower variance. We describe differences in HRS and total cell density in diagnostic biopsies of relapse/refractory and relapsed- free cHL patients. Higher HRS:LAM ratio in relapsed patient presume more potent HRS-microenvironment interaction with the possible prognostic role.

E1145

HODGKIN LYMPHOMA PATIENTS WITH HIGH NUMBER OF MACROPHAGES IN TUMOR TISSUE - RISK PROFILE AND TREATMENT OUTCOME

B. Andjelic[1,*] M. Perunicic Jovanovic[2], L. Jakovic[1], D. Antic[1], M. Todorovic[1],

J. Bila[1], A. Sretenovic[1], V. Djurasinovic[1], M. Smiljanic[1], V. Vukovic[1], J. Jelicic[1], B. Mihaljevic[1]
[1]Clinic for Hematology, [2]Department for Histopathology, Clinical Center of Serbia, Belgrade, Serbia

Background: The treatment approach in Hodgkin Lymphoma (HL) is risk adopted. Thus, patients have to be stratified into certain risk groups based on clinical stage and risk factors before selecting the appropriate therapy. In the past decade, many studies were performed with the aim to identify reliable prognostic biomarkers for HL. Among potentially very powerful biomarkers is considered the number of macrophages in tumor tissue, with negative prognostic impact of their high content in tumor.
Aims: The aim of this study was to thoroughly evaluate high risk group of HL patients according to number of macrophages in tumor tissue, in order to identify patients who potentially require more effective treatment approach.
Methods: The retrospective study was performed on selected patients with newly diagnosed classical HL, initially treated with ABVD in the period 2000-2008. The selection criteria was based on ROC curve analysis which determined 8 as the most appropriate cut off value for number of CD68+macrophages in 1000x magnification high power field (hpf). The analysis was performed on 61 patients with high number (higher or equal 8) of CD68+macrophages/hpf. The examined parameters in survival and multivariate analysis were presence of bulky disease, ESR≥50 mm/h, B symptoms, elevated LDH and high IPS score (3-7).
Results: The median follow up was 71 months (range 2-162 months). The median age was 31 yrs (range 17–84). Five-years overall survival (OS) was 68,9% and 5-years event free survival (EFS) was 54,1%. In univariate analysis patients with ESR≥50 mm/h, B symptoms and elevated LDH had significantly shorter OS (p=0.047, p=0.011, p=0.045, respectively), while there was a trend toward worse OS in patients with bulky disease (p=0.058). EFS was significantly shorter in patients with ESR≥50 mm/h, B symptoms, elevated LDH and high IPS (p=0.047, p=0.044, p=0.017, p=0.033, respectively). Multivariate analysis identified presence of B symptoms as the independent risk factor for poor OS (p=0.018) and elevated LDH as the independent risk factor for poor EFS (p=0.023).
Summary and Conclusions: The further stratification in high risk groups of HL patients could be potentially useful for selecting the adequate treatment approach. More effective treatment approach is potentially required in patients with high number of CD68+macrophages with present B symptoms and/or elevated LDH. Still, these have to be confirmed through randomized clinical trials.

E1146

LYMPHOMA SURVIVORSHIP AND CARDIOVASCULAR DISEASES: DETECTION OF EARLY CARDIAC DYSFUNCTION

M.P. Simula[1,*] A.M. Mamusa[1], S. Usai[1], G. Locci[2], E. Angelucci[1]
[1]1Struttura Complessa di Ematologia e Centro Trapianti. Ospedale Oncologico di Riferimento Regionale. Cagliari, Italia, [2]Unità Operativa complessa di CardiologiaOspedale Oncologico di Riferimento Regionale. Cagliari, Italia., ASL Cagliari, Cagliari, Italy

Background: Improvements in the treatment of Lymphomas have resulted in an increasing number of long term survivors. This patient's population is at risk of developing late therapy related complications as cardiovascular diseases and secondary cancers.
Aims: In our institution since September 2014 the Hodgkin's (HL) and aggressive non Hodgkin's Lymphomas (NHL) long term survivors are followed up in a dedicated clinic. This approach allows clinicians to better appreciate and monitor not only signs and symptoms of the known hematologic disease but also of other medical problems that can affect people undergone previous radiation therapy and/or chemotherapy (survivorship). An additional target of this project is to define a program of early detection of otherwise asymptomatic cardiovascular, endocrine, respiratory, neurologic and oncologic disease. In this work we focus on the preliminary results of screening of early cardiovascular disturbances.
Methods: We collected data regarding cardiovascular diseases in 216 patients and performed electrocardiographic and echocardiografic evaluation in 79 patients selected mainly according to the age, cardiovascular risk factor, time from therapies, type and amount of antiblastic (antracyclines) and mediastinal radiotherapy received.
Results: We analyzed data regarding 216 patients coming in our clinic from 15 September 2014 to 16 February 2015, 119 were affected by HL and 97 by NHL. One hundred fifteen are females, 101 males; median age at observation is 53 (range 22-89). All of them are in complete response for lymphoma for at least 5 years from the completion of curative therapy. Thirty seven patients (17%) had known cardiovascular problems developed after lymphoma treatment (some of them had more than one defects): 9 isolated arterial hypertension, 14 ischemic cardiac disease, 4 valvular insufficiency, 1 dilatative cardiomyopathy, 5 arrhythmia, 2 cardiac failure, 1 aortic ectasia, 2 cerebrovascular ischemia. Electrocardiographic and echocardiografic evaluation has been performed in 79 patients selected mainly according to the age, cardiovascular risk factor, time from therapies, type and amount of antiblastic (antracyclines) and mediastinal radiotherapy received. Thirty eight out of 79 (48%) showed previous unknown cardiac disturbance: particularly 21 presented diastolic relaxation abnormality, 15 valvular insufficiency and 5 aortic sclerosis of low-moderate grade, 1 has low grade myocardic thickness and 3 arterial hypertension. The median age of patients with cardiovascular abnormalities discovered during the screening is 49 (range 32-70), 28 of them had received therapy for HL and the other 10 for NHL.
Summary and Conclusions: Our analysis confirms that an high percentage of patient survived to lymphomas can develop cardiovascular diseases. Their monitoring can detect silent dysfunctions as diastolic relaxation abnormality considered an early sign of cardiomyopathies.

Indolent Non-Hodgkin lymphoma – Clinical

THE CHANGING FACE OF GASTRIC MALT-LYMPHOMA: THE VIENNA UNIVERSITY EXPERIENCE

M. Raderer[1,*] B. Kiesewetter[1], W. Dolak[2], S. Wöhrer[3], M. Mayerhöfer[4], I. SImonitsch-Klupp[5], A. Chott[6], U. Jäger[7]
[1]Oncology, [2]Gastroenterology, Medical University Vienna, Vienna, [3]Krankenhaus Wr Neustadt, Wr Neustadt, [4]Radiology, [5]Pathology, Medical University Vienna, [6]Pathology, Wilheminenspital, [7]Haematology, Medical University Vienna, Vienna, Austria

Background: In the past, the stomach has been thought to be the most common site of origin for extranodal marginal zone B-cell lymphoma of the mucosa associated lymphoid tissue (MALT-lymphoma), with the large majority of cases being associated with Helicobacter pylori (HP) infection.
Aims: As changes in clinicopathological characteristics and incidence have been suggested by scattered reports, we have assessed characteristics and outcome of patients with gastric MALT lymphoma from a tertiary referral center.
Methods: Between 1999 and January 2015, a total of 320 consecutive patients with MALT lymphoma were diagnosed, treated and followed at our institution. We have retrospectively re-assessed all patients with gastric MALT-lymphoma from this cohort in terms of stage, HP-infection, pathological characteristics, treatment and outcome.
Results: In total, 116 / 320 patients (36%) with MALT lymphoma were of gastric origin, while the large majority of patients had extragastric MALT lymphoma. Only 4 /116 patients (3%) also had a diffuse-large B-cell lymphoma component along with MALT lymphoma. Using a standardized staging regimen, we found 25 pts (22%) to have multiorgan-involvement, including 3 (2.6%) with bone marrow involvement, while 91 had localized disease (78%). Out of 99 patients with a fully tested HP-status, 34 (34%) were negative for HP and 65 positive. Interestingly, 9 of these patients had been diagnosed before 2004 (9/49, 18%) and 25 between 2004-2015 (25/50, 50%). In total, 40% of patients assessed had monoclonal gammopathy, and plasmacytic differentiation was present in 31%. In addition, 29% of patients were found to have an underlying autoimmune disease, with chronic autoimmune thyroiditis being most common. In terms of treatment, 76 patients (66%) had antibiotics as first line therapy, 31 systemic therapy (27%), while the remaining patients had surgery, radiation or wait and see. After a median follow-up of 63 months, 85% (99/116) are alive, while 17 (15%) have died. Transformation to DLBCL was only seen in one patient after therapy, while 2 developed clonally unrelated nodal DLBCL. HP-status was not associated with relapse following first line therapy (p=0.066), and there was no difference in estimated time to progression between the two cohorts. Interestingly, 14 HP-negative patients were treated with antibiotics alone, resulting in 5 CR and 1 PR (46%), 5 stable disease and 3 progressions; results of antibiotic treatment in HP negative patients were not significantly different for estimated time to progression (p=0.1) and progression following first line therapy (p=0.38).
Summary and Conclusions: These results suggest that the rate of gastric MALT lymphoma amongst the cohort of MALT lymphomas as a whole is decreasing, while the rate of HP-negative gastric MALT lymphomas was much higher (34%) than stated in the literature in the past. In addition, cautious interpretation of our data suggests an increase of HP-negativity over the last 10 years. Surprisingly, a relevant percentage of patients can be managed with antibiotic therapy alone without compromising patients`prognosis. Further studies on the pathogenesis and therapy of HP-negative patients are needed in order to optimize therapy and avoid overtreatment. In addition, our data suggest that the risk of transformation to DLBCL in the course of the disease is minimal.

E1148

INTERIM ANALYSIS OF A PHASE 1B STUDY EVALUATING THE SAFETY OF GS-9820, A SECOND-GENERATION PI3K DELTA-INHIBITOR, IN RELAPSED/REFRACTORY LYMPHOID MALIGNANCIES

A. Kater[1,*] S. Tonino[1], M. Kersten[1], A. Hagenbeek[1], M. van Oers[1], M. Spiering[1], M. Chamuleau[2], J. Doorduijn[3], A. Viggiano[4], S. Jun[4]
[1]Hematology, Academic Medical Center, [2]Hematology, VU Medical Center, Amsterdam, [3]Hematology, Erasmus Medical Center, Rotterdam, Netherlands, [4]Clinical Research, Gilead Sciences, Foster City, United States

Background: In B-cells, phosphatidylinositol 3-kinase delta (PI3Kδ) mediates cell survival and proliferation, and its activity is critical for retaining B cells in lymphoid tissues. Idelalisib inhibits PI3Kδ in B-cell malignancies, and is indicated for the treatment of 1st line 17p deleted and relapsed chronic lymphocytic leukemia (CLL) in combination with rituximab. Idelalisib also demonstrated high response rates in relapsed follicular lymphoma (FL) and small lymphocytic leukemia (SLL). GS-9820 is a second-generation, PI3Kδ-inhibitor and was evaluated in B-cell malignancies including CLL and non-Hodgkin's lymphoma (NHL).
Aims: The primary objective was to determine the maximum tolerated dose (MTD) and to assess safety including the incidence and severity of elevated transaminase levels, diarrhea and pneumonitis which are observed with idelalisib.
Methods: Subjects with relapsed B-cell malignancies and measurable lymphadenopathy (LAD) with ≥1 prior therapy received GS-9820 at doses of 50, 100, 200, or 400 mg, orally, twice daily (BID). The dose escalation stage (n=12) had a 3+3 design and measured safety, efficacy and pharmacologic properties. Additional subjects (n=27) enrolled in the dose expansion cohort at 400 mg BID. Antitumor activity was evaluated every 2 months including CT scans, with adjustments for redistribution lymphocytosis, consistent with PI3Kd inhibition. Nodal PR (nPR) is defined as ≥50% reduction in LAD. Subjects received GS-9820 until disease progression or unacceptable toxicity.
Results: As of July 2014, 15/39 subjects remain on treatment. Reasons for discontinuation include disease progression (11), death (4) (all unrelated to GS-9820), adverse events (AE) (14) and other (9). Response rates assessed by independent review committee were; overall 33.3% (95%CI (19.1-50.2)), for CLL subset (n=22) 33.3%, for NHL subset (n=17; 8 MCL, 4 DLBCL) 28.6%. nPR in CLL subset was 84.6%. The median duration of response was not reached and maximum duration of response was up to 11.9 months. No dose limiting toxicities were reported. AEs (subject incidence >20%) were cough, diarrhea, dyspnea, fatigue, peripheral edema and rash. Severe adverse events (grade 3 or 4) reported by >1 subject were pneumonia (5, 12.8%), pyrexia (4, 10.3%) sepsis (2, 5.1%) and diarrhea (2, 5.1%). AEs considered related to study drug by the investigator (subject incidence >10%) were pyrexia, dysgeusia, diarrhea and increase in AST or ALT. Three subjects had elevations in transaminase levels at grade 3 or 4 in the 400 mg BID dose cohort. No subjects reported pneumonitis and 8 subjects reported pneumonia[a].
Summary and Conclusions: Interim analysis of this phase 1b study of GS-9820 demonstrates clinical efficacy and safety comparable to idelalisib. Based on the similarity to idelalisib, no further clinical development is planned. [a]pneumonia included AEs of pneumonia, viral pneumonia, organizing pneumonia.

E1149

LONG TERM SAFETY AND ACTIVITY OF CLADRIBINE IN MUCOSA ASSOCIATED LYMPHOID TISSUE LYMPHOMA (MALT LYMPHOMA)

B. Kiesewetter[1,*] W. Dolak[2], I. Simonitsch-Klupp[3], M.E. Mayerhoefer[4], M. Raderer[1]
[1]Department of Internal Medicine I, Clin. Div. of Oncology, [2]Department of Internal Medicine III, Clin. Div. of Gastroenterology and Hepatology, [3]Department of Pathology, [4]Department of Radiology, Medical University Vienna, Vienna, Austria

Background: The purine analogue 2-chloro-deoxyadenosine (2CDA, cladribine) +/- rituximab (R) was successfully tested in MALT lymphoma patients achieving remission rates of 80-100%. However, studies using 2CDA in other indications have reported the potential for prolonged hematological side effects and secondary malignancies. To date, there have been no data on long term effects of 2CDA in MALT lymphoma patients.
Aims: In view of this, we have retrospectively analysed long term safety and activity of 2CDA in MALT lymphoma patients.
Methods: From 1998-2004, 49 patients were treated with either 2CDA alone (0.12 mg/kg i.v. d1-5, every 28 days) or R-2CDA (R 375 mg/m2 i.v. d1, 2CDA 0.1 mg/kg s.c. d1-4, every 21 days) for a maximum of six cycles. All patients were treated within clinical trials and had undergone a standardised follow-up (FUP) protocol (three-monthly for the first two years, then six-monthly for the first five years, annually thereafter) minimizing a potential bias in the detection of late sequels and relapses. This retrospective analysis had been approved by the Ethical Board of the Medical University of Vienna.
Results: Patients included in this analysis had received either 2CDA alone (n=17, 35%) or combined with R (n=32, 65%). The median age at treatment start was 60 years. Response to treatment was 100% for 2CDA and 78% for R-2CDA, respectively and the median number of applied cycles was four and six, respectively. All documented relapses (n=17) occurred within a median time of 13 (interquartile range; 10-42) and 15 (IQR; 8-33) months, suggesting long term remissions in patients "outlasting" the initial post-treatment period. After a median FUP of 55 months (IQR; 42-70) three of 49 patients aged 59, 70 and 77 had developed prolonged pancytopenia starting 1, 3 and 83 months after treatment. All patients had a bone marrow biopsy and in one patient myelodysplastic syndrome (MDS) was diagnosed. Two of three patients died with ongoing panzytopenia after 14 and 89 months while the third recovered to normal blood counts. Noteworthy, all three patients had received the maximum number of six cycles and in all 2CDA was not the sole treatment administered. Thus additional triggers for cytopenia/MDS cannot be ruled out. In one patient, R-CHOP was given for relapse before MDS occurred while the other two were pretreated with abdominal radiation or radioimmunotherapy. At the time of analysis 35/49 (71%) are alive with 25/35 (71%) in ongoing complete remission, two (6%) in ongoing stable disease, and eight (23%) free of lymphoma after 2nd line. Fourteen patients (29%) have died including two patients who died after only one cycle of treatment due to unrelated reasons and one patient who withdrew consent after four cycles. As reported, two patients died

with pancytopenia 14 and 89 months after initiation of treatment. In addition four patients died from secondary malignancies (gastric cancer, B-cell lymphoma, SCLC, skin cancer) after median 48 months (range; 12-93) and five due to cancer-unrelated reasons after median 55 months (range; 11-124). Median overall survival was not reached (Figure 1: Survival curve for MALT lymphoma patients receiving cladribine treatment, n=49).

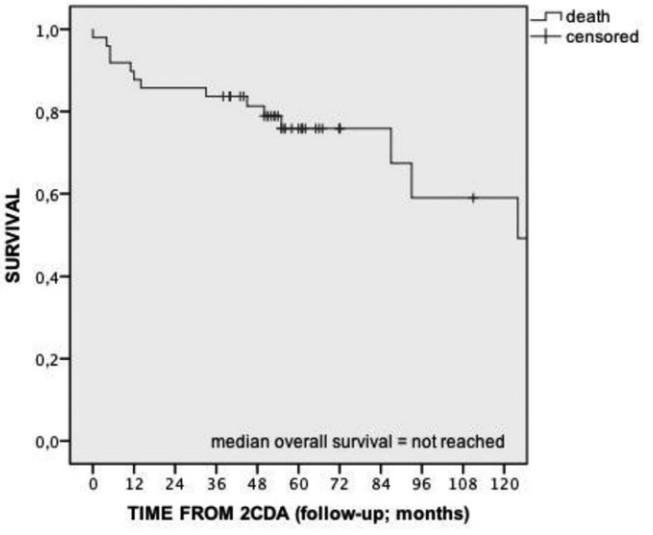

Figure 1.

Summary and Conclusions: After a median FUP of 55 months, 8/49 patients (16%) treated with 2CDA for MALT lymphoma have developed a secondary malignancy. In most of these cases, however, a causative role of 2CDA is relatively unlikely given the nature and time of development of these cancers. In addition, 3/49 patients had prolonged pancytopenia/MDS. While the number of patients in our series is relatively small, these data suggest that with the high rate of remissions and the fact that the median survival was not reached after more than 5.5 years 2CDA might be safely applied also in terms of long term toxicities. However, prolonged pancytopenia may occur particularly in older patients.

E1150

NON-GASTRIC MALT LYMPHOMAS (NG-MALT). CLINICAL CHARACTERISTICS AND OUTCOME IN A SERIES OF 185 PATIENTS: ASSESSING PARAMETERS OF PROGNOSTIC SIGNIFICANCE

C. Kalpadakis[1,*] G. Pangalis[2], P. Konstantinidou[3], T. Vassilakopoulos[4], M. Siakantaris[5], V. Nikolaou[6], P. Roussou[7], X. Yiakoumis[2], E. Katodritou[3], C. Apostolopoulos[7], S. Sachanas[2], P. Tsirkinidis[2], S. Papadaki[3], M. Moschogiannis[2], A. Stavroulaki[1], M.C. Kyrtsonis[8], F. Kontopidou[9], P. Korkolopoulou[10], G. Levidou[10], D. Rontoyianni[11], S. Kokoris[12], E. Koulieris[2], P. Panayiotidis[8], C. Antoniou[6], H. Papadaki[1], M. Angelopoulou[4]
[1]Hematology, University of Crete, Heraklion, [2]Hematology, Athens Medical Center - Psychikon Branch, Athens, [3]Hematology, Theagenion Cancer Hospital, Thessaloniki, [4]Hematology, [5]1st Department of Internal Medicine, [6]Dermatology, [7]3rd Department of Internal Medicine, [8]1st Department of Propedeutics, [9]2nd Department of Internal Medicine, [10]Pathology, University of Athens, [11]Pathology, Evangelismos General Hospital, [12]Hematology Laboratory, University of Athens, Athens, Greece

Background: NG MALT lymphomas may arise at any anatomic site. Recent data suggest that primary localization may have an impact on patients' clinical course and outcome.
Aims: To investigate whether anatomic localization is associated with specific disease features and outcome in a large series of NG MALT lymphoma patients and to identify possible prognostic parameters.
Methods: 185 patients, from 6 Hematology Units in Greece, with biopsy-confirmed NG-MALT lymphoma, were retrospectively analyzed. Survival probability was estimated using the Kaplan-Meier method.
Results: The main characteristics of the studied population are given in table 1. Fourteen different sites of involvement were recorded. The most common were skin (22%), salivary gland (SG) (20%), ocular adnexa (OA) (13%) and lung (12%). Seventy-two% presented with limited stage disease, while 78% were classified as low risk according to IPI. A history of autoimmune disorders was present in 24%, with Sjogren's syndrome being the most common. Gastroscopy was performed in 87 pts; a MALT lymphoma was identified in 18% and *H.pylori* (HP) (+) gastritis in 16%. Bone marrow was infiltrated in 12%. Treatment was not uniform, comprised mainly of systemic therapies [chemotherapy (CT) in 22%, Rituximab (R)-CT in 34%, R monotherapy in 9%, IFN-a (3%)], local therapies (surgery in 13%, radiotherapy in 9%, R locally in 1%), while 6 pts (3%) were placed on follow up observation. *Correlations of anatomic site with specific disease features:* 1. SG was more often associated with advanced disease stage (p=0.001). 2. SG and thyroid had more often an autoimmune background (p<0.001). 3. OA was strongly associated with *HP*(+) gastritis (p=0.002). 4. Small intestine and lung had more frequently paraproteinemia (p=0.001). After a median follow-up time of 74 months (1-369) the median failure free (FFS), overall (OS) and disease specific survival (DSS) were 14,8, 25,5 and 25,5 years, respectively. Small intestine, lung and multiple MALT site disease (>2) had a shorter median FFS compared to all other MALT localizations (92 *vs* 197,7 months) (p=0.02). Patients could be grouped into 3 different risk categories according to their disease localization: Group 1 (skin, large intestine, thyroid, SG and liver) had the most favorable FFS (median not reached), group 2 (head and neck localization, breast, kidney and OA) had an intermediate prognosis (median FFS 178 months), while group 3 (lung, small intestine, thymus, bladder, brain and multiple MALT sites) were associated with the worst outcome (median FFS 81,8 months) (p=0.013). Age<60 years was a favorable factor for FFS (not reached *vs* 145,8 months) (p=0.034). IPI was a strong prognostic factor for FFS: IPI 0/1 (median FFS not reached), IPI 2/3 (median FFS 37,9 months), IPI 4 (median FFS 8,6 months) (p<0,0001).

Table 1. Patients' Characteristics.

Characteristics	#of patients (%)
Localization

Median	25,5 years
5-Year/10-Year	95%/93%

N= number of pts assessed

Summary and Conclusions: NG MALT lymphomas display a highly favorable clinical course and survival. The present study shows that certain anatomic sites were highly associated with specific disease features. In addition lung, small intestine and multiple MALT sites of involvement carried the most adverse prognosis. Furthermore, age<60 and low IPI were associated with improved FFS.

E1151

FLUDARABINE TREATMENT FOR WALDENSTRÖM MACROGLOBULINEMIA-ASSOCIATED NEUROPATHY – 20 YEARS EXPERIENCE OF A SINGLE CENTER

S. Sarghi[1,*] C. Dartigeas[2], M. Delain[2], L. Benboubker[2], K. Amraoui[2], S. Lissandre[2], O. Herault[2], P. Colombat[2], J. Praline[3], E. Gyan[2]
[1]Hematology, CH Meaux, Meaux, [2]Hematology, [3]Neurology, CHRU Tours, Tours, France

Background: Waldenström macroglobulinemia (WM) is a malignant indolent incurable lymphoproliferative disease characterized by the association of the evidence of a lymphoplasmacytic proliferation and a monoclonal component of IgM. WM-related polyneuropathy (WM-PN) is its most frequent neurological complication. WM-PN diagnosis is difficult and underestimated due to the heterogeneity of the mechanisms and of clinical presentations.The presence of neuropathy is widely accepted as an indication for treatment in WM but the choice and time of the appropriate therapy can be challenging due to different toxicity profile of each option, the non-curable characteristic of the disease and the heterogeneous response to treatment of different subtypes of neuropathy
Aims: The aim of our study was to present our local experience of the use of fludarabine, as a single agent or in combination with rituximab or cyclophosfamide (fludarabine-based chemotherapy) for the treatment of Waldenström macroglobulinemia associated neuropathies.
Methods: Seventy patients with IgM monoclonal immunoglobulin and neuropathy were addressed to our hematology department in the last 20 years: 27 patient were diagnosed with monoclonal gamapathy on undetermined significance (MGUS) median age 67 years, 39 patients were diagnosed with WM, median age 74 years and 4 patients with other low grade non Hodgkin lymphoma, median age 66 years. Treatment was proposed to 32 WM patients, from whom 17 with fludarabine based chemotherapy. Our primary objective was to evaluate the neurological response to treatment by clinical evaluation, electromyography and the 10 points INCAT disability score, the secondary objectives were the treatment-free survival (TFS) and the hematological response.
Results: Of 17 patients (IPSSWM low- intermediate- high: 3-12-2), 13 started treatment for neurological impairment only and 4 patients had in addition hematological treatment criteria. All patients were treated with 4 to 6 cycles of chemotherapy adapted to tolerance: 1 received RFC (rituximab-fludarabine-cyclophosphamide) regimen, 11 received RF regimen, 5 received fludarabine alone. Neurologically, 5 patients had pure axonal neuropathy; 11 patients presented demyelinating neuropathy and 2 patients demyelinating neuropathy with secondary axonal lesions. In 8 patients anti MAG antibodies were detected and 11 patients presented severe forms of neuropathy. The neurological response after treatment: 11 patients presented clinical improvement, 5 patients presented stable clinical disease, 1 patients dissociated response, the INCAT score had significant improvement, more than 2 points, in 7 patients, and 1 point improvement in 4 patients. EMG registered only partial amelioration in 3 cases of axonal neuropathy and 1 case of non severe demyelinating neuropathy. The hematological response: median peak reduction 75% (min 33%, max 100%). The median TFS for neurological or hematological criteria was not reached, the mean TFS 92.5 months [min 68.3, max 116.7].
Summary and Conclusions: The fludarabine based chemotherapy for WM-PN allows good control of the symptomatology and long treatment-free survival. Further trials are needed to establish the optimal moment to treat in the evolution of the neuropathy.

Background: Rituximab (R)-chemotherapy induction followed by R maintenance is the current standard of care for patients with follicular lymphoma (FL). In recent years, several studies have investigated the optimal dose and schedule of R based on pharmacokinetic (PK) data. These studies have proposed a presumptive 'active' level of 25 µg/ml. However, scanty data are available with regard to the PK of R during maintenance and its possible relationship with the patients' characteristics and outcome.
Aims: Here, we report the preliminary analysis of PK data correlated with patients' clinical characteristics and outcome during R maintenance.
Methods: Patients with grade 1, 2 or 3a FL in maintenance therapy with iv R (375 mg/m^2) administered every 2 (patients treated front-line) or 3 months (after salvage immuno-chemotherapy) were investigated. R plasma trough concentrations (C_{tr}) and the area under the curve (AUC) were determined using a sensitive validated ELISA assay. PK data were then correlated with the patients' clinical characteristics and outcome.
Results: From March 2013 to March 2014, 101 patients have been recruited by 12 FIL centers. The median age was 60 years (IQR 30-84) and 50 (48.5%) were males. According to body mass index (BMI) 44 (43%) patients were overweight and 10.8% were obese. At study entry, 92 patients were in first complete response (CR), 19/92 in second CR and 9 in partial response (PR), of whom 2 after salvage therapy. In 85/101 (group 1) and in 16/101 (group 2) patients, R was administered every 2 or 3 months, respectively. After a median follow-up of 23 months from the start of R maintenance, 91 patients were in CR, 3 in PR and 7 had relapsed. The median C_{tr} level was 32 µg/ml (0.0 µg/ml – 200 µg/ml) in all patients, 33 µg/ml (0 µg/ml-188 µg/ml) in patients treated with R every 2 months and 22.8 µg/ml (0 µg/ml-200 µg/ml) in patients treated every 3 months, respectively (p=0.7). A higher median R C_{tr} level (36 µg/ml *vs* 22 µg/ml, p=0.04) and a higher AUC (61.23 *vs* 41.9, p=0.011) were found in females. No correlation between C_{tr}, AUC and BMI were documented, but a trend towards higher levels were found in patients with a BMI <30 (C_{tr}=40.38 µg/ml *vs* 31.96 µg/ml, p=0.23; AUC=54.19 *vs* 42.55, p=0.13). This preliminary analysis did not show any relationship between the quality of response (CR *vs* PR), the outcome (response *vs* relapse) and the C_{tr} levels and AUC; however, in a subanalysis of group 1, more patients with lower C_{tr} relapsed during R maintenance (38.8 µg/ml *vs* 33.9 µg/ml, p=0.01) and, notably, 4/6 who relapsed had C_{tr} levels under 25 µg/ml.
Summary and Conclusions: Our study confirms the favorable R PK profile in female patients and in the 2 months administration scheme. At present, probably because of the relatively short follow-up and low number of events during maintenance, no relationship between PK data and outcome has so far emerged and a longer observation time is required.

E1153

HYPOGAMMAGLOBULINEMIA AT LONG-TERM AFTER RITUXIMAB/ CHEMOTHERAPY TREATMENT FOR LYMPHOMA, AND USE OF INTRAVENOUS IMMUNOGLOBULINS FOR RECURRENT INFECTIONS.

M. Ferraro[1,*] B. Sanchez-Gonzalez[1], A. Esquerra[1], F. Garcia[1], C. Fernandez-Rodriguez[2], E. Torres[1], A. Senin[1], E. Gimeno[1], A. Salar[1]
[1]Hematology, Hospital del Mar, [2]IMIM, Barcelona, Spain

Background: Rituximab (R) is a monoclonal antibody against CD20 that causes suppression of B-lymphocytes and may induce hypogammaglobulinemia, with the subsequent increased risk of infections. B-cells usually recover within 6-12 months after R administration. Actually, many patients can be exposed to rituximab during prolonged periods of time, either following maintenance or because of retreatment.
Aims: This retrospective study sought to evaluate (at long term) the kinetics of gammaglobulins during the first 4 years after R treatment, the influence of prolonged R exposition (following maintenance and/or second/third line treatment) and its impact on the use of intravenous immunoglobulins (IVIG).
Methods: We identified 194 patients who received R or R-chemotherapy for lymphoma between 2005 and 2011 in our Lymphoma Unit. Patient clinical histories were evaluated with special interest in: type of R-chemo received, maintenance with R, use of other anti-CD20 monoclonal antibodies and treatment at relapse. Quantitative serum immunoglobulin levels (sIg) prior to and at the end of first line treatment and every 12 months was recorded, as well as need for IVIG replacement therapy and relevant infectious events.
Results: median age of 67 years, 41 % female. Lymphoma types: aggressive (58%), indolent follicular (29%), indolent non-follicular (13%). First R-containing treatment: R (10%), R-purine analogs (6%) and R-chemo (84%). During the 4-year study period, second-line treatment was administered in 71 patients (R: 13%, R-purine analogs: 13%, R-chemo: 52%, chemo without R: 22%) and, 53 and 10 patients received R as maintenance or Ibritumomab as consolidation, respectively, in first or subsequent line of therapy. 85 patients had a total of 125 infectious adverse events: 53 during R or R-chemo (36% grade 1-2), 18 during R-maintenance (all but 1 grade 2) and 54 off R-therapy (39% grade 1-2). Median lymphocyte count, gammaglobulin, and levels of IgG, IgA and IgM are showed prior and post-therapy and at +12, +24 and +48 months:

Table 1.

	Lymphocytes (x10e9/L)	Gammaglobulin (g/L)	IgG (mg/dl)	IgA (mg/dl)	IgM (mg/dl)
Pre-Therapy	1.37	9.4	897	188	76
Post-Therapy	1.05	7.5	712	136	48
+12 months	1.31	8.4	778	148	54
+24 months	1.42	8.4	765	143	56
+48 months	1.62	8.8	824	168	64

Of note, prior treatment with R, 14% of patients had reduced levels of gammaglobulins (<6.6 g/L) and 24.5% of patients had a level of IgG <700 mg/dL. In the whole population, median levels of IgG, IgA and IgM were significantly reduced at the end of the first treatment (p<0.0001, Wilcoxon test for paired

samples), and also at months +12, +24 and +48. However, the kinetic of levels of IgG-IgA-IgM was significantly different according to R exposition. Patients receiving only one schema of R or R-containing chemo showed a faster recovery with normal values of IgG, IgA and IgM at +12 months. Interestingly, patients who received more than one treatment of R-chemo or R-maintenance after R-chemo had a prolonged reduced levels of all gammaglobulins that remained under normal values even at +48 months (figure 1). Even though 30% of cases continued with reduced levels of IgG at +48 months, only 8 patients (4%) ultimately required IVIG replacement.

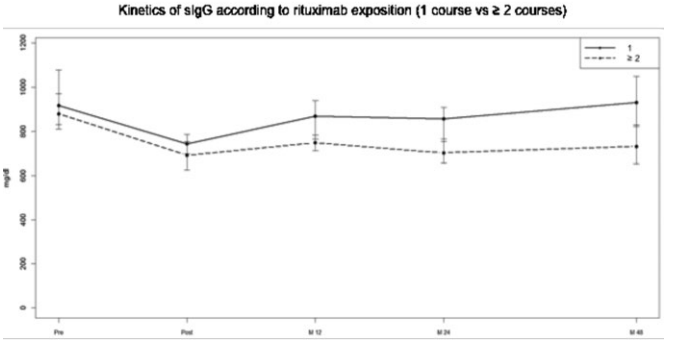

Figure 1.

Summary and Conclusions: Lymphoma patients receiving more than one treatment of R or R-containing chemo and those receiving R-maintenance are at increased risk of long-term hypogammaglobulinemia. With the increasing use of R, it is important to monitor sIg levels even though the incidence of symptomatic hypogammaglobulinemia that prompted IVIG administration is infrequent.

E1154

UPDATED RESULTS FROM A MULTICENTER, OPEN-LABEL, DOSE-ESCALATION PHASE 1B/2 STUDY OF SINGLE-AGENT OPROZOMIB IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES, INCLUDING WALDENSTRÖM MACROGLOBULINEMIA

D. Siegel[1,*] J.L. Kaufman[2], N. Raje[3], J. Mikhael[4], P. Kapoor[5], S. Treon[6], J. Castillo[6], L. Neuman[7], M. Obreja[7], I. Ghobrial[6]
[1]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, [2]Winship Cancer Institute, Emory University, Atlanta, [3]Harvard Medical School, Boston, [4]Mayo Clinic, Scottsdale, [5]Mayo Clinic, Rochester, [6]Dana-Farber Cancer Institute, Boston, [7]Onyx Pharmaceuticals, Inc., an Amgen subsidiary, South San Francisco, United States

Background: Oprozomib (OPZ) is an oral epoxyketone proteasome inhibitor that has shown promising antitumor activity in a phase 1b/2 study (NCT01416428) in patients with hematologic malignancies, including Waldenström macroglobulinemia **(**WM; Siegel *et al*., *Blood* 2014;124: abstract 1715). In the phase 1b portion of the study, the maximum tolerated dose of single-agent OPZ when administered once daily on days 1, 2, 8, and 9 of a 14-day cycle (2/7 schedule) or on days 1–5 of a 14-day cycle (5/14 schedule) to patients with hematologic malignancies was 300 mg/day and 240 mg/day, respectively.
Aims: We present updated efficacy and safety results from patients with WM enrolled in the phase 2 portion of the study.
Methods: Adult patients with hematologic malignancies who have relapsed after receiving ≥1 line of therapy are eligible for enrollment. The primary objective of the phase 2 portion of the study (the target enrollment for the phase 2 portion is 66 patients with WM) is to determine the best overall response rate (ORR; minimal response or better). In the phase 2 portion of the study, single-agent OPZ is being administered once daily on days 1, 2, 8, and 9 of a 14-day cycle (2/7 schedule: 240 mg/day during cycle 1; 300 mg/day thereafter if well tolerated) or on days 1–5 of a 14-day cycle (5/14 schedule: 240 mg/day). All patients provided informed consent. Efficacy and safety results are presented for patients with WM in the phase 2 portion of the study.
Results: As of November 3, 2014, a total of 129 patients with hematologic malignancies were enrolled in the phase 1b/2 study. Of those patients, 21 had WM and were enrolled in the phase 2 portion of the study and treated with OPZ. Four patients with WM were enrolled in the 2/7 dosing schedule; 17 patients with WM were enrolled in the 5/14 schedule. The median age of patients was 64.5 years (range, 63–67 years) in the 2/7 schedule and 62 years (range, 44–85 years) in the 5/14 schedule. The median number of prior regimens was 2.5 (range, 1–8) in the 2/7 schedule and 3 (range, 1–7) in the 5/14 schedule. Preliminary median treatment duration was 6.6 weeks (range, 0.3–8.1 weeks) in the 2/7 schedule and 8.1 weeks (range, 0.7–31.6 weeks) in the 5/14 schedule. All 21 patients with WM in the phase 2 portion were response-eligible. The ORR in the 2/7 schedule was 25% (1 of 4 patients; 1 partial response); the ORR in the 5/14 schedule was 53% (9 of 17 patients; 5 partial responses and 4 minimal responses). The most common adverse events (AEs) are shown in the Table. Grade 3 AEs occurring in >1 patient included nausea and vomiting (2 patients each); there were no grade 4 AEs. Antiemetic medication was administered to 3 patients (75%) in the 2/7 schedule and 17 patients (100%) in the 5/14 schedule. Four patients in each schedule (100% in the 2/7 schedule; 24% in the 5/14 schedule) received antidiarrheal medication. No on-study deaths occurred in patients with WM. No patients enrolled in the 2/7 schedule and 7 patients (41%) enrolled in the 5/14 schedule discontinued treatment due to an AE. Three patients (75%) in the 2/7 schedule and 11 patients (65%) in the 5/14 schedule had ≥1 dose reduction due to an AE.

Table 1. AEs occurring in ≥30% of WM patients (by schedule)

	2/7 schedule (n=4)		5/14 schedule (n=17)	
AE, n (%)	Any grade	Grade 3–4	Any grade	Grade 3–4
Nausea	3 (75)	1 (25)	14 (82)	1 (6)
Diarrhea	3 (75)	0 (0)	11 (65)	1 (6)
Constipation	1 (25)	0 (0)	10 (59)	0 (0)
Fatigue	1 (25)	0 (0)	9 (53)	0 (0)
Vomiting	2 (50)	1 (25)	6 (35)	1 (6)
Decreased appetite	0 (0)	0 (0)	6 (35)	0 (0)
Gastroesophageal reflux disease	2 (50)	0 (0)	2 (12)	0 (0)

Summary and Conclusions: Single-agent OPZ has promising antitumor activity in patients with WM. Enrollment in both treatment schedules is ongoing. Updated results will be presented at the meeting.

E1155

WHICH GUIDELINES TO TRUST? CRITICAL APPRAISAL OF CLINICAL PRACTICE GUIDELINES FOR MANTLE CELL LYMPHOMA SHOWS HIGH VARIABILITY AMONG RECOMMENDATIONS.

M. Marchetti[1,*] N.L. Liberato[2]
[1]Hematology - Oncology Unit, Hospital C. Massaia, ASTI, [2]Internal medicine Dpt, ASL-PAVIA, Casorate Primo, Italy

Background: Guidelines are evidence-based tools supporting everyday clinical practice. Therefore, several national and international scientific and governament institutions regularly produce guidelines. Unfortunately, major inconsistencies are usually found among basic recommendations, which limits both applicability and harmonization. Some excellence institutions overcame such a hurdle developing high-quality local clinical pathways. Nevertheless, guideline representation through an ontology-based format may permit a greater insight into inconsistencies and ambiguities.
Aims: In a pilot phase of a guideline harmonization project sustained by the Italian Society of Hematology, we tested the comparability of guidelines for frontline treatment of mantle cell lymphoma (MCL).
Methods: We applied the ADAPTE standard to search, appraise and compare guidelines: those published in English language after the year 2010 were selected. Clinical practice guidelines (CPG) reporting evidence levels and grading of recommendations were listed separately from coonsensus statements and clinical pathways. CPG quality was assessed by the standard tool AGREE. Finally, we extracted implicit ontologies out of the recommendations and compared them across guidelines.
Results: We retrieved 11 documents from 7 countries, including 5 clinical practice guidelines (CPG), 2 clinical pathways, 1 consensus statement and 1 hybrid document. Four different grading systems for guidelines were adopted, only 2 of them using GRADE system. AGREE score for the 5 CPG ranged from 25% to 57%, the weakest areas being applicability, editorial independence and stakholders. The two CPG adopting GRADE system scored highest at AGREE evaluation. Major inconsistencies among guidelines regarded the criteria used to choose a therapy plan. Analysis of ontologies allowed us to classify the decisional criteria suggested for prompting frontline choices into 7 classes: age, performance status, comorbidity, biologic aggressiveness (blastoid variant, proliferation index), clinical presentation (indolent disease, symptoms, nodal disease), prognostic score (MIPI, IPI), tumor burden (included stage). Each guideline incorporated only a small subset of the above decisional criteria and overlap among guidelines was minimal. Rituximab-bendamustine and Rituximab-CHOP were recommended as frontline therapy for transplant inelegible patients by all the guidelines, however, only 2 of them transparently indicated a preference ranking among therapies. Recommendations to other chemoimmunotherapies (R-CVP, R-Chl, R-FC, R-CVAD/R-MA) were highly heterogeneous. Rituximab maintenance was recommended by five out of five guidelines updated in 2014, but the recommendation was usually not restitricted to patients treated with frontline RCHOP. Radiotherapy was consistently recommended for stage I-II disease, usually as consolidation after chemotherapy. Indication to ASCT consolidation in younger patient with advanced disease was not always stringent, however it was in almost all the CPGs. Suggested induction regimen included high-dose aracytin, except for one CPG suggesting the use of Rituximab-bendamustine. Only one CPG and one algorithm reported criteria for consolidation allogeneic SCT in patients with a first complete remission. Three guidelines

provided recommendations for management of compromised patients. No guideline suggested the use of frontline regimens containing bortezomib, ibrutinib or idelalisib.
Summary and Conclusions: Inconsistency among guidelines does not reside only in paucity of comparative high-quality evidence, rather, in lack of transparent methods for linking evidence to recommendations, in disagreement on ontologies and in empiric management of uncertainty. Guideline harmonization projects may prompt an improvement of guideline quality and allow a more critical adoption by physicians.

E1156

CIRCULATING ADAMTS-13 IS REDUCED IN PATIENTS WITH WALDENSTROM'S MACROGLOBULINEMIA AND IS ASSOCIATED WITH INCREASED IGM LEVELS AND DISEASE FEATURES BUT NOT WITH THE LEVELS OF VON WILLEBRAND FACTOR

E. Kastritis[1,*] E. Terpos[1], M. Gavriatopoulou[1], C. Skevaki[2], E. Eleutherakis-Papaiakovou[1], D. Kalapanida[1], M. Bakogeorgos[1], M. Politou[3], I. Papassotiriou[2], M. Dimopoulos[1]
[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, [2]Department of Clinical Biochemistry, "Aghia Sophia" Children's Hospital, [3]Laboratory of Hematology and Blood Bank Unit, "Aretaieio" Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background: ADAMTS-13 is a protease, which cleaves the cell bound large ultrapolymeric von Willebrand factor (vWF) strings. Circulating ADAMTS-13 is primarily synthesized and released from hepatic stellate and endothelial cells. Acquired functional deficiency of ADAMTS-13 results in excessive platelet aggregation and disseminated vWF/platelet-rich thrombus formation. Hivert et al (Blood 2012) and our group (ASH 2013, # 3194) have shown that increased levels of vWF, the only known substrate of ADAMTS-13, are associated with poor prognosis in patients with symptomatic WM.
Aims: Our aim was to investigate the possible association of ADAMTS-13 antigen (Ag) levels with features of WM and possible biologic implications of the ADAMTS-13 / vWF interaction in WM patients' prognosis.
Methods: Our study included 42 patients with symptomatic WM who were treated and followed in the Department of Clinical Therapeutics of the University of Athens (Greece), 22 patients with asymptomatic WM and 19 healthy controls of matched gender and age. ADAMTS-13 antigen levels were measured in stored serum, collected at diagnosis and before initiation of therapy, using a commercially available kit (R&D Systems, Minneapolis, MN, USA).
Results: The median age of patients with symptomatic WM was 65 years (range: 37-83 years) and 54% were males. Anemia (Hb<11.5 g/dL) was present in 78%, platelet counts <100x10^9/L in 17%, beta2-microglobulin >3 mg/dl in 56%, while 7.5% had serum LDH ≥250 U/L and 58% had serum albumin <3.5 g/dL. Median serum IgM was 3340 mg/L (range 246-9563 mg/dL). According to ISSWM, 22% had low, 43% intermediate and 35% high risk WM, respectively. Reasons to initiate therapy included cytopenias in 42%, B-symptoms in 15%, hyperviscosity in 12%, neuropathy in 10% and other reasons in 21%. Primary therapy based on rituximab was given in 93% of the patients and 54% achieved at least 50% reduction of IgM. Median ADAMTS-13 levels in patients with symptomatic WM were 848 ng/ml (range 471-1622 ng/ml), in those with asymptomatic WM were 875 ng/ml (range 280.5-1466 ng/nl) and in healthy controls were 1170 ng/ml (range 770-1598 ng/ml). Thus, there was a significant difference of ADAMTS-13 levels between patients with either symptomatic or asymptomatic WM and normal individuals (p<0.001 and p=0.002 respectively) but there was no difference between symptomatic and asymptomatic WM (p=0.934). There was a negative correlation between levels of ADAMTS-13 and levels of IgM (r=-0.544, p<0.001), beta2-microglobulin (r=-0.376, p=0.01) and the infiltration of the BM by lymphoplasmatic cells (r=-0.338, p=0.03),and a positive correlation with serum albumin levels (r=0.373, p=0.016). Accordingly, in patients with hyperviscosity syndrome, serum ADAMTS-13 was lower (p=0.04). There was no association of ADAMTS-13 levels and vWFAg levels, in patients with either symptomatic or asymptomatic WM (p>0.5 for both). Thus, a direct link between increased vWFAg levels, which are found in patients with WM, and compensatory ADAMTS-13 levels cannot be supported by our data. The levels of ADAMTS-13 had no prognostic association with overall or progression free survival in patients with symptomatic WM.
Summary and Conclusions: This is the first evaluation of ADAMTS-13:Ag levels in the serum of WM patients. Serum ADAMTS-13:Ag levels are lower compared to healthy controls and inversely correlate with IgM levels, beta2-microglobulin and the degree of bone marrow infiltration but do not increase in compensation to increased levels of vWF Ag.

E1157

DOES AGE ADJUSTED CHARLSON COMORBIDITY SCORE STRONGLY PREDICT OUTCOME OF THE PATIENTS WITH FOLLICULAR LYMPHOMA TREATED WITH IMMUNOCHEMOTHERAPY?

J. Jelicic[1,*] M. Todorovic[1], B. Andjelic[1], A. Sretenovic[1], D. Antic[1], J. Bila[1], D. Stanisavljevic[2], V. Djurasinovic[1], V. Vukovic[1], M. Smiljanic[1], B. Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, [2]Department of statistics, Faculty of Medicine, Belgrade, Serbia

Background: The clinical outcome of patients with follicular lymphoma (FL) has been improved since the introduction of rituximab. However, the management and optative outcome of patients with lymphoma is frequently complicated by their comorbid conditions.
Aims: The aim of this study was to evaluate possible influence of comorbidities on the overall survival (OS) of patients with FL, using correlation between clinical outcome and comorbid status expressed through Cumulative Illness Rating Scale (CIRS) and age adjusted Charlson comorbidity index (aaCCI).
Methods: A total of 140 patients (84 female/56 male) from age of 20-74 years (median 52 years) were analyzed. Majority of patients (94.3%) were in advanced clinical stage, III and IV according to the Ann Arbor classification. Bulky disease was present in 35.7% patients, B symptoms in 67.1%, leukemic phase of disease in 7.1% of patients. Bone marrow infiltration had 67.1% patients and histopathological grade (Gr) 3 of disease had 25.6% of patients. Regarding the Follicular Lymphoma International Prognostic Index 2 (FLIPI2), low score was present in 4.4% patients, intermediate in 47.8% and high score in 47.8%. According to CIRS (minimal score 14), 58.5% of patients were without comorbid condition (CIRS 14) and 41.5% had at least one comorbidity (CIRS≥15). In a view of aaCCI, 63.1% patients had aaCCI 0-2 and 36.9% had aaCCI≥3.
Results: All patients were treated with immunochemotherapy including R-CHOP protocol (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisolone) applied in 92.1% of patients and R-CVP protocol (rituximab, vincristine, prednisolone) applied in 7.9%. Partial and complete remissions were achieved in 92.1% patients, and 7.9% did not respond to initial medical treatment. There was no statistical difference regarding OS between patients who were treated with R-CVP protocol comparing to patients treated with R-CHOP (Log Rank $\chi^2$1.436, p>0.05). According to the lymphoma grade, there was difference in 5–years survival between patients with Gr 1-2 and Gr 3 (Log Rank χ^2=5.291, p=0.06), 84% in patients with Gr 1-2 comparing to 68% in those with Gr 3. The patients with B symptoms had poorer outcome with 5–years survival of 78%, comparing to the patients without B symptoms whose 5–years survival was 90% (Log Rank χ^2=1.672, p<0.05). Leukemic phase of lymphoma was not in correlation with the worst outcome (Log Rank χ^2=0.04, p>0.05), neither was bulky disease (Log Rank χ^2=1.672, p>0.05). The FLIPI2 was highly predictive in our group of patients (Log Rank χ^2=20.361, p<0.01). OS in patients with CIRS≥15 after 1, 2 and 5 years was 92%, 87% and 80% respectively, and 98%, 95% and 89% for those with CIRS 14. Regarding aaCCI, OS in patients with aaCCI≥3 after 1, 2 and 5 years was 94%, 82% and 76% respectively, and 97%, 93% and 88% for those with aaCCI 0-2. Multivariate analysis among CIRS, aaCCI, lymphoma histopathological grade and FLIPI2, revealed that only FLIPI 2 was independent prognostic parameter associated with worse OS (HR=18.18, 95% CI 2.359-140.134).
Summary and Conclusions: In the rituximab era prognostic index FLIPI2 still remains the most predictable value for OS in FL patients, while histopathological Gr 3 illustrated the different, more biologically aggressive form of disease. Among FL patients, aaCCI was associated with poorer outcome and should be calculated in this population.

E1158

TOXICITY AND EFFICACY OF BENDAMUSTINE IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AND INDOLENT LOW GRADE NON-HODGKINS LYMPHOMA (INHL); A MULTI-CENTRE OBSERVATION OF REAL LIFE EXPERIENCE IN THE UK

D. Murray[1,*] K.C. Thein[2], S. Basu[3], P. Bassett[4], S. Chaganti[1], S. Paneesha[5], S. Shafeek[2], V. Tandon[6], S. Francis[3]
[1]Clinical Haematology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, [2]Clinical Haematology, Worcester Acute Hospitals NHS Trust, Worcester, [3]Clinical Haematology, Royal Wolverhampton Hospitals NHS Trust, Wolverhampton, [4]Statsconsultancy Ltd, Amersham, [5]Clinical Haematology, Heart of England NHS Foundation Trust, Birmingham, [6]Clinical Haematology, Walsall Healthcare NHS Trust, Walsall, United Kingdom

Background: Bendamustine has shown resurgence as a new 'old' drug effective in both CLL and iNHL with a favorable side-effect profile (Rummel MJ et al, 2013, Lancet, 381:1203 & Fischer K et al, 2012, J Clin Oncol, 30:3209). Data outside of the trial setting is lacking.
Aims: To analyze the response rate and toxicity of bendamustine in a large heterogeneous cohort of patients treated in the United Kingdom.
Methods: We collected data on 161 patients treated with bendamustine over 2 years across 5 hospitals in the UK. Toxicity was assessed by red cell & platelet transfusion, hospital admissions, G-CSF use during admission and dose reduction. Univariate analysis of each factor assessed association with response, toxicity, progression-free survival (PFS) and overall survival (OS). PFS and OS were assessed by Cox regression.
Results: Mean age was 71 years (47-89). Diagnosis: CLL (n=108) and iNHL (n=53). Bendamustine was front line therapy in 57 patients (35%), relapse therapy in 104 (65%). ECOG performance status (PS) was 0-1 in 108 (67%)

patients (range 0-3). Treatment was part of a trial in 19 patients (12%). Median dose in CLL was 70mg/m2 and in iNHL 90mg/m2 (range 45-120), used as a single therapeutic agent in 20%, and combined with rituximab in 76%. Supportive therapy with septrin, anti-fungal and G-CSF was used in 64 (40%), 43 (27%) and 47 (29%) patients respectively. Improved response to bendamustine in the whole cohort significantly correlated with front-line use (p=0.02) and lower PS (p=0.01), but not age. In the CLL cohort, first line bendamustine overall response rate (ORR) was 90%, complete response (CR); 51%. In the CLL relapsed setting ORR was 76%, CR was 18%. Deletion of 17p and 11q did not impact on ORR. In the iNHL cohort, first line bendamustine ORR was 100%, CR was 53%. In the iNHL relapsed setting the ORR was 81%, CR of 28%. Age, bulky disease, stage or bone marrow involvement did not affect ORR in iNHL. Red cell transfusions were administered in 67 patients (43%), with higher PS predictive of this (p=0.03). Of these patients, only 35 (53%) received irradiated blood. Platelet transfusions were administered in 23 patients (15%). Admission during treatment occurred in 82 patients (53%), with male sex predictive of this (p=0.04). G-CSF administration during these admissions occurred in 28 patients (19%), with a higher number of co-morbidities predictive of this (p=0.008). Dose reduction after cycle 1 occurred in 17 patients (11%). Median PFS in all patients was 17 months, median OS was 29 months. In CLL median PFS was 16 months, median OS was 28 months. Deletion of 17p had no influence on OS (p=0.11) or PFS (p=0.25). In iNHL, median PFS was 21 months, median OS was 66 months (see figure 1). Poor performance status (p <0.001) and treatment in relapsed setting (p=0.04) predicted inferior PFS. In multivariate analysis higher performance status (p <0.001), female gender (p=0.04) and lower eGFR (p=0.004) predicted poorer OS.

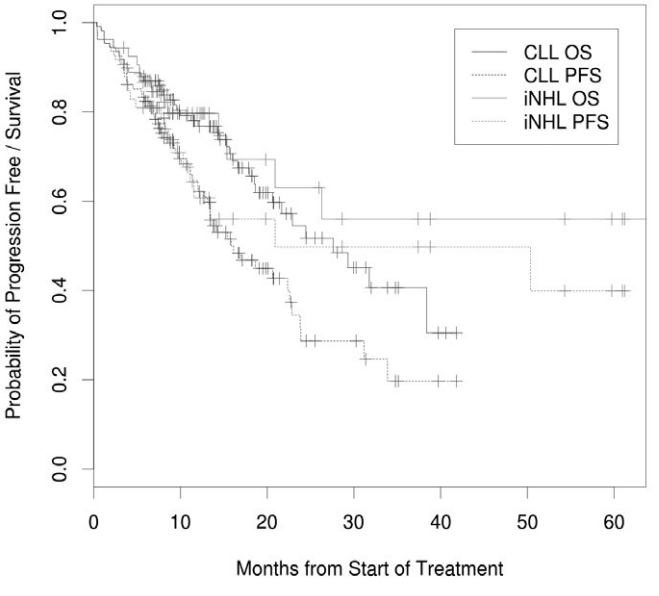

Figure 1. Overall PFS and OS for iNHL and CLL.

Summary and Conclusions: Our data suggests bendamustine is an effective therapy for CLL and iNHL. It delivers comparable efficacy to published trial data even in non-trial patients, particularly in front-line therapy. Of note, response in CLL was not affected by cytogenetic status. Similarly, response in iNHL was not affected by bulky disease or marrow involvement. In our study we found a high incidence of hospital admissions (53%) and blood product use. Several factors including gender, performance status, co-morbidities and renal function were found to independently correlate with toxicity. This study may help to improve patient selection for this chemotherapeutic agent.

E1159

MODELING THE EPIDEMIOLOGY OF FOLLICULAR LYMPHOMA (FL) IN FRANCE

X. Troussard[1,*] A. Herrera[2], E. Cornet[3], P. Solal-Céligny[4]
[1]Laboratoire d'hématologie biologique, CHU Caen - Hôpital de la Côte de Nacre, Caen, [2]Service Médecine interne immunologie, Hôpital Antoine-Béclère, Clamart, [3]Laboratoire d"hématologie biologique, CHU Caen - Hôpital de la Côte de Nacre, Caen, [4]Service d'Oncologie Médicale, ICO site Paul Papin / ICO site René Gauducheau, Angers / Saint Herblain, France

Background: As of 2014, there were few reliable publication sources of epidemiology data for Non-Hodgkin Lymphoma (NHL) in France, particularly with regard to indolent forms such as Follicular Lymphoma (FL). In addition, epidemiology registries provide useful data on disease incidence but no information is available on the number of relapsed FL patients. At the same time, new and effective drugs will be made available to the Hematologist/Oncologist community and thus, there will be an increase in the complexity of therapeutic algorithms.
Aims: The innovative modeling approach intends to offer a better understanding of the size of FL relapsed patient population in France. The objective of the model was to determine the yearly incidence of FL patients in first line and later lines of therapy between 2014 and 2018. Thus, the model provides relevant data to determine the patient population size that will be eligible for the new compounds and that could be implemented into a prospective economic model.
Methods: First, we used the "Registre Régional des Hémopathies Malignes de Basse-Normandie" (RRHMBN) to collect real world patient characteristics, such as patient subgroups and tumor staging. The RRHMBN is dedicated to Hematological malignancies and supported by official Health Authorities: "Institut National du Cancer"(INCA) and "Institut National de Veille Sanitaire" (INVS). Then, we applied these findings to the French National Network of Registers "FRANCIM" incidence and survival data. Thus, in 2014 the estimated number of patients with low risks (FLIPI 0-1, 36%) or high risk (FLIPI ≥2, 64%) is 985 and 1750 respectively. In 2018, it is estimated to reach 1151 and 2048 patients respectively. Afterwards, we applied progression free survival (PFS) results from medical literature for each standard of care treatment. The analysis showed that 36% of patients were classified FLIPI 0-1 and 60% of them had a stage I or II and they did not receive any treatment. 90% of patients with stages III/IV were treated by Rituximab alone (R) leading to a PFS equal to 26 months. Others patients stages III/IV and 90% of FLIPI≥2 were treated with Rituximab (R)−Cyclophosphamide (C)−Hydroxydaunorubicin (H)−Vincristine (O)−Prednisone (P) leading to a PFS equal to 42.2 months. For the remaining 10% of patients with FLIPI≥2, the Rituximab (R)−Cyclophosphamide (C))−Vincristine (O)−Prednisone (P) regimen led to a PFS equal to 34 months.
Results: The table below shows the yearly number of FL patients eligible for treatment in first and subsequent lines of therapy as produced by the model.

Table 1.

Category	Line of Therapy	2014	2016	2018
FL				
Stage I/II	1st line (L)	39	43	46
	≥ 2nd L	29	31	35
	Sub-total	68	74	81
Stage III/IV RCHOP	1st line (L)	1 755	1 898	2 052
	≥ 2nd L	1 086	1 174	1 271
	Sub-total	2 841	3 072	3 323
Stage III/IV RCVP	1st line (L)	350	379	410
	≥ 2nd L	238	258	278
	Sub-total	588	637	688
Total	1st line (L)	2 144	2 320	2 508
	≥ 2nd L	1 353	1 463	1 584
	Total FL population	3 497	3 783	4 092

Summary and Conclusions: Our modeling approach compensates for a lack of real world information on relapsed FL. We have shown that there is a significant number of relapsed patients who are in need of new treatments in France. The model produces estimates for the number of patients in later lines in need of novel therapies by 2018 and provides efficient prospective data that can be integrated into medico-economic model development. Furthermore, these data address a current unmet medical need for the development of new FL algorithms that are required for the upcoming therapies in the relapsed setting.

E1160

MANAGEMENT OF PRIMARY HEPATIC NON-HODGKIN'S LYMPHOMA AND CORRELATION WITH HCV INFECTION: EXCELLENT RESULTS WITH CONVENTIONAL CHEMOTHERAPY

C. Cerchione[1,*] A. De Renzo[1], M. Masarone[2], C. Cimmino[1], M. Persico[2], M. Notarangelo[1], F. Perna[1], C. Mainolfi[3], I. De Sio[4], G. Ciancia[5], M. Picardi[1], F. Pane[1]
[1]Hematology, AOU "Federico II", Napoli, [2]Hepatology, University of Salerno, Salerno, [3]Radiology, AOU "Federico II", [4]Internal Medicine, Second University, [5]Pathology, AOU "Federico II", Napoli, Italy

Background: Primary Hepatic (PHL) non-Hodgkin's Lymphoma is a rare entity, frequently associated with a poor prognosis. PHL was first described in 1965 by Ata el al and in 1986 Caccamo et al defined PHL as a localized lymphoma, limited to the liver without extrahepatic involvement. Small series of PHL have been reported, suggesting a non-fortuitous association with Hepatitis C Virus (HCV) infection. The prognosis is believed to be dismal, with early recurrence and short survival. To date, less than 150 cases have been published.
Aims: Eleven adult consecutive patients observed in our Division from 1990 to 2013 (median age: 58 years) fulfilled the diagnostic criteria for Primary Hepatic Lymphoma.
Methods: Our series of patients were derived from 1083 patients with non-

Hodgkin's Lymphoma observed in our institution in the same period (*i.e.* with a prevalence of 1.0% for PHL). We performed a study of the viral status and the result of cytotoxic treatment. The disease occurred in middle-aged patients (median age: 58 years). The main presenting complaint was right upper quadrant abdominal pain (4/11 patients). Tumor markers (Alfa-fetoprotein and CEA) were normal in 8 patients tested. Liver scans demonstrated either a solitary nodule or multiple lesions. Pathologic examination revealed diffuse large B cell lymphoma in seven patients, two cases of follicular lymphoma, one of small lymphocytic lymphoma and one case of T cell lymphoma. Eight patients (72%) were HCV-positive. Eight patients were treated with CHOP regimen (6 CHOP and 2 R-CHOP), two patients with R-FN, while a patient with a single focal lesion underwent to surgical treatment.
Results: The complete remission rate was 100% (11/11) after frontline therapy, and only one patient relapsed but underwent remission after additional chemotherapy courses; one of these patients, who had HCV-related cirrhosis, died because of hepato-renal syndrome, and another one died because of Acute Myeloid Leukemia.

Table 1.

NAME	CHEMO	ALIVE/ DEAD	DISEASE FREE SURVIVAL	OVERALL SURVIVAL FROM DIAGNOSIS
A.F.	R-CHOP X 6	ALIVE	86	91
C.M.	CEOP X 6	ALIVE	157	161
C.A.	CEOP X 6	ALIVE	200	204
M.A.	CHOP X 6	ALIVE	223	228
M.M.	R-CHOP X 6	ALIVE	120	123
P.F.	R-F X 6	ALIVE	39	44
P.R.	R-FN X 6	ALIVE	36	40
S.M.	CHOP X 6	DEAD	144	167
S.G.	CEOP X 6	ALIVE	188	192
T.L.	R-FN X 6	ALIVE	47	53
T.L.	R-FN X 6	ALIVE	114	119

Summary and Conclusions: Our study confirms the rarity of PHL. In our Division, the outcome of patients with PHL, who are treated with combination chemotherapy, seems excellent. The frequent association of PHL with HCV infection suggests a possible role of this virus in lymphomagenesis. HCV-infection does not appear to influence the outcome.

E1161

ORBITAL AND OCULAR ADNEXAL MALT LYMPHOMAS: A LONG-TERM OUTCOME

S. Park[1,*] M. Kim[2], S. Koh[2], K. Lee[2], J. Son[3], M. Kang[4], M. Hyun[5]
[1]hemato-oncology, Kyungpook University hospital, [2]hemato-oncology, [3]ophthalmology, [4]radio-oncology, [5]Yeungnam University hospital, Daegu, Korea, Republic Of

Background: OAML(ocular adnexal mucosa-associated lymphoid tissue type lymphoma) is uncommon but its incidence is constantly increasing. There have been many attempts to identify prognostic factors for OAML. Recently, a new staging system and treatment modalities have been developed.
Aims: We studied the clinical features of OAML and evaluated the effectiveness of radiotherapy as a treatment modality. We also studied prognostic factors correlated with overall and progression-free survival in patients with OAML.
Methods: Ninety-four patients who were diagnosed with OAML at Yeungnam University Hospital between 1995 and 2014 were enrolled. Information on the patient age, tumor location, symptoms, and biochemistry profiles were collected. Computed tomography (CT), magnetic resonance imaging (MRI), positron emission tomography (PET), and bone marrow biopsies were performed in order to establish the stage. Most patients were treated with external beam irradiation (median dose 30 Gy). Treatment response was evaluated by using orbital CT or PET. The progression-free survival was analyzed in patient subgroups classified according to tumor bilaterality, the Ki 67 index, and the TNM-based stage.
Results: The median follow-up duration was 48 months (range 2–220 months). The median progression-free survival was 42 months (range 2–202 months). The median overall survival was 92.5 months (range 3–236 months). Seven patients experienced relapses, and 5 patients died. The 5-year progression-free survival and overall survival rates were 94.7% and 96.8%, respectively. The relapse rate was 7.4%. In the radiotherapy-only group, 6 of 86 patients had recurrences, but they achieved remission after additional treatment. Twelve of the 86 patients in the radiotherapy-only group had remnant lesions, but a remission rate of 92% was achieved even without additional treatment. Cervical lymph node metastasis was identified in 1 of 84 patients who underwent imaging, and bone marrow involvement was observed in 1 of 92 patients who underwent biopsy. Lactate dehydrogenase and β_2-microglobulin levels were not found to be correlated with relapse. Statistical analysis did not identify any correlation between progression-free survival and tumor bilaterality, the Ki 67 index, or the tumor stage.
Summary and Conclusions: Patients with OAML have a good prognosis. Because of the high survival rate and low relapse rate of OAML, it is difficult to identify prognostic factors that influence progression-free survival. Moreover, owing to the rarity of patients with advanced stages of OAML, additional studies are necessary to identify the economic benefits of performing thorough staging procedures. We concluded that radiotherapy is a very effective treatment modality for localized OAML, supporting the findings of previous studies.

E1162

RITUXIMAB WITH OR WITHOUT CHLORAMBUCIL FOR THE TREATMENT OF EXTRANODAL MARGINAL ZONE B-CELL LYMPHOMA: RESULTS OF A MONOCENTRIC STUDY.

L. Rigacci[1,*] S. Kovalchuk[1], L. Mannelli[1], F. Lancia[1], G. Benelli[1], B. Puccini[1], A. Bosi[1]
[1]Haematology, AOU Careggi, Firenze, Italy

Background: Apart from localized gastric disease, there is no consensus on standard initial treatment of mucosa-associated lymphoid tissue lymphoma.
Aims: This study was launched to evaluate the use of Rituximab (R) alone or Rituximab plus Chlorambucil (RC) in patients not previously given systemic anticancer therapy.
Methods: All patients with histologically confirmed diagnosis of MALT lymphoma were selected from our data base. Only patients treated with R or RC were analyzed and evaluated. The scheme: rituximab 375 mg/sqm weekly for 4 doses, then monthly for 4 infusions alone or in combination with chlorambucil at the dosage of 0,1 mg/Kg/die for 45 days, then on days 1 to 15 monthly for 4 months.
Results: From January 2000 to February 2013, 136 patients with diagnosis of MALT lymphoma were diagnosed and treated in our Institution, 76 of them uniformly treated with R or RC. The median age at diagnosis was 68 years (range 32-85). In 20 patients the disease was localized in conjunctiva; 17 in the stomach; 14 in the lung; 13 in salivary glands; 3 intestine; 2 respectively in lacrimal gland, liver, skin; 1 in breast, cheek and tongue. Stage was IA in 63 patients (83%), IB in 1, IIA in 5 patients and IIB in 1, IIIA in 1 patient, IVA in 4 patients and IVB in 1. Bone marrow biopsy was negative in 59 patients, positive in 5 and not performed in 12 patients. The proliferative index was evaluated in 50 patients with Mib1 monoclonal antibody: 42 patients showed less than 30% of positivity and 8 had more than 30% of positivity. The diagnosis of MALT in 4 patients was associated with Sjogren Syndrome, in 4 patients with a positive HCV and in 1 with sclerodermia. According to treatment, 61 patients were treated with Rituximab plus Chlorambucil; 15 were treated with Rituximab alone.
At the end of treatment 68 patients (89%) obtained a complete remission and 7 (11%) a partial remission with an overall response rate of 100%. With a median observation period of 65 months (range 1-158) the overall survival was 88%. 9 patients died, 6 for disease progression (3 after a relapse) and 3 for causes not related to lymphoma. 12 patients (16%) relapsed, 8 of these patients were retreated with Rituximab and obtained a new complete remission. Both treatments were well tolerated without unexpected toxicities.
Summary and Conclusions: After a long follow-up the combination of Rituximab and Chlorambucil or Rituximab alone proved to be low toxic, feasible and effective therapy for MALT lymphomas.

Infectious diseases, supportive care

E1163

GRANULOCYTE TRANSFUSIONS IN THE TREATMENT OF SEVERE INFECTIONS DURING PROLONGED NEUTROPENIA: SINGLE CENTER EXPERIENCE IN YEARS 2005 - 2014

L. Vrablova[1], S. Blahutova[2], L. Raida[1], T. Szotkowski[1], J. Hubacek[1], R. Urbanova[1], P. Rohon[1], I. Maresova[1], L. Liskova[1], K. Indrak[1], Z. Cermakova[2], M. Kolar[3], T. Papajik[1], E. Faber[1,*]
[1]Hemato-Oncology, FACULTY HOSPITAL OLOMOUC; FACULTY OF MEDICINE AND DENTISTRY, PALACKY UNIVERSITY IN OLOMOUC, Olomouc, [2]Blood center, University Hospital Ostrava-Poruba, Ostrava-Poruba, [3]Microbiology, Faculty Hospital Olomouc, Faculty of Medicine and Dentistry, University Palacky, Olomouc, Olomouc, Czech Republic

Background: Use of granulocyte transfusions (GT) in patients with hematologic malignancy and prolonged neutropenia complicated with severe infection represents a strategy which positive and negative aspects are discussed.
Aims: To evaluate the efficacy and safety of GT applied over the last ten years period (2005-2014).
Methods: A single center retrospective analysis was performed. GT were collected after stimulation with 40mg i.v. Solu-Medrol from unrelated AB0 and Rh compatible donors. HLA compatibility was not evaluated and family donors were not used. Separation was performed at Cobe Spectra - Caridian BCT blood separator. GT were stored at room temperature and given to the patients on the day of collection after irradiation of the packs with 32 Gy using Gammacell 3000 Elan blood irradiator (Cs^{137}). Decisions to give GT in individual patients were made collectively after agreement minimally of 3 physicians (usually patients´ physician, head of the ward and head of Department). Decisions to stop GT treatment were taken according to clinical response to GT and degree of hematologic reconstitution. All patients were pre-medicated with Hydrocortison 100mg i.v. given immediately prior transfusion.
Results: GT were given to 41 patients (15 female and 26 male) at age from 22 to 69 years (median 45.5). There were 26 cases of acute leukemia, 7 patients with myelodysplastic syndrome, 5 patients with chronic lymphocytic leukemia and 3 patients with lymphoma. In most patients disease was active at the time of GT initiation (30; 73.2%), only 11 patients were in hematologic remission. 30 patients were after chemotherapy while 3 patients were after allogeneic hematopoietic stem cell transplantation. Duration of severe neutropenia (less than $0.5x10^9$/l) was from 4 to 80 days (median 19 days). Antibiotics were applied in all patients for 1 to 126 days (median 14 days) before initiation of GT. The main clinical indications were soft-tissue inflammations (26 cases) and pneumonias (16). 14 patients have suffered from proven invasive fungal infections (9 aspergilosis and 5 candidiasis) while coincident Gram-positive or Gram-negative sepsis was present in 9 and 16 cases, respectively, complicated in 12 patients with septic shock. Together 191 GT were given – in a single patient from 1 to 17 GT (median 3.5). GT contained from 0.5 to $3.0x10^{10}$ granulocytes per one transfusion unit (median $1.3x10^{10}$). No side-effects both in donors and patients were recorded. Decrease of fever, complete resolution of infection and clinical improvement after GT was observed in 36 (87.8%), 29 (72.5%) and 34 (82.9%) of patients, respectively. Clinical deterioration occurred in 6 (14.6%) patients (4 – 9.8% – of these were fatalities). In six patients immediately after GT treatment allogeneic stem cell transplantation was performed. We have not observed any significant clinical consequences of GT in these patients after transplantation, one patient transplanted with active disease died early after relapse of acute leukemia while all other patients achieved full donor chimerism with remission of hematologic disorder.
Summary and Conclusions: We can conclude, that in our hands GT harvested from unrelated donors after stimulation with steroids and transfused in selected patients with severe infections during prolonged neutropenia have a high efficacy and safety and enabled not only successful management of infections in most cases but also safe proceeding to allogeneic stem cell transplantation leading to cure in a significant proportion of our patients. Acknowledgement: Grant of IGA LF UP 01-2015.

E1164

INDUCTION PHASE INFECTIONS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA AND IMPACT OF STEROID DOSE ON THE INCIDENCE OF INFECTIONS: A RANDOMIZED CONTROLLED STUDY

T. Bayhan[1,*] S. Unal[1], B. Tavil[1], S. Aytac[1], B. Kuskonmaz[1], T. Tastemel[2], S.D. Canoruc[2], M. Tuncer[1], M. Cetin[1], F. Gümrük[1]
[1]Division of Pediatric Hematology, [2]Department of Pediatrics, Hacettepe University, Ankara, Turkey

Background: Infection is the most common cause of treatment related mortality in childhood acute lymphoblastic leukemia (ALL). Patients with ALL are prone to infections especially during induction phase of treatment.
Aims: Aim of the study is to determine incidence of common infections and infectious agents in pediatric patients with ALL during induction phase of treatment, and compare the infection frequency between the groups treated with 10 mg/kg or 20 mg/kg high dose methylprednisolone (MPZ).
Methods: Pediatric patients newly diagnosed with ALL between 2008 and 2014 were enrolled. Patients were treated according to modified St Jude Total XV Protocol, and they were randomized for high dose MPZ treatment, which was given for seven days before induction treatment at a dose of 10 mg/kg or 20 mg/kg orally. A retrospective data review, from electronical database and paper files, was performed. The incidences of diarrhea, pneumonia, neutropenic fever, typhlitis, fungal infections, use of antifungal agents, mucositis, vancomycin resistant enterococci colonization during induction phase were recorded.
Results: A total of 154 patients with newly diagnosed ALL were included in the study. Median age of patients at diagnosis was 5 (1-19) years. Neutropenic fever occurred in 87 (56.5%) of patients (Table 1), 30 of patients had neutropenic fever two or more times. Median duration of neutropenic fever was 2 (1-15) days. Microorganisms isolated in peripheral blood, central venous catheter (CVC), or urine samples in 48 (31.2%) of the patients. In peripheral blood cultures gram positive/negative ratio was 2.9, in CVC cultures this ratio was 3. CVC infection was detected in 42 (27.3%) of patients. Fungal infection was seen in 10 (6.5%) of patients. Infection related mortality occurred in 4 (2.6%) patients at induction, and one patient died due to tumor lysis syndrome at the induction phase. Of the patients, 141 were available for comparison of infection rates according to MPZ dose (78 received 10mg/kg, and 63 received 20 mg/kg MPZ). Only diarrhea frequency was statistically significantly more common in group treated with 20mg/kg dose of MPZ (*p*; 0,02).

Table 1. Infection rates in induction phase

Characteristics	n (%)
Neutropenic fever	87 (56.5%)
Catheter infection	42 (27.2%)
Diarrhea	33 (21.4%)
Mucositis	31 (20.1%)
Pneumonia	26 (16.9%)
Cellulitis, skin infections	14 (9%)
Fungal infection	10 (6.5%)
VRE colonization	13 (8.4%)
Typhilitis	5 (3.2%)

Summary and Conclusions: Our study revealed that 56.5% of patients had experienced neutropenic fever during induction phase. Catheter infections were among the most common reason of infections. Gram positive bacterial infections were seen three times more frequent than gram negatives in both peripheral blood stream and central venous catheters. In our study majority of induction deaths was secondary to infections (4/5). Additionally, the higher doses of MPZ had no impact on the rates of the various infections except for diarrhea and diarrhea was more common among the dose of 20 mg/kg group that might be related to oral application of the drug.

E1165

RELATIVE DOSE INTENSITY OF CHEMOTHERAPY AND PREVENTION OF FEBRILE NEUTROPENIA WITH BIOSIMILAR FILGRASTIM: A MULTICENTRIC OBSERVATIONAL STUDY OF 633 LYMPHOID MALIGNANCY PATIENTS (THE ZOHÉ STUDY)

P. Rodon[1,*] G. Damaj[2], G. Salles[3], B. Bareau[4], I. Gasnereau[5], C. Aubron-Olivier[5], C. Haïoun[6], P. Solal-Céligny[7]
[1]Hematologie-Oncologie, Centre Hospitalier, Perigueux, [2]Dept of hematology, University hospital, school of medicine, Caen, [3]Hematologie, Hospices Civils de Lyon – Université Claude Bernard, Pierre Benite, [4]Hématologie / Médecine, Hôpital Privé Sévigné, Générale de Santé, City Cesson Sévigné, [5]Sandoz France, Levallois-Perret, [6]CHU. Henri Mondor, Creteil, [7]Institut de cancérologie de l'Ouest, Saint-Herbalin, France

Background: Guidelines recommend granulocyte-colony stimulating factor (G-CSF) use to reduce the risk of neutropenic infections in patients receiving chemotherapy (CT) and to enable full-dose delivery. ZOHé is a French prospective non-interventional, longitudinal study describing biosimilar filgrastim (Zarzio®) use in routine practice, in patients receiving CT for solid tumor or lymphoid malignancies (LM).
Aims: To describe patients, Zarzio® treatment patterns, relative dose intensity (RDI) maintenance and outcomes in the LM cohort.
Methods: Patients ≥18 years old receiving treatment for LM were recruited. This analysis reports the impact in real life of EORTC guidelines on G-CSF prophylaxis for chemotherapy-induced febrile neutropenia (CIN/FN). Zarzio® treatment characteristics along with CT in terms of dose, day of initiation, duration and proportion of patients for which CT RDI was conserved (dose maintained in ≥85% of CT cycles) have been recorded. Data were collected at Zarzio® initiation time and 3 months after inclusion.
Results: 633 evaluable patients were recruited from June 2013 to April 2014. 32 patients (5%) received a CT regimen associated with a FN risk ≥20% justifying by itself the G-CSF prophylaxis. However, in patients receiving CT regimen with FN risk of <10%, 10-20% or unknown, the vast majority (586, 97.5 %) had at

least one risk factor for increased incidence of FN such as elderly patients (aged 65 and over) or advanced disease stage. Prophylaxis was initiated as either primary or secondary in 427 (67.5%) and 206 (32.5%) patients respectively. Zarzio® was started on average 6.5±2.2 days (median=6) after CT and given for 5.9±1.7 days (median=5). Dosing was 30MIU/day in 80%, 48MIU/day in 20% of the cases. 16.7% of patients developed at least one Grade 3 or 4 CIN episode of which 4.9% were febrile. CIN/FN-related hospitalizations were experienced by 5.7% of patients. 420 patients were evaluable for RDI (data collection was optional): the majority of patients 85.2% had a preserved RDI over 3 months follow-up (table). 37 non serious adverse events (AE) considered to be related to G-CSF by the investigator were recorded. One AE led to a modification of Zarzio® dose, 7 to Zarzio® treatment discontinuation.

Table 1. Relative dose intensity maintenance

Table: Relative dose intensity maintenance	Patients (n=420)		
	NHL (n=266)	HL (n=56)	Other chronic lymphoproliferative disorders (n=98)
Mean RDI (% ± SD)	94.1 ± 24.5	95.8 ± 25.8	92.4 ± 23.2
Median RDI (%, (Min-Max))	100 (0-266.7)	100 (16.7-200.3)	100 (0-138.4)
RDI conserved (n, (%))			
Yes	230 (86.5)	48 (85.7)	80 (81.6)
No	36 (13.5)	8 (14.3)	18 (18.4)

Summary and Conclusions: In this routine practice French cohort BS filgrastim (Zarzio®) appears effective for RDI maintenance in the vast majority of the patients. According to the EORTC guidelines, Zarzio® was initiated on primary prophylaxis treatment in 67.5% of patients and mostly at day 6 after CT.

E1166

BK VIRUS-HEMORRHAGIC CYSTITIS FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION: CLINICAL CHARACTERISTICS AND UTILITY OF LEFLUNOMIDE TREATMENT

Y.H. Park[1,*] J.H. Lim[1], H.G. Yi[1], M.H. Lee[1], C.S. Kim[1]
[1]Hematology and Oncology, Inha University Hospital, University of Inha College of Medicine, Incheon, Korea, Republic Of

Background: BK virus-hemorrhagic cystitis (BKV-HC) is a potential cause of morbidity and mortality in patients having undergone allogeneic stem cell transplantation (Allo-SCT).
Aims: We analyzed the clinical features of BKV-HC following Allo-SCT and discussed the utility of leflunomode therapy for BKV-HC.
Methods: From January 2005 to June 2014, among the 69 patients underwent Allo-SCT in our institution, the patients who experienced BKV-HC were investigated retrospectively. BK virus was confirmed by a qualitative PCR-based assay. Severity of HC was graded as: grade 0 (no hematuria), grade I (microscopic), grade 2 (macroscopic), grade 3 (macroscopic hematuria with presence of blood clots), and grade 4 (macroscopic hematuria clots and renal impairment due to urinary obstruction). Grade 3 and 4 were defined as high-grade HC. Complete response (CR) was defined as complete improvement in symptoms without hematuria; partial response (PR), downgrading of severity with persistent hematuria; no response (NR), unchanged or worsening urinary symptoms.
Results: HC was observed in 30 patients (43.5%), and among them, 18 patients (26.1%) were identified as BKV-HC. The median patients' age (12 males and 6 females) was 45 years (range, 13-63). The diagnosis of the patients were acute myeloid leukemia (AML, n=11), aplastic anemia (n=4), myelodysplastic syndrome (MDS, n=2), and non-Hodgkin lymphoma (n=1). The donor types were a HLA-matched sibling donor for 6 patients, HLA-matched unrelated donor for 9, and a haploidentical familial donor for 2. Nine patients (52.9%) received myeloablative conditioning regimen. Seven (38.9%) of patients received antithymoglobulin containing preparative regimen for *in vivo* T-cell depletion. The median onset and duration of BKV-HC was on day 21 (range, 7-97) after transplantation and 22 days (range, 6-107). There was no significant difference between the onset in patients with low-grade HC or with high-grade HC (21 days *vs* 21 days, p=0.633). Half of the patients had an acute graft-versus-host-disease (GVHD). Among them, seven (77.7%) patients developed an acute GVHD after onset of BKV-HC and, conversely, 2 (22.3%) patients developed a BKV-HC after the diagnosis of acute GVHD. Nine (50.0%) patients had concomitant cytomegalovirus viremia. Eleven patients (62.1%) had grade I-II HC and 7 patients (38.9%) had high-grade HC. Majority of the patients received supportive treatment, including intravenous hydration and/or blood transfusion. Urinary urethra catheter was inserted in 3 patients with grade 3 HC and 2 patients with grade 4 HC. After supportive care, treatment results showed that 9 patients (50.0%) achieved CR, 4 patients (22.2%) PR, and 5 patients (27.8%) NR. Out of the 7 patients who had high-grade HC, 1 had CR, 1 PR, and 5 NR, respectively. Among the 5 unresponders, one died of BKV-HC associated renal failure. The remaining 4 patients (3 AML and 1 high-risk MDS) were treated with leflunomide and tolerated well, with 3 patients having mild gastrointestinal symptoms, including anorexia and abdominal bloating. After leflunomide treatment, 2 (50%) patients achieved CR and 2 (50%) achieved PR. The median duration from the start of leflunomide therapy to response was 13 days (range, 8–17). There was no recurrence of hematuria in 2 patients achieving CR after discontinuation of leflunomide therapy.
Summary and Conclusions: BKV-HC was commonly observed in patients with HC following Allo-SCT. In high-grade BKV-HC patients who fail supportive care, leflunomide may be a feasible option without significant toxicity.

E1167

A COMPARISON OF ORAL LEVOFLOXACIN AND CEFEPIME IN PATIENTS WITH LOW-RISK FEBRILE NEUTROPENIA BY THE JAPAN FEBRILE NEUTROPENIA STUDY GROUP

I. Yoshida[1,*] K. Tamura[2], I. Oze[3], T. Takahashi[4], M. Hino[5], K. Hatanaka[6], Y. Nakao[5], H. Narumi[7], T. Itoh[8], K. Ohyashiki[9], M. Tanimoto[10], A. Urabe[11], A. Kanamaru[12], T. Masaoka[13]

Background: Febrile neutropenia(FN) is a known severe adverse event in cancer patients undergoing chemotherapy. However, It is known that there is a group of patients with FN who falls into low risk for developing severe complications.
Aims: To determine whether low risk FN can be managed with oral antimicrobials, we conducted prospective study to evaluate oral use of levofloxacin (LVFX) .
Methods: We conducted a multicenter prospective study on cancer patients with low risk FN. Eleven institutions participated in the study which was approved by the institutional review board of each institution. Low risk was determined based on the Multinational Association of Supportive Care in Cancer (MASCC) score. After chemotherapy, only those patients with a neutrophil count of less than 500/μL, or less than 1,000/μL but expected to fall below 500/μL, and a recorded body temperature of over 38.0°C once or 37.5°C persistently for 1 hour were enrolled in the study. It consists of two components, *i.e.* either non-randomized treatment with LVFX or randomized treatment in which patients received either oral LVFX or intravenous cefepime (CFPM), a broad-spectrum cephalosporine. Primary endpoint is treatment success at 7th day; success is defined as defervescence and improvement in clinical symptoms and laboratory results. Secondary endpoints are safety profiles for 7-day study period and survival at 30th day.
Results: A total of 65 patients were enrolled. The results were analyzed as per protocol parameters. In the CFPM group (n=24), treatment success at 7th day was 66.7% (95%CI, 44.68-84.67), while In the LVFX group (n=41), it was 53.7% (95%CI, 37.42-69.34). The difference was not statistically significant (p=0.304). Serious adverse events were not observed in either group. All patients were alive at 30th day.
Summary and Conclusions: The study did not show a significant difference in effect or safety profiles between LVFX and CFPM in low risk FN, although the number of patients was too small. However, since all patients in the LVFX group survived at 30th day with no sequelae, oral use of LVFX could be considered a treatment option in low risk patients.

E1168

LONGITUDINAL RISK OF HERPES ZOSTER IN PATIENTS WITH NON-HODGKIN LYMPHOMA RECEIVING CHEMOTHERAPY: A NATIONWIDE POPULATION-BASED STUDY

S.F. Cho[1,*] W.H. Wu[2], C.S. Chang[3]
[1]Division of Hematology & Oncology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, [2] School of Medicine, I-Shou University, [3]Division of Hematology and Oncology, E-Da Hospital, Kaohsiung, Taiwan, ROC

Background: The outcome of patients with non-Hodgkin lymphoma (NHL) was improved in recent decades, the treatment related adverse events on the quality of life may be emerging as an issue.
Aims: This study aims to evaluate the incidence rate and risk factors of herpes zoster in patients with NHL receiving anti-lymphoma treatment.
Methods: This study was conducted using the National Health Insurance Research Database (NHIRD) of Taiwan. The study cohort included patients with NHL between 2002 and 2008. Propensity score matching was performed to correct for sample selection bias. Logistic regression analyses were performed to obtain odds ratios (ORs) and 95% confidence intervals (95% CIs) for the risk evaluations.

Results: From 2002 to 2008, there were 3865 NHL patients with median age of 55 years who received CHOP/CEOP or R-CHOP/R-CEOP as front-line treatments; 2188 of these patients received CHOP/CEOP, and 1677 patients received R-CHOP/R-CEOP. The overall incidence rate of herpes zoster was 12.21% (472/3865); 11.79% (258/2188) of the patients received conventional chemotherapy and 12.76% (214/1677) of the patients received rituximab-containing chemotherapy. For the patients who received conventional chemotherapy, the risk factors included female gender, multiple courses of chemotherapy and autologous hematopoietic stem cell transplantation. For the patients who received rituximab-containing chemotherapy, the risk factors included female gender, diabetes mellitus, multiple courses of chemotherapy, autologous hematopoietic stem cell transplantation and higher accumulated rituximab dose. The analysis of the cumulative incidence rate revealed that the majority of the herpes zoster episodes occurred within the first two years after the diagnosis of NHL. After adjusting for the propensity score matching, rituximab-containing chemotherapy was not associated with a higher overall incidence rate of herpes zoster (p: 0.155). However, the addition of rituximab to conventional chemotherapy increased the short-term risk of herpes zoster with adjusted ORs of 1.38 (95% CI=1.05-1.81, p:0.021) and 1.37 (95% CI=1.08-1.73, p:0.010) during the 1-year and 2-year follow-up periods, respectively.
Summary and Conclusions: This nationwide population-based study evaluated the incidence rate and risk factors of herpes zoster in NHL patients who were receiving anti-lymphoma therapy. The incorporation of rituximab into conventional chemotherapy increased the short-term risk of herpes zoster.

E1169

MACROPHAGES FROM SEPSIS SURVIVING MICE PRESENT DIFFERENTIAL GENE EXPRESSION ASSOCIATED WITH AN IMMUNOTOLERANT PROFILE

J.M. Mota[1,*] V. Wagatsuma[2], J. Temporal[3], F. Cunha[4], H. Noushmehr[2], E. Rego[1]
[1]Clinics, [2]Bioinformatics, [3]Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil, [4]Pharmacology, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil

Background: Sepsis survivors are at a higher risk to present abnormalities of the immune system and die of secondary infections caused by low virulence pathogens. Such immunosuppressive state may favor tumorigenesis and experimental data obtained in murine models showed that sepsis led to expansion of regulatory T cells (Tregs) and macrophage polarization towards M2-like phenotype (characterized by high IL-10 production accompanied by low production of IL-12 and associated with suppression of T cell responses).
Aims: To report how sepsis affects the gene expression profile of macrophages.
Methods: C57Bl/6 mice were anesthetized and submitted to cecal and ligation puncture to induce severe sepsis. Naïve mice were used as controls. All animals received ertapenem 20 mg/kg ip. 6 h after surgery and bid for 3 days. Survivors (50%) were killed for bone marrow harvesting at day 15. Macrophages were differentiated using sarcoma L929 supernatant and adherent cells were collected after 7 days. M1 and M2-macrophage were used as controls and polarized through IFN-γ (50 ng/mL) plus LPS (10 ng/mL) and IL-10 (20 ng/mL), respectively. Naïve mice were inoculated with bone marrow-derived macrophage (BMDM) (10,000 cells) plus B16 melanoma (30,000 cells). Tumor growth and survival were assessed. RNA from isolated BMDM was isolated by columns and the cDNA was labeled and put in microarray slides. Data was analyzed using R (version 3.1.2, 2014-10-3) and Bioconductor (version 2.14). Differential gene expression was considered significant with a fold change of 20 for up and -2.0 for down-regulated genes and p <0.01. Pathway analyses were made through Nextbio. Data were deposited at GEO database (code GSE64498).
Results: Tumor growth was increased and overall survival was reduced in the group inoculated with BMDM from post-sepsis mice, compared with those who received BMDM obtained from naïve mice. In the microarray analysis, a set of 64 genes were up-regulated and 94 genes were found to be down-regulated. Genes related to innate immunity (*e.g.* Ccl5, Cxcl16, C3, Cfb, Ccr5 Tlr7 and Ccl8) and interferon alpha/beta signaling (*e.g.* Oasl1, Ifit3, Ifit2, Irf7 and Ifit1) were in general down-regulated. Also, several genes that encode chemotactic mediators were up-regulated (*e.g.* Ccl2, Ccl7, Ccl12) in BMDM from post-sepsis mice.
Summary and Conclusions: BMDM obtained from sepsis surviving mice present differential gene expression associated with an immunotolerant profile.

E1170

VIRAL RESPIRATORY TRACT INFECTIONS IN CHILDREN WITH MALIGNANCY: ISTANBUL PERSPECTIVE

Z. Karakas[1,*] S. Aydogdu[1], A.G. Gencay[1], E. Uysalol[1], S. Karaman[1], A. Somer[2], N. Salman[2], S. Badur[3]
[1]Pediatric Hematology, [2]Pediatric Infectious Disease, [3]Microbiology, Istanbul University, Istanbul Medical Faculty, Istanbul/, Turkey

Background: Viral infections can cause a variety of clinical pictures in children on immunosuppression. RSV is the most commonly encountered viral respiratory pathogen in oncology patients, with parainfluenza virus (PIV) types 1, 3, 2, rhinovirus, influenza A and B following in order of decreasing frequency.
Aims: To evaluate the viral respiratory tract infections in children with malignancy
Methods: In this study, nasopharyngeal specimens were obtained from chidren in our Hematology-Oncology clinic who had such respiratory symptoms as fever, rhinorrhea, sneezing, cough or findings consistend with pneumonia on auscultation or imaging and also from patients who shared a room with them. Appropriate antiviral therapy was instituted after evaluation of the samples, namely, ribavirin po for 14 days for those positive for RSV and their roommates, and oseltamivir po for 5 days for those positive for influenza and their roommates.
Results: Between October 1st 2013 and February 15th 2015, a variety of viral respiratory pathogens were identified on specimens obtained on 32 occasions from 26 patients who were admitted due to a variety of malignancies, namely, acute lymphoblastic leukemia, acute myeloblastic leukemia and lymphomas. The alarming symptom was cough in 19 episodes (59.3%), fever in 4 episodes (12.5%), fever and cough in 9 episodes (%28.2). Pneumonia was diagnosed through pysical examination and imaging on 8 episodes (%24.2). 14 patients received ribavirin po, 6 patients received oseltamivir po and 15 of these patients also received intravenous immunoglobulin due to an IgG level below 500 mg/dL. Most of our patients had mixed infections where 2,3 or 4 pathogens were identified (RSV +PIV 2-3, hMPV +ADV, RSV +PIV4, RSV +rhinovirus, RSV +HBovCor229 +CorHKU, Corona63 +Corona43 +CoronaHKU +rhinovirus, ADV +rhinovirus, rhinovirus +Corona 63, RSV +rhinovirus +HBovCorona229 +ADV +hMPV, coronavirus +influenza A). 11 of the patients had rhinovirus, with 4 having rhinovirus only and 7 having rhinovirus and other viruses), 9 had coronavirus (3 had coronavirus 43, 1 had coronavirus 229, 2 had coronavirus 63, 2 had coronaHKU), 10 patients had RSV, with 4 having it in isolation and 6 having it as part of a mixed infection. 6 patients had parainfluenza viruses, with 4 having PIV only and 2 having a mixed infection. 2 patients each had human bocavirus, ADV and hMPV. 5 patients had influenza A (4 were H1N1 and 1 was H3N2), one patient had influenza B. Six of our patients got infected with different respiratory viruses at different times (Table). Eight patiens were given antivirals despite their lack of symptoms as prophylaxis because they shared a room with an infected patient. One patient who had familial hemophagocytic lymphohistiocytosis was younger than 6 months and therefore could not receive ribavirin. One patient with ALL was positive for CoronaHKU and H1N1, and received IVIG and oseltamivir and had to be transfered to the intensive care unit due to respiratory distress, hypotension and shock.

Table 1.

TABLE: Viral agent, clinic presentation and treatment

Patient (n,%)	Viral Agent	Syptom	Clinic presentation	Treatment
4 (12,5%)	RSV	Fever	URTI, pneuomonia	Ribavirin+IVIG (if IgG<500 mg/dl)
3 (9,3%)	INF A	Cough	URTI	Oseltavimir+IVIG(if IgG<500 mg/dl)
4 (12,5%)	RHINO	Cough	URTI	Supportive
1 (3,1%)	INF B	Cough	URTI	Supportive
4 (12,5%)	PARAINF V.	Cough, fever	URTI	Supportive
2 (6,2%)	METAPNEUMO V+ OTHERS	Cough	URTI	IVIG (if IgG<500 mg/dl)
4 (12,5%)	RSV+RHINO	Cough, fever	URTI	Ribavirin IVIG(if IgG<500 mg/dl
1 (3,1%)	H1N1+OTHER	Cough, fever	URTI, pneuomonia	Oseltavimir+IVIG(if IgG<500 mg/dl)
3 (9,3%)	RSV+OTHER	Cough	URTI, pneuomonia	Ribavirin+IVIG (if IgG<500 mg/dl)
3 (9,3%)	CORONA VIRUSES	Cough	URTI	Supportive
3 (9,3%)	RHINO+OTHER	Cough	URTI	Supportive

RSV:Respiratory syncytial virüs H1N1: İnfluenza A virüs Rhino:Rhino virüs İnf B:İnfluenza B virüs, Parainf: Para influenza virüs Metapneumo V+Others: Metapneumo virus, Adeno virüs, Corona virüs 229 İnfluenza A+Others: İnfluenza A, Corona HKU RSV+Others: RSV, Parainfluenza virüs 2,3,4, Human Boca Virus, Rhino virus Corona viruses: Corona 63, Corona HKU, Corona OC43 Rhino+Other: Rhinovirus, Corona virüs 63, URTI:Upper respiratory tract infection

Summary and Conclusions: Viral infections of the respiratory tract can kill immunocompromized children. Early diagnosis, close monitoring and treatment with antivirals and IVIG for those infected with influenza A and RSV, and meticulous supportive care for those infected with other viruses are needed to prevent mortality.

E1171

NEUTROPHIL CD64 INDEX AS A BIOMARKER OF EARLY SEPSIS IN MALIGNANT HEMATOLOGIC DISEASE

S. yuxi[1,*] W. liru[1]
[1]Hematology, Fu-xing Hospital, Capital Medical University, Beijing, China, Beijing, China

Background: Malignant hematologic disease with sepsis has been character-

ized by high mortality and difficulties in diagnosis at early stage. A good biomarker may help us to improve the accuracy of diagnosis and to reduce the mortality rate.
Aims: The aim of this study was to investigate the usefulness of neutrophil CD64 expression in blood and procalcitonin (PCT) in the early diagnosis of sepsis in malignant hematologic disease.
Methods: Ninety-seven hematological malignancies were enrolled in the study. Sixty-three hematological malignancies were classified into three groups: no infection (n=35), local infection (n=20) and sepsis (n=43). Another 20 healthy people were included as a control group. Blood samples were collected within 24 hours after admission for neutrophilic CD64 index and neutrophilic CD163 index. Procalcitonin (PCT), high-sensitivity C-reactive protein (hs-CRP) were also determined in all groups.
Results: CD64 index and CD163 index did not differ between control group and no infection group (P>0.05); CD64 index were significantly increased in the groups with local infection and sepsis compared to the group without infection (P<0.0001); CD64 index were also significantly increased in the group with sepsis compared to the group with local infection (P<0.0001); The sensitivity, specificity, overall area under the receiver operating characteristic curve of CD64 index, CD163 index, PCT and hs-CRP for the diagnosis of early sepsis were determined. CD64 index had the highest sensitivity of 68.9%, specificity of 85% and overall area of 0.739 using a cut-off of > or =2.195. The cut-off value, highest sensitivity, specificity and overall area were 0.13ng/ml, 81.4%, 60% and 0.732 for PCT, 30.15mg/L, 79.1%, 60% and 0.716 for hs-CRP, and 448.895, 88.4%, 30% and 0.535 for CD163 index.
Summary and Conclusions: We conclude that neutrophil CD64 index can be incorporated with specific hematologic criteria as an additional marker for diagnosis of early sepsis in hematological malignancies.

E1172

FIVE CASES OF PNEUMOCYSTIS PNEUMONIA (PCP) INFECTION IN PATIENTS FOLLOWING TREATMENT WITH BENDAMUSTINE/RITUXIMAB: PROPHYLAXIS SHOULD BE CONSIDERED AS STANDARD PRACTICE

E. Groarke[1,*] T.M. Abkur[1], M. Saeed[1], S.Z. Ahmed[1], R. McArthur[1], J. Nally[2], M. Leahy[1], H. O'Leary[1], D. O'Keeffe[1]
[1]Department of Haematology, [2]Department of Pharmacy, University Hospital Limerick, Limerick, Ireland

Background: Pneumocystis pneumonia (PCP) is a life threatening infection associated with immunocompromised patients. It was initially described in HIV patients but is also well described following certain chemotherapy agents. It has a high morality rate, particularly in non-HIV patients (35 – 50%)[1]. PCP prophylaxis has been shown to effectively prevent PCP in at risk patients. Bendamustine is an alkylating chemotherapy agent, which is being increasingly used in clinical practice, particularly in treatment of lymphoproliferative disorders and myeloma. It is known to cause grade 3-4 lymphopenia in 74% of patients[2]. At present there is no standard recommendation for PCP prophylaxis with bendamustine treatment.
Aims: Identify all cases of PCP following bendamustine treatment in our unit and assess factors which increase the risk of infection.
Methods: Patients with a confirmed diagnosis of PCP who had received bendamustine were identified. Their case notes and investigations were reviewed.
Results: Seventy-two patients received bendamustine therapy between November 2009-February 2015. We identified five cases of PCP in our institution in patients undergoing treatment with bendamustine / rituximab (6.9%). Four cases of PCP occurred prior to routine introduction of PCP prophylaxis (August 2012) and 1 case occurred subsequently in a patient whose prophylaxis had been stopped. The patients infected consisted of 3 males and 2 females (average age of 69.6 years). Two patients received treatment for low grade Non Hodgkin Lymphoma (NHL), 2 for Chronic Lymphocytic Leukmaemia (CLL) and 1 patient received treatment for Waldenstrom's Macroglobulinemia (WM). None of our patients were on PCP prophylaxis at the time of infection. All infections were clinically and radiologically suggestive of PCP and 4 were confirmed using quantitative PCR on sputum samples. Four patients were undergoing treatment with bendamustine / rituximab at the time of infection (ranging from cycle 1-3 of treatment). One patient completed treatment twelve months earlier. All patients were lymphopenic (<0.5) at time of infection (average 0.18), 2 patients had a sustained lymphopenia (>2 weeks) prior to infection, and 4 had evidence of hypogammaglobulinemia prior to infection (average IgG 3.48, IgA 1.49, IgM 2.82).
Summary and Conclusions: PCP infection is common following bendamustine /rituximab treatment. It can occur during the first course of treatment and it occured up to twelve months after treatment in our patient cohort. Patients with severe lymphopenia (<0.5) and hypogammaglulinemia appear to be at particularily high risk of PCP infection. We recommend that all patients who receive bendamustine / rituximab treatment should be considered for PCP prophylaxis from the start of treatment and it then should be continued until adequate lymphocyte recovery occurs.

SEVUPARIN DEMONSTRATES ANTI-ADHESIVE EFFECTS IN MALARIA PATIENTS SUGGESTING ITS POTENTIAL CLINICAL BENEFITS IN SEVERE MALARIA AND SICKLE CELL DISEASE

A.M. Leitgeb[1,*] E. Holmer[1], M. Lindgren[1], M. Wahlgren[2], A.M. Dondorp[3]
[1]Dilaforette AB, Solna, [2]Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden, [3]Mahidol Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine Mahdiol University, Bangkok, Thailand

Background: Microvascular obstruction is one of the main pathological events leading to the development of severe falciparum malaria and pain during vaso-occlusive crises (VOC) in sickle cell disease (SCD) patients. Excessive sequestration of *falciparum* infected red blood cells (IRBC) in malaria, and of sickle blood cells (SSRBC) in SCD are typical features of severe states of these diseases. The *falciparum* parasite and the SSRBC employ heparan sulfate (HS) during the process of adherence to the endothelium and to other blood cells causing obstructions of the blood flow. Inhibition of these abnormal cell and pathogen interactions with sevuparin working as a decoy receptor could restore a hampered blood flow and stop the parasite growth. Heparin and low molecular weight heparins (LMWHs) have demonstrated clinical benefits in the treatment of severe malaria (Munir M *et al.*, Heparin in the treatment of cerebral malaria. Paediatr Indones. 20, 47-50,1980) as well as of VOC in SCD (Qari MH *et al.*, Reduction of painful vaso-occlusive crisis of sickle cell anaemia by tinzaparin in a double-blind randomized trial. Thromb Haemostat 98: 392-396, 2007); however, the associated risk of bleeding limits their clinical use. Therefore, sevuparin was designed to maintain the anti-adhesive properties of heparins while minimizing the anti-thrombin-mediated anticoagulant activity. A 5-fold lower anticoagulant potency is found in sevuparin in comparison with LMWH. A double blind, randomized Phase I study in healthy volunteers has previously been completed.
Aims: A Phase I/II clinical study with sevuparin in patients with uncomplicated *falciparum* malaria was conducted with the aim to demonstrate sevuparins anti-adhesive effects.
Methods: The Phase I/II study consisted of an open labelled dose escalation phase followed by an open labelled, randomized phase. The study was designed to determine the tolerability and *ex vivo* efficacy of sevuparin when administered as an iv injection as adjunctive therapy to atovaquone/proguanil (Malanil®) in subjects affected with uncomplicated *Plasmodium falciparum* malaria, as compared to Malanil® alone (control). Subjects were treated with 4 daily intravenous (iv) injections of sevuparin during three consecutive days (12 doses).
Results: Sevuparin was found to be safe and well tolerated in patients with *falciparum* malaria when given by iv injections as adjunct therapy with Malarone®. Exploratory analysis revealed a potentially clinically meaningful anti-adhesive effect since 1) mature IRBC previously being sequestered, appeared in the circulating blood of sevuparin treated patients as compared to controls, one hour after sevuparin injection (p=0.031) and 2) the number of ring-stage IRBC was significantly decreased already one hour after the first injection of sevuparin while the parasites continued to expand in control patients not given sevuparin (p=0.022), suggests that the binding of malaria parasite (merozoite) to RBC for invasion was inhibited. These effects are consistent with previous *in vitro* results with sevuparin in both malaria and SCD related experiments. Sevuparin has been found to block IRBC and SSRBC binding to endothelium, and also to reverse already established blockade of the blood flow during malaria sequestration and during vaso-occlusion related to SCD in animals *in vivo*. In addition, sevuparin blocks the malaria merozoite invasion into RBC *in vitro*.
Summary and Conclusions: In the Phase I/II study in patients with uncomplicated *falciparum* malaria, sevuparin reverses the adhesion of blood cells and pathogens to endothelium and other blood cells. These anti-adhesive effects of sevuparin have the potential to normalize blood flow in indications like severe malaria and VOC in SCD, which could impact the overall outcome of these patients. Potentially sevuparin might have impact on other indications were reversing and preventing vascular obstruction can improve the disease status and progress.

E1174

EFFECTIVENESS OF ANKAFERD BLOOD STOPPER IN PROPHYLAXIS AND TREATMENT OF ORAL MUCOSITIS SEEN IN CHILDHOOD CANCERS AND CORRELATION WITH PLASMA CITRULLINE LEVELS

T. Patiroglu[1,*] N. Sahin[1], E. Unal[1], M. Kendirci[2], M. Karakukcu[1], M.A. Ozdemir[1]

[1]Pediatric Hematology, [2]Pediatric Metabolism, Erciyes University Medical Faculty, Kayseri, Turkey

Background: In last 3 decades, success rate has been markedly increased in childhood cancers; however, chemotherapy-related adverse events remain to be an important issue. Oral mucositis, one of the toxic effects of chemotherapy, is observed in 52-80% of the children receiving cancer therapy. Ankaferd Blood Stopper (ABS) is an herbal product that is used as a hemostatic agent. In previous studies, it was shown that ABS has anti-microbial, anti-inflammatory effects as well as positive effects on healing of tissue injury.

Aims: In our study, it was aimed to investigate effectiveness of ABS in prophylaxis and treatment of oral mucositis in patients receiving chemotherapy at childhood. In addition, plasma levels of citrulline, a biochemical marker for mucosal barrier injury, were measured and effectiveness of ABS therapy in mucositis was correlated by quantitative data in addition to clinical assessment.

Methods: This was a randomized, controlled and open study which included 27 patients aged 4-17 years receiving chemotherapy regimens with strong mucotoxic effect. The patients were asked to perform standard oral care (SOC) upon first day of chemotherapy for 10 days and oral mucosa was assessed daily upon completion of chemotherapy based on World Health Organization scale for oral mucositis. In addition, blood samples were drawn immediately before initiation of chemotherapy and at the period where mucositis became most intensive. Same patients receiving same chemotherapeutic agents in the second course of chemotherapy were asked to gurgle by using ABS four times daily in addition to SOC. Mucosa ratings were performed before second chemotherapy course and at the period where mucositis became most intensive, and blood samples were drawn to measure citrulline levels in second chemotherapy course.

Results: The study included 27 patients (mean age: 9.1±4.4 years; 15 boys [56%]). Stages of oral mucositis were found to be significantly lower in the second chemotherapy course given SOC plus ABS when compared to first chemotherapy course given SOC alone (p=0.007). Mean plasma citrulline level obtained before and after chemotherapy decreased from 44.08±11.20 to 23.99±12.16 nmol/mL in chemotherapy course given SOC alone (p<0.001) while it decreased from 38.67±11.46 to 26.78±11.99 nmol/mL (p<0.001). When extent of decrease in plasma citrulline level was assessed, it was greater in courses given SOC alone compared to those given SOC plus ABS (p=0.009).

Summary and Conclusions: ABS can be considered to be an approach with potential benefits, although its effectiveness hasn't been proven in the prophylaxis and treatment of oral mucositis. Based on our results, ABS exhibited beneficial effects in the prophylaxis and treatment of oral mucositis. However, multi-center experiences and further studies with larger sample size are needed for introduction of ABS into primary oral care and treatment protocols of oral mucositis.

E1175

SAFETY OF BIOSIMILAR FILGRASTIM IN PATIENTS WITH LYMPHOMA AND MYELOMA UNDERGOING NEUTROPENIA-INDUCING CHEMOTHERAPY: A SUBANALYSIS OF THE NEXT STUDY

S. Leprêtre[1,*] F. Maloisel[2], D. Kamioner[3], C. Berthou[4], H. Albrand[5]
[1]Henri Becquerel Hospital, Rouen, [2]Sainte-Anne Clinic, Strasbourg, [3]Hôpital Privé de l'Ouest Parisien, Trappes, [4]Hôpital Morvan, Brest, [5]Hospira France, Meudon La Foret, France

Background: Febrile neutropenia (FN) is a major risk factor for infection-related morbidity/mortality as well as a dose-limiting toxicity in patients (pts) undergoing chemotherapy (CT). Biosimilar filgrastim (Nivestim™, Hospira Inc.) is a granulocyte-colony stimulating factor (G-CSF) licensed for the treatment of neutropenia and FN induced by myelosuppressive CT.

Aims: NEXT (Nivestim™safety profile in patiEnts treated with cytotoXic CT in real-life clinical pracTice) assessed the safety of biosimilar filgrastim in pts undergoing CT for malignancies.

Methods: NEXT was a prospective, non-interventional, longitudinal, multicenter study conducted in France to evaluate the safety of biosimilar filgrastim. Recorded data included demographic and clinical characteristics; treatment-related data on efficacy and safety, such as adverse events (AEs) and FN. Pts were monitored for 1–6 CT cycles with three visits at inclusion, during treatment, and following CT. Here we present data for pts with lymphoma and myeloma.

Results: Of the total pts analyzed, 408 had lymphoma (mean age±standard deviation (SD): 63.3±16.3 years [62.0% male]) and 47 had myeloma (mean age±SD: 71.2±8.8 years [66.0% male]). At inclusion, the majority of pts had no prior FN (lymphoma: 89.2%; myeloma: 76.6%); 27.5% of lymphoma pts and 59.6% of myeloma pts had prior CT, while 26.7% and 38.3% of lymphoma and myeloma pts, had prior G-CSF therapy, respectively. Almost all pts received biosimilar filgrastim prophylactically (lymphoma: 98.8%; myeloma: 97.9%). In the group treated with curative intent, the median time to initiation of biosimilar filgrastim therapy was 14.0 days after the start of the last CT cycle for both lymphoma and myeloma pts; mean treatment duration±SD was 5.2±1.5 days and 3.0±0.0 days for lymphoma and myeloma pts, respectively. In this group, 40.0% of lymphoma pts and 100.0% of myeloma pts received a dose of 30 MIU; all pts received subcutaneous (SC) administration of biosimilar filgrastim. In the prophylactic group, the median time to initiation of biosimilar filgrastim was 6 days and 6.5 days after the last CT dose for lymphoma and myeloma pts, respectively; mean treatment duration±SD was 6.6±4.0 days and 5.9±4.5 days for lymphoma and myeloma pts, respectively. In this group, 72.5% of lymphoma pts and 78.3% of myeloma pts received a dose of 30 MIU; all pts received biosimilar filgrastim by SC administration. Anti-infective prophylaxis was reported in 42.9% of lymphoma pts and 67.4% of myeloma pts. In the prophylactic group, 7.1% (95% confidence interval [CI] 4.9, 10.1) of lymphoma pts and 10.9% (95% CI 4.3, 23.5) of myeloma pts experienced FN. More overall pts with lymphoma experienced an AE than those with myeloma (21.5% *vs* 8.5%). The most common AEs (>5.0% of pts) were bone/muscular disorders (lymphoma: 16.0%; myeloma: 4.3%) and muscle pain (lymphoma: 15.5%; myeloma: 4.3%). In this analysis, 7.1% of lymphoma pts and 10.9% of myeloma pts prescribed prophylactic treatment were hospitalized for FN and/or infection. The mean duration of hospitalization±SD for FN and/or infection was 11.4±17.4 days for lymphoma pts (data not available for myeloma pts), <3% of pts had a CT dose reduction (lymphoma: 2.8%; myeloma: 2.3%) and <12% of prophylactic pts (lymphoma: 5.9%; myeloma: 11.4%) had a delay in administration of CT due to FN and/or infection.

Summary and Conclusions: Biosimilar filgrastim was effective and well-tolerated in pts undergoing CT for hematological malignancies and is an alternative therapeutic option for pts with CT-induced neutropenia.

E1176

THE EFFICACY OF SERUM GALACTOMANNAN ANTIGEN TEST AS SURVEILLANCE TOOL OF IN-VASIVE PULMONARY ASPERGILLOSIS DURING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH PRIMARY ANTIFUNGAL PROPHYLAXIS

R. Kim[1,*] Y.J. Choi[1], J. Youk[1], H. Park[1], Y. Koh[1,2], W.B. Park[1], J.O. Lee[2,3], S.M. Bang[2,3], I. Kim[1,2], S.S. Yoon[1,2], S. Park[1,2]
[1]Department of internal medicine, Seoul National University Hospital, [2]Cancer Research Institute, Seoul National University College Of Medicine, Seoul, [3]Department of internal medicine, Seoul National University Bundang Hospital, Bundang-Gu, Korea, Republic Of

Background: A serum galactomannan antigen (GM Ag) test has been used as routine surveillance tool of invasive pulmonary aspergillosis (IPA) for hematology patients who underwent allogeneic stem cell transplantation (alloSCT). In an era of effective primary antifungal prophylaxis (PAP), the routine surveillance of IPA with GM Ag test during alloSCT for hematologic malignancy need to be re-evaluated.

Aims: The purpose of this study was to evaluate the efficacy of GM Ag test as a routine surveillance tool for early detection of IPA in hematology patients receiving alloSCT and PAP, especially with micafungin.

Methods: From 2013 to 2014, medical records of 111 patients who received alloSCT for hematologic malignancy were analyzed. As an institutional protocol, all patients underwent routine surveillance with GM Ag tests twice a week during alloSCT, and received PAP with fluconazole or micafungin, if applicable. The diagnoses with IPA were classified according to the European Organization for Research on Treatment of Cancer/Mycoses Study Group (EORTC/MSG) criteria. GM Ag tests with one of respiratory symptom/sign or fever at the same time, were considered to have high suspicion of IPA, otherwise GM Ag tests without any symptom/sign/fever were considered to have low suspicion of IPA. Patient informed consent was waived because of the retrospective design of the study.

Results: For 111 patients, a total of 681 GM Ag tests were performed (median, 4 per patient [range 1-21]). The incidences of breakthrough IPA were as follows: 583(85.8%) no IPA, 72(10.6%) possible IPA, 21(3.1%) probable IPA, and 4(0.6%) proven IPA. The optimal cutoff index of GM Ag for diagnosis of probable/proven IPA was found to be 0.8. Probable/proven IPA were diagnosed in 6(1.0%) tests with GM Ag index <0.8, and in 19(36.5%) tests with GM Ag index ≥0.8 (P<0.001). Sensitivity and specificity were 76.0% and 95.0%, respectively. Of a total of 111 patients, PAPs with fluconazole and micafungin were performed in 79(64.9%) and 28(25.1%) patients, respectively. The cumulative incidences of probable/proven IPA at 3 months after completion of alloSCT were 1.5% in PAP with micafungin, and 4.0% in PAP with fluconazole (HR 0.18, 95% confidence interval 0.02-1.33, P=0.093, Log rank P=0.06). In patients receiving PAP with fluconazole, 423 GM Ag tests were performed. Among them, 204(48.2%) tests had low suspicion of IPA, and positive predictive value (PPV) was 33.3%. The performance of GM Ag tests improved when there is high suspicion of IPA, with PPV of 50.0%. In patients receiving micafungin prophylaxis, 136 GM Ag were tested. 57(41.9%) GM Ag tests had low suspicion on IPA. They all had GM Ag index <0.8, and no probable/proven IPA was diagnosed (NPV 100.0%, PPV not applicable). 79(58.1%) GM Ag tests had high suspicion of IPA, in which 72(91.1%) had GM Ag index <0.8 with NPV of 100%. Of the rest 7(8.9%) tests with GM Ag index ≥0.8, 2(2.5%) tests were proven to be probable/proven IPA with PPV of 28.6%, and 5 (71.4%) tests were false positive.

Table 1.

Groups	% (95% CI)
All GM Ag tests (N=681)	
Sensitiviy	76.0 (54.9 - 90.6)
Specificity	95.0 (93.0 - 96.5)
PAP with fluconazole (N=423)	
with low suspicion of IPA (N=204)	
PPV	33.3 (16.5-54.0)
NPV	99.5 (97.1-100.0)
with high suspicion of IPA (N=219)	
PPV	50.0 (18.7-81.3)
NPV	99.0 (96.3-99.9)
PAP with micafungin (N=136)	
with low suspicion of IPA (N=57)	
PPV	not applicable
NPV	100.0 (not applicable)
with high suspicion of IPA (N=79)	
PPV	28.6 (3.7-71.0)
NPV	100.0 (95.0-100.0)

Summary and Conclusions: In comparison to PAP with fluconazole, patients who received PAP with micafungin during alloSCT have lower incidence of IPA. Most of GM Ag tests in PAP with micafungin were negative or false positive, which renders routine surveillance of IPA by serum GM Ag tests less useful.

E1177

BIOSIMILAR FILGRASTIM IN PATIENTS UNDERGOING NEUTROPENIA-INDUCING CHEMOTHERAPY: OVERALL RESULTS FROM THE NEXT OBSERVATIONAL STUDY

F. Maloisel[1,*] S. Leprêtre[2], D. Kamioner[3], B. Christian[4], H. Albrand[5]
[1]Sainte-Anne Clinic, Strasbourg, [2]Henri Becquerel Hospital, Rouen, [3]Hôpital Privé de l'Ouest Parisien, Trappes, [4]Hôpital Morvan, Brest, [5]Hospira France, Meudon La Foret, France

Background: Febrile neutropenia (FN) is a frequent and potentially serious complication of cytotoxic chemotherapy (CT). Biosimilar filgrastim (Nivestim™, Hospira Inc.) is a granulocyte-colony stimulating factor (G-CSF) approved in France for the treatment of neutropenia and FN resulting from myelosuppressive CT. Previous clinical trials have demonstrated similar efficacy and safety of biosimilar filgrastim to the reference product (Neupogen®, Amgen Inc).
Aims: NEXT (Nivestim™safety profile in patiEnts treated with cytotoXic CT in real-life clinical pracTice) evaluated the safety of biosimilar filgrastim in pts undergoing CT for malignancies.
Methods: NEXT was a prospective, non-interventional, longitudinal, multicenter study conducted in France to assess the safety of biosimilar filgrastim. Recorded data included demographic and clinical characteristics as well as treatment-related data on efficacy and safety, including adverse events (AEs) and FN. Pts were monitored for 1–6 CT cycles with three visits at inclusion, during treatment, and following CT. Here we present the overall study results.
Results: Of 2114 pts enrolled in the study, 2102 pts were included in the analysis (mean age±standard deviation [SD]: 63.5±12.7 years; 50.2% male). More patients had solid tumors (75.0%) than hematological malignancies (25.0%). At baseline, 92.5% of pts had no prior FN; 34.4% had previous CT; 20.2% had received previous G-CSF therapy. The majority (98.2%) of pts received prophylactic biosimilar filgrastim (primary prophylaxis: 91.0%; secondary prophylaxis: 7.3%). Of the pts receiving prophylactic biosimilar filgrastim, 79.9% received a dose of 30 MIU and therapy was administered subcutaneously in 99.4% of these pts. In the prophylactic group, median time to initiation of biosimilar filgrastim was 2 days after the last CT dose; mean treatment duration±SD was 6.0±3.8 days. Anti-infective prophylaxis was reported in 14.5% of these pts. The incidence of FN in this group was 4.9%, occurring a median time (range) of 14.0 (-13.0–155.0) days following the first CT cycle. Infections were reported in 3.1% of prophylactic pts, occurring a median time (range) of 23.5 (0.0–155.0) days following the first CT cycle. 4.9% of prophylactic patients were hospitalized for FN and/or infection; occurring 5.5 (0.0–64.0) median (range) days after initiating biosimilar filgrastim. 3.6% of pts were hospitalized for FN and/or infection after the first CT cycle, with ≤1% patients hospitalized for FN after each subsequent cycle. Reductions in CT dose due to FN and/or infection occurred in 4.7% of patients receiving prophylaxis. During the study 20.4% of pts had ≥1 AE; 12.7% of pts reported muscle and/or bone disorders and muscle pain (12.1%). The other most common AEs included gastrointestinal disorders (5.5%), nausea (3.0%), general disorders and administration site disorders (2.4%), diarrhea (2.3%) and headache (1.8%). Of the 205 physicians who completed the questionnaire concerning treatment and prevention of CT-induced FN, 73.1% routinely prescribed G-CSF therapy for prophylactic and curative reasons. The most common reasons for prescribing biosimilar filgrastim were cost savings and comparable efficacy and safety.
Summary and Conclusions: Biosimilar filgrastim (Nivestim™) was effective and well-tolerated in both the prophylactic and curative setting in patients undergoing chemotherapy for solid tumors and hematological malignancies. In real-world practice, most physicians prescribed G-CSF therapy for prophylactic or curative intentions in their patients receiving myelosuppressive chemotherapy.

E1178

ORGANIZING PNEUMONIA IN HEMATO-ONCOLOGY PATIENTS: A SOMEWHAT DISREGARDED DIFFERENTIAL DIAGNOSIS

G. Brás[1,*] M. Alpoim[1], R. Pinto[1], A. Carneiro[1], F. Príncipe[1], J. Guimarães[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar de São João, Porto, Portugal

Background: Organizing Pneumonia (OP) is defined by clinical and imagiological aspects of pneumonia, with histological pattern of intra-alveolar buds of granulation tissue, consisting of intermixed myofibroblasts and connective tissue. OP develops in the context of an immune deregulation, a perpetuation of the inflammatory response in the presence of infection, autoimmune diseases or drug exposure. In hemato-oncology, OP has been extensively studied in the allogeneic transplant setting and, more recently, it has also been described in lymphoproliferative diseases, myelodysplastic syndromes and chronic myeloproliferative diseases.
Aims: Analyze clinical characterisitics and outcomes of diagnosed OP in hemato-oncology patients, outside the allogeneic transplant setting.
Methods: Retrospective revision of biopsy-proven OP cases diagnosed in patients with hematological diseases, in a Portuguese hospital centre, between 2005 and 2014.
Results: Ten cases with biopsy-proven OP were obtained. The median age was 62 years (33-75) and 7 cases (70%) were male. The hemato-oncological diagnoses were: Lymphoma (n=7; 70%); B-cell Acute Lymphoblastic Leukemia (n=1; 10%); Myelodysplasia (n=2; 20%); Acute Myeloid Leukemia (n=2; 20%). In two (20%), the OP diagnosis was made simultaneously with onset of hematological disease, seven (70%) during chemotherapy and one (10%) during the first 100 days after autologous transplantation. Prior to the OP diagnosis, none was submitted to bone marrow allogeneic transplantation or pulmonary radiotherapy. Clinically, nine (90%) patients had fever and nine (90%) had respiratory insufficiency. Of the latter, three (30%) patients needed non-invasive ventilation and two (20%) invasive ventilation. The thoracic CT scan reported findings varying between nodules (n=4; 40%), consolidations (n=3; 30%), interstitial infiltrates (n=3; 30%), ground-glass opacities (n=3; 30%) and pleural effusions (n=3; 30%), with findings overlapping in 9 (90%) cases. The perpetuation of an unfavorable clinical course despite antimicrobial/antifungal therapy or the lack of typical CT findings led to the decision of lung biopsy. Percutaneous transthoracic CT-guided lung biopsy was performed in eight (80%) patients and thoracotomy in other two (20%), with no procedure related complications. In terms of OP therapy, corticosteroids were the choice in nine (90%) patients (n=5 isolated; n=4 in association with azithromycin; n=1 no treatment), with clinical and imagiological improvement in seven cases. Pulmonary aspergillosis was a non-confirmed differential diagnosis in 5 (50%). Of the 4 OP exacerbations, 2 occurred with hematological disease progression. Of the 6 (60%) deaths, 4 occurred with hematological disease evolution, 2 with OP exacerbation in association with sepsis/multiorganic dysfunction. The Overall Survival and the Exacerbation Free Survival were 12 months and 4 months, respectively.
Summary and Conclusions: OP should be considered a differential diagnosis of pulmonary lesions in hemato-oncological diseases. The lack of specificity of the clinical and imagiological presentation, urges the need of considering the lung biopsy in highly suspicious lesions. The correct diagnosis is essential to begin the treatment with corticosteroids, which showed to be capable of reasonable clinical and imagiological disease control in our series.

E1179

THE EFFICACY OF POLYVINYLPYRROLIDONE – ZINC GLUCONATE AND TAURINE GEL (GEL X) IN PROPHYLAXIS AND TREATMENT OF ORAL MUCOSITIS IN CHILDREN TREATED WIH CHEMOTHERAPY

A. Colita[1,2,*] A. Bediman[1], A. Colita[3], C. Arion[4]
[1]Pediatric Hematology & BMT, Fundeni Clinical Institue, [2]Pediatric Clinic, "Carol Davila" University of Medicine and Pharmacy, [3]Hematology @ BMT Department, Coltea Hospital, [4]Hematology @ BMT Department, Fundeni Clinical Institue, Bucharest, Romania

Background: Polyvynilpyrrolidone-zn gluconate and taurine (GelX) is an oral lubricating gel used in the management of oral mucositis (OM). OM is an important medical and nursing problem secondary to use of chemotherapy, associated with oral pain and reduced oral intake, difficult to manage, especially in young children, with important impact for quality of life and nutritional status.

GelX forms an adherent barrier and cover the oral mucosa lesions, thus protecting the sensitive nerves endings and lubricating the oral tissue.
Aims: To evaluate the efficacy of Gel X as prophylactic or curative treatment for children treated with chemotherapy for hematologic malignant diseases.
Methods: We conducted a single-centre prospective and observational study in children with acute leukemias receiving chemotherapy according to the BFM protocols. The parents signed the informed consent. The study was non-sponsored. In the prophylactic arm, the oral cavity nursing with GelX started on the first day of chemotherapy and continued until the recovery from neutropenic phase; for the curative arm, the oral cavity nursing started on the first day of chemotherapy with other oral rinses and was switched to GelX after OM development and continued until OM recovery. The oral rinses were recommended to be used at least 3 times a day according to the product specifications. The OM was assessed daily by the physicians using the WHO grading 0-4 (0=absent, 1= soreness and/or erythema, 2= erythema, ulcers and patient can swallow solid food, 3= ulcers with extensive erythema and patient cannot swallow solid food, 4=mucositis to the extent that alimentation is not possible). We performed also a patient assessment for pain (general, mouth and throat) VAS scale 1-5 (1=no pain, 2=mild pain, 3=moderate pain, 4=severe pain, 5=very severe pain) and saliva VAS scale 1-5 for a) swallowing (1=normal, 2=cannot swallow certain solid foods, 3=can only swallow soft foods,4=can only swallow liquid foods,5=cannot swallow), b) saliva amount (1=normal amount, 2=mid loss of saliva, 3=moderate loss of saliva, 4=severe loss of saliva, 4=severe loss of saliva, 5= no saliva) and c) consistency of saliva (1=normal, 2=slightly thick, 3=moderately thick, 4=extremely thick, 5=saliva that dries in mouth or lips). The tolerability of oral rinses was evaluated daily by the patients or parents using the Visual Analog Scale (VAS) scoring 1-5: 1= tolerable without any problems, 2=satisfactory, 3= indifferent, 4= unsatisfactory, 5=intolerable. The OM pain reduction and food intake improvement were assessed by the patients/parents using the VAS scoring 1-5 (1=excellent, 2=good, 3=slight effect, 4=almost no effect, 5=no effect at all). Basic statistics univariate analysis were performed using statistical software with the Fisher's exact test. The "P" values <0.05 were considered as statistically significant differences.
Results: A total of 15 patients were enrolled in this analysis, 8 in the prophylactic arm (group A) and 7 in the curative arm (group B). Characteristics of the groups were shown in Table 1. The OM maximum grade was higher in the B group than in the A group, p=0,018. The patient/parent assessment of mouth pain (p=0,01) and of saliva consistency (p=0,033) were significantly lower in the prophylactic group. We also observed a significant difference regarding the OM pain reduction (p=0,001), oral intake improvement (p=0,001) and use of systemic analgesics (p=0,005). There were no difference in the median value of tolerability of GelX rinses between the group A and B.

Table 1.

	prophylactic arm (group A)	curative arm (group B)	P=
No.of patients	8	7	-
Age (years) median, (range)	5,5 (2-10)	4, (0,75-5)	-
Sex: M/F	3/5	1/6	0,287
Diagnosis: ALL/AML	5/3	6/1	0,287
OM maximum grade, (range)	1, (1-3)	4, (3-5)	***0,018***
Patient assessment median, (range)			
- General pain	1, (1-2)	2, (2-3)	0,123
- Mouth pain	2, (1-3)	4, (3-5)	***0,001***
- Throat pain	1, (1-2)	3, (1-4)	0,369
- Swallowing	1, (1-4)	3, (1-4)	0,304
- Amount of saliva	1, (1-2)	2, (1-5)	0,091
- Consistency	1, (1-4)	2, (1-5)	***0,033***
Tolerability of oral rinses, median, (range)	1, (1-2)	2, (1-4)	0,369
OM pain reduction, median days	2, (0-4)	7, (4-8)	***0,001***
Oral intake improvement, median days	2,(0-3)	8, (5-10)	***0,001***
Systemic analgesic treatment with analgesics	2/8	7/7	***0,005***

Summary and Conclusions: There are limited data regarding the use in children as prophylactic or curative measures. In our study, the oral spray was administered as prophylaxis or as curative treatment. Our results showed better results in the OM development and quality of life in the prophylaxis arm. These results, however, should be considered as informative and larger cohorts of patients needs to be analyzed.

E1180

INFECTION AND COLONIZATION BY CARBAPENEM RESISTANT KLEBSIELLA PNEUMONIAE IN HAEMATOLOGY PATIENTS

M.D. Madrigal[1,*] C. Blazquez[1], R. Saldaña[1], V. Rubio[1], S. Pérez-Cortés[2], M.D. López[2], S. Garzón[1]
[1]Hematology, [2]Infections disease, Hospital de Jerez, Jerez de la Frontera, Spain

Background: Klebsiella Pneumoniae is a frequent nosocomial pathogen inhabiting the digestive tract. In the era of antibiotic resistance and multi-drug resistant bacteria, the emergence and spread of carbapenem-resistant Klebsiella pneumoniae (CRKP),has become a major health concern for hospitalized patients. Hematological patients are particularly prone to infection by CRKP due to a combination of factors: prolonged neutropenia, recurrent use of chemotherapy and broad spectrum antibiotics, severe mucositis, immunosuppression, catheters.
Aims: Description an outbreak of CRKP colonization between May and September 2014 in our centre despite strict hygiene.
Methods: Colonization (carrier state) was defined as the presence of at least one rectal swab positive for CRKP. Eradication of colonization was confirmed when three consecutive rectal swabs are negative after decontamination therapy (after 3 days, 7 days and 1 month). Infection was defined as the presence of the microorganism from blood cultures or other body site (urinary tract in particular) with clinical signs. Carbapenemase detection was made by Hodge test and disk diffusion, confirmed by specific PCR.
Results: 11 patients were identified as carriers CRKP over a period of 4 months. *(Patients characteristics are described in table 1)*. Colonization was followed by a microbiologically documented infection in 5 patients (1 septic shock, 1 bacteraemia concomitant UTI and followed by septic shock, 1 bacteraemia, catheter and soft tissue infection, 2 UTIs recurrent). As risk factors, four of these patients had severe neutropenia and only one patient had a normal WBC count, but suffered from gastrointestinal GVHD. All infected patients were initially treated with high doses carbapenem therapy administered by prolonged infusion (3 hours) combined with gentamicin and/or fosfomicine and/or tigecycline. In two episodes of bacteremia we used second-line treatment with ceftazidime/avibactam, with good safety profile and efficacy (negative cultures at 72 hours). The infection-related mortality rate was 40% (2/5).
Decontamination therapy consisted in oral gentamicin (80 mg/6h for 14 days), if three days after rectal swab continued positive, treatment was started with oral neomicine and estreptomicin (40/80 mg, 1 tablet/8h) or treatment was repeated with gentamicin. 10 patients received decontamination therapy (1 patient developed septic shock and died before receiving treatment) being successful in 5 of them (50%). It was necessary to repeat courses with an average of two lines (1-4) and a median duration of 2 month (15days-6meses).

Table 1.

PATIENT	AGE GENDER	DIAGNOSIS	TREATMENT	RESOLUTION OF COLONIZATION	DECONTAMINATION THERAPY LINES	INFECTION	RESOLUTION OF INFECTION	OUTCOME
1	67/F	MPDs	IS for GVHD	No	3	UTI	Yes	Death [b]
2	54/M	AML	Chemotherapy	No	4	Bacteraemia Catheter Soft tissue	Yes Yes Yes	Alive
3	17/M	AML	Allo-SCT	No	4	UTI recurrent	Yes	Alive
4	33/F	AML	IS for GVHD	No	1	UTI Bacteraemia Septic shock	Yes Yes No	Death [a]
5	65/M	AML	2ºAllo-SCT	-	-	Septic shock	No	Death [a]
6	39/M	AML	Chemotherapy	Yes	4	-	-	Alive
7	24/M	HD	Chemotherapy	Yes	2	-	-	Death [b]
8	80/M	MDS	5-AZA	Yes	2	-	-	Alive
9	68/M	MPDs	HU	Yes	1	-	-	Alive
10	49/F	AML	2ºAllo-SCT	Yes	1	-	-	Death [b]
11	59/M	CLL	Chemotherapy	No	2	-	-	Alive

[a] Death from CRKP infections. [b] Death from other non-CRKP causes

Summary and Conclusions: 1. In our center 5/11 colonized patients developed infection. Our experience with ceftazidime/avibactam was favourable because it managed to eradicate bloodstream infection. 2. We have done a good control of the outbreak in only four months. Special health measures such as surveillance with weekly rectal swabs, bed isolation and strict hygiene measures have been very important in controlling the spread of the epidemic. 3. Hematology patients need several courses of decontamination therapy to succeed.

E1181

INFECTIONS IN PATIENTS WITH MYELODYSPLASTIC SYNDROME/ ACUTE MYELOID LEUKEMIA TREATED WITH AZACITIDINE: REPORT FROM A SINGLE CENTER

A.M. Quinto[1,*] E. De March[1], M. Castelli[1], G. Binotto[1], G. Semenzato[1,2], F. Adami[1]
[1]Department of Medicine, Hematology and Clinical Immunology Section, University of Padua, [2]Venetian Institute of Molecular Medicine, Padua, Italy

Background: Infections are common and potentially fatal events affecting patients with myelodysplastic syndromes (MDS). Predisposing factors that are likely to be associated with increased risk of infections in MDS patients are neutropenia and/or neutrophil functional impairment; B-, T- and NK-cell defects; secondary iron overload related to red blood cell transfusions; comorbidities; treatment toxicity; previous severe infections. Few data are available on the incidence and pathogens involved in infectious events, most of these originating from retrospective studies or clinical trials with primary end points other than infection.
Aims: An Italian single Center real-life experience assessing the incidence, risk factors and impact of infections on outcome of patients with MDS treated with hypomethylating agents is herein reported.

Methods: From March 2008 to October 2013, 50 patients, aged 40 years and older (median age: 69, 40-84 years) with diagnosis of MDS (WHO2008 categories: 22.4% RA/RCMD, 32.6% RAEB-1, 28.5% RAEB-2, 12.2% CMML, 4% AML), were treated with 5-azacitidine (75 mg/m^2/die for 7 days every 4 weeks), both in on-label and off-label drug use setting. Forty-four percent of patients had intermediate-2 or high International Prognostic Scoring System, 68% were neutropenic and 12% had high MDS-Comorbidity Index. Prophylactic antibiotics were administered to 12 patients (24%), prophylactic antifungal to 17 patients (34%) and granulocyte colony-stimulating factor was administered to 24 patients (48%).
Results: Median number of cycles received by a single patient was 5 (range 1-21); 48% received more than 6 cycles of therapy. 30.4% of the entire cohort was considered responsive to treatment (14.4% hematologic improvement, 8% partial response, 8% complete response, according to IWG2006 criteria); 24% of patients achieved a stable disease. Out of 50 patients, 25 (50%) developed 25 infectious events (1 for each patient), during 325 treatment cycles (7.7%); 14/25 (56%) events required hospitalization. Only one patient died from an infectious complication. Twenty-two of 25 infectious events (84%) were bacterial, mostly pneumonia; 3 (12%) were fungal (invasive aspergillosis) and 1 (4%) was viral (H1N1). Infectious events did not significantly affect overall survival (27 *vs* 18 months, p=0.606), progression free survival (6.0 *vs* 6.1 months, p=0.48) or overall response to therapy (13 *vs* 17.4%, p=0.693). However, no complete responses were documented in the cohort of patients who suffered from infectious episodes. In a univariate analysis, age, sex, low neutrophil count, high comorbidity index, antibiotic prophylaxis and use of G-CSF were not found to be associated with infections. Only high IPSS and the presence of pancytopenia, seemed to be correlated with an increased risk for infections.
Summary and Conclusions: Infectious events, specifically bacterial infections, are one of the most frequent complications during therapy with azacitidine in patients with MDS. These data suggest that there are not predisposing risk factors for infection in patients except those connected with disease severity (high IPSS and pancytopenia). Routine antibiotics, antifungal prophylaxis and/or use of G-CSF appear not to reduce the incidence of infectious events. Moreover, bearing in mind the risk of bacterial and fungal resistance associated with extended use of anti-infective drugs, they should be used with caution in selected subsets of MDS patients.

E1182

EVALUATION OF SERUM GALACTOMANNAN ASSAY FOR THE DIAGNOSIS OF INVASIVE ASPERGILLOSIS IN CHILDREN WITH HEMATOLOGICAL MALIGNANCIES

A. Jha[1,*] D. Bansal[2], S. Prakash[3], A. Chakraborty[3]
[1]Hematology-oncology, Bhaktapur Cancer Hospital, kathmandu, Nepal, [2]Hematology-oncology, [3]medical microbiology, PGIMER, Chandigarh, India

Background: Fungal infection is a major concern during treatment of hematological malignancies. Establishing diagnosis is a challenge and often frustating for the treating physicians. Rapid and diagnostic test is valuable for timed intervention. Galactomannan assay is a non invasive test, however it's efficacy needs to be validated in our population.Only few studies in Indian population, hence to establish a clinically relevant cut off value this prospective study is done.
Aims: Diagnostic efficacy of galactomannan assay (GA) for invasive aspergillosis (IA) is variable. the cut off value is debated.
Methods: Children ≤14-years with hematological malignancies and fever were enrolled prospectively. Blood sample for GMA was drawn on day of admission; levels were measured with *Platellia Aspergillus* enzyme immunoassay. Diagnostic criteria were adapted from EORTC-MSG. GMA was evaluated at various cut-offs, with proven, probable and possible episodes being considered as disease group.
Results: 100 febrile episodes in 78 patients were included. Mean-age was 6.1 years. Majority (75%) episodes were in patients with ALL, followed by AML (17%). CT-scan-lung was performed in 23 episodes. BAL, transbronchial-lung-biopsy and functional-endoscopic-sinus-surgery were performed in 2-episodes, each. Post-mortem investigations included autopsy (1) and organ biopsies (6). Diagnosis of IA was proven and probable in one case each. A possible diagnosis was made in 23 episodes; remaining 75 were categorized as "No IA". Other fungal infections diagnosed included mucormycosis (3), candidiasis (1) and fusariosis (1). Best results were obtained with a cut-off value of 1.0, with sensitivity, specificity, positive and negative predictive value of 60%, 93%, 75 and 87, respectively. With GMA >1.0 as cut-off, the probability of a positive test to be true or false positive was 0.71 (95% CI: 0.48-0.88) and 0.28 (95% CI: 0.12-0.52), respectively. For a negative test, the probability of true negative was 0.87 (95% CI: 0.78-0.93) and false negative was 0.13 (95% CI: 0.16-0.22). The sensitivity dropped to 40%, at cut-off value of 1.5 and specificity was 38%, at a cut-off of 0.5. Significant correlation of a higher GMA was observed with pulmonary nodules (p=0.037), duration of Amphotericin >10-days (p=0.043) and mortality (p=0.001).
Summary and Conclusions: Confirming the diagnosis of aspergillosis is a challenge; this renders assessment of efficacy of GMA difficult. At a cut-off value of 1.0, the sensitivity and specificity were 60% and 93%, respectively.

E1183

ANIDULAFUNGIN THERAPY FOR HIGH RISK OF INVASIVE FUNGAL INFECTION HEMATOLOGIC PATIENTS: ITS ROLE IN REAL-LIFE SINGLE CENTER EXPERIENCE.

S. Lozano[1,*] P. Arregui[1], A. Zabalza[1], I. Aoiz[1], M. Alvarellos[1], A. Gorosquieta[1], K. Pérez de Equiza[1], E. Olavarria[1]
[1]Haematology, Complejo Hospitalario de Navarra, Pamplona, Spain

Background: Anidulafungin in an echinocandin licensed for the treatment of invasive candidiasis in adult non-neutropenic patients. This drug is neither metabolized by the liver, nor has renal elimination. Liver dysfunction is common after allogeneic stem cell transplantation and intensive chemotherapy. In our hospital patients who fulfill criteria of high risk for Invasive fungal infection (IFI) routinely receive antifungal prophylaxis with voriconazole. It has become routine clinical practice to substitute voriconazole for anidulafungin in cases with hepatic involvement of GVHD and/or liver toxicity manifested as elevated liver function tests (LFTs).
Aims: The aim of this study is to analyze the safety, toxicity and feasibility of off label anidulafugin as prophylaxis and treatment of high risk of IFI hematologic patients in a real life scenario.
Methods: We have retrospectively studied all episodes of adult high risk of IFI hematological patients treated with anidulafungin in our hospital from March 2010 to October 2014. IFI was defined according to EORTC guidelines.
Results: Fifty patients were included, 38 were treated once, 9 twice and 3 thrice, thus 65 different therapy episodes were finally analized. Median age was 50 years (IQR 39.2-61.2), with 63.1 % (n=41) cases being male. Most (81.6%) had undergone allogeneic stem cell transplantation (Allo-SCT). The most common baseline diagnoses were acute leukemia in 31 (47.7%) and non Hodgkin´s lymphoma in 12 (8.3%). Fifty-five cases (85%) had no prior history of IFI. The remaining ten cases previously had proven (n=3), probable (n=5) or possible (n=2) IFI and therefore received secondary anti-fungal prophylaxis. Anidulafungin was administered as prophylaxis in 48 episodes (73.9%), in 3 episodes for proven candidiasis (4.6%) and in 14 (21.5%) as empirical treatment of IFI. Elevated LFTs was the most common cause to commence on anidulafungin (n=46, 71.8%), in 19 of them (29.7%) voriconazole had to be discontinued. Other reasons to start anidulafungin were chronic graft versus host disease (n=6), voriconazole intolerance (n=4), hallucinations due to voriconazole (n=3), candidiasis (n=3), and others (n=3). Median number of days on therapy was 11 (IQR 5-19.5). Treatment with anidulafungin was well tolerated in most of our patients (93.8%). The drug was withdrawn in three cases: one due to acute kidney failure, one due to drug intolerance during infusion and one due to progressive liver failure. Among the 48 cases receiving anidulafungin as prophylaxis there were 36 with abnormal LFTs and 6 with liver GVHD. In this very high risk of IFI cohort there were 3 proven (2 cases of mucormicosis and one *C.guillermondii* candidemia), 2 probable and one possible IFI, during the duration of prophylaxis or in the week following the discontinuation of anidulafungin. In addition, 4 more proven IFIs were diagnosed in the following 100 days: one disseminated histoplasmosis (day 11), one C.krusei candidemia (day 18), one pulmonary invasive aspergillosis (day 10) and one esophageal candidiasis (day 36). All patients but the last one, had received other anti-fungal agent after anidulafungin was discontinued. Nearly half of the patients receiving anidulafungin as prophylaxis (45.8%) died during the 100 days follow up period, 2 of them (9.6%) due to IFI.
Summary and Conclusions: Anidulafungin is a safe and feasible alternative to azole therapy, especially in patients with elevated LFTs or liver involvement by GVHD. Further studies are needed to establish the role of anidulafungin in this patient population.

E1184

LOW-RISK MYELODYSPLASTIC PATIENTS SUPPORTED WITH ERYTHROPOIETIN PLUS LIPOSOMIAL IRON SHOWS A REDUCED NUMBER OF FEBRILE EPISODES THAN PATIENTS WITH INTRAVENOUS IRON SUPPORT.

G. Giordano[1,*] F. D'Amico[2], A. Commatteo[3], G. Berardi[4], D. Berardi[5], B. Carabellese[6], R. Gigli[3], M. Magri[3], A. Licianci[3], L. di Marzio[3]
[1]medicine, Regional Hospital "A. Cardarelli", Campobasso, [2]Foundation "J. Paul II", campobaso, [3]Regional Hospital "A. Cardarelli", [4]family medicine, Campobasso, [5]University "La Sapienza", Rome, [6]nuclear medicine, Regional Hospital "A. Cardarelli", Campobasso, Italy

Background: Intravenous iron support simultaneous to erythropoietin administration improve response to erythropoietin in myelodysplastic patients. Oral liposomal iron, bypassing normal intestinal mechanism of absorption, shows similar effects, better than oral iron sulfate, usually poorly absorbed. Ther'are many evidences that iron, useful for bacterial growth, might increase risk of infection.
Aims: Aim of this study is to verify incidence of number of febrile episodes in low-risk myelodysplastic patients without support or supported with erythropoietin (epo) only or with epo plus oral liposomal iron, oral iron sulfate or iv sodium ferrigluconate.
Methods: This study is a retrospective, multicentric study.Between july 2008 and december 2014, 107 patients affected by low-risk refractory anemia were

studied.Median follow-up was 24 months (R12-60).20 patients had no support, 27 epo support, 30 epo+liposomial iron (14 mg 2 tablets orally/day for 3 months), 15 epo+iron sulfate (525 mg2 tablets orally/day for 3 months), 15 epo+iv sodium ferrigluconate (62.5 mg iv in NS 100 ml in 1 h/day for 5 day/month).All patients supported with epo received calcium levofolinate 7.5 mg/day orally +Vitamin B12: 400 mg/day orally.Epo support was performed with originator or biosimilar epo alpha or epo zed 40000 IU sc/week or with epo beta 30000 IU sc/week.Statistical analysis was performed by Chi Squre test and Fisher exact test.

Results: In group with no support median hemoglobin level was 9.5 g/dl (R8-11). Median neutrophils count was 1000/mcl (R300-2500). Median packed red blood cells unit (PRBCU) transfused was 0.2/month (R0-0.5). Median number of febrile episodes/year was 1.5 (R0-2). In group supported with epo only median hemoglobin level after 3 month treatment was 11 g/dl (R7.5-12). Median neutrophils count was 800/mcl (R400-1200). Median packed red blood cells unit (PRBCU) transfused was 0.4/month (R0-0.7). Median number of febrile episodes/year was 2 (R0-2).In group supported with epo+iron sulfate median hemoglobin level after 3 month treatment was 10.5 g/dl (R8-12). Median neutrophils count was 750/mcl (R300-1100). Median packed red blood cells unit (PRBCU) transfused was 0.3/month (R0-0.6). Median number of febrile episodes/year was 3 (R0-3). In group supported with i.v. sodium ferrigluconate median hemoglobin level after 3 month treatment was 12 g/dl (R9-13). Median neutrophils count was 700/mcl (R250-1000). Median packed red blood cells unit (PRBCU) transfused was 1.5/month (R1-3). Median number of febrile episodes/year was 6 (R0-9). In group supported with liposomial iron median hemoglobin level after 3 month treatment was 12.8 g/dl (R10-13). Median neutrophils count was 280/mcl (R150-1300). Median packed red blood cells unit (PRBCU) transfused was 0.2/month (R0-1). Median number of febrile episodes/year was 1 (R0-2).

Summary and Conclusions: Number of febrile episodes is low in each treatment group. Febrile episodes seem not related to basal neutrophil count or hemoglobin level reached after 3 month treatment. Number of febrile episodes is higher in group with higher transfusion need and in group treated with i.v. sodium ferrigluconate (p 0.02). Probably liposomial iron support provides a reduced amount of non- transferrin bound iron that might block bacterial growth. These data need confirmation on a larger cohort of patients.

E1185

RISK FACTORS FOR FEBRILE NEUTROPENIA AND BLOODSTREAM INFECTIONS IN RECIPIENTS OF HEMATOPOIETIC STEM CELL TRANSPLANTS

I. Stoma[1,*] A. Uss[2], I. Karpov[1], N. Milanovich[2], I. Iskrov[2], I. Lendina[2], S. Vlasenkova[2]
[1]Belarusian state medical university, [2]City clinical hospital №9, Minsk, Belarus

Background: Number and indications for Hematopoietic Stem Cell Transplantations (HSCTs) in adults continue to grow worldwide. Febrile neutropenia (FN) remains one of the most common complications in the HSCT patients. Bloodstream bacterial infections (BSI) stay common causes of FN among neutropenic patients. Choice of initial strategy of antibacterial treatment in FN patients is based mainly on clinical and epidemiological risk factors, because of the low frequency of culture isolation and reduced clinical manifestations of infection.

Aims: The aim of the study was to determine the risk factors for febrile neutropenia or microbiologically proven bloodstream infection in adult patients receiving HSCT.

Methods: 242 patients undergoing allogeneic or autologous HSCT at the Belarus National Centre for Hematology and Bone Marrow Transplantation from January 2013 to January 2015 were monitored and their clinical data was reviewed. Age of the patients included in this study was 18-65 years, 42% of them were male, 58% - female. The primary outcome was the episode of FN(fulfilled criteria of Freifeld *et al.*, 2011), the secondary outcome was microbiologically proven bacterial bloodstream infection (BSI). Isolation of pathogens was performed by standard means with BacT/ALERT Standard Aerobic/Anaerobic bottles and BacT/ALERT 3D automated microbial detection system, identification and antibiotic resistance was studied with VITEK 2 system and disc-diffusion methods.

Categorical variables were analyzed with χ2 test and Fisher's exact test, and continuous variables were analyzed with the Mann-Whitney U test and Odds Ratio. A multivariate analysis with logistic regression was conducted for the categorical variables with P-value ≤0,2 in previously performed univariate analysis. Significant P-value considered to be <0,05.

Results: There were 87 patients with episodes of FN, the incidence of FN in HCST recipients was 36%. Among them 39 patients had microbiologically proven BSI, *i.e.* 16% of all HSCT recipients or 45% of those who had FN. Most of the cases of BSI were caused *by E. coli, Kl. pneumoniae, P. aeruginosa, A. baumannii, Streptococcus spp.* Among independent statistically significant risk factors for both FN and BSI were: profound neutropenia (OR 2,34, 95% CI 1,19-13,24, p=0,012 for FN; OR 2,44, 95% CI 1,96-9,54, p=0,005 for BSI); neutropenia duration >14 days (OR 1,37, 95% CI 1,08-12,93, p=0,049 for FN; OR 1,68, 95% CI 1,14-8,73, p=0,045 for BSI) and active main disease on start of HSCT procedure (OR 3,41; CI 2,32-8,63, p=0,01 for FN; OR 1,28, CI 1,04-3,81, p=0,049 for BSI). Prior to HSCT patients colonization with ESBL-positive *Enterobacteriaceae spp.* and prior ICU hospitalization had a trend towards the statistical significance as a risk factors of BSI, what may be proved by using larger number of patients in the future studies (OR 1,64, 95% CI 0,89-4,36, p=0,64 for colonization; OR 2,31, 95% CI 1,27-6,41, p=0,72 for ICU hospitalization).

Summary and Conclusions: The above named risk factors and most common pathogens should be taken into account when choosing a clinical approach to empiric antibacterial treatment and prophylaxis in adult HSCT patients.

E1186

ANALYSIS OF 75 CASES OF ACUTE LEUKEMIA WITH INVASIVE FUNGAL DISEASE

C. Wang[1], Y. Fu[1], Y.H. Tan[1,*]
[1]Tumor Center, First Hospital of Jilin University, Changchun, China

Background: Acute leukemia patients are susceptible to invasive fungal disease, proper diagnosis and treatment is important for reducing morbidity and mortality.

Aims: To analyze the clinical characteristics of invasive fungal infections in patients with acute leukemia (AL), explore the early diagnosis and prevention strategy.

Methods: Acute leukemia patients with invasive fungal disease (IFD) treated in cancer center of the First Hospital of Jilin University from 2014 January -12 months were analyzed retrospectively according to the "criteria for the diagnosis and treatment principles of hematological malignant patients with invasive fungal disease (The Fourth Edition of China)", the outcome of the disease and the curative effect were analyzed simultaneously.

Results: In 211 cases of AL patients, 75 cases (35.5%) include 49 AMLs and 26 ALLs occurred IFD, the male to female ratio was 49:26, the median age was 48 years old (8□83 years old). 73 cases were lungs IFD, 1 case was liver and spleen IFD, 1 case was intestinal IFD. Among of the 75 cases, there were 1 case with proven IFD (blood culture positive for Candida), 8 cases with probable IFD, 23 cases with possible IFD and 43 cases with uncertain IFD. Host factors included neutropenia (70 cases, 93.3%), the application of hormone for more than 3 weeks (10 cases, 13.3%), a history of previous fungal infection (4 cases, 5.3%), allogeneic transplantation (1 cases, 1.3%), prior application of broad-spectrum antibiotics was confirmed in 69 patients (92%). 31 cases (41.3%) showed specific CT signs, wherein the air crescent sign in 1 case, pulmonary cavity in 1 case, liver and spleen buphthalmos sign in 1 cases, and the rest cases showed compact, clear boundary lesions, including 5 cases with halo sign. 30 cases (40%) of patients showed non-specific CT signs, such as small nodules, multiple patchy shadow, ground glass shadow, emphysema or bronchiectasis. Positive G test was found in 12 patients and positive GM test was in 10 cases, of which both test positive was in 9 cases. All 23 patients with possible IFD were identified as fungal infections according to the subsequent treatment response and disease evolution, 23 cases (53.5%) was eventually identified as fungal infection in 43 uncertain IFD patients, so in total 75 patients, 55 patients were eventually identified as fungal infection, accounting for 26.6% of all patients with 211 leukemia patients. All 75 patients received antifungal treatment, including 9 cases of target therapies, 46 cases of diagnosis driven therapies, 20 cases of empiric therapies. 7 cases (77.8%) were effective in target therapies, 36 cases (78.3%) was eventually identified as fungal infection in 46 diagnosis driven therapies patients, in which 31 case (86.1%) were effective. 10 cases (50%) was confirmed with fungal infection in 20 empiric treatment patients, and were all effective. The overall effective rate was 89.1% (48/55).

Summary and Conclusions: IFD is one of the main causes of infection in acute leukemia patients. High resolution CT and G test, GM test were important in the diagnosis of IFD. Early diagnosis and treatment is the key to improve the efficacy of IFD. The application of "criteria for the diagnosis and treatment principles of hematological malignant patients with invasive fungal disease (The Fourth Edition of China)" can be a very good guide for the clinical diagnosis and treatment.

E1187

ACINETOBACTER BAUMANNII SURVEILLANCE MEASURES IN HAEMATOLOGICAL MALIGNANCIES PATIENTS

V. Calafiore[1,*] E. Mauro[1], C. Conticello[1], T. Pollicino[1], V. Zammit[1], E. Spina[1], E. Martino[1], M.C. Pirosa[1], R. Manuele[2], A. Imbriani[3], P.F. Fiumara[1], F. Di Raimondo[1]
[1]Division of Hematology, [2]Division of Infectious Diseases, [3]Division of Microbiology, Azienda Policlinico-OVE, University of Catania. Via Citelli n. 6, 95124, Catania, Italy

Background: Acinetobacter baumannii is a gram-negative, strictly aerobic,nonfermentative coccobacillus that causes infections in immunocompromised and chronically ill patients. Recently, it has emerged as a major cause of health care-associated infections (HCAIs) in addition to its capacity to cause community-acquired infections. It is associated with multidrug resistance and it is considered to be among the most difficult anti-microbial-resistant bacilli to control and treat. Given to its antimicrobial resistance, treatment options are severely limited, and to the best of our knowdlwdge there aren't any controlled trials to guide therapeutic choices. In severely ill patients multidrug-resistant *Acinetobacter* infections are associated with an extremely high morbility and mortality rate. It is therefore necessary the developement of measures that can prevent or early identify Acinetobacter infection.

Aims: Despite the high proportion of infection related death, particularly sustained by multidrug-resistant bacteria among wich A. Baumanii, there are only few reports on Acinetobacter infection and measures to prevent and treat the bacillus spread and infection in patients affected by haematological malignancies. Moreover, these reports are case reports or describe small population of patients. Here we describe our experience on Acinetobacter measures of early detection.
Methods: Between January 2014 and December 2014 pharyngeal swabs were performed on 139 haematological patients on the date of admission in the hematology Section of Catania University and none was positive for Acinetobacter. We also performed 32 serial pharyngeal swabs on hospitalized patients and when cases of Acinetobacter bacteraemia were detected (2 cases) as empirical test to early detect contamination and treat positive symptomatic cases.
Results: Seven swabs were positive for A. Baumanii, all in heavily treated and advanced stage patients (3 AML patients, 1 MM, 2 CLL, 1 LNH) and, of these, 3 patients died for concomitant complications, 2 patients developed Acinetobacter baumannii bacteremia that caused septic shock and death, and 2 were successfully treated with inhaled colistin for the eradication of bacterium from the respiratory tract, preventing bacteriemia. This method was not described before and allows an early detection of the Bacillus. Moreover, it could be used not only for cohorting patients but also as a signature marker for subsequent clinical infections. In addiction, early treatment with aerosolized Colistin for the eradication of MDRAB colonization in the respiratory tract resulted as salvage therapy for the 2 patients described that are still alive after eradication.
Summary and Conclusions: In conclusion A. Baumanii colonization are difficult to manage in immunocompromised patients but an appropriate swabs surveillance, application of strict infection control measures and use of aerosolized Colistin therapy could be of help.

E1188

DOES NEUTROPENIA AFFECTS HERPES VIRUS REACTIVATION IN CRITICALLY ILL PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND PNEUMONIA?
D. Tikhomirov[1,*] T. Garanzha[1], V. Troitskaya[2], T. Tupoleva[1], T. Romanova[1], G. Galstyan[3], E. Parovychnikova[2], F. Filatov[1]
[1]Laboratory of Virology, [2]Department of Hematology, [3]Intensive care unit, Hematology Research Center, Ministry of Health of the Russian Federation, Moscow, Russian Federation

Background: Chemotherapy applied in hematological malignancies management leads to blood cells count decreasing which in turn leads to a deterioration in the condition of the patient. Leucocyte count diminishment involves not only tumor cells but neutrophils as well. It can cause ICU admission. Neutrophils are essential for immune regulation and opportunistic infection prevention. Nevertheless life-threatening complications like nosocomial pneumonia and or respiratory failure can occur within any granulocyte count during chemotherapy. Herpes viruses tend to reactivate in immunodeficient person. Acute herpes virus infection can cause lung injury.
Aims: The aim of the study was to estimate frequency of herpes viruses in critically ill patients with hematological malignancies and pneumonia during immunodeficiency
Methods: 38 critically ill patients with hematological malignancies suffered from pneumonia were enrolled in the study: 18 with acute leukemia, 8 with ly… 2… le… si… D… P… **R**… h… o… B… (2… si… d… E… vi… p… ir… fi… fr… w…

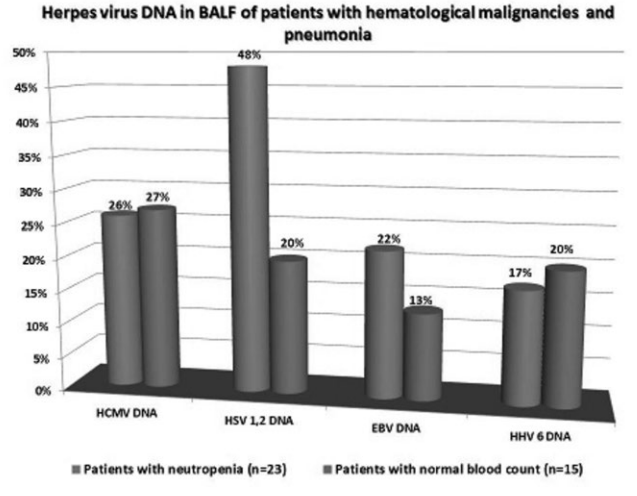

Figure 1

Summary and Conclusions: Obtained data show twice higher frequency of herpes virus DNA detection in BALF of immunodeficient hematological patients. Viral load is also higher if neutropenia occurs. This proves, granulocyte count reduction can be associated with viral lung injury complications.

E1189

NOCARDIA INFECTION IN PATIENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION
M. Stamouli[1,*] A. Bouhla[1], K. Girkas[1], M. Atta[1], N. Papanikolaou[1], C. Economopoulou[1], C. Roubakis[1], A. Vassilatou[1], K. Godopoulos[1], E.D. Ioannidou[1], K. Petevi[1], E. Pessach[1], S. Papageorgiou[1], V. Pappa[1], E. Bazani[1], P. Tsirigotis[1]
[1]2nd Department of Internal Medicine Propaedeutic, Attikon University Hospital, Haidari, Greece

Background: Patients undergoing allogeneic stem cell transplantation are at increased risk of opportunistic infections. *Nocardia*, a gram positive bacterial agent, is an uncommon cause of infection. The diagnosis of Nocardiosis can be quite challenging because of technical difficulties (difficulty in obtaining adequate samples and growing cultures). The disease usually presents in a subacute manner in immunocompromised patients but its course is often life threatening.
Aims: The objective of this study was to record the incidence of nocardiosis in patients who received stem cell transplants in our hospital and to describe their clinical characteristics.
Methods: Seventy patients who had undergone allogeneic stem cell transplantation between 2009 and 2014 were retrospectively evaluated. Reason for transplant, graft *vs* host disease (GvHD), site of infection, *pneumocystis jiroveci* prophylaxis, treatment regimens and outcome were recorded.
Results: In the above period of six years, 40 out of 70 patients developed graft *vs* host disease (acute GvHD:24 cases, chronic GvHD:23 cases) that required corticosteroid treatment. None of the remaining 30 patients developed nocardiosis. Of the 40 patients with GvHD, 35 patients received co-trimoxazole as prophylaxis for *pneumocystis jiroveci* and five patients alternative prophylaxis such as pentamidine and atovaquone. Again in the 35 patients who received co-trimoxazole, no nocardiosis occurred, while three out of five patients (60%) on alternative prophylaxis developed infection due to *nocardia*: osteomyelitis in a man with acute lymphoblastic leukemia, disseminated disease (involving the lung, brain, liver, spleen, kidneys and possibly the duodenum) in a man with myelofibrosis and pulmonary nocardiosis in a woman with chronic myeloid leukemia. The woman eventually died of nocardiosis. The two men with nocardiosis were successfully treated with adequate antibiotic combinations (one of them is still under co-trimoxazole).
Summary and Conclusions: Though uncommon, nocardiosis should be kept in mind when it comes to patients undergoing allogeneic stem cell transplantation. Graft *vs* host disease and its treatment seriously affect the host's immune status and could increase patient susceptibility to the disease in this subgroup of patients. Interestingly in our center all patients who were diagnosed with nocardiosis were not receiving co-trimoxazole as prophylaxis for pneumocystis jiroveci while none of the patients under co-trimoxazole prophylaxis ever developed any infection caused by *Nocardia spp*.

E1190

INFECTIOUS COMPLICATIONS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES/ACUTE MYELOID LEUKEMIA TREATED WITH 5-AZACITIDINE
S. Ramos[1,*] M. Santos[1], R. Tenreiro[1], M. Pereira[1], E. Cortesão[1], L. Rito[1], M.L. Ribeiro[1]
[1]Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Azacitidine (AZA) is the standard of care for high-risk myelodysplastic syndromes (MDS). Its mechanism of action includes demethylation, cytotoxicity and the induction of apoptosis. Thus, cytopenias are a major problem during the first cycles of treatment, when hematological improvement has not yet been achieved. The risk of infection in this period of treatment has been demonstrated to be substantial. Indeed, in the AZA-001 trial, infections occurred in about 50% of AZA-treated patients. The incidence and features of these infectious complications has been addressed mainly in controlled clinical trials, with highly selected patients, making it controversial to extrapolate the results to "real life" patients.
Aims: We aimed to compare the incidence of infectious complications during AZA treatment in a cohort of "real life" patients with the published data.
Methods: We retrospectively evaluated the incidence of infectious complications during AZA treatment in a cohort of patients with high risk MDS and Acute Myeloid Leukemia (AML).
Results: Fifty one patients started AZA treatment between 31/07/2006 and 24/03/2014. Median age at diagnosis was 69 years (49-83 yrs, 34 males, 17 females). Median age at the start of treatment was 71 years (49-83). There were 44 MDS and 7 AML. MDS classification according to the WHO 2008 was: Refractory cytopenia with multilineage dysplasia (n=10); Refractory anemia with excess blasts 1 (n=12); Refractory anemia with excess blasts 2 (n=17); Chronic Myelomonocytic Leukemia (n=4); Refractory anemia with ring sideroblasts (n=1). AZA was started at a median of 4.99 months from diagnosis in a standard dose of 75 mg/m2, on a 5-2-2 schedule. A median of 5 (1-34) cycles of AZA were delivered to each patient. In a total of 353 cycles, 31 (8.8%) infectious episodes occurred in 12 patients (23.5%). The median time to first infection was 1.9 (0.2-41.9) months. Six patients (11.8%) had a single episode of infection after a median of 3.2 months from the start of AZA (0.4-41.9 months).

In the 6 patients who had two or more infectious episodes, the second one occurred after a median of 4.7 (3.2-25.2) months from the start of AZA. The median neutrophil count at the time of infection was 0.35 (0-16)/μL. In 17 of 31 (54.8%) infections, grade 3-4 neutropenia was present. In these 31 infectious episodes, a positive microbiologic test was available in 11 cases (35.4%). Eighteen bacteria and one fungus were isolated (table). Twenty-three hospitalizations were required in 11 (91.7%) of the 12 patients who had infections, with a median duration of 17 (2-59) days. The most frequent infection sites were the lungs (32.2%) and the skin (19.4%). Infections were the attributable cause of death in 7 hospitalized patients: five of them died due to pneumonia and 2 to fever of unknown origin. Eighteen patients with MDS (38.3%) progressed to AML under AZA, after a median of 7.5 (2.5-23.0) months. With a median follow-up of 16.3 (2.1-223.7) months, 15 patients were alive, resulting into a median overall survival of 20,5 (10,1-30,8) months.

Table 1.

Product	Microbiologic result
Blood	*Staphylococcus epidermidis* (n=2) Oxacilin-resistant *Staphylococcus haemolyticus* *Staphylococcus hominis* *Staphylococcus aureus* (n=2) *Pseudomonas aeruginosa* (n=2) *Escherichia coli (n=2)* *Enterobacter cloacae* *Enterococcus faecium* *Acinetobacter baumannii*
Bronchoalveolar lavage	*Staphylococcus aureus*
Sputum	*Aspergillus flavus*
Skin	Methicillin resistant *Staphylococcus aureus*
Urine	*Escherichia coli* *Klebsiella pneumoniae*
Faeces	*Clostridium ramosum*

Summary and Conclusions: We found a relatively high probability of infectious complications following treatment of MDS/AML with AZA, especially pneumonia, wich was also the main cause of death. However, in our cohort, the incidence of infections (23.5%) was inferior of that related in the published data. We concluded that in a setting of not highly selected patients, like our cohort, infections during AZA treatment are not more incident than those described in the literature.

E1191

FACTORS AFFECTING THE OUTCOME OF FEBRILE NEUTROPENIA IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES

H. Zawam[1], W. Edesa[1], R. Salama[1,*] M. Gaber[2], M. Sherief[3], C. Naseef[1], N. Ezzat [1]
[1]Clinical oncology department, [2]Clinical pathology department, [3]Chemical pathology department, Cairo university, Cairo, Egypt

Background: Febrile neutropenia(FN) is one of the most seroius complications in patients (pts) with hematological malignancies.The prompt initiation of empirical antiboitics within 1 hour of fever has lead to reduction of mortality and improvement of survival .Several risk assesment guidlines have been adopted to identify pts as low and high risk of complications.We conducted this single institution study to determine specific risk factors that may affect the outcome in pts with FN.
Aims: To identify specific factors that may affect the response to treatment in pts with febrile neutropenia.
Methods: During the peroid of 1st of April 2014 untill the end January 2015, pts with hematological malignancies who presented to clinical oncology department and developed FN during management were enrolled in this prospective analysis. At the onset of fever, pts underwent complete physical examination, in addition to blood culture, urine and stool culture. Computer tomography of the chest and paranasal sinuses and serial galactomannan (GM) test were requested in cases with uncontrolled fever or suspected invasive fungal infection (IFI).Polymerase chain reaction analysis of bacteria and fungi from the blood and bronchoalveolar lavage were performed in selected cases.The data were analyzed using chi-square test.
Results: One hundred and thirty five (135) pts were identified and analyzed. The mean age was 38.5 years (range 14-76). 51% had acute myeloid leukemia, 36% acute lymphoblastic leukemia (ALL), non hodgkin's lymphoma, chronic lymphocytic leukemia, and multiple myeloma were diagnosed in 7%, 4%, and 2% respectively .According to Multinational Association for Supportive Care in Cancer (MASCC) index, 80 pts (60%) were categorised as high MASCC score (<21), while 55 pts (40%) had low MASCC score (>21). Blood culture was negative in 114 pts (84%), while it was positive in 21 pts(16%). Gram negative bacteria constituted 60% of cases, while gram positive were 40 %.Serial GM test was positive in 24 pts only (17%),88 pts (65%) did not receive antifungal agents. Fluconazole was used as antifungal prophylaxis in the majority of pts (n=95)(71%), of those who did not receive fluconazole (n=40), only 15 pts (37.5%) developed IFI and were classified according to 2008 European organization for research and treatment of cancer/invasive fungal infections cooperative group and the national institute of allergy and infectious diseases mycoses study group (EORTC/MSG) Consensus; 12 pts had probable fungal infections,2 pts had possible fungal infections and 1 patient had definitive fungal infection. The choice between first line antibiotics (ceftazidime, maxipime, imipenem) or antifungal (amphotericin, voriconazole) had no impact on the recurrence of FN attacks (P<0.08 and p<0.23 respectively).In terms control of fever on 1st line antibiotics, there was statistically significant difference in favour of low risk MASCC score (p<0.001),change of antibiotics due to uncontrolled fever was required in 62 pts (45%),there was a significant difference between defervescence and low/high MASCC score (P<0.001). With respect to first antifungal used, a significant correlation was observed between low/high MASCC score and control on first antifungal therapy (P<0.006). In the present study ,16 pts(12%) only were diabetics, there was no significant correlation between diabetes and uncontrolled fever, prolonged neutropenia .Prolonged FN (>7days) was observed in 40 % of pts ,the use of corticosteroids, and non administration of granulocyte colony stimulating factor (G-CSF) were the predominant risk factors (P<0.001 ,P<0.002 respectively). In terms of mortality, only pts with high MASCC score(n=11) (8%) had the worst outcome compared to low score(n=1) (P<0.0001).
Summary and Conclusions: There are multiple factors that may affect the outcome of pts with FN and it should be taken in considerations during mangment of FN such as MASCC score, previous use of corticosteroid and G-CSF adminstration during FN.

VARIOUS PATTERNS OF HEPATITIS B VIRUS REACTIVATION IN B CELL LYMPHOMA

A. Nakaya[1,*] S. Fujita[1], A. Satake[1], T. Nakanishi[1], Y. Azuma[1], Y. Fujita[1], M. Hotta[1], H. Yoshimura[1], K. Ishii[1], T. Ito[1], S. Nomura[1]
[1]First Department of Internal Medicine, Division of Hematology and Oncology, Kansai Medical University, Osaka, Japan

Background: It has been reported that reactivation of hepatitis B virus (HBV) could be fatal in patients with malignancy following systemic immunosuppressive chemotherapy, especially combined with rituximab. The prophylactic nucleoside analog therapy is recommended in the current guidelines to treat HBV reactivation in which the incidence of HBV reactivation was proved to be reduced. On the while, how HBV reactivation exhibits clinical course in patients with lymphoma treated with rituximab-containing chemotherapy has to be elucidated.
Aims: To investigate various patterns of HBV reactivation in lymphoma patients receiving Rituximab-contaionig chemotherapy.
Methods: We retrospectively analyzed 541 patients with B cell lymphoma who were treated with rituximab-containing regimens between 2006 and 2013 at Kansai Medical University Hospital.

Table 1. Characteristics of 18 patients with HBV infection in B-cell lymphoma.

Age	Sex	Diagnosis	Chemotherapy	HBsAg	HBcAb	HBsAb	HBV DNA (log copies/ml)	HBV prophylaxis	Reactivation	HBV treatment after reactivation	IgG(mg/dl)	Time to event(days)

Abbreviations: DLBCL, diffuse large B-cell lymphoma; FL, follicular lymphoma; MCL, mantle cell lymphoma; HBV, hepatitis B virus; HBsAg, hepatitis B surface antigen; HBsAb, hepatitis B surface antibody; HBcAb, hepatitis B core antibody; ASCT, autologous stem cell transplantation; M, male; F, female; Time to event, days to reactivation/breakthrough

Results: A total of 541 patients were studied. Most common subtype of lymphoma was diffuse large B-cell lymphoma. Among 541 patients, 14 patients (2.5%) were hepatitis B antigen (HBs Ag) positive carrier. Among these 14 carriers, 12 patients whose HBV-DNA level was positive at diagnosis were treated with nucleoside analog. Two patients whose HBV-DNA were undetected at diagnosis, without prophylactic nucleoside analog, converted to reactivation after the chemotherapy. Two patients who received prophylactic nucleoside analog therapy developed breakthrough hepatitis long after diagnosis (median: 351 days). One-hundred and seven patients (19.7%) had occult HBV infection (HBs Ag negative, HBc Ab positive or HBs Ab positive). Among occult patients, 5 patients converted to reactivation (de novo hepatitis) during the chemotherapy and received nucleoside analog. All of these de novo hepatitis patients were presented with hypogammaglobulinemia (median: 511 mg/dl) at reactivation. Of all reactivated patients, 2 patients underwent autologous stem cell trans-

plantation (ASCT). One was a carrier received prophylactic nucleoside analog, and whose HBV-DNA became undetected, but she developed secondary reactivation long after ASCT. The other was de novo hepatitis, he converted to late-onset reactivation after ASCT. These two patients were also presented with hypogammaglobulinemia (median: 301 mg/dl) at reactivation.
Summary and Conclusions: We achieved improvement on management against HBV reactivation through the guideline to prevail on us to use prophylactic nucleoside analog therapy. Here we addressed that HBV reactivation could exhibit various patterns as we develop to treat lymphoma with new immunosuppressive agents as well as hematopoietic cell transplantation. Therefore, we have to pay attention to each pattern of HBV reactivations in treating them beyond the guidelines.

LB2080

REACTIVATION OF HEPATITIS B INFECTION IN HAEMATOLOGY PATIENTS RECEIVING RITUXIMAB THERAPY: EVIDENCE OF SUB-CLINICAL ALT FLARES IN HBSAG-/HBCAB+ PATIENTS

S. Mackenzie[1,*] S. Cheeseman[1], L. Waters[2], M. Scully[1], K. Ardeshna[1], D. Linch[1], J. Lambert[1]
[1]Department of Haematology, [2]Department of HIV Medicine, University College London Hospital, London, United Kingdom

Background: Reactivation of hepatitis B virus (HBV) following Rituximab therapy is a well-recognized phenomenon. In patients with pre-existing serological markers of chronic (surface antigen positive [HBsAg+]) HBV infection, the rate of Rituximab-associated HBV reactivation is approximately 80-100% in the absence of nucleotide analogue (NA) prophylaxis. In patients with serological markers of past infection (HBsAg-negative [HBsAg-]/core antibody positive [HBcAb+]), this rate varies between 0% and 45%. European guidelines therefore recommend that all patients are HBV serotyped (with HBsAg and HBcAb) prior to treatment with Rituximab. Patients with active hepatitis B disease should not receive therapy with Rituximab, and those with positive HBV serology but no active disease should be referred to a hepatologist for specialist monitoring and therapy, including measuring HBV DNA levels and starting prophylactic NA therapy.
Aims: To determine: i) the proportion of patients appropriately screened prior to Rituximab and if HBsAg-/HBcAb+, the proportion tested for HBV DNA levels: ii) the rate of ALT flares in the HBsAg-/HBcAb+ patients
Methods: Between January - October 2014, Haematology patients in a tertiary level centre who received Rituximab were identified from the electronic prescribing database. Pathology records were used to determine demographic characteristics, evidence of HBV serotyping, HBV DNA levels and whether HBsAg-/HBcAb+ patients received NA therapy. Patients with a high ALT at any time following Rituximab were categorised into groups of ALT >50 or >150 IU/L.
Results: Of the 230 patients administered Rituximab, 82% had malignant diagnoses and 18% non-malignant diagnoses. 166 patients (72%) underwent HBV serotyping. Of these, 19 (11%) were HBsAg-/HBcAb+ and 2 were chronic HBsAg+/HBcAb+ carriers. Of the HBsAg-/HBcAb+ patients, seven (33%) were tested for HBV DNA at least once and none were positive. Both HBsAg+/HBcAb+ patients had detectable HBV DNA. Four (21%) of the HBcAb+ and both the HBsAg+ patients were started on NA therapy. The proportion of patients with an ALT >50 IU/L following Rituximab therapy was higher in the HBcAb+ group compared to the HBcAb- group (47% *vs* 25% p = 0.04). There was a trend to a greater number of patients with an ALT >150 IU/L in the HBcAb+ group compared to the HBcAb- group, but this was non-significant (21% vs. 13% p = 0.07). Of the 64 patients who did not undergo any HBV serotyping, 30 patients (18%) had an ALT of >150 and one developed an ALT of >1000 IU/L.
Summary and Conclusions: Although there were no patients with HBV DNA-confirmed reactivations in the HBsAg-/HBcAb+ patients in this study, the higher proportion of patients with an ALT >50 IU/L in the HbsAg-/HBcAb+ group suggests that there were sub-clinical ALT flares in this group, and suggests that the frequency of HBV DNA monitoring impacts on the measured reactivation rate in previous studies. The study also highlights that increased awareness amongst Haematology clinicians is needed to improve rates of HBV serotyping prior to and monitoring for reactivation following Rituximab administration to avoid preventable HBV-related complications.

USING PET/CT TO ASSESS FDG NODAL UPTAKE AND IMPACT OF VIRAEMIA IN HIV-POSITIVE PATIENTS: A COMPARISON OF REACTIVE LYMPHADENOPATHTY, MULTICENTRIC CASTLEMAN DISEASE AND HIV-RELATED LYMPHOMA

S.C. Mackenzie[1,*] N. Ranganathan[2], M. Noursadeghi[1], S.G. Edwards[2], R. Miller[2]
[1]Division of Infection and Immunity, University College London Hospital, [2]HIV and Sexual Health , Mortimer Market Centre, Camden Provider Services, Central and North West London NHS Foundation Trust, London, UK, London, United Kingdom

Background: PET/CT is a widely used imaging modality in the investigation, diagnosis, staging and assessment of treatment response in patients with lymphoma and has an increasing role in investigating HIV-positive patients with pyrexia of unknown origin (PUO). Its use in differentiating malignancy from infection in the evaluation of intracranial lesions in the context of HIV, for example, is well-recognized. HIV-related immunosuppression predisposes patients to a number of additional phenomena however, including opportunistic infections, HIV-related reactive lymphadenopathy, immune reconstitution and the lymphoproliferative disorder Multicentric Castleman disease (MCD). These can lead to false-positive interpretations of malignancy, particularly in untreated patients with high viral loads (VL) and therefore special consideration is required when evaluating PET/CT in patients with HIV. There remains considerable debate about which factors are most important in predicting the aetiology of lymphadenopathy using PET/CT in the HIV setting.
Aims: To compare PET/CT findings in HIV-positive patients with lymphoma, reactive lymphadenopathy and MCD to identify differentiating factors. We aimed to look specifically at the effect of VL on nodal and splenic characteristics and used radiological parameters to assess this.
Methods: Patients with HIV who presented with PUO and who subsequently had imaging with18F-FDG PET-CT were identified. Patients were categorised into 4 groups after final diagnosis: i) reactive lymphadenopathy ii) MCD iii) HIV-associated lymphoma and iv) confirmed infectious or other miscellaneous condition; the latter group were excluded from analysis in this study. Electronic records were used to record baseline demographic characteristics and CD4 count, plasma HIV load and ART status. All lymphoma and MCD diagnoses were confirmed on biopsy and all patients with reactive lymphadenopathy had extensive inpatient investigations which excluded an infectious or other aetiology. PET/CT imaging was reviewed by a radiologist and SUV_{max}, distribution of lymphadenopathy and liver-spleen ratio calculated.
Results: 80 patients were identified, of which 39 had HIV-related reactive lymphadenopathy, 26 had lymphoma and 15 had MCD. The mean age was 42 years and 74% were male. There were higher median SUV_{max} values among patients with lymphoma compared to reactive lymphadenopathy and MCD (12.0 vs. 5.6, p=0.0021, 12.0 vs. 5.7, p=0.0041, respectively). There was a trend to higher median SUV_{max} values in the reactive lymphadenopathy group with a detectable VL compared to the undetectable group, but this difference was not significant (5.9 *vs* 4.0) and there was no difference between the MCD and reactive lymphadenopathy groups. Reversal of the liver:spleen avidity ratio was observed more commonly among those with detectable viral loads but did not aid discrimination between diagnoses.
Summary and Conclusions: This is the largest PET/CT series of HIV-positive patients with fever and lymphadenopathy. Significantly higher SUV_{max} values were observed among lymphoma cases and despite MCD being a lymphoproliferative disorder, showed similar median SUV_{max} values to reactive lymphadenopathy. There was no effect of high or low viraemia on SUV_{max} in patients with both MCD or lymphoma which may be helpful clinically when serial PET/CT imaging is available. Finally, this study confirms that both histological and radiological evidence of HIV-related reactive nodal changes were seen even in patients with complete serum virological suppression and this should therefore be borne in mind when investigating HIV-positive patients for lymphoma.

ANTIMICROBIAL-RESISTANT GRAM-NEGATIVE BACTERIA IN BLOODSTREAM INFECTIONS IN PATIENTS WITH PEDIATRIC HEMATOLOGY & ONCOLOGY AND PEDIATRIC BONE MARROW TRANSPLANTATION UNIT

A. Akcay[*] D. Atay[1], F. Erbey[1], B. Varol[2], D. Arman[2], G. Ozturk[1]
[1]Department of Pediatric Hematology- Oncology and Bone Marrow Transplantation Unit, Acibadem Univercity Medical Faculty, Acibadem Atakent Hospital, [2]Department of Microbiology, Bahcelievler Medical Park Hospital, Istanbul, Turkey

Background: Patients with cancer are at high risk for infections caused by antibiotic resistant gram-negative organism.
Aims: To survey blood cultures taken from the patients hospitalized in pediatric hematology & oncology clinic and pediatric bone marrow transplantation unit and inspect the antibiogram of antimicrobial-resistant gram-negative organisms.
Methods: The blood cultures taken from children hospitalized in pediatric hematology & oncology and pediatric bone marrow transplantation clinics from April 2011 to April 2014 during fever and/or clinic infection existence were evaluated retrospectively. The gram-negative organisms grew in the blood cultures and their antibiograms were inspected. Antibiotic-resistance was classified as multidrug resistant (MDR), extensively drug resistant (XDR) and pandrug resistant (PDR).
Results: Pathogen organisms had grown in 632 (12%) of 5287 blood cultures. Among all of the organisms, 86.5% gram positive and 13.5% (n=85) gram negative organisms were identified. Forty-three (50%) of gram negative organisms were antimicrobial-resistant. The anti-microbial resistant gram-negative organisms identified in the blood cultures were *Klebsiella pneumoniae* (n=24; 11 with ESBL resistant, 11 with MDR/XDR; and 2 with PDR), *Acinetobacter baumannii* (9; 8 with MDR/XDR; and 1 with MDR), *Pseudomonas aeruginosa* (n=5; 4 with MDR/XDR and 1 with MDR), Escherichia coli (n=5 with ESBL resistant).
Summary and Conclusions: In pediatric hematology-oncology patients, bloodstream infections with antibiotic-resistant gram negative pathogens has recently increased. They are associated with increased morbidity and mortality. It is clear that the introduction of novel antibiotics will lead to improvements in the treatment of MDR, XDR and PDR.

E1193

CAR MEDIATES DIFFERENTIATION AND MIGRATION OF ERYTHROPOIETIC PROGENITOR CELLS AND IS SPECIFICALLY DOWN-REGULATED IN MDS

K. Bauer[1,*] S. Machherndl-Spandl[2], S. Suessner[3], M. Danzer[3], J. Proell[3], J. Lauf[4], G. Eisenwort[1], W.R. Sperr[1], H.-U. Klein[5], G. Hoermann[1], N. Häfner[6], M.C. Béné[7], U. Platzbecker[8], A. Weltermann[2], C. Gabriel[3], T. Lion[1], U. Germing[9], P. Bettelheim[2], P. Valent[1]
[1]Medical University of Vienna, Vienna, [2]Elisabethinen Hospital Linz, [3]Transfusion Service of Upper Austria, [4]Labor Europaplatz, Linz, Austria, [5]University of Muenster, Muenster, [6]Jena University Hospital, Jena, Germany, [7]CHU de Nantes, Nantes, France, [8]University of Dresden, Dresden, [9]Heinrich-Heine-University, Düsseldorf, Germany

Background: Myelodysplastic syndromes (MDS) are myeloid neoplasms characterized by peripheral cytopenia, an accumulation of dysplastic cells in the bone marrow (BM) and a high risk of transformation to acute myeloid leukemia. Transfusion-dependent anemia develops in most patients. In the refractory anemias the accumulation of dysplastic erythroid BM progenitor cells (EryPC) which paradoxically accompanies peripheral anemia, is a typical finding.
Aims: The biochemical basis of the maturation defect of erythroid cells and their abnormal accumulation in the BM are still unknown. Therefore, we were interested to examine abnormally regulated and functionally relevant genes expressed in MDS EryPC.
Methods: In our study, we have established a screening program involving mRNA expression profiling studies of EryPC in patients with low-risk MDS and control BM samples obtained from patients with other BM neoplasms as well as patients with unexplained cytopenia, normal BM or reactive/deficiency cytopenias. EryPC were defined as $CD45^{low}/CD105^{+}$ cells and purified from BM mononuclear cells by multicolor flow cytometry (MFC) and cell sorting. mRNA expression profiles were analyzed by Affymetrix array technology and confirmed for a panel of selected mRNA species by qPCR.
Results: In mRNA- and MFC-validation experiments, we found that the major Coxsackie-Adenovirus Receptor (CAR) is specifically down-regulated in $CD45^{low}/CD105^{+}$ EryPC in MDS patients when compared to EryPC in normal BM or other control cohorts. In line with this observation, the immature erythroblastic cell lines HEL, K562 and KU812 stained negative for CAR. Lentiviral transduction of the full-length *CAR* gene into these cells resulted in a significantly increased expression of various erythroid differentiation antigens, including CD36, CD71 and Glycophorin-A as determined by flow cytometry and qPCR. Furthermore, *CAR* transduction resulted in an increased migration of HEL cells against a serum protein-gradient in a transwell assay. Transfection with truncated variants of *CAR* did not result in an increased expression of erythroid antigens or an increased directed migration.
Summary and Conclusions: In conclusion, our data show that CAR is a functionally relevant molecule that promotes the expression of early erythroid differentiation antigens on myeloid progenitor cells and their migration against blood serum proteins. In patients with MDS, CAR is downregulated on EryPC, which may have implications both in terms of the pathogenesis of the disease and the application of this novel marker in diagnostic MFC algorithms. With regard to functional consequences, we hypothesize that CAR-deficiency is pathogenetically relevant as it may not only contribute to the maturation-defect of EryPC in MDS but also to the related accumulation of erythroid cells in the BM that is accompanying the peripheral anemia in these patients.

E1194

RUNX1 MUTATION AND LOW RUNX1 TRANSACTIVATING ACTIVITY PREDICT HIGHER RISK OF AML TRNASFORMATION AND INFERIOR LEUKEMIA-FREE SURVIVAL IN CHRONIC MYELOMONOCYTIC LEUKEMIA

M.-C. Kuo[1,2,*] L.-Y. Shih[1,2], S.-C. Tsai[1], S.-T. Liang[3], Y.-J. Huang[1], Y.-S. Shih[1], T.-H. Lin[1], C.-Y. Lai[2], D.-C. Liang[3]
[1]Chang Gung Memorial Hospital, [2]Chang Gung University, Taoyuan, [3]Mackay Children's Hospital and Mackay Medical College, Taipei, Taiwan, ROC

Background: We have previously described a high frequency of *RUNX1* mutations in chronic myelomonocytic leukemia (CMML), the prognostic impact of *RUNX1* mutation and its biological activity on disease progression remain to be investigated.
Aims: We aimed to correlate *RUNX1* mutation status and its biological activity with clinical features in patients with CMML as well as to determine the role of RUNX1 mutants in secondary acute myeloid leukemia (sAML) transformation.
Methods: Bone marrow (BM) samples from 105 CMML patients at diagnosis were examined for *RUNX1* mutations by PCR-based analysis covering entire coding sequences from exons 3 to 8 of *RUNX1b* gene. Additional 25 genes related to the myeloid neoplasms were also analyzed. The RUNX1 mutant activity on target *C-FMS* gene induction was determined by luciferase reporter assay. The relative activity of each RUNX1b mutant was derived by measurement of luciferase intensity of each transfectant and normalized with wt-RUNX1b. Pyrosequencing was used to measure allele burden of mutated genes.
Results: Thirty-six of 105 patients (34.3%) with CMML had *RUNX1* mutations, 33 of them had co-existing mutations, including 13 *SRSF2*, 10 *ASXL1*, 9 *TET2*, 8 *EZH2*, 6 *NRAS*, 5 *CEBPα*, 3 *CBL*, 3 *SETPB1*, 3 *U2AF1*, 3 *SF3B1*, 2 *DNMT3A*, 2 *FLT3*-TKD, and one each of *IDH2*, *PTPN11*, *MLL*-PTD, and *CSF3R*. The RUNX1 mutants were grouped into high and low activity according to their relativet ransactivating activities (cut-off was 0.52), 30% of 103 CMML patients had low RUNX1 activities. Both *RUNX1* mutation and low biological activity were significantly associated with lower platelet count, higher WBC count and monocytosis, and higher BM blasts. Patients with low activity were younger and had more CMML2 subtype. There was no correlation of hemoglobin level, cytogenetics or IPSS-R with *RUNX1* mutation status or mutant activity. Forty-five patients progressed to sAML, 32 had matched paired CMML/sAML samples available for clonal evolution analysis; 17 were positive for *RUNX1* mutations at both phases. The allele burden of *RUNX1* mutations remained stable except 3 in which a new *RUNX1* mutant clone emerged while the previous one declined at sAML phase and accompanied the co-emergence of *NRAS* mutation and *FLT3*-TKD in one each of them. In addition, *RUNX1* mutant clones evolved in another two patients and with the acquisition of *IDH2 with FLT3-ITD* and *SRSF2* mutations, respectively in each of them during sAML progression. We also found that one lost *TET2* mutation and the other lost *JAK2*V617F during disease progression. *RUNX1* mutation was associated with an increased risk of sAML transformation compared with non-mutated patients (58% *vs* 33%, *P*=0.021) and shorter leukemia-free survival (LFS) (23.3±3.1 months *vs* 47.8±17.7 months, *P*=0.042) but with no impact on overall survival (12.5±3.2 months *vs* 13.2±1.5 months, *P*=0.147). CMML patients with low RUNX1 activities had a higher risk of sAML transformation (64.5% *vs* 31.9%, *P*=0.004) and inferior LFS (19.7±4.6 months *vs* 47.8 months, *P*=0.010) compared with high activity group. By including additional gene mutations for outcome analysis, both *RUNX1* mutation status and biological activity were the most important prognostic predictors.
Summary and Conclusions: Our results showed that *RUNX1* mutation and low RUNX1 transactivating activity predicted higher risk of sAML progression and shorter LFS in CMML patients. (Grant support: NHRI- EX103-10003NI, OMRPG3C0021, MMH-E-101009, MOST103-2321-B-182-015, and MOHW103-TD-B-111-09).

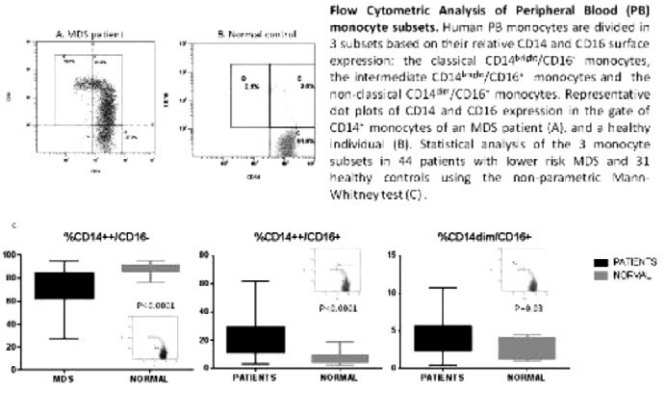
E1195

ABNORMAL MONOCYTE POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROMES

M. Velegraki[1,*] H. Koutala[1], E. Rousaki[1], A. Damianaki[1], S. Mastrodemou[1], C. Pontikoglou[1], H. Papadaki[1]
[1]Haemopoiesis Research Laboratory, University of Crete, School of Medicine, Heraklion, Greece

Background: Immune deregulation is implicated in the pathogenesis of Myelodysplatic Syndromes (MDS). Monocytes are an important part of the innate immune system; circulating human monocytes are phenotypically and functionally heterogenous. They typically express the CD14 antigen and are divided in the $CD16^{-}$ (classical) monocytes and the $CD16^{+}$ monocytes which can be further subdivided in the $CD14^{bright}/CD16^{+}$ (intermediate) monocytes and the $CD14^{dim}/CD16^{+}$ (non-classical) monocytes. Classical monocytes seem to be involved in tissue repair while intermediate monocytes are mainly pro-inflammatory. The role of the monocyte cell subsets in the pathogenesis/pathophysiology of MDS has not been extensively studied.
Aims: The aim of this study was to investigate for quantitative abnormalities in peripheral blood (PB) monocyte subsets of patients with MDS that might have an impact on the pathogenesis/pathophysiology of the disease.
Methods: We have studied 44 patients with Very Low/Low risk MDS according to the R-IPSS score and 31 age and sex matched healthy individuals. Four-colour Flow Cytometry was used to assess the three monocyte subsets based on their relative CD14 and CD16 surface expression. Furthermore, the Mean Fluorescence Intensity (MFI) of the CCR2 and the CX_3CR1 chemokine receptors, which are characteristically expressed by monocytes, was determined in each monocyte subpopulation.
Results: Analysis was performed within the CD14+ cell population. A significant increase in the proportion of the $CD16^{+}$ monocytes was observed in MDS patients (26.4±15.4%) compared to normal controls (10.2±4.9%) (P<0.0001) which was associated with a significant decrease of the $CD16^{-}$ monocytes in patients (73.6±15.3%) compared to controls (89.8±4.9%) (P<0.0001). Among the $CD16^{+}$ monocytes, the most prominent increase was observed in the intermediate $CD14^{bright}/CD16^{+}$ monocytes which were increased both as cell proportions (22.1±13.8%) and absolute cell numbers (133.5±118.5/μl) in patients compared to healthy controls (7.8±4.2% and 50.1±36.3/μl, respectively) (P<0.0001 and P=0.0012, respectively). Furthermore, the percentages of the $CD14^{bright}/CD16^{+}/CCR2^{+}$ and the $CD14^{bright}/CD16^{+}/CX_3CR1^{+}$ cells, were increased in MDS patients (19.2±14.2% and 16.2±13.3%, respectively) compared to normal controls (6.9±3.2% and 7.4±4.8%, respectively) (P=0.0008 and P=0.0273, respectively). The $CD14^{bright}/CD16^{+}$ monocytes of MDS patients consisted of a higher proportion of $CCR2^{+}$ (91.8±6.4%) and a lower proportion

of CX_3CR1^+ (87.1±15.6%) cells compared to healthy individuals (87.7±6.7% and 97.3±3.6%, respectively) (P=0.04 and P=0.001, respectively). Interestingly, the MFI of CCR2 was significantly increased in the $CD14^{bright}/CD16^+$ monocytes of MDS patients (12.9±3.2) compared to normal controls (7.2±2.4) (P<0.0001) (Figure 1).



Flow Cytometric Analysis of Peripheral Blood (PB) monocyte subsets. Human PB monocytes are divided in 3 subsets based on their relative CD14 and CD16 surface expression: the classical $CD14^{bright}/CD16^-$ monocytes, the intermediate $CD14^{bright}/CD16^+$ monocytes and the non-classical $CD14^{dim}/CD16^+$ monocytes. Representative dot plots of CD14 and CD16 expression in the gate of $CD14^+$ monocytes of an MDS patient (A), and a healthy individual (B). Statistical analysis of the 3 monocyte subsets in 44 patients with lower risk MDS and 31 healthy controls using the non-parametric Mann-Whitney test (C).

Figure 1.

Summary and Conclusions: We have showed for first time that patients with lower risk MDS display significantly increased numbers of circulating $CD14^{bright}/CD16^+$ monocytes which are also phenotypically altered. The possible involvement of this abnormal cell population in the excessive pro-inflammatory cytokine production and ineffective hematopoiesis of lower risk MDS is currently under investigation.

E1196

GLUTATHIONE S-TRANSFERASE P1 (GSTP1) PROMOTER HYPERMETHYLATION IN MDS/AML: ASSOCIATION WITH SPECIFIC CHROMOSOME ABBERATIONS

S. Zachaki[1], A. Daraki[1], M. Kalomoiraki[1], C. Stavropoulou[1], D. Koumbi[1], K. Manola[1], A. Parcharidou[2], P. Kollia[3], C. Sambani[1,*]
[1]Health Physics, Radiobiology & Cytogenetics, NCSR "Demokritos", Athens, Greece, [2]Bedford Hospital NHC, Bedford, United Kingdom, [3]Department of Genetics &and Biotechnology, Faculty of Biology, Athens, Greece

Background: Gene silencing by epigenetic alterations is a common event in carcinogenesis. The GSTP1 gene is a well-known housekeeping gene involved in carcinogen detoxification. Its expression has been linked to cancer incidence and drug resistance. It has been reported to be the target of somatic CpG island promoter hypermethylation in various types of human neoplasia, such as prostate, breast and liver cancer. Recently, there is an ongoing preclinical and clinical platform of drug discovery based on the activity of GSTP1 inhibitors in stimulating multilineage differentiation of hematopoietic progenitors.
Aims: The aim of the study was to investigate the possible contribution of epigenetic inactivation of the GSTP1 gene in MDS and AML *via* DNA promoter hypermethylation. We also assessed possible associations of GSTP1 methylation pattern with specific chromosomal aberrations and the presence of $A^{313}G$ GSTP1 germline inactivating polymorphism.
Methods: Our case-control study enrolled 116 patients [(62 MDS, 29 *de novo* AML and 25 AML cases preceded by MDS (MDS-AML)] and 25 healthy donors. Cytogenetic analysis of bone marrow samples was successfully performed for all patients at diagnosis. Total genomic DNA was extracted from patients' and controls' samples using the QIAamp DNA-extraction midi kit (Qiagen, Hilden, Germany). GSTP1 promoter methylation status was studied by methylation-specific PCR (MSP) using the CpG WIZ® GSTpi Amplification Kit (Chemicon, Canada, USA). The $A^{313}G$ GSTP1 genotyping was performed by Real-Time PCR on the Biorad CFX96 (Biorad, California, USA) using GoTaq® qPCR Master Mix (Promega, USA).
Results: Our results showed that GSTP1 gene promoter was hypermethylated in 39 out of 116 patients (33.6%). All control samples were found to be completely unmethylated. Hypermethylation of GSTP1 promoter was found in 21 out of 62 MDS (33.9%), 6 out of 29 AML (20.7%) and 12 out of 25 MDS-AML cases (48.0%). A significantly increased frequency was observed in MDS (p<0.001) and MDS-AML patients (p<0.001). The GSTP1 promoter hypermethylation was not found to be associated with the $A^{313}G$ GSTP1 polymorphism. Stratification of patients according to their cytogenetic findings revealed a significantly increased frequency of methylated cases in the group of patients showing a normal karyotype, as compared to those with an abnormal karyotype (60.0% *vs* 38.9%, respectively). Among patients with an abnormal karyotype, the most common chromosome aberrations were trisomy 8 (+8), -5/del(5q) and -7/del(7q) followed by del(20q) and loss of Y chromosome (-Y). The higher frequencies of GSTP1 hypermethylation were found in cases with -7/del(7q) (45.0%) and -5/del(5q) (33.5%) (p<0.001).
Summary and Conclusions: The results indicate an important role of the GSTP1 epigenetic silencing in MDS/AML pathogenesis, extending our knowledge on epigenetic alterations of the GSTP1 gene in hematological malignancies. The remarkably high frequency of GSTP1 promoter hypermethylation in patients with chromosome 7 abnormalities is consistent with the use of DNA demethylating agents in treatment of MDS with loss of chromosome 7. Further, the findings might suggest that GSTP1 hypermethylation could be a potential epigenetic biomarker for MDS response to treatment, mainly in cases under treatment with GSTP1 inhibitors.

