Results: *Runx1;Runx3* DKO mice showed shorter disease latency in RIM as compared to the control mice. Although MoMuLV inoculation commonly induce T cell leukemia/lymphoma, majority of the *Runx1;Runx3* DKO mice developed biphenotypic leukemia with myeloid features. Retrovirus integrations into integrin α9 (*Itga9)* locus, which resulted in Itga9 overexpression, were exclusively found in *Runx1;Runx3* DKO mice. We confirmed that overexpression of Itga9 in *Runx1;Runx3* DKO cells increased the incidence of leukemia. In human AML, high expression of ITGA9 was found in AML cells with t(8;21) and inv(16) and associated with a poor prognosis.
Summary and Conclusions: We identified Itga9 as a cooperative hit with *Runx1* and *Runx3* deficiencies in leukemogenesis. This synergism was confirmed in human RUNX-related leukemias. Better understanding of the cooperating mechanism between abnormalities in ITGA9 and RUNX transcription factors will give further directions in developing therapies for human leukemias.

Acute myeloid leukemia - Biology 3

Prodi", Bologna, [8]Department of Experimental Oncology, European Institute of Hematology, Milan, [9]Department of Biological, Geological and Environmental Sciences, University of Bologna, Bologna, Italy

Background: Next Generation Sequencing studies identified 9 functional categories of mutations in acute myeloid leukemia (AML), with >99% of cases having at least one of those mutations (*Ley et al.* NEJM 2013). However, multiple genetic hits participate to AML pathogenesis, and metabolic dysregulations, as the one induced by *IDH1/2* mutations, play oncogenic functions (*Ward et al.* Cancer Cell 2010).
Aims: To define novel functional categories of AML mutations affecting relevant and druggable biological processes, with focus on genetic determinants of metabolic plasticity.
Methods: Out of 455 whole exome sequencing (WES) cases from onco-hematological patients collected in the NGS-PTL project, we analyzed 37 AML cases, belonging to our cohort of 239 *FLT3*-WT samples (886 AML total). We performed 100 bp paired-end WES (HiSeq2000, Illumina) and mapped the sequenced reads with Burrows-Wheeler Aligner. Variants where called with MuTect or GATK for single nucleotide variant (SNV) and indels detection, respectively (>90% confidence). Gene expression profiling (GEP) was performed using HTA2.0 microarray (Affymetrix) on 56 bone marrow samples, including AML (≥80% blasts) and healthy controls.
Results: We detected an average of 26 somatic variants per patient (range 7-65) by WES. Gene ontology annotation identified 8 novel relevant functional categories of mutated genes: transcription, translation and post-translational modifications, protein degradation, cytoskeleton, cell cycle, DNA damage, cell survival and metabolism. Since metabolic pathways are promising targets for tailored therapies (*e.g.* IDH1/2 and glutaminase inhibitors), we focused our analysis on them. We identified 82 variants (74 SNVs, 2 frameshift and 4 nonframeshift deletions, 2 stopgains) targeting 70 genes involved in metabolism, with 78% of patients carrying at least one mutation in a metabolic gene and 35 variants rated as damaging by CONDEL algorithm. Among mutations in metabolic genes, the most represented pathways were amino acids, lipids, CoA and nucleotides metabolism, transport and bioenergetics pathways. Notably, *IMPDH2*, a mediator of MYC-induced proliferation involved in nucleotide interconversion, was mutated and overexpressed in our AML cohort (*p=0.01*), suggesting a potential oncogenic function. Moreover, *ALDH2*, a regulator of hematopoietic stem cell functions which is involved in multiple metabolic pathways and associates with metabolic remodeling, was mutated and 2-fold downregulated in AML blasts. Seven genes were mutated in 5-8% of samples: *RETSAT, HSPG2*, *CHPF*, *ABCA2*, *ND1*, *APOBR*, *NAAA*. *RETSAT*, *HSPG2* and *CHPF* mutations were predicted as "drivers" by DOTS-Finder tool. Bioenergetic pathways were affected by mutations in glycolysis and gluconeogenesis (*GPI*, *ITPA*), oxidative phosphorylation (*ND1*, *ND4*, *ND5*, *CYTB*), pentose phosphate pathway (*H6PD*, *PGLS*).
Patients carrying mutations in the bioenergetic pathway showed a strong trend towards reduced overall survival, which did not associate with unfavorable molecular mutations.
Summary and Conclusions: Metabolism is the most represented class of mutated genes (8.6% of variants) in our *FLT3*-WT AML cohort after signaling, leading us to propose a novel functional category. Our data suggest that, along with mutations in established oncogenes and tumor suppressors involved in metabolic control (*KRAS*, *TP53,* MYC pathway), a number of genetic determinants participate to leukemia metabolic plasticity and oncogenic mutations of metabolic enzymes may drive leukemogenesis, impact on patients' survival and become novel targets for personalized therapies.

THE PAN-CLASS I PI3 KINASE INHIBITOR, NVP-BKM120, DEMONSTRATES ANTI-LEUKEMIC ACTIVITY IN ACUTE MYELOID LEUKEMIA

M. Allegretti[1,*] M.R. Ricciardi[1], R. Licchetta[1], S. Mirabilii[1], S.Orecchioni[2], F. Reggiani[2], G.Talarico[2], R. Foà[1], F. Bertolini[2], S. Amadori[3], A. Tafuri[4]

[1]Cellular Biotechnologies and Hematology, Sapienza University of Rome, Rome, [2]Division of Clinical Haematology-Oncology, European Institute of Oncology, Milan, [3]Department of Hematology, Tor Vergata University Hospital, [4]Department of Clinical and Molecular Medicine, Sapienza University of Rome, Rome, Italy

Background: Aberrant activation of PI3K/Akt/mTOR pathway is a common feature of acute myeloid leukemia (AML) patients contributing to chemoresistance, disease progression and unfavourable outcome. Therefore, inhibition of this pathway may represents a potential therapeutic approach in AML. NVP-BKM120 (BKM120) is a pan-class I PI3K inhibitor which exerts anti-proliferative and cytotoxic effects on several solid tumors and hematological malignancies by inhibiting PI3K/Akt/mTOR activity.
Aims: To evaluate the pre-clinical activity of BKM120 on AML cell lines and primary samples.
Methods: BKM120 (Novartis) was tested on AML cell lines (U937, NB-4, HL-60/Mx2, OCI-AML2, HL-60, OCI-AML3, THP-1, MOLM-13 and KG-1) and on 15 primary AML samples. Given the role of PI3K/Akt/mTOR in cell metabolism, BKM120 was then combined with dichloroacetate (DCA), a glycolitic modulator, on selected AML samples. Cell cycle and apoptosis were analyzed by Acridine-Orange and AnnexinV (AnnV)/PI staining, respectively. Signaling modulations and metabolic changes were evaluated by western blot and by the XF24 Flux analyzer, respectively. *In vivo* experiments were performed on non-obese diabetic severe combined immunodeficient interleukin-2 receptor g-null mice.
Results: Basal expression and phosphorylation levels of PI3K/Akt/mTOR pathway components were initially assessed on AML cell lines and primary samples. Despite some heterogeneity, all cell lines shared the constitutive activation of PI3K/Akt/mTOR axis. Moreover, 7 of the 9 primary samples tested showed a higher phospho/total Akt ratio than normal mononuclear cells (MNCs) and displayed p-mTOR (S2448 and S2481) and p-4EBP1 (T37/46) overexpression, suggesting the aberrant activation of PI3K/Akt/mTOR pathway. BKM120 exposure resulted in a dose-dependent dephosphorylation of Akt (S473) and Gsk3α/β (S21/9) in all cell lines tested and affected, at higher doses, mTOR activity inducing the dephosphorylation of mTOR (S2448 and S2481), p70S6K (S371) and 4EBP1 (T37/46). Blockade of PI3K/Akt/mTOR signaling inhibited cell growth (IC50s: 0.7-1.2μM) and induced a significant ($p<0.005$) dose- and time-dependent apoptosis in all cell lines. Cytotoxicity was preceded by a temporary G_2/M block that was rapidly followed by induction of apoptosis, as demonstrated by the increase of the subG_0/G_1 peak at 72h. Efficacy of BKM120 was then confirmed on primary samples: at 144h, AnnV$^+$ cells increased from 19.5±9.6% (vehicle) to 48.0±23.6% ($p<0.001$) at 5μM. Dephosphorylation of Akt (S473), achieved in 3/3 primary samples, supported the target inhibition. Conversely, BKM120 failed to show considerable cytotoxicity on normal and PHA-activated MNCs (8.0% and 4.4% apoptosis net increase at 5μM, respectively). Metabolic perturbations induced by BKM120 were then assessed on AML cells demonstrating a dose-dependent reduction of basal and maximal respiration as well as ATP production in both cell lines and primary samples. Furthermore, BKM120 strongly synergized (CI<0.6) with DCA to trigger apoptosis at lower doses on AML cell lines and primary samples. Finally, *in vivo* administration of BKM120 in a xenotransplant mouse model of AML markedly inhibited leukemia progression and induced a significant ($p<0.001$) improvement of overall survival.
Summary and Conclusions: Our data demonstrated that BKM120, as single agent or in combination with other drugs (*i.e.* glycolytic modulators), has a significant anti-leukemic activity towards AML cell lines and primary samples, thus supporting its clinical evaluation as a therapeutic agent for AML patients.

ACUTE MYELOID LEUKEMIA DERIVED MACROPHAGE MIGRATION INHIBITORY FACTOR DRIVES INTERLEUKIN-8 PRO-SURVIVAL SIGNALS IN THE TUMOR MICROENVIRONMENT

A. Abdul-Aziz[1,*] M. Shafat[1], S. Rushworth[1], K. Bowles[1,2]

[1]Department of Molecular Hematology, University of East Anglia, [2]Department of Hematology, Norfolk and Norwich University Hospitals NHS Trust, Norwich, United Kingdom

Background: Despite recent significant advances in the understanding of the biology of acute myeloid leukemia (AML) the clinical outcomes for the majority of AML patients, particularly the elderly, remain poor. There is increasing evidence that the AML microenvironment plays an important role in AML survival and proliferation. The bone marrow microenvironment is composed of multiple cell types that via direct cell-to-cell interactions and soluble factors promote the survival of leukemic cells and affect their response to therapy. *In vitro*, primary AML blasts rapidly undergo spontaneous apoptosis, however we and others have shown that the same primary AML cells survive when cultured on bone marrow derived mesenchymal stem cells (BM-MSC). Furthermore dis-

ruption of the interaction between AML cells and BM-MSC increases AML cell sensitivity to chemotherapy. These observations indicate that the pro-survival apoptotic defect in AML is not cell autonomous but highly dependent on extrinsic signals derived from the microenvironment.
Aims: Our aim is therefore to investigate the bidirectional interaction of AML cells and BM-MSC.
Methods: Primary AML blasts and primary AML BM-MSC were obtained from patient's bone marrow. Primary AML blasts $1x10^6$ were co-cultured on confluent primary BM-MSC. Conditioned medium was then collected from these cultures and analyzed using Proteome Profiler Human XL Cytokine Array and target specific ELISAs. Real-time PCR was also used to verify the array data.
Results: Using the XL Cytokine array we found that IL-8 and MIF increased significantly in the media from AML/BM-MSC co-cultures compared to media from either AML or BM-MSC alone. The observed changes in IL-8 and MIF were confirmed by ELISA assays. RT-PCR was used to measure MIF and IL-8 gene expression from RNA extracted from AML or BM-MSC cultured alone or in combination. Results indicate that MIF is upregulated in AML in response to BM-MSC co-culture and IL-8 was upregulated in BM-MSC in response to co-culture with AML. Next we used recombinant MIF and IL-8 as well as inhibitors of MIF (ISO-1) and IL-8R (SB225002) to define their specific role in BM-MSC/AML co-cultures. Recombinant human MIF increases IL-8 mRNA and protein expression in BM-MSC but not in AML. Moreover, the MIF inhibitor, ISO-1, inhibits AML induced IL-8 expression and secretion by BM-MSC. Finally, we report that IL-8 protects primary AML from spontaneous apoptosis *in vitro* which is reversed by the IL-8R inhibitor, SB225002.
Summary and Conclusions: BM-MSC respond to signals from AML cells which results in changes in the expression of pro-survival cytokines. Hence, BM-MSC and AML cells act together in the formation of the pro-tumoral microenvironment. MIF/IL-8 regulated BM-MSC/AML crosstalk may represent a novel target for future AML therapies.

XPO1 INHIBITION USING SELINEXOR SYNERGIZES WITH CHEMOTHERAPY IN ACUTE MYELOID LEUKEMIA (AML) BY TARGETING DNA REPAIR GENES

X. Yu[1], T. Kashyap[2], P. Ranganathan[1], B. Bhatnagar[1], S. Shacham[2], M. Kauffman[2], W. Blum[3], Y. Landesman[2], R. Garzon[1,*]
[1]Medicine, The Ohio State University, Columbus, [2]Karyopharm Therapeutics, Newton, [3]The Ohio State University, Columbus, United States

Background: Targeting nuclear exporter receptors such as Exportin 1 (XPO1) is a novel approach to restore tumor suppressor function in AML. Selinexor, a selective inhibitor of XPO1, is currently being tested in a Phase 1 clinical trial in AML. Preliminary data indicate that selinexor is well tolerated, safe and active in AML patients. However, considering the molecular complexity of AML, it is unlikely that this disease can be cured with monotherapy and therefore we asked whether adding already established effective drugs such as Topo IIα inhibitors to selinexor will enhance or improve its anti-leukemic effects in AML.
Aims: To investigate the anti-leukemic activity and mechanisms of selinexor in combination with Topo IIα inhibitors in AML cell lines and patients blasts.
Methods: IC_{50} values for selinexor and Topo IIα inhibitors were determined using MTS assays in AML cells lines and patients. Synergy was calculated using the Chou-Talalay method.
Results: To evaluate whether the combination of selinexor and Topo IIα inhibitors (idarubicin, etoposide and mitoxantrone) induce synergy, we treated the AML cell lines MOLM-13 and MV4-11 with selinexor and each of the Topo IIα inhibitors separately at two-fold dilutions of their individual IC_{50} values, and measured cell proliferation at 48 hours. Concomitant treatment of selinexor with Topo IIα inhibitors resulted in synergy (combination index (CI) values <1) in all cell lines. Treatment of AML patients blasts (n=3) with selinexor and idarubicin at 4-fold dilutions of their individual IC_{50} values showed synergy as well. High-throughput studies on protein expression in tumor cells after selinexor treatment indicate that several DNA damage repair proteins are down-regulated. Based on these data, we reasoned that the synergistic effects of selinexor with Topo IIα inhibitors could be explained in part by selinexor induced down-regulation of DNA repair proteins thus preventing leukemia cells from repairing chemotherapy-induced DNA damage. A dose dependent reduction in mRNA (RT-PCR) and protein levels (WB) of the DNA damage repair genes *Chk1, Rad51, MSH2* and *MSH6* were observed as early as 6 hours after selinexor treatment and before apoptosis was observed (50 to 200 nM). *Chk1 and Rad5* mRNA and protein levels decreased the most (2 and >10 fold decrease respectively) and was caused by decrease MYC binding to these genes promoters which resulted in reduced transcriptional activation. Similar depletion of these DNA repair proteins was also observed in 4 AML patient samples incubated with selinexor at IC_{50} concentrations. Topo IIα inhibitors cause double stranded DNA breaks which can be repaired by the homologous repair (HR) pathway. HR is governed by multiple proteins that include Rad51. To measure the ability of cells to carry out HR in the presence of selinexor, we used the HeLa DR cells with an HR integrated plasmid. These cells carry two copies of inactive Green Fluorescent Protein (GFP) genes integrated into the genome. The cells are treated with an enzyme ICSE1 that cuts at 1 site within the GFP. If HR occurs then there is repair of the double strand break and GFP events are observed. Using this assay, when Hela DR cells are treated with selinexor, we observed a 7 fold decrease in the number of GFP expression compared to control cells ($P<0.05$). Animal studies are currently undergoing.
Summary and Conclusions: Our data showed that selinexor synergizes with anthracyclines to kill AML blasts by targeting DNA repair. Therefore, we propose to combine selinexor with Topo IIα inhibitors in a Phase 1 clinical trial.

P557

MAPPING WHOLE-EXOME SEQUENCING DATA OF ACUTE MYELOID LEUKEMIA PATIENTS INTO KEGG PATHWAYS

A. Padella[1,*] G. Simonetti[1], I. Iacobucci[1], I. DoValle[2], E. Zago[3], F. Griggio[3,4], M. Garonzi[4], M. Manfrini[1], V. Guadagnuolo[1], S. Bernardi[5], C. Papayannidis[1], M.C. Abbenante[1], G. Marconi[1], G. Melloni[6], L. Riva[6], S. Bruno[1], M.C. Fontana[1], E. Zuffa[1], E. Franchini[1], C. Baldazzi[1], M. Cavo[1], N. Testoni[1], E. Ottaviani[1], P.G. Pellicci[7], M. Sazzini[8], A. Ferrarini[4], M. Delledonne[3,9], D. Remondini[2], G. Martinelli[1,9]
[1]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Seragnoli Institue, [2]Department of Physics, University of Bologna, Bologna, [3]Personal Genomics, [4]Department of Biotechnology, University of Verona, Verona, [5]Unit of Blood Diseases and Stem Cell Transplantation, University of Brescia, Brescia, [6]Center for Genomic Science of IIT@SEMM, Istituto Italiano di Tecnologia, [7]Department of Experimental Oncology, European Institute of Oncology, Milan, [8]Department of Biological, Geological and Environmental Sciences, University of Bologna, [9]NGS-PTL consortium, Bologna, Italy

Background: Acute Myeloid Leukemia (AML) is a highly heterogeneous disease and a complex network of events contribute to the pathogenesis. Recently, functional categorization of mutated genes in AML identified 9 classes of affected genes. However, how genomic alterations cooperate to induce AML, the pathways affected by the mutated genes and their prognostic value are still unknown.
Aims: To better stratify AML patients and identify novel molecular biomarkers based on the mapping of genomic alterations in biological pathways and correlation with clinical outcome.
Methods: We sequenced the exome of 33 cases of AML at diagnosis using the Illumina Hiseq2000 platform. We usedthe GATK and MuTect tools to call mutations and we selected variants with a minor allele frequency (MAF) lower than 0.05. We mapped variants in biological pathways using KEGG database and we identified putative driver genes with DOTS-finder and MutSig.
Results: A validation rate equal to 89% (26 validated variants out of 29) was obtained by Sanger sequencing analysis of variants. Our cohort included 16 patients belonging to the intermediate risk cytogenetic prognostic group and 17 patients belonging to the high-risk one (*p=0.002*). For each patient, we mapped the mutated genes into KEGG pathways and we performed unsupervised clustering analysis based on the represented KEGG pathways. We identified 4 groups of patients characterized by significant differences in the number of mutated pathways (*p=0.032*), with an average of 74 (group 1), 58 (group 2), 28 (group 3) and 9 (group 4) mutated pathways per patient. We identified the PI3K-Akt signalling as the top mutated pathway (23 out of 33 patients). Notably, the frequency of patients with mutations in that pathway differed among groups: 100% of patients in group 1 and 2, *versus* 62% and 20% of patients in group 3 and 4, respectively. Moreover, we were able to identify a common mutated gene in group 1, *KRAS,* which was defined a putative driver gene by both DOTS-finder and MutSig tools. On the other hand, 6 out of 8 patients of group 2 had *TP53* mutations . Group 3 and 4 showed a heterogeneous distribution of mutated pathways: the top mutated pathways in group 3 were the PI3K-Akt signalling and the Metabolic pathways, with 6 patients with mutations out of 8; whereas the top mutated pathway in group 4 counted 5 out of 10 patients with mutations in the Metabolic pathway. Klapan-Meier survival curves showed a significant correlation of the 4 groups with clinical outcome (*p=0.047*), with group 2 having an extremely unfavourable prognosis, as expected from *TP53* mutated patients. Subclassification of group 3 and 4 patients according to molecular characterization and correlation with clinical outcome are ongoing.
Summary and Conclusions: In summary, by mapping WES data into KEGG pathways, we were able to distinguish 4 groups of patients. Two of them were characterized by distinct molecular biomarkers able to stratify patients with different prognosis. *KRAS* was identified as putative driver gene in AML by two different tools, underling its importance in the disease pathogenesis. Interestingly, our analysis defined a potential association between two patients lacking *TP53* mutations and *TP53*-mutated cases (in group 2), in terms of KEGG pathway clusterization, which could be defined only by omics analysis. Our results confirm the different prognostic risks of AML patients with *KRAS* or *TP53* mutations and highlight the relevance of WES data interpretation according to mutated pathways for patient stratification at diagnosis.

PBX3 AND MEIS1 COOPERATE THROUGH MULTIPLE MECHANISMS TO SUPPORT HOX-INDUCED MURINE LEUKEMIA

M.-P. Garcia-Cuellar[1], J. Steger[1], E. Füller[1], K. Hetzner[1], R. Slany[1,*]
[1]Genetics, University Erlangen, Erlangen, Germany

Background: Hox homeobox transcription factors drive leukemogenesis efficiently only in the presence of Meis or Pbx proteins.
Aims: In this study we investigated the importance of a cooperation of Meis1 and Pbx3 for Hoxa9 mediated transformation.
Methods: Protein-protein interactions, protein-stability and half-life as well as DNA binding capability and transformation efficiency were tested *in vitro* and *in vivo*.
Results: A biochemical analysis of the Meis1-Pbx3 cooperation revealed that in the absence of Pbx3, Meis1 stability was greatly reduced. As shown by a deletion analysis Meis1 degradation was contingent on a motif coinciding with the Pbx-binding domain. Either deletion of this sequence or binding to Pbx3 prolonged Meis1 survival by preventing poly-ubiquitination and proteasome mediated decay. Meis1 break-down could be also blocked directly by inhibition of the ubiquitin proteasome system indicating a tight posttranscriptional control. In addition, Meis1 and Pbx3 cooperated genetically as overexpression of Pbx3 induced endogenous Meis1 transcription. These functional interactions translated to *in vivo* activity. Blocking Meis1/Pbx3 dimerization abrogated the ability to enhance proliferation and colony forming cell numbers in primary cells transformed by Hoxa9. Furthermore, expression of Meis1 target genes *Flt3* and *Trib2* was also dependent on Pbx3/Meis1 dimerization. This correlated with the requirement of Meis1 to bind Pbx3 in order to form high affinity DNA/Hoxa9/Meis1/Pbx3 complexes *in vitro*. Finally, kinetics and severity of disease in transplantation assays indicated Pbx3/Meis1 dimers as rate-limiting factors for Hoxa9 induced leukemia.
Summary and Conclusions: Here we show that Pbx3 and Meis1 form stable dimers and we present evidence that this dimers are the actual functional units whose formation is rate limiting for efficient leukemia induction by Hoxa9.

Background: The development of acute myeloid leukemia (AML) is associated with accumulation of acquired genetic alterations in hematopoietic progenitor cells. The study performed by the TCGA consortium has enabled for the discovery of recurrent mutations in 23 genes in AML. However, many patients with normal karyotype carry no mutations in any of the currently recognized driver genes associated with leukemogenesis, suggesting that AML has relevant changes not yet defined.
Aims: We performed whole-exome sequencing (WES) of tumor-normal matched samples to identify new driver mutations in AML patients with normal karyotype lacking *NPM1, CEBPA* and *FLT3*-ITD mutations. Novel candidate genes, together with other previously described,[1] were resequenced in an independent cohort of intermediate-risk AML patients. . The obtained results were further *in silico* analysed.
Methods: WES was performed on matched samples from 7 *de novo* AML patients, lacking cytogenetic alterations, *NPM1, CEBPA* and *FLT3*-ITD mutations (discovery cohort). Library preparation and exome capture were performed according to the manufacturer protocol for sequencing with an Illumina platform. WES data were analyzed using and in-house bioinformatic pipeline. Candidate variants were validated using an Ion AmpliSeq™ Custom Panel in an Ion Torrent platform (Life-Technologies). Furthermore, a custom panel of 87 genes (55 genes from in-house results and 32 genes reported to be mutated in ≥2% of patients in the TCGA study[1]) was analysed in an independent validation cohort of 100 patients with intermediate-risk AML using SureDesign Tool (Agilent). To prioritize the best candidate genes we studied the significance of the network in which they participate. Samples were provided by the Hospital La Fe Biobank.
Results: In the discovery cohort, we identified 94 SN*Vs* non-synonymous coding mutations and 8 small indels, with an average of 30 mutations per sample (range 22-37). We confirmed 60% of the candidate variants affecting 56 genes. Among them, 15 genes had been shown previously to be recurrent. Over the validation cohort we detected a mean of 6.81 mutations per sample (range 1-17). We identified a total of 193 variants affecting 65 different genes, been 41 mutated in more than one patient. After prioritization we found 9 individual genes with a a higher frequency in our cohort than expected in the 1000g database and with a strong potential of being involved in AML pathogenesis ($P \leq 0.01$). To improve our knowledge of the interactome of AML, these genes were also analyzed for functional enrichment of gene ontology terms and grouped according to their biological function. As a result, we defined a network in which 27 out of the 41 genes selected by harboring recurrent deleterious mutations were significantly more connected that the random expectation ($P < 0.05$).
Summary and Conclusions: This study shows a comprehensive analysis of AML combining WES with a custom panel of targeted genes by NGS. We identified recurrent deleterious mutations in 9 genes with a strong potential to be involved in AML pathogenesis and have defined a functional module in the interactome of intermediate-risk AML patients.

P560

INVESTIGATING THE ROLE OF BONE MARROW ADIPOCYTES IN REGULATING SURVIVAL AND PROLIFERATION OF ACUTE MYELOID LEUKEMIA

M. Shafat[1,*] A. Abdul-Aziz[1], M. Fenech[2], J. Turner[2,3], K. Bowles[1,4], S. Rushworth[1]
[1]Department of Molecular Hematology, [2]Department of Medicine, University of East Anglia, [3]Department of Endocrinology, [4]Department of Hematology, Norfolk and Norwich University Hospitals NHS Trust, Norwich, United Kingdom

Background: Most patients diagnosed with acute myeloid leukemia (AML) die of the disease despite currently available chemotherapy. The bone marrow (BM) microenvironment is a key player supporting AML blast survival. The BM microenvironment consists of many cell types not directly of the hematopoietic lineage, including bone marrow adipose tissue (MAT). MAT accounts for approximately 50% of BM volume in the axial skeleton of adult humans. Adipocytes store energy primarily as triglyceride which can be released following lipolysis as free fatty acid (FFA) and are taken up by cells for conversion into energy. How this energy source is utilised locally in the bone marrow by AML has not been well characterised to date.
Aims: The aim of this study is to determine the role of human bone marrow adipocytes in the support of AML blast survival *in vitro* and their protection against chemotherapy-induced apoptosis.
Methods: Primary AML blasts and primary AML BM mesenchymal stem cells (MSC) were obtained from patients' bone marrow. BM derived MSC were differentiated *in vitro* into adipocytes (MSC-Ad) and co-cultured with primary AML blasts. BrdU incorporation, annexin V and PI staining were used to determine proliferation and apoptosis of AML blasts. Lipolysis was measured by determining free fatty acid and glycerol release. Dodeconic acid fluorescent fatty acid analog (DFFAA) was used to measure uptake of FFA by AML blasts. Western blot analysis was used to determine the level of proteins associated with triglyceride breakdown; hormone sensitive lipase (HSL), phosphorylated HSL and fatty acid binding protein 4 (FABP4). Cytarabine and daunorubicin were used to determine the chemotherapy-induced apoptosis.
Results: Our results show AML blasts co-cultured with MSC-Ad have increased proliferation and reduced apoptosis by day 6 compared to AML blasts in monoculture. Cell cycle analysis shows a higher percentage of AML blasts from MSC-Ad co-culture in the M and G2 phase compared with monoculture. Furthermore we found that MSC-Ad had enhanced lipolysis in response to AML co-culture. We observed increase in free fatty acid and glycerol release in AML/MSC-Ad co-culture media compared to media from MSC-Ad alone. The uptake of FFA was then examined in AML blast co-culture with MSC-Ad. Flow cytometry analysis shows an increase in fluorescence (DFFAA) within AML blasts when co-cultured with MSC-Ad loaded with DFFAA. In addition, Western blot analysis of HSL, an enzyme that hydrolyzes triglycerides of the lipids, shows an increase in phosphorylation. FABP4 which is a lipid transport protein is also increased in MSC-Ad when cultured with AML blasts. Finally, chemotherapy induced apoptosis was significantly reduced in AML/MSC-Ad co-culture compared to AML blasts on their own.
Summary and Conclusions: Here we report that MSC-Ad upregulate lipolysis in response to co-culture with AML blasts. Furthermore MSC-Ad support the survival and proliferation of AML blasts and provide a protective microenvironment against standard cytotoxic chemotherapy. We hypothesize that pro-survival metabolic activity in AML blasts is supported by AML directed transfer of free fatty acid from adipocytes in the bone marrow microenvironment and that targeting this interaction may provide the foundation of novel micro-environment directed treatment strategies for AML in the future.

P561

COMPARATIVE FUNCTIONAL ANALYSIS OF THE MOLECULAR NETWORK OF 7 SELECTED MLL FUSION PROTEINS

A. Skucha[1,*] M. Muhar[2], A. Stukalov[1], J. Colinge[3,4], K. Bennett[1], J. Zuber[2], G. Superti-Furga[1], F. Grebien[5]
[1]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, [2]IMP - The Research Center of Molecular Pathology, Vienna, Austria, [3]Institut de Recherche en Cancérologie de Montpellier Inserm, [4]Université Montpellier 1 - ICM Val d'Aurelle Campus Val d'Aurelle, Montpellier, France, [5]Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria

Background: The Mixed Lineage Leukemia gene (MLL) is a frequent target of

chromosomal rearrangements in human malignancies. Many MLL-rearrangements are associated with pediatric leukemias with poor clinical outcomes. Balanced translocations result in the fusion of the MLL gene to over 65 different fusion partner genes, leading to the production of novel chimeric proteins. Critical effectors of distinct MLL fusion proteins have previously been identified, and some of them were shown to hold great potential for targeted therapies. However, it is not clear if these effectors are conserved among all MLL fusion proteins or if different molecular mechanisms of transformation exist for distinct MLL fusion proteins.
Aims: We aim to delineate common critical effectors of 7 selected MLL fusion proteins that are presumed to differ in their oncogenic mechanisms (MLL-AF1p, MLL-AF4, MLL-AF9, MLL-CBP, MLL-EEN, MLL-ENL, MLL-GAS7).
Methods: Stable cell lines allowing for inducible expression of 7 selected, affinity-tagged MLL fusion proteins were prepared and expression of transgenes was verified by qRT-PCR and Western Blotting. Affinity purification coupled to mass spectrometry (AP-MS) identified novel interactors of 7 MLL fusions protein complexes. To assign functional information to the candidate genes we employed a pooled RNAi screening approach. The MLL-AF9-positive MOLM-13 cell line was transduced with pools of viral vectors allowing for the expression of 6 shRNA targeting the same candidate gene. Using this setup we have established a screening methodology that is suitable for positive and negative selection readouts. This dual read-out highly increases the significance of true hits and strongly decreases the false positive rate.
Results: Advanced statistical filtering using a novel, improved algorithm developed by us yielded a densely connected protein-protein interaction network of >950 proteins around 7 MLL fusions, including many known MLL-interactors. 128 proteins were found to interact with ≥5 of the 7 MLL-fusions. This list of conserved MLL-interactors is highly enriched for proteins with a function in chromatin metabolism and transcriptional control. RNAi screening performed in a 'mini-pool' format was used to functionally dissect the conserved MLL-fusion interactome. As a result, 35 novel interactors of MLL fusion proteins were selected for further validation experiments.
Summary and Conclusions: In conclusion, we developed a robust experimental pipeline allowing for the functional characterization of cellular effects of MLL fusion proteins in a comprehensive and comparative manner, which will contribute to further insight into the molecular mechanisms of MLL-fusion dependent leukemogenesis.

RETINOIC ACID AND ARSENIC TRIOXIDE TRIGGER DEGRADATION OF MUTATED NPM-1 RESULTING IN APOPTOSIS OF AML CELLS

H. El Hajj[1], Z. Dassouki[1], C. Berthier[2], E. Raffoux[2], L. Ades[2], O. Legrand[3], R. Hleihel[1], U. Sahin[2], N. Tawil[1], A. Salameh[1], K. Zibara[4], N. Darwishe[1], M. Mohty[3], H. Dombret[2], P. Fenaux[5], H. De The[6], A. Bazarbachi[1,*]
[1]American University of beirut, Beirut, Lebanon, [2]Saint Louis, [3]Hopital Saint Antoine, Paris, France, [4]Lebanese University, Beirut, [5]Saint Louis, Paris, [6]Saint Louis, Beirut, Lebanon

Background: *Nucleophosmin-1 (NPM-1)* is the most frequently mutated gene in acute myeloid leukemia (AML). Addition of retinoic acid (RA) to chemotherapy was proposed to improve survival of some of these patients.
Aims: Investigate the efficacy and molecular mechanism of action on arsenic and retinoic acid (RA) combination on *NPM-1* mutated AML
Methods: AML derived cell lines and freshly isolated blasts from AML patients were treated *in vitro* with Retinoic acid, arsenic trioxide and their combination. Five elderly AML patients with normal karyotype, *NPM-1* mutation, without *FLT-3 ITD*, who were judged unfit to chemotherapy, received RA/arsenic on a compassionate basis.
Results: We found that in AML cell lines or primary samples, RA or arsenic trioxide synergistically induce proteasomal degradation of mutant NPM-1, leading to differentiation and apoptosis. *NPM-1* mutation not only delocalizes NPM-1 from the nucleolus, but also disorganizes promyelocytic leukemia (PML) nuclear bodies. Combined RA/arsenic treatment significantly reduced bone marrow blasts in three patients and restored the sub-nuclear localization of both NPM-1 and PML.
Summary and Conclusions: These findings could explain the proposed benefit of adding RA to chemotherapy in *NPM-1* mutant AMLs, and warrant a broader clinical evaluation of regimen comprising a RA/arsenic combination.

CLINICAL SAFETY AND ACTIVITY OF AG-120, A FIRST-IN-CLASS, POTENT INHIBITOR OF THE IDH1 MUTANT PROTEIN, IN A PHASE 1 STUDY OF PATIENTS WITH ADVANCED IDH1-MUTANT HEMATOLOGIC MALIGNANCIES

S. de Botton[1,*] D.A. Pollyea[2], E.M. Stein[3], C. DiNardo[4], A.T. Fathi[5], G.J. Roboz[6], R. Collins[7], R.T. Swords[8], I. Flinn[9], J.K. Altman[10], M.S. Tallman[3], H. Kantarjian[4], K. Colby[11], B. Fan[11], M. Goldwasser[11], M. Prahl[11], S. Agresta[11], R.M. Stone[12]
[1]Institut Gustave Roussy, Villejuif, France, [2]University of Colorado Cancer Center, Aurora, [3]Memorial Sloan-Kettering Cancer Center, New York, [4]University of Texas MD Anderson Cancer Center, Houston, [5]Massachusetts General Hospital Cancer Center, Boston, [6]Weill Cornell Medical College, New York, [7]University of Texas Southwestern Medical Center, Dallas, [8]Sylvester Comprehensive Cancer Center, Miami, [9]Sarah Cannon Research Institute, Nashville, [10]Robert H. Lurie Comprehensive Cancer Center, Chicago, [11]Agios Pharmaceuticals, Cambridge, [12]Dana-Farber Cancer Institute, Boston, United States

Background: Somatic mutations in the metabolic enzymes isocitrate dehydrogenase (IDH) 1 and 2 occur in a spectrum of solid and hematologic malignancies. Mutant IDH1/2 in cancer cells results in the neomorphic production of the oncometabolite, D-2-hydroxyglutarate (2-HG), which impairs cellular differentiation via an epigenetic mechanism. AG-120 is a first-in-class, oral, potent, reversible and selective inhibitor of mutated IDH1 protein. In IDH1-mutant primary human blast cells cultured *ex vivo*, AG-120 lowered 2-HG and restored cellular differentiation. We report preliminary results from the ongoing, first-in-human, phase 1, open-label, single-arm study of AG-120 (NCT02074839).
Aims: Primary objectives are to evaluate the safety, tolerability, and maximum tolerated dose (MTD), pharmacokinetics (PK), pharmacodynamics (PD), and clinical activity.
Methods: Patients with advanced, IDH1-mutant, hematological malignancies including relapsed or refractory (RR) acute myeloid leukemia (AML), elderly untreated AML who are not candidates for standard therapy, and recurrent or refractory myelodysplastic syndromes, are eligible to receive continuous, single-agent, oral AG-120 once (QD) or twice (BID) daily in 28-day cycles. Informed consent is obtained prior to entry. Sequential cohorts are being enrolled, with expansion cohorts planned. Blood and bone marrow samples are collected for PK/PD assessment. Response is assessed on Days 15, 29, and 57, and every 56 days thereafter. Objective responses are investigator assessed using International Working Group criteria.

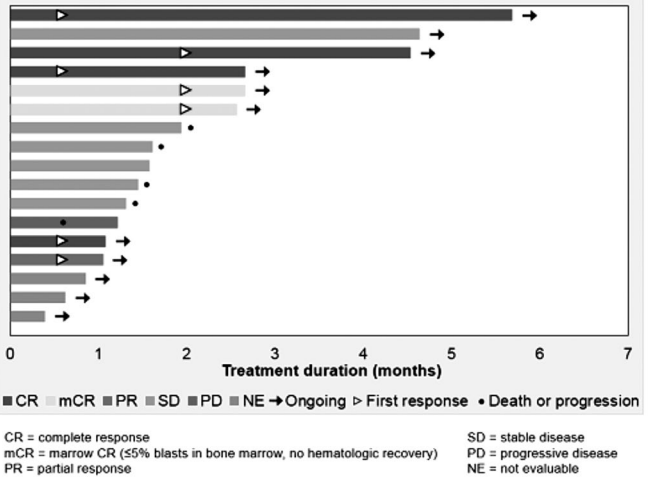

Figure 1. Duration of AG-120 treatment and best overall response.

Results: As of 17 October 2014, 17 patients had received AG-120 and 11 remained on study. All had RR AML (8 men/9 women), median age 73 years (range, 42-87) and median number of prior chemotherapy regimens 2 (range, 1-5). Doses administered were 100 mg BID (n=4), 300 mg QD (n=4), 500 mg QD (n=4), and 800 mg QD (n=5). Median treatment duration at data cut-off was 1.6 months (range, 0.4-5.7). Therapy has been well tolerated and the MTD has not yet been reached. Fourteen patients experienced adverse events (AEs), the most common (>20% of patients) were nausea, fatigue, dyspnea, vomiting, pyrexia, and cough. Serious AEs occurred in 8 patients: 1 differentiation syndrome, 1 tongue edema and grade 3 QT prolongation (dose-limiting toxicity; 800 mg QD), and 6 non-drug-related deaths, 5 of which occurred after discontinuation of AG-120 due to progressive disease and 1 due to disease-related intracranial hemorrhage while on treatment. Preliminary PK analyses showed high plasma expo-

sure and drug accumulation following oral administration and a mean half-life of >32 hours. PD analyses showed up to 98% inhibition of plasma 2-HG at all dose levels. Objective responses were observed in 7/14 efficacy-evaluable subjects (4 CR, 2 marrow CR, 1 PR), with durable responses of up to 5.7 months, and all responders remain on treatment (Figure 1). Six patients had stable disease and 1 had disease progression. Consistent with preclinical data, responses were associated with differentiation of myeloblasts into mature cell types. Dose escalation continues and updated safety, efficacy, and PK/PD data will be presented. As of 20 February 2015, 41 patients have been treated in 5 dose escalation cohorts from 100 mg BID to 1200 mg QD.

Summary and Conclusions: AG-120, a first-in-class, oral, potent, selective inhibitor of mutant IDH1, has been well tolerated to date. Durable single-agent responses of up to 5+ months have been observed. IDH1 inhibition resulted in reduced 2-HG and profound cell differentiation effects in some patients. Updated data from this ongoing study will be presented.

P564

TOSEDOSTAT PLUS LOW DOSE CYTARABINE COMBO INDUCES A HIGH RATE OF RESPONSES THAT CAN BE PREDICTED BY GENETIC PROFILING IN AML: FINAL RESULTS OF A PHASE II MULTICENTER STUDY

Maria Misericordia, Clinica Ematologica, Centro Trapianti e Terapie Cellulari "Carlo Melzi" DISM, Udine, [8]Genova University, Hematology, Genova, [9]Urbino University, Institute of Biomathematics, Urbino, Italy

Background: Elderly patients with acute myeloid leukemia (AML) have an extremely poor outcome. In addition, intensive induction chemotherapy is often unsuitable. Tosedostat is a new, orally bioavailable inhibitor of members of the M1 and M17 classes of aminopeptidases that includes the zinc-dependent aminopeptidases. Tosedostat was proven to be effective as single agent, with a manageable safety profile, in both de novo and relapsed AML.

Aims: We assumed that the addition of tosedostat to low-dose cytarabine may improve the response rate and remission duration over what is expected with chemotherapy or tosedostat alone.

Methods: This was a phase II, prospective, multicenter study, designed according to Fleming's method. Fixing the lowest acceptable rate as 10% and the successful rate as 25%, with a significance level a=0.05 and a power 1-b=0.80, the sample size was estimated in 33 patients. Thirty-three patients (median age 75 years) received Tosedostat 120 milligrams orally once daily from day 1 to day 240, coupled with intermittent low-dose cytarabine given subcutaneously at 20 milligrams twice/day from day 1 to day 10 of each cycle. Courses of cytarabine were repeated every 4 weeks in the absence of disease progression or unacceptable toxicity, up to 8 cycles. To identify possible biomarkers associated to sensitivity/resistance, global gene expression profiling (GEP, Affymetrix Transciptome Array 2.0) was performed on purified AML cells obtained from 29 patients.

Results: Median white blood cell count at diagnosis was $3.05x10^9$/l (range: $0.26\text{-}24.53x10^9$/l). Seventeen out of 33 patients had an intermediate karyotype, 13/33 an unfavorable karyotype and 3/33 were not evaluable. Sixteen patients had a *de novo* AML, whereas 17 had a secondary AML. Induction-period mortality was 12%, with 4 deaths occurring in aplasia. According to intent-to-treat, the CR rate was 45.4% (15/33 patients). Interestingly, 3/33 additional patients obtained a partial response, translating in an impressive overall response rate of 54.4%. In addition, 4/33 patients remained in stable disease for a median time of 9 months (range: 4-14). Seven patients did not respond at all and died with progressive disease after having received a median of 2 cycles of cytarabine and 45 days of tosedostat. In responding patients, the median time for the achievement of best response was 74 days (range 22-145). Statistical analysis showed that responding patients (CR+PR) had a longer median overall survival than non-responders (P=0.018). Ten out of 18 (55%) responding patients are still in remission (8CR, 2 PR) after a median follow-up of 319 days (range: 47-548); 2 patients are still alive with stable disease. Twenty-one patients died [while in aplasia (4), due to resistant disease (7) or due to progressive disease (8)] after a median CR duration of 5 months (2-17). As far as GEP analysis was concerned, we studied 29 cases and identified a molecular signature associated with the clinical response (CR *vs* no CR). Based on that, an algorithm to predict the clinical response was developed and validated.

Summary and Conclusions: The tosedostat and low-dose cytarabine combo produced a CR rate superior to what expected (45.4% *versus* 25%), and thus met the primary endpoint of study. Moreover, the achievement of CR could be efficiently predicted by the gene expression pattern. Further, potential biomarkers were identified by GEP. The study was registered at European Union Drug Regulating Authorities Clinical Trials (EudraCT) n.2012-000334-19.

Acknowledgements: Chroma Therapeutics and CTI Biopharma are gratefully acknowledged for providing Tosedostat for the patients free of charge.
The study was supported in part by AIL Pesaro Onlus.

LOW-DOSE LENALIDOMIDE AND CYTARABINE COMBO PRODUCES A HIGH COMPLETE REMISSION RATE THAT CAN BE PREDICTED BY GENETIC PROFILING IN AML PATIENTS AGED ≥70 YEARS: FINAL RESULTS OF A PHASE II STUDY

A. Isidori[1,*] F. Ferrara[2], F. Di Raimondo[3], F. Loscocco[1], F. Fuligni[4], A. Gazzola[4], M. Rossi[4], A. Laginestra[4], M.R. Caraci[3], V. Zammit[3], E. Spina[3], G. Sparaventi[1], L. Malerba[1], M. Rocchi[5], E. Gabucci[1], C. Clissa[1], P.P. Piccaluga[4], G. Visani[1]
[1]Azienda Ospedaliera Ospedali Riuniti Marche Nord, Hematology and Stem Cell Transplant Center, Pesaro, [2]Cardarelli Hospital, Hematology, Napoli, [3]Ferrarotto Hospital, Catania University, Hematology, Catania, [4]Department of Experimental, Diagnostic and Specialty Medicine, Hematopathology section, S.Orsola-Malpighi Hospital, Bologna University, Bologna, [5]Urbino University, Institute of Biomathematics, Urbino, Italy

Background: Outcome for patients aged ≥70 years with acute myeloid leukemia (AML) is extremely poor. Intensive induction chemotherapy is frequently unsuitable. Thus, novel therapies are needed.

Aims: We designed a prospective phase II study to assess the efficacy of the low-dose lenalidomide and cytarabine combo in patients with AML aged ≥70 years.

Methods: The study was designed according to the MiniMax design. The primary outcome was the complete remission rate (CR+CRi) according to the SWOG criteria. Fixing the lowest acceptable rate (P0) as 17% and the successful rate (P1) as 30%, with a significance level alpha=0.05 and a power 1-beta=0.90, the sample size was estimated to be 66 patients. Sixty-six patients (median age 76 years) were enrolled in the study. Median white blood cell count at diagnosis was $3.9x10^9$/l (range: $0{,}45\text{-}49{,}7x10^9$/l). Thirty-six out of 66 patients had an intermediate karyotype, 25/66 an unfavorable karyotype and 5/66 were not evaluable. Twenty-eight patients had a *de novo*, whereas 38 patients had a secondary AML. Patients received low-dose lenalidomide (10 mg/day orally, days 1-21) and low-dose cytarabine (20 mg/m^2 twice daily subcutaneously, days 1-15). Therapy was repeated every 6 weeks, up to 6 cycles. To identify possible biomarkers associated to sensitivity/resistance, global gene and miRNA expression profiling (Affymetrix Transciptome Array 2.0) was performed on purified AML cells obtained from 26 patients.

Results: After the first cycle of therapy, 8/66 patients died in documented aplasia. One patient died during cycle 1 (acute heart failure). The cumulative induction-period mortality was 13%. Three patients are too early. According to intent-to-treat, the CR rate was 36.3% (24/66 patients), the PR rate was 3% (2/66) with an overall response rate (ORR) of 39.3%. Four patients died in CR, one in PR, whereas 6/26 responding patients are still in CR after a median follow-up 358,5 days (range: 89-1787). The remaining 15 patients who achieved a CR/PR relapsed after a median time of 12 months and died due to progressive disease. Statistical analysis showed that responding patients had a longer median overall survival than non-responders (P <0.0001). Interestingly, cytogenetic risk and bone marrow blats at diagnosis were not predictive of CR. Conversely, by studying the miRNA and gene expression profile in 26 patients, we identified a molecular signature, including 306 genes and 3 miRNA associated with the clinical response (CR *vs* no CR). Noteworthy, the involved genes belonged to relevant functional categories such as NF-kB cascade, protein kinase signaling and immune response. Based on the expression of such genes/miRNA, treatment response could be predicted with high accuracy (88.5%, 23/26 samples correctly classified), with 87% sensitivity, 91% specificity, and 93% positive predictive value for responders. Moreover, we developed an algorithm to predict response based on the expression of 16 genes only, that correctly identified 14/14 CR patients.

Summary and Conclusions: The low-dose lenalidomide and cytarabine combo produced a CR rate superior to what expected when designing the trial (36.3% *versus* 30%), and thus met the primary endpoint of study. Moreover, the achievement of CR could be efficiently predicted by the gene expression pattern. The combo warrants further investigation in a randomized, phase III trial. The study was registered at EMA with the EUDRACT no 2008-006790-33.

Acknowledgements: Celgene is acknowledged for providing Lenalidomide for the patients.
The study was supported in part by AIL Pesaro Onlus.

OVERALL SURVIVAL (OS) AND CLINICAL OUTCOMES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) TREATED WITH AZACITIDINE (AZA) OR INTENSIVE CHEMOTHERAPY (IC) IN THE AZA-AML-001 STUDY

H. Döhner[1,*] D. Selleslag[2], J. Cavenagh[3], J.F. Seymour[4], M. Minden[5], C. Récher[6], G. Martinelli[7], J. Mayer[8], P. Font López[9], H.-J. Kim[10], W.-C. Chou[11], A. Kew[12], Y.H. Min[13], S. Songer[14], L.M. Lucy[14], C. Beach[14], H. Dombret[15]
[1]Universitätsklinikum Ulm, Ulm, Germany, [2]Algemeen Ziekenhuis Sint-Jan, Brugge, Belgium, [3]Barts Health NHS Trust, London, United Kingdom, [4]Peter

MacCallum Cancer Centre, East Melbourne, Australia, [5]Princess Margaret Cancer Centre, Toronto, Canada, [6]Institut Universitaire du Cancer de Toulouse Oncopole, Centre Hospitalier Universitaire de Toulouse, Toulouse, France, [7]Institute of Hematology and Medical Oncology "L. e A. Seragnoli",, Bologna, Italy, [8]Fakultni Nemocnice Brno, Brno, Czech Republic, [9]Hospital General "Gregorio Maranon", Madrid, Spain, [10]College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of, [11]National Taiwan University Hospital, Taipei, Taiwan, ROC, [12]Queen Elizabeth II Health Services Centre, Halifax, Canada, [13]Yonsei University College of Medicine, Seoul, Korea, Republic of, [14]Celgene Corporation, Summit, United States, [15]Hôpital Saint Louis, Institut Universitaire d'Hématologie, University Paris Diderot, Paris, France

Background: There is no universally accepted approach to AML treatment (Tx) for older pts. IC is recommended for pts aged ≥60 years with favorable prognostic features (NCCN guidelines, 2014). However, many older pts can not tolerate IC. Such pts often receive low-dose cytarabine (LDAC), which is associated with a median OS of only ~5 months (Burnett, *Cancer*, 2007; Kantarjian, *JCO*, 2012). There is an unmet need for tolerable Tx options that prolong OS to a similar or greater extent than IC. The phase 3, randomized AZA-AML-001 study compared AZA with conventional care regimens (CCR) in older pts with AML. Before randomization, pts were preselected to receive 1 of 3 CCR per investigator choice of preferred Tx option: IC, LDAC, or best supportive care only. Pts were then randomized to receive AZA or CCR and received their preselected Tx.
Aims: To compare OS and clinical outcomes with AZA *vs* IC in the subgroup of pts in AZA-AML-001 preselected to receive IC before randomization.
Methods: Pts aged ≥65 years with newly diagnosed *de novo* or secondary AML (>30% bone marrow [BM] blasts) and ECOG PS 0-2, WBC ≤15x10^9/L, and intermediate- or poor-risk cytogenetics were enrolled. Pts received IC (cytarabine IV x7days (d)+an anthracycline IV x3d, with ≤2 subsequent cycles) or AZA (75 mg/m^2/d SC x7d/28d cycle). OS and 1-year survival were estimated using Kaplan-Meier methods. OS was compared between Tx groups by log-rank test. Hazard ratios (HRs) and 95% CI are from an unstratified Cox proportional hazards model. Rates and durations of complete remission (CR) and CR with incomplete blood count recovery (CRi) (IWG 2003), and RBC transfusion independence (TI) in pts transfusion-dependent at baseline, were assessed. Rates of grade 3-4 treatment-emergent adverse events (TEAEs), defined as new or worsening AEs during Tx, were assessed. To account for differences in Tx exposure, TEAE incidence rates (IR) per 100 pt-years of Tx exposure are reported.
Results: Of all pts in AZA-AML-001 (N=488), 87 (18%) were preselected to receive IC (AZA n=43, IC n=44). Median number of Tx cycles of AZA was 8 (range 1-24) and of IC was 2 (1-3). At baseline in the AZA and IC groups, median ages were 71 yrs (AZA range 65-79, CCR 65-81); 16% and 18% of pts, respectively, had ECOG PS of 2; median BM blasts were 72% (7-100%) and 70% (6-100%); median WBC count was 3.8x10^9/L (1-15) and 2.2x10^9/L (1-90); and 35% and 34% of pts had poor-risk cytogenetics. Median OS was comparable in the AZA and IC groups: 13.3 *vs* 12.2 months, respectively (HR=0.85 [95% CI 0.52, 1.38], p=0.5032) (Figure 1). One-year survival with AZA was 55.8% (95% CI 39.8%, 69.1%) *vs* 50.9% (35.2%, 64.6%) with IC (Δ4.9%; 95% CI -16.2%, 26.0%). In the AZA and IC groups, respectively, 30% and 36% of pts attained CR, and 12% and 11% achieved CRi. Median durations of CR+CRi in the AZA and IC groups were 17.3 (95% CI 3.7, not reached) and 19.8 (8.2, 26.3) months, respectively. RBC TI rates with AZA *vs* IC were 57% *vs* 35%, respectively. Proportions of pts with grade 3-4 TEAEs and [IRs] in the AZA and IC groups, respectively, were: anemia 12% *vs* 14% [14 *vs* 45]; neutropenia 30% *vs* 33% [37 *vs* 99]; febrile neutropenia 33% *vs* 31% [40 *vs* 92]; thrombocytopenia 23% *vs* 21% [29 *vs* 64]; and (any) infections 49% *vs* 50% [60 *vs* 149].

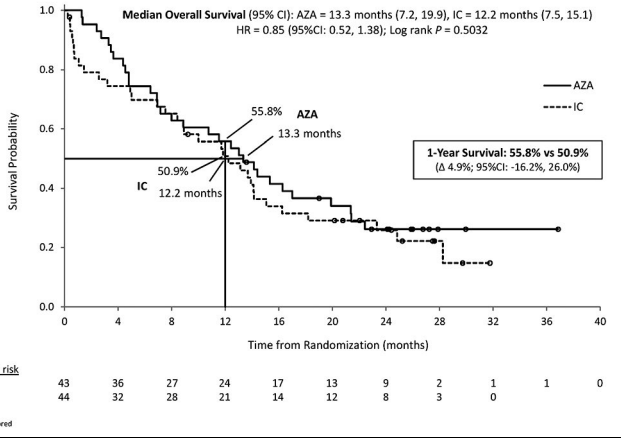

Figure 1. Overall survival in patients preselected to intensive chemotherapy.

Summary and Conclusions: AZA and IC were associated with comparable OS, 1-year survival, and rate and duration of remission in these older pts with AML. AZA was better tolerated than IC, with lower incidence rates of hematologic TEAEs and infections. AZA may be a good option for older pts with AML who are fit for IC but choose not to undergo high-intensity Tx.

UPDATED RESULTS FROM A PHASE 2 STUDY OF PRACINOSTAT (P) IN COMBINATION WITH AZACITIDINE (AZA) IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

G. Garcia-Manero[1,*] E. Atallah[2], S. Khaled[3], M. Arellano[4], M. Patnaik[5], V. Esquibel[6], K. Wood[6], B. Medeiros[7]
[1]Department of Leukemia, University of Texas, MD Anderson Cancer Center, Houston, [2]Department of Hematology/Oncology, Medical College of Wisconsin, Milwaukee, [3]Dept of Hematology/Hematopoietic Cell Transplantation, City of Hope, Duarte, [4]Winship Cancer Institute, Emory University, Atlanta, [5]Department of Hematology, Mayo Clinic, Rochester, [6]MEI Pharmaceuticals Inc, San Diego, [7]Division of Hematology/Oncology, Stanford Cancer Center, Stanford, United States

Background: Elderly AML patients, deemed unsuitable for intensive therapy, have limited treatment options. We previously reported a high initial response rate in the first stage of a phase 2 study of P plus AZA in this population (ASH 2014). This report presents updated results, which include additional patients.
Aims: The study was designed to evaluate the efficacy and safety of the combination of pracinostat and azacitidine in elderly patients with AML
Methods: Eligibility includes previously untreated AML (≥ 20% bone marrow blasts), age ≥ 65 years, unsuitable for intensive therapy due to co-morbidities and/or AML related features, and intermediate or high-risk cytogenetics. Study therapy includes P, 60 mg p.o. 3 alternate days/week for 3 weeks plus AZA, 75 mg/m^2 /day 1-7 or day 1-5 and 8-9 either s.c. or i.v. with cycles repeated every 28 days until progressive disease, lack of response, or intolerance. The primary endpoint is CR+CR_i+ morphologic leukemia free state (MLFS) per IWG criteria. Response assessments occur at the end of cycle 1 or 2 then every other cycle or when clinically indicated. A Simon 2-stage statistical design is utilized with the following assumptions: null=0.10, alternate=0.25, α=0.10, power=0.90. Stage 1 n=27 and total stage 2 n=40.
Results: Between 12/2013 and 12/2014 50 patients from 15 study sites were enrolled. At this time, 47 are evaluable for efficacy. Baseline disease characteristics for all patients include: median age 75 (range 66-84); 32 *de novo* AML, 13 evolved from AHD, 5 treatment-related; 28 intermediate-risk and 20 high-risk cytogenetics and 2 unknown; baseline bone marrow blast counts ranged from 20% to 89% with a median of 40%. The primary endpoint of CR +CRi +MLFS has been observed in 22/47 evaluable patients (47%) to date, including 14/47 (30%) CR. Current median duration of response is 15+ weeks (range: 1- 48+ weeks). Disease progression has not been observed in any responders. 30 patients continue on study (range 11- 52+ weeks). The 60-day all-cause mortality rate is 10% (5/50). Median overall survival has not been reached. Treatment emergent adverse events (TEAEs) Grade ≥3 seen in >5% of patients: febrile neutropenia 30%; thrombocytopenia 22%; neutropenia 10%; cellulitis 10%; anemia 8%; fatigue 8%; sepsis 6%, and pancytopenia 6%. TEAE's leading to study therapy discontinuation: peripheral motor neuropathy (1), parainfluenza (1), atrial fibrillation/prolonged QTc/(1), subdural hematoma after a fall (1), and sepsis (3).
Summary and Conclusions: P plus AZA produces a high rate of durable responses in this AML population. Updated data, including EFS and OS estimates, will be presented at the meeting. These phase 2 data warrant definitive evaluation in a phase 3 study.

P569

AG-221, AN ORAL, SELECTIVE, FIRST-IN-CLASS, POTENT INHIBITOR OF THE IDH2 MUTANT ENZYME, INDUCED DURABLE RESPONSES IN A PHASE 1 STUDY OF IDH2 MUTATION-POSITIVE ADVANCED HEMATOLOGIC MALIGNANCIES

C. DiNardo[1,*] E.M. Stein[2], J.K. Altman[3], R. Collins[4], D.J. DeAngelo[5], A.T. Fathi[6], I. Flinn[7], A. Frankel[8], R.L. Levine[2], B.C. Medeiros[9], M. Patel[10], D.A. Pollyea[11], G.J. Lurie Comprehensive Cancer Center, Chicago, [4]University of Texas Southwestern Medical Center, Dallas, [5]Dana-Farber Cancer Institute, [6]Massachusetts General Hospital Cancer Center, Boston, [7]Sarah Cannon Research Institute, Nashville, [8]University of Texas Southwestern Medical Centre, Dallas, [9]Stanford Comprehensive Cancer Center, Stanford, [10]Florida Cancer Specialists SCRI, Sarasota, [11]University of Colorado Cancer Center, Aurora, [12]Weill Cornell Medical College, New York, [13]Sylvester Comprehensive Cancer Center, Miami, [14]Agios Pharmaceuticals, Cambridge, United States, [15]Institut Gustave Roussy, Villejuif, France

Background: Somatic mutations in the metabolic enzymes isocitrate dehydrogenase (IDH) 1 and 2 occur in a spectrum of solid and hematologic malignancies. Mutant IDH1/2 in cancer cells results in the neomorphic production of the oncometabolite, D-2-hydroxyglutarate (2-HG), which impairs cellular differentiation via an epigenetic mechanism. AG-221 is a first-in-class, oral, potent, selective, reversible inhibitor of mutant IDH2. Data from the ongoing, first-in-human, phase 1, open-label, dose escalation study (NCT01915498) are reported.
Aims: To assess safety and define the maximum tolerated dose (MTD) of AG-221 and inform the dosing schedule for expansion cohorts and future phase 2 studies. Secondary objectives include preliminary evaluation of clinical efficacy and measurement of pharmacokinetic/pharmacodynamic (PK/PD) markers and cellular differentiation.
Methods: Patients with IDH2 mutation-positive advanced hematologic malignancies (acute myeloid leukemia [AML] or myelodysplastic syndromes) receive oral AG-221 once or twice daily in continuous 28-day cycles. Informed consent is obtained prior to entry. Dosing began at 30 mg twice daily and increased in subsequent cohorts. Response is determined by blood and bone marrow examinations according to International Working Group criteria. PK/PD analyses of AG-221 and 2-HG are conducted.
Results: As of 1 Oct 2014, 73 patients have received AG-221 (median age 67 years [range, 33-90], 53% men, 75% with relapsed/refractory [RR] AML) and 38 (52%) remain on therapy, with 45 (62%) evaluable for efficacy. Median treatment duration is 1.9 (range, 0.1-8.8) months, and 18 patients have been on study for ≥4 months. There are 10 dose cohorts, MTD has not been reached, and the highest daily cumulative dose is 300 mg. The most common adverse events (AEs) were nausea, pyrexia, diarrhea and fatigue, with 81% of patients experiencing any AE, including AEs that were not related to AG-221. There have been 4 AEs leading to discontinuation. The majority of serious AEs (SAEs) were disease-related, with 13 patients experiencing 21 treatment-related SAEs, including leukocytosis in 3 patients. Of 11 deaths reported, 2 were assessed as possibly related to treatment. AG-221 demonstrated adequate plasma exposure, with a mean half-life >40 hours. After multiple AG-221 doses, plasma 2-HG was reduced from the elevated levels observed at baseline, with inhibition of up to 98% in subjects with the IDH2-R140Q mutation. Objective responses were observed in 25 (56%) efficacy-evaluable patients, defined as having Day 28 bone marrow biopsy information available (6 CR, 4 marrow CR, 5 CR with incomplete platelet or hematologic recovery, 10 PR). There were durable responses of up to 8.8 months and 5 responders proceeded to transplant (Figure 1). As of 20 Feb 2015, 145 patients have been enrolled, 104 in dose escalation and 41 in four expansion arms of 1) age ≥60 years (y) with RR AML, or any age if relapsed after stem cell transplant (SCT); 2) age <60 y with RR AML excluding relapse after SCT; 3) age ≥60 y with untreated AML declining standard therapy; 4) any hematologic malignancy not eligible for arms 1-3.

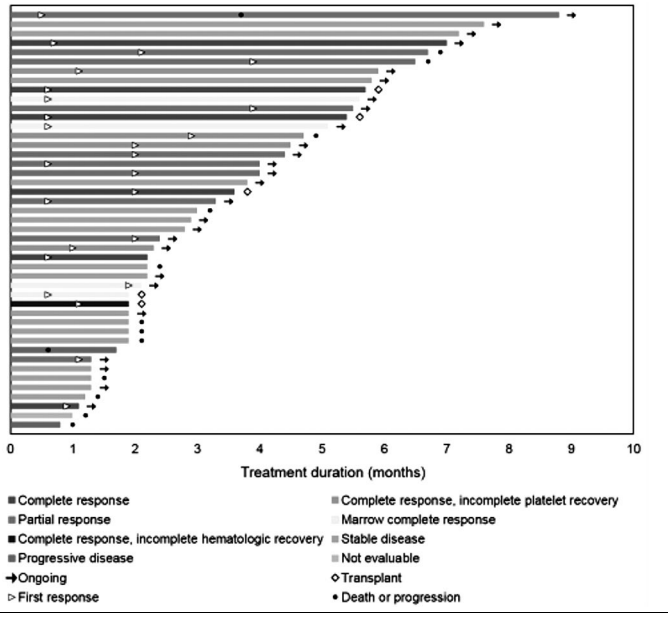

Figure 1. Duration of AG-221 treatment and best overall response, all efficacy evaluable patients as of 1 October 2014.

Summary and Conclusions: In patients with IDH2 mutation-positive advanced hematologic malignancies, AG-221 therapy was well tolerated, displayed favorable PK/PD properties, and resulted in durable remissions of up to 8.8 months. These results continue to validate mutant IDH2 as a therapeutic cancer target and demonstrate the safety of AG-221. Updated clinical results will be presented.

P570

ORAL TETRA-ARSENIC TETRA-SULFIDE FORMULA IS BETTER THAN INTRAVENOUS ARSENIC TRIOXIDE IN TREATING ACUTE PROMYELOCYTIC LEUKEMIA: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

G.-L. He[1,*] Y.-J. Chang[1], H.-H. Zhu[1], S.-Z. He[2], X.-J. Huang[1]
[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, [2]School of Public Health, Sun Yat-sen University, Guangzhou, China

Background: The chromosomal aberration t(15;17) plays a central role in the development of acute promyelocytic leukemia (APL) and results in the formation of PML/RARa fusion protein. Arsenic trioxide (ATO) and all-trans retinoic acid (ATRA) target the PML and RARa proteins respectively, which made APL changes from a highly fatal disease to a highly curable disease. However, ATO must be intravenously administered in a hospital setting. The development of an orally active arsenic-containing formulation with comparable efficacy and adverse effects is highly desirable. Increasingly clinical trials and articles demonstrated that an oral tetra-arsenic tetra-sulfide (As4S4) treatment alone can serve as a highly effective and safe remission induction and maintenance therapy.
Aims: To estimate the efficacy and safety of Oral As_4S_4 -containing formula named the Realgar-*Indigo naturalis* formula (RIF), combined with ATRA therapy in APL.
Methods: Cochrane Library, PUBMED, EMBASE, Chinese National Knowledge Infrastructure, and WanFang Data were searched for randomized controlled trials (RCT). Oral RIF+ATRA (RIF group) *versus* intravenous arsenic trioxide (ATO)+ATRA (ATO group) as treatment of APL, the complete remission (CR) rate and the incidences of adverse events of two groups were compared. Meta-analysis was conducted to generate combined odds ratios (ORs) with 95% confidence intervals (CIs) by RevMan 5.2.
Results: Data from 5 RCTs involving 343 APL patients were identified. For the CR rate, the RIF group and the ATO group showed a similar efficacy in the different treatments (95.57% *vs* 93.33%). For CR rate of RIF group *vs* CR rate of ATO group, ORs increased with the year of clinical trials (2008,OR:0.7; 2011,OR:2.97 and 2013 OR:3.72), which suggested RIF as the first-line treatment of APL stabilized and improved year by year. Besides, time to CR, 2-year DFS, 3-year DFS and mortality also showed that oral RIF+ ATRA had effect no worse than intravenous ATO+ATRA. At the end of consolidation therapy, the PML-RARα transcript was undetectable in any patient in both the RIF group and ATO group (two RCT were involved which was 113 patients). Notably, although there were no statistical difference in 3 articles which mentioned adverse events affecting the liver, meta-analysis suggested remarkable difference: happening of hepatic dysfunction in RIF group were lower than ATO group (OR=0.57, 95%CI 0.34-0.95, P=0.03). Moreover, rate of headache and infection in RIF group were also lower than ATO group, (OR=0.06, 95%CI 0.01-0.46, P=0.007) and (OR=0.34, 95%CI 0.14-0.32, P=0.02), respectively. Means of medical cost for postremission treatment in 15 months was 10701.9 RMB for RIF group, compared to 49957.5 RMB for ATO group. The cost of RIF group was only less than a quarter to ATO group (P<0.00001). The rates of other events were similar in the two groups.
Summary and Conclusions: Oral RIF plus ATRA is not inferior to intravenous ATO plus ATRA as treatment of APL. RIF as the first-line treatment of APL stabilized and improved year by year.The security of oral RIF is better than intravenous ATO, and the maintenance treatment costs of RIF is lower than ATO therapy in APL. PML-RARα transcript for the treatment of RIF+ATRA was 100%, suggested RIF+ATRA may be considered as a postremession treatment. It may be considered as a new strategies therapy in APL: oral RIF Replace intravenous ATO.

Acute myeloid leukemia - Clinical 4

LATE RESPONSES AND OVERALL SURVIVAL (OS) FROM LONG TERM FOLLOW UP OF A RANDOMIZED PHASE 2 STUDY OF SGI-110 (GUADECITABINE) 5-DAY REGIMEN IN ELDERLY AML WHO ARE NOT ELIGIBLE FOR INTENSIVE CHEMOTHERAPY

P. Kropf[1,*] E. Jabbour[2], K. Yee[3], C. O'Connell[4], R. Tibes[5], G.J. Roboz[6], K. Walsh[7], N.A. Podoltsev[8], M. Savona[9], J.-P. Issa[10], Y. Hao[11], S. Naim[11], M. Azab[11], H. Kantarjian[2]
[1]Fox Chase Cancer Center, Philadelphia, [2]University of Texas, MD Anderson Cancer Center, Houston, United States, [3]Princess Margaret Cancer Center, Toronto, Canada, [4]USC Keck School of Medicine, University of Southern California, Los Angeles, [5]Mayo Clinic Arizona, Scottsdale, [6]Weill Cornell/NY Presbyterian Medical Center, New York, [7]The Ohio State University, Columbus, [8]Yale University School of Medicine, New Haven, [9]Vanderbilt Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, [10]Fels Institute, Temple University, Philadelphia, [11]Astex Pharmaceuticals Inc., Pleasanton, United States

Background: SGI-110 (guadecitabine) is a novel hypomethylating agent (HMA) given subcutaneously (SC) and provides a prolonged *in vivo* exposure to its active moiety decitabine. We previously reported results from a multicenter randomized dose-response study of guadecitabine given at 2 doses in a 5-day regimen in 51 treatment naïve elderly AML patients not eligible for intensive chemotherapy (Yee *et al.*, 2014). There was no significant differences in overall composite complete response (CRc: CR+CRp+CRi) or safety between the two doses; however 14 patients were still on treatment at the time of the analysis.
Aims: To report on long term follow up including additional late responders and overall survival (OS).
Methods: Previously untreated elderly (≥65y) AML patients who were not eligible to receive intensive chemotherapy were randomized 1:1 to either 60 or 90 mg/m^2/d SC for 5-days in 28-day cycles. Overall composite CR (CRc: CR+CRp+CRi) was the primary endpoint. OS, and Safety were secondary endpoints.
Results: Fifty one patients were treated (24 and 27 on 60 and 90 mg/m2 doses respectively). Patients' characteristics were generally balanced between the 2 doses and represented a poor prognosis population: 73% were ≥75 y old; 47% had poor risk cytogenetics; 45% secondary AML; and 35% poor performance status (PS 2). No differences in either CRc or CR were observed in the previous and current analysis between the 2 treatment doses so data are presented here for the overall patients treated. Two additional patients developed CR with longer follow up (one on each arm) bringing total patients with CR to 19 (37%) and the total patients with CRc to 29 (57%): 19 CR; 7 CRi, and 3 CRp. Median follow up now reached 21.1 months (m) (range 17.2-30.0 m). Median number of cycles administered was 5 (range 1-24). Of the 29 CRc patients, the majority (20 or 69% of responders) occurred after at least 3 cycles and 6 of them (21% of responders) occurred after at least 6 cycles. Two late responders occurred after 8 and 9 cycles respectively. With death events reported in 34/51 patients (67%) the median OS is 10.5 m (95% CI: 5.3-18.1 m). The most common Grade≥3 Adverse Events (AEs) assessed as drug-related by investigators were neutropenia and thrombocytopenia (35% each), febrile neutropenia (20%), leukopenia (18%), and anemia (16%).
Summary and Conclusions: Unlike cytotoxic chemotherapy where responses tend to occur in the first 2 cycles, AML responses with HMA guadecitabine tend to occur after multiple cycles with potential for late responses even after 6 cycles. Clinical activity as demonstrated by 57% CRc including 37% CR and median OS of 10.5 months in this elderly poor prognosis population is promising. A Phase 3 trial in previously untreated AML patients not eligible for intensive chemotherapy has been initiated with 5-day regimen at 60 mg/m^2/d SC.

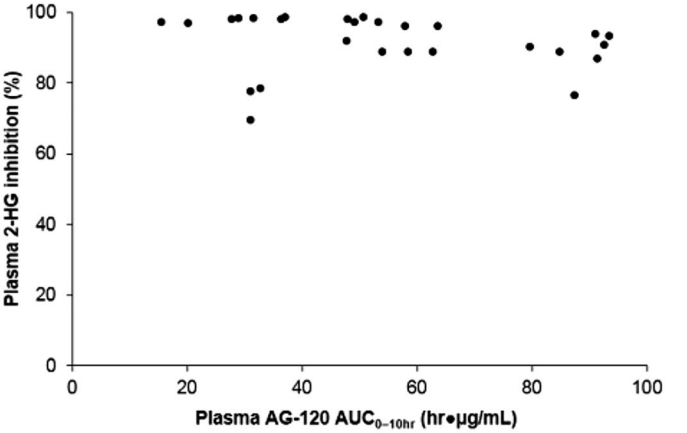
PHARMACOKINETIC/PHARMACODYNAMIC EVALUATION OF AG-120, A POTENT INHIBITOR OF THE IDH1 MUTANT PROTEIN, IN A PHASE 1 STUDY OF IDH1-MUTANT ADVANCED HEMATOLOGIC MALIGNANCIES

B. Fan[1,*] Y. Chen[1], F. Wang[1], K. Yen[1], L. Utley[1], M. Prahl[1], K. Colby[1], K. Straley[1], C. Bowden[1], S. Biller[1], S. Agresta[1], H. Yang[1]
[1]Agios Pharmaceuticals, Cambridge, United States

Background: Isocitrate dehydrogenase 1 and 2 (IDH1/2) are critical metabolic enzymes, catalyzing the oxidative decarboxylation of isocitrate to produce alpha-ketoglutarate (α-KG) in the citric acid cycle. Somatic IDH1/2 mutations occur in multiple solid and hematologic tumors, including acute myeloid leukemia. Mutant IDH1/2 proteins possess novel enzymatic activity, catalyzing the reduction of α-KG to produce the oncometabolite, D-2-hydroxyglutarate (2-HG). Accumulation of 2-HG drives multiple oncogenic processes, including impaired cellular differentiation. AG-120 is a first-in-class, oral, potent, reversible, selective inhibitor of the mutated IDH1 protein and has been shown to lower 2-HG levels and restore cellular differentiation in IDH1-mutant primary human blast cells cultured *ex vivo*. We conducted *in vivo* pharmacokinetic/pharmacodynamic (PK/PD) studies in an IDH1-mutant xenograft mouse model to assess the correlation between AG-120 exposure and 2-HG inhibition, and to predict exposure required for efficacy in humans. AG-120 is currently being assessed in a first-in-human, phase 1 study enrolling patients with IDH1-mutant, advanced hematologic malignancies (NCT02074839).
Aims: To compare early PK/PD data from the ongoing, first-in-human, phase 1 study of AG-120 with PK/PD data from *in vivo* and *in vitro* models.
Methods: The AG-120 phase 1, open-label, dose-escalation study includes evaluation of safety, tolerability, maximum tolerated dose (MTD) of AG-120, PK/PD (including 2-HG levels) and clinical activity. Single-agent AG-120 is administered orally once (QD) or twice (BID) daily in continuous 28-day cycles. Informed consent is obtained prior to entry. Patients included in this analysis received doses of 100 mg BID, 300 mg QD, 500 mg QD, and 800 mg QD (N=17). Blood was collected at multiple time points for determination of PK/PD. Concentrations of AG-120 and 2-HG in plasma samples were determined using qualified LC-MS/MS-based methods. Analyses were performed using WinNonLin®. PK/PD relationships for AG-120 were also evaluated *in vivo* in an HT1080 IDH1-R132C-mutant xenograft mouse model following oral administration, and potency was assessed *in vitro* in a number of cell lines carrying IDH1 mutations.
Results: Preliminary analyses demonstrated a favorable PK profile for AG-120 in humans following oral administration. Mean exposure was high at all dose levels tested, and AG-120 displayed a long plasma half-life (>32 hours). Following multiple AG-120 doses, substantial reductions in mean plasma 2-HG concentrations to levels seen in healthy volunteers were observed at all doses (up to 98% 2-HG inhibition). With exposure-response analysis, substantial and constant plasma 2-HG inhibition was achieved from multiple AG-120 100 mg BID doses at the AG-120 $AUC_{0\text{-}10hr}$ value of 15.5 hr•µg/mL (Figure 1). These findings showed good correlation with PK/PD analyses in the HT1080 IDH1-R132C mutant xenograft mouse model. *In vitro* studies showed potent inhibition of 2-HG production with AG-120 treatment in cells expressing IDH1-R132C, -R132H, and -R132S mutations but not in those expressing the IDH2-R140Q mutation, demonstrating selectivity for IDH1 mutations.



2-HG = D-2-hydroxyglutarate; IDH = isocitrate dehydrogenase

Figure 1. AG-120 plasma exposure and 2-HG inhibition correlation in patients with IDH1 mutations.

Summary and Conclusions: AG-120 demonstrated a favorable PK profile in humans following oral administration, with high plasma exposure and a long half-life, supporting QD dosing. AG-120 inhibited plasma 2-HG to within normal levels found in healthy volunteers. Inhibition of 2-HG production by AG-120 translated well from *in vitro* to *in vivo* and from pre-clinical models to humans.

P573

CHARACTERISATION OF TP53 MUTATIONS IN ADULT ACUTE MYELOID LEUKEMIA (AML) PATIENTS: MUTUAL EXCLUSIVITY WITH FLT3 AND NPM MUTATIONS STRONG ASSOCIATION WITH COMPLEX KARYOTYPE AND POOR OUTCOME

A. Ferrari[1,*] C. Papayannidis[1], C. Baldazzi[1], I. Iacobucci[1], E. Zuffa[1], M. Perricone[1], V. Robustelli[1], C. Venturi[1], M.T. Bochicchio[1], C. Sartor[1], M.C. Abbenante[1], V. Guadagnuolo[1], A. Padella[1], G. Simonetti[1], N. Testoni[1], E. Ottaviani[1], M. Cavo[1], G. Martinelli[1]
[1]University of Bologna, Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy

Background: AML is a heterogeneous disease with a variety of structural and numerical chromosomal and genetic alterations that provided important prognostic information capable to guide therapy and predict outcome. The reported *TP53* mutation rate in AML is low (2.1%). By contrast, the incidence of *FLT3* disruption is frequent (20-30%) and is an independent predictor of unfavourable outcome of acquired clinical resistance to *FLT3* inhibitors. *TP53* mutations in AML with a complex karyotype (CK) is higher (69-78%), and patients (pts) with complex karyotype (CK-AML) have generally a poor outcome but few data are available for association between the most common AML associated lesions such as *FLT3, NPM1, DNMT3A, IDH2* and *TP53* mutation or CK.
Aims: To investigate the frequency, the types of mutations, the associated cytogenetic, the molecular abnormalities, the correlation with known molecular alterations (*FLT3, NPM*, etc.) and the prognostic role *TP53* mutations in adult AML pts.
Methods: 236 adult AML pts AML pts with FAB-M0-7, miscellaneous cytogenetic abnormalities and normal karyotype (nK) were examined for *TP53* mutations using several methods, including Sanger sequencing, NGS (20/236) and HiSeq 2000 platform (38/236) and were correlated with cytogenetic analysis. Analysis was focused on coding sequences (RefSeq GRCh37/hg19 NG_017013.2).
Results: By PCR and subsequent Sanger sequencing, mutations of *TP53* were detected in 33 cases (14%). Nine pts revealed 2 mutations. 75.8% of all mutated pts had CK (25/33) by contrast the frequency of mutations was lower in "no CK-AML" pts (24.2%). Overall, between pts with CK, *TP53* mutation frequency is 43.1% (25/58). 38 *TP53* point mutations and 4 *TP53* deletions were found. M237I mutation was found in 4 pts. This mutation was described to severely compromised p53 expression level. The majority of alterations are located in the DNA binding domain (38/42; 90%), 9 of these were located in hot spot sites. Almost all mutations in coding regions were classified by the IARC database (http://p53.iarc.fr/TP53GeneVariations.aspx) as deleterious. WES analysis done in 38 pts (33 *TP53* wt and 5 pts *TP53* mutated) revealed no genes exclusively mutated in the 5 *TP53* mutated pts. 174 and 117 pts were analysed for concomitant presence of *TP53* mutations and *FLT3/NPM1* disruption/mutation revealing a significant relation between pts with *FLT3-ITD* or *NPM1* and *TP53* wild-type (p=0.015 and 0.009 respectively). Of note, alterations of *TP53* were significantly associated with poor outcome in terms of both overall survival (Figure 1A; P <0.0001) and disease free-survival and that *TP53* compare to *FLT3* mutations have worse impact on prognosis (Figure 1B; P <0.0001).

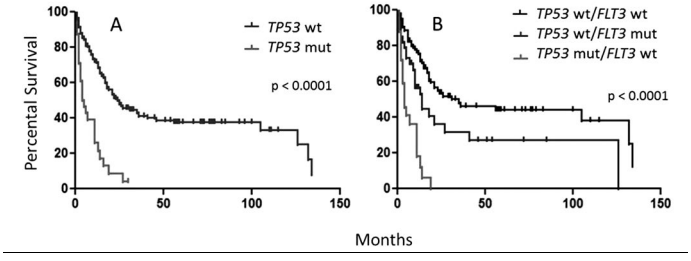


Figure 1. A) Overall survival in AML adult patients considering *TP53* mutational status alone and B) in combination with *FLT3* mutations.

Summary and Conclusions: Our data demonstrated that *TP53* mutations occur in 14% of AML with a higher frequency in the subgroup of CK-AML (p<0.0001-Fischer's exact test) and are mutually exclusive with *FLT3* and/or *NPM1*; they predicted to be deleterious and significantly correlated with worse prognosis and may confer resistance to conventional and innovative therapy. For these reasons, *TP53* mutation screening should be recommended at least in CK-AML pts.

P574

PHASE 1 TRIAL OF G-CSF, CLADRIBINE, CYTARABINE, AND DOSE-ESCALATED MITOXANTRONE (G-CLAM) IN ADULTS WITH NEWLY DIAGNOSED AML OR HIGH-RISK MDS

A. Anwar[1,*] A. Halpern[1], B. Scott[1], P. Becker[1], M. Othus[1], P. Hendrie[2], E. Ranker[3], A. Perdue[3], T. Chen[2], S. Buckley[1], K. Orlowski[1], M. Powell[1], F. Appelbaum[1], E. Estey[1], R. Walter[1]
[1]Fred Hutchinson Cancer Research Center, [2]University of Washington, [3]Seattle Cancer Care Alliance, Seattle, United States

Background: Standard-dose cyarabine with an anthracycline ("7+3") has remained the mainstay of induction chemotherapy for newly diagnosed AML. Recently, some randomized studies have demonstrated improved outcomes with regimens containing high-dose cytarabine, cladribine, or escalated doses of anthracyclines during induction.
Aims: Given these findings and the previously established tolerability and efficacy of G-CLAM in relapsed/refractory AML, we aimed to determine the maximum tolerated dose (MTD) of mitoxantrone within G-CLAM in adults with newly diagnosed AML or high-risk MDS (>10% blasts).
Methods: Eligibility included a treatment-related mortality (TRM) score of ≤6.9 (corresponding to a risk of early death with standard induction chemotherapy of ≤3%) and adequate organ function (LVEF ≥45%, creatinine ≤2.0 mg/dL, bilirubin ≤2.5-times upper limit of normal). Excluded were patients with concomitant illness with expected survival <1 year and those with active, uncontrolled infection. Cohorts of 6-12 patients were assigned to 1 of 4 total dose levels of mitoxantrone (12, 14, 16, or 18 mg/m^2/day on days 1-3, as compared to 10 mg/m^2/day used in standard-dose G-CLAM). Other drug doses were G-CSF 300 or 480 µg/day (for weight <76 kg *vs* ≥76 kg; days 0-5), cladribine 5 mg/m^2/day (days 1-5), and cytarabine 2 g/m^2/day (days 1-5). A second identical course of G-CLAM was given in the case of persistent disease. Dose-limiting toxicity (DLT) was defined as: 1) any grade 3 non-hematologic toxicity lasting >48 hours that resulted in >7 day delay of the subsequent treatment cycle, with the exception of febrile neutropenia or infection; 2) any grade ≥4 non-hematologic toxicity, with the exception of febrile neutropenia or infection or constitutional symptoms, if recovery to grade ≤2 within 14 days.
Results: 31 patients (20M, 11F), median age 58 (range: 27-77) years, median TRM score 2.83 (range: 0.15-5.54) with newly diagnosed AML (n=25), or high-risk MDS (n=6) and cytogenetically favorable (n=1), intermediate (n=23), and adverse (n=6) disease characteristics were enrolled (failed karyotyping: n=1; MRC criteria). One DLT occurred each at dose levels 3 and 4 (respiratory failure in both cases), establishing G-CLAM with mitoxantrone at 18 mg/m^2/day as the MTD in our study. One patient died within 28 days of treatment initiation from thrombocytopenia-related intracranial hemorrhage. Overall, 29/31 patients (93.5%, exact 95% confidence interval [CI]: 78.6-99.2%) achieved a CR (n=24 [77.4%, 95% CI: 58.9-90.4%]), CRp (n=2 [6.5%, 95% CI: 0.8-21.4%]), or CRi (n=3 [9.7%, 95% CI: 2.0-25.8%]) with 1-2 cycles of chemotherapy; one patient at dose levels 1 and 2 each had persistent disease. Only 2 patients required 2 cycles to best response. 26/29 (89.7%, 95% CI: 72.7-97.8%) had no evidence of residual disease by flow cytometry at best response. After multivariable adjustment, the CR rate was similar and overall response rate was favorable as compared to 300 patients treated with 7+3 on the SWOG S0106 trial (OR=1.25, p=0.64, and OR=4.68, p=0.045, respectively). Among responders, median times to an absolute neutrophil count ≥500 and a platelet count of 50,000 were 25 (range: 19-38) and 24 (range: 18-45) days, respectively. Besides infections and neutropenic fever, maculopapular rash, nausea, and hypoxia (fluid overload/infection-related) were the most common grade ≥3 adverse events.
Summary and Conclusions: G-CLAM with mitoxantrone up to 18 mg/m^2/day is feasible, well tolerated, and effective in newly diagnosed AML/high-risk MDS. A phase 2 study has been initiated.

P575

OVERALL SURVIVAL (OS) WITHOUT COMPLETE REMISSION (CR) IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): AZACITIDINE (AZA) *VS* CONVENTIONAL CARE REGIMENS (CCR) IN THE AZA-AML-001 STUDY

[1]Princess Margaret Cancer Centre, Toronto, Canada, [2]Hôpital Saint Louis, Institut Universitaire d'Hématologie, University Paris Diderot, Paris, France, [3]University of Alberta Hospital, Edmonton, Canada, [4]Peter MacCallum Cancer Centre, East Melbourne, Australia, [5]Dana-Farber Cancer Institute, Boston, United States, [6]Universitätsklinikum Leipzig, Leipzig, Germany, [7]Policlinico Umberto I - Università La Sapienza, Rome, Italy, [8]Royal Adelaide Hospital, Adelaide, Australia, [9]Kyungpook National University Hospital, Daegu, Korea, Republic of, [10]Tom Baker Cancer Centre, Calgary, Canada, [11]AOU San Luigi Gonzaga, Torino, Italy, [12]Asan Medical Center, Seoul, Korea, Republic of, [13]Celgene Corporation, Summit, United States, [14]Universitätsklinikum Ulm, Ulm, Germany

Background: The international phase 3 AZA-AML-001 study compared treatment (Tx) effects of AZA *vs* CCR on OS in older patients (pts) with AML; AZA prolonged median OS by ~4 months (10.4 *vs* 6.5 months, overall p=0.10) (Dombret, *Haematologica*, 2014:LB2433). AZA is known to improve OS *vs* CCR in pts with higher-risk myelodysplastic syndromes (HR-MDS) who have not achieved CR during Tx (Gore, *Haematologica*, 2013). MDS and AML are biologically and clinically distinct; it is unknown whether OS benefits in the absence of CR shown for AZA in HR-MDS extend to AML.
Aims: This *post hoc* exploratory analysis examined Tx effects on OS in subgroups of pts in AZA-AML-001 who did not attain CR on-study.
Methods: Eligible pts were aged ≥65 years with newly diagnosed AML with >30% bone marrow blasts, and with ECOG PS of 0-2, WBC count ≤15x10^9/L, and intermediate- or poor-risk cytogenetics. Before randomization, pts were preselected to receive 1 of 3 commonly used CCR per investigator choice of most appropriate Tx: intensive chemotherapy (IC; cytarabine IV x7days (d)+an anthracycline IV x3d, with ≤2 subsequent cycles), low-dose cytarabine (LDAC; 20mg SC BID x10d/28d cycle), or best supportive care only. Pts were then randomized to AZA (75 mg/m^2/d SC x7d/28d cycle), or to CCR and received their preselected Tx. CR (IWG 2003) was adjudicated centrally by an Independent Review Committee blinded to Tx assignment. Median OS and 1-year survival

were estimated using Kaplan-Meier methods. OS was compared between AZA and CCR groups by log-rank test stratified by ECOG PS and cytogenetic risk. OS was compared between AZA and LDAC and AZA and IC within preselection groups by unstratified log-rank test. Hazard ratios (HR) and 95% CIs are from a stratified Cox proportional hazards model. Results should be interpreted cautiously, as OS comparisons of pt subgroups defined by post-randomization outcomes may be biased. The current analysis did not control for time-dependency of response or interactions between Tx and response that could influence OS.
Results: Of all pts in AZA-AML-001 (AZA n=241, CCR n=247), 47 (19.5%) in the AZA arm and 54 (21.9%) in the CCR arm attained CR and were excluded from these analyses. Median OS in the remaining pts in the AZA *vs* CCR groups was 6.9 (95%CI: 5.1, 8.9) *vs* 4.2 (95%CI 3.2, 5.1) months, reflecting a 23% reduced risk of death with AZA; HR=0.77 (95%CI 0.62, 0.95), p=0.0171 (Figure 1). Estimated 1-year survival was 33.8% with AZA and 20.4% with CCR (difference 13.4% [95%CI 4.5%, 22.4%]). For pts with no CR who were preselected to receive LDAC, median OS with AZA (n=126) *vs* LDAC (n=120) was 8.1 *vs* 4.2 months, respectively (HR=0.75 [95%CI 0.57, 0.99], p=0.0390), and 1-year survival was 36.8% *vs* 16.4% (difference 20.4% [95%CI 9.4%, 31.3%]). For pts with no CR who were preselected to receive IC, median OS with AZA (n=30) *vs* IC (n=28) was 8.0 *vs* 7.5 months, respectively (HR=0.81 [95%CI 0.46, 1.44], p=0.4765), with 1-year survival of 40.0% *vs* 40.2%.

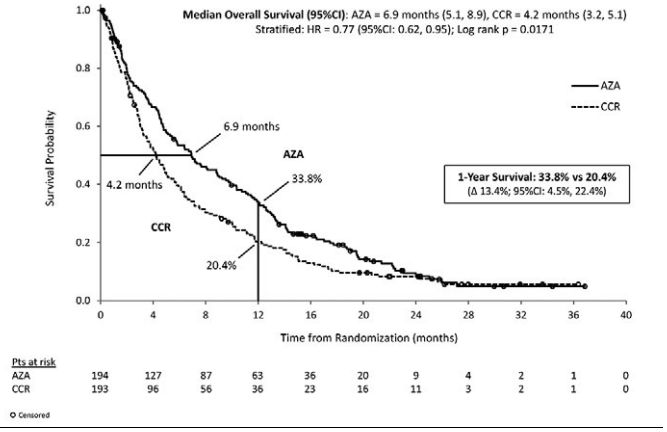

Figure 1. Overall survival for patients who did not achieve CR.

Summary and Conclusions: The relative benefit on OS seen with AZA *vs* CCR for all pts in AZA-AML-001 was maintained in pts who did not attain CR on-study. Similarly, median OS with AZA was almost twice that with LDAC in pts preselected to receive LDAC who did not achieve CR. Clinically meaningful improvements in 1-year survival rates with AZA *vs* CCR (13.4%) and with AZA *vs* LDAC (20.4%) in this analysis are similar to those reported for all AZA-AML-001 pts (12% and 15%, respectively; Dombret, *Haematologica*, 2014). These findings suggest that CR is not necessary to gain a survival benefit with AZA *vs* other commonly used Tx for older pts with AML.

P576

ABSOLUTE QUANTIFICATION OF THE PRETREATMENT PML-RARA MOLECULAR TRANSCRIPT BY DROPLET DIGITAL PCR DEFINES THE RELAPSE RISK IN ACUTE PROMYELOCYTIC LEUKEMIA

F. Albano[1,*] A. Zagaria[1], L. Anelli[1], N. Coccaro[1], G. Tota[1], C. Brunetti[1], C.F. Minervini[1], L. Impera[1], A. Minervini[1], A. Cellamare[1], P. Orsini[1], C. Cumbo[1], P. Casieri[1]G. Specchia[1]
[1]D.E.T.O., Hematology - University of Bari, Bari, Italy

Background: The persistence of resistant leukemic cells after treatment is responsible for relapse in 10-20% of acute promyelocytic leukemia (APL) patients. Until now, the white blood cells count at diagnosis has been considered the most important prognostic factor in APL, able to better identify those patients at higher risk of relapse.
Aims: In this study we performed absolute quantification of the *PML-RARA* transcript by droplet digital polymerase chain reaction (ddPCR) in newly diagnosed APL patients to verify the the prognostic impact of the *PML-RARA* initial molecular burden.
Methods: *PML-RARA* expression analysis was performed by ddPCR in 76 APL patients at diagnosis with Bio-Rad's QX200 system. Primers and probes for *PML-RARA* isoforms were selected according to the standardized protocol for TaqMan based RT-qPCR analysis. After amplification, ddPCR data were analyzed with QuantaSoft analysis software (version 1.7.4). Target concentration in each sample was expressed as *PML-RARA* copies/ng.
Results: ddPCR analysis revealed that the amount of *PML-RARA* transcript at diagnosis in the group of patients who relapsed was higher than in that with continuous complete remission (CCR) (272 *vs* 89.2 *PML-RARA* copies/ng, p=0.0004, respectively). Moreover, considering the arbitrary cut-off of 124 *PML-RARa*/ng (the median value of our APL series), a higher proportion of patients who relapsed (85.7%) had >124 *PML-RARa*/ng compared to the CCR group (39.6%) (odds ratio 0.10; p=0.002). Further parameters (age, sex, WBC count, M3/M3v, bcr transcript type, FLT3 mutation status, CD34 and CD2 expression, relapse risk score) were assessed to verify the presence of different amounts of the fusion gene transcript at diagnosis among these different categories but yielded no statistically significant differences. ROC analysis detected the optimal *PML-RARA* concentration threshold as 209.6 *PML-RARa*/ng (AUC, 0.78; p <0.0001) for discriminating between outcomes (CCR *versus* relapse). Among the 67 APL patients who achieved CR after the induction treatment, those with >209.6 *PML-RARa*/ng had a worse relapse-free survival (RFS) (p=0.0006). At 5-year follow-up, patients with >209.6 *PML-RARa*/ng had a cumulative incidence of relapse of 50.3% whereas 7.5% of the patients with suffered a relapse (p <0.0001). There was no difference in terms of overall survival (OS) between patients with ≤209.6 *PML-RARa*/ng and those with >209.6 *PML-RARa*/ng. It is noteworthy that when the group of patients with early death was excluded from the OS analysis, the difference between the two groups was statistically significant (p=0.02). Cox proportional hazards regression model analysis was performed for RFS identifying the amount of *PML-RARA* before induction treatment as the sole independent prognostic factor for APL relapse (HR 9.26, p=0.0009).
Summary and Conclusions: Our results identified the amount of *PML-RARA* before induction treatment as the sole independent prognostic factor for APL relapse. In our experience the experiments performed with the ddPCR technology were absolutely reproducible, allowing easy measurement of the absolute copies number of the *PML-RARA* transcript, and with high precision. We conclude that the pretreatment *PML-RARA* molecular burden defined by ddPCR could therefore be used to improve risk stratification in order to develop more individualized treatment regimens for high-risk APL patients.

PREVALENCE AND CLINICAL CHARACTERISTICS OF SETBP1 MUTATIONS IN MYELOID DISORDERS

N. Winkelmann[1,*] J. Reichert[1], V. Schaefer[1], A. Waldau[1], J. Rinke[1], A. Hochhaus[1], T. Ernst[1]
[1]Jena, University Hospital, Jena, Germany

Background: *SETBP1* mutations have recently been discovered and characterized in myelodsyplastic syndrome (MDS), secondary acute myeloid leukemia (sAML), myelodysplastic/myeloproliferative neoplasms (MDS/MPN), and aplastic anemia. Even though they are infrequent (1-5% in the above mentioned diseases), they are associated with a poor prognosis. The role of *SETBP1* mutations during disease progression for individual patients has rarely been investigated so far.
Aims: To address this subject, we have screened 401 patients with World Health Organization-defined AML (n=48), sAML (n=95), MDS (n=93), classical MPN (n=113), MDS/MPN (n=40), and aplastic anemia (n=12) in an unselected single-center cohort. In addition, we analyzed 103 follow up samples of patients during disease evolution at a median of 10 months (range, 3-65 months) from diagnosis.
Methods: Mutational screening was performed from bone marrow samples or peripheral blood using bidirectional Sanger sequencing of genomic DNA covering the entire SKI homology domain of *SETBP1*.
Results: In total, we found *SETBP1* mutations in 10 patients (2.5%, MDS/MPN, n=6; sAML, n=2; MDS, n=2) who were all included in our clinical follow up. The median age of patients harboring *SETBP1* mutations was 63 years (range, 48-80 years). The majority of patients had a normal karyotype (n=5), chromosomal alterations were: monosomy 7 (n=2), trisomy 8, trisomy 21, loss of chromosome Y (n=1 each). All mutations were located within known somatic hotspots according to the COSMIC database (codons 868, 870, 871, 942). One patient showed a novel 12 base pair deletion starting at codon 867, reaching into the known mutational hotspot. Germline material was available in 5/10 patients and confirmed the somatic origin of mutations. In our clinical follow up, 9 of 10 patients with *SETBP1* mutations had progressive disease and underwent intensive chemotherapy with consecutive allogeneic stem cell transplantation (ASCT, n=3), demethylating treatment with azacytidine as a bridging therapy to ASCT (n=3), palliative chemotherapy with cytarabine (n=2), or best supportive care with transfusion dependency (n=2). One patient with a codon 942 mutation (271993G>GA:942R>R/Q) was diagnosed with MDS RAEB II and had stable disease over 65 months under continuous cytoreductive/demethylating therapy. 2/3 transplanted patients had early relapse after 6 and 2 months, respectively. In the first patient, the *SETBP1*-clone dissolved for 6 months after allotransplant, but re-appeared in relapse. In the second patient, the clone harboring the *SETBP1* mutation persisted through engraftment and was always detectable by Sanger sequencing. One patient has remained in complete remission for 14 months after ASCT.
Summary and Conclusions: Mutated *SETBP1* is associated with rapid disease progression of early relapse in a variety of hematologic diseases, even after ASCT. Since *SETBP1* mutations were never lost during disease progression they may drive disease progression in subgroups of patients and their presence may guide treatment/surveillance decisions in the future.

LB578

PRELIMINARY PHASE II RESULTS OF ARA-C AND IDARUBICIN IN COMBINATION WITH SELECTIVE INHIBITOR OF NUCLEAR EXPORT (SINE) COMPOUND SELINEXOR (KPT-330) IN PATIENTS WITH RELAPSED OR REFRACTORY AML

W. Fiedler[1,*] M. Heuser[2], O. Ottmann[3], M. Kebenko[1], F. Thol[2], A. Trummer[2], C. Brandts[3], C. Bokemeyer[1], S. Theile[4], A. Kranich[5]
[1]Department of Internal Medicine II and Clinic (Oncology Center), University Medical Center Hamburg-Eppendorf, Hamburg, [2]Department of Hematology, Hemostasis, Oncology und Stem Cell Transplantation, Hannover Medical School, Hannover, [3]Department of Medicine II, University Hospital Frankfurt, Frankfurt, [4]GSO Hamburg, Hamburg, Germany, [5]GSO Global, Amsterdam, Netherlands

Background: Acute myeloid leukemia (AML) is one of the most common leukemia's affecting adults. Although 70-80% of patients achieve a complete remission (CR), patients with AML who fail to achieve a CR after the first cycle of induction therapy and those with relapsed disease have a bleak prognosis. Currently no standard regimen exists for the treatment of patients with relapsed AML and a great clinical need exists for new treatment options. Selinexor, an oral first-in-class Selective Inhibitor of Nuclear Export (SINE) compound, inhibits XPO1 mediated nuclear export to induce cytotoxicity in cells with genomic damage such as tumor cells. *In Vivo* model with selinexor alone or combination with AraC significantly prolonged the survival of leukemic mice from a median survival of 24 days (APL+vehicle) to 39 days, respectively (P <0.0001). Combination therapy prolonged survival (P <0.0001), with some mice being cured of the disease. Phase I clinical study demonstrates encouraging results in AML patient. The role of selinexor as a mono therapy is currently under investigation in phase II.
Aims: This phase II trial explores the efficacy & tolerability of Ara-C and idarubicin in combination with selinexor in patients with relapsed or refractory AML.
Methods: Patients with relapsed/refractory AML are treated with Ara-C (100 mg/m^2, continuous infusion, day 1-7), idarubicin (10 mg/m^2, day 1, 3, 5) every 4 weeks. In the majority of the patients selinexor is administered twice weekly orally starting on day 2 (40 mg/m^2). A small cohort of patients received selinexor after registration and before first induction cycle for correlative studies. The primary endpoint is percentage of patients achieving a complete response or complete remission without normalization of peripheral blood counts (CRi). Other endpoints are partial response rate, percentage of patients undergoing subsequent allogeneic stem cell transplant, early death rate, overall survival (OS), event-free survival and toxicity.
Results: As of 20-April-2015, 18 patients with AML have been enrolled in 3 sites. Informed consent was obtained from all patients. Median age was 56 years. Out of 18 patients, 17 patients received ≥1 induction and 15 patients (9 male, 6 female) were evaluable for efficacy at the time of analysis. In average, patients received 2.4 therapies prior to study start. Overall response rate was 53% (13% of patients achieved CR, 40% of patients achieved CRi). Stable disease was observed in 13% of patients. Sixty-seven percent of patients received or were planned for stem cell transplant or donor lymphocyte infusion. Drug related AEs comprised 61% of all CTC Grade 3/4 and 46% of all CTC Grade 1/2 events. Grade 3/4 drug related adverse events (AEs) include febrile neutropenia (71%), diarrhea (71%), anorexia (57%), thrombocytopenia (43%), leukopenia (43%), anemia (29%) and nausea (29%). Grade 1/2 drug related AEs include: diarrhea (86%), vomiting (71%), nausea (71%), anorexia (43%), constipation (43%), fatigue (29%) and oral mucositis (29%). No drug-related deaths occurred.
Summary and Conclusions: The prognosis of relapsed/refractory AML patients is remarkably poor. Our findings suggest that treatment with Ara-C and idarubicin in combination with selinexor might be a potentially effective strategy for patients with relapsed/refractory AML without unexpected toxicities. Most common AEs were of low CTC grade.

CLL - Biology: Cell-intrinsic defects

P578

NOTCH1 MUTATIONS ARE ASSOCIATED WITH LOW CD20 EXPRESSION LEVELS IN CHRONIC LYMPHOCYTIC LEUKEMIA: EVIDENCE FOR A NOTCH1-MEDIATED EPIGENETIC MECHANISM

F. Pozzo[1,*] T. Bittolo[1], F. Arruga[2], P. Bulian[1], P. Macor[3], E. Tissino[1], B. Gizdic[2], F.M. Rossi[1], R. Bomben[1], A. Zucchetto[1], D. Benedetti[1], M. Degan[1], G. D'Arena[4], A. Maria Misericordia, Udine, [7]Department of Internal Medicine and Hematology, Maggiore General Hospital, University of Trieste, Trieste, [8]Division of Hematology-Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, [9]Division of Hematology, S. Eugenio Hospital, University of Tor Vergata, Roma, Italy

Background: In chronic lymphocytic leukemia (CLL), *NOTCH1* mutations have been associated with clinical resistance to anti-CD20 immunotherapy (Stilgenbauer *et al.* Blood, 2014, Dal Bo *et al.* Ann Hematol, 2014).
Aims: To investigate whether *NOTCH1* mutations could affect CD20 expression in CLL.
Methods: *NOTCH1* mutations were investigated by ARMS PCR, Sanger and next generation sequencing. CD20 expression was evaluated by flow cytometry and QRT-PCR. CLL-like MEC-1 cells were transfected with vectors containing the *NOTCH1* intracellular domain (NICD) carrying either the 7541-7542delCT (NICD-mut) or a stop codon at the beginning of NICD sequence (c.5304G>A, NICD-null).
Results: i) In a cohort of 692 CLL, 87 were *NOTCH1* mutated (*NOTCH1*-mut, 81 cases with the c.7541-7542delCT, 6 with other *NOTCH1* mutations). In 495 CLL, evaluated with a FITC-conjugated anti-CD20, variable CD20 levels were found, with the highest levels in trisomy 12 CLL. *NOTCH1*-mut expressed lower mean fluorescence intensity (MFI) values than *NOTCH1* wild type (*NOTCH1*-wt) cases in both trisomy 12 (20 *NOTCH1*-mut, 69 *NOTCH1*-wt; mean MFI 1,893±196 *vs.*7,051±819; p<0.0001) and non-trisomy 12 (40 *NOTCH1*-mut, 366 *NOTCH1*-wt; mean MFI 1,858±203 *vs* 2,426±112; p=0.017) CLL. Superimposable results were obtained in the remaining 197 CLL, evaluated with a PE-Cy7-anti-CD20, both in trisomy 12 (6 *NOTCH1*-mut, 17 *NOTCH1*-wt; mean MFI 12,926±3,676 *vs* 28,216±5,228; p=0.027) and non-trisomy 12 (21 *NOTCH1*-mut, 153 *NOTCH1*-wt; mean MFI 10,207±1,310 *vs* 15,208±1,578; p=0.017) CLL. Consistently, in 275 CLL (46 *NOTCH1*-mut), transcript levels of *MS4A1*, encoding for CD20, were lower in *NOTCH1*-mut than in *NOTCH1*-wt cases both in trisomy 12 (p=0.006) and non-trisomy 12 (p=0.019) categories. ii) By cell sorting according to CD20 expression in 3 *NOTCH1*-mut CLL, CD20^{low} sorted cells always had a higher *NOTCH1* mutational burden than CD20^{high} cells (*i.e.* 32% *vs* 15%, 38% *vs* 32%, 48% *vs* 39%). iii) CD20 expression was up-regulated in-vitro by gamma-secretase inhibitors (GSI). iv) In keeping with CD20 levels, *NOTCH1*-mut showed lower relative lysis induced by rituximab, in complement-dependent-cytotoxicity assay, than *NOTCH1*-wt cells (6 *NOTCH1*-mut, 7 *NOTCH1*-wt; mean relative lysis 2.5% *vs* 29.4%; p=0.045). v) The stable transfection of the mutated NICD into MEC-1 cells resulted in a strong downregulation of CD20, and, consistently, NICD-mut cells showed lower relative lysis by rituximab (p=0.043). vi) We investigated the interactions of RBPJ, a transcription factor acting either as activator or repressor of NOTCH1 pathway when respectively bound to NICD or hystone deacetylases (HDACs). Compared to controls, NICD-mut cells had RBPJ preferentially complexed to NICD, by co-immunoprecipitation experiments, and showed higher levels of HDACs interacting with the *MS4A1* promoter, by chromatin immunoprecipitation assay. vii) In NICD-transfected cells, treatment with the HDAC inhibitor valproic acid (48 hrs) increased *MS4A1* transcript (NICD-mut, mean increase (MI)=1.7, p=0.001; NICD-null, MI=1.5 p=0.003) and CD20 protein (NICD-mut, MI=1.3, p=0.041; NICD-null, MI=1.4, p=0.029) expression. Similar results were obtained in primary CLL both for *MS4A1* transcript (7 *NOTCH1*-mut, MI=1.5, p=0.05; 6 *NOTCH1*-wt, MI=1.8, p=0.02) and CD20 protein (*NOTCH1*-mut, MI=1.3, p=0.05; *NOTCH1*-wt, MI=1.3, p=0.005).
Summary and Conclusions: *NOTCH1*-mut CLL are characterized by low CD20 levels that may confer resistance to anti-CD20 immunotherapy. The low CD20 expression is due to an epigenetic dysregulation that might be reverted by GSI and/or HDAC inhibitor therapy.

P579

MYD88 L265P SOMATIC MUTATIONS INFLUENCE GENE EXPRESSION AND THERAPEUTIC RESPONSE IN CHRONIC LYMPHOCYTIC LEUKEMIA

R. Improgo[1,2], B. Tesar[1,2], J. Klitgaard[1,2], R. Magori-Cohen[3,4], L. Yu[1,2], S.M. Fernandes[1], D. Chaudhary[5], W. Miao[5], D.L. Romero[5], W.F. Westlin[5], H.T. Kim[3], J.R. Brown[1,2,*]
[1]Department of Medical Oncology, Dana-Farber Cancer Institute, [2]Department of Medicine, Harvard Medical School, [3]Department of Biostatistics and Com-

putational Biology, Dana-Farber Cancer Institute, [4]Department of Biostatistics, Harvard School of Public Health, Boston, [5]Nimbus Discovery, Inc, Cambridge, United States

Background: Several driver mutations have recently been identified in CLL, including the MYD88 L265P mutation. MYD88 L265P mutations are highly recurrent in B-cell malignancies such as Waldenstrom's Macroglobulinemia (>90%) and ABC-DLBCL (29%). MYD88 is an adaptor molecule in the Toll-like receptor (TLR) and Interleukin-1 Receptor (IL-1R) pathway. Upon TLR/IL-1R stimulation, MYD88 forms a complex with IL-1R-associated kinase 4 (IRAK4). IRAK4 then phosphorylates IRAK1 leading to its degradation and activation of nuclear factor kappa-B (NF-kB) signaling.
Aims: This study aims to understand the functional consequences of MYD88 L265P mutations in CLL.
Methods: We first profiled the expression of CLL samples with known MYD88 mutation status, using Affymetrix U133 Plus 2.0 arrays. We then used CellTiter-Glo to assess how MYD88 L265P mutations influence response to therapy. Finally, we performed Western blot analysis and ELISA to characterize TLR/IL-1R signaling upon drug treatment.
Results: In our cohort of 160 CLL patients, we identified 10 patients harboring MYD88 L265P mutations (6.25%), all with mutated IGHV status. To determine gene expression changes driven by MYD88 L265P, we compared the expression of these MYD88 L265P samples (n=10) to MYD88 wild-type CLL cells possessing IGHV mutated status (n=76). Using Prediction Analysis for Microarrays (PAM), we identified 28 differentially expressed genes between the two groups. We next examined the expression of these 28 genes across all CLLs (n=150) in relation to clinical features. Using a penalized Cox model, we identified 4 predictive genes, CHL1, UGT2B17, BCAT1, and PDE8A with active coefficients 0.186, 0.174, 0.158, and -0.373, respectively. The composite signature of these 4 genes is strongly associated with overall survival (p=2.6E-09, Cox proportional hazards) and is independent of high-risk clinical features including unmutated IGHV, 17p deletion, and 11q deletion. We next evaluated the response of MYD88 wild-type *versus* L265P CLL cells to pathway inhibition. Inhibition of the B-Cell Receptor pathway with ibrutinib led to modest dose-dependent cell death in both wild-type and MYD88 L265P cells (n=6 per group), with the latter exhibiting slight resistance to ibrutinib (p=0.036). We then tested a highly selective IRAK4 kinase inhibitor, ND-2158 (Nimbus Discovery), to inhibit the TLR/IL-1R pathway downstream of MYD88. CLL cells exhibited dose-dependent cell death upon single agent IRAK4 inhibition, with no difference in sensitivity between MYD88 wild-type and L265P cells. Combination treatment with ibrutinib and ND-2158 resulted in even more marked cell death in both MYD88 wild-type (p=0.0009 *vs* ibrutinib alone; p=0.007 *vs* ND-2158 alone) and L265P CLLs (p=0.003 *vs* ibrutinib alone; p=0.04 *vs* ND-2158 alone). To characterize IRAK4 inhibition in CLL cells, we investigated IRAK1 and IkBa levels by Western blot and evaluated production of the cytokine CCL3 by ELISA, as a measure of TLR-mediated NF-kB signaling. As expected, activation of the TLR pathway via CpG stimulation led to a decrease in IRAK1 levels, increased phospho-IkBa over total IkBa ratio, and increased CCL3 production. Conversely, treatment of cells with ND-2158 inhibited these processes in a dose-dependent manner.
Summary and Conclusions: MYD88 L265P mutations drive expression changes that influence clinical outcome in CLL. IRAK4 inhibition in CLL perturbs TLR signaling downstream of MYD88 leading to inhibition of the NF-kB pathway and resulting in cancer cell death in both MYD88 wild-type and L265P CLLs.