E1197

CIRCULATING MICRORNAS IN PLASMA OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES

M. Dostalova Merkerova[1,*] Z. Krejcik[1], A. Hrustincova[1], E. Ratajova[1], M. Belickova[1], J. Cermak[2]
[1]Department of Genomics, [2]Clinical Department, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Myelodysplastic syndromes (MDS) represent a wide range of hematopoietic stem cell disorders characterized by ineffective hematopoiesis, peripheral blood cytopenias, and a tendency to evolve into acute myeloid leukemia. MicroRNAs (miRNAs) are short endogenous non-coding RNA molecules that play an essential role in the regulation of gene expression at post-transcriptional levels. Existence of miRNAs has been recognized not only in the intracellular environment but it has recently been shown that these molecules are also present in a wide variety of body fluids, including blood plasma. Cell free miRNAs (referred to as circulating miRNAs) have been repeatedly proved to function as new promising semi-invasive diagnostic markers of various types of cancer but only little information is known about their deregulation in MDS.
Aims: In this study, we focus on alteration of miRNA levels circulating in plasma of MDS patients with the emphasis on differences between low and high risk disease.
Methods: Peripheral blood plasma was collected from 40 patients with untreated primary MDS and from 10 healthy, age-matched donors with no medical history. Written informed consent was obtained from all tested subjects in accordance with the Institutional Review Board. Total RNA was extracted from plasma using Qiagen miRNeasy mini kit. Agilent Human miRNA Microarrays were used to assess the amount of 2,006 human miRNAs in blood plasma from 13 MDS patients and 6 healthy donors. The microarray results were confirmed in the complete set of samples by RT-qPCR.
Results: Statistical analyses identified significant differences in a plasma profile of circulating miRNAs between different study groups. In MDS, 19 down-regulated and 25 up-regulated miRNAs were detected compared to healthy controls. Some hematopoiesis and/or oncology-associated miRNAs were found in the list of deregulated molecules, *e.g.* down-regulation of miR-92a-3p, miR-142-3p/5p, miR-320a/b/d/e, and miR-451a, and up-regulation of miR-150-5p, miR-188-5p, and miR-548q. Low-risk and high-risk groups of patients significantly differed in levels of several miRNAs, namely in reduction of miR-185-5p and miR-4306 and elevation of miR-548q, miR-623, miR-4707-5p, miR-4721, and miR-4739 in high-risk patients.
Summary and Conclusions: Expression profiling of plasma miRNAs in patients with MDS revealed several miRNAs with altered levels gradually changing within the disease progression, suggesting that circulating miRNAs may be new candidate molecular markers for monitoring of the disease.
This work was supported by the grant NT13847-4 from the Ministry of Health of the Czech Republic.

***IN VITRO* CULTURE OF BM CELLS OF MDS PATIENTS AND CYTC POLYMORPHISMS CAN PREDICT THE *IN VIVO* HEMATOLOGICAL RESPONSE OBSERVED DURING IRON CHELATION THERAPY WITH DEFERASIROX**

D. Cilloni[1,*] M. Podestà[2], C. Cossu[2], C. Calabrese[1], F. Sabatini[2], L. Del Corso[3], P. Niscola[4], M. Crugnola[5], A. Poloni[6], M.T. Voso[7], S. Fenu[8], A. Pelizzari[9], F. Salvi[10], D. Gioia[10], E. Masiera[10], E. Balleari[3], G. Saglio[1], F. Frassoni[2]
[1]Dept of Clinical and Biological Sciences, University of Turin, Orbassano, [2]stem cell laboratory, G. Gaslini Institute, [3]dept of Internal Medicine, University of Genova, Genova, [4]S. Eugenio Hospital, Rome, [5]University of Parma, Parma, [6]University of Ancona, Ancona, [7]University "Cattolica", Roma, [8]San Giovanni Hospital, Rome, [9]University of Brescia, Brescia, [10]SS Arrigo e Biagio Hospital, Alessandria, Italy

Background: Several studies showed that iron chelation therapy (ICT) can induce hematological improvement and transfusion independence in a significant percentage of MDS patients. However, we do not have clinical or biological parameters to identify patients with high probability of such hematological response.
Aims: The aim of the study was to identify either a molecular marker and/or an *in vitro* assay to predict *in vivo* hematological improvement to deferasirox treatment.
Methods: 22 MDS patients from 9 Italian Centers were enrolled in the study.

Five were RA, 4 RARS, 8 RCMD, 4 RAEB I, 1 CMML. In 6 of them ICT induced RBC transfusion independence during the first 6 months of therapy, one experienced hematological improvement but he stopped therapy after few months for progression.
BM samples were collected from 22 patients before deferasirox treatment and during follow up. BM cells were incubated with deferasirox 50 micromolar for 12 hrs and tested for colony formation in semisolid culture medium. In addition, different mitochondrial genes, including COX1, COX2 and CytB were sequenced in all the patients enrolled.
Results: In 8 out of 22 patients (3 RA, 2 RARS, 2 RCMD, 1 CMML) the *in vitro* incubation with deferasirox resulted in a significant increase of colonies (BFU-E, CFU-GM and CFU-GEMM). (mean value of BFU-E: 9±4 before incubation and 19±11 after incubation). Interestingly, 6 of these 8 patients who showed an "*in vitro*" response experienced transfusion independence after *in vivo* treatment with deferasirox. The responders continued to maintain the "*in vitro* response " throughout subsequent analysis during the follow-up. The other two 22 "*in vitro* responder" could not be evaluated for *in vivo* response.
By contrast patients who did not respond *in vitro* to deferasirox did not reduce the transfusion requirement. In parallel we analyzed mtDNA in BM MNC cells and we found a strict association between two polymorphisms of CytB (14766 and 15326) and the hematological response to deferasirox therapy.
Summary and Conclusions: The hematological improvement during deferasirox therapy in MDS patients can be predicted by colony assay after *in vitro* incubation with deferasirox. Mitocondrial gene polymorphisms seems to be associated with hematological response. Several other patients are under evaluation and may confer further solidity to this correlation. At the same time, new studies may shed new light on the mechanism of deferasirox activity.

MUTATIONAL PROFILE IN MYELODYSPLASTIC SYNDROMES BY HIGH-DEPTH NEXT GENERATION SEQUENCING AND CLINICAL RELEVANCE
M.T. Cedena[1,*] R. Ayala[1], I. Rapado[1], J. Martínez-López[1]
[1]Hematology, H. 12 Octubre, Madrid, Spain

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clinical entities. Cytogenetic abnormalities are an important hallmark of prognosis, but they are only present in 30-50% of patients. New technologies, such as next generation sequencing (NGS), have found somatic mutations in a considerable number of patients.
Aims: To optimize the technique of high-depth NGS in our center, to compare our preliminary results with the main previously published outcomes and to define their clinical significance in SMD patients.
Methods: We analyzed the mutational profile and copy number variation (CNV) of 86 MDS patients, using the *Ion Torrent Proton (Life Technologies)* system for NGS. We selected a library of 35 genes related to myeloid pathologies. An optimal depth of coverage, median about 2000, and uniform sequence coverage (92%) were reached, contributing to a high sensitivity. Additionally, clinical characteristics were considered: sex, age, WHO classification, cytogenetic risk, IPSS-R, and outcome.
Results: Eighty six MDS patients, median age: 76 (range: 44-90), were selected. The diagnosis, according to WHO classification, were: RA (4), RARS (9), RCMD (32), RAEB1 (13), RAEB2 (11), MDS associated with isolated del5q (2), CMML (12), and MDS/AML 20-30% blasts (3). Very low, low, intermediate, high and very high risk categories according to IPSS-R were found in 23, 26, 11, 9, and 15 patients, respectively. The median follow-up time was 12 month (range: 1-50). A total of 163 somatic mutations were found in 76 out of 86 patients (88%). The more frequent mutations were: TET2 (21%), SF3B1 (19%), ASXL1 (15%), TP53 (13%), DNMT3A (13%), JAK2 (13%), RUNX1 (9%), EZH2 (8%), ZRSR2 (7%), IDH1 (7%), CBL (6%), MLL (6%), IDH2 (6%), ETV6 (6%) and the remainder had frequencies of ≤5%. The results are very similar to those than have been previously published. CNV analyses showed alterations, gains or losses of copies, in 65 out of 86 patients (76%). HRAS, involved in regulating cell division, the erythroid transcription factor GATA1 and the transcriptional regulator ATRX presented gains in an appreciable proportion of patients, 28%, 23% and 20%, respectively. In contrast, genes, such as KIT and TET2, presented losses of copies in 16% and 15% of patients. Considering the clinical characteristics, SF3B1 mutations were associated to WHO classification and IPSS-R; and TP53 mutations were associated to cytogenetic risk and to IPPS-R. In univariate analysis, cytogenetic risk, IPSS, IPSS-R, WHO classification and presence of TP53 mutations were associated with shorter survival. Patients with TP53 mutations had a significantly poorer overall survival than those without the mutation (median 7 m *versus* 38 m; *P=0.001*). In multivariate analysis, only TP53 remained the independent prognostic factor for overall survival (HR=5.2; 95% CI: 2.0-13.5; P=0.001).
Summary and Conclusions: Taking into account mutations and CNV, and using methods of high-depth NGS, more than 95% of MDS patients present genetic abnormalities. TP53 mutations, that were closely associated to high risk cytogenetic and poor prognosis categories of IPSS-R, remained the independent prognostic factor for overall survival. In conclusion, high-depth NGS seems to be a promising tool to improve our understanding of the genetic alterations in SMD in order to consider them in future algorithms for diagnosis and prognosis.

Orsola-Malpighi Hospital, Hematology, Bologna, [5]S.Giuseppe Moscati Hospital, Hematology and Transplant Center, Avellino, [6]Pugliese-Ciacco Hospital, Hematology, Catanzaro, [7]Department of Experimental, Diagnostic, and Specialty Medicine, Hematopatology Section, S. Orsola-Malpighi Hospital, Bologna University, Bologna, [8]Fondazione GIMEMA, Roma, [9]Urbino University, Institute of Biomathematics, Urbino, Italy

Background: Myelodysplastic syndromes (MDS) are hematologic neoplasms characterized by ineffective hematopoiesis and an increased risk of transformation into acute myeloid leukemia. The pathogenesis and the outcome of MDS is thought to evolve from accumulation and selection of specific genetic or epigenetic events. We hypothesized that genetic variants in DNA repair, synthesis or methylation genes may affect the clinical course of MDS patients.
Aims: To investigate the prognostic value of genetic polymorphisms in BER system, DNA synthesis and folate-metabolizing genes on survival of MDS patients.
Methods: We genotyped 113 MDS patients, 54 with IPSS low/int-1 receiving only best supportive care (BSC) (low risk group) and 59 with IPSS int-2/high treated with azacitidine (high risk group), for the following polymorphisms: xRCC1 194 and 399, xRCC3 241, TS5'-UTR (2R/3R and G/C) and 3'-UTR (6bp+/6bp-), MTHFR 677 and 1298, APE1 148. Genomic DNA was analyzed by High Resolution Melting assay and restriction digests of PCR products. Overall survival (OS) was calculated using the Kaplan-Meier estimate probabilities, and differences between survival curves were analyzed by the log-rank test. The association between genetic variants and survival was assessed using stepwise logistic regression model.
Results: For all target genes, the distribution of genotypes was consistent with the Hardy-Weinberg equilibrium. The median period of observation of patients was 27 months for low risk group and 13 months for high risk group. In the low risk group,xRCC1 399 GG [Hazard ratio (HR)=4.65; p=0.05], TS3'-UTR -6/-6 (HR=7.07; p=0.02), TS5'-UTR 2R/3G, 3C/3G, 3G/3G (HR=11.44; p=0.02) and MTHFR 677 TT (HR=67.12; p=0.0001) variant alleles were associated with a statistically significant adverse clinical outcome, if compared to the reference groups. Interestingly, when we subsequently analyzed the association between the genetic variants and OS in the high risk group, we found that 3 out of the 4 variants associated with an adverse outcome in the low risk group were still significantly associated to lower survival even in the high risk group [XRCC1 399 GG (HR=5.71 p=0.002),MTHFR 677 TT (HR=8.58 p=0.0001), TS3'-UTR +6/+6 (HR=0.097 p=0.004)]. Finally, we performed an exploratory analysis to investigate the combined effect of the unfavorable genotypes on survival. In the low risk group, the 3-year OS was 33% for those patients with ≥2 variant alleles, as compared to 62.5%, and 100%, respectively, for those with 2 or 0/1 variant alleles. The predictive role of the combination of the adverse genotypes on survival was confirmed also in the high risk group, suggesting that patients with a higher number of genetic polymorphisms had a shorter survival. Interestingly, treatment with azacitidine conferred a survival advantage to patients with unfavorable genetic variants, resulting in the absence of a survival difference between low-risk patients treated with BSC only and high-risk patients treated with azacitidine.
Summary and Conclusions: These data suggest, for the first time, that genetic variants in TS, MTHFR andxRCC1 genes could independently modulate OS of both low and high risk MDS patients, representing a possible new prognostic marker able to provide guidance for clinical management of MDS patients.

SIRPB1: BIOMARKER OF RESPONSE TO 5-AZACITIDINE TREATMENT IN MDS AND AML PATIENTS
V. Guadagnuolo[1,*] C. Papayannidis[1], I. Iacobucci[1], M.C. Fontana[1], G. Simonetti[1], A. Padella[1], E. Imbrogno[1], S. Paolini[1], M.C. Abbenante[1], S. Parisi[1], C. Sartor[1], E. Ottaviani[1], A. Ferrari[1], M. Delledonne[2], M. Malagola[3], C. Filì[3], D. Russo[3] M. Cavo[1], G. Martinelli[1]
[1]Department of Hematology and Medical Sciences "L. and A. Seràgnoli", Bologna University, Bologna, [2]Department of Biotechnology, Verona, [3]Unit of Blood Diseases and Cell Therapies, Brescia, Italy

Background: Myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) are a group of diseases of the elderly that initiates in a hematopoietic stem cell and are characterized by clonal hematopoiesis and uncertain prognosis, mostly due to cytogenetic background. In both diseases, 5-Azacitidine (5-Aza) has been successful, inducing prolonged survival and delayed AML evolution.

Aims: To identify the genes mostly predictive of treatment response we use high-throughput genomic analysis (SNP arrays and/or NGS-RNA-seq and/or NGS-WES and/or GEP) in azacitidine-sensitive and resistant MDS/AML patients. Furthermore, we sought to correlate the specific alterations with clinical outcome.
Methods: The high-density CytoScan HD Array (Affymetrix, Inc) includes 2.67 million markers for copy number analysis, with 750,000 SNP probes, and 1.9 million non polymorphic (based on Copy Number Variants, CNV) probes for comprehensive whole-genome coverage. The results obtained by SNP Array, were analyzed by Chromosome Analysis Suite (ChAS) v1.2 (Affymetrix Inc.): using this software it is easy to distinguish between aberrations and artifacts, moreover it let to discover which genes are involved in the disease and their type of lesion (*e.g.* loss, gain, loss of heterozigosity, allelic imbalance, high copy gain, homozygous copy loss). We used also another important software, which is Nexus Copy Number™ v7.5 (BioDiscovery): it present the same features of ChAS, but it also allows to compare two or more group of patients with a statistical relevance.
Results: We treated 246 adult patients with MDS or AML: 214 patiens were AML and 32 were MDS with a median age of 59 and 70 years, respectively. Forty-five pts were treated with 5-Aza (32 MDS/13 AML), while 201 AML were treated with conventional chemotherapy. Forty-five MDS/AML patients were treated with at least one complete cycle of 5-Aza (75 mg/sqm/daily). SNP arrays was done in 22/45 (49%), 13 pts were defined "insensitive/resistant". Macroscopic CNAs affecting a complete chromosome or its arms were detected in 5 of 22 pts (23%), while classical cytogenetic was able to detect only two cases of trisomy 8 (9%), suggesting superiority of SNPs array for CNAs identifications. Chromosomic aberrations disease-related are more statistically frequent on patients "insensitive" *versus* patiens "sensitive" (64% *vs* 35%) ($p \leq 0.01$). Moreover we found that from the median of chromosomic alterations lenghts (in kbp) the group of "insensitive" MDS/AML patients to 5-Aza therapy present more losses than "sensitive" ones. By Nexus Copy Number software, we identify 137 genes highly differentially gain (SIRPB1 and KIT with $p \leq 0.05$) or loss (SIRPB1, LCE1C, BCAS1, EXD3 with $p \leq 0.05$) or LOH between "insensitive" *versus* "sensitive" to 5-Aza ($p \leq 0.05$). Among these genes, we focused on SIRPB1 (cytoband 20p13, 56Kbps), since it was loss on 14/22 (64%) "insensitive" pts (p=0,023) and gain on 7/22 (32%) "sensitive" ones (p=0,0324), respectively. SIRPB1 common deletion region length is 27 kbps and the common amplified region length is 30 kbps. By NGS-WES we analyzed 35/214 (16%) AML samples at diagnosis. We found mutations in SF3B1, NPM1, CBL, RUNX1, BCOR, KIT, GATA2, IDH2, KDM6A, KIAA1324L, PRIM2, RRN3, APOBR and again in SIRPB1 an heterozygous missense variant (rs45545343; p. H/D).
Summary and Conclusions: We conclude that SIRPB1 is a promising marker of response in patients with myelodysplastic syndromes and acute myeloid leukemia treated with 5-Azaciditine.

E1202

RPS14 EXPRESSION IN MYELODYSPLASTIC SYNDROME WITHOUT 5Q DELETION

K. Quiroz [1,*] C. Guillén [2] R. Ayala [1] J. Martínez [1]
[1]Haematology, Hospital 12 de Octubre, [2]Haematology, Hospital de Móstoles, Madrid, Spain

Background: Reduced RPS14 expression in myelodysplastic syndrome (MDS) with 5q deletion and the better prognostic of these patients are well demonstrated, however the role of lower expressed RPS14 in MDS without 5q deletion remains unknown.
Aims: We studied RPS14 expression in MDS patients without 5q deletion and the role it plays in their prognosis and survival.
Methods: This study included bone marrow samples of 87 patients, 58 MDS patients (15 with 5q deletion and 43 without 5q deletion), 4 myelomonocytic leukemia, 12 chronic myeloproliferative disorders, 10 acute myeloid leukemia patients and 3 healthy donors; between years 2000 and 2014. We used the ABI PRISM® 7900HT (Applied Biosystems) detection system to quantify RPS14 expression. Statistical analysis was performed using the Statistical Package of Social Sciences (SPSS 15.0). Survival was estimated by the Kaplan-Meier method and compared with the log-rank test.
Results: Myelodysplastic syndrome and chronic myelomonocytic leukemia patients showed RPS14 lower expression than acute myeloid leukemia, chronic myeloproliferative disorders patients and healthy donors (p=0,08). MDS patients with 5q deletion showed lower RPS14 expression when compared to MDS patients without 5q deletion. The 56% (24/43) of MDS without 5q deletion shown low RPS14 expression. The mean follow-up of the patients was 51 months (0,1-172). There was no significant difference for overall survival rate between RPS14 lower and normal expression patients with MDS without 5q deletion. Patients in Intermediate-1 group with RPS14 lower expression, had longer overall survival than Intermediate-1 patients with RPS14 high expression (81% *vs* 50%).p=0.08 (Figure 1).
Summary and Conclusions: Lower expression of RPS14 in MDS without 5q deletion patients is associated with prolonged survival in Intermediate-1 prognosis group.

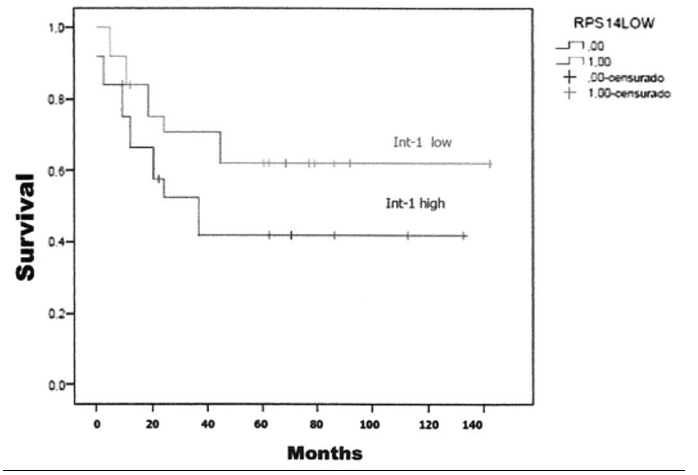

Figure 1.

E1203

AUTOPHAGY LEVEL WAS ABNORMAL IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

H. Wang[1,*] L. Guo[1], Z. Shao[1]
[1]Hematology, General Hospital, Tianjin Medical University, Tianjin, China

Background: Myelodysplastic syndromes (MDS) are clonal hematopoistic stem/preginitor cells disorders with cytopenia, myelodysplasia, ineffective hematopoisis, and high risk transform to acute myeloid leukemia (AML). The majority of patients are hepercelluar bone marrow while decreased peripheral blood cells.
Aims: To explore the change of autophagy and its significance in the myelodysplastic syndrome (MDS) patients by detecting the expression level of Beclin 1, mTOR, LC3 in bone marrow mononuclear cells (BMNC).
Methods: Thirty-eight patients with MDS and 26 non-malignant anemia patients were enrolled in this study. The iron content of BMNC was detected by iron staining. The level of reactive oxygen species (ROS) was detected by flow cytometry. The quantity of autophagic vacuoles were detected by transmission electron microscopy (TEM) and monodansylcadaverine (MDC) staining. The LC3 protein positive cells were counted by Immunofluorescence assays. The expression of Beclin 1, LC3A, mTOR mRNA were measured by real time PCR. The expression of Beclin 1 and LC3 proteins were detected by Western blotting.
Results: (1) The iron particles appeared more in MDS patients when viewed under a microscope and the intracellular iron content of MDS patients was also higher than that of controls. (2) The ROS level of MDS patients was significantly higher than that of controls. (3) The autophgic vacuoles of double membrane that surrounds lysosomes appeared in MDS patients. (4) The percentage of MDC positive cells was significantly higher in MDS patients than that of controls. (5) The percentage of LC3 protein cells was also increased in MDS patients (6.13%±1.03% *vs* 1.5%±0.58%, P<0.05. (6) The expression of Beclin 1, LC3A mRNA in low-risk and intermediate-1 MDS were higher compared with controls (3.61±3.02 *vs* 1.55±1.03 and 6.56±3.97 *vs* 1.21±0.95 respectively, both P<0.05. The expression of mTOR mRNA was down-regulated in low-risk and intermediate-1 MDS compared with controls (0.39±0.37 *vs* 1.50±1.03□P<0.05. There were no significant difference in expression of Beclin 1 and mTOR mRNA among the intermediate-2 and high-risk MDS and the controls. (7) The expression of Beclin 1 protein and LC3B were higher in MDS patients than that of controls.
Summary and Conclusions: The enhanced autophagy in low-risk and intermediate-1MDS might be considered as a cell protective mechanism. The relatively defective autophagy in intermediate-2 and high-risk MDS might contribute to its progress to AML.

E1204

CLINICAL RELEVANCE OF IL-6 AND TNF-ALFA IN THE CHARACTERIZATION OF LEUKEMIC STEM CELLS IN MDS PATIENTS

E. Cortesão[1,2,3,*] A.C. Gonçalves[2,3], C. Geraldes[1,2,3], A. Pereira[3,4], L. Ribeiro[1,3], J. M. Nascimento Costa[2,3,5], A.B. Sarmento Ribeiro[1,2,3,6]
[1]Hematology, Centro Hospitalar e Universitário de Coimbra (CHUC), Portugal, [2]Faculty of Medicine, University of Coimbra, [3]Center of Investigation on Environment Genetics and Oncobiology, Coimbra, [4]Internal Medicine Department, Hospital da Figueira da Foz, Figueira da Foz, [5]Oncology, Centro Hospitalar e Universitário de Coimbra (CHUC), Portugal, [6]Center for Neuroscience and Cell Biology and Institute for Biomedical Imaging and Life Sciences, Coimbra, Portugal

Background: Myelodysplasic Syndrome (MDS) is considered a clonal hematopoietic stem cell (HSC) disease, whereby the existence of changes in these type of cells, besides being based on the aetiology of the disease can also affect the progression to AML. Recently, a small subset of these cells was identified with unique ability to auto renovate and differentiate into different lineages of cancer cells that comprise the tumour, the cancer stem cells (CSC). These cells have been identified in many types of cancers, in particular cancer of the brain, breast, prostate, colon and pancreas, as well as in multiple myeloma and leukaemia (leukemic stem cells, LSC). Moreover, the development of MDS is accompanied by immune changes and production of antibodies and cytokines, such as IL-6 and TNF-α. However, the evaluation of these cytokines in the LSC and HSC has not been examined in patients with MDS.
Aims: To assess the relevance of IL-6 and TNF-α in HSC and LSC characterization, in MDS patients, in order to identify new prognostic and predictive markers as well as new therapeutic targets.
Methods: Analysis of clinical and analytical data of 102 patients with *de novo* MDS. The distinction between HSC and LSC was performed by flow cytometry using a panel of monoclonal antibodies conjugated with fluorescent probes in the following combinations: CD34/CD117/CD123/GIP and CD34/CD11/CD123/IL-6/TNF-α. All data were analysed using statistical tests (p<0,05).
Results: The sample consisted of 102 MDS patients with median age of 74 years (22-89) and with a ratio Male/Female 0.8. The MDS subtypes according to the WHO are: refractory cytopenia with multilineage dysplasia (RCMD) (n=52), refractory cytopenia with unilineage dysplasia (RCUD) (n=12), refractory anemia with excess blasts (RAEB) -1 (n=8), RAEB-2 (n=8), refractory anemia with ringed sideroblasts (RARS) (n=6), 5q- syndrome (n=4) and chronic myelomonocytic leukemia (CMML) (n=12), with IPSS: low (n=37), intermediate-1 (n=39), intermediate-2 (n=10) and high (n=1). Eleven patients progressed to AML: 7 patients with RAEB-2, 2 patients with RCMD, 1 patient with RAEB-1 and another with CMML. In our study we noticed an increase statistically significant in CD34+ cells in MDS patients in more advanced stages (RAEB-2), as well as in cells that co-express CD117, which can be related to the evolution of these patients to AML. Furthermore, the increase in CD34+/CD117+ cells observed in patients with RCMD may identify those who have a higher risk of leukemic transformation. Analysis of stem cell also allowed the identification of two groups of cells, one phenotypically 'normal' (HSC) and other with neoplastic characteristics (LSC) that differentially express the inflammatory cytokines IL-6 and TNF-α in the several MDS subtypes studied. The expression of IL-6 was observed in the HSC in RAEB-2 and in the LSC in refractory thrombocytopenia subtype. TNF-α was also observed in the HSC in CMML and in the LSC in RAEB-2 subtype. The presence of both cytokines in patients with RAEB-2 (p <0.05) is marked, although IL6 predominates in HSC and TNF-α in LSC. On the other hand, the presence of stem cells with the phenotype CD34+/ CD117+/IL-6+ may influence the progression to AML (p <0.05), and is also associated with a decreased overall survival (p <0.05).
Summary and Conclusions: These results suggest the importance of IL-6 and TNF-α in distinguishing two groups of hematopoietic stem cells in MDS patients, as they could influence the development and progression of the disease, as well as patient survival.

E1205

CONCORDANCE BETWEEN CYTOLOGY AND FLOW CYTOMETRY IN THE DIAGNOSIS OF CHRONIC MYELOMONOCYTIC LEUKEMIA

I. González-Gascón Y Marín[1,*] C. Muñoz-Novas[2], B. Alvarez-Flores[3], M.S. Infante[1], C. Heras[1], M.A. Foncillas[1], J.Á. Hernández Rivas[1]
[1]Hematology, [2]Hospital Universitario Infanta Leonor, [3]Flow Citometry, Laboratorio Central BR Salud, Madrid, Spain

Background: The diagnosis of chronic myelomonocytic leukemia (CMML) relies on cytology and cytogenetics, and both play an important role in the prognosis of this entity. Recently, other complementary tests such as flow cytometry (FCM) have been incorporated in clinical practice and become especially relevant in the diagnosis of doubtful cases.
Aims: The aim of this study was to analyze the discrepancies of the percentage of monocytes and the sum of promonocytes plus blasts (PM+BL) between cytology and FCM in CMML
Methods: In this study we carried out a retrospective analysis of the discrepancies between the percentage of monocytes and the sum of promonocytes plus blasts (PM+BL) at diagnosis, in cytological and FC bone marrow aspirate reports of 17 CMML cases diagnosed at our institution between 2010 and 2014. The diagnosis was stabilized according to the 2008 WHO classification. In order to identify myeloid precursors, promonocytes, monocytes, dysplastic changes in the monocytic population, and granulocytic maturation patterns by FCM, a panel with the following antibodies in 2 tubes was used: CD16/CD13/CD34/CD33/CD117/CD11b/CD45/HLA-DR and CD36/CD64/CD34/CD33/CD14/CD11b/CD45/HLA-DR. The acquisition of cells was performed in a flow cytometer BD FACSCanto II™ (BD Biosciences) and data were analyzed using InfinicytTM program (Cytognos). Statistical analysis was performed using SPSS version 21.0. The interclass correlation coefficient (ICC) was used to assess agreement between the 2 diagnostic methods and was interpreted as follows: excellent ICC >0.9; very good ICC 0.7-0.9; good ICC 0.5-0.70; moderate ICC 0.3-0.50, poor ICC <0.30
Results: Table 1 summarizes patient's characteristics, as well as the percentages of monocytes and BL+PM assessed by cytology and FCM. It is worth noting that most cases (15/17) were classified as CMML-1, and in the only 2 patients with CMML-2, the percentage of BL+PM detected by FCM was below 10%. FCM detected dysplastic alterations in all cases, being the most prevalent: hipogranulation in mature neutrophils, abnormal maturation patterns in neutrophils, increased percentage of monocytes, and altered expression of monocytic markers such as CD13 and CD33. We failed to find statistically significant differences in the percentage of BL+PM detected by cytology or FCM respectively (4 *vs* 2.8 P=0.2) neither in the percentage of monocytes (9 *vs* 10.7; P=0.2). In addition, the concordance between the percentages of BL+PM (ICC=0.453) and monocytes (ICC=0.488) by cytology and FCM was moderate.

Table 1. Patients characteristics and percentages of monocytes and BL+PM assessed by cytology and flow cytometry.

Patient	Gender	Age	2008 WHO	FAB	Cariotype	% BL+PM cytology	% BL+PM FCM	% monocytes cytology	% monocytes FCM	Outcome	Follow up (months)
1	Male	72	CMML-1	MD	Normal	2	2.88	9	6.7	Alive, progression	47
2	Male	55	CMML-1	MD	Normal	9	1	5	13.1	Alive, stable disease	25
3	Male	81	CMML-1	MP	Normal	3	2.09	6	6.52	Alive, progression	43
4	Female	91	CMML-1	MD	Normal	8	4.7	5	13.01	Dead	29
5	Female	75	CMML-1	MD	Normal	0	1.23	11	20.03	Alive, stable disease	45
6	Male	76	CMML-2	MP	Normal	17	9.58	9	10.36	Alive, progression	20
7	Male	73	CMML-1	MD	45X, -Y	0	3.34	7	10.01	Dead	27
8	Female	81	CMML-1	MD	Normal	2	4.66	10	12.63	Alive, stable disease	16
9	Female	81	CMML-1	MD	Normal	0	4.71	14	11.49	Alive, stable disease	32
10	Male	68	CMML-1	MD	Normal	0	0.34	25	10.7	Alive, stable disease	29
11	Female	78	CMML-1	MD	47XX, +8	7	3.6	11	11.2	Alive, stable disease	46
12	Male	85	CMML-1	MD	Normal	8	0	3	6	Alive, stable disease	12
13	Male	79	CMML-1	MP	Normal	4	2.62	10	11.35	Dead	14
14	Female	82	CMML-1	MD	Normal	2	3.71	7	6.43	Alive, stable disease	9
15	Male	73	CMML-2	MP	Normal	15	1.28	10	10.01	Alive, stable disease	7
16	Male	58	CMML-1	MD	Normal	4	2.56	9	7.76	Alive, stable disease	6
17	Male	81	CMML-1	MD	Normal	9	8.35	17	16.99	Alive, stable disease	3

Summary and Conclusions: FCM supported the diagnosis of CMML in all our cases, and therefore should be implemented specially in unclear cases by cytology. We could not find adequate concordance between cytology and FCM in the determination of the percentage of BL+PM, and monocytes. Cytology should still be considered the gold standard for the classification of CMML-1 and CMML-2 according to the 2008 WHO criteria.

E1206

MOLECULAR PROFILE OF TRANSFORMED AND NON TRANSFORMED INDIAN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

R. Chaubey[1,*] S. Sazawal[1], M. Mahapatra[1], S. Chhikara[1], R. Saxena[1]
[1]Hematology, All India Institute of Medical Sciences, New Delhi, India

Background: Myelodysplastic syndromes are characterized by bone marrow failure and a risk of progression to acute leukemia. So far, blast counts and cytogenetic abnormalities are known as major determinants of the risk for transformation. Molecular pathogenesis and the molecular basis for its progression to AML remain largely undefined. Although some case reports are available but no molecular study from India is available on the transformed MDS cases. Probably this is the only study with largest transformed MDS cases from Indian subcontinent.
Aims: This study was an attempt to look for the molecular changes that may be associated with transformation in MDS patients by comparing the molecular profile of transformed and non transformed cases.
Methods: Both DNA and RNA were extracted from mononuclear cells from patients Blood/ BM. Conventional cytogenetics was used for the detection of karyotypic abnormalities. Nested PCR was used for the screening of RAS gene mutations and RT-PCR was used to detect FLT3-ITD mutation and hTERT expression respectively. Telomerase activity was measured by PCR-ELISA-TRAP Assay. Methylation specific PCR was used to detect the methylation status of TSGs (p15, SOCS-1, FHIT & Calcitonin).
Results: A total of 100 MDS patients were studied, progression was observed in twenty one patients and no progression was found in 79 cases. Of the transformed cases, two patients progressed from RA to AML, 10 patients from RAEB2 to AML, 5 patients with RAEB-1 to AML, 1 patient with RAEB-2 to ALL, 2 patients with RA to RCMD and 1 patient with RAEB2 with del 5q to MF. The median time of progression was 15 months (Range 1-16 months). Of these progressed patients 6 were females and 15 were males. Median age of the transformed patients was 48 years (range : 9-77 years) whereas for non transformed 48 years (range :11-44 years).In non transformed patients favorable cytogentics was more evident than transformed patients (p <0.03).FLT3 mutations was not found in any patient or suppressor genes. The frequency of RAS mutations were significantly higher in transformed patient as compared to non transformed cases. Telomerase activity was significantly increased in transformed patients (p<0.009). Of all the four tumor suppressor genes studied, frequency of hypermethylation was significantly increased for the three genes in transformed patients *i.e.*, p15 (p<0.02), SOCS 1 (p<0.02), FHIT gene (p<0.02). After multivariate analysis of all the factors, $p15^{INK4b}$ gene methylation was found as an independent predictor for progression of disease (HR 5.15, 95% CI, 1.64-16.1 p=0.005) (Figure 1).

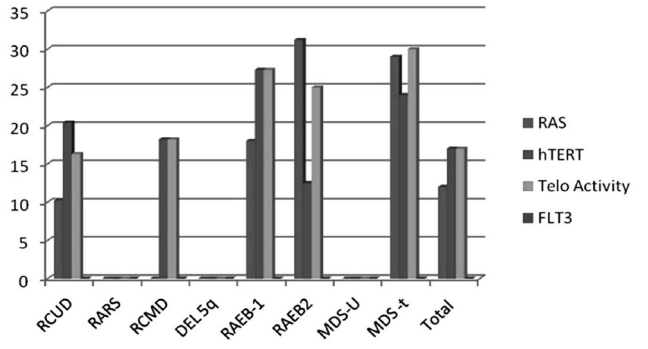

Figure 1. Frequency (%) of mutations within different WHO subtypes of MDS.

Summary and Conclusions: Molecular profiling of the Myelodysplastic Syndromes may give the information about the transformation and prognosis of the patients. Gene methylation may be one of the important factors in the process of transformation.

Myelodysplastic syndromes - Clinical

E1207

MANAGEMENT OF MYELODYSPLASTIC SYNDROMES WITH ERYTHROPOIESIS STIMULATING AGENTS : EVALUATION OF ERYTHROPOIETIC ASPECTS AND ANALYSIS OF RESPONSE

C. Cerchione[1,*] O. Vitagliano[1], L. Simeone[1], A.E. Pareto[1], I. Soriente[2], A.M. D'Arco[2], P. Danise[2], F. Alfinito[1], F. Pane[1]
[1]Hematology, AOU "Federico II", Napoli, [2]Hematology, Ospedale Umberto I, Nocera Inferiore (SA), Italy

Background: Erythropoiesis stimulating agents (ESAs) are the frontline treatment in lowriskanemic MDS patients and an employment of this therapy in the earlier stage of the disease can delay the need for RBC transfusion, hypothetically by slowing the disease course. It is matter of debate whether the clinical response is a result of proliferation and maturation of the dysplastic clone or stimulation of residual normal erythropoiesis by ESAs.
Aims: Macrocytosis is one of the cytological hallmarks of dyserithropoiesis in MDS : an analysis of the erythropoietic response to ESAs therapy in a cohort of anemic non trasfusion-dependent MDS patients, enrolled in a retrospective register, RECAMDS, subgroup of Italian MDS register, was performed.
Methods: 137 patients, treated with standard-dose ESAs, have been retrospectively analyzed (Table 1). Data analysis was performed, according to IWG 2006 criteria, at the baseline, after three and six months of continuous treatment, with a subanalysis of the patients according to WHO and R-IPSS risk stratification. ESAs treatment was started at mean Hb concentration of 9.5 g/dl, mean serum EPO concentration : 41mU/L, after a mean time from diagnosis of six months (r.1-118).
Results: Overall response rate (ORR) was 83% (114/137) and no difference among WHO and IPSS subgroups was found :76% achieved response after three months of treatment, while other 7% after six months. 2 patients with stable disease (non responders IWG), in which treatment was continued, achieved response after 9 months. In the macrocytic-responders group 87% exhibits again macrocytosis after 3 months, while 13% become normocytic. In the normocytic-responders group 92% exhibits again normocytosis, while 4/52 (8%) become macrocytic : in these 4 patients after three months there was a contemporary worsening in neutropenia and thrombocytopenia, with transfusion-dependence, regarded as first signs of progression of disease. Non responders were 23/137 (17%) : in the macrocytic-non responders group 89% exhibit again macrocytosis after 3 months, while 11% become normocytic; in the normocytic group 80% exhibits again macrocytosis, while 20% become normocytic : of these 74% become transfusion-dependent at 6 months (median time to transfusion 12 months : range 1-23).

Tablel 1.

MDS PATIENTS	137
M	66 (48%)
F	71 (52%)
WHO	
AR	44 (32%)
DEL 5q	9 (6%)
RAEB-1	5 (4%)
RAEB-2	2 (2%)
RARS	20 (14%)
RCMD	57 (41%)
R-IPSS	
VERY LOW	46 (34%)
LOW	79 (58%)
INTERMEDIATE	10 (7%)
HIGH	2 (1%)
ERYTHROPOIESIS	
BASELINE HB (mean, g/dL)	9.5 g/dL (r. 7.1-11.3)
BASELINE SERUM EPO (mean, mU/mL)	41 mU/mL (r.3-30)
OVERALL RESPONSE RATIO	
RESPONDERS	114/137 (83%)
RESPONDERS AT 3 MONTHS	105/137 (76%)
RESPONDERS AT 6 MONTHS	9/137 (7%)
RESPONDERS AT 9 MONTHS (NON RESPONDERS IN IWG 2006)	2/137 (2%)
NON RESPONDERS	23/137 (17%)

Summary and Conclusions: These preliminary data can suggest that, in the majority of MDS patients responsive to ESA treatment, the increase of hemoglobin concentration occurs mainly stimulating erythroid production in MDS clones; in the minority of patients probably it happens recruiting residual polyclonal erythropoiesis. It is interesting to note that stimulating effects of ESAs last even when the expression of dysplasia progresses.

E1208

IMPACT OF TREATMENT WITH RECOMBINANT HUMAN ERYTHROPOIETIN ALPHA ON CARDIAC REMODELING IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES: RESULTS FROM A PROSPECTIVE STUDY

L. Del Corso[1,*] G.M. Rosa[2], M. Bergamaschi[1], D. Bianco[2], T. Calzamiglia[3], P. Ghione[2], R. Ghio[1], F. Goretti[4], E. Molinari[1], O. Racchi[5], M. Scudelletti[6], R. Tassara[7], E. Arboscello[1]
[1]Hemato-Oncology, [2]Cardiology, IRCCS-AUO San Martino-Ist, Genova, [3]Internal Medicine, Asl 1, Sanremo, [4]Internal Medicine, Asl 2, Pietra Ligure, [5]Hemato-Oncology, Asl 3 Villa Scassi, Genova, [6]Internal Medicine, Asl 4, Sestri Levante, [7]Internal Medicine, Asl 2, Savona, Italy

Background: Myelodysplastic syndromes (MDS) are typical diseases of the elderly. The most frequent symptom is anemia. Both age and comorbidities have a relevant negative impact on the clinical outcome. In the case of a concomitant cardiac disease, the presence of anemia and its related iron overload, frequently observed in transfusion-dependent MDS pts, synergistically act with a harmful effect on the probability of survival. It is not a case that cardiac disease is the more common single comorbidity observed in the majority of MDS cohorts. Erythropoiesis stimulating agents (ESAs) have been demonstrated to reduce the transfusion requirements in pts affected by MDS with low/Intermediate-1 IPSS. Anemia appears to be strongly associated with cardiovascular morbidity and mortality.
Aims: Aim of our study is to investigate of early treatment with rHuEPO alpha may reverse cardiac remodeling, improve Ejection Fraction (EF) and reduce cardiovascular morbidity in "lower risk" MDS pts.
Methods: From January 2013 to January 2015, 40 MDS pts were included in a prospective observational multicentric study; 15 females and 25 males, of mean age 78 (range 61-92). According to the WHO 2008 classification, morphological MDS diagnosis were as follows: 17% Refractory Anemia (RA), 55% Refractory Cytopenia with Multilineage Dysplasia, 8% Refractory Anemia with Ringed Sideroblasts, 2% del 5q syndrome, 17% Refractory Anemia with excess of blasts-1. All pts had PSS low or int-1 risk and epo serum levels <500 mU/L.ESAs treatment was allowed when hemoglobin (Hb) was lower than 10.5 g/dL. All pts were analyzed with echocardiography before starting ESAs and every 6 months during the treatment. All echocardiography measurements were carried out according to the recommendations of the American Society of Echocardiography by un external investigator. Left ventricular mass (LVM) was calculated according to the Devereux formula and indexed to height. Left ventricular hypertrophy (LVH) was defined by a LVM index >47 in women and >50 in men. We also analyzed comorbidity by CIRS and cardiovascular risk factors. All pts were treated with rHuEPO alpha 40000 U weekly.
Results: At baseline all patients were transfusion-free and with mean Hb concentration of 9.66 g/dl. The rate of erythroid response to rHuEPO according to IWG criteria 2006 was 54%. No thrombotic events was eported. One or more comorbidity of any grade of severity was seen in 90% of pts at diagnosis. The more common comorbidity was cardiac (62,5%). Cardiovascular disorders were more frequent among older subjects (52% in >75y *vs* 30% in <75y), and among males. The median EF at baseline was upper than 55% and half pts had normal LVM. In 90% of pts with erythroid response EF was stable, in 10% improved and in 0% decreased while LVM was reduced in 35% of pts. The EF improvement and decrease of LVM was more evident in pts with cardiovascular comorbidities. None pts among "responders group" had cardiac comorbidity worsening ooor hospitalization. Anemia improvement and FE increase were associated with an imanananprovement of quality of life (QOL). The median observation time was 10 months (range 1-24). During the study period, 4 patients (10%) have died, respectively: 2 sepsis, 1 hearth failure, 1 leukemia evolution.
Summary and Conclusions: rHuEPO alpha treatment is effective and safe also in pts with cardiac comorbidities. In responders "lower risk" MDS pts, early treatment has been shown to improve FE and reverse cardiac remodeling with conseguence a reduction of cardiovascular risk/ hospitalization and improvement qment men uality of life. In pts with cardiac comorbidities the benefit of early treatment was more evident. The aim of our ongoing prospective study is to demonstrate the relationship between Hb levels, FE and LVM, cardiovascular events and mortality. This correlation is more evident in patients with cardiac comorbidities. Further larger studies are warranted to confirm these data and to evaluate if rHuEPO treatment could be worthwhile in term of cost-efficacy in the very old pts.

E1209

ACUTE MYELOID LEUKEMIA PROGRESSION IN ARGENTINEAN PATIENTS WITH MYELODYSPLASTIC SYNDROMES.

A. Enrico[1,*] M.G. Flores[2], J. Arbelbide[3], L. Kornblihtt[4], R. Crisp[5], W. Correa[1], J. Gonzalez[2], R. Bengio[6], M. Narbaitz[6], L. Pardo[7], N. Watman[8], Y. Bestach[6], M. Rosenhain[9], A. Basquiera[10], I. Larripa[6], M. Iastrebner[11], C. Belli[6]
[1]Hematology, Hospital Italiano La Plata, La Plata, [2]Hematology, Hospital Duran, [3]Hematology, Hospital Italiano de Buenos Aires, [4]Hematology, Hospital de Clinicas Universidad de Buenos Aires, [5]Hematology, Hospital Posadas, [6]Hematology, Academia Nacional de Medicina, [7]Hematology, Sociedad Argentina de Hematología, [8]Hematology, Hospital Ramos Mejia, [9]Hematology, Hospital Tornu, Ciudad de Buenos Aires, [10]Hematology, Hospital Privado Centro Medico de Cordoba, Cordoba, [11]Hematology, Centro Medico OSECAC, Ciudad de Buenos Aires, Argentina

Background: At least, one third of patients with Myelodysplastic Syndromes (MDS) develop Acute Myeloid Leukemia (AML) during the follow-up depending on diverse prognostic factors and their respective group of risk. Once the leukemic evolution occurs, the outcome of patients is very poor with short survival.
Aims: To analyze prognostic variables and scoring systems regarding leukemic evolution in Argentinean population. Also, to test each category of risk trying to access differences in terms of overall survival in patients with or without leukemic evolution.
Methods: This is a multicentric retrospective study of 966 MDS patients (532 patients belonging to the Argentinean MDS Registry sponsored by de Argentinean Society of Hematology and the remaining to a previous multicentric study) diagnosed from 1981 to 2014. Patients were classified following FAB and WHO criteria and 59 patients presented with secondary MDS. The median age was 66.7 (14-95) years with 74.6% above 60 years, a male/female (546/420) ratio of 1.3. During the follow-up (median: 18.3 months), 424 (43.9%) died and 211 (25%) evolved to AML. BM transplanted patients were censored till the moment of the procedure.
Results: Age (limit of 60 years), percentage of bone marrow blast (0-2, 3-4, 5-9, ≥10%), hemoglobin level (<8, 8-<10, ≥10 g/dL), platelets (<50, 50-100, >100x 10^{12} /L) and neutrophil count (limit of 800 /μL), cytogenetic group of risk (according to the IPSS-R), and red blood cell transfusion requirements were significant predictive variables for leukemic evolution (Kaplan-Meier and Long-Rank test, p<0.05). FAB and WHO classifications and scoring systems (IPSS, IPSSR) also allowed us to differentiate groups of risk for evolution to AML.
The majority of prognostic categories showed statistical differences when we tried to ascertain if patient that evolve to AML depict differences in term of survival when compared with patients that do not evolve (Table 1). However, higher blast counts, worst cytogenetic findings and, correspondingly, higher IPSS and IPSSR groups of risk showed similar survival regardless their leukemic progression. Among patients who died during the follow-up, those patients that previously evolved to AML showed lower age (p<0.001), hemoglobin level (p=0.022), neutrophil (p<0.001) and platelet count (p=0.015), and higher blast percentages (p<0.001)

High	41	14	42	21	=0.013
Very High	24	**12**	35	**13**	**=0.904**

Summary and Conclusions: Clinical parameters, age, classifications and the applied scoring systems were useful tools to evaluate prognosis in our series that showed a similar rate of leukemic progression to previous reports. Interestingly, the survivals in patients with higher blast percentages, worst cytogenetic findings and, correspondingly, higher IPSS and IPSSR groups of risk were similar between patients with or without evolution to AML.

E1210

PULMONARY INFECTIONS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES RECEIVING AZACYTIDINE TREATMENT

R. Latagliata[1,*] F. De Angelis[1], M.L. De Luca[1], I. Carmosino[1], F. Vozella[1], C. Montagna[1], A. Romano[1], L. Petrucci[1], A. Salaroli[1], M. Molica[1], G. Colafigli[1], M. Mancini[1], M. Breccia[1], G. Alimena[1], C. Girmenia[1]
[1]Cellular Biotechnologies and Hematology, University Sapienza, Rome, Italy

Background: Azacytidine (AZA) is a demethylating agent widely used in the treatment of patients with high-risk Myelodysplastic Syndromes (MDS). Pulmonary infections represent the most frequent complication in these patients, however, their incidence, etiology and impact in the overall outcome during AZA treatment are still unclear. A major problem in the characterization of infections in MDS patients receiving AZA treatment is represented by the low level of clinical and microbiological documentation being most of patients managed on an outpatient basis.
Aims: Aim of this study was to evaluate the incidence and clinical role of pulmonary infections in a cohort of MDS patients receiving AZA treatment in our Institute, where the availability of a dedicated hematological emergency ward made their access and their infective diagnostic work-up homogeneous in the presence of fever or other infective clinical signs.
Methods: We retrospectively evaluated 86 MDS patients (M/F 52/34, median age 70 years, range 41-82) treated with AZA at our Institution from 04/2009 to 01/2015. All patients received AZA cycles at standard dosage (75 mg/m^2 for 7 days every 28 days) as outpatients. Microbiological work-up included blood cultures, culture from other sites, galactomannan assay from serum and from sputum/bronchoalveolar lavage.
Results: The total number of AZA cycles was 988, with a median of 8 cycles per patient (range 1-56 cycles). There were 41 episodes of lung infection documented by chest CT in 32 patients (37.2% of patients and 4.1% of AZA cycles). Based on the above diagnostic work-up, pulmonary infiltrates were considered of fungal origin in 9 cases (21.9%), associated to bacteremia in 3 cases (7.3%) and of unknown origin in the remaining 29 cases (70.7%). As to the time of occurrence of lung infections, 12 episodes were documented in the first 2 cycles of AZA treatment (14% of 86 patients), 13 after the cycles 3-5 (13.3% of 71 evaluable patients), and the remaining 16 episodes beyond the fifth cycle of AZA treatment (29.6% of 54 evaluable patients) (Figure 1). Overall, a pulmonary fungal disease was documented in 6 of 165 (3.6%) cycles 1-2, in 1 of 196 (0.5%) cycles 3-5 and in 2 of 627 (0.3%) cycles since cycle 6 (p=0.001). Out of 32 patients who developed a pulmonary infection 25 (78%) interrupted the AZA treatment within 3 months from the infectious episode due to deterioration of clinical conditions, hematologic disease progression and/or death, including 8 of 9 (89%) patients who developed a pulmonary fungal disease.

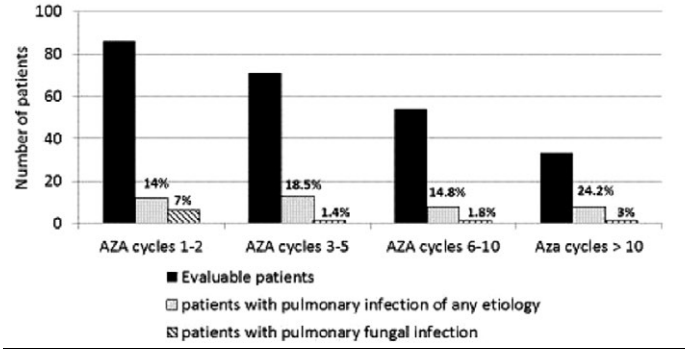

Figure 1. Incidence of pulmonary infections according to AZA cycles.

Summary and Conclusions: In conclusion, pulmonary infections are a common complication in MDS patients receiving AZA treatment, and are often associated to an interruption of AZA therapy. Pulmonary fungal infections are more frequently observed early during the first cycles of treatment. It should be defined if the poor outcome of patients who develop pulmonary infections during AZA therapy is an epiphenomenon of an immunologic deterioration associated to the hematologic disease progression or is independently related to the complication. If confirmed in other experiences, the results of our study raise the issue of the need of an antibacterial and/or antifungal prophylaxis particularly during the first months of AZA therapy.

E1211

HIDDEN MDS: A PROSPECTIVE STUDY TO CONFIRM OR EXCLUDE MDS IN PATIENTS WITH ANEMIA OF UNCERTAIN ETIOLOGY

O. Lopez Godino[1,*] J. Bastida[2], A. Vicente Sánchez[3], S. Bonanad Boix[4], B. Xicoy Cirici[5], J.C. Caballero Berrocal[2], F. López Cadenas[2], I. Rodríguez Hernández[6], M. Arnao Herráiz[3], M. Jiménez Lorenzo[6], I. Llopis Calatayud[3], F. Millá[6], C. del Cañizo Roldán[2], M. Díez Campelo[2]
[1]Hematology department, [2]Hospital Universitario de Salamanca, Salamanca, [3]Hospital de la Ribera, Valencia, Spain, [4]Hematology department, Hospital de la Ribera, Valencia, [5]Hematology department, [6]Hospital Germans Trias i Pujol, Badalona, Spain

Background: Anemia is one of the most frequent abnormalities detected in hemograms and it can be the first sign of MDS, especially in the elderly patients. Diagnosis of MDS when anemia is the only abnormality can be complicated, so the diagnosis is delayed until the degree of anemia becomes severe (transfusion dependency) and/or other cytopenias/blasts appears.
Aims: To analyze the impact on the diagnosis of MDS among anemic patients, by systematically and prospectively reviewing all hemograms performed in 3 centers in Spain.
Methods: We performed a prospective study within 69 days (Dec 2012-March 2013). Ethic committee approved the protocol as an observational study. All hemograms performed in the laboratories (137,453 hemograms) were reviewed. Those with Hb level <12g/dL and/or MCV >100 fL were selected (2,702 patients). Surgery and oncology departments patients or with a known disease causing anemia were excluded. In the second step, a complete peripheral blood analysis was performed (reticulocyte count, peripheral blood smear, Vitamin B12, folic acid, ferritin, renal, thyroid and hepatic function). The results were reviewed with the clinical history and if no cause of anemia/macrocytosis was found, the patient was referred to the haematologist (n=221).
Results: From 137,453 hemograms, we selected 211 candidates to MDS screening. 133 final diagnoses have been made (see Table 1), included 12 MDS. 23 patients have currently been investigated. In 117 patients, we could not complete the study due to comorbidity/age >90 years (N=99) or death (N=18).

Table 1.

	Salamanca	Hospital de la Ribera	German Trias i Pujol	TOTAL
Days	69	63	37	169
Nº of revised hemograms	60.655	53.863	22.935	137.453
Revised patients	442	2.125	135	2.702
Patients candidates	182	101	7	211
Total diagnostics	93	36	4	133
In study	22	1	0	0
Hematological malignacies detected	5 MDS 2 MGUS 2 TTP 1 AML 1 cMPN Ph(-) 1 AA	7 MDS 1 MGUS		12 MDS 3 MGUS 2 TTP 1 AML 1 cMPN Ph (-) 1 AA
Iron deficiency	57	0	1	58
Hypothyroidism	4	3	0	7
Megaloblastic	15	24	0	39
Others	5	1	3	9
Not included (age/comorbidities)	89	9	1	99
Death	18	0	0	18

Summary and Conclusions: This prospective approach is a reasonable screening procedure in the hematological laboratories and will probably allow us to diagnose the more relevant causes of anemia including MDS, early, avoiding delay in providing the patients with the necessary intervention.

E1212

EFFECTIVENESS OF AZACITIDINE COMPARED TO CONVENTIONAL CARE REGIMENS FOR THE TREATMENT OF HIGH-RISK MYELODYSPLASIA IN THE REAL-WORLD: RESULTS FROM THE DUTCH POPULATION-BASED PHAROS MDS REGISTRY

A. Dinmohamed[1,*] O. Visser[2], W. Posthuma[3], M. Hoogendoorn[4], V. Mattijssen[5], J. Wegman[6], H. Koene[7], M. van Marwijk Kooy[8], S. Klein[9], H. Sinnige[10], J. van Esser[11], P. Wijermans[12], G. Huls[13], P. Huijgens[2,14], P. Sonneveld[1], A. van de Loosdrecht[14], M. Jongen-Lavrencic[1]
[1]Hematology, Erasmus MC Cancer Institute, Rotterdam, [2]Registration and Research, Comprehensive Cancer Centre the Netherlands, Utrecht, [3]Internal Medicine, Reinier de Graaf Group, Delft, [4]Internal Medicine, Medical Center Leeuwarden, Leeuwarden, [5]Internal Medicine, Rijnstate Hospital, Arnhem, [6]Internal Medicine, Deventer Hospital, Deventer, [7]Internal Medicine, Antonius Hospital, Nieuwegein, [8]Internal Medicine, Isala Clinics, Zwolle, [9]Meander Medical Center, Amersfoort, [10]Internal Medicine, Jeroen Bosch Hospital, Den Bosch, [11]Internal Medicine, Amphia Hospital, Breda, [12]Internal Medicine, Haga Hospital Leyenburg, The Hague, [13]Hematology, Radboud University Medical Center, Nijmegen, [14]Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: In 2009, azacitidine (AZA) was registered in Europe for the treatment of transplant-ineligible patients with high-risk myelodysplastic syndromes (HR-MDS). Population-based studies assessing its effectiveness compared with that of conventional care regimens (CCRs) in daily practice are lacking.
Aims: In this population-based study, we assessed the effectiveness of AZA on overall survival (OS) in HR-MDS compared with that of two CCRs.
Methods: We identified 515 transplant-ineligible, WHO-defined MDS patients diagnosed between 2008-2011 from the Dutch PHAROS MDS registry, which encompasses ~40% of the Dutch population (31 centers) and is notified by the nationwide Netherlands Cancer Registry. The PHAROS MDS registry includes data on patient features at baseline, classification, prognostication, treatment, response to treatment and survival. All cases were confirmed by bone marrow

examination. Overall, 151 (29%) patients were lower-risk and 113 (22%) higher-risk by IPSS. In the remaining 251 (49%) patients, an IPSS score could not be computed mainly due to unperformed cytogenetics. CCRs were defined as best supportive care (BSC) only, including treatment with growth factors, and intensive chemotherapy (IC). OS was measured from time to HR-MDS diagnosis, which was estimated by the Kaplan-Meier method and compared by the log-rank test. Unstratified Cox proportional hazard models were used to estimate the hazard ratio (HR). Hematological response was assessed according to the revised IWG-MDS criteria (Cheson 2006). Grade 3-4 adverse events (AEs) were graded by CTCAE v3.

Results: Of all 113 HR-MDS patients, 65 received AZA, 32 BSC only and 16 IC. As expected from a real-world population, patients who received BSC only were older and had poorer ECOG performance status (ie, ≥2) than patients who received AZA or IC. Their median age (range) was 77 (52-88), 74 (55-83) and 66 (52-75) years, and 25%, 3% and 0% had an ECOG score ≥2, respectively. After a median follow-up of 14.7 months, the median OS (95% CI) was 17.6 months (15.1 to 24.7) in the AZA group *versus* 9.1 months (3.5 to 14.3) in the BSC only group (HR 0.60, *p*=.027; Figure 1A) and 19.0 months (4.8 to 25.3) in the IC group (HR 0.73, *p*=.321; Figure 1B). One-year survival (95% CI) was 72% (59% to 81%) in the AZA group *versus* 38% (21% to 54%, *p*=.005) and 75% (46% to 90%, *p*=.935) in the BSC only and IC group, respectively. AZA and IC were given for a median (range) of 7 (1-26) and 2 (1-3) cycles, respectively, and BSC only for a median of 3.9 (0.0-26.4) months. Responses of CR, PR and mCR were seen in 12%, 3% and 15% in the AZA group, 38%, 0% and 31% in the IC group and 0%, 0% and 0% in the BSC only group, respectively. Further, hematological improvements were seen in 42%, 38% and 0% in the AZA, IC and BSC only group, respectively. Grade 3-4 anemia, thrombocytopenia and neutropenia, respectively, were seen during treatment in 48%, 52%, and 71% with AZA, 44%, 88% and 69% with IC and 44%, 40%, and 19% with BSC only.

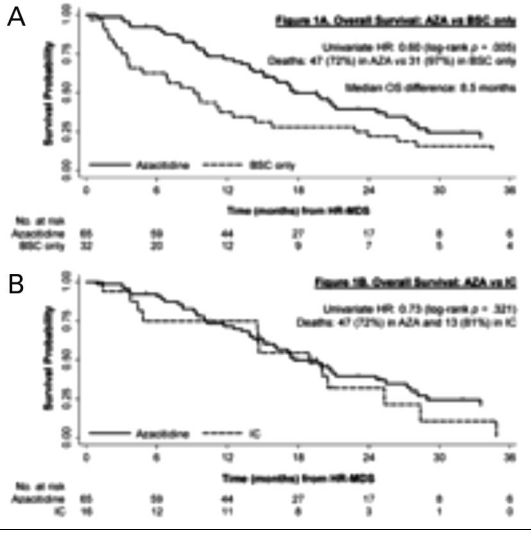

Figure 1.

Summary and Conclusions: In our population-based study, AZA prolonged median OS compared with BSC only, but not with IC. Overall response rates and grade 3-4 hematological AEs were similar with findings from the AZA-001 trial (Fenaux 2009). However, our real-world patient population experienced poorer survival than reported in the AZA-001 trial. Population-based studies provide data complimentary to findings from clinical trials and are important to assess uptake and outcome of new interventions in daily practice and may be part of guideline development. Our results, however, should be interpreted with caution due to the modest patient numbers and the fact that population-based studies are uncontrolled and confounded by indication.

E1213

CLINICAL CHARACTERISTICS, TREATMENT AND OUTCOMES OF PATIENTS WITH THERAPY-RELATED MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKAEMIA (T-MDS/AML)

S. Maung[1,*] C. Burke[1], J. Hayde[2], R. Desmond[1], J. McHugh[1], H. Enright[1]
[1]Haematology, [2]Pharmacy, Tallaght Hospital, Trinity College Medical School, Dublin, Ireland, Dublin, Ireland

Background: Therapy-related myeloid neoplasms (t-MN) include therapy-related acute myeloid leukaemia (AML), therapy-related myelodysplastic syndromes (MDS) and therapy-related myelodysplastic syndrome/myeloproliferative neoplasms MDS/MPN) occurring as a late complication of cytotoxic chemotherapy or radiation. t-MN is becoming increasingly common and known to be associated with poor outcomes.

Aims: To identify incidence, characteristics, treatment and outcomes of t-MN patients in our centre.

Methods: We investigated the clinical characteristics, treatment and outcomes of patients with t-MN diagnosed in a single centre between 2003 and 2014 and compared with 198 *de novo* MDS patients for whom we have comprehensive data.

Results: Of 446 patients with AML (152) or MDS (294) diagnosed between 2003 and 2014, we identified 39 patients with features of t-MN (8.7%); 35 patients with t-MDS (11.9%) and 4 with t-AML (2.6%). Median age at presentation and gender distribution were similar to *de novo* MDS with 25.6% of patients under 65 years. The degree of cytopenias at presentation was greater in t-MN group but the percentage of marrow blasts at diagnosis was comparable between two groups. Twenty two patients (56.4%) had a prior haematological malignancy, 10(25.6%) had solid tumours and 3 (7.7%) had cytotoxic therapy for autoimmune disorders. Thirty four patients (87%) received chemotherapy, 12(31%) received radiotherapy and 7(18%) received combined chemotherapy and radiation as primary therapy. The time from therapy to development of t-MN was shortest for patients with haematological disorders (45.5 months) compared to solid tumours (84.5 months) and autoimmune disorders (109 months). Patients who developed t-MN after acute leukaemia had had topoisomerase II inhibitors with other cytotoxic agents and were found to have the shortest latency (16.5 months) and overall poor survival. A higher proportion of patients with higher risk cytogenetics were observed in t-MN group compared to *de novo* MDS. Forty one percent of patients had a normal karyotype and were observed to have better survival (31 *vs* 13 months). Improved survival was associated with very low, low and intermediate risk IPSS-R. Twenty two patients received best supportive care, 12 received Azacitidine and 5 received intensive chemotherapy, of which 2 had allogeneic marrow transplantation. For patients treated with Azacitidine, a median of 4 courses were given with 25% achieving partial response, haematological improvement or stable disease. Median overall survival for all patients was 14 months (0-122) compared to 30 months (0-156) in *de novo* MDS. Survival declined markedly after two years and 5-year survival was only 13.8%. Improved survival was associated with blast count <5%, prior radiotherapy only, lower risk IPSS-R and a normal karyotype. Patients who received Azacitidine had similar survival to those who were treated with intensive chemotherapy (10.5 *vs* 14 months) (Table 1).

Table 1. Characteristics, survival and treatment of patients with t-MN.

Category	Number (%)	Latency (months)	Survival (months)
Primary disorder			
Haematological disorder	**22(56.4%)**	**45.5 (3-132)**	**14 (0-74)**
▪ Acute leukaemia	6	16.5 (3-46)	14 (5-57)

▪ Breast	3	60 (23-152)	8 (5-96)
▪ Prostate	3	44 (12-130)	46 (4-68)
▪ Others	4	163 (66-366)	37 (0-122)
Autoimmune disease[1]	**3 (7.7%)**	**109 (28-131)**	**24 (18-29)**
More than one disorder[2]	**4 (10.3%)**	**44 (24-103)**	**8.5 (5-13)**
Primary therapy			
Chemotherapy alone	27 (69.2%)	54 (0-163)	14 (0-122)
▪ Alkylating agents	22	71 (23-163)	12.5 (0-96)
▪ Topoisomerase II inhibitors	17	54 (3-152)	14 (1-96)
▪ Others	25	---	---
ASCT	3	83 (32-110)	30 (5-74)
Radiotherapy alone	5 (12.8%)	71.5 (12-366)	42 (0-68)
Combined chemotherapy & radiotherapy	7 (17.9%)	84 (23-153)	7 (5-96)
Diagnostic parameters			
Blast count in bone marrow			
▪ <5%	24 (61.5%)	---	21.5 (0-122)
▪ >5%	15 (38.5%)	---	8 (1-96)
Cytogenetics (available in 34 patients)			
Normal	**14 (41.2%)**	**67 (3-366)**	**31 (4-122)**
Abnormal	**20 (58.8%)**	**45 (12-152)**	**13 (0-96)**
▪ Complex>3 abnormalities	8	---	---
▪ Monosomy 7	2	---	---
▪ Translocation of chromosome 3	1	---	---
▪ MLL rearrangement	2	---	---
▪ Trisomy 8	1	---	---
▪ Any other single or double abnormalities	6	---	---
IPSS-R (available in 32 patients)			
Lower risk	**16 (50%)**	**61 (3-366)**	**31 (0-122)**
▪ Very low	5	66 (13-132)	29 (5-122)
▪ Low	7	68 (3-366)	44 (30-59)
▪ Intermediate	4	40.5 (22-74)	7.5 (0-36)
Higher risk	**16 (50%)**	**49 (0-152)**	**10.5 (1-96)**
▪ High	8	44.5 (14-131)	13.5 (4-96)
▪ Very high	8	77 (0-152)	7 (1-14)
Treatment for t-MN			
Supportive care only	22 (56.4%)	---	28 (0-122)
Azacitidine	12 (30.8%)	---	10.5 (5-57)
Intensive chemotherapy	5 (12.8%)	---	14 (5-96)
Allogeneic stem cell transplant	2 (5.1%)	---	---

MPN- Myeloproliferative neoplasm; 1- Autoimmune haemolytic anaemia, Rheumatoid arthritis, Fibrosing alveolitis (received either Methotrexate or Azathioprine); 2- Inflammatory bowel disease/Prostate cancer, AML/Prostate cancer, Ovarian cancer/Breast cancer, Myeloma/Urothelial cancer; ASCT- Autologous stem cell transplant; t-MN- Therapy-related myeloid neoplasms

Summary and Conclusions: Patients with t-MN showed more adverse features of MDS and cytogenetics hence have lower survival. A longer latency period and better survival is observed in patients who received prior radiotherapy only. Patients with low blast count at presentation, normal karyotype and radiotherapy only as primary treatment had a survival advantage. The use of IPSS-R can identify patients with good outcome and can be useful in risk-adapted approach to management. Azacitidine is effective in selected patients not fit for intensive therapies; however no survival advantage was noted in our small cohort.

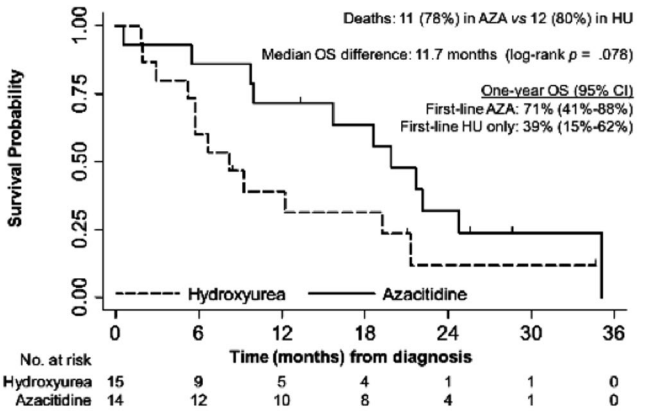
E1214

CLINICAL FEATURES, TREATMENT DECISIONS AND TREATMENT OUTCOMES OF PATIENTS WITH CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) IN THE REAL-WORLD: RESULTS FROM THE DUTCH POPULATION-BASED PHAROS MDS REGISTRY

A. Dinmohamed[1,*] O. Visser[2], W. Posthuma[3], J. Wegman[4], J. van Esser[5], V. Mattijssen[6], S. Klein[7], P. Wijermans[8], M. van Marwijk Kooy[9], G. Huls[10], P. Huijgens[2,11], I. de Greef[1], P. Sonneveld[1], A. van de Loosdrecht[11], M. Jongen-Lavrencic[1]

[1]Hematology, Erasmus MC Cancer Institute, Rotterdam, [2]Registration and Research, Comprehensive Cancer Centre the Netherlands, Utrecht, [3]Internal Medicine, Reinier de Graaf Grup, Delft, [4]Internal Medicine, Deventer Hospital, Deventer, [5]Internal Medicine, Amphia Hospital, Breda, [6]Internal Medicine, Rijnstate Hospital, Arnhem, [7]Internal Medicine, Meander Medical Center, Amersfoort, [8]Internal Medicine, Haga Hospital Leyenburg, The Hague, [9]Internal Medicine, Isala Clinics, Zwolle, [10]Hematology, Radboud University Medical Center, Nijmegen, [11]Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: CMML is a very rare hematological malignancy characterized by features of both myelodysplastic syndromes and myeloproliferative neoplasms. Clinical practice guidelines for the management of CMML are ill-defined due to the scarcity of CMML-specific phase 3 clinical trials. Clinical characterization and clinical decision-making can be supported by information gained from population-based studies.
Aims: To present clinical features, treatment decisions and treatment outcomes of newly diagnosed CMML patients in daily practice in the Netherlands.
Methods: We identified 85 CMML patients (median age 74 years, age range 54-94 years, 63% males) diagnosed between 2008-2011 from the Dutch population-based PHAROS MDS registry, which encompasses ~40% of the Dutch population (31 centers) and is notified by the nationwide Netherlands Cancer Registry. For all cases, the diagnosis was confirmed by bone marrow examination and classified according to WHO 2008 classification. The PHAROS MDS registry includes data on patient characteristics at baseline, classification, prognostication, treatment, response to treatment and survival. Overall survival (OS) was measured from time of diagnosis until death or latest follow-up.
Results: Of all patients, 72% were diagnosed in patients over 70 years of age. The vast majority of patients had an ECOG performance score ≤1 (92%) and ≥1 co-morbidity at diagnosis (84%). Overall, 84% patients had CMML-1 and 16% CMML-2. Cytogenetic assessments were performed in 52 (62%) patients, of which 73%, 12% and 15% had good, intermediate or high-risk cytogenetics based on the definition used in the CPSS (Such 2013), respectively. Cytogenetic assessment decreased with older age from 83% in 18-59-year-olds to 44% in over 80-year-olds (*p* for trend=.027). Data on *ASXL1* mutational status were not available for patients diagnosed during the study period of 2008-2011. A wait-and-see strategy was applied in 32 (38%) patients, of which 11 (34%) ultimately started with therapy after a median of 8.9 months after diagnosis. Of 64 patients who received first-line therapy, 19 received hydroxyurea (HU) only, 19 transfusions only, 14 AZA, 11 EPO and 1 lenalidomide. Only 14 (22%) of 64 patients received second-line therapy: 9 received AZA, 2 HU, 2 transfusions only and 1 proceeded to an allograft. With respect to treatment outcome, we assessed the outcome of first-line AZA (*n*=14, median age 72.5 years; 93% ECOG score ≤1) *vs* first-line HU without cross-over to AZA (*n*=15, median age 72 years; 87% ECOG score ≤1). Their characteristics are shown in Figure 1. Median OS (95% CI) was 19.9 (9.8-24.8) *vs* 8.2 (2.9-19.3) months in the AZA and HU treated group, respectively (log-rank *p*=.078; Figure 1). AZA was given for a median (range) of 5.5 (1-30) cycles and HU for a median of 5.1 (0.3-35.8) months. Hematological improvements per revised IWG-MDS criteria (Cheson 2006) were observed in 29% and 0% in the AZA and HU treated group, respectively.
Summary and Conclusions: In our population-based study, risk-stratification by means of cytogenetic assessment decreased with older age. Without cytogenetics, accurate risk-stratification cannot be made, which possibly could lead to inappropriate, risk-adapted management. Although limited by small patient numbers, there was a trend towards higher median OS in patients receiving AZA as opposed to those receiving HU only. In the absence of CMML-specific phase 3 trials, population-based studies are important for providing data on clinical characteristics and treatment outcomes of CMML patients.



Variable	AZA (*n* = 14)	HU (*n* = 15)	*P*	Variable	AZA (*n* = 14)	HU (*n* = 15)	*P*

E1215

A NEW PROGNOSTIC INDEX TO PREDICT SHORT-TERM PROGNOSIS IN MDS PATIENTS TREATED WITH AZACITIDINE; COMBINATION OF P53 EXPRESSION AND CYTOGENETICS

S. Nishiwaki[1,*] M. Ito[2], S. Okuno[1], Y. Harada[1], S. Yamamoto[1], T. Iwasaki[1], I. Sugiura[1]

[1]Division of Hematology and Oncology, Toyohashi Municipal Hospital, Toyohashi, [2]Department of Pathology, Japanese Red Cross Nagoya First Hospital, Nagoya, Japan

Background: Azacitidine (Aza) is a currently used demethylating agent for myelodysplastic syndrome (MDS). Since Aza epigenetically modulates various genes, there may be a new prognostic factor to predict outcome of MDS patients treated with Aza. p53 is a tumor suppressor protein encoded by the *TP53* gene. Although it was reported that p53 expression was associated with poor outcome in del(5q) myelodysplastic syndrome (MDS) patients treated with lenalidomide, its value is controversial in MDS patients treated with Aza.
Aims: In this study, we intended to identify prognostic factors including p53 expression of bone marrow in the era of Aza for MDS.
Methods: We retrospectively analyzed 60 consecutive MDS patients treated with Aza. To assess p53 protein expression, immunohistochemical analyses of bone marrow clot sections were performed. Patients were categorized as p53-positive when the percentage of p53-positive cells was 5% or more. The prevalence of p53 expression was analyzed as a prognostic factor.
Results: Median age was 73 years old (range 48-90). In 29 patients, p53 was positive. Numbers of patients according to the World Health Organization (WHO) (2008) classification were 4 refractory cytopenia with unlineage dysplasia, 15 refractory cytopenia with multilineage dysplasia, 16 refractory anemia with excess blasts with type 1, 14 refractory anemia with excess blasts with type 2 and 11 acute myeloid leukemia, and those according to WHO classification-based prognostic scoring system (WPSS) were 2 very low, 10 low, 9 intermediate, 24 high and 15 very high. There was no significant difference of WPSS distribution between p53-negative and -positive patients. As to cytogenetic abnormalities, it was normal in 29 patients, complex or monosomy7 (poor cytogenetics) in 14 and other abnormalities in 17. There was more patients with poor cytogenetics in p53-positive cohort than those in p53-negetive cohort (P=0.03). More patients in p53-negative cohort responded to azacitidine treatment than those in p53-positive cohort according to International Working Group response criteria revised in 2006 (42% *vs* 17%; P=0.04). Overall survival (OS) was significantly lower in p53-positive patients compared with p53-negetive patients (85% *vs* 59% at 12 months after the start of Aza administration; P=0.006). Multivariate analysis demonstrated that p53-positive was a significant prognostic factor for OS along with poor cytogenetics [p53-positive: Hazard ratio (HR) 1.26, 95%CI 1.04-1.53; P=0.02, poor cytogenetics: HR 3.72, 95%CI 1.52-9.11; P=0.004]. We propose a new prognostic index to predict short-term prognosis of MDS patients in the era of Aza; High: p53-positive and poor cytogenetics, Intermediate: p53-positive or poor cytogenetics, and Low: p53-negetive and absence of poor cytogenetics. OS was significantly different among

three groups according to this new prognostic index (Low 92%, Intermediate 65% and High 27% at 12 months; P<0.0001) (Figure 1).

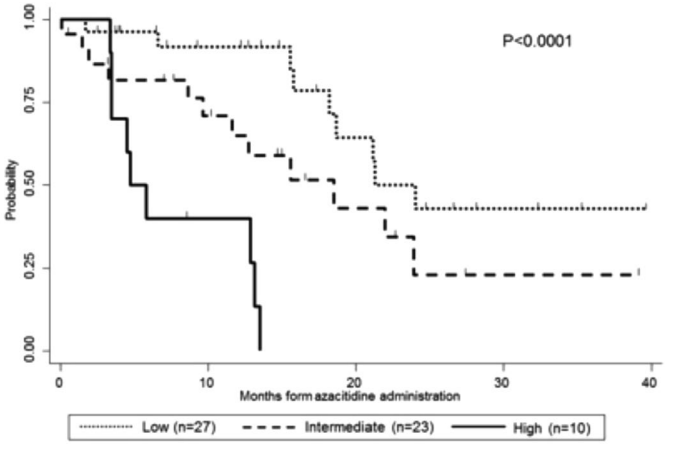

Figure 1.

Summary and Conclusions: p53 expression of bone marrow was a significant prognostic factor in MDS patients treated with Aza. In combination with cytogenetic abnormalities, it is possible to predict short-term prognosis.

E1216

DIAGNOSIS, PROGNOSTICATION AND TREATMENT OF MYELODYSPLASTIC SYNDROMES (MDS) IN DAILY PRACTICE: RESULTS FROM THE DUTCH POPULATION-BASED PHAROS MDS REGISTRY

A. Dinmohamed[1,*] O. Visser[2], W. Posthuma[3], P. Huijgens[2,4], P. Sonneveld[1], A. van de Loosdrecht[4], M. Jongen-Lavrencic[1]
[1]Hematology, Erasmus MC Cancer Institute, Rotterdam, [2]Registration and Research, Comprehensive Cancer Centre the Netherlands, Utrecht, [3]Internal Medicine, Reinier de Graaf Group, Delft, [4]Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: The Dutch Population-based HAematological Registry for Observational Studies (PHAROS) in MDS is established to document clinical features, management and outcomes of newly diagnosed MDS patients in the Netherlands. The PHAROS registry documents data in addition to the minimal dataset collected by the nationwide Netherlands Cancer Registry (NCR). The purpose of the PHAROS MDS registry is to provide insight into the delivery of care to MDS patients in order to improve the quality of diagnosis and management of MDS patients in the Netherlands.
Aims: To assess clinical features, classification, prognostication and management of newly diagnosed MDS patients in daily practice in the Netherlands.
Methods: We identified 536 WHO-defined MDS patients (median age 75 years, age range 23-94 years, 60% males) diagnosed between 2008-2011 from the PHAROS MDS registry, which covers ~40% of the Dutch population (31 centers) and is notified by the NCR. All cases were confirmed by bone marrow (BM) examination. The PHAROS MDS registry includes data on patient characteristics at baseline, classification, prognostication, treatment, response to treatment and survival.
Results: Of all patients, the vast majority had an ECOG performance score ≤1 (91%) and ≥2 co-morbidities (57%). Further, 21% had received therapy for a prior malignancy and 5% were transfusion dependent. In BM aspirates, the percentage of erythroid, myeloid and megakaryocytic dysplasia (ie, <10% or ≥10%) was reported in 35%, 45% and 30% of the records, respectively. Assessment of ringsideroblasts was done in 70% of all BM aspirates. The degree of BM fibrosis and CD34-positivity were assessed in 82% and 74% of all BM biopsies, respectively. In 17% of all MDS cases, a MDS subtype could not be assigned. Cytogenetic assessments were performed in 61% of the patients, and decreased sharply with older age from 78% in 18-59-year-olds to 43% in over 80-year-olds (*p* for trend <.001). As a result, risk stratification could not be performed in a substantial number of patients as cytogenetic data are essential to assess prognosis. In patients with data available to assess prognosis by IPSS-R (*n*=268), 20%, 25%, 22%, 17% and 16% had very low, low, intermediate, high and very high risk MDS at diagnosis. Overall survival by IPSS-R risk group is shown in Figure 1A. A total of 64 (74%) of 86 patients aged <65 years received first-line therapy: 22% received an allograft, 8% lenalidomide, 6% azacitidine (AZA), 14% growth factors, 13% intensive chemotherapy and 38% supportive care only (Figure 1B). Among 345 (77%) of 450 patients aged ≥65 years, the corresponding percentages were: 0%, 1%, 17%, 34%, 2% and 46 (Figure 1B). Data on subsequent treatment are shown in Figure 1B as well. Of all 102 AZA-treated patients, 36% received AZA outside the EMA-approved indication.

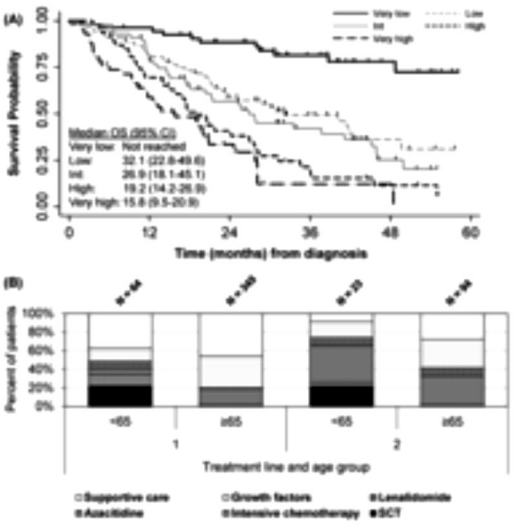

Figure 1.

Summary and Conclusions: We show that most patients from daily practice do not undergo a full and proper diagnostic work-up, such as assessment of dysplasia and cytogenetics, as recommended by previous and current European guidelines for the diagnosis of MDS (Malcovati 2013). Although treatment options in MDS are limited, especially for the elderly, prognosis should at least be assessed in order to accurately inform patients about their life expectancy and to provide information on appropriate risk- and age-adapted treatment options. Population-based registries, such as PHAROS, can be useful instruments to evaluate guideline adherence. Also, they provide information complementary to findings from clinical trials as the latter usually addresses a small minority of the general patient population.

E1217

THE UTILITY OF GRANULOCYTE MATURATION PATTERNS ASSESSED BY FLOW CYTOMETRY IN THE DIAGNOSIS OF MYELODYSPLASTIC SYNDROME

S. Meisenberg[1,*] S. Bastow[1], R. Ansell[1], E. Bart-Smith[1], G. Shah[1], R. Johnston[1], T. Corbett[1], T. Chevassut[1], K. Boyd[1], C. Dalley[1]
[1]Haematology, Brighton and Sussex University Hospitals NHS Trust, East Sussex, United Kingdom

Background: The routine role of flow cytometry (FC) in the diagnosis of myelodysplastic syndrome (MDS) is currently limited to the quantitative measurement of bone marrow (BM) CD34+ blast percentage. However, morphologic diagnosis can be challenging, particularly when dysplastic changes in the marrow are subtle. The expression of specific antigens at various stages of normal granulopoiesis is tightly controlled but dysgranulopoiesis may be associated with variant antigen expression which can be identified by FC.
Aims: 1) To assess the utility of variant granulocyte maturation antigen patterns (GMAP) in supporting MDS diagnosis. 2) To develop an immunophenotyping scoring system to rank dysgranulopoiesis.
Methods: The BD FACsCanto II analyser™ and BD FacsDiva software™ were used for acquisition and interpretation. A total of 60 BM aspirate samples from adult patients were analysed; 31 controls (normal n=18, previous lymphoma n=5, staging lymphoma n=1, paraproteinaemia n=3, myeloma n=3, systemic lupus erythematosus n=1) and 26 confirmed MDS cases based on the standard WHO diagnostic criteria. Three patients with subtle dysplastic BM, insufficient for diagnosis, were also included. The International Prognostic Scoring System for MDS (IPSS-R) risk stratify patients with MDS; low risk n=16 (IPSS-R >1.5-3.0), intermediate risk n=5 (IPSS-R >3-4.5) and high risk n=5 (IPSS-R >4.5-6). Antibodies CD10, CD11b, CD13, CD16, CD34, and CD45 were added to aspirates. Parameters assessed were total CD34+ blast percentage, CD11b/CD16 GMAP, CD13/CD16 GMAP, and four previously published scoring parameters[1,2] which include myeloblast%, B progenitor%, myeloblast *vs* lymphocyte CD45 ratio and granulocyte: lymphocyte side scatter peak channel ratio. Each feature carries 1 point and a total score ≥2 is suggestive of changes often seen in MDS.
Results: The majority of control subjects showed standard GMAP (Figure 1); 84% showed a uniform 'biphasic' pattern with CD13/CD16 and 81% showed a uniform 'orthogonal' pattern with CD11b/CD16. Eighty-five percent of MDS patients correlated with morphology by deviating from the standard 'biphasic' GMAP using CD13/CD16 whereas 77% deviated from the standard 'orthogonal' GMAP using CD11b/CD16. Of patients with low risk MDS, 63% had deviated

GMAP with CD11b/CD16 and 69% had deviated GMAP with CD13/CD16. Compared to control BM, all GMAP deviations in MDS patients presented as a non-uniform pattern or as a reduction of CD11b and/or CD16 expression. A GMAP score <2 was calculated in 90% of controls. A score ≥2 was seen in 85% of total MDS patients. A score ≥2 was seen in 75% of patients with low risk IPSS-R. Interestingly, of 3 morphologically sub-diagnostic patients, 2 had scores ≥2 and two had deviated GMAP using CD11b/CD16 and CD13/CD16. Patients with low risk IPSS-R had a median GMAP score of 2, those with intermediate risk IPSS-R had a median score of 4 whereas high risk IPSS-R patients had a median score of 5.

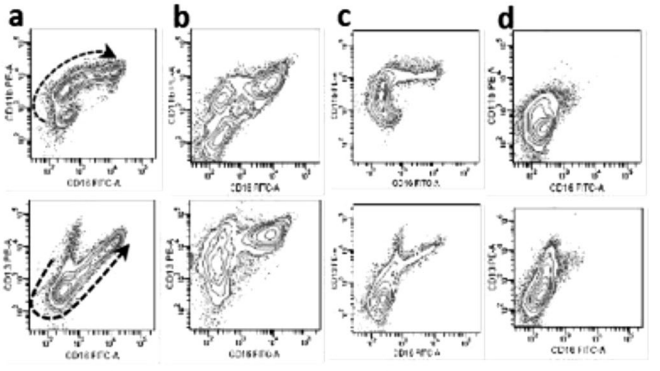

Diagram 1 Contour plots of GMAP using CD11b/CD16 (top panel) and CD13/CD16 (bottom panel); (a) shows the characteristic uniform 'orthogonal' and 'biphasic' patterns seen in the majority of control BM. The arrows show the direction of granulocyte maturation; (b) shows non-uniform GMAP in a patient who had sub-diagnostic morphological dysplasia which was insufficient for diagnosis; (c) shows a reduction of CD16 expression in a MDS patient with low risk IPSS-R; (d) shows an almost complete loss of CD11b and CD16 expression in a MDS patient with intermediate risk IPSS-R.

Figure 1.

Summary and Conclusions: We have shown that GMAP has diagnostic utility in MDS and that median GMAP scores may rank to IPSS-R score. Validation of the GMAP and GMAP score using a larger MDS patient cohort, and refinement by inclusion of FC assessment of dysmegakaryopoiesis is warranted.

E1218

PATIENTS WITH THERAPY-RELATED CHRONIC MYELOMONOCYTIC LEUKEMIA (TR-CMML) HAVE SHORTER MEDIAN OVERALL SURVIVAL THAN *DE NOVO* CMML (DN-CMML): MAYO CLINIC EXPERIENCE

S. Subari[1,*] M. Patnaik[2], D. Alfakara[2], N. Gangat[2], M. Elliott[2], W. Hogan[2], M. Litzow[2], A. Al-Kali[2]
[1]Gaziantep University, Gaziantep, Turkey, [2]Hematology, Mayo Clinic, Rochester, United States

Background: CMML is a malignant hematologic neoplasm characterized by peripheral blood monocytosis and bone marrow dysplasia. The World Health Organization (WHO) classifies therapy-related myeloid neoplasms (tr-MN) as another category. It is known that tr-MNs tend to have a worse prognosis than *de novo* MN (dn-MN). Tr-CMML is an under-described entity with scarce literature in comparison to dn-CMML.
Aims: To study the differences in clinical outcomes between tr-CMML and dn-CMML patients.
Methods: A retrospective single institution study chart review of cases with CMML at Mayo Clinic Rochester between 1994- 2011 was performed. DN-CMML, tr-CMML and leukemic transformation (LT) were defined according to WHO classification (Swerdlow *et al.* 2008). Prior exposure to chemotherapy, radiotherapy or both were defined as tr-CMML while lack of both as dn-CMML. Cytogenetic risk was defined according to Such E. *et al.* (Hematologica 2011). Appropriate IRB approval was obtained in accordance with the Helsinki declaration. Comparison between group medians was done using Wilcoxon test, to comparison values were done contingency and Onaway analyses (Means/Anova/Pooled t), while survival estimates were calculated using Kaplan-Meier curves JMP V10.
Results: Out of 265 CMML patients, 30 (11%) had tr-CMML. Median age was 72 years, with 19 (63%) patients being males. Labs at diagnosis included median white blood cell (WBC) of $16.8x10^9$, hemoglobin (Hg) 10.5 g/dL, platelet (PLT) $65x10^9$, monocytes (Mon) $3.8x10^9$, bone marrow (BM) blasts 4% (range 0-18), peripheral blood blasts (PB) 0% (0-7), Lactate dehydrogenase (LDH) 241 U/L. CMML-1 was found in 28/30 patients (93%) and CMML-2 in 2 patients (7%). Splenomegaly was present in 7 (23%) patients and absent in 21(70%). Two pts had splenectomy (7%). Cytogenetic were low 21 pts (72%), intermediate 2 (7%), and high in 6 (20%). LT was seen in 5 (17%) patients. When evaluating prior therapy, 17(57%) patients were treated with chemotherapy (CT), 6 (20%) patients were treated with radiotherapy (RT) and 7 (23%) CT+RT. Out of 265 patients, 235(89%) had dn-CMML. Median age was 71, with 158 (67%) were males. Labs at diagnosis were median WBC $12x10^9$, Hg 10.4 g/dL, PLT $95x10^9$(p=0.046), Mon $2.1x10^9$, BM blasts% 4 (range 0-19), PB 0% (0-19), LDH 222 U/L. CMML-1 was found in 210 pts (89%) and CMML-2 in 25 pts (11%). Splenomegaly was present in 57 (24%) and absent in 166 (71%). Twelve pts had splenectomy (5%). Cytogenetic were low 163 pts (71%), intermediate 31(13%), high 37(16%). LT was found in 26(11%) patients. Median overall survival was 30 months in dn-CMML *vs* 11 months in tr-CMML group (p=0.02). Upon comparing LT between these groups, time to LT was 10 *vs* 11 months, respectively (p=0.6). Median overall survival was in CT+ group 9 months, in RT+ group 4.4 months and in CT/RT+ group 13 months (p=0.7).
Summary and Conclusions: Tr-CMML comprises a small portion of all CMML cases (11%). Upon comparison, only lower platelets were found to be statistically significant compared to dn-CMML. Median overall survival in dn-CMML group was longer than tr-CMML group but LT seemed to be similar in terms of incidence and time to occurrence. Prior therapy (CT *vs* RT) in tr-CMML patients did not effect median overall survival. Additional larger studies are needed to confirm our results.

E1219

PROGNOSTIC FACTORS FOR TREATMENT FREE SURVIVAL IN PATIENTS WITH MYELODYSPLASTIC SYNDROME WHO STOPPED HYPOMETHYLATING AGNETS WITHOUT PROGRESSION

H. S. Lee[1,*] J.H. Moon[2], H.J. Kim[3], J.-W. Cheong[4], D.-Y. Jo[5], H. Kim[6], H.-S. Eom[7], S.-M. Bang[8], W.S. Lee[9], Y. Park[10], M.H. Lee[11], J.H. Lee[12], S.H. Bae[13], M.K. Kim[14], Y.S. Kim[15]

Background: Hypomethylating agents (HMA) constitute an essential tool in the treatment of myelodysplastic syndrome (MDS). The use of these drugs as treatment for MDS was shown prolonged survival in MDS. However, there were no definitive prognostic factors to predict survival or treatment outcomes after using HMA in MDS. And guideline about HMA treatment recommend continuous therapy because patients can be shown rapid progression if they stop the treatment. However, in real clinical practice, many patients are impossible to continue treatment of HMA because they have more problems such as comorbidities, old age, poor economics, etc than patients have those who enrolled to clinical trials.
Aims: The purposes of this study were to estimate porgnostic factors for survival in patients with MDS who were treated with HMA, and especially, to document prognostic factors for HMA treatment free survival (TFS) in patients who were stopped HMA without disease progression because of other causes such as toxicities, cost, etc.
Methods: The medical records of this study were collected from nationwide registry data which was performed in AML/MDS working party in South Korea. Data from patients at fourteen university hospitals in South Korea between Jan 2001 to Oct 2013 were collected retrospectively. All included patients had been diagnosed to MDS and they were treated with HMA such as azacitidine or decitabine as front line therapy and they were treated continuously at least four cycles. The evaluation of response were estimated by IWG response cri-

teria. Early response was defined to be shown response after two cycles of HMA treatment. The TFS was defined duration from the end date of HMA therapy to the date of disease progression, relapse, or death from any causes.
Results: The median age of the 217 patients was 68 years (range, 24-92 years) and the male to female ratio was 1.8:1.0. 144 patients were treated with azacitidine and 71 patients with decitabine. 109 patients stopped HMA therapy because of disease progression and the others stopped HMA therapy without progression because of other causes. The 5 years overall survival rates (OS) and TFS of patients who were more than 65 years old, have blast counts more than 5% in bone marrow, have poor cytogenetics, have higher risk of IPSS(International Prognostic Scoring System), WPSS (WHO Classification-Based Prognostic Scoring System) and IPSS-R (Revised International Prognostic Scoring System) were inferior than those of patients less than 65 years old, blast less than 5% in bone marrow, good cytogenetics, lower risk of IPSS, WPSS, and IPSS-R (Table 1). Especially, the 5 years OS and TFS of patients who stopped HMA therapy because of other cause without disease progression were also inferior in bone marrow blast more than 5%, higher risk of IPSS, WPSS and IPSS-R than those of patients who bone marrow blast less than 5%, lower risk of IPSS, WPSS, and IPSS-R. However, patients who have early good response including hematologic improvement, and more than stable disease according to IWG response criteria, and early improvement of platelet counts were also shown trends to be superior OS and TFS, but not shown significant differnences (early good response *vs* not good response ; 70.2% *vs* 45.6%, p=0.228 (OS), 54.0% *vs* 46.0%, p=0.172 (TFS), and early platelet response *vs* not shown ; 70.2% *vs* 43.3%, p=0.179 (OS), 54.0% *vs* 43.4%, p=0.124 (TFS)).

Table 1. Factors affecting OS and TFS (treatment free survival).

Value	5yrs OS (%)	*p*-value	5yrs TFS (%)	*p*-value
Age, years				
< 65	46.0	0.055	37.4	0.022
≥ 65	36.1		23.9	
BM blast, %				
< 5	55.4	< 0.001	45.8	< 0.001
≥ 5	16.6		0.0	
Cytogenetics				
Good	36.0	0.001	23.6	0.013
Intermediate	32.2		0.0	
Poor	19.4		18.8	
IPSS risk, n (%)				
Lower risk	48.7	< 0.001	39.5	< 0.001
Higher risk	21.6		10.3	
WPSS risk, n (%)				
Lower risk	59.4	< 0.001	49.0	< 0.001
Higher risk	21.4		0.0	
IPSS-R risk, n (%)				
Lower risk	48.0	< 0.001	36.4	0.005
Higher risk	19.6		11.9	

Summary and Conclusions: In our study, good prognostic factors for OS and TFS were younger age (<65 years), blast counts in bone marrow (<5%), good cytogenetics, lower risk of IPSS, WPSS, and IPSS-R. And in case of patients who stopped HMA therapy without disease progression because of other causes, they might be shown prolonged survival in less than 65 years old, blast less than 5% in bone marrow, lower risk of IPSS, WPSS, and IPSS-R. However, further studies are needed to determine more impressive clinical factors to predict survival in patients with MDS treated with HMA in clinical real practice.

E1220

HYPOMETHYLATING AGENTS ARE EFFECTIVE IN SHRINKING SPLENOMEGALY IN PATIENTS WITH CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML): MAYO CLINIC EXPERIENCE

S. Subari[1,*] M. Patnaik[2], D. Alfakara[2], D. Zblewski[2], C. Hook[2], S. Hashmi[2], W. Hogan[2], M. Litzow[2], A. Al-Kali[2]
[1]Gaziantep University, Gaziantep, Turkey, [2]Hematology, Mayo Clinic, Rochester, United States

Background: CMML is a malignant hematologic neoplasm characterized by peripheral blood monocytosis and bone marrow dysplasia. Cytoreductive therapy (Hydroxyurea) and hypomethylating agents (HMA) (Decitabine (DAC) and Azacitidine (AZA)) are the main therapy options. Splenomegaly is commonly found in CMML patients. As of today, no consensus criteria for response in CMML exist, and most clinicians use MDS International Working Group (IWG) criteria (Cheson *et al.* 2006). Such criteria do not account for spleen response. In addition, data is scarce on HMA effect on splenomegaly.
Aims: To study the efficacy of HMA on splenic size in CMML patients.
Methods: A retrospective single institution study chart review of cases with CMML at Mayo Clinic Rochester between 1994- 2011 was performed. Spleen size was documented only via clinical examination. Due to lack of criteria on splenomegaly response, we used "modified" splenic response criteria of international working group-myeloproliferative neoplasms research and treatment (IWG-MRT) and European LeukemiaNet (ELN) consensus report for myelofibrosis (Tefferi A. *et al.* 2013). In our study, CR was resolution of splenomegaly and PR was shrinkage over 50%. Patients with splenectomy were excluded. Appropriate IRB approval was obtained in accordance with the Helsinki declaration. Comparison between group medians was done using Wilcoxon test, while survival estimates were calculated using Kaplan-Meier curves JMP V10.
Results: Out of 269 CMML patients, 36 (13.4%) were treated with HMA. Median age was 70 years, with 21(58%) patients being males. Labs at treatment included median white blood cell (WBC) was $14.4x10^9$, Hemoglobin (Hg) 10.2 g/dL, platelet (PLT) $67x10^9$, monocytes $3.36x10^9$. CMML-1 was found in 26 patients (72%) and CMML-2 in 10 patients (28%). When evaluated patients with treated HMA therapy, 29(81%) patients were treated with DAC and 7(19%) patients were treated with AZA. Median number of therapy cycles was 4.5. Out of 36 patients, 11(31%) had splenomegaly documented at time of start of HMA and at follow-up. Median age was 66, with 7(64%) were males. Labs at treatment were median WBC $39.3x10^9$, Hg 10 g/dL, PLT $67x10^9$, monocytes $3.37x10^9$. CMML-1 was found in 8 patients (73%) and CMML-2 in 3 patients (27%). Nine (82%) patients had DAC and 2 (18%) AZA. Median number of therapy cycles was 4. When evaluated pretreatment splenic size below left costal margin with physical examination, median splen size was 6 cm (range 1-18 cm) while during treatment best median spleen size was 2 cm (range 0-13cm). Among these patients splenic complete and partial response (CR 3/PR 2) was 45% with rest having stable spleen response (SR). Median cycles of therapy for CR/PR group was 5(range 4-6) *versus* 3 (range 1-6) in SR group. Median survival was 10 months in splenic response positive (CR/PR) whereas 4.8 months in SR group (p=0.11).
Summary and Conclusions: HMA is frequently used for CMML patients. Significant improvement was found on splenic size after HMA treatment for many splenomegalic CMML patients. In addition splenic responders correlated with longer length of therapy. Overall Survival in splenic positive response group was longer than negative response group, but this did not reach statistical significance, likely due to small number of sample. Additional larger studies are needed to confirm our results.

E1221

HEMATOLOGIC MALIGNANCIES, MOSTLY MYELODYSPLASTIC SYNDROMES AMONG 1740 INFLAMMATORY BOWEL DISEASE PATIENTS: LONG TERM FOLLOW-UP DATA FROM A TERTIARY CENTER

A. Salihoglu[1,*] N. Serin[2], N. Esatoglu[2], H. Yilmaz[2], Y. Sengul[2], I. Hatemi[3], Y. Erzin[3], A. F. Celik[3]
[1]Hematology, [2]Internal Medicine, [3]Gastroenterology, Istanbul Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: It is not an uncommon situation that patients (pts) with inflammatory bowel disease (IBD) are referred to hematology for suspected hematologic malignancies (HM). There is concern that IBD and medications especially thiopurines and anti TNF agents used in the treatment may be associated with increased risk of various HM.
Aims: We aimed to describe IBD pts who developed HM.
Methods: Retrospective review of medical records from all 1740 pts treated for IBD at a single gastroenterology clinic from 1999 to 2014 was performed. Pts with HM were further evaluated for the following parameters in the Table 1 and mean corpuscular volume (MCV) before azathioprine (Aza) use, MCV at the time of HM diagnosis and duration of Aza treatment. Informed consent was obtained from all pts.
Results: In total 6 pts (3/3, M/F) were identified with HM (5 MDS and 1 AML). Characteristics of the pts are summarized in Table 1. Median ages at diagnosis of IBD and HM were 38.5 (18-55) and 48.5 (29-59) respectively. All of these 6 pts except one had been exposed to Aza and 4 were treated also with anti TNF. All 5 patients experienced leukopenia during Aza therapy. Median time of Aza treatment duration was 10 (6-18) months. Median time between IBD and HM was 6.5 years. At the time of IBD diagnosis MCV changed between 84-101 fl. Only 1 patient had a MCV >100 fl before Aza. At the time of HM diagnosis 4 pts had a MCV of >100 fl. Most of the pts (4/6) did not have active IBD at time of HM diagnosis. Iron deficiency anemia with/without chronic disease anemia was seen in 5 of 6 pts. Median hemoglobin was 11.7 (6.9-12.5) g/dl.

Table 1. Patients characteristics. AML, acute myeloid leukemia; Aza, azathioprine; MDS, myelodysplastic syndrome; GIBD, gastrointestinal Behcet disease; MTX, methotrexate; SSZ, salazopyrin; TNF, tumor necrosis factor.

Patient number	Sex	IBD	Age at diagnosis of IBD	Aza treatment	Other agents	Type of HM	Age at diagnosis of HM	Time between IBD and HM (years)	Follow-up time (years)	Life status at end
1	M	CD	32	yes	Anti TNF, MTX	MDS	47	15	15	alive
2	F	CD	18	yes	Anti TNF, SSZ	MDS	29	11	11	alive
3	M	CD	45	yes	Anti TNF	MDS	50	5	5	alive
4	F	GIBD	25	yes	Steroids, anti TNF	MDS	30	5	8	alive
5	F	UC	55	yes	SSZ	AML	59	4	5	alive
6	M	CD	52	no	SSZ	MDS	52	0.15	0.5	alive

Summary and Conclusions: Overall risk of myeloid malignancies mostly MDS may be increased in pts with IBD either related to the disease itself or as a consequence of its treatment. Pts with leukopenia during Aza and MCV >100 fl (after exclusion of other causes) may be prone to develop HM and deserve increased awareness. Concomitant iron deficiency may affect values especially MCV and its increase.

E1222

IMPACT OF AZACITIDINE ON RED BLOOD CELL ALLOINMUNIZATION IN MYELODISPLASTIC SYNDROME

S. Ortiz Zuluaga[1,*] C. Villegas[1], M.T. Orero[1], K. Javier[1], P. Pérez[1], R. Collado[1], D. Ivars[1], M. Roig[1], I. Luna[1], F. Carbonell[1]

Background: Reed blood cell (RBC) transfusion remains an essential component for the management of patients with myelodisplastic syndrome (MDS). Alloimmunization to RBC antigens is an important complication associated to multiple transfusion. The incidence of alloimmunization in MDS ranges from 12 to 56%. Hipomethylating agents such as Azacitidine (AZA) and Decitabine are standard care for the treatment of patients with MDS, however its impact in RBC alloimmunization has not been evaluated.
Aims: The objective of this study was to examine whether AZA may influence over the incidence of RBC alloimmunization in MDS.
Methods: Clinical and transfusion data regarding all consecutive patients with MDS and secondary acute myeloid leukemia from MDS who received >6 RBC concentrates between January 2009 and December 2014 were recorded. Data included: diagnosis according WHO 2008 classification, RBC support, treatment (AZA *versus* supportive care), alloantibody detection and identification, and the time between first transfusion and evidence of alloantibodies. We compare the data with that of MDS patients who received >6 RBC units between 1995 and 2008, previous to AZA approbation by EMEA.
Results: A total of 59 patients (34 males/25 females) with a median age of 75 years (53-89) received ≥6 RBC units between 2009-2014. Twenty-seven patients received AZA (75 mg/m2/day, 7 days without administration on the weekend) when a median of 6 cycles (range 1-14). Thirty-two patients received best supportive therapy (BSC) (RBC transfusions and erythropoietin when baseline level is low). The median follow-up from first transfusion was 13 months for AZA group and 12 months for BSC group. We identified 6 cases (18.8%) of alloimmunization in the BSC group and no cases in the AZA group (p=0.02). The WHO 2008 subtype and alloantibodies specificities are showed in Table 1. During a median follow-up of 23 months, the incidence of RBC alloimmunization in 94 patients who received their first transfusion before 2009 was 14.9% (14 patients) without differences with the 2009-2014 group (6 patients: 10.2%) (p=0.39). We observed significant differences in number of RBC units transfused between AZA group (median 24 units; range 6-212) and BSC group (median 10.5 units; range 6-198) (p <0,005). The median RBC units transfused per month was higher in AZA group (3.5; range 0.09-14) than in BCS group (0.91; 0.17-21) (p=0.002). A higher number of RBC units were transfused to patients in 1995-2008 group (median 36; range 6-307) compared to 2009-2014 group (median 17; range 6-206) (p<0.001). However, they were no significant differences in the median RBC units per month between groups. The alloantibody free survival from first transfusion was significantly superior in patients who received AZA (Figure 1) (Log-rank p=0,046).

Table 1. The WHO 2008 subtype and alloantibodies.

	RCUD	RARS	RCMD	RAEB 1	RAEB 2	AML	MDS/MP	5q-
No. Patients	5	9	18	2	10	7	6	2
Alloantibodies	2	0	2	0	0	0	1	1

RCUD: Anti-C, Anti-D; RCMS: Anti-E, Anti-Kell; MDS/MP: Anti-Kell; 5q-: Anti-Kell.

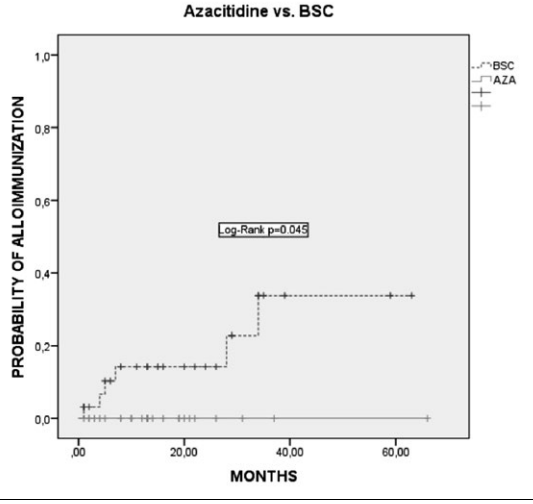

Figure 1. Time to alloimmunization from first transfusion.

Summary and Conclusions: Patients with MDS who received treatment with AZA form RBC antibodies at a lower rate than patients who received supportive care. However, these results were not influenced by the period in which the transfusion was performed. We suggest that the immunosuppression due to AZA therapy could develop an immunological tolerance or no response to incompatible transfusions.

E1223

IRON CHELATION THERAPY IN MYELODYSPLASTIC SYNDROME (MDS) IN ROUTINE CLINICAL SETTING: AN INTERIM ANALYSIS OF THE NON-INTERVENTIONAL STUDY EXSEPT

F. Nolte[1,*] O. Rubanov[2], R.-B. Kühn[3], C. Schumann[1], S. Kreil[1], G. Metzgeroth[1], C. Johr[4], S. Albrecht[4], W.-K. Hofmann[1]
[1]Hematology and Oncology, University Hospital Mannheim, Mannheim, [2]Office-based Hematology/Oncology specialist, Hameln, [3]Office-based Hematology/Oncology specialist, Oldenburg, [4]Novartis, Nuremberg, Germany

Background: MDS is a diverse group of hematopoietic stem cell disorders with anemia as one of its major clinical features often leading to transfusion dependency. A substantial proportion of MDS patients (pts) experiences iron overload (IOL) due to chronic red blood cell transfusion. Although the impact of IOL on morbidity and mortality in patients with MDS remains a matter of debate, there is some evidence that iron chelation might be beneficial in this patient group. Deferasirox (DFX) is an oral iron chelator, which has been shown to be effective in removing excess iron from the body.
Aims: The study was planned to evaluate the feasibility, safety and effectivity of the iron chelator DFX in a setting outside of clinical trials.
Methods: In the present non-interventional study EXSEPT, started in Aug 2010 and closed recruitment in Dec 2014 with a 2-year-follow-up-period still ongoing, we have performed a subgroup analysis with interim data on 199 patients with MDS and iron overload (data cut-off in Nov 2013). A total of 294 pts with IOL due to different transfusion requiring diseases were enrolled in this prospective, multicenter study. Efficacy was measured by change in serum ferritin (SF) during chelation with DFX. All pts were treated with DFX according to the guidelines for iron chelation therapy in pts with MDS. Within the first year, visits were planned every 3 months and twice in the second year. Pts with at least 1 follow-up visit were eligible for analysis and last observation was carried forward defined as last visit. Dose groups of 5 mg steps were analyzed according to the prescribed dose given.
Results: 190 pts with MDS and IOL were analyzed with 57% being male pts. Median age was 74 years (range 14-93). The IPSS risk categories were available in 62% and were as follows: low in 19.5%, intermediate-1 in 26.8%, intermediate-2 in 9.5% and high in 4.7% of the pts, respectively. Mean baseline SF level was 2090 ng/mL (range 423 to 5840 ng/mL) and showed a moderate mean reduction of 237 ng/mL during course of DFX treatment until last visit. The reduction in iron burden differed within the initially planned dose groups with no effective reduction in the dose groups <10 mg/kg (+207 ng/mL; mean baseline 1759 ng/mL; n=27) and 10-≤15 mg/kg (-28 ng/mL; mean baseline 1750 ng/mL; n=16) compared to an effective reduction in the planned dose groups 15-≤20 mg/kg (- 625 ng/mL; mean baseline 2236 ng/mL; n=14) and 20-≤25 mg/kg (-348 ng/mL; mean baseline 2094 ng/mL; n=46). Mean creatinine levels increased slightly from baseline serum creatinine level of 0.90 mg/dL to 1.06 mg/dL at last visit. Adverse events were documented in 152 pts (80%). DFX was generally well tolerated, with the most common adverse events being gastrointestinal disturbances (15%), decrease in renal creatinine clearance (8%) and blood creatinine increase (7%).
Summary and Conclusions: We performed this analysis to evaluate the safety and efficacy of DFX in a routine setting outside clinical trials. The results demonstrated efficacious iron chelation using adequate doses of DFX in elderly pts with MDS. Changes in SF were moderate possibly reflecting the early stage of the study with limited data on pts with visits >6 months. Moreover, treatment was possibly sub-optimal in pts with doses below 10 mg/kg/days, but no data on the reason for the chosen dose were available. DFX was generally well tolerated, with the most common adverse events being gastrointestinal disturbances. This study with all its limitations due to the non-interventional nature supports the results of previously conducted trials.

E1224

HEMOCHROMATOSIS GENE MUTATIONS MAY AFFECT THE SURVIVAL OF PATIENTS WITH MYELODYSPLASTIC SYNDROME

M. Lucijanić[1,*] V. Pejša[1], Z. Mitrović[1], T. Štoos-Veić[2], A. Livun[3], O. Jakšić[1], T. Vasilj[1], M. Piršić[1], V. Hariš[1], R. Kušec[3]
[1]Hematology department, [2]Department of Clinical Cytology and Cytometry, [3]Clinical Institute of Laboratory Diagnosis, Divison of Molecular Diagnosis and Genetics, Universitiy Hospital Dubrava, Zagreb, Croatia

Background: Myelodysplatic syndrome patients are at risk of developing an iron-replete state and hemochromatosis due to frequent transfusion dependency and characteristics of the disease itself.

Aims: The recent availability of potent oral iron chelators is renewing an interest in the assessment of the possible impact of *HFE* genetics in MDS**.**
Methods: 36 newly diagnosed patients with MDS were studied for parameters of iron metabolism in addition to C282Y and H63D mutations of the *HFE* gene.
Results: Mutations were present in 11 out of 36 patients (31%), which was not different from our general population and were equally distributed among MDS subtypes. Mutated patients had higher ferritin levels (p=0.039) and lower TIBC (p=0.018). Ferritin was found to be higher for the untransfused mutated patients (p=0.017), but not for transfusion-dependent patients in whom ferritin levels correlated significantly with the number of blood units received (p=0.04). There was no difference in the number of blood units received between the mutated and wild type patients. A new observation made was that the mutated patients had a lower overall survival (OS) in addition to a poorer leukemia free survival (LFS) (p=0.004 and p=0.003, respectively) (Figure 1).

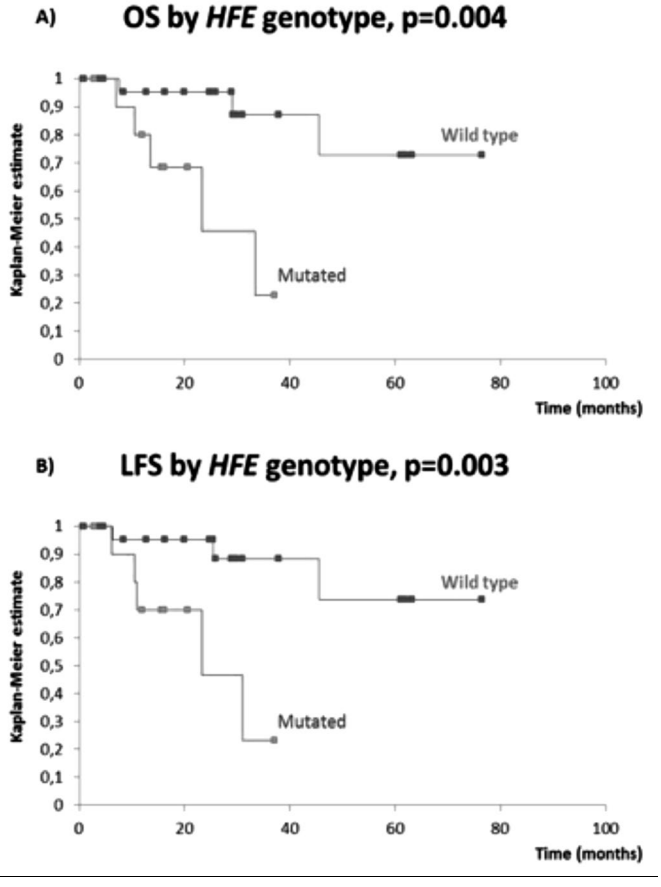

Figure 1.

Summary and Conclusions: The *HFE* gene mutations are not more frequent in MDS patients. Iron overload in mutated patients was higher. The effect of mutations on survival could be mediated by changes in iron metabolism. The *HFE* gentopye may predict MDS prognosis and there is a need for further studies. It remains a challenging question if *HFE* mutated MDS patients should be considered for potent iron chelation therapy.

E1225

P53 EXPRESSION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME AT DIAGNOSIS AND FOLLOWING TREATMENT WITH AZACITIDINE

S. Maung[1,*] N. Strahan[1], R. Desmond[1], J. McHugh[1], C. Burke[1], J. O'Loughlin[2], M. Jeffers[2], H. Enright[1]
[1]Haematology, [2]Cellular Pathology, Tallaght Hospital, Trinity College Medical School, Dublin, Ireland, Dublin, Ireland

Background: The Myelodysplastic Syndromes (MDS) are a heterogeneous group of malignant stem cell disorders characterised by ineffective and dysplastic haematopoiesis resulting in a hypercellular and dysplastic bone marrow with a risk in some patients of transformation to acute myeloid leukaemia (AML). Previous studies have demonstrated consistent correlation between immunohistochemical staining for the tumour suppressor gene p53 (*TP53*) and the presence of *TP53* mutation identified by molecular methods including deep sequencing. P53 expression has also been shown to have value as an independent prognostic indicator in some haematological malignancies, including Del(5q) MDS.

Aims: Our study aimed to assess the prognostic impact of p53 expression in bone marrow biopsies at diagnosis in MDS patients (n=47). We also set out to assess the effect, if any, of treatment with the hypomethylating agent Azacitidine on p53 expression.
Methods: Formalin-fixed paraffin embedded 4µm sections of bone marrow trephines were stained with Dako p53 mouse monoclonal antibody (DO-007) using standard protocol. Three hundred haematopoietic cells were manually counted. Positive expression is defined as strong nuclear staining in at least 1% of the haematopoietic cells examined
Results: p53 expression (strong positivity in >1% of cells examined) was seen in a significant number of patients (22%) at diagnosis of MDS (n=10). Using a cut-off point of 5% of cells, strong positivity was identified in 14% (n=6). P53 expression was correlated with MDS WHO category and IPSS-R score. Strong p53 staining in >5% of cells was associated with a significantly lower survival rate. Not surprisingly, patients with known cytogenetic abnormalities involving the short arm of chromosome 17 had particularly strong expression of p53. Comparison of p53 expression in marrow biopsies prior to treatment and following 4 cycles of treatment in 25 patients treated with Azacitidine showed varying patterns, with significant decrease in expression following treatment in 11 patients (44%). Patients with higher levels of expression had more substantial decrease in expression post treatment. No association was observed between changes in p53 expression and survival among Azacitidine treatment group but this may be due to a small sample size (Figure 1).

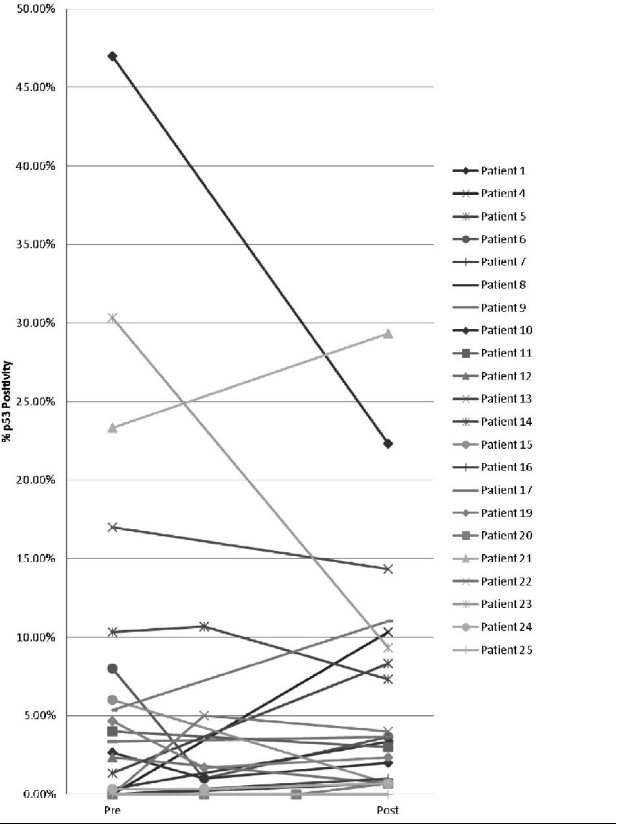

Figure 1. Difference in P53 expression pre and post treatment with Azacitidine.

Summary and Conclusions: Immunohistochemical analysis of p53 expression in marrow trephine biopsies shows significant promise for future use as a readily available prognostic indicator with a short turn around time for patients with MDS. Further research is warranted to assess the on the impact of Azacitidine and other therapeutic agents on p53 expression, and to establish whether immunohistochemical analysis of p53 expression might help predict either disease responsiveness or resistance.

E1226

SUBGROUP ANALYSES OF A PHASE 3 STUDY IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES FAILING HMA TREATMENT: IDENTIFICATION OF A HOMOGENEOUS POPULATION WHO BENEFIT FROM RIGOSERTIB THERAPY

G. Gaidano[1,*] U. Platzbecker[2], K.-A. Kreuzer[3], T. Bernal de Castillo[4], L. Silverman[5], G. Garcia-Manero[6], H. Loferer[7], P. Fenaux[8]
[1]Amedeo Avogadro University of Eastern Piedmont, Novara, Italy, [2]Universitätsklinikum Dresden, Dresden, [3]Universitätsklinikum Köln, Köln, Germany, [4]Hos-

pital Central de Asturias, Oviedo, Spain, [5]Icahn School of Medicine at Mount Sinai, New York, [6]MD Anderson Cancer Center, Houston, United States, [7]Onconova Europe GmbH, Munich, Germany, [8]Hospital St Louis, Paris, France

Background: Myelodysplastic syndrome (MDS) is heterogeneous, with varying categories and prognosis as defined by the Revised International Prognostic Scoring System (IPSS-R; Greenberg 2012). Patients with higher IPSS-R scores have worse clinical outcomes; those with Very High Risk (VHR) IPSS-R have the worst prognosis, with most dying of bone marrow failure complications. ONTIME was the first randomized study in patients with MDS failing hypomethylating agents (HMAs), with overall survival (OS) as the primary endpoint. ONTIME enrolled RAEB-1, RAEB-2, RAEB-t and CMML patients previously treated with HMAs, with marrow blast count at entry of 5-30%. Thus, it included a heterogeneous population of MDS patients. When the study was designed, little information was available regarding the prognosis for patients with MDS failing HMAs. Subsequently, Prebet and others showed a short survival expectancy (<6 months) for these patients (Prebet, JCO 2011; Jabbour, Cancer 2010). ONTIME demonstrated a 2.3-month benefit in median OS (mOS) in the ITT population that was not statistically significant (8.2 mo rigosertib *vs* 5.9 mo BSC; p=0.33; HR=0.87; n=299). The study was well-balanced, permitting post-hoc analyses of OS in defined subgroups of patients, including those with the worst prognosis, based on the (i) types of failures of HMA therapy, (ii) duration of exposure to HMA therapy, (iii) prognostic risk categories per the IPSS-R, and (iv) cytogenetic aberrations.
Aims: We sought to identify MDS subtypes who may benefit from rigosertib for a future clinical trial by defining a prospective patient population based on data from ONTIME and biological rationale.
Methods: Distribution of OS in each risk category and each arm was estimated by Kaplan-Meier method and log-rank test was used for treatment effect. Hazard ratio was estimated by Cox regression.
Results: We analyzed OS in patients classified as Primary 5-Azacytidine (AZA) Failures (patients who failed to respond to or progressed during AZA treatment) or as Secondary AZA Failure (patients who responded and then progressed), following Prebet 2011. The mOS was longer with rigosertib than with BSC among the Primary AZA Failure patients (8.6 months *vs* 4.6 months; p=0.032; HR=0.65) but not among patients classified as Secondary AZA Failure (5.5 months for rigosertib, 6.8 months for BSC; p=0.87; HR=1.05). In both treatment arms, the IPSS-R results correlated with OS in this study. Among patients who had VHR IPSS-R, the mOS was significantly longer with rigosertib than with BSC (7.6 *vs* 3.2 months; p=0.0050; HR=0.56); in contrast to all other IPSS-R risk categories (see Table 1). All of the patients with monosomy 7 and 66% of those with trisomy 8 were also VHR IPSS-R. The analysis of karyotypic aberrations found that mOS was significantly longer with rigosertib than with BSC for patients with the monosomy 7 (5.6 mo rigosertib *vs* 2.8 mo BSC; p=0.0033; HR=0.24) or trisomy 8 (9.5 mo rigosertib *vs* 4.5 mo BSC; p=0.035; HR=0.34) mutations.

Table 1. Overall survival by IPSS-R risk category (intention-to-treat).

IPSS-R Risk Category	N	Median (months)	N	Median (months)	Log-rank p-value	Hazard ratio (Rigosertib/BSC) (95% CI)
Overall	199	8.2	100	5.9	0.33	0.87 (0.67-1.14)
Intermediate	14	9.1	14	12.6	0.48	1.39 (0.56-3.47)
High	67	9.7	26	9.7	0.93	1.03 (0.61-1.74)
Very High	**93**	**7.6**	**41**	**3.2**	**0.0050**	**0.56 (0.37-0.84)**
Unknown	24	8.2	19	6.3	0.79	0.90 (0.44-1.82)

Summary and Conclusions: We conducted in-depth analysis of ONTIME, and found that patients with the worst prognosis at entry, and thus with the greatest unmet medical need, appeared to benefit most from rigosertib treatment; namely, those with Primary AZA Failure, VHR- IPSS-R, and monosomy 7. The duration of prior HMA treatment inversely correlated with survival benefit. Based on these results, a new randomized prospective controlled study in this high-risk MDS patient population comparing rigosertib to physician's choice will be conducted to confirm these important observations.

E1227

PROGNOSTIC AND PREDICTIVE VALUE OF IPSS-R IN ASSESSING OVERALL SURVIVAL (OS) IN A PHASE III STUDY OF RIGOSERTIB IN SECOND-LINE HIGHER-RISK (HR) MDS PATIENTS

L. Silverman[1,*] P. Fenaux[2], A. Al-Kali[3], M. Baer[4], M. Sekeres[5], G. Roboz[6], G. Gaidano[7], B. Scott[8], P. Greenberg[9], U. Platzbecker[10], D. Steensma[11], K.-A. Kreuzer[12], L. Godley[13], R. Collins[14], E. Atallah[15], N. Azarnia[16], G. Garcia-Manero[17]
[1]Icahn School of Medicine at Mount Sinai, New York, United States, [2]Hospital St Louis, Paris, France, [3]Mayo Clinic, Rochester, [4]University of Maryland, Baltimore, [5]Cleveland Clinic, Cleveland, [6]Weill Cornell Medical College, New York, United States, [7]Amedeo Avogadro University of Eastern Piedmont, Novara, Italy, [8]Fred Hutchinson Cancer Research Center, Seattle, [9]Stanford Medical School, Stanford, United States, [10]Universitätsklinikum Dresden, Dresden, Germany, [11]Dana-Farber Cancer Institute, Boston, United States, [12]Universitätsklinikum Köln, Köln, Germany, [13]University of Chicago Medical Center, Chicago, [14]University of Texas, Southwestern Medical Center at Dallas, Dallas, [15]Froedtert Hospital and Medical College of Wisconsin, Milwaukee, [16]Onconova Therapeutics, Inc., Newtown, [17]MD Anderson Cancer Center, Houston, United States

Background: ONTIME was a randomized (2:1) controlled study of rigosertib (RIG) *vs* best supportive care (BSC) in 299 pts with HR-MDS who had relapsed after, failed to respond to, or progressed during treatment with hypomethylating agents (HMAs). The study showed a non- significant trend favoring RIG in the analysis of overall survival (OS). The Revised International Prognostic Scoring System (IPSS-R) is a refinement of an earlier widely used index for risk assessment and prognosis for MDS (Greenberg 2012). Here we present the results of analyses in the subgroup of patients with very high risk (VHR) per the IPSS-R.
Aims: To examine the utility of the IPSS-R and the correlation between baseline characteristics and OS in a Phase III study of 2nd-line HR -MDS pts with IPSS-R VHR.
Methods: A log-rank test was run on each baseline disease characteristic from the 93 RIG and 41 BSC pts with IPSS-R VHR in the ONTIME study.
Results: Promising improvement (p<.01) with RIG on median OS *vs* BSC was shown in several subgroups defined by baseline characteristics (see Table 1). Overall, adverse events (AEs) were reported in 100% of RIG pts and 95% of BSC pts with IPSS-R VHR. AEs ≥Grade 3 in ≥10% of pts were: anaemia (RIG 24%, BSC 11%), thrombocytopenia (21%, 11%), febrile neutropenia (17%, 11%), neutropenia (15%, 13%), pneumonia (12%, 13%).

Table 1. Median (months) OS by baseline disease characteristics in Pts with IPSS-R VHR.

Characteristic	RIG N	RIG OS	BSC N	BSC OS	Log-rank p-value	Hazard ratio (RIG/BSC) (95% CI)
All patients with IPSS-R VHR	93	7.6	41	3.2	0.0050	0.56 (0.37-0.84)
Primary HMA failure*	55	8.1	21	2.6	0.0055	0.48 (0.28-0.81)
FAB classification of RAEB-t	23	5.8	9	3.4	0.0031	0.26 (0.10-0.68)
ECOG performance status 0 or1	79	8.9	30	3.6	0.0006	0.44 (0.28-0.71)
Bone marrow blast 20-30%	24	5.9	9	3.4	0.0020	0.25 (0.10-0.64)
Hemoglobin < 9 g/dL	63	6.9	21	2.3	<0.0001	0.30 (0.17-0.54)
Platelet count = 40 $\times 10^9$/L	37	10.1	13	4.4	0.0009	0.27 (0.12-0.62)
Neutrophil count = 0.8 $\times 10^9$/L	24	8.5	12	2.7	0.0038	0.29 (0.12-0.70)
FAB classification of CMML	1	9.2	5	4.7	<0.0001	--

*Failed to respond to or progressed during HMA treatment (Prebet 2011)

Summary and Conclusions: IPSS-R is a useful prognostic tool for 2nd-line MDS pts. After HMA failure, MDS pts with IPSS-R VHR in certain subgroups identified by baseline disease characteristics showed an OS advantage when treated with RIG compared to BSC. Such characteristics should be considered in the design of future 2nd-line studies in MDS patients with IPSS-R VHR.

E1228

INCREASED IMMUNE ACTIVATION AND IMPAIRED CELL SUPPRESSION ON MYELODYSPLASTICS SYNDROMES PROGRESSION

A. Perazzio[1,2,*] M.D.L. Chauffaille[1,2]
[1]Hematology, Unifesp, [2]Hematology, Fleury Laboratory, São Paulo, Brazil

Background: The Myelodysplastics Syndromes (MDS) are characterized by clonal proliferation of bone marrow cells with inefficient production. Its pathogenesis is still unknown. Some patients present autoimmune phenomena and abnormal immune function. Furthermore, some immune alterations remain unexplained according to the disease progression
Aims: This study aims determine cell-mediate suppression by Treg in MDS patients in 2 periods: zero and 12months
Methods: Peripheral blood of 38 patients was obtained initially (T0) and after 12 months (T12). Tregulatory (Treg) were sorted by flow citometry and cocultured for 7 days with T effector cells (Teff) in different concentration (Teff isolated with stimulation by phytohemagglutinin(Teff+PHA), Teff:Treg:1:1 and Teff:Treg:8:1) to evaluate cell-mediate suppression by Treg and quantify interleucines production (IL2, IL4, IL6, IL10, IL17, TNFa and IFNg) in culture supernatant by CBA. Relative gene expression of IRF-1(exons 2 and 4/5) was detected by qRT-PCR in peripheral Treg cells and peripheral blood and gene expression of Foxp3 was detected only in peripheral Treg cells
Results: Treg number (T0=5,6x10^5±2,8 *vs* T12=4,8x10^5±2,60; p=0.3) and Teff percentage (T0=16,8%±9,5 *vs* T12=13,1%±6,3; p=0.06) did not differ after 12 months, albeit there was a trend toward a decrease of Teff. Co cultures of Treg:Teff 1:1 showed an increased Teff proliferation in T12 (41,9%±3,1) compared to T0 (28,2%±4,7; p=0.02). The cytokine production was significantly

increased in culture supernatant (pg/mL) after 12 months: isolated Teff+PHA (IL2:p=0,048;IL4:p=0,001;IL6:p<0,001;IL10:p=0,001;TNF:p=0,024;INF:p<0,001 ;IL17:p<0,001), coculturesTeff:Treg:1:1 (IL2:p=0,007;IL4:p=0,002;IL6:p<0,001; IL10:p<0,001;TNF:p=0,002,INF:p<0,001;IL17:p<0,001) and Teff:Treg:8:1 (IL2:p=0,85;IL4:p=0,128;IL6:p=0,001;IL10:p<0,001; TNF:p=0,08; INF:p=0,002; IL17:p<0,001). Relative genetic expression of IRF-1 exon 4/5 was increased in whole blood (T0=0,02±0,14 *vs* T12=0,99±0,2;p=0,001) and Treg (T0=0,07±0,07 *vs* T12=0,14±0,08; p<0.001) after 12 months. However, genetic expression of exon 2 was only increased in whole blood (T0=0,002±0,01 *vs* T12=0,01±0,01; p<0.001), while the genetic expression of Foxp3 in Treg did not present statistical differences (T0=0,06±0,06 *vs* T12=0,07±0,12; p=0.57). Interestingly, a moderate positive correlation between the genetic expression of Foxp3 and IRF-1 exon 4/5 (R=0,659; p=0.002)

Summary and Conclusions: The increase of Teff proliferation and cytokine production suggests an impairment of Treg suppression ability and might be related to dysfunctions in inhibition by contact and inhibitory cytokine production. The initial reduced expression of IRF-1 in MDS patients evolved with an important increase during the disease progression. This gene is a powerful tumor suppressor and its low expression may be associated to disease progression. Moreover, IRF-1 is involved in several immune functions and high expression was described in MDS patients with autoimmune manifestations, thus the observed higher expression of IRF-1 might be associated to increased cytokine production, like IFN. In mice, IRF-1 inhibits Foxp3 expression in Treg cells. However, our results showed a positive correlation of IRF-1 exon 4/5 and Foxp3. Thus it is possible that the high IRF-1 expression was disproportionally induced by Foxp3 in MDS patients along disease progression

E1229

IMMUNE EXACERBATION ON MYELODYSPLASTICS SYNDROMES

A. Perazzio[1,2,*] M.D.L. Chauffaille[1,2]
[1]Hematology, Unifesp, [2]Hematology, Fleury Laboratory, São Paulo, Brazil

Background: The Myelodysplastics Syndromes (MDS) are characterized by clonal proliferation of bone marrow cells with inefficient production. However, the pathogenesis is still unknown. Some patients present autoimmune phenomena and abnormal immune function

Aims: This study aims to evaluate T cell function in MDS patients. Associated to autoimmune manifestations and prognostic scores will be detailed and compared to controls

Methods: The diagnosis of MDS was made according to WHO classification including the analysis of peripheral blood/marrow cell morphology and karyotype, and patients were stratified for prognosis according to IPSS, IPSS-R, WPSS. Peripheral blood from 38 MDS patients, 28 HC(healthy controls) and 17 AID (autoimmune disease composed by lupus and rheumatoid arthritis) were obtained. Tregulatory (Treg) were sorted by flow citometry and cocultured for 7 days with T effector cells (Teff) in different concentration (Teff isolated with stimulation by phytohemagglutinin, Teff:Treg:1:1 and Teff:Treg:8:1) to evaluate cell-mediate suppression by Treg and quantify interleukines production (IL2, IL4, IL6, IL10, IL17, TNFa and IFNg) in culture supernatant by CBA. Relative gene expression of IRF-1 was detected by qRT-PCR in peripheral Treg cells and peripheral blood, and Foxp3 was detected only in peripheral Treg cells. Antinuclear antibodies (ANA) were determined by indirect immunofluorescence. Total complement (CH100) and C2 serum levels were determined by radial immunohemolysis

Results: Treg number (x10^5cells) was not different in the MDS patients subgroups determined according to prognosis score: IPSS (high=4,9±1,1 *vs* low=5,6±1,6; p=0,5), WPSS (high=5,8±2,2 *vs* low=5,2±0,4; p=0,29), and IPSS-R (high=5,8±2,5 *vs* low=5,6±0,6; p=0,6). Hemoglobin serum levels was lower in high risk (7,9mg/dL±1,2) compared to low risk patients (9,9mg/dL±0,2; p=0.025), according to IPSS score. There was no difference in Treg number (x10^5cells) according to the presence of normal (5±0,8) or abnormal karyotype (6,5±1,2; p=0.12). Treg number (x10^5cells) was significantly higher in MDS (5±2,8) than in HC (3,1±2,0; p=0.007) and AID (2,8±2,4; p=0.008). Peripheral Teff percentage was similar in HC (20±8,3), MDS (13,3±9,0; p=0,27) and AID (14±6,8; p=0,98). Suppression of proliferation Teff mediated by Treg cell was decreased in the AID group compared to HC (p=0,03) and MDS (p<0.003). Overall cytokine production detected in culture supernatant was decreased in MDS, except for IL17, which was higher in AID (98,7pg/mL±155) compared to HC (16,4pg/mL±49,3) and MDS (9,1pg/mL±95,7; p<0.001). The relative gene expression of IRF-1 exon 2 (0,01±0,015 *vs* 0,001±0,01; p<0.02) and 4/5 (0,10±0,11 *vs* 0,02±0,14; p<0.01) in total peripheral blood were lower in MDS patients compared to IAD. Additionally, relative gene expression of IRF-1 exon 4/5 in Treg cell was increased in AID (0,11±0,11; p=0,005) compared to MDS(0,07±0,07) and HC (0,02±0,07; p=0,003). The relative gene expression of Foxp3 in Treg cell was similar in the three groups (MDS=0,06±0,06 *vs* AID=0,04±0,1 *vs* HC=0,04±0,04; p=0,96). MDS (46,2U/mL±2,1) patients presented lower CH100 than IAD (98,2U/mL±1,5; p=0,014). The frequency of ANA-positive individuals was higher in MDS than in HC (p=0.029)

Summary and Conclusions: Our results showed that suppression of Teff cell by Treg cell in MDS is similar to the controll, however the peripheral number of Treg cell is higher than in HC and AID, suggesting that function might be increased in MDS patients. One can hypothesize that it occurs secondarily, in an attempt of controlling the disease immune hyper activation. Interestingly, cytokine production was globally impaired in MDS, revealing a possible exhaustion of immune system, emphasized by complement consumption

E1230

LONG-LASTING HEMATOLOGIC RESPONSE TO AZACITIDINE IN MYELODYSPLASTIC SYNDROMES: UPDATE OF CLINICAL RESULTS FROM A SINGLE INSTITUTION

C. Finelli[1,*] C. Clissa[2], M.Y. Follo[3], S. Parisi[1], S. Mongiorgi[3], M. Stanzani[1], C. Bosi[4], L. Cocco[3], M. Cavo[1]
[1]Hematology, S.Orsola-Malpighi University Hospital, Bologna, [2]Hematology, S.Salvatore Hospital, Pesaro, [3]Biomedical Sciences-Human Anatomy, University of Bologna, Bologna, [4]Hematology, Guglielmo da Saliceto Hospital, Piacenza, Italy

Background: Although Azacitidine (AZA) has proven effective in myelodysplastic syndromes (MDS), the duration of haematologic response is usually limited (median: 13.6 months) *(Fenaux 2009)*. The French Group *(Itzykson 2011*) identified some clinical and haematologic parameters (poor ECOG performance status (p.s.), IPSS intermediate and poor risk cytogenetics, circulating blasts, high transfusion need) independently associated with a a poorer outcome, and these 4 criteria were integrated in a 3-risk-group prognostic score.

Aims: These data prompted us to retrospectively analyse our MDS pts treated with AZA who showed a favourable long-lasting response to AZA (*i.e.*: duration of response ≥20 months), in order to enucleate the clinical and hematologic features of long-responder pts.

Methods: The type of response was defined according to IWG criteria *(Cheson 2006)*: Complete Remission (CR), Partial Remission (PR), Marrow CR (mCR), Hematologic Improvement (HI). The response duration was measured from the date of achievement of a first response until the date of disease progression or death. Overall Survival (OS) was measured from the start of AZA treatment. Moreover, we quantified the degree of phosphoinositide-phospholipase C (PI-PLC) beta1 methylation and gene expression before and during AZA administration.

Results: From September 2004 in our Institution, 70 pts (50 males, median age 70, range 37-87 yrs) were treated with AZA. 40/70 pts (57.1%) showed a favourable response. 6 pts underwent allogeneic stem cell transplantation. 11/70 pts (15.7%, 27.5% of the responder pts) (4 males, median age: 68, range 60-84 yrs) showed a response duration ≥20 months. At AZA onset, WHO diagnosis was: RCMD-RS: 1 pt; RAEB-1: 4 pts; RAEB-2: 5 pts; MDS with Fibrosis: 1 pt. MDS was therapy-related in 3 pts. ECOG p.s. was <2 in all cases. IPSS risk was: Low: 1 pt; INT-1: 3 pts; INT-2: 6 pts; High: 1 pt. WPSS risk was: Low: 1 pt; INT: 2 pts; High: 5 pts; Very High: 3 pts; IPSS-R risk was: Low: 2 pts; INT: 3 pts; High: 4 pts; Very High: 2 pts. IPSS cytogenetic risk was: Good: 5 pts; INT: 4 pts; Poor: 2 pts. Transfusion need was high (≥4 RBC units/8 weeks) in 4 pts. No patient showed circulating blasts. Following Itzykson's AZA prognostic scoring system, the risk was: Low: 3 pts; INT: 8 pts. The pts received a median of 24 (8-59) cycles of AZA (3 lower-risk pts discontinued therapy after 8th cycle). The median duration of treatment was 35 (8-68) months. The best response achieved was: CR in 6 pts; marrow CR+HI: 1 pt; HI: 4 pts. First Response and Best Response were observed after a median of 1 (1-5) and 8 (1-12) cycles, respectively. An abnormal karyotype persisted in 3 pts. The median duration of response was 40 (21-75) months. In 8 pts, after the 1st 8 cyles, the intervals between cycles were prolonged on average up to 8 weeks, and in 5 pts erythropoietin was added during the maintenance therapy. Grade >2 non hematologic toxicity was observed in 2 pts. In 8 pts the disease evolved into AML (4 pts), or into a more advanced MDS (2 pts), or into a chronic myeloproliferative neoplasm (2 pts). 6 pts are still alive, and 2 pts are still maintaining the response after 49 and 71 months, respectively. Median OS from the start of AZA was 50 (25-125) months. All the pts showed an increase in PI-PLCbeta1 expression, that was maintained along with the hematologic response.

Summary and Conclusions: Our data show that a limited but significant fraction of MDS pts show a long-lasting hematologic and molecular response to AZA.

E1231

THE EFFICACY OF THE 5-AZACITIDINE IN THE THERAPY-RELATED MYELOID NEOPLASIA: A RETROSPECTIVE MULTICENTRIC EXPERIENCE

M. Riva[1,*] A. Molteni[1], L. Borin[2], M. Bernardi[3], A. Pellizzari[4], A. Freyrie[5], M. Della Porta[6], M. Nichelatti[1], E. Ravano[1], G. Quaresmini[7], J. Mariotti[8], D. Caramazza[9], M. Ubezio[6], S. Guarco[5], F. Gigli[10], R. Greco[1], R. Cairoli[1]
[1]Hematology, AO Niguarda Ca' Granda, Milan, [2]Hematology, Ospedale San Gerardo, Monza, [3]Hematology, Ospedale San Raffaele, Milan, [4]Hematology, Spedali Civili, Brescia, [5]Hematology, Ospedale Maggiore Policlinico, Milan, [6]Hematology, Policlinico San matteo, Pavia, [7]Hematology, Ospedale Papa GiovannixXIII, Bergamo, [8]Transfusion and Hematology, AO "Treviglio-Caravaggio", Treviglio, [9]Hematology, Ospedale di Circolo e Fondazione Macchi, Varese, [10]Hematology, Istituto Europeo di Oncologia, Milan, Italy

Background: Therapy-related myelodysplastic neoplasia (t-MDS/AML) is an increasingly complication in patients (pts) treated with radiotherapy or

chemotherapy for previous hematologic or solid tumors. Conventionally, these pts are considered having a bad prognosis and allogeneic stem cell transplantation is the gold standard therapy. However, this approach is often not exploitable due to patient ineligibility or lack of stem cells donor. In these cases, if pts had a medullar blast count below 30%, 5-azacitidine (5-AZA) may be a suitable alternative. Very few data in this setting are available.
Aims: To evaluate the effectiveness of 5-AZA in this group of pts in the clinical practice. To assess the influence of cytogenetic risk into the outcome.
Methods: A retrospective analysis of t-MDS/AML cases into a large cohort of pts treated with 5-AZA in 10 centers in Lombardia region was performed. The cytogenetic risk was evaluated in according to the recently developed cytogenetic system for Myelodysplastic Syndromes (Schanz JCO 2012) and used as parameter in the prognostic score IPSS-R. Considering the small sample, the "very low", "low" and "intermediate" risk patients were evaluated together and their survival was compared to the survival of the "high" or "very high" cytogenetic risk pts. Response to therapy was considered evaluable if pts had reached, at the time of observation, at least 6 cycles of 5-AZA. The Kaplan Meier method, followed by the Logrank test was applied to evaluate the survival, starting from the beginning of treatment, and in relationship to the cytogenetic stratification.
Results: From a population of 187 pts affected by a myeloid malignancy with a medullar blast count <30% and treated with 5-AZA, data about 29 cases of t-MDS/AML were carried out. Of these 16 were female and 13 were male. Median age was 70 (range 40-87). Bone marrow blasts count was ≥20% in 2 cases, ≥10% in 10 cases and <5% in 3 cases. In 13 cases Red Blood Cells transfusion dependence was present. In the other 16 cases median hemoglobin level was 9.4 g/dl (range 8.6-12). Only 2 pts had platelet count (PLT) <10.000/mm^3, in other 10 case PLT were <50.000/mm^3. In 7 cases neutrophil count was less than 800/mm^3. The median number of 5-AZA courses administered was 5 (range 1-20). A response to the treatment (including the cases of "stable disease" maintenance) was achieved in 15 cases on 21 evaluable. The median survival was 12.1 months (Figure 1a). The median survival of the responders was significantly higher than the non responders one (23.8 months *versus* 4.3 months; p=0.023, Figure 1b).
The cytogenetic analysis, at the starting therapy time, was available in 27 cases. Considering the cytogenetic risk, the pts were divided as shown in Table 1.

Table 1.

Cytogenetic risk	Very Low	Low	Intermediate	High	Very High
Pts (n°)	1	8	2	7	9

The survival of "very low", "low" or "intermediate" cytogenetic risk pts did not differ significantly from the survival of "high" or "very high" risk ones (p=0.1890; Figure 1c).

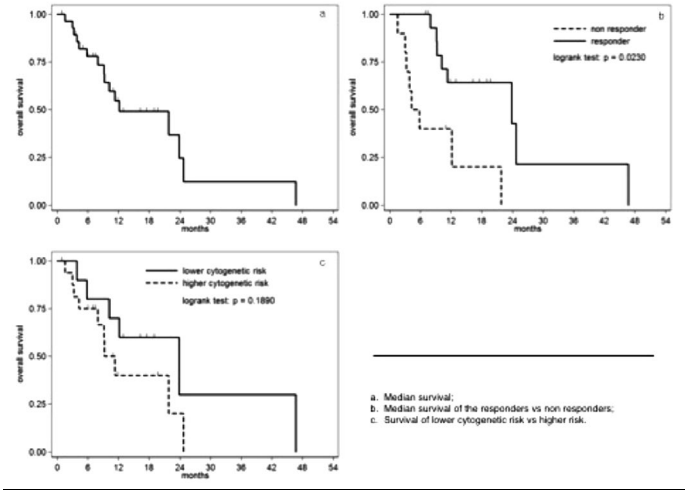

Figure 1.

Summary and Conclusions: Treatment in t-MDS/AML patients with 5-azacitidine seems to be effective to induce a response in these patients (71.4% of evaluables). Responding pts had a significative benefit in overall survival. The presence of a "high" or "very high" cytogenetic risk according to the IPSS-R stratification did not influenced the survival.

Myeloma and other monoclonal gammopathies - Biology

AN ENDOGENOUS RETROVIRUS EXAPTATION EVENT SIGNIFICANTLY CONTRIBUTED TO THE GENERATION OF SOLUBLE RANKL MRNA: IMPLICATIONS ON THE TRANSCRIPTIONAL PROFILE OF THE TRANSCRIPT VARIANT

S. Papamichos[1,*] D. Margaritis[1], E. Spanoudakis[1], A. Christoforidou[1], Z. Bezirgiannidou[2], S. Vakalopoulou[3], E. Vlachaki[4], G. Koutra[5], S. Dapdapi[6], P. Ntonti[1], I. Kotsianidis[1]
[1]Department of Haematology, Medical School, Democritus University of Thrace, [2]Blood Transfusion Center, University Hospital of Alexandroupoli, Alexandroupolis, [3]Second Propedeutic Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, [4]Thalassaemia Unit, Hippokration General Regional Hospital, Thessaloniki, [5]Cardiac Intensive Care Unit, General Hospital of Kavala, Kavala, [6]Thalassaemia Unit, University Hospital of Alexandroupoli, Alexandroupolis, Greece

Background: Transposable elements (TEs) are known to promote genomic plasticity by affecting both the expression patterns and the splicing motifs of genes. Endogenous retroviruses *(*ERVs) represent remnants of ancient retroviral insertions into the host genome DNA that throughout the course of Vertebrate evolution became fixed in the germ line. Human ER*Vs* lack the ability to retrotranspose however their long terminal repeats (LTRs) contain transcription regulatory elements that, in the sense orientation, are functional and could be adopted for use by nearby host genes. *TNFSF11*, the gene encoding for RANKL, generates by alternative splicing two validated mRNA variants. *TNFSF11* variant 1 (NM_003701.3) contains five exons and encodes for the membrane-bound form of RANKL. Proteolytic cleavage of this transmembrane form allows for the generation of a soluble form of the protein. *TNFSF11* variant 2 (NM_033012.3) contains a set of alternate 5′ exons compared to variant 1, lacks the exon encoding for the intracellular and transmembrane domains of membrane-bound RANKL and can be directly translated into the soluble form of RANKL protein. Originally identified in SCC-4 and T3M-1 Cl.2 squamous cell carcinoma cell lines, it has been deduced that variant 2 is predominantly expressed in malignant cell types. Interestingly, it has recently been suggested that transcription of this variant is mediated via a distinct proximal promoter sequence.
Aims: Highlight, via *in silico* analysis, that exon 1A of *TNFSF11* variant 2 (soluble RANKL mRNA, *sRANKL*) was evolutionary provided by an exapted ERV-classI sequence. Show that transcription regulatory sequences of the putative *sRANKL* proximal promoter were also provided by this genetic element as well as by a nearby, upstream, TEs.
Methods: *TNFSF11* and the genomic region spanning 5000 nts upstream were downloaded from the NCBI Gene database and scanned for the presence of TEs by RepeatMasker. *TNFSF11* locus syntenic alignments of numerous mammals were downloaded from the UCSC Genome Browser Database. The syntenic DNA segments extracted were scanned by RepeatMasker. EMBOSS Cpgplot was used to identify putative CpG islands located in the genomic region spanning 5000 nucleotides upstream *sRANKL* transcriptional start site (TSS). PROMO Version 3.0.2 software was used to evaluate transcription factor (TF) binding affinity of the region spanning 250 nucleotides upstream *sRANKL* TSS; assumed to include precious regulatory elements of the variant's putative proximal promoter. Only human factors and human binding sites were concidered, applying a stringent maximum matrix dissimilarity rate of 7.
Results: *TNFSF11* exon 1A locates in a region reported from RepeatMasker to match a sense orientation LTR78 element, belonging to the ERV-classI family. Thorough computational analysis, considering fragments of interrupted repeats as joined by RepeatMasker, combined with in-depth phylogenetic analysis strongly support that the genomic region ranging from 1638 nts upstream to 3155 nts downstream *sRANKL* TSS was evolutionary provided by a "TE cluster"; namely a region where older TEs, integrated into the host genome, were interrupted by the insertion of younger ones. The genomic region spanning 4000 nts upstream *sRANKL* TSS contains CpG-rich genomic content. A CpG island was identified in this region, ranging from 2977 to 2775 nts upstream *sRANKL* TSS. Of note, the DNA segment including the CpG island was evolutionary provided by a LTR12C genetic element, locating short upstream the "TE cluster". The region spanning 250 nts upstream *sRANKL* TSS includes many high-affinity TF binding sites. A putative binding site for *CREB1*, a potent stimulator of *TNFSF11* variant 1 expression, locates 41 nts upstream *sRANKL* TSS. In addition, potential binding sites for factors inducing gene transcription during T cell-dependent immune response (for example *STAT4* and *NFATC2*) as well as for factors regulating apoptosis and tumor-suppression (*TP53, IRF1*) were identified (Figure 1).
Summary and Conclusions: Exaptation of an ERV-classI repeat allowed for a novel *TNFSF11* transcriptional pattern to occur. TEs, especially ERVs, are known to represent common targets of DNA methylation. Transcription of these genetic elements increases in the hypomethylated tumor microenvironment.

In this context, the CpG-rich content of the region spanning 4000 nts upstream *sRANKL* TSS, including the presence of a CpG island, could explicate the observed preferential expression of *sRANKL* in malignant cells.

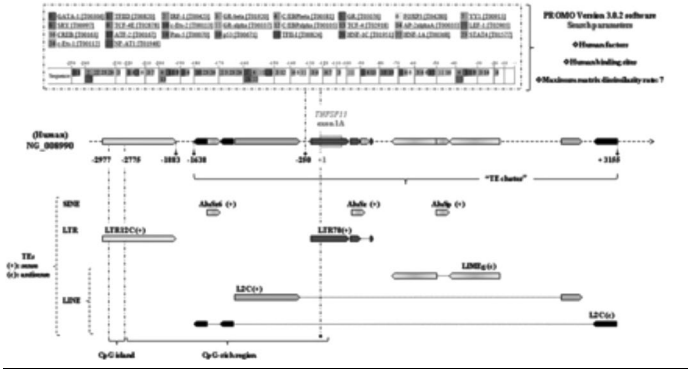

Figure 1.

E1233

IMPACT OF NOVEL THERAPIES ON MULTIPLE MYELOMA SURVIVAL-CURRENT AND FUTURE OUTCOMES

A. Drawid[1,*] S. Kaura[2], D. Kiely[3], M. Hussein[2], M. Kaman[1], N. Gilra[1], B. Durie[4]
[1]ZS Associates, Princeton, NJ, [2]Celgene Corporation, [3]Celgene, Summit, NJ, [4]Cedars-Sinai Outpatient Cancer Center at the Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA, United States

Background: Multiple myeloma (MM) survival improved dramatically with the introduction of new therapies in the mid-late 2000s. These therapies essentially transformed MM from an acute condition to a potentially manageable chronic disease. The impact of further advances in MM therapy is uncertain, but can be projected by analyzing historical data and expected future clinical trial outcomes.
Aims: The aim of the study is to estimate the current and future patient outcomes in MM, specifically overall survival, using a novel approach.
Methods: For the historical perspective in the US (1990-2008), we calculated overall survival for patients diagnosed in a given year (cohort OS) by analyzing data from Surveillance, Epidemiology & End Results (SEER). For the predictive analysis, we calculated cohort OS using a patient flow model by integrating data from clinical trials, cancer registries and demographics as well as assumptions from key opinion leaders. We simulated progression of each cohort based on treatment rates and time spent in each line of therapy. The resulting OS curves were calibrated to 19 years of historical data.
Results: The median cohort OS in the US remained relatively static from 1990-2001 at ~30 months, but increased by ~43% to 43 months in 2008. The median cohort OS is expected to continue rising to ~72 months in 2022, which represents ~67% improvement from 2008 and ~140% improvement from 2001 (Figure 1). The life expectancy of patients diagnosed with MM in 2022 would thus be ~75 years, but will still be shorter than the current ~86 year life expectancy of the general population at the median diagnosis age at ~69 years. In European geographies, we expect to see similar trends, albeit with a slight delay that reflects the access restrictions and adoption patterns of novel therapies by treating physicians.

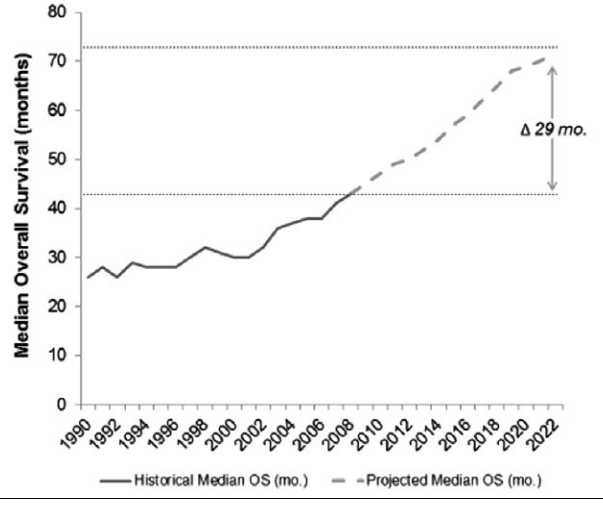

Figure 1.

Summary and Conclusions: This analysis highlights the dramatic improvements in MM survival since 2000 and the expected improvement in the future, demonstrating the transformative impact and value of novel therapies. Over the next few years, with better scientific understanding of MM and the use of novel drug regimens, we expect to see additional improvement of ~67% in OS for MM patients. Nevertheless, there is opportunity to further bridge the life expectancy gap between the general population and MM patients.

E1234

LOOKING FOR HYPOXIA FINGERPRINT IN MALIGNANT PLASMA CELL APPLIED TO NORMOXIC ENVIRONMENT.

K. Kocemba[1,*] P. Dudzik[1], W. Placha[1], D. Kusior[1], B. Ostrowska[1], M. Majka[2], P. Laidler[1]
[1]Department of Medical Biochemistry, [2]Department of Clinical Immunology and Transplantology, Jagiellonian University Medical College, Krakow, Poland

Background: Background: Recently, it was described that myeloma cells are chronically exposed to hypoxic environment in the bone marrow. Although the stabilization and nuclear localization of HIF-1 alpha protein in malignant plasma cells, was confirmed in many studies, the hypoxia transcriptional signature was not revealed thus far in MM patient. In fact, in order to determine such signature it has to be demonstrated how the long term sorting process of CD138 positive cells, conducted in the presence of oxygen, influences the expression of genes triggered in hypoxic environment.
Aims: Aim: To determine the stability of the hypoxia induced transcriptional expression profile of malignant plasma cells applied to oxygen environment, what mimics the condition during the sorting process of CD138 positive cells. Our goal is to *provide the bases* for a proper determination of hypoxia signature in multiple myeloma patients, taking into the consideration the influence of diagnostic procedure (CD138 cell sorting) on hypoxia-induced gene expression changes in malignant plasma cells.
Methods: Methods: Malignant plasma cells were cultured in hypoxic environment for 16h. The proper hypoxic stimulation was confirmed by the presence of HIF-1 alpha transcription factor in hypoxic cells by western blot and up-regulation of established hypoxia target genes by RT-PCR. Among the analyzed gene (ADM, BNIP3, VEGFA, PFKFB4, AK3L) we chose *PFKFB4*, as an excellent surrogate *marker* of *hypoxia in malignant plasma cells. Next,* we determined the stability of the hypoxia induced transcriptional expression changes of PFKFB4 in malignant plasma cells applied to oxygen environment, mimicking the conditions during the sorting process of CD138 positive cells. Upon indicated time points we analyzed the influence of normoxic environment on hypoxia-induced stabilization of HIF-1 alpha (Western Blot) and on expression of hypoxia-induced PFKFB4 (RT-PCR). The analysis was performed in the room temperature and in 4^0C.
Results: Results: In our present study we identified *PFKFB4*, as an excellent surrogate *marker* of *hypoxia in malignant plasma cells. We demonstrated very low expression of* PFKFB4 in normoxic condition in all analyzed cell lines, opposite to other established HIF-1 alpha target genes, which expression differs between different cell lines. Importantly, *PFKFB4* was strongly upregulated by hypoxia in all tested multiple myeloma cell lines. Next, we determined the stability of the hypoxia induced HIF-1 alpha accumulation and hypoxia-induced changes of PFKFB4 mRNA expression in malignant plasma cells applied to oxygen environment, what mimics the condition during the sorting process of CD138 positive cells. Our study revealed that HIF-1 alpha transcription factor is stable for at least 6h in hypoxic cells applied to normoxic environment, provided they are kept in 4^0C. Nevertheless, however, in room temperature (RT), the HIF-1 alpha transcription factor is not detected anymore upon 5 minutes in normoxic environment. As for the hypoxia-induced transcriptional response, we determined that PFKFB4 mRNA expression changes in malignant plasma cells are significantly influenced by normoxic environment (RT), after the estimated time required for CD138 sample preparation (from the bone marrow aspiration to the step of RNA isolation of CD138 sorted plasma cells).
Summary and Conclusions: Summary and Conclusions: Our research demonstrated that hypoxia-induced changes in the gene expression are not stable in normoxic environment during the time required for the bone marrow (BM) aspirate preparation. Thus, based on this study, we can conclude that the delay in CD138 plasma cells analysis strongly influences the gene expression of surrogate hypoxia markers in malignant plasma cells and only very strict laboratory practice allows the detection of hypoxia-induced transcriptional signature in malignant plasma cells. Our study clearly points the approach, which should be applied for BM aspirates to detect the hypoxia-induced gene expression profile.

IN HOUSE NEXT GENERATION SEQUENCING METHOD OF INMUNOGLOBULIN GENES FOR MINIMAL RESIDUAL DISSEASE QUANTIFICATION IN MULTIPLE MYELOMA

S. Barrio[1], R. Maldonado[1], C. Marin[1], B. Sanchez-Vega[1], I. Rapado[1], R. Malumbres[2], R. Ayala[1], T. Cedena[1], B. Paiva[2], R. Garcia-Sanz[3], C. Jimenez[3], M.V. Mateos[3], L. Rosiñol[4], J. Blade[4], J. San Miguel[2], J.J. Lahuerta[5], J. Martinez[1,*]
[1]Hematologia Traslacional, Fundacion Hospital 12 de Octubre, Madrid, [2]Centro

de Investigación Médica Aplicada (CIMA), Universidad de Navarra, Pamplona, [3]Servicio de Hematología, Hospital Universitario, Salamanca, [4]Servicio de Hematología, Hospital Clinic, Barcelona, [5]Servicio de Hematología, Hospital 12 de Octubre, Madrid, Spain

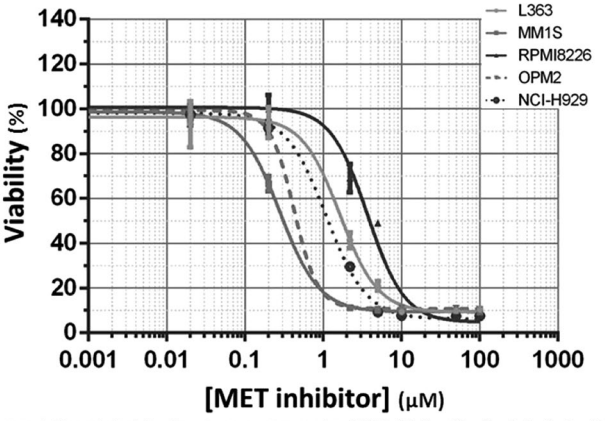
Background: Multiple myeloma (MM) is a B-cell malignancy characterized by the bone marrow (BM) accumulation of a clonal population of plasma cells, which secretes a monoclonal IgH protein. The first step to the cure of MM is achieving a clinical complete response (CR). However, a majority of patients relapse in part due to the persistence of low levels of pathological plasma cells after treatment (Minimal residual disease (MRD)), sometimes more 10^8 pathologic plasma cells. In addition, residual cells have a heterogeneous clonal architecture and clonal evolution. Accordingly, the technology employed to assess MRD should not also be able to identify pathological clones, but also be able to assess clonal evolution.
Next generation sequencing (NGS) allows the identification of clonogenic B or T cells with high sensitivity and specificity and is suitable for detection of MRD as shown recently in patients with chronic lymphocytic leukemia (CLL).
Aims: To present a new method for quantification of immunoglobulin (Ig) gene clonal rearrangements from a polyclonal background by next generation sequencing (NGS). To test the suitability of the method for minimal residual disease (MRD) detection in Multiple Myeloma (MM) patients compared with Flow Cytometry (FC) data.
Methods: We analyzed DNA from bone marrow samples of 50 patients (50 diagnostic samples and 76 follow-up samples). The method employs the primers developed by BIOMED-2 for IGH (VDJ, DH-JH) and IGK (VJ and Kdel), and a set of specific mathematical and bioinformatics tools.
First, we identified the clonal rearrangement(s) (clonotype) in the diagnostic sample by fragment analysis and NGS. Second, we searched the NGS sequences from follow-up samples to detect the presence of the clonotype identified in the diagnostic sample.
PCR fragments shorter and longer than 250pb were sequenced with Proton and PGM sequencers respectively (Ion Torrent) following manufacturer instructions (Life Technologies) with slight modifications.
Sensitivity was calculated with serial dilutions of samples of known MRD values with polyclonal samples.
In follow-up samples we analyzed at least 1 µg of DNA to achieve a sensitivity of 10^{-5} EMR values were calculated using the DIFF algorithm and the equation: $EMR=[Lc*(D/K)]/Lt^2$
Where: *Lc* sample clonal reads, *Lt* sample total reads, *D* ng of gDNA used for PCR amplification, and *k* ng of gDNA per diploid cell.
Results: The sensitivity of the method is 10^{-5} for 150.000 cells. Reproducibility is >90%. The *linear correlation coefficient* between NGS and FC data for diagnosis and follow-up samples was R=59 and R=0.51, respectively. The Pearson *correlation* coefficient was 0.765, p<0.0001 for diagnostic and 0.716, p<0.0001 for follow-up samples. The Ig variable region usage identified by NGS was in accordance with the described in the literature for MM.
Summary and Conclusions: NGS sequencing of Ig genes with the Ion Torrent methodology is an effective technology to identify and quantify pathological clonal cells in MM. It is a methodological and economical alternative to CF and other methods for MRD follow-up.

E1236

MET INHIBITION AS A NEW THERAPEUTIC OPTION IN MULTIPLE MYELOMA PATIENTS WITH MET OVEREXPRESSION

A. Canal[1,*] J. Martinez[1], D. Rueda[2]
[1]Hematologia traslacional-Biología molecular, [2]Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Through the last years, the importance of HGF/MET signaling related to Multiple Myeloma (MM) pathogenesis has been described. Because of this, the inhibition of this signaling pathway could constitute a new therapeutic target. Nowadays, there are lots of drugs whose mechanism of action is inhibiting this signaling pathway.
Aims:-Analyze the mechanism of action that one MET inhibitor has on MM patient's plasma cells and MM cell lines. - Discover any possible synergism combination among MET inhibitor and other antimyeloma drugs (Dexamathasone, Lenalidomide, Bortezomib and Melphalan). - Evaluate the effect of MET inhibitor on MM clonogenic cells.
Methods: Bone marrow plasma cells from: 44 MM patients at diagnosis, 8 patients without bone marrow infiltration and 6 MM cell lines, were studied. *MET* and *L1-MET* expression was carried out on cDNA from plasma cells purified from all the samples. Levels of expression were quantified on the three types of samples by SYBR assay; GUSB was used as control gene and MM cell line U266 as control sample. Methylcellulose assays were carried out to study the effect of MET inhibitor on MM clonogenic plasma cells. MET mutations were studied by Next Generation Sequencing on MM plasma cells. Dose response curves for cell viability of MM plasma cells and cell lines treated with MET inhibitor, antimyeloma drugs or combination of both was stablished by MTT assay. Combinations were carried out with IC30, IC50 and IC70 values for each drug alone and plasma cell to study synergistic combinations.
Results: MM patients showed *MET* overexpression regarding to control bone marrows that don't have plasma cell infiltration (*p-value*=.0012). MM cell lines MM1S and OPM2, were the most sensitive to MET inhibitor treatment (IC50 of 0.06 and 0.26 µM, respectively). These cell lines only showed *MET* expression. *L1-MET* and *MET* transcripts were exhibited by RPMI, U266 and NCI-H929 MM cell lines and have higher IC50 values (3.6, 1.31, 1.09 µM, respectively). This relation between *L1-MET*, *MET* levels expression and IC50 values were also showed in MM patient's plasma cells. We didn't observe any mutation on *MET* gene, so aberrant MET activation in MM is not due to activated mutations on this gene but for *MET* overexpression. Besides that, MET inhibitor had cytotoxic effect on clonogenic plasma cells around IC50 values; we didn't observe any colony at higher concentrations of 0.02 µM MET inhibitor. MM cell lines resistant to MET inhibitor presented synergism among the MET inhibitor and anti-myeloma drugs (Dexamathasone, Lenalidomide, Bortezomib and Melphalan), having high dose reduction index (DRI) (from 3.08 to 62.7) (Figure 1).



Representative cytotoxicity dose response curves for MET inhibitor. The X-axis indicates the dosage (µM) and the Y-axis indicates the percentage of cell viability (%). Colors represent different MM cell lines grouped by *MET* and *L1-MET* level expression.

Figure 1. Cytotoxicity of MET inhibitor.

Summary and Conclusions: MET inhibition could be a new therapeutic option in multiple myeloma. MET inhibition is synergistic with proteasome inhibitors and immunomodultor drugs, as well as it kills clonogenic myeloma cells. *L1-MET* transcript may be a biomarker in MM treated with MET inhibitors.

E1237

INITIAL EVALUATION OF NOVEL DUAL PIM/PI3K AND TRIPLE PIM/PI3K/MTOR INHIBITORS IN MULTIPLE MYELOMA

M. Reidy[1,*] M. vanDijk[1], N. Keane[1,2], M. O'Neill[3], M.E. O'Dwyer[1,2]
[1]Apoptosis Research Center, [2]Haematology, National University of Ireland, Galway, Galway, [3]Inflection Biosciences, Dublin, Ireland

Background: Multiple myeloma (MM) is characterised by clonal expansion of malignant plasma cells in the bone marrow (BM). Despite significant advances in treatment it remains incurable. This is largely due to the supportive role the BM environment plays in migration, survival, proliferation and drug resistance. BM microenvironmental signalling along with other factors such as treatment with proteasome inhibitors (PI) can contribute to activation of the PI3K/AKT survival pathway. Multiple small-molecule inhibitors have been developed to target PI3K/AKT or mTOR kinases, but the efficacy of these drugs is likely to be compromised by the stimulation of compensatory signalling pathways. The redundancy of signalling pathways provides back-up mechanisms allowing escape from targeted inhibition. One such compensatory pathway is that driven by PIM kinases, which produce parallel oncogenic signals to AKT and mTOR and share several downstream molecular targets. As with PI3K/AKT, the BM microenvironment plays a major role in PIM activation. PIM1 and particularly PIM2 are known to be highly expressed in MM and play important roles in regulating MYC-driven transcription, apoptosis, cytokine signalling, cell proliferation and protein translation. Combinations of separate PI3K and PIM inhibitors have shown evidence of synergy in MM cell lines and animal models and a PIM kinase inhibitor has recently shown activity in relapsed/refractory MM.
Aims: We wished to evaluate the activity of a novel family of kinase inhibitors capable of inhibiting not only PIM kinases but also PI3K/AKT (dual inhibitors) and PI3K/AKT/mTOR (triple inhibitors).
Methods: We evaluated the in-vitro activities of a single pan-PIM (pPIMi), dual PIM/PI3K (IBL-202) and triple PIM/PI3K/mTOR (IBL-301) inhibitor in a number of MM cell lines alongside the pan-PI3K inhibitor GDC-0941 and the pan-PIM inhibitor AZD1208. IBL-202 and IBL-301 are low nanomolar pan-PIM/PI3K and pan-PIM/PI3K/mTOR inhibitors respectively. These dual and triple inhibitors show excellent kinase selectivity profile against a panel of 456 kinases. Cell viability was assessed using the Cell-Titre Glo assay and apoptosis was deter-

mined using Annexin-V/PI staining. To examine the impact of the microenvironment on the efficacy of these compounds MM cells were co-cultured with HS-5 stromal cells or in a hypoxic glove box (1% O_2).
Results: Inhibiting PIM kinases and the PI3K pathway simultaneously using IBL-202 was significantly more potent than a pan-PI3K inhibitor, GDC-0941 alone or pan PIM kinase inhibitors pPIMi or AZD1208. This was observed in all MM cell lines tested and in addition for the compound IBL-301, a triple inhibitor of PIM kinases, PI3K and mTOR. IC50 values were in the 0.5μM and 0.05μM range for IBL-202 and IBL-301, respectively. In comparison pPIMi and GDC-0941 scored an IC50 value between 5 and 10μM while the IC50 for AZD1208 was >20μM (Figure 1). In addition IBL-202 and IBL-301 caused a reduction in pAkt and known PIM targets, pBad and pS6. Bortezomib caused a marked increase in levels of PIM2 in MM cell lines. A combined treatment of IBL-202 or IBL-301 with bortezomib resulted in a synergistic effect in these cell lines (CI<1). In an effort to mimic the tumour microenvironment MM cell lines were co-cultured with the stromal cell line HS-5s. We observed strong induction of PIM2 in MM cells following co-culture. Co-culture protected MM cell lines against bortezomib-induced cell death, while promoting the apoptotic effect of both IBL-202 and IBL-301 with an increase in Annexin V positive cells from 15% to 40%. This suggests that microenvironmental stimulation could potentially induce synthetic lethality in the presence of these inhibitors. The tumour microenvironment in MM patients is hypoxic compared to healthy controls. Hypoxic conditions led to an increase in levels of PIM1 which is reported to regulate the surface expression of the CXCR4 receptor. The CXCR4 receptor is important for MM cell survival, migration and microenvironment interaction. We have observed a decrease in levels of CXCR4 following treatment with IBL-202 in a dose dependent manner. The dual and triple inhibitors are optimized with respect to their *in vitro* ADME properties and have excellent oral bioavailability. In-vivo IBL-301 has been well tolerated, with no signs of toxicity even 20 times above the efficacious dose in a transgenic ($KRAS^{V12}$NSCLC) mouse model. Testing of IBL-202 in a relevant MM mouse model is planned in the near future.

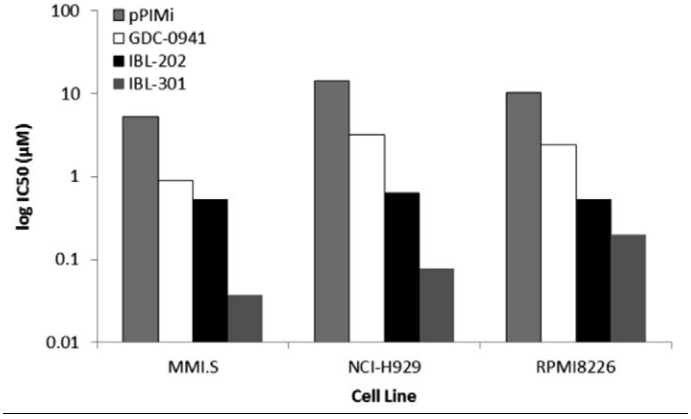


Figure 1.

Summary and Conclusions: IBL-201 and IBL-301 show promising activity in MM cellular models with increased potency compared to inhibitors targeting PIM or PI3K alone and warrant further evaluation in this disease.

E1238

PILOT ASSESSMENT OF PROXIMITY EXTENTION IMMUNOASSAY IN PATIENTS WITH MONOCLONAL GAMMOPATHIES: PARALLEL EVALUATION OF 92 CANCER-RELATED PARAMETERS IN BONE MARROW AND IN SERA

J. Minarik[1,*] E. Kriegova[2], P. Schneiderova[2], J. Zapletalova[3], P. Pusciznova[1], J. Hrbek[4], Z. Hermanova[2], T. Pika[1], J. Bacovsky[1], M. Herman[4], V. Scudla[1]
[1]Department of Hemato-oncology, [2]Department of Immunology, [3]Department of Biophysics and Statistics, [4]Department of Radiology, Faculty of Medicine and Dentistry of Palacky University and University Hospital Olomouc, Olomouc, Czech Republic

Background: The assessment of prognostic factors in cancer is vital for correct stratification and targeted therapy. In multiple myeloma, both tumor cells and bone marrow microenvironment play an important role in pathogenesis, and take part on the development and the extent of myeloma bone disease (MBD).
Aims: The aim of our project was to address the utility of Proximity Extention ImmunoAssay technique (PEA) in patients with monoclonal gammopathies instead of standard ELISA techniques in the assessment of tumor microenvironment parameters.
Methods: We assessed 92 cancer-related parameters from the Oncology I ^{96x96} protein biomarker panel (Olink, Uppsala, Sweden). The parameters are known to be altered in various cancer types and are related to angiogenesis, cell-cell signaling, growth control and inflammation. Both sera and bone marrow samples were acquired from 30 patients with monoclonal gammopathies-25 patients with multiple myeloma (MM) and 5 individuals with monoclonal gammopathy of undetermined significance (MGUS) taken at the time of diagnosis.PEA is a sensitive and specific alternative of ELISA methods. For each sample there are two different antibody probes labeled with A- and B-oligonucleotides. Proximity of the oligonucleotide chains to the binding site leads to PCR amplification of the signal with specific primers. For statistical estimation we used Mann-Whitney U-test, Kruskal-Wallis test and Spearman correlation analysis at $p<0.05$ and Principal Component Analysis (GenEx, SSPS).
Results: In 3 patients the data did not pass the quality control. In the rest 27 individuals we analysed parallelly bone marrow and sera analytes. In 58 analytes the levels in bone marrow and serum were significantly different, with up to 38 fold difference (over 5 log scale), the rest 34 analytes had similar levels in both bone marrow and sera. Out of the whole panel, 9 analytes were significally different when comparing individuals with or without the presence of renal impairment. We found 19 proteins that significantly differed between MGUS and MM in both serum and bone marrow. There were several perspective candidate biomarkers correlating with disease stage, extent of myeloma bone disease, M-protein type and therapeutic outcome, such as tartrate resistant alkalinephosphatase-5 (TRAP-5), matrix metalloproteinase 1 (MMP-1), tumor necrosis factor (TNF), transforming growth factor alpha (TGF-α), Fas antigen ligand (FasL), Fms-related tyrosine kinase 3 ligand (Flt3-L) or epithelial cell-adhesion molecule (Ep-CAM).
Summary and Conclusions: Proximity ImmunoAssay is a very sensitive technique enabling parallel assessment of several analytes. Unlike ELISA, it has many fold larger dynamic range, and is suitable for analyte levels beyond the calibration curve. Out of the Oncology panel, 9 parameters were influenced by renal impairment. Despite limited number of patients, we could trace several potential candidates for the assessment of MM pathogenesis as well as for the extent of myeloma bone disease.
Supported by the grant NT14393.

E1239

THE USE OF MAGE C1 AND FLOW CYTOMETRY TO DETERMINE AND MONITOR THE MALIGNANT CELL TYPE IN MULTIPLE MYELOMA

K. Wienand[1,*] K. Shires[1]
[1]Clinical and Laboratory Sciences, Division of Haematology, University of Cape Town, Cape Town, South Africa

Background: Multiple Myeloma (MM) is a haematological malignancy, characterised by the accumulation of neoplastic plasma cells in the bone marrow (BM). Unfortunately, the full disease mechanism and exact malignant cell phenotype of this cancer remains unresolved. This affects effective MM treatment, as it limits the development of target-specific drugs and importantly prevents optimal detection of residual primary disease-causing cells. There is a definite need to identify a common molecular marker that is expressed in the majority of the diseased patients and directly associated to disease pathogenesis, thereby allowing monitoring of the malignant disease-causing cell directly. Cancer testis antigen MAGE C1 has been extensively studied in MM, is putatively involved in the pathogenesis of the cancer and is expressed in >90% of symptomatic MM patients at diagnosis, indicating a potential link to the malignant cell phenotype and use as a minimal residual (MRD) marker.
Aims: The aim of this study was to use aberrant MAGE C1 expression to identify the malignant cell phenotype in MM using flow cytometry and then investigate the use of this marker to monitor MRD in patients undergoing therapy.
Methods: BM and peripheral blood (PB) was collected from fifteen untreated symptomatic MM patients at diagnosis, with PB also being collected every three months over a two year period. Additional BM and PB samples were collected from five healthy donors for comparison. Mononuclear cells were isolated using density-gradient centrifugation, stabilized in 80% ethanol and analysed via flow cytometry following incubation with relevant B-cell development cell-surface markers and the nuclear-staining antibody MAGE C1.
Results: MAGE C1 expression was observed consistently in the early stem cells ($CD34^+$) and early pro-B to pre-B cells ($CD34^{-/+}/CD19^+$), as well as the proliferating plasma cells in the MM BM and PB. The expression of MAGE C1 in the $CD34^+$ cells suggests that these cells are the disease progenitors that sustain the downstream accumulation of abnormal plasma cells. The reactivation of MAGE C1 expression in a sub group of these plasma cells may be responsible for the proliferation, leading to a second disease mechanism that accelerates plasma cell mass expansion. The expression of MAGE C1 in the PB indicates that the malignant phenotype is also found in circulation and thus could easily be used for MRD monitoring. Importantly, the changes in MAGE C1 expression correlated to the decrease/increase in serum M protein, beta-2-microglobulin and creatinine levels over the two year treatment period, connecting this cancer marker to disease pathogenesis and indicating a direct link to active disease. It was further observed that current treatments are targeting different cell populations not necessarily eradicating all the malignant cell types.
Summary and Conclusions: MAGE C1 was successfully used to determine the malignant cell phenotype as well as to monitor MRD with specific B cell markers via flow cytometry. MRD monitoring using PB is easily accessilbe to

all MM patients compared to stressful BM biopsies. Furthermore, analysis of PB using this assay is similar than current flow cytometry methods giving a clear indication of the malignant cells found in circulation with better sensitivity to residual disease. MAGE C1 expression in PB can provide clinicians with access to the percentage of malignant cells in circulation prior to ASCTs as well as other MM treatments in a time efficient manner in turn improving the outcome of patients.

E1240

PERSONAL HISTORY OF INFECTIONS ASSOCIATED WITH AN INCREASED RISK OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS) AND MULTIPLE MYELOMA: A POPULATION-BASED NESTED CASE-CONTROL STUDY

C. Mcshane[1,*] L.J. Murray[1], O. Landgren[2], M.C. Bradley[3], C. Hughes[4], L.A. Anderson[1]
[1]Centre for Public Health, Queens University Belfast, BELFAST, United Kingdom, [2]Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, [3]Cancer Prevention Fellowship Program, National Cancer Institute, Maryland, United States, [4]School of Pharmacy, Queens University Belfast, BELFAST, United Kingdom

Background: Infections are a major contributor to the global cancer burden and are a leading cause of morbidity and mortality in individuals with monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma (MM). Both MGUS and MM are associated with immune dysregulation which may not only increase the propensity to infection but may also act as a trigger for the development of MGUS and/or progression to MM or associated lymphoproliferative disorders.
Aims: To investigate the association between prior common community-acquired infections and subsequent risk of MGUS and MM using the UK Clinical Practice Research Datalink (CPRD).
Methods: Conditional logistic regression models were used to estimate odds ratios (OR) and associated 95% Confidence Intervals (CI) excluding the 12 month period prior to MGUS/MM diagnosis/control selection. Findings were adjusted for a number of potential confounders including age at diagnosis, comorbidities, autoimmune disease, prior cancer, and lifestyle variables.
Results: In total, 4,654 MGUS and 3,801 MM patients matched to 23,101 and 18,991 controls respectively were identified. A personal history of infections was associated with an increased risk of both MGUS and MM, with the strongest associations observed for MGUS (MGUS: OR 1.32, 95% CI 1.23-1.41; MM: OR 1.22, 95% CI 1.13-1.32). A number of infections, in particular those affecting the respiratory tract were more commonly diagnosed in individuals who later developed MGUS/MM. A dose response relationship was also evident, with individuals more prone to infections more likely to later develop MGUS/MM.
Summary and Conclusions: The findings of this study suggest infections may play an important role in the etiology of the plasma cell disorders and/or be markers of an underlying immune disturbance. Further exploration of the mechanisms involved may aid our understanding of the pathogenesis of MGUS and MM.

E1241

INFLUENCE OF ABC TRANSPORTERS' GENETIC PROFILES IN THE DEVELOPMENT OF MONOCLONAL GAMMOPATHIES

S.I. Fernandes[1,2,3,*] A.C. Gonçalves[4], J. Jorge[4], C. Geraldes[5], R. Alves[4], A. Pires[4], S. Veiga[4], E. Cortesão[5], L. Ribeiro[5], A.B. Sarmento Ribeiro[4]
[1]University Clinic of Hematology, [2]Applied Molecular Biology, Faculty of Medicine of University of Coimbra, Coimbra, [3]Department of Biology, University of Aveiro, Aveiro, [4]Faculty of Medicine, University of Coimbra, [5]University Clinic of Hematology, University Hospital of Coimbra, Coimbra, Portugal

Background: Genetic variability inxenobiotic transport related proteins can influence drugs' efficacy and could contribute to the susceptibility to hematological conditions, such as Monoclonal Gammopathy of Unknown Significance (MGUS) and Multiple Myeloma (MM). ABC (ATP-binding cassette) transporters superfamily includes membrane proteins which function is to transport substrates through intra- and extracellular membranes. MDR1 and MRP1 are membrane transporter proteins that, besides the above described functions, may play a role in development, progression and therapeutic outcome in several hematological pathologies.
Aims: In this context, we investigated the relevance of polymorphisms in *MDR1* (C3435T) and *MRP1* (G1666A) genes as risk factors for the development of monoclonal gammopathies, such as MGUS and MM, as well as their possibility of prognostic risk factors.
Methods: This study included 145 patients diagnosed with monoclonal gammopathies (GM) (68 MGUS, 77 MM) and 121 healthy controls (CTL). The genetic profiles of *MDR1* (C3435T) and *MRP1* (G1666A) were assessed by RFLP-PCR. The strength of association between polymorphisms and disease's development risk were estimated by odds ratio (OR) with 95% confidence interval (CI 95%). The influence of these polymorphisms in the patients overall survival (OS) was calculated by Kaplan Meier method.
Results: Our results show that allele C from *MDR1* is the most prevalent in CTL (52.1%) and in MGUS (52.2%), while allele T is predominant in MM (52.0%). Moreover, both alleles have the same prevalence in CTL (50.0%), and genotype CT is the most common in all groups (CTL=46.3%; GM=62.8%; MM=70.1%; MGUS=54.4%). As to *MRP1* gene, we observed that allele A is the most frequent in all groups (CTL=72.6%; GM=67.9%; MM=67.5%; MGUS=68.4%) and we also perceived that the most common genotype is AG (CTL=54.8%; GM=51.7%; MM=46.8%; MGUS=57.4%). After calculating the OR for individual genotypes we realized that CC genotype from *MDR1* is a protector factor for the development of MM (OR=0.37; p=0.0093; CI95% 0.17-0.79) and CT genotype represents a risk factor for the development of GM in general (OR=1.9; p=0.0092; CI95% 1.2-3.2) and for the development of MM (OR=2.7; p=0.0012; CI95% 1.5-4.9). The Kaplan Meier analysis revealed that MM patients with the AA genotype in *MRP1* gene have a decreased overall survival in about 18 months (AA-20.1±2.4 months; AG or GG-38.1±3.9 months; p=0.035).
Summary and Conclusions: This work suggests that *MDR1* and *MRP1* genotypes can be predictive of the predisposition to the development and progression of monoclonal gammopathies. However, their role in therapy response remains unknown.

E1242

ANALYSIS OF RHOU AND RHOV EXPRESSION IN MULTIPLE MYELOMA REVEALS A POSSIBLE CORRELATION WITH BONE MARROW DEPENDENCE

S. Canovas Nunes[1,2,*] L. Quotti Tubi[1,2], E. Mandato[1,2], M. Carrino[1,2], F. Zaffino[1,2], S. Manni[1,2], R. Zambello[1,2], F. Adami[1], L. Trentin[1,2], G. Semenzato[1,2], F. Piazza[1,2]
[1]Department of Medicine, University of Padova, [2]Venetian Institute of Molecular Medicine, Padova, Italy

Background: Rho GTPases, in their active GTP-bound state, interact with effector proteins controlling many biological processes: cytoskeletal regulation, membrane trafficking, cell adhesion and polarization, transcriptional activity, apoptosis and proliferation. The RhoUV subfamily consists of two atypical Rho proteins: RhoU and RhoV that due to their spontaneous activation are normally expressed at very low levels in most cell types and tissues. In Multiple Myeloma (MM), a tumor microenvironmental niche, which protects MM cells from chemotherapy and proapoptotic noxae, is created by the adhesion between primary malignant plasma cells and stromal cells. RhoU and RhoV GTPases are able to alter cell-cell/cell-extracellular matrix adhesion, cell motility and actin dynamics. Also, RhoU levels are known to be upregulated upon IL-6 stimulus, which is a pivotal growth factor for malignant plasma cells. On these basis, we hypothesize that changes in the expression of these GTPases and therefore in their function could lead to dynamic alterations of MM-associated niche.
Aims: Analyze RhoU and RhoV expression and actin cytoskeleton dynamics in normal B cells *versus* MM malignant plasma cells. Evaluate if changes in the expression of these GTPases have an impact in adhesion, migration/motility and structural features of MM cells. Study the role of RhoU and RhoV in malignant cell-stromal cell adhesion and in the creation of protective bone marrow niches.
Methods: mRNA expression was analyzed by qRT-PCR in MM cell lines, MM cells from patients and normal B cells from healthy donors. Malignant plasma cells were isolated from bone marrow or peripheral blood of patients using "EasySep CD138 positive selection kit". Normal B cells were purified using "EasySep human B cell isolation kit". Fluorescence microscopy was performed using Zeiss LSM 700 microscope. Staining was done with Phalloidin 594 (Abcam), rabbit anti-RhoU or RhoV (Abcam), goat anti-rabbit Alexa fluor 488 (Life Technologies) and DAPI (Vector).
Results: MM cell lines showed a significantly higher expression of RhoU and RhoV as compared to normal B cells. While RhoV displayed the highest expression in stroma/IL-6-dependent cell line (INA-6), RhoU was expressed at high levels in INA-6 but also in U-266, in this latter probably because of its autocrine IL-6 production. Remarkably, RhoU and RhoV expression was actively modulated when MM cell lines were co-cultured with stromal cells. MM patients also showed a significantly higher expression of both proteins when compared to normal B cells. Interestingly, in the stage of plasma cell leukaemia (PCL) RhoV mRNA levels were high but RhoU levels seemed to be even lower than in normal B cells. Immunofluorescence showed that RhoU and RhoV colocalize with actin in normal B cells while in INA-6 these were located both in the cytoplasm and nucleus. Upon co-culture of INA-6 with stromal cells, RhoU accumulated in the nucleolus. In freshly purified plasma cells from MM patients' bone marrow, RhoU and RhoV were found both in the cytoplasm and nucleus being RhoU particularly abundant in the nucleolus. On PCL patients there was a very low signal for both proteins and RhoV seemed to be present only in the cytoplasm.
Summary and Conclusions: RhoU and RhoV are widely over-expressed in MM. Their expression seems to correlate with bone marrow dependence, being that it decreases in more aggressive, bone marrow-independent stages where malignant plasma cells are no longer dependent on the stromal signals. RhoU and RhoV could be important in MM pathogenesis and suitable targets to disrupt the MM plasma cell adhesion to protective bone marrow niches.

E1243

GRANULOCYTE-LIKE MYELOID DERIVED SUPPRESSOR CELLS (G-MDSC) ARE INCREASED IN MULTIPLE MYELOMA DUE TO IMMUNOLOGICAL DYSREGULATION OF MESENCHYMAL STEM CELLS (MSC)

C. Giallongo[1,*] N. Parrinello[1], D. Tibullo[1], P. La Cava[1], C. Conticello[1], M. Cavalli[1], A. Chiarenza[1], G.A. Palumbo[1], A. Romano[1], F. Di Raimondo[1]
[1]Division of Hematology, Azienda Policlinico-OVE, University of Catania, catania, Italy

Background: Granulocytic-Myeloid-derived suppressor cells (G-MDSC), a heterogeneous population of myeloid cells with peculiar immunosuppressive properties against T-cells due to increased levels of Arginase-1 (Arg-1), are increased in Multiple Myeloma (MM), as recently described by our and other groups. MM plasma-cells depend on the bone marrow microenvironment for the growth and survival; important in this context is the role of mesenchymal stem cells (MSCs), stromal adult stem cells with immunomodulatory properties.
Aims: Investigating the role of MSCs from MGUS and MM patients on expansion and activation of G-MDSCs.
Methods: G-MDSC (CD11b+CD33+CD14-HLADR-) were evaluated by flow cytometry and functional test, including the expression of the enzyme arginase (ARG-1) and ability to suppress lymphocytes activation when co-cultured with T-lymphocytes obtained from normal donors. Briefly, human peripheral blood mononucleated cells (PBMCs) isolated from healthy volunteer donors were cultured alone, with HD (n=6), MGUS (n=5) or MM MSCs (n=6) (1:100 ratio). After one week, PBMCs were collected. G-MDSCs were then isolated using anti-CD66b magnetic microbeads. The phenotype of G-MDSC was confirmed by cytofluorimetric analysis. Their immunosuppressive capacity was analyzed, evaluating T-cell anergy when co-cultured with autologous CFSE-labeled T cells stimulated by phytohaemagglutinin (PHA).
Results: G-MDSC percentage in MM was greater than healthy controls (61.2±1.6% *versus* 51.7±1.4%, p<0.001). We found a T-cell anergy dose- and time-dependent driven by MM-G-MDSC, due to overexpression of ARG-1 (p=0.0012). Only MM MSCs-educated G-MDSC exhibited suppressor effect with a reduction of T cell proliferation of about 34±9.6% (p<0.01) compared to G-MDSC control (isolated from PBMCs cultured in medium alone). Notably, neither MDSCs control nor myeloid cells co-cultured with HD or MGUS MSCs showed suppressor activity on T cell proliferation. Using real time PCR, we analyzed the expression of immune modulatory factors (Arg-1, NOS2, COX2, TNFα, TGFβ, IL6, IL10, IL1β) by MSCs after 48 h of co-culture with PBMCs. MM MSCs showed an increase of COX2, IL6, IL10, IL1β, TGFβ and NOS2 expression (p<0.05) compared to HD MSCs, suggesting that multiple mechanisms are involved in MDSCs induction by MM MSCs. The same immune modulatory factors were investigated in MDSCs before incubation with T cells. MM MSCs-educated MDSCs expressed higher levels of arginase1, NOS2 and IL6 (p<0.05) compared to MDSCs control.
Summary and Conclusions: MSCs from MM but not MGUS patients are able to activate G-MDSCs with potential implication in immune escape that favours plasma-cells growth, survival and resistance to drugs.

E1244

MICRORNA PROFILE IN BONE MARROW FIBROBLASTS FROM PATIENTS WITH MULTIPLE MYELOMA

V. Desantis[1,*] I. Caparrotta[2], L. Beltrame[2], L. Di Marzo[1], S. Marchini[2], I. Catacchio[1], M. D'Incalci[2], A. Vacca[1], M.A. Frassanito[1]
[1]Department of Biomedical Sciences and Human Oncology (DIMO), Section of Internal Medicine and Clinical Oncology, Azienda ospedaliera Consorziale policlinico di Bari, Bari, [2]Department of Oncology, Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy, Mario Negri, Milan, Italy

Background: Multiple Myeloma (MM) is a plasma cell dyscrasia with specific localization in the bone marrow that is almost invariably preceded by a Monoclonal Gammopathy of Undetermined Significance (MGUS). Several studies have clearly proved that a permissive microenvironment is required for MM to emerge. Recently, we demonstrated that bone marrow fibroblasts (cancer associated fibroblasts, CAFs) from 1st diagnosed MM patients show a relevant activated phenotype that acts as a promoter for MM initiation and progression as well as angiogenesis (1). The microRNAs (miRNA, miR) are a class of highly conserved short non-coding RNA molecules that regulate gene expression at the post-transcriptional level. They are involved in regulation of several biological processes, including cell proliferation, differentiation, apoptosis, morphogenesis and metabolism. Specific miRNA expression signatures can distinguish cancer from benign tissues and may provide the basis for developing new diagnostic and therapeutic strategies. Despite numerous studies focused on the miRNAs profile in MM cells, their analysis on CAFs has not been investigated yet.
Aims: We wondered whether miRNAs could play an important role in the functional conversion of MGUS CAFs into the activated phenotype of the 1st diagnosed MM CAFs.
Methods: CAFs were purified from bone marrow aspirates of 15 patients with MGUS and 15 patients with 1st diagnosed MM using appropriate microbeads, and cultured *in vitro* until the second passage. 100ng of RNA enriched in miRNA fraction were labeled and hybridized onto commercially array slides. Differentially expressed miRNAs were analyzed with Rank Product algorithm. The resulting *p*-values were corrected for multiple testing using the False Discovery Rate (FDR) method by Benjamini and Hochberg. Results were validated using quantitative real-time PCR.
Results: CAFs from 1st diagnosed MM patients show a different miRNA profile compared to those from MGUS patients. Heighten differentially expressed miRNAs were identified: 8 were up-regulated, and 10 down-regulated.
Among the up-regulated miRNA, 5 were significantly up-regulated (miR-125b-5p, miR-5100, miR-199a-5p, miR-214-3p and miR-27b-3p) and they were engaged in tumor growth, differentiation, proliferation and drug resistance. Among the down-regulated miRNA, 5 were significantly down regulated (miR-4281, miR-4530, miR-4430, miR-6089 and miR-6087), and they were involved in post-transcriptional regulation of gene expression for differentiation and metastatic progression. In particular, miR-199a-5p and miR-214-3p play a major role in fibroblast activation by targeting Caveolin1, a key player in TGFβ signaling, and miR-125b-5p is involved in tumor drug resistance (Figure 1).

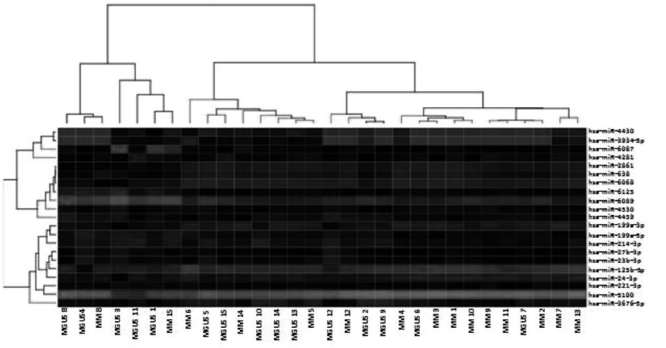

Figure 1.

Summary and Conclusions: These findings indicate that miRNA profile differs between 1st diagnosed MM and MGUS patients and that the activated phenotype of 1st diagnosed CAFs might be related to the expression of specific miRNAs. Several studies are ongoing to identify a correlation between the differentially expressed miRNAs and the activated phenotype of CAFs and their role in the cross-talk between MM plasma cells and CAFs.

TUMOR NECROSIS FACTOR-RELATED APOPTOSIS-INDUCING LIGAND AND DEATH RECEPTORS: RELEVANCE IN THE PATHOGENESIS OF MONOCLONAL GAMMOPATHIES

C. Geraldes[1,2,3,*]A.C. Gonçalves[2,4], R. Alves[2,4], E. Cortesão[1,2,3], L. Ribeiro[5], J.M. Nascimento Costa[2,6], A.B. Sarmento-Ribeiro[1,2,4]
[1]Clinical Haematology Department, Coimbra University Hospital Center, [2]Centre for Research on Environment, Genetics and Oncobiology, [3]University Clinic of Hematology, [4]Applied Molecular Biology and University Clinic of Hematology, [5]Clinical Haematology Department, [6]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Tumor Necrosis Factor-related Apoptosis-inducing Ligand (TRAIL) was identified in 1995 and, since then, growing interest has emerged in oncology due to its reported ability to selectively trigger cancer cell death. Pro-apoptotic TRAIL signaling is mediated through DR4 (also TRAIL-R1) and DR5 (also TRAIL-R2) receptors. Despite intensive investigations very little is known regarding expression of TRAIL and pro-apoptotic TRAIL receptors in plasma cells (PCs) of patients (pts) with monoclonal gammopathies (MG).
Aims: The aim of this investigation is to contribute to clarify the involvement of TRAIL and death TRAIL receptors in the development of MG, in the progression of MGUS to MM and in the prognosis of MM.
Methods: Between April 2010 and July 2013, we evaluated bone marrow PCs from 125 pts with MG, 59 symptomatic multiple myeloma (MM), 66 monoclonal gammopathy of uncertain significance (MGUS) and 11 healthy controls (Ctr). PCs were analysed by flow cytometry and the 2 populations were identified by gating CD138+/CD19- and CD138+/CD19+. We evaluated the expression of TRAIL, TRAIL-R1 and -R2 with monoclonal antibodies in both populations by flow cytometry. The results are expressed as percentage of PCs expressing these proteins and expression levels in mean intensity of fluorescence (MIF).
Results: In our population, median age was 70 (39-86) years, 52% were male. We found that the mean percentage of CD138+/CD19+ PCs expressing TRAIL and TRAIL-R1 in MM (70,8% and 73%, respectively) is significantly higher than in MGUS (54,8% and 46,1%, respectively) pts (p=0,0001) and in MGUS compared to Ctr (46,2% and 13,2%; p=0,043 and p=0,0001, respectively); TRAIL-

R2 was also higher in MGUS *vs* Ctr (56,7% *vs* 17%, p=0,0001). TRAIL expression level in PCs with the same phenotype was higher in MM (46,6±3,4 MIF) than in MGUS (35,3±1,4 MIF) pts (p=0,026), as well as the level of expression of TRAIL-R1 and -R2 in MM (32,7±1,1 MIF and 44,8±2,2 MIF, respectively) and in MGUS (37,1±1,7 MIF and 60,9±1,9 MIF, respectively) pts compared to Ctr (27,5±0,65 MIF and 24,8±0,7 MIF, respectively; p=0,0001). We also evaluated the expression of TRAIL and TRAIL pro-apoptotic receptors in CD138+/CD19- PCs in MGUS and in MM pts. In MM, we found increased expression levels of TRAIL and TRAIL-R2 in CD138+/CD19+ (46,6±3,4 MIF and 44,8±2,2 MIF, respectively) compared to CD138+/CD19- (29,2±1,8 MIF and 34,2±2 MIF, respectively) PCs (p=0,0001). Similar data were observed in MGUS pts only for TRAIL-R2 (60,9±1,9 MIF in CD138+/CD19+ *vs* 54,8±2,4 MIF in CD138+/CD19- PCs; p=0,001). In our investigation, we also searched for prognostic markers in MM pts and we found a significant better survival for pts with a percentage of CD138+/CD19- PCs expressing TRAIL superior to 13,5% (p=0,008).

Summary and Conclusions: Our study showed that TRAIL and TRAIL pro-apoptotic receptors, R1 and R2, are highly expressed in CD138+/CD19+ PCs of MG pts compared to Ctr with increased levels in MM *versus* MGUS, suggesting a significant role of these proteins in the development and progression of MG. We also demonstrated a prognostic impact of TRAIL expression in MM pts, with an improved prognosis associated with a higher percentage of CD138+/CD19- PCs expressing TRAIL.

THE NOVEL MOLECULE STK405759 HAS SELECTIVE CYTOTOXICITY AGAINST MULTIPLE MYELOMA *IN VITRO* AND *IN VIVO*

G. Rozic[1,*] J. Jakubikova[2], A. Duek[1], A. Avigdor[1], A. Nagler[1], M. Leiba[1]
[1]Division of Hematology & BMT, Sheba Medical Centre, Tel Hashomer, Ramat gan, Israel, [2]Department of Medical Oncology, Jerome Lipper Multiple Myeloma Center, Harvard Medical School, Dana-Farber Cancer Institute, Boston, United States

Background: Despite advances in treatment, including high-dose chemotherapy and novel agents such as proteasome inhibitors and immunomodulators, multiple myeloma (MM) remains incurable due to development of drug resistance in the bone marrow microenvironment.

Aims: To evaluate the use of STK405759, a synthetic small molecule, as a potentially novel drug for MM treatment in preclinical models.

Methods: Cytotoxic activity of STK405759 was evaluated byxTT assay. Apoptosis and cell cycle were checked by flow cytometry. Protein expression was assessed by Western blot. Histochemistry was used to evaluate apoptosis in tumors of mousexenograft model.

Results: Our data show that STK405759 has a potent cytotoxic activity against a wider variety of MM cell lines and patient-derived MM cells, regardless of their sensitivity to conventional therapy or novel agents. In contrast, the viability of normal peripheral blood mononuclear cells derived from healthy donors and MM patients was not inhibited. Importantly, STK405759 induced cell death of RPMIS cells co-cultured with HS-5 BMSCs. At low concentrations (nanomolar), STK405759 triggered G2 cell cycle arrest and induced apoptotic cell death associated with the cleavage of caspase-8 and poly (ADP-ribose) polymerase, as well as down-regulation of the Mcl-1 anti-apoptotic protein. These biological responses were associated with decreased AKT and CREB protein expression in MM cell lines. Combination studies of STK405759 with bortezomib, lenalidomide or dexamethasone showed significant synergistic cytotoxicity in MM cells. *In vivo* studies revealed decreased MM tumor burden and prolonged survival of STK405759-treated mice as compared with controls. STK405759 induced apoptosis of tumors cells from treated mice.

Summary and Conclusions: Our results from *in vitro* and *in vivo* studies showed the anti-myeloma activity of STK405759 and provided the rationale for further evaluation of STK405759 as monotherapy and combination therapy for treating patients with MM.

CYTOGENETIC ABNORMALITIES OF UNDETERMINED CLINICAL SINIGICANCE CORRELATE WITH POOR PROGNOSIC FACTORS IN MULTIPLE MYELOMA

M. Kim[1,*] E.J. Lee[1], H.J. Kang[1], H.-S. Kim[1], H.C. Cho[2], H.J. Kim[1], D.S. Lee[3], Y.K. Lee[1]
[1]Hallym University Sacred Heart Hospital, [2]Kangdong Sacred Heart Hospital, [3]Seoul National University Hospital, Seoul, Korea, Republic of

Background: The prognosis of multiple myeloma (MM) depends on the underlying cytogenetic subtype. Recurrent cytogenetic changes including hyperdiploidy of odd-numbered chromosomes, -13/13q- and balanced translocations involving *IGH* have already been incorporated into risk stratification strategies and are used in standard clinical practice. Nevertheless, MM often exhibits a heterogenous and complex karyotype, and many other chromosomal abnormalities of uncertain clinical significance are observed.

Aims: We performed a comprehensive analysis for the relationship between cytogenetic abnormalities of undetermined prognostic significance and known prognostic factors in MM.

Methods: Conventional G-banding was performed in 333 newly diagnosed MM. Karyotypes were described using the most recent version of the International System for Human Cytogenetic Nomenclature. Translocations with breakpoints at p10, p11, q10, or q11 were all regarded as whole arm (centromere to centromere) translocations. Poor prognostic indicators as follows: hemoglobin (Hb) level <10 g/dL, calcium level >12 mg/dL, IgG level >7 g/dL or IgA level >5 g/dL, b2-microglobulin level >5.5 mg/L, and albumin level <3.5 g/dL. Creatinine level >2 mg/dL, IgA type, lambda type, elevated free light chain level >100 mg/dL, abnormal kappa/lambda ratio of >4.0 or <0.5, and elevated LDH level were also included.

Results: Among the 333 MM patients, 212 showed a normal or good/intermediate karyotype (195 with normal karyotype; 17 with abnormal karyotype associated with good or intermediate prognosis); these served as the control group in this study. The remaining 121 had other cytogenetic abnormalities (with or without hyperdiploidy, or translocations associated with good or intermediate prognosis). Chromosomes 1p (12.0%), 1q (18.9%), 6q (7.2%), 8q (6.9%), 11q (5.4%), 12p (5.1%), 14q (9.3%) and 19q (5.1%).showed frequent abnormalities. Common breakpoints were p10-12, p13, p22 in 1p, q10-12, q21, q25, q32 in 1q; q21, q25 in 6q; q10, q22, q24 in 8q; q10, q13 in 11q; p10-12 in 12p; q24, q32in 14q and q10, q13.3 in 19q (Figure 1). Certain chromosomal abnormalities were associated with known prognostic factors (p-value <0.05): 8q-IgA type; 1q-IgG level of >5 g/dL or IgA level of>3 g/dL; 14q-kappa or lambda type chains >100 mg/dL; 1p, 1q, 6q, and 19q-Hb <10.0 g/dL; 1p and 12q-albumin <3.5 g/dL; 14q and 19q -creatinine >2.0 mg/dL; 1p, 1q, 6q, or 19q-b2-microglobulin >5.5 mg/L; 1p, 8q, 11q, and 14q-calcium >12 mg/dL; 1p, 3p, 12p, or 14q-elevated LDH level.

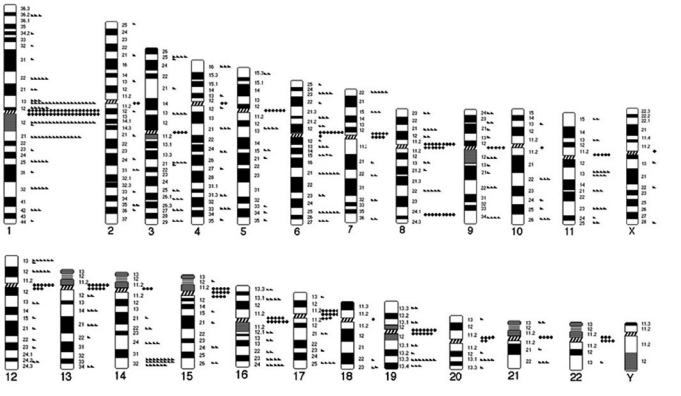

Figure 1.

Summary and Conclusions: We analyzed the distribution and clinical significance of the less commonly occurring cytogenetic abnormalities for the first time. Abnormalities in chromosomes 1p, 1q, 3p, 6q, 8q, 11q, 12q, 14q, and 19q were associated with clinical factors associated with a poor prognosis. Not all chromosomes showing frequent aberrations correlated with prognostic factors, indicating that it is not the presence of a cytogenetic abnormality in itself, but the particular chromosome(s) involved in the abnormality that is the key factor that determines the initial clinical characteristics of MM

Background: A 15-20% of plasma cells (PCs) is the main prerequisite for diagnosis of genetic abnormalities by FISH techniques in bone marrow interphase plasma cell dyscrasia patients. Plasma cells (PCs) enrichment from bone marrow samples patients are frequently performed by the traditional method of immunomagnetic separation (magnetic activated cell sorting, MACS) using anti-CD138 MicroBeads. The main inconveniences of the MACS method are: its high cost, it is unsuccessful if the percentage of PCs in the initial sample is less than 5% and the PCs positive selection affect to the quality of the cells. RosetteSep Human Multiple Myeloma Enrichment Cocktail The RosetteSep

enrichment cocktail cross-links unwanted cells in human bone marrow to multiple red blood cells (RBCs) using Tetrameric Antibody Complexes (TAC), forming immunorosettes. This increases the density of the unwanted cells, in such a way that they pellet along with the free RBCs when centrifuged over Ficoll-Paque PLUS. Desired cells are never labeled with antibodies and are easily collected as a highly enriched population at the interface between the plasma and Ficoll-Paque PLUS. With this above negative selection cells technique, it obtain a great quantity and high quality cells.
Aims: The aim of this paper is to find the optimal algorithm, results and advantages in cost and pure and quality cell populations of the RosetteSep separation technique for samples of 50 bone marrow plasma cell dyscrasia patients with various percentages of neoplastic cells for applying FISH methods in these diseases.
Methods: Specimens: We analysed 76 heparinized bone marrow aspirates with known PCs dyscrasias for FISH diagnosis of genetic abnormalities. The percentage of monoclonal PCs varied between 0.48 and 73.5% (mean 14.39%) according to flow cytometry analysis on the previous study before PCs selection. The cytology analysis was used when the percentage was between 3 to 4%, to determine the PCs infiltration, when there was an infiltration ≥7% or presence of cell nests the sample was processed. Cell separation: RosetteSep technique was used for separation of PCs in all specimens. Briefly, we added RosetteSep Multiple Myeloma Enrichment Cocktail at 50 µl/ml of bone marrow aspirate sample, incubated 20 minutes at room temperature and diluted it with an equal volume of Ficoll-Paque PLUS. After centrifuging for 20 minutes at 1200xg at room temperature we removed and washed the enriched cells from the density medium (plasma interface). For all cases, enrichment was accomplished. Flow cytometry analysis: It was proved the percentage of PCs before and after the separation. Enriched sample was stained with CD38-FITC and CD45-V450 and acquired using a BD FACSCanto II. Percentage of PCs among non-erythroid cells was obtained by Infinicyt software (Cytognos). FISH analysis: FISH analysis was carried out following standard procedures on interphase cells. The number of interphase cells analyzed were 200.
Results: 76 bone marrow samples were analyzed from patients with a range age between 38-89 years old (mean 67 years old). 19 sample patients with ≤5% of preselected PCS by flow cytometry (0.48%>4.9%) showed hemodilution (1 cases). Cytology analysis were carried out in spite of do the PCs selection in the rest of the bone marrow samples with ≤5% PCs (6 cases); the PCs selection was realized when the samples showed a ≥7% of PCs and/or nest *cells* by cytology. All samples were successfully separated. The median of PCs after enrichment was 60.5% (range 45.93- 86.75%). We obtained results in all of 77 FISH samples analyzed.
Summary and Conclusions: The introduction of RosetteSep contributed markedly in increasing the effectiveness of plasma cell separation from bone marrow samples, mainly in samples with low plasma cell content where the MACS method is not unsuccessful (<5%), its negative selection strategy enabled us to obtain sufficient amounts of highly purified and quality PCs required for subsequent diagnosis techniques proposed. On the other hand, the above technique has a low cost as opposed to MACS. The increase in the PCs concentration permits better FISH results incrementing the genetic abnormality detections which have a high prognosis value in these pathologies.

CT IS SUPERIOR TOx-RAY IN DIAGNOSING OSTEOLYTIC LESIONS IN THE SPINE AND PELVIS: A PROSPECTIVE STUDY OF NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

M. Hinge[1,*] K.T. Andersen[1], T. Lund[2], H.B. Jørgensen[3], P. Holdgaard[3], T.E. Ormstrup[4], L.L. Østergård[4], T. Plesner[1]
[1]Department of Internal Medicine, Section of Haematology. Institute of Regional Health Research, University of Southern Denmark, Vejle Hospital, Vejle, [2]Department of Haematology, Odense University Hospital, Odense, [3]Department of Nuclear Medicine, [4]Department of Radiology, Vejle Hospital, Vejle, Denmark

Background: The presence of osteolytic lesions may define if a patient has multiple myeloma needing treatment or smouldering myeloma, and once developed the skeletal damage tends to be irreversible. Thus, a sensitive examination of the skeleton at diagnosis is of great importance for the decision to start anti-myeloma treatment. Conventionalx-ray has been the method of choice in many centres, despite increasing evidence that other imaging modalities may be more sensitive, especially in the spine and pelvic areas.
Aims: In a prospective clinical trial we have compared low-dose Computed Tomography (CT) head to head with conventionalx-rays for the demonstration of osteolysis in the spine and pelvis in newly diagnosed multiple myeloma patients. Simultaneously the value of adding 18-flourdeoxyglukose (^{18}FDG) Positron Emission Tomography (PET) and Single Photon Emission computed tomography (SPECT) to CT was evaluated.
Methods: 35 previously untreated multiple myeloma patients (21 males, 14 females; mean age 64 (49-81)) were included in a prospective single centre phase-II study evaluating the safety and efficacy of a five drug combination of doxorubicin, cyclophosphamide, bortezomib, dexamethasone and lenalidomide. Informed consent was obtained. At baseline the bone status of the patients was evaluated by conventionalx-ray, CT, ^{18}FDG-PET-CT and SPECT-CT. The presence of osteolysis in the pelvis and spine was determined byx-ray and CT, and focal activity was studied using PET-CT and SPECT-CT. The imaging was evaluated by a group of dedicated experts.x-rays were evaluated independently from CT.
Results: CT was significantly more sensitive thanx-rays for detection of osteolytic lesions in both pelvis ($p<0.01$, n:32) and spine ($p<0.05$, n:32). Osteolysis in the pelvis was diagnosed in 69% (24/35) of the patients by CT and only in 28% (9/32) of the patients byx-ray. Two patients were diagnosed with osteolysis in the pelvis usingx-ray, which was not found at CT. In the first of these, PET was also positive, and after retrospective comparison to a follow-up CT-scan osteolysis was also recognized on the study CT. The second, had in addition to a negative CT, also negative PET and SPECT, and after retrospective comparison to follow-upx-rays, the studyx-ray was considered as false positive due to misinterpreting of intestinal air. In the spine osteolysis or malignant fractures were diagnosed in 69% (24/35) of the patients by CT and in 38% (12/32) byx-rays. In the spine none of the patients with osteolysis byx-rays had a negative CT. Additionally, CT revealed three cases with imminent affection of the spinal cord and one with extra medullary disease. In both spine and pelvis PET positive foci were found in 9% (1/11) of the negative CT-scans, while PET was negative in 50% (12/24) of the positive CT-scans of pelvis, and in 48% (11/23) of the positive CT-scans of spine (no corresponding PET of spine to one of the 24 positive CT-scans). SPECT was occasionally positive, in positive CT-scans (spine:14/23, pelvis:8/21) but never in CT-negative, indicating that SPECT positivity may reflect enhanced bone remodelling in the respective areas.
Summary and Conclusions: CT of the pelvis and spine diagnose significantly more patients with osteolysis thanx-rays of the respective anatomical area, and should be the preferred modality for the diagnosis of bone involvement in multiple myeloma. The additional value of adding the more expensive and time-consuming ^{18}FDG-PET or SPECT to CT was in this study low.

SEVERE INFECTION IN ELDERLY PATIENTS TREATED WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: ANALYSIS OF THE INTERGROUPE FRANCOPHONE DU MYÉLOME (IFM) 2009 01 PROTOCOL

P. Rodon[1,*] B. Pegourie[2], L. Garderet[3], P. Casassus[4], O. Decaux[5], M. Roussel[6], C. Chaleteix[7], B. Royer[8], M. Tiab[9], X. Leleu[10], C. Mathiot[11], C. Hulin[12], P. Moreau[13], O. Lortholary[14], J.-P. Fermand[15]
[1]Hematologie, Centre Hospitalier, Perigueux, [2]Hematologie, CHU, Grenoble, [3]Hematologie, Hopital St Antoine APHP, Paris, [4]Hematologie, Hopital Avicenne APHP, Bobigny, [5]Medecine Interne, CHU, Rennes, [6]Hematologie, CHU, Toulouse, [7]Hematologie, CHU, Clermont-Ferrand, [8]Hematologie, CHU, Amiens, [9]Hematologie, Centre Hospitalier, La Roche sur Yon, [10]Hematologie, CHU, Lille, [11]Hematologie, Institut Curie, Paris, [12]Hematologie, CHU, Nancy, [13]Hematologie, CHU, Nantes, [14]Maladies infectieuses, Hopital Necker APHP, [15]Immunologie clinique, Hopital St Louis APHP, Paris, France

Background: The combination of bendamustine, bortezomib and dexamethasone (BVD) demonstrated a high efficacy and a good tolerability in elderly patients with relapsed and/or refractory multiple myeloma (RRMM). However, severe infection was a major toxicity.
Aims: We reviewed clinical aspects and risk factors of severe infection occurring in the IFM 2009 01 protocol.
Methods: The IFM 2009 01 protocol evaluated the BVD combination as 2nd-line treatment in elderly patients (>65 years) with RRMM (Rodon P. *et al.*, Haematologica 2015;100(2):e56-9). Twelve cycles were scheduled: 6 monthly cycles followed by 6 cycles every 2 months. Patients did not receive any prophylactic antibiotics. All adverse events were collected and graded prospectively according to the National Cancer Institute Common Terminology Criteria for Adverse Events (version 3.0). We report here an analysis of the episodes of severe infection (grade 3 or more).
Results: Seventy-three patients were included. The median age was 75.8 years (range 66-86). The median number of cycles administered was 7. The overall response rate was 69.8%. The median progression-free survival was 10.8 months, and the median overall survival was 23 months. Twenty episodes of grade 3 or more infection occurred in 17 patients (23.2%): lung and respiratory tract infection 13 episodes, bloodstream infection 6 episodes and pyelonephritis 1 episode, respectively. A recurrence of lung infection was observed in 3 patients. Fourteen episodes were diagnosed in the early phase of therapy (within the 4 first BVD cycles). Only 1 severe infection underwent during a chemotherapy-induced neutropenic phase (absolute neutrophil count <1000/mm^3). Fifteen episodes occurred among 34 patients older than 75 years *versus* 5 episodes in 39 younger patients (p=0.0028). Sepsis was responsible of death in 5 of these 17 patients (29.4%), all occurring in the early phase of the BVD therapy.
Summary and Conclusions: Infection was a major severe adverse event in elderly patients treated for RRMM in the IFM 2009 01 protocol, occurring in approximately one quarter of the patients. Its incidence was significantly higher in patients older than 75 years. Severe episodes of infection mainly occurred in the early phase of treatment. The mortality rate was high. These findings suggest that a systematic prophylactic use of antibiotics may be needed in this population of patients.

E1251

IMMUNOGLOBULIN HEAVY/LIGHT CHAIN IMMUNOASSAYS FOR RESPONSE EVALUATION IN MULTIPLE MYELOMA: COMPARISON WITH IMMUNOFIXATION, SERUM FREE LIGHT CHAIN, AND MULTICOLOR FLOW- CYTOMETRY

Y. Suehara[1,*], K. Matsue[1], H. Takamatsu[2], K. Endean[3], S. Harding[3], K. Fukumoto[1], M. Fujisawa[1], H. Sugihara[1], M. Takeuchi[1]
[1]Division of Hematology/Oncology, Department of Medicine, Kameda Medical Center, Kamogawa, [2]Cellular Transplantation Biology, Kanazawa University Graduate School of Medical Science, Kanazawa, Japan, [3]The Binding Site Group Ltd, Birmingham, United Kingdom

Background: Multiple myeloma (MM) patients are monitored to assess treatment response. Serum immunoglobulin (Ig) heavy/light chain immunoassays are new methods, which allow quantification of Ig light chain types (IgGκ, IgGλ, IgAκ, IgAλ).
Aims: We compared Ig heavy/light chain assays with standard methods for response assessment, and evaluated advantages and limitations of this test. We also studied whether the test predicted prognosis.
Methods: 368 samples were obtained from 128 patients with IgG and IgA type MM at Kameda Medical Center and Kanazawa University Hospital (median age: 70 years, range: 44-89; median follow-up: 29 months, range: 0.9-189.6). The proportions of patients in ISS stages 1, 2, and 3 were 24%, 37%, and 39%, respectively. Paraprotein type was IgG in 84 patients (59 IgGκ, 25 IgGλ) and IgA in 44 (23 IgAκ, 21 IgAλ). Samples were taken at various times after treatment and analyzed retrospectively by serum Ig heavy/light chain immunoassays. Heavy/light chain ratio (HLCR) was calculated with Ig'κ (G or A) as the numerator and compared to normal ranges (IgGκ: 3.84-12.07 g/L; IgGλ: 1.91-6.74 g/L; IgGκ/IgGλ: 1.12-3.21; IgAκ: 0.57-2.08 g/L; IgAλ: 0.44-2.04 g/L; IgAκ/IgAλ: 0.78-1.94). The results were compared to serum protein electrophoresis (SPEP), immunofixation electrophoresis (IFE), and serum free light chain immunoassay (FLC). HLC-pair suppression was defined as uninvolved immunoglobulin of the same isotype 50% below the lower limit of normal (IgGκ, IgGλ, IgAκ, IgAλ). Residual neoplastic plasma cells (MM-PCs) in bone marrow were assessed by multicolor flow cytometry (MFC) in 158 samples from 66 patients at very good partial response (VGPR), complete response (CR), and stringent CR (sCR). MFC negativity was defined as <10^{-4} MM-PCs. Overall survival (OS) and progression-free survival (PFS) were estimated by the Kaplan-Meier method, and survival was compared using the log rank test.
Results: MM responses were assessed according to international response criteria. Patients' samples at various responses were: Before therapy, n=60 (16%); sCR, n=81 (22%); CR, n=30 (8%); VGPR, n=136 (37%); and PR, n=61 (17%). Normal HLCR was obtained at sCR, CR, VGPR and PR in 70 (86%), 29 (97%), 76 (55%) and 9 (15%) cases, respectively. Among PR samples with normal HLCR, many SPEPs showed small M-spike with broad polyclonal peak. In the sera from patients who achieved a CR or better, abnormal HLCR and FLC ratio were seen at rates of 9.7% and 22.3%, respectively, and no sera had abnormal value in both assays simultaneously. Among the patients who achieved a VGPR or better, patients with a normal HLCR had fewer MM-PCs than those with an abnormal HLCR (median 1x10$^{-3.42}$ *vs* 1x10$^{-3.04}$, respectively, P=0.01). Shorter OS were shown in patients with highly abnormal HLCR; >100 or <0.01 at diagnosis than in those without (36.3 months *vs* not reached, P=0.038). Longer OS were observed in patients who achieved HLCR normalization at best response than in those who did not (not reached *vs* 119.7 months, P=0.0002). Presence of HLC pair suppression at best response was associated with poorer OS, but that at diagnosis was not (Figures 1,2 and 3).

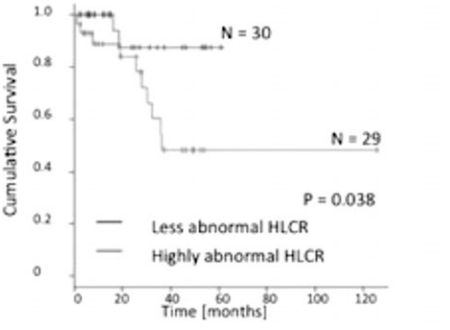

Figure 1. Highly abnormal HLCR at diagnosis is associated with shorter OS.

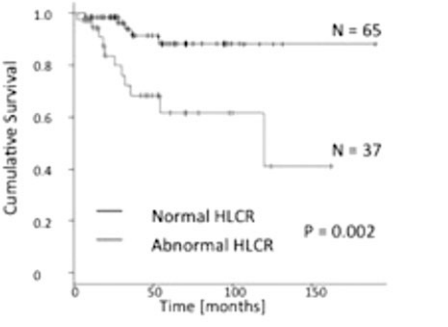

Figure 2. Abnormal HLCR at best response is associated with shorter OS.

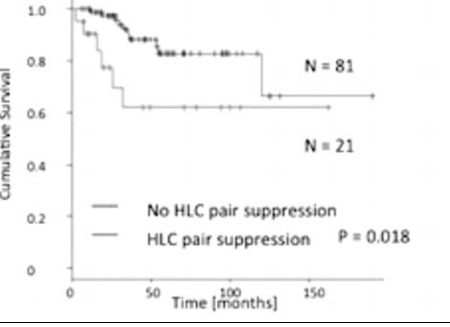

Figure 3. HLC pair suppression at best response is associated with shorter OS.

Summary and Conclusions: This study suggests the usefulness of HLC assays for the assessment of MM response. Highly abnormal HLCR at diagnosis was a poor prognostic factor. Abnormal HLCR and HLC-pair suppression at best response were associated with poorer survival. Response assessment by SPEP alone seems inaccurate, especially in patients with PR or VGPR with uninvolved Ig recovery. HLC assay enables more accurate estimation of involved Ig quantification, and should be used for response assessment in the near future.

E1252

DYNAMIC CONTRAST-ENHANCED MAGNETIC RESONANCE IMAGING PARAMETERS CORRELATE WITH ANGIOPOIETIN-1/ANGIOPOIETIN-2 RATIO AND OTHER HIGH-RISK FEATURES IN PATIENTS WITH MULTIPLE MYELOMA

E. Terpos[1,*], D. Matsaridis[2], V. Koutoulidis[2], F. Zagouri[1], D. Christoulas[1], A. Koureas[2], E. Kastritis[1], L.A. Moulopoulos[2], M.A. Dimopoulos[1]
[1]Department of Clinical Therapeutics, [2]First Department of Radiology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) studies the kinetics of the distribution of paramagnetic contrast in the microvessels and in the interstitial space of the studied tissue. It has been previously reported that DCE-MRI parameters correlate with increased angiogenesis and event-free survival of patients with multiple myeloma (MM) in the conventional chemotherapy era.
Aims: The aim of this study was to evaluate the value of DCE-MRI in the era of novel anti-myeloma agents and explore possible correlation with angiogenic cytokines that have prognostic value in MM, such as the ratio of angiopoietin-1/angiopoietin-2 (Angp-1/Angp-2).
Methods: We studied 46 MM, previously untreated, patients (24M/22F, median age 67 years, range 33-88 years) at diagnosis (37 with symptomatic MM and 9 with smoldering MM-SMM) and 5 patients with MGUS. All patients underwent MRI of the lumbar spine and DCE-MRI was performed. The following perfusion parameters that were firstly described by our group (Moulopoulos *et al.*, Ann Oncol 2003;14:152-8) were evaluated: Wash-in (WIN), washout (WOUT), time-to-peak (TTPK), time-to-maximum slope (TMSP) and WIN/TMSP (WTSP). All these parameters can be obtained from the time-intensity curves and the first derivative function [f(t)=d(DSE)/dt] of the EMG equation. The following serum indices of angiogenesis were also measured on the day of MRI: VEGF, Angiogenin (Ang), Angp-1 and Angp-2, using an ELISA methodology (R&D Systems, Minneapolis, MN, USA).
Results: MRI evaluation of the spine revealed that 11 (23.9%) patients had focal, 12 (26.1%) diffuse, 16 (34.8%) normal, and 7 (15.2%) had a variegated pattern of marrow involvement. Symptomatic MM patients had increased WIN values [median 18.7 sec^{-1}, range (2-111 sec^{-1})] compared to SMM [5.7 (1.3-30), p<0.05) and MGUS patients [1.7 (1.1-5), p=0.001]. TTPK values were decreased and WTSP values were increased in both symptomatic MM [47 sec (18-76 sec) and 0.47 sec (0.04-9.73 sec), respectively] and SMM [60.4 (36-98) and 0.35 (0.02-1.01) respectively] MM patients compared to MGUS patients [77 (67-120) and 0.04 (0.02-0.1), p<0.05 for all comparisons]. Only symptomatic patients had decreased TMSP values [32 sec (11-56 sec)] compared to MGUS patients [46 (41-71), p=0.004]. Patients with normal MRI pattern had increased WIN, TMSP and WTSP values and decreased WOUT and TTPK values compared to other patients (p<0.05 for all comparisons). The Angp-1/ Angp-2 ratio was reduced in symptomatic MM patients [13.5 (1.8-39.7)] compared to SMM patients (22.1 (9.9-32.3); p=0.017] and MGUS patients [64.2 (26.7-89.5); p<0.001]. TTPK values correlated with serum Angp-2 (r=-0.330, p=0.018) and Angp-1/Angp-2 ratio (r=0.361, p=0.009), as well as serum M-protein (r=-0.331, p=0.02). WIN values correlated with M-protein (r=0.432, p=0.002), albumin (r=-0.376, p=0.008), β2-microglobulin (r=0.335, p=0.021), hemoglobin (r=-0.309, p=0.028) and serum creatinine (r=0.371, p=0.007). The median follow up of symptomatic myeloma patients was 31 months and the median overall survival was 67 months. All symptomatic patients were treated with novel agent-based regimens. Thirteen patients progressed after first line therapy. There was a trend for shorter time to progression in patients with low TTPK values (<upper quartile, median TTP 44 months) compared to patients with high TTPK values (median TTPK not reached, p=0.09).
Summary and Conclusions: DCE-MRI parameters, such as the TTPK, correlate with increased angiogenic capacity, as reflected by the low ratio of Angp-1/Angp-2, while others, such as the WIN, correlate with high risk features of MM. Higher number of patients and longer follow-up is needed to reveal if DCE-MRI can be of prognostic significance in the era of novel anti-MM agents.

E1253

SERUM LEVELS OF VON WILLEBRAND FACTOR (VWF) BUT NOT OF ADAMTS-13 PREDICT FOR EARLY DEATH IN PATIENTS WITH AL AMYLOIDOSIS, INDEPENDENTLY OF CARDIAC BIOMARKERS

E. Kastritis[1,*] M. Gavriatopoulou[1], E. Terpos[1], N. Simos[2], N. Kanelias[1], E. Eleutherakis-Papaiakovou[1], C. Pamboucas[1], E. Psimenou[1], E. Papadopoulou[1], S. Toumanidis[1], M. Roussou[1], A. Tasidou[3], I. Papassotiriou[2], M. Dimopoulos[1]
[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, [2]Department of Clinical Biochemistry, "Aghia Sophia" Children's Hospital, [3]Department of Haematopathology, Evangelismos Hospital, Athens, Greece

Background: The deposition amyloid fibrils composed of immunoglobulin light chains in tissue microcirculation causes organ dysfunction in systemic light chain (AL) amyloidosis. Light chains or of oligomers of light chains may also have a direct toxic effect on cells such a myocardial cells or endothelia l cells. vWF is mainly produced, stored and secreted by endothelial cells (ECs), is critical for thrombus formation but the secretion of vWF by ECs is also triggered by several conditions and may reflect a state of "stimulation" of the endothelium. ADAMTS-13 is a protease, primarily synthesized and released from hepatic stellate and endothelial cells, which cleaves the cell bound large ultrapolymeric vWF strings. Both vWF antigen (vWFAg) and ADAMTS-13 antigen levels have been implicated as prognostic markers associated with cardiovascular events, potentially reflecting endothelia dysfunction. Cardiac dysfunction is the main determinant of prognosis in AL amyloidosis, but the role of endothelium has not been studied.
Aims: To evaluate the prognostic role of vWF and ADAMTS-13 in patients with AL amyloidosis.
Methods: Both vWFAg and ADAMTS-13 levels were measured in stored serum, using commercially available assays, in 81 consecutive patients with newly diagnosed AL amyloidosis who were treated in the Department of Clinical Therapeutics (University of Athens, Greece) and in 30 age-matched healthy controls.
Results: Median age was 68 years (range 42-82 years) and the median number of involved organs was 2; heart was involved in 62% and kidneys in 74%. Median NTproBNP level was 2,318 pg/mL (range 33-75,000 pg/mL); 36% had NTproBNP ≥4,000 pg/mL and 28%, 38% and 34% of patients had Mayo stage -1, -2 and -3, respectively. Primary therapy based on bortezomib was given in 52%, on lenalidomide in 44%, while 4% received MDex. Median survival was 47 months; 3- and 6-month mortality was 12% and 20%, respectively. The median serum level of vWFag in patients with AL amyloidosis was 181 (range 20-557) U/dL, significantly higher than in healthy controls (median: 84 U/dL, range 48-124; p <0.001). Median ADAMTS-13 levels were similar between AL patients and controls (median 1044 *vs* 1170 ng/ml, p=NS). There was no correlation of vWF and ADAMTS-13 levels, and no association of vWFag levels with renal, cardiac, nerve or liver involvement or with the levels of NTproBNP, hsTnT or Mayo stage, eGFR, serum albumin levels or proteinuria or the levels of involved free light chains. ROC curve analysie identified that levels of vWFag within the top quartile (≥230 U/dL) were associated with a very poor outcome (median survival 4 months *vs* 47 months, p=0.001). There was no association of ADAMTS-13 levels with any outcome (early death or overall survival). In multivariate analysis vWFag levels ≥230 U/dL were independently associated with a high risk of death at 6 months (HR: 15, 95% CI 2.6-84, p=0.002) together with NTproBNP ≥4,000 pg/mL (HR: 16.8, 95% CI 3- 94, p=0.001) and for overall survival (HR: 2.64, 95% CI 1.2-5.8, p=0.01), along with NTproBNP levels ≥4,000 pg/ml (HR: 4.17, 95% CI 1.98- 8.8, p<0.001). Among patients with both vWF≥230 IU/L and NTproBNP>4000 pg/ml, 75% died within 3 months from initiation of therapy.

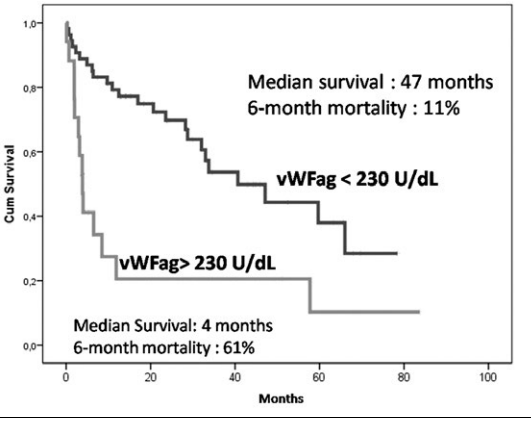

Figure 1.

Summary and Conclusions: Serum vWFag levels in patients with AL amyloidosis are elevated, without a compensatory increase of ADAMTS-13, are not correlated with other features of the disease and are associated with a high risk of early death independently of cardiac biomarkers.

E1254

CHEMOTHERAPY-INDUCED NEUROPATHY AMONG MULTIPLE MYELOMA PATIENTS AND THE INFLUENCE OF CHEMOTHERAPEUTIC AGENTS: RESULTS FROM THE POPULATION-BASED PROFILES STUDY.

A. Beijers[1,*] S. Oerlemans[2,3], F. Mols[2,3], M. Eurelings[4], M. Minnema[5], L. van de Poll-Franse[2,3], G. Vreugdenhil[1,6]
[1]Internal Medicine, Máxima Medical Center, Veldhoven and Eindhoven, [2]Netherlands Comprehensive Cancer Organisation (IKNL), Netherlands Cancer Registry, Eindhoven, [3]CoRPS-Centre of Research on Psychology in Somatic diseases, Department of Medical and Clinical Psychology, Tilburg University, Tilburg, [4]Department of Neurology, Spaarne Hospital, Hoofddorp, [5]Department of Hematology, UMC Utrecht Cancer Center, Utrecht, [6]Departmen of Medical Oncology, Maastricht University Medical Center, Maastricht, Netherlands

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common adverse event of antimyeloma treatment, which may affect patients' health-related quality of life (HRQOL). Because there is no proven therapy for CIPN, it is important to closely monitor the development of this side effect in order to modify chemotherapy dose on time.
Aims: To evaluate the prevalence and severity of CIPN and the influence of antimyeloma treatment with neurotoxic chemotherapy on the development of CIPN among a population-based sample of multiple myeloma (MM) patients.
Methods: All MM patients diagnosed between 2000 and 2014 as identified by the Netherlands Cancer Registry, location Eindhoven, and alive at questionnaire

invitation, were eligible. 130 patients completed the EORTC QLQ-CIPN20 on average 3.5 years after diagnosis (74% response). Data on chemotherapy regimens, treatment response at time of the survey and dose reductions of chemotherapy were extracted from the medical files. All patients gave written informed consent.

Results: Patients received treatment with one (49%) or more (42%) neurotoxic agents, including thalidomide (50%), bortezomib (48%), lenalidomide (39%) and/or vincristine (7%). Overall, 54% of patients reported at least one neuropathy symptom ('quite a bit' or 'very much' combined). The most reported neuropathy symptoms during the past week were trouble getting an erection (46% of men), tingling toes/feet (30%), numbness in toes/feet (20%), tingling fingers/hands (19%) and trouble opening jars/bottles (19%). There were no differences in neuropathy symptoms between patients who received treatment with only one *vs* a combination of more neurotoxic agents. Patients who received chemotherapy in the past 3 months reported a trend of more experienced neuropathy (64%), compared to patients treated more than 12 months before (50%) (p=0.12). In addition, they reported significantly more severe neuropathy with worse sensory scale scores (mean 21 *vs* 12; p=0.01), respectively. Patients with relapsed or progressive MM (n/N=35/130) received treatment in the past 3 months in 31%, and 51% of patients reported CIPN. Of them 34% reported the highest (4th quartile) and therefore worst sensory subscale scores. A dose modification of chemotherapy was applied in 72% of patients, of whom 50% received a dose reduction because of neurotoxicity. Dose modifications did not seem to adversely affect treatment response rates.

Summary and Conclusions: CIPN is a common dose-limiting side effect reported by more than half of patients with MM. The neuropathy is less severe 12 months after last treatment. However, patients with MM receive neurotoxic treatment throughout a considerable period of life after diagnosis. Regardless of the poor prognosis, 31% of patients with relapsed or progressive MM were still actively treated with chemotherapy, with a high neuropathy symptom burden, which may negatively affect their HRQOL.

E1255

FRONTLINE INDUCTION THERAPY FOR MULTIPLE MYELOMA (MM) IN REAL-WORLD CLINICAL PRACTICE: THIRD INTERIM ANALYSIS OF THE MULTINATIONAL, OBSERVATIONAL EMMOS STUDY (NCT01241396)

M. Mohty[1,*] E. Terpos[2], M.-V. Mateos[3], A. Palumbo[4], W. Legiec[5], M. Beksac[6], E. Laane[7], M.A. Bekadja[8], D. Nemet[9], V. Peceliunas[10], M. Cavo[11], P. Moreau[12], T. Masszi[13], P. Background: There is a lack of objective data on variation in treatment practices and outcomes for MM between countries.

Aims: The prospective, non-interventional EMMOS study was designed to capture real-world data regarding treatments for MM at different stages of the disease.

Methods: Consenting adult patients (pts) initiating any new line of therapy for MM, irrespective of treatment line at study entry or type of therapy, were eligible for inclusion in the EMMOS registry. A multi-staged site/pt recruitment model was applied to minimize selection bias; enrolment was stratified by country, region, and practice type. At baseline, pts' medical and disease features, treatment history, and remission status were documented. Prospective data regarding treatment, efficacy, and safety (treatment-emergent adverse events [TEAEs]) were electronically captured every 3 mos until 2 yrs after the last pt enrolled. Responses were investigator-assessed; no predefined response criteria were mandated. Here we report results from the third interim analysis of the study, with a focus on frontline therapy in MM pts who had undergone stem cell transplantation (SCT) at the time of data extraction.

Results: Between October 2010 and October 2012, 2353 pts were enrolled in 22 countries in Europe and Africa. Enrolment by practice type was 44% academic, 29% regional, 16% private, and 11% local clinics. The date of data extraction for the present analysis was 29 December 2014, at which time 772/2353 pts had undergone SCT in any treatment line. In the SCT population: pts' median age at MM diagnosis was 57.0 yrs (range, 25-74); 58% of pts were male; 13% had severe renal impairment; and 71% had bone lesions. In 679 pts with available staging data, 69% had ISS stage II/III disease (89% Salmon-Durie stage 2/3). Median duration of follow-up from diagnosis was 40 mos (range, 4-345) and from study entry was 28 mos (range, 0.4-46). The majority of pts (658/772; 85%) underwent only a single SCT procedure during the course of their disease. 534/772 (69%) pts were recorded (retrospectively or prospectively) as having received SCT in frontline. Prospective treatment data were available for 385 SCT pts, of whom 297 (77%) had received SCT upfront and 88 (23%) had received SCT in later lines. As part of their frontline treatment, 293 (76%) pts had received bortezomib-based combinations and 92 (24%) had received non-bortezomib combinations. Response rates to frontline therapy are summarized in the Table 1. Rates of higher-quality responses (very good partial response or better [≥VGPR]) appeared higher with bortezomib-based compared with non-bortezomib-based frontline therapy (65% *vs* 49%). Safety data were analyzed in the 293 pts who had received bortezomib-based combinations in frontline. The most common TEAEs were nausea (19%), diarrhea (18%), and pyrexia (17%). Peripheral sensory neuropathy and neuropathy peripheral were each reported in 28 (10%) pts. 12 (4%) pts experienced ≥1 serious TEAEs that were considered to be at least possibly related to bortezomib.

Table 1. Best response to frontline therapy (response-evaluable population, n=309)*.

	≥VGPR		PR		SD/MR		PD	
	n	%	n	%	n	%	n	%
Btz-based combinations (n=235)	152	65	64	27	14	6	5	2
Non-Btz-based combinations (n=74)	36	49	28	38	10	14	0	0
Total (all frontline combinations; n=309)	188	61	92	30	24	8	5	2

*Response data were missing for 76/385 SCT pts with available prospective data on frontline therapy received; this included 58/293 pts who received bortezomib-based combinations and18/92 pts who received non-bortezomib combinations as frontline therapy.
Abbreviations: Btz, bortezomib; MR, minimal response; PD, progressive disease; PR, partial response; SD, stable disease; VGPR, very good partial response.

Summary and Conclusions: Data from this real-world observational study appear to reflect experience in the prospective clinical trial setting. Bortezomib-based therapy was commonly used as part of frontline treatment in pts undergoing SCT in routine clinical practice, and produced substantial response rates. No new safety signals for bortezomib were observed.

E1256

ANALYSIS OF OVERALL SURVIVAL IN MULTIPLE MYELOMA PATIENTS WITH ³3 LINES OF THERAPY INCLUDING A PI AND AN IMID, OR DOUBLE REFRACTORY TO A PI AND AN IMID USING REAL WORLD DATA

S. Usmani[1,*] A. Desai[2], T. Ahmadi[3], Y. Ng[2], G. Sung[2], M. Mehra[2]

[1]Levine Cancer Institute/Carolinas Healthcare System, Charlotte, NC, [2]Janssen Global Services, Raritan, NJ, [3]Janssen Research and Development, Spring House, PA, United States

Background: Novel agents under evaluation for multiple myeloma (MM) treatment show promising initial results. Interpretation of these findings is challeng-

ing due to limited information about the natural history of MM in relapsed patients, particularly in patients treated with recently approved agents. Previously, an International Myeloma Working Group study determined the outcomes of patients refractory to bortezomib and at least 1 IMiD (Kumar S *et al.* Leukemia 2012; 26: 149). Since then pomalidomide (IMiD) and carfilzomib (PI) have been approved for relapsed and refractory MM in the United States (US).
Aims: To use real-world data to define the treatment landscape and natural history of heavily pretreated MM by identifying a cohort of patients with MM double refractory to a PI and IMiD or who had received ≥3 lines of therapy (LOT; including a PI and IMiD).
Methods: The data source was the IMS LifeLink: IMS Oncology Electronic Medical Records (EMR) Database (IMS Health Incorporated, all rights reserved) comprising US patients only. Cohort identification of the initial population included patients from the index period of 2000-2011, excluding those with prior cancer diagnoses. Approximately 88% of patients were diagnosed with MM in 2006 or later. Patients who received ≥3 LOT (including a PI and IMiD) and had shown disease progression within 60 days of completion of the most recent regimen, or had disease refractory to both a PI and IMiD were identified as the target population. MM drugs considered for regimen analysis included PIs (bortezomib, carfilzomib), IMiDs (thalidomide, lenalidomide, pomalidomide), and chemotherapy/steroids (melphalan, cyclophosphamide, dexamethasone). Median overall survival (OS) was assessed based on age; gender, ECOG status at last line of therapy; degree of refractoriness; or prior LOT (≥6 *vs* <6).
Results: Of screened 4,030 patients with multiple myeloma, 101 were excluded for prior cancer diagnoses, 2,918 patients were available for regimen analysis, and 500 met the criteria for the target population. Median ages at diagnosis and eligibility were 66 and 70 years, respectively. At eligibility, 52% were male and 26% had an ECOG score ≥2. Of the 500 patients, 177 received ≥3 prior LOT including a PI and IMiD. The remaining 323 (65%) patients met the criteria of double refractory disease, 22% of whom were triple (n=61) and quadruple (n=9) refractory. Overall, patients received a median of 3 (range, 1-25) prior LOT. All patients received 1 LOT after designation of eligibility, 298 received 2 LOT, and 169 received 3 LOT. Exposure to novel agents was 22% (carfilzomib, 16%; pomalidomide, 6%) at first LOT with >80% as a single agent. Median OS for the full eligible population of 500 patients was 239 days. Median OS was significantly higher in patients aged <65 *versus* ≥65 years (289 *vs* 204 days; P <0.01), but was not significantly different by gender (male, 228 days *vs* female, 260 days). Median OS was 228 days for double refractory patients, 154 days for triple/quadruple refractory, and 350 days for those that received ≥3 prior LOT including a PI and IMiD but were not double refractory. Median OS was 239 days for ECOG score ≤2 *versus* 87 days for ECOG score >2 (P <0.0001). Median OS was 274 days in patients with ≥6 prior LOT compared with 190 days in those with <6 prior LOT (P=0.09).
Summary and Conclusions: These real-world data confirm poor outcomes in patients relapsed or refractory to current MM treatments and highlight the unmet clinical need for novel therapeutic agents for the treatment of heavily treated patients.

E1257

DETECTING EARLY RELAPSE IN MULTIPLE MYELOMA AFTER ASCT: USEFULNESS OF IMMUNEASSAYS

M.M. Andrade Campos[1,*] I. Murillo Florez[2], E. Colorado Ledesma[2], P. Giraldo[3]
[1]Traslational Research Unit, CIBERER, IIS-A, Hematology, Miguel Servet University Hospital, [2]Hematology, Miguel Servet University Hospital, [3]Traslational Research Unit, CIBERER, IIS-A, FEETEG, Zaragoza, Spain

Background: There are new tools for accurate follow-up and diagnosis assessment in Multiple Myeloma (MM) patients. While the Free Light chain immunoassay (FLC) (Bindingsite, Birmingham, UK) is part of the mandatory response assessment according to IMWG-criteria and recently one of the criteria for diagnosis, the role of the Heavy/Light Chain immunoassay (HLC), is still under investigation with promissory results. Relapses in MM patients are frequent and there is an especial interest in select therapy for consolidation/maintenance after Autologous Stem Cell Transplantation (ASCT) and to detect early relapse to optimize the therapy. We hypothesized that the combination of these techniques could permit to detect early biological (non-symptomatic) relapses (EBR) in these kind of patients.
Aims: To analyze the usefulness of HLC and FLC to detect EBR in MM after ASCT in our hospital.
Methods: A retrospective study was performed including all consecutive patients treated in our center, following these criteria: Diagnosed of secretory MM, upfront-therapy including ASCT between May 2011-August 2014, assessed with our protocol including FLC, HLC, serum and urine electrophoresis (SPE, UPE) with immunofixation (IFX), previous to ASCT, after 12 weeks and every 3 months later with a minimum follow-up of 6 months after ASCT. EBR was defined as an increase of 25% on M-protein (any amount for patients on CR/SR) and/or an increase of >o=20mg/dl for FLC, and/or 25% increase on involved HLC with abnormal ratio. For urine, an increase >500mg/24 hrs of involved free-chain protein.
Results: Fifty-five patients were registered. Median follow-up 21 months. MF ratio: 29/26, mean age 59.5 y (33-71). Immunoglobulin subtype: IgG-Kappa: 41.8% (23), IgG-Lambda: 23.6% (13), IgA-Kappa: 16.4% (9), IgA-Lambda: 7.3% (4), Bence-Jones-Kappa: 3.6% (2), Bence-Jones-Lambda: 7.3% (4). Durie-Salmon Stage: IA: 13.5% (7), II-A: 32.7% (17), III-A: 44.2% (23), III-B: 9.6% (5), missing-data 3 case. All patients received Bortezomib based therapy and MEL200 as conditioning regimen. Status pre-ASCT: minimal response: 12%, Partial Response (PR): 50.0%, very-good-PR (VGPR): 28.0%, complete response (CR): 6% and string response (SR): 4.0%. After ASCT, evaluation reveals that 13.0% achieved SR, 13.0% CR, 30.4% VGPR and 39.1% PR. During follow-up, 27/50 (54.0%) patients who achieved at least PR after ASCT, had a clinical relapse/progress, median PFS 24 months (19.8-28.1). EBR were detected in 19/27 relapsed patients at median time 7 (2-19) months before symptomatic relapse. The EBR were detected by FLCr (31.6%), HLCr (21.0%), FLC+SPE (10.5%), FLC+IFX (5.2%), FLC+HLC+SPE (15.8%), FLC+HLC+SPE+UPE (15.8%).
Summary and Conclusions: Both FLC and HLC are useful tools to detect EBR, in our cohort in more than 50% of patients ahead other techniques. A review of the criteria to re-introduction of therapy and research on this field are warranted.

E1258

MYELOMA MULTIPLE IN PATIENTS AGED ≥80 YEARS, A GROUP IN CONSTANT GROWTH: EXPERIENCE OF A SINGLE CENTER

C. Villegas[1,*] P.L. Pérez[1], M.T. Orero[1], S. Ortiz[1], K.P. Javier[1], R. Collado[1], D. Ivars[1], M. Roig[1], I. Luna[1], F. Carbonell[1]
[1]HEMATOLOGIA, HOSPITAL GENERAL UNIVERSITARIO, VALENCIA, Spain

Background: In the last decades, the median age at diagnosis of MM cases and the proportion of very old patients (>80 years) have increased. However they are underrepresented in clinical trials.
Aims: The objective of this study is to analyze the clinical features and outcome of very elderly patients with MM and the impact of therapeutic advances in this group of patients.
Methods: We conducted a retrospective analysis of patients with MM diagnosed at HGUV who were 80 years of age or older. The characteristics evaluated included ISS staging, hemoglobin, calcium, renal function, M-protein, cytogenetic study and bone disease. We review treatment, response rate (RR), early mortality and overall survival (OS), and we compare the outcome with those of patients from 65 to 79 years old.
Results: Among 311 patients with MM diagnosed at HGUV from January 1990 to December 2014, 70 (22.5%) were ≥80 years (median age 82.5 years, range 80-93 years) and 166 (53.4%) between 65-79 years, 46% (n=32) males and 54% females (n=38). The proportion of ≥80 years patients increase from 18% in 1990-1999 to 22.4% in 2000-2009 and to 25.6% in 2010-2014. Compared to 65-79 years, octogenarian had more frequently ISS 2-3 (73 *vs* 89.6%, p=0.02) and renal impairment (56.9%vs67.2%;p=0.35), with a similar incidence of severe RI (21.5% and 22.4% respectively). No significant differences were observed in hemoglobin, calcium, and bone disease between both groups. Cytogenetic data were available for 43 patients (63.2%). The incidence for del 17p was 2.4%, 4.9% for t(4;14) and 14.6% for del (13) in ≥80 years group and 4.5%, 9.1% and 6.8% respectively in 65-79 years. There was no significant differences in proportion of smoldering MM between ≥80 years old patients (13.3%) and 65-79 years group (17.7%)(p=0.29). Data from front line therapy were available for 59 patients. Fifteen patients (25.3%) were considered unable to tolerate standard therapy, 4 (6.7%) received steroid alone and 11 (18.6%) only supportive therapy. As first line treatment, 24 patients received melphalan-prednisone (MP) and 13 bortezomib-based regimens (BBR) (with MP:6, Dexamethasone:5 or bendamustine:2). Overall RR (≥partial response) was 44% in ≥80 years. RR were higher in 65-79 years group (60.25%). The median follow up was 27 months in the younger group and 15 months in ≥80 years. Early mortality (≤2 months) was 17.14% in octogenarians and 11.44% in the 65-79 years group. (p=0.236) The median OS was 18 months for ≥80 years and 35 months for 65-79 years group (Log Rank p=0.009). However, there was no significant difference when we excluded patients without active treatment due to comorbid conditions or the smoldering MM. In the subset of 65-79 years, patients treated with VMP had better OS compared with MP (42 *vs* 29 months; p=0,026). However in the ≥80 years group no significant difference in OS between patients treated with MP and BBR was observed.
Summary and Conclusions: Our study evidences that octogenarian MM patients shows shorter OS compared with old patients between 65-79 years. The high rate of ≥80 years patients who are not fit for standard treatment (25%), the high frequency of early mortality (17%) and advanced ISS staging have a negative impact on survival. We have not observed an improvement on OS with BBR in octogenarian patients, however the number of patients was low. Beside the fact that we need more clinical trials that include octogenarian patients, we think that these patients are frail and need an especial approach in terms of treatment and management.

E1259

RESPONSE AND EARLY RELAPSE ASSESSMENT IN MULTIPLE MYELOMA TREATED WITH BORTEZOMIB: ROLE OF HEAVY/LIGHT-CHAIN IMMUNEASSAY

M.M. Andrade Campos[1,*] E. Colorado Ledesma[2], I. Murillo Florez[2], P. Giraldo[3]
[1]Traslational Research Unit, CIBERER, IIS-A, Hematology, Miguel Servet University Hospital, [2]Hematology, Miguel Servet University Hospital, [3]Traslational Research Unit. CIBERER, IIS-A, FEEHA, Zaragoza, Spain

Background: Multiple Myeloma (MM) is characterized by multiples relapses, for that reason the objective of MM therapy is to achieve the most deeper and sustained response; actual approaches included a consolidation and/or a maintenance period with a close monitorization to assess the relapses and identified the best moment to re-start the therapy. The routinely follow-up for minimal residual disease in MM is based in the M-protein quantification by serum and urine electrophoresis (SPE, UPE) with immunofixation (IFX). The incorporation of Serum Free Light Chain Assay (FLC), and the quantification of paired clonal and non-clonal immunoglobulins (HLC) in serum, offers the possibility to assess the response to therapy more accurately detecting early non-symptomatic (biological) relapses (EBR).
Aims: To analyze the usefulness of HLC and FLC during MM follow-up to detect EBR in patients who received Bortezomib-based first line therapy in MM patients in our center.
Methods: Since January 2008 we have incorporate in the protocol for M-components assessment the quantification of FLC, later the HLC; both at baseline and in follow-up of MM. We have analyzed these parameters in all consecutive patients diagnosed as secretory MM who complete at least 4 cycles of Bortezomib-based upfront therapy between Jan 2008-Jun 2014 in our center.
Results: A total of 135 MM patients started bortezomib-based therapy. Median follow-up 25 months. Females: 40.7%, mean age 69.6 y (32-91). Subtype: IgG-Kappa: 38.2%, IgG-Lambda: 9,8%, IgA-Kappa: 17.9%, IgA-Lambda: 15,4%, IgDL: 1.6%, Bence-Jones-Kappa: 6,5%, Bence-Jones-Lambda: 8,9%, oligosecretory: 1.6%. Durie-Salmon Stage: IA: 9.8%, IB: 1.6%, II-A: 27.6%, IIB: 8.9%, III-A: 21.1%, III-B: 21.1%. ISS: I: 25.2%, II: 32.5%, III: 23.6%. The 21.1% of patients were not included in the analysis of response by uncompleted treatment. Response at end of therapy: minimal response: 5.1%, PR: 44.3%, VGPR: 16.5%, CR: 14.4% SR: 7.2%, Failure: 12.5%. During follow-up 65.7% patients, who achieved at least PR had clinical relapsed/progressed, in 86.9% of them, a previous EBR were detected at a mean of 4.4 months before; methods who detected BER: FLCr (28.8%), HLCr (13.5%), FLC+SPE+IFX (9.6%), FLC+IFX (5.8%), FLC+HLC+SPE (28.8%), FLC+HLC+SPE+UPE (5.7%) Median PFS 20 months (12.8-27.1) Biological PFS: 18 m (12.1-23.8).
Summary and Conclusions: Both FLCr and HLCr are sensitive and précised tools to perform MRD assessment response in MM, in our cohort a 42.3% of EBR were detected ahead of other techniques. More investigations on the role of EBR for therapy initiation are necessary.

E1260

MAJOR CARDIOVASCULAR EVENTS AND COMORBIDITIES IN PATIENTS NEWLY DIAGNOSED WITH MULTIPLE MYELOMA

N. Brandenburg[1], S. Phillips[2], N. Minton[3,*] S. Oliveria[2]
[1]Global Drug Safety and Risk Management, Celgene, Berkeley Heights, [2]Epidemiology Research Group, New York, [3]Drug Safety, Celgene, Berkeley Heights, United States

Background: Multiple myeloma (MM) is a common hematological cancer in the United States and 62% of patients (pts) diagnosed with MM are aged ≥65. While cardiovascular diseases (CVDs) are prevalent in the older population, the prevalence of CVD and CVD risk factors in pts with newly diagnosed MM (NDMM) have not been well described. In a Swedish study comparing the risk of arterial thrombosis (coronary artery disease and cerebrovascular disease) between 18,627 MM pts diagnosed between 1958 and 2006 relative to 70, 991 controls matched by age, sex, and county of residence, the risk of arterial thrombosis was significantly increased at 1, 5, and 10 years of follow-up (hazard ratio at 1 year=1.9; 95% confidence interval, 1.8-2.1). Mechanisms by which MM pts may be at increased risk of arterial thrombosis are not well understood and thus it is important to understand the prevalence of CVD comorbidities in NDMM pts.
Aims: To describe and characterize the prevalence of prior CVD comorbidities including major arterial events, in NDMM pts and to compare the prevalence of these comorbidities in pts <75 and ≥75 years of age.
Methods: This was a descriptive analysis of NDMM pts aged ≥18 years with Medicare/Medicare Part D coverage in the SEER-Medicare database from July 1, 2007 to December 31, 2009. Pts had continuous enrollment 6 months prior to and 3 months after diagnosis and did not have renal disease requiring dialysis. Comorbidities were identified using International Classification of Diseases, 9th Revision-code-based algorithms.
Results: We identified 3,920 NDMM pts, of whom 1,937 (49.4%) were female, 2,770 (70.7%) were White, and 3,662 (93.4%) were ≥65 years at diagnosis (1,457 (37.2%) were ≥age 75). A Charlson comorbidity score of 0 (lowest risk for 10-year mortality) was present in 2,544 (64.9%) pts. Overall, 212 (5.4%) and 130 (3.3%) NDMM pts had a previous diagnosis of acute coronary syndrome or myocardial infarction (MI) and prior diagnoses of stroke or transient ischemic attack (TIA) were noted in 179 (4.6%) and 123 (3.1%) pts, respectively. Heart failure (HF) was noted in 706 (18.0%) pts, atrial fibrillation in 382 (9.7%) pts, and conduction disorders in 323 (8.2%) pts. Of conditions associated with increased cardiovascular risk, 2,256 (57.6%) had hypertension, 2,109 (53.8%) had hyperlipidemia, and 706 (18.0%) had diabetes.
Most CVD comorbidities were more prevalent among those aged ≥75 (Table 1).

Table 1. Comorbidities Present in Multiple Myeloma Patients at Diagnosis by Age <75 and ≥75 in the SEER-Medicare Database between July 1, 2007 and December 31, 2009 (N=3,920).

	Overall N=3,920	<75 years N=1,851	≥75 years N=2,069
Comorbidity	**N (%)**	**N (%)**	**N (%)**
Acute coronary syndrome/unstable angina	212 (5.4)	87 (4.7)	125 (6.0)
Acute myocardial infarction	130 (3.3)	46 (2.5)	84 (4.1)
Atrial fibrillation	382 (9.7)	104 (5.6)	278 (13.4)
Stroke	179 (4.6)	66 (3.6)	113 (5.5)
Transient ischemic attack	123 (3.1)	46 (2.5)	77 (3.7)
Conduction disorders	323 (8.2)	88 (4.8)	235 (11.4)
Diabetes	706 (18.0)	363 (19.6)	343 (16.6)
Heart failure	706 (18.0)	231 (12.5)	475 (23.0)
Hyperlipidemia	2,109 (53.8)	990 (53.5)	1,119 (54.1)
Hypertension	2,256 (57.6)	994 (53.7)	1,262 (61.0)

Summary and Conclusions: While the background prevalence of major arterial events (acute coronary syndrome, MI, stroke, TIA) was low, there were large numbers of pts with other CVD comorbidities at MM diagnosis. Existing HF at MM diagnosis was noted in 23% of those ≥75 years of age. Recognition of these underlying CVD comorbidities may influence clinical management of NDMM and may assist in understanding the pathogenesis of arterial thromboembolism in these pts.

E1261

ASSESSING TREATMENT RESPONSE IN MULTIPLE MYELOMA: IMPLICATIONS OF USING BONE MARROW PLASMA CELL CONTENT AS A MARKER OF DISEASE BURDEN

A.K. Abou Hussein[1,*] S.V. Rajkumar[1], A. Dispenzieri[1], M. Gertz[1], M. Lacy[1], F. Buadi[1], S. Hayman[1], D. Dingli[1], Y.L. Hwa[1], J. Lust[1], S. Russell[1], P. Kapoor[1], R. Go[1], R. Kyle[1], S. Kumar[1]
[1]Hematology, Mayo Clinic- Rochester/Minnesota, Rochester, United States

Background: Unlike the majority of malignancies, myeloma tumor burden can be assessed either directly by the tumor cell content per bone marrow examination, or indirectly by the quantity of paraprotein being secreted by the plasma cells. Contemporary response criteria primarily place primacy on the quantitation of serum or urine monoclonal protein, or should these be inadequate, serum free light chain levels. Bone marrow plasma cell content (BMPC) is currently a secondary metric employed when the aforementioned are non-applicable, as in non-secretory myeloma, as well as to characterize deep responses such as complete response.
Aims: To study the correlation between marrow plasmacytosis and monoclonal protein levels, differential treatment effects, and possible implications of any discrepancies.
Methods: We identified 845 patients with newly diagnosed MM treated at Mayo Clinic who demonstrated measurable disease by serum or urine M protein (1 gm/dl and 200 mg/24 h, respectively) or by serum FLC (dFLC >=10 mg/ml); 628 (74%) were evaluable by BMPC criteria. Comparisons were made between (i) treatment responses based on IMWG criteria and BMPC change, (ii) variations of response with respect to specific regimens, and (iii) the effect on survival outcomes.
Results: The median age of the group was 60.5 y; 59% were male, and 58% were alive at the time of analysis. Initial therapy included conventional chemotherapy (13%), dexamethasone (13%), IMiD based (44%), proteasome inhibitor (PI) based (19%), or PI-IMiD combination (11%). When using IMWG criteria, 74% demonstrated partial response, ranging between 58% for conventional therapies to 94% with PI-IMiD combinations. Similarly, when using BMPC criteria for PR per >=50% decrease, 73% of the evaluable patients achieved PR. Overall, 484 (80%) of the 604 patients who were evaluable by both BMPC and M protein demonstrated concordant results by BM and M protein/FLC measurement. Of the remaining 120 patients, 50 demonstrated PR solely by BMPC criteria, while 70 achieved PR by M protein/FLC measures only. When measurable BMPC was defined as >=20%, 679 patients were evaluable by both measures, and the concordance rate remained at 80%. The ratio between serum M protein reduction (%) and the BMPC reduction (%) was compared between conventional and novel therapies. The ratio was significantly lower with conventional therapies (median 0.83) when compared to novel therapies (median 1.02), p <0.01. This suggests

that the BMPC% does not decrement proportionately to the degree of decrease in M protein with novel therapies, which could be consistent with a cytostatic rather than a cytotoxic effect. The median OS for those with a concordant PR by the two measures was superior compared to those who were discordant or not in a PR by either system (p=0.02).
Summary and Conclusions: The current convention of identifying PR by specifying BMPC reduction by >50% with a baseline of >=30% is concordant with M protein criteria for PR in 80% of this cohort. Using a lower threshold of 20% BMPC at baseline had no demonstrable change in PR concordance. Superior median OS was associated with PR concordance between both M protein and BMPC assessments.

E1262

PATIENT EXPERIENCE WITH LIGHT CHAIN AMYLOIDOSIS: A SURVEY FROM THE AMYLOIDOSIS RESEARCH CONSORTIUM

I. Lousada[1,*] R. Comenzo[2], H. Landau[3], S. Guthrie[4], G. Merlini[5]
[1]Amyoidosis Research Consortium, [2]Tufts Medical Center, Boston, [3]Memorial Sloan-Kettering Cancer Center, New York, [4]Prothena Biosciences Inc, South San Francisco, United States, [5]Fondazione IRCCS Policlinico San Matteo and University of Pavia, Pavia, Italy

Background: Light chain (AL) amyloidosis is caused by an accumulation of misfolded proteins, resulting in dysfunction of vital organs (*e.g.*, heart, kidneys, liver, soft tissue). The protean clinical features of AL amyloidosis reflect its systemic nature, and initial symptoms are often nonspecific (*e.g.*, weight loss, fatigue). Consequently, a correct diagnosis is frequently made only after the disease has become advanced. Therapy is directed at the plasma cells that produce the pathogenic proteins. In advanced disease, treatment may be associated with significant adverse effects. 20% to 30% of patients die within 3 to 6 months of initiating therapy. Diagnosing the disease and accessing appropriate therapy pose significant challenges, and there is a paucity of literature depicting the patient experience. This not only impacts patients' quality of life (QoL) but likely also their survival. Such information may identify unmet clinical needs and ways to improve patient care and disease outcomes.
Aims: The primary aims of this study were to identify the challenges in establishing a diagnosis of AL amyloidosis and to gain insight into the AL patient experience.
Methods: Patients, family members, and caregivers were invited to participate in an anonymous online survey through email and social media channels of the Amyloidosis Foundation and an amyloidosis awareness group on Facebook. The 16-question survey was developed by the authors and was available to participants online from January 29 to February 5, 2015. Eight follow-up questions were sent via email to those who responded.
Results: A total of 507 persons completed the survey (patients, 57%; family members, 34%; caregivers, 8%). Most responders were female (63%) and between 50 and 69 years of age (63%). Average age at diagnosis was 57 years. Initial symptoms included fatigue, shortness of breath, weakness, neuropathy, swelling of the legs, and enlarged tongue. The organs most frequently involved included the heart (36%) or kidney (28%); 21% reported multiple organ involvement. Time from initial symptoms to correct diagnosis was more than 1 year in 38% of responders; 31% met with 5 or more physicians before a correct diagnosis was made (Figure 1). Diagnosis occurred at 144 institutions. 62% of responders were evaluated at an amyloidosis center, and 43% received treatment at an amyloidosis center. Almost half (40%) the responders reported receiving no disease-specific information or education. Clinical trial information was provided to only 24%. Almost half (46%) the responders would consider enrolling in a clinical trial if they felt well informed; yet 45% did not know how to enroll. Difficulty tolerating treatment was reported by 54% (93/173) of responders. Following therapy, no improvement in QoL was reported by 30%, with some improvement and definite improvement reported by 40% and 30%, respectively (175 QoL responses). Updated results will be presented.

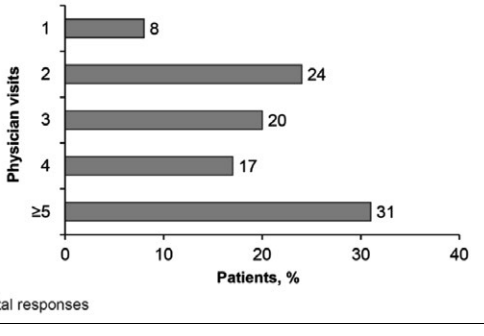

Figure 1. Number of physician visits before establishment of a diagnosis.

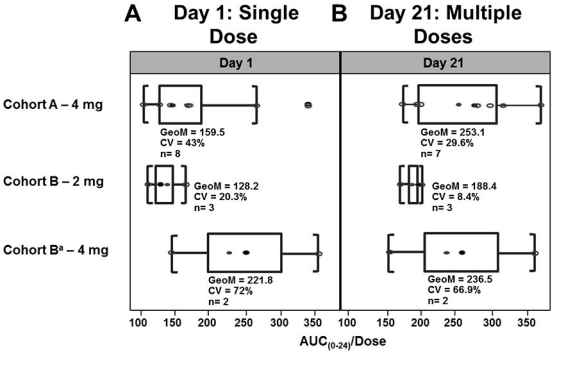
Summary and Conclusions: A correct diagnosis of AL amyloidosis often requires numerous physician visits to different medical specialists and often occurs when disease is advanced. The responses obtained in this patient survey highlight the challenges experienced by patients with AL amyloidosis. These data may identify opportunities to educate patients and physicians in order to expedite diagnosis, facilitate appropriate disease management and access to clinical trials, and ultimately improve patient survival.

E1263

POMALIDOMIDE+LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA AND RENAL IMPAIRMENT: PHASE 1 PHARMACOKINETICS AND SAFETY

J. Matous[1,*] D. Siegel[2], S. Lonial[3], R.D. Harvey[3], C. Kasserra[4], Y. Li[4], M. Chen[4], T. Doerr[4], L. Sternas[4], M. Zaki[4], C. Jacques[4], J. Shah[5]
[1]Colorado Blood Cancer Institute, Denver, [2]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, [3]Emory University, Atlanta, [4]Celgene Corporation, Summit, [5]Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Twenty percent to 40% of patients (pts) with multiple myeloma (MM) exhibit renal impairment (RI), which is associated with poor outcomes (Eleutherakis-Papaikovou *et al.*, *Leuk Lymphom,* 2007; Knudsen *et al.*, *Eur J Haematol,* 2000). Two percent to 13% of these patients require dialysis (Blade *et al.*, *Best Pract Res Clin Haematol*, 2005). More than 95% of pomalidomide (POM) is hepatically metabolized, and <5% is renally excreted as the parent drug; hydrolysis products and phase I metabolites of POM are less potent with respect to antimyeloma and immunomodulatory effects (Hoffmann *et al.*, *Cancer Chemother Pharmacol*, 2013). POM in combination with low-dose dexamethasone (LoDEX) has shown efficacy in pts with refractory or relapsed and refractory MM (RRMM) and moderate RI (creatinine clearance [CrCl] <30-44 mL/min; Siegel *et al.*, *Blood,* 2012; Weisel *et al.*, *J Clin Oncol,* 2013). However, POM+LoDEX has not yet been fully studied in pts with severe RI (CrCl <30 mL/min; serum creatinine ≥3 mg/dL) because these pts were excluded from prior trials.
Aims: MM-008 is a multicentre, open-label phase 1 study designed to assess pharmacokinetics (PK) and safety of POM+LoDEX in RRMM pts and normal or severely impaired renal function with or without dialysis.
Methods: Pts with RRMM (≥1 prior treatment [Tx]) and normal kidney function or mild RI (creatinine clearance [CrCl] ≥60 mL/min; Cohort A-control arm), severe RI (CrCl <30 mL/min) not requiring dialysis (Cohort B), and severe RI requiring dialysis (Cohort C) were eligible. Cohort A received POM 4 mg, and Cohort B received POM 2 or 4 mg on days 1-21 of a 28-day cycle, following a 3+3 dose-escalation design. Cohort B results informed the 4-mg dosage used in Cohort C. All cohorts received DEX 40 mg (20 mg for pts aged >75 yrs) on days 1, 8, 15, and 22. Tx continued until disease progression or unacceptable toxicity. Dose-limiting toxicities (DLTs) were defined as: grade (Gr) 4 neutropenia, febrile neutropenia, Gr 4 thrombocytopenia involving ≥30% decrease in platelet count from baseline and requiring >1 platelet transfusion, Gr 3 thrombocytopenia with significant bleeding (requiring hospitalization and/or platelet transfusion), Gr 4 infection, or ≥Gr 3 other non-hematologic toxicity related to POM. Serial plasma samples were analyzed to generate PK parameters.
Results: Current data for 15 treated pts were available (8 in Cohort A, 3 in Cohort B at 2 mg, and 4 in Cohort B at 4 mg). Median age was 66 yrs (range, 46-76 yrs), 60% (9/15 pts) were male, all had Eastern Cooperative Oncology Group performance status 0 (6/15 pts) or 1 (9/15 pts), and a median time from diagnosis of 3.8 yrs (range, 0.6-12.5 yrs). No DLTs were reported for any cohort in cycle 1. The most common Gr ≥3 adverse events (AEs) were neutropenia (47%), anemia (40%), infection (33%), and fatigue (13%). Median relative dose intensity was consistent across cohorts (0.9-1.1). Mean dose-normalized exposure ($AUC_{0\text{-}24}$) is shown in the Figure 1. One patient in Cohort A discontinued due to dyspnea and 1 discontinued due to pulmonary fibrosis; 1 in Cohort B 4 mg discontinued due to rash. No deaths have occurred during Tx or follow-up visits at 28 days post-Tx discontinuation.



[a] 3 patients in cohort B, 4 mg, were evaluable for pharmacokinetics; only 2 patients were evaluable for pharmacokinetics for each time point.
$AUC_{(0\text{-}24)}$, area under the plasma concentration-time curve from time of dosing (0) to 24 hr; CV, coefficient of variation; GeoM, geometric mean.

Figure 1.

Summary and Conclusions: The ongoing prospective trial MM-008 is examining the PK and safety of POM+LoDEX in pts with RRMM and severe RI. Preliminary PK data demonstrate similar mean dose-normalized exposure at a clinical dose of 4 mg POM in pts with severe RI and no or mild RI. Preliminary safety data and tolerability in this RRMM population are encouraging.

E1264

ALLOGENEIC STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA: 15-YEAR EXPERIENCE AT A SINGLE CENTER

A. Lario[1,*] D. Morillo[1], A. Vázquez[1], M. Cabero[1], C. Regidor[1], J.L. Bueno[1], I. Krsnik[1], J.R. Cabrera[1]
[1]Hospital Universitario Puerta de Hierro Majadahonda (Madrid), Majadahonda (Madrid), Spain

Background: Allogeneic stem cell transplantation (allo-SCT) may cure multiple myeloma (MM) but its role is still under discussion mainly for two reasons: the high morbidity and mortality related to the procedure (TRM) and the impressive results that can be attained with the new drugs.
We present our series of 29 patients with MM and an allo-SCT (2000-2015).
Aims: We present our results with Allo-SCT in a selected population and its posibility to control the disease.
Methods: *Patients:* N=29 (16 female, 13 male). Median age at diagnosis: 45 years (range 21-56). ISS-1: 9 patients (31%), ISS-2: 7 patients (24.1%), ISS-3: 13 patients (44.8%). Eighteen patients had previously received an autologous SCT (62%). The median time from diagnosis to allo- SCT was 494 days (range 122-1,668). State of the disease pre-SCT: complete remission (CR): 7 (24.1%), very good partial remission (VGPR): 10 (34.4%), partial remission (PR): 9 (31%), stable disease (SD): 2 (6.9%), progressive disease (PD) 1 (3.4%). *Transplantation procedure:* The conditioning regimen was myeloablative in 5 patients (17.2%); non-myeloablative in 24 (82.7%). Sixteen patients (55.1%) had received radiotherapy as part of the conditioning regimen. Type of donor: Related Adult Donor (RD): 21 (72.4%), Unrelated Adult Donor (UD): 5 (17.2%), Umbilical Cord Blood: 1 (3.4%), Haploidentical donor: 2 (6.9%).
Results: Response at day 100+: CR: 14 (48.2%), VGPR: 4 (13.8%), PR: 4 (13.8%), SD: 1 (3.4%), PD: 3 (10.4%), Not Evaluable: 3 (10.4%). The cumulative incidence of grade II-IV acute GVHD was 34.4% (10 patients), 7 of which received an allo-SCT from RDs and 3 from UDs. The incidence of moderate-to-severe chronic GVHD was 38% (11 patients). Two patients presented an overlap syndrome. Eleven patients progressed (38%) and were treated with a combination of anti-MM drugs and donor lymphocyte infusion. Ten patients died (34.4%), 6 from transplant-related complications (20.6%) and 4 because of MM progression. Nineteen patients are alive at the time of this report (65.5%), 10 of them in continuous complete remission (34.4%) having not required any further treatment for their disease. Their current ECOG performance status is: 0-1: 12 patients (63.2%), ≥2: 7 patients (36.8%). The median overall survival (OS) from diagnosis is 2,619 days (range 539-6,195). The median overall survival from allo-SCT is 1,951 days (range 25-5,963).
Summary and Conclusions: Allo-SCT when performed in a selected population of MM patients, has a low TRM even when using UD. A significant proportion of patients remain disease-free for a long time. Patients progressing may revert to a CR. The long OS of our series suggests a role of allo-SCT in the control of the disease.

E1265

TUMOR GROWTH IS ASSOCIATED WITH INCREASED MCD VALUES AND TISSUE EXPRESSION OF ENDOGLIN IN MULTIPLE MYELOMA

M. Devetzoglou[1], G. Tsirakis[1,*] R. Vyzoukaki[2], S. Kyriakaki[1], M. Kaparou[3], G. Metochianakis[2], I. Stagakis[1], E. Fasoulaki[2], I. Miminas[2], M. Alexandrakis[4]
[1]Haematology Department, University Hospital of Heraklion Crete, [2]Haematology Lab. University Hospital of Heraklion Crete, [3]Division of Haematology, Venizeleion Hospital of Heraklion Crete, [4]Laboratory of Haematology and Haematology Department, University Hospital of Heraklion Crete, Heraklion, Greece

Background: In multiple myeloma (MM) malignant plasma cells interact with bone marrow (BM) microenvironment's components and modify it, favoring in multiple manners tha expansion of the clone. The genesis of new blood vessels, in order to provide the suitable conditions for the expanding malignant mass is a dynamic and complex pathological phenomenon with a major role in tumor growth, invasion and disemination.
Aims: The aim of the present study was to evaluate the expression of endoglin in the BM of MM patients. An effort was made to correlate this marker with mast cell dencity (MCD), the angiogenic cytokine angiopoietin-2(angiop-2) and plasma cell nuclear antigen (PCNA).
Methods: BM microvascular dencity (MVD) was estimated by endoglin using immunohistochemical methods in 57 patients with MM up to diagnosis. MCD was evaluated with the same method. Circulating levels of angiop-2 were measured by ELISA in the same group of patients. Plasma cell proliferation index, PCNA was estimated with immunochemical methods. The same parameters were measured in 20 age- and sex-matched healthy controls.
Results: We found that endoglin-MVD along with the MCD and serum levels of angiop-2 and PCNA were increased significantly in patients with MM in comparison to control group ($p<0.001$ in all cases). Angiop-2 serum levels were also higher in advance disease stages($p<0.001$). Similarly CD105 expression, MCD, PCNA values were significantly increased in parallel with the stage of the disease. CD105 expression correlated significantly with MCD($r=0.566$, $P<0.001$), angiop-2($r=0.399$, $p<0.002$) while there was a trend to correlate with PCNA($r=0.0228$, $p>0.08$). All the measured parameters were higher in pre-treatment group in comparison with the post-treatment group($p<0.001$ in all cases).
Summary and Conclusions: Our results showed that angiop-2 and CD105 expression which reflect BM neovascularisation are increased in MM patients and correlate positively with MCD values. This findings indicate that CD105 and MCD could be used as potential tumor markers for disease severity and as possible target for MM treatment.

E1266

LONG-TERM OUTCOMES OF LENALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE (RD) IN CHINESE PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): MM-024 EXTENDED ACCESS PROGRAM (EAP)

Z. Cai[1,*] J. Jin[1], F. Chen[2], D.-B. Zhou[3], L. Yu[4], X. Ke[5], X. Li[6], D. Wu[7], F. Meng[8], D. DeMarco[9], J. Zhang[9], J. Mei[9], J. Hou[10], X. Du[11]
[1]The 1st Hospital, Zhejiang University, Hangzhou, [2]Xiangya Hospital of Central South University, Changsha, [3]Peking Union Medical College Hospital, [4]The 301 Hospital-Chinese PLA General Hospital, [5]Peking University Third Hospital, Beijing, [6]Shanghai 6th Hospital, Shanghai, [7]The 1st Affiliated Hospital of Soochow University, Suzhou, [8]Nanfang Hospital of Southern Medicine University in Guangzhou, Guangzhou, China, [9]Celgene Corporation, Summit, NJ, United States, [10]Department of Hematology, Shanghai Changzheng Hospital, Shanghai, [11]Guangdong General Hospital, Guangzhou, China

Background: In China, the Rd regimen is approved for use in relapsed/refractory multiple myeloma (RRMM) pts who have received ≥ 1 prior treatment (Tx). Approval was based on the efficacy and safety of Rd demonstrated in the MM-021 study, a phase 2 multicenter registration trial in which 199 pts were enrolled (Hou, J Hematol Oncol 2013), and the global MM-009/MM-010 trials (Dimopoulos; Weber, N Engl J Med 2007). MM-024 is an EAP initiated to provide continued Rd Tx for pts enrolled in MM-021, and as a follow-up on the long-term safety of the Rd regimen.
Aims: To present updated safety and efficacy outcomes from the MM-024 EAP.
Methods: MM-024 comprises of Tx and safety follow-up phases. Eligible pts for the Tx phase had participated in the MM-021 study, were still on Tx for ≥1 year (yr) and were progression-free. Pts received the same regimen of Rd as in MM-021 (lenalidomide 25 mg/day on days 1-21, and low-dose dexamethasone 40 mg/day on days 1, 8, 15, and 22 of each 28-day cycle). Starting doses of Rd were the same as the last doses received in MM-021 unless dose adjustments were required prior to rollover, per protocol. Tx was continued until progressive disease (PD) or withdrawal due to toxicities, and pts were followed for a maximum of 5 yrs (including 1 yr spent in MM-021). Pts who discontinued Tx in MM-021, and those who discontinued the MM-024 Tx phase were entered into safety follow-up phase. The primary endpoint was safety; secondary endpoints included progression-free survival (PFS) and overall survival (OS). All efficacy endpoints were measured from the enrollment date of MM-021.
Results: Of the 199 pts in the MM-021 trial, 80 transferred into the MM-024 study (data cutoff November 5, 2014); 41 pts entered the EAP Tx phase, 15 of whom are still receiving Tx. Overall, 26 pts discontinued Tx: 23 due to PD; 2 due to death; and 1 was lost to follow-up. Median follow-up for the treatment cohort was 43.3 months (mos) from initial enrollment in MM-021. In the safety population (n=80), median age was 59 yrs (range 35-76) and 28.8% of pts were aged >65 yrs. Most pts (80.0%) had Durie-Salmon stage III disease at baseline. All pts had received prior Tx for MM, median number was 4. A total of 6.3% of pts had undergone surgery and 3.8% of pts had received radiation Tx; 71.3% of pts had received prior bortezomib, 73.8% had received prior thalidomide, and 51.3% had received both. In the treatment cohort (n=41) median PFS was 36 mos, median OS has not been reached. In the safety population (n=80), 60% of pts had grade (Gr) 3-4 treatment-emergent adverse events (TEAEs); among the most common TEAEs (all grades) were anemia (58.8%), decreased neutrophil count (47.5%), upper respiratory tract infection (33.8%), neutropenia (32.5%), fatigue (23.8%), and thrombocytopenia (18.8%). Gr ≥3 TEAEs included neutropenia (20.0%), decreased neutrophil count (13.8%), anemia (11.3%), pneumonia (8.8%), and decreased white blood cell count (7.5%) (Table 1). No TEAEs led to Tx discontinuation; however, TEAEs led to lenalidomide dose reduction (7.5%), interruption (42.5%), or both (18.8%). There were 2 second primary malignancies reported, one of which occurred in the MM-021 study (solid duodenal tumor and nasopharyngeal carcinoma).
Summary and Conclusions: After 43.3 mos of follow-up in the treatment cohort, median PFS was 36 mos; in the MM-021 final analyses (cutoff date September 26, 2012) median PFS was 8.3 mos. The MM-024 safety profile was comparable to MM-021. This indicates long-term use of Rd is well tolerated and remains an effective Tx in Chinese pts with RRMM who have received multiple prior Tx.

Table 1. Gr 3-4 TEAEs reported in ≥3% of pts.

	MM-024 (N = 80)	MM-021 (N = 199)
Hematologic AEs		
Neutropenia	16 (20.0)	50 (25.1)
Anemia	9 (11.3)	52 (26.1)
Thrombocytopenia	5 (6.3)	29 (14.6)
Leukopenia	5 (6.3)	19 (9.5)
Nonhematologic AEs		
Pneumonia	7 (8.8)	26 (13.1)
Upper respiratory tract infection	5 (6.3)	8 (4.0)
Fatigue	4 (5.0)	8 (4.0)
Hypocalcemia	3 (3.8)	5 (2.5)
Hypokalemia	3 (3.8)	14 (7.0)
Investigations		
Decreased neutrophil count	11 (13.8)	17 (8.5)
Decrease white blood cell count	6 (7.5)	14 (7.0)
Decrease platelet count	4 (5.0)	14 (7.0)
Discontinuation due to AEs	0	18 (9.0)

All values n (%).
TEAE, treatment-emergent adverse event.

E1267

STAT3 EXPRESSION IS ASSOCIATED WITH POOR SURVIVAL IN YOUNG PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

S.-H. Jung[1,*] H.-W. Choi[2], M.-G. Shin[2], D.-H. Yang[1], J.-S. Ahn[1], Y.-K. Kim[1], H.-J. Kim[1], J.-J. Lee[1]
[1]Department of hematology-oncology, [2]Department of laboratory medicine, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic of

Background: The signal transduced and activator of transcription 3 (STAT3) is a key signaling molecule implicated in the regulation of growth and malignant formation, and is considered as prognostic marker in various type of cancer.
Aims: In this study, we investigated the prognostic significance of STAT3 expression in young patients with newly diagnosed multiple myeloma (MM).
Methods: Ninety-four patients under the age of 65 years were enrolled between June 2005 and March 2013. Dual immunochemical staining (IHC) for phosphotyrosine-STAT3 (PY-STAT3) and CD138 on paraffin-embedded bone marrow sections at diagnosis was performed to evaluate tumor cell-specific PY-STAT3 expression. Patients with PY-STAT3 expression were classified into two groups according to diffuseness of IHC staining (a cut off value -30%): weak or strong.
Results: PY-STAT3 was detected in 10 patients (10.6%) at diagnosis and three showed strong-expression. Compared to PY-STAT3 negative patients, PY-STAT3 positive patients show higher C-reactive protein and serum calcium level at diagnosis. Over a median follow up of 38.9 months, PY-STAT3 positivity had predictive value for progression-free survival (PFS) (*P*=0.001) and overall survival (OS) (*P*=0.003). In addition, the median PFS was significantly shorter for strong-positive patients than for other patients. (8.7 months in strong-positive *vs* 11.1 months in weak-positive *vs* 23.0 months in negative patients, respectively, *P* <0.001). In 60 patients who received front-line autologous stem cell transplantation, PY-STAT3 positive patients showed poor PFS compared to PY-STAT3 negative patients (4.2 *vs* 19.2 months, *P*=0.013). In the multivariate analysis, PY-STAT3 expression was an independent prognostic factor for PFS (relative risk (RR) of 2.706, *P*=0.014) and OS (RR of 3.091, *P*=0.044) in young patients with MM (Figure 1).

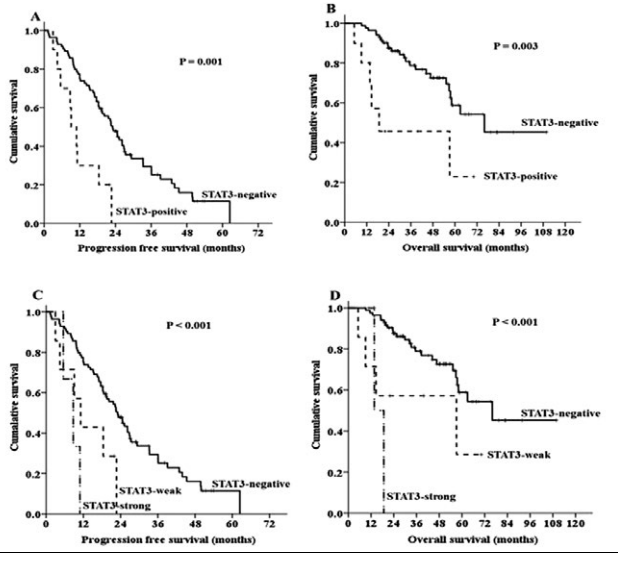


Figure 1. Kaplan-Meier survival curbes for progression-free survival and overall survival according to PY-STAT3-positivity (A, B) and diffuseness of PY-STAT3 expression (C, D).

Summary and Conclusions: These data suggested that PY-STAT3 positivity using dual IHC method was significant prognostic marker in young patients with MM.

E1268

HEPATITIS B REACTIVATION IN MULTIPLE MYELOMA PATIENTS WITH RESOLVED HEPATITIS B UNDERGOING CHEMOTHERAPY

J.Y. Lee[1,*] S.H. Lim[1], M.-Y. Lee[1], H. Kim[1], D.H. Sinn[1], G.-Y. Gwak[1], M.S. Choi[1], J.H. Lee[1], C.W. Jung[1], J.H. Jang[1], W.S. Kim[1], S.J. Kim[1], K. Kim[1]
[1]Samsung Medical Center, Seoul, Korea, Republic of

Background: Despite increasing reports of hepatitis B virus (HBV) reactivation in multiple myeloma (MM), HBV reactivation in patients with resolved hepatitis B [hepatitis B surface antigen (HBsAg)-negative/anti-hepatitis B core antigen antibody (anti-HBc)-positive] is still poorly characterized.
Aims: The aim of this study was to clarify its frequency and risk factors.
Methods: A total of 230 MM patients with resolved hepatitis B were retrospectively reviewed for HBV reactivation and biochemical flare.
Results: During a median 2.4 years of follow-up, HBV reactivation was diagnosed in 12 patients (5.2%). The cumulative rates of HBV reactivation at 2 years and 5 years were 5% and 8%, respectively. A baseline anti-HBs-negative status (*P*=0.033) and high-dose therapy/autologous stem cell transplantation [HDT/ASCT (*P*=0.025)] were significant risk factors that were positively associated with HBV reactivation. In subgroup analysis of patients treated with HDT/ASCT (n=127), a baseline anti-HBs-negative status was the only significant risk factor for HBV reactivation (hazard ratio, 4.64; 95% CI, 1.47-14.7; *P*=0.009).
Summary and Conclusions: These data show that evaluation of anti-HBc is needed for MM patients, and suggest that monitoring of HBV DNA should be considered for patients with resolved hepatitis B undergoing HDT/ASCT, especially those who are anti-HBs-negative.

E1269

POTENTIAL THERAPEUTIC TARGETS IN PLASMA CELL DISORDERS: A FLOW CYTOMETRY STUDY

K. Lisenko[1,*] S. Schönland[1], U. Hegenbart[1], K. Wallenwein[1], U. Braun[1], E. Mai[1], J. Hillengass[1], M. Raab[1], A. Jauch[2], A.D. Ho[1], H. Goldschmidt[1,3], M. Hundemer[1]
[1]Department of Hematology, Oncology and Rheumatology, [2]Insitute of Human Genetics, [3]National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, Germany

Background: The discovery of new targets for tailored therapy is a major improvement in oncology and tools for rapid and reliable detection of those targets are essential. Clinical trials show the benefit of recently developed therapeutic antibodies against antigens on malignant B-cells. Although the occurrence of these antigens on malignant plasma cells is sporadic, targeting those antigens is a therapeutic option in patients with plasma cell disorders.
Aims: The aim of this study was to assess plasma cell disorders cases for biomarkers that have exhibited promise in targeted cancer therapy.
Methods: We retrospectively analyzed patients with amyloid light-chain (AL) amyloidosis (n=30), monoclonal gammopathy of unknown significance (n=9), smoldering myeloma (n=17), newly diagnosed symptomatic multiple myeloma cases (n=25) and multiple myeloma cases in progressive stage of disease (n=22) that were diagnosed in our clinic from Mai to October 2014. An analysis of CD52, CD20, CD30, CD22, CD27, CD38, CD81, CD138 and SLAMF7 expression on bone marrow plasma cells was performed by multiparametric flow cytometry. Furthermore we studied FISH analysis data of all patients for t(11;14) in order to correlate immunophenotyping and genetic parameters.
Results: The expression frequency of CD52, CD30 and CD22 on plasma cells was similar to other studies (12-35%, 0-19% and 0-8%, respectively). Unexpectedly, we observed a high CD20 expression frequency on plasma cell in AL-amyloidosis up to 37% of all examined cases. t(11;14) correlated positively with CD20 expression on plasma cells in AL-amyloidosis (p=0.016). Furthermore, we found that the expression level of SLAMF7 is decreased in advanced plasma cell disorders (p=0.025) and that a diminished expression level of SLAMF7 is associated with low expression of CD27 and CD81 on malignant plasma cells in newly diagnosed multiple myeloma.
Summary and Conclusions: This study provides a contribution to targeted therapy options in plasma cell disorders. Particularly, it puts an emphasis on anti-CD20 antibodies as therapeutic agents in AL-amyloidosis. Regarding the therapeutic options of the SLAMF7 antibody elotuzumab these data advise that target expression diminished during the course of the disease and that analysis of SLAMF7 expression before application of elotuzumab might help to estimate the efficacy of elotuzumab in clinical trials.

E1270

SERUM LEVELS OF FMS-LIKE TYROSINE KINASE LIGAND IN MULTIPLE MYELOMA PATIENTS ARE CORRELATED WITH MARKERS OF TUMOR PROGRSSION

M. Kokonozaki[1], R. Vyzoukaki[1], K. Pappa[2], Z. Gitti[1], N. Androulakis[1], Z. Charoniti[1], A. Papadopoulou[1], D. Hatzisimeon[1], A. Sfiridaki[3], M. Alexandrakis[4,*]
[1]Laboratory of Haematology, University Hospital of Heraklion Crete, [2]Depart-

ment of Internal Medicine, [3]Division of Haematology, Venizeleion Hospital of Heraklion Crete, [4]Laboratory of Haematology, Department of Haematology, University Hospital of Heraklion Crete, Heraklion, Greece

Background: Fms-like tyrosine kinase 3 (FLT3) ligand (FLT3-L) is a potent hematopoietic cytokine that affects the growth and differentiation of progenitor and stem cells both *in vivo* and *in vitro*. It is probably involved in early B cell development.
Aims: The aim of the present study was to estimate the levels of FLT3L in serum of patients with multiple myeloma(MM) and its relationship with parameters of tumor progression such as Ki-67, the bone marrow infiltration and B-cell activating factor (BAFF)
Methods: We studied 52 newly diagnosed MM patients with mean age 67±8 years, of them 27 had IgG myeloma, 21 IgA and 4 light chain. According to ISS 10 were in stage I, 18 in stage II and 24 in stage III. 18 age and sex matched healthy volunteers were used as control group. All assays were performed at the end of the study, in order to avoid interassay variability. The detection of biological parameters in the serum was performed by a solid-phase sandwich ELISA. Immunohistochemical methods were used in order to determine Ki-67 proliferation index(Ki-67 PI).
Results: Our results indicate that the serum levels of FLT3L and BAFF and the the expression of Ki-67 were significantly higher in patients with MM compared to controls ($p<0.001$ for all cases). Moreover, the serum levels of FLT3L were significantly different among the three stages of disease, with higher values in advancing disease stage ($p<0.001$). Additionally, a positive correlation was found between FLT3L and Ki-67 ($p<0.001$) and BAFF ($p<0.003$), while there was a tendency to correlation between FLT3L and bone marrow infiltration ($p<0.07$)
Summary and Conclusions: Our results showed that FLT3L serum levels were increasd in parallel with ISS stage. The correlation with parameters of disease activity supports the involvement of FLT3L in the mechanisms of promotion of MM growth. Its prognostic impact remains to be proven.

E1271

THE ROLE OF DIAGNOSTIC DELAY IN MULTIPLE MYELOMA: "A DELAY PARADOX"

R. Ríos-Tamayo[1,*] J. Sáinz[1], J.M. Puerta[1], A. Romero[1], P.A. González[1], P. López[1], J.M. de Pablos[1], E. López[1], L. Moratalla[1], M. Jurado[1]
[1]Hematology, University Hospital Virgen de las Nieves, Granada, Spain

Background: The delay in the diagnosis of cancer can influence the outcome. Little is known about the impact of diagnostic delay in multiple myeloma (MM).
Aims: The aim of this study was to prospectively explore the impact of the diagnostic delay in the outcome of newly diagnosed symptomatic MM patients (NDMM). The primary objective was to describe the time in months (m) between the first MM-related symptom and the diagnosis, and between diagnosis and treatment initiation. The secondary objective was to determine whether times to diagnosis and treatment influenced overall survival (OS).
Methods: The dates for the first MM-related symptom, date of diagnosis and date of the induction therapy were recorded for all NDMM in our population-based MM registry, along with variables of prognostic interest. The OS curves were estimated by the Kaplan-Meier method.
Results: 215 consecutive NDMM patients were included in the study, 111 males (51,6%) and 104 females, median age 65 years (12-89). Median OS was 31.3 (21.7-40.9) months (m). There were no significant differences in survival according to sex. The median of diagnostic delay was 4 m (0.2-80). Mean delay for men was 5.5 m and 6.6 m for women (p=ns). Patients with less than 4m of delay had an OS of 19.8 m (11.4-28.2) whereas for those with delay of 4 m or higher, OS was 50.3 m ($p<0.001$). According to sex, OS for patients with <4 *vs* ³4 m was 18.8 *vs* 80.9 m (p=0.001) and 20.4 *vs* 42.7 m (p=0.088), for men and women respectively. Median time from diagnosis to treatment was 13 days. When comparing prognostic factors in both groups, we found that patients with delay of <4 m had ISS1 in 21.3% *vs* 34% (p=0,07), mean serum creatinine 2.3 *vs* 1.6 mg/dL (p=0.03) and mean lactate dehydrogenase (LDH) 338 *vs* 240 U/L (p=0.009). No statistically differences were found for free light chain involved-uninvolved ratio or high risk cytogenetic abnormalities. The percentage of patients with isolated anemia, isolated renal failure or a combination as MM-defining event was higher in the group of <4 m of delay: 64.3%, 57.1% and 59.1% respectively.
Summary and Conclusions: We conclude that the apparent worse prognosis in patients with early diagnosis (less than 4 m) is due to the presence in this group of patients of poorer prognostic factors, in particular a deeper renal impairment, higher levels of LDH and more advanced ISS stage. Early diagnosis in MM seems to be associated to specific MM-defining events and a more aggressive disease.

E1272

SALVAGE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR RELAPSED MULTIPLE MYELOMA

B. A. Zannetti[1,*] A. Pezzi[1], B. Gamberi[2], E. Zamagni[1], P. Tosi[3], S. Rocchi[1], C. Cellini[4], P. Tacchetti[1], S. Ronconi[5], L. Pantani[1], K. Mancuso[1], M. Martello[1], B. Santacroce[1], M. Cavo[1]
[1]"Seràgnoli" Institute of Hematology, Sant'Orsola-Malpighi University Hospital, Bologna, [2]Dipartimento Oncologico e Tecnologie Avanzate, IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, [3]Unità Operativa di Ematologia, Ospedale "Infermi", Rimini, [4]Unità Operativa Complessa di Ematologia, Ospedale Santa Maria delle Croci, Ravenna, [5]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) Srl-IRCCS, Meldola, Italy

Background: High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) is a standard frontline therapy for multiple myeloma (MM). Therapeutic options for patients (pts) with relapsed MM after ASCT include novel agents, conventional chemotherapy or salvage ASCT (sASCT), with no standard of care.
Aims: To evaluate the efficacy and safety of novel agents incorporated into sASCT.
Methods: We retrospectively analyzed 66 MM pts who relapsed after up-front single or double ASCT and received sASCT at four italian centres.
Results: Induction therapy in preparation to up-front ASCT (single 67%, double 33%) consisted in conventional chemotherapy (35%) and was thalidomide-based in 58% of pts. Best high-quality response to up-front ASCT included CR (43%) and VGPR (32%). Median age at sASCT was 60 years. Median progression free survival (PFS1) from upfront ASCT to relapse was 44 months. 72.7% of pts received sASCT at first disease progression. Re-induction regimens were bortezomib (bort)-based (84.1%) and IMiDs-based (15.9%). Responses to re-induction therapy included: CR 17.5%, VGPR 30.2%, ≥PR 82.5%. ORR was higher and median time to response was shorter with bort-based in comparison to IMiDs-based regimens, also adjusting for the treatment received as first line (88.2% *vs* 60%, p=0.049; 2.2 *vs* 4.2 months, p=0.01, respectively). 64% of pts already had harvested stem cells for sASCT while 24 pts needed a further peripheral blood stem cells (PBSC) mobilization. 41.7% of them received G-CSF plus plerixafor. Overall, the median number of PBSC harvested was 3.5 (IQR: 2.9-4.9)x 10^6 CD34+/kg. High-dose melphalan was the standard regimen before sASCT and was used at 200 mg/sm in 64.4% of pts. Responses to sASCT included: CR 43.9%, VGPR 33.3%, ≥PR 93.9%. 29% of pts improved from <CR before sASCT to CR after sASCT (p=0.0001). With a median follow up of 2 years after sASCT, 39 pts (59.1%) experienced progression. Median PFS from sASCT (PFS2) was 17.3 months. PFS2 was significantly shorter in pts with PFS1 ≤24 months (9.6 *vs* 18.3 months, p=0.003), in pts who did not receive sASCT at first disease progression (9.7 *vs* 18.3 months, p=0.03), in pts with EMD (9.9 *vs* 18.3 months, p=0.008) and in pts who received reinduction therapy with an IMiDs-based regimen (9.9 *vs* 18 months, p=0.01), also adjusting for treatment received as first line. In multivariate analysis PFS1 ≤24 months (HR 0.21, CI 0.08-0.56) and the presence of EMD (HR 6.6, CI 1.8-24.2) were associated with a shorter PFS2. 23 pts (35%) died after sASCT, mainly due to disease progression (74%). TRM at day+100 was 3%. Median OS from ASCT (OS1) and sASCT (OS2) was 166 and 43 months, respectively. OS2 was significantly shorter in pts with PFS1 ≤24 months (14.2 *vs* 58.3 months, p=0.003), in pts who did not receive sASCT at first disease progression (13.7 *vs* 58.3 months, p=0.008), in pts with EMD (13.9 *vs* 58.3 months, p=0.03) and in pts who failed CR after sASCT (30 months *vs* not reached, p=0.006). In multivariate analysis PFS1 ≤24 months (HR 0.26, CI 0.09-0.80) and CR after sASCT (HR 0.27, CI 0.09-0.80) were associated with a shorter OS2.

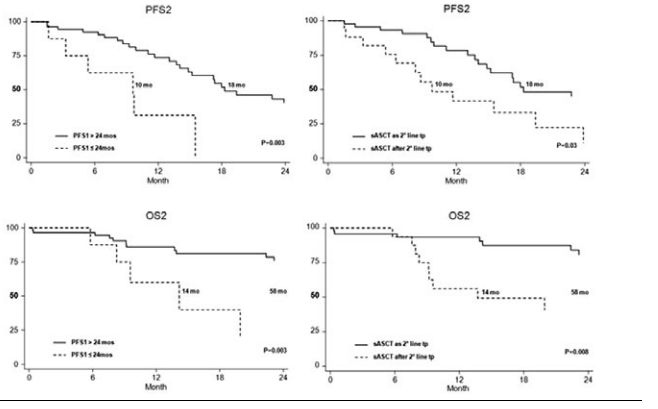

Figure 1.

Summary and Conclusions: Novel agent-based sASCT is a safe and effective procedure for relapsed MM. TRM is similar to that observed in the up-front setting. Patients who are more likely to benefit from sASCT are those in first relapse, with PFS1 >24 months and achieving CR.

E1273

BENCE JONES PROTEINURIA IN SMOLDERING MULTIPLE MYELOMA AS PREDICTOR MARKER OF PROGRESSION TO SYMPTOMATIC MULTIPLE MYELOMA

V. González-Calle[1,*] R. García-Sanz[1], E. Sobejano[1], E. Ocio[1], N. Puig[1], N. Gutiérrez[1], A. García de Coca[2], J.M. Hernández[3], R. Hernández[4], A. Bárez[5],

J.M. Alonso[6], C. Aguilera[7], F. Escalante[8], G. Martín[9], R. López[9], P. de la Fuente[10], M.V. Mateos[1]
[1]Hospital Universitario De Salamanca, Salamanca, [2]Hospital Clinico Universitario De Valladolid, Valladolid, [3]Complejo Asistencial De Segovia, Segovia, [4]Complejo Asistencial De Zamora, Zamora, [5]Hospital Nuestra Señora De Sonsoles De Ávila, Avila, [6]H. Río Carrión De Palencia, Palencia, [7]H. Del Bierzo Ponferrada, Ponferrada, [8]Complejo Asistencial De León, León, [9]Hospital Virgen Del Puerto De Plasencia, Plasencia, [10]Complejo Asistencial De Burgos, Burgos, Spain

Background: Smoldering multiple myeloma (SMM) is a plasma cell disorder with no evidence of myeloma-related symptomatology (hypercalcemia, renal insufficiency, anemia or bone lesions). SMM has a risk of progression to symptomatic multiple myeloma (MM) of approximately 10% per year. However, this risk is not uniform and several prognostic factors for the progression to MM have been identified at diagnosis of SMM. The proportion of bone marrow plasma cells (BMPC), the serum monoclonal protein level and the serum immunoglobulin free light chain ratio (FLC) were identified by the Mayo Clinic Group; the proportion of bone marrow aberrant plasma cells assessed by flow cytometry plus immunoparesis were described by the Spanish Myeloma Group. According to recommendations made by International Myeloma Working Group (IMWG), a 24-h urine protein electrophoresis and immunofixation to identify the presence of Bence Jones (BJ) proteinuria should be performed at diagnosis. BJ proteinuria is a myeloma feature associated with renal function and tumor burden as well. However, there is lack of evidence about the role of BJ proteinuria in SMM as predictor marker of progression to MM.
Aims: The purpose of this study was to investigate the role of the presence of Bence Jones proteinuria at diagnosis in SMM as predictor of progression to MM.
Methods: We reviewed the medical records of all patients diagnosed with SMM in Castilla-León (western region of Spain), between 1983 and 2013, according to the IMWG criteria defined in 2003. The primary endpoint was time to progression to MM.
Results: A total of 152 patients with SMM were included in the analysis. The median age at diagnosis was 70 years (range: 34-90). The serum M-protein at diagnosis ranged from 1 to 2.8 g/dL (median, 2.5). Seventy percent of SMM patients were Ig G subtype. The proportion of bone marrow plasma cells ranged from 1% to 55% (median, 14). Bence Jones proteinuria was detected at diagnosis in 41 patients (27%) and the average amount of BJ proteinuria was 280 mg in 24h urine. We identified 36 high-risk SMM patients(24%) with serum M-protein greater than 3g/dL and more than 10% BMPC. Fifty eight patients (38%) had more than 95% phenotipically abnormal plasma cells by flow cytometry plus immunoparesis. The serum FLC ratio was assessed at diagnosis in 18 patients and it was abnormal (<0.26 or >1.65) in 15 patients (83%). FISH at diagnosis was available in 41 patients. Four of them (10%) had high-risk cytogenetic abnormalities: *t(4;14)* or *del 17p*. The median follow-up for survivors was 65 months. Progression to symptomatic MM occurred in 74 patients (49%). The median time to progression (TTP) to MM in the whole series was almost 6 years. SMM with BJ proteinuria had a significantly shorter median TTP to active disease as compared with patients without BJ proteinuria (21.7 months *vs* 88.3 months ;HR: 2.6, 95% CI: 1.6-4.4; p=0.001). The progression risk at 2 years in the BJ group of SMM was 51%. Multivariate analysis selected BJ proteinuria at diagnosis as an independent variable for progression to symptomatic MM (HR: 2.47, IC 95%: 1.32-4.63; P=0.005). We identified 3 risk categories according to amount of BJ proteinuria: 0 mg per 24h; up to 500 mg/24h; or greater than or equal to 500 mg/24h, with a median TTP of 7, 3 and 1.1 years, respectively (HR: 2.4; 95% IC (1.6-3.64); p <0.001).
Summary and Conclusions: The presence of Bence Jones proteinuria at diagnosis in SMM patients is associated with significantly higher risk of progression to active MM (51% risk of progression at 2 years). Moreover, the presence of 500 mg or more of BJ proteinuria can be considered as a marker for the identification of ultra high risk SMM.

E1274

RE-TREATMENT *VS* CHANGE THERAPY IN FIRST RELAPSE: POST-HOC ANALYSIS OF 476 PATIENTS WITH MULTIPLE MYELOMA (MM) INCLUDED IN TWO PROSPECTIVE TRIALS

M. Offidani[1,*] L. Corvatta[2], S. Bringhen[3], S. Gentili[1], F. Gay[3], L. Maracci[1], G. Ciccone[4], M. Boccadoro[3], P. Leoni[1], A. Palumbo[3]
[1]Clinica di Ematologia AOU Ospedali Riuniti di Ancona, Ancona, [2]UOC Medicina, Fabriano, [3]Myeloma Unit, Division of Hematology, University of Torino, [4]Unit of Clinical Epidemiology, AOU Città della Salute e della Scienza di Torino e CPO-Piemonte, Torino, Italy

Background: In patients with MM, the choice of salvage therapy at first relapse between re-treatment with the same drug of induction or change class of drug is widely empirical and subjective even if PFS1 duration is usually highly thought of.
Aims: To analyze the outcome in terms of 2ndPFS and PFS2 of first salvage therapies in patients with MM included in 2 prospective trials (VMP *vs* VMPT-VT and MPR *vs* Mel-200) by comparing patients re-treated with the same new-drug used in induction or with other new-drug class.
Methods: We analyzed 476 patients relapsed after first-line therapy that underwent salvage therapies based on Bortezomib (126 pts), Lenalidomide (142 pts), Thalidomide (36 pts), chemotherapy (63 pts), autotransplant (92 pts) and allogeneic transplant (7 pts). Out of these 476 patients, 311 meet the inclusion criteria for this study that was re-treatment or change therapy with Bortezomib-based or Lenalidomide-based therapy without transplantation.
Results: In the elderly group (257 pts), salvage therapy included bortezomib (15%, 2ndPFS=8.8 months), lenalidomide (50%, 2ndPFS=16.6 months), thalidomide (12%, 2ndPFS=8.6 months), chemotherapy (21%, median 2ndPFS=6.6 months). As regard younger patients (219 pts), 44% received bortezomib (median 2ndPFS=7.2 months), 7% received IMiDs (median 2ndPFS=14.3 months), 41.5% bortezomib followed by autotransplant (media 2ndPFS=21.5 months), 3% received allotransplant (median 2ndPFS=35.7 months). Out of 311 patients considered for comparison of re-treatment *vs* change therapy, 52 patients were re-treated (ptsR: 37 Bortezomib-based and 15 Lenalidomide-based) whereas 259 changed therapy (ptsC: 162 Lenalidomide-based, 97 Bortezomib-based). The 2 groups of patients were comparable for the main prognostic factors (age, ISS stage, cytogenetic, renal function, plasmocitoma and maintenance) and for follow-up (median 57.3 *vs* 56.2 months). PtsR received salvage therapy at a median time of 30.4 months (4.2-64.4 months; <12 months=4 pts; 12-24 months=12 pts; >24 months=36 pts) while ptsC after a median time of 25.1 months (1.2-63.9 months; p=0.001). In the whole population, median 2ndPFS and PFS2 was 23.1 and 39.0 months, respectively. Median 2ndPFS of ptsR was 8.8 months compared with 12.7 months of ptsC (p=0.038). Median PFS2 of ptsR was 39.9 months compared with 38.8 months of ptsC (p=0.584). Splitting PFS1 duration in two periods, in patients with a PFS1 duration up to 27 months, change of therapy allowed 2ndPFS and PFS2 significantly longer compared with those of re-treatment (2ndPFS: 21 ptsR=5.3 *vs* 164 ptsC=10.2 months; HR=1.9, 95%CI=1.2-3.1, p=0.006; 3yrsPFS2: ptsR=20% *vs* ptsC=34%, HR=1.5, 95%CI=1.0-2.5, p=0.080) whereas, when PFS1 was longer than 27 months, 2ndPFS and PFS2 became similar between the two therapeutic options (2ndPFS: 31 ptsR=16.3 *vs* 95 ptsC=16.6 months, HR=1.2, 95%CI=0.6-2.1, p=0.614; 3yrsPFS2: ptsR=90% *vs* ptsC=92%, HR=1.1, 95%CI=0.6-1.9, p=0.779).
Summary and Conclusions: Our data suggest that changing therapy seems to be preferable at least until PFS1 is longer than that expected by a given regimen while re-treatment may be consider behind this time to save drugs for subsequent relapses. However, these results should be confirmed by a randomized trial comparing these two strategies, at least for relapses occurring between 2 or 3 year after diagnosis.

E1275

AL AMYLOIDOSIS AND QUALITY OF LIFE OUTCOMES

R. Warsame[1,*] S. Kumar[1], T. Carrie[1], G. Morie[1], M. Lacy[1], B. Francis[1], H. Suzanne[1], L. Nelson[1], D. David[1], L. John[1], L. Yi[1], P. Kapoor[1], R. Go[1], S. Zeldenrust[1], R. Kyle[1], S.V. Rajkumar[1], A. Dispenzieri[1]
[1]Hematology, Mayo Clinic, Rochester, United States

Background: Patients with light chain amyloidosis (AL) often have delayed diagnosis and present with significant symptomatology; this in turn results in decreased quality of life (QOL). With improving treatment options providing longer survival, it is becoming increasingly important to assess treatment toxicity and QOL. However there is a paucity of data in the literature of QOL in AL patients. At Mayo Clinic, we employ a "Hematology Patient Reported Symptom Screen" (HPRSS) at each visit, which is a three question assessment of fatigue, pain and overall QOL.
Aims: Our objective was to determine if health related quality of life metrics are prognostic in AL.
Methods: We performed a retrospective chart review of newly diagnosed patients with AL seen at our institution between 2009 and 2014 to collect clinical data and HPRSS scores. HPRSS is scored on a scale of 0-10; 10 being the worst for fatigue or pain, and 10 being the best overall QOL. The scores are collected at each visit, and analyzed at diagnosis, 3 months, 6 months and 1 year. There were 322 patients identified with evaluable HPRSS scores. Only those patients who died within the first year or had at least 12 months of follow-up were included (n=305).
Results: The median scores (interquartile range) for fatigue, pain, and QOL at diagnosis were 6 (3,7), 2 (0,5), 5 (3,8), respectively. The median overall survival (OS) for the entire cohort was 39.1 months, and 145 patients died in the first year. There was a significant difference in baseline HPRSS between the 1-year or better survivors and the early death patients in the domains of *fatigue* (5 [IQR 3, 7] *versus* 7 [IQR 5, 8], p<0.0001) and *QOL* (6 [IQR 4, 8] *versus* 5 [IQR 3, 7], p=0.006), but not in the pain domain (2 [IQR 0, 5] *versus* 2 [IQR 0.5]). There were significant baseline differences in the early death group for alkaline phosphatase, bilirubin, creatinine, and Mayo stage. On univariate analysis both *fatigue* and *QOL* were prognostic for OS. On multivariate which included Mayo staging and autologous stem cell transplant, only baseline *fatigue* remained an independently prognostic value. In order to compare change in HPRSS scores over time, we limited the subsequent analyses to those 126 patients who had both baseline and 12 month measurements. QOL scores improved significantly 6 [IQR 3.5, 8] à 7 [IQR 5, 8] between the two measurements, two sided Wilcoxon signed rank p=0.01, but there were no significant changes in fatigue scores (5 [IQR 2,

5]à 4.5 [IQR 3, 6], p=NS) or pain scores (2 [IQR 0,4]à 1.5 [IQR 0, 4], p=NS) over time. Approaching the data slightly differently, one could score whether patients HPRSS scores *worsened* by 1 point, remained *stable*, or *improved* by 1 point over time. The respective proportions were: for fatigue, 37%, 20%, and 43%; for QOL, 31%, 17%, and 52%; and for pain, 36%, 25%, and 39%. There was no difference in OS based on change or lack of change of QOL or fatigue, but patients whose pain worsened had a significant better OS. (Figure 1)This was predominantly driven by those 67 patients who did not undergo ASCT and presumably received bortezomib based therapy.

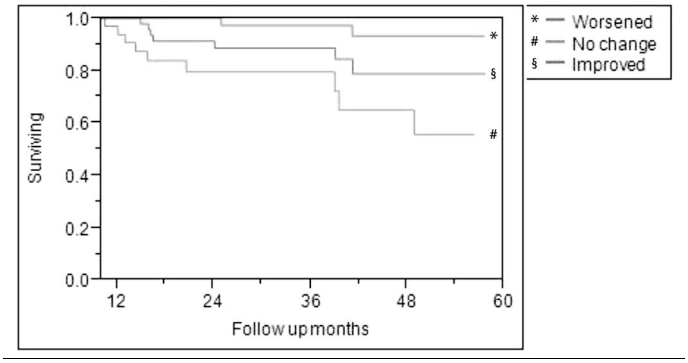

Figure 1. Change in HPRSS scores from diagnosis to 12 month of pain.

Summary and Conclusions: Patient reported fatigue and QOL are important predictors of outcomes in newly diagnosed AL patients. These simple measures can be incorporated in to routine clinical practice and should be considered an important end point for future clinical trials.

E1276

THE ROLE OF INITIAL 18F-FDG PET/CT IN PATIENTS WITH POEMS SYNDROME

J. Jang[1], H. Cho[1,*] J.Y. Lee[1], H. Park[1], Y.D. Kim[1], S.J. Kim[1], Y.R. Kim[1], J.-W. Cheong[1], Y. H. Min[1], J.S. Kim[1]
[1]department of internal medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: In POEMS syndrome, the identification and biopsy of an osteosclerotic lesion or a lymph node typical of Casleman's disease is essential to establish the diagnosis and plan appropriate treatment.
Aims: The aim of this study is to evaluate the usefulness to detect and select lesions for the diagnostic biopsy in patients suspected POEMS syndrome
Methods: We reviewed 21 patients with POEMS syndrome retrospectively. The 16 patients of them received an (18)F-FDG PET/CT scan using a Discovery DSTe PET/CT scanner (GE medical Systems, Milwaukee, WI). All patients also had undergone bone Ga-scintigraphy.
Results: We reviewed 21 patients with POEMS syndrome retrospectively. The 16 patients of them received an (18)F-FDG PET/CT scan using a Discovery DSTe PET/CT scanner (GE medical Systems, Milwaukee, WI). All patients also had undergone bone Ga-scintigraphy.
Results: The median age was 47.5 year and the ratio of male to female was 1.9. The typical 5 features of peripheral neuropathy (100%), organomegaly (74%), endocrinopathy (74%), M protein (100%), and skin change (84%) were observed. Sclerotic bone lesions (81%) and extravascular volume overload (84%) were also commonly observed. The high serum VEGF level at diagnosis was detected in all tested patients (n=17). Although most cases of sclerotic bone were detected by plainx-ray or Ga-scintigraphy, 5 of 17 cases were detected by only (18)F-FDG PET/CT scan. Plasmacytoma was detected in 7 patients (33%). Except one case, plasmacytoma were revealed by (18)F-FDG PET/CT scan. Multiple lesions of plasmacytoma were detected in two patients. One patient who did not take (18)F-FDG PET/CT scan showed bone pathology on Ga-scintigraphy and discovered plasmacytoma by excisional biopsy. Castleman's disease was suspected on the (18)F-FDG PET/CT scan in two patients (10%) and one case was pathologically confirmed by biopsy. Of 16 patients who had undergone (18)F-FDG PET/CT scan, 12 patients showed abnormal bone lesions or hypermetabolic lesions. Sclerotic bone was seen in 11 patients, abnormal hypermetabolic focus suspected plasmacytoma was seen in 6 patients, and multiple lymphadenopathy with FDG uptake was seen in 2 patients. Plasmacytoma was confirmed by biopsy in five patients and Castleman's disease in 1 patient. In two cases of plasmacytoma, (18)F-FDG PET/CT scan revealed hypermetabolic abnormalities, which were not detected by Ga-scintigraphy or plainx-ray. As the first line treatment, 12 patients received autologous stem cell transplantation (ASCT), 5 patients received chemotherapy with or without radiation and four patients received high-dose steroid, radiation or immune modulators only. Two of five patients with chemotherapy underwent ASCT as second line treatment. The median follow-up duration was 43.4month (11.2-99.8). Four-year overall survival rate was 74.5%. Six of seven patients with plasmacytoma received local radiotherapy with systemic therapy (Table 1).

Table 1. Characteristics of 16 patients who had undergone (18) F-FDG PET/CT scan.

Patient No.	Age	Sex	The Finding by PET-CT	Biopsy proof	Site of biopsy	Results
1	63	M	Abnormal intense FDG uptake with osteoblastic activity in L5, left S1 and right iliac crest	Yes	lumbar spine	Plasmacytoma
2	33	F	No definite abnormal focus			
3	35	F	Bone destruction in the right ileum shows intense FDG uptake	No	Rt.ilium	
4	41	M	No definite abnormal focus			
5	43	F	Sclerotic lesion in Rt.ischium and sacral bone			
6	46	M	Osteosclerotic lesion involving iliac bone with intense FDG uptake, suggestive of malignancy	Yes	iliac bone	Plasmacytoma
7	49	M	Extensive pathologic lymphadenopathy and Multiple osteoblastic or sclerotic lesions in axial skeleton			
8	41	M	Multiple well-enhancing (r/o multicentric Castleman's disease) and multiple small osteosclerotic lesions in the axial skeleton	No		
9	44	M	Multiple osteosclerotic lesions in the axial skeleton and left femur			
10	57	F	No definite abnormal focus			
11	52	M	Multicentric Castleman's disease	Yes	Retropancreatic lymph node	Castleman's disease
12	28	M	Multiple sclerotic bony lesions			
13	46	M	No definite abnormal focus			
14	68	M	Osteolytic lesion in the Lt ischium with intense FDG uptake, suggestive of malignancy	Yes	Lt. iliac bone	Plasmacytoma
15	26	M	Osteolytic lesion in the right acetabulum shows intense FDG uptake, suggestive of malignancy	Yes	acetabulum	Plasmacytoma
16	59	F	Osteolytic and sclerotic lesion involving sacrum, suggestive of malignancy	Yes	sacrum	Plasmacytoma

Summary and Conclusions: (18)F-FDG PET/CT scan is useful in detecting and selecting bone lesions and accompanying plasmacytoma or Castleman's disease for the reliable diagnosis of POEMS syndrome. Furthermore, this finding has potential clinical application in therapy evaluation and follow-up as well as diagnosis.

E1277

TRIAL EFFICACY *VS* REAL WORLD EFFECTIVENESS IN FIRST LINE TREATMENT OF MULTIPLE MYELOMA

J. Liwing[1,*] B.M. Heeg[2], S. Karstorp[1], M. Postma[3], R. Silvennoinen[4], M. Putkonen[5], P. Anttila[6], K. Remes[5], N. Abildgaard[7], A. Waage[8], H. Nahi[1]
[1]Department of Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden, [2]Ingress-health, Rotterdam, [3]Unit of PharmacoEpidemiology & PharmacoEconomics, Institute of Science in Healthy Aging & health caRE (SHARE), Groningen, Netherlands, [4]Kuopio University Hospital, Kuopio, [5]Turku University Hospital, Turku, [6]HUS, Helsinkki, Finland, [7]Department of Hematology, Odense University Hospital, Odense, Denmark, [8]Department of Hematology, St Ola*vs* Hospital, Trondheim, Norway

Background: Large randomized clinical trials (RCT) are the foundation of the registration of newly developed drugs. A potential problem with RCTs is that the inclusion/exclusion criteria will make the population different from the actual population treated in real life. Hence, it is important to understand how the results from the RCT can be generalized to a general population.
Aims: The primary aim of the present study was to assess the generalizability of the large 1st line RCTs in Multiple Myeloma (MM) to the Nordic setting and to understand potential difference and magnitude in outcomes between RCTs and patients treated in standard care in the Nordics.
Methods: A retrospective analysis was performed on an incident cohort of 2960 MM-patients from 24 hospitals in Denmark, Finland, Norway and Sweden. The database contained information on patient baseline characteristics, treatments and outcomes. Data from relevant 1st line MM RCTs was selected from the treatment MP (Waage, A., *et al.*, Blood. 2010], MPT (Waage, A., *et al.*, Blood. 2010) and VMP (San Miguel, J.F., *et al.*, N Engl J Med, 2008) and baseline characteristics were compared to newly diagnosed Nordic MM treated patients. Potential difference in response and overall survival (OS) was estimated by adjusting the RWE population to the RCT population using matching adjusted indirect comparisons. Patients were matched on age (median approximated to mean), gender, calcium, beta2-microglobulin and ISS score 3. These variables were selected because they were reported in all trials and have previously been identified as having prognostic value.
Results: Patients in the Nordic database treated with MP (n=880) had a response rate of (PD, NR, PR, VGPR, ≥nCR) of (13%, 39%, 38%, 6%, 4%). After matching (n=347), the response rate was slightly worse (12%, 43%, 36%, 6%, 3%). This can be compared to the response rate from the RCT of (7%, 53%, 33%, 3%, 4%). OS for Nordic MP treated patients was 2.67 years (2.25-3.17). After matching the OS was 3.37 years (2.86-3.96) and this can be compared to the trial with OS 2.40 years (2.23-2.66). Patients treated with MPT (n=283) in the Nordic countries had a response rate of (5%, 14%, 52%, 20%, 9%). After matching (n=179) the response rate was slightly changed to (6%, 20%, 50%, 13% 11%). The corresponding RCT response results were 14%, 29%, 34%, 10%, and 13% respectively. OS for Nordic MPT treated patients was 4.15 years (3.73- 4.74). After matching the OS was 4.28 years (3.98-NA) years and compared to 2.42 years

(2.08-3.17) OS observed in the corresponding trial. Patients treated with VMP (n=59) in the Nordic countries had a response rate of (4%, 5%, 40%, 18%, 33%). After matching (n=31) the response rate was improved to (8%, 11%, 28%, 8%, 45%). This corresponding response rates shown in the trial are 1%, 23%, 33%, 8%, and 33% respectively. OS for Nordic MP treated patients was 4.86 years (3.79-NA). After matching the OS was 4.86 years (4.86-NA) and this can be compared to the trial with OS 4.70 years.

Summary and Conclusions: Surprisingly Nordic treated MM patients do very well compared to, and even better than, patients treated in RCTs. Since the OS for all tested treatments improves after matching to the RCT baseline characteristics, patients recruited to the RCTs seems to be a bit better than ordinary Nordic patents. The database used in the present study, and the used method, can be valuable for generalizing the results to the Nordic setting and estimating potential difference for future RCTs and Nordic MM treated patients. Future research should include different data cuts to see whether the analyses are biased by differences subsequent treatments applied in RCTs and clinical practice.

E1278

HEAVY/LIGHT CHAIN IMMUNOPARESIS AS A NOVEL MARKER OF POOR OUTCOMES IN SYSTEMIC AL AMYLOIDOSIS

S. Sachchithanantham[1], O. Berlanga[2], A. Alvi[2], N. Wassef[3], S. Mahmood[1], R. Sayeed[1], J. Gillmore[1], H. Lachmann[1], C. Whelan[1], P. Hawkins[1], A. Wechalekar[1,*]
[1]National Amyloidosis Centre, UCL, London, [2]The Binding Site Group Ltd, Birmingham, [3]Biochemistry, Royal Free London NHS Foundation Trust, London, United Kingdom

Background: Monoclonal free light chain (FLC) levels together with cardiac biomarkers represent the basis of current risk-stratification models for AL amyloidosis, with high-risk patients demonstrating poor survival. However there exists a need to identify new prognostic biomarkers that help assess outcomes, particularly in patients surviving initial therapy. Suppression of heavy/light chain (HLC) immunoglobulins has been shown to add prognostic value in plasma cell dyscrasias, but similar studies in AL amyloidosis are lacking.

Aims: To assess the frequency of HLC immunoparesis in AL patients and contrast the results in relation to outcome.

Methods: The study included 170 patients with systemic AL amyloidosis seen at the National Amyloidosis Centre (London, UK). Serum samples were tested nephelometrically for FLC and heavy/light chain (HLC, *i.e.* IgGκ, IgGλ, IgAκ, IgAλ, IgMκ and IgMλ) concentrations using Freelite® and Hevylite® assays, respectively (The Binding Site Group Ltd, UK); and total immunoglobulins (IgG, IgA and IgM). Immunoparesis was defined either by total immunoglobulin (Ig) measurements as the concentration of any Ig class below the lower limit of normal (*i.e.* in g/L: IgG<6, IgA<0.8, IgM<0.5; total Ig suppression), or by HLC immunoassays as levels of any HLC isotype below the lower limit of their respective reference range (*i.e.* in g/L: IgGκ<4.03; IgGλ<1.97; IgAκ<0.48; IgAλ<0.36; IgMκ<0.29; IgMλ<0.17). Cardiac involvement was defined by the presence of amyloid deposits in tissue biopsies and/or N-terminal pro-brain natriuretic peptide (NTproBNP) levels >332 ng/L. Survival studies were carried out using Kaplan-Meier curves with the log rank test used to indicate significance. Median survival for all patients was 26.2 months, and for patients with cardiac involvement 14.8 months.

Results: HLC measurements identified immunoparesis of at least one HLC isotype in 145 (85%) patients; and severe immunoparesis, defined as two or more HLC isotypes suppressed by at least 50% below normal levels, in 29 (17%) patients. High monoclonal FLC levels (>180 mg/L, n=82(61%)) associated with shorter survival in all patients (median OS 14.8 *vs* 43.1 months; p=0.05), but not in a landmark analysis of 127 patients alive at 6 months (p=0.33). By contrast severe HLC immunoparesis associated with shorter survival in the latter group of patients alive at 6 months (20.2 *vs* 42.8 months; p=0.09); with results approaching significance. In a subset analysis of 89 patients with cardiac involvement and alive at 6 months, severe HLC immunoparesis strongly impacted outcome (median survival 8.8 *vs* 29.9 months, p=0.007) (Figure 1) whereas monoclonal FLC levels reported no significant association (p=0.23). Systemic immunoparesis as determined by total Ig measurements offered no prognostic information in any patient-group.

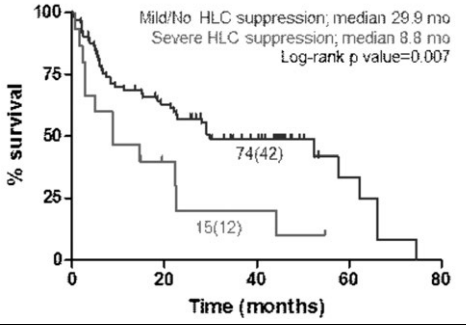

Figure 1.

Summary and Conclusions: HLC suppression is a common occurrence in AL amyloidosis and may add to current models for the prognostication of patients.

E1279

ELEVATED FACTOR VIII LEVELS CARRY A POOR OVERALL SURVIVAL IN NEWLY DIAGNOSED SYSTEMIC LIGHT CHAIN (AL) AMYLOIDOSIS PATIENTS

S. Mahmood[1,*] A. Riddle[2], S. Sachchithanantham[1], T. Lane[1], D. Foard[1], R. Sayed[1], K. Patel[1], M. Fontana[1], T. Youngstein[1], C. Youngstein[1], M. Coyne[1], C. Whelan[1], H. Lachmann[1], J. Gillmore[1], P. Hawkins[1], K. Gomez[2], A. Wechalekar[1]
[1]Inflammation, National Amyloidosis Centre, [2]Haemophilia Department, Royal Free Hospital, London, United Kingdom

Background: Immunoglobulin light chains form amyloid fibrils and are deposited in different tissues in systemic light chain (AL) amyloidosis. Von Willebrand Factor (vWF) is a multimeric adhesive glycoprotein which promotes platelet adhesion to the subendothelium at sites of vascular injury and platelet-platelet interactions under high shear-rate conditions. VWF acts as a carrier for FVIII, acting to protect FVIII from rapid proteolysis.

Aims: To examine the coagulation factors, specifically FVIII, VWF antigen and anti-thrombin in newly diagnosed systemic AL patients, and to assess the prognostic utilities of these investigations.

Methods: One hundred patients with suspected AL amyloidosis referred to the National Amyloidosis centre, London were prospectively examined between May and December 2013. All patients underwent a detailed assessment for organ involvement as per standard protocol. In addition, patients had blood samples taken for baseline activated partial thromboplastin time (APTT), prothrombin time (PT), thrombin time (TT), clauss fibrinogen, factor assays, protein C, protein S and anti-thrombin levels, in conjunction with the Royal Free Hospital based bleeding questionnaire. All assays were carried out using an ACL TOP™ coagulometer [Instrumentation Laboratory (IL), Bedford, USA], using each patient's frozen platelet poor plasma aliquots.

Results: The analysis included 70 newly diagnosed AL patients of the 100 suspected systemic AL referrals. Examining this group, 41% male and the median age 66.1 years (range 56.4-75), cardiac (70% with Mayo stage 3 in 40%), renal (79%), liver (39%), PNS (13%) and ANS involvement (13%). Single organ involvement was present in 27%, with greater than 2 organ involvement in 39%. The bleeding questionnaire reported a bleeding score of 1 in 18.6% and greater than 3 in 7%, with a variable duration of symptoms ranging from 1-60 months. The sites of bleeding included cutaneous (n=17), oral (n=7), epistaxis (n=5), haemarthrosis (n=1), muscle haematoma (n=1) and following surgery (n=2). Coagulation screen abnormalities were present in 28.6% (excluding patients on warfarin), with prolongation of the thrombin time in 48.6%. Interestingly, of 14 patients with an albumin less than 25mg/L, 57% had a low anti-thrombin level, and by univariate analysis this factor was associated with survival (HR: 0.96, 95% CI 0.94-0.98, p<0.005). One striking finding was 94% and 91% had elevated factor VIII and von Willebrand factor antigen, with median levels of 260 IU/dL (range 120-630) and 252 IU/dL (range 101-745) respectively. The plasma metalloproteinase (ADAMTS 13) was normal in all patients. Examining the prognostic significance of both VWF antigen and FVIII; a FVIII >280 IU/dL was associated with a poor overall survival outcome, median survival 11.8 *versus* 17.1 months (p=0.013), illustrated in Figure 1.

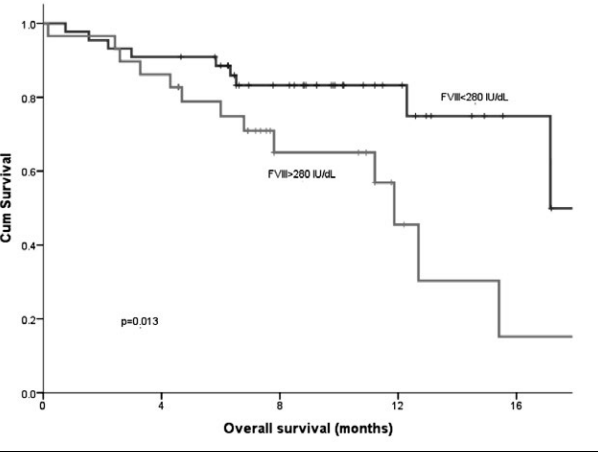

Figure 1.

Summary and Conclusions: In newly diagnosed patients with systemic AL amyloidosis, greater than 90% of patients had elevated VWF antigen and FVIII levels, which may suggest increased platelet-platelet interactions within the endothelium or potential sites of vascular injury that occur with immunoglobulin

amyloid fibrils interacting at these sites. Examining these coagulation factors independently, a FVIII>280IU/dL was associated with a significantly poor outcome. Low anti-thrombin levels also statistically negatively impacted survival.

E1280

FIRST REPORT OF A PROSPECTIVE STUDY ON WHOLE-BODY DYNAMIC CONTRAST ENHANCED MRI IN NEWLY DIAGNOSED MYELOMA PATIENTS TREATED WITH UP-FRONT AUTOLOGOUS TRANSPLANTATION: DESCRIPTIVE STUDY AT BASELINE

K. Belhadj[1,*] A. Luciani[2], P. Beaussart[2], S. Bastuji-Garin[3], C. Lin[4], E. de Kerviler[5], B. Arnulf[6], J. Dupuis[1], F. Le Bras[1], P. Zerbib[2], B. Chafiq[1], C. Haioun[1], A. Rahmouni[2]

[1]Hémopathies Lymphoïdes, [2]Imagerie Médicale, [3]Santé Publique, CHU Henri Mondor, Créteil, France, [4]Nuclear Medicine and Molecular Imaging Center, Chang Gung Memorial Hospital, Taipei, Taiwan, ROC, [5]Radiologie, [6]Immunologie Clinique, CHU Saint-Louis, Paris, France

Background: Bone disease is the hallmark of multiple myeloma (MM). MRI is the most sensitive non-invasive imaging technique for detection of bone marrow involvement. It provides relevant information on the pattern of marrow infiltration (focal and/or diffuse). Recent studies showed an independent prognostic value of baseline whole-body MRI. Whole-Body Dynamic Contrast Enhanced MRI (WB-DCE-MRI) provides functional parameters reflecting MM angiogenesis, useful for patient staging and response assessment. Like PET/CT, WB-DCE-MRI could be useful to evaluate MRD and to predict long-term outcomes.
Aims: To report the results of Whole Body Dynamic Contrast Enhanced MRI (WB-DCE-MRI) in patients with newly diagnosed MM with CRAB criteria at baseline. First results of the multi-centric cohort EVALICEMM (NCT01171430).
Methods: Patients were prospectively enrolled in this multi-centric IRB approved study to investigate the role of WB-DCE-MRI to identify skeletal and extra-skeletal lesions at baseline, and to assess with a second and third WB-DCE-MRI, interim response (before high-dose therapy) and response at the end of treatment (one month after autologous stem cell transplant). T1 and T2 signal intensity of focal lesions and bone marrow were analyzed together with the DCE-MRI quantitative enhancement values of the bone marrow (BMEmax) and of focal lesions (FLEmax). Extra-skeletal lesions and existence of epidural lesions were also noted. We here report on the main findings at baseline.
Results: The main characteristics of the 79 patients enrolled between July 2010 and January 2014 who underwent WB-DCE-MRI at diagnosis are as follows: median age of 59 y (range: 54-62), isotype IgG in 61%, IgA in 19% and light-chain in 20% of cases, ISS stage I, II and III respectively in 45, 37 and 18% of patients, median value of β2M was 3.5 mg/l (range 2.6-4.9) and adverse cytogenetic features (deletion 17p or t(4;14)) were observed in 13 of the 64 documented cases. At baseline WB-DCE-MRI, 52 patients (66%) presented with diffuse bone marrow involvement together with focal lesions, 12 with diffuse bone marrow involvement (15%) and 15 with focal lesions alone (19%). There was a significant correlation between T1/T2 signal intensity abnormalities and the dynamic enhancement parameters, both regarding focal lesions and bone marrow, with BMEmax significantly higher in patients with diffuse involvement (186% *vs* 91%, p<0.001). Mean FLEmax in active lesions was 285%. Six patients (8%) presented with extra-skeletal abnormalities (spleen n=3, muscle n=2, lung n=1) and thirteen patients (17%) had epidural lesions. A correlation was observed between BMEmax and International Staging System (p=0.003) and between BMEmax and β2M level (p=0.0017). No significant correlation was observed between BMEmax and adverse cytogenetic features.
Summary and Conclusions: At baseline, functional parameters derived from WB-DCE-MRI are well correlated to T1/T2 bone marrow signal abnormalities. BMEmax appears to be correlated to ISS stage and to β2M level. Extra-skeletal findings are present in 8% of patients which should advocate whole body imaging.

E1281

PROGNOSTIC IMPACT OF SERUM FREE LIGHT CHAIN (SFLC) EVALUATION IN PATIENTS WITH NEWLY DIAGNOSED SYMPTOMATIC MULTIPLE MYELOMA (MM) RECEIVING BORTEZOMIB (BTZ) -BASED REGIMENS

P. Tacchetti[1,*] E. Zamagni[1], A. Pezzi[1], S. Rocchi[1], L. Pantani[1], G. Marzocchi[1], B.A. Zannetti[1], E. Borsi[1], K. Mancuso[1], F.A. Dico[1], I. Rizzello[1], C. Terragna[1], M. Cavo[1]

[1]Bologna University School of Medicine, Seràgnoli Institute of Hematology, Bologna, Italy

Background: sFLC assay is an important tool for the diagnosis and monitoring of MM, however data on prognostic significance in symptomatic MM treated with novel agents are still limited.
Aims: We performed a retrospective analysis aimed at investigating the role of sFLC evaluation over time as predictor of outcomes in newly diagnosed symptomatic MM receiving btz.
Methods: Patients treated with a first line btz-based regimen and who had sFLC assay serially evaluated were selected. sFLC assay (Freelite; The Binding Site, Birmingham, UK) was performed by BN II nephelometer (Date Behring, Deerfield, IL, USA).
Results: 150 patients were available for analysis, 90 (60%) received btz incorporated into a program of auto transplant and 60 (40%) combined with conventional chemotherapy. One-hundred and nineteen patients (79%) had a Ig secreting MM, 28 (19%) a light chain only MM and 3 (2%) a non-secretory disease. At baseline, 128 patients (85%) showed an abnormal sFLC ratio (sFLCR). After treatment, 71 patients (47%) achieved a complete response (CR) and 113 (75%) showed a normalization of sFLCR: of these 69 (61%) were in CR whereas 44 (39%) had a monoclonal-protein (M protein) still detectable by electrophoresis or immunofixation (p<0.001). With a median follow-up of 31 months (mo), 59 patients (39%) progressed and 27 (18%) died. The median time to progression (TTP), progression free survival (PFS) and overall survival (OS) were 44, 39 and 75 mo, respectively. At baseline, an involved/uninvolved sFLCR ≥100 (categorized as high) resulted as the most powerful value for discriminating outcomes of survival and was observed in 43% of patients. High and low sFLCR groups were equally distributed between transplant and non-transplant regimens (p=0.109). High baseline sFLCR correlated with Bence Jones isotype (p<0.001), ISS stage III (p<0.001), higher bone marrow infiltration (p=0.003), higher creatinine (p=0.018) and beta-2-microgloblin level (p<0.001), lower haemoglobin concentration (p=0.003), and presence of del(13q) (p=0.001); whereas no correlation was found with t(4;14) or del(17p). High sFLCR, compared to sFLCR <100, was associated with a lower probability to normalize sFLCR after treatment (67% *vs* 81%, p=0.046), and shorter TTP (35 *vs* 50 mo, p=0.003) and PFS (32 *vs* 50 mo, p=0.008), whereas the OS was similar in the two groups (81% *vs* 76% at 3 years, p=0.36). Conversely, survival outcomes were significantly superior in patients who achieved a normalization of sFLCR in comparison with those who failed this objective with median TTP of 49 *vs* 18 mo, (p<0.0001), median PFS of 49 *vs* 17 mo (p<0.0001) and median OS of 75 *vs* 43 mo (p<0.0001), respectively. Moreover, achievement of sFLCR normalization maintained its prognostic value for TTP (p=0.003) and PFS (p=0.003), along with achievement of CR (p=0.032 and p=0.018, respectively) and ISS I/II (p=0.001 and p<0.001, respectively), by Cox regression analysis. Finally, an involved/uninvolved sFLCR ≥100 was observed in 38% of patients at relapse and was associated with earlier start of salvage therapy, compared with sFLCR <100 (89% *vs* 64% at 3 mo, p=0.0426).
Summary and Conclusions: High sFLCR at baseline was associated with shorter TTP and PFS, and at relapse with a short-lasting treatment-free phase. Conversely, normalization of sFLCR after treatment was a robust prognostic indicator of longer disease control, irrespective of achievement of conventional CR. Evaluation of sFLC, in addition to M protein, allows to better define the tumour burden throughout the course of the disease.

E1282

EVALUATION OF THE CHROMOSOMAL ABERRATION PATTERN IN IMMUNOGLOBULIN LIGHT CHAIN AMYLOIDOSIS

M.-Y. Lee[1,*] K. Kim[1], H.S. Kim[1], J.Y. Lee[1], S.H. Lim[1], S.J. Kim[1], G.Y. Lee[1], J.E. Lee[1], J.-O. Choi[1], J.-S. Kim[2], H.-J. Kim[3], S.-Y. Lee[3], J.-H. Min[4], E.-S. Jeon[1]

[1]Internal medicine, [2]Pathology, [3]Laboratory Medicine & Genetics, [4]Neurology, Samsung medical center, Seoul, Korea, Republic of

Background: Chromosomal aberrations of plasma cells are well recognized as important pathogenetic and prognostic factors in multiple myeloma, whereas it has remained unclear in immunoglobulin light chain (AL) amyloidosis in particularly Asian patients.
Aims: The purpose of this study is to identify prognostic cytogenetic risk factors by interphase FISH in AL amyloidosis cohort patients in Korea.
Methods: A total of 184 patients with systemic AL amyloidosis were retrospectively analyzed from April 1995 to August 2014 in Korea.
Results: Cytogenetic testing by interphase fluorescence *in situ* hybridization (FISH) had been performed in 80 (44%) patients with AL amyloidosis, and 29 (36%) patients had abnormal FISH as follows; most common abnormality is gain of 1q21 (18%) followed by t(11;14), deletion 13, t(4;14), deletion 17, t(14;20) and t(14;16). Patients with abnormal FISH results had more bone marrow plasma cells (median 16.5 *vs* 30%, p=0.011). Median overall survival (OS) was significantly longer in patients without gain of 1q21 (39.2 months) as compared to in patients with gain of 1q21 (12.2 months, p=0.043). There was no statistical significantly difference, but patients with t(11;14) or deletion 13 had a shorter median OS (18.9 *versus* 36.3 months, p=0.367 or 15.2 *vs* 34.7 months, p=0.517).
Summary and Conclusions: In conclusion, our results suggest that detection of gain of 1q21 is an adverse prognostic factor in patients with AL amyloidosis. And further prospective and large studies of FISH test are warranted.

E1283

IMPACT OF NF-KB EXPRESSION IN THE PROGNOSIS OF MULTIPLE MYELOMA PATIENTS TREATED WITH BORTEZOMIB IN FRONTLINE REGIMENS

C. Geraldes[1,2,3,*] A.C. Gonçalves[3,4], R. Alves[3,4], E. Cortesão[1,2,3], L. Ribeiro[1], J.M. Nascimento Costa[3,5], A.B. Sarmento-Ribeiro[1,3,4]

[1]Clinical Haematology Department, Coimbra University Hospital Center, [2]University Clinic of Hematology, [3]Centre for Research on Environment, Genetics and Oncobiology, [4]Applied Molecular Biology and University Clinic of Hematology, [5]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Nuclear factor κappa B (NF-kB) is a heterodimeric transcription factor that promotes transcription of several anti-apoptotic growth factors, proteins, and cytokines, after its nuclear translocation. NF-kB is normally present in the cytoplasm in association with its inhibitor, IkB. Bortezomib inhibits degradation of Iκ-B and therefore blocks NF-kB activity. As NF-κB is highly expressed in myeloma cells, its inhibition by bortezomib promotes their apoptosis. Bortezomib is frequently included in the frontline regimens to treat multiple myeloma (MM) patients. However, the prognostic impact of NF-kB expression levels in plasma cells from newly diagnosed MM patients, treated with bortezomib, is largely unknown.
Aims: To analyze the expression levels of NF-kB in CD138+/CD19- and CD138+/CD19+ plasma cells from MM patients, at diagnosis, and to determine its impact in response and in overall survival of patients treated with bortezomib as frontline regimen.
Methods: We evaluated 24 newly diagnosed MM patients, between April 2010 and April 2013, treated with bortezomib (+ dexamethasone,±cyclophosphamide) as first-line regimen. NF-kB expression levels were analyzed with monoclonal antibodies by flow cytometry in CD138+/CD19+ and CD138+/CD19- plasma cells from bone marrow samples collected at diagnosis. NF-kB expression levels are mentioned in mean intensity of fluorescence (MIF). Response evaluation was determined according to International Myeloma Working Group response criteria. For statistical analysis, *software* IBM SPSS *Statistics* v22 was used.
Results: Twenty-four patients (42% male) were studied, with a median age of 61 (41-75) years; 21/24 (88%) patients presented response to bortezomib. We analyzed NF-kB expression levels in CD138+/CD19+ and CD138+/CD19- plasma cells in patients with and without response to bortezomib (1 CR, 4 VGPR, 16 PR). According to our results, patients with response to bortezomib presented higher NF-kB expression levels in CD138+/CD19- plasma cells (26,2±1,7 MIF *vs* 19,7±1,8 MIF; p=0,032). In CD138+/CD19+ plasma cells, we didn't find differences in NF-kB expression levels (38±2,3 MIF e 33,6±5,6 MIF, respectively). Based on these results, we searched for a prognostic impact of NF-kB expression levels in MM patients with response to bortezomib. Among these patients, median NF-kB expression levels in CD138+/CD19- and CD138+/CD19+ plasma cells were 26,2±1,7 MIF and 38±2,3 MIF, respectively (p=0,0001). We also found that NF-kB expression levels higher than or equal to 25 MIF in CD138+/CD19- plasma cells are associated to a longer survival: median survival not reached compared with 26,1 months (95% CI; 22,4-29,8); p=0,022, for NF-kB expression levels lower than 25.
Summary and Conclusions: Plasma cells from MM patients with different phenotypes present distinct NF-kB expression levels. Higher NF-kB expression levels in CD138+/CD19- plasma cells are associated with increased response rates to bortezomib and with a benefit in overall survival. These results suggest that NF-kB expression levels in CD138+/CD19- plasma cells from MM patients might be considered a potential biomarker for response to bortezomib and prognosis.
This work was supported by CIMAGO (project nº 23/09).

CIRCULATING BCMA BINDING TO ITS LIGAND BAFF PREVENTS NORMAL ANTIBODY PRODUCTION IN MULTIPLE MYELOMA PATIENTS

J. Berenson[1,*] E. Sanchez[1], A. Gillespie[1], N. Harutyunyan[1], G. Tang[1], J. Gottlieb[1], S. Vardanyan[1], M. Li[1], C. Andreu-Vieyra[2], M. Ghermezi[1], C. Wang[1], J. Ben-Zvi[1], G. Garzio[1], H. Chen[1]
[1]Hematology/Oncology, Institute for Myeloma & Bone Cancer Research, [2]Hematology/Oncology, Oncotherapeutics, West Hollywood, United States

Background: A hallmark of multiple myeloma (MM) is the low levels of uninvolved immunoglobulin (Ig) levels. B-cell maturation antigen (BCMA) is a receptor expressed in mature non-malignant and malignant B lymphocytes, including plasma cells. We previously demonstrated that BCMA is present in the serum of MM patients and that its levels predict overall survival (Sanchez *et al.* Br J Haematol 2012).
Aims: We hypothesized that circulating BCMA binds to its ligands, preventing normal plasma cell development and antibody production in MM patients.
Methods: BCMA-Fc and control Ig were obtained (R&D Systems). Human BCMA and mouse BAFF, and mouse plasma IgA, IgA and IgM levels were measured with ELISA (R&D Systems & Bethyl Laboratories). rhBCMA-mBAFF complexes were determined using an ELISA. Plates were pre-coated with a monoclonal mouse anti-BAFF capture Ab. Plasma samples were incubated and an anti-human-BCMA detection Ab was added. Human serum IgA and IgG levels were determined in MM patients using nephelometry (Immage 800, Beckman Coulter). Hevylite® Assays (Binding Site) were used to quantify the levels of heavy-light chain isoform pairs.
Results: To determine the effects of human BCMA on plasma Ig levels in immune competent mice, rhBCMA-Fc or control Ig-Fc (100 mg) was injected into C57 Bl or Balb/c mice. rhBCMA-Fc resulted in significant decreases in IgA, IgG and IgM levels. Decreases in IgA levels were observed when compared to baseline levels on days 4 and 6 (P=0.0031 and P=0.0064, respectively), and the controls (P=0.0087 and P=0.0221). Mouse IgG levels also showed a reduction compared to baseline (P=0.0023), the Ig-Fc (P=0.0014) and control (P=0.0129) groups. IgM levels showed similar decreases when compared to the untreated (P=0.0001) and Ig-Fc (P=0.0088) groups. We determined if rhBCMA-mBAFF complexes formed *in vivo*. Complexes were detected by ELISA at high levels in plasma from mice dosed with BCMA-Fc, whereas none were found in samples in control Ig-Fc or untreated mice. Next, we determined the relationship of serum BCMA levels to uninvolved Ig levels in MM pts. For pts with IgA (n=134) or IgG (n=313) MM, higher BCMA levels (≥100 ng/ml) correlated with below normal levels of uninvolved IgG in IgA MM and uninvolved IgA in IgG MM, whereas lower BCMA levels (<100 ng/ml) correlated with normal uninvolved levels (P <0.0001). Using the Hevylite Assay, similar results were observed BCMA levels compared to uninvolved IgG isoforms in both pts with involved IgG lambda (n=62, P=0.0006) and IgG kappa (n=117, P <0.0001) MM.
Summary and Conclusions: We demonstrate the formation of circulating BCMA-BAFF complexes in MM, and administration of recombinant BCMA to normal mice results in marked reductions in their antibody levels. We also show that BCMA levels inversely correlate with uninvolved Ig levels in MM pts. Thus, the lack of normal antibody production in MM pts results in part from circulating BCMA binding its ligands, preventing production of normal antibody-producing cells.

E1285

BORTEZOMIB CONSOLIDATION FOLLOWING ASCT FOR MULTIPLE MYELOMA (MM) IMPROVES RESPONSE DEPTH, WITH ACCEPTABLE TOXICITY AND PRESERVED QUALITY OF LIFE

N. Rabin[1,*], C. Nicholas[2], R. Owen[3], B. Popova[2], O. Schofield[2], A. Rawston[3], R. de Tute[3], J. Lyons-Lewis[1], S. Moore[4], D. Hughes[5], K. Yong[1]
[1]Department of Haematology, University College London Hospitals, [2]Cancer Research UK and UCL Cancer Trials Centre, University College London, London, [3]Haematology Malignant Diagnostic Services, Leeds Teaching Hospitals, Leeds, [4]Department of Haematology, Royal United Hospitals Bath, Bath, [5]Department of Haematology, Royal Free London Hospital, London, United Kingdom

Background: Consolidation following autologous stem cell transplantation (ASCT) may improve depth of response and prolong time to next treatment, but there is no established standard of care.
Aims: To explore the effect on response depth, progression free survival (PFS) and quality of life (QOL) in patients on a single arm phase 2 post ASCT bortezomib consolidation trial (BCT)
Methods: Bortezomib-naïve patients with at least stable disease were enrolled 3 to 4 months following ASCT, and received Bortezomib at 1.3mg/m^2 (17 started with IV, the rest with SC) on days 1, 8, 15, 22 of a 4-week cycle, maximum 8 cycles. Disease response (IMWG) was assessed at 3, 6 and 12 months post ASCT. Minimal residual disease (MRD) by multiparametric flow cytometry was assessed at the same time points from patient 15 onwards. Toxicity and QOL (EORTC-QLQ-C30) were assessed at each cycle and end of treatment. PFS and OS were measured from date of registration and estimated using the Kaplan-Meier method.
Results: 40 patients were recruited December 2009-March 2014, 22 (55%) were male. Median age was 61 years (range 43-69), isotypes were: 22 (59%) IgG, 9 (24%) IgA, 1 (3%) IgD, 5 (14%) LC only, 1 NS and 2 unknown. Induction regimens pre-ASCT were thalidomide (33 patients, 83%), idarubicin and dexamethasone (5 patients, 13%), and unknown in 2 (5%). All patients received melphalan 200mg/m^2 conditioning for ASCT. At trial entry, median time from diagnosis and from ASCT were 11.0 months (8.6-18.1), and 3.4 months (2.7-4.3) respectively. Of the 40 patients enrolled, 1 withdrew before treatment, 1 progressed in cycle 1, and 2 stopped treatment in/after cycle 1 (treatment related adverse events); 36 patients (90%) completed more than 1 cycle of treatment. A further 10 (25%) patients stopped treatment early, 5 due to toxicity (4 neuro-toxicity and 1 elevated alkaline phosphatase), 4 due to patient/physician choice, and 1 for disease progression. 21 (53%) patients had a dose delay, 15 (38**%**) patients had a dose modification, and 28 (70%) at least one dose omitted. A median of 8 cycles of trial treatment were received. After a median follow up of 30.0 months, 25 patients (63%) are alive without progression, 13 (33%) are alive having progressed, and 2 (5%) have died of MM. BCT improved response depth in assessable patients who completed more than 1 cycle of treatment (N=34): 4 (12%) ≥CR, 19 (56%) VGPR, 10 (29%) PR and 1 (3%) SD pre-treatment, increasing to 7 (21%) ≥CR, 20 (59%) VGPR, 4 (12%) PR, 1 (3%) PD and 2 (6%) N/A at 12 months post ASCT; 11 patients (32%) improved response. Median PFS is 35.5 months (95% CI, 27.5-43.5), with a 2 year PFS of 77.7% (95% CI, 62.8-92.6). 23 patients had MRD assessed at 3 or 6 months post ASCT, of whom 18 had follow up samples at 12 months (end of consolidation). Of these, 9 were MRD+ at the earlier time point, and 4 of these converted to MRD- at 12 months. All MRD- patients remained MRD- at 12 months. Eleven (28%) patients experienced a total of 15 grade 3 adverse events; 6 (neuropathy), 4 (infection), 1 (fatigue), 1 (elevated alkaline phosphatase), 1 (hearing impairment), 2 (haematological). In addition 1 patient had a grade 4 infection (cycle 1, treatment discontinued) and 1 grade 4 back pain. EORTC-QLQ-C30

scores for global health status, and physical, emotional and social functioning did not change significantly throughout treatment.
Summary and Conclusions: Consolidation therapy using weekly Bortezomib post ASCT is well tolerated and associated with a deepening of response, including MRD- rate. This post-ASCT strategy deserves further study.

E1286

SUPERIOR EFFICACY OF VTD OVER VCD BEFORE AND AFTER AUTOLOGOUS STEM-CELL TRANSPLANTATION IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

M. Cavo[1,*] L. Pantani[1], A. Pezzi[1], F. Gay[2], M.T. Petrucci[3], F. Patriarca[4], E. Zamagni[1], D. Vincelli[5], A.M. Carella[6], P. Tacchetti[1], N. Testoni[1], P. Di Bartolomeo[7], T. Caravita[8], A.M. Cafro[9], A. Gabbas[10], G. Ameli[1], R. Rizzi[11], N. Cantore[12], F. Morabito[13], P. Sonneveld[14], A. Palumbo[2]

San G.Moscati, Avellino, [13]Presidio Ospedaliero dell'Annunziata. Az.Osp. di Cosenza, Cosenza, Italy, [14]Dept. of Hematology, Erasmus MC, Rotterdam, Netherlands

Background: A triplet bortezomib-based induction regimen and autologous stem-cell transplantation (ASCT) are the current standard of care for young, newly diagnosed, multiple myeloma (MM) patients (pts). However, due to the lack of randomized trials comparing different regimens incorporating bortezomib, the treatment choice is ultimately based upon physician's preference or single center's policy. Bortezomib-thalidomide-dexamethasone (VTD) has been approved by EMA in this setting. Bortezomib-cyclophosphamide-dexamethasone (VCD) is an alternative to VTD, although efficacy results have not been backed by phase III studies.
Aims: To compare the efficacy of VTD *vs* VCD before and after ASCT.
Methods: 107 pts who were randomized to the VTD arm of the GIMEMA-MMY-3006 study were compared with an equal number of Italian pair mates who were treated with VCD and ASCT as part of the EMN02 trial. Baseline case matching criteria were age (±2 years), ISS stage (1 *vs* 2 *vs* 3), presence of t(4;14) and/or del(17p) positivity. Induction treatment consisted of three 21-day cycles of either VTD (bortezomib 1.3 mg/m^2 on d 1, 4, 8, and 11; thalidomide 100-200 mg daily; dexamethasone 40 mg on d 1, 2, 4, 5, 8, 9, 11, and 12) or VCD (bortezomib and dexamethasone as in VTD; cyclophosphamide 500 mg/m^2 on d 1 and 8). Melphalan dose prior to ASCT was 200 mg/m^2 (Mel-200). Response was evaluated according to IMWG criteria.
Results: In comparison with VCD, VTD yielded a higher rate of ≥VGPR both before (38% *vs* 60%, p=0.001) and after (63% *vs* 78%, p=0.014) ASCT, including a significantly higher probability of CR (5% *vs* 19%, p=0.001, and 14% *vs* 39%, p<0.001, respectively). Pts with t(4;14) and/or del(17p) had a significantly higher probability to achieve ≥VGPR after VTD induction therapy as compared to those receiving VCD (86% *vs* 43%, p=0.004). In pts with advanced ISS stage (2-3), the superior efficacy of VTD over VCD was retained both before ASCT (CR: 25% *vs* 5%, p=0.002; ≥VGPR: 67% *vs* 38%, p=0.001) and after ASCT (CR: 43% *vs* 11%, p<0.001; ≥VGPR: 85% *vs* 64%, p=0.007). Any grade 3-4 hematological toxicity was higher with VCD *vs* VTD induction therapy (12% *vs* 5%). Grade ≥2 peripheral neuropathy (PN) (NCI CTCAE, version 3.0) was slightly, but not significantly, higher for pts on VTD as compared to those on VCD (12% *vs* 9%, p=0.19). However, when the threshold of grade ≥3 PN was considered, the difference between the two groups significantly favoured pts treated with VCD (2% *vs* 7%, p=0.004), although it is worth noting that only a single pt on VCD and 2 pts on VTD discontinued treatment due to PN. No significant difference in the median dose of CD34+ cells/kg infused to support Mel-200 was observed between pts reveiving VTD or VCD (4x10^6 *vs* 4.5x10^6/kg).
Summary and Conclusions: The triplet VTD induction therapy was associated with significantly higher pre-ASCT CR and ≥VGPR rates compared to VCD, confirming that VTD is one of the most active bortezomib-based induction regimens in preparation for subsequent ASCT. The superior efficacy of VTD over VCD was confirmed also after ASCT and was retained across subgroups of pts with ISS stage 2-3 and a high-risk cytogenetic profile [t(4;14) and/or del(17p)]. Data from the current analysis need to be confirmed by randomized studies designed to prospectively compare VTD *vs* VCD induction therapy before ASCT.

E1287

IMPACT OF SERUM ALPHA 1-ACID GLYCOPROTEIN (AAG), A POTENTIAL PATIENT SELECTION MARKER FOR FILANESIB, ON SURVIVAL AND RESPONSE TO CONVENTIONAL THERAPIES IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA (RMM)

S. Hussain[1], R. Aitchison[2], J. Regensburger[2], A. Engebretson[1], A. Dispenzieri[1], S.V. Rajkumar[1], B. Tunquist[3,*] S. Kumar[1]
[1]Division of Hematology, Mayo Clinic, Rochester, [2]Biostatistics & Data Management, [3]Translational Medicine, Array BioPharma, Boulder, United States

Background: Serum AAG (orosomucoid) is an acute-phase reactant protein that has been shown to correlate with disease stage as well as overall survival (OS) in patients with multiple myeloma (MM). More recently, it has been proposed as a response marker for patient outcome to filanesib (ARRY-520), a novel kinesin spindle protein inhibitor undergoing evaluation for the treatment of MM. To date, RMM patients with serum AAG concentrations >110 mg/dL have not demonstrated objective responses to single-agent filanesib, while the response rate for patients below this cut point is approximately 23%. It is hypothesized that this lack of response may be caused by AAG binding to filanesib, reducing free concentrations of serum filanesib, while having no appreciable effect on other MM drugs.
Aims: The current study evaluated the prognostic value of AAG for OS, and its ability to predict response in RMM patients treated with standard MM regimens.
Methods: AAG levels in plasma samples from patients with RMM who had received at least one prior therapy (median 4 prior lines; range, 1 to 14) were measured in a central laboratory (ICON Laboratory Services) using a validated assay (Randox Laboratories). Patients were followed for objective response to their next line of therapy and for overall survival. The relationship between AAG concentrations and treatment outcomes were assessed with univariate and multivariate analyses.
Results: AAG levels were measured in plasma from 247 patients (60% male, median age 62 yrs) with RMM who had subsequent follow-up for OS. The median time of plasma collection was 30 months after diagnosis of MM (range, 0.5 to 280 months). At the time of analysis, 60% of patients had died and the median OS from date of plasma collection was 27.2 mos. The median plasma AAG level was 81.1 mg/dL (range 25-266); 20% had high AAG (>110 mg/dL, the cutoff used for filanesib study). AAG status correlated with the International Staging System (ISS) prognostic index and other prognostic factors for MM (*e.g.*, LDH, β2M, number of prior regimens). In a univariate analysis, AAG status was prognostic for OS: median OS was 16 mos for those with high AAG compared with 30 mos for those with low AAG (hazard ratio=1.5; p=0.04). However, in a multivariate analysis that included other prognostic factors, the effect of AAG on OS was not significant (HR=1.3, p=0.2). Importantly, there was no correlation between patient AAG concentrations and objective response (≥PR) to standard therapies initiated within 60 days following AAG measurement that included stem cell transplant, treatment with proteasome inhibitors and/or immunomodulatory agents (overall response rate=59% *vs* 55%, respectively, for patients with low or high AAG, p=0.80).
Summary and Conclusions: In this retrospective study in patients with RMM, plasma AAG concentration was not an independent prognostic factor for OS or predictive of response to conventional MM therapies. These results suggest that the value of AAG as a predictor for response may be unique to treatment with filanesib amongst current myeloma therapies. This may be due to direct binding of AAG to filanesib. The predictive and prognostic nature of AAG as a patient exclusion biomarker for filanesib treatment is being evaluated in an ongoing randomized study (NCT01989325).

E1288

BORTEZOMIB FOR THE TREATMENT OF MULTIPLE MYELOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

K. Scott[1 2,*] A. Howman[3], P.J. Hayden[4], K. Wheatley[3], A. Will[5], I. Coyne[2]
[1]Irish Clinical Oncology Research Group (ICORG), [2]School of Nursing & Midwifery, Trinity College Dublin, Dublin, Ireland, [3]Cancer Research Clinical Trials Unit, University of Birmingham, Birmingham, United Kingdom, [4]Dept. of Haematology, St James's Hospital, Dublin, Ireland, [5]Cochrane Haematological Malignancies Group, University Hospital of Cologne, Cologne, Germany

Background: Multiple myeloma is a plasma cell malignancy accounting for approximately 1% of cancers diagnosed and 12% of haematological malignancies. The first-in-class proteasome inhibitor, bortezomib, is commonly used in all myeloma disease settings. We conducted a systematic review and meta-analysis to evaluate the accumulated clinical evidence of bortezomib treatment of myeloma.
Aims: To assess the clinical benefits and side effects of bortezomib compared to other therapies, doses, administration methods and treatment schedules. Primary objectives were to assess effects of bortezomib on overall survival (OS) and progression-free survival (PFS). Secondary objectives included response rates (RR), adverse events (AE), treatment-related death (TRD) and health-related quality of life (HRQoL).
Methods: We searched MEDLINE, the Cochrane Central Register of Controlled Trials and EMBASE (till end of Nov 2014), conference proceedings and clinical trial registries for randomised controlled trials (RCTs). Two review authors independently extracted outcomes data and assessed risk of bias. Hazard ratios (HR) and their confidence intervals (CI) were extracted for OS and PFS and Odds Ratios (OR) for RRs, AEs and TRD. Trial authors were contacted if summary statistics were missing. Log-rank statistics were estimated if not available.
Results: Sixteen relevant RCTs involving 5630 patients were identified and

12 trials included in the meta-analysis. Four trials of different doses, administration and treatment schedules were reviewed qualitatively. Overall risk of bias was considered to be generally low. We estimated OS benefit from 4118 patients (Peto OR=0.77 (95% CI: 0.69 to 0.86, P <0.00001) and PFS benefit from 4344 patients (Peto OR=0.67 (95% CI: 0.61 to 0.72, P <0.00001) in favour of bortezomib. Meta analysis of complete and overall RR also produced statistically significant results in favour of bortezomib. Subgroup analyses by disease setting revealed improvements in all outcomes. For therapy setting, a statistically significant benefit was observed in all outcomes except OS following consolidation therapy. Bortezomib treatment led to statistically significant increased risks of thrombocytopenia, neutropenia, gastro-intestinal toxicities, peripheral neuropathy, infection and fatigue. A greater risk of cardiac disorders was observed in one comparison group (bortezomib *vs* no bortezomib with different background therapy or *vs* other agents), however, no evidence of increased risk of TRD. Only 4 trials analysed HRQoL and could not be meta-analysed.
Summary and Conclusions: This systematic review and meta-analysis demonstrates myeloma patients receiving bortezomib benefit in terms of OS, PFS and RR. Bortezomib should be considered a standard therapy for myeloma. However, we are unable to draw conclusions regarding optimal combination therapy containing bortezomib. Further evaluation of the newer proteasome inhibitors and more studies of HRQoL are also needed.
This abstract is based on a protocol of Cochrane Review published 11/11/2013, Issue 11. Upon completion and approval, the final version is expected to be published in the Cochrane Database of Systematic Reviews (www.thecochranelibrary.com).

E1289

CAN OVERALL SURVIVAL BE IMPROVED IN ELDERLY MULTIPLE MYELOMA PATIENTS?

B.M. Heeg[1,*], J. Liwing[2], S. Karstorp[2], M. Postma[3], R. Silvennoinen[4], M. Putkonen[5], P. Anttila[6], K. Remes[5], N. Abildgaard[7], A. Waage[8], H. Nahi[2]
[1]Ingress-health, Rotterdam, Netherlands, [2]Department of Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden, [3]Unit of PharmacoEpidemiology & PharmacoEconomics, Institute of Science in Healthy Aging & health caRE (SHARE), Groningen, Netherlands, [4]Kuopio University Hospital, Kuopio, [5]Turku University Hospital, Turku, [6]HUS, Helsinki, Finland, [7]Department of Hematology, Odense University Hospital, Odense, Denmark, [8]Department of Hematology, St Olavs Hospital, Trondheim, Norway

Background: The ongoing introduction of novel therapies for MM provides clinicians and patients various treatment options in numerous lines of treatment. Understanding the current treatment practices and the outcomes in different age groups is of vital importance to understand whether these new treatment should be used in patients from all age groups and where options for treatment optimization exist.
Aims: (i) To describe treatment patterns and corresponding outcomes in terms of response, time to next therapy (TTNT) and overall survival (OS) of Nordic Multiple Myeloma (MM) patients with a focus on age. (ii) To investigate whether age affected the patients' probability of being treated with a conventional (*e.g.* melphelan prednisone) or a novel treatment (bortezomib, thalidomide or lenalidomide) and whether this treatment choice affected OS in the elderly.
Methods: A retrospective analysis was performed on incident 2960 MM-patients from 24 hospitals in Denmark, Finland, Norway and Sweden. The database contained information on patient baseline characteristics such as age, gender, international staging system (ISS) stage, albumin, creatine, MM type and response, TTNT and OS over eight lines of treatment. The patients were stratified over three age groups (<65, 65<75 and ≥75) for which baseline characteristics, treatments, response, TTNT and OS were reported. To validly compare the effectiveness (OS) of novel *vs* conventional treatments in first line, propensity score matching was used and also multivariate cox-regressions.
Results: Patients were on average 67 years old, 48% were male and 28%, 41% and 31% in ISS stages I, II and III, respectively. The chance of being treated with a conventional therapy increases with age in all lines of therapy. In first line, 13% in younger patients <65 years and 72% of elderly patients ≥75 years were treated with a conventional. Patients seemed to respond better on novel therapies. In first line, patients aged ≥75 years treated with a conventional treatment, novel treatment and stem cell transplantation had a 9%, 28% and 69% probability on a ≥very good partial response respectively. Patients' ≥75 with no response or progressive disease on first line had a median OS of 1.54 years whereas patients in the same age group with (near) complete response had a median OS of 3.27 years. For patients aged ≥75 years, a matched treatment comparison using propensity scoring showed significantly longer OS for novel therapies 3.61 (2.66-6.44) years *versus* conventional therapies 2.14 (1.78-2.57) years. Multivariate cox-regression models gave a similar result with an estimated hazard ratio of 0.45 (0.24-0.98).
Summary and Conclusions: This paper shows that in this incident cohort elderly patients are significantly more likely to be treated with a conventional MM therapy than younger patients, while elderly patient do significantly benefit from novel therapies in first line compared to conventional therapies in terms of longer OS. Hence, there is a potential to improve therapy for and further increase the OS among elderly MM patients with novel treatment options.

E1290

PROGNOSTIC IMPACT OF CIRCULATING PLASMA CELLS ON SURVIVAL OF PATIENTS WITH MULTIPLE MYELOMA

M. Granell[1,*], X. Calvo[2], A. García[3], L. Escoda[4], C.M. Martínez[1], M. Teixidó[3], M.T. Giménez[4], P. Sanz[1], D. Campoy[3], A. Vicent[4], L. Rosiñol[2], J. Sierra[1], J. Bladé[2], C. Fernández de Larrea[2]
[1]Hematology, Hospital de la Santa Creu i Sant Pau, [2]Amyloidosis and Myeloma Unit. Hematology Department, Hospital Clínic and IDIBAPS, Barcelona, [3]Hematology, Hospital Arnau de Vilanova, Lleida, [4]Hematology, Hospital JoanxXIII, Tarragona, Spain

Background: The prognosis of patients with plasma cell leukemia (PCL) is extremely poor. In multiple myeloma (MM) not fullfiling criteria of PCL, the finding of plasma cells in peripheral blood is a marker for highly proliferative disease. The current definition of PCL requires the presence of an absolute peripheral blood plasma cell count >2x 10^9/L and >20% PC in differential white cell count. Recently, it has been suggested a lower cut-off of ≥5% or ≥0.5x 10^9/L of nucleated peripheral blood cells to redefine this entity.
Aims: To investigate whether the presence and number of circulating plasma cells by morphology can be used as a predictor marker of survival in patients with MM not fulfilling PCL criteria, trying to find the threshold to a new definition of PCL.
Methods: Three hundred and seventy patients (male/female 203/167; median age 69 years, range 28-90) diagnosed with symptomatic MM or primary PCL following the International Myeloma Working Group criteria between January 2008 and December 2012. For inclusion, peripheral blood smears at diagnosis had to be available for review. This study was conducted in four University Hospitals from Catalonia. Clinical data including age, gender, Durie-Salmon and ISS stage, initial treatment and follow up were collected from medical records. Patients were treated according to local protocols. Wright-Giemsa stained peripheral blood smears were systematically reviewed. A minimum of 100 nucleated cells per smear were counted. Patients were classified in three groups: *MM-low* group defined as <5% or <0.5x10^9/L circulating plasma cells, *MM-high* group defined as 5% to 20% and/or 0.5x10^9/L to 2x10^9/L circulating plasma cells, and PCL defined as >20% and/or >2x10^9/L circulating plasma cells.
Results: Of the 370 patients studied, 357 (96.5%), 9 (2.4%) and 4 (1.1%) were included in the *MM-low*, *MM-high* and PCL groups, respectively. Patients in the *MM-high* group had lower platelet counts (median 91x10^9/L *vs* 214x10^9/L, p <.0001) and higher bone marrow plasma cells at diagnosis (median 50% *vs* 39%, p=0.031) than the *MM-low* group. Median survival of patients in the *MM-low*, *MM-high* and PCL groups were 52 (95% CI 42.4-61.5), 7 (95% CI 4.0-9.9) and 12 (95% CI 3.1-20.8) months, respectively (Figure 1). *MM-high* group was associated with shorter survival (Hazard ratio 4.34, 95% CI 2.16-8.74) independently of age, Durie-Salmon stage and International Staging System. Within the *MM-low* group, no differences were found between patients with 0% circulating PC (N: 292, median survival 52 months, 95% CI 40.6-63.3) and 1% to 4% circulating PC (N: 65, median survival 53 months, 95% CI 31.7-74.2).

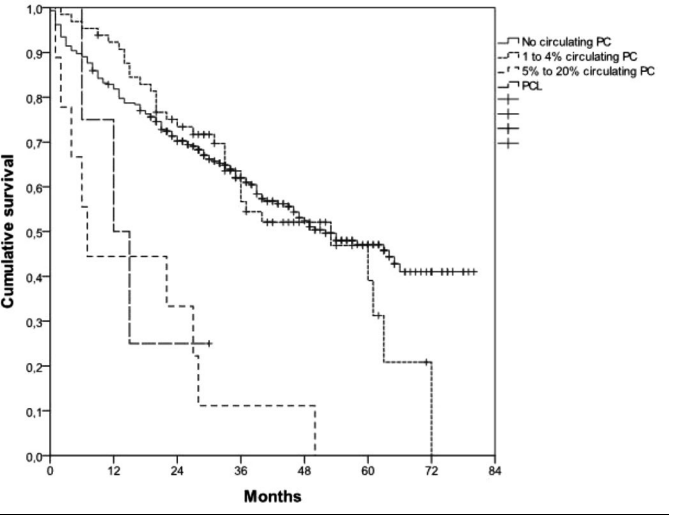

Figure 1.

Summary and Conclusions: The presence of either >5% or >0.5x10^9/L circulating plasma cells in patients with MM has similar adverse prognostic impact that PCL as currently defined. Despite the limited number of cases, our findings support the perception that the definition of PCL should be revisited. The proposal for this new threshold for PCL definition deserves confirmation in other independent study.

E1291

A POPULATION BASED STUDY OF NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS IN LATVIA (2007-2009 YEARS)

D. Auzina[1,2,3,*] S. Lejniece[1,2], J. Nazarovs[4], I. Strele[5]
[1]Department of Internal Diseases, Riga Stradins University, [2]Chemotherapy and Haematology Clinic, Riga East Clinical University Hospital, Riga, Latvia, [3]A.Kirchenstein Institute of Microbiology and Virology, Riga Stradins University, [4]Pathology Centre, Riga East Clinical University Hospital, Riga, Latvia, [5]Department of Public Health and Epidemiology, Riga Stradins University, Riga, Latvia

Background: Multiple myeloma (MM) is the second most common hematologic malignancy found in adult population. Specific end-organ damage caused by the disease, such as renal disease, anemia and bone lesions are associated with worse prognosis of MM patients.
Aims: To identify primary diagnosed MM patients from National Center of Hematology with primary diagnosed MM between 2007 and 2009 and to analyze 5-year survival rate.
Methods: This retrospective 3-year study included 162 patients from National Center of Hematology with primary diagnosed MM between 2007 and 2009. Statistical analyses were performed using Graph Pad Prism 5, SPSS statistical software (version 20). Survival curves were analyzed accordingly Kaplan-Meier method and statistically compared using the log-rank test. 5-year survival rate were analyzed for all group and for some subgroups. The survival factors were analyzed without taking in to account the therapy received. During the time period (2007- 2009), the novel agents in Latvia were not State paid and Velcade was available only as a third treatment line. Autologus stem cell transplantation was applied for just 12 patients.
Results: We have analyzed dates of 162 patients (n=66 (41%) males, n=96 (59%) females), with an age range from 48 to 85, mean age (Mean±SD) was 67.49±9.02 years. 47.5% of the patients were older than 70 years. The most frequently reported symptoms were bone pain (51%) and fatigue (25%). MM in 7% was diagnosed during routine blood tests. Most of patients (56%) were in stage III (*Salmon-Durie* staging system), but 25% were in II stage and 19% in I stage. M-protein in serum mean concentrations was 32.42±23.42 g/l (range 0-104), but in patients with III stage it was-48.83±25.36 g/l. Bone lesions had 56% (n=105) patients. >3 lytic bone lesions with vertebral fractures were detected in n=68 (42%) cases. Renal disease was proved in n=77 (48%) cases (glomerular filtration rate (GFR) <60 ml/min/1.73m^2). 12 patients with MM needed hemodialysis. 3 patients were with extramedullary involvement. Five-year survival rate in analyzed group was 25.9%.The median survival period for all patients was 30.3 month (95% CI 24.8-35.9 month). Statistically better survival was in patients under 70 years of age (p <0.001). The 5-year survival rate was 41.2% of patient <70 years, but in patients >70 years it was 9.1%. The most important survival factor was stage of disease (*Salmon-Durie*). Better survival was proved with early stage of MM. We didn't find statistically significant survival difference between 2nd and 3rd stage (p=0.274). Patients with 1st stage of disease 5 year survival rate was 51.6%, but 2nd-22% and 3rd-18.9%. The second most important survival factor was renal disease with statistically significant worse survival (p<0,001). The 5-year survival rate in patient group with renal disease was 32.9%, but without it-18.2%. We found statistically significant survival difference between groups according to hemoglobin level. Patients with Hb <85 g/L had statistically significant worse survival, than with Hb level 85 to 100g/L (p=0.016) and with Hb >100g/L (p<0.001). 5-year survival rate in patients with Hb <85 g/L was 12.2%, but with Hb 85 to 100 g/L-22.2% and with Hb >100 g/L-34.5%.
Summary and Conclusions: 1) 5-year survival rate for patients with primary diagnosed MM from 2007 till 2009 in Latvia was 25.9%. 2) Important survival factors for patients with MM were found to be age more than 70 years, advanced MM stage (*Salmon-Durie*), renal disease and anemia. 3) MM in Latvia was diagnosed at late stage (56% patients were at 3rd stage) with bone lesions in 65% of cases and renal failure (48%).

E1292

OUTCOME OF NEWLY DIAGNOSED SYMPTOMATIC MULTIPLE MYELOMA IN VERY ELDERLY PATIENTS (AGED 80 YEARS OR MORE)

N. Sgherza[1,*] A. Melaccio[2], A. Iacobazzi[1], R. Ria[2], A. Vacca[2], A. Guarini[1]
[1]Haematology Unit, National Cancer Research Centre, Istituto Tumori "G. Paolo II", Bari, Italy, [2]University of Bari "Aldo Moro", Medical School, Department of Biomedical Science, Internal Medicine "G. Baccelli", Bari, Italy

Background: Multiple Myeloma (MM) is a plasma cell neoplasm typical of the elderly, with a median age at diagnosis of 65 years. The increase in median age in western countries has led to an increase in the incidence of this disease; in addition the introduction of novel agents, such as the immuno-modulatory drugs thalidomide and lenalidomide, and the proteasome inhibitor bortezomib, has considerably changed the therapeutic scenario both for young and elderly patients with MM.
Aims: The aim of our study is a retrospective analysis of the outcome of very elderly (80 years or more) patients with newly diagnosed symtomatic MM to determine the characteristics of this subset of patients.
Methods: We collected data from 47 very elderly (80 years or more) patients (M/F: 23/24) diagnosed and treated from January 2008 to December 2014.
Results: Median follow-up was 31 months (range 6-98) after diagnosis. Median age at diagnosis was 83 years (range 80-89) and PS was <2 in 37 cases (79%). One or two concomitant diseases requiring specific treatments were present in 29 patients (62%), and 3 or more concomitant diseases were present in 8 patients (17%). MM was IgG lambda in 9 patients, IgG k in 26 patients, IgA k in 5 cases, IgA lambda in 4 cases, and micromolecular in 3 cases. According to the ISS, 17 patients were classified as III stage, 10 as II stage and 20 patients as I stage. Bone lytic lesions were present at diagnosis in 34 patients (72%), representing the most CRAB feature. Anemia (median value: 8.4 g/dL) was present in 32 patients (68%); hypercalcemia was present in 4 patients (8%) and renal failure was present in 2 patients (4%). First line therapy was bortezomib (once-weekly administration)/dexamethasone in 10 patients (21%), melphalan/prednisone +/- thalidomide in 9 patients (19%) and bortezomib/melphalan/prednisone in 28 patients (60%). According to IMWG response criteria, 19 patients (40%) achieved CR, 12 (26%) achieved PR, 5 (11%) achieved VGPR, and 8 (17%) achieved stable disease; 3 patients (6%) experienced progressive disease. Hematologic toxicity was infrequent but usually weak/moderate (grades 1 & 2 on the WHO scale) and 24 patients received erythropoiesis-stimulating agents. Extrahematologic toxicity was observed in 17 patients (36%), and neuropathy was the most common adverse event for treatment. 25 patients (53%) had at least one disease progression since diagnosis and were therefore switched to second-line therapy. The median time to first disease progression was 21 months (range 6-58) since start of first-line therapy. Second line therapy was bortezomib (once-weekly administration)/dexamethasone in 5 patients, and lenalidomide/dexamethasone in 20 patients. 5 patients received bendamustine/dexamethasone as third line of treatment in disease progression. 31 patients (66%) are still alive for a median overall survival of 22 months (range 7-92). 14 patients died due to disease progression and 2 died due to causes not related to MM.
Summary and Conclusions: A study in a larger series of patients is warranted but our experience showed that no upper age limit should be applied for the administration of new drugs with MM; these treatments could be offered to very elderly patients, including those with severe concomitant diseases. A study in a larger series of patients is warranted but our experience showed that no upperage limit should be applied for the administration of new drugs with MM; these treatments could be offeredto very elderly patients, including those with severe concomitant diseases.

E1293

INTENTION TO TREAT *VS* AGE OF DIAGNOSIS. ANALYSIS OF BENEFITIAL EFFECT OF NEW AGENTS IN THE TREATMENT OF NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM)

F. Escalante[1,*]S. Cerdá[1], M. Fuertes[2], V. Martínez-Robles[1], B. Ballina[1], L. Villalobos[1], P. Escribano[1], J.-A. Rodríguez-Garcia[2]
[1]Hematología, [2]Complejo Asistencial Universitario de León, León, Spain

Background: Beneficial effect on survival after the introduction of high-dose chemotherapy supported by hematopoietic progenitors and new therapeutic agents (thalidomide, bortezomib and lenalidomide) in the treatment of NDMM patients is recognized by the entire scientific community.
Aims: Evaluate the early introduction the new anti-myeloma agents is short-term survival in NDMM patients.
Methods: Characteristics of patients: n: 322. Median age: 74 years (38-100). Gender: male/female: 192/130. Age at diagnosis (ADx-years): A1 (<65): 82, A2 (66-75): 108; A3 (>75): 132. Exposure to new agents according to ADx in 1st line and before 6 months: A1: 34 and 10 (54%), A2: 37 and 24 (52%) and A3: 22 and 10 (24%) (p.01).
Results: The short-term survival (SV6 & SV12) is lower in patients Exposed *versus* No-Exposed to new agents. SV6 & SV12 in Patients Exposed to new agents is similar among the three age groups. This lack of difference is kept until 24 months. Only statistically significant differences are observed in the analysis at 3 years (SV36m of 81 *vs* 65/58%, p.01; no differences between the 2 groups over 65 years). Landmark: to avoid bias initial selection (characteristics of patients, early mortality, palliative treatments in the "old-era"...) we have performed an analysis excluding patients who had died before 6 months of diagnosis. 72 patients (62 in group NO-Exposed and 10 in the Exposed) were excluded. The SV12, SV24 and SV36 (%) according to age groups (<65, 66-75,>75) were 97, 94, 93 (ns); 91, 82 and 79 (ns) and 84, 72 and 65 (p.02 between groups <and>65). The overall survival was 77 *vs* 56 *vs* 49 months (p.018). In the subanalysis by age and exposure differences in SV short, medium and long term are still maintained, with significant differences.
Summary and Conclusions: Early introduction of new therapeutic agents in NDMM patients influence short-term survival independent of the age.
This therapeutic approach achieves an effect not previously described: the absence of differences in survival by age groups until 36 months from diagnosis. Better post-induction (intensification, consolidation, maintenance) treatment in the group of non-candidate patients could improve these results. Recent studies show the beneficial effect of "continuous" treatment in this group of patients (GEM2005, MM-015, FIRST) (Figure 1).

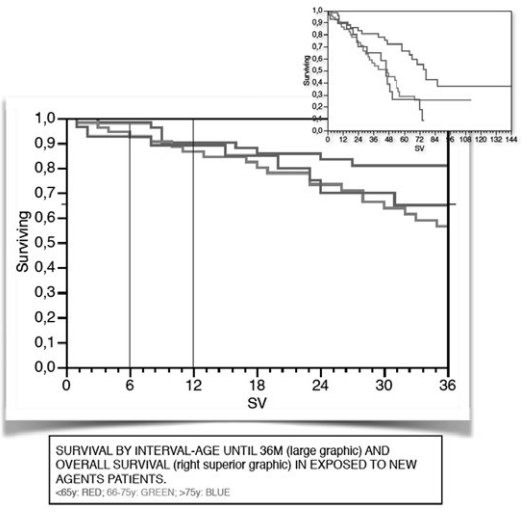

Figure 1.

E1294

SUBCUTANEOUS *VERSUS* INTRAVENOUS BORTEZOMIB: A REAL-LIFE STUDY ON MULTIPLE MYELOMA PATIENTS

S. Mangiacavalli[1,*] F. Cocito[1], V. Ferretti[1], C. Cartia[1], M. Cazzola[1,2], A. Corso[1]
[1]Hematology, IRCCS Fondazione Policlinico San Matteo, [2]Hematology, University of Pavia Fondazione Policlinico San Matteo, Pavia, Italy

Background: Intravenous Bortezomib (i.v. Bor) has emerged as a standard of care for the treatment of patients (pts) with multiple myeloma (MM). Similar efficacy and better safety profile have been showed with subcutaneous administration of Bor (s.c. Bor).
Aims: To compare efficacy and tolerability of standard marketing patented combination regimens (1° line therapy with VTD/VMP, treatment at relapse with VD) incorporating s.c. *vs* i.v. Bor outside clinical trials.
Methods: After local Ethic Committee approval, we reviewed data of 276 consecutive MM pts treated at our Hematologic division between July 2005 to December 2014. We collected data regarding up-front (VTD/VMP regimen), as well as treatment at relapse (VD regimen) with s.c./i.v. Bor. Standard criteria were applied to evaluate response rate and toxicity.
Results: A) 1° line-VMP: 43 pts were analyzed, 15 with s.c. *vs* 28 with i.v. Bor. Pts received similar number (N°) of cycle (5,5 (range 1-9) *vs* 5 (range 1-9), p=0.605). There were no difference in terms of ORR (³PR, 73% *vs* 63%, p=0.709) as well as of CR+nCR rate (27% *vs* 29%, p=0.53). Grade 3-4 Bor-related toxicity rate were comparable: 11% *vs* 12% respectively for s.c. *vs* i.v. administration (p>0,9). None of the pts in both group developed grade 3-4 Bor-related peripheral neuropathy (PN). B) 1° line VTD (as induction before transplant): 96 pts were analyzed, 15 with s.c. 81 *vs* with i.v. Bor. Pts received similar N° of cycle (4 (range 1-5) *vs* 4 (range 1-6), p=0.9). There were no difference in terms of ORR (³PR, 87% *vs* 84%, p>0.9) as well as of CR+nCR rate (7% *vs* 16%, p=0.22). Grade 3-4 toxicity rates were significantly lower with s.c. Bor (none *vs* 34% respectively for s.c. *vs* i.v. administration (p=0,045)) with none of pts treated with s.c. Bor developing grade 3-4 PN *vs* 7.7% in pts treated with i.v. Bor. C) VD at relapse: 201 pts were analyzed, 28 with s.c. *vs* 173 with i.v. Bor. Pts received similar N° of cycle (4 (range 1-8) *vs* 4 (range 1-9), p=0.27). Pts receiving s.c. Bor had higher ORR (³PR, 69% *vs* 48%, p=0.05), in particular we found a significantly higher rate of CR+nCR (19% *vs* 6%, p=0.02). Grade 3-4 toxicity rates were significantly lower with s.c. Bor (14 *vs* 43% respectively for s.c. *vs* i.v. administration (p=0,045)) with none of pts treated with s.c. Bor developing grade 3-4 PN *vs* 12.8% in pts treated with i.v. Bor.
Summary and Conclusions: This real life data confirms the efficacy and the good toxicity profile of the subcutaneous administration of Bor in all settings of patients.

E1295

THE AMPLIFICATION OF 1Q21 IS AN ADVERSE PROGNOSTIC FACTOR IN CHINESE PATIENTS WITH MULTIPLE MYELOMA

L. Chen[1,*] W. Yu[1], R. Zhang[1], X. Qu[1], H. Qiu[1], R. Guo[1], J. Li[1]
[1]Hematology, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: The prognostic heterogeneity of multiple myeloma (MM) is largely due to different genetic abnormalities. Cytogenetic analysis has revealed that most of MM harbor chromosome aberrations. Amplification of 1q21 is one of the most common chromosomal aberrations.
Aims: In the present study, we examined the amplification of 1q21 in Chinese patients with newly diagnosed multiple myeloma and analyzed the relationship between this genetic event and clinical features of patients.
Methods: Interphase fluorescence *in situ* hybridization (I-FISH) was applied to detect the 1q21 amplification in 86 Chinese patients with newly diagnosed MM.
Results: 1q21 amplification (≥3 red signals) was found in totally 40 of 86 (46.5%) cases, among which 29 with 3copies of 1q21 and 11 with at least 4 copies of 1q21. There was no significant difference in sex, age, International Stage (ISS), Durie-Salmon stage, immunoglobulin subtype, C-reactive protein, erythrocyte sedimentation rate, β2-microglobulin, hemoglobin, platelet number and albumin concentrations among those patients without1q21 amplification, with 3copies of 1q21 and with at least 4copies of 1q21 (p>0.05). Further analysis revealed a significant difference of overall survival (OS) (p=0.047) and progression-free survival (PFS) (p=0.001) among the three arms. Bortezomib could not significantly improve the OS (p=0.626) or PFS (p=0.514) for patients with at least 4 copies of 1q21.
Summary and Conclusions: These findings suggest that 1q21 amplification especially more than 4 copies represents a factor for poor prognosis in MM patients receiving Bortezomib-based regimens.

E1296

USE OF EARLY CHANGES IN GENE EXPRESSION OF PLASMA CELLS MAY PREDICT RESPONSE TO BORTEZOMIB IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

K. Liapis[1,2,*] T. Bagkratouni[2], E. Kastritis[2], S. Vasileiou[3], F. Panitsas[3], C. Liakou[2], E. Charitaki[3], E. Bournakis[2], E. Terpos[2], S. Delimpasi[3], N. Charchalakis[3], M.A. Dimopoulos[2]
[1]Haemato-oncology Unit, The Royal Marsden Hospital, The Royal Marden NHS Foundation Trust, London, United Kingdom, [2]Department of Therapeutics, Alexandra Hospital, [3]Department of Hematology, Evangelismos Hospital, Athens, Greece

Background: Maximizing the response rate of first-line therapy (≥VGPR) in multiple myeloma is prognostically important since it has been associated with improved progression-free and overall survival. Molecular changes in plasma cells after treatment with bortezomib caused by the *in vivo* interaction between drug and tumor may be used as a predictor of response to therapy. Studies of gene expression have revealed that certain genes associated with the proteasome (*PSMD4*, *BIRC5*, *KIAA1754*) may represent clinically useful prognostic factors.
Aims: We aimed to examine the use of early changes in the expression of these genes as predictors of the quality of response to first-line bortezomib-based therapy in newly-diagnosed multiple myeloma.
Methods: We studied prospectively changes in the expression of three genes (*PSMD4*, *BIRC5*, *KIAA1754*) induced by bortezomib and their possible correlation with response rates, in 25 patients (16 men, 9 women) with newly-diagnosed multiple myeloma between March 2009 and March 2010. Monitoring continued until January 2014. 19 patients received a combination of bortezomib with dexamethasone (VD) and 6 received a combination of bortezomib, melphalan, and prednisolone (MPV). Bortezomib was administered intravenously with the classic biweekly regimen. Bone marrow aspiration and plasma cell collection was performed at diagnosis (Day 0) and on the seventh day (Day +7) of treatment (*i.e.*, before the third dose of bortezomib). For the purposes of comparison, we analyzed 5 patients who had thalidomide-based treatment (3 patients had thalidomide-dexamethasone, and 2 patients had thalidomide, melphalan, and prednisolone). Selective isolation of CD138+ plasma cells was performed with use of magnetic beads, confirmed with flow cytometry, and followed by the isolation of RNA. We studied gene expression by means of RT-PCR. The observed changes in gene expression were recorded as upregulation (*Up*), downregulation (*Down*), or no change (*No change*). We used changes in the expression of actin gene in order to normalize the variation in the expression of the 3 genes in study. All patients gave written informed consent for the study.
Results: VGPR/CR reached 8 of 30 patients (26.6%), PR 15 of 30 patients (50%), and SD/PD was seen in 7 of 30 patients (23.4%). We found that the changes in the expression of the RNA of the *BIRC5* gene (P=0.001) and *KIAA1754* gene (P<0.001) were associated significantly with the quality of response to bortezomib-based treatment, whereas the changes in the expression of the *PSMD4* gene were not associated with the quality of response to bortezomib (P=0.132). In particular, an upregulation in the expression of *KIAA1754* was associated with the achievement of VGPR/CR, whereas a downregulation in the expression of *BIRC5* was associated with an inferior response. All patients who achieved VGPR/CR had the following *BIRC5*/*KIAA1754* combinations: *Down*/*Up* or *No change*/*Up.* Patients in whom SD/PD was seen had the following *BIRC5*/*KIAA1754* combinations: *Up*/*Down*, *Up*/*No change,* and *No change*/*Down*. Patients who reached a PR usually had *BIRC5*/*KIAA1754* combinations: *Up*/*Up*, *Down*/*Down*, or *No change*/*No change*. We also found that the expression of *PSMD4*, *BIRC5*, and *KIAA1754* was not affected by thalidomide-based treatment.
Summary and Conclusions: We found that the early changes (Day +7) in the expression of *BIRC5* and *KIAA1752* genes were significantly associated with the prediction of response to bortezomib-based treatment, but were not altered

after treatment with thalidomide. These results are specific to the probability of response to first-line bortezomib and, therefore, could be used as part of a risk stratification system for early modification of first-line treatment in patients with newly-diagnosed multiple myeloma. These data may have relevance for the emerging concept of precision medicine.

E1297

ANTI-GRP78 MONOCLONAL ANTIBODY PAT-SM6 IN REFRACTORY AND EXTRAMEDULLARY MULTIPLE MYELOMA: PRECLINICAL AND CLINICAL EVIDENCE FOR A COMBINATORIAL STRATEGY WITH NOVEL AGENTS

L. Rasche[1,*] V. Dubljevic[2], C. Lapa[3], J. Düll[1], F. Hensel[4], S. Knop[1], A. Rosenwald[5], H. Einsele[1], S. Brändlein[5]
[1]Internal Medicine, Hematology and Oncology, University Hospital Wuerzburg, Würzburg, Germany, [2]Patrys limited, Melbourne, Australia, [3]Nuclear Medicine, University Hospital Wuerzburg, [4]Patrys GmbH, [5]Pathology, University Wuerzburg, Würzburg, Germany

Background: Despite enormous progress in multiple myeloma (MM) therapy the development of effective therapeutic strategies for relapsed and drug refractory patients continues to represent an unmet medical need. We have developed an IgM monoclonal antibody (PAT-SM6) which interferes with Glucose Regulated Protein 78 (GRP78), a heat shock protein frequently reported to be involved in the mediation of drug resistance. In an initial phase I trial with heavily pretreated MM patients, PAT-SM6 treatment showed a disease stabilization rate of 33% when used as single agent. Objective responses according to the IMWG criteria were not seen.
Aims: In this study we further evaluated PAT-SM6 in refractory MM disease.
Methods: We used an *in vitro* drug combination model to investigate the effect of PAT-SM6 in combination with other MM drugs. Immunohistochemical staining with PAT-SM6 and control antibodies on bone marrow specimens and extramedullary lesions was performed. PAT-SM6 was also tested in combination with Lenalidomide (Len) and Bortezomib (BTZ) on the basis of a compassionate use program in one patient with refractory extramedullary MM after informed consent.
Results: Immunohistochemical staining with PAT-SM6 showed stable GRP78 antigen expression throughout various stages of MM including cases with extramedullary disease. Resistance to immunomodulatory drugs (Len) or proteasome inhibitors (BTZ) did not affect GRP78 expression. Previous data showed that treatment with single agent PAT-SM6 reduced tumor load and M protein levels in a 5T33 murine model of aggressive MM in a dose dependent manner. PAT-SM6 combined with MM drugs such as Len, BTZ, Carfilzomib (CFZ) and Dexamethasone (Dexa) showed additive and synergistic effects in some (but not all) tested MM cell lines when analyzed by the Chou Talalay method. Interestingly, synergy was also observed in BTZ, Len and/or Dexa resistant cell lines. A patient with plasmoblastic Len and BTZ resistant MM experienced partial remission of intra- and extramedullary plasma cell tumors after treatment with PAT-SM6 in combination with Len and BTZ. Remission was not durable but repeated biopsies at progression showed preserved target expression at the extramedullary sites giving hope that a prolonged or intensified antibody treatment can sustain remission in future patients.
Summary and Conclusions: The Anti-GRP78 antibody PAT-SM6 showed promising activity *in vitro* and in a late stage MM patient with aggressive tumor biology and drug resistance. Further studies focusing on refractory patients using antibody combinations with novel agents are warranted to elucidate the future role of PAT-SM6 in the treatment of MM.

E1298

ACCURACY OF THE SERUM TOTAL LIGHT CHAIN RATIO AS A PREDICTOR OF ABNORMAL SERUM FREE LIGHT CHAIN RATIOS

M. Pereira[1,*] N. Costa e Silva[2], C. Geraldes[1], L. Ribeiro[1], F. Rodrigue [2]
[1]Clinical Hematology Department, [2]Clinical Pathology Department, Coimbra University Hospital Centre, Coimbra, Portugal

Background: The identification and quantification of serum free light chains (sFLC) with the determination of the kappa/lambda sFLC ratio has been shown to be superior to serum total light chains (sTLC) and to the analysis of the urinary excretion of light chains, in the diagnosis, management and follow-up of plasma-cell dyscrasias. However, the price of the sFLC test can be much higher than that of sTLC (reaching a five-fold difference, in our country). This difference in cost means that the test is still frequently unavailable in lower-income countries, and in smaller Centers in middle-income countries.
Aims: We aim to determine the extent to which the determination of the sTLC and of their ratio can be a surrogate marker for sFLC evaluation, as determined by its sensitivity, sensibility and positive and negative predictive value (PPV and NPV).
Methods: We analysed all samples processed in our Lab between the introduction of the test in 01-09-2005 and 28-02-2015, selecting only those cases with a simultaneous evaluation, in the same blood sample, of total kappa LC, total lambda LC, free kappa LC and free lambda LC; any samples not fulfilling this criterion were excluded. The reference interval used for the sFLC ratio was 0.26-1.65 (inclusive), and 1.35-2.65 (inclusive) for the sTLC ratio. Borderline deviations from the reference interval were defined as a decrease or increase of 10% over the lower and upper limits of the reference interval, respectively.
Results: We obtained 960 samples fulfilling the criteria defined above. The sTLC ratios were abnormal in 76.7% of samples with an abnormal sFLC ratio, but in only 31.3% of samples with a normal sFLC ratio ($p<0.001$). This reflects an inter-rater agreement of 71.5% (Cohen's kappa=0.42, $p<0.0001$). The sensitivity of the sTLC ratio for the prediction of an altered sFLC ratio was, therefore, 76.6% (95% CI: 71.7-81.1%), with a specificity of 68.7% (95% CI: 64.9-72.3%), a PPV of 56.2% (95% CI: 51.5-60.9%) and a NPV of 84.9% (95% CI: 81.5-87.9%). The area under the receiver operating characteristic (ROC) curve (AUC) was 0.73, which represents a diagnostic test with a moderate accuracy. Considering only samples with borderline deviations of the sFLC ratio, as defined above, the percentage of abnormal sTLC ratios decreased to 66.7% (remaining 31.2% in patients with normal sFLC ratios, $p=0.002$). For these borderline cases, concordance decreased to 68.7% (kappa=0.06, $p=0.0008$). Specificity was unaffected, at 68.7%; although the NPV increased to 98.6% (95% CI: 97.0-99.5%), the PPV was only 5.7% (95% CI: 3.0-9.8%). Accuracy was poor, with an AUC of 0.68. When the sFLC ratio was more than twice the upper limit or less than half the lower limit of normal, the sensitivity of the sTLC ratio increased to 83.3% (95% CI: 77.8-87.9%), while the NPV remained acceptable at 91.9% (95% CI: 89.1-94.2%).
Summary and Conclusions: We found that the sTLC ratio is a test with a moderate accuracy at identifying altered sFLC ratios, which are the current gold-standard. Overall, sensitivity, specificity and PPV were fair; the NPV was approximately 85%, which meant that only 15% of patients with a normal sTLC ratio would in fact have an abnormal sFLC ratio. Although the accuracy of the test was poor for borderline samples, its NPV was excellent at approximately 99%. These data suggest that, within the context of very limited monetary resources, the sTLC ratio could optimize the allocation of resources, by helping to exclude those patients who are unlikely to have an altered sFLC ratio, and prioritizing the use of sFLC tests in those patients more likely to have abnormal results.

E1299

CLINICAL FEATURES, PROGNOSIS AND TREATMENT OUTCOME OF THE OF THE EXTRAOSSEUS PLASMA CELL NEOPLASIA: PLASMACYTOMA, MULTIPLE MYELOMA AND PRIMARY PLASMA CELL LEUKEMIA

J. Jelicic[1,*] J. Bila[1], V. Vukovic[1], V. Djurasinovic[1], B. Andjelic[1], A. Sretenovic[1], M. Smiljanic[1], D. Antic[1], M. Todorovic[1], B. Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, Belgrade, Serbia

Background: Extraosseous localizations of solitary plasmacytoma (ESP), or symptomatic multiple myeloma (EMM) including primary plasma cell leukemia (PCL), are rare presentations of plasma cell neoplasia (PCN).
Aims: The aim of this study was to analyse clinical characteristics, prognosis, and treatment outcome in patients with extraosseous ESP, EMM and primary PCL.
Methods: The study included analysis of the 560 newly diagnosed patients with PCN for the past fourteen years, of which 42 patients (25 males/17 females, median age 57.5 years, range 19-74yrs) had extraosseous PCN. ESP was diagnosed in 24 patients (57.2%), EMM in 12 (28.6%) and PCL in 6 (14.3%). Regarding the type of M protein, the distribution was as following: IgG (50%), light chains (29.4%), IgA (11.8%), IgD (5.9%) and IgM (2.9%). Using the immunofixation electrophoresis (IEF) and serum free-lite test (FLT), low paraprotein concentrations were detected in 27/34 patients (79.4%). Non-secretory disease was confirmed with negative IEF and normal FLT ratio in 8/24 patients (33.3%). The most frequent localizations of the extraosseus PCN were: Oral cavity or pharynx (25%); Paravertebral tumours (16.7%); Muscle infiltration of the thoracal/abdominal wall (13.9%); Salivary glands (8.3%); Lymph nodes (8.3%); and maxillary sinus (8.3%). Less frequent localizations were stomach, colon, and testis found in 1/42pts (2.4%). Majority of the patients with EMM were diagnosed with clinical stage III (CS, Durie&Salmon, 76.2%). Regarding International Scoring System (ISS), 66.7% patients with EMM had ISS1-2, and 33.3% had ISS3. Renal impairment existed in 4 patients (9.5%). Applied treatment was as follows: Radiotherapy (RT, 19% pts); chemotherapy±RT (HT±RT, 54.8%pts); and HT+autologous stem cell transplantation (HT+ASCT, 26.2%pts).
Results: Initial overall treatment response (CR/VGPR/PR) was achieved in 95.2% of analysed patients. In the group of patients with ESP, the 5-year survival was achieved in 90%pts, without reached median overall survival (OS). Among 24 patients with ESP, 41.7% relapsed/progressed within first 4 years of follow-up (range 1-14yrs). PD to symptomatic myeloma occurred in: 4/10pts (40%) treated with RT; and in 6/14pts (42.9%) treated with RT±HT. Median OS of the patients with ESP who progressed to MM was 113 months (95% CI, 70.216-157.469), with 5-year survival achieved in 58% pts, and 50 months of median EFS. Patients with EMM had median OS 84 months (95% CI, 45.194-122.806), and 5-year survival of 62% pts. Median EFS for this group was 48 months (95% CI, 43.467-52.533). The patients with PCL had the worst outcome

with median overall survival (OS) of 36 months (95% CI, 4.564-67.436) (Log Rank 3.864, p<0.05), 5-year survival of 36% pts, and median EFS of 25 months (95% CI, 5.539-44.461, Log Rank 7.923; p<0,05). There was no significant difference in the OS of the patients with EMM/PCL regardless the type of M protein (Log Rank 1.127, p>0,05) or its concentrations (Log Rank 1.708, p>0.05), CS (Log Rank 1.841, p>0,05) or ISS score (Log Rank 3.852, p>0.05), and extraosseal localization (Log Rank 7.210; p>0,05).
Summary and Conclusions: In analyzed group, immature origin of the extraosseus PCN is expressed through low-secretory features of predominantly rare types of M protein. There is no difference in the course of ESP disease regardless the treatment approach while primary PCL, as the principal representative of extramedullary disease retains the most aggressive features despite the introduction of novel therapies.