P580

THE GAIN OF THE SHORT ARM OF CHROMOSOME 2 (2P) IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) RESULTS IN XPO1 OVEREXPRESSION AND DRUG RESISTANCE

A. Cosson[1,*] E. Chapiro[1,2], J. Lambert[3], H.-A. Cung[1], C. Algrin[1,2], F. Damm[4], C. Gabillaud[2], F. Davi[1,2], H. Merle-Béral[1,2], S. Choquet[2], M. Uzunov[2], V. Morel[2], V. Leblond[2], K. Maloum[2], S. Leprêtre[5], P. Feugier[6], C. Lesty[2], J. Lejeune[3], L. Sutton[7], S.A. Susin[1], F. Nguyen-Khac[1,2]
[1]Cell Death and Drug Resistance in Lymphoproliferative Disorders Team, Centre de Recherche des Cordeliers - INSERM UMRS1138, [2]Groupe Hospitalier Pitié-Salpêtrière, [3]Hôpital Saint Louis, Assistance Publique - Hôpitaux de Paris, PARIS, [4]Genetics of Tumors, Institut Gustave Roussy - INSERM U1170, VILLEJUIF, [5]Service d'Hématologie, Hôpital Becquerel, Rouen, [6]Service d'Hématologie, Hôpital Brabois, VANDOEUVRE-LES-NANCY, [7]Clinique Hématologique, Hôpital d'Argenteuil, ARGENTEUIL, France

Background: CLL is a very heterogeneous disease in terms of response to treatment, with some patients reaching complete and prolonged remissions, while others relapsing early and requiring several lines of treatments. This highly variable course is partly explained by the existence of a heterogenic panel of genetic alterations (mutations, chromosomal abnormalities) that allow the development of drug-resistant aggressive CLL subclones. Therefore, a functional characterization of the cytogenetic alterations associated to CLL drug resistance may provide new means of improving the current therapeutic strategies. We and others have already reported that the gain of 2p (2p+) is recurrent in CLL. However, the candidate gained gene(s) on the 2p remain to be identified.
Previously unpublished data: We have observed that the 2p gain is frequent in previously untreated CLL Binet stages B/C (21/132, 15.9%), and is associated with bad prognostic factors, such as 11q deletion (p=0.0008) and unmutated *IGHV* (p=0.02). Using a SNP-array approach, we have identified a minimally gained region of 1.28Mb on 2p16.1-15. This region included the gene *CRM1*/*XPO1* (Chromosome Region Maintenance 1/Exportin-1), a gene also recurrently mutated in CLL. A qPCR assessment confirmed that *XPO1* was over-expressed in the CLL 2p+ patients (1.4-fold increase compared to CLL 2p-; p=0.02).
Aims: The objective of our work was to identify the potential role of *XPO1* in CLL drug resistance by using the selective XPO1 inhibitor Selinexor (KPT-330, provided by Karyopharm Therapeutics), which is currently in Phase II human clinical trials in hematological and solid cancers.
Methods: We have analyzed 36 CLL 2p+ and we have searched for *XPO1* mutations in 436 CLL samples. CLL drug resistance associated to *XPO1* over-expression/mutation was assessed by measuring the rate of programmed cell death (PCD) on cells from CLL 2p- and wildtype (wt) *XPO1* (n=20), CLL 2p+/*XPO1*wt (n=8) and on CLL *XPO1*mut (n=6). After 24 hours treatment with Fludarabin+Cyclophosphamid+Rituximab (FCR), Ibrutinib, Idelalisib+Rituximab (Ide+R) and Selinexor, cells were stained with Annexin-V and propidium iodide and PCD was assessed by flow cytometry. KPT-301 was used has a negative control.
Results: (i) *XPO1* was found mutated in 23/436 (5.3%) CLL and in 2/30 (6.7%) CLL 2p+; (ii) Selinexor induced PCD in CLL 2p-/*XPO1*wt (35% of PCD). The results were similar in all tested CLL, independently from prognostic factors (del13q, tri12, del11q, del17p, *IGHV* status), while sparing the non leukemic cells from CLL patients or B cells from healthy donors; (iii) CLL *XPO1*mut were significantly resistant to PCD induced by Selinexor (p=0.003). In contrast, the mutations in *XPO1* had no effect in FCR and Ibrutinib PCD induction; (iv) CLL 2p+ cells were resistant to PCD induced by all tested drugs: FCR (p=0.01), Ibrutinib (p=0.003), Ide+R (p=0.004) and Selinexor (p=0.0001).
Summary and Conclusions: Our data show that CLL 2p+ is associated to FCR, Ibrutinib and Ide+R drug resistance. Strikingly, Selinexor, a new XPO1 inhibitor, is unable to induce PCD in CLL 2p+ and/or XPO1mut, which strongly suggests a key role for *XPO1* in the CLL drug resistance associated to the 2p gain. Altogether, our work provide substantial progress in the understanding of the role of *XPO1* in CLL drug resistance and suggests that the assessment of the 2p gain and the mutations in *XPO1* will be considered before to decide a CLL therapy. As 2p gain could be observed in other B malignancies, it is tempting to expand these recommendations before opting for a Selinexor treatment.

A LONGITUDINAL STUDY OF NEXT GENERATION SEQUENCING IN CHRONIC LYMPHOCYTIC LEUKEMIA SHOWS EVIDENCE OF CHEMOTHERAPY-INDUCED MUTAGENESIS AND SNOWBALLING EFFECT DUE TO LOSS OF P53/ATM-MEDIATED DNA REPAIR

S. Karim[1,*] G. Johnson[1,2], A. Pettitt[1,2], K. Lin[1,2]
[1]Department of Molecular and Clinical Cancer Medicine, University of Liverpool, [2]Royal Liverpool and Broadgreen University Hospital, NHS Trust, Liverpool, United Kingdom

Background: Somatic mutations in multiple genes have been associated with adverse outcome in CLL. However, the causes and interrelationships of such mutations remain unclear.
Aims: To deepen our understanding of the causes and interrelations of the somatic mutations throughout the disease course.
Methods: We analysed CLL samples obtained from 32 patients immediately before (n=10) or after chemotherapy (n=22) for exon mutations in 15 genes (TP53, ATM, NOTCH1, SF3B1, BIRC3, LRP1B, SAMHD1, FBXW7, PCLO, HIST1H1E, XPO1, CHD2, MYD88, POT1 and ZFPM2) using HaloPlex enrichment and Ion Torrent PGM (average depth:2200x, limit of detection:1%).
Results: With SNPs excluded, a total of 60 somatic non-synonymous SNVs &11 indels (VAF:2-98%) from the first 12 genes were identified in 26 of the 32 samples. The most common mutated genes were SF3B1, ATM, TP53, and PCLO found in 11, 10, 9 and 8 cases, respectively. ATM and TP53 mutations did not co-exist in any sample, while most of the SF3B1 (9/11), PCLO (5/8) and other (11/13) gene mutations were found in samples with mutations in either TP53 or ATM. Moreover, both of TP53 and ATM appeared to be the dominant mutant genes in 18 samples, being either the only mutation (in 5 samples) or the one with the highest level of mutant and/or deleted alleles (in 13 multi-gene mutated samples). Strikingly, all but 2 of the 22 samples (91%) from treated patients showed mutations in at least 1 gene compared with only 60% (3/5) in the untreated group (P=0.08). Furthermore, among 15 samples bearing mutations in multiple (2-4) genes, 14 (93%) were from patients who had received chemotherapy, compared with only 1 (7%) in the untreated group (P=0.009). In a longitudinal study, 27 sequential samples before (n=20) or post (n=7) treatment from 22 cases who had somatic mutations already detected were used to study evolution of these mutant clones using the same deep sequencing approach. Including those initially studied, data from a total of 2-3 sequential samples with an average interval of 29

months of each of these 22 cases were compared. Results showed that most (92%) of mutations detected at time of disease progression/drug-resistance existed in samples taken at early stages. But a mutation in ATM, FBXW7, LRP1B and SF3B1 in 5 cases emerged only during disease progression or development of drug resistance. Interestingly, except the one in SF3B1, all other 4 mutations appeared following the expansion of pre-existed either TP53 or ATM mutation. A clear trend of expansion of the mutated subclones was found in majority (94%) of cases. TP53 and ATM were still the most common mutated genes before disease progression or treatment. They were dominant over other mutated genes coexisting in the same clones during clonal evolution. Competition for expansion between subclones bearing mutations in different genes or different mutations in same genes was documented in some cases, suggesting a convergent clonal evolution.
Summary and Conclusions: The observed association between prior treatment and somatic mutations is consistent with the idea that DNA-damaging chemotherapy can be mutagenic *in vivo*. Furthermore, the high frequency of mutations in TP53 and ATM, their association with other mutations and their dominance over these other mutations during the course of CLL progression suggests the existence of a "snowballing effect" in which defective DNA repair due to loss of ATM/p53 function facilitates the acquisition of additional mutations. In addition, this study provided evidence supporting that convergent evolution of CLL clone plays a role in CLL progression.

TP53 MUTATIONS ARE EARLY EVENTS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) DISEASE PROGRESSION AND PRECEDE CLONAL EVOLUTION TO COMPLEX KARYOTYPES

F. Baran-Marszak[1,2,*] G. Lazarian[1], E. Tausch[3], A. Sebaa[1], V. Bianchi[1], V. Eclache[1], R. Letestu[1], S. Stilgenbauer[3], F. Cymbalista[1]
[1]Hematologie biologique, Hopital Avicenne APHP, [2]INSERM U978, Université Paris 13, Bobigny, France, [3]Hematology, Universitätsklinikum, Ulm, Germany

Background: *TP53* abnormalities lead to resistance to purine analogues and are found in over 40% patients with refractory CLL. At diagnosis, no more than 5% of CLL carry 17p deletion and most cases harbour mutations within the other *TP53* allele. Incidence of *TP53* mutations as sole alteration is also approximately 5%, but dependent on the sensitivity of the technique. Complex karyotype (more than 2 abnormalities) has recently been considered as a stronger adverse prognostic factor than presence of *TP53* alteration. However, there are no longitudinal studies examining simultaneously the presence of 17p deletion, *TP53* mutations and karyotype abnormalities in the same patients.
Aims: Assess the sequence of events of clonal evolution through the longitudinal study of a cohort of high risk patients. Determine the impact of minor *TP53* mutated clones by NGS in a routine setting.
Methods: We conducted a retrospective longitudinal study of 33 high risk CLL (defined by either *TP53* alteration at baseline or relapsed/refractory disease). Del17p was detected by FISH and *TP53* mutations by Sanger sequencing of exons 4 to 9 as well as by NGS (Ion Torrent and Illumina). Two to five samples per patient over 4.9 years (1.7-10.7 years) were studied. An excellent correlation between Illumina and Ion Torrent technologies was obtained.
Results: A *TP53* abnormality was found in 55% (17/33) of the patients at any time point of progression. At diagnosis, only 7/17 patients carried a del17p among which 5 harboured a *TP53* mutation on the other allele. In 3 additional cases, *TP53* mutation was detected as sole alteration. The use of NGS technology allowed the detection of a minor *TP53* mutated clone (3.5% to 20% allele frequency) in 4 additional cases. At diagnosis, only 4/17 cases had a complex karyotype, and all of them had a *TP53* mutation. During progression, clonal evolution was found in 11 patients: i) 17p deletion was detected at a later time point in 7 patients, 5 of which had a previous *TP53* mutation, ii) A novel *TP53* mutation was detected in 3 cases and an additional subclonal *TP53* mutation in 4 patients iii) in 8 patients with non-complex karyotype at diagnosis, a complex karyotype was found during progression. All of them had a *TP53* mutation preceding the evolution to a complex karyotype. In this group of *TP53* mutated cases, 12/17 cases harboured a complex karyotype at some point, as compared to only 4/15 cases in the group without *TP53* alteration (among these 2 had del11q)(p=0,01). Regarding treatment, two patients showed clonal evolution while untreated. In 4/6 patients, we observed an expansion of the TP53 mutated clone after fludarabine-based regimen. Interestingly, in all 4 patients receiving ibrutinib, the allelic burden of *TP53* mutation remained the same after 1 year.
Summary and Conclusions: Presence of *TP53* mutation identifies patients with genomic instability. Small mutated clones are present at an early stage of the disease and precede other signs of clonal evolution, most importantly the development of a complex karyotype. 17p deletion is either a later event, or detected later because of a lower sensitivity of the FISH technique. Complex karyotype occurs as clonal evolution event in patients with preexisting *TP53* mutated (sub)clones, and therefore in itself may not be associated with poor prognosis when *TP53* can be assessed by a sensitive technique such as NGS. NGS allows early detection of *TP53* mutated clones, and is achievable on a routine basis with a dedicated sequencing assay. We strongly recommend early and iterated detection of *TP53* mutations in CLL progressive cases.

P584

EXPRESSION OF DNA HYDROXYMETHYLATION-RELATED GENES IS ASSOCIATED WITH PROGNOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA

M. Van Damme[1,*] E. Crompot[1], N. Meuleman[1], P. Mineur[2], D. Bron[1], L. Lagneaux[1], B. Stamatopoulos[1]
[1]Laboratory of Clinical Cell Therapy, Jules Bordet Institue - ULB, Brussels, [2]Department of Hemato-Oncology, Grand Hôpital de Charleroi, Charleroi, Belgium

Background: Epigenetics plays a crucial role in cancer physiopathology. DNA hydroxymethylation is catalyzed from methylated DNA by Ten Eleven Translocation (TET) enzymes requiring co-factors produced by Isocitrate Dehydrogenase (IDH) proteins. This modification could be a step in the demethylation process and could thus have an impact on gene expression. TET2 mutations have already been reported in several leukemias. However, little is known about hydroxymethylation in B-chronic lymphocytic leukemia (CLL).
Aims: We intend to characterize the mRNA expression of enzymes (TET1, 2, 3, IDH1 and 2) involved in DNA hydroxymethylation in purified B cells obtained from CLL patients.
Methods: Expression of TET1, 2, 3, IDH1 and 2 mRNA was assessed by qPCR on purified leukemic B-cells from a cohort of 214 CLL patients with a median follow-up of 75 (6-380) months and compared with those of purified peripheral normal B-cells. The influence of CLL microenvironment on TET enzyme expression, was investigated by culture of CLL cells (n=10) in the presence or absence of bone marrow mesenchymal stromal cells (BMSC).
Results: TET1, 3 and IDH2 are underexpressed in leukemic B-cells compared with healthy volunteers B-cells (P=0.0221, 0.0013, <0.0001 respectively) while IDH1 is overexpressed (P=0.0037). Expression of TET2 is similar in both groups. When we stratified patients according to low and high expression, TET2 and IDH1 significantly predict treatment-free survival (TFS): patients with high TET2/IDH expression had a median TFS of 110 months while patients with low expression presented a median TFS of 78 months (P=0.0071/0.0123). Finally, we observed a decreased TET1 expression (P=0.0371) and an increased TET3 (P=0.0273) and IDH2 expression (P=0.0039) in CLL-cells after co-culture with BMSC. Further analysis in 14 CLL patients shows that ZAP70+ patients present higher hydroxymethylated DNA than ZAP70- patients.
Summary and Conclusions: This is the first report that DNA hydroxymethylation enzymes are deregulated in B-CLL compared to normal B cells: 1) TET2 and IDH1 overexpression have a good prognostic value; 2) TET1, TET3 and IDH2 expression is modulated by microenvironment interactions, resulting in CLL cells survival. Our observations suggest that DNA hydroxymethylation plays a major role in CLL physiopathology and support the potential therapeutic benefit of agents targeting epigenetics in CLL patients.

P585

SF3B1 MUTATIONS AND ALTERATIONS OF FOXP1 TRANSCRIPTION IN CHRONIC LYMPHOCYTIC LEUKAEMIA

H. Roudot[1,2,*] F. Baran-Marszak[1,2], V. Eclache[1], J.-F. Collon[1], V. Lévy[3], N. Varin-Blank[2], F. Cymbalista[1,2], R. Letestu[1,2]
[1]Hématologie biologique, Hôpital Avicenne AP-HP, [2]INSERM U978, Université Paris 13, [3]Hématologie, Hôpital Avicenne AP-HP, Bobigny, France

Background: Spliceosome mutations have been described in various myeloid and lymphoid malignancies. In chronic lymphocytic leukaemia (CLL), SF3B1 is mutated in a variable proportion of cases, depending on the studies, ranging approximately from 5 to 20% and the presence of these mutations correlates with an adverse prognosis. Recently, a modification in the species of FOXP1 transcripts, consisting in the appearance of a truncated variant, has been described in 3 patients with SF3B1 K700E or N626Ymutation (Quesada Nat Genet 2012).
Aims: In this work, we aimed to study the transcription profile of FOXP1 in a series of CLL patients, and in control samples. In a second step we investigated a validation cohort, and studied the sensitivity of the technique.
Methods: Peripheral blood mononuclear cells (PBMC) were obtained from 10 normal subjects and 60 patients with CLL after informed consent. The expression of the FOXP1 truncated and the full length transcripts was studied by real-time quantitative PCR. SF3B1 mutations were detected by Sanger sequencing of the exons 14, 15, and 16.

Results: We selected 32 patients with at least one adverse prognostic factor (unmutated IGHV, CD38 +, ZAP-70 +), explored SF3B1 by Sanger sequencing and found 4 mutated cases. Then we studied FOXP1 transcription profile in 10 control samples, the 4 SF3B1 mutated samples and 6 additional CLL samples with wild type SF3B1. The FOXP1 truncated transcript was found at a very low level of expression in the control samples contrasting with the high level measured in the SF3B1 mutated samples, finally the expression of FOXP1 truncated variant in unmutated samples was similar to that observed in controls. In a validation cohort, including 28 patients with the same selection criteria and/or the presence of 11q deletion, we performed the FOXP1 study and SF3B1 sequencing. We found an overexpression of the FOXP1 truncated transcript in 8 patients. SF3B1 mutations were identified in 7 of these patients whereas no mutation was detected in samples with low FOXP1 truncated variant expression. Most of the cases with SF3B1 mutations and overexpression of the FOXP1 truncated variant presented an 11q deletion, however the majority of the samples tested with 11q deletion were not SF3B1 mutated. Overall, in the 11 mutated samples, we identified five different mutations of SF3B1 (3 Y623C, 1 R625H, 3 K700E, 1 G740V and 3 G742D). Finally, using dilutions of mutated sample in unmutated sample, we evaluated the sensitivity of the test at approximately 5%.
Summary and Conclusions: In this study, we investigated a cohort of patients and controls to evaluate the impact of various SF3B1 mutations on the splicing of FOXP1 transcripts. A high expression of the FOXP1 truncated variant was observed in any case with SF3B1 mutation. Therefore, FOXP1 transcription profile could become an alternative tool to identify functionally relevant mutations in the SF3B1 gene. Moreover, we described 4 additional mutations of SF3B1 (affecting the 3 exons tested) that impact FOXP1 splicing. Finally, it is of major interest to explore the FOXP1 transcription variants regarding their functions and their involvement in the mechanisms leading to CLL progression.

P586

ADDITIONAL TRISOMIES AMONGST PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA CARRYING TRISOMY 12: THE PARTNER CHROMOSOME MAKES A DIFFERENCE

Papanicolaou Hospital, Thessaloniki, Greece, [14]Cancer Sciences, Faculty of Medicine, University of Southampton, Southampton, United Kingdom

Background: Trisomy 12 (+12), the second most frequent recurrent chromosomal aberration in chronic lymphocytic leukemia (CLL), is associated with clinical and biological heterogeneity. We and others previously reported a minor fraction of +12 cases with co-existence of trisomy 19 displaying distinctive clinicobiological characteristics. However the respective cohorts were small, precluding definitive conclusions.
Aims: Detailed characterization of cases with multiple trisomies in a large series of CLL patients carrying +12, aiming to identify distinctive profiles that would assist in further dissecting the heterogeneity of this major cytogenetic subgroup.
Methods: Within a multi-institutional series of 4486 CLL patients with available classic cytogenetic data, we identified 713 cases (16%) with trisomy 12, of whom 87 (12%) harbored multiple trisomies. Sixty-eight of these 87 cases (78%) had co-existing +19 (group A: +12,+19 CLL), while the remaining 19/87 cases (22%) had other co-existing extra chromosome(s) (group B: +12,+other trisomy CLL). The median time from diagnosis to karyotype analysis was 1.5 months (range, 0-194); the great majority of cases with available treatment/survival information were untreated prior to testing (73/78 cases, 94%). FISH data for the Döhner model aberrations was available in 67/87 (77%) cases. Within the same CLL series, we identified 68 cases with isolated +12 and available clinicobiological data, which were used as a control group for the survival analysis (group C).
Results: In group A, 43/68 (63%) cases also harbored +18. Extra structural abnormalities were detected in 12/63 (18%) cases, mostly concerning deletions and/or translocations involving the 13q chromosome in 7/12 (58%) cases. Interestingly, the great majority of cases harboring extra structural abnormalities (10/12, 83%) displayed +12+18+19 highlighting an association between +18 and clonal evolution. In contrast, no structural abnormalities were observed in group B, within which trisomy 3 predominated, being detected in 8/19 (42%) cases, followed by trisomies 18 and 22 in 6 (32%) and 4 (21%) cases respectively Moreover, different clinicobiological profiles were observed between the two groups. In particular, group A displayed (i) higher incidence of M-CLL (42/45, 95% *vs* 6/8, 75%, p=0.045); (ii) younger median age at diagnosis (59 years *vs* 67 years, p=0.007); (iii) ubiquitous surface IgG expression (23/23, 100% *vs* 2/8, 25%, p<0.0001); (iv) higher incidence of del(13q) (27/51, 53% *vs* 0/11, 0%, p=0.0002); and (v) higher incidence of monoclonal gammopathy (23/37, 62% *vs* 2/8, 25%, p=0.05). Group B displayed higher incidence of: (i) clinical/laboratory autoimmunity (5/10, 50% *vs* 2/33, 6% in group A, p=0.0009); and (ii) other malignancies (6/11, 55% *vs* 4/48, 8% in group A, p=0.0002). Furthermore, each group displayed significant differences (p<0.05) when compared to control group C regarding the aforementioned features. Regarding survival analysis, Groups A and B exhibited longer overall survival compared to Group C (median OS: not reached for Groups A and B *vs* 8 years in Group C; log-rank test, group A *vs* C, p=0.08, and group B *vs* C, p=0.036).
Summary and Conclusions: The presence of extra trisomies defines subgroups of cases with distinctive clinicobiological profiles within +12 CLL cases, further highlighting their heterogeneous biological background and clinical outcome.

P587

MUTATIONS IN THE TP53 GENE SHOW FEATURES OF SOMATIC HYPERMUTATION PROCESS WITH PROMINENT DIFFERENCE BETWEEN IGHV MUTATED AND UNMUTATED CHRONIC LYMPHOCYTIC LEUKEMIA

N. Tom[1,*] J. Malcikova[1,2], L. Radova[1], B. Kantorova[1], F. Pardy[1], S. Pavlova[1,2], K. Pal[1], M. Mraz[1], B. Tichy[1], M. Doubek[1,2], Y. Brychtova[2], K. Plevova[1,2], J. Mayer[1,2], M. Trbusek[1,2], S. Pospisilova[1,2]
[1]Molecular Medicine, CEITEC - Central European Institute of Technology, [2]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: Introducing somatic hypermutations (SHM) into genes coding for heavy and light chains of immunoglobulins (*IGHV*, *IGLV*) is a physiological process indispensable during antibody maturation. SHM introduction is a two-step process, which in the first step involves deamination of cytosine to uracil by an enzyme Activation-Induced (Cytidine) Deaminase (AID). During the second step, uracil and potentially also flanking nucleotides are removed and error-prone DNA polymerases (mainly polymerase eta) are recruited to fill the gap. Off-targeting of AID may result in mutations in non-immunoglobulin genes, including tumor suppressor gene *TP53*.
Aims: We explored the *TP53* mutation patterns with regards to SHM features emphasizing the differences between mutations occurring in *IGHV* unmutated (U-CLL) and *IGHV* mutated (M-CLL) groups of patients.
Methods: In order to reduce the selection bias, we used the set of *TP53* mutations detected using ultra-deep Next Generation Sequencing (NGS) with high sensitivity (0.2%) allowing to consider the minor subclonal mutations with less prominent selective advantage. For NGS analysis, Illumina Miseq platform has been used with average coverage 34788; (range 1674-177021). For variant detection, an in house bioinformatics pipeline was established. Statistical evaluation was performed by shearwater algorithm computing Bayes classifiers based on a betabinomial model. Only point substitutions were taken into account. Altogether, 464 *TP53* mutations in 73 high risk CLL patients were analyzed. 121 mutations were found in M-CLL cases and 343 mutations were detected in U-CLL patients. The high number of mutations should be attributed to the high number of minor subclonal mutations detected mainly in patients in relapse after treatment. In 60% of patients, results from repeated examinations were included (2-4 examinations per patient; each mutation detected in more than one consecutive sample was considered only once). 72.6% of patients received treatment before the first or during consecutive analyses.
Results: U-CLL showed a higher proportion of mutations in C:G pairs comparing to M-CLL (66% *vs* 51% of all mutations; P=0.003). Out of these, G:C>A:T substitutions, the primary result of AID cytidine deamination, were the prevalent events observed in U-CLL but not M-CLL (59.6% *vs* 40.3% of all C:G mutations; P=0.009). Focusing on the AID-targeted sequence motif RGYW/WRCY, no difference between the two subgroups was observed (2.5% *vs* 3.1%; P=ns). However, we found a significant overrepresentation of mutations in GNW motif in U-CLL (14.58% of all mutations *vs* 6.61% in M-CLL; P=0.025). GNW is a strand-biased motif derived from RGYW most frequently targeted by AID in *IGLV* genes. On the other hand, *TP53* mutations detected in M-CLL cases showed the features of targeting by polymerase eta: (i) frequent targeting of A:T pairs (49% *vs* 34% in U-CLL; P=0.003); with prominent

strand bias favoring A over T (13.8 fold *vs* 3.1 fold in U-CLL; P=0.002; (ii) prevalence of mutations in WA/TW motifs (40.5% *vs* 23.91% in U-CLL; P<0.0001) with strand bias favoring WA observed in both groups, but extremely prominent in M-CLL (23.5 fold in M-CLL *vs* 4.37 fold in U-CLL; P=0.014).
Summary and Conclusions: We documented the significantly different patterns of *TP53* mutations in U-CLL *vs* M-CLL. Mutations detected in U-CLL showed the features corresponding to the first step of SHM process: deamination by AID with strand bias possibly attributable to AID activity on the transcribed strand. In contrast, spectra of mutations detected in M-CLL cases suggested the more prominent involvement of polymerase eta during the second SHM step. *Supported by CZ.1.07/2.3.00/30.0009, CZ.1.05/1.1.00/02.0068, NT13519, NT13493, NT11218, MUNI/A/1180/2014, NGS-PTL/2012-2015/no.306242, MSMT-CR (2013-2015, no.7E13008)*

Background: Idelalisib (Zydelig), a first-in-class, selective, oral inhibitor of PI3Kδ, is approved in the US and EU for the treatment of chronic lymphocytic leukemia (CLL) in combination with rituximab and as monotherapy for patients with follicular lymphoma who have received at least two prior systemic therapies.
Aims: To further characterize the safety profile of idelalisib, we integrated adverse event data from 8 clinical trials.
Methods: The analysis included 760 subjects with CLL, indolent non-Hodgkin lymphoma, or other B-cell malignancy who received IDELA alone (doses=50 mg BID to 350 mg BID) or as part of a combination regimen (IDELA doses=100 or 150 mg BID). Most subjects were heavily pre-treated with relapsed disease.
Results: Common adverse events (AEs) are presented in the Table 1, along with important laboratory results. AEs leading to dose modification included transaminase elevations (13%), diarrhea/colitis (11%), and rash (5%); discontinuations due to these AEs were infrequent (3%, 5%, and 2%, respectively); dose interruption allowed successful re-challenge in most patients. Pneumonitis occurred in 2.3% (monotherapy) and 3.9% (combo therapy) of subjects. Grade ≥3 diarrhea/colitis had a later onset (peak incidence of 9% between 6-12 mo.); other AEs occurred most often in the first 6 months and declined thereafter.

Table 1.

	Monotherapy N = 354		Combo therapy N = 406	
N (%)	Any Gr.	≥ Gr. 3	Any Gr.	≥ Gr. 3
Adverse Events				
Diarrhea/colitis	131 (37)	38 (11)	161 (40)	68 (17)
Pyrexia	96 (27)	7 (2)	169 (42)	47 (12)
Nausea	91 (26)	5 (1)	125 (31)	30 (7)
Cough	80 (22)	3 (1)	118 (29)	21(5)
Rash	60 (17)	7 (2)	99 (24)	30 (7)
Chills	49 (14)	0	86 (21)	23 (6)
Pneumonia	47 (13)	40 (11)	74 (18)	56 (14)
Vomiting	53 (15)	5 (1)	60 (15)	18 (4)
Dyspnea	43 (12)	7 (2)	68 (17)	20 (5)
Laboratory Abnormalities				
Neutropenia	162 (46)	83 (23)	234 (58)	151 (37)
Anemia	102 (29)	18 (5)	145 (36)	34 (8)
Thrombocytopenia	94 (27)	37 (11)	143 (35)	50 (12)
Transaminase increase	176 (50)	56 (16)	190 (47)	53 (13)

Summary and Conclusions: As well-characterized in this large dataset, IDELA has an acceptable safety profile.

P589

PHASE I, FIRST-IN-HUMAN TRIAL OF BI 836826 (AN ANTI-CD37 ANTIBODY) IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY (R/R) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

versität Heidelberg, Medizinische Klinik, Abteilung Innere Medizin V, Hämatologie, Onkologie und Rheumatologie, Heidelberg, Germany

Background: BI 836826 is a novel Fc-engineered IgG1 type II antibody targeting CD37, a tetraspanin predominantly expressed on normal and malignant B-cells, with a dual cytotoxic mode of action by directly inducing apoptosis and increasing antibody-dependent cellular-cytotoxicity. *Ex vivo*, BI 836826 treatment results in a significantly greater depletion of CLL cells than rituximab, irrespective of genetic risk. We report preliminary results of an ongoing Phase I, first-in-human, dose-escalation study of BI 836826 in pts with R/R CLL (NCT01296932; 1270.1).
Aims: To investigate the maximum tolerated dose (MTD), safety, pharmacokinetics, and efficacy of BI 836826 monotherapy in pts with R/R CLL.
Methods: Pts with R/R CLL after ≥2 prior therapy lines were eligible if they had adequate organ function, neutrophils ≥1000/µL and platelets ≥25000/µL. Increasing doses of intravenous (IV) BI 836826 (1-400 mg) were administered as a rate-controlled IV infusion in a modified 3+3 design. In Course 1, 10% of the total BI 836826 dose (not exceeding 10 mg) was administered on day 1 with the total dose remaining administered on day 2 of a 14-day course. In subsequent courses, BI 836826 was administered on day 1. The MTD will be determined based on dose-limiting toxicity (DLT; defined as any drug-related non-hematologic adverse event [AE] ≥grade 3, except infusion-related reactions [IRRs]) observed during the first treatment course. All pts provided written informed consent.
Results: To date, 33 pts (mean age 66.2 yrs; 70% male) have been treated with BI 836826 (1 mg [n=3], 3 mg [n=3], 9 mg [n=6], 25 mg [n=6], 50 mg [n=3], 100 mg [n=3], 200 mg [n=6], 400 mg [n=3]). Dose escalation is ongoing. At screening, 12 pts (36.4%) were Binet stage C or Rai III/IV. Pts had received a median of 4 (range 2-10) prior therapy lines. Molecular genetics at baseline were del(17p) and/or TP53 mutation in 63.6%, and del(11q) in 29.0%; 72.7% had unmutated IGHV. Four treatment courses were planned, 18 pts (54.5%) completed 8 courses. Five pts (15.2%) stayed on therapy beyond 8 courses due to sustained clinical benefit. One pt in the 200 mg cohort had a DLT of grade 3 hypophosphatemia. Dose escalation is ongoing and the MTD has not yet been determined. The most frequent AEs were IRRs (66.7%), chills (60.6%), pyrexia (51.5%), anemia (42.4%), thrombocytopenia (42.4%), neutropenia (39.4%), diarrhea (36.4%), and nausea (33.3%). Drug-related AEs included IRRs (66.7%), chills (57.6%), pyrexia (48.5%), neutropenia (36.4%), and thrombocytopenia (27.3%). Serious AEs included pyrexia (9.1%), neutropenia, leukopenia, cardiac failure, and IRRs (all 6.1%). PK exposure increased with increasing doses and short half-lives were observed. Of 26 evaluable pts (*i.e.*, received full intended dose) at ≥9 mg doses, the overall response rate based on investigator assessment was 42.3% (all partial remission); 14 pts (53.8%) had stable disease. Of 23 pts with elevated baseline counts at ≥9 mg doses, a ≥50% lymphocyte reduction was observed in 78.3% and a reduction to <4000/µL was observed in 52.2%, including pts with high-risk genetic features.
Summary and Conclusions: Promising responses have been observed with BI 836826, even at low doses. The safety profile was acceptable with AEs predominantly IRRs and cytopenias which were manageable with routine supportive care.
These data support further clinical evaluation of BI 836826 as a single agent and in combination.

P590

TELOMERE LENGTH AND POT1 MUTATIONS IN CLL: INCIDENCE, ASSOCIATIONS AND CLINICAL IMPACT IN THE COMPLEMENT 1 TRIAL

B.M. Chelliah Jebaraj[1,*] E. Tausch[1], R. Schlenk[1], S. Kless[1], C. Galler[1], P. Hillmen[2], F. Offner[3], A. Janssens[4], T. Zenz[5], Govindbabu K.[6], S. Grosicki[7], J. Mayer[8], P. Panagiotidis[9], A. McKeown[10], I. Gupta[11], H. Doehner[1], S. Stilgenbauer[1]
[1]Department of Internal Medicine III, University of Ulm, Ulm, Germany, [2]Department of Haematology, St. James' University Hospital, Leeds, United Kingdom, [3]Universitair Ziekenhuis Gent, Gent, [4]Department of Hematology, Universitaire Ziekenhuizen Leuven, Leuven, Belgium, [5]Department of Internal Medicine V, University of Heidelberg, Heidelberg, Germany, [6]Kidwai Memorial Institute of Oncology, Bangalore, India, [7]Department of Hematology, ZSM of Chorzow, Chorzow, Poland, [8]Department of Internal Medicine - Hematooncology, University Hospital Brno and Medical Faculty MU, Brno, Czech Republic, [9]Hematology Clinic, University of Athens, Athens, Greece, [10]GlaxoSmithKline, Uxbridge, United Kingdom, [11]GlaxoSmithKline, Collegeville, PA, United States

Background: *POT1* mutations in CLL have been reported to be functionally relevant by a dominant negative effect, leading to uncapping of the telomeric ends, thereby enabling telomerase to aberrantly elongate the telomeres, causing fusion events and chromosomal aberrations. However, their impact on telomere length and outcome has not been established in a clinical trial cohort.
Aims: To study the impact of *POT1* mutations on telomere length and disease outcome in a clinical trial cohort.
Methods: We assessed telomere length associations with disease characteristics, especially with that of *POT1* mutations in the Complement 1 (OMB110911) trial (1st line chlorambucil (Chl) *vs* ofatumumab-Chl (O-Chl)) in patients considered inappropriate for fludarabine-based therapy. Telomere length was analysed using quantitative PCR from baseline samples of 368 patients (82.3%) with available DNA and this cohort was representative of the full trial population with regard to baseline characteristics. Validation of the technique was done using terminal restriction fragment length analysis (TRF) (R^2=0.859, P<0.001) in an independent control sample set (n=18) and 6 of these samples were included in every batch as controls.
Results: Analysis of telomere length associations was performed by dichotomizing the cohort based on the median telomere length (4.53kb). No significant association of telomere length was found with the clinical characteristics age, sex, Binet stage and ECOG status while short telomeres were significantly associated with high WBC count (P<0.001), high β2-MG (P<0.001), and high CIRS score (P<0.01). As previously reported in a similar trial (CLL8, Jebaraj *et al.*, ASH 2013), short telomeres were significantly associated with other adverse prognostic factors namely, unmutated *IGHV* (P<0.001), 17p- (P<0.04) and 11q- (P<0.001). Also gene mutations in *NOTCH1* (P<0.001), *SF3B1* (P<0.02), *TP53* (P<0.02), *ATM* (P<0.001) and *BIRC3* (P<0.01) were all significantly associated with short telomeres. *POT1* mutations were found in 7.6% (n=28 of 368 cases) cases in Complement1 and the mutations were predicted to be dominant negative in function. *POT1* mutations were not significantly associated with any of the clinical characteristics or genomic aberrations. Interestingly, there was also no significant association of telomere length with *POT1* mutations (4.76 kb *vs* 5.34 kb, P=0.68). At a median follow-up of 31.7 months, there were 245 (67%) events for progression free survival (PFS) and 60 (16.3%) events for overall survival (OS). Incidence of *POT1* mutations (Chl: n=16, O-Chl: n=12, P=0.70) and short telomeres (Chl: n=95, O-Chl: n=89, P=0.83) were balanced in both treatment arms. Analysis of the impact of *POT1* mutations showed no significant association with remission rate, PFS and OS. In contrast, short telomeres were found to be significantly associated with reduced overall response (72.0% *vs* 87.6%, P<0.001), shorter PFS (HR=1.98, P<0.001, Figure 1) and OS (HR=1.88, P=0.02). To evaluate their independent prognostic impact, we performed multivariable analysis by Cox regression including as variables the treatment arms, 11q-, +12q, 17p-, mutation status of *IGHV, TP53*, *NOTCH1, SF3B1, BIRC3, MYD88, ATM, FBXW7, POT1* and telomere length. For PFS, O-Chl (HR 0.43, P<0.001), 17p- (HR 3.01, P=0.001), *NOTCH1* (HR 1.45, P=0.04), *TP53* (HR 1.78, P=0.04 and telomere length (HR 1.71, P=0.001) were identified as independent factors, while for OS, only 17p- had an adverse prognostic impact (HR 3.90, P<0.01).

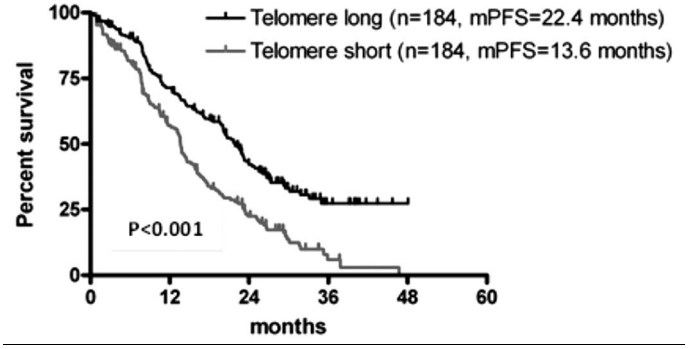

Figure 1. Progression free survival.

Summary and Conclusions: In the Complement1 trial short telomeres were found to be significantly associated with various adverse clinical and biological prognostic disease characteristics and poor outcome, including PFS and OS, but had no association with *POT1* mutations. There was no association between *POT1* mutations and clinical outcome.

P591

PREVALENCE AND CHARACTERISTICS OF CENTRAL NERVOUS SYSTEM (CNS) INVOLVEMENT BY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

P. Strati[1,*] J.H. Uhm[1], C.A. Hanson[1], K.G. Chaffee[1], S.J. Achenbach[1], T.G. Call[1], T.D. Shanafelt[1]
[1]Mayo Clinic, ROCHESTER, United States

Background: Clinically significant "extramedullary" involvement by CLL is rare, with only 192 cases reported in literature between 1975 and 2012. Although the CNS has been the most commonly reported site, either as CLL or Richter Transformation (RT), the available information is derived exclusively from case reports of individual patients.
Aims: To determine the prevalence and characteristics of CNS involvement in CLL.
Methods: We used the Mayo Clinic CLL database to identify all patients with CLL/small lymphocytic lymphoma (SLL) who were followed at our center between 07/1997 and 11/2014 and who underwent an MRI of the head or of the spine because of neurological symptoms.

Results: Of 4317 patients with CLL followed at Mayo between 07/1997 and 11/2014, 1115 (26%) had an MRI of the head or spine to evaluate neurologic symptoms. Of these, 47 (1%) had radiological findings indicative of CNS involvement by a lymphoproliferative neoplasm (21 leptomeningeal involvement, 26 parenchymal brain involvement). Of these 47 patients, 24 underwent concomitant lumbar puncture (LP) and tissue biopsy, 5 tissue biopsy only, 13 LP only, and 5 had no tissue obtained. Tissue biopsy revealed CLL infiltration in 11 cases, infiltration by RT in 9 cases (diffuse large B-cell lymphoma [DLBCL] in 8 cases, peripheral T-cell lymphoma in 1 case), other etiologies in 6 cases (2 progressive multifocal leukoencephalopathy, 2 vasculitis, 3 primary brain tumors), and normal brain tissue in 2 cases. Of the 13 patients with MRI abnormalities who underwent a LP only, 4 demonstrated clinically significant CLL involvement. Collectively, 24 (0.5%) of 4317 CLL patients cared for at our center over a 17 year interval developed clinically significant CNS involvement by CLL or RT.
Summary and Conclusions: Although neurologic symptoms are frequent in patients with CLL/SLL and prompt diagnostic MRI imaging in up to 26% of CLL cases, radiographic findings suggestive of CNS involvement by CLL or RT are rare (about 1% of patients). Tissue confirmation with brain biopsy is necessary to confirm the diagnosis of lymphoproliferative neoplasm and the subtype (CLL *vs* DLBCL) in such cases. Clinically significant CNS involvement by CLL or RT is a relatively rare event, observed in 0.5% of CLL patients (~1 of every 200 patients).

P592

MAKING THE RIGHT CHOICE: THE ROLE OF FITNESS STATUS IN THE MANAGEMENT OF FIRST-LINE TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS (CLL FITNESS STUDY)

Background: While fludarabine+cyclophosphamide+rituximab (FCR) has shown a survival advantage in CLL, it cannot be considered the standard of care for all patients, due to prolonged cytopenias and increased susceptibility to infections in particular among the elderly. For these reasons, FCR is the treatment of choice for young fit patients with CLL, while recent studies have demonstrated that elderly patients with comorbidities may benefit from chlorambucil, in association with anti-CD20 antibodies. How these findings translate into everyday care is still to be defined and several factors have been proposed, but none validated, in helping physicians make better decisions.
Aims: We designed an investigator-driven, multicenter, observational, retrospective study based on the review of medical records. The study aimed at defining the most relevant parameters when choosing the first-line treatment in clinical practice and how these parameters associate with treatment tolerance.
Methods: The target population included patients with CLL, requiring first-line treatment at participating centers between Jan 1, 2009 and Dec 31, 2010. Information on global health status, disease parameters, treatment and follow-up was collected.
Results: Four hundred and forty eight patients from 37 Italian sites were evaluated. Eight participating centers treated ≥10 CLL patients per year in the front line setting, 12 centers 5-10 and 14 centers <5. The median age was 66 years, with a male:female ratio of 1.5:1. The most frequent treatment choices -FCR (195) and alkylating agent (AA) as monotherapy (79 patients)- were further analysed. FCR- and AA-treated patients were significantly different in terms of baseline features and, not surprisingly, FCR-treated patients showed younger age, less comorbidities and better ECOG performance status. Investigators reported age as the most relevant parameter in selecting treatment, followed by ECOG PS, comorbidities (based on clinical evaluation) and disease burden. Seventy one percent of FCR-treated patients received the planned number of cycles, but 53% required dose reduction or delay. At multivariate analysis, age was the only factor able to predict tolerance to FCR (p=0.032), with CIRS index showing a trend to significance (p=0.058). In 70% of cases discontinuations and reductions of FCR were related to toxicities. The most frequent AEs included neutropenia (36%), general (17%) and gastrointestinal disorders (14%), infections (11%), thrombocytopenia (8%) and anemia (5%). More than 90% of physicians who chose FCR, after evaluating response and tolerance, would choose again the same first-line therapy.
Summary and Conclusions: Our data suggest that age, together with the comorbidity burden, is widely used for the treatment choice in both FCR and AA-treated patients, remains the best predictor of tolerance to therapy and accurately guides first-line treatment in CLL patients. In the AA-group functional and mental status have also some relevance, while the biologic profile was less significant. The use of FCR was associated with a lower frequency and grade of infections than reported, reasonably due to a higher awareness of the potential toxicity among hematologists. A broader use of infectious prophylaxis as well as a younger median age of the patients receiving FCR in our study as compared to CLL8 most likely accounts for the lower incidence of hematologic toxicities recorded. In the general practice, the use of FCR is becoming safer likely due to an improved a priori selection of the target population and a better management of the side effects.

P593

EFFICACY OF PHOSPHATIDYLINOSITOL-3 KINASE INHIBITORS WITH DIVERSE ISOFORM SELECTIVITY PROFILES FOR INHIBITING THE SURVIVAL OF CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

E. Göckeritz[1,*] S. Kerwien[1], M. Hallek[2], G. Krause[1]
[1]Department of Internal Medicine 1, [2]University Clinic of Cologne, Cologne, Germany

Background: Pharmacological inhibition of phosphatiylinositide-3-kinase (PI3K)-mediated signaling holds great promise for treating chronic lymphocytic leukemia (CLL). PI3K inhibitors exhibit various degrees of isoform specificity, which influences their effectiveness on CLL cells. Specifically targeting the p110-δ isoform, which dominates B cell receptor signaling and is preferentially expressed in CLL cells is an attractive treatment option.
Aims: Three structurally related PI3K inhibitors were investigated that target the PI3K-δ isoform for their ability to inhibit the survival of CLL cells *in vitro*. The purely PI3K-δ-selective inhibitor idelalisib was compared to copanlisib (BAY 80-6946) and duvelisib (IPI-145), with isoform target profiles that additionally include PI3K-α or PI3K-γ, respectively. In addition, the direct cell killing capacity of PI3K inhibitors in combination with CD20 antibodies was assessed as well as interference with antibody-dependent cell mediated cytotoxicity.
Methods: Freshly isolated B lymphocytes and PBMC's from CLL patients as well as CLL-derived JVM-3 cells were treated *in vitro* for 48 hours with copanlisib, duvelisib and idelalisib. Annexin/7-ADD negative cells were subsequently determined by flow cytometry. In addition, migration of primary CLL cells towards SDF-1 upon inhibitor treatment was determined as an index of migrated cells in a two-chamber based assay. Survival-inhibition of inhibitor-treated CLL cells in coculture with bone marrow stromal cell line HS-5 was also determined by flow cytometry.as well as combination treatments with CD20 antibodies. Interference of ADCC through inhibitors was assessed by measuring LDH release after 4 hour co-cultivation of JVM-3 cells as target and healthy donor PBMC's as effector cells.
Results: The concentrations leading to halfmaximal reduction of the survival of CLL cells were more than ten-fold lower for copanlisib than for idelalisib and duvelisib. At concentrations reflecting the biological availability of the different inhibitors, high levels of apoptotic response among CLL samples were attained more consistently with copanlisib than with idelalisib. Copanlisib selectively reduced the survival of CLL cells compared to T cells and to B cells from healthy donors. In addition copanlisib and duvelisib impaired the migration of CLL cells towards CXCL12 to a greater extent than equimolar idelalisib. Similarly copan-

lisib and duvelisib reduced the survival of CLL cells in co-cultures with HS-5 cells more strongly than idelalisib. Survival inhibition by copanlisib and idelalisib was enhanced by the monoclonal CD20 antibodies rituximab and obinutuzumab (GA101), while antibody-dependent cellular cytotoxicity mediated by alemtuzumab and peripheral blood mononuclear cells was not substantially impaired by both PI3K inhibitors for the CLL-derived JVM-3 cell line as target cells.
Summary and Conclusions: Among the investigated PI3K-δ-selective inhibitors, the cytotoxicity for CLL cells of copanlisib by far surpassed that of idelalisib and duvelisib. Targeting the α- and δ- p110 isoforms with copanlisib may be therefore a useful strategy for the treatment of CLL and warrants further clinical investigation. Taken together, targeting p110-δ showed promising clinical efficacy for CLL treatment, but could be further improved by PI3K inhibitors showing more potent direct tumor cell killing than idelalisib.

P594

HEALTH RELATED QUALITY OF LIFE AND PATIENT REPORTED OUTCOMES OF OFATUMUMAB PLUS CHLORAMBUCIL *VERSUS* CHLORAMBUCIL MONOTHERAPY IN THE COMPLEMENT1 TRIAL

S. Manson[1,*] A. McKeown[1], C.-N. Chang[2], I. Gupta[3], P. Hillmen[4]
[1]GlaxoSmithKline, Uxbridge, United Kingdom, [2]GlaxoSmithKline, Research Triangle Park, [3]GlaxoSmithKline, Collegeville, United States, [4]Leeds Teaching Hospitals, Leeds, United Kingdom

Background: The COMPLEMENT1 study has demonstrated a statistically significant improvement in PFS in patients who are treated with ofatumumab plus chlorambucil in the first line setting for CLL over chlorambucil monotherapy and the combination therapy was well tolerated. Given that ofatumumab was added to chlorambucil, it is important to consider the impact of ofatumumab on health related quality of life (HRQoL).
Aims: Given that ofatumumab was added to chlorambucil, it is important to consider the impact of ofatumumab on health related quality of life (HRQoL).
Methods: During the COMPLEMENT1 trial, the QLQ-C30 and the QLQ-CLL16 patient questionnaires were administered in patients during treatment, during the follow up stage and at the time that progression was identified. The primary specified patient reported outcomes were health related quality of life and fatigue from the QLQ-C30 questionnaire.
Results: In HRQoL, there was no significant difference (p=0.67) or clinically relevant difference between the arms at any time point measured during treatment. In the fatigue scale, there was similarly no significant differences noted between the arms (p=0.17) during treatment. This trend of no clinically significant changes in HRQoL and fatigue continued during follow-up (p=0.49 and p=0.10 respectively). A summary of HRQoL scores measured on a scale of 0 to 100 with 100 being the maximum HRQoL can be seen in Figure 1.

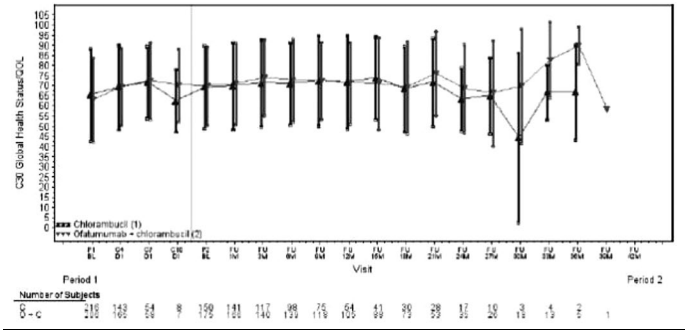

Figure 1.

Summary and Conclusions: These results demonstrate that adding ofatumumab to frontline chlorambucil therapy do not result in any perceptible changes in HRQoL or fatigue, with any adverse events having minimum impact. This is consistent with the adverse event profile of ofatumumab in the COMPLEMENT1 study, which demonstrated high tolerability irrespective of age and fitness.

P595

GENOMIC PROFILE OF CHRONIC LYMPHOCYTIC LEUKEMIA IN KOREA: ETHNIC DIFFERENCE IN RECURRENT MUTATIONS IDENTIFIED BY TARGETED EXOME SEQUENCING

J.-A. Kim[1,*] B. Hwang[2], S.N. Park[3], S. Huh[2], K. Im[3], Q. Choi[4], S.Y. Kim[1], S.M. Hwang[5], J.R. Huh[6], E.-J. Seo[7], J. Ahn[2], S. Kwon[8], S.S. Yoon[9], D. Bang[2], D.S. Lee[10]
[1]Laboratory Medicine, Seoul National University College of Medicine, [2]Department of Chemistry, Yonsei University, [3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, [4]Laboratory Medicine, Chungnam National University College of Medicine, Daejeon, [5]Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, [6]Department of Pathology, [7]Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, [8]Department of Electrical and Computer Engineering, Seoul National University, [9]Department of Internal Medicine, [10]Department of Laboratory Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in western countries, while it is extremely rare in Asian countries. Yet, genetic profiles of CLL have not been reported in Asian.
Aims: Aim of our study is to characterize the genomic profiles of Korean CLL and to find out ethnic differences in somatic mutations with prognostic implications.
Methods: A total of 71 patients with CLL was enrolled (median age at diagnosis 61 year, range 23-81). We performed target exome sequencing for 87 gene panel using next-generation sequencing (n=48). Targeted genes were sequenced by IlluminaHiSeq 2500 and the sequencing reads were analyzed, based on the pipeline of bioinformatics tool. Candidate mutations were confirmed by Sanger sequencing. Among 71 patients, G-banding (n=60) and fluorescent *in situ* hybridization (FISH) for RB deletion, 13q deletion, chromosome 12 enumeration, and TP53 deletion (n=51) were performed.
Results: Overall, 43 out of 48 patients (89.6%) harbored at least one mutation and mean number of mutation per patient was 2.8 (range 0 -9). Average coverage of target regions was >800-fold. Aberrant karyotypes were observed in 28.3% by G-banding and 66.7% by FISH. The targeted exome sequencing analysis revealed 136 substitutions and insertion/deletions. Most recurrent mutation (>10% frequency) was *ATM* (21%) followed by *TP53* (15%), *FAT4* (15%), *LAMB4* (13%), *NFKBIE* (10%), *NOTCH1* (10%) and *SF3B1* (10%). Mutations of *ITPKB, SF3B1, NFKBIE* and *TP53* was associated with adverse prognosis (*P*=0.033, *P*=0.023, *P*=0.016, and *P*=0.023, respectively, by conventional cox regression model, P<0.05). *BRD2* and *LAMB4* mutation was mutually exclusive (r=0.55, P<0.05). Mutation of *NOTCH1, TP53, and SF3B1* showed similar incidence with Caucasian, while mutation of *ATM, BCOR, SAMHD1, KLHL6, ITPKB and EGR2* was higher than Caucasian. Especially, *ATM* mutation showed 2 fold higher incidence (20%) than Caucasian. *MYD88* mutation (4%) showed lower incidence than Caucasian. Novel mutations in Korean CLL was FAT4 (15%) and LAMB4 (15%) mutation, which was not reported in CLL of Caucasian.
Summary and Conclusions: Mutation profile of Korean CLL was different with those of Caucasian, while profile of cytogenetic aberrations was similar to those of Caucasian. Novel mutations discovered in the present study must be validated through large cohort study, which might suggest a clue for an ethnic difference in incidence. Future evaluation of therapeutic strategies should be taken into account for these mutated genes.

P596

CYTOTOXICITY FOR CHRONIC LYMPHOCYTIC LEUKEMIA CELLS OF THE CD37 ANTIBODY BI 836826 IN COMBINATION WITH CHEMOTHERAPEUTIC AGENTS OR PI3K INHIBITORS

G. Krause[1,*] I. Baki, [1]S. Kerwien[1], E. Knödgen[1], L. Neumann[1], K.-H. Heider[2], M. Hallek[1]
[1]Dept. I of Internal Medicine, University Hospital Cologne, Cologne, Germany, [2]Boehringer Ingelheim RCV GmbH & Co KG, Vienna, Austria

Background: The Fc-engineered CD37 antibody BI 836826 showed promising direct cell killing activity for chronic lymphocytic leukemia (CLL) cells *in vitro* and is currently investigated in early phase clinical trials.
Aims: To explore its potential for combination therapy, its direct cytotoxicity was assessed in combinations with the DNA alkylating agents chlorambucil and bendamustine, the nucleoside analogue fludarabine or the PI3K inhibitors idelalisib and copanlisib.
Methods: Freshly isolated B lymphocytes from CLL patients were treated *in vitro* for 48 hours with fixed concentrations of chemotherapeutic agents (3 and 10 µM) and monoclonal antibodies (mAbs, 10 µg/ml). The percentages of viable cells, which were not stained by annexin V and 7AAD, were subsequently determined by flow cytometry. The effects of binary combinations were calculated as fractional products of the separate single agent effects.
Results: Among the examined mAbs only BI 836826 and alemtuzumab significantly reduced the survival of CLL cells in a set of twelve CLL samples. The mean relative survival of CLL cells after treatment with BI 836826 was approximately 50%. The percentages of CLL samples, in which the relative survival was reduced by more than 5%, after treatment with BI 836826, alemtuzumab, obinutuzumab and rituximab were 83, 70, 25 and 17%, respectively. The three investigated chemotherapeutic agents significantly reduced the survival of CLL cells at a concentration of 10 µM and also of 3 µM in the case of fludarabine. In combinations BI 836826 enhanced the cytotoxicity of chemotherapeutic agents more efficiently than the other tested antibodies including alemtuzumab and obinutuzumab.. By combinations of BI 836826 with 10 µM of the chemotherapeutic agents the median relative survival of CLL cells was reduced to 20%. In a different set of CLL samples BI 836826 enhanced the cytotoxicity of the PI3K inhibitors idelalisib and copanlisib more efficiently than the CD20 antibodies rituximab and obinutuzumab. The mutual enhancement of cytotox-

icity by BI 836826 in combination with PI3K inhibitors was slightly stronger than that with chemotherapeutic agents. The apoptotic response to the combination of BI 836826 with PI3K inhibitors was more evenly distributed among samples than with chemotherapeutic agents.
Summary and Conclusions: In line with its remarkable capacity of inducing apoptosis in CLL cells, combinations of BI 836826 with chemotherapeutic agents and PI3K inhibitors consistently resulted in higher percentages of apoptotic cells than correspondent combinations including the mAbs in current clinical use.

P597

SOLUBLE CALRETICULIN PREDICTS FOR TIME TO FIRST TREATMENT OF PATIENTS WITH EARLY CHRONIC LYMPHOCYTIC LEUKEMIA

S. Molica[1,*] G. Digiesi[2], R. Mirabelli[1], G. D'Arena[3], A. Antenucci[2], L. Tomao[2], M. Gentile[4], C. Battaglia[1], F. Morabito[4], P. Musto[3], L. Conti[2]
[1]Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, [2]Clinical Pathology, I, IRCCS Regina Elena,, Roma, [3]Hematology-Oncology, IRCCS Referral Cancer Center of Basilicata, Rionero in Vulture, Potenza, [4]Hematology-Oncology, Azienda Ospedaliera Cosenza, Cosenza, Italy

Background: Increased circulating levels of soluble calreticulin (sCRT) are found in the sera of patients with autoimmune disease and in lung cancer they correlate with the hystopathologic subtype. However, studies addressing the issue in patients with hematologic malignancies are absent.
Aims: We analyzed the correlation between well-established clinico-biological parameters of prognostic relevance in chronic lymphocytic leukemia (CLL) and serum levels of CRT by evaluating the impact of these variables on the time to first treatment (TFT) in a series of 70 previously untreated CLL patients in Binet stage A.
Methods: For this purpose peripheral venous blood samples collected at the time offirst diagnosis and stored at−70 ◦C were analyzed for the quantitative determination of circulating CRT level using a commercial Human CRT ELISA assay (CUSABIO, Biothech CO, LTD).
Results: Circulating levels of sCRT of CLL Binet stage A patients did not differ (median, 0.55 ng/mL; range, 0.1-2.9) from levels of healthy controls (median, 0.4; range 0.1-1.2)(P=0.09). The analysis restricted to the cohort of patients with CLL revealed that levels of sCRT did not correlate with age (P=0.25), gender (P=0.70), LDH (P=0.90), ß2-microglobulin (P=0.48), CD38 (P=0.41), ZAP-70 (P=0.50), mutational status of IGHV (P=0.65). In contrast, a positive correlation with peripheral blood (PB) lymphocytosis (P=0.04) and Rai substages (P=0.03) was observed. After a median follow-up time of 36 months (range, 1-204 months) 19 out of 70 (27.1%) patients experienced progressive disease requiring therapy according to IWCLL criteria. Receiver operating characteristic (ROC) analysis identified a serum concentration of 0.8 ng/mL as the threshold (area under curve [AUC]=0.67; sensitivity 0.58; specificity 0.78) that best allowed the identification of two subsets of patients with different clinical outcomes with respect to TTFT (Hazard ratio [HR], 4.51; P=0.0002). Finally, in multivariate analysis along with serum level of sCRT (P=0.003), Rai substages (P=0.02) and PB lymphocytosis (P=0.02) entered the Cox model at a significant level.
Summary and Conclusions: In CLL CRT, an antigen highly expressed by stromal cells, may stimulate B-cell antigen receptor (BCR) therefore contributing to the protective effect that stroma exerts on CLL cells. Our results shed a new light on the role of CRT as predictor of disease-progression in early CLL.

LB598

RESULTS OF A PHASE 3 RANDOMIZED CONTROLLED STUDY EVALUATING THE EFFICACY AND SAFETY OF IDELALISIB (IDELA) IN COMBINATION WITH OFATUMUMAB (OFA) FOR PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

T. Robak[1,*] M. Wach[2], J.A. Jones[3], C. Owen[4], J.R. Brown[5], A.R. Menter[6], L. Ysebaert[7], N. Wagner-Johnston[8], F. Awan[3], K. Taylor[9], A. Schuh[10], P. Cannell[11], K. Morris[12], L. Background: IDELA is a selective oral PI3Kδ inhibitor approved in combination with rituximab for previously treated patients with CLL.
Aims: This open-label study (NCT01659021) compared the safety and efficacy of IDELA plus OFA *vs* OFA in patients with relapsed or refractory CLL.
Methods: Patients with CLL progressing ≤24 months from last therapy, and who had received ≥2 cycles of a purine analogue or bendamustine, were randomized 2:1 to either Arm A (IDELA 150 mg BID continuously plus OFA, 300 mg IV week 1, then 1 gm IV weekly x 7 and q 4 week x 4) or Arm B (OFA, same as Arm A except 2 gm was substituted for 1 gm dosing). Stratification was performed for relapsed *vs* refractory, del17p and/or TP53 mutation, and *IGHV* mutation. Response and progression were assessed by an independent review committee (IRC) based on clinical data and imaging using modified IWCLL 2008 criteria. The primary endpoint was PFS and alpha-protected secondary endpoints were confirmed ORR, lymph node response (LNR), OS, PFS in patients with del17p and/or TP53 mutation, and CR rate. Results are from the final analysis of the primary endpoint.
Results: Patient characteristics were balanced in the 2 arms: median age 68; Rai II/III/IV 18/13/51%, median number of prior regimens 3, refractory disease 49%, del17p/TP53 mut 40%, *IGHV* unmut 78%. The median exposure to IDELA was 12.3 months (range: 0.2-23.9). Disposition and efficacy are shown in the Table 1. There was a disproportionate dropout rate with an excess of Arm B patients discontinuing prior to PD or death. Efficacy results, demonstrating superiority of the combination, were consistent across risk groups. The median duration of response was 14.9 months and 6.7 months in Arm A and B patients, respectively. The most frequent non-haematologic Gr ≥3 AEs in Arm A patients were diarrhea/colitis (20.2%), pneumonia (12.7%), and febrile neutropenia (11.6%). Grade 3/4 ALT/AST elevation occurred in 12.9% of Arm A patients. Infusion-related reactions of any Grade/Gr ≥3 were reported in 16.8%/ 2.3% and 26.7%/1.2% of patients in Arms A and B, respectively. Deaths in Arm A occurred in 16.8% of patients on-study (until 30 days post-discontinuation) and 6.9% off-study; and in Arm B in 9.3% of patients on-study and 16.3% off-study. TEAEs leading to death were reported in 10.4% (exposure-adjusted rate=0.10/yr) and 7.0% (exposure-adjusted rate=0.18/yr) of patients in Arms A and B, respectively.

Table 1.

	Arm A (IDELA/OFA)	Arm B (OFA)	HR / OR[1]
Pts randomized/dosed	174/173	87/86	
Months on study (range)	13.6 (1.1-24)	5.8 (0-20)	
Reason for study D/C[2]			
PD (%)	34 (19.5)	41 (47.1)	
Death (%)	22 (12.6)	6 (6.9)	
AE / MD decision (%)	21 (12)	19 (21.8)	
Withdrew consent/other (%)	13 (7.5)	15 (17.2)	
Med PFS, mo	16.3	8.0	HR = 0.27, p < 0.0001[3]
ORR, %	75.3[4]	18.4	OR = 15.9, p < 0.0001[3]
LNR, %	93.3	4.9	OR = 487, p < 0.0001[3]
Med OS, mo	20.9	19.4	HR = 0.74, p = 0.27
Med PFS: del17p/TP53mut, mo	13.7	5.8	HR = 0.32, p < 0.0001

[1]odds ratio; [2]per MD; [3]null hypothesis formally rejected; [4]includes 1 CR

Summary and Conclusions: IDELA plus OFA yielded superior PFS, ORR, and LNR compared to OFA in patients with previously treated CLL, including within high-risk subgroups. Safety was manageable with a profile similar to that previously observed with IDELA in CLL trials.

Chronic myeloid leukemia - Clinical 2

Background: Imatinib mesylate (Gleevec, IM) remains a standard for chronic phase CML (CP-CML) therapy. The recommended dose is 400 mg/d. Pharmacokinetic studies pointed-out the inter-individual variability in IM exposure. The value of IM dose optimization based on pharmacokinetic parameters is controversial.
Aims: We conducted the first prospective randomized trial to evaluate the efficacy and the feasibility of IM daily dose optimization based on imatinib [C]min (trough level) in newly diagnosed CP-CML patients (OPTIM-imatinib trial, EudraCT 2008-006854-17).
Methods: Patients (pts) diagnosed with CP- CM for less than 3 months, not previously treated or treated by IM 400 mg/d for less than 1 month were eligible and treated with IM 400 mg/d. IM [C]min was determined at day 15 after enrollment, 20 to 24h after intake. Pts with a [C]min <1000 ng/ml were randomized between a dose-increase strategy to improve the [C]min ≥1000 ng/ml (C1) *versus* observation only (C2). Pts with adequate dosage (≥1000 ng/ml) were allocated to the standart arm (C3). All pts were managed according to the ELN 2009 recommendations (amended for ELN 2013 recommendations). IM [C]min levels were assessed monthly for pts in C1 and C2 and every 3 months in C3. The primary end-point was major molecular response (MMR) at 12 months (missing data were analyzed as failures).
Results: 139 pts were enrolled in the OPTIM-imatinib trial from Oct 2010 to Mar 2014. Median age was 64y (25 to 88y), sex ratio (M/F) was 1.4 and Sokal score distribution was 21%, 41% and 38% for high, intermediate and low categories respectively. Six pts were not randomized (3 were intolerant to IM and 3 declined the dosage). In 86 pts (65%) [C]min was below 1000 ng/ml (median 619; 180 to 998). 43 pts were randomized in C1 and 43 in C2. 47 pts were allocated to C3 (median 1328 ng/ml; 1007 to 3294). At 3 months, median [C]min was 838 ng/ml in the adapted C1 arm, 566 and 998 ng/ml in the C2 and C3 arms respectively. These values were 987, 601and 996 ng/ml at 6 months; 1062, 604 and 935 ng/ml at 9 months and 998, 653 and 930 ng/ml at 12 months. The corresponding mean daily doses of IM in C1, C2 and C3 were 540, 395 and 400 mg/d at 3 months; 614, 390 and 397 mg/d at 6 months; 621, 390 and 394 mg/d at 9 months and 628, 394 and 385 mg/d at 12 months. A higher rate of dose reductions was recorded in C3 suggesting that some of these pts may be over dosed. 19 pts (14%) out of the 133 randomized pts were switched from IM to second generation TKIs during the first 12 months based on the investigator decision, 11 for intolerance (4 in C1, 3 in C2 and 4 in C3), 4 for failure and 4 for non-compliance. No SAE was observed in the adapted arm as compare to 6 in C3. In an intent to treat analysis, MMR was achieved in 27 out of 43 pts (63%; 95% CI, 49 to 77) at 12 months in the C1 dose-adaptation arm *versus* 16 out 43 pts (37%; 95% CI, 23 to 51) in the C2 non-adapted arm (p=0,031), as compared to 22 out of 47 pts (47%; 95% CI, 33 to 61) in C3 (p=0.12).
Summary and Conclusions: The dose adaptation strategy was successfully applied in 95% of the pts recruited. Two third of them were considered under dosed based on IM [C]min. The individualized dose adaptation strategy resulted in a significant increase in the proportion of pts achieving MMR at 12 months (63% *versus* 37%), a magnitude similar to the results reported in studies with second generation TKIs first line. These results may influence the choice of first line therapy and may provide a strong rational to optimize the use of IM and IM generic formulations.
This study was sponsored by the Clinical Research Office of Hôpital de Versailles and supported by a grant from the Programme Hospitalier de Recherche Clinique (PHRC-I).

Background: The Optim dasatinib trial validated a dose optimization strategy driven by dasatinib residual plasmatic level (EudraCT 2008-006854-17). We reported that dasatinib dose individualization was associated with a lower risk of pleural effusion and produced high levels of deep molecular responses (Rousselot *et al.* EHA2014). Dasatinib discontinuation was included in the trial and we report the first prospective dasatinib STOP study in dasatinib first line patients.
Aims: The aim of the study was to test the value of early discontinuation of dasatinib in early molecular responders.
Methods: First line patients included in the OPTIM-dasatinib trial, in MR4.5 for 2 years and on dasatinib for at least 3 years were eligible. The OPTIM-dasatinib trial started to recruit patients in Jun 2009, therefore no patient was eligible for the discontinuation study until Jun 2012. Loss of major molecular response (MMR) was used as the criteria to resart dasatinib as validated for imatinib treated patients in the A-STIM study.
Results: From Aug 2012 to Nov 2014, 20 patients were offered to discontinue dasatinib in MR4.5. Median age (52y, range 32-70) and Sokal score distribution (low, 45%; intermediate 30%; high 25%) was similar to the whole population. Sex ratio was 1 (10 males; 10 females) as compare to 1.3 in the whole population. Five patients were included in the adapted arm, 2 in the non-adapted arm and 13 in the standard arm. All patients were early molecular responders (BCR-ABLIS ≤10%) at 3 months and all except one were in major molecular response at month 6 (BCR-ABLIS ≤0.1%). Mediane time for dasatinib therapy was 43 months (range 36.3 to 56.5). Median time for the achievement of MR4.5 was 10 months (range 5.6 to 23.4). Median follow-up after discontinuation was 13.2 months. Ten patients (50%) restarted dasatinib after a median of 6.1 months (range 3.3 to 14.5). Median duration of treatment free remission (TFR) was 11.4 months. At 12 months, the proportion of patients in TFR was 41% (95 CI, 17.5 to 65.7) (Figure 1).

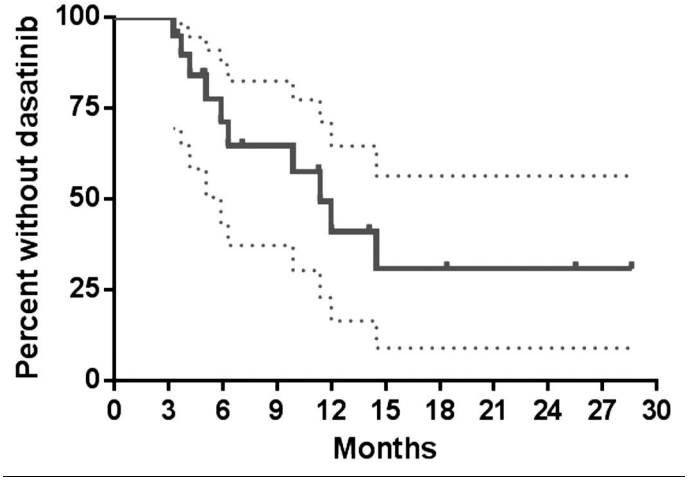

Figure 1. Treatment free remission.

Summary and Conclusions: No published study has described the kinetic of the molecular response before treatment discontinuation. For the first time we report a prospective follow-up of patients included in a prospective clinical trial testing dasatinib first line before discontinuation. Our patients were selected to be early molecular responders and were discontinued after the shortest duration of therapy reported to date. Despite the use of dasatinib and with the limitation of a short follow-up, we failed to improve TFR as compare to previous studies with imatinib first or second line or second generation TKIs second line. Our results suggest that early molecular response is not the path to cure and that duration of therapy is probably the most important parameter to consider before making the decision to discontinue tyrosine kinase inhibitors.

P600

REAL LIFE ANALYSIS OF CML MANAGEMENT DEMONSTRATES THAT SECOND-LINE THERAPY IS FREQUENTLY USED BUT IS PREMATURELY DISCONTINUED FOR INTOLERANCE: REPORT OF THE GROUPE QUÉBÉCOIS DE RECHERCHE EN LMC-NMP

L. Busque[1,*] M.-O. Gratton[2], M. Harnois[2], L. Mollica[1], P. Laneuville[3], H.J. Olney [4], R. Delage[5], S. Assouline[6]
[1]Hematology, Hôpital Maisonneuve-Rosemont, Université de Montréal, [2]Hematology, Hôpital Maisonneuve-Rosemont, [3]Division of Medicine and Oncology, McGill University Hospital, [4]Hematology, Centre Hospitalier Universitaire de l'Université de Montréal - Hôpital Notre-Dame, Montreal, [5]Hematology, Centre Hospitalier Universitaire de Québec - Université Laval, Quebec, [6]Hematology, Sir Mortimer B. Davis - Jewish General Hospital, Montreal, Canada

Background: Since the introduction of imatinib two decades ago, there has been a continual evolution in the management of CML. With the advent of second-generation tyrosine kinase inhibitors (TKI) and better molecular monitoring tools, the decision making for CML patients has become increasingly complex. A variety of treatment guidelines has emerged to help clinicians make decisions based on evidence obtained from clinical trials. However, little is known about the utilization of these guidelines in the real life setting, where patients have more co-morbidities than in clinical trials, and where clinical decision-making may deviate from the strict application of therapeutic guidelines due to diverse factors, such as drug availability, patient choice, and the definition of tolerance and resistance.
Aims: To evaluate in an unbiased, population-based registry the patterns of utilization of CML treatments in the second- and third-line setting in order to assess the discordance between real life data and those expected from clinical trials.
Methods: The CML patient registry of CML-MPN Quebec Research Group (www.gqr-lmc-nmp.ca) prospectively follows 590 patients with CML in 18 oncology centers across the province of Québec. All patients have provided informed consent to participate in the registry. For this interim analysis, 266 patients diagnosed after 2002 and with complete clinical data have been analysed.
Results: The mean age of the cohort was 54 years (range 18-92). The most frequently used front-line TKI included: imatinib (83%), dasatinib (8.6%), and nilotinib (5.6%). In this cohort, a high proportion of patients (44%) needed second-line treatment. The two main causes of first-line discontinuation were resistance (45%) and intolerance (42%). The distribution of the second-line therapy was: dasatinib (43%), nilotinib (29%), stem cell transplantation (8.5%), and other treatments (14%). Thereafter, second-line TKI therapy was discontinued at the following rates: dasatinib was discontinued in 48% of patients after a mean of 9.6 months due mostly to intolerance (48%) and resistance (28%). Similarly, nilotinib was discontinued in 55% of patients after a mean of 15 months, the main cause of discontinuation being intolerance (53%) and resistance (26%). Third-line treatment was instituted in 60 of 100 patients. The most frequent choices were: nilotinib (33%), dasatinib (29%), stem cell transplantation (16%), best supportive care (5%), interferon (2%) or other (11%). Surprisingly, intolerance lead to less discontinuation in the third-line setting (nilotinib: 20%; dasatinib: 10%) and mean time on treatment was longer (nilotinib: 24 months; dasatinib: 25 months).
Summary and Conclusions: Registry-based real life data indicate that intolerance is a predominant trigger for switching therapy in first- and in second-line treatment of CML. This is in contrast with clinical trial data where resistance is the most frequent cause of treatment discontinuation, particularly in second-line. We also observed a paradoxical tolerance benefit for nilotinib and dasatinib when used in third-line. We hypothesize that the increased flexibility associated with real life setting renders physicians more prone to change therapy in the presence of lower grade side effects that would not justify therapy modification in the setting of a clinical trial. Interestingly, in the third-line setting, which is the last resort for most patients, they are more willing to endure their adverse effects and continue on therapy.

P601

CARDIOVASCULAR (CV) AND PULMONARY ADVERSE EVENTS (AES) IN PATIENTS (PTS) TREATED WITH BCR-ABL TYROSINE KINASE INHIBITORS (TKIS): UPDATED ANALYSIS FROM THE FDA ADVERSE EVENT REPORTING SYSTEM (FAERS)

J. Cortes[1,*] M. Mauro[2], J.L. Steegmann[3], G. Saglio[4], A. Soitkar[5], N. Wallis[5]
[1]University of Texas MD Anderson Cancer Center, Houston, TX, [2]Memorial Sloan Kettering Cancer Center, New York, NY, United States, [3]Hospital de la Princesa, Madrid, Spain, [4]University of Turin, Turin, Italy, [5]Bristol-Myers Squibb, Princeton, NJ, United States

Background: The publicly available FAERS database includes AEs reported to pharmaceutical companies and voluntary reports submitted from pts and physicians. FAERS can be mined as part of postmarketing surveillance to identify potential safety signals based on exposure of a broader population than clinical trials. A prior report of FAERS through Sept 2012 described CV and pulmonary AE signals for pts treated with dasatinib (DAS), imatinib (IMA), and nilotinib (NIL) (Cortes 2015, *AJH*).
Aims: As FAERS identifies potential signals emerging over time, a reanalysis using the previous criteria was conducted through Dec 2013. Although data may be sparse (potential 'Weber effect') on recently approved bosutinib (BOS), and altered due to potential 'notoriety effect' of FDA suspension of ponatinib (PON), due to interest in emerging safety signals associated with both agents, they were included in the present analysis.
Methods: Data mining using the validated Multi-Item Gamma Poisson Shrinker (MGPS) Bayesian method is an accepted tool to identify drug-event associations in surveillance databases. MGPS provides a robust estimate of disproportionality (reporting frequency of drug-event pair compared to expected frequency) referred to as the Empirical Bayesian Geometric Mean, and the corresponding 90% CI (EB05, EB95). EB05 ≥2 indicates a 95% chance an event is reported at least 2x as frequently as expected. A threshold of EB05 ≥4 (4x expected reporting frequency) was used to identify events more likely to be clinically relevant and attributable to drug. We assessed the frequency of preferred terms in 3 MedDRA system organ classes (SOCs) with safety signals associated with DAS/IMA/NIL (cardiac; respiratory, thoracic and mediastinal; and vascular) in pts ≥18 years (yrs) and for age cohorts: 18-45, 46-64, and ≥65 yrs.
Results: Drug-event associations with an EB05 ≥4 were identified for DAS/IMA/NIL (Table 1). Drug-event pairs that reached EB05 ≥4 for all 3 of these agents included pleural and pericardial effusions. NIL was uniquely associated with EB05 ≥4 for vascular occlusive events. While no events reached EB05 ≥4 for BOS/PON, EB05 ≥2 was noted for pleural effusion with both, and for pericardial effusion, peripheral arterial occlusive disease, and hypertension with PON. In all age cohorts, pleural effusion with DAS/IMA and pericardial effusion with DAS reached EB05 ≥4. Peripheral and cardiac vascular AEs were noted with NIL with EB05 ≥4 in pts ≥46 yrs. Key limitations were the inclusion of terms in only 3 MedDRA SOCs and the reclassification of preferred terms by SOC since the last report; additionally, there was an inability to establish causality or to determine incidence of safety signals, and the possible effect of outside influences on reporting frequency.

Table 1. Drug-event pairs with EB05 ≥4.

TKI	MedDRA PT	EB05 ≥4
Dasatinib	Chylothorax	72.22
Dasatinib	Pleural effusion	30.95
Dasatinib	Pericardial effusion	11.40
Dasatinib	Pulmonary edema	5.45
Dasatinib	Pulmonary hypertension	4.96
Dasatinib	Pleurisy	4.80
Imatinib	Pleural effusion	5.35
Imatinib	Pericardial effusion	4.34
Nilotinib	Peripheral artery stenosis	54.92
Nilotinib	Intermittent claudication	40.55
Nilotinib	Peripheral arterial occlusive disease	32.82
Nilotinib	Arteritis	20.68
Nilotinib	Arterial stenosis	17.17
Nilotinib	Coronary artery stenosis	16.39
Nilotinib	Arterial disorder	14.88
Nilotinib	Femoral artery occlusion	12.27
Nilotinib	Peripheral ischemia	7.79
Nilotinib	Angina pectoris	7.75
Nilotinib	Acute coronary syndrome	5.96
Nilotinib	Acute myocardial infarction	5.59
Nilotinib	Pleural effusion	5.54
Nilotinib	Arteriosclerosis	4.73
Nilotinib	Pericardial effusion	4.69
Nilotinib	Myocardial ischemia	4.28

MedDRA PT, MedDRA preferred term; TKI, tyrosine kinase inhibitor.

Summary and Conclusions: This analysis suggests a strong association of pleural effusion with DAS, with a weaker association with IMA/NIL. An association between NIL and multiple vascular events was identified. Due to limited exposure and potential bias for BOS/PON, no signals reached EB05 ≥4; however, some events reached EB05 ≥2 and warrant monitoring in future analyses with longer follow-up.

P602

LONG-TERM BOSUTINIB IN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA (CML) AFTER PRIOR IMATINIB FAILURE

T.H. Brümmendorf[1,2,*] J.E. Cortes[3], H.J. Khoury[4], H.M. Kantarjian[3], D.-W. Kim[5], P. Schafhausen[2], M. Zeremski[6], N. Bardy-Bouxin[7], M. Shapiro[8], E. Leip[8], C. Gambacorti-Passerini[9], J.H. Lipton[10]
[1]Universitätsklinikum Aachen, Aachen, [2]Department of Internal Medicine II, Hubertus Wald Tumor Center - University Cancer Center Hamburg, Hamburg, Germany, [3]University of Texas MD Anderson Cancer Center, Houston, TX, [4]Winship Cancer Institute of Emory University, Atlanta, GA, United States, [5]Seoul St. Mary's Hospital, Seoul, Korea, Republic of, [6]Pfizer Inc, La Jolla, CA, United States, [7]Pfizer Global Research and Development, Paris, France, [8]Pfizer Inc, Cambridge, MA, United States, [9]University of Milano-Bicocca, Monza, Italy, [10]Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Bosutinib (BOS) is a Src/Abl tyrosine kinase inhibitor for adults with Ph+ CML resistant/intolerant to prior therapy.
Aims: We assess long-term efficacy/tolerability of BOS after ≥5 y *vs* ≥2 y follow-up from last enrolled patient (pt).
Methods: Data were from an ongoing phase 1/2 study in chronic phase CML pts on 2nd-line BOS (500 mg/d start dose) after imatinib failure (n=284). Informed consent was obtained from all pts.
Results: 41% of pts remained on BOS at 5 y (54% at 2 y; per protocol, 1 y=48 wk); 60% and 50% had newly attained or maintained baseline major cytogenetic response (MCyR) or complete cytogenetic response (CCyR) (most in ≤2 y). Kaplan-Meier probability of maintaining MCyR or CCyR in responders was similar at 2 y (76%, 79%) and 5 y (71%, 71%); 6 and 7 pts, respectively, lost MCyR and CCyR >2 y. Cumulative incidence of on-treatment transformation to accelerated phase (AP)/blast phase (BP) CML at 5 y was 4%; 55% discontinued without transformation 2 y transformed to AP in y3-5. Kaplan-Meier overall survival was 84% at 5 y (91% at 2 y; 40% censored 37 pts discontinued BOS y3-5 (*vs* 131 ≤2 y), mostly for disease progression (n=11), AE (n=7, y3: coronary artery disease, scleroderma, renal failure; y4: ascites and serositis [same pt], blood creatinine increased, pulmonary hypertension; y5: thrombocytopenia), and unsatisfactory efficacy (n=7). Common newly occurring AEs (in >5 pts) in y3 were cough (n=7), blood creatinine increased (n=7), pyrexia (n=6), and blood creatine phosphokinase increased (n=6); y4: blood creatinine increased (n=6), pleural effusion (n=6); y5, none in >5 pts. Newly occurring AEs of interest (Table 1) were most common in y1-2; vascular AEs >y2 were primarily hypertension (y3, n=5; y4, n=3; y5, n=2). Four on-treatment deaths occurred y3-5, none BOS-related.

Table 1.

Newly Occurring AEs*					
n (%)	Year 1 N=284	Year 2 N=189	Year 3 N=148	Year 4 N=130	Year 5 N=124
Diarrhea	239 (84)	3 (2)	0	1 (1)	0
Cardiac	23 (8)	7 (4)	8 (5)	7 (5)	4 (3)
Vascular	11 (4)	8 (4)	5 (3)	4 (3)	5 (4)
Renal	14 (5)	4 (2)	8 (5)	7 (5)	5 (4)

**Not experienced by same patient previously (denominator=patients on treatment each y; 1 y=52 wk).*

Summary and Conclusions: BOS showed durable efficacy and manageable toxicity; a large proportion of chronic phase CML pts with prior imatinib failure remained successfully treated at 5 y.

P603

IMATINIB DISCONTINUATION IN CHRONIC MYELOID LEUKEMIA: A RETROSPECTIVE ANALYSIS ON PATIENTS IN CLINICAL PRACTICE

G. Rege-Cambrin[1,*] C. Fava[1], I. Dogliotti[1], P. Berchialla[2], E. Gottardi[1], M. Cerrano[3], D. Ferrero[3], M. Nicolosi[4], P. Pregno[4], E. Orlandi[5], D. Cattaneo[6], A. Iurlo[6], G. Catania[7], R. Davide[8], G. Saglio[1]

Città della Salute e della Scienza di Torino, Turin, [5]Hematology Unit, Fondazione IRCCS Policlinico San Matteo, Pavia, [6]UOC Oncoematologia, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, [7]Division of Hematology, AOU San Bagio e Antonio e Cesare Arrigo, Alessandria, [8]Division of Hematology, Ospedale S. Croce e Carle, Cuneo, Italy

Background: The introduction of Tyrosine Kinase Inhibitors (TKIs) has dramatically changed the prognosis of chronic myeloid leukemia (CML). For patients who maintain deep molecular remission for many years, it is now under discussion the possibility to discontinue TKI therapy. In the last 8 years different studies analyzed the outcome of patients who discontinued imatinib. For most of these studies, the main criteria for discontinuation were the duration of complete molecular response (CMR) and the depth of molecular response, defined at least as MR4.
Aims: To present our experience with imatinib discontinuation in clinical practice.
Methods: We retrospectively analyzed the outcome of patients treated in 6 Divisions of Hematology in Piemonte and Lombardia, who discontinued imatinib. All these patients had discontinued imatinib in CMR defined at least as MR4. After discontinuation patients were monitored. In case of loss of response, therapy was restarted. Only patients with a minimum follow-up of 6 months were included. Statistical methods: We estimated MR4 relapse-free survival and treatment-free remission (TFR) with the Kaplan-Meier method. Prognostic factors for MR4 relapse-free survival were assessed by univariate Cox regression model analysis.
Results: We analyzed a total of 46 patients who discontinued imatinib from August 2003 to October 2014. Median age was 53 year old (46-67). 24 were male, 22 were female; 27 (61%), 13 (30%) and 4 (9%) were low, intermediate and high Sokal score respectively; 43% (20/47) were pre-treated with interferon α (IFN). Reasons for discontinuations were comorbidities for 3 patients, patient request for 26 cases, intolerance for 13 patients, desire of pregnancy for 4 patients. Median time to CMR after the initiation of imatinib was 18 months (10-40). Median duration of CMR was 37 months (31-56) before stop. Median time of treatment with imatinib was 62 months (49-100). At 12 months, estimated MR4 relapse-free survival was 57.7% (95%CI 44.7%>74.2%). After a median follow-up of 37 months (14-77), estimated MR4 relapse-free survival was 42.9% (95%CI 29.8%>61.7%) (Figure 1). Overall, 24% (11/46) of patients lost major molecular remission (MMR). Only 2 patients lost Complete Cytogenetic Remission (CCyR). Median time to loss of MR4 was 4 months (2-7). Most of the patients lost MR4 within the first 7 months (figure 1). 48% (22/46) restarted treatment; median time to restart treatment was 6 months (4-12). 4 patients lost MR4 but never restarted treatment. No patients progressed. We assessed age, sex, Sokal score, previous IFN therapy, duration of imatinib therapy, time to CMR, and CMR duration until discontinuation as potential prognostic factors for MR4 relapse-free survival, but no statistically significant association were found. Patients who had to restart the therapy were treated with imatinib (19/22), nilotinib (2/22), vaccine (1/22). All of them regained at least an MMR (14 patients re-achieved a response ≥MR4). All patients were alive at the last follow up with the exception of one who died of colon cancer.

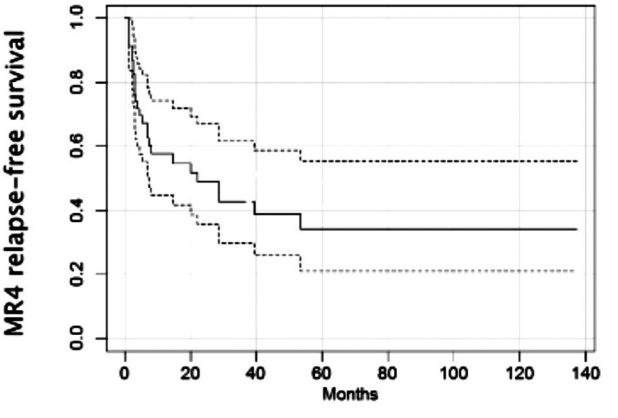

Figure 1. MR4 relapse-free survival.

Summary and Conclusions: Our experience, aligned to the literature, confirms that treatment discontinuation is feasible and safe for CML patients treated with imatinib front-line or after INF. No progressions occurred among our patients, considering that 75% of our population had a follow-up longer than 77 months. A close molecular monitoring is however required. 64% of patients regained a deep response, and may be considered for a second attempt of discontinuation.

P604

VALIDATION OF A NEW PROGNOSTIC SCORE AIMED TO IDENTIFY THREE GROUPS WITH DIFFERENT PROBABILITIES OF DYING OF CHRONIC MYELOID LEUKAEMIA IN 1,120 PATIENTS WITH FIRST-LINE IMATINIB TREATMENT

M. Pfirrmann[1,*] J. Hasford[1], A. Turkina[2], W. Prejzner[3], D. Zackova[4], A. Colita[5], A. Zaritskey[6], J.-L. Steegmann[7], K. Indrak[8], M. Baccarani[9]

Hospital Universitario de la Princesa, Madrid, Spain, [8]Department of Hemato-oncology, University Palackianae, Olomouc, Czech Republic, [9]Department of Hematology and Oncology L. and A. Seragnoli, S Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy

Background: A new prognostic score for differentiating cumulative incidence probabilities (CIPs) of dying of chronic myeloid leukemia (CML) was developed in the IN-study section of the European Treatment and Outcome Study (EUTOS) registry. From 2002 to 2006, all patients were enrolled in prospective, controlled clinical trials. They had Philadelphia chromosome-positive chronic-phase (CP) CML and started first-line imatinib-based treatment within half a year after diagnosis. In the OUT-study section of the registry, patients were prospectively registered, but, as the only contrast to the IN-study, not part of clinical trials.
Aims: To compare the performance of the Sokal, the Euro, the EUTOS, and the new score in the OUT-study data
Methods: Survival was counted from start of imatinib treatment and censored at the time of allogeneic stem cell transplantation (SCT) in first CP. Only death after recorded disease progression was regarded as death due to CML. CIPs of dying of CML were estimated, treating death due to any other cause as a competing event. All prognostic scores were calculated at diagnosis of CML. Overall level of significance was 0.05.
Results: Applying the same inclusion criteria as for the IN-study section, 1,120 patients of the OUT-study section were evaluable with regard to all prognostic scores and survival. These patients came from registries in Russia, the Czech Republic, Poland, Spain, and Romania. Median observation time was 5.6 years. Allogeneic SCT in first CP was performed in 29 patients (3%, 7 died). Without prior SCT in first CP, 116 patients died, 6-year CIP was 11% [95%>confidence interval (CI): 9-14%]. In 56 cases (48% of 116), cause of death was CML. Six-year CIP of death due to CML was 5% [95%>CI: 4-7%] and 6% [95%>CI: 5-8%] for death due to other causes. The new prognostic score identified 681 low-risk (61% of 1,120), 302 intermediate- (27%), and 137 high-risk patients (12%). Their 6-year CIPs of dying of CML were 3% [95%>C.I.: 2-5%], 6% [95%>C.I.: 3-9%], and 17% [95%>C.I.: 11-25%]. In the corresponding risk groups of the Sokal score the 6-year CIPs resulted in 3% [n=450, 95%>C.I.: 2-5%], 5% [n=411, 95%>C.I.: 3-8%], and 11% [n=259, 95%>C.I.: 8-16%] and with the Euro score in 4% [n=466, 95%>C.I.: 2-6%], 5% [n=523, 95%>C.I.: 3-7%], and 15% [n=131, 95%>C.I.: 9-23%]. The EUTOS score found a 6-year CIP of 5% [n=971, 95%>C.I.: 3-6%] for its low-risk and of 12% [n=149, 95%>C.I.: 7-18%] for its high-risk group. Each of the 4 prognostic scores provided significantly higher probabilities of dying of CML for the high-risk group as compared with each of the non-high-risk group(s) (all p values <0.005). The new prognostic score was also able to identify significantly different CIPs of dying of CML between the low- and the intermediate-risk group (p=0.04).
Summary and Conclusions: Judging from the CIPs and the distribution of the patients into the risk groups, the new score showed the best prognostic performance also in the out-study patients. Only the new model identified three risk groups with pairwise significantly different CIPs of dying of CML. With similar CIPs, the new score identified a much larger group of low-risk patients than the Sokal and the Euro score. Altogether, validation of the new score in the out-study data was successful. In the 681 patients of the low-risk group (61%), the new score showed an excellent long-term outcome when starting treatment with imatinib. Due to the worse results, for the high-risk patients (12%), an upfront comparison between different tyrosine kinase inhibitors would be highly desirable.

P605

PROGRESSION OF CHRONIC PHASE CHRONIC MYELOID LEUKEMIA TO ADVANCED PHASE ON TKI THERAPY: A POPULATION BASED ANALYSIS FROM THE SWEDISH CML REGISTER

S. Söderlund[1,*] T. Dahlén[2], M. Creignou[3], F. Sandin[4], U. Olsson-Strömberg[1], A. Dreimane[3], B. Markevärn[5], A. Själander[6], H. Wadenvik[7], L. Stenke[2], J. Richter[8], M. Höglund[1]
[1]Department of Medical Sciences, Uppsala University and Section of Hematology, Uppsala University Hospital, Uppsala, [2]Department of medicine, division of hematology, Karolinska University Hospital Solna, Stockholm, [3]Department of hematology, Linköping University Hospital, Linköping, [4]Regional Cancer Center, Uppsala University Hospital, Uppsala, [5]Department of hematology, Umeå University Hospital, [6]Department of public health and Clinical medicine, Umeå University, Umeå, [7]Section of Hematology and Coagulation, Sahlgrenska University Hospital, Göteborg, [8]Department of Hematology and Vascular Disorders, Skåne University Hospital, Lund, Sweden

Background: Chronic myeloid leukemia (CML) chronic phase (CP) patients treated with tyrosine kinase inhibitors (TKIs) today have an excellent prognosis, but those progressing to accelerated phase (AP) or blast crisis (BC) still have a dismal outcome. The primary goal of CML treatment is therefore to prevent disease progression, and with Imatinib treatment progression rates have been reduced to less than 3% per year. By identifying risk factors for progression already at diagnosis, and by early therapeutic intervention in patients showing insufficient treatment response, the progression rates may be further reduced. The Swedish CML register is population-based and contains data on Swedish CML patients at diagnosis and follow up. The estimated coverage is >95% of newly diagnosed CML patients. This gives us an opportunity to characterize CML patients who are diagnosed in CP and progress to AP or BC during TKI treatment in a population based material.
Aims: To characterize CML patients diagnosed in CP and treated with TKIs who progress to AP or BC within 24 months from diagnosis with regard to baseline characteristics, adherence to national guidelines for CML management and to evaluate progression rates and outcome in a population based setting.
Methods: Patients diagnosed in CP and treated with TKIs between 1 Jan 2007 and 31 Dec 2012 were selected from the Swedish CML register database and those who progressed within 24 months from diagnosis were further evaluated through review of patient charts.
Results: In total, 437 CP CML cases, aged 61 (47-72) years, were registered during the study period. Nineteen patients (4.6%), all treated with Imatinib first line, progressed to advanced phases (5 AP, 13 BC, 1 unknown). Six of these progressed within 6 months, seven between months 6-12 and six during the second year from diagnosis. This corresponds to a cumulative probability of progression of 3.1% at 12 months and 4.6% at 24 months. At baseline, 37% of progression patients were EUTOS high risk, as compared to 13% of patients who did not progress (p=0.014). Patients later progressing to AP/BC had a higher percentage of blast cells in peripheral blood at diagnosis (median 2.4 *vs* 1.0%, p<0.001) and lower platelet counts (322 *vs* 429x10^9/l; p=0.022). No difference between progression and non-progression cases were observed with respect to age, WBC, Hb, Sokal and Hasford score. Adherence to national guidelines for monitoring was suboptimal in several progression cases. Thus, at 6 months, 42% of the patients that later progressed to AP/BC were not subject to genetic evaluation by cytogenetics or qRT-PCR. Clonal evolution was noted in 5 patients (28%) as an early sign of progression.
First line treatment of AP/BC consisted of chemotherapy in combination with TKI switch in 6 patients, TKI switch only in 7 patients, TKI dose increase in 2 patients and palliative chemotherapy in 2 patients. Eight BC patients and 1 AP patient underwent allogeneic HSCT. Median survival after transformation to AP/BC was 1.4 years (Figure 1).

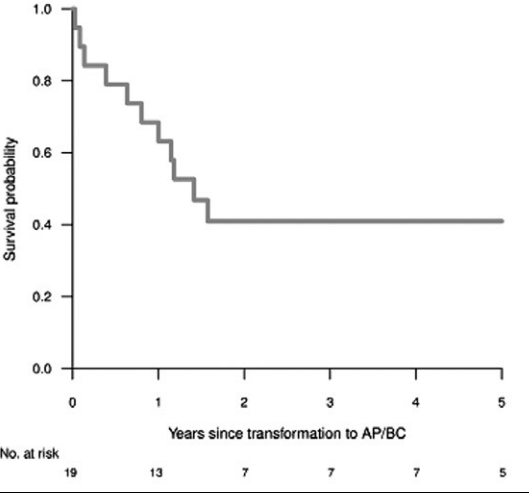

Figure 1.

Summary and Conclusions: The cumulative probability of progression from CML CP to AP or BC at 24 months from diagnosis in this Swedish population based cohort[JR1] [SS2] was 4.6%, which is similar to findings in studies based on more selected patient groups. Median survival for patients progressing to AP/BC was poor. The proportion of patients progressing to AP/BC may be reduced by more stringent monitoring and by earlier therapeutic intervention as prescribed in national and international guidelines.

P606

INTERFERON-ALPHA REVISITED: INDIVIDUALIZED IMMUNE-MODULATION EASED UP SELECTION PRESSURE OF TKI ON BCR-ABL MUTATED CLONES AND IMPROVES MOLECULAR RESPONSE IN HIGH-RISK CML PATIENTS

V. Polivkova[1], P. Rohon[2], N. Curik[1], H. Klamova[1], O. Cerna[3], M. Divoka[2], J. Zach[1], M. Novak[2], I. Marinov[1], S. Soverini[4], E. Faber[2], K. Machova Polakova[1,*]
[1]Institute of Hematology and Blood Transfusion, Prague, [2]Department of Hemato-Oncology, Palacky University, Faculty of Medicine and Dentistry, Olomouc, [3]Department of Internal Medicine and Hematology, 3rd Faculty of Medicine, Charles University in Prague, Prague, Czech Republic, [4]Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, Italy

Background: CML patients in whom the tyrosine kinase inhibitor (TKI) therapy

(imatinib, dasatinib, nilotinib) fails due to T315I BCR-ABL kinase domain mutation, should be switched to ponatinib or for bone marrow transplantation. However, in individual cases these treatment scenarios cannot be applied. We used treatment with interferon-α (IFN, given solo, sequentially or together with TKI) assuming that TKI-independent mechanism of action may lead to T315I mutant clone repression.

Aims: To study an effect of IFN-based treatment on mutated BCR-ABL transcript level and overall response of CML patients who failed on TKIs. In addition to that to assess the role of the sensitive measurement of BCR-ABL mutant mRNA load dynamics and immune response induced by IFN in individualized treatment.

Methods: Six CML patients who had failed on TKIs due to T315I or other highly resistant mutational profile have been treated with individual IFN-based treatment strategies. Kinase domain mutations in cDNA of BCR-ABL were analyzed in total 54 samples (median 6 samples of each patient, range 5-15) of peripheral blood leukocytes using next-generation deep sequencing (GS Junior, Roche Applied Science). The T315I clone reactivity on lowering imatinib concentration (2.0, 1.0, 0.4 and 0 μM imatinib) was studied *in vitro* on KCL22-R cell line resistant to 4.0 μM imatinib with 45% of BCR-ABL T315I. KCL22-R were incubated in each imatinib concentration for 14 days and checked for mutation. The basic immune-profile was analyzed in 5/6 CML patients using flow-cytometry detecting populations of CD4+, CD8+, regulatory T-cells (Tregs) and NK cells in specific time points (*e.g.* before IFN initiation, during IFN-based treatment).

Results: The switch of TKI to IFN-based treatment resulted in decreasing of mutated BCR-ABL mRNAs to undetectable levels in 4/6 patients. Three of those patients achieved major molecular response (MMR). IFN has been stopped, based on non-mutated BCR-ABL transcripts detection, continuing with solo nilotinib in 1/4 patient who achieved complete cytogenetic remission (CCgR). One case of MMR responding patient on solo IFN treatment showed decreased levels of CD3+ T-lymphocytes and elevated levels of NK cells. Other two patients who achieved MMR after IFN expressed elevated levels of NK cells representing probably an immune activation on dasatinib pre-treatment following with restoring immunological surveillance after application of combined treatment IFN with TKI. In 2/6 cases TKI cessation and IFN introduction did not contribute to the BCR-ABL mutations reduction and response improvement.

No changes in the BCR-ABL T315I transcript levels have been observed after 14 days of incubation of KCL22-R upon easement of selective pressure of imatinib. We assume that longer time of incubation, which is ongoing, would be necessary to follow-up any changes.

Summary and Conclusions: In this work we showed that CML patients with TKI multi-resistant mutation T315I or other highly resistant BCR-ABL mutations may achieve CCgR or MMR thanks to IFN-based individualized treatment. These achievements may relate to immune-mediated anti-leukemic effects in this specific group of patients resulting in BCR-ABL clones repression. The sensitive measurement of mutated BCR-ABL transcript levels augments safety of this individualized treatment strategy.

P607

PREDICTION OF THE NUMBER OF CML- PATIENTS IN GERMANY: UP TO 20,000 ARE TO BE EXPECTED IN THE NEAR FUTURE

M. Lauseker[1,*] R. Gerlach[2], M. Tauscher[2], J. Hasford[1]
[1]Institute for Medical Information Sciences, Biometry, and Epidemiology, Ludwig-Maximilians-Universität, [2]Kassenärztliche Vereinigung Bayerns, München, Germany

Background: Since introducing Tyrosine Kinase Inhibitors (TKI) into the treatment of chronic myeloid leukemia (CML) the survival rates have increased remarkably and thus the patient numbers are rising too. It has been estimated that the prevalence of CML rises annually by about 10%, but exact figures are missing. As the treatment costs are considerable, a prediction of the number of patients in the future is of interest for a proper assessment of the economic impact.

Aims: Our first objective was to estimate prevalence and incidence of CML by using routine data from the Bavarian Association of Statutory Health Insurance Physicians (Kassenärztliche Vereinigung Bayerns). Based on these estimates the second objective was to find a model to predict patient numbers in Germany for the future accounting also for the changes in demography.

Methods: Data on ICD-10 codes as well as prescribed medication were available for about 10 million people in the statutory health insurance system in Bavaria for the years 2008 to 2013. Only patients with at least two recordings of CML (ICD C92.1) and a CML-related treatment (TKI, Interferon, Hydroxyurea, Busulfan) were included to avoid misclassification bias.

As survival rates could not be estimated from our data base, corresponding values were adapted from two recent publications, which both reported age-specific relative survival rates (Nennecke *et al.*, Bundesgesundheitsblatt 2014, and Smith *et al.*, BMJ open 2014), as well as current survival rates for the German population, obtained from the German Federal Statistical Office (GFSO). Data on the expected population projection - in twelve different scenarios, structured by birth rate, life expectancy and migration balance - was provided by the GFSO as well.

Results: The mean estimated raw incidence rate was 1.851 for women and 2.249 for men; the age-standardized (Old European Standard Population) rates were 1.300 and 1.768 for women and men. For mid-2009, we estimated the prevalence for men/women (each per 100,000 inhabitants): 0.100/0.285 (age 0-19 years), 1.065/1.904 (20-29), 3.523/3.798 (30-39), 6.778/6.845 (40-49), 7.919/11.151 (50-59), 19.282/21.935 (60-69), 22.877/28.194 (70-79) and 15.419/26.440 (80 and older). Based on the population data described above, we estimated a total number of about 7,000 CML patients in Germany for 2009. The estimations of the number of patients in the future according to the twelve population scenarios combined with the different survival assumptions (and the average of both) are depicted in Figure 1. An increase of the prevalence is expected in every scenario. Differences were due to the chosen survival scenario rather than due to the population scenarios. The number of patients in the most probable average survival scenarios will increase for the next 25 to 35 years.

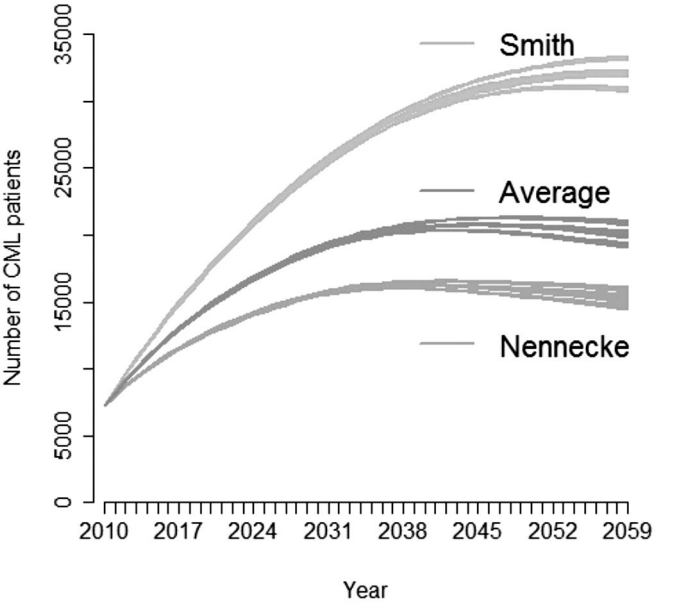

Figure 1.

Summary and Conclusions: The estimated incidence rates presented here are comparatively higher than in recent publications. Using a restrictive definition for case patients we do not think that there is much overestimation.

We expect the number of CML patients to increase further for at least 20 years, probably even longer. The survival estimate by Smith is based on relatively few patients and might thus lead to an overestimation. Vice versa, the estimate by Nennecke is in part based on patients known by death certificate only and might be slightly too pessimistic. From our point of view, the mean survival scenario seems to be the most realistic one, thus in Germany a maximum of about 20,000 CML patients is to be expected.

P608

KILLER IMMUNOGLOBULIN-LIKE RECEPTORS CAN PREDICT TKI TREATMENT-FREE REMISSION IN CHRONIC MYELOID LEUKEMIA PATIENTS

G. Caocci[1,*] M. Greco[1], R. Littera[2], S. Lai[2], S. Galimberti[3], C. Baraté[3], O. Mulas[1], C. Labate[4], C. Carcassi[2], B. Martino[4], G. La Nasa[1]
[1]Hematology, Department of Medical Sciences, [2]Medical Genetics, Department of Medical Sciences, University of Cagliari, Cagliari, [3]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, [4]Division of Hematology, Ospedali Riuniti, Reggio Calabria, Italy

Background: Discontinuation of Tyrosine Kinase inhibitors (TKIs) in chronic myeloid leukemia (CML) patients is currently a much debated challenge. Several drug-, disease- and patient-related parameters have been suggested to be predictive of durable treatment-free remission (TFR). Despite the well known anti-tumor effect of the innate immune system, few data exist on the role of natural killer (NK) cells and their killer-cell immunoglobin-like receptors (KIRs) in CML. In a previous report we found that a decreased frequency of the KIR2DL2 inhibitory receptor and homozygosity for KIR A haplotype were significantly associated to achievement of undetectable molecular response ($UMR^{4.5}$). A more recent report by other authors found that early disease relapse after TKI discontinuation was associated to both low numbers and impaired function of NK cells.

Aims: The primary aim of this study was to investigate whether NK cells and/or the KIR gene system could provide us with predictive immune-biomarkers of stable TFR in CML. A second endpoint was to evaluate which other patient/disease factors were related to relapse/non relapse after stopping TKI treatment.
Methods: The distribution of KIR and human leucocyte antigen (HLA) gene frequencies, KIR and HLA genotypes and KIR-ligand combinations were investigated in 22 chronic-phase CML patients who discontinued TKI treatment after achieving UMR$^{4.5}$. Age at diagnosis, gender, white blood cell (WBC) and platelet (PLT) counts, Sokal risk, splenomegaly, previous interferon treatment, rapidity in obtaining UMR$^{4.5}$ and overall treatment duration were also included in the binary logistic regression model in which TFR was considered as a dependent variable.
Results: Median age at diagnosis was 68 years (range 37-88) and 16/22 of the patients were males (72.8%); splenomegaly was detected in 13 patients (59%), ranging from 1 to 16 cm below the costal margin. Sokal risk was low in 54.5% of the patients, intermediate in 40,9% and high in 4.6%. Median follow-up was 11.5 years. Six/22 patients (27.3%) had been previously treated with interferon followed in 5 cases by imatinib; 14 patients were treated upfront with imatinib and 2 with nilotinib. All patients achieved UMR$^{4.5}$ after a median of 17 months (range 3-96) and, within the framework of a clinical protocol, discontinued TKI treatment at a median of 72 months from the start of treatment (range 23-105). The 36-month probability of TFR was 58.7%. The majority of relapses occurred within 8 months of interrupting therapy. TFR was significantly higher in patients not carrying the inhibitory KIR2DL2 receptor (81.4% *vs* 36.4%, p=0.039) (Figure 1). There was also a trend toward better TFR in patients homozygous for KIR A haplotype (80% *vs* 41.7%). Younger age, male sex and lower duration of treatment were significantly associated with relapse. All relapsed patients regained UMR$^{4.5}$ after restarting treatment with the same TKI.

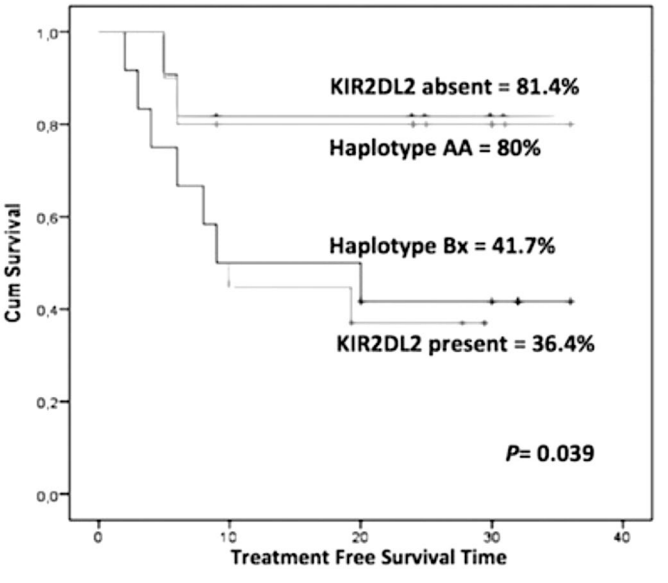

Figure 1.

Summary and Conclusions: Further investigation into innate immunity and the modulation of NK cell function could represent an important step ahead in the management and recovery from CML. Our results show that patients carrying the KIR2DL2 inhibitory receptor are at risk for not maintaining durable TFR. Previous reports show that homozygosity for KIR A haplotype is associated to better immune response with resistance to viral infection and tumor cells. Our findings suggest that this genotype could be a useful predictive marker when deciding whether or not to withdraw treatment in CML patients.

AML1-EVI-1 FUSION GENE INHIBITED DIFFERENTIATION AND APOPTOSIS IN ZEBRAFISH MYELOPOIESIS

L.-J. Shen [1,*]F.-Y. Chen[1]
[1]hematology, Renji Hospital,Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: *AML1-Evi-1* is a chimeric gene generated by the t(3;21)(q26;q22) translocation, which leads into malignant transformation of hematopoietic stem cells (HSCs) by many mechanisms which have not been thoroughly elucidated.
Aims: We established a stable line of zebrafish expressing the human *AML1-Evi-1* fusion gene under the control of a heat stress-inducible bidirectional promoter, named as Tg(*AE*:HSE:EGFP) line, to study its roles in hematopoiesis and hematologic malignancies.
Methods: Using Wright Giemsa stain detected the blood cell distribution in peripheral blood and kidney. The changes of hematopoietic regulatory factors were examined through RT-PCR and whole mount *in situ* hybridization. Agilent microarray analysis was performed to find the most relevant Kyoto Encyclopedia of Genes and Genomes (KEGG) terms associated with differentially expressed genes (DEGs) between wild type and Tg(*AE*:HSE:EGFP) F2 generation. Furthermore, we investigated the *in vivo* effects of histone deacetylase inhibitor, valproic acid (VPA), on *AML1-Evi-1*-expressing cells.

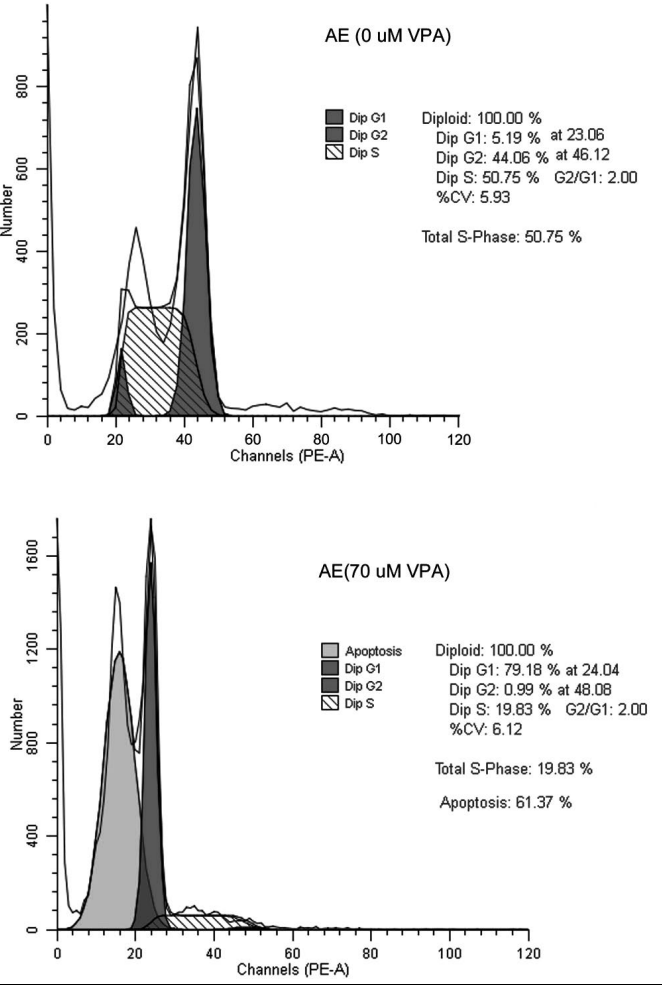

Figure 1.