LB2086

EFFICACY AND SAFETY OF LENALIDOMIDE AND DEXAMETHASONE COMBINATION IN PATIENTS WITH POEMS SYNDROME PRE-TREATED OR INELIGIBLE FOR HIGH-DOSE THERAPY: RESULTS OF A PROSPECTIVE TRIAL

A. Nozza[1,*] E. Nobile-Orazio[2], F. Adami[3], F. Gallia[2], B. Chiara[4], F. Terenghi[2], A. Santoro[1]
[1]Hematology, Humanitas Cancer Center, [2]2° Neurology - Translational Medicine, Humanitas Clinical and Research Center, Rozzano, [3]Clinical and Experimental Medicine -Hematology & Clinical Immunology, [4]Department of Neurosciences, University of Padova, Padova, Italy

Introduction: POEMS syndrome is a rare multisystemic disease. Several treatments have been proposed for POEMS even if there is so far no controlled study. Lenalidomide has anti-angiogenic activity through inhibition of VEGF and TNF alpha.
Aims: This study plans to evaluate efficacy and toxicity of Lenalidomide in POEMS. Lenalidomide 25 mg/day was given for 21 days in association with weekly Dexamethasone 40 mg until progression or toxicity. Response to treatment was assessed by a specifically prepared clinical scale which evaluates ten hematological and clinical parameters(clinical response evaluation scale ", CRES, range 0-20), as welll as by the Overall Neuropathy Limitations Scale (ONLS), an expanded MRC sum score, the INCAT sensory sum score and EMG, to evaluate neurological response. The primary end-point was the response to therapy after six monthly cycles of RD. Pts were considered responders if they showed an improvement of at least 1 point in the ONLS scale and at least 3 in the CRES scale.
Methods: From 10/09 to 10/14, we performed a pilot study with Lenalidomide plus dexamethasone (RD) in 20 patients with POEMS - All Pts had a median ONLS score of 4.5 (range 1-8), and monoclonal component (lambda restricted in 88%) - Serum VEGF levels were >1000 pg/ml in all but two pts (88.9%) with a median level of 4043 pg/ml (range 687-13856). Osteoscleoriotic bone lesions were found byx-ray in 12 pts (67%), while Castelman Disease was histologicallly confirmed in 2 pts. Skin changes were observed in 16 pts (89%), hepatosplenomegaly in 14 (78%) pleural effusion, ascites or peripheral edema in 6 pts (33%) and endocrine alterations in 16 (89%).
Results: Response evaluation after 6 months of RD was done in 16 out of 18 pts: 2 pts had dropped out during the first cycle (1 lost to follow-up, 1 for withdrawal of informed consent): 15/18 of included pts (83.3%) completed the 6 cycles of therapy and were improved at six month in the clinical or neurological scale or both, while one patient not improved and suspended the treatment after 4 cycles. 13 pts (72.2%) had improved by at least 3 points in CRES, ranging from 3 to 7 points (mean score at entry 10.36; mean score at six month 7.18; p=0.0006). 10 pts (55.6%) improved by at least one point in the ONLS with an improvement ranging from 1 to 3 points (mean score at entry 4.3; mean score at six month 3.6; p=0.0176), five remained stable and one patient had deteriorated by two points. Six patients are still on treatment, after a median follow-up of 33 months (range 10-52 months)- 5 Pts discontinued treatment for complete response-stable disease after a median of 30 months (range 25-32 months) and only one relapsed 20 months later. In 4 pts the disease progressed after 10, 21, 29 and 35 months. No patient discontinued treatment due to toxicity. Lenalidomide was reduced in 43% of patients mainly for haematological toxicity (grade II-III), and dexamentasone was reduced in all patients, and stopped in 30%. Has not been reported any thrombotic events or secondary neoplasia in patients enrolled.
Summary and Conclusions: Conclusions: This prospective trail confirms that lenalidomide is very effective and well tolerated in the majority of patients, regardless of any previous treatments and it has a prolonged efficacy in POEMS Syndrome.

HIGH PREVALENCE OF RAS PATHWAY MUTATIONS IN CMML PATIENTS WITH HIGH COLONY GROWTH

K. Geissler[1,*] A. Zopf[2], E. Jäger[3], C. Gabriel[2], P. Bettelheim[4], P. Valent[5]
[1]5th Department of Medicine, Hospital Hietzing, Vienna, [2]Blood Transfusion Service of Upper Austria, Austrian Red Cross, Linz, [3]Department of Laboratory Medicine, Medical University of Vienna, Vienna, [4]1st Department of Medicine, Elisabethinen Hospital, Linz, [5]1st Department of Medicine, Medical University of Vienna, Vienna, Austria

Background: Some time ago we reported that extensive *in vitro* formation of colony-forming unit-granulocyte-macrophage (CFU-GM) without exogenous growth factors is found in a subset of patients with chronic myelomonocytic leukemia (CMML) *(Geissler K et al. Leuk Res 1988)*. Subsequently we found that this spontaneous myeloid colony formation depends on low endogenously produced granulocyte/macrophage colony-stimulating factor (GM-CSF) concentrations in the culture system *(Geissler K et al. J Exp Med 1996)*. Moreover we have reported that CMML patients with high spontaneous CFU-GM growth (>100/10^5PBMNC) have a worse prognosis compared to patients with low CFU-GM growth *(Sagaster V et al. Ann Hematol 2004)*. The "RASopathies" are a group of genetic syndromes caused by germline mutations in genes that encode components of the RAS signaling pathway including NRAS, KRAS, NF-1, CBL, and PTPN11 *(Niemeyer CM. Haematologica 2014)*. Besides their developmental defects they share a predisposition to JMML. Molecular alterations of these components in murine hematopoietic cells can lead to a CMML like disease *in vivo* and to spontaneous myeloid colony formation *in vitro* due to hypersensitivity of granulomonocytic precursors against GM-CSF *(Wang J et al. Blood 2010)*. The significance of spontaneous CFU-GM growth in man regarding molecular aberration profiles in CMML remains unknown.
Aims: Based on current knowledge we speculated that mutations in the RAS signaling pathway may play a significant role in autonomous CFU-GM formation in CMML.
Methods: In this study we reanalyzed CMML cells from our patients with respect to the presence of molecular aberrations of RAS pathway components and correlated the results with *in vitro* CFU-GM growth. For this purpose we used deep DNA sequencing of 27 CMML associated genes.
Results: Our results show a high prevalence of RAS pathway mutations in CMML patients with high spontaneous CFU-GM formation. Mutations in the components of the RAS pathway were found in 12/15 (80%, NRAS 7, KRAS 1, NF1 2, CBL 2) CMML patients with high colony growth and in 2/9 (22%, NRAS 1, CBL 1) patients with low spontaneous colony formation (p=0.008; Fisher exact test). Mutations of RAS pathway components were mutually exclusive. In all patients with RAS pathway mutations additional mutations were observed in other genes, particularly in components of DNA methylation and/or the spliceosome. Finally, as expected, we found a significant influence of RAS pathway mutations and of high CFU-GM formation, respectively, on overall survival in patients with CMML.
Summary and Conclusions: Our findings suggest that CMML with high spontaneous colony growth is a RAS pathway-dependent malignancy which may have clinical implications concerning prognostication and therapeutic strategies aimed at targeting the hyperactive RAS signaling pathway in these patients.

ACQUIRED UNIPARENTAL DISOMY OF CHROMOSOME 14 IN MYELOID MALIGNANCIES TARGETS THE IMPRINTED MEG3-DLK1 LOCUS

A. Chase[1 2,*] W. Leung[1,2], W. Tapper[1], A. Jones[1], L. Knoops[3], C. Rasi[4], L. Forsberg[4], P. Guglielmelli[5], V. Hall[2], L. Chiecchio[2], L. Docherty[1,2], H. White[1,2], J. Score[12], K. Zoi[6], J. Dumanski[4], A. Vannucchi[5], D. Mackay[1,2], N.C. Cross[1,2]
[1]School of Medicine, University of Southampton, Southampton, [2]Wessex Regional Genetics Laboratory, Salisbury District Hospital, Salisbury, United Kingdom, [3]Cliniques Universitaires Saint-Luc de Duve Institute, Université catholique de Louvain, Brussels, Belgium, [4]Department of Immunology, Uppsala University, Uppsala, Sweden, [5]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, [6]Biochemical Research Foundation, Academy of Athens, Athens, Greece

Background: Whole or partial chromosomal acquired uniparental disomy (aUPD) is a common finding in myeloid malignancies and typically acts to convert a somatically-acquired heterozygous mutation to homozygosity with loss of the normal allele. Examples are aUPD of chromosomes 4q, 7q and 9p associated with mutations of *TET2*, *EZH2* and *JAK2* respectively. Several other regions of recurrent aUPD have been identified; *e.g.* chromosome 14q aUPD (aUPD14) is seen in about 1% of myeloid malignancies and also in population cohorts of elderly individuals at a frequency of about 0.04%. Indeed, chromosome 14q is the most commonly affected region in such cohorts.

Aims: To identify the molecular target of aUPD14.
Methods: Acquired UPD14 cases identified by SNP array analysis were analysed by whole exome sequencing, *MEG3* methylation by quantitative methylation-specific PCR of bisulphited DNA and *MEG3* and *DLK1* expression by RT-qPCR.
Results: Whole exome sequencing of six aUPD14 cases, of which 3 had been diagnosed with a myeloid neoplasm and 3 had been picked up in a population-based screen of elderly individuals, found no recurrent variants and therefore we considered alternative possibilities. Inherited, constitutional UPD14 is associated with Temple syndrome (maternal UPD) or Wang-Kagami syndrome (paternal UPD), developmental disorders which result from inappropriate expression of genes within the imprinted *MEG3-DLK1* locus at 14q32. The non-methylated maternal chromosome expresses the non-coding *asRTL1, MEG3, MEG8* genes as well as multiple miRNAs and snoRNAs, whilst the methylated paternally inherited chromosome expresses the protein-coding genes *DLK1, RTL1* and *DIO3*. Since *MEG3-DLK1* is deregulated in diverse cancers (including overexpression of *DLK1* in myelofibrosis) and this locus falls within the minimal region of aUPD14, we investigated the possibility that it might be the target of aUPD14. *MEG3* methylation analysis was performed on 22 cases with aUPD14 (21 with myeloid neoplasia, one healthy older individual) and six cases with a myeloid neoplasia and trisomy 14. Of 8 cases with aUPD14 estimated to affect >50% of cells *i.e.* a B-allele frequency >0.75, all 8 showed a methylation value three standard deviations above that of controls indicating loss of the maternal chromosome and gain of the paternal chromosome ($p<0.01$). Loss of maternal chromosome 14 was also apparent in cases with lower levels of aUPD14 and overall the degree of methylation imbalance strongly correlated with the level of aUPD ($r=0.76$; $p=0.0001$). By contrast, no consistent parental bias was seen in cases with trisomy 14. To determine if *MEG3* methylation is more widespread in myeloid malignancies, we examined a further 48 CMML cases with unknown aUPD status and 48 MDS/MPN cases known not to have aUPD14 by SNP array analysis. We identified three additional cases with increased *MEG3* methylation of which two had no evidence of aUPD by microsatellite analysis, thus suggesting alternative mechanisms of *MEG3-DLK1* deregulation. Using RT-qPCR we found increased *DLK1* expression but no consistent change in *MEG3* expression in two cases with aUPD14 compared to controls. Interestingly we also saw altered expression of *DLK1* and *MEG3* expression in myeloid neoplasias without aUPD14, further suggesting that deregulation of the *MEG3-DLK1* locus is not restricted to cases with aUPD14.
Summary and Conclusions: We conclude that aUPD14 is a recurrent abnormality targeting the imprinted *MEG3-DLK1* locus, and that deregulation of this locus may be more widely associated with myeloid malignancy, as well as clonal hemopoiesis in apparently healthy older individuals.

E1302

CIRCULATING ENDOTHELIAL CELLS (CEC) AS A SURROGATE MARKER FOR EVOLUTION IN PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

M.L. Antelo[1], N. Ramirez[2], A. Angona[3], A. Alvarez-Larran, [3]E. Perez-Valderrrama[2], C. Mansilla[2], M. Ciaurriz[2], J. Rifon[4], E. Olavarria[5], M. Rodriguez-Calvillo[1,*]
[1]Haemathology and Hemotherapy, Complejo Hospitalario de Navarra, [2]Navarrabiomed Fundacion Miguel Servet, Pamplona, [3]Haemathology and Hemotherapy, Hospital del Mar, Barcelona, [4]Haemathology and Hemotherapy, Clinica Universidad de Navarra, Pamplona, Spain, [5]Haemathology and Hemotherapy, Hammersmith, London, United Kingdom

Background: The normal circulating endothelial cell (CEC) reference range established in healthy donors is 1-20 CECs/mL blood. Changes in endothelial cells play an important role in a variety of disorders including the classical Ph-negative chronic myeloproliferative neoplasms (MPNs) Polycythaemia vera (PV) and Myelofibrosis (MF). An elevated number of CECs has been described in these diseases but also has lead to a wide variation in the reported range of CECs.
Aims: The aims of the present study were: (1) To compare the quantification of CECs in Ph-negative MPNs using two different platforms, Cell-Search system-Veridex® and Polychromatic Flow Cytometry; (2) to establish variations of CEC numbers in different risk-adapted MPNs according to time from diagnosis (for PV patients) and to DIPPS (for MF patients).
Methods: The study included 49 consecutive patients that were divided into 4 groups: PV up to 10 years from diagnosis (n=10), PV with less than 10 years from diagnosis (n=10), low DIPSS MF (n=9) and high DIPSS MF (n=10). As a control group, 10 healthy blood donors (HC) were also studied. Assessment of the circulating CECs by the Cell-Search system was performed using a semiautomated fluorescence microscope. CD146+ cells were immunomagnetically isolated and labeled with anti-CD105, CD45 and nuclear stain DAPI. A camera is used to scan stained cells and evaluates potential CEC candidates by image analysis software. Assessment of the circulating CECs by flow cytometry was performed. using KDR, CD34, CD45 and CD133 monoclonal antibodies. Each analysis included 1,000,000 events.
Results: The statistical comparison of the CEC numbers showed significant differences between PV patients and MF patients (Mann Whitney U test, $p<0.001$) but also between Low and High DIPPS MF ($p=0.022$). Regarding the flow cytometry population, statistical analyses found significance for the same comparisons: $p<0.001$ between PV patients and MF patients and $p=0.009$ between Low and High DIPPS MF. No statistically significant differences were found between patients with PV for either method. Both PV and MF groups had a significant higher number of CEC compared to healthy donors ($p<0.001$) (Table 1).

Table 1.

GROUP	CellSearch system CD146+CD105+CD45- (CEC/4ml)	Flow Cytometry CD34+KDR+133+ (%)
Control group	10.50 (3-26)	0.0006975 (0.000144-0.002331)
P. Vera up to 10 years	58.50 (17-130)	0.0001345 (0-0.233905)
P.Vera >10 years from diagnosis	64.00 (9-507)	0.0049305 (0-0.05922)
Low DIPPS MF	84.00 (31-288)	0.0277855 (0-0.71932)
High DIPPS MF	268.00 (69-7497)	0.153546 (0.00504-0.595544)

Summary and Conclusions: Our results suggest a role for CEC in the pathogenesis of PV and MF and indicate that: (1) the CEC value could useful for the evaluation of disease progression in PV and MF patients; (2) The standardized method of CEC quantification (Veridex®) correlates with flow cytometry determination of this population.

SUPERVISED MULTI-CLASSIFIER SEPARATION OF THE PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

V. Skov[1,*] M. Burton[2], M. Thomassen[2], T. Stauffer Larsen[3], L. Kjær[1], C. Hasselbalch Riley[4], M.K. Jensen[1], O.W. Bjerrum[5], T.A. Kruse[2], H.C. Hasselbalch[1]
[1]Department of Hematology, Roskilde Hospital, University of Copenhagen, Roskilde, [2]Department of Clinical Genetics, [3]Department of Hematologyx, Odense University Hospital, Odense, [4]Department of Hematology L, Herlev Hospital, University of Copenhagen, Herlev, [5]Department of Hematology L, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

Background: Since the discovery of a point mutation in the Janus kinase 2 (JAK2V617F) gene in 2005, the concept of essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF) as separate disease entities has been questioned and replaced by the hypothesis of a biological continuum from ET over PV to PMF in JAK2V617F positive patients. Transformations from ET to PV and of both entities to myelofibrosis are frequent and the similarities between JAK2V617F positive ET and PV suggest that overlap between them are more common than previously recognized. Recently, by performing unsupervised Principal Component Analysis (PCA) on gene expression data from these three disease entities, we yielded further support to a biological continuum from ET over PV to PMF with overlap between ET and PV. However, no study has applied supervised classification to explore the molecular classification of ET, PV and PMF which may add information to the clinical diagnosis.
Aims: By using supervised classification methods, the aim of the study was to investigate if ET, PV, and PMF can be separated into distinct groups and to examine if an overlap between these three entities exists.
Methods: Gene expression microarray studies have been performed on whole blood from patients with ET (n=19; 9/10 patients JAK2V617F-/+), PV (n=41; 1/40 patient JAK2V617F-/+), and PMF (n=9; 7/2 JAK2V617F-/+) using Affymetrix HG-U133 2.0 Plus microarrays. A voting procedure involving eleven different support vector machine learning algorithms SVM and KSVM for pattern recognition were chosen for multi-class classification. The top 5-100 genes were used to train the models with SVM/KSVM and leave one out cross validation (LOOCV). A balanced accuracy and a significance level of the classification methods were determined. The gene sets used in the classification procedure were subjected to functional analysis.
Results: In total, the 11 different SVM and KSVM classification algorithms correctly predicted 15 of 19 (79%) patients with ET, 28 of 41 (68%) patients with PV, and 8 of 9 (89%) patients with PMF. The classification models showed a balanced accuracy of 79%. The performance of the classification methods was highly significant ($p=1x10^{-6}$). The results revealed that 4 of 4 misclassified patients with ET were classified as PV of whom 3 were JAK2 positive indicative of a possible transition towards PV. 10 of 13 misclassified patients with PV were classified as ET and the remaining 3 as PMF. One of 9 patients with PMF was misclassified as ET. These results may add more precise molecular phenotype information to the diagnosis. The resulting gene sets used in the classification model included 117, 91, and 92 genes in ET *vs* PV/PMF, PV *vs* ET/PMF, and PMF *vs* ET/PV, respectively. To explore the

biology of the three gene sets using functional analysis, an association with nucleotide binding, inflammation, metabolic process and secretory system was shown in ET *vs* PV/PMF, plasma membrane, metabolic process, signal transduction, and inflammation in PV *vs* ET/PMF, and immune system, signal transduction, secretory system, and transcriptional regulation in PMF *vs* ET/PV.
Summary and Conclusions: We have performed supervised classification of gene expression data from patients with ET, PV, and PMF. Our data show that ET, PV and PMF may be separated into distinct disease entities with overlap between ET and PV providing further support to a biological continuum from ET over PV to PMF. Moreover, our study may add important information to the clinical diagnosis of ET, PV, and PMF.

SERUM LEVELS OF MATRIX METALLOPROTEINASES AND THEIR TISSUE INHIBITORS ARE ELEVATED IN JAK2V617F MUTATED COMPARED TO CALR MUTATED MYELOFIBROSIS AND TRIPLE NEGATIVE ESSENTIAL THROMBOCYTEMIA PATIENTS

L.T. Lima[1,*] D. Prudente Teixeira Nunes[1], G. Wataru Gomes[1], M.D.L. Chauffaille[2], M.R. Régis Silva[3], C. Cilento Ponce[3], F. Attié de Castro[4], M. Cliquet[5], M.T. dos Santo[6], M. Mitne Neto[6], E.M. Guerra-Shinohara[1]
[1]Department of Clinical and Toxicological Analyses, Faculty of Pharmaceutical Sciences, University of Sao Paulo, [2]Department of Clinical and Experimental Oncology, [3]Department of Pathology, Federal University of Sao Paulo, Sao Paulo, [4]Department of Clinical, Toxicological and Bromatological Analyses, School of Pharmaceutical Sciences of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, [5]Department of Hematology, Hospital Complex of Sorocaba, Catholic University of Sao Paulo, Sorocaba, [6]Research and Development, Fleury Group Inc, Sao Paulo, Brazil

Background: Myelofibrosis (MF) and essential thrombocythemia (ET) are myeloproliferative neoplasms (MPN) resulting from acquired hematopoietic stem cell mutations. MF and ET patients may harbor $JAK2^{V617F}$, MPLW515K/L or calreticulin mutations ($CALR^{MUT}$). The mechanism by which mutant CALR alters cellular function to result in myeloid proliferation remains unclear. Matrix metalloproteinases (MMPs) and their tissue inhibitors (TIMPs) are involved in tumor neoangiogenesis which plays important role in hematological neoplasias progression and prognosis.
Aims: To investigate expression of RNAm and serum levels of MMPs, TIMPs, and plasma markers of angiogenesis (VEGFA and FGF2) according to $JAK2^{V617F}$ and CALR mutational status in MPN patients.
Methods: Sixty-five MPN patients were studied: 21 primary MF (PMF), 23 ET, and 21 myelofibrosis post-ET (MPET). MPN diagnosis was defined according to the 2008 WHO criteria. $JAK2^{V617F}$, MPLW515K/L and MMP2, MMP9, TIMP1 and TIMP2 gene expression were evaluated in peripheral leukocytes by real time PCR, using TaqMan MGB probes. CALR mutations were analyzed in $JAK2^{V617F}$ and MPL W515K/L negative samples by Sanger sequencing method. Protein levels of MMPs, TIMPs, VEGFA and FGF2 were measured Luminex technology.
Results: The frequencies of $JAK2^{V617F}$ mutated patients were: 52% (N=11) in PMF, 52% (N=12) in ET and 57% (N=12) in MFPET. CALR mutations were detected in 38% (N=8) of PMF, 13% (N=3) of ET and 33% (N=7) of MPET patients. One ET patient presented MPLW515L mutation. We found higher protein levels of MMP9 in PMF $JAK2^{V617F}$ mutated patients (N=11) compared with $CALR^{MUT}$ ones (N=8) (158.3 *vs* 55.8 ng/mL; P=0.023). MFPET $JAK2^{V617F}$ patients (N=12) presented higher levels of MMP9 (131.0 *vs* 84.5 ng/mL; P=0.049), TIMP2 (119.8 *vs* 103.3 ng/mL; P=0.049), VEGFA (139.0 *vs* 11.16 pg/mL; P=0.008) and FGF2 (21.5 *vs* 6.6 pg/mL; P=0.027) compared with $CALR^{MUT}$ (N=8). For ET, we found that triple negatives (N=6) showed lower MMP2 (122.4 *vs* 156.6 ng/mL; P=0.048) and TIMP2 (97.5 *vs* 106.4 ng/mL; P=0.020) levels in comparison with JAK2 mutated (N=12).
Summary and Conclusions: Our data proposes that $JAK2^{V617F}$ mutated patients exhibit higher levels of proteins involved in angiogenesis compared with CALR mutated and triple negative counterparts. These findings suggest that CALR mutated and triple negative patients may present a less aggressive course of the disease than $JAK2^{V617F}$ mutated ones. *FAPESP 2012/12957-5.*

E1306

THE MUTATION OF THE SPLICING GENE SRSF2 PERFORMED BY HRM SCREENING IN THE DIAGNOSIS OF CMML

M. Torres Ochando[1,*] C. Bilbao Sieyro[1], M.T. Gómez Casares[1], G. Santana Santana[1], T. Molero Labarta[1]
[1]Hematology, Dr. Negrin Hospital, Las Palmas, Spain

Background: Recent works associate the mutation of the splicing gene SRSF2 (PRO95) with chronic myelomonocytic leukemia (CMML), a clonal complex neoplasm that belongs to the group of myelodysplastic syndromes/myeloproliferative neoplasms (MDS /MPN) of the 2008 WHO classification, reaching a prevalence of 40- 50%. This gene is located on chromosome 17q25.1, is involved in the regulation of the stability of DNA and its mutation coexists with others in a high prevalence.
Aims: The aim of this retrospective study was to analyze SRSF2 mutations using high resolution melting (HRM) as a screening method, in a series of patients diagnosed with CMML and its relationship with different variables which will be discussed below.
Methods: We included 96 patients diagnosed and followed up between 2010-2014: CMML (n=36, CMML-1, 78% (n=28), CMML-2, 22% (n=8). FAB: Myelodysplastic 42% (n=15), myeloproliferative 58% (n=21)), MDS and AML (n=50), other (n=10) (3 CLL, 2 thrombocytosis, 1 ITP, 1 HL, 3 MGUS). We used DNA from total bone marrow nucleated cells. The samples were studied by real-time PCR and HRM as a screening method. Primers were described by Terra L.Lasho *et al.* (Blood 2012 120: 4168-4171) with a PCR product of 327 bp. By Melting analysis we obtained 2 possible results, mutated *vs* non mutated. The analysis was done in duplicate, including C +, C- and wild type reference. The positive cases were sequenced by Sanger method. We did not observe false positives or negatives when we sequenced the results obtained by HRM. Statistical analysis was performed by Clopper-Pearson method for the analysis of the prevalence, Log Rank (Mantel-Cox), Breslow (Generalized Wilcoxon), Tarone-Ware method for OS analysis, Mann-Whitney test to compare the medians, student t-test was applied to compare means.
Results: 79.3% (23/29) of patients with CMML and 20.7% (6/29) of the patients with MDS and AML presented SRSF2mut. None of the 10 patients with other diagnosis showed mutations. We observed a significant association (P<0.001) between SRSF2mut and CMML, in our series of patients. A bivariate analysis was performed in the group of 36 patients with CMML, in relation to the presence or absence of SRSF2mut (details on Table 1). SRSF2mut prevalence in this subgroup was 63.89%. The mutational profile observed (n=21) was p.Pro95His (n=10) p.Pro95Leu (n=4) p.Pro95Arg (n=3) 24bp del (n=3). Karyotype at diagnosis was normal in 15 patients. The mean age at diagnosis was 71 years, with no age difference observed in relation to SRSF2mut (SRSF2mut=71.87 years *vs* SRSF2wt=69.54 years). A higher prevalence of SRSF2mut was observed in myeloproliferative FAB variants (71.4% (n=15) (P=0.310)) and type 2 OMS (75.0% (n=6) (P=0.682)). Hemoglobin levels were similar in both groups (10.57 g/dl for SRSF2mut and 11.06 for SRSF2wt). The mean platelet count was lower for patients with SRSF2mut, 125000/ul *vs* 205000/ul for SRSF2wt, (p=0.058). The median survival time was 4 years (Me=5.1 years). The treatment and follow-up were not homogeneous. There was no difference in survival between the two groups (P=0.396). Of interest, 17 patients with CMML-1 WHO progressed to type 2. All of them were SRSF2mut. Three patients progressed to AML, all were SRSF2mut. One patient with CMML-1 (WHO) presented 2 spliceosome mutations (SRSF2mut and SF3B1mut.).

Table 1.

Variable	Results	IC and p-value
SRSF2mut prevalence in LMMC	**63,89% (n=23) SRSF2mut** 36,11% (n=13) SRSF2wt	*IC (95%) = (46,22 – 79,18)* *IC (95%) = (20,82 – 53,78)*

OS (days)	**Global= 1471,74** M_e= 1868	
OS (days) and SRSF2mut/SRSF2wt.	SRSF2mut= 1648,58 M_e= 2521 SRSF2wt= 1334,09 M_e= 1868	*p-value=0.396*
SRSF2 and Hemoglobine (g/dl) at the diagnosis.	**SRSF2mut = 10,57.** σ =1,86. M_e= 11 (Q1: 9,5 y Q3: 11,70). **SRSF2wt = 11,06.** σ = 2,00. M_e=11,5 (Q1: 9,75 y Q3: 12.75).	*p-value= 0.466*
SRSF2 and platelets count (ul) at the diagnosis.	**SRSF2mut (n=23)= 125000**. σ =73275. M_e=116000 (Q1: 58000 y Q3: 178000). **SRSF2wt (n=12)= 205000**. σ=166503,47.M_e=191000 (Q1: 65200 y Q3: 275000).	***p-value = 0,058***
SRSF2 in CMML, MDS and AML.	**SRSF2mut:** - **CMML(n=23)= 79,3%** - **MDS and AML (n=6)= 20.7%** **SRSF2wt:** - **CMML (n=13)= 22.8%** - **MDS and AML (n=44)= 77.2%**	***p-value< 0.001***

Summary and Conclusions: We found a higher association between SRSF2mut and CMML in our series of patients than others reported before, maybe it depends on the use of HRM as a screening method. We found also a tendency in the association of myeloproliferative FAB subtypes and type 2 of WHO with SRSF2mut, as well as with a lower platelet count. Whether this mutation is or not associated with increased aggressiveness of the disease should be proved. Based on our results, detection of SRSF2mut by HRM screening could be a useful diagnostic tool in CMML since is a feasible technique that could be easily performed in hematology diagnostic laboratories.

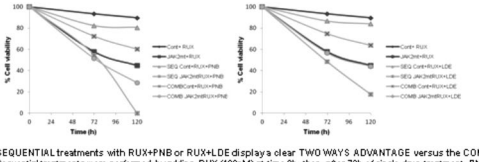
FINDING MOLECULAR/EPIGENETIC SIGNATURES IN PHILADELPHIA NEGATIVE MPNS: A NOVEL TOOL FOR STRENGTHENING DISEASE STATUS CLASSIFICATION AND TAILORING PERSONALIZED DRUG STRATEGIES

R. Garcia [1]M. Roldan [2]P. Altea [2]M. Rivas [1]A. Fernandez [1]A. Rosell [1]J. Ruiz [1]M. Martin [2,*]
[1]Hematology-Ibima, Hematology Department, Hospital Virgen de la Victoria, Campus Teatinos SN 29010, Malaga, [2]Molecular Oncology, GENYO. University of Granada Centre for Genomics and Oncological Research, Granada, Spain

Background: Nowadays, there is a lack of data addressing possible epigenetic alterations and their impact on disease status/evolution in Philadelphia-negative myeloproliferative neoplasms (MPNs). Even so, a significant number of clinical trials are currently using inhibitors of histone deacetylases, but little is precisely known about the impact of histone modifications and chromatin remodeling in MPNs (1). In line, only in a recent study has been shown a correlation between phosphorylated STAT5 and acetylated histone H3 pharmacodynamic readouts, in a preclinical study using JAK2 (V617F)-driven disease models (2). In JAK2 mutant cells, it has been already proposed a prominent role of Akt/mTOR pathways besides Jak/Stat itself (3). Nonetheless, it is plausible to conceive that the pathogenic mechanism operating in these cells might ensue from a complex network of adaptational changes, affecting sequentially other signalling pathways such as Sonic Hedgehog.
Aims: Hence, we propose that in MPNs, it would be crucial to find out combinatorial profiles of molecular/epigenetic targets. Thus, the so-called "Molecular/Epigenetic Signatures", would have the potential to address unresolved questions in the prognosis and therapeutic of MPNs: i) establishing an improved starting diagnostic profile at the molecular/epigenetic level; ii) potential capacity for better disease prognosis; iii) implementation of tailored drug strategies according to patient profiles; iv) novel tool for following up the therapeutic efficacy, providing a guide to address "drug decision making" (including second line strategies).
Methods: Accordingly, we studied molecular/epigenetic signatures in a JAK2V617F CD34+ cell model, based on combinatorial profiles composed by: Akt/mTOR activity; histone deacetylases (HDACs) activity; acetylated-lysine 4 of histone 3 (H_3K_4Ac); and Gli1 expression level, as a master transcription factor in Sonic Hedgehog pathway. In addition, we aimed to test the effect of single and double drug treatments on the proposed combination of markers using Ruxolitinib, a JAK2 inhibitor; Panobinostat, pan-HDACs inhibitor; LDE225, antagonist of the Sonic Hedgehog signalling downstream target Smoothened; BMK120, a class I PI3K inhibitor; and Everolimus, an mTOR inhibitor (all the drugs kindly provided by Novartis Pharma). Moreover, we aimed to address whether sequential drug additions in double-drug treatment strategies would provide significant advantages *versus* classical combinatorial (simultaneous) additions.
Results: The molecular/epigenetic profiles investigated here shed novel signatures with potential to establish a more detailed disease status diagnosis (see supporting Figure for details). Moreover, the molecular/epigenetic signatures correlated well with the impact on cell viability/proliferation of the different drug treatments assayed in our cell model, thus turning out as a potent profiling tool to test the efficacy of different therapeutic strategies. In addition, the sequential drug strategies for Ruxolitinib+Panobinostat, and Ruxolitinib+ LED225, displayed clear advantage *versus* combined (simultaneous) additions, based on a two ways effect: by improving its efficacy reducing cell viability/proliferations capacity, and reducing drug toxicity side effects in control cells by decreasing drug concentrations. Our data could open the pave to solve the aforementioned unresolved questions in the prognosis and therapeutic intervention of MPNs.



SEQUENTIAL treatments with RUX+PNB or RUX+LDE display a clear TWO WAYS ADVANTAGE versus the COMBINED treatment strategy. Sequential treatments were performed by adding RUX (100nM) at time 0h, then, after 72h of single drug treatment, PNB (5nM) or LDE (5nM) were added to cell cultures. Cell samples were subsequently analyzed at 72h and 120h from the starting time. Combined treatments consisted in a direct addition at time 0h of RUX (100nM) plus PNB (20nM) or LDE(10nM) for the total length of 120h. Data displayed supported what was so-called as "two ways advantage" for RUX+PNB and RUX+LED sequential treatments versus the classical combined strategies: i) side toxicity in control CD34+ cells was reduced more than a 25%; ii) increased efficacy of sequential treatments, which requires four times lower concentration of PNB than in the combined approach

Figure 1.

Summary and Conclusions: Our data could open the pave to solve the aforementioned unresolved questions in the prognosis and therapeutic intervention of MPNs.

E1308

TNIP1 AS A NOVEL REARRANGEMENT PARTNER FOR 5Q32 PDGFRB IN EOSINOPHILIA-ASSOCIATED MYELOID NEOPLASM

A. Buijs[1,*] L. van der Veken[1], S. Wittebol[2]
[1]Medical Genetics, University Medical Center Utrecht, Utrecht, [2]Internal Medicine, Gelderse Vallei Hospital, Ede, Netherlands

Background: A 5q32 *PDGFRB* rearrangement is a diagnostic criteria for a rare distinctive myeloproliferative neoplasm (MPN), often presenting with prominent eosinophilia. Most common is a t(5;12)(q32;p13) resulting in an *ETV6-PDGFRB* fusion mRNA. Variant translocations with a 5q32 *PDGFRB* gene rearrangement present with other fusion genes. In all cases the result is an aberrant, constitutive activation of the tyrosine kinase receptor. To date more than 19 *PDGFRB* rearrangement partners have been reported. The identification of *PDGFRB*-rearranged MPNs is of utmost diagnostic and therapeutic importance, as in the pre-imatinib era acute transformation could occur within a relatively short period of time. *PDGFRB* rearranged MPNs have been shown to be sensitive to tyrosine kinase inhibitors such as imatinib.
Aims: Here we reported on a 76-years-old woman, recently presenting with a MPN with leukocytosis, thrombocytosis, eosinophilia and mastocytosis.
Results: GTG banding of cultured bone marrow resulted in a normal female karyotype. Eosinophilia prompted us to investigate the status of *PDGFRA*, *PDGFRB* and *FGFR1* by FISH analyses. Loss of a distal *PDGFRB* signal on one chromosome 5 was demonstrated using 5q32 *PDGFRB* rearrangement probes, suggesting either an interstitial deletion or an unbalanced translocation involving 5q32 *PDGFRB*. Subsequent FISH analysis using a 5q subtelomere probe was indicative for a deletion. SNP-array analysis (CytoSNP-850k;Illumina) demonstrated an ~897 kb deletion likely with breakpoints within the 5q32 *PDGFRB* and 5q33.1 *TNIP1* genes.
Summary and Conclusions: *TNIP1* encodes TNFAIP3-interacting protein 1, a negative co-regulator of the NF-kB pathway. Loss-of-function mutations in *TNIP1* have been reported in diffuse large B-cell lymphoma (DLBDL), and *TNIP1* splice variants have been implicated in lymphoma and acute myeloid leukemia (AML). The transcriptional orientation of *TNIP1* and *PDGFRB* would allow expression of a 5' *TNIP1-PDGFRB* 3' fusion mRNA, in line with other *PDGFRB* gene fusions. The amino-terminal TNFAIP3-interacting protein 1 moiety that would be present in a TNFAIP3-interacting protein 1-PDGFRB chimeric protein contains several coiled-coil domains, which is canonical for dimerization and constitutive activation of the tyrosine kinase domain of PDGFRB. The patient has started treatment using 400 mg of imatinib daily. We will present on ongoing molecular characterization and treatment-response of the MPN with this novel, cytogenetically cryptic *TNIP1-PDGFRB* gene rearrangement. Our data underscore testing for cryptic rearrangements in MPN with eosinophilia.

E1309

ACTIVATED STAT5 AS NOVEL STEM TARGET IN JAK2 V617F POSITIVE MYELOPROLIFERATIVE NEOPLASMS (MPN)

E. Hadzijusufovic[1,2,3,*] A. Keller[2], F. Schur[1], S. Cerny-Reiterer[1,2], G. Hoermann[4], M. Mayerhofer[5], C. Boudot[6], F. Gouilleux[6], L. Müllauer[7], R. Moriggl[8], P. Valent[1,2]
[1]Department of Medicine I, Medical University of Vienna, [2]Ludwig Boltzmann Cluster Oncology, [3]Department of Internal Medicine, University of Veterinary Medicine Vienna, [4]Department of Laboratory Medicine, Medical University of Vienna, [5]Hanusch Hospital, Vienna, Austria, [6]Faculté de Pharmacie, Université de Picardie Jules Verne, Amiens, France, [7]Department of Clinical Pathology, Medical University of Vienna, [8]Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria

Background: Myeloproliferative neoplasms (MPN) represent the most common myeloid neoplasms and have an increasing incidence in the Western World. Three major categories of JAK2 V617F+ MPN have been defined by the WHO: essential thrombocythemia (ET), polycythemia vera (PV), and primary myelofibrosis (PMF). Currently, drug therapies used in JAK2 V617F+ MPN are only able to suppress abnormal cell production for a certain time period but are not able to eradicate the disease, which may be due to resistance of neoplastic stem cells (NSC). However, so far little is known about target expression profiles in MPN NSC. The JAK2-STAT5 pathway has recently been implicated as a potential target-pathway in CML NSC. This pathway also mediates proliferation and survival in MPN cells. It has also been described that mutated JAK2 leads to STAT5 overexpression and STAT5 activation in MPN. However, little is known about expression and function of STAT5 in MPN NSC.
Aims: The aims of our project were to examine the expression of activated STAT5 (pSTAT5) in putative CD34+/CD38- NSC in JAK2 V617F-transformed MPN and to ask whether pSTAT5 serves as a therapeutic NSC-target.
Methods: We analyzed 32 bone marrow (BM) samples obtained from patients with JAK2 V617F+ MPN, 17 BM samples obtained from patients with JAK2 V617F- MPN, and 7 non-reactive BM samples. Expression of pSTAT5 in NSC was determined by flow cytometry. Furthermore, we employed two JAK2 V617F+ cell lines, HEL and SET-2. The effects of JAK2- and STAT5-targeting drugs on proliferation were examined by measuring ^{3}H-thymidine uptake, and drug effects on apoptosis were examined by assessing the levels of activated caspase-3 by flow cytometry. We used two STAT5 inhibitors, pimozide and piceatannol, and four JAK2 inhibitors: AZD1480, TG101348, R763 and ruxolitinib. In select experiments, the effects of STAT5- and/or JAK2 inhibitors on primary MPN cells were examined.
Results: We have detected a significantly higher expression of pSTAT5 in the putative CD34+/CD38- NSC fractions in our JAK2 V617F+ MPN patients when compared to normal CD34+/CD38- BM stem cells. JAK2 V617F-

patients showed no statistically significant difference in pSTAT5 expression in the stem cell compartment compared to normal stem cells. As assessed by flow cytometry, immunocytochemistry and Western blotting, HEL cells and SET-2 cells were found to constitutively express pSTAT5, and that incubation with STAT5- or JAK2 blockers leads to a decrease in pSTAT5 expression. In addition, we found that all JAK2 inhibitors and all STAT5 inhibitors counteract proliferation in HEL cells and SET2 cells, and in most instances these drugs also induced apoptosis in these cell lines (IC_{50} and ED_{50} values are shown in the Table 1). Similar effects were found when the targeting drugs were applied on BM cells isolated from MPN patients. Again, all drugs tested were found to suppress proliferation of MPN cells in a dose-dependent manner. In one experiment, we examined the effects of the JAK2 blockers on CD34+/CD38- cells in a BM sample isolated from a patient with ET. Here, only TG101348 (5 μM, 48 hours) was able to decrease the numbers of NSC significantly, whereas the other JAK2 inhibitors showed only slight effects on CD34+/CD38- NSC.

Table 1.

	piceatannol	pimozide	AZD1480	TG101348	R763	ruxolitinib	
HEL	10 -17.5	5 - 7.5	0.5 - 1	1- 2	1 -2	1 - 2	IC_{50}
SET-2	10 -17.5	5 - 7.5	0.05 - 0.1	0.1 - 0.25	0.01 - 0.05	0.025 - 0.05	(μM)
HEL	>50	10 - 25	>50	2.5 - 5	>50	>50	ED_{50}
SET-2	>50	<10	1 - 2.5	1 - 2.5	2.5 - 5	>5	(μM)

Summary and Conclusions: In summary, our data show that NSC in JAK2 V617F+ MPN express pSTAT5, and that targeting of STAT5 may be a novel interesting approach to control NSC expansion in these malignancies. Whether drug-induced suppression of pSTAT5 in NSC is effective clinically remains to be determined in clinical trials.

E1310

PROGRESSION TO MYELOPROLIFERATIVE NEOPLASMS WAS ASSOCIATED WITH MUTATIONS OF THE JAK2 AND CALR GENES IN PATIENTS WITH IDIOPATHIC LEUKOCYTOSIS AND THROMBOCYTOSIS

N. Mori[1,*] K. Yoshinaga[1], M. Ohwashi[1], M. Shiseki[1], J. Tanaka[1]
[1]Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Idiopathic leukocytosis and erythrocytosis are hematological disorders without specific causes. Frequent V617F mutations on the *JAK2* gene have been reported in patients with polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). We also found *JAK2* V617F mutations in one of 11 patients with idiopathic erythrocytosis. Recently mutations of the *CSF3R, SETBP1,* and *ETNK1* genes have been found in chronic neutrophilic leukemia and atypical chronic myeloid leukemia. Moreover an autosomal mutation was found in the *CSF3R* gene in a family with chronic neutrophilia. However, mutations associated with idiopathic leukocytosis and unexplained thrombocytosis have largely been unknown.
Aims: To elucidate the relevance of gene mutations, we analyzed mutations of the *CSF3R, JAK2, CALR, SETBP1,* and *ETNK1* genes in idiopathic leukocytosis and thrombocytosis.
Methods: Leukocytosis is defined as a total white blood cell (WBC) count more than two standard deviations above the mean, or a value greater than 11,000/μL. Those patients who satisfied the following criteria were included in the study: leukocytosis (predominantly neutrophils); the absence of apparent causes of leukocytosis; and documentation of the leukocytosis over a prolonged period of time. The period of observation was 1 year or longer in most patients. Those patients with unexplained persistent thrombocytosis (greater than 350,000/μL) who did not satisfy the criteria of ET (World Health Organization classification) were included in the study. Neutrophils or mononuclear cells were collected obtaining written informed consent from 16 patients with idiopathic leukocytosis (n=10), thrombocytosis (n=3), PV (n=1), and ET (n=2). Five of the patients were males and 11 were females. Neutrophils from peripheral blood were purified by dextran sedimentation followed by hypotonic lysis and centrifugation with Ficoll-Conray. Mononuclear cells were isolated from bone marrow by Ficoll-Conray gradient centrifugation. Genomic DNA was extracted using the QIAamp DNA blood mini kit (Qiagen, Valencia, CA, USA). Mutations within hot spots of the *CSF3R, JAK2, CALR, SETBP1,* and *ETNK1* genes were analyzed by direct sequencing in both directions using a 3730xL DNA Analyzer (Life technologies, Carlsbad, CA, USA) and/or allele specific polymerase chain reaction analysis. The current study was conducted within the guidelines and with the approval of ethical committee.
Results: *JAK2* V617F mutations were found in one of the 10 patients with idiopathic leukocytosis, one PV patient, and one of the two ET patients. No mutations of the *CSF3R, SETBP1,* and *ETNK1* genes were found in idiopathic leukocytosis, thrombocytosis, PV or ET patients. Type 1 mutations of the *CALR* gene were detected in two of the three unexplained thrombocytosis, and one of the two ET patients. All of the three patients with the type 1 mutations of the *CALR* gene were females. One idiopathic leukocytosis patient with *JAK2* V617F mutation has developed PV, whereas one idiopathic leukocytosis patient without the mutations has developed leukemia. The other 8 patients with idiopathic leukocytosis have a stable disease. One patient with unexplained thrombocytosis developed MF.
Summary and Conclusions: Our study suggests that idiopathic leukocytosis and unexplained thrombocytosis are heterogeneous conditions regarding mutations of the *JAK2* and *CALR* genes and clinical courses.

E1311

TO TAKE HOME: HOW MUCH VALUE IS LOW BURDEN OF JAK2 V617F ALLELE MUTATION?

L. Torres-Miñana[1,*] M. Moreno[1], N. Cruz[1], C. Bilbao[1], J. Gonzalez[2], G. Santana[1], T. Gomez-Casares[1], T. Molero[1]
[1]Hematology, [2]Statistical Service, H. Dr Negrin GC, Las Palmas de GC, Spain

Background: The discovery of the JAK2 V617F mutation and its association with distinct haematological and clinical characteristics has prompted studies to assess the predictive value of JAK2 V617F and the allele burden for the most common complications of Mieloproliferative neoplasm (MPN, like Policitemic Vera -PV-, Essential Thrombocitosis -ET-, Myelofibrosis -MF-), and its relationship with prognosis and survival. The studies support the contention that quantification of JAK2 V617F allele burden might convey relevant clinical information in well-defined categories of MPN cases. They also show that a high JAK2V617F allele burden is associated with more severe disease with lower hemoglobine, more prevalent massive splenomegaly, increased rate of venous thrombosis (VT) and higher prevalence of bleeding events.
Aims: In this study we compare clinical and hematologic characteristics of patients with low allele burden with the rest.
Methods: In this retrospective study, we selected peripheral blood samples of 89 patients with Ph-negative MPNs. 45 were men and 44 women, with ages between 27 and 86 years old (mediane 53 years). We analyzed JAK2V617F status, the allele burden and its relationship with hematologic and clinical parameters like bleeding, deep vein thrombosis among others. The cutoff value for the allele burden was set to ≥10% for high and intermediate levels and <10% for low levels. JAK2 V617F mutation analysis was performed through High Resolution Melting and Sanger sequencing. For the statistical analysis, patient's characteristics were compared by Fisher's exact test for categorical variables, Mann-Whitney U test for continuous variables and Shapiro. Wilk to check the normality of the data of quantitative variables. All analyses were two sided, and significance was set at a p- value of 0.05. SPSS statistical package (v. 15.0) was us.
Results: In our series 20.2% of the cases presented low allele burden (PV 1/46, ET 14/34, MF 3/9). The presence of low allele burden was not associated with hematologic parametres compared to high and intermediate burden. In PV, arterial thrombosis was detected in 0% of low buden cases compared to high burden cases with 24% incidencie (p>0,05). On the same way, there was VT in 20% of high burden cases *versus* 0% of low burden cases. On the other hand, arterial thrombosis cases in patients with ET happened in 3% with low budden and 6% with high and intermediate burden; in VT cases, there were 14.3% episodes in low burden and 20% cases with high and intermediate burden. The allele burden was not associated with the necessity of transfusions, phlebotomy or bleeding. In ET, patients with low allele burden presented lower use of hydrea (p=0,035). We found that 16.7% of deaths presented low burden in contrast to 83% with high and intermediate burden.
Summary and Conclusions:-According to our results, PV and TE patients with low JAK2 V617F allele burden presented lower vein and arterial thrombotic risk. - Patients with ET with low allele burden would require with lower frequency hydrea treatment and it is probably relationated to myeloproliferative activity. - We need to increase our series in order to confirm our results, nevertheless, we believe that to get a better insight about the stratification of patients according to mutant allele burden may be important to achieve a personalized and more specific/effective treatment.

E1312

CHRONIC INFLAMMATION BIOMARKERS IN MYELOPROLIFERATIVE NEOPLASMS

V. Čokić[1,*] J. Santibanez[1], D. Šefer[2], S. Vignjević[1], D. Marković[1], M. Buač[1], D. Djikić[1], M. Budeč[1]
[1]Institute for Medical Research, University of Belgrade, [2]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: Chronic inflammation contributes to the initiation and pathophysiology of cancers, including myeloproliferative neoplasms (MPNs). Unfortunately the new JAK1/2 inhibitors act only on symptoms and currently there is no cure for MPNs. The recent JAK1/2 inhibitor trials in MPNs unexpectedly showed that reducing inflammation can be more beneficial to patients than targeting gene mutants. Among chronic inflammation biomarkers, TGF-β and IL-6 have a central role, possessing both immunomodulatory and fibrogenic activities. TGF-β upregulates IL-6 and the levels of these cytokines are increased in MPNs.
Aims: We aim to evaluate the pro-inflammatory TGF-β, IL-6, NF-kB and anti-inflammatory IL-10 signaling pathways in MPNs.
Methods: We analyzed 63 patients with essential thrombocythemia (ET), 92 with polycythemia vera (PV), and 50 with primary fibrosis (PMF), and per 10

patients with secondary erythrocytosis and healthy controls. To evaluate the proposed signaling pathways in CD34+ hematopoietic progenitors, of 20 MPN patients, microarray analysis was used.
Results: Statistically significant leukocytosis was observed in PV *vs* secondary erythrocytosis and in JAK2V617F mutation positive *vs* negative PMF patients. Moreover, thrombocytosis was generally present in MPNs, while JAK2V617F allele burden significantly decreased the level of thrombocytosis in ET and PMF. Regarding TGF-β signaling related genes of hematopoietic progenitors: transcription factor Dp-1 (TFDP1) was significantly decreased in PMF, while cyclin-dependent kinase inhibitor 2B (CDKN2B) was increased in PV *vs* controls. Also, bone morphogenetic protein receptor, type II (BMPRII) was enhanced in ET and PV, whereas TGF-β receptor 1 in all MPNs. Regarding IL-6 signaling pathway related genes: interleukin 6 signal transducer (IL6ST) and mitogen-activated protein kinase kinase 1 (MAP2K1) were increased in ET and PV *vs* healthy controls. Considering NF-kB signaling related genes: tumor necrosis factor receptor superfamily (TNFRSF1A) and TNFRSF1A-associated via death domain (TRADD) were increased in PMF and PV, respectively. In addition, TNFRSF1A had more prominent overexpression in JAK2V617F mutation positive patients than in MPN patients with no JAK2V617F mutation, reaching statistical significance in ET. Analysis of IL-10 signaling pathway related genes revealed significant increase of biliverdin reductase A (BLVRA) and heme oxygenase 1 (HMOX1) in PV and ET, respectively.
Summary and Conclusions: The presented inflammation biomarkers will provide a better understanding of molecular mechanisms implicated in the development and progression of MPNs.

E1313

THE PRESENCE OF THE JAK2V617F POINT MUTATION AFFECTS OSTEOCLAST FUNCTION IN PATIENTS WITH CHRONIC MYELOPROLIFERATIVE NEOPLASMS

E. Spanoudakis[1,*] M. Papoutselis[2], P. Miltiades[2], S. Papamichos[2], C. Tilkeridis[2], C. Tsatalas[2], I. Kotsianidis[2]
[1]Hematology, [2]Democritus University of Thrace, Alexandroupolis, Greece

Background: Myeloproliferative neoplasms (MPN) patients are at increased risk for femoral fracture and the development of osteoporosis, compared to age-matched population groups (1). The JAK2V617F is a gain of function point mutation that occurs frequently in MPN patients and deranges many cellular properties of their hemopoietic cells.
Aims: Therefore we speculate that genetically modified JAK2 can slightly modify osteoclast homeostasis, a gain of function that can be implicated in increased bone resort ion and deregulation of the hematopoietic stem cell niche in MPN patients.
Methods: Peripheral blood was drawn from 18 newly diagnosed MPN patients (14 essential thrombocythemia, 2 primary myelofibrosis, 2 polycythemia vera diagnosed according to 2008 WHO criteria) and from 4 age-matched normal donors (ND). Osteoclast (OCL) forming assays were started from $2x10^5$ positively selected monocytes. OCL were formed also under the presence of the pan-JAK Inhibitor AG-490. Genomic DNA was extracted from the formed osteoclasts and the JAK2V617F/JAK2WT genomic DNA ratio was calculated by using the Taqman based JAK2MutaQuant Kit (IPSOGEN). Comparisons between groups were performed by using the Mann-Whitney for unpaired and the Wilconxon Rank test for paired samples.
Results: OCLs formed from monocytes derived from heterozygous for the JAK2V617F mutation (+/-) MPN patients, were significantly more compared to those from the JAK2 wild type(WT) MPN patients and to ND as well [OCL per 10.000 monocytes, Median Value of osteoclasts (MV) (min-max) was for JAK2V617F (+/-) MPN patients: 960 (159-3674), for JAK2 WT MPN patients: 204 (81-1286), p=0.03, and for ND was: 322 (215-522) and p=0.05 when comparing JAK2V617F(+/-) to ND, Mann-Whitney test]. The ratio of JAK2V617F/JAK2WT genomic DNA was increased in OCLs compared to the input monocyte cells. The median enrichment of OCLs for the JAK2V617F mutated clone was 12% (3.3%>26% and p<0.01, Wilconxon Rank test). Compared to ND OCLs from patients with JAK2V617F (+/-) are more susceptible to JAK2 inhibition (Mann-Whitney test, p=0.03) but this was not statistically significant for JAK2 WT MPN patients (Mann-Whitney test, p=0.1).
Summary and Conclusions: The acquisition of the JAK2V617F point mutation in hematopoietic cells capable for osteoclastogenetic differentiation provides them with increased OCL forming ability but these OCLs are concurrently becoming more vulnerable to JAK2 kinase inhibition. This deregulation in osteoclast homeostasis can contribute to osteoporosis development in MPN patients and probably in the mobilisation of hemopoietic progenitor cells towards the periphery.

E1314

INTERLABORATORY EVALUATION OF TARGETED NEXT GENERATION SEQUENCING FOR MYELOPROLIFERATIVE NEOPLASMS ASSOCIATED MUTATIONS

E. Verger[1,*] A. Chauveau[2], C. Conejero[3], R. Tang[4], J.-J. Kiladjian[5], V. Ugo[2], F. Delhommeau[4], S. Giraudier[3], B. Cassinat[1]
[1]Cellular biology department, Saint-Louis Hospital, AP-HP, Paris, [2]Hematology department, CHU, Brest, [3]Hematology department, Henri Mondor Hospital, AP-HP, Créteil, [4]Hematology department, Saint-Antoine, AP-HP, [5]Center for Clinical Investigations, Saint-Louis Hospital, AP-HP, Paris, France

Background: Classic myeloproliferative neoplasms (MPN) include polycythemia vera, essential thrombocythemia and primary myelofibrosis and share an association with molecular abnormalities such as JAK2V617F or CALR mutations. Numerous somatic mutations have been identified in MPN patients including mutations in signaling pathways, in epigenetic or splicing regulators, and in oncogenes. Although the relationship between mutations and the pathophysiology of MPN is not clear, some mutations are important for diagnostic classification whereas others have prognostic relevance, making more pregnant the need for high throughput sequencing approaches. Next generation sequencing (NGS) is capable of quickly allowing the assembly of a single multi-gene panel relevant to MPN, but as NGS becomes a clinical tool, a full understanding of the variables affecting sequencing analysis output is required.
Aims: In this multicentric study, we evaluated different NGS platforms 1) for their robustness in the identification of mutations relevant to MPN diagnosis, and 2) by comparing quantitative data for these variants.
Methods: Four laboratories participated in this study. All of them analysed 14 DNA samples from MPN patients. Two NGS platforms (MiSeq-Illumina (n=3), PGM-Ion Torrent (n=1)) with different exon sequencing approaches (amplicon sequencing (TSCA-Illumina (n=2), AmpliSeq-Lifetech (n=1) or Haloplex-Agilent (n=1)) were evaluated. The gene panels slightly differed between groups, but a common set of 10 genes was present in each center: *JAK2, MPL, ASXL1, TET2, EZH2, IDH1, IDH2, DNMT3A, LNK, SRSF2*. Sequencing data were analysed on each platform using local pipelines (VariantStudio-Illumina (n=2), SureCall-Agilent (n=1) and IonReporter-life tech (n=1)) and compared between laboratories with variant allele frequencies (VAF)>2% and depth>50X filters.
Results: Comparative analysis of all labs found 32 mutations, all validated by Sanger sequencing or allele-specific PCR, on 8 common genes. Twenty four (75%) of these mutations on 6 genes were detected by all platforms with VAF between 12% and 85%. The discrepancies between labs focused on 2 genes: *ASXL1* and *SRSF2*. PGM platform missed all deletions or duplications in *ASXL1* gene (4/4). Low coverage was observed for SRSF2 hotspot point mutations in 2 platforms (AmpliSeq-PGM and TSCA-MiSeq). Three labs have integrated *CALR* gene on their panel design, only the lab using SureCall analysis identified large deletions in this gene. We observed a tight correlation of JAK2V617F VAF (23% to 85%, n=9) among the different platforms (standard deviation average (SDA): 2.4, range: 0.37-3.94). In addition the different NGS technologies were well correlated with qPCR results (r^2=0.86). Excepted for 2 frameshift variants in *DNMT3A* and *ASXL1*, an excellent reproducibility was observed in quantitative values of VAF (n=32 mutations) among participants (SDA: 4.35, range: 0.37-19.5).
Summary and Conclusions: This inter-laboratory comparison demonstrates that NGS is a reliable technology for mutations screening in MPN and would permit a rapid molecular characterization. Moreover, we observed an excellent accuracy of quantitative evaluation of VAF in particular with comparable results between NGS and qPCR for JAK2V617F, and a good reproducibility regardless platform characteristics and chemistry approaches. In summary, although customized optimization to enhance variants detection remains necessary (low depth, bioinformatics tools for indel detection), this comparative assessment of NGS pipelines gives important insights into sequencing and analysis strategies for routine hospital transfer.

E1315

A 7- GENE SIGNATURE DEPICTS THE BIOCHEMICAL PROFILE OF EARLY PREFIBROTIC MYELOFIBROSIS

V. Skov[1,*] M. Burton[2], M. Thomassen[2], T. Stauffer Larsen[3], C. Hasselbalch Riley[4], A.B. Madelung[5], L. Kjær[1], H. Bondo[5], I. Stamp[5], M. Ehinger[6], R. Dahl-Sørensen[1], N.B. Mortensen[1], K. Nielsen[7], J. Thiele[8], M.K. Jensen[9], O.W. Bjerrum[10], T. A. Kruse[2], H.C. Hasselbalch[1]
[1]Department of Hematology, Roskilde Hospital, University of Copenhagen, Roskilde, [2]Department of Clinical Genetics, [3]Department of Hematologyx, Odense University Hospital, Odense, [4]Department of Hematology L, Herlev Hospital, University of Copenhagen, Herlev, [5]Department of Pathology, Næstved Hospital, Næstved, Denmark, [6]Department of Pathology, Lund University Hospital, Lund, Sweden, [7]Department of Pathology, Aarhus University Hospital, Aarhus, Denmark, [8]Department of Pathology, University of Cologne, Köln, Germany, [9]Department of Pathology, Roskilde Hospital, University of Copenhagen, Roskilde, [10]Department of Hematology L, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

Background: The Philadelphia-negative myeloproliferative neoplasms include essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). Recent studies have shown that a large proportion of patients classified as ET actually have prefibrotic myelofibrosis (pre-MF). Because prognosis and likely in the future also treatment of both entities are different, it is important to distinguish between them. According to the WHO classification, bone marrow histology is a major component of the distinction between ET

and pre-MF. However, the differential diagnosis between these two entities can be challenging.
Aims: We aimed at identifying a simple gene signature-composed of a few genes-which were able to distinguish true ET from pre-MF.
Methods: Gene expression profiles have been generated on whole blood from 17 patients with ET using Affymetrix HG-U133 2.0 Plus microarrays. Seven carefully chosen genes were used to develop a supervised classification model to predict the signature of ET patients. The biochemical variables lactate dehydrogenase (LDH) and leukocyte count were used to divide patients into subgroups, taking into account that the leukocyte count may be elevated in ET and pre-MF due to other factors than the myeloproliferation per se (*e.g.* inflammation and other cancer), whereas the LDH is elevated in myeloproliferative cancer only as a result of clonal myeloproliferation provided that other reasons are excluded (*e.g.* liver disease and hemolysis). In addition, we a priori assumed the leukocyte count to be normal in "genuine" ET (no increase in granulopoiesis), whereas pre-MF is often associated with an elevated leukocyte count and thrombocythemia. Bone marrow biopsies from 14 of the 17 patients were evaluated by 4 independent hematopathologists.
Results: Based on the LDH and leukocyte values, 9 patients were assigned to the ET group and 8 patients were assigned to the pre-MF group; however, the composition of patients in the LDH and leukocyte groups differed. Using LDH as the clinical variable, the resulting 7-gene signature including MPO, CEACAM8, CRISP3, MS4A3, CEACAM6, HEMGN, and MMP8 correctly predicted 8 of 8 patients in the pre-MF group (sensitivity 100%) and correctly classified 8 of 9 patients in the ET group (specificity 89%) and showed a balanced accuracy of 94%. Using the leukocyte value as the clinical variable, the 7-gene signature resulted in 62% sensitivity, 78% specificity, and a balanced accuracy of 70%. The performance of the 7-gene signature using LDH as the clinical variable was tested against the bone marrow evaluation from the hematopathologists showing a concordance of 71%, 79%, 62%, and 38%. Gene ontology analysis and literature research show that the 7 genes are involved in key processes associated with the pathophysiology of MPNs. CRISP3, MMP8 and MPO are neutrophile granula proteins that play important roles in immune and inflammatory responses. CEACAM6 and CEACAM8 are involved in cell adhesion, cellular invasiveness, angiogenesis, and inflammation. MS4A3 is a hematopoietic cell cycle regulator, and HEMGN plays an important role in differentiation, proliferation and hematopoietic development.
Summary and Conclusions: Supervised classification was able to distinguish between ET and pre-MF with a balanced accuracy of 94%. Our findings suggest that classification using LDH as the clinical variable may add support to the clinical diagnosis of these two entities. Prospective studies of a larger cohort of patients are being planned to substantiate LDH as a simple parameter in the distinction between ET and pre-MF.

E1316

PLATELET ANALYSIS INCREASES THE DETECTION OF MUTATIONS IN TRIPLE-NEGATIVE ESSENTIAL THROMBOCYTHEMIA PATIENTS

A. Angona[1,2,3,*] C. Besses[1,2], A. Alvarez-Larrán[1,2,3], L. Camacho[2], R. Longarón[2,4], S. Pairet[2,4], È. Torres[4], C. Fernández-Rodriguez[2,3], B. Bellosillo[2,4,5]
[1]Hematology, Hospital del Mar, [2]Grup de Recerca Clínica Aplicada en Neoplàsies Hematològiques-IMIM, [3]Universitat Autònoma de Barccelona, [4]Pathology, Hospital del Mar, [5]Universitat Pompeu Fabra, Barcelona, Spain

Background: Mutations in *JAK2* (50-60%), *CALR* (15-30%) and *MPL* (1-5%) have been identified in patients with essential thrombocythemia (ET). However, there is still a percentage of ET patients (10-30%) who are wild-type for mutations in these genes when isolated granulocytes or peripheral blood are analyzed. This subgroup of patients called "triple-negative" has not been extensively studied with regard to the presence of *JAK2, CALR* and *MPL* mutations in platelets.
Aims: To analyze *JAK2*V617F, *CALR* and *MPL* mutational status in platelets from a cohort of triple negative ET patients.
Methods: From a whole cohort of 236 ET patients consecutively diagnosed in a single institution, we included 33 ET patients (14%) lacking *JAK2*V617F (determined by quantitative allele-specific PCR), *MPL* exon 10 mutations (W515, S505; analyzed by Sanger sequencing) and *CALR* exon 9 mutations (analyzed by PCR followed by fragment analysis) in granulocytes.
Mutational analysis. Platelet RNA was extracted with Trizol and 1ug total RNA was reverse transcribed. The mutational analysis of *JAK2*V617F was performed by quantitative allele-specific real time PCR. Analysis of exon 10 of the *MPL* gene (S505, W515) was performed by next generation sequencing (NGS) (454 GS Junior, Roche), with a median coverage of 1335x (range 497-4863). Mutations were confirmed by CAST-PCR. The mutational analysis of exon 9 of the *CALR* gene was performed by PCR, using a 6-carboxyfluorescein labeled reverse primer, followed by fragment analysis in a Genetic Analyzer 3500DX (Applied Biosystems) or by NGS deep sequencing (454 GS Junior) with a median coverage of 1326.5x (range 607-1686).
Results: *JAK2*V617F was detected in 3 out of 33 (9.1%) patients analyzed, with allele burdens of 16%, 20% and 33%. *MPL* mutations (W515L) were detected in 3 out of 33 patients by NGS. Two cases with *MPL* W515L allele burden of 12% and 26% in platelets were confirmed by CAST-PCR. The third case with only a 3% of mutant allele burden was not confirmed. Interestingly, the coexistence of *JAK2*V617F and *MPL*W515L was observed in one case with a mutant allele burden of 16% and 12% respectively. Regarding *CALR,* two cases showed deletions in exon 9 by NGS with allele burdens of 1% and 2%. These mutations were not confirmed by fragment analysis.
Summary and Conclusions: In summary, we have confirmed the presence of *JAK2*V617F and/or *MPL* mutations in 4/33 (12%) ET patients previously considered as triple-negative. Platelet analysis increases the sensitivity of driver mutation detection in this subset of ET patients when compared to conventional analysis on whole blood or isolated granulocytes.

BONE MARROW STROMA MEDIATED PROTECTION OF MPN CELLS FROM RUXOLITINIB- AND VORINOSTAT-INDUCED APOPTOSIS REQUIRES MAPK-JNK AND PI3K-AKT/PKB SIGNALING PATHWAY ACTIVATION

B. Cardoso[1,2], H. Belo[1], J. Barata[3], A. Almeida[1,2,*]
[1]IPO Lisboa, [2]CEDOC, Faculdade de Ciêcnias Médicas, Universidade Nova de Lisboa, [3]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

Background: The classical BCR-ABL-negative myeloproliferative neoplasms (MPN) are characterized by increased proliferation of hematopoietic precursors in the bone marrow resulting in elevated numbers of terminally differentiated cells. Despite the recent advances in the understanding of the biology of MPN, there is still no curative treatment for MPN except for bone marrow transplantation. The discovery of JAK-STAT constitutive activation in the majority of MPN patients led to the development of clinical studies targeting MPN with Ruxolitinib, a JAK1/2-specific inhibitor. However, despite achieving significant reductions in splenomegaly and symptomatic improvement in MPN patients, JAK inhibition failed to induce complete remissions and eradicate the malignant clone. In alternative, histone deacetylase inhibitors have shown success in the treatment of several hematological malignancies but their efficacy in MPN is limited.
Aims: Given that both Ruxolitinib and the HDAC inhibitor Vorinostat fail to eradicate the neoplastic clone in MPN patients, we investigated the hypothesis that the bone marrow stroma may confers resistance to these drugs by preventing their cytotoxic effects on neoplastic cells.
Methods: We made use of a co-culture system in which MPN cell lines (SET-2, HEL and UKE-1) are placed in direct contact with the HS-5 bone marrow stromal cell line or its conditioned media. Upon exposure of MPN cells to the bone marrow microenvironment and following treatment with different drugs, the cells are harvested to analyze cellular viability, gene expression by quantitative-PCR and signaling pathway activation by Western-blot.
Results: The treatment of the SET-2 cell line with both Vorinostat and Ruxolitinib promoted apoptosis and decreased proliferation. However, apoptosis was significantly abrogated when SET-2 cells were cultured in the presence of a stromal layer of HS-5 cells or HS-5 conditioned medium. The stroma protective effect was maintained for up to 6 six days and was also dependent on drug concentration. The bone marrow stroma protective effect correlated with altered expression in MPN cells of genes associated with inflammatory processes, apoptosis and proliferation (*CDKN1A*, *IER3*, *BIRC3*, *TNFRSF8*, *TNFRSF9*, *COX2*, *IL1B*), and with the activation of signaling pathways important for cellular homeostasis, such as PI3K-PKB/Akt, MAPK-JNK, JAK-STAT and NF-κB as shown by increased phosphorylation of PKB/Akt (Ser473); GSK3α/β (Ser9/Ser21); S6 (Ser235/236); STAT3/5 (Tyr705/Tyr694) and p65/RELA (Ser536). Importantly, the pharmacological inhibition of PI3K-PKB/Akt and MAPK-JNK signaling pathways completely abrogates the protective effect bone marrow stroma on SET-2 cells.
Summary and Conclusions: Overall, we show that bone marrow stroma protects MPN cells from the cytotoxic effects of two pharmacological agents of different classes: Vorinostat and Ruxolitinib. This protective effect is likely achieved, through the up-regulation of genes associated with apoptosis (*IER3, BIRC3*, *TNFRSF9*) and relies on the activation of pro-survival signaling pathways such as PI3K-PKB/Akt and MAPK-JNK. We did not observe any effects of the bone marrow stroma on proliferation or differentiation, suggesting that the main effect of bone marrow stromal cells is to prevent apoptosis of the neoplastic cells. Our results identify a possible cell non-autonomous mechanism by which Ruxolitinib fails to eradicate the neoplastic clone in MPN patients and may indicate novel therapeutic targets for MPN.

E1318

FREQUENCY AND ALLELE BURDEN OF CALR MUTATIONS IN CHINESE WITH ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS WITHOUT JAK2 V617F OR MPL MUTATIONS

N. Li[1], Q.-M. Yao[1], R.P. Gale[2], J.-L. Li[1], L.-D. Li[1], X.-S. Zhao[1], H. Jiang[1], Q. Jiang[1], B. Jiang[1], H.-X. Shi[1], S.-S. Chen[1], K.-Y. Liu[1], X.-J. Huang[1], G.-R. Ruan[1,*]
[1]Peking University People's Hospital and Institute of Hematology, BeiJing, China, [2]Haematology Research Center, Division of Experimental Medicine, London, United Kingdom

Background: CALR mutations are detected in about 50% of persons of pre-

dominately European descent with essential thrombocythemia (ET) or primary myelofibrosis (PMF) with wild-type alleles of JAK2 and MPL. The role of CALR mutations in the aetiology of ET and PMF is unknown and correlates between CALR mutation, mutant allele burden and clinical features are being studied.
Aims: To study the frequency of CALR mutations and clinical correlates in Chinese populations.
Methods: We studied 1088 Chinese with diverse myeloproliferative neoplasms including ET (N=234) and PMF (N=50) without JAK2^{V617F} or MPL exon 10 mutations. Detection of CALR exon 9 mutations was done by PCR amplification followed by fragment length analysis and direct sequencing.
Results: CALR mutation was detected in 53% (95%CI, 46-60%) of subjects with ET and 56% (95% CI, 41-70%) of subjects with PMF. 152 CALR mutations were identified clustering into 15 types including deletions (N=8), insertions (N=3) and complex indels (N=4). We also identified 9 new mutation (Figure1). Mean (±SD) mutant allele burden was 31±12% (range, 0.5-69%). Persons with PMF had higher CALR mutant allele burdens than those with ET (38±8% *vs* 29±12%; *P*<0.001). Amongst persons with CALR mutations, those with PMF had different clinical features from those with ET.
Summary and Conclusions: These data may be useful for diagnosing ET and PMF in Chinese who are about 40% of all persons with ET and PMF and for monitoring therapy-response. They also highlight similarities and differences in CALR mutations between Chinese and persons of predominately European descent with these diseases.

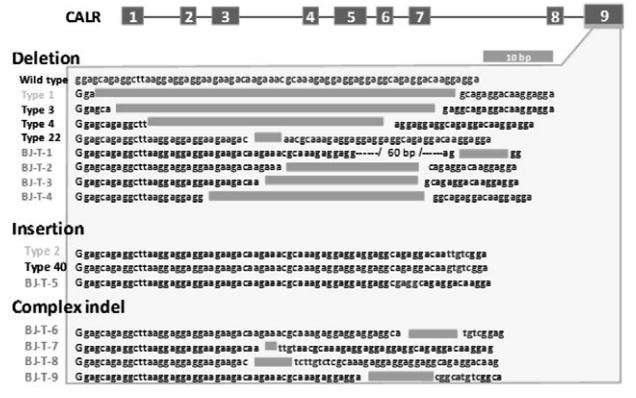

Figure 1. Genomic positions of the 15 mutation types.

GENE AND PROTEIN EXPRESSION ANALYSES OF THE MTOR SIGNALING PATHWAY IN MYELOPROLIFERATIVE NEOPLASMS

V. Čokić[1,*] P. Mossuz[2], R. Puri[3], B. Beleslin-Čokić[4], O. Mitrović-Ajtić[1], T. Subotički[1], M. Diklić[1], D. Leković[5], M. Gotić[5,6]
[1]Institute for Medical Research, University of Belgrade, Belgrade, Serbia, [2]Département d'Hématologie, Institut de Biologie et Pathologie, CHU Grenoble, Grenoble, France, [3]Division of Cellular and Gene Therapies, Center for Biologics Evaluation and Research, Food and Drug Administration, Silver Spring, United States, [4]Clinic of Endocrinology, Diabetes and Diseases of Metabolism, Clinical Center of Serbia, Belgade, [5]Clinic of Hematology, Clinical Center of Serbia, [6]Medical faculty, University of Belgrade, Belgrade, Serbia

Background: The main target of activated phosphoinositide-3-kinase (PI3K)/AKT is the serine/threonine kinase mammalian target of rapamycin (mTOR). JAK inhibition, used in therapy of myeloproliferative neoplasms (MPNs), abolished the activation of JAK/STAT and PI3K/mTOR signaling pathways.
Aims: We intend to reveal gene and protein markers of MPN pathogenesis, with an accent to PI3K/AKT and mTOR pathway members and related genes.
Methods: Using cDNA microarray analysis of 25.100 unique genes, we studied the gene expression profile of hematopoietic CD34$^+$ progenitor cells and granulocytes obtained from peripheral blood of subjects with essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). The microarray analyses of the hematopoietic progenitor cells and granulocytes were performed from 20 MPN subjects: JAK2 positive ET, PV, PMF subjects, and JAK2 negative ET, PMF subjects. The granulocytes for proteomic studies were pooled in 4 groups: PV with JAK2 mutant allele burden above 80%, ET with JAK2 mutation, PMF with JAK2 mutation and ET/PMF with no JAK2 mutation.
Results: The number of differentially regulated genes was about two fold larger in hematopoietic CD34$^+$ progenitors compared to granulocytes. Thirty-six genes (including *RUNX1, TNFRSF19*) were persistently highly expressed, while 42 genes (including *FOXD4, PDE4A*) were underexpressed both in hematopoietic CD34$^+$ progenitors and granulocytes. Using proteomic studies, significant upregulation was observed for MAPK and PI3K/Akt signaling regulators that control myeloid cell apoptosis, differentiation and proliferation (GADD45B, CRIP1, SIPA1). When the status of mTOR signaling pathway related genes was analyzed, PI3K/Akt regulators were preferentially upregulated in hematopoietic progenitors of MPNs, with downregulated major components of the protein complex EIF4F.
Summary and Conclusions: Molecular profiling of hematopoietic progenitors and granulocytes of MPN determined gene expression patterns beyond their recognized function in disease pathogenesis that included dominant upregulation of PI3K/AKT signaling.

E1320

THE ANTIPROLIFERATIVE EFFECT OF SIMVASTATIN IS ASSOCIATED WITH EPIGENETIC MECHANISMS IN NEOPLASTIC MAST CELLS

H. Karlic[1,*] D. Neidhart[2], F. Haider[2], S. Spitzer[2], F. Varga[2]
[1]Ludwig Boltzmann Cluster Oncology, [2]Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling and 1st Medical Department, Hanusch Hospital, Vienna, Austria

Background: There is growing evidence that statins like simvastatin show antileukemic activities (Bockorny and Dasanu, 2015). A multitude of experimental studies have established their pro-apoptotic, anti-proliferative, anti-invasive, and radiosensitizing effects. Although several cellular pathways activated by statins have been identified, the precise mechanisms by which statins inhibit neoplastic cell growth remain elusive and likely vary with the type of malignancy. Statins are 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors that act on the mevalonate pathway and inhibit synthesis of cholesterol, geranylgeranyl pyrophosphate (GGPP) and farnesyl pyrophosphate (FPP). Consequently, they prevent posttranslational isoprenylation of small GTPases, and inhibit their activity. In neoplastic cells, activated RAS-GTPase, the founding member of the gene family, down-regulates the expression of the pro-apoptotic gene FAS via epigenetic DNA-methylation by DNMT1 (Thaler *et al.*, 2013).
Aims: The aim of this study was to investigate possible epigenetic mechanisms, which are responsible for the antiproliferative activity of statins on neoplastic mast cells.
Methods: Here we performed *in vitro* analyses from human mast cell leukemia lines (HMC 1.1. and HMC 1.2.) following 3 days of simvastatin-treatment. For comparative reasons a bisphosphonate-based inhibitor of the mevalonate pathway (ibandronate) and a demethylating agent (decitabine) were used in pharmacological concentrations. Modulation of gene expression from selected genes, were analysed from gene chip data (Affymetrix) with respective bioinformatics tools (Pathvisio and GSEA) and confirmed and via real time PCR and immune blotting.
Results: Dose response curves showed a significantly lower sensitivity of HMC 1.2 (EC50: 16.8 µM) as compared to HMC 1.1 (EC50: 3.5 µM). It remains to be established, if this is associated with the Kit D816V mutation, which is only present in HMC 1.2. Treatment with simvastatin upregulated the microRNA612 and down-regulated the epigenetic key enzymes *DNMT1* and *HDAC2.* This was associated with down-regulation of the repair mediator *TYMS* (thymidilate synthase) and the associated metabolic pathway (one carbon/folate metabolism, see Figure 1) as well as the *BRCA* genes, the latter being just observed with simvastatin but not with ibandronate or decitabine, thus indicating a specific effect of statin on DNA-repair.

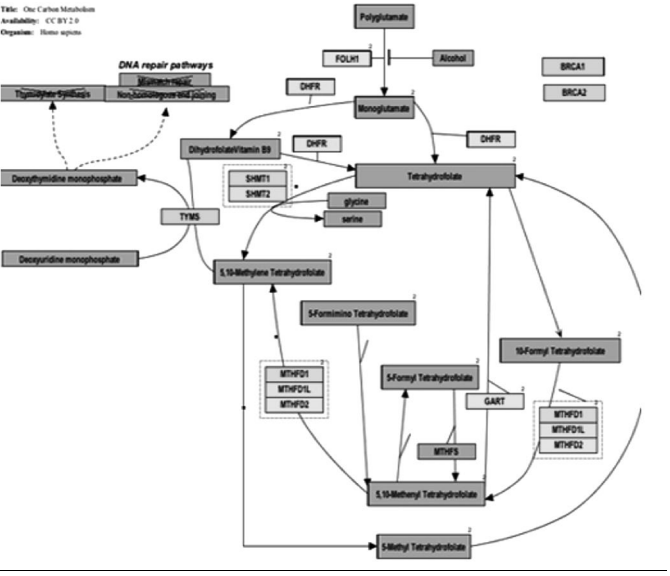

Figure 1. One carbon metabolism pathway (green: down-regulation, red: up-regulation).

Summary and Conclusions: In conclusion this study shows that the antiproliferative effect of statins is associated with principal epigenetic mechanisms including DNA-demethylation, histone modification as well as expression of microRNA in mast cell leukemia lines, thus confirming similar data from solid cancer cell lines (Karlic *et al.*, 2015). It remains to be elucidated, whether statin-mediated reduction of mediators for DNA repair is a possible cause or a consequence of the observed epigenetic and antiproliferative mechanisms.

CD30 EXPRESSION ON NEOPLASTIC MAST CELLS IN SYSTEMIC MASTOCYTOSIS-CORRELATION OF ASSESSMENT BY IMMUNOHISTOCHEMISTRY AND MULTIPARAMETER FLOW CYTOMETRY WITH RESPECT TO CLINICAL PARAMETERS

F. Bellos[1,*] K. Sotlar[2], S. Schnittger[1], C. Haferlach[1], T. Haferlach[1], W. Kern[1]
[1]MLL Munich Leukemia Laboratory, [2]Institute of Pathology, Ludwig-Maximilians-University Munich, Munich, Germany

Background: Systemic mastocytosis (SM) is a rare disease and clinical presentation is highly variable from taking rather indolent to very aggressive courses, seldom even with the presentation of mast cell leukemia. CD30 (Ki-1 antigen) expression on neoplastic mast cells (MC) evaluated by immunohistochemical staining (IH) on bone marrow (BM) biopsies has been reported to be present in patients with more aggressive variants of MC. When assessed by multiparameter flow cytometry (MFC) it might also contribute to improved diagnostic accuracy. Only scarce data exists on correlation of CD30 expression detected by MFC with clinical SM parameters.
Aims: To compare CD30 expression on MC of patients with SM detected by either MFC or IH and to correlate results with patient characteristics and disease characteristics as well as with cytogenetics (CG) determined by chromosome banding analysis and with molecular genetics (MG).
Methods: We studied BM of 60 patients with SM by MFC. CD30 expression was quantified by a five color staining assay with monoclonal antibodies against CD30, CD45, CD117, CD2 and CD25. Aberrant MC were defined as CD117/CD45 positive cells with coexpression of CD2 and/or CD25. Mean fluorescence intensities (MFI) of CD30 were determined in MC and correlated to CD30 MFI in lymphocytes to derive CD30 index. For 22 patients data on MC infiltration and CD30 expression by IH was assessed while CG and MG were done in 29 and 50 patients, respectively. *KIT*D816V mutation was analyzed using melting curve-based RNA mutation analysis applying PNA clamping according to Sotlar *et al.* [Am J Pathol. 162: 737-746, 2003]. Expression of CD30 by MFC was correlated to results of CD30 expression by IH and results of CG and MG.
Results: 26 patients were male and 34 female. Median age was 61 years (20-81 years). Aberrant karyotypes were found in 3 patients while 26 had a normal karyotype. *KIT*D816V mutation was found in 46/50 patients. In 6/60 patients concurrent hematological non-mast cell disease (AHNMD) was diagnosed. Mean (±SD) MC infiltration was 20%±26% (range, 1.5%>85%) by IH and 0.5%±2.3% (range, 0.01%>17%) by MFC. Mean (±SD) CD30 index was 20.5±24.3 (range, 3-154), mean (±SD) CD30 expression by IH was 9%±17% (range, 0%>70%). Percentages of MC infiltration detected by IH and MFC correlated significantly (p=0.002, r=0.819). No correlation of MFC CD30 index with age, sex, concomitant AHNMD, grade of MC infiltration or percentage of CD30 positive MC by IH was found. Interestingly, we detected a trend to higher CD30 index in patients with *KIT*D816V mutation (21.0±26.4 *vs* 10.9±9.4, n.s.) and a trend to lower CD30 index in patients with abnormal karyotype (11.6±10.3 *vs* 13.8±8.5, n.s.).
Summary and Conclusions: CD30 expression on neoplastic MC in patients with SM is a dynamic parameter and can be assessed by MFC. CD30 expression may be stronger in patients harbouring *KIT*D816V mutations compared to those who do not. Patients with abnormal cytogenetics show a trend to lower CD30 expression on MC. The expression of CD30 on neoplastic MC in patients with SM should be further analyzed by MFC and IH in combination to substantiate the present findings.

E1322

INCIDENCE OF CALR MUTATIONS IN PATIENTS WITH CEREBRAL VENOUS THROMBOSIS WITHOUT OVERT CHRONIC MYELOPROLIFERATIVE NEOPLASM

E. Verger[1,*] I. Crassard[2], B. Cassinat[1], S. Bellucci[3]
[1]Cellular Biology Department, APHP St Louis, [2]Neurology Department, [3]Clinical Hematology Department, APHP Lariboisiere, Paris, France

Background: In Myeloproliferative neoplasms (MPN) including Essential Thrombocythemia (ET), Polycythemia Vera (PV) and Myelofibrosis thrombosis is the main cause of morbidity and mortality. Venous thromboses are observed in about 2 to 15 % of patients according to the MPN subtype. Venous thromboses at unusual sites are not exceptional and even typical of MPN as reported affecting the splanchnic territory in 5-10 % of the patients with PV or ET and the cerebral circulation reaching up to 1 % in ET. The JAK2V617F mutation is present in 95% of cases with PV and 60% of cases with ET or Myelofibrosis. With the discovery of this mutation, the diagnosis of MPN was greatly facilitated and it was shown that a MPN at an early stage or even at a latent stage may be responsible for the splanchnic thrombosis in a significant proportion of patients. By contrast, the JAK2V617F mutation was very rare in patients with cerebral venous thrombosis (CVT) and no patent signs of MPN, as we previously reported (Bellucci *et al.*, 2008) in a series of 87 patients. Recently, mutations in the *CALR* gene were reported in the majority of patients having MPN with non-mutated JAK2.
Aims: We looked for the presence of JAK2V617F and *CALR* mutations in patients with CVT and no hematological signs of patent MPN in order to see whether CVT may reveal MPN at a latent stage in a particular subgroup of patients.
Methods: From September 2007 to April 2014, 167 patients with CVT were included in our study: a patent MPN was carefully ruled out. Hematocrit was checked to be repeatedly below 52 % in men and 48 % in women and the platelet count to be repeatedly below 400G /L in order to rule out PV and ET respectively, according to the WHO classification. Diagnosis of CVT was based on magnetic resonance imaging (MRI) combined with MR venography and/or helical cerebral CT venography. We looked for the JAK2V617F mutation using an allele specific real-time PCR assay (Mutaquant®, Qiagen) and for the *CALR* mutations using PCR followed by fragment analysis, which also allowed to calculate the mutant allele burden.
Results: The JAK2V617F mutation was detected in 2 patients. In patient 1 (male, 56 years old) the allele burden was low at 0.5 %: an antiphospholipid syndrome was evidenced requiring antivitamin K therapy. After a follow-up of 32 months no MPN was detected. In patient 2 (female, 21 years old) the JAK2V617F mutation was also low at 3.2 %. CVT occurred concomitantly to oestroprogestative intake. Blood counts were still normal 10 months after the diagnosis of CVT. In 2 patients a type 1 *CALR* mutation (p.L367fs*46) was detected. Patient 3 (male, 47 years old) had a venous recurrent thromboembolic disease with a first deep venous thrombosis 2 years before the CVT and a recurrence 22 months later. Patient 4 (female, 19 years old) presented with CVT after oestroprogestative intake. The mutant *CALR* allele burden was low, at 10 and 12% in patient 3 and 4 respectively. No MPN and no thrombophilic abnormality were observed after a follow-up of 22 and 11 months in patient 3 and 4 respectively.
Summary and Conclusions: The incidence of the JAK2V617F and *CALR* mutations in patients with CVT without overt MPN was very low in this study. In this large cohort of 167 patients JAK2V617F mutation occurred in 2 patients (1.2%) and *CALR* mutations in 2 other patients. Interestingly all allele burdens were low suggesting that these patients may be at an early stage of the disease which may justify a prolonged follow-up. We do not recommend a systematic research of these mutations in such patients but it may be helpful in some particular cases with CVT without any etiology.

E1323

COMPARISON OF THREE DIAGNOSTIC METHODS TO DETECT CALRETICULIN MUTATIONS IN MYELOPROLIFERATIVE NEOPLASMS

F. Girodon[1,*] J.-H. Park[2], S. Ramla[2], D. Bouchot[2], M. Courtois[2], M. Bas[2], S. Benali[2], F. Bailly[2], B. Favre[2], J. Guy[2], L. Martin[3], M. Maynadié[1], S. Carillo[4]
[1]Laboratoire Hématologie, Plateau Technique Biologie, Dijon, [2]Laboratoire Hematologie, [3]service d'anatomopathologie, Plateau Techniqe de Biologie, Dijon Cedex, [4]laboratoire, CHU, Nimes, France

Background: Calreticulin (*CALR*) mutations have recently been reported in 70-84% *JAK2V617F*-negative myeloproliferative neoplasms (MPN), and this detection has become necessary to improve the diagnosis of MPN.
Aims: The aim of our study was to compare in parallel on a large cohort of ET patients three diagnostic methods [High Resolution Melting (HRM) analysis, product sizing analysis and Sanger sequencing] in the detection of *CALR* mutations.
Methods: Based on the 2008 WHO diagnostic criteria, a total of 298 ET patients from the hematology laboratory, University hospital in Dijon, France, were retrospectively studied.
Results: Altogether, a *JAK2V617F* or a *MPL* exon 10 mutation was observed in 179 (60%) and 13 (4.5%) patients, respectively. Finally 83 ET patients (33 males, 50 females) with a mean age of 63 y at the time of diagnosis (ranging from 20 to 95 years) diagnosed from 2005 to 2013 did not harbor any mutation and were considered as "double-negative" and thus tested using three molecular methods for a *CALR* mutation. Using the HRM method, a positive curve was noted in 54 patients, whereas no *CALR* mutation was observed in 28. Of note, in one patient there was no DNA amplification. Using the product sizing analysis, a *CALR* mutation was noted in 55 ET patients, and no mutation was

seen in 28. Finally, using Sanger sequencing, 50 ET patients harbored a *CALR* mutation, whereas no DNA amplification was noted in 4 samples. Taking altogether, a *CALR* mutation was noted in 56 patients and was of type 1 (leading to a deletion of 52 bp) or type 2 (leading to an insertion of 5 bp) in 28 (49%) and 20 (35%) patients, respectively. The 8 (16%) remaining mutations were 2 deletions of 46bp, 1 deletion of 1bp, 1 deletion of 2bp, 1 deletion of 25bp, 1 deletion of 33bp, 2 indel (1 insertion of 4bp and deletion of 2 bp and 1 insertion of 5bp and deletion of 1 bp). A false negative test was observed in 1, 2 and 2 in product sizing analysis, HRM method and Sanger sequencing, respectively. The 2 false negatives cases in HRM had either negative curves (patient #1) or curves with low amplitude (patient #2) contrary to the product sizing analysis that showed the presence of one (patient #1) or several mutant peaks (patient #2). Of note, in patient #2 the sequencing analysis showed a 25bp deletion associated with an intron mutation. The 2 false negative cases in sequencing analysis had both positive curves in HRM and mutant peaks in product sizing analysis however with low allelic burden (13% and 8% respectively). The false negative case in product sizing analysis had a deletion of 1bp that was not well separated from the wild type peak in product sizing analysis despite the HRM curves were positive and the sequencing analysis showed a deletion of 1 bp. The sensitivity for the HRM, the product sizing analysis and Sanger sequencing was 96.4%, 98.2% and 89.3% respectively, whereas the specificity was 96.3%, 100% and 100%. In our cohort, the product sizing analysis was the most sensitive method with an easy interpretation, while the HRM was sometimes difficult to interpret. On the other hand, when large series of samples were tested, HRM provided results in a short delay in comparison to the other methods that required more time. Finally the sequencing method, which is the reference method, had the lowest sensitivity but allowed to describe precisely the type of the mutations.

Summary and Conclusions: In routine laboratory activity, product sizing analysis and HRM are globally similar to detect the *CALR* mutations and may be used as first-line screening tests, followed by Sanger sequencing if positive to confirm and to determine the type of the mutations.

E1324

ALTERNATIVE SPLICING VARIANT COULD BE RESPONSIBLE OF MORGANA UNDER-EXPRESSION IN ACML

C. Panuzzo[1,*] G. Carrà[1], S. Crivellaro[2], R. Piazza[3], U. Familiari[2], S. Rocca[4], F. Fusella[4], G. Saglio[2], M. Brancaccio[4], A. Morotti[2]
[1]Clinical and Biological Sciences, [2]San Luigi Hospital, Turin, [3]Dep. of Health and Sciences, Monza, [4]University of Turin, Turin, Italy

Background: Morgana/chp-1 is a chaperone protein regulating ROCK activity and it is involved in centrosome duplication and tumorigenesis. Morgana +/- mice develop with age a fatal transplantable myeloproliferative disease similar to aCML, presenting centrosome amplification as well as cytogenetic abnormalities in bone marrow (BM). Notably, low morgana expression levels were found in the BM of aCML-affected patients and in a portion of CML Philadelphia positive patients. To assess whether morgana gene (CHORDC1) mutations can be responsible for low morgana expression levels in aCML patients we screened exome sequencing data obtained; no mutation were detectable suggesting that more complex regulatory mechanisms are involved in Morgana underexpression.
Aims: The aim of this study was to understand the mechanism responsible of Morgana reducted expression in aCML in order to identify a new pathway druggable to restore Morgana levels.
Methods: RNAs extracted from 9 primary aCML bone marrow samples collected at diagnosis after informed consent was reverse transcripted in c-DNA using random examers. The amplification products derived from Morgana gene were purified using Gel Extraction System and sequenced with ABI Prism 3100 Capillary Genetic Analyzer (Applied Biosystems). To evaluate the amount of the wild type and alternative transcript, we used two specific TAQMAN probes, one able to recognise only the wild type form and one other able to recognise both the transcripts. Protein analysis were performed by immunohistochemistry (IHC) experiments on formalin-fixed, paraffin-embedded bone marrows. Exome sequencing was used to extend to a larger portion of aCML patients and to analyze another pathology (AML) in order to verify the specificity of this inactivation.
Results: In addition to the main Morgana mRNA we found the co-existence of another transcript; direct sequencing of amplification products confirmed the presence of an alternative transcript (AS) which lacks the entire exon 3 of Morgana; this phenomenon produces a change on the correct reading frame and as consequence after 9 nucleotide the generation an earlier STOP codon. The product of this new transcript isn't a functional protein. Next we decide to quantify this alternative transcript by using one probe able to recognize both the transcripts and one probe spanning the exons 4 and 5 of Morgana and so able to recognize only the wild type form. We observed that unlike the group of healthy donors all the aCML where Morgana wild type is low have an high presence of alternative transcript. Surprisingly in the little percentage of aCML with normal Morgana level the alternative splicing is not significantly expressed. The generation of this AS colud be the mechanism responsible of Morgana down-expression in aCML; in fact all the patients with high alternative trascript shown very low level in Morgana protein, analysed by IHC. All these data where confirmed by exome sequencing, where the alternative transcript is observed on a large portion of aCML while in 10 AML tested it is not detectable, suggesting the specificity of this type of regulation in this myeloproliferative neoplasm
Summary and Conclusions: In this preliminary work, we identify one Morgana AS responsible of aCML reduced Morgana expression. This could be a consequence of mutations of those genes that are involved in the regulation of the spliceosome even in the absence of spliceosome gene mutations, alternative splicing of specific genes has also been reported with important biological consequences and potential therapeutic opportunity.

E1325

MUTATION ANALYSIS OF JAK2, MPL, CALR, ASXL1, TET2, IDH1, IDH2, DNMT3A, AND SF3B1 IN MYELOPROLIFERATIVE NEOPLASM

J.H. Kong[1,*] J. Kim[2], M.H. Chang[3], Y.-C. Mun[4], S.Y. Hyun[1], K.Y. Shim[1], J.I. Lee[1]
[1]Division of Hematology/Oncology, Department of Medicine, [2]Laboratory Medicine, Wonju Christian Hospital, Yonsei University College of Medicine, Wonju, [3]Division of Hematology/Oncology, Department of Medicine, National Health Insurance Service Ii San Hospital, Goyang-Si, [4]Division of Hematology/Oncology, Department of Medicine, Ewha Womans University School of Medicine, Seoul, Korea, Republic of

Background: Myeloproliferative neoplasms (MPNs) are blood diseases characterized by clonal hematopoiesis, chronic excessive production of differentiated blood cells and increased risk for thrombosis and secondary leukemic transformation, which included polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). JAK2 or MPL mutations are found in 50-70% of patients with PMF or ET, whereas calreticulin (CALR) mutations account for the majority of the remaining cases. However, MPN patients often showed different clinical phenotype despite having the same mutation, and other somatic mutations have been identified in some patients with MPN.
Aims: We evaluated incidence and clinical implication of several frequent mutations in Korean MPN patients, including *JAK2 V617F*, *JAK2* exon 12, *MPL, CALR*, *ASXL1*, *TET2*, *IDH1*, *IDH2*, *DNMT3A*, and *SF3B1*.
Methods: We enrolled 87 Philadelphia negative MPN patients whose archived peripheral blood or bone marrow sample collected at the time of diagnosis or first referral were available. Mutations were analyzed by direct sequencing and clinical data was collected retrospectively.
Results: We recruited 21 (25.8%) PV, 54 (59.6%) ET, and 12 (13.5%) PMF patients. *JAK2 V617F* was the most frequently detected mutation accounting for 69.0% (n=60) of MPN; 81.0% (n=17) of PV, 66.7% (n=36) of ET, and 58.6% (n=7) of PMF patients (Figure 1). *JAK2* exon12 mutation was detected in 1 PV patient. *CALR* mutations were found in 30.8% (n=8) of JAK2 mutation negative MPN. It was not observed in PV, but one ET patient had *CALR* and *JAK2 V617F* mutation concurrently. Mutations in *ASXL1, TET2*, *DNMT3A*, and *SF3B1* were also found in 9 (10.3%), 8 (9.2%), 4 (4.6%), and 1 (1.1%) MPN patients, respectively, and these mutations were found exclusively with *CALR* mutation. No *MPL, IDH1* nor *IDH2* mutation was detected in this cohort. *JAK2 V617F* mutation was associated with the absence of symptom, high leukocyte count, and low erythropoietin level with statistical significance. Patients with *CALR* mutation had lower leukocyte count and hemoglobin level, and higher platelet count than patients who had *JAK2 V617F* mutation only, or had neither *CALR* nor *JAK2 V617F* mutation. *JAK2 V617F* and *CALR* mutation did not affect overall survival significantly. But patients with *JAK2 V617F* mutation and without *CALR* mutation seemed to have worse survival than patients without *JAK2 V617F* mutation or with *CALR* mutation.

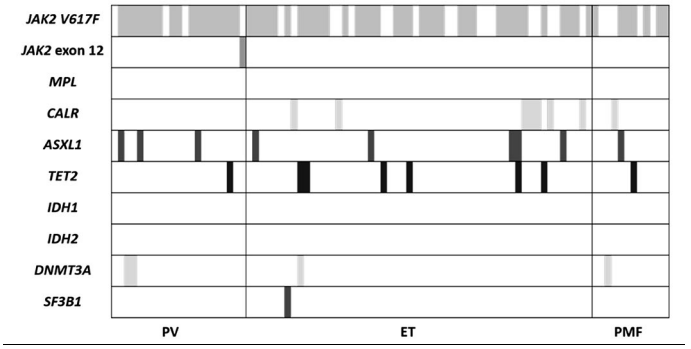

Figure 1. Mutational profile of 87 myeloproliferative disease.

Summary and Conclusions: It is first data of *JAK2 V617F*, *JAK2* exon 12, *MPL, CALR*, *ASXL1*, *TET2*, *IDH1*, *IDH2*, *DNMT3A*, and *SF3B1* mutation in Korean population. To validate of these clinical implication and prognostic value, extension of patient number and follow up period would be warranted.

E1326

MARKERS OF CLONAL HEMATOPOIESIS IN PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

L. Polushkina[1,*] I. Martynkevich[1], V. Shuvaev[1], E. Petrova[1], M. Fominykh[1], L. Martynenko[1], N. Cybakova[1], M. Petrova[1], E. Shabanova[1], I. Zotova[1], T. Zamotina[1], A. Zhernyakova[1], K. Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: In 2013 several researchers published data describing recurrent mutations-insertions and deletions-in 9th exon of *CALR* gene among patients (pts) with Philadelphia -negative myeloproliferative neoplasms (Ph(-)MPN). Mutations were not found in pts with polycythemia vera (PV). Frequency of *CALR* mutations in pts with essential thrombocythemia (ET) and primary myelofibrosis (PMF) is from 20 to 50%, respectively. Studies in mouse models showed JAK/STAT pathway activation in cells expressing mutated *CALR*. It has been observed that mutations in genes *CALR, JAK2, MPL* are mutually exclusive. Hence, mutations in 9th exon of *CALR* gene can be regarded as a new marker of clonal hematopoiesis like *JAK2* and *MPL* mutations. Recent retrospective studies have shown that *CALR*-ins/del burdening associated with milder disease and increased overall survival (OS) compared with cases *JAK2*(+) or *MPL*(+) Ph(-)MPN.
Aims: The goal of our study was to determine frequency of *JAK2, MPL, CALR* mutations in Ph(-)MPN pts and to analyze OS in groups with different clonal markers and triple-negative.
Methods: We examined 182 pts with Ph(-)MPN: 76 pts with PV, 63 pts with ET and 43 pts with PMF. The detection of V617F mutation of *JAK2* for each patient was done. *JAK2V617F*-negative pts with PV underwent the analysis of mutations in 12th exon of *JAK2* with direct sequencing. For *JAK2*V617F-negative pts with ET and PMF investigation of 9th exon of *CALR* was carried out through high resolution melting (HRM) followed by direct sequencing of mutated samples. *JAK2*(-) and *CALR*(-) samples were tested for *MPL 515* codon mutations with PCR-RFLP method. Karyotype research was done for patients with available bone marrow samples.
Results: *JAK2V617F* mutation was determined in 74/76 (97,3%) PV pts, in 26/63 (41,27%) ET pts and in 21/43 (48,83%) PMF pts. 2/76 (2,7%) pts with PV had mutations in 12th exon of *JAK2*. 515 codon mutations of *MPL* observed in 3/43 (6,97%) cases of PMF and in 3/63 (4,76%) cases of ET. Frequency of *CALR* mutations among pts with PMF and ET was 20,63% (13/63) and 13,95% (6/43), respectively. There was no reliable differences in OS in groups of pts with *JAK2*(+), *MPL*(+), *CALR*(+) and without mutations (p=0.127) (fig.1), but it should be mentioned that 4 of 6 pts, who died pts had unfavorable karyotype (+7, +8, del(5q), complex). It was not taken into account when determining OS. Interestingly, 3-year OS in *CALR*-mutated group was 100% while OS in *MPL*(+) and triple-negative group was 67% and 80%, respectively.

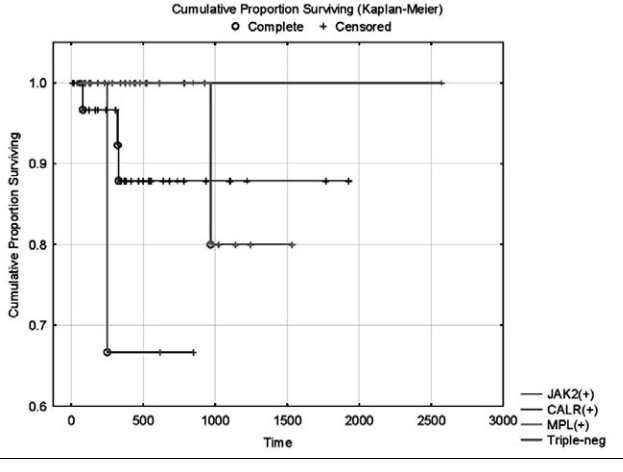

Figure 1.

Summary and Conclusions: *CALR* mutations are highly specific marker of clonal hematopoiesis along with *JAK2* and *MPL* mutations. However, genetic testing of clonal markers is insufficient. Only complex molecular genetic and cytogenetic analysis of tumor cells has crucial importance for diagnosis and prognosis of Ph(-)MPN.

Background: The past decade has witnessed a significant progress in the understanding of the molecular pathogenesis of myeloproliferative neoplasms (MPN). A large number of genes have now been implicated but their relative importance, interactions and implications for prognosis remain unknown.
Aims: The aim of this study was to use a panel of mutations shown to be associated with MPN to determine their relative importance and to identify driver mutations and novel variants to elucidate the pathogenesis and predict survival in patients with MPN in a multiracial country.
Methods: We performed targeted sequencing on normal controls and patients with MPN from 3 different races (Malay, Chinese and Indian) in Malaysia who were diagnosed with polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) according to the 2008 WHO diagnostic criteria for MPNs. Patients from 3 tertiary-level hospitals were recruited prospectively over 3 years and informed consents were obtained. DNA was extracted from peripheral blood myeloid cells at diagnosis and high-throughput sequenced using an Ion Torrent PGM and AmpliSeq targeting platform, with a panel of 26 MPN-related genes.
Results: 22 patients (9 PV, 8 ET, 5 PMF) and 3 normal controls were recruited into the study. 9 of 22 (40.9%) patients were Malay men and the median age of the study population was 58y (range 26-75y). 19 of 22 (86.4%) patients harbored the $JAK2^{V617F}$ mutation which was detected in 9 (100%) PV, 5 (62.5%) ET and 5 (100%) PMF patients; 7 of the 19 $JAK2^{V617F}$ positive patients (2 PV, 2 ET and 3 PMF) also harbored potentially pathogenic variants involving the *ASXL1, DNMT3A*, *TET2*, *U2AF1*, and *RUNX1* genes. 2 of the 3 $JAK2^{V617F}$ negative ET patients had *MPL* exon 10 and *TET2* mutations. Several novel variants involving the *DNMT3A, TET2, RUNX1, SH2B3* and *CHEK2* genes were identified in the study. The 3 PMF patients with $JAK2^{V617F}$ mutation in combination with *ASXL1, DNMT3A*, *TET2, U2AF1* and *RUNX1* variants presented with severe clinical phenotypes, with marked anaemia, elevated leucocyte counts, hyperferritinaemia, massive splenomegaly of >15cm, hepatomegaly and debilitating constitutional symptoms. DIPSS-plus score was intermediate-2 for 1 Chinese patient and high for 2 Malay patients who both died within 2 years from diagnosis. None of these 3 patients developed thrombosis. However, 5 patients (3 PV and 2 ET) in the study who developed thrombosis all had the $JAK2^{V617F}$ mutation only. 3 ET patients developed bleeding. 2 of these patients had $JAK2^{V617F}$ mutation alone and 1 patient had a combination of *MPL exon 10* and a *TET2* variant.
Summary and Conclusions: MPN in Malaysia is found predominantly in older Malay men with a higher incidence of $JAK2^{V617F}$ positivity in the different subtypes when compared to other studies. PMF patients who harbor the $JAK2^{V617F}$ in combination with *ASXL1, DNMT3A, TET2, U2AF1* and *RUNX1* putatively pathogenic variants are found to have more severe clinical phenotypes with very poor prognosis. Further studies are required to explore this finding and the novel variants found in this study further.

E1328

GATA-1, BUT NOT FOG-1, FLI-1 OR CALR, IS UP-REGULATED IN ESSENTIAL THROMBOCYTHEMIA INDEPENDENTLY FROM JAK2 AND CALR MUTATIONS

C. Graham[1], J. Lally[1], L. Brown[1], C. Rinaldi[1,*]
[1]Haematology, United Lincolnshire Hospital Trust and University of Lincoln, Lincoln, United Kingdom

Background: GATA-1 is the founding member of the GATA transcription factor family and it is essential for cell maturation and differentiation within the erythroid and megakaryocytic lineages. We and others have demonstrated that elevated GATA-1 expression is found in the bone marrow of Essential Thrombocythaemia (ET) patients, independent of JAK2V617F and CALR mutations. GATA-1 is able to coordinate lineage specification through its ability to bind both DNA and protein partners that include; Friend of GATA (FOG-1) and the Friend leukaemia integration 1 (FLI-1) transcription factors. FOG□1 is vital for megakaryocyte and erythroid□lineage commitment and its expression largely overlaps spatiotemporally with that of GATA-1. FLI-1 is an ETS family member that is expressed at high levels in megakaryocytic progenitors. In conjunction with GATA-1, FLI-1 targets those genes responsible for megakaryopoiesis. Calreticulin (CALR) is a calcium-binding protein involved in signaling and protein expression that is believed to be responsible for clearing misfolded proteins and involved in expression regulation. CALR mutations reported in myeloproliferative neoplasms create translation frameshifts in exon 9 which truncate the C-terminal calcium binding domain and create a novel C-terminal peptide. Initial

reports support CALR mutations as early and disease-initiating mutations that favor expansion of the megakaryocytic lineage. CALR mutations are mutually exclusive with JAK2 or MPL mutations.
Aims: We wanted to study the expression of GATA-1 in peripheral blood (PB) of patients with ET, together with FLI-1, FOG-1 and CALR, trying to identify if there is a common altered pathway and/or any correlation with JAK2 and CALR mutational status.
Methods: PB specimens were collected from 36 patients diagnosed with ET, 17 JAK2 mutated (47%), 4 CALR (11%) mutated, 1 MPL mutated (3%) and 14 with no molecular abnormalities, and compared with a cohort of healthy volunteers. Samples were enriched for the mononuclear fraction by Ficoll separation. Total RNA was extracted and analysed by Real Time PCR for GATA-1, FOG-1, FLI-1 and CALR expression relative to the housekeeping gene GAPDH using the $2^{-\Delta\Delta CT}$ method.
Results: We confirmed the data obtained in bone marrow demonstrating that GATA-1 is significantly up-regulated in ET patients also in PB and that GATA-1 overexpression is independent from JAK2V617F and CALR mutations. However, the transcription factors FOG-1 and FLI-1 do not appear to be subject to the same regulatory control in ET as that of GATA-1, remaining at the same level of expression as the controls. Interestingly we also found a significant downregulation in CALR mRNA comparing with controls and this is indipendent from CALR mutation as well.
Summary and Conclusions: These results suggest that GATA-1 is specifically deregulated in ET. GATA-1 overexpression is isolated and indipendent from its co-factor FOG-1 or FLI-1. Very interestingly CALR is downregulated in ET samples indipendently from CALR mutation or JAK2 matation, however more data are required to better understand the mechanisms of this deregulation.

PEGYLATED INTERFERON TREATMENT IMPROVES SURVIVAL IN POLYCYTHEMIA VERA PATIENTS: A SINGLE CENTER EXPERIENCE

E. Crisà[1,*] K. Garvey[1], G. Benevolo[2], C. Aguzzi[1], N. Barbara[2], A. Borchiellini[1], E. Beggiato[3], P. Manzini[4], P. Francia di Celle[5], L. Riera[5], U. Vitolo[2], M. Boccadoro[1], D. Ferrero[1]
[1]Hematology, University of Turin, [2]Hematology, A.O.U. Città della Salute e della Scienza, [3]Hematology, A.O. Ordine Mauriziano di Torino, [4]Laboratory Medicine, [5]Department of Molecular Biotechnology and Health Sciences, A.O.U. Città della Salute e della Scienza, Torino, Italy

Background: Polycythemia vera (PV) is a myeloproliferative disease with a reported median survival of 14-15 years (Tefferi *et al.*, 2014). The outcome is mainly affected by thrombo-embolic events and evolution to myelofibrosis (MF) and acute myeloid leukemia (AML).
Aims: The primary aim of the study was to evaluate the incidence of thrombosis, MF and AML according to prognostic factors and therapeutic strategies in a large series of PV patients. The secondary aim was to evaluate the outcome and the variation in JAK2 allele burden in the patients treated with pegylated interferon-alpha (peg-IFN-α).
Methods: Since 1995, 227 patients were consecutively diagnosed with PV at the "A.O.U. Città della Salute e della Scienza" hospital of Turin. Hydroxyurea (HU) was the first line treatment for the patients who required cytoreductive therapy. Since 2006, we treated with peg-IFN-α the younger patients (age<65 years) at high thrombotic risk or intolerant/resistant to phlebotomy. The use of alchilant agents was limited to the oldest patients who were refractory/resistant to HU.
Results: Median age at diagnosis was 66 years old and median follow-up was 8 years (13 to 244 months). Eleven% of patients presented with a thrombotic event at diagnosis and no correlation with the blood count was found. Sixty-nine% of patients were at high thrombotic risk for age or history of thrombosis, however only the 13.3% of the whole cohort had a major thrombotic event during follow-up. Major and minor thrombosis were statistically associated with age over 60 and thrombotic history (p=0.034) but not with other cardiovascular (CV) risk factors (hypertension, diabetes, smoking, hyperlipidemia) and the treatment. Overall survival (OS) was longer than what reported in other studies, with 90% and 58% of patients still alive at the median follow-up of 8 years and at the maximum follow-up of 17 years, respectively. Regarding treatment, 97% of patients received anti-platelet (89%) or anticoagulant agents (8%) and 86% of patients received cytoreductive therapy, 88% with HU. Twenty-four patients were treated with peg-IFN-α for at least 3 months (range 3-110) and their survival was longer than patients treated with HU (p=0.034) or with alkylating agents (p=0.0023) (100% alive at the last follow-up). Even if peg-IFN-α was available only from 2006, patients treated with peg-IFN-α had a median follow-up from diagnosis similar to patients treated with HU (86 *vs* 97 months). Of note, median age at diagnosis in the peg-IFN-α group was 53 and only 11% of the patients had previous thrombosis. However, at multivariate analysis the treatment with peg-IFN-alfa was confirmed to positively impact on survival, regardless of the age and the thrombotic history. Moreover, a reduction of JAK2 quantitative burden was observed in 58% of the patients treated with peg-IFN-α, an encouraging data considering that the median treatment duration was still relatively short (median 26 months). Overall peg-IFN-alfa was fairly tolerated, with a discontinuation rate of 25%, as described in other studies (Quintas-Cardama *et al.*, 2006). Fifteen% of patients developed MF, a slightly higher percentage than what reported by Tefferi *et al.* in 2014, but in line with data previously published (Cervantes *et al.*, 2008). The median MF-free survival was 17,8 years. AML evolution occurred in 5.7% of patients only.
Summary and Conclusions: Our study confirmed some known prognostic factors for thrombotic occurrence (age and thrombotic history) but no other CV risk factors, probably due to the positive role of the anti-platelet therapy.
Peg-IFN-α is a promising therapy in PV, not only to control symptoms, but also in a quantitative reduction of JAK2 mutation and OS improvement.

E1330

TERT RS2736100_C POLYMORPHISM AS PREDISPOSITION FACTOR FOR MYELOPROLIFERATIVE NEOPLASMS

K.P. Kiss[1,*] T. Krahling[1], K. Balassa[1], N. Meggyesi[1], A. Bors[1], J. Csomor[2], A. Batai[2], G. Halm[2], M. Egyed[3], S. Fekete[2], P. Remenyi[2], T. Masszi[2], A. Tordai[1], H. Andrikovics[1]
[1]Hungarian National Blood Transfusion Service, [2]St. Istvan and St. Laszlo Hospital, Budapest, [3]Kaposi Mor Hospital, Kaposvar, Hungary

Background: The TERT rs2736100 single nucleotide polymorphism was found to be a susceptibility factor for a variety of cancers (lung, glioma, bladder), and recently for sporadic and familial myeloproliferative neoplasms.
Aims: The aim of our study was to investigate the role of TERT rs2736100 and JAK2 rs12343867 polymorphisms in a large cohort of Hungarian MPN

patients regarding their frequency and their effect on clinical characteristics.
Methods: LightCycler melting analysis was applied to identify the risk allele of TERT rs2736100_C and JAK2 rs12343867_C tagging 46/1 haplotype, in 209 polycythemia vera (JAK2 V617F positive PV), 281 essential thrombocytosis (ET), 94 primary myelofibrosis (PMF) patients and 400 healthy individuals.
Results: In the ET cohort 148 (53%) JAK2 V617F, 95 (34%) CALR and 9 (3%) MPL gene mutation positive and 29 (10%) triple negative cases; while in the PMF cohort 51 (54%) JAK2 V617F, 25 (27%) CALR and 7 (7%) MPL gene mutation positive and 11 (12%) triple negative cases were identified. Both genetic variants showed increased allele frequencies in MPN patients compared to controls (TERT rs2736100: 62.7±2.8% *vs* 48.8±3.5%, p<0.0001; OR [±95%CI]: 1.7 [1.5-2.1]; JAK2 rs1234386: 45.7±2.9% *vs* 29.8±3.2%, p<0.0001; OR [±95%CI]: 2.0 [1.6-2.4]. Beside the allelic model, the difference remained significant in all tested models (dominant, recessive, genotypic). Carriership of the TERT rs2736100_C allele (dominant model) increased MPN susceptibility equally in JAK2 V617F or CALR positive MPN patients (OR=2.8 [1.9-4.1] in JAK2 V617F positive, OR=2.3 [1.3-4.1] in CALR positive groups, p=0.5 for JAK2 V617F *vs* CALR positive groups comparison) as well as in PV, ET or PMF subgroups. In contrast, the effect of the JAK2 rs12343867_C allele was more pronounced in the JAK2 V617F positive group (OR=3.5 [2.6-4.8] in JAK2 positive, OR=1.6 [1.0-2.4] in the CALR positive groups, p=0<0.001 for JAK2 V617F *vs* CALR positive groups comparison). Combined hetero- or homozigosity conferred even higher risk for MPN (combined heterozigosity: OR: 6.0 [3.4-10.4], combined homozigosity: OR: 9.6 [4.4-21.1]). In the whole MPN cohort, TERT rs2736100_C carriers displayed higher white blood cell count (9 *vs* 11 G/L, p=0.019) compared to homozygous AA patients. The frequency of different complications (splenomegaly, venous and arterial thrombosis, myelofibrotic or leukemic transformation) were not associated with the investigated TERT polymorphism either alone or in combination with the JAK2 haplotype.
Summary and Conclusions: In the present study, in an independent large cohort, we confirmed that, TERT rs2736100_C polymorphism predisposes to the development of MPN regardless of the molecular background or disease type.

E1331

PATIENT SELF-CARE INTERVENTIONS: DO THEY IMPACT MPN-RELATED FATIGUE?

R. Scherber[1,*] S. Zhenya[2], H. Geyer[1], A. Dueck[3], M. Clark[4], M. Goldstein[5], H. Kosiorek[6], M. Boxer[7], A. McCallister[8], M. Cotter[2], B. VanHusen[9], C. Harrison[10], R. Mesa[11]
[1]Internal Medicine, Mayo Clinic, Scottsdale, [2]MPN Forum, Ashville, [3]Biostatistics, Mayo Clinic, Scottsdale, [4]Division of Psychology, Mayo Clinic, Rochester, [5]Psychiatry & Human Behavior, Brown University, Providence, [6]Section of Biostatistics, Mayo Clinic, [7]Arizona Oncology, Scottsdale, [8]MPN Forum, Providence, [9]MPN Research Foundation, Chicago, United States, [10]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [11]Hematology and Oncology, Mayo Clinic, Scottsdale, United States

Background: The Philadelphia chromosome negative myeloproliferative neoplasms include essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF). Fatigue is a prominent feature of these disease subtypes which leads to reduced quality of life and impaired daily functioning. We have previously evaluated the results of our initial phase I project evaluating fatigue among MPN patients (Emanuel et. al. Blood 2013;a1595). Among the 879 online respondents, patients most often employed exercise, diet, social interaction, nutrition, rest, and relaxation techniques to reduce their fatigue. Despite our previous efforts, little is known to date about the degree of relief obtained from these specific fatigue-alleviating strategies.
Aims: The aim of this study is to evaluate fatigue-alleviating strategies in MRF.
Methods: A 70-item internet-based survey was developed and hosted by the Mayo Clinic Survey Research Center. The survey was promoted online via multiple MPN-related webpages including the *MPN Forum*, *MPN Net*, *MPN Research Foundation*, and *MPN Voice* during late February to March of 2014. The MPN-SAF including the 10-item Brief Fatigue Inventory (BFI) was used to assess disease burden (Blood. 2011 Jul 14;118(2):401-8). Fatigue was characterized using a set of questions to evaluate timing, frequency, duration, triggers, and impact on daily activities. Patients were queried as to whether they had utilized individual interventions to alleviate fatigue and were asked to rate the success of each intervention on a 1 (not at all successful) to 5 (very successful) scale.
Results: Fatigue was prevalent and severe among survey respondents (BFI 24-hour worst fatigue item: score ≥1 95.3%, mean score 6.2 (SD=2.7)). Average BFI score was 4.4 (SD=2.4). In selecting one or more times of day when fatigue is most noticed, patients most often noticed their fatigue in the evening (44.0%) or afternoon (42.4%), compared to the morning (17.7%) or continuously throughout the day (23.4%). Fatigue triggers included physical work (58.8%), stress (48.5%), exercise (41.6%), medications (25.2%), intellectual work (24.3%), eating (16.9%) and sexual activity (6.6%). Approximately half of patients felt that their fatigue was "about the same" over the last 6 months (48.7%). However, large portion of patients felt that their fatigue had worsened (40.7%), with only a minority of patients feeling that their fatigue had improved (10.7%). Fatigue affected aspirations (64.5%), travel (61.0%), long term planning (58.3%), and vacation planning (57.2%). Most patients felt that fatigue limited their normal daily activities (69.1%). Numerous self-care strategies were implemented in order to reduce fatigue, including setting priorities, postponing essential activities, exercise, and naps. Of these interventions, patients most often felt that scheduling activities during peak energy times, pacing activities, labor saving devices, and setting priorities were most efficacious in reducing their fatigue (greater than 70% of patient attempting these strategies felt them to be "very" or "somewhat" successful). Moderate/severe fatigue (categorized as BFI score ≥4) was present more frequently in those who did not exercise as compared to those who reported exercising at least once per week [188/248 (75.8%) *vs* 671/1181 (56.8%); p<0.001]. BFI score as compared to exercise frequency per week is displayed in Figure 1. Exercise appears to have a dose impact, as each level of physical activity is associated with lower fatigue. All interventions except exercise and volunteer activities were attempted by a significantly higher proportion of patients with moderate/severe fatigue than those with none/mild fatigue level.

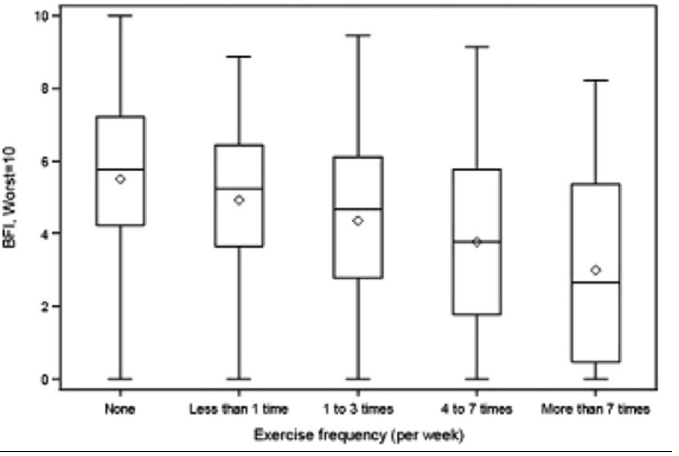

Figure 1. Box plot for BFI score by exercise frequency.

Summary and Conclusions: Overall patients with MPNs experience disabling fatigue that greatly lowers their quality of life. This is the first published summary evaluating the effectiveness of non-pharmacologic interventions utilized to alleviate fatigue among MPN patients. The unique role of exercise in alleviating MPN related fatigue needs further prospective investigation. We plan to use the results of this survey to inform an at-home interventional trial to investigate the impact of a variety of fatigue reduction techniques.

Cuore, Roma, [10]Division of Hematology, Hematology unit Frosinone, Frosinone, [11]Allergy Unit, Azienda Ospedaliera Universitaria Integrata of Verona, Verona, [12]Department of Experimental and Clinical Medicine, University of Florence, Firenze, Italy

Background: According to the World Health Organization (WHO) classification, the diagnosis of Systemic Mastocytosis (SM) relies on bone marrow (BM) examination and is based on a major and four minor criteria. The somatic 'autoactivating' point mutation D816V in the KIT receptor gene is one of the minor criteria, founded in the great majority of patients (90%) and it plays a central role

in the pathogenesis of the disease. Indolent Systemic Mastocytosis (ISM) is the most common variant of SM, characterized by a very low MC burden and associated with very different clinical pictures. A highly sensitive diagnostic methods for D816V detection are required to assure an appropriate diagnosis and to reduce false-negative results. The recent development of "ultra-deep amplicon sequencing" (UDS) technologies has opened the way to a more accurate characterization of molecular aberrations with higher sensitivity of screening for known and unknown mutations.

Aims: Our aims were: i) to set-up and optimize a UDS-based mutation screening strategy of the KIT gene on the Roche GS Junior Instrument; ii) to test the sensitivity of our UDS assay to detect the D816V mutation; iii) to investigate the presence of additional KIT mutations in SM.

Methods: We decided to take advantage of a next generation sequencing approach to perform an UDS KIT gene mutation analysis on 24 bone marrow (BM) samples from patients whit ISM that were negative for the D816V mutation by Sanger Sequencing which has a sensitivity of 20%. Fusion primers were designed to generate ten partially overlapping amplicon covering the whole KIT transcript (exons 1-21) by RT-PCR. To determine the lower detection limit of our UDS-assay, serial dilutions of the HMC-1 cell line (harboring the D816V mutation) into an unmutated K562 cell line in ratios such as to simulate the following mutation loads were sequenced: 50%, 37.5%, 25%, 12.5%, 5%; 2.5%, 1.25%, 0.5%, 0.25%.

Results: UDS of cell line dilutions showed a high accuracy of D816V mutation detection and linearity of mutation calling over the entire range down to 0.25%. The UDS technology allowed to detected the D816V mutation, below the lower detection limit of Sanger Sequencing, with an abundance from 0.5% to 11%, in 15/24 ISM patients. Two additional sequence variations were detected in a large proportion of patients. These two variations included a 3bp in-frame deletion in exon 15 (GenBankx06182.1: c.2164_2166delAGC; p.S715del) found in 12/24 patients and a 12bp in frame-deletion in exon 9 in all patients, whit an abundance ranging from 83% to 97% (GenBankx06182.1: c.1550_1561delGTAACAACAAAG; p.G510_K513del). Previously published studies indicate that the KIT Gly-Asn-Asn-Lys$^{510\text{-}513+/-}$ alternatively spliced located immediately downstream to the extracellular KIT domain and KIT Ser$^{715+/-}$, an interkinase KIT domain, are expressed in normal human hematopoietic cell, leukemic cell lines, acute myeloid leukemia blast and GISTs and represent rather a splice variant of KIT transcript. Interestingly our results showed the presence of the transmembrane domain M541L (GenBankx06182.1: c.1642A>C; p.Met541Leu) KIT-activating mutation in exon 10, with an abundance of 50%, in addition to D816V, in 3/24 ISM. This mutation is known to retain sensitivity to imatinib mesylate (Figure 1).

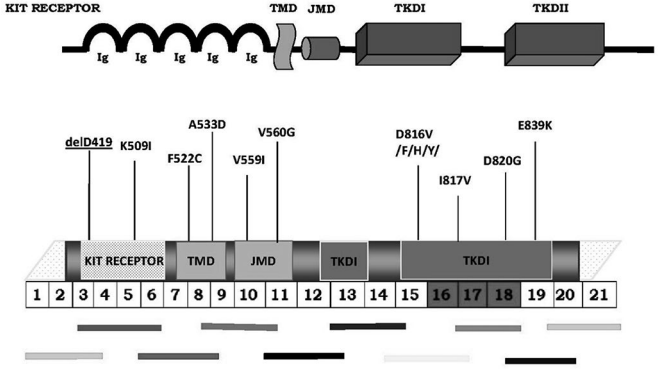

Figure 1.

Summary and Conclusions: Our preliminary results suggest that our-UDS based KIT gene mutation screening assay might be a reliable and sensitive alternative to conventional sequencing methods for the detection of the D816V. We are now planning to investigate whether the greater sensitivity of UDS allows to detect the D816V mutation in peripheral blood mononuclear cells from patients with a suspected clonal mast cell disorder. These results could represent a starting point to plan other extensive studies to better understand the exact role of KIT receptor alterations in SM. Supported by ELN, AIL, AIRC, PRIN, progetto Regione-Università 2010-12 (L. Bolondi), FP7 NGS-PTL project.

RUXOLITINIB *VS* BEST AVAILABLE THERAPY IN PATIENTS WITH POLYCYTHEMIA VERA TREATED IN THE RESPONSE STUDY: A SUBGROUP ANALYSIS OF HYDROXYUREA- AND NON-HYDROXYUREA-TREATED PATIENTS

F. Passamonti[1,*] C.N. Harrison[2], F. Pane[3], P. Zachee[4], J.-J. Kiladjian[5], A.M. Vannucchi[6], M.M. Jones[7], S. He[7], J. Li[8], M. Khan[8], D. Habr[8], S. Verstovsek[9]

[1]Ospedale di Circolo e Fondazione Macchi, Varese, Italy, [2]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [3]University of Naples Federico II, Naples, Italy, [4]ZNA Stuivenberg, Antwerp, Belgium, [5]Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [6]University of Florence, Florence, Italy, [7]Incyte Corporation, Wilmington, [8]Novartis Pharmaceuticals Corporation, East Hanover, [9]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Ruxolitinib (RUX) is a JAK1/JAK2 inhibitor that proved superior to best available therapy (BAT) in controlling hematocrit (HCT) and improving splenomegaly and symptoms in patients (pts) with polycythemia vera (PV) treated in the RESPONSE study. Because RESPONSE enrolled pts who had an inadequate response to or unacceptable side effects with hydroxyurea (HU), we performed a subgroup analysis to explore the efficacy of non-HU treatment options in the BAT arm.

Aims: An exploratory analysis to compare key efficacy parameters of RUX with HU and non-HU BAT in pts with PV who were resistant to or intolerant of HU by modified ELN criteria.

Methods: RESPONSE is an open-label phase 3 study; pts with splenomegaly (≥450 cm^3 by MRI) who had HU-resistant disease or HU intolerance by modified ELN criteria were randomized 1:1 to RUX 10 mg bid or BAT. BAT included single-agent HU, interferon, anagrelide, immunomodulators, pipobroman, or no medication. HU was chosen based on the treating investigators' judgment that these patients could derive some benefit in the absence of more suitable alternative treatments. All pts received low-dose daily aspirin. The primary composite endpoint was the proportion of pts who achieved both HCT control without phlebotomy (PBT) from wk 8 to 32 (with ≤1 PBT postrandomization and prior to wk 8) and a ≥35% reduction in spleen volume from baseline at wk 32 by MRI. The proportion of pts who achieved a complete hematologic response (CHR) at wk 32 was a key secondary endpoint. Symptoms were assessed using the Myeloproliferative Neoplasm Symptom Assessment Form (MPN-SAF). Pts in the BAT arm could cross over to RUX starting at wk 32 if they had disease progression or did not achieve the primary endpoint. The primary analysis occurred when all pts reached wk 48 or discontinued.

Results: Overall, 110 pts were randomized to RUX and 112 to BAT. In the BAT arm, 66 pts received HU as their initial treatment, and 45 pts received non-HU treatment as their initial BAT (interferon, n=13; anagrelide, n=8; immunomodulators, n=5; pipobroman, n=2; no medication, n=17); 1 BAT pt did not receive study drug and was excluded from this analysis. Six pts changed BAT. Non-HU treatment pts were pooled for analysis because few pts received any individual treatment option as their initial BAT. Demographic characteristics were generally well balanced across groups. The primary composite endpoint was achieved in 1.5% of HU and 21% of RUX pts; no non-HU BAT pts achieved a primary response. Larger proportions of pts receiving RUX achieved spleen volume reductions, HCT control, CHR, and symptom responses than pts receiving HU- or non-HU BAT (Table 1). The proportion of pts who had PBT from wk 8 to 32 was substantially lower in the RUX arm than among pts receiving HU or non-HU treatments in the BAT arm.

Table 1. Efficacy in patients who received RUX, BAT, HU BAT, and non-UH BAT.

n (%)	RUX (n=110)	BAT[a] (n=112)	HU BAT (n=66)	Non-HU BAT (n=45)
Primary response at week 32	23 (21)	1 (1)	1 (2)	0
Spleen volume reduction ≥35%	42 (38)	1 (1)	1 (2)	0
HCT control	66 (60)	22 (20)	15 (23)	7 (16)
CHR at week 32	26 (24)	10 (9)	7 (11)	3 (7)
Phlebotomies from week 8 to 32	(n=106)	(n=109)	(n=65)	(n=44)
≥1	21 (20)	68 (62)	41 (63)	27 (61)
≥3	3 (3)	22 (20)	10 (15)	12 (27)
Symptom response[b]	(n=74)	(n=81)	(n=49)	(n=32)
≥50% reduction in MPN-SAF total symptom score at week 32	36 (49)	4 (5)	2 (4)	2 (6)

[a] 1 patient was randomized but did not receive study drug.
[b] In patients with scores at both baseline and week 32.

Summary and Conclusions: In the phase 3 RESPONSE study in pts with PV who had an inadequate response to or unacceptable side effects from HU, RUX treatment is effective in controlling HCT without PBT, decreasing spleen volume, and improving PV-related symptoms when compared with HU and non-HU standard treatment options.

E1335

RISK OF PREGNANCY COMPLICATIONS AND EFFECT OF DIFFERENT TREATMENTS IN WOMEN WITH ESSENTIAL THROMBOCYTHEMIA: A RETROSPECTIVE MONOCENTER ANALYSIS OF 62 PREGNANCIES.

S. Betti[1,*] E. Rossi[1], T. Za[1], A. Ciminello[1], F. Bartolomei[1], P. Chiusolo[1], V. De Stefano[1]

[1]Institute of Hematology, Catholic University, Roma, Italy

Background: A high rate of obstetric complications occurs in women with

essential thrombocythemia (ET), with a consistent high risk of early fetal loss and a probability of live births around 60%. A variety of therapeutic strategies has been proposed, with a risk-driven intensity of treatment. The role of the JAK2 V617 mutation as predictor of pregnancy complications and possible therapeutic driver is controversial.

Aims: To assess in a retrospective cohort of ET patients the JAK2 V617F-related risk of pregnancy complications and the efficacy of different treatments during antepartum and postpartum periods.

Methods: We analysed 62 pregnancies occurred in 38 women with ET (median 2 pregnancies per woman, range 1-3) during the years 2001-2014. The median age of the patients at diagnosis was 29 years (range 18-41); the age at conception was >35 years in 33 pregnancies (53%). Nineteen women (50%) carried the JAK2V617F mutation. Two of them had hepatic vein thrombosis and TIA before first conception, respectively. One terminated pregnancy, one blighted ovum and one miscarriage due to Turner syndrome were excluded from further analysis. Antepartum treatment consisted of low molecular weight (LMWH)+aspirin (ASA) in 32 pregnancies, ASA in 14, LMWH in 6; seven pregnancies were left untreated. Interferon was administered during 9 pregnancies. The impact of different antepartum therapeutic strategies was estimated by a multivariate proportional hazards regression model over the weeks of gestation. Puerperium periods were defined as 6 weeks after delivery at ≥20 week of gestation and were treated with LMWH in 45 of 51 cases.

Results: Among the evaluable pregnancies the rate of live births was 83% (49/59); miscarriage occurred in 8, stillbirth in 2, abruptio placentae with neonatal death in 1, intrauterine fetal growth retardation in 6. Overall, 17 obstetric complications (OC) were considered ET-related (17/59, 29%) and occurred in 7 cases during LMWH+ASA (22%), in 2 during ASA (14%), 3 during LMWH (50%), and 5 in the untreated pregnancies (71%). No thrombosis complicated antepartum-periods. Antithrombotic treatment reduced by 88% the risk of OC in comparison *versus* untreated pregnancies (odds ratio, OR 0.12, 95%CI 0.02-0.69). The rate of OC was 43% in pregnancies of JAK2 V617F-positive women (13/30) and 14% in the pregnancies of the JAK2 V617F-negative women (4/29) (OR 4.77, 95%CI 1.33-17.18); however after exclusion of the untreated pregnancies the risk associated with the JAK2 V617F mutation was no more significant (OR 3.33, 95%CI 0.85-13.00). A multivariate proportional hazards regression model including age >35 yrs, JAK2 V617F mutation, and antepartum ASA, LMWH, and interferon, retained only ASA as a variable associated with the outcome (OR for complications 0.28, 95%CI 0.10-0.80, p=0.01). Among the 6 untreated puerperium periods, one was complicated by cerebral vein thrombosis (17%), whereas no thrombosis occurred during the remaining puerperium periods treated with LMWH.

Summary and Conclusions: In ET patients JAK2 V617F is associated with an increased risk of OC, which was prevented by treatment; namely, in this cohort antepartum ASA was highly effective in preventing ET-related OC; therefore, LMWH should be reserved only to women with additional risk factors for venous thromboembolism independent of ET. The rate of puerperium-related venous thrombosis is high and prompts LMWH prophylaxis.

E1336

ANALYSIS OF PHENOTYPE AND OUTCOME IN ESSENTIAL THROMBOCYTHEMIA WITH CALR AND JAK2 MUTATIONS

C. Al Assaf[1,*] F. Van Obbergh[1], J. Billiet[2], E. Lierman[1], T. Devos[3], C. Graux[4], A.-S. Hervent[2], T. Tousseyn[5], P. De Paepe[6], P. Papadopolous[1], L. Michaux[1], P. Vandenberghe[1]

[1]Center for Human Genetics, KU Leuven and University Hospitals Leuven, Leuven, [2]Laboratory of Hematology, AZ Sint-Jan, Brugge, [3]Department of Hematology, University Hospitals Leuven, Leuven, [4]Department of Hematology, Mont-Godinne University Hospital, Yvoir, [5]Department of Pathology, University Hospitals Leuven, Leuven, [6]Department of Pathology, AZ Sint-Jan, Brugge, Belgium

Background: The *JAK2* V617F mutation, the thrombopoietin receptor mutation *MPL* W515K/L and the Calreticulin (*CALR*) mutations are mutually exclusive in essential thrombocythemia (ET) and support a novel molecular categorization of ET. The most recently discovered *CALR* mutations account for up to 30% of ET cases.

Aims: In a retrospective study, we have examined the clinical phenotype and outcome in a Belgian cohort of 165 ET patients in relation to their mutational status.

Methods: A cohort of 107 *JAK2* V617F negative ET cases diagnosed at several Belgian hospitals was collected and analyzed for *CALR* and *MPL* mutations. We also collected a control cohort of 58 *JAK2* V617F positive ET diagnosed in the University Hospitals Leuven and sequenced for *CALR* mutations. The median follow-up of the whole cohort of 165 patients was 8 years with a range of 1-34 years.

Results: 62 (65.3%) *JAK2* V617F/*MPL* W515K/L negative patients were carrying an indel in *CALR*, including 37 cases (59.6%) of Type 1 (c.1092_1143del) and 19 cases (30.6%) of Type 2 (c.1154_1155insTTGTC) indels. We have also identified one ET patient positive for both *CALR* and *JAK2* V617F mutations. We compared the hematological and clinical features between *CALR* +ve patients and *JAK2* V617F +ve patients. This revealed that *CALR* mutations are associated with younger age, male gender, higher platelet counts, lower leukocyte counts, lower erythrocyte counts, hemoglobin and hematocrit ratio. Dividing the *CALR* +ve group into Type 1 and Type 2 showed that *CALR* Type 1 was associated with male gender and higher platelets compared to *JAK2* V617F +ve patients. *CALR* mutant patients had a better overall survival than the *JAK2* V617F positive patients. However, in the group of patients ≤60 years old *CALR* +ve group had a better overall survival over *JAK2* V617F +ve group. Nonetheless, the group of patients older than 60 years showed no difference in the overall survival between the *CALR* +ve group and the *JAK2* V617F +ve group. In our cohort, *CALR* +ve patients present a higher risk of progressing to MF, but no difference in myelofibrosis-free survival or leukemia-free survival was found (Figure 1).

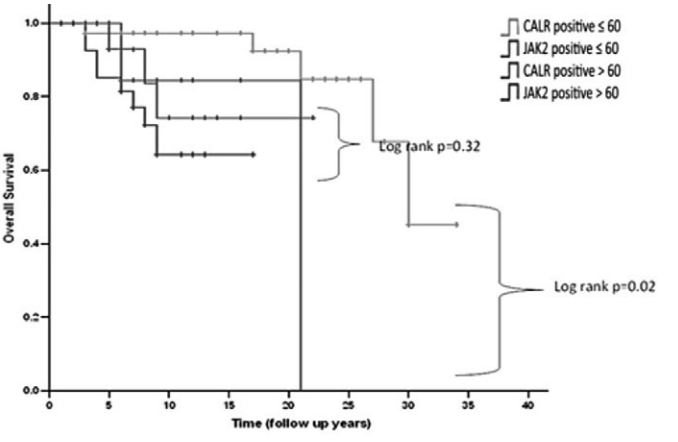

Figure 1.

Summary and Conclusions: Our study confirms that *CALR* +ve ET is phenotypically distinct from *JAK2* V617F +ve ET, with differences in the clinical presentation and the disease course. *CALR* was also associated with better overall survival, restricted to ET patients less than 60 years old. Our study extends the growing body of evidence that *CALR* mutated ET has a distinct phenotypic and hematological profile compared to the *JAK2* V617F +ve group and corroborates the observations from other similar studies.

E1337

MUTATIONAL STATUS AND CARDIOVASCULAR COMPLICATIONS IN PATIENTS WITH STRICTLY WHO 2008-DIAGNOSED ESSENTIAL THROMBOCYTHEMIA: A MONOCENTRIC STUDY

I. Bertozzi[1,*] E. Peroni[1], G. Bogoni[1], G. Coltro[1], F. Fabris[1], M.L. Randi[1]

[1]Dep. Internal Medicine-DIMED, University of Padova, padova, Italy

Background: Patients with essential thrombocythemia (ET) may carry JAK2, MPL, or a calreticulin gene (CALR) mutation. The somatic mutations in CALR are mutually exclusive with JAK2 and MPL mutations and is the second most mutated gene in ET. Mutant CALR is a result of frameshift mutations, caused by exon 9 deletions (type-1) or insertions (type 2). About 10% of ET patients are still now triple negative (3NEG) for these mutations.

Aims: In the current study, we looked for phenotypic or prognostic differences between ET patients stratified on the basis of their mutational status, the IPSET-thrombosis (IPSET-T) score.

Methods: The study involved 183 patients (median follow-up 10.3 years [range 0.2-31]) with a diagnosis of ET strictly fulfilling the 2008 WHO criteria. All these patients are regularly followed twice a year at our Department. The study was approved by the institutional Ethics Committee of Padua Hospital. In agreement with the IPSET-T score, we assessed our patients' thrombotic risk based on: patient's age at diagnosis; cardiovascular (CV) risk factors; prothrombotic conditions and mutational status. Real-time quantitative PCR for JAK2 and direct sequencing for MPL and CALR mutations were used. Cox proportional hazard regression model was used for multivariable analysis. MPL-mutated patients were not considered in the statistical analysis.

Results: Patients stratified by molecular status, IPSET-T score and cardiovascular events during follow-up are summarized in Table 1. The rate of thrombosis during follow-up was 0.5% pats/year for low-risk patients, 2.3% for intermediate-risk cases, and 5.1% for the high-risk group. After stratifying patients by mutational status, the thrombosis rate was 4.2%, 1.6% and 0.7% patients/year, respectively, for JAK2V67F, CALR (1.6% pats/y for CALR-1 and 1.5% pats/y for CALR-2) and 3NEG patients. In multivariable analysis adjusted for sex and age at diagnosis the presence of JAK2V617F mutation maintains a negative prognostic impact in predicting thrombosis both when compared with CALR mutations (HR 2.6; 95% CI 1.2-5.5; p=0.013) and when compared with triple negative (HR 5.3; 95% CI 1.3-22.5; p=0.022); no differences were demonstrated comparing CALR and 3NEG patients. The patients distribution in agreement with IPSET-t score was similar in CALR type 1, type

2 and 3NEG patients. Hemorrhages occurrence was similar in all mutational groups.

	JAK2	*MPL*	*CALR type 1*	*CALR type 2*	3NEG
N (%)	114 (62.3%)	3 (1.6%)	25 (13.6%)	19 (10.4%)	22 (12%)
Mean age at diagnosis (y)	53.9 ± 16.1	62.6 ± 6.3	50.8 ± 16.2	51.4±14.9	41.2 ± 16.2
Mean WBC at diagnosis (x10^9/L)	8.7 ± 2.4	7.3 ± 0.1	7.7 ± 2.1	7.5 ± 4.1	7.9 ± 2.9
Mean hemoglobin at diagnosis (g/L)	140 ± 15	135 ± 11	130 ± 13	133 ± 13	133 ± 14
Mean platelets at diagnosis (x10^9/L)	706 ± 226	726 ± 234	830 ± 205	963 ± 474	751 ± 236
IPSET-T score					
low-risk	0 (0%)	1 (33.3%)	18 (72%)	17 (89%)	18 (81%)
intermediate risk	26 (22.8%)	1 (33.3%)	3 (12%)	2 (22%)	3 (13.6%)
high risk	88 (77.2%)	1 (33.3%)	4 (16%)	0 (0%)	1 (4.5%)
Patients with at least a thrombotic event (%)	47 (41.2%)	1 (33.3%)	5 (20%)	3 (15.8%)	2 (0.9%)
Patients with at least a bleeding event (%)	21 (18.4%)	0 (0%)	6 (24%)	4 (21.1%)	3 (13.6%)

Table 1.

Summary and Conclusions: It is known that ET patients carrying JAK2 mutation have a higher thrombotic risk compared to other ET having higher hemoglobin and WBC counts. CALR mutated patients, in contrast, are associated with higher platelet and lower hemoglobin and WBC counts. In our cohort, *CALR* mutations as well as the absence of any known mutation (3NEG) segregate with factors associated with a lower thrombotic risk. Interestingly, all CALR type 2 and 84% of CALR type 1 have a low-intermediate IPSET-T score and have a congruously lower rate of thrombosis during follow-up. Therefore, *CALR* mutation does not have a negative impact on thrombotic risk. We did not obtain a significant difference in hemorrhagic events occurrence. Our data provide evidence that evaluation of JAK2, MPL, and CALR mutation status is not only important for diagnosis but also for the evaluation of thrombotic risk.

E1338

CLINICAL SIGNIFICANCE OF CIRCULATING MICROPARTICLES IN PH-MYELOPROLIFERATIVE NEOPLASMS (MPN)

Y. Han[1,*] W. Zhang[1], S. Zhao[1], J. Qi[1], J. Cen[1], A. Sun[1], C. Ruan[1], D. Wu[1]
[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Microparticles (MPs) are small membrane vesicles that are classified a as follow: platelet-derived MPs (PMPs), endothelial MPs (EMPs), red blood cell MPs (RMPs) and tissue factor MPs (TF^+MPs) based on their origins. Philadelphia chromosome-negative myeloproliferative neoplasms (Ph^-MPN) are disorders characterized by abnormal hematopoiesis, thrombosis and JAK2V617F mutation. Although MPs are considered as biomarkers reflecting procoagulant state in cancer patients, whether they exist in the patients with Ph^-MPN remains unclear.
Aims: Our objective in this study was to measure the variation of the four types of MPs in the patients with MPN and to Figure out their correlations with JAK2V617F mutation and some clinical complications, especially thrombosis and splenomegaly.
Methods: Ninty-two patients with MPN were enrolled in this study, including 60 essential thrombocythemia (ET), 20 polycythaemia vera (PV), and 12 primary myelofibrosis (PMF). 30 healthy volunteers were selected as normal controls. Venous blood wasanticoagulated with sodium citrate (1:9). Plasma samples were measured by flow cytometry for RMPs, PMPs, TF+MPs and EMPs with phycoerythrin (PE)-conjugated monoclonal antibodies CD235a, CD61, CD142, and CD62E, respectively. Forward scatter was set in scale using fluorescent microspheres of 0.8μm and standard fluorescent microbeads (0~0.8μm) in diameter were used to set the microparticle gate. Data were presented as mean and standard deviation. Meanwhile, genomic DNA was extracted from mononuclear cells and amplified by allele specific polymerase chain reaction (PCR).
Results: (1) Levels of RMPs, PMPs, EMPs and TF^+MPs in patients with Ph^-MPN was(135.2±291.60)/μl, (960.7±1539.1)/μl, (808.8±1244.5)/μl and (103.2±303.6)/μlrespectively; they were all significantly higher than control group (P<0.05). Moreover, levels of all four types of MPs in PMF group demonstrate significantly higher than PV group (P<0.05), and RMPs in PMF group was significantly higher than ET group (P<0.05).(2) Ph^-MPN patients with thrombosis complication showed higher levels of all four types of MPs than those without thrombosis complication(P<0.01). (3) Ph^-MPN patients with splenomegaly showed higher levels of all four types of MPs than those without splenomegaly (P<0.01). (4) All four types of MPs in the JAK2V617F mutation group were higher than the group in which those patients without mutation (P<0.05).
Summary and Conclusions: Ph^-MPN patients reveals higher levels of all four types of MPs than normal controls, especially in patients complicated with thrombosis or splenomegaly. MPs in PMF patients possess more obvious increase than PV and ET groups. Patients with JAK2V617F mutation showed higher levels of the four types of MPs than that without JAK2V617F mutation. Consequently, MPs play an crucial role in the pathogenesis of Ph^-MPN, and the MPs released may promote the formation of thrombosis.

E1339

MATRIX METALLOPROTEINASE 2,3,9,10 AND 13 GENE MUTATIONS IN MYELOPROLIFERATIVE DISEASES

S. Maral[1,*] S.M. Bakanay[2], O. Sahin Balçık[3], E. Gündüz[3], M. Albayrak[4], A. Kosar[5]
[1]Hematology Department, [2]Atatürk Research and Trainning Hospital, [3]Turgut Ozal Medical School and Hospital, [4]Dışkapı Research and Trainning Hospital, [5]Lokman Hekim Hospital, Ankara, Turkey

Background: Clonal myeloid disorders develop as a result of an acquired mutation in the multipotent stem cells or early precursor cells. Matrix metalloproteinases (MMP) are proteolytic enzymes that play role in arrangement of tissues, morphogenesis, wound healing and maturation. Additionally, they are consigned in pathological pathway of tumor invasion, angiogenesis and metastasis. The genetic polymorphisms may influence the functions of these enzymes.
Aims: In this study the association of myeloproliferative diseases (MPD) with polymorphisms in MMP2, MMP3, MMP9, MMP10 and MMP13genes were investigated.We aimed to show is there any relationship with MMPs and disease prognosis and fibrosis of bone marrow.
Methods: Fiftyseven patients and 22 control cases were included in the study. The study group was composed of 28 patients with polycythemia vera (PV), 12 patients with essential thrombocytosis (ET) and 17 patients with secondary polycythemia (SP) patients. The ET and PV patients were diagnosed according to 2008 WHO diagnostic criteria and they were either receiving medical therapy and/or phlebotomy. DNA isolation was done from peripheral blood samples by PureLink TM Genomic DNA Kit. MMP2 gene-735 C>T (rs2285053), MMP3 gene -1612 5A → 6A (rs35068180), MMP9 gene Gln279Arg (rs17576 G>A), MMP10 gene +180G>A and MMP13 gene -77A>G polymorphisms were investigated. Polymerase chain reaction products of the investigated gene region were observed in%3 agarose gel. Genotype was determined by DNA sequencing after each polymorphism was recognized.
Results: The ratios of heterozygote patients for MMP2 were 39.3%in PV, 47.1% in SP, 41.7% in ET and 27.3% in control groups. Similarly, the ratios of heterozygote patients for MMP3 were 38.3% in PV, 47.1% in SP, 33.3% in ET and 68.2% in control groups, respectively. There was not any significant difference between groups regarding MMP2 and MMP3 mutations. The MMP9 polymorphism was most commonly reported in ET group (50%) while there was not any MMP9 polymorphism reported in the control group (p=0.001). There was not any statistically significant difference between groups regarding the MMP10 polymorphisms. Heterozygote patients for MMP13 were determined as 71.4% in PV, 70.6% in SP, 75.0% in ET and 50.0% in control groups. Heterozygote MMP13 patients were statistically significantly more common in PV and ET groups than the control group (p=0.001).
Summary and Conclusions: We have determined that MMP9 gene Gln279Arg and MMP13 gene -77A>G polymorphysms were associated with ET while MMP13 -77A>G polymorphysms were associated with PV. The MMP gene polymorphysims were not associated with SP development. Increased number of megakaryocytes and increased thrombocyte outflow in ET patients may be associated with increased MMP9 polymorphisms. On the other hand, MMP13 polymorphisms may be associated with the acceleration of bone marrow fibrosis. Further studies are warranted to determine the association of MMP9 and MMP13 polymorphisms in patients with MPD.

E1340

KARYOTYPE OF CIRCULATING PROGENITOR CELLS OF MYELOID LINEAGE COULD BE RELATED TO CLINICAL COURSE OF MYELOFIBROSIS

R. Lozynskyy[1,*] M. Lozynska[2], Z. Maslyak[1], Y. Vyhovska[1]
[1]Hematological, Institute of Blood Pathology and Transfusion Medicine NAMS, [2]Diagnostics of Hereditary Pathology, Institute of Hereditary Pathology of NAMS, Lviv, Ukraine

Background: Granulocyte colony stimulating factor (G-CSF) is known to stimulate mitosis of myeloid progenitors as well as non-committed stem cells that could harbour hidden mutations and give rise to new pathological clones in myelofibrosis (MF), especially leukemic. The level of circulating stem cells is elevated during the disease progression. However, the total level of these cells is low in peripheral blood (PB), and most of them don't proliferate without specific stimulation. Unfavorable karyotype of bone marrow (BM) is negative prognostic feature of the pathological process in MF. Karyotype peculiarities are revealed only in dividing cells using conventional cytogenetic methods, but not in stem cells, and the information obtained during the investigation is limited to BM, whereas the pathological cells are also presented in blood, spleen and other organs. A lot of driver point mutations with impact on total survival of the patients with MF are revealed. For instance, mutation as *CALR* gene is related to favorable prognosis, and mutation of *ASXL1* gene is related

to poor outcome of the disease. However, there are no data confirming correlation of unfavorable karyotype with mutation of *ASXL1* or other genes in MF.
Aims: The aim of the study was to examine cytogenetic properties of myeloid progenitor cells, circulating in the peripheral blood of patients with myelofibrosis.
Methods: The study group consisted of 34 patients with confirmed diagnosis of both idiopathic, post-polycythemia vera, and post-essential thrombocythemia MF. The PB was cultivated for 24 h with G-CSF in order to obtain mitoses of circulating stem cells and to stimulate divisions of blast cells and promyelocytes. Control analysis were performed in non-stimulated BM using standard approaches. G-method of differential staining was used for cytogenetic studies of both PB and BM.
Results: Cytogenetic abnormalities were revealed in 47% of patients. The spectrum of the most common anomalies obtained in this study included deletions and translocations of chromosome 1, deletions of 5q and 20q, trisomies of chromosomes 3, 8, 9, 12, monosomies of chromosomes 3, 5, 7, 9, 11, 13, 15, 17, and polyploidy. Karyotype of G-CSF-stimulated PB matched the BM karyotype in most patients. Although there were some differences in proportions between abnormal clones in the cases of mosaic karyotypes. Polyploidy was more characteristic for the BM and was observed in 30% of cases that included single polyploid metaphases, whereas incidence of polyploidy in the PB was 6%. Most of the polyploidy metaphases were presented as tetraploid ones, however, near-tetraploid, near-triploid and octaploid were also revealed in some cases. The study of G-CSF-stimulated blood was successful for the majority of patients in whom cytogenetic studies of BM failed. High mitotic index according to cytogenetic analysis of PB with concomitant chromosome abnormalities were accompanied by IPSS score >=2 and DIPSS score >=3 for other clinical indicators. If BM aspiration for cytogenetic analysis was unsuccessful, but cytogenetic abnormalities were found in the study of PB, the disease course was unfavorable, because of appearance of transfusion dependency, significantly increased leukocytosis with increasing changes in leukogram, or even transformation to acute leukemia and death. The follow-up within 1 year showed that the cytogenetic changes in PB in some cases were preserved or further evolved with the appearance of additional chromosomal abnormalities and worsening of the patient's condition.
Summary and Conclusions: Cytogenetic studies of PB in MF using *in vitro* stimulation with G-CSF could complement cytogenetic analysis of BM and determination of the mutation status. The spectrum of anomalies obtained during cytogenetic analysis of both G-CSF-stimulated PB and BM aspirate are very similar. Therefore, the cytogenetic analysis of an *in vitro* G-CSF-stimulated PB may be an acceptable alternative to repeated BM punctures in cases of significant fibrosis that makes BM difficult or impossible to aspirate. Cytogenetic abnormalities in the blood of patients in our group were associated with unfavorable course of MF. Collection of PB for cytogenetic analysis in dynamics may become potential additional criterion for monitoring the effectiveness of treatment and the disease progression. The absence of need to repeat BM puncture is an additional factor that could contribute to greater adherence of the patients to diagnostic and treatment procedures. Regular monitoring of cytogenetic changes could help searching for chromosomal loci with candidate genes involved in the disease progression.

E1341

IPSET-THROMBOSIS BETTER IDENTIFIES THROMBOSIS FREE SURVIVAL

Ö.G. Sevindik[1,*] S. Mersin[1], A. Katgı[1], S. Tunalı[1], S. Medeni Solmaz[1], C. Acar[1], I. Alacacıoğlu[1], Ö. Pişkin[1], M.A. Özcan[1], F. Demirkan[1], B. Ündar[1], G.H. Özsan[1]
[1]Department of Hematology, Dokuz Eylul University, İzmir, Turkey

Background: Essential thrombocythemia (ET) is the most common among the myeloproliferative neoplasms (MPNs). For better predicting the occurrence of thrombotic events, an International Prognostic Score of Thrombosis for ET (IPSET-Thrombosis) was recently developed.
Aims: We aimed to investigate the validity of IPSET-Thrombosis in a Turkish patient cohort, and to compare the efficacy of IPSET-Thrombosis and conventional risk scoring systems in predicting thrombosis free survival.
Methods: We retrospectively evaluated the clinical characteristics and risk factors for thrombosis in 112 Turkish patients. Median thrombosis free survival and Harrell C-Concordance indexes were calculated for both conventional and IPSET-Thrombosis.
Results: Median age of 112 patients included in the study was 61 (27-90) years at the time of diagnosis. When patients were stratified according to the conventional risk stratification system, 43.8 % of patients were in low risk and 56.2% were in high risk group. 22.4% of low risk and 42.9% of high risk patients had an at least one occasion of thromboembolic event. When patients were stratified according to the IPSET-Thrombosis, 33% were in low risk, 26.8% were in intermediate risk and 40.2% were in high risk group. Considering IPSET-Thrombosis risk groups 5.4% of low risk, 26.7% of intermediate risk and 66.2% of high risk patients had an at least one occasion of thromboembolic event. Regarding IPSET-Thrombosis risk groups, 10 year thrombosis free survival was 86.8% for low risk, 39.4% for intermediate risk and 32.9% for high risk groups (p<0.001). Harrell C-concordance indexes of conventional and IPSET-Thrombosis were 0.60 and 0.77 respectively (Figure 1).

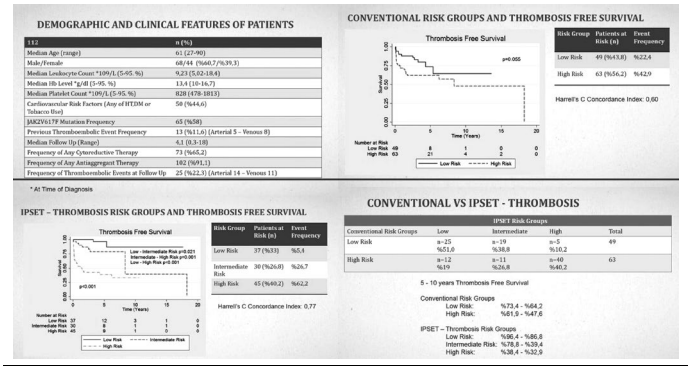

Figure 1.

Summary and Conclusions: By validating the reproducibility of IPSET-Thrombosis in Turkish ET patients, we conclude that IPSET-Thrombosis identifies thrombosis free survival better than the conventional risk stratification system.

E1342

EFFICACY OF RUXOLITINIB IN MYELOID NEOPLASMS WITH PCM1-JAK2 FUSION GENE

I.C. Casetti[1,*] J.D. Milosevic[2], E. Rumi[3], D. Selleslag[4], E. Lierman[5], D. Pietra[3], C. Cavalloni[1], M. Bellini[1], C. Milanesi[3], C. Astori[3], R. Kralovics[2], P. Vandenberghe[5], M. Cazzola[1,3]
[1]Deparmente of Molecular Medicine, IRCCS Policlinico San Matteo, Pavia, Italy, [2]CeMM Research Center for Molecular Medicine, Austrian Academy of Sciences, Vienna, Austria, [3]Department of Hematology Oncology, IRCCS Policlinico San Matteo, Pavia, Italy, [4]Department of Hematology, AZ Sint-Jan, Brugge, [5]Center for Human Genetics, KU Leuven/University Hospital Leuven, Leuven, Belgium

Background: In September 2014 Schwaab *et al.* published two cases of myeloid neoplasms associated with *PCM1-JAK2* and *BCR-JAK2* fusion genes treated with ruxolitinib. While they reported a very good initial response for both cases, relapse occurred after 18 and 24 months respectively. The authors concluded that the response of myeloid disorders with *JAK2* fusion genes to ruxolitinib is short-lived, but that ruxolitinib may be an important bridging therapy prior to ASCT.
Aims: To report the follow-up of our two cases of myeloid neoplasms/Chronic eosinophilic leukemia (CEL) with a *PCM1-JAK2* fusion gene treated with Ruxolitinib.
Methods: We monitored at 3, 6, 12, 24 and 36 months the number of metaphases with t(8;9) through cytogenetics, the proportion of rearranged nuclei through FISH, and the amount of PCM1-JAK2 fusion transcript through quantitative real time PCR analysis.

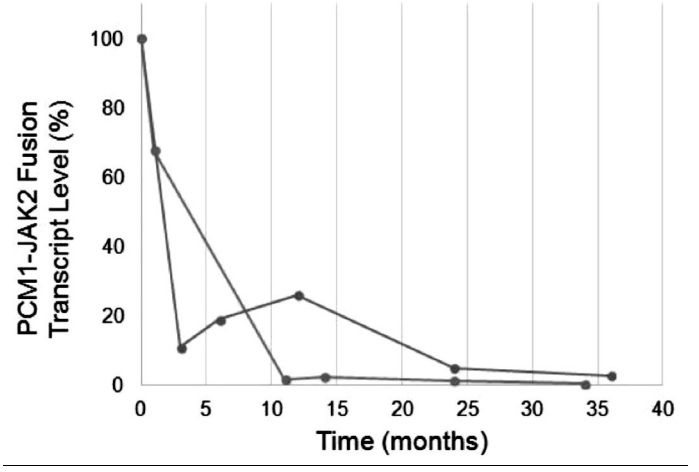

Figure 1. The two lines represent the fold difference in transcript levels normalized to the baseline sample considered as 100%.

Results: The first case was a 72-year-old male with a PCM1-JAK2 positive CEL who gradually obtained a complete cytogenetic remission over a period of 15 months of therapy with ruxolitinib at a dose of 10- 20 mg bid. The hematological course of this patients beyond 15 months, under continued treatment with ruxolitinib (10 mg, bid) was uneventful, with moderate anemia ((Hb>120 g/L) not requiring blood transfusions, with normal leukocytes and platelet counts and normal eosinophil counts. Consecutive cytogenetic and FISH studies on bone marrow showed complete cytogenetic remission. In addition, the meas-

urement of disease burden by real-time quantitative RT-PCR showed a 2log decrease at 34 months as compared with the disease burden at the start of ruxolitinib. The last reevaluation was done three months before his death to unrelated cardiac problems (septic endocarditis) 36 months after the start of ruxolitinib, without- evidence of relapse. The second case was a 31-year-old female affected with CEL. She started Ruxolitinib in 2011 at 15 mg BID and obtained a complete clinical remission. She obtained a reduction of aberrant metaphases and aberrant nuclei with t(8;9) and a marked reduction of the PCM1-JAK2 fusion transcript. She is still alive in complete hematological remission. Both patients therefore achieved durable complete hematologic remissions and cytogenetic response lasting for 3 year in each case respectively. Figure 1 shows the marked reduction of the PCM1-JAK2 fusion transcript.
Summary and Conclusions: These cases demonstrate that the response of myeloproliferative neoplasms with PCM1-JAK2 fusion genes can be long-lived, without use of ASCT.

CLINICAL FEATURES OF JAPANESE POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA PATIENTS HARBORING CALR, JAK2V617F, JAK2EX12DEL, AND MPLW515L/K MUTATIONS

M. Okabe[1,*] H. Yamaguchi[1], K. Usuki[2], Y. Kobayashi[3], E. Kawata[3], J. Kuroda[4], S. Kimura[5], K. Tajika[6], S. Gomi[6], N. Arima[7], S. Mori[8], S. Ito[9], M. Koizumi[10], Y. Ito[11], S. Wakita[1], K. Arai[1], T. Kitano[1], F. Kosaka[1], K. Dan[1,12], K. Inokuchi[1]
[1]Department of Hematology, Nippon Medical School, [2]Department of Hematology, NTT Medical Center Tokyo, Tokyo, [3]Department of Hematology, Japanese Red Cross Kyoto Daini Hospital, [4]Division of Hematology and Oncology, Kyoto Prefectural University of Medicine, Kyoto, [5]Division of Hematology, Respiratory Medicine and Oncology, Department of Internal Medicine, Faculty of Medicine, Saga University, Saga, [6]Department of Hematology, Yokohama Minami Kyousai Hospital, Yokohama, [7]Department of Hematology, Kitano Hospital, Osaka, [8]Hemato-Oncology Department, St Luke's International Hospital, Tokyo, [9]Department of Medical Oncology, Iwate Medical University, Morioka, [10]Department of Gastroenterology, Asahi General Hospital, Asahi, [11]Department of Hematology, Tokyo Medical University, Tokyo, [12]Medical Education Center, Ryotokuji University, Urayasu, Japan

Background: Myeloproliferative neoplasms (MPNs) are characterized by the monoclonal proliferation of one or more lines of myeloid cells due to hematopoietic stem cell abnormalities. MPNs involve hyperplasia of differentiated blood cells and an increased risk of thrombosis, and can progress to leukemia. The risk of complication of polycythemia vera (PV) and essential thrombocythemia (ET) by thrombosis in Japanese patients is clearly lower than in western populations, suggesting that genetic background such as race may influence the clinical features.
Aims: This study aimed to clarify the relationship between genetic mutations and haplotypes and clinical features in Japanese patients with PV and ET.
Methods: This study prospectively analyzed 74 PV and 303 ET patients who were diagnosed at facilities which agreed to participate in this study. Comparisons were made with 232 normal controls. Mutation biased polymerase chain reaction and direct sequencing were used to assess *JAK2V617F*, *JAK2Ex12del, MPLW515L/K* mutations, and the single nucleotide polymorphisms, which are located near the *JAK2V617F* mutation, to determine *JAK2* 46/1 haplotype. *CALR* mutations were analyzed by direct sequencing of exon 9. Statistical analyses were performed with SPSS software (version 12.1.4). Linkage analysis was performed with haploveiw ver.4.2.
Results: Genetic mutations in PV patients included *JAK2V617F* (93.2%; 69/74), *JAK2Ex12del* (5.4%; 4/74), and *MPL* mutations (1.4%; 1/74). Genetic mutations in ET patients included *JAK2V617F* (60.9%; 180/294), *CALR* (16.0%; 47/294), and *MPL* (3.7%; 11/294) mutations. There were 57 ET patients (19.4%) who did not have any of these mutations. There were no clinical differences, including *JAK2V617F* allele burden, between PV patients harboring the various genetic mutations. However, *CALR* mutation-positive ET patients had a significantly lower WBC count (p=0.003), Hb value (p<0.001), Ht value (p<0.001), and NAP score (p=0.015), and significantly more platelets (p=0.003), relative to *JAK2V617F*-positive ET patients and ET patients with no mutations. Compared to Type 1 *CALR* mutation (p.L367fs*46 deletion)-positive ET patients, those with Type 2 mutations (p.K385fs*47 insertion) had a significantly higher platelet count (p=0.048). The single nucleotide polymorphisms rs12340895, rs10974944, rs12343867, and rs1159782, which are located near JAK2V617F, exhibited linkage disequilibrium between PV patients, ET patients, and normal controls. Compared to normal controls, the frequency of the *JAK2* 46/1 haplotype was significantly higher among patients with *JAK2V617F* (p<0.001), *JAK2Ex12del* (p<0.001), or *MPL* mutations (p<0.001), whereas no significant difference was found among *CALR* mutation-positive patients. The cumulative incidence of thrombosis from diagnosis of PV and ET was 9.6% and 9.0%, respectively, after 10 years. The cumulative incidence of thrombosis showed an increasing trend among PV patients aged ≥60 years (p=0.098), but no significant difference was found in any of the other parameters (history of thrombosis, WBC count, NAP score, 46/1 haplotype, various genetic mutations. In ET patients, the cumulative incidence of thrombosis was significantly higher among those with a history of thrombosis (with history: 18.0% in 10 years *vs* no history: 7.0% in 10 years; p=0.043). *JAK2V617F*-positive patients had a higher cumulative incidence of thrombosis (12.3%) relative to those with *CALR* mutations (6.25%), the *MPLW515L/K* mutation (0%), or no mutation (0%), although the differences were not significant.
Summary and Conclusions: The incidence of developing thrombosis after an ET or PV diagnosis was about 9% each, which are lower than those observed in western countries. We did not find a significant correlation between *CALR* mutations and the 46/1 haplotype. *JAK2V617F*-positive ET patients and *CALR* mutation-positive patients may have different mechanisms of occurrence and clinical features of ET, suggesting the potential need for therapy stratification in the future.

E1344

BONE MINERAL DENSITY IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA AND POLYCYTHEMIA VERA

S. Farmer[1,*] V. Shanbhogue[2], S. Hansen[2], C. Stahlberg[2], A.P. Hermann[2], H. Vestergaard[2], H. Frederiksen[2]
[1]Dept. of Haematology, [2]Odense University Hospital, Odense C, Denmark

Background: Several systemic inflammatory diseases are associated with osteoporosis and increased risk of fractures which at least in part may be caused by low bone mineral density (BMD). Chronic inflammation is today a model for cancer development and may also play an important role in the pathology of chronic myeloproliferative neoplasms (CMPN). Patients with essential thrombocythemia (ET) and polycythemia vera (PV) have an increased risk of fractures in comparison with a matched background population as shown in population based studies.
Aims: The aim of this study was to assess BMD in CMPN patients in a clinical cross sectional study.
Methods: Patients with ET or PV according to WHO 2010-criteria *International Classification of Diseases,* 10th revision were recruited from the Department of Haematology, Odense University Hospital, Denmark. Dual energyx-ray absorption (DXA) was used to measure BMD at the hip and the spine L1-L4. Patients were compared with individuals from a cohort of healthy, Danish, Caucasian (n=499) recruited from the general population of the municipality in Odense. Each CMPN patient was individually matched with a subject from this cohort on age, sex, weight and height.
Results: 46 patients and 46 controls were included, 55% were females and 45 were men. Mean age was 56 years. The results of BMD measurements were presented in the Figure 1 demonstrating that BMD measurement in both hip and spine were comparable with the reference group.

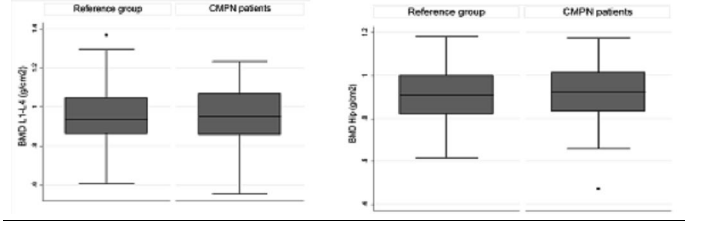

Figure 1.

Summary and Conclusions: This study assessed BMD in CMPN patients and compared results with healthy individuals. Results of the BMD measurements in both hip and spine were comparable with the reference group. This study does not explain the increased risk of fractures found in CMPN patients. BMD alone may not be accurate in predicting fractures in CMPN, and our results calls out for further studies with advanced imaging modalities or assessment of biochemical bone turn over markers.

E1345

PREVALENCE OF EOSINOPHILIAS (EOS), IDIOPATIC HYPEREOSINOPHILIA AND HYPEREOSINOPHILIC SYNDROME (HES) IN A LARGE (ONE MILLION) POPULATION IN NORTH ITALY (THE ROMAGNA GREATER AREA)

M. Rondoni[1,*] G. Poletti[1], N. Tommasini[1], M. Rosetti[1], L. Baldrati[1], F. Monti[1], M. Salvucci[2], A. Lucchesi[3], S. Tomassetti[4], E. Ottaviani[5], P. Savini[6], E. Zuffa[2], P.P. Fattori[3], G. Martinelli[5], P. Tosi[4], R.M. Dorizzi[1]
[1]Department of Clinical Pathology, Centro Servizi Pievesestina AUSL Romagna, Pievesestina di Cesena (FC), [2]Department of Hematology-Oncology, Ravenna Hospital, AUSL Romagna, Ravenna, [3]Department of Hematology-Oncology, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Meldola, [4]Department of Hematology-Oncology, Ospedale "Infermi" Rimini, Rimini, [5]Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, [6]Department of Internal Medicine, Faenza Hospital, Faenza, Italy

Background: The Eosinophilias (Eos) encompass a broad range of nonhema-

tologic (secondary or reactive) and hematologic (primary, clonal) disorders. Hypereosinophilia has been defined as a peripheral blood eosinophils (Eo) count greater than 1,500/mm^3 The HES is characterized by marked unexplained blood and tissue Eos and defined (1975) by Chusid's criteria: (1) blood Eo ≥1500/mm3 for longer than 6 months, (2) lack of evidence for parasitic, allergic, or other known causes of Eos, and (3) presumptive signs or symptoms of organ involvement. Disease prognosis relies on identifying the origin of Eos. The 2008 WHO establishes a semimolecular classification of eosinophilic disorders (ED) based on the presence of recurrent molecular alterations (PDGFRA, PDGFRB, or FGFR1), or of other clonal markers, and where HES is a diagnosis of exclusion. The incidence and prevalence of ED and HES is not well characterized, and also the frequency of PDGFRA rearrangement is really unknown, with a high median rate of 23% from 8 clinical studies, that probably depends from the selection bias of patients.

Aims: The aim of this study was to investigate the prevalence of ED in the Greater Romagna Area (AVR), an homogeneous large geographic area served by the Italian National Health System (INHS).

Methods: The Hub Laboratory (HL) of AVR serves more than one million (1.124.866 in 2012) inhabitants living in an area of about 5000 square km in North of Italy, that provides Laboratory Medicine service for all general practitioners and for all the hospitals of the INHS. It includes hematology laboratory, and genetic sections. The results of all the tests carried out by the HL since 2009, including the differential cell counts (DIFF), are stored in the LIS database. We downloaded from the LIS the DIFF results obtained in 2012 and selected the cases with ≥1.5x10^9/L Eo among the 574.380 unique individuals with at least one DIFF. In order to verify if the first Chusid criteria for HES was satisfied we searched for other DIFF requests in the semesters before and after the selected cases and for Eo ≥1.5x10^9/L in these DIFFs. For this total cohort of possible HES patients, we performed further data extraction from LIS with the intent to exclude the more frequent causes of secondary Eos (*e.g.* total IgE, fecal parasites, CRP, vitamin B12, bone marrow smears and cytogenetic). Moreover we matched the clinical records (InfoClin, LOG80, ONAMB) of the uncertain cases for final diagnosis.

Results: Of 574.380 unique individuals with one DIFF in 2012, 452 satisfied the first Chusid's criteria, and on these cohort we will performed our investigations. Here we report the preliminary results on 44 patients (10% of the total cohort). We excluded 27 patients with secondary Eos (61,3%), and 15 asymptomatic patients no further investigated despite a persistent mild Eos (<2.5x 10^9/L), and finally we identified 2 patients with sign and symptoms of HES, with a prevalence in the AVR of 0.034%. Of note, the 2 patients were male, and died in 3 and 15 months without evaluation of the presence of molecular rearrangements.

Summary and Conclusions: The low prevalence of HES (<0.05%) is confirmed by these preliminary data. With the completion of this analysis we will achieve a better characterization of ED and, since we are investigating half of the resident population of AVR, also the real prevalence of these rare diseases will be known, including PDGFRA positive clonal disease, primary HES, but probably with the exclusion of the ED with specific tissue Eos without peripheral Eos.

E1346

A SCORING SYSTEM BASED ON LEUKOCYTE ALKALINE PHOSPHATASE ACTIVITY AND PERIPHERAL GRANULOCYTE PRECURSOR PERCENTAGE PREDICTS JAK2 V617F MUTATION IN PATIENTS WITH PRIMARY MYELOFIBROSIS

R. Invernizzi[1,*] E. Travaglino[1], L. Roma[1], R. Bastia[1], V. Rosti[1], L. Villani[1], G. Bergamaschi[1], F. Quaglia[1], G. Barosi[1]
[1]IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: Patients with primary myelofibrosis (PMF) may carry mutations of *JAK2*, *MPL* or *CALR* (calreticulin) gene. The genetic subtypes of PMF are different as regards clinical course, disease progression and overall survival. The mutation in the *JAK2* gene consisting of a valine-to-phenylalanine change at position 617 (*JAK2* V617F) was reported in half and more of the patients. This mutation increases JAK2 kinase activity and is significantly associated with higher blood cell count, granulocyte activation and thrombosis risk.

Aims: Since increased leukocyte alkaline phosphatase (LAP) expression is considered a granulocyte activation marker and variable LAP levels are found in PMF, the aims of our study were to evaluate LAP activity in PFM patients searching for possible correlations among LAP score, *JAK2* V617F mutation status, and clinical-pathological features; moreover, in patients treated with a JAK1/2 inhibitor, to determine possible correlation between LAP levels and degree of response to therapy.

Methods: We evaluated LAP activity by cytochemistry in peripheral blood smears from 266 PMF patients at diagnosis, whereas *JAK2* V617F mutation status was assessed by polymerase chain reaction (PCR). On the basis of a ROC curve analysis we defined a simple scoring system to predict *JAK2* V617F mutation with high sensitivity and specificity. Then, we prospectively tested this score system in a new cohort of 105 PFM patients.

Results: *JAK2* V617F mutation was identified in 162 patients (61%). In these patients LAP scores were significantly higher than in nonmutated cases (P<0.0001), without difference in relation to the allele burden. Score values above the normal range were observed only in patients carrying the mutation. No correlation was found between LAP score and white blood cell or platelet count, hemoglobin concentration, splenomegaly, IPSS risk group, while there was a significant inverse correlation between LAP score and peripheral granulocyte precursor percentage. A ROC curve analysis allowed us to identify a LAP score of 100 (AUC=0.81, 95% CI 0.76-0.86) and a peripheral granulocyte precursor percentage of 10 (AUC=0.80, 95% CI 0.64-0.79) as optimal cut-off to discriminate mutated patients with good sensitivity and specificity (range 84-98%). On the basis of these variables, we awarded 0 points (LAP score <100, or peripheral granulocyte precursors ≥10%), 1 point (peripheral granulocyte precursors <10%) or 2 points (LAP score ≥100), and developed a simple scoring system to predict *JAK2* V617F mutation. All cases with a score of 3 carried the mutation, while 94% of patients with a score of 0 showed a wild-type gene. Then, we prospectively tested this score system in a new cohort of 105 PFM patients obtaining superimposable results. Nineteen PMF patients, 16 carrying the *JAK2* V617F mutation and 3 nonmutated, were treated with the JAK1/2 inhibitor Ruxolitinib. Eleven patients had a ≥50% reduction in spleen volume, 2 cases achieved a modest decrease in spleen size, whereas in 6 cases no spleen response was observed. In all cases, LAP score significantly decreased during treatment (P=0.02); however, no correlation was found between LAP levels or peripheral granulocyte precursors percentages and response to therapy.

Summary and Conclusions: We confirmed the association between LAP levels and *JAK2* V617F mutation; moreover, we suggest a very simple, low expensive and reproducible method based on old techniques to predict this gene mutation.

E1347

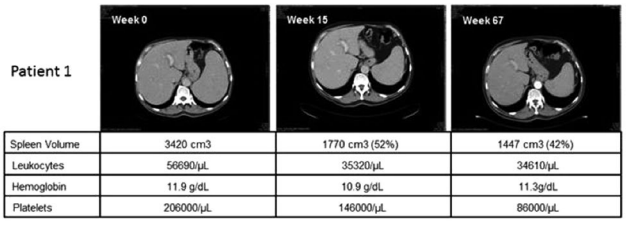
RUXOLITINIB IN CHRONIC MYELOMONOCYTIC LEUKEMIA AND SYMPTOMATIC SPLENOMEGALY

K. Geissler[1,*] T. Rand[2], E. Jäger[3], A. Zopf[4], G. Mitterbauer-Hohendanner[3]
[1]5th Department of Medicine, [2]Department of Radiology, Hospital Hietzing, [3]Department of Laboratory Medicine, Medical University of Vienna, Vienna, [4]Blood Transfusion Service for Upper Austria, Austrian Red Cross, Linz, Austria

Background: In patients with myelofibrosis the JAK1/2 inhibitor ruxolitinib has been shown to reduce splenomegaly and constitutional symptoms. Efficacy was also seen in patients without the JAK2 V617F mutation suggesting that some drug effects may be due to a general attenuation of cytokine signaling (*Ostojic A et al. Drugs Today 2011*). In patients with chronic myelomonocytic leukemia (CMML) symptomatic splenomegaly and constitutional symptoms may be also a clinical problem and there is no generally accepted standard treatment for the myeloproliferative form of CMML. *In vitro* findings by us (*Geissler K et al. J Exp Med 1996*) and others (*Padron E et al. Blood 2013*) suggest that divergent molecular aberrations in CMML seem to converge within the GM-CSF signaling pathway. Since JAK2 is a sentinel kinase in this pathway (*Hansen G et al. Cell 2008*) ruxolitinib may be an attractive drug in CMML.

Aims: Clinical observations from case reports may be helpful to support treatment concepts.

Methods: We report our findings in 2 CMML patients with symptomatic splenomegaly and constitutional symptoms receiving ruxolitinib off label.



Computed tomographies and spleen volumes at different time points are shown. Spleen volumes were calculated using the formula S Vol = 30 + 0·58 (width x length x thickness) (*Prassopoulos P et al. Eur Radiol 1997*). Numbers in brackets give the percentages of spleen size as compared to the spleen volumes prior to ruxolitinib treatment (week 0). * Patient 2 had gastrointestinal bleeding at that time.

Figure 1. Effect of ruxolitinib on spleen volumes in two patients with chronic myelomonocytic leukemia.

Results: Patient 1 is a 75-year-old man with CMML-1 since 10/2011, JAK2 V617F mutation, progressive splenomegaly and constitutional symptoms refractory to hydroxyurea. After informed consent ruxolitinib (2x20mg/d) was started in 5/2013. Within 1 week constitutional symptoms subsided. CT confirmed a reduction in spleen volume of 48% at week 15 (Figure 1). Initiation of

ruxolitinib was associated with a clear reduction of white blood cell (WBC) counts without clinically relevant changes in platelet counts and hemoglobin values. The patients response regarding splenomegaly and constitutional symptoms is continuing without a clear decline in JAK2 V617F allele burden (94.6% at week 0, 89.7% at week 67). Patient 2 is a 72-year-old man with CMML-1 and mutations in NRAS, and SRSF2, respectively. Because of rapidly increasing WBC counts (from 25990/mm^3 to 62920/mm^3 within 6 weeks), symptomatic splenomegaly and constitutional symptoms the patient received ruxolitinib (2x20mg/d) in 8/2012 after providing consent. Constitutional symptoms disappeared within 1 week. A reduction of spleen volume of 38% at week 15 and of 48% at week 21 of ruxolitinib therapy was observed (Figure 1). Initiation of ruxolitinib was followed by a stabilization of WBC counts with no major hematological toxicity. Spontaneous relative to stimulated *in vitro* CFU-GM formation, which has been shown by us to be GM-CSF-dependent (*Geissler et al. J Exp Med 1996*), decreased from 101% before ruxolitinib to 36% at week 5. After 8 months the patient lost his response to ruxolitinib and was treated with azacitidine. Having achieved a second transient response he died 22 months after diagnosis due to progressive disease.

Summary and Conclusions: We show here for the first time spleen response and disappearance of constitutional symptoms by ruxolitinib in 2 patients with CMML. The response in patient 1 which was seen without reduction in the JAK2 allele burden as well as culture data obtained during ruxolitinib therapy in patient 2 are in line with the assumption that inhibition of GM-CSF-dependent signaling may be at least in part responsible for these effects. Ruxolitinib may be an interesting molecule to be systematically studied in patients with CMML.

E1348

CLINICAL DIFFERENCES IN ESSENTIAL THROMBOCYTHEMIA PATIENTS WITH AND WITHOUT THROMBOTIC COMPLICATIONS

A. Zherniakova[1,*] V. Shuvaev[1], I. Martynkevich[1], L. Polushkina[1], K. Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Thrombosis is the main factor causing disablement in essential thrombocythemia (ET) patients. Currently, the connection between increased blood platelets and leukocytes values, as well as *JAK2V617F* mutation presence and the risk of thrombotic events in ET is well-known.

Aims: The aim of this study is to analyze clinical characteristics in ET patients with and without thrombotic complications.

Methods: The subject for this study were 218 patients who had been diagnosed at the Russian Research Institute of Hematology and Transfusiology outpatient department over a period of 10 years (2003-2013). The ET patients were divided into 2 groups: those with thrombosis (Thr+) (n=67) and those without (Thr-) (n=151). During the study, the following parameters were observed: age, sex ratio, blood test data, and the frequency of *JAK2V617F* mutation. The Mann-Whitney U test for quantitative variables and the Chi-square test with Yate's contingency correction were used for statistical analysis. Statistical significance was set at the p<0.05 level.

Results: In group Thr+ the following thromboses were observed: arterial 38 (56.7%), venous 21 (31.4%), and both 8 (11.9%). The majority of ET patients with thrombosis had had thrombotic events before ET was established and 7 of them developed it during the follow-up (median follow-up=24 months). Other variables were: group Thr+ median age 58.1 and group Thr- 59.6 years; sex ratio in group Thr+ 44 (65.7%) female and 23 (34.3%) male, in group Thr- 117 (77.5%) female and 34 (22.5%) male (p=0.09). No statistical differences were found in blood count analysis values at the point of ET detection. Mean values (standard deviations): in group Thr+ hemoglobin-14.1 (20) g/dL, WBC-10.10 (3.75)x10^9/L, platelets-932 (407)x10^9/L and group Thr- hemoglobin-13.9 (16) g/dL, WBC-9.86 (3.56)x10^9/L, platelets-914 (358)x10^9/L. *JAK2V617F* mutation was detected in 84% of the ET patients in group Thr+ and in 48% of those in group Thr- (p=0.004). The risk of thrombosis according to the IPSET-thrombosis scale in group Thr+ was as follows: low-7.6%, intermediate-20.9% high-71.5% and 42.3%, 37.8%, 19.9% in group Thr- (p<0.0001).

Summary and Conclusions: ET patients show difference in thrombotic events development. Risk factors for thrombosis include: age>60 years, cardiac risk factors, thrombotic complications in patient case history, and *JAK2V617F* mutation. *JAK2V617F* mutation and IPSET-thrombosis scores assist in individualizing therapeutic strategy. This helps provide dynamic thrombosis prevention, extend the patient's life duration, and improve their quality of life.

E1349

LONG-TERM RESULTS OF PREDNISONE TREATMENT FOR THE ANEMIA OF MYELOFIBROSIS

J.-C. Hernandez-Boluda[1,*] A. Martínez-Trillos[2], V. García-Gutiérrez[3], F. Ferrer-Marín[4], B.xicoy[5], A. Alvarez-Larrán[6], A. Kerguelen[7], P. Barba[8], M. Gómez[1], J.-C. Herrera[1], J.-G. Correa[2], F. Cervantes[2]
[1]Hematology, Hospital Clínico Universitario, Valencia, [2]Hematology, Hospital Clinic, Barcelona, [3]Hematology, Hospital Ramón y Cajal, Madrid, [4]Hematology, Hospital Morales Meseguer, Murcia, [5]Hematology, Hospital Germans Trias i Pujol, Badalona, [6]Hematology, Hospital del Mar, Barcelona, [7]Hematology, Hospital La Paz, Madrid, [8]Hematology, Hospital Vall d'Hebron, Barcelona, Spain

Background: Corticosteroids are generally considered to have modest activity in the treatment of the anemia of myelofibrosis (MF), but the available data are limited.

Aims: To retrospectively evaluate the efficacy and long-term outcome of single-agent prednisone, usually given after failure of other therapies, in MF patients with severe anemia. In addition, to analyze the pre-treatment clinical variables associated with the response to such therapy.

Methods: Among 511 patients diagnosed with primary MF (PMF: 345) or MF evolving from a previous essential thrombocythemia (ET) or polycythemia vera (PV) (post-ET/PV MF: 166) from 1978 to 2014, thirty cases (PMF: 27, post-ET MF: 3) were eligible for the study. Initial prednisone dose was 0.5-1 mg/kg daily, with progressive tapering to the minimum effective dose in responders. Responses were assessed according to the revised International Working Group for Myelofibrosis Treatment and Research (IWG-MRT) consensus criteria (Tefferi *et al.,* Blood 2013).

Results: Median follow-up was 17.4 months (interquartile range [IQR]: 5.5-29.1). Twelve patients (40%) achieved anemia response according to the IWG-MRT criteria, after a median time of 1.1 months (IQR: 0.9-1.6) on treatment. The median daily dose to attain the response was 45 mg (IQR: 22.5-60), and the median daily maintenance dose in responders was 10 mg (IQR: 6-15). Median response duration was 12.3 months (IQR: 9.3-29.7). At univariate analysis, constitutional symptoms and more than 2% circulating blasts at treatment start had borderline statistical significance for a lower probability of response. A platelet increase >50x 10^9/L was observed in 3 out of 11 patients (27%) with baseline counts <100x 10^9/L. Median survival from prednisone start was significantly longer in anemia responders (5.0 years, 95% CI: 3.5-6.5, *versus* 1.5 years, 95% CI: 0.2-2.8; P=0.002).

Summary and Conclusions: Prednisone has clear therapeutic activity in the anemia of MF and should be considered in patients failing conventional anemia-treating agents.

E1350

CLINICAL CHARACTERISTICS OF CALR MUTATIONS IN JAPANESE PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

Y. Sugimoto[1,*] K. Ohishi[2], M. Ikejiri[3], K. Nakatani[3], M. Masuya[1], T. Nobori[3], N. Katayama[1]
[1]Hematology & Oncology, Mie University, [2]Transfusion Service, [3]Laboratory Medicine, Mie University Hospital, Tsu, Mie, Japan

Background: Recurrent *CALR* mutations were recently identified in myeloproliferative neoplasms patients without mutated *JAK2* or *MPL*.

Aims: We analyzed these three mutations in Japanese patients with essential thrombocythemia (ET) in our single institute and elucidated clinical characteristics of patients with *CALR* mutation.

Methods: Genomic DNA was isolated from granulocytes in peripheral blood of 66 patients with ET. Mutational analyses of *JAK2*V617F, *JAK2* exon 12, *CALR* exon 9, and *MPL* exon 10 were performed with quenching probe method or Sanger sequencing.

Results: Our ET cohort (male/female, 35/31; age, 16 y.o.-85 y.o.; median age, 63 y.o.) consisted of 30 (45.5%) patients with *CALR* exon 9 frame shift mutation, 24 patients (36.4%) with *JAK2*V617F, 2 patients (3.0%) with *MPL*W515, and 10 patients (15.2%) without these three mutations (triple negative). From genomic analysis of *CALR* mutations, all of them were heterozygous and the details of *CALR* mutation type were as follows: type 1, 52-bp deletion (n=15, male/female, 9/6); type 2, 5-bp TTGTC insertion (n=11, male/female, 9/2); type 4, 34-bp deletion (n=2, male/female, 1/1); novel frame shift deletions (c.1100_1152del53insG and c.1097_1130del34) (n=2, male/female, 1/1). One of novel mutations is a single amino acid variant of type 1 mutation and the other one is 2 amino acid variant of type 4 mutation. Next, we compared the clinical parameters between *CALR*-mutated ET and *JAK2*-mutated ET. *CALR* mutations were detected in the majority of male patients and relatively younger female ET patients, while frequency of *JAK2*V617F mutation was higher in elder female patients. Platelet counts of *CALR*-mutated patients tended to be higher than those of *JAK2*-mutated patients (1013x 10^9 /L *vs* 778x 10^9 /L, p=0.05). A progressive increase in the number of platelets (>300x 10^9 /year) was observed in 7 out of 30 *CALR*-mutated ET, but in only one out of 24 *JAK2*-mutated ET. However, thrombotic events were not observed in 30 *CALR*-mutated patients, while they did occur in 6 out of 24 *JAK2*-mutated patients and 3 out of 10 triple negative patients. Significant difference was not observed between type 1 and type 2 *CALR* mutations, regarding clinical characteristics because patient numbers were small. Disease progression was observed in three out of eleven ET cases

with *CALR* type 2 mutation about twenty years after diagnosis of ET: two patients developed severe secondary myelofibrosis (MF), and one patient developed acute myeloid leukemia (FAB M7). All of them were male with type 2 *CALR* mutation. Both of two secondary MF patients had cytogenetic abnormalities including 1q21 and 6p23. One of them is still alive after allogeneic bone marrow transplantation, but the other patient died of hemorrhagic cerebral infarction due to tumor embolism. A patient with secondary leukemia contained complicated karyotype including 1q32 abnormality and died of chemorefractory leukemia (Table 1).

Table 1. ET with transformation to severe MF or acute leukemia.

Age (y.o.)	Sex	ET onset (y.o.)	Transformation	Mutation type	Karyotype
39	M	20	Secondary MF	*CALR* type2	der(6)t(1;6)(q21;p23)
61	M	38	Secondary MF	*CALR* type2	dup(1)(q21q32), add(6)(p23)
62	M	40	Acute myeloid leukemia (M7)	*CALR* type2	44, XY, add(1)(q32), der(5)t(5;14)(q13;q11.2), der(8)t(8;8)(p12;q11.2), add(10)(p11.2), -14, -17, -18, -22, +2mar /42, idem, -Y, -4, -7, +8, add(9)(q34)

Summary and Conclusions: Platelet counts were higher and tended to increase at a higher rate in patients with *CALR*-mutated patients than in those with *JAK2*-mutated patients. However, incidence of thrombotic events was significant lower in *CALR*-mutated patients. Disease progression was observed in three male patients with type 2 *CALR* mutation and cytogenetic abnormalities including 1q. It is reported that PMF patients with type 2 *CALR* mutation exhibit comparably worse survival than those with type 1 *CALR* mutation. Although patient numbers are limited, combination of *CALR* type 2 mutation and specific cytogenetic abnormalities might be related to disease progression.

E1351

SIMULATION IN CONTINUING EDUCATION: IMPROVING HEMATOLOGIST EVIDENCE-BASED DECISIONS FOR MYELOPROLIFERATIVE NEOPLASM MANAGEMENT

E. Van Laar[1,*] D. Blevins[2], R. Levine[3], R. Mesa[4]
[1]Oncology, Medscape, LLC, New York, [2]MedSims, Medscape LLC, Durham, [3]Leukemia Service, Memorial Sloan-Kettering Cancer Center, New York, [4]Division of Hematology and Oncology, Mayo Clinic, Scottsdale, United States

Background: Due to the rarity of the disorders, many hematologists, especially those in the community setting, lack experience in diagnosis, treatment and monitoring of myeloproliferative neoplasms (MPN). Prompt, accurate diagnosis and appropriate initiation of treatment are important because polycythemia vera (PV) and myelofibrosis (MF) are associated with shortened life expectancy, serious complications, and impaired quality of life.
Aims: Underlying clinical practice gaps and educational needs were identified, and a study was conducted to determine whether online, simulation-based educational interventions could improve competence and performance of hematologists in managing patients with MPN.
Methods: A cohort of US-practicing hematologists who participated in simulation-based educational interventions was evaluated. The interventions consisted of 4 cases presented in a platform that allowed learners to choose from numerous lab tests and assessment scales as well as thousands of diagnoses, treatments, and monitoring approaches. Participant clinical decisions were analyzed using artificial intelligence technology, and instantaneous or delayed clinical guidance was provided employing current evidence-based and expert faculty responses. To assess the impact of simulation-based education on clinical decisions, each participant's decisions were collected after clinical guidance and compared with that same individual's baseline data. A 2-tailed paired T-test was used to determine statistical significance.
Results: The assessment sample consisted of 284 hematologists who made at least 1 clinical decision within the simulation and proceeded to the final, debrief section. As a result of clinical guidance provided through simulation, significant improvements were observed in several areas of management of patients with MPN, specifically: In PV: -11% improvement in the diagnosis of PV (62% post intervention *vs* 56% baseline, *P*<.013); -109% improvement in the selection of appropriate initiation of therapy (JAK2 inhibitor/interferon alpha) for a patient with PV refractory to hydroxyurea (48% post intervention *vs* 23% baseline, *P*<.001); -79% improvement in MPN symptom monitoring for a patient with PV (50% post intervention *vs* 29% baseline, *P*<.001); In MF: -29% improvement in the diagnosis of primary MF (63% post intervention *vs* 49% baseline, *P*<.002); -124% improvement in the selection of appropriate initiation of therapy (JAK2 inhibitor) for a patient with primary MF (60% post intervention *vs* 27% baseline, *P*<.001); -75% improvement in MPN symptom monitoring for a patient with MF being managed with a JAK2 inhibitor (40% post intervention *vs* 23% baseline, *P*<.001).
Summary and Conclusions: This study demonstrated the success of simulation-based educational interventions on improving the evidence-based practice patterns of hematologists in the management of patients with MPN. Despite the marked improvement in competence and performance, hematologist education needs specific to accurate MPN diagnosis, treatment selection, and symptom monitoring remain. The education gaps uncovered during this intervention and the evolving treatment landscape outside of the United States lay a foundation for future global education initiatives to bridge education gaps in MPN.

E1352

CLINICAL CHARACTERISTICS OF POLYCYTHEMIA VERA PATIENTS, RECEIVING DIFFERENT TYPES OF THERAPY

D. Shikhbabaeva[1,*] V. Shuvaev[1], I. Martynkevich[1], A. Abdulkadyrova[1], V. Udaleva[1], T. Zamotina[1], M. Fominykh[1], R. Golovchenko[1], I. Zotova[1], L. Polushkina[1], K. Abdulkadyrov[1]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Achievements of fundamental sciences in study the pathogenesis of Polycythemia Vera (PV) made possible to create drugs with target mechanism of action. It is important to determine indications for target drugs with consideration their high cost and possible side effects.
Aims: Aim of study was to investigate clinical features of PV, receiving different types of therapy.
Methods: 252 patients (pts) (147 female, 107 male), median age 59 years (range 20-86), median of observation 6.1 year. Pts were divided into 4 groups: phlebotomy and erythrocytapheresis (Phleb/Aph), therapy with hydroxyurea (HU), with interferon-alpha (IFN), combined therapy with hydroxyurea and interferon-alpha (HU+IFN). The endpoints were: clinical and laboratory features, treatment outcomes, thrombosis incidence and overall survival (OS). Responses to therapy were evaluated according to ELN criteria. Statistical analysis was conducted with Kruskal-Wallis ANOVA and Chi-square tests. Survival analysis was performed by Kaplan-Meier method with log-rank test.
Results: The Phleb/Aph group consisted of 36 pts with median age 57 years. Baseline complete blood count (CBC): HB 18.6 g/dl (13.1-23.8), RBC $6.78x10^{12}$/l (5.36-9.30), HCT 57.6 (46.9-75.0), WBC $8.8x10^{9}$/l (4.3-16.4), PLT $337x10^{9}$/l (143-796). Splenomegaly was observed in 17%. Phleb/Aph procedures performed with rate from 0.10 to 9.7 (mean 5.1) procedures per year. Complete response (CR) was achieved in 5.5%, partial response (PR) in 67%, no response (NR) was seen in 27.5% of patients. The outcome in myelofibrosis (MF) was observed in 2.8%. Thrombotic episodes occurred in 19%. The HU group included 173 pts (median age 61 years). CBC data: HB 18.7 g/dl (13.94-25.6), RBC $7.22x10^{12}$/l (5.22-10.29), HCT 59.3 (47.1-82.0), WBC $12.5x10^{9}$/l (3.6-64.8), PLT $535x10^{9}$/l (136-1642). Splenomegaly was observed in 35%. Mean daily dose of HU was 0.7 (0.3-1.5) g. 7.5% achieved in CR, 76.5% had PR and NR in 16%. The MF transformation was observed in 3.5%. Thrombotic incidence was in 6.6%. The IFN group consisted of 11 pts with median 53 years. CBC: HB 17.6 g/dl (13.5-21.5), RBC $6.66x10^{12}$/l (5.90-7.48), HCT 54.2 (43.0-64.2), WBC $12.3x10^{9}$/l (3.6-23.7), PLT $562x10^{9}$/l (312-1087). Splenomegaly was detected in 64%. Mean weekly dose of IFN was 8.27 (4-12) million IU. CR was achieved in 36%, PR in 36%, NR was seen in 28%. The outcome in MF was observed in 28%. Thrombotic complications did not occurred. The HU+IFN group consisted of 32 pts with median age 51 years. CBC: HB 19.0g/dl (13.2-22.3), RBC $7.45x10^{12}$/l (5.17-9.99), HCT 60.4 (48.8-72.8), WBC $11.0x10^{9}$/l (5.1-21.0), PLT $549x10^{9}$/l (171-1189). Splenomegaly was observed in 53%. Mean daily dose of HU was 0.8 (0.5-1.5) g, mean weekly dose of IFN was 8.27 (6-30) million IU. CR wasn't achieved in this group, PR had 75% and NR in 25%. The outcome in MF was seen in 6%. Arterial thrombotic episodes occurred in 6%. Statistically significant differences between groups were obtained: age of patients (p=0.006), RBC(p<0.01), HCT (p<0.01), WBC (p<0.01), PLT (p<0.01), splenomegaly (p=0.04), response to therapy (p<0.01). Groups didn't differ in the frequency of postPV-MF (p=0.23), the overall frequency of thrombosis (p=0.19), arterial (p=0.56) and venous (p=0.34) thrombosis, and OS (p=0.29).
Summary and Conclusions: PV is one of the most frequent myeloproliferative neoplasms with various clinical symptoms. The choice of therapy depends on the patient's age and clinical symptoms. The most of PV patients don't have a clinically significant response to therapy or achieve only a partial response. This PV population might have perspective of improved treatment results and OS with administration of targeted drugs in future.

COMPLETE HEMATOLOGIC CONTROL WITH RUXOLITINIB IN PATIENTS WITH POLYCYTHEMIA VERA (PV) RESISTANT TO OR INTOLERANT OF HYDROXYUREA

C.N. Harrison[1,*]T. Masszi[2], P. Zachee[3], F. Pane[4], A.M. Vannucchi[5], S. Verstovsek[6], M.M. Jones[7], D.S. Hunter[7], S. He[7], J. Li[8], M. Khan[8], D. Habr[8], J.-J. Kiladjian[9]
[1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [2]St. István and St. László Hospital, Budapest, Hungary, [3]ZNA Stuivenberg, Antwerp, Belgium, [4]University of Naples Federico II, Naples, [5]University of Florence, Florence, Italy, [6]The University of Texas MD Anderson Cancer Cen-

ter, Houston, [7]Incyte Corporation, Wilmington, [8]Novartis Pharmaceuticals Corporation, East Hanover, United States, [9]Hôpital Saint-Louis et Université Paris Diderot, Paris, France

Background: Ruxolitinib (RUX) is a JAK1/JAK2 inhibitor that has shown superiority over standard therapy for the treatment of PV for patients (pts) with an inadequate response to or unacceptable side effects from hydroxyurea (HU). RUX was well tolerated and effective in controlling hematocrit (HCT), decreasing splenomegaly, and improving symptoms. PV is a trilineage disease, and in addition to elevated HCT, pts often have elevated white blood cell (WBC) and platelet (PLT) levels.
Aims: To explore the efficacy of RUX *vs* best available therapy (BAT) in controlling HCT, WBC, and PLT levels in RESPONSE.
Methods: Pts with PV who were HU-resistant/intolerant by modified ELN criteria and required phlebotomy (PBT) for HCT control were randomized 1:1 to RUX 10 mg bid or BAT. The primary composite endpoint was the proportion of pts who achieved HCT control without PBT from wk 8-32 (with ≤1 PBT wk 0-8) and a ≥35% reduction in spleen volume from baseline (BL) at wk 32. Pts on BAT could cross over to RUX after wk 32. In this preplanned analysis of a wk 80 data cutoff, hematologic parameters were assessed by BL level (HCT, >45% and ≤45%; WBC and PLT, by BL quartile [Q1-Q4]).
Results: Pt characteristics (RUX, n=110; BAT, n=112) were well balanced between groups. Median HCT was 43.3% *vs* 44.0% (RUX *vs* BAT); despite having HCT control with PBT within 2 wk of randomization, many pts had HCT >45% at BL (RUX, 25% [n=28]; BAT, 22% [n=25]); PLTs (median, 397 *vs* 444×10^9/L) ranged from: RUX, 100-1852×10^9/L (Q1, 250; Q3, 650); BAT, 78-1604×10^9/L (Q1, 261; Q3, 654); and WBCs (median, 16.5 *vs* 16.3×10^9/L) from: RUX, 3.0-67.0×10^9/L (Q1, 11.1; Q3, 22.5); BAT, 2.9-82.8×10^9/L (Q1, 10.4; Q3, 23.1). At data cutoff, 82.7% of RUX pts remained on treatment and no pts remained on BAT (median exposure, 111 and 34 wk). As previously reported, significantly more RUX pts achieved the primary composite endpoint (21% *vs* 1%; *P*<.0001) and complete hematologic response (CHR) at wk 32 compared with BAT (24% *vs* 9% *P*=.003; Vannucchi *NEJM* 2015). These improvements were durable in RUX pts, with probabilities of 0.96 and 0.69 of maintaining a primary response and CHR at wk 80, respectively. In comparison to BAT pts, more RUX pts achieved WBC ≤10×10^9/L (RUX: BL, 21%; wk 32, 41%; BAT: BL, 21%; wk 32, 31%) and PLT ≤400×10^9/L (RUX: BL, 51%; wk 32, 61%; BAT: BL, 46%; wk 32, 41%). For pts with uncontrolled HCT (>45%) at BL despite PBT (Figure 1A), mean HCT in the RUX arm declined to <45% while mean HCT for BAT-treated pts remained mostly >45% and above RUX-treated pts. For pts whose HCT was <45% at BL, mean values in the RUX arm were also consistently lower than in the BAT arm. Pts with near normal WBC or PLT counts at BL (Q1, Q2) had levels that remained at or near BL values over the course of treatment. For pts with higher WBC or PLT counts at BL (Q3, Q4), mean values improved with RUX and were lower than with BAT. Pts with the highest WBC counts at BL (Q4) had the largest reductions (Figure 1B), with mean values in the RUX arm approximately 15×10^9/L or lower from wk 8 onward and those in the BAT arm >25×10^9/L.

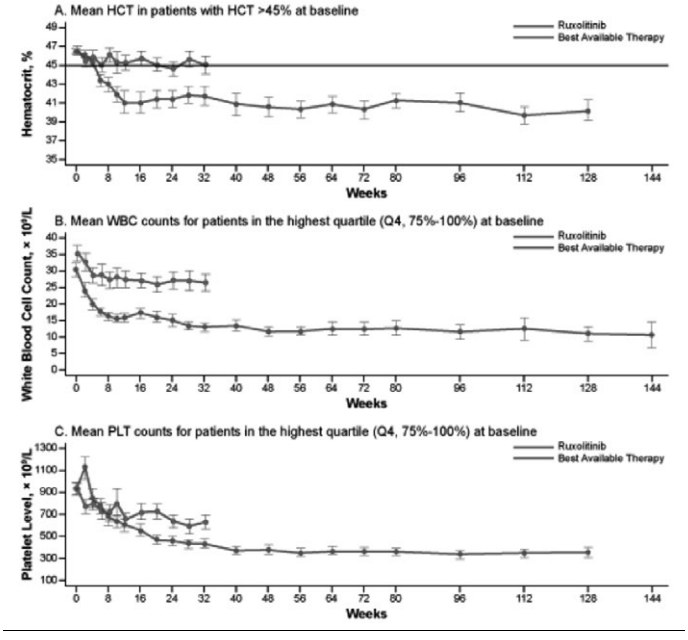

Figure 1. Mean (+/- standard erros) HCT, WBC, and PLT levels by baseline categories and time.

Similar results were seen in pts with the highest PLT counts at BL (Figure 1C), with mean values in the RUX arm reaching <500×10^9/L from wk 20 onward while those in the BAT arm remained elevated.
Summary and Conclusions: In RESPONSE, long-term RUX treatment led to control of HCT, WBC, and PLT levels, with the largest reductions for pts with the most elevated values at BL. RUX provided durable and comprehensive hematologic control in pts with PV who had an inadequate response to or unacceptable side effects from HU.

LB2091

PHASE 1/2, DOSE-ESCALATION STUDY OF ORAL NS-018 IN PATIENTS WITH PRIMARY MYELOFIBROSIS (PMF), POST-POLYCYTHEMIA VERA MF (POST-PV MF), OR POST-ESSENTIAL THROMBOCYTHEMIA MF (POST-ET MF)

T. Uno, S. Verstovsek[1,*] R. Mesa[2], M. Talpaz[3], E. Ritchie[4], M. Wadleigh[5], O.M. Odenike[6], C. Jamieson[7], B. Stein[8]
[1]Department of Leukemia, University of Texas, MD Anderson Cancer Center, Houston, TX, [2]Mayo Clinic, Scottsdale, AZ, [3]Comprehensive Cancer Center, University of Michigan, Ann Arbor, MI, [4]Cornell University, New York, NY, [5]Dana Faber Cancer Institute, Boston, MA, [6]University of Chicago Medical Center, Chicago, IL, [7]Moores Cancer Center, University of California, San Diego, CA, [8]Feinberg School of Medicine, Northwestern University, Chicago, IL, United States

Background: NS-018 is an oral, selective, small molecule inhibitor of Janus kinase 2 (JAK2)
Aims: The purpose of this study is to determine the safety and tolerability of orally administered NS-018 in patients with PMF, post-PV MF, or post-ET MF
Methods: This multicenter, Phase 1/2, 3+3 dose-escalation study of NS-018 enrolled patients with IPSS intermediate-1, intermediate-2, or high risk PMF, post-PV MF, or post-ET MF. Patients were ≥18 years, ECOG PS ≤2 and required therapy. NS-018 was dosed orally QD or BID in 28-day cycles. Responses were assessed according to IWG consensus criteria, changes in spleen size by manual palpation and QOL with the Myelofibrosis Symptom Assessment Form (MF-SAF). The Phase 1 portion of the study is completeand is presented here.
Results: Patients: 48 patients were enrolled across 10 cohorts. Patient characteristics: 37 PMF, 5 post-PV MF, 6 post-ET MF; median age (range) 69.5yrs (38-83); M/F:29/19; 35 JAK2V617F+; and 22 previously treated with a different JAK2 inhibitor. Dosing and tolerability: Dose levels included 75, 125, 200, 300 and 400 mg QD and 100, 200, 250, 300 and 400 mg BID. Systemic exposures based on Cmax were approximately dose proportional across the tested range from 75 to 400 mg. At 400 mg QD/BID, NS-018 was not well-tolerable-based on the proportion of drug-related neurologic AEs. Dizziness (Grade2 and 3), peripheral neuropathy (Grade1), headaches(Grade1), disturbance in attention (Grade1), vertigo (Grade1), dysesthesia (Grade1), and nervous system disorder (Grade1) were observed at 400 mg BID. Dizziness (Grade1 and 3), paresthesia (Grade1), disturbance in attention (Grade1), and aphasia (Grade1) wereobserved at 400 mg QD. At NS-018 doses <400 mg, 300 mg QD was better tolerated than 250 mg or 300 mg BID, with a lower rate of neurologic AEs and discontinuations due to AEs. For the 300 mg QDcohort (n=15), the most frequent drug-related AEs across all grades were decreased platelet count (≥Grade 3, 20%); Grade 3 related AEs were platelet count decreased (13%) and dizziness (7%); and Grade 4 related AEs were platelet count decreased (7%). Overall, 31 patients (65%) discontinued treatment due to AEs (n=9), progressive disease (n=11), MD/patient decision (n=9), or no clinical benefit after 6 cycles (n=2). The AEs leading to discontinuation included thrombocytopenia (Grade 4), transient ischemic attack (Grade 2), muscle contraction involuntary (Grade 2), dizziness (Grade 1), insomnia (Grade 1),neutropenia (Grade 3), electrocardiogram QT prolonged (Grade 3), hemolytic anemia (Grade 3), dizziness (Grade 2), dysphagia (Grade 2), nervous system disorder (Grade 1), and hemolysis (Grade 3). Responses: Of 36 evaluable patients with baseline splenomegaly ≥5 cm and treatment for ≥1 cycle, 20 (56%) patients showed ≥50% reduction in spleen size (confirmed for ≥8 weeks in 16 patients). In addition, 12 patients showed splenic clinical improvement (CI) for ≥8 weeks, 4 patients hemoglobin CI, and 1 patient platelet CI. Median (range) time to splenic response and duration of response: 1 cycle (1-12) and 6 cycles (1-25). Splenic reductions ≥50% are shown in the Table 1 for the specified patient groups. Changes in MF-SAF and PK and PD results will be presented.

Table 1.

	Splenic reduction (in evaluable patients)
All doses	20/36 (56%)
300mg QD	5/9 (56%)
300mg BID	3/6 (50%)
Prior different JAK inhibitor treated	9/19 (47%)

Summary and Conclusions: The RP2D dose was 300 mg QD. This dose provided a durable dosing schedule,an acceptable safety profile,was associated with splenic size reduction and clinical improvement. Phase 2 is ongoing and includes patients previously treated with a different JAK2 inhibitor.

Non-Hodgkin & Hodgkin lymphoma - Biology

XRCC1 399GG GENOTYPE PREDICTS LONG LASTING CR AND SIGNIFICANTLY LONGER OVERALL SURVIVAL IN RESISTANT LYMPHOMA TREATED WITH BENDA-BEAM AND ASCT

G. Visani[1,*]F. Loscocco[1], E. Giacomini[2], A. Ruzzo[2], P.M. Stefani[3], S. Capria[4], P. Galieni[5], F. Gaudio[6], G. Specchia[6], G. Meloni[4], F. Gherlinzoni[3], S. Falcioni[5], R. Gonella[7], M. Gobbi[7], B. Sarina[8], A. Santoro[8], F. Fuligni[9], G. Nicolini[1], F. D'adamo[1], C. Clissa[1], E. Gabucci[1], P.P. Piccaluga[9], M. Magnani[2], A. Isidori[1]
[1]AORMN, Hematology and Stem Cell Transplant Center, Pesaro, [2]Department of Biomolecular Sciences, Section of Biochemistry and Molecular Biology, University of Urbino "Carlo Bo", Urbino, [3]Ca'Foncello Hospital, Hematology, Treviso, [4]Department of Biotechnologies and Hematology, University "La Sapienza", Roma, [5]Ascoli Piceno Hospital, Hematology, Ascoli Piceno, [6]University of Bari Medical School, Division of Hematology, Bari, [7]San Martino Hospital, Hematology, Genova, [8]Department of Oncology and Hematology, Istituto Clinico Humanitas, Rozzano, Milano, [9]Department of Experimental, Diagnostic, and Specialty Medicine, Hematopathology Section, S. Orsola-Malpighi Hospital, Bologna, Italy

Background: We demonstrated (Visani *et al.*, Blood 2011, Blood 2014) the efficacy of a new conditioning regimen with bendamustine, etoposide, cytarabine, and melphalan (Benda-BEAM) prior to autologous stem cell transplant (ASCT) in heavily pretreated lymphoma patients (72% CR at 41 months after ASCT; 3 years PFS 75%). Biological markers predicting response to Benda-BEAM would significantly impact the clinical decision making. Cytotoxic activity of Bendamustine is enhanced by inhibition of the base excision repair (BER) DNA-damage response pathway, suggesting that the BER enzymes play a key role in the repair of DNA damage caused by Bendamustine. Accordingly, we evaluated the impact of the BER family genetic variants, in lymphoma patients receiving the Benda-BEAM conditioning regimen pre-ASCT.
Aims: To evaluate the prognostic significance ofxRCC1 G399A,xRCC3 C241T and ADPRT T2444C non-synonymous genetic variants on clinical outcome of Hodgkin (HD) and non-Hodgkin (NHL) lymphoma patients treated with BeEAM-ASCT.
Methods: All 43 patients with resistant/relapsed NHL (n=28) or HD (n=15), enrolled in the clinical trial (EUDRACTnumber2008-002736-15), were analyzed. Peripheral blood samples were available for somatic DNA extraction and genotyping analysis. Three Single Nucleotide Polymorphysms (SNPs) of BER genes [XRCC1 399 (rs25487 G/A, Arg/Gln),xRCC3 241 (rs861539 C/T, Thr/Met), ADPRT T2444C (rs1136410 T/C, Val/Ala)] were analyzed by PCR-HRM (High Resolution Melting) assay and restriction digests of PCR products. X^2 test and Fisher's exact test were used to analyze the association between the pathological features and SNPs. All the candidate genotypes were evaluated to identify a potential correlation with overall survival (OS) using long-rank test and Cox regression model. For all the target genes, the distribution of genotypes was checked for Hardy-Weinberg equilibrium.
Results: In univariate analysis, thexRCC1 399 GG andxRCC3 241 TT genotype were associated with significantly longer overall survival (OS), if compared with the other genetic variants (p=0.035, p=.0.025). Multivariate analysis confirmed the prognostic role ofxRCC1 GG on OS (p=0.005). Interestingly, all patients carryingxRCC1 399 GG genotype reached CR, independently from the disease type (HD and NHL), thus suggesting a possible positive predictive role for thexRCC1 399 GG genotype in influencing both CR and OS of heavily pretreated lymphoma patients. On the other hand, CR rate for patients bearing thexRCC1 399 AA or GA genotype were 75% and 84%, respectively. Analyzing pre-treatment features and genetic variants, we observed that patients carrying the ADPRT 2444 CC or CT genotype had a chemoresistant disease, whereas with TT genotype had a chemosensitive disease. Interestingly, the disease status at transplant was a strong predictor of both PFS and OS in the clinical trial. On the other hand, no association was found between the disease type or others clinical features and SNPs in BER genes.
Summary and Conclusions: xRCC1 399GG genotype is predictive for longer duration of overall survival in lymphoma patients treated with Benda-BEAM conditioning pre-ASCT. Moreover, the presence ofxRCC1 399 GG genotypes was associated with the achievement of CR in 100% of patients carrying this genotype.xRCC1 399 genotype could, thus, represent a biomarker in patients with lymphoma, treated with Bendamustine BEAM regimen and ASCT.

FUNCTIONAL DEFECTS OF T CELLS OF LYMPHOMA PATIENTS AFTER DIFFERENT CHEMOTHERAPY REGIMENS ACTIVATED BY THE BISPECIFIC ANTIBODY AFM11

J. Düll[1,*] L. Rasche[1], H. Einsele[1], M. Topp[1]
[1]Medizinische Klinik II, Hämatologie, Würzburg, Germany

Background: Patients who suffer from hematological malignancies like B cell lymphoma have to undergo chemotherapy. There is a high risk for a relapse or

a refractory disease for older patients and patients suffering from MCL. Unfortunately, there are only poor options for younger patients after autologous Stx transplantation and for older patients who are not eligible for transplantation. In this situation new immunotherapy and antibodies gain in importance. One of them is the bispecific T cell engager CD19-CD3 antibody AFM11. The T cells system of the patients seems to play a critical role in response or non-response to T cell engaging antibodies.
Aims: We try to evaluate the T cell system of the patients after chemotherapy (R-Benda, R-CHOP, HD-BEAM). As a preclinical study we explore the potential of the TandAb antibody AFM11 in heatlhy donors and lymphoma patients to describe the function and possible defects of patients T cells after chemotherapy.
Methods: We examine the blood of 32 patients with different lymphoma and chemotherapies 6 weeks after their last chemotherapy. 17 healthy donors donated blood for the control group. The lymphocytes are analyzed by multicolor FACS staining. Absolut cell counts are calculated by the percentages in the lymph gate in relation to the lymphocytes absolute number in the central lab. For quantification of cytokines of the AFM11 engaged T cells CBA technology was used. Proliferation assays were performed with CFSE dilution technique. For lytic activity a FACS based lysing assay was performed with Annexin and PI readout. The effector to target ratio was decreased for higher sensitivity of this assay to a ratio of 1:25 (E:T).
Results: A full immune recovery of the immune system of lymphoma patients six weeks after chemotherapy is not verifiable. We find less CD3 cells (median 200 cells/µl -chemo group *vs* 1200cells/µl-healthy), NK cells (median 48-chemo group *vs* 222 cells/µl-helathy) and no B cells in comparison to healthy donors. Regulatory T cells-known as suppressor cells- are much higher in the R-Bendamustin and HD-Beam group. These findings can be relevant for the treatment of patients with a T cell engaged antibodies like bispecific antibodies with one CD3 component. To clarify the function of the T cells we performed standardized T cell assays with AFM11. There is no difference between healthy donors and patients regarding the proliferation of T cells after AFM11 activation. T cells of patients after R-CHOP and HD BEAM therapy produce high amounts of IL10 (average: 30pg/ml) in comparison to the R-Benda group (average: 10pg/ml). The IL2 production of patients T cells treated with R-Bendamustin and HD -BEAM was reduced from 700pg/ml (healthy donors and R-CHOP) to 300pg/ml. The specific lyse is 25% reduced in patients after chemotherapy without any significance difference in the subgroups of the different chemotherapy protocols. To investigate differences between the subgroups and for a better sensitivity of the lysing assay we decreased the effector to target ratio from 1:2 to 1:25. With this step we see reduced lysing capacity of patients T cells after R-Bendamustin and HD BEAM treatment.
Summary and Conclusions: T cells of lymphoma patients after different chemotherapy regiments are reduced and have functional defects. This may affect the *in vivo* response to bispecific antibodies like AFM11. If this findings correlate with the *in vivo* response will be evaluated in an ongoing phase I trial with AFM11 in lymphomas.

DESIGN AND DEVELOPMENT OF A NOVEL, HIGHLY POTENT AND SELECTIVE PI3K-DELTA INHIBITOR, CPL-302-215, AS POTENTIAL TREATMENT OF HEMATOLOGIC MALIGNANCIES

A. Stanczak[1,*] B. Dymek[1], P. Turowski[1], P. Gunerka[1,2], M. Zagozda[1], M. Dziachan[1], M. Sekular[1], M. Szydlowski[3], E. Bialopiotrowicz[3], P. Juszczynski[3], J. Hucz-Kalitowska[1], K. Dubiel[1], M. Wieczorek[1]
[1]Innovative Drugs R&D Department, Celon Pharma S.A., Kielpin Lomianki, [2]Department of Medical Biotechnology, Medical University of Lodz, Lodz, [3]Dept. of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: The phosphatidylinositol-3-kinase δ (PI3Kδ) has emerged as a promising target for the treatment of many hematological malignancies, such as chronic lymphocytic leukemia (CLL) and non-Hodgkin lymphomas (NHL). Recent clinical trials have demonstrated that Idelalisib, a specific PI3Kδ inhibitor, achieved significant antitumor activity in CLL and NHL. However, Idelalisib can have serious side effects, *i.e.* hepatotoxicity, severe diarrhea or colitis, pneumonitis, and intestinal perforation. Therefore, there is an urgent need to develop PI3Kδ inhibitors which entail diminished adverse events.
Aims: The aim of the study was to investigate the therapeutic potential of a novel PI3Kδ inhibitor CPL-302-215 in hematologic malignancies.
Methods: Using knowledge-based drug design approach we have designed a novel small molecule PI3Kδ inhibitor, CPL-302-215, structurally different from other known δ-selective inhibitors. To establish the activity and the selectivity of the compound among class I of PI3K lipid kinases and selected protein kinases, we have used kinase activity assay, ADPGlo™. Additionally, the biological potency and selectivity of a developed inhibitor was evaluated in a cell viability assays and Western blot analysis in a number of hematological cell lines. Finally, using an *in vivo* mouse model a bioavailability, as well as microsomal stability was assessed.
Results: Our results indicate that CPL-302-215 inhibits PI3Kδ kinase with low nanomolar concentrations (IC_{50}=5,3nM) comparable to Idelalisib (IC_{50}=4,1nM). Additionally, CPL-302-215 exhibits exceptional selectivity over γ, β and α isoforms of PI3K (2080, 2000, and 63-fold, respectively) in comparison to Idelalisib (27, 100 and 117-fold, respectively). Moreover, CPL-302-215 does not inhibit protein kinases from the Celon Pharma's selectivity panel at the concentration of 1µM. In cell-based viability assays CPL-302-215 inhibits some NHL cell lines. Western blot analysis has shown that CPL-302-215 significantly inhibits phosphorylation of Akt in Raji cell line after anti-IgM stimulation (IC_{50}<50nM). Additionally, in a PI3Kγ-specific cell line RAW 264.7, compound selectivity has been confirmed by showing no effect on Akt phosphorylation after C5a stimulation up to the concentration of 5µM in opposite to Idelalisib which reduced phosphorylation of Akt in 5µM. Analysis on microsomes (mouse, rat, dog and human), showed that CPL-302-215 is showing virtually no CYP-mediated metabolism. Therefore, a pharmacokinetics study was conducted to characterize CPL-302-215 disposition in mice plasma. Orally (30mg/kg) and intravenously (10mg/kg) administered CPL-302-215 displayed attractive bioavailability and reached appreciably high concentrations in plasma (p.o. AUC=5,157µg/ml*h^{-1}, Tmax=0,5h, Cmax=3,038µg/ml; i.v. AUC=2,492µg/ml*h^{-1}, Cmax=1,053µg/ml; F=82,82%). Currently, the therapeutic potential of CPL-302-215 on primary cells from CLL patients is being evaluated.
Summary and Conclusions: We have designed CPL-302-215-a very potent and selective PI3Kδ inhibitor, both in the kinase- and cell-based assays. Preclinical data from NHL cell lines indicate the therapeutic potential of CPL-302-215 in hematologic malignancies. Moreover, our compound is very stable on various species and has attractive bioavailability in mice. The activity and unique selectivity of CPL-302-215 qualifies it for the consideration as a drug with wide therapeutic window and limited side effects in clinical use.

E1357

NR4A1 AND NR4A3 POSSESS FUNCTIONAL REDUNDANCY BY REGULATING PRO-APOPTOTIC GENES IN AGGRESSIVE LYMPHOMAS.

A. Deutsch[1,*] B. Rinner[2], K. Wenzl[1], K. Troppan[1], B. Pursche[1], C. Beham-Schmid[3], P. Neumeister[1]
[1]Hematology, Internal Medicine, MUG, [2]ZMF, MUG, [3]Hematolpathology, Pathology, MUG, Graz, Austria

Background: Recently, we described a significant down-regulation of NR4A1 (Nur77) and NR4A3 (Nor-1) -two members of the orphan nuclear receptors acting together as critical tumor suppressor genes in acute myeloid leukemia- in aggressive lymphoma. NR4A1 over-expression proved its pro-apoptotic function in aggressive lymphoma cells and its lymphoma suppressive properties *in vivo* was demonstrated in axenograft mouse model.
Aims: Since the role of down-regulated NR4A3 in aggressive lymphomas is unknown, we aimed to investigate the function of NR4A3 in lymphoid malignancies.
Methods: For functional characterization NR4A3 was over-expressed in a SuDHL4 lymphoma cell line by using an inducible lentiviral construct followed by various apoptotic assays and by axenograft mouse experiment. To further compare the transcriptional activity as nuclear receptor of NR4A3 to NR4A1, both receptors were separately over-expressed in aggressive lymphoma cell lines (Karpas-422 and SuDHL4 as GCB- cell line, RI-1 and U2932 as ABC-cell lines) followed by mRNA expression analysis of intrinsic (BIK, BID, BMF, Noxa, BAK, Bax, Puma, Bim, Bcl-2, Bcl-X and Mcl-1) and extrinsic (FasL, Fas, Trail, DR4 and DR5) apoptotic genes.
Results: Induction of NR4A3 expression led to a significantly higher proportion of induced SuDHL4 cells undergoing apoptosis as demonstrated by DNA cleavage, Annexin V staining and increased caspase 3-7 activity suggesting functional redundancy to NR4A1 in aggressive lymphomas. To test the tumor suppressor function of NR4A3 *in vivo*, the stably transduced SuDHL4 lymphoma cell line was further investigated in the NOD scid gamma (NSG) mouse model. Induction of NR4A3 in SuDHL4 abrogated tumor growth in the NSG mice, in contrast to vector control- and uninduced SuDHL4 cells, which formed massive lymphoid tumors. Interestingly, mRNA expression analysis of apoptotic genes in aggressive lymphoma cells demonstrated that NR4A1 and NR4A3 over-expression induced Trail, Bim, Puma, BIK, BID and BAK in a similar pattern.
Summary and Conclusions: Our data demonstrate that NR4A3 has pro-apoptotic properties which are functionally redundant to NR4A1 and define NR4A3 as novel tumor suppressor in aggressive lymphomas.

CD3+/CD8+/CD16+/CD56-/CD57+ T-LGLL REPRESENTS A DIFFERENT SUBSET WITH DISTINCT CLINICAL AND BIOLOGICAL FEATURES

G. Barilà[1,2,*] A. Teramo[1,2], G. Calabretto[1,2], C. Ercolin[1,2], A. Cabrelle[2], E. Boscaro[1], M. Facco[1,2], F. Piazza[1,2], L. Trentin[1,2], G. Semenzato[1,2], R. Zambello[1,2]
[1]Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, [2]Venetian Institute of Molecular Medicine, Padua, Italy

Background: T-Large Granular Lymphocyte Leukemia (T-LGLL) is a chronic and heterogeneous lymphoproliferative disorder characterized by clonal expansion of CD3+ Large Granular Lymphocyte (LGL) with effector memory phenotype (CD3+/CD8+/CD57+/CD45RA+/CD62L-), although rare forms of CD4+ LGLL are described and characterized by CD4+/$CD8^{-/dim}$ expression. Most patients present an indolent course but can become symptomatic due to the

development of cytopenia, in particular neutropenia. At last, somatic activating STAT3 mutations were discovered in approximately 30-40% of T-LGLL patients.
Aims: Aim of this study is the characterization of different clinical and biological features of T-LGLL patients through evaluation of clinical, namely the presence of neutropenia, and biological features including phenotypic analysis, the presence of STAT3 mutation, activation and expression of its target Mcl-1.
Methods: In 87 patients with diagnosis of T-LGLL, LGLs were analysed for the presence of neutropenia and by flow cytometry using antibody for CD3, CD4, CD8, CD16, CD56, CD57; DNA samples from these 87 patients were available for STAT3 mutation analysis through Sanger sequencing and PCR ARMS for Y640F and D661Y mutations. Western Blotting analysis for pSTAT3 Tyr 705, STAT3 and Mcl-1 level was performed.
Results: A cohort of 87 patients affected by T-LGLL was studied by FACS analysis; 56/87 (64%) patients were CD3+/CD4-/CD8+ T-LGLL (CD8+ T-LGLL) while 31/87 (36%) patients were CD3+/CD4+/CD8$^{-/dim}$ T-LGLL (CD4+ T-LGLL). STAT3 exon 21 somatic mutation analysis with Sanger sequencing and PCR ARMS analysis was then performed and 30 out of 87 (34%) patients resulted mutated (21 with Y640F, 7 with D661Y, 1 with D661V and 1 with N647I). All mutated patients were in CD3+/CD4-/CD8+ group while all CD3+/CD4+/CD8$^{-/dim}$ patients resulted wild type. Additional FACS analysis with CD16, CD56 and CD57 antibodies was performed in CD3+/CD4-/CD8+ cohort identifying four distinct subgroups: CD16+/CD56-/CD57±subgroup (33/56, 59%), CD16-/CD56-/CD57+ subgroup (5/56, 9%), CD16-/CD56+/CD57+ subgroup (15/56, 27%) and CD16+/CD56+/CD57+ (3/56, 5%). Interestingly, 27/28 mutated patients were in the CD16+/CD56-/CD57±subgroup while only one mutated patient fall in the CD16-/CD56-/CD57+ subgroup. Patients with CD3+/CD8+/CD16+/CD56-/CD57±phenotype presented higher level of pSTAT3 Tyr705 than other CD8+ T-LGLL and CD4+ T-LGLL patients, but not significantly differences in STAT3 and Mcl-1 level were found. Finally, mean ANC (absolute neutrophil count) in CD3+/CD8+/CD16+/CD56-/CD57±was significantly lower than the remaining CD8+ and CD4+ patients (800±547 *vs* 2744±1046, p<0,01).
Summary and Conclusions: In conclusion, a subgroup of patient characterized by high frequency neutropenia, STAT3 exon 21 mutation and STAT3 activation has been identified among the whole population of CD3+/CD8+/CD16+/CD56-/CD57±T-LGLL. Interestingly, no significant differences in STAT3 level and his downstream target Mcl-1 were found among different cell subsets. Taken together, these data may suggest a causal relationship between STAT3 mutation and activation and the development of neutropenia. Further studies are in progress to clarify the pathways involved in this setting.

E1359

STAT5B MUTATION ANALYSIS IN A COHORT OF T-LGL LEUKEMIA PATIENTS

A. Teramo[1,2,*] G. Barilà[1,2], A. Cabrelle[2], G. Calabretto[1,2], C. Ercolin[1,2], E. Boscaro[1], S. Teolato[1], E. Pagnin[1], M. Facco[1,2], L. Trentin[1,2], G. Semenzato[1,2], R. Zambello[1,2]
[1]Department of Medicine, Hematology and Clinical Immunology Branch, University of Padova, [2]Venetian Institute of Molecular Medicine (VIMM), Padova, Italy

Background: T-cell large granular lymphocyte (T-LGL) leukemia is a heterogeneous disorder characterized by chronic expansion of cytotoxic T lymphocytes. The World Health Organization (WHO) recognizes within its classification only the indolent T-LGL leukemia (T-LGLL). However, several cases of aggressive T-LGLL have been reported, presenting symptoms of acute illness, hepatosplenomegaly, lymphadenopathy, lymphocytosis, anemia or thrombocytopenia. In these cases leukemic LGLs typically displayed a CD3+/CD8+/CD56+ immunophenotype. Recently, activating STAT mutations have been discovered in T-LGLL patients, STAT3 mutations in 30-40% of T-LGLL indolent patients, while STAT5b mutations were found only in very few cases, but these latters being more frequently detectable in patients with severe clinical course.
Aims: We analyzed STAT5b mutation frequency in a series of 52 patients affected by T-LGLL, with the aim to characterize the associated clinical and biological features.
Methods: Immunophenotypic characterization was obtained by flow cytometer analysis. STAT3 and STAT5b mutations were analyzed by Sanger sequencing. FACSAria cell sorter was used to purify T-LGLs depending on their cell surface markers. T-cell Receptor rearrangement was analyzed on DNA by PCR. Activation of STAT3 and STAT5b was evaluated by Western Blot analysis.
Results: Fifty-one patients showed the classical indolent T-LGLL, with neutropenia, as the relevant clinical feature in 15 patients. One case showed an aggressive clinical course presenting high leucocytosis with a doubling time of 4 weeks, fatigue and moderate hepatosplenomegaly; no neutropenia were present at the diagnosis. Mutation analysis did not reveal any STAT5b mutations in all the indolent T-LGLL. On the other hand, two STAT5b mutations (N642H and Y665F) were demonstrated in the aggressive case of T-LGLL. STAT5b mutations resulted mutually exclusive with STAT3 mutations, reported in 17 cases. By Flow analysis, all the patients with indolent T-LGLL have a LGL clone expressing CD57 antigen. In STAT5b mutated patient proliferating cells were CD3+/CD8+/CD56+/CD57-ve. By selecting for CD16 and CD158b antigens expression in LGLs of this patient, three LGL subsets were recognized, namely a) CD158b+/CD16-, b) CD16+/CD158b- and c) CD16-/CD158b- subsets. Performing mutation analysis on sorted cells, CD158+/CD16- cell subset resulted STAT5b wild type, CD16-/CD158b- subset showed both N642H and Y665F mutations and the small CD16+/CD158- subpopulation carried Y665F mutation. By evaluation of TCR rearrangement, all the three LGL populations were found monoclonally rearranged. As expected, we found that patient's LGLs displayed low level of STAT3 activation and very high level of STAT5b activation as compared to indolent T-LGLL cases, leading to an increased transcription of Bcl-xl.
Summary and Conclusions: In this report we demonstrated for the first time the presence of intraclonal heterogeneity in a patient with aggressive STAT5b mutated LGL leukemia, characterized by one immunodominant STAT5b mutated clone coexisting with additional smaller LGL expansions showing different pattern of STAT5b mutation. The tight link between STAT5b mutations and the aggressive form of T-LGLL supports the importance of STAT5b mutations in the pathogenesis of this disease and indicates a new potential target for the therapy of the aggressive T-LGLL.

E1360

B-CELL CLONALITY IN BONE MARROW IS PREDICTOR OF OUTCOME IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS TREATED WITH HIGH-DOSE CHEMOTHERAPY

O. Gavrilina[1,*] E. Zvonkov[2], E. Parovichnikova[1], A. Kovrigina[3], E. Nikulina[4], A. Sudarikov[4], Y. Sidorova[4], N. Gabeeva[2], S. Kravchenko[5], S. Kulikov[6], V. Savchenko[1]
[1]Department of Hematological Oncology and BMT, [2]Department chemotherapy of lymphomas, [3]Department of pathology, [4]Laboratory molecular hematology, [5]Departmen of chemotherapy, [6]Biostatistics department, National Research Center for Hematology, Moscow, Russian Federation

Background: Bone marrow involvement (BM) is a factor of poor prognosis for diffuse large B-cell lymphoma (DLBCL). Bone marrow involvement is a poor prognostic factor for patients treated with CHOP-like and with high-dose chemotherapy. Bone marrow involvement in DLBCL by histology is detected in 10-30% patients. The importance of B-cell clonality examination in bone marrow as a prognostic and staging factor has not been yet described in the literature.
Aims: To evaluate the significance of the clonal immunoglobulin heavy chain gene rearrangement analysis performed by PCR for identification of the bone marrow involvement frequency and its value for staging and prognosis in patients with d*e novo* DLBCL treated with high-dose chemotherapy (HDC).
Methods: We performed a retrospective analysis, including 113 adult patients (median age 45 years, range 17-69) with newly diagnosed DLBCL who were enrolled in HDC protocol (mNHL-BFM-90 program or scheme R-DA-EPOCH/R-HMA) since June 2007 till January 2015. 54 of the 113 patients had a GCB and 59-non-GCB phenotype; 23 pts (20%) had low IPI risk, 26 pts (23%) had low-intermediate, 25pts (22%) had high-intermediate, 39 pts (35%) had high risk. B-cell clonality was evaluated using PCR amplification by IGH (FR1, FR2, FR3) and IGK (Vκ-Jκ, Vκ/intron-Kde) gene rearrangements with multiplex BIOMED-2 primer sets and subsequent fragment analysis using ABI PRISM 3130 Genetic Analyzer (Applied Biosystems).
Results: In 28 out of 113 patients, bone marrow involvement (25%) was revealed: in 15 patients bone marrow involvement was identified by histological examination and in 13 patients only by clonality of bone marrow. 13 patients with only B-cell clonality in bone marrow were classified by IPI: 3 (23%) patients had high IPI, 7 (54%) patients-high-intermediate IPI and low-intermediate IPI-3 (23%) patients. So, in 9% patients had to change the risk group according to bone marrow involvement. In group of patients with only B-cell clonality in bone marrow (13 patients), we performed immunohistochemical examination of bone marrow trephine biopsy. In 7 (54%) of 13 cases we detected small number of CD20+ tumor cells in bone marrow, in other 6 cases we didn't prove bone marrow involvement by this examination. Univariate analysis of the entire cohort (n=113) revealed that age, IPI, extranodal involvement and phenotype were not of prognostic significance (p >0.05), but b-cell clonality in bone marrow was (p=0.05). In multivariate analysis, detection of B-cell clonality in bone marrow was an independent predictor of OS and relapse-free survival (RFS) (p ≤0.05). (Figure1A,B). OS, RFS in patients with histological detection bone marrow involvement and with only B-cell clonality in the bone marrow did not differ.

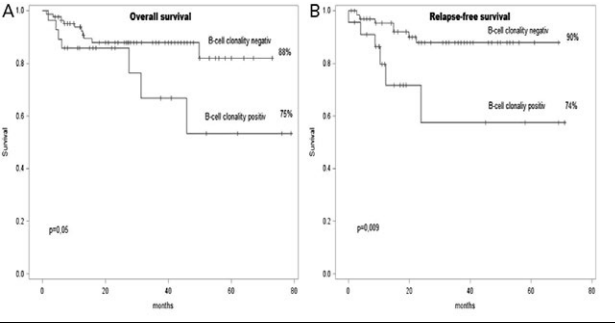

Figure 1.

Summary and Conclusions: Detection of B-cell clonality in the bone marrow seems to be an independent predictor of outcome in *de novo* DLBCL pts, treated with high-dose chemotherapy, while IPI and phenotype DLBCL cannot be considered as risk factors for this group of patients. It seems reasonable to include the detection of bone marrow B-cell clonality at primary diagnostics of the DLBCL for staging and predicting response in HDC.

E1361

SILENCING PROGRESSION OF TUMOR SUPPRESSIVE MICRORNAS ESSENTIALLY CONTRIBUTES TO DEVELOP AGGRESSIVE T-CELL LYMPHOMA

A. Kitadate[1,*] S. Ikeda[1], M. Ito[1], K. Teshima[1], N. Hasunuma[2], N. Takahashi[1], A. Komatuda[1], T. Miyagaki[3], M. Sugaya[3], H. Tagawa[1]
[1]Department of Hematology, Nephrology, and Rheumatology, Akita University Graduate School of Medicine, [2]Department of Dermatology, Akita University, Akita, [3]Department of Dermatology, Tokyo University, Tokyo, Japan

Background: Multistep genetic alterations including microRNA(miRNA/miR) are occurring during developing aggressive cancer. We have shown that some tumor suppressive miRNAs including miR-150 and miR-16 were diminished in metastatic cutaneous T-cell lymphoma (CTCL), and that miR-150 could inhibit invasion and metastasis of CTCL cells by targeting a chemokine receptor CCR6 (Blood 2014). Furthermore, we recently found that when examined expression of these miRNAs against early and advanced CTCL, miR-150 and miR-16 were decreased during disease progression. These findings suggest that dysregulation of these miRNAs is deeply associated with the pathogenesis of early to advanced CTCL.
Aims: The aim of this study was to determine the possible role of miR-16 and miR-150 in the CTCL progression.
Methods: CTCL cell lines (My-La, HH, MJ, and Hut78) were employed for this experiment. We established a mouse model which died after day 30-35 after transplantation of CTCL cells into NOD/Shi-scid IL-2γnul(NOG) mouse due to tumor cell invasion and metastasis, namely "CTCL mouse". For *in vivo* administration of miRNA, miR-150 and/or miR-16 plus atelocollagen was injected into tail vein of CTCL mice after day14 from CTCL cell transplantation. Injection was conducted by every 5 days.
Results: Firstly we examined *in vivo* transplantation of miR-16, miR-150 stably transduced CTCL cells into NOG mice, and found that not only miR-150 but also miR-16 transduced CTCL cells injected NOG mice showed significant survival extentions than control mice. Interestingly, miR-16 transduced showed stronger tumor inhibition capability than miR-150 transduced, despite of lacking migration-inhibition capability. This result suggests that miR-16 might possess the other tumor suppressive function. Therefore we conducted functional analysis of miR-16, and found that miR-16 could lead to strong cellular senescence against CTCL cells. In miR-16 transduced CTCL cells, p21, which is a key mediator of senescence, was strongly up-regulated in a p53 dependent manner. Because it has been known that Bmi-1 negatively regulates not only p16 but also p21, we examined Bmi-1 expression against miR-16 transduced CTCL cells and found its down-regulation. This result suggested that miR-16 directly regulate Bmi-1 against CTCL cells leading to p21 up-regulation. To examine whether Bmi-1 could directly interact promoter region of *CDKN1A/p21* gene, we conducted cross-linking/chromatin immunoprecipitation (ChIP) assay against CTCL cells, and demonstrated the direct interaction. To examine whether miR-150 and/or miR-16 could lead tumor inhibition *in vivo*, we conducted intravenous administration of these miRNAs against CTCL mice. Though administration of either miR-16 or miR-150 extended survival of CTCL mice, use of both miR-150 and miR-16 yielded to the most survival extension because miR-150 and miR-16 cooperatively can inhibit distinct tumorigenic cascades of CTCL. Finally, we found that a histone deacetylase inhibitor, vorinostat/SAHA, led CTCL cells to induce senescence and migration inhibition with restoration of both miR-150 and miR-16, and their target proteins.
Summary and Conclusions: miR-150 and miR-16 collaborate to inhibit tumorigenic potential via down-regulating distinct tumor-associated cascades. Our findings suggest that miR-150 and miR-16 could be, at least in part, epigenetically silenced during disease progression and their restoration as well as vorinostat treatment could be key therapeutic strategy against CTCL.

E1362

AKT GENE EXPRESSION IS REGULATED BY THE AP-1 TRANSCRIPTION FACTORS JUNB AND CJUN IN ALK+ ANAPLASTIC LARGE CELL LYMPHOMA (ALCL): A NOVEL CROSSTALK MECHANISM

G. Rassidakis[1,*] V. Atsaves[2], R. Zhang[2], D. Ruder[2], Y. Pan[2], V. Leventaki[3], F.X. Claret[4]
[1]Pathology and Cytology, Karolinska University Hospital & Karolinska Institute, Solna, Stockholm, Sweden, [2]Systems Biology, The University of Texas M.D. Anderson Cancer Center, Houston Texas, [3]Pathology, St. Jude Children's Research Hospital, Memphis, TN, [4]Systems Biology, The University of Texas M.D. Anderson Cancer, Houston Texas, United States

Background: Anaplastic lymphoma kinase-positive (ALK+) anaplastic large cell lymphoma (ALCL) is an aggressive T-cell non-Hodgkin lymphoma type characterized by the t(2;5) resulting in overexpression and activation of the NPM-ALK oncogenic kinase. The NPM-ALK is known to activate multiple signaling pathways including the phosphatidylinositol-3-kinase (PI3K)/AKT/mTOR and the JAK/STAT3 pathways resulting in cell cycle and apoptosis deregulation. ALK+ ALCL is also characterized by strong AP-1 activity and overexpression of two AP-1 transcription factors, CJUN and JUNB, which are upregulated by NPM-ALK, and further contribute to ALCL oncogenesis.
Aims: We hypothesized that a biologic link between AP-1 activity and AKT kinase may exist, which operates in ALK+ ALCL. Therefore, the purpose of this study was to identify specific interactions of two AP-1 transcription factors, JunB and cJun, with AKT1 gene promoter in ALK+ ALCL and in non cancerous cell systems. In addition the biologic effects of AP-1 transcriptional control on AKT gene were analyzed.
Methods: Three ALK+ ALCL cell lines (Karpas 299, SR-786 and SUP-M2), as well as Jurkat and HEK293T cells were used in the study. AKT1 gene promoter was analyzed using chromatin immunoprecipitation (ChIP), site-directed mutagenesis, gene reporter assays and transient transfections. JunB and cJun genes were knocked down using specific siRNA constructs. Quantitative real-time RT-PCR and Western blotting were used to assess RNA and protein levels. Cell proliferation, cell viability and colony formation assays were also applied following gene silencing or pharmacologic inhibition studies.
Results: Using ChIP, reporter assays and site-directed mutagenesis, we show that JUNB and cJUN bind directly to the *AKT1* promoter at specific AP-1 binding sites, thus inducing *AKT1* transcription in ALK+ ALCL. Knockdown of JUNB and CJUN in ALK+ ALCL cell lines downregulated *AKT1* mRNA and promoter activity and was associated with lower AKT1 protein expression and activation. Of note, JUNB and CJUN seem to cooperate for the transcriptional regulation of AKT1 gene. We also provide evidence that this is a transcriptional control mechanism shared by other cell types even though it may operate in a way that is cell context specific. In addition, STAT3-induced control of *AKT1* transcription was functional in ALK+ ALCL and blocking of STAT3 and AP-1 signaling synergistically affected cell proliferation and colony formation.
Summary and Conclusions: Our findings uncover a novel transcriptional crosstalk mechanism that links AP-1 and AKT kinase, which coordinate uncontrolled cell proliferation and survival in ALK+ ALCL. These mechanisms may confer resistance to chemotherapy.

E1363

IDENTIFICATION OF LEUKEMIC STEM CELL CANDIDATES IN AN ATL MOUSE MODEL OF HBZ TRANSGENIC MICE

W. Kuribayashi[1,2,*] T. Mizukami[1], K. Takizawa[1], K. Sugata[3], M. Kuramitsu[1], K. Nozima[1], H. Momose[1vY]. Asada[4], A. Iwama[2], M. Matsuoka[3], I. Hamaguchi[1]
[1]Department of Safety Research on Blood and Biological Products, National Institute of Infectious Diseases, Tokyo, [2]Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Chiba, [3]Laboratory of Virus Control, Institute for Virus Research, Kyoto University, Kyoto, [4]Faculty of Pharmaceutical Sciences, Tokyo University of Science, Chiba, Japan

Background: Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus type 1 (HTLV-1). Only about 2-5% of HTLV-1-infected patients will develop ATL, and the response to chemotherapy is extremely poor because of intrinsic or acquired drug resistance. Thus, we hypothesized the existence of chemotherapy resistant leukemic stem cells (LSCs) in ATL. Recently, LSCs with characteristics of self-renewal, tumorigenicity, multipotency, asymmetric division, and drug- resistance were identified and characterized in various types of solid tumors and leukemias. We have previously identified ATL stem cell candidates in an ATL model using Tax transgenic (Tax-Tg) mice (Yamazaki *et al.*, Blood 2009). It has been shown that the HTLV Tax protein is crucial to initiate malignant transformation and spreading of ATL. Recently, HTLV-1 bZIP factor (HBZ) was also identified as an important factor in the development of ATL. HBZ transgenic (HBZ-Tg) mice also show ATL-like lymphoma/ leukemia and are thought to be an ATL model mouse (Satou *et al.*, PLoS Pathog, 2011).
Aims: We aimed to identify and characterize ATL stem cells in the HBZ-Tg mouse and compare their properties with ATL stem cells in the Tax-Tg mouse to clarify the clonal evolution of ATL stem cells and molecular mechanisms underlying ATL development and drug resistance.
Methods: We isolated and characterized splenic lymphomatous cells (named Ht48) derived from HBZ-Tg mice, transplanted 1×10^7 Ht48 cells intraperitoneally into C57BL/6 mice to assess tumorigenicity. Then, we performed forescence activated cell sorting (FACS) of Ht48 cells, and tested proliferative activity both *in vivo* and *in vitro* analyseslu.
Results: The transplanted mice showed massive splenomegaly and died within 25 days. The ATL cells had infiltrated into multiple tissues such as spleen, liver, and ovary. To evaluate serial transplantability of Ht48 cells, we performed nine consecutive serial transplantations. Ht48 cells regenerated the ATL-like disease and regained the original phenotypes ($CD4^-CD8^-/CD4^-CD8^+/CD4^+CD8^+$) after each transplantation. Next, we performed side population (SP) analyses to identify drug resistance. SP cells with high drug

resistance existed among Ht48 cells. Interestedly, more than 40% of c-kit+ cells were enriched with SP cells, while less than 5% of c-kit+ cells compared the other population. As expected, both SP and c-kit+ cells showed a high proliferative activity *in vitro* and *in vivo*, and these cells could differentiate into all lineages of ATL cells *in vivo*. These results suggest that c-kit expression is important to maintain ATL stem cell functions such as drug resistance and high tumorigenicity in Ht48 cells. To characterize ATL stem cells in detail, we divided c-kit+ cell fractions into four subpopulations and cultured the cells for six days to clarify which population of c-kit+ cells are LSCs. We found c-kit+/CD4-/CD8- cells possessed higher proliferative activity than any other subpopulation. In addition, a neutralizing antibody against c-kit ligand (SCF) inhibited ATL stem cell proliferation *in vitro*. ATL stem cell candidates gave rise to all cell types in Ht48 cells *in vivo*. These data indicated that ATL stem cells require an extrinsic signal from the niche to differentiate into all types of ATL cells. Finally, we performed comprehensive gene expression analyses of ATL stem cells in both HBZ- and Tax-Tg mice and identified some candidate genes that can trigger and maintain LSC development.
Summary and Conclusions: We identified ATL stem cell candidates in HBZ-Tg mice, and c-kit plays a key role in maintenance of LSCs and tumor development in a mouse model of ATL.

E1364

A NEW MOUSE MODEL FOR MATURE B-CELL LYMPHOMA REVEALING REQUIREMENT FOR FAS DOWNREGULATION IN LYMPHOMAGENESIS
E. Sugihara[1,*] N.H.[1], S. Ueno[1], H. Saya[1]
[1]Division of Gene Regulation, Institute for Advanced Medical Research, Keio University School of Medicine, Tokyo, Japan

Background: Non-Hodgkin's lymphoma (NHL) mostly includes mature B-cell lymphomas, such as Burkitt lymphoma (BL), diffuse large cell lymphoma (DLBCL), and follicular lymphomas, which are all derived from germinal-center B (GCB) cells. Despite recent advances in the drug development for lymphoma, there are still patients with refractory and relapsed lymphoma. To analyze the detailed molecular mechanisms during lymphomagenesis, we require appropriate mouse models, with short latency, in which monitoring the whole process from the cell of origin to full-blown lymphoma is easy.
Aims: To analyze the factors involved in mature B-cell lymphomagenesis, we attempted to develop a new mouse model for lymphoma, originating from GCB cells.
Methods: Naive B-cells derived from C57BL/6 wild type (WT) or *Ink4a/Arf-/-* mice were cultured *ex vivo* and stimulated with IL-4 and anti-CD40 antibody to differentiate into GCB cells. GCB cells were retrovirally transduced with *c-Myc*, which is highly expressed in most human lymphomas, and then transplanted into sublethally irradiated syngeneic mice. Primary cultured lymphoma cells were treated with the reagents described below. Human NHL cell lines including 4 Burkitt lymphoma (Daudi, Ramos, Raji, and Namalwa) and 9 DLBCL (DB, Toledo, OCI-Ly19, WSU-DLCL2, SU-DHL6, NU-DHL1, NU-DUL1, OCI-Ly3, and OCI-Ly10) were used.
Results: Approximately 60% of mice transplanted with *Ink4a/Arf-/-* derived *c-Myc*-GCB cells, via intraperitoneal injection, exhibited splenomegaly and enlarged lymph nodes in the axilla, inguinal, and intestinal regions, and eventually died. Mice transplanted with WT derived *c-Myc*-GCB cells did not show any signs of lymphoma. Tissues from these mice showed mature B-cell immunophenotype (B220+IgM+IgD+) and were histopathologically similar to human BL. Remarkably, lymphoma cells from all mice did not show Fas expression at protein and mRNA levels in contrast to the original GCB cells that showed high Fas expression. Furthermore, lymphoma cells, which spontaneously developed in all λ-Myc mice (a transgenic mouse carrying *c-Myc* under the control of the Igλ light chain enhancer), showed no Fas expression. Fas is a cell death receptor which has an important role in negative selection of GCB cells, with self-reactive antibody and low-affinity antibody. To analyze the role of Fas downregulation in lymphoma formation, *Ink4a/Arf-/-* GCB cells were transduced with *c-Myc* and shRNA for Fas and then transplanted. All mice transplanted with shFas-transduced GCB cells developed lymphoma and died faster than mice transplanted with shControl-transduced GCB cells. To further analyze Fas regulation in lymphoma cells, we carried out primary culture of lymphoma cells. Fas expression was restored after CD40 ligand or anti-CD40 antibody treatments, suggesting that reduced CD40 signaling may be one of the reasons for Fas downregulation. Further, we found that 11 out of 13 human lymphoma cell lines, including 3 BL and 8 DLBCL, exhibited low expression of Fas whereas 2 cell lines exhibited high expression of Fas that induced apoptosis upon Fas ligand treatment. Among those Fas-downregulated cells, Fas expression was restored not only after CD40 ligand treatment, but also after a DNA methyltransferase inhibitor 5-Aza-dC treatment or an HDAC-inhibitor TSA treatment, indicating that Fas expression is also regulated by epigenetic mechanisms in human lymphoma cells.
Summary and Conclusions: The findings in this study suggest that Fas downregulation is a crucial event for mature B-cell lymphomagenesis to escape from immune surveillance and that restoration of Fas expression, such as anti-CD40 antibody treatment or epigenetic inhibitors, may be a promising strategy for NHL treatment.

MOLECULAR DIAGNOSIS BY GENE EXPRESSION PROFILING IN FORMALIN FIXED PARAFFIN EMBEDDED TISSUE-BURKITT LYMPHOMAS WITH EXPRESSION OF BCL2
N. Masque Soler[1,*] M. Szczepanowski[1], C.W. Kohler[2], S.M. Aukema[3], I. Nagel[3], R. Siebert[3], B. Burkhardt[4], R. Spang[2], W. Klapper[1]
[1]Pathology Institute-Haematopathology Section and Lymph Node Registry, University Hospital Schleswig-Holstein, Kiel, [2]Institute of Functional Genomics, University of Regensburg, Regensburg, [3]Institute of Human Genetics, University Hospital Schleswig-Holstein, Kiel, [4]Department of Paediatric Hematology and Oncology, University Children's Hospital Münster, Münster, Germany

Background: Mitochondrial membrane protein BCL2 is widely expressed in many lymphoma entities but rarely in Burkitt lymphoma (BL). Expression of BCL2 can be considered as an indicator of diffuse large B cell lymphoma (DLBCL) where morphology is unclear. Co-expression of BCL2 and MYC has been reported to be an indicator of poor prognosis in DLBCL. Occasionally BCL2 expression occurs in BL and in lymphomas with features intermediate between BL and DLBCL (intermediates). Gene expression profiling (GEP) has helped to define the molecular features of BL (mBL). However, only few BCL2-positive BL have been assessed by GEP in order to elucidate if their molecular pattern shifts to more intermediate or DLBCL profiles.
Aims: To evaluate applicability of our recently developed BL and DLBCL molecular classifier using formalin fixed and paraffin embedded (FFPE) tissue on diagnostically ambiguous cases. To understand to what extent BCL2 expression is compatible with the diagnosis mBL. To assess the prognostic value of BCL2 expression in BL.
Methods: A cohort of 154 BL diagnosed by morphology, immunophenotype and fluorescence *in situ* hybridization (FISH) for *MYC* and t(8;14)/*MYC-IGH* translocations was analyzed for BCL2 expression by immunohistochemistry using two different antibodies. These constructed a tissue microarray (TMA).
A group of 17 lymphomas (age range 3-24, median 11 years of age) with the morphological an immunophenotypical features of BL but BCL2 expression (5% >90% in lesion) were additionally labelled by GEP using RNA from FFPE material. In 5 cases BCL2-positive and BCL2-negative areas of the biopsy block were macrodissected and analyzed separately. To assess if BCL2 expression in mBL correlated with poorer prognosis 43 further BL cases registered within the NHL-BFM database were compared to the initial BCL2-positive mBL cohort for clinical variables including outcome.
Results: In the TMA cohort BCL2 expression was detected in 21,3% (33/150) of the cases. No differences in clinical features and outcome were detected between BCL2-positive and BCL2-negative BL in 43 patients treated according to paediatric NHL-BFM protocols. Using GEP, 13/17 (76,5%) cases were classified as mBL and 4/17 (23,5%) as intermediates. The 5 lymphomas with spatial differences in BCL2 expression classified as mBL in both, BCL2-positive and BCL2-negative areas. In this group of predominantly paediatric patients, none of the 4 intermediate cases relapsed according to clinical follow-up.
Summary and Conclusions: Molecular classification indicates that lymphomas with the clinical and pathological features of BL but expression of BCL2 display molecular profiles compatible with mBL. BCL2 expression is not associated with inferior survival in pediatric BL. Diagnostically ambiguous lymphomas by histopathology and FISH can be reliably labelled by our GEP-based aggressive lymphoma classifier in FFPE specimens.

E1366

PROTEIN KINASE CK2 IN DIFFUSE LARGE B-CELL LYMPHOMA: DEFINING ITS ROLE TO SHAPE NEW THERAPIES
E. Mandato[1,2,*] F. Zaffino[1,2], A. Casellato[1,2], P. Macaccaro[1,2], S. Canovas Nunes[1,2], M. Pizzi[1], L. Trentin[1,2], G. Semenzato[1,2], F. Piazza[1,2]
[1]Department of Medicine, University of Padova, [2]Venetian Institute of Molecular Medicine, Padova, Italy

Background: CK2 is a serine-threonine protein kinase formed by the assembly in a tetramer of two catalytic (a) and two regulatory (b) subunits. This enzyme regulates a wide variety of cellular processes, including cell proliferation, differentiation and survival. It is overexpressed and overactive in several solid tumors and hematologic malignancies and promotes a "non-oncogene addiction" phenotype in cancer cells. Our and other groups have shown that B cell tumors, such as chronic lymphocytic leukemia, mantle cell lymphoma and multiple myeloma, rely on high activity of CK2 and are extremely sensitive to the cytotoxic effect of CK2 inhibition induced either by gene silencing or with the clinical grade compound CX-4945 (Silmitasertib). It is well known that the strength of the B cell receptor (BCR) signaling influences mature B cell commitment and survival, and is a powerful determinant of B cell derived lymphoma cell growth. CK2, through a "lateral" regulation of BCR-dependent signaling cascades, could be involved in normal and malignant BCR-elicited signaling. Indeed, B cell specific CK2b knockout mice, generated in our laboratory, display a marked reduction of follicular B cells (FoB), suggesting a critical role of this kinase in FoB cell development and maintenance.
Aims: We culled to investigate CK2 levels and activity in diffuse large B-cell lymphoma (DLBCL), an aggressive germinal center derived B cell tumor. Further-

more, we intended to study the potential of combining CK2 inhibition with the BCR blockade as a therapeutic option for this neoplasia.
Methods: Immunohistochemistry was performed on 4 µm-thick formalin-fixed and paraffin-embedded sections. To inhibit CK2 we employed CX-4945, a selective ATP-competitive compound currently under scrutiny in phase I clinical trials. To evaluate protein changes after treatments, cells were lysed and Western Blot experiments carried out. To assess cell survival, MTT tests and AV/PI staining were performed. Combination Index (CI) was calculated in accordance with the Chou and Talalay method. To stimulate the BCR aIgM or aIgG antibodies were used. Acquisition was done with FACS Canto and analysis with FlowJo software.
Results: CK2 was found to be over expressed in a series of primary samples of activated B-cell-like (ABC) and germinal center B-cell-like (GCB) DLBCL and in ABC- and GCB-DLBCL cell lines as compared to normal counterparts. CK2 inhibition with CX-4945 caused apoptosis of both types of DLBCL cell lines in a dose dependent fashion even at low concentrations not toxic to normal B lymphocytes. Moreover, CX-4945 boosted the effects of Fostamatinib, an effective BCR signaling inhibitor, increasing malignant B cell death. Also, the downregulation of CK2 catalytic activity led to a reduction in Ca^{++} release from endoplasmic reticulum (ER) stores and impaired AKT activation after BCR stimulation.
Summary and Conclusions: Our study shows that CK2 levels and activity are abnormally high in DLBCL, and its inhibition causes strong apoptosis of lymphoma cells. CK2 is likely to lie downstream from chronic active and tonic BCR signaling, presumably controlling AKT activation and Ca^{++} release from ER stores, two critical events regulating B cell activation, survival and expansion. These findings suggest that CK2 inhibition could target multiple sites of the BCR-dependent pro-survival cascade, and could pave the way for the inclusion of CX-4945 in rational drug combination therapies with BCR pathway inhibitors such as Ibrutinib and Fostamatinib that are currently under clinical trials in DLBCL patients.

E1367

INHIBITORS OF MTOR/PI3K/AKT PATHWAY EXTEND THERAPEUTIC OPPORTUNITY IN WALDENSTRÖMS MACROGLOBULINEMIA CELLS THAT DISPLAY RESISTANCE TO BOTH ABT-199 AND IBRUTINIB.
K. Chitta[1,*] A. Paulus[1], S. Akhtar[1], A. Novak[2], S. Ansell[2], M. Gertz[2], R. Kyle[2], C. Rivera[1], V. Roy[1], J. Foran[1], P. Martin[3], M. Coleman[3], T. Sher[1], S. Ailawadhi[1], A. Chanan-Khan[1]
[1]Mayo Clinic, Jacksonville, [2]Mayo Clinic, Rochester, [3]Weill Cornell Medical Colleage, New York, United States

Background: Recent investigations support a role for constitutively active B-cell receptor (BCR), and Toll-like receptor (TLR) signaling in the pathogenesis of Waldenström macroglobulinemia (WM), a rare and indolent B cell disorder. Clinically, mitigation of BCR signaling with the first in class BTK inhibitor, ibrutinib, has shown promising results. However, clinical responses to ibrutinib alone are less than optimal and development of ibrutinib-resistant disease is being recognized as an important and impending dilemma. It has also been shown that Bcl-2 family of anti-apoptotic proteins supports BCR/TLR induced proliferation and survival of WM cells by prevention of apoptosis. This defective apoptotic signaling is associated with aggressive clinical behavior, chemoresistance, and a poor prognosis in many B-cell cancers, including WM. We have previously shown the utility of disrupting pro-apoptotic Bcl-2 protein interactions in WM, chronic lymphocytic leukemia and multiple myeloma and that this functional interference results in re-sensitization (or heightened sensitivity) of tumor cells towards chemoimmunotherapy. As such, we examined the effects of ABT-199, a Bcl-2 specific small molecule inhibitor; in preclinical models of WM and found these cells to be sensitive to ABT-199; an observation, which echoes early clinical efficacy noted in WM patients part of a phase 1 clinical trial. As resistance to ibrutinib is being noted in patients and early reports on ABT-199 suggest that resistance to its activity is imminent, we established 1.) WM models resistant to ibrutinib, 2.) WM models resistant to ABT-199 and 3.) WM models resistant to both ibrutinib and ABT-199. These models were then used to delineate common survival pathways that may lend therapeutic cross-sensitivity in cells resistant to ibrutinib and/or ABT-199.
Aims: To evaluate the effect of mTOR/PI3K/AKT inhibitors on WM cells resistant to Ibrutinib and ABT-199.
Materials and Methods: WM cell lines (BCWM.1, MWCL.1 and RPCI-WM1; WT-WM cells) including their ibrutinib resistant (IR-WM), ABT-199 resistant (ABTR-WM) or dual-ibrutinib/ABT-199 resistant (dual resistant WM) clones were developed in the laboratory and used in this study.
Results: A comparison of expression pattern of Bcl-2 family members, Bcl-2, Mcl-1, BCL-xL, A1 (anti-apoptotic members), Noxa, Puma, Bim (pro-apoptotic initiators) and Bak and Bax (pro-apoptotic effectors), revealed that IR-WM cells and ABTR-WM cells showed differential expression of Bcl-2 family members. Cell growth (MTS) assays using ABT-199 indicated that IR-WM cells remain sensitive to ABT-199 with an IC_{50} ranging between 2-4uM. ABT-199 induced a dose dependent increase in MOMP with concomitant induction of apoptotic cell death in IR-WM cells, the latter confirmed by observation of PARP-1 cleavage. ABT-199 induced intrinsic apoptosis with the activation of caspase 9 and caspase 3 in all the cells tested. This data indicated the Bcl-2 pathway as being relevant and essential in IR-WM cell lines. Further, combined addition of ABT-199 with ibrutinib showed synergistic cell death (as calculated using CalcuSyn software, Biosoft UK) in IR-WM cells. However, prolonged and incremental exposure to ABT-199 in 1.) WT-WM cell lines and 2.) in IR-WM cell lines resulted in outgrowth of tumor clones that displayed resistance to both ibrutinib and ABT-199. Interestingly, these drug resistant (IR-WM, ABTR-WM and dual-resistant) WM clones showed constitutive activation of AKT. As such, we tested multiple inhibitors of the mTOR/PI3K/AKT pathway (everolimus, LY294002 or MK2206) and observed a dose and time dependent cytotoxicity in the aforementioned drug-resistant WM models.
Summary and Conclusions: Drug resistance in WM as in other B-cell cancers is inevitable despite combination therapy and can result in development of tumor clones that are cross resistant to multiple drugs. However, even in this complex biological dynamic, these drug-resistant clones fortuitously may shift survival signaling towards an alternative (but common) pathway, lending therapeutic cross-sensitivity. Data from our ibrutinib, ABT-199 or dual-resistant preclinical models affirms this notion and suggests these cells common preference for AKT-mediated survival signaling when continual stress from ibrutinib and/or ABT-199 is applied.

E1368

HIGH THROUGHPUT *IN VITRO* COMBINATION SENSITIVITY SCREEN IN HEMATOLOGIC MALIGNANCIES WITH DUVELISIB, A DUAL PI3K-DELTA,GAMMA INHIBITOR
K. Faia[1,*] K. White[1], J. Proctor[1], P. Andrade[1], M. Pink[1], R. Rickles[2], J. Grenier[2], E. Boghaert[3], A. Souers[3], J. Leverson[3], V. Palombella[1], K. McGovern[1], J. Kutok[1]
[1]Infinity Pharmaceuticals, [2]Horizon CombinatoRx, Cambridge, [3]AbbVie Inc, North Chicago, United States

Background: Phosphoinositide-3 kinases (PI3Ks) are key cellular signaling proteins that act as a central node for relaying signals from cell-surface receptors to downstream mediators. PI3K-δ and PI3K-γ isoforms are expressed in normal leukocytes, as well as many hematological malignancies such as indolent non-Hodgkin lymphoma (iNHL) and chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). Given the key role for PI3K-δ and PI3K-γ in immune cell function, targeting these isoforms may provide opportunities to develop differentiated therapies for the treatment of hematologic malignancies. Duvelisib (IPI-145) is an oral dual inhibitor of PI3K-δ and PI3K-γ currently in clinical development in hematologic malignancies.
Aims: In order to gain mechanistic insights into the cellular response to duvelisib and identify novel combination pairings for duvelisib in a broad spectrum of hematologic malignancies, a high-throughput pharmacology screen was conducted. *In vivo* combination validation studies were also performed.
Methods: Duvelisib was evaluated alone and in combination with 35 compounds comprising a diverse panel of standard-of-care agents and emerging drugs in development for hematologic malignancies. Target and pathway inhibitor redundancy was included to observe similar patterns of activity across the cell line panel. These compounds were tested in 20 cell lines including diffuse large B-cell (DLBCL), follicular, T-cell, and mantle cell lymphomas, and multiple myeloma. Growth inhibition (GI) was measured by ATPLite (Perkin Elmer) in a 6x6 or 9x9 dose combination matrix.
Results: Single agent activity was seen in 14 cell lines treated with duvelisib, with a median GI50 of 0.59 µM. A scalar measure of the strength of synergistic drug interactions (Synergy Score) was devised and filtering on scores exceeding the mean self-cross plus twice the standard deviation revealed a synergy hit rate of 19.3% across the matrix of drug combinations and cell lines. Synergy was most prominent in DLBCL and follicular lymphoma cell lines and seen with approved and emerging drugs used to treat hematologic malignancies, including, but not limited to, dexamethasone, inhibitors of the B-cell receptor signaling pathway, such as ibrutinib, and the BCL-2 inhibitor venetoclax (ABT-199). Synergy patterns were similar among agents that target the same molecules or pathways helping to validate activities seen in combination with duvelisib. In select cell line GI studies and *in vivo* DoHH2 lymphoma murinexenograft models, the combination of selective PI3K-δ and PI3K-γ inhibitors showed enhanced effects compared to either inhibitor alone. Combination effects with select drugs and duvelisib were also seen in DoHH2 murinexenografts.
Summary and Conclusions: These studies support enhanced activity of combined PI3K-δ and PI3K-γ inhibition in lymphoma models and identified synergistic pairings with the PI3K-δ and PI3K-γ inhibitor, duvelisib. These results provide a rationale for exploring the combination of duvelisib and other therapeutic agents in clinical studies.

ARTISAN PCR: HIGHLY RELIABLE IDENTIFICATION OF FULL-LENGTH B-CELL RECEPTOR SEQUENCES
M.T. Koning[1,*] V. Boersma[1], C.A. van Bergen[1], S.M. Kielbasa[2], H. Veelken[1]
[1]Department of Hematology, [2]Department of Medical Statistics, Leiden University Medical Center, Leiden, Netherlands
Background: Full-length, error-free B-cell receptor (BCR) sequences are

instrumental to study B-cell function in health, autoimmunity, and lymphoma. Current amplification strategies are usually based on multiplex primers annealing to conserved upstream V segment regions. These primers obscure mutations at their binding site and are prone to amplification bias or even complete amplification failure (Koning *et al.*, 2014). We designed an alternative assay employing Anchoring Reverse Transcription of Immunoreceptor Sequences and Amplification by Nested PCR (ARTISAN PCR).

Aims: To demonstrate improved success rate of full-length BCR identification by ARTISAN PCR compared to multiplex strategies.

Methods: 39 EBV-transformed lymphoblastoid cell lines (LCL) were selected for clonality by flow cytometry. In addition, biopsy material (peripheral blood, bone marrow, lymph node, spleen, pleura) from 24 patients diagnosed with either chronic lymphocytic leukemia, monoclonal B-cell lymphocytosis, Waldenström's macroglobulinemia, multiple myeloma, follicular lymphoma, mantle cell lymphoma, marginal zone lymphoma or Burkitt's lymphoma (3 each) was selected. Poly(A)-RNA was isolated (Dynabeads; Invitrogen) and subjected to 5'RACE cDNA synthesis (Smartscribe, Clontech) with gene-specific primers that anneal to the Ig constant region of interest. Anchor-tagged cDNA was PCR-amplified with an anchor-specific forward primer and nested constant region-specific reverse primers. Nested barcoding primers further increased target specificity and enabled the combination of numerous PCR products in one sequencing run. For comparison, cDNA was amplified by conventional multiplex PCR (IGH FR1, IGK A, and IGL Clonality Assays, Invivoscribe) utilizing generic primers designed to anneal to V and J regions. EBV LCL amplicon libraries were sequenced on the PacBio platform (Pacific Biosciences) at a minimum of 8 cycles. Lymphoma biopsy amplicons were cloned and sequenced by Sanger sequencing.

Results: ARTISAN PCR on the 39 LCL yielded 52 clonal VDJ, 22 VJ-κ, and 39 VJ-λ sequences. 10 VJ amplicons were unproductive. In total, functional complete BCRs were readily identified for all LCL, of which 27 were identified as monoclonal and 12 as biclonal. By the Invivoscribe protocol, 6 VDJ, 1 VJ-κ, and 10 VJ-λ were missed, corresponding to success rates of 88%, 95%, and 74%, respectively, compared to ARTISAN PCR. Complete BCRs were identified for 38 of 51 (75%) LCL B-cell clones by Invivoscribe. ARTISAN PCR identified a complete functional clonal BCR in all 24 lymphoma biopsies (7 IgM-κ, 13 IgM-λ, 2 IgA-λ 2 IgG-κ). With the Invivoscribe approach, a complete functional clonal BCR was identified in 13 cases (54%). In 4 cases, no VDJ could be identified, and in 8 cases, no functional VJ. Neither in the LCL nor in the lymphoma biopsies was a clonal amplicon found by the Invivoscribe assays that was missed by ARTISAN PCR. Sequence analysis of the BCR obtained by ARTISAN PCR revealed individual reasons for each instance of Invivoscribe assay failure. In 19 instances, mutations in V or J primer binding sites led to deleterious mismatches. In 9 cases, lack of a primer for the particular lambda V allele family prevented VJ identification. In one case, a truncation obliterated the FR1 primer binding site. The cumulative error rate (cDNA synthesis, PCR, sequencing) of ARTISAN PCR was $1{,}26 \times 10^{-4}$ in the LCL panel at a minimum of 8 cycles of PacBio sequencing.

Summary and Conclusions: ARTISAN PCR permits reliable high-throughput identification of full-length BCR transcripts and proves vastly superior to a commercial assay based on multiplex primers.

NFKBIE MUTATIONS OCCUR IN 15% OF GCB DLBCL AND IN VARIOUS OTHER LYMPHOID MALIGNANCIES

D. Nörenberg[1,*] M. Frick[1], L. Couronné[2], D. Lenze[3], C.D. Baldus[1], C. Bastard[4], J. Okosun[5], J. Fitzgibbon[5], B. Dörken[1], C.A. Schmitt[1], T. Zenz[6], M. Hummel[3], O.A. Bernard[7], F. Damm[1]

[1]Department of Hematology, Oncology, and Tumor Immunology, Charité, University Medical Center, Berlin, Germany, [2]Service d'hématologie adulte, Assistance publique-Hôpitaux de Paris (APHP), Hôpital Necker, Paris, France, [3]Institute of Pathology, Charité, University Medical Center, Berlin, Germany, [4]INSERM U918, Université de Rouen, Centre Henri Becquerel, Rouen, France, [5]Centre for Haemato-Oncology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom, [6]Department of Translational Oncology, National Center for Tumor Diseases (NCT), German Cancer Research Center (DKFZ), Heidelberg, Germany, [7]INSERM, U1170, Institut Gustave Roussy, Villejuif, France

Background: Massively parallel sequencing technology in chronic lymphocytic leukemia (CLL) has recently identified acquired recurrent somatic mutations in the gene *NF-κB inhibitor I kappa B epsilon* (*NFKBIE*), a retrocontrol of NF-κB signaling. NF-κB activity is a hallmark of various haematological malignancies, and activating mutations in NF-κB transcription factors or upstream signaling components such as CD79b, CARD11, or TNFAIP3/A20 are common findings in lymphoid neoplasms. However, little is known regarding the prevalence of *NFKBIE* mutations in lymphoid malignancies other than CLL.

Aims: Since gene mutations are rarely specific of a given tumor entity and those identified in a given lymphoid malignancy are frequently found in other diseases, we aimed to assess the presence and frequency of *NFKBIE* mutations in a larger cohort of patients with lymphoid malignancies and to evaluate the range of mutational burden.

Methods: We investigated the mutational hotspot of *NFKBIE* in a series of 623 patients with lymphoid neoplasms. 113 chronic lymphocytic leukemias (CLL), 170 diffuse large B-cell lymphomas (DLBCL), 179 follicular lymphomas (FL), 57 mantle cell lymphomas (MCL), 94 T-cell acute lymphoblastic leukemias, 9 small lymphocytic lymphomas (SLL), and 1 mucosa-associated lymphoid tissue (MALT) lymphoma were analyzed by Sanger sequencing or targeted deep sequencing.

Results: Together, frameshift mutations in *NFKBIE* were detected in 24 out of 623 (3.9%) investigated patients. While *NFKBIE* mutations were rare in FL (3/179=1.7%), MCL (1/57=1.8%), and T-ALL (1/94=1.1%) patients, a higher frequency was detected in the CLL (6/113=5.3%), SLL (1/9=11.1%), and DLBCL cohorts (11/170=6.5%). Furthermore, the only patient with a MALT lymphoma in this series harbored a *NFKBIE* mutation. For 118 DLBCL patients, information was available on the cell-of-origin subtype derived from the immunohistochemistry-based Hans classification. We found a high frequency of *NFKBIE* mutations in the subgroup with germinal center B-cell-like (GCB) DLBCL (9/59=15.3%), whereas only one of the 59 Non-GCB DLBCLs showed a *NFKBIE* mutation (1/59=1.7%; *P*=0.017 GCB *vs* Non-GCB in Fisher's exact test). Next, we evaluated the mutation burden of 12 *NFKBIE* mutated lymphoma patients (6 CLL and 6 DLBCL based on DNA availability) by deep sequencing. The mutation burden varied from 8% to 47% (mean coverage of 1260 reads per patient sample). These data indicate that *NFKBIE* mutations may be part of both major and subclone variations.

Summary and Conclusions: In summary, we show a 3.9% prevalence of *NFKBIE* mutations in a large set of 623 patients with lymphoid malignancies. *NFKBIE* mutations were most frequently found in CLL, SLL and DLBCL patients. We further identified GCB DLBCL to harbor the highest prevalence of *NFKBIE* mutations, reaching a frequency of 15.4%.

NK CELLS CYTOTOXICITY IS AFFECTED BY VARIOUS BTK INHIBITORS

M. Siernicka[1,2,*] K. Bojarczuk[1], M. Bobrowicz[1], M. Różańska[1], M. Taha[3], C. Fauriat[3], J. Golab[1], M. Winiarska[1]

[1]Department of Immunology, [2]Postgraduate School of Molecular Medicine, Medical University of Warsaw, Warsaw, Poland, [3]CRCM [Immunity and Cancer], Inserm, U1068, Institut Paoli-Calmettes; Aix-Marseille Université, UM 105; CNRS, UMR7258, Marseille, France

Background: Targeting Bruton's tyrosine kinase, due to a huge therapeutic potential of ibrutinib, is becoming an attractive therapeutic approach in the treatment of hematological malignancies derived from B-cells. However, we have demonstrated that NK cell cytotoxicity, degranulation and cytokine secretion are significantly impaired upon ibrutinib treatment (Bojarczuk *et al.*, Leukemia 2014). Since NK cells are effectors in antibody dependent cell-mediated cytotoxicity (ADCC), which constitute one of the major mechanisms of anti-CD20 monoclonal antibodies widely used in hematooncology, in our ongoing studies we are focused to determine in details the influence of various BTK inhibitors on NK cells cytotoxicity, degranulation, cytokine expression and expression of activatory NK cells receptors.

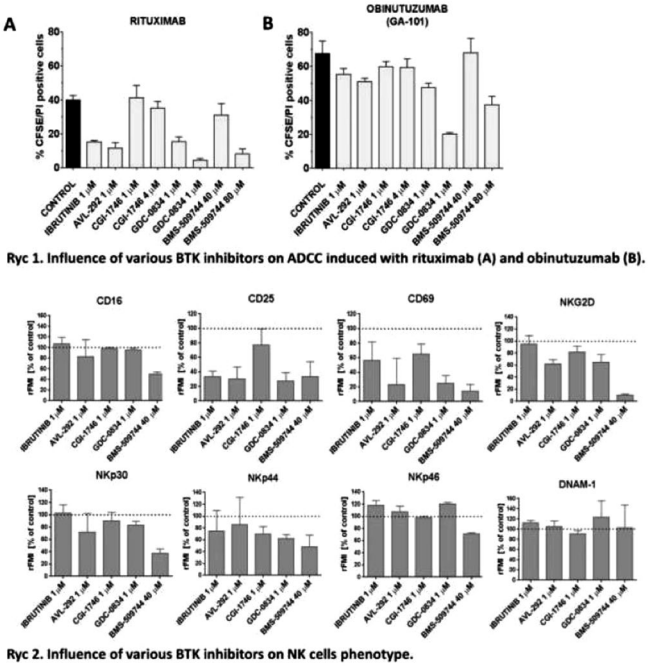

Figure 1.

Aims: The aim of the studies is to elucidate the influence of various BTK inhibitors on the antitumor activity and phenotype of primary NK cells isolated from blood samples of healthy volunteers as well as patients with leukemia and lymphomas.
Methods: All experiments were performed fully *in vitro* using human primary NK cells isolated from PBMC of healthy donors and NK cells from patients with B-cell derived tumors. ADCC was determined using anti-CD20 monoclonal antibodies (rituximab, ofatumumab, obinutuzumab). To determine cytolytic activity of NK cells we used CFSE/PI flow cytometry assay and/or CD19 and PI staining to determine absolute counts of B cells. Cytokine secretion and NK cells degranulation evaluated as the expression of CD107a on the surface of NK cells were determined with flow cytometry upon incubation with target cells for 4 h. Phenotype of NK cells pre-incubated with tested compounds was determined with flow cytometry using antibodies conjugated with fluorochromes.
Results: The initial results of the studies show that various BTK inhibitors differentially regulate NK cells antitumor activity and affect phenotype of NK cells. Interestingly, obinutuzumab-induced ADCC is not inhibited in the presence of BTK inhibitors in contrast to type I anti-CD20 monoclonal antibodies (Figure 1).
Summary and Conclusions: Our studies are focused on better understanding how newly approved inhibitors influence NK cells antitumor functions. This knowledge is especially important in light of combination therapies when monoclonal antibodies are used with small molecule inhibitors. On the basis of our observations we conclude that combining obinutuzumab with BTK inhibitors is a better therapeutic strategy than simultaneous combination of type I anti-CD20 antibodies and BTK inhibitors.

E1373

VDJH USAGE IN TRANSFORMED FOLLICULAR LYMPHOMA

M. Garcia Alvarez[1,*,#], S. Alonso Álvarez[1,#], M. Alcoceba[1,#], A. Balanzategui[1], I. Prieto Conde[1], C. Jiménez[1], M.E.A. Sarasquete[1], M.C. Chillón[1], A. Antón[1], R. Mardonado[1], M. Hernández Ruano[1], R. Corral[1], L. Marín[1], N. Puig[1], A. Martín[1], N. Gutiérrez[1], B. Vidriales[1], O. Blanco[1], R. García Sanz[1], M.D. Caballero[1,§], M. González[1,§]
[1]Department of Hematology, University Hospital of Salamanca, SALAMANCA, Spain
#*Equal contribution;* §*Equal senior contribution.*

Background: Follicular lymphoma (FL) is the second most frequent non-Hodgkin lymphoma in western countries. Transformation into aggressive lymphoma continues being one of the worst events in the disease history. There is a growing interest in connecting new approaches into the biological basis of transformation and clinical application. IgH gene rearrangements in B lymphoproliferative disorders have identified the preferential use of certain VDJH gene segments, correlated in some cases with clinical prognosis. In this aspect, transformed follicular lymphoma (tFL) has not been yet studied.
Aims: To study the IGHV gene usage and clinical features in patients diagnosed of tFL and to compare with FLs that do not undergo transformation, as well as with diffuse large B-cell lymphoma (DLBCL), classified as GCB and non-GCB by immunostaining according to Hans algorithm.
Methods: A total of 213 non-Hodgkin lymphoma (NHL) patients from a single centre were included in the study, distributed in three groups: i) tFL patients (n=32), most of them with paired samples at diagnosis and transformation (n=25, 78%); ii) FL with no documented transformation at a median follow up of 66 months (n=74); and iii) DLBCL patients (n=107; 44% GCB, and 56% non-GCB). Clonal IGH rearrangements were amplified according to the BIOMED-2 protocol and PCR products were sequenced. Germline IGH genes were identified using IMGT/V-QUEST database. Statistical comparisons were performed using SPSS 20.0.
Results: Complete VDJH rearrangements were identified in 31 out of 32 tFL patients (97%). In addition, other case was discarded due to the identification of a different clone, and it was recorded as secondary NHL. A bias in the IGHV gene usage was observed in tFL patients, with IGHV3-23 (20%), IGHV3-48 (17%), and IGHV4-34 (17%) genes accounting for 54% of the cohort. These genes are common in both FL and DLBCL. However, and despite differences were no statistical significant, a higher frequency of IGHV3-48 was shown in tFL than in DLBCL (22% *vs* 6%), while IGHV4-34 showed higher frequency in tFL than in FL (19% *vs* 8%). Moreover, IGHV4-34 was found only in the non-GCB DLBCL subgroup. Regarding the clinical outcome, the average time to transformation of tFL is 54 months (range 4-222 months). Interestingly, we found a longer time to transformation in patients with IGHV4-34 as compared with patients using other IGHV (99 *vs* 44 months, p=0.023). Finally, and interestingly, only two patients have <2% SHM and both cases were composite of FL+DLBCL at diagnosis.
Summary and Conclusions: Clonality analysis is necessary to discriminate secondary NHL rather than tFL. IGHV in tFL gene usage is biased, similar to those of DLBCL and FL, as expected. Patients using IGHV4-34 showed longer time to transformation than other IGHV. This study should be considered as preliminary, requiring larger and homogeneous cohorts.

GENOME-WIDE DNA COPY NUMBER IMBALANCES ASSOCIATED WITH HIV POSITIVE PLASMABLASTIC LYMPHOMAS

P. Willem[1,*] S. Boy[2]
[1]Haematology and Molecular Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, [2]Department of Pathology, Sefako Makgatho Health Sciences University, Medunsa, Pretoria, South Africa

Background: Plasmablastic lymphoma (PBL) is a rare B-cell lymphoma preferentially occurring in immunosuppressed patients. Over the past few years this highly aggressive lymphoma has significantly increased in incidence in HIV-infected individuals from Southern Africa. Despite this increasing incidence and highly aggressive nature, very few studies have addressed the molecular pathogenesis of this lymphoma. These studies were limited to single case reports and candidate-gene approaches, with only one study investigating the presence of copy number aberrations by an unbiased, though low- resolution (1 Mb) BAC array approach. Thus, the molecular basis of HIV associated PBL remains mostly unknown. We have previously characterized a cohort of 45 patients with PBL of the oral cavity (31 with a documented HIV positive status) for immunophenotypic features and well-known chromosomal translocations. New to our study, was the finding of 7 cases (16%) with rearrangements of both immunoglobulin heavy chain alleles. These double-hit lymphomas underscore the aggressive nature of this disease in HIV infected individuals, stressing the need to elucidate its molecular pathology to inform better treatment strategies.
Aims: To investigate genome-wide DNA copy number imbalances associated with HIV related PBL using high-resolution molecular inversion probe (MIP) arrays.
Methods: We used whole-genome molecular inversion probe arrays, (OncoScan FFPE Express (MIP) platform, Affymetrix, Santa Clara, CA), which generates high quality copy number data from formalin-fixed paraffin-embedded (FFPE) samples, to investigate the genetic content of HIV associated PBL on 30 FFPE specimens. MIP data were analyzed with the Nexus 7 Copy number software (Biodiscovery, Hawthorne, CA) using the SNP-FASST2 segmentation algorithm and the Nexus default settings for significance. Copy-number threshold was 2,5 for gain and 1,5 for losses.
Results: We observed a considerable variability in the number of aberrations from one patient to the other ranging from 1 to over 100 aberrations per sample. The sum of aberrations revealed that gains were more frequent than losses and preferentially involved chromosomes regions 1q12qter, 6p22p21, 11q14qter, 12p, and chromosome 7. Analysis with the Genomic Identification of Significant Targets in Cancer (GISTIC) software also identified multiple significant regions of gains and losses. The most significant focal gain on 11p13, included the two genes CD44 and PDHX. The interleukin IL10 and MAPKAPK2 genes, both involved in stress and inflammation processes, were also amongst the most significant gains on chromosome 1q32.1. These gains were confirmed by fluorescence *in situ* hybridization using BACs RP11-595K11 and RP11-343H5 that span these loci respectively. MAPKAPK2 encodes for a kinase regulated through direct phosphorylation by p38 MAP kinase, as such it is involved in CD40-induced B-cell proliferation and its up-regulation may favor B-cell proliferation. Losses were less frequent. Of interest, we observed 2 significant focal losses at the common fragile sites FRA-16D and FRA-3B hosting the WWOX and FHIT genes respectively. Deletions at WWOX and FHIT are the commonest aberrations (85%) reported in primary effusion lymphoma, a disease closely related to PBL (Figure 1).

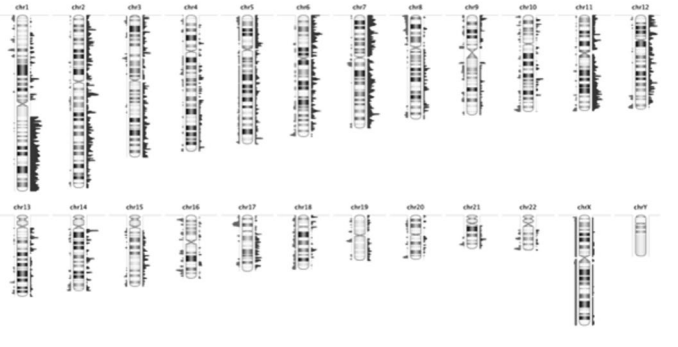

Figure 1. Summary of copy number aberrations in 30 PBL samples.

Summary and Conclusions: Genome-wide DNA copy number imbalances in HIV associated PBL specimens are heterogeneous in number from patient to patient. Significant recurrent focal gains at 11p13 and 1q32.1 warrant further studies aimed at determining their role in the pathogenesis of the disease.

E1375

EFFICACY OF THE PAN PI3K-INHIBITOR COPANLISIB COMPARED TO SELECTIVE PI3K-A, -B, -Δ INHIBITORS IN MANTLE CELL LYMPHOMA (MCL)

A. Zoellner[1,2,*] J. Arnd[3], G. Hutter[2], Y. Zimmermann[2], W. Hiddemann[1,2], M. Dreyling[1,2]
[1]Internal Medicine III, Haematology and Oncology, LMU, [2]Clinical Cooperative Group Leukemia, [3]2Clinical Cooperative Group Leukemia, Helmholtz Center Munich, Munich, Germany

Background: Immuno-chemotherapy is the current therapeutic standard in MCL. However, new therapeutic approaches are urgently warranted in relapsed and refractory disease.
Aims: Inhibitors of the different isoforms of the Phosphatidylinositol 3-kinase (PI3K) show promising results in clinical trials and have been recently registered for follicular lymphoma. We here investigate different PI3K inhibitors in mono and combination treatment.
Methods: Established MCL cell lines (Granta519, Jeko1, Jurkat, Rec1) were cultivated under standard conditions in RPMI1640 supplemented with fetal bovine serum. Cells were exposed to A66 (PI3K-α inhibitor) (5μM), TGX-221 (PI3K-β inhibitor) (5μM), Idelalisib (PI3K-δ inhibitor) (5μM), Copanlisib (5μM) and combinations of A66+Idelalisib and TGX-221+Idelalisib. Viable cells were counted after 24h, 48h and 72h, using a cell viability analyser based on trypan blue exclusion test. Additionally metabolic activity was tested after 48h and 72h using a TTC-assay. Western Blot-experiments were performed in Granta519 and Jeko1 cell lines exposed to the inhibitor-combinations and Copanlisib monotherapy). Similarly, cell viability of 4 patient samples was analysed after 72h exposure to A66, TGX-221, Idelalisib and Copanlisib (multiple concentrations between 30 nM and 10 μM) using a luminescent cell viability assay based on quantitation of ATP. Each experiment were performed in triplicates.
Results: Copanlisib significantly reduced cell growth in all cell lines (Granta519: 32%; Jeko1: 8%; Jurkat 16%; Rec1: 22%). Monotherapy with A66 (Granta519: 93%; Jeko1: 83%; Jurkat 89%; Rec1: 78%), TGX-221 (Granta519: 101%; Jeko1: 86%; Jurkat 64%; Rec1: 71%) and Idelalisib (Granta519: 103%; Jeko1: 69%; Jurkat 63%; Rec1: 75%) showed much only moderate effects. Unexpected, the combination of TGX-221+Idelalisib (Granta519: 101%; Jeko1: 68%; Jurkat 54%; Rec1: 77%) was not more effective than Idelalisib monotherapy, additive effects were only observed in the control cell line Jurkat. In contrast, the combination of A66+Idelalisib (Granta519: 95%; Jeko1: 35%; Jurkat 46%; Rec1: 46%) showed synergistic effects in 3 of 4 cell lines and additive effects in Granta519. TTC-assayshowed comparable results. In Western Blot analysis, treatment with Copanlisib strongly influenced AKT(S) and GSK3α/β as well as 4E-BP1(S) and Rictor phosphorylation. In contrast, combination of Idelalisib and A66 downregulated p42/44 and p38 MAPK. Finally, in patient samples Copanlisib significantly reduced cell growth in all samples investigated so far (0,625 μM-Pat1: 32%; Pat2: 17%; 0,5 μM-Pat4: 45%). In contrast monotherapy with A66 (0,625 μM-Pat1: 80%; Pat2: 71%; Pat3: 83% Pat4: 109%), TGX-221 (0,625 μM-Pat1: 56%) and Idelalisib (0,625 μM-Pat1: 48%; Pat2: 72%; Pat3: 40%; Pat4: 98%) were significantly less effective.
Summary and Conclusions: Copanlisib is highly effective in both cell lines and patient samples. Especiallythe combination of a and d inhibitor showed strong synergism comparable but not achieving the activity of Copanlisib. These results are due to different phosphorylation of PI3K downstream kinases which may explain the observed high clinical activity of less selective PI3K inhibitors.

E1376

WALDENSTROM MACROGLOBULINEMIA CELLS WITH PLASMACYTIC-PREDOMINANT FEATURES ARE INSENSITIVE TO DISRUPTION OF B-CELL RECEPTOR SIGNALING BUT RETAIN HEIGHTENED SENSITIVITY TO PROTEOTOXIC STRESS

A. Paulus[1], S. Akhtar[2], X. Wang[2], P. Wallace[3], S. Ailawadhi[2], S. Ansell[4], A. Novak[4], M. Gertz[4], R. Kyle[4], P. Martin[5], M. Coleman[5], A. Chanan-Khan[2], K. Chitta[2,*]
[1]Cancer Biology, [2]Mayo Clinic Florida, Jacksonville, [3]Roswell Park Cancer Institute, Buffalo, NY, [4]Mayo Clinic, Rochester, [5]Weill Cornell Medical College, Cornell, United States

Background: In contrast to other B-cell malignancies, Waldenströms macroglobulinemia (WM) is a unique clinicopathologic entity in which the tumor compartment is comprised of a heterogeneous mixture of monotypic B-lymphocytes, lymphoplasmacytic cells and plasma cells. As such, anti-WM treatment strategies to date have leveraged experience from other B-cell cancers (comprising alkylating agents, anti-CD20 monoclonal antibodies) as well plasma cell disease (proteasome inhibitors). Recently, the BTK-inhibitor, ibrutinib, became the first drug to secure FDA-approval for treatment of WM. Ibrutinib has shown remarkable clinical activity in patients with chronic lymphocytic leukemia (CLL), a cancer of small mature B-cells but has been less effective in patients with plasma cell disease such as multiple myeloma (MM) (*Vij R et al. ASH 2014*). This observation carries important clinical and biological implications as the WM tumor compartment consists of both B-cells and plasma cells. It is now increasingly being recognized that the phenotypic profile of the WM tumor compartment can drastically shift after treatment with drugs that predominantly eradicate the B-lymphocyte population, resulting in a WM tumor population enriched with plasma/plasmacytoid cells (*Barakat et al., Am J Clin Pathol 2011; Morice et al. Mod Pathol 2009*). To evaluate if plasmacytic-WM cells are sensitive to ibrutinib as well as the underlying molecular basis of response, we utilized a molecularly validated WM model (RPCI-WM1) that displays plasmacytoid features ($CD19^{lo}/CD20^{lo}/CD138^{high}$), is $MYD88_{L265P}$+, and was established from a WM patient who had received multiple lines of chemotherapy (comparing against a WM cell line [BCWM.1] with B-lymphocytic-predominant features- $CD19^{hi}/CD20^{hi}/CD138^{low}$).
Aims: To evaluate if plasmacytic-WM cells are sensitive to ibrutinib as well as the underlying molecular basis of response.
Methods: Flow cytometry, western blot, mitochondrial membrane permeability (MOMP) assay, RNA-Seq (Illumina Hi-Seq), micro-RNA profiling (Exiqon qPCR array, real-time qPCR), methylation profiling (Infinium HumanMethylation 450K array), whole exome sequencing (WES) and mate-pair sequencing.
Results: Cell viability and apoptosis assays confirmed our initial hypothesis, revealing RPCI-WM1 cells as insensitive to ibrutinib (5uM) and contrastingly demonstrated their sensitivity to a first in class 19S proteasome inhibitor, VLX1570 (250nM), the latter causing immense proteotoxic stress and mitochondrial damage. Immunophenotype analysis demonstrated upregulation of several antigens on RPCI-WM1, which are typically restricted to plasma cells. Whole transcriptome profiling by RNA-Seq and gene pathway enrichment analysis in RPCI-WM1 cells, showed differential changes where upregulated genes were significantly enriched within the Protein Transport ($p<1.8E-98$) and Response to Unfolded Protein Gene Ontology groups ($p<5.9E-20$); downregulated genes were significantly localized within the B-cell receptor-signaling pathway (Broad MSigDB) ($p<6.1E-14$). As BCR signaling has been linked to dysregulated expression of several micro-RNAs (miRs), we examined miR expression in RPCI-WM1 cells and observed a decrease in several miRs, which target and regulate components involved in BCR activation (notably miR-155). To examine further epigenetic changes that may account for decreased BCR signaling, we examined the global methylation profile of RPCI-WM1 and BCWM.1 cells and noted hypermethylation of the promoter sites (200 base pairs upstream) for a number of transcription factors involved in the BCR pathway. Ongoing WES and mate-pair sequencing data is anticipated to reveal additional molecular alterations that account for the divergent responses to ibrutinib in WM cells that display predominantly plasmacytic features.
Summary and Conclusions: We have conducted a comprehensive immunophenotype and genomic/epigenomic analysis of plasmacytic-WM cells *vs* B-lymphocytic WM cells, using validated preclinical models representative of the phenotypic heterogeneity present in the human WM tumor compartment. Overall our data suggests that significant architectural differences between the two tumor cell types account for their differential sensitivity to the BCR signaling disruptor, ibrutinib or the novel 19S proteasome inhibitor, VLX1570. These findings will be validated in primary patients-derived WM cells. Further, these observations provide rationale for optimizing (or sequencing) ibrutinib therapy in distinct subgroups of WM patients as based on the predominance of plasma/plasmacytic WM cells, present in their individual tumor compartments.

E1377

EVALUATION OF GENOMIC IMBALANCES AND MIRNA EXPRESSION IN PATIENTS WITH MYCOSIS FUNGOIDES

F. Huaman Garaicoa[1,2,3,*] A. Roisman[1], M. Arias[4], C. Trila[5], M. Fridmanis[6], A. Abeldaño[4], S. Vanzulli[7], M. Narbaitz[2,3], I. Slavutsky[1]
[1]Laboratorio de Genética de las Neoplasias Linfoides, Instituto de Medicina Experimental (IMEX), CONICET- Academia Nacional de Medicina, [2]Laboratorio de Patología, Fundaleu, [3]Laboratorio de Patología, Instituto de Investigaciones Hematológicas (IIHEMA), Academia Nacional de Medicina, [4]Servicio de Dermatología, [5]Servicio de Patología, Hospital Dr. Cosme Argerich, [6]Servicio de Dermatología, [7]Laboratorio de Anatomía Patológica, Instituto de Estudios Oncológicos (IEO), Academia Nacional de Medicina, Buenos Aires, Argentina

Background: Mycosis fungoides (MF) is a clonally derived lymphoproliferative disorder that preferentially involves the skin, which etiology and pathogenesis remains elusive. Morphological and clinical features are not always accurate enough to predict the disease outcome. Comparative genomic hybridization and microarrays have shown imbalances of *CDKN2A* (p16) (9p21) and *C-MYC* (8q24) genes, with probable prognostic value in this pathology. In addition, miR-155 overexpression was observed in several hematological and solid tumors, promoting genomic instability, proliferation, and survival of malignant cells.
Aims: In this study, we have evaluated *CDKN2A* losses and *C-MYC* gains and their association with miR-155 expression, in patients with diagnosis of MF. Results were correlated with clinicopathologic features of patients.
Methods: The study was performed on formalin-fixed and paraffin-embedded biopsies from 32 patients with MF (22 males; median age 62.3 years, range: 31-81 years): 28 cases showed tumor stage MF (T-MF), 13 of them in histologic transformation to a large T-cell lymphoma (TR-MF) and 4 cases with folliculotropic MF (F-MF) variant. FISH analysis using OTS9P21.3 (*CDKN2A*) and OTS8Q24 (*C-MYC*) probes (LiVE-Lexel, Argentina), was performed. Gene expression was quantified by real time PCR using TaqMan Gene Expression Assays. Ten control samples from benign skin diseases were also evaluated.

The study was approved by the local Ethics Committee. All individuals provided their informed written consent.
Results: FISH study was performed in 26 patients, 19 (73%) showed genomic alterations (GA): 11 (42.31%) cases had *CDKN2A* deletion, 8 (30.77%) showed *C-MYC* gains and 3 (11.54%) exhibited both anomalies. *CDKN2A* deletion was observed in 7/13 (54%) TR-MF, 3/4 (75%) F-MF and 1/9 (11%) T-MF meanwhile *C-MYC* gain was detected in 6/13 (46%) TR-MF and 2/4 (50%) F-MF. Thus, GA rate was: TR-MF 92%, F-MF 75% and T-MF 11% (p=0.006). These aberrations were more frequent in trunk and lower limbs (75%) in contrast with head, neck and upper limbs (25%) (p=0.012). Patients with GA showed higher CD30+ by immunohistochemistry (56.25%) and progression to histological transformation (75%) than cases with no alterations (NA) (10% and 20%, respectively) (p<0.03). Clinical response to treatment was absent in 8/16 (50%) of cases with GA *vs* 1/10 (10%) patients with NA (p=0.03). Although no significant differences were reached, mean LDH (532.6 UI) and Beta 2 microglobulin levels (3.4 mg/L), median proliferation index (Ki-67) (62.86%) and extracutaneous relapse (25%) with respect to those with NA. In addition, the group with GA showed shorter overall survival (96 months) compared to cases with NA, that not reached the median survival (Log-rank p=0.04), indicating their association with poor outcome. Gen expression analysis showed miR-155 upregulation in 27% TR-MF and 50% F-MF and in only 8% T-MF. No miR-155 expression was observed in controls. The correlation with FISH results found miR-155 overexpression in 33% of patients with GA and 12.5% of cases with NA.
Summary and Conclusions: Our results showed higher proportion of 9p21 losses than 8q24 gains in MF patients. TR-MF exhibited the highest frequency of GA, supporting a role in the process of neoplastic transformation. Although the number of F-MF is reduced in our series, this morphological variant would seem to be associated to an increased frequency of genomic imbalances. Moreover, our findings on miR-155 expression support its relation with genomic instability and tumor development in this pathology.

E1378

MULTIPLE INJECTIONS OF ANTIBODY-RADIONUCLIDE-CONJUTAGES TARGETING CD37 INCREASES TOLERABILITY IN NUDE MICE BEARING NON-HODGKIN LYMPHOMAxENOGRAFTS

H. Heyerdahl[1,*] A.H.V. Repetto-Llamazares[1], J. Dahle[1]
[1]Research and Development, Nordic Nanovector ASA, Oslo, Norway

Background: CD37 is an internalizing transmembrane glycoprotein predominantly expressed by normal B cells and also B-cell malignancies, thus an interesting target for targeted therapies. The novel anti-CD37 antibody-radionuclide-conjugate (ARC) ^{177}Lu-DOTA-HH1 (Betalutin^{TM}), containing the short-ranged beta-emitter lutetium-177, is currently being tested as single injection therapy in a clinical phase I/II trial for non-Hodgkin B-cell lymphomas.
Aims: The present work is the first to explore the anti-tumor efficacy and tolerability of multiple dosing of ^{177}Lu-DOTA-HH1 in mice bearing non-Hodgkin B-cell lymphomaxenografts.
Methods: Ten million Ramos human lymphoma cells were injected subcutaneously on flanks of in-house bread mice from the strain Hsd:Athymic Nude-*Foxn1^{nu}*. Tumor-bearing mice and mice without tumor for tolerability control were given 2-4 weekly injections of 300 MBq/kg ^{177}Lu-DOTA-HH1 i.v (n=16-18 tumors in 10-11 mice, 3-4 non-tumor bearing mice). Control mice were given 4 injections of 0.9% NaCl (n=19 tumors in 10 mice, 3 non-tumor bearing mice). Tumor size, body weight and hematology were monitored regularly after administration.
Results: A tumor growth delay was observed in all groups given multiple injections. The delay was increased in the group given 3 injections compared to the group given 2 injections due to the increased radioactive dose. Durable complete regression >100 days was observed in 56% of the tumors in mice given 3 injections, compared to 28% in mice given 2 injections. It was found that 4 weekly injections of 300 MBq/kg ^{177}Lu-DOTA-HH1 were above the maximum tolerable dose, as 5 of 12 mice had to be euthanized at day 37 after initial injection due to radiation toxicity recognized by rapid weight loss and severely reduced health condition in combination with low hematology values. None of the 14 mice given 3 weekly injections of 300 MBq/kg ^{177}Lu-DOTA-HH1 needed to be euthanized due to radiation toxicity. An average decrease in body weight of 5% was seen for this therapy group during injections, with continued increase of body weight observed one week after last injection. Hematology analysis showed transient reduction in white blood cells (WBC) and platelet counts in all mice receiving treatment with ^{177}Lu-DOTA-HH1, with NADIR values (WBC: 9-25% of baseline values; platelets: 22-44% of baseline values) occurring 1-2 weeks after last injection. Platelet counts returned to baseline levels within 4-6 weeks and WBC within 7-9 weeks after last injection. A total injected activity of 900 MBq/kg was found tolerable in this multiple injection regime, compared to previously published single injection data showing a maximum tolerated dose of 400 MBq/kg and 50% toxicity-related deaths within 25 days after injection in nude mice given 800 MBq/kg (Repetto-Llamazares *et al.,* PLoS ONE 2014).
Summary and Conclusions: Weekly injections increase tolerability of ^{177}Lu-DOTA-HH1 compared to high dosage single injection in nude mice, allowing a higher total activity to be administered.

E1379

OFATUMUMAB OVERCOMES CD59-DEPENDENT RESISTANCE TO COMPLEMENT-DEPENDENT CYTOTOXICITY IN HUMAN B-CELL LYMPHOMA MODEL

M. Dwojak[1,*] M. Bobrowicz[1], M. Siernicka[1], B. Pyrzynska[1], K. Bojarczuk[1], J. Golab[1], M. Winiarska[1]
[1]Department of Immunology, Medical University of Warsaw, Warsaw, Poland

Background: Anti-CD20 monoclonal antibodies (mAbs) have revolutionized the treatment of CD20-positive lymphoid malignancies. Unfortunately, anti-CD20 immunotherapy is not without its obstacles. It turns out that nearly 50% of patients do not respond to treatment or the resistance appears in the further course of therapy. Accumulating evidence indicates that that resistance is related to the expression of membrane complement inhibitors, *i.e.* CD59 on the surface of target cells.
Aims: The aim of this study was to evaluate the efficacy of the rituximab-or ofatumumab-triggered complement-dependent cytotoxicity (R-CDC or O-CDC) against CD59-overexpressing lymphoma cells and to determine the amount of CD59 and CD20 which allows anti-CD20 mAbs to effectively trigger CDC.
Methods: Raji, human Burkitt's lymphoma cell line, found to be CD59-negative, was chosen to create stable CD59-expressing cell line using pLVX-IRES-Puro-CD59 lentiviral construct. Cell cloning by serial dilution was performed to establish different populations of transductants with various CD59 expression and invariable CD20 expression. All experiments evaluating expression of membrane antigens was performed with flow cytometry. The effectiveness of anti-CD20 mAbs was assessed in a series of distinct clones using MTT-reduction assay.
Results: The results show that CD59 expression, independently of CD20 level, has a critical influence on R-CDC and negatively correlates with the capability of rituximab to trigger the complement cascade (Figure 1A-D). To determine if this inhibitory effect of CD59 can be surmounted, using a panel of different clones we performed CDC assay with ofatumumab-a fully human anti-CD20 antibody. Interestingly, we observed that ofatumumab overcomes CD59-dependent resistance of B-cell lymphoma cells (Figure 1E).

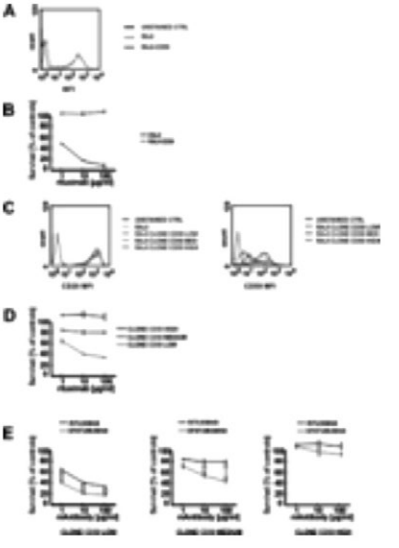

Figure 1.

Summary and Conclusions: Our study clearly shows that CD59 expression level affects the efficacy of anti-CD20 monoclonal antibodies and this observation seems to be clinically relevant. We suggest that evaluation of CD59 expression should be included in the diagnostic panels for leukemia/lymphoma immunophenotyping by flow cytometry. Moreover, determination of CD59 levels can have far-reaching implications for the planning of clinical therapeutic regimens. Since ofatumumab is capable to overcome a negative effect of CD59, it is substantiated to include ofatumumab in therapeutic regimens for patients with high CD59 expression.

E1380

THE EXPRESSION OF FOXO4 REGULATES LYMPHOMA STEM CELL-LIKE CHARACTERISTICS AND RESISTANCE TO TREATMENT IN B-CELL NON-HODGKIN LYMPHOMA

K.J. Ryu[1,*] C. Park[1], M. Hong[2], Y.H. Ko[3], W.S. Kim[4], S.J. Kim[4]
[1]Samsung Biomedical Research Institute, Research Institute for Future Medicine, [2]Pathology, Kangnam Sacred Heart Hospital, Hallym University Medical Center, [3]Pathology, [4]Medicine, Samsung Medical Center, Seoul, Korea, Republic of

Background: Although lymphoma cells are relatively sensitive to chemotherapeutic agents, a subset of cells remains as being viable even during treatment. This subset of lymphoma cells might have stem cell-like properties including tumor initiating ability, and result in resistance to chemotherapy such as doxorubicin. However, there is limited data about the presence of lymphoma stem cells and its association with treatment resistance. In this study, we used a group of lymphoma cells that maintained the viability after the exposure to antitumor agents including doxorubicin and phenylbutyrate as a model of cancer stem cells because doxorubicin is the most commonly used chemotherapeutic agent and phenylbutyrate, a histone deacetylase inhibitor is reported to induce stem cell characteristics in cancer cell lines.
Aims: We analyzed gene expression profiles and biological characteristics of viable lymphoma cells during the treatment with high concentration of doxorubicin and phenylbutyrate, and explored a potential marker for lymphoma stem cells that are associated with treatment resistance.
Methods: Human lymphoma cell lines including BJAB, Toledo (diffuse large B-cell lymphoma), Daudi, and Raji (Burkitt's lymphoma) were incubated with the IC90 concentration of doxorubicin (300nM) or phenylbutyrate (8mM) for 48 hours. After incubation, viable cells were sorted, and analyzed for their resistance to treatment. Gene expression profiles of those viable cells were evaluated with cDNA microarray, and biological characteristics including stem cell-like properties were also analyzed. Membrane proteomics was performed to explore surface markers for lymphoma stem cells, and immunohistochemistry for candidate markers were performed in the paraffin tissue of patients with non-Hodgkin B-cell lymphoma.
Results: Lymphoma cells could maintain their viability after they were exposed to the IC90 concentration of doxorubicin and phenylbutyrate for 48 hours in the experiment with four types of B-cell lymphoma cell lines. These viable lymphoma cells sorted after their exposure to treatment showed resistance to treatment and significantly better ability of colony formation and sphere formation than control cells ($P < 0.05$). The expression of stem cell-related genes including OCT4, NANOG, and SOX2 was also increased in viable cells after treatment. The comparison of gene expression profiles between survived cells after treatment and control cells showed that 42 gene were up-regulated in both conditions (doxorubicin and phenylbutyrate treatment). Among them, FOXO4 was significantly overexpressed in viable cells. The expression of FOXO4 was confirmed with primary lymphoma cells derived from malignant effusion of three patients with B-cell non-Hodgkin lymphoma. The amplification of FOXO4 expression in lymphoma cell lines also increased colony formation whereas the knockdown of FOXO4 decreased the expression of OCT4, NANOG and SOX2, and colony forming ability in lymphoma cells. The analysis of membrane proteins in these lymphoma cells survived after phenylbutyrate treatment showed increased expression of ENO1. The immunohistochemistry with paraffin tissue of patients with B-cell non-Hodgkin lymphoma showed nuclear expression of FOXO4 and membranous expression of ENO1.
Summary and Conclusions: A small subset of lymphoma cells resistant to treatment might have stem cell-like characteristics, and the expression of FOXO4 might play a crucial role in their maintenance. The membranous expression of ENO1 in this small subset of lymphoma cells might suggest the probability of ENO1 as a stem cell marker in B-cell non-Hodgkin lymphoma.

E1381

GLYCOLYTIC INHIBITOR 2-DEOXY-GLUCOSE SUPPRESSES CELL PROLIFERATION IN NON-HODGKIN LYMPHOMA CELLS THROUGH DOWN-REGULATION OF HIF-1 AND C-MYC

T. Wang[1,*] Y. Pang[1], F. Chen[1], H. Huang[1], F. Xiao[1], J. Zhong[1], H. Zhong[1]
[1]Division of Hematology, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China

Background: Metabolic reprogramming is linked to tumourigenesis, disease progression, clinical outcome and resistance to chemotherapy. However, the significance of glycolytic metabolism in non-Hodgkin's lymphoma (NHL) remains unclear.
Aims: To investigate the role of glycolysis in the pathogenesis of lymphoma and the potential target for therapy.
Methods: Cell proliferation and cytotoxicity were detected using Cell Counting Kit-8. Glucose consumption was determined via glucose uptake assay. Lactic acid generation was estimated using a lactic acid detection kit. Apoptosis and cell cycle analysis were measured by flow cytometry. Real-time PCR was performed to determine the levels of glycolysis-related genes. Cleavage of caspase-3 and PARP-1 as well as expressions of HIF-1α and c-MYC were demonstrated via western blot.
Results: Activation of glycolysis-related genes was seen in malignant tissues from patients with NHL, and a panel of NHL cell lines as well. Consistent with the gene expression levels, multiple NHL cell lines exhibited the glycolytic metabolic phenotype, suggesting a role of glycolysis in the pathogenesis of NHL. The glycolytic inhibitor 2-DG significantly suppressed the abilities of glucose consumption and lactic acid production in NHL cell lines. In consert with suppression of the metabolic phenotype, proliferation of NHL cell lines were significantly inhibited by 2-DG in a time- and dose-dependent manner. In contrast, no difference was observed in normal lymphocytes after 2-DG treatment. The Burkitt lymphoma cell line Raji was less sensitive to 2-DG than other cell lines *e.g.* SU-DHL-4, DB, Namalwa, Jeko-1. However, when cultured under hypoxia, the IC50 value of 2-DG for hypoxic Raji cells was significantly lower compared with its normoxic counterpart, accompanied by a more marked inhibition of cell proliferation, glucose cosumption and lactic acid generation. Meanwhile, hypoxic Raji cells displayed apoptosis induction after 2-DG treatment. Furthermore, down-regulation of HIF-1α and c-MYC were observed only in hypoxic Raji cells (Figure 1).

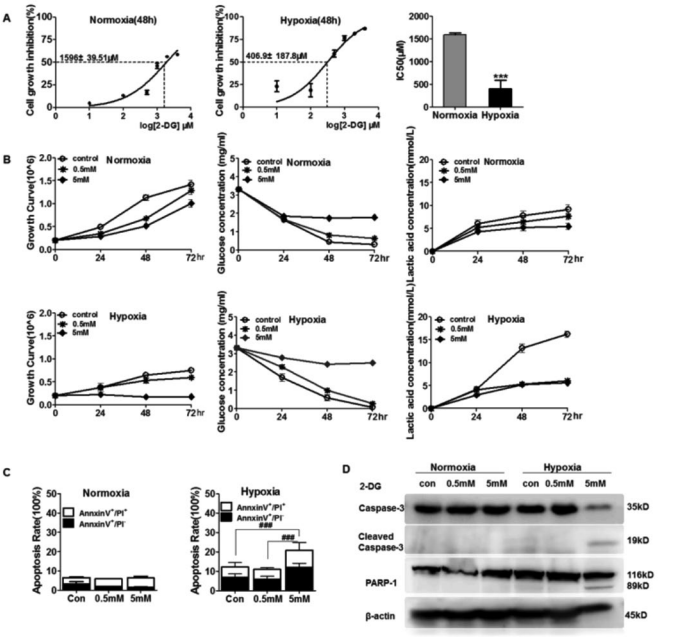

Figure 1.

Summary and Conclusions: In conclusion, these results present novel insight into critical roles of glycolytic pathway activation in NHL progression. Inhibition of glycolytic pathway may provide a new therapeutic strategy for the treatment of NHL.

IMMUNOPHENOTYPIC CHARACTERIZATION AND CLINICAL BEHAVIOUR IN CD19+CD5+ (NON-CLL) LYMPHOPROLIFERATIVE DISORDERS MUTATED AND UNMUTATED WITH AND WITHOUT T(11,14)

L. Lopez-Anglada[1,*] M. Alcoceba[2], M. Garcia-Alvarez[2], FJ. Diaz-Galvez[3], M. Bourgeois[4], J.A. Queizan[5], A. Ahmadi[6], R.H. Cantalejo[7], G. Martin[8], I.F. Graciani[9], E. de Cabo[3], M.C. Montes-Fernandez[10], S. Fernandez-Ferrero[11], J.M. Alonso[12], M. Gonzalez-Diaz[2], M.B. Vidriales[2]
[1]Haematology, Hospital Universitario 12 de Octubre/ I+12, Madrid, [2]Haematology, Hospital Clínico de Salamanca/ IBSAL, Salamanca, [3]Hospital del Bierzo, Ponferrada, [4]Hospital Clínico Universitario de Valladolid, Valladolid, [5]Haematology, Complejo Asistencial de Segovia, Segovia, [6]Haematology, Hospital Nuestra Señora de Sonsoles, Avila, [7]Haematology, Hospital Santos Reyes, Aranda de Duero, [8]Haematology, Hospital Virgen del Puerto, Plasencia, [9]Hospital Río Hortega, Valladolid, [10]Haematology, Hospital Virgen de la Concha, Zamora, [11]Haematology, Complejo Asistencial de León, Leon, [12]Hospital Rio Carrion, Palencia, Spain

Background: Mantle cell lymphoma (MCL), characterized by the presence of t(11;14)(q13;q32), shows a typical immunophenotype CD19+CD5+ that can be identified by flow cytometry (FC) and is easily distinguished from CLL. However, cases with typical MCL-immunophenotype lacking t(11;14) are frequently detected in the clinical routine. Further, clinical presentation could be variable and may show a different IGHV mutational status.
Aims: Characterize FC CD19+CD5+ (non-CLL) lymphoproliferative disorders (LPD), trying to identify immunophenotypic profiles that may predict the presence of t(11;14) and to find molecular differences associated to clinical behaviour.
Methods: We retrospectively reviewed a total of 98 patients with CD19+CD5+ (non-CLL) LPD detected by FC in the clinical laboratory of the University Hospital of Salamanca (Spain), in which information of immunophenotype, cytogenetics, and molecular biology (MB) (bcl-1 and IGHV mutational status) was available. The clonal B-cell population was detected in peripheral blood (n=50), bone marrow (n=29) and/or lymph node (n=19). Erythrocyte-lysed samples were stained with large panels of monoclonal antibodies, using 4-color direct immunofluorescence technique according to previously described methods, aimed to identify and characterize B neoplastic cells; the complete diagnosis was performed with ancillary techniques as MB (bcl-1 and IGHV

mutational status), karyotype and fluorescent *in situ* hybridization (FISH) for t(11;14).
Results: Out of the 98 samples with CD19+CD5+ immunophenotype (no CLL), 52% were t(11;14) positive (most of them studied by the tree techniques: 9% Karyotype(Kt)+FISH+BM+; 11% Kt+FISH+BM-; 22% Kt-FISH+BM+; 47% Kt-FISH+BM- and 11% Kt-FISH-BM+). FISH was the most useful technique, being positive in 88% of the positive cases. 84% of the t(11;14) positive cases showed typical CD22+/CD23- immunophenotype and bright expression of CD20+ and FCM7+, CD38 expression was negative in 53% of the cases. Negative cases for t(11;14) showed CD22+/CD23- in a slightly lower frequency (62%) being more heterogeneous, but with similar expression of CD20; CD38 was positive in a 33% of these cases. Concerning clinical behaviour and IGHV mutational status, the percentage of mutated cases was higher among leukemic cases (88%) than among nodal cases (35%), both with and without t(11;14). Despite no differences in OS, unmutated cases could be associated with more aggressive behaviour due to the need for earlier treatment (TTT median 15 days *vs* 29 months; p<0.001) and a higher progression risk (SLP median 52 months *vs* NR; p<0.001). Among the 98 CD19+CD5+ (non-CLL) cases, 8 were non-classifiable chronic LPD, 4 were classified as SMZL, 4 as SLL, 2 as DLBCL, 1 as FL and 79 as MCL. Overall, 75% of cases received therapy (of which 73% of them had nodal behaviour; 27% leukemic behaviour). The time to treatment was longer in leukemic than in nodal cases (median 82 months *vs* 15 days; p<0.001).
Summary and Conclusions: Although typical MCL's-immunophenotype cases are frequently detected, t(11;14) is present only in half of the cases and there is no clear difference in immunophenotype between cases t(11;14) positive and t(11;14) negative. Despite no differences in OS, and taking into account that patients were not treated uniformly, unmutated cases could be linked to more aggressive behaviour due to the need for earlier treatment and to an increased risk of progression, while mutated forms are generally presented as a less aggressive disease.

E1383

ANALYSIS OF THE IGVH SOMATIC MUTATIONS IN SPLENIC MARGINAL ZONE LYMPHOMA
H.L. Julhakyan[1,*] B. Biderman[1], A. Sudarikov[1]
[1]Hematological Scientific Center, Moscow, Russian Federation

Background: Splenic marginal zone lymphoma (SMZL), a specific type of small B-cell lymphoma and characterized by a peculiar morphology with micronodular pattern of infiltration, biphasic cytology, and the almost constant presence of marginal zone differentiation.
Aims: The aim of our study to determine the immunoglobulin variable heavy chain (IgVH) gene usage and somatic mutation patterns in a series of SMZL patients and to correlate these findings with the clinical features and outcome.
Methods: Among a total of 125 SMZL patients diagnosed and followed up in our Center during the last 14 years, 24 were included in the present study, based on the availability of tissue specimens or frozen cell material. Diagnosis was based on standard WHO criteria. In all patients, the diagnosis was based on peripheral blood and BM findings. The baseline clinical and laboratory features as well as follow-up and outcome were recorded for every patient. Rearranged IgVH genes were amplified essentially in reactions that contained only one of the 5' leader region primers for the indicated 6 VH families and a 3'J primer. All PCR reactions were performed using appropriate positive and negative controls.
Results: The studied population included 15 women and 9 men with a median age at diagnosis of 60 years (range, 32 to 77 years). All patients had splenomegaly, with a median spleen size of 10 cm below the left costal margin. None of them had lymph node enlargement, except for the splenic hilar lymph nodes. BM infiltration was evident in all patients, either by conventional morphology and immunohistochemistry or by flow cytometry. B-symptoms were present in all patients. Anemia (hemoglobin<12 g/dl) and thrombocytopenia (platelets <100×109/l) were recorded in 14 and 7 patients respectively. Autoimmune hemolytic anemia was present in 3 patients, while paraproteinemia was detected in 10 patients, being of the IgM isotype in all cases except one. Serum lactate dehydrogenase (LDH) was elevated in 17, serology for hepatitis C was negative in all patients. All patients underwent splenectomy as first-line therapy. The rearranged VH genes identified for each case seemed to represent functional rearrangements because no stop codons or crippling mutations were identified. A comparison of the VH genes to reported germline sequences revealed that 6 cases used the VH3 family VH gene segments, 2 the VH4 family, 16 the VH1 family segments. The VH1 family genes V1-2 were used in 16 cases. In 4 out of 24 cases (16.67%), IgVH genes were in germline or near germline configuration, whereas in 20 cases (83.33%), IgVH genes were somatically mutated. We have shown no differences in clinical and laboratory characteristics, immunophenotype, outcome or overall survival were found between the mutated and unmutated cases. There was a trend for worse survival in unmutated *versus* mutated SMZL cases (median survival 70 *vs.*109 months), but the difference did not reach statistical significance.
Summary and Conclusions: Our analysis also showed the selective use of VH1 family genes in a high proportion of SMZL cases (66.67%), while VH4 and VH3 family genes were represented at a lower frequency (8.33% and 25%, respectively). The present study revealed that a significant fraction of SMZL cases derive from naive B-cells with unmutated IgVH genes, thus indicating that this is a heterogeneous group of disease with respect to its cellular origin. A prognostic significance of mutation status was not observed in this study.

E1384

FLOW CYTOMETRY IMMUNOPHENOTYPING AND CYTOLOGICAL ANALYSES OF CSF: A COMPARISON OF PERFORMANCES FOR LYMPHOMATOUS CELL DETECTION
M. Costopoulos[1,*] T. Belleville[1], C. Settegrana[1], K. Maloum[1], Z. Azgui[1], M. Brissard[1], P. Bonnemye[1], S. Choquet[2], K. Hoang-Xuan[3], V. Leblond[2], H. Merle-Beral[1], M. Le Garff-Tavernier[1]
[1]Biological Haematology Department, [2]Hematology Department, [3]Neuro-Oncology Department, Pitie-Salpetriere Hospital, Paris, France

Background: Leptomeningeal involvement of lymphomas is a rare and aggressive condition, mainly occurring in large B-cell lymphomas (DLBCL) and Burkitt lymphomas. It is defined by the presence of malignant cells in the cerebrospinal fluid (CSF) and can be prevented by intrathecal chemotherapy. The prevalence of this affection is uncertain and may be explained by the various existing techniques. Cytomorphological (CM) examination is considered to be the "gold standard" but remains insufficiently sensitive due to the frequent sample paucity. Provided these limits, a multimodal investigation of CSF is required. Flow cytometry (FCM) techniques tend to be more sensitive and specific. The approach consisting of drawing the CSF sample on a Transfix™ tube is currently largely used for FCM and prevents early cell mortality.
Aims: The aim of our study was to assess the value of FCM in detecting CSF disease in a large cohort of patients with aggressive lymphomas.
Methods: This retrospective study was conducted on all CSF samples referred to our laboratory and coming from patients with primary cerebral lymphoma or other non-Hodgkin lymphomas (NHL) between January 2013 and September 2014. We matched FCM and CM results obtained from the analysis of 204 CSF drawn (107 patients). In this purpose, 2 samples were collected: 1 ml for CM analysis (with albumen added during cytospin and May Grünwald Giemsa staining) and 1 ml on a Transfix-containing tube (Cytomark). A cytological sample was classified as negative or positive by CM evaluating lymphocyte features defining lymphoid cells as typical or atypical. Immunophenotyping was performed on a FACSCanto II (BD Biosciences) using an 8-colour panel (anti-CD19, kappa, lambda, CD5, CD3, CD4, CD8 and CD45). A CSF sample was considered as positive by FCM when a cluster of at least 20 events with immunophenotypic features of neoplastic cells were detected. CM and CSF results were treated in a double-blind manner.
Results: We confirm that Transfix-treated CSF prevent early cell mortality and improves the quality of FCM tests. Identifying and analyzing cells by FCM remains possible even if the total cell count is ≤1 leucocyte/µl in CM count (n=70). Overall, 178 (87%) samples showed similar results by CM and FCM with presence (n=25) or absence (n=153) of lymphomatous cells. Seven percent of samples were classified as suspicious by one technique. Among them, 9 samples were positive by FCM but negative by CM. This lack of accuracy is due to poor cellularity in the CSF in patients with low-volume disease or to innocent aspect of neoplastic cells. False negative cases occur because of low sensitivity of CM compared with FCM. In contrast, three samples were positive by CM but negative by FCM. False positive results by CM can be generated by the presence of confounding atypical-like reactive lymphocytes. On the other hand, false negative results by FCM can be explained by the cell size (inherent cells parameter) particularly large lymphocytes outside the scope of our analysis or by the loss of one gating marker.
Summary and Conclusions: To date the debate pertaining FCM diagnostic accuracy as well as prognostic impact when compared to CM examination is still open. CSF is a biological sanctuary extremely accessible to FCM studies. Our results suggest that FCM increases the sensitivity and specificity of leptomeningeal disease detection. FCM is a well-reproducible quantitative method suited for the identification of small cell populations. In conclusion, both methods should be applied concurrently for complementary diagnosis assessment in patients with lymphomas.

EXPRESSION OF SOXC CLUSTER AND MIR-17-92 POLYCISTRON IN MANTLE CELL LYMPHOMA PATIENTS
A. Roisman[1,*] F. Metrebian[2], D. Kohan[3], H. García Rivello[3], M. Narbaitz[2], E. Campo[4], L. Hernández[4], I. Slavutsky[1]
[1]Laboratorio de Genética de Neoplasias Linfoides, Instituto de Medicina Experimenta. CONICET-Academia Nacional de Medicina, [2]Departamento de Patología, Instituto de Investigaciones Hematológica, ANM, [3]Servicio de Patología, Hospital Italiano, Buenos Aires, Argentina, [4]Molecular Pathology., Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona., Spain

Background: Mantle cell lymphoma (MCL) is an aggressive B-cell lymphoid malignancy that accounts for approximately 6% of all non-Hodgkin´s lym-

phomas. *SOX4*, *SOX11* and *SOX12* genes, constitute the SOXC family of transcription factors involved in embryonic neurogenesis and tissue remodeling. Among them, *SOX11* shows aberrant expression in MCL, being considered a new molecular marker of adverse prognosis in this pathology; meanwhile recently it has shown that *SOX4* can bind and regulate the promoter of Dicer, a microRNA biogenesis factor. Furthermore, several studies have demonstrated the oncogenic role of miR-17-92 cluster in hematological malignancies, being scarce the information about the association between this cluster and SOXC expression levels in MCL.

Aims: In this study, we have performed a Gene Expression Analysis (GEA) of SOXC cluster and their correlation with the expression of miR-17, miR18a, miR19b and miR92a, members of the polycistronic oncomiR-17-92 in MCL patients.

Methods: mRNA samples of 45 MCL patients (15 males; mean age: 56.7 years, range: 34-71 years) and 12 normal controls were analyzed. Gene expression was quantified by real time PCR using TaqMan Gene Expression Assays. *GUSB* and *RNU6B* were used as housekeeping genes to normalize the expression of SOXC and miR17-92 clusters, respectively. The proliferation index was evaluated by immunohistochemistry with the Ki67 antibody. The analysis of mRNA expression data was done using the two-tailed Mann-Withney test. To calculate the expression cut-off values with the highest sensitivity and specificity, receiver operating characteristics curves were used. The study was approved by the Ethics Committee of our Institution. All individuals gave their informed consent.

Results: The analysis of SOXC members showed upregulation, of SOX11 and SOX12 in 60% and 71% patients, respectively, while SOX4 was downregulated in 45% of cases, compared to normal controls. GEA of SOX11 and SOX12 showed higher expression levels (2.1±0.24 and 3.1±0.16, respectively), with respect to SOX4 (1.2±0.21) (p=0,006 and p<0.0001, respectively). Moreover, an inverse relationship between the expression of SOX11 and SOX4 was detected (p=0.0017), being the last one undetectable in patients with high expression of SOX11. Regarding to the members of the miR17-92 cluster, miR17 and miR18a were downregulated in 86% and 84.4% of our cohort, respectively; meanwhile, miR19b and miR92a were upregulated in 95% of cases each, compared to controls. GEA revealed that miR19a (3.24±0.1) and miR92a (2.59±0.1) exhibited increased expression levels than miR17 (-2.7±0.15) and miR18a (-2.8±0.19) (p<0.0001). A positive correlation between miR92a with miR17 (p=0.0001), miR18a (p=0.0013), and miR19b (p<0.0001) mRNA levels, was observed. Moreover, we found a positive correlation between SOXC members and miR18a expression (p<0,012). In addition, patients overexpressing *SOX11*, *SOX12* and miR92a showed a higher percentage of Ki67 positive cells (37-41%), compared to cases without expression, but without reaching significant differences.

Summary and Conclusions: Our findings in MCL patients show for the first time an inverse correlation in the expression profiles of *SOX11* and *SOX4* genes. Additionally, and to the best of our knowledge, we found new evidence linking the differential expression pattern between SOXC genes and miR18a, suggesting an interaction that could add new insights in the biologic characterization of this pathology.

E1386

THE IMPACT OF MUTATION STATUS OF SOCS1 IN PATIENTS WITH HIGH-GRADE DIFFUSE LARGE B-CELL LYMPHOMA.

O. Gavrilina[1,*] E. Zvonkov[2], N. Siverina[3], B. Biderman[3], A. Sudarikov[3], E. Parovichnikova[1], S. Kulikov[4], V. Savchenko[5]
[1]Department of Hematological Oncology and BMT, [2]Department chemotherapy lymphomas, [3]Laboratory of molecular hematology, [4]Department of boistatistics, [5]National Research Center for Hematology, Moscow, Russian Federation

Background: Suppressor of cytokine signaling 1 (SOCS1) is a negative regulator of JAK/STAT pathway. Nowadays there are studies that demonstrated high frequency of SOCS1 mutations in patients with diffuse large B-cell lymphomas. There is only one publication about the prognostic value of SOCS1 mutations in DLBCL patients with CHOP-like therapy.

Aims: To evaluate the frequency and prognostic impact of mutation status of SOCS1 in patients with *de novo* high-grade DLBCL treated with high-dose chemotherapy (HDC).

Methods: We performed a trial, including 22 adult patients (median age 40 years, range 20-66) with newly diagnosed DLBCL who were enrolled in HDC protocol (mNHL-BFM-90 program) since July 2007 till January 2014. Their clinical characteristics: m:f=9:13, extranodal involvement>1 in 13 (59%) patients, bone marrow involvement in 5 (23%) patients, high proliferative activity Ki-67>80% in 17 (77%) patients, GCB: non-GCB type=13:9, IPI risk>2 in 17 (77%) patients. Mutations of SOCS1 were detected using sequencing PCR products, which were received by single-round PCR. DNA for PCR was extracted from sections of frozen tumor samples. Amplification of VH gene rearrangements to control the tumor cells was performed by BIOMED-2 multiplex polymerase chain reaction protocol.

Results: In 8 (36%) of 22 patients the SOCS1 mutations were detected. By sequence analysis, we identified 18 (7 deletions, 11 single nucleotide substitutions) SOCS1 mutations. We didn't verify hotspots. Mutation status of SOCS1 gene didn't correlat with clinical characteristics of patients.

The median follow-up time in 22 patients was 46 months (range: 5-65 month). Four patients had died of the disease (~18%) and 18 patients were either alive. Univariate analysis of the entire cohort (n=22) revealed that age, IPI, extranodal involvement, Ki-67 and phenotype were not of prognostic significance (p >0.05). In a multivariate analysis, detection of SOCS1 mutations in patients with high grade DLBCL was an independent predictor for overall survival (OS) (p <0.05). OS in DLBCL patients with SOCS1 mutations and without was 62,5% and 90%, respectively. Event-free survival (EFS) was 62,5% and 71,4%, respectively. (Figure1A-B). There was no difference in overall survival and event-free survival in subgroups between SOCS1 deletions and SOCS1 single nucleotide substitutions, between SOCS1 single mutation and SOCS1 multiple mutations.

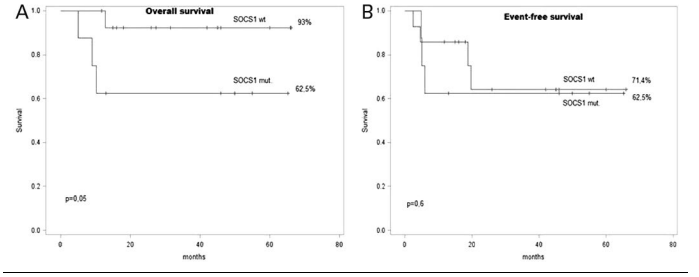

Figure 1.

Summary and Conclusions: Though a group of analyzed patients is small, however the detection of SOCS1 mutations seems to be an independent predictor of outcome in high grade DLBCL patients, treated with high-dose chemotherapy, while IPI and phenotype DLBCL cannot be considered as risk factors for this group of patients. It seems to be reasonable to continue a study of mutation status of SOCS1 gene in high-grade DLBCL patients, because it's may be a single gene prognostic biomarker in DLBCL. If it will be confirmed, this biomarker could determine an indication for autologous transplantation in this group of patients as first-line therapy.

LB2092

CARDIAC GLYCOSIDES SELECTIVELY INDUCE HEMATOLOGICAL MALIGNANCY CELLS APOPTOSIS THROUGH NKA/IP3R SIGNALING PATHWAY

T. Wang[1], J. Chen[1], Y. Xu[2], Y. Guo[3], J. Ouyang[2], J. Li[2,*]
[1]Nanjing University, [2]Nanjing Drum Tower Hospital, Nanjing, [3]the First People's Hospital of Changzhou, Changzhou, China

Background: Cardiac glycosides have been used to treat heart diseases for centuries because of their inhibition effects on Na^+/K^+-ATPase (NKA). Recently, more and more studies indicate that low doses of cardiac glycosides can inhibit cancer cells proliferation and induce apoptosis, but there is no evidence suggests which types of cancer cells are more sensitive to cardiac glycosides and until now the anti-apoptotic mechanism is still not quite clear yet. In our previous work, we found that low doses of cardiac glycosides without inhibition of NKA can trigger intracellular signaling pathway (NKA/IP_3R-Ca^{2+} oscillation-NF-kB) which regulates cells proliferation and apoptosis. Here we found that Burkitt's lymphoma cells are the most sensitive cells to cardiac glycosides and the mechanism is that Burkitt's lymphoma cells overexpress c-myc which is regulated by cardiac glycosides triggered signaling pathway (NKA/IP_3R-Ca^{2+}oscillation-NF-kB).

Aims: We attempt to elaborate on the following points: 1) The suppose that cardiac glycosides regulate the activity of NF-κB and c-myc and induce Raji cells apoptosis through NKA/IP_3R-Ca^{2+} oscillation-NF-kB signaling pathway will be certificated. 2) We set up Burkitt's lymphoma animal model to investigate cardiac glycosides anti-tumor activity *in vivo* study.

Methods: *In vitro* study: 1) Cells: 11 types of human malignant hematological cell lines and 7 types of primary culture of human malignant hematological cells were used. 2) Cardiac glycosides treatment: digoxin, digitoxin and ouabain were used. 3) Cells Proliferation rate was measured by Cell Counting Kit-8. 4) Cells apoptosis rate was detected and quantificated by Annexin-V-FLOUS Staining Kit followed by flow cytometry. 5) NF-kB activity was measured by the TransAM NF-κB p65 Kit. 6) NKAa1, IP_3R and c-myc protein level were measured by western-blot, mRNA level were measured by realtime-PCR. *In vivo* study: BALB/c-nu mice models of human Burkitt's lymphoma were established by injecting Raji cells subcutaneously. To study the effect of digoxin onxenograft engraftment rate, digoxin was injected into the abdominal cavity daily 3 days before or 1 day after tumor cells implantated into mice. Mice weight and volume ofxenograft tumors were measured daily. Western Blot, immunohistochemical staining and immunofluorescence staining were used to analyze c-myc protein level ofxenograft tumors.

Results: 1) Low doses of cardiac glycosides can inhibit human malignant hematological cells proliferation and induce apoptosis, Burkitt's lymphoma cells including primary culture cells and Raji cells are the most sensitive cells. 2) Burkitt's lymphoma cells overexpress c-myc not only protein level but also mRNA level, NF-kB is over activated in Burkitt's lymphoma cells. Cardiac glycosides can decrease the c-myc expression level and inhibit NF-kB activity. 3) Cardiac glycosides can increase Burkitt's lymphoma cells NKAa1 expression.

By using siRNA to knock down NKAa1, NKAa1 expression is decreased and this abolish the anti-apoptotic effect of cardiac glycosides and also abolish the effect of cardiac glycosides on c-myc and NF-kB activity. 4) *In vivo* study, by using naked mice with hypodermic injection Raji cells to set up Burkitt's lymphoma animal model. Digoxin reducedxenograft engraftment rate of Burkitt's lymphoma significantly if mice were treated with digoxin before tumor cell implantation. Digoxin suppressed the growth of subcutaneous tumors at the fifth day when mice were treated with digoxin after tumor established. This effect lasted until the endpoint of the observation. Digoxin reduced c-myc protein expression of tumor cells.

Summary and Conclusions: Compare to other human malignant hematological cells, Burkitt's lymphoma cells are the most sensitive cells to cardiac glycosides, this maybe because these cells overexpress c-myc which is regulated by cardiac glycosides triggered signaling pathway (NKA/IP_3R-Ca^{2+} oscillation-NF-kB). Cardiac glycosides also have anti-tumor *in vivo* study. Burkitt's lymphoma is a high grade malignancy, until now, there is no effective therapy method. Our finding suggests a positive new medicine for the therapy of Burkitt's lymphoma which may increase the survival time of Burkitt's lymphoma patients.

FLOW CYTOMETRIC CHARACTERIZATION OF LEUKOCYTE SUBPOPULATIONS IN BONE MARROW FROM UNTREATED PATIENTS WITH GAUCHER DISEASE TYPE 1: PRONOUNCED T-CELL RESPONSE AND STEM CELL DEFECT?

M. Klimkowska[1,*] E. Pawlowicz[2], A. Jeppsson-Ahlberg[1], M. Machaczka[2]
[1]Department of Clinical Pathology and Cytology, [2]Hematology Center Karolinska, Karolinska University Hospital, Stockholm, Sweden

Background: Gaucher disease (GD) is a lysosomal storage disease, with deficient activity of glucocerebrosidase due to autosomal recessive mutations in *GBA1* gene. The defect causes ubiquitous macrophage infiltration in parenchymatous organs and bone marrow in all clinically distinguished phenotypes (GD 1-3), with additional nervous system involvement in type 2 and 3. Patients with GD demonstrate a variety of abnormal immunological responses and tendency to develop lymphoproliferative diseases. As the role of chronic inflammation in GD-affected organs was postulated, the role of respective immunological cell types is being discussed. Up till now studies focused exclusively on leukocyte subpopulations and cytokine profiles in peripheral blood.

Aims: The study aimed to characterize leukocyte subsets in bone marrow aspirates from treatment-naïve patients with Gaucher disease type 1 by multiparameter flow cytometry (FC), in comparison with data from healthy controls.

Methods: Twelve patients with GD1, previously untreated, followed at the Karolinska University Hospital Hematology Center were enrolled (4 females, 8 males). Bone marrow aspirates were taken between 2008 and 2013, as a part of routine clinical follow-up, and analyzed by flow cytometry. For comparison, bone marrow flow cytometry data on 12 healthy subjects, age and sex matched to GD-patients, were retrieved from the database of Department of Clinical Pathology and Cytology at the same institution. Samples were routinely processed, stained with monoclonal antibodies (Beckton Dickinson, DAKO), acquired using 4 color Canto A or 8 color Canto II cytometers (BD), and analyzed using BD FACSDIVA™ software. Analysis included cells present in mononuclear cell gate in each analyzed tube. The following cell populations were highlighted in each subject: CD3+ T-cells and fractions (CD4+, CD8+, CD4+/8+, CD4-/8-, T/NK-cells), CD56+/CD3- NK-cells, CD19+ B-cells at different stages of maturation. Besides, CD34+ stem cells, CD117+ precursors, CD14+ monocytes and CD33+ mononuclear immature myeloid cells were analyzed. For statistical analysis, Shapiro-Wilk test was used for verification of value distribution, and t-test and Mann Whitney U test for comparisons between groups.

Results: Median age was 55.5 years (mean 58.8±18.8) in GD patients and 57.5 yrs (57.6±17.3) in controls. Four GD patients were previously splenectomized. Bone marrow aspirates from GD1 patients contained more T-cells and respective fractions but the CD4/CD8 ratio was lower as compared to healthy controls; the differences were however not significant. Patients with GD1 had minimally fewer NK-cells, B-cells and plasma cells, with the exception of the CD19+/CD5+ B-cell fraction. They had also significantly fewer CD34+ stem cells, with almost the same proportion of CD33+ or CD14+ cells as controls. Splenectomized GD patients had significantly fewer precursor cells (CD34+, CD117+) but more NK-cells as compared to non-splenectomized ones. There were also non-significant trends for higher amounts of T-cell, B-cell and monocytes in splenectomized patients (Table 1).

Table 1. Leukocyte subsets in bone marrow in flow cytometry analysis.

Cell subsets	Gaucher disease (%total; mean±SD)	Controls (%total; mean±SD)	p-value
CD34+ stem cells	0.9±0.39	1.36±0.49	0.02
CD117+ precursors	1.13±0.47	1.46±0.53	0.12
CD33+ immature myeloid cells	5.02±1.67	5.01±1.14	0.4
CD14+ monocytes	3.29±1.52	3.29±1.09	0.64
CD3+ T-cells	9.73±5.39	7.98±4.46	0.49
CD4+	4.47±3.52	4.27±3.03	0.84
CD8+	4.63±2.02	3.26±2.03	0.11
CD4/CD8 ratio	1.03±0.68	1.55±1.26	0.26
CD4+CD8+ double positive T-cells (DPT)	0.18±0.16	0.09±0.09	0.14
CD4-CD8- double negative T-cells (DNT)	1.03±0.84	0.63±0.51	0.3
CD3+CD56+ natural killer/T-cells	1.1±0.72	0.76±0.6	0.1
CD3-CD56+ NK-cells	2.41±3.51	2.5±2.06	0.14
CD19+ B-cells	2.16±1.82	2.18±0.95	0.3
CD20+ mature B cells	1.61±1.55	1.6±0.85	0.3
CD10+ immature B-cells	0.38±0.48	0.72±0.77	0.3
CD5+ B-cells	0.44±0.54	0.35±0.37	0.73
CD38++ Plasma cells	0.27±0.19	0.31±0.19	0.49

Summary and Conclusions: Presented findings provide for the first time an overview of leukocyte subpopulations in GD1 patients who did not receive any eznyme replacement or substrate reduction therapy. On the contrary to some reports concerning lymphocyte subsets in peripheral blood from GD patients, our data suggest a more pronounced T-cell response and possibly a stem cell defect in the bone marrow of GD1 patients, where the actual Gaucher cells

infiltrates are present. This trend was even more pronounced in splenectomized patients, in whom the natural course of the disease varies from persons with preserved spleen.

E1388

FREQUENCY OF AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME IN CHILDREN WITH CHRONIC IMMUNE CYTOPENIAS AND NEWLY DIAGNOSED LYMPHOMA

Z. Kaya[1,*] M. Isik[1], E.U. Bagriacik[2], F.G. Pinarli[3], U. Kocak[1], I. Yenicesu[1], T. Gursel[1]
[1]The Pediatric Hematology Unit of the Department of Pediatrics, [2]Department of Immunology, [3]Department of Pediatric Oncology, Medical School Of Gazi University, Ankara, Turkey

Background: Autoimmune lymphoproliferative syndrome (ALPS) is caused by defective lymphocyte homeostasis resulting from mutations in FAS-mediated apoptotic pathway. It is characterized by chronic non-malign organomegaly and/or immune cytopenias and/or lifelong increased risk for lymphoma. Although there are only 300 families that has been described all over the world, the actual incidence is probably much higher than that.
Aims: The aim of the present study was to investigate ALPS in children with newly diagnosed lymphoma, chronic immune cytopenias with/without nonmalign organomegaly.
Methods: We studied a total of 34 children, including newly diagnosed lymphoma (n:13), non-malign organomegaly in association with immune cytopenias (n:6), chronic immune thrombocytopenic purpura (cITP) (n:10) and autoimmune hemolytic anemia (AIHA) (n:5) which meet diagnostic criteria of proven and probable ALPS. Their CD3+CD4-CD8- double negative T cells were isolated from peripheral blood mononuclear cells and then analysed by flow cytometry using anti-CD3, anti-CD4 and anti-CD8 coated magnetic beads. T cell apoptosis was assessed in peripheral blood using flow cytometry and staining with Annexin V. Soluble Fas ligand (sFasL) and interleukin (IL-10) 10 levels were measured using quantitative ELISA method. Other hematological and biochemical parameters were recorded from the patients clinical files.
Results: Eighteen (53%) of the 34 cases met the diagnostic criteria of proven or probable ALPS. Frequencies of proven and probable ALPS were 38% and 15%, respectively. The distribution of underlying condition was lymphoma (proven n:7) (21%), non-malign organomegaly (proven n:4, probable n:1) (16%), cITP (proven n:1, probable n:3) (10%) and AIHA (proven n:1, probable n:1) (6%). Elevated double negative T lymphocyte (>5%) and increased lymphocyte apoptosis ranged between 50-80% of all patients, but high sFasL (>200pg/ml) and IL 10 (>20pg/ml) levels were found in only 10-30% of them. Double negative T lymphocyte and lymphocyte apoptosis were significantly higher in patients with lymphoma and non-malign organomegaly compared to patients with cITP or AIHA ($p<0.05$). Ninety percent of lymphoma patients had anemia and/or thrombocytopenia in association with hypergammaglobulinemia which are secondary diagnostic criteria of ALPS.
Summary and Conclusions: Our data indicate that investigation of ALPS is warranted in children with lymphoma presenting with hematologic abnormalities at diagnosis, chronic non-malign organomegaly with immune cytopenias and probably in cITP and AIHA developing organomegaly on follow up.

E1389

PLASMA LEVELS OF PRESEPSIN (SOLUBLE CD14-SUBTYPE) AS A NOVEL PROGNOSTIC MARKER FOR HEMOPHAGOCYTIC SYNDROME

S. Nanno[1,*] H. Koh[1], T. Katayama[1], M. Hashiba[2], A. Sato[2], Y. Makuuchi[1], J. Nagasaki[1], T. Yoshimura[1], H. Okamura[1], M. Nishimoto[1], A. Hirose[1], M. Nakamae[1], T. Nakane[1], M. Hino[1], H. Nakamae[1]
[1]Hematology, Graduate School of Medicine, Osaka City University, Osaka, [2]Development Research, Mochida Pharmaceutical Co., Ltd., Shizuoka, Japan

Background: It is well known that hemophagocytic syndrome (HPS) is a rare, potentially fatal cytokine-related disorder, caused by genetic factors or triggered by infections, malignancies, autoimmune diseases and transplantation. Previous studies reported that soluble interleukin-2 receptor (sIL-2R), ferritin and cytokines such as interferon-γ (IFN-γ), tumor necrosis factors-α (TNF-α), interleukin (IL)-6 and IL-10 may be associated with the prognosis of patients developing HPS. Recently, presepsin (soluble CD14 subtype), a fragment of CD14 highly expressed on the membrane surface of monocytes/macrophages, has been reported as a new diagnostic marker for sepsis (Endo S, *et al.* 2012). The release mechanism is thought to be associated with phagocytosis of microorganisms based on the animal data (Shirakawa K, *et al*. 2010). A phenomenon wherein activated macrophages eat blood cells is commonly observed in patients with HPS. We therefore hypothesized that presepsin may be a more useful prognostic marker for HPS than previously reported markers.
Aims: Our purpose was to examine 1) whether presepsin was a superior prognostic marker for HPS compared with sIL-2R, ferritin, IFN-γ, TNF-α, IL-6 and IL-10, and 2) which combination of presepsin with one of the other markers was a more useful predictor of survival when compared to any of the other markers on its own.
Methods: We retrospectively analyzed consecutive patients with HPS, from whom blood samples were obtained at our institution between April 2006 and August 2014. We diagnosed HPS using the modified HLH-2004 criteria. Plasma levels of presepsin were measured by the PATHFAST® Presepsin kit (LSI Medience Corporation, Japan) and serum levels of cytokines were determined by the Bio-Plex Pro Cytokine Assay® system (Bio-Rad Laboratories, CA). We used Cox models to investigate the association between the levels of these markers at onset of HPS and day-90 mortality. In composite model analysis, using Cox models, we compared the group of patients with a higher median value of presepsin and higher median values of each of the other markers, with the others who did not have higher values for these markers.
Results: A total of 14 patients aged 22-65 years (median 46.5) were enrolled, and 12 were evaluable, and of these, nine underwent allogeneic hematopoietic cell transplantation. The median follow-up time in all patients and in survivors (n=4) was 250 days (range, 11-1185) and 900 days (343-1185), respectively. In addition, the course of seven patients was complicated by the following infections at the onset of HPS: bacteria (n=2), fungus (n=3), virus (n=1) and virus plus fungus (n=1). In univariable Cox models, there were no significant variables: presepsin (Hazard ratio per 1 SD 1.3, P=0.53), sIL-2R (1.4, P=0.28), ferritin (1.6, P=0.23), IFN-γ (1.4, P=0.30), TNF-α (1.1, P=0.81), IL-6 (0.5, P=0.48) and IL-10 (1.5, P=0.32). However, only the combination of presepsin (≥1,936 pg/ml) and sIL-2R (≥4,586 U/ml) was significantly associated with day-90 mortality (Hazard ratio 14.5, P=0.02), whereas no other combination was significant (1.0, P=0.98 for ferritin-included model; 1.9, P=0.53 for IFN-γ; 2.7, P=0.33 for TNF-α; 1.0, P=0.98 for IL-6; and 5.3, P=0.10 for IL-10, respectively).
Summary and Conclusions: Our results suggest that the composite model of presepsin and sIL-2R levels at the onset of HPS, possibly a reflection of the activation of macrophages and T cells respectively, may be a novel and powerful predictor of the prognosis for HPS.

E1390

INFECTIONS IN CHILDREN WITH CHRONIC NEUTROPENIA-A 13-YEAR EXPERIENCE IN A TERTIARY CARE CENTER

M. Schmidt[1,*] S. Dumitras[2], A. Ciobanu[2], A. Ivanov[2], I. Miron[2]
[1]Hemato-Oncology, "Sf.Maria" Children's Hospital, [2]Hemato-Oncology, "Sf Maria" Children's Hospital, Iasi, Romania

Background: Patients with severe congenital(SCN), autoimmune(AN) and idiopathic neutropenia(IN) have frequent bacterial infections resulting in high morbidity in early childhood. Few data on specific morbidity and mortality are available in the literature for developing countries.
Aims: To describe incidence and type of infections requiring hospitalization and antibiotic treatment in children with chronic neutropenia diagnosed in our Department during a 13-year period.
Methods: Children less than 18 years of age presenting neutropenia (ANC<1.000/μL in infants and ANC<1.500/μL in children) of >6 months duration were evaluated. We reviewed the charts of all such patients seen at our center from January 2002 to December 2014.Exclusion criteria were pancytopenia, thrombocytopenia of less than 100.000/ μL, known hematologic malignancy, previous chemotherapy.
Results: A total of 34 patients with chronic neutropenia were identified(15 females and 19 males).Six patients had severe congenital neutropenia(17%), 18 patients had AN(52%) and 10 patients had IN(33%). The median overall follow-up was 5,2 years(range, 1-11,6 years). G-CSF was used only on demand(febrile infections) in 15/34 patients, in all patients(100%) with SCN,8/18(44%) patients with AN and 1/10(10%) patients with IN. All children did not receive antibiotic prophylaxis. One patient with SCN underwent unrelated donor hematopoietic stem cell transplantation.In 7 of 18 children with AN, neutropenia disappeared after a median of 18 months(range 10 to 54 months). From birth to the last follow-up, a total of 120 infections requiring hospitalization occurred in 21/34 patients.92/120 episodes were concentrated in 6/6 patients with SCN, 19 episodes in 9/18(50%) patients with AN and 9 episodes in 6/10(60%) patients with IN. Microbiological characterization was possible in 23/120 episodes and showed Gram positive bacteria in 10 cases and Gram negative bacteria in 13 cases. The most frequently occurring bacteria was *Staphylococcus aureus*(9 cases),*Escherichia coli*(5 cases), *Klebsiella pneumonia*(2 cases) and *Pseudomonas aeruginosa*(2 cases*), Enterococcus*(2 cases).Mouth infections(17%), pneumonia(16%), otitis(15%) and skin/subcutaneous infections(15%) were the most frequent localizations. During follow-up, 11 life-threatening infectious episodes occurred in 5 patients,10 of these episodes occurred in patients with severe congenital neutropenia. The median length of hospitalization was 14,3 days for the patients with SCN, 7,1days for the patients with AN and 5,7 days for the patients with IN. No septic deaths occurred. The median ANC before G-CSF was found 377/μl in patients with SCN, 487/μl in patients with AN and 980/μl in patients with IN.
Summary and Conclusions: The majority of patients presented a benign clinical course. The largest number of infectious episodes was in patients with congenital neutropenia. Oral cavity was the main involved site. Despite the fact that antibiotic and G-CSF were used only on demand and not as prophylaxis, no septic deaths were observed.

E1391

OUTCOME OF LANGERHANS CELL HISTIOCYTOSIS IN CHILDREN UNDER THE AGE OF 24 MONTHS- LCH-III PROTOCOL

M. Moschovi[1,*] M. Nikolaou[1], A. Zampogiannis[1], N. Tourkantoni[1], J. Nikas[2], C. Hadjigeorgi[2]
[1]Hematology-Oncology Unit, 1st Department of Pediatrics, University of Athens, [2]Radiology Department, Aghia Sofia Children's Hospital, Athens, Greece

Background: Langerhans cell histiocytosis (LCH) is a rare childhood disease with annual pediatric incidence 2-5 cases/1000000/year. It is most common between 1 to 3 years of age. Prognosis is dependent upon the number of organs involved, and the age of the patient at the onset of the disease. Patients under the age of 24 months usually present with multisystem LCH and have a potentially fatal outcome. Gastrointestinal tract involvement (GTI) in LCH is a rare condition, typically noted in children less than two years of age; 86% of reported patients presented GTI under one year of age; 59% of reported patients have died within 18 months of diagnosis, suggesting a poor prognosis.
Aims: The spectrum of clinical presentations and outcome of LCH in children younger than 24 months of age was the aim of our study.
Methods: Eleven children, who were diagnosed with LCH in the first two years of age and treated in our Unit, were enrolled in this study. The age ranged from 26 days to 24 months (mean: 10 months). All patients were treated according to the LCH-III protocol and completed the chemotherapy regiment at least 2-7 years ago. All patients remain in follow-up.
Results: Five cases presented with multisystem disease in the first 6 months of life, including intestine involvement, 3 cases had multiple bone lytic lesions in rare sites, one case had periorbital mass and 2 cases had juvenilexanthogranuloma in the first month of life. All cases received chemotherapy according to the LCH-III protocol. Four cases (36%) with multisystem disease had reactivation within 8-12 months from the end of the chemotherapy and achieved second remission. All the cases still remain in remission.
Summary and Conclusions: 1) Although children with LCH under the age of 24 months have a poor outcome, the new treatment protocols achieve a higher survival rate for this patient group. 2) Reactivation of the disease is still high (36%) and occurred in the first 12 months from the end of therapy. The cases with reactivate disease had a second chance for stable remission. 3) In two cases, there was a rapid progression of the disease from the single organ involvement, intestine and single bone lesion, respectively to the multiple organs involvement. 4) The rate of dissemination of the disease may denote differences in the pathophysiology of the disease.

E1392

HYPERTRYPTASEMIA OF UNCERTAIN SIGNIFICANCE: A NOVEL CONDITION DETECTED IN A SCREEN OF 1330 UNSELECTED CASES IN A HEMATOLOGY CENTER

K. Blatt[1,*] S. Herndlhofer[1], G. Hoermann[2], W.R. Sperr[1,3], P. Valent[1,3]
[1]Department of Internal Medicine I, Division of Hematology & Hemostaseology, [2]Department of Laboratory Medicine, [3]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, Austria

Background: In systemic mastocytosis (SM) and other myeloid neoplasms, patients often have a slightly elevated serum tryptase (15-30 ng/ml). However, an increased tryptase may also be found in allergic patients and sometimes even in healthy individuals.
Aims: In this study, we explored the relative distribution of cases with elevated tryptase in various neoplasms and non-neoplastic states.
Methods: Tryptase-levels were measured in 1330 cases, including 914 patients with hematological neoplasms (myeloproliferative neoplasms, n=156; myelodysplastic syndromes, MDS, n=241; acute myeloid leukaemia, AML, n=317; SM, n=81; lymphomas, n=59; acute lymphoblastic leukaemia, n=26), 136 with non-neoplastic hematological disorders, 102 with non-hematological conditions, and 178 healthy subjects.
Results: In healthy individuals, the median serum tryptase-level amounted to 5.2 ng/ml. Elevated tryptase-levels were primarily found in myeloid neoplasm (SM: 90% of patients; AML: 38%; MDS: 25%). We also identified 15 cases (1.2%) in whom tryptase-levels were slightly elevated, but neither an allergic disease nor a hematologic disease could be identified. The median age of these 15 individuals was 44 years (range: 24-72 years) and the female-to-male ratio was 2:1. The median tryptase-level at first presentation was 20.6 ng/ml (range: 14.5-35.5 ng/ml). In all cases, tryptase-levels remained stable in the follow-up. Bone marrow examinations did not reveal any signs of a myeloid neoplasm, and in none of the cases, an abnormal karyotype or a *KIT* mutation at codon 816 were detected. Blood counts and differential counts were normal in all cases, and no molecular aberrations were detected by multiplex-PCR.
Summary and Conclusions: We have identified a cohort of apparently healthy individuals with a persistently elevated tryptase-level. We propose to call this condition hypertryptasemia of unknown/uncertain significance.

E1393

AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME IN A FAMILY WITH PYRUVATE KINASE DEFICIENCY

M. Economou[1,*] A. Teli[1], E. Papadopoulou[1], A. Taparkou[1], D. Adamidou[2], E. Farmaki[1], A. Kattamis[3]
[1]First Department of Pediatrics, Aristotle University of Thessaloniki, [2]Blood Bank, Hippokration General Hospital, Thessaloniki, [3]First Department of Pediatrics, University of Athens, Athens, Greece

Background: Autoimmune lymphoproliferative syndrome (ALPS) is a rare congenital disease caused by defective mediated FAS lymphocyte apoptosis and characterized by non-malignant lymphoproliferation, hepatosplenomegaly, autoimmune manifestations and increased risk for lymphoma.
Aims: To describe the presence of ALPS in a family with pyruvate kinase deficiency.
Methods: We report on a family with three boys and a girl with known pyruvate kinase deficiency, followed at our outpatient clinic. The family was studied after initial diagnosis of pyruvate kinase deficiency in the family's first child. The boy had an additional history of secondary to infection autoimmune haemolytic anemia. His latest laboratory profile was compatible with a known mild haemolytic anemia and a recently diagnosed hypergammaglobulinemia. Both of his brothers presented splenomegaly and markers of mild haemolytic anemia. In addition, however, both had a direct Coombs test and in one of them extreme hypergammaglobulinemia was detected. Proband's sister had only haematological parameters of mild haemolytic anemia attributed to pyruvate kinase deficiency, as did the father. Proband's mother had a history of splenectomy, autoimmune haemolytic anemia and immune thrombocytopenia, also presenting with hypergammaglobulinemia.
Results: The family's history of splenomegaly could be attributed to pyruvate kinase deficiency, however, hypergammaglobulinemia and autoimmune manifestations raised suspicion of ALPS. Peripheral blood lymphocytes analysis by flow cytometry for double negative T cells revealed elevated circulating TCRαβ$^+$ cells in the proband, his mother and both of his brothers. In addition, elevated levels of serum vitamin B12 were found. These findings reinforced our suspicion for ALPS and blood sample was analysed for mutation in gene coding for FAS for definitive ALPS diagnosis, which secured diangosis.
Summary and Conclusions: ALPS should be suspected in patients with persistent splenomegaly and autoimmune manifestations as to achieve prompt diagnosis and establish appropriate management.

E1394

THE RESEARCH PARAMETER NEUT-X IN VITAMIN B12 DEFICIENCY

E. Petridou[1] A. Kotanidou[1] A. Agorasti[1,*]
[1]Laboratory Haematology, General Hospital Ofxanthi, Xanthi, Greece

Background: The SysmexxE-5000 analyzer (using fluorescence flow cytometry) provides a new parameter representing the structure of the neutrophils, NEUT-X. High values of NEUT-X reflect the presence of hypersegmented giant neutrophils.
Aims: The aim of this study is to investigate the NEUT-X parameter in non anemic patients with vitamin B12 deficiency.
Methods: The patients enrolled in this study were recruited from a larger cohort of patients who were referred to our laboratory for determination of vitamin B12, folate or ferritin levels without anaemia (haemoglobin levels within the reference intervals for age and gender). Exclusion criteria were pregnancy, C-reactive protein levels >5 mg/L, white blood cells count >10,00x 10^3/μL and absolute neutrophil cells count >6,00x 10^3/μL. 97 patients with vitamin B12 deficiency were included in the study (patient group). 149 healthy individuals (matched in age and gender) were randomly selected as a control group. Full blood count was performed with SysmexxE-5000 analyzer, vitamin B12, ferritin and folate acid levels were determined by Roche Elecsys Systems (electro chemiluminescence technology). Patients with vitamin B12 deficiency have had a blood film reviewed. Statistical analysis: chi-square test, Student's t-test and Mann-Whitney U test were applied. Values of P <0.05 were considered to indicate statistical significance.
Results: The two groups did not present a statistically significant difference in haemoglobin levels (P=0,065), white blood cells count (P=0,429), absolute neutrophil cells count (P=0,251), (Table 1), ferritin levels (P=0.623) and folate acid levels (P=0,135), (data no shown). Patient group found to have significantly higher NEUT-X values when compared with control group (P=0,013) (Table 1).

Table 1. Comparison between the two groups.

Group	N (male / female)	Hb, gr/dL	Vitamin B12, pg/mL	WBC, x10³/μL	Neut#, x10³/μL	NEUT-X, ch
Patients	97 (37 / 49)	13,6 ± 1,1	113 ± 70	7,11 ± 2,65	4,28 ± 2,49	138,8 ± 3,2 ¶
Healthy individuals	149 (49 / 100)	13,8 ± 0,9	293 ± 126	6,75 ± 1,55	3,83 ± 1,19	137,8 ± 2,7

Hb: haemoglobin, WBC: white blood cells, Neut#: absolute neutrophil cells
Data are presented as mean±SD. Patient group versus *control group: P=0,013*

Summary and Conclusions: The increased NEUT-X value found in non anemic patients with vitamin B12 deficiency reflects the hypersegmentation of the neutrophils. NEUT-X parameter could be considered for the early diagnosis of vitamin B12 deficiency, as the alteration of the morphological features of the neutrophils (represented by high NEUT-X) is observed in a non anemic population, with normal white blood cells count.

E1395

CHRONIC NEUTROPENIA IN CHILDHOOD-EXPERIENCE FROM A SINGLE CENTER

T.H. Karapınar[1,*] Y. Oymak[1], Y. Ay[1], S. Aydın Köker[1], E. Töret[1], F. Hazan[2], C. Vergin[1]
[1]Pediatric Hematology and Oncology, [2]Genetics, Dr. Behcet Uz Children Training and Research Hospital, Izmir, Turkey

Background: Neutropenia is defined as the reduction in the absolute number of neutrophils (ANC) in the blood circulation. Neutropenia is a relatively frequent and often a secondary finding in childhood. It can be classified as acute or chronic depending on its duration, lower or higher than 3 months. Acute neutropenia is most commonly associated with viral infections, is often well tolerated and normalizes rapidly, whereas chronic neutropenia (CN) has more complex clinical manifestations. CN can be due to a heterogeneous group of diseases in children. The differential diagnosis of CN often requires much time and a lot of investigations.
Aims: The aim of the present study is evaluated the reasons and clinical manifestations of the CN in childhood in a single children's hospital.
Methods: Between October 2004 and April 2014, values of patients with CN were evaluated retrospectively at the Dr. Behcet Uz Children Hospital. Patients with chemotherapy-induced neutropenia, those secondary to lympho-myeloproliferative disorders, systemic autoimmune diseases, myelodysplastic syndromes, and common variable immunodeficiency were excluded. Thirty-one patients were diagnosed as CN.
Results: All patients were followed up to maximum 114 months or until neutropenia was recovered. The median duration of following was 29 months. The median age of diagnosis was 21 months. Thirteen of the patients (41.9%) were before the age of 12 months at initial diagnosis. Seven of 13 patients with ≤12 months at initial diagnosis (53.8%) were identified as congenital neutropenia (CoN). There was no difference between the age >12 months and ≤12 months at onset according to ANC at diagnosis. Twenty-two of all cases (70.9%) were detected during acute infections. Hospitalization due to recurrent infections was determined in 11 patients (35.5%). Most of the recurrent infections site was lung (81.8%). CoN was identified in 14 patients (45.1%). Eight of 14 patients (57.1%) required GCSF treatment and no advers effect of GCSF was seen in any of these patients. Fifteen patients (48.3%) was considered as idiopathic neutropenia. Interaction between idiopathic and congenital neutropenia groups was evaluated. Whereas there was no difference for age, ANC or application with infection at diagnosis, there was an difference for sex and spontane recovery of neutropenia. Neutropenia was spontaneously recovered in 10 of all patients (32.2%) during a follow-up of 7-52 months.
Summary and Conclusions: In current study, we found a higher congenital neutropenia ratio in CN than other reports, it may be due to higher consanguineous marriages in our country. However, CN is a finding that required several laboratory investigations, prolonged follow-up, and advanced molecular analysis, it's etiology can be remain idiopathic.

E1396

STUDY OF ALPHA HEMOGLOBIN STABILIZING PROTEIN EXPRESSION IN PATIENTS WITH B THALASSEMIA AND SICKLE CELL ANEMIA AND ITS IMPACT ON CLINICAL SEVERITY

M. Deghedy[1,*] H. Mahmoud[2], I. Ragab[1], A. Shoeib[1], S. Abdel Ghani[1]
[1]Pediatrics, [2]Laboratory Hematology, Ain Shams University, Cairo, Egypt

Background: The α hemoglobin stabilizing protein (AHSP) is an erythroid protein that specifically binds α-Hb and prevents its precipitation suggesting that it may function to limit free α-Hb toxicities. Our aim was to study the level of AHSP level in β thalassemia syndromes in relation to their clinical severity and to compare it with its level in sickle cell anemia.
Aims: We compared patients with β-thalassemia (n=37), divided into β-thalassemia major (BTM)(n=19) and β-thalassemia intermedia (BTI) (n=18) with 12 patients with sickle cell anemia.
Methods: Comparison as regards clinical severity, age at presentation, transfusion dependency, initial hemoglobin electrophoresis, mean pre-transfusion hemoglobin level, use of hydroxyurea and AHSP expression by real time quantitative PCR.
Results: Median AHSP was significantly higher in patients with sickle cell anemia 2275 (3898) compared to patients with thalassemia 283 (718), P=0.001, with no significant difference in AHSP between BTM and BTI (P=0.346). It was significantly higher in non-transfusion dependent patients with β thalassemia (NTDT) compared to transfusion dependent ones (P=0.019), and in patients on hydroxyurea therapy (P<0.001). However, there was no significant difference in its level according to clinical severity score (P=0.946) or splenectomy status (P=0.145).
Summary and Conclusions: AHSP Expression was higher in sickle cell anemia *versus* thalassemia, with no significant difference between BTM and BTI. Expression was higher in patients with NTDT and on hydroxyurea therapy.

E1397

HEMOPHAGOCYTIC SYNDROMES IN SAUDI CHILDREN: SINGLE CENTER EXPERIENCE

A. Alzahrani[1,*] G. Elyamany[2], H. Elfaraidi[1], N. Othman[1], A. Shaker[2], F. Al-Batniji [1], M. Awad[2], F. Alabbas[1]
[1]Pediatric Hem/Onc and BMT Department, [2]Pathology and Laboratory Medicine, Prince Sultan Military Medical City, Riyadh, Saudi Arabia

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare aggressive and life-threatening syndrome of excessive immune activation due to cytokine overproduction from excessively activated lymphocytes and macrophages. It most frequently affects infants from birth to 18 months of age, but the disease is also observed in children and adults of all ages. Chemo-immunotherapy-based treatments have improved the survival of patients with HLH, but outcomes of the patients are still unsatisfactory.
Aims: To evaluate patients' characteristics, laboratory and molecular findings and treatment outcome.
Methods: We retrospectively analyzed data of 11 HLH patients who were admitted to the Pediatric Hematology Department of Prince Sultan Military Medical City, Riyadh, Saudi Arabia between 2005 and 2014. HLH was diagnosed according to the HLH-2004 diagnostic guidelines. We defined primary HLH as Patients who were found to have a genetic abnormality and/or early-onset diseases (age 0-2 years) with family history were considered as having familial HLH.
Results: Patient characteristics are summarized in Table1.The median age at onset of HLH is 12 months. There was female predominance (8/12). Consanguinity rates significantly were high (75%) and positive family history in 5 cases. Of 12 patients, 9 were defined as primary, and 3 were secondary HLH (cases 4, 5 and 8). All patients met the criteria of HLH; at least five out of a total of eight criteria. (Figure 1) To dates, 6 of the 12 patients are still alive (50%), 4 of the patients died before HSCT, whereas one patient died of relapse after matched unrelated donors and one lost follow up.

Table 1. Patient characteristics.

#	Age	Sex	Consanguinity	Family history	Associated Infection	HLH criteria	Molecular Mutation	Treatment	HSCT	Outcome
1	4 months	M	+	+	-	6/8	PRF1	HLH 2004	Haplotype	Alive
2	4 months	M	+	+	EBV	7/8	STX-11	HLH 2004	No	Died
3	13 months	F	+	+	Candida	5/8	STX-11	HLH 2004	No	Died
4	3 years	M	-	-	Dengue Fever	5/8	Negative	HLH 2004	No	Alive
5	8 years	F	-	-	EBV	7/8	Not done	HLH 2004	No	Died
6	2 months	F	+	-	-	6/8	Negative	HLH 2004	Haplotype	Alive
7	11 months	F	+	+	-	6/8	STX-11	HLH 2004	Cord SCT	Alive
8	4 years	F	+	-	Dengue Fever	5/8	Negative	HLH 2004	No	Lost follow up
9	7 years	F	+	-	-	5/8	Not done	Refused treatment	No	Died
10	3 months	F	+	-	-	5/8	PRF1	HLH 2004	URD HSCT	Died
11	6 months	M	+	+	Gram +ve cocci	6/8	STX-11	HLH 2004	MRD HSCT	Alive
12	7 years	F	-	-	HAV	6/8	Pending	HLH 2004 Anakinra	On therapy	Alive

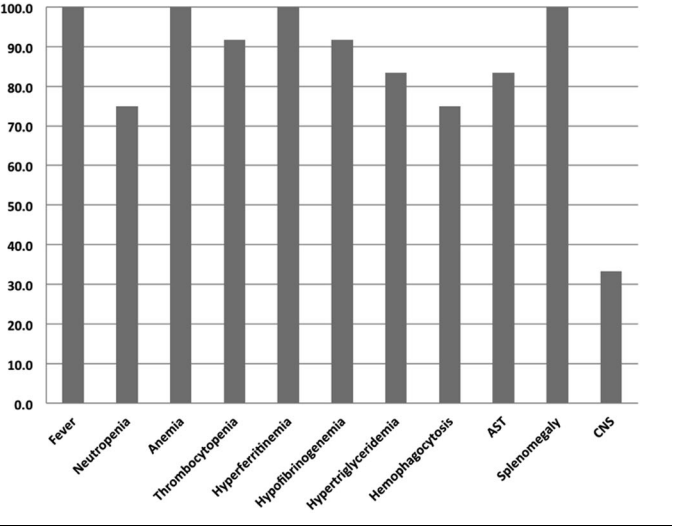

Figure 1. Patient clinical and laboratory parameters.

Summary and Conclusions: Hemophagocytic lymphohistiocytos is a serious and potentially life threatening disorder in children and rarely in adults. Familial HLH is the most common encountered type of syndrome. Chemotherapy regimen is not ideal yet to control the disease. Bone marrow transplantation is the only available cure. Awareness of the clinical symptoms and of the diagnostic criteria of HLH is important as correct diagnosis with adequate treatment with immunosuppressive /immunomodulatory agents in time can be life saving in these patients. Research to uncover the gene responsible for the disease by collaborative group is recommended.

E1398

LONG TERM TREATMENT WITH CONTINUOUS LOW DOSE LENALIDOMIDE RESULTS IN PET/CT DOCUMENTED EXCELLENT PARTIAL REMISSION IN A PATIENT WITH SEVERE MULTI-SYSTEMIC LANGERHANS CELL HISTIOCYTOSIS

A. Burchardt[1,*] D. Steiner[2], M. Rummel[1]
[1]Hematology, [2]Nuclear medicine, Universitätsklinikum Gießen und Marburg, Gießen, Germany

Background: Langerhans cell histiocytosis (LCH) is a non malignant orphan disease of clonal dentritic cells with a possible affection of any organ. Diagnosis is often difficult due to a wide clinical spectrum of presentation, ranging from a single lesion right up to a multi-systemic disorder. Treatment options are consisting of radiotherapy for bone lesions till conventional chemotherapy e. g. with cytarabin, etoposide and vinblastin. In multi-systemic organ involvement cladribine (2-CdA) is often used. Treatment with Thalidomide as could be a different option. In 2013 we already described a female patient (pat) achieving a complete remission of localized LCH of the vulva with Lenalidomide (Len) treatment. Positron emission tomography (PET), more specifically PET/CT has been well validated for staging and treatment response monitoring in oncology patients (pts). The use of PET/CT in LCH has been reported, but its use in adult pts is not well established. Especially in adult pts with severe comorbidities like renal insufficiency it is a very useful tool. In addition, other information like the metabolic activity defined as mean standardized uptake values (SUV) of LCH lesions can be very helpful.
Aims: Here we present the first pat with a multifocal aggressive and repeatedly relapsing LCH with an outstanding response to continuous long term treatment with low dose Len (10 mg every other day).
Methods: Case report.
Results: A 69 year old man with severe comorbidities (diabetes, renal insufficiency, coronary heart disease) was diagnosed in Jun 2011 with multi-systemic LCH. In between Aug 2011 and Dec 2011 he received 4 cycles of 2-CdA (0.14 mg/kg/BW) and obtained only a partial remission (PR). In May 2012 he presented with a multi-systemic relapse/reactivation in different lymph nodes and involvement of other organs like parotid gland, muscle, bone and testes. After histological confirmation and PET/CT based staging in Jul 2012, first cycle of Len 10 mg/d for 21 days q 4 weeks was started. A few days later a substantial benefit with decreasing cervical lymph nodes was noticed. Due to moderate leukocytopenia weekly G-CSF was used. PET/CT in Dec 2012 showed again PR and due to a cardiac intervention Len was stopped for 6 weeks. Due to a mild anemia, retreatment with Len 5 mg/d was initiated in Feb 2013. Because of a slight lymph node decrease only, Len dose was escalated up to 10 mg every other day as a continuous treatment option. PET/CT in Sept 2013 showed a mixed response, in May 2014 PET/CT showed an acceptable remission with a SUV decrease in the LCH lesions. Current PET/CT in Feb 2015 shows an excellent PR with only small residues submandibular and in left testicle (Table 1).

Table 1.

	PET/CT Jul 2012	PET/CT Sept 2013	PET/CT Feb 2015
Lymph node right neck [SUV]	15.1	14.8	2.8
Testicle right [SUV]	12.0	6.7	0
Testicle left [SUV]	0	8.5	4.9

Summary and Conclusions: We present a case of a highly effective treatment with continuous low dose treatment of Len in a pat with multi-systemic LCH. Long term treatment of Len is well tolerated without severe side effects. A dose of 10 mg every other day appears to be very effective with manageable toxicities. PET/CT based surveillance provides additional information of metabolic activity in the LCH lesions and is a very helpful tool, especially in pts with comorbidities like renal impairment.

E1399

SUSTAINED INFLAMATORY CYTOKINES IN NAÏVE GAUCHER DISEASE: A LINK WITH MULTIPLE MYELOMA?

M.M. Andrade Campos[1,*] J. Gervas-Arruga[2], P. Giraldo[3]
[1]Traslational Research Unit. Ciberer. IIS-A, Hematology. Miguel Servet University Hospital., [2]Traslational Research Unit. IIS-A., FEETEG, [3]Traslational Research Unit. CIBERER., IIS-A. FEETEG, Zaragoza, Spain

Background: Gaucher disease (GD), the most common lysosomal storage disorders, (~1/100,000 habitants outside Ashkenazi population), is secondary to the deficit of B-glucocerobrosidase activity leading to an accumulation of glycil-ceramide in monocyte-macrophagic system, it characterized by a latent chronic inflammation and expressed by hyperferritinemia, hypergammaglobulinemia, altered calcium homeostasis, metabolic syndrome and an imbalanced pro-inflammatory cytokine expression. The incidence of Monoclonal Gammopathy of Uncertain Significance (MGUS) and multiple myeloma (MM) and other B-cell disorders is increased in type 1 GD (GD1) patients (3.5-12.5 folds). Previous reports have identified osteoclastogenesis induced by TNFa and others cytokines like IL-6 in GD1 mouse models also some cytokines like MIP1a and TNF have gained importance in the pathogenesis of MM-bone marrow microenvironment induced changes. Based on that we hypothesize that deregulation of cytokines resulting from glucocerebroside accumulation may influence the development of hematologic malignancies in GD1.
Aims: To analyze and compare a panel of proinflammatory cytokines profile among MGUS, MM and GD1patients and correlate with outcomes.
Methods: A protocol was conducted with the Aragon biobank for select 4 cohorts of frozen stored plasma collected at least 5 years ago and with available follow-up data: 36 MGUS (58.3% women, mean age: 75 years, range 53-89), 11 IgGk; 6 IgGL; 5 IgAk; 8 IgAL; 3 IgMk; 3 doble IgG+IgA. Forty-nine MM (42% women, mean age 68 years, range 39-89), 20 IgGk; 5 IgGL; 8 IgAk; 5 IgAL, 8 ligth chain disease and 3 IgG+IgA. Concerning ISS classification 44.0% MM patients had a score 1, and 31.7% score 3; thirty-eight naïve GD1 patients (36.8% women, mean age 39.2 years, range: 17-79) and 71 healthy controls. A panel of eight cytokines (IL4, IL6, IL7, IL10, IL13, MIP1α, MIP1β and TNF) was tested (Luminex®100 platform, Millipore cytokine kits). Clinical and analytical data were obtained from the records of the Hematology Department and from the Spanish Registry of GD (FEETEG). Non-parametric tests Mann-Whitney-U and Kruskall-Wallis-H were used. Period of study: February-Sept 2014.
Results: After 5 years 21 MM and 8 MGUS patients had died (42.8%, 22.2%), 4 MGUS developed a MM (11.1%); 7 MM and 8 MGUS developed a second tumour (14.2%, 22.2%). One GD1 patients developed a MM and 2 a solid tumour. Cytokine analysis: significant difference ($p<0.05$) were observed in IL4; MIP-1α; MIP-1β and TNFα values between controls, MGUS, MM and GD1 patients; Also for IL13 in MM and GD1. MM and GD1 not showed differences in the median values of IL4 and IL13. These groups showed significant differences in MIP-1α, MIP-1β and TNFα values. In MM there are significant differences in IL4 and MIP-1α between ISS 1 and ISS 3. In addition there are significant differences in MIP-1α between IgGk *vs* IgAL and in MGUS patients who progressed to MM. Inside the most expressed cytokines MM showed the highest MIP-1α values, but GD naïve patients showed the highest inflammatory cytokines MIP-1β and TNFα respect all cohorts (Table 1). There were not significant differences in cytokines profile between patients that develop a second neoplasia.

Table 1. General overview (medians).

	Controls	GD1	MGUS*	MM*
IL4	•	Δ	↑	↑
IL6	•	•	•	•
IL7	•	•	•	•
IL-10	•	•	•	•
IL-13	•	↑	•	↑
MIP-1α	•	↑✓	↑	↑✓
MIP-1β	•	↑✓	↑	↓✓
TNF-α	•	↑✓	↑	↑✓

•: not-significant difference respect to controls. Δ: increased values, no significance. ↑: increased values significance difference ($p<0.05$). *: For MIP-1α, significant difference between MM IgGk vs. IgAL, and between MGUS vs. MGUS progressed to MM were registered. ✓ : Significant difference was found between GD1 vs MM. ✓ difference, but lowest value respect to GD or MM.

In MM there were significant differences between ISS-1 and ISS-3 for IL-4 and MIP1a

Summary and Conclusions: Cytokines produced in response to glucocerebroside accumulation, could be a critical factor in the pathogenesis of MGUS and MM in GD, both patients presents alterations on cytokines profiles, specially in MIP-1β, TNFα and MIP-1α that could be a good biomarker to predict transformation to MM.

AUTOIMMUNE HEMOLYTIC ANEMIA: DESCRIPTIVE STUDY OF 100 CASES

K. Zahra[1,*] N. Ben Sayed[1], H. Regaieg[1], N. Amri[1], M. Zaier[1], Y. Ben Youssef[1], A. Khelif[1]
[1]Hematology, Hopital Farhat Hached, Sousse, Tunisia

Background: Autoimmune haemolytic anemia (AIHA) is caused by autoanti-

body-induced hemolysis (the premature destruction of circulating red blood cells). Usually idiopathic, it is also associated with infection, lymphoproliferative disorders, autoimmune diseases, and some drugs.
Aims: Study the epidemiological, clinical, biological, etiological and therapeutic aspects of AIHA.
Methods: This is a retrospective and analytic study about 100 cases of AIHA observed in the hematology and internal medicine departments of Sousse, over a period of 14 years. In this work, we have tried to describe the clinical aspects of these AIHA and evaluate the contribution of different diagnosis exploration and therapeutic means used.
Results: There were 40 men and 60 women (sex ratio=0.66) with a median age of 51 years [14-87]. Regarding the medical history, 19 patients were hypertensive, of whom 8 were receiving Methyldopa, 9 patients were diabetic, 7 had thyroid dysfunction and 18 had a history of autoimmune disease. The circumstances of discovery were an anemic syndrome in 80 of patients, mainly due to paleness and asthenia. Physical examination revealed icterus in 42 cases, splenomegaly in 41 cases, hepatomegaly in 8 cases, lymph node in 16 cases and fever in 21 cases. Concerning biology, regenerative anemia was normocytic in 43 cases and macrocytic in 48 cases, thrombocytopenia below 100000/mm^3 was observed in 13 patients. There were also biological signs of hemolysis: hyperbilirubinemia in 70 patients, high LDH rate in 68 patients. Direct Coombs test was positive for IgG in 55 cases, C in 12cases, Ig G+C in 20cases, IgA in 1 case, IgG+C +IgM in 4 cases and cold agglutinins search returned positive in 8 cases. There was Evans syndrome in 14 patients. AIHA was idiopathic in 45 cases including 3 cases of pregnancy. In the other cases, it was secondary to lymphoproliferative desorders in 20 cases, autoimmune disorders in 25 cases, drug taking (Methyldopa) in 8 cases, associated with a myelodysplastic syndrome Methyldopa in 1case and CMV infection in 1 case. The therapeutic consisted of transfusion in 37 cases and all patients received corticosteroid treatment in addition to folic acid therapy and etiological treatment in the non idiopathic cases. A complete remission was obtained in 55 cases. In severe cases of chronicity or relapse, immunosuppressive therapy was prescribed in 14 patients, anti-CD20 monoclonalantibody were prescribed in 8 patients and splenectomy was performed in 3 patients.
Summary and Conclusions: Glucocorticoids and/or intravenous immunoglobulins are the mainstay of the treatment in the majority of patients with warm AIHA. When these treatments fail, patients often require cytotoxic drugs or splenectomy. The current research in many other autoimmune diseases that can sometimes be associated with AIHA should still allow a better understanding of the mechanisms involved in the occurrence of these diseases and to refine treatments whose essential aim is to improve the effectiveness of both new and already available treatments (including rituximab) in order to limit the use of corticosteroids.

E1401

PROSPECTIVE STUDY OF PLASMA BIOMARKERS ASSOCIATED WITH THE INFLAMMATORY RESPONSE IN TYPE 1 GAUCHER DISEASE PATIENTS TREATED DURING ONE YEAR WITH VELAGLUCERASE ALFA

M. Andrade-Campos[1,*] J. Gervas[2], I. Garcia[3], O. Salamero[4], P. Martinez-Odriozola[5], J.-A. Mendez[6], F. Garcia-Bragado[7], C. Fernández[8], L.-I. Sancho-Val[9], H. Cano[10], J. Perez[11], J.-M. Hernandez-Rivas[12], J.-F. Lorenzo[13], M. Lopez-Dupla[14], M. Callao[15], P. Giraldo[2]
[1]Unidad de Investigación Traslacional. CIBERER, HUMS, [2]Unidad de Investigación Traslacional. CIBERER, [3]Pediatrics, Miguel Servet University Hospital, Zaragoza, [4]Haematology, Vall d'Hebron, Barcelona, [5]Internal Medicine, Basurto Hospital, Bilbao, [6]Haematology, Ourense Hospital, Ourense, [7]Internal Medicine, Josep Trueta Hospital, Girona, [8]Haematology, Cabueñes Hospital, Gijon, [9]Haematology, Alcañiz Hospital, Alcañiz. Teruel, [10]Haematology, Arcos del Mar Menor University Hospital, Murcia, [11]Internal Medicine, Vall d'Hebron, Barcelona, [12]Haematology, Salamanca University Hospital, Salamanca, [13]Internal Medicine, Burgos Hospital, Burgos, [14]Internal Medicine, JoanxXIII Hospital, Tarragona, [15]Internal Medicine, Arnau de Vilanova Hospital, Lleida, Spain

Background: Background: It is wide accepted that Gaucher patients have an impairment in their immune system, clinically reflected by a infections tendency and biologically by a chronic inflammatory state. The role of cytokines in this inflammatory state is partially known, and the modifications in this profile in GD patients under enzymatic replacement therapy (ERT) are under investigation. Our group has reported some changes on the cytokine profile in patients with severe bone involvement[1] and some inflammatory biomarkers of macrophage activation related to the iron profile[2].
The progressive infiltration by engorged macrophages led to a production of proinflammatory cytokines into bone marrow microenvironment, altering of the bone turnover, producing imbalance in cellular function, angiogenesis and patchy infiltration by Gaucher cells.
Aims: Aims: To explore the changes in the biomarkers of immune response in a cohort of Spanish type 1 Gaucher disease patients (GD1) after one year on Velaglucerase alfa therapy.
Methods: Patients and Methods: A total of 17 GD1 patients from 15 centers, were included in a prospective protocol following these criteria: symptomatic patients of both sexes, aged older than 4 years, naïve or previously treated but without ERT at least one month previous to be included. The study included blood counts, liver and spleen volume by MRI and bone marrow MRI evaluation following S-MRI protocol, and determine bone mineral density by Quantiative Ultrasound expressed by Z-score, and biomarkers: Chitotriosidase, CCL18/PARC, ferritin, immunoproteins and the following cytokine profile: IL-10, IL-13, IL-4, IL-6, IL-7, Mip1a, Mip1b,TNFa, performed at baseline and 12 months after therapy. The study was approval by ethical committees and designed according Helsinki declaration rules; every one patient signed the informed consent and commitment to use a safe contraceptive method during the study period and 3 months after completion of treatment. Non-parametric tests Mann-Whitney-U and Kruskall-Wallis-H were used. Period of study: November 2011- April 2014.
Results: Results: General characteristics: 9 males, 8 females, mean age: 37.5 years (9-72). 3 splenectomized patients (17.6%); genotype: 3 N370S homozygous one heterozygous for N370S/L444P and the rest heterozygous for N370S/other. Seven patients (41.2%) have previous history of bone disease complications. All patients received velaglucerase alfa 30U/kg iv every two weeks for 1 year in every day clinical practice. Patients achieved an objective response on disease goals, after normalization and/or stabilization in blood counts and visceral volumes no significant variation were observed. Nevertheless a significant increase in the Z-score was observed after one year on Velaglucerase alfa therapy. Respect to biomarkers, a reduction or stabilization of CT activity and CCL/18 concentration were observed, also ferritine concentration and serum free light chains do not show significant variation. The cytokine profile showed a decrease in all inflammatory cytokines tested, however for Mip1a (p=0.027) and TNFa (p=0.023), a significant reduction were registered. Table1. No infusion reactions were reported, neither antibodies against velaglucerase alfa.

Table 1. Comparative reduction of cytokines between baseline and 12 months.

	IL10	IL13	IL4	IL6	IL7	Mip 1a	Mip 1b	TNF a
Chi X^2	3.415	0.000	2.668	1.606	1.545	8.159	3.308	4.263
grade	2	2	2	2	2	2	2	2
significance	0.181	1.000	0.263	0.448	0.462	0.017	0.191	0.023

Summary and Conclusions: Velaglucerase alfa is a well-tolerated therapy in every day clinical practice. In our cohort we observed as part of the response to therapy a significant decrease on the inflammatory state reflected through the cytokine reduction.

E1402

A CASE OF INDOLENT SYSTEMIC MASTOCYTOSIS IN A GIRL TREATED WITH INTERFERON

Y. Altuner Torun[1,*] M.C. Serbetci[2], F. Mutlu Sarıguzel[3], A.B. Ergul[4]
[1]Pediatric Hematology, [2]Kayseri Education and Research Hospital, Kayseri, Turkey, [3]Immunology Department, [4]Peiatrics, Kayseri Education and Research Hospital, Kayseri, Turkey

Background: Mastocytosis refers to a group of myeloproliferative disorders characterized by excessive proliferation and accumulation of mast cells in tissues. It is rare in both adults and children and occurs in less than 0.01% of the general population.
Aims: A 5-year old girl who was diagnosed as cutaneous mastocytosis by our dermatology department when she was four months of age, was admitted to our pediatric hematology department by hepatosplenomegaly. In physical examination, widespread maculopapuler and itchy lesions were determined.
Methods: The assessment of bone marrow aspiration was found to be consistent with mast cells (rate >10%). Flow cytometry on bone marrow sample revealed that there was CD117/CD25 positivity of 18.4% and CD117/CD2 positivity of 0.7%. Diagnosis of SM was verified by one major and one minor WHO criteria: presence of multifocal, dense aggregates of mast cells in bone marrow (major criteria) confirmed by expression of CD2, CD25, and CD117 in bone marrow (minor criteria). Also serum tryptase level was 356 ng/ml (>20 ng/ml).
Results: We were diagnosed smouldering SM (a part of indolent SM) because of high serum tryptase level, organomegaly, and infiltration of mast cells in the bone marrow. During follow up, systemic anaphylaxis was determined and treated for three times. We recommended the self-administration of epinephrine on demand for anaphlactoid episodes. Treatment with montelucast, interferon alfa-2a and methylprednisolon produced a marked and sustained reduction in her symptoms, cutaneous lesion, and tryptase level (Figure 1A-B).

Figure 3.

Summary and Conclusions: Consequently, we report on the first case of indolent SM that was successfully treated with montelucast, interferon alfa-2a and methylprednisolon in children.

E1403

USEFULLNESS OF SERUM FERRITIN LEVEL >10,000 NG/ML TO DIAGNOSIS HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH) IN ADULTS.

E. Colorado Ledesma[1,*] M.M. Andrade Campos[2], R. Rupay[3], A. Montes-Limon[1], N. Espinosa[1], N. Fernandez-Mosteirin[1], C. Salvador Osuna[1], P. Giraldo[4]
[1]Hematology, Miguel Servet University Hospital., [2]Traslational Research Unit. CIBERER. IIS-A, Hematology. Miguel Servet University Hospital., [3]Miguel Servet University Hospital., [4]Traslational Research Unit. CIBERER., IIS-A. FEEHA, Zaragoza, Spain

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare pathology characterized for clinical and laboratory alterations secondary to an uncontrolled immune activation that lead a severe inflammation systemic status. HLH can be congenital or acquired, idiopathic or secondary to infections, neoplasms (specially hematologic neoplasms) or rheumatic diseases. The diagnosis of HLH is based in the criteria determined by the Histiocyte Society, hyperferritinemia is a key criteria, it is specific for HLH in pediatric population; although some reports had outstand the value of serum ferritin (SF) over 10,000 ng/mL as the first suspicion clue for HLH. It is remarkable that HLH carry-on a mortality rate around 90% and diagnosis in adults is difficult and the value of SF is not fully established. Based on that, we perform a review to assess this aspect in hospitalized adults patients with SF >10,000 ng/mL in our institution.
Aims: To identified adults patients with SF >10,000 ng/mL, assess the HLH diagnostic criteria and describe the possible causes for high SF values and the usefulness of this cut-off for HLH diagnosis.
Methods: A chart review was performed. All hospitalized-adults with a SF level >10,000 ng/mL were selected to lead the retrospective assessment of the HLH criteria using the clinical and laboratory data available in the electronic medical registry. At the same time, selected patients were crossed with the transfusion service to check transfusion records; also patients with family history of congenic HLH were excluded. For HLH diagnosis the presence of 5-6/6 following criteria: >10,000 ng/dL SF, fever, splenomegaly, 2-3 cytopenias, hypertriglyceridemia (>252 mg/dL) and bone marrow hemophagocytosis (BMH), (sCD25 and NK functionality studies were not available in our center). Period of study: Jun-2009 to Jan-2015.
Results: A total of 78 patients were identified in the first screening for SF >10,000 ng/mL; twenty-three patients full flied HLH criteria assessment. Mean age: 53.91 y.o. (16-82). Male/female ratio: 12/11. According to criteria revision: 6 patients full flied 6/6 criteria and 18 patients 5/6 criteria. According to each criteria all patients presented fever and hyperferritinemia; mean SF level: 28,938 ng/mL (12,606.9-61,557.0), Cytopenias: 22/23 patients presented it, Mean values: Hb: 7.1 (2.3-12.5) g/dL, Absolute neutrophils count (17 patients <1.00x10^3/mL): 0.19x10^3/mL (0.00-10.4), Platelets: 18 (1-90)x10^3/mL. Mean serum triglycerides: 559 (252-1011) mg/dL, BMH: 13/17 patients with bone marrow aspiration performed show BMH. Splenomegaly: 18/23 patients. At the same time others biochemistry alterations (liver enzymes, LDH, bilirubin, coagulopathy) were registered in all patients. Neurological, pulmonary and skin alterations were recorded in 8, 9 and 3 patients. Possible etiologies of secondary HLH: infections: 7 cases, neoplasms: 12, both: 3 cases and other 1 case. Mortality: the median time duration of the hospitalization were 23 days (3-60), with the exception of 2 cases, one male with leishmaniosis and a female with Evan's syndrome and CMV infection are alive, the rest of the patients (91.3%) died during the hospitalization period.
Summary and Conclusions: HLH is a rare multisystemic syndrome with higher mortality rate, probably related with the difficulties during the diagnosis process. In our cohort the value of ferritin levels >10,000 ng/mL was a good biomarker to start the suspicion of the illness. More accuracy is necessary to identified and treats this severe pathology. In case of acceptance a complete review of all screened patients will be presented.

DUSP4-MEDIATED ACCELERATED T-CELL SENESCENCE IN IDIOPATHIC CD4 LYMPHOPENIA

A. Bignon[1], A. Régent[2], L. Klipfel[1], L. Mouthon[2], K. Balabanian[1,*]
[1]INSERM U996, Clamart, [2]INSERM U1016, Paris, France

New Information: This work has been prepublished online as Blood First Edition paper, March 2, 2015; DOI 10.1182/blood-2014-08-598565.
Background: Idiopathic CD4 lymphopenia (ICL) is a rare heterogeneous immunological syndrome of unclear etiology. ICL predisposes patients to severe opportunistic infections and frequently leads to poor vaccination effectiveness.
Aims: Chronic immune activation, expansion of memory T cells and impaired TCR signaling has been reported in ICL, but the mechanistic and causative links remain unclear.
Methods: To gain insight into the functional pathways implicated in ICL pathophysiology, we compared the gene expression profiles of $CD4^+$ T cells sorted from the blood of ICL patients and control groups of age-matched healthy subjects and patients with $CD4^+$ T-cell lymphopenia secondary to sarcoidosis. These arrays enabled us to identify an ICL-related genetic signature with predominant involvement of two gene groups, one related to TCR response and the other strikingly associated with T-cell aging. Among the first group, expression of the dual-specific phosphatase 4 (DUSP4), which negatively regulates MAPK activation, was increased similar in this respect to $CD4^+$ T cells from elderly subjects. Functional studies further linked this overexpression to accelerated T-cell senescence in ICL.
Results: We showed that late-differentiated T cells in 20 ICL patients displayed defective TCR responses and aging markers similar to those found in T cells from elderly subjects. Intrinsic T-cell defects were caused by increased expression of DUSP4. Normalization of *DUSP4* expression using a specific siRNA improved $CD4^+$ T-cell activity in ICL, as this restored TCR-induced ERK activation and increased the expression of the co-stimulatory molecules CD27 and CD40L. Conversely, repeated TCR stimulation led to defective signaling and *DUSP4* overexpression in control $CD4^+$ T cells. This was associated with gradual acquisition of a memory phenotype and curtailed by *DUSP4* silencing.
Summary and Conclusions: These findings identify a premature T-cell senescence in ICL that might be caused by chronic T-cell activation and a consequential DUSP4-dependent dampening of TCR signaling.

FINALLY A METHOD FOR ROUTINE DIAGNOSIS OF SOUTH-EAST ASIAN OVALOCYTOSIS

P.M. Mclaughlin[1,*] B.A. Van Oorschot[2], J. van der Wal[1], M. Veldthuis[3], J.C. Slijfer[1], M.R. Hardeman[4], R. van Wijk[2]
[1]Clinical Chemistry and Hematology, Certe medical diagnostic laboratories, Groningen, [2]Clinical Chemistry and Hematology, University Medical Hospital Utrecht, Utrecht, [3]Red Blood Cell Diagnostics, Sanquin, [4]Translational Physiology, Academic Medical Center Amsterdam, Amsterdam, Netherlands

Background: South East-Asian Ovalocytosis (SAO), is a dominantly inherited red cell membrane defect caused by a small deletion in exon 11 of *SLC4A1,* the gene encoding band 3. The deletion is commonly accompanied by a missense mutation in exon 4 (p.Lys56Glu). The 9 amino acid-long deletion eventually results in a markedly increased rigidity of the red cell membrane. Nevertheless, individuals affected are usually clinically asymptomatic and only in children slight haemolysis has been observed. Although, the homozygous state of the mutation was believed to be incompatible with life, recently a homozygous SAO child with severe dyserythropoietic anemia and distal renal tubular acidosis has been described. The hall mark of the disease is the presence of macro-elliptocytes, some with a transverse ridge across the central clearing, on the blood smear (Figure 1C). This is currently the only way to reliable diagnose the disease. The condition is wide-spread in certain ethnic groups as the condition protects against invasion of several malaria strains. However de precise Figure and incidence is unknown, as the investigation of the blood smear is not part of daily routine laboratory practice.
Aims: To establish a highly specific method to diagnose SAO using the CELL-DYN Sapphire automated haematology analyser.
Methods: EDTA samples of regular primary-care patients at our laboratory were examined on the CELL-DYN Sapphire Haematology Analyser using the complete blood cell count mode (CBC). Positive identification of SAO was followed by measurements using the Reticulocyte mode (CBC+RETC) and blood-smear analysis. To confirm our findings, anonymised EDTA samples were subjected to osmotic gradient ektocytometry on the LoRRca MaXis and DNA analysis of exons 4 and 11 of *SCL4A1* and for typical cellular behavioural examina-

tion by the automated Rheoscope Cell Analyser (ARCA). All cases sent were positively confirmed as being a SAO-carrier, and the physician was subsequently notified on these results.

Results: Analysis of scatterplots generated by our routine blood cell analysers revealed a small cluster of red cells in the 7/90° optical platelet scatterplot in conjunction with a slightly lowered MCV (Figure 1A). Examination of these red blood cells on a smear demonstrated typically SAO associated Macro-Elliptocytes (Figure 1C). Analysis of the CBC+RETC mode showed a typical first small peak close to the Y-axis followed by a broad asymmetric peak, displaying the heterogenic distribution of the Cellular Heamoglobin Concentration (CHC; Figure 1B). Using these two parameters we identified 32 SAO-carriers in our population. SAO was confirmed by morphology, DNA, ektocytometric (Figure 1D) and Rheoscopic analysis. Comparison with other Haematology Analysers revealed that this feature is probably due to the M.A.P.S.S. technique algorithm which is unique for the CELL-DYN Sapphire.

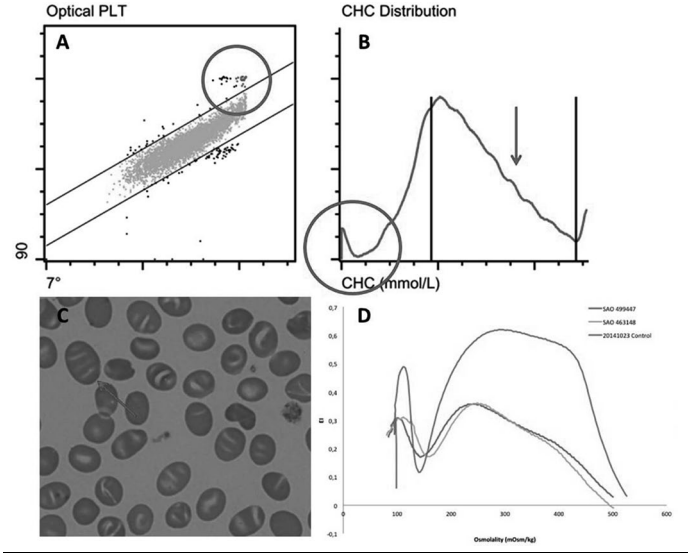

Figure 1.