Results: Three of 146 (2.1%) mosaic F0 zebrafish embryos were identified as the stable positive germline transgenic zebrafish, including 2 males and 1 female. The Transgenic F1 generation were mated to create homozygous Tg(*AE*:HSE:EGFP) line. Immature myeloid cells and hematopoietic blast cells were accumulated in peripheral blood and single cell suspension from kidney in adult Tg(*AE*:HSE:EGFP) zebrafish. *AML1-Evi-1* presented an intensive influence on hematopoietic regulatory factors. Consequently, primitive hematopoiesis was enhanced by upregulation of *gata2* and *scl*, erythropoiesis was downregulated due to the suppression of *gata1*, while early stage of myelopoiesis was flourishing

according to the higher expression of *pu.1* but inhibited along with the lower level of *mpo* expression. These characters closely resemble to the main aspects of human myeloid leukemia. Therefore, this model facilitated dissection of *AML1-Evi-1*-mediated pathomechanism *in vivo*, and enabled high-throughput scale screens to identify the potential therapeutic targets. Microarray analysis demonstrated that *AML1-Evi-1* upregulated Proteasome, Cell cycle, Glycolysis/Gluconeogenesis, Tyrosine metabolism, Drug metabolism, and PPAR pathway. Meanwhile, transforming growth factor β (TGFβ), Jak-STAT, DNA replication, Mismatch repair, p53 pathway, JNK signaling pathway, and Nucleotide excision repair were distinctly suppressed. It's worth noting that histone deacetylase 4 was dramatically decreased. Factors involved in cell proliferation were obviously suppressed after 3-day treated with VPA. Accordingly, higher proportion of G1 arrest and apoptosis were manifested by the propidium iodide staining.
Summary and Conclusions: The phenotypes of Tg(*AE*:HSE:EGFP) fish resemble to those of the human's MDS-RAEB or AML. *AML1-Evi-1* could promote the primitive hematopoietic cell proliferation and apoptosis resistant, inhibit myeloid cells differentiation through synergy of several pathway and factors. We propose VPA to be an attractive choice in the molecular targeting therapy of *AML1-Evi-1*-related leukemia.

P610

THE INFLUENCE OF SF3B1 MUTATIONS ON THE RESPONSIVENESS OF BLOOD CANCERS TO MOLECULAR THERAPEUTICS

F. Liberante[1,*] K. Lappin[1], M.-F. McMullin[1], K. Savage[1], K. Mills[1]
[1]Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom

Background: In recent years, high-throughput sequencing has identified mutations in the SF3B1 gene in a variety of blood cancers such as myelodysplastic syndromes (MDS), acute myeloid leukemias (AML) and chronic lymphocytic leukemias (CLL). The majority of mutations reported involved a single nucleotide substitution that alters a lysine codon into a glutamate (K700E). This alteration, along with all other known mutations, resides within the HEAT domains of the protein. This narrow localisation of the substitutions in combination with the absence of nonsense mutations suggests that SF3B1 mutations lead to alteration of function rather than simple haploinsufficiency. Furthermore, their prevalence implies the mutations are relevant to these diseases, if not disease-causing. In terms of clinical utility, identifying therapies which target cells harbouring mutant SF3B1 would be of great benefit, as there is pressing need to improve available therapies for all these diseases; particularly MDS, a disease of the elderly.
Aims: To explore the tractability of SF3B1 mutations by standard and advanced molecular therapies; using isogenic pre-clinical models of myelodysplasia and acute myeloid leukemia harbouring the mutant protein.
Methods: A lentiviral platform was used to introduce wild-type or mutant SF3B1 into cell lines representing the spectrum of MDS>AML, including MDS-L, SKM-1 and OCI/AML-3. The system allows finely tuneable conditional expression of the gene. The effects of variable gene expression, both mutant and wild-type on the susceptibility of these cells to molecular agents was assessed by cytology, proliferation, viability and apoptosis assays. Further genome-editing via CRISPR/Cas9 nucleases is being used to create isogenic models. In addition, other molecular effects, such as reduced DNA damage response were assessed.
Results: The conditional expression system was successful in producing titratable levels of the mutant protein. Cells which over-expressed the mutant protein had reduced proliferation compared to those harbouring only the wild-type gene. Those cells also had higher rates of spontaneous death in culture without further insult. Furthermore, the mutant expressing cells showed altered DNA damage repair after exposure to DNA-damaging chemotherapies, such as Etoposide. In line with this defect, they also demonstrated greater sensitivity to Poly ADP Ribose Polymerase inihibitors (PARPi).
Summary and Conclusions: This study has shown that an altered spliceosome, via SF3B1 mutation, results in a DNA damage repair defect. In terms of clinical applicability, this finding supports the idea that these mutant cells, with resulting DNA repair defects, can be treated with compounds that target DNA repair. One of the newest classes of small molecules in multiple clinical trials, are Poly ADP Ribose Polymerase inhibitors (PARPi), which showed a selective effect on mutant cells. In conclusion, these data suggest that this class of compounds has great potential in the treatment of SF3B1 mutant blood cancers; especially MDS or secondary AML.

Background: Global hypomethylation and targeted hypermethylation are considered defining characteristics of human tumors, including myeloid neoplasias (MN). Folate, methionine and vitamin B12 can influence the supply of methyl groups and, therefore, the biochemical pathways of methylation processes. Moreover, single nucleotide polymorphisms in genes that encode DNA methyltransferases (DNMTs) as well as enzymes from folate/methionine metabolism can influence the DNA methylation status, as well as the individual susceptibility to develop MN, namely Acute Myeloblastic Leukemia (AML), Myelodysplastic Syndromes (MDS) and Myeloproliferative Neoplasias (MPN), including Chronic Myelogenous Leukemia (CML).
Aims: In this context, we analyzed the influence of the polymorphisms in *DNMT1*, *DNMT3a*, *DNMT3b*, *RFC1*, *CBS* and *MTRR* genes in DNA methylation status and its role as risk and prognosis factors for myeloid neoplasia.
Methods: This study enrolled 333 patients diagnosed with myeloid neoplasia (80 AML, 106 MDS, 147 MPN, being 77 CML) and 261 healthy controls. The genetic polymorphisms of *DNMT1* (rs759920), *DNMT3a* (rs2289195), *DNMT3b* (rs2424908), *RFC1* (rs1051266), *MTRR* (rs162036), MTHFR (rs1801131, rs1801133), and *CBS* (844ins68) were assessed by RFLP-PCR and Tetra-primer-ARMS-PCR. The localized methylation status was analyzed through *p15*, *p16*, *DAPK,* and *KEAP1* methylation profile by MSP. Global methylation status was assessed by 5-methylcytosine (5mC), 5-hydroxymethylcytosine (5hmC) levels and LINE-1 methylation. The statistical analysis was carried out by variance analysis, $\chi 2$ test, and Fisher exact test ($p<0.05$).
Results: Our results show that *CBS, MTHFR*, *DNMT1,* and *DNMT3b* genes influence the localized and global methylation status in a genotype-dependent manner. Moreover, *DNMT1* AA and *DNMT3b* CT genotypes were protector factors for MDS development [OR 0,49 (CI95% 0,27-0,90), p=0,03; OR 0,50 (CI95% 0,28-0,83), p<0,001]. The *DNMT3a* AG genotype was also a protector factor for AML development [OR 0,16 (CI95% 0,05-0,52), p<0,001]. Besides that, individuals with *DNMT1* GG genotype have an increase risk for develop SMD about 1,78-fold (CI95% 1,03-2,01; p=0,04), while those with the *DNMT3a* GG and *DNMT3b* CC genotypes have an increase risk for develop AML about 6,82-fold (CI95% 1,22-37,95; p=0,03) and 2,01-fold (CI95% 1,07-11,48; p=0,03), respectively. The *RFC1* GG genotype also increases the risk of CML development about 2,65-fold (CI95% 1,53-4,57; p<0,001). Moreover, *DNMT3a* genotype can influence prognosis since MDS patients with *DNMT3a* GG genotype had lower survival (p=0,032). We also observed that allele C from MTHFR polymorphisms (rs1801133) and the AC genotype from the same gene (rs1801131) significantly increase 1,55-fold (IC95%: 1,08-2,23; p=0,031) and 2,01-fold (IC95%: 1,25-3,21; p=0,012) the risk of MDS development, respectively.
Summary and Conclusions: These results suggest that genetic polymorphisms in DNMTs and folate/methionine metabolism genes can influence the DNA methylation status, the susceptibility to develop MN and the prognosis of MDS patients.

APG101 (SOLUBLE CD95-FC) IMPROVES BFU-E GROWTH IN LOWER RISK MYELODYSPLASTIC SYNDROME WITH COLLAPSED ERYTHROPOIESIS: A PRECLINICAL STUDY

A. Raimbault[1], S. Bondu[1], C. Pierre-Eugène[1], C. Deudon[1], L. Willems[1], N. Chapuis[1], R. Sapena[2], A. Rouquette[3], C. Kunz[4], H. Fricke[4], O. Kosmider[1], V. Bardet[1], M. Fontenay[1,*]
[1]Hematology, AP-HP Hôpitaux Universitaires Paris Centre, Cochin, Université Paris Descartes, [2]Hematology, AP-HP Hôpitaux Universitaires Paris Centre, Cochin, [3]Epidémiologie et Biostatistiques, AP-HP Hôpitaux Universitaires Paris Centre, Cochin, Université Paris Descartes, Paris, France, [4]Apogenix GmbH, Company, Heidelberg, Germany

Background: The production of red blood cells is negatively regulated by caspase-dependent apoptosis of immature precursors mediated by death receptor CD95 when activated by its ligand, CD95L, in the bone marrow. CD95 is overexpressed at $CD34^+$ progenitor cell surface in two thirds of patients with low/int-1 risk myelodysplastic syndromes, and this contributes to anemia. CD95 overexpression may depend on methylation level (1) and on single nucleotide poly-

morphisms (SNP) at -1377 and -670 from ATG in the 5'UTR of *CD95* gene promoter. We have previously reported that resistance to erythropoiesis-stimulating agents (ESA) was significantly associated with CD95 overexpression and poor residual erythropoiesis.
Aims: In a preclinical study, we investigated an alternative therapeutic strategy for anemia in lower risk MDS based on inhibition of CD95-dependent apoptosis of erythroid precursors.
Methods: From a cohort of 250 MDS patients and 30 controls, CD95 and CD95L expression was quantified by flow cytometry, and SNP rs2234767 (-1377G>A) and rs1800682 (-670A>G) were determined by Sanger sequencing. The effect of APG101, a fusion protein consisting of the extracellular domain of human CD95 and Fc fragment of human IgG1, on erythropoiesis was investigated in 20 low/int-1 MDS and 6 control bone marrow samples from patients with another type of anemia in liquid cultures and/or clonogenic assays.
Results: CD95 and CD95L were overexpressed in 146/250 (58%) and in 48/82 (58%) MDS patients, respectively. In 147 samples, we showed that the -1377G allele, to which the transcription factor SP1 can bind, is more frequent in MDS compared to controls and that the -1377G/-670A haplotype is associated with a higher CD95 expression level than the -1377A/-670G ancestral haplotype (P=0.042). CD95L epigenetic regulation is currently under study. In liquid cultures, APG101 increased the number of erythroid progenitors of BFU-E type and the proliferation of erythroblasts by inhibiting apoptosis of immature precursors in 4 MDS samples, but not in 3 controls. In a series of 20 MDS with high CD95 expression level, APG101 improved the growth of bone marrow mononuclear cell (BMMC)-derived BFU-E in 15 MDS patients which erythropoiesis was initially collapsed with ≤15 BFU-E/10^5 BMMC, independently of CD95L level. APG101 had no effect on BFU-E number of control samples. More importantly, APG101 does not increase the expansion of non-erythroid leukemic clusters counted at day 7 of clonogenic assays.
Summary and Conclusions: These results delineate a subgroup of lower risk MDS with high CD95 expression and collapsed erythropoiesis that could benefit from alternative strategy to ESA. This provides with arguments for a phase I/II clinical trial in ESA-resistant lower risk MDS.

P613

AZACITIDINE IMPROVES THE T-CELL REPERTOIRE IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA WITH MULTILINEAGE DYSPLASIA

C. Fozza[1,*] G. Corda[1], F. Barraqueddu[1], P. Virdis[1], S. Contini[1], A. Isoni[1], F. Dore[2], E. Angelucci[3], M. Longinotti[1]
[1]Biomedical Sciences, [2]University of Sassari, Sassari, [3]UO Ematologia e CTMO Ospedale Oncologico A. Businco, Cagliari, Italy

Background: Patients with myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) with multilineage dysplasia show several immunological abnormalities. Azacitidine represents a therapeutic option for these disorders and, beside the well known effects on bone marrow precursors, has been demonstrated to potentially influence T-cell polarization.
Aims: The aim of this study is to monitor the kinetic of the T-cell receptor (TCR) repertoire during Azacitidine treatment in order to explore its potential ability, not only to restore the hematopoietic function, but also to reverse the immune derangement typical of these patients
Methods: Our study consisted in a flow cytometric and spectratyping analysis performed on the peripheral blood of 11 patients (5 with MDS and 6 with AML with multilineage dysplasia) and 30 normal controls. Each patient was evaluated at baseline and then every 3 cycles of Azacitidine. The flow cytometry analysis was based on a panel of 24 beta variable (BV) family-specific antibodies. The profile of the third complementarity-determining-region (CDR3) in separated helper and cytotoxic T-cells was then analyzed by spectratyping. After immunomagnetic CD4+/CD8+ cell separation, RNA extraction and reverse transcriptase PCR, CDR3 fragment analysis was performed through capillary electrophoresis.
Results: By flow cytometry, we first demonstrated a variable improvement from baseline to the following evaluations in the frequency of CD3+ (mean 63.00% *vs* 68.24%, p=0.03), CD4+ (40.09% *vs* 42.05%, p=0.04) and CD8+ cells (20.27% *vs* 25.10%, p=0.02), whereas the frequency of CD16+ CD56+ cells was stable (8.50% *vs* 8.45%, p=0.22). Also the frequency of regulatory T-cells (0.53% *vs* 0.45%, p=0.84) and BV expansions was substantially stable in both CD4+ (mean 1.60% *vs* 2.53%, p=0.36) and CD8+ cells (5.20% *vs* 5.60%, p=0.79). Noteworthy, when monitored by spectratyping during their treatment our patients showed significant changes in their CDR3 profiles, which were much more evident in helper T lymphocytes. In fact, the frequency of skewed B*Vs* was significantly decreased from baseline to the following evaluations in the CD4+ subset (mean 81.45% *vs* 70.17%, p=0.004). In more details the mean frequency of skewed subfamilies in CD4+ cells decreased from 81.45% at baseline to 75.91% at 3 months, 80.86% at 6 months, 58% at 9 months, 17% at 12 months and 22% at 18 months. This pattern was even more pronounced in patients responding to Azacitidine (89.60% *vs* 61.47%, p=0.002). Also in the CD8+ subset a slight but statistically significant trend towards a reduction in the frequency of skewed CDR3 profiles (mean 99.27% *vs* 98.74%, p=0.01) was demonstrated. Beside our patients showed a substantially stable frequency of oligoclonal profiles in both CD4+ (mean 3.00% *vs* 2.74%, p=0.47) and CD8+ cells (11.82% *vs* 11.61%, p=0.19).
Summary and Conclusions: Our findings firstly confirmed in our patients an overall derangement of the TCR repertoire. However this pattern seems to gradually improve during Azacitidine treatment, as witnessed by the improvement in T-cell counts observed on flow cytometry but much more by the progressive restoration of the CDR3 diversity detected by spectratyping, especially within the CD4+ subset. Therefore our data suggest that Azacitidine could be potentially able to reverse the immune derangement typical of patients with MDS and AML with multilineage dysplasia.

P614

REPOPULATING PROGENITOR CELLS IN PRIMARY MDS BONE MARROW CELL CULTURE IN SEVERE HYPOXIC CONDITIONS

E. Masala[1,*] F. Buchi[1], S. Pillozzi[2], A. Valencia Martinez[1], T. Rondelli[3], A. Gozzini[1], A. Sanna[1], A. Bosi[1], P. Dello Sbarba[2], V. Santini[1]
[1]Experimental and Clinical Medicine, [2]Pathology and Experimental Oncology, [3]General Laboratory, University of Florence, Florence, Italy

Background: Myelodysplastic Syndromes (MDS) are clonal disorders. However, whether the transforming event occurs in a myeloid committed cell or in earlier progenitor (stem cell ?) it is still not ascertained. Evidence have been accumulated in both senses, but certainly, MDS initiating cells must be capable of sufficient repopulating capacity to perpetuate the disease.
Aims: We evaluated the repopulating ability and stem cell potential of hypoxia maintained primary bone marrow (BM) progenitors derived from Myelodysplastic Syndromes (MDS).
Methods: Thirty seven BM samples were obtained at diagnosis from MDS patients (WHO: 10 RA, 12 RCMD, 7 RAEB, 8 AL/post MDS). Mononuclear BM cells were isolated and cultured with TPO, FLT3-L, SCF, IL-3 in severe hypoxic conditions (0,3%O_2, 5%CO_2, 95%N_2), for 10-13 days (LC1). The stem cell potential of these cultures was explored by transferring cells to growth-permissive secondary cultures in normoxia (LC2), in the presence of SCF, G-CSF, IL-6, IL-3, and according to the Culture-Repopulating Ability (CRA) assay methodology, cell proliferation was evaluated daily. Expression of CD34, CD38, CD117, CD133 was determined and when present, the persistence of chromosomal aberrations was analyzed by FISH at various stages of cell culture. In parallel, MDS mononuclear BM cells were intravenously injected in sublethally irradiated NOD-SCID mice before hypoxic culture and after LC1 (1x10^6 cells inoculated per mouse). Mice were sacrificed at day 56 after graft. The presence of CD45+ human cells in the peripheral blood of injected mice was evaluated by flow cytometry analysis every two weeks, and quantified to evaluate the repopulating ability and the different engraftment capacity of cells before hypoxic culture and after hypoxic selection. Mice marrow trephines as well as spleen and liver biopsies were also evaluated morphologically to test the engraftment of human MDS cells.
Results: In all 37 MDS cases studied, cultured cell number decreased of one log or more after 10-13 days of culture in hypoxic conditions. Only 12/37 MDS cases showed a significant repopulating ability at day 17 of LC2, all classified as Low/INT1 IPSS risk category. In IPSS high and INT-2 risk cases, repopulating ability according to CRA method was absent. CD34+ cells were always decreased after hypoxia and did not co-express CD38. We demonstrated the persistence of chromosomal aberrations in CD34pos/CD38neg cells after hypoxic culture in 5 MDS cases (del5q, +8, del20q, -Y, complex karyotype). We observed in sublethally irradiated NOD-SCID mice transplanted with hypoxia cultured cells a significantly higher percentage of CD45+ human cell that in mice transplanted with non hypoxia selected cells, at days 28 after transplantation (5,5% *vs* 0,56%); at the same time, the analysis of cells derived from mice spleen showed a significantly higher percentage of CD45+ human cell (1,83%) in mice transplanted with hypoxia selected cells than mice transplanted with non selected cells (0,16%); by the other hand, the analysis of cells derived from mice bone marrow showed an higher percentage of CD45+ human cells in mice transplanted with non hypoxia selected cells than mice transplanted with selected cells (2,16% *vs* 1,26%).
Summary and Conclusions: Severe hypoxic culture conditions are maintaining a sub-population of MDS cells endowed with increased repopulating capacity *in vitro* and *in vivo* in sublethally irradiated NOD-SCID mice. Most importantly, repopulating ability was observed exclusively in IPSS lower risk MDS cases.

P615

DIAGNOSTIC UTILITY OF MYELOID NUCLEAR DIFFERENTIATION ANTIGEN EXPRESSION AND OTHER FLOW CYTOMETRIC PARAMETERS IN MYELODYSPLASTIC SYNDROME

S. Venkatesan[1,*] S. Soni[2], M. Aggarwal[1], A. Chopra[2], R. Kumar[2], H. Pati[1]
[1]Hematology, [2]Laboratory Oncology, All India Institute Of Medical Sciences, New Delhi, India

Background: Diagnosis of myelodysplastic syndrome (MDS) based on morphology is particularly difficult in low grade MDS (*i.e.* <5% blasts, no ring sideroblasts and karyotypic abnormality). Hence, a more objective method is essential. Currently there are various guidelines for standardization of flow cytometry (FCM) in MDS. However; their widespread applicability may be challenging especially in resource limited settings, due to vast array of markers recommended by these guidelines.

Aims: This study was conducted to assess the utility of expression of MNDA along with quantitative FCM approach using "mini-panel" of antibodies (CD34, CD10, CD19, CD45, CD11b, CD15 and CD56) in MDS diagnosis.
Methods: Bone marrow aspirates (BMA) collected from 52 consecutive patients with suspected diagnosis of MDS were divided into three groups: (1) proven MDS (n=12) based on morphology and/or cytogenetics (2) suspected MDS (n=6), non-contributory morphology and cytogenetics (3) non-MDS (n=34). Sixteen control BMA were also studied. 44 cases (12 MDS, 06 suspected MDS and 26 non MDS)were analyzed for MNDA expression (on granulocytes, blasts, monocytes and lymphocytes) and 52 cases were analyzed for seven quantitative parameters: (1) CD34+ myeloblasts% in nucleated cells (2) CD34+ B-cell progenitor% in all CD34+ cells (3) lymphocyte/myeloblast CD45 mean fluorescence intensity ratio (4) granulocyte/lymphocyte SSC peak channel ratio and the proportion of CD34+ myeloblasts expressing (5) CD15 (6) CD11b and (7) CD56. ROC curves were constructed for each parameter. A score of 1 was given to each of these parameters beyond the cut-off and score ≥3 was considered as FCM positive.
Results: MNDA expression in granulocytes and myeloblasts was significantly lower in MDS cases as compared to controls (p=0.003 and 0.001 respectively). The percentage of MNDA negative granulocytes (mean+SD, 79.9%+13.4%, p<0.001) was higher in MDS cases as compared to non MDS (53.46%+19.6%). Similar differences were also seen in myeloblasts (88.85%+7.3% in MDS *Vs* 60.3%+18.15% in non MDS, p<0.001). Monocytes, however; failed to show any significant difference between these groups (p=0.802). ROC cut-off value for granulocytes had sensitivity and specificity of 75% and 76.92%, respectively and for myeloblasts 91.6% and 88.5%, respectively for discriminating between MDS and non MDS. MNDA expression was significantly reduced in suspected MDS as compared to non MDS cases in both: granulocytes (p=0.032) and myeloblasts (p=0.004). On the basis of ROC cut offs, MNDA expression was altered in either granulocytes or myeloblasts (single abnormality) in five/six cases (83.3%) where four/six cases (66.7%) had dual abnormality (altered in both granulocytes and myeloblasts). However significant difference between the suspected MDS and non MDS was seen in the presence of dual abnormality only (p=0.022) and not in case of single abnormality (p=0.336). In other quantitative FCM parameters assessed, a score of ≥3 successfully distinguished MDS from non-MDS with a sensitivity of 100% and specificity of 95.2%. After incorporating MNDA score into the quantitative FCM scoring (total 8 parameters), score ≥3 successfully discriminated suspected MDS from non MDS cases (p=0.005) and MDS from non MDS (p<0.001) with a sensitivity and specificity of 100% and 95.24%, respectively which is similar to those obtained at a score of ≥3 with quantitative approach (Figure 1 and Figure 2).

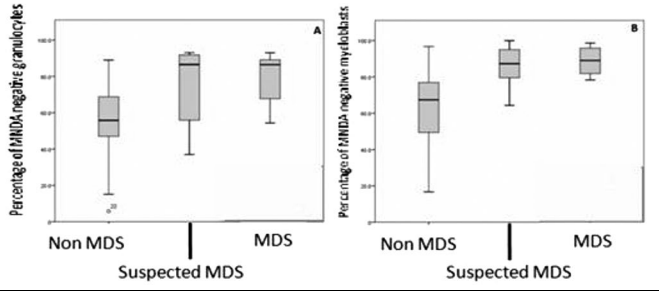

Figure 1. Box and whisker plot showing MNDA expression in different groups of patients. Percentage of MNDA negative granulocytes (A) and percentage of MNDA negative myeloblasts (B) in non MDS, suspected MDS and MDS cases.

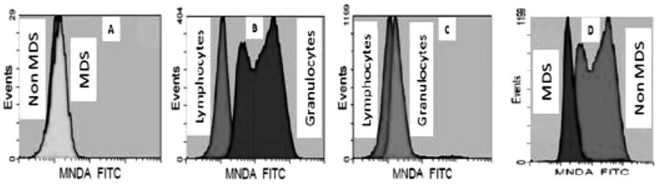

Figure 2. MNDA analysis in non MDS and MDS cases. MNDA expression is displayed for lymphocytes and granulocytes in a histogram. (A) Lymphocytes showing similar MNDA expression in both MDS and non MDS used as internal negative control (B) MNDA expression in granulocytes in a non MDS patient. (C) MNDA expression in granulocytes in a MDS patient.

Summary and Conclusions: Both MNDA analysis and quantitative FCM approach using "mini panel" of antibodies are independently able to discriminate MDS from non MDS and controls and correctly categorize suspected MDS as a distinct group. On merging the two approaches, the sensitivity and specificity of flow cytometric analysis did not improve. More studies validating this in a large cohort of patients are required before any conclusion can be reached regarding superiority of any method.

Myelodysplastic syndromes - Clinical 2

P616

OVERALL SURVIVAL (OS) AND BASELINE DISEASE CHARACTERISTICS IN MDS PATIENTS WITH PRIMARY HMA FAILURE IN A RANDOMIZED, CONTROLLED, PHASE III STUDY OF RIGOSERTIB

G. Garcia-Manero[1,*] P. Fenaux[2], A. Al-Kali[3], M. Baer[4], M. Sekeres[5], G. Roboz[6], G. Gaidano[7], B. Scott[8], P. Greenberg[9], U. Platzbecker[10], D. Steensma[11], K.-A. Kreuzer[12], L. Godley[13], R. Collins[14], E. Atallah[15], N. Azarnia[16], L. Silverman[17]
[1]MD Anderson Cancer Center, Houston, United States, [2]Hospital St Louis, Paris, France, [3]Mayo Clinic, Rochester, [4]University of Maryland, Baltimore, [5]Cleveland Clinic, Cleveland, [6]Weill Cornell Medical College, New York, United States, [7]Amedeo Avogadro University of Eastern Piedmont, Novaro, Italy, [8]Fred Hutchinson Cancer Research Center, Seattle, [9]Stanford Medical School, Stanford, United States, [10]Universitätsklinikum Dresden, Dresden, Germany, [11]Dana-Farber Cancer Institute, Boston, United States, [12]Universitätsklinikum Köln, Köln, Germany, [13]University of Chicago Medical Center, Chicago, [14]University of Texas, Southwestern Medical Center at Dallas, Dallas, [15]Froedtert Hospital and Medical College of Wisconsin, Milwaukee, [16]Onconova Therapeutics, Inc., Newtown, [17]Icahn School of Medicine at Mount Sinai, New York, United States

Background: ONTIME was a randomized (2:1) study of rigosertib (RIG) *vs* best supportive care (BSC, including optional low-dose ARA-C) in 299 pts with higher-risk MDS who had relapsed after, failed to respond to, or progressed during treatment with hypomethylating agents (HMAs). For MDS patients who fail HMAs, there are no FDA-approved therapies. Thus an unmet medical need exists for effective second-line therapies. ONTIME showed a significant treatment effect with RIG in the subgroup of patients with "primary HMA failure" (Garcia-Manero *et al.*, Blood 2014).
Aims: To describe differences in overall survival (OS) after primary or secondary HMA failure in 299 patients treated with RIG (N=199) or BSC (N=100) in a Phase III study.
Methods: We evaluated the correlation between baseline disease characteristics and OS in pts with primary HMA failure (RIG N=117; BSC N=52) as ascertained by a centralized, blinded reader.
Results: Pts with primary HMA failure were generally male (69%), age 50-86 years (median 73), at high or very high risk per IPSS-R (80%), with 5-19% bone marrow blast count (92%). A meaningful difference in median OS between RIG and BSC was observed not only in the overall population of pts with primary HMA failure, but also in several subgroups (see Table 1). Overall, adverse events (AEs) were reported in 99% of RIG pts and 88% of BSC pts. The following AEs >=Grade 3 were reported by ≥ 10% of pts: anaemia (16% RIG *vs* 10% BSC), thrombocytopenia (15% *vs* 6%), neutropenia (15% *vs* 8%), febrile neutropenia (13% *vs* 10%), pneumonia (12% each).

Table 1.

Median (months) OS by Baseline Disease Characteristics in Pts with Primary HMA Failure						
	RIG		BSC		Log-rank p-value	Hazard ratio (RIG/BSC) (95% CI)
Characteristic	N	OS	N	OS		
All patients with Primary HMA Failure	117	8.6	52	4.5	0.011	0.63 (0.44-0.90)
IPSS-R category of high or very high	97	8.6	38	4.1	0.0015	0.52 (0.35-0.79)
Bone marrow blast = 5%-19%	93	10.1	36	4.7	0.0079	0.58 (0.39-0.87)
Duration of prior HMA treatment < 9 months	79	8.6	37	4.5	0.0014	0.49 (0.31-0.76)

Summary and Conclusions: Patients with primary HMA treatment failure and certain subgroups identifiable on the basis of baseline disease characteristics randomized to RIG showed an improvement in OS compared to BSC. Such characteristics should be considered in the design of future trials in second-line in primary HMA failure patients.

P617

INFERIOR LONG-TERM OUTCOME OF FRONT-LINE HYPOMETHYLATING AGENT COMPARED TO SUPPORTIVE CARE IN PATIENTS WITH LOWER RISK MDS: PROPENSITY SCORE MATCHED ANALYSIS

J.H. Moon[1,*] Y.J. Lee[1], S.K. Sohn[1], J.S. Ahn[2], H.J. Kim[2], M.K. Song[3], H.J. Shin[3], W.S. Lee[4], S.M. Lee[4], Y. D. Joo[5], H. Kim[6], D.Y. Kim[7], H.S. Lee[8], Y.S. Kim[8], Y.Y. Cho[9]
[1]Hematology/Oncology, Kyungpook National University Hospital, Deagu, [2]Hematology/Oncology, Chonnam National University Hwasun Hospital, Hwasun, [3]Hematology/Oncology, Busan National University Hospital, [4]Hematology/Oncology, Inje University Busan Baik Hospital, [5]Hematology/Oncology, Inje University Haewoondae Baik Hospital, Busan, [6]Hematology/Oncology, Ulsan University Hospital, Ulsan, [7]Hematology, Asan Medical Center, Seoul, [8]Hematology/Oncol-

ogy, Kosin University Gosper Hospital, Busan, [9]Hematology/Oncology, Daegu Catholic University Medical Center, Deagu, Korea, Republic of

Background: Supportive care (BSC) including hematopoietic cytokines still remains an important component of treatment for lower-risk myelodysplastic syndrome (LR-MDS) including low or intermediate-1 risk by International Prognostic Scoring System (IPSS) even in the era of hypomethylating agents (HMA). The role of front-line HMA for LR-MDS has not been clearly defined yet.
Aims: We evaluated the long-term outcomes of patients with LR-MDS treated with front-line HMA compared to those treated with supportive care.
Methods: The data of 353 patients diagnosed with LR-MDS from Oct 1992 to Jul 2013 were retrospectively evaluated. The prognostic factors affecting overall survival were evaluated within all population. Then, we performed a case-constrol study using 122 patients with propensity score matched (PSM) population.
Results: Initial patient population (n=353) included 110 patients treated with BSC and 243 treated with HMA. Patients characteristics (age, gender, IPSS risk groups, IPSS blast score, IPSS cytopenia score) were similar between two groups, however, ECOG performance status (PS) and IPSS cytogenetic score were biased between two groups. ECOG-PS 2-3 were 32 patients (29.1%) in BSC and 20 (9.3%) in HMA group (p<0.001) and IPSS cytogenetic score ≥0.5 were 27 patients (25.2%) and 33 (14.6%) in HMA group (p=0.032). In the multivariate analysis, ECOG-PS 2-3 (HR 4.586, p<0.001), IPSS blast ≥0.5% (HR 2.549, p<0.001) and front-line HMA therapy (HR 2.019, p=0.006) were unfavorable factors affecting OS. Using PSM population, we performed a case-control study comparing the outcomes of 61 patients in each group who treated with BSC and front-line HMA. Patient characteristics were well balanced between two group. In the multivariate analysis, ECOG-PS 2-3 (HR5.036, p<0.001), IPSS blast ≥0.5% (HR 2.157, p=0.035), and first-line HMA therapy (HR 2.213, p=0.026) were still unfavorable factors for OS. The 5-year OS rate was 62.5±10.8% in BSC group and 41.0±7.4 in HMA group, respectively (p=0.049). Infection was the main cause of death among patients who received HMA ≤4 cycles (61.3%) compared to those who received HMA >4 cycles (22.2%, p=0.051) (Figure 1).

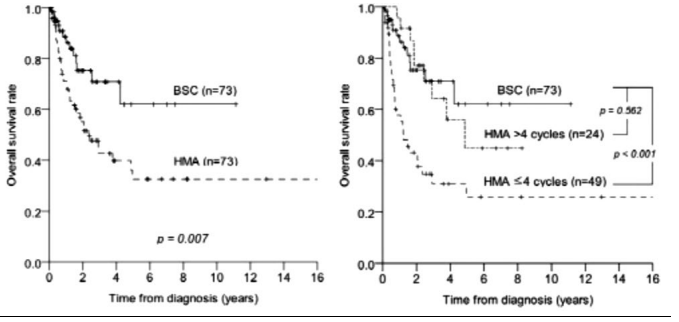

Figure 1.

Summary and Conclusions: Front-line HMA for patient with LR-MDS showed inferior long-term outcomes compared to BSC in PSM population. Early infection-related mortality could compromise the favorable effect of HMA. The effect of HMA on later leukemic transformation and resistance should be elucidated in the future studies.

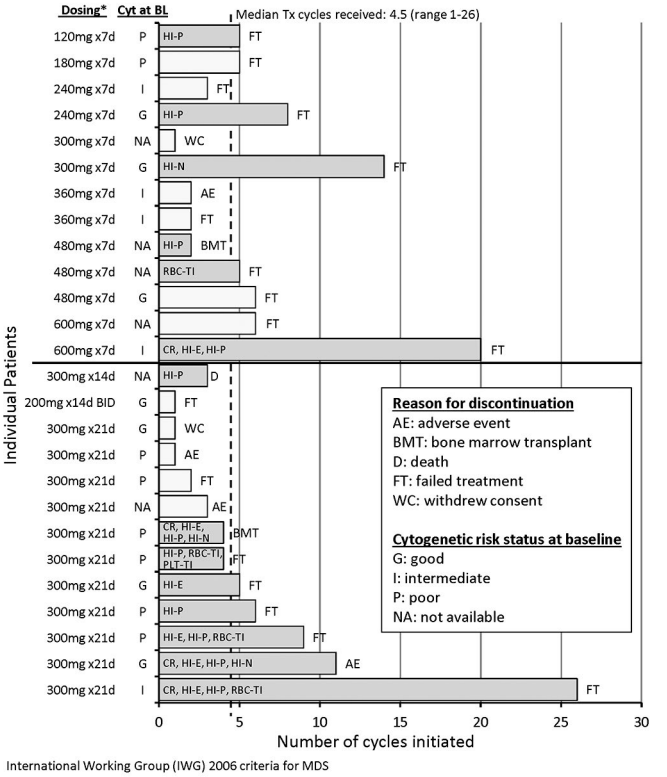
P618

EFFICACY OF CC-486 (ORAL AZACITIDINE) TREATMENT (TX) IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS)

G. Garcia-Manero[1,*] M.R. Savona[2], S.D. Gore[3], P. Conkling[4], C.R. Cogle[5], J. Hetzer[6], Q. Dong[6], K. Kumar[6], S.M. Ukrainskyj[6], C. Beach[6], B.S. Skikne[6]
[1]University of Texas, MD Anderson Cancer Center, Houston, [2]Vanderbilt University Medical Center, Nashville, [3]Yale Cancer Center, New Haven, [4]Virginia Oncology Associates, Norfolk, [5]University of Florida, Gainesville, [6]Celgene Corporation, Summit, United States

Background: CC-486 has clinical activity in patients (pts) with IPSS-defined lower-risk MDS (Garcia-Manero, ASH 2010, 2012). This *ad hoc* analysis assessed CC-486 efficacy in a small group of pts with HR-MDS (IPSS Intermediate [INT]-2 or High-risk) from 2 phase I/II studies. While all pts had HR-MDS, CC-486 dosing schedules in these studies varied between administration for 7 days (d) per 28d cycle and extended administration (CC-486 x14 or x21d/28d cycle); prognostic disease variables at baseline differed; and, at study entry, some pts were MDS Tx-naïve while others had progressive disease despite prior Tx.
Aims: To explore whether differences in dosing schedules, prognostic disease features, and receipt of prior MDS Tx influenced overall response rate (ORR) with CC-486 in pts with HR-MDS.

Methods: Pts received CC-486 120mg to 600mg QD x7d/28d cycle (7D cohort) or in an extended dosing schedule (ED cohort): 300mg QD x21d/28d (21D); 300mg QD x14d/28d (QD-14D); or 200mg BID x14d/28d (BID-14D). Dosing schedules in the ED cohort were analyzed collectively. Prognostic Risk Index scores for this *ad hoc* analysis were calculated as 1 point each for the following abnormalities at baseline: Hgb <11 g/dL, ANC <1.0x10^9/L, platelets <100x10^9/L, BM blasts ≥5%, and transfusion of ≥4 RBC units or ≥2 platelet units in the 56 days before study entry. ORR (IWG 2006) included complete or partial remission, RBC or platelet transfusion independence, and any hematologic improvement. ORR was evaluated based on dosing cohort (7D or ED), prior MDS Tx (yes/no), and prognostic Risk Index scores (≤3/>3 abnormalities).
Results: In all, 13 pts (50%) comprised the 7D cohort and 13 (50%) comprised the ED cohort (21D n=11, QD-14D n=1, BID-14D n=1). At baseline, most pts had IPSS INT-2 MDS (n=24, 92%), were male (n=19, 73%), and had ECOG PS of 0-1 (n=22, 85%). Pt diagnoses were RAEB-1 (n=11, 42%), RAEB-2 (n=11, 42%), RCMD (n=3, 12%), and RA (n=1, 4%). Overall, 11 pts (42%) had received prior MDS Tx (ESAs, growth factors, thalidomide, lenalidomide, and/or hypomethylating agents [HMAs, n=7]). Median ages in the 7D and ED groups were 69 (range 31-91) and 75 (47-87) years, respectively. Median time since diagnosis was 3.9 months (range 0.7-40) in the 7D group and 5.3 months (0.4-119) in the ED group. Median Hgb, ANC, and platelet counts in the 7D group were 9.1 g/dL, 0.6x10^9/L, and 54x10^9/L, respectively, and in the ED group were 9.0 g/dL, 0.4x10^9/L, and 19x10^9/L. Most pts (n=17, 65%) had prognostic Risk Index scores >3. One pt (7D cohort) was not evaluable for response (no post-baseline data). ORR for all pts was 56% (14/25) (Figure 1), including 5/8 pts with poor-risk cytogenetics. ORR in the 7D and ED cohorts were 46% (6/13) and 67% (8/12), respectively. ORR in pts who had received prior MDS Tx was 40% (4/10, including 2/7 pts who had received prior HMA Tx and responded to CC-486) and in pts who had no prior MDS Tx was 67% (10/15). ORR in pts with prognostic Risk Index scores ≤3 and >3 were 50% (4/8) and 59% (10/17), respectively.



International Working Group (IWG) 2006 criteria for MDS

*All but 1 patient received CC-486 doses once daily (QD)

BL = baseline; CYT = cytogenetics; CR = complete remission; HI = hematologic improvement; HI-P = HI platelet lineage; HI-E = HI erythroid lineage; HI-N = HI neutrophil lineage; RBC = red blood cell; PLT = platelet; TI = transfusion independence

Figure 1. CC-486 in patients with Higher-risk MDS.

Summary and Conclusions: More than one-half of these pts with HR-MDS attained a hematologic response with CC-486. In this small patient group, prolonged exposure to CC-486 resulted in a higher proportion of response. Absence of prior MDS therapy was associated with better response, though prior HMA Tx did not preclude response to CC-486. Baseline prognostic Risk Index score did not influence ORR, suggesting that underlying molecular pathways or genetic factors may have a greater influence on Tx response.

P619

AZACITIDINE (AZA) IN HIGHER RISK MDS PATIENTS WITH CHROMOSOME 7 ABNORMALITIES (ABN 7): RESULTS OF A RETROSPECTIVE STUDY FROM THE GFM AND GESMD REGISTRIES

M. Díez Campelo[1,2,*] J.I. Lorenzo[3], R. Itzykson[4], S. Rojas Porras[1], R. Guièze[4], E. Luño[1], C. Berthon[4], J.M. Hernández Rivas[1], O. Beyne-Rauzy[4], J. Pérez de Oteiza[1], N. Vey[4], B. Xicoy[1], S. Park[4], A. Bailén García[1], D. Bordessoule[4], J. Bargay[1], E. Gyan[4], E. Such[1], S. Visanica[4], T. Cedena[1], S. De Botton[4], M. Tormo[1], S. Ame[4], M. Calabuig[1], A. Stamatoullas[4], F. Ramos[1], J. Delaunay[4], M.Á. Ruiz Guinaldo[1], C. Salanoubat[4], A. Fernández González[1], F. Isnard[4], G. Sanz[1], R. Guieze[4], C. del Cañizo[1], P. Fenaux[4]
[1]Hematology, GESMD, Valencia, [2]Hematology, Hospital Universitario de Salamanca, Salamanca, [3]Hematology, Hospital La Fe, Valencia, Spain, [4]Hematology, GFM, Paris, France

Background: Cytogenetic alterations are the most discriminative prognostic variables in MDS, complex karyotype (CK) and Abn7 having the poorest outcome. Data from small series have suggested that non complex Abn 7 are associated with relatively favorable response to AZA in MDS.The paradigm that CR or PR is necessary to prolong OS with AZA treatment has also been challenged.
Aims: We analyzed in a large series of higher risk MDS with Abn 7 treated with AZA the impact of response on survival compared to best supportive care (BSC).
Methods: This study analyzed 235 patients with higher risk (IPSS Int-2 and high) MDS with Abn 7 included in the French and Spanish MDS registries. 115 patients received AZA (75 mg/m^2/d for 7 days [n=92] or 5 days [n=23] every 4 weeks; median number of cycles, 5 [range, 1 - 32]) and 120 received only BSC (control group). The effect of response to AZA (IWG 2006 criteria) on outcomes was evaluated by time-dependent multivariable methods.
Results: Baseline characteristics were similar in both groups (Table 1). 91 AZA-treated patients were evaluable for response. The ORR was 42.8% (n=39), including 16.4% CR and 26.4% SD with HI. Among non-responders, 53.8% had SD without HI and 46.2% progressed. 11 (16%) of 67 RBC transfusion dependent patients became transfusion independent. The ORR was 43% in pts with CK, 35% in pts with non complex and -7 and 50% in pts with non complex and del(7q) (p=0.1 for complex *vs* non complex Abn 7). At last follow up, 61 patients had relapsed or progressed (53%) and 92 (80%) had died. AML-free survival and OS estimates at 1 and 2 years were 62 and 31% and 43% and 16%, respectively. In multivariable time-dependent analyses in the overall series response to AZA, IPSS risk group, and CK had a significant independent impact on OS and AML-free survival. Compared to untreated patients, any type of response to AZA and SD without HI was significantly associated with a reduced risk of mortality and AML progression (Tables 2 and 3).

Table 1. Patients and disease characteristics.

VARIABLE	AZA N=115	SUPPORTIVE CARE N=120	P
Age. mean years	67.4	67.4	
Age. median	69.7	73.8

P621

TREATMENT OF HIGHER-RISK MYELODYSPLASTIC SYNDROME (MDS) WITH AZACITIDINE: A 4-YEAR POPULATION-BASED ANALYSIS FROM BRITISH COLUMBIA, CANADA

M. Ankenman[1,*] D. Hogge[1], S. Narayanan[1], M. Power[1], Y. Abou Mourad[1], M. Barnett[1], S. Nantel[1], H. Sutherland[1], D. Forrest[1], R. Broady[1], C. Toze[1], A. Gerrie[1], K. Song[1], T. Nevill[1]
[1]Leukemia/BMT Program of BC, Vancouver, Canada

Background: MDS is a clonal disorder with propensity to transform to AML. Prior to 2010, treatment was limited to supportive care or, in young patients (pts), stem cell transplantation (SCT). Azacitidine (AZA), a hypomethylating agent, produces hematologic improvement (HI) in 50% of higher-risk MDS pts and prolongs overall survival (OAS; Fenaux, 2009). Health Canada approved AZA in October 2009 after which the British Columbia Cancer Agency (BCCA) began funding the drug for MDS pts in the province of BC.
Aims: The research objective was to review patterns of AZA use and to determine its efficacy in a population-based analysis.
Methods: An IRB-approved retrospective review of pts receiving AZA for MDS in BC was performed by obtaining dispensing records from the BCCA pharmacy data base and clinical notes from the Cancer Agency Information System. Final analysis date was August 1, 2014.
Results: Between 01/2010 and 04/2014, 181 pts were treated with AZA in BC; there were 127 males and 54 females with median age 71 years (range 1-90). Diagnosis (WHO 2008) was (oligoblastic) AML (60 pts), RAEB-2 (45 pts), RAEB-1 (24 pts), therapy-related neoplasm (19 pts), CMML (16 pts), RCMD (14 pts) or MDS, unclassifiable (3 pts). IPSS karyotype was available in 136 pts - 34% were good-risk/normal, 40% were intermediate-risk and 26% were poor-risk. Pts were treated at teaching hospitals in Vancouver (VAN, 72 pts), BCCA sites outside Vancouver (BCCA, 44 pts) or one of 14 smaller hospitals (OTHER, 65 pts) of which only 3 sites treated >5 pts. Starting AZA dose was 75 mg/m^2/d in 78%, 50 mg/m^2/d in 9%, 37.5 mg/m^2/d in 6% or other in 7% of pts. Overall, 50% of pts received 75 mg/m^2/d throughout treatment; 36%, 29% and 12% of pts required ≥1, 2 or 3 dose reductions. AZA doses were re-escalated in 20% of pts and 9% of pts were increased to 100 mg/m^2/d. Median number of AZA cycles given was 5 (range 1-42) with 60% of pts receiving ≤5 cycles; 35 pts (19%) received only one cycle and 37 pts (20%) received 2-3 cycles. Pts receiving ≤3 cycles was similar at VAN, BCCA and OTHER (42%, 30% and 45% of pts, respectively). IWG responses were evaluable in 163 pts and were CR (18 pts, 11%), PR (4 pts, 2%) or HI (47 pts, 29%); 14 pts (9%) had stable disease. HI by lineage was 64% erythroid (73% major), 49% platelet (79% major) and 34% neutrophil (85% major). Bone marrow exam follow-up was done infrequently in responding pts making upgrading from HI to PR/CR problematic and determination of cytogenetic response not possible. Responses were independent of cytogenetic classification with overall response (HI+PR+CR) similar in good- (52%) and poor-risk (44%) karyotypes. Reason for stopping AZA could not be determined in 35% of pts; most common identifiable reasons were lack/loss of response (43%), death from complications of MDS/AML (36%), decision to proceed to SCT (10%) and AZA side effects/patient discretion (10%). Median OAS for the entire cohort was only 7 months (range 1-37) with 43 pts (24%) alive at date of analysis. Including only the 109 pts receiving ≥4 cycles, median survival was 13 months.
Summary and Conclusions: This population-based analysis of AZA treatment outcomes in MDS suggests that many pts are not given adequate trials (≥4 cycles) at standard doses. This may explain why, despite IWG response rates

in line with the pivotal randomized trial, median survivals were inferior to expectations. Physician and patient education on the importance of adequate dosing and duration of therapy is ongoing in BC.

P622

ASSOCIATION OF AZACITIDINE AND LENALIDOMIDE (COMBINATION *VS* SEQUENTIAL TREATMENT) IN HIGH-RISK MYELODYSPLASTIC SYNDROMES. UPDATE OF THE RESULTS OF A RANDOMIZED PHASE II MULTICENTER STUDY

Maria delle Croci Hospital, Ravenna, [7]Hematology, S. Maria della Misericordia University Hospital, Udine, [8]Clinical and Experimental Medicine, University of Parma, Parma, [9]Oncology, I.R.S.T., Meldola (FC), [10]Hematology, S. Martino University Hospital, Genova, [11]Hematology, University of Modena, Modena, [12]Hematology, University of Ferrara, Ferrara, [13]Chair of Hematology, University of Brescia, Brescia, [14]Hematology, Infermi Hospital, Rimini, Italy

Background: Azacitidine (AZA) is able to induce hematologic responses in 50-60% of patients (pts) with Myelodysplastic Syndromes (MDS) and moreover to prolong survival in higher risk MDS pts. However the duration of therapeutic response to AZA is limited, with a median survival advantage of only 9.5 months. Recently, several studies have evaluated the efficacy and safety of combining, in high-risk MDS pts, AZA with Lenalidomide (LEN), either administered concurrently *(Sekeres, 2010; 2012)*, or sequentially *(Platzbecker, 2013)*, in both cases showing promising results, although in a limited number of pts.
Aims: The aim of this study was to evaluate the efficacy and safety of the combination *vs* the sequential use of AZA and LEN in high-risk MDS pts (IPSS score risk: High or INT-2). Primary endpoint: ORR, defined as the Rate of Complete Remission (CR), Partial Remission (PR), Marrow Complete Remission (mCR), and Hematological Improvement (HI), following the International Working Group (IWG) criteria *(Cheson, 2006)*.
Methods: A randomized, phase II, multicenter, open label study, including pts with MDS (WHO 2008 classification) with International Prognostic Scoring System (IPSS) risk High or Intermediate-2, without previous treatment with AZA or LEN. ARM 1 (combined treatment): AZA: 75 mg/m2/day (days 1-5) I.C.+LEN: 10 mg/day (days 1-21), orally, every 4 weeks. ARM 2 (sequential treatment): AZA: 75 mg/m2/day (days 1-5) I.C.+LEN: 10 mg/day (days 6-21), orally, every 4 weeks. The induction treatment was planned for 8 cycles (32 weeks). For responder patients (CR, PR, mCR, or HI) the same treatment will be continued until disease progression or unacceptable toxicity. A sample size of 44 pts was planned. At the time of this analysis, 44 pts have been enrolled, 22 pts are still on therapy, and 7 of them have not yet completed 6 cycles of treatment.
Results: From March 2013, 44 pts (27 males), with a median age of 72 (48-83 yrs) were enrolled, from 13 hematologic italian Centers. At baseline, WHO diagnosis was: RCMD: 2 pts; RCMD-RS: 1 pt ; RAEB-1: 11 pts; RAEB-2: 30 pts; IPSS risk was: Intermediate-2: 32 pts; High: 9 pts; not determined (N.D.) (because of lack of cytogenetic data): 3 pts. (all with RAEB-2). IPSS cytogenetic risk was: Good: 16 pts; intermediate: 12 pts; Poor: 13 pts. 21 pts were randomly assigned to ARM 1, and 23 pts to ARM 2. At the time of this analysis, 44 pts have been enrolled, 28/44 pts (63.6%) completed ≥6 cycles of treatment, and are evaluable for response. 22/28 pts (78.6%) showed a favourable response to treatment, following the International Working Group (IWG) criteria *(Cheson, 2006)* : 9 pts achieved Complete Remission (CR), 2 pts attained Partial Remission (PR), 2 pts showed Marrow Complete Remission (mCR), and 9 pts obtained Hematological Improvement (HI). Responder pts were: 11/13 (84.6%) in ARM 1 (2 CR; 2 PR; 1 mCR; 6 HI), and 11/15 (73.3%) in ARM 2 (7 CR; 1 mCR; 3 HI), respectively. A grade >2 non hematologic toxicity was observed in 18/43 (41.9%) pts. 21/43 pts (48.8%) had a dose reduction of LEN because of hematologic or non-hematologic toxicity. 11 pts died; 6 pts showed progression to AML.
Summary and Conclusions: Our results, although preliminary, seem to confirm the feasibility of the association of AZA and LEN in high-risk MDS pts. Ongoing analyses are aimed to assess possible relationships between response to therapy and specific alterations affecting inositide signalling molecules, mutational status and microRNA profiling.

P623

CLINICAL IMPACT OF DEL (11Q) IN PATIENTS WITH DE NOVO AND SECONDARY MYELODYSPLASTIC SYNDROMES- A SINGLE INSTITUTION EXPERIENCE

H. Alkhateeb[1,*] M. Damlaj[1], A. Al-Kali[1], N. Gangat[1], K.H. Begna[1], M.R. Litzow[1], W.J. Hogan[1], M.A. Elliott[1], R.P. Ketterling[2,3], M.S. Patnaik[1]

[1]Hematology, [2]Cytogenetics, [3]Hematophatology, Mayo Clinic, Rochester, MN, United States

Background: Del(11q) is an uncommon cytogenetic abnormality (<1%) in patients with myelodysplastic syndromes (MDS), and when associated with disruption of the *MLL* gene portends an inferior survival. With the recent revision of the IPSS, isolated del 11q (non-*MLL*) is considered to be a favorable karyotype.
Aims: To describe the incidence, clinical features and outcomes of 11q deleted MDS and the impact of the *MLL* gene rearrangement.
Methods: After due IRB approval, patients diagnosed with MDS from 2000-2015 at Mayo Clinic Rochester were screened. Consecutive cases of MDS with del (11q) were identified and reviewed. Patients underwent a bone marrow aspirate at diagnosis and all clinical and pathologic data including FISH studies and cytogenetics were retrospectively reviewed. The cohort was stratified into three groups according to the underlying karyotype; isolated del (11q), del (11q) with an additional structural abnormality, and del (11q) with a complex karyotype. Survival analysis was estimated by Kaplan-Meier method and log ranks was used to compare the curves.
Results: A total of 1550 MDS patients were screened and, 23 (1.5%) with del (11)q were identified. Eleven patients (47%) were males. Four (17%) patients had secondary MDS, while the remainder had de novo disease. The median age at diagnosis was 70 years. Median presenting features included the following; absolute neutrophil count (ANC) of $1.8x10^9$, hemoglobin (Hb) of 8.8 g/dl, platelets (Plt) $75x10^9$, and bone marrow (BM) blasts of 3%. The median follow up was 12 months and over all 17 deaths (74%) and 2 (%) leukemic transformations were documented. The median OS for *MLL* rearranged *versus* non rearranged patients was 16 *vs* 24 months, respectively (p=0.49). Patients were then grouped based on additional cytogenetic abnormalities. Group 1: Six pts had del (11q) as a sole abnormality, one of who had a *MLL* rearrangement. IPSS-R stratification score included 4 with low risk and 2 with intermediate risk. Median overall survival (OS) was 30 months (*P*=0.0094) comparing survival among the three groups and diminished to 28 months with *MLL* rearrangement (*P*=0.0015). Group 2: Nine pts had del (11q) and an additional structural abnormality, with only one of these demonstrating the MLL rearrangement. None of the additional karyotypic abnormalities were considered poor prognosis based on IPSS-R. As per the IPSS-R score, there were 5 intermediate risk and 3 low, 1 missing data. Median OS was 24 months *vs* 9 months without and with *MLL* rearrangement, respectively (*P*=0.0015) comparing survival based on *MLL* rearrangement among the three groups. Median OS of the group was 21 months. Group3: Eight patients with del (11q) with a complex karyotype, of which three demonstrated the MLL rearrangement (2 with therapy related MDS). Notably there were no patients with a monosomal karyotype. As per the IPSS-R score, there were 6 very high risk and 2 high risk. Median survival of the group was 7 months. Median OS again diminished with *MLL* rearrangement at 5.6 *vs* 10 months, respectively (*P*=0.0015) (Figure 1).

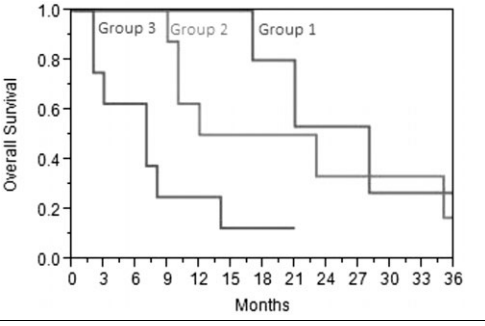

Figure 1.

Summary and Conclusions: Del (11q) is a rare karyotype in MDS with an incidence of <2%, 25% with del (11q) have associated *MLL* gene rearrangements. Although non-*MLL* rearranged isolated del (11q) is classified as a very good cytogenetic aberration, the observed OS in our group was inferior to IPSS-R predicted survivals. In subgroup analysis *MLL* gene rearrangements independently impacted OS.

P624

A PROGNOSTIC MODEL FOR PREDICTING SURVIVAL AFTER STOPPING HYPOMETHYLATING AGENT IN MYELODYSPLASTIC SYNDROME

H. Kim[1,*] J.H. Moon[2], J.-C. Jo[1], J.S. Ahn[3], Y.-R. Do[4], H.J. Shin[5], W.S. Lee[6], Y. D. Joo[7], H.S. Lee[8], Y.Y. Cho[9], Y. Choi[1], S.K. Park[10], J.-H. Park[11]

[1]Division Of Hematology and Cellular Therapy, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, [2]Kyungpook National University Hospital, Daegu, [3]Chonnam National University Hwasun Hospital, Hwasun, [4]Keimyung University Dongsan Medical Center, Daegu, [5]Busan National University Hospital, [6]Inje University Busan Baik Hospital, [7]Inje University Haeundae Baik Hospital, [8]Kosin University Gosper Hospital, Busan, [9]Daegu Catholic University Medical Center, Daegu, [10]Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, [11]Department of Hematology and Oncology,

Myongji Hospital, Gyeonggi-do, Korea, Republic of

Background: Hypomethylating agent (HMA) is widely used for the treatment of myelodysplastic syndrome (MDS) not only for hematopoietic cell transplantation (HCT) ineligible patients but also HCT eligible patients for a bridging therapy. However survival after HMA stop is very dismal although more intensive therapy like HCT can expect longer survival. However, we don't know which patient can survive longer even after stopping HMA is still unknown.
Aims: We wanted to know which clinical factors will be important for predicting prognosis after HMA failure. Here we present a prognostic model for predicting survival after stopping HMA in MDS.
Methods: Data were retrospectively collected. All MDS patients who had received HMA were selected. For the analysis of prognostic model after stopping HMA, we excluded patients with on-going HMA therapy, patients who stopped HMA for planned HCT or patients who died during HMA therapy.
Results: We retrospectively collected 236 MDS patient who had received HMA. We excluded on going HMA therapy, stopping HMA for planned HCT or stopping HMA by death. Therefore total 187 patients were selected for this analysis. Median survival after HMA stop was 11.4 (95% CI, 9.369-13.432) months. HCT or supportive care had longer survival than chemotherapy (p=0.024) as a salvage therapy after HMA stop. Many clinical factors were validated as prognostic factors for predicting survival; gender (p=0.568), age<70y (p=0.034), ECOG 0 or 1 (p=0.065), prior cancer or multiple comorbidity (p=0.017), initial IPSS-R very low/low/intermeidate (p=0.001), time to HMA start >4 weeks (p=0.067), azacitidine as HMA (p=0.127), HMA treatment duration <3M (p=0.346), SD/HI as best response to HMA (p=0.003), CR/PR/SD as final response to HMA (p<0.001), HMA stop by progression/loss of response (p=0.002). Multivariate analysis revealed that age<70 (HR 1.766, 95% CI 1.156-2.698; p=0.008), no prior cancer or multiple comorbidity (HR 2.340, 95% CI 1.127-4.859; p=0.023) or CR/PR/SD final response (HR 2.225, 95% CI 1.480-3.344; p<0.001) were prognostic factors. Median survival for favorable (no risk factor; n=55), intermediate (1 risk factor; n=97) or poor risk group (2 or more risk factors; n=34) were 30.653 (95% CI 17.786-43.520), 10.349 (95% CI, 8.267-12.431) or 5.322 (95% CI, 2.757-7.888) months, respectively (p<0.001; Figure 1).

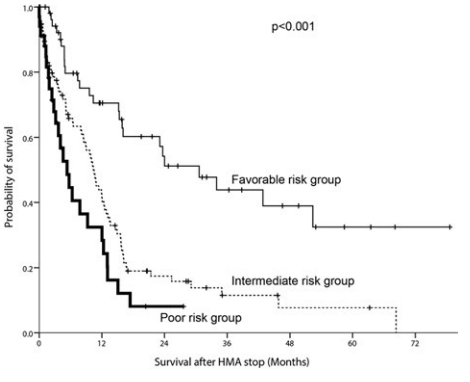

Figure 1.

Summary and Conclusions: Our data showed that survival after stopping HMA was dismal, but some prognostic factors can predict longer survival among them even with supportive care.

P625

CORRELATION OF OVERALL SURVIVAL (OS) WITH BONE MARROW BLAST (BMBL) RESPONSE IN PATIENTS (PTS) WITH MYELODYSPLASTIC SYNDROMES (MDS)

L. Silverman[1,*], P. Fenaux[2], P. Greenberg[3], E. Demakos[1], V. Santini[4], J. Seymour[5], S. Navada[1], M. Petrone[6], B. Snyder[6], N. Azarnia[6], G. Garcia-Manero[7]
[1]Icahn School of Medicine at Mount Sinai, New York, United States, [2]Hospital St Louis, Paris, France, [3]Stanford Medical School, Stanford, United States, [4]University of Florence, Florence, Italy, [5]Peter MacCallum Cancer Centre and University of Melbourne, Melbourne, Australia, [6]Onconova Therapeutics, Inc., Newtown, [7]MD Anderson Cancer Center, Houston, United States

Background: BMBL% is the prognostic variable with the greatest impact on outcome in MDS patients at diagnosis and subsequent time points. Current composite response criteria (IWG, Cheson 2006) do not consistently correlate with OS. Treatment impact of BMBL as an independent response criterion has not been adequately evaluated.
Aims: To evaluate the correlation between OS and BMBL in pts with higher-risk (HR) MDS.
Methods: We accessed 4 datasets encompassing 7 studies with 887 pts and evaluated the correlation of BMBL response/stabilization at 4- and 12-week timepoints with OS. The 4 studies were: ONTIME, a Phase III randomized study of 2nd-line rigosertib (RIG) *vs* best supportive care (BSC) (N=299; Silverman, ASH 2014); 4 Phase I/II studies of RIG in pts with MDS/AML (N=39; Silverman, Hematol Oncol 2014); AZA-001, a Phase III study of azacitidine (AZA) *vs* 3 conventional care regimens (N=358; Fenaux, Lancet Oncol 2009; Gore, Haematologica 2013); Cancer & Leukemia Group B (CALGB) Study 9221, a Phase II, randomized trial of 1st-line AZA *vs* BSC (N=191; Silverman, J Clin Oncol 2002). Change in blasts was defined similarly in each of the 4 studies: BM complete response is BMBL ≤5%; BM partial response is ≥50% decrease from baseline, but BMBL still >5%; stable disease is <50% decrease or increase from baseline.
Results: In ONTIME, landmark time-dependent analyses showed correlation of BMBL response/stabilization with OS at 4 wks (P=0.011) and 12 wks (P<0.001). In the 4 Phase I/II studies, BMBL response/stabilization at 4-8 weeks was associated with a quadrupling of median OS (P<0.001). In Study AZA-001, time-dependent analysis of BMBL stabilization was associated with a significantly reduced risk of death in both treatment cohorts (P<0.001) compared to progression. In Study 9221, landmark analysis of BMBL response/stabilization showed a 6-fold improvement in OS (P<0.001).
Summary and Conclusions: These studies, spanning more than a decade with different therapeutic agents and settings, demonstrate a consistent positive correlation between BMBL response and OS in pts with HR-MDS, including pts on supportive care. This suggests that use of reduction/ stabilization in BMBL can serve as a new early response parameter, as an intermediate clinical endpoint for evaluation of new agents, and as a biomarker for disease progression in HR-MDS itself.

BMF syndromes incl. PNH - Clinical

P626

THE INTERIM ANALYSIS OF PROSPECTIVE OBSERVATIONAL STUDY WITH PNH-TYPE CELLS IN JAPANESE PATIENTS WITH BONE MARROW FAILURE (THE OPTIMA STUDY)

N. Obara[1,*] S. Chiba[1], K. Hosokawa[2], C. Sugimori[2], M. Yanamoto[3], H. Noji[4], Y. Yonemura[5], Y. Nakamura[6], K. Ando[6], T. Kawaguchi[7], T. Shichishima[4], H. Ninomiya[1], J.-I. Nishimura[3], Y. Kanakura[3], S. Nakao[2]
[1]Department of Hematology, University of Tsukuba, Tsukuba, [2]Dept. Cellular Transplantation Biology, Kanazawa Univarsity, Kanazawa, [3]Dept. Hematology and Oncology, Osaka University, Osaka, [4]Dept. Cardiology and Hematology, Fukushima Medical University, Fukushima, [5]Dept. Transfusion Medicine and Cell Therapy, Kumamoto University, Kumamoto, [6]Dept. Hematology and Oncology, Tokai University, Isehara, [7]Dept. Cellular Transplantation Biology, Kumamoto University, Kumamoto, Japan

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a disease deriving from an acquired mutation of the phosphatidylinositol glycan class A (*PIGA*) gene in the hematopoietic stem cells. In some cases of aplastic anemia (AA) or low-risk types of myelodysplastic syndromes (MDS), it is known that PNH-type cells can be often detected through the high-resolution flow cytometry-based method. Because these patient groups are reported to have a good response to immunosuppressive therapies as opposed to the other patient groups lacking PNH-type cells, detection of these cells is potentially useful in determining a treatment plan for the cases of bone marrow failure syndromes. To confirm this preliminary information, a large cohort study is needed.
Aims: In order to determine the prevalence and significance of PNH-type cells in bone marrow failure patients, we conducted a nationwide multi-center prospective 0bservational investigation, the OPTIMA study (Observation of GPI-anchored protein-deficient cells in Japanese patients with bone marrow syndrome and in those suspected of having PNH).
Methods: A nationwide multi-center prospective observational study (OPTIMA) was started in July 2011 to determine the prevalence of patients with bone marrow failure syndromes who carried PNH-type cells and to clarify the clinical significance of the presence and quantitative changes of these cells with regard to the clinical features. Each of the 6 laboratories in different universities was assigned as a regional analyzing center. The percentage of PNH-type cells was measured by the high-resolution flow cytometry-based method, originally established in Kanazawa University. At the six individual laboratories, cross validations were conducted to minimize the inter-laboratory variations in the detection sensitivities, cutoff values, etc. For the detection of PNH-type granulocytes, the liquid FLAER method (≥0.003%) was used, and cocktail method (≥0.005%) with CD55 and CD59 antibodies was used for PNH-type erythrocyte detection.
Results: As of July 2014, flow cytometry data have been collected from 1739 patients and are included in this interim analysis. Of these patients, 67 (3.9%) were diagnosed with PNH, 546 (31.4%) with AA, 475 (27.3%) with MDS, and 651 (37.4%) with bone marrow failure (BMF) of unknown etiology. Overall, 172 (9%) patients had ≥1% of both PNH-type erythrocytes and granulocytes: 66 (98.5%) patients with PNH; 66 (12.1%) with AA; 22 (4.6%) with MDS; and 18 (2.8%) with BMF of unknown etiology. In total, 607 (34.9%) patients had ≥0.005% PNH-type erythrocytes and ≥0.003% PNH-type granulocytes. These consisted of the followings: all 67 (100%) patients with PNH; 295 (54.0%) with AA; 85 (17.9%) with MDS; and 160 (24.6%) with BMF of unknown origin. No patients with MDS-RAEB-1 or -2 had PNH-type cells. Lactate dehydrogenase (LDH) levels ≥1.5 × upper limit of normal range were seen in 4% patients with 0.005-1% PNH-type erythrocytes, 37% patients with 1-10% PNH-type erythrocytes, and 97.4% patients with ≥10% PNH-type erythrocytes.Periodic blind validation tests revealed that inter-laboratory differences in absolute measurements of PNH-type cells were always within 0.02%.
Summary and Conclusions: A high-resolution flow cytometry-based method that enables the detection of very low percentages of PNH-type cells was successfully transferred to 6 laboratories across Japan. Our results demonstrated that the proportion of patients identified as having small percentages of PNH-type cells differed depending on diagnosis (PNH, AA, MDS, or unknown BMF) and that elevated LDH levels (>1.5xupper limits of normal range) were more frequently associated with higher percentages of PNH-type erythrocytes. PNH-type cells didn't detected in patients with MDS-RAEB-1 or -2. Our findings suggest that the high-resolution method is helpful as a diagnostic tool in BMF syndromes, including AA, MDS, and PNH, and may prove useful in understanding the pathophysiology of these disorders.

P627

HYPOMEGAKARYOCYTIC THROMBOCYTOPENIA (HMT): AN IMMUNE-MEDIATED BONE MARROW FAILURE CHARACTERIZED BY AN INCREASED NUMBER OF PNH-PHENOTYPE CELLS AND PLASMA THROMBOPOIETIN LEVELS

K. Ishiyama[1,*] H. Yamazaki[2], C. Saito[1,3], Y. Zaimoku[2,4], H. Maruyama[4], S. Nakao[4]
[1]Department of Hematology, [2]Division of Transfusion Medicine, Kanazawa University Hospital, [3]Department of Hematology, Ishikawa Prefectural Central Hospital, [4]Cellular Transplantation Biology, Kanazawa University Graduate School of Medical Science, Kanazawa, Japan

Background: Chronic thrombocytopenia is one of the most common abnormalities that are seen at hematology clinics. Although immune thrombocytopenic purpura (ITP) is the most frequent diagnosis of chronic thrombocytopenia without anemia and leukocytopenia, there are a considerable number of cases exhibiting megakaryocytic hypoplasia which do not meet the diagnostic criteria for ITP, aplastic anemia (AA), myelodysplastic syndrome (MDS), or paroxysmal nocturnal hemoglobinuria (PNH). Patients with hypomegakaryocytic thrombocytopenia (HMT) are usually followed without therapy when their thrombocytopenia is mild, *i.e.*, $50x10^9$/L. However, some patients may progress to aplastic anemia (AA) after a long observation period, which is often refractory to immunosuppressive therapy (IST). It is therefore important to elucidate the pathophysiology of patients with HMT at the time of diagnosis, even when their thrombocytopenia is not severe. We previously conducted a retrospective analysis of 29 patients with HMT and found that 55% patients possessed an increased number of glycosylphosphatidylinositol (GPI) anchored protein (GPI-AP)-deficient blood cells (PNH-type cells), which are often detected in patients with AA and are associated with a better response to IST than patients not possessing PNH-type cells. Ten of such 16 PNH(+) patients received cyclosporine (CsA) monotherapy and 60% (6/10) responded to the therapy (unpublished observation). Prospective studies may help to clarify the pathophysiology and prognosis of HMT.
Aims: To further characterize the clinical findings of HMT, we began a multi-center prospective observational study in 2009 (UMIN-CTR 000002729).
Methods: The inclusion criteria were WBC $>3x10^9$/L, Hb >10 g/dL and Plt $<100×10^9$/L with a decreased number of megakaryocytes. The patients who met the diagnostic criteria for well-established hematologic diseases including ITP, AA, MDS and PNH were excluded. PNH-type cells were detected using a high-sensitivity flow cytometry assay at the time of diagnosis and annually thereafter. The cutoff values of the assay were >0.003% for granulocytes and 0.005% for erythrocytes. The plasma thrombopoietin (TPO) levels were determined at the time of enrollment using an ELISA. The therapeutic plans were left to the discretion of each institution. The data were collected in January 2015 for this interim analysis.
Results: From August 2010 to March 2014, 25 HMT cases (male/female, 14/11) were enrolled. The median of age was 65 years (range, 25-79). The mean of the complete blood cell counts was as follows: white blood count (WBC) 4.1 (2.77-8.50)$x10^9$/L; hemoglobin (Hb) 11.9 (10.0-14.8) g/dl, and platelet (Plt) 40.0 (1.0-95.0)$x10^9$/L. PNH-type cells were detected in seven of the 25 cases (28%) and the median clone size of the PNH-type cells in PNH(+) patients was 0.073%, (range, 0.015% - 20.5%) in granulocytes and 0.069% (range, 0.0% - 3.8%) in erythrocytes. The TPO level ranged from 0.4 - 42.8 fmol/ml (median, 8.4 fmol/ml). Eleven (44%) patients showed TPO levels greater than 9.1 fmol/ml, which is the lowest level observed in our patients with typical AA (Seiki, *et al.* Haematologica, 2013). The patients with high TPO levels (TPO^{high} patients) showed significantly lower Hb levels (11.0 *vs* 12.4, $P<0.03$) and a higher prevalence of increased PNH-type cell numbers (64% *vs* 0%, $P<0.001$) than patients with low TPO levels (TPO^{low} patients). A total of six patients were treated with CsA or prednisolone (PSL) while the other 19 patients left untreated; four TPO^{high} patients, including three PNH(+) and one PNH(-) patient, were treated with CsA and all three PNH(+) patients responded well to the therapy. Two TPO^{low} patients treated with PSL improved. Among the 19 untreated patients, the hematological parameters of 11 patients remained unchanged during the median follow-up period of 30 months. On the other hand, thrombocytopenia progressed in one TPO^{low} patient and four of seven (57%) TPO^{high} patients, which include two PNH(+) patients. Notably, two TPO^{high} PNH(+) untreated patients progressed to moderate AA in 15 and 12 months after the diagnosis of HMT. One TPO^{low} patient developed acute myeloid leukemia in 18 months and one TPO^{low} patient demonstrated spontaneous resolution of the thrombocytopenia (Figure 1).

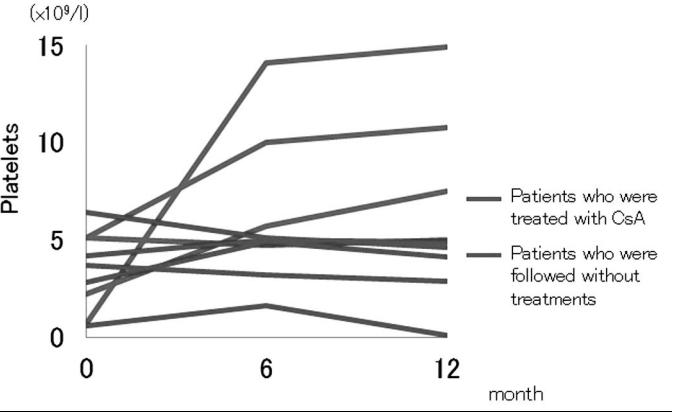

Figure 1. Changes of the platelet count in TPO^{high} patients with hypomegakaryocytic thombocytopenia (HMT).

Summary and Conclusions: This prospective analysis confirmed our previous

observation that approximately 50% of all patients with HMT have an immune pathophysiology similar to AA. Early treatment with CsA may therefore improve the prognosis of HMT patients who are generally followed up without therapy until their thrombocytopenia progresses. A long-term follow-up is needed to clarify the influence of CsA therapy on the natural course of HMT.

P628

OUTCOME OF STEM CELL TRANSPLANTATION IN PATIENTS WITH SHWACHMAN- DIAMOND SYNDROME WITH OR WITHOUT SECONDARY MDS/AML: AN ANALYSIS OF THE GERMAN SHWACHMAN-DIAMOND SYNDROME COHORT BY THE SCNIR- EUROPE

S. Mellor-Heineke[1,*] A. Nickel[1], U. Grote[1], K. Welte[1], C. Zeidler[1]
[1]Department of Molecular Hematopoiesis, Hannover Medical School, Hannover, Germany

Background: Shwachman-Diamond Syndrome (SDS) is a rare autosomal recessive disorder characterized by exocrine pancreatic insufficiency, bone marrow failure and a varying degree of congenital abnormalities including the skeleton, liver, heart and the immune system as well as psychomotor retardation. It has been documented that SDS patients have an increased risk to develop myelodysplasic syndrome (MDS), pancytopenia and leukemia, particularly acute myeloid leukemia (AML). So far, stem cell transplantation is the only therapeutic option for SDS patients with secondary bone marrow failure or leukemia.
Aims: The aim of this analysis is to evaluate the outcome on SCT in patients with Shwachman-Diamond Syndrome.
Methods: In the SCNIR we have collected long term data on 41 German patients with a clinical diagnosis of Shwachman-Diamond Syndrome. In 37 patients SDS diagnosis was confirmed by detection of compound heterozygous SBDS gene mutations. Here we report on the outcome of stem cell transplantation (SCT) in 9 patients with SDS in Germany, which were performed between 1999 and 2014. Reasons for SCT were MDS (1 patient), secondary leukemia (2 patients), pancytopenia (4 patients), cytogenetic abnormality (deletion 20q) (1 patient) and severe lung infections (1 patient).
Results: Patients' characteristics are as follows: Gender (4 female, 5 male), age at SCT (1.5 years - 30 years), median follow-up time post- SCT (52 months), G-CSF treatment prior to SCT (n=3), stem cell source (MUD: n=6, MSD: n=2, haploidentical: n=1). The majority of patients received a Fludarabine/Treosulfan or Fludarbine/Melphalan based conditioning regimen in combination with ATG or Campath. 2 patients received a second SCT due to graft failure. Outcome: 3 patients received a SCT due to secondary hematologic malignancy: AML (n=2) and MDS (n=1). Both patients with AML have died. Patient 1 (AML) received a MUD SCT without anti-leukemic therapy and 37% blasts in the bone marrow. The preparative regimen consisted of Busulfan, Melphalan, VP-16 and ATG. After initial engraftment, the patient relapsed on day +101 and died 1 month later due to disease progression. Patient 2 (AML) received AML- induction therapy with Ara-C and Daunorubicin. He went into prolonged aplasia and received a haploidentical SCT from this mother after a conditioning regimen with Fludarabine, Thiotepa, ATG and total lymphoid irradiation. He died due to severe bacterial infection on day+11. Patient 3 (MDS with complex karyotype) is alive and well 107 months after SCT. The patient received a MUD SCT after a preparative regimen of Fludarabine, Treosulfan, Melphalan and Campath. Patient 1 and 3 developed bacterial sepsis and acute Graft *versus* Host Disease (GvHD) within the first 100 days after SCT (grade I and II). 6 patients received a SCT (MUD: n=4, MSD: n=2) for other reasons: pancytopenia (n=4), deletion 20q (n=1) and severe lung infections (n=1). Complications within 100 days post SCT included acute GvHD grade II (n=2), bacterial sepsis (n=2), hepatic candidiasis (n=1) and primary (n=1) and secondary (n=1) graft failure with successful second SCT. 1 patient (pancytopenia) died due to idiopathic pneumonia syndrome on day+80 after he had received a cord blood transplant (conditioning regimen: Fludarabine, Treosulfan, Melphalan, ATG). The other 5 patients are alive 8-106 months after SCT.
Summary and Conclusions: In summary, out of 9 patients with SDS who underwent SCT, 6 have survived documenting that SCT is the treatment of choice in patients who developed leukemia or pancytopenia.

P629

PEARSON SYNDROME: MULTISYSTEM MITOCHONDRIAL DISORDER WITH BONE MARROW FAILURE

A. Yoshimi[1,*] S. Grünert[1], M. Kuhlen[2], A. Borkhardt[2], K. Suzuki[3], U. Kontny[4], S. Bielack[5], H. Cario[6], C. Niemeyer[1]
[1]Department of Pediatrics and Adolescent Medicine, University of Freiburg, Freiburg, [2]Center for Child and Adolescent Health, Heinrich Heine University, Duesseldorf, Germany, [3]Department of Pediatrics, Nagoya University Graduate School of Medicine,, Nagoya, Japan, [4]Department of Hematology, Oncology and Stem Cell Transplantation, RWTH Aachen University Medical School, Aachen, [5]Pediatrics 5 (Oncology, Hematology, Immunology), Klinikum Stuttgart-Olgahospital, Stuttgart, [6]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany

Background: Pearson syndrome (PS) was originally reported as a fatal disease in infancy characterized by sideroblastic anemia with vacuolization of marrow precursors and exocrine pancreas dysfunction. In addition, involvement of multiple other organs and subsequent development of Kearns-Sayre Syndrome (KSS) have also been reported. Both PS and KSS are associated with single mitochondrial DNA (mtDNA) deletions. There are few systematic studies on PS because of its rarity.
Aims: To characterize the clinical and hematological presentations and courses of patients with PS.
Methods: We retrospectively reviewed clinical and laboratory data of 20 patients (12 M/ 8 F) with PS diagnosed between 1987 and 2012 in Germany.
Results: The median hemoglobin level was 5.9 g/dl (2.2-9.8 g/dl) and the mean corpuscular volume of red cells (MCV) was elevated or normal in 12 and 14 patients, respectively (unknown in 4). Some patients had normal neutrophil and platelet counts at diagnosis (n=5/6), but all of them developed bi- or pancytopenia later. The hemoglobin F level was elevated for age in 8 of 9 patients examined. Bone marrow was normo- and hypocellular in 13 and 7 patients, respectively. All patients had vacuolization of erythroid and myeloid precursors, but ringed sideroblasts are only observed in 13 of 19 patients examined. Serum lactate was elevated in 14 of 15 patients studied. The diagnosis of PS could be confirmed by the detection of mtDNA deletion in all patients. The median age at the time of the last follow-up was 39 months (6 months to 14 years). Hematological recovery was observed in most patients with a longer follow-up time. Ten patients became transfusion independent at a median age of 27 months (11 to 67 months), while one patient was still transfusion dependent when he died at the age of 8 years. Various symptoms and organ dysfunctions developed during clinical courses, including failure to thrive/short stature (n=8, median age of presentation: 26 months (m)), liver dysfunction (n=2, 21 m), renal tubulopathy/Fanconi syndrome (n=5, 32 m), pancreas insufficiency (n=6, 13 m), cardiac disease (n=3, 45 m), diabetes (n=1, 19 m), other endocrine dysfunctions (n=4, 63 m), hearing loss (n=1, 115 m), ophthalmoplegia (n=1, 19 m), retinitis pigmentosa (n=1, 92 m), cataract (n=1, 39 m), muscle hypotonia (n=4, 31 m), ataxia (n=2, 54 m) and encephalopathy (n=1, 74 m). Seven patients died of acute metabolic acidosis with other complications at the median age of 49 months (14-101 months). The longest survivor (death at 14 years of age) suffered from KSS-like disease.
Summary and Conclusions: These findings suggest that PS is a multisystem mitochondrial disorder in infancy with bone marrow failure as the main presenting feature. Because patients can initially present with only anemia, clinicians should consider PS as a differential diagnosis of hypoproliferative anemia in early childhood. Although hematological improvement can be expected in long survivors, patients have highly heterogeneous clinical courses with varied extents of multi-organ involvement. Therefore, intensive monitoring and managing of multisystem complications are crucial.

P630

PEARSON SYNDROME: A RETROSPECTIVE COHORT STUDY FROM THE MARROW FAILURE STUDY GROUP OF THE AIEOP (ASSOCIAZIONE ITALIANA EMATO-ONCOLOGIA PEDIATRICA)

P. Farruggia[1,*]A. Di Cataldo[2], R.M. Pinto[3], P. Elena[4], A. Macaluso[5], L. Lo Valvo[2], M.E. Cantarini[6], A. Tornesello[7], P. Corti[8], F. Fioredda[4], S. Varotto[9], B. Martire[10], I. Moroni[11], G. Puccio[12], G. Russo[13], C. Dufour[4], M. Pillon[9]

San Gerardo, Monza, [9]Dipartimento di Oncoematologia Pediatrica, Università di Padova, Padova, [10]Dipartimento di Scienze e Chirurgia Pediatriche, Oncoematologia Padiatrica, Ospedale Policlinico- Giovanni XXIII, Bari, [11]Child Neurology Department, Fondazione IRCCS Istituto Neurologico C. Besta, Milano, [12]Department of Sciences for Health Promotion and Mother and Child Care, University Of Palermo, Palermo, [13]Unit of Paediatric Haematology and Oncology, Università di Catania, Catania, Italy

Background: Pearson Syndrome is a multisystem disorder caused by mutation of mitochondrial DNA (mtDNA). It typically consists of hypoplastic macrocytic anemia with vacuolated marrow precursors, lactic acidosis and exocrine pancreatic dysfunction. Additional manifestations may include myopathy, neurologic symptoms, skin lesions and renal tubular acidosis.
Aims: To provide clinical, biochemical and hematological insights through the analysis of a reasonably sized cohort of patients.
Methods: A retrospective analysis via dedicated Case Report Form including more than 160 items sent to all 55 A.I.E.O.P. (Associazione Italiana di Ematologia ed Oncologia Pediatrica) Centers. Information was collected on all presumed PS patients diagnosed in Italy in the period 1993-2014.
Results: this series, with 11 enrolled patients, is one of the largest ever reported. The principal characteristics of the patients are shown in Tables 1 and 2.

The median age at diagnosis was 299 days. At onset, among the 11 patients, pancytopenia was present in 5, anemia associated with leucopenia and/or neutropenia in 5, isolated anemia in 1; the median value of Hgb was 5.7 gr/dL, the lowest value of platelets was 72,000/μL and neutropenia (present in 10 children) was severe (Absolute Neutrophil Count (ANC) <0.5x10^9/L) in 1, moderate (ANC 0.5-1x0^9/L) in 8, and mild (ANC of 1.3xx10^9/L) in another. HbF was assessed in 5 patients outside the neonatal period and it was found elevated (>2%) in all of them. BM examination was performed in all patients: a precursor vacuolization associated with reduced cellularity was found in 6 children, isolated vacuoles in 2, mild dyserythropoiesis in 1, and hypocellularity in 2. One patient evolved, after allogenic Bone Marrow Transplantation, into acute myeloid leukemia. No solid tumor was observed. Exocrine pancreatic deficiency and neurologic symptoms were observed respectively in 3 and 8 children. A hypertrophic cardiomyopathy was present in 4 out of 10 evaluated patients. Serum lactate was dosed in all patients and found elevated in all but one. A plasmatic amino acid analysis was performed in 10 children: in 9/10 alanine was high. Urine organic acids were analyzed in 9 patients: in 7/9 an increased excretion of lactate and fumaric acid was noted; interestingly an increase of malic acid excretion was also found in 4/9 patients. All patients were transfused with packed red blood cells (PRBC), 6 with platelets and 2 with plasma. A spontaneous improvement of the Hgb values was noted in 8 of the 9 evaluable patients. Therapy with EPO was attempted, without any efficacy, in 3 children. Granulocyte-colony stimulating factor (GCSF) was administered in 3 patients with proven efficacy in one of them. After a median FUP of 5.7 years 8/11 patients died (two at less than 6 months of life), 1 was lost at FUP at 45 months of age, and only 2/11 patients are alive (at the age of 2.9 and 6.6 years respectively). In 3 cases sepsis was the cause of the death.

Table 1. Clinics and laboratory.

Sex	bp del.	Hepatomegaly	Splenomegaly	Ins. Ex. Pancreas	IDDM	Growth Impair.	VWT	Neurol. Sympt.	Kearn/Sayre	Eye Problems	↑ serum Lactate	↑ Serum Alanine

8	Yes	Yes	No	ND	↑	No	↓ cellularity	NP	Yes	D (0,53)	Sepsis
9	No	No	?	↑	ND	Yes	Vacuoles AND ↓ cellularity	Yes	Yes	D (10,42)	AML
10	Yes	Yes	Yes	↑	ND	Yes	Vacuoles AND ↓ cellularity	Yes	Yes	D (10,44)	Renal failure
11	Yes	Yes	No	↑	ND	Yes	↓ cellularity	Yes	Yes	D (3,9)	Sepsis

Pt: patient. NK: not known. ND: not determined. D/A: dead/alive. EPO: Erythropoietin. BM: bone marrow. FUP: Follow-up. AML: Acute Myeloid Leukemia.

Summary and Conclusions: PS is a rare disease. Our report enables to estimate the likely incidence of PS in our country as 1/million newborns. Furthermore it shows for the first time that an increased level of serum alanine along with increased excretion of fumaric acid and hypertrophic cardiomyopathy, even though never described in previous reports, are a common finding in PS patients. Finally it seems that transfusion independency is highly probable in case of survival after the first 2-3 years of life.

P631

SCREENING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONES BY MULTICOLOR FLOW CYTOMETRY USING FLUORESCENT AEROLYSIN (FLAER) - A SINGLE CENTRE STUDY OF 212 PATIENTS

K. Rahman[1,*] N. Hussain[1], R. Gupta[1], G. Yadav[1], M. Singh[1], S. Nityanand[1]
[1]Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired clonal stem cell disorder with varied clinical manifestations, consequent to deficiency of membrane-bound glycosylphosphatidylinositol (GPI) anchored protein. It is known to be associated with other hematological conditions like aplastic anemia (AA) and myelodysplastic syndrome. In the last few years fluorescent aerolysin (FLAER) based flow cytometry analysis has become the gold standard for screening of these abnormal PNH clones.
Aims: FLAER based flow cytometric screening for PNH clones in patients presenting with pancytopenia, features of hemolysis or thrombophilia; and to correlate the clone size with the clinical and laboratory parameters.
Methods: A total of 212 patients were screened between January 2014 to February 2015 using FLAER based flow cytometry protocols. Stain -Lyse -Wash technique was used. Neutrophils and monocytes were analyzed using a four color antibody panel which included FLAER/CD24/CD15/CD45 and FLAER/CD33/CD14/CD45 respectively. For red blood cell analysis a combination of CD235/CD59 was used. A minimum of 5000 polymorphs and 3000 monocytes were analyzed. The patients were divided into three groups based on clone size, small (<10%), medium (11-49%) and large (≥50%). A correlation between the clone size along with clinical and laboratory parameters was performed.
Results: The indication for screening included pancytopenia (n=172), evidence of hemolysis (n=25) and as a part of thrombophilia workup (n=15). A total of 53/212 patients tested positive of which 45/172, 8/25 and 0/15 were for the above mentioned indications respectively. Amongst the patients who underwent a bone marrow examination at our centre, 43 showed features of aplastic anemia whereas 10 patients showed variably cellular marrow with erythroid hyperplasia. Flow cytometric examination showed large clone sizes in 47% (25/53), medium in 19% (10/53) and a small clone size in 34% (18/53) patients respectively. The patients with features of hemolysis showed larger clone sizes (large clone-6 and medium clone -2) as compared to pancytopenic/AA group. 3 of the 16 (18.8%) patients from the pancytopenia/AA group, who were on antothymocyte globulin therapy, showed a clonal PNH evolution with large clone sizes. On comparing the clone size with other laboratory parameters, larger clone size was found to be directly and significantly correlated with a higher S. LDH levels, S. creatinine and reticulocyte count.
Summary and Conclusions: Most common indication of the present study was pancytopenia. FLAER appeared to be a sensitive technique for detection of PNH clone in these patients. The clone size in patients presenting with hemolytic features was higher as compared to those with pancytoepnia/AA. A fair proportion of patients on ATG therapy showed clonal PNH evolution.

P632

LONG TERM OUTCOME OF IMMUNOSUPPRESSIVE THERAPY IN A LARGE COHORT OF 1430 PATIENTS OF APLASTIC ANEMIA FROM A SINGLE TERTIARY CARE CENTRE IN INDIA

P.K. Singh[1,*]R. Maiwall[2], M. Agarwal[1], P. Manivannan[1], A. Purohit[1], P.C. Misra[1], T. Seth[1], M. Mahapatra[1]
[1]Hematology, All India Institute of Medical Sciences, [2]Hepatology, Institute of Liver and Biliary Sciences, New Delhi, India

Background: Acquired aplastic anemia (AA) is a T-cell mediated suppression of hematopoietic stem cells. Treatment options available in these patients as an alternative to allogenic stem cell transplantation include weak androgens (Stanozolol, Danazol) or immunosuppressive therapy [Cyclosporine(CsA) and/or Antithymocyte Globulin(ATG)]. There is paucity of studies showing superior response rates for ATG+CsA as compared to other conventional treatments. ATG is limited by its high cost.
Aims: To analyse and compare the response of ATG+CsA to other treatment options in AA using the standard response criteria.
Methods: Consecutive patients of AA (n=1430) were enrolled in this retrospective study. Patients were randomly allocated to different treatment protocols. Response was measured as time to attainment of CR or PR. Response was also assessed for relapse and clonal evolution with respect to treatment groups.
Results: Patients with AA (mean age 22±16.9 years, 70% males) were followed up for median of 4 months (range 0.5 to 132 months) of which 5% patients died. Anemia (97%) was the major symptom followed by bleeding (70%) fever (47%) and jaundice in 4.5% patients. In 5% patients the stress cytogenetics was positive. Very severe (VSAA): Severe (SAA): Non-Severe (NSAA) were 15%: 76%: 9%, respectively. Treatment given to patients included; Stanazolol-37.5%, CsA-8.5%, Stanazolol+CsA-35%, ATG+CsA-15.5% and others-3.5%. The median time to PR and CR was 4 and 7 months respectively. There was a significant difference in the overall response (OR) rates (CR+PR) of ATG+CsA with respect to other treatment protocols (59% *vs* 30%; p<0.001). The OR rates were also significantly different with respect to severity of AA *i.e.* (45%.*vs* 10%; p<0.001) in VSAA, (61%*vs* 32%; p<0.001) in SAA but not in NSAA. (77% *vs* 48%; p=0.07). The rates of CR and PR were also significantly superior in the ATG+CsA group as compared to others (34% *vs* 15%; p<0.001) and (25% *vs* 15%; p<0.001) respectively. The relapse even though non-significant was noted more frequently in the ATG+CsA group as compared to others (3.2% *vs* 1.2%; p=0.07). The rate of clonal evolution to acute leukemia was almost similar in both the groups (0.8% *vs* 0.5%; p=0.64).
Summary and Conclusions: Although matched sibling allogenic bone marrow transplant is the gold standard treatment for aplastic anemia, but immunosuppressive therapy with ATG+CsA is a good alternative superior to other conventional treatments. However, alternative immunosuppressive therapy can still be considered for patients with non-severe aplastic anemia.

P633

COMBINED IMMUNOSUPPRESSIVE THERAPY IN PATIENTS WITH APLASTIC ANEMIA WITH REPEATED COURSES OF ATG

E. Mikhaylova[1,*] Z. Fidarova[1], E. Ustinova[1], V. Troitskaya[1], I. Galtseva[1], I. Shitareva[1], N. Tsyba[1], E. Parovichnikova[1], V. Savchenko[1]
[1]Chemotherapy of Hemoblastoses and Bone Marrow Transplantation,

Research Center of Hematology of Russian Ministry of Health, Moscow, Russian Federation

Background: According to published data, current immunosuppressive therapy (IST) proved to be effective in 70-90% of patients with AA. However, not all the questions are solved, particularly, treatment of patients with AA refractory to IST without HLA-compatible donor.
Aims: The purpose of the study is optimization of treatment algorithm of patients with AA
Methods: A total of 86 patients with AA were included in the study: 51 males and 35 females at median age 23 years (range 17-65 years). The median period from AA diagnosis to IST was 4 months (range 1-25 months). Severe forms of AA (SAA) were detected in 66 patients, non-severe (NSAA) in 20 pts. PNH-clone was detected using flow cytometry before treatment and monitored during of IST. The combined IST consisted of Antithymocyte Globulin (ATG 20 mg/kgx5 days in 81pts, rabbit ATG 3.75 mg/kgx5 days in 5 pts) and Cyclosporin A (CsA) during 2 years (at least one year after achieving of remission).
Results: IST with several courses of ATG and long-term treatment of CsA was effective in 73 from 86 pts (84.9%): 54 (81.8%) from 66 pts with SAA and 19 (95%) from 20 pts with NSAA. After one course of ATG+CsA positive response was received in 53 (61.6%) from 86 pts and after two courses of ATG in 16 (18.6[LE1]%) . Three courses of ATG were conducted in 5 patients with SAA, 3 of them achieved partial remission. After 3 months from the beginning of IST positive response was achieved in 52.8% and after 6 months in 83, 4% pts with AA. Overall survival and 7 years event-free survival were 89% (95% CI: 83-96%) and 93% (95% CI: 88-97%), respectively. PNH clone was detected in 20 (60.6%) from 33 pts before IST: granulocyte PNH clone did not changed in 16 from 20 pts during period of observation, in 3 patients decreased more than in 5 times and in 1 cases clone was eliminated. Response to IST attained in 17 (85%) from 20 PNH^+ pts and only 8(61%) from 13 PNH^- pts.
Summary and Conclusions: Thus, IST with repeated courses of ATG and long-term treatment of CsA provided a positive response and long-term survival in the most of patients with AA in the study, including SAA. The second course of ATG significantly improves results of the IST, and the optimal period of time to second course in patients with no answer to the first ATG course should be 3- 6 months from the start of treatment no longer. Patients with no response to two courses of ATG could be assigned to a group of patients with refractory AA. These patients require further intensive therapy and alternative methods of treatment (thrombopoietin receptor agonist, alemtuzumab, chelation therapy). As well the results of our research support that PNH+ pts has a better response to the IST than PNH-.

P634

PRELIMINARY DATA ON L-LEUCINE THERAPY OF DBA PEDIATRIC PATIENTS

G.S. Ovsyannikova[1,*] M.A. Maschan[1], G.A. Novichkova[1], N.S. Smetanina[1,2]
[1]Hematology, Federal Clinical Scientific Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, [2]Hematology, Russian National Research Medical University named after N.I.Pirogov, Moscow, Russia, Moscow, Russian Federation

Background: The first line of therapy for patients with Diamond-Blackfan anemia (DBA) is oral corticosteroids. Initially respond only 80% of patients, less than a half can keep it for extended periods. The majority of DBA patients received regular blood transfusions. Animal models showed efficacy of L-leucine, a translation enhancer, in the DBA and 5q- syndrome, which has the same altered ribosome function as the DBA. It was observed that treatment with L-leucine improves hemoglobin level and induce transfusion independence in patients with DBA and 5q- syndrome.
Aims: To evaluate the overall safety and efficacy of L-leucine therapy transfusion dependent DBA patients.
Methods: After approval by Local Ethics Committee and obtained signed informed consent form six children (aged 2 - 8 years, 3 girls and 3 boys) were enrolled in the study. The diagnosis of DBA in all patients was established according to the criteria of the DBA Working Group of the European Society for Paediatric Haematology and Immunology. L-leucine (700 mg/m2) was given orally 3 times daily during 9 months. The criteria of efficacy of L-leucine therapy were haemoglobin (Hb) levels, reticulocytes count (Retic) and soluble transferring receptor (sTFR).The safety was monitored by blood chemistry parameters, urine analysis, amount and severity of adverse events. Response criteria were: complete response - Hb >90 g/L and transfusion-independence; partial response - Hb <90 g/L and increased Retic >1% and any increase in transfusion interval from baseline; no response - no change in transfusion requirements and no significant change in Hb or Retic.
Results: Baseline Retic range in all cases was 0.1-0.5%; transfusions - every 3 weeks. Complete response was obtained in 2 (30%) cases (both girls 2 years old). One of these patients has mutation in gene*RPL11* ex. 2 c.65delT (p.Cys21Ser_fs*33) hetero. In the other case the whole genome sequencing is in the progress. No response - in 4 cases; their genotype: *RPS19*ex. 2 c.3G>A (Met1Ile) hetero; *RPL5*ex. 3 c.187 C>T (Gln63*);*RPS19* ex. 2 c.31 C>T (Gln11*) hetero. Increasing growth rate was noticed in all cases: twice-higher compare to the same period of time before the study. No one showed any kind of adverse events. The blood chemistry parameters were within reference range in all cases.
Summary and Conclusions: The L-leucine therapy might be perspective for some DBA patients.

P635

GENETIC VARIANTS OF COMPLEMENT C5 AND POLYMORPHISMS OF COMPLEMENT C3 IN CHINESE PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

Q. Zhang[1], B. Han[1,*] L. Wang[1], Y. Du[1]
[1]Department of Hematology, Peking Union Medical Colleague Hospital, Beijing, China

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a clonal hematopoietic stem cell disorder, which is characterised by intravascular hemolysis, an abnormal tendency of thrombosis, and various degrees of bone marrow failure. Eculizumab suppresses the terminal complement system, by inhibiting the cleavage of C5,with subsequent decrease of cytolysis of PNH erythrocytes . 3.2% of the Japanese PNH population did not respond to eculizumab,due to a single missense C5 heterozygous mutation, c.2654G→A. The prevalence of this mutation was similar to that of healthy Japanese population (3.5%) and was also identified in the Han Chinese population(1/120). Mutant C5 did not bound to and was not blocked by eculizumab. Meanwhile, eculizumab preserves upstream components that culminate in C3b-mediated extravascular hemolysis, which results in the permanent transfusion requirements. British researchers found that eculizumab-treated patients who had homozygote C3S/C3S allele had a significantly higher degree of C3 loading on PNH. But the PNH complement C3 alleles screening was conducted mainly in Europe, not in Asia.
Aims: We intend to study genetic variants of complement C5 and polymorphisms of complement C3 in Chinese patients with PNH in order to determine its potential impact on Eculizumab efficacy.
Methods: 220 patients with PNH (diagnosed by CD55/CD59, Flaer analysis) and 259 normal controls were included. DNA was extracted from peripheral blood mononuclear cells . Complement C5 exon 21 PCR products and C3 genotypes were analyzed by Sanger method, in order to search the gene mutation of complement C5 gene (rs56040400),and to analyses the genetic polymorphisms of C3 (rs2230199).
Results: For patients with PNH, there were 118 males and 102 females, with a medium age of 39 years(4-75 years), mean LDH 1078 (IU/L), mean Hb 82 (g/L). 152 patients were classic PNH, 68 patients were aplastic anemia with PNH clone, five patients had thrombosis. In normal control group, there were 138 male and 121 females with a medium age of 35 years(8-72 years). In both the PNH patients and normal control subjects,we found no a single missense C5 heterozygous mutation. When we analysed C3 genetic polymorphisms,they were all homozygous SS allele, no F allele was found.
Summary and Conclusions: In the small sample of Chinese PNH patients and normal subjects,we found no C5 exon gene mutations that had been reported before, and only SS polymorphism was seen in C3 polymorphismsin analysis. These data suggest that Chinese patients will probably not affected by the C5 mutation when exposed to Eculizumab, but may undergo C3 mediated extravascular hemolysis.

EFFECT OF IMID COMPOUNDS ON CD38 EXPRESSION ON MULTIPLE MYELOMA CELLS: MOR202, A HUMAN CD38 ANTIBODY IN COMBINATION WITH POMALIDOMIDE

R. Boxhammer[1,*] S. Steidl[1], J. Endell[1]
[1]MorphoSys AG, Martinsried/Planegg, Germany

Background: MOR202 (MOR03087), a human CD38 antibody currently under evaluation in a phase I/IIa trial, mediates antibody-dependent cell-mediated cytotoxicity/phagocytosis (ADCC/ADCP) of multiple myeloma patient-derived cells with high potency (EC_{50} ~200 pM).
Aims: To evaluate *in vitro* the ability of the IMiD compounds lenalidomide and pomalidomide, both of which are approved for multiple myeloma, to modulate CD38 expression and enhance the cytotoxicity of MOR202.
Methods: CD38 expression +/- lenalidomide and +/- pomalidomide on multiple myeloma cell lines was analyzed by flow cytometry. The antitumor activity of pomalidomide combined with MOR202 was evaluated *in vitro*; analyses included the induction of direct cytotoxicity on multiple myeloma cells and the activation of immune effector cells. On a functional level, the combinatorial effects of MOR202 with pomalidomide were assessed in ADCC assays. Different incubation schemes were used to separate the effect of pomalidomide on target and effector cells, as well as in the evaluation of the combined effects. The observed combination effects were analyzed for synergistic potential using the fractional product concept.
Results: Pomalidomide and lenalidomide mediated a substantial CD38 upregulation on multiple myeloma cell lines. Pomalidomide as a single agent demonstrated activation of effector cells with high potency (EC_{50} ~150 nM), and demonstrated cytotoxic effects on multiple myeloma cell lines. Additionally, pomalidomide dose-dependently induced an up to 3-fold CD38 upregulation (EC_{50} ~20 nM) on CD38-expressing multiple myeloma cell lines. Pomalidomide-mediated effects were time-dependent, with the most pronounced effects after 72 h incubation. Combining MOR202 with pomalidomide led to a synergistic enhancement of cytotoxic activity. The synergic benefit ranged 1.2-3.1-fold above theoretical additivity depending on the cell line used, and was most prominent in the case of strong CD38 upregulation.
Summary and Conclusions: Upregulation of CD38 was mediated by both lenalidomide and pomalidomide and may represent a class effect of IMiD compounds. The cytotoxic activity of MOR202 on multiple myeloma cells was enhanced by pomalidomide via multiple mechanisms: direct cytotoxicity, CD38 upregulation and activation of effector cells. These results provide a mechanistic rationale for the combination of MOR202 with IMiD compounds and warrant further clinical evaluation.

P637

CENTROSOME ASSOCIATED GENES PATTERN FOR RISK SUBSTRATIFICATION IN MULTIPLE MYELOMA

F. Kryukov[1,2,*] P. Nemec[3], L. Radova[4], E. Kryukova[1,2], Z. Kufová[1,2], L. Sedlarikova[3,5], S. Sevcikova[3], R. Hajek[1,2,3]
[1]Department of Haematooncology, Faculty of Medicine, University of Ostrava, [2]Department of Haematooncology, University Hospital of Ostrava, Ostrava, [3]Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, Masaryk University, [4]The Central European Institute of Technology, Masaryk University, [5]Department of Clinical Hematology, University Hospital Brno, Brno, Czech Republic

Background: Multiple myeloma (MM) is a lymphoproliferative disease characterized by the clonal expansion of neoplastic plasma cells within the bone marrow. The genome of the malignant plasma cells is extremely unstable characterized by a complex combination of structure and numerical abnormalities. Our previous study defined centrosome associated genes pattern with impact in myeloma pathogenesis. Revealed molecular signature is related to OS as well as to clinical parameters and ISS staging (Kryukov *et al.*, 2013).
Aims: The objective of our study was to create and validate risk stratification model based on previously described centrosome associated genes pattern in MM.
Methods: One hundred and fifty patients were evaluated for this study. The patients' baseline characteristics were as follows: males/females 79/71, median age of 67 years (range 38-90 years). Newly diagnosed (90/150) and relapsed (60/150) patients were included in this study; most of them had advanced stage of MM (DS II/III n=110; ISS II/III n=144). Interphase FISH with cytoplasmic immunoglobulin light chain staining (clg FISH) and gene expression profiling (GEP) were performed on CD138+ plasma cells separated by MACS. Training and validation cohort includes 72 and 78 pts, resp.
Results: Using multinomial logistic regression 12 candidate genes (*BUB1, BUB1B|PAK6, RAD51, PLK1, BRCA1, CENPA, BARD1, AURKA, MAD2L1, CENPH, XRCC2* and *CDC25C|FAM53C*) for patients, risk stratification were defined. Based on expression of these genes, patients can be stratified into three groups - "High-", "Mediate-" and "Low expressed". The overall survival of patients in "High" and "Medium" subgroups was significantly worse than in patients in "Low" subgroup for both training and validation cohorts and was in concordance with previously published results (Kryukov *et al.* 2013). To characterize the prognostic significance of centrosome associated genes pattern (CAGP), multivariate Cox proportional hazards survival model was used. Significantly worse prognosis was found for united "High & Medium" group (HR=2.182; 3-year OS=28.3%) compared to "Low" group (3-year OS=63.8%, p<0.01). Besides CAGP, the following parameters were used for multivariate Cox proportional hazards survival model: ISS stadium, β2-microglobulin, del 17p13, t(4;14), amp 1q21. The variables in the multivariate model were the only variables, which remained statistically significant when potential predictors were combined together as well as CAGP, which was forced into the model. Among all subsequently tested combinations of predictors, the best results in risk of death assessment were obtained for CAGP combined with del 17p13 (p<0.001). It is worth to mention that both prognostic factors were independent. United "High & Medium" CAGP subgroup as well as TP53 deletion had significantly higher risk of death assessment (HR=3.189 and HR=3.699 resp. p<0.005). Survival characteristics for different risk groups are presented in the Table 1.

Table 1. Survival characteristics for different risk groups (validation cohort, n=69).

Stratification group	Survival Median	3-years Overall Survival
Low Risk CAGP	47.2 months	69.2%
High Risk CAGP	22.5 months	28.3%
TP53-	33.3 months	46.1%
TP53+	5.9 months	14.3%
Low Risk CAGP/TP53-	47.2 months	69.2%
Low Risk CAGP/TP53+	5.9 months	25.0%
High Risk CAGP/TP53-	22.8 months	24.7%
High Risk CAGP/TP53+	0.7 months	0.0%

"Low Risk CAGP" group includes patients with "Low expressed" centrosome associated gene pattern. "High Risk CAGP" group includes patients with united "High & Medium expressed" centrosome associated gene pattern.
"TP53+" group includes patients with deletion 17p13; "TP53-" group includes patients without deletion 17p13 (positivity cutoff >20%).

Summary and Conclusions: We have created a new GEP-based model for classification of every patient into one of three prognostic subgroups, which can be easily used in routine practice. This approach can be used independently as well as in combination with other factors. Best results in risk of death assessment are obtained when the new stratification model is used in combination with detection of TP53 loss analyzed by FISH. Thus, the new model can be used for substratification of prognosis in patients with TP53 loss. These findings need to be confirmed on larger cohort with longer follow-up.

BONE MARROW MESENCHYMAL STROMAL CELLS FROM HEALTHY DONORS SECRETE EXOSOMES THAT INHIBIT *IN VIVO* TUMOR GROWTH AND ANGIOGENESIS IN MULTIPLE MYELOMA

T. Umezu[1,*] S. Imanishi[2], K. Azuma[2], S. Yoshizawa[3], K. Ohyashiki[3], J. Ohyashiki[2]
[1]Department of Molecular Science, [2]Institute of Medical Science, [3]Department of Hematology, Tokyo Medical University, Tokyo, Japan

Background: The bone marrow microenvironment plays a key role in the growth and survival of multiple myeloma (MM) cells. MM cells interact with mesenchymal stromal cells (MSC) in the bone marrow, resulting in cell proliferation and angiogenesis. The bone marrow derived MSC is one of the most promising source of cell therapy. Resently, MSC-derived exosomes have been found to be efficacious in animal models for the treatment of non-neoplastic disease, such as cardiovescular disease and liver injury, because MSC-derived exosomes carry and transfer their cargo, which promote therapeutic response.
Aims: We sought to determine the anti-tumor effect of MSC-derived exosomes by nude mouse heterotransplant model, aiming to establish the exosome-based theraputic approch using MSC-derived exosomal miRNAs.
Methods: Human MSCs obtained from bone marrow of healthy donors (BM-MSC; age 19 to 72) were purchased from Lonza. BM samples were obtained

from MM patients (age 62 to 77) in accordance with the Declaration of Helsinki and using protocols approved by the research Ethics Committee of Tokyo Medical University (IRB No. 2648), and MSCs derived form MM patients (MM-MSCs) were isolated by the classical adhesion method. Hypoxia-resistant myeloma cell line (RPMI8226-HR) established in our laboratory were cultured at 1% O_2. Exosome secreted from MSCs (MSC-exosome) were isolated from conditioned medium using a Total Exosome Isolation Reagent (Invitrogen). The size of MSC-exosomes was confirmed using a NanoSight LM10. To examine whether MSC-exosomes could be transferred into recipient cells, RPMI8226-HR cells or human endothelial cells, were cultured with fluorescent dye-labeled MSC-exosomes. Exosomal miRNA profiling was done using a TaqMan low-density array (ABI), and Student's t-test was used to determine statistical significance for comparisons between MM patient and healthy donor groups using R software. In Matrigel plug assay, BALB/c nude mice were injected subcutaneously with 400 µL Matrigel containing myeloma cell lines with or without MSC-exosomes. After 3 weeks, the Matrigel plugs were harvested, and stained with anti-CD31 antibody to analyze vessel density.
Results: BM-MSCs displayed long spindle shape, and there was no morphological difference between the BM-MSCs from non-aged donors (19 and 21 years) and that from aged donors (68 and 72 years). In contrast, MM-MSCs displayed the flat cellular morphology. The nanoparticle size distribution of MSC-exosomes was approximately 50 nm, and there were no significant differences in size and amount of exosomes in BM-MSCs and MM-MSCs. We found a diferential exosomal miRNA expression profile between BM-MSCs and MM-MSCs. Then we could subdivide miRNAs as follows: (1) miRNAs upregulated in BM-MSCs, (2) miRNAs upregulated in MM-MSCs. We also found the transport of these exosomal miRNAs derived from BM-MSCs into either myeloma cell or human endothelial cell via exosomes using *in vitro* model. MM-MSC-exosomes enhanced angiogenesis and cell proliferation of MM cells in Matrigel plug containing RPMI8226-HR cells. Of note is that BM-MSC-exosomes significantly reduced the density of CD31 positive endothelial cells and the remarkable decrease of myeloma cells in Matrigel plug, indicating the anti-tumor effect of BM-MSC-exosomes. The growth inhibitory effect was more prominent in BM-MSC-exosomes from non-aged donors.
Summary and Conclusions: Our results suggest that the BM-MSC-exosomes is able to transfer the miRNAs, which have the ability to inhibit tumor growth and angiogenesis in MM. The present study provide a theraputic potential of exosomes derived BM-MSCs in MM.