Summary and Conclusions: South East Asian ovalocytosis is a rare disease in Europe and it is therefore difficult to study. We established a method by which SAO can be easily and reliably diagnosed using routine laboratory haematology parameters. When applied to a subpopulation in the Nothern part of the Netherlands, a considerable and higher than expected population of SAO carriers was detected. This method can be used to prevent embryonic lethality or the severe clinical presentation that accompanies homozygosity for SAO.

Platelets disorders

E1404

EFFICACY OF HIGH-DOSE METHYLPREDNISOLONE AS A FIRST-LINE THERAPY IN ADULT PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA

K. Aydın[1], E. Gürkan[2,*] F. Baslamisli[2]
[1]Dept of Internal Medicine, [2]Dept of Hematology, Çukurova University Medical School, Adana, Turkey

Background: Guidelines for the emergency treatment of clinically important bleeding or prophylactic treatment before surgery/invasive procedures in ITP patients recommend several approaches either as high-dose methylprednisolone (HDP) or intravenous Ig (IVIG) and sometimes anti-D to provide a safe platelet count. There are various reports suggesting that IVIG treatment may result in a more rapid response thus more effective in these indications. The recommendations are usually based on the results of few number of controlled studies and more on individual experience.

Aims: In this study we tried to compare the efficacy of high-dose methylprednisolone with IVIG and conventional prednisolone (CDP) therapy as a firstline treatment in adult patients with ITP.

Methods: This retrospective study included 140 adults with either previously untreated acute ITP (51) or persistent/chronic ITP (22/67) patients with an acute attack. Patients with a platelet count <30x10^9/L or <50x10^9/L with a clinically significant bleeding were treated either by CDP therapy (1 mg/kg/day until response) or HDP (20 mg/kg/day for 3 days) or IVIG (1g/kg/day for 2 days). All the patients in three groups continued treatment with oral prednisolone (1 mg/kg/d) until stable platelet count was reached. Steroids were then tapered off in 4-6 weeks. Responses after the treatment and clinical course of the patients were evaluated.

Results: Of 140 patients enrolled initial platelet counts were similar in all treatment arms. HDP was given to 92 (65,7%), IVIG to 32 (22,8%) and CS to 16 (11,4%) of patients. The median follow up patients was 21.5, 13.1 and 9.3 months in HDP, IVIG and CDP groups respectively (P<0.05). HDP received patients showed the first response sooner (platelet counts ³30x10^9/L) compared to IVIG and CDP patients which was 6, 10 and 12 days respectively (P<0.05). Median platelet count at first response was similar between the three groups. Long-term complete response (>6 months) was higher in HDP group (57.6%) compared to IVIG (37.5%) and CS (25%) of patients (P <0.05). The initial treatment choice did not effect the response type. Relapse rate after achieving stable response was 62.8%, 81.3% and 88.9 % in HDP, IVIG and CDP group patients but the differences were statistically insignificant (P >0.05). Overall a negative correlation was observed between the response rates and age of the patients in all of the three groups (R=-0.172, P=0.04). Long-term remission rates also decreased as the patients become older in all the groups (R=-0,22, P=0,02).

Summary and Conclusions: Our results support that HDP can be more comfortably proposed as firstline treatment in adult patients with ITP. Due to its effectiveness, low cost, and convenience of use, high-dose methyl prednisolone still seems to be the best choice as initial treatment in ITP.

Background: Eltrombopag is a thrombopoietin receptor agonist (TPO-RA) approved for treating chronic primary ITP patients. Nevertheless, due to the non-existence of clinical trials there are no clear efficacy and safety data of eltrombopag in secondary ITP.

Aims: To evaluate the efficacy and safety results using eltrombopag for treating secondary ITP patients in routine clinical practice in Spain.

Methods: 33 secondary ITP patients from 23 Spanish centers who had been treated with eltrombopag and included in the Spanish Eltrombopag ITP Registry were retrospectively evaluated. However, 5 patients were excluded from the final analysis because three of them were aplastic anaemias, one was an amegakaryocytic thrombocytopenia and another one was a acute myeloid leukemia related thrombocytopenia.

Results: Our secondary ITP case series included nine hepatitis C virus-ITP, five lymphoproliferative disorders, four systemic lupus erythematosus (SLE), three HIV-ITP, two synchronous HCV-HIV-ITP, two psoriatic arthritis, one Evans Syndrome, one common variable immunodeficiency and one Sjögren syndrome. The median age of our cohort was 54 (IQR, 35-66) years. There were 17 women and 11 men. 25% of patients had a Charlson Comorbidity Index score of 2 or more at diagnosis. The median time from secondary ITP diagnosis to eltrombopag initiation was 36 (IQR, 1-76) months. The median number of therapies before starting eltrombopag was 2 (IQR, 1-4), including rituximab (28%), romiplostim (17%) and splenectomy (10%). At the time of treatment start, 15 of 28 patients (53%) patients were receiving concomitant treatment for secondary ITP, mainly including corticosteroids (31%) or immunoglobulins (21%). 7 of 28 (25%) patients had bleeding symptomatology during the month preceeding the starting eltrombopag. At eltrombopag initiation the median platelet count was 9x 10^9/L (IQR, 6-15x10^9/L). 25 of 28 (89%) patients responded to eltrombopag treatment. 23 patients (82%) achieved a complete response (CR; platelet count >100x10^9/L). To point out that 2 patients needed concomitant treatment with low prednisone doses to achieve or maintain the response. It was a slight difference between men and women regarding the response and complete response rates obtained: men achieved 82% and 73% respectively meanwhile women achieved 94% and 83%. The proportion of patients achieving platelet response was quite similar regardless the other studied parameters: age (87% and 92% for patients <65 years-old and ≥65 years-old, respectively), use of concomitant ITP medication at baseline (87% and 93% for patients with and without concomitant baseline ITP medication use) and bleeding at starting eltrombopag (100% and 87% for patients with and without bleeding, respectively). Three patients achieved complete response after only one month of tretament without relapsing afterwards. In five patients splenectomy was made few months after eltrombopag treatment (3 patients were in CR). Only two patients failed to achieve response with eltrombopag treatment: common variable immunodeficiency and one HIV patients. After a 9 months median follow-up, 15 patients maintain the response. Only 3 patients relapsed from their disease. Only two adverse events were reported: a grade 2-3 cephalea in a SLE patient and a death caused by respiratory insufficiency in a HIV patient with a CR ITP at that moment.

Summary and Conclusions: Our case series describe the great efficacy and safety results observed with the use of eltrombopag in our secondary ITP patients. Our data suggest some diseases may not benefit from the use of eltrombopag. However more studies are needed to confirm the possible usefulness of TPO-RAs in this variety of secondary ITP cases.

ITP PATIENTS IN THE ASIA PACIFIC: ARE THEY DIFFERENT?

B. Chong[1, 2,*] J.-W. Lee[3], J.H. Jang[4], T.-J. Chiou[5], L.H. Lee[6], O. Ilhan[7], P. Angchaisuksiri[8], R. Marouf[9], A.-S. Goh[10], S.C. Ng[11], S. Okamoto[12], K. Galvez[13], J.J. Nelson[14], S. Davidson[1], R. Odegbami[15], T. Brears[15]

[1]Centre for Thrombotic and Bleeding Disorders Research, [2]Department of Haematology, St Geogre Hospital, Sydney, Australia, [3]Seoul St Mary's Hospital, [4]Samsung Medical Centre, Seoul, Korea, Republic of, [5]Taipei Veterans General Hospital, Taipei, Taiwan, ROC, [6]Singapore General Hospital, Singapore, Singapore, [7]Ankara University, Ankara, Turkey, [8]Ramathibodi Hospital, Bangkok, Thailand, [9]Mubarak Alkabeer Hospital, Jabriya, Kuwait, [10]Penang Hospital, [11]Subang Jaya Medical Centre, Penang, Malaysia, [12]Keio University, Tokyo, Japan, [13]Hospital Pablo Tobón Uribe, Medellin, Colombia, [14]GlaxoSmithKline, North Carolina, United States, [15]GlaxoSmithKline, London, United Kingdom

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by auto-antibody induced platelet (PLT) destruction and reduced PLT production, leading to a low PLT count. The availability of robust epidemiological and clinical data on ITP in regions outside Europe and the United States is limited. The International ITP Registry is a prospective cohort study which seeks to collect epidemiological and clinical data of recently diagnosed primary ITP adult patients, predominantly from the Asia-Pacific region. The International Registry has been established for >4 years.

Aims: To contrast and compare the International ITP Registry population with the Intercontinental Cooperative Immune Thrombocytopaenia Study Group Pediatric and Adult Intercontinental Registry on Chronic ITP (PARC-ITP Registry) adult population. The PARC-ITP Registry was selected as it represents a prospective cohort including newly diagnosed ITP patients, with a comparably sized adult cohort which is well established (>4 years) across the regions in which epidemiological data is already available[1].

Methods: Clinical and laboratory data from the International ITP Registry were compared with clinical and laboratory data reported for adults enrolled in the PARC-ITP registry.

Results: At the time of this comparison 306 patients were enrolled across 10 countries in the Asia-Pacific, Middle East and Latin America regions in the International ITP Registry with data available from 299 patients. The PARC Registry had 340 adult patients enrolled in 31 countries across Europe, Canada, United States, Latin America, the Middle East, and Asia. Patient characteristics are presented in Table 1. The International ITP Registry has a clear predominance of patients of Asian origin (68%) whereas the PARC-ITP Registry population is principally Caucasian (63%). A female predominance is seen in both cohorts. Comorbidities were reported more often in the International Registry group (67.5% *vs* 30%). Hypertension is the most often reported comorbidity in both groups. Of the comorbidities related to ITP diagnosis that are available for comparison, diabetes occurs more often in the International Registry group and thyroid disease is reported at similar rates in both groups (Table 1). Mean PLT count at baseline was 29.0x 10^9/L (range 1-96x 10^9/L) in the International Registry group and 25.4x 10^9/L (range 0-133x 10^9/L) in the PARC Registry adults. Corticosteroids were the most frequently used first-line treatment in both groups-68% in the International Registry and 59% in the PARC-ITP Registry adults. IVIg is used in both populations at much lower rates-18% in the International Registry and 6% in the PARC-ITP Registry adults. Splenectomy is uncommon, with 13 patients in our group having splenectomy, splenectomy is not reported on in the PARC-ITP Registry publication. TPO-receptor agonist use is reported in the International Registry group (n=23) but not reported on in the PARC-ITP Registry group. Anti-D is reported both groups at rates <5%, and both groups have similar rates of not treated patients (Table 1). Clinical signs of bleeding were assessed by location in both Registries. The International Registry also records severity of bleeding. Bleeding at any site was seen in 34% of patients in the International Registry whereas PARC -ITP Registry reports manifestations of bleeding in 69% of adults.

Table 1. Patient characteristics.

	PARC ITP		International ITP	
Number males n (%)	110 (32)		125 (41.8)	
Number of females n (%)	230 (68)		174 (58.2)	
Mean age in years (range)	39.0 (16.1- 85.8)		48.6 (18 - 96)

Treatments %				
Corticosteroids (all)	59		68	
IVIg	6		18	
Anti-D	2		3	
TPO agonists	Not reported		7	
Splenectomy	Not reported		5	
No treatment	29^		33^	
Platelet count at diagnosis (x10 ^{9}/L)				
Mean	25.4		29.0	
Range	0-133*		1-96#	
Bleeding (any site) n (%)	236 (69%)		103 (34%)	
Investigations n (%)	Negative	Positive	Negative	Positive
Antiphospholipid abs.	123 (94)	8 (6)	49 (89)	6 (11)
Antinuclear abs.	193 (90)	22 (10)	117 (65)	63 (35)
Platelet associated abs.	38 (53)	34 (47)	NA	NA
HIV	216 (99)	2 (1)	166 (99)	1 (1)
Hepatitis C	213 (97)	7 (3)	190 (99)	2 (1)
Helicobacter pylori	48 (69)	22 (31)	27 (59)	19 (41)

* PARC ITP used PLT count < 150 x 10^9/L for diagnosis

International ITP Registry used PLT count < 100 x 10^9/L for diagnosis

^ The PARC-ITP Registry reports no treatment as initial management. The ITP Registry reports no treatment recorded overall

Summary and Conclusions: Comparative data showed similarities in gender distribution, presenting platelet counts, diagnostic testing and first line therapy, whereas differences occurred in co-morbidity, bleeding, and second line therapies.

CLINICAL FEATURES OF PATIENT WITH SEVERE ACQUIRED ADAMTS13 DEFICIENCY IN THROMBOTIC THROMBOCYTOPENIC PURPURA

D. Oh[1,*] I.-H. Kim[2], C.-W. Jung[3], J.-W. Le [4], H.G. Lee[5], S.K. Sohn[6]
[1]Internal Medicine, CHA University, Seongnam, [2]Internal Medicine, Seoul National University College of Medicine, [3]Internal Medicine, Sungkyunkwan University School of Medicine, [4]Internal Medicine, Catholic University College of Medicine, [5]Internal Medicine, Konkuk University School of Medicine, Seoul, [6]Internal Medicine, Kyungpook National University, Daegu, Korea, Republic of

Background: Diagnostic and prognostic value of ADAMTS13 activity is controversial. We previously reported the characteristics of severe ADAMTS13 deficiency in thrombotic thrombocytopenic purpura (TTP) and patients with severe ADAMTS13 deficiency (Jang MJ *et al*., Int J Hematol 2011;93:163-9).
Aims: In this study we updated it by adding more patients to know the clinical characteristics of patients with severe ADAMTS13 deficiency at presentation.
Methods: One-hundred sixty nine patients with TTP from January 2005 to June 2014 were analyzed. ADAMTS13 activity and inhibitors were measured by immunoblotting of degraded von Willebrand factor. Clinical information was retrospectively collected and analyzed.
Results: Patients with severe ADAMTS13 deficiency at presentation had lower serum creatinine levels (P<0.0001), lower platelet counts (P<0.0001), and higher total bilirubin levels (P=0.0001) than patients with non-severe ADAMTS13 deficiency. Treatment outcomes did not differ significantly between two groups in response, remission, and mortality rate. After adjusting for clinical and laboratory features, multivariate analysis revealed age over 60 year old is an independent risk factor for TTP-associated mortality (P=0.0249).
Summary and Conclusions: TTP with severe ADAMTS13 deficiency is a unique subgroup characterized by lower platelet count and relatively good renal function. The severity of ADAMTS13 deficiency at presentation does not have prognostic significance.

E1408

A PERSONALIZED REFERENCE INTERVAL FOR PLATELET COUNT REDUCES THE PREVALENCE OF UNEXPLAINED THROMBOCYTOPENIA AND INCREASE THAT OF REACTIVE THROMBOCYTOSIS IN ELDERLY PEOPLE

P. Noris[1,*] C. Zaninetti[1], G. Biino[2], E. Civaschi[1], F. Melazzini[1], C.L. Balduini[1]
[1]Department of Internal Medicine, Policlinico San Matteo Foundation and University of Pavia, [2]Institute of Molecular Genetics, National Research Council of Italy, Pavia, Italy

Background: The reference interval for platelet count currently in use in most Western countries is 150-450 or 150-400x10^9 platelets/L. However, many studies indicated that women have more platelets than men and platelet count progressively decreases with ageing. Moreover, ethnicity-related differences have been identified and the related genetic factors have begun to be unveiled.
Aims: To evaluate the outcome of a personalized reference range recently identified by the study of 40,978 Italian healthy subjects and which takes into account age and sex: 165-473x10^9 platelets/L, regardless of gender, under 15 years of age; 136-436 and 120-369x10^9/L in women and men, respectively, between 15 and 64 years; and 119-396 and 112-361x10^9/L in women and men, respectively, over 64 years (PLoS One 2013;81:e54289).
Methods: The new personalized reference range was applied retrospectively, in parallel to that presently in use of 150-450x10^9/L, to a series of 925 consecutive Italian patients admitted to a department of Internal Medicine. The investigated population was mainly composed of elderly subjects (mean age 74±14.2 years). Clinical records were used to identify the potential causes of thrombocytopenia and thrombocytosis in each patient. The institutional review board of the hospital approved the protocol, and all patients gave written informed consent in accordance with the Declaration of Helsinki.
Results: The prevalence of thrombocytopenia was 21.3% with the traditional reference range and 16.9% with the personalized one. Switching from thrombocytopenic to non-thrombocytopenic affected in most cases subjects without any apparent cause of reduced platelet count, whose number dropped from 67 to 37. So, the personalized range reduced by 44.8% the number of subjects with unexpectedly low platelet counts. Also a few patients with chronic liver disorders turned from thrombocytopenic to non-thrombocytopenic. The prevalence of thrombocytosis increased from 9.1% with the traditional range to 12.2% with the personalized range, and switching always occurred in patients with potential causes of high platelet count, the majority classified as affected by inflammatory disorders.
Summary and Conclusions: The most relevant effect of personalized reference intervals for platelet count in elderly medical patients was the reduction by nearly half in the proportion of subjects with an unexplained form of thrombocytopenia. Introducing the new range into the clinical practice is therefore expected to prevent many subjects to receive a series of unnecessary and expensive tests, this benefiting both involved people and the health system.

E1409

ROLE OF ASHWELL-MORELL RECEPTOR MEDIATED HEPATIC CLEARANCE OF PLATELET IN IMMUNE THROMBOCYTOPENIA (ITP): PLATELET KINETIC STUDIES AND AUTOANTIBODY TYPE DATA IN CLINICAL PRACTICE

S. Cantoni[1], M. Carpenedo[2,*] D. Sica Lanfranco[3], A. Centroni[3], M. Nichelatti[4], R. Cairoli[5]
[1]Hematology and Oncology Department, Ospedale Niguarda Cà Granda, Milan, [2]Hematology and Transplant Unit, A.O San Gerardo di Monza and University of Milan Bicocca, Italy, Monza, [3]Hematology and Biochemistry Department, [4]Department of Biostatistics, Ospedale Niguarda Cà Granda, [5]Hematology and Oncology Department, A.O. Ospedale Niguarda Ca' Granda, Milan, Italy

Background: Detection of antibodies (Abs) against platelet GPIIb-IIIa and/or GPIb-IX is a characteristic feature of immune thrombocytopenia (ITP) and Fc-mediated clearance of platelet (plt) by splenic macrophages has so far been addressed as the main mechanism of plt destruction. Recently, an Fc-independent mechanism has been proposed which involves mainly anti-GPIb Abs (1) which were shown to induce plt activation leading to GPIb desialyation. In turn, plt lacking sialic acid (desialylated plt) are removed by the hepatic Ashwell-Morell receptor (AMR or asialoglycoprotein receptor).
Aims: In order to test the clinical relevance of this novel mechanism of plt clearance, plt kinetic studies and Ab type data were retrospectively reviewed in a group of ITP patients (pts).
Methods: Charts of ITP pts who had data on both plt kinetic studies and Ab testing were reviewed. Pts are enrolled in a local Italian database (REL-ITP database), and informed consent to clinical data use is given at enrollment
Results: A total of 53 pts (M 24) were identified: 41 already splenectomized between year 2000 and 2014, 12 evaluated for splenectomy. All pts underwent or are candidate to splenectomy for steroid-dependent ITP; 1 pt only was primarily refractory to steroids and IVIG treatment. All but 2 pts achieved a complete response to splenectomy. 31/53 (58.4%) of pts tested positive to one or more than one antiGP Abs. Results of platelet kinetic studies and Ab testing are summarized in Table 1. Extra splenic clearance doesn't differ significantly (Fisher's test p=0.531) between Ab negative or positive pts.

Table 1.

Ab pattern	n(%)	site of plt clearance (111-Indium labeled plt)		
		splenic	hepatic	mixed
All patients	53 (100)			
Ab negative	22 (41.6)	17 (77.3%)	0 (0%)*	5 (22.7%)*

*Fisher's exact test: p=0.531

Summary and Conclusions: Recent data have proposed that Ab type may determine plt fate in ITP by activating either Fc- or non Fc-mediated mechanisms of plt clearance resulting in splenic or hepatic uptake respectively. However, our data on plt kinetic and Ab type do not support such a mechanism being operative in ITP pts: no correlation was found between Ab type, number (single *vs* multiple antiGP) of Ab positive test and site of plt clearance. On the other hand, it is well known that plt desialylate as they circulate, thereby becoming the primary AMR ligand. Desialylation also occurs when plt are activated by a number of physiological stimuli (2). It may well be that AMR-mediated hepatic plt clearance rather represents a physiological mechanism involved in clearance of activated plt-a role for the AMR has been proposed in attenuating the coagulopathy associated with sepsis (3-4)-and in the regulation of TPO production by hepatocytes (5).

E1410

DIAGNOSIS AND MANAGEMENT OF THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP) IN AUSTRALIA-FINDINGS FROM THE FIRST FIVE YEARS OF THE AUSTRALIAN TTP REGISTRY (2009-2014)

P. Blombery[1,2,*] L. Kivivali[1], S. Engelbrecht[1,3], D. Pepperell[4], E. Wood[1,5], S. Cohney[1,6]
[1]Monash University, [2]Peter MacCallum Cancer Centre, Melbourne, [3]Gold Coast University Hospital, Queensland, [4]Fiona Stanley Hospital, Perth, [5]Monash Medical Centre, [6]Western Hospital, Melbourne, Australia

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare, life-threatening thrombotic microangiopathy. In 2009, the Australian TTP registry was established and began collecting data on patients presenting with TTP throughout Australia.
Aims: To summarise findings of the first five years (2009-2014) of TTP diagnosis and management from the Australian TTP registry.
Methods: Registry data from June 2009 to October 2014 were reviewed.
Results: 57 patients were identified with TTP (ADAMTS13 <10%) accounting for 72 clinical episodes. ADAMTS13 inhibitor testing was performed in 9/57 (16%) patients reflecting the limited availability of accredited testing facilities. 67/72 episodes were treated with therapeutic plasma exchange (PEX) with cryodepleted plasma (40% episodes), fresh frozen plasma (36%) or a mixture (22%). Exposure to plasma products was significant with a median exposure of 55.9L per episode. PEX was not commenced until 2 or more days after date of diagnosis in 15% of episodes. Adverse reactions to PEX were common with documented allergic reactions (including life-threatening) in 21% of episodes. Adjunctive immunosuppression was documented in 76% episodes (corticosteroid 71%, rituximab 39%). Platelets were transfused in 15% of episodes with no documented adverse reactions.
Summary and Conclusions: Australian TTP registry data reveal a heterogenous approach to the diagnosis & management of TTP in Australia from 2009-2014. Identified areas for potential practice improvement include a standardised approach to TTP diagnostic testing, improving access to timely PEX and a more uniform approach to adjunctive immunosuppression and supportive care.

E1411

RECENT TIME TRENDS IN THE UPTAKE OF SPLENECTOMY IN ADULTS DIAGNOSED WITH CHRONIC IMMUNE THROMBOCYTOPENIA: A NATIONWIDE HISTORICAL COHORT STUDY IN DENMARK, 1996-2012

K. Cetin[1], S. Wetten[2,*] C. Christiansen[3], M. Nørgaard[3], U. Heide-Jørgensen[3]
[1]Center for Observational Research, Amgen Inc, Thousand Oaks, United States, [2]Center for Observational Research, Amgen Ltd, Uxbridge, United Kingdom, [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by isolated thrombocytopenia leading to an increased risk of bleeding. Low platelet counts in ITP result from both increased antibody-mediated platelet destruction and decreased platelet production. Because the spleen often removes circulating antibody-coated platelets and can be the site of antibody production, splenectomy can be an effective treatment option. Although it is generally viewed as a standard second-line treatment in adults with ITP, splenectomy has its risks (perioperative and long-term), and there are no clear clinical criteria (*e.g.*, previous response to steroids) that predict response. Additionally, spontaneous remissions are possible, and newer nonsurgical second-line therapies are available. Some clinicians and patients are therefore opting to avoid or defer splenectomy. We sought to investigate recent trends in the uptake of splenectomy in adults with chronic ITP (cITP) in Denmark.
Aims: To compare the rate of splenectomy in three time periods (1996-2001; 2002-2007; 2008-2012) in a cohort of adults diagnosed with cITP.
Methods: Using the Danish National Registry of Patients (DNRP), we included all adults (≥18 years) diagnosed with cITP (≥2 ITP diagnoses made ≥180 days apart) in Denmark from 1996 to 2012. The date of cITP diagnosis was defined as the date of the first ITP diagnosis occurring ≥180 days after the initial diagnosis and after the patient's 18th birthday. The DNRP was also used to identify if and when patients had undergone splenectomy and the presence of comorbidities. We computed the cumulative incidence of splenectomy (treating death as a competing risk) after a diagnosis of cITP by time period of diagnosis. Cox proportional hazards regression analyses were used to assess whether the hazard (rate) of splenectomy after a cITP diagnosis varied by time period of diagnosis, adjusting for gender, age, and presence of comorbidities. Patients were followed from the date of cITP diagnosis until 10 years post-cITP, death, emigration, or end of follow-up in 2012.
Results: We identified 1,993 non-splenectomized adults diagnosed with cITP. Women accounted for nearly 58% of the cohort; and 31%, 35%, and 34% of patients were aged 18-40, 41-65, and ≥66 years, respectively, at the time of cITP diagnosis. During a median follow-up of 3.9 years [range: <0.1-10.0], approximately 9% (n=177) underwent splenectomy. Among these patients, the median time to splenectomy following the cITP diagnosis was 0.5 years (range: <0.1-9.9). The 1- and 3-year cumulative incidence of splenectomy after the diagnosis of cITP was lower in more recent time periods of diagnosis (Table 1). After adjusting for gender, age, and comorbidities, patients diagnosed with cITP in 2008-2012 were less than half as likely to undergo splenectomy compared with patients diagnosed in 1996-2001 (adjusted hazard ratio: 0.4 [95% CI: 0.3-0.7]).

Table 1. Cumulative incidence of splenectomy in adults following a diagnosis of chronic ITP by time period of chronic ITP diagnosis.

Time period of chronic ITP diagnosis	Cumulative incidence of splenectomy (95% confidence interval)	
	1-year	3-year
1996-2001	10.1% (7.6-12.9)	12.9% (10.1-16.0)
2002-2007	5.9% (4.3-7.8)	8.7% (6.8-11.0)
2008-2012	3.4% (2.3-4.9)	5.1% (3.6-6.9)

Summary and Conclusions: Less than 10% of nearly 2,000 adults diagnosed with cITP in Denmark from 1996 to 2012 underwent splenectomy during a median follow-up of 3.9 years. The incidence of splenectomy after a diagnosis of cITP was lower for patients diagnosed in more recent years.

E1412

EFFICACY AND PROGNOSIS OF SHORT TERM AND VERY LOW-DOSE IVIG THERAPY (200 MG/KG/D) FOR NEWLY DIAGNOSED ACUTE IMMUNE THROMBOCYTOPENIC PURPURA IN CHILDREN

K. Lee[1,*] J. Kim[1], J. Kim[1], Y.-J. Shim[2], U. Kim[3]
[1]Pediatrics, Kyungpook National University School of Medicine, [2]Pediatrics, ng University Dongsan Medical Center, Daegu, [3]Pediatrics, Incheon Medical Center Baekryung Hospital, Incheon, Korea, Republic of

Background: High-dose intravenous immunoglobulin G (IVIG) is the first therapy for childhood acute immune thrombocytopenic purpura (aITP). Individual low-dose method has been applied in the Department of Pediatrics, Kyungpook National University Hospital since 1984. We have reduced the daily dose from 400 to 200 mg/kg daily until platelet count (PLT) over 50,000/uL since 2000.
Aims: This study evaluated the efficacy of short term and very low dose IVIG (VLD-IVIG) therapy according to individual clinical response.
Methods: Forty-six childhood ITP Patients who's PLT less than 20,000/uL were evaluated from January 2007 to December 2013. We treated them with VLD-IVIG (200 mg/kg/day for 1~5 days) initially until rising PLT over 50,000/uL and then any patients without the response were treated additional IVIG up to 2g/kg totally.
Results: The mean age of 22 male and 24 female ITP was 26 months. The mean PLT was 8,300/uL at the time of diagnosis. Thirty nine patients responded with VLD-IVIG only. Four patients needed only one day, 11 patients 2 days, 9 patients 3 days, 10 patients 4 days, and 5 patients 5 days of IVIG (200 mg/kg) respectively. Six of 7 patients who did not raise PLT above 50,000 with VLD-IVIG had response after full dose (total 2 g/kg). Only 1 patient did not response with IVIG and needed corticosteroids and 1 patient recurred within 2 weeks after therapy. The mean numbers of IVIG injection to 50,000/uL was 3 times (621 mg/kg of dose). The mean PLT after therapy was 108,692/uL. The mean duration to recover PLT more than 150,000/uL was 2 months. No patient was diagnosed to chronic ITP. The mean follow-up duration was 24 months and mean PLT was 336,410/uL at last follow-up date.
Summary and Conclusions: The short term VLD-IVIG therapy according to individual clinical response is effective and is recommended for acute ITP to reduce admission days and cost of high dose IVIG therapy.

E1413

THE ROLE OF REGULATORY T CELLS IN IMMUNE THROMBOCYTOPENIA OF CHILDHOOD

M. Stratigaki[1,*] G. Martimianaki[1], N. Katzilakis[1], P. Bourbaki[1], M. Pesmatzoglou[1], E. Stiakaki[1]
[1]Pediatric Hematology-Oncology, University of Crete, University Hospital of Heraklion, Heraklion Crete, Greece

Background: Immune thrombocytopenia (ITP) is one of the most common blood diseases and the commonest acquired bleeding disorder in childhood. Although the development of autoantibodies against platelet glycoproteins by B cells remains central in the pathophysiology of ITP, dysfunctional cellular immunity has also great importance. $CD4^+CD25^+Foxp3^+$ T cells (T_{reg} cells) take part in the regulation of immune responses and maintenance of self-tolerance. It has been also shown that these cells play a key role in the pathogenesis of autoimmune diseases.
Aims: The aim of this study was the determination of the sub-populations of CD3+CD8+CD25+, CD3+CD4+CD25+, CD4+$CD25^{high}$ and CD4+$CD25^{high}$-Foxp3+ T cells in children with immune thrombocytopenia and the correlation with the levels of platelets' number and the disease phase.
Methods: Peripheral blood of 21 children, 12 with acute ITP (age range 5

months-11 years) and 9 children (age range 8-16 years) with chronic immune thrombocytopenia was studied. The percentage of regulatory T lymhpocytes' subpopulations was estimated with flow cytometry. The median platelets' number was 11900/µl in the group of acute ITP and 46600//µl for the patients in the chronic phase of the disease.
Results: According to our findings between acute and chronic phase of immune thrombocytopenia was not observed statistically significant difference in the levels of CD3+CD8+CD25+, CD4+CD25^{high} and CD4+CD25^{high}Foxp3+ T cells subpopulations. The levels of the CD3+CD4+CD25+ T cells sub-population were statistical significantly reduced in children with acute immune thrombocytopenia in contrast with children with chronic immune thrombocytopenia (2.94±0.68 *vs* 5.10±0.16, p=0.029). No statistically significant difference was observed in the levels of regulatory T cells between diagnosis of immune thrombocytopenia and the phase of recovery of number of platelets in normal values.
Summary and Conclusions: Between acute and chronic childhood ITP the number of $CD3^+CD4^+CD25^+$ T_{reg} cells was estimated with significant difference. This reduction of the $CD3^+CD4^+CD25^+$ T_{reg} cells in acute ITP might be one of the mechanisms implicated in the pathophysiology of the disease in children.

E1414

INCIDENCE OF MALIGNANCY IN ADULT PATIENTS WITH AUTOIMMUNE THROMBOCYTOPENIC PURPURA: A 12 YEAR SINGLE CENTER EXPERIENCE

M. Ayesh (Haj Yousef)[1,*] A. Dawood[1], Y. Khader[2]
[1]Medicine, [2]Public health, Jordan University of Science and Technology, Irbid, Jordan

Background: Autoimmune thrombocytopenia (ITP) is an autoimmune disorder characterized by immune-mediated platelet destruction and suppressed platelet production. Depending on the presence or absence of associated disease, ITP is divided into primary and secondary types. Few studies have addressed the association between ITP in adult patients and malignant neoplasms.
Aims: To estimate the incidence of malignant neoplasms in adult patients with ITP.
Methods: All patients diagnosed with ITP and with a platelet count <100×10^9/L, between September 2002 and January 2015 were included in the study. Patients were retrospectively reviewed for diagnosis of malignancy, and inclusion criteria included concurrent ITP or ITP preceding the diagnosis of a malignant neoplasm within 1 year.
Results: A total of 86 patients (62 females and 24 males) were diagnosed between 2002 and 2015. Their ages ranged from 16 to 91 years with a mean (SD) of 35.7 (15.3) years. Among these patients, 13 (15.1%) developed malignancy during the study period. The incidence of malignancy was significantly higher in males ≥30 years old than in males ≤30 years old. It was 6.9% among patients aged 31-50 years and 58.8% among patients aged ≥50 years. Hodgkin's and marginal lymphoma were the most common cancers detected in this group of patients.
Summary and Conclusions: ITP had a strong association with malignant neoplasms, especially in male patients over 50 years of age. Hodgkin's and marginal zone lymphoma were among the cancers strongly associated with ITP. The results suggest that patients over 50 years of age with ITP should be examined for an underlying malignant condition. ITP may occur concurrently or precede the occurrence of malignant disease, which would have great diagnostic significance. ITP may also be the first early sign of the disease. Thus, prompt determination of the cause of ITP could be of great importance for the diagnosis, monitoring and therapy of malignant neoplasms.

E1415

AN OBSERVATIONAL CLINICAL PRACTICE STUDY OF ROMIPLOSTIM IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA (ITP)-PLATON INTERIM RESULTS

G. Mihaylov[1,*] G. Kuchma[2], J. Obernauerová[3], B. Skopec[4], Z. Sninska[5], N. Tzvetkov[6], D. Niepel[7], P. Černelč[4]
[1] Clinic of Hematology, Specialized Hospital for Active Treatment of Hematology Diseases AD, Sofia, Bulgaria, [2]Department of Hematology, Regional Clinical Hospital №1, Orenburg, Russian Federation, [3]Department of Hematology, Regional Hospital Mlada Boleslav, Mlada Boleslav, Czech Republic, [4]Department of Hematology, University Medical Center Ljubljana, Ljubljana, Slovenia, [5]Department of Hematology and Blood Transfusion, University Hospital St. Cyril and Metod, Bratislava, Slovakia, [6]Clinic of Hematology, University Multiprofile Hospital for Active Treatment "Dr. Georgi Stranski" EAD, Pleven, Bulgaria, [7]Medical Department, Amgen CEE Headquarters, Vienna, Austria

Background: The thrombopoietin-receptor agonist romiplostim is indicated for adult splenectomised patients (pts) with ITP who are refractory to other treatments and may be considered as second line treatment for adult non-splenectomised pts where surgery is contra-indicated.
Aims: The aim of this ongoing study is to assess the use of romiplostim in clinical practice in Bulgaria, Czech Republic, Slovenia, Slovakia, Romania and Russia.
Methods: This international single-arm, non-interventional, multicenter, retrospective and prospective study is enrolling adult pts with ITP, who have received at least one application of romiplostim according to the licensed indication. A period of 6 months prior to romiplostim initiation was documented retrospectively from pt files; the prospective observation period started at the time of romiplostim initiation. The total planned observation period is 2 years. All pts provided written informed consent. Assessed parameters included pt demographics, romiplostim application, dosage, adverse drug reactions (ADRs) and reasons of discontinuations, concomitant ITP therapies, clinically relevant bleeding events, and consumption of resources. Data from a protocol-defined interim analysis (IA) at 1 year of prospective observation are reported here.
Results: 66 pts were analyzed for the IA (47% male, median age at romiplostim initiation 48 [range 19-82] years, splenectomized n=27, non-splenectomized n=39). Of these, 58 (88%) completed 1 year of study, 8 (12%) discontinued from the study (adverse drug reactions n=1, administrative decision n=2, lost to follow-up n=5). The median time from ITP diagnosis to romiplostim initiation was 2.89 (0-42) years. 34 pts (51.5%) had received ≥3 prior ITP therapies. During the 6 months before romiplostim initiation the event rate per 100 pt years was 111 (95% CI 75.1, 156.8) for bleeding and 92 (95% CI 73.2, 113.0) for ITP-related hospitalizations. The median platelet count at romiplostim start was 19.0 (range 1-411)x 10^9/L, increasing to 52.0 (range 2-361)x 10^9/L after 1 week and remaining above 50x 10^9/L for the period until IA data cut-off at 1 year (Figure 1). During the 1-year observation period for IA, pts received a median romiplostim dose of 2.13 (range 0.1-9.1) µg/kg/week and a median of 31 (range 2-53) injections. The event rate per 100 pt years during the 1-year romiplostim treatment period was 58 (95% CI 39.0, 83.6) for bleeding (no grade 3/4 events) and 94 (95% CI 69.3, 125.4) for ITP-related hospitalizations. 4 pts (6.1%) experienced a total of 11 ADRs, with 2 pts experiencing 2 serious ADRs each (thrombosis, dysphagia, lymphocytosis, leucocytosis). 51 pts (77.3%) were hospitalized for 77 ITP-related events during the 1 year observation period for IA for the following reasons: platelet transfusion (n=5, 9.8%), ITP treatment administration (n=24, 47.1%), bleeding event (n=14, 27.5%), infection-related (n=5, 9.8%), splenectomy (n=7, 13.7%), ADR (n=1, 2.0%), other (n=21, 41.2%).

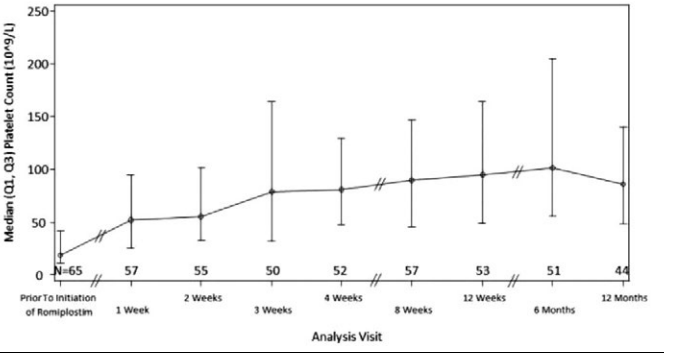

Figure 1.

Summary and Conclusions: These interim data show that platelet counts in ITP patients treated with romiplostim in clinical practice increased and were maintained within the desired range of 50-250x 10^9/L. The bleeding event rate was lower during romiplostim treatment. Romiplostim was generally well tolerated.

E1416

MULTI-CENTER, PROSPECTIVE STUDY TO EVALUATE THE EFFICACY OF "BIWEEKLY" ROMIPLOSTIM IN ADULT IMMUNE THROMBOCYTOPENIA (ITP); PROLONGED DOSE INTERVAL ≥2 WEEKS IS NOT RECOMMENDABLE

S. Park[1,*] S.S.Y.[2], J.H. Lee[3], J.S. Park[4], J.W. Lee[5], J.H. Jang[1]
[1]Samsung Medical Center, [2]Seoul National University Hospital, [3]Asan Medical Center, Seoul, [4]Ajou University Hospital, Suwon, [5]Seoul St. Mary's Hospital, Seoul, Korea, Republic of

Background: Romiplostim is recommended to administer weekly in adult immune thrombocytopenia (ITP) patients. However, the optimal dose interval has rarely been studied.
Aims: This is a multi-center, prospective study to evaluate the efficacy of "biweekly" romiplostim in maintaining platelet count ≥30x 10^9/L during 4 or more weeks.
Methods: Treatment was started with weekly injection (starting dose, 1mcg/kg), and the dose was escalated until achieving titrated dose that maintains platelet count 50-200x10^9/L for 4 consecutive weeks. Then, patients moved to biweekly schedule, and if platelet count became <30x 10^9/L, patients returned back to weekly schedule. The process could be repeated twice. But platelet count <30x

10^9/L on 2nd biweekly schedule, the study was finished after 4 weekly doses.
Results: Between Jul 2013 and Dec 2014, a total of 18 patients were enrolled (median platelet count, 14x10^9/L). After the 1st weekly schedule, 10 of 18 (55.6%) attained titrated dose of median 3mcg/kg and proceeded to 1st biweekly schedule. However, all of them failed in maintaining platelet count ≥30x 10^9/L for at least 4 weeks, and returned back to 2nd weekly schedule. 8 of 10 were titrated (median, 5mcg/kg) and moved to 2nd biweekly romiplostim; 3 of 8 (37.5%) showed platelet counts ≥30x 10^9/L during 4, 8, and 10 weeks. However, all 8 patients eventually experienced drop of platelet and entered onto the last stage; 2 (25%) almost did not respond to romiplostim at this time (Figure 1).

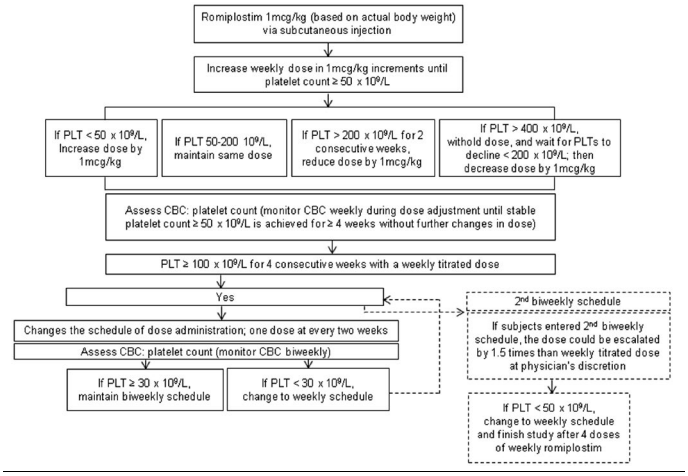

Figure 1. Overall treatment algorithm.

Summary and Conclusions: Lengthening the dose interval of romiplostim more than a week is not desirable for stably maintaining the platelet count and associated with fluctuating platelet response.

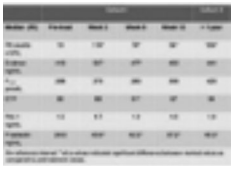
E1417

EFFECT OF THROMBOPOIETIN RECEPTOR AGONISTS ON COAGULATION AND PLATELET ACTIVATION IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

L. Garabet[1,*] S. Lee[2], M.-C. Mowinckel[3,4], C. Jonassen[5], H. Liebman[6], J. Bussel[2], P. M. Sandset[3,4,7], W. Ghanima[8]
[1]Cenetre for laboratory medicine, Østfold Hospital Trust, Fredrikstad, Norway, [2]Department of pediatrics, Unit of platelet disorders, Weill Cornell medical college, New York, United States, [3]Research Institute of Internal Medicine, [4]Departmet of hematology, University Hospital, Oslo, Oslo, [5]Cenetre for laboratory medicine, Østfold Hospital Trust, Fredrikstad, Norway, [6]Department of medicine, Norris Cancer Hospital, Los Angeles, United States, [7]Institute of Clinical Medicine, University Hospital, Oslo, Oslo, [8]Department of medicine, Østfold Hospital Trust, Fredrikstad, Norway

Background: Thrombopoietin receptor agonists (TPO) are effective treatment in immune thrombocytopenia (ITP). Thrombotic events were reported in up to 6% of patients in TPO-agent trials in raising concerns of coagulation and platelet activation.
Aims: To evaluate the effect of TPO-agents on coagulation and platelet activation.
Methods: The study comprised 2 ITP cohorts. Cohort 1 (n=26) with sequential blood samples at 0 (pretreatment) and 2, 6 and 12 weeks on treatment with TPO. Cohort 2 (n=18) patients on long-term treatment with TPO-agents (>1 year) in whom blood samples were collected only once. Markers of coagulation and fibrinolysis including endogenous thrombin potential (ETP) by calibrated automated thrombography (CAT) assay, prothrombin fragments 1+2 (F_{1+2}), plasminogen activator inhibitor-1 (PAI-1) activity, and D-dimer as well as soluble P-selectin as a marker of platelet activation were measured in all samples. Healthy controls (n=20) were analyzed for P-selectin only.
Results: Mean age was 55 years (32% males). Nineteen patients were treated with romiplostim, 22 with eltrombopag and 3 with avatrombopag. Median values of D-dimer, PAI-1, ETP (normalized against pooled normal plasma), P-selectin and platelet counts are shown in the Table 1. Platelet counts increased significantly after initiation of TPO treatment. No difference was found between pretreatment and on treatment (both cohorts) values of D-dimer, F_{1+2} or PAI-1. Median ETP at 6 weeks higher than pretreatment values (p=0.042); remaining levels at 2 and 12 weeks and cohort 2 did not differ from pretreatment. A statistically significant increase in P-selectin was found shortly after initiation of TPO-agents (2 weeks)(p=0.002) and through 6 (p=0.0001) and 12 weeks (p=0.003) into treatment. A higher level of P-selectin was also found in cohort 2 compared to pretreatment levels of cohort1. Pretreatment levels of P-selectin did not differ from healthy controls (mean 22.5 ng/mL) (p=0.4), however, all on treatment levels of P-selectin in cohort 1 (p=0.002, 0.001, 0.008 respectively) and cohort 2 (p=0.006) were significantly higher than healthy controls.

Table 1.



Summary and Conclusions: Conclusion: Evaluation of the coagulation and fibrinolytic systmes shows that thrombopoietic agents cause no activation of these systems confirming a previous study performed on eltrombopag. However, the finding of increasing soluble P-selectin during treatment with TPO may indicate degranulation of alpha-granules and hence platelet activation.

E1418

SPLENECTOMY IN THE TPO MIMETIC ERA-STILL REASONABLE APPROACH?

E. Konířová[1,*] O. Černá[2], L. Červinek[3], T. Kozák[2], M. Šimkovič[4], M. Trněný[1]
[1]1st Department of Medicine-Department of Hematology, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, [2]Department of Internal Medicine and Hematology, 3rd Faculty of Medicine, Charles University, Prague, [3]Department of Internal Medicine-Hematology and Oncology, University Hospital and Masaryk University, Brno, [4]2nd Department of Medicine-Department of Hematology, Charles University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic

Background: Immune thrombocytopenia (ITP) is an acquired, immunologically determined disease characterized by a decrease in platelet count and the associated increased risk of bleeding. The spleen plays a major role in the pathogenesis of ITP, it is the site of antibody production and often the major site of antibody-mediated platelet destruction. Splenectomy was the first method for ITP therapy and has long been the standard second-line treatment for adults with ITP who do not respond to corticosteroids. Recent advances in the understanding of etiopathogenetic mechanisms of ITP led to the development of novel therapies and changed the role of splenectomy in the management of ITP.
Aims: Describe the population indicated for splenectomy (before and after new guidelines). Evaluated efficacy and safety of splenectomy and therapeutic possibilities for refractory patients.
Methods: We retrospectively analyzed the data of 98 patients with primary ITP from four Czech hematological centers who underwent splenectomy between years 1995 and 2014. The response was evaluated according to the ITP International Working Group guidelines.
Results: In total, 98 patients (66% females) underwent splenectomy for ITP between 1995 and 2014 in four Czech hematological centers. The median age at diagnosis was 36 years (range 6-72) and median age at splenectomy was 38 years (range 17-73). 56% patients who were splenectomized before year 2010 had chronic ITP while 72% patients had chronic ITP if the splenectomy was performed after year 2010. Minority of patients had newly diagnosed ITP, in a subgroup of patients splenectomized before year 2010 it was 19% and in a subgroup of patients splenectomized after year 2010 were none with newly diagnosed ITP's. While the median interval between diagnosis and splenectomy in patients who were splenectomized before 2010 was 13 months, the median interval in patients who were splenectomized after 2010 was longer (32 months). After 2010, splenectomy was used most often as a third-line treatment. 25 patients in our group underwent labelled platelet scanning before splenectomy, majority of them had splenic uptake. The median platelet count before splenectomy was 65x 10^9/l (range 1-330x 10^9/l). 77 patients (79%) were prophylactic vaccinated against encapsulated bacterial pathogens. 61% of patients underwent splenectomy with an open technique and 39% with a laparoscopic technique and the rate of laparoscopic splenectomies increased over time. Of the 98 patients, 10 (11%) achieved a response (R) and 83 (84%) a complete response (CR), the overall response rate was 95%. 28 (29%) patients relapsed after a median time 6 months (range 1-125). 8 patients (8%) experienced peri-operative and 3 patients (3%) post-splenectomy complications. In 33 patients (34%) splenectomy was not successful because of the relapse or lack of response, but new treatment options especially TPO mimetics improved the outcome of these refractory patients.
Summary and Conclusions: Splenectomy is an effective treatment for ITP with two thirds of patients achieving long-term response and still has a place in the management of ITP. Recent trend is to postpone splenectomy until the chronic phase of the disease.

E1419

ASSOCIATION OF SINGLE NUCLEOTIDE POLYMORPHISMS IN SOME IMMUNOREGULATORY GENES WITH IMMUNE THROMBOCYTOPENIA

M. Pavkovic[1,*] S. Trkovska-Terzieva[1], S. Genadieva-Stavric[1], O. Karanfilski[1], T. Sotirova[1], L. Cevreska[1], A. Stojanovic[1]
[1]University Clinic for Hematology, Skopje, Macedonia

Background: Immune thrombocytopenia (ITP) is an autoimmune disease characterized by thrombocytopenia due to platelet autoantibodies, causing an accelerated clearance of opsonized platelets by phagocytes. The etiology of ITP remains unclear, but both genetic and environmental factors can have a role in the development of ITP.
Aims: The aim of our study was to investigate a possible association of some single nucleotide polymorphisms (SNP) in genes for interleukin beta IL1β(-511C/T), tumor necrosis factor beta TNFβ(+252G/A), tumor necrosis factor alpha TNFα(-308G/A), cytotoxic T lymphocyte antigen 4 CTLA(+49 A/G), Fc gamma receptor FCGR2A-H/R131 and FCGR3A-V/F158 with ITP.
Methods: We analyzed 125 adult ITP patients (35 men, 90 women) with median age of 47(range 14-83) and 120 healthy matched controls. The median follow up was 44 months (12-384). All 125 patients were initially treated with corticosteroids, 38 were splenectomized. Forty two (34%) patients had refractory or unresponsive form of disease, according to the definition of the International Working group for ITP. Genotyping was performed by using polymerase chain reaction and restriction fragment length polymorphism methods. The distribution of genotypes and allele frequencies were compared with a chi-squared.
Results: Our results demonstrated significantly different distribution of the TNFβ(+252 G/A) genotypes and allele frequencies in patients with ITP (G/G=3, A/G=38, A/A=84) comparing with controls (G/G=16, A/G=35, A/A=69), p=0.005 and p=0.009. We didn't found significant differences in the genotype distribution or allele frequencies for TNFα(-308G/A) and ILβ (-511C/T), p=0.363 and p=0.845. There was significantly different genotype distribution and allele frequencies for TNFα(-308G/A) between patients with unresponsive ITP (n=83; G/G=75, A/G=8, A/A=0) and responsive ITP (n=42; G/G=30, A/G=11, A/A=1), p=0.016 and p=0.009. There was no significant difference in genotype distribution and allele frequencies for TNFβ(+252G/A) and ILβ(-511C/T) between these two groups of patients. Our results demonstrated significantly higher frequency of high affinity FCGR3A-158V allele in ITP patients comparing with controls (47.2% *versus* 37.5%; p=0.037). We did not found significant differences in the allele frequencies for FCGR2A-131H/R, p=0.478. In the group of patients with unresponsive and responsive ITP we found significantly different genotype distribution and allele frequencies for FCGR3A, p=0.036 and p=0.008 respectively. Our results confirmed that, the combination of high affinity FCGR2A-131H and FCGR3A-158V allele was more common in patients with ITP than in control subjects (55% *versus* 40%; p=0.024). Analysis of CTLA-4 polymorphisms did not confirmed significant differences in genotype distribution between ITP patients and controls, p=0.43.
Summary and Conclusions: Results of this study, suggest possible role of FCGR3A, TNF-β and TNF-α polymorphism in the etiology, development and clinical form of immune thrombocytopenia.

E1420

SWITCHING THROMBOPOIETIN RECEPTOR AGONIST (TPO-RA) IN ADULT IMMUNE THROMBOCYTOPENIA (ITP) PATIENTS: A RETROSPECTIVE CASE SERIES

S. Cantoni[1], M. Carpenedo[2,*] V. Coccini[3], R. Cairoli[1], E.M. Pogliani[3]
[1]Hematology and Oncology Department, A.O. Ospedale Niguarda Ca' Granda, Milan, [2]Hematology and Transplantation Unit, A.O San Gerardo di Monza and University of Milan Bicocca, Italy, [3]Hematology and Transplant Unit, A.O San Gerardo di Monza and University of Milan Bicocca, Monza, Italy

Background: Availability of TPO-RA offers a new opportunity of treatment with high response rates for ITP patients (pts). However, a small fraction of pts do not respond or lose response-*i.e.* desired platelet (plt) count achieved but not sustained over time-at follow-up or experience wide fluctuations in plt counts with either romiplostim (R) or eltrombopag (E). Albeit rare, untoward effects may lead to treatment discontinuation. Finally, pts preference may be an important issue considering the different route and timing of administration of the two drugs and the alimentary restrictions needed for proper E absorption. Availability of two TPO-RAs with different molecular structure and site of binding within the TPO receptor, makes it appealing to try switching with the aim of overcoming treatment limitations of either agent (1-3).
Aims: Data on TPO-RA switch in everyday clinical practice are presented.
Methods: Charts of ITP pts receiving TPO-RAs at two collaborating Centers were reviewed. All pts are enrolled in a local data-base and informed consent to clinical data use is given at enrollment.
Results: A total of 59 pts received either R or E between Jan 2009 and Dec 2014. 14/59 (24%) underwent TPO-RA switch (Table 1). All pts had received maximum product dose as per prescribing information prior to switch. Of the 5 pts switching because of lack of response to first TPO-RA, only 1 (#3) responded when switch from E to R, but developed neutralizing antibodies to R. Four of 6 pts who lost response on first TPO-RA responded to the second TPO-RA; the 2 non responders were splenectomized pts who had received multiple lines of therapy prior to TPO-RA treatment. Both pts switched for plt count fluctuations responded but one pt only achieved stable plt counts. Pts's preference was the reason for switching in one pt only who was receiving R; she did not respond to E and was switched back to R regaining a response.

Table 1.

N	REASON FOR SWITCHING	PREVIOUS THERAPY	TPO-RA SEQUENCE	OUTCOME after switching	COMMENTS
	1 st TPO-RA FAILURE sex, age				
1	M, 82 yrs	Dex, IVIG	R --> E	NR	NR to RTX; not elegible to spl
2	M, 47 yr	PDN, RTX	E --> R	NR	NR to CyA
3	F, 38 yr	PDN, IVIG	E --> R	CR->loss of response: Ab to R	Spl performed after Ab developm-> CR
4	F, 30 yr	PDN, IVIG	R --> E	NR	Re to MMF
5	F, 44 yr	Dex, IVIG, CyA	R --> E	NR	NR to cyclophospamide; not eligible to spl
	LOSS OF RESPONSE sex, age				
6	M, 23 yr	PDN	E --> R	Re	Spl performed for pt's preference->CR
7	F, 58 yr	PDN + IVIG, spl	R --> E	CR	platelet count fluctuation
8	M, 43 yr	PDN, spl, Dex	R --> E	NR	off therapy for pt's preference
9	M, 61 yr	PDN, IVIG, spl, VCR, RTX	R --> E	NR	off therapy for pt's preference
10	M, 19 yr	DEX, IVIG	R --> E	CR	Ab to R; E as bridge to spl -> CR
11	F, 56 yr	PDN, IVIG	R --> E	CR	E discontinuation for CR; off therapy
	PLT COUNT FLUCTUATION sex, age				
12	F, 64 yr	PDN,spl	R --> E	CR	persistent platelet count fluctuation
13	F, 21 yr	PDN, IVIG	E --> R	CR	resolved platelet count fluctuation
	PATIENT'S PREFERENCE sex, age				
14	F, 68 yr	PDN, spl	R --> E	NR	switched back to R; Re regained

R: Romiplostim; E: Eltrombopag
IVIG: intravenous immunoglobulin; DEX: dexamethason; RTX: rituximab; Spl: splenectomy; PDN: prednisone; VCR: vincristine; Cya: Cyclosporine; MMF: mycophenolate mofetil: Ab: antibodies; CR: complete response; Re: response; NR: no response;

Summary and Conclusions: Availability of two TPO-RAs offers a safe and often effective treatment alternative in pts not achieving the desired plt response on either R or E. However, differently from published case series (1-3) among our pts it seems that lack of response to either one of the two available TPO-RA identifies a subgroup of pts least likely to respond when switched to the second available TPO-RA. Similarly to reported series (1-3), plt count fluctuation stabilize in approximately 50% of cases upon switching. Finally, re-exposure to R (pt #14) was not associated with response loss, which confirms our published observation (4) of absence of tachyphylaxis.

E1421

A STUDY OF HUMAN KILLER CELL IMMUNOGLOBULIN-LIKE RECEPTOR(KIR) AND MULTI-DRUG RESISTANCE (MDR)GENE POLYMORPHISMS IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA

N.M. El-beblawy[1], N.S. Elbarbary[1,*] T.M. Kamal[1], P.M. Mahmoud[1]
[1]Ain Shams University, Pediatric Department, Cairo, Egypt

Background: Childhood immune thrombocytopenia (ITP) is a common pediatric hematologic disorder characterized by increased destruction of antibody-sensitized platelets with normal to increased megakaryocytes in the bone marrow, as well as the presence of thrombocytopenia with otherwise normal red cells and leukocytes, absence of splenomegaly and the absence of other causes of thrombocytopenia. Although the etiology of ITP remains unclear, it is generally accepted that both environmental and genetic factors play an important role in the development of the disease.
Aims: To analyze the allelic and genotypic frequencies of MDR and KIR genes polymorphisms in healthy and ITP Egyptian subjects. In addition we assessed the potential role of these polymorphisms in relation to types of ITP, progression of disease and response to different treatment modalities.
Methods: A total of 48 pediatric ITP patients (24 newly diagnosed, 24 chronic) and 35 healthy controls were investigated via PCR-RFLP analysis for MDR1 and KIR2 genes.
Results: The frequency of MDR1 gene in patients and control was not significant (P=0.090). CT genotype was the highest distribution among all ITP cases(62.50% (n=30) and control (48.60%(n=17). There was a significant difference in age at diagnosis of MDR_1 gene with the CC genotype had the eldest age and lowest initial platelets count (P=0.029 and P=0.004). The distribution of KIR2 gene among all ITP patients and controls was significant

(P=0.026)with (KIRDL2-/KIRDS2-) genotype was the most prevalent among patients.
Summary and Conclusions: The frequency of MDR1 polymorphisms were not associated with susceptibility to the development and clinical progression of the disease. However, KIR2 gene polymorphisms were independently associated with childhood ITP in Egyptian patients with highest prevalence among (KIRDL2-/KIRDS2-) genotypes.

E1422

ROMIPLOSTIM AS A PREPARATION TREATMENT BEFORE SPLENECTOMY IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

E. Burnasheva[1,*] Y. Shatokhin[1], I. Snezhko[1], O. Gerasimova[2], O. Matveeva[1], E. Kuzub[1]
[1]Hematology, [2]Transfusiology, Rostov State Medical University, Rostov-on-Don, Russian Federation

Background: Splenectomy is used as a second line therapy for immune thrombocytopenia (ITP) in patients with corticosteroid resistance. The operation may be risky for patients with a platelet count less than 30-40x 10(9/L) leading to severe hemorrhagic complications. Massive platelet transfusion often leads to immune complications. Moreover, it can be difficult to find retaining platelets in enough supply to be able to provide to the patient.
Aims: In the following trial romiplostim was used to reduce platelet transfusion requirement in splenectomized patients over pre- and postoperative periods.
Methods: Over a 3-week period, 12 patients with ITP (7 females and 5 males at age 26-42 years old) with a median platelet count of 7,3-7,5x10^9/L were treated with romiplostim once weekly.
Results: All that patients had resistance to corticosteroid therapy and bleeding episodes such as epistaxis, gum bleeding or skin hemorrhages. Immune globulin G therapy failed in hemorrhagic syndrome and did not cause the increase in platelet count. After 3 injections of romiplostim all patients demonstrated decrease of hemorrhagic manifestations. A median platelet count were 148±52,9x10^9/L. All patients were splenectomized. Nobody of them needed platelet transfusion in pre- or postoperative periods. No peri- or postoperative complications have developed. In 10 patients a platelet count increased up to 421±62,7x10^9/L on the second week after splenectomy. Two patients demonstrated a platelet count of 1457±132x10^9/L in 10 days after operation. In 4 weeks of treatment with heparin and hydroxycarbamide, their platelet count achieved the level of 402±37,5x10^9/L. No thrombotic complications in all patients in postoperative period have developed. Over next 11+-4,5 months all splenectomized patients had a complete clinical and biochemical remission.
Summary and Conclusions: Thus, romiplostim could be recommended as a preparation treatment before splenectomy in patients whose ITP does not respond to corticosteroids, according to our material. However, a high risk of thrombotic complications in postoperative period should be considered

E1423

GLANZMANN THROMBASTHENIA IN CHILDREN : TWENTY FIVE YEARS FOLLOW-UP

Z. Salcioglu[1,*] H. Sayilan Sen[1], G. Aydogan[1], F. Akici[1], D. Tugcu[1], Z. Baslar[2]
[1]Pediatric Hematology and Oncology Clinic, İstanbul Kanuni Sultan Süleyman Education and Research Hospital, [2]Internal Medicine, Hematology Department, İstanbul University, Cerrahpaşa Medical School, İstanbul, Turkey

Background: Glanzmann Thrombasthenia is a rare bleeding disorder. The cause of the disease is the qualitative or quantitative abnormalities of platelet membrane glycoprotein GPIIb-IIIa complex. Severity and frequency of the bleeding episodes may change from patient to patient.
Aims: In this report, clinical and laboratory features of 33 patients that were followed between 1990-2015 were evaluated.
Methods: Information of patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005.
Results: They were 16 males (48.5%) and 17 females (51.5%). The age of onset was between 1 month and 7 years (mean 2.8 years). Familial consaguity was present in 17 (51.5%) of the patients. Bleeding time was prolonged and thrombocyte function tests were correlated with Glanzmann disease. Flow cytometric tests were done in 27 patients. Type 1 disease was present in 5 (18.5%), type 2 in 10 (37%), type 3 in 12 (44.5%) of the patients. The bleeding types seen in our patients were as follows; oral mucosal bleedings 81.8%, superficial skin bleedings 72.7%, epistaxis 66.6%, menorrhagia 15.1%, heamaturia 6%, haemarthrosis 6% and intracranial bleeding 1.8%. Local therapies, antifibrinolytic agents, oral contraceptives and if severe bleeding is present thrombocyte suspensions were given. For five of our patients with six bleeding attacks rFVIIa was used. One of our patients died due to tuberculous pericarditis and dilated cardiomyopathy.Follow up duration was between 1 and 24 years (mean 11.4 years). There was not any documanted alloimmunization. Thirty two of our patients are still alive and being followed up.
Summary and Conclusions: In Turkey where consanguineous marriages are common, patients with mild bleeding may be underdiagnosed. It is also known that even diagnosed patients may seek help only when they have severe bleeding problems. As a result; we believe that in order to diagnose these patients as early as possible, to perform their follow-ups and scan their families and to provide adequate patient education and genetic counselling, a nationwide program should be organized.

E1424

DIAGNOSTIC VALUE OF TESTS USED AT IMMUNE THROMBOCYTOPENIA DIAGNOSIS TO DETECT ASSOCIATED DISEASES. A PROSPECTIVE MULTICENTER COHORT STUDY

G. Moulis[1,*]T. Comont[1], N. Brun[2], C. Dingremont[3], B. Castel[4], S. Arista[5], S. Madaule[6], P. Montané de la Roque[7], L. Prudhomme[8], L. Sailler[1], L. Balardy[9], C. Borel[10], S. Background: The frequency of immune thrombocytopenia (ITP)-associated diseases is not well known. The diagnostic values of the tests performed at ITP onset in order to detect these diseases are discussed or unknown.
Aims: To compare the diagnostic value of the tests used at ITP diagnosis to detect ITP-associated diseases in the overall ITP population, in the presence of signs evocative of these diseases and in the absence of these signs.
Methods: Study population was the patients included between June 2013 and December 2014 in the CARMEN (*Cytopénies Auto-immunes : Registre Midi-PyréneEN*) registry. This multicenter registry is aimed at the prospective follow-up of all incident ITP adults in the French Midi-Pyrénées region (3 million inhabitants). Each investigator prospectively follows every patient newly diagnosed for ITP in routine visit or hospital stay, providing informed consent was received. ITP is defined in accordance with French guidelines: platelet count <150x 109/L and exclusion of other causes of thrombocytopenia. Investigations performed at ITP diagnosis are recorded with their results. We assessed their positivity rates in the entire cohort and depending on the clinical and biological context. These rates were expressed in frequencies and in number of patients needed to test (NNT) to observe one positive test.
Results: We included 113 patients. Median age was 65 years (range: 17-95). Half of the patients were female, 24 (21.2%) had a secondary ITP, 58 (51.3%) had bleeding signs, median platelet count was 16x109/L (range: 1-126) and 72 patients were treated for ITP within the month following the diagnosis. Bone marrow aspirate was performed in 87 patients. Four myelodysplastic syndromes (MDS) were found (2 refractory cytopenia with unilineage dysplasia and 2 with multilineage dysplasia); these 4 ITPs had platelet count <10x 109/L and responded to corticosteroids. The NNT to detect 1 MDS was 12 in case of anemia or neutropenia and 52 in case of isolated thrombocytopenia (among patients aged >60 years, NNTs were 10 and 25, respectively). The NNTs for antinuclear antibodies (ANAs, tested in 92 patients without known connective tissue disease, positive if titer≥1/160) were similar in case of clinical signs of unknown connective tissue disease (NNT=2) or not (NNT=3). Antiphospholipid antibodies were positive in only 1 lupus patient (36 tested). The NNT for positive direct antiglobulin test (tested in 47 patients) was 4 in case of anemia or low haptoglobin level, and 7 otherwise. The NNT for hypogammaglobulinemias (<5g/L) on serum protein electrophoresis (tested in 92 patients) was 23 in case of lymphopenia and 69 otherwise. No patient had a history of repeated or severe infections. HCV, HBV and HIV were tested in respectively 89, 97 and 86 patients, including 7 with elevated alanine aminotransferase. No new infection was detected. The NNT for Helicobacter pylori testing (n=11) was 2 in case of gastro-intestinal symptoms and 3 otherwise. Thyroid stimulating hormone (TSH) or thyroid autoantibodies were tested in 57 patients without history of thyroiditis. None had thyroiditis clinical signs. Isolated autoantibodies or mild TSH abnormalities were found in 9 patients but no specific treatment was started.
Summary and Conclusions: Except for ANAs (whose presence may discuss the use of hydroxychloroquine), NNTs were at least two-fold higher in case of evocative context, discussing the systematic use of these tests. HIV, HCV and HBV revealed by ITP seem very rare in France.

E1425

STUDY OF ADAMTS13 LEVELS IN PATIENTS WITH THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP) DURING PREGNANCY

F. Piras[1,*] L. Russo[1], M. Marchetti[1], L. Barcella[1], M. Testa[1], A. Rambaldi[2], M. Noris[3], C. Savignano[4], V. Toschi[5], A. Falanga[1]
[1]Immunohematology and Transfusion Medicine Department, [2]Hematology Department, Hospital Papa GiovannixXIII, [3]Clinical Research Center for Rare Diseases, Mario Negri Institute, Bergamo, [4]Transfusion Medicine Department, Azienda Ospedaliero Universitaria, Udine, [5]Immunohematology and Transfusion Medicine Department, Hospital San Carlo Borromeo, Milano, Italy

Background: TTP is an acute, life threatening thrombotic microangiopathy associated to a congenital or acquired deficiency of the von Willebrand factor cleaving protease ADAMTS13. Limited data on utility of ADAMTS13 measurements during pregnancy are available.
Aims: Aim of this study was to evaluate the importance of closely monitoring ADAMTS13 levels on pregnancy outcome.
Methods: Four consecutive pregnant women with TTP (2 congenital, 1 acquired and 1 with probably congenital) were enrolled into the study. ADAMTS-13 activity (chromogenic assay), inhibitors (mixing studies), and anti-ADAMTS-13 antibodies (ELISA) were measured in plasma.
Results: Patient 1, a 35 y.o. woman with acquired TTP history not-related to pregnancy had a TTP relapse at 21th week gestation (first pregnancy). A complete ADAMTS13 activity deficiency associated to anti-ADAMTS13 auto-antibodies was detected. Oral steroids and weekly plasma exchange (PEX) were started. However, ADAMTS13 activity remained significantly low (<5%) and she prematurely delivered (25th week) an alive baby. At remission she had persistent ADAMTS13 activity deficiency associated to auto-antibodies. Patient 2, a 21 y.o. woman developed TTP during her first pregnancy (15th week). She had a complete ADAMTS13 activity deficiency and no auto-antibodies, was successfully treated with plasma infusion therapy plus steroids, and delivered on term a healthy baby. At clinical remission, she had no ADAMTS13 activity and no auto-antibodies. A possible congenital TTP diagnosis was hypothesized. About two years later (May 2014) she was again pregnant. No ADAMTS13 activity or auto-antibodies were detected, and at molecular analysis a compound homozygosity for two novel ADAMTS13 mutations was found. She received prophylactic plasma infusions and delivered (38th week) a healthy baby without disease manifestations. Patient 3, a 28 y.o. woman with a HELLP syndrome history during her first pregnancy. She developed TTP during her second pregnancy, PEX treatment was started, however cesarean section was performed at the 32th week because of clinical worsening, with a successful outcome. She had a persistent low ADAMTS13 activity levels with no auto-antibodies, and at molecular analysis a compound heterozygosity for two novel ADAMTS13 mutations was found. Patient 4, a 30 y.o. woman developed TTP after her first pregnancy. After the delivery, she developed severe thrombocytopenia, and an evaluation of ADAMTS13 levels was performed. She had a complete ADAMTS13 activity deficiency and no auto-antibodies. The inherited nature of severe ADAMTS-13 deficiency in this patient was established by phenotype family analysis. The results of ADAMTS13 levels of parents showed a moderate reduction in ADAMTS13 activity in the mother (47%) and father (43%), associated with no antibodies. The genetic analysis is under investigation.
Summary and Conclusions: Our data endorse the utility of ADAMTS13 study for differential diagnosis between congenital and acquired TTP and subsequent type of treatment with either plasma infusion or plasma exchange. In addition, our data indicate that the measurement of ADAMTS13 can represent an effective means to monitor women at risk of TTP recurrence in pregnancy.

Quality of life, palliative care, ethics and health economics

E1426

SYMPTOMS, QUALITY OF LIFE AND HEALTH CARE UTILISATION IN MULTIPLE MYELOMA-A LONGITUDINAL STUDY OF PREDICTIVE DEMOGRAPHIC AND CLINICAL FACTORS

C. Ramsenthaler[1,*] P. Kaler[2], C. Pannell[1], R. Siegert[3], W. Gao[1], P. Edmonds[4], S. Schey[5], I. Higginson[1]
[1]Department of Palliative Care, Policy and Rehabilitation, [2]Department of Palliative Care, Policy and Rehabiltation, Cicely Saunders Institute, London, United Kingdom, [3]School of Public Health and Psychosocial Studies and School of Rehabilitation and Occupational Studies, Auckland University of Technology, Auckland, New Zealand, [4]Department of Palliative Care, [5]Department of Haematological Medicine, King's College Hospital, London, United Kingdom

Background: Multiple myeloma remains an incurable cancer with evidence that patients suffer more symptoms than in other haematological conditions. Palliative care services are rarely involved.
Aims: We aimed to determine how symptom prevalence, severity and quality of life as well as cost/health care utilisation change over time, and what demographic, clinical and social factors predict changes.
Methods: We recruited patients into a 14-site multicentre, longitudinal observational study, consenting patients at various stages of their illness (newly diagnosed, stable and progressive/relapsed disease). At baseline and then on up to 4 occasions over eight months, patients completed self reported demographic, clinical, symptom, palliative, quality of life and service use questionnaires. Clinical details were abstracted from medical records. We used myeloma-specific and generic, validated scales, including the Myeloma Patient Outcome Scale (MyPOS), a quality-of-life questionnaire specifically developed for multiple myeloma. We tested for predictors using multivariable analysis, adjusting for confounders.
Results: 257 patients with multiple myeloma with a median age of 69 years (range: 34-92) and on average 2.5 years post-diagnosis participated. 18.2% were newly diagnosed, 47.9% had stable disease and 32.7% had relapsed disease or were in the advanced, palliative phase of illness. Patients reported a mean of 5.1 (SD=2.7) symptoms. Over 70% had pain, 88.7% fatigue and 61.1% breathlessness. The most burdensome symptoms in the advanced stages were fatigue, poor mobility, pain, and tingling in the hand/feet. Over the eight months, patients showed distinct trajectories according to whether they were in an early or advanced treatment-interval or in an early or advanced treatment-free interval. Trajectories of physical functioning did not follow other domains of quality of life. The strongest predictors of higher levels of symptoms and health care service use at the end of follow-up were initial scores on MyPOS, type of myeloma, performance status and co-morbid conditions.
Summary and Conclusions: Burden of symptoms in multiple myeloma is high and symptoms are not resolved even during the treatment-free intervals. Those with a high symptom burden and with light chain disease are at increased risk for poor HRQOL, should be monitored and could potentially be considered for early referral to palliative care services.

NET SURVIVAL AND EXCESS MORTALITY AFTER A FOLLICULAR OR DIFFUSE LARGE B CELL LYMPHOMA: TREND BY EUROPEAN AREA.

M. Mounier[1,*] N. Bossard[2], L. Remontet[2], A. Belot[3], P. Minicozzi[4], R. De Angelis[5], R. Capocaccia[5], A. Monnereau[6], X. Troussard[7], M. Sant[4], M. Maynadié[8], R. Giorgi[9]
[1]Registre des Hémopathies Malignes de Côte d'Or, EA 4184, Université de Bourgogne, Dijon, [2]Laboratoire de Biométrie et Biologie Evolutive, Equipe Biostatistique Santé, Service de Biostatistique, Hospices Civils de Lyon, Lyon, France, [3]Cancer Research UK Cancer Survival Group, Department of Non-Communicable Disease Epidemiology, Faculty of Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Analytical Epidemiology and Health Impact Unit, Department of Preventive and Predictive Medicine, Fondazione IRCCS, Istituto Nazionale dei Tumori, Milan, [5]Centro Nazionale di Epidemiologia, Sorveglianza e Promozione della Salute (CNESPS), Istituto Superiore di Sanità, Rome, Italy, [6]Registre des hémopathies Malignes de la Gironde, Institut bergonié, Bordeaux, [7]Registre régional des hémopathies Malignes de la Basse Normandie, Centre Hospitalier Universitaire de Caen, Caen, [8]Service d'Hématologie Biologique, Centre Hospitalier Universitaire de Dijon, Dijon, [9]UMR S912 Sciences Economiques & Sociales de la Santé et Traitement de l'Information Médicale (SESSTIM), Marseille, France

Background: Since the 1990's, Non Hodgkin Lymphoma (NHL) has been affected by profound changes with a better knowledge of the disease and new therapeutic tools. Follicular (FL) and Diffuse Large B-cell Lymphoma (DLBCL) were the first to benefit of these.

Aims: To evaluate changes on survival in the general population; to compare FL and DLBCL cancer mortality across European areas by studying the trend of net survival; and estimating the effect of age and year at diagnosis on the excess mortality hazard (EMR) in order to study the care management over time.
Methods: FL or DLBCL diagnosed between 01-01-1996 and 12-31-2004, and aged ≥15 years were selected from the EUROCARE-5 database. Vital status was at 12-31-2008 (French registries at 12-31-2007). Registries that covered the entire period were included and categorized into 5 areas (Northern, UK, Central, Eastern and Southern Europe). We estimated the 5-year age-standardized net survival (5-year NS), using the Pohar-Perme's estimator. To model effects of covariate on the EMR, the flexible model of Remontet *et al.* has been used in combination with a model-building strategy as proposed by Wynant and Abrahamowicz.
Results: 13,988 FL and 25,320 DLBCL have been studied. An improvement of the 5-year NS for the more recent year of diagnosis was observed. An area disparity was evident within the last period [2002-04] with an age-standardized 5-year NS varying from 61%[54-69] to 75%[69-80] for FL and from 46%[43-50] to 58%[54-62] for DLBCL between Eastern and Northern Europe. A significant effect of the year on the EMR was observed for all areas and ages, except in Eastern Europe for DLBCL. The dynamic of the EMR varied among areas and ages.
Summary and Conclusions: These results identify differences across Europe. There remained an area-related difference in FL and DLBCL survival especially in extreme ages (youngest and oldest patients) even if the gap has reduced in recent years of diagnosis.

E1428

IMPLEMENTATION OF "LEAN" WORKING PRACTICES AND AN INTEGRATED ECP SYSTEM RESULTED IN A 50% INCREASE IN PATIENT TREATMENTS WITH THE SAME NUMBER OF NURSES EMPLOYED IN THE UNIT

B. Linic[1], F. Child[1], S. Saglam[1], M. Mootien[1], M. Gyimesi[1], G. Concha[1], R. Dona[1], S. Hizon[1], D. Guerrero[1], P.M. Button[2,*] J.A. Button[2]
[1]Guys Hospital, London, [2]ProcEx Solutions Ltd, Wales, United Kingdom

Background: We previously predicted substantial efficiency and productivity opportunities through the implementation of lean working practices and use of a Therakos integrated photopheresis system ("Cellex") for the administration of extracorporeal photopheresis (ECP). The challenge faced in 2013/2014 was to substantially increase the number of patients receiving ECP with no increase in staff costs, together with a relocation of the ECP unit.
Aims: The aim of this study was to implement lean working practices and the use of integrated ECP systems to increase the number of patients who could be treated without increasing nursing staff.
Methods: We implemented lean working practices and changed the configuration of our instruments to two Therakos "XTS" photopheresis systems and four Therakos "Cellex" systems. This new process was implemented in the St. Thomas ECP unit a few weeks before moving to Guys Hospital. We then underwent a 5-day *kaizen* (rapid improvement) event shortly after moving into the new ECP unit at Guys Hospital. We implemented a standardized planning concept offering fixed appointment times depending on the type of machine required and whether the patient could tolerate double-needle or single-needle mode (Table 1). This standard approach enabled us to fill vacant slots by telephoning "reserve" patients 1-2 days in advance, ensuring that all slots were being filled and thus utilizing as much of our capacity as possible.

Table 1.

Location	Treatment	Mon 11:30-20:00	Tue 08:00-20:00	Wed 08:00-20:00	Thu 08:00-20:00	Fri 08:00-20:00	Sat 08:00-18:00	Capacity Needed	Capacity Given	Nurse	WTE
Guys Hospital ECP unit											
	"XTS" system	12:30	12:30	12:30	12:30	12:30	12:30	526	520	1	0.61
	15:30	15:30	15:30	15:30							
	"Cellex" system	12:30	12:30					329	312		0.24
	(single-needle)	15:30	15:30								
	"Cellex" system	12:30	09:00	09:00	09:00	09:00	09:00	2993	3016	2, 3, 4	2.63
	(double-needle)	15:30	12:30	12:30	12:30	12:30	12:30				
			15:30	15:30	15:30	15:30	15:30				

Results: The weekly average increased from 43 treatments per week in 2012 to 63 per week in 2014-a 50% increase. A trend analysis was performed for treatment numbers *versus* week number in the period May 2013 to May 2014 as illustrated in the plot below (Figure 1).
Summary and Conclusions: Implementation of these new practices has meant that we are able to treat significantly more patients in the unit with the same number of nurses. We continue to see an upward trend in treatment numbers. We were able to eliminate Sunday sessions and treat the extra patients in a 6-day week with the same number of nurses. The elimination of working on Sunday has released funding towards the cost for the extra treatments.

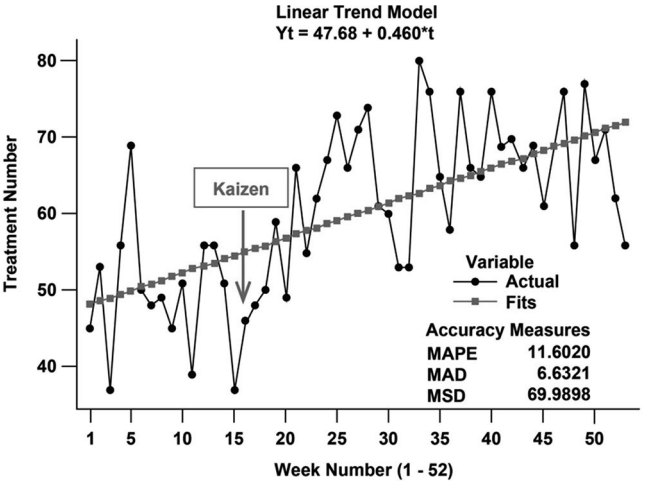

Figure 1. Trend analysis plot for ECP volumes at Guys Hospital May 2013-May 2014.

E1429

PROGNOSTIC VALUE OF NEURO-PSYCHOLOGICAL PARAMETERS IN CLINICALLY FIT OLDER PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

S. Dubruille[1], Y. Libert[1], M. Maerevoet[2], M. Roos[3], A. Collard[3], D. Razavi[1], D. Bron[2,*]
[1]Psycho-Oncology, [2]Hematology, [3]Oncogeriatry Unit, Institut Jules Bordet (ULB), Bruxelles, Belgium

Background: A Comprehensive Geriatric Assessment (CGA) is currently recommended to detect vulnerable cancer patients for whom chemotherapy may lead to severe impairment on functionality, quality of life, or survival. Although CGA is useful for a better management of older patients with unsuspected problems, little is known about the reliability of CGA to optimize the therapeutic approach in patients with malignant hemopathies. Particularly, the prognostic value of neuro-psychological parameters such as cognition, in older patients with hematological malignancies admitted to receive chemotherapy, are poorly investigated.
Aims: To assess in "clinically fit" (go-go and slow-go) patients with malignant hemopathies, the reliability of different clinical parameters of CGA as a prognostic tool to predict one-year overall survival (OS) treatment-related toxicity and loss of autonomy after treatment.
Methods: Between October 2010 and June 2013, CGA was proposed to 107 consecutive older patients (65+-yrs) with hematological malignancies, admitted to the hospital and judged clinically fit, by their refereeing physicians, to receive chemotherapy. An initial full-dose or reduced-dose chemotherapy has been administrated to them according to a multidisciplinary team decision. Nutritional disorder was screened by MNA (<23.5). Psychological disorder was assessed by GDS-4 (>1) and HADS (>13) and cognitive impairment by MMS (<27) and MoCA (<26). Log-rank test and multivariate Cox proportional hazards model were used to predict one-year OS.
Results: Ninety patients -completely assessed by CGA- were evaluable for one year OS; Non Hodgkin's Lymphoma (53%), Multiple myeloma (16%), Acute Myeloid Leukemia and Myelodysplastic Syndrome (15%), Chronic Lymphocytic Leukemia (14%) and Myeloproliferative Neoplasms (2%). Median age is 74 (65-89) yrs. 56% are males. 80% were considered as "vulnerable" when evaluated with CGA (≥2 impairments). During the first year of follow-up, 28% (n=22) of older patients treated for hematological malignancies died. Although the leading cause of death (82%) was the disease progression, 18% died due to toxicity related to treatment. Retrospectively, the CGA total score (≥2 impairments) had no impact on the initial treatment choice and was not predictive for one-year OS. In univariate analysis, nutritional (p=0.946) and psychological disorders (p=0.884) were not associated with OS. In a multivariate analysis, age (p=0.015; HR=1.1) and diagnosis (p<0.001; HR=7.2), were major prognostic factors of OS. Regarding specific CGA measures, the multivariate analysis showed that mild cognitive impairment (evaluated with a MMS<27 and a MoCA<26) had the strongest prognostic value (p=0.03; HR=3.6) for OS. The loss of autonomy after treatment is still under-evaluation. In our "clinically fit" hematological patients, a poor

CGA score does not translate into a worse survival, more likely because of two reasons: the disease itself remains the major cause of death and malnutrition, a reversible impairment after effective treatments, strongly impacts CGA. The objective of an effective screening tool should thus be the identification of the population who could benefit from optimal treatment combined with a comprehensive management of unsuspected specific problems.
Summary and Conclusions: Our observations in "clinically fit" older hematological patients suggest that 1) the major cause of death is the disease itself and the priority should be to identify all patients susceptible to benefit from full dose chemotherapy 2) an abnormal CGA are not specific enough and does not translate into a worse one year OS 3) some specific measures factors in the CGA (such as cognitive impairment) are highly correlated with one-year OS 4) age remain a continuous variable with a poor prognostic factor. Prospective trials are needed to further determine whether the combination of optimal treatment and improved management of impaired functions, including cognition, could lead to a better OS.

E1430

NOA PROGRAM INFLUENCING SURVIVAL IN CML PATIENTS FROM RESOURCE CONSTRAINT SETTINGS

U. Yanamandra[1,2,*] K.K. Sahu[2], P. Karunakaran[2], A. Khadwal[2], G. Prakash[2], S. Naseem[3], N. Varma[2], S. Varma[2], P. Malhotra[2]
[1]Internal Medicine, AFMC, Pune, [2]Clinical Hematology, [3]HematoPathology, PGIMER, Chandigarh, India

Background: Patient assistance program are a huge boon in the resource constraint settings in aiding patients to combat malignant disorders from public perspective. The average daily income in these countries is much lower than the daily expenditure of the anticancer medication. The Novartis Oncology Access (NOA) is a patient-access program sponsored by Novartis Oncology and administered by The Max Foundation (MAX) that provides imatinib free of charge to patients of chronic myeloid leukemia (CML) in resource-restricted countries who are not able to afford this treatment. There is no study to-date from India on the efficacy of this program. Also most studies from other countries/MAX have no control population for comparison.
Aims: To assess the role of NOA program on survival of CML patients. Our objectives were to study OS in all CML patients enrolled either in NOA program or on self-purchased medication. Subset analysis to study the role in AYA, middle aged & elderly CML patients was also done.
Methods: It is a single centre observational study from North India. Patients of both sexes with diagnosed CML (ELN guidelines) aged more than 12 years were included. Total of 1677 case files were screened of which 1241 patients with complete records were analysed. This included 263 adolescents and young adults (AYA) and 168 elderly CML patients. The patients were divided into two arms-NOA arm (wherein patient was supplied with lifetime free medication) and self-purchased (SP) arm (patients procured medication on own expenses). Survival was analysed using telephonic calls, hospital records and OPD visits over the last 3 months. Statistical analysis was done using SPSS version 16.0.
Results: Amongst 1241 patients 67% of the patients were in the NOA arm. The two groups were not significantly different in mean age, median delay in diagnosis, median duration of hydrea therapy and median delay in starting imatinib (Table 1). The average monthly income was significantly (p-0.001) higher in SP arm (≈109€) than NOA arm (≈57€). The average cost for CML therapy in our settings is approximately 60€ per month. The mean duration of therapy was significantly (p-0.001) higher in NOA arm (1533.16+1055.35) than SP arm (1080.53+982.82). Frequency of change in dose/type TKI was significantly lower amongst patients under NOA (p<0.001). Cumulative Survival was much better in patients in NOA arm than SP arm, with the difference being statistically significant (p<0.001) with the effect being pronounced only in AYA-CML and adult CML, but not in elderly CML (Figure 1).

Table 1: Baseline characterstics.

Variable	NOA		Not on NOA/Self Purchased		P value
	Mean	SD	Mean	SD	
Age (years)	38.59	19.12	41.45	19.55	0.108
Income (INR)	4419.09	4721.14	8449.86	8508.875	0.001
Median Duration of Hydrea therapy (months)	7.0468	17.19	8.039	30.84	0.685
Delay in starting Imatinib from Diagnosis (days)	280.53	695.56	248.56	693.09	0.625
Delay in Diagnosis (days)	176.39	298.815	160.84	384.821	0.634
Mean Duration of Therapy (days)	1533.16	1055.35	1080.53	982.82	0.001
Mean OS (days)	1695.75	1204.21	1251.43	1113.186	0.001

Summary and Conclusions: Patient assistance programs being carried out in a systematic manner would help in improving the outcomes of CML patients. The retrospective nature of the study and uncertainty of exact compliance of the patients were the limitations of the study. This study emphasises the effectiveness of NOA program in improving the survival of CML patients.

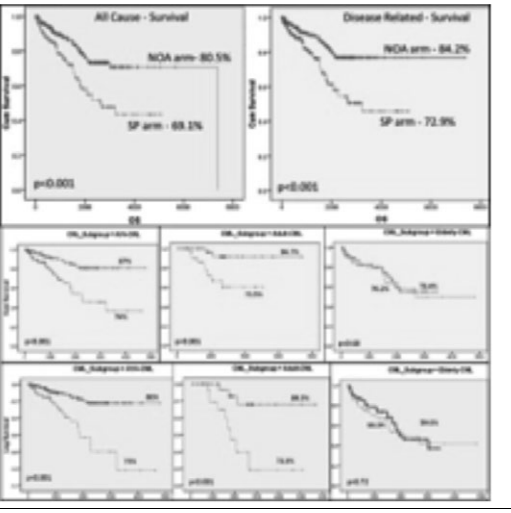

Figure 1.

E1431

A MULTI-CENTRE COST COMPARISON OF INTEGRATED *VERSUS* "OFF-LINE" SYSTEMS FOR PERFORMING EXTRACORPOREAL PHOTOPHERESIS PROCEDURES

A. Bobhot[1], N. Azar[2], G. Adorno[3], E. Fiorelli[3], P.M. Button[4,*]
[1]Department of Transfusion Medicine, Hautepierre Hospital, Strasbourg, [2]Unité d'Hémobiothérapie, Hôpital de la Pitié-Sâlpétrière, Paris, France, [3]RTN-Policlinico-Tor-Vergata, Rome, Italy, [4]ProcEx Solutions Ltd, Wales, United Kingdom

Background: A multicenter cost-analysis study of extracorporeal photopheresis (ECP) providers at four centers was carried out to compare "off-line" and integrated systems. Patients in these hospitals are treated with ECP for acute and chronic graft *versus* host disease (GvHD), cutaneous T-cell lymphoma (CTCL), solid organ transplantations, and various dermatological disorders. All four centers have the option of performing ECP using either an integrated system or by using a selection of off-line systems.
The integrated Therakos photopheresis system delivers ECP via a unique one-step process where the patient remains connected to the system for treatment. This eliminates the risk of improper infusion and also alleviates the need for a crossmatch of re-infused materials. The off-line system requires the removal and isolation of the collected cells from the patient to a regulated cell manipulation facility for further processing. According to European Guidelines for minimal cell manipulation, off-line procedures should be performed in a class A laminar airflow cabinet located in a class D laboratory. During off-line" procedures, cultures of the product for aerobic, anaerobic bacteria, and fungi should be done immediately before reinfusion into the patient.
Aims: The aim of this study was to compare the cost of performing ECP using the off-line systems *versus* the Therakos integrated system.
Methods: The additional costs of materials, overhead, and labor incurred by use of the off-line system were considered in this study. For a meaningful cost comparison it is important not to be misled by comparing the costs of off-line kits and Therakos system procedural kits alone.
Results: The average cost of performing ECP using the off-line systems was more expensive than the Therakos integrated system (€1,349.01 *vs* €1,285.81) (Table 1).

Table 1.

	Pitié-Sâlpétrière		Hautepierre Strasbourg			PTV Rome		EFS Nancy	
	Off-line (Macopharma)	Integrated (Therakos)	Off-line (UVA PIT)	Off-line (Macopharma)	Integrated (Therakos)	Off-line (UVA PIT)	Integrated (Therakos)	Off-line (Vilber Lourmat)	Integrated (Therakos)
Collection of leukocyte concentrate (PTC)	€173.75	€1,009.20	€215.00	€215.00	€1,074.00	€168.36	€991.86	€793.60	€781.52
EFS leukocyte procedural cost	—	—	—	—	—	—	—	—	€576.50
Biologic analysis (patient)	€59.00	€59.00	€59.00	€59.00	€59.00	€53.00	€53.00	€15.66	€15.66
Biologic analysis (cell collection)	€31.05	—	€29.00	€29.00	—	€32.00	—	€54.00	—
Transportation of cells to CT area	€7.76	—	€5.00	€5.00	—	€5.00	—	€6.54	—
Irradiation of leukocyte concentrate	€616.55	—	€605.00	€360.00	—	€450.00	—	€580.37	—
Biologic analysis (irradiated cells)	€76.00	—	€76.00	€76.00	—	€31.00	—	€43.20	—
Transportation of cells to ward	€7.76	—	€5.00	€5.00	—	€5.00	—	€6.54	—
Injection (triple access)	€12.00	—	€12.00	€12.00	—	€1.00	—	—	—
Personnel costs	€108.00	€40.50	€134.00	€134.00	€82.00	€180.00	€48.00	€161.43	€52.20
Bed retention cost/treatment (per hours used)	€337.50	€156.00	€325.77	€325.77	€144.79	—	—	€42.43	—
Total cost	€1,429.37	€1,264.70	€1,465.77	€1,220.77	€1,359.79	€925.36	€1,092.86	€1,703.77	€1,425.88

	Off-line	Integrated system
Average cost	€1,349.01	€1,285.81

Summary and Conclusions: The substantial reduction in patient treatment times offered by the Therakos integrated system improves patient quality of life, increases staff capacity to undertake additional treatments, and decreases bed retention time. In all four centers only one treatment per day can be carried out per bed using the off-line systems compared to three treatments per day per bed using the integrated system. The cost of performing ECP using the Therakos integrated system is comparable to the cost of treatments using the off-line systems.

E1432

HEALTH-RELATED QUALITY OF LIFE IN LEBANESE CHILDREN WITH SICKLE CELL DISEASE

A. Inati[1,*] S. Bou Sleiman[2], R. Akiki[2], E. Lteif[2], M. Kahale[3], H.A. Abbas[4]
[1]Lebanese American University, [2]Lebanese University, Beirut, [3]Nini Hospital, Tripoli, Lebanon, [4]University of Texas M D Anderson Cancer Center, Houston, United States

Background: Sickle Cell Disease (SCD) is a common genetic disorder associated with serious acute and chronic complications necessitating frequent hospitalizations and heavily impacting on quality of life (QoL) of affected patients. To date, there are no data on QoL of Lebanese patients with SCD.
Aims: To assess Health Related QoL (HRQoL) of children with SCD through self and proxy reporting of the PedsQL (4.0) questionnaire, compare it with that of age matched healthy controls, and identify socio-demographic and clinical factors that contribute to variation of QoL in SCD.
Methods: SCD children (age range 8-18 years) with no evidence of end organ damage, stroke or mental disease from 2 comprehensive SCD centers in Northern Lebanon and Beirut and healthy age sex-matched siblings (age range 8-16 years) were included in this study. PedsQL$^{4.0}$ was presented to the groups and general, physical and psychosocial scores were calculated as previously described.
Results: 47 SCD patients (66% SS, 32% SB0, 2% SD, 49% males, 51% females, mean age 12.3±3 years) and 30 sibling controls (53% males, 47% females, mean age 12.6±2.3 years) were given the PedsQL (4.0) questionnaire. All patients had received at least one transfusion. 93%, 74%, 59% of patients received folic acid, penicillin or hydroxyurea (HU), respectively. Mean general (54±20 *vs* 78±13), physical (49±25 *vs* 79±13) and psychosocial (57±19 *vs* 77±14) scores were significantly lower in patients than their age-matched siblings ($p<0.0001$ for all three). Patients receiving folic acid had significantly higher levels for general (56±18 *vs* 28±7), physical (51±24 *vs* 19±9) and psychosocial (59±19 *vs* 33±12) scores ($p<0.05$). More females than males had a general score below the median (median=55.4) ($p<0.05$). There was a positive correlation between patients' general scores and each of psychosocial score and number of siblings ($r=0.9$, $p<0.05$). Physical score was positively correlated with hemoglobin at presentation, age at first transfusion and the number of siblings of the patients ($r=0.9$, $p<0.05$). Psychosocial score was positively correlated with the age at first acute chest syndrome event ($r=0.9$, $p<0.05$). No significant impact of pain, hospitalization rate, joint necrosis, osteomyelitis, total number of transfusions, HU or penicillin intake on HRQoL scores could be detected.
Summary and Conclusions: Lebanese children with SCD have significantly decreased HRQoL compared to their siblings for all scores. The tendency for higher scores among males compared to females patients may be attributed to the more favorable nature of boys in Lebanese society. The strong association between FA treatment and higher scores underscore the beneficial impact of this inexpensive medication. The lack of impact of HU on HRQoL is surprising and may be related to the small sample size and the suboptimal compliance with this treatment in this patient group. Conclusively, the staggering difference among patients and siblings warrants a strong intervention to improve patients' QoL by advising caregivers and parents about the importance of addressing early the multiple psychosocial and physical challenges that patients with SCD face.

E1433

IMPACT OF CARFILZOMIB ON HEALTH-RELATED QUALITY OF LIFE: RESULTS FROM A PHASE 2 POST-HOC ANALYSIS OF SINGLE-AGENT CARFILZOMIB (PX-171-003-A1) IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA

D.S. Siegel[1,*] T. Martin[2], M. Wang[3], R. Vij[4], A.J. Jakubowiak[5], S. Lonial[6], S. Trudel[7], K. Cocks[8], D. Revicki[9], E. Bacci[10], S. Panjabi[11], R.Z. Orlowski[3], S. Jagannath[12]
[1]John Theurer Cancer Center at Hackensack University, Hackensack, [2]University of California at San Francisco, San Francisco, [3]MD Anderson Cancer Center, Houston, [4]Washington University School of Medicine, St Louis, [5]University of Chicago, Chicago, [6]Winship Cancer Institute, Emory University School of Medicine, Atlanta, United States, [7]University of Toronto Princess Margaret Hospital, Toronto, Canada, [8]KCStats Consultancy, Leeds, United Kingdom, [9]Evidera, Bethesda, [10]Evidera, Seattle, [11]Onyx Pharmaceuticals, Inc., an Amgen subsidiary, South San Francisco, [12]Mount Sinai Medical Center, New York, United States

Background: In the single-arm phase 2 study PX-171-003-A1 (NCT00511238), heavily pretreated patients (pts; median 5 prior lines of therapy) with relapsed and refractory multiple myeloma (RRMM) who received single-agent carfilzomib achieved meaningful clinical benefit as evidenced by durable responses (Siegel *et al*., *Blood* 2012;120:2817-25). In addition, the tolerability profile of carfilzomib was found to be acceptable. In pts with RRMM who have active symptoms, treatment-related toxicities, and multiple comorbidities, it is important to preserve health-related quality of life (HRQL) while improving clinical outcomes.
Aims: To assess HRQL in pts treated with single-agent carfilzomib via the Functional Assessment of Cancer Therapy/Gynaecologic Oncology Group-Neurotoxicity (FACT/GOG-Ntx) questionnaire.
Methods: Pts with RRMM (N=266) previously treated with bortezomib and an immunomodulatory agent (thalidomide or lenalidomide) were enrolled in the single -arm phase 2 study PX-171-003-A1. Pts completed the FACT/GOG-Ntx at screening and on day 1 of cycles 3, 5, 7, 9, and 11 and at the end of treatment (EOT) visit. Minimally important difference (MID) thresholds for changes over time (2 points for physical wellbeing [PWB], social wellbeing [SWB], emotional wellbeing [EWB], and functional wellbeing [FWB]; 3 points for total FACT-G; 3.3 for the neurotoxicity [Ntx] subscale) were used to establish the proportion of pts who improved, were stable, or worsened at each assessment. Longitudinal effect sizes were calculated as change from baseline divided by the pooled standard deviation. Change from baseline to best response in HRQL was evaluated by response group.
Results: Median pt age was 63 years old (range, 37-87); 58% were male. Most pts (80%) had progressed during their most recent therapy or within 60 days of completing treatment. Pts who completed the FACT/GOG-NTX from screening to cycle 3 dropped from 84.2% to 47.0% overall; however, expected completion rate (pts alive and on treatment) was high throughout the study (≥72.3%). The majority (n=169, 64%) had a HRQL assessment completed at baseline and during at least 1 other assessment period. The majority of pts were considered stable or improved at each assessment point over the study period using the pre-specified MIDs. Specifically, the proportion who were stable or improved was greatest for SWB (83% to 89%), EWB (79% to 89%), and Ntx domains (80% to 86%). A smaller majority of pts were stable or improved on the PWB (70% to 79%) and FWB (64% to 73%) domains. Longitudinal effect sizes showed some small but clinically relevant improvements in EWB (0.26 to 0.39 from cycle 5) and SWB (0.13, 0.20, and 0.10 at cycles 3, 7, and EOT, respectively). PWB had declined moderately (-0.37) by the EOT visit, and there was a small reduction in FWB at cycle 3 (-0.14) and EOT (-0.26). Pts with a partial response (PR) or better had improvements in HRQL across all domains (Figure 1). Pts with stable disease (SD)/minimal response (MR) or progressive disease (PD) had declining HRQL on PWB and FWB domains. Pts with PD also demonstrated a decline on EWB domain; SWB was not correlated with response.

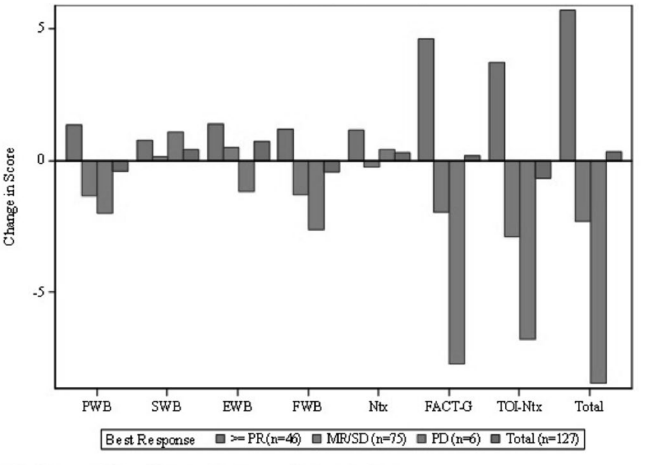

Figure 1. FACT/GOG-Ntx acores by best response.

Summary and Conclusions: For the majority of pts with available assessments, HRQL was maintained following treatment with carfilzomib. HRQL scores generally correlated with response to treatment. The effect of carfilzomib on HRQL is being assessed in randomised phase 3 trials.

E1434

PATIENTS' PERCEPTIONS OF RECEIVING A DIAGNOSIS OF A HAEMATOLOGICAL MALIGNANCY, FOLLOWING THE SPIKES PROTOCOL

L. Dixon[1,*]
[1]Liverpool Medical School, Liverpool, United Kingdom

Background: Sharing potentially devastating news with a patient is often considered the most difficult task of a healthcare professional. The quality of the

delivery of the bad news can have a direct impact on patients' emotions and adjustment to the condition; therefore doctors have a great responsibility.
Aims: The main aim of this study was to learn the theory behind breaking bad news and discover patients' perceptions of receiving bad news in the haematology setting; including what they thought was done well and areas that could be improved. The study was designed following the SPIKES protocol because it comprises the basic principles and provides a structure. There is an ever increasing amount of literature available surrounding this topic. Yet, there is a noticeable lack of research concentrating on the experience from the patient's view.
Methods: A questionnaire was written based on the steps of the SPIKES model. The questions were divided into sections. The first section, titled 'patient demographics', aimed to elicit personal information without comprising anonymity. The next six sections represented the six steps of the SPIKES model. There were a mixture of qualitative responses and multiple choice answers; however the participants were always able to give qualitative responses if they felt there were no multiple choice answers that represented their views. The participants were asked the questions by interviewers, who documented their answers. The interviewers were also available to explain the questions to the participants. The questionnaire was attempted by 20 participants who were in/out patients at Arrowe Park Hospital. The inclusion criteria for participation comprised a diagnosis of a haematological malignant disease and treatment for the disease at this hospital. Additionally, it was essential the patients gave voluntary and informed verbal consent.
Results: Due to help from the interviewers, all of the 20 questionnaires attempted were completed and used in this study. The participants rated their experience: 55% said 'excellent'; 25% reported 'good'; 5% said 'satisfactory' and 15% stated 'poor'. 'Poor' was rated more commonly by women and participants aged 45-64. Those who received their diagnosis within the past few years tended to have a better consultation. The main differences between the 'excellent' and 'poor' consultations include the doctor's sensitivity and the patients having their understanding checked. Problem areas include only 35% of patients were asked their existing knowledge and 85% of consultations failed to discuss the impact of the diagnosis on daily life.
Summary and Conclusions: Overall, most patients were happy with their consultation. The areas patients particularly praised were the set-up of the consultation and how sensitively the news was delivered. The knowledge section was done well generally, however it showed the greatest difference between 'poor' and 'excellent' consultations; therefore should be improved to standardise the experience. Other areas patients felt needed improvement include the doctor determining the patient's existing knowledge and what they would like to know. With a poorer prognosis, doctors should work on reassurance and conveying hope. Most consultations could be improved by the doctor exploring the effect of the diagnosis on other areas of the patient's life. This study was limited by a small sample size and potential recall bias.

E1435

IMPACT OF BURDEN OF THALASSEMIA MAJOR ON HEALTH RELATED QUALITY OF LIFE IN OMANI CHILDREN

S. Tony[1,*] M. Sadoon[1], M. Zachariah[1], P.Y. Wali[1]
[1]Child Health, Sultan Qaboos University Hospital, Muscat, Oman

Background: The availability of oral iron chelators and new techniques for detection of iron overload has markedly improved the prognosis and survival of patients with beta thalassemia major. The chronic nature of the disease however poses a significant burden affecting many aspects of patient's life such as physical activities, family adjustments and school performance. As chronically affected children are more vulnerable than adults and are less able to express their concern, health related quality of life (HRQoL) serves as an important domain for patients' perception of the disease on physical and psychosocial health functions. The impact of the disease on HRQoL in young Omani patients with thalassemia has not been evaluated earlier.
Aims: We aimed to evaluate the HRQoL in Omani children with thalassemia major by using Pediatric Quality of Life Inventory (PedsQL) 4.0 domain scores; assess the domain scores based on child and parent reporting and correlate the association between demographic-clinical characteristics and total PedsQL scores in thalassemic children to improve health care.
Methods: This cross-sectional study was done at the pediatric thalassemia day care center, Sultan Qaboos University Hospital Muscat, Oman from August 2013-February 2014. All patients with thalassemia major (5-18 years) on regular hypertransfusion/chelation were included. Demographic and clinical information were obtained from electronic patients' records. The 23-item PedsQL 4.0 Generic Core Scales with 4 Multidimensional Scales and 3 Summary Scores was used to assess the HRQoL based on parent and child reports. The 4 Multidimensional Scales included the essential core domains for pediatric HRQoL measurement: physical functioning (8 items), emotional functioning (5 items), social functioning (5 items) and school functioning (5 items). The 3 summary scores included the physical summary score, psychosocial health summary score and the total scale score. The physical summary score is the sum of all items of physical functioning and the psychosocial health summary score is the sum of all items of the emotional functioning, social functioning and school functioning. Appropriate forms in Arabic were distributed to children (aged 5-7, 8-12 and 13-18 years) and parents. Questionnaires were completed independently by children above 8 years and their parents. Children aged 5-7 years were interviewed by nurses.Statistical analysis was done using SPSS version 19.
Results: Patients' perception: The mean total summary (73.57±18.46) and the psychosocial health summary (74.55±18.25) scores were higher than the physical health summary score (72.26±22.34). School functioning score (68.05±21.3) was the lowest, followed by emotional (74.85±19.8) and social functioning (80.72±21.4) scores. Older patients were more likely to have higher HRQoL compared to their younger counterparts. Caregivers' perception: Similar to the patients perception, mean total summary (76.36±19.84) and psychosocial health summary (78.73±18.45) scores were higher than the physical health summary score (69.91±19.86). School functioning score was the lowest (69.71±18.96). In both groups gender had no significant association with HRQoL scores. Both groups revealed that patients with pre-transfusion Hb levels ≤9.5 and serum ferritin >1000 ng/ml had lower total summary score than those with Hb levels >9.5 g/dl serum ferritin ≤1000 ng/ml (Table 1).

Table 1. Clinical and demographic characteristics of Omani patients with thalassemia major.

Characteristics	n = 42
Age; median (range), years	11 (5-18)
Gender	n (%)
Male	23 (54.8)
5-7 year	11 (26.2)
8-12 year	10 (23.8)
13-18 year	2 (4.8)
Female	19 (45.2)
5-7 year	8 (14.3)
8-12 year	8 (19)
13-18 year	5 (11.9)
Age at diagnosis; median (range), months	6 (2- 31)
Age at initial transfusion; median (range), months	8.15 (2-31)
Age at onset of iron chelation; median (range), months	24.3 (16-46)
Duration of transfusion; median (range), years	9.15 (3.4-17.5)
Frequency of transfusion, weeks	
Mean ±SD	3.10 ± 0.44
Median (range)	3 (2-4)
</= 3	31
> 3	11
Pre-transfusion hemoglobin, g/dl	
Mean ±SD	9.48 ± 0.43
Median (range)	9.4 (8.7-10.7)
</= 9.5	25
> 9.5	17
Serum Ferritin, ng/ml	
Mean ±SD	1374 ± 534
Median (range)	1393.5 (463-3723)
</= 1000	10
>1000	32
Chelation, n	
Deferiprone	15
Deferasirox	16
Combination of Deferasirox and Deferiprone	11

Summary and Conclusions: Physical health function was more affected than psychosocial health function from both patients' and caregivers' perspective. School functioning domain was the most affected parameter of the psychosocial summary score in both child and parent reports. Overall, children with higher hemoglobin and lower serum ferritin levels scored better reflecting the significance of adequate blood transfusion and optimal chelation in these patients. Patients' ratings of HRQoL were lower for themselves, suggesting the need for emotional and social support. This study indicates that there is a need to address children's psychosocial and physical requirements in order to improve their quality of life. There is also a need to improve the ability of schools to adjust for the special needs of these children for better performance.

E1436

QUALITY OF LIFE IN PATIENTS WITH LOWER RISK MYELODYSPLASTIC SYNDROMES WITH SEVERE THROMBOCYTOPENIA TREATED WITH ELTROMBOPAG: INTERIM RESULTS OF A RANDOMIZED, PLACEBO-CONTROLLED PROSPECTIVE TRIAL

SS. Antonio e Biagio e Cesare Arrigo, Alessandria, [22]Policlinico Umberto I, Università La Sapienza, Roma, Italy

Background: About 10% of low and Intermediate-1 risk (International Prognostic Scoring System, IPSS) patients with myelodysplastic syndromes (MDS) experience severe thrombocytopenia. Bleeding and the scarce efficacy of platelet (PLT) transfusions drive research in novel treatments. Eltrombopag is an oral agonist of the thrombopoetin-receptor (TPO-R) indicated for treating chronic immune thrombocytopenic purpura. Eltrombopag's potential in increasing platelet (PLT) counts in lower risk MDS has not been evaluated. We present interim results on the efficacy of eltrombpag in lower risk MDS with severe thrombocytopenia in a Phase II, multicentre, prospective, placebo-controlled, single-blind study (EQoL-MDS).
Aims: Primary endpoints are safety and efficacy of eltrombopag in low and intermediate-1 IPSS risk. Secondary endpoints include changes in quality of life (QoL), PLT transfusion requirement, incidence and severity of bleeding, and survival.
Methods: Inclusion criteria are adult age; PLT<30 Gi/L; ECOG performance status <4; ineligibility for, relapsed or refractory to other treatments; and naive to TPO-R agonists. Eltrombopag/placebo (2:1) is administered at a 50 mg daily starting dose with 50 mg increases every 2 weeks to maximum 300 mg to target PLT 100 Gi/L. Dose interruptions or reductions are required for PLT >200 Gi/L or adverse events. PLT response is defined as Response if: 1) baseline PLT>20 Gi/L: absence of bleeding and PLT≥50Gi/L; 2) baseline PLT<20 Gi/L: PLT>20 Gi/L and increase by at least 100%, not due to PLT transfusions; and Complete Response if PLT≥100 Gi/L and absence of bleeding. QoL scores are evaluated by the EORTC QLQ-C30 and by the MDS-specific instrument, QOL-E.
Results: Sixty-four patients (34 males) of mean age 67, SD±13 have been randomized at the time of the present report. Thirteen patients had comorbidities. ECOG performance status was 0 in 24 cases, 1 in 37 cases, 2 in 2 cases and 3 in one. According to the WHO 2008 classification, 19 patients had refractory cytopenia with unilineage dysplasia, 9 had refractory anemia with ringed sideroblasts, 29 had refractory cytopenia with multilineage dysplasia (of which 15 with ringed sideroblasts), 5 had refractory anemia with excess blasts-1 and 2 were unclassified. IPSS score was low in 21 cases. Mean baseline platelet (PLT) counts were 16 SD±9 Gi/L, mean hemoglobin levels 10.8 SD±2.6 g/dL and mean white blood cell count was 5 SD±4 Gi/L. Twenty-two patients were red blood cell transfusion-dependent. Thirty patients had a WHO bleeding scale of 1, 6 experienced mild blood loss and 2 gross blood loss; 13 patients had required PLT transfusions in the 8 weeks prior to randomization. Fifty-seven patients were evaluable for response at 3 weeks. Of the 29 patients receiving eltrombopag, 10 (32%) responded *versus* none in the placebo arm with a median PLT rise of 46±1 Gi/L (p=0.009). Poor QOL-E scores were registered in the physical (N=33), functional (N=30), social (N=40), and fatigue (N=20) domains. Significant improvements in fatigue were perceived by patients in the eltrombopag arm from median QOL-E baseline score 73, interquartile range (IQR) 56-82, to median 81, IQR 62-91, at 3 weeks (p=0.006) and confirmed by the EORTC QLQ-C30 scores (p=0.012). Though QOL-E social scores did not change in the eltrombopag arm, there was a significant worsening in the placebo arm, from median 50, IQR 6-69, to median 25, IQR 13-50 (p=0.041), not detected by the EORTC QLQ-C30.
Summary and Conclusions: Early after treatment initiation with eltrombopag, one third of lower risk MDS patients with severe thrombocytopenia experience significant improvements in PLT counts accompanied by improvements in fatigue.

E1437

MEDICAL AND SOCIO-ECONOMIC IMPACT OF A FREE HEALTHCARE POLICY ON MIGRANTS WITH ACUTE MYELOID OR LYMPHOID LEUKEMIA

A.M. Ronchetti[1,*] C. Georges-Tarragano[2], M. Castie[3], E. Raffoux[1], N. Boissel[4], E. Lengline[1], G. Socie[5], H. Dombret[1], T. Cluzeau[1]
[1]Adult Hematology Department, [2]Health-care Access Department, [3]Social Department, [4]Adolescents and Young Adults Department, [5]Hematopoietic Stem Cell Transplantation Department, Saint-Louis hospital, Paris, France

Background: Acute leukemia is a rare disease. However, it occurs all over the world and there is a wide disparity in access to treatment. The French National Health Insurance (NHI) is one of the most generous insurance systems in Europe in providing care for foreign citizens. Since 2000, the NHI has provided free health coverage for irregular aliens who have been in France longer than 3 months, called *Aide Medicale d'Etat* (AME). The AME assumes all healthcare costs with no charges. For foreigners who are in France for less than 3 months, there is also a critical care fund.
Aims: We have been interested in evaluating the outcome of patients who presented with acute leukemia while being in France with no health insurance from a medical, social and economic point of view.
Methods: From 2006 to 2013, 52 irregular aliens with acute leukemia (AL) were treated in the Saint-Louis Hospital in Paris (France). Medical and social datas were collected by reading medical files and evaluating the computerized medical records. To determine the treatment cost for each patient, the hospital financial unit used an approach based on a day's costs. In 2013, the cost of one day of hospitalization in our hematology intensive care unit was €2,816.89 (US $3,764.82). We used an exchange rate of: €1=US $1.34.
Results: Fifty-two patients have been included (31 with an acute myeloid leukemia (AML) and 21 with an acute lymphoïd leukemia (ALL)). Thirty-five of them (67%) came in France after a diagnosis of AL in their country and 18 have already been treated before. The other patients already lived in France illegally without a visa. Median age was 38,5 in the AML group and 31,2 in ALL group. We first observed that these patients received an appropriate therapy, based on intensive chemotherapy for the majority of them. For AML, the complete remission (CR) rate was 80.6%, 48% of patients were able to receive stem cell transplantation with a median time between CR and allogenic stem cell transplantation (ASCT) of 143 days (71-158). For ALL, CR was 95.2%; 52% of patients were able to receive ASCT with a median time of 142 days (91-681). Overall, the survival rate was 52% for AML and 50% for ALL, with a median follow-up of 36 months. All patients were supported socially during treatment and benefited all from the AME after three months in France. Nevertheless, one-third of the patients lived in precarious conditions during their treatment (No personal accommodation or socially isolation). Social situations during treatment did not affect the outcome in our cohort. At follow-up, only 8 patients had returned to their countries. Long-term social data were available only for 11/24 patients who stayed in France and in CR. They all had regularized administrative situations but half of them still lived in precarious conditions. We calculated the median total cost of care for the patients with AML to be €284,389 (US $381,081). The median total cost of care for the patients with ALL was €314,421 (US $421,325). The economic portion of the study revealed that 38% of the patients had a hospital debt of €2.16 (US $2.90) million in total.
Summary and Conclusions: Acute leukemia is a rare disease that requires expensive care. There is a wide disparity in access to care, which causes migration to countries where expensive and innovative agents are available. This study included 52 irregular aliens who benefited from the AME and were treated for acute leukemia in France. Their outcome was similar to that of other patients with health coverage. These foreign patients thus benefited from appropriate medical and social management, but this left a large financial impact on the hospital budget.

E1438

KNOWLEDGE ASSESSMENT AND EDUCATIONAL INTERVENTION AT A PATIENT CENTERED CANCER SYMPOSIUM

L. Padrnos[1,*] R. Bennett[2], Q. Wu[3], D. Northfelt[1], J. Mikhael[1], R. Tibes[1], S. Nagi Reddy[3], N. Khera[1], R. Mesa[1]
[1]Hematology Oncology, Mayo Clinic Hospital Arizona, Scottsdale, [2]Arizona State University, Tempe, [3]Research Biostatistics, Mayo Clinic Hospital Arizona, Scottsdale, United States

Background: A diagnosis of cancer leads to significant information requirements for patients to make health care decisions. In this situation, many patients demonstrate a knowledge deficit that can translate to decreased quality of life, personal life disruptions and decreased compliance. Through analysis of patient centered cancer symposiums in 2013 and 2014, this deficit can be mitigated by patient education. This requires identifying knowledge deficits and desired information topics.
Aims: The aim of this study is to evaluate the impact of a patient centered cancer symposium on the knowledge level, patient reported symptom burden, and desired information from a broad population of cancer patients.
Methods: Surveys were distributed to the attendees of the "Living with and Surviving Cancer" patient symposium in January 2015. Surveys included demographic data, EORTC QLQ-C30, Linear Analogue Self Assessment (LASA), as well as a questionnaire evaluating disease comprehension, symptom burden, information sources and desired topics of improved understanding.
Results: 113 patients completed the pre-intervention survey to date. The average age of participants was 64.7 years with a female predominance (55%). Disease types included hematologic malignancies (N=50), breast cancer (N=25), prostate cancer (N=17), bladder/renal cancer (N=10) and other solid tumors (N=26). The majority of patients were greater than 3 years from cancer diagnosis (48%). Most patients reported a history of cancer treatment (91%) and half were undergoing cancer treatment at the time of the symposium (55%). Most respondents reported "quite a bit" or greater comprehension of their disease (81%), screening tests (74%), making end of life decisions (73%), disease monitoring tools (72%), nutrition (70%), disease symptoms (68%), common side effects of chemotherapy (81%) and radiation therapy (68%), relationship management (68%), and stress management (66%). The lowest percentage of understanding ("quite a bit"/"very much") was reported for financial considerations (50%), fatigue management (49%), symptoms associated with relapse (46%), pain management (38%), long term side effects of chemotherapy (33%), and legal issues regarding disease and treatment (14%). A large proportion of

participants indicated "quite a bit" or greater desire for increased understanding of their disease (79%), risk factors (78%), screening tests (81%), nutrition (84%), and symptom management (70%). To manage stress, participants reported utilizing exercise (65%), spirituality (58%) and anti-anxiety medication (21%). Similarly, to manage fatigue, participants reported utilizing exercise (65%), yoga (13%) and spirituality (43%). Participants reported highest level of stress directly following diagnosis (73%) while fatigue level was highest during treatment (56%). Mean overall quality of life on the LASA was 7.6 (SD 1.79). Reported mean overall quality of life in the past week based on the EORTC QLQ-C30 survey was 5.1 (SD 1.16).
Summary and Conclusions: A cancer diagnosis creates a knowledge deficit that can complicate the numerous decisions, directly or indirectly, related to cancer care. Individuals diagnosed with cancer pursue information to improve their disease understanding and management. A patient centered symposium can serve as a forum to assess desired information and provide education in hopes of easing the knowledge discrepancy experienced by patients and possibly improving their health care experience overall. Further results of cancer knowledge and the impact of this intervention are being assessed.

E1439

COST-EFFECTIVENESS OF IDELALISIB IN COMBINATION WITH RITUXIMAB FOR THE TREATMENT OF RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN PORTUGAL

M.G. Silva[1,*] M. Gouveia[2], J. Alarcao[3], F. Fiorentino[3], J. Carda[4], R.M. Costa[5], J.M. Mariz[6], J. Raposo[7], M. Borges[3]
[1]Instituto Português de Oncologia de Lisboa de Francisco Gentil, [2]Católica Lisbon School of Business and Economics, [3]Center for Evidence Based Medicine, Faculty of Medicine, University of Lisbon, Lisbon, [4]Centro Hospitalar Universitário de Coimbra, Coimbra, [5]Hospital Garcia de Orta, Lisbon, [6]Instituto Português de Oncologia de Lisboa de Francisco Gentil, Porto, [7]Centro Hospitalar Lisboa Norte, Lisbon, Portugal

Background: CLL is the most common leukemia in the Western world and is clinically characterized by peripheral blood B-cell lymphocytosis as well as lymphadenopathy, organomegaly, cytopenias and systemic symptoms in advanced stages. All CLL patients eventually relapse and most require multiple treatment regimens. Idelalisib, a potent, oral, selective inhibitor of PI3Kδ has been approved, in combination with rituximab, for the treatment of adult patients with CLL who have received at least one prior therapy. The cost-effectiveness of this and other recently approved agents for common indolent lymphoproliferative disorders may become a socio-economical concern in a large number of countries.
Aims: To assess the cost-effectiveness of idelalisib in combination with rituximab compared to rituximab plus placebo in patients with relapsed/refractory CLL from a Portuguese societal perspective.
Methods: The international cost-effectiveness model was adapted to Portuguese health settings and is based around a partitioned survival approach, classifying patients by survival status (alive/dead), and for those alive by disease status (pre- or post-progression after prior therapy) (Figure 1). The model begins with 100% of individuals in the pre-progression state. During any given cycle, patients can be dead, alive in the pre-progression state or alive in the post-progression state. Those in the latter state remain there until death (there is no modelling of remission). Costs and benefits are estimated at fixed time points (cycle length is one week) for a fixed period of time (lifetime horizon). Costs and outcomes were discounted at a 5% annual rate, as recommended by Portuguese guidelines. One-way sensitivity analyses assessed the robustness of the model. Clinical efficacy and safety data were based on the published results from the phase 3 idelalisib plus rituximab clinical trial. Survival curves were extrapolated using a Weibull function. Utility data was taken from published evidence. The consumption pattern of outpatient resources (visits, medication, diagnostic exams, etc) was estimated based on a geographically representative national expert panel. The experts responded independently to a questionnaire sent by mail and the responses were analyzed using the simple average of the values of the responses and excluding any outliers, using the trimmed mean. The unit costs were taken from Portuguese legislation and NHS references. Diagnosis-Related Groups database (DRG) for 2013 was used to estimate inpatient costs with adverse events (AE). Inpatient episodes were identified using the appropriate code (ICD 9-CM).

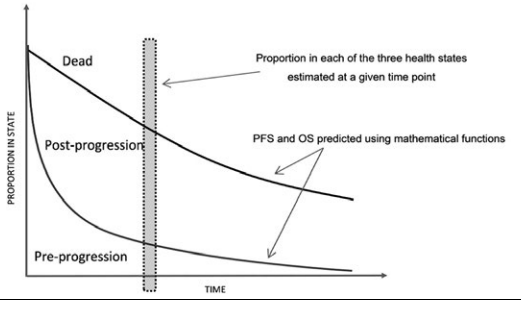

Figure 1.

Results: Survival gains (measured as life years [LYs] and quality-adjusted life years [QALYs]) were higher with idelalisib plus rituximab. Combination of idelalisib to rituximab, compared with placebo plus rituximab, led to increased direct costs (drug acquisition) but reduced the costs related to AEs and end-of-life costs. Treatment with idelalisib plus rituximab yielded a gain of 2.51 QALYs, 5.16 LYG and an increase of € 82,189 in total cost, resulting in an incremental cost-effectiveness ratio (ICER) of € 32,702 per QALY and € 15,935 per LY. Univariate analyses showed that ICER values were robust and ranged from € 31,288 to € 34,176 per QALY when different parameters were varied.
Summary and Conclusions: The use of idelalisib plus rituximab in the treatment of relapsed/refractory CLL, compared with rituximab plus placebo, is cost-effective in Portugal.

E1440

QUALITY OF LIFE OF ANTICOAGULATED PATIENTS: SURVEY SATISFACTION

J. Loza[1,*] A. Pereda[1], I. Gonzalez[1], P. Chavez[1], A. Campeny[1], E. Perez[1], R. Diez[1], M. Quintana[1], F. Rodriguez[1], A. Mendizabal[1], C. Menchaca[1], M. Ardanaz[1], J. Guinea[1]
[1]Hematología, Hospital Universitario Araba, Vitoria-Gasteiz, Spain

Background: Four years after the arrival of direct-acting anticoagulants onto the market the controversy over their place in preventing embolisms during non-valvular AF in relation to classical warfarin continues. A symptom of this situation is the major differences over penetration of these drugs in different European countries. A treatment that aimed to replace warfarin based on not needing periodic controls of the level of anticoagulation has not quite settled.
Aims: In these past years we have encountered several analyses both from the pharmaceutical industry and healthcare professionals from various disciplines and public health managers on the efficacy, safety, advantages, disadvantages, in short, on the efficiency of these drugs. However, this discussion has lacked the opinion of users on those issues incumbent upon them; comfort, the value of safety and their position on the cost of drugs both for them and for public health.
Methods: To bridge this gap we have undertaken a survey on the degree of comfort or discomfort of dicumarinics for 1244 anticoagulated patients with acenocumarol in the HUA and healthcare centres of this area. Four questions were put to them on comfort in regard to professional activity and another four related to family life; after these they were asked to classify their level of comfort on a scale from 1 to 10. They were also asked whether they would prefer a drug that does not require controls, whether they would prefer it to be more expensive for public health, more costly for them and finally, whether it was less safe in case of serious accidents.
Results: The results reveal that the average comfort level was 7.6 on a scale from 1, maximum discomfort to 10, total comfort. The level of comfort was less, 6.6, for the youngest patients and in relation to professional activity. A total of 61% of patients would prefer to use a drug that did not require periodic controls. This percentage would reduce to 47% in case it were more expensive for public health and 31% more expensive for the patient. Finally, only 3.9% would prefer this kind of drug if they were less safe in case of a serious accident. The results show us a highly acceptable level of comfort, and it coincides with the fact that only 61% would prefer a drug that does not require control. They also show us that this preference reduces in relation to both the public and private cost and a clear safety preference on comfort.
Summary and Conclusions: We believe that within the discussion on the introduction of new anticoagulants, in addition to considering their efficacy, efficiency, compliance and side effects, we would have to sound out the opinion of users in regard to relevant topics such as the comfort, cost and safety as to whether or not an antidote exists.

E1441

QUALITY OF LIFE EQ-5D RESULTS FROM THE AETHERA TRIAL: A PHASE 3 STUDY OF BRENTUXIMAB VEDOTIN CONSOLIDATION FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANT FOR HL

S. Ramsey[1,*] A. Nademanee[2], T. Masszi[3], J. Holowiecki[4], M. Abidi[5], A. Chen[6], P. Stiff[7], S. Viviani[8], Y. Zhu[9], V. Bonthapally[9], E. Thomas[10], N. Hunder[10], J. Walewski[11]
[1]Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle, [2]City of Hope National Medical Center, Duarte, United States, [3]Szent Istvan es Szent Laszlo Korhaz Rendelointezet Haematologiai es Ossejt-transzplantacios osztaly, Budapest, Hungary, [4]Oddzial Transplantacji Szpiku Centrum Onkologii- Instytut M. Sklodowskiej-Curie, Oddzial Gliwicach, Gliwice, Poland, [5]Karmanos Cancer Institute/Wayne State University, Detroit, [6]Oregon Health and Science University/Center for Hematologic Malignancies, Portland, [7]Loyola University Medical Center, Maywood, United States, [8]Istituto Nazionale dei Tumori, Milano, Italy, [9]Takeda Pharmaceuticals International Company, Cambridge, [10]Seattle Genetics, Inc., Bothell, United States, [11]Centrum Onkologii Institut im. Marii Sklodowskiej-Curie, Warsaw, Poland

Background: The AETHERA trial demonstrated that early consolidation treatment with brentuximab vedotin (BV) post-ASCT significantly improved PFS in

patients with Hodgkin lymphoma (HL). Peripheral neuropathy (PN) was the most common adverse event.
Aims: Here, we report the results of the Quality of Life (QoL) component of the AETHERA trial.
Methods: After ASCT, 329 patients were randomized to BV 1.8 mg/kg q3wk or placebo for up to 16 cycles. The EQ-5D questionnaire, including the descriptive system and visual analog scale (VAS), was administered at each cycle, end of treatment (EOT), and q3 months during follow up until 24 months from Day 1. Utility index value scores were calculated using the time trade-off (TTO) method for US- and UK-based value sets. Differences between arms were compared to the lower bound of an estimated minimally important difference (MID) in cancer patients (Pickard *et al.* 2007).
Results: In both arms, EQ-5D scores declined from baseline to 24 months. Slightly lower scores were seen with BV *vs* placebo from months 9-18, but this resolved by end of follow up. In the analysis as randomized (US TTO), the difference between arms was <0.06 (MID) at all timepoints except for months 15 and 18. Scores by cycle were similar in the 2 arms; mean differences did not reach the MID threshold. In both arms, scores for patients with progressive disease (PD) per investigator were lower over time *vs* patients with no PD. In the BV arm, scores for patients reporting PN were similar to those who did not. Similar results were obtained with US- or UK-based value sets. EQ VAS scores did not show an important difference between arms at any timepoint (Table 1).

Table 1. US-indexed EQ-5D TTO scores.

	BV N=165 Mean	Placebo N=164 Mean	Mean Difference (BV-placebo) (95% CI)
Baseline	0.897	0.907	-0.010 (-0.035, 0.014)
3 mos	0.869	0.884	-0.014 (-0.048, 0.019)
6 mos	0.868	0.872	-0.004 (-0.041, 0.032)
9 mos	0.816	0.860	-0.043 (-0.087, 0.001)
12 mos	0.799	0.859	-0.059 (-0.109, -0.010)
15 mos	0.782	0.852	-0.071 (-0.126, -0.015)
18 mos	0.776	0.837	-0.061 (-0.121, 0.000)
21 mos	0.783	0.814	-0.029 (-0.094, 0.037)
24 mos	0.757	0.787	-0.030 (-0.102, 0.042)

Summary and Conclusions: As assessed using the EQ-5D questionnaire, treatment with BV did not have a sustained impact on QoL in HL patients. In both arms, decreased QoL was observed after progression.

E1442

ON DEATH AND DYING: CULTURAL END-OF-LIFE ISSUES IN MULTIPLE MYELOMA

M. Pereira[1,*] L. Ruzickova[1], C. Geraldes[1], L. Ribeiro[1]
[1]Clinical Hematology Department, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Multiple Myeloma (MM) is a chronic, virtually incurable, neoplastic condition characterized by increasingly shorter periods of disease remission followed by relapse. This reality, taken together with the fact that bone pain is one of the clinical markers of disease, means that MM patients are frequent users of palliative and hospice care. Historically, patient deaths took place at home, within the family setting. However, in developed countries, patients are increasingly spending their end-of-life twilight in a Hospital ward, often at the cost of a marked decrease in quality of life. This loss of quality of life (QoL) is compounded by a loss of dignity when patients die in Emergency Rooms, which are often crowded and impersonal.
Aims: This study aims to analyze the end-of-life period in a cohort of MM patients in a tertiary referral Center in a middle-income country, to better characterize the problem and help develop palliative and hospice care solutions to improve the QoL and dignity of dying MM patients.
Methods: We analyzed a cohort of 372 MM patients diagnosed between 01-01-2001 and 12-31-2014, for whom end-of-life data was available.
Results: After a median follow-up of 84.1 months, the median overall survival for this cohort was 42.1 months. A total of 64.0% of patients died during the follow-up period. Decedents were, on average, half-a-decade older than survivors (73.4±0.7 *vs* 68.0±1.0, p<0.001). Among decedents, 29.8% died within the first 12 months of diagnosis, and 2.9% died 10 years (120 months) or more after diagnosis; there were no differences in the age at death for the two groups, or the intermediate (12-120 months) cohort (73.6±10.8, 74.9±9.2 and 70.5±12.3 years, respectively, p=NS). We found that 54.6% of patients died within our tertiary referral Hospital setting (72.9±10.4 years *vs* 73.9±12.4, p=NS), corresponding to 49.7% in a ward (Hematology or other) and 4.9% in the emergency room floor, less than 12 hours after presentation to the Hospital. Longer survivors were more likely to die outside our Center (OS=48.9±122.9 months), compared to patients dying *in situ* (30.7±27.9 months, p<0.001). Patients dying in the ER were over a decade older (79.4±3.8 *vs* 67.4±9.0 years, p=0.04) than patients dying in a ward; there was no difference in the length of disease between the two groups.
Summary and Conclusions: In our real life cohort of patients treated in a tertiary referral Center in a middle-income country, we observed a worrying trend, with nearly 55% of patients dying away from home, in our Hospital. Notably, nearly 5% of patients died in the Emergency Room, which is the least desirable outcome for end-of-life quality and dignity.
While longer experience with the disease (reflected in longer survival) was a predictor of death outside the Hospital, age failed to associate with in-Hospital *vs* out-of-Hospital death. Age did, however, predict for death in the Emergency Room floor, as opposed to death in the ward, perhaps reflecting a more restricted systemic reserve and a shorter exitus mortis.
Palliative and hospice care programs should address this reality, and develop adequate alternatives to serve the population and improve end-of-life in chronic, painful, neoplastic conditions.

E1443

UTILITY VALUES FOR PATIENTS WITH INDOLENT NON-HODGKIN LYMPHOMA (INHL) IN TOP FIVE EUROPEAN COUNTRIES (EU-5)

M. Cognet[1,*] V. Taieb[1], M. Bec[1], A. Gauthier[1], G. Collins[2]
[1]Amaris consulting UK Ltd, London, [2]Department of Haematology, Oxford NIHR biomedical research centre, Churchill Hospital, Oxford, United Kingdom

Background: To our knowledge, there is no published data to inform quality of life of relapsed or refractory patients with iNHL. In oncology, cost-effectiveness models often include three health states: progression free survival (PFS), progressive disease (PD) and death, for which accurate utilities are needed.
Aims: In order to inform future HTA submissions, this study aims to review and generate utility estimates for patients with previously-treated iNHL.
Methods: First, a literature search was conducted in MEDLINE and on UK HTA websites. Thirty-two publications were screened and only one relevant study, published in 2006, was identified (Wild et al). Utilities were estimated at 0.805 (SE=0.018) for PFS and 0.618 (SE=0.056) for PD. This study supported a NICE STA, and was criticised for its small sample (33 patients had PD). As the retrieved information was not recent and criticised, additional data collection through a web-survey including socio-demographic and clinical questions, as well as the EQ-5D, was considered. Remission was defined as no sign of active disease and progression defined as a patient experiencing symptoms of the cancer. Given the burden of iNHL in Europe, the questionnaire was conducted in France, the United Kingdom, Germany, Italy and Spain. First, an analysis of utilities per health state (*i.e.* remission and progression) of patients recruited to our study was performed using the English tariff then, we combined the results of Wild *et al.* with those of our study using a Bayesian approach. To do so, means and standard errors reported by Wild *et al.* were used to specify prior distributions.
Results: The results of this web-survey show that the quality of life of a patient with iNHL is impacted by disease progression. 82 patients were included in the web-survey between the 25th of June 2014 and the 13th of August 2014 (*i.e.* 18 in Spain, 16 in France, 18 in the UK, 15 in Italy and 15 in Germany). All of these patients were previously treated, and several of them received several lines of therapy (*i.e.* 21 patients received 2 lines of therapy or more). The patients with the highest utility scores were those who had experienced a remission of their disease (N=55, u=0.713, SD=0.31). Those patients who had the lowest utility scores were those in progression (N=27, u=0.506, SD=0.35). The mean utility increment in patients in remission compared to patients in progression was 0.207. Compared to Wild *et al.*, this difference is wider in our analysis (*i.e.* 0.207 compared to 0.187 in Wild *et al.*) and patient' quality of life was lower in both states of remission and progression as shown by our analysis. Whilst in our study some patients were heavily treated, this information was not recorded by Wild *et al.*, which might explain the different results.
Summary and Conclusions: In the EU-5, the EQ-5D is a standardised and validated generic instrument which can be used to elicit utility in iNHL patients. This study confirmed that patient' quality of life is higher in disease remission than in progression. This study also shows how to use Bayesian statistics to refine estimates already available in the literature, which can be of interest for study questions related to small patient populations.

E1444

THE IMPACT OF PALLIATIVE RADIOTHERAPY ON QUALITY OF LIFE IN MULTIPLE MYELOMA PATIENTS WITH PAINFUL BONE DESTRUCTIONS

M. Rudzianskiene[1,*] A. Inciura[1], R. Gerbutavicius[1], R. Dambrauskiene[1], E. Juozaityte[1], V. Rudzianskas[1], M. Jonkaityte[2]
[1]Oncology Institute, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: Multiple myeloma (MM) is still an incurable neoplasm of plasma cells that accounts for approximately 10% of all hematological malignancies. As a result, the most common clinical features of MM are diffuse osteopenia, osteolytic bone destructions, pathologic fractures, hypercalcemia and bone pain resulting from increased osteoclasts activity. Osteolytic lesions are detected in 70-80% of patients and increase the risk for pathological fractures, spinal cord compression and requirement for surgery or radiotherapy to bone destruc-

tions. Skeletal related events impair survival and undermine quality of life (QoL). Radiotherapy, surgery and analgesics are required in order to overcome pain, to evoke recalcification and to improve the QoL of MM patients.
Aims: To evaluate the impact of palliative radiotherapy on QoL in patients with MM and painful bone destructions.
Methods: 46 patients (27 women and 19 men, median age: 69 years) with MM and painful bone destructions were treated by palliative radiotherapy with 24 weeks follow-up. Patients completed QoL questionnaires including the EORTC QLQ-C30 version 3.0 and EORTC QLQ-MY20 before treatment and after 4 weeks. The EORTC QLQ-C30 consists of 30 items on five functional scales, nine symptom scales and a scale of global QoL. The EORTC QLQ-MY20 consists of 20 items on two functional scales and two symptoms scales. The patients' single items responses were linearly transformed to scores from 0 to 100 according to the EORTC scoring rules. High scores on the functional scales indicate a good functional status of the patient and high scores on global health status indicate a high QoL, while high scores on symptoms scale indicate poor health condition. We have analyzed the influence of clinical criteria (sex, age, clinical stage of disease, Karnofsky index, type of paraprotein, hemoglobin level, irradiated sites, performed surgery, concurrent chemotherapy, pain score at admission, type of pain medication) on QoL scores before and after radiotherapy.
Results: Before radiotherapy better functional scores (p=0,017) and lower symptoms scores (p=0,042) were observed in men, than in women. Significant higher symptom scores were observed in patients with bone destructions in the spinal column (p=0,038 and p=0,028) than in other affected sites. Better global health status and functional scale were found in patients with mild pain score at the admission (p=0.023 and p=0.031). Results showed that after radiotherapy emotional function improved in patients older than 65 years (p=0.04), female (p=0.005), receiving opioid analgesics (p=0.01), without surgery (p=0.008), in patients with higher level (>82 g/l) of hemoglobin (p=0.007), with Karnofsky index ≥60 (p=0.006), with concurrent chemotherapy (p=0.01), with severe pain at admission (p=0.03), with irradiated spinal vertebral (p=0.001), in III clinical stage of MM (p=0.005). Fatigue decreased in patients with severe pain at admission (p=0.01). Pain decreased in patients with higher level (>82 g/l) of hemoglobin (p=0.03), with Karnofsky index ≥60 (p=0.05), in III clinical stage of MM (p=0.05). Cognitive functioning improved in patients with higher level (>82 g/l) of hemoglobin (p=0.05), with Karnofsky index ≥60 (p=0.02), without concurrent chemotherapy (p=0.008), with severe pain at admission (p=0.05). Disease symptoms decreased in patients without concurrent chemotherapy (p=0.05), in III clinical stage of MM (p=0.05). Global health status improved in patients with IgM, IgD and light chains MM (p=0.04), with irradiated spinal vertebral (p=0.009).
Summary and Conclusions: Demographic and clinical criteria influence the QoL characteristics before radiotherapy. Palliative radiotherapy improves health-related quality of life with MM and painful bone destructions.

QUALITY OF LIFE IN MULTIPLE MYELOMA: VALIDATION OF THE TURKISH VERSION OF THE QLQ-MY20 INSTRUMENT

O.G. Sevindik[1], I. Alacacioglu[1,*] K.B. Payzin[2], T. Yavuzsen[3], F. Gediz Ozdemirkiran[2], T. Yildirim[4], S. Medeni Solmaz[1], O. Piskin[1], M.A. Ozcan[1], G.H. Ozsan[1], F. Demirkan[1]
[1]Department of Hematology, Dokuz Eylul University, [2]Department of Hematology, Izmir Ataturk Training Hospital, [3]Department of Medical Oncology, [4]Department of Internal Medicine, Dokuz Eylul University, İzmir, Turkey

Background: Health-related quality of life (HRQoL) has become an important outcome measurement in hematological malignancies. Different instruments are introduced to accurately define and scale various quality of life items. QLQ-MY20 is produced by EORTC to quantify HRQoL in multiple myeloma patients and validated in different patient populations.

Aims: Our aim was to validate the quality of life questionnaire (QLQ)-MY20 instrument in patients with multiple myeloma (MM) in Turkey.
Methods: The Turkish versions of QLQ-C30 v3 and QLQ-MY20 instruments were applied to patients who were diagnosed and treated at two tertiary centers in Izmir, Turkey. Validity and reliability tests were performed. Test-retest was carried out in a selected group of patients.
Results: 86 patients who were diagnosed with MM were included in the study. Questionnaire completion rates were high, and instrument was well accepted. Internal consistency tests demonstrated good convergent and divergent validity. Regarding reliability analysis, cronbach's α coefficients were all >0.7 for all scales of both QLQ-C30 and QLQ-MY20 except functional cognitive scale of QLQ-C30 questionnaire (Table 1).
Summary and Conclusions: Turkish version of QLQ-MY20 questionnaire is reliable and valid for the assessment of HRQoL in patients with MM and can be used in clinical trials in Turkish community.

BRENTUXIMAB VEDOTIN IN PATIENTS AT INCREASED RISK OF HODGKIN LYMPHOMA PROGRESSION POST AUTOLOGOUS STEM CELL TRANSPLANT: EVALUATION OF HEALTHCARE RESOURCE UTILIZATION IN THE AETHERA TRIAL

V. Bonthapally[1,*]E. Ma[1], S. Viviani[2], J. Radford[3], P. Brice[4], B. von Tresckow[5], E. Thomas[6], J. Teasell[6], A. Gnanasakthy[7], D. Odom[7], Y. Zhu[1], S.-Y. Lee[1], P. Carlson[1], D. Huebner[1], J. Sweetenham[8], C. Moskowitz[9], J. Walewski[10]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, [2]Fondazione IRCCS Istituto Nazionale Dei Tumori, Milan, Italy, [3]University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom, [4]Hopital Saint Louis, Paris, France, [5]University Hospital of Cologne, Cologne, Germany, [6]Seattle Genetics, Inc., Bothell, [7]RTI Health Solutions, Durham, [8]Huntsman Cancer Hospital, University of Utah, Salt Lake City, [9]Memorial Sloan Kettering Cancer Center, New York, United States, [10]Maria Sklodowska-Curie Institute and Oncology Centre, Warszawa, Poland

Background: Brentuximab vedotin received approval for the treatment of relapsed/refractory Hodgkin lymphoma (HL) after failure of autologous stem cell transplant (ASCT) or ≥2 prior therapies. AETHERA is a randomized, double-blind, Phase 3 study of brentuximab vedotin and best supportive care (BSC) *versus* placebo and BSC for patients at increased risk of HL relapse or progression following ASCT. Brentuximab vedotin consolidation therapy post-ASCT substantially improved progression-free survival (PFS) per independent review with a median PFS of 43 months in the brentuximab vedotin arm compared with 24 months in the placebo arm (HR=0.57, P=0.001). The most common treatment-emergent grade ≥3 adverse events (AEs) were neutropenia (29% brentuximab vedotin *vs* 10% placebo), peripheral sensory neuropathy (10% *vs* 1%), thrombocytopenia (4% *vs* 3%), peripheral motor neuropathy (6% *vs* 1%), and anemia (4% *vs* 2%). Treatment discontinuation due to AEs occurred in 33% *vs* 6% of patients, and 53 patients died on-study (17% *vs* 16%). High risk patients who relapse post-ASCT often report a high disease and treatment burden requiring healthcare intervention.
Aims: To compare the healthcare resource utilization (HRU) associated with brentuximab vedotin and placebo for the treatment of patients at risk of HL progression post-ASCT in the AETHERA trial.
Methods: HL patients aged ≥18 years at high risk for post-ASCT disease progression, defined as a history of refractory HL, relapse or progression <12 months after frontline therapy, or extranodal involvement at the time of pre-ASCT relapse, were eligible. Patients were randomized to receive brentuximab vedotin 1.8 mg/kg or placebo via IV infusion on day 1 of each 21-day cycle, for a maximum of 16 cycles or until disease progression. All medical care encounters that occurred from time of informed consent up to 24 months post first study treatment were collected for the intent-to-treat population. The total number of hospitalizations, outpatient visits, and the number of missed days of work/other activity for patients or caregivers, were summarized by treatment group.
Results: A total of 329 patients (median age 32 years [range 18-76]; 53% male) were randomized to receive brentuximab vedotin (n=165) or placebo (n=164) at 78 sites in the USA and Europe. There were 68 (41%) *vs* 61 (37%) patients with ≥1 hospitalization on the brentuximab vedotin *vs* placebo arms, respectively, with a total of 176 *vs* 198 hospitalizations. The hospitalization rate per patient-year was 0.58 (95% CI: 0.49, 0.67) *vs* 0.65 (95% CI: 0.56, 0.74). The median duration of stay was 16 *vs* 26 days per patient. The most common reasons for hospitalization were disease-related signs and symptoms (36% *vs* 40%) and AEs (29% *vs* 15%). There were 119 (72%) *vs* 133 (81%) patients with ≥1 outpatient visit, with a total of 2687 *vs* 3803 visits. The

outpatient visit rate per patient-year was 8.84 (95% CI: 8.51, 9.18) *vs* 12.43 (95% CI: 12.03, 12.82). The most common reasons for outpatient visits were disease-related signs and symptoms (36% *vs* 42%) and AEs (22% *vs* 14%). There were 85 (52%) *vs* 94 (57%) patients with ≥1 missed day of work/other activity, with a median number of 15 *vs* 26 missed days. There were 7 (4%) *vs* 24 (15%) caregivers with ≥1 missed day of work/other activity, with a median number of 7 *vs* 16 missed days.
Summary and Conclusions: Preliminary results suggest a trend toward lower HRU with brentuximab vedotin compared with placebo. These data prompt further investigation of the economic impact of early consolidation post-ASCT with brentuximab vedotin in HL.

E1449

COST-EFFECTIVENESS AND QUALITY ASSURANCE IN BONE MARROW ANALYSIS: AN AUDIT OF SAMPLING TECHNIQUE AND SPECIALISED HAEMATOLOGICAL TEST REQUESTING AT A HAEMATO-ONCOLOGY CENTRE

H. Tilly Shabir[1], P. Flore[1], P. Greaves[1,*]K. Saja[1]
[1]Haematology, Barking Havering and Redbridge NHS Trust, London, United Kingdom

Background: There is little published data on 'real-life' practice of bone marrow assessment in haematology, particularly in publicly funded healthcare systems where budgetary restraints and demonstrable cost-effectiveness must be applied to high-quality evidence-based practice. The British Committee on Standards in Haematology (BCSH) outlines standards for biopsy quality and additional specalised haematological testing (cytogenetics by fluorescent in-situ hybridisation (FISH) and G-banding, immunophenotyping by flow cytometry). As knowledge of the prognostic implications of specialised testing increases, there is greater tendency to order more costly tests (currently £200/€280 per immunophenotyping sample, £110/€150 for G-banding to £441/€605 for myeloma FISH panel) without influencing clinical management.
Aims: The objective of this audit was to assess current practice in our busy haemato-oncology unit against national guidelines and determine a pragmatic approach to bone marrow assessment which is equitable, evidence-based and deliverable within a restricted budget.
Methods: Bone marrow reports on consecutive procedures undertaken between January and October 2014 were examined (n=365) using the hospital's pathology database. Inadequacy of aspirate was defined by a report stating 'haemodilute and aparticulate'.
Results: Indications for bone marrow included 23% acute leukaemia (AL) diagnosis/response assessment, 21% cytopenias/suspected myelodysplasia (MDS), 16% suspected multiple myeloma (MM), 15% lymphoma staging and 6% myeloproliferative disease. 19% aspirates were unfit for morphological analysis. Trephine lengths were recorded in 82% of cases (range 1-38mm, median 16mm) with only 50% exceeding the BCSH minimum standard (16mm) and 11% deemed entirely inadequate for assessment. Approximately £65,000/€90,000 in total was spent on specialised testing: £15,000/€20,000 on immunophenotyping and £50,000/€70,000 on cytogenetics. 34% of cases had incorrect specialised tests sent. 20% and 13% of diagnostic AL samples were sent without immunophenotyping and cytogenetics respectively. Cytogenetics and immunophenotyping were sent on 76% and 21% of MDS requests and 63% and 14% of MM requests respectively: both recommended in BCSH guidelines but rarely contributing to clinical management. 15% of lymphoma staging requests were submitted for immunophenotyping and 9% for cytogenetics without additional contribution to diagnosis.
Summary and Conclusions: Our study suggests that special tests are frequently missed or inappropriately requested with clinical and cost implications: an analysis against which there is little published data to compare. Sample quality is often suboptimal and while often unavoidable highlights a need for continuous assessment of operator skill. Current national and international guidelines increasingly request more specialised tests against the backdrop of questionable clinical value and increasing financial restraints, while national and international bodies recommend we 'choose wisely'. This challenges practicing clinicians to rationalise evidence-based best care, consensual guidelines and budgetary contraints in an age of increasing scientific discovery but with spiralling costs and increased scrutiny of healthcare economics.

E1450

BLOOD AND PLATELET TRANSFUSIONS FOR HAEMATOLOGY PATIENTS REQUIRING PALLIATIVE CARE: WHAT CAN UK HOSPICES PROVIDE?

R. Ackroyd[1], S. Ackroyd[2,*] R. Sheils[3]
[1]Palliative Medicine, Calderdale and Huddersfield NHS foundation Trust, Halifax, [2]Haematology, Bradford Royal Infirmary, Bradford, [3]Palliative Medicine, Overgate Hospice, Halifax, United Kingdom

Background: There is increasing evidence that haematology patients benefit from palliative care services. Often haematology patients require more intensive supportive treatment including IV antibiotics, blood and platelet transfusions, for symptom control and to maintain their quality of life, even near the end of life. Specialist palliative care services in the UK may not always provide these supportive treatments and this may be a barrier to haematology patients needing palliative care.
Aims: To identify what blood products UK hospices are able to provide for haematology patients
Methods: A mixed categorical and free text questionnaire was sent via email to all Medical directors of adult hospices in the UK and Ireland with inpatient services. 168 Questionnaires were sent.
Results: The response rate was 42% (n=70). Please see Table 1.

Table 1.

Provision of transfusion	Yes	Sometimes	No
RED CELL transfusion 9am-5pm, Monday-Friday	62 (94%)	4 (6%)	n/a
RED CELL transfusion out of hours	15 (23%)	30 (45%)	21 (32%)
PLATELET transfusions 9am-5pm, Monday-Friday	38 (58%)	4 (6%)	24 (36%)
PLATELET transfusions out of hours	11 (24%)	13 (28%)	22 (48%)

Summary and Conclusions: There was variation in what services are offered by the palliative care units. Medical Staff being non-resident had implications for whether transfusions could be done out of hours. Although the same training is required to administer red cells and platelets, more units were able to provide red cell transfusions. There were misconceptions regarding timing of platelet transfusions, storage and need for continuous agitation. With further education hospices that provide red cell transfusions should be able to provide platelet transfusions. Close working between haematologists and palliative care with regard to transfusion decisions is important to embed these supportive treatments in palliative care practice which ultimately can improve patient care.

E1451

COST-EFFECTIVE ANALYSIS OF PROPHYLAXIS WITH LAVIVUDINE FOR PREVENTION OF REACTIVATION IN OCCULT HEPATITIS B (OBI) IN PATIENTS WITH NON HODGKIN LYMPHOMA CD20+ UNDERGOING CHEMOTHERAPY

C. Cerchione[1,*] A. De Renzo[1], M. Masarone[2], C. Cimmino[1], M. Raimondo[1], G. Signoriello[3], M. Notarangelo[1], G. Giagnuolo[1], M. Persico[2], F. Pane[1]
[1]Hematology, AOU "Federico II", Napoli, [2]Hepatology, Università di Salerno, Salerno, [3]Department of Statistical Sciences, Second University, Napoli, Italy

Background: Occult HBV infection (OBI) is defined by the persistence of HBV in the liver without serum HBsAg and HBV-DNA. It represents a life threatening event during immunosuppressive chemotherapies. An OBI occurs in approximately 18% of HBcAb+ patients. International guidelines suggest surveillance for HBV markers in immunosuppressed patients, in particular monoclonal antibodies. In our study, the prevalence of OBI reactivation in Non-Hodgkin Lymphoma (NHL), in 498 NHL patients in our centre of Southern Italy, was 10.42% in HBcAb+ HBsAb- patients. In this work, we want to perform a cost-effectiveness analysis regarding the use of Lamivudine for the prevention of reactivation in OBI in patients with Non-Hodgkin Lymphoma undergoing chemotherapy with or without Rituximab. In fact, considering guidelines and literature, universal prophylaxis should have been applied to all HBcAb positive HBsAg negative patient. A cost-benefit issue arises : is it more cost-effective to treat all the HBcAb positive HBsAg negative patients with Lamivudine to prevent the OBI reactivation occurrence in a small quote of them, or may it be more effective a "wait and see" protocol?
Aims: Our idea was to perform a cost-effectiveness analysis, comparing the costs of prophylaxis of an eventual HBV reactivation and the "monitoring" approach that was used in our patient based on the international guidelines.
Methods: We calculated the cost of prophylaxis with Lamivudine in a time interval of twelve months, which encompasses the time of a standard Rituximab-containing chemotherapeutic protocol and a minimum time of follow-up. It has to be noticed that, very often, NHL patients need more than one chemotherapy cycle to obtain NHL remission, and, sometimes, if they do not obtain a complete remission, undergo to long-term "maintenance" treatments with Rituximab. These patients (HBcAb positive) are at high risk of HBV reactivations, due to long times of immunosuppression.

Table 1.

	Unitary Cost	n. patients	Total per patient	Duration [days]	Total
Cost of prophylaxis					
Lamivudine	€ 3,18	48	€ 152,64	360	€ 54.950,40
HBV DNA monitoring	€ 130,00	48	€ 6.240,00	6	€ 37.440,00
HBsAg monitoring	€ 17,00	48	€ 816,00	6	€ 4.896,00
AST/ALT monitoring	€ 5,74	48	€ 275,52	12	€ 3.306,24
Total	**€ 155,92**	**48**	**€ 7.484,16**		**€ 100.592,64**
Cost of HBV Reactivation					
HBV DNA monitoring	€ 130,00	48	€ 6.240,00	6	€ 37.440,00
AST/ALT monitoring	€ 5,74	48	€ 275,52	12	€ 3.306,24
Cost of DRG 205 [v24 Grouper]	€ 3.769,10	5	-	-	€ 18.845,50
Total	**€ 3.904,84**	-	-	-	**€ 40.746,24**

Drg 205: Liver disease except malignancies, cirrhosis, alcoholic hepatitis with cirrhosis.

Results: Nevertheless, even if our calculations underestimated the costs of prophylaxis, the "monitoring approach" resulted cost- effective. Moreover, even though in our series no serious events in terms of morbidity and/or mortality occurred, in other literature reports a monitoring approach did not guarantee patients survival. These detrimental results could be ascribed to the delayed start of Lamivudine treatment if the monitoring is not adequately strict. Also, it has been reported that performing only the transaminase monitoring should not be acceptable to prevent severe reactivations. Our monitoring approach resulted efficacious probably because of the monthly ALT assay was strictly observed Table 1.

Summary and Conclusions: We report an advantage in the "monitoring" approach even if, due to the retrospective nature of our study, we cannot draw any firm conclusion on which should be the best approach (universal prophylaxis *vs* monthly ALT monitoring). A randomized controlled trial might be needed to properly address this issue.

E1452

DEMAND MANAGEMENT OF ANALYTICAL REQUEST IN ERYTHROPATHOGY SECTION OF A TERTIARY HOSPITAL

M.D.L.O. Abio Calvete[1,*] M.E. Botón Contreras[1], M.C. Fernández Jimenez[1], J. Cuesta Tovar[1], M.J. Murga Fernández[1]
[1]Hematología y Hemoterapia, Hospital Virgen de la Salud, Toledo, Spain

Background: The analytical requests to clinical laboratory have experienced in the latest years changes increasing the amount of them. During 2010-2012 a significant increasing of the number of requests for erythroid maturation factors and of the number of repetitions of these factors in the same patient during the same year were observed, coming from primary care centers (PCC). Given this, an intervention was performed for a more efficient management of demand; a corrective action was established from November 2011 on, to reduce the number of unnecessary requests.

Aims: 1) Reduce the number of unnecessary requests for erythroid maturation factors (ferritin, vitamin B12 and folate), without limiting the ability to request testing by physicians, so no analysis of any of the requests made was denied. 2) Encourage the ordering physician awareness of the usefulness of certain tests, the expenses incurred and diagnostic clinical advantage provided.

Table 1.

Requests	2010	2012	2013	2014
Ferritin	94876	126708	108045	107436
Folate	11685	32199	49278	47657
Cobalamin	11677	35856	51882	50069

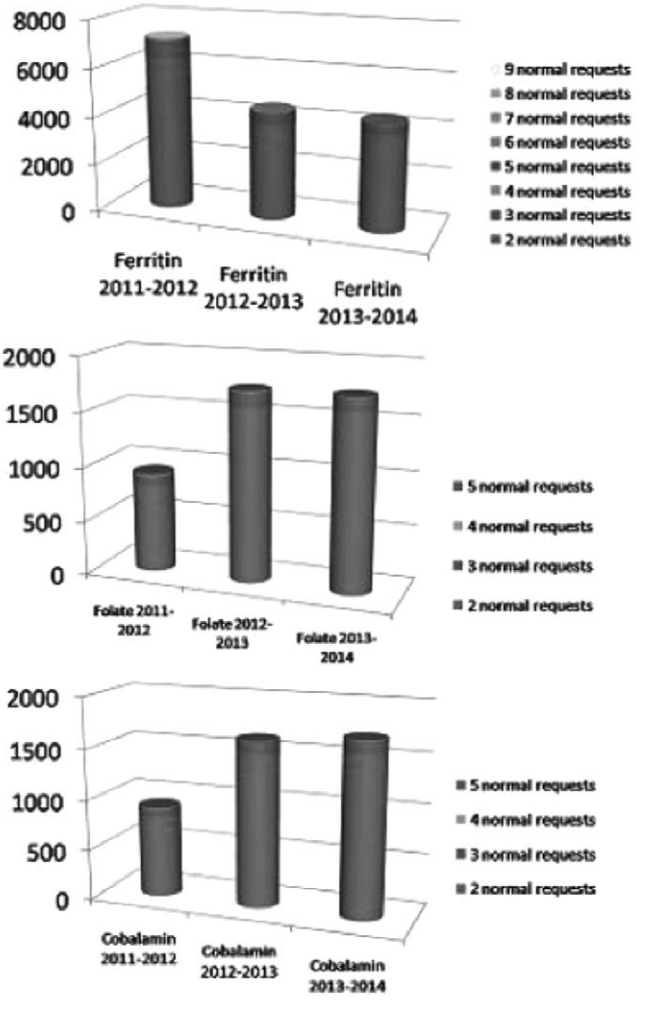

Figure 1.

Methods: A descriptive and analytical study was conducted within 2 years after developing corrective action (01/11/12-31/10/14). Requests of maturational factors have been analyzed in the population covered by our center (health area: 483 422 inhabitants), taking the total number of requests from PCC of each test and the number of repetitions of them on the same patient with a normal prior determination. This measure was taken to inform the physician that with a normal result, there is no need to repeat the determination of these factors unless there are clinical changes that warrant. To that end a comment was added next to the result when it was within normal limits: *"normal ferric profile (or cobalamin or folate). Repeat within one year only if there are alterations in blood count, the patient is treated with iron, folate or cobalamin, if clinical and/or laboratory changes or (in the case of ferric profile) family history and/or hemochromatosis or hyperferritinemia in the patient".* Also we have conducted briefings to primary care physicians about the measure and its results.

Results: After establishing the tool indicated at the end of 2011, a gradual reduction in the total number of requests was observed (Table 1), but especially in the number of determinations to patients who had normal previous result, especially if we consider the cut of 3 or more normal test. Note that no longer exist patients with more than 5 determinations made in one year, as it happened before (Figure 1). During the first year, a significant increase in the number of requests for folate and cobalamin was observed. This fact seems justified because in 2012 these tests were added to the computerised requests of the PCC. Previously the physician had to remember to include it and write it manually. Ferritin already existed in the prior computer application and therefore the same effect doesn't occur. Despite this increase, an effect of the intervention can be observed since the first year: the number of patients with 4 or more normal determinations decreased and afterwards the total number of requests remains stable and the number of repeats with normal previous result decreased as well.

Summary and Conclusions: The measure produced a greater decrease in the total number of requests and subsequent repeats. The decrease was more pronounced in the first year of its establishment. Subsequently seems

to remain effective in controlling demand and thus health spending, so we believe this tool should be maintained in the coming years to efficiently manage the requests for erythroid maturation factors.

E1453

MICRO-COSTING STUDY OF RITUXIMAB SUBCUTANEOUS INJECTION *VERSUS* INTRAVENOUS INFUSION IN DUTCH SETTING

J. Mihajlović[1,2,*] P. Bax[1], E. van Breugel[1], H.M. Blommestein[3], M. Hoogendoorn[4], W. Hospes[5,6], M.J. Postma[1,7]
[1]Unit of PharmacoEpidemiology & Pharmacoeconomics, University of Groningen, Groningen, Netherlands, [2]Mihajlović Health Analytics, Novi Sad, Serbia, [3]Erasmus University, Rotterdam, [4]Department of Haematology, Medical Center Leeuwarden, Leeuwarden, [5]Department of Pharmacy, Isala Clinics, Zwolle, [6]Department of Pharmacy, Ommelander Zorggroep, Winschoten/Delfzijl, [7]Institute of Science in Healthy Aging & health caRE (SHARE), University Medical Center Groningen (UMCG), Groningen, Netherlands

Background: Rituximab for subcutaneous (SC) administration has recently been approved for use in common forms of diffuse large B-cell lymphoma (DLBCL). This form of rituximab is supplied in ready-to-use vials that do not require individual dose adjustment. It is expected that SC-injection will shorten the treatment time per administration of rituximab in comparison with currently available intravenous (IV) infusion.
Aims: The goal of this study is to identify and compare all direct costs of IV and SC rituximab given to the DLBCL patients in the Netherlands.
Methods: Using a prospective, observational, bottom up, micro-costing study we collected primary data on the direct medical costs of the preparation, administration and acquisition of rituximab. Drug costs and spillage, labor costs, material costs and remaining daycare costs were identified using standardized forms, structured using guideline prices and compared for the IV and SC forms of rituximab.
Results: Measurements were done on 53 administrations (33 IV and 20 SC). The mean total costs of the IV infusion were €2174, and €1907 for the SC injection. The estimated difference of €267 per administration was mainly due to spillage costs and differences in chair time, related daycare costs and drug costs.
Summary and Conclusions: Rituximab administered in the form of SC injection is less costly than its IV form. Taking into account their equal effectiveness, favorable pharmacoeconomic profile of SC rituximab can result in significant savings when transferred to the total DLBCL population in the Netherlands.

E1454

BIOSIMILAR FILGRASTIM FOR THE PREVENTION OF FEBRILE NEUTROPENIA IN ELDERLY DLBCL PATIENTS HAS COST EFFECTIVENESS COMPEERED WITH ORIGINAL FILGRASTIM

N. Takezako[1,*] N. Sekiguch[1], A. Nagata[1], M. Kurimoto[1], S. Noto[1], A. Miwa[1]
[1]Hematology, Disaster Medical Center of Japan, Tachikawa, Japan

Background: According to American Society of Clinical Oncology guideline on the use of granulo- colony-stimulating factors (G-CSF), primary prophylaxis is recommended for the prevention of febrile neutropenia (FN) in patients who are at high risk based on age, medical history, disease characteristics, and myelotoxicity of the chemotherapy regimen. G-CSF use allows a modest to moderate increase in dose-density and dose-intensity of chemotherapy regimens. Prophylactic G-CSF for patients with diffuse aggressive lymphoma aged 65 years and older treated with R-CHOP should be given to reduce the incidence of FN. A similar biologic medicinal product, commonly referred to as biosimilar, is a copy version of an approved original biologic medicine whose data protection has expired. Among of them, biosimilar filgrastim have been approved and become available in Europe on the basis of comparable quality, safety and efficacy to the originator product. In Japan, biosimilar filgrastim approved in 2013. However, biosimilar filgrastim has not been used widely in Japan though it may have the reduction effect of costs. Here we investigated the efficacy and the cost saving effect in use of biosimilar filgrastim.
Aims: To evaluate the efficacy and the cost saving effect in use of biosimilar filgrastim.
Methods: From July 2013 to December 2014, our Institution used the biosimilar filgrastim (Filgrastim BS®; Mochida Industrial Products, Tokyo, Japan), at dosage of 75μg/day from day +10, for FN prophylaxis and hematological recovery in elderly diffuse large B cell lymphoma (DLBCL) patient who received R-CHOP therapy. These patients were retrospectively compared with same elderly patients who received original filgrastim (Gran®; Kyowa Hakko Kirin Co., Ltd, Tokyo, Japan), at dosage of 75μg/day from day +10 as FN prophylaxis after R-CHOP (from April 2010 to June 2013). Comparisons between qualitative variables were carried out using the χ^2 test. Statistical analyses were performed with the software package Stata version 11 (Stata Corp LP, College Station, TX, USA). In all analyses, P values were 2-tailed, and a P value less than 0.05 was considered to be significant.
Results: A total of 102 elderly patients with DLBCL were identified for this study, comprising 41 patients treated with Filgrastim BS® and 61 treated with Gran®. Comparisons of patient outcomes between groups are presented in Table 1. There was no statistically significant difference among the two patient cohorts. Mortality during therapy was similar in two group (p=0.647). Furthermore, number of injection during one cycle was significant less in Filgrastim BS® group (4.2 *vs* 5.0; p <0.001). In addition, mean medical costs during hospitalization were statistically lower in the Filgrastim BS® group than in the Gran® group (1,356.3±94.1 *vs* 2,357.2±113.4 Euro; p <0.001).

Table 1.

	Biosimilar filgrastim	Original filgrastim	*p* value
Age (year)	71 ± 13	69 ± 14	0.645
Sex (male / female)	20 / 21	32 / 29	0.842
Injection (/ cycle)	4.2 ± 1.7	5.0 ± 1.8	<0.001
FN (episode / total cycle)	7 / 218	12 / 327	0.672
Mortality (number)	1 / 41	2 / 61	0.647
Cost (Euro) (/ cycle)	256.1 ± 8.5	473.2 ± 29.5	<0.001
Cost (Euro) (/ patient)	1356.3 ± 94.1	2357.2 ± 113.4	<0.001

Summary and Conclusions: According to our study, it is revealed that biosimilar filgrastim (Filgrastim BS®) has similar efficacy and safety compared with original filgrastim in febrile neutropenia prophylaxis after R-CHOP therapy in elderly patients. This data confirm previous evidence that supports the non-inferiority of biosimilar filgrastim in this setting. Furthermore, mean medical costs during chemotherapy were statistically lower in the Filgrastim BS® group than in the Gran® group.

E1455

IS CLINICAL TRIAGE EFFECTIVE? AN AUDIT OF OUTPATIENT REFERRALS TO THE HAEMATOLOGY DEPARTMENT AT NORTHWICK PARK HOSPITAL, LONDON NORTHWEST NHS TRUST

M. Camilleri[1,*] F. Chowdhury[1]
[1]Haematology, Northwick Park Hospital, Harrow, United Kingdom

Background: The haematology service at Northwick Park Hospital is known to be busy, with a minimum of seven follow-up clinics and five new patient clinics running weekly. One Friday afternoon new patient session has been introduced last year as a measure to keep up with the new outpatient referrals that come to the department. In order to manage these referrals better, a local consultant-led triage system screens and inputs each one onto a common departmental database.
Aims: The aim is to increase the efficiency and safety of the outpatient service by assessing the necessity of each referral and making sure patients are seen within the right time frame by the appropriate clinician.
Methods: To assess this, an audit was carried out on all the new outpatients referred to the haematology department at Northwick Park Hospital over a 6 month period. Data was extracted and analysed using simple descriptive statistical tools available on Microsoft Excel.
Results: There were 1016 referrals recorded from July 2014 to December 2014, with most cases being triaged within 1 to 3 days on receipt of referral. 14% of these were rejected, either because they were deemed inappropriate (41%) or the patient would have benefitted from an alternative specialist review (11%). Out of all the accepted referrals 24% needed the red cell service, 29% required clotting advice and 34% of patients needed review at a white cell clinic. 14% of haematology referrals had no specified reason documented. 74% of referrals come from primary care, with 55% coming directly from the GP and another 19% via the *Choose and Book* patient scheme. The vast majority of rejected referrals came from primary care (96%) with most clinical questions requiring only simple advice, at times given over the phone. 71% were direct GP referrals and 25% were *Choose and Book* electronic referrals. Triaging cases to avoid unnecessary consultations is very likely to have positive financial implications, considering that costs of GP referrals to the NHS come to £15 billion per year. 156 patients (15%) needed to be seen urgently within a two week period, were the majority were referred due to a white cell disorder (69%). Such cases constitute an average of 40% of a typical new patient clinic list (2 slots out of 5 per clinic session), with an appreciable number of patients ending up requiring hospital admission for expedited work-up.

Summary and Conclusions: With the ever rising demand for specialty referral, rationalizing the limited human and fiscal resources in secondary/tertiary care is becoming important. Every hospital seeks to see the appropriate referrals first; preventing unnecessary consultations whilst picking up urgent cases early. This audit has shown that clinical triage and assessment has significant strengths conveying several advantages. Filtering out inappropriate referrals saves the GP money and prevents unnecessary waiting times. Also, referrals can be directed to the most appropriate setting, making patient care more efficient. With 2/3 of our urgent appointments being made up of white cell disorders, a good triage system helps fast-track diagnosis of possible cancer. Clinical triage, coupled with peer review and readily accessible consultant feedback to GPs through letters or phone, may prove to be both cost- and clinically-effective in today's busy practice.

E1456

PROGRESSION-FREE SURVIVAL AS THE PRIMARY ENDPOINT IN ONCOLOGY TRIALS: ITS VALUE AND CREDIBILITY FROM DIFFERENT STAKEHOLDERS' PERSPECTIVES

C. Quinn[1,*] S. Palmer[2], J. Bruns[3], C. Grant[1], D. Sykes[1], S. Kaura[4]
[1]PRMA consulting Ltd, Fleet, [2]Centre for Health Economics, University of York, York, United Kingdom, [3]Deutsche Krebsgesellschaft, Berlin, Germany, [4]Celgene Corporation, Summit, New Jersey, United States

Background: The primary and secondary endpoints selected for oncology trials have to meet the needs of diverse stakeholders: patient groups, clinicians, regulators, and health technology assessment (HTA) agencies, each of whom considers trial outcomes from a different perspective. Progression-free survival (PFS; time from randomization until progression or death from any cause) is becoming a more widely accepted measure of treatment efficacy, but there is tension between regulators and payors regarding its acceptability as a primary endpoint: payors still consider overall survival (OS; time from randomization until death from any cause) the 'gold standard' because of uncertainty about translating PFS gain to OS whereas regulators accept non-OS endpoints in order to drive faster approvals.
Aims: The aim of this paper is to present and discuss PFS as a credible endpoint among different stakeholders, considering the heterogeneity in stakeholder perspectives and preferences that needs to be accommodated in clinical trial design and endpoint selection in order to provide adequate information for all decision-makers.
Methods: We conducted a targeted review of the published and grey literature to identify regulatory and HTA guidance on PFS as an endpoint. We identified examples of decisions by both regulators and HTA agencies in which PFS data were presented as the primary outcome and compared the assessment of the products by regulators and different HTA agencies. Afatinib (A), erlotinib (E), and bevacizumab (B) were identified as examples of products for which decision-making appears to have been influenced by the use of PFS data.

Table 1.

Cancer	Drug	FDA	EMA	NICE (UK)	TC (France)	G-BA (Germany)
NSCLC	A	Yes	Yes	Yes + interim OS+PAS	ASMR 5	5 subgroups, benefit range: Indication of major benefit to added benefit not proven
	E	Yes	Yes	Yes + interim OS+PAS	ASMR 4	NA
Ovarian	B	Yes	Yes	No Too much uncertainty	ASMR 4	NA

Results: We identified several publications by regulatory and HTA agencies that report PFS to be a valid and credible endpoint in oncology trials; its suitability is determined by the type and stage of cancer. The magnitude of PFS gain and the associated uncertainty are considered by all stakeholders, but decision-making processes vary. Regulators assess the magnitude and certainty of survival gain in order to assess the risk-benefit profile. Clinicians and patients use PFS data to make decisions about individual treatment options. Payors use the data to assess the opportunity cost of recommending one drug rather than another. This variation in processes is demonstrated in the following decisions by regulators and HTA agencies for submissions based on PFS data (Table 1). ASMR 4, minor improvement over standard of care (SOC); ASMR 5, no improvement over SOC; NA, assessment not publicly available; PAS, patient access scheme.
Summary and Conclusions: PFS is a valid and credible endpoint, and measure of efficacy, in many oncology trials; by reducing trial length compared with OS, efficiency is also improved and fewer patients exposed to a clinical trial. Limitations associated with PFS are largely manageable. The value of PFS needs to be consistently recognized by HTA agencies, and approaches harmonized between HTA agencies and regulators.

E1457

IMBALANCES IN THE ANNUAL EHA CONGRESS. THE FUTURE OF HAEMATOLOGY

J. Loza[1,*] A. Pereda[1], P. Chavez[1], I. Gonzalez[1], A. Campeny[1], E. Perez[1], R. Díez[1], M. Quintana[1], F. Rodriguez[1], A. Mendizabal[1], C. Menchaca[1], M. Ardanaz[1], J. Guinea[1]
[1]Hematology, Hospital Universitario Araba, Vitoria-Gasteiz, Spain

Background: During the last EHA congress in Milan, our attention was brought to the existing imbalance between the time and space dedicated to oncohaematology in relation to other areas of haematology: red blood cell series, haemostasis and transfusion.
Aims: We have proposed reviewing whether this imbalance is timely or maintained over the last few years.
Methods: we reviewed the weight of the various areas of haematology in the last 10 EHA Congresses, based on book abstracts of communications that can be consulted on the European Haematology Association's official publication's website. We have classified communications into six sections: oncohaematology, red blood cell series, haemostasis, transfusion, transplant of haematopoietic cells and various. We analysed their percentage weight and time pattern.
Results: we detected that the participation of the RBC series varied between 4% and 6.9% with an average of 5.5%, haemostasis between 6.9% and 15.6% with an average of 9% and transfusion between 1% and 3.8% with an average of 2.1%. Oncohaematology occupied between 42% in 2005 and 67.4% in 2014, with an average of 60%. Of the 10,868 communications presented between simultaneous sessions and posters, 60% referred to Oncohaematology, 5.6% to RBC series, 9.1% to haemostasis, 2.1% to transfusion, 6.8% to transplant and 16.5% to various other issues: the taking part of patients, management, efficiency of treatments, granulocytic function and a long etc. of topics difficult to fit into the other five haematology areas. If we analyse the parallel sessions, those aimed at oncohaematology varied between 14 in 2005 to 27 in 2014 with an average of 20, which meant 64% of the total sessions. However, only one session in 3 of the 10 congresses was dedicated to transfusion (<1%). The study of the variation in the last 10 years revealed a gradual increase in the existence of oncohaematology in congresses mainly from 2009, maintenance of the RBC series and haemostasis in general below 10% and a trend towards a gradual disappearance of transfusion. We only need point out that in the last 10 years there have only been three parallel sessions which have tackled this field of our speciality.
Summary and Conclusions: We observed a gradual separation from Haematology as a speciality in favour of oncohaematology, with a gradual loss of the other three parts of the speciality, which could lead in the medium term to reconsidering the survival of the Haematology speciality as we know it today.

E1458

HEMATOLOGY AND SOCIAL MEDIA: COMMUNICATION AND EDUCATION IN THE MODERN ERA

E. Graves[1,*] A. McGregor[1], J. Young[1], R. Evans[1]
[1]Haematology, Newcastle Upon Tyne Hospitals, Newcastle Upon Tyne, United Kingdom

Background: Medical education, professional networking and communication are changing as social media becomes more integral to the lives of academics, doctors, health care professionals and patients. Social media (SoMe) is gaining popularity as a platform for informal, user-directed learning; the ease with which educational material and discussion can be accessed from multiple devices is key to this.
Aims: We aimed to develop a hematology-oriented presence within SoMe. We wanted to promote Hematology as a specialty willing to engage in international and truely multi-disciplinary dialogue via the most modern platforms. We also wanted to create an educational dialogue that would allow interested parties, from the smallest to largest institutions, to participate in teaching and the dissemination of knowledge.
Methods: We chose Twitter, a free, widely used SoMe microblogging website as it allows instant dissemination and discussion of educational material. Our Twitter profile (@TeamHaem) contains a short biography of who we are and our objectives. @TeamHaem established a Twitter presence by 'following' education and medical professionals, enabling us to see their status updates. We subsequently asked them to 'tweet' about us; therefore gaining our own followers. We created case-led discussions, which evolve over time and are

designed to be topical and relevant to our followers, targeting their various skill sets and levels of expertise. We used a blogging website to create the backbone of our case and Twitter to lead the discussion. Images, such as blood films, radiographs and marrow histology can be posted in addition to links from journal articles. Any follower can contribute or can simply watch the case developing. We react to followers' suggestions and encourage evidence-based discussion, closing each case with a summary. We moderate discussion and explicitly refrain from offering medical advice.
Results: @TeamHaem has been operational since 2012 and we currently have 1296 followers from 112 countries around the world, including doctors, nurses, students, pharmacists and biomedical scientists. We have published 32 interactive cases so far. We have also presented at medical education conferences and participated in the twitter coverage of various hematology conferences, including The Americal Society of Hematology 2014 congress which was the topic of over 20,000 tweets. We have encountereed numerous difficulties with this project, including technological literacy, compliance with confidentiality and SoMe guidelines, time management and promotion of the service to non-Twitter users. These obstacles have been overcome by following published guidelines, seeking advice from senior colleagues, presenting at local and national meetings and publishing in specialty specific newsletters.
Summary and Conclusions: Hematology is a specialty that is frequently scientifically ground-breaking. Many in the field are interested in methods of sharing knowledge and promoting the specialty, as well as learning from colleagues. @TeamHaem is an entirely novel programme which has succeeded in developing an international network for professionals and students working in Hematology. We have over 1000 followers from more than 100 countries and continue to curate high quality educational networks and debate for the Hematology community.

E1459

NARROWBAND ULTRAVIOLET-B PHOTOTHERAPY IN A PEDIATRIC PATIENT WITH CHRONIC GRAFT-*VERSUS*-HOST DISEASE

I. Eker[1,*] O. Gürsel[1], M. Topdemir[2], G. Açıkgöz[3], O. Babacan[4], A.E. Kürekçi[4]
[1]Pediatric Hematology, [2]Pediatrics, Gulhane Military Medical Faculty, [3]Dermatology, [4]Pediatric Hematology, Gülhane Military Medical Faculty, Ankara, Turkey

Background: The advantage of narrowband UVB (NB UVB) phototherapy for inflammatory skin diseases in adults and children is unquestionable, but its use in graft *versus* host disease (GVHD) has been scarcely reported.
Aims: We present here a 15 years-old boy, in whom complete and durable remission was achieved with the addition of NB UVB.
Methods: A 15 years old male patient with monosomy 7 positive bilineage acute leukemia, underwent allogeneic peripheral blood stem cell derived hematopoietic stem cell transplantation (allo-HSCT), from his full-matched 50 years old mother. Conditioning consisted of total body irradiation (12 Gy/total), cyclophosphamide (120mg/kg) and etoposide (30 mg/kg). Methotrexate and cyclosporine were used for GVHD prophylaxis. 2.18x 10^6/kg CD34+ stem cells were transplanted. Full engraftment was achieved with neutrophil, platelet and erythrocyte recovery being 16 days, 22 days and 23 days respectively. He presented with overlap syndrome type GVHD on the 30th day of transplantation with a score of 3 in the skin and a final global assessment of severe GVHD. He was resistant to steroid, but remission was achieved with the combination of tacrolimus and mycophenolate mofetil. He was in hematological complete remission with good health condition and without immunosuppression for 2 months, until his second presentation with overlap syndrome type GVHD on the 128th day of transplantation with a score of 3 in the skin and a final global assessment of 'severe' GVHD. A partial remission was achieved with methylprednisolon, but there were not any response to treatment in his exfoliative skin lesions, especially which were localized on his upper extremity and palmar face of his hands (Figure 1). On the 132th day of transplantation NB UVB phototherapy was started as an adjuvant therapy to steroid, tacrolimus and mycophenolate mofetil. By means of a Waldmann UV-7002 K (Villingen-Schwenningen, Germany) cabin NB UVB phototherapy was administered. Treatments were given three times weekly and the starting dose was determined by the minimal erythema dose with increments of 0.02 mJ/cm^2 every two treatments. After the 10th treatment, complete remission was achieved and skin lesions were totaly resolved in the patient who received a total of 2.94 j/cm^2 therapy until that time. He is on the 165th day of transplantation at the time of this report, steroid therapy was discontinued. Tacrolimus and mycophenolate therapies planned to continue with the goal of reaching the 30th NB UVB treatment.
Results: Narrowband UVB is controlled administration of UVB component of sunlight. It is a method of treatment in which, UVB with 311-313 nm wavelength is used to treat a wide range of inflammatory skin diseases, especially psoriasis and vitiligo. In particular, phototherapy alters antigen presentation and T-cell responsiveness in skin, primarily via inactivation of Langerhans cell antigen-presenting capacity and secretion of immunosuppressive cytokines.

Figure 1.

Summary and Conclusions: NB-UVB phototherapy is a useful adjuvant therapeutic modality, effectiveness of which is proven in GVHD and can be indicated in the treatment of patients with cutaneous GVHD as a nonaggressive adjuvant therapy to immunosuppressive drugs.

HEMOGLOBINOPATHIES WITH HIGH OXYGEN AFFINITY

W. Torres[1,*] M. García Roa[1], A. Manubens[1], M. Gutierrez Alvariño[1], A. Pedraza Navarrete[1], D.S. Toral Ibarra[1], P. Ropero Gradilla[1], J.M. Nieto[1], F. De la Fuente-Gonzalo[1], A. Villegas[1], R.B. Martinez Martínez[1], F.A. González Fernández[1]
[1]Hematologia y Hemoterapia, Hospital Universitario Clinico San Carlos de Madrid, Madrid, Spain

Background: Hemoglobinopathies are the world's most frequently found monogenic disorders. Depending on the replaced amino acid nature and its location in the globin chain, changes will be observed in the hemoglobin molecules' stability, solubility and function that finally lead to clinical haemoglobinopathies. In the cases with high oxygen affinity, the decrease in the liberation of the oxygen determines a secondary erythrocytosis.
Aims: In this work, we present 18 unrelated families of Caucasian race and of Spanish origin, with eleven variants of hemoglobin or hemoglobinopathies with high oxygen affinity, which were diagnosed in our laboratory.
Methods: The haemoglobinopathies were characterized either through electrophoresis in an alkaline pH (8.6 pH) cellulose acetate, or an isoelectrofocussing (IEF) in polyacrylamide gel (5.5-8.5 pH), or agar citrate (pH 6.0) electrophoresis or reverse phase HPLC for globin chains or ionic exchange HPLC. Hemoglobin function was established through P50 in the oxygen balance curve plotted by a TCS Haemox-Analyzer (TCS Medical Products Co., Huntingdon Valley, PA, USA). The molecular analysis was completed by automatic sequencing of the α and/or β genes' PCR-amplified products using the ABI Prism TM dRhodamine Terminator Cycle Sequencing Ready reagents kit (PE Applied Biosystems, Foster City, AC) and the sequence was studied in an ABI Prism 310 Genetic Analyzer (PE Applied Biosystems).
Results: All the demographic data, hematrimetric results, P50 and chromatography findings are summarized in Table 1.

Table 1.

*One generation. **Two generations. ***Three generations. M: male. F: female

Summary and Conclusions: Of the eleven haemoglobinopathies, in four (the Hb San Diego, the Hb Johnstown, the Hb Malmö and the Hb Columbia-Missouri), the change of amino acid affects zones of the contact a^1b^2; in two variants (the Hb Strasbourg and the Hb Syracuse), it affects the unions with 2,3-DPG in the central cavity; in the other two (the Hb Badalona and the Hb La Coruña), the cavity of contact with the group heme is affected; in one (Hb Bethesda), it affects the zone of contact a^1b^1; in another one (Hb Andrew-Minneapolis) it affects the extreme C-terminal contacts of β chain and in the last one (Hb Olympia), the position 20 of the chain in the helix B in the surface of the protein is affected. In all cases, the change of amino acid, though of different form, facilitates that the quaternary structure of the hemoglobin becomes stable in its relaxed configuration so the transfer of oxygen and the P (50) value are decreased. All cases were sent to our laboratory because of shown erythrocytosis. In the majority of them, the diagnosis was done during an analysis of routine or for being relatives of the first ones. Although it is rarely diagnosed, the reported 18 families that show 11 different variants in the same geographic area lead us to think that the percentage of secondary erythrocytosis in hemoglobinopathies of this type could be even higher and, therefore, their systematic detection should be emphasized in erythrocytosis of unknown origin and, more so, when a family history is available.

E1461

TRANSFUSION-DEPENDENT HEREDITARY SPHEROCYTOSIS AND COMPLETE DISTAL RENAL ACIDOSIS: THE FIRST CASE WITH A HOMOZYGOUS EXON 12 C.1430C>A (P.SER477X) MUTATION OF THE SLC4A1 GENE

L. Kager[1,2,*] K. Boztug[1,3], P. Zeitlhofer[4], G. Fritsch[2], M. Minkov[5], B. Fahrner[1], A. Dossenbach-Glaninger[6], O. Haas[1,2,4]
[1]St. Anna Children's Hospital, Department of Pediatrics, Medical University Vienna, [2]Children's Cancer Research Institute, [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, [4]medgen.at GmbH, [5]Pediatrics, [6]Laboratory Medicine, Hospital Rudolfstiftung, Vienna, Austria

Background: Mutations in the *SLC4A1* gene, which encodes a bicarbonate anionic exchange protein (AE1 or Band 3), cause a rare and unique combination of hereditary spherocytosis (HS) and distal renal acidosis (dRTA). The fast majority of patients reported so far are compound heterozygotes. So far only three types of homozygote mutations in this gene have been documented, namely one with a p.V488M in exon 13 (Ribeiro *et al.*, Blood 96:1602;2000), one with a p.S667F in exon 16 (Toye *et al.*, Blood 111:5380;2008) and another one p.Ala858Asp in exon 19 (Fawaz *et al.*, Europ J Haematol 88:350;2012).
Aims: To determine the genetic cause of complete dRTA in combination with HS.
Methods: A Turkish boy presented with a severe transfusion-dependent hemolytic anemia, complete dRTA and a psychomotor developmental delay since birth. Regular transfusions obstructed the establishment of a firm HS diagnosis with a flow cytometric assay that is based on the reduced binding of eosin-5-maleimide (EMA) to spherocytes. However, this test was abnormal in his consanguine parents and his two siblings, who all had subclinical signs of spherocytosis, despite normal RBC counts. These findings therefore prompted us to screen the family for causative mutations in the *SLC4A1* gene.
Results: Sequencing of the entire coding region revealed two homozygous sequence changes in the patient, namely a disease-relevant nonsense mutation c.1430C>A (p.Ser477X) in exon 12 and a disease-unrelated single nucleotide polymorphism c.2312-48T>G (rs13306780). The nonsense mutation creates a stop codon and results in a C-terminally truncated protein that only contains the cytoplasmic domain and the first three trans-membrane segments. In accordance with an autosomal recessive inheritance pattern of the disease, both parents as well as his siblings were heterozygous carriers of this gene-disrupting sequence variant.
Summary and Conclusions: The respective p.Ser477X mutation was previously found in only two heterozygous individuals with an incomplete form of dRTA. These cases were identified when families with HS were screened with an urine acidification test for this purpose (Rysava *et al.*, Nephrol Dial Transplant 12:1869;1997), whereas our patient is the first one who is affected by this mutation in a homozygous form. The recurrence of this identical mutation in an apparently unrelated family therefore may imply a common founder origin and proves that, if homozygote, it produces the complete clinical picture of a severe transfusion-dependent form of HS together with a complete dRTA. Whether the psychomotor development delay is directly related to the mutation or presents a preventable consequence of the hemolytic anemia and renal disturbance remains to be shown.

E1462

CHARACTERIZATION OF 6 HEMOGLOBINOPATHIES OCCURRING WITH CYANOSIS AND/OR LOWERING THE OXIGEN SATURATION

W. Torres[1,*] M. Garcia Roa[1], M. Gutierrez Alvariño[1], E. Coria[1], L. Sanchez Noboa[1], D.S. Toral Ibarra[1], P. Ropero Gradilla[1], F. De la Fuente Gonzalo[1], J.M. Nieto[1], A. Villegas[1], R.B. Martinez Martinez[1], F.A. Gonzalez Fernandez[1]
[1]Hematologia y Hemoterapia, Hospital Universitario Clinico San Carlos de Madrid, Madrid, Spain

Background: Structural hemoglobinopathies are the result of mutations in globin genes. In over 95% of cases the structural alteration corresponds to the substitution of a single amino acid in the sequence of the globin chains. Until now described over 1000 different variants being in most cases clinically and phenotypically silents. However in some instances the amino acid change may determine that the heme iron chain with the mutation this oxidized permanently or submit a decreased affinity for oxygen enrolled in these situations with cyanosis and/or decreased oxygen saturation.
Aims: In this work, we want to present the molecular characterization of six variants of hemoglobin that his suspicion was conducted by the existence of a decrease in oxygen saturation and/or cyanosis unexplained, which were diagnosed in our laboratory.
Methods: The haemoglobinopathies were characterized either through ionic

exchange HPLC or reverse phase HPLC for globin chains. Hemoglobin stability was determined using the isopropanol test, while the function was established through P50 in the oxygen balance curve plotted by a TCS Haemox-Analyzer (TCS Medical Products Co., Huntingdon Valley, PA, USA). The molecular analysis was completed by automatic sequencing of the α and/or β genes' PCR-amplified products using the ABI Prism TM dRhodamine Terminator Cycle Sequencing Ready reagents kit (PE Applied Biosystems, Foster City, AC) and the sequence was studied in an ABI Prism 310 Genetic Analyzer (PE Applied Biosystems).
Results: All the demographic data, hematrimetric results, P50 and chromatography findings are summarized in Table 1.

Table 1.

Fam	Nº patients (age/sex)	Hb (g/dL)	metHB (%)	isopropanol test	p50	HPLC Hb	HPLC Chains	Molecular mutation
1*	1 (35/M)	17.9	Not done	-	↑	HbA / HbX	β^A; α^A;α^X	Hb M-Boston [α²58(E7) His→Tyr; CAC>TAC]
2**	3 (35/F;32/F; 62/F)	10.6-12.1	10.5-12.3	+	N	HbA / HbX	β^S; β^A; α	Hb M-Hyde-Park [β92(F8) His→Tyr: CAC>TAC]
3*	1 (19/F)	11.36	9.5	+	N	HbA / HbX	β^S; β^A; α	Hb M-Saskatoon [β63(E7) His→Tyr; CAT>TAT]
4*	1 (34/M)	12.3	0.5	-	↑	HbA / HbX	β^A; α^A;α^X	Hb Titusville [α2 94(G1)Asp→Asn; CAC>TAC]
5*	1 (22/M)	15.6	18.5	+	Not done	HbA / HbX	β^S; β^A; α	Hb Higashitochigi [β25626(B667)Gly>0; del GGT]
6**	2 (5/M; 32/M	10.8-12.8	Not done	+	↑	N	β^S; β^A; α	Hb Arta [β45(CD4) Phe→Cys; TTT>TGT]

*one generation. **two generations. M: male; F: female.

Summary and Conclusions: In the Hb M-Boston and M-Saskatoon changing the distal histidine for tyrosine in α and β chains respectively and the Hb M-Hyde Park changing the proximal histidine for tyrosine in anchoring the β chain Heme group to both chains, determines the oxidation of iron the heme group permanently to yield an electron and thus can not capture oxygen, this being the cause of the decrease in oxygen saturation and cyanosis in these hemoglobinopathies. In Hb Titusville changing aspartic for asparagine at position G1 α chain involved in the contact α1β2 determines Hb stabilization conformationally deoxy T or so has a low affinity for oxygen being the reason the decrease in oxygen saturation and cyanosis. Hb Higashitochigi, the loss of a glycine in the helix B distorted indirectly heme pocket at the end distal level of the distal histidine conformocionales miss the relationships between helix B and helix E end which favors the oxidation of iron central. In the Hb Arta the mutation affects segment CD is critical in the transition from deoxy T or R configuration or oxy Hb, changing a phenylalanine for cysteine at this level configuration favors what deoxy T and so determines a lower affinity for oxygen chain. The possibility of the presence of structural hemoglobinopathies must be taken into account in cases of cyanosis and decreased oxygen saturation unexplained. Although no clinical impact a confirmation saves people carrying extensive and unnecessary studies.

E1463

IDENTIFICATION OF TWO NEW MISSENSE MUTATIONS AND A 5BP DELETION IN THE ERYTHROID-SPECIFIC PROMOTOR OF THE PKLR GENE IN TWO UNRELATED PATIENTS WITH NON-SPHEROCYTIC HEMOLYTIC ANEMIA

L. Kager[1,2,*] M. Minkov[3], K. Boztug[1,4], P. Zeitlhofer[5], B. Fahrner[1], A. Dossenbach-Glaninger[6], O. Haas[1,2,5]
[1]St. Anna Children's Hospital, Department of Pediatrics, Medical University Vienna, [2]Children's Cancer Research Institute, [3]Pediatrics, Hospital Rudolfstiftung, [4]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, [5]medgen.at GmbH, [6]Laboratory Medicine, Hospital Rudolfstiftung, Vienna, Austria

Background: Pyruvate kinase (PK) deficiency is the most common form of non-spherocytic hemolytic anemia (NSHA), which concurs with significant comorbidities. As an autosomal recessive disease it results from a variety of functionally impairing mutations that are scattered over the entire coding region of the *PKLR* gene, although they show a somewhat ethnicity- and region-specific biased distribution. More than 200 different mutations have been documented so far, but only two of these, which were functionally characterized in detail, reside in the promotor region (Zanella *et al.* Brit J Haematol, 130:11, 2005).
Aims: To determine the genetic cause of a suspected PK deficiency.
Methods: We present two children from unrelated families, a five month-old girl and a three-year old boy, who both suffer from severe transfusion-dependent NSHA since birth. PK enzyme activity was not determined before initiation of transfusions. However, this test still revealed a moderate reduced activity in both the children's healthy parents, who all had normal RBC counts. In consideration of these clues, we Sanger sequenced the entire coding region of the PKLR gene in the two patients and subsequently verified the parental inheritance pattern of all identified sequence changes.
Results: Our mutation screening confirmed that both patients were compound heterozygote carriers of causal *PKLR* mutations. The girl had a previously recorded maternally-derived exon 9 (c.1174G>A; p.Ala392Thr) missense mutation and a novel paternally-derived 5bp deletion in the promoter region (c.-39-49_-39-45delTCTCT). The boy had two hitherto unknown missense mutations, namely a maternally-derived c.907-908delCC (p.Pro303GlyfsX12) in exon 7 and a paternally-derived c.1381g>A (p.Glu461Lys) in exon 10. The ensuing shift in the reading frame of the former prematurely interrupts amino acid synthesis after AS 313 and truncates the protein, whereas the other one converts a highly conserved amino acid from an acid to a basic one.
Summary and Conclusions: We succeeded to determine the genetic cause of a suspected PK deficiency in two patients and thereby uncovered three novel mutations in the *PKLR* gene, namely two missense ones in exons 7 and 10 and a 5bp deletion in its erythroid-specific promotor, which is so far only the third one of its kind. The identification of underlying mutations is an essential prerequisite not only for further functional studies that can provide important insights into the respective disease mechanism but it also provides the necessary basis for adequate counseling of the affected families.

E1464

HB PUERTA DEL SOL, HB VALDECILLA, HB GRAN VÍA, HB MACARENA, AND HB EL RETIRO: DESCRIPTION OF 5 NEW HEMOGLOBINOPATHIES

F. De La Fuente Gonzalo[1,*] J.M. Nieto[1], D. Velasco[2], E. Cela[3], E. Del Campo[4], A. Fernández-Teijeiro[5], A. Escudero Soto[6], R.B. Martínez Martínez[1], A. Villegas[1], F.A. González Fernández[1], P. Ropero Gradilla[1]
[1]Hematology, Hospital Clínico San Carlos, [2]Laboratorio BR-Salud, Hospital Infanta Sofía, [3]Pediatria, Hospital Gregorio Marañon, Madrid, [4]Analisis Clínicos, Hospital Universitario Marques de Valdecilla, Santander, [5]Oncohematología Pediatrica, Hospital Universitario Virgen de la Macarena, Sevilla, [6]Hematology, Hospital Gregorio Marañon, Madrid, Spain

Background: Structural hemoglobinopathies are due to mutations that cause the change of the amino acid sequence of the protein chain. Some of these variants have altered electrophoretic mobility. They do not have a clinical impact but can cause interference in the analytical determination of some parameters such as the glycated hemoglobin in diabetic patients. Thalassemias are the most common monogenic disorders worldwide and represent a serious health problem in areas where their incidence is high. The α-thalassemias are due to a deficiency or absence of synthesis of the α-chain of hemoglobin (Hb). The defects in the post-translational modifications produce hyper-unstable Hbs that are not detected by most of electrophoretic or chromatographic methods available so far.
Aims: We shown 5 new α-chain Hb variants. One is a structural variant having altered electrophoretic mobility and the other 4 are hyper-unstables and behave as α-thalassemias.
Methods: We studied 7 patients, belonging to 6 unrelated families. The first 2 families were studied because they showed a peak of abnormal Hb during routine analytical assays. The other 4 families were studied because they had microcytosis and hypochromia with normal Hb A2 and Hb F without iron deficiency. Haematological data were obtained on a haematology analyzer. HbA2 and F quantification and the separation of abnormal Hb were performed by ion-exchange HPLC. The abnormal Hb also was separated by capillary electrophoresis. The study of the globin chains was performed by reversed-phase HPLC. The most frequent mutations were ruled out by α-*globin StripAssay*. The molecular characterization was performed by specific sequencing.
Results: The haematological parameters and the genotype of the studied subjects are summarized in Table 1. The electrophoretic and chromatographic studies are recruited in Table 2.

Table 1. Haematological parameters and genotype of the studied subjects.

Family	Age (years)	Sex	Hb (g/dL)	MCV (fL)	MCH (pg)	HbA_2 (%)	Hb F (%)	Hb X (%, by HPLC-Variant)	Genotype
A	46	M	16	84.2	29.2	2.9	0.7	14.3	$\alpha\alpha^{PS}/\alpha\alpha$
B	4	M	10	78.9	26	3	0.3	17.5	$\alpha\alpha^{PS}/\alpha\alpha$
	1	M	12.6	78.7	25.9	3	0.2	17	$\alpha\alpha^{PS}/\alpha\alpha$
C	86	M	11.9	66.6	21.1	2.5	0.3	--	$\alpha^{V}\alpha/-\alpha^{3.7}$
D	38	M	11.3	83.4	27.1	2.7	0.4	--	$\alpha^{GV}\alpha/\alpha\alpha$
E	1	M	13	76.2	23.3	2.3	1.7	--	$\alpha^{M}\alpha/\alpha\alpha$
F		M	15.4	76.6	24.3	2.9	0.3	--	$\alpha^{ER}\alpha/\alpha\alpha$

M=Male; F=Female; α^{PS}=Puerta del Sol; α^{V}=Valdecilla; α^{GV}=Gran Vía; α^{M}=Macarena; α^{ER}=El Retiro

Table 2. Chromatographic and electrophoretic studies.

HEMOGLOBIN	IE-HPLC	CE	RP-HPLC	MUTATION
PUERTA DEL SOL	Yes, R.T. 4.36 min	Yes, FZ4	No, β^A, α^A	α_1 49 Ser>Arg
VALDECILLA	No	No	No	α_2 Initiation Met>Ile
GRAN VÍA	No	No	No	α_2 32 Met>Arg
MACARENA	No	No	No	α_2 119 Pro>Ser)
EL RETIRO	No	No	No	α_2CD120/121(+GTG)

Summary and Conclusions: Hb Puerta del Sol has the same mobility than HbS by IE-HPLC but a lower percentage. This variant has a normal blood count. In the Hb Valdecilla the initiation codon is affected and the carrier shows a thalassemia trait with anemia, microcytosis and hypochromia. This mutation is also associated in trans to an heterozygous α^+-thalassemia deletion. Within the non deletional α-thalassemia, a very important group are those due to the lack of stability of the α-globin chain, which causes the called hiper-unstables Hbs. The three new Hbs (Gran Vía, Macarena and El Retiro) described in this work are hiper-unstables although by different mechanisms. In Hb Gran Via, instability could be due to the replacement of a Met (apolar) by an Arg (polar positively charged) at position 13 of the B helix of the α_2 chain. This mutation alters the sequence of 6 residues (CD30-CD35) involved in the contact between α1/β1 subunits Hb tetramer. In Hb Macarena, residue 119 of the α helix H chain is affected, which has a key role interacting with the stabilizing protein alpha chain of hemoglobin (AHSP). For Hb Macarena, its hiperinstability is probably due to a decreased affinity for the AHSP. Most hemoglobinopathies are the result of a point mutation, while only a few such as Hb El Retiro originate as a result of small insertions or deletions. In Hb El Retiro a Val (apolar) is inserted at position 122 (H5), therefore displacing a polar positively charged amino acid (His) involved in α1/β1 contact. This could be the cause of instability of this hemoglobinopathie. All these variants, although uncommon and privatives to some families, reveal the complexity and variety of disorders that can be found in the genes coding for Hb, having over 1000 different Hb variants described to date. Some variants such as Hb Valdecilla, Hb Gran Vía, Hb Macarena and Hb El Retiro, with significant clinical impact if associated with other forms of α-thalassemia could lead to more serious forms of this group of pathologies as is the Hb H disease. Therefore, it is important to maintain an adequate program of screening of these diseases in countries where prevalence is high to prevent the occurrence of severe forms.