ANTITUMORAL ACTIVITY OF AMILORIDE IN MULTIPLE MYELOMA THROUGH APOPTOSIS INDUCTION, REGARDLESS OF TP53 MUTATIONAL STATUS

E. Rojas[1,*] I. Misiewicz-Krzeminska[1], S. Hernández[1], T. Paíno[1], L.A. Corchete[1], I. Isidro[1], M.V. Mateos[1], E. Ocio[1], N.C. Gutiérrez[1]
[1]Instituto de Biologia Molecular y Celular del Cancer, CSIC/Universidad de Salamanca, Salamanca, Spain

Background: Multiple myeloma (MM) remains incurable despite the novel agents with different mechanisms of action. Therefore, the investigation of the potential antimyeloma activity in other therapeutic agents is stillneeded. The antihypertensive agent, amiloride, has been demonstrated to inhibit tumor cell proliferationin different experimental models. Here we explore the activity of amiloride in myeloma cells.
Aims: To investigate the antimyeloma effect of amiloride in myeloma cell lines and primary samples and to identify the potential mechanisms involved.
Methods: Seven human myeloma cell lines (NCI-H929, JJN3, KMS12-BM, KMS12-PE, U266, MM1S and RPMI-8226) and 9 bone marrow (BM) samples from MM patients were used for the experiments. Cell viability, apoptosis and cell cycle analyses were carried out by CellTiter-Glo assay, annexin V staining and PI/RNASE solution following manufacturer's instructions, respectively. Caspases 3/7, 8 and 9 activities were evaluated by luminescent Caspase-Glo®Assays and the measuring of mitochondrial membrane potential ($\Delta\Psi_m$) by flow cytometry analyses. The gene expression was quantified by Taqman assay qRT-PCR. Synergy with bortezomib and dexamethasonewas calculated with the "CalcuSyn" software program.
Results: To test the antiproliferative effect of amiloride, myeloma cells were treated with increasing concentrations of the compound (0.1mM-1mM) for 24, 48 and 72 hours. Amiloride displayed potent antimyeloma activity in the panel of 7 cell lines. A substantial induction of apoptotic cell death (greater than 40% at 24 h and 60% at 48 h) and cell cycle blockade (a 12% increase in G_0/G1, and a 10% and 5% decrease in the G_2/M and S phases of cell cycle, respectively) was observed in all MM cell lines. The apoptosis induced by amiloride was not related to the TP53 mutational status, since amiloride was still able to induce cell death through a p53-independent pathway in p53 mutated cell lines, such as U-266, KMS12-BM and JJN3. Moreover, this drug caused a notable decrease in mitochondrial membrane potential ($\Delta\Psi_m$) and an activation of caspases 3/7, 8 and 9. Mechanistic studies showed that amiloride□triggered apoptosis was associated with the overexpression of BAX, BAK1, BBC3, TNFRSF10B, FAS, CDKN1B and CDKN1A, even in those MM cell lines in which p53 gene was mutated. Further, we evaluated the potential synergism of amiloride with other antimyeloma agents. H929 and JJN3 cell lines were treated for 48 h with combinations of suboptimal doses of amiloride, and bortezomib and dexamethasone, in double combinations. Amiloride was synergistic with bortezomib in NCI-H929 and JJN3 cell lines (CI=0.80 and 0.89, respectively). The combination indexes for dexamethasone were in the additive range. Finally, the antiproliferative/cytotoxic effect of amiloride in BM cell subpopulations obtained from 9 patients with MM was assessed. *In vitro* studies confirmed the antimyeloma efficacy of amiloride in patient samples and showed a clearly lower cytotoxicity in the remaining cell subpopulations compared to tumor plasma cells.
Summary and Conclusions: Our results demonstrate a potent and selective antimyeloma effect of amiloride by p53-dependent and independent pathways. The present data support the investigation of amiloride as a treatment option for MM patients, either alone or in combination.

BORTEZOMIB-RESISTANCE OF BONE MARROW FIBROBLASTS IN MULTIPLE MYELOMA IS CLOSELY CONNECTED TO ACTIVATION OF AUTOPHAGY AS SURVIVAL MACHINERY

L. Di Marzo[1,*] V. Desantis[1], D. Vergara[2], K. De Veirman[3], I. Catacchio[1], L. Rao[1], M. Maffia[2], K. Vanderkerken[3], A. Vacca[1], M.A. Frassanito[1]
[1]Biomedical and Human Oncology Sciences, Azienda Ospedaliero-Consorziale Universitaria Policlinico di Bari, Bari, [2]Department of Biological and Environmental Sciences and Technologies, University of Salento, Lecce, Italy, [3]Department of Hematology and Immunology, Myeloma Center Brussels, Vrije Universiteit Brussel (VUB), Brussels, Belgium

Background: Cancer-associated fibroblasts (CAFs) are a relevant cell type within the stroma of many tumors entailed with high malignancy grade, progression, and poor prognosis. In multiple myeloma (MM), CAFs give a noteworthy contribution in terms of growth, proliferation, and survival of tumor cells[1].
Aims: Since drug resistance of MM cells depends on tumor microenvironment, we analyzed the mechanism which involves CAFs in bortezomib-resistance of MM cells.
Methods: Proteomic, phospho-proteomic, western blot, immunofluorescence and flow cytometry studies were performed to demonstrate the effect of CAFs on the bortezomib-induced apoptosis of MM cells.
Results: CAFs purified from bone marrow of bortezomib-resistant patients were *in vitro* insensitive to the bortezomib treatment, and protected MM cells as RPMI8266 cell line and CD138+ plasma cells from bortezomib-induced apoptosis. The effect was related to the ability of bortezomib-resistant CAFs treated with bortezomib to secrete high levels of prosurvival cytokines/growth factors, namely insulin-like growth factor 1 (IGF-1), interleukin-6 (IL-6), interleukin 8 (IL-8), and transforming growth factor beta (TGFβ), compared to CAFs purified from 1st diagnosed patients. Proteomic and phospho-proteomic studies suggested that resistance of CAFs to bortezomib was related to a cellular stress condition. Flow cytometry and immunofluorescence studies showed that bortezomib-resistant CAFs had higher production of reactive oxygen species (ROS) compared to CAFs purified from 1st diagnosed patients. When treated with bortezomib cells increased the ROS expression and activated the autophagy pathway. Indeed, the bortezomib treatment induced an increase of microtubule-associated protein light chain 3 (LC3)-II with a reduction of p62 proteins, two autophagic markers, and inhibited the phosphorylation status of mTor, the major autophagic pathway. Finally we demonstrated that TGFβ, which acts in autocrine way, activated prosurvival autophagy and induced bortezomib resistance.
Summary and Conclusions: Our results highlight that CAFs from bortezomib resistant patients are insensitive *in vitro* to the bortezomib treatment and protect MM cells from bortezomib-induced apoptosis. The *in vitro* resistance of bortezomib-resistant CAFs to drug treatment is closely connected to activation of autophagy as prosurvival machinery. Accordingly, we speculate that targeting CAFs in MM patients may be envisaged as a cell-based therapeutic strategy.

POLYMORPHISMS WITHIN THE CEREBLON AND BETA-CATENIN ENCODING GENES IN PATIENTS WITH MULTIPLE MYELOMA

A. Butrym[1,2,*] J. Rybka[2], P. Lacina[3], K. Gembura[3], D. Frontkiewicz[4], T. Wróbel[2], K. Bogunia-Kubik[3], G. Mazur[4]
[1]Dept. of Physiology, [2]Dept. of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw Medical University, [3]Laboratory of Clinical Immunogenetics and Pharmacogenetics,, L. Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, [4]Department of Internal, Occupational Diseases and Hypertension, Wroclaw Medical University, Wrocław, Poland

Background: The recent studies have suggested that cereblon (CRBN) is essential for the anti-myeloma (MM) activity of immunomodulatory drugs (IMiDs), such as thalidomide and lenalidomide and that dysregulation of Wnt/β-catenin pathway may be one of the possible reasons of lenalidomide resistance.
Aims: This prompted us to analyze the effect of the polymorphisms within the genes coding for cereblon (*CRBN* (rs121918368, C>T)) and β-catenin (*CTNNB1* (rs4135385, A>G; rs4533622, A>C).
Methods: MM patients (n=144) and healthy individuals (n=126) were genotyped using the Light SNiP assays.
Results: The *CTNNB1* (rs4135385) *AA* homozygosity was more frequent among patients with better response to CTD - cyclophosphamide, thalidomide, dexamethasone (8/11 *vs* 42/72, p-=0.047) and were at lower risk of disease progression after thalidomide treatment (22/31 *vs* 8/18, p=0.078). Patients carrying the *CTNNB1* (rs4533622) *AA* genotype were better responders to the first line therapy with thalidomide containing regiments (p<0.05). No significant association was observed between the effect of lenalidomide therapy and polymorphisms studied. However, the occurrence of neutropenia during lenalidomide therapy was more frequent among the *CTNNB1* (rs4135385) *AA* carriers (p=0.019) while the *CTNNB1* (rs4533622) *AA* homozygosity characterized patients with high grade (3-4) neutropenia (p=0.044). No association was found for the *CRBN* polymorphism.
Summary and Conclusions: The response to chemotherapy in patients with multiple myeloma is associated with the *CTNNB1* polymorphism.

A NEW NEXT GENERATION SEQUENCING STRATEGY TO EVALUATE GENETIC ABNORMALITIES IN MULTIPLE MYELOMA

C. Jiménez[1,*] M. Jara[2], N.C. Gutiérrez[1], M.E. Sarasquete[1], N. Puig[1], M.I. Prieto-Conde[1], M. García-Álvarez[1], M. Alcoceba[1], E. Sebastián[1], A. Balanzategui[1], C. Chillón[1], R. Corral[1], L.A. Marín[1], M.V. Mateos[1], J.F. San Miguel[3], M. González[1], A. Orfao[2], R. García-Sanz[1]
[1]University Hospital of Salamanca, [2]Cancer Research Centre (IBMCC-USAL/CSIC), Department of Medicine, University of Salamanca, Salamanca, [3]Clínica Universidad de Navarra, Centro de Investigación Médica Aplicada (CIMA), Pamplona, Spain

Background: Approximately 60% of multiple myeloma (MM) patients harbor a translocation predominantly involving the *IGH* locus at 14q32. *IGH* translocations are a primary event and determine the prognostic outcome of a patient. These events are routinely assessed by FISH, which can easily detect the *IGH* translocation, although the partner chromosome frequently remains unknown. Next Generation Sequencing (NGS) techniques may overcome this limitation with the additional advantage of identifying the precise localization of the breakpoints. This would allow the subsequent design of patient specific PCRs for monitoring the aberrant chromosomal translocation over disease evolution. Moreover, this methodology may provide other relevant information, such as the identification of the clonal V(D)J rearrangements, IgH isotypes or somatic gene mutations.
Aims: To design a NGS-based strategy in order to investigate the landscape of relevant chromosomal abnormalities and gene lesions in a series of MM patients.
Methods: A custom pull down panel to identify *IGH* translocations, V(D)J rearrangements and the most common somatic mutations in myeloma patients (involving *NRAS*, *KRAS*, *HRAS*, *TP53*, *MYC* and *BRAF* genes) was designed. Samples from 48 newly diagnosed MM patients, enrolled in GEM2005 clinical trial, were included in the study. DNA was extracted from bone marrow CD138+ plasma cells separated by autoMACS®. Regions of interest of the aforementioned genes were captured with the NimbleGen strategy (Roche NimbleGen, Inc., Madison, WI). Massive parallel sequencing was performed in a GS FLX+ System with a mean of 350 bp paired-end read length and a mean depth of more than 23.000X per sample (>95% coverage). Results were correlated with FISH, molecular and clinical data of the patients.
Results: In a preliminary analysis (with ≥40 bp overlap depth and ≥90% overlap identity), we could confirm the presence of 9/17 *IGH* translocations that had been detected by FISH (5 t(11;14), 2 t(4;14), 1 t(14;16) and 1 t with unknown partner). Breakpoints in *IGH* were located in μ switch and enhancer regions (67%) and in *IGHJ* region (33%). One unknown partner chromosome turned out to be chromosome 12q24, and the breakpoint was located between *SCARB1* and *UBC* genes. Interestingly, this patient was the only one in this series that had an associated amyloidosis. We also detected 6 potential additional translocations that will be further analyzed for confirmation. Regarding IgH subclass, we could observe that the splice process occurred between μ switch (S) region and $S\gamma_1$ (in 50% cases), $S\gamma_2$ (20%), $S\gamma_3$ (10%), $S\gamma_4$ (10%) and $S\alpha_1$ (10%). This preliminary analysis also allowed us to identify the V(D)J rearrangement in 18 patients (38%). Finally, mutation analysis revealed the presence of missense protein-coding alterations in 19/48 (40%) patients, distributed as follows: 7/48 (15%) *NRAS*, 7/48 (15%) *KRAS*, 7/48 (15%) MYC, 2/48 (4%) *TP53*, 0/48 (0%) *HRAS* and 0/48 (0%) *BRAF*.
Summary and Conclusions: Our capture-based NGS study allows the simultaneous identification of *IGH* translocations, V(D)J rearrangements, IgH isotype switching and somatic mutations in myeloma patients. The precise location of the breakpoints can be used as a target for minimal residual disease detection. Lastly, it is also interesting the discovery of novel translocations, as it is the case of the t(12;14) translocation that we have found here. Nevertheless, this study still requires further optimization and standardization that will involve both biological and bioinformatics evaluation.

P643

HUMAN MYELOMA CELL ENGRAFTMENT IN NEXT GENERATION HUMANIZED MICE EXPRESSING HUMAN INTERLEUKIN 6

T. Silzle[1,*] G. Pellegrini[2], D. Kenkel[3], S. Cogliatti[4], M.G. Manz[5], C. Driessen[1]
[1]Department of Oncology/Haematology, Cantonal Hospital St. Gallen, St. Gallen, [2]Laboratory for Animal Model Pathology, Institute of Veterinary Pathology, University of Zurich, [3]Institute of Diagnostic and Interventional Radiology, UniversityHospital Zurich, Zurich, [4]Institute of Pathology, Cantonal Hospital St. Gallen, St. Gallen, [5]Department of Haematology, UniversityHospital Zurich, Zurich, Switzerland

Background: Multiple myeloma (MM) remains a non-curable disease for most patients, and novel therapeutic options need to be evaluated. The clonal heterogeneity and plasticity of human MM disease emphasizes the need to use primary human MM cell populations that reflect this in preclinical murine MM models. However, the engraftment of primary human MM cells in immunocompromised mice is poor, likely due to the fact that murine hematopoetic growth factors and in particular Interleukin-6 (IL-6), which is important for intramedullary MM growth, share only little homology with their human counterparts. This poor engraftment of human MM cells severely limits the usefulness of xenograft MM models for the assessment of novel therapies in the preclinical setting *in vivo*.
Aims: To explore whether expression of human IL-6 in immunocompromised mice would allow efficient engraftment and systemic bone marrow growth of human MM cells in immunocompromised mice, providing the basis for an improved MM *in vivo* model.
Methods: $2x10^6$ human RPMI8226 and INA-6 (an IL6-dependent human MM cell line) cells were injected into the femur of adult humanSIRAPα transgenic/humanIL6 and humanTPO-knockin Rag2-/- gamma chain-/- mice (TPO-IL6-SIRPα mice). Mice were sacrificed 38-54 days after injection and analyzed by histology and immunohistochemistry, FACS and Mikro-CT. Paraproteinemia was detected by ELISA for human light chains.
Results: 5/5 RPMI8226-injected mice developed a measurable paraproteinemia and showed infiltration by myeloma cells also at distant bone marrow sites (sternum), as detected by histology. 3/5 mice developed a soft tissue tumor in the parafemural tissue. Two mice showed a massive infiltration and systemic bone marrow spread to vertebral column, tibia, contralateral femur, hip and humerus with dense infiltration of the marrow cavity and often locally destructive growth with myeloma cells invading the surrounding tissue. Both mice developed paraplegia due to infiltration of the spinal cord at day 54. Mikro-CT revealed osteolytic lesions and generalized loss of trabecular structure, resembling human MM. Hepatic involvement was noticed in both animals by histology. One animal showed small foci of myeloma cells in the perirenal soft tissue. Ongoing experiments likewise demonstrate engraftment of the IL6 dependent cell line INA-6. Further experiments using human primary MM cells are ongoing and will be presented at the meeting.
Summary and Conclusions: Our data suggest that human TPO-IL6-SIRPαRag2-/-γc-/- mice considerably support the systemic growth of human myeloma cells in the bone marrow. TPO-IL6-SIRPα mice may therefore provide the basis for a next generation xenograft MM model that allows studying primary human cells from the intramedullary phase of MM *in vivo*.

P644

OVEREXPRESSION OF SALIVARY-TYPE AMYLASE REDUCES THE SENSITIVITY TO BORTEZOMIB IN MULTIPLE MYELOMA CELLS

S. Mizuno[1,*] I. Hanamura[1], A. Ota[2], S. Karnan[2], T. Narita[3], M. Ri[3], M. Goto[1], M. Gotou[1], N. Tsunekawa[1], M. Shikami[4], S. Iida[3], Y. Hosokawa[2], H. Miwa[5], R. Ueda[6], N. Masakazu[1], A. Takami [1]
[1]Division of Hematology, Department of Internal Medicine, [2]Department of Biochemistry, Aichi Medical University, Aichi Medical University, Nagakute, [3]Department of Medical Oncology and Immunology, Nagoya City University Graduate School of Medical Sciences, Nagoya, [4]Department of Hematology, Daiyukai General Hospital, Ichinomiya, [5]Department of Internal Medicine, Toyama Hospital, Tsu, [6]Department of Tumor Immunology, Aichi Medical University, Nagakute, Japan

Background: Despite recent progress in treatments for multiple myeloma, a complete cure remains elusive. Amylase-producing myeloma, mainly reported in East Asian and European countries, exhibits refractoriness to chemotherapy including bortezomib with a dismal prognosis. To overcome the obstacle, it is critical to elucidate the mechanisms by which amylase-producing myeloma cells survive after chemotherapy.
Aims: The aim of this work was to elucidate the mechanisms by which ectopic

overexpression and production of amylase contributes to the chemoresistance in myeloma.
Methods: We generated a human myeloma cell line in which the transfected *AMY1* gene was stably expressed. RPMI-8226 was lentivirally transduced to express salivary type amylase (8226/AMY1) or lacZ (8226/mock) as mock control. Cells were treated with anti-myeloma drugs (dexamethasone, bortezomib and lenalidomide). Cell viability and growth of treated cells were examined by the MTS assay. Apoptosis was quantitated by flow cytometry using annexin V - FITC staining. Gene expression changes associated with *amylase* expression were analyzed by microarray gene expression profiling. Cells were subcutaneously injected to mice (n=3 mice, each group), and DMSO or bortezomib (0.3 mg/kg) was administered twice a week for *in vivo* study. The tumor volumes of mice were observed every 3 to 4 days.
Results: Cell proliferation after 48 hours exposure to dexamethasone (40 mM), bortezomib (2 nM), and lenalidomide (1 mM) were significantly high in 8226/AMY1 compared with mock *in vitro* (Figure 1). The degree of apoptosis was significantly reduced in 8226/AMY1 after exposure to bortezomib and lenalidomide, but it was similar when treated with dexamethasone. *In vivo*, tumor growth of 8226/AMY1 markedly increased compared with mock, but did not show significance (Figure 2A). The ratio of tumor size treated with bortezomib to that with DMSO on days 46 was significantly high in 8226/AMY1 compared with mock (p=0.017) (Figure 2A), indicating that bortezomib was less effective in 8226/AMY1 compared with mock *in vivo*. Gene expression analysis by microarray identified 5 genes differentially up-regulated in 8226/AMY1 including the *TCL1A* gene, which codes T-cell leukemia/lymphoma 1 oncoprotein to function as a coactivator of the cell survival kinase AKT, as well as 7 differentially down-regulated.

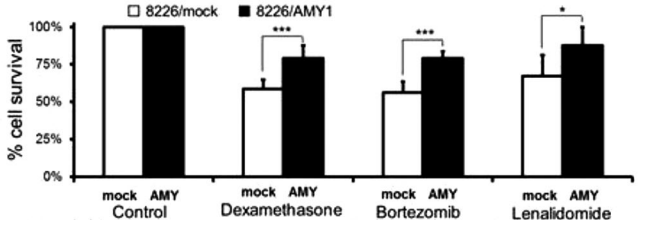

Figure 1. 8226/AMY1 showed the reduced sensitivity to anti-myeloma drugs *in vitro*.

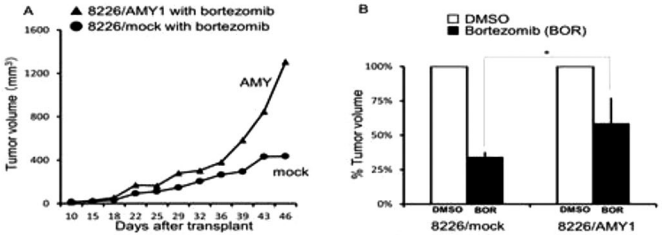

Figure 2. 8226/AMY1 showed the reduced sensitivity to bertezomib *in vivo*.

Summary and Conclusions: We demonstrated that 8226/AMY1 cells had reduced susceptibility to dexamethasone, bortezomib and lenalidomide *in vitro* partly through inhibition of apoptosis induced by these reagents. 8226/AMY1 also showed a weakened anti-tumor effect of bortezomib in exnografted mice. Up-regulation of *TCL1* may influence the anti-myeloma drug resistance by the mechanism of promotion of Akt-induced cell survival and proliferation in 8226/AMY1. Our data provide clues for elucidating the molecular pathology and developing treatment approaches for not only amylase-producing myeloma but relapsed and refractory myeloma.

Multiple myeloma - Clinical 3

A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS OF TREATMENTS FOR PATIENTS WITH TRANSPLANT-INELIGIBLE NEWLY DIAGNOSED MULTIPLE MYELOMA

W. Katja[1,*] C. Doyen[2], M.A. Dimopoulos[3], A. Yee[4], M. Kropff[5], J.J. Lahuerta[6], A. Martin[7], K. Travers[7], N. Abildgaard[8], J. Lu[9], J. Van Droogenbroeck[10], C. Geraldes[11], M. Petrini[12], L. Voillat[13], J.-P. Vilque[14], E. Voog[15], T. Facon[16]

Universitaria Ospedale S. Chiara Dip. Oncologia, Pisa, Italy, [13]Centre Hospitalier William Morey, Chalon, [14]Centre François Baclesse, Nice, [15]Centre Jean Bernard, Le Mans, [16]Hopital Claude Huriez, Lille, France

Background: Commonly recommended standards of care for patients (pts) with transplant-ineligible newly diagnosed multiple myeloma (NDMM) include melphalan and prednisone (MP) combined with thalidomide (MPT) or bortezomib (VMP). The randomized, controlled phase 3 FIRST trial demonstrated that continuous treatment with lenalidomide and low-dose dexamethasone (Rd continuous) significantly improved progression-free survival (PFS, the primary study endpoint) and overall survival *vs* MPT in pts with NDMM (Benboubker, *N Engl J Med,* 2014). In the absence of a head-to-head comparison, an indirect comparison of Tx across separate trials can be performed. However, cross-trial comparisons may be biased by differences in pt populations, sensitivity to modeling assumptions, and differences in the definitions of outcome measures.
Aims: A mixed-Tx comparison (MTC), a type of network meta-analysis (NMA), was used to evaluate the relative effect of Rd compared with VMP on overall survival (OS) and PFS.
Methods: A systematic literature review was conducted in Embase, PubMed, and CENTRAL using keywords for MM combined with Tx of interest: lenalidomide, thalidomide, bortezomib, interferon, and bendamustine as monotherapy, combination Tx, and MP combination Tx. The search was then narrowed to randomized trials of clinical efficacy in Tx-naive pts published between 1988 and September 2014. To avoid potential biases, quality assessments for each study were conducted using key questions derived from the Cochrane Handbook for Systematic Reviews of Interventions (Higgins, *BMJ,* 2011). The assessments were validated by independent investigators. Study comparability and Tx relevance were assessed to compare VMP with Rd using MPT as a common comparator. To reduce bias and better reflect the real-world situation, the analysis network was further limited to studies evaluating MPT on a fixed-dose schedule (per the thalidomide summary of product characteristics and current clinical practice). Random- and fixed-effects Bayesian MTC meta-analyses comparing Tx hazard ratios (HRs) for OS and PFS were conducted. The comparison described herein was conducted for research purposes and does not represent a validated hypothesis.

Table 1. Extracted data from studies in the primary analysis network.

Study Information				OS	PFS
Author	Study Group	Tx	Tx	HR (95% CI) *P* Value	HR (95% CI) *P* Value
Facon 2007	IFM 99/06	MPT (n=125)	MP (n=196)	0.59 (0.46-0.81) 0.0006	0.51 (0.39-0.66) < 0.0001
Hulin 2009	IFM 01/01	MPT (n=133)	MP (n=116)	0.68 (0.48-0.96) 0.28	0.61 (0.46-0.82) 0.001
San-Miguel 2013	VISTA	VMP (n=344)	MP (n=338)	0.695 (0.508-0.84) 0.001	0.558 (0.43-0.72) 0.008
Benboubker 2013	MM-020 (FIRST)	Rd (n=535)	MPT (n=547)	0.78 (0.64-0.96) 0.02	0.72 (0.61-0.85) < 0.001
Sacchi 2011	NR	MPT (n=64)	MP (n=54)	0.52 (0.28-0.97) 0.07	0.57 (0.35-0.94) 0.02

Results: The network was composed of 5 trials (IFM 0101, IFM 99/06, Sacchi 2011, VISTA, and FIRST) evaluating Rd continuous, VMP, MP, and MPT (Table 1). An analysis of OS using fixed-effects NMA models documented a significantly lower risk of death with Rd compared with VMP (HR=0.69 [95% credible interval

(CrI), 0.48-0.98]), MPT (HR=0.78 [95% CrI, 0.64-0.95]), and MP (HR=0.48 [95% CrI, 0.36-0.64]). A significantly lower risk of progression or death was detected from a PFS analysis of Rd compared with MPT (HR=0.71 [95% CrI, 0.61-0.85]) or MP (HR=0.40 [95% CrI, 0.31-0.51]). A numerical trend in PFS in favor of Rd was observed when compared with VMP (HR=0.72 [95% CrI, 0.51-1.02]).
Summary and Conclusions: A significant advantage in OS was associated with Rd continuous compared with other first-line Tx (VMP, MPT, and MP). Pts treated with Rd continuous had a lower risk of progression than those treated with MPT and MP. Conclusions are focused on efficacy and do not consider any potential differences in safety.

P646

UPDATED RESULTS FROM A MULTICENTER, OPEN-LABEL, DOSE-ESCALATION PHASE 1B/2 STUDY OF SINGLE-AGENT OPROZOMIB (OPZ) IN PATIENTS (PTS) WITH HEMATOLOGIC MALIGNANCIES, INCLUDING MULTIPLE MYELOMA (MM)

R. Vij[1,*] M. Savona[2], D. Siegel[3], J.L. Kaufman[4], A. Badros[5], I. Ghobrial[6], A. Paner[7], S. Jagannath[8], A. Jakubowiak[9], J. Mikhael[10], P. Kapoor[11], L. Neuman[12], M. Obreja[12], J. Berdeja[13]
[1]Washington University, St. Louis, [2]Vanderbilt University, Nashville, [3]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, [4]Winship Cancer Institute, Emory University, Atlanta, [5]University of Maryland, Baltimore, [6]Dana-Farber Cancer Institute, Boston, [7]Rush University, Chicago, [8]Mt Sinai Hospital, New York, [9]University of Chicago Medical Center, Chicago, [10]Mayo Clinic, Scottsdale, [11]Mayo Clinic, Rochester, [12]Onyx Pharmaceuticals, Inc., an Amgen subsidiary, South San Francisco, [13]Sarah Cannon Research Institute, Nashville, United States

Background: Preliminary findings from an open-label, phase 1b/2 study (NCT01416428) investigating OPZ in pts with hematologic malignancies (including MM) were presented previously (Vij *et al.*, Blood 2014;124: abstract 34). In the phase 1b portion of the study, the maximum tolerated dose (MTD) of OPZ administered once-daily on days 1, 2, 8, and 9 of a 14-day cycle (2/7 schedule) or on days 1-5 of a 14-day cycle (5/14 schedule) was 300 mg/day (mg/d) and 240 mg/d, respectively. In addition, results from 27 pts who were enrolled in the phase 2 portion of the study on the 5/14 schedule at the MTD (240 mg/d) were presented previously (Vij *et al.*, Blood 2014;124: abstract 34).
Aims: We present updated data from the phase 2 portion of the study (NCT01416428).
Methods: The study is enrolling adult pts with hematologic malignancies who have relapsed after receiving ≥1 line of therapy. The primary objective of the phase 2 portion of the study is to determine the best overall response rate (≥partial response). Given the encouraging anti-MM efficacy of OPZ, in order to improve the gastrointestinal tolerability of OPZ, the study protocol was amended so that pts on both the 2/7 and 5/14 schedules could receive a reduced dose of OPZ during cycle 1 (150 and 240 mg/d, respectively), followed by a higher dose of OPZ during cycles ≥2, if tolerated (180 and 300 mg/d, respectively). Enrollment of pts with MM is continuing in the phase 2 portion of the study in the 2/7 schedule (240/300 mg/d) and 5/14 schedule (150/180 mg/d); the target enrollment is 94 pts with MM. Preliminary safety results are presented for pts with MM who enrolled in the phase 2 portion of the study following modification of the treatment schedules. All pts provided informed consent.

Table 1. Common AEs of interest.

	Phase 2: 2/7 schedule (240/300 mg/d) (n=10)		Phase 2 5/14 schedule (150/180 mg/d) (n=9)	
	All Gr n (%)	Gr 3-4 n (%)	All Gr n (%)	Gr 3-4 n (%)
Any AE	10 (100)	7 (70)	9 (100)	6 (67)
Hematologic AEs				
Neutropenia	1 (10)	1 (10)	2 (22)	0 (0)
Thrombocytopenia	1 (10)	0 (0)	1 (11)	0 (0)
Anemia	0 (0)	0 (0)	1 (11)	1 (11)
Non-hematologic AEs				
Diarrhea	7 (70)	1 (10)	9 (100)	0 (0)
Nausea	6 (60)	1 (10)	9 (100)	0 (0)
Vomiting	3 (30)	0 (0)	3 (33)	0 (0)
Increased blood creatinine	1 (10)	0 (0)	2 (22)	0 (0)
Constipation	0 (0)	0 (0)	2 (22)	0 (0)
Upper respiratory tract infection	0 (0)	0 (0)	2 (22)	0 (0)

Results: As of November 3, 2014, 19 pts with MM were enrolled in the phase 2 portion of the study on the modified treatment schedule, including 10 pts who enrolled on the 2/7 schedule (240/300 mg/d) and 9 pts who enrolled on the 5/14 schedule (150/180 mg/d). Preliminary median treatment duration was 5.6 weeks (range, 0.1-11.3) and 6.7 weeks (range, 3.0-16.7), respectively. Median patient age was 69 years (range, 51-77) and 60 years (52-75), respectively. Response data from the 2/7 schedule (240/300 mg/d) and 5/14 schedule (150/180 mg/d) were not available due to limited treatment exposure. Common adverse events (AEs) of interest are shown in the Table 1. No grade 4 AEs occurred in the two schedules. Two pts (20%) in the 2/7 schedule (240/300 mg/d) and 0 pts in the 5/14 schedule (150/180 mg/d) discontinued treatment due to an AE. Two pts (20%) in the 2/7 schedule (240/300 mg/d) and 1 patient (11%) in the 5/14 schedule (150/180 mg/d) had ≥1 dose reduction due to an AE.
Summary and Conclusions: The gastrointestinal tolerability profile of OPZ improved at dosing levels below the MTD in the 2/7 schedule (240/300 mg/d) and 5/14 schedule (150/180 mg/d). Common grade ≥3 AEs in both treatment schedules included diarrhea, nausea, and vomiting. Updated results from the phase 2 portion of the study will be presented at the meeting.

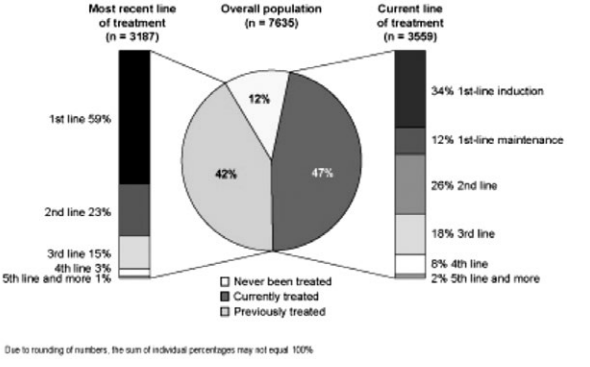
P647

MULTIPLE MYELOMA MANAGEMENT: PRACTICE PATTERNS ACROSS EUROPE

M.S. Raab[1,*] M. Cavo[2], M. Delforge[3], C. Driessen[4], L. Fink[5], A. Flinois[5], S. Gonzalez-McQuire[6], L. Karlin[7], M.-V. Mateos[8], P. Schoen[9], K. Yong[10]
[1]Department of Internal Medicine, University of Heidelberg, Heidelberg, Germany, [2]"Seràgnoli" Institute of Hematology and Medical Oncology, Bologna University School of Medicine, Bologna, Italy, [3]Department of Hematology, UZ Leuven, Leuven, Belgium, [4]Department of Oncology and Hematology, Kantonsspital St Gallen, St Gallen, Switzerland, [5]Kantar Health, Montrouge, France, [6]Global Health Economics, Amgen (Europe) GmbH, Zug, Switzerland, [7]Centre Hospitalier Lyon Sud, Lyon, France, [8]Hematology Service, University Hospital Salamanca, Salamanca, Spain, [9]Value, Access & Policy, Amgen (Europe) GmbH, Zug, Switzerland, [10]Department of Haematology, University College London, London, United Kingdom

Background: The paradigm of multiple myeloma (MM) therapy has changed markedly over the last 2 decades and continues to evolve, with varying practice patterns across Europe. However, data describing patient management in clinical practice are limited.
Aims: This cross-sectional study estimated the size of each line of treatment for symptomatic MM patients in a real-world setting in Belgium, France, Germany, Italy, Spain, Switzerland and the UK in 2014.
Methods: Data were collected using chart reviews by oncologists/haematologists who manage ≥10 patients with MM per month and were personally responsible for initiating treatments in MM. Data included patient characteristics and current treatment for all patients with symptomatic MM seen during a 2-4-week observation period (depending on number of patients seen during this time) regardless of time since diagnosis, disease stage and current treatment strategy.

Figure 1. Treatment statuses of patients with symptomatic multiple myeloma.



Results: In total, 435 physicians collected data for 7635 patients. Physicians were haematologists/onco-haematologists (68%) or oncologists (32%). Most patients (62%) were ≥65 years and median time since diagnosis was 33 months. Overall, 23% of patients had an International Staging System (ISS) score of I, 37% a score of II and 37% a score of III at diagnosis. Patient characteristics were similar across countries, except for Spain, where fewer patients had ISS III MM (24%). Figure 1 shows treatment statuses of patients. Nearly half (47%) of patients were on active treatment, most of whom were on 1st line therapy. For patients on treatment at the time of the study, bortezomib-based regimens were the most commonly used at 1st line (48% of patients), except in the UK where thalidomide was more frequently used (56%). At 2nd line, lenalidomide was most commonly used (59%), except in the UK, where bortezomib was mainly used. Lenalidomide was also the most common agent overall at 3rd line (51%). Even though only recently reimbursed, the use of pomalidomide was prominent in 4th and 5th line regimens (32% and 43%, respectively). Bendamustine was seldom used at 1st or 2nd line therapy; in later lines, this agent was more commonly used in Germany, Spain and France than in other countries. Overall, 19% of patients currently receiving 1st line treatment had received a stem cell transplant (SCT; this snapshot does not include patients for whom SCT was planned in 1st line); 70% of patients receiving 5th line or later treatment had previously received an SCT. Main reasons for discontinuing previous antitumour therapy were remission and/or disease stabilised (61%) and completed planned cycles (38%). Main reasons for never treating patients were lack of

symptoms (62%) and waiting for biochemical progression (45%). However, in Germany, patient refusal was a frequent reason (19%) and in Switzerland poor life expectancy was selected for 27% of patients.
Summary and Conclusions: Half of patients seen were on active therapy. However, data suggest that many do not receive subsequent treatment lines. Those who reached later lines were more likely to have had a previous SCT. Although treatment practices were broadly similar across countries, there were some notable differences in the agents used. These real-world data provide useful information for designing clinical trials and for health economic evaluations of new and existing agents.

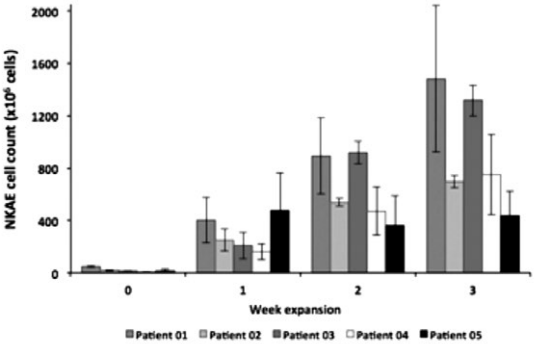
P648

MULTIPLE INFUSIONS OF AUTOLOGOUS ACTIVATED AND EXPANDED NATURAL KILLER CELLS: A NEW THERAPEUTIC OPTION FOR MULTIPLE MYELOMA

A. Leivas[1,*] R.M. Risueño[2], A. Pérez-Martínez[3], M.J. Blanchard[4], D. Campana[5], J.J. Lahuerta[1], J. Martínez-López[1]
[1]Department of Hematology, Hospital Universitario 12 de Octubre, Madrid, [2]Leukemia Stem Cell Group, Josep Carreras Leukemia Research Institute, Barcelona, [3]Department of Pediatric Onco-Hematology, Hospital Universitario La Paz, [4]Department of Hematology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [5]Department of Pediatrics, National University of Singapore, Singapore, Singapore

Background: Multiple myeloma (MM) remains an incurable disease. Natural killer (NK) cell infusions could be a novel treatment strategy. NK cells exert cytotoxicity against MM cells. Moreover, it has been suggested that enhanced NK cell cytotoxicity might be part of the mechanism of action of effective anti-myeloma drugs such as lenalidomide or bortezomib. By co-culture with the genetically modified cell line K562-mb15-41BBL it is possible to expand *ex vivo* large numbers of activated NK cells from MM patients.
Aims: We are conducting a phase I clinical trial to evaluate feasibility, safety and tolerability of K562-mb15-41BBL-expanded autologous NK cells (termed "NKAEs") infused in MM patients in combination with anti-myeloma drugs (EudraCT 2012-000514-11). Patients eligible for this trial have MM and persistent or progressing disease.
Methods: Five MM patients on 2nd or later relapse have been enrolled in this phase I clinical trial to date. To activate and expand NK cell, peripheral blood mononuclear cell (PBMCs) were co-cultured with K562-mb15-41BBL cells and 100 IU/ml IL-2. We collected 200 ml of peripheral blood (PB) from patients every cycle (n=4) to produce autologous NKAEs under GMP conditions and cells were harvested on day 14 and 21 for infusions. Four cycles of pharmacological treatment with 2 infusions of $7.5x10^6$ autologous NKAEs/kg on day 1 and 8 of each cycle were performed. NKAEs purity was analyzed by multiparametric flow cytometry. NK cells presence in PB was also assessed by PB smear examination before and after each infusion. C-Myc, telomerase and BCR-ABL expression were determined by real time-PCR.

A)



B)

Patients	Situation Before Inclusion	Complete Treatment	Response	Response Duration	Hematologic Toxicity
01	Biological Progression	YES	Partial Response	13 Months	NO
02	Biological Progression	YES	Stable Disease	9 Months	GII
03*	Very Good Partial Response	NO (2 CYCLES)	Not evaluable (NE)	4 Months	NO
04	Biological Progression	YES	Stable Disease	4 Months	NO
05	Biological Progression	YES	Stable Disease	4 Months	NO

Figure 1. A) Results of NKAE expansion procedures (n=17) from patients included on EudraCT 2012-000514-11 clinical trial. Results are shown as mean ± standard deviation of 4 independent expansion procedures from each patient. B) Summary of EudraCT 2012-000514-11 clinical trial.

Results: Of the 5 patients enrolled, 3 received lenalidomide-based treatment and 2 bortezomib-based treatment. Patients received a total of 34 NKAEs infusions. We have not observed any serious toxicity attributable to NKAE infusion. One patient had grade II neutropenia, which did not require dose adjustment. The 5 MM patients enrolled had 23% (±10%) NK cells of PBMCs. We collected $21x10^6$ ($\pm17x10^6$) NK cells from PB. After 1 week NKAEs number increased x17 fold, at 2nd week fold was x33. We collected $550x10^6$ ($\pm50x10^6$) NKAEs from culture for the first infusion. At 3rd week NKAEs number reached $992x10^6$ and 92% (±7%) purity of NKAEs (Figure 1A). The expression of c-Myc and telomerase were not altered in NKAE end products. The expression of BCR-ABL disappeared from cultures after the first week, and was undetectable in PB after NKAE therapy. PB smear examination showed an increase ofx2.5 fold of activated circulating lymphocytes: $7x10^5$ lymphocytes/L before infusion, reaching $1.75x10^6$ lymphocytes/L after infusion. Patient 01 achieved a partial response and maintained it for 13 months after NKAEs infusion. Patient 02 started NKAEs infusion while in relapse and, achieved stable disease, which was maintained for 9 months before disease progression. Of note, bone marrow infiltration by MM plasma cells decreased at least 50% at the end of NKAE treatment in these two patients. Patient 03 had disease progression 2 months after stopping treatment due to unrelated toxicity. Patients 04 and 05 recently finished NKAEs treatment and achieved disease stabilization 4 months after the first NKAE infusion (Figure 1B).
Summary and Conclusions: Clinical-grade NKAEs can be obtained from MM patients undergoing treatment, and multiple infusions of NKAEs are feasible without serious toxicities. NKAEs showed clinical anti-myeloma activity, with one heavily treated patient achieving durable partial response. These results and clinical observations warrant further development of NKAEs infusion as a treatment modality for refractory MM.

P649

MULTIPLE MYELOMA MANAGEMENT: OUTCOMES IN REAL-WORLD PRACTICE

K. Yong[1,*] M. Delforge, C. Driessen[3], L. Fink[4], A. Flinois[4], S. Gonzalez-McQuire[5], L. Karlin[6], M.-V. Mateos[7], M.S. Raab[8], P. Schoen[9], M. Cavo[10]
[1]Department of Hematology, University College London, London, United Kingdom, [2]Department of Hematology, UZ Leuven, Leuven, Belgium, [3]Department of Oncology and Hematology, Kantonsspital St Gallen, St Gallen, Switzerland, [4]Kantar Health, Montrouge, France, [5]Global Health Economics, Amgen (Europe) GmbH, Zug, Switzerland, [6]Centre Hospitalier Lyon Sud, Lyon, France, [7]Hematology Service, University Hospital Salamanca, Salamanca, Spain, [8]Department of Internal Medicine, University of Heidelberg, Heidelberg, Germany, [9]Value Access & Policy, Amgen (Europe) GmbH, Zug, Switzerland, [10]"Seràgnoli" Institute of Hematology and Medical Oncology, Bologna University School of Medicine, Bologna, Italy

Background: Advances in therapy and management have improved survival for patients with multiple myeloma (MM), many of whom live to receive several lines of therapy. With increasing numbers of available therapies, it is timely to examine real-world treatment practices and the course of patient journeys.
Aims: To investigate patient characteristics, treatment durations and outcomes, treatment-free intervals (TFI) and symptom burden across the treatment pathway in Belgium, France, Germany, Italy, Spain, Switzerland and the UK.
Methods: Data were obtained from chart reviews by physicians managing patients with MM, who completed retrospective forms on patient characteristics and treatment from diagnosis for up to 14 patients seen in the previous 3 months, with a quota for patients who had completed specific treatment lines. Patients were included in reverse chronological order.
Results: In total, 435 physicians retrospectively reviewed 4997 patient charts. Median time from diagnosis in patients at 1st line was 19 months, at 2nd line 44 months and at ≥3rd line 65 months. Profiles of patients diagnosed in the last 12 months were similar across countries; common presentations were bone pain (61%), anaemia (39%), vertebral fracture (21%), renal dysfunction (20%) and hypercalcemia (19%). Almost all patients (95%) received ≥1 line of therapy, 61% received ≥2, 38% ≥3, 15% ≥4 and 1% ≥5. Of the 38% of patients eligible for stem cell transplantation (SCT), 95% received SCT at 1st and/or 2nd line; proportions of patients receiving SCT were similar across countries. Median duration of 1st line therapy was 6 months, followed by a median TFI of 10 months. TFI was longer in patients who received SCT (16 months [n=444] *vs* 7 months in those who did not [n=935]). Time to progression (TTP) decreased with later lines of therapy, from median 18 months at 1st line to 5 months at 4th line. Depth of response, as assessed by treating physician, decreased with each additional line of therapy: 74% of patients achieved at least very good partial response (≥VGPR) in 1st line, while only 11% achieved ≥VGPR at 5th line. Better response levels were associated with longer TTP; in 1st line, median TTP for patients in complete response (CR) was 30 months, VGPR, 21 months and PR, 13 months. At the end of each treatment line, patients who were not planned to receive further treatment were significantly (p <0.05*)* more likely to have had a worse response to treatment, a poor overall condition, more adverse events (AEs), shorter life expectancy and to have received suboptimal dosing owing to comorbidities or treatment-related AEs compared to patients who were planned to or those who received a further line of therapy. The most

common AEs at 1st line were neuropathy (45% of patients, all grades), anaemia (23%), neutropenia (22%) and thrombocytopenia (15%). AEs affected optimal treatment dosing in 23% of patients at 1st line, increasing to 45% at 3rd line.
Summary and Conclusions: Information on real-world patient outcomes may be valuable to physicians when assessing treatment options and discussing these options with patients. The data suggest that while over half of patients receive 2nd line therapy, only 15% receive ≥4 lines. Diminishing benefits with each line of therapy, and increasing incidence of AEs leading to suboptimal treatment dosing, highlight the challenges when making treatment decisions across the pathway. The data also indicate which patients are most likely to discontinue therapy, which may help physicians to plan MM treatment strategies.

Orsola, Malpighi, Bologna, Italy, [6]Faculty of Science, Masaryk University, Brno, Brno, Czech Republic, [7]UMC Utrecht, Utrecht, Netherlands, [8]National and Kapodistrian University of Athens, Athens, Greece, [9]Arcispdedale S. Maria Nuova, Reggio Emilia, Italy, [10]Celgene International Sàrl, Boudry, Switzerland, [11]Celgene Corporation, Summit, United States, [12]Hospitalier Peltzer-La Tourelle, Verviers, Belgium, [13]Aarhus University Hospital, Aarhus, Denmark, [14]Centre Uddevalla Sjukhus, Uddevalla, Sweden

Background: EU PASS is an observational, non-interventional post-authorization study designed to investigate the safety of lenalidomide (LEN) and other agents in the treatment (Tx) of RRMM patients (pts). Venous thromboembolic events (VTEs) are recognized as possible adverse events (AEs) associated with the administration of LEN+dexamethasone (DEX). Larocca (*Blood*, 2012) reported that the incidence of grade 3/4 deep vein thrombosis (DVT) and pulmonary embolism (PE) during the first 6 mos of Tx was similar in selected newly diagnosed MM pts treated with LEN+low-dose DEX randomized to receive either acetylsalicylic acid (ASA) 100 mg/day (2.3%) or low-molecular-weight heparin (LMWH) enoxaparin 40 mg/day (1.2%; *P*=0.452). In the observational MELISSE study of pts treated with IMiD immunomodulatory drugs in 52 IFM centers, 443 pts received thromboprophylaxis at therapy initiation: 307 pts (59%) received ASA, 88 pts (17%) received LMWH, and 81 pts (15.5%) did not receive VTE prophylaxis (Leleu, *Thromb Haemost.* 2013). Through the first year of follow-up, the cumulative incidence of VTEs was 6% (n=31). Overall, VTEs occurred irrespective of whether pts were on ASA or LMWH prophylaxis (*P*=0.62).
Aims: To describe the incidence of VTE (DVT/PE) among RRMM pts enrolled in the PASS, to identify risk factors for VTE, and to compare the incidence of VTE in pts receiving different types of anti-thrombotic prophylaxis and no prophylaxis.
Methods: RRMM pts who had received ≥1 prior Tx were enrolled at the investigator's discretion into a LEN or background cohort (other regimens); this analysis focused only on pts who were treated in the LEN cohort. Thromboprophylactic medication was administered per local standard practice. Baseline risk factors for VTE were extracted. Incidence rates of VTE were calculated for events that occurred during the first 6 mos of follow-up based on pt-mos of exposure to single agents (ie, LMWH, ASA) and pt-mos of no exposure.
Results: A total of 2164 pts received LEN therapy for RRMM. Pts in the LEN cohort had a median age of 68 yrs (range, 25-95 yrs), and 54% were male. The proportion of pts prescribed low-dose DEX (≤160 mg) was 74.2%. Among 1529 pts with new or continuing thromboprophylaxis at baseline, 36.5% received ASA, 24.9% received LMWH, 7.1% received other anti-platelet medications, and 5% received warfarin. Over the entire follow-up interval, 123 pts (5.7%) experienced a VTE. Only 2 pts experienced a VTE while receiving warfarin therapy. Baseline risk factors associated with VTE were previous history of VTE (odds ratio [OR]=1.71; 95% CI, 1.06-2.77), age (OR=2.10; 95% CI, 1.36-3.25), and body mass index (OR=1.47; 95% CI, 0.98-2.21). Considering only single thromboprophylaxis agent use during the first 6 mos of IMiD therapy, the incidence of VTE was highest among pts not receiving prophylaxis during the month the VTE occurred: 1.64 per 100 pt-mos. VTE incidence rates were similar among pts treated with either ASA (0.686 per 100 pt-mos) or LMWH (0.636 per 100 pt-mos). In either case, a significant protective effect was noted for use of either ASA (relative risk [RR]=0.42, *P*=0.003) or LMWH (RR=0.39; *P*=0.004).
Summary and Conclusions: The incidence of VTE among RRMM pts in the PASS (5.7%) was similar to that previously reported in another large cohort study (MELISSE). Identified VTE risk factors were similar to those previously identified (age, prior VTE, BMI). Similar to previously reported results comparing ASA and LMWH, equivalent reductions in VTE risk were identified for pts receiving thromboprophylaxis with either ASA or LMWH.

P651

MANAGEMENT OF ADVERSE EVENTS IN THE STRATUS TRIAL, A PHASE 3B STUDY EVALUATING SAFETY AND EFFICACY OF POMALIDOMIDE+ LOW-DOSE DEXAMETHASONE IN REFRACTORY OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA

M. Cavo[1,*] M.A. Dimopoulos[2], P. Moreau[3], A. Palumbo[4], P. Corradini[5], K. Weisel[6], E. Ocio[7], C. Doyen[8], P. Anttila[9], R. Raymakers[10], J. San Miguel[11], X. Yu[12], N. Milller[13], J. Herring[12], A. Slaughter[13], T. Peluso[13], L. Sternas[12], M. Zaki[12], M. Delforge[14]
[1]Bologna University School of Medicine, Bologna, Italy, [2]National and Kapodistrian University of Athens, Athens, Greece, [3]University Hospital Hôtel-Dieu, Nantes, France, [4]University of Torino, Torino, [5]Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy, [6]University Hospital of Tuebingen, Tuebingen, Germany, [7]Hospital Universitario de Salamanca & Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain, [8]CHU Dinant Godinne UcL Namur, Yvoir, Belgium, [9]Helsinki University Hospital Comprehensive Cancer Hospital, Helsinki, Finland, [10]University Medical Center Utrecht, Utrecht, Netherlands, [11]Clinica Universidad de Navarra, CIMA, Pamplona, Spain, [12]Celgene Corporation, Summit, United States, [13]Celgene International Sàrl, Boudry, Switzerland, [14]University Hospital Leuven, Leuven, Belgium

Background: To allow for full-dose treatment (Tx) and maximize therapeutic benefit, management of adverse events (AEs) in patients (pts) with relapsed/refractory multiple myeloma (RRMM) must be optimized. Pts with RRMM who have been exposed to multiple prior Tx may present with comorbidities and be susceptible to frequent AEs. In the pivotal MM-003 study of pomalidomide+low-dose dexamethasone (POM+LoDEX) in pts with heavily pre-treated RRMM, most pts did not have dose reductions and there were few discontinuations due to AEs (Delforge, EHA 2013). Frequent grade (Gr) 3-4 AEs associated with POM+LoDEX were neutropenia, anemia, thrombocytopenia, and infections.
Aims: This sub-analysis examined the safety profile and management of AEs for pts enrolled in the STRATUS trial.
Methods: Pts with refractory or relapsed and refractory disease (progressive disease [PD] within 60 days of last prior Tx) who failed prior lenalidomide and bortezomib Tx and had adequate prior alkylator therapy were included. Key exclusion criteria were: absolute neutrophil count <800/μL, platelet count <75,000 or <30,000/μL (for pts with <50% or ≥50% of bone marrow nucleated cells as plasma cells, respectively), hemoglobin <8 g/dL, creatinine clearance <45 mL/min, and peripheral neuropathy (PN) ≥Gr 2. POM 4 mg was administered D1-21 of a 28-day cycle in combination with LoDEX 40 mg/day for pts aged ≤75 yrs or 20 mg for pts aged >75 yrs on D1, 8, 15, 22 until PD or unacceptable toxicity. Pts required mandatory thromboprophylaxis. AEs were graded according to the National Cancer Institute Common Terminology Criteria for AEs v 4.0. Pts were followed for subsequent anti-myeloma Tx, OS, and second primary malignancy until 5 yrs post enrollment. The primary endpoint of this sub-analysis was safety.

Table 1.

	POM + LoDEX (n = 599)
Dose management	
Median average dose, mg POM (range)	4.0 (1.87, 4.00)
≥ 1 dose reduction for any AE (%)	18
Dose reduction for neutropenia (%)	4.7
Dose reduction for febrile neutropenia (%)	1.0
Patients with specified AEs (any grade) who received supportive care (%)	
Infection (n = 357)	
Granulocyte colony-stimulating factor	53.2
Anti-infective	88.8
Neutropenia (n = 341)	
Granulocyte colony-stimulating factor	73.6
Anemia (n = 287)	
Red blood cell transfusion	57.1
Thrombocytopenia (n = 204)	
Platelet transfusion	32.4
Median time to AE onset, days (range)	
Infections/Infestations (n = 357)	38.0 (1.0-397.0)
Neutropenia (n = 341)	19.0 (1.0-369.0)
Anemia (n = 287)	21.0 (1.0-436.0)
Thrombocyopenia (n = 204)	15.0 (1.0-498.0)

AE, adverse event; LoDEX, low-dose dexamethasone; POM, pomalidomide.

Results: 604 pts have been enrolled as of Sept 15, 2014; 599 pts were evaluable for safety. Median follow-up was 9.3 mos. The most frequent Gr 3-4 hematologic AEs were neutropenia (42%), anemia (29%), and thrombocytopenia (22%); 5% of pts experienced Gr 3-4 febrile neutropenia. The most frequent Gr 3-4 non-hematologic AEs included infections (30%) and fatigue (5%); 11% of pts experienced Gr 3-4 pneumonia. Gr 3-4 venous thromboembolic events (VTEs) occurred in 1% of pts and 4% had at least 1 VTE of any grade. PN of any grade occurred in 15% of pts, with 1% of pts experiencing Gr 3-4 PN. Management of AEs was primarily via dose reductions and/or supportive care (Table 1). 18% and 58% of pts had POM dose reductions or interruptions, respectively due to AEs. The most common AEs leading to dose reductions or dose interruptions, respectively were neutropenia (4.7% and 19.4%), thrombocytopenia (3.3% and 9.7%), and pneumonia (1.5% and 7.3%). Discontinuation of POM due to AEs was infrequent (5%)

and the most frequently occurring AEs leading to POM discontinuation included pneumonia (0.7%), thrombocytopenia (0.7%), anemia (0.3%), and neutropenia (0.3%). Updated data will be presented at the congress.
Summary and Conclusions: This is the largest study conducted to date with POM+LoDEX in a heavily pre-treated RRMM pt population. POM+LoDEX was generally well tolerated with an acceptable safety profile that was consistent with the pivotal trials. There were few discontinuations due to AEs and most AEs could be managed with dose reductions and/or supportive care.

P652

SINGLE CENTER EXPERIENCE WITH EARLY *VERSUS* LATE AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA

G. Varga[1,*] P. Reményi[2], G. Mikala[2], M. Réti[2], L. Gopcsa[2], Á. Bátai[2], Z. Csukly[2], L. Lengyel[2], É. Torbágyi[2], A. Barta[2], J. Fábián[2], D. Lévai[1], G. Szombath[1], P. Farkas[1], H. Andrikovics[3], A. Tordai[3], T. Masszi[1,2]
[1]Haematology, 3rd Department of Internal Medicine, Semmelweis University, [2]Department of Haematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, [3]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, Budapest, Hungary

Background: In the last couple of years a heated debate developed between supporters of first line autologous stem cell transplant (ASCT) in every multiple myeloma (MM) patients whenever it is feasible and those who think that with the arrival of novel agents (thalidomide, bortezomib and lenalidomide) we can get comparable results without the toxicity of ASCT which we can therefore delay and spare for relapse. Randomized studies from the nineties showed conflicting results regarding the progression free survival (PFS) and overall survival (OS) benefit associated with high dose treatment, and trials exploring this question in the era of novel agents are currently running. These are expected to be reported within the next years, but until then our strategies should mainly be based on retrospective comparisons.
Aims: We analyzed the outcome of 548 myeloma patients transplanted in our centre over 18 years.
Methods: Transplants performed within 12 months from the start of the first chemotherapy were counted as early, others as late. PFS was calculated from the day of ASCT and OS from the first chemotherapy.
Results: The median time from first treatment to ASCT was 9.8 (3.4-192) months in the whole cohort, 7.3 (3.4-11.9) in the early and 16.9 (12-192) in the late ASCT subgroups. The overall response rate post-ASCT was higher in the early group with significantly more CRs (58.1 *vs* 46.8%, p=0.016). The pre-ASCT results were superior with novel agents both in the early and late cohorts, but following the ASCT these differences disappeared. The PFS was significantly longer in the early than the late group [30.2 (26.1-34.3) *vs* 23.3 (16.8-29.8) months; p=0.036], but there was no OS advantage [95.5 (83.8-107.2) *vs* 100.4 (80.7-120.1); p=0.211] (Figure 1). The results were similar in subgroups treated with novel agents [PFS in early *vs* late 31 (25.8-36.2) months *vs* 22.2 (14.9-29.4); p=0.105; OS 84.3 (70.9-97.7) *vs* 122.4 (90.5-154.3) respectively; p=0.101] and without [PFS 27.8 (21.1-34.5) *vs* 27.8 (18.9-36.7) in early *vs* late; p=0.138; OS 97.2 (84-110.4) *vs* 99.1 (93.4-104.8) respectively; p=0.772] however within the subgroups the differences were not significant.

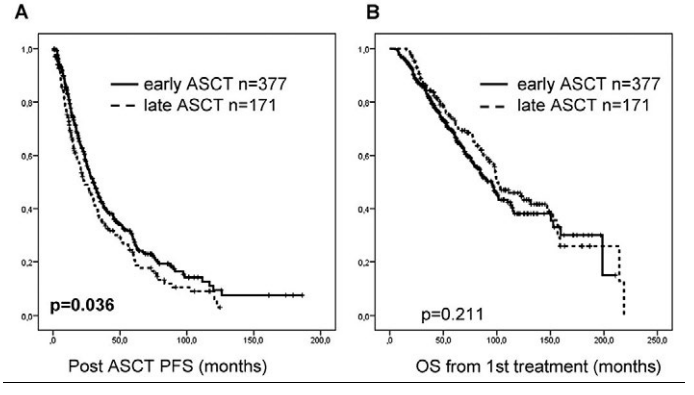

Figure 1.

Summary and Conclusions: Our findings confirmed the results of prior retrospective studies: early ASCTs resulted in more CRs and VGPRs, and a significant post-ASCT PFS benefit, but no OS difference. However one has to be careful with the interpretation of retrospective studies. Even with novel agents there is a significant proportion of patients unsalvageable at relapse. For others transplant becomes unfeasible due to deterioration of performance status or comorbidity. As these patients have never had ASCT they remain unaccounted for in any retrospective ASCT data sets. Another worry is that ASCT may be less effective later in the disease course due to clonal drift resulting in increased chemoresistance. Only prospective randomized studies can answer these questions.

P653

OPROZOMIB (OPZ) AND DEXAMETHASONE (DEX) IN PATIENTS (PTS) WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED RESULTS FROM DOSE ESCALATION IN A PHASE 1B/2, MULTICENTER, OPEN-LABEL STUDY

P. Hari[1,*] K.H. Shain[2], P. Voorhees[3], N. Gabrail[4], M. Abidi[5], J. Zonder[6], R. Boccia[7], P.G. Richardson[8], L. Neuman[9], H. Wong[9], S. Dixon[9], C.P. Prada[8]
[1]Medical College of Wisconsin, Milwaukee, [2]Moffitt Cancer Center, Tampa, [3]University of North Carolina, Chapel Hill, [4]Gabrail Cancer Center, Canton, [5]Spectrum Health, Grand Rapids, [6]Karmanos Cancer Institute, Wayne State University, Detroit, [7]Center for Cancer and Blood Disorders, Bethesda, [8]Dana-Farber Cancer Institute, Boston, [9]Onyx Pharmaceuticals, Inc., an Amgen subsidiary, South San Francisco, United States

Background: The oral proteasome inhibitor OPZ has shown promising antitumor activity in pts with hematologic malignancies, including multiple myeloma (MM; Vij, *Blood* 2014;121:abstract 34).
Aims: We present updated results from an ongoing, single-arm, phase 1b/2 study (NCT01832727) that is evaluating the safety and tolerability of OPZ with DEX in pts with RRMM.
Methods: Pts with RRMM who have received 1-5 prior lines of therapy (≥1 regimen including lenalidomide and/or bortezomib) are eligible. Pts are receiving OPZ tablets (PO) on days 1, 2, 8, and 9 (2/7 schedule) or on days 1-5 (5/14 schedule) of a 14-day cycle. All pts are receiving DEX (20 mg PO) on days 1, 2, 8, and 9. Treatment is being administered until pt withdrawal, disease progression, or unacceptable toxicity. The starting OPZ dose was 210 mg on both schedules. OPZ doses are being escalated in 30-mg increments using standard 3+3 dose escalation. The primary objectives of the phase 1b study are to determine the maximum tolerated dose (MTD), recommend the phase 2 dose (RP2D) of OPZ with DEX, and to evaluate safety and tolerability. Response is being assessed by IMWG criteria, with minimal response (MR) and near complete response defined by modified EBMT criteria. Safety is being assessed by CTCAE, v4.03. All pts provided informed consent.
Results: As of January 19, 2015, 22 and 19 pts were enrolled on the 2/7 and 5/14 schedules, respectively. Preliminary data are available for a total of 35 pts enrolled as of November 3, 2014 (2/7 schedule, n=19; 5/14 schedule, n=16), 31 of whom were evaluable for response (2/7 schedule, n=17; 5/14 schedule, n=14). The median age of pts was 63 years (2/7 schedule) and 63.5 years (5/14 schedule). Pts received a median of 3 (range, 1-5) prior regimens in the 2/7 schedule and 2 (range, 1-5) prior regimens in the 5/14 schedule. Preliminary median OPZ treatment duration was 15 weeks in the 2/7 schedule (range, 1.3-51.3 weeks) and 5.7 weeks in the 5/14 schedule (range, 0.7-24.7 weeks). No dose-limiting toxicities (DLTs) occurred in the 2/7 schedule. In the 5/14 schedule, 3 DLTs occurred (210-mg/day dosing level: grade 2 subarachnoid hemorrhage; grade 3 transaminitis; and grade 4 thrombocytopenia); the MTD was 180 mg/day. The MTD was not reached in the 2/7 schedule up to a dosing level of 300 mg/day. In both schedules combined, the most common adverse events (AEs) of any grade were diarrhea, nausea, and fatigue; the most common grade ≥3 AEs were anemia, diarrhea, and thrombocytopenia (Table 1). Two grade 5 AEs of sepsis occurred: 1 in the 2/7 schedule (240 mg/day) and 1 in the 5/14 schedule (210 mg/day). Three pts on the 2/7 schedule and 9 pts on the 5/14 schedule discontinued treatment due to an AE. Five pts in each schedule had their OPZ dose reduced due to an AE. On the 2/7 schedule, the overall response rate (ORR; ≥partial response [PR]) was 35.3% and the clinical benefit rate (CBR; ≥MR) was 41.2% (6 pts had a PR, 1 had an MR, and 8 had stable disease [SD]). On the 5/14 schedule, the ORR was 7.1% and the CBR was 35.7% (1 pt had a PR, 4 had an MR, and 6 had SD).

Table 1. AEs occurring in ≥25% of pts or grade ≥3 AEs occurring in ≥2 pts.

	2/7 schedule n=19		5/14 schedule n=16	
AE, n (%)	Any grade	Grade ≥3	Any grade	Grade ≥3
Hematologic AEs				
Anemia	8 (42)	5 (26)	5 (31)	2 (13)
Thrombocytopenia	7 (37)	4 (21)	4 (25)	1 (6)
Nonhematologic AEs				
Diarrhea	17 (89)	3 (16)	14 (88)	4 (25)
Nausea	17 (89)	0 (0)	14 (88)	4 (25)
Fatigue	11 (58)	0 (0)	10 (63)	2 (13)
Vomiting	8 (42)	0 (0)	10 (63)	2 (13)
Decreased appetite	4 (21)	0 (0)	6 (38)	0 (0)
Constipation	5 (26)	0 (0)	3 (19)	0 (0)
Headache	6 (32)	0 (0)	2 (13)	0 (0)
Dyspepsia	3 (16)	0 (0)	4 (25)	0 (0)
Hyperglycemia	5 (26)	1 (5)	2 (13)	0 (0)
Hypocalcemia	2 (11)	0 (0)	4 (25)	0 (0)
Hypertension	2 (11)	1 (5)	4 (25)	1 (6)
Increased blood creatinine	2 (11)	0 (0)	4 (25)	1 (6)
Decreased platelet count	1 (5)	0 (0)	4 (25)	3 (19)
Upper abdominal pain	0 (0)	0 (0)	4 (25)	1 (6)
Pneumonia	1 (5)	1 (5)	3 (19)	3 (19)
Decreased white blood cell count	2 (11)	0 (0)	2 (13)	2 (13)

Summary and Conclusions: In the 5/14 schedule, the MTD was 180 mg/day; the MTD was not reached in the 2/7 schedule. Preliminary results suggest that OPZ with DEX has promising antitumor activity in pts with RRMM receiving the 2/7 schedule; this schedule has been selected as the recommended phase 2 schedule. Dose escalation will continue in the 2/7 schedule until the MTD or RP2D is determined. Updated data (including pharmacokinetics) for both schedules will be presented at the meeting.

P654

PROGNOSTIC IMPACT OF IMMUNOPHENOTYPIC RESPONSE AND NORMALIZATION OF SERUM FREE LIGHT CHAIN AMONG PATIENTS WITH MULTIPLE MYELOMA

K. Fukumoto[1,*] Y. Suehara[1], M. Fujisawa[1], H. Sugihara[1], M. Takeuchi[1], K. Matsue[1]
[1]Division of Hematology/Oncology, Department of Medicine, Kameda Medical Center, Kamogawa, Japan

Background: With the development of novel therapeutic agents, more than 30% of patients with multiple myeloma (MM) achieve complete response (CR) as defined by the International Myeloma Working Group (IMWG) criteria. However, most of the patients that achieve CR ultimately die due to relapse, suggesting the presence of minimal residual disease (MRD) in these patients. Multicolor flow-cytometry (FCM) allows the detection of < 10^{-4} clonal plasma cells (PCs) in normal bone marrow and has been used for detecting MRD after treatment. FCM-defined immunophenotypic response (iR, clonal PCs<10^{-4}) has emerged as a more relevant prognostic factor in patients with MM. However, the relevance of the prognostic impact of IR and the normalization of serum free light chain (sFLC) ratio remain unclear.
Aims: To investigate the impact of FCM-defined CR (iR), conventional immunofixation negative CR (CR), and CR plus FLC κ/λ normal CR (sCR) on the prognosis of patients with MM who obtained more than very good partial response (VGPR) at Kameda Medical Center, Kamogawa, Japan.
Methods: Among the 265 patients treated at our hospital between April 2004 and February 2015, 102 patients that achieved more than VGPR (70 CR, 32 VGPR) were included in this study. The study population consisted of 64 males and 38 females with a median age of 69 years. All patients received at least one course of novel agent-containing therapeutic regimen. Treatment response was assessed using the IMWG criteria. Best response to treatment during the course of disease was evaluated by simultaneous analysis by immunofixation electrophoresis (IFE), sFLC measurements, and FCM analysis of bone marrow PCs. FCM defined MRD was evaluated by single tube 6-color FCM using CD45, CD38 gating strategy, with combination with CD19. iR was defined as less than 10^{-4} neoplastic PCs in bone marrow samples determined by FCM. Overall survival (OS) and disease free survival (DFS); OS was defined from the day of diagnosis to death from any cause, with censoring performed the date of last contact. DFS was calculated from the date of achieve CR, sCR, or iR to relapse from the respective response date. Survivals were analyzed by the Kaplan-Meier method, and differences between curves were calculated by two-sided log-rank test. Subjects were classified into four categories; MFC positive or negative and κ-λ ratio normal or abnormal, and PFS and OS were compared between groups.
Results: Among 102 patients who achieved more than VGPR, iR, sCR, CR and VGPR was obtained 43 (42%), 80 (78%), 70 (69%) and 32 (31%) of patients, respectively. Normalization of FLC ratio with CR and VGPR was observed in 61 (87%) and 19 (59%) of patients, respectively. iR was achieved in 33 (49%) of the CR patients, in 8 (25%) of the VGPR patients, and in 39 (90.7%) of the iR patients who attained normal κ/λ. The patients with iR and normal FLC showed significantly longer DFS compared to those without iR, although OS was not different between patients with or without iR. However, these survival differences were not translated to the OS among the groups due to less. On multivariate Cox regression analysis, only achievement of iR emerged as an independent prognostic factor for DFS (Figure 1).

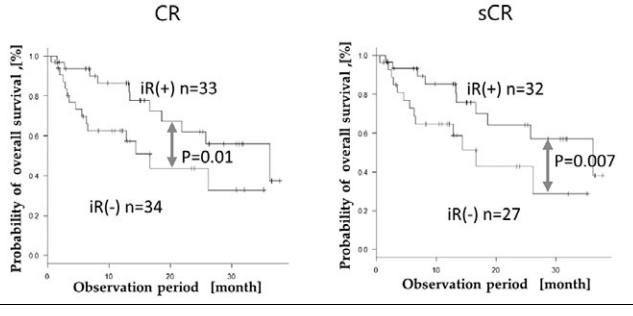

Figure 1. Impact of iR on DFS in patients with CR and sCR.

Summary and Conclusions: Although both achievement of CR, normalization of sFLC κ/λ, and iR appeared to confer on longer DFS and OS, obtaining iR seems to have greater implications for longer survival compared to CR or FLC κ/λ normalization. MFC is a rapid, affordable, and easy performable method for measurement of MRD and iR could be considered as a goal of treatment for patients with MM.

Multiple myeloma - Clinical 4

P655

A PRIOR CANCER DIAGNOSIS IS NOT A RISK FACTOR FOR THE DEVELOPEMENT OF SUBSEQUENT CANCERS IN MULTIPLE MYELOMA PATIENTS

G. Jónsdóttir[1,*] S.H. Lund[1], M. Bjorkholm[2], M. Hultcrantz[2], O. Landgren[3], S.Y. Kristinsson[1]
[1]Faculty of medicine, University of Iceland, Reykjavik, Iceland, [2]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [3]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Patients with multiple myeloma (MM) have been shown to have an increased risk of subsequently developing certain types of cancers, such as acute myeloid leukemia, myelodysplastic syndromes, gastrointestinal and non-melanoma skin cancer. With improved survival in MM patients the incidence of subsequent cancers will increase in the future. Also we have previously shown that the development of a subsequent cancer is associated with a decreased life expectancy. Therefore it is of great importance to identify potential risk factors. Treatment-related factors have been considered to be the main contributing factor to the observed risk increase, but research regarding other risk factors is limited. Prior studies have found genetic instability to be associated with carcinogenesis. In this study we hypothesize that prior cancer is a proxy for genetic instability that could be a potential risk factor for subsequent cancer development in MM patients.
Aims: To investigate whether any form of cancer diagnosis prior to MM diagnosis is an independent risk factor for developing a subsequent cancer after the MM diagnosis.
Methods: All patients diagnosed with MM in Sweden from January 1st, 1958 to December 31st, 2011 were identified from the Swedish Cancer Registry (SCR). All prior and subsequent cancer diagnoses were identified through cross-linkage with the SCR. Patients with a cancer diagnosis after MM diagnosis were classified as cases. For each case, 1-3 controls without a cancer diagnosis after MM diagnosis, matched for age, gender, and date of MM diagnosis, were selected from the cohort. The controls had to be alive when the corresponding case developed subsequent cancer. The type of prior and subsequent cancer was classified according to the International Classification of Disease version 7. Prior cancer diagnosis was compared between cases and controls. Subgroup analysis was performed for each subsequent cancer subtype according to appropriate organ system. Conditional logistic regression was used for the statistical analysis in R.
Results: Results: A total of 26,627 patients were diagnosed with MM during the study period. Of these, 1,645 (6.2%) developed subsequent cancer (cases) and 4,334 MM patients were chosen as matched controls. MM patients with a prior cancer diagnosis did not have a statistically significant increased risk of developing a subsequent cancer compared to MM patients without a prior cancer (odds ratio (OR) 1.19; 95% confidence interval (CI) 0.97-1.46). In a subgroup analysis, prior cancer in MM patients was not associated with increased risk of developing the following cancers: breast (OR=1.21; 95% CI 0.52-2.77), ear, nose and throat (OR=0.90; 95% CI 0.09-8.68), endocrine (OR=0.94; 95% CI 0.18-5.01), female reproductive (OR=0.91; 95% CI 0.26-3.15), hematological (OR=0.84; 95% CI 0.43-1.66), gastrointestinal (OR=0.89; 95% CI 0.56-1.43), kidney and urinary tract (OR=1.86; 95% CI 0.92-3.75), male reproductive (OR=0.58; 95% CI 0.31-1.12), melanoma (OR=1.35; 95% CI 0.52-3.47), nervous system (OR=0.72; 95% CI 0.15-3.38), non-melanoma skin cancer (OR=1.52; 95% CI 0.98-2.36), and respiratory (OR=2.02; 95% CI 0.84-4.86).
Summary and Conclusions: In this large case-control study we report that a prior cancer diagnosis is not associated with increased risk of developing a subsequent cancer in MM patients. Our findings are of major clinical relevance and suggest that the best available therapy should not be withheld from MM patients due to concern for subsequent cancer, irrespective of a prior cancer diagnoses. Further research is needed to shed light on the risk factors for subsequent cancers in MM patients.

P656

MELPHALAN IN COMBINATION WITH BORTEZOMIB AND DEXAMETHASONE (BMDEX) PRODUCES MORE DURABLE RESPONSES THAN CYCLOPHOSPHAMIDE (CYBORD): A MATCHED CASE-CONTROL STUDY

P. Milani[1,*] A. Foli[1], M. Basset[1], G. Merlini[1], G. Palladini[1]
[1]Department of Molecular Medicine, Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy

Background: At present, the majority of patients with AL amyloidosis are treated with combinations of alkylating agents, bortezomib, and dexamethasone. High response rates and short times to response have been reported with these regimens. Cyclophosphamide is used more commonly (CyBorD), but in some centers melphalan is also prescribed (BMDex). At our center both regimens are used, and cyclophosphamide is preferred in patients with potentially reversible contraindications to stem cell transplant and in subjects with renal failure.
Aims: In the present case-control study, we compared the outcome of patients treated with CyBorD and BMDex.

Methods: Eighty-seven newly-diagnosed consecutive patients treated with BMDex were matched with 87 controls who received CyBorD. Matched variables were cardiac stage (with stage III patients having NT-proBNP >8500 ng/L included in a separate stage, IIIb), revised Mayo stage, renal stage, systolic blood pressure <100 mmHg, and bortezomib (1.3 mg/m^2 in all patients) and dexamethasone (40 mg in 26% of patients) dosages.
Results: Cardiac stage was I, II, IIIa, and IIIb in 14%, 42%, 22%, and 22% of patients, respectively. Renal stage was I, II, and III in 53%, 30%, and 27% of cases, respectively. There was no difference in plasma cell infiltrate (median 13% *vs* 12%, P=0.190) and dFLC (median 199 mg/L *vs* 212 mg/L, P=0.953) between the BMDex and CyBorD groups. Patients treated with BMDex were older (median 69 *vs* 60 years, P<0.001). Severe adverse events were observed in 22% of patients treated with BMDex and in 13% of those receiving CyBorD (P=0.108). Most common were cytopenia (6% *vs* 1%, P=0.054) and fluid retention (9% *vs* 8%, P=0.787). Hematologic response rate was 69% in the BMDex group and 55% in the CyBorD group (P=0.061), and CR/VGPR was reached in 55% of patients in the BMDex arm and in 39% in the CyBorD arm (P=0.033). Differences in cardiac (16% *vs* 17%) and renal (29% *vs* 25%) response rates were not significant. Projected overall survivals at 3 years in cardiac stages I, II, IIIa, and IIIb were 100% *vs* 100%, 72% *vs* 51% (P=0.059), 42% *vs* 47% (P=0.605), 12% *vs* 12% (P=0.352) in the BMDex and CyBorD arms, respectively. In the overall population, time to second-line therapy was longer with BMDex (74% *vs* 40% of responses maintained at 3 years, P=0.050). This was due to a longer duration of CR/VGPR (89% *vs* 57% maintained at 3 years, P=0.019), while duration of PR was similar in the two arms (median 9 *vs* 13 months, P=0.093). However, relapsing patients were efficiently rescued, and there was no difference in overall survival of patients achieving CR/VGPR with BMDex and CyBorD (83% *vs* 82% at 3 years).
Summary and Conclusions: Profound reductions in the concentration of the amyloidogenic light chain can be obtained with both BMDex and CyBorD. However, responses are more durable in patients exposed to melphalan, and BMDex may be preferred when there is no need to preserve stem cells.

P657

EVALUATION OF CURRENT CLINICAL MODELS FOR RISK OF PROGRESSION FROM SMOLDERING MULTIPLE MYELOMA TO MULTIPLE MYELOMA IN 287 PATIENTS FOLLOWED IN THE CZECH REPUBLIC

Background: Two risk stratification models predict the progression from smoldering multiple myeloma (SMM) to multiple myeloma (MM). i) the Mayo Clinic model uses percentage of bone marrow plasma cells (BMPCs) and serum monoclonal protein (M-protein) and free light chain (FLC) ratio, ii) the PETHEMA model uses immunoparesis and the percentage of abnormal PCs (aPCs) by flow cytometry.
Aims: The primary end point was to estimate the cumulative risk of MM occurring during the follow-up of our cohort. The secondary end points were: to validate known clinical models and to establish a new risk model by the Czech Myeloma Group (CMG model) with better prediction of ultra high-risk SMM group.
Methods: Data for this study were obtained from the Registry of Monoclonal Gammopathies (RMG) acquired from hematologic centers of the Czech Republic. In total, 361patients with SMM were enrolled in the RMG study from May 2007 to June 2013. In total, 79.5% (287/361) of patients were analyzed.
Results: 287 SMM patients were followed with median 2.4 years. MM was developed in 51.9% (149/287) of patients. The risk of progression was 16%, 31.2%, 54.8% and 73.4% at 1, 2, 5 and 10 years after diagnosis, respectively. The key predictors factors of progression were as follows: serum (iFLC/uFLC) ratio >30 (HR 2.4 [1.4-4.1], p<0.001), BMPCs ≥15% (HR 2.1 [1.5-3.0]; p<0.001), immunoparesis (HR 2.0 [1.3-2.9]; p<0.001), M - protein concentration ≥2.3 g/dL (HR 2.00 [1.4-2.7]; p<0.001), beta2 microglobulin ≥2.0 mg/l (HR 1.8 [1.2-2.7]; p=0.001), and thrombocyte count ≤250x10^9/l (HR 1.7 [1.1-2.4]; p=0.005). Distribution of SMM patients according to risk groups based on the Mayo Clinic model (Dispenzieri 2008) confirmed predictive power of this model based on low and intermediate- risk group, but did not confirm high-risk group. The high-risk group was represented only by 4 SMM patients. At 2 years, no-risk group had 20.2% risk of progression compared to 23.2%, 45.4% and 25% in groups with 1, 2 or 3 risk factors, respectively (p=0.014) (Figure 1). SMM group with 1, 2 and 3 risk factors in comparison to the reference group had HR (1.14 [0.54- 2.41]; p=0.732, HR 2.58 [1.25- 5.35]; p=0.011, HR 2.18 [0.47-10.03]; p=0.317, n=146), retrospectively. Immunoparesis and ≥95% aPC was used to validate the PETHEMA model (Perez-Persona 2007). The rates of progression at 2 years were 5.9%, 20% and 41.4% for groups with 0, 1 or 2 risk factors, respectively (p=0.058) (Figure 1). SMM group with 1 and 2 risk factors in comparison to the reference group had HR (1.51 [0.40-5.69]; p=0.546, HR 3.31 [0.78-14.06]; p=0.104, n=62), retrospectively. Based on the 3 parameters with independent predictive value in the univariate analysis (immunoparesis, serum M-protein quantity ≥2.3 g/dL and iFLC/uFLC >30) we proposed a new CMG model. The risk of progression from SMM to MM at 2 years was 18.5%, 20.9%, 41.9% and 78.7% if 0, 1, 2 or 3 risk factors are present (p<0.001) with HR of 1.4 [0.7-2.9]; p=0.28, 2.5 [1.2-5.0]; p=0.008, 6.7 [3.0-15.2]; p<0.001, n=139), respectively (Figure 1).

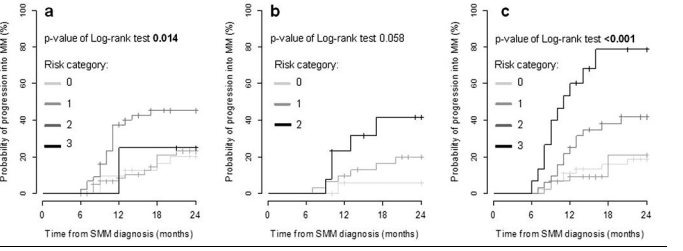

Figure 1. Comparison of 2 year risk of progression of CMG risk model (c) with the existing models developed by Mayo clinic group (a) and PETHEMA group (b).

Summary and Conclusions: We confirmed the validity of previously considered clinical models by the Mayo Clinic group (except high-risk group) and the PETHEMA group. New CMG model for the risk of progression from SMM to MM was established. Better identification of ultra high-risk group with prediction of 79% risk of progression to MM within two years based on easily accessible clinical parameters is advantage.

VENETOCLAX (ABT-199/GDC-0199) MONOTHERAPY FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA: PHASE I SAFETY AND EFFICACY

S. Kumar[1,*] R. Vij[2], J. L. Kaufman[3], J. Mikhael[4], T. Facon[5], P. Moreau[6], M. Amiot[6], S. Alzate[7], L. Morris[7], J. Ross[7], M. Dunbar[7], M. Zhu[7], S. Agarwal[7], J. Leverson[7], S. Enschede[7], R. Humerickhouse[7], C. Touzeau[6]
[1]Mayo Clinic, Rochester, [2]Washington University School of Medicine, St. Louis, [3]Winship Cancer Institute of Emory University, Atlanta, [4]Mayo Clinic Arizona, Scottsdale, United States, [5]CHRU Lille, Hopital Huriez, Lille, [6]CHU de Nantes, Hotel Dieu-HME, Nantes, France, [7]AbbVie, North Chicago, United States

Background: The anti-apoptotic protein BCL-2 has been implicated in mediating the survival of multiple myeloma (MM) cells. Venetoclax is a potent, selective, orally bioavailable small-molecule BCL-2 inhibitor. Venetoclax induces cell death in MM cell lines and primary samples *in vitro*, especially in cells which express a high ratio of *BCL2* to *MCL1*, such as those with t(11;14). The current Phase 1 study evaluates safety and efficacy of venetoclax in patients with relapsed/refractory MM.
Aims: Primary objectives are to evaluate safety, pharmacokinetics (PK), and recommended Phase 2 dose (RPTD); other objectives include preliminary efficacy and impact of chromosomal abnormalities.
Methods: In dose-escalation cohorts, venetoclax was given orally daily at 300, 600, 900, or 1200 mg after a 2-week dose ramp-up. Patients were monitored for tumor lysis syndrome.
Results: As of 12/19/2014, there were 28 patients with median age 65 (12/16 female/male); 9 were ISS stage I, 11 stage II, and 6 stage III. Median (range) prior therapies: 6 (1-13). 23 received prior bortezomib-containing regimens (15 were refractory), 26 lenalidomide (12 were refractory), and 13 autologous

hematopoietic stem cell transplant. 10 patients were t(11;14)-positive. Adverse events (AE; all grades) occurring in ≥20% patients: diarrhea (32%), nausea (32%), neutropenia (21%), and fatigue (21%). Grade 3/4 AEs (≥10%): thrombocytopenia (18%), anemia (14%), and neutropenia (14%). 7 patients had serious AEs, with 1 (epigastric pain) possibly related to venetoclax. 17 patients have discontinued: 14 due to disease progression (PD), 2 for AEs (worsening shortness of breath, hypokalemia), and 1 withdrew consent; 11 are still receiving therapy. 2 deaths occurred (both due to PD). 2 dose-limiting toxicities were seen at 600 mg (cohort was expanded): epigastric pain, nausea with abdominal pain. No patient had tumor lysis syndrome. Preliminary PK (n=11; 300 and 600 mg): mean C_{max} and AUC_{24} were approximately dose-proportional with high intra-dose variability. 21 of 28 patients were evaluable for preliminary efficacy (Table 1).

Table 1. Best response by t(11;14) status.

n (%)	t(11;14)-positive (n=7)	t(11;14)-negative (n=14)
Complete response (CR)	1 (14)	0
Partial response (PR)	1 (14)	0
Minimal response (MR)	1 (14)	0
Stable disease (SD)	2 (29)	9 (64)
Disease progression (PD)	1 (14)	2 (14)
Discontinued	1 (14)	3 (21)
Overall response rate (CR+ PR)	2 (29)	0
Median (range) time on study	5.1 (1.2–8.6)	1.9 (0.4–6.8)

Summary and Conclusions: Venetoclax monotherapy was well tolerated in heavily-pretreated relapsed/refractory MM. Responses (including CR) and longer time on study were observed in t(11;14)-positive patients. RPTD was achieved; this study is now enrolling in the safety expansion cohort at 1200 mg (with 2-week ramp-up).

P659

IMPACT OF FISH ABNORMALITIES ON RISK OF PROGRESSION IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

S. Paul[1], S. Kochuparambil[1], S.V. Rajkumar[1], A. Dispenzieri[1], M. Gertz[1], M. Lacy[1], F. Buadi[1], S. Hayman[1], D. Dingli[1], Y.L. Hwa[1], J. Lust[1], S. Russell[1], P. Kapoor[1], R. Go[1], R. Kyle[1], S. Kumar[1,*]
[1]Division of Hematology, Mayo Clinic, Rochester, United States

Background: Genetic abnormalities can be detected in the clonal plasma cells in nearly all patients with myeloma, and remains the most important prognostic factor in this disease. These abnormalities can be seen in the plasma cells at all stages of the disease spectrum from MGUS to SMM to active MM. In SMM, various abnormalities have been shown to increase the risk of progression to MM. The relevance of these findings in MGUS is unknown.
Aims: The study was performed to define the impact of common FISH abnormalities on risk of progression to multiple myeloma.
Methods: We reviewed the records of 10,244 patients with a diagnosis of MGUS, and identified 382 in whom a FISH test was performed at some time during the course of MGUS, but prior to any progression to SMM or MM. Impact of various FISH abnormalities on the risk of progression to SMM or MM was analyzed.
Results: The median age at diagnosis was 62 years; 57% were male. The estimated median follow up from MGUS diagnosis was 33 months for the entire cohort, 20 patients (5%) had progressed at the time of analysis (5 SMM, 15 MM). FISH demonstrated at least one abnormality in 207 (54%) patients, was normal in 58 (15%) and had insufficient plasma cells in 117 (31%). Among the 265 patients with a productive FISH, del13q was seen in 73 (28%), del17p in 6 (2%), any chromosome 14 translocation in 89 (34%), other chromosome 14 abnormality in 48 (18%), and trisomies of one or more chromosomes in 85 (32%). Considering only the 207 patients with an abnormal FISH, the distribution of the abnormalities above were 35%, 3%, 43%, 23% and 41%, respectively. Presence of t(11;14), del17p and any trisomy were all associated with increased risk of progression, while presence of any of the high-risk translocation (t(4;14, 14;16, or 14;20) did not affect the risk of progression. Overall, trisomy, t(11;14) or del17p were present in 146 (38%) of the patients and was associated with a 6 fold increased risk of progression (95% CI; 2, 38). We repeated the analysis excluding 7 patients who had progression to SMM or MM within 1 year of FISH, and the results were similar with an increased risk of progression in the presence of one of these three abnormalities.
Summary and Conclusions: The spectrum of abnormalities in MGUS appear similar to those in MM, except for presence of abnormalities in only a little over half of the patients (compared to 97% in MM), likely a reflection of low plasma cell burden. Interestingly, the FISH abnormalities associated with a better outcome in patients with MM appear to increase the risk of disease progression in MGUS. This raises the intriguing hypothesis that certain abnormalities are associated with a faster transition to MM state but remain alive longer in the MM phase, thus suggesting that the improved outcomes seen with these abnormalities reflect more of a lead-time bias in diagnosis of symptomatic disease.

P660

POST RELAPSE OUTCOMES IN YOUNG PATIENTS WITH MULTIPLE MYELOMA IN THE ERA OF NOVEL AGENTS

N. Vallumsetla[1], S. Kumar[1], M. Gertz[1], U. Painuly[1], A. Dispenzieri[1], M. Lacy[1], F. Buadi[1], R. Go[1], D. Dingli[1], N. Leung[1], R. Kyle[1], V. Rajkumar[1], P. Kapoor[1,*]
[1]Hematology, Mayo Clinic, Rochester, United States

Background: About 10-15% of patients with multiple myeloma (MM) are ≤50 years of age at diagnosis. Age is known to impact survival outcome for patients with MM. Young patients tend to have significantly longer overall survival (OS) compared to their older counterparts. Our previous accounts have suggested that in contradistinction to the observations in the elderly, young patients have not demonstrated incremental survival improvement over the past decade. Herein, we attempt to determine the disease course in young patients following first relapse in the novel agent era, and compare outcomes with a matched cohort of elderly patients (≥65 years of age) with relapsed MM.
Aims: To evaluate post relapse outcomes in young (≤50 years of age at diagnosis) MM patients, diagnosed between 01/01/2000-12/31/2011.
Methods: Of 242 consecutive young patients with active MM, diagnosed between 2000-2011 and evaluated within 90 days of their diagnosis of MM at Mayo Clinic, Rochester,149 (61.5%) had a documented first relapse prior to our data cut-off date (12/31/2014). Patients were assigned to 2 year groups based on the timing of the diagnosis: Group A (2000-2005; n=79) and Group B (2006-2011; n=70). The outcomes from diagnosis were compared to a reference cohort of elderly patients (≥65y of age), matched (1:1) by the timing of diagnosis, using the Kaplan-Meier method and log-rank test. Additionally, post relapse outcomes were compared to a similar reference cohort of elderly MM patients that had a documented relapse.
Results: The median OS from diagnosis for young MM patients (n=242) was 100.5 months [CI: 91- NR (not reached)]. The median estimated follow-up of the entire cohort was 85 months from diagnosis. The median time to first progression was 33 months (CI 28-38) in 207 young patients for whom the complete progression-related data were available. In Group A, young patients had a superior OS from diagnosis [median 100 months (CI 81-NR) *vs* 38 months (CI 25-49) in elderly; p<0.0001)] and from first relapse [median OS 59 months (CI 38-75) *vs* 22 months (CI 15-33) in elderly; p<0.0001] (Figure 1A). In Group B, OS from diagnosis was better in the young [median NR (CI 76-NR) *vs* 54 months (CI 37-71); p<0.0001]. However, OS from first relapse in the young patient cohort in Group B was not different from that of the reference cohort of elderly patients [median 43 months (CI 26-NR) *vs* 37 months (CI 20-54), respectively; p=0.25] (Figure 1B). Similar observations were made for disease specific survival in the 2 groups (data not shown). Therapy-related information stratified by the year groups is provided in Table 1. While the use of novel agents at relapse increased in the elderly (p<0.0001) as well as the young patients (p=0.03) in the more recent period (2006-2011), a greater proportional increase is evident in the older patient cohort.

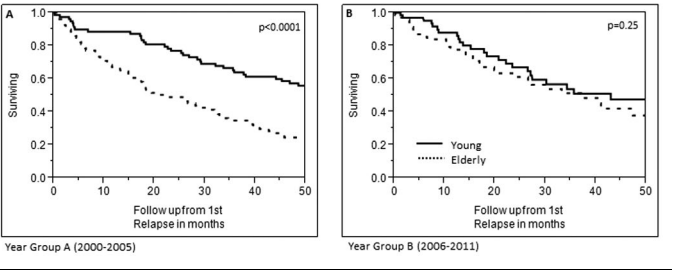

Figure 1. Survival outcomes in young *vs* elderly from first relapse.

Table 1. Therapies utilized at first relapse.

Therapy	Young		Elderly	
	Group A (%)	Group B (%)	Group A (%)	Group B (%)
I) Novel Agent-based	74	88	49	83
Immunomodulatory drug (IMiD)	57	32	39	39
Proteasome inhibitor (PI)	16	35	5	35
IMiD+PI combination	1	21	5	9
II) Conventional agents-based	26	12	51	17

Summary and Conclusions: Although overall survival from diagnosis is superior for young patients with MM compared to the elderly, outcomes from first relapse for the 2 age groups are similar in recent period (2006-2011). While this observation may be attributed to improved survival in the elderly at relapse,

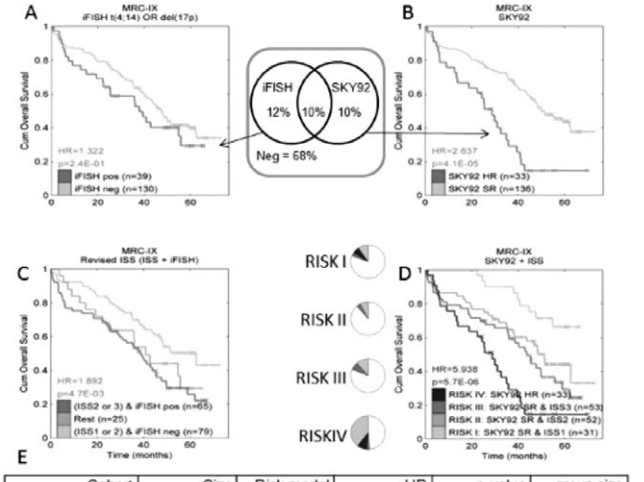
likely related to increased use of novel agents at relapse, our results also underscore that disease course for young patients is not different than that of the elderly after first relapse, indicating that our current approaches for the young patients with MM require substantial improvement.

P661

SKY92 GEP, IFISH AND ISS COMPARISONS FOR RISK STRATIFICATION IN MULTIPLE MYELOMA

E. van Beers[1,*] M. van Vliet[1], L. de Best[2], W. Gregory[3], G. Morgan[4], H. Goldschmidt[5], R. Kuiper[1], M. van Duin[6], A. Broijl[6], P. Sonneveld[6]
[1]science & technology, [2]operations, skylinedx, Rotterdam, Netherlands, [3]Clinical Trials Research Unit, University of Leeds, Leeds, United Kingdom, [4]Myeloma Institute at UAMS, UAMS, Little Rock, United States, [5]Sektion Multiples Myelom der Medizinischen Klinik V und des Nationalen Centrums für Tumorerkrankungen (NCT), University of Heidelberg, Heidelberg, Germany, [6]hematology, Erasmus Medical Center Rotterdam, Rotterdam, Netherlands

Background: Prognostic biomarkers are valuable for risk assessment in clinical settings in Multiple Myeloma which is a heterogeneous disease with variable outcome. Markers that have extensively and consistently been related to prognosis are t(4;14), del(17), ISS, and GEP signatures. Ideally a prognostic marker is robust across datasets, identifies a relevant fraction of patients and captures as much of the risk as possible. We evaluated four risk models for their clinical performance in two large datasets, HOVON65/GMMG-HD4 and MRC-IX. We compare HR, p-value, proportion of high risk cases and concordance between high risk models. Importantly, we show how individual patients may or may not be high risk depending on the model used.
Aims: To provide insight in the prognostic value of four different high risk models A) iFISH t(4;14) and/or del(17); B) SKY92 [1]; C) iFISH+ISS [2] and D) SKY92+ISS [3] in 2 different datasets.
Methods: 230 cases from HOVON-65/GMMG-HD4 (GSE19784) and 169 from MRC-IX (GSE15695) having GEP, iFISH, ISS data were analyzed. Kaplan Meier analyses were used to calculate Cox proportional hazard ratios and p-values. Venn diagrams visualize the overlap between the high risk models. Note that HOVON65/GMMG-HD4 data is the trainingset for EMC92/SKY92 [3]
Results: iFISH high risk (A) and SKY92 high risk (B) were compared for hazard ratio (p-value), proportion and overlap in two clinical cohorts. All hazard ratios except for iFISH (A) in MRC-IX were significant with p<0.05. The largest HR was observed for SKY92+ISS (D) for the highest risk category in comparison to the lowest risk category of SKY92, namely HR=13,6 in HOVON-65/GMMG-HD4 (Figure 1D) and HR=5,9 in MRC-IX (Figure 1). The two cohorts HOVON65 and MRC-IX have similar overlap of patients positive for iFISH, SKY92 or both (14/12/12% and 12/10/10% respectively) suggesting the robustness of these categories.



E

Cohort	Size	Risk model	HR	p-value	group size
HOVON-65/GMMG-HD4	N=230	A	2.505	**4.6E-05**	27%
		B	4.674	**6.4E-12**	25%
		C	2.989	**6.6E-05**	27%
		D	13.557	**2.4E-10**	25%
MRC-IX	N=169	A	1.322	2.4E-01	23%
		B	2.637	**4.1E-05**	20%
		C	1.892	**4.7E-03**	38%
		D	5.938	**5.7E-06**	20%

Figure 1. Shows four prognostic models applied to the (n=169) MRC-IX dataset. OS Kaplan Meier analyses were performed using risk model A, B, C or D (see aim). The overlap between high risk cases in model A and B is given in the Venn diagram. The pie charts visualize - for model D - the enrichment of iFISH t(4;14) (light grey) and del(17) (dark grey), or both (black) in each of the four strata. E) table with hazard ratios between for the extreme strata in each model.

Summary and Conclusions: SKY92 (model B) is a better prognostic marker than iFISH (model A) or FISH+ISS (model C) with twofold higher HR. Besides, addition of ISS to SKY92 (model D) is relatively easy to perform and is powerful for the identification of a group of patients with favorable prognosis as judged by the median OS which is not reached at 60 months in both cohorts.

MARKERS OF DISEASE EVOLUTION IN SMOLDERING MULTIPLE MYELOMA (SMM)

E. Nikolaou[1,*] T. Tzenou[1], A. Bitsani[1], V. Bartzis[1], S. Kotsanti[1], E. Koulieris[1], M. Dimou[1], D. Maltezas[1], T. Iliakis[1], P. Panayiotidis[1], M.-C. Kyrtsonis[1]
[1]University of Athens-Medical School, Laikon General Hospital of Athens, Athens, Greece

Background: SMM is an asymptomatic plasma cell dyscrasia that fulfills the diagnostic criteria of MM, without end organ damage symptoms. Ten percent of the patients are at risk of progression to symptomatic MM of which fewer will evolve within the first 2 years. For these latest patients, it is wondered whether they should be treated if they could be accurately recognized. Biomarkers proposed for that purpose are increased serum free light chains (FLC) or ratio (FLCR), plasma cell BM infiltration above 60% (that already categorizes patients as symptomatic MM), at least one bone lytic lesion by sensitive imaging techniques, etc.
Aims: To investigate prognostic markers of disease evolution in SMM, including FLC/FLCR levels, BM infiltration, skeletal findings, serum syndecan levels and other classical MM biomarkers.
Methods: We studied 147 SMM patients, diagnosed and followed -up in our department. Median age was 69 years (31-86) while 42% were males. Seventy-two percent, 21% and 7% were Durie-Salmon staged 1, 2 and 3 respectively, while 63%, 18% and 19% were ISS staged I, II and III respectively. MM type was IgG in 72%, IgA in 24% and light-chain in 3% of the population, while 2 patients (1%) were biclonal. Soluble syndecan-1 was measured by ELISA in 77 frozen samples collected at diagnosis. Serum FLCs were estimated by nephelometry (FREELITE, The Binding Site Ltd., Birmingham, UK). Serum FLC ratio (FLCR) κ/λ or λ/κ was calculated with the uninvolved LC as denominator. Statistical analysis was performed with SPSS v21.0. Survival was calculated with Log-rank test and depicted with Kaplan-Meier method.
Results: During a median follow-up time of 64 months, 50 patients (36%) evolved to MM. Median time to evolution was 15,5 months Factors highly statistically related to the probability of evolution were LC type MM (p<0,001), IgM <25mg/dl (p<0,001), the presence of at least 1 osteolytic lesion but also of diffuse osteoporosis (p=0,004), BM infiltration >60% and also BM infiltration 30-59% as compared to 10-29% (all p<0,001), FLCR>100 (7 pts, p<0,001), FLCR>8 (48 pts, p<0,001), involved FLC >100 mg/L (46 pts, p<0,001), IgA or IgG >30g/L (29 pts p<0,002) and soluble syndecan-1>120pg/ml (20/77 pts, p=0,001). However none of these factors alone could produce an 80% probability of evolution within two years. This was only possible by combining factors in models, thus patients with at least two factors of FLCR>100, soluble syndecan-1>120pg/ml and IgM <25mg/dl (N-10), had a 90% probability of disease evolution within two years.
Summary and Conclusions: Serum FLC/FLCR, skeletal status, immunoparesis, BM infiltration, soluble syndecan-1 serum levels are all important prognostic factors of disease evolution in SMM patients. The best models to recognize high-risk SMM should still be found and carefully validated in retrospective series because both the administration of an unneeded treatment and the delayed therapy could be harmful.

P663

EFFICIENCY AND TOXICITY OF CYCLOPHOSPHAMIDE BASED STEM CELL MOBILIZATION IN RELAPSED MULTIPLE MYELOMA PATIENTS: OBSERVATIONS FROM THE ONGOING PHASE III TRIAL RELAPSE

Background: High dose chemotherapy (HD) with subsequent autologous stem cell transplantation (ASCT) is the standard treatment for newly diagnosed multiple myeloma (NDMM) patients and has recently been shown to be effective in the relapsed multiple myeloma (RMM) setting in a prospective phase III trial.[1] Stem cell mobilization in NDMM patients is a safe procedure associated with a low rate of failure to collect sufficient numbers of stem cells after stimulation with chemotherapy and G-CSF. However, the number of preceding chemotherapy cycles and exposure to melphalan have been identified as factors negatively correlated with mobilization success.[2]
Aims: We report data on the efficiency and toxicity of cyclophosphamide based stem cell mobilization in RMM patients from the ongoing phase III trial ReLApsE.
Methods: ReLApsE (EudraCT 2009-013856-61, ISRCTN 16345835) is a randomized, open, multicenter phase III trial of continued lenalidomide/dexamethasone *vs* lenalidomide/dexamethasone induction followed by HD, ASCT and lenalidomide maintenance in a planned study population of 282 MM patients up to 75 years of age in their 1st to 3rd relapse. Patients without available stem cell transplants from earlier apheresis undergo stem cell mobilization and apheresis in both trial arms after three cycles of lenalidomide/dexamethasone to allow for HD and ASCT either as part of the ReLApsE trial or as a subsequent treatment. Mobilization consists of high dose cyclophosphamide (HD-CY; 2*2 $g*m^{-2}$) followed by G-CSF (filgrastim 10 $\mu g*kg^{-1}*d^{-1}$ or lenograstim 300 $\mu g*m^{-2}*d^{-1}$) from day 5 until the last day of apheresis. In patients who fail to harvest sufficient numbers of stem cells, the administration of plerixafor is recommended.
Results: Until February 2015, 186 patients were randomized. Thirty patients underwent stem cell mobilization of which 29 received HD-CY plus G-CSF. Two patients died from HD-CY associated complications (sepsis) and one patient was withheld from stem cell apheresis due to a coinciding myocardial infarction. Of the 26 patients who underwent stem cell apheresis after HD-CY plus G-CSF, 9 patients (34.6%) succeeded and 17 patients (65,4%) failed to collect sufficient numbers of stem cells (≥$2*10^6$ $CD34^+$ cells*kg bw^{-1}). Additional application of plerixafor was initiated in 16 patients and enabled successful apheresis in 13 patients (81.3%).
Summary and Conclusions: Stem cell mobilization with HD-CY plus G-CSF in RMM allows for sufficient stem cell collection in only 35% of patients undergoing apheresis and is associated with marked toxicity. However, with addition of plerixafor as a rescue strategy following HD-CY plus G-CSF, successful stem cell collection is feasible in 85% of RMM patients undergoing apheresis. Our data underline the importance of collection of additional stem cell transplants during first-line treatment, as at this time-point stem cell mobilization is far more efficient and less toxic. If mobilization is performed in the relapsed setting, HD-CY administration and subsequent surveillance should be performed in an inpatient setting to enable early detection of infections and treatment of any severe adverse events.

HEAVY LIGHT CHAIN RATIO NORMALIZATION ALLOWS IDENTIFICATION OF ELECTROPHORETIC NON-COMPLETE RESPONSE PATIENTS WITH IMPROVED OUTCOMES: A LONG TERM FOLLOW UP UPDATE FOR BMT CTN 0102 CORRELATIVE STUDY

A. D'Souza[1,*] M. Pasquini[1], B. Logan[1], S. Giralt[2], A. Krishnan[3], J. Antin[4], A. Howard[5], M. Horowitz[1], S. Goodman[6], G. Laport[7], M. Qazilbash[8], A. Mendizabal[9], F. Sahebi[3], D. Weisdorf[10], D. Vesole[11], E. Stadtmauer[12], D. Maloney[13], P. Hari[1]
[1]Medical College of Wisconsin, Milwaukee, [2]Memorial Sloan Kettering Cancer Center, New York, [3]City of Hope, Duarte, [4]Dana Farber Cancer Institute, Boston, [5]The National Marrow Donor Program, Minneapolis, [6]Vanderbilt-Ingram Cancer Center, Nashville, [7]Stanford University, Palo Alto, [8]MD Anderson Cancer Center, Houston, [9]The EMMES Corporation, Rockville, [10]University of Minnesota, Minneapolis, [11]John Theurer Cancer Center, Hackensack, [12]University of Pennsylvania, Philadelphia, [13]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: The prognostic value of pre-transplant heavy light chain (HLC) and free light chain (FLC) response over conventional electrophoretic response in the post-transplant setting is not well understood.
Aims: We correlated FLC and HLC assays with conventional electrophoretic response criteria to study their prognostic impact over 6 years of follow-up among 497 patients enrolled in the BMT CTN0102 trial of tandem autologous (autoHCT) *versus* tandem autoHCT-allogeneic (alloHCT) transplantation.
Methods: Pre-transplant serum samples prior to first autoHCT were analyzed centrally for FLC (Freelite™) and HLC (Hevylite™). Corresponding disease status (IMWG uniform response criteria) was determined by independent data review committee. An HLC-CR was defined as normalization of ratios across all 3 measured HLC pairs or the normalization of clonal isotype with normal ratios of uninvolved pairs. The demographics of the 497 patients with HLC and FLC pre-transplant samples were concordant with the main study (Krishnan *et al.* Lancet Oncol. Dec 2011; 12(13): 1195).
Results: 56 patients in conventional CR were also in HLC-CR. Comparing HLC-CR *vs* conventional CR, sensitivity was 100%, specificity 39%, PPV and NPV values 17% and 100% respectively. Of 211 pts in a conventional response better than or equal to very good partial response (>VGPR), 188 were in HLC-CR (Sensitivity=89%). Comparing HLC-CR *vs* conventional >VGPR: specificity was 52%, PPV 58% and NPV 87%. FLC ratio normalization (FLC-CR) *vs* conventional >VGPR disease state had a sensitivity of 47%, specificity 81% and PPV and NPV of 64% and 67% respectively. Adjusted multivariate models including baseline conventional response, myeloma stage and study arm were used to compare the prognostic utility of HLC-CR and FLC-CR. HLC-CR was an independent predictor of superior PFS (p-0.016), freedom from relapse (p-0.035) and survival (p-0.012) (Figure 1) while FLC-CR was not. A pre-transplant HLC-CR but not FLC-CR was associated with improved outcomes for patients not in electrophoretic CR/VGPR.

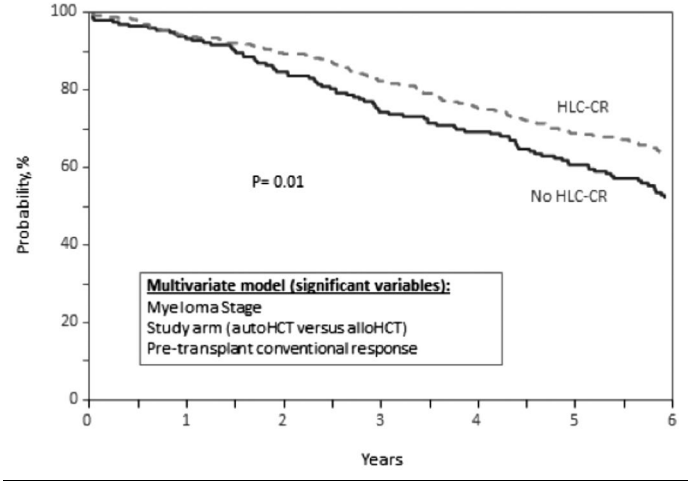

Figure 1. Adjusted survival by HLC remission status.

Summary and Conclusions: We conclude that 1) HLC normalization, but not FLC normalization, is additionally informative about patients not in electrophoretic CR/VGPR and 2) achievement of pre-transplant HLC-CR is a powerful predictor of improved post-transplant outcomes regardless of pre-transplant conventional response.

Myeloproliferative neoplasms - Clinical 2

CLINICAL IMPACT OF BONE MARROW MORPHOLOGY FOR THE DIAGNOSIS OF ESSENTIAL THROMBOCYTHEMIA: COMPARISON BETWEEN THE BRITISH STANDARDS (BCSH) AND THE WHO CRITERIA

G. Jeryczynski[1,*] B. Gisslinger[1], M. Schalling[1], L. Müllauer[2], A.-I. Schiefer[2], J. Thiele[3], H. Gisslinger[1]
[1]Department of Internal Medicine I, [2]Institute of Pathology, Medical University of Vienna, Vienna, Austria, [3]Institute of Pathology, University of Cologne, Cologne, Germany

Background: Accurate diagnosis of essential thrombocythemia (ET) persists to be a controversial and challenging issue and is usually performed by applying either the 2014 British Committee for Standards in Haematology (BCSH) guidelines or the 2008 World Health Organization (WHO) criteria. The critical point is that according to the WHO classification bone marrow morphology (BM) is recognized as a major feature, while the BCSH guidelines are more focused on an exclusion of the other subtypes of myeloproliferative neoplasia (MPN) and thus do allow ET diagnosis without BM examination. However, prefibrotic/early stages of primary myelofibrosis (prePMF) may also present with thrombocytosis, while failing to meet the diagnostic signs and symptoms characterizing overt PMF. Since clinical outcome in prePMF patients is considerably worse than in ET patients accurate diagnosis is pivotal to provide adequate management in these cases. Moreover, a small fraction of polycythemia vera (PV) patients may present with low hemoglobin and hematocrit levels, but a platelet count in keeping with BCSH- and WHO-defined ET, thus mimicking phenotypically ET at onset.
Aims: The aim of this study was to investigate the prognostic relevance of BM morphology for ET diagnosis as underscored by the WHO classification *versus* the first set of the BCSH criteria that do not include BM evaluation.
Methods: A clinic-pathological database including 350 MPN patients was created by clinicians and hematopathologists from a major Austrian center. Treatment-naive BM biopsies were centrally re-reviewed at a multiheaded microscope by two of the authors, who were completely blinded to initial data (except for age and gender). Follow-up data including clinical course and mutation status were analyzed after the completion of the histopathology review. For purpose of this study we selected two cohorts of ET patients presenting with a sustained platelet count >450x10^9/L: (1) 164 ET patients in accordance with the diagnostic requirements of the BCSH (A1-A3) that included no BM biopsy examination. (2) 122 patients in strict agreement with the diagnostic guidelines of the WHO including BM biopsy evaluation as major criterion. Both cohorts were compared and analyzed regarding their presenting clinico-pathological data, mutation status and follow-up. Diagnosis of post-ET myelofibrosis or progression into overt myelofibrosis with myeloid metaplasia was made according to well-known criteria.

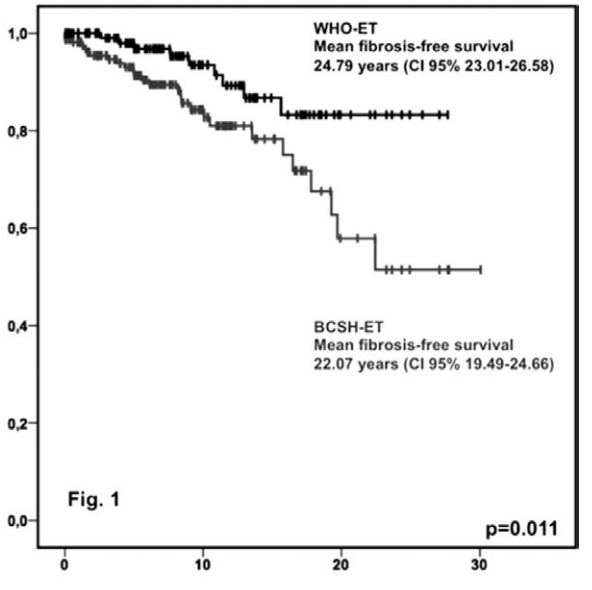

Figure 1.

Results: Following the BCSH criteria, 164 patients were diagnosed as ET. When reclassifying those cases according to the WHO criteria including BM morphology examination, 56 (34.1%) patients were diagnosed as prePMF and 17 (10.4%) as PV. Comparison of clinical features of BCSH-ET and WHO-ET revealed significant differences in white blood cell counts, LDH levels, fibrosis grades in the BM biopsy and in progression to overt myelofibrosis. Fibrosis-free survival was significantly shorter in BCSH-ETs (Figure 1). When reclassifying the BCSH cohort according to WHO criteria, overall survival and progression free survival were significantly shorter in WHO-confirmed prePMF.
Summary and Conclusions: Our results highlight the central role of BM biopsy in the accurate diagnosis and differentiation of ET and prePMF. The differences in clinical features and outcome underscore the importance of an accurate initial diagnosis.

P666

MYELOPROLIFERATIVE NEOPLASMS AND INFECTIONS; A POPULATION-BASED STUDY ON 9,665 PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS DIAGNOSED IN SWEDEN 1987-2009

M. Hultcrantz[1,*] S.H. Lund[2], T. M.-L. Andersson[3], M. Björkholm[1], S.Y. Kristinsson[1,4]
[1]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [2]Faculty of Medicine and Department of Hematology, University of Iceland and Landspitali National University Hospital, Reykjavik, Iceland, [3]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, [4]Faculty of Medicine and Department of Hematology, University of Iceland and Landspitali National University Hospital, Reykjavik, Sweden

Background: Patients with myeloproliferative neoplasms (MPNs) are at an elevated risk of thrombosis and their life expectancy is shorter compared to the normal population. Survival has improved during recent years due more effective disease management and new targeted treatments. There is however limited information on morbidity and mortality due to infections in patients with MPNs.
Aims: To assess the risk of infections in MPN patients and matched controls in a population-based setting in Sweden.
Methods: All patients with MPNs reported to the Swedish Cancer Register and/or registered in the national Inpatient Register from 1987 to 2009 were included in the study. For each MPN patient, four controls matched for age, sex, and county of residence, were randomly selected from the Swedish Total Population Register. End of follow-up was December 31st 2010. Information on type and date of infection was obtained from the Swedish Patient Registry which captures information on all individual patient-based discharge diagnoses from inpatient (since 1987) and outpatient care (since 2001) as well as from the Cause of Death Register where all dates and causes of death are recorded. The risk of infection was analyzed using Cox regression where death was considered a competing risk. Separate analyses were performed for the overall risk of infection as well as subsets of bacterial and viral infections. Results are presented as hazard ratios (HRs) and 95% confidence intervals (CIs). In addition, the cumulative incidence of infection and death from any cause in MPN patients diagnosed during different calendar periods are illustrated by cumulative incidence curves.
Results: In total, 9,655 MPN patients and 38,660 matched controls were identified. There was a statistically significant two-fold risk elevation for infections (HR=1.9; 95% CI 1.8-2.0, p<0.0001) in MPN patients compared to controls. The risks of bacterial and viral infections were significantly increased (HR=1.8; 1.6-1.9, p<0.0001 and HR=3.0; 2.7-3.3, p<0.0001, respectively). The HRs of sepsis was 3.5 (3.2-4.0), pneumonia 2.2, (2.0-2.3), urinary tract infection 1.5 (1.2-1.6) compared to matched controls, all statistically significant. In addition, there was an increased risk of viral hepatitis with a HR of 3.8 (2.8-5.2, p<0.0001) in relation to controls. A significantly elevated risk of infections was observed in patients of all MPN subtypes compared to matched controls.
The risk elevation remained stable over time when MPN patients diagnosed during different calendar periods were analyzed separately (Figure 1). The overall risk of infection were HR 2.1 (1.9-2.4), 2.1 (1.9-2.3), 1.9 (1.8-2.1), and 2.2 (1.9-2.5) in MPN patients diagnosed during the years 1987-1992, 1993-1998, 1999-2004, and 2005-2009, respectively, compared to matched controls.

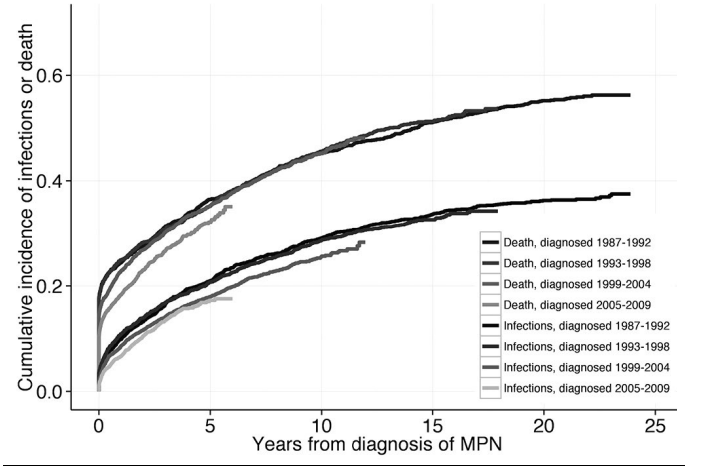

Figure 1.

Summary and Conclusions: MPN patients are at an increased risk of bacterial and viral infections compared to matched controls. The findings are particularly relevant since the JAK2 inhibitors have been shown to further increase the risk of opportunistic infections and reactivation of viral infections. Taken together, our results indicate that the risk of infection and possible immunosuppressive effects need to be considered when choosing optimal treatment in MPN. In addition, further studies are needed to identify subsets of patients that may benefit from infectious prophylaxis.

P667

UNFAVORABLE KARYOTYPE AND MOLECULAR NEGATIVITY SIGNIFICANTLY INFLUENCE THE INFECTIOUS RISK IN MYELOFIBROSIS: EVALUATION ON 426 PATIENTS

N. Polverelli[1,*] M. Breccia[2], G. Benevolo[3], R. Latagliata[2], L. Catani[1], M. Perricone[1], D. Sollazzo[1], G. Colafigli[2], M. Nicolosi[3], A. Campana[3], U. Vitolo[3], G. Alimena[2], G. Martinelli[1], M. Cavo[1], N. Vianelli[1], F. Palandri[1]
[1]Department of Experimental Diagnostic and Specialty Medicine (DIMES), Institute of Hematology "L. and A. Seràgnoli", S. Orsola-Malpighi University Hospital, Bologna, [2]Cellular Biotechnologies and Hematology, University Sapienza, Rome, [3]Hematology, Città della Salute e della Scienza Hospital, Turin, Italy

Background: Infectious complications represent one of the main causes of morbidity and mortality in patients (pts) with Primary Myelofibrosis (PMF), Post-Essential Thrombocythemia and post-Polycythemia Vera MF (PET/PPV-MF). An increased infectious risk has been reported in pts treated with ruxolitinib (RUX), a JAK1/2 inhibitor with potent immune-suppressive properties. However, very few data are available on outcome and risk factors of this potentially fatal complication.
Aims: To evaluate risk factors for severe infections in a large cohort of MF patients.
Methods: Clinical and laboratory data of pts with MF were retrospectively collected from the database of 3 Italian Hematology Centers in University Hospitals. Severe infections were defined as grade 3/4 according to the CTCAE. The study was approved by the Ethic Committee of each participating Centers.
Results: Between 1980 and Aug 2014, 426 pts with PMF (319 pts, 75%), or PET-MF (13%) or PPV-MF were diagnosed and followed for a median follow-up of 4 yr (0.5-30.1). Baseline characteristics were (median): age, 67 y (range, 26-87); ≥65 y, 55%; male, 57%; hemoglobin (Hb), 12 g/dL (4-17.9); Hb <10 g/dL, 24%; PLT, 372×10^9/L (15-2513); PLT <100×10^9/L, 8.0%; spleen enlargement, 69% (spleen length ≥5cm: 32.4%); constitutional symptoms, 15%. International Prognostic Score System (IPSS) was low (11%), intermediate-1 (intm-1, 21%), intermediate-2 (intm-2, 43%), high (24%). Molecular analysis was performed on 253 pts (59%) and was positive in 84% (*JAK2*V617F), 14% (*CALR*), 3% (*MPL*W515K/L); 6 pts (2%) were triple negative. Karyotype was abnormal in 34 (16.6%) out of 204 evaluable pts (unfavorable in 10 pts; 5%). Overall, 81 pts (19%) experienced 112 grade 3-4 infectious events, for an incidence rate of 3.3% pt-y. The cumulative incidence was 16%, 26.8% and 43.6% at 5, 10 and 20 y, respectively (Figure 1). Infections were: bacterial (101 events, 90.2%; pneumonia: 54 cases, 53.4%); VZV reactivations (7 events, 6.2%), nodal TBC (2 events, 1.8%), fungal lung infections (2 events, 1.8%). Infectious complications represented the causes of death in 9 (8%) out of 126 deceased pt. Among baseline features, age≥65 y (p=0.004), leukocyte ≥25x10^9/l (p=0.02), spleen length>5 cm (p=0.03), high/intm-2 IPSS (p=0.01), unfavorable karyotype (p<0.001) and JAK2/CALR/MPL negativity (p=0.002) significantly correlated with higher infectious risk; in multivariate analysis, unfavorable karyotype and molecular negativity confirmed their negative impact (p=0.008 and p=0.03, respectively). Overall, 81 pts at intm-2/high IPSS risk were treated with RUX for a median time of 16 mos (1-45). Infection-free survival at 5 y was significantly worse in RUX-treated pts (66%) compared to non RUX-treated intm-2/high risk pts (86%, p=0.01). Among RUX-treated pts, only age ≥65 y correlated with an increased risk of infectious complications (p=0.015).

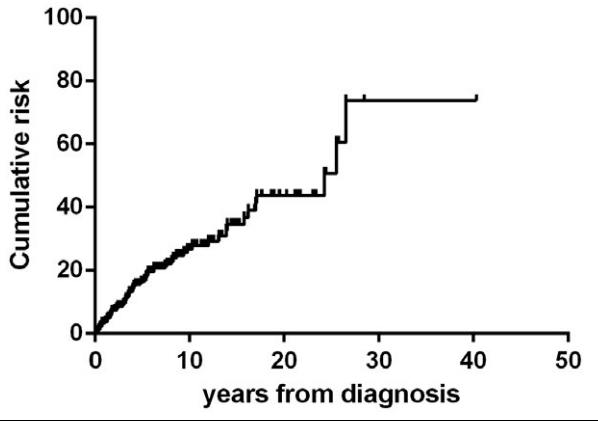

Figure 1.

Summary and Conclusions: This large study confirms severe infections as frequent events involving 19% of MF pts and representing the ultimate cause of death in 8% of the cases. Molecular/cytogenetic data identify a subset of patients at higher infectious risk. In RUX-treated pts, a higher incidence of infections was observed; in this particular subpopulation, only older age represented a significant risk factor for severe infectious complications.

P668

PRIMARY MYELOFIBROSIS, POST-ET AND POST-PV MYELOFIBROSIS HAVE DISTINCT CLINICAL PROFILES AND SYMPTOMATIC BURDENS: AN ANALYSIS BY THE MPN QUALITY OF LIFE INTERNATIONAL STUDY GROUP (MPN-QOL ISG)

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm (MPN) that may arise as primary (PMF) or result from progression of polycythemia vera (PPV-MF) or essential thrombocythemia (PET-MF). Independent of subtype, MF patients share a debilitating symptom profile and high mortality rate. Historically, all MF patients have been treated similarly without impact of subtype. Recent data suggests perhaps a different natural history amongst subtypes of MF (Passamonti *et al.*, Blood 2014).
Aims: We sought to evaluate impact of MF subtype on MPN total symptom burden and symptom profiles.
Methods: Data was collected among an international cohort of patients with MF including PMF, ETMF and PVMF as reported previously (Emanuel *et al.*, JCO 2013). Subjects completed the Brief Fatigue Inventory (BFI) and Myeloproliferative Neoplasm Symptom Assessment Form (MPN-SAF) instruments. Items were scored on a 0 (absent) to 10 (worst imaginable) scale. MPN-SAF TSS items included fatigue, concentration, early satiety, inactivity, night sweats, itching, bone pain, abdominal discomfort, weight-loss, and fever. For individuals completing at least 6 of the 10 MPN-SAF TSS items, the survey was scored by multiplying the average score across items by 10 to achieve a 0 to 100 scaled score. Demographics, clinical variables and symptom scores were compared between myelofibrosis groups using ANOVA F-tests or chi-squared tests.
Results: *Patient Population*. A total of 835 MF subjects (PMF=488; PET-MF=192; PPV-MF=155) were prospectively enrolled and administered the MPN-SAF and BFI. Most patients were of expected age for MPNs (mean 60.9 years) with a mean disease duration of 8.7 years. Splenomegaly (68.9%) and laboratory abnormalities (62.4%) including anemia (51.4%) and thrombocytopenia (31.3%) were common. Prior hemorrhage (8.7%), phlebotomy use (12.9%) and prior thrombosis (13.2%) were infrequent. *Clinical Features by MF Subtype*. MF subgroups differed by mean age (p<.001) and MPN duration (p<0.001). PMF patients had significantly higher rates of anemia (p=0.005), thrombocytopenia (p=0.006) and laboratory abnormalities (p=0.03) with the lowest mean hemoglobin (p=0.0053) and platelet counts (p<0.001). PMF patients also had the lowest rates of prior thrombosis (p<0.001) and prior hemorrhage (p<0.001). As expected, PPV-MF patients demonstrated the highest rate of current/previous phlebotomies (p<0.001) along with the highest rates of enlarged spleens (p=0.007). *MF Symptom Burden by Disease Subtype*. Mean Total Symptom Scores were similar between PMF (27.2), PET-MF (26.4) and PPV-MF (26.4; p=0.83; Figure 1), however individual symptom patterns differed

by MF subtype. PMF patients had the most frequent and symptomatic fevers (21%, p=0.03; TSS 0.6, p=0.049) and weight loss (45%, p=0.04; TSS 2.1, p=0.007). Inactivity was least common (69%, p=0.01) in PET-MF whereas pruritus was most common amongst PPV-MF patients (60%, p=0.02). No significant differences were noted for items of worst fatigue, early satiety, abdominal discomfort, inactivity, concentration, itching or bone pain (all p>.05) between MF subtypes.

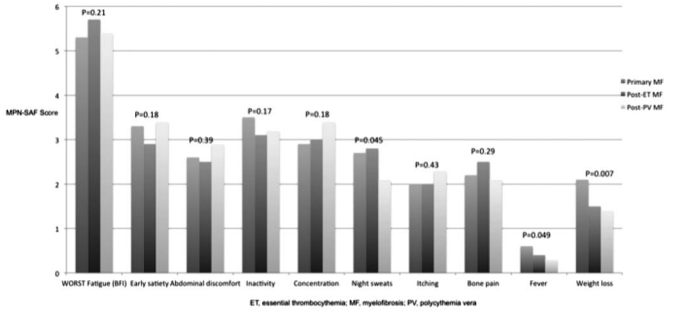

Figure 1. MPN-SAF TSS for individual items by myelofibrosis subtype.

Summary and Conclusions: The results of this study confirm recent reports that that PMF, PET-MF and PPV-MF exhibit unique clinical and symptomatic profiles. PMF patients demonstrate more significant constitutional symptoms. No difference in scores for these items was noted between PET-MF and PPV-MF, contrary to previous findings. Further research is needed to determine if this finding is of clinical relevance in the determination of therapy.

P669

IMPACT OF CALR AND ASXL1 MUTATIONS ON SURVIVAL AND DISEASE COMPLICATIONS IN ESSENTIAL THROMBOCYTHEMIA AND PREFIBROTIC PRIMARY MYELOFIBROSIS STRICTLY DIAGNOSED ACCORDING TO THE WHO-CLASSIFICATION

M. Schalling[1], B. Gisslinger[1], G. Jeryczynski[1], T. Berg[2], A. Harutyunyan[2], J. Milosevic[2], K. Bagienski[2], N. Them[2], F. Schischlik[2], V. Buxhofer-Ausch[1], G. Nirnberger[3], A.-I. Schiefer[4], L. Müllauer[4], R. Kralovics[1,2], J. Thiele[5], H. Gisslinger[1,*]
[1]Department of Internal Medicine I, Medical University of Vienna, [2]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, [3]Institute for Bioconsulting, Breitenfurth, [4]Institute of Pathology, Medical University of Vienna, Vienna, Austria, [5]Institute of Pathology, University of Cologne, Cologne, Germany

Background: In 2013, the landscape of myeloproliferative neoplasms (MPN) was altered dramatically by the identification of somatic mutations in the calreticulin (CALR) gene. With this discovery molecular information, in addition to the JAK2V617F mutation, can be implemented as an affirmative variable for discrimination of MPNs from reactive myeloid proliferations for the first time. Previously, the clinical course of essential thrombocythemia (ET) or primary myelofibrosis (PMF) in patients carrying the CALR mutation has been reported to be more indolent than in JAK2 positive patients and was associated with increased survival.
Aims: Our aim was to investigate the different impacts of CALR mutations on the prognosis and clinical outcome in prefibrotic PMF (prePMF) and WHO-classified ET (WHO-ET). Additionally, the same investigations were made concerning ASXL1 (exon12) mutations, with ASXL1 being one of the most common bystander mutated genes in MPNs.
Methods: In a cohort of 348 patients with the clinical diagnosis of either WHO-ET or PMF, mutational analysis for CALR was available. For study entry, the following eligibility criteria had to be fulfilled: a) availability of mutation analysis for JAK2, MPL and CALR; b) availability of representative, treatment-naive bone marrow biopsy; c) availability of a histological and clinical consensus on the diagnosis; d) complete long-term documentation of clinical data and outcome.
Results: Consenting clinico-pathological findings were consistent with 115 cases of WHO-ET and 85 patients with prePMF. In contrast to the most recent publications, the present study revealed a different CALR mutation frequency in ET (Table 1). This discrepancy in the frequencies of CALR positivity in our ET cohort may be due to our strict adherence to the WHO criteria for diagnosis of ET. Regarding prePMF, we observed CALR mutations in 39% of the patients. 92% of the JAK2/MPL wt subgroup carried the CALR mutation, with JAK2, MPL and CALR wt being observed in only 3% of prePMF. The most striking differences between WHO-ET and prePMF were seen in the comparison of the overall survival (Figure 1A, 1B). While the CALR mutation did not have any beneficial influence on survival in WHO-ET, it was associated with a superior overall survival in prePMF. Such a difference was not seen in the time to transformation into overt MF, and there was only a slightly shorter time to progression to fibrosis in CALR wt prePMFs. There was a trend showing that CALR mutated prePMF patients have shorter thrombosis-free survival compared to CALR wt prePMF patients. No impact of the CALR mutations on thrombosis-free survival in WHO-ET was observed. ASXL1 (exon12) mutations revealed no impact on overall survival (Figure 1C).

Table 1.

	Total cohort (N=200)	WHO-ET (N=115)	prePMF (N=85)	P
Age at diagnosis, years				0,04
Median (range)	58,85 (19-88)	56,4 (19-84)	60,7 (27-88)	
Sex				0,587
Male/female	78/122	43/72	35/50	
Observation period, years				0,066
Median (range)	8 (0-30)	8,5 (0-28)	7,4 (0-30)	
CALR positive				0,001
No. (%)	54 (27)	21 (18,3)	33 (38,8)	
ASXL1(ex12) positive	(N=190)	(N=108)	(N=82)	0,0868
No. (%)	17 (8,9)	13 (12)	4 (4,9)	

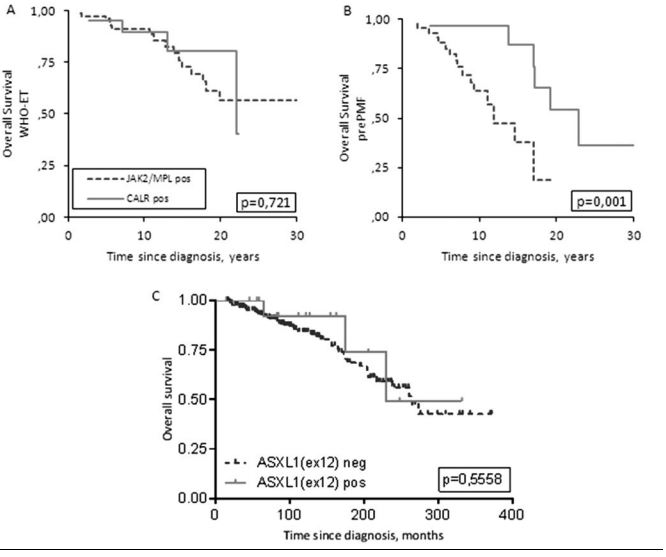

Figure 1. Kaplan-Meier analyses for A) CARL analyzed WHO-ET, B) CARL analyzed prePMF and C) ASXL1(ex12) analysed WHO-ET and prePMF.

Summary and Conclusions: The present data confirm that WHO-ET and prePMF are biologically different sub-entities of MPNs. In prePMF, almost all patients are now associated with known disease-causing mutations. Our data support the classical approach in the diagnosis of thrombocytosis, using BM histology to differentiate WHO-ET from prePMF and more accurately estimate the outcome of the disease.

P670

RUXOLITINIB PROVIDES CONSISTENT HEMATOCRIT CONTROL IN PATIENTS WITH POLYCYTHEMIA VERA (PV) RESISTANT TO OR INTOLERANT OF HYDROXYUREA

M. Griesshammer[1,*] F. Passamonti[2], S. Durrant[3], J.-J. Kiladjian[4], S. Verstovsek[5], M. M. Jones[6], D.S. Hunter[6], S. He[6], S. Urva[7], J. Li[7], M. Khan[7], D. Habr[7], A.M. Vannucchi[8]
[1]Johannes Wesling Clinic, Minden, Germany, [2]Ospedale di Circolo e Fondazione Macchi, Varese, Italy, [3]Royal Brisbane & Women's Hospital, Brisbane, Australia, [4]Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [5]The University of Texas MD Anderson Cancer Center, Houston, [6]Incyte Corporation, Wilmington, [7]Novartis Pharmaceuticals Corporation, East Hanover, United States, [8]University of Florence, Florence, Italy

Background: Ruxolitinib (RUX) is a JAK1/JAK2 inhibitor that has shown superiority over best available therapy (BAT) in patients (pts) with PV who had an inadequate response to or unacceptable side effects from hydroxyurea (HU). In RESPONSE, a higher proportion of RUX-treated pts achieved hematocrit (HCT) control without phlebotomy (PBT) than BAT-treated pts (60% *vs* 20%). Pts with inconsistent HCT control may be at a higher risk for thromboembolic events than those who have HCT aggressively targeted to ≤45%.

Aims: Because HCT values can fluctuate over time, and given the importance of a target HCT of ≤45% in PV, we performed an analysis to determine the percentage of time patients maintained HCT control on treatment (ie, HCT ≤45%) in each study arm.
Methods: RESPONSE is a randomized (1:1) open-label phase 3 study to evaluate the efficacy and safety of RUX *vs* BAT in pts with PV who are resistant to or intolerant of HU by modified ELN criteria. Pts with splenomegaly (≥450 cm^3 by MRI) who required PBT for HCT control received RUX 10 mg bid or single-agent BAT. The primary endpoint was the proportion of pts who achieved both HCT control without PBT from wk 8 to 32 (with ≤1 PBT from randomization to wk 8) and a ≥35% reduction from baseline in spleen volume at wk 32, as assessed by MRI. The primary analysis occurred when all pts reached wk 48 or discontinued. In this preplanned analysis at wk 80 data cutoff, the total percentage of time pts had HCT >45% during randomized treatment was estimated. A linear relationship between HCT and time was assumed for any consecutive 2 assessments with no PBT in between. If any PBT was done between 2 assessments and HCT was ≤45% at later assessment, HCT was assumed to be ≤45% immediately after the PBT, and the time patients had HCT >45% was not calculated between the 2 time points; however, if HCT after the PBT was >45%, the time between the 2 time points was assumed to be with HCT >45%.
Results: Pts were randomized to RUX (n=110) or BAT (n=112). Baseline characteristics were well balanced between arms (median HCT, 43.3% *vs* 44.0%; pts with HCT >45%, 25.5% *vs* 22.3%). At data cutoff, 82.7% of pts randomized to RUX remained on treatment and no pts remained on BAT (median exposure, 111 and 34 wk). In the RUX arm, mean HCT decreased continuously from wk 2 to 12 and then remained relatively stable thereafter. A larger proportion of pts in the RUX arm achieved HCT ≤45% than pts in the BAT arm (Figure 1). For pts who had uncontrolled HCT (ie, >45%) at baseline despite PBT, mean HCT in the RUX arm declined to <45% and was lower than that in the BAT arm over the course of treatment. The mean change from baseline in HCT ranged from −3.12% to −4.36% in the RUX arm (from wk 12 to 80) and from +0.06% and +1.03% in the BAT arm (from wk 12 to 32). Over the duration of treatment, pts in the BAT arm spent 12 times more in percentage of time with a HCT >45% than pts in the RUX arm (median, 39.1% [Q1-Q3, 12.9-65.9] *vs* 3.0% [Q1-Q3, 0.0-16.7]). Pts who achieved HCT control without PBT from wk 8 to 32 with RUX (n=66) had an 89% probability (95% CI, 0.78-0.95) of maintaining the response for 80 wk from the initial response. From wk 8 to 32, more BAT pts required PBT (≥1 PBT: 62% *vs* 20%; ≥3 PBT: 20% *vs* 3%); 90% of RUX pts did not have a PBT from wk 32 to 80.

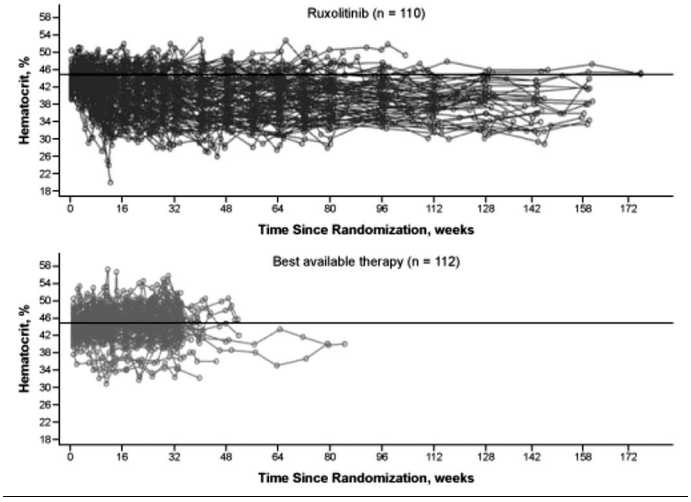

Figure 1. Plot of hematocrit over time for individual patients.

Summary and Conclusions: In RESPONSE, pts who received RUX experienced more consistent control of HCT to ≤45% than those who received BAT. Sustained HCT ≤45% is a key treatment goal for reducing the risk of thromboembolic events in PV, as supported by results of the CytoPV trial.

P671

PHASE 2 STUDY OF A NOVEL CONTROLLED-RELEASE FORMULATION OF ANAGRELIDE (GALE-401) IN SUBJECTS WITH MYELOPROLIFERATIVE NEOPLASM (MPN)-RELATED THROMBOCYTOSIS

S. Verstovsek[1,*] M. Saltzman[2], S. Dakhil[3], A. Bessudo[4], R. Lyons[5], W. Jawien[6], D. Berenzon[7], R. Mena[8], P. Glidden[9], G. Choy[9], R. Laliberte[9], B. Hamilton[9]
[1]Leukemia Department, MD Anderson Cancer Center, Houston, [2]Innovative Medical Research of South Florida, Aventura, [3]Cancer Center of Kansas, Wichita, [4]California Cancer Associates for Research and Excellence, Encinitas, [5]Cancer Care Centers of South Texas/USONcology, San Antonio, [6]California Cancer Associates for Research and Excellence, Fresno, [7]Wake Forest University School of Medicine, Winston-Salem, [8]East Valley Hematology & Oncology Medical Group, Burbank, [9]Galena Biopharma, Inc., Portland, United States

Background: Despite advances in the diagnosis and management of MPNs, treatment of essential thrombocythemia (ET) has remained largely unchanged since the introduction of anagrelide in the US (1997) and Europe (2004). Anagrelide reduces platelet production by inhibition of megakaryocyte hypermaturation, and also inhibits cyclic AMP phosphodiesterase III. Common drug related adverse events (AEs; *e.g.*, headache, palpitations, fluid retention, etc.) might be due to this latter mechanism. As the marketed anagrelide product is an immediate release (IR) formulation with peak plasma levels that may exceed that needed for platelet reduction, an alternate formulation that modifies this pharmacokinetic (PK) profile may improve patient tolerability and treatment outcomes. This led to the development of a controlled-release (CR) formulation of anagrelide (GALE-401). To-date, 98 healthy subjects were enrolled among 5 Phase 1 clinical trials of anagrelide CR at doses ranging from 0.2 to 0.6 mg once or twice daily for up to 42 days. Anagrelide CR induced significant reductions in platelet counts that were not distinguishable from IR, despite C_{max} and AUC_{0-T} values that were 29% and 55% of IR. These trials supported the initiation of a Phase 2 study in MPN-related thrombocytosis, preliminary results for which are reported here.
Aims: The primary objective of the study was to estimate the overall platelet response rate (ORR). Secondary objectives included safety, tolerability, and pharmacokinetics (PK).
Methods: This is an open-label, single-arm, Phase 2 trial. Eligible subjects include those with chronic myelogenous leukemia (CML), polycythemia vera (PV), primary myelofibrosis (PMF) or ET, platelet count ≥600 K/μL, and not previously refractory to anagrelide. Anagrelide CR was given at a starting dose of 0.5 mg twice daily and individually titrated to maintain a target platelet count of 150 - 400 K/μL. Platelet response is defined as complete response (CR, ≤400 K/μL) or partial response (PR, ≤600 K/μL or ≥50% reduction from baseline), and maintenance of the reduction for at least 4 weeks. Safety evaluations include routine physical and laboratory evaluations. The PK profile is assessed at the starting dose, weekly sampling during dose titration, and at the final titrated dose level.
Results: Eighteen (18) subjects who provided written informed consent were enrolled, median age 65 yrs (range 40-80), 10 females/8 males, 13 ET, 4 PV, and 1 PV/ET. Prior treatments for thrombocytosis included hydroxyurea (n=8), anagrelide (8), and none (7). Mean platelet count decreased rapidly to <600 K/μL at 4 weeks, at which time the mean dose was 1.8 mg/day. To-date, the confirmed overall response rate is 67% (12/18) with 4 CR and 8 PR. A total of 151 AEs were reported, of which 69 were study drug related including headache (8 subjects); palpitations (4); abdominal pain, AST increased, and nausea (3 each); and diarrhea, fatigue, hypotension and tachycardia (2 each). Most related AEs were Grade 1-2 in severity. Study drug related serious AEs were reported for 2 subjects and included Grade 3 headache and Grade 3-4 cholestatic jaundice/increased creatinine. Six subjects discontinued treatment for reasons that included study drug related AE (2), subject request (2), investigator decision (1) and other (1). Plasma PK analyses are ongoing.
Summary and Conclusions: Anagrelide CR induced rapid platelet count reductions at daily doses and ORR as anticipated with the IR formulation. AEs were mostly Grade 1-2 in severity and consistent with anagrelide's known side effects, however additional dosing experience in the current trial or comparative controlled studies may be needed to further elucidate the safety profile. Study treatment is ongoing and 6-month data are being collected for analysis and presentation.

P672

SAFETY OF RUXOLITINIB IN PATIENTS WITH POLYCYTHEMIA VERA: RESULTS FROM THE CLINICAL TRIAL PROGRAM

S. Verstovsek[1,*] R. Mesa[2], B. Martino[3], J.-J. Kiladjian[4], M.M. Jones[5], S. He[5], D. Habr[6], I. Alecu[7], A.M. Vannucchi [8]
[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, [2]Department of Hematology/Oncology, Mayo Clinic Cancer Center, Scottsdale, AZ, United States, [3]Department of Hematology, Ospedale Bianchi-Melacrino-Morelli, Reggio Calabria, Italy, [4]Department of Hematology, Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [5]Incyte Corporation, Wilmington, DE, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States, [7]Novartis Pharma AG, Basel, Switzerland, [8]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: Polycythemia vera (PV) is a myeloproliferative neoplasm that is characterized primarily by erythrocytosis and an increased risk of thrombosis. To control blood counts and manage PV-related symptoms, some patients may require chronic therapy. The most common drug treatment is hydroxyurea (HU); however, some patients may develop unacceptable side effects or have an inadequate response to HU.
Aims: To evaluate the long-term safety of the JAK1/JAK2 inhibitor ruxolitinib (Rux) in the PV clinical trial program.
Methods: This analysis of Rux safety included data from 3 clinical trials: (1) a phase 2, single-arm, open-label study in patients who were resistant to or intolerant of HU (ClinicalTrials.gov identifier, NCT00726232); (2) RESPONSE, an ongoing, randomized, open-label phase 3 clinical trial (NCT01243944) com-

paring Rux with best available therapy (BAT) in patients who are resistant to or intolerant of HU; and (3) RELIEF, a randomized, blinded, phase 3b comparative trial (NCT01632904) of Rux *vs* HU in patients generally well controlled on HU but reporting symptoms. Data were pooled for Rux-treated patients from the 2 studies with HU-resistant/intolerant patients (phase 2 study and RESPONSE), including patients in RESPONSE who crossed over to Rux following BAT treatment.

Results: Overall, the HU-resistant/intolerant group (n=241) included 457 patient-years of exposure (median Rux exposure [range], 19.5 months [0.3-66.7 months]). The most common adverse events for patients treated with Rux who were HU-resistant/intolerant included diarrhea (8.7 per 100 patient-years of exposure), headache (8.5), and pruritus (7.4); most events were grade 1 or 2 (Table 1). Grade 3 or 4 thrombocytopenia and anemia each occurred in 3.7% of patients over the duration of follow-up. The rate of herpes zoster was 5.0 per 100 patient-years. Nonmelanoma skin cancer occurred at a rate of 2.8 per 100 patient-years (*vs* 2.7 per 100 patient-years in RESPONSE patients randomized to BAT during BAT treatment). There were 7 transformations to myelofibrosis during Rux treatment; 3 of these occurred after crossover from BAT. There were 2 transformations to acute myeloid leukemia (AML); 1 occurring after crossover. These rates of transformation to myelofibrosis and AML were consistent with those published for similar patient populations with PV (Fiannzi. *Blood* 2005;105:2664-70; Passamonti. *Am J Med* 2004;117:755-61; Alvarez-Larran. *Blood* 2012;119:1363-9). The thromboembolic event rate was 2.2 per 100 patient-years (*vs* 8.2 per 100 patient-years in RESPONSE patients randomized to BAT during BAT treatment). In the RELIEF trial, median exposure was 21.6 weeks in the Rux arm (n=54). Adverse events that occurred during the blinded phase were generally consistent with those observed in studies of patients who were HU-resistant/intolerant.

Table 1. Nonhematologic adverse events in ruxolitinib-treated patients who were resistant to or intolerant of HU.

	Patients With HU-Resistance/Intolerance* (n=241)	
	All Grades	Grade 3 or 4
Adverse Event,† n (rate per 100 patient-years of exposure)		
Diarrhea	40 (8.7)	0
Headache	39 (8.5)	2 (0.4)
Pruritus	34 (7.4)	1 (0.2)
Fatigue	32 (7.0)	2 (0.4)
Dizziness	31 (6.8)	0
Cough	30 (6.6)	0
Dyspnea	28 (6.1)	3 (0.7)
Weight increased	28 (6.1)	0
Constipation	26 (5.7)	1 (0.2)
Abdominal pain	25 (5.5)	2 (0.4)
Back pain	25 (5.5)	2 (0.4)
Pyrexia	25 (5.5)	2 (0.4)
Muscle spasms	25 (5.5)	1 (0.2)
Arthralgia	25 (5.5)	0
Herpes zoster	23 (5.0)	3 (0.7)
Nasopharyngitis	23 (5.0)	0

*Patients with HU-resistance/intolerance from (1) the phase 2 trial and (2) RESPONSE, including patients randomized to Rux and those who crossed over to Rux from BAT
†Nonhematologic adverse events with rates ≥5 per 100 patient-years

Summary and Conclusions: This long-term follow-up of Rux experience in the PV clinical trial program provides evidence that supports the safety and tolerability of Rux in patients who have an inadequate response to or are intolerant of HU.

Myeloproliferative neoplasms - Clinical 3

P673

EFFECT OF RUXOLITINIB ON MARKERS OF IRON DEFICIENCY: AN ANALYSIS OF THE RESPONSE TRIAL

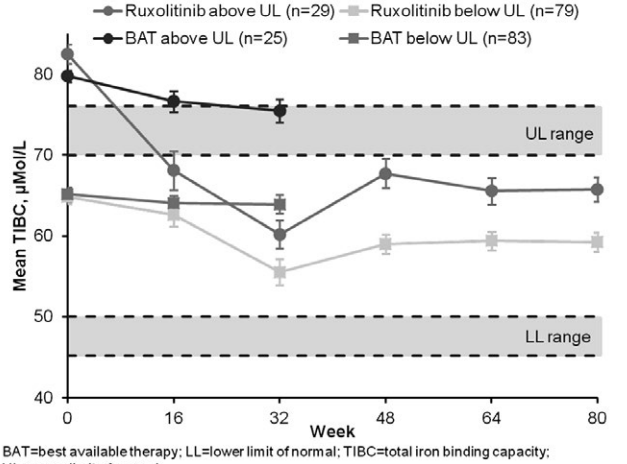
S. Verstovsek[1,*] C.N. Harrison[2], J.-J. Kiladjian[3], C. Miller[4], A.B. Naim[5], D.C. Paranagama[5], D. Habr[6], A.M. Vannucchi[7]
[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, [2]Haematology/Oncology and Cellular Pathology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [3]Department of Hematology, Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [4]Saint Agnes Cancer Institute, Baltimore, MD, [5]Incyte Corporation, Wilmington, DE, [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States, [7]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: Patients with polycythemia vera (PV) often rely on phlebotomy to control their hematocrit. Frequent phlebotomies may result in a state of iron deficiency, which can be associated with various complications, such as restless leg syndrome and cognitive dysfunction. The RESPONSE trial demonstrated that ruxolitinib lowers hematocrit and reduces the need for phlebotomy in patients with PV who have had an inadequate response to or are intolerant of hydroxyurea (HU).
Aims: A subanalysis of the RESPONSE trial data was conducted to evaluate the effect of ruxolitinib on markers of iron deficiency.
Methods: Total iron binding capacity (TIBC), ferritin, mean corpuscular volume (MCV), and serum iron were Total iron binding capacity (TIBC), ferritin, mean corpuscular volume (MCV), and serum iron were measured at baseline and over time in patients randomized to ruxolitinib and best available therapy (BAT); in the BAT group, these measures were assessed before and after crossover to ruxolitinib. Transferrin iron saturation (TS) was calculated based on observed iron and TIBC. Patients within each arm were stratified into 2 groups: patients with baseline values within the normal range and patients with baseline values outside of the normal range; this was determined for each patient based on the normal ranges for each of the study sites. Values outside of the normal ranges indicative of iron deficiency included TIBC above the upper limit of normal; and ferritin, MCV, serum iron, and TS below the lower limits of normal.

Table 1. Values for markers of Iron deficiency at baseline and week 32 in patients with evidence of iron deficiency at baseline.

Mean(SD)	Ruxolitinib (randomized)		BAT (randomized)	
	Baseline	Week 32	Baseline	Week 32
Ferritin, pMol/L	19.7 (8.0)	134.1 (99.2)	21.7 (7.2)	43.2 (64.0)
Serum Iron, µMoL/L	3.7 (1.2)	16.4 (7.5)	3.9 (1.1)	6.4 (5.4)
MCV, FL	70.3 (6.5)	81.1 (8.9)	70.6 (6.6)	73.1 (10.6)
TS,%	6.00 (2.9)	31.1 (14.9)	6.6 (3.4)	10.6 (9.6)
TIBC, Mol/L	82.5 (6.3)	60.2 (4.2)	79.8 (3.6)	75.5 (6.2)

Increases in ferritin, iron, MCV, and TS=improvement; decreases in TIBC=improvement.



BAT=best available therapy; LL=lower limit of normal; TIBC=total iron binding capacity; UL=upper limit of normal.
*Highest/lowest UL and LL based on cut offs across study sites. In patients with TIBC above the UL at baseline, mean TIBC improved (lowered) during ruxolitinib therapy to the normal range. Patient sample sizes in the legend represent the number of patients at baseline.

Figure 1. Mean (SE) total iron binding capacity over time for patients with baseline values above the upper limit and below the upper limit of normal*.

Results: The majority of patients (in both study arms) had laboratory values outside of normal limits at baseline: TIBC, n=54 (24.3%); ferritin n=141 (63.5%);

MCV, n=137 (61.7%); serum iron, n=181 (81.5%); MCV+iron, n=127 (57.2%); TS, n=197 (88.7%). Among patients with evidence of iron deficiency at baseline, use of iron supplementation was infrequent (<20% of patients) and balanced between treatment arms. Changes in TIBC over time are shown in Figure 1 and Table 1. In patients with elevated TIBC at baseline, mean TIBC improved (ie, lowered) to levels within the normal range during ruxolitinib treatment (in patients randomized to ruxolitinib and after crossover from BAT), but remained above the normal limit during BAT treatment. Consistent with these findings, ferritin, MCV, serum iron, and TS improved (ie, increased) in patients with low baseline levels during ruxolitinib therapy, but remained outside of the normal limits during BAT treatment (Table 1). Similar patterns were also observed when evaluating these markers by gender. Mean values for patients with normal iron status at baseline remained within normal ranges during ruxolitinib therapy.
Summary and Conclusions: In patients with PV who have had an inadequate response to or are intolerant of HU, normalization of 5 markers of iron deficiency was observed with ruxolitinib therapy, while in the BAT arm, there was little or no change in these parameters.

P674

RUXOLITINIB REDUCES JAK2P.V617F ALLELE BURDEN IN PATIENTS WITH MYELOFIBROSIS

M. Deininger[1], J. Radich[2], T. Burn[3], R. Huber[3], D. Paranagama[3], S. Verstovsek[4,*]
[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]Fred Hutchinson Cancer Research Center, Seattle, WA, [3]Incyte Corporation, Wilmington, DE, [4]The University of Texas, MD Anderson Cancer Center, Houston, TX, United States

Background: The *JAK2* c.1849G>T (p.V617F) mutation leads to constitutive activation of JAK2 and contributes to dysregulated JAK signaling in myeloproliferative neoplasms. COMFORT-I, a phase 3 study of ruxolitinib *versus* placebo in patients with intermediate-2 or high-risk myelofibrosis (MF), demonstrated rapid and durable reductions in splenomegaly and symptom improvement with ruxolitinib *versus* placebo.
Aims: This analysis was a long-term (maximum of 4 years) follow-up of COMFORT-I to determine if ruxolitinib, an oral JAK1/JAK2 inhibitor, continued to reduce allele burden in patients with the *JAK2*p.V617F mutation.
Methods: *JAK2*p.V617F-positive patients (n=236) were identified from the COMFORT-I dataset. Presence of this mutation was not an eligibility requirement of the trial; but for patients having baseline data demonstrating a *JAK2*p.V617F mutation, allele burden was assessed by genomic DNA isolation from peripheral blood at baseline and weeks 24, 48, 120, 144, 168, and 216. Allele burden was defined as the percentage of mutant allele relative to the total (wild-type+mutant). Complete molecular remission (CMR), partial molecular remission (PMR), and relapse of molecular remission were defined based on the IWGd spleen response (≥ 35% reduction from baseline to week 24) were also assessed with respect to *JAK2*p.V617F mutation.
Results: On average, allele burden decreased in ruxolitinib-treated patients and increased during placebo treatment. The mean/median (range) maximal change in the ruxolitinib randomized arm was −27%/−16% (−100%, 36%), and in patients who crossed over from placebo to ruxolitinib was −19%/−11% (−100%, 12%). Of the 28 patients (12%) achieving a > 50% decrease in allele burden, 20 achieved a PMR and 6 achieved a CMR, with median times to response of 22.2 and 27.5 months, respectively. Allele burden reductions were independent of baseline allele burden; patients with high and low allele burdens both had significant reductions. Patients were grouped into tertiles of maximal percentage allele burden reduction from baseline, with mean/median changes within tertile 1: −62.6%/−63.4%; tertile 2: −15.3%/−14.8%; and tertile 3: −0.5%/−2.2%. Patients with the largest decreases (tertile 1) had the shortest mean/median times from diagnosis at baseline (tertile 1: 36.8/15.2 mo; tertile 2: 52.5/21.7 mo; tertile 3: 44.8/22.1 mo). Comparison of clinical responses across tertile groups indicated that patients with greater allele burden decreases had a larger percent reductions in spleen volume (mean/median changes at week 24 for tertile 1: −41.2%/−45.2%; tertile 2: −38.3%/−37.1%; tertile 3: −23.4%/−22.7%) as well as a greater proportion of patients with a ≥ 35% decrease in spleen volume at week 24 (tertile 1: 63.9%; tertile 2: 55.6%; tertile 3: 31.4%). Even patients with smaller decreases in *JAK2*p.V617F allele burden (31.4% of 35 patients in tertile 3), as well as patients who were *JAK2*p.V617F-negative at baseline (27.5%), had spleen responses.
Summary and Conclusions: Patients treated with ruxolitinib continued to show reductions in allele burden independent of baseline allele burden with ongoing treatment up to 4 years. *JAK2*p.V617F reductions correlated with reductions in spleen volume; however, ruxolitinib is associated with marked spleen volume reductions regardless of mutation status. Patients with shorter disease duration had greater allele burden reductions, suggesting a potential benefit for earlier treatment.

P675

SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS WITH INTERMEDIATE-1-RISK MYELOFIBROSIS (MF) FROM AN OPEN-LABEL, MULTICENTER, SINGLE-ARM EXPANDED-ACCESS STUDY

P. Giraldo[1,*] F. Palandri[2], G.A. Palumbo[3], A. Zaritskey[4], E. Calistri[5], A. Skotnicki[6], T. Devos[7], D. Saavedra[8], M. Griesshammer[9], H.K. Al-Ali[10], R. Tavares[11], A.M. Vannucchi[12], V. Gupta[13], P. Raanani[14], B. Tannir[15], J. Ghosh[16], J. Perez Ronco[15], L. Foltz[17]

Almazof Federal Center for Heart, Blood, and Endocrinology, St. Petersburg, Russian Federation, [5]Ospedale Ca'Foncello di Treviso, Treviso, Italy, [6]Jagiellonian University, Krakow, Poland, [7]UZ Leuven, Gasthuisberg Campus, Leuven, Belgium, [8]Fundación Colombiana de Cancerología, Clínica Vida, Medellín, Colombia, [9]Johannes Wesling Clinic, Minden, [10]University of Leipzig, Leipzig, Germany, [11]Universidade Federal de Goiania, Goiania, Brazil, [12]University of Florence, Florence, Italy, [13]Princess Margaret Cancer Centre, Toronto, Ontario, Canada, [14]Rabin Medical Center, Petah Tikva, Israel, [15]Novartis Pharma AG, Basel, Switzerland, [16]Novartis Pharmaceuticals Corporation, East Hanover, United States, [17]St. Paul's Hospital, University of British Columbia, Vancouver, British Columbia, Canada

Background: RUX is a potent JAK1/JAK2 inhibitor that has demonstrated reductions in splenomegaly and MF-related symptoms and improved survival in patients (pts) with intermediate (Int)-2- and high-risk MF in the 2 phase 3 COMFORT studies. JUMP (JAK Inhibitor Ruxolitinib in MF Patients) is a phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with Int-1 MF. As of December, >2200 pts have enrolled in 25 countries.
Aims: To assess the safety and efficacy of RUX in a cohort of pts with IPSS Int-1 MF (N=163).
Methods: Pts with MF classified as high risk, Int-2 risk, or Int-1 risk with a palpable (≥5 cm) spleen were eligible. Starting doses were based on baseline platelet (PLT) counts (5 mg bid [≥50 to <100×10^9/L], 15 mg bid [100 to 200×10^9/L], or 20 mg bid [>200×10^9/L]) and were titrated during treatment. The primary endpoint was safety and tolerability of RUX. Additional analyses included changes in palpable spleen length and symptoms using the FACT-Lymphoma Total Score (FACT-Lym TS). The final analysis will be performed after all pts have completed 24 mo of treatment or ended due to commercial availability.

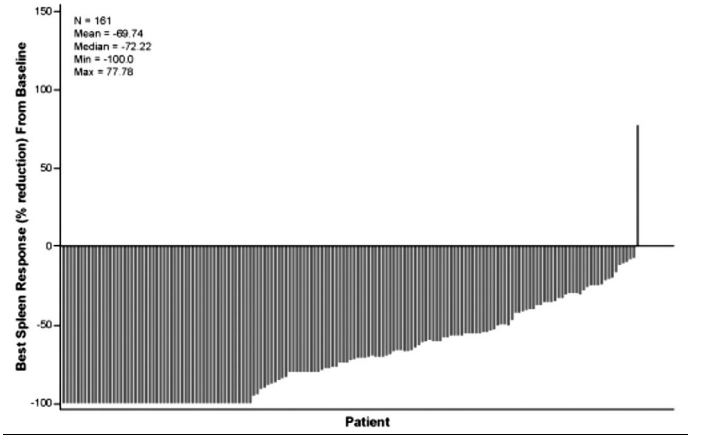


Figure 1. Best percentage reduction from baseline in spleen length by week 72.

Summary and Conclusions: JUMP is the largest study to date of pts with MF treated with RUX and includes the largest cohort of pts with Int-1-risk MF, a risk group not included in the COMFORT studies. Pts with Int-1-risk MF achieved spleen size reductions and symptom improvement consistent with those seen in the overall JUMP population. The safety and efficacy of RUX in Int-1 pts in JUMP is consistent with that in the phase 3 COMFORT studies.

P676

INTERIM ANALYSIS OF A PHASE II PILOT TRIAL OF RUXOLITINIB COMBINED WITH DANAZOL FOR PATIENTS WITH MYELOFIBROSIS SUFFERING FROM ANEMIA

K. Gowin[1], A. Dueck[2], J. Mascarenhas[3], R. Hoffman[3], S. Nagi Reddy[2], C. Reeder[2], J. Camoriano[2], V. Fauble[2], R. Tibes[2], K. Gano[2], V. Ghurye[2], P. Koenig[2], R. Mesa[2,*]
[1]Hematology and Medical Oncology, [2]Mayo Clinic Arizona, Scottsdale, [3]Mount Sinai, New York, United States

Background: Approximately 75% of myelofibrosis (MF) patients develop anemia during evolution of the disease process predicting decreased survival. Previous studies exploring the effect of danazol in the treatment of anemia in MF demonstrate responses in anemia of 30-55%. In prior randomized, controlled studies, ruxolitinib demonstrated improvements in splenomegaly, symptom burden, and even survival yet improvements in cytopenias were uncommon.
Aims: We designed a phase II multicenter pilot study to evaluate the efficacy and tolerability of combination therapy with ruxolitinib and danazol in MF patients with anemia.
Methods: This is a pre-planned interim analysis of a Simon optimum two-stage phase II trial, minimum of 10 and a maximum of 27 patients. Participants received

ruxolitinib 10mg (plat >75x10x9) BID or 5mg (plat <75x10x9) BID with tapered danazol up to 200mg orally TID. Dose escalation was allowed after completion of 28 days for lack of response or for disease progression. Patients without progression were continued for 6 cycles at 56 days each. Treatment modifications were based on adverse events (AE) including thrombocytopenia, leukopenia, and elevation in creatinine and transaminases. Treatment responses were evaluated every cycle by the IWG-MRT response criteria (Blood 2006). Patient reported outcome questionnaires (MPN-SAF and EORTC QLQ-C30) were administered at baseline, prior to treatment cycles, and at study discontinuation.

Results: *Patients:* Ten of the 14 evaluable patients enrolled (median age 70.5, range 57-78, M:F ratio 4:1) are included in this analysis. Eight patients had primary MF, 1 post essential thrombocytosis MF, and 1 post polycythemia vera MF. Jak2 V617F mutation was positive in 30%. All were DIPSS Int-2 or higher and 40% received an erythrocyte transfusion in the last month. Med baseline hemoglobin was 9.0 g/dL (range 8.3-12.4), med platelet level 172x10 (9)/L (range 56 - 346). Most (90%) had received prior therapy. *Tolerability:* Seven patients completed treatment, with med duration of treatment received of 45 days (range 24-287). Treatment discontinuation was due to progression of disease in 2 patients, unrelated AE in 1, stem cell transplant in 1, unrelated death in 1, comorbidity in 1, and decline of therapy in 1. Hematologic Grade 3 or >AE included anemia (60%), neutropenia (20%), and leukopenia/thrombocytopenia (10%). Non-hematologic Grade 3 or >AE included electrolyte abnormalities (20%), edema (10%), infection (10%), and intracranial hemorrhage (10%). *Efficacy:* Overall, treatment response per IWG-MRT response criteria included stable disease in 60%, clinical improvement in 30% (all spleen responses), and progressive disease in 10%. The median change in hemoglobin and platelet count from baseline was 0.60 g/dL (range -0.3-1.8) and 35.5x10(9)/L (range -143 - 140) respectively, however 7/10 (70%) had improvement at some point during treatment in level of anemia and/or thrombocytopenia. Among patients with a baseline and at least one post-baseline MPN-SAF TSS, 30% of patients had at least 50% improvement from baseline. Responses might have been confounded due to impact of prior therapies.

Summary and Conclusions: On interim analysis, an improvement in anemia and/or thrombocytopenia was observed in some treated patients however; the clinical improvement in 30% of patients treated was limited to spleen response. Combination therapy was well tolerated with no major incremental toxicity attributable to the addition of danazol. Maturation of data is needed to fully evaluate efficacy of ruxolitinib and danazol combination therapy for the treatment of MF associated anemia.

P677

BONE MARROW FIBROSIS BY WHO GRADE AND QUANTITATIVE IMAGE ANALYSIS IS REDUCED BY PRM-151 IN PATIENTS WITH MYELOFIBROSIS AND ASSOCIATED WITH IMPROVED BONE MARROW MORPHOLOGY AND INCREASED PLATELET COUNTS

E. Trehu[1], O. Pozdnyakova[2,*] R. Hasserjian[3], M. Salama[4], R. Mesa[5], L. Foltz[6], V. Gupta[7], J. Mascarenhas[8], E. Ritchie[9], R. Hoffman[8], R. Silver[9], M. Kremyanskaya[8], H. Kantarjian[10], J. Gotlib[11], S. Verstovsek[10]
[1]Research and Development, Promedior, Inc., Lexington, [2]Pathology, Brigham and Women's Hospital, [3]Pathology, Massachusetts General Hospital, Boston, [4]Pathology, University of Utah, Salt Lake City, [5]Hematology, Mayo Clinic, Scottsdale, United States, [6]Hematology, St. Paul's Hospital, Vancouver, [7]Hematology, Princess Margaret Hospital, Toronto, Canada, [8]Hematology, Mount Sinai Medical Center, [9]Hematology, Weill Cornell Medical Center, New York, [10]Leukemia, MD Anderson Cancer Center, Houston, [11]Hematology, Stanford Cancer Institute, Stanford, United States

Background: PRM-151 (PRM) is a recombinant form of Pentraxin-2, an endogenous human protein that acts at sites of tissue damage, inducing macrophage differentiation to prevent and reverse fibrosis. 27 patients (pts) with Primary Myelofibrosis (MF), post-Polycythemia Vera MF, or post-Essential Thrombocythemia MF and ≥Grade 2 MF received PRM-151 10 mg/kg IV QW (n=8) or Q4W (n=7), or ruxolitinib plus PRM-151 10 mg/kg IV QW (n=6) or Q4W (n=6).

Aims: This study investigates the reduction of BM (BM) fibrosis by quantitative image analysis and WHO MF grading, and the changes in BM fibrosis and histotopography in pts treated with PRM-151.

Methods: Morphologic analysis was performed on serial BM specimens from 25 pts: 4 at baseline (BL) and 12 weeks, 9 at BL, 12 and 24 weeks, 3 at BL, 12, 24, and 36 weeks, and 8 at BL, 12, 24, 36, and 48 weeks. Two hematopathologists blinded to treatment assessed reticulin grade, collagen quantity, osteosclerosis quantity, cellularity, megakaryocytic morphology and topography, myeloid to erythroid (M:E) ratio and presence of erythroid islands. Pts were divided into fibrosis responders by morphologic analysis (FR: ≥1 grade decrease or stable grade 1 at the last follow-up) and non-responders (FNR: worsened grade or persistent grades 2 or 3 at the last follow-up), and platelet (PLT) responders (PR: ≥12 week doubling or normalization in PLT in pts with baseline PLT count <100x10^9/L and/or PLT transfusion independence in pts requiring ≥2 PLT transfusions in prior 12 weeks) and PLT non-responders (PNR). Computer assisted image analysis (CIA) was performed on whole slide scans from serial BM specimens from 26 pts at the same timepoints as the morphologic analysis (1 additional pt at BL and 12 weeks) for objective quantification of overall fibrosis level and osteosclerosis of all post-treatment samples compared to baseline samples. Area occupied with bone trabeculae (% of total core biopsy) and reticulin fibers (% of hematopoietic areas excluding the fat) were calculated. Values of bone and reticulin fibers were compared across serial sections of each patient to determine the trend.

Results: At baseline 2 patients had WHO MF-1, 9 pts - MF-2 and 14 pts - MF-3. There were 9 FR and 16 FNR; the baseline fibrosis grades in the FR group were 1 pts - MF-1, 3 pts - MF-2, and 5 pts - MF-3. No differences in BM morphology between FR and FNR or between PR and PNR groups were seen at the baseline. The FR group had reduced collagen quantity (p=.007) and a trend toward reduced osteosclerosis (p=0.1) at the last timepoint compared to the FNR group. CIA revealed statistically significant decreased fibrosis in all treated samples (p=0.003) but no significant difference in 12 weeks samples (p=0.28) in treated patients compared to baseline (Figure 1). FR pts showed a trend for fewer paratrabecular megakaryocytes (44% *vs* 81%, p=0.08). There were 8 PR and 17 NPR. PR was associated with normalization of the M:E ratio (p=0.03) and borderline association with fibrosis reduction (p=0.09).

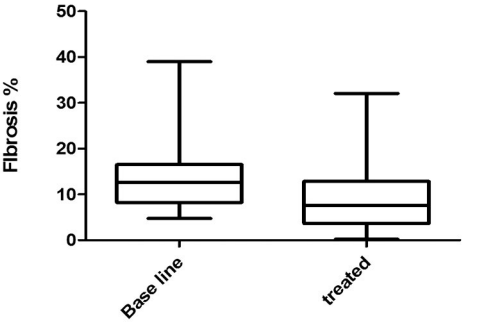

Figure 1. Fibrosis reduction by quantitative image analysis at baseline and post-baseline (p=.0031).

Summary and Conclusions: Reduction in BM fibrosis and improved PLT counts in pts treated with PRM-151 appear to be associated with reduction in collagen and osteosclerosis, improvements in megakaryocytic topography, and normalization of the M:E ratio. Post treatment fibrosis reduction is confirmed by CIA analysis and may be a useful adjunct to conventional morphologic-based grading, as it may more accurately assess fibrosis heterogeneity following therapy. Studies of intra- and inter-patient differences between CIA and morphologic analyses are in progress.

Background: Mastocytosis is a rare disease characterized by abnormal proliferation and accumulation of mast cells (MC) in several organs and tissues (skin, bone marrow, liver, gastrointestinal tract, lymphnodes). WHO classification includes mastocytosis into cutaneous mastocytosis (CM) and systemic mastocytosis (SM) that is subdivided in indolent (ISM), "smoldering" (SSM),

systemic mastocytosis-associated hematologic non-mast disease (SM-AHN-MD), aggressive SM (ASM), mast cell leukemia (MCL), solitary mastocytoma. Difference in incidence of CM and SM correlates with age at onset. While the diagnosis of SM requires the presence of multifocal dense mast cell infiltrates in one or multiple extra-cutaneous organs (mostly bone marrow, due to the origin of MCs), mastocytosis encompasses a wide range of clinical entities, extremely heterogeneous for clinical course and prognosis. Due to its heterogeneity, mastocytosis is a multidisciplinary disease. Concerns remain about the possible misdiagnosis or lack of identification of different subtypes of mastocytosis due to different diagnostic procedures between various specialties. For example, in pediatric cases, invasive procedures are not mandatory considering the good prognosis.

Aims: The Italian Mastocytosis Registry was set up in 2009 to collect data of mastocytosis patients at a multidisciplinary and national level.

Methods: Patient data are being routinely collected after written informed consent in 18 Italian centers. An on-line database (www.registroitalianomastocitosi.it) has been created for data collection. Patients' features at onset of disease according to age, type of mastocytosis and specialty are shown in Table 1.

MCD: mast cell disease; CM: cutaneous mastocytosis; SM: systemic mastocytosis.

Results: Data on 431 patients have been collected from 5 hematology centers (97 patients) and 11 multidisciplinary centers (334 patients). Clinical evaluations were available at onset of disease in 134 patients. At diagnosis, 87% of these 134 patients presented systemic symptoms; 89 (66%) presented cutaneous symptoms (CM: 35/63 (56%) ≤11 yrs, 3/3 (100%) 12-19 yrs, 46/56 (82%) ≥20 yrs; SM: 2/2 (100%) ≤11 yrs, 2/2 (100%) 12-19 yrs, 25/36 (69%) ≥20 yrs). 83 (62%) patients were asymptomatic at onset. Of these, 28 (34%) presented symptoms in a median time of 15 months (range 3-271). SM was reported in 143 (33%) cases: 2 at ≤11 yrs, 3 at 12-19 yrs, 138 at ≥20 yrs. Of these, 65 (45%) had progressed from a CM: 0 (0%) at ≤11 yrs, 1 (2%) at 12-19 yrs, 64 (98%) at ≥20 yrs. First diagnosis was made <18 years of age in 183 (42%) patients. Table 2 shows therapeutic options (total exceeds 100% because therapy combination is allowed). 94 of 431 patients were evaluated for both bone marrow percentage of mast cell infiltrate and tryptase serum level and there was a significantly positive correlation between the two (Spearman rank correlation=0.81; p=0.005). Number of bone marrow biopsies performed was compared between hematology and other multidisciplinary centers and no statistical difference was observed (p=0.345). We also compared the number of positive bone marrow biopsies between the two types of centers; again, there was no statistical difference (p=0.248).

Summary and Conclusions: The on-line database is a useful tool for data collection at a national level. In spite of the complexities of the multidisciplinary context, our study confirms a homogeneous approach with a high level of knowledge among Centers in terms of diagnostic algorithm and treatment, in keeping with the recent guidelines

P679

HIGH RATE OF DISCORDANCY REGARDING DIAGNOSIS AND SUBCLASSIFICATION OF SYSTEMIC MASTOCYTOSIS ON BONE MARROW BIOPSIES BETWEEN INITIAL LOCAL AND CENTRALIZED REFERENCE HEMATOPATHOLOGY

M. Jawhar[1,*] J. Schwaab[1], N. Naumann[1], H.-P. Horny[2], K. Sotlar[2], W.-K. Hofmann[1], A. Fabarius[1], G. Metzgeroth[1], A. Reiter[1]

[1]Department of Hematology and Oncology, University Hospital Mannheim, Mannheim, [2]Department of Pathology, Ludwig-Maximilians-University, Munich, Germany

Background: Advanced systemic mastocytosis (SM) is associated with a poor prognosis. The median overall survival is approximately 0.5, 2 and 3.5 years in patients (pts.) with mast cell leukemia (MCL), SM and associated non-mast cell lineage hematologic neoplasm (SM-AHNMD) and aggressive SM (ASM), respectively. AHNMD is usually a myeloid neoplasm such as chronic myelomonocytic leukemia (CMML), myelodysplastic/myeloproliferative neoplasm unclassified (MDS/MPNu) or chronic eosinophilic leukemia (CEL). A thorough histologic and immunohistochemical examination, *e.g.* tryptase, CD117 (KIT) and CD25, of the bone marrow (BM) is required for appropriate diagnosis and subclassification including markers for characterization of AHNMD, *e.g.* CD34 for blasts or CD14 for monocytes. ASM is diagnosed through the presence of C-findings, *e.g.* cytopenias, liver function abnormalities, splenomegaly, ascites, hypoalbuminemia, weight loss, or osteolyses. The *KIT* D816V mutation is present in >80% of SM pts. and plays a pivotal role in the pathogenesis of SM.

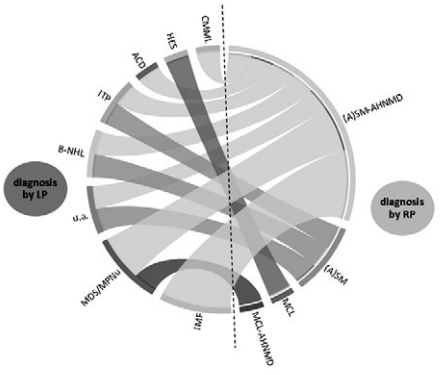
Aims: We sought to retrospectively evaluate the concordance of diagnosis and subclassification of SM between two consecutively performed BM trephine biopsies.

Methods: Within the ´German Registry on Disorders of Eosinophils and Mast Cells´, we retrospectively analyzed 65 pts. (median age 64 years, range 40-85; male 65%) who had two consecutive diagnostic BM trephine biopsies (median time between biopsies 4 months, range 0-71). The initial biopsy was evaluated by a local pathologist (LP) while *KIT* D816V$^+$ SM was diagnosed in the subsequent biopsy in all 65 pts. by reference pathologists (RP) of the 'European Competence Network on Mastocytosis (ECNM)'.

Results: According to the WHO classification, final diagnoses by RP were SM or aggressive SM [(A)SM (n=27)], (A)SM-AHNMD (n=34), MCL (n=3) and MCL-AHNMD (n=1). In peripheral blood, the serum tryptase level (normal value <11.4 ng/ml) was elevated in 59/59 (median 132 ng/ml, range 12-1690) pts. and *KIT* D816V was detectable in 57/60 (95%, median allele burden 26%, range 1-76) pts. in 15/65 (23%) pts., the initial diagnoses by LP were inconsistent and included primary myelofibrosis (n=3), MDS/MPNu (n=3), indolent B-cell lymphoma (n=2), autoimmune thrombocytopenia (n=2), CMML (n=1), hypereosinophilic syndrome (n=1), anemia of chronic disease (n=1) or without pathological findings (n=2). Twelve of those 15 (80%) pts. with discordant diagnosis had (A)SM-AHNMD with AHNMD being subclassified as MDS/MPNu, n=6; CMML, n=3; MDS, n=2; CEL, n=1) (Figure 1). Immunohistochemical markers for qualitative and quantitative assessment of MCs, *e.g.* CD117 (KIT) or CD25, were only used in 43/65 (66%) and 24/65 (37%) cases, respectively. In 50 concordantly diagnosed patients (median time between biopsies 6 months, range 1-8), the extent of MC infiltration was quantified by LP in only 34/50 (68%, median 20%, range 5-90) pts., subclassification of SM was not consistent because AHNMD was not diagnosed in 9/50 (18%) pts. and *KIT* D816V mutation anaylsis was suggested or performed in only 13/50 (26%) correctly diagnosed SM pts.

Summary and Conclusions: Adequate diagnosis and subclassification of SM warrants an evaluation of BM histology/immunohistochemistry by reference hematopathologists in combination with molecular genetics (*KIT* D816V) and clinical parameters. A more frequent evaluation of serum tryptase would help

to prevent misdiagnosis.



Circos diagram: pairwise linking between diagnosis assigned by local pathologist (LP, left) vs. reference pathologist (RP, right). The width of the ribbon/column correlates to the relative frequency of individual diagnosis. Systemic mastocytosis (SM) or aggressive SM, (A)SM; (A)SM with associated clonal hematologic non-mast cell lineage disease, (A)SM-AHNMD; mast cell leukemia, MCL; idiopathic myelofibrosis, IMF; myelodysplastic/myeloproliferative neoplasm unclassified, MDS/MPNu; autoimmune thrombocytopenia, ITP; B-cell non-Hodgkin lymphoma, B-NHL; chronic myelomonocytic leukemia, CMML; hypereosinophilic syndrome, HES; anemia of chronic disease, ACD; without pathological findings, u.a.

P680

CLINICAL AND MOLECULAR CHARACTERISTICS OF PATIENTS WITH SYSTEMIC MASTOCYTOSIS AND ASSOCIATED ACUTE MYELOID LEUKAEMIA

S. Kreil[1,*] J. Schwaab[1], M. Jawhar[1], S. Schnittger[2], H.-P. Horny[3], N.C. Cross[4,5], W.-K. Hofmann[1], A. Reiter [1]

[1]Department of Hematology and Oncology, University Hospital Mannheim, Mannheim, [2]Münchner Leukämielabor, [3]Department for Pathology, Ludwig-Maximilians-Universität, Munich, Germany, [4]Wessex Regional Genetics Laboratory, Salisbury, [5]Human Genetics, University of Southampton, Southampton, United Kingdom

Background: In systemic mastocytosis (SM), the most aggressive clinical course has been reported from aggressive SM (ASM) and mast cell leukaemia (MCL) with median survival times of 2-3 years and less than 6 months, respectively. A significant proportion of patients with indolent SM (ISM), ASM or MCL may present with an associated haematological non-mast cell lineage disease (AHNMD) which most commonly represents chronic myelomonocytic leukaemia (CMML), myelodysplastic/myeloproliferative neoplasm unclassified (MDS/MPN-U), myeloproliferative neoplasm unclassified (MPN-U) or chronic eosinophilic leukaemia (CEL). Very rarely, an associated acute myeloid leukaemia [(A)SM/MCL-AML] is diagnosed which can be either *de novo* or secondary, *e.g.* evolving from CMML, MDS/MPN-U, MPN-U or CEL. A *KIT* D816V mutation is present in >90% of patients with advanced SM and plays a pivotal role in its pathogenesis. However, recent data have suggested that additional mutations, *e.g.* in *TET2*, *SRSF2*, *ASXL1* or *RUNX1* etc., are detectable at variable frequencies in >80-90% of patients with (A)SM/MCL-AHNMD (Schwaab *et al.*, Blood 2013).

Aims: To analyse the clinical presentation, genetic profile, treatment and prognosis of (A)SM/MCL-AML.

Methods: Retrospective analysis of 11 patients (male, n=6; female, n=5) with SM-AML recruited within the "German Registry on Disorders of Eosinophils and Mast Cells".

Results: SM was diagnosed prior to AML (n=8), concomitantly with AML (n=1) or due to lack of durable remission following intensive chemotherapy of AML (n=2).The median age at diagnosis of SM and AML was 55 years (range 26-78) and 62 years (range 27-75), respectively. The subtype of SM was ASM (n=9) or ISM (n=2) while AML was *de novo* (n=6) or secondary (CMML, n=3; MPN-U, n=2, MDS/MPN-U, n=1). At time of diagnosis of AML, cytogenetic analysis of 6 patients with available material/data revealed a complex karyotype (n=1), monosomy 7 (n=1), trisomy 8 (n=1) or a normal karyotype (n=3). The KIT D816V mutation was identified in 10 of 11 (91%) patients and additional mutations in 8 of 8 (100%) patients with available material. The number of additional mutations in individual patients was 1 (n=3), 2 (n=2) and >2 (n=3). The most frequently identified mutations included *RUNX1* (n=4), *ASXL1* (n=3), *SRSF2* (n=3), and *TET2* (n=2). Ten patients received intensive chemotherapy according to disparate AML study protocols (*e.g.* daunorubicin/ara-C or mitoxantrone/high-dose ara-C). Seven patients achieved a complete remission. Two patients died as consequence of treatment or disease-related complications 2 and 12 months after start of chemotherapy. Six patients received an allogeneic stem cell transplantation (ASCT) immediately after chemotherapy (n=1), in first remission (n=3) or following relapse (n=2) after remission. Four patients died a median of 13 months (range 1-36) after ASCT while 2 patients are alive 9 and 29 months, respectively, after ASCT. Of the non-transplanted patients (n=5), 4 patients died within the first 13 months following diagnosis of AML while only one patient is alive 70 months after diagnosis and conventional treatment of AML. The single patient without intensive chemotherapy died 4 months after diagnosis of AML. Overall, median survival after diagnosis of SM was 3 years (range 0.7-16.6) and 13 months (range 2-74) after diagnosis of AML, respectively.

Summary and Conclusions: SM-AML is a rare entity with a very poor prognosis. Diagnosis of SM may be missed when presenting simultaneously with AML. The high frequency of additional mutations suggests a pathogenetic role for the aggressive clinical course and poor prognosis. Long-term survival is more likely in patients achieving complete remission following intensive chemotherapy with or without subsequent ASCT.

Indolent Non-Hodgkin lymphoma - Clinical

P681

VALIDATION OF THE SIMPLIFIED PROGNOSTIC SCORE FOR SMZL OF THE SMZLSG (SMZL STUDY GROUP) IN A SERIES OF PATIENTS TREATED WITH RITUXIMAB MONOTHERAPY, AND LONG TERM OUTCOME OF RITUXIMAB RESPONDERS

C. Kalpadakis[1,*] G. Pangalis[2], M. Angelopoulou[3], S. Sachanas[2], F. Kontopidou[4], M. Moschogiannis[2], M. Ximeri[1], A. Dimitrakopoulou[5], P. Tsirkinidis[2], M.-C. Kyrtsonis[6], T. Tzenou[6], X. Yiakoumis[2], E. Koulieris[2], P. Panayiotidis[6], H. Papadaki[1], T. Vassilakopoulos[3]
[1]Hematology, University of Crete, Heraklion, [2]Hematology, Athens Medical Center-Psychikon Branch, [3]Hematology, [4]2nd Department of Internal Medicine, University of Athens, [5]Immunology Laboratory, Laikon General Hospital, [6]1st Department of Propedeutics, University of Athens, Athens, Greece

Background: Rituximab monotherapy is a highly effective therapy for SMZL. However, there is a subset of patients not responding to rituximab with compromised survival. Several prognostic factors have been proposed without reproducible results.
Aims: To assess the long term outcome of rituximab treated patients and validate the reproducibility of the simplified risk stratification score of the SMZLSG in a series of SMZL patients treated homogeneously with rituximab monotherapy as a first line therapy.
Methods: The study population included 76 patients who had received rituximab as 1st line therapy for SMZL between 2003 and 2014. The prognostic system is based on the on the combination of 4 factors: haemoglobin levels <9.5 g/dL, platelet counts <80×10^9/L, elevated LDH and the presence of extrahilar lymphadenopathy (outside the splenic and hepatic hilum). All variables were considered to have the same statistical weight and were assigned the same value of one point each. The prognostic score was calculated as the sum of the 4 variables (0 or 1; range 0-4). Three risk groups were identified: low (A) for patients with 0 points, intermediate (B) for patients with 1 or 2 points and a high risk group (C) for patients with 3 or 4 points. The Kaplan-Meier method was used to estimate survival and the log-rank test to compare survival curves.

Table 1. Main characteristics, stratification and outcome of our patients.

Characteristics	At Diagnosis	At Treatment Initiation
	# (%)	
Male Sex	33/76 (43)	33/76 (43)
Median Age, years (Range)	65 (41-91)	65 (41-91)
Hb <9,5 G / dl	14/76 (18)	16/76 (21)
PLTS <80 × 10^3 / µl	6/76 (8)	9/76 (12)
LDH> N	23/74 (31)	28/74 (38)
Extrahilar Lymphadenopathy	20/75 (27)	21/75 (28)
Group A	34/73 (47)	27 (37)
Group B	36/73 (49)	42 (58)
Group C	3/73 (4)	4 (5)
7-Year PFS (%)		
Group A 83		
Group B 48		
Group C 50		

Results: Among 76 patients with SMZL included in the present study, 73 had complete data for all four variables and were therefore analyzed for the prognostic system (Table 1). The median age was 65 years (45-95). The main clinical characteristics and the stratification of our patients in the three 3 groups are presented in table. Among the 76 SMZL patients, 3 did not respond to or progressed during rituximab treatment, for an overall response rate of 96%. At 1, 2, 3, 4, 5, and 7 years, PFS was 95%, 88%, 83%, 74%, 69%, and 69% respectively. At the time of this analysis 6 deaths were recorded, 3 due to the disease and 3 urelated. The 7-year overall survival and disease-specific survival were 87% and 91% respectively. According to the simplified prognostic score the stratification of our patients in the three risk groups at treatment initiation were as follows: 27/73 (37%) were classified into group A, 42/73 (58%) into group B and 4/73 (5%) into group C. 7-year PFS were 83% for group A, 48% for group B and 50% for group C (p=0.051). Difference in 7-year PFS was more prominent when groups B and C were analyzed together (7-year PFS for group B+C was 49% *vs* 83% group A, p=0.02). In order to evaluate long term outcome of rituximab responders, 24 patients who had received rituximab and remained in remission for ≥5 years were analyzed. The 5-year PFS was 96%. At a further median time of 24.5 months (range, 4-72) beyond 5 years, 22 patients still remain in remission, while two relapsed at 6 and 62 months, respectively. The subsequent 5-year PFS (10 years post-treatment) was 96%.
Summary and Conclusions: This study validates the applicability of the SMZLSG prognostic system regarding PFS, in a series of 73 SMZL patients homogeneously treated with Rituximab monotherapy. The long-term disease-specific survival exceeded 90%. This study confirms the efficacy of Rituximab as first line treatment in SMZL and demonstrates the potential for a long-term disease control, beyond the initial 5 years, in a substantial patient subgroup.

P682

INCIDENCE OF TRANSFORMATION IN FOLLICULAR LYMPHOMA: MULTICENTRE RETROSPECTIVE ANALYSIS OF THE SPANISH GROUP OF LYMPHOMA AND AUTOLOGOUS STEM-CELL TRANSPLANTATION (GELTAMO)

S. Alonso[1,*] M. Alcoceba[1,^] L. Magnano[2,^] M. Garcia-Alvarez[1], M. Andrade[3], G. Rodrigue[4], F. García-Pasarolls[5], A. Salar[5], M.J. Terol[6], E. Vega[7], C. Grande[7], E. Pardal[8], A. Martin[1], A. Lopez-Guillermo[2,#] D. Caballero[1,#]
[1]Hematologia, Hospital Universitario de Salamanca, Salamanca, [2]Hematologia, Hospital Clinic, Barcelona, [3]Hematologia, Hospital Miguel Sevet, Zaragoza, [4]Hematologia, Hospital Virgen del Rocio, Sevilla, [5]Hematologia, Hospital del Mar, Barcelona, [6]Hematologia, Hospital Clinico de Valencia, Valencia, [7]Hematologia, Hospital 12 de Octubre, Madrid, [8]Hematologia, Hospital Virgen del Puerto, Plasencia, Spain
^*Equal contribution;* [#]*Equal senior contribution.*

Background: Follicular lymphoma (FL) may, over time, transform into an aggressive lymphoma, usually diffuse large B-cell lymphoma (DLBCL). Transformed follicular lymphomas (tFL) have a worse prognosis due to poorer response to treatment than primary DLBCL. The incidence of transformation is estimated in ~3% per year, although it varies largely between different studies (24%>70% overall). These differences are mainly due to different criteria to define tFL, to lack of evidence of tFL by biopsy, absence of clonality studies discarding secondary *de novo* NHL, studies performed in the pre-Rituximab era, or different follow-up times among studies. With all this pitfalls, the actual incidence of transformation remains an open question.
Aims: The aim of the present study is to analyse the incidence and prognostic impact of transformation in patients with FL in a large retrospective series of the Spanish group of Lymphomas (GELTAMO).
Methods: A total of 1096 patients (grade I, II, and IIIa) from 8 Spanish centres diagnosed of FL between 2000 and 2010 were included in the study. Data were obtained from the database of centres willing to participate in this study. True tFL (FL to DLBCL) were recorded. Composite FL+DLBCL, discordant tFL (FL in bone marrow and DLBCL in adenopathy or *viceversa*), and downgrading tFL (DLBCL at diagnosis and relapse of FL) were excluded from the preliminary analysis. This study was approved by the Salamanca University Hospital Ethic Committee.
Results: Seventy-one patients (median follow up of 6 years) were transformed to DLBCL (6,5%). Cumulative incidence of transformation at 5, 10, and 15 years was of 5%, 8%, and 14%, respectively. Median time to transformation was 30 months, ranged 3-150. Considering survival from diagnosis of FL, tFL patients had a shorter OS than non-transformed (20% *vs* 68%, p<0,0001). Most of the tFL patients (92%) have previously received treatment for FL, 56% of them with Rituximab. Median number of treatment lines before transformation was 2 (1-6). Patients receiving Rituximab as first line therapy showed decreased time to transformation at 15 years (10% *vs* 19%, p=0.025). Other factors influencing risk of tFL included no response to first line therapy, age at diagnosis >60 years, FLIPI, and Ann Arbor stage. Consolidation therapy with autologous transplant for tFL showed an increase in OS (67% *vs* 8%, p=0.001). However, these results should be confirmed in prospective studies.
Summary and Conclusions: High risk FLIPI, Ann Arbor stage III-IV, age >60 years, not use of Rituximab in first line therapy, and response to first line have shown to predispose to a higher risk of transformation. Autologous transplantation could have a benefit in terms of OS in transformed patients. Effort should be made in order to clarify criteria for transformation, and biological studies on tumoral samples at diagnosis and at transformation will help to determine pathogenesis of transformation in helping to design clinical trials with new molecules based on molecular characteristics of transformation.

P683

PROSPECTIVELY DEFINED TRIAL- (N=13) AND PATIENT- (N=3837) LEVEL ANALYSIS OF COMPLETE RESPONSE RATES AS SURROGATE END-POINTS FOR PROGRESSION-FREE SURVIVAL (PFS) IN FIRST-LINE FOLLICULAR LYMPHOMA (FL)

D. Sargent[1,*] Q.S. Shi[1], S. De Bedout[2], C. Flowers[3], N. Fowler[4], T. Fu[5], A. Hagenbeek[6], M. Herold[7], E. Hoster[8], J. Huang[9], E. Kimby[10], M. Ladetto[11], F. Morschhauser[12], T. Nielsen[13], K. Takeshita[5], N. Valente[9], U. Vitolo[14], E. Zucca[15], G. Salles[16]

[1]Mayo Clinic, Rochester, United States, [2]Celgene, Boudry, Switzerland, [3]Winship Cancer Institute, Emory University, Atlanta, [4]MD Anderson Cancer Center, Houston, [5]Celgene, Summit, United States, [6]Dept. of Hematology, Academic Medical Center, Amsterdam, Netherlands, [7]HELIOS Klinikum, Erfurt, [8]Klinikum der Universitaet Muenchen, Munich, Germany, [9]Genentech, San Francisco, United States, [10]Karolinska Institute, Stockholm, Sweden, [11]Azienda Ospedaliera Santi Antonio e Biagio e Cesare Arrigo, Alessandria, Italy, [12]Lille University Hospital Center, Lille, France, [13]Roche, Basel, Switzerland, [14]A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy, [15]Istituto Oncologico della Svizzera Italiana, Bellinzona, Switzerland, [16]Hospices Civilis de Lyon, Université Lyon-1, Lyon, France

Background: Current first-line treatments for FL provide prolonged disease control (median PFS ~7 years). Thus, studies evaluating first-line treatment options based on the accepted regulatory endpoint of PFS require extended patient follow-up, increasing the challenges associated with clinical development of novel treatments by prolonging the evaluation process.
Aims: The Follicular Lymphoma Analysis of Surrogacy Hypothesis (FLASH) group conducted a prospectively planned meta-analysis with individual patient data (IPD) to evaluate whether the treatment effect on clinical endpoints at early landmarks, for example, complete response rate(s) at 24 (CR24) or 30 months (CR30), could accurately predict treatment effect on PFS.
Methods: Randomized controlled trials testing first-line treatments in FL, published after 1990, with available IPD were eligible. Association between CR rates and PFS was assessed at both the trial and patient level. Treatment effects on PFS and binary CR endpoints were quantified by hazard ratios (HRs) and odd ratios (ORs), respectively. The trial-level correlation of CR rate with PFS was evaluated using linear regression (R^2_{WLS}) and copula bivariate (R^2_{Copula}) models. Prespecified criteria for establishing surrogacy required either R^2_{WLS} or R^2_{Copula} ≥0.80 with a lower bound of the 95% confidence interval (CI) >0.60, and neither <0.70. The patient-level association between CR status (at 24 and 30 months) and PFS was assessed using a stratified Cox model with a landmark approach and by the global OR using a bivariate copula model. The minimum treatment effect on CR needed to predict a significant PFS difference was calculated.
Results: Of 13 eligible randomized first-line trials, 8 explored induction and 5 explored maintenance regimens; IPD was available for 3837 patients (Table 1). Nine trials included an experimental arm exploring a rituximab-based regimen. The prespecified threshold for CR30 surrogacy was met: R^2_{WLS} was 0.88 (95% CI, 0.77-0.96) and R^2_{Copula} was 0.86 (95% CI, 0.72-1.00), demonstrating that treatment effect on CR30 predicted effect on PFS in previously untreated FL. A minimum 10% improvement in CR30 over a control rate of 50% predicted a significant improvement in PFS. Multiple sensitivity and IPD surrogacy analyses supported the robustness of the primary CR30 analysis. Treatment effects on CR24 also met prespecified surrogacy criteria for R^2_{WLS} 0.84 (95% CI, 0.63-0.95), but not for R^2_{Copula}; CR24 analyses were influenced by one outlier study.

Table 1. Correlation of CR30 and CR24 with progression-free survival.

		Trial-Level Surrogacy		Patient-Level Surrogacy (Copula)
	N of Trials (N of pts)	R^2_{WLS}[a] (95% CI)	R^2_{Copula}[a] (95% CI)	Global OR[b] (95% CI)
CR30				
Overall	13 (3837)	0.88 (0.77-0.96)	0.86 (0.72-1.00)	11.84 (10.03-13.65)
With/Without rituximab				
Rituximab trial	9 (2851)	0.85 (0.62-0.97)	0.80 (0.56-1.00)	11.08 (9.13-13.03)
Non-rituximab trial	4 (986)	0.91 (0.05-1.00)	0.96 (0.90-1.00)	14.40 (9.96-18.84)
Treatment setting				
Induction trial	8 (2207)	0.89 (0.75-0.98)	0.89 (0.74-1.00)	10.34 (8.27-12.41)
Maintenance trial	5 (1630)	0.93 (0.84-1.00)	0.89 (0.71-1.00)	14.14 (10.82-17.46)
CR24				
Overall	11 (2728)	0.84 (0.63-0.95)	0.67 (0.35-0.99)	8.27 (6.82-9.71)

Note: Some studies were excluded because of high proportion of missing CR data.
Abbreviations: CI, confidence interval; CR, complete response; CR30, complete response rate at 30 mo; CR24, complete response rate at 24 mo; OR odds ratio; pts, patients.
[a]R^2 values range from 0 (no association) to 1 (perfect prediction).
[b]**Global odds ratio** represents the OR for progression-free survival status beyond a particular time point comparing patiehts with CR versus non-CR.

Summary and Conclusions: This large IPD meta-analysis of chemo/immunotherapy trials demonstrates that treatment effect on CR30 is a robust predictor of the treatment effect on PFS in first-line FL; the correlation of CR24 and PFS treatment effects is promising but requires further confirmation. The use of the CR30 endpoint may expedite the evaluation of, and thus improve the speed of access to, promising novel therapeutics for this patient population.

P684

MYD-88 L265P IN A SERIES OF CD5(-) CLONAL B-CELL LYMPHOCYTOSIS OF MARGINAL ZONE ORIGIN (CD5- CBL)

C. Kalpadakis[1,*]G. Pangalis[2], M. Angelopoulou[3], M. Roumelioti[4], S. Sachanas[2], P. Korkolopoulou[5], F. Kontopidou[6], A. Dimitrakopoulou[7], E. Koulieris[2], M. Moschogiannis[2], M.-C. Kyrtsonis[4], T. Tzenou[4], S. Kokoris[8], X. Yiakoumis[2], P. Tsirkinidis[2], C. Pontikoglou[1], D. Rontoyianni[9], H. Papadaki[1], P. Panayiotidis[4], T. Vassilakopoulos[3]

[1]Hematology, University of Crete, Heraklion, [2]Hematology, Athens Medical Center-Psychikon Branch, [3]Hematology, [4]1st Department of Propedeutics, [5]Pathology, [6]2nd Department of Internal Medicine, University of Athens, [7]Immunology Laboratory, Laikon General Hospital, [8]Hematology Laboratory, University of Athens, [9]Pathology, Evangelismos General Hospital, Athens, Greece

Background: CD5- CBL displays features consistent with marginal zone origin. This entity may be associated with monoclonal gammopathy, frequently of the IgM type. Therefore differential diagnosis from Waldenstrom macroglobulinemia (WM) /lymphoplasmacytic lymphoma (LPL) is mandatory. The recently identified gain of function L265P MYD 88 mutation is considered a sensitive and specific marker of WM and might be a valuable tool to differentiate the two entities.
Aims: To determine the presence of L265P MYD-88 mutation in a well characterized series of CD5- CBL pts along with an extended analysis of the morphologic, clinical, immunophenotypic and histologic features in order to identify whether some of these cases may be in fact WM/LPL.
Methods: We retrospectively evaluated 40 patients with CD5- CBL presenting in the blood and/or in the bone marrow (BM), without evidence of any other disease localization or signs of chronic and/or active inflammation, autoimmunity, organomegaly or cytopenia. The identification of MYD 88 L265P mutation was performed in blood/BM mononuclear cells with allele specific PCR. For the purpose of the present analysis, patients were divided in 3 groups: Group 1 included patients with a mutated MYD 88. Group 2 consisted of MYD 88 wild type patients with paraproteinemia, whereas patients with wild type MYD 88 but without paraproteinemia were classified as group 3.

Table 1. Patients' characteristics according to the presence of MYD-88 L265P mutation.

	PATIENTS' CATEGORY		
	GROUP 1	GROUP 2	GROUP 3
Characteristics	MYD-88(+) N=8	MYD-88(-) with MG* N=12	MYD-88(-) without MG N=20
Male sex	5 (62%)	4 (33%)	8 (40%)
Median age (range) [years]	71 (51-79)	66 (46-80)	69 (54-83)
Median lymphocyte count x10^9/L (range)	3.85 (2.4-11.25)	3.51 (1.0-7.8)	5.07 (1.4-29.2)

**MG*=monoclonal gamopathy

^2 pts did not have circulating clonal B-cells

^^1 pt did not have circulating clonal B-cells

Results: All patients were asymptomatic at diagnosis presenting predominantly with lymphocytosis, or more rarely with a paraproteinemia. Thirty-six patients

had lymphocytosis, while circulating clonal B-cells were found in 93%. Blood lymphoid population consisted mainly of small lymphocytes, admixed with villous lymphocytes and monocytoid cells in various proportions. Paraproteinemia was evident in 20 cases. BM was invariably infiltrated with features of plasmacytic differentiation in 15 cases, 12 of which were associated with the presence of paraproteinemia. The L265P MYD-88 mutation was present in 8 cases (20%). The laboratory, morphologic, immunophenotypic and histologic characteristics of the three groups are shown in the Table 1. All MYD-88 (+) cases (group 1) had paraproteinemia (5 IgM, 2 IgG and 1 IgM plus IgG) and 6 of them also displayed plasmacytic differentiation in the BM. Regarding group 2 patients (N=12), 6 had an IgM paraprotein and 6 plasmacytic differentiation in the BM. Among the 20 group 3 patients, only 3 showed plasmacytic differentiation in the BM. Thus, MYD-88 mutated cases had more frequently IgM paraproteinemia, higher percentage of BM infiltration and plasmacytic differentiation, and CD38 expression. At a median follow-up time of 41 months, 1 patient progressed to SMZL and 4 developed cytopenias due to extensive BM infiltration. The limited number of patients in each group and the relative short follow-up time prevent any correlation between the MYD-88 and outcome.

Summary and Conclusions: Almost 2/3 (12/20) of pts with monoclonal gamopathy were MYD-88 (-) and therefore these pts are still classified as CD5- CBL. Further on our study shows for the first time, that 20% of CD5- CBL cases harbor the L265P MYD 88 mutation - a marker that is WM specific. The L265P MYD mutated subgroup displayed more often plasmacytic differentiation, CD38 expression, and a paraprotein of the IgM type. Whether these cases represent true WM or borderline cases between these two entities remains to be clarified.

P685

EFFICACY AND SAFETY OF R-COMP REGIMEN IN NON HODGKIN LYMPHOMA PATIENTS WITH CARDIOVASCULAR COMORBIDITIES

O. Annibali[1,*] F. Chiodi[1], C. Sarlo[1], N. Cenfra[2], S. Tomassini[3], S. Mecarocci[2], G. Cimino[2,3], G. Avvisati[1]
[1]Hematology Unit, University Campus Bio-Medico, Rome, [2]Hematology Unit, ICOT Santa Maria Goretti Hospital, Latina, [3]Department of Cellular Biotechnology and Hematology, University of Rome "Sapienza", Rome, Italy

Background: Anthracyclines-based regimens remain the gold standard for the treatment of Lymphomas, although the associated cardiac toxicity may limit their use, especially in frail and elderly patients.

Aims: The aim of this study was to evaluate the efficacy and tollerability of RCOMP inpatients with poor-risk lymphoma and cardiovascular comorbidity

Methods: From October 2008 to January 2015 we treated 44 newly diagnosed patients with poor-risk lymphoma and cardiovascular comorbidity using the R-COMP regimen (rituximab, cyclophosphamide, non-pegylated liposome-encapsulated doxorubicin, vincristine and prednisone)

Results: Median age was 74 years (range:46-83 yrs ; 45% ≥75 years). As for histology, 22/44 (50%) were Diffuse Large B-cell Lymphoma; 8/44 (18%) Mantle-cell Lymphoma; 5/44 (11%) Follicular Lymphoma; 3/44 (7%) Peripheral B-cell Lymphoma; 4/44 (9%) Nodal Marginal Zone Lymphoma; 2/44 (4%) other B-cell indolent Lymphoma. IPI score was Intermediate-High/High in 61,3% of the patients, 75% had an advanced Ann-Arbor stage and 43% presented at diagnosis with extranodal involvement. The median age adjusted Charlons comorbidity index was 6 (range: 3 to 9). Cardiovascular risk factors were considered: hypertension (30/44pts: 68%), 14/44 pts (31,6%) had a history or recent acute myocardial infarction and 4/44 (10%) suffered of Atrial fibrillation. Treatment was well tolerated and toxicities were limited grade III/IV cytopenia. Complete remission was achieved in 30/44 (68%) and partial response in 6/44 (14%). Progressive disease was present in 8/44 (18%). After a median follow up of 18 months, the median OS (Overall Survival) was not reached and 4/36(11%) responders relapsed. Cardiac toxicity was observed in one patients who died for pulmonary edema, while two patients developed arrhythmias.

Summary and Conclusions: This study confirm the efficacy and tolerability of R-COMP regimen in elderly patients with cardiovascular comorbidities.

P686

THE EFFECTIVENESS OF ANTIVIRAL THERAPY IN PATIENTS WITH HEPATITIS C ASSOCIATED INDOLENT LYMPHOMA (IL+C)

S. Lepkov[1,*] I. Subortseva[2], S. Kosura[1], G. Storojakov[1], O. Kolomiytsev[3], J. Rybuchina[3], P. Zeinalova[3], A. Kovrigina[2], N. Kokosadse[3]
[1]Therapy, Russian Research Medical University Moscow, [2]Hematology, Hematology Research Center, [3]Oncology, Cancer Research Center, Moscow, Russian Federation

Background: B-cell indolent non-Hodgkin's lymphoma is typical manifestation of chronic extrahepatic hepatitis C. The incidence of HCV infection in patients with B-cell indolent non-Hodgkin's lymphomas is approximately 15%.

Aims: In our study included 93 patients with indolent lymphoma and hepatitis C markers (IL+C) and control group of 146 patients with indolent lymphomas without markers of hepatitis C (IL-C). In patients with indolent lymphoma associated with hepatitis c proteins of virus expression on tumor cells in 82% patients.

Methods: In 93 patients with IL+C 43 patients received antiviral therapy as the first treatment. 50 patients with IL+C received polychemotherapy therapy as first line of therapy. All patients with indolent lymphomas without markers of hepatitis C received only chemotherapy.

Results: Antiviral therapy(AVT) in patients with IL+C received complete remission(CR)-77%, partial remission(PR) - 11%, stabilization-4%, 8% progression. All patients, in whom antiviral therapy was not effective(stabilization+progression), virus proteins of hepatitis C on tumor cells was not detected. On chemotherapy in patients with IL+C CR received in 64%, PR-23%, stabilization-9%, 4%>progression. All patients with progression on chemotherapy on tumor cells was detected proteins of hepatitis C virus. On chemotherapy in patients in control group with IL-C received CR in 53%, PR-31%, the stabilization-5%, 11%>progression. The median relapse-free survival(RFS) in patients with IL+C on AVT was 36mth. The median RFS in patients with IL+C on chemotherapy was 19 months. The median RFS in patients with IL-C on chemotherapy was 33 months. 37 patients with relapse IL+C after chemotherapy was conducted AVT. CR was received in 81% of patients, PR was achieved in 11% and stabilization/progression+8% of patients. The median RFS in patients with IL+C recurrence after chemotherapy for AVT was 31 months.

Summary and Conclusions: The effectiveness of AVT was significantly higher than chemotherapy in patients with IL+C. Median disease-free for patients with IL+C significantly more on antiviral therapy. AVT should be the first line therapy in patients with the IL+C.

P687

COMPARISON OF SUBCUTANEOUS AND INTRAVENOUS RITUXIMAB IN THE MAINTENANCE SETTING: UPDATED SAFETY RESULTS OF THE PHASE III SABRINA STUDY IN PATIENTS WITH FOLLICULAR LYMPHOMA

A. Davies[1,*] B. Mihaljević[2], S. Mercadal[3], G. Mihaylov[4], S. Leppä[5], D. Cotting[6], F.J. Munoz[7], K. Veenstra[8], N. Berthillon[9], M. Barrett[10], D. MacDonald[11]
[1]Faculty of Medicine, University of Southampton, Southampton, United Kingdom, [2]Institute of Hematology, Clinical Center of Serbia School of Medicine, Belgrade, Serbia, [3]Hematology Department, Catalan Institute of Oncology, Barcelona, Spain, [4]Department of Haematology, Hospital for Treatment of Hematological Diseases, Sofia, Bulgaria, [5]Department of Oncology, Helsinki University Central Hospital Cancer Center, Helsinki, Finland, [6]Pharmaceuticals Division PDOC, [7]Clinical Science, [8]Statistical Programming, [9]Product Development, F. Hoffmann-La Roche Ltd, Basel, Switzerland, [10]Clinical Science, Roche Products Ltd, Welwyn Garden City, United Kingdom, [11]Department of Medicine, QEII Health Sciences Centre, Halifax, Canada

Background: Subcutaneous rituximab (R^{SC}) offers improved patient (pt) convenience and healthcare resource savings *versus* intravenous rituximab (R^{IV}). The phase III SABRINA study (NCT01200758) investigated induction R^{SC} or R^{IV} in combination with chemotherapy followed by maintenance R^{SC} or R^{IV} in pts with follicular lymphoma (FL). With a median follow-up time of 14 months, the R^{SC} and R^{IV} arms had similar response rates and safety profiles, without any new clinically relevant safety findings reported for R^{SC}. However, longer follow up is needed to define the safety of R^{SC} *versus* R^{IV} in the maintenance setting.

Aims: We present an updated safety analysis of R^{SC} and R^{IV} for the maintenance phase of SABRINA (median follow-up time 26 months).

Methods: Pts with treatment-naïve CD20+ grade 1-3a FL (n=410) were randomised to receive R^{SC} or R^{IV} (n=205/arm), stratified by FL International Prognostic Index score, chemotherapy regimen and region. All pts received R^{IV} 375 mg/m^2 in cycle 1; for cycles 2-8, pts received R^{SC} 1400 mg or R^{IV} 375 mg/m^2 every 3 weeks. Pts received ≤8 cycles of CHOP (cyclophosphamide, doxorubicin, vincristine and prednisone) or 8 cycles of CVP (cyclophosphamide, vincristine and prednisone). During maintenance, pts received R^{SC} or R^{IV} every 8 weeks. Non-serious AEs were reported for 28 days following the last dose of rituximab. Serious AEs (SAEs) were recorded for 1 year post-treatment or until the start of new anti-lymphoma treatment. SAEs considered possibly related to study treatment were recorded indefinitely.

Results: In total, 407 pts received ≥1 dose of rituximab (safety population). Six R^{SC} pts discontinued treatment after cycle 1 (R^{IV} in both arms) and were included in the R^{IV} safety population (R^{SC} n=197 [81 male, 116 female]; R^{IV} n=210 [109 male, 101 female]). In total, 86% of pts started maintenance (R^{SC} n=172, 87%; R^{IV} n=178, 85%). During maintenance, the most common AEs were of the system organ class (SOC) infections and infestations (R^{SC} 41%; R^{IV} 42%); most were grade 1/2 upper respiratory tract infections, urinary tract infections or nasopharyngitis. Grade ≥3 infections were reported in 8% (R^{SC}) and 3% (R^{IV}) of pts. Other common AEs (≥15% pts) belonged to the SOCs general disorders and administration site conditions (R^{SC} 28%; R^{IV} 19%; difference mainly driven by grade 1 injection site erythema [R^{SC} 8%; R^{IV} 0%]); gastrointestinal disorders (R^{SC} 24%; R^{IV} 19%); musculoskeletal and connective tissue disorders (R^{SC} 23%; R^{IV} 21%); respiratory, thoracic and mediastinal disorders (R^{SC} 18%; R^{IV} 17%); blood and lymphatic system disorders (17% each; most were grade ≥3 [10% of pts/arm]); and skin and subcutaneous tissue disorders (R^{SC} 16%; R^{IV} 15%). SAEs reported during maintenance (≥2% of pts) were: infections and infestations (R^{SC} 8%; R^{IV} 2%); gas-

trointestinal disorders (R^{SC} 1%; R^{IV} 4%); musculoskeletal and connective tissue disorders (R^{SC} 2%; R^{IV} 1%); blood and lymphatic system disorders (R^{SC} 1%; R^{IV} 2%); and neoplasms (R^{SC} <1%; R^{IV} 2%). In both arms, grade ≥3 AEs were more common in females (R^{SC} 27%; R^{IV} 29%) than in males (R^{SC} 18%; R^{IV} 19%) during maintenance. In total, 5% (R^{SC}) and 3% (R^{IV}) of pts discontinued maintenance due to AEs. At data cut off, 27 pts (R^{SC} n=11, 6%; R^{IV} n=16, 8%) had died.

Summary and Conclusions: Maintenance R^{SC} and R^{IV} were well tolerated in treatment-naïve pts with FL, with no new safety signals noted for R^{SC}. Availability of R^{SC} administration over approximately 6 minutes has positive implications for pt convenience and healthcare resource savings, without compromising safety or efficacy.

P688

TWO DOSES OF POLATUZUMAB VEDOTIN (POV, ANTI-CD79B ANTIBODY-DRUG CONJUGATE) PLUS RITUXIMAB (R) IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) FOLLICULAR LYMPHOMA (FL): DURABLE RESPONSES AT LOWER DOSE LEVEL

J. Sharman[1,*] I. Flinn[2], R. Advani[3], C. Diefenbach[4], K. Kolibaba[5], O. Press[6], L. Sehn[7], A. Chen[8], G. Salles[9], H. Tilly[10], B. Cheson[11], S. Assouline[12], M. Dreyling[13], A. Hagenbeek[14], P.L. Zinzani[15], C. Jones[16], S. Jones[16], W. Chu[16], J. Hirata[16], M. Wenger[16], F. Morschhauser[17]

Background: Based on early evidence of cumulative toxicity of PoV at a dose of 2.4 mg/kg (Morschhauser ASH 2014; NCT01691898), a dose of 1.8 mg/kg dose was explored.
Aims: To report updated results of the dose comparison. Safety and efficacy of PoV after 8 treatment cycles were also analyzed.
Methods: Patients (pts) with R/R FL received PoV at 2.4 mg/kg or 1.8 mg/kg with R 375mg/m^2, q21d until progression or unacceptable toxicity. Five pts with R/R FL from the Phase 1 study (Palanca-Wessels ASH 2013) treated with PoV 2.4 mg/kg were included in the analysis. Data at completion of PoV treatment were compared with data after 8 cycles.
Results: Forty-five pts received PoV+R (25, 2.4 mg/kg; 20, 1.8 mg/kg). Median follow-up was 14 mo. for 2.4 mg/kg *vs* 8 mo. for 1.8 mg/kg. When limited to the first 8 treatment cycles, median follow-up was similar at 6 mo. for both groups. Baseline characteristics were balanced between the two cohorts, except for age (median 68 yrs 2.4 mg/kg, 62 yrs 1.8 mg/kg) and tumor volume (SPD 1824 mm^2 at 2.4 mg/kg, 2655mm^2 at 1.8 mg/kg). Overall, 40% (10/25, 2.4 mg/kg) and 50% (10/20, 1.8 mg/kg) of pts were refractory to their last treatment. At data cut-off for this analysis, pts received a median of 10 and 9.5 treatment cycles in the 2.4 mg/kg and 1.8 mg/kg groups, respectively, with median dose intensities after cycle 8 of 88% and 99%, respectively. Safety is shown in the Table 1. Peripheral neuropathy (PN) was more frequent with PoV 2.4 mg/kg, and discontinuation (d/c) rates due to all causes were 56% *vs* 30% with the 1.8 mg/kg dose. After 8 treatment cycles, d/c rates were similar for both doses (28% *vs* 25%). An 84-year old pt in the 2.4 mg/kg cohort died 2 mo. after cycle 12 due to pulmonary congestion.

Table 1. Safety profiles of PoV+R for all treatment cycles and truncated after cycle 8

Adverse events, n (%) (MeDRA SOC)	PoV 1.8 mg/kg all cycles (N=20)	PoV 2.4 mg/kg all cycles (N=25)	PoV 1.8 mg/kg 8 cycles (N=20)	PoV 2.4 mg/kg 8 cycles (N=25)
Any AE Grade 3-4	10 (50)	13 (52)	10 (50)	13 (52)
Neutropenia	7 (35)	4 (16)	7 (35)	4 (16)
Febrile neutropenia	2 (10)	1 (4)	2 (10)	1 (4)
Serious AE	6 (30)	8 (32)	6 (30)	6 (24)
Deaths	-	1 (4)	-	-

AE leading to study discontinuation 6 (30) 14 (56) 5 (25) 7 (28) Grade 2-4 periph. neuropathy1 8 (40) 18 (72) 5 (25) 10 (40) Grade 3+ infection 1 (5) 3 (12) 1 (5) 2 (8) AE per CTCAE V4.03. AEs G3/4 ≥10% reported; 1 MedDRA SMQ peripheral neuropathy (wide).

ORR was similar in for both levels: 19/25 (76%) at 2.4 mg/kg, 15/20 (75%) at 1.8 mg/kg. CRs were achieved in 11/25 (44%) patients at 2.4 mg/kg and 2/20 (10%) patients at 1.8 mg/kg. Duration of response was 12 mo. for 2.4 mg/kg and not estimable for 1.8 mg/kg group. After 8 cycles, ORR remained similar; 64% for 2.4 mg/kg and 60% for 1.8 mg/kg. Median PFS was 15 mo. at 2.4 mg/kg and not reached in the 1.8 mg/kg group (Figure 1).

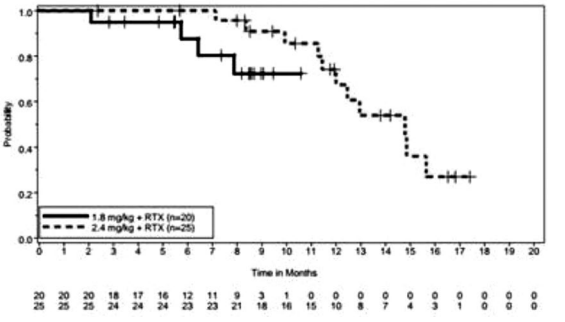

Figure 1. PFS for PoV+R (PoV at 2.4 mg/kg and 1.8 mg/kg).

Summary and Conclusions: PoV+R in R/R FL showed high ORR at both doses, with higher CR at 2.4 mg/kg. D/c rates, mostly due to cumulative PN, were high. AEs and d/c rates were reduced at both doses if only the first 8 cycles are considered *vs* those reported through study completion. The safety of PoV can be improved by shorter treatment and/or lower dose. Updated PFS will be presented.

P689

IDELALISIB EFFICACY AND SAFETY IN FOLLICULAR LYMPHOMA PATIENTS FROM A PHASE 2 STUDY

P. Zinzani[1,*] G. Salles[2], S.J. Schuster[3], S. de Vos[4], N.D. Wagner-Johnston[5], A. Viardot[6], C.R. Flowers[7], M. Will[8], M. Breuleux[8], W.R. Godfrey[8], B. Sorensen[8], A.K. Gopal [9]
[1]Institute of Hematology "L. e A. Seràgnoli", Bologna, Italy, [2]Hospices Civils de Lyon, Université Claude Bernard, Pierre-Bénite, France, [3]Abramson Cancer Center of the University of Pennsylvania, Philadelphia, [4]David Geffen School of Medicine at UCLA, Los Angeles, [5]Washington University School of Medicine, St Louis, United States, [6]University Hospital of Ulm, Ulm, Germany, [7]Winship Cancer Institute of Emory University, Atlanta, [8]Gilead Sciences, Foster City, [9]University of Washington School of Medicine, Seattle, United States

Background: There is an unmet need for new treatment options in follicular lymphoma (FL), particularly for heavily pretreated, high-risk patients refractory to anti-CD20 and chemotherapy. Idelalisib, a PI3Kδ inhibitor, showed antitumor activity and acceptable tolerability as monotherapy in a pivotal phase 2, open-label study in indolent non-Hodgkin lymphoma (iNHL) refractory to rituximab (R) and an alkylating agent (NCT01282424).
Aims: This post hoc analysis evaluated efficacy and safety in the FL patient subset.
Methods: Double refractory patients with histologically confirmed iNHL received oral idelalisib 150 mg BID until disease progression (PD) or unacceptable tolerability; patients with FL (grade 1, 2, or 3a; n=72) were included in this analysis; all patients provided informed consent. Responses were evaluated by an independent review committee using standardized criteria. The primary endpoint was the overall response rate (ORR).
Results: At study entry, patients' median age was 62 y, 54% had a high-risk FLIPI score, 22% had bulky disease, and 17% had FL grade 3a. Median (range) number of prior treatments was 4 (2-12); 86% were refractory to their last therapy (32/50 to bendamustine). At data cutoff, median (range) treatment duration was 6.5 (0.6-31.0) mo, with 65 (90%) patients off treatment (PD, 38; adverse events [AEs], 15; investigator decision, 7; death, 5). Lymph node size decreased during treatment by ≥50% SPD in 57%. The ORR (95% CI) was 56% (43-67; P<0.001), including 10 complete responses (CR) and 30 partial responses. Kaplan-Meier (KM) - estimated median (range) time to response was 2.6 (1.6-11.0) mo, median response duration was 11 mo (27 mo in patients with CR), and progression-free survival was 11 mo, substantially longer *vs* the last regimen. Median overall survival (OS) was not reached; KM-estimated OS at 1, 1.5, and 2 y was 87%, 74%, and 68%. The most common AEs (any/grade ≥3,%) were diarrhea (51/14), cough (32/0), pyrexia (29/4), fatigue (28/0), and nausea (28/3). Rates of grade ≥3 transaminase elevation, pneumonitis, neutropenia, anemia, and thrombocytopenia were 14%, 4%, 22%, 3%, and 6%.
Summary and Conclusions: Idelalisib demonstrated rapid, durable responses that were substantially longer than those with the previous regimen with acceptable safety in highly refractory, relapsed FL patients with limited treatment options.
Supported by Gilead Sciences.

P690

IDELALISIB MONOTHERAPY RESULTS IN DURABLE RESPONSES IN PATIENTS WITH RELAPSED OR REFRACTORY WALDENSTROM'S MACROGLOBULINEMIA (WM)

S. Coutre[1,*] J. Leonard[2], C. Flowers[3], A. Davies[4], W. Jurczak[5], J. Byrd[6], S. Spurgeon[7], S. Peterman[8], L. Holes[8], Y. Cho[8], B. Sorenson[8], W. Godfrey[8], A. Gopal[9]

[1]Stanford University Medical Center, Stanford, [2]Weill Cornell Medical Center, New York, [3]Winship Cancer Institute at the Emory University School of Medicine, Atlanta, United States, [4]Southampton General Hospital, Southampton, United Kingdom, [5]Malopolskie Centrum Medyczne S.C., Krakow, Poland, [6]Ohio State University Comprehensive Cancer Center, Columbus, [7]Oregon Health & Science University, Portland, [8]Gilead Sciences, Foster City, [9]University of Washington School of Medicine, Seattle, United States

Background: Idelalisib (Zydelig), a selective oral inhibitor of PI3Kδ, demonstrated considerable anti-tumor activity in patients with relapsed/refractory iNHL in phase 1 (Flinn, 2014; Study 02) and refractory iNHL in phase 2 (Gopal, 2014; Study 09) trials. This analysis evaluates outcomes in the subset with WM.
Aims: To evaluate the combined safety and efficacy of idelalisib monotherapy in pts with WM in 2 clinical trials.
Methods: Eligible patients (pts) with WM included those with relapsed/refractory disease (phase 1), or those with disease refractory to both rituximab and an alkylating agent (phase 2). Idelalisib dosages were 150 mg QD, and 50 mg-200 mg BID (phase 1), and 150 mg PO BID (phase 2) and were administered continuously until disease progression. WM response was assessed by IgM levels and CT imaging (Owen, 2013).
Results: Enrolled pts, (phase 1 N=9; phase 2 N=10), had a median age of 63 and 60 years [range 42-83] and 78% and 80% were male, respectively. Patients had received a median of 4 prior regimens in both groups. Overall response rate (ORR) was 5/9 (56%), and 8/10 (80%; Table 1). Median time to minor or first response was 2 months, and most responses continued to improve over 6 months or longer. Median DOR was 32.8 months (phase 1) and not yet reached (phase 2). 67% have continued response at 2 years (phase 2). Median PFS is 33.3 months, and 22.1 months, respectively. Interestingly, >3 gram/dL improvements in hemoglobin were noted in 5/9 and 7/10 subjects, respectively, over 3-6 month timeframe. Grade ≥3 adverse events included increased ALT/AST 5/9, and 1/10, and diarrhea/colitis 1/9, and 3/10. One G3 ALT elevation and 1 G3 diarrhea resulted in study discontinuation.