E1465

IDA AND ON THE TREATMENT OF IDA DNA DAMAGE: 8-HYDROXY-2-DEOXYGUANOSINE LEVEL

B. Esen[1], S. Akarsu[2,*] S. Aydin[3]
[1]University of Firat, Faculty of Medicine, Department of Pediatrics, [2]University of Firat, Faculty of Medicine, Department of Pediatric Hematology Oncology, [3]University of Firat, Faculty of Medicine, Department of Biochemistry, Elazig, Turkey

Background: Iron deficiency anemia (IDA) is a common and an important health problem in developing countries. Ionized form is potentially dangerous while the iron components which are in the form of inorganic components have an important duty. Ionic iron causes damages at the cellular level by forming free radicals. Therefore, decreases and increases in the level of iron have clinic significances. Reactive Oxygen Species (ROS) lead to the formation of oxidative base damages in DNA. Among these forms the most common one and the one which has the best known mutagenity is 8-hydroxy-2'-deoxyguanosine (8-OHdG).
Aims: We aimed to determine IDA and its different forms of treatments' (p.o., i.m., i.v.); probable oxidative damage on DNA by looking at the level of 8-OHdG. In this way, we aimed to bring a new perspective to the treatment of IDA.
Methods: The total number of patients studied was 80 and 60 of them had IDA and the rest were healthy control group. The patients were divided into 4 subgroups: (First group: Oral treatment (p.o.) group with 20 patients]; Second group: Intramuscular treatment (i.m.) group with 20 patients]; Third group: Intravenous treatment (i.v.) group with 20 patients]; Fourth group: Healthy control group 20 patients]. Blood and urine samples were taken from all patients totally four times; just before the treatment, at the twenty-fourth hour of treatment, at the first week of treatment and at the third month of the treatment. 8-OHdG levels detected in blood and urine samples were compared with the control group.
Results: Especially at the twenty-fourth hour of treatment and also at each stage, statistical significance high was detected at the 8-hydroxy-2-deoxyguanosine blood and urine level in i.v. group compared to other groups ($p<0.05$).
Summary and Conclusions: IDA and the treatment of it affect the level of 8-OHdG. Oral iron therapy should be the top priority on children. If p.o. iron therapy cannot be applied, i.m. iron therapy can be preferable. Intravenous iron treatment might be chosen if the indications make a need.

LB2088

SEVERE NEONATAL JAUNDICE DUE TO A *DE NOVO* GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENT CLASS I MUTATION

R. Del Orbe Barreto[1,*] B. Arrizabalaga[2], L. Manco[3], C. Bento[4], L. Ribeiro[4], J.C. García-Ruiz[2]
[1]Biocruces Health Research Institute, [2]Hematology, Cruces University Hospital., Barakaldo, Spain, [3]CIAS/Departamento de Ciências da Vida, Universidade de Coimbra, [4]Serviço de Hematologia Molecular, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: G6PD deficiency is the most common human enzyme deficiency worldwide. Acute hemolysis induced by exposure to oxidative stress, as infection, drugs or fava beans ingestion, is the most frequent clinical presentation, however G6PD deficiency can be a major contributor to neonatal hyperbilirubinemia. To date different mutations causing chronic non spherocytic hemolytic anemia (CNSHA) have been identified. Most of these class I mutations lead to amino acids replacements close to the dimer interface and the "structural NADP+", suggesting that that the integrity of these regions is very important to form stable dimmers.
Aims: To report a case a of a newborn infant with severe G6PD deficiency associated with a *de novo* G6PD class I mutation.
Methods: The patient was born by caesarean section after a 39 weeks gestation. Parents of Spanish origin were non-consanguineous and no family members had a history of anemia or jaundice. A few minutes after birth the patient developed clinical respiratory distress accompanied by skin pallor and jaundice. Hb of 9 g/dL and data of extravascular hemolysis were evidenced. He required a blood transfusion and later blood exchange transfusion at 15 hours of life for hyperbilirubinemia (maximum of 17.4 mg/dL, mostly indirect). The episode was associated with mild thrombocytopenia requiring transfusion of a platelet unit. Biochemical analysis: All tests and evaluations were performed in accordance with the Declaration of Helsinki and after parents' informed consent given. G6PD enzyme activity assays in the red blood cell hemolysates were performed by quantitative spectrophotometer analysis according to the recommendations of the International Committee for Standardization in Hematology (ICSH). DNA analysis: Mutation screening of genes encoding erythrocyte enzymes, beta globin and membrane proteins was performed on a Next Generation Sequencing platform (Ion Torrent PGM, Life technologies, Carlsbad, CA, USA). The founded variants were confirmed by direct sequencing by dideoxy chain termination reaction using the ABI PRISM BigDye Terminator v1.1 Cycle Sequencing kit (Applied Biosystems, *Foster City,* USA). Investigation of the new mutation was assessed by bi-directional sequencing of G6PD gene in proband's and mother's independent DNA samples obtained from EDTA peripheral blood, buccal cells and hair. HLA-STR markers were analyzed in proband and relatives to confirm mother-child genetic relationships using Luminex (Gen-Probe Transplant Diagnostics, Stamford, CT, United States).
Results: Enzymatic study was performed in the reference laboratory, in which a G6PD deficiency was present (145 mU/10^9 RBC; normal value: 221-570 mU/10^9 RBC) and confirmed with a second quantification (<35 mU/10^9 RBC). The sequencing analysis on the male proband, revealed a previously described cytosine to timine transition at position c.827 on exon 8, resulting in the amino acid change proline to leucine at the residue position 276 (c.827C>T; p.Pro276Leu). The c.827C>T mutation was absent in the proband's mother genomic DNA, suggesting that this is a spontaneously occurring new genetic alteration *i.e.*, a *de novo* G6PD mutation.
Summary and Conclusions: We report a case of a severe G6PD deficient male with neonatal persistent jaundice accompanied by mild anemia and evidence of extravascular haemolysis, requiring a blood transfusion and later blood exchange transfusion at 15 hours of life for hyperbilirubinemia. NGS analysis is a powerfull tool that let to conduct a comprehensive screening for different diseases in a serious situation such as neonatal jaundice, where the enzyme activity assays and peripheral morphology cannot provide sufficient data to establish a diagnostic approach. In conclusion, this *de novo* p.Pro276Leu mutation underlying a CNSHA phenotype (class I variant) maps near the dimer interface of G6PD protein, and may severely compromise the formation of the dimmer affecting enzyme stability and the steady-state level of G6PD is so low, limiting for the survival of red cells even in the absence of any oxidant challenge.

Red blood cells and iron - Clinical

E1466

THE CLINICAL FEATURES AND TREATMENT OF IRON OVERLOAD IN PYRUVATE KINASE DEFICIENCY (PKD): DATA FROM THE PKD NATURAL HISTORY STUDY (NHS)

D.H. Morton[1], C. Knoll[2], J. Rothman[3], B. Glader[4], E. Neufeld[5], W. Barcellini[6], S. Eber[7], H. Yaish[8], J. Despotovic[9], A. Thompson[10], N. Usmani[11], K. Nottage[12], H. Wang[13], J. Kunz[14], D. Guo[5], W. London[5], K. Conner[1], E. Merica[15], R. Grace[5,*]

Lurie Children's Hospital of Chicago, Chicago, IL, [11]UMass Memorial Children's Medical Center, Worcester, MA, [12]St. Jude Children's Research Hospital, Memphis, TN, [13]DDC Clinic for Special Needs Children, Middlefield, OH, United States, [14]Zentrum für Kinder- und Jugendmedizin, Heidelberg, Germany, [15]Agios Pharmaceuticals Inc, Cambridge, MA, United States

Background: Both transfusion-associated and transfusion independent iron overload occur in individuals with congenital hemolytic anemias, particularly in those with ineffective erythropoiesis. The prevalence and monitoring practices differ by type of anemia, and these are not well described for PKD.
Aims: To describe the demographic features, co-inheritance of hereditary hemochromatosis, iron monitoring, and chelation practices in transfusion dependent and transfusion independent PKD patients (pts) with iron overload.
Methods: Between March 2014 and January 2015, 105 pts with PKD enrolled on the PKD NHS at 14 IRB approved sites. For this study, baseline and retrospective enrollment data were included. Log_{10} transformation was applied to liver iron concentration (LIC) by T2* MRI and ferritin values to improve normality. Analysis of variance was performed to test for associations of LIC and/or ferritin with categorical covariates of interest. General linear regression models were used to identify the association of LIC and ferritin with continuous variables. Analyses were performed in the overall cohort and repeated excluding the 46 Amish pts with a homozygous 1436G>A mutation. Significant results are reported for those that were identified in either of the analyses.
Results: Of the 105 PKD pts, iron screening data were available for 71 (68%) with ferritin [35/71 Amish] and 49 (47%) with LIC [40/49 Amish]. Ferritin was significantly higher in pts who had a prior splenectomy, even after controlling for transfusion history (p=0.01). Higher ferritin correlated with higher LIC (n=38; p<0.0001, Figure 1); however, LIC was not significantly higher in pts with prior splenectomy (p=0.23). In the 9 pts with available LIC measurements who had never been transfused or only transfused for acute stressors, 7 had a LIC >4 mg/g dry weight (DW) liver. Based on clinical screening, 4 (3.8%) pts had a homozygous mutation associated with hereditary hemochromatosis (HH), and 8 (7.6%) pts were heterozygotes. HH was not found to be significantly associated with an elevated ferritin (p=0.23) or LIC (p=0.80). Older age was significantly associated with higher baseline ferritin (p=0.005).
21 non-Amish pts (20%) had received chelation therapy starting at a median age of 11.4 years (range 1-44 years). Median ferritin and LIC at the start of chelation were 1131 ng/ml (range 182-5630) and 8.3 mg/g DW liver (4.3-46), respectively. Chelator types included: Deferoxamine (n=9), deferasirox (n=13), deferiprone (n=2), and combination chelation (n=2). Of the 21 who received chelation, 5 had complications: abdominal pain, ulcers, diarrhea, serum sickness, rash, kidney stone, hearing loss, and/or vision loss. Only 1 pt had a LIC measured both before and during/after chelation; thus, there is insufficient data to report efficacy by LIC. Two pts had phlebotomy for iron removal with no improvement in ferritin or LIC.

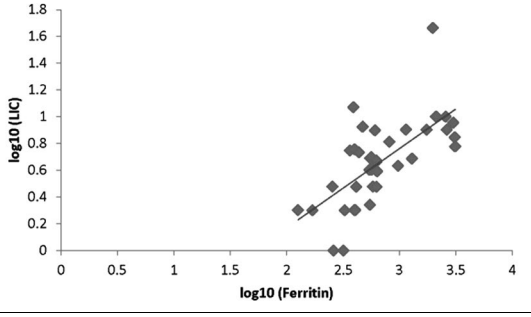

Figure 1. Correlation of ferritin (ng/ml) and liver iron concentration (mg/g dry weight liver) in the Pyruvate kinase deficiency natural history study (n=38).

Summary and Conclusions: Iron overload assessed by ferritin or LIC was common in all age groups regardless of transfusion history when monitored in this cohort of PKD pts, but monitoring had not been performed in 30% of this cohort. The efficacy of chelation in PKD is unknown, as most pts in this cohort were not adequately monitored. Since the cohort in the NHS with iron testing was mainly Amish, these results may not apply to PKD pts with other mutations. Ferritin correlates well with LIC in this cohort; thus, regular ferritin testing starting in early childhood could be considered to screen PKD pts for iron overload.

E1467

THE QUESTIONING OF THE NEED FOR MONTHLY MONITORING OF PROTENURIA AMONG PATIENTS WITH BETA THALASSEMIA MAJOR USING DEFERASIROX

F. Gumruk[1,*] O. Unlu[2], H. Kucuker[2], A.D. Tutal[1], T. Bayhan[1], S. Unal[1]
[1]Hacettepe University, Division of Pediatric Hematology, [2]Hacettepe Universtity, Faculty of Medicine, Ankara, Turkey

Background: The major cause of morbidity and mortality among patients with beta-thalassemia major (BTM) is transfusional iron accumulation in heart, liver and endocrine organs and iron chelation is the mainstay of the treatment in these patients. Deferasirox is an oral, once-daily active iron chelating agent and nephrotoxicity is a common toxicity among users. Nephrotoxicity of deferasirox is usually manifested with usually clinically significant rises in serum creatinin levels or rarely with renal failure especially among patients with concomitant health problems. Proteinuria is also one of the potential adverse effects of deferasirox and monthly follow-up for proteinuria is suggested by FDA and EMA.
Aims: In this study, we aimed to investigate the necessity for monthly monitoring for proteinuria among patients with BTM on deferasirox.
Methods: Thirthy-seven patients with BTM on deferasirox therapy were enrolled. Median age of the patients was 23 years (4-39); 22 being females. At the time of initiation of deferasirox all patients had normal serum creatinine, glomerular filtration rate and spot urine protein/creatinine ratios. All patients were monitored for proteinuria q3 or q4 weeks after initiation of deferasirox with serum creatinin and spot urine protein/creatinine ratios throughout the course of deferasirox treatment. The management of patients who developed spot urine protein/creatinine ratio ≥0.8 were recorded.
Results: The median follow-up time of the 37 patients was 44 months. Throughout this follow-up time 1490 times of testing was done for proteinuria detection. Although all patients were ordered urine test at each visit (1987 order), 1490 of the patients delivered their urine samples to laboratory; indicating a test compliance of 75%. Of the patients, 7 (18.9%) developed significant proteinuria (ratio ≥0.8). Of the 1490 measurements, 12 tests (0.8%) were proteinuric. The risk of proteinuria was higher at ages above a cut-off point of 23 years (p=0,019). Patients who were on deferasirox at doses above 29 mg/kg/day were found to have higher risk of proteinuria development (p=0.004). The patients who developed proteinuria had a concomitant rise in serum creatinine level more than 50% of the serum creatinine level measured at deferasirox initiation. Of the proteinuria occurences, three resolved after 1 week of drug cessation. The rest of the proteinura cases resolved spontaneously in 1 to 3 visits of time, without any intervention. None of the patients required hospitalization for proteinuria.
Summary and Conclusions: The compliance of the patients for monthly follow-up proteinuria is not satisfactory. Additionally, the proteinuria usually resolves without any complication or major intervention. Potentially more risky groups (age above 23 years-old and dose above 29 mg/kg/day) might be suggested to be followed monthly, other than monitoring all of the patients.

E1468

CAUSES OF NEWLY DIAGNOSED ANAEMIA IN GENERAL PRACTICE: THE RELEVANCE OF MCV

K. Stouten[1,*] J. Riedl[1], P. Sonneveld[2], M.-D. Levin[1]
[1]Albert Schweitzer hospital, Dordrecht, [2]Erasmus MC, Rotterdam, Netherlands

Background: Anemia is a common finding amongst the elderly population and its prevalence rises from about 5.6% in the age group 50-64 years to about 23.1% in the age group 85+ years. In recent years it has been shown anemia is associated with increased mortality and morbidity and decreased quality of life. Despite anemia being such a frequently encountered clinical problem, surprisingly few data are available on the prevalence of the underlying causes. Several studies on causes of anemia in the general population have been published, but these generally included relatively small patient numbers and provided a limited analysis of underlying causes. A large cohort study of general practice patients with newly discovered anemia was set up to allow for an extensive analysis of the causes of anemia and to assess the validity of MCV-based algorithms used for the diagnosis of the underlying cause.
Aims: To analyse the causes of anemia in general practice and assess the validity of MCV-based algorithms.
Methods: Patients were included after presenting to one of the 63 participating general practitioners with a newly diagnosed anemia (*i.e.* no diagnosis of anemia in the preceding two years). Anemia was defined as hemoglobin level

below 13.7 g/dL (8.5 mmol/L, men) and below 12.1 g/dL (7.5 mmol/L, women). The inclusion period lasted from the 1st of February 2007 until the 1st of February 2013. The follow-up period ended on the 1st of September 2013. Both men and women were included when aged 50 years or older. A wide range of parameters was analyzed for each patients to aid diagnosis. Two experts independently reviewed the laboratory results of all patients and established the underlying cause of anemia. In case of discordance, the experts deliberated until a consensus was reached. The population was divided into age groups (50-64, 65-74. 75-84 and 85+), class of anemia (based on MCV) and type of anemia (based on hemoglobin). The differences between age groups, classes and types were analyzed.

Results: A total number of 2513 patients were included in the study, 1238 men (median age 72 years) and 1275 women (median age 77 years). A single cause of anemia was found in 2284 patients (90.9%). Anemia of chronic disease was found 823 times (29.8%), renal anemia 340 times (12.3%), haemoglobinopathy 17 times (0.6%), hemolysis 16 times (0.6%) and possible bone marrow disease 105 times (3.8%). Vitamin B12 deficiency was found 115 times (4.2%), iron deficiency 516 times (18.7%) and folic acid deficiency 23 times (0.8%). Other causes were found 106 times (3.8%). The cause remained unknown in 703 cases (25.4%). Iron deficiency and haemoglobinopathy were significantly associated with microcytic anemia, while anemia of chronic disease and unknown were significantly associated with normocytic anemia. Hemolysis, possible bone marrow disease, vitamin B12 and folic acid deficiency and other causes were significantly associated with macrocytic anemia. Apart from haemoglobinopathy, all causes were found in each class at least once. Other observations included a prevalence of renal anemia rising with age. In addition, anemia of chronic disease and unknown anemia were associated with mild anemia, while iron deficiency and hemolysis were associated with severe anemia.

Summary and Conclusions: Several diagnostic algorithms developed for determining the cause of anemia generally attribute a specific set of causes to microcytic, normocytic and macrocytic anemia. Here it was shown causes of anemia should not be excluded based solely on the MCV value, indicating these existing algorithms should be reconsidered.

E1469

USEFULNESS OF LASER ASSISTED OPTICAL ROTATIONAL CELL ANALYZER (LORRCA) IN THE DIAGNOSIS OF HEREDITARY HAEMOLYTIC ANAEMIAS

A. Zaninoni[1], C. Vercellati[1], E. Fermo[1], A.P. Marcello[1], A. Zanella[1], W. Barcellini[1], P. Bianchi[1,*]

[1]Oncohematology Unit-Physiopathology of Anemias Unit, Foundation IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Hereditary hemolytic anemias (HAs) are heterogeneous disorders mainly due to defects of red cell (RBC) membrane and metabolism. Hereditary spherocytosis (HS), elliptocytosis, and more rarely stomatocytosis (dehydrated, DHSt and overhydrated), are caused by defects of cytoskeleton or membrane permeability. Among RBC enzyme defects pyruvate kinase (PK) deficiency is the most common, followed by glucose-6-phosphate isomerase (GPI), and pyrimidine 5'-nucleotidase (P5'N) deficiency. Because of the rarity and heterogeneity of these diseases, diagnosis may be often challenging, notwithstanding the availability of a battery of laboratory tests. Ektacytometry, and more recently, laser-assisted optical rotational cell analyser (LoRRca MaxSis, Mechatronics Instruments, NL), able to measure RBC deformability in osmotic gradient conditions (Osmoscan), is reported to be a useful tool in the detection of RBC membrane disorders and in particular for the differential diagnosis of HSt; few data are available in other haemolytic anemias.

Aims: To evaluate the diagnostic power of LoRRca MaxSis in the diagnosis of RBC membrane disorders and other haemolytic conditions in a cohort of 84 patients with a confirmed diagnosis of haemolytic anemia of different cause

Methods: We analysed the Osmoscan curves in 54 cases with RBC membrane disorders (47 HS, 7 DHSt), 17 cases with enzymopathies (11 PK, 4 GPI, 2 P5'N), 7 with congenital dyserythropoietic anemia type II (CDAII) and 6 patients with paroxysmal nocturnal hemoglobinuria (PNH). Among them 5 HS, 2 PK, 3 GPI, 2 P5'N and 5 CDAII patients were splenectomysed. Normal ektacytometry curves were obtained from 75 healthy control subjects. The evaluated parameters were: 1) Omin (osmolality at which the elongation index (EI) is minimal, coinciding with the 50% haemolysis in osmotic fragility assays), 2) EImax (maximal deformability), 3) Ohyper (osmolality at ½EImax, representing cellular hydration status). Moreover, patients' curves were compared with a normal control reference curve interval. All the analyses were performed on EDTA blood sample, stored at 4°C and within 48h from collection.

Results: All the 47 HS (27 spectrin, 16 band3 deficiency and 4 with undetectable defect at SDS-PAGE analysis) showed typical altered ektacytometry curve, consistently with the reduced area of the curve and regardless the biochemical membrane defect. (Figure 1a). The 7 DHSt patients displayed the typical left-shift of the curve (Figure 1b). All GPI cases showed an altered enlarged Osmoscan curve associated with significant increased Ohyper (Figure 1c). No alterations were found in not-splenectomised PK (n=9), CDAII (n=2) cases, and in all PNH cases (Figure 1d). However, osmoscan curves of splectomized PK (n=2), CDAII (n=5), and P5'N (n=2) patients fell in a defined atypical area, regardless the pathology (Figure 1e).

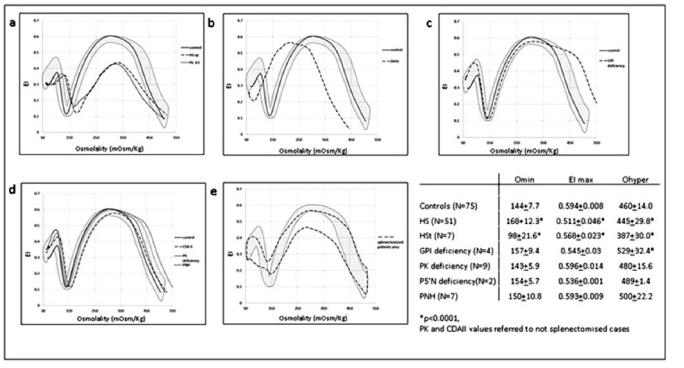

Figure 1.

Summary and Conclusions: All the HS and DHSt patients analysed showed diagnostic Osmoscan curves. Among the analysed parameters Omin and EImax were more significantly altered in HS patients, whereas Ohyper was significantly increased in GPI deficiency. For the first time abnormal Osmoscan curve was described in GPI deficiency, offering a new tool for the diagnosis of this rare enzyme defect. Splenectomy may interfere on the RBC deformability evaluation, thus suggesting caution in the interpretation of curves. Osmoscan analysis performed by LoRRca Maxsis represents a useful and feasible first step screening test in the diagnosis of RBC membrane disorders and other rare haemolytic anemias.

E1470

IDIOPATHIC AND CONGENITAL ERYTHROCYTOSIS: A STUDY OF A LARGE COHORT

M.L. Randi[1,*] E. Cosi[1], E. Peroni[1], M.C. Putti[2], I. Bertozzi[1], C. Santarossa[1], F. Fabris[1]

[1]Dept of Medicine-DIMED, [2]Women's and Children's Health-SDB, Pediatric Hemato-Oncology, University of Padua, Padova, Italy

Background: Idiopathic Erythrocytosis (IE) is an absolute erythrocytosis (estimated prevalence 1.1 casesx 1000 persons) without an identified cause and its diagnosis is based on the exclusion of primary or secondary erythrocytosis. Familial erythrocytosis (FE) are rare diseases sometimes recessively transmitted and we and others have studied patients with congenital erythrocytosis (*i.e.* VHL mutation) while the relatives carrying the same heterozygous mutation show no signs of erythrocytosis. Therefore, FE may be diagnosed as IE, as well as 1% of patients with Polycythemia Vera (PV) who do not carry a *JAK2* mutation (*JAK2*-WT).

Aims: We tried to recognize, within a large cohort of patients with erythrocytosis, simple features able to discriminate IE, FE and PV.

Methods: Over the last 20 years, we followed 99 patients with *JAK2*-wild-type (JAK2-WT) erythrocytosis in whom a complete molecular study was available. The molecular study was performed during follow up in all the patients diagnosed before 2005. 78 patients were considered as IE after exclusion of secondary causes of erythrocytosis or a negative family history; 21 patients have been classified as FE in the presence of a familial pattern or the demonstration of *EPO-R*, *PHD2*, *VHL* or *HIF1-2-alpha* mutation. As controls we used 136 PV patients carrying *JAK2*V617F (allele burden 49±31%) or *JAK2* exon 12 mutations. The Ethical Committee of Padua Hospital approved the study. Nominal variables were compared with thex^2 test and continuous variables with the Mann-Whitney test. Logistic regression model was used for multivariate analysis.

Results: The clinical and laboratory data of our patients, collected at diagnosis, are summarized in the Table 1 (serum EPO [EPOs] in FE is extremely variable and not considered in the statistical analysis). FE patients were significantly younger in comparison with both IE and PV ($p < 0.001$). In multivariate analysis, low EPOs, high platelet count, thrombosis at or before diagnosis and splenomegaly were confirmed as independent features non-suggestive for IE when compared to PV. During follow-up no haematological progression to myelofibrosis (MF) or acute leukaemia (AL) was observed in IE and FE, while 9 PV patients evolved in MF and 3 in AL. None of FE nor IE patient out of the 28 (35.9%) with a follow-up longer than 5 years nor the 12 (8.3%) with a FU longer than 10 years progressed into an over PV.

Summary and Conclusions: This is a large cohort of IE and FE patients compared with PV patients followed in a single centre. Our data suggest that, in a patient with erythrocytosis associated with increased platelet count and/or splenomegaly and suppressed EPOs, PV as to be suspected. In contrast, normal spleen, normal platelets count and no cardiovascular complications argued

against early forms of PV. This study confirms that IE is a common and indolent form of erythrocytosis with a low risk of thrombosis. The role of phlebotomies and low-dose aspirin is still debated, but cytotoxic drugs seem to be avoided. We failed to identify simply clinical or laboratory data that can distinguish IE and FE even if the latest is found often in very young people. The observation of isolate erythrocytosis even, if sporadic, has to be evaluated as a possible genetic disease.

Table 1.

	IE	FE	PV (controls)	p IE vs PV	P FE vs PV
N° of patients	78	21	136	-	-

LEFT VENTRICULAR GLOBAL FUNCTION INDEX AND LEFT VENTRICULAR MASS VOLUME RATIO BY CMR: ASSOCIATION WITH HEART FAILURE AND ARRHYTHMIAS IN THALASSEMIA MAJOR PATIENTS

A. Meloni[1], M.G. Neri[1], S. Pulini[2], M.G. Bisconte[3], N. Romano[4], M. Lendini[5], V. Positano[1], A. Vallone[6], M. Missere[7], P. Keilberg[1], A. Pepe[1,*]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]U.O. Ematologia Clinica, Ospedale Civile "Spirito Santo", Pescara, [3]U. O. Ematologia, A. O. Cosenza-Presidio Osp. Annunziata, Cosenza, [4]S.C. Medicina Trasfusionale, AO Arcispedale "S. Maria Nuova", Reggio Emilia, [5]Centro trasfusionale, Osp. Giovanni Paolo II, Olbia, [6]Istituto di Radiologia, Az. Osp. "Garibaldi"-Presidio Ospedaliero Nesima, Catania, [7]Dipartimento di radiologia, Università Cattolica del Sacro Cuore, Campobasso, Italy

Background: Recently two novels indicators of left ventricular (LV) performance assessed by Cardiovascular Magnetic Resonance (CMR) have been introduced: the LV global function index (LVGFI) and the LV mass/volume ratio (LVMVR). The LVGFI combines LV stroke volume, end-systolic and end diastolic volumes, as well as LV mass, integrating structural as well as mechanical behaviour. Elevated LVMVR is indicative of concentric remodelling. A LVGFI <37% and a LVMVR>1 were shown to be associated with the occurrence of cardiovascular events in no-thalassemic populations.
Aims: This retrospective cohort study aimed to systematically evaluate in a large historical cohort of thalassemia major (TM) in the CMR era whether the LVGFI and the LVMVR were associated with a higher risk of heart failure and arrhythmias.
Methods: We considered 812 TM patients (391 M, 30.4±8.6 years), consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network. LVGFI and LVMRI were quantitatively evaluated by SSFP cine images. The T2* value in all the 16 cardiac segments was evaluated and a global heart T2* value <20 ms was considered indicative of myocardial iron overload (MIO).
Results: Eighty (9.9%) patients had a LVGFI<37% and, compared to the patients with a normal LVGFI, they showed a significant higher frequency of heart failure (43.8% *vs* 4.2%; P<0.0001) and of arrhythmias (7.5% *vs* 3.0%; P=0.036). Patients with a LVGFI<37% had a significant higher risk of heart failure (odds-ratio-OR=17.59, 95%CI=9.95-21.09; P=<0.001). The risk remained significant also adjusting for the presence of MIO (OR=15.54, 95%CI=8.05-26.27; P=<0.001). Patients with a LVGFI<37% had a significant higher risk of arrhythmias (OR=2.62, 95%CI=1.03-6.66; P=<0.001). No adjustement was performed since arrhythmias were not associated to MIO. Thirty (3.7%) patients had a LVMVR≥1% and, compared to the patients with a normal LVMRI, they showed a significant higher frequency of heart failure (20.0% *vs* 7.7%; P=0.015) but not of arrhythmias. Patients with a LVMVR≥1% had a significant higher risk of heart failure (OR=3.01, 95%CI=1.18-7.64; P=0.021). The risk remained significant also adjusting for the presence of MIO (OR=3.44, 95%CI=1.31-9.01; P=0.012). In a multivariate model including LVGFI, LVMVR and heart iron, the significant predictors of heart failure were a LVGFI<37% (OR=14.05, 95%CI=7.66-25.77; P=<0.001) and a global heart T2*<20 ms (OR=1.94, 95%CI=1.08-3.47; P=0.026).
Summary and Conclusions: In TM patients a LVGFI<37% was strongly associated with an higher risk of heart failure, independent by the presence of MIO. Moreover, patients with a LVGFI<37% were more likely to have arrhythmias. A widespread program using CMR exploiting its multi-parametric potential can have considerable power for the early identification and treatment of patients at risk for heart failure.

E1472

SIGNIFICANT IMPROVEMENT OF SURVIVAL BY T2* MRI IN THALASSEMIA MAJOR

A. Pepe[1,*] A. Meloni[1], G.C. Del Vecchio[2], M.A. Romeo[3], M.R. Gamberini[4], F. Bonetti[5], M.G. Neri[1], E. Chiodi[6], V. Vinci[7], V. Positano[8], C. Borgna-Pignatti[9]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Pediatric Unit, Uiversity of Bari, Bari, [3]Division of hematology, Unit of Thalassemia, Policlinico Vittorio Emanuele, University of Catania, Catania, [4]Pediatria, Adolescentologia e Talassemia, Arcispedale "S.Anna", Ferrara, [5]Pediatric Hematology Unit, Policlinic Foundation San Matteo IRCCS, Pavia, [6] Servizio Radiologia Ospedaliera-Universitaria, Arcispedale "S. Anna", Ferrara, [7]Istituto di Radiologia, Az. Osp. "Garibaldi", Presidio Ospedaliero Nesima, Catania, [8]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, Italy, Pisa, [9]Clinica Pediatrica, Università di Ferrara, Ferrara, Italy

Background: In 2004 seven Italian centers reported survival data for patients with thalassemia major (TM) and showed that heart disease due to iron overload was the most common cause of death (Borgna *et al.* Haematologica 2004). In the same years the accurate and noninvasive assessment of cardiac siderosis was made possible in Italy by the introduction of the T2* cardiovascular magnetic resonance (CMR).
Aims: We aimed to evaluate if the deployment of T2* CMR had an impact on the mortality rate.
Methods: Four centers contributed to the present study, updating the data of the enrolled patients until August 31, 2010. For the patients who died, the date of the death represented the end of the study. 577 patients (264 females and 313 males) were included.
Results: One-hundred and fifty-nine (27.6%) patients died, 124 of whom (77.9%) died before the year 2000. MRI was not performed in 406 patients (70.4%) and no patient had been scanned before his/her death. Among the survivors, MRI was not performed in the 59% of the cases (P<0.0001). The absence of an MRI scan was a significant univariate prognosticator for death (HR=43.25, 95%CI=11.32-165.33, P<0.0001). The study was restricted to the patients dead after 2004 (19/159=12%) or followed until August 2010 (N=357). In this subgroup of 376 patients, MRI was not performed in the 52.4% of the survivors and in all dead patients (P<0.0001). The absence of a MRI exam was reconfirmed as a strong predictive factor for death (HR=49.37, 95%CI=1.08-2263.24, P=0.046). The Kaplan-Meier curve is showed in Figure 1. The log-rank test revealed a significant difference in the curves (P<0.0001).

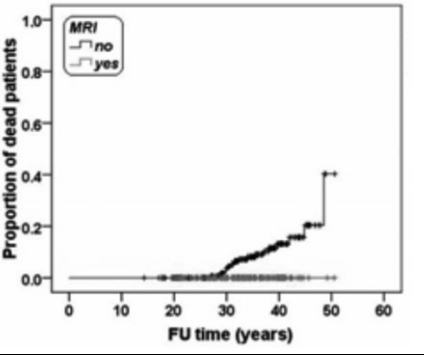

Figure 1.

Summary and Conclusions: Our data suggests that the use of T2* CMR, that enables individually tailored chelation regimes reducing the likelihood of developing decompensated cardiac failure, allowed the reduction of cardiac mortality in chronically transfused TM patients.

Background: A spectrum of large clinical programs has established the efficacy and safety of the oral iron chelator deferasirox (DFX) in transfusion-dependent patients with iron overload. We report the results from a multicenter, prospective, open-label, observational study reflecting the standard clinical practice in thalassemia centers in Greece.
Aims: To assess the safety profile of DFX in transfusion-dependent patients with iron overload.
Methods: Patients with hemoglobinopathies and transfusional iron overload, baseline serum ferritin levels <4000 ng/mL, and for whom the physician decided to initiate chelation with DFX under the local approved label and standard medical practice, were included in the study. Patients with myelodysplastic syndromes, severe cardiac siderosis (T2* <10 ms), left ventricular ejection fraction <56%, serum creatinine (SrCr) >upper limit of normal (ULN), alanine aminotransferase (ALT) ≥500 U/L, creatinine clearance (CrCl) <60 mL/min or significant proteinuria were not eligible.
Results: Of the 230 patients enrolled, 226 were evaluated (4 patients were excluded due to screen failures); a subset of the enrolled patients were pediatric (age <16 years, n=24). Mean age was 35.1±13.8 (pediatric, 8.7±4.2; adults, 38.3±10.9) years. The most common underlying conditions for transfusional iron overload were β-thalassemia major (66.8%, n=151), thalassemia intermedia (17.7%, n=40), and sickle cell anemia (9.3%, n=21). Prior chelation treatment was reported for 146 (64.6%) patients, most common being a combination of deferoxamine and deferiprone (19.0%; n=43). None of the patients had prior DFX exposure. Of the 226 evaluable patients, 179 completed the 12-month observation period, whereas 47 withdrew from the study prematurely. The 3 main reasons for discontinuation were adverse events (AEs; 7.1, n=16), lost to follow-up (4.4%, n=10), and consent withdrawal (2.2%, n=5). A total of 356 non-serious AEs were reported in 103 (45.6%) patients, of which 167 AEs observed in 65 patients (28.8%) were reported to be related to DFX. The most common non-serious AEs related to DFX were increase in SrCr above ULN (8.4%), upper abdominal pain (4.9%), and diarrhea (4.0%). Twenty-one (9.3%) patients experienced 56 serious AEs (SAEs), of which 13 SAEs in 3 patients (1.3%) were reported to be related to DFX, including gastrointestinal disorders (9 events), abnormal ALT, albumin above ULN, musculoskeletal pain and cholecystectomy (all 1 event each). The mean SrCr levels increased from 0.69 mg/dL at baseline to 0.74 mg/dL at 12 months, and the mean CrCL decreased from 127 mL/min at baseline to 123 mL/min (p<0.001 and p=0.015 for the mean differences, respectively). Transaminases (ALT and aspartate aminotransferase, [AST]) did not show an increase at any point in time. Notably, while AST showed a decreasing trend at 12 months (p=0.052), ALT decreased significantly at 12 months (p<0.001). Of the 15 patients who underwent ocular examination, an improvement was seen in 1 patient, while no changes were observed in the remaining patients. Of the 13 patients who underwent auditory examination, an improvement was noted in 1 patient, 1 patient showed deterioration, and 11 patients did not show any change.
Summary and Conclusions: This 1-year, multicenter, observational study conducted in Greece, under standard clinical practice, showed that the safety profile of DFX was consistent with previously published data.
Acknowledgement: We acknowledge the efforts of personnel from all sites, involved in this study. Authorship was based on study enrollment.

E1474

DESCRIPTIVE ANALYSES OF DEFERASIROX SAFETY AND EXPOSURE IN PATIENTS AGED >65 *VERSUS* 18 TO ≤65 YEARS

N. Gattermann[1], J.B. Porter[2], C. Rose[3], A. Bruederle[4], J. Han[5], N. Coello[5], M.D. Cappellini on behalf of EPIC study investigators[6,*]
[1]Heinrich-Heine-Universitat, Düsseldorf, Germany, [2]University College London, London, United Kingdom, [3]Hôpital Saint-Vincent de Paul, Lille, France, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharmaceuticals, East Hanover, United States, [6]Università di Milano, Ca Granda Foundation IRCCS, Milan, Italy

Background: Patients discontinued from the EPIC study most frequently due to adverse events (AEs). Discontinuation rates due to AEs were notably higher in the MDS cohort (n=78/341, 22.9%; mean age 67.9 yrs) compared with the overall EPIC population (n=153/1744, 8.8%; mean age 30.6 yrs); most frequently due to gastrointestinal (GI)-related AEs (Gattermann *et al.* Leuk Res 2010). Altered drug exposure is known to be clinically relevant in elderly patients for different drugs. It is hypothesized that differences in deferasirox pharmacokinetics (PK) could contribute to observed differences in AEs.
Aims: 1. To determine whether there is a higher incidence of selected AEs in elderly adult (>65 yrs) *vs* younger adult patients (18-≤65 yrs); 2. To investigate whether variations in AE frequency were due to differences in deferasirox PK.
Methods: EPIC study design and inclusion/exclusion criteria have been previously described (Cappellini *et al. Haematologica* 2010). Patients initially received deferasirox 10-30 mg/kg/day, depending on blood transfusions frequency, with dose adjustments of 5-10 up to 40 mg/kg/day, based on 3-month serum ferritin trends and safety markers. For this safety analysis, frequency of selected AEs of clinical interest over 1 year (abdominal pain, diarrhea, nausea, vomiting, gastroenteritis, rash, renal-related) were summarized by age category. Relative risk and 95% confidence intervals (CI) were estimated based on a non-modeling approach. For PK analyses, steady state trough deferasirox concentration ($C_{trough,ss}$) and concentration measured 2 hours post-dose (C_{2hr}) – surrogates for drug exposure (AUC) and peak levels (C_{max}), respectively – were described by age category in all patients with available data, regardless of underlying disease, and in MDS patients only. A regression analysis of deferasirox dose-normalized concentration *versus* age was also performed at Weeks 12 and 28.
Results: In total, 1079 patients ≥18 yrs were enrolled: n=837 aged 18-≤65 and n=242 aged >65 yrs. Overall, 210/242 patients >65 yrs had MDS. The frequencies and relative risks of reported AEs of interest are summarized (Table 1). There was a significantly increased risk of diarrhea and renal AEs in patients aged >65 *vs* 18–≤65 yrs and a significantly reduced risk of rash. Distributions of deferasirox dose-normalized $C_{trough,ss}$ and C_{2hr} were comparable between patients aged >65 *vs* 18–≤65 yrs in the overall patient population with PK available (n=748) and within MDS patients only (n=232). There was no trend for altered total drug exposure or peak levels between the two age categories.

Table 1. Frequencies and relative risks of reported AEs on interest in younger adult (18-≤65 years) *versus* elderly adult (>65 years) patients in the EPIC study.

AE	Frequency in elderly adult patients, n (%)	Frequency in younger adult patients, n (%)	Relative risk	95% CIs
Renal AEs	15 (6.2)	20 (2.4)	2.59	1.35, 4.99
Diarrhea	112 (46.3)	244 (29.2)	1.59	1.34, 1.89
Vomiting	31 (12.8)	88 (10.5)	1.22	0.83, 1.79
Abdominal pain	71 (29.3)	203 (24.3)	1.21	0.96, 1.52
Nausea	52 (21.5)	150 (17.9)	1.20	0.91, 1.59
Rash	24 (9.9)	146 (17.4)	0.57	0.38, 0.85
Gastroenteritis	4 (1.7)	44 (5.3)	0.31	0.11, 0.87

Summary and Conclusions: There were differences in the deferasirox AE profile between patients aged >65 *vs* 18–≤65 yrs. Diarrhea was the only GI-related AE significantly more frequent in patients >65 yrs; others did not differ significantly. Renal AEs were also significantly more frequent in patients >65 yrs, possibly due to higher baseline serum creatinine levels, common in older patients. AE variations did not appear attributable to differences in deferasirox exposure as assessed by $C_{trough,ss}$ and C_{2hr}. Therefore, this analysis does not support the need for considering deferasirox dose adjustments based on differences in drug exposure in elderly patients. Since the majority of elderly patients had MDS, concomitant medications/underlying complications may have influenced the AE profile, and should, therefore, be considered during deferasirox therapy to anticipate and manage AEs.

E1475

SERUM CYSTATIN C IN SICKLE CELL DISEASE: RELATION TO CARDIOVASCULAR DYSFUNCTION AND SICKLE CELL NEPHROPATHY

A. Tantawy[1,*] A.A. Adly[1], E. Ismail[2], M. Abd Elazeem[1]
[1]Pediatrics, [2]Clinical Pathology, Ain Shams University, Sairo, Egypt

Background: Sickle cell disease (SCD) patients have ongoing hemolysis and inflammation secondary to the sickling phenomenon. Many mechanisms contribute to the complex pathophysiology of SCD, with dysfunction of the vascular endothelium as a unifying theme. Renal dysfunction is a leading cause of morbidity in sickle cell disease. Cystatin C has been recognized as a useful marker of renal dysfunction and a strong predictor for risk of cardiovascular events.
Aims: To determine the level of cystatin C in 53 children and adolescents with SCD compared with 35 age- and sex-matched healthy controls and to assess its relation to markers of hemolysis, iron overload, renal affection and endothelial dysfunction.

Methods: SCD patients in steady state were studied stressing on transfusion history, hydroxyurea therapy, hematological profile, serum ferritin and urinary albumin creatinine ratio (UACR). Cystatin C was measured by enzyme linked immunosorbent assay (ELISA). Ecchocardiograhy was performed and carotid intima media thickness (CIMT) of the common carotid artery was assessed using high resolution ultrasonography. Heart disease was defined by at systolic left ventricle (LV) dysfunction (LV shortening fraction <30% or LV ejection fraction <55%).
Results: Cystatin C levels were significantly higher in SCD patients compared with control group (584.3±232.8 ng/mL *versus* 100.4±40.6 ng/mL; p<0.001). SCD patients with nephropathy or heart disease had significantly higher levels than those without (p<0.001 and p=0.041, respectively). Patients who had history of frequent sickling crisis (>3 attacks/ year) had higher cystatin C levels than those who were in steady state (p=0.034). SCD patients on regular hydroxyurea therapy had lower cystatin C levels than untreated patients (p=0.039). CIMT was elevated among SCD patients than controls (0.64±0.12 mm *versus* 0.42±0.02 mm; p<0.001). Cystatin C was positively correlated with corrected WBCs count (r=0.328, p=0.016), UACR (r=0.605, p<0.001) and CIMT (r=0.588, p<0.001). The cutoff value of cystatin C at 580 ng/mL could differentiate SCD patients with and without nephropathy with 77.8% sensitivity and specificity of 84.6% while the cutoff value 650 ng/mL could differentiate SCD patients with and without heart disease with 100% sensitivity and specificity of 74.4%.
Summary and Conclusions: Cystatin C may be considered a biological marker for vascular dysfunction and subclinical atherosclerosis in SCD as reflected by its positive correlation with CIMT. Serum cystatin C correlates with the level of albuminuria and may be a reliable method to measure renal function in SCD. Elevated Cystatin C levels would help in early crisis prediction and to identify patients at risk of cardiac complications as well as monitoring the response to hydroxyurea therapy. Further longitudinal studies are needed to verify the practical utility of Cystatin C measurement and validate the cutoff values for detection of cardiac and renal complications in SCD.

DEFERASIROX IMPROVES LIVER FIBROSIS IN B THALASSAEMIA MAJOR PATIENTS. A 5 YEARS FOLLOW UP STUDY
E. Vlachaki[1,*] E. Sinakos[1], D. Adamidou[1], E. Gigi[1], E. Chologitas[1], A.-K. Panteliadou[1], F. Klonizakis[1], E. Mandala[1]
[1]Ippokratio Hospital Thessaloniki, Thessaloniki, Greece

Background: β Thalassemia major (βTM) patients often develop liver fibrosis due to transfusion related liver iron overload and/or hepatitis virus C (HCV) infection. Transient elastography (TE) is a non-invasive method that accurately measures liver stiffness (LSM) and therefore could serve as a helpful tool for the fibrosis assessment.
Aims: To evaluate prospectively the liver fibrosis status in β TM patients being chelated with deferasirox only and explore the contribution of iron overload in liver fibrosis course.
Methods: We conducted a prospective 5 years (2008-2013) follow-up study in 22 βTM patients (9 males/13 females) with a median age of 32 (20-47) years. All patients were HCV PCR negative and on regular transfusion regime (2 RBC units every 15 days) retaining a pre-transfusion Hb level >9,5gr/dl, had no other comorbidities and were not on other medications of known effect on LSM. During the study period 7 female patients had to discontinue chelation therapy for 16(12-18) months due to successful pregnancies and restarted deferasirox 12 (8-16) months before the 2nd fibrosis evaluation. Patients were assessed with TE (LSM in kPa) at baseline-within 35(5-47) days after having been switched to 35(30-40) mg/Kg deferasirox-and reexamined with the same method by the same operator at 5 years. Readings of >8 kPa were considered indicators of severe liver fibrosis. Serum ferritin levels (ng/ml) and MRI T2* liver and cardiac imaging (using Anderson-Pennell protocol in ms) were concurrently run for the evaluation of iron overload.
Results: When we analysed the whole group of patients we found a significant positive correlation between ferritin changes and kPa fluctuation (p<0,004) and a modest negative correlation among kPa and MRI T2* changes (p<0.06) during the study period. Nevertheless there were no significant differences in mean kPa, ferritin levels or liver MRI T2* readings between baseline and 5 years follow up measurements (6.995 *vs* 6.573, 1133 *vs* 1035 and 8.21 *vs* 8.19 respectively). Interestingly enough, when we excluded patients that discontinued deferasirox from the analysis we found significant differences in the mean values of the examined parameters {kPa: 7.5 *vs* 6.093 (p<0.035), MRI T2*: 6.5 *vs* 8.2 (p<0.05), ferritin: 1125 *vs* 941, at baseline and 5 years follow up respectively}. In this subgroup there was also a consistent strong positive correlation between kPa and ferritin fluctuations (p<0.009) and negative correlation with liver MRI T2* changes, although not significant. In more details, 14 patients succeeded complete or partial reversal of the liver fibrosis, including 4 with severe disease at baseline, 1 remained stable and there was no case of progression.
Summary and Conclusions: Based on our data it seems that undisturbed iron chelation with deferasirox could offer significant improvement in liver fibrosis as assessed by means of TE. This is also in line with a better control in iron overload as shown by the decrease in ferritin levels together with the improvement in liver MRI T2* succeeded throughout the 5 years treatment period. Duration, compliance and other than the iron overload reduction possible modes of action are open research fields in order to establish the use of deferasirox in reversing or stabilizing liver fibrosis in βTM patients.

E1477

PREMATURE ATHEROSCLEROSIS IN CHILDREN WITH BETA- MAJOR THALASSEMIA: NEW DIAGNOSTIC MARKER
L. Sherief[1,*] A. Ali[1], O. Dawood[2], H. Sherbiny[3], M. Abd Alhady[3], O. Abd Alazez[4], M. Nour[3]
[1]Pediatric Hematology & Oncology, [2]Radiology, [3]Pediatric, [4]Biochemistry, Zagazig university, Zagazig, Egypt

Background: Early vascular alteration, atherosclerosis and coronary artery disease have emerged as important cardiovascular complications in beta-thalassemia major (BTM) patients due to oxidative stress of iron overload.
Aims: were to assess the prevalence of premature atherosclerosis among BTM patients, and to investigate the diagnostic value of serum osteoprotogrin (OPG) as marker for atherosclerosis
Methods: This prospective cross-sectional study included ninety-eight children; as sixty-five children with beta thalassemia major aged 5-18 years, on regular blood transfusion regimen represented the patient group. While thirty-three healthy children, with comparable age and gender, were assigned as control group. All participants were evaluated for laboratory investigations including; complete blood count, liver and kidney function tests, hepatitis B and C screening, C- reactive protein, lipid profile, serum ferritin and serum osteoprotogrin. Carotid artery intima media thickness (CAIMT) was performed by duplex ultrasound for patients and controls.
Results: Our BTM patients were transfusion-dependent for as long as 8.5±3.8 years with significantly higher serum ferritin levels (2490±1579 ng/dl *vs* 83±32 ng/dl, p=0.001), and C-reactive protein (5.7±5.7 *vs* 0.9±0.9 when compared to controls. Significantly higher serum triglyceride (128±20 *vs* 101±7 mg/dl, p=0.009) and atherogenic index of plasma (0.45±0.12 *vs* 0.22±0.04, p=0.001) were recorded in patients than comparisons. Carotid arteries intima media thickness (CAIMT) of both side; were significantly increased for patients (Rt 0.62±0.2 *vs* 0.29±0.07 mm, p=0.001 & Lt 0.66±0.17 *vs* 0.29±0.05 mm, p=0.001) when compared with healthy controls, and showed positive correlation with body mass index (BMI), serum triglyceride, atherogenic index of plasma, and serum osteoprotogrin levels. Assay of serum osteoprotogrin (OPG) revealed significantly higher levels for thalassemia patients than healthy peers (427±102 *vs* 324±126 pg/ml, p=0.02). Of particular interest is the obvious positive correlation between OPG levels and CAIMT of both sides (Rt r 0.54, p=0.001 &Lt r 0.479, p=0.001).
Summary and Conclusions: subclinical atherosclerosis started prematurely in children with beta- thalassemia. Carotid artery intima media thickness appeared to correlate well with serum osteoprotogrin. This finding highlighted the possible validity of OPG assay as an early predictor of atherosclerosis in thalassemia children

E1478

ASSESSMENT OF LIVER IRON CONCENTRATION IN PATIENTS WITH THALASSEMIA MAJOR USING MRI TECHNOLOGY: FINAL RESULTS OF A PROSPECTIVE COMPARATIVE STUDY BETWEEN T2* AND FERRISCAN
E. Voskaridou[1,*] M. Douskou[2], D. Christoulas[3], V. Komninaka[1], M. Dimopoulou[1], M. Aliberti[2], E. Terpos[4]
[1]Thalassemia and Sickle Cell Disease Reference Center, Laikon General Hospital, [2]Bioiatriki Medical Center, [3]Department of Hematology, 251 General Air-Force Hospital, [4]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Iron overload is a significant complication of hemoglobinopathies. Iron accumulates mainly into the endocrine glands, the liver and the heart leading to potentially life-threatening events. The accurate monitoring of total body iron is extremely important in patients with thalassemia major. Magnetic resonance imaging (MRI) is the most accurate non-invasive technique for the evaluation of iron overload in thalassemia patients. The MRI gradient echo (T2*), the reciprocal of T2* (known as R2*) and the spin echo (T2) techniques have managed to quantify tissue iron in the liver and the heart with high sensitivity. Another MRI methodology, which is firstly described by St. Pierre *et al.* (Blood 2005;105:855-61) evaluates liver iron concentration (LIC) using R2 (where R2=1/T2) signal decay rates, commercially available as FerriScan. In that study there was a significant correlation between R2 values and biopsy results. The FerriScan analysis produces a map of liver iron and calculates a mean LIC measurement.
Aims: The aim of this prospective study was to compare the results of the LIC evaluation obtained by conventional MRI and by FerriScan in patients with thalassemia major.
Methods: We prospectively studied 21 patients (9M/12F, median age 45 years, range 38-61 years) with thalassemia major who are followed-up in our Center. All patients had MR examinations of the liver that were performed on a General

Electric 1.5T Signa HDxt scanner (GE Healthcare, Milwaukee, USA). The pulse sequence used to estimate the T2* relaxation time of the examined tissues is a multi-echo fast gradient echo which has the ability to acquire 3 to 16 echoes in a breath hold time of 12 to 18 sec. The post processing of the data is performed with use of relevant software on a GE Advantage Windows 4.6 workstation according to the relevant literature. On the same day serum ferritin was measured, while LIC was evaluated using the FerriScan methodology. More specifically, images were transmitted to the FerriScan Analysis Centre in DICOM format, according to the FerriScan protocol. Images were analyzed off-site, as previously described by St Pierre *et al.*, and average LIC results were returned electronically to our center.
Results: All patients were under oral chelation therapy at the time of evaluation. Their ferritin levels were (mean±SD) 712±648 ng/ml. LIC based on T2* and R2* values were 7.81±6.32 mg/g dry weight and 302±259 Hz, respectively. LIC values estimated by FerriScan were 131±133 mmol/kg. There was a strong correlation between R2* and FerriScan values (r=0.940, p<0.0001). Both R2* and FerriScan values strongly correlated with ferritin levels (r=0.707, p<0.001 and r=0.721, p<0.001 respectively). There was no superiority of one of the MRI techniques *versus* the other regarding its correlation with serum ferritin (p=0.467).
Summary and Conclusions: This study demonstrated a very strong positive correlation between R2* values and FerriScan-determined LIC. Furthermore, we did not find any difference between the correlations of R2* or FerriScan with serum ferritin. This may be the result of very effective chelation therapies, as all our patients were under chelation treatment. However, if this result is confirmed in a larger series of patients, it could potentially lead to more timely patient results and cost savings as R2* is cheaper and easier to be performed compared to FerriScan.

E1479

25-OH VITAMIN D DOWN-REGULATES *IN VITRO* PRODUCTION OF ANTI-ERITHROCYTE ANTIBODIES IN AUTOIMMUNE HAEMOLYTIC ANAEMIA
B. Fattizzo[1,*] A. Zaninoni[1], J. Giannotta[1], A. Cortelezzi[2], W. Barcellini[1]
[1]UO Oncoematologia, Fondazione IRCCS Ospedale Maggiore Policlinico, [2]UO Oncoematologia, Fondazione IRCCS Ospedale Maggiore Policlinico e Università degli Studi, Milano, Italy

Background: Vitamin D is a well known regulator of bone and calcium balance that has multiple immune-modulating activities. Reduced levels of 25-OH vitamin D have been found in various autoimmune diseases, such as systemic lupus systemic lupus erythematous and multiple sclerosis, and its levels and supplementation did correlate with disease clinical severity.
Aims: We evaluated a) the effect of vitamin D on the *in vitro* production of anti-RBC autoantibodies in patients with autoimmune haemolytic anaemia (AIHA); b) vitamin D levels, VDR expression and immunemodulatory cytokines.
Methods: Clinical and haematological parameters, serum samples and informed consent were collected at the time of enrolment from January 2013. 25-OH vitamin D levels, VDR and IL-6, IL-10, IL-17, TNF-alfa and IFN-gamma were evaluated in 40 patients and in 40 age and sex matched healthy controls, using ELISA kits. Heparinized blood samples from 7 AIHA patients were tested for anti-RBC production in unstimulated and PWM-stimulated 48h cultures with or without vitamin D at increasing concentrations (10, 20 and 40 ng/mL). The number of immunosuppressive therapy lines (steroids, immunosuppressors, rituximab, splenectomy) were retrospectively collected.
Results: Laboratory features of the patients (15 males and 25 females; mean age 58 years; 18 CAD, 18 WAIHA and 4 DAT negative AIHA) are shown in Figure 1a. Vitamin D levels were significantly reduced in patients *versus* controls, regardless sex, age nor season at sampling. VDR was increased in patients compared to controls; IL-6, IL-10, IL-17 and IFN-gamma serum levels were higher in AIHA patients *versus* controls, whereas TNF-alfa was significantly reduced. As shown in Figure 1b, vitamin D (at 10, 20, and 40 ng/mL) exerted a dose dependent inhibition on *in vitro* production of anti-RBC antibodies, with a delta% reduction of 6, 16 and 31 in unstimulated conditions, and 2, 1, 16 in PWM-stimulated conditions, respectively. As regards treatment at sampling, 24 patients were under low dose steroids (*e.g.* 0,2-0,5 mg/Kg/day prednisone); vitamin D status was comparable in treated and untreated cases. Retrospectively, 2 cases were therapy naïve, 13 cases had been treated with steroid only, 15 cases with both steroid and a second line treatment (9 rituximab and 4 cyclophosphamyde), and 10 with more than 2 lines of therapy (4 splenectomy, 10 rituximab and 6 cyclophosphamyde). Vitamin D levels were significantly lower in patients who had been treated with 2 or more lines of therapy (1,72±1 *versus* 2,78±2 ng/mL, p=0.04).
Summary and Conclusions: Vitamin D deficiency/insufficiency was observed in patients with AIHA, both therapy naive or previously treated, with concomitant alteration of immuno-modulatory cytokine levels. Moreover, we found increased VDR expression, possibly reflecting an up-regulation due to ligand deficiency or increased shedding because of reduced receptor recruitment. Vitamin D deficiency was more evident in relapsed/refractory patients, suggesting a more pronounced immune disregulation in these cases. *In vitro* studies demonstrated a dose dependent inhibitory effect of vitamin D on the production of anti-RBC auto-antibodies even at very low concentrations and suggested that vitamin D supplementation may be useful in AIHA.

A CROSS-SECTIONAL STUDY COMPARING DIFFERENT HEMATOLOGICAL AND BIOCHEMICAL DISEASE MARKERS FOR CLINICAL DIAGNOSIS OF IRON DEFICIENCY
D. Enko[1,*] H. Wagner[2], G. Kriegshäuser[1], R. Stolba[1], G. Halwachs-Baumann[1]
[1]Institute of Laboratory Medicine, General Hospital Steyr, Steyr, [2]Department of Applied Statistics, Johannes Kepler University Linz, Linz, Austria

Background: Iron deficiency (ID) is a widespread condition throughout the world. It is considered to be one of the most prevalent forms of malnutrition. Heightened awareness of the adverse consequences of ID, such as changes in cognitive development, immune function, energy metabolism or temperature regulation, has renewed efforts to reduce the prevalence of this micronutrient insufficiency. Nevertheless, no full international consensus exists on disease markers to be used for assessing the human iron status. Furthermore, uncertainty about the optimal epidemiologic approach and the quantitative measurement of its severity still exists.
Aims: This study was conducted to compare performances of serum ferritin and transferrin saturation (TSAT) with the soluble transferrin receptor (sTfR)/log ferritin and reticulocyte hemoglobin content (CHr), also known as Thomas-plot, to serve as biomarkers in patients with ID. Furthermore, separate logistic regression models, for patients without (C-reactive protein [CRP-] value ≤0.5 mg/dl) and with acute-phase reaction (CRP-value >0.5 mg/dl) were used to predict functional ID.
Methods: This cross-sectional study was approved by the Ethical Committee of Upper Austria (Linz, Austria), and is in accordance with the current version of the Helsinki Declaration. A total of 445 hospitalized adult patients with suspected ID were investigated for complete blood cell count, ferritin, TSAT, sTfR, sTfR/log ferritin ratio and CHr (*i.e.* Thomas-plot). All in all, 31.69% (n=141) were male and 68.31% (n=304) were female. The median age was 70 years (range: 18-92). Patients below 18 years of age were excluded from the study. Descriptive statistics were computed for the categorical and metric variables and to compare different parameters and definitions of ID. Logistic regression models for the probability of functional ID (CHr <28 pg) were constructed for all 445 patients, for 225 patients without (C-reactive protein [CRP] ≤0.5 mg/dL) and 220 patients with acute-phase reaction (CRP >0.5 mg/dL).
Results: Based on the Thomas-plot analyses, 153/445 (34.38%) patients were identified with ID. When ID was diagnosed by means of serum ferritin levels <30 ng/mL and TSAT levels <20%, 105/445 (23.60%) and 215/445 (48.31%) patients were identified with ID, respectively. Based on the logistic regression models for the probability of functional ID (CHr <28 pg), the sTfR/log ferritin ratio showed the best positive predictive values (PPV) (62.50 and 64.41%) to indicate functional ID in patients without as well as with acute-phase reaction

compared to sTfR (58.14 and 61.67%), ferritin (32.50 and 32.86%) and TSAT (26.74 and 42.86%).
Summary and Conclusions: In conclusion, the prevalence of ID in the study population investigated here varied with marker selection and its definition. Ferritin and TSAT demonstrated weaknesses in the detection of functional ID (CHr <28 pg). Regarding the results of this work, for routine laboratory diagnosis, however, we suggest to use Thomas-plot analyses in combination with ferritin single-marker measurements to efficiently identify patients with ID.

E1481

CONGENITAL DYSERYTHROPOIETIC ANEMIA TYPE III AND PRIMARY HEMOCHROMATOSIS; COEXISTENCE OF MUTATIONS IN KIF23 AND HFE
M. Liljeholm[1,*] A.-L. Vikberg[2], I. Golovleva[2], A. Wahlin[1]
[1]Hematology, Department of Radiation Sciences, [2]Department of Biosciences/Clinical and Medical Genetics, University of Umea, Umea, Sweden

Background: Congenital dyserythropoietic anemia type III, CDA III, is a very rare hereditary disorder. The disease is caused by mutation c.2747C>G, p.P916R in *KIF23,* a protein with crucial role in cytokinesis, the final step of mitosis. In the Västerbotten CDA III family, 48 individuals in 6 generations have been diagnosed with CDA III. Secondary hemochromatosis, a clinical problem in CDA I and II, has not been reported in CDA III. Absence of iron accumulation in CDA III has been explained by intravascular hemolysis, leading to urinary loss of iron. However, we have recently seen that some individuals in the Västerbotten family, both CDA III positive and negative ones, have elevated ferritin levels. The prevalence of primary hemochromatosis caused by mutations in the *HFE* gene is high in northern Europe.
Aims: To study the coexistence and clinical appearance of mutations in *KIF23* c.2747C>G and *HFE* c.845G>A and c.187C>G in the Västerbotten family.
Methods: DNA from 37 CDA III positive individuals and 21 of their CDA III negative siblings, was examined by PCR-TaqMan genotyping. *HFE*-genotype was established concerning *HFE* c.845G>A and *HFE* c187C>G.
Results: Heterozygous mutation of *HFE c.845G>A* or *c.187C>G* was found in 18 CDA III positive individuals. Both mutations were found in six CDA III patients. Nine of the CDA III negative siblings carried heterozygous mutations, and two homozygous mutations of either of the examined loci of the *HFE* gene. Two were found to have heterozygous mutations of both loci. Treatment with phlebotomy to normalize ferritin and transferrin iron saturation (TSAT) was indicated in the CDA III negative person with homozygous mutation of *HFE* c.845G>A, in two CDA III positive individuals with single heterozygous mutations (ferritin 1084 ug/L and 987 ug/L, TSAT 80% and 100%) and in one CDA III positive patient with coexistence of *HFE* c.845G>A and c.187C>G (ferritin 700 and TSAT >55%). So far, phlebotomies have been performed without problems in spite of anemia. All patients were screened for diabetes. One CDA III positive male with heterozygous *HFE* c.187C>G (ferritin 1084 ug/L, TSAT 80%) was diagnosed with type II diabetes mellitus.
Summary and Conclusions: Mutations in one or two of the examined *HFE*-loci were found in 65% of CDA III positive cases and in 62% of their CDA III negative siblings. One CDA negative female with homozygous *HFE* c.845G>A needed treatment with phlebotomy. Three patients with CDA III, heterozygous *HFE*-mutations, and laboratory signs of iron overload have started treatment with phlebotomy. Heterozygous mutation of the *HFE*-gene seems to be sufficient to generate pathologic iron overload when occurring concomitantly with a haemolytic disorder such as CDA III. Screening for primary hemochromatosis should be performed in patients with congenital dyserythropoietic anemia.

E1482

ERYTHROCYTE-DERIVED MICROVESICLE RELEASE DURING *EX-VIVO* CARDIOPULMONARY BYPASS PROCEDURES
R. Huisjes[1,*] K. de Vooght[1], C. Lau[1], T.-J. van Laar[2], M. de Jong[2], M. Buijsrogge[3], W. van Solinge[1], R. van Wijk[1], R. Schiffelers[1]
[1]Department of Clinical Chemistry and Haematology, [2]Division of Heart & Lungs, [3]Department of Thoracic Surgery, UMC Utrecht, Utrecht, Netherlands

Background: Cardiopulmonary bypass procedures (CPB) are commonly used during heart surgery. The stressful conditions that this procedure imposes on blood cells may cause damage leading to loss of cellular contents or vesiculation of the cells. In this study we examined the effects of CPB in both an ex-vivo and in-vivo set-up on erythrocyte behavior and erythrocyte-derived microvesicle release.
Aims: To study the effects of CPB on deformability and phosphatidylserine (PS) exposure of erythrocytes, the release of microvesicles (MVs) during this procedure, and their ability to induce thrombin generation.
Methods: We investigated MV formation, in particular erythrocyte-derived MVs, during ex-vivo CPB. In this set-up 150 ml of heparinized blood from 3 healthy volunteers was hemodiluted and pumped through a membrane oxygenator back to the venous blood reservoir. Osmotic gradient ektacytometry was performed to study the deformability of erythrocytes after ex-vivo CPB. After ex-vivo CPB M*Vs* were purified by differential centrifugation from platelet-free plasma. Nanoparticle Tracking Analysis (NTA), Western blot analysis, and hemoglobin measurements were carried out to confirm the presence of M*Vs* in whole blood from healthy volunteers in this ex-vivo CPB model. The isolated M*Vs* after ex-vivo CPB were added to an automated thrombin generation test to determine its effects on blood coagulation, whereas in this test the formed thrombin is able to split a substrate to a fluorescent product. Microvesicle formation after routine CPB with patients (n=30) samples was studied similarly as after ex-vivo CPB.
Results: The number of erythrocyte-derived M*Vs* after ex-vivo CPB increased concomitantly with both the number of microcytic erythrocytes and PS expression on erythrocytes as determined by flow cytometry. Despite this vesiculation, deformability of the erythrocytes as determined by osmotic gradient ektacytometry did not significantly alter during the ex-vivo CPB procedure. The formed M*Vs* were found to be able to stimulate thrombin formation, thereby highlighting the potential contribution of M*Vs* on side effects of CPB. Remarkably, except for one sample, patient blood samples obtained after CPB contained free hemoglobin but did not contain erythrocyte microvesicles (MVs) (Figure 1).

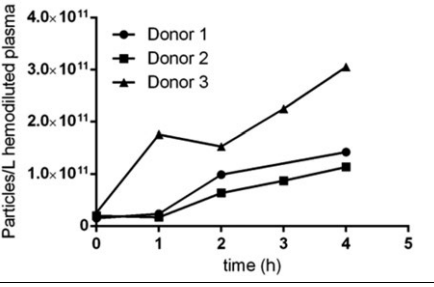

Figure 1.

Summary and Conclusions: In this study we show that hemoglobin containing erythrocyte-derived M*Vs* are generated during an ex-vivo CPB procedure. These nascent M*Vs* are able to induce thrombin generation, we therefore hypothesize that the reported diffuse inflammation after CPB could, at least partly, be mediated by vesicles formed in blood. Patients samples after CPB did not contain erythrocyte-derived MVs, possibly indicating high-clearance rates of M*Vs* in patient blood, suggesting that patients are at risk when clearance systems (*e.g.* macrophages) get saturated.

E1483

HS-TROPONINE T RELATES WITH MYOCARDIAL IRON OVERLOAD IN TRANSFUSION DEPENDENT THALASSEMIC PATIENTS
C. Vetro[1,*] A. Meloni[2], R. Rosso[1], I. Monte[3], M.G. Neri[2], G. Colletta[1], M. Romeo[1], B.ximenes[1], A. Romano[1], C. Conticello[1], F. Di Raimondo[1], A. Pepe[2]
[1]A.O. "Policlinico-Vittorio Emanuele", University of Catania, Division of Haematology, Unit of Thalassemia, Catania, [2]Fondazione G. Monasterio CNR-Regione Toscana, CMR Unit, Pisa, [3]A.O. "Policlinico-Vittorio Emanuele", University of Catania, Cardio-Torax-Vascular Department, Catania, Italy

Background: Myocardial iron overload (MIO) is the main cause of Heart failure (HF) in β-thalassemia major (β-TM) patients. The transfusion-related hemosiderosis leads to myocardial damage thus influencing the clinical outcome. Measurement of high sensitive-troponine-T (hsTnT) provides diagnostic and prognostic information in patients with coronary artery disease, heart failure and even in the general population. No data are available in literature about hs-ThT and MIO in transfusion dependent thalassemia (TDT) patients.
Aims: We aimed to evaluate the relationship between MIO quantified by Magnetic Resonance Imaging (MRI)T2* and hs-ThT serum levels in a consecutive cohort of 50 TDT patients enrolled into the MIOT network.
Methods: This pilot study recruited 50 consecutive TDT patients from June 2013 to January 2014 at Division of Haematology, Unit of Thalassemia, University of Catania, Italy. Male/Female ratio was 1:1; Median age was 32 years (range 16-48). All of them were suffering from β-TM, except 2 male patients suffering from Thalassemia Intermedia with Major-like phenotype. Myocardial iron overload (MIO) was quantified by a multislice multiecho T2* sequence (Meloni *et al.*, Int J Cardiol, 2014). Biventricular function parameters were evaluated by cine images (Marsella M *et al.* Haematologica 2011). HF was defined if clinically evident signs or symptoms were present. Raw data were expressed as mean±standard deviation. Comparison between groups was performed using the Mann-Withney test. Odds ratio were calculated with Chi^2 test. Correlation was performed using the Spearman correlation. Sensitivity and specificity were calculated with Receiver operating characteristic (ROC) analysis. P<0,05 was considered as statistically significant.
Results: Median value of hs-TnT was 3,925 ng/L, ranged between 3 and 60,3 ng/mL (normal range 0-14). Overall, 5 patients presented levels of hs-TnT greater than 14 ng/mL. 6 patients presented Heart Failure (HF), 1 with augmented levels of hs-TnT. In our population we confirmed that both the presence of a global Heart T2* <20 msec (Odds Ratio 15,6; 95%CI 2,25-108,12; p<0,0001) and the number of cardiac segments with T2*<20msec was related

with HF (Table 1). Presence of an HF related with higher levels of hs-TnT with a cutoff value between 4,23 ng/L (sensitivity: 100%, specificity: 65,12%) and 5,2 (sensitivity: 83,3%, specificity: 67,44%) (AUC:0,7; p<0,01) (Figure 1). A relationship was found between levels of hs-TnT and the number of myocardial segments with T2* <20 msec (p=0,011), but not with the global Heart T2* (p=0,85). However, clustering patients according to the presence of severe cardiac siderosis (global heart T2*<20 msec), patients with significant iron overload had levels of hs-TnT significantly greater than patients with global T2* ≥20 (5,74 ng/mL±9,15 *vs* 10,5±5 ng/mL; p<0,0001). 38 patients underwent biventricular function evaluation. Of these, 22 (57,9%) had a left, right or biventricular dysfunction. In these patients there was a trend toward higher levels of hs-TnT compared to patients without impairment (8,85±12,52 *vs* 4,49±4,19), without reaching the statistical significance (p=0,068).

Table 1. HF *vs* occurrence of cardiac siderosis (defined as T2*<20msec). Comparison between groups (Mann-Withney test).

	Patients with HF	Patients without HF	p
	(N=6)	(N=44)	
Global heart T2* (ms)	35.55±10.58	16.89±5.57	0.001
Number of segments with T2* <20 ms	2.48±4.47	11.17±4.22	0.001

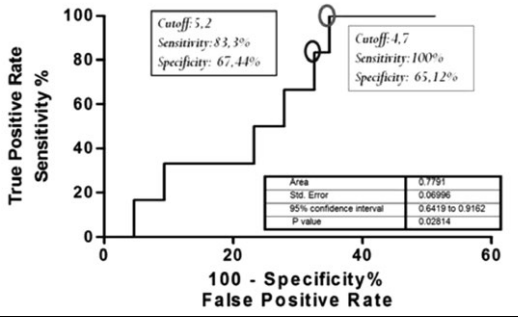

Figure 1.

Summary and Conclusions: Our findings suggest that in TDT patients, hs-TnT would be a sensitive index of myocardial impairment consequent to iron overload.

E1484

COMPARISON OF IRON CHELATION EFFECTS OF DEFEROXAMINE, DEFERASIROX, AND COMBINATION OF DEFEROXAMINE AND DEFERIPRONE ON LIVER AND CARDIAC T2* MRI IN THALASSEMIA MAIOR

S. Ansari[1,*] G. Miri Ali Abadi[2], A. Azarkeivan [3]
[1]Hematology, Iran University, Tehran, [2]Hematology, Zahedan University, Zahedan, [3]Hematology, Blood Transfusion Research, Tehran, Iran

Background: Cardiac complications due to chronic transfusion-induced iron overload are the most common cause of death in patients with thalassemia major. Successful treatment with iron chelators is required to prevent iron deposition in various tissues.
Aims: The aim of this study is to compare iron chelation effects of deferoxamine, deferasirox, and combination of deferoxamine and deferiprone on cardiac iron load in these patients measured by T2* MRI.
Methods: 108 patients with thalassemia major aged over 10 years who had iron overload in cardiac T2* MRI assay, were studied in terms of iron chelators effectiveness and efficacy on reduction of myocardial siderosis. 104 completed the treatment. The first group received only DFO, the second group only DFX, and the third group a combination ofDFO and deferiprone. Myocardial iron was measured at baseline and 12 months after the beginning of treatment through T2* MRI technique.
Results: In the DFO group, myocardial T2* was increased from 12.0±4.1 ms at baseline to 13.5±8.4 ms at 12 months (p=0.10). Significant improvement was observed in myocardial T2* of theDFX group from 13.0±4.5 ms at baseline to 17.5±7.1 ms at 12 months (p<0.001). In the combined treatment group, myocardial T2* was increased from 11.6±3.8 ms at baseline to 16.8±9.9 ms at 12 months (p=0.001). These differences among the three groups were not significant at the 12 months (p=0.09). A significant improvement was observed in liver T2* at 12 months compared to baseline in the deferasirox group (p=0.01) and the combination group (p=0.005), while this improvement was not significant in the deferoxamine group (p=0.72). The most common reported adverse effect in all three groups was mild and transient gastrointestinal side effects.
Summary and Conclusions: In comparison to deferoxamine monotherapy, combination therapy with deferoxamine and deferiprone and deferasirox monotherapy have a significant impact on reducing iron overload and improvement of myocardial and liver T2*.

MRI PROSPECTIVE SURVEY ON CARDIAC AND HEPATIC IRON AND CARDIAC FUNCTION IN TRANSFUSION-DEPENDENT THALASSEMIA INTERMEDIA PATIENTS TREATED WITH DESFERRIOXAMINE, DEFERIPRONE AND DEFERASIROX

A. Meloni[1], M.E. Lai[2], M.G. Neri[1], C. Argento[3], A. Pietrapertosa[4], A. D'Ambrosio[5], C. Salvatori[6], S. Renne[7], E. Chiodi[8], V. Positano[1], A. Pepe[1,*]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Ospedale Microcitemico, Ospedale Microcitemico, Cagliari, [3]Centro di Talasssemia, Ospedale San Giovanni Di Dio, Agrigento, [4]Servizio Regionale Talassemie, Policlinico di Bari, Bari, [5]UOS di Emato-Oncologia Pediatrica, AOU Senese Policlinico S. Maria alle Scotte, Siena, [6]U.O.S. Sistemi informativi (UOSI), Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [7]Struttura Complessa di Cardioradiologia-UTIC, P.O. "Giovanni Paolo II", Lamezia Terme, [8]Servizio Radiologia Ospedaliera-Universitaria, Arcispedale "S. Anna", Ferrara, Italy

Background: Few studies have evaluated the efficacy of iron chelation therapy in thalassemia intermedia (TI) patients.
Aims: Our study aimed to prospectively assess by quantitative Magnetic Resonance imaging (MRI) the efficacy of the three available chelators in monotherapy in transfusion dependent (TD) TI patients.
Methods: Among the 325 TI patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) network, we selected 103 TI patients TD with an MRI follow-up (FU) study at 18±3 months who had been received one chelator alone between the two MRI scans. Iron overload was assessed by the T2* multiecho technique. Hepatic T2* values were converted into liver iron concentration (LIC) values. Biventricular function parameters were quantified by cine SSFP sequences.
Results: Three groups of patients were identified: 27 patients (13 females, mean age 40.12±10.31 years) treated with desferioxamine (DFO-mean dosage 37.52±8.69 mg/kg/die**),** 23 patients (14 females, mean age 34.73±10.67 years) treated with deferiprone (DFP-dosage 71.70±14.46 mg/kg/die) and 14 patients (9 females, mean age 36.63±10.92 years) treated with deferasirox (DFX-mean dosage 27.75±5.04 mg/kg/die). Excellent/good levels of compliance were similar in the DFO (92.6%), DFP (100%) and DFX (100%) groups (P=0.345). The mean starting age of regular transfusion was 14.73±15.89 years. At baseline in DFO group two patients (7.4%) showed a global heart T2*<20 ms and one of them showed no cardiac iron at the FU. At baseline in DFP group two patients (8.7%) showed a global heart T2*<20 ms and one of them showed no cardiac iron at the FU. All the 5 patients (35.7%) under DFX therapy with pathological global heart T2* at the baseline remained at the same status at the FU. The percentage of patients who maintained a normal global heart T2* value was comparable for DFO (100%), DFP (100%) and DFX (88.9%) groups (P=0.164). Among the 46 patients with hepatic iron at baseline (MRI LIC ≥3 mg/g/dw), the reduction in the MRI LIC values was significant only in the DFO group (DFO: -3.39±6.38 mg/g/dw P=0.041; DFP: -2.25±6.01 mg/g/dw P=0.136 and DFX: -0.36±5.56 mg/g/dw P=0.875). The decrease in MRI LIC values was comparable among the groups (P=0.336). The number of patients with a MRI LIC<3 mg/g/dw went up from 10 (37%) to 11 (40.7%) in the DFO group, from 6 (26.1%) to 8 (34.8%) in the DFP group and from 2 (14.3%) to 8 (57.1%) in the DFX group. The percentage of patients who maintained a normal MRI LIC value was comparable for DFO (90%) *vs* DFP (50%) and DFX (100%) groups (P=0.191). In no group there was a significant change in biventricular volumes, ejection fractions and left ventricular mass index (Figure 1).

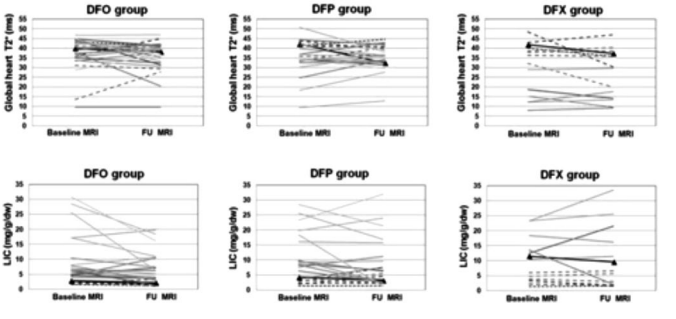

Figure 1.

Summary and Conclusions: Prospectively in transfusion-dependent TI patients at the dosages used in the clinical practice, DFO and DFP showed 100% efficacy in maintaining a normal global heart T2* value while DFX had 100% efficacy in maintaining a normal LIC value. Further prospective studies involving more patients with iron at the baseline are needed to establish which is the most effective drug in reducing iron levels.

E1486

TISSUE DOPPLER IMAGING IN CHILDREN WITH SICKLE CELL DISEASE: EVALUATION OF PULMONARY HYPERTENSION

I. Youssry[1,*] A. El Sisi[2], C. Ghobrial[1], M.F. Shaltout[2]
[1]Hematology &BMT unit, Pediatric department, [2]Cardiology unit, pediatric department, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: The prevalence of Pulmonary Hypertension (PHT) in young children with sickle cell disease (SCD) is unclear. However, early detection and intervention of this potentially lethal problem may reverse the problem and prevent its serious consequence. For diagnosing PHT in SCD, an elevated tricuspid regurgitant velocity (TRV) ≥2.5 m/s appears to have limitations in specificity. However, new parameters characteristic of the right ventricular (RV) function in patients with PHT by means of Tissue Doppler Imaging (TDI) may increase the probability of a correct diagnosis of PHT.
Aims: Our aim was estimating the prevalence of PHT in children with SCD and to assess the clinical, laboratory and cardiac parameters for correct diagnosis of PHT.
Methods: fifty SCD children with mean age 11.28±7.48 years and fifty healthy control were enrolled. Various clinical and laboratory evidence of hemolysis and inflamation were assessed. Conventional echocardiography and Tissue Doppler Imaging were done for all patients and control. Pulmonary artery systolic pressure (PASP) was measured using TRV; the maximal transtricuspid gradient was calculated according to the simplified Bernoulli equation.
Results: The frequency of PHT was 18%, 9/50 patients had TRV ranged from 2.51 to 3.59 m/s. The TDI showed evidence of diastolic dysfunction at the right ventricle as evidenced by significant increase in Tricuspid Es, As and Es/As in 10 patients (20%). Nine out of these10 patients had TRV ranged from 2.51 to 3.59 m/s. Cases with PHT showed significant increase in aortic root diameter, LVEDD and PA diameter than cases without PHT, p-value=0.024, 0.000, 0.000 respectively. Cases with PHT showed significant increase in RVET, PAT/RVET, IVRT-LV, TRV and PASP than cases without PHT, p-value=0.005, 0.005, 0.001, 0.000, 0.000 respectively. The TDI showed significant increase in Tricuspid Es, As and Es/As in cases with PHT than cased without PHT, p-value=0.019, 0.004 and 0.001 respectively. Furthermore, cases with PHT showed significant high systolic blood pressure, high LDH level, high reticulocytic count, high builirubin level, low Hb and high platelet count.
Summary and Conclusions: Tissue doppler imaging combined with Echocardiography may be useful in diagnosing PHT.

E1487

TOWARD BETTER PATHOPHYSIOLOGICAL CHARACTERIZATION AND THERAPEUTIC SOLUTION IN BETA-THALASSEMIA TRAIT PATIENTS WITH IRON OVERLOAD. PRELIMINARY REPORTS FROM AN ONGOING STUDY

F. Busti[1,*] N. Campostrini[1], S. Badar[1], A. Ferrarini[2], L. Xumerle[2], A.C. Giuffrida[3], G. De Matteis[4], R. Manfredi[5], P. Capelli[6], A. Castagna[1], M. Delledonne[2], O. Olivieri[1], D. Girelli[1]
[1]Department of Medicine, [2]Department of Biotechnology, University of Verona, [3]Blood Transfusion Center, University Hospital, [4]Department of Life and Reproduction Science, [5]Department of Radiology, [6]Department of Pathology, University of Verona, Verona, Italy

Background: A certain degree of iron overload (IO) is sometimes seen in subjects with β-thalassemia trait (βTT), a mild form of non-transfusion-dependent β-thalassemia. The pathogenesis is unclear, but recently a population study in Sri Lankan children has shown that βTT is characterized by mild hepcidin suppression due to increased erythropoietic activity (Jones E, Blood 2015). In individual patients, this may be further aggravated by genetic (*i.e.* mutations in hemochromatosis genes) or acquired factors (*e.g.* alcohol abuse or non-alcoholic liver diseases). Treatment of IO in βTT is problematic, since "standard" large-volume phlebotomies are not feasible in mildly anemic subjects, as well as the lack of approval of oral iron chelators and of specific guidelines. Deferoxamine (DFO) is the only approved therapy, but it is poorly applicable because of inconvenient parenteral administration and side effects. Sporadic case reports have suggested the use of "mini-phlebotomies" in βTT patients with IO, but feasibility and efficacy of such approach has not been evaluated in patients' series.
Aims: This study has been designed to better characterize factors involved in the development of relevant IO in βTT patients, and to evaluate feasibility and efficacy of mini-phlebotomies to remove IO in this condition.
Methods: Up to now we have enrolled 17 consecutive βTT patients with IO (14 males and 3 females, mean age 58 years) addressed to our tertiary referral center for Iron Disorders in Verona (northern Italy). IO was documented through increased ferritin levels (in most cases >1000 ng/ml, in repeated assays), and either MRI or liver biopsy when indicated. All subjects gave written informed consent. The study plan includes collection of detailed information about clinical history through a structured questionnaire, measurement of serum hepcidin by in-house mass spectrometry-based method, and a comprehensive genetic analysis of the five hemochromatosis genes (HFE, HFE2, HAMP, TFR2, SLC40A1) through next-generation-sequencing (NGS).
Results: Mean Hb values were not uniform (9.5-13.5 g/dl), in agreement with the known phenotypic variability of the βTT. A substantial alcohol consumption (>100 g/day) appears a common acquired cofactor in βTT patients with IO, while NGS (up to now performed in 13/17 patients) did not reveal potentially pathogenic variants out of the known H63D in HFE. Nine patients started treatment with "mini-phlebotomies" and four of them have reached the iron depletion. None of the patients experienced a worsening of anemia during the treatment.
Summary and Conclusions: In our region, the occurrence of clinically significant iron overload is not rare in βTT subjects, and is likely multifactorial in most cases, with high alcohol intake and the H63D variant appearing as the most frequent cofactors contributing to further hepcidin suppression. Preliminary results suggest mini-phlebotomies as a valuable approach for this peculiar category of patients.

E1488

DIAGNOSIS OF FUNCTIONAL IRON DEFICIENCY: HEPCIDIN AS NOVEL BIOMARKER *VERSUS* CONVENTIONAL CLINICAL BIOMARKERS

D. Enko[1,*] H. Wagner[2], G. Kriegshäuser[1], R. Stolba[1], G. Halwachs-Baumann[1]
[1]Institute of Laboratory Medicine, General Hospital Steyr, Steyr, [2]Department of Applied Statistics, Johannes Kepler University Linz, Linz, Austria

Background: Hepcidin is a peptide hormone, which is produced in the liver and excreted in the kidneys. It is considered as a key regulator of human iron homeostasis, lowering the serum iron in the blood circulation by binding and down regulating the iron exporter protein ferroportin in the basolateral site of duodenal enterocytes and reticuloendothelial macrophages. High hepcidin serum-levels decrease the iron transport out of the enterocytes as well as the ability of macrophages to export recycled iron from senescent enterocytes.
Aims: The aim of the present study was to investigate, whether hepcidin is a useful additional clinical biomarker to reflect the actual human iron status, especially functional iron deficiency (ID), as a state of inadequate iron supply to erythropoietic precursor cells in the bone marrow despite the presence of storage iron in the hepatocytes/macrophages.
Methods: This study was approved by the Ethical Committee of Upper Austria (Linz, Austria), and is in accordance with the current version of the Helsinki Declaration. All in all, 233 consecutive hospitalized adult patients with suspected ID, were included. In total, 33.91% (n=79) were male and 60.09% (n=154) were female. The median age was 69.0 (range: 20.0-93.0) years. Patients below 18 years of age were excluded from the study. All subjects were investigated for hepcidin, reticulocyte hemoglobin content (CHr), soluble transferrin receptor (sTfR)/log ferritin ratio (*i.e.* Thomas plot), sTfR, ferritin, transferrin saturation (TSAT), C-reactive protein (CRP) and for complete blood cell count. The hepcidin measurements were performed with the recently launched European Community (CE)-marked enzyme-linked immunoabsorbent assay (ELISA) (Hepcidin-25 bioactive ELISA; DRG Instruments GmbH, Marburg, Germany). Functional ID was defined as a CHr <28 pg. Separate logistic regression models were calculated with all potential biomarkers to evaluate and compare the predictive performance with respect to functional ID in patients without (CRP ≤0.5 mg/dL) and with (CRP >0.5 mg/dL) acute-phase reaction, respectively.
Results: The hepcidin measurements correlated with parameters of iron metabolism. There was a positive correlation with serum ferritin (p <0.0001, Pearson correlation coefficient 0.2608) and TSAT (p=0.0349, Pearson correlation coefficient 0.1383), and a negative correlation with transferrin (p <0.0001, Pearson correlation coefficient -0.6021), sTfR (p <0.0001, Pearson correlation coefficient -0.3736), and iron (p=0.1617, Pearson correlation coefficient -0.0920). There was also a positive correlation between CRP and hepcidin (p <0.0001, Pearson correlation coefficient 0.2581). One hundred seventeen patients with CRP >0.5 mg/dL showed a distinctly higher hepcidin median value (35.60 [range: 4.27-80.03] ng/mL) as compared to 116 patients with CRP ≤0.5 mg/dL (18.55 [range: 3.77-73.01] ng/mL). With respect to functional ID, sTfR/log ferritin ratio and sTfR were of better positive predictive value (PPV) (sTfR/log ferritin ratio: 58.33 and 70.83%; sTfR: 60.00 and 60.00%) than when compared to hepcidin (PPV: 37.74 and 42.86%) and ferritin (PPV: 27.54 and 46.15%) in both subgroups.
Summary and Conclusions: In the logistic regression modelling and when compared with the sTfR/log ferritin ratio or the sTfR measurements, hepcidin as well as ferritin, both biomarkers are known as acute-phase reactants, were only of low predictive value to reflect functional ID.

E1489

CORRELATION OF GENOTYPE WITH PHENOTYPE IN BETA THALASSAEMIA INTERMEDIA IN SRI LANKA

S. Perera[1,*] I. Silva[2], M. Hapugoda[1], N. Wickramaratne[3], I. Wijesiriwardena[4], D. Efremov[5], C. Fisher[6], D. Weatherall[6], A. Premawardhena[1]
[1]Faculty of Medicine, University of Kelaniya, Kelaniya, [2]Hemal's Thalassaemia Care Unit, North Colombo Teaching Hospital, Ragama, [3]Faculty of Applied Sciences, Sabaragamuwa University of Sri Lanka, Belihuloya, [4]Faculty of Medicine, University of Sri Jayawardenapura, Nugegoda, Sri Lanka, [5]Molecular Hematology Unit, International Centre for Genetic Engineering & Biotechnology (ICGEB), Rome, Italy, [6]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom
Background: Previous studies on thalassaemia in Sri Lanka revealed that a

third of patients attending thalassaemia clinics in Sri Lanka have intermedia phenotype and has shown to be presented with a wide phenotypic diversity. The majority of them have Hb E beta thalassaemia, but a significant minority has been shown to have co-inheritance of beta thalassaemia minor with extra alpha globin genes.
Aims: In our previous study we have studied a group of beta thalassaemia intermedia patients without E beta thalassaemia for the molecular basis of intermedia phenotype. In this study we investigated the possibility of correlating the preliminary genetic analysis results in our thalassaemia intermedia study cohort with the phenotype with aiming to unravel phenotypic diversity with genotypic heterogeneity.
Methods: Fifty (50) unrelated thalassaemia intermedia patients were identified from the five main thalassaemia centers in the Island with mostly presented to the adult thalassaemia clinic at Ragama. Clinical severities of the intermedia patients were assessed and they were categorized into "mild", moderate and severe phenotypic groups according to the clinical severity. DNA analysis of the beta globin gene, alpha globin gene and SNPs of Hb F regulators were performed by Southern blot analysis, GAP PCR, MLPA and DNA sequence analysis of PCR products.
Results: Seventeen (34%), of the total thalassaemia intermedia population were homozygous or compound heterozygous for beta mutations. Five of the homozygotes carried two mild beta alleles including a rare promoter mutation-90 C>T, Hb variant alleles of Hb G-Szuhu and Hb G-Coushatta. Nine inherited with two sever beta alleles with alpha gene deletions either one or two. Of the other three individuals who carried two beta alleles with normal alpha gene, one had single nucleotide polymorphismxmn I +/+. Individuals who had inherited with two mild beta alleles and a sever mutation with Hb G-Szuhu and Hb G-Coushatta almost invariably had a mild phenotype. Those individuals who had inherited two severe beta alleles with alpha gene deletions invariably had a severe phenotype. It was unable to explain the phenotype in two individuals in this group with the existing genetic data. Thirty three (66%) of the total thalassaemia intermedia population were heterozygous for beta mutations IVSI-5 G>C (n=12), IVSI-1 G>A (n=11) being the commonest. Twenty eight of the heterozygotes carried excess alpha genes and had a mild to moderate phenotype. In this group of individuals who had inherited with single beta allele with normal alpha genes, the genetic study could not explain the phenotype in five individuals.
Summary and Conclusions: Thalassaemia intermedia patients in Sri Lanka showed a considerable heterogeneity both phenotypically and genotypically. The clinical outcome of our thalassaemia intermedia patients were mostly explained by the genotypes linked to the alpha and beta gene cluster. About three fourth of the cases found with beta thalassaemia intermedia phenotypic had mutations on the alpha and beta globin gene clusters. Co-inheritance of additional alpha globin genes and beta thalassaemia minor was accounted to be the most common finding for their clinical presentation. However in a minority, the existence of other causative genetic determinants remains to be molecular defined.

E1490

EVALUATION OF EMERGENCY CARE FOR ADULT SICKLE CELL PATIENTS: A MONOCENTRIC STUDY

M.-A. Azerad[1,*] M.Q. Tran Thi[2], T. Besse- Hammer[3], B. Dumoulin[3], S. Depauw [4], B. Dohet[1], T. Preseau[2], A. Efira[1]
[1]Hematology, [2]Emergency Care Unit, [3]Clinical Research Unit, [4]Psychology Unit, CHU Brugmann, Brussels, Belgium

Background: Pain relief is the key point for patients admitted for sickle cell crisis in emergency care units.We present a prospective monocentric trial aiming to improve sickle cell patient support in our hospital
Aims: The primary objective was the evaluation of the pain relief in adult patients admitted for sickle cell crisis in our emergency department. Upon admission, a standard protocol based on international and local guidelines with hyper-hydration and high doses of intravenous morphine was used. Morphine was administered according to patient's EVA (Analogic visual Evaluation) pain scale. We in parallel conducted a hetero-evaluation of the patient's pain by the nursing team. The secondary objectives were the evaluation of morphine dose required for pain relief, patient's satisfaction and the length of hospitalization. This study also comprised of an ancillary part aiming to determine a predictive score of crisis severity based on standard laboratory parameters.
Methods: This observational prospective mono centric study was approved by the local ethics committee. Written informed consent was obtained from patients during routine hematology follow up visits or more rarely in the emergency care setting. Patients were enrolled from February 2013 until February 2015. Pain was evaluated through EVA upon admission, after 1 hour, 3h, 6h and then every 6 hour until pain relief. Patient satisfaction was analyzed with a questionnaire developed by our psychologist and graded from 1 (very bad) to 5 (very good).
Results: 104 observations were obtained for 51 patients as some patients had been hospitalized more than once. Mean waiting time before the start of treatment was 18.6 minutes. More than 65% of patients waited less than 10 minutes. Morphine doses used were less than those mentioned in literature and in our local guidelines. Pain was systematically under scored by the nurse team (hetero EVA). Unexpectedly, women received significantly (p<0.001) more morphine than men. Mean patient's satisfaction score was good (3.8).There was a significant correlation between morphine dosage, waiting time until start of treatment and patient satisfaction. We observed an improvement in patient satisfaction as the study moved along. Analysis of laboratory data and length of hospitalization are still ongoing.
Summary and Conclusions: The main aim of our study was to reinforce collaboration between the different teams taking care of patients in an emergency care setting as well as during hospitalization. This multidisciplinary approach allows a dramatic improvement in patient satisfaction during the study. A significant inverse correlation was found between morphine dosage, waiting time until treatment and patient satisfaction. We observed that continuous education of medical and paramedical staff is mandatory to improve quality of care in this case.

E1491

IMPROVING MACROCYTOSIS DIFFERENTIAL DIAGNOSIS BY RDW-SD

T. Nascimento[1,*] J.R. Pinheiro[1], R. Barreira[1], P. Ferreira[1], J.P. Ferreira[1], A.T. Simões[1], J. Azevedo[1], S. Ramon[1], J.C. Almeida[1], M.L. Ribeiro[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Macrocytosis is defined as a mean corpuscular volume (MCV) >100fL. Blood cells morphology and biochemical parameters are essential to differentiate megaloblastic anemia (MA) from other causes of macrocytosis.The red cell distribution width (RDW) evaluates the degree of anisocytosis. It can be expressed as a coefficient variation of the MCV (RDW-CV).
Aims: The objectives of this study were to compare the sensitivity of RDW-CV and RDW-SD to detect anisocytosis, in the presence of macrocytosis, and their impact in the differential diagnostic of MA.
Methods: We analyzed 152 samples with macrocytosis (78 with anemia; 74 without; 26 suggestive of MA). They were divided in 8 groups: on chemotherapy, hydroxyurea, alcoholic/hepatic disorders, hemolytic anemia, aplastic anemia, myelodisplastic syndrome, hypothyroidism, and other disorders. The samples were processed in HORIBA, Abbott and Sysmex instruments, in order to monitor the reproducibility and the ability to screen out of range values. The reference values were calculated for each equipment (150 blood donors). Data were analyzed with descriptive statistics, t-student, ANOVA, ROC (GraphPad Prism5).
Results: The objectives of this study were to compare the sensitivity of RDW-CV and RDW-SD to detect anisocytosis, in the presence of macrocytosis, and their impact in the differential diagnostic of MA. Reference values span from the minimum to maximum obtained values: RDW-CV 12.03-14.49%; RDW-SD 36.5-46.68fL. Hemoglobin(Hb) values were reproducible (p=0.8727), but MCV, RDW-CV and RDW-SD differ significantly (p<0.0001). Patients with anemia: Hb median 10.2g/dL[5.4;11.7]; MCV105.8±7fL, RDW-CV14.9±2.4% and RDW-SD56.9±9.8fL; patients without anemia: Hb median 13.5g/dL[12;16.8], MCV103±5.4fL, RDW-CV13.3±1.2% and RDW-SD50.2±5.1fL. It was found more cases of MA in "other disorders" group (n=10/63), followed by "hydroxyurea" (n=7/20), and "chemotherapy" (n=4/28). MA and non-MA parameters means showed no significant differences (p>0.05). However, RDW-CV were borderline (MA 14.9±2; non-MA 15.8±3.1) and RDW-SD were elevated (57.3±11.1; 60±11.8, respectively). Regarding to ROC analysis, it was found a better anisocytosis discrimination for RDW-SD, since it presented a higher area under the curve (AUC) than RDW-CV (0.97 and 0.79, respectively). The best cut off for RDW-CV was 14.45% (sensitivity-84.8%; specificity-82.69%) and for RDW-SD was 44.35fL, with improved results for sensitivity and specificity (93.75% and 94.23%, respectively).
Summary and Conclusions: In macrocytosis, RDW-SD is more sensitive than RDW-CV, improving anisocytosis discrimination. For this reason, RDW-SD may become helpful when MA is considered, as it triggers, earlier than RDW-CV, an alert that requires further actions, like blood smear review and vitamin B12/folic acid quantification.

E1492

PROSPECTIVE STUDY ON THE EFFECT OF FOK-I GENE POLYMORPHISM ON BONE HEALTH IN YOUNG PATIENTS WITH B-THALASSAEMIA MAJOR

M. Dimitriadou[1], A. Christoforidis[1], L. Fidani[2], M. Economou[3,*] V. Perifanis[3], A. Teli[3], E. Vlachaki[3], G. Katzos[1]
[1]1st Pediatric Department, [2]Medical Biology and Genetics, School of Medicine, Aristotle University of Thessaloniki, [3]Thalassaemia Unit, Ippokratio General Hospital, Thessaloniki, Greece

Background: Low bone mass, a major cause of morbidity in patients with b-thalassaemia major (b-TM) has a multifactorial pathogenesis with genetic factors greatly contributing to it. Fok-I vitamin D receptor (VDR) polymorphism has been significantly related to low bone mineral density and can serve as a useful genetic marker in predicting bone disease.
Aims: We sought to estimate the degree of genetic contribution of Fok-I gene polymorphism of VDR to the evolution of bone mass in patients with b-TM assessed with imaging techniques and biochemical parameters of bone metabolism over a period of two years.
Methods: Sixty-four children and young adults (33 males and 31 females) with mean decimal age of 23.20±5.41 (range: 9.25- 32.41 years) were recruited in this study. All patients were genotyping for Fok-I gene polymorphism and were

assessed with both Dual energyx-ray Absorptiometry (DXA) and Quantitative Ultrasound Sonography (QUS) at baseline and two years after. Z-scores were calculated based on normal age and sex matched Caucasian population. Metabolites of vitamin D, intact PTH, total calcium, inorganic phosphorous and alkaline phosphatase were measured at the serum pre transfusion.
Results: No deviation of the genotype distribution from the Hardy-Weinberg equilibrium was noticed: FF genotype accounted for 44.29%, ff genotype for 12.86% and heterozygosity (Ff) for 42.85%. A moderate proportion of patients had decreased DXA Z-scores (Z-score ≤-2) predominately in total hip (31%) and secondary in lumbar spine (15.6%). On the contrary, just a few patients (7.8%) had decreased QUS values measured at tibia. Patients being homozygous for the f allele had apparently higher BMD z-scores compared with those carrying the F allele in homo- or heterozygosity, however, with a difference that did not reached significance. Interestingly enough, a significant deterioration in BMD Z-scores measured at femur (FF: p=0.004 Ff: p<0.001, ff: p=0.024) and total hip (FF: p=0.022, Ff: p=0.005) was recorded for all type of genotypes, except for ff genotype and with regards to the total hip DXA values. In contrast, QUS values measured at tibia were significantly improved in patients carrying the FF genotype (p=0.035). An increased prevalence of serum $25(OH)D_3$ deficiency (59.4%) and $25(OH)D_3$ borderline (12.5%) was recorded. When stratified according to $25(OH)D_3$ levels, no statistically significant difference in the evolution of DXA or QUS parameters was observed. Regarding DXA Z-scores measured at hip, a significant deterioration was recorded in all groups, independently of the status of $25(OH)D_3$.
Summary and Conclusions: Fok-I gene polymorphism of VDR seems to have an impact on bone health of patients with beta-thalassaemia major in contrast to vitamin D levels. No level of agreement was observed between the two imaging techniques in identifying thalassaemic patients with impaired bone status.

E1493

GROWTH DIFFERENTIATION FACTOR-15 AND CARDIOVASCULAR DISEASE IN THALASSEMIA INTERMEDIA
A. Tantawy[1,*] A.A. Adly[2], E. Ismail[3], O. Yousef[4], M. Ali[2]
[1]pediatrics, Ain Shams, [2]Pediatrics, Ain Shams University, [3]clinical pathology, Ain Shams, [4]Cardiology, Ain Shams University, Cairo, Egypt

Background: Heart disease is the leading cause of mortality and one of the main causes of morbidity in β-thalassemia. Growth differentiation factor-15 (GDF-15), a member of the transforming growth factor-β superfamily, is a marker of ineffective erythropoiesis in several anemias.
Aims: To determine the level of GDF-15 in children and adolescents with TI in relation to clinical characteristics, iron overload, hemolysis and therapy and to assess its value a potential marker for cardiovascular complications and subclinical atherosclerosis.
Methods: Thirty-five TI patients without symptoms for heart disease were studied. Patients were subjected to detailed medical history and thorough clinical examination with special emphasis on disease duration, evidence of renal, hepatic or cardiac disease, splenectomy status. For transfusion status, patients were classified as: transfusion-dependent (patients on regular-interval transfusion protocols [once every 1-3 months for a pre-transfusion hemoglobin of ≥8 g/dL] initiated mainly for failure to thrive in childhood, bone deformities, progressive splenic enlargement, persistent worsening anemia; and non transfusion dependent (patients who never received transfusion or required incidental transfusions for transient severe anemia secondary to infections or surgery). GDF-15 was measured and correlated to echocardiographic parameters and carotid intima media thickness (CIMT).
Results: A total of 11 patients (31.4%) were splenectomized. By echocardiography, 16 patients (45.7%) had pulmonary hypertension risk and 12 patients (34.3%) had systolic left ventricular dysfunction. TI patients had significantly higher tricuspid regurgitation velocity (TRV), p<0.001, and lower left ventricular ejection fraction and fractional shortening than controls (p<0.001). CIMT was significantly increased among patients compared to controls (p<0.001). The median (IQR) of GDF-15 level in TI patients was 1500 (1000-2850) pg/ml compared to 110 (80-200) pg/ml in controls (p<0.001). Transfusion dependent TI patients had higher GDF-15 than non-transfusion dependent patients (p<0.001). TI patients with splenectomy, pulmonary hypertension risk, and heart disease had higher GDF-15 levels than those without. Hydroxyurea-treated patients had lower GDF-15 levels than untreated patients. ROC curve analysis revealed that the cutoff value of GDF-15 at 1500 pg/mL could differentiate patients with and without heart disease with a sensitivity of 87.5% and specificity of 100%, AUC 0.945; p<0.001. GDF-15 levels were positively correlated with age (r=0.463, p=0.005), disease duration (r=0.567, p<0.001), transfusion index (r=0.767, p=0.005), indirect bilirubin (r=0.345, p=0.043), LDH (r=0.612, p=0.002) and serum ferritin (r=0.949, p<0.001), while negatively correlated to hemoglobin (r=-0.408, p=0.015). Moreover, positive correlations were observed between GDF-5 and TRV (r=0.620, p<0.001) as well as CIMT (r=0.499, p=0.024).
Summary and Conclusions: Ineffective erythropoiesis as reflected by high GDF-15 levels is the hallmark of disease process in TI. GDF-15 may be considered a risk marker for pulmonary and cardiovascular complications as well as subclinical atherosclerosis in children and adolescents with β-TI. Levels are closely related to markers of hemolysis and iron overload. Elevated levels of GDF-15 may have clinical implications on treatment besides defining TI patients at risk of cardiac complications. A marker of ineffective erythropoiesis as GDF-15 may be a potentially valuable tool for monitoring the response to therapy, thus, promote earlier intervention and improve clinical outcomes in TI patients.

E1494

SOLUBLE FMS LIKE TYROSINE KINASE-1 (SFLT-1) : AN EARLY MARKER FOR GLOMERULAR DYSFUNCTION IN SICKLE CELL NEPHROPATHY
I. Youssry[1,*] S. Makar[2], R. Fawzy[2], M. Wilson[2], G. AbdAllah[2], E. Fathy[2], H. Sawires[2]
[1]Head of the Pediatric Hematology & BMT unit, [2]Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Given the potential role of angiogenesis in the pathophysiology of sickle cell nephropathy (SN), novel biomarkers are needed for early diagnosis of SN before irreversible kidney damage.
Aims: Our aim was to determine the relationship between serum level of the anti-angiogenic factor soluble FMS-like tyrosine kinase-1 (sFLT-1) and other biomarkers of renal damage as microalbuminuria (MA), for early diagnosis of SN.
Methods: 47 Sickle cell disease (SCD) patients and 49 healthy controls were enrolled. Microalbumine was determined in patients' urine sample. Blood samples were tested for sFLT-1, serum creatinine and various hemolysis and inflammation markers. Also, peripheral blood monocyte expression of sFLT-1 was measured using real time PCR.
Results: Serum level of sFLT-1 (pg/ml) in SCD patients was higher than the control level (Median/range/IQR=142/ 60-1300/61 pg/ml *vs* 125/ 110-187/52 pg/ml respectively), (*p*=0.006). The median (range) of sFLT-1 level was higher in SCD patients with MA compared to SCD patients with normoalbuminuria (NA), 185(140-1300) *vs* 125(60-189) mg/g respectively), (p=0.004). There was significant positive correlation between serum level of sFLT-1 and MA, lactate dehydrogenase (LDH) and indirect bilirubin (r=0.59, 0.39, 0.30 & *p*=<0.001, 0.007, 0.041, respectively). The sensitivity of sFLT-1 in early detection of renal affection in SCD was 93.6%, while the specificity was 68.6%. Finally, we identified the monocytes as a possible source of increased sFLT-1 in SCD patients.
Summary and Conclusions: sFLT-1 may constitute a novel renal biomarker that can predict SN, enabling early diagnosis to prevent progression of renal damage.

E1495

ORAL IRON-BASED PHOSPHATE BINDER, FERRIC CITRATE, INCREASES IRON MEASURES IN DIALYSIS-DEPENDENT AND NON-DIALYSIS DEPENDENT PATIENTS WITH CHRONIC KIDNEY DISEASE
S. Fishbane[1,*] L. Loram[2], T. Ganz[3]
[1]Department of Medicine, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY, [2]Keryx Biopharmaceuticals, Boston, MA, [3]David Geffen School of Medicine, UCLA, Los Angeles, CA, United States

Background: Ferric citrate is an iron-based phosphate binder with demonstrated significant improvement in serum phosphate control and in iron markers including serum iron, transferrin saturation and serum ferritin in both dialysis and non-dialysis (ND)-dependent CKD patients.
Aims: We evaluated the temporal change in serum iron measures relative to the amount of iron administered as ferric citrate in both ND-dependent CKD and end-stage renal disease (ESRD) subjects.
Methods: In a previous 52-wk Phase 3 clinical trial evaluating efficacy and safety of ferric citrate, a subset of dialysis subjects on ferric citrate did not receive IV iron (n=48). Serum iron parameters were measured and% change from baseline was calculated. Serum iron parameters were also evaluated in subjects participating in a Phase 2 clinical trial of ND-dependent CKD patients administered ferric citrate for 12 wk (n=61) to determine the safety and efficacy of ferric citrate to control serum phosphorus and transferrin saturation (TSAT). The subjects were not receiving IV iron or erythropoeisis stimulating agents for the duration of the trial. In both trials, the percent change of serum iron parameters was calculated per gram of iron administered (based on cumulative dose for the duration of the trial). Each tablet of ferric citrate contains 210 mg elemental iron and the dose of ferric citrate was titrated to control serum phosphorus to treatment target.
Results: In both clinical trials, ferric citrate significantly improved serum iron and TSAT levels with significantly increased hemoglobin in the ND-dependent CKD subjects and maintained hemoglobin in the ESRD subjects. TSAT, hemoglobin and iron administered in the ND-dependent CKD subjects are depicted in the Figure 1 as mean±SEM. The percent change in serum iron in the ND-dependent CKD subjects was 0.47±0.09% (mean±SEM) per gram of iron administered as ferric citrate and% change in TSAT was 0.58±0.09% per g iron administered. In the ESRD subjects, the% change in serum iron and TSAT were lower than that seen in the ND-dependent CKD subjects at 0.05±0.02% per g iron (mean±SEM) and 0.05±0.02% per g iron administered respectively. The average dose of iron administered was 1.2 g/day for 12 weeks (~5-6 tablets/day of ferric citrate) in the ND-CKD subjects and 1.4 g/day (~7 tablets/day of ferric citrate) for 52 weeks in ESRD subjects.

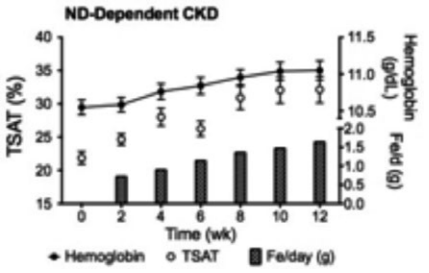

Figure 1.

Summary and Conclusions: Treatment with oral ferric citrate yielded significant and sustained improvement in iron measures in both dialysis-dependent and ND-dependent CKD subjects. The changes in both serum iron and TSAT are small relative to the iron administered, attesting to low fractional absorption of iron. In addition, the percent increase in iron parameters decreased over time indicative of physiologic negative feedback mechanisms regulating the amount of intestinal iron absorption.

E1496

THE SPECTRUM OF A-THALASSEMIA AND B-THALASSEMIA MUTATIONS IN SOUTH WEST IRAN

B. Keikhaei[1,*]
[1]Thalassemia, Health Institute,Research Center for Thalassemia and Hemoglobinopathy, Ahvaz, Iran

Background: Carrier screening, genetic counseling, prenatal diagnosis and aborted affected fetus are successful programs in reducing new delivery of β-thalassemia major and severe form of α- thalassemia in Iran**.** As both alpha and beta thalassemia are highly prevalent in south west Iran. The increasing knowledge about mutation types might be an important guide for genetic counseling sectors.
Aims: The purpose of this study is to detect the accurate frequency and type of Alpha and Beta mutations in pre marital candidate couples.
Methods: A total of 600 couples (1200 individuals) were recruited in this study. Five milliliter of EDETA and clot blood were drawn and obtained from each subject. Cell blood count, Hemoglobin electrophoresis was done for everybody. The common deletional alpha thalassemia was determined by polymerase chain reaction based direct amplification assay.DNA sequencing was done to detect beta and non deletional alpha mutations. DNA study for beta mutation was performed on each individual with MCV <80, MCH <27 and Hb A2>3.5.However, alpha mutation was conducted with MCV <85, MCH <27.5 and Hb A2<3.5.
Results: The frequency of carrier state for beta thalassemia and alpha thalassemia (silent, minor and Hb H) were 7 and 15% respectively. The mutation at codon 36-37 (-T) was found the first mutation with a frequency of 21.2%. The other mutations, at decreasing frequencies ranging from 18.3 to 1.1 were: IVS I-110:18.3%,IVSII-I :14.8%,CD8 (-AA):5.6%,IVSI-I: 4.2%,CD 44(-C): 4%,CD5:4%,CD39(C-T):3.4%,IVS1-5:3.2%,CD8-9:2.6%,CD82=83:2.6%,-28:2.6%,IVSI-6:2.4%,-88:1.9%,25bp del: 1.6%,IVSII-848:1.1%,IVSI-(-24):1.1%,IVSI(-17):1.1. The prevalence of the other mutations was very rare. The alpha mutations with a decreasing frequency was as follow:-α3.7 heterozygote: 38.2%,-α3.7 homozygote: 11.6%,-Med: 3.8%, CD 19:3.5%, Poly A4:2.5%,-α3.7/-Med:2.5%,Poly A6:2.3%,-α4.2 heterozygote: 1.6%, IVSI -Donor site: 1.5%, 5NT-del: 1.4%,-20.5:1.2%. The frequency of the other mutations was below 1%.
Summary and Conclusions: This study shows the high prevalence of alpha and beta thalassemia in south west Iran. The most alpha and beta thalassemia mutations were-α3.7 and CD 36-37 respectively. This is in concordance with Amin Doosti-Irani *et al.* study. The most alpha thalassemia mutation is in the line of most Iranian and Arabian countries studies. But the predominant beta mutation in our study is not in the top list of Najmabadi H *et al.* study. Both alpha and beta thalassemia are highly prevalent in south west Iran. The increasing knowledge of health sectors about alpha and beta thalassemia frequency and mutation types will enable them to manage better genetic counseling.
Key Words: South West Iran, Alpha mutation, Beta mutation.

E1497

DO WE HAVE TO CHELATE PATIENTS WITH THALASEMIA MAJOR HAVING FERRITIN LEVELS <500 MG/L?

G. Aydogan[1,*] Z. Salcioglu[1], F. Akici[1], H. Sen[1], D. Tugcu[1], M. Gokce[1], A. Aycicek[1], G. Keskindemirci[1], N.A. Ayaz[1], C. Bayram[1]
[1]Pediatric Hematology, Kanuni Sultan Suleyman Education And Research Hospital, Istanbul, Turkey

Background: In developing countries ıron load can be determined by measuring ferritin levels. By following ferritin levels, alterations of iron status can be predicted. The general recommendation is to decrease the dose of DFX or stop chelation when the level of ferritin is <500 µg/L There is no study regarding the use of deferasirox or deferipron at low ferritin levels. But case reports related to iron toxicity with low ferritin levels had been published.
Aims: So, we aimed to evaluate the toxicity due to chelation therapy at ferritin levels of <500µg/L.
Methods: Children followed up at our pediatric hematology outpatient clinic with the diagnosis of Thalasemia Major are involved to the study. The charts of patients having regular blood transfussions and deferasirox therapy were reviewed retrospectively and they were evaluated for hepatotoxicity and nephrotoxicity when their ferrin levels were <500µg/L.
Results: Of 21 patients, 22 times ferritin levels became <500 µg/L (106 µg/L - 495 µg/L). In 16 of these low levels of ferritin, chelation dose was decreased, but in 6 of them the dose was not decreased due to the fact that te results were brought late by the patients. The ages of patients under chelation therapy while their ferritin levels were low was between 58 month and 21 years (median 9 years). Deferasirox was used in 20 patients, 1 patient was having deferipiron. The duration that patients have ferritin <500µg/L was between 22weeks and 91 weeks. None of the patients had any clinical and laboratory (BUN, Kreatinin, AST and ALT) derrangement.
Summary and Conclusions: Ferritin levels may change as a response to inflammation, liver function abnormalities and ascorbate deficiency. There are studies showing no significant correlation between cardiac iron load and ferrtin levels. Even with moderately elevated ferritin levels iron toxcity may ensue. So, it is a must to predict the toxicity of chelation therapy and continue chelation. There was no clinical and laboratory influence of deferasirox therapy for patients having ferritin <500µg/L. But larger controlled series are needed for saying deferasirox therapy is safe at low ferritin levels.

E1498

KLF10 GENE EXPRESSION AS A SECONDARY MODIFIER IN BETA THALASSEMIA AND SICKLE CELL DISEASE (SCD) PATIENTS AND A PHARMACOGENOMIC BIOMARKER FOR HYDROXYCARBAMIDE TREATMENT RESPONSE

M. Elalfy[1,*] N. Elsherif[1], T. Kamal[2], N.H. Aly [1]
[1]Pediatric Hematology and Oncology, [2]Genetics, Ain Shams University, Cairo, Egypt

Background: Many genes have been uncovered which could modify γ- globin chain production and hence level of fetal hemoglobin (HbF) ameliorating the phenotype of beta hemoglobinopathies and SCD as well as the response to hydroxycarbamide (HU). KLF10 indirectly increase gamma globin chain synthesis.
Aims: the aim of the study was to evaluate the frequency of different genotypes for KLF10 gene in B-TM, B-TI,SCD patients compared to healthy controls via DNA extraction and PCR and to assess its relation to disease phenotypes, (HU), clinical and laboratory response.
Methods: This case control study included 80 patients; 48 beta thalassemia major (B-TM), 16 sickle cell disease (SCD) and 16 thalassemia intermedia (B-TI) patients (in a ratio 3:1:1), compared with 50 matched controls. All included SCD and B-TI patients were on stable dose of HU therapy. Assessment of KLF10 gene relation to phenotype was done using baseline HbF, transfusion index, while evaluation of response to HU therapy was done through comparing the frequency of vaso-occlusive crises and transfusion 2 years before and after start of therapy as well as an increase more than 20% in baseline HbF level.
Results: The frequency of mutant KLF10 genotype and the mutant allele (T) was significantly higher among B-TM (30%) compared to B-TI, SCD patients (0%,7.1%)and control(6%) (p=0.04). There was no significant difference between different KLF10 genotypes among B-TM patients as regards age at onset of disease, initial HbF%, transfusion index and mean pretransfusion Hb in last 2 years prior to the study(p=0.12, p=0.08, p=0.73, p=0.59, p=0.42 respectively), nor between homozygous SCD patients for normal KLF10 and mutant KLF10 gene as regard age of onset of disease, the percentage of patients who suffered from avascular necrosis, stroke, acute chest syndrome (p=0.69,p=0.27,p=0.18,p=0.15respectively). Yet Homozygous SCD patients for normal KLF10 gene had significantly lower TI/OR decrease transfusion frequency longer interval between transfusions (p=0.002). The percentage of clinical and laboratory responders and non responders to HU between different KLF10 genotypes among B-TI, SCD patients was comparable (p=0.679), (p=0.931). The frequency of mutant KLF10 genotype and the mutant allele (T) was significantly higher among B-TM (30%) compared to B-TI, SCD patients (0%,7.1%) and control (6%) (p=0.04). There was no significant difference between different KLF10 genotypes among B-TM patients as regards age at onset of disease, initial HbF%, transfusion index and mean pretransfusion Hb in last 2 years prior to the study(p=0.12, p=0.08, p=0.73, p=0.59, p=0.42 respectively), nor between homozygous SCD patients for normal KLF10 and mutant KLF10 gene as regard age of onset of disease, the percentage of patients who suffered from avascular necrosis, stroke, acute chest syndrome (p=0.69, p=0.27, p=0.18, p=0.15 respectively). Yet Homozygous SCD patients for normal KLF10 gene had significantly lower TI/OR decrease transfusion frequency longer interval between transfusions (p=0.002). The percentage of clinical and laboratory responders and non responders to HU between different KLF10 genotypes among B-TI, SCD patients was comparable (p=0.679), (p=0.931).
Summary and Conclusions: Although KLF10 gene has not a standalone role

as an HbF modifier, yet our data supports its importance in ameloriating phenotype among beta hemoglobinopathies. Further evaluation of KLF10 gene expression among B-TI, SCD patients as a potential pharmocogenomic marker to differentiate between responder and non responder to HU is warranted.

E1499

THINKING OF HEREDITARYxEROCYTOSIS: THE FIRST STEP TO THE DIAGNOSIS

M. Santos[1,*] B. Mesquita[2], T. Maia[1], H. Almeida[1], C. Bento[1], L. Ribeiro[1]
[1]CHUC, Coimbra, [2]Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal

Background: Hereditaryxerocytosis (HX) or Dehydrated Hereditary Stomatocytosis is a rare autosomal dominant hemolytic anemia (1 in 50000 live births), resulting from a red blood cell (RBC) membrane permeability disorder. HX has a wide range of clinical phenotypes: while some patients are asymptomatic, others have compensated hemolysis, with slight macrocytosis and reticulocytosis, mild splenomegaly and/or gallbladder lithiasis. In spite of not requiring frequent transfusion, most of the HX patients have iron overload. In the peripheral blood smear (PBS) a variable number of cup-cells can be observed, but are frequently overlooked.
Aims: To review the clinical features and hematological parameters on patients with HX in order to understand the most important steps to the diagnosis of this rare disease, and also to show the high phenotypic variability of HX.
Methods: Collection of all the clinical and laboratory data of all the patients with HX diagnosis (confirmed by the presence of *PIEZO1* mutations) followed in our department.
Results: Our population consists in 7 patients, with male predominance (n=5) and median age at diagnosis of 30 years (0-59). This group of patients showed a heterogeneous disease phenotype: mean hemoglobin of 13,2 g/dL (10,4-14,8), mean globular volume of 96,5fl (87,7-105), mean corpuscular hemoglobin concentration of 34,6 g/dL (33,1-35,3), mean reticulocyte count of 232,8 G/L (94,9-600), mean total bilirrubin of 27,3 µmol/L (9-50), mean LDH between normal values (330 U/L (99-493)) and ferritin of 574,7ng/ml (168-1489). On clinical presentation only one patient showed the classical signs and symptoms associated with HX, as can be observed in Table 1. One patient presented with *hidrops fetalis* at birth but with Hb of 19g/dl and in a few weeks develops hemolytic anemia with macrocytosis, reticulocytosis, hyperferritinemia and liver and spleen enlargment while, in the opposite side of the clinical spectrum, 2 patients were asymptomatic, showing only a slight macrocytosis or reticulocytosis and hyperferritinemia. The only common feature to all patients was the presence of cup-cells in the PBS and 6/7 had hyperferritinemia. Five patients had family history of anemia and/or hyperferritinemia.

Table 1.

Patients	1	2	3	4	5	6	7
Anemia	**Yes**	**Yes**	No	No	No	No	No
Macrocitosis	**Yes**	**Yes**	No	No	**Yes**	No	No
Reticulocitosis	**Yes**	**Yes**	**Yes**	**Yes**	No	**Yes**	No
Cup-cells	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**
Hyperferritinemia	**Yes**	**Yes**	**Yes**	No	**Yes**	**Yes**	**Yes**
Splenomegaly	**Yes**	No	**Yes**	**Yes**	No	No	No
Hepatomegaly	**Yes**	No	No	No	No	No	**Yes**
Previous cholecystectomy	No	**Yes**	**Yes**	**Yes**	No	No	No

Summary and Conclusions: Reviewing the data on these 7 patients with HX due to *PIEZO1* mutations we could observe a high phenotypic variability and that the main steps to the diagnosis were the clinical suspicion and the identification of cup-cells in the PBS. The high association between HX and hyperferritinemia misleads its diagnosis, which is overlooked on the etiological workup of hyperferritinemia. In the era of molecular biology, we want to emphasize the importance of the RBC morphology to the diagnosis of HX and the current tendency to ignore the PBS observation is probably the main cause for the disease underdiagnosis. The diagnosis of HX is essential because, unlike the most congenital hemolytic anemia, the splenectomy is contraindicated, since it is associated with severe thromboembolic disease.

E1500

EFFECTIVENES OF MAGNETIC RESONANCE IMAGING FOR MEASURING OF PITUITARY IRON OVERLOAD IN PATIENTS WITH THALASSEMIA

Y. Oymak[1,*] S. Okur[2], T.H. Karapinar[1], Y. Ay[1], K. Demir[3], M. Gurcinar[4], S. Aydin Koker[1], N. Muminoglu[5], E. Toret[1], C. Vergin[1]
[1]Pediatric Hematology, [2]Pediatri, Dr. Behcet Uz Children's Hospital, [3]Pediatric Endocrinology, Dokuz Eylül University, [4]Radiology, Bilrad MR, [5]Pediatric Hematology, Dr. Behcet Uz Children's Hospitai, Izmir, Turkey

Background: In patients with b-thalassemia major iron deposition resulting from complications related with morbidity and mortality. Iron accumulation starts in the reticuloendothelial system and subsequently accumulates in all parenchymal organs. One of the affected parenchymal organs is pituitary gland. Although thalassaemic patients are chelated adequately, pituitary siderosis may lead to hypopituitarism.
Aims: The aim of this study was to evaluate the magnetic resonance imagine (MRI) signal intensity of pituitary gland if it was suitable to measure pituitary siderosis.
Methods: The ratio of the average anterior pituitary gland signal intensity to that of the pterygoid muscles and that of nasopharyngeal fat was assessed in 60 patients with b-thalassemia major by using signal intensity ratio of T1-weighted MRI. All patients were taking deferasirox. In all patients, an endocrine evaluation was performed, including measurements of spontaneous gonadotropins, thyroid hormones, growth hormone and insülin like growth factor. Also liver iron content (LIC) was measured with R2 MRI.
Results: A total of 60(M/F=34/26) pediatric patients with mean age of 11.5±4.5(range 1.8-19.0) years were enrolled the study. The mean serum ferritin level and LIC values were 1127.1±615.7 ng/ml and 2.1±1.2 mg iron/g dry tissue weight (dw) respectively. Any patients had high LIC level. The measurements of anterior pituitary gland wasn't correlated median age of the patients and median of other hormone levels. Only TSH level and pituitary-to-fat ratio was correlated (r=0.32, p=0.033). Nine patients (15%) had pubertal retardation and six patients (10%) subclinical hypotiroidsm. There wasn't difference between the patients who had and hadn't hypotyroidism in terms of anterior pituitary MRI. Also there wasn't difference between the patients who had and hadn't pubertal retardation in terms anterior pituitary MRI.
Summary and Conclusions: Our data suggest that iron accumulation of anterior pituitary gland measurement by using MRI wasn't succesful. This may be related that there were no patient who had high level of LIC. So the patients' anterior pituitary glands may not be affected by iron accumulation due to priority in iron accumulation of the reticuloendothelial system.

LB2089

ASSESSMENT OF THE EFFECTS OF ANEMIA ON CARDIOVASCULAR FINDINGS IN OBESE ADOLESCENTS

Ö. Yıldırım[1], T. Demircan[2], Ö. Kızılca[2], P. Kuyum[3], M. Kır[2], A. Abacı[4], N. Ünal[2], N. Arslan[3], E. Böber[4], S. Yılmaz Bengoa[5], H. Ören[5,*]
[1]Pediatrics, [2]Pediatric Cardiology, [3]Pediatric Gastroenterology, [4]Pediatric Endocrinology, [5]Pediatric Hematology, Dokuz Eylül University Faculty of Medicine, İzmir, Turkey

Background: Obesity that develops during childhood is a major risk factor in terms of cardiovascular diseases in further life. In obese adolescents, anemia may develop due to inflammation of obesity and iron deficiency anemia and it may be a risk factor that affects the cardiological progress negatively in these patients.
Aims: The purpose of this study is to assess the effects of anemia on cardiovascular findings in obese adolescents by using echocardiography.
Methods: Twenty nine obese adolescent patients with anemia and 33 obese adolescents without anemia who were 12-18 years old were echocardiographically investigated in the Pediatric Cardiology Outpatient Clinic. Thirty three adolescents who had similar age and gender and whose body mass indexes were between 3-85 percentiles were included as the control group. Patients data were obtained from the relevant departments and the hospital patient files. All patients were examined according to their cardiac risk factors, blood pressures, pulse rates, and physical examination findings. Blood counts, liver and renal function tests were noted. Serum iron parameters, thyroid function tests, fasting glucose, lipid profiles, insülin, and CRP values of the obese adolescents were recorded. The patients were examined according to their diet, presence of intolerance to the effort, sleep apnea, thrombosis, and fatigue symptoms. Echocardiographic parameters of all patients were examined.
Results: There were not any difference between groups in terms of age and sex. Anemia was mild (mean Hb: 11.5±0.79 g/dL) in the anemic obese group. Hypertension, presence of intolerance to the effort, and fatique were statistically significantly high in both obese groups compared to the control group. There was statistically significant difference between obese groups in terms of diet and cardiac pulse rate. Anemic obese adolescents were dieting more in order to loose weight and tachycardia was found at a higher rate. In laboratory examinations of anemic obese and obese groups, a significant difference was detected in terms of average values of ferritin, CRP, and fibrinogen. Ferritin was found significantly low, CRP and fibrinogen levels were found significantly high in the anemic obese group. According to M-mode echocardiographic examination results, a significant difference was detected in terms of averages of interventicular diastolic diameter, left ventricular posterior wall diastolic diameter, left ventricle mass, and left ventricle mass index in obese patients compared to the control group; there was no significant difference in these parameters between the anemic and nonanemic obese patients. Ratio of mitral peak early diastolic flow velocity to peak early diastolic myocardial velocity (Mitral E/E') by tissue Doppler echocardiography was slightly higher in both of the obese groups.
Summary and Conclusions: Early symptoms of subclinical left ventricular diastolic dysfunction were detected in obese adolescents. Mild anemia did not show any difference except higher cardiac pulse rate. Since severe anemia may change the results and be one of the cardiovascular risk factors in obese adolescents, it is necessary to avoid low iron diet programs in these children.

Stem cell transplantation - Clinical

E1501

ACTIVATION OF MONOCYTES AND DENDRITIC CELLS IN PATIENTS WITH ACUTE GRAFT-*VERSUS*-HOST DISEASE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

E. Hofmann[1,*] P. Stein[2], J. Dopheide[3], H. Schild[4], E.-M. Wagner[1], M. Radsak[1]
[1]IIIrd Deparment of Medicine, [2]Center for Thrombosis and Haemostasis, [3]IInd Department of Medicine, [4]Institute of Immunology, Johannes-Gutenberg University Medical Center, Mainz, Germany

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the treatment of choice for a variety of hematologic malignancies. Graft-*versus*-host disease (GVHD) is a key contributor to treatment related morbidity and mortality and consequently limits the efficacy of HSCT. GVHD may involve liver, skin, gastrointestinal tract or other organs leading to severe and life-threatening organ damage as well as to a high risk of opportunistic infections. Early diagnosis of GVHD and the consequent initiation of the adequate treatment are important factors that contribute to a favourable outcome.
Aims: Several studies indicate that innate immune responses play an important role in development of acute GVHD. Thus, we are interested in activation state of monocytes and dendritic cells in HSCT patients asking whether there are differences in activation of these cell types as early indicators of GVHD and maybe useful for the early identification of patients at risk of developing GVHD.
Methods: In this retrospective study, we analysed cryoconserved peripheral mononuclear cells (MNCs) from 17 patients with acute GVHD and 16 patients without GVHD. All patients had received HSCT after conditioning treatment with fludarabine, melphalan and alemtuzumab and gave informed consent for blood analyses. The following surface markers were analysed on monocytes and dendritic cells (DCs) by multi-color flow cytometry using fluorochrome conjugated monoclonal antibodies: TREM-1, CD86, HLA-DR, CD16, CD14, CD83, CD40, CD11c, CD123. In addition serum samples from a subset of 13 acute GVHD patients and 8 controls were analysed by enzyme-linked immunosorbent assay (ELISA) to detect soluble TREM-1 (sTREM-1). For statistical analyses, two groups were compared by Pearson's test for correlations and unpaired Student's t-test considering $p<0.05$ as statistically significant.
Results: In flow-cytometry analysis we found an increased expression of CD83 on plasmacytoid DCs (125.1 +/- 26.97 *vs* 38.06 +/- 20.65) as well as on myeloid DCs (122.5 +/- 27.33 *vs* 10.13 +/- 12.86) in patients with acute GVHD. We observed no differences in the expression of the surface markers (CD86, CD40, TREM-1) on monocyte subpopulations. Nevertheless, sTREM-1 ELISA revealed a significant difference between patients with acute GVHD and the controls (244.7 +/- 35.89 *vs* 101.4 +/- 18.83). Laboratory parameters as C-reactive protein (CRP) correlated positively with sTREM-1 levels in patients with acute GVHD (r=0.692). Other laboratory parameters *e.g.* eosinophils or platelets showed no significant differences between the groups.
Summary and Conclusions: We found an increased expression of CD83 on DCs in patients with acute GVHD. Furthermore, sTREM-1 levels in this group were significantly higher as well as CRP and s-TREM-1 levels showed a positive correlation. Other parameters as eosinophils, platelets or monocyte phenotype were not informative as markers for GVHD. However, the small number of patients and the retrospective character of our study are currently limiting the possibility to draw clearcut conclusions. Nevertheless, we conclude that ELISA of sTREM-1 could be a new marker to identify patients and initiate early treatment for GVHD, and warrant further prospective studies to evaluate the clinical value of this new marker.

E1502

COMPARISON OF CONDITIONING REGIMENS FOR RELAPSED/REFRECTORY LYMPHOMA PATIENTS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION: BEAM *VS* HIGH DOSE ICE

A.K. Gunes[1,*] S. Dagdas[1], F. Ceran[1], M. Falay[1], G. Ozet[1], N. Zengin[2]
[1]Hematology, [2]Oncology, Ankara Numune Training and Research Hospital, ankara, Turkey

Background: High-dose chemotherapy in conjunction with auto-SCT is widely recognized as the preferred modality of treatment for patients with relapsed or refractory Hodgkin disease or non-Hodgkin lymphoma at the time of chemosensitive relapse. Despite different drug combinations and conditioning regimens before auto-SCT, the optimal choice is undetermined. Several studies have been made to identify a regimen with superior antitumor activity and acceptable toxicity.
Aims: In this retrospectical analysis, we compared the efficacy and the toxicity of the BEAM and high dose ICE conditioning regimens in relapsed NHL and relaps/refractory Hodgkin Lymphoma patients.
Methods: A total of 83 patients with HL or NHL treated with Auto-SCT at our center between 2004-2013 are analyzed retrospectively. Patients were considered eligible for transplantation, if they met the following inclusion criteria: age between 16 and 65 years, ECOG performance status 0-2 (WHO (World Health Organization)), left ventricular ejection fraction greater than 55%, creatinine clearance greater than 60 ml/min and adequate lung and liver function. The Bearman Regimen Toxicity Scale is specifically used to rate the complications caused by chemotherapy during hospitalization for SCT.
Results: 52 patients (%62,7) received BEAM, 31 patients (%37,3) received hd-ICE. Between two groups there is no difference by age, diagnosis, transfused CD 34 yield, disease status at transplant, refractory case distribution, ECOG score at transplant. The descriptive values are in Table 1. The Renal toxicity in any grade BEAM group is%4 (1 grade I and 1 grade III) by the way the renal toxicity in ICE group is%32 (6 with grade I, 1 with grade II, 3 with grade III) (p=0,01). The GIS toxicity with any grade in BEAM group is%25 (10 with grade 1, 3 with grade 2) while in ICE GIS toxicity is%22,5 (4 with grade 1, 3 with grade 2) (p=0,415). The mucositis in BEAM group in any grade is% 26,3 while in ICE is%25 (p=0,857). Hepatotoxicity in BEAM group is%10, there is no hepatoxicity in ICE group. (p=0,041). Transplant related mortality rate is%2,4 (2 patients, 1 BEAM group, 1 ICE group). The main cause of death in ICE group is renal failure, while in BEAM group it is sepsis. In the BEAM group the mean neutrophil engraftment occurred on 11,2 days (9-21 day) while in ICE group 9,77 days (8-14 day) (p=0,047). The mean platelet engraftment in BEAM group is 14,2 days (8-41 days) in ICE group the mean is 11,4 days (8-24 days) (p=0,024)When the total patients analyzed, the CR rate in 100 days after transplant in the BEAM group is%63,5, in the ICE group%45,2 (p=0,062).In refractory Hodgkin group CR rate in 100.day, in BEAM group is%6,1, in ICE group% 7,1 (p=0,844). The partial remission rate for refractory Hodgkin group BEAM is%14, ICE is%33,3 (p=0,047).1 year overall survival rate in BEAM group%87,2, in ICE group% 90,4. 1 year PFS in BEAM group%72,7 in ICE group%58.(p=0,039). If the refractory Hodgkin group is excluded 1 year PFS in BEAM group%81,7, in ICE group%74,2. (p=0,345).In ICE group after 6,3 years follow-up, OS is%54, PFS is%45. In BEAM group after 6,3 year follow up OS is%65,3 PFS%51,9. (p=0,041).

Table 1. Descriptive factors of BEAM and hdICE group.

	Total (n=83)	BEAM (n=52)	ICE (n=31)
Age	36,7 (16-63)	39,3	32,5
Male	51 (% 61)	35	16
Female	32 (%39)	17	15
NHL	34	24	10
HL	49	28	21
Relapsed HL	30	16	14
Refractory HL	19	12	7
Mean CD 34	5,35x10^6/kg	4,55 x10^6/kg	6,64 x10^6/kg
ECOG score	0,86 (0-2)	0,91	0,83
Disease status at transplant			
CR	19	13	6
PR	45	27	18
Refractory	19	12	7

Summary and Conclusions: Despite the common use of BEAM and hdICE regimens as conditioning regimens for auto-SCT in patients with lymphoma, there have been few reports comparing these two regimens.The high dose ICE conditioning regimen provides us a shorter neutrophil and platelet engraftment time, a lower hepatotoxicity and a higher response rate for refractory Hodgkin patients whereas a marked increase in renal toxicity and a lower PFS and OS in contrast to BEAM. According to our study analysis, Hd ICE as a conditioning regimen for auto-SCT should be considered for refractory Hodgkin Lymphoma patients. Prospective and randomized studies require defining the most efficient conditioning regimens for relapsed/refractory lymphoma patients.

E1503

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR NON-MALIGNANT HEMATOLOGICAL DISORDERS

Y. Elnahass[1,*] H.K Mahmoud[1], M.A Samra[1]
[1]National Cancer Institute, Cairo, Egypt

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) from a geno-identical matched sibling (MSD) is one of the most successful therapies in patients with non-malignant hematological disorders.
Aims: The aim of this study was to illustrate and report the out-come of allo-HSCT in different non-malignant hematologicconditions treated at our Institute.
Methods: This study included 273 patients with severe aplastic anemia (SAA), 152 patients with B-Thalassemia major (BTM), 31 patients with Fanconi's anemia (FA), 20 patients with congenital immunodeficiency diseases (ID), and 13 patients with inherited metabolic disor-ders (IMD) allografted from a MSD. This study included 273 patients with severe aplastic anemia (SAA), 152 patients with B-Thalassemia major (BTM), 31 patients with Fanconi's anemia (FA), 20 patients with congenital immunodeficiency diseases (ID), and 13 patients with inherited metabolic disorders (IMD) allografted from a MSD. All donors were siblings and at least 6/6 HLA matched. PBSC Donors were injected subcuta-

neously with (G-CSF, 10ug/kg daily for 5 days) and mobilized PBSC was collected the day of last injection.
Results: In SAA, the 8-year overall survival (OS) of the whole group patients was 74%. OS was significantly better in patients conditioned with fludarabine and cyclophosphamide (Flu/Cy) than in those who received cyclophosphamide and antithymo-cyte globulin (Cy/ATG) (p=0.021). Acute graft-*versus*-host disease (aGVHD) grade II-IV occurred in 15% while chronic GVHD (cGVHD) occurred in 28%. In BTM, the 12-year dis-ease-free survival (DFS) of the whole group of BTM patients was 72.4%. DFS was 74% for peripheral blood stem cell (PBSC) group compared to 64% in the BM stem cell group. The inci-dence of graft rejection was significantly lower in patients who received PBSC than in those who received BM (9% *vs* 25%) (p=0.036). AGVHD grade II-IV and cGVHD occurred in 15% and 12% of the whole group of BTM patients respectively. In FA, the 5-year OS was 64.5%. Graft rejection occurred in 10% of patients. Grade II-IV aGVHD occurred in 16% while cGVHD occurred in 4%. In ID, the 5-year OS was 62%. Graft rejection occurred in two (10%) patients. Three patients (15%) developed grade II-IV aGVHD, 2 of them progressed. In SAA, OS was significantly better in patients conditioned with fludarabine/ cyclophosphamide (Flu/Cy) than in those who received Cy/ATG (p=0.021). Acute graft-*versus*-host disease (aGVHD) grade II-IV occurred in 15% while cGVHD occurred in 28%. In BTM, DFS was 74% for peripheral blood stem cell (PBSC) group compared to 64% in the BM stem cell group. The incidence of graft rejection was significantly lower in patients who received PBSC than in those who received BM (9% *vs* 25%) (p=0.036). AGVHD grade II-IV and cGVHD occurred in 15% and 12% of the whole group, respectively. In FA, the 5-year OS was 64.5%.Graft rejection occurred in 10% of patients. Grade II-IV aGVHD occurred in 16% while cGVHD occurred in 4%. In ID, graft rejection occurred in 2 (10%) patients. Three patients (15%) developed grade II-IV aGVHD. In IMD, OS was 46% at 5 years. Graft rejection occurred in 8% of patients.
Summary and Conclusions: Allo-HSCT provides a higher DFS rate over conventional therapies for patients with non-malignant hematological disorders with prolonged survival.

E1504

FERTILITY IN OUR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT PATIENTS: RESULTS FOR 23 YEARS OF EXPERIENCE
P. Topcuoglu[1,*] P. Ataca[1], E. Atilla[1], S. Civriz Bozdag[1], S.K. Toprak[1], G. Gurman[1]
[1]Hematology, Ankara University School of Medicine, Ankara, Turkey

Background: Survival after allogeneic hematopoietic stem cell transplantation (Allo-HSCT) has increased due to effective supportive treatment. Infertility is a major late side effect after transplantation. However, healthy pregnancies and births were reported previously.
Aims: In this paper, we aim to present our patients' fertility after Allo-HSCT.
Methods: We retrospectively evaluated the fertility in 122 (14%) eligible patients from 849 patients who underwent Allo-HSCT between 1989-2012 at Ankara University Hematology Department and survived 2 years or more after transplantation and desired pregnancy. We used Pearsonchi-square test to compare groups. P<.05 was considered statistically significant.

Table 1. Distribution and comparison of fertile and infertile patients.

Parameters	Fertility Yes % (n=26)	Fertility No (n=96)	P
Diagnosis			
Acute leukemia (AML, ALL, sec leukemia) 0.014*	38.4% (10/26)	57.3% (55/96)	
Chronic MPD (CML, PMF)	42.3% (11/26)	28.2% (27/96)	
Bone marrow Failure (AAA, PNH, MDS)	19.3% (5/26)	5.2% (5/96)	
Others (Lymphoma, Myeloma)	0% (0/22)	9.3% (9/96)	
Relative *vs* non-relative donors	100% (26/26)	96% (92/96)	0.88
Chemotherapy prior to ASCT 0.032*	77% (20/26)	93% (89/96)	
Radiotherapy prior to ASCT	0% (0/26)	3% (3/96)	0.45
Myeloablative conditioning regimen	96% (25/26)	90% (86/96)	0.48
TBI in conditioning regimen	0.4% (1/26)	13% (12/96)	0.29
Acute GVHD	35% (9/26)	39% (37/96)	0.82
Chronic GVHD	54% (14/26)	65% (62/96)	0.37
Disease relapse	12% (3/26)	31% (30/96)	0.04*

Results: In 122 patients (56 F/66 M), the mean age during Allo-HSCT in female patients was 33.48±8.41, whereas 32.85±7.92 in male patients. 35 patients had (29%) a child whereas 16 patients/patient partners (13%) had history of pregnancy complications prior to transplantation. The mean follow-up period after transplantation was 119 months (range 18-300 months). From totally 31 pregnancies (23 partners of male patients *vs* 8 female patients), 6 of the female patients (11%) and 20 of the male patients (30%), had a child after Allo-HSCT. From 23 pregnancies of male patients partners, there were 4 abortus, 1 stillbirth, 1 gestational diabetes, 1 gestational hypertension; whereas from 8 pregnancies of female patients there were 2 abortus, 1 preeclampsia, 1 gestational diabetes were detected as pregnancy complications. The mean time from Allo-HSCT to pregnancy was 68 months (range, 4-144) in male while 63 months (range, 8-108) in female patients. All patients who had given birth after Allo-HSCT had received transplants from full-match HLA sibling donors or relatives. 9 of 56 female patients (16%) had regular menstrual cycles after transplantation. Several parameters compared between fertile *vs* unfertile patients were shown in Table 1.
Summary and Conclusions: Treatments prior to Allo-HSCT may have damaging effects on gonadal tissue and induce infertility as previously reported. The benign nature of the initial diagnosis, lack of chemotherapy regimen before transplantation, early age and no relapse of the primary disease contribute to fertility in our study. Unexpectedly, we found no relation between the myeloablative conditioning regimen, radiotherapy prior to Allo-HSCT, TBI usage and frequency, and development of acute and chronic GVHD with infertility. Fertility preservation of recipients should be considered before transplantation.

E1505

MESNA'S CONCENTRATION IN URINE CAN BE MAINTAINED BY CONTINUOUS INTRAVENOUS INFUSION OF MESNA: A BETTER METHOD TO PREVENT HEMORRHAGIC CYSTITIS IN HSCT
Q. Jiang[1,*] H. Huang[1], Q. Liu[1], J. Sun[1], H. Zhou[1], Z. Fan[1], Y. Zhang[1], F. Huang[1], Y. Chai[1], D. Xu[1], Y. Lu[2], Q. Wei[1], G. Yu[1], X. Li[1], M. Dai[1], N. Xu[1], D. Zhou[2], H. Zhao[2], K. Shen[1], Y. Zhou[1], Q. Zhang[2], F. Meng[1]
[1]Department of Hematology, Nanfang Hospital, [2]Southern Medical University, Guangzhou, China

Background: The clinic protective effect of continuous intravenous infusion of MESNA on cyclophosphamide-induced HC in HSCT has been demonstrated by our team. But what is the mechanism? This work was supported by the National Natural Science Foundation of China (No. 30901367, 31070866), Outstanding Young Teachers' foundation of SMU (C1031694).
Aims: To detect the MESNA's Concentration in urine and serum, hoping to illustrate the mechanism.
Methods: (1) In preliminary prospective study: 66 allogenic HSCTs were prospectively randomized into the MESNA continuous i.v. (continuous) group and the MESNA intermittent (0, 3, 6, 9h) i.v. (intermittent) group. (2) In retrospective study: 394 allogenic HSCTs were retrospectively analyzed between both groups. (3) The MESNA concentration in urine and serum of both groups were detected by HPLC. The three observation points of both group (n=5) were as follows: Before CTX and MESNA, immediately after CTX administration, 12h after the beginning of CTX.
Results: (1) Preliminary prospective study (32 *vs* 34 cases) shows that HC occurs 34.38% *vs* 0 within +30d (P=0.001), and 40.63% *vs* 5.88% within +60d (P=0.002) between intermittent and continuous group. (2) Retrospective study (160 *vs* 234 cases) shows that HC occurs 18.75% *vs* 7.26% within +30d (P=0.001) and 28.13% *vs* 12.82% within +60d (P=0.000) between intermittent and continuous group. The mean HC occurrence time are +19.77d *vs* +27.20d (P=0.037), respectively. (3) The MESNA concentration in urine is as low as zero in intermittent group 12h after CTX; while in continuous group, it varied between (439.47±34.34) μM and (268.21±24.51) μM in urine, as well as between (56.62±1.10) μM and (37.06±2.95) μM in serum.
Summary and Conclusions: Continuous i.v. of MESNA is efficient in the prevention of HC in HSCT. Keeping enough MESNA concentration in urine is the key factor in HC prevention.

E1506

PHARMACOKINETICS, PHARMACODYNAMICS, SAFETY, AND EFFICACY STUDY OF PLERIXAFOR IN CHINESE PATIENTS WITH NON-HODGKIN LYMPHOMA (NHL)
J. Zhu[1,*] H. Chen[2], Z. Li[3], H. Chen[4], J. Hu[5], J. Li[6], Y. Li[7], Y. Su[8], J. Wu[7], R. Lai[7], X. Huang[2]
[1]Beijing Cancer Hospital, [2]Peking University People's Hospital, Beijing, [3]Institude of hematology & Hospital of Blood Disease, CAMS, Tianjin, [4]307 Hospital of PLA, Beijing, [5]Shanghai Ruijin Hospital, Shanghai, [6]Jiangsu Province Hospital, Nanjing, [7]Sanofi R&D, Beijing, China, [8]Sanofi R&D, Bridgewater, United States

Background: Plerixafor, a small molecule antagonist of the chemokine receptor 4, has been approved in US and Europe for use in combination with granulocyte-colony stimulating factor (G-CSF) to mobilize hematopoietic stem cells to the peripheral blood (PB) for collection and subsequent autologous transplantation in patients with NHL and multiple myeloma.
Aims: This study was designed to investigate for the first time the safety, pharmacokinetics (PK), pharmacodynamics (PD) and efficacy profiles of plerixafor with G-CSF in Chinese NHL patients.
Methods: Eligible NHL patients were given G-CSF (10 μg/kg/day subcuta-

neously) for 4 days in the morning and randomized to receive plerixafor 240 µg/kg or placebo subcutaneously on the evening of day 4. Apheresis was initiated around 1 hour after the next morning dose of G-CSF (approximately 9 to 10 hours post dosing of plerixafor/placebo). This regimen was repeated until 5x 10^6 CD34+ cells/kg were collected or for up to day 8. Venous blood samples were collected at specific time points post the first dosing on the evening of day 4 for assessing plasma plerixafor concentration and PB CD34+ cells count. Patients with ≥2 × 10^6 CD34+ cells/kg collected, underwent pre-transplantation chemotherapy followed by transplantation within 2 months.
Results: A total of 32 Chinese NHL patients [15 males, 17 females, median age 28 years, mean weight 68.5 kg, ECOG PS 0-1] were randomized and treated in this study. Overall, the demographics and baseline characteristics of these patients were similar in the 2 treatment arms. Plerixafor was rapidly absorbed after the first subcutaneous administration in these patients with peak plasma concentrations occurring at a median t_{max} of 0.47 hours and then declined with a mean terminal half-life of 3.61 hours. Mean plasma C_{max}, AUC_{0-10}, AUC, CL/F and Vz/F were 786 ng/mL, 2580 ng.h/mL, 3010 ng.h/mL, 5.73 L/h and 29.0 L, respectively. The PB CD34+ cell count generally did not change significantly over time following the placebo treatment. However, following the first plerixafor dosing on day 4, a mean 2.1 to 2.7-fold increase of the PB CD34+ cell count from baseline was observed from 2 to 10 hours with the maximum at 8 hours post dosing. The incidence of adverse events was similar between the 2 treatment arms and no unexpected adverse events were observed. 71.4% (10/14) patients in the plerixafor plus G-CSF arm, and 5.6% (1/18) patients in the placebo plus G-CSF arm achieved the target of ≥5x 10^6 CD34+ cells/kg collected.
Summary and Conclusions: The PK and PD profiles of plerixafor in Chinese NHL patients were comparable to those of NHL patients observed in previous studies. Plerixafor with G-CSF regimen was safe and effective in mobilizing CD34+ cells for transplantation in these Chinese NHL patients.

E1507

THE ROLE OF STEM CELL TRANSPLANTATION FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) RESISTANT TO TYROSINE KINASE INHIBITORS WITH BCR-ABL KINASE DOMAIN MUTATION T315I

E. Morozova[1], J. Vlasova[2,*] B. Afanasyev[3]
[1] Hematological Department, [2]Daily Hospital, Hematological Department, [3]Director, R.M. Gorbacheva Institute of Pediatric Oncology Hematology and Transplantation St. Petersburg State Medical I. Pavlov University., St.Petersburg, Russian Federation

Background: Treatment of CML based on the use of tyrosine kinase inhibitors (TKIs). Resistance to TKIs therapy is associated with the development of kinase domain mutations. The threonine-to-isoleucine mutation at codon 315 of the breakpoint cluster region/v-abl Abelson murine leukemia viral oncogene protein fusion Bcr-Abl (T315I) is insensitive to currently available TKIs. In 2012, ponatinib (Iclusig®) was approved for treatment patients who have failed first-line therapy, have the T315I mutation, or have progressed, and became an alternative to SCT.
Aims: Evaluate the role of Stem Cell Transplantation (SCT) in the treatment of patients CML with T315I mutation.
Methods: 14 patients with TKI-resistant CML who had T315I mutations underwent 16 transplantations. At the time of SCT, 5 patients were in chronic phase, 4 patients were in accelerated phase, 1 patient was in blast crisis phase; and 4 patients were in second chronic phase. All patients had received TKI and had become resistant: 4 patients received imatinib, 6-nilotinib, 4-dasatinib. The median time from CML diagnosis to SCT was 39 months (range, 14-119 months), and the median time from fist detection of T315I to SCT was 10 months (range, 4-72 months). In 6 cases, donors were HLA-identical siblings, 8-unrelated donors. 12 patients were male, 2-female, age was 17-55 years (median 33.5 years).Conditioning regimen: in 4 cases was myeloablative, 12-reduced-intensity conditioning. Source graft in 5 cases was bone marrow (BM), 9-peripheral stem cells (PBSC), 2 BM+PBSC.
Results: Survived 5 patients of 14. The best responses after SCT were a complete molecular response (CMR) in 6 patients, and complete cytogenetic response (CCyR) in 1 patient, The best outcome was for patients who underwent transplantation in chronic phase, and all of those patients remained alive and in complete molecular remission: 3 patients in the 1 st and 1-in the 2nd reached after abolition of the basic immunosuppression and resumption of TKIs. In 1 patient reported relapse after SCT and achieving CMR-progress in blast crisis phase, currently under chemotherapy in combination with TKIs. Duration of observation for living patients to date 1- 66 months, median 7 months. Overall survival of patients who underwent SCT was 43.8%, with a median-up follow 7 months.
Summary and Conclusions: The current results indicated that SCT is an effective strategy for patients with CML who have the T315I mutation, particularly in earlier stages.

E1508

GRANZYME B EXPRESSION IN T-REGULATORY CELLS ON DAY +14 AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO-HSCT) IS A STRONG PREDICTOR OF ACUTE GRAFT-*VERSUS*-HOST DISEASE (GVHD)

M. Drokov[1,*] E. Parovichnikova[1], L. Kuzmina[1], I. Galtseva[2], Y. Muratova[2], K. Nikolay[2], V. Vasilieva[1], V. Savchenko[1]
[1]Bone Marrow Transplant Department, [2]Flow Cytometry Department, NATIONAL RESEARCH CENTER FOR HEMATOLOGY, Moscow, Russian Federation

Background: As we previously reported on ASH (ASH2014, №5871) : we found out that percent of CD4+CD25highGranzymeB+ cells among CD4+cells at day +30 after allo-HSCT in patients who never developed aGVHD was statistically higher (9,49%±2,79; p=0.003) than in patients at day of aGVHD onset (3,8%±1,78) and who developed aGVHD in future after day +30 (3,38%±1,47).
Aims: Find an easy way to assess of aGVHD development
Methods: Peripheral blood samples were collected in EDTA-tubes at day +14 after allo-HSCT. Because of WBC mediana-0.28*10^9/L (0.02-0.8) we use PBMC from 15 patients with hematological malignancies (AML=12, ALL n=1, LPD=1, CML=1, CMML=1) after allo-HSCT (n=9 with standard immunosuppression (MMF+CSA+ATG), and n=6 with cyclophosphamide (CY) on day+3,+4. All patients in CY group was in advanced or high risk disease at a time before allo-HSCT. The anti-CD4-APC-Cy7, anti-CD25-APC, anti-CD127-FITC and anti-Granzyme B-PE (Becton Dickinson, USA) antibodies were used to determine T-regulatory cells population as $CD4^+CD25^{high}$ (Gregg *et al.*, 2005) and $CD4^+CD25^{high}CD127^{low}$. We did not include anti-FoxP3 antibodies as FoxP3 is not so specific in humans and particularly after allo-HSCT due to technical difficulties, several isoforms and etc. $CD4^-$ lymphocytes ($CD8^+$ and NK-cells certainly containing granzyme B) were used as internal positive control. Geometric mean fluorescence intensity (gMFI) was used to assess Granzyme B expression. 50000 of $CD4^+$ cells were analyzed on a BD FACSCanto II (Becton Dickinson, USA).
Results: Four patients (26, 6%) (n=2 (22%) in standard IST group and n=2 (33%) in CY group) have developed aGVHD (II-IV) at a median time of +32 day (20-54) after HSCT. As we can see on chart 1: in a group with standard immunosuppression therapy (IST) the level of Granzyme B was higher in patients who never developed aGVHD in future (1653±273 gMFI units) in CD4+CD25highCD127low and (1646±287) in CD4+CD25high cell population. In a group without standard immunosuppression-only CY on day +3, +4 at dose 50 mg/kg. (Luznik *et al.*, 2008) the results was inverse. Patients who developed aGVHD in future have a higher level of Granzyme B expression (3716 gMFI units in CD4+CD25highCD127low and 4673 gMFI units in CD4+CD25high population). This data show us that we can use low granzyme B expression in T-regulatory cells on day +14 after allo-HSCT as aGVHD predictor only in a group with standard IST (Figure 1).

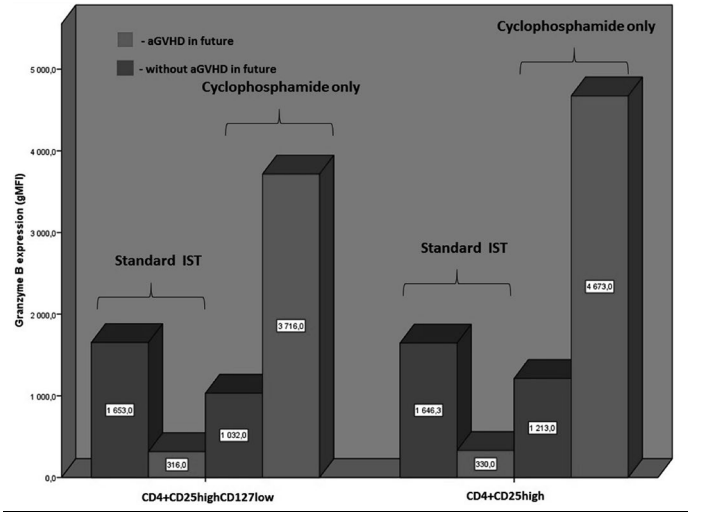

Figure 1.

Summary and Conclusions: Despite the fact that the analyzed group is small, we suggest that low expression of Granzyme B in Treg cells (despite assessment method) after allo-HSCT in patients with standard IST may predict aGVHD onset. This fact, of course, needs further investigation.

E1509

THE ROLE OF TREGS AND TIM3 IN HEMATOPOIETIC STEM CELL TRANSPLANTATION

C. Li[1,*] C. Ma[1], X. Chen[1], X. Yu[1], H. Liu[1], J. Ma[1], L. Ye[1], D. Wu[1]
[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Tregs in DC-CIK infusion play a critical role in immunosuppressive.
Aims: (1) To detect CD4+CD25+CD127-T cells (Tregs) from DC-CIK, which were infused to patients with high-risk or refractory hematologic malignancies after allogeneic hematopoietic stem cell transplantation(allo-HSCT) and to dis-

cuss the relationship between Tregs,Tim3 and aGVHD by detecting proportions of Tregs and expression of Tim3 in patients' peripheral blood.
Methods: (1) Detected the percentage of Tregs in DC-CIK by flow cytometry and compared the occurrence of aGVHD with patients who developed aGVHD but without DC-CIK infusion. (2) Sorted Tregs from DC-CIK by flow cytometry, using MTT assay and mixed lymphocyte reaction to research the inhibition function of Tregs from DC-CIK *in vitro*. (4) Detected the expression of Tim3 on CD4+ T cells, CD8+ T cells, CD3-CD56+ cells and CD4+CD25+ T cells in patients with or without aGVHD, respectively.
Results: (1) 32 patients with high-risk or refractory hematologic malignancies were treated with DC-CIK after allo-HSCT. 25 cases of DC-CIK were donor-derived and 7 cases were receptor-derived. (2) When the percentage of Tregs in DC-CIK was less than 5%, we defined as low proportion group, while high proportion group was defined when the percentage was more than 10%. 5%>10% was defined as middle proportion group. 10 cases were in low proportion group, 16 cases in middle proportion group and 6 cases in high proportion group. (3) 4/32(12.5%) patients with DC-CIK treatment developed I-II aGVHD and 3 of them were in low proportion group, 1 in middle proportion group. 10/27(37.03%) patients without DC-CIK treatment developed aGVHD. 7 of them developed I-II aGVHD and 3 developed III-IV. The incidence and degree of aGVHD in DC-CIK treatment group was significantly lower than none DC-CIK treatment group (P<0.05). (4) The percentage of Tregs in patients with aGVHD was lower than patients without aGVHD (P<0.05). (5) The Tim3 expression on CD4+ T cells, CD8+ T cells and CD4+CD25+ T cells were higher in patients with aGVHD than without aGVHD (P<0.05). While the expression was no significantly difference in CD3-CD56+ cells between the two groups(P<0.05).
Summary and Conclusions: (1)DC-CIK infusion after allo-HSCT can reduce the incidence of aGVHD and do not influence the effect of graft *versus* leukemia (GVL) at the same time, thus being a promising method to improve the cure rate of leukemia and providing a novel approach to cell biology treatment. (2) Tregs negatively regulate immune reaction post allo-HSCT on the occurrence and progress of aGVHD while Tim3 can promotes the occurrence and progress of aGVHD through positively regulating immune reaction. Further research will be needed to provide approach to reduce recurrence of aGVHD and gain more methods on the preventation and treatment of aGVHD.

E1510

SUCCESSFUL STEM CELL MOBILIZATION AND AUTOLOGOUS STEM CELL TRANSPLANTATION AFTER PRETREATMENT CONSISTING OF BENDAMUSTINE, PREDNISONE AND BORTEZOMIB IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA
W. Poenisch[1,*] M. Plötze[1], B. Holzvogt[1], M. Andrea[1], T. Schliwa[1], S. Heyn[1], G.N. Franke[1], M. Jentzsch[1], S. Leiblein[1], S. Schwind[1], T. Lange[1], V. Vucinic[1], H.K. Al-Ali[1], D. Niederwieser[1]
[1]Hematology/Oncology, University of Leipzig, Leipzig, Germany

Background: Bendamustine is a bifunctional alkylating agent with low toxicity that produces both single- and double-strand breaks in DNA, and shows only partial cross resistance with other alkylating drugs. Treatment of patients with newly diagnosed multiple myeloma (MM) using bendamustine and prednisone in comparison to melphalan and prednisone results in superior complete response rate and prolonged time to treatment failure. So far, however, reliable information on stem cell toxicity and mobilization of stem cells for autologous stem cell transplantation (SCT) after induction treatment with a combination of bendamustine, prednisone and bortezomib (BPV) is missing.
Aims: Examining feasibility of induction therapy with Bendamustine, Prednisone and Bortezomib (BPV) for Stem Cell Mobilization and Autologous Stem Cell Transplantation in 35 Patients with newly diagnosed/untreated Multiple Myeloma.
Methods: A retrospective analysis of peripheral blood stem cell mobilization and autologous SCT was performed in 35 patients with MM who had received at least one cycle of a BPV induction therapy consisting of bendamustine 60mg/m^2 on days 1 and 2, bortezomib 1.3mg/m² on days 1, 4, 8 and 11, and prednisone 100mg on days 1, 2, 4, 8 and 11 between October 2008 and May 2014. The mobilization regimen consisted of cyclophosphamide 4 g/m^2 and G-CSF (2x5µg/kg). Apheresis was started as soon as peripheral CD34$^+$ counts exceeded 20x10^6/L with a harvest target of 8x10^6 CD34$^+$/kg. The minimal accepted target was 2x10^6 CD34$^+$/kg. The transplantation conditioning therapy consisted of melphalan 200mg/m^2.
Results: A median number of two (range 1-5) BPV cycles were given. The majority of patients (n=31, 89%) responded with 2 sCR, 5 nCR, 11 VGPR, and 13 PR. Three patients had MR, and 1 SD. Stem cell mobilization and harvest was successful in all patients. In 19 of 35 patients (54%) a single apharesis was sufficient to reach the target. The median number of aphareses was one (range 1-4) and the median CD34$^+$ cell-count/kg was 13.5 (range 3.2-33.1)x10^6. All patients received an autologous SCT. Engraftment was successful in 34 of 35 patients. The median time to a leukocyte count >lx10^9/L was 11 days and the time to untransfused platelet count of >50x10^9/L was 13 days. 34 patients (97%) responded after the autologous SCT with 11 sCR, 2 CR, 7 nCR, 7 VGPR, and 7 PR. The progression free survival at 18 months was 87% and overall survival was 92%.
Summary and Conclusions: Conclusion: Stem cell mobilization and autologous SCT is feasible in MM patients who have received BPV induction therapy.

E1511

MINIMAL RESIDUAL DISEASE MONITORING BY FLOW CYTOMETRY IN CLL POST ALLOGENEIC STEM CELL TRANSPLANT (ALLOHSCT)
M. Sartor[1,*], D. Gottlieb[1]
[1]Haematology, Weatmead Hospital, Sydney, Australia

Background: Recent studies have demonstrated improved outcomes in patients with CLL who achieve MRD negativity within 12 months of alloHSCT.
Aims: We aimed to quantitate residual CLL after alloHSCT for the purposes of directing post-transplant chemo-immunotherapy to optimise outcomes.
Methods: We recently published a method for a single tube 10 colour flow cytometry assay to detect MRD in CLL and have used it for the quantitation of MRD post alloHSCT in a cohort of 11 patients transplanted for CLL between 2011 and 2014 at our institution.
Results: Sixty-eight MRD assessments were performed (median 5 per patient, range 1-13), the majority on PB (80%). Three patients died within the first 12 months post-transplant due to transplant related complications. Six patients attained MRD negative status very early post-transplant (range 1-6 months) and remain MRD negative and in remission at a median follow-up of 24 months (range 6-48 months). Two patients with persistent MRD at all times up to 12 months post-transplant were treated pre-emptively in response to rising MRD by tapering immunosuppression and administering escalating doses of DLIs, both without and on the final occasion with a preceding cycle of lympho-depleting chemotherapy. One patient has achieved MRD levels below 0.01% in PB within 22 months post alloHSCT. The other patient (17p- disease) has responded to treatment and has had stable residual disease up to 19 months post alloHSCT and now has progressive disease and has started treatment with ibrutinib.
Summary and Conclusions: Monitoring MRD at regular intervals gives a dynamic assessment of disease trends that is more meaningful than a single MRD assessment at 12 months post-transplant and may be a better indicator of disease trajectory. The application of MRD monitoring to guide pre-emptive immune interventions or targeted therapies shows promise in preventing clinical relapse post alloHSCT and warrants further investigation.

HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PRIMARY IMMUNE DEFICIENY DISEASES: A SINGLE CENTER EXPERIENCE
T. Patiroglu[1,*] M. Karakukcu[1], H.H. Akar[2], E. Unal[1], M.A. Ozdemir[1]
[1]Pediatric Hematology, [2]Pediatric Immunology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Primary immunodeficiency diseases (PID) are rare heterogeneous genetic disorders that can result in serious complications such as life-threatening infections. Hematopoietic stem cell transplantation (HSCT) is the only curative treatment for many of PID.
Aims: The aim of this study is to present the outcome of HSCT for PID in a single center experience in Kayseri in Turkey.
Methods: Herein, we present a retrospective analysis of 20 patients who underwent HSCT for PID from 2010 to 2015. The outcomes of PID patients were analyzed retrospectively.
Results: In a 5-year period, 20 patients (Female=10, Male=10) with PID who underwent HSCT were screened retrospectively. In the presented study, the patients were included with combined immunodeficiency (CID) (n=6), chronic granulomatous disease (n=2), hemophagocytic lymphohistiocytosis (n=4), Griscelli syndrome type 2 (n=2), B-cell immunodeficiency plus bone marrow failure (n=2), severe congenital neutropenia (n=1),x-linked lymphoproliferative disease (n=1), T-cell deficiency plus relapsed Non-Hodgkin Lymphoma (n=1), and leukocyte adhesion deficiency type 1 (n=1). Eleven patients, six patients, two patients, and one patient received related HLA matched HSCT, haplo HSCT, unrelated matched HSCT, and miss matched HSCT, respectively. The median age of the diagnosis of PIDs was 10.5 months (3-33 months). The median age of HSCT was 21 months (6-80 months). The median follow-up was 3.5 months (range, 2-17 months). Eleven, six, and one patients received matched, haploidentical, and mismatched HSCT have survival rates 73% and 50%, and 100% with overall survival of 65%, respectively. In the CID patients, Immunoglobulin dependency has been observed only one patient with Artemis gene defect. The mean neutrophil engraftment was 14.25±3.08 days. The mean platelet engraftment was 24.7±11.4 days. The ratio of GVHD was 25%.
Summary and Conclusions: These results showed that haploidentical HSCT as well as HLA-matched related HSCT may provide good results for PID again. It may be concluded that HSCT can be performed with an encouraging outcome in developing countries such as Turkey in patients with PID.

E1513

DECITABINE BRIDGING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF MDS RETROSPECTIVE EFFICACY ANALYSIS
H. Zheng[1], J. Wang[1], J. Zhou[1], P. Wang[1], C. Fu[1,*] D. Wu[1], A. Sun[1], H. Qiu[1], Z. Jin[1], Y. Han[1], X. Tang[1], X. Ma[1]

[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: A retrospective analysis of decitabine bridge therapy followed by allo-HSCT in 25 patients with MDS from July 2010 to December 2013, the First Affiliated Hospital of Soochow University, Department of Hematology.
Aims: To evaluate the efficacy of DAC (decitabine) bridge therapy followed by allo-HSCT (allogeneic hematopoietic stem cell transplantation) in patients with MDS.
Methods: We compared the 25 patients with the same period 33 patients who receive other treatments followed by allo-HSCT,comparing patients' mCR rate, OS and GVHD after DAC bridge therapy.
Results: With decitabine bridge therapy,64% patients achieved marrow complete remission,and the control group was 15.1% (64% *vs* 15.1%) (P<0.05). Decitabine bridging group of early transplant-related mortality than the control group (4% *vs* 18.2%), but the difference was not statistically significant (P=0.106). To follow-up deadline, decitabine group mortality was 12%, the control group was 30.3% (P<0.05). Decitabine group of 2-year OS was 83%, the control group was 59% (P<0.05). Patients with IPSS intermediate-1 receiving decitabine bridging the OS rate was higher, and transplant-related mortality rate less than the control group, the differences were statistically significant. GVHD occurred decitabine bridging group was 56% and the control group aGVHD incidence of 48.5% (P=0.713). aGVHD extent decitabine group is less than the control group (P<0.05). The incidence of occurrence of cGVHD was 41.7% in the control group, the control group was 31.6%.
Summary and Conclusions: decitabine bridging therapy followed by allo-HSCT in the treatment of myelodysplastic syndrome is safe and effective.

E1514

THE OUTCOMES OF HAPLOIDENTICAL HEMATOPOETIC STEM CELL TRANSPLANTATION PERFORMED WITH UNMANIPULATED DONOR STEM CELLS AND POST-TRANSPLANT CYCLOPHOSPHAMIDE IN HIGH RISK CHILDREN

M. Yesilipek[1,*] V. Uygun[2], G. Karasu[1], S. Cakı Kılıc[3], H. Daloglu[4], Ö. Özbörü[3]
[1]Pediatric Hematology, Bahcesehir University School of Medicine, Istanbul, [2]Pediatric Hematology, Bahcesehir University School of Medicine, Antalya, [3]Pediatric Hematology, Medicalpark Goztepe Hospital, Istanbul, [4]Pediatric Hematology, Medicalpark Antalya Hospital, Antalya, Turkey

Background: The patients who have a rare frequency of HLA group with a low chance for a matched donor or need urgent HSCT, haploidentical transplantation from the relative donors promises as a good alternative. In recent years, some of haploidentical transplantations are performed with unmanipulated bone marrow or peripheral blood stem cells which the GVHD prophylaxis includes a more intense chemotherapy approach. This approach is now more popular by post-transplant high dose cyclophosphamide (PTCY). However, there is limited experience in children.
Aims: In this study, we present the children who transplanted haploidentically in our center, with unmanipulated bone marrow or peripheral blood stem cells and GVHD prophylaxis with post-transplant high dose cyclophosphamide.
Methods: We assessed 16 HSCT in 15 patients retrospectively, who underwent haploidentical related HSCT with unmanipulated bone marrow or peripheral blood stem cells and used post-transplant high dose cyclophosphamide for GVHD prophylaxis. Five of patients were male and 10 were female between 3.5-17 years old, median 9 years old. One patient was AML developed after Ewing Sarcoma and one was ALL progressed from CML. Another patient was transplanted for aplasia developed after a haploidentical transplantation from his mother which had performed with CD34 positive selection. One patient underwent second haploidentical transplantation because of relaps. Four patients were in the first complete remission, five were in the second and three were in the third in the transplantation date. Donors were their mother in ten transplantation, the father in five, and a sibling in one patient. For the conditioning regimen BU+FLU+Etoposid was used for seven patients and two patients with BU+FLU+ATG/, BU+CY+Mel,/BU+FLU+ATG and FLU+CY+Mel, and one patient with BCNU+Etoposid+ARA-C+Mel. Fifty mg/kg CY on the 3rd and 5th day and CsA or tacrolimus with MMF or MP were also used for GVHD profilaxis. The source of stem cells was bone marrow in six transplantation while bone marrow and peripheral blood stem cell were used in ten transplantation. The median count of TNC, MNC, CD34+ and CD3+ was $12{,}9x10^8$ (4,1-39), $8{,}8x10^8$ (4,8-14,3), $5{,}9x10^6$ (2,5-16) and $2{,}9x10^8$ (1,1-7,8), respectively.
Results: All patients engrafted with a median of 16 days (16-23) and 18 days (11-37) for neutrophil and thrombocyte recovery, respectively. Grade 1 acute GVHD developed in one patients, and grade 2 in 4 and 3 in 3 patients, while limited chronic GVHD developed in two patients. Three patients had hemorrhagic cystitis and four developed VOD. Two patients were lost in the first 100 days because of sepsis (TRM 12, 5%). After 100 days, a patient died of progression of the primary disease and one patient was lost because of pneumonia. One patient with diagnosis of Hurler showed graft rejection. The rest ten patients (66.6%) are disease-free (OS is 73.3%) and on the follow up of median 10 months (between 4-20 months).
Summary and Conclusions: The advantages of using unmanipulated hematopoetic stem cells are low laboratory costs, no worry for waiting for a suitable donor, and less risk for graft failure or T cell deficiency. Our results are consistent with these circumstances in our high risk patients and encouraging for haploidentical HSCTs. However our results should be accepted as a preliminary report with these few patients. We think that, it should be studied for more patients and also for comparing with other haploidentical HSCT modalities with longer follow up.

E1515

THE EBMT RISK SCORE CAN PREDICT THE OUTCOME AFTER ALLOGENEIC HEMATOPOIETC CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA AMONG EGYPTIAN PATIENTS

S. Desoukey[1,*] O. Fahmy[1,2], H. Kamel[3,4], A. Galal[5], H. Messner[5]
[1]Internal Medicine, Hematology, Kasr Al-Ainy school of Medicine, Cairo University, [2]Nasser Institute Hospital, [3]Hematology and Oncology, National Cancer Institute, [4]Stem Cell Transplantation, Nasser Institute Hospital, Cairo, Egypt, [5]Hematology and Oncology, Princess Margaret Hospital, Toronto, Canada

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is a potentially curative therapy for many patients diagnosed with acute myeloid leukemia (AML). However, the success of this procedure has been limited by high transplant-related mortality. Moreover, it is a high-cost procedure and can present a financial challenge for patients and health care systems in developing countries. Risk stratification and outcome prediction among AML patients receiving transplantation are required to guide decision making. The European Group for Blood and Marrow Transplantation (EBMT) risk score, previously devised for chronic myeloid leukemia, has been validated as a simple tool to predict the outcome of allogeneic HSCT for other acquired hematological disorders including AML.
Aims: The aim of this study was to evaluate the predictive validity of the EBMT risk score to the outcome of allogeneic HSCT in a cohort of Egyptian patients diagnosed with AML.
Methods: This is a retrospective single-center observational study. It was conducted using data of 291 consecutive patients diagnosed with AML and underwent first allogeneic HSCT between January 1997 and December 2008 at Nasser Institute Hospital. Patients diagnosed with AML-M3 were excluded. Median age of all patients at time of transplantation was 21 years (range, 1 to 57 years); with 114 patients (39%) aged 18 years or younger and 113 patients (39%) were female. HCT was performed in first complete remission for 209 patients (72%) and in second remission or beyond for 82 patients (28%).The majority of patients (89.6%) received myeloablative condition regimen. All donors were HLA-identical siblings. Peripheral blood stem cells were used as graft source in 96.2% of patients. Median follow-up duration among survivors was 12 months (range, 0-107 months). We calculated the EBMT risk score for all the patients and the overall survival (OS) and transplant-related mortality (TRM) were analyzed. Required parameters for the calculation of the score were extracted from patients' database and files.
Results: In univariate analysis the EBMT risk score was a significant variable predictive of OS. Survival decreased with increasing EBMT risk score. The projected 2- year OS rates were 71%, 50%, 37%, 25%, and 0% for scores 0, 1, 2, 3 and 4/5, respectively (p<0.0001). The EBMT risk score also was highly predictive of TRM. The 2-year cumulative incidence of TRM rates were 23%, 48%, 54%, 65% and 100% for scores 0, 1, 2, 3, and 4/5, respectively, (P<0.0001). In multivariate analysis the EBMT was confirmed as prognostic factor for both OS (p=0.03, HR=0.5, 95%CI=0.27-0.92) and TRM (p=0.0007, HR=0.39, 95%CI=0.23-0.67) (Figure 1).

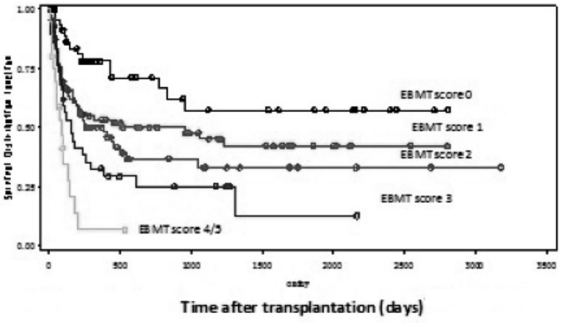

Figure 1. Probability of survival for patients who underwent allogeneic HSCT for AML at Nasser Institute, by the EBMT risk score.

Summary and Conclusions: The EBMT riak score is shown to be predictive of the outcome after allogeneic HSCT among Egyptian patients with AML and can be incorporated into risk-adapted decision-making before transplantation.

E1516

FACTORS AFFECTING SURVIVAL IN PATIENTS WITH ACUTE LEUKEMIA WHO RECEIVED DONOR LYMPHOCYTE INFUSION IN THE TREATMENT OF FIRST RELAPSE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

F. Kurnaz[1,*] L. Kaynar[2], B. Eser[3], F. Altuntas[4], S. Sivgin[3], C. Pala[5], C. Sahin[6], A. Unal[3], M. Cetin[2]
[1]Hematology, Harran University, Sanliurfa, [2]Hematology, [3]Erciyes University, Kayseri, [4]Ankara Yurtaslan Oncology Hospital, [5]Hematology, Ankara Diskapi Hospital, Ankara, [6]Internal Medicine, Mugla University, Mugla, Turkey

Background: Leukemia relapse after allogeneic stem cell transplantation (SCT) remains an important problem. Beside the best treatment option in patients with relapsed acute leukemia is not certain; cytoreductive chemotherapy followed by donor leukocyte infusion (DLI) is one of the treatment modality in relapse patients.
Aims: In this study we evaluated the factors affecting on overall survival (OS) in allogeneic SCT patients who received DLI after first relapse.
Methods: Acute leukemia patients who were in their first relapse after allo-SCT were evaluated retrospectively. The data of 54 patients [26 acute myeloid lekemia (AML) and 28 acute lymphoblastic leukemia (ALL)] between March 2004 and March 2013 was collected from patients' files and also confirmed with the data by computed file system. In this retrospective study 54 relapsed patients in their first relapse after allo-SCT who received fludarabine based chemotherapy followed by DLI were evaluated.
Results: The probability of OS after diagnosis for AML at 1, 3, 6, 12 and 24 months were 96%, 92%, 76%, 56% and 27%, respectively and for ALL were 100%, 92%, 81%, 62% and 25%, respectively. The median OS was 17 (1-66) months for AML and 10 (3-39) months for ALL; there was not a statistically significant difference between these patients (p>0,05) at the end of follow up. A total of 10 patients developed acute GVHD after DLI (18.5%). GVHD was seen more frequently in the patients who received more than one DLIs than the patients who received only one DLI (p=0.7), there was not a significant increase at probability of OS in patients who had acute GVHD after DLIs (p>0.05). Increased number of DLIs (p=0,001), and increased time period from transplantation to DLI (p=0,005) were predictive for survival in cox multiple regression analysis.
Summary and Conclusions: The chemotherapy regimens especially including lymphocyte depleting agents, such as fludarabin, before DLI may be effective in the treatment of patients with relapsed acute leukemia after allo-SCT. This study showed that increased number of DLI improves the OS, and efforts to enhance the number DLIs should be considered in leukemia patients that relapsed after allo-SCT.

E1517

CD4+ CELL COUNT ON DAY+30 PREDICT OVERALL SURVIVAL AND TRANSPLANT RELATED MORTALITY IN ACUTE LEUKAEMIA PATIENTS AFTER ALLOPBSCT

D. Pastore[1,*] M. Delia[1], A. Mestice[1], P. Carluccio[1], A. Ricco[1], A.V. Russo Rossi[1], C. Pasciolla[1], P. Pinto[1], S. D'Agostino[1], C. Brunetti[1], G. Specchia[1]
[1]Hematology with Transplantation, Policlinico, Bari, Italy

Background: Allogeneic peripheral stem cell transplantation (alloPBSCT) from a related or unrelated donor is a well established strategy for patients with acute leukaemia. However, this procedure is associated with increased morbidity and mortality because of graft *versus* host disease (GvHD), immune reconstitution impairment and a high risk of infections.
Aims: In our study we evaluated the lymphocyte subset recovery after alloPBSCT and its impact on transplant related mortality (TRM) and overall survival (OS) in acute leukaemia patients.
Methods: We evaluated the immune reconstitution of CD3+/CD4+, CD3+/CD8+ and NK cells performed at 30, 100, 180 and 360 days after alloPBSCT in 122 patients with acute leukaemia. Patients were transplanted with unmanipulated PBSC from an HLA matched related donor (MRD) (n=85) or an HLA (8/8) matched unrelated donor(MUD) (n=37). Median age was 38 years (range 18-61); diagnoses were acute myeloid leukaemia (n=96) and acute lymphoblastic leukaemia(n=26); 80% of patients underwent myeloablative conditioning (busulphan, cyclophosphamide in MRD and busulphan, cyclophosphamide and ATG in MUD) and 20% underwent reduced intensityconditioning (busulphan, fludarabine, ATG).
Results: The median counts of CD3+/CD4+ were 98, 160, 200, 262 µl at 30, 100,180 and 360 days, respectively. The median counts of CD3+/CD8+ were 180, 350, 500 and 670 µl at 30, 100, 180 and 360 days, respectively. The median counts of NK cells were 110, 260, 270 and 260 µLat 30, 100, 180 and 360 days, respectively. Considering the entire patient population the median cell count rose above 200 µl after day 180 for CD3+/CD4+ and after day 45 for CD8+cells; the median NK cells count rose above 100 µl after day 30. The median CD3+/CD4+ cell count on day +30 for the entire patient population was 98 µl (range 20-190) and TRM at 2 years was significantly higher in patients not achieving this CD4 cell count (38% *vs* 15%, p<0.001); patients with a low CD3+/CD4+ count (<98 µl) on day +30 had a higher risk of dying of infections (30% *vs* 11%, p>0.003). Median OS in patients not achieving CD4+ of 98 µl at 30 days was 40 months while median OS in patients with more than 98 CD4+ at 30 days was not reached. Univariate analysis at 100 days showed a significant association between CD4 cell recovery and transplant from a related donor (p=0.003), myeloablative conditioning (p=0.04) and absence of aGvHD (grade II-IV)(p=0.002). In multivariate analysis, transplant from a related donor (p=0.05) and absence of aGvHD(grade II-IV) (p=0.002) were significantly associated with a better CD4 cell recovery. CD3+/CD8+ and NK cells recovery did not correlate with a different TRM risk or OS.
Summary and Conclusions: Our results support the relationship between immune reconstitution of CD4+, OS and TRM. The CD4+ cell count on day +30 is able to predict OS and TRM after myeloablative alloPBSCT in acute leukaemia patients.

E1518

HBV CLEARANCE IN HBSAG+ PATIENTS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IS HERALDED BY GVHD OF LIVER

T.-D. Tan[1,*] M.-C. Wu[1], L.-W. Chiou[1], A.-C. Feng[2]
[1]Hematology and Medical Oncology, [2]Clinical Research and Statistics, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, ROC

Background: Alloimmune reaction has been reported to be effective in clearing chronic hepatitis B (HBV) infection. However, the successful rates of HBV surface antigen (HBsAg) clearance after allogeneic hematopoietic stem cell transplantation are not clear.
Aims: We surveyed the seroconversion rate and chronologic change of HBsAg titers retrospectively from the hematologic malignancy patients with HBsAg+ underwent allogeneic stem cell transplantation at our transplant unit.
Methods: Between 2001 ad 2013, we have twelve patients of HBsAg+ out of 210 patients undergoing allogeneic stem cell transplantation. All of them were under anti-HBV prophylaxis with either lamivudine or entecavir and included myeloablative or reduced intensity conditioning regimens for AML, ALL, NHL, HL, and multiple myeloma patients.
Results: In these twelve HBsAg+ patients, 3 from HBsAg+ donors and one of them got seroconversion with HBsAg cleared. The other 9 patients received stem cells from HBsAg- and anti-HBsAb+ donors with 5 of them got successful clearance of HBsAg and HBV DNA undetectable (55.5%) with the earliest seroconversion seen on sixth month after transplantation. Three of them got malignant disease recurrence in the first year. None of our patients got symptomatic flare of hepatitis B or even fulminant hepatitis. In four patients, we can see the clearance of HBsAg is heralded by graft *versus* host disease with low or undetected HBV DNA (Figure 1).

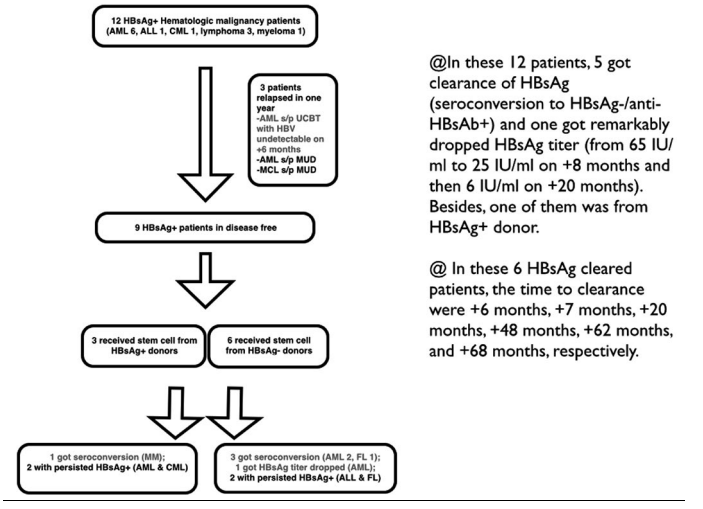

Figure 1. Disposition of HBsAg+ patients underwent allogeneic stem cell transplant in cohort 1.

Summary and Conclusions: HBsAg+ hematologic malignancy patients can attain high successful rate of seroconversion when underwent allogeneic stem cell transplantation from HBsAg-/anti-HBsAb+ donors via graft *versus* host effect. The risk of fulminant hepatitis flare is minimal in these patients whom anti-HBV prophylaxis performed.

E1519

OUTCOMES OF CORD BLOOD TRANSPLANTATION WITH NON-TOTAL BODY IRRADIATION CONDITIONING REGIMEN CONSISTING OF FLUDARABINE AND BUSULFAN FOR PATIENTS WITH ADVANCED HEMATOLOGYIC MALIGNANCIES

K. Tsuda[1,*] S. Sakaue[1], Y. Takahashi[1], T. Isshiki[1], N. Takei[1], K. Kobayashi[1], T. Tanimoto[2], Y. Satou[3], M. Kurama[3], T. Komatsu[1]

[1]Division of Hematology and Rheumatology, Teikyo University Chiba Medical Center, Ichihara, [2]Division of internal medicine, Navitas Clinic, Tokyo, [3]Division of Hematology, Tsukuba Memorial Hospital, Tsukuba, Japan

Background: Cord blood transplantation (CBT) has increasingly become an alternative therapy in patients who lack suitable related or unrelated donors with advanced hematologic malignancies. Non-total body irradiation (TBI) conditioning regimen has a high degree of usability for medical institutions where TBI cannot be performed promptly. However, in contrast to bone marrow or peripheral blood stem cell transplantation, the optimal non-TBI conditioning regimen is not established in CBT yet.
Aims: We investigated the outcomes of CBT with non-TBI conditioning regimen consisting of fludarabine and busulfan in patients with advanced hematologic malignancies.
Methods: Patients who underwent their first CBT using single unit umbilical cord blood between April 2004 and December 2014 in Teikyo University Chiba Medical Center and Tsukuba Memorial Hospital were included for the present study. They were treated with non-TBI conditioning regimen consisting of fludarabine 30 mg/m^2 for 6 days and busulfan 0.8 mg/kgx 4 for 2 or 4 days. Graft-*versus*-host disease (GVHD) prophylaxis was provided by tacrolimus only.
Results: A total of 53 patients received CBT. The median age was 62 years old (range, 26-74 years). Acute myeloid leukemia was the predominant diagnosis (53%, n=28), followed by Non-Hodgkin lymphoma (n=8). The remaining diagnosis included multiple myeloma (n=7), myelodysplastic syndrome (n=6), primary myelofibrosis (n=2) and chronic myeloid leukemia (n=2). Only 16 patients (30%) were in remission at transplantation. Median numbers of infused total nucleated and CD34-positive cells were 2.9x 10^7 /kg (range, 1.9-5.5) and 0.58x 10^5 /kg (range, 0.2-2.1), respectively. The cumulative incidence of neutrophil engraftment was 62% (95% confidence interval [CI], 48%-74%), with a median time to recovery of 23 days (range, 14-47 days). The cumulative incidence of grade II-IV and grade III/IV acute GVHD was 22.9% (95% C.I., 12.5-35.0%) and 5.7% (95% C.I., 1.5%-14.3%), respectively. Twelve patients developed chronic GVHD and the cumulative incidence of chronic GVHD was 20.8% (95% C.I., 10.8-32.9%). At one year, the cumulative incidence of treatment related mortality was 42%. The leading cause of non-relapse mortality was infection (n=9) followed by graft failure (n=3), acute GVHD (n=3), chronic GVHD (n=2) and hemorrhage (n=2). At one year, overall survival was 25.0% (95% C.I., 13.9-37.6%). Univariate and multivariate analysis revealed that poorer overall survival was significantly associated with age ≥70 (p<0.01). Overall survival at 1 year among patients younger than 70 years old was 28% (95% C.I., 15.8-42.0%) (Figure 1 and Figure 2).

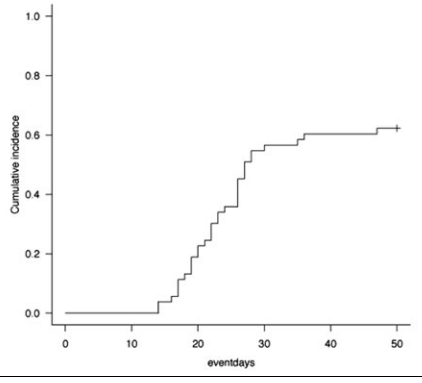

Figure 1. The cumulative incidence of neutrophil engraftment.

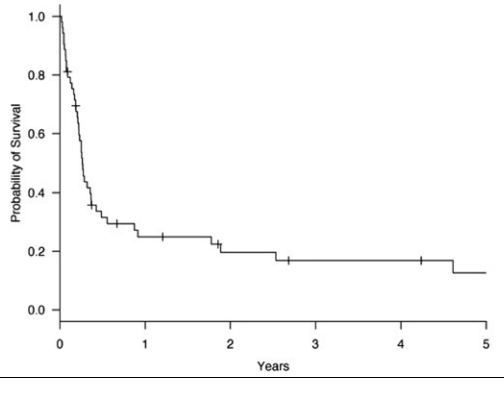

Figure 2. Kaplan-Meier estimates of overall survival.

Summary and Conclusions: Our results suggest that conditioning regimen with fludarabine and busulfan in CBT is a feasible option for patients younger than 70 years in medical institutions where TBI cannot be performed.

E1520

A PORTABLE MICROSCOPIC CELL COUNTER (ADAM II) FOR ENUMERATING CD34+ CELLS

J.H. Oh[1,*] Y. Jung[1], M.S. Kim[1], S.R. Bong[1], S.H. Hong[1], J.Y. Kim[1], H.J. Park[1], J.K. Hwang[1], C. Chung[1], C.S. Lim[2], H. Koh[3], Y.-H. Lee[4]
[1]NanoEntek, [2]Department of Laboratory Medicine, Korea University Medical Center, [3]Department of Translational Medicine, Hanyang University Graduate School of Biomedical Engineering, [4]Department of Pediatrics, Hanyang University Medical Center, Seoul, Korea, Republic of

Background: Accurate determination of CD34+ cell numbers is of considerable clinical importance and essential in the field of stem cell transplantation. Several flow cytometry assays for enumerating CD34+ cell have been proposed, but differences in gating methods between users lead to variability in the results. Also flow cytometry assays require expensive instrumentation, have high reagent costs, and, in most cases, are technically difficult. Therefore, a new instrument that produces CD34+ cell counts more simply and reproducibly is required.
Aims: We previously developed a new CD34+ cell counting device (Adam II) that uses a microchip and microscopic cell counter. Our aim here was to evaluate the Adam II as a CD34+ cell counter by comparing it with a conventional flow cytometer.
Methods: We used peripheral blood stem cell (PBSC) samples from 17 patients with hematological malignancies and 11 cryopreserved umbilical cord blood (UCB) samples. Each individual donor provided written informed consent prior to us obtaining the samples, and the study was approved by the Institutional Review Board of Hanyang University Hospital. To assess the precision and linearity of the Adam II, CD34+ cell counts obtained with it were compared with those from flow cytometry. For measurements, samples were introduced into the Adam II CD34 tube containing lyophilized fluorescence mixtures. The reacted samples were then loaded into the chips and read. For flow cytometry, we used a Stem Cell Enumeration kit (BD Biosciences, Franklin Lakes, NJ) to stain the samples, and the relative proportions of CD34+ cells were obtained with a FACS Calibur (BD Biosciences). To assess linearity, samples were serially diluted with mononuclear cells separated from the peripheral blood of a healthy adult, and to assess reproducibility, some samples were counted 10 times, and coefficients of variations (CVs) were calculated.
Results: Linear regression analysis revealed a close correlation between the data for CD34+ cell fractions (%) obtained with the Adam II and those obtained with the FACS Calibur for both PBSCs (r^2=0.98) and UCBs (r^2=0.93). The two methods also gave very similar results for the viability of the PBSCs (r^2=0.94). A dilution test of the Adam II method gave a linearity coefficient of r^2=0.99, and the method proved to be reliable in the samples serially diluted over the expected range: thus, four PBSC dilutions at CD34+ cell concentrations of 0.44, 0.18, 0.08 and 0.03% had C*V*s of 7.86, 13.66, 20.83 and 38.46%, respectively.
Summary and Conclusions: We have established a close correlation between CD34+ cell counts and viability assays with the FACS Calibur and the Adam II. This suggests that the Adam II CD34+ cell counting device could be useful for stem cell assays given its advantages of reproducibility, accuracy, convenience, and low expensive.

E1521

LONG-TERM OUTCOMES FOLLOWING REDUCED-INTENSITY STEM CELL TRANSPLANTATION: THE CRITICAL IMPORTANCE OF THE DEVELOPMENT OF GRAFT-*VERSUS*-HOST DISEASE

E. Nevill[1,*]R. Broady[1], D. Hogge[1], D. Forrest[1], M. Barnett[1], S. Nantel[1], C. Toze[1], A. Gerrie[1], K. Song[1], S. Narayanan[1], H. Sutherland[1], J. Lavoie[1], C. Dalley[1], M. Power[1], E. Conneally[1], Y. Abou Mourad[1], T. Nevill[1]
[1]Leukemia/BMT Program of BC, Vancouver, Canada

Background: Allogeneic stem cell transplantation (AlloSCT) is the most effective treatment for a wide variety of hematologic diseases. The development of reduced-intensity conditioning transplantation (RICT) has allowed alloSCT to be used in patients (pts) of advanced age or with comorbidities.
Aims: The study objective was to determine the incidence of acute/chronic graft-*versus*-host disease (GVHD), treatment-related-mortality (TRM) and relapse rate and to calculate Kaplan-Meier estimates of overall survival (KM OAS) following RICT.
Methods: An IRB-approved retrospective chart and data base review was performed on all pts that underwent RICT at Vancouver General Hospital between 05/01 and 12/13. Final analysis date was August 1, 2014.
Results: During the study period, 220 pts underwent RICT with all patients signing IRB-approved consent forms; there were 150 males and 70 females with median age of 58 years (range 18-68). Diagnoses were CLL (73 pts), lymphoma (42 pts), AML (40 pts), myeloma (25 pts), MDS (10 pts), myelofibrosis (8 pts), CML (4 pts) or other (18 pts). A total of 232 RICT were performed-209 pts had one, 11 pts had two [10 for graft failure (GF)] and 1 pt had 3 (for GFx 2) RICT. Conditioning was Fludarabine (Flu)/Busulfan (Bu) (71 pts), Flu/Cyclophosphamide (Cy) (64 pts), Flu/Bu/Campath (42 pts), Flu/Bu/ATG (37 pts) or other (18 pts); GVHD prophylaxis was Cyclosporine

and either Methotrexate (228 pts) or Mycophenolate (4 pts). Donor source was matched related (MRD, 140 pts) or unrelated (MUD, 59 pts) and mismatched related (7 pts) or unrelated (MMUD, 26 pts). Following RICT, 59%, 53% and 42% of patients did not require red cell, platelet or any transfusion support, respectively. Neutrophils >0.5 occurred a median of 18 days (range 0-138) post-RICT (19 pts never went <0.5). Acute GVHD occurred in 32% of MRD, 38% of MUD and 58% of MMUD pts and chronic GVHD occurred in 72%, 55% and 54% of these cohorts, respectively. GF was identified 13 times in 11 pts; 6 of these pts are alive and well. KM OAS after FluCy MRD RICT is 41% at 10 years, 51% at 5 years after BuFlu MRD RICT and 53% at 5 years after MUD/MMUD RICT. There are 86 pts alive in continuous complete remission (CCR), 85 pts relapsed (13 of whom are still alive in remission) and 48 pts (21%) died of treatment-related complications (TRM). MUD/MMUD pts receiving Campath had a lower incidence of acute (32%) and chronic (44%) GVHD compared to those receiving ATG (62% and 76%, respectively) but a higher incidence of relapse (50% *versus* 22%, respectively) and a lower 5-year OAS (48% *versus* 68%, p=0.14). In the entire cohort, 11% developed acute GVHD only, 39% chronic GVHD only, 26% both and 24% neither. Outcome was most favourable, and similar, for the "chronic only" and "both" groups (combined N=151) with 78 pts (52%) in CCR; relapse and TRM occurred in 45 (30%) and 27 (18%) pts, respectively (1 pt had GF). In the "acute only" group, 7 pts (27%) remain in CCR, 12 pts relapsed (46%) and 6 pts (23%) experienced TRM (1 pt had GF). In the "neither" group, 30 pts (55%) relapsed, 13 pts (24%) died of TRM, 11 pts (20%) had GF and 1 pt (2%) remains in CCR.

Summary and Conclusions: RICT results in long-term survival for many pts with hematologic malignancies with similar outcomes seen with MRD and MUD/MMUD. In the latter group, *in vivo* T-cell depetion with ATG is associated with better outcomes than with Campath due to a lower risk of relapse with ATG. Despite the morbidity associated with GVHD, its development (particularly the chronic form) is critical to a successful outcome with RICT.

E1522

AUTOLOGOUS STEM CELL TRANSPLANT IN AL AMYLOIDOSIS: AN EFFECTIVE TREATMENT FOR SELECTED PATIENTS

M. D'Adda[1,*] F. Schieppati[1], S. Ferrari[1], A. Belotti[1], C. Pagani[1], E. Cerqui[1], C. Bottelli[1], D. Dalceggio[1], G. Rossi[1]
[1]hematology, spedali civili, brescia, Italy

Background: High-dose melphalan (HDM) followed by autologous stem cell transplant (ASCT) has been routinely used as a treatment option for systemic light chain AL amyloidosis since the first report in mid-1990s. The high treatment-related mortality (death before post-transplant day 100) reported in literature (11-40% in different papers) has decreased over the last years with the improvement in patient selection. Particularly, in the largest Mayo Clinic series of 422 subjects, patients with cardiac troponin-T <0.06 ng/L and NT-proBNP <5000 ng/L had TRM <1%; besides, patients achieving hematologic complete response/very good partial remission (CR/VGPR) had superior overall survival than those achieving hematologic partial response (PR) and no response.

Aims: To evaluate the outcome of the autologous stem cell transplant in patients with AL Amyloidosis

Methods: Twenty-one ASCT were performed between 2001 and 2014 in 16 patients with AL amyloidosis (10 male and 6 female), in our center. The median age at the time of ASCT was 58 years (range 38-68). Ten patients had 2 or more involved organs. All 16 patients had: normal troponin-I value, NT-proBNP <5000 ng/L, PS 0-1, cardiac ejection fraction over 50%, CO diffusion capacity over 50%; three had creatinine clearance <50 ml/min. Five patients collected stem cells after cyclophosphamide (1,5-4 g/m^2), the others after G-CSF alone. Seven patients proceeded directly to ASCT without "induction therapy". Five patients received CyBorD (5/5 obtained hematologic PR, 3/5 organ response) and 4 patients other induction regimen (without any response). Eleven patients were treated with ASCT as 1st line therapy, 5 in 2nd or 3rd line. Patients received melphalan 200 mg/m^2 (12 ASCT) or dose adjusted HDM (100-140 mg/m^2, 9 ASCT), depending on clinical decision. Five patients received double ASCT.

Results: Median follow up is 39 months (range 3-168); only 1 patient died (+48 months), for progression. All the others were alive at the last visit. Overall hematologic and organ response rate after ASCT were 81% and 56%, without significant differences between patients treated with "induction therapy" before HDM and patients that proceeded directly to ASCT. Two of 5 patients with double ASCT improved response after second course (after 82 and 144 months follow up they maintain a hematologic CR without organ involvement). Median hospitalization for ASCT was 24 days (range 17-45), without any threatening-life side effect. Eight of 16 patients needed new therapy for progressive disease after a median follow up of 22 months (range 6-52): 5 of them had achieved hematologic PR after ASCT, 1 patient achieved hematologic VGPR but no organ response and 2 had no hematologic response. Eight patients are in follow up without other therapy after ASCT: 1 had optained no response, 2 hematologic PR, 1 VGPR and 4 CR. These 4 patients in persistent hematologic CR performed ASCT as 1st line therapy and 3 of them have long follow up (+82, +144, +168 months).

Summary and Conclusions: HDM followed by ASCT is an effective treatment option in AL-amyloidosis, which may be effective even in patients non responding to previous treatment with non myeloablative drugs. According to the data of the literature, our experience suggests that a careful selection of patients is critical for good outcomes and that particular cardiac biomarkers (cardiac troponin-T <0.06 ng/L and NT-proBNP <5000 ng/L) are useful to guide the choice of therapy. Also in our patients, hematologic CR after HDM seems to be an important factor for long survival without other therapy. Therefore, consolidation therapy (IMiDs and proteasome inhibitors) should be considered for patients who do not obtain at least a VGPR/CR after HDM. Finally, in our experience the best results are in patients treated with ASCT as 1st line therapy.