Table 1.

	Phase 1 [Study 02] (n=9)	Phase 2 [Study 09] (n=10)

NE	1 (11%)	0

Summary and Conclusions: These combined data suggest single-agent idelalisib monotherapy is active in Waldenstrom's macroglobulinemia. Durable responses were seen in the majority of subjects. Marked improvements in hemoglobin level are also associated with response. The safety profile was acceptable and manageable, with no apparent disease-specific safety signals. Phase 3 clinical trials of idelalisib with combination therapy are in progress for pts with iNHL, including WM (NCT00710528, NCT01282424).

Hoffmann-La Roche Ltd, Welwyn Garden City, United Kingdom, [15]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [16]Georgetown University Hospital, Washington DC, United States

New Information: These data have been submitted to ASCO and ICML. The EHA submission contains additional data describing NHL subtypes and median duration of maintenance therapy, plus a PFS curve.
Background: Treatment options are limited and outcomes poor for patients with rituximab-refractory (Rit-ref) indolent non-Hodgkin lymphoma (iNHL). Bendamustine (B) has shown a median progression-free survival (PFS) outcome of 9 months and response duration of 10 months in Phase II trials in Rit-ref iNHL. Obinutuzumab (GA101/Gazyva [G]) is a glycoengineered type II anti-CD20 antibody with activity and an acceptable safety profile in Rit-ref iNHL shown in Phase I/II studies; obinutuzumab is not currently licensed in NHL. Preclinical studies have shown that combining G and B increases their activity; thus, this combination (GB) has potential for improved efficacy in comparison with B alone.
Aims: To evaluate efficacy and safety of GB *versus* B alone in patients with Rit-ref iNHL.
Methods: GADOLIN (NCT01059630) is a randomized, open-label Phase III study in patients with CD20-positive Rit-ref iNHL. In the control (B) arm, patients received single-agent therapy with B 120mg/m^2 (days 1 and 2, cycles 1-6); in the test (GB) arm patients received B 90mg/m^2 (days 1 and 2, cycles 1-6) in combination with G 1000mg (days 1, 8, and 15 of cycle 1 and day 1 of cycles 2-6) for up to six 28-day cycles. All patients gave informed consent. Non-progressing patients in the GB arm received further G monotherapy every 2 months for up to 2 years. The primary endpoint was PFS assessed by an independent radiology facility (IRF), with 80% power to detect a 43% improvement in median PFS.
Results: At a protocol-specified interim analysis, 396 patients were randomized to receive B (n=202 [198 were treated]) or GB (n=194). On February 4, 2015, the IDMC recommended to unblind the study and release the data to the scientific community as the primary endpoint (PFS) had been met. Baseline characteristics were balanced between the treatment arms and follicular lymphoma was the most common iNHL subtype (82.2% B *vs* 79.9% GB). The median age was 63 yrs and patients had received a median of two prior therapies. The median observation time was 20 months for B and 22 months for GB. IRF-assessed median PFS was 14.9 months for B and not reached (NR) for GB (hazard ratio [HR] 0.55, 95% confidence interval [CI]: 0.4-0.74; p=0.00011) (Figure 1).

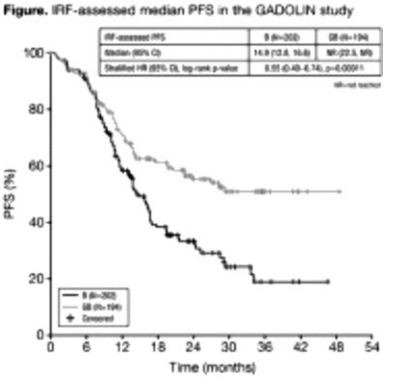

Figure 1. IRF-assessed median PFS in the GADOLIN study.

The median investigator-assessed PFS was 14 months for B and 29 months for GB (HR 0.52, 95% CI: 0.39-0.70; p<0.0001). There were no significant differences in IRF-assessed overall response rate (63.0% B *vs* 69.1% GB) or complete response (12.2% B *vs* 11.2% GB) at the end of induction, in IRF-assessed best overall response up to 12 months from the start of treatment (76.6% B *vs* 78.6% GB), or in preliminary overall survival (OS; median OS NR in either arm). The median duration of post-induction G monotherapy was 10.8 months, 74% of patients received at least one dose of G and 25% received all 12 doses. In the treatment period, there were fewer Grade ≥3 adverse events with B than with GB (62.1% B *vs* 68.0% GB), notably neutropenia (26.3% B *vs* 33.0% GB) and infusion-related reactions (3.5% B *vs* 8.8% GB), but more Grade ≥3 thrombocytopenia (16.2% B *vs* 10.8% GB), anemia (10.1% B *vs* 7.7% GB) and pneumonia (5.6% B *vs* 2.6% GB).
Summary and Conclusions: G combined with B (90 mg/m^2) followed by G maintenance significantly improved PFS *vs* B alone (120 mg/m^2) in Rit-ref iNHL. The clinically meaningful PFS improvement with GB is the first randomized evidence of benefit for a novel anti-CD20 antibody in Rit-ref iNHL.

Stem cell transplantation - Experimental

RECURRENT TP53 ALTERATIONS IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA RELAPSING AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

J. Hoell[1,*] S. Ginzel[1,2], C. Eckert[3], M. Gombert[1], U. Fischer[1], M. Stanulla[4], M. Schrappe[4], U. zur Stadt[5], P. Bader[6], J. Alten[4], B. Strahm[7], A. Moericke[8], G. Escherich[9], A. von Stackelberg[3], C. Peters[10], A. Borkhardt[1], R. Meisel[1]
[1]Department of Pediatric Oncology, Heinrich Heine University Duesseldorf, Duesseldorf, [2]Department of Computer Science, Bonn-Rhine-Sieg University of Applied Sciences, Sankt Augustin, [3]Pediatric Hematology and Oncology, Charité University Hospital, Berlin, [4]Pediatric Hematology and Oncology, Hannover Medical School, Hannover, [5]Center for Diagnostic, University Medical Center Hamburg Eppendorf, Hamburg, [6]University Hospital for Children and Adolescents, Frankfurt/Main, [7]Pediatric Hematology and Oncology, University Medical Center, Freiburg, [8]Department of Pediatrics, University Medical Center Schleswig-Holstein, Kiel Campus, Kiel, [9]Clinic of Pediatric Hematology and Oncology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [10]St Anna Children's Hospital, Vienna, Austria

Background: Survival rates of many childhood malignancies at relapse -including patients relapsing with acute lymphoblastic leukemia (ALL) post allogeneic hematopoietic stem cell transplantation (allo-SCT)- remain very poor. These patient groups are the focus of the German-wide INdividualized therapy FOr Relapsed Malignancies in childhood (INFORM) initiative. Our group is focusing on post allo-SCT relapses since they exhibit a dismal prognosis despite various therapeutic efforts.
Aims: Since ALL relapses post allo-SCT escape both chemotherapeutic and immunologic therapies, they are assumed to display other genetic alterations compared to ALL relapses following conventional chemotherapy. The aim of our present study therefore is to identify the landscape of genetic alterations of ALL relapses post allo-SCT by whole-exome sequencing (WES). This will result in a better understanding of the pathobiology of these specific ALL cases and in more personalized treatment strategies through the identification of druggable targets. Achieving remission prior to secondary allo-SCT represents the primary clinical aim.
Methods: WES of germline and tumor DNA was performed on a HiSeq 2500 (Illumina). Obtained sequence reads were aligned to the human reference genome. Resulting variation calls were annotated by Variant Effect Predictor and imported into an in-house MySQL database. MuTect and VarScan2 were employed for identification of somatic nucleotide variations (SNVs) of each oncogenome.
Results: To address the genetic landscape of relapsed ALL following both chemotherapeutic and immunologic therapy, we sequenced five samples per patient: initial leukemia, first remission, first relapse, remission post allo-SCT, and relapse post allo-SCT. Since the latter generally occur in a situation of hematopoietic chimerism, it is important to have two genetic germline backgrounds (recipient=patient in first remission, stem cell donor=remission post allo-SCT) available subtracted to uncover those mutations exclusively defining the relapse post allo-SCT. To allow comparative analysis, we defined the following three "oncogenomes" (OGs): OG1 (initial leukemia), OG2 (first relapse), OG3 (relapse post allo-SCT). We report the results of the first 5 patients of our study. Patient age at initial diagnosis was 4-10 years (4x high, 1x medium risk; 3x B-, 2x T-ALL). Time from relapse diagnosis to allo-SCT (4x matched donor, 1x matched sibling donor) ranged from 3-5,5 months, relapse following allo-SCT occurred between 3-7 months, all patients died 1-4 months thereafter. Median numbers of leukemia-specific SN*Vs* in OG1-3 were 25, 42 and 69, respectively. More specifically, we identified 17 recurrently mutated genes present in OG3s of ≥2 patients (*e.g.* NOTCH1, TOP2A, WNT2). Of these, 9 were OG3 specific. Most notably, TP53 was mutated in 4/5 patients. One patient carried a TP53 germline mutation; 3 had novel TP53 mutations only present in their OG3s. Moreover, leukemic blasts showed plasticity concerning the mutational status of the nucleoside exporter NT5C2. Activating mutations in this gene were previously shown to drive chemotherapy resistance in relapsed ALL. We found a total of 3 SN*Vs* (1 known) in NT5C2 in the OG2s of 2/5 of our patients, but these disappeared again in the OG3s once selection pressure of maintenance chemotherapy employing nucleoside analogues had been withdrawn.
Summary and Conclusions: Comprehensive genetic analysis of the first 5 children with ALL relapsing post allo-SCT has shown leukemic cell plasticity (loss of acquired NT5C2 mutations) as well as identified several recurrent genetic alterations (*e.g.* NOTCH1, TOP2A, WNT2), most notably affecting TP53. Moreover, we have successfully established a bioinformatic analysis pipeline addressing the …two germlines" challenge in our post allo-SCT patient cohort.

MESENCHYMAL STROMAL CELLS STIMULATE PROLIFERATION AND CYTOKINE PRODUCTION OF GROUP 3 INNATE LYMPHOID CELLS

M. Munneke[1,*] A. Cornelissen[2], S. Omar[3], M. Spruit[3], J. Bernink[3], M. Kleijer[2], H. Spits[3], C. Voermans[2], M. Hazenberg[1]
[1]Dept. of Hematology, Academic Medical Center, [2]Dept. of Hematopoiesis, Sanquin Research and Landsteiner Laboratory, [3]Dept. of Cell Biology and Histology, Academic Medical Center, Amsterdam, Netherlands

Background: Graft-*versus*-host disease (GvHD) remains a challenging complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Transplantation of mesenchymal stromal cells (MSCs) is a frequently used secondary line of treatment for patients with steroid-refractory GvHD. The beneficial effects of MSCs in this context are mainly ascribed to their ability to modulate inflammation by inhibiting proliferation of (alloreactive) T cells. In addition MSCs might enhance tissue repair activities of other cells. We previously reported on the association between the activation status of a novel family of lymphocytes, called innate lymphoid cells (ILCs), and a reduced susceptibility to GvHD. Activated ($CD69^+$) ILC3s expressed the gut-homing marker $\alpha_4\beta_7$ and represent potent producers of the tissue-protective interleukin (IL)-22.
Aims: To test the hypothesis that MSCs may potentiate the tissue protective effects of ILC3s.
Methods: MSCs were harvested and expanded from bone marrow obtained from otherwise healthy human adults undergoing cardiac surgery with median sternotomy. ILC3s were freshly isolated from tonsils obtained from pediatric tonsillectomies. Co-cultures were performed in the presence of IL-2, for 5 days in a 1:1 ratio after which the cells were analyzed for proliferation (using a dye dilution assay) and cytokine production (by means of qPCR and intracellular cytokine stain).
Results: We observed an increased proliferation of ILC3s in the presence of MSCs (+/- pre-incubation with IFN-γ) as compared to a condition without MSCs (P=0.002). ILCs express CD127, the α-chain of the IL-7 receptor, which was downregulated upon co-culture with IL-7 producing MSCs. When IL-7 was blocked with neutralizing antibodies proliferation was significantly reduced. As compared to NK cells, ILC3s were found to have a low expression of genes encoding inhibitory cytokine receptors, such as the receptors for IL-10 and prostaglandin E2. Co-culture with MSCs resulted in an enhanced production of IL-22 (P=<0.0001) by $NKp44^+$ ILC3s. Also $NKp44^-$ ILC3s, which *ex vivo* express only low levels of IL-22, responded with a significantly enhanced IL-22 production. After co-culture with ILC3s, MSCs showed expression of the integrins vascular cell adhesion molecule 1 (VCAM1) and intracellular adhesion molecule 1 (ICAM1).
Summary and Conclusions: IL-22-producing $NKp44^+$ ILC3s represent the dominant ILC subset in the intestinal lamina propria and have important functions in mucosal homeostasis and immunity. IL-22 directly induces survival and proliferation of epithelial cells and stimulates secretion of antimicrobial peptides. Here we propose a mechanism for how MSCs may contribute to the control of GvHD, by promoting expansion and IL-22 production of tissue-restoring ILC3s. That MSCs and ILCs could serve as allies in combating GvHD is emphasized by the induced expression of the integrin VCAM1, a ligand for $\alpha_4\beta_7$, which we observed to be expressed on circulating ILCs before allo-HSCT. Further studies are needed to address the *in vivo* implications of these findings.

ENDOTHELIAL CELL MICROPARTICLES-DELIVERY MIR-155 PROMOTES THE DEVELOPMENT OF AGVHD BY MODULATING T CELLS

Q. Wu[1,*]H. Shen[1], M. Hong[1], L. Xia[1]
[1]Institute of Hematology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Elevation of endothelial cell microparticles (EMPs) has been proved in acute graft-*versus*-host disease (aGVHD) patients after allogeneic hematopoietic stem cell transplantation (allo-HSCT) and recently found associated with the onset of aGVHD. However, how EMPs regulate T cells function and lead to the pathogenesis of aGVHD is rarely known.
Aims: We aimed to confirm that EMPs produced by injuried endothelial cells can regulate T cells function through carrying microRNA-155 (miR-155) in process of aGVHD by series of *in vivo* and *in vitro* experiments.
Methods: We first compared dynamic change of miR-155 of MPs in plasma of aGVHD patients, pre-aGVHD patients (+7d, +14d, +21d and +28d after allo-HSCT) and non-aGVHD patients using qRT-PCR. We then compared the expression of miR-155 in EMPs derived from TNF-α-stimulated endothelial cell line EA.hy926 cells and untreated EA.hy926 cells. Nextly, we transferred miR-155 agomir into EA.hy926 cells, collected EA.hy926 cells derived EMPs and co-cultured EMPs with T cells. Then we observed the fusion of EMPs and T cells by confocal laser-scanning microscope and measured the change of miR-155 level in T cells. Simultaneously, ELISA was used to detect secreted TNF-α, IL-4, IL-10 of T cells, Annexin V-FITC/PI double-labeled flow cytometry was used to detect apoptosis and Western blot was used to determine the caspase-3 and bcl-2 expressions of T cells. Survival rates of mice were calculated and scored clinical signs of aGVHD were determined in the C57BL/6 ($H\text{-}2^{b+}$) donor to BALB/c ($H\text{-}2^{d+}$) recipient MHC-mismatched aGVHDmodel, then miR-155 in MPs and in MPs-depleted plasma were examined in aGVHD mice.
Results: In this study, we found miR-155 level in MPs from peripheral blood was significantly higher in pre-aGVHD patients (+7d, +14d, +21d and +28d after allo-HSCT) compared with non-aGVHD patients and slightly decreased at aGVHD point. Similarly, in aGVHD mice, miR-155 in plasma MPs was sig-

nificantly higher on +3d, +7d, +14d after allo-BMT while slightly lower at aGVHD point. *In vitro,* TNF-α can induce EA.hy926 cells damage to release EMPs rich of miR-155, which was further demonstrated to be delivered into T cells and resulted in the up-regulation of miR-155 in T cells and the activation of T cells including decreased apoptosis and the transition from Th2 to Th1.This result was confirmed by the observation that EMPs derived from TNF-α and antagomir155 co-treated EA.hy926 cells increased caspase-3 expression and decreased bcl-2 expression in T cells.
Summary and Conclusions: Altogether, our data suggest that EMPs-delivery miR-155 is involved in the development of aGVHD through modulating T cell function. MiR-155 in EMPs might serve as an early predictive index as well as an early intervention target of aGVHD.

P694

PRESENCE OF KIR2DS1 RECEPTOR IN DONORS OF ALLOGENEIC HEMATOPOIETIC TRANSPLANTATION DUE TO MYELOID MALIGNANCIES IMPROVES OVERALL SURVIVAL IN RECIPIENTS WITH HLA-C2 ANTIGENS

A. Bors[1,*] K.P. Kiss[1], H. Andrikovics[1], S. Benko[1], Z. Illes[1], D. Inotai[1], A. Szilvasi[1], A. Gelle-Hosso[1], K. Rajczy[1], Z. Csukly[2], A. Batai[2], E. Torbagyi[2], A. Barta[2], L. Lengyel[2], P. Remenyi[2], T. Masszi[2], A. Tordai[1]
[1]Hungarian National Blood Transfusion Service, [2]St. Istvan and St. Laszlo Hospital, Budapest, Hungary

Background: Recognition of HLA-C2 antigen of recipient cells by the activating killer immunoglobulin like receptor (KIR), KIR2DS1 receptor on donor natural killer (NK) cell may lead to increased graft *versus* leukemia effect in patients with myeloid malignancies treated by allogeneic hematopoietic transplantation (HSCT) influencing disease free (DFS) and overall survival (OS).
Aims: The goal of the present study was to examine the effect of donor KIR status in conjunction with recipient HLA-C type on the outcome of HSCT.
Methods: In our cohort, 249 consecutive adult patients, who underwent first allogeneic HSCT (HLA-identical sibling n=117 and unrelated donor n=132) for a malignant myeloid condition, namely acute myeloid leukemia (AML, n=157), bi-phenotypic acute leukemia (n=10), chronic myeloid leukemia (n=24), myeloproliferative neoplasm (n=23) and myelodysplastic syndrome (n=35) at a single center between 2007 and 2013, were retrospectively analyzed. Median follow-up was 36 months (range 6-92 months). Genotyping for the presence of KIR genes was performed by an allele specific multiplex PCR using archived DNA samples. Low resolution HLA-C typing was performed by sequence specific oligonucleotides as part of the routine work-up prior to HSCT.
Results: The frequency of the donor KIR2DS1 gene in the entire cohort was 36.5% (91/249) while the distribution of HLA-C1/C2 groups was as follows: HLA-C1: 36.5% (91/249), HLA-C1/C2: 47.4% (118/249), HLA-C2: 16.1% (40/249). There was no difference in DFS or OS between patient subgroups stratified by the presence or absence of KIR2DS1 or HLA-C1/C2. As expected, patients with sibling donors showed significantly better DFS and OS. Further analyzes were performed exclusively focusing on the patient subgroup with KIR2DS1 positive donors (n=91). Within this subgroup, we found improved DFS and OS for patients carrying at least one copy of the HLA-C2 antigen (*i.e.* HLA-C2 homozygous and heterozygous patients combined, n=54) compared to those homozygous for the HLA-C1 antigen (n=47). DFS at 3 years for HLA-C2 carriers was 55.9% compared to HLA-C1 homozygotes with 39.4% (p=0.14). Similar comparison for OS showed 62.3% for the former and 42.3% for the latter subgroup (p=0.068). Upon performing a further stratification, we performed an identical comparison exclusively for the AML patient subgroup (HLA-C2 carriers: n=36 and HLA-C1 homozygous: n=22) indicating a 3 years DFS of 60.4% for HLA-C2 carriers compared to 45.1% for HLA-C1 homozygotes (p=0.19) and a 3 years OS of 71.7% for the former and 45.7% for the latter (p=0.047). In spite of the impressive differences of the above survival rates, due to the low case numbers, only OS among AML patients with KIR2DS1 and HLA-C2 combination was significantly better. Performing a multivariate analyzes by Cox regression among AML-patients considering age, sex, the type of conditioning (myeloablative or reduced intensity conditioning) and type of donor as covariates, the association of a favorable OS with the simultaneous presence of KIR2DS1 and HLA-C2 remained significant (hazard ratio=0.422, 95% confidence interval: 0.179-0.995, p=0.049).
Summary and Conclusions: Our results indicate that the combination of donor KIR2DS1 and recipient HLA-C2 may be a favorable genetic constellation in allogeneic HSCT for AML with respect to overall survival.

P695

ENDOTHELIAL MICROPARTICLE IS INVOLVED IN THE DEVELOPMENT OF ACUTE GVHD AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

D. Nie[1], Q. Wu[1], L. Xia[1], M. Hong[1,*]
[1]Hematology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, wuhan, China

Background: Endothelial microparticles (EMPs) are membrane-bound subcellular microparticles produced by endothelial cells in response to activation or apoptosis. Accumulating evidences have indicated that endothelial injury and EMPs release are initial steps in the development of acute graft-*versus*-host-disease (aGVHD) after allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the roles of EMPs in the feedback of endothelial injury and the development of aGVHD are poorly understood.
Aims: To investigate the role of EMPs in the development of aGVHD through evaluating their effects on endothelial cell survival and function.
Methods: Dynamic change of plasma EMPs was compared by flow cytometry in aGVHD patients and non-aGVHD patients (7, 14, 21 and 28 days after transplantation), aGVHD occurring point, and normal controls. Meanwhile, plasma TNF-αwas measured by ELISA among aforementioned groups. Primary human umbilical vein endothelial cells **(**HUVEC)and human umbilical vein endothelial cell line EA.hy926 were both treated with different concentrations of TNF-αto induce EMPs release. The level of EMPs in the supernatant was detected by confocal laser scanning microscopy and FCM with PE-labeled CD62E and FITC-labeled CD31. After treating EA.hy926 cells with 20μg/ml EMPs for 24h, we evaluated their apoptosis rates by Annexin V-FITC/PI double-labeled flow cytometry, intracellular nitric oxide (NO) production by Nitrate reduction enzymatic method, Fas and eNOS mRNA by Real-time PCR, and protein level of Fas, eNOS and phosphorylation-eNOS by Western-blot. Moreover, the angiogenic activity of EA.hy926 cells was measured by *in vitro* Matrigel tubulogenesis assay.
Results: The level of both serum EMPs and TNF-αin aGVHD group showed an increased tendency within 28d after allo-HSCT. Serum EMPs peaked at day 21, while TNF-αpeaked before EMPs. Moreover, the number of EMPs at day 21 was significantly higher in aGVHD group compared with non-aGVHD group (13819±1513 *vs* 2208±363/μL,P<0.05) at day 21. Significantly higher was found in the patients in aGVHD point group in comparison to the other groups including control groups, pre-aGVHD group and non-aGVHD group. *In vitro*, TNF-αwas found to stimulate endothelial cells to release EMPs in a dose-dependant manner. After treated with 100ng/ml TNF-α, the levels of $CD62E^{+}$EMPs increased significantly in both primary HUVEC and endothelial cell lines (HUVEC 27.7±0.54 *vs* 5.47±0.17; EA.hy926 36.5±0.63 *vs* 11.9±0.28%, P <0.05). In addition, the ratio of CD62E/CD31 of EMPs indicating that TNF-αinduced activated EMPs release instead of apoptosis EMPs. After treated with EMPs, EA.hy926 cells exhibited a significant increase of cell apoptosis rate (48.9±3.2% *vs* 7.8±1.2%, P <0.05), accompanied with an increase of Fas mRNA and protein expression. Meanwhile, they were found to produce less NO (77.54±4.52 μmol/gprot *vs* 30.85±3.20μmol/gprot, P <0.05) with decreased eNOS and phosphorylation-eNOS expression after treatment. And the tubule formation function was found weakened because the endothelial tubule length in EMPs-treated group were significantly shorter than that of control group (P <0.05).
Summary and Conclusions: At the onset of aGVHD, TNF-αinduced the damage of endothelial cells to release activated EMPs, which promote the development of aGVHD through inducing the apoptosis of endothelial cells and impair endothelial function.

P696

SIMPLE, EFFICIENT, AND SAFE PROCESSING OF FROZEN-THAWED UMBILICAL CORD-DERIVED MESENCHYMAL STROMAL CELLS APPLIED FOR THE TREATMENT OF GVHD

T. Nagamura-Inoue[1,*] Y. Mori[1], A. Takahashi[1], T. Shimazu[1], H. Tsunoda[1], A. Tojo[1]
[1]Department of Cell Processing and Transfusion, Research Hospital,The Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Background: Human umbilical cord (UC) is a rich source for mesenchymal stromal cells (MSCs), and UC-MSCs have been reported to have multilineage potential including neural differentiation. In recent reports, MSCs have the ability to migrate to inflammatory tissues and suppress adverse immune reactions. BM-derived MSCs have been already applied for the patients with acute graft *versus* host disease (aGVHD) with promising efficacy. To avoid the potential risk of BM harvest from the donor, we intended to use umbilical cord (UC) as an alternative source for MSCs, especially for the treatment of GVHD in clinic. There were several problems in the processing of UC to be resolved. Here we introduced the new device in the explant method and found a suitable cryopreservation method of UC for clinical use.
Aims: The object of this study was to explorer an efficient and safe processing and quality evaluation methods for UC-MSCs GMP-grade banking for clinical use.
Methods: UC was collected after informed consent from the mother. MSCs (P1) were isolated from minimal size of fresh UC by an improved explants method using Cellamigo® to protect the fragments floating during the culture. The culture medium was refreshed every 3 days and the adherent cells and tissue fragments were harvested using trypsin. P1 MSCs were submitted for the quality control test including infection tests, chromosomal analysis, flowcytometry analysis and mixed lymphocyte reaction (MLR) assay to evaluate the immunosuppressive potency of the UC-MSCs. The remaining UC was cut in cross-section and incised longitudinally, immersed in the cryoprotectant StemCellbanker® and cryopreserved. After confirmation of the unit quality including 6-month baby's health, we thaw the UC and isolate MSCs by the above method

and continue to culture for further expansion in 5-stack Cellstack® chambers by P3. MLR was performed on UC-MSCs using CFSE-staining method, as *in vitro* functional assay. CFSE-labeled responder cells were analyzed by FACS. *In vivo* assay, we injected UC-MSCs into NOG mice with xenogeneic GVHD triggered by human peripheral mononuclear cells (MNC).
Results: The number of UC-MSCs isolated from 1 g of UC using the explant method with Cellamigo® was $2.9\pm1.4\times10^6$/g, which was significantly higher than that obtained without Cellamigo® ($0.66\pm0.53\times10^6$/g) (n=6, P <0.01) when cells reached 80-90% confluence. In addition, the processing time and incubation time required to reach 80-90% confluence were reduced in the improved explant method compared to the conventional method. Next, we compared the cryoprotectants to find a suitable cryopreservation method of UC tissue for clinical use. The highest yield of cells was obtained from frozen-thawed UC with serum- and xeno-free cryoprotectant, Stem-Cellbanker®, when compared with others. We obtained 1.5±0.96 MSCs from of frozen-thawed UC with Stem-Cellbanker® compared to those from fresh UC (n=4). UC-MSCs (P1) were further expanded in a large scale culture until P3. The expected final products showed more than 1×10^9 /g of original UC tissue, resulting in 30×10^9 per whole UC at least. The UC-MSCs showed spindle-shaped plastic adherent with positive CD105, CD73, CD90, CD44 and negative for CD45, CD34, CD14, CD19, and HLA -DR. They also have the ability of differentiation into adipocytes, chondroblasts *in vitro, although* osteoblasts differentiation was not enough. In MLR, 3rd party-derived UC-MSCs efficiently inhibited the responder T cells, triggered by allogeneic dendritic cells (DC). Furthermore, we found the xeno-GVHD mice treated with UC-MSCs showed a longer survival compared to the control.
Summary and Conclusions: We improved the explant method using stainless mesh resulting in the efficient and safe processing for isolation of MSCs from UC and developed the simple and safe cryopreservation method of UC tissue for clinical use. We demonstrated UC-MSCs have the immunosuppressive effect on the activated T cells in allogeneic 3rd party MLR setting. Conclusively, UC-MSCs may be a feasible alternative non-invasive source of BM-MSCs for GVHD treatment and can be considered for the prompt clinical applications.

P697

THE IMPACT OF NFAT INHIBITION ON NEUTROPHIL EFFECTOR FUNCTIONS IN PATIENTS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

K. Plein[1], D. Teschner[1,*] C. Michel[1], P. Stein[2], E.M. Wagner[1], M. Theobald[1], H. Schild[3], M. Radsak[1,3]
[1]Department of Hematology, Medical Oncology, & Pneumology, [2]Center for Thrombosis and Hemostasis, [3]Institute of Immunology, University Medical Center of the Johannes Gutenberg-University Mainz, Mainz, Germany

Background: Patients after allogeneic hematopoietic stem cell transplantation (HSCT) are threatened by opportunistic infection like invasive fungal diseases (IFD) partly due to immunosuppressive medication *e.g.* by calcineurin inhibitors like cyclosporine A (CsA). The nuclear factor of activated T cells (NFAT) is known as an important transcription factor downstream of calcineurin in the adaptive immune systems, but it also seems to play an important role in innate immune response by polymorphonuclear neutrophils (PMN), as indicated by recent data in rodent models.
Aims: The aim of our work is to elucidate the relevance of NFAT-dependent signals in PMN and the significance for antifungal immunity in human.
Methods: Firstly, isolated PMN from healthy donors were analyzed *in vitro* in absence or presence of CsA. In detail, we examined phagocytosis, L-selectin shedding, degranulation, generation of reactive oxygen species (ROS) and release of inflammatory mediators like IL-8 and TNF-α. After activation with lipopolysaccharide (LPS) and zymosan, phagocytosis, degranulation and L-selectin shedding were measured by flow cytometry using polychromatic microspheres and surface markers (CD11b, CD62L, CD66b). In addition, generation of ROS was analyzed by dichlorofluorescein assay (DCF), whereas activation-induced release of inflammatory mediators was measured by enzyme-linked immunosorbent assay (ELISA) and intracellular flow cytometry. Furthermore, migratory response of PMN was examined in a transwell migration assay. Secondly, blood samples of patients after HSCT under continuous CsA medication (n=17) and healthy volunteer donors (n=8) were analyzed *ex vivo* at two different time points after allogeneic HSCT (day 25-35 and 125-135) concerning their PMN effector functions as described above.
Results: CsA had no significant influence on expression of activation markers and shedding of CD62L *in vitro*. Moreover, no substantial influence of CsA on generation of ROS was detected compared to untreated controls. Along with that, activation-induced synthesis of IL-8 was not influenced in presence of CsA. However, CsA rather enhanced phagocytosis of PMN (83.5% +/- 1.7 (CsA) *vs* 71.0 +/- 1.5 (control), after stimulation with LPS), whereas their migratory capabilities were reduced (30.2% +/- 10.8 *vs* 40.1 +/- 0.9, spontaneous; 114.0% +/- 2.3 *vs* 79.8 +/- 0.6, yeast activated). Regarding the *ex vivo* analysis of HSCT patient and healthy donor blood samples, production of ROS was slightly decreased under CsA therapy (31.7% +/- 4.5 *vs* 41.4 +/- 7.0, zymosan). In contrast, CsA medication showed a stimulating effect on PMN phagocytosis which is in line with our *in vitro* data (54.2% +/- 4.1 *vs* 43.8 +/- 1.5, LPS), as well as on PMN activation (CD11b: 11897 MFI +/- 983 *vs* 9321 +/- 1279, LPS) and degranulation (CD66b: 22328 MFI +/- 2365 *vs* 9668 +/- 1359, LPS), whereas L-selectin shedding was unaffected. Furthermore, an increased production of IL-8 and TNF-α was detectable (IL-8: 18.7% +/- 4.3 *vs* 5.5 +/- 2.6; TNF-α: 20.9% +/- 3.4 *vs* 4.0 +/- 2.0, both zymosan).
Summary and Conclusions: We found an increased phagocytic activity *in vitro* and *ex vivo* in human PMN upon NFAT/calcineurin inhibition, whereas other effector mechanisms were unaffected or rather decreased *in vitro*. In addition, HSCT patients under CsA treatment displayed enhanced degranulation and inflammatory mediators production in PMN *ex vivo*. It is currently unclear whether these findings are clinically relevant for the innate immune response after HSCT and further studies are needed to distinguish this obviously multidimensional interaction of NFAT inhibition and innate immune response.

Background: Acute graft-*versus*-host disease (GVHD) is a major complication of allogeneic hematopoietic cell transplantation (HCT). Recently, much attention has been given to the role of innate immune responses in its pathogenesis. Host tissue damaged by HCT conditioning releases molecules that mediate danger signals, which bind to pattern recognition receptors on antigen-presenting cells, such as Toll-like receptors (TLRs), activate the innate immune response, and induce the upregulation of cytokines, leading to the amplification and maintenance of GVHD. The monocyte/macrophage is an important cell component in the innate immunity system; IL-32 augments the GVH reaction in contrast to the inhibitory effect of macrophage colony-stimulating factor (M-CSF). We analyzed the gene expression profiles of IL-32 and M-CSF-induced macrophages, and monocytes from HCT patients, and focused on transforming growth factor β-activated kinase 1 (TAK1), which plays a key regulatory role in various cytokine-mediated innate immunity signal transduction cascades, including the downstream signaling of TLRs.
Aims: The aim of this study was to clarify the roles of TAK1 on GVHD pathogenesis using TAK1 inhibitor *in vitro* and in an allogeneic mouse HCT model.
Methods: The present study was performed according to a protocol approved by the ethics committee of our institute, and informed consent was obtained from all the patients and healthy volunteers participating in the study. Transcriptional profiles of cytokine-induced macrophages from healthy volunteers and monocytes from post-HCT patients, as substitute for tissue macrophages (*N*=9; seven experienced GVHD, while two did not), were examined by microarray analysis and Gene set enrichment analysis (GSEA). Allogeneic mixed cell reactions (alloMCRs) were performed in the presence of 5Z-7-Oxozeaenol (OZ), a selective inhibitor of TAK1, or not. The impact of TAK1 inhibition by OZ on the production of the pro-inflammatory cytokines by LPS-stimulated monocytes was evaluated using a human proteome profiler array. In the MHC-mismatched mouse HCT model (donor, B6; recipient, BALB/c), recipient mice were given 5 μg of OZ from day 12 to day 25 to validate the effect of TAK1 inhibition on survival and GVHD severity.
Results: Gene expression signatures of M-CSF or IL-32 induced macrophages revealed difference in the TLR signaling pathway. Although the number of analyzed post-HCT patients was insufficient to make a definite clustering of monocyte gene expression, there were certain changes in the expression of TLR signaling molecules, depending on GVHD, and particularly the expression level of TAK1, a key molecule of the pathway, was elevated in monocytes from GVHD patients, accompanied by upregulation of TNFα, IL-1β, and IL-6. The TAK1 inhibitor, OZ, suppressed pro-inflammatory cytokine production in LPS-stimulated monocytes, and reduced lymphocyte proliferation in alloMCRs. OZ also reduced the donor T-cell response after dendritic cell (DC) stimulation in both donor DC and recipient DC. Finally, post-conditioning alteration of TAK1 activity significantly improved the survival of recipient mice compared with controls in the MHC-mismatched mouse transplant model (P <0.01) with a reduction in GVHD scores after day 16 (P <0.01).
Summary and Conclusions: Our findings suggest that TAK1 is a key molecule in post-transplant innate immune and inflammatory responses, and this could be a novel therapeutic target in GVHD.

P699

DISTINCT EXOSOMAL MIRNA EXPRESSION OF LATE ONSET GRAFT-*VERSUS*-HOST DISEASE IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

S. Yoshizawa[1,*] T. Umezu[2], Y. Saitoh[1], M. Gotoh[1], D. Akahane[1], C. Kobayashi[2], J. H. Ohyashiki[3], K. Ohyashiki[1]
[1]Department of Hematology, [2]Department of Molecular Science, [3]Institute of Medical Science, Tokyo Medical University, Tokyo, Japan

Background: Exosomes, small endosome-derived extracellular vesicles, are present in various biological fluids, such as plasma. They contain a wide range of functional proteins, mRNAs, and miRNA, thus have potential in facilitating molecular diagnosis. A recent study by Xiao *et al.* demonstrated that specific plasma miRNA signature could serve as an independent biomarker for the prediction, diagnosis, and prognosis of classic acute GVHD. Unlike classic acute GVHD, however, molecular mechanism of persistent, recurrent, late onset acute GVHD has not fully elucidated.
Aims: We therefore set out to determine clinically relevant exosomal miRNAs in patients developing late onset acute GVHD after HSCT.
Methods: We evaluated blood samples obtained from 10 patients who underwent HSCT for treatment of hematologic diseases between February 2012 and November 2013 at our institution. This study consisted of 5 patients with late onset acute GVHD (gut, n=2, liver, n=2, skin and gut, n=1), and 5 patients without GVHD (control). The diagnosis of acute GVHD was based on clinical symptoms or histologically proven by biopsy in the target organs. Patients with typical manifestations of acute GVHD occurring beyond 100 days after transplantation were considered as having late onset acute GVHD, according to the new classification made by NIH consensus criteria. Exosoms were isolated from plasma using a Total exosome isolation kit for plasma (Life Technologies). To identify exosomal miRNAs specific for late onset acute GVHD, we then compared exosomal miRNA expression between late onset acute GVHD and non-GVHD using TaqMan miRNA Array (Life Technologies). The validation of the microarray data was done by qRT-PCR. Expression levels of candidate miRNAs (miRNA-A, and B) was analyzed sequentially in a subset of late onset acute GVHD patients. Wilcoxon rank-sum test was used to determine statistical significance for comparisons between late onset acute GVHD groups and non-GVHD groups using R software. P values less than 0.05 were considered to indicate statistically significant differences.
Results: We found that exosomal miRNA are differently expressed in late onset acute GVHD compared to non-GVHD controls: a subset of miRNAs were significantly up-regulated in the exosomes of late onset acute GVHD (p□0.005) when compared with non-GVHD. Accordingly, the predicted target genes of the miRNA-A and B were obtained from MirTarBase: ERBB2, KLF13, CBFB for miRNA-A and DCX, RELN, BMI1, FBXW7 for miRNA-B were validated by luciferase reporter assay in the literature. The Database for Annotation, Visualization and Integrated Discovery (DAVID) Bioinformatics tools provided functions of the target genes for miRNA-A and B linked inflammation, T-cell activation, and immune system development and nucleotide-binding. Notably, the expression levels of the miRNA-A and B changed subsequently prior to the occurrence of clinical manifestations.
Summary and Conclusions: Although the number of patients in the current study is small, our study indicates that altered expression of certain exosomal miRNAs may play an important role in the occurrence of GVHD, therefore, may be helpful for as a potent predictive biomarker for managing patients with GVHD.

B LYMPHOCYTES ARE IMPORTANT EFFECTOR CELLS IN ANTI-AML RESPONSES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

M. Gillissen[1,2,*] E. Yasuda[1], S. Levie[1], A. Bakker[1], M. Kedde[1], Y. Claassen[1], C. Huisman[2], T. Beaumont[1], P. van Helden[1], H. Spits[1], M. Hazenberg[2]
[1]AIMM Therapeutics, [2]Academic Medical Center (AMC), Amsterdam, Netherlands

Background: Unleashing the tumor-specific immune response by immunotherapies such as checkpoint inhibitors or allogeneic stem cell transplantation can result in long lasting tumor regression. It is thought that T cell responses are responsible for tumor rejection.
Aims: Here we tested the hypothesis that B cells contribute to tumor regression following immunotherapy by analysing the tumor-specific antibody repertoire in patients with acute myeloid leukemia (AML), a high-risk malignancy with a poor prognosis. These patients received an allogeneic hematopoietic stem cell transplantation (HSCT) that reset the immune system and led to potent graft *versus* leukemia (GvL) responses.
Methods: We selected three patients who despite the high-risk nature of their AML remained disease free after allogeneic HSCT. Of these patients we established antibody-producing clonal B cell lines following transduction of memory B cells from peripheral blood with BCL-6 and Bcl-xL and screened those for producing antibodies specifically binding to surface antigens on AML cell lines and AML blasts.
Results: A number of antibodies were identified that recognized various primary AML blasts isolated from newly diagnosed AML patients, but did not bind to healthy bone marrow, peripheral blood mononuclear cells or tissues such as liver, skin and colon. Some of the antibodies induced complement dependent cytotoxicity. Strikingly, other AML-specific antibodies (about 40% of the repertoire) induced direct cell death of cultured AML cell lines and of primary AML blasts, independent of complement or effector cells. Cytotoxicity of the antibodies was rapid, characterized by swelling and blebbing of the cells and occurred both at 37ºC and 4ºC, suggesting activation of a non-apoptotic pathway. Indeed, target cell death could not be prevented with pan-caspase inhibitors Z-VAD or Q-VD. These characteristics of cell death fit with killing of tumor cells through a necrotic pathway like oncosis. A possible target recognized by a number of these antibodies will be discussed.
Summary and Conclusions: Together, these data indicate that highly potent, tumor selective antibodies can be elicited following allogeneic HSCT in AML patients. The direct cytotoxic activities against tumor cells of a proportion of these antibodies suggest that they contribute to the GvL response.

P701

FEMUR TARGET CELL TRANSPLANTATION CAN BE ACHIEVED BY MAGNETISM-INDUCED CELL TARGET TRANSPLANTATION (MAGIC-TT) IN MURINE TRANSPLANTATION MODEL

H. Huang[1,*] Y. Ye[1], Q. Jiang[1], Q. Mai[2], C. Yin[1], Y. Lu[2], J. Wang[2], L. Liu[2], Y. Zhou[1], X. Sun[2], M. Zhang[2], J. Qin[2], L. Yuan[2], Y. Yuan[2], Q. Zhang[2], J. Sun[1], Q. Liu[1]
[1]Department of Hematology, Nanfang Hospital, [2]Southern Medical University, Guangzhou, China

Background: Organ target cell transplantation will improve stem cell homing efficiency, as well as avoiding possible complications of cell diffused distribution. Here we set up a novel cell transplantation system named Magnetism-induced cell target transplantation (MagiC-TT). This work was supported by the National Natural Science Foundation of China (No. 30901367, 31070866), Outstanding Young Teachers' foundation of SMU (C1031694).
Aims: To explore the distribution and survival of donor cells transplanted by MagIC-TT *in vivo and ex vivo.*
Methods: 1) Magnetized cells: Two kinds of cells were used, C57BL/6 RFP+ mesenchymal stem cells (MSC-RFP) and C57BL/6 GFP+ CD45+ (CD45-GFP) cells. MSC-RFPs was bought from Cyagen Biosciences Inc, China, and were magnetized by self-made Au@Fe nano-particle, positive cells were sorted by MACS column. CD45-GFPs were sorted from C57BL/6 GFP-transgenic mice bone marrow by MACS anti-CD45 beads and column. 2) *Ex vivo* study: Both magnetized MSC-RFPs and CD45-GFPs and their wild type controls were study of cell morphology, cell proliferation, cell cycle and cell viability, as well as cells' migration to magnetism, transwell migration and matrigel migration assays. 3) *In vivo* study: To MSCs-RFP study, fifty C57BL/6 female GFP transgenic mice were divided into 3 magnetized cell groups and 2 non-magnetized cell groups, magnetized and wt MSCs were injected into the femur cavity of the mice. To the CD45-GFP cell study, forty C57BL/6 female mice (4 groups) were transplanted after 7.5Gy irradiation. At different time points after cells injection, FACS, bioluminescence, pathologic observation with fluorescence and confocal microscopy, together with real-time PCR were used to detect GFP and RFP cells in peripheral blood, bone marrow, liver, spleen, thymus and lung, etc. Femurs and humeri of recipients were decalcified with self-made semi-solid decalcification (SSD) to clarify the distribution of donor cells and their relationships with the microenvironment.
Results: 1) *Ex vivo* study: There were no differences between magnetized and non-magnetized MSCs or CD45 cells in cell morphology, cell proliferation, cell cycle and cell viability. The Fe particles exist within or on the surface of magnetized MSCs or CD45 cells observed by electric microscope. Within the magnetic field, magnetized cells can migrate through matrigel and transwell membrane much more efficiently, 174±22 *vs* 2±1 per 200X microscopic vision (P<0.0001); they also can migrate horizontally towards magnetism in matrigel. The most interesting is, magnetized MSCs even grow well on the roof of 24-plate (grows against gravity) in the culture medium. 2) In early hours after transplantation, lots of magnetized RFP+ or GFP+ cells exit within femur and knee joint in magnetized cells groups while few in the control groups, while many non-magnetized MSCs and CD45-GFP distributed in the lung while few in magnetized cell group. After few days without any magnetism, RFP+ or GFP+ were observed to migrate to the spleen, kidney, gut and other organs, showing the slowly release of target-transplanted-cells from femur.3) To the CD45-GFP study, the blood recovery in MagIC-TT group is much faster than the controls, especially for the platelet.
Summary and Conclusions: These results demonstrated that femur target cell transplantation can be achieved by MagIC-TT, which can be widely used for cell transplantation and cell therapy in the future.

Stem cell transplantation - Clinical 2

P702

COMPLEMENT-BINDING DONOR-SPECIFIC ANTI-HLA ANTIBODIES AND RISK OF PRIMARY GRAFT FAILURE IN HEMATOPOIETIC STEM CELL TRANSPLANTATION

S. Ciurea[1,*] P. Kongtim[1], U. Popat[1], F. Aung[2], R. Champlin[1], K. Cao[1]
[1]Stem Cell Transplantation, [2]Pathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Detection of donor-specific anti-HLA antibodies (DSA) has been associated with graft rejection in all forms of transplantation. The mechanism by which DSA increase the risk of graft failure remains unclear.
Aims: We hypothesized that complement-binding DSA are associated with engraftment failure in hematopoietic stem-cell transplantation.
Methods: We analyzed 122 haploidentical transplant recipients tested prospectively for DSA. Retrospective C1q testing was done on 22 allosensitized recipients.
Results: Twenty-two of 122 patients (18%) had DSA, 19 of which were females (86%). Seven patients with DSA (32%) rejected the graft. Median DSA level at transplant for patients who failed to engraft was 10,055 MFI *versus* 2,065 MFI for those who engrafted (p=0.007). Nine patients with DSA were C1q positive in the initial samples with median DSA level 15,279 MFI (range 1,554-28,615), compared with 7 C1q negative patients with median DSA level 2,471 MFI (665-12,254) (p=0.016). Of 9 patients, who tested positive for C1q in the initial samples, 5 patients remained C1q positive at time of transplant [all with high DSA levels (median 15,279, range 6,487-22,944)] and experienced engraftment failure, while 4 patients became C1q negative pre-transplant and all engrafted the donor cells (p=0.008) (Figure 1).

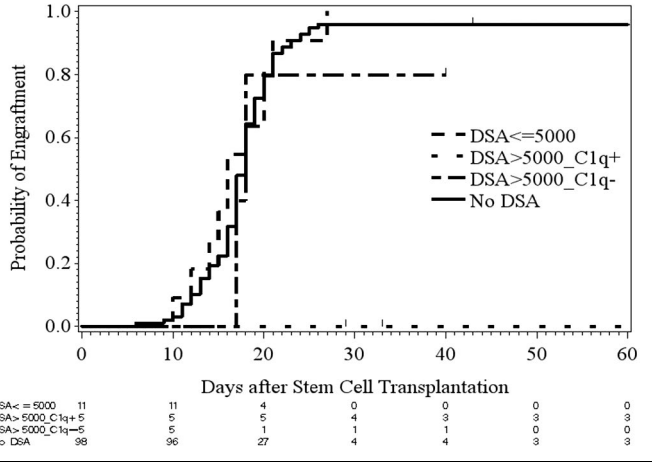

Figure 1.

Summary and Conclusions: Patients with high DSA levels (>5,000 MFI) and complement-binding antibodies (C1q positive) appear to be at much higher risk of primary graft failure. C1q should be assessed in patients with DSA prior to hematopoietic stem-cell transplantation. Reduction of DSA to non-complement binding levels might prevent engraftment failure in hematopoietic stem cell transplantation.

P703

DURABLE REMISSIONS AFTER SEQUENTIAL TRANSPLANTATION USING T-REPLETE NON-MYELOABLATIVE CONDITIONING FOR RELAPSED/ REFRACTORY ACUTE MYELOID LEUKAEMIA AND MYELODYSPLASIA

S. Hassan[1,*] J. Davies[2], M. Smith[1], D. Tsitsikas[3], H. Oakervee[1], S. Hallam[1], D. Taussig[2], J. Gribben[2], J. Cavenagh, [1]
[1]Haemato-Oncology, St Bartholomews Hospital, [2]Haemato-Oncology, Barts Cancer Institute, [3]Haematology, Homerton University Hospital, London, United Kingdom

Background: Allogeneic transplantation remains the only curative treatment for most patients with relapsed/refractory AML and high risk MDS. Conventionally, patients are treated with intensive chemotherapy to induce remission prior to transplantation. However, many patients cannot proceed to transplant using this approach because of toxicities, delayed engraftment and failure to achieve remission. The sequential allogeneic transplantation approach was introduced to address these concerns by giving intensive chemotherapy to reduce the leukaemic burden and then proceeding immediately to reduced intensity conditioned transplantation to provide a long-lasting graft-vs-leukaemia effect. To date, this approach has only been reported using T cell depleted conditioning in the context of myeloid disorders.
Aims: Following the low toxicity associated with our T-replete transplantation approach using non-myeloablative fludarabine cyclophosphamide conditioning in other clinical settings, we performed a prospective single-centre study using this transplant strategy as part of a sequential approach for patients with relapsed/refractory AML and high risk MDS.
Methods: Patients received daunorubicin (45mg/m^2 D-15-D-13) and cytarabine (1500mg/m^2 *bd* D-15-D-9) followed by fludarabine (25mg/m^2 D-6-D-2) and cyclophosphamide (1g/m^2 D-3-D-2). GvHD prophylaxis was with methotrexate and ciclosporin (CSA).
Results: 44 patients were enrolled on study between 2007 and 2014 after written informed consent. Median follow-up was 51 months. Median age was 53 years (range 23-68). Patients had refractory AML(50%), relapsed AML(30%), untreated AML(5%) and MDS(15%). Most patients (65%) had an intermediate or high co-morbidity index. No patients were in remission pre-therapy. All patients were transplanted from fully HLA-matched donors (50% sibling donors, 50% unrelated donors). All patients who survived beyond day 30 engrafted. Median time to neutrophil engraftment was 21 days. 3 year NRM was 38%, split equally between infection and GVHD. 35% developed acute GVHD (grade II-IV) and 33% of all assessable patients had chronic GVHD requiring immunosuppression, half of whom died from GVHD-related causes. Early deaths were more common in those over 60 years. Only one patient had CMV disease (colitis) and no other clinically significant viral complications occurred. No patients received donor lymphocyte infusions. With a median follow up of 5 years, the cumulative incidence of persistent or relapsed disease was 35%. 1 year and 3 year overall survival (OS) was 42% and 30% respectively. No factors impacted upon overall survival. Patients with adverse cytogenetics had a significantly higher risk of relapse (p=0.08). Patients with chronic GVHD demonstrated a trend to reduced relapse. Patients with relapsed AML and MDS had excellent outcomes with 5 yr OS of 42% and 67% respectively.
Summary and Conclusions: The rationale of using lower intensity chemotherapy and non-myeloablative conditioning followed by T-replete transplantation facilitated the treatment of an older, less fit patient group, whilst maintaining comparable outcomes to more aggressive strategies. This treatment approach is particularly effective in those with relapsed AML and MDS.

P704

SERUM FERRITIN IS INDEPENDENT OF DISEASE RISK INDEX FOR OVERALL SURVIVAL FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION

L. Chee[1,*] M. Tacey[2,3], B. Lim[3], D. Ritchie[1]
[1]Department of Clinical Haematology and Bone Marrow Transplant Unit, [2]Melbourne EpiCentre, The Royal Melbourne Hospital, [3]Department of Medicine, The University of Melbourne, Parkville, VIC, Australia

Background: Elevated serum ferritin has been associated with inferior survival and relapse outcomes following allogeneic stem cell transplantation (SCT). Serum ferritin is commonly used as a surrogate marker for iron overload. However, a recent meta-analysis showed no impact of liver iron concentration assessed by MRI on survival outcomes. The relationship between ferritin and survival outcome may be related to either the direct effect of iron on organ function or reflect the transfusion and/or comorbidities associated with pre-SCT disease status.
Aims: Correlation of iron studies pre-SCT with clinical outcomes.
Methods: We undertook a retrospective analysis of all allogeneic SCT recipients for haematological malignancy between 2000-2013. Iron studies were performed pre-SCT and Day 100, 12 months and 24 months post-SCT. We assessed overall survival (OS), relapse free survival (RFS) and non-relapse mortality (NRM) as a function of pre-transplant ferritin and transferrin saturation. Co-variates included in univariate analysis and then multivariate analysis if predictive of OS or RFS included age, gender, disease type, disease risk index (DRI), conditioning intensity, graft source, donor type, cytomegalovirus status, graft-*versus*-host disease (GVHD) prophylaxis and acute and/or chronic GVHD treated as time-dependent covariates.
Results: 602 patients were identified (Male n=339, Female n=263). The median age was 49 years. The main underlying diagnoses were acute myeloid leukaemia (AML) (n=223; 37%), Non-Hodgkin lymphoma (NHL) (n=96; 16%) and acute lymphoblastic leukaemia (ALL) (n=89; 15%). The pre-SCT conditioning regimen was myeloablative (n=372; 62%), reduced intensity (n=181; 30%) and non-myeloablative (n=49; 8%). Graft source was peripheral blood (PB) (n=476; 79%), bone marrow (BM) (n=96; 16%), cord blood (n=27; 4%) and both PB and BM (n=1; 0.2%). Donor type was sibling (n=362, 60%), unrelated (n=207; 34%), cord (n=26; 4%) and other family relation (n=7; 1%). Post-SCT GVHD prophylaxis was primarily with Cyclosporin and Methotrexate for the related and unrelated donor transplants and Mycophenolate mofetil for the cord blood transplants. DRI was low (n=53; 9%), intermediate (n=371; 62%), high (n=149; 25%), very high (n=5; 1%) and unable to be calculated in 24 (4%). The median ferritin levels were pre-SCT 1079ug/L, post-SCT D100 2074ug/L, 12 months 993ug/L and 24 months 740ug/L. A pre-SCT ferritin level above the median was associated with inferior OS (HR 1.84, 95%CI: 1.41-2.39) and increased relapse rates (HR 1.44, 95%CI: 1.07-1.93). High transferrin satura-

tions (>50%) were associated with inferior OS (HR 1.44, 95%CI: 1.09-1.90) but not with relapse outcomes (HR=1.10, 95%CI: 0.80-1.53). Univariate analysis determined DRI (High: HR 3.91, 95%CI: 2.08-7.35 and Very high: HR 6.4, 95%CI: 2.03-20.19 when compared to Low), disease type (NHL: HR 0.42, 95%CI: 0.27-0.66 when compared to AML) and chronic GVHD (HR 0.46, 95%CI: 0.34-0.63) as the other most significant variables impacting OS. On multivariate analysis, pre-transplant ferritin above median remained statistically significant for inferior OS (HR 1.89, 95%CI: 1.42-2.52) but lost its association with increased relapse risk (HR 1.28, 95%CI: 0.86-1.90) with DRI a strong confounding factor (High: HR=3.33, 95%CI: 1.44-7.71 and Very high: HR=10.35, 95%CI: 1.76-60.75). Pre-SCT ferritin level thresholds of 1000ug/L and 2500ug/L remained a significant predictor for OS. The main causes of death in the high/low ferritin groups were progressive disease (25%/14%), infection (7%/5%) and GVHD (6%/5%).

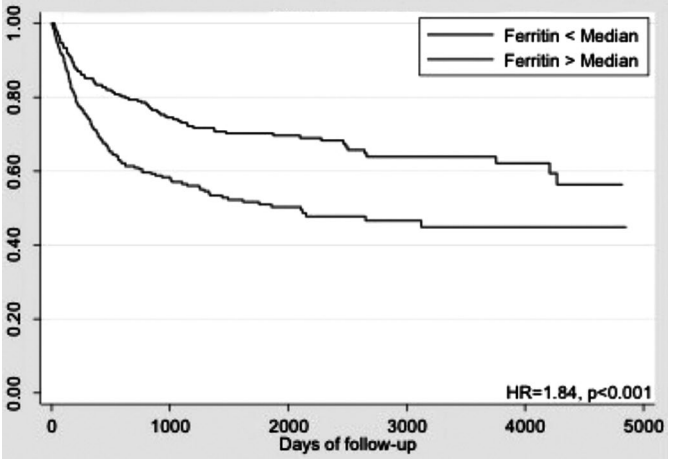

Figure 1. Kaplan-Meier survival estimates: by median ferritin.

Summary and Conclusions: A high pre-transplant serum ferritin remains an important prognostic variable in allogeneic SCT independent of DRI. Serum ferritin was a better predictor of survival outcome in comparison to transferrin saturation in our cohort of patients, although no significant prediction of relapse risk was found after adjustment for DRI.

P705

COMBINATION THERAPY WITH INOLIMOMAB AND ETANERCEPT FOR SEVERE STEROID-REFRACTORY ACUTE GRAFT-*VERSUS*-HOST DISEASE

L. Van Groningen[1,*] A. Liefferink[1], A. de Haan[2], N. Schaap[1], P. Donnelly[1], N. Blijlevens[1], W. van der Velden[1]
[1]Hematology, [2]Epidemiology, Radboudumc, Nijmegen, Netherlands

Background: After allogeneic stem cell transplantation (SCT) the occurrence of acute graft-*versus*-host disease (aGVHD) is an important cause of morbidity and mortality. Treatment of aGVHD consists of high-dose steroids in first-line with approximately a 50% response rate. However patients who prove refractory to this therapy, especially those who suffer from grade III-IV aGVHD with gastrointestinal involvement, have a very poor prognosis. Different therapeutic strategies have been used for second-line therapy, but responses have remained disappointing. In literature both inolimomab (monoclonal antibody targeting the interleukin-2 receptor subunit α that inhibits activated alloreactive T cells) and etanercept (TNFα-receptor fusion protein that scavenges TNFα) have shown promising results when used as monotherapy. Therefore combination therapy with these drugs might prove beneficial in patients with steroid-refractory aGVHD as two pivotal pathways in aGVHD pathogenesis are inhibited.
Aims: In this study we evaluated the efficacy and safety of second-line combination therapy, inolimomab and etanercept, for patients with steroid-refractory aGVHD. Primary endpoints were the overall response rate (ORR) on day 28 of second-line therapy and the 6-month estimated overall survival (OS).
Methods: Second-line treatment with inolimomab and etanercept started when steroid-refractory aGVHD was determined. Inolimomab was administered intravenously in a dose of 0.3 mg/kg daily from day 1 to 8 and a dose of 0.4 mg/kg every other day from day 9 to 28. Etanercept was given subcutaneously twice weekly at a dose of 25 mg during 4 weeks. Primary endpoints were overall respons rate (ORR) on day 28 of second-line therapy and the 6-month estimated overall survival (OS).
Results: From February 2010 to February 2014 21 patients with steroid-refractory grade III-IV aGVHD received treatment with the combination therapy inolimomab and etanercept. 19 had GI involvement and mean albumin levels at diagnosis were 27 g/l. Of the 21 patients 6 achieved a complete response (CR) and 4 patients a partial response (PR), bringing the overall response rate on day 28 to 48% (10/21). On day 56, the overall response rate was 33% with 5 patients retaining CR and 2 a PR. The estimated 6-month and 2-year overall survival were dismal; 24% (5/21) and 10% (2/21). Statistical significant risk factors for treatment response were determined namely aGVHD after donor lymphocyte infusion (p=0.01) and GVHD involving the liver stage 2-4 (p=0.03). There were no infusion-related adverse events. Infectious complications occurred frequently and consisted predominantly of bacteriemias with gut residing pathogens, invasive mould disease and CMV and EBV reactivation and disease.
Summary and Conclusions: Combination therapy with inolimomab and etanercept in patients with steroid-refractory grade III-IV aGVHD was moderately effective with regards to achieving a remission, but nevertheless overall survival was dismal, with only 10% of patients being alive at last follow up. New strategies are urgently needed with more effective drugs but also with approaches directed at prevention of refractory GVHD and incorporation of biomarkers that facilitate risk-adapted therapy.

P706

PURE RED CELL APLASIA IN MAJOR ABO MISMATCHED ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IS ASSOCIATED WITH SEVERE PANCYTOPENIA

F. Aung[1,*] B. Lichtiger[1], R. Gabriela[2], A. Alousi[2], S. Ahmed[2], B. Andersson[2], Q. Bashir[2], C. Stefan[2], C. Hosing[2], R. Jones[2], P. Kebriaei[2], I. Khouri[2], Y. Nieto[2], O. Betul[2], S. Parmar[2], M. Qazilbash[2], N. Shah[2], E. Shpall[2], R. Champlin[2], U. Popat[2]
[1]Transfusion Medicine, [2]Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: The persistence of anti-donor isohemagglutinins in Major ABO mismatched allogeneic stem cell transplantation (HCT) leads to pure red cell aplasia (PRCA). In our previous report of 12 patients with PRCA, severe pancytopenia was observed in one patient who eventually had a second transplant (Aung *et al.* B J Haematol 2013 Mar; 160(6):798-805). Furthermore, ABO antigens are expressed on or adsorbed from plasma on granulocyte and platelets and production of these may be impaired by isohemagglutinins.
Aims: To further investigate this observation we analyzed a larger cohort of patients with PRCA to determine the frequency of pancytopenia and natural history of pancytopenia in patients with PRCA after major ABO incompatible HCT.
Methods: We reviewed 707 patients who received a major ABO-mismatched HCT between January 2003 and December 2012 at our institution. Pure red call aplasia was determined to be present when the bone marrow biopsy on post-transplant day 30 demonstrated absent or nearly absent erythroid precursors with absence of donor red cells on forward red cell typing of the recipient and the recipient being red cell transfusion dependent. Pancytopenia was defined as ANC $<1.5x10^9$/L or requiring G-CSF, Platelets $<50x10^9$/L or transfusion dependent, and PRCA with red cell transfusion dependence as above at 90 days after allogeneic SCT.
Results: 83 (11.7%) patients (29[35%] males: 54[65%] females) had PRCA and of these 13 (16%) (10 [77%] males]: 3[23%] females), median age 53 [range 27-66 years] had pancytopenia at day 90 after transplant. There was a female preponderance of PRCA patients, however a male predominance was noted in PRCA patients with severe pancytopenia. None of these patients had any other reason for persistent pancytopenia like CMV or other viral infection or use of drugs like ganciclovir or disease recurrence. On post-transplant day 90, median absolute neutrophil counts (ANC) was 0.93 K/UL with all patients having intermittent G-CSF. The median platelet count was 14 KL/UL (range 6-34) and all patients were platelet and red cell transfusion dependent. Of the 13 PRCA patients with pancytopenia, 2 (15%) received a second transplant due to persistent pancytopenia/graft failure, 4 (31%) patients did not recovered their platelet counts despite red cell and ANC recovery and died (3 from disease recurrence/1 from myocardial infarction). 1 (8%) patient was lost to follow up. In the remaining 5 (38%) patients, neutropenia and thrombocytopenia resolved after resolution of PRCA. Red cell recovery occurred at a median of 188 (97-549) days post-transplant, ANC recovered at median of 296 (145-743) days post-transplant, and Platelets recovered at median of 296 (190-1250) days post-transplant.
Summary and Conclusions: Severe pancytopenia is frequently (16%) associated with PRCA in major ABO incompatible HCT. Neutropenia and thrombocytopenia resolve after resolution of red cell aplasia in the majority of patients.

P707

DONOR CHIMERISM AS MARKER OF RELAPSES AFTER BONE MARROW TRANSPLANTATION.

I. Barkhatov[1,*] A. Evdokimov[2], A. Shakirova[1], V. Teplyashina[1], S. Bondarenko[1], A. Chukhlovin[1], L. Zubarovskaya[1], B. Afanasyev[1]
[1]R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, [2]R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, FIRST PAVLOV SAINT PETERSBURG STATE MEDICAL UNIVERSITY, St.Petersburg, Russian Federation
Background: Allogeneic hematopoietic stem cell transplantation is an effective treatment for different hematological malignances. Efficiency of donor cell engraftment is determined by donor chimerism evaluation, *i.e.* determining of genetically different cell populations coexistence in patient. We assume that the kinetics of chimerism in patients with hematologic malignancies, in turn, may be defined in

terms of relapse probability, and it could be used as a marker of minimal residual disease (MRD) after allogeneic transplantation of HSCs (allo-HSCT).
Aims: Evaluation of donor chimerism definition in assessing the likelihood of posttransplant relapses.
Methods: We have analyzed 440 allo-HSCT's in patients with various hematologic malignancies. For the donor chimerism monitoring we used standard panels of human DNA markers based on STR variability (short tandem repeats, microsatellites). The ratios of donor and recipient cells were calculated according to the data derived from fragment analysis, using the Genemarker program. The study was performed on days +15, +30, +45, +60 and +100 after transplantation.
Results: Achieving of full donor chimerism (95%) significantly increases the 5-year survival (p=0.001) and reduces the probability of disease recurrence (p=0.01). Among patients with mixed chimerism the stability of donor chimerism level is most important, being associated with lower risk of relapse (p=0.013). Thus, in patients with stable mixed chimerism, the markers molecular markers of MRD had no significant effect either on overall survival, or the likelihood of relapse (p=0.55 and p=0.34 respectively). Meanwhile, we had found an inverse correlation between the level of donor chimerism and expression of relapse markers, *i.e. WT1* (R=-0.4, p=0.0001) and *EVI1* (R=-0.16, p=0.03). Similar data were obtained when analyzing expression of the chimeric transcripts: *BCR-ABL* (R=-0.26, p=0.0001), *MLL-AF4* (R=-0.36, p=0.003), TEL-AML (R=-0.37, p=0.003). Hovewer, this dependence with other markers (*CBFB-MYH11*, *PML-RARα*, *RUNX1-RUNX1T1*) could be also obtained.
Summary and Conclusions: Monitoring of donor chimerism after allo-HSCT adequately reflects the dynamics of donor cells engraftment and may be used as an adequate method for predicting recurrence of the disease, but it can not be used as a single method in MRD analysis.

P708

PERIPHERAL BLOOD EOSINOPHIL COUNT AT DAY 28 AS A PROGNOSTIC INDICATOR IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

K. Kawamoto[1,*] Y. Shibasaki[2], H. Kobayashi[1], T. Ushiki[1], N. Sato[3], T. Yano[3], M. Moriyama[1], T. Kuroha[3], J. Takizawa[1], S. Hashimoto[3], M. Narita[1], T. Furukawa[3], H. Sone[1], M. Masuko[2]
[1]Department of Hematology, Endocrinology and Metabolism, Niigata University Faculty of Medicine, [2]Division of Stem Cell Transplantation, Niigata University Hospital, Niigata City, [3]Department of Hematology, Nagaoka Red Cross Hospital, Nagaoka City, Japan

Background: Peripheral blood eosinophilia has been reported as a favorable prognostic indicator for patients with hematologic disease after allogeneic hematopoietic stem cell transplantation (HSCT). It has been reported to be associated with chronic Graft *versus* Host Disease (GVHD) and decreased relapse rate. Eosinophils play an important role in alloimmune reactions after HSCT. However, the relationship between eosinophilia after HSCT and acute GVHD is still controversial, and the clinical relevance of peripheral blood eosinophil count (PB-Eos) at the early phase after HSCT is not clear.
Aims: The purpose of this study was to clarify the clinical relevance of PB-Eos at the early phase after HSCT.
Methods: We enrolled 180 adult patients with hematological neoplasms who underwent their first HSCT between November 2004 and August 2013 at Niigata University Hospital and Nagaoka Red Cross Hospital in this study. Forty-four of the 180 patients were excluded from the analysis because of graft failure, using corticosteroids before day 28 after HSCT, or inadequate laboratory data. We analyzed retrospectively 136 patients, including 55 with acute myelogenous leukemia, 40 with acute lymphoblastic leukemia, 22 with myelodysplastic syndrome, 3 with myeloproliferative neoplasm, 2 with chronic myelogenous leukemia, 3 with adult T cell leukemia, 1 with mixed lineage leukemia, and 10 with malignant lymphoma. Median age of patients was 42 years (range: 16-66). Fifty-six patients received related stem cell transplantation, 50 received unrelated stem cell transplantation, and 30 received cord blood transplantation. Chi-squared analysis and Fisher's exact test were used to assess the relationship between PB-Eos and acute GVHD. Overall survival (OS) was based on Kaplan-Meier estimates. Cumulative relapse rate (RR) was based on Gray's estimates. Multivariate Cox regression for OS and Fine-Gray regression for RR were used to identify the independent risk factors.
Results: Median PB-Eos at day 28 was 48 /μl (range: 0-3078 /μl). We divided the patients into 2 groups, those with PB-Eos of more than 50 /μl and those with PB-Eos of less than 50 /μl at day 28. According to univariate analysis, PB-Eos of <50 /μl at day 28 tended to indicate a poor prognosis of OS (p=0.096). In multivariate analysis adjusting for age, grade 2-4 acute GVHD after day 28, disease status and conditioning regimen, and PB-Eos of less than 50 /μl at day 28 were independent poor prognostic factors for OS (HR: 1.86 (1.05-3.31), p=0.034). In patients with acute GVHD of any grade, PB-Eos of <50/μl at day 28 was an independent prognostic factor for OS (HR: 3.14 (1.34-7.34), p=0.0085) and RR (HR: 4.45 (1.65-12.06), p=0.003). In contrast, it was not a prognostic factor for OS or RR in patients without acute GVHD. Next, we analyzed the relationship between PB-Eos and acute GVHD. PB-Eos was not associated with development of grade 2-4 acute GVHD after day 28 by Chi-squared analysis (p=0.55) and grade of acute GVHD by Fisher's exact test (p=0.37). Furthermore, in patients with grade 2-4 acute GVHD after day 28, PB-Eos of <50/μl at day 28 was also an independent prognostic factor for OS (HR: 3.87 (1.12-13.37), p=0.033) and RR (HR: 4.88 (1.26-18.82), p=0.021).
Summary and Conclusions: PB-Eos at day 28 is an independent prognostic indicator for OS in HSCT. In particular, lower RR may contribute to better OS in patients with acute GVHD. The presence of eosinophils at the early phase of HSCT could predict a good prognosis in HSCT.

P709

AUTOLOGOUS STEM CELL TRANSPLANTATION WITH HIGH-DOSE MITOXANTRONE AND MELPHALAN IN PATIENTS WITH HODGKIN AND NON-HODGKIN LYMPHOMA: LONG-TERM SURVIVAL AND TOXICITY DATA

B. Gungor[1], M. Yeral[2], M. Adam[1], C. Unsal[1], C. Boga[2], H. Ozdogu[2], Y. Koc[1,*]
[1]BMT Unit, MedicalPark, Antalya, [2]BMT Unit, Baskent University, Adana, Turkey

Background: In patients with high risk or relapsed lymphoma, a satisfying response rate and long-term survival cannot be achieved by conventional chemotherapy regimens. Despite reports of high-dose chemotherapy regimens coupled with or without autologous stem cell transplantation (Auto-SCT), medical literature reporting long-term survival and toxicity data beyond 10 years is rare. In the autologous transplant setting, use of high-dose mitoxantrone coupled with high-dose melphalan as conditioning protocol (HDMTZMEL) is relatively less frequent, compared to the well known BEAM regimen.
Aims: In this study, we report disease-free (DFS), long-term overall survival (OS) and long-term toxicity in patients with lymphoma treated with HDMTZMEL conditioning regimen followed by Auto-SCT during the past 15 years (2000-2014).
Methods: 107 patients relapsed or resistant diffuse large B-cell NHL (DLBCL, n=49) or Hodgkin lymphoma (HL, n=58) underwent Auto-SCT after administration of the conditioning regimen consisting of high-dose mitoxantrone (60 mg/m^2) and melphalan (180 mg/m^2) following greater than 50% response to the salvage regimens; DHAP or ICE or IIVP and/or HD-VP16. Treatment did not include prophylactic cranial radiotherapy. Patients over 65 years of age and with CNS involvement prior to salvage regimen and refractory to both initial therapy and the salvage regimens were excluded. Patients had a median age of 39 (16-63) and proceeded with Auto-SCT only after CR or PR was achieved.
Results: Following salvage chemotherapy, 68 (63.5%) patients achieved CR, and 36 (36,4%) achieved PR. Transplant related mortality (TRM) rate at day +100 was%0,9 in all patients, with an OS rate of 72.4% and 67,2% at 5 and 10 years, respectively. In patients with DLBCL, 5 and 10 year OS were 70.4%, whereas patients with HL had 74.9% and 67.4% OS rates, respectively. Five-year DFS was calculated as 62.9% (66.8% for DLBCL, 61.8% for HL) and did not change at 10 years and beyond. No statistically significant difference in OS and DFS rates was found between patient groups. In the DLBCL group, relapse was not observed after 29 months, whereas late relapses were observed until 57 months in patients with HL. In both groups, OS at 15 years were identical to OS at 10 years. Patients transplanted in CR had an OS rate of 80.4% at 5 yr (78.8% for NHL, 82.7% for HL, 71.5% after 10 years) whereas patients transplanted in PR had an OS rate of 55.7% at 5 and 10 years (52.5% for NHL, 57.7% for HL) and beyond (CR *vs* PR, p=0.01 for NHL and p=0.3 for HL). Patients transplanted in CR had an DFS rate of 72.9% at 5 yr and beyond (76.2% for NHL, 71.9% for HL) whereas patients transplanted in PR had an DFS rate of 42.4% at 5 and beyond (43.8% for NHL, 44.9% for HL) and beyond (CR *vs* PR, p=0.004 for all patients, p=0.2 for NHL and p=0.04 for HL). Late complications and toxicities during the post-transplant period include; late relapses (>3 years post-transplant) among patients with HL (n=3), secondary malignancy between 1-3 years (n=2,1 AML, 1 MDS), delayed platelet engraftment (n=2), congestive heart failure (n=1) corresponding to a late toxicity rate of 2.8% (Figure 1).

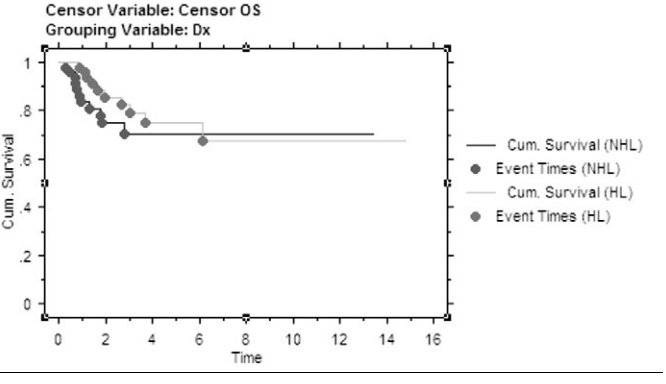

Figure 1. Kaplan-Meier cum. Survival plot for OS.

Summary and Conclusions: In patients with relapsed or resistant DLBCL and HL sensitive to pre-transplant salvage chemotherapy, HDMTZMEL conditioning regimen is capable of inducing high rates of OS and DFS rates with a low toxicity profile. In the DLBCL group, patients undergoing transplantation in CR have significantly higher overall survival and cure rate. In both DLBCL and HL groups, DFS is significantly better if the patients are transplanted in CR.

P710

RISK FACTORS FOR TRANSPLANTATION-ASSOCIATED THROMBOTIC MICROANGIOPATHY AND OUTCOME OF PATIENTS, FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

K. Balassa[1,*] H. Andrikovics[1], P. Remenyi[2], A. Batai[2], A. Bors[1], K.P. Kiss[1], L. Lengyel[2], E. Torbagyi[2], A. Barta[2], A. Szilvasi[3], K. Rajczy[4], D. Inotai[3], A. Tordai[1], T. Masszi[2]

[1]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, [2]Department of Hematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, [3]Laboratory of Transplantation Immunogenetics, [4]Bone Marrow Donor Registry, Hungarian National Blood Transfusion Service, Budapest, Hungary

Background: Transplantation-associated thrombotic microangiopathy (TA-TMA) is a feared complication of allogeneic hematopoietic stem cell transplantation (allo-HSCT) due to its high mortality. Endothelial damage and activation, attributed to multiple clinical factors, are thought to be the key elements in the induction of TA-TMA.
Aims: Our work focused on the assessment of the frequency, risk factors and prognostic impact of TA-TMA in allo-HSCT.
Methods: Data of 425 consecutive adult patients, who underwent first allo-HSCT for a malignant hematological condition at a single centre between 2007 and 2013, were retrospectively analysed.
The median age at transplantation was 43 years (range 19-73 years). The most common indications for the procedure were acute leukaemias. The donor stem cells originated from a sibling donor in 217/425 (51%) patients. Myeloablative conditioning (MAC) was administered to 267 (63%) patients, whereas 158 (37%) patients received reduced intensity conditioning. Graft-*versus*-host disease (GvHD) prophylaxis consisted of cyclosporin-, or tacrolimus-based regimens.
Results: The cumulative incidence of TA-TMA was 19% (80/425) in the entire cohort, and 65 (81%) patients developed TA-TMA within the first 100 post-transplant days. The majority of TA-TMA patients (83%) also suffered from acute GvHD (aGvHD), usually preceding TA-TMA. Several risk factors were identified in association with the manifestation of TA-TMA: aGvHD grade II-IV ($p<0.001$), unrelated donor type ($p<0.001$), MAC ($p=0.003$), tacrolimus-based GvHD prophylaxis ($p=0.003$) and cytomegalovirus (CMV) reactivation/disease ($p=0.004$). Overall survival rates of patients with TA-TMA were significantly lower compared to patients without the complication ($p<0.001$, 48-months overall survival 20+/-5 *vs* 52+/-3%). Among those affected by TA-TMA, the survival was poorer ($p=0.05$), if clinical signs of organ damage were present. Within the TA-TMA group, severe (grade III-IV) aGvHD influenced the survival the most adversely.
Summary and Conclusions: TA-TMA developed early following HSCT and was precipitated by several patient, and transplantation related risk factors, such as aGvHD, unrelated donor, MAC, tacrolimus administration and CMV infection. The survival of patients with TA-TMA was significantly poorer compared to patients without TA-TMA.
Our findings confirm that TA-TMA remains a severe complication of allo-HSCT, with the contribution of multiple factors and poor prognosis.

P711

REITERATED THERAPEUTIC DRUG MONITORING (TDM) TO BETTER CONTROL TARGETED EXPOSURE TO IV BUSULFAN IN INFANTS AND OLDER CHILDREN UNDERGOING HEMATOPOIETIC STEM-CELL TRANSPLANTATION (HSCT)

P. Bourget[1], B. Neven[2], A. Amin[1,*] M. Chomton[2], G. Cros[2], E. Elkaim[2], M.-L. Fremond[2], D. Moshous[2], F. Touzot[2], F. Ader[1], A. Lalli[1], A. Petain[3], L. Nguyen[3], S. Blanche[2]

[1]Department of Clinical Pharmacy, [2]Pediatric Hematology-Immunology and Rhumatology Department, University Hospital Necker-Enfants Malades, Paris, [3]Pharmacokinetic Department, Institut de Recherche Pierre Fabre, Toulouse, France

Background: Busulfan (Bu) is the standard backbone for HSCT conditioning regimens (CR) worldwide. It has a narrow therapeutic window (TW), and graft rejection and toxicity may be related to Bu exposure. In infants, Bu exhibits large pharmacokinetic (PK) variability, and its metabolic clearance is non-linearly related to body weight (BW). In this setting, Bu dosage is stratified according to BW and commonly monitored once after the 1st of 16 total 2-hr infusions (96-hr exposure).
Aims: To optimize Bu duration/intensity exposure in children undergoing HSCT, we studied the possible contribution of double TDM of IV Bu in children receiving Bu-based CR for HSCT, by comparing the targeted and calculated exposure values after performing 1 PK (1st dose, PK1) and finally 2 PK (1st dose, PK1, and 9th dose, PK2).
Methods: In this single-centre observational study (05/2012-02/2015), 50 patients (Pts) receiving Bu based myeloablative CR for HSCT were prospectively included with median follow up of 12 months [0-33]. There were 33 males and 17 females. Median age was 16.5 months [1-193] and BW 11.0 kg [3-59]. Most Pts had non-malignant diseases, received allogenic HSCT and Bu-based CR in combination with fludarabine. The 1st dose and the tight and high TW were set up according to EBMT-ESID recommendations [ΣAUC=20,706-23,180 µmol/L*min]. Bu PK was assessed on 3 plasma samples/PK (LC-MS2 analysis) with area under the concentration-time curve (AUC) calculation from the 1st and 9th doses, using the NONMEM® software. AUC calculated after the 1st dose and extrapolated to the 16th one were compared by a Wilcoxon signed-rank test to the targeted AUC and to the sum of $AUC_{1\text{-}6}$ with TDM1 applied from the 7th dose with or without TDM2 applied from the 14th dose; $p\leq0.025$ was considered statistically significant.
Results: An initial median Bu posology of 1.16 mg/kgx4/day for 4 days was given. We demonstrate that: (a) calculated total AUC obtained from 2 PK differ significantly from those calculated after no PK ($p=2.7006$ E-6) or PK1 alone ($p=3.4750$ E-7), (b) double TDM allows achieving no difference between the targeted AUC desired by the medical staff in view of diseases *vs* calculated AUC ($p=0.8939$), (c) calculated total AUC obtained after no PK or PK1 alone significantly differed from targeted AUC. In 2/50 (4%) Pts, PK did not lead to change Bu dosage. In 9/50 (18%) and 12/50 (24%) Pts, dosage was modified after PK1 (TDM1 Group) or PK2 alone, respectively. In 27/50 (54%) Pts, changes were required twice, after PK1 and PK2 (Double-TDM Group). The median total doses of Bu were as follows: (a) a theoretical value of 220.8 mg (20.2 mg/kg) would have been given without any TDM (16 consecutive doses), (b) 194.7 mg (18.1 mg/kg) were administered in the TDM1 Group (16 doses), (c) 242.8 mg (19.5 mg/kg) were administered in the Double-TDM Group, preventing the unnecessary infusion of 20.0 mg of Bu *vs* PK1 alone in these Pts. In 15/50 (30%) Pts, a decision of discontinuation of Bu exposure was taken as the target desired by the medical staff was achieved after 13 (6 Pts) or 14 (9 Pts) doses; the mean total amounts of Bu were 273.2 mg (15.0 mg/kg) and 231.0 mg (15.6 mg/kg), respectively, *vs* 336.3 mg (18.5 mg/kg) and 278.2 mg (19.5 mg/kg) theoretically after TDM1 alone.
Summary and Conclusions: In this pediatric series, the double TDM of Bu is a relevant and feasible option to better achieve a narrow TW and to potentially minimize the risk of overexposure. Correlations with toxicities (VOD, aGVH), CR, OS are under analysis. Based on these data, the double-TDM procedure is routinely applied in our centre.

P712

FACTORS DETERMINING THE EFFECTIVENESS OF ACUTE GRAFT *VERSUS* HOST DISEASE PROPHYLAXIS AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION WITH MULTIPOTENT MESENCHYMAL STROMAL CELLS

N. Petinati[1,*] I. Shipounova[1], A. Bigildeev[1], N. Sats[1], N. Drize[1], L. Kuzmina[2], E. Parovichnikova[2], V. Savchenko[3]

[1]Physiology of Hematopoiesis lab., [2]High Dose Chemotherapy, Depressions of Hematopoiesis and Bone Marrow Transplantation Department, [3]National Research Center for Hematology, Moscow, Russian Federation

Background: Currently acute graft-*versus*-host disease (aGVHD) is one of the main problems after allogeneic bone marrow transplantation (allo-BMT) in patients with hematological malignancies. The new method involving the use of donors' multipotent mesenchymal stromal cells (MSC) was developed (ClinicalTrials.gov NCT01941394). In some cases prophylaxis of aGVHD with MSC failed. The reasons of failure could be either the result of particular qualities of donor-recipient interaction, patient status or characteristics of MSC samples.
Aims: The aim of the study was to analyze the main characteristics of MSC used for aGVHD prophylaxis based on the clinical outcome.
Methods: The study included 67 patients received allo-BMT from related donors after informed consent. The patients were randomized into 2 groups: first received standard prophylaxis of aGVHD (34) and the second (33) were additionally infused with MSC from the bone marrow of corresponding hematopoietic stem cells donor. MSC were cultivated in aMEM with 4% donors' platelet lysate. MSC were administered intravenously when the blood counts indicated recovery (peripheral blood leukocytes reached $1x10^9$/l). For analysis MSC were cultivated in standard conditions (aMEM, 10% fetal calf serum) for 3 passages. Relative expression level (REL) of 30 genes involved in proliferation, differentiation and immunomodulation was estimated by RT-qPCR in all MSC.
Results: Observation of the patients for 100 days (typical time of aGVHD manifestation) had revealed significant 3-time decrease in aGVHD development in the group of patients who received MSC (9.4% aGVHD grade II-IV) when compared to the standard prophylaxis group (29.4% aGVHD grade II-IV), $p=0.041$. MSC injection did not affect the engraftment as well as the relapse frequency. Overall survival of the patients was significantly higher in the MSC received group $p=0.048$. Three of 32 MSC samples had been ineffective for preventing aGVHD. Analysis of individual donor characteristics (gender, age, body mass index), found no significant differences between the MSC, effective and ineffective for preventing aGVHD. The cumulative MSC production of ineffective samples was 2 fold lower ($p=0.05$) than effective ones. REL of CSF1, FGFR1 and PDGFRB was 4 ($p=0.0005$), 2.5 ($p=0.02$) and 2.5 ($p=0.02$) fold decreased correspondingly in ineffective samples. REL of other 27 studied genes involved in proliferation, differentiation and immunomodulation did not differ significantly in MSC effective and ineffective for aGVHD prophylaxis.
The combination of predictors that characterize the most suitable for the prevention of aGVHD MSC samples was revealed by multiple logistic regression

analysis. A model calculating the probability of the success of MSC samples application was proposed:

$$logit(P)=2.5-0.26*CFH+0.02*IDO1-0.65*IGF1$$

where logit(P)=ln[P/(1-P)], P - probability of successful prophylaxis, CFH, IDO1 and IGF1 - REL of corresponding genes in tested MSC. Chi-square goodness of fit test p=0.0053. The calculated efficiency of this model was 95%. CFH and IDO1 are important for immunomodulation by MSC, while IGF1 is the gene associated with aging. So this statistical model seems reasonable for primary estimation of MSC efficiency for aGVHD prophylaxis.

Summary and Conclusions: The high variability of all analyzed characteristics among MSC from different donors was shown. By means of the proposed models ineffective MSC samples could be discharged. Such strategy hopefully will prevent the development of aGVHD in the maximum number of patients.

Stem cell transplantation - Clinical 4

Background: Allogeneic stem cell transplantation (AlloSCT) represents an effective treatment for relapsed and refractory follicular lymphoma (FL) and it is the only curative treatment approach in this particular clinical setting. Indeed, graft *versus* lymphoma (GVL) effect is superior in patients affected by FL as compared to those affected by diffuse large B-cell lymphoma (DLBCL). Therefore, also patients with active disease at time of AlloSCT can achieve a long-term survival. Grade 3B FL, both for its histological features and clinical behavior, is generally considered as an aggressive lymphoma. However, it is completely unknown the outcome of patients with Grade 3B FL receiving AlloSCT.
Aims: We investigated the impact of histologic grade on the outcome of AlloSCT in relapsed/refractory FL patients
Methods: In this study, we retrospectively analysed a cohort of 62 FL pts transplanted in 5 Italian Institutions between December 2001 and November 2014. All patients fulfilled the following criteria: 1) confirmed histologic diagnosis of FL including revised histological grading of each case; 2) pre-transplant disease status and response evaluated by computed tomography (CT) and/or positron emission tomography (PET) and assessed according to criteria established by Cheson *et al.,* JCO 2007. Fifty (80.6%) patients had a diagnosis of grade 1-3A and 12 of Grade 3B FL. Twenty-eight (45%) patients were transplanted from related, 28 (45%) from unrelated and 6 (10%) from haploidentical donors. Thirty-three patients (53%) were characterized by the presence of active disease before AlloSCT [20 partial remission, 1 stable disease and 11 disease progression (PD)]. No significant pre-transplant clinical differences (age, disease status, previous chemotherapy lines, stem cell source and donor types) were observed in patients with grade 1-3A *versus* 3B.
Results: Considering the whole patient cohort, we confirmed the favorable outcome after AlloSCT with 5-years EFS, PFS and OS estimates of 83.6% (95% CI, 78.2% to 89%), 61.3% (95% CI, 54.7% to 67.9%) and 69.1% (95% CI, 63% to 75.2%), respectively. No differences in EFS, PFS and OS were observed among Grade 1, 2 and 3A. Conversely, Grade 3B FL patients were characterized by a worse outcome compared to the other FL in terms of 5-years EFS [24.2% (95% CI, 21.5% to 26.9%) *vs* 90.7% (95% CI, 86.2% to 95.2%); p=0.0004], PFS [11.1% (95% CI, 0.7% to 21.5%) *vs* 72% (95% CI, 65.3% to 78.7%); p<0.0001] and OS [42.8% (95% CI, 27.2% to 58.4%) *vs* 74.7% (95% CI, 68.3% to 81.1%); p=0.02] estimates. Among patients with active disease and grade 1-3A, AlloSCT confirmed its high efficacy with 5-years EFS, PFS and OS estimates of 75.2% (95% CI, 67% to 83.4%), 55.9% (95% CI, 46.6% to 65.2%) and 63% (95% CI, 56% to 71%) respectively. Conversely, all grade 3B patients with active disease before AlloSCT suffered an early relapse (p<0.01), suggesting a lower GVL efficacy compared to other FL grades. Grade 3B histology retained its independence for EFS, PFS and OS in multivariate analysis including: age, pre transplantation disease status, graft source (peripheral blood *versus* bone marrow), intensity of the conditioning regimen (RIC *versus* MAC), acute and chronic GVHD occurrence and previous autologous SCT.
Summary and Conclusions: Overall, these data confirm the favorable prognosis of relapse/refractory FL patients Grade 1-3A undergoing AlloSCT, including those with active disease. Conversely, our study suggests that 3B FL patients should be treated like DLBCL rather than FL. This different approach might be particularly important among patients with active disease before AlloSCT.

P714

ALPHA/BETA T-CELL DEPLETED ALLOGENEIC STEM CELL TRANSPLANTATION FROM MATCHED RELATED AND UNRELATED DONOR GRAFTS IN PATIENTS WITH HIGH RISK HEMATOLOGICAL MALIGNANCIES

M.D. De Witte[1,*] G. Fleurke[2], L. van de Wagen[2], I. Slaper[3], J. Kuball[1,2]
[1]Hematology, [2]Laboratory of Translational Immunology, [3]Cell Therapy Facillity, University Medical Center Utrecht, Utrecht, Netherlands

Background: The outcome of allo-SCT in patients with poor risk leukemia is still hampered by GVHD and relapse. The innate immune system has been reported to contribute to tumor control, with lower incidence of GVHD. Specific depletion of αβ T- cells - key players in the development of GVHD - will render NK cells and γδT cells within the allograft. Recently reported results have shown

the great promise of this approach in haploindentical transplantations. Within this study, we aim to extend αβT- cell depleted allo-SCT to patients with a mathed related donor (MRD) or matched unrelated donor (MUD).
Aims: An "Innate-Tx" (αβ T cell depleted allograft from MRD/MUD) is aimed to serve as a low toxicity allo-SCT platform for futee immune interventions. As such it should have reduced levels of GVHD as compared to T cell replete allo-SCT, withour an increase in clinical significant infections or relapse.
Methods: All patients with hematological malignancies and an indication for allo-SCT were eligible. Either HLA matched siblings or HLA matched (9 or 10/10) unrelated donors (MUD) were eligible. αβT-cell reduction was performed by negative selection with anti-αβTCR antibodies in combination with magnetic microbeads, using the automated CliniMACS device (Miltenyi Biotec, Bergisch Gladbach, Germany). The maximal contamination with αβT-cells was $5x10^5$/kg. The conditioning regimen consisted of: ATG (Genzyme®) 4 or 6 mg/m^2+fludarabine 120 mg/m^2+busilvex AUC=90 followed by αβT- cell depleted grafts from matched related or unrelated donors. No additional immune suppression was given post allo-SCT.
Results: A ~4 log depletion of αβT-cells has been observed in the product with a recovery of ~75% of $CD34^+$ cells. The combination of ATG/fludarabine/busilvex was well tolerated with a hematological recovery within 3 weeks. Most patients received a pre-emptive low dose DLI ($1x10^5$ T cells/kg). Primary engraftment (chimerism >95%) was observed in all patients (n=14). Immune reconstitution primarily consisted of NK cells, showing a contraction around 4 months post SCT. In addition, γδT cells were present at normal numbers up to 6 months post SCT, whereas the adaptive immune repertoire shows a delayed reconstitution. Under this "innate control", no increase in CMV or EBV reactivations has been observed so far. Up to date, none of the patients developed aGVHD >grade II, none of the patients developed a relapse and no treatment related deads have been observed.
Summary and Conclusions: Here we show that an conditioning regimen of ATG/busilvex/fludarabin in combination with an αβT- cell depleted allo-SCT from MRD/MUD results in a swift reconstitution of innate cells (NK cells and γδT cells) the first 6 months post transplantation, followed by a subsequent reconstitution of the adaptive immune repertoire. After a median follow-up of 5 months, we observed low levels of aGVHD, without a concomitant increase in graft failure and infections. To address the incidence of cGVHD, relapse rate and overall survival a longer follow-up is required. However, the low incidence of aGVHD in this protocol suggests that this transplantation strategy can serve as a platform for subsequent interventions such as administration of tumor specific drugs, vaccination or tranfer of tumor specific T cells.

P715

OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT IN PATIENTS WITH MDS/MPN OVERLAP SYNDROMES- A SINGLE INSTITUTIONAL EXPERIENCE

P. Sharma[1], S. Shinde[2,*] N. Gangat[3], A. Al-Kali[3], S. Hashami[3], M. Litzow[3], W. Hogan[3], S. Khan[4], V. Rodriguez[4], M. Patnaik[3]
[1]Internal Medicine, [2]Hematology/ Oncology, [3]Hematology, [4]Pediatric Hematology, Mayo Clinic, Rochester, United States

Background: Clonal myeloid neoplasms with overlapping features of myelodysplastic syndrome (MDS) and myeloproliferative neoplasms (MPN), based on the 2008 WHO criteria, are categorized as MDS/MPN overlap syndromes. This subgroup includes well-defined entities such as, chronic myelomonocytic leukemia (CMML), juvenile myelomonocytic leukemia (JMML) and atypical chronic myeloid leukemia (aCML), along with lesser-defined entities such as, refractory anemia with ring sideroblast and thrombocytosis (RARS-T) and MDS/MPN- unclassifiable (MDS/MPN-U). Clinical outcomes are variable and allogeneic hematopoietic stem cell transplant (allo-HCT) remains the only potentially curative option.
Aims: To describe transplant and survival outcomes in patients with MDS/MPN overlap syndromes that underwent allo-HCT.
Methods: After IRB approval, consecutive patients with MDS/MPN overlap who underwent allo-HCT from 1990 to 2014 were identified and data was retrospectively abstracted.
Results: Of 51 patients (males: 62%) with MDS/MPN overlap, 36 had CMML (70%), 6 JMML (12%), 8 MDS/MPN-U (16%) and 1 aCML (2%). Median age was 54 years (range, 18- 68 years) in adult patients and 38 months (range, 3- 72 months) in JMML patients. (a) CMML: Of 36 patients (median age 51 years, range 66-18 years), 19 (52%) had CMML-1 (13 myeloablative conditioning, MAC; 6 reduced intensity conditioning, RIC) and 17 had CMML-2 (9 MAC; 8 RIC). The proportion that proceeded directly to transplant without prior chemotherapy was similar between MAC (12 patients/ 55%) and RIC (8 patients/ 57%). Post-transplant CR was achieved in 23 (64%) patients (MAC: 15, RIC 8). Median follow-up was 21 months (range 0.7- 191) with 2 years overall survival of 44% (n=16) and non-relapse survival of 36% (n=13). Common causes of non-relapse mortality (NRM) were related to chronic GVHD (27%) and sepsis (27%). 27 patients (75%) experienced acute-GVHD (grade 3/4: 9, 33%) and 22 (61%) had chronic-GVHD. More patients with chronic-GVHD died due to non-relapse causes (71% NRM *versus* 40% in those without chronic-GVHD). In multivariate analysis, engraftment failure (n=1, p <0.001) and higher HCT-comorbidity index (HCT-CI) were independent predictors of survival (HCT-CI >3, n=23; HCT-CI ≤3, n=13; p=0.03), and importantly, none of the conventional risk stratifying models predicted survival (Patnaik BJH 2014). (b) JMML: All 6 patients underwent MAC allo-HCT (5 peripheral blood stem cell transplant (PBSCT) and 1 umbilical cord blood transplant, (UCT)). Acute-GVHD occurred in 1 (grade 2) and chronic-GVHD in 2 patients. Median follow-up was 11 years and at last follow-up, 1 patient had died (1.8 years post-transplant) due to sepsis following bowel obstruction. 2 patients relapsed in the first year post-transplant and achieved remission with subsequent transplants. (c) MDS/MPN-U: Of the 8 patients (5 PBSCT, 1 BMT, 2 UCT), 6 (75%) underwent RIC allo-HCT. 7 patients (88%) experienced acute-GVHD (grade 3/4: 3, 43%) and 4 had chronic-GVHD. Median follow-up was 15 months. At last follow up, 4 patients (50%) were alive, 3 died due to relapse (3 months, 5 months, 19 months) and 1 died in remission due to immune mediated lung injury. (d) aCML: One female with aCML received PBSCT following MAC. She died 6.7 years post-transplant due to chronic-GVHD (Table 1).

Table 1. Clinical and laboratory features of CMML patients who have undergone allogeneic stem cell transplant.

Key: WBC, white blood cell count; ANC, absolute neutrophil count; AMC, absolute monocyte count; TNC, total nucleated cells.

Summary and Conclusions: Allo-HCT is a viable treatment option for patients with MDS/MPN overlap syndromes, with 3-year combined disease-free survival rates of 32% in adults with CMML and aCML, 43% in JMML and 1-year disease-free survival rate of 62% in adults with MDS/MPN-U. In patients with CMML, engraftment failure and co-morbidity index have prognostic implications, while conventional prognostic models were unable to predict transplant outcomes.

P716

FEASIBILITY OF LENALIDOMIDE MAINTENANCE AFTER NONMYELOABLATIVE ALLOGENEIC TRANSPLANTATION (NMAT) IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

I. Khouri[1,*] A. Gulbis[2], C. Ledesma[1], M. Korbling[1], F. Turturro[3], C. Bueso-Ramos[4], E. Jabbour[5], R. Bassett jr[6]
[1]Stem Cell Transplantation and Cellular Therapy, [2]Pharmacy Clinical Programs, [3]Lymphoma/Myeloma, [4]Hematopathology, [5]Leukemia, [6]Biostatistics, MD Anderson Cancer Center, Houston, United States

Background: NMAT is an effective therapy for relapsed/refractory CLL patients (pts). Results and safety using the FCR (fludarabine, cyclophosphamide, rituximab) regimen were previously described (Khouri *et al.* Cancer 2011; 117:4679-

88). About 50% of pts with refractory disease at study entry required immunomanipulation (IMM)[early immunosuppression withdrawal after NMAT and donor lymphocyte infusion (DLI)]. This is a significant cause of morbidity and graft-*versus*-host- disease (GVHD). Maintenance with lenalinomide post NMAT may improve outcomes by promoting the immune-mediated graft-*versus*-tumor effect and lessen the need for IMM.
Aims: To assess the feasibility (dose, toxicity and GVHD) of lenalidomide maintenance after NMAT in CLL.
Methods: This is a phase II randomized study that included relapsed/refractory CLL pts who were eligible to undertake NMAT after FCR conditioning [later replaced with the advent of the BFR regimen (bendamustine, fludarabine, rituximab) in 2011 (Khouri *et al. Blood* 2014; 124:2306)]. Pts were randomized at day 90-100 post NMAT to receive lenalinomide if they had persistent active CLL, engrafted donor cells, and no active GVHD, with ANC≥1,500/μL and platelets ≥70,000/μL. Lenalidomide was initiated at 5mg every other day (qod) with an increase to 10mg/day if tolerated.
Results: Of the 38 pts studied, 17 (48%) met the eligibility for randomization. Characteristics of non-randomized pts (n=21; Group A), pts randomized to receive lenalinomide maintenance (LM+) (n=8, Group B), or not (n=9, Group C) were similar and included median age (60, 55 and 56 years in the 3 groups, respectively), sex distribution, and percent of pts with ≥3 prior therapies (60% *vs* 38% *vs* 44%, respectively), percent of pts with β2-microglobulin ≥3 mg/L at study entry, refractory disease (75% *vs* 50% *vs* 67%, in the 3 groups respectively), unmutated status (100% *vs* 67% *vs* 100%, in the 3 groups respectively), donor/recipient CMV, sex-mismatched distributions and donor type (matched unrelated in 65%, 50% and 56%, in Groups A,B and C, respectively). Presence of 17p deletion was detected in 30% of Group A and 22% in Group C; none of the pts randomized to LM+ had 17p deletion. FCR was the NMAT conditioning in 55%, 75% and 78% of pts in the 3 groups, respectively, and the remaining pts received BFR. One pt refused LM+ after randomization. Maximum tolerated dose for LM+ was 5 mg qod in one pt due to dermatitis, 5 mg/day in 2 pts (cytopenia in one; liver toxicity and cytopenia in the other), 10 mg/day in 4 pts (1 opted to stop at 2.5 months and one died of pneumonia at 2 months; one achieved complete remission (CR) and stopped LM+ at 4 months due to rash and pt later relapsed; and one took 10 mg/day for 1 year without achieving CR. The need for IMM was 53%, 57% and 56%, in groups A, B, and C respectively. DLIs were needed in 10% *vs* 38% and 22%, respectively. The incidence of acute grade 2-4 GVHD was 47% for group A, and 50% *vs* 11% for groups B and C (P=0.11). The incidence of chronic GVHD was 40% *vs* 42% *vs* 59% in the 3 groups, respectively. Treatment-related-mortality at 1-year was 30% *vs* 12.5%, and 11%, in Groups A, B and C, respectively. With a median follow-up time of 31 months (range, 13-65), the 3-year overall survival rates for groups A,B and C were 42% *vs* 56% *vs* 63.5%, respectively (P=0.6) and the progression-free survival rates were 30% *vs* 25% *vs* 67%, respectively. The use of BFR resulted in a trend for a better OS (2-year 83% *vs* 54%) and PFS (64% *vs* 33%) than the FCR regimen.
Summary and Conclusions: This trial suggests that maintenance lenalidomide after NMAT for CLL is not feasible and that alternative strategies are needed to treat persistent disease . The preliminary results after BFR conditioning are encouraging and a larger trial is ongoing to confirm these findings.

P717

ENGRAFTMENT SYNDROME (ES) AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: A HIGH INCIDENCE IN HAPLOIDENTICAL SETTING
Y. Chen[1,*] L.-P. Xu[1], K.-Y. Liu[1], H. Chen[1], Y.-H. Chen[1], X.-H. Zhang[1], Y. Wang[1], X.-J. Huang[1]
[1]Peking University People's Hospital, Institute of Hematology, Beijing, China

Background: Engraftment syndrome, a clinical entity presented with non-infectious fever, skin rash within peri-engrfatment period, has been described in patients receiving various types of allogeneic stem cell transplantation (SCT). However, ES in haplo setting remains poorly characterized, and the prognosis and appropriate management are unclear.
Aims: Here, we attempted to determine the incidence, manifestations, and outcomes of ES after haploidentical SCT.
Methods: We compared the incidence of ES in 516 patients received haploidentical SCT and in 393 patients received HLA-identical sibling SCT, between Octorber 2001 and Octorber 2012 were collected retrospectively. ES was described as unexplained fever and skin rash within 24 h of the start of neutrophil recovery by Maiolino's criteria.
Results: The incidence of ES was significantly higher in haploidentical type than the other one (21.9% *vs* 2.0%, $P < 0.001$). Major symptomes included fever (119/121, 98.3%), skin rash (98/121, 81.0%) and diarrhea (51/121, 42.1%), with the median time of +10 (6-20) days. Significantly higher median increases in CRP level were observed in 13 samples of ES group than in 38 samples of the non-ES group (99.0 *vs* 13.9 mg/L, $P<0.001$). Similarly, the results showed higher plasma concentration of C3 in the ES group compared with non-ES group (meadian: 1.30 *vs* 1.16 g/L, $P=0.003$). ES patients had a significantly higher incidence of grade II-IV aGVHD and than the non-ES group (42.1% *vs* 24.6%, $P<0.001$). No difference of non-relapse mortality or overall survival were noted between ES group and non-ES group in each transplant setting.
Summary and Conclusions: Higher incidence of ES was observed in haploidentical type, but it did't predict poor clinical outcomes.

P718

A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL OF PLERIXAFOR+G-CSF *VS* PLACEBO+G-CSF TO MOBILIZE ≥5 X 106 CD34+ CELLS/KG IN CHINESE NHL PATIENTS FOR AUTOLOGOUS TRANSPLANTATION

Background: Plerixafor, a small molecule chemokine receptor 4 (CXCR4) antagonist, has been shown to increase mobilization of CD34+ cells for Caucasian non-hodgkin's lymphoma (NHL) patients in a Phase 3 trial.
Aims: This Phase 3 trial was conducted to confirm efficacy and safety of plerixafor in Chinese NHL patients.
Methods: Patients in first or second complete remission or partial remission received morning granulocyto colony stimulating factor (G-CSF, 10μg/kg/day). Since Day 4 evening, patients started plerixafor 0.24 mg/kg/day or placebo (1:1 ratio) in addition to G-CSF treatment for a maximum of 4 apheresis days. Apheresis could be discontinued if optimal target ($5x10^6$ CD34+ cells/kg) was reached earlier.
Results: One hundred patients were randomized. A total of 12 patients (3 in plerixafor arm and 9 in placebo arm) discontinued mainly due to adverse events (1 in plerixafor arm and 7 in placebo arm). Patients' demographics and baseline characteristics were similar between groups. The primary endpoint was met as 62% (31/50) patients in the plerixafor group, and 20% (10/50) patients in the placebo group achieved optimal target ($p<0.0001$). 88% patients with plerixafor and 66% patients with placebo reached minimum target ($2 X 10^6$ CD34+ cells/kg). Median time needed to achieve optimal target was 2 days in plerixafor group and not reached in placebo group. Median time to engraftment of neutrophil (10 days for both groups) and platelet (19 days *vs* 17 days) were similar between groups. The incidence of adverse events was similar between groups (62.7% *vs* 63.3%). Neither unexpected adverse events nor serious adverse events were observed in treatment period.
Summary and Conclusions: This study demonstrated that plerixafor plus G-CSF was superior to G-CSF alone to mobilize CD34+ cells for autologous transplantation in Chinese NHL patients. Patients who received plerixafor plus G-CSF were statistically significantly more likely to achieve both optimal and minimum CD34+ cells collection targets and in less time than patients receiving G-CSF alone. Plerixafor plus G-CSF was a safe and well tolerated mobilization regimen in this Chinese NHL population.

P719

INFLUENCE OF CYP3A5 GENE POLYMORPHISMS ON PHARMACOKINETICS OF TACROLIMUS MODIFIED-RELEASE ONCE-DAILY AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION
T. Yamashita[1,*] N. Fujishima[2], M. Miura[3], T. Niioka[3], M. Abumiya[3], K. Teshima[1], K. Ubukawa[1], M. Nara[1], M. Fujishima[1], Y. Kameoka[1], M. Hirokawa[1,4], N. Takahashi[1]
[1]Akita University Graduate School of Medicine, Department of Hematology, Nephrology, Rheumatology, [2]Akita University Graduate School of Medicine, Department of blood transfusion, [3]Akita University Hospital, Department of Pharmacy, [4]Akita University Graduate School of Medicine, Department of General internal medicine and Clinical laboratory medicine, Akita, Japan

Background: Modified-release, once-daily dosage of tacrolimus (Tac-QD) has been developed to provide more convenient dosing and to improve patient adherence. Tac-QD is confirmed to have equivalent safety and efficacy as twice-daily tacrolimus (Tac-BID), and the renal dysfunction side effect of Taq-QD is the same as Taq-BID. Tac-QD is strongly affected by cytochrome P450 (CYP) 3A4/5, which is expressed in the small intestine and hepatocytes. The blood concentration of tacrolimus in a patient who has received renal transplantation with CYP3A5 **3/*3* (poor metabolizer ; PM) is higher than CYP3A5 **1/*1* or **1/*3* (extensive metabolizer ; EM) patients. Furthermore, the azole antifungal agents, fluconazole, itraconazole and voriconazole, are routinely used as prophylaxis against Aspergillus infection and administered to HSCT recipients receiving tacrolimus, and those azole antifungal agents potently inhibit the activity of CYP3A. 24 patients who underwent allogeneic HSCT were

enrolled. Before HSCT, CYP3A5 **3* allele was detected using a PCR-restriction fragment length polymorphism method. After HSCT, continuous infusion of 0.03 mg/kg/day tacrolimus was administered to prevent acute graft-*versus*-host disease (aGVHD). On days 20-30 after transplantation, patients were switched to Tac-QD administered about 4 times orally. We collected venous blood samples just before (C_{0h}) to determine the blood concentration of Tac-QD and check the organs dysfunction. From day 7 after oral administration of Tac-QD, 21 patients were administered orally azole antifungal agent. After the co-administration of azole antifungal agent, we were subjected to the same test. Before and after the co-administration of azole antifungal agent and Tac-QD, blood concentrations of tacrolimus were determined by the chemiluminescence magnetic microparticle immunoassay.

Aims: We identified influence of CYP3A5 gene polymorphisms on Tac-QD in patients after hematopoietic stem cell transplantation (HSCT).

Methods: 24 patients who underwent allogeneic HSCT were enrolled. Before HSCT, CYP3A5 **3* allele was detected using a PCR-restriction fragment length polymorphism method. After HSCT, continuous infusion of 0.03 mg/kg/day tacrolimus was administered to prevent acute graft-*versus*-host disease (aGVHD). On days 20-30 after transplantation, patients were switched to Tac-QD administered about 4 times orally. We collected venous blood samples just before (C_{0h}) to determine the blood concentration of Tac-QD and check the organs dysfunction. From day 7 after oral administration of Tac-QD, 21 patients were administered orally azole antifungal agent. After the co-administration of azole antifungal agent, we were subjected to the same test. Before and after the co-administration of azole antifungal agent and Tac-QD, blood concentrations of tacrolimus were determined by the chemiluminescence magnetic microparticle immunoassay.

Results: 14 patients have CYP3A5 **3/*3* (PM) and 10 patients have CYP3A5 **1/*1* or **1/*3* (EM). Before the co-administration of azole antifungal agent, we did not recognize significant differences between CYP3A5-PMs and CYP3A5-EMs about C_{0h} and dose of tacrolimus. However, after the co-administration of azole antifungal agent, although CYP3A5-PMs had a reduced dose of Tac-QD than CYP3A5-EMs (p=0.041), C_{0h} of tacrolimus was higher with a significant difference (p=0.034). Additionally, acute renal dysfunction occurring in patients with elevated C_{0h} of tacrolimus was remarkable. The risk factors of acute renal dysfunction were CYP3A5-PM (p=0.024) and C_{0h} with azole antifungal agent co-administration of tacrolimus (p=0.020). C_{0h} of tacrolimus which is a measure of the onset acute renal dysfunction was 10 ng/ml. The virus infection and fungal infection showed no significant differences between CYP3A5-PMs and CYP3A5-EMs.

Summary and Conclusions: In this study, we recognized that C_{0h} of tacrolimus with azole antifungal agent co-administration in CYP3A5-PMs was higher than that of CYP3A5-EMs, and acute renal dysfunction was occurred. Therefore, when we administer Tac-QD with azole antifungal agent co-administration in CYP3A5-PMs, Tac-QD dosage should be individualized based on therapeutic drug monitoring and CYP3A5 genotype information.

INTERFERONA: A POTENTIAL EFFECTIVE TREATMENT FOR MINIMAL RESIDUAL DISEASE IN ACUTE LEUKEMIA/MYELODYSPLASTIC SYNDROME AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-D. Mo[1,*] X.-H. Zhang[1], L.-P. Xu[1], Y. Wang[1], C.-H. Yan[1], H. Chen[1], Y.-H. Chen[1], W. Han[1], F.-R. Wang[1], J.-Z. Wang[1], K.-Y. Liu[1], X.-J. Huang[1,2,3]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, [3]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: Preemptive intervention with donor lymphocyte infusion (DLI) based on minimal residual disease (MRD) status is one of the most important methods for relapse prophylaxis in acute leukemia patients receiving allogeneic hematopoietic stem cell transplantation (HSCT). However, some patients could not receive further DLI because of provider refusal; in addition, some patients disagree to receive DLI after HSCT. Interferon (IFN)-α may be the potential alternative option for MRD positive patients after allogeneic HSCT.

Aims: The safety and efficacy of preemptive IFN-α were investigated and were compared with those of preemptive DLI in patients who were minimal residual disease (MRD) positive after allogeneic HSCT.

Methods: Patients receiving allogeneic HSCT were eligible if they had acute leukemia or myelodysplastic syndromes and MRD turning positive after HSCT. The patients who could receive DLI were assigned to a preemptive DLI group (n=49). The patients who could not receive DLI or be disagree to receive DLI after HSCT received preemptive IFN-α(n=25). MRD was monitored according to leukemia-associated immunophenotypes and genes. Informed consent was obtained from all patients, and the study was conducted in accordance with the Declaration of Helsinki. The study protocol was approved by the Ethics Committee of Peking University People's Hospital.

Results: A total of 25 patients received preemptive IFN-α, and the median duration of IFN-αtherapy was 35 days (4-180 days). Nine patients relapsed, and 1 patient died from severe pneumonia. The 2-year cumulative incidence of chronic graft-*versus*-host disease (cGVHD) after HSCT was 88.0% and 59.1% in IFN-α and DLI groups (*P*=0.006). The MRD status after preemptive intervention was comparable between IFN-α and DLI groups, and the 2-year cumulative incidence of relapse was 33.7% and 39.4%, respectively (*P*=0.812). The 2-year cumulative incidence of non-relapse mortality was 4.0% and 2.1%, respectively, in IFN-α and DLI groups (*P*=0.678). The 2-year probabilities of disease-free survival was 67.5% and 58.5%, respectively, in IFN-α and DLI groups (*P*=0.711). In multivariate analysis, early-onset MRD, persistent MRD after intervention, and non-cGVHD after intervention were significantly associated with poorer clinical outcomes.

Summary and Conclusions: Preemptive IFN-α may be the potential alternative option for MRD-positive patients who could not receive preemptive DLI after HSCT.

P722

INCIDENCE, RISK FACTORS, AND OUTCOME OF EARLY HEMOSTATIC COMPLICATIONS IN PATIENTS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE MULTICENTER STUDY OF 551 PATIENTS

Y. Han[1,*] W. Han[1], L. Hu[1], Y. Tang[1], J. Wang[1], H. Qiu[1], A. Sun[1], C. Ruan[1], D. Wu[1]
[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Hemostatic disorders are common and potentially fatal complications in patients undergoing allogeneic hematopoietic stem-cell transplantation. However, Limited data exists on early diagnosis and prevention of these complications.

Aims: To explore the incidence, risk factors, and outcome of early hemostatic complications in patients after allogeneic hematopoietic stem cell transplantation.

Methods: In this study, 551 allogeneic transplantation recipients were enrolled to investigate the incidence, risk factors, and outcome of thrombotic or bleeding complications in the first 100 days after transplantation.

Results: Of all the patients, 261 cases (47.4%) developed bleeding events, the cumulative incidence of minor, moderate, and severe bleeding was 28.9%, 14.9% and 3.8%, respectively. The incidence of thrombotic complications was 4.5% (25/551 cases), consisting of 15 cases of veno-occlusive disease, 7 thrombotic microangiopathy, 2 pulmonary embolism, and 1 deep vein thrombosis. Risk factor analysis demonstrated that veno-occlusive disease, II-IV acute graft-*versus*-host disease and cord blood transplantation were independent predictors for bleeding complications in multivariant analysis and platelet counts less than 10×10^9/L were significantly associated with severe bleeding. Meanwhile, mismatched donor, polyomavirus BK infection, cytomegalovirus infection and II-IV acute graft-*versus*-host disease were potential risk factors for late-onset hemorrhagic cystitis, while total body irradiation conditioning regimen and high-risk disease status prior to transplantation were significantly associated with the occurrence of thrombotic disorders. Severe hemorrhage and early-onset of thrombotic disorders independently increased the mortality of allogeneic transplantation recipients. However, late-onset hemorrhage cystitis did not appear to affect the survival rate significantly.

Summary and Conclusions: Our study demonstrated that hemostatic complications following transplantation have much high mortality. Therefore, early diagnosis and therapeutic intervention of hemostatic complications are crucial to improve the outcome of allogeneic hematopoietic stem cell transplantation recipients.

A PROSPECTIVE CLINICAL TRIAL OF PROLONGED AUTOLOGOUS ERYTHROPOIETIN (EPO) SECRETION FROM TARGTEPO IN EPO-DEPENDENT END STAGE RENAL DISEASE PATIENTS SHOWED EPO INDEPENDENCE FOR OVER 8 MONTHS

S. Blum[1,*] N. Shapir[2], R. Miari[2], A. Liran[2], B. Lerner[1], K. Doenyas-Barak[3], S. Efrati[3], D. Schwartz[4], G. Chernin[4], G. Neil[5]
[1]Clinical Department, [2]R&D, Medgenics Inc., Misgav, [3]Research & Development unit and Nephrology unit, Assaf-Harofeh Medical Center, Zrifin, [4]Nephrology and Dialysis Department, The Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [5]R&D, Medgenics Inc., Wayne, United States

Background: Recombinant human Erythropoietin (rHuEPO) along with iron supplementation corrects anemia in most patients with End Stage Renal Disease (ESRD) but is associated with supra-physiological peak serum concentration (C_{max}) of EPO and may cause thromboembolic complications in these patients. The Transduced Autologous Restorative Gene Therapy system (TARGT™) is an *ex-vivo* gene therapy platform that provides autologous, continuous protein or peptide therapy in the physiological range. The system consists of several 2x30 mm pieces of dermal tissue (Micro-Organ, MO), extracted under local anesthetic in which its fibroblasts cells are transduced with a viral vector containing a gene of interest. $TARGT_{EPO}$ refers to a TARGT that provides EPO. After culture, and measurement of *in-vitro* EPO production, one or more transduced MOs secreting EPO ($TARGT_{EPO}$s) are re-implanted subcutaneously as required for delivering the target dose. Patients are treated with local steroid injection to stabilize secretion. The system allows dose flexibility and the TARGTs may be added or removed according to the *in-vivo* secretion levels.
Aims: We present here initial results from an-ongoing open label ascending dose exploratory clinical study of $TARGT_{EPO}$ in patients with anemia due to ESRD.
Methods: This study was approved by the Ethics Committees of the participating sites in Israel and the $TARGT_{EPO}$ product was cleared for clinical testing by the Israeli Ministry of Health. All patients have signed an informed consent prior to enrollment in the study. We have completed the enrollment of patients in the first out of 3 cohorts (the low dose) with 6 EPO-dependent patients treated with a total of up to 3 $TARGT_{EPO}$ units each, secreting a total of 25 IU/Kg/Day of autologous EPO. All patients continued their previous regimen of intravenous supplemental iron.
Results: Efficacy data in this ongoing study is being continuously assessed as per protocol. Patient follow-up post implantation is ongoing, while the first patient implanted has completed 8 months of follow up with stable EPO secretion and stable Hb. Results obtained from the 6 patients enrolled thus far suggest stabilization of serum EPO levels at the physiological range of ≤20 mIU/ml and the resulting Hb levels between 9-12 g/dL without rHuEPO or transfusion while $TARGT_{EPO}$s are still functioning. Comparative analysis of serum EPO levels revealed significantly lower C_{max} with $TARGT_{EPO}$ compared to rHuEPO. Also, comparison of extrapolated Area Under the Curve (AUC) of rhEPO *vs* actual $TARGT_{EPO}$ AUC, revealed that $TARGT_{EPO}$ maintained Hb within the desired range in these patients with an order of magnitude smaller exposure to EPO compared to rHuEPO. This observation may have significant clinical benefits. No treatment related serious adverse events have been reported.
Summary and Conclusions: $TARGT_{EPO}$ is a promising novel therapy for anemia and the TARGT platform may have promise for other diseases requiring protein or peptide based treatment.

P724

ADOPTIVE IMMUNOTHERAPY OF MULTIPLE MYELOMA (MM) WITH ALLOGENIC CAR T-CELLS TARGETING CS1: ENHANCEMENT OF CAR ACTIVITY THROUGH CS1 GENE INACTIVATION IN EFFECTOR CELLS

R. Galetto[1,*] I. Chion-Sotinel[1], P. Francon[1], J. Smith [1]
[1]Cellectis, Paris, France

Background: Chimeric antigen receptor (CAR)-redirected T-cells have been successfully used in patients with refractory leukemia by targeting the CD19 molecule, yielding long-term durable remissions and raising hopes that a wider application of CAR technology may lead to a new paradigm in cancer treatment. Nevertheless, the CAR approach is restricted to targeting antigens expressed at the tumoral cell surface but absent from T-cells, since CAR expression will deplete antigen-expressing T-cells and thus reduce the chances to efficiently produce CAR specific T-cells. Multiple Myeloma (MM) is a B-cell neoplasia characterized by clonal expansion of malignant plasma cells in the bone marrow, and although currently available therapies can improve overall survival it still remains incurable in most patients. Immunotherapy against MM is one area in which extensive research is being made, with novel antigenic targets being considered to drive eradication of plasma cells. Among these, the CS1 glycoprotein is highly expressed on tumor cells from most of patients with MM, making it an attractive antigen for CAR targeting.
Aims: Expression of CS1 on normal CD8+ T-cells is potentially an obstacle for the development of CAR T-cells targeting CS1. The objective of this work was therefore to evaluate if CS1 expression on T-cells could have an impact on CAR activity.
Methods: To address this limitation, Transcription Activator-Like Effector Nuclease (TALEN) gene editing technology was used to inactivate the CS1 gene in T-cells, prior to transduction with a lentiviral vector encoding an anti-CS1 CAR.
Results: We will present data showing that non-gene-edited T-cells expressing an anti-CS1 CAR display limited cytolytic activity against MM cells expressing the CS1 antigen as well as a progressive loss of CD8+ T-cells in the effector cell population. In contrast, CS1-gene-edited CAR cells display significantly increased cytotoxic activity with the percentage of CD8+ T-cells remaining unaffected. Experiments in an orthotopic MM mouse model are currently ongoing, in order to investigate the impact of CS1 gene disruption on *in vivo* antitumoral activity.
Summary and Conclusions: Gene editing technology can also be used to manufacture T-cells from third-party healthy donors to generate allogeneic "off-the-shelf" engineered CAR+ T-cell-based frozen products. We have previously demonstrated that TALEn mediated inactivation of the TCRa constant (TRAC) gene can be achieved at high frequencies and eliminate the potential for edited T-cells to mediate Graft *versus* Host Disease (GvHD). Furthermore, multiplex genome editing can lead to the production of double KO (TRAC and CS1) T-cells, allowing large scale manufacturing of allogeneic, non alloreactive CS1 specific T-cells that display enhanced antitumor activity. This technology therefore offers the possibility of developing an off-the-shelf cell therapy product that would be immediately available for administration to a large number of MM patients.

P725

EVALUATING HUMAN T-CELL THERAPY OF CYTOMEGALOVIRUS ORGAN DISEASE IN HLA-TRANSGENIC MICE

S. Thomas[1,2,*] N. Lemmermann[3], S. Klobuch[1], J. Podlech[3], B. Plachter[3], M. Theobald[4], M. Reddehase[3], W. Herr[1,2]
[1]Department of Internal Medicine III, University Hospital of Regensburg, [2]Regensburg Center of Interventional Immunology, University of Regensburg, Regensburg, [3]Institute for Virology, [4]Department of Internal Medicine III, University Medical Center of the Johannes Gutenberg-University, Mainz, Germany

Background: Reactivation of human cytomegalovirus (HCMV) can cause severe disease in recipients of hematopoietic stem cell transplantation. Although preclinical research in murine models as well as clinical trials have provided 'proof of concept' for infection control by pre-emptive CD8 T-cell immunotherapy, there exists no predictive model to experimentally evaluate parameters that determine antiviral efficacy of human T cells in terms of virus control in functional organs, prevention of organ disease, and host survival benefit.
Aims: Here we introduce a novel mouse model for testing HCMV epitope-specific human T cells. In this, we combined the well-described murine model of mCMV infection of the immunocompromised host with the strong T-cell immunogenicity of the HLA-A*0201 restricted HCMV epitope $pp65_{495-503}$ NLVPMVATV (NLV). We generated a chimeric recombinant mCMV expressing the NLV epitope (mCMV-NLV) during the infectious cycle to allow organ manifestation of the infection in the natural host similar to that seen in immunocompromised patients.
Methods: For construction of the chimeric virus mCMV-NLV we integrated the coding gene sequence of the HLA-A2.1 restricted $pp65_{495-503}$ peptide epitope NLVPMVATV (NLV) of HCMV into the immediate-early (IE)2/m128 gene of mCMV-Δm157. To determine *in vivo* antigenicity of mCMV-NLV and protective activity of NLV epitope-specific T cells, we infected sublethally irradiated HLA-A2.1 transgenic NOD/SCID/IL-2Rγc$^{-/-}$ mice transgenic (NSG/HHD) by intraplantar injection with $1x10^5$ PFU of mCMV-NLV, a dose that would be lethal after approximately 12 to 17 days. Shortly thereafter, we adoptively transferred murine or human NLV-specific T cells in order to mimic the clinical setting of pre-emptive therapy, and analyzed viral titers in spleen and lungs as well as numbers of infected cells in livers of individual mice on day 11.
Results: After infection of immunocompromised NSG/HHD mice, mCMV-NLV resulted in a rapid systemic infection that could be effectively combated by adoptively transferred murine and human NLV-specific CD8 T cells as well as by human CD8/CD4 T cells transduced with an NLV-specific T-cell receptor. Upon transfer, the T cells infiltrated host tissues in an epitope-specific manner, confining the infection to nodular inflammatory foci. This resulted in a significant reduction of viral load, prevention of organ pathology, and prolonged survival. Collectively, these data demonstrated that NLV-specific human T cells mediate HCMV NLV-specific immune control in mCMV-NLV infected NSG/HHD mice, even across the human-mouse species barrier.
Summary and Conclusions: The model has proven its potential for a preclinical testing of the protective antiviral efficacy of HCMV epitope-specific human T cells in the evaluation of new approaches to an immunotherapy of CMV disease.

P726

NOVEL HUMAN IL-15 SUPERAGONIST PROMOTES LONG-TERM PERSISTENCE AND REACTIVITY OF HUMAN EBV- AND LEUKEMIA-SPECIFIC CD8+ T CELLS WITH STEM CELL MEMORY AND CENTRAL MEMORY PROPERTIES IN HUMANIZED MICE

A. Mades[1], S. Khan[1], M. Theobald[1], U.F. Hartwig[1,*]
[1]III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) using leukemia-reactive T cells has evolved as a promising strategy to improve antileukemic immunity. However, durable clinical responses are often hampered by limited sustained reactivity of fully differentiated effector T cells or graft-vs-host disease when HLA-matched donor-derived T cells are applied. In addition to the transfer of leukemia-reactive stem cell memory (T_{SCM}) and central memory (T_{CM}) T cells, IL-15 has emerged as a promising cytokine to improve ACT as it facilitates the *in vitro* generation of leukemia-reactivity from naive $CD8^+CD45RA^+$ precursors, supports engraftment of adoptively transferred $CD8^+$ T cells in lymphopenic hosts and promotes homeostasis and formation of T cell memory.
Aims: In the current study we therefore investigated whether a novel IL-15 superagonist could promote engraftment, expansion, persistence and cytolitic acvtivity of human $CD8^+$ T cells in humanized NSG mice.
Methods: A novel high affinity human IL-15 superagonist (IL15N72D-IL15Rα/Fc referred to as ILR-Fc) was generated by exchanging asparagine (N) to aspartic acid (D) at position 72 reported to increase the biological activity of IL-15. The modified IL-15 sequence was then linked to the IL-15-binding Sushi-domain of IL-15Rα. To improve bioavailibility of the IL-15 complex the truncated IL-15Rα was fused to the Fc-domain of human IgG1. HLA-A2 reactive $CD8^+$ T cells were generated by repetitive stimulation of human $CD8^+$ T cells isolated from peripheral blood mononuclear cells (PBMC) by MACS® with HLA-A2 expressing K562 transfectants. To generate Epstein-Barr Virus (EBV) and acute myeloid leukemia (AML)-specific T cells *in vitro*, naive $CD8^+CD45RA^+$ T cells were isolated using the naive T cell isolation kit (Miltenyi Biotec) and repetitively stimulated with autologous, EBV-peptide loaded dendritic cells and peptide loaded PBMC or with HLA-matched primary AML blasts and feeder cells in the presence of a optimized cytokine cocktail and the Gsk3 inhibitor TWS119, which modulates the Wnt-signaling pathway resulting in strong enrichment of T cells with a T_{SCM} and T_{CM} phenotype. Phenotypic and functional analyses *in vitro* were performed by FACS and IFN-g ELISPOT- or ^{51}Cr-release assays, respectively.
Results: The Expi293 Expression System™ (Invitrogen) was applied to produce soluble ILR-Fc. Following transfection and expansion of modified 293T cells growing in suspension protein-A affinity based purification of ILR-Fc resulted in ≥1mg recombinant protein/25 ml culture. *In vitro* bioactivity analyses of ILR-Fc as compared to IL-15 (N72D) produced in E coli revealed that ILR-Fc was ≥10 fold more active when tested on M07e cells. To test for growth promoting effects on T cells in a lymphopenic environment, we first injected ILR-Fc into NSG mice previously humanized by engraftment of human $CD34^+$ hematopoietic stem cells and observed robust expansion of primarily human $CD8^+$ T cells. Strong effects on expansion of splenic $CD8^+$ T cells could be further confirmed following injection of ILR-Fc into C57BL/6 mice. Moreover, upon transfer of EBV- and AML-reactive $CD8^+$ $CTL_{SCM/CM}$ into NSG mice engrafted with autologous EBV-immortalized B cells or HLA-matched AML blasts, resp., we observed prolonged persistence and superior reactivity in mice receiving weekly i.p. injections of 60 ug ILR-Fc/mouse (equivalent to 10 ug IL-15) when compared to mice receiving T cells and 10 ug E. coli-derived IL-15. This extended bioactivity was partially attributed to an increased half-life of ILR-Fc in the serum as determined by IL-15 ELISA. In addition, ILR-Fc treatment resulted in strongly reduced AML burden and regression of EBV-lymphoma. Finally, adoptively HLA-A2-specific cytototxic $CD8^+$ T lymphocytes (CTL) caused xenogeneic GvHD in NSG mice in the presence of ILR-Fc when compared to mice injected with $CD8^+$ CTL alone.
Summary and Conclusions: These studies demonstrate that ILR-Fc has potent and prolonged bioactivity to facilitate $CD8^+$ T cell persistence and activity in lymphopenic hosts and might thus serve as a valuable tool to improve selective $CD8^+$ T cell-mediated immunotherapy.

P727

DENDRITIC CELL VACCINATION IN POSTREMISSION THERAPY OF AML: RESULTS OF A CLINICAL PHASE I TRIAL AND OF PRECLINICAL STUDIES TESTING COMBINATORIAL APPROACHES

F. Schnorfeil[1,2,*] F. Lichtenegger[1,2], M. Rothe[1,2], M. Schlüter[1,2], J. Neitz[1,2], M. Brüggemann[3], A. Moosmann[4], B. Wagner[5], R. Henschler[5], T. Köhnke[2], V. Bücklein[2], T. Altmann[2], C. Geiger[6], W. Hiddemann[2], I. Bigalke[7], G. Kvalheim[7], D. Schendel[6], M. Subklewe[1,2]
[1]Clinical Cooperation Group Immunotherapy, Helmholtz Zentrum München, [2]Department of Internal Medicine III, Klinikum der Universität München, Munich, [3]Department of Hematology, University Hospital Schleswig-Holstein, Kiel, [4]Clinical Cooperation Group Immunooncology, Helmholtz Zentrum München, [5]Department of Transfusion Medicine, Cellular Therapeutics and Hemostaseology, Klinikum der Universität München, [6]Institute of Molecular Immunology, Helmholtz Zentrum München, Munich, Germany, [7]Department of Cellular Therapy, The Norwegian Radium Hospital, Oslo University Hospital, Oslo, Norway
Background: Immunotherapy is a promising treatment strategy to eradicate residual chemorefractory leukemic cells in AML patients. We are currently conducting a proof-of-concept phase I/II (6+14 patients) clinical trial using *next-generation* dendritic cells for postremission therapy of AML (NCT01734304). Besides therapeutic vaccination, immune checkpoint modulation represents another strategy to enhance anti-tumor immune responses, which is now being tested in various hematological malignancies.
Aims: The primary endpoint of the clinical trial is feasibility and safety, and secondary endpoints are immunological responses and disease control, with a particular focus on MRD conversion. In preclinical studies we examine combinatorial approaches using DCs together with immune checkpoint modulation to augment T cell activation and thus the efficacy of DC vaccination.
Methods: *Next-generation* DCs are generated in a GMP-compliant 3-day protocol including a TLR7/8 agonist containing maturation cocktail. DCs are loaded with ivt-RNA encoding WT1 and PRAME as leukemia-associated antigens and CMVpp65 as an adjuvant and surrogate antigen. Patients are vaccinated intradermally with $5x10^6$ DCs of each antigen up to 10 times within 26 weeks in weekly to monthly intervals. To test the combinatorial approach, DCs and autologous T cells are cocultured *in vitro* with or without antibodies blocking inhibitory ligand-receptor interactions (PD-L1, PD-1 or LAG-3) or an immunomodulatory drug (lenalidomide). IFNγ secretion and proliferation are measured by FACS-based assays.
Results: Eight patients have been enrolled into the trial so far. In 6/6 cases, leukapheresis yielded sufficient monocytes to generate DCs for clinical application. DCs secreted IL-12p70, migrated, expressed all three antigens and activated antigen-specific T cells *in vitro*. Three patients have completed the vaccination schedule. Delayed-type hypersensitivity (DTH) responses at the vaccination site were observed in 4/4 patients, but no grade III/IV toxicities. Multimer analyses revealed the induction of antigen-specific T cell responses in 2/2 patients: a 10-fold increase of WT1-specific and a 6-fold increase of CMVpp65-specific T cells in a CMV-seronegative patient were detected. TCR repertoire analyses by next-generation sequencing revealed an enrichment of particular clonotypes at DTH sites, supporting the induction of antigen-specific immune responses. A patient with an impending relapse during the vaccination schedule was treated with a combination of DC vaccination and 5-azacytidine, resulting in MRD conversion. In preclinical studies, the blockade of PD-L1, PD-1 or LAG-3 in DC-T cell cocultures resulted in 1.4-, 2- or 5.9-fold augmented IFNγ secretion. Addition of lenalidomide induced a 5.4-fold increase in IFNγ secretion. All four agents additionally enhanced T cell proliferation.
Summary and Conclusions: We conclude that *next-generation* DCs are capable to induce tumor-specific immune responses *in vivo*. Moreover, our *in vitro* studies suggest that the efficacy of DC vaccination can be enhanced by concurrent immune checkpoint modulation.

P728

COMBINATION OF IBRUTINIB AND ANTI-CD19 CHIMERIC ANTIGEN RECEPTOR T CELLS FOR THE TREATMENT OF RELAPSING/REFRACTORY MANTLE CELL LYMPHOMA (MCL)

M. Ruella[1,*] S. Kenderian[1,2], J. Fraietta[1], O. Shestova[1], S. Qayyum[3], Q. Zhang[3], X. Liu[3], M. Maus[1,4], S. Lacey[1], A. Mato[4], S. Schuster[4], C. June[1], M. Wasik[3], S. Gill[1,4]
[1]Translational Research Program, University of Pennsylvania, Philadelphia, PA, [2]Hematology and Oncology, Mayo Clinic, Rochester, MN, [3]Pathology and Lab. Medicine, [4]Hematology and Oncology, University of Pennsylvania, Philadelphia, PA, United States

Background: The Bruton Tyrosine Kinase (BTK) inhibitor Ibrutinib displays considerable activity in mantle cell lymphoma (MCL), yet approximately 30% of patients do not respond and among responders only one third experience complete remission (CR). Furthermore, the therapy invariably leads to drug resistance and a median response of 17.5 months (Wang ML, NEJM, 2013). Infusion of autologous T cells transduced with chimeric antigen receptors (CAR) against the B-cell specific CD19 antigen (CART19 or CTL019) leads to dramatic clinical responses in the majority of patients with acute lymphoblastic leukemia and chronic lymphocytic leukemia (Maude SA, NEJM, 2014; Porter D, NEJM, 2011). The role of CTL019 in MCL, where bulky disease may impair T cell infiltration, has not yet been established. Ibrutinib has shown particular efficacy in reducing tumor masses while mobilizing neoplastic B cells into the peripheral blood.
Aims: We sought to investigate the combination of two novel potent approaches, ibrutinib and CTL019, for treatment of MCL.
Methods: MCL cell lines were obtained from ATCC (Mino, Jeko-1, SP-49) while MCL-RL was generated in our laboratory from a pleural effusion of a MCL patient. CTL019 were produced as previously described by lentiviral transduction of healthy donor T cells using an anti-CD19-CD3zeta-41-BB construct (Milone M, Mol. Ther., 2009). For *in vivo* experiments, ibrutinib was dissolved in HP-beta-cyclodextrin/H_20 and administered in the drinking water to mice with established disease, usually from 7 days after tumor injection until the end of the experiment.
Results: *In vitro* studies with established MCL-derived cell lines and MCL-RL show a variable response to ibrutinib with an IC50 ranging from 10 nM to

10 μM as determined in the MTT conversion assay. MCL-RL was the most sensitive cell line with an IC50 of 10nM, similar to primary MCL. These different cell lines could therefore be used to model both ibrutinib-sensitive and ibrutinib-resistant MCL. Both ibrutinib-sensitive and ibrutinib-resistant cell lines, but not the CD19-negative control MOLM14 cell line, when exposed to allogeneic CTL019 strongly activated the T cells as detected by CD107a degranulation, cytokine production and CFSE proliferation assays. *In vitro* assays with MCL cell lines and different doses of CTL019 with increasing concentration of ibrutinib demonstrated an additive tumor killing with the combination CTL019 and ibrutinib. However, supra-physiologic doses of Ibrutinib (>/=1 uM) impaired cytokine production and T cell proliferation *in vitro*; these concentrations of ibrutinib are not typically reached in the clinical setting. In order to confirm these results *in vivo* we established a novel MCL model, using the MCL-RL cell line. Intravenous injection of MCL-RL cell line transfected with the GFP/luciferase gene into immunodeficient NOD/SCID-gamma chain knockout (NSG) mice resulted in 100% MCL engraftment in liver and spleen, with eventual dissemination into lymph nodes and bone marrow. Treatment with three different doses of allogeneic CTL019 (0.5, 1 and 2 million/mouse) led to a dose dependent anti-tumor effect. A similar dose response to CTL019 was also observed in the ibrutinib resistant Jeko-1 cell line. We treated MCL-RL xenografts *in vivo* with different doses (0, 25 and 125 mg/Kg/day) of ibrutinib, with a median overall survival respectively of 70, 81 and 100 days ($p<0.001$). Importantly, a direct *in vivo* comparison of the highest ibrutinib dose (125 mg/kg) and CTL019 showed a significantly improved tumor control for mice treated with CTL019. MCL-RL xenografts were treated with vehicle, ibrutinib, CTL019 or the combination of CTL019 and ibrutinib. The combination resulted in an improved tumor control with 80% of mice achieving long-term disease-free survival (Figure 1A). In addition, we found that mice treated with ibrutinib had higher numbers of circulating CTL019 cells (Figure 1B).

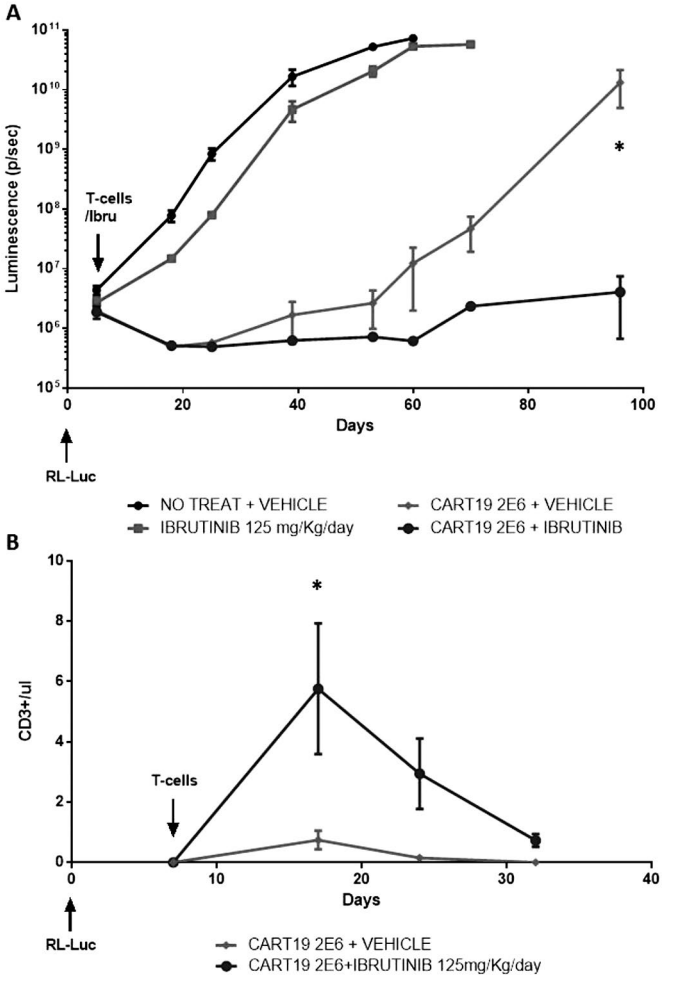

Figure 1.

Summary and Conclusions: This preclinical model demonstrates for the first time that a small molecule inhibitor of B cell receptor signaling (ibrutinib) can be combined with CTL019 in a rational manner that augments the anti-tumor effect and leads to enhanced survival.

P729

INTERIM ANALYSIS OF PHASE I/II TRIAL IN HIGH-RISK PEDIATRIC PATIENTS POST ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT (HSCT) TREATED WITH *EX VIVO* EXPANDED DONOR-DERIVED ADENOVIRUS-SPECIFIC T CELLS

W. Ip[1,2,*] A. Stansfield[3], A. Skulte[3], K. Gilmour[1], M. Brocklesby[1], G. Ahsan[1], P. Amrolia[4], P. Veys[4], B. Gaspar[1,2], W. Qasim[1,2]
[1]Department of Clinical Immunology, Great Ormond Street Hospital, [2]Molecular and Cellular Immunology Section, Institute of Child Health, [3]Cell Medica Ltd., [4]Bone Marrow Transplantation Department, Great Ormond Street Hospital, London, United Kingdom

Background: Adenovirus (ADV) is a cause of significant morbidity and mortality after pediatric HSCT. Antiviral drug therapy is routinely given for ADV viremia in HSCT patients, but can be associated with significant toxicity. While antiviral drug therapy may attenuate viremia, T cell reconstitution is required for sustained viral clearance. Adoptive virus-specific immunotherapy offers the possibility of durable viral control in the post transplant setting.
Aims: In order to assess the safety and tolerability of an ADV cell therapy (ACT) Cell Medica is evaluating an expanded anti-ADV T cell product in a clinical trial in three centers in children who reactivate ADV after T cell-depleted transplantation. Here we report on the clinical experience of the first five patients treated in the ASPIRE clinical trial (EUDRA CT 2011-001788-36).
Methods: Patients were consented to receive ACT on reactivation of ADV (defined as two consecutive positive PCRs>1000 copies/mL) post-transplant, in addition to routine antiviral drugs. Cell administration did not occur until 28 days post-transplant due to continuing *in vivo* persistence of conditioning antibodies. The primary dose was $1x10^4$/kg total CD3+ T cells. Patients were monitored post adoptive cellular therapy up to 180 days. If the patient exhibited significant levels of ADV viremia requiring treatment ≥4 weeks post-infusion they were eligible to receive a secondary maximum target dose of $1x10^5$/kg total CD3+ T cells and were monitored for a further 180 days. Lymphocytes for the expansion process were sourced from the transplant donor either from peripheral blood or a 5 mL aliquot of the original stem cell donation. The one-touch rapid expansion process for generation of this ACT was based on exposure of T cells to overlapping peptides covering the entire hexon V protein and 10 days expansion in the presence of cytokines; cells were then harvested and cryopreserved. The ADV-specific T cells were formulated in 4.5% human serum albumin and 10% dimethylsulfoxide with ≥$1x10^2$ ADV-specific T cells per kg body weight of recipient. Study endpoints included incidence and severity of GvHD, cytopenias and grade 3-4 adverse events.
Results: Patients were consented to receive ACT on reactivation of ADV post-transplant. All five patients analyzed cleared viremia post ACT. Two SAEs were reported; one pancreatitis and one GvHD (skin GvHD stage III; gut GvHD stage II). Additionally, one Suspected Unexpected Serious Adverse Reaction (SUSAR) was reported which was subsequently downgraded following attribution to astrovirus encephalitis.

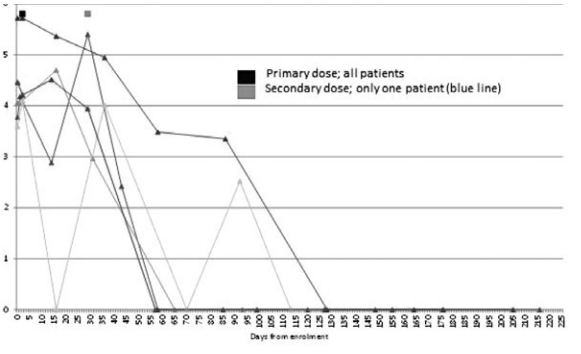

Figure 1. Log PCR *vs* days from enrolment.

Summary and Conclusions: In a small number of initial subjects ADV viremia in pediatric patients post HSCT was controlled following ACT. A number of AEs and SAEs were reported, in keeping with expectations for this patient population. The trial is ongoing.

P730

LIPOSOME-BASED SPECIFIC TARGETING OF A STAT3-INHIBITOR TO CANCER-PROMOTING MACROPHAGES: A NOVEL THERAPUTIC PARADIGM IN MULTIPLE MYELOMA

M.N. Andersen[1,*] A. Etzerodt[1], M.B. Maniecki[2], N.F. Andersen[3], S.K. Moestrup[1], M. Hokland[1], H.J. Møller[2]
[1]Department of Biomedicine, Aarhus University, Faculty of Health, [2]Department of Clinical Biochemistry, [3]Department of Haematology, Aarhus University Hospital, Aarhus, Denmark

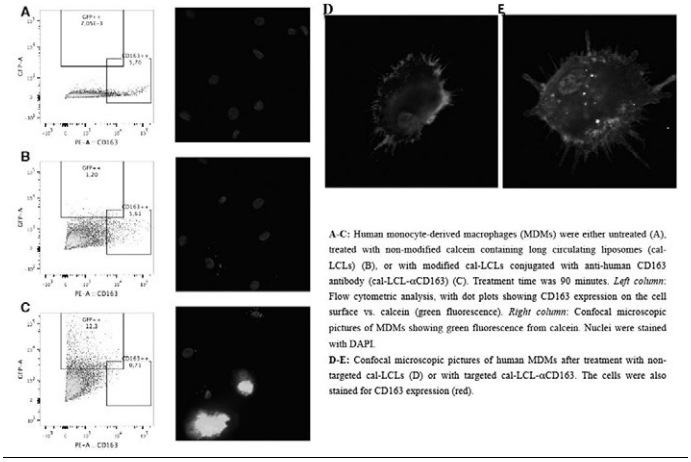
Background: Tumor-associated macrophages (TAMs) play an important role

in cancer by suppression of adaptive immunity and promotion of angiogenesis and metastasis. In multiple myeloma, as well as other haematological malignancies, there is an association between infiltration of CD163+ macrophages in the tumor microenvironment and poor outcome. This association has also been found for most other human cancers. Importantly, expression of the haemoglobin scavenger receptor CD163 is increased on TAMs and other alternatively activated macrophages (M2). Activity of the transcription factor STAT3 is increased in both stromal and malignant cells, and inhibition of STAT3 in tumor-associated myeloid cells has been proposed as a target for novel anti-cancer therapy. Inhibiting STAT3 could potentially repolarize TAMs towards a pro-inflammatory (M1) phenotype, and restore anti-tumor functions. *In vivo,* ablation of the *Stat3* gene, specifically in cells of the haematopoietic system, has been shown to elicit a strong anti-tumor immune response in a mouse model of melanoma. Therefore, CD163-targeted inhibition of STAT3 within TAMs may be a novel treatment paradigm in malignant diseases.

Aims: We aimed to produce a novel drug, long-circulating liposomes (LCLs) containing a STAT3 inhibitor, target this drug specifically to M2 macrophages with high CD163 expression, and evaluate the effect on STAT3 activation in the cells.

Methods: *In vitro,* monocyte-derived macrophages (MDMs) were targeted using a liposome-based system, in which the molecule/drug of interest was packaged within LCLs. LCLs containing either green fluorescent protein calcein (cal-LCLs) or a STAT3-inhibitor (STAT3i-LCLs) were produced using microfluidics technique. Subsequently, LCLs were modified by conjugation with anti-human-CD163 antibodies (LCL-aCD163). MDMs were cultured in RPMI-1640 medium containing 10% foetal calf serum, 10ng/mL M-CSF, and 1ng/mL GM-CSF, and were matured for 7-8 days before experiments were performed. For confocal microscopy, MDMs were cultured on cover slips. For STAT3-activation experiments, MDMs were first treated with the STAT3 inhibitor, and then stimulated with 50ng/mL IL-10 for 15min to induce STAT3 activation. Cells were then fixed, permeabilized, stained with anti-human-P-Y705-STAT3 PE conjugated monoclonal antibody, and analysed on a LSR Fortessa flow cytometer.

Results: Stable cal-LCLs and STAT3i-LCLs were produced, with a radius of 50-80 nm (measured by dynamic light scattering). Here, we show that cal-LCL uptake was markedly higher in MDMs with the highest CD163 expression (the 5-10% most CD163 expressing cells). Using a validated flow cytometric assay for detection of activated (phospho-Y-705) STAT3, we evaluated the ability to inhibit this activation in human MDMs. After stimulation with IL-10 the median fluorescence intensity (MFI) for P-Y705-STAT3 PE increased from ~150 to 290. This increase could only be partially reduced by free STAT3 inhibitor or non-targeted STAT3i-LCLs, but with the targeted STAT3i-LCL-aCD163, we were able to reduce the STAT3 activity to the unstimulated level, or below (MFI ~100 to 150).



A-C: Human monocyte-derived macrophages (MDMs) were either untreated (A), treated with non-modified calcein containing long circulating liposomes (cal-LCLs) (B), or with modified cal-LCLs conjugated with anti-human CD163 antibody (cal-LCL-αCD163) (C). Treatment time was 90 minutes. *Left column*: Flow cytometric analysis, with dot plots showing CD163 expression on the cell surface vs. calcein (green fluorescence). *Right column*: Confocal microscopic pictures of MDMs showing green fluorescence from calcein. Nuclei were stained with DAPI.

D-E: Confocal microscopic pictures of human MDMs after treatment with non-targeted cal-LCLs (D) or with targeted cal-LCL-αCD163. The cells were also stained for CD163 expression (red).

Figure 1.

Summary and Conclusions: We have shown that LCLs can be effectively targeted to the most CD163-expressing cells (which includes TAMs), and that this delivery system can be used to effectively inhibit STAT3 within human MDMs *in vitro*.

In perspective, this may lead to the first *in vivo* experiments of targeted inhibition of STAT3 specifically within TAMs.

P731

ANTIBODY-TARGETED CYCLODEXTRIN NANOPARTICLES DELIVER SIRNA AND ACHIEVE THERAPEUTIC GENE SILENCING IN BLOOD FROM ACUTE MYELOID LEUKAEMIA (AML) PATIENTS

J. Guo[1,*] K.A. Fitzgerald[1], E.G. Russell[2], R. Darcy[3], T.G. Cotter[2], S.L. McKenna[4], M.R. Cahill[5], C.M. O' Driscoll[1]

[1]School of Pharmacy, [2]Bioscience Research Institute, University College Cork, Cork, [3]Centre for Synthesis and Chemical Biology, University College Dublin, Dublin, [4]Cork Cancer Research Centre, University College Cork, [5]Department of Haematology, Cork University Hospital, Cork, Ireland

Background: Delivery of small interfering RNA (siRNA) using multifunctional nanoparticles has been investigated to treat solid cancers; however the application of this approach to blood cancers is at an early stage. Modified cyclodextrins have successfully delivered siRNA in a range of *in vivo* pre-clinical animal models of disease including prostate cancer [1], inflammatory bowel disease [2] and Huntington's disease [3].

Aims: The aims of this study are: to formulate an antibody (Fab) targeted cyclodextrin (CD) nanoparticle (NP) for siRNA delivery to treat AML, to assess the efficacy of this NP *in vitro* using KG1 (AML) cells and *ex vivo* using AML primary patient samples, and to evaluate the NP as an adjuvant therapy for traditional chemotherapy.

Methods: An amphiphilic cationic CD was synthesised as previously described [4]. This CD was complexed with siRNA and co-formulated with a PEGylated lipid (DSPE-PEG). The resulting NP was tagged with a Fab to give CD.siRNA.DSPE-PEG-Fab (NP-Fab) targeting the CD123 receptor overexpressed on AML stem cells. Incorporation of Fab was assessed by SDS-PAGE. The NP-Fab was characterised for particle size, surface charge and stability using a Malvern Zetasizer Nano ZS. Agarose gel retardation assay was performed to determine the ability of nanoparticles to bind siRNA and protect it from serum degradation. *In vitro* toxicity was examined in KG1 cells using the MTT assay. *In vivo* toxicity was assessed in C57BL/6 mice using ELISA and haematoxylin and eosin (H & E) staining. Competitive internalisation of nanoparticles was evaluated using FACS. Confocal microscopy was used to investigate intracellular trafficking of nanoparticles. Targeted gene knockdown was quantified using real-time qPCR and western blotting. Anti-leukaemia efficacy was investigated in KG1 cells and AML primary cells using a CCK-8 Kit and a colony-formation assay.

Results: The incorporation of DSPE-PEG into CD.siRNA NP significantly increased the size and reduced the charge, further incorporation of Fab significantly increased the size but did not affect the charge. The NP-Fab had a size of ~200 nm with a nearly neutral surface charge of 4 mV, and resisted aggregation in OptiMEM. The NPs displayed minimal *in vitro* and *in vivo* toxicities. Pre-treatment with free Fab significantly ($P<0.05$) reduced uptake of the antibody-targeted NP in KG1 cells, suggesting specific ligand-receptor mediated internalisation. Confocal microscopy data indicated that endosomal escape of antibody-targeted NP was time-dependent. The NP-Fab incorporating Bromodomain-containing protein 4 (BRD4) siRNA displayed significantly ($P<0.05$) higher gene knockdown efficiency in KG1 cells and AML primary cells compared to the siRNA delivered by the commercial cationic lipid vector, Lipofectamine 2000. Use of the Fab-targeted NP in combination with Cytarabine (Ara-C) resulted in a synergistic therapeutic response, achieving up to 90% growth inhibition of primary cells.

Summary and Conclusions: The antibody-targeted CD-based NP containing therapeutic siRNA is a novel therapeutic strategy with potential to treat AML, particularly when combined with chemotherapeutics. Future work is underway to investigate pharmacokinetics, tissue distribution, and anti-cancer efficacy in a pre-clinical AML mouse model.

CLINICAL GRADE ACTIVATED NATURAL KILLER PRODUCTS FOR ADOPTIVE IMMUNOTHERAPY AGAINST HIGH-RISK MALIGNANCIES

A. Pérez Martínez[1,*] D. Corral-Sanchez[2], L. Fernandez[3], A. Leivas[4], J. Valentín[5], R. de Paz[6], R. Rodriguez[7], D. Campana[8], J. Martínez[4]

[1]Servicio de Hemato-Oncología Infantil. Hospital La Paz., [2]Servicio de Pediatría, Universidad Autónoma de Madrid, [3]Clinical research, Oncologic National Research Center (CNIO), [4]Servicio de Hematología, Hospital 12 de Octubre, [5]Innate Immune Group, Instituto de Investigación del Hospital La Paz (idiPaz), [6]Servicio de Hematología, [7]Servicio de Inmunología, Hospital La Paz, Madrid, Spain, [8]Department of Paediatrics, National University of Singapore Centre for Translational Medicine, Singapore, Singapore

Background: Natural Killer (NK) cells may exert a graft-*vs.*-leukemia/tumor effect without concomitant severe graft *vs* host disease. Different clinical-grade highly active human NK cell products are being used against malignancies.

Aims: Our study investigates the NK cell recovery, T cell depletion, phenotype and cytotoxicity of three different ways of good manufacturing practice (GMP)-grade NK cell products.

Methods: In four different clinical trials, we have infused three different activated NK cell products obtained after: i) enrichment from healthy haploidentical donors peripheral blood mononuclear cells (PBMNCs) collected by non-mobilized apheresis by two steps procedure, depletion of CD3+ cells and selection of CD56+ cells, using CliniMACS device and *ex-vivo* stimulation with IL-15 overnight (NKIL15), EudraCT 2009-010016-15; ii) expansion from autologous PBMNCs from multiple myeloma patients using as feeder K562 cells expressing interleukin (IL)-15 and 4-1 BB Ligand (K562-mb15-41BBL), (NKAE), EudraCT 2012-000514-11; iii) or expasion from healthy haploiden-

tical PBMNCs obtained by whole blood using the same feeder K562 cellular line, EudraCT 2012-000054-63 and EudraCT 2012-005146-38. The final cell products were analyzed for microbiological test and by flow cytometry for CD3+CD56- and CD3-CD56+ cells. In addition, haploidentical NKAE products were analyzed for the surface expression of CD25, CD69, NKG2D, DNAM and NCRs by tye appropiate combination of flurochrome-conjugated monoclonal antibodies. The NK cytolitic activity was tested in a 2h BATDA release assay against K562, A673, Jurkat and U266 in an 8:1 E/T ratio.

Results: Thirty-three activated NK cell products consisted on haploidentical NKIL15 (n=8), haploidentical NKAE (n=11) and autologus NKAE (n=14) were infused on 17 patients suffering from advanced malignancies (6 pediatric refractory sarcomas, 7 pediatric refractory acute leukemias, and 5 adults patients suffering from high risk multiple myeloma, respectively) on 4 different clinical trials. Safety. No microbial contamination was detected in any product. BCR-ABL1 quantification was negative after infusion in all patients treated with NKAE activated with K562 feeders. From NKIL15 the median NK cell recovery was 25% (range 10-41%) and the T cell depletion was 5.34x10-5 (5.1 log). From NKAE the expansion of CD56+CD3- cells after 14 days of culture was 268.47-fold (range 28- to 1547-fold) after 14 days of coculture from donors and 74.4-fold (range 13- to 551-fold) from multiple myeloma patients. Expansion of CD3+ T cells was minimal (median recovery 2.31-fold; range 0.13- to 5-fold from haploidentical donor and 0.36-fold; range 0.0001- to 1.7-fold from patients PBMCs). The CD56+CD3- cells, NK cells, obtained from NKIL15 and NKAE products were similar. However, CD56-CD3+ cells, T cells, were significantly lower in NKIL15 product, Figure 1. Haploidentical NKAE product expanded higher NK cells but also significantly higher T cells than autologous NKAE product (p=0.002). The surface expression of the activating receptors CD69, CD25, NKp44,NKp46, NKp30 and DNAM was up-regulated, Figure 2. NKAE and NKIL15 products had a significantly higher lytic activity than unstimulated NK cells (97 and 75% *versus* 42%; 34 and 57% *versus* 23%, 40-60% *versus* 19% and 60-52% *versus* 21%) in K562, A673, Jurkat and U266, respectively.

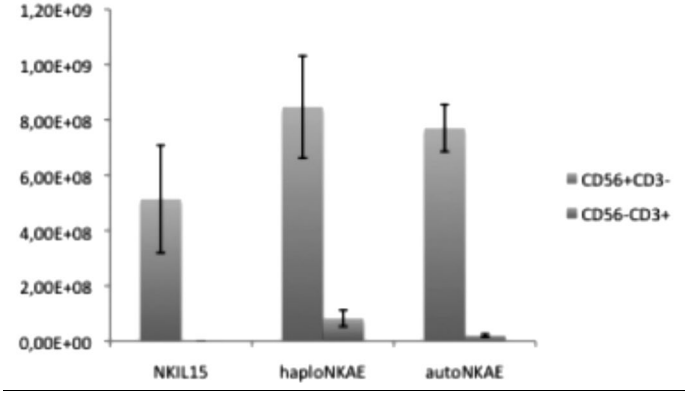

Figure 1.

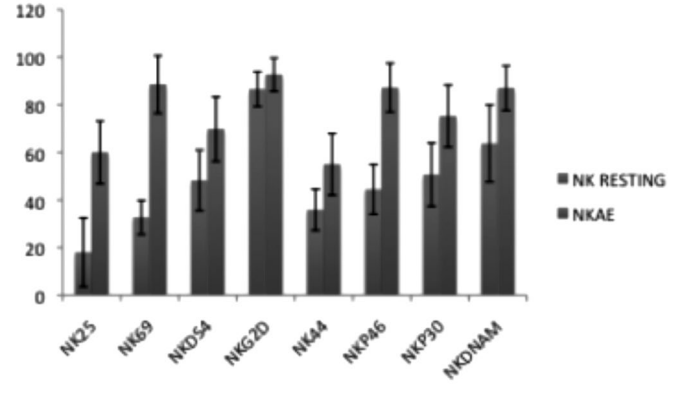

Figure 2.

Summary and Conclusions: In conclusion, our results indicate that different procedure of GMP-grade purification of highly activate NK cells with extremely low T cell content are feasible for clinical use. The T cells contained are lower in NKIL15 and autologous NKAE products than in haploidentical NKAE products.

P733

IMPROVED SAFETY AND EFFICACY OF A HIGH-AFFINITY A2.1-RESTRICTED SINGLE-CHAIN P53-SPECIFIC TCR FOR ADOPTIVE IMMUNOTHERAPY

H. Echchannaoui[1,2,*] J. Petschenka[1,3], E. Antunes[1], M. Theobald[1,2,4]
[1]III. Medical Department of Hematology, Oncology and Pneumology, University Medical Center of the Johannes Gutenberg University Mainz, [2]German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), [3]Institute for Translational Oncology (TRON), University Medical Center, [4]Research Center Immunology (FZI), Johannes Gutenberg University, Mainz, Germany

Background: Adoptive transfer of T cells retrovirally transduced with a tumor-associated antigen (TAA) -specific T cell receptor (TCR) has shown promise in the treatment of cancer patients. Mutation and overexpression of the p53 tumor suppressor protein are the most common genetic alterations in human cancers. We used HLA-A2.1 transgenic mice to generate a high-affinity CD8-independent TCR specific to the widely expressed human p53(264-272) tumor-associated antigen. However, a safety concern of TCR gene transfer is the pairing of natural and introduced TCR chains resulting in the potential generation of self-reactive T cells.

Aims: We aim at improving adoptive T cell-based immunotherapy by generating optimized specific TCR format with reduced potential for TCR mispairing-associated self-reactivity and enhanced tumor recognition.

Methods: To overcome TCR mispairing formation, we designed a single chain (sc) TCR format by connecting the variable TCRa domain to the TCRb chain via a short peptide linker co-expressed with a truncated TCRa constant domain. The TCR sequences were cysteine-modified, codon-optimized and cloned into one single 2A-based retroviral vector. The choice of target tumor antigens for cancer immunotherapy is of central importance as the transfer of high-avidity T cells may potentially induce severe on-target toxicity by damaging normal cells expressing the antigen. Here, we evaluated the safety issues raised by the risk of p53TCR gene transfer-associated on/off-target toxicities in A2.1 transgenic mouse models of adoptive transfer.The antitumor efficacy was assessed in syngeneic and NodScid IL-2R gamma chain-null mice (NSG) xenograft models.

Results: *In vitro* studies showed that, scTCR-modified $CD4^+$ and $CD8^+$ T cells displayed similar high-avidity compared to the full-length TCR, as determined by peptide titration in cytotoxicity assays and were able to mediate specific lysis of p53 mutant $A2.1^+$ tumor cells. However, in contrast to the full-length TCR, the optimized scp53TCR did not result in mispairing-mediated lethal off-target autoimmunity *in vivo*. We next assessed the potential of scTCR-modified T cells to cause on-target autoimmunity, using $A2.1K^b$ transgenic mice expressing human p53 (Hupki). We observed that transfer of scTCR-specific T cells did not result in a depletion of hematopoietic compartment, as mice recovered normal white blood cell counts and survived without any sign of toxicity. Importantly, high-avidity scTCR-modified T cells were able to eradicate established tumors in syngeneic and xenograft mouse models.

Summary and Conclusions: Together, our study provided evidence that an optimized high-affinity scTCR-specific for the broadly expressed tumor-associated antigen p53(264-272) can eradicate tumor cells without inducing off/on-target toxicities in murine models of adoptive T-cell transfer. These data demonstrate the improved safety and therapeutic efficacy of high-affinity scp53TCR for a broad-spectrum immunotherapy of malignant disease.

HYDROXYUREA FOR B-THALASSEMIA: A META-ANALYSIS

A. Algiraigri[1,2,3,*] N. Wright[2], A. Kassam[1]
[1]Community Health Science, University of Calgary, [2]Paediatric Hematology/Oncology/BMT, Alberta Children Hospital, Calgary, Canada, [3]Haematology, King Abdulaziz University, Jeddah, Saudi Arabia

Background: β-thalassemia is one of the most common inherited diseases worldwide. Severe forms of β-thalassemia require life-long blood transfusions, resulting in iron overload with multi-organ morbidity and mortality. Hydroxyurea (HU), an oral chemotherapeutic drug, is anticipated to decrease the need for transfusions, either completely or partially by raising hemoglobin levels and thus decreasing the short and long term complications of chronic transfusions.
Aims: To evaluate the clinical efficacy and safety of HU in β-thalassemic patients of any age.
Methods: *Search strategy:* We searched MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), ongoing trials registers, and major preceding conferences. Hand searches were also conducted using reference lists from primary studies. *Selection criteria:* Randomized controlled trials (RCTs) and observational studies (sample size ≥5) assessing the clinical efficacy of HU alone for three months or longer, for the treatment of patients with β-thalassemia were included. *Data collection and analysis:* Two authors acted as reviewers and independently assessed study quality and extracted data from the included studies. β-thalassemia classification and response evaluation outlined in the following Table 1. Effect size was estimated as a proportion (responders over sample size). All data was analyzed using Stata, Version 13.0.

Table 1.

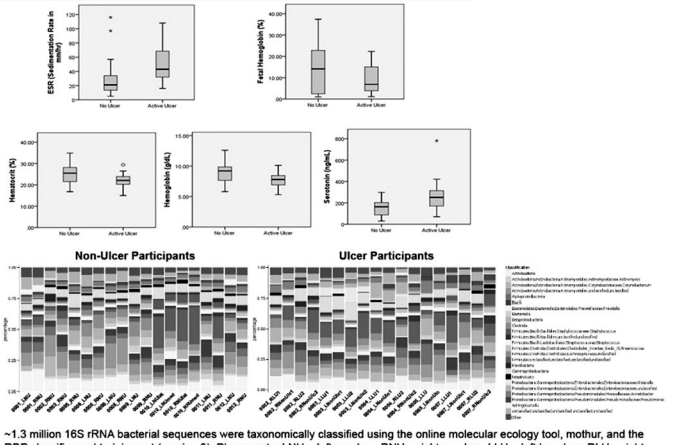
Disease	Subgroup	Key features	Response assessment
β-thalassemia major (β-TM)	1) Classical β-TM; or 2) Severe E/ β-thalassemia	Life-long transfusion needs	1. Complete response (CR): complete cessation of transfusion 2. Overall response (OR): ≥50 reduction of transfusion
Severe non-transfusion dependent β-thalassemia (severe NTDβT)	1) Classical β-Thalassemia intermedia; or 2) Moderate E/ β Thalassemia	≥4 transfusions/year or every 3 months & not meeting β-TM definition	1. CR: as above 2. OR: as above
Mild NTDβT	1) Classical β-thalassemia intermedia; or 2) Mild E/ β Thalassemia	No or <4 transfusions/year	Response rate (RR): ≥1g/dL increase in Hemoglobin (Hb)

Results: For β-TM, 11 observational studies involving 620 patients were included. HU was associated with a significant decrease in transfusion need with CR of 41% (95% CI, 25-58%) and OR of 71% (95% CI, 56-84%). In severe NTDβT, 8 (1 RCT & 7 observational) studies involving 305 patients were analyzed. HU was associated with a significant decrease in transfusion need with CR of 55% (95% CI, 34-75%) and OR of 79% (95% CI, 69-88%). For mild NTDβT, 14 (1 RCT and 13 observational) studies involving 344 patients were included. HU therapy was effective in raising Hb by 1g/dL from baseline in 54% (95% CI, 43-65%). All of the studies had several limitations, such as small sample size, lack of comparison group, under-reporting of data and methods, and being mostly observational studies. Adverse events (AEs) were transient and improved with temporary cessation of the drug and/or adjustment of the dose.
Summary and Conclusions: HU appears to be effective in the management of β-thalassemia by decreasing the need for chronic blood transfusions completely or partially in a significant number of patients. It appears to be well tolerated and associated with mild and transient AEs. Patients with β-thalassemia may benefit from a trial of HU, though large RCT assessing efficacy should be done to confirm the findings of this meta-analysis.

P735

PHENOTYPIC VARIATIONS IN SICKLE CELL DISEASE: AN EXPLORATION OF THE ROLE OF THE ENVIRONMENT AND SKIN MICROBIOME ON LEG ULCERS

C. Minniti[1,*] V. Bonham[2], K. Findley[3], K. Abdallah[3], A. Buscetta[4]
[1]Hematology, Einstein College of Medicine, Bronx, New York, [2]bonhamv@mail.nih.gov, National Intitutes of Health, NHGRI, [3]National Institutes of Health, NHGRI, [4]National Institutes of Health, NHGRI, Bethesda, United States
Background: There is extensive phenotypic variation in SCD, a monogenetic inherited disorder that affects millions worldwide. Fetal hemoglobin and alpha chain number have been identified as genetic disease modifier, but alone do not explain the marked interpatient and intrapatient variability of acute and chronic complications, which can affect every organ. Efforts have been hampered by the difficulty in precisely defining clinical phenotypes, such as acute pain crisis, and acute chest syndrome.Leg ulcers are a debilitating complication of SCD, associated with severe anemia, chronic pain, elevated TRV, priapism, thrombophilia, renal insufficiency, and a negative predictor of survival. They are easy to identify and recall both by the patient and the health care provider. Their prevalence in patients with SCD is 10 times higher than in the general population and varies in different geographic locations
Aims: We hypothesize that leg ulcerations in SCD are multifactorial and include contributions from the skin microbiome, genetic and environment factors, both physical and social.
Methods: The study will recruit 60 adults with SCD, 30 with and 30 without leg ulcers in a NHGRI sponsored trial. Clinical, laboratory, and social characteristics are prospectively obtained. Samples for microbiome analysis are collected at the center of the wound, the periwound, and the opposite leg. Microbial DNA was extracted, the 16S rRNA molecular marker sequenced (V1V3 region), and the PCR products purified and quantified for sequencing using the Illumina MiSeq Benchtop Sequencer platform.
Results: Laboratory measures from the first 35 participants in the study were significantly different between the leg ulcer and non-leg ulcer groups: lupus anticoagulant, glucose, hematocrit, hemoglobin, platelet count, ferritin, hemoglobin reticulocyte, ESR, and serotonin ($p<0.1$). The leg ulcer group had higher mean values for absolute reticulocyte count, serotonin, and ESR ($p=0.42$, $p<0.05$, and $p<0.1$, respectively), and significantly lower values for hemoglobin (Hb), hematocrit (hct) and fetal hemoglobin (HbF) at $p<0.05$, $p<0.05$, and $p<0.1$, respectively. For the first 12 participants who had their microbiome sequenced preliminary analysis of the relative abundance of bacteria on the malleoli of SCD participants with and without leg ulcers reveals that the bacterial community structure differs in participants with leg ulcer and non-ulcer. No significant differences were found for demographic characteristics between the active and no leg ulcer groups (Figure 1).



~1.3 million 16S rRNA bacterial sequences were taxonomically classified using the online molecular ecology tool, mothur, and the RDP classifier and training set (version 9). Please note: LNU – left no ulcer, RNU – right no ulcer, LLU – left leg ulcer, RLU – right leg ulcer, LNonUlc – left non ulcerated skin, and RNonUlc – Right non ulcerated skin.

Figure 1.

Summary and Conclusions: Clinical and laboratory differences exist in patient with SCD and leg ulcers, when compared to patients without ulcers. The microbiome of patients who have leg ulcers is different from patients that do not develop them and could contribute to their occurrence. Stress levels are higher, as demostrated by higher levels of serotonin and so are markers of inflammation (ESR). Family and education variables do not seem to responsible for this end organ complication.

P736

PERICARDIAL EFFUSION IS A MARKER OF INCREASED CARDIAC MORTALITY IN THALASSEMIA MAJOR PATIENTS

A. Meloni[1], P. Toia[2], V. Positano[1], R. Renni[3], G.R. Giugno[4], C. Cirotto[5], G. Izzi[6], M.P. Smacchia[7], M.G. Neri[1], G. Restaino[8], V. Positano[1], A. Pepe[1,*]

Ferrari", Casarano (LE), [4]U.O.C. Pediatria e Neonatologia, Az. Osp. Gravina, Caltagirone (CT), [5]Servizio Trasfusionale, Azienda USL n° 1, Sassari, [6]U.O. Pediatria Oncoematologia, Dipartimento Materno-Infantile, Parma, [7]DAI Pediatria - UOC Oncoematologia, Policlinico Umberto 1, Roma, [8]Dipartimento di Radiologia, Università Cattolica del Sacro Cuore, Campobasso, Italy
Background: In different types of not-hematological diseases the presence of a small pericardial effusion (PE) was associated with worse survival even after adjustment for patient characteristics, suggesting that it is a marker of underlying disease. In thalassemia major (TM) pericardial effusion was shown to be

one of the manifestations of heart disease but its potential prognostic importance has never been investigated in the modern era. Cardiovascular Magnetic Resonance (CMR) by cine SSFP sequences was demonstrated to be extremely sensitive to even a small amount of PE.
Aims: This is the first prospective study evaluating if the presence of pericardial effusion is associated with increased cardiac mortality in TM.
Methods: 1259 patients (648 females, mean age 31.02±8.64 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) were prospectively followed from their first Magnetic Resonance Imaging (MRI) scan. CMR was used to quantify myocardial iron (MIO) overload by a multislice multiecho T2* approach and to assess biventricular function parameters and to detect PE by cine SSFP sequences.
Results: PE was present in 25 (2.0%) patients. Patients with and without PE were comparable for age and ratio of men/women. At the baseline, the percentage of patients with MIO (global heart T2* value <20 ms) was comparable between patients with and without PE (12.0% *vs* 28.7%; P=0.074) and left ventricular and right ventricular ejection fractions were not significantly different between the two groups. Mean follow-up (FU) time was 44.55±20.35 months and there were 15 deaths. Nine death were due to cardiac causes. Cardiac mortality was greater for patients with PE compared to those without an effusion (8.0% *vs* 0.6%, P=0.013). PE was a significant predictive factor for cardiac death (hazard ratio-HR=19.25, 95%CI=3.96-93.66, P<0.0001). PE remained a significant prognosticator for death also in a multivariate model including MIO (PE: HR=35.24, 95%CI=6.59-188.57, P<0.0001 and global heart T2* <20 ms: HR=6.89, 95%CI=1.60-29.69, P=0.010) (Figure 1).

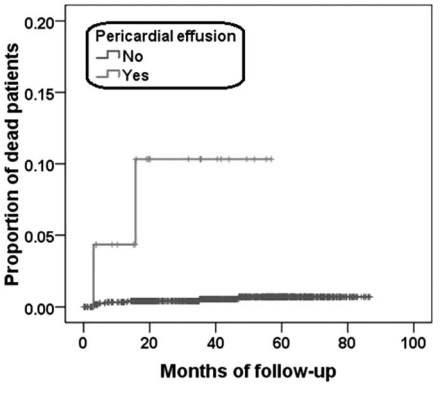


Figure 1.

Summary and Conclusions: PE is quite rare in TM patients and it is not related to myocardial iron overload. An important role in the development of PE could be played by the 'iron-induced' pericardial siderosis but, due to the limitations of the current non-invasive CMR techniques, we were not able to address this issue. PE was found to be a strong predictor for cardiac death, independently by the presence of myocardial iron overload. The non-invasive diagnosis of pericardial effusion is important for a more complete definition of the cardiac involvement of TM patients. The increased risk of cardiac death associated with PE may be used along with other clinical characteristics when estimating a patient's prognosis and monitoring.

P737

OUTCOMES OF A COHORT OF CHILDREN WITH HEMOGLOBINOPATHY RECEIVING ORAL IRON CHELATORS FOR TREATMENT OF TRANSFUSIONAL IRON OVERLOAD IN TURKEY: RESULTS OF 3-YEAR FOLLOW-UP STUDY

A.S., Istanbul, [21]Child Health and Disease, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Tissue damage due to iron overload is an ineluctable complication in chronically transfused children with hemoglobinopathies. Lifelong iron chelation therapy is therefore necessary to reduce iron accumulation; however, compliance issues associated with parenteral treatments remain a challenge. Oral iron chelators (OIC) provide an attractive alternative due to their longer half-life, which permits once daily or three times a day dosing regimens.
Aims: We aimed to investigate the outcomes of two oral iron chelators, namely, deferiprone (DFP) and deferasirox (DFX) for transfusion dependent children with hemoglobinopathies in Turkey.
Methods: This multicenter, nation-wide, prospective, non-interventional, 3 year follow-up study evaluated OIC for the treatment IOL. Patients aged 2-18 years with beta-thalassemia major (bTM) or sickle cell anemia (SCA) who were suffering from TIO and on OIC treatment were included. Recommended assessments included demographics, laboratory and imaging results related to TIO, and serious adverse events.
Results: Hereby, we present 3 year follow-up results of this prospective study. Of 474 patients included from 30 centers, 450 (95%) (50.7% female, mean [standard deviation-SD-] age: 9.3 (4.1) years) were diagnosed as bTM whereas 24 (5%) (33.3% female, mean [SD] age: 9.9 (4.2) years) as SCA. Of the patients, 338 (71.3%) completed the study. Results of key laboratory parameters are summarized in Table 1. There were 165 (48.8%) patients with hemoglobin level of ≤9 g/dL at month 36. Serum ferritin (SF) levels significantly decreased with DFX therapy; however, no significant change was observed with DFP therapy. This discrepancy can be explained with the low patient numbers on DFP treatment (n=35). The rate of patients with SF levels of <1000 ng/mL was increased from baseline to month 36 (DFX: 19% to 37% *vs* DFP: 9% to 26%). Additionally, the mean DFX dose was increased from 26.3±6.1 mg/kg to 29.4±10.6 mg/kg on month 36. As compared to <20mg/kg dose, patients who were on ≥20mg/kg of DFX had a significant decrease in SF level. According to the Cox regression analysis, DFX alone was 2.23 times (95% CI: 1.281-3.867) more successful in reducing SF levels of patients below 1000 ng/mL as compared to DFP. There was a positive correlation between SF level and alanine aminotransferase (ALT) for both DFX and DFP.

Table 1. Results of selected laboratory parameters.

DFX: Deferasirox, DFP: Deferiprone, SD: Standard deviation.

Summary and Conclusions: This study comprises the overall prospective largest pediatric cohort including bTM and SCA patients suffering from TIO and under OIC treatment. In DFX treated patients receiving >20mg/kg, a decrease in SF was observed; however, it was lower than that reported in randomized trials most likely due to few patients receiving the recommended DFX dose of over 30 mg/kg to gain negative iron balance. There was no clinically significant change in liver or kidney function in these patients receiving DFX or DFP. About half of the patients had a hemoglobin level of ≤9 g/dL after 36-month follow-up, revealing that such patients still do not receive optimal transfusion regimens according to current guidelines. Results of three-year follow-up of the study demonstrate that in order to achieve optimal therapeutic goals, it is important to personalize the treatment through active dose adjustments and address potential compliance issues that can arise from multi-year oral treatments.

RARE INHERITED ANAEMIAS: A CLINICAL-GRADE VALIDATED TARGETED RESEQUENCING PANEL YIELDS HIGH DIAGNOSTIC RATES AND IMPROVES TARGETED MANAGEMENT

N. Roy[1,2,*] J. Mason[3], M. Proven[3], H. Dreau[3], K. Wray[1], C. Babbs[1], D. Roberts[4], J. Teo[5], J. Curtin[5], G. Hall[6], A. Qureshi[6], W. Atoyebi[2], E. Wilson[3], D. Higgs[1], S. Henderson[3], A. Schuh[7]

[1]Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, [2]Department of Haematology, [3]BRC/NHS Translational Molecular Diagnostics Centre, [4]NHS Blood and Transplant, John Radcliffe Hospital, Oxford, United Kingdom, [5]Department of Paediatrics, Sydney Children's Hospitals Network, Westmead, Australia, [6]Department of Paediatrics, John Radcliffe Hospital, [7]Department of Oncology, Churchill Hospital, Oxford, United Kingdom

Background: There is a substantial need for improved molecular-diagnostic testing of patients with rare inherited anemias, whether isolated or in the context of pancytopenia. Due to the rarity of these disorders, no routine testing is available. In practice, clinicians must refer patient samples to multiple specialist centers for diagnostic investigations, which often leads to delays in diagnosis and high costs without the certainty of obtaining a molecular diagnosis. Next generation sequencing (NGS) methodology offers an avenue to overcome many of these issues. Targeted resequencing panels have been used for patients with rare anaemias in a research setting but technical and scientific barriers have hampered the transfer of this technology into a routine diagnostic setting. These include the extensive validation required for diagnostic tests and bioinformatic validation of coverage to highlight regions where pertinent mutations may have been missed. Finally, there is limited information regarding the clinical utility of this type of resequencing strategy in this patient group.
Aims: To meet this need we developed and validated a method for the routine diagnosis of congenital red-cell disorders by NGS with the aims of (1) demonstrating the feasibility of achieving clinical-grade validation for a targeted resequencing panel, (2) developing and providing an open-source tool for evaluation of DNA sequence coverage in a clinical setting, (3) assessing the diagnostic yield of the strategy in the diagnosis of congenital anemia/pancytopenia and (4) assessing the clinical utility and impact on management of results generated by this approach.
Methods: We designed a resequencing panel to target 34 genes known to cause anemia and/or pancytopenia [Diamond-Blackfan anemia (DBA), dyskeratosis congenital (DKC), Schwachman-Diamond syndrome (SDS), sideroblastic anemia, congenital dyserythropoietic anemia (CDA) and the enzyme deficiencies G6PD, PKLR and pyrimidine 5' nucleotidase] and used it to assess patients with unexplained anemia in whom acquired causes have been excluded. We also developed an open-source tool for evaluation of sequence coverage in a diagnostic clinical laboratory setting that determines the discoverability of all known mutations in each gene for every individual sample, a functionality currently unavailable in commercial software.
Results: We validated diagnostic findings from NGS with Sanger sequencing and microarray, and found 100% specificity and 99.7% sensitivity (95% CI 97.9-99.9%). We then analysed 57 clinical samples. A molecular diagnosis was made in 24 cases (42%), corresponding to a total of 34 mutations of which 21 were novel. The clinical utility of our diagnostic approach is apparent as accurate molecular diagnosis led to changes in patients' therapies such as splenectomy for patients with PK deficiency or trial of steroids for Diamond-Blackfan anemia.
Summary and Conclusions: We have developed a robust and useful platform for routine molecular diagnosis across the spectrum of congenital anemias and shown a high diagnostic yield, which translated into clinical utility by targeting therapies appropriately.

P739

A PROSPECTIVE CROSS-SECTIONAL STUDY ON OPTHALMOLOGIC COMPLICATIONS AMONG PATIENTS WITH SICKLE CELL DISEASE IN LEBANON

A. Inati[1,*] G. Azar[1], S. Farah[2], M. Kahale[1], D. Khammash[2], H.A. Abbas[3]
[1]Nini Hospital, Tripoli, [2]Lebanese American University, Beirut, Lebanon, [3]MD Anderson Cancer Center, Houston, United States

Background: Sickle cell disease (SCD) is a hereditary disorder characterized by abnormal β-globin chain synthesis leading to vaso-occlusion, hemolytic anemia, recurrent infections and end organ failure. Vaso-occlusive effects on the vascular eye bed may be detectable before patients report visual symptoms.
Aims: This study aims at determining the prevalence and risk factors of ophthalmological complications in a Lebanese SCD cohort and delineating the importance of early detection of asymptomatic eye findings in this cohort.
Methods: This is a prospective observational ongoing cross-sectional study of a SCD cohort in North Lebanon. Ophthalmologic examination consisted of bilateral best-corrected visual acuity (BCVA) measurements, slit-lamp examinations, direct and indirect ophthalmoscopy and wide-field retinal photographs. Fundus fluorescein angiography (FFA) was performed in patients with reduced BCVA or retinal photograph abnormalities. Frequencies and descriptive data were generated using Statistica.
Results: 79 patients, 40 females, 39 males, mean age 15.6±10.5 years were tested. 70%, 28.5% and 1.5% had HbSS, Sβ and SD. Mean steady state hemoglobin, LDH, and ferritin were 8.6±0.87 g/dl, 520.1±203 U/L and 924±1028 ng/ml, respectively. 62% were on hydroxyurea and 86% had history of intermittent blood transfusions. BCVA was >20/50 in 97% and between 20/50 and 20/100 in 3%. Anterior and posterior segment findings were detected in 44% and 48% of patients respectively. The most common anterior segment findings were comma shaped conjunctivae and pallor in 70% and 36%. Posterior segment manifestations included salmon patches in 10.5%, black sunbursts in 31.5%, retinal vascular tortuosity in 26.3% and disc sign in 10.5%. Proliferative sickle retinopathy (PSR) was present in 39.5% of patients, mean age 17.5 years, age range 4 -35 years. Stages 1, 2, 3 and 4 were seen in 5%, 23.6%, 8% and 3% of patients. No patient had stage 5 PSR. Patients with anterior and posterior segment findings had a statistically significant older mean age than those who did not (19.6±10.4 and 18.6±11.5 years *versus* 12.3±9.6 and 13.2±8.7 years, p<0.05). Anterior manifestations were significantly more frequent among patients who had cholecystectomy compared to those who did not (63% *versus* 36.8%, p<0.05), those with a median hematocrit lower than 25.9% than those with higher hematocrit (59% *versus* 31.5%, p<0.05) and in those with a higher transfusion load (60.8 *versus* 21.8 transfusions, p=0.02). A significantly higher level of black sunbursts was found in patients who had cholecystectomy compared to those who did not (32% *versus* 11%, p<0.05).
Summary and Conclusions: Ophthalmologic complications are frequent among young Lebanese patients with SCD and tend to increase with age. Despite the small sample size, the high rate of PSR at a very young age is worrisome. The higher frequency of ophthalmic complications in patients with cholecystectomy, low hemoglobin and high transfusion rate suggest a possible underlying hemolytic etiology besides the well established vaso-occlusive etiology. Early identification of affected patients particularly those at high risk for PSR through effective screening can help introduce timely targeted treatment thereby improving visual outcomes and preventing vision loss.

P740

PREVALENCE OF G6PD DEFICIENCY IN PATIENTS WITH SICKLE CELL DISEASE AND IMPACT ON DISEASE SEVERITY IN LEBANON

A. Inati[1,*] M. Noureldine[2], G. Amhez[2], M. Kahale[2], H.A. Abbas[3]
[1]Nini Hospital, Tripoli, [2]Lebanese American University, Beirut, Lebanon, [3]MD Anderson Cancer Center, Houston, United States

Background: Glucose-6-phosphate dehydrogenases (G6PD) and sickle cell disease (SCD) occur due to defects in hemoglobin stability or structure, respectively. Sickle cell trait and G6PD deficiency are found in 2.1% and 2.09% of the Lebanese population. To date, the rate of co-inheritance of both SCD and G6PD deficiencies in Lebanon has not been determined.
Aims: The primary objective is to determine the co-inheritance rate of G6PD deficiency and SCD in Lebanon. The secondary objective is to delineate the impact of G6PD deficiency co-inheritance on SCD related morbidity and mortality.
Methods: Patients with SCD, followed in 2 comprehensive SCD referral centers in mid and North Lebanon were tested for G6PD deficiency using spot test. All abnormal tests were confirmed by repeat testing. High pressure liquid chromatography (HPLC) was utilized for diagnosis of SCD. Pertinent demographic, clinical, and hematologic information was collected. Statistical analysis was done using Statistica (v. 12.5). Statistical significance was set for p <0.05.
Results: A total of 121 patients with SCD, 57% males, 43% females, mean age 12.5±11.3 years, median follow-up 12.6 years, were screened for G6PD deficiency. 72.5% had HbSS, 21.5% $S\beta^0T$, 4.2% $S\beta^+T$ and 1.6% SD, respectively. 6/121 (5%) patients were found to be deficient for G6PD. Hematologic and clinical features are listed in Table 1.

Table 1. General clinical and laboratory characteristics of SCD patients.

HbS at diagnosis	71±14.9 %
HbF at diagnosis	20.5±12.3 %
HbA1 at diagnosis	6.2±13 %
Mean steady state hemoglobin	8.7±1 g/dL
Mean steady state LDH	493.3±188 unit
Mean steady state indirect bilirubin	1.8±1 unit
Mean steady state total bilirubin	1.9±1.1
Mean steady state heptaglobin	0.5±1.7 unit
Mean steady state reticulocyte	9.5±4.8 %
Mean steady state serum ferritin	610±783 unit
N with acute splenic sequestration(ASS)	44.50%
Patients who have undergone cholecystectomy	53%
Age at cholecystectomy (years)	14.4±23
Mean number of transfusions	24.9±41
Hepatomegaly present	53%
Hydroxyurea treatment	61.60%

Steady state hemoglobin, LDH, haptoglobin, and ferritin were 8.7±1 g/dL, 493±188 unit, 0.5±1.7 and 610±783 ng/dcl, respectively. Acute splenic sequestration (ASS), cholecystectomy and persistent splenomegaly beyond 6 years of age were seen in 44.5%, 26% and 20% of patients, respectively. 40% of patients had splenectomy (surgical in 13% and auto-splenectomy in 26%). Mean HbA1 at diagnosis and steady state ferritin of SCD patients were significantly different among G6PD deficient and G6PD wildtype patients. Specifically, HbA1 was 21.3% in G6PD deficient patients *versus* 5% in wild type (p=0.01);

and steady state ferritin was 1410.9 unit in G6PD deficient patients, while it was 568.6 unit in G6PD wildtype SCD patients (p=0.0002). Number of transfusions, age at cholecystectomy, steady state hemoglobin, LDH, heptaglobin, reticulocyte count or bilirubin were not statistically different between the two groups. In Fisher's exact test analysis, we did not find a correlation between G6PD status and each of gender, splenomegaly, splenectomy, ASS, cholecystectomy or hepatomegaly. Three SCD patients (2.5%) who had wildtype G6PD died during the course of this study but was independent on G6PD status.
Summary and Conclusions: This is the first study on SCD and G6PD deficiency co-inheritance in Lebanon. G6PD deficient SCD patients had significantly higher steady state ferritin levels despite no increased rate of transfusions. Hence, it is possible that G6PD deficiency can alter the iron regulatory and storage pathways via mechanisms that are still to be elucidated. However, this warrants that SCD patients with G6PD deficiency should be monitored more closely for increased iron overload complications.

Infectious diseases, supportive care 2

P741

ANTIFUNGAL PROPHYLAXIS IN HAEMATOLOGY PATIENTS: FREQUENCY AND DRUG CLASS OF CHOICE ACCORDING TO TYPE OF HAEMATOLOGICAL MALIGNANCY (AFHEM STUDY)

J.-P. Gangneux[1], J. El-Cheikh[2], R. Herbrecht[3], I. Yakoub-Agha[4], D. Caillot[5], M. Michallet[6,*]
[1]CHU, Rennes, [2]IPC, Marseille, [3]CHU, Strasbourg, [4]CHU, Lille, [5]CHU, Dijon, [6]HCL, Pierre-Bénite, France

Background: The mortality rate associated with invasive fungal disease (IFD) remains very high (≥40%). Patients in haematology units are at high risk of IFD, and more acurate data is needed on medical practice and use of antifungal therapies.
Aims: An objective of this study was to describe the frequency and characteristics of systemic antifungal prophylaxis strategy in French patients suffering from haematological malignancy and hospitalized in a haematology unit in routine medical practice.
Methods: Multicenter, cross-sectional, prospective French observational study conducted in 24 hematology units (717 beds including 368 sterile beds) over 5 consecutive days on adult or paediatric patients with hematological malignancies and hospitalized during this period.
Results: Overall, 494 patients who signed a consent form were classified into 4 groups according to their risk of Invasive Fungal Infections (IFI). Group 1 includes patients who received allogeneic hematopoietic stem cell transplant (HSCT) (N=147), Group 2 patients suffering from AML or MDS who did not receive allogeneic HSCT (N=131), Group 3 patients suffering from ALL who did not receive allogeneic HSCT (N=71) and Group 4 all the patients not included in the groups 1, 2 or 3 (N=145). 246 patients received systemic antifungal therapeutic strategy. Among them, the proportion of patients who received prophylactic strategy was for Group 1: 95/119 (79.8%), Group 2: 56/78 (71.8%), Group 3: 12/19 (63.2%), Group 4: 24/30 (80.0%). Half of the patients from groups 2 and 3 presented neutropenia for at least 10 days when enrolled in the study compared to 17% for groups 1 and 4. 82% (78/95) and 73% (41/56) of the patients from groups 1 and 2 were placed in sterile room (either in laminar flow sterile room or Immunair™ bed or in highly purified room) compared to 50% (6/12) of the patients from Group 3 and 54% (13/24) from Group 4. In Group 1: 75% (71/95) of patients received an azole, mostly fluconazole (44/71); 13/95 received echinocandins, mostly caspofungin (11/13); 11/95 received polyenes. In Group 2: 89% (50/56) of patients received an azole, mostly posaconazole (35/56); 6/56 polyenes and 1/56 echinocandins. In Group 3: 33% (4/12) of patients received oral fluconazole; 3/12 posaconazole, 3/12 polyenes and 3/12 echinocandins. In Group 4: 92% (22/24) patients received an azole, mostly posaconazole (16/24); 1/24 polyenes and 1/ 24 echinocandins.
Summary and Conclusions: Prophylaxis is now the leading strategy used in hematology, whatever the disease conditions of the patients with overall 76% of treated patients receiving it. Overall, prophylaxis is mainly based on oral azoles : fluconazole and posaconazole. Fluconazole is still used in high risk patients (allogeneic HSCT) and low risk patients (Group 4). Posaconazole is mainly used in AML/MDS patients, but also in ALL patients not receiving HSCT where its use is off-label. Echinocandins are mainly used in high risk patients. Caspofungin is the most-used echinocandin although it is not licensed for prophylaxis.

INVESTIGATING CYTOPENIA MAY REVEAL BONE MARROW METASTASIS: A SINGLE CENTER EXPERIENCE FROM THE HEMATOPATHOLOGIST POINT OF VIEW

A. Paolini[1,*] G. Bonacorsi[1], F. Forghieri[1], P. Zaldini[2], M. Morselli[1], G. Leonardi[1], A. Cuoghi[1], P. Bresciani[1], L. Potenza[1], V. Coluccio[1], M. Maccaferri[1], E. Colaci[1], S. Bigliardi[1], V. Fantuzzi[1], L. Faglioni[1], F. Soci[1], V. Nasillo[1], A. Messerotti[1], V. Pioli[1], L. Arletti[1], E. Lugli[1], A. Gilioli[1], M. Milani[3], A. Maiorana[3], R. Marasca[1], F. Narni[1], M. Luppi[1]
[1]Department of Medical and Surgical Sciences for Children and Adults, University of Modena and Reggio Emilia, Modena, [2]Clinical Chemistry, Laboratory and Endocrinology Unit, Azienda Ospedaliera ASMN, IRCCS, Reggio Emilia, [3]Department of Laboratories and Pathologic Anatomy, University of Modena and Reggio Emilia, Modena, Italy

Background: Bone marrow (BM) involvement by non-hematopoietic neoplasms usually occurs as a late event during the course of oncologic diseases. Most patients with BM metastases have hematological abnormalities, such as one or more cytopenias.
Aims: BM biopsy is a key diagnostic tool to investigate unexplained persistent cytopenias. Limited information is reported in the literature about the incidence of BM metastasis during the course of solid malignancies, with considerable variability depending on the different types of neoplasms.

Methods: A total of 10736 BM trephine biopsies were examined at the Hematopathology Laboratory of the Azienda Ospedaliero-Universitaria Policlinico of Modena, from January 2004 to December 2014. After processing, all samples were stained with Hematoxylin-Eosin (H&E), Giemsa and Silver impregnation (Gomori reaction). After morphologic evaluation, the appropriate immunohistochemical panel, including cytokeratin (CK) mix (AE1-AE3), was performed. Further characterizations of non hematopoietic neoplasms were carried out in collaboration with the Pathologic Anatomy laboratory.
Results: Solid cancer metastasis was documented in 107 of all 10736 BM biopsy samples (0.99%). Concomitant BM aspirates and touch imprints were evaluable in 92 (86%) cases. Median patient age was 68 years (range 7-88 years; excluding a pediatric case, the interval span was 37-88 years). Males and females were 49 (46%) and 58 (54%) of the 107 cases, respectively. The most frequent metastatic tumors were, in order of frequency, as follows: breast (39.25%), gastrointestinal (16.82%), lung (13.08%) and prostate (12.15%) carcinomas. Among them, a previous diagnosis of solid cancer was missing in 25 cases (23.36%). Primary tumor site was determined in 16 out of these latter 25 cases (64%), namely breast 5 (20%), lung 4 (16%), kidney 2 (8%), prostate 1 (4%), neuroendocrine 2 (8%), gastro-intestinal 1 (4%) and cervix 1 (4%). In the remaining 9 cases (36%), the rapid deterioration of clinical conditions contraindicated further diagnostic investigations. However, epithelial origin was documented according to CK mix positive staining, without other specific markers. Cytopenias were the most common hematological finding, namely, in order of frequency: anemia (75.7%), thrombocytopenia (64.5%), and more rarely, leukopenia (23.4%). Of note, pancytopenia was present in 13.1% of patients only. The finding of BM metastases predicted unfavorable outcome, with a median survival from observation of 7 weeks (range 0-361 weeks). This wide range was conditioned by the presence of few breast cancer patients still responsive to hormone therapy (15 women (14%) surviving more than one year).

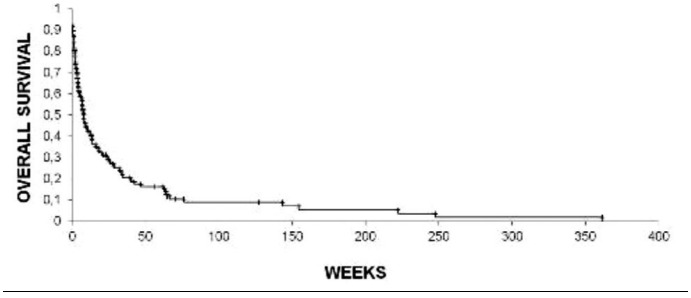

Figure 1. BM metastases patients (n=107).

Summary and Conclusions: BM biopsy is an invasive procedure mainly used for the diagnosis of hematopoietic disorders. Involvement of the BM by non-hematopoietic lesions can incidentally be observed by the hematopathologist. Our case series highlighted that persistent unexplained cytopenias in solid cancer patients can be the first indicator of BM metastases. Although rarely, the finding of BM metastasis can lead to the first diagnosis of solid organ malignancies. However, patients with BM metastasis have a poor outcome and, for most of them, only supportive care can be considered.

P743

DORIPENEM *VERSUS* MEROPENEM AS THE FIRST-LINE MONO-THERAPY IN HIGH-RISK FEBRILE NEUTROPENIC PATIENTS WITH ACUTE LEUKEMIA: A RANDOMIZED, CONTROLLED TRIAL

N. Sugawara[1,*] T. Oyake[1], Y. Fujisawa[1], R. Sasaki[2], T. Mine[3], Y. Tsukushi[4], I. Hanamura[5], M. Asahi[1], Y. Suzuki[1], Y. Okano[1], Y. Fujishima[1], Y. Aoki[1], S. Kowata[1], S. Ito[1], Y. Ishida[1]
[1]Hematology and Oncology, Internal Medicine, Iwate Medical University School of Medicine, Morioka, [2]Hematology, Internal Medicine, Iwate Prefectural Chubu Hospital, Kitakami, [3]Hematology, Internal Medicine, Morioka Red Cross Hospital, Morioka, [4]Hematology, Internal Medicine, Hachinohe Red Cross Hospital, Hachinohe, [5]Hematology, Internal Medicine, Aichi Medical University School of Medicine, Nagoya, Japan

Background: Febrile neutropenia (FN) is often observed in chemotherapy of hematological malignancy (HEM) such as acute leukemia (AL). Carbapenem antibiotics having a potent and broad antimicrobial activity against both gram-positive and gram-negative bacteria including Pseudomonas aeruginosa, are good candidates as the first-line therapy drug in high-risk FN patients. In the IDSA guideline 2010 on the use of antimicrobial agents in FN, mono-therapy with an anti-pseudomonal beta-lactam, such as piperacillin-tazobactam (TAZ/PIPC), cefepime (CFPM) or carbapenem [only meropenem (MEPM) and imipenem-cilastatin (IPM)], is recommended as an empirical therapy for high-risk FN patients. Doripenem (DRPM) is a newer carbapenem with few data available as for the efficacy and safety in the setting of FN patients.
Aims: We conducted a randomized, cooperative group and open-label trial comparing DRPM (1.0 g every 8 hours) with MEPM (1.0 g every 8 hours) as the first-line empirical antibacterial therapy for high-risk FN patients with AL and myelodysplastic syndrome (MDS).
Methods: One hundred and forty-six hospitalized high-risk FN patients with HEM (AML 96, ALL 23, APL 13, MDS-AML 9, MDS (RAEB-2) 5 cases) during or after chemotherapy were randomized to each drug group (DRPM, 72; MEPM, 74). The study drug was started to administer as a mono-therapy and continued at least for 5 days without severe drug toxicity, and the efficacy and safety were evaluated.
Results: The overall response rate at 7 days in DRPM and MEPM group were not significantly different (DRPM: 67.6%, MEPM: 52.9%, respectively, P=0.098). Both the resolution of fever by mono-therapy at day 3 to 5 (DRPM: 56.9%, MEPM: 47.0%, respectively, p=0.26), and survival at day 30 (DRPM: 98.4%, MEPM: 98.5%, respectively, p=0.312) were not significantly different in the two groups. The cases needed for anti-MRSA agent and antifungal agent tended to be observed less frequently in DRPM rather than in MEPM group [DRPM: 36.9%, MEPM: 50.0% (p=0.185), DRPM: 26.1%, MEPM: 32.3% (p=0.535), respectively]. Only grade 1-2 adverse events were observed in both groups (liver dysfunction, renal dysfunction, diarrhea and rash), and they were less often in DRPM group significantly (DRPM: 29.8%, MEPM: 40.8%, respectively, p=0.046). These adverse events were clinically acceptable in the two groups, and most of patients could continue the treatment by both study drugs.
Summary and Conclusions: Our clinical study suggested that DRPM had the non-inferiority of efficacy in comparison with MEPM as the first-line therapy in high-risk FN patients with AL and MDS, and both drugs could be well tolerated clinically.

P744

THE RATE OF HUMAN HERPES VIRUS 6 INFECTION IN ACUTE LEUKEMIA AND LYMPHOMA PATIENTS

T. Lobanova[1,*] D. Tihomirov[1], T. Garanja[1], V. Troitskaya[1], A. Sokolov[1], Z. Fidarova[1], A. Sidorova[1], E. Parovichnikova[1]
[1]Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: Human herpes virus 6 (HHV-6) is increasingly detected in hematopoietic stem cell transplantation (HSCT) recipients and in patients who recover after chemotherapy courses. HHV-6 may cause serious complications such as encephalitis, myelosupression, pneumonitis, hepatitis, cystitis, unexplained fever, rash and is associated with graft-*versus*-host disease. The virus DNA is detected in blood of 40% to 60% patients after HSCT, HHV-6 infection - in 10-15% of such patients. DNA polymerase chain reaction (qPCR) is the common method of HHV-6 detection. HHV-6 infection lacks specific clinical syndromes and is often revealed with CMV infection/reactivation. On time diagnostics and early beginning and prolonged antiviral treatment (ganciclovir, foscarnet or cidofovir) may favorably affect the patient survival and neurologic symptoms.
Aims: To estimate the frequency of HHV-6 infection reactivation in patients (pts) with acute leukemias and aggressive lymphomas after chemotherapy and auto-HSCT.
Methods: For the period from January 2013 to December 2014 in the Department of Hematological Oncology and BMT 68 pts (23 ALL, 42 AML, 3 DLBCL) were analyzed. Auto-HSCT was carried out in 6 cases. Blood, bone marrow, cerebrospinal fluid and urine samples were collected in patients who had febrile neutropenia and other infection complications after courses of chemotherapy or auto-HSCT. HHV-6 DNA was detected in biological fluids by realtime PCR. The lower limit of detection for the assay was 500 copies/mL.

Table 1.

Patients	Ds	Male/Female	Age	Auto-HSCT	+CMV	Symptoms& infections	Period of treatment (Ganciclovir)	Reccurency HHV-6	Total Treatment iv
1 pt	AML	M	42	-	-	Febrile fever, cytopenia	3 weeks	+	6 weeks
2 pt	ALL	M	24	+	-	Encephalitis	2,5 weeks	+	9 weeks
3 pt	ALL	F	34	+	+	Febrile fever, cytopenia	4 weeks	-	4 weeks
4 pt	ALL	M	37	+	-	Hemorrhagic cystitis	4 weeks	-	4 weeks
5 pt	DLBCL	M	54	+	-	Hemorrhagic cystitis	4,5 weeks	-	8 weeks
6 pt	DLBCL	F	55	-	-	Febrile fever, cytopenia	4 weeks	-	4 weeks

Results: HHV-6 DNA was detected in 35% cases (n=24; 9/24 ALL, 13/24 AML, 2/24 DLBCL). Four out of 24 pts were after auto-HSCT. Only in 8,8% (6/68) of cases (including 4 pts after auto-HSCT) we associated the HHV-6 detection and clinical symptoms (3 ALL, 2 DLBCL, 1AML). Prolonged cytopenia (more than 40 days) and febrile fever had 3 pts, cystitis 2 pts, encephalitis 1 pt. (Table 1). All 6 pts were treated with ganciclovir (10mg/kg iv) during 4 weeks with conversion to valganciclovir (per os) during the next 2 weeks. The median ganciclovir treatment time was 4 weeks but in 2 cases of recurrent infection the treatment was prolonged until 6 (6-9) weeks. Early cessation of therapy (after 2 weeks) caused viremia reccurence and viral load increasing of HHV-6 in 2 pts. The clinical symptoms fully disappeared after 3-5 days of treatment. The median time to virus clearance was 4 (4-8) weeks.
Summary and Conclusions: Our study showed high frequency of HHV-6 DNA detection (35%) in immunocompromised pts, only 8,8% had HHV-6 associated infection, most of them were after auto-HSCT. Early conversion therapy to valganciclovir per os caused reccurent HHV-6 infection (33%). Thus, HHV-6 infection required long treatment.

P745

IMPACT OF DECTIN-1 POLYMORPHISMS ON SUSCEPTIBILITY OF INVASIVE FUNGAL DISEASE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

M. Fischer[1,*] B. Spies-Weisshart[1], K. Schrenk[1], B. Gruhn[2], S. Wittig[2], A. Glaser[3], A. Hochhaus[1], S. Scholl[1], U. Schnetzke[1]
[1]Internal Medicine II/ Oncology and Hematology, [2]Klinik für Kinder- und Jugendmedizin, [3]Institut für Humangenetik, Universitätsklinikum Jena, Jena, Germany

Background: Patients with acute myeloid leukemia (AML) who undergo induction chemotherapy are at high risk for invasive fungal disease (IFD). Dectin-1 (Dendritic cell-associated C-type lectin-1), a C-type lectin family member represents one of the most important and intensively studied pattern recognition receptor (PRR) of the innate immune system and single nucleotide polymorphisms (SNP) in the Dectin-1 gene have been associated with an increased risk of infectious complications. In detail, the heterozygous Dectin-1 variant Y238X coding for an early stop codon has been associated with invasive aspergillosis (IA) in recipients of hematopoietic stem cell transplantation.
Aims: We sought to investigate the impact of two different Dectin-1 SNPs on developing IA in 164 patients with newly diagnosed AML during anthracycline-based induction chemotherapy (cytarabine combined with idarubicin or mitoxantrone). The occurrence of infectious complications (sepsis, general pneumonia, IFD) were analyzed.
Methods: Genotyping of Dectin-1 SNPs (rs16910526 and rs7309123) was performed by TaqMan method and pyrosequencing in 164 adult AML patients. IFD was defined according to the EORTC/MSG consensus guidelines. Multiple logistic regression analyses were applied to evaluate the association between Dectin-1 polymorphism and infectious events.
Results: We could demonstrate that patients carrying the homozygous Dectin-1 SNP rs7309123 (G/G genotype, n=43 patients) revealed a significantly higher risk for developing both pneumonia in general (p=0.018, odds ratio (OR): 2.46; 95% confidence interval (CI): 1.2 - 4.9) and pulmonary IFD (p=0.023, OR: 2.3; 95% CI: 1.2 - 4.5). In detail, 24 patients harbouring homozygous Dectin-1 SNP developed pneumonia in general whereas 18 of them fulfilled criteria for IFD. No significant correlation was observed between the occurrence of sepsis and either SNP. Importantly, no differences were found between patients with heterozygous Dectin-1 SNP rs16910526 (Y238X, T/G genotype, n=13 patients) and wild type carriers with regard to all analyzed infectious complications.
Summary and Conclusions: To our best knowledge, this study represents the first analysis demonstrating that a haplotype containing the Dectin-1 SNP rs7309123 influences the risk of developing invasive fungal disease in patients with acute myeloid leukemia undergoing induction chemotherapy.

P746

ANTIFUNGAL PROPHYLAXIS WITH POSACONAZOLE IN ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROME PATIENTS TREATED WITH INTENSIVE CHEMOTHERAPY. A MULTICENTER RETROSPECTIVE STUDY OF REAL-LIFE PRACTICE

D. Serrano[1,*] M. Calleja[2], E. Yebra[3], P. Martinez[4], M. Polo[5], A. Serrano[6], P. Herrera[7], A. de la Fuente[8], C. Teno[9], A. Figuera[10], A. Arriero[10], J.L. Lopez[11], A.C. Franco[1], G. Rodriguez-Macias[1], J.L. Diez-Martin[1]
[1]Hematology, Hospital General Universitario Gregorio Marañon, [2]Hematology, Hospital General Universitario Principe de Asturias, [3]Hematology, Hospital General Universitario Severo Ochoa, [4]Hematology, Hospital General Universitario 12 de octubre, [5]Hematology, Hospital Universitario Clinioc San Carlos, [6]Hematology, Hospital Madrid Sanchinarro, [7]Hematology, Hospital General Universitario Ramon y Cajal, [8]Hematology, MD Andersson, [9]Hematology, Hospital General Universitario Getafe, [10]Hematology, Hospital General Universitario La Princesa, [11]Hematology, Fundacion Jimenez Diaz, Madrid, Spain

Background: Patients diagnosed with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS) who receive intensive induction chemotherapy to achieve complete remission (CR) are considered to be at high risk for developing invasive fungal infection (IFI) during the neutropenic phase (NP). IFI occurs in up to 10% of patients diagnosed with AML/MDS on induction treatment, and is fatal in approximately 40% of cases. Moreover, IFI may compromise the subsequent chemotherapeutic strategies. Difficulty of making a rapid diagnosis of the fungal disease and the high mortality associated, have led to use primary antifungal prophylaxis (PAP) to prevent the occurrence of IFI
Aims: To collect the experience with posaconazole as PAP in patients diagnosed with AML or MDS in hospitals from our environment (Madrid-Spain). Specific goals of this study were to assess IFI rates in our patients (incidence of proven or probable IFI during the NP) the efficacy of this prophylaxis, the rate of adverse events, infection-associated mortality, and overall mortality
Methods: A multicenter, observational, retrospective study of incidence of IFI in patients diagnosed with AML and MDS, who received posaconazole as PAP, and treated with intensive induction chemotherapy, was carried out in 11 hospitals in Madrid (Spain) between 2009 and 2012. In order to achieve a minimum 100 evaluable patients each hospital collected around 10 consecutive AML/MDS patients showing deep neutropenia defined as <500 neutrophils/µL for more than 7 days and <100 neutrophils/µL for more than 4 days. All patients received posaconazole, oral suspension, 200 mg three times daily, at least for one day. Patients follow-up was stopped when a new chemotherapy treatment was started, after 30 days-off posaconazol, or if the patient died
Results: 102 patients fulfilled the inclusion criteria. 63% were male with a median age of 61 years. Diagnosis was AML 94% (8% in first relapse) and MDS 6%. Anthracycline-based chemotherapy was used in 92% of patients; CR was achieved in 72% and partial remission in 10%. All patients developed <500 neutrophils/µL with a median duration of 23 days (range 8-99) and <100 neutrophils/µL for a median of 16 days (range 4-84). Posaconazole was used a median of 19 days (range 1-90). In 48 patients (47%) PAP was successful, but 35 (34%) needed a change in antifungal therapy: empirical treatment due to maintained fever in 21 patients (21%) and to treat IFI in 14 patients (IFI was diagnosed as possible in 10, probable in 3 and proven in 1) In all cases, lung was the organ involved. Switch from posaconazole a different intravenous prophylaxis due to mucositis, or poor oral intake, was a further cause of PAP failure in 13% of patients. Drug discontinuation because of liver or gastrointestinal toxicity, was observed in 5% of patients. Overall mortality was 6% (bacterial infections in 3 patients; thrombotic and hemorrhagic events in 2 patients, and 1 patient due to progression leukemia) with no IFI attributable mortality in our patients.
Summary and Conclusions: Despite the limitations of this retrospective, multicenter, real-life study, PAP with posaconazole reduced the incidence of probable and proven IFI to 4% of patients diagnosed with AML and MDS and treated with intensive induction chemotherapy. Nevertheless empirical antifungal treatment was maintained in a fever-driven approach in 21% of the patients. Poor oral intake represents a further handicap with this PAP that might be solved in the near future with the new upcoming drug presentation

P747

COMMUNITY ACQUIERED RESPIRATORY VIRUS IN ADULTS PATIENTS WITH HEMATOLOGICAL DISEASE: CLINICAL CHARACTERISTICS AND OUTCOME IN RSV AND HPIV INFECTION

A. García-Noblejas[1,*] A. Lorenzo[1], L. Cardeñoso[2], M. Villanueva[1], R. de la Cámara[1]
[1]Hematology, [2]Microbiology, Hospital La Princesa, Madrid, Spain

Background: Community-acquired respiratory viruses (CARV) are a frequent cause of respiratory infections in immunocompromised patients with an increased risk for progression to pneumonia and fatal outcome. The diagnosis of these infections are moving from the classical techniques (virus isolation by cell culture, direct antigen detection) to nucleic acid amplification test usually directed to several viruses.
Aims: The aim of this study was to describe CARV infections in haematological patients based on multiplex PCR DNA microarray platform, focusing on Respiratory Syncytial Virus (RSV) and Human Parainfluenza Virus (HPIV) infections due to their higher frequency and clinical relevance.
Methods: We have analysed retrospectively 570 specimens from 211 consecutive haematological patients with clinical symptoms of respiratory infection from November 2012 to April 2014. The collected samples, nasopharyngeal exudates and/or bronchoalveolar lavages (BAL), were tested with the CLART® Pneumovir assay (Clinical Array Technology, Genomica, Spain) that detect 19 CARV*s.* Patients were classified as upper (URTID) or lower respiratory tract infection disease (LRTID) according to the published criteria of the Fourth European Conference Infections in Leukaemia (ECIL-4) (Hirsch HH, *et al.* Clin Infect Dis. 2013;56(2):258-66).
Results: There were 195 positive cases (34%) in 570 specimens from 211 haematological patients. Ninety nine patients had a positive result at least once. Viruses detected were: 64 RSV, 35 HPIV, 64 rhinovirus, 8 metapneumovirus, 2 enterovirus, 2 coronavirus, 2 bocavirus, 4 adenovirus and 14 patients with several viruses isolate in the same sample. Fifty-nine patients were diagnosed with RSV or HPIV URTDI/LRTID (Table 1).
All patients with RSV were diagnosed from November to April. Nevertheless, HPIV were diagnosed during all the year with a maximum incidence in June (6 cases). Twenty-nine (49%) patients were treated with oral ribavirin, mostly

when RSV was diagnosed. Patients with no treated RSV, had solved the symptoms when positive test was informed. Ribavirin dosage used was that recommended in ECIL-4. Median ribavirin treatment duration was 14 days (1-35). Treatment was well tolerated. There were two engraftment delays in two transplantation patients with RSV and LRTD (one autologous and one allogeneic). One of them died of Pseudomonas aeruginosa pneumonia without neutrophil engraftment. There were two deaths (6%) due to RSV pneumonia. One death occurred in an AML patient treated with chemotherapy without any other microbiological documentation. The other fatal case occurred in a T-NHL patient hospitalized for autologous stem cell transplantation with CMV coinfection. Both patients received ribavirin since RSV infection diagnosis. No deaths related to HPVI were described. In the whole series time to solve symptoms was 14 (3-59) days and time to achieve a negative test was 20 days (7-119).

Table 1. Patients with RVS or HPIV disease.

		RSV	HPIV
Number of cases	59	32	27

Lymphopenia <300/µl	11 (20%)	8 (25%)	3 (12%)
Ribavirin treatment	29 (49%)	24 (75%)*	5 (20%)*
Interval, symptoms-diagnosis	5 (1-20)	5 (1-20)	5 (2-14)
Interval, diagnosis-resolution	14 (3-59)	16 (6-59)	11 (3-21)
Interval, diagnosis-testnegative	20 (7-119)	15 (7-119)	25 (16-38)

URTID: Upper respiratory tract infection
LRTID: Lower respiratory tract infection
* Statically significant

Summary and Conclusions: CARV infection is a frequent cause of respiratory tract infectious disease. The most important CAR*Vs* by clinical relevance and frequency are RSV and HPIV. In our series LRTID was diagnosed in 34% patients with RSV and 22% patients with HPIV but fatal complications occurred only in RSV infection (6%) in spite of treatment. Oral ribavirin is a treatment option, but can be associated with engraftment delay. More studies are necessary to established treatment criteria, dosage, duration and efficacy of ribavirin treatment in this population. The value of follow-up PCR tests in this patient population neither has been established.

P748

LEVEL OF PENTRAXIN-3 IN PATIENTS WITH ACUTE LEUKEMIA IN SEPTICEMIA AND ITS PROGNOSTIC VALUE

M. El-Defrawy[1,*] A. El-Ghandour[1], H. Naenaa[1], M. El-Bordeny, [2]H. Mohammed[1]
[1]Hematology, [2]Clinical Pathology, Medical Faculty of Alexandria, Alexandria, Egypt

Background: In acute leukemia, sepsis is a potentially fatal complication. Pentraxin 3 is a protein rapidly produced in response to primary inflammatory signals. It shows high levels in sepsis, especially associated with vascular and end organ failure.
Aims: The study aimed to measure the level of Pentraxin 3 in septicaemia in patients with acute leukemia and correlate its level to higher risk of complications compared to C-reactive protein (CRP).
Methods: The study took place from January, 2012 to December, 2013 including 60 acute leukemia patients with sepsis, during severe neutropenia (ANC<500) and after receiving chemotherapy. Samples were analyzed for serum CRP and plasma PTX3 on days 1, 2 & 3 by ELISA. Blood cultures were done to all patients.
Results: The studied group had a male to female ratio of 1:1, age ranged from 18-62 years (median of 40 years). 41 patients had Acute Myeloid Leukemia while 19 had Acute Lymphoblastic Leukemia. High Pentraxin 3 levels on first day of sepsis is a strong indicator for poor prognosis (septic shock, mortality and coagulopathy outcomes) compared to CRP ($p<0.01$). PXT3 showed sensitivity of 100% and specificity of 70% for prediction of poor prognosis where CRP showed 88.5% and 60.5% respectively (Table 1 and Figure 1).

Table 1. Area under the curve represents significance, sensitivity and specificity of Pentraxin 3 and CRP in day 1 among patients in sepsis.

Test Result Variable(s)	Area	Std. Error(a)	Asymptotic Sig.(p)	Asymptotic 95% Confidence Interval	
				Lower Bound	Upper Bound
Pentraxin day 1	0.920	0.057	0.001*	0.809	1.032
CRP day 1	0.778	0.109	0.022	0.565	0.991
			Sensitivity %	Specificity %	
Pentraxin day 1	3.3500		100	70	
CRP day 1	89.00		88.5	60.5	

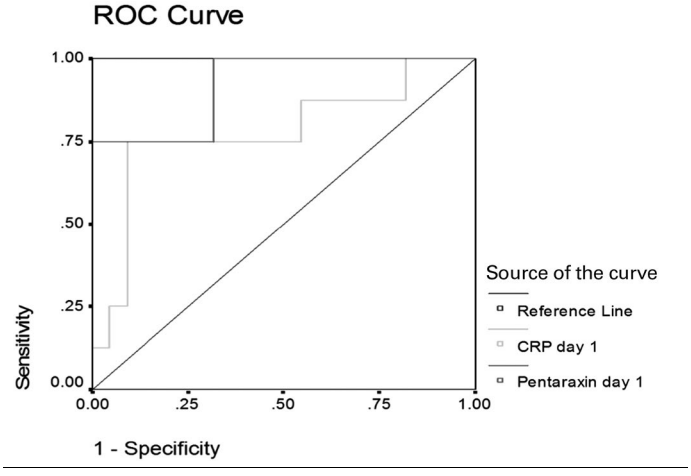

Figure 1. ROC curve to determine the sensitivity and specificity of CRP and Pentraxin 3 at day 1.

Summary and Conclusions: PXT3 is highly recommended in diagnosis of sepsis in patients with acute leukemia during neutropenia and shows high sensitivity and specificity in prediction of poor prognosis (septic shock, mortality and coagulopathy outcomes) in comparison to CRP.

Non-malignant hematopoietic disorders

IDENTIFICATION OF CLONALITY IN IDIOPATHIC HYPEREOSINOPHILIA USING TARGETED EXOME SEQUENCING

J.-S. Lee[1,*] H. Seo[2], K. Im[3], S.N. Park[3], J.-A. Kim[1], S.Y. Kim[1], S. Kwon[4], J.H. Kim[2], D.S. Lee[1,3]
[1]Department of Laboratory Medicine, [2]Division of Biomedical Informatics, Seoul National University Biomedical Informatics (SNUBI) and Systems Biomedical Informatics National Core Research Center, [3]Cancer Research Institute, Seoul National University College of Medicine, [4]Department of Electrical Engineering, Seoul National University, Seoul, Korea, Republic of

Background: Idiopathic hypereosinophilia (IHE) has been a disorder of uncertain etiology, characterized by persistent elevation of blood eosinophil count exceeding $1.5x10^3$/uL. So far, the diagnosis has been made through the exclusion of either reactive or clonal causes of hypereosinophilia. When end-organ damage due to eosinophilic infiltration is present, idiopathic hypereosinophilic syndrome (IHES) is diagnosed. IHE and IHES are heterogeneous diseases and have not been studied well so far. The nature of eosinophilic proliferation is still unclear, whether benign or clonal, but WHO classification of hematologic neoplasm described IHE and IHES with defined diagnostic criteria in the section of myeloproliferative neoplasm.
Aims: Purpose of this study was to investigate the frequency of somatic mutations in patients with IHE/IHES through targeted exome sequencing.
Methods: Bone marrow was collected from a total of 20 patients fulfilling WHO 2008 criteria for IHE (n=8) and IHES (n=12) along with 15 patients diagnosed with reactive eosinophilia as a control group. In all patients, fluorescence *in situ* hybridization (FISH) for *BCR/ABL1*, *PDGFRa, PDGFRb*, and *FGFR1* was performed for excluding myeloproliferative neoplasms associated with eosinophilia with known cytogenetic aberrations. We designed capture sequencing for 88 genes known for recurring mutation in hematologic malignancies using target capture by Sureselect (Agilent, Santa Clara, CA, USA) followed by sequencing using IlluminaHiSeq 2500. The sequencing reads were analyzed based on the pipeline of bioinformatics tool. Candidate mutations were confirmed by Sanger sequencing and also sequenced using matched saliva samples (germline) from patients.
Results: The average coverage of target regions was >800-fold. The targeted exome sequencing analysis revealed 193 substitutions and insertion/deletions (Indels), median 3 per patient (range 0-86). Of these 193mutations, we identified somatic mutations in 4 genes according to interpretation algorithm; *MPL* (2/20, 10%)*, SCRIB* (2/20, 10%), *ASXL1* (3/20, 15%), and *STAG2* (3/20,15%). The findings above highly suggest that these genes are likely related to pathogenesis of hypereosinophilia.
Summary and Conclusions: Four recurrent mutations were identified in 6 patients (30%) by targeted exome sequencing analysis. Due to a limitation of small number patients enrolled in the present study, a future larger validation cohort is needed to test the frequency of the identified variants. We suggest that mutation analysis of the 4 genes (*MPL, SCRIB*, *ASXL1* and *STAG2*) could be help to unveil clonal proliferation of eosinophil and here we propose them as a potential candidate for the diagnostic work-up for hypereosinophilia. Furthermore, this discovery of somatic mutations in IHE/IHES will provide a baseline data for the tailored treatment of hypereosinophilia.