E1523

TROUGH LEVEL MONITORING OF INTRAVENOUS BUSULFAN TO ESTIMATE THE AREA UNDER THE PLASMA DRUG CONCENTRATION-TIME CURVE IN PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANT RECIPIENTS

T. Nishikawa[1,*] E. Watanabe[2], K. Ikawa[3], Y. Kodama[1], T. Tanabe[1], Y. Shinkoda[1], Y. Okamoto[1], Y. Kawano[1]
[1]Pediatrics, [2]Clinical Pharmacy and Pharmacology, Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, [3]Clinical Pharmacotherapy, Hiroshima University, Hiroshima, Japan

Background: Busulfan is an alkylating agent that plays an important role in myeloablative preconditioning regimens in the setting of hematopoietic stem cell transplantation (HSCT). A relationship between the busulfan dose intensity, expressed as the area under the plasma busulfan concentration *versus* time curve (AUC), and certain HSCT outcomes has been described. Although intravenous busulfan is considered to have a much more predictable pharmacokinetic profile than oral busulfan, there remains strong variation, particularly in children. Therapeutic drug monitoring for appropriate dose adjustment is therefore recommended in all patients treated with regimens containing high-dose busulfan.

Aims: Traditionally, the busulfan AUC is calculated using six plasma concentrations obtained within the six hours following busulfan infusion and before the second dosing of busulfan ($AUC_{0-\infty}$). The application of fewer samples to calculate the busulfan AUC would result in cost savings (workload, assay costs) and reduce patient inconvenience related to obtaining blood samples. In this study, we investigated the correlation between the busulfan concentration and $AUC_{0-\infty}$ to determine the best clinical method for monitoring the drug level.

Methods: Intravenous busulfan was infused via a central venous catheter for two-hour periods every six hours for a total of 16 doses over four days. Following the administration of a single dose of busulfan as a test dosing and the first dosing of busulfan for the conditioning regimen, blood samples were collected from each patient at six time-points (1, 2, 2.25, 2.5, 3 and 6 hours from the start of the infusion). The busulfan concentrations in the plasma were measured using high-performance liquid chromatography. The busulfan AUC from 0 to infinity ($AUC_{0-\infty}$) was calculated according to the trapezoidal method using MOMENT program, employing all six of the available data points. The relationships between the $AUC_{0-\infty}$ and plasma busulfan concentrations obtained at individual time points after intravenous administration were assessed using Pearson's correlation coefficient. Limited sampling strategies (LSSs) using one, two, or three plasma busulfan concentrations were developed by multiple linear regression. The associations between the actual $AUC_{0-\infty}$ and the predicted $AUC_{0-\infty}$ based on LSS were described using the adjusted coefficient of determination (r^2); values of >0.9 were considered to be acceptable. The degree of bias and precision of the LSS was measured using the mean prediction error (bias) and root-mean-squared prediction error (precision) methods. Bias and precision values of <15% were considered to be acceptable.

Results: Pharmacokinetics samples (total: 46 AUCs) were collected from all 29 patients. The mean (±standard deviation) $AUC_{0-\infty}$ was 1,124 (±321) μM min. The relationship between the AUC calculated using available all time-points (actual $AUC_{0-\infty}$) and the AUC predicted using each one time-point at 1 hour (C_1), 2 hours (C_2), 2.25 hours ($C_{2.25}$), 2.5 hours ($C_{2.5}$), 3 hours (C_3) or 6 hours (C_6) after the start of the two-hour infusion (predicted $AUC_{0-\infty}$). The $AUC_{0-\infty}$ predicted based on C_6 (trough level) was significantly correlated with, and not statistically different from, $AUC_{0-\infty}$ (r^2=0.929, P <0.0001, mean bias 0.282% (95% confidence interval: -2.01 to 2.57), precision: 7.91%). These results met the criteria for acceptability (adjusted r^2 >0.9, mean bias <15% and precision <15%). In contrast, the limited AUCs derived from the other sampling points (C_1, C_2, $C_{2.25}$, $C_{2.5}$ and C_3) did not meet the criteria. LSSs using one- (C_6), two- (C_2 and C_6), or three-sample (C_2, C_3 and C_6) were developed by multiple linear regression that showed excellent agreement with $AUC_{0-\infty}$.

Summary and Conclusions: We created the LSSs using one, two, or three time-point to estimate the $AUC_{0-\infty}$ in children receiving intravenous busulfan prior to HSCT. These $AUC_{0-\infty}$ well predicted the actual $AUC_{0-\infty}$ with good precision and little bias. In single-point sampling strategies, the $AUC_{0-\infty}$ predicted by the LSS (C_6) and $AUC_{0-\infty}$ using the six data points demonstrated excellent agreement.

E1524

A BENDAMUSTINE CONTAINING FLUDARABIN-BASED REDUCED INTENSITY CONDITIONING FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN REFRACTORY/RELAPSED CLASSICAL HODGKIN LYMPHOMA

N. Mikhaylova[1,*] M.O. Popova[1], Y. Osipov[1], E. Borzenkova[1], E. Kondakova[1], M. Ivanova[1], A. Kozlov[1], V. Vavilov[1], O. Slesarchuk[1], I. Moiseev[1], O. Pirogova[1], A. Alyanskiy[1], E. Babenko[1], M. Vladovskaya[1], S. Bondarenko[1], L. Zubarovskaya[1], B. Afanasyev[1]

[1]Raisa Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, First Pavlov State Medical University of Saint-Petersburg, Saint-Petersburg, Russian Federation

Background: Autologous hematopoietic stem cell transplantation (autoHSCT) is the standard treatment for pts with relapsed and refractory cHL (rr-cHL) but 20-30% responders to second line chemotherapy eventually have relapse. Allogeneic hematopoietic stem cell transplantation (alloHSCT) is a method with high curative potential in rr-cHL, but the role of alloHSCT is still a subject of controversy because of high treatment-related mortality (TRM) of myeloablative conditioning regimens (CR). Reduced intensity conditioning (RIC) regimens have emerged as a potential option with acceptable TRM in chemosensitive pts. High toxicity of melphalan containing RIC in highly pretreated rr-cHL induces to look for a new ways for CR. Bendamustin has a good safety profile as a CR in non-Hodgkin lymphomas[1] and showed high efficacy as a salvage monotherapy in rr-cHL[2].

Aims: Efficacy and toxicity of a bendamustine containing RIC for alloHSCT in pts with rr-cHL

Methods: For 3-year period (2012-2014) 13 pts with rr-cHL alloHSCT with a bendamustine containing RIC have been performed. This RIC was modification of BFR regimen[1] and consist of intravenous (i.v.) fludarabine (Flu) at a total dosage of 90 mg/m2 over three days and bendamustine (Be) i.v. at 130 mg/m2/day during the same three days. Primary end-points were engraftment/rejection rate, organ toxicity, incidence of GvHD and infection complication. Secondary end-points were a progression-free survival (PFS), overall survival (OS) and treatment-related mortality (TRM) at 100 days and 2 years after alloHSCT. Pts characteristics are outlined in Table 1.

Results: The engraftment was achieved in 100% of pts with median day +20 (14-44). Rejection was not registered. Cumulative incidence of mucositis grade 3-4 was 7,7%, severe renal toxicity-7,7%. There was no severe hepatic toxicity, but VOD was observed in one patient. Infection complication: severe bacterial infection/sepsis were registered in 15% of pts, CMV reactivation in two pts and one of them had CMV reactivation before alloHSCT. Probable invasive aspergillosis (IA) according EORTC/MSG criteria had 3 pts before alloHSCT. The only one patient had relapse of IA at day +20. Two patient developed IA after alloHSCT at days +100 and +235 which were associated with GvHD and corticosteroid treatment. Cumulative incidence of aGvHD in study group grade 1-2 was 53%, 3-4-7,6%. Cumulative incidence of chGvHD was 38,5%, severe-15%. There was no TRM at 2 years follow up. Progression-free survival at 100 days after alloHSCT was 76,9%, PFS at 2 years was 69,2%. Complete or partial remission of HL at the moment of HSCT was associated with the best PFS at 2 years *vs* stable or progression disease (89% *vs* 25%, p=0,02). OS at 100 days and at 2 years after alloHSCT was 92,3%. One patient died from the progression of the underlying disease in early period after alloHSCT.

Table 1. Patient characteristics, n=13.

Median age,	years	30 (20-49)
Time from diagnosis to alloHSCT,	months	43 (27-119)
Lines of CT / autoHSCT	numbers	6 (4-7) / 10
Brentuximab	before alloHSCT	7
	after alloHSCT	2
Status of cHD at the moment of alloHSCT	CR	4
	PR	5
	SD	2
	PD	2
Donor type	MRD	5
	MUD	8
GvHD prophylaxis	Standard tacro/CsA + Mtx/MMF + ATG in MUD	4
	Cyclophosphamide-base Cy alone or Cy + tacro/CsA + MMF	8
Source of graft	BM	8
	PB	5
Median CD34+ count	millions	4,2 (1,4-7,2)
Median follow up	months	6 (3-33)

Summary and Conclusions: The FluBe RIC for alloHSCT had 100% engraftment rate in our study group with acceptable toxicity and absence of TRM and rejection. The administration of a bendamustine containing RIC was associated with good PFS at day 100 (76,9%), as well with promising long-term OS (92,3%) and PFS (69,2%), especially in chemosensitive pts (89% 2y-PFS).

E1525

EFFICACY OF ORAL GLUTAMINE IN THE PREVENTION OF MUCOSITIS IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION. EXPERIENCE OF A SINGLE CENTER

A. Santamaría López[1,*] L. Alvarez Pequeño[1], R. Cidre López[1], Á. Fernández Fernández[1], C. Albo López[1]

[1]Haematology, Complejo Hospitalario Universitario de Vigo, Vigo, Spain

Background: Mucositis is an inflammatory reaction produced by chemo and/or radiotherapy, which affects the whole gastrointestinal tract. The main symptoms are oral dryness, odynophagia, diarrhea and painful ulcerations. Glutamine is a non-essential amino acid that helps to maintain the integrity of the digestive tract. In high metabolic stress your intake exceeding the body's synthesis capacity and deficiency may occur. Some studies suggest that this amino acid can prevent the onset of mucositis.

Aims: Analyze whether the use of oral glutamine supplementation decreases the incidence of mucositis, severity and duration in patients undergoing hematopoietic stem cell transplantation (HSCT).

Methods: A retrospective observational study was performed reviewing 274 hospital histories of patients undergoing HSCT inxeral Cíes Hospital, from 2002 to 2010 and from May to December 2014. Mucositis degree was evaluated in patients who have received glutamine (YG) or not (NG) regarding the HSCT type and conditioning regimen. The data was processing using R statistical software using correlation matrices according the p Holms method.

Results: 147 males and 127 females were included, with a median age of 49 years (1-70). In the 191 autologous HSCT predominant diagnosis were myeloma and lymphoma (87'4%), most of them receiving high doses of melphalan -BEAM, MEL200- (79'6%). 83 were allogeneic HSCT and predominant diagnosis was acute leukemia, receiving busulphan more than two days 42'2%, total body irradiation (TBI) 21'7%, reduced intensity conditioning (RIC) 22'9% and others 13'2%. Mucositis was seen in 95'5% of the autologous HSCT, III-IV degree 43'1% and 35'3%, NG and YG groups respectively. 81'9% of allogeneic HSCT developed mucositis, III-IV degree 42'9% *vs* 39'6%, NG *vs* YG. Mucositis degree, duration and the use of opioids and parenteral nutrition (PTN) in both groups, as well as mucositis depending on conditioning regimen are shown in Table 1. The TBI and RIC groups were not evaluated by of the small number of patients in each group. As shown in the Table 1 there is a significantly relation between the use of glutamine and reducing severe mucositis in autologous HSCT. Correlation is also observed with duration of mucositis and opidoids use. Not so in the allogeneic group in which no significant differences probably related to the sample size and the existence of other factors that may influence their appearance are observed (methotrexate use for GVHD prophylaxis, oral GVHD,…).

Table 1. Mucositis degree, duration, use of opioids and parenteral nutrition in autologous and allogeneic HSCT, and grade of mucositis based on conditioning regimens.

	Autologous HSCT			Allogeneic HSCT		
	NG (n=123)	YG (n=68)	*P* value	NG (n=35)	YG (n=48)	*P* value
Grade of mucositis - I-II - III-IV	56 (45.5%) 53 (43.1%)	37 (54.4%) 25 (36.8%)	0.005	12 (34.3%) 16 (45.7%)	19 (39.6%) 21 (43.8%)	0.16
Duration (days)	9.3±2.9	8.1±3	0.007	10.9±4.7	12.2±4.5	0.14
Use of Opioids	87 (79.8%)	41 (67.2%)		25 (89.3%)	36 (90%)	
Duration (days)	8.9±2.8	8.1±2.9	0.04	10.3±3.8	10.6±4.1	0.11
Use of PTN	69 (63.3%)	28 (45.2%)		19 (67.9%)	23 (57.5%)	
Duration (days)	8.4±2.8	8.5±3.3	0.09	12.1±4	11.7±5.6	0.01
Conditioning regime	High doses of melphalan			Busulphan (>2 days)		
	NG (n=94)	YG (n=58)		NG (n=13)	YG (n=22)	
Grade of mucositis - I-II - III-IV	44 (46.8%) 41 (43.6%)	33 (56.9%) 19 (32.8%)	0.06	4 (30.8%) 7 (53.8%)	9 (40.9%) 12 (54.5%)	0.13

Summary and Conclusions: In the present study we have found a lower incidence of severe mucositis in patients who have received glutamine undergoing autologous SCT, so we would recommend its use. We cannot draw any conclusions from their use on allogeneic setting.

E1526

THIOTEPA FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION (AHSCT) IN SOLID TUMORS

R. Suzuki[1,*] Y. Takahasi[2], M. Inoue[3], H. Kanamori[4], Y. Hashii[5], H. Sakamaki[6], K. Kawa[7], K. Kato[8], Y. Atsuta[9], S. Kojima[2]
[1]Cancer Center, Shimane University, Izumo, [2]Pediatrics, Nagoya University, Nagoya, [3]Hematology, Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, [4]Hematology, Kanagawa Cancer Center, Yokohama, [5]Pediatrics, Osaka University, Osaka, [6]Hematology, Tokyo Metropolitan Komagome Hospital, Tokyo, [7]Japanese Red Cross Kinki Block Blood Center, Osaka, [8]Pediatrics, Japanese Red Cross Nagoya First Hospital, [9]Japanese Data Center for HSCT, Nagoya, Japan

Background: Thiotepa (*NN'N"*-triethylenethiophosphoramide) is a multifunctional alkylating agent known to produce a significant anticancer effect in a variety of hematological malignancies and solid tumors. Since its molecular weight is as low as 189 g/mol, a good penetration of thiotepa to central nervous system (CNS) has been reported. Because of the high concentration in cerebrospinal fluid, thiotepa is recognized as one of the key agents for CNS tumors, primary CNS lymphoma, and AHSCT. However, thiotepa is currently unavailable in Japan due to the problem in drug supply.
Aims: The aim of this study is to clarify the significance of thiotepa use for AHSCT in solid tumors in Japan.
Methods: Data were retrospectively analyzed using Japan nation-wide database by the Japan Society for Hematopoietic Cell Transplantation.
Results: Thiotepa was used for 1,083 of 3,850 patients who received AHSCT for solid tumors. The median age was 9 years (renge: 0-71), and 679 patients (63%) were younger than 16 years. The main indication was breast cancer (314 of 444), primary CNS tumors (241 of 486), rhabdomyosarcoma (153 of 416), neuroblastoma (147 of 1,017), germ cell tumor (61 of 540), Ewing sarcoma (54 of 298) and hepatoblastoma (46 of 139). Various preconditioning regimens were used, but the median dose of thiotepa was 600 mg/m3 of 12 mg/kg. More than 80% of patients were treated in combination of alkylators. Thiotepa+melphalan was the most frequently used regimen, with a total of 534 patients, particularly for CNS tumors, rhabdomyosarcoma, neuroblastoma, germ cell tumor, and hepatoblastoma. Thiotepa+cyclophospamide with or without other agents was used for 330 patients mostly for breast cancer. Thiotepa+etoposide with or without other agents was used for 97 patients preferentially for CNS tumors and Ewing sarcoma. The 5-year overall survival of patients transplanted with thiotepa was 52%, and was significantly better than that without thiotepa (48%, P=0.03). The survival benefit was evident in primary CNS tumor (P=0.001), Ewing sarcoma (P=0.02) and rhabdomyosarcoma (P=0.05), but not for other tumors including breast cancer, neuroblastoma, germ cell tumor and hepatoblastoma (Figure 1).

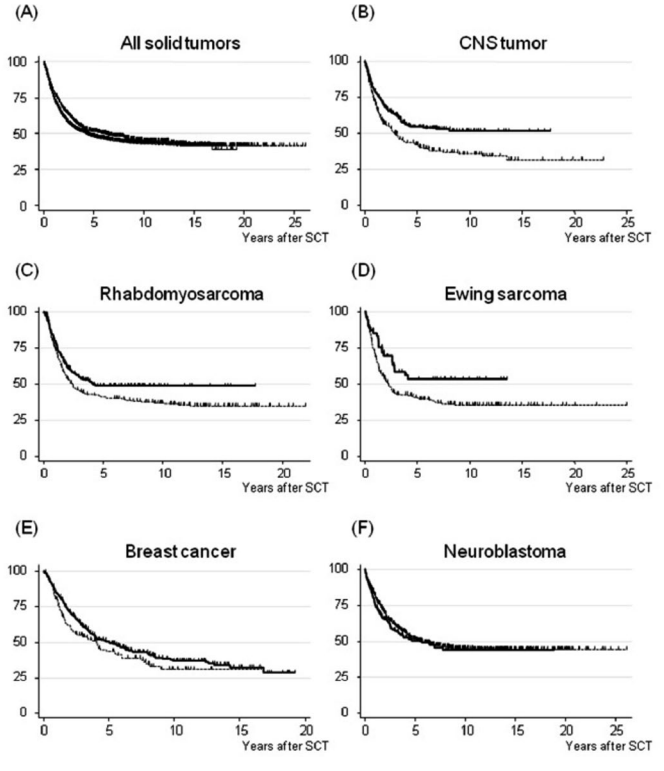

Figure 1.

Summary and Conclusions: Thiotepa is potentially useful for certain solid tumors as preconditioning for AHSCT. These findings should be confirmed in prospective studies.

E1527

DELAYED RECONSTITUTION AND IMMATURE PHENOTYPE OF NATURAL KILLER(NK) CELLS FOLLOWING POSTRANSPLANT CYCLOPHOSPAMIDE IN 30 UNMANIPULATED HAPLOIDENTICAL TRANSPLANTATION PATIENTS. A PROSPECTIVE ANALYSIS

A.M. Pérez-Corral[1,*] D. Champ[1], J. Anguita[1], C. Pascual[1], J. Gayoso[1], M. Bastos-Oreiro[1], M. Kwon[1], D. Serrano[1], P. Balsalobre[1], C. Martinez-Laperche[1], E. Sarmiento[1], I. Buño[1], J.L. Díez-Martín[1]
[1]Hematology, Gregorio Marañon Hospital, Madrid, Spain

Background: NK cells exert an important role in postransplant immune reconstitution, relapse prevention, infection control and graft *versus* host disease(GVHD).They are the first lymphoid subpopulation to recover after a conventional bone marrow transplantation.Their reconstitution and maturation process resembles normal ontogeny, and is crucial for the development of their functional capacities. Unmanipulated Haploidentical transplantation (Haploid SCT) with postransplant cyclophosphamide is an emerging alternative for patients with no identical sibling donor.
Aims: We prospectively analyse NK reconstitution post Haploid SCT in 30 patients comparing with simultaneous 8 patients with HLA identical sibling donor (HLAid SCT), and its relationship with CMV reactivation and GVHD.
Methods: Between November 2012 and July 2014,30 patients received Haploid SCT and 8 HLAid SCT in Gregorio Marañon Hospital.Peripheral blood was used in all cases.GVHD prophylaxis included high dose Cyclophosphamide on +3,+4/cyclosporineA/mycophenolatemofetil for Haploid and cyclosporine A/Methotrexate for HLAid. Table1 shows patients characteristics,with no relevant differences between the two groups, except for longer engraftment times and lower acute GVHD incidence in Haploid group.For analysis of NK reconstitution flow cytometry on FC500/Navios Beckman Coulter® was used. Total NK cells, CD56 intensity and expression of NKG2A, NKp30, Nkp46 and NKG2D was studied at +15, +30, +60, and +90.For comparison Mann-Whitney U-test was used.
Results: Median NK cells/mm3 on +15 and +30 were significantly lower on Haploid than HLAid group (0 (0-2) and 34,5 (16-177) *vs* 60 (52-125) and 230 (122,5-387,7); p<0.01),being similar on+60 and +90 (112 (52-225) and 147 (84,2-211,7) for Haploid *vs* 95 (42-119) and 101 (63,2-177,7) for HLAid; p ns).NK cells reached normal levels on +30 in HLAid group,while in +60 in Haploid patients.High percentages of immature CD56bright(CD56b) NK cells and high expression of immature receptor NKG2A appeared on Haploid on +30 with further decrease (CD56b 77% (68.5-88.5), NKG2A 84% (77-93) on +30, 38% (25-48) and 72% (61-85,5) on +60, 35% (23-43) and 62%(53,7-77) on +90). Compared with HLAid patients,CD56b cells and NKG2A expression were significantly higher (p<0.05) on Haploid group on +30, +60 and +90. Expression of activating receptors NKP46/ NKp30,and inhibitor NKG2D,linked to NK maturation,were only decreased in Haploid group on +15 (p<0.05),with appropriate expression and no differences on +30, +60 and +90.Expression of NKP46 tended to be higher in Haploid on +30 (81% (54,5-92,5) *vs* 59,5% (42,5-69,5)), (p 0.05).In Haploid group, patients with acute GVHD II-IV had lower NK cells/mm3 at +30 (Median 28,5 *vs* 132) and +60 (Median 67,5 *vs* 103) than those with GVHD 0-I; p ns.No differences in receptor expression was detected between patients with and without GVHD or CMV reactivation.

Table 1.

		Haploid	HLAid	p

Days Neutrophils>500/mm3		17 (16-19)	15(14.2-16.7)	0.05
Days Platelet>20000/mm3		30 (28-40)	12 (10-13)	0.00
Acute GVHD				0.01
	0	9	0	
	I	7	4	
	II	12	1	
	III-IV	2	3	
Chronic GVHD		1	1	0.3

Summary and Conclusions: After Haploid SCT with postransplant Cyclophosphamide NK cell reconstitution is delayed comparing with HLAid SCT,reaching normal levels at +60. NK maturation in Haploid is also different. NK cells remains in an immature phenotype with high proportion of CD56b NKG2A+ cells longer than in HLAid patients. Interestingly cytotoxic capacity seems preserved, with activating and inhibitor no KIR receptor expression, normally linked to maturation, similar to HLAid patients from +30 onwards. Patients with clinically significant GVHD had worse NK reconstitution in terms of lower total counts in the first 60 days. These observations bring interest about the possible benefit of early NK infusions on Haploidentical setting to overcome this impaired NK reconstitution.
Acknowledgments: Foundation Mutua Madrileña.

E1528

UTILITY OF CHIMERISM ANALYSIS IN DETECTION OF POST-TRANSPLANT DISEASE RELAPSE IN PATIENTS WITH MYELOID NEOPLASMS UNDERGOING REDUCED INTENSITY CONDITIONING ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION

M. Hefazi[1,*] A. Al-Kali[2], S. Hashmi[2], K. Begna[2], W. Hogan[2], N. Gangat[2], M. Litzow[2], D. Viswanatha[2], M. Patnaik[2]
[1]Department of Internal Medicine, [2]Division of Hematology, Mayo Clinic, Rochester, United States

Background: Reduced intensity conditioning (RIC) has expanded allogeneic hematopoietic stem cell transplantation (allo-HCT) to elderly patients and to those with additional comorbidities. However, relapse of myeloid neoplasms after RIC allo-HCT remains a major problem. Although chimerism analyses are frequently used for post-transplant surveillance, their utility in the detection of relapse is controversial.
Aims: We sought to determine the utility of peripheral blood (PB) and bone marrow (BM) chimerism analyses for the detection of post-transplant disease relapse after RIC allo-HCT.
Methods: After IRB approval, consecutive patients with myeloid neoplasms (MDS and AML) who underwent their first RIC allo HCT between 2005 and 2014 were reviewed. Clinical and laboratory data were retrospectively abstracted. BM biopsies (including chimerism studies) that were done for post-transplant surveillance, as well as concurrent CBC, and PB (sorted and unsorted) chimerism results that were done within 5 days of the BM biopsies were analyzed.
Results: A total of 137 patients, 59% male, with a median age of 59 years (range 18-69), were identified. Ninety-two (67%) had AML and 45 (33%) had MDS. After a median follow up of 19 months, 29 (21%) patients (21 with AML and 8 with MDS) had disease relapse. Of these, 14 (48%) relapsed within the first 100 days, 8 (28%) between day 101 and 200, and 7 (24%) after day 200. A total of 316 bone marrow biopsies were reviewed. Of these, 53 (17%) were consistent with disease relapse (41 with AML and 12 with MDS). As shown in the Table 1, full donor chimerism was still present concurrent with BM relapse within a respectable number of cases (32% of unsorted PB, 43% of lymphoid-sorted PB, 79% of myeloid-sorted PB, and 15% of unsorted BM chimerisms). Furthermore, mixed donor chimerism without the morphological or cytogenetic evidence of relapse was also seen in 37% of lymphoid-sorted PB and 7% of unsorted BM chimerisms. Unsorted BM and PB chimerisms had the best sensitivity for identifying disease relapse (85% and 78%, respectively), whereas unsorted PB and myeloid-sorted PB chimerisms had 100% specificity. CBC abnormalities preceded the relapse in 25 (86%) out of the 29 patients, with circulating blasts in 13 (45%), isolated thrombocytopenia in 10 (34%), and pancytopenia in 5 (17%), being early predictive markers. Negative change in serial chimerisms prompted an evaluation for possible relapse in only 1 (3%) patient. In 4 (14%) patients, relapse was not suspected, but was diagnosed on a routine BM biopsy that showed only cytogenetic relapse (3 patients) and at an extramedullary site (laryngeal chloroma) without BM involvement (1 patient). The overwhelming majority of patients (15 out of 21 AML and 8 out of 8 MDS relapses) had circulating blasts at the time of relapse confirmation on BM biopsy.

Table 1. Results of 316 concurrent* BM biopsy and chimerism studies performed in 137 AML/MDS patients after RIC allo-HCT.

		PB (unsorted) chimerism results available (N = 88)		Lymphoid-sorted PB chimerism results available (N = 81)		Myeloid-sorted PB chimerism results available (N = 82)		BM (unsorted) chimerism results available (N = 260)	
		No relapse on BM Bx (N = 79)	Relapse on BM Bx (N = 9)	No relapse on BM Bx (N = 67)	Relapse on BM Bx (N = 14)	No relapse on BM Bx (N = 68)	Relapse on BM Bx (N = 14)	No relapse on BM Bx (N = 226)	Relapse on BM Bx (N = 34)
Chimerism result	Full donor	N = 79	N = 2	N = 42	N = 6	N = 68	N = 11	N = 210	N = 5
	Mixed donor	N = 0	N = 7	N = 25	N = 8	N = 0	N = 3	N = 16	N = 29

	80-89%	n = 0	n = 0	n = 6	n = 2	n = 0	n = 0	n = 1	n = 2
	70-79%	n = 0	n = 1	n = 5	n = 4	n = 0	n = 1	n = 0	n = 1
	< 70%	n = 0	n = 5	n = 7	n = 1	n = 0	n = 0	n = 0	n = 22
		PB (unsorted)		Lymphoid-sorted PB		Myeloid-sorted PB		BM (unsorted)	
Test Sensitivity**		78%		57%		21%		85%	
Test Specificity**		100%		62%		100%		92%	

* Performed within 5 days of each other
** Sensitivity and specificity for diagnosis of relapse are calculated based on chimerism results of full vs. mixed donor

Summary and Conclusions: Chimerism studies, and in particular myeloid-sorted PB chimerism, have a limited role in the detection of post-transplant relapse in patients with myeloid neoplasms. Close monitoring of CBC results, including early detection of thrombocytopenia, circulating blasts, and pancytopenia still remains a very effective strategy.

E1529

BUSULFAN THERAPEUTIC DRUG MONITORING IS NEEDED IN POPULATIONS WITH GENETIC HETEROGENEITY UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION

B. Al-Lawati[1], M. Al-Khabori[2,*] M. Al-Zaabi[1], S. Al-Kindi[2], D. Dennison[2], M. Al-Huneini[2], K. Al-Farsi[2], M. Tauro[2]
[1]Pharmacy, [2]Hematology, Sultan Qaboos University Hospital, Muscat, Oman

Background: Busulfan (Bu) based preparative regimens in allogeneic stem cell transplantation are commonly used. Previous studies have shown that Bu at a fixed dose of 3.2 mg/Kg/day (FBD) given intravenously decreases variability in drug pharmacokinetics and this decreases the dependency on therapeutic Bu drug monitoring (TDM). We hypothesized that in a population with genetic heterogeneity, like Oman, the FBD may not be adequate and TDM is still needed.
Aims: Therefore, we planned to compare the Bu dose given using TDM with the FBD of 3.2 mg/Kg/day.
Methods: We retrospectively reviewed consecutive patients who received allogeneic stem cell transplantation at Sultan Qaboos University Hospital during the period of January 2003 to December 2014. Included patients received intravenous Bu based preparative regimen using TDM. Patients with acute leukemia, myelodysplasia, thalassemia major and sickle cell disease were included in this study. We used Bland-Altman plot to compare the daily dose between the TDM and FBD using 3.2 mg/day. We then normalized the dose using patients' weights (mg/Kg/day) and assessed the impact of age, gender, weight, height and serum bilirubin on the difference between the normalized TDM and FBD.
Results: Sixty-one patients (Males 28, Females 33) with a median age of 16.5 y (Range: 2.7-55.9) were included. The median and the interquartile range (IQR) for weight, height and serum bilirubin were 49 Kg (IQR: 23.2-62.5), 152 cm (IQR: 130-164) and 10 micromol/l (IQR: 4-17) respectively. Indication for transplantation was acute leukemia/myelodysplasia in 30, sickle cell disease in 23 and thalassemia major in 8 patients. The mean difference in daily dose between the TDM based and FBD was 40 mg with clinically significant differences (Bland-Altman agreement limits: -39 to 119; see Figure 1). The median normalized difference between the TDM based and FBD methods was 4.3 mg/kg/d (Range: 2.4-8.1). In the multivariable linear regression model, weight (p=0.0278) and gender (p=0.0288) were statistically significant predictors of the normalized difference with a coefficient of determination of 47% for the model.

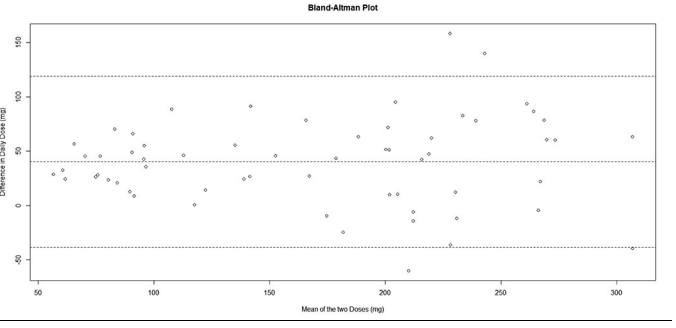

Figure 1.

Summary and Conclusions: TDM remains important for appropriate dosing of Bu in preparative regimens of allogeneic stem cell transplantation especially in populations with genetic heterogeneity. Although, the gender and weight can help predict the difference, the unexplained variance remains high. We recommend Bu TDM to be used as a standard of care.

E1530

HEMATOLOGICAL RECOVERY AFTER INTRA-BONE MARROW CORD-BLOOD TRANSPLANT WAS ENHANCED THROUGH LOCAL ENGRAFTMENT OF INJECTED SITE. A SINGLE CENTER PROSPECTIVE PHASE I/II TRIAL IN JAPAN

N. Kurita[1,*] Y. Yokoyama[1], S. Suzuki[1], M. Seki[1], M. Sakata-Yanagimoto[1], N. Obara[1], Y. Hasegawa[1], F. Frassoni[2], S. Chiba [1]
[1]Department of Hematology, University of Tsukuba, Tsukuba, Japan, [2]Stem Cell and Cell Therapy Lab, Istituto G. Gaslini, Genoa, Italy

Background: Cord-blood transplantation (CBT) is an effective option for hematological diseases. However, high rate of graft failure and delayed engraftment were the major limitations of CBT and as a consequence, CBT is associated

with a high risk of morbidity and mortality. Intrabone-marrow CBT (iBM-CBT) has been proposed as a measure which can solve the problems.
Aims: We conducted phase I/II prospective single-center trial of iBM-CBT with 15 cases to evaluate its safety and effectiveness. And another aim of this study was to identify the site of early hematopoiesis after iBM-CBT.
Methods: 15 adult patients (median age 59 years, range 32-64) with hematological malignancies (AML, 8; ALL, 4; NHL,3) were enrolled in University of Tsukuba Hospital, Tsukuba, Japan. Of them, three patients were not in remission. HLA matching was 5/6, and 4/6, for 5, and 10, respectively. Unwashed units were used to avoid loss of the cord-blood cells. The cord blood was divided in four syringes, and was infused in the superior-posterior iliac crest bilaterally under general anesthesia for one case, or local anesthesia for fourteen cases. Median transplanted cell dose was 2.8×10^7/kg (range 2.0-5.0). The primary endpoint was injection-related complication and the probability of hematological recovery after iBM-CBT. Secondary endpoints included the incidence of transplant-related mortality (TRM), acute GVHD, overall survival (OS), and disease-free survival (DFS). We compared donor chimerism in the iliac bone (the injected site) with that in the sternal bone (the remote site from the injection) 14 days after intra-bone marrow injection. This trial was registered on the UMIN website, number UMIN000006175.
Results: Between October 2011 and July 2014, 15 consecutive patients underwent iBM-CBT. Transient hypotension was observed after intrabone injection in one case, which was thought to be due to vasovagal reflex and the sedatives. The neutrophil recovery (≥0.5×10^9/L) and platelet recovery (≥5.0×10^9/L) were seen in 14 cases (93%), and 13 cases (87%), respectively. The median time to neutrophil and platelet recovery were 17 days (range 12-27) and 44 days (range 32-99), respectively. Acute GVHD developed in 34% (grade II-IV), and 0% (grade III-IV). TRM within one year was not observed. Estimated 1-year OS and DFS were 79% and 67%, respectively. The early donor chimerism was significantly higher in the iliac bone (median 95.2%, range 67.3-99.7), where cord blood had been injected, compared to the sternal bone (median 94.4%, range 22.3-98.8) (P=0.006; Wilcoxon signed-rank test) (Figure 1).

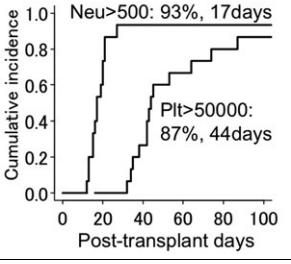

Figure 1.

Summary and Conclusions: Our data suggest that iBM-CBT was well tolerated and can promote prompt hematological recovery. Local anesthesia is sufficient to control pain associated with the procedure and the cord blood does not have to be washed. The dominance of donor chimerism in the iliac bone before engraftment suggests that local engraftment just after iBM-CBT contributes to early hematopoiesis of the recipients.

E1531

EXCELLENT LONG-TERM OUTCOME OF AUTOLOGOUS TRANSPLANTATION WITH INTERMEDIATE-DOSE INTENSIVE MELPHALAN (100 MG/M2, MEL100) FOR MULTIPLE MYELOMA: A SINGLE CENTRE STUDY
K. Fukushima[1,*] T. Sudo[1], T. Tamaki[1]
[1]Department of Hematology, Rinku General Medical Center, Izumisano, Japan

Background: It is generally accepted that high-dose melphalan therapy, followed by autologous hematopoietic cell transplantation, should be the treatment of choice in younger transplant-eligible patients with multiple myeloma (MM). The optimal therapeutic approach in elderly patients with MM remains unclear. Newer agents, including bortezomib and lenalidomide, have become available, and their use should be considered in this population. We carefully evaluated transplant-eligibility in both young and older patients (50s to 70s), and considered the treatment procedure: reduced intensity melphalan conditioning that reported several study. Here we report on the excellent long-term outcome of autologous tandem transplantation with intermediate-dose intensive melphalan in patients with MM.
Aims: We aimed to determine the long-term efficacy, and associated adverse events, of autologous tandem transplantation with intermediate-dose intensive melphalan for MM.
Methods: We retrospectively analysed data from 37 patients, treated at our institution with pre-planned 2 or 3 courses of intermediate-dose intensive melphalan (100 mg/m^2, MEL100) followed by peripheral blood stem cell (PBSC) transplantation, between 2000 and 2009. Eligibility criteria for inclusion were as follows: (1) histologically and clinically confirmed symptomatic MM; (2) aged 40-79 years; (3) transplant-eligible; (4) adequate organ function with Eastern Cooperative Oncology Group performance status <3; and (5) provision of written informed consent. The median age of patients was 60 years (range, 43-77 years). Pre-transplant disease status, according to the Durie and Salmon system, was as follows: stage I (n=5), stage II (n=6), stage III (n=28). The rate of response better than very good partial response (VGPR) was 29% at pre-transplant with dexamethasone alone or VAD (Vincristine-Adriamycin-Dexamethasone) regimen. All cases of PBSC mobilization were performed with cyclophosphamide plus granulocyte-colony stimulating factor. Five patients underwent allogeneic hematopoietic cell transplantation after tandem autotransplantation, because of disease progression.
Results: The 5-year overall survival (OS) was 50%, and cumulative incidences of relapse and non-relapse mortality were 26% and 24%, respectively. All patients who were followed up for more than 5 years post-transplantation are alive. Complete remission was achieved in 16 (37%) patients. The median day of neutrophil engraftment was day 11; there were no cases of engraftment failure. Only 2 patients died within 100 days post-transplantation (1 case of sepsis and 1 case of disease progression). Surprisingly, survival during the follow-up period was higher in patients carrying a 13 chromosome deletion (13q-) (10/11, 91%), compared with patients with a normal karyotype (9/26, 34%).
Summary and Conclusions: These data demonstrate the effectiveness of 2 or 3 courses of intermediate-dose intensive melphalan followed by stem cell transplantation in older patients with MM. Thus, the MEL100 regimen is not only feasible in older patients, but also prolonged overall survival. Patients with a 13q deletion showed a particularly good response to this treatment, particularly considering the poor prognosis often associated with such deletions. Although recent data shows the potential of novel treatments such as proteasome inhibitors and immunomodulating agents, the treatment protocol reported here should be considered to achieve prolonged progression-free survival.

E1532

IMPACT OF DONOR AGE ON PERIPHERAL BLOOD AND BONE MARROW HEMATOPOIETIC STEM CELL HARVEST
H. Cho[1,*] H. Park[1], J. Lee[1], J. Jang[1], S.J. Kim[1], Y. Kim[1], J.S. Kim[1], Y.H. Min[1], J.-W. Cheong[1]
[1]Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Hematopoietic stem cell transplantation (HSCT) is still one of the most important treatment modalities for the patients with hematologic malignancies. For allogeneic HSCT, increasing difficulty in proper donor selection leads to broaden the range of donor age than before. However, the exact clinical impact of donor age on peripheral blood (PB) and bone marrow (BM) hematopoietic stem cell (HSC) harvest is unclear.
Aims: This study was conducted to evaluate the impact of donor age on PB and BM HSC harvest.
Methods: We retrospectively reviewed the yields of allogeneic PB or BM HSC harvest from 384 healthy sibling or unrelated donors who donated their HSC to adult patients receiving allogeneic HSCT at Severance hospital between Jan. 2000 and Feb. 2015. For PB-HSCT, granulocyte colony-stimulating factor (G-CSF), either filgrastim or lenograstim, was injected subcutaneously with doses of 10 μg/kg/day either as a single or split from 4 days before harvest to the end of the procedure.
Results: Among 384 donors, 290 (75.5%) donated PB HSC and 85 (22.1%) BM HSC. Nine (2.3%) sibling donors provided both BM and PB stem cells due to insufficient number of BM stem cell in initial harvest. Median age was 37 (range 14-73) years, and the number of donors with age <50 years was 244(84.1%), 50-59 years 34 (11.7%), and ≥60 years 12 (4.1%). Donors with older age needed more sessions of harvest (Table 1. p=0.032) to complete the harvest. The median CD34+ cell counts at the first day of harvest was also significantly different according the age of donor; 4.03 (range 0.34-24.55)x 10^8 in patients with age <50 years, 2.85 (range 0.16-10.21)x 10^8 in 50-59 year, and 1.89 (0.64-3.37)x 10^8 in ≥60 years (p <0.001). The median total CD34+ cells collected were also reversely correlated with the age of donor (p <0.001). Two of 12 (16.7%) donors over 60 year-old did not collect more than 1.4x 10^8 CD34+ cells finally which are probably needed to give >2.0x 10^6/kg CD34+ cells in 70kg recipients. The age of donors providing BM HSC was younger (median 33, range 13-56 years) than those providing PB stem cells. The number of donors with age<50 years and ≥50 years was 88 (93.6%) and 6 (6.4%), respectively. The median CD34+ cell counts at the first day of harvest were 1.56 (range, 0.06-8.11)x 10^8 and 1.08 (range, 0.31-1.37)x 10^8 in donors with age <50 years and ≥50 years, respectively (p=0.015). The median counts of total collected CD34+ cells after completion of harvest were 1.81 (range, 0.06-8.11)x 10^8 and 1.08 (range, 0.31-1.37)x 10^8, respectively (p=0.03). Median CD34+ cells/kg body weight of recipients were significantly higher in donors with age<50 year than in those with age ≥50 years (2.59 *vs* 1.81x10^6, p=0.025).
Summary and Conclusions: This study showed that the majority of elderly donor could provide sufficient PB or BM HSC for allogenetic HSCT, but number of collected HSC was reversly correlated with the age of donor. Especially because the risk of insufficient harvest was increased in PB HSC donor with

age >60 and in BM HSC donor with age >50, more consideration should be given in case of these elderly donors.

BASELINE PERIPHERAL BLOOD CD34+ CELL COUNT DOES NOT INFLUENCE PLERIXAFOR SUCCESS RATE

A. Ferreira Baptista[1,*] C. Geraldes[1], M. Pereira[1], R. Sofia[1], C. Emília[1], A.I. Espadana[1], M.L. Ribeiro[1]
[1]Serviço de Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Plerixafor, a CXCR4 chemokine antagonist, has been shown to significantly improve blood stem cell collection mediated by granulocyte-colony-stimulating factor (G-CSF). Peripheral blood CD34+ cell counts (PB CD34+) after different mobilization schemes have been shown to correlate with apheresis yields and are widely used as the main variable to start apheresis. However, doubts remain if there are predictive factors that can be used before starting plerixafor administration in order to ration the use of this expensive drug.
Aims: To investigate if lower baseline PB CD34+ correlate with inferior collection success rates.
Methods: We retrospectively analyzed 62 patients that received plerixafor between 13-10-2008 and 31-12-2014. Five patients were excluded due to insufficient data. Plerixafor was given as part of a preemptive strategy or salvage therapy after failure to mobilize or collect sufficient CD34+ cells following chemomobilization. It is the standard operating procedure at our centre to target a collection of 2 × 10^6 CD34+ cells/kg for lymphoma and of 4 × 10^6 CD34+ cells/kg-enough for two autologous stem cell transplants (ASCT)-for multiple myeloma (MM) patients. However, for the purpose of this analysis, the 2 × 10^6 CD34+ cells/kg target was considered as a collection success for all patients. Plerixafor was given at a dose of 0.24 mg/kg subcutaneously 11 hours prior to apheresis in conjunction with G-CSF (10 µg/kg/day). Baseline PB CD34+ were determined after 4 G-CSF administrations and before the first plerixafor was given.
Results: Of the 57 patients, 33 (57.9%) were males. Median age was 57 years [18-67]. In 12 patients (21.11%) the diagnosis was Hodgkin Lymphoma, in 14 (24.56%) Multiple Myeloma, in 30 (52.63%) Non-Hodgkin Lymphoma and in 1 (1.75%) Waldenström Macroglobulinemia. In 20 patients (35.09%), Plerixafor was used preemptively. The PB CD34+ after the first plerixafor correlated with the initial PB CD34 (r=0.60, p<0.001). The number of CD34+ cells collected after the first apheresis also correlated with PB CD34+ at baseline (0.60, p<0.001) and, to a higher degree, to the PB CD34+ after the first plerixafor (r=0.78, p<0.001).The number of CD34+ cells collected after the first apheresis was higher in patients with PB CD34+ ≥5 /mL at baseline (2.9±0.46 *vs* 1.8±0.29x10^6 cells /kg, p=0.02). The number of plerixafor administrations needed to achieve a total collection of ≥2.0x10^6 cells/kg was higher in patients with a baseline PB CD34+ under 5 /mL (2.1±0.13 *vs* 1.6±0.15, p=0.0094). The percentage of patients achieving this goal after a single administration of plerixafor was more than two-fold higher when the baseline count was ≥5 cells /mL (47.8% *vs* 20.6%, p=0.030; 50.0 *vs* 25.0% for Myelomas and 47.1 *vs* 19.2% for Lymphomas). However, the ratio of patients achieving a collection of ≥2.0x10^6 cells/kg both after the first apheresis (47.1% *vs* 56.5%, p=NS) and at the end of all the aphereses with plerixafor (64,7% *vs* 78,3%, P=NS) was unaffected by the initial PB CD34+. The optimal cut-off point to predict for better collection results as defined above was 4.795 cells /mL at baseline, with a sensitivity of 66.7% and a specificity of 61.1%.
Summary and Conclusions: In our series, higher baseline PB CD34+ correlated with faster and higher PB CD34+ increase and therefore the need for a lower number of apheresis. Nevertheless, it does not significantly influence the probability of reaching our goal of sufficient CD34+ cells for one ASCT.

E1534

AUTOLOGOUS PERIPHERAL BLOOD CD34+ CRYOPRESERVED WITH 5% DIMETHYL SULFOXIDE COMPARED TO 10%: BETTER VIABILITY OF CD34+ AND NO NEUROLOGICAL SIDE EFFECTS

V. Pavone[1,*] A. Mele[1], A. Musarò[1], R. De Francesco[1], C. De Risi[1], M.R. Morciano[1], G. Greco[1], M. Fina[1], D. Carlino[1], B. Rossini[1], S. Sibilla[1], S. Citiso[1], E. Prete[1], B. Vannata[1], M. Caputo[1], L. Abbruzzese[1]
[1]Haematology and TMO, Hospital Card. G. Panico, Tricase (Le), Italy

Background: Dimethyl sulfoxide (DMSO) is extensively used as a cryoprotectant in stem cell preservation, but is associated with toxicity and adverse reactions in the transplant recipient. Cryopreservation using 5% DMSO instead of 10% DMSO is a strategy to reduce the adverse effects.
Aims: We compare the use of 5% DMSO *versus* 10% DMSO in terms of median and viability of CD34+ cells infused, haematological engraftment, number of febrile neutropenia and treatment related mortality (TRM).
Methods: 118 consecutive patients with haematological malignancies submitted to autologous transplant were included in the study. 81 (69%) were stored in 10% DMSO (from January 2012 to September 2013) and 37 (31%) in DMSO 5% (from October 2013 to January 2015).

Table 1. Results of cryopreserved HPC and haematological recovery.

	Group 5% DMSO	Group 10% DMSO	p
Median CD34+ infused cells (x10^6/Kg) (range) >4 x 10^6/Kg (N,%)	4,47 (1,91-8,35) 20 (54%)	3,85 (1,17-12) 33 (47%)	0,317
Median viability CD34+ (range) > 70% (N,%)	99% (94-100) 37 (100%)	81,5 (31-99,6) 62 (82%)	0,004
Median days to >0,5 ANC x10^9/L (range) > 12 days (N,%) Median days to >20 platelets x 1^09/L (range) > 14 days (N,%)	10 (8-16) 2 (6%) 12 (9-26) 10 (30%)	10 (6-27) 6 (12%) 13 (5-42) 15 (29%)	0,34 0,8
Median days of hospitalization from day 0 > 24 days (N,%)	21 (14-36) 8 (22%)	21 (12-69) 10 (20%)	0,89
Febrile neutropenia	25 (68%)	52 (66%)	0,853
Neurological toxicity	0	3 (4%)	0,23
Mucositis	28 (76%)	57 (76%)	0,97
Diarrhea	22 (59%)	47 (63%)	0,74
Renal toxicity	2 (5%)	2 (5%)	0,23
Hepatic toxicity	2 (5%)	2 (5%)	0,44

Results: Patients were similar in terms of median age, diagnosis, number of previous treatments, disease status at transplant. Median time to transplant from diagnosis was similar in the two groups but higher number of patients in DMSO 10% were transplanted after one year from diagnosis (85% *vs* 43%, p<0,001). Median of CD34+ cells infused was similar in the two groups, Table 1. Reduction in DMSO concentration to 5% was associated with higher CD34+ cells viability (99% *vs* 86%; p<0,008). No significant difference in median time to neutrophil (ANC) and platelets (PLT) engraftment was demonstrated in the two groups of patients, Table 1. DMSO concentration did not influence median day of hospitalization and febrile neutropenia. No differences in terms of mucositis, diarrhea, renal or hepatic toxicity were observed. No neurological side effects were observed in the group of patients with DMSO 5%, instead 3 events (4%) were registered in the DMSO 10% group, (p=0,23). After 14 months of median follow-up (range, 1-37), the estimated 1y TRM was 6% in the DMSO 5% *vs* 13% in DMSO 10%, p=0,45 (Figure 1).

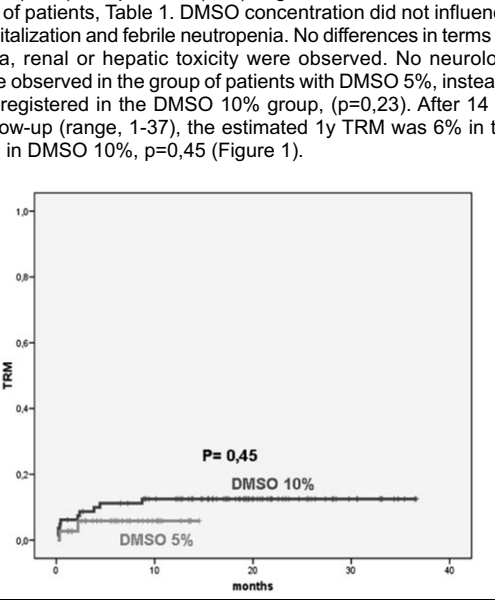

Figure 1.

Summary and Conclusions: Our results suggest that reduction in DMSO concentration to 5% was associated to higher viability of CD34+ cells infused without affecting median CD34+ cells infused and haematological reconstitution. At the same time, an equivalent 1y EFS was experienced between the two groups of patients studied. Interesting, neurological side effects were not observed in DMSO 5%. Further studies and longer follow-up is needed to evaluate fully efficacy and long term safety of cryopreservation of cells with 5% DMSO.

E1535

SINGLE *VERSUS* TANDEM AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA-RETROSPECTIVE STUDY

P. Silva[1,*] C. Pinho Vaz[1], F. Campilho[1], R. Branca[1], L. Leite[1], S. Roncon[2], A. Campos[1]
[1]Bone Marrow Transplant Service, [2]Cell Therapy Service, Instituto Portugues de Oncologia Francisco Gentil, E.P.E.-Porto, Porto, Portugal

Background: High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) is the main treatment of Multiple Myeloma (MM). However, an alternative approach with tandem ASCT has been studied but response rates, progression free survival (PFS) and overall survival (OS) are not well established and conflicting results had been published.
Aims: Compare single *versus* tandem ASCT after high dose chemotherapy in terms of responses, PFS and OS.
Methods: Retrospective study of all cases (n=176) of MM treated with high-dose chemotherapy followed by ASCT (single or tandem) in our center during six years (January/2008 to December/2014). The initial intention to treatment was tandem ASCT. However, the majority of patients only had collected peripheral blood progenitor cells (PBPC) for one ASCT or refuse a second ASCT. We performed a demographic and clinical survey of the population and evaluated response to induction chemotherapy (before the ASCT) and to single or tandem ASCT (2 and 6 months after ASCT) according to the criteria of the International Myeloma Working Group (IMWG). We performed the analysis of OS and PFS by the Kaplan-Meier method/log-rank test, Chi-square test.

Table 1. Main characteristics of study population.

	All patients	Tandem ASCT	Single ASCT	p-value
Number of Patients	176	50	126	
Age at Diagnosis

NOTES: *t(4;14) and del 17p; RC - complete response; VGPR – very good partial response; PR – partial response; SD – stable disease

Results: Fifty patients underwent tandem ASCT and 126 single ASCT with a median follow-up of 42 months (9-132). Median age was 57 years (30-69) with a slight male prevalence (51.1%). Tandem ASCT group had a lower median age (54 *vs* 59, p=0.01) but no other demographic or clinical differences were found between the two groups (Table 1). Type of response to induction chemotherapy were also similar. After transplant, rates of response were also comparable between the two groups: the tandem ASCT group had 56.2% complete response (CR), 20.8% very good partial response (VGPR) and 22.9% partial response (PR), while the single ASCT group had 62.3% CR, 11.3% VGPR and 25.5 PR and 0.9% without a response (p=0.92). The PFS at 3 years and 5 years was higher in patients undergoing tandem ASCT (75.8% *vs* 59.0% and 68.5% *vs* 33.3%, p=0.04), but showed no OS difference between the two groups: tandem ASCT *vs* single ASCT at 3 and 5 years (100.0% *vs* 96.0% and 79.0% *vs* 74.2%, p=0.27). These results were similar even after excluding CR to induction chemotherapy: PFS at 3 and 5 years was 73.9% *vs* 49.1% and 67.2% *vs* 32.0%; p=0.021; OS was, respectively, 100.0% *vs* 89.9% and 69.2% *vs* 70.0%, p=0.75. Transplantation related mortality was absent in the two groups.
Summary and Conclusions: In our study, tandem ASCT improved PFS when compared with a single ASCT, even in those who not achieved a CR after the induction chemotherapy. However, it failed to significantly prolong overall survival.

E1536

IS ALLOGENEIC STEM-CELL TRANSPLANTATION AN OPTION FOR PATIENTS WITH ACUTE LEUKEMIA AND MYELODISPLASTIC SYNDROME TRANSPLANTED WITH ACTIVE DISEASE? A CENTER EXPERIENCE

E. Perez-López[1,*] O. López-Godino[1], M. Cabrero[1], S. Alonso[1], L. López-Corral[1], M. Diez-Campelo[1], M.C. Cañizo[1], L. Vazquez[1], M.B. Vidriales[2], M.D. Caballero[1]
[1]Universitary hospital of Salamanca, Salamanca, Spain, [2]Hematology, Universitary hospital of Salamanca, Salamanca, Spain

Background: The prognosis of patients with refractory/relapsed acute leukemia (rAL) or myelodisplastic syndrome (MDS) is poor. Although patients with refractory disease are not good candidates for allogeneic hematologic stem cell transplantation (HSCT), this could be the only curative option. Due to the absence of reports on long-term follow up in this population, transplant indication in those patients is a permanent focus of debate.
Aims: To evaluate the outcome and efficacy of salvage HSCT for rAL and MSD.
Methods: We examined retrospectively all the patients transplanted at our Unit since1999 to 2003 who recived a HSCT in this situation.Diagnosis was in 74 patients (myeloid/lymphoblastic n=36/10) and MDS (n=28).Criteria of refractoriness was defined as patients had never achieved a complete remission (CR). Feasibility and efficacy of HCT was analyzed in terms of related mortality (TRM), event free survival (EFS) and overall survival (OS).

Table 1.

	n (%)
Patients sex	
Male	37 (50%)

Related	45 (60%)
Unrelated	22 (32%)
Haploidentical	6 (8%)
GVHD prophylaxis	
calcineurin inhibitors-regimens (+MMF or +methotrexate	38 (52%)
tacrolimus and rapamicine	25 (34%)
other inmunosupresion	10 (14%)

Results: The main characteristics of the patients at transplant were: median age 55 years (14-69); disease status at transplant: refractory 37 (50%), relapse 17 (23%), untreated 8 (10%) and aplastic 12 (30%); median of blasts at transplant was 10% (5-72). 70 (94%) of the patients had evaluable pretrasplantation cytogenetics: 12 favorable (16%), 29 intermediate (40%) and 29 unfavorable (39%) (according MRC and IPSS-R). Median time from diagnosis to HCT was 7 months (1-160). All the patients but one engrafted. Median time to reach >500 granulocytes and >20000 platelets were 17 (10 to 41) and 12 (6 to 70) respectively. The incidence of acute-GVHD (aGVHD) was 61% (14% grade III-IV) with median onset of 26 days (8-130); in evaluable patients, incidence of chronic-GVHD (cGVHD) was 45% (24% severe) with a median onset of 163 days (84-451). (other characteristics in Table 1). Response to transplant was evaluated at days +21 or 28, +56 and +100. At day +100: 43 patients (58%) were in complete remission (CR), 13 (17%) have progressed and 18 (24%) have died,mostly due to disease (n=12). With a median follow up of 30 months among patients alive, the estimated OS and EFS at 6 monthsat 1 year and 3 years was 63%, 50%,37% and 47%, 38% and 30% respectively. The overall TRM was 17% (10% at day +100). In the univariate analysis, to maintain CR at +100 and to develop cGVHD were the only factors associated with a better OS and EFS (p<0.05); these variables mantained their significance in the mul-

tivariate analysis. Although patients with favourable cytogenetics findings had a trend to a better relapse free survival as compared with intermediate and unfavourable (74% *vs* 41%; p=0.1), we couldn't demonstrate its impact in OS and EFS in the univariate and multivariate analysis. Status disease at transplant and blast percentaje has not significance in both OS and EFS also. The main cause of death was progression disease (n=29, 40%). Median time to disease progression was 183 days (6 to 4773). Considering those patients who were on CR at +100, 76% of them (33/43) maintained the CR and 53% of them (23/43) remained alive and disease free at last follow up to (156 months). Analysing the influence of cGVHD in this selected group of patients on CR at +100, the estimated probability of relapse at 1 year was 43% in those without cGVHD (n=14) *vs* 11% in those who developed cGVHD (n=29) (p=0.02).
Summary and Conclusions: Our results indicate that patients with rAL or MDS could benefit from HSCT even with high leukemia burden and should be considered as transplant candidates. We have shown that HSCT can induce long-term disease remission and possibly cure in those who developed cGVHD especially who are on CR at +100.

E1537

RETROSPECTIVE AUDIT OF A SINGLE CENTRE USE OF FRESH FROZEN PLASMA WITH OR WITHOUT PLASMA EXCHANGE TO REDUCE ISOAGGLUTININ TITRES PRIOR TO MAJOR ABO MISMATCHED HAEMATOPOIETIC STEM CELL TRANSPLANTS

M.L. Tung [1,*] C. Thow[2], J. Mah[2], T. G. Soh[2], M. Poon Li Mei[1], L.K. Tan[1]
[1]Haematology-Oncology, National University Cancer Institute, National University Health System, [2]Department of Laboratory Medicine, National University Hospital, Singapore, Singapore

Background: ABO major mismatched transplants are known to be associated with various immune mediated complications such as immediate hemolysis, delayed red cell engraftment and pure red cell aplasia. Reduction of incompatible (recipient) isoagglutinins pretransplantation has been thought to reduce the incidence of these complications, though the optimal strategy for this remains unclear. Use of donor group fresh frozen plasma (FFP) infusions with or without plasma exchange (PLEX) has been one of the strategies used, but the literature on the safety and efficacy of this method has been sparse.
Aims: The aim of our retrospective audit was to assess the efficacy of donor-type FFP infusion on anti-A and/or B isoagglutinin reduction and clinical outcomes associated with this strategy of isoagglutinin reduction.
Methods: All patients undergoing major or bidirectional ABO-mismatched bone marrow (BM), peripheral blood (PBSC), and cord blood (UCBT) hematopoietic stem cell transplantation (HSCT) between 2010 -2014 were identified from our institutional database. All patients received daily donor-type FFP infusion till day of stem cell infusion if their antidonor isoagglutinin titres (Anti-A or Anti-B titres) were ≥1:16, and PLEX was considered on the day of stem cell infusion if the antibody titres remained ≥1:16. In addition, for all major ABO incompatible HSCTs, the stem cell product was red cell-depleted, while for bidirectional ABO incompatible HSCTs, the stem cell product was red cell- and plasma-depleted.
Results: We identified 45 patients, 33 who received a major ABO mismatched (73%) and 12 (27%) who had a bidirectional ABO mismatched HSCT during this period (Table 1). Amongst these patients, 43 (96%) had an underlying malignant disease whilst only 2 had a benign condition (Figure 1).

Table 1. ABO donor recipient pairs in the study.

ABO Incompatibility	Total Number of Patients tested	Blood Group		No. of patients
		Recipient	Donor	
Major	33	O	A	18
		O	B	9
		O	AB	3
		A	AB	0
		B	AB	3
Bidirectional	12	A	B	4
		B	A	8

Of the 45 patients identified, 29 patients (65%) required FFP with a median of 3871 ml (Range: 750ml-10 900 ml) received per patient. Median antibody titres were 1:64 (Range: 32-1024) before intervention and 1:32 (Range: 2-256) post intervention. Eight of the 29 patients had reduction of antibody titres to ≤16 and did not need PLEX. Amongst the other 21 patients, 11 went on to receive PLEX, while 10 did not due to either patient or physician choice. No significant major side effects from FFP infusion was noted in all patients though 5 patients (17%) suffered minor infusion reactions such as urticaria. No episodes of immediate hemolysis or disseminated intravascular thrombosis were seen in any of the patients at the time of the graft infusions. Incidence of pure red cell aplasia was 4% (n=2). There were no significant major side effects from FFP infusion, though 5 patients (11%) suffered minor reaction like urticaria. There were no episodes of immediate hemolysis or disseminated intravascular thrombosis seen in any patient at the time of ABO-incompatible graft infusions. Incidence of pure red cell aplasia was 4% (n=2). There were 11 early transplant deaths (24%) and 2 suffered graft failure (4%).

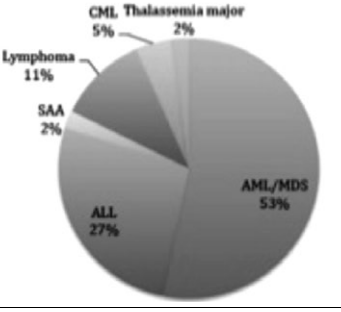

Figure 1. Indications for tranplant.

Summary and Conclusions: Our findings suggest that that the use of donor-type FFP was safe, and was able to reduce anti-donor issoagglutinins by one fold dilution (from median 1:64 to 1:32). Interestingly, despite only 50% of patients who were recommended to receive PLEX actually receiving it, there did not appear to be an increase in severe infusional reactions, hemolysis or PRCA incidence in the patients in our study. Our findings confirm the safety and efficacy of donor-type FFP in reducing isoagglutinin titres, but also question whether the threshold at which PLEX is recommended may be raised especially with the current concomitant use of red cell depletion in the stem cell products.

E1538

BONE MARROW EOSINOPHILIA CORRELATES WITH TREATMENT OUTCOMES BOTH AFTER AUTOLOGOUS AND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Y. Georgieva[1,*] Y. Petrov[2], B. Spassov[3], G. Balatzenko[4], P. Ganeva[2], V. Madzharova[1], G. Mihaylov[3], G. Arnaudov[2], M. Guenova[1]
[1]Laboratory Haematopathology & Immunology, [2]Department of Transplantation of Hematopoietic Stem Cells, [3]Clinical Hematology, [4]Laboratory of Cytogenetics and Molecular Biology, National Specialised Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria

Background: Many studies have shown the beneficial influence of eosinophils (Eo) in diverse neoplasms independent of other standard prognostic factors. Besides, eosinophilia in the blood and tissue is a common feature of graft *versus* host disease (GvHD) and contributes to the allogeneic response, as revealed in investigations in animal models and clinical observations. Data from a number of cohorts indicate that elevated Eo blood counts could be associated with better outcomes following allogeneic hematopoietic stem cell transplant (HSCT). However, whether the degree of bone marrow eosinophilia influences transplant outcomes has not been established yet, neither the significance of eosinophilia after autologous transplantation.
Aims: The aim of the study was to evaluate how the existence and degree of peripheral blood (PB) and bone marrow (BM) eosinophilia after auto-HSCT and allo-HSCT influenced transplant outcomes.
Methods: A total of 310 consecutive pts who received HSCT at the National Hematology Hospital, Sofia were included in this retrospective study. Auto-HSCT was performed in 246 pts, 148 male and 98 female, at a mean age of 48.5 years (ranging 19-67), while allogeneic-in 64 patients, 45 male and 19 female, including 35 from related and 29 from unrelated donors, at a mean age of 37.4 years (20-59). PB and BM Eo were evaluated at day 100 and at a next time point depending on the follow-up schedule. Eosinophilia was defined as an Eo count >0.5x10(9)/L in PB and >3.5% in the BM. Information about the following events was recorded: peripheral cell engraftment, acute (a)GvHD and chronic (c)GvHD, viral reactivation, and deaths. Overall survival (OS) was defined as the time from transplantation until death from any cause.
Results: A biphasic pattern of eosinophilia was noted after HSCT. The first peak occurred prior to day 100 then the second one, beyond day 100. At day 100 PB eosinophilia was detected in 4.9% of all pts, while increased BM Eo were seen in 27.7%, without any correlation between PB and BM counts, with no significant difference between auto- and allo-HSCT and regardless of the donor type. No differences in engraftment, viral reactivation, aGVHD or cGVHD depending on Eo counts were established. At this time point PB eosinophilia did not correlate with OS in neither groups, however increased BM Eo were associated with better outcomes in the overall cohort of allo-transplanted pts (100% *vs* 51% OS in pts with low Eo, and median not reached *vs* 24 months, respectively; log rank p=0.001). Beyond day 100 PB eosinophilia was rarely seen in only 2.3% of all pts, while BM Eo were increased in 33.8% regardless

of the type of HSCT. Similarly, PB eosinophilia did not correlate with OS in neither groups of pts, however increased BM Eo were associated with longer OS both in auto-transplanted (100% *vs* 85.7% OS in pts with low Eo, mean 72 *vs* 63 months, respectively; log rank p=0.03), and in allo-transplanted pts (94% *vs* 61.5% OS in pts with low Eo, mean 41 *vs* 27 months, respectively; log rank p=0.007) (Figure 1).

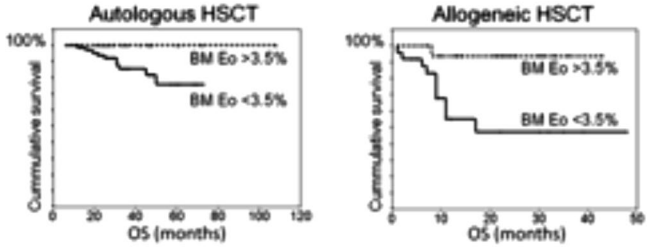

Figure 1. Overall survival curves for patients with and without BM eosinophilia beyond day 100.

Summary and Conclusions: Better outcomes could be expected in patients with BM eosinophilia regardless of the PB Eo counts and the type of transplantation. Interestingly, based on the results common mechanisms might be speculated in allogeneic and autollogous HSCT, however the pathophysiology behind eosinophilia remains to be investigated. Further studies are also warranted to elucidate the causative mechanisms behind the clinical benefits of increased eosinophils.

E1539

AUTOLOGOUS PERIPHERAL BLOOD HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) FOR MULTIPLE MYELOMA WITHOUT CRYOPRESERVATION OF STEM CELL,SINGLE CENTER EXPERIENCE

M. Ramzi[1,*] R. Vojdani[1], M. Karimi[1], M. Dehghani[1]
[1]hematology and medical oncology, shiraz university of medical sciences, shiraz, Iran

Background: Hematologic malignancy currently represents the main indication for HSCT. Clearly, autologous and allogeneic HSCT are established therapies in many of hematologic malignancies. High dose therapy (HDT) supported by autologous HSCT are the preferred choice for lymphoproliferative disorders and multiple myeloma. Several clinical trials have shown the superiority of high-dose therapy (HDT) and autologous stem cell transplantation over conventional dose therapy for patients with multiple myeloma.
Aims: There is limited experiences with noncryopereserved autologous transplantation.In this report we will describe our experiences with this method.
Methods: During 10 years we treated 152 patients with multiple myeloma (mean age=53 range: 31-70) with a conditioning regimen of Melphalan 140-200 mg/m^2. Patients were treated by intensive chemotherapy followed by reinfusion of non- cryopreserved autologous stem cells. The source of stem cell in all patients was peripheral blood. All apheresis products were kept in a conventional blood bank refrigerator at 4°C for 2 -3days before infusion.
Results: The median time of hospitalization was 19days (range: 16-37).The median time to platelet count >20×10^9/L was 14 days (range: 10-35). Also, the median time to absolute neutrophil count >0.5 × 10^9/L was 11 days (range: 9-22). All the 152 patients were engrafted and there was not graft failure in this study group. Responses (complete and partial response) were seen in all the 152 patients. Transplant-related mortality in this study group was 1.3%.
Summary and Conclusions: All patients in our study showed hematopoietic engraftment after receiving the HDT and non-cryo preserved stem cell. According to our experiences and results we concluded HDT and autologous stem cell transplantation without cryopreservation is effective and safe method which simplifies the procedure and is feasible and cost saving in our patients with diagnosis of multiple myeloma.

LB2095

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CHILDREN WITH HEMOPHAGOCYTIC SYNDROME: SINGLE CENTER EXPERIENCE

G. Ozturk[1,*] A. Akcay[1], F. Erbey[1], D. Atay[1]
[1]Department of Pediatric Hematology- Oncology and Bone Marrow Transplantation Unit, Acibadem Univercity Medical Faculty, Acibadem Atakent Hospital, Istanbul, Turkey

Background: Hematopoietic stem cell transplantation (HSCT) is the only curative treatment for patients with primary hemophagocytic lymphohistiocytosis (HLH) and for patients with secondary HLH who fail to respond to therapy.
Aims: To observe the conditioning regimen, efficacy, side effects of HSCT for HLH.
Methods: We retrospectively reviewed children with HLH who received HSCT. From April 2011 to February 2015, a total of 15 allo-HSCT in 14 cases (9 were females) were evaluated including 13 cases with familial HLH and a case with secondary HLH related otoimmun disease who fail to respond therapy. The median age was 19 months (3 months-9 yr). Eight patients received HLA-matched related HSCT, five received HLH-match unrelated HSCT and two received unrelated cord blood transplantation with conditioning regimen of etoposide, busulphan, cycphosphamid and ATG (ATG in 13 pts). Cyclosporine (in 9 pts) or cyclosporin and methorexate (in 6 pts) were used for prevention of graft *versus* host disease (GVHD).
Results: The mean overall survival time was 11 months (1-46 months). Eleven patients were successfully engrafted. Acute GVHD occurred in 5 cases, including 3 cases with skin, a case with skin+liver, and a case with gastrointestinal GvHD. Chronic GVHD (cGVHD) occurred in 3 cases. Hepatic veno-occlusive disease were developed in 6 (40%) patients. Five cases died after allo-HSCT. Three patients died (reactivation of disease=1, infection=1, other=1) before day +100, and another 2 patients died (reactivation of disease=1, infection=1) after day 100. In four HSCT, failed to engraft (a case developed recurrent HLH and died from infection after a second HSCT).
Summary and Conclusions: The allo-HSCT is successful in treating primary and secondary HLH who refractory to therapy.

LB2096

POST TRANSPLANT ERYTHROCYTOSIS IN ELEVEN CASES

S.K. Toprak[1,*] G. Pekcan[1], P. Ataca[1], E. Atilla[1], S. Civriz Bozdag[1], M. Kurt Yuksel[1], P. Topcuoglu[1], M. Ozcan[1], G. Gurman[1]
[1]Hematology, Ankara University School of Medicine, Ankara, Turkey

Background: Post transplant erythrocytosis (PTE) is not an expected complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Only Mahmood *et al.* reported PTE in 3 aplastic anemia cases in literature.
Aims: We aim to present 11 PTE diagnosed as; 4 acute myeloblastic leukemia (AML), 2 paroxysmal nocturnal hemoglobinuria (PNH), 1 myelodysplastic syndrome (MDS), 2 chronic myeloid leukemia (CML), 1 primary myelofibrosis (PMF), 1 fanconi aplastic anemia patient.
Methods: We retrospectively evaluated 11 PTE patients from 945 allo-HSCTs in our center.
Results: Patients' characteristics are shown in Table. All patients are male. They have transplanted from full matched related donors except one patient has 1 mismatch and received stem cells from unrelated donor. PMF and fanconi aplastic anemia patients received stem cells from bone marrow, others transplanted by peripheral blood stem cells. 1 CML patient relapsed after allo-HSCT but followed in remission with tyrosine kinase inhibitors. None of them had either leukocytosis or thrombocytosis. All of the patients had hyperviscosity symptoms with no organomegaly. Erythropoietin levels in the upper limit of normal in all patients. No JAK2V617F mutation positivity was detected. 2/11 patients had bronchiolitis obliterans (BO) and 5/11 diagnosed as chronic liver Graft *vs* Host Disease (GVHD) during follow-up. None of them are smokers. All patients received cyclosporine (CsA) for GVHD prophylaxis.

Table 1.

Disease	Age	Pre transplant status	HLA Match/donor	GVHD prophylaxis	Conditioning Regimen	GVHD (Graft vs Host Disease) site	Post transplant status	Hb (g/dl) /Hct (%) and time after transplant
AML	38	CR	Full/related	CsA+MTX	MA	Skin Liver	Remission	17.9/52, 5 years
PNH	29	Aplastic	Full/related	CsA+MTX	RIC	Skin	Remission	17.6/51, 3 months
AML	49	2.CR	Full/related	CsA+MTX	MA	Skin, GI,Lung eye	Remission	17.5/54.5 , 4 years
MDS	17	Transfusion dependent	1 Mis match/unrelated	CsA+MP	MA	Skin, liver,GI	Remission	17.7/51.7 , 4 years
PNH	26	Aplastic	Full/related	CsA+MMF	RIC	-	Remission	17.5/55, 5 years
AML	33	2.CR	Full/related	CsA+MTX	MA	Liver	Remission	17.6/51, 6 years
Fanconi Aplastic Anemia	21	Transfusion dependent	Full/related	CsA/MMF+MTX	RIC	GI	Remission	17.5/51.6 , 1 year

AML	32	2.CR	Full/related	CsA/MMF+MTX	MA	Eye, Liver,Lung	Remission	16.7/50.7 , 6 years
PMF	57	Transfusion dependent	Full/related	CsA+MTX	MA	-	Remission	17.7/50.4 , 2 years
CML	45	Active disease	Full/related	CsA+MTX	MA	-	Relapsed/remission with TKI	16.8/50.2 , 11 years

Table 1. Patients' characteristics (CR: Complete Remission, GI: Gastrointestinal, RIC: Reduced intensity Conditioning, MA: Myeloablative, MTX: Methothrexate, TKI: Tyrosine Kinase Inhibitor)

Summary and Conclusions: Liver GVHD, BO and cyclosporine could lead to secondary erythrocytosis however there is no evidence for causality. All of our patients were male which is a risk factor for erythrocytosis similar to hypertension and smoking. Remarkably, all of the patient except one had erythrocytosis a year after allo-HSCT. Further surveillance of the cases will improve our knowledge over erythrocytosis.

Stem cell transplantation - Experimental

IMMUNOPHENOTYPIC CHARACTERIZATION OF HUMAN MOBILIZED HEMATOPOIETIC STEM AND PROGENITOR CELLS: BIOLOGICAL AND CLINICAL IMPLICATIONS

V. Giai[1,*] E. Saraci[1], E. Marzanati[1], C. Scharenberg[2], P. Omedè[1], E. Hellström-Lindberg[2], A. Palumbo[1], B. Bruno[1], M. Boccadoro[1], D. Ferrero[1]
[1]Hematology Division, University of Torino, Torino, Italy, [2]Center for Hematology and Regenerative Medicine, Karolinska Institutet, Stockholm, Sweden

Background: In the last years, peripheral hematopoietic stem and progenitor cells (HSPC) have been widely used for transplantation procedures, instead of bone marrow HSPC. The advantages consist in a quicker hematological and immunological reconstitution and in a reduced morbidity and mortality. Unfortunately, very few is known about the proportions of HSPC in the peripheral CD34+ cells.
Aims: In the present study, we intend to investigate the composition of circulating HSPC subpopulations and analyze whether the differences in the number of re-infused precursors could influence the hematopoietic engraftment after an hematopoietic stem cell transplantation.
Methods: Multicolor flowcytometry was run to examine 9 base-line peripheral blood (PB) samples and 5 bone marrow (BM) samples from healthy donors and 33 mobilized peripheral blood (mPB) samples from hematological patients prior CD34+ cells harvesting.
Results: Common myeloid progenitors (CMP) showed a higher ratio in PB compared to BM (47.8%±9.5 *versus* 27.6%±9.5) while granulocyte-macrophage progenitors (GMP) were lower in PB compared to BM (10.3%±6.9 *versus* 23.8%±7.2). Progenitors fractions were equally distributed in BM (27.6%±9.5 for CMP, 23.8%±7.2 for GMP and 27.6%±16.2 for megakaryocyte-erythroid progenitors -MEP). No significant differences were noticed between PB and BM hematopoietic stem cells (HSC) (1.54±1.22 in PB *versus* 2.11±0.69 in BM) (Figure1a). Comparing base-line PB and mPB, no significant differences were shown between the subpopulations (Figure1b). Among mPB samples, cyclophosphamide chemotherapy mobilized a higher ratio of CMP (61.1%±12.05) and a lower percentage of GMP (11.09%±4.74) unlike patients who had received other drugs (CMP 49.06%±14.12 and GMP 27.59%±10.92). No differences were found in HSC proportions (Figure1c). In the two patients mobilized with the anti-CXCR4 Plerixafor instead of C-GSF only, more elevated proportions of GMP were released: 37.8% in patient#1 and 33.8% in patient#2 compared to the average 16.31% of the "G-CSF only" mobilized samples (Figure1d). In the analysis of CXCR4 expression among the subpopulations, we observed a significant higher mean fluorescence intensity of this marker on GMP (Figure1e). Furthermore, a strong correlation between the number of total peripheral CD34+ cells and mobilized CMP, GMP and MEP was shown (Figure1f); no correlation was displayed with mobilized HSC. White blood cells (WBC) count exhibited significant correlation with the number of mobilized HSC (Figure1g), but not with CMP/GMP/MEP. The next step was to detect possible relationships between the number of re-infused progenitors or HSC and the hematological recovery in patients receiving an auto-transplantation conditioned by high dose chemotherapy. A tendency to inverse correlation was shown between the number of re-infused progenitors and the days of aplasia (Figure1h-1m), as well as between the number of re-infused CMP and MEP and platelet levels during aplasia time (Figure1o-1q).

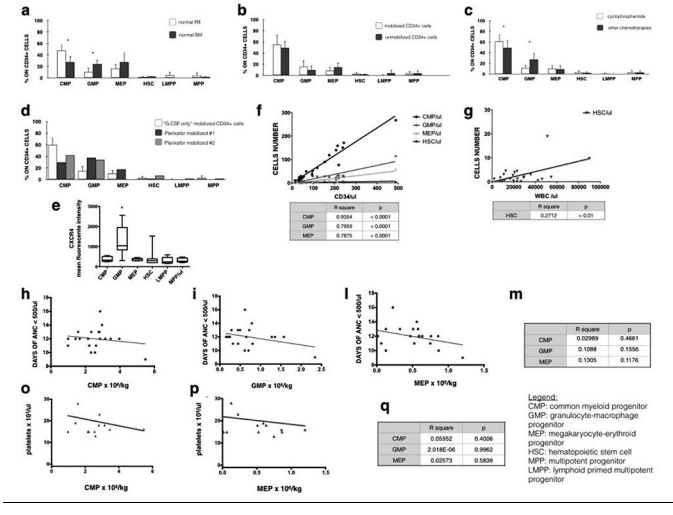

Figure 1.

Summary and Conclusions: With these data, we confirmed the heterogeneity of HSPC composition between PB and BM; chemo and mobilization regimens can strongly influence the proportions of mobilized HSPC. Furthermore, the number and type of re-infused progenitor could effect the engraftment kinetic and the hematological recovery. Further studies on mobilized HSPC and the correlation with clinical data will provide new sensitive tools for improving the outcomes of hematopoietic stem cell transplantation.

E1541

EXPRESSION OF TH17/TREGS AXIS ASSOCIATED REGULATORY FACTORS IN PATIENTS WITH ACUTE GRAFT-*VERSUS*-HOST DISEASE

Q. Liu[1,*] L. Xuan[1], X. Wu[2], L. Gao[1], X. Wang[2], Y. Li[2]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is one of the most valid methods for the treatment of malignant hematological diseases. Graft-*versus*-host disease (GVHD)□which remains the main complication after allo-HSCT□leads to the high transplant-related mortality. GVHD occurs as a result of T cell activation. Acute GVHD (aGVHD) is suggested to be predominantly related to T helper 1 (Th1) responses. Recent investigations have discovered the possible role of Th17 cells and regulatory T cells (Tregs) in the development of aGVHD. Th17 cells are found to have a direct role in the development of aGVHD, and adoptive transfer of *in vitro*-differentiated Th17 cells is capable of inducing lethal aGVHD. Clinical and experimental studies have suggested that Tregs could prevent and treat aGVHD, while preserve graft-*versus*-tumor activity. However, the controls of Th17/Tregs axis on the occurrence and development of aGVHD are not fully understood.
Aims: To investigate the expression levels and clinical significance of Th17/Tregs axis associated regulatory factors in patients with aGVHD.
Methods: The expression levels of Th17/Tregs axis associated regulatory factors (IL-17A, IL-23R, RORc, STAT-1, STAT-3, Foxp3, CD25, CTLA-4, GITR and TLR8) were analyzed in peripheral blood from 20 patients with aGVHD at the following two time points (at the onset of aGVHD and two weeks after the treatment), using real-time reverse transcription polymerase chain reaction with SYBR Green I staining. Fifteen patients responded effectively to the treatment within two weeks, and 5 did not respond within two weeks. Twenty healthy donors were selected for the control. The β_2-microglobulin gene was used as an endogenous reference, and the relative mRNA expression level of each gene was evaluated by the $2^{-\Delta Ct}$×100% method.
Results: The expression levels of RORc, STAT-1 and STAT-3 genes in the untreated patients with aGVHD were significantly higher than that in the healthy donors (P<0.001, P<0.001 and P<0.001), while the expression levels of IL-17A and IL-23R genes were similar between the untreated patients with aGVHD and the healthy donors (P=0.147, P=0.190). The expression levels of GITR and TLR8 genes in the untreated patients with aGVHD were also significantly higher than that in the healthy donors (P=0.003, P<0.001). The expression levels of Foxp3, CD25 and CTLA-4 genes were similar between the untreated aGVHD patients and the healthy donors (P=0.298, P=0.934 and P=908). The expression level of TLR8 gene in the patients with aGVHD was significantly decreased after effective treatment (P=0.035). The expression levels of IL-17A, IL-23R, RORc, STAT-1, STAT-3, Foxp3, CD25, CTLA-4 and GITR genes in untreated patients with aGVHD had no significant change after effective treatment (P=0.778, P=0.875, P=0.730, P=0.177, P=0.925, P=0.397, P=0.778, P=0.470 and P=0.638). The expression level of Foxp3 gene was significantly decreased after ineffective treatment (P=0.043). The expression levels of IL-17A, IL-23R, RORc, STAT-1, STAT-3, CD25, CTLA-4, GITR and TLR8 genes were similar in patients at aGVHD onset and after ineffective treatment (P=0.686, P=0.500, P=0.686, P=0.345, P=0.225, P=0.345, P=0.345, P=0.893 and P=0.345).
Summary and Conclusions: Th17/Tregs axis associated regulatory factors might influence in the occurrence and development of aGVHD□

E1542

MECHANISMS OF FATAL CARDIOTOXICITY FOLLOWING HIGH-DOSE CYCLOPHOSPHAMIDE THERAPY AND A METHOD FOR ITS PREVENTION

T. Nishikawa[1,*] E. Miyahara[1], K. Kurauchi[1], E. Watanabe[2], Y. Okamoto[1], Y. Kawano[1]
[1]Pediatrics, [2]Clinical Pharmacy and Pharmacology, Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan

Background: High-dose cyclophosphamide (CY) is a mainstay in most conditioning regimens for hematopoietic stem cell transplantation. Recently, administration of posttransplantation of CY in high doses has been attracting attention as novel strategy for preventing graft-*versus*-host disease. CY is activated by the hepatic cytochrome P-450 (CYP) enzyme system to form 4-hydroxycyclophosphamide (HCY), which is in equilibrium with aldocyclophosphamide (AldoCY). AldoCY decomposes to form cytotoxic phosphoramide mustard and the byproduct acrolein. Alternatively, aldoCY is oxidized to the inactive metabolite *o*-carboxyethylphosphoramide mustard (CEPM) by aldehyde dehydrogenase1 (ALDH1). The dose-limiting toxic effect of CY, observed only after administration of high doses, is cardiotoxicity.
Aims: Since the mechanism underlying this phenomenon has not yet been elucidated, and no definitive risk factors have yet been identified, we investi-

gated the cardiotoxic mechanisms of high-dose CY. To determine preliminary mechanisms that may prevent the occurrence of CY-induced cytotoxicity in H9c2 embryonic rat cardiomyocytes cell line, we also evaluated the protective effects of potential cardioprotectant agents.
Methods: A rat cardiac myocardial cell line, H9C2, was exposed to CY metabolized by S9 fraction of rat liver homogenate mixed with co-factors (CYS9). The degree of cytotoxicity was then evaluated by MTT assay, LDH release, production of reactive oxygen species (ROS), and incidence of apoptosis. We also investigated how the myocardial cellular effects of CYS9 were modified by antioxidant N-acetylcysteine (NAC), isorhamnetin (ISO), and β-ionone (BIO) a CYP inhibitor. Quantifying CY and CY metabolites, using LC/MS/MS, we assayed culture supernatants of CYS9 with or without potential cardioprotectant agents (PCA). In addition, we observed the cytotoxicity of CYS9 and the protective effects of PCA using a live-cell imaging system.
Results: Assay results for MTT showed that treatment with CY (125-500 μM) did not induce cytotoxicity. CYS9, however, exhibited myocardial cytotoxicity when CY concentration was 250 μM or more. After 250 μM of CY was metabolized in S9 mix for 2 h, the concentration of HCY was 18±4, CEPM 27±5 μM, and acrolein 31±1 μM. NAC, ISO, and BIO all inhibited CYS9-induced cytotoxicity. When treated with ISO or BIO, metabolism of CY was significantly inhibited. Pretreatment with NAC, however, did not inhibit the metabolism of CY. Compared to control samples, we observed no difference in HCY, a significant increase of CEPM, and a significant decrease of acrolein. Furthermore, NAC pre-treatment did not affect intracellular ROS levels produced by CYS9. Live-cell imaging also confirmed that CYS9 induced acute cytotoxicity, which was inhibited by NAC.
Summary and Conclusions: We ascertained that, when metabolized *in vitro* by S9, CY would produce similar levels of metabolic substance concentrations as *in vivo*. When H9C2 was pre-treated with NAC, ISO, and BIO, each inhibited cell damage by CYS9. When treated with ISO and BIO, we observed that CY metabolism itself was inhibited. This result suggests that cardiac cell damage may depend on individual differences in CY metabolic capacity. As preventative drugs, however, both BIO and ISO seem likely to interfere with antitumor effects and are thought to be unsuitable. Pre-treatment with NAC did not inhibit CY metabolism: compared to control samples, while HCY concentration was similar, CEPM concentration statistically significantly increased. Less acrolein, however, was present after exposure to NAC. The increase in CEPM suggests that scavenging of acrolein by NAC prevents inhibition of ALDH1. Consequently, through a mechanism related to its ability to inhibit acrolein, NAC may attenuate cardiotoxicity associated with high-dose CY.

SCA1+ MESENCHYMAL STROMAL CELLS INHIBIT GRAFT-*VERSUS*-HOST DISEASE IN MICE AFTER BONE MARROW TRANSPLANTATION

F. Wen[1,*] H.-J. Zhang[1], W. Yin[1], X. Hu[1]
[1]Department of Transfusion Medicine,xijing Hospital, the Fourth Military Medical University,xi'an, China

Background: Mesenchymal stromal cells (MSCs) have therapeutic potential for the prevention and treatment of graft-*versus*-host disease (GVHD). Although the treatment of GVHD using MSCs has been studied in phase I/II and phase III clinical trials, the results of clinical trials seem contradictory. MSCs comprise several subpopulations, which have not been individually assessed for their role in GVHD suppression. However, previously conducted pre-clinical experiments or clinical trials for investigating the effects of MSCs on GVHD have predominantly used MSCs mixtures. We speculate that the heterogeneity of MSCs mixtures may be responsible for the contradictory outcomes of previous studies. Some MSCs subpopulations may be immunosuppressive, whereas others may be immune stimulatory. Therefore, it is necessary to explore the therapeutic effects of MSCs subpopulations which remain unknown. Sca1 is a marker expressed by hematopoietic progenitors and stem cells. Hu *et al.* previously identified bone-associated $CD45^{-}Ter119^{-}CD31^{-}Sca1^{+}$ cells as a common progenitor of niche mesenchymal cells in adults. Thus, Sca1 is also a cell marker that is expressed by a primitive subpopulation of adult MSCs.
Aims: In this study, we aimed to assess the immunosuppressive effect of bone-associated $Sca1^{+}$ MSCs on acute GVHD (aGVHD) and elucidate the related mechanisms in a MHC-mismatched mouse model of allogeneic hematopoietic stem cell transplantation (HCT).
Methods: The clinical manifestation of aGVHD was evaluated by the loss of body weight, diarrhea, clinical scores, survival period and pathological changes of target organs. The infiltration of T cells and the expression of CD80/86 in target organs were analyzed by flow cytometry. The expression of CTLA-4 in splenocytes was tested by Real-time PCR.
Results: Our results showed that: (1) Non-cultured $Sca1^{+}$ MSCs decreased the severity of aGVHD and prolonged the survival period of allogeneic HCT recipients; (2) The effect of $Sca1^{+}$ MSCs on aGVHD was slightly better than that of MSCs mixture, but not in a statistically significant way; (3) Infusion of $Sca1^{+}$ MSCs reduced donor T cell infiltration into GVHD target organs; (4) The expression of CD80 and CD86 on splenic dendritic cells was decreased in $Sca1^{+}$ MSCs injected recipients; (5) The expression of cytotoxic T-lymphocyte antigen-4 (CTLA-4), a negative regulator of T cells, was elevated in the recipient splenocytes.
Summary and Conclusions: Bone-associated $Sca1^{+}$ MSCs subpopulation suppressed GVHD and should be considered as a potential strategic treatment of aGVHD.

IN VITRO EXPANDED HUMAN CD4+CD25+FOXP3+ REGULATORY T CELLS IN NUTRIENT-DEPRIVED MEDIUM AS A POTENTIAL ARMAMENT IN THE PREVENTION OF GRAFT-*VERSUS*-HOST DISEASE

T.-J. Chiou[1,*] T.-H. Chu[1], S.-T. Chu[2], W.-F. Tzeng[3]
[1]Division of Transfusion Medicine, Department of Medicine, Taipei Veterans General Hospital and National Yang-Ming University School of Medicine, [2]Institute of Biochemstry, National Taiwan Univeristy, Taipei, [3]Department of Life Science, Fu-Jen University, New Taipei City, Taiwan, ROC

Background: Allogeneic haematopoietic stem cell transplantation (HSCT) has been used to treat some of haematological malignancies and inherited or acquired non-malignant diseases. Unfortunately, graft-*versus*-host disease (GVDH) occurred approximately 15% in transplant recipients and decreases the success of allogeneic HSCT. At present, no effective treatment can completely prevent the GVHD from allogeneic HSCT patients. CD4+CD25+FoxP3+ regulatory T cells (Tregs) have been shown to be important in maintaining immune homeostasis and preventing autoimmunity. However, 5% to 10% Tregs could be measured in human CD4+ T cells and few Tregs would convert to conventional activated T cells because of losing FoxP3 expression. It had been reported to correlate with the occurrence and severity of GVHD in some study.
Aims: In order to study the potential use CD4+CD25+FoxP3+ Tregs for the prevention of GVHD, we attempt to evaluate the better efficient method to increase the number of induced Treg cells (iTregs) in the donor's PB and stabilize the FoxP3 in iTreg cells.
Methods: PBMC were prepared from blood of healthy donors by Ficoll-Hypaque density gradient centrifugation. T cells were isolated by negative selection. CD4+ cells were harvested, and then activated with anti-CD3/CD28 beads in the presence of IL-2, TGF-β and retinoic acid (RA) containing RPMI1640 medium. During the Tregs induction, the activated T cells were performed under low nutrient supplement (5% FBS) for three days then refreshed the cells into the full nutrient supplement (10% FBS) for another four days. The harvested cells were analyzed by flow cytometry method with fluorescence-conjugated CD-antibodies, including CD4, CD25, CD127 and FoxP3. The protocol was shown in Figure 1A.

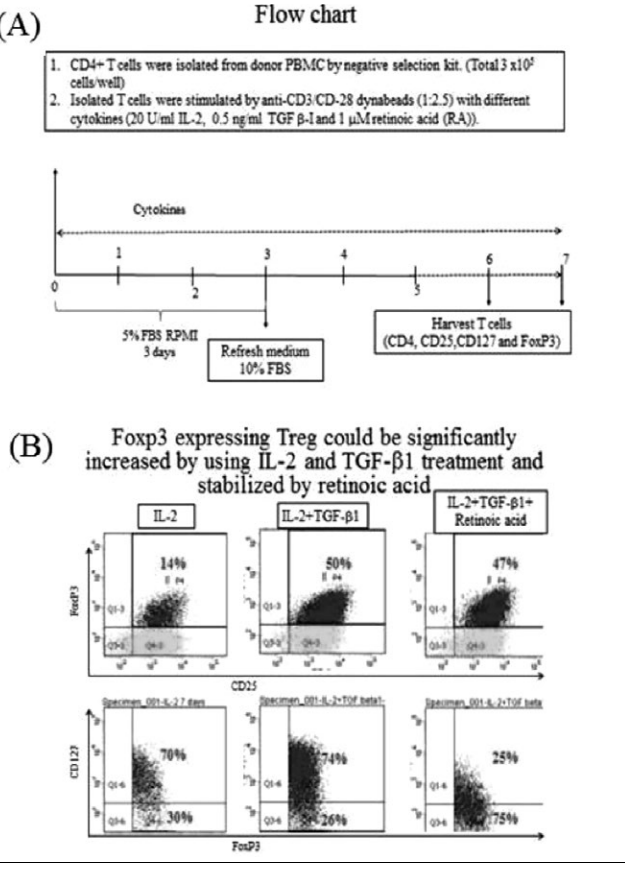

Figure 1.

Results: Our data showed that FoxP3+Tregs in PBMC were increased from 3.5% to 30% under IL-2 (20U/ml) and TGF-β (0.5ng/ml) containing medium, after T cell activation. Most importantly, the number of FoxP3+Treg cells was

increased from 30% to 50% with the 3-day-nutrient deprivation in advance, comparing with the full nutrient supplement for 7 days. The addition of retinoic acid (1mM) stabilized the FoxP3+ Tregs during this incubation period. Besides, FoxP3+ and CD127 - shown in Figure 1B, the combination of RA and TGF-β increased the functional iTreg cells to >70% (from 30% to 75% in this representative data). Finally, activated T cells differentiated to FoxP3+ Treg cells and stabilized by RA significantly, under this particular treatment.
Summary and Conclusions: Our study showed that the combination of IL-2, TGF-β and RA in 3-day-nutrient-deprived medium could induce naïve CD4+CD25+ cells to express and stabilize FoxP3 markedly. Further, we will develop the iTreg suppression assay to clarify the biological function of iTregs *in vitro*. GVHD mouse model will be established by using allogeneic HSCT to verify iTreg's function *in vivo*, too.

PROGNOSTIC SIGNIFICANCE OF IMMUNOLOGIC RECOVERY AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION IN PATIENTS WITH LYMPHOMAS

M. Cioch[1,*] A. Goracy[1], D. Jawniak[1], J. Manko[1], M. Wach[1], E. Wasik-Szczepanek[1], M. Hus[1]
[1]Department of Haematooncology and Bone Marrow Transplantation, Medical University in Lublin, Lublin, Poland

Background: Autologous peripheral blood stem cell transplantation (APBCST) is now established therapy for patients (pts) with refractory and relapsed lymphomas (Hodgkin lymphoma-HL and non-Hodgkin's lymphoma-NHL). A lot of factors influence on post transplant outcome: performance status, activity of disease at time of APBSCT and chemosensitivity to salvage therapy.
Aims: The aim of our study was the analysis of immunologic recovery after APBSCT as another important factor with prognostic significance.
Methods: A total 28 consecutive pts with lymphomas (16 with NHL and 12 with HL) at Department of Haematooncology and Bone Marrow Transplantation at Medical University of Lublin were recruited to this study. In NHL group there were 5 female and 11 male (median age 50.5) and in HL group there were 7 female and 5 male (median age 27.5). The day before myeloablative regimen blood samples for flow cytometry analysis were taken. In the transplantation procedure pts were received BEAM (27 pts) or CBV (1 pt) regimen. Next blood samples were taken at 30 and 100 day after transplantation procedure. At 100 day after APBSCT pts underwent clinical evaluation with CT or PET to establish activity of disease (Complete Remission-CR or not Complete Remission-nCR).
Results: Analysis of flow cytometry results compared with disease activity showed at 100 day after APBSCT: higher level of T helper cells (CD3+CD4+; CD3+CD4+CD45RO+; CD4+CD25high) in pts with CR compared with nCR (p=0.0069; p=0.0025, p=0.0095); higher level of dendritic cells (BDCA1+CD19-) in pts with CR compared with nCR (p=0.017), and higher level of T regulatory cells (Foxp3+CD4+CD25high in pts with CR compared with nCR (p=0.0095).
Summary and Conclusions: Our analysis of immunologic recovery after APBSCT showed that CR status in pts with lymphomas is associated with higher level of T helper cells, dendritic cells and T regulatory cells. Such ascertainments encourages to searching new methods of immune reconstitution acceleration and enrichment of transplant source with those cells.

COMPARISON BETWEEN HEALTHY DONOR-DERIVED BONE MARROW MESENCHYMAL STEM CELLS BM-MSCS AND HUMAN DERMAL FIBROBLASTS: IMPACT ON CLINICAL APPLICATIONS OF HMSCS

M. Al Bagami[1,2,*] H. Ouled Haddou[1,2], I. Marcq[1], V. Debuysscher[1], C. Ossart[2], A. Regnier [2], J.-P. Marolleau[1,2], H. Bouhlal[1,2]
[1]EA 4666, Lymphocyte Normal/Pathologique et Cancers Curs, CHU Sud, [2]Service Hématologie clinique-Thérapie cellulaire, CHU Sud, Amiens, France

Background: The results of clinical applications of human Mesenchymal Stem Cells (hMSCs) depend on clinical and biological factors. The quality of stem cell culture will affect success rate. Stem cell culture contamination by fibroblasts can be happened. The identification of the differences between these two cell types plays an important role to improve the quality of the therapeutic uses of hMSCs.
Aims: Our present work is the first work to compare the phenotype and functional properties of primary human Dermal fibroblasts HDF to hMSC from Bone Marrow BM to reflect the impact of the possible contamination of bone morrow derived hMSC (BM-hMSC) by fibroblasts.
Methods: In this study, hMSCs were obtained from the BM of (Healthy donor, n=5) and compared to primary HDF. The following parameters were used for this comparison: cell morphology, cell proliferation tests, cell cycle, immunophenotype, pluripotent and differentiation capacity into osteoblastic and adipogenic lineages. Genes expression profile was determined in BM-MSCs and HDF by Q-PCR.
Results: Our results show that both of BM-hMSCs and HDF cells have homogenous fusiform, fibroblast-like appearance. Human derived fibroblasts showed, significantly (p<0.001), high proliferative ability than hMSCs, which induces a shortening of doubling time (27.3-/+3h *vs* 44.5-/+ 8h for HDF and BM-MSCs, respectively; p<0,0001). The analysis of cell cycle show that HDF cultures contained, significantly p<0.001, two-fold higher cell number at synthesis stage (S) than in BM-hMSC cultures. Both cell types share the same immunophenotypic feature for these surfaces markers CD45(-), HLA-DR(-), CD73(+), CD90(+), CD105(+), and CD166(+) but CD146 and CD10 were differently expressed on BM MSCs *vs* HDF. Both of cell types have a potential to differentiate into osteoblastic and adipogenic lineages showed by specific stains.This result was confirmed by the expression levels of Runx2, PAL and Osterix (osteoblasts); and PPAR-γ2 (adipocytes). However, expression of these genes in osteoblasts and adipocytes derived from HDF remains, significantly p<0.05, two times lower than the expression in osteoblasts and adipocytes obtained in BM-MSCs differenced cells.
Summary and Conclusions: Our results confirm the similarities of morphology and phenotype of both HDF and BM-MSCs. The differentiation potential of BM-MSCs can not be used to distinguish between HDF and BM-MSCs as we showed that HDF could differentiate into other cell types as osteoblasts and adipocytes. The genes expression profile in osteoblasts and adipocytes derived from BM-MSCs and HDF can be used to distinguish between these tow cell types as we found the genes expression in osteoblasts and adipocytes derived from HDF were significantly lower than in BM-hMSCs. These results may explain the unexpected results of hMSCs in therapeutic applications. In this current study, new marker was identified to discriminate HDF from BM-hMSCs in order to improve the quality of the therapeutic uses of hMSCs.

E1547

COMPARISON OF RED BLOOD CELL AND PLASMA DEPLETION EFFICIENCIES OF TWO METHODS FROM CORD BLOOD: AUTOMATED SEPAX (BIOSAFE) AND MANUAL CELLEFFIC (KANEKA)

P. Yurdakul[1,*] E.B. Gencer[1], H.Y. Akin[1], N. Sato[2], C. Fricke[3], M. Beksac[1,4]
[1]Cord Blood Bank, Ankara University Faculty of Medicine, Ankara, Turkey, [2]Kaneka Corporation-Japan, Osaka, Japan, [3]Kaneka Pharma Europe German Branch, Eschborn, Germany, [4]Hematology, Ankara University Faculty of Medicine, Ankara, Turkey

Background: Volume reduction is a routine procedure in cord blood (CB) banking. Two major automated systems have been in use for depletion of excess plasma and red blood cells (RBC) from CB, the most commonly used SEPAX (Biosafe) and AutoXpress Platform (Thermogenesis) systems. Both automated systems were proven to be efficient post processing, yielding high Total Nucleated Cell (TNC) recovery rates as well as viabilities. Nonwoven matrices are being used clinically as filters and scaffolds owing to their ability to trap cells. A novel filtration system was described by KANEKA Corporation (Japan) for processing of CB. This filtration system uses a nonchemical- coated/nonwoven polyester fabric filter, which traps CD34+ cells through affinity without the need of centrifugation or potentially toxic chemicals.
Aims: To compare Red Blood Cell and Plasma Depletion Efficiencies of Two Methods from Cord Blood: Automated SEPAX (Biosafe) and Manual Celleffic (Kaneka).
Methods: Twenty one CB units collected in utero from consented maternal donors were included in the study. CBU plasma and red cell depletion was performed either with only Celleffic or with both Sepax/Celleffic systems. CBUs with below criteria were accepted: 1. CBUs with collection volumes of ≥40 mL and ≤100 mL (with CPD) were chosen for Celleffic only group and CBUs with collection volumes >100 mL were chosen for Sepax *vs* Celleffic comparison group and processed as follows: CBU was split equally in half and after assesment of pre TNC and pre CD34+ cell counts for each split bag, half of the initial CBU was processed with automated SEPAX (Biosafe) and the other half with Celleffic (Kaneka) 2. All CBUs and maternal donors were negative for infectious disease markers 3. CBUs were processed within 48 hrs after collection. Post process TNC, CD34+ cell, mononuclear cells (MNC), RBC and neutrophil recovery rates as well as viability were assessed for all groups and compared for the split CBUs. The comparative results of two processing methods were analysed statistically using Student's T-test.
Results: CBU with collection volumes ≤100 mL (n=12) were processed only with Celleffic whereas CBU with collection volumes >100 mL (n=9) were processed in both systems. There were no significant differences for any of the pre-processing values of the parameters analyzed between two groups (Celleffic only and Celleffic *vs* Sepax). Figure 1 indicates depletion and recovery results of variables after processing with only Celleffic. Figure 2 denotes the comparison between these two systems for the same five parameters. Celleffic was favorable in terms of RBC depletion rates (p=0.008) while Sepax was found to be superior for post TNC and MNC recovery rates (p=0.008 and p=0.015, respectively). There were no significant differences between two systems regarding CD34+ hematopoietic stem cell (HSC) recovery and NRBC cell depletion rates (p=0.674 and p=0.236, respectively). Post processing TNC viability after Celleffic was slightly higher than after Sepax (96% and 94%, respectively; p=0.017).

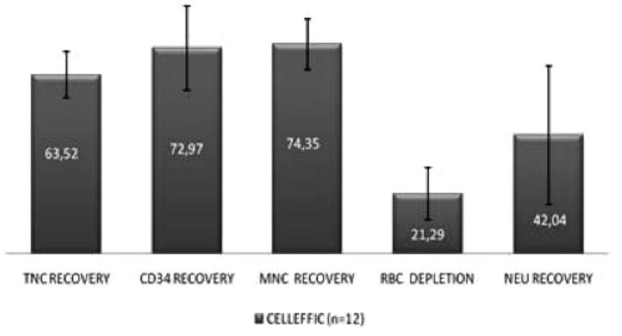

Figure 1. Mean and SD values in percentages of cell recovery (TNC, HSC, MNC, Neutrophil) or red blood cell depletion.

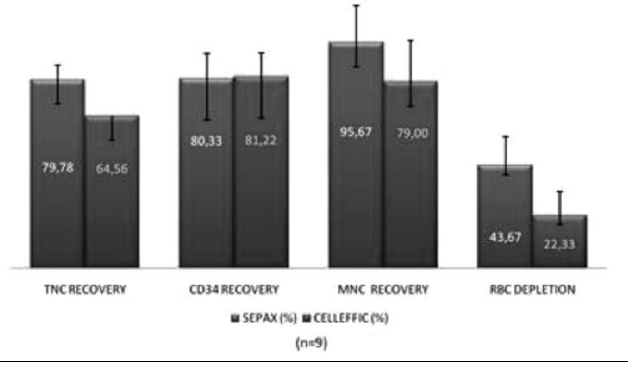

Figure 2. Comparison of two systems in terms of recovery or depletion.

Summary and Conclusions: The filtration method developed by Kaneka is claimed to be simple, cost-effective, and nontoxic without requiring costly equipment mostly suitable for developing laboratories with an average turn over rate. This small sized prospective parallel study shows that both methods are comparable in terms of HSC recovery. The Cellefic system has a higher red cell depletion capacity whereas Sepax was more effective for TNC/MNC recovery. Colony forming potential as well as post thaw viability/recovery rates of both systems are currently being analyzed.

E1548

THE EFFECTS OF -ADRENERGIC AGONIST OF ISOPROTERENOL ON MIR-886-3P AND MIR-23A EXPRESSION IN HUMAN MESENCHYMAL STEM CELLS

S. Kaviani[1,*] H. Zamani[1], A. Atashi[1], F. Parhizkar[1]
[1]Hematology, Tarbiate Modares University, School of Medical Sciences, Tehran, Iran

Background: Mobilization of Hematopoietic Stem Cells (HSCs) for transplantation and the importance of -adrenergic signals in induction of this process, have been well investigated. However, little is known about the role of -adrenergic signals in mobilization of HSCs and factors influenced by these signals. The chemokine Stromal Derived Factor 1 (*SDF-1*) which is expressed by human bone marrow-derived mesenchymal stem cells (hMSCs), has a key role in mobilization of HSCs and *miR-886-3p* and *miR-23a* can regulate the expression of this chemokine.
Aims: In this study, To investigate the role of *miR-886-3p* and *miR-23a* in mobilization process, The expression of both miRNAs were evaluated in hMSCs treated by Isoproterenol (a -adrenergic agonist).
Methods: In this study, hMSCs were isolated and cultured from human bone marrow. After doing flowcytometric analysis, the cells were treated with 100 M Isoproterenol. Total RNA was extracted at 12 and 48 hours post treatment, and also from untreated hMSCs as a control. Then *miR-886-3p* and *miR-23a* expression levels were quantified by quantitative Reverse Transcriptase PCR.
Results: The expression level of *miR-886-3p* was increased significantly at 12 and 48 hours post treatment (P<0.05). In addition, the expression level of *miR-23a* was decreased at 12 hours post treatment and increased significantly at 48 hours post treatment (P<0.05).
Summary and Conclusions: Isoproterenol induces *miR-886-3p* in hMSCs. miR-23a is firstly decreased and then increased by treating with Isoproterenol. So both miRNAs can contribute in mobilization process.

Thrombosis and vascular biology

SOLUBLE FMS-LIKE TYROSINE KINASE-1 IN CHILDREN AND ADOLESCENTS WITH THALASSEMIA INTERMEDIA: RELATION TO PULMONARY VASCULOPATHY AND SUBCLINICAL ATHEROSCLEROSIS

A. Tantawy[1,*] A.A. Adly[1], E. Ismail[2], O. Yousef[3], M. Ali[1]
[1]Pediatrics, [2]Clinical Pathology, [3]Cardiac, Ain Shams University, Cairo, Egypt

Background: The study of vascular biomarkers has greatly enhanced our understanding of the underlying pathophysiology of atherosclerosis including soluble biomarkers and physiological parameters such as measures of arterial stiffness and endothelial function. The hypercoagulability in TI has been attributed to several factors, including a procoagulant activity of hemolyzed circulating red blood cells, increased platelet activation, coagulation factor defects, depletion of antithrombotic factors, and endothelial inflammation. Iron-mediated endothelial dysfunction may be mediated either directly through the inactivation of endothelium-derived nitric oxide (NO) or indirectly through the promotion of reactive oxygen species formation. Soluble fms-like tyrosine kinase-1 (sFLT-1) is a member of the vascular endothelial growth factor receptor (VEGFR) family. By adhering to and inhibiting VEGF and placenta growth factor, it induces endothelial dysfunction.
Aims: We assessed the level of sFLT-1 in children and adolescents with TI, correlating it with markers of hemolysis and iron overload as well as cardiovascular complications.
Methods: Thirty-five patients were studied stressing on history of cardiac disease, splenectomy, transfusion history and chelation/hydroxyurea therapy and serum ferritin. sFLT-1 levels were measured by enzyme linked immunosorbent assay. Ehocardiography and measurement of carotid intima media thickness (CIMT) were done for all subjects.
Results: TI patients had significantly higher Tricuspid Regurgitation Velocity (TRV) with lower ejection fraction and fractional shortening than controls (p<0.001). CIMT was significantly increased among patients compared with control group (0.43±0.02 mm *versus* 0.36±0.02 mm; p<0.001). sFLT-1 was significantly higher in TI patients compared to control group (median [IQR], 110 [80-155] pg/mL *versus* 70 [60-90] pg/mL; p<0.001). Splenectomized patients as well as those who had pulmonary hypertension had higher sFLT-1 levels than those without (p<0.001). Hydroxyurea-treated patients had lower sFLT-1 levels than untreated patients. Significant positive relations were observed between sFLT-1 and indirect bilirubin (r=0.357, p=0.035) as well as serum ferritin (r=0.879, p<0.001) while levels were negatively correlated with hemoglobin (r=-0.398, p=0.018). TRV and CIMT were positively correlated with sFLT-1 levels (p<0.001). ROC curve analysis revealed that the cut-off value of of sFLT-1 at 110 pg/mL could differentiate patients with and without pulmonary hypertension with a sensitivity of 86.96% and specificity of 100%, AUC 0.944; p<0.001.
Summary and Conclusions: Measurement of sFLT-1 as a marker of vascular dysfunction in β-TI may provide utility for early identification of patients at increased risk of pulmonary and cardiovascular complications. The relation between sFLT-1 and CIMT provides a link between endothelial dysfunction and subclinical atherosclerosis.

E1550

ASSOCIATION OF THE DYNAMIC STATUS OF COAGULATION FACTORS WITH L-ASPARAGINASE ADMINISTRATION IN THE INDUCTION PHASE OF PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA AND LYMPHOBLASTIC LYMPHOMA

Y. Kubota[1,*] Y. Ikeda[1], C. Oyama[1], T. Aoki[1], K. Isobe[1], M. Mori[1], Y. Arakawa[1], R. Hanada[1], K. Koh[1]
[1]Department of Hematology/Oncology, Saitama Children's Medical Center, Saitama, Japan

Background: Although L-asparaginase (L-asp) is one of the most important medication used in pediatric acute lymphoblastic leukemia (ALL) and lymphoblastic lymphoma (LBL) treatment, it has been associated with several adverse effects, including thrombosis. Thrombosis is caused by multiple factors, including prothrombic properties of tumor cells, genetic factors, indwelling central venous catheters, corticosteroids, and L-asp. L-asp plays a major role in thrombosis because it reduces the synthesis of hemostatic factors in the liver. The timing of thrombosis is generally late in the induction phase; however, little is known regarding the dynamic status of hemostatic factors.
Aims: This study was conducted to analyze the dynamic status of hemostatic factor levels in the induction phase of ALL treatment, including L-asp and to determine the association between L-asp and thrombosis.
Methods: We retrospectively analyzed 69 pediatric patients (61 with ALL and eight with LBL) who received Berlin-Frankfurt-Munster chemotherapy at a single institution between October 2009 and November 2014. All patients received an intramuscular injection of *Escherichia coli*-derived L-asp (5000 U/m^2/injec-

tion) on days 12, 15, 18, 21, 24, 27, 30, and 33. One patient had cerebral venous thrombosis. Hemostatic factors analyzed in this study included fibrinogen (Fib), alpha-2-plasmin inhibitor (α_2-PI), antithrombin-III (AT-III), plasminogen (PLG), and platelets (Plt). Although platelets are not an L-asp dependent factor, their levels were analyzed because of their association with hemostasis. We analyzed the levels of each hemostatic factor at time point (TP)1 (at diagnosis), TP2 (day 12, before the initial L-asp administration), TP3 (day 22, after the fourth L-asp administration), and TP4 (after protocol Ia). Additionally, we analyzed the periods required by each hemostatic factor level to decrease below the normal range and to recover to the normal range following the initial L-asp administration; this is defined the period analysis. All data were analyzed by one way analysis of variance.
Results: In TP1, Plt decreased below the normal range because of the myelosuppression of tumor burden. Fib increased above the normal range because of the proinflammatory effects of tumors, while other factors were in the normal range. In TP2, Plt levels remained suppressed, Fib decreased below the normal range, and AT-III increased above the normal range, while α_2-PI and PLG were in the normal range. In TP3, the levels of all factors decreased. In TP4, Plt and Fib levels recovered to the normal range, while AT-III, PLG, and α_2-PI were below the normal range. Our period analysis showed the following results: median periods for each hemostatic factor that decreased below the normal range were as follows: Plt, 0 days; Fib, 0 days; α_2-PI, 3 days; AT-III, 5 days; and PLG, 4 days. During the early induction phase, Plt and Fib levels decreased significantly faster than AT-III and α_2-PI levels ($p < 0.05$). Additionally, the median periods required by each hemostatic factor to recover to their normal ranges were as follows: Plt, 21.5 days; Fib, 29 days; α_2-PI, 29 days; AT-III, 30.5 days; and PLG, 31 days. During the late induction phase, Plt levels recovered significantly faster than AT-III and PLG levels; Fib levels recovered significantly faster than PLG levels ($p < 0.05$).
Summary and Conclusions: During the early induction phase, bleeding risk, rather than thrombosis, may increase because Plt and Fib levels decreased below their normal ranges, which occurs faster than the decrease in the levels of antithrombic factors, including AT-III and PLG. During the late induction phase, the thrombotic risk may increase because of the faster recovery of Plt and Fib levels as compared with that of PLG and AT-III levels. One patient developed cerebral venous thrombosis on day 35 in protocol Ia, which confirmed our hypothesis. Therefore, clinicians need to be more cautious regarding the possibility of thrombosis in the late induction phase.

E1551

UPPER AND LOWER EXTREMITY DEEP VEIN THROMBOSIS IN CHILDREN:A SINGLE CENTER EXPERIENCE

M. Cetin[1,*] S. Aytac[1], T. Bayhan[1], S. Unal[1], B. Tavil[1], B. Kuskonmaz[1], F. Gumruk[1]
[1]Pediatric Hematology, Hacettepe University, Ankara, Turkey

Background: Deep Vein Thrombosis (DVT) in children can be caused by a combination of several risk factors such as poor blood circulation, damage to the veins and thrombophilia.
Aims: Our aim is to evaluate the causes, risk factors and clinical outcome of upper (UEDVT) and lower extremity (LEDVT) DVT in our center.
Methods: We retrospectively evaluate their clinical and laboratory results by the way of searching their paper based & electronic files.
Results: Our database revealed 352 children having various types of thrombosis between January 2009 to December 2014 and 70 out of 352 were diagnosed as DVT. There were 44 male and 26 female with a median age of 60 months (minimum 1 month- maximum 216 months)in this group. The location of UEDVT involved internal jugulary vein (n=16) and superior vena cava(SVC) (n=5) whereas LEDVT include femoral and iliac veins(n=39), popliteal veins(n=10). More than half of these DVTs were associated with a cathether related thrombosis on which 4/5 SVC, 15/16 jugulary vein thrombosis and 21/49 LEDVTs. All except 5 patient having an underlying chronic diseases such as malignancy, nephrotic syndrome, immune deficiency, congenital cardiac disorders, metabolic diseases. One out of these 5 patient was diagnosed as a hereditary protein C deficiency after having a recurrent LEDVT and pulmonary thrombosis. Recurrent thrombotic episodes(n=13) was observed in 10 patients and 9 of these patient having LEDVT had 12 recurrent episodes including (6 pulmonary thrombosis, 4 LEDVT, 1 renal venous thrombosis and 1 sinevenous thrombosis). One patient who initially had UEDVT experienced recurrent episode of SVC thrombosis. Factor V Leiden mutation was found to be heterozygous in 15/50 and normal in 35/50. Homozygous prothrombin 20210A mutation were detected in 2 out of 50 and 8/50 were heterozygous. Homozygous MTHFR C677T and MTHFR A1298C mutation was found in 3/50 and 8/23 respectively. PAI 4G/5G heterozygous mutation was found in 15/22 patient. Most of them(%65) initially treated with LMWH and TPA were used as a thrombolytic agent in 6 of them without any complication. Vena cava inferior filter was used in 3 patients having LEDVT. During the follow up period 2 had postphylepitic syndrome and 1 had an amputation and 9 patient deceased because of the primary disesase.
Summary and Conclusions: Our single center experience showed that children having spontenous DVT is very rare and most of these DVT episodes were due to underlying disorder and associated risk factors (aquired and hereditary).

E1552

RECURRENCES AFTER SPLANCHNIC VENOUS THROMBOSIS: RISK FACTORS AND EFFECT OF DIFFERENT TREATMENTS IN A RETROSPECTIVE MONOCENTER COHORT OF 154 PATIENTS

V. De Stefano[1,*] F. Bartolomei[1], A. Ciminello[1], S. Betti[1], T. Za[1], P. Chiusolo[1], E. Rossi[1]
[1]Institute of Hematology, Catholic University, Roma, Italy

Background: Non-cirrhotic non-malignant splanchnic vein thrombosis (SVT) is a rare clinical entity associated with heterogeneous underlying disorders; chronic myeloproliferative neoplasms (MPN) and thrombophilia are the leading systemic causes of SVT. Long-term treatment is a clinical challenge and the optimal duration of anticoagulation is uncertain.
Aims: To assess in a retrospective cohort of non-cirrhotic non-malignant SVT patients the risk factors for recurrent thrombosis and the efficacy of antithrombotic long-term secondary prophylaxis.
Methods: We analysed a retrospective cohort of 154 patients with a first SVT referred to our Thrombosis Center between 1995 and 2014 (M/F 68/86, median age at SVT 45 years, range 1-83); 12% of patients had hepatic vein thrombosis and 88% thrombosis of one or more sites of the spleno-mesenteric-portal venous axis. SVT was unprovoked in 84 patients (54%); inherited or acquired thrombophilia was diagnosed in 56 patients (36%). Forty-seven patients (30%) had diagnosis of overt MPN; JAK2 V617F mutation was present in 50 of 131 tested patients (38%). Long-term antithrombotic treatment was given to 112 patients: 80 (53%) were receiving anti-vitamin K treatment (AVK), 16 aspirin (ASA) (10%), and 8 AVK+ASA (5%); 50 patients (32%) discontinued any prophylaxis after 6-12 months of AVK treatment. The probability of recurrent thrombosis after SVT and the impact of different risk factors or treatments were estimated by the Kaplan-Meier method and a multivariate proportional hazards regression model.
Results: During a total observation time of 748 years, 25 patients (16%) had a recurrent thrombotic event: 15 a recurrent SVT, 7 a venous recurrence in other sites, and 3 an arterial recurrence. The overall incidence of recurrences was 3.3% pts-years. The cumulative probability of recurrence was 6.1% at 1 year, 16.2% at 5 years, and 25.7% at 10 years. Recurrence occurred in 10 cases during AVK treatment (2.1% pts-years) and in 15 cases without AVK (5.3% pts-years). The univariate hazard ratio (HR) for recurrent thrombosis in patients without AVK was double than in patients on treatment (HR 2.02, 95%CI 0.97-5.28). A multivariate proportional hazards regression model having as dependent variable the recurrence of thrombosis included as covariates gender, age >45 yrs at SVT, family history of venous thrombosis, absence of provoking causes of SVT, presence of thrombophilia, diagnosis of overt MPN, cytoreductive treatment, AVK or ASA treatment. Male gender and age >45 years were associated with a higher risk of recurrence (HR 2.6, 95%CI 1.04-6.53, and HR 1.18, 95%CI 1.18-8.97, respectively); AVK treatment was significantly effective in preventing recurrences (HR 0.35, 95%CI 0.13-0.91). A modified model with the variable JAK2 V617F and without the redundant variable MPN was applied on the 131 patients checked for the mutation, retaining only the presence of JAK2 V617F as positive predictor of recurrence (HR 6.7, 95%CI 1.76-25.44) and confirming the efficacy of AVK (HR 0.15, 95%CI 0.04-0.57). A sub-analysis of the patients with overt MPN or carriers of JAK2 V617F confirmed the efficacy of AVK, whereas the use of ASA had no significant impact in preventing recurrences.
Summary and Conclusions: In this monocenter cohort thrombophilia and MPN/JAK2 V617F mutation were confirmed to be the systemic risk factors for SVT more represented. Male gender, age >45 years, and the presence of JAK2 V617 mutation resulted independent risk factors for recurrence. Long-term treatment with AVK decreased the rate of recurrences at least by 65% in the overall cohort as well as in the MPN subgroup.

E1553

THROMBIN INDUCES VASCULAR LEAKAGE THROUGH MACROPHAGE MIGRATION INHIBITORY FACTOR AND AUTOPHAGY DURING SEPSIS

C.-H. Chao[1,*] H.-R. Chen[2], T.-M. Yeh[1]
[1]Department of Medical Laboratory Science and Biotechnology, [2]The Institute of Basic Medical Sciences, National Cheng Kung University, Tainan, Taiwan, ROC

Background: Sepsis is a disease, of which the systemic inflammation-induced vascular leakage and disseminated intravascular coagulation leads to multiple organ failure. Thrombin, a serine protease mediating critical pathological roles during sepsis, not only activates coagulation cascades but also acts as a cytokine to induce vascular hyper-permeability and inflammation. In previous study, it has been demonstrated that thrombin could induce endothelial cells to secret macrophage migration inhibitor factor (MIF). MIF is another critical pro-inflammatory cytokine secreted in sepsis, and it has also been indicated to induce the formation of autophagy. However, the interplay between MIF and autophagy on thrombin-induced vascular hyper-permeability during sepsis has not yet been revealed.
Aims: We aim to investigate whether thrombin-induced vascular hyper-permeability is through MIF-mediated autophagy in sepsis.
Methods: Human microvascular endothelial cell line (HMEC-1) was co-treated with thrombin with or without MIF/autophagy inhibitors and the permeability

was monitored by real-time cell analyzer (RTCA) and trans-well permeability assay *in vitro*. We also used lipopolysaccharide (LPS)-intraperitoneally injected mice as endotoxemia mice model to test whether MIF and autophagy inhibitors could rescue LPS-induced vascular leakage and septic shock. To measure vascular leakage level of endotoxemia mice model, Evans blue dye was intraperitoneally injected into mice and the vascular leakage of the mice was determined by the concentration of Evans blue dye in peritoneal lavage.
Results: We found that thrombin activity in plasma was significantly increased in endotoxemia mice. In addition, treating HMEC-1 cells with thrombin could induce MIF secretion and autophagy formation within 30 minutes and accompanied with VE-cadherin translocation. Next, we used MIF and autophagy inhibitors to rescue endothelial barrier dysfunction. Blocking MIF by ISO-1, p425 and anti-MIF antibodies could rescue thrombin-induced endothelial hyperpermeability both in RTCA and trans-well assay. Blocking the autophagolysosome formation by bafilomycin A1 (BafA1) and chloroquine (CQ) partially block thrombin-induced endothelial hyper-permeability in RTCA. Co-treatment of PI3K inhibitor (3-methyladenine, 3-MA) or ROS scavenger (N-acetyl-L-cysteine, NAC) with thrombin effectively attenuated thrombin-increased endothelial permeability in trans-well permeability assay.In addition, inhibition of MIF could block the thrombin-induced autophagy, revealing that thrombin-induced autophagy is mediated by MIF. Furthermore, in endotoxemia mice model, peritoneal injection of LPS increased the MIF secretion, while bovine serum albumin (BSA) did not show similar effect. Injection of ISO-1 and BafA1 with LPS eliminated LPS-induced vascular leakage, indicating that this effect was mediated by MIF and autophagy.
Summary and Conclusions: Our results suggest that thrombin-induced vascular hyper-permeability is mediated by MIF and autophagy and this study may provide potential therapeutic target for treating sepsis in the future.

E1554

BLOOD RHEOLOGY DISTURBANCES INCREASES VTE-RISK IN CHILDREN WITH ACUTE LYMPHPBLASTIC LEUKEMIA
I. Kolesnikova[1,*] E. Roitman[2], S. Roumyantsev[1]
[1]FSCC of Pediatric Hematology Oncology and Immunology, [2]Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: Central hemodynamics and blood rheology disorders are well-known factors leading to thrombosis. High risk of venous thromboembolism (VTE) have accompanied acute lymphoblastic leukemia (ALL) like another malignancies. Besides the chemotherapy has negative effect on cardiac function which can lead to blood velocity decrease. And hemorheological changes could be caused due to proinflammatory cytokines negative influence on red blood cells aggregability.
Aims: To investigate blood rheology features as VTE risk factor in children with acute lymphoblastic leukemia.
Methods: The study's population consist 48 children (age <17.6 y.o.). In all patients we investigated BNP level. Whole blood viscosimetry (shear rates 5-300 s^{-1}), plasma viscosimetry (shear rates 250 s^{-1}), erythrocytes aggregability and deformability were investigated. All patients had not any symptomatic organs failures.
Results: From 48 patients 1) in 8 cases BNP was elevated more 82 ng/L (up to 208 ng/L), and 2) in 6 patients had thrombosis and three from them were with increased BNP. All cases thrombi had revealed at the area of central venous line. All patients had normal plasma viscosity (1,1-1,5 mPa*s) and unimpaired erythrocyte deformability. Despite it whole blood viscosity was increased by shear rates 5-300 s^{-} and mainly by shear rates 5-75 s^{-1}(eta by 5s^{-1}: 4,2-7,9 mPa*s; eta by 75s^{-1}: 2,3-4,1 mPa*s). The last assumes erythrocytes hyperaggregability in all patients.
Summary and Conclusions: As a whole, hemorheological profile is impaired moderately in children with ALL. Totally increased blood viscosity and erythrocytes hyperaggregability and hidden ventricle overload (presumably, this is a temporary) signed by elevated BNP allows together to aggravate circulatory disorders. We assume that the revealed hemorheologic features could be one trigger to start of VTE despite standard antithrombotic prevention in children with acute lymphoblastic leukemia. The study is continued now.

E1555

ADAMTS-13 A NOVAL MARKER LINKING BETWEEN MICRO AND MACRO- VASCULAR DISEASE IN YOUNG TYPE -1 DIABETES PATIENTS
A. Tantawy[1,*] M. Salem[1], A.A. Adly[1], Y. Dawish[2]
[1]Pediatrics, [2]clinical pathology, Ain Shams University, cairo, Egypt

Background: Several observations that vascular damage and endothelial dysfunction occur early in the course of diabetic microangiopathy have been reported.The net effect of all these changes is to convert the endothelium from a thromboresistant to a thrombogenic surface and, consequently, impairment of coagulation and of anticoagulant pathways. Recently it was demonstrated elevated level of VWF in type1 diabetics which is degraded by a metallo protease, ADAMTS-13. It's hypothesized that elevated VWF level was due to reduced level of ADAMTS-13**.** Deficiency of Von Willebrand factor (VWF)-cleaving protease (ADAMTS13) causes platelet thrombosis in the microcirculation.
Aims: to determine whether diabetic micro-angiopathy was associated with abnormally modulated haemostasis and to demonstrate whether a correlation existed between the thrombotic tendency, as measured by ADAMTS-13 levels and macrovascular complications measured as dyslipdemia and CIMT.
Methods: Seventy children and adolescents with type 1 diabetes attending the Pediatric Diabetes Clinic, Pediatric Hospital, Ain Shams University were compared with 40 age- and sex-matched healthy controls. The mean age of patients was 12.6±4.9 years and with a M/F ratio of 1.2/1.Detailed medical history with special emphasis on disease duration and insulin therapy, thorough clinical examination,blood pressure (BP) measurement, as well as screening for diabetic complications, was performed. Laboratory assessment of high-sensitivity C-reactive protein, Lipid profile, albumin/creatinine ratio, renal functions and glycosylated hemoglobin (Hb A_1c) were assayed. Carotid intima-media thickness was measured using ultrasound as well as ADAMTS 13 level using ELISA technique.
Results: The mean cIMT was higher in diabetics than controls (0.6 mm±0.1 *vs* 0.4 mm±0.1, p=0.000). Moreover, it was higher in diabetics with positive microalbuminuria compared to normo-albuminuric patients (mean 0.7 mm±0.1 *vs* 0.6 mm±0.1, p=0.018). cIMT was found to positively correlate with: age in diabetics (r=0.76, p=0.000,), body mass index (r=0.82, p=0.000). In diabetics, mean aggregate cIMT positively correlated with duration of diabetes (r=0.66, p=0.000), mean systolic blood pressure SDS(r=0.82, p=0.000) as well as Hb A_1c (r=0.40, p=0.004) and correlated negatively with high density lipoprotein -cholesterol (HDL-C) (r=−0.88, p=0.000).The mean ADAMTS-13 serum levels were significantly lower in diabetics compared to controls with the lowest values in complicated patients. Mean ADAMTS-13 levels were negatively correlated with ACR(r=2.1,p<0.05), mean CIMT(r=1.9,p<0.01), HbA1c (r=2.4,p<0.05)and mean random blood glucose(r=2.7,p<0.001). Moreover mean ADAMTS 13 levels were negatively correlated with TG,TC,high sensitivity CRP and LDL(p<0.01). Multiregression linear analysis showed that, UACR, and hs-CRP were independently related to ADAMTS 13 levels in type 1 diabetics (p<0.05).The mean ADAMTS 13 levels were related to severity of MVCs as patients with combined or more than one MVCs had significantly lower levels compared to patients with single MVCs.
Summary and Conclusions: ADMTS13 levels were eleveted and young type1 diabetics and related to metabolic control, dyslipidemia, CIMT as well as severity of MVCs.

E1556

PROGNOSTIC SIGNIFICANCE OF THE ABSOLUTE MONOCYTE COUNTS IN LUNG CANCER PATIENTS WITH VENOUS THROMBOEMBOLISM
G.-W. Lee[1,*] S.-I. Go[1]
[1]Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic of

Background: Lung cancer is one of the most prevalent types of cancer in which VTE occurs among malignancies presenting with VTE. Advanced disease stage, elderly, adenocarcinoma, smoking history, comorbidities, and chemotherapy have been reported to be risk factors for VTE in patients with lung cancer. VTE in lung cancer is associated with an increased risk of mortality
Aims: We investigated the clinical significance of the absolute monocyte count (AMC) as a predictor of the response to anticoagulation and survival in lung cancer patients with venous thromboembolism (VTE).
Methods: We retrospectively reviewed 1,707 patients with pathologically proven lung cancer who visited the hospital between July 2008 and May 2014. Among them, the clinical data of patients newly diagnosed with VTE and treated with anticoagulation were compared between the low and high AMC groups according to the median value of AMC (640/μL) at the time of VTE diagnosis.
Results: The incidence of VTE was 7.9% during the study period. Most of the patients had non-small-cell lung cancer (82.1%), stage IV (64.2%), and pulmonary thromboembolism (76.1%) and were incidentally diagnosed with VTE (76.9%). The patients' characteristics and laboratory values were not significantly different between the low and high AMC groups. Among patients available for evaluation of the response to anticoagulation, the high AMC group was significantly more refractory to anticoagulation than the low AMC group (no response to anticoagulation: 21.7% *vs* 6.8%, respectively; p=0.044). Additionally, the high AMC group showed worse overall survival (OS) than the low AMC group (median: 9.6 months *vs* 5.9 months; p=0.038). On multivariate analysis, high AMC, low albumin, and advanced stage were independent poor prognostic factors for OS.
Summary and Conclusions: High AMC is associated with refractoriness to anticoagulation and poor prognosis in lung cancer patients with VTE.

E1557

PREDICTIVE POTENTIAL OF MARKERS OF COAGULATION, FIBRINOLYSIS AND ANGIOGENESIS IN CANCER PATIENTS
E.A. Beleva[1,*] T. Deneva[2], E. Karaslavova[3], V. Popov[1], J. Grudeva[1]
[1]Clinical Oncology, Medical Faculty, [2]Clinical Laboratory, Faculty of Pharmacy, Medical University-Plovdiv, [3]Faculty of Biology, Plovdiv University "Paisii Hilendarski", Plovdiv, Bulgaria

Background: In cancer setting hemostatic system exhibits recognized pleiotropic effects in the processes of tumor initiation, growth, metastasis and angiogenesis. However, the predictive potential of various hemostatic markers regarding treatment efficacy and disease progression remains disputable.
Aims: To determine dynamics of the procoagulant activity of tissue factor bearing microparticles (MP-TF) throughout chemotherapy, its correlation to levels of soluble urokinase plasminogen activator receptor (suPAR) and angiopoietin-2 (Ang-2).
Methods: Single institution prospective observational study including 128 cancer patients who underwent chemotherapy in 2013/2014 for breast (44), lung (28), colon (37), ovarian (19) cancers. Patients were subsequently followed up: before chemotherapy (ChTh) initiation, after three cycles, after six cycles and three months post therapy cessation. A control group of 30 healthy volunteers was studied as well. Written informed consent was obtained from both study groups. Serum levels of suPAR and Ang-2 were determined by ELISA and MP-TF procoagulant activity was measured by a combined immune-chromogenic method (Zymuphen MP-TF).
Results: MP-TF procoagulant activity was twice higher in cancer patients compared to controls (0.9421vs.0.4300 pg/ml, p<0.0001). Sequential testing of MP-TF in patients with lung, colorectal and ovarian cancers revealed decrease in their procoagulant activity during treatment followed by a significant rise in activity after therapy cessation (0.9421 *vs* 1.4103 pg/ml, p<0.0001). No significant dynamics in MP-TF was observed in patients with breast cancer (0.9814 *vs* 0.8733 pg/ml, p=0.785). SuPAR and Ang-2 showed marked two- to threefold decrease during ChTh that is sustained after its cessation. MP-TF activity correlates negatively with suPAR and Ang-2 (ρ_{ang2} -0.259, ρ_{suPAR} -0.296, p=0.0001). All three markers had AUC >0,70 and therefore could be identified as reliable diagnostic tool for the presence of malignant disease. Amongst them MP-TF had greatest potential as independent predictor (Beta 0,408, p<0.0001).
Summary and Conclusions: MP-TF procoagulant activity, suPAR and Ang-2 could serve as surrogate markers for biologic activity and therapeutic efficacy.

E1558

DURABLE LONG TERM REMISSIONS WITH EARLY USE OF RITUXIMAB IN PATIENTS WITH THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP)

S. Iqbal[1,*] I. Tailor[1], S. Zaidi[1], I. Motabi[1], N. Al-Shehry[1], M. Al-Moshary[2], A. El-Ghazaly [1], S. Al-Mudaibegh[1], G. Murtaza[1], T. Hussain[1]
[1]Department of Adult Hematology/BMT, [2]Hematopathology/ Transfusion Medicine Service/ Blood Bank Department, King Fahad Medical City, Riyadh, Saudi Arabia

Background: Adult onset acquired thrombotic thrombocytopenic purpura (TTP) is a life-threatening disease mediated by autoantibodies directed against ADAMTS13. Therapeutic plasma exchange (TPE) and immunosuppressive therapies have largely remained the mainstay of treatment. Several studies have reported promising results with early use of rituximab.
Rituximab is a safe and effective treatment for newly diagnosed TTP, and has shown in a prospective, multicentre trial to decrease the number of plasma exchanges (PEX) required to achieve remission, to decrease the length of inpatient stay and to reduce the risk of relapse by over 80% when compared to historical controls.
Aims: We report our experience with early use of rituximab in patients with initial severe manifestations (cardiac or neurological involvement) or those who were failing to show early response to TPE from a tertiary care centre in Saudi Arabia.
Methods: This is retrospective data of ten patients with TTP who received rituximab either for refractory disease or sever manifestations of TTP since 2006 to 2014 at our teritary care hospital, saudi Arabia.
Results: Total of ten patients with TTP received rituximab either for refractory disease or sever manifestations of TTP since 2006 to 2014.There were six females (60%) and four males (40%). The median age was 33±12.08. Nine of the ten patients (90%) had neurological involvement ranging from headache, dizziness, confusion, seizures and focal neurological signs. Four patients (40%) had renal impairment. Two patients (20%) had associated systemic lupus erythematosis(SLE). Five patients (50%) were refractory to plasma exchange while the rest received early rituximab due to cardiac or neurological involvement at treating physician's discretion. Four patients received Rituximab within 5 days of diagnosis. Seven patients received weekly four doses of Rituximab at 375mg/m2 while two patients received eight and five doses weekly. One patient with SLE received two doses at 1000mg each as per Rheumatology protocol for the benefit of treatment of concurrent SLE. Nine out of ten (90%) achieved complete response; no subsequent relapses occurred with median follow-up of 16 months (range, 6-62 months). There was one death during the early course of disease due to delayed presentation. Number of mean plasma exchanges in early rituximab group who received Rituximab within five days was 13.5 while it was 17.4 in those who received later than day 5. Number of mean total plasma volumes exchanged in early Rituximab group were 11.1 (range 7.8-15.5) compared to 16.15 in later group (range 11.2-25.2). There were no serious immediate complications noted. On longer term clinical follow up, we have not found any increased tendency of infections or any case of leukoencephlopathy.
Summary and Conclusions: The results suggest that early use of Rituximab is associated with decrease number of plasma exchanges, increased duration of remission and decreased risk of relapse with excellent safety profile as suggested by earlier studies. We also noticed maximum benefit is seen if Rituximab given at the earliest. We need further randomized controlled trials testing efficacy of upfront Rituximab. Based on these observations, our group is planned for prospective study for the early use of rituximab.

E1559

ASSESSMENT OF LOW MOLECULAR WEIGHT HEPARIN ANTICOAGULANT EFFECT IN CHILDREN USING THROMBODYNAMICS GLOBAL HEMOSTASIS ASSAY

P. Zharkov[1,*] M. Gracheva[1], E. Seregina[1], A. Poletaev[1], E. Bondar'[1], A. Pshonkin[1], N. Ershov[1], F. Ataullakhanov[1,2,3,4,5,6]
[1]Federal Research Clinical Centre Of Pediatric Hematology Oncology And Immunology N.A. D. Rogachev, [2]National Research Center for Hematology, [3]Center for Theoretical Problems of Physicochemical Pharmacology RAS, [4]Department of Physics, Lomonosov Moscow State University, [5]The Faculty of Biological and Medical Physics, Moscow Institute of Physics and Technology, [6]Research Department, HemaCore LLC, Moscow, Russian Federation

Background: *In vitro* studies show that thrombodynamic (TD) method is sensitive for anticoagulant effect of low molecular weight heparins (LMWH), but there is still no information of its utility in anticoagulation monitoring in children with deep venous thrombosis (DVT) during active cancer treatment.
Aims: to assess anticoagulant effect of LMWH in children with DVT using Thrombodynamic assay.
Methods: Twenty-one children aged 5 months to 13 years with objectively confirmed DVT during active cancer treatment were enrolled in this prospective observational study. All children were prescribed for LMWH treatment starting with 100 IU/kg/bid on the day of thrombosis detection. Anti-Xa activity and novel global hemostasis test Thrombodynamics were used to assess coagulation status in all patients before and on the 4th day of anticoagulation. Hypercoagulability in TD was defined when clot growth velocity (V) was above reference range, hypocoagulability -when V was below reference range. For all calculations, OriginPro 8.0 (Microcal Software, Northampton, MA, USA) have been used.
Results: The day of thrombosis detection 13 patients had hypercoagulability in TD: V=30.3-45.5 um/min (median 33,9 um/min, normal range is 22-29 um/min in children), while 8 had normal results. After 4 days of LMWH therapy TD revealed significant shift (*P<<0.05, pair-sample t-test) to hypocoagulability range: V=6.3-33.9 um/min (median 9.7 um/min); anti-Xa activity=0.14-0.79 IU/ml (median 0.43 IU/ml). There was a strong correlation between anti-Xa activity and value of 1/V during LMWH treatment: Spearman correlation coeff.=0.77 (Sign. 0.0001).
Summary and Conclusions: Thrombodynamics reveal significant shift from hypercoagulability range on thrombosis to hypocoagulability in consequence of anticoagulant treatment with LMWH that is in good agreement with anti-Xa activity.

E1560

CRP, D-DIMER, LEUKOCYTE, BLAST AND PLATELET COUNTS AT THE TIME OF ALL DIAGNOSIS AS POSSIBLE BIOMARKERS FOR EARLY CEREBRAL VEIN THROMBOSIS

S. Mertanen[1,*] O. Laine[2], M. Rämet[2], M. Vesanen[3], E. Elonen[1], U. Wartiovaara-Kautto[1]
[1]HUCH Cancer Center, Division of Hematology, Helsinki University Central Hospital, Helsinki, [2]Department of Internal Medicine, Tampere University Hospital, Tampere, [3]Department of Internal Medicine, Turku University Central Hospital, Turku, Finland

Background: Thrombotic complications in cancer patients are mostly venous, cerebral vein occlusion (CVT) representing often the most drastic consequences in patients' lives. A majority of thromboses occurs during the first months following ALL diagnosis and introduction of treatment (Vu *et al.* 2015). They possibly have an adverse impact on the overall survival (Ku *et al.*, 2009). Older age, presence of a catheter, comorbidities as well as introduction of asparaginase (ASP) have been linked to deep venous thrombosis in leukemia patients. However, very limited data exists on biomarkers already available at diagnosis of ALL predicting the risk of thrombosis during the early treatment course of ALL.
Aims: We performed a multicenter retrospective study aiming at characterizing the incidence and patterns as well as possible predictive factors for thrombosis during the multiagent treatment of ALL before allogenic stem cell transplantation.
Methods: We reviewed the charts of 161 consecutive patients diagnosed with ALL and recruited to a national treatment study (ALL2000) in four university hospitals and one central hospital in Finland during years 2000-2012.
Results: In all, 31 patients (19%) suffered from thrombosis during the three months follow-up time. 13 (42%) of the thromboses occurred within two

months after ALL diagnosis. 32% (n=10) of the thrombotic events were localized in patients' cerebral veins detected by MRI and seven of them took place remarkably early in the treatment course and before the introduction of ASP (cycle 3, day 8). None of the patients with CVT had been diagnosed with leukemia in central nervous system. Plasma CRP, fibrinogen degradation product (DD), and blood hemoglobin, leukocyte, blast and platelet counts recorded at ALL diagnosis were also investigated. In patients acquiring thrombosis a trend, nearly reaching statistical significance, towards a lower platelet count and higher CRP, DD, leukocyte and blood blast count at leukemia diagnosis was detected. This was even more pronounced in patients who suffered from CVT.

Summary and Conclusions: A large proportion of thromboses possibly affecting regular ALL treatment and patients' survival occurs very early after the leukemia diagnosis despite low platelet counts at diagnosis and during the multiagent cytostatic treatment. At diagnosis, high CRP, high DD, high leukocyte and high blood blast count as well as low platelet count possibly reflect the role of ALL disease itself in provoking thrombosis, especially CVTs. In order to confirm these findings prospective studies are still called for.

E1561

CHILDREN WITH CEREBRAL INFARCT DUE TO CRANIOCERVICAL ARTERIAL DISSECTION IN A SINGLE CENTER

S. Aytac[1,*] K. Karli Oguz[2], M. Cetin[1], F. Gumruk[1]
[1]Pediatric Hematology, [2]department of Radiology, Hacettepe University, Ankara, Turkey

Background: Children with craniocervical arterial dissection is being recognized increasingly in the recent years and it is reported to be associated with a high morbidity rate in the childhood period. Treatment is challenging however anticoagulation and antiplatelet treatment are the treatment options. CAD is an important cause of childhood arterial ischemic strokes which occured between 7.5%>20%.

Aims: Our aim is to evaluate our patients who had had arterial ischemic stroke secondary to craniocervical arterial dissection in our center.

Methods: We retrospectively reviewed our patients who had had arterial ischemic stroke secondary to craniocervical arterial dissection. All of these patients' diagnoses were based on cranial and neck magnetic resonance (MR) imaging, MR angiography and computed tomography (CT) angiography in presence of appropriate clinic setting and a past history of trauma.

Results: Of the 305 children with thrombosis diagnosed in our center, 64 were acute arterial cerebral thrombosis and of those 4(6.2%) patients were diagnosed as arterial dissection. In all of these patients past history revealed a trauma and all patients had evidence of cerebral ischemia at the time of diagnosis. Hereditary prothrombotic risk factors were homozygout MTHFR in 2 patient and heterozygout FV Leiden mutation in one patient. Recurrent stroke was not observed in our group.

Summary and Conclusions: Long term mortality rates of childhood onset arterial ischemic stroke were reported as 2-11% and overall rate of intracranial hemorrhage was shown to be about 5% in this group of patients. In our ischemic stroke group, cervicocranial dissection rate (6.2%) seems to be lower than the rate reported in the literature which may be up to 20% of strokes in childhood and adolescence. This may be due to underdiagnosis of these patients, in that diagnosis should be based on primarily clinical suspicion and vascular imaging of the neck and brain. Children who developed neurological abnormalities after a blunt trauma to the head and/or neck should alert the physicians to have the possibility of carotid artery injury. It is important to remember that ischemic infarcts are usually not visible on CT during the first 12 hours of the acute stage. Cranial MR imaging especially with introduction of the diffusion-weighted imaging have been much more sensitive in detection of the acute ischemic lesions.Furthermore detection of extracranial dissections usually require demonstration of an intramural thrombus which is hyperintense on subacute stage especially on fat-saturated T1-weighted imaging or an intimal flep as a linear structure traversing the lumen.

E1562

A BESPOKE 'APP' FOR THE INVESTIGATION AND MANAGEMENT OF DEEP VEIN THROMBOSIS

S. Patel[1,*] S. Deplano[1], G. Davies[1], R. Chinn[1], A. Letchworth[1], B. Gordon[1],
[1]Chelsea and Westminster NHS Foundation Trust, [2]MedicalPath2Safety®, London, United Kingdom

Background: Deep vein thrombosis (DVT) is a common condition that may lead to potentially fatal complications, such as pulmonary embolism. The development of an application, the 'app', guides clinicians to the appropriate diagnostic management and treatment for patients with suspected DVT in acute setting. The 'app' offers guidance on the two-level DVT Wells score, D-dimer measurement and ultrasound imaging requests. It uses formal clinical decision rules in conjunction with blood tests to enable a more structured clinical diagnosis of DVT. It offers guidance on the management and treatment of DVT covering contraindications/cautions for anticoagulation therapy, prescription dosing and patient counselling information. Information from the 'app' is pre-populated in the discharge summary facilitating discharge with accurate summary of investigations and management. The 'app' has been developed in accordance with hospital and national guidelines with an aim to standardise the pathway ensuring patient quality and safety.

Aims: To improve the pathway for the investigation and management of patients with suspected DVT with electronic technology to ensure patient safety, quality and experience.

Methods: Stakeholders (clinical, radiology and nursing staff; information and 'app' development teams) agreed on the vision and requirements such as objectives; data metrics for diagnosis, management, patient and staff satisfaction, workflow and time; clinical aspects (ward area, patient exclusions, pathway); ethics approval and technical system (user device, software, server, network, configuration criteria, access rights) to deliver an electronic decision-support safety system, in an 'app' format, to guide clinicians to the appropriate diagnostic investigations and treatment for patients with suspected/confirmed DVT. Timelines for implementation phrases and go-live date were set. Stages for development, testing, installation, further validation, training and monitoring were performed. Supporting materials and user guides were created. The 'app' will be trialled for 3 months to assess benefits and performance compared to the current paper system using a DVT proforma. This timeframe will provide feedback whether our vision is delivered and if our strategies are working for better patient care, accurate and relevant investigation and appropriate management.

Results: *Audit results for investigation and management of DVT (WS: Wells Score; USS: Ultrasound):* 92% (47/51) of patients had a history and examination recorded; 18% (9/51) of patients had a WS; 100% (6/6) of patients with a DVT likely WS had USS within 4 hours of request or therapeutic enoxaparin and USS within 24 hours; No (0/2) patients with DVT likely WS had a repeat USS 6-8 days with positive D-Dimer and negative USS; 100% (3/3) of patients with DVT unlikely WS had a D-Dimer test; 50% (1/2) of patients with DVT unlikely WS and positive D-dimer had USS within 4 hours or therapeutic enoxaparin and USS within 24 hours; 100% (4/4) of patients with confirmed DVT had appropriate anticoagulation therapy.The audit showed the lack of documentation of the two-level DVT Wells score, thus difficult to evaluate whether patients were management appropriately due to limited data available and confirming non-compliance to hospital guidance. Results will be compared to an audit post implementation of the 'app'.

Summary and Conclusions: Clinical teams are aware the current paper system is not effective and have developed and introduced a novel decision-support pathway, in an 'app' format, to guide the clinician step-by-step for appropriate investigation and management of suspected and confirmed DVT, with a mission to 'see, feel and change'.

E1563

EFFICACY OF THROMBOPROPHYLAXIS IN THE PREVENTION OF THROMBOSIS IN PREGNANCY. EFFECTS ON THE INCIDENCE OF MISCARRIAGES

C. Miranda Castillo[1,*] A. Garcia Raso[2], A. Velasco[1], G. Salvatierra[1], R. Vidal[2], P. Llamas[2]
[1]Hematology, Hospital Rey Juan Carlos Móstoles, [2]Hematology, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Background: The etiology of gestational vascular complications (GVC) is not accurately known, however it has been proposed that activation of haemostasis may cause poor placental development and thrombosis. Antithrombotic prophylaxis with LMWH and/or aspirin could prevent the development of CVG by controlling of hemostasis during pregnancy.

Aims: To analyse the type and dose of thromboprophylaxis in a group of pregnant women. To study the relationship between antithrombotic prophylaxis and GCV development.

Methods: We studied 162 pregnant women referred to the Hematology consultation in HURJC and HUFJD. All of them were pregnant at the time of consultation. Thrombotic and CVG risk factors were estimated and it was decided to have expectant management or to start prophylaxis with LMWH +/- aspirin, according to our protocol. The following data were collected: prophylactic medication and dose, obstetric history, history of miscarriages, history of thrombosis, prior pregnancy complications and thrombophilia.

Results: The mean age was 35.7 years (range=22-43); mean gestational age at first visit was 12.6 weeks. 51.2% (n=83) women had no living children; and 69.9% (n=114) had have abortions. 63.6% (n=103) were referred with a history of abortion, 72.7% (n=83) in the 1st trimester, 18.5% (n=10) in the 2nd and 8.8% (n=21) in the 3rd. In addition, 70 women had other pregnancy complication history: preeclampsia (8.5% n=6), implantation failure (18.6% n=13), and fetal death (22.8% n=16). In this group 19.8% (n=32) had at least

one thrombotic event before pregnancy. 58% (n=94) had thrombophilia: 13.8% C677T homozygous, 26.5% FV Leiden, 16% PT20210A and 8.5% AFS. 47 patients (29%) had complications during pregnancy or childbirth. 49% of newborns experienced some complications, being the most common: prematurity (n=27) and low weight (n=15). There was no perinatal death. Risk factors (previous thrombosis, maternal age, recurrent miscariages, presence of thrombophilia) were studied and treatment was prescribed as indicated. In 53.3% of the patients prophylaxis was started in the first trimester). LMWH prophylaxis was effective in preventing thrombosis during pregnancy, (statistically significant p <0.0001). 108 (88.5%) of women treated with LMWH had a live birth. Although didn´t found no statistically significant relationship between antithrombotic phrofilaxys and prevention of abortions or fetal loss, 87.9% (n=73) women with no living children who received LMWH prophylaxis during pregnancy were able to have a live birth (p=0.394).
Summary and Conclusions: In our study group LMWH prophylaxis was effective in preventing thrombosis. Although there is no statistically significant relationship between antithrombotic prophylaxis and prevention of abortions or fetal loss, 87.9% of women with no living children who were prescribed with LMWH were able to have a live birth.

E1564

THROMBIN GENERATION (TG) POTENTIAL AND ACTIVATED PROTEIN C (APC) RESISTANCE IN PATIENTS ON CHRONIC ORAL ANTICOAGULANT THERAPY WITH VITAMIN K ANTAGONIST (VKA)

C. Verzeroli[1,*] M. Marchetti[1], C. Giaccherini[1], V. Milesi[1], L. Barcella[1], A. Falanga[1]
[1]Immunohematology and Transfusion Medicine, Hospital Papa GiovannixXIII, Bergamo, Italy

Background: Atrial fibrillation (AF) and cardiac valvular prosthesis (CVP) expose patients to high risk of stroke that significantly contribute to morbidity and mortality. In these diseases despite the clinical benefit of oral anticoagulation with VKA (*i.e.* Warfarin) for thrombosis prevention, major bleeding may be frequent and devastating**.** The dose of VKA is determined for each patient by monitoring the Prothrombin-International Normalized Ratio (PT-INR). Some recent studies showed that, though with in therapeutic range PT-INR some patients can suffer serious bleeding complications or recurrent thromboses, suggesting that PT-INR do not always reflect the real bleeding or thrombotic risk and therapeutic effect of VKA.
Aims: This prospective study aim to characterize the TG potential in a group of AF or CVP patients on VKA, in order to investigate whether a correlation exists between TG and PT-INR and whether TG might be useful to identify subjects at higher bleeding risk.
Methods: Thirteen patients with AF (6M/7F, median age 77 years, (59-86)) and 7 patients (7M, median age 65 years (58-76)) who underwent CVP intervention were enrolled at the Hemostasis and Thrombosis Center of Papa GiovannixXIII Hospital, Bergamo, Italy, after gave informed written consent. All patients were on VKA treatment. To be included into the study the patients should have at least 65% in-range PT-INR in the previous year and 100% in-range PT-INR in the previous 3 months. Enrolled patients were prospectively followed up for one year. TG was performed by the Calibrated automated thrombogram (CAT) in platelet-poor plasma collected at the same day of PT-INR control (13 samples/each patient). TF 5pM was used as a trigger of TG assay. TG curves were described in terms of lag-time, endogenous thrombin potential (ETP), peak height and time to peak (ttP). ETP-based APC resistance was evaluated by CAT assay in the presence of 2 nM APC and results expressed as normalized APC sensitivity ratio (nAPCsr). Thirty healthy subjects (14M/16F) with no antiplatelet, anticoagulant or, for women, no oral contraceptives or hormone replacement therapies, acted as a control group.
Results: TG assay showed that lag-time and ttP were significantly prolonged while ETP and peak height were significantly lower in patients compared to controls (p<0.01), particularly in CVP patients. PT-INR correlate positively with lag-time (R=0.58, p<0.000) and ttP (R=0.61; p<0.000) and negatively with ETP (R=0.78; p<0.000) and peak height (R=0.78; p<0.000). The correlation between PT-INR and ETP and peak remain statistically significant also after correction for age. Interestingly, patients with similar PT-INR showed wide differences in TG value. nAPCsr, fixed at 1 in controls, was significantly (p<0.01) reduced in patients (0.6±0.14) suggesting that patients on VKA were more sensitive to the anticoagulant activity of APC. During follow-up, a total of four bleeding events were registered: two minor bleedings in AF patients, and two bleedings (one minor and one major) in CVP patients: all these patients presented with in-range PT-INR but very low TG potential.
Summary and Conclusions: The variability of TG values in patients with similar PT-INR and the occurrence of bleeding complications in patients with in-range PT-INR but very low thrombin generation values, suggest that TG assay can be more sensitive in detecting a hemorrhagic phenotype. This strategy can be useful in monitoring those patients initiating and/or receiving multiple antithrombotic drugs.

E1565

POLYPHARMACY IN PATIENTS TREATED WITH NON-VITAMIN K ANTAGONIST ORAL ANTICOAGULANTS (NOACS) AND THEIR IMPLICATION IN THE PERIOPERATIVE SETTING. RESULTS FROM THE "REAL LIFE" COHORT

I. Valcarce[1,*] P. Olivera[1], V. Pons[1], V. Cortina[1], L. Lopez-Andreoni[1], G. Artaza[1], F. Bosch[1], A. Santamaria[1]
[1]Department of Hematology, University Hospital Vall d' Hebron, Barcelona, Spain

Background: The use of NOACs has increased especially in elderly patients polymedicated. The drug-drug interactions and polypharmacy are a significant problem mainly affecting the geriatric population. Some studies have considered this issue, but most of them focused only on relevant interactions. It is important to evaluate the impact of polymedication on NOACs patients in special situations such as the perioperative setting and to determine whether some of the commonly used drugs may modulate the anticoagulant effect of NOACs.
Aims: To determine the degree of polypharmacy and the incidence of possible drug interactions between daily used drugs and NOACs in perioperative setting and whether they affect NOACs plasma concentrations or not.
Methods: From June 2014 to December 2014 we consecutively reviewed 33 patients diagnosed of atrial fibrillation treated with NOACs that needed to undergo a surgical procedure. Perioperative management was performed following the PM guidelines from the Spanish Forum of anticoagulants and Anaesthesia. NOACs plasma concentrations were measured the day of the procedure using the Direct Thrombin Inhibitor Assay from IL (Bedford-MA-USA) for Dabigatran and the Technoclone anti-Xa assay from Technoclone (Vienna-Austria) for Rivaroxaban and Apixaban. Every drug each patient had daily taken was recorded and assessed considering the drug transport (P-glycoprotein) and metabolism either if they are cytochrome substrates, inhibitors or inducers.
Results: A total of 33 patients were included. Median age was 74 years (range 61-94), 17 (51.5%) were female. From them, 8 patients received dabigatran, 20 rivaroxaban and 5 apixaban.The number of medications consumed ranged from 2 to 16 and averaged 6.9 (SD+/-3.13) drugs per patient. The most frequent were proton pump inhibitors, hypogycemics, antihypertensive, statins and beta-blockers. A considerable number of routine taken drugs share the cytochrome for its metabolization with NOACs, none of them are strong inhibitors or inducers of cytochrome or transport P-glycoprotein as if to provoke a change on NOACs plasma concentrations. We just found five drugs that modulated the NOACs effect (Amiodarone, Atorvastatin, Carvedilol, Diltizem and Omeprazole). Some of the considered moderate inducers or inhibitors of either cytochrome or P-glycoprotein did not show any modulation of NOACs plasma concentrations. No association between the number of taken drugs and bleeding events was found.
Summary and Conclusions: In a real clinical setting we found that the commonly used drugs would have little impact on NOACs plasma concentrations. So we might conclude that NOACs are safe in polymedicated patients, even in special situations such as the perioperative setting.

E1566

IMMOBILIZATION AS A RISK FACTOR IN VENOUS THROMBOEMOLISM. DIFFERENCES BY SEX AND AGE

A. García Raso[1,*] C. Miranda[2], T. Arquero[3], S. Monsalvo[3], R. Vidal[3], R. Mata[3], P. Llamas[3]
[1]Hematolgy, Health Care Institute Fundación Jiménez Díaz, Madrid, [2]Hematolgy, Rey Juan Carlos University Hospital, Mostoles, [3]Hematolgy, Fundacion Jimenez Diaz University Hospital, Madrid, Spain

Background: Many studies recognize the importance of immobilization as a risk factor for venous thromboembolism (VTE), the OR ranging from 5.5 to 11.1 depending on the series. Retrospective studies have shown that 59% of cases of VTE occur in hospitalized patients (35% for nonsurgical causes). It has also been reported that 42% of pulmonary embolism (PE) initiated during hospitalization. Blood flow in the venous valves is slow, especially in the lower limbs; an effect is accentuated with immobilization. This is the reason why a prolonged bed rest may be a risk factor.
Aims: Study immobilization as a risk factor for venous thromboembolism, and analyze differences according to the characteristics of the patient and the thrombotic event
Methods: We studied 438 patients with VTE. In this group immobilization was defined as non-surgical patients bed-ridden at least four days, two months prior to the diagnosis of thrombosis.
Results: 53% (n=232) of patients included in the study were male and 47% (n=206) female, with a mean age of 55.2 (±17.9) years. The distribution of patients according to thrombosis localization was: DVT-LL 49.4% (n=217), 26.9% PE (n=118), DVT+PE 8.8% (=39), DVT-UL 2.3% (n=10), SVT 3.9% (n=17) and VT-UL 8.7% (n=38). Immobilization was determined as a trigger and risk factor for thrombotic event in 32 patients (7.4%), and was associated with the development of venous thrombosis with an OR of 2.84 (CI 95%: 1.35 to 6.71, p=0.0048). The relationship with VTE according to thrombosis localization is shown in Table 1. Immobilization was a risk factor for SVT and DVT-UL. Immobilization was a risk factor for thrombosis in men but not in women

(Table 2). In addition, it was a risk factor for patients younger than 55 years but not in older patients (Table 2).

Table 1. Association between immobilization thrombosis localization.

GROUP	OR	CI (95%)	p
TVP-MMII	3,46	(1,54-8,53)	0,002
TEP	1,60	(0,48-4,90)	0,427
TVP-MMII+TEP	6,94	(2,16-21,3)	0,02
TV-LI	1,99	(0,29-8,43)	0,425

Table 2. Association between immobilization and VTE. Analysis by sex and age.

GROUP	OR	CI (95%)	p
Women	2,40	(0,84-2,58)	0,1054
Men	3,33	(1,21-11,7)	0,0181
<55 years	6,90	(1,95-43,8)	0,0013
≥55 years	1,53	(0,60-4,42)	0,3822

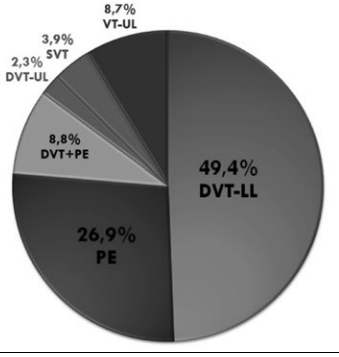

Figure 1.

Summary and Conclusions: Immobilization is an important risk factor for the development of thrombotic events with greater relevance in male and younger patients.

E1567

PROPHYLAXIS FOR VENOUS THROMBOEMBOLIC DISEASE IN PREGNANCY AND POSTPARTUM PERIOD

S. Grille[1,*] V. Castro[1], P. Turcatti[1], D. Mussio[1], G. Laporte[2], F. Medici[2], C. Senatore[2], C. Rodriguez[2], G. Vitureira[2], L. Sosa[3], W. Lauría[2], C. Guillermo[1], L. Diaz[1], M. Stevenazzi[1]
[1]Catedra de Hematologia, [2]Clínica Ginecotologica B, [3]Clínica Médica, Hospital De Clinicas. Facultad De Medicina. Universidad De La Republica, Montevideo, Uruguay

Background: Venous thromboembolism (VTE) remains one of the leading direct causes of maternal death. Risk stratification is difficult and recommendations for prophylaxis have low grade of evidence. Risk factors for VTE and prophylaxis guidelines have been highlighted by the Royal College of Obstetricians and Gynaecologists (RCOG). Thromboprophylaxis is a cost-effectiveness way to reduce VTE high morbi-mortality.
Aims: To determine the risk factors of VTE during pregnancy and postpartum period present in our population, and to assess compliance with a written alert used in our clinical practice.
Methods: We conducted a prospective, descriptive and analytical study at Hospital de Clinicas, Montevideo, Uruguay between 1/2014 to 2/2015. We enrolled hospitalized pregnant and puerperal patients and stratified them, through a written alert in the medical record, in high, intermediate or low risk for VTE. We used a local modification of the RCOG guidelines (2009) to identify those patients at risk and to guide prophylaxis with low-molecular-weight heparin (LMWH).
Results: We included 348 patients in whom the risk stratification for VTE through written warning and according thromboprophylaxis were performed. 38,2% (n=133) were pregnant and 61,7% (n=215) were puerperal. Median age: 23 years (range 15-43). 3,4% (n=12) were at high risk and 36,4% (n=127) at intermediate risk. All high risk patients received adequate pharmacological prophylaxis with LMWH. Of the 127 intermediate-risk patients, 66,9% (n=85) received adequate pharmacological prophylaxis. VTE was developed in only 1 patient of the intermediate group who received prophylaxis with LMWH. Non bleeding complications were observed.
Summary and Conclusions: Awareness of the thrombotic risk, as conferred by an easy and suitable risk assessment has the potential to improve VTE prophylaxis in pregnancy and puerperal patients. In our service, 39,8% of admitted patients had criteria for pharmacological prophylaxis for VTE.

E1568

THE CALIBRATED AUTOMATED THROMBOGRAM AS A USEFUL TOOL IN DETERMINATION OF PROTHROMBOTIC PHENOTYPE

V. Shmeleva[1,*] O. Matvienko[1], S. Kapustin[2], V. Kobilyanskaya[1], T. Morosova[1], L. Papayan[1]
[1]Laboratory of Blood Coagulation, [2]Laboratory of Biochemistry, Russian Research Institute of Haematology and Transfusion, St-Petersburg, Russian Federation

Background: The assessment of prothrombotic phenotype is important to determine optimal primary and secondary prophylaxis in patients with thrombophilia. Application of integral global assays promises to be useful in this aspect. The Calibrated Automated Thrombography (CAT) is known to determine haemostatic misbalance and it reflects the action of both procoagulant and anticoagulant factors.
Aims: Aim of our study was to determine intermediate phenotype in asymptomatic carriers of known prothrombotic mutations and in thrombophilic patients with diagnosed thrombotic complications.
Methods: Genotyping was done by PCR and restriction fragment length polymorphism analysis. Factor I 455 G/A, factor II (FII) 20210 G/A, factor V 1691 G/A (FVLeiden), factorxII 46 C/T, PAI-I 675 4G/5G, TPA 311 I/D, GpIa 807 C/T, GpIbα 434 C/T, GpIIIa 1565 T/C, platelet receptor P2RY12 H1/H2, MTHFR 677 C/T, endothelial nitric oxide synthase 786 T/C, ApoE E2/E3/E4, AGT 704 T/C, ACE 287 I/D and angiotensin receptor 1 1166 A/C polymorphisms were detected. Homocysteine (Hcy) was measured by high-performance liquid chromatography with fluorescence detection. Hyperhomocysteinemia (HHcy) was defined as Hcy levels more than 95% percentile measured in age and sex matched control group. Lupus anticoagulants (LA) were diagnosed according to the SSC-ISTH criteria: a sensitive APTT, the DRVVT, and confirmatory tests. Activities of FVIII, protein C and antithrombin were measured. The study involved 100 persons: 85 patients with VTE and/or recurrent pregnancy loss and 15 asymptomatic carriers of known prothrombotic mutations-7 FVLeiden heterozygous, 6 FII20210G/A heterozygous and 2 double heterozygous. CAT was done according to Hemker *et al.* at 5 pM TF and 4 μM phospholipids in platelet poor plasma (PPP) with PPP plasma+/-TM reagent.
Results: From the parameters of the thrombin generation curve (Lag time, endogenous thrombin potential (ETP), peak thrombin (PT), time to peak), as well as ETP and PT inhibition, no one showed significant correlation with FVIII activity, studied polymorphisms and/or HHcy. None of the patients demonstrated antithrombin or protein C deficiency. Among 85 patients with VTE and/or recurrent pregnancy loss 18 patients had FV Leiden (FVL) mutation, 5-FII20210G/A mutation, 1 was heterozygous for both mutations, 5 had LA, 10-increased FVIII activity, 19-moderate HHcy. Significant correlation with LA ($p<0,05$) was found for lag-time ($R=0,45$), ETP ($R=-0,45$) and PT ($R=-0,44$) both in presence and absence of TM. ETP and PT reduced in the presence of TM. Values below 21% for ↓ETP and/or 14% for ↓PT *i.e.* activated protein C resistance (APCR) were found in 100% of FVL and LA patients, 90% of asymptomatic carriers of FVL and 50% of patients with increased FVIII. Abnormal ↓PT was more sensitive to detect APCR. FII 20210G/A carriers demonstrated increased ETP (*i.e.* >2114 nMmin in the absence of TM and >1433 nMmin in the presence of TM-values above 95% persentile of controls) in 80% of cases. APCR was found by CAT in 20% of FII 20210G/A carriers.
Summary and Conclusions: We consider CAT to be useful in evaluating haemostatic abnormalities in thrombophilia patients. In cost-effectiveness aspect in a number of cases it could be preferable to a standard approach that includes a wide panel of genetic and functional tests. Clinical utility of abnormal CAT results in asymptomatic carriers of factor V Leiden and prothrombin G20210A mutations needs further elucidation, but we suggest that an integrated approach defining an individual's intermediate phenotype could help in identifying individuals with high risk for thrombotic event that would benefit from active primary thromboprophylaxis.

E1569

LMWH PROPHYLAXIS THROMBOTIC EVENTS IN HODGKIN LYMPHOMA PATIENTS

A. Poletaev[1,*] A. Balandina[1], V. Kopelevich[2], I. Shitareva[2], F. Ataullakhanov[1], S. Kravchenko[2]
[1]Federal Scientific Clinical Centre of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, [2]National Research Center for Hematology, Moscow, Russian Federation

Background: Patients with Hodgkin Lymphoma(HL) have a high risk of venous thrombotic complication. LMWH is used for thrombosis prophylaxis throughout the therapy. However this prophylaxis do not prevent all thrombotic complications thus routine laboratory monitoring is not recommended for low-dose

LMWH. The problem of adequate laboratory diagnostic to identify high-risk group and to prevent thrombotic complications is still remains.
Aims: The aim of this was to examine the state of hemostatic system in primary patients with HL and to identify the number of thrombotic risk factors (RF) in these patients. The evaluation of the effectiveness of heparin therapy remains important.
Methods: Twenty four primary patients (median 31 yr, 18-60 yrs, 12 men and 12 women), staging by Ann Arbor II-8, III-7, IV-9 patients, were enrolled in this study. The number of thrombotic RF by NCCN scale is from 3 to 7. The patients were treated by BEACOPP-14. LMWH was administered in doses 70-113 IU/kg 2 times a day. aPTT, PI, TT, fibrinogen and D-dimer levels, and the global hemostasis assays Thromboelastography (TEG) and Thrombodynamics (TD) were performed to evaluate the hemostatic state of patients on diagnosis (before oral contraceptives for women), on 1 and 8 day of all chemotherapy cycles.
Results: Hypercoagulation was detected in 75% of primary patients with at least one of the tests before treatment (45% by TD, 55% by TEG, 16% by aPPT), 40% by TEG and TD, 20% by aPPT and TD, 13% by aPPT and TEG. D-dimers were higher in 33% of patients. Throughout the chemotherapy cycles in patients with ineffective LMWH prophylaxis was revealed the significant($p<0.05$) increase in global assays parameters (TD V(velocity)>25 um/min, TEG alpha>40 deg) and in D-dimer level compared to patients with effective prophylaxis (medians 387ng/ml (min 62-max 5109) and 195ng/ml (min 53-max 3571) respectively). Blood samples were collected after 4 hours of LMWH injection. Despite low-dose LMWH prophylaxis the D-dimer level was significantly($p<0.05$) increased from 1 cycle (median 213 ng/ml, min 71-max 5109) to 8 cycle (median 349ng/ml, min 79-max 4376) of chemotherapy.
Summary and Conclusions: Primary patients with HL revealed hypercoagulation by global hemostasis assays, TD and TEG, before chemotherapy. Despite LMWH prophylaxis nearly 40% of patients remained hypercoagulation state by global hemostatic assays and D-dimer level. The combination of global assays parameters, D-dimer level and thrombotic RF is prospective in indicating high-risk group and monitoring and correction of LMWH prophylaxis in patients with HL.

E1570

CATALASE C−262T GENE POLYMORPHISM AS A POSSIBLE RISK FACTOR FOR VENOUS THROMBOEMBOLISM IN THE POPULATION OF NORTH-WESTERN RUSSIA

S. Kapustin[1,*] V. Shmeleva[2], L. Aleksanyan[3], N. Saltykova[4], S. Svitina[3], V. Soldatenkov[4]
[1]Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation, [2]Laboratory of Hemostasis, [3]Laboratory of Biochemistry, [4]Surgery Department, Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation

Background: The role of genetic mechanisms in most cases of venous thromboembolism (VT) is still unclear. We have recently shown, that in addition to known molecular determinants of inherited thrombophilia, genetic variations associated with endothelial dysfunction (ED) could be involved in pathogenesis of VT. Oxidative stress is an important mechanism of ED development which occurs due to imbalance between reactive oxygen species production and antioxidant system activity. Catalase is an important enzyme of antioxidant system which activity depends on the variation(s) in the promoter of the respective gene.
Aims: To evaluate the role of catalase C−262T gene polymorphism as a possible risk factor for VT in the population of North-Western Russia.
Methods: Retrospective study involved 300 patients with VT (147 men and 153 women, mean age 42.3±12.6 years) and 203 sex- and age-matched healthy controls (HC). All individuals originated from the North-Western region of Russia and gave informed consent for participation in the study. Catalase C−262T gene polymorphism was discriminated by PCR-RFLP technique. The differences in genotype distributions between the groups were estimated by Fisher`s exact test. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated using the GraphPad Prism software.
Results: Catalase −262T allele was more frequently seen in VT patients than in HC (44.3% *vs* 34.9%, OR=1.5; 95% CI: 1.0-2.1; p=0.042). Heterozygosity for this polymorphism was present in 39.0% of VT cases compared to 30.0% in controls (OR=1.5; 95% CI: 1.0-2.2; p=0.046). Catalase −262T allele occurred more frequently in the group of 200 patients with early-onset disease (at age 45 or less) than in those who suffered from the first VT episode after 45 years old (46.0% *vs* 40.0%, respectively). The frequency of homozygous −262TT genotype was 2-fold higher in young patients than in those with late-onset VT (6.5% *vs* 3.0%, respectively). When compared to HC group, the presence of the catalase −262T allele has been proved to be a significant risk factor for VT development in young patients originated from the North-Western region of Russia (OR=1.6; 95% CI: 1.1-2.4; p=0.026). At the same time, the difference between the group of patients with late-onset VT and HC for the proportion of individuals positive for −262T variant was not statistically significant (40.0% *vs* 34.9%, respectively, OR=1.2; 95% CI: 0.8-2.0; p=0.45).
Summary and Conclusions: We suggest that catalase C−262T gene polymorphism is a possible risk factor for VT development in young patients from the North-Western region of Russia.

EVALUATION OF ABO BLOOD GROUP DISCREPANCIES IN A TERTIARY CARE CENTRE IN SPAIN

M. Tenorio[1,*] G. Moreno[1], A. Jiménez[1], V. García Gutiérrez[1], C. Anabelle[1], C. Maria[1], H. Pilar[1], J. López-Jiménez[1]
[1]Haematology and Haemotherapy, Hospital Ramón y Cajal, Madrid, Spain

Background: ABO incompatible blood transfusion is associated with major morbidity and mortality. Solving ABO discrepancies is an essential step towards a safe transfusion practice.
Aims: To evaluate the frequency, main causes and clinical impact of ABO blood group discrepancies detected in our hospital in a two-year period of time.
Methods: We retrospectively analyzed all ABO discrepancies recorded in Ramón y Cajal Hospital Blood Bank from 1st January 2013 to 31st December 2014. The results included both in-patients and out-patients but not blood donors. ABO blood group determination in our centre includes forward and reverse group using column agglutination technology (AutoVue Innova, 0.8% Affirmagen A1, B Grouping Red Blood Cell, and ABO/Rh Reverse cassette). When ABO discrepancies are detected, sample and reagent suitability is checked and the cited automatized test is then repeated. Once confirmed, manual red cell (Anti-A, Anti-B Diagast) and serum (A1, B cells Affirmagen 3.5%, Ortho Clinical Diagnostics) tube testing at different temperatures (immediate centrifugation, room temperature and at 4ºC) is performed. If unexpected positive reactions are seen in the serum test, a 3-cell antibody screen (Surgiscreen, Ortho Clinical Diagnosis) is also carried out. When relevant, antibody identification panels (11- cell microcolumn Liss-Coombs and papain-treated red cells panels, DianaGel-Grifols), direct antiglobulin test (polyspecific and monospecific anti-IgG and C3d, Menarini reagents) and adsorption and elution tests (acid glycine elution or 56ºC elution) were also undertaken. When necessary, samples were sent to the Blood Regional Centre for molecular analysis. The causes for the discrepancy were assessed as well as the clinical impact of the subsequent resolution of the ABO blood group problem.
Results: A total of 155 patients presented ABO discrepancies. The main causes for the discrepancy were: ABO major incompatibility allogeneic stem cell transplantation (ASCT) (9.7%), ABO minor incompatibility ASCT (12.3%), both major and minor incompatibility ASCT (1.3%); "A" subgroups (6.5%), out-of-group transfusion (2.6%), acquired immunodeficiencies (18.7%), alloantibodies (3.2%), autoantibodies (2.6%), cryoagglutinins (4.5%), technical errors (11%), age-related (6.5%) and others (19.4%). In the "A" variants group, 6 A_2B were detected (5 with anti-A_1 active at 37ºC) and 4 A_2 were detected (2 with anti-A_1 active at 37ºC). The alloantibodies identified were anti-M (n=4) and anti-H (n=1). The "others" group consisted of samples with diminished serum testing results in column agglutination technology but normal reverse grouping in test tube at lower temperatures (4ºC). Solving ABO discrepancies lead to specific blood unit selection and preparation in 51 patients through antigen phenotype match (n=5), compatible blood cross-match (n=49), not allowing O transfusion (anti-H: 1 case) and pre-warming of blood and minimizing low temperatures during cardiac surgery (1 cryoagglutinin with cardiac valve surgery). No hemolysis was observed in the patients who received blood transfusions.
Summary and Conclusions: Currently, ABO incompatible ASCT is the main cause of ABO discrepancy in our hospital followed by acquired immunodeficiency and by technical issues. Automatized ABO discrepancies should be confirmed in test tube method and at low temperatures in the serum test. ABO discrepancy resolution lead to specific transfusion practice decisions in about a third of these patients.

E1572

USE OF A PEGYLATED CARBOXYHEMOGLOBIN BOVINE IN SEVERE LIFE-THREATENING ANEMIA

R. Jubin[1,*] J. Berryman[1], R. Prince[1], H. Misra[1], A. Abuchowski[1]
[1]Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States

Background: Patients who cannot receive blood transfusions in the presence of severe anemia can sustain significant morbidity and mortality. Religious beliefs and hemolytic reactions are the most common reasons for not transfusing a patient. Pegylated bovine carboxyhemoglobin (Sanguinate; SG), a therapeutic drug, has been used in 5 such patients including a patient who developed a severe hemolytic reaction following stem cell transplantation. SG is a therapeutic drug designed to carry carbon monoxide (CO) and oxygen in the mammalian vasculature for delivery to tissues to synergistically treat inflammation and vasoconstriction and other comorbidities characterized by tissue hypoxia.
Aims: Perform post-hoc analysis of clinical findings; their relationship to individual patient diagnosis/associated comorbidities and SG intervention.
Methods: Five patients with hemoglobin (Hb) levels under 3.5 g/dL were treated with repeated doses of SG. Diagnoses included AML, hemolytic reaction, acute

chest syndrome and sickle cell crisis. Patients ranged in age from 19 to 61. A unit of SG consists of 500 mL (40 mg/mL). Total doses ranged from 1 unit/day for 2 to 4 days up to 8 units given over 9 days.
Results: No adverse events associated with SG were reported. Each investigator reported clinical improvements in their patient following administration of SG, despite continuing low Hb levels. The number and size of allowed blood draws were restricted; therefore analysis of clinical chemistries was limited. Patients with reported extreme fatigue or neurological deficit each demonstrated increases in responsiveness or self-reported comfort within close temporal association with SG treatment. One patient had a significant increase in cerebral oximetry and another showed improvements in cerebral blood flow measured by TCD. A patient with hyperhemolysis reported feeling well with no pain and no shortness of breath despite severe anemia (Hb 2.5) and had improved mobility following a total of 8 units of SG. A patient who had undergone a stem cell transplant developed immune hemolytic anemia, with resulting extreme fatigue and tachycardia. He received 4 once-daily units of SG, during which time his heart rate normalized and was reported to be alert and oriented.
Summary and Conclusions: Evidence indicates that SG has potential therapeutic benefit in patients who have life-threatening anemia and cannot receive blood transfusions for personal or medical conditions. As vasoconstriction, inflammation, and oxygen deprivation are significant factors in severe hemolysis and ischemia, SG through the therapeutic actions of CO and oxygen may interrupt the ischemic cascade and improve clinical symptoms of hypoxia due to severely low hemoglobin levels. The improved clinical status in these patients suggests that SG has potential utility in patients with severe anemia who are unable to receive blood transfusions. Since submission to ASCO2015, preclinical and *in vitro* studies with SG have been shown to demonstrate anti-inflammatory activity as well as active CO and oxygen transfer. SG is currently in clinical development. A protocol is under development to treat patients for whom blood transfusion is not an option.

E1573

CLINICAL COURSE AND OUTCOME OF NEWLY DIAGNOSED ACUTE LEUKEMIA PATIENTS PRESENTED WITH HYPERLEUKOCYTOSIS IN THAILAND: A 10-YEAR SINGLE-CENTER RETROSPECTIVE STUDY

A. Khuhapinant[1,*] T. Naorungroj[1]
[1]Medicine, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Hyperleukocytosis is defined as peripheral WBC count ≥100x 10^9/L or blast count ≥50x 10^9/L. It is one of the most emergent life-threatening conditions in acute leukemia (AL) and confers early and high mortality, low complete remission (CR) rate and high relapse rate. Patients with hyperleukocytosis may suffer from vascular infiltration of CNS and lungs, and fatal bleeding in vital organs. Most such patients belongs to monoblastic subtype of acute myeloid leukemia (AML). Current treatment would include prior intensive leukapheresis followed by intensive chemotherpy.
Aims: To study an incidence, clinical and laboratory presentation, treatment modalities and outcome of newly diagnosed AL patients presented with hyperleukocytosis.
Methods: This was a retrospective, descriptive chart review study. All newly diagnosed AL patients presented with hyperleukocytosis in Siriraj Hospital, Mahidol University, Thailand during 2000-2009 were included. Data collection comprised demographic data, presenting clinical manifestation, initial WBC and blast count, chemistry panel, types of AL (AML, acute lymphoblastic leukemia (ALL) and subtypes), treatment modalities with complications, and outcome including overall survival (OS) and disease-free survival (DFS).
Results: Of all 1,232 AL patients, 136 patients (66 male) were collected. Median age was 46.52 years (range 13-87), and AML:ALL was 118:18 of which M4, M1 and M5 were the majority subtypes (34, 26 and 20, respectively). Normal karyotype was found in 48 of 74 patients. Presentation (%) with fever, alveolar hemorrhage, hypoxemia, acute respiratory distress syndrome, ischemic and hemorrhagic stroke, headache, dizziness/ vertigo, blurred vision, and abnormal bleeding were 29.4, 2.9, 12.5, 3.7, 2.9, 2.2, 12.5, 4.4, 6.6 and 42.6, respectively. Median WBC and blast count (x 10^9/L) were 201.42 (58.59-978.00) and 159.90 (0.54-806.40), respectively. Only 129 patients received treatments with either leukapheresis (2), chemotherapy (120) or combination of both (7). CR rate was 34.85% after front-line treatment, and median OS and DFS were 2.86 and 7.87 months, respectively. Major causes of death (%) were infection, bleeding, stroke and respiratory failure for 47.8, 16.2, 5.1 and 5.1, respectively.
Summary and Conclusions: Hyperleukocytosis as initial presentation in acute leukemia is associated with poor prognosis and overall survival. More rapid, emergent and appropriate treatment is required to improve outcome.

E1574

DETECTION OF UNEXPECTED RED CELL ALLOANTIBODIES BY THE ENZYME/NACL GEL TEST ONLY

A. Argyrou[1,*] F. Vakos[1], K. Kamitaki[1], K. Manta[1], A. Podaras[1], C. Kiriakopoulos[1], M. Kokkinou[1], C. Maraki[1], A. Gafou[1]
[1]Blood Bank, General and Oncology Hospital "Agioi Anargyroi", Athens, Greece

Background: In the patient's pretransfusion testing, the antibody screening helps in detecting the presence of significant red blood cell (RBC) alloantibodies. Performing a low ionic strength solution (LISS) indirect antiglobulin test (IAT) at a minimum couple of donor's reagent RBC expressing all the clinically significant antigens, is considered as the only obligatory step. The additional step of hemagglutination testing by using enzyme treated RBC could further contribute in determining the presence of unexpected alloantibodies.
Aims: The determination of the frequencies/ specificities of "enzyme only" detected RBC- alloantibodies in the routine RBC antibody screening.
Methods: In a general hospital of 300 beds (>80% oncology patients), 10523 blood samples, were submitted for routine pretransfusion testing, during a 41-months-period (11/2010- 5/2014). According to National Blood Bank Center's guidelines for blood group serology, all samples were tested for ABO blood group, RhD antigen and RBC unexpected alloantibodies. The RBC antibody screening was carried out with a 3-cell panel RBCs LISS IAT on Liss/Coombs cards, and also with an enzyme test (ET) with a 3-papaine-treated-cell panel on NaCl cards, according to the manufacturer's instructions. In the case of a positive screening test result, an antibody identification test was carried out, using an 11-cell panel LISS IAT and an 11 papaine-treated cell panel test (ET). Results were considered "inconclusive" either when there was no specific alloantibody identified or when the test reaction was too weak to interpret accurately. A positive screening test followed by a negative panel investigation was considered "false positive" result. The inconclusive results, the false positive ones, as well as the cases of autoantibodies were categorized as "unwanted positive reactions".
Results: During the study period, 10523 samples were tested. Positive RBC antibody screening (positive IAT/ positive ET, or negative IAT/ positive ET) was recorded in 168 patients. Negative IAT/ positive ET screening was found in 54.76% of them (n=92, 47.8% men, 52.2% women). A history of previous transfusion, was recorded in 50 patients (54.34%), while 34 (36.95%) of them had never been transfused before and 8.69% (n=8) had an unknown history of transfusion. A history of labor or miscarriage was recorded in 44 women (91,66%). The frequencies/specificities of RBC antibodies detected only by the ET technique are shown in Table 1.

Table 1.Frequencies and specificities of RBC antibodies detected with the ET technique only.

ANTIBODY DETECTION	FREQUENCY	PERCENTAGE
Specific antibodies		
• ANTI E	26	28.26
• ANTI Cw	3	3.3
• ANTI D	2	2.2
• ANTI C	2	2.2
• COMBINED ANTI E & ANTI c	1	1.1
• ANTI Jkb	2	2.2
• ANTI Lea	6 (natural occuring 5/6)	6.52
• ANTI Leb	1	1.1
• ANTI P1	1	1.1
Unwanted positive reactions		
• AUTO ANTIBODIES	6	6.52
• NON SPECIFIC	17	18.47
• INCONCLUSIVE	19	20.65
• FALSE POSITIVE	6	6.5
TOTAL	92	100

Summary and Conclusions: 1. The ET technique helps in detecting clinically significant RBC alloantibodies (*e.g.* anti Jkb) which could be missed if we used the IAT technique only (early phase of alloimunization? low- titter antibodies?). 2. Larger studies could lead to more data about the frequency/ specificity of detected RBC alloantibodies and help in defining the necessity or not of performing the ET technique in general patient population or among specific subpopulations.

E1575

SUCCESSFUL COMPATIBLE PHENOTYPE TRANSFUSION PROTOCOL TO PREVENT ALLOIMMUNIZATION IN SICKLE CELL DISEASE

S. Redondo Velao[1,*] A. Pérez-Corral[1], E. Cela[2], V. Pradillo[1], C. Pascual[1], C. Beléndez[2], C. Garrido[1], C. Coomonte[1], C. Falero[1], J.L. Díez- Martín[1], J. Anguita[1]
[1]Hematology, [2]Gregorio Marañón Hospital, Madrid, Spain

Background: Transfusion of red blood cells (RBCs) is used to treat and prevent complications of sickle cell disease (SCD). Alloimmunization to non-ABO antigens is commonly encountered in part due to antigen disparity between blood donors and patients for ethnic reasons and in part due to the frequency of pro-inflammatory factors present at time of transfusion.

Aims: We report our experience in one single reference center.
Methods: We retrospectively analyzed pediatric patients with SCD and at least one RBC transfusion in Gregorio Marañón Hospital (pediatric reference center for SCD patients in Madrid) through a query of blood bank database. Patients were excluded if they were alloimmunized prior to be transfused in our center. Transfusion indications included acute complications, therapy for prevention cerebral vascular events and pre-stem cell transplantation. Since 2009 a pediatric RBC matching protocol is applied at our blood bank for every new SCD patient who is going to have a hypertransfusion regimen. It entails matching for ABO, D, C, E, c, e and Kell. Before first transfusion, fully phenotype is performed (ABO, D, C, E, c, e, Kell, Jk^a, Fy^a and S) and registered in the database. If further alloimmunization occurs extended matching is employed.
Results: A total of 32 patients (19 males, 13 females) with HbSS and history of one or more RBCs transfusion between 1998 to 2015 were included; 23 were African, 8 African-American and 1 Asian. The median age of the first transfusion was 4 years (5 months-16 years). Of the 32 patients, 13 (40.63%) were on chronic transfusion therapy for prevention cerebral vascular events (6) or pre-stem cell transplantation (7); 19 (59.37%) were transfused because of acute complications such as acute chest syndrome (6), splenic sequestration (6), vaso-occlusive crisis (4) and acute febrile illness (3); 11 received bone marrow transplantation and 19 were on chronic Hydrea treatment; of the 32 patients, 24 (75%) were transfused under the pediatric RBC matching protocol, and 8 (25%) were transfused matching only ABO and D. Median transfusion per patient was 11.5 RBCs (1-57) with total transfusions of 482 RBCs resulting in the formation of 5 new RBC alloantibodies in four patients (AntiKpa, AntiM+S, AntiK, AntiFy^a). The global alloinmunization rate was 1.037% per 100 units transfused and the alloinmunization under pediatric RBC matching protocol was 12.5% per patient; no case was associated with hemolytic transfusion reaction. The characteristics of alloimmunized patients are shown in Table 1. The median number of RBCs transfused pre new antibody was 3 (2-17) and there was no clear association between the number of units transfused and alloinmunization. Of the 4 alloimmunized patients, 2 were on chronic transfusion and 2 were transfused due to acute complications, 3 of them were transfused with Rh (C,E,c,e) and Kell matched RBCs, and the other one was transfused before the matching protocol was use.

Table 1. Characteristics of alloimmunized patients with SCD (N=4).

CHARACTERISTICS	PATIENT 1	PATIENT 2	PATIENT 3	PATIENT4
SEX	Male	Female	Male	Male
AGE ALLOINMUNIZATED	4 years	10 years	2 years	5 months
DATE FIRST TRANSFUSSION	31.06.07	7.06.14	12.06.98	7.09.10
UNITS RBC TRASFUSSION PRE ALLOIMMUNIZATION	17 RBCs*	1RBC pre anti-M 8 RBCs pre anti-S	3 RBCs	2 RBCs
TIME BETWEEN FIRST TRANSFUSION AND ALLOIMMUNIZATION	32 months	1 month 6 months	1 month	4 months
SPECIFICITY ALLOANTIBODY	Anti-Kpa.	1ª. Anti-M. 2ª. Anti-S.	Anti-K	Anti- Fy^a
CAUSE OF TRANSFUSSION	Acute Chest Syndrome.	Prevention Cerebral Vascular Event.	Prevention Cerebral Vascular Event and Pre Stem Cell Transplantation.	Vaso-occlusive crisis.
APPLIED RBC MATCHING PROTOCOL BEFORE ALLOIMMUNIZATION	YES	YES	NO	YES

*RBCs: red blood cells.

Summary and Conclusions: As previously described, we confirm that limited RH (C,E,c,e) and K phenotype matched transfusion could be enough to successfully reduce the incidence of alloantibody production in SCD. With this protocol we manage a very low alloinmunization rate (1.037% per 100 units transfused), with only 5 alloimmunizations in 4 patients which did not jeopardize subsequent transfusions. This scenario allows routine transfusion protocols to prevent SCD complications.

E1576

THE MIRNA PROFILE OF PLATELETS STORED IN A BLOOD BANK AND ITS RELATION TO CELLULAR DAMAGE FROM STORAGE

T. Pontes[1,*] C. Moreira-Nunes[1], J. Maués[2], L. Lamarão[3], J.A. Lemos[3], R. Montenegro[1], R. Burbano[1]
[1]Institute of Biological Sciences, [2]Human and Medical Genetics, Federal University of Pará, [3]Laboratory of Genetics and Molecular Biology, Foundation Center for Hemotherapy and Hematology of Pará_HEMOPA, Belém, Brazil

Background: Millions of blood products are transfused each year, and many lives are directly affected by transfusion. Platelet concentrate (PC) is one of the main products derived from blood. Even under good storage conditions, PC is likely to suffer cell damage. The shape of platelets changes after 5 to 7 days of storage at 22°C. Taking into consideration that some platelet proteins undergo changes in their shape and functionality during PC storage.
Aims: Characterize the most highly expressed miRNAs in PC using high coverage sequencing, examine quantitative changes in miRNA levels during and after storage in a blood bank and validate by real-time quantitative polymerase chain reaction (RQ-PCR) most expressed miRNAs in 40 PC bags tubes to propose candidate miRNAs as biomarkers of PC storage damage.
Methods: Sixteen PC bags were collected and each PC bag tube was cut into six equal pieces to perform experiments with platelets from six different days of storage. Thus, on the first day of storage, 1/6 of the tube was used for miRNA extraction, and the remaining 5/6 was stored under the same conditions until extraction of miRNAs on each the following five days. Samples were sequenced on an Illumina Platform to demonstrate the most highly expressed miRNAs. Two miRNAs, mir127 and mir320a, were selected from miRnome and two were selected based on literature to validated by real-time quantitative PCR (RQ-PCR).
Results: Our sequencing results suggests the use of the miRNAs mir127 and mir320a as biomarkers to assess the "validity period" of PC bags stored in blood banks for long periods. Preliminary validation results suggest statistical difference the four selected miRNAs from the fourth day storage ($p<0.05$). Thus, bags can be tested on the 5th day of storage for the relative expression levels of this miRNAs (Figure 1).

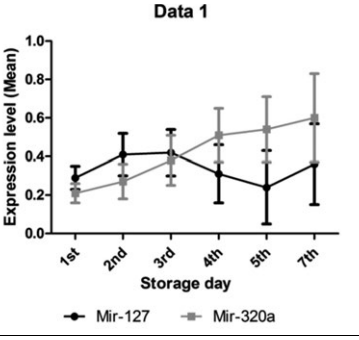

Figure 1.

Summary and Conclusions: We suggest using candidate miRNAs as molecular biomarkers of storage damage that can be used as tools to evaluate the quality of stored PC. The use of miRNAs as biomarkers storages damage is unprecedented and will contribute to improved quality of blood products for transfusions.

E1577

MONITORING HEMOSTATIC POTENTIAL OF PLATELETS DURING STORAGE OF PLATELET CONCENTRATES FOR TRANSFUSION

C. Giaccherini[1,*] M. Marchetti[1], C. Verzeroli[1], C.J. Tartari[1], L. Russo[1], A. Vignoli[1], E. Diani[1], B. Woodhams[2], A. Falanga[1]
[1]Immunohematology and Transfusion Medicine, Hospital Papa GiovannixXIII, Bergamo, Italy, [2]Haemacon ltd, Bromley, United Kingdom

Background: Platelet concentrates (PCs) are extensively used either prophylactically to prevent bleeding in onco-hematology patients with thrombocytopenia, or therapeutically to control active bleeding. For a successful transfusion, platelets in PCs should have a good hemostatic potential to have an effective and immediate action.
Aims: In this study we evaluated variations in platelet activation and aggregation properties during standard storage of PCs and the influence of blood group on these changes.
Methods: Seventy pooled buffy-coat-derived PCs (O group=43, A group=27) were analyzed on the day of preparation (D0) and after 3 day-storage (D3) at 22°C on lateral agitation. Platelet aggregation was assessed by Born method (300,000 plts/ul) in response to collagen (5mg/ml), TRAP-6 (40mM) or arachidonic acid (1mM). Levels of degranulation markers (Platelet factor 4 (PF4), β-Thromboglobulin (β-TG), Thrombospondin-1 (TSP-1) and Vascular Endothelial Growth Factor (VEGF)), together with soluble form of membrane surface proteins, *i.e.* P-selectin and glycoprotein V (sGPV), were evaluated in PC supernatants by ELISA. Data were analyzed according to blood group and statistical analysis performed using SPSS statistic data editor.
Results: Platelet aggregation potential after three days of storage was significantly ($p<0.01$) decreased in response to TRAP-6 (-35%) and collagen (-58.5%). Moreover, platelets from A group showed lower aggregation capacity to all agonists used, both in D0 and D3, compared to those from O groups (p=ns). Analysis of PC supernatants showed that levels of the soluble form of the two platelet membrane surface molecules, P-selectin and GPV, significantly ($P<0.01$) increased from D0 to D3, respectively of 49% and 123%, probably due to platelet degranulation and to the presence of protease activity in PC bags. Similarly, level of α-granule proteins significantly ($p<0.01$) raised during storage. We observed marked differences in percentage increment according to the type of α-granule proteins and blood groups analyzed. Particularly, PF4 and β-TG, which levels significantly ($p<0.001$) correlates ($r=0.932$), raised respectively about 140% and 110%, and the increase was higher in A group; TSP-1 level increased only about 33% and mainly in O group; finally, VEGF level raised about 180% in both blood groups. All these data suggest the occurrence of a differential and regulated release of platelet α-granules subsequent

to activation. A significant (p<0.05) inverse correlation was found between the decrease of aggregation potential induced by TRAP-6 and the increase in PF4 (r=-0.335), β-TG (r=-0.415) and sGPV (r=-0.420) levels.
Summary and Conclusions: During storage, platelets become activated and change their hemostatic phenotype; this reflects in an increased release of α-granules content and a lower ability to aggregate in the presence of agonists. Platelets of A group seem to be more sensitive to these phenomena. The significant correlation found between degranulation and platelet aggregation suggests that measurement of these proteins can be a valuable surrogate of platelet aggregation for evaluation of platelet hemostatic potential. Further studies are required to define the strength of these markers to identify PCs that could not display a full functionality and reactivity in the recipient.

Background: Autologous peripheral blood stem cell (PBSC) transplantation has a fundamental role in first line treatment of multiple myeloma (MM) and has been shown to improve complete remission and overall survival rates in relapsed Non Hodgkin Lymphomas (LNH). GCSF with or without chemotherapy represents the conventional PBSC mobilization regimen; according to standard criteria apheresis start at level of 20x10^6/L CD34+ cells. Nevertheless, 10% to 20% of patients fail the harvest of an adequate amount of PBSCT.
Aims: The combined administration of Plerixafor and GCSF at steady state or during haematological recovery after chemotherapy allows a sufficient PBSC harvest even in this group of poor mobilizers. In fact, many authors demonstrated that, in poor mobilizers, CD34+ PBSC reach a peak 9 hours after plerixafor administration and in this time-frame the CD34+ cell count may become sufficient to start apheresis. The aim of our study was to assess the feasibility and safety of a regimen combining GCSF (10 µg/kg, on days 1-4) and plerixafor (0,24 mg/kg on day +4), with leukaphereses started at a lower level of circulating CD34+ cells (10x10^6/ L).
Methods: Patients and methods: Between July 2014 and February 2015 we enrolled 10 pts affected with LNH. Seven were male e 3 female, median age was 48 (range 36-62). Seven pts were proven and 3 were predicted very poor mobilizer. The CD34 mobilization profile was evaluated by testing CD34+ levels every 3 on day +4 of CGSF alone (6 patients) or starting on day +10 during recovery post DHAP chemotherapy (3 patients). In case an increase of CD34+ cells of at least 10 /microl was not reached, we administered plerixafor on day +5. Thereafter we tested CD34+ count every 3 hours and we began leukapheresis as soon as CD34 count reached 10/mL.
Results: Results: All patients successfully performed leukaphereses and reached the target value of CD34 (2.x 10^6/kg) with one (in 5 pts) or two (5 pts) procedures. Median value of cd34+ cells/ul at +3, +6, +9, +12 hours at day +5 were 15.5, 15.8, 19.11, 16.8, respectively; median value of CD34 harvested at day +5 was 1.7x 10^6/kg (range 0,86-7,63). Five pts needed a second plerixafor dose and apheresis and the median value of CD34/ul at +3, +6, +9, +12 hours were 13, 8.7, 8.27, 7.5, respectively; median value of CD34 harvested at day +6 was 1.2x 10^6/kg (range 0.61-3.18). In the overall series the median value of CD34 harvest was 2.66x 10^6 CD34/kg (range 1.97-7.67). 5 pts underwent to PBSC transplantation and the median of neutrophils and platelets engraftment were 12 and 18 days respectively.
Summary and Conclusions: Conclusion: An early (hour +3) evaluation of CD34+ levels after plerixafor allows detecting early CD34 increase that would be missed with standard monitoring protocols (hour +12). Moreover the early evaluation of Cd34 mobilization profile starting on day +4 allows identifying patients who are predicted to become poor mobilizers so that a further dose of plerixafor may be added to standard schedule. This strategy may be successful in rescuing patients that, according to standard criteria, would never reach the minimum level of CD34+ cells to start leukaphereses.

GENETIC RISK FACTORS IN HUMORAL IMMUNE RESPONSE TO PLATELET ANTIGENS HLA AND HPA SYSTEMS IN MULTITRANSFUSED HEMATOLOGICAL PATIENTS

L.L. Golovkina[1,*] T. Pushkina[1], P.E. Mikhaylova[2], A.V. Savchenko[3]
[1]Immunohematology, [2]Chemotherapy of Hemoblastosis and Bone Marrow Failure, [3]General Head, National Research Centre for Hematology of Ministry of Healthcare Service Russian Federation, Moscow, Russian Federation

Background: Humoral immune response to alien antigens reduces number of compatible and, hence, safe blood components transfusions. Alloimmunization of recipients to HPA (Human Platelet Antigens) and HLA (Human Leukocyte Antigens) I class antigens is one of the common immunological complications in platelet transfusions. Molecules HLA II class play an important role in the initiation of humoral immune response as amino acid structure of peptide-binding sites of immune cells influences on presentation of alien peptide to T-lymphocyte's receptors. HLA-restricted mechanisms of alloimmunization are not investigated enough in transfusiology.
Aims: to investigate the association of the HLA and HPA genotypes with antibody formation to HLA and HPA systems in multitransfused Russian hematological patients.
Methods: serums of 228 multitransfused patients [100 with aplastic anemia (AA) and myeloproliferative syndrome (MDS), 76 with acute myeloblastic leukemia (AML), 52 with acute lymphoblastic leukemia (ALL)]; DNAs of 178 the same patients (57 with AA and MDS, 44-with ALL, 77-with AML). All investigated people were of Eastern European origin.HLA-DRB1,-DQB1 (low and high resolution) (Dynal, Protrans, BAG) and HPA-1,-2,-3,-4,-5,-6,-15 genotyping by PCR-SSP (BAG, Protrans). Patients were initially screened for HLA class I using standard microlymphocytotoxic test; and for HPA antibodies using ELISA with native and modified (without HLA) platelets. HPA-typed platelets were used for detection of anti-HPA antibodies specify. The statistical calculation was performed using Chi-square and Fisher exactly (in small groups) criteria, p value <0,05 were considered significant. HLA haplotype were estimated via maximum-likelihood analysis using the Arlequin software version 3.5.