P750

DEVELOPMENT OF A NOVEL ANTI-NEUTROPENIC FACTOR CLINICAL CANDIDATE FOR HEMATOPOIESIS DEFICIENCIES

R. Jubin[1,*] D. Parmar[1], P. Buontempo[1], G. Gitlin[1], D. Byczkowski[1], M. Boro[1], Y. Chen[1], J. Campor[1], P. Reddy[1], H. Misra[1], A. Abuchowski[1]
[1]Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States

Background: A novel anti-Neutropenic factor (ANF) consisting of a pegylated granulocyte colony-stimulating factor with improved pharmacokinetic/pharmacodynamics (PK/PD) properties was developed through a combinatorial PEGylation approach to create a clinical candidate ideally suited for treating conditions of severe neutropenia.
Aims: Analyze ANF and marketed therapeutic(s) in parallel to identify unique properties of ANF thereby expediting selection of a superior clinical candidate for specific human clinical trials.
Methods: A series of *in vivo* and *in vitro* pre-clinical studies were conducted in comparison to marketed forms of filgrastim (F) or PEG-filgrastim (PF). Following pre-requisite and unremarkable GLP-toxicology studies, a phase 1 clinical study was conducted in healthy volunteers (signed, consenting) to assess safety and tolerability of ANF as well as the PK and PD. Subcutaneous, single dose treatment of ANF (or PF) with ascending dose were evaluated in a double-blind study that included PK, neutrophil and CD34+ analytical parameters to determine if pre-clinical ANF findings could also be observed within healthy human subjects. ANF was evaluated in a dose-escalation (5 - 50µg/Kg) study with each cohort including randomized treatment and controls. PF was administered at the single 6mg dosage (80-100µg/Kg), single-use syringe as a standard of care supplied by manufacturer.
Results: Rat neutropenia model dosage study results indicated the blood PD parameters of ANF were significantly superior to both F and marketed PF. Area under the curve (AUC) kinetic analysis showed the absolute neutrophil count (ANC) of ANF was equivalent at 4X lower dosage (25 *vs* 100µg/Kg) and yielded significantly higher ANC than marketed PF when administered at equivalent 100µg/Kg dosage. A follow-on *in vitro* human neutrophil maturation study was conducted to evaluate CD34+ stem cell maturation effects of ANF compared to PF. Similar to rat study findings, ANF yielded a 4-6 fold increase in *de novo* neutrophil (CD66+) counts. Phase I clinical interim safety results were unremarkable, with no severe adverse events in any cohorts (ANF or PF). The ANF PK/PD parameters within the phase 1 study were similar to pre-clinical findings. PD results (ANC and CD34+) were markedly prolonged in the ANF treatment groups even at the lowest cohort. Mean ANC counts for all ANF cohorts showed an ANC C_{max} between 162 - 177hrs in contrast to PF that reached max concentrations at 52hrs. AUC analysis showed that ANF at 10µg/Kg was equivalent to PF at 100 ug/Kg (standard of care) demonstrating a >8-fold potency effect over PF in healthy volunteers. Peripheral blood CD34+ counts also yielded similar results; average ANF C_{max} was prolonged by 2 days over PF (7 *vs* 5 days). PK results were prolonged with ANF in both the pre-clinical rat and phase-1 human study that correlated with the PD results.
Summary and Conclusions: Collectively these data showed that ANF, a novel anti-neutropenic factor, has unique, prolonged PK/PD attributes as compared to PF, and these qualities may provide an improved clinical benefit in further clinical studies. Phase 2 efficacy studies in severe neutropenia are planned to further understand the potential clinical applications and benefits of ANF.

P751

PRECLINICAL PHARMACOKINETIC/PHARMACODYNAMIC RELATIONSHIPS FOR AG-348, AN INVESTIGATIONAL SMALL-MOLECULE ACTIVATOR OF PYRUVATE KINASE

Y. Chen[1,*]P. Kosinski[1], G. Histen[1], C. Kung[1], H. Kim[1], L. Dang[1], J. Popovici-Muller[1], J. Hixon[1], L. Silverman[1], S. Biller[1], H. Yang[1]
[1]Agios Pharmaceuticals, Cambridge, United States

Background: Pyruvate kinase (PK) deficiency is a rare, autosomal recessive, inborn error of metabolism caused by a functional deficiency of the R isoform of PK (PK-R). It is characterized by life-long hemolytic disease and serious long-term comorbidities such as poor growth and development in children, iron overload, and multi-organ dysfunction. Current treatments are palliative only, and there are no approved drugs that directly target the underlying enzyme defect. PK-deficient red blood cells display metabolic changes related to defective glycolysis, including a build-up of upstream intermediate, 2,3-diphosphoglycerate (2,3-DPG) and a deficiency in the product, adenosine triphosphate (ATP). AG-348 is a first-in-class, oral, small molecule allosteric activator of PK-R. AG-348 treatment of PK-deficient red blood cells *ex vivo* increased PK-R enzyme activity and induced metabolic changes consistent with increased glycolytic activity, including reductions in 2,3-DPG levels and increases in ATP levels. First-in-human, phase 1 trials of AG-348 in healthy volunteers have recently been completed.
Aims: Pharmacokinetic/pharmacodynamic (PK/PD) studies were conducted to evaluate the effect of AG-348 on red blood cell metabolism *in vivo* in PK-R wild-type (WT) mice, rats, and monkeys.
Methods: PK-R WT C57/BL6 mice, Sprague Dawley rats, and cynomolgus monkeys were administered single or multiple (twice daily) doses of AG-348 by oral gavage for 3 and 7 days (mice and rats) or 5 days (monkeys). Dose levels tested were 1 mg/kg, 10 mg/kg, 50 mg/kg, and 150 mg/kg in mice and rats, and 3 mg/kg, 10 mg/kg, 25 mg/kg, and 70 mg/kg in monkeys. After the first and last dose, blood samples were collected to evaluate plasma drug exposure and pharmacodynamic (PD) markers in whole blood, including 2,3-DPG and ATP levels, and PK-R activity.
Results: In WT mice, rats, and monkeys, a single dose of AG-348 resulted in AG-348 exposure-related increases in PK-R activity concomitant with a reduction in 2,3-DPG levels, but no significant change in ATP levels. After multiple doses of AG-348, the increase in PK-R activity and decrease in 2,3-DPG was comparable to that observed after a single dose. In contrast to the single-dose study, ATP levels increased in an exposure-related manner after multiple doses (Figure 1). *In vitro* IC_{50} values for purified red blood cell PK-R activity correlated well with estimated *in vivo* potencies in mice, rats, and monkeys.
Summary and Conclusions: *In vivo* PK/PD studies in WT mice, rats, and monkeys found no significant species-related differences in pharmacokinetics following single and multiple oral doses of AG-348 and demonstrated an indirect PK/PD relationship across all three species. In whole blood samples, robust changes in all three PD markers (2,3-DPG, ATP, and PK-R activity) were observed following multiple doses, which correlated with AG-348 plasma exposure. Changes in PD markers showed good cross-species consistency, and there was good correlation of *in vivo* and *in vitro* data. These studies in mice, rats, and monkeys effectively predicted the changes in 2,3-DPG and ATP levels observed in single and multiple ascending dose clinical studies in healthy volunteers.

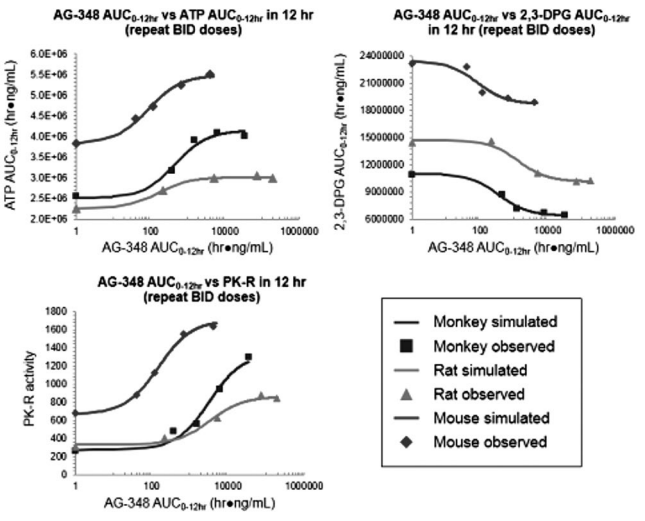

Figure 1. Correlation of AG-348 plasma exposure and ATP, 2,3-DPG and PK-R activity in WT mice, rats, and monkeys following multiple, twice daily (BID) dosing.

P752

EFFICACY AND SAFETY OF ELTROMBOPAG IN PATIENTS WITH MODERATE, SEVERE AND VERY SEVERE APLASTIC ANEMIA

D. Nance[1,*] G. Rodgers[1], M. Nuttall[2]
[1]Internal Medicine Division of Hematology, University of Utah Huntsman Cancer Institute, Salt Lake City, [2]Hematology and Oncology Department, Central Utah Clinic, Provo, United States

Background: Aplastic anemia is a rare, life-threatening, bone marrow failure disorder in adults with few treatment options, particularly for those who are not bone marrow transplant candidates. Eltrombopag is an orally bioavailable, synthetic, small molecule, non-peptide thrombopoietin-receptor agonist that interacts with the transmembrane domain of the thrombopoietin receptor (TPO-R). As with thrombopoietin, the binding of eltrombopag to the TPO-R initiates a number of signal transduction events which leads to an increase in the production of mature megakaryocytes and platelets. Eltrombopag has been shown to be effective in a limited number of patients to increase platelet counts in patients with moderate, severe, and very severe aplastic anemia, and to reduce the need for frequent platelet transfusions.
Aims: The primary aim of this study is to evaluate the efficacy of eltrombopag in patients with moderate to very severe aplastic anemia. Efficacy is defined as a stable platelet count of 50,000/μL or more during any 4 week period within the possible 12 weeks while on study. The secondary aims include recording adverse events, identifying maximal platelet counts, hemoglobin and absolute neutrophil counts, odds of responding during treatment, and proportion of patients achieving at least twice their baseline platelet value at any point during the study.
Methods: This is a prospective, phase II, investigator-initiated clinical research trial. After IRB approval, patients meeting inclusion criteria and having platelet counts that dropped below 30,000/μL or with clinically significant bleeding were enrolled with informed consent. Data collected included: serial complete blood counts, peripheral smears, complete metabolic panels, pharmacokinetic testing of eltrombopag, serum thrombopoietin levels and urinalysis.
Results: Nine patients have been enrolled in the trial, and 8 have completed at least 12 weeks of therapy and 4 weeks of follow up. One patient withdrew from the study due to a concomitant liver injury, not study related. Thrombopoietin level at the time of study entry was available for 8 of the 9 patients; average 2,863pg/mL (range 1452-4000), reference range 7-99 pg/mL. Efficacy: 3 patients (38%) had a complete response (platelet count of >50 K/μL) and 1 patient (12%) had a partial response (decreased need for platelet transfusion) during treatment and in the first 4 weeks of follow up. The minimum effective eltrombopag dose was 150mg po daily. The average time to increase in platelet count was 7 weeks, range 2-12 weeks. All patients who had a response maintained the response at time of censure (average 4-43 weeks. In the 3 patients who responded, a mean increase in hemoglobin (9.5 to 10.6 g/dL) occurred and liberation from red blood cell transfusions was observed and 2 had improvement of neutrophil count to >1.5 K/μL. 2 additional patients showed improvement in absolute neutrophil count; therefore, 4 of 8 patients had increases from baseline to liberation from granulocyte colony stimulating factor therapy (0.9 to 3.0 K/μL). No serious adverse events were observed. No patient stopped the drug due to side effects of the medication.
Summary and Conclusions: Eltrombopag at a dose of 150-300mg daily is safe in individuals with aplastic anemia with 50% achieving reduction or elimination of need for supportive platelet transfusions. An additional subset of 25% of patients who did not meet the primary study endpoint experienced improvement in neutrophil count, and/or hemoglobin level, with an overall response rate of 75%.

P753

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: SINGLE CENTER EXPERIENCE

Y. Oymak[1], E. Toret[1,*] Y. Ay[1], T. Karapinar[1], B. Demirag[1], Y. Yaman[1], O. Carti[1], G. Ozek[1], M. Bulut[1], F. Hazan[2], C. Vergin[1]
[1]Pediatric Hematology-Oncology, [2]Medical Genetics, Izmir Dr Behcet Uz hospital, Izmir, Turkey

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare disorder which presents as prolonged fever, severe cytopenia and hepatosplenomegaly. It is classified as primary (genetic) and secondary (acquired) HLH according to the underlying etiology. If left untreated, patients with HLH survive for only a few months.
Aims: There were few studies related with HLH series. As the reported series continue knowledge about this rare disease will increase and make a contribution to advence its prognosis. In this study we present our experience with patients with HLH.
Methods: We retrospectively analyzed data of 46 HLH patients who were admitted to the Pediatric Hematology Department of Dr. Behçet Uz Children's Hospital, Izmir, Turkey between July 2008 and October 2014. Patients were diagnosed based on the revised diagnostic criteria criteria (HLH-2004) of the International Histiocyte Society.
Results: Of 46 patients, six (M/F=3/3) were defined as primary and 40(M/F=23/17) were secondary HLH. Consanguinity rate was 35%. Perforin, sytaxin, and RAB27A mutations were detected in three, two, and one of primary HLH patients, respectively. Malignancy, infection and rheumatologic diseases were related in 5 (11%), 29 (63%) and 12 (26%) of secondary HLH patients. The mean age of primary and secondary HLH patients was 2.3(0.2-11.0) years and 5.5(0.2-17.0) years respectively (p=0.074). Fever, organomegaly, hyperferritinemia, hemophagocytosis, hypertrigylseridemia, hypofibrinogenemia were seen 100.0%, 85.0%, 85.0%, 52.2% and 54.3% respectively. The *central nervous system* was involved in a total of 11(23.9%) patients; 10 had *seizure and one had visual loss.* The median follow-up duration was 10(1-84) months. Five year survival rate fort he patients was 79%. Hematopoetic stem cell transplantation *were performed* in five primary HLH patients.
Summary and Conclusions: This study present clinical findings of patients with primary and secondary HLH. We think that this study will contribute the data related with HLH which is rare and fatal disorder.

P754

MANAGEMENT OF CYCLIC NEUROPENIA: DIAGNOSIS AND THERAPY

C. Zeidler[1,*] U. Grote[2], S. Mellor-Heineke[2], A. Nickel[2], K. Welte[1]
[1]Molecular Hematopoiesis, [2]Medical School Hannover, Hannover, Germany

Background: Cyclic neutropenia (CyN) is a hematologic disorder characterized by regular oscillations of the bone marrow maturation leading to peripheral blood neutrophil counts with consistent, usually 21-day, periodicity. Other blood cells, *e.g.* platelets, may also show a cyclic pattern. CyN is inherited as an autosomal dominant disorder and mainly attributed to mutations in *ELANE* (formerly *ELA2*). Other gene mutations may also cause blood cell periodicity related with regular fevers and infections, *e.g. tumor necrosis factor receptor gene* (TRAPS) or *MEFV* (*MEditerranean FeVer*). *ELANE* mutations are also responsible for a substantial proportion of congenital neutropenia (CN) with persistent low neutrophil counts.
Aims: Investigation of the natural course and management of cyclic neutropenia.
Methods: The Severe Chronic Neutropenia International Registry (SCNIR) collected data on 80 patients with CyN (37 with *ELANE* mutation, 9 *ELANE* negative, 34 not tested) since 1994. Eleven families with a total of 24 patients were identified.
Results: *Diagnosis:* It is most important to discriminate between CN and CyN, since patients with *ELANE* associated CN have a high risk of leukemic transformation whereas patients with *ELANE* associated CyN do not, although some mutations are associated with both phenotypes, even in the same kindred. To document the cyclic pattern of blood counts 3 CBCs per week over a period of six weeks are required to proof CyN. Depending on the cycle phase, bone marrow morphology may change between normal and maturation arrest of granulopoiesis. Intriguingly, one patient harbored both *ELANE*- and *TNFR1A*-mutations suggesting there is an overlap of patients suffering from Cyclic Neutropenia and Periodic Fever Syndrome. *Treatment:* The efficacy of daily subcutaneous Granulocyte-Colony Stimulating Factor (G-CSF) has been proven in randomized controlled trials with congenital, cyclic and idiopathic neutropenia. Sixty-seven patients (83,8%) received G-CSF at a median dose of 1,94 μg/kg/d. Long-term follow-up indicates that these patients experience fewer mouth ulcers, febrile events and (bacterial) infections when treated with recombinant human granulocyte-colony stimulating factor (rHuG-CSF), despite a persistence of the cycling of blood counts. However, the cycle length and duration of nadir is shortened with treatment. G-CSF can be administered every day or every other day for patients with cyclic neutropenia. Ordinarily it is easier to start with

a very low dose, 0.5 to 3 mcg per kilogram per day given on a daily basis, going up gradually to find the lowest effective dose. Both children and adults respond well to G-CSF and adverse events are relatively infrequent. The most common acute adverse events associated with G-CSF therapy are bone pain and headache. Less frequent administration of larger doses can intensify bone pain, so weekly or twice weekly injections are seldom tolerated, and increasing the frequency of administration may ameliorate the bone pain. Treatment responses tend to be quite stable once an effective dose for the individual patient is found. The dose should be gradually adjusted for body weight in growing children, with monitoring of the response. *Supportive care:* Chronic periodontal disease may occur in untreated CyN. In addition to sufficient neutrophil counts, good dental hygiene and regular professional treatment are necessary to prevent tooth loss. Psychosocial support can help alleviate the psychological and financial burdens of a chronic illness, and can be provided both by health professionals and by patient/parent groups which are established in many countries already.
Summary and Conclusions: CyN patients benefit from G-CSF treatment. Correct disgnosis is important for the long-term management and counseling.

P755

RELATION BETWEEN GLUTATHIONE S TRANSFERASE GENES (GSTM1, GSTT1 AND GSTP1) POLYMORPHISMS AND CLINICAL MANIFESTATIONS OF SICKLE CELL DISEASE IN EGYPTIAN PATIENTS

H. Ellithy[1,*] G. Shaheen[2], S. Yousry[2]
[1]Internal medicine- clinical hematology unit, [2]Clinical pathology, Kasr Al-ainy school of medicine- Cairo university, Cairo, Egypt

Background: Sickle cell disease (SCD) is characterized by clinical manifestations that resulted from sickling of Hb S, which is augmented by accumulation of oxygen free radicals that cause oxidation of Hb S. Defective normal antioxidant protective mechanism predispose to clinical manifestations of SCD like vaso-occlusive crisis (VOC) and acute chest syndrome (ACS). The glutathione system plays an important role in the removal of endogenous products of peroxidation of lipids and so protects cells from the deleterious effects of oxidative stress. Impairment of glutathione system due to genetic polymorphisms of glutathione S transferases (GSTs) genes is expected to increase risk of SCD clinical manifestations. GSTs genes polymorphisms may have ethnic-dependent polymorphism frequencies. The association of *GSTM1*, *GSTT1* and *GSTP1* polymorphisms and various diseases such as cancer and inflammatory diseases has been proved in various studies.
Aims: Understanding the impact of GSTs gene polymorphisms on severity of SCD manifestations, may help to improve the quality of life of SCD patients, by using prophylactic measures that decrease oxidative stresses, such as antioxidants, in patients at risk of developing sever manifestations due to impairment of their defense reductive mechanisms, namely patients who carrying the predisposing GSTs genotypes. So in this study, we aimed at outline the relation between GSTs gene polymorphisms and severity of SCD manifestations.
Methods: In this study, we measured the frequency distribution of the 3 GSTs genes polymorphisms (GSTM1, GSTT1 and GSTP1) in 100 Egyptian adult SCD patients and 80 corresponding controls.GSTM1 and GSTT1 genotypes was determined by multiplex polymerase chain reaction (PCR) with using a housekeeping B globin gene as internal control. GSTP1 polymorphism were determined with a polymerase chain reaction-restriction fragment length polymorphism assay [PCR-RFLP]. Patients were followed up prospectively between June 2012 and June 2014 to evaluate the relation between GSTs genes polymorphisms and the frequency of complications of SCD, in the form of severity of anemia, number of VOC attacks, acute chest syndrome and pulmonary hypertension. The patients were assessed for the severity of anemia by the average number of units of packed red cells (PRCs) transfused per year. The average number of VOC per year was documented.
Results: In our study, the frequency distribution of the GSTs null genotypes was found in 58% of SCD patients, with the highest prevalence for GSTM1 (42%), followed by GSTT1 (32%). Absence of both GSTM1 and GSTT1 genes was found in 16% of SCD patients. Regarding GSTP1 polymorphisms distribution, highest prevalence was for wild genotype (59%), followed by heterozygous genotype (35%) then homozygous genotype (6%). There was no statistically significant difference in the distribution of the GSTs gene polymorphisms between SCD patients and the controls. GSTM1 null genotype was significantly associated to ACS and VOC (P value=0.03 and 0.01 respectively), it also associated to pulmonary hypertension and high requirement of blood transfusion, but not of statistical significance. GSTT1 null genotype was associated with significantly increased requirement of blood transfusion (P value=0.01), however risk of pulmonary hypertension, ACS, and VOC were not increased significantly (P value=0.1, 0.8 and 0.2 respectively). Absence of both GSTM1 and GSTT1 genes significantly predisposed to pulmonary hypertension (P value=0.04). Non wild GSTP1 polymorphism not predisposed to clinical manifestations of SCD in the form of pulmonary hypertension, ACS, frequent VOC or increased requirement of blood transfusion (P value=0.7, 0.6, 0.9 and 1 respectively).
Summary and Conclusions: In this study, the null status of GSTM1 and GSTT1 genes were identified as important risk factors for developing sever clinical manifestations of SCD. Further studies are needed to confirm our findings. Identifying GSTM1 and GSTT1 null genotype as risk factors for developing sever manifestations of SCD may help to categorize SCD patients whom are genetically at risk of developing sever manifestations due to defective antioxidative defense mechanism, in order to minimize severity of their symptoms by using prophylactic antioxidants and other measures that improve their reductive defense mechanisms.

CASES OF SECONDARY HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: A SINGLE CENTER EXPERIENCE

S. Karaman[1,*] D. Demirkol[2], I. Yildiz[3], K. Nisli[4], I. Bilge[5], H. Aktürk[6], A. Citak[7], S. Anak[1], A. Unuvar[1], G. Ozturk[1], Z. Karakas[1], O. Devecioglu[1]
[1]Pediatric Hematology, Istanbul University, Istanbul Medical Faculty, Istanbul, [2]Pediatric Intensive Care Unit, Koc University School of Medicine, [3]Ambulatory Pediatrics, [4]Pediatric Cardiology, Istanbul University, Istanbul Medical Faculty, [5]Pediatric Nephrology, Koc University School of Medicine, [6]Pediatric Infectious Diseases, Istanbul University, Istanbul Medical Faculty, Istanbul/, [7]Pediatric Intensive Care Unit, Istanbul University, Istanbul Medical Faculty, Istanbul, Turkey

Background: Hemophagocytic lymhohistiocytosis (HLH) is a life-threatening hematologic disorder characterized by fever, hepatosplenomegaly or splenomegaly, and cytopenias that accompany with elevated liver enzymes, hyperferritinemia, hypertriglyceridemia, and hypofibrinogenemia. There are two types as primary (congenital) and secondary. HLH may ocur secondary to infections, malignancies, immun deficiency syndromes, and rheumatologic and metabolic disease.
Aims: To describe the profile and the treatment of children with secondary hemophagocytic lymphohistiocytosis (HLH).
Methods: Secondary HLH, who were admitted to the Department of Pediatrics, Istanbul Faculty of Medicine Hospital, from January 2003 through December 2014, were retrospectively evaluated.
Results: There were 38 secondary HLH cases, of that 49% were females and the mean age was 6.7±4.2 (range: 1-17.0) years. Primary causes were distributed among patients as follows: sixteen cases with rheumatological diseases, eleven with malignancies, seven with infectious diseases, one with metabolic disorder, one with epilepsy, one with hemolytic anemia, and one with chronic granulomatous disease. Mean ferritin value was 22693.8±26312.3 (range: 1114-100 000) ng/mL. Six cases (15.7%) were treated with high dose methylprednisolone (HDMP), three (7.9%) with intravenous immunoglobulin (IVIG) only; four (10.5%) with HDMP+plasma exchange (PE); 10 (%26.3) with HDMP+PE+IVIG; 12 (31.5%) with HDMP+IVIG; 2 (5.2%) PE+IVIG, and one (2.6%) with standard steroid treatment.
Summary and Conclusions: HDMP is a very effective treatment especially for macrophage activation syndrome. In case of progressive disease adding PE +/- IVIG is an important issue.

P757

MYCHOPHENOLATE MOFETIL AND SIROLIMUS AS TREATMENT OF AUTOIMMUNE LYMPHOPROLIFERATIVE DISEASE IN CHILDREN: A SINGLE CENTER EXPERIENCE

M. Miano[1,*] K. Perri[1], A. Todiere[1], E. Palmisani[1], C. Micalizzi[1], J. Svahn[1], M. Calvillo[1], P. Terranova[1], T. Lanza[1], C. Dufour[1], F. Fioredda[1]
[1]Haematology Unit, G Gaslini Research Institute, Genoa, Italy

Background: Autoimmune Lymphoproliferative Syndrome (ALPS) is an erratic disorder with wide phenotypic expressions that vary from asymptomatic pictures to very severe clinical manifestations. Steroids and intravenous immunoglobulin are commonly used to switch off the disease, although they may not be effective or may require long-term administration to maintain remission, which may lead to severe side effects. Mycophenolate mofetil (MMF) and sirolimus have been used as alternative option in this setting but experiences are still limited.
Aims: To evaluate the efficacy and toxicity of the use of MMF and sirolimus in children for treatment of ALPS in a single center
Methods: ALPS was defined according to the revised criteria of the consensus conference held in 2009. Clinical records of all ALPS patients followed at our Center were revised. Complete and partial response (CR, PR) was defined as follows. Lymphoproliferation: lymphonodes/spleen volume reduction with (CR) or without (PR) return to normal size. Platelets >100.000 (CR), or 20-100x10^3/mmc (PR) and doubled number compared to the baseline. Haemoglobin: grade 2 but no need of transfusion (PR). Neutrophil: >1,5 (CR), or 0,5-1,5x10^3/mmc (PR) and double number compared to the baseline.
Results: From January 2002 to December 2014, 26 subjects (50% females, 50% males) aged 0.1-40 yrs (median 10.5) with probable (35%) or definitive (65%) diagnosis of ALPS were studied. 18/26 (70%) of patients showed cytopenia, and the remaining 8 patients (25%) suffered from lymphoproliferation with or without other symptoms (fever, asthenia, headache). 6/26 (23%) did not need any treatment. Sixteen out of the remaining 20 (80%) patients were initially treated with steroids: 3/16 (19%) of them responded, 13 (81%) did not. 4/20 (20%) patients received MMF (3) and Azatioprine (1) as first

line therapy and achieved a CR and PR in 3 and 1 cases, respectively.12/13 non-responders to steroids received MMF as 2nd (8), or further line (4) therapy and achieved a complete (7) or partial (5) response. The remaining child received and responded to sirolimus. Three patients who partially responded MMF where shifted to sirolimus with the aim to further improve the response. Two of them achieved a CR and the remaining one maintained the PR. Overall, 16/16 patients who received MMF and 4/4 who received Sirolimus responded to the treatment. Both drugs were well tolerated. Median age at last follow-up (FU) was 17 years (range 6.3-49.6) and median duration of fup was 5.2 years (range 0.4-12).
Summary and Conclusions: This is the largest report on children receiving MMF and Sirolimus shows that they are safe and effective in ALPS. Results must be validated by clinical trials.

P758

ADULT DISSEMINATED LANGERHANS CELL HISTIOCYTOSIS IN THE US: A POPULATION-BASED STUDY USING THE SURVEILLANCE, EPIDEMIOLOGY, AND END RESULTS (SEER) PROGRAM
M.V. Shah[1,*] C. Hook[1], T. Call[1], R. Go[1]
[1]Division of Hematology, Mayo Clinic, Rochester, United States

Background: Adult disseminated Langerhans Histiocytosis (AD-LCH) is an extremely rare multisystem histiocytic disorder of the dendritic cells. Accurate estimates of its incidence and survival are important for assessing optimal patient care and prognosis. However, most of the current data are in the pediatric population. Comparative epidemiologic study of AD- LCH in a large population is lacking and clinical studies remain limited to small series.
Aims: To investigate the epidemiology and outcomes of patients with AD-LCH. using the Surveillance, Epidemiology, and End Results (SEER) Program database.
Methods: SEER, a program of the U.S. National Cancer Institute, collects cancer incidence and survival data from population-based cancer registries covering approximately 28% of the US population. We identified AD-LCH cases using ICD-O-3 histology code 9754/3 who were >18 years of age at the time of diagnosis. We calculated the incidence rates (case/1,000,000) using the 2000-2009 SEER 18 registries and age-adjusted those to the US 2000 standard population. Patient level data were analyzed to determine demographic findings and clinical outcome. To measure the relative risk of subsequent malignancies compared to the general population, we calculated a standardized incidence ratio (SIR) for each type of second and higher primary cancer (observed/expected). We used SEER*Stat (v 8.1.5) for incidence and SIR statistical calculations.
Results: In the years 2000-2009, a total of 40 cases of AD-LCH were reported in the SEER database with the overall incidence of 0.07 per 1,000,000 individuals (95% CI: 0.05 - 0.10). The incidence according to racial groups (adult and pediatric cases combined) was: Whites 0.22 (95% CI: 0.18 -0.25), Black 0.08 (95% CI: 0.04-0.14), American Indian/Alaska Native 0.16 (95% CI: 0.03-0.6), and Asian/Pacific Islander 0.21 (95% CI: 0.12-0.32). The incidence was significantly lower among Black compared to White population (rate ratio: 0.35; 95% CI: 0.17-0.67; p<0.001). The incidence was similar among both sexes (male/female ratio=1.03) and the median age at diagnosis was 46 years (range, 20-86 years). Males were more likely to be diagnosed at a younger age compared to females (36 *vs* 51 years; p=0.01). After a median follow-up of 83 months (range, 16-323), 19 patients have died. The causes of death were malignancies (7 patients), vascular diseases (6 patients), accident (1 patient) and 'other causes' (5 patients). The median overall survival was 255 months (Figure 1A). The relative survival was similar between patients diagnosed in the 1978-1993 and 1994-2009 eras (Figure 1B). Nine patients developed more than one malignancy including acute myeloid leukemia (AML; 2 patients), lung cancer (1), and non-Hodgkin lymphoma (1). Compared to the general population, AD-LCH patients had an increased risk of developing AML (SIR 58.6; p<0.05).

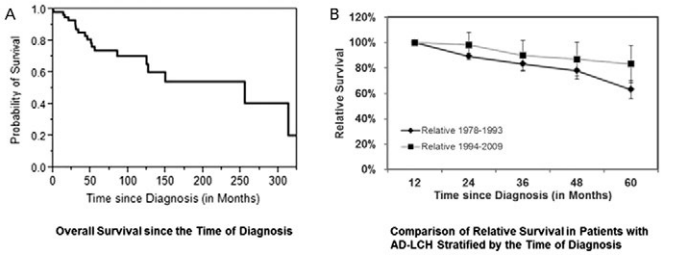

Figure 1.

Summary and Conclusions: AD-LCH is a very rare malignancy that is less common among the Black population. The prognosis is relatively good with overall median survival of more than two decades after diagnosis. There is an increased risk of subsequent development of AML.

P759

MULTICENTRE OBSERVATIONAL PROSPECTIVE COHORT STUDY LOOKING AT CARDIOVASCULAR RISK AND PURE RED CELL APLASIA ASSOCIATED WITH EPOETIN THETA IN 1039 PATIENTS WITH CHRONIC KIDNEY DISEASE
A. Lammerich[1,*] P. Balcke[2], P. Bias[1], M. Wiesholzer[2]
[1]Biosimilars Clinical Development, Teva ratiopharm, Merckle GmbH, Ulm, Germany, [2], Department of Internal Medicine, University Hospital St. Poelten and Karl Landsteiner Institute of Nephrology and Haematology, St Poelten, Austria

Background: In 2010 the EU Authorities recommended to limit haemoglobin (Hb) levels within the range of 10 to 12 g/dL for adults when giving Erythropoiesis-Stimulating Agents (ESAs) to patients with chronic kidney disease (CKD). In addition, rare cases of pure red cell aplasia (PRCA) have been reported through post-marketing surveillance.
Aims: The primary objective was to assess the incidence and severity of cardiovascular events including ischemic stroke in patients treated with epoetin theta (EPO θ) for anaemia associated with CKD. The secondary objective was to monitor the safety of EPO θ, including PRCA.
Methods: In this observational, non-interventional, cohort study 55 study centres from 4 European countries observed 1039 consecutive patients with advanced or end-stage renal disease who received EPO θ for at least 6 months. Up to 4 visits could be documented at study start, month 2, 4 and 6 respectively. Spontaneous as well as reportable adverse events (RAEs) were collected, the latter being grouped as "cardiac disorders", "cardiac failure", "myocardial infarction", and "ischaemic stroke" with respective defined subterms. Furthermore, EPO θ doses and available Hb values were recorded. For a post-hoc analysis, classification by 33.3% and 66.6% percentiles resulted in 3 tertiles for individual mean Hb levels: low Hb level (≤10.7 g/dL), medium Hb level (>10.7 to ≤11.47 g/dL) and high Hb level (>11.47 g/dL) and for mean weekly EPO θ doses: low dose (≤62 IU/kg per week), medium dose (>62 to ≤125 IU/kg per week) and high dose (>125 IU/kg per week), respectively.
Results: 101 RAEs were documented in 89 patients (8.6%) with an event rate of 0.0992 events per ½ person year. 64 patients died (6.1%), but none of the deaths were related to EPO θ. Among the Hb classes, the lowest incidence of RAE was found at medium Hb level (6.2%) compared to low (11.3%) and high Hb level (7.8%). The incidence for ischemic stroke is more than double in the high Hb level class (1.5% *vs* 0.6% for low and medium Hb level). The incidence of any RAEs was higher in the high dose group (10.1%) compared to medium (8.0%) and low dose group (7.6%). Constellations associated with higher risk for any cardiovascular RAE or ischaemic stroke are high dose/high Hb (13.3%), high dose/low Hb (12.6%), and low dose/low Hb (12.1%). Lower risk for RAEs is associated with medium Hb (high dose/medium Hb: 3.8%, low dose/medium Hb: 5.3%). The event rate for Adverse Drug Reactions (ADRs) that affected terms other than the predefined reportable ADRs was 0.0081 events per ½ person year. No cases of PRCA were reported in this study.
Summary and Conclusions: This observational study confirmed that the lowest approved effective EPO θ dosage and dose frequency should be used to reach an individual target Hb level in the medium Hb range of 10 to 12 g/dL. These results confirm the prescribing recommendations and support a favourable risk-benefit ratio for treatment with EPO θ.

Immune thrombocytopenia

P760

ADJUSTED CORTICOSTEROID RISK FUNCTION OF SEVERE INFECTION IN PRIMARY IMMUNE THROMBOCYTOPENIA ADULTS. A NATIONWIDE NESTED CASE-CONTROL STUDY.

G. Moulis[1,2,*] L. Sailler[2,3], M. Lapeyre-Mestre[2,4]
[1]Internal Medicine, Toulouse University Hospital, [2]UMR 1027, INSERM-University of Toulouse, [3]Toulouse University Hospital, Toulouse, France, [4]Clinical Pharmacology, Toulouse University Hospital, Toulouse, France

Background: Corticosteroid (CS)-related infection risk in immune thrombocytopenia (ITP) is unknown.
Aims: The objective of this study was to assess the CS risk function of severe infection in persistent or chronic primary ITP adults, adjusted on other immunosuppressive treatments (rituximab, splenectomy, immunosuppressants) and intravenous immunoglobulin exposures.
Results: We identified 161 cases (including 9 opportunistic infections). The model with the best goodness of fit was CS exposure during the month before the index date (OR: 2.48, 95% CI: 1.61-3.83). The risk existed from doses ≥5 mg PEQ daily (*vs* <5 mg: 2.09, 95% CI: 1.17-3.71). No impact of previous cumulative exposure was measured.
Summary and Conclusions: Maintaining supraphysiological CS dose is associated with the risk of severe infection in persistent or chronic primary ITP patients.

P761

ELTROMBOPAG SAFETY AND EFFICACY FOR PRIMARY CHRONIC IMMUNE THROMBOCYTOPENIA IN CLINICAL PRACTICE

Background: Eltrombopag is a thrombopoietin receptor agonist (TPO-RA) drug. It is considered effective and safe in chronic immune thrombocytopenia (ITP) patients. However, the results from clinical trials could not accurately reflect what happens in the clinical practice.
Aims: To evaluate the efficacy and safety of eltrombopag in primary chronic ITP in a real world setting.
Methods: 164 primary chronic ITP patients from 33 Spanish centers who had been treated with eltrombopag were retrospectively evaluated. Nevertheless 12 patients were excluded from the final analysis because they were not treated for primary chronic ITP.
Results: The median age of our cohort (72% women) was 63 (IQR, 45-75) years. The median months with ITP diagnosis was 81 (IQR 30 - 192). The median number of therapies prior to administration of eltrombopag was 3 (IQR, 2-4), including splenectomy (68%) and rituximab (23%). At the time of eltrombopag start, 45 of 152 (30%) patients were receiving concomitant treatment for ITP, mainly corticosteroids and/or immunoglobulins (29%). Forty-six (30%) patients had bleeding signs/symptoms the month before treatment start. The median platelet count at eltrombopag initiiation was $22x10^9$/L (IQR, 8-$39x10^9$/L). Platelet responses were observed in 135 of 152 (88.4%) patients. The proportion of patients achieving platelet response was quite similar regardless of age (86.7% and 91.4% for patients <65 years-old and ≥65 years-old, respectively), gender (93.4% and 76.7% for women and men respectively), splenectomy status (87.5% and 89.4% for splenectomised and nonsplenectomized patients, respectively), use of concomitant ITP medication at baseline (90.9% and 87.9% for patients with and without concomitant baseline treatment), bleeding at eltrombopag initiation (82.6% and 91.5% for patients with and without bleeding, respectively) and baseline platelet count (85.9% and 90.9% for patients with less than and more than $20x10^9$/L platelets, respectively). Demographic (age, gender), baseline disease characteristics (platelet count, splenectomy status, concomitant ITP treatment or presence of bleeding) were examined as possible predictors of platelet response. However, no predictive factor was statistically significant. The median of days to platelet response was 12 (95%CI, 9-13). The proportion of cumulative platelet response time observed during the 15-months period under examination was 75.2%.
28 patients (18.4%) experienced adverse events, mainly grade 1-2. The commonest adverse effects reported were diarrhea and headache. Seven patients had hepatobiliary laboratory abnormalities. One patient had superficial venous thrombosis and one patient had myelofibrosis grade II.
Summary and Conclusions: This abstract describes the results of the Spanish Eltrombopag ITP registry. To the best of our knowledge, this is the largest "real-world" primary chronic ITP eltrombopag treatment reported study.
Here we describe eltrombopag efficacy and safety after a 15 months follow-up for a clinical practice group of 152 adult primary chronic ITP patients. Our "real-world" results are in line with the excellent results of eltrombopag in ITP clinical trials[11]. Eltrombopag was well tolerated in our study. We only observed 18.4% of adverse events. 98% of them were grade 1-2.

P762

IDENTIFICATION OF B CELL SUBSETS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

E.E. Schippers[1,*] N. Cooper[2], C. Graham[3], P. Kelleher[3], V. Papalois[2]
[1]Erasmus University Rotterdam, Rotterdam, Netherlands, [2]Hammersmith Hospital, [3]Chelsea and Westminster Hospital, London, United Kingdom

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterised by antibody-mediated platelet destruction. The pathogenesis of ITP remains poorly defined, resulting in untargeted treatment and additional side effects. It has been evident that B cells have multiple functions in the regulation of immune responses, besides the production of allo-antibodies.
Aims: We investigated the phenotype of B cells in ITP patients.
Methods: Using a twelve-colour flow cytometry, we identified the frequency of $CD19^+$ B lymphocytes, $CD24^+CD38^+$ transitional cells, $CD24^-CD38^+$ plasmablasts, $CD27^-IgD^+$ naïve B cells, $CD27^+IgD^+$ non-class switched, $CD27^-IgD^-$ class switched, $CD21^+CD27^+$ resting, $CD21^-CD27^+$ activated and $CD21^-CD27^+$ exhausted memory B cells. We included 21 ITP patients and 10 healthy controls after obtaining informed consent. Patients were separated into different groups based on current and past treatment. 11 patients were not on any treatment at the time of blood sampling, 8 patients had received rituximab treatment and 4 patients used trombopoietin receptor agonists.
Results: When taken as a whole group, patients with ITP had a significantly decreased ($p<0.05$) frequency of plasmablasts, CD27+ class switched, non-class switched and resting memory B. Naïve B cells and exhausted memory B cells were significantly increased in ITP patients compared to controls. ITP patients who were on no treatment showed the same distribution of B cell subsets. Patients who had received Rituximab between 1 and 7 years previously had significantly reduced plasmablasts, CD27+ class switched, non-class switched and resting memory B cells when compared to ITP patients who had never received Rituximab. Frequency of naïve B cells and exhausted memory B cells was significantly increased in this group. In contrast, patients who used thrombopoietin receptor agonists had almost normal B cell subsets. There remained a significant increase in the frequency of exhausted memory B cells in this cohort. All other subtypes were not significantly different to controls.
Summary and Conclusions: Overall, there seems to be a shift from mature B cell to immature B cells in ITP patients compared to controls. This might suggest exhaustion of memory B cells, caused by constant stimulation of memory B cells by auto-antigens. Our findings indicate a major role for medication, in the change of B cell distribution, with an unexpected long term effect on memory B cells many years after rituximab therapy despite no clear evidence of increased infection, whilst trombopoietin receptor agonists may have an improvement in B cell phenotype. Further understanding might give a better insight in the effects of different therapies and this could cause the need for revision of current therapeutic options.

P763

BETA2 GLYCOPROTEIN I EXPRESSION IN MONOCYTES IS DECREASED IN IMMUNE THROMBOCYTOPAENIA AND REGULATED BY IL-6

X.-H. Zhang[1,*] X.-L. Zhu[1], J.-M. Zhang[1], J.-Z. Zhao[2], Q.-M. Wang[1], F.-E. Feng[1], H.-X. Fu[1], M. Lv[1], L.-P. Xu[1], K.-Y. Liu[1], X.-J. Huang[1]

[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking University People's Hospital, Department of Clinical Laboratory, Beijing, China

Background: Numerous reports have indicated dys-regulated expansion of cytokine profiles from specific T-cell subsets in immune thrombocytopaenia (ITP). In particular, elevated interleukin-6 (IL-6) levels inversely correlate with platelet count. β2-glycoprotein I (β2-GPI) is a plasma glycoprotein that acts as a complement regulator (Gropp *et al.* Blood. 2011) and might be involved in the pathogenesis of ITP. Recent studies have proven the presence of β2-GPI mRNA in human peripheral blood monocytes. Whether monocytes can be 'educated' by IL-6 to regulate β2-GPI expression remains unknown. The role of anti-IL-6R antibodies in controlling β2-GPI/IL-6 imbalance in ITP needs to be exploited.
Aims: To elucidate the reciprocal relationship between β2-GPI and IL-6, and evaluate the potential role of anti-IL-6R antibodies in regulating β2-GPI in patients with ITP.
Methods: Twenty-four consecutive patients with primary ITP with 24 healthy donors were enrolled in this prospective study. The levels of serum IL-6 and plasma β2-GPIwere measured using ELISA. The purity of human peripheral blood monocytes obtained from ITP patients and healthy donors was assessed by cytofluorimetric analysis using FITC-conjugated anti-CD14 antibodies. Intracellular β2-GPI and IL-6 expression was determined by Western blot and flow cytometry. DNA fragmentation was assessed by propidium iodide staining followed by flow cytometric analysis. β2-GPI and IL-6 mRNA expression in monocytes was assessed by RT-PCR. To further determine the role of IL-6, monocytes were pre-treated with IL-6 or anti-IL-6R antibodies *in vitro*. β2-GPI mRNA expression and β2-GPI levels in monocytes and cell supernatants were determined.
Results: β2-GPI was down-regulated and IL-6 was up-regulated in both peripheral blood samples and CD14+ monocyte lysates in patients with ITP compared with healthy controls. Negative correlations were observed between β2-GPI and IL-6 levels in peripheral blood samples and monocytes. To further confirm the negative correlation between the expression of IL-6 and β2-GPI, flow cytometry with staining intracellular antigens revealed an increased frequency and number of monocytes with lower β2-GPI expression and positive higher IL-6 expression. To eliminate the possibility that increased β2-GPI expression may be due to cell apoptosis, we analysed DNA fragmentation by cytofluorimetric analysis in the two groups, and no significant hypodiploid peaks were detected. Decreased β2-GPI expression in cell lysates from healthy donors pre-treated with IL-6 *in vitro* was observed, and this level did not significantly differ with the levels observed in ITP patients. Down-regulated secretion of this protein in cell supernatant was also observed. More importantly, β2-GPI mRNA expression was inhibited in monocytes. Decreased expression of β2-GPI at the molecular and genetic levels was reversed by the addition of anti-IL-6R antibodies.
Summary and Conclusions: Our results are the first to suggest that patients with ITP may have decreased β2-GPI expression in monocytes, which was inhibited by persistently high IL-6 expression. The effect of anti-IL-6R antibodies in correcting imbalanced β2-GPI/IL-6 levels may suggest the promoting therapeutic potential of anti-IL-6R antibodies in ITP patients.

P764

THE UNITED KINGDOM IMMUNE THROMBOCYTOPENIA (UK ITP) REGISTRY: PRELIMINARY FINDINGS ON BLEEDING EVENTS EXPERIENCED BY ITS PARTICIPANTS

U. Doobaree[1,*] R. Nandigam[1], A. Newland[1], D. Provan[1]
[1]Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: Primary immune thrombocytopenia (pITP) is a rare bleeding disorder in which platelets are destroyed through immune-mediated mechanisms. This leads to a reduction in platelet count and at particular low level there is an increased susceptibility to bleed. There is much heterogeneity in outcome for individuals with low platelet counts, which can range from no bleeding to severe intracranial haemorrhages. What influences its occurrence and its severity is not well understood.
Aims: The Registry was set up to provide much required evidence on the natural history of ITP, occurrence of comorbidities and treatment effectiveness. The main purpose of this study is to investigate the occurrence of bleeding in this cohort and identify likely contributory and preventative factors.
Methods: The Registry relies on the contribution of haematology teams across the country to provide adequate data to conduct its studies. To date, it has 62 centres throughout the UK but aims to expand internationally to increase recruitment and improve collaboration. The findings reported here are from univariate analyses which were preliminary to a more in-depth study.
Results: These initial findings were obtained on a cohort of 1454 (58.2% females; 76% European ancestry) participants with a median age at diagnosis of 49.2 [interquartile range (IR) 30.8, 63.9; mean 47.9] years old. Their mean platelet count at diagnosis was $38.8x10^9$/L. Among participants who reported bleeding episodes before and around diagnosis of pITP, 53% were cutaneous bleed (*e.g.* petechiae, purpura, and haematoma), 24% were haematomas affecting 'not specified' sites, 20% affected the eye, 20% occurred in the oral cavity, 19% were epistaxis, 11% were 'not specified' mucocutaneous bleed and 6% occurred in the gastrointestinal tract (exc. oral). Cutaneous bleed continued to be one of the commonest complaints (36%) after ITP diagnosis (at which point treatment may have been started) whereas the distribution of the other sites' bleed stayed almost the same as pre-diagnosis. Intracranial bleed was experienced by 0.7% before and around ITP diagnosis and 1.3% after. Advancing age and being female were found to be significantly associated with bleeding after ITP diagnosis.
Summary and Conclusions: Skin-related bleed appeared to be the most complaint at and after diagnosis of ITP. Whether any types/sites of bleed were related to different platelet counts levels and other characteristics remained to be established. The associations depicted in this analysis were noteworthy for further stratified analysis by certain characteristics (*e.g.* gender) and treatments as well as for identifying likely confounders/proxy/explanations (*e.g.* anticoagulation therapy used in the treatment of DVT) before engaging in more elaborate multivariate analysis.

P765

THYROID DYSFUNCTION IN IMMUNE THROMBOCYTOPENIA: MORE THAN AN ASSOCIATION

M. Aggarwal[1,*] M. Mahapatra[1], R. Saxena[1]
[1]Hematology, All India Institute Of Medical Sciences, New Delhi, India, New Delhi, India

Background: Immune thrombocytopenia is characterized by immune mediated platelet destruction in addition to suppression of platelet production by the bone marrow (BM) megakaryocytes leading to variable degree of thrombocytopenia and bleeding manifestations. It could be newly diagnosed, persistent or chronic and primary or secondary. Primary ITP is an autoimmune disorder characterized by isolated thrombocytopenia in the absence of other causes or disorders that may be associated with thrombocytopenia. Secondary ITP includes those associated with antiphospholipid syndrome, infection with Helicobacter pylori, hepatitis C, HIV, lymphoproliferative disorders, systemic lupus erythematosis, thyroid dysfunction etc. In these cases, treatment of the underlying condition helps in recovery of platelet counts and thus prevents bleeding. Mild-moderate thrombocytopenia is found commonly in patients with hyperthyroidism due to reduced non immune platelet survival. Similarly, mild thrombocytopenia occurs in some patients with hypothyroidism due to impaired production.
Aims: To study the prevalence of thyroid dysfunction in Immune thrombocytopenia.
Methods: This was a prospective observational study, which included patients with age >12 years, diagnosed as ITP on the basis of peripheral smear and/or bone marrow examination. They were evaluated for secondary ITP. Serum T4 and TSH levels and Anti thyroid peroxidise antibodies were done by electro-chemi-illuminence test. All patients were treated as per standard guidelines, with regular follow up for assessement of bleeding and platelet counts. Those with treatable secondary causes like H. Pylori or thyroid dysfunction were treated accordingly in addition to immunosuppressive therapy for ITP. Females with severe thrombocytopenia and menorrhagia were also given hormonal treatment.
Results: A total of 168 patients of immune thrombocytopenia were enrolled, with thyroid function tests available in 146 patients. Mean age was 30.6 years, with 67.8% females (n=114). Most of our patients were having either persistent ITP (n=42, 25%) or chronic ITP (n=101, 60%), with a median duration of symptoms being 2 years. Abnormal T4 levels were present in 29 patients (27 hypothyroid and 2 hyperthyroid). Total 26 patients had abnormal TSH. Of these, antithyroid peroxidase antibodies were demonstrated in 9 patients (31%) with abnormal T4. Raised antithyroid antibodies were present in 14 patients (54%) with raised TSH. These were significantly associated with both abnormal T4 (p value 0.038) and TSH (p value 0.021). Subclinical hypothyroidism was present in 14 patients. Hypothyroidism (high TSH, or low T4) were significantly associated with presence of anti-nuclear antibodies (p value 0.011). Presence was abnormal thyroxine levels (p value 0.04), abnormal thyroid stimulating hormone levels (p value 0.039) and presence of anti thyroid peroxidase antibodies (p value 0.02) were associated with chronic or persistent ITP. None of these were associated with response to treatment.
Summary and Conclusions: Thyroid dysfunction was present in 43 patients (29%). Both hypothyroidism (clinical and overt) and hyperthyroidism were seen, latter being less common. Mildly raised T4 can be due to effect of estrogen containing pills prescribed frequently to females with menorrhagia. Estrogens bind to thyroid hormone binding protein and cause elevated total T4 levels, free T4 levels are likely to be normal in these cases. Disproportionately low TSH can be seen with patients on glucocorticoids. Most of our patients had been on steroids before they presented to us, thus explaining the abnormal relation in T4 and TSH. Association of hypothyroidism and antinuclear antibodies highlights that two autoimmune diseases tend to occur together. Presence of antithyroid peroxidase antibodies in these cases suggests autoimmune nature of thyroid dysfunction and perhaps common occurence of multiple autoimmune disorders in these patients. Due to increased prevalence of thyroid dysfunction in ITP patients, thyroid function tests should be a part of secondary ITP work up at diagnosis and periodically thereafter.

Screening with TSH alone is likely to be insensitive in ITP patients and we suggest combined T4 and TSH for this screening. Results of treatment of thyroid disease and impact on platelet count have been variable.

P766

ELEVATED SERUM THROMBOPOIETIN LEVEL IN IMMUNE THROMBOCYTOPENIA IN PREGNANCY

X. Zhang[1,*] H. Zhou[1], F. Jing[1], Z. Kong[1], M. Hou[1]
[1]Department of Hematology, Qilu Hospital, Shandong University, Jinan, China

Background: Thrombopoietin (TPO), the ligand of c-mpl protein, is the major regulator of megakaryocyte maturation and platelet production. Up to 10% of all pregnancies would present thrombocytopenia, most of which are caused by gestational thrombocytopenia (GT). Immune thrombocytopenia (ITP) appears in 1 to 2 per thousand pregnancies, which may lead to bleeding complications in both the mothers and their infants. Previous studies showed that TPO levels were mildly increased or within the normal range in ITP patients. However, little data is available about the TPO levels of ITP in pregnancy or gestational thrombocytopenia.
Aims: To determine the serum levels of TPO in ITP in pregnancy, gestational thrombocytopenia, healthy pregnancy, age-matched nonpregnant ITP and controls. And to assess the value of serum TPO levels for differential diagnosis of thrombocytopenia in pregnancy.
Methods: Blood samples were obtained from ITP in pregnancy, gestational thrombocytopenia, healthy pregnancy, age-matched nonpregnant ITP and nonpregnant healthy control at Qilu Hospital, Shandong University. Platelet count was determined by complete blood count (CBC). Serum TPO concentration was analyzed by a commercially available ELISA kit, according to the manufacturer's instructions. This study was approved by the Medical Ethical Committee of Qilu Hospital, Shandong University. Informed consent was obtained from each patient.
Results: The TPO result and the platelet count of different groups are summarized in the Table 1. In all these five groups, ITP in pregnancy displayed the highest TPO level (P<0.01). The serum TPO level in ITP in pregnancy was significantly elevated compared with that in GT (P<0.01). It might be helpful to differentiate the two disorders by TPO level since TPO level in 26/31 ITP in pregnancy was 500 pg/ml or higher, but none of the GT patients' TPO level exceeded 500 pg/ml. Furthermore, the level in GT was mildly higher than healthy pregnancy (P<0.05). ITP in pregnancy presented a markedly higher TPO level than nonpregnant ITP (P<0.01). Numerous studies over the past two decades had documented that TPO levels were high when thrombocytopenia was due to megakaryocyte deficiency, and low when due to increased platelet destruction. Taken together the previously published studies and our data, it could be inferred that the pathogenesis of ITP in pregnancy might be different from nonpregnant ITP. The TPO level in nonpregnant ITP was slightly higher than nonpregnant healthy control, which was generally in consistence with most of the previous studies. The platelet count in healthy pregnancy was mildly lower than nonpregnant healthy control. Meanwhile, the healthy pregnancy had slightly higher TPO level than nonpregnant heathy control. We did not find a correlation between platelet count and thrombopoietin level in any group.

Table 1.

	ITP in pregnancy n=31	gestational thrombocytopenia n=27	healthy pregnancy n=29	age-matched nonpregnant ITP n=25	nonpregnant healthy control n=27
Plt count ($\times 10^9$/L), median (range)	20, (9-43)	81, (53-97)	238, (203-277)	27, (1-49)	278, (221-297)
TPO (pg/ml), mean ± SD	1350 ± 646	197 ± 62	65 ± 23	92 ± 44	38 ± 16

Summary and Conclusions: TPO levels might be useful for differential diagnosing ITP in pregnancy from other causes of thrombocytopenia in pregnancy. These findings need to be further explored.

P767

CHRONIC IMMUNE THROMBOCYTOPENIA IN CHILDHOOD: EVALUATION OF THE DATA OVER 30 YEARS BASED ON THE REVISED CRITERIA OF INTERNATIONAL WORKING GROUP

B. Koc[1,*] N. Ozdemir[1], J. Alakbarlı[1], H. Apak[1], T. Celkan[1], I. Yıldız[1]
[1]Pediatric Hematology and Oncology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Childhood immune thrombocytopenia (ITP) is usually a self-limited acquired bleeding disorder lasting from a few weeks to several months. About 20% of children with newly diagnosed ITP develop a chronic course. The International Working Group (IWG) recently standardized the terminology and definitions of ITP.
Aims: We evaluated the data of children with chronic ITP based on the revised criteria to investigate the natural course of this disease.
Methods: The medical records of 564 children diagnosed with ITP from 1978 to 2014 were reviewed according to the IWG criteria and data of the patients with chronic ITP were included.
Results: Eighty-six patients (M/F: 1.09) with chronic ITP were included. Median age at admission was 6 years (range: 1-16 years). Median platelet count at admission was $20x10^9$/L (range: 1-$4x10^9$/L). The most frequent bleeding symptoms at admission were petechia and/or echimosis (86%), followed by mucosal bleedings (39.5%) such as epistaxis (24%), gingival/oral mucosal bleeding (15%), severe menstrual hemorrhage (1%), gastrointestinal bleeding (2.3%), hematuria (3.5%) and subconjunctival hemorrhage (1%). Intracranial hemorrhage was not observed in none of patients at admission or on follow-up. Bone marrow examination was performed in 65% of the patients; megakaryocytes were increased in 80% and decreased in 1.7% and normal in the remainder. Chronic infections were detected in two patients (Hepatitis B carrier (n:1) and *Helicobacter pylori* infection (n: 1)), 1 patient was diagnosed with SLE and 1 patient was diagnosed with Evans syndrome. Laboratory results showed direct coombs test and anti-nuclear antibody positivity in 8% and anticardiolipin antibodies in 1% of the patients. Spontaneous remission (>$100x10^9$/L platelet count) was detected in 28% of the patients and the mean duration time to spontaneous recovery was 3.5 years. Twenty patients (23%) underwent splenectomy. The platelet counts increased to >100000/mm3 in 90% of the patients after splenectomy. None of the patients who had splenectomy had complication related to surgery. During follow-up period treatment was given to patients with bleeding or platelet count <$20x10^9$/L. Treatment options were steroids (n:68), IVIG (n:38), anti-D immunoglobulin (n:12), rituximab (n:5), dapsone (n:3) and vincristine (n:1).
Summary and Conclusions: The etiology remains unknown in children with chronic ITP. Our data of 30 years showed that platelet counts recovered spontaneously in one-third of the patients about 3.5 years after the diagnosis. Splenectomy is a safe and effective treatment option in children as in adults and may be considered in selected cases.

P768

RESPONSE LOSS AND DEVELOPMENT OF NEUTRALIZING ANTIBODIES DURING LONG-TERM TREATMENT WITH ROMIPLOSTIM IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP)

M. Carpenedo[1,*] S. Cantoni[2], V. Coccini[1], E.M. Pogliani[1], R. Cairoli[2]
[1]Hematology and Transplant Unit, A.O San Gerardo di Monza and University of Milan Bicocca, Italy, Monza, [2]Hematology and Oncology Department, A.O Ospedale Niguarda Cà Granda, Milan, Italy

Background: In ITP patients (pts) failing immunosuppressants, an alternative approach is to enhance platelet (plt) production stimulating thrombopoiesis. Clinical development of first-generation thrombopoietic agents (TPO) was halted due to induction of neutralizing antibodies (Abs) against both recombinant and endogenous TPO. Romiplostim (R) is a second-generation TPO receptor agonist (TPO-RA) with no sequence homology to TPO, thus avoiding the risk of eliciting cross-reacting Abs . However, Kuter *et al.* reported development of neutralizing Abs to R in 2/291 treated pts. Both pts were tested after their plt counts fell and in both cases these neutralizing Abs were no longer present at re-testing after withdrawal of R. No pt had Abs that cross-reacted with eTPO (1).
Aims: To describe prevalence and time course of response loss to R and the results of neutralizing Abs testing in a group of ITP pts treated at 2 Centers.
Methods: 44 pts received R between Sept 2009 and Dec 2014 for ITP not responsive to immunosuppressants. All pts are enrolled in a local Italian data base (REL-ITP data base), and informed consent to clinical data use is given at enrollment. Whenever feasible, blood samples of pts losing response to R were collected and sent for R neutralizing Ab testing (performed as immunoassay), according to R manufacturer instruction.
Results: Among our pts, 5/44 (11%) were non responders to R. An additional 32% of pts (14/44) although responders, are not evaluable since: 2 lost to follow up; 3 discontinuation due to SAE (1 bone marrow fibrosis; 2 thrombotic events); 5 bridge to splenectomy; 3 late responders to either splenectomy or rituximab. Therefore a total of 25 pts are evaluable for loss of response. Of these pts: 11/25 discontinued R after achieving a stable response and are in follow up, off any therapy; 8/25 are currently receiving R with stable response; 6/25 have lost response while on therapy. Outcome of these 6 pts is summarized in Table 1. Neutralizing R Abs testing could be carried out in 4 of 6 pts (#1 to 4) and 3/4 (# 1,2,3) tested positive. These Abs did not cross react with eTPO. 4/6 pts went into long-term remission when switched to a different therapy: #1 rituximab, #2 and #3 splenectomy, # 5 eltrombopag; 2/6 pts (#4 and 6) were heavily pre-treated, splenectomized pts and never regained a response. Pts #2 and #3 were re-tested for Abs, at 9 and 7 mos from first detection respectively and both tested negative.
Summary and Conclusions: The second generation TPO-RA romiplostim is an effective and well tolerated therapy for ITP pts not responding to immunosuppressants. Pts seldom discontinue treatment due to adverse events but over time a fraction of responding pts need dosage increase in order to maintain their plt count (1) or are unable to maintain a sustained response (2). Response loss doesn't seem to be so rare an event accounting for 24% of pts in our series. Similarly to Kuter's data (1), in 3 of our pts abrupt

loss of response was associated with development of neutralizing Abs to R, not cross-reacting with endogenous TPO and resolving after R withdrawal.

LONG-TERM FOLLOW-UP SPLENECTOMY FOR IMMUN THROMBOPENIA PURPURA

B. Mohamed[1,*] B. Rostom[2], B. Yahia[1]
[1]Département de Médecine, Faculté de Médecine.Université Saaad Dahleb, [2]Département de médecine, Faculté de Médecine. Unicersité Saad Dahleb, Blida, Algeria

Background: Splenectomy was the first effective treatment for ITP, reported nearly 100 years ago. At many centers splenectomy is still the second line treatment for patients with ITP who have failed corticosteroids. The surgical approach has been improved by laparoscopic splenectomy, offered to most patients.
Aims: We report here the long-term outcome of a large cohort of ITP splenectomized patients. Criteria for response were defined as follows: complete response (CR), all post-splenectomy platelet counts>150×109/L without ever receiving treatment after splenectomy; partial response (PR), all other patients with platelet counts >50×109/L without therapy after splenectomy; failure, platelet counts <50×109/L or patients who received therapy after splenectomy.
Methods: We retrospectively analyzed the data on 159 patients (64 males, 95 females) who underwent splenectomy for ITP between 1999 and 2014. 53 underwent laparoscopic splenectomy, introduced in our center from 2006. Mean age was 31years (7→63 years), 43 were less than 16 years. Platelets before splenectomy was de 27.000 ($10.10^3 \rightarrow 37.10^3$/µl). The median interval from diagnosis to splenectomy was 19 months with a range of 5-39 months. Diagnosis has been reconsidered in 4 patients: splenic lymphoma 2, familial thrombopenia 2.
Results: One hundred forty three patients (90%) achieved a complete remission the first month after splenectomy. There was 1 death in operative period. The immediate postoperative complications: infection 3, thromboembolic events in 4 patients. Accessory spleens were identified 11 cases, 9 from laproscopic splenectomy. After the first year: CR 132(85%), partial remission 32 (20%), failure 23(16%). After the second year, among 113 patients followed, we observed 24 cases of failure. After 5-year: 51 patients (32%) were lost follow-up, Among 108 patients, 17 Failure, 15 PR. Seventy-six (70%) remained in a prolonged complete remission with a persistently normal platelet count, never having received any postsplenectomy treatment. Seven patients of the complete responders to surgery relapsed after an initial complete response. All 17 patients in the failure group received prednisone after splenectomy, 2 received rituximab, 3 received cyclophosphamide, 1 received high-dose dexamethasone. Any patients died of hemorrhage during neither follow-up nor cases of overwhelming post-splenectomy infection.
Summary and Conclusions: This study shows that splenectomy is a safe procedure and effective in approximately two thirds of patients with chronic ITP. However, the durability of responses, the ability to predict who respond will remain uncertain. Further studies are required to establish whether surgery-sparing treatments of chronic ITP, such as high-dose dexamethasone, anti-D and anti-CD20 immunoglobulins, thrombopoietin mimetics, have similar or even superior efficacy, risk and cost ratios compared to splenectomy.

Bleeding disorders

WHOLE EXOME-SEQUENCING TO IDENTIFY GENETIC RISK FACTORS OF INHIBITOR IN KOREAN SEVERE HEMOPHILIA A PATIENTS

K. Yoo[1,*] E. Cho[2], T. Lee[2], Y. Park[3], H. Kim[4], S. Kim[5]
[1]Korea Hemophilia Foundation, [2]Green Cross Genome, [3]1Kyung Hee University Hospital at Gandong, [4]Sungkyunkwan University School of Medicine, Seoul, [5]Inha University college of medicine, Incheon, Korea, Republic of

Background: The development of inhibitor against factor VIII is a serious complication in the treatment of hemophilia A. *F8* mutation type plays an important role in inhibitor development, however, patients who share the same *F8* mutation with discordant inhibitor status suggest the presence of other genetic risk factors. Studies on genetic determinants other than *F8* mutation yielded inconsistent results, therefore the genetic background of the risk remain largely unknown.
Aims: This study was designed to investigate the genetic risk factors underling the development of inhibitor in Korean severe hemophilia A patients by whole exome sequencing with next-generation sequencing.
Methods: A total of 89 severe hemophilia A patients (55 with inhibitors and 34 without inhibitors) underwent sequencing of the exome on NextSeq500 (Illumina) following capture by SureSelect Human All Exon V5 UTR kit (Agilent). Mapping of reads was performed on reference genome (hg19) by BWA and variant calling by GATK. Initially, we screened *F8* mutations and the candidate mutations were confirmed by Sanger sequencing, MLPA and intron22 inversion test. Then we performed case(inhibitor)-control(non-inhibitor) association studies using SNP-set Kernel Association Test (SKAT-O test, gene-based test) and mixed-effect logistic regression analysis (EMMAX).
Results: A mean depth of 81X was achieved and the mean 63,103 variants were identified per patient. Large deletion, nonsense, small insertion/deletion, missense mutation and inversion 22 of *F8* were found in 10, 11, 20, 18 and 22 patients, respectively. All the patients with large deletions and all except one case with nonsense mutations developed inhibitors. We found the 8 immune genes (*IL28RA, SMARCAL1, HLA-B, TNFRSF10C, RAG1, PLXNC1, ITGAD, LAIR1*) at P<0.05 by SKAT-O test and 95 immune related variants at P<0.05 by EMMAX. When we narrowed the patients with inversion 22, we identified ten immune related variants at P<0.05.
Summary and Conclusions: This study reveals new candidate genes associated with the risk of development inhibitor in Korean hemophilia A patients.

P771

SCREENING FOR AN ACQUIRED VON WILLEBRAND SYNDROME IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

B. Sokołowska[1,*] K. Bykowska[2], A. Nowaczyńska[3], M.A. Kowalska[4], S. Chocholska[5], E. Mendek-CZajkowska[2], A. Walter-Croneck[5], T. Gromek[5], A. Dmoszyńska[5], M. Hus[5]
[1]Department of Hematology and Bone Marrow Transplantation, Medical University of Lublin, Lublin, [2]Institute of Hematology and Blood Transfusion, Warszawa, [3]Department of Hematology and Bone Marrow Transplantation, Meducal University of Lublin Poland, Lublin, Poland, [4]The Children's Hospital of Philadelphia, Philadelphia, United States, [5]Department of Hematology and Bone Marrow Transplantation, Medical University of Lublin, Lublin, Poland

Background: Acquired von Willebrand syndrome (AvWS) is a rare bleeding disorders but it is particularly frequent in myeloproliferation. ET(essential thrombocythemia), one form of myeloproliferation, is characterised not only by thrombotic but also by bleeding complications. It is very important to know if AvWS may cause bleeding tendency in ET patients.
Aims: The aim of the study was to look for AvWS in ET patients using a screening evaluation of vWF antigen and activity and factor VIII activity.
Methods: We have examined 106 patients with ET(80 females and 26 males, mean age 54(23-82). In 22 patients(20,75%) bleeding episodes occurred . We have evaluated factor VIII level (FVIII) and von Willebrand factor antigen (VWF:Ag) and activity. In order to evaluate von Willebrand factor activity we have used two reagents: von Willebrand Factor Activity kit Hemosil™, and von Willebrand Factor Collagen binding kit Technoclone. In the first method a specific anti -vWF monoclonal antibody directed against glycoprotein Ib receptor reacts with the vWF in patient plasma. In the second method we evaluated the ability of vWF in binding to collagen. If all values : VWF:Ag, VWF:Activity and FVIII are within the normal range, AvWS may be excluded. If at least one parameter is abnormally low diagnosis of AvWS is probable. To differentiate the type of AVWS(1, or 2A, 2B or 2M) we calculate the ratios: 1:VWF Activity/VWF:Ag, 2:FVIII/VWF:Ag.
Results: We have detected: low level of VWF:Ag in 8 (8,42%) patients, low VWF: activity measured by Hemosil reagent in 19 (20,43%) patients, low VWF collagen binding activity in 27(27,42%) of patients. In a group of 12 patients low levels of both forms of vWF activities have been observed. We

have detected low factor VIII level only in 3 (3,13%) patients. Summing up, we have discovered abnormalities in 34 patients. According to AvWS definition, the diagnosis is based not only on laboratory abnormalities but also on clinical symptoms. Based on this we have diagnosed AvWS in 9 (41%) patients from the group of ET patients with bleeding episodes.
Summary and Conclusions: In 41% of ET patients presenting bleeding episodes this tendency may be caused by AvWS. We propose to use a screening evaluation mentioned above, to avoid bleeding complication connected with AvWS.

P772

INTEREST OF A NEW RAPID COMMERCIAL ASSAY FOR THE ANALYSIS OF VON WILLEBRAND MULTIMERS IN AGAROSE GEL

G. Nouadje[1], D. Francois[2], T. Ligneel[1], R. Bironien[2], G. Beaulieu[1], M. Vasse[2,*]
[1]Research & Development, Sebia, Lisses, [2]Biology, Hopital Foch, Suresnes, France

Background: The analysis of von Willebrand factor (vWF) multimers is necessary for the classification of hereditary and acquired forms of von Willebrand disease (vWD). Only a few specialized laboratories are skilled enough to perform this analysis due to the complexity of the method itself and to its very slow turnaround time (2- 3 days). In fact, vWF multimers are usually separated in "Home- made" discontinuous SDS agarose gel (difficult to produce) followed by a western blotting step. Multimers are then identified by immunofluorescence or other staining techniques.
Aims: We present here the use of a new commercial method for multimer analysis, which is rapid (6 hours), easy to perform (no western blot), reproducible (ready to use SDS agarose gel). This method assesses the overall size distribution of vWF multimers (low, intermediate, high and very high molecular weight).
Methods: vWD were diagnosed on quantification of vWF by both immunological (vWF:Ag) and functional assays based on ristocetin cofactor activity (vWR:Co), bleeding time (BT), platelet count, ristocetin induced platelet aggregation (RIPA). Plasma from patients diagnosed with different von Willebrand disease (vWD) types were loaded and separated by the new assay, in continuous SDS agarose gel system (no stacking and running gel) within 110 mn Multimers were probed in gel by immunofixation using horse-radish peroxide (HRP) conjugated to a rabbit anti-vWF (90 min). Visualisation of multimers was achieved by colorimetry using commercially available TTF1/TTF2 reagents. Curves were produced using the manufacturer's gel scanner and interpretation software.
Results: The results obtained with this new method are shown in the figure. In normal plasma at least 9 to 12 main multimer bands can be detected (line C). Line 1 corresponding to a type 1 vWD in basal conditions (vWF:Ag=49%; vWR:Co=47%) shows a weaker coloration than controls, but all the multimers were present. Coloration of all the multimer bands increased after desmopressin infusion (lane 2; vWF:Ag=178%; vWR:Co=188%). Lanes 3 and 4 correspond respectively to the plasma of a patient with a suspected acquired vWD (avWD) in basal conditions (vWF:Ag=49%; vWR:Co=28%) and after purified vWF infusion (vWF:Ag=101%; vWR:Co=58%). There was an absence of high molecular weight multimers (HMW) in both samples, strengthening the hypothesis of an avWD with an accelerated turn-over of HMW multimers of vWF concentrates. Line 5 shows the plasma of a pregnant woman (38th week/1st gestation) who reported unusual bruises from childhood. BT was very prolonged, and a discrepancy was noted between vWF:Ag (225%) and vWR:Co (86%). There was an absence of HMW multimers and a large excess of vWF dimers, suggesting a type 2:C. Lane 6 corresponds to the plasma of a pregnant woman who reported a familial history of vWD (24th week/1st pregnancy). BT was very prolonged, vWF:Ag was 132% and vWR:Co slightly slower 77%):Co. The absence of HMW multimers as well as RIPA results suggested a type 2:A.

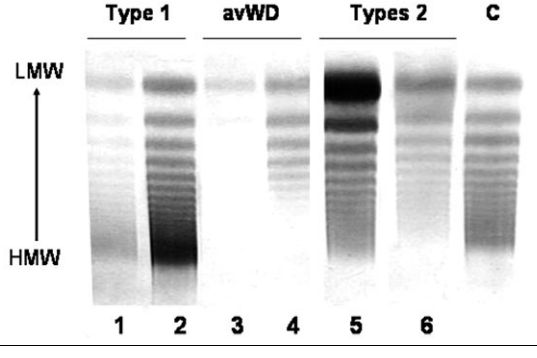

Figure 1.

Summary and Conclusions: The method for vWF multimer analysis described here is simple to carry out, produces results within 6 hours, and is performed on a commercially available instrument. This is particularly valuable in emergency situations such as preterm labor or urgent surgery, when the patient has no document specifying its vWD type. This technique which is the first line multimer analysis would also help for extensive screening and studies.

P773

DENGUE VIRUS NONSTRUCTURAL PROTEIN 1-INDUCED ANTIBODIES CROSS-REACT WITH HUMAN PLASMINOGEN AND ENHANCE ITS ACTIVATION

T.-M. Yeh[1,*] Y.-C. Chuang[1]
[1]Medical Laboratory Science and Biotechnology, NATIONAL CHENG KUNG UNIVERSITY, Tainan, Taiwan, ROC

Background: Dengue virus (DENV) infection is the most common mosquito-borne viral disease, which can cause life-threating dengue hemorrhagic fever and dengue shock syndrome (DHF/DSS). Abnormal activation of the coagulation and fibrinolysis system is one of the hallmarks associated with DHF/DSS patients. However, the mechanism to cause hemorrhage in DHF/DSS is still elusive. In previous studies, plasminogen (Plg) cross-reactive antibodies which can recognize DENV nonstructural protein 1 (NS1) were found in dengue patients. However, it is unclear whether these antibodies are indeed induced by DENV NS1.
Aims: To test whether dengue NS1 indeed can induce antibodies crossreact with human Plg and enhance its activation.
Methods: We immunized mice with recombinant NS1 from both bacteria and drosophila to test whether NS1 can induce Plg-cross-reactive antibodies.
Results: Results from NS1-immunized mice sera indicated NS1 immunization induced antibodies which could cross-react with Plg. To study the effects of these NS1-induced Plg-cross-reactive antibodies on fibrinolysis, we isolated several Plg cross-reactive anti-NS1 monoclonal antibodies (mAbs) from these mice and found some of these mAbs could enhance Plg activation. In addition, epitope mapping by phage-displayed random peptide library revealed that one of these mAbs (2A5) could recognize NS1 C-terminal residues 305-311 which share sequence homology with Plg region 609-616. Synthetic peptide of NS1 305-311 could inhibit both 2A5 and its antigen-binding fragment (Fab) binding to and enhancing Plg activation.
Summary and Conclusions: Our results suggest that DENV NS1 can induce Plg cross-reactive antibodies through molecular mimicry, which can enhance Plg activation and contribute to the pathogenesis of DHF/DSS.

P774

GENERAL DECREASE OF CIRCULATING MICROPARTICLES IS RELATED TO THE PRESENCE OF FVIII INHIBITORS IN HEMOPHILIA A PATIENTS

A. Silveira Cassette[1,*] M. Moreira[1], S. Béla[1], H. Araújo[2], A. Teixeira-Carvalho[1], F. Campos-Nunes[3], D. Chaves[2], O. Martins-Filho[1]
[1]Laboratório de Biomarcadores de Diagnóstico e Monitoração, Centro de Pesquisas René Rachou, [2]Serviço de Pesquisa, Fundação Hemominas, [3]Faculdade de Farmácia, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: The cell activation in the blood is associated with plasma membrane remodeling, resulting in the shedding of membrane-derived microparticles (MPs) rich in accessible phosphatidylserine and in specific cell-surface antigens. There are limited data about the role of MPs in hemophilia A [HA] and especially in FVIII inhibitors development.
Aims: This study aimed to assess the MPs dosage in patients with HA and positive [HAα-FVIII(+)] (n=34) or negative [HAα-FVIII(−)] (n=68) for inhibitors.
Methods: The study was conducted in Fundação Hemominas, Belo Horizonte, MG, Brazil. The recruitment of participants and the methodology of the study were approved by the Brazilian ethics committees. MPs were analyzed by flow cytometry using the classical MPs marker, annexin, and fluorochrome-labeled monoclonal antibodies against specific cell surface markers: T cells (CD3); platelets (CD41a); granulocytes (CD66); leukocytes (CD45); erythrocytes (CD235a); and endothelial cells (CD51/61).
Results: The meaning of circulating MPs were markedly increased in HAα-FVIII(-) when compared to HAα-FVIII(+) in T cells (33.58±15.08 *vs* 13.20±14.70; p<0.01); platelets (203.10±450.00 *vs* 50.86±54.64; p=0.03); granulocytes (12.05±7.95 *vs* 6.78±6.08; p<0.01); leukocytes (241.10±419.30 *vs* 71.29±45.87; p=0.02); endothelial cells (31.57±11.42 *vs* 22.22±11.41; p<0.01) (MPs/μL±standard deviation). In contrast, the meaning MPs/μL of erythrocytes were higher in HAα-FVIII(+) (12.64±10.01 *vs* 8.58±9.53; p<0.01).
Summary and Conclusions: We found recently that HAα-FVIII(−) patients has increased activation of all leukocytes and synthesis of pro-inflammatory cytokines. These data could explain the increased presence of MPs in these patients. Increases in circulating MPs counts may be a good prognostic for

inhibitors clearance and could be used as an important biomarker for the inhibitors development. More research is needed to fully understand the role of MPs in hemophilia A. Financial support: Fundação Hemominas, Fapemig, CAPES and CNPq.

P775

MICROVESICLES ARE A POTENTIAL BIOMARKER FOR THROMBOSIS AND DIC IN ACUTE LEUKEMIC PATIENTS: A CROSS-SECTIONAL STUDY

D. Gheldof[1,*] J.-M. Dogné[2], C. Graux[3], F. George[3], A. Sonet[3], B. Chatelain[3], F. Mullier[3]
[1]CHU Dinant-Godinne UcL, [2]Unamur, Namur, [3]CHU Dinant-Godinne UcL, Yvoir, Belgium

Background: Thrombosis is a common complication of patients with malignancies. Patients with hematological malignancies have a 28 fold increased risk to develop venous thromboembolism (VTE). Among patients with acute myelogenous leukemia (AML), the incidence of VTE is 5.2%, and among patients with acute lymphoblastic leukemia (ALL), the incidence of VTE is 4.5% in the first two years of disease. Despite their influence on mortality and morbidity, the mechanisms inducing a hypercoagulable state are not fully understood to date. Multifactorial causes include physic immobility, chemotherapy adverse effects and the overexpression of several procoagulant substances by cancer cells (cytokines, cysteine protease and tissue factor). Recent studies strongly demonstrate that cancer cells shed microvesicles (MVs) harboring tissue factor (TF-MVs). These TF-M*Vs* have a primary role in thromboembolism by expression of procoagulant phospholipids (PL) such as phosphatidylserine, and TF. Tissue factor, the most potent initiator of the coagulation cascade, plays a critical role in hemostasis. Moreover several studies strongly suggest that TF-M*Vs* and their activity may have prognostic value in identifying cancer patients with increased risk of developing venous thromboembolism (VTE) or disseminated intravascular coagulation (DIC)
Aims: The aim of this study is to find a link between procoagulant state in patient with acute leukemia and M*Vs* procoagulant activity (PCA). The other aim is to assess if MVs-PCA could be a good biomarker to predict thrombotic events.
Methods: Blood samples from 38 patients with acute leukemia newly diagnosed were obtained at Day-0 (before treatment), D-3 and D-7 (3 and 7 days after treatment). Extracellular vesicles were isolated and concentrated by ultracentrifugation. EVs-PCA and E*Vs* associated tissue factor activity was measured a commercial bio-immunoassay (Zymuphen MP-TF®), respectively.
Results: Among acute leukemic patients, 3 patients have an increased E*Vs* PCA at D-0 and 2 of them developed a thrombotic event. The remaining patients without thrombotic events (n=35) do not show an increased EVs-PCA. One patient has an increased extracellular vesicles procoagulant activity at D-3 and develop a DIC at D-5. Three patients have an increased EVs-tissue factor activity (>2pg/ml), among these, two developed a thrombotic event and one had haemorrhage. A plasma from patient with induced DIC has no increased extracellular vesicles tissue factor activity from D-0 to D-7 (<2pg/ml).
Summary and Conclusions: This study shows the link between thrombotic events and MVs-PCA, and suggests the role of M*Vs* derived from leukemic blast and others cells in procoagulant state in AL. Moreover, M*Vs* PCA could have a predicting value for venous thromboembolism and DIC in patients with acute leukemia and could inform haematologists for the thrombosis prophylaxis.

P776

THERAPEUTIC APPROACH TOWARDS SYMPTOMATIC THROMBOCYTOPENIA IN DENGUE HEMORRHAGIC FEVER

T. Jameel[1,*]
[1]Faculty of Medicine Rabigh, King Abdul Aziz University Jeddah KSA, Jeddah, Saudi Arabia

Background: Immune-mediated destruction of platelets is thought to be the mechanism of thrombocytopenia seen after the viremic phase of dengue haemorrhagic fever (DHF). Immuno-suppressants such as steroids, immune globulin and Anti D immunoglobulin are effective in the treatment of this type of immune thrombocytopenic purpura.
Aims: To evaluate the efficacy of oral Prednisolone in the rate of resolution of thrombocytopenia and monitoring of complications in patients recovering from Dengue haemorrhagic fever.
Methods: A controlled study was carried out on diagnosed cases Dengue haemorrhagic patients presenting with sever thrombocytopenia and symptoms like confluent ecchymosis, epistaxis and purpuric rashes. This study was conducted in Ittefaq hospital (trust) Lahore, during the period of October to December 2013. Treatment group received steroids in two forms *i.e.* 1st line therapy prednisolone (1mg/kg) orally or as 2nd line therapy of initial I/V high dose (prednisolone) in pulse doses *i.e.* 40 mg bid for four days and later oral prednisolone as in 1st line therapy with omeprazole 20 mg bid in addition to standard treatment. Control group received standard supportive care only.
Results: A total of 341 suspected patients were admitted in hospital. Serological diagnosis was confirmed in 166 patients. CBC revealed platelet count $\leq 100x10^9$/l in 106 patients. A group of symptomatic febrile patients have platelet count $<20x10^9$/l was selected for therapeutic intervention. 1st line therapy (oral prednisolone was stated in 43 patients. In Fourteen patients 2nd line therapy (high dose dexamethasone pulse) therapy was instituted. Seven of them attained complete response whereas two patients achieved partial response. Four patients were shifted to Anti D therapy. Three deaths occurred during our study. Rest of all the patients improved and were discharged in due course of time.
Summary and Conclusions: This small scale preliminary study shows promising results in reducing the morbidity of patients in a relatively serious stage but large scale double blinded randomized controlled studies are needed before making recommendations on use of steroids in symptomatic thrombocytopenic patients with dengue haemorrhagic fever.

Venous and arterial thrombosis

PREVALENCE AND PREDICTIVE MODEL OF MYELOPROLIFERATIVE NEOPLASM-RELEVANT MOLECULAR MARKERS IN ISCHEMIC STROKE PATIENTS

Y.-Y. Chen[1,*] C.-C. Chen[1], C.-E. Huang[1], H.-J. Chou[1], H.-Y. Chou[1], Y.-S. Chen[1], H.-Y. Ho[1], C.-P. Li[1], J.-D. Lee[2]
[1]Division of hematology oncology, [2]Department of Neurology, Chang Gung Memorial Hospital, Chiayi, Pu-Tz City, Taiwan, ROC

Background: Myeloproliferative Neoplasm (MPN) has three major clonal molecular markers, including *JAK2*V617F, *CALR* and *MPL* mutation. MPN is also highly correlated with thromboembolic disease including ischemic stroke. However, the prevalence of these markers in patients with cerebral infarction is little known and the clinical characteristics of these patients remain unclear.
Aims: In this study, we aimed on the prevalence of *JAK2*V617F, *CALR* exon 9 and *MPL* mutation in patients with ischemia stroke. We also wanted to know if the clinical characters were different from unmutated patients with ischemic stroke.
Methods: In this study, more than 150 patients were enrolled. We used Allele-specific PCR (AS-PCR), real-time AS-PCR and Illlumina paired-end sequencing to detect the mutation including *JAK2*V617F, *CALR* exon 9 and *MPL* in the DNA of patients' granulocytes. Clinical characteristics were also recorded for comparison including age, gender, complete hemogram, thromboembolic events and risk factors of ischemic stroke including hypertension, diabetes mellitus, family history of stroke, atrial fibrillation, smoking history and hypercholesterolemia.
Results: In this study, more than 8% of stroke patients carried *JAK2*V617F mutation. two of these patients were homozygous for *JAK2*V617F mutation and had phenotype of essential thrombocytosis. If we excluded these 2 patients, the prevalence of *JAK2*V617F mutation was still more than 7%, which is higher than general population. Stroke patients harboring *JAK2*V617F mutation were mostly low allele burden without clinical phenotype of MPN. Only 2 patients carried heterozygous *CALR* mutation but the mutation didn't occur inside exon 9 nor affect KDEL amino acid domain of the calreticulin protein. No *MPL* mutation was detected in this study. We correlated patients' clinical parameters with their mutational status. Several characteristics were found closely related to the status of *JAK2*V617F mutation, including age, hemogram and stroke related risk factors. Using these parameters, we developed a scoring system to predict stroke patients at risk of having *JAK2*V617F clonal mutation. The scoring system composed of age older than 60 years, circulating white blood cell count greater than $10x10^9$/L, hemoglobin level greater than 14g/dL, platelet count greater than $400x10^9$/L and presence only 1 or no stroke factor. Each item give a score of 1, minimal score 0 and maximal score 5. Higher score, higher incidence of *JAK2*V617F mutation (Score 0-1: 2.8%; Score 2: 11.3%; Score 3: 20%; Score 4-5: 50%).
Summary and Conclusions: The prevalence of mutant *JAK2*V617F in stroke patients was higher than general population. Using our scoring system, identify stroke patients at risk of carrying *JAK2*V617F mutation is warranted.

P778

DENGUE VIRUS NON-STRUCTURAL PROTEIN 1 INDUCES VASCULAR LEAKAGE THROUGH MACROPHAGE MIGRATION INHIBITORY FACTOR SECRETION AND GLYCOCALYX DEGRADATION

C. Chen[1,*] Y.-C. Chuang[2], T.-M. Yeh[3]
[1]The Institute of Basic Medical Sciences, Medical College, National Cheng Kung University, [2]Department of Medical Laboratory Science and Biotechnology, Medical College, National Cheng Kung University, [3]Department of Medical Laboratory Science and Biotechnology, Medical College, National Cheng Kung University, Tainan, Taiwan, ROC

Background: Dengue virus (DENV) is a member of flaviviridae and it causes the most common mosquito-borne disease, including the life-threatening dengue hemorrhagic fever (DHF) and shock syndrome (DSS). In the pathogenesis of DHF/DSS, vascular leakage is the most characteristic feature, of which the mechanisms remain unclear. DENV non-structural protein 1 (NS1) is a highly conserved protein and its serum level is positively-correlated with the severity of the disease. Cytokine secretion, autophagy and disruption of endothelial barrier are factors cause vascular leakage, but how they are regulated by DENV NS1 has not yet been described.
Aims: The purpose of this study is to test whether DENV NS1 disrupted endothelial barrier function through macrophage migration inhibitory factor (MIF)-induced autophagy and glycocalyx degradation.
Methods: The *E. Coli* generated recombinant NS1 (rNS1) and *Drosophila* generated recombinant NS1 (CTK-NS1) were used. The expression and secretion of MIF in human microvascular endothelial cell line (HMEC-1) were determined by RT-PCR and ELISA. Endothelial permeability was determined by real-time cellular analysis and transwell permeability assay. *In vivo* permeability assay was demonstrated by Evans blue permeability assay and abdominal lavage in mice. The distribution of junction proteins and autophagy were observed by immunofluorescence assay and transfection of tf-LC3 construct. The degradation of glycocalyx was determined by MMP-9 expression in primary cultured human peripheral blood mononuclear cells (PBMC), heparanase-1 (HPA-1) protein level in HMEC-1 cells and CD138 concentration in mice peritoneal lavage and human patient serum samples.
Results: We first demonstrated that rNS1 induced vascular leakage *in vitro* and *in vivo*, and the permeability was rescued by treating heat-denatured rNS1 or co-treating rNS1 neutralizing antibodies. CTK-NS1 could also induce endothelial hyperpermeability. We then demonstrated that rNS1 induced the secretion of MIF in various cell types including HMEC-1 and PBMC. MIF concentration was also increased in the peritoneal lavage of rNS1-injected mice, and this phenomenon was rescued by co-treating NS1 neutralizing antibodies. In addition, rNS1 induced the LC3-I-to-LC3-II conversion and phosphorylated mTOR reduction, which indicated autophagy formation. The conversion of EGFP to mRFP in tf-LC3 transfected HMEC-1 cells further revealed that rNS1 induced the formation of autophagolysosome and autophagic bodies. The disarray of VE-cadherin and ZO-1 in HMEC-1 was induced by rNS1 and could be reversed by either MIF or autophagy inhibitors, which indicated the involvement of MIF and autophagy. Atg5 knockdown HMEC-1 stable clone could resist rNS1-induced hyperpermeability, indicating the importance of autophagy in endothelial permeability. Both MIF inhibitors and autophagy inhibitors rescued rNS1-induced endothelial hyperpermeability *in vitro* and *in vivo*, which further confirmed the mediation of MIF and autophagy in rNS1-induced vascular leakage. In patient serum samples, the increase in MIF and CD138 concentration were observed, indicating the correlation of glycocalyx degradation and vascular leakage. The glycocalyx degradation enzymes MMP-9 and HPA-1 were increased by rNS1 in PBMC and HMEC-1, indicating rNS1-induced glycocalyx degradation.
Summary and Conclusions: Taken together, these results suggest that NS1 may play pathogenic roles in DENV-induced vascular hyperpermeability through MIF secretion and glycocalyx degradation.

P779

PROVOKED VENOUS THROMBOEMBOLISM IN NON-CANCER PATIENTS: ARE THEY THE SAME?

C.C. Chua[1,*] H.Y. Lim[1], M. Sleeman[1], P. Ho[1,2]
[1]Clinical Haematology, Austin Health, Melbourne, [2]Clinical Haematology, Northern Health, Epping, Australia

Background: Venous thromboembolism (VTE) can be classified as provoked if there is a clear identifiable provoking factor. Collectively they have been shown to be associated with a lower risk of recurrence, and are often treated in a similar fashion.
Aims: To evaluate the association between different categories of provoked VTE in our study population and their risk of recurrence
Methods: Retrospective evaluation of all non-cancer VTE from July 2011 to December 2012 at Austin and Northern Health, Melbourne, Australia. The follow up was continued through to December 2014.
Results: 779 VTE cases were identified during our study period of which 50.6% were female with a median age of 63 years. Cases with no provoking factors (n=303, 39%) had a higher risk of recurrence at 11.9% (RR 2.4, p<0.001) and were more likely to be subsequently diagnosed with malignancy (3.3%, RR 3.2, p=0.03). Cases with provoking factors (n=476, 61%) included surgery (35.1%), non-surgical causes of immobility or injury including hospitalizations (38.4%), travel greater than 4 hours (14%), estrogen-related (11%), catheter-associated (1%) and local inflammatory processes such as cellulitis (0.4%). Of the provoked cases, travel had the highest recurrence rate (10.6%), comparable to unprovoked VTE (RR 0.89, p=0.771). Non-surgical causes of immobility or injury had the second highest recurrence rate of 5.5% (RR 0.46, p=0.024), followed by surgery at 3.6% (RR 0.30, p=0.005). Estrogen-related VTE had a lower trend of recurrence at 1.9% (RR 0.16, p=0.067). None of the VTE associated with catheter or local inflammatory processes recurred during our follow up period, however numbers were small (n=7). Provoked VTE had a significantly shorter time to recurrence than unprovoked VTE, with 76% occurring within the first 12 months of the initial event (median 8 months *versus* 18 months, p=0.02). Whether an episode of VTE was provoked did not appear to influence the rate of VTE-related deaths (p=0.89).

Table 1. Provoking factors and risk of recurrence in VTE.

	Total	Recurrence	Percentage	Relative Risk	95% CI	P-value
Unprovoked	303	36	11.9%	1.00		
Provoked (overall)	476	24	5.0%	0.42	0.26 to 0.70	<0.001
Travel	66	7	10.6%	0.89	0.42 to 1.92	0.771
Immobility or injury (non-surgical)	183	10	5.5%	0.46	0.23 to 0.90	0.024
Surgery	167	6	3.6%	0.30	0.13 to 0.70	0.005
Estrogen related	53	1	1.9%	0.16	0.02 to 1.13	0.067
Catheter associated	5	0	0.0%	0.69	0.05 to 10.03	0.789
Local inflammatory process	2	0	0.0%	1.39	0.11 to 17.75	0.801

Summary and Conclusions: Provoked VTE is not a homogenous group, and recurrence rates depend on the identifiable provoking factor. Reversible factors such as surgery, estrogen exposure, catheter or local inflammatory process demonstrated lower risk of recurrence. The high risk of recurrence associated with travel raises the question of the validity of travel as a "true" provoking factor. Further studies are warranted to better define travel as a provoking factor, as this will influence the optimal treatment and future outcomes for travel related VTE.

P780

COAGULATION PROCESS AND FIBRINOGEN GENETIC VARIABILITY ARE STRONG RISK FACTORS FOR ATHEROGENESIS, MYOCARDIAL INFARCTION AND THE EXTEND OF THE DISEASE IN SUBJECTS SUSPECTED FOR STABLE ANGINA

Z. Pallantza[1,*] M. Karagrigoriou[1], M. Kozanitou[1], G. Mallios[1], E. Andronopoulou[1], P. Parigori[1], N. Papageorgiou[1], D. Tousoulis[1]
[1]Athens Ippokratio Hospital, Athens, Greece

Background: It is well known that altered coagulation as well as fibrinogen genetic variability contribute to atherogenesis. In the present study we examined the combined effects of the rs1800790, rs2070011 fibrinogen polymorphisms on coagulation and endothelial function as well as the effect of coagulation on atherosclerotic manifestations.
Methods: We enrolled 422 patients with stable angina (SA) and 277 controls. The rs1800790 (G455A) and the rs2070011 (G58A) polymorphisms were estimated by appropriate genotyping. Fibrinogen and D-Dimer levels, as well as factors (f) V, X activity were measured by standard coagulometry techniques. Flow-mediated dilation (FMD) was assessed by brachial ultrasound.
Results: We have found the 455AA homozygosity was associated with raised fibrinogen levels in both groups (p=0.035 controls and p<0.001 SA). In addition, homozygotes for the 58A allele had lower fibrinogen levels in controls (p=0.038). Both the 58AA (p=0.027) and 455AA homozygotes (p=0.022) had higher levels of D-Dimer in the SA group. The 455AA homozygotes had also increased fV activity in the SA group (p=0.048). No effects were observed on fX activity and FMD. Further analysis revealed that fibrinogen levels were strongly associated with SA (1.005 [1.003-1.007], p<0.001) as well as the presence of MI (1.003 [1.001-1.005], p=0.001). Similarly, D-Dimer levels were also strong predictors of CAD (1.001 [1.001-1.002], p<0.001), but not of MI (1.000 [1.001-1.001], p=0.083). Surprisingly, when fV and fX activities were examined for possible associations with clinical presentations, we found that fV activity was associated with increased number of diseased vessels (1.016 [1.001-1.030], p=0.037), while fX activity was strongly related to MI (0.985 [0.973-0.997], p=0.013).
Summary and Conclusions: The rs1800790 variant increases significantly fibrinogen, D-Dimers levels and fV activity, contributing to atherogenesis. In addition, fibrinogen and D-Dimers levels are strong predictors of SA and MI. Interestingly, in our study we have shown for the first time to our knowledge that fV and fX are associated with the number of diseased vessels and the risk of MI respectively.

P781

LONGTERM CANCER RISK AFTER VENOUS THROMBOEMBOLISM

L. Eischer[1,*] P. Kyrle[1], M. Kammer[2], S. Eichinger[1]
[1]Hamatology and Hemostasis, [2]Core Unit for Medical Statistics and Informatics, Medical University Of Vienna, Wien, Austria

Background: A venous thromboembolic event (VTE) may indicate an underlying cancer. In population based studies the likelihood of cancer is highest during the first year but a persistent increase has been reported also in the years thereafter. Data on the risk in patients who completed anticoagulant treatment and recommendations regarding screening are lacking.
Aims: To evaluate the long-term risk of cancer in a well-defined cohort of patients with an unprovoked VTE.
Methods: We prospectively followed patients with a first unprovoked VTE after discontinuation of anticoagulation and excluded those with long-term antithrombotic therapy, major thrombophilia or pregnancy. Study endpoint was diagnosis of cancer. The ratio of the observed cases and the number of cases expected based on national cancer incidence rates was calculated and expressed as standardized incidence ratio (SIR). The study was approved by the local ethics committee and all patients consented.
Results: 43 (3.6%) of 1188 patients (mean age 48 years, 638 women, median duration of anticoagulation 7.2 months) were diagnosed with cancer (colon 8, breast 7, lung 6, hematologic 6, prostate 4, skin 1, brain 1, others 10) during a median follow up of 70 months (range 3-216). Cancer patients were significantly older (57 *vs* 48 years, p<0,001) but did not differ from non-cancer patients regarding proportion of women (49 *vs* 54%), blood cell counts (hemoglobin 14.2 *vs* 14.2 g/dl; platelets 232 *vs* 238 G/l; leukocytes 6.5 *vs* 6.8 G/l), body mass index (both 27 kg/m^2) or D-Dimer (469 *vs* 463 µg/ml). The probability of cancer was 0.7% (95% CI 0.1-1.3%), 1.7% (95% CI 0.9-2.5%) and 3.0% (95% CI 1.8-4.2%) after 1, 2 and 5 years. The corresponding SIR did not significantly differ from expected rates in an age- and sex-matched general population (1.2, 1.3 and 1.0) (Figure1).

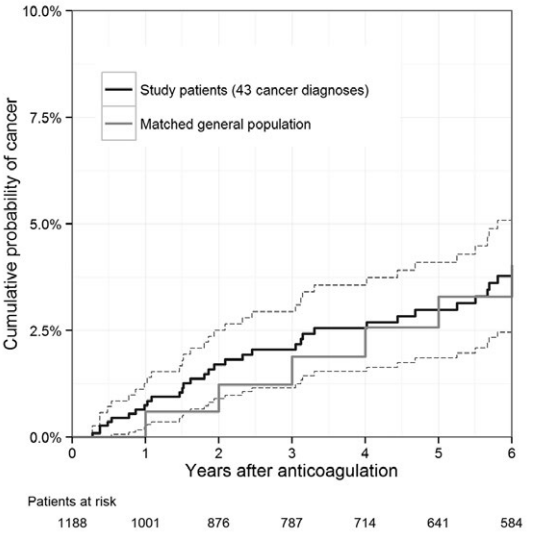

Figure 1.

Summary and Conclusions: In patients with unprovoked VTE the long-term incidence of cancer after anticoagulation is low. Cancer types are heterogeneous and specific screening strategies do not seem to be warranted.

P782

POLYMORPHISM OF GENES INVOLVED IN LIPID METABOLISM AS A RISK FACTOR FOR VENOUS THROMBOEMBOLISM

S.P. Svitina[1,*] V. Shmeleva[1], V. Soldatenkov[1], V. Kargin[1], L. Papayan[1], S. Kapustin[1]
[1]FSBI "Russian Research Institute of Haematology and Transfusiology", St. Petersburg, Russian Federation

Background: Venous thromboembolism (VTE) is one of the leading causes of morbidity and mortality in industrialized countries, and is known as a multifactorial disease. Along with the classic risk factors, significant role in the development of VTE has been assigned to genetic predisposition. Although conventional genetic risk factors have been involved in the disease process, VTE often occurs in the absence of known risk factors. Doubtless, some forms of dyslipidemia are risk factors for arterial thrombosis. However, based on the recent research, lipid metabolism disorders have a high probability to be implicated in pathogenesis of VTE.
Aims: The aim of this study was to investigate the role of allelic polymorphism of some genes involved in lipid metabolism: apolipoprotein E (ApoE), apolipoprotein CIII (ApoCIII), lipoprotein lipase (LPL) and hepatic lipase (LIPC), in patients with VTE.
Methods: We retrospectively analyzed DNA samples of 300 patients with VTE (147 men and 153 women, average age 39,9±12,4 years), including 200 individuals with the debut of VTE under the age of 45 years. Isolated deep vein thrombosis (DVT) has been diagnosed in 170 patients, whereas in 67 persons DVT complicated by pulmonary embolism (PE) ("DVT+PE"), and 63 individuals have had PE without signs of DVT (isolated PE). The control group consisted of 100 sex- and age-matched healthy persons without history of thrombosis. Polymorphism of the ApoE (E2/E3/E4), ApoCIII (C3175G and −455 T/C), LPL (Asn291Ser) and LIPC (-514 T/C) genes was determined by polymerase chain reaction with subsequent restriction digest. Statistical analysis was performed using the program GraphPad Prism 5.0. Differences in the distribution of alleles and genotypes were assessed by Fisher's exact test.
Results: The distributions of alleles and genotypes of analyzed genes in patients with VTE had no significant differences from those in healthy controls. Nonetheless, ApoE E3/E4 genotype was more frequently seen in men with thrombosis when compared to group of women (24,5% *vs* 15,0%; OR=1,8; 95%CI: 1,0-3,3; p=0,043). Significant increase in proportion of homozygotes for the LIPC −514T allele was observed in the "DVT+PE" group (69,2% *vs* 52,9% in patients with isolated DVT; OR=2,0; 95%CI=1,1-3,7; p=0,027). The ApoCIII −455CC genotype was more prevalent in patients who had their first episode of VTE after 45 years than in those with early-onset disease (26,5% *vs* 14,9%, respectively; OR=2,0; 95%CI=1,0-4,1; p=0,043). On the other hand, the proportion of homozygotes for the ApoCIII −455T allele was significantly higher in young patients (37,4% *vs* 22,0% in the group with late-onset VTE; OR=2,1; 95%CI=1,1-4,0; p=0,023).
Summary and Conclusions: Our data indicate that polymorphism of some genes affecting lipid metabolism could influence the risk and course of VTE. ApoE genotype E3/E4 is a potent risk factor for VTE development in men. Polymorphism −455 T/C of the ApoCIII gene could influence the age of VTE debut. Furthermore, the risk of PE development in patients with DVT may depend on their LIPC genotype.

P783

HIGH LEVELS OF FIBRINOGEN, BUT NOT FIBRINOGEN GENETIC VARIANTS PREDICT CORONARY ARTERY DISEASE IN SUBJECTS WITH HYPERTENSION AND DIABETES MELLITUS TYPE 2

Z. Pallantza[1,*] M. Karagrigoriou[1], A. Vlachopoulou[1], G. Papacharalampous[1], D. Gubini[1], L. Plavoukou[1], N. Papageorgiou[1], D. Tousoulis[1]
[1]Athens Ippokratio Hospital, Athens, Greece

Background: It is well established that hypertension (HTN) and diabetes mellitus (DM) are strongly associated with coronary artery disease (CAD). In addition, controversial data exist related to the role of fibrinogen genetic variants in atherosclerosis-CAD. Therefore, we examined the effects of the rs180070 and rs2070011 fibrinogen polymorphisms on coagulation, inflammation and on the risk for CAD in patients with DM and HTN admitted with stable angina pectoris symptoms.
Methods: A total of 744 subjects were enrolled in 3-year period. Fibrinogen polymorphisms were determined by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique. Fibrinogen, interleukin-6 (IL-6), high sensitivity C-reactive protein (hsCRP) CD40L, D-dimers and factors V, X activity were measured with appropriate laboratory methods.
Results: The AA homozygosity of rs180070 was associated with significantly higher levels of fibrinogen in both HTN and DM (p=0.05, p=0.04 respectively). The presence of AA genotype (rs180070) was also significantly associated with increased risk of CAD in the general population [OR: 3.2, 95% CI, (1.01-10.1, p=0.049)]. While it was associated with higher IL-6 an D-dimers, but not hsCRP levels in the general population. Interestingly, multivariate logistic regression analysis showed that fibrinogen levels >443 mg/dl were associated with higher risk for CAD [OR: 3.9, 95% CI, (1.7-9.4, p=0.002)] compared to levels <347 mg/dl in the general population. Similar associations were observed in HTN and DM patients. In hypertensive patients, higher fibrinogen levels >443 mg/dl [OR: 3.5, 95% CI (1.14-10.9, p=0.029), but not the AA genotype of rs180070 [OR: 3, 95% CI (0.78-11.9, p=0.11)] were independent predictors of CAD. Similarly, in DM only fibrinogen remained an independent predictor of CAD [OR 5.86, 95% CI (1.1-31.2, p=0.038)].
Summary and Conclusions: We have shown that the presence of AA genotype (rs180070) is associated with increased levels of D-dimers and IL-6 promoting atherosclerosis, as well as risk for CAD. However, elevated fibrinogen levels >443 mg/dl remain the most significant predictor of CAD both in HTN and in DM subjects.

P784

VENOUS THROMBOEMBOLISM IN NORTHEAST MELBOURNE, AUSTRALIA: EVALUATION OF EPIDEMIOLOGY, RISK FACTORS AND TREATMENT STRATEGIES IN THE WARFARIN ERA

H.Y. Lim[1,2,*] C.C. Chua[1], M. Sleeman[1], P. Ho[1,2]
[1]Haematology, Austin Health, Heidelberg, [2]Haematology, Northern Health, Epping, Australia

Background: Venous thromboembolism (VTE) is associated with significant morbidity, mortality and economic cost (approximately AUD$117 000 per person, *Access Economics 2008*). Despite advances in thrombosis management, management strategies remain heterogenous with a paucity of real-world VTE data.
Aims: To provide a holistic evaluation of VTE management in the warfarin era including identifying potential causal effects and complications.
Methods: Retrospective evaluation of VTE from July 2011 to December 2012, at two major hospitals in Northeast Melbourne, Australia.
Results: 1003 patients, with a median age of 63 (range 19-97) years and an overall male predominance (52%), presented with a total of 1025 episodes - 574 (56%) pulmonary embolism (PE), 422 (41%) deep venous thrombosis (DVT). 23% (n=234) had active malignancy at time of diagnosis with 14 patients (1.4%) subsequently being diagnosed. Median follow up was 33.5 (range 23-53) months. *Non-cancer patients:* 63% had provoked VTE and thrombophilia screen was performed in 41%. 20% had previous VTE and 7.5% reported positive family history. Median duration of anticoagulation was 6 and 7 months for DVT and PE respectively. Majority (90%) was on warfarin for long-term anticoagulation. 5% required other interventions - IVC filter (n=29) and thrombolysis (n=13). 19% had end-of-treatment repeat imaging and residual clot was observed in 56%. On extended follow-up, clot persistence was not associated with increased recurrence (OR 1.9 [0.6-6.2]). 7% had recurrent thrombosis with increased risk in unprovoked VTE (OR 2.2 [1.3-3.80], p=0.004). 60% of recurrence occurred within 12 months of initial VTE. 5.6% reported grade III/IV bleeding with 56% occurring within the first month of anticoagulation. Bleeding risk was independent of duration of anticoagulation. All-cause mortality rate was 14%. In the below knee DVT (BKDVT) sub-analysis, 1.5% was subsequently diagnosed with cancer, similar prevalence to those with major VTE (1.7%), defined as proximal DVT and/or PE. BKDVT were more likely to be provoked (71% *vs* 60%, p<0.001) and recurrence was similar to major VTE (9% *vs* 7%, p=0.36). Mortality rate was 5.5% with no thrombosis-related deaths. *Cancer patients:* These patients were older (67 *vs* 61 years, p<0.001) and had higher clot burden with more PE (64% *vs* 53%, p=0.004), proximal DVT (63% *vs* 46%, p=0.0008) and bilateral DVT (16% *vs* 5%, p<0.001). Metastatic cancer was associated with increased unprovoked events (p=0.015). Cancer patients were more likely to require IVC filters and lifelong anticoagulation (p<0.001). Recurrence/clot extension (17%) and Grade III/IV bleeding (10%) were more common (p=0.02). Mortality rate in this cohort was 68% with higher incidence of complications-related deaths (p<0.001).
Summary and Conclusions: Recurrence rate was 4% in the first 12 months with unprovoked VTE being a major risk factor. Cancer patients experience more complications with higher clot burden and all-cause mortality rate. Interestingly, BKDVT, often considered a minor VTE, had comparable rates of recurrence and subsequent cancer detection to major VTE suggesting that BKDVT may not be as benign as it seemed. Further evaluation of new treatment strategies as well as clinical and laboratory risk assessments are required to improve the management for VTE. This data will serve as an important baseline for future comparison in the new era of novel oral anticoagulants.

Background: MYD88^{L265P} and CXCR4^{WHIM} are highly prevalent somatic mutations in Waldenström's Macroglobulinemia (WM). MYD88^{L265P} triggers WM growth via Bruton's Tyrosine Kinase, a target of ibrutinib. CXCR4^{WHIM} mutations confer *in vitro* resistance to ibrutinib.
Aims: The primary aim of this study was to determine in a prospective, multicenter study the overall and major response rates of ibrutinib monotherapy in previously treated and symptomatic WM patients requiring therapy. Secondary aims of this study included determination of progression-free survival, drug safety, and impact of MYD88 and CXCR4 mutations on treatment outcome.
Methods: Symptomatic WM patients with >1 prior therapies were eligible. Ibrutinib (420 mg) was administered daily until progression, or unacceptable toxicity. Dose modifications for toxicity were permitted. Central pathology review was performed in all patients. Genotyping for MYD88 L265P and CXCR4 WHIM mutation status was performed in 63 and 62 patients, respectively.
Results: 63 patients with a median of 2 prior therapies (40% with refractory disease) were enrolled. Post-therapy, median serum IgM levels declined from 3,520 to 880 mg/dL; hemoglobin rose from 10.5 to 13.8 g/dL, and bone marrow involvement declined from 60% to 25% (p<0.01 for all comparisons). Overall and major response rates were 90.5% and 73.0%, and the median times to at least minor and major responses were 4 and 8 weeks, respectively. Overall responses were similar regardless of baseline age (<65 *vs.* ≥65 years), ECOG status (0 *vs.* ≥1), pre-therapy WM IPSS score, serum β_2-microglobulin levels (<3.0 *vs.* >3.0 mg/L), hemoglobin (<11 *vs.* >11 g/dL), serum IgM (<4,000 *vs.* ≥4,000 mg/dL), BM disease involvement (<50% *vs.* ≥50%), prior relapsed or refractory status, and prior lines of therapy (1-3 *vs.* >3). Fifty-six (88.9%) patients expressed MYD88^{L265P}, and 21 (33.9%) had CXCR4^{WHIM} mutations. Overall and major response rates were highest in patients with MYD88^{L265P}CXCR4$^{wild\text{-}type(WT)}$ (100% and 91.2%), followed by MYD88^{L265P}CXCR4^{WHIM} (85.7% and 61.9%), and MYD88^{WT}CXCR4^{WT}(71.4% and 28.6%) mutation status. The 2-year PFS (Figure A) and overall survival rates (Figure B) were 69.1% and 95.2%, respectively. Subset analysis showed that >3 prior lines of therapy, high pre-therapy IPSS score, and MYD88^{WT}CXCR4^{WT} mutation status associated with inferior progression-free survival. Grade >2 treatment-related toxicities included neutropenia (22.2%) and thrombocytopenia (14.3%) that were more common in heavily pre-treated patients; atrial fibrillation in patients with a prior arrhythmia history (3.2%); procedure-related bleeding (3.2%); and epistaxis related to marine oil supplements (3.2%). Serum IgA and IgG levels were unchanged, and treatment-related infections were infrequent.

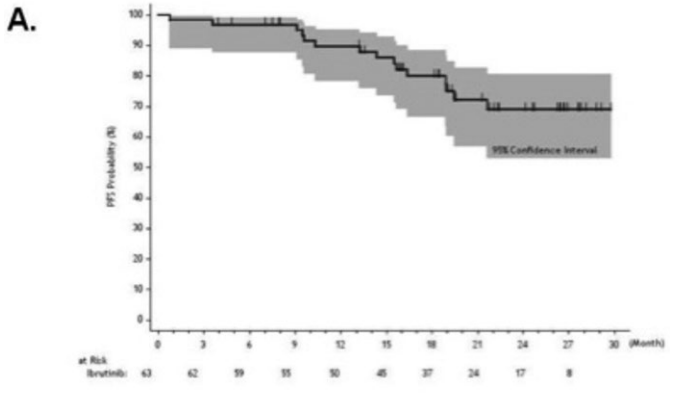

Figure 1. A

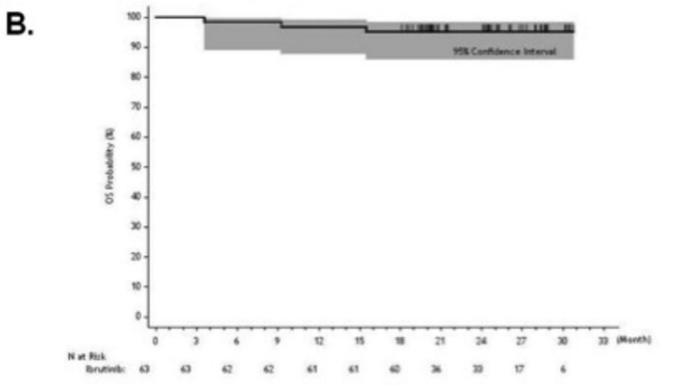

Figure 1. B

Summary and Conclusions: Ibrutinib is highly active in previously treated WM patients. An overall response rate of 90.5%, and 2-year progression-free and overall survival rates of 69.1% and 95.2%, respectively, was achieved with ibrutinib monotherapy. Ibrutinib responses were influenced by MYD88 and CXCR4 mutation status. Overall, treatment toxicity was moderate and no unexpected toxicities were observed.

S786

LOW IKZF1 EXPRESSION IS ASSOCIATED WITH FAVORABLE OUTCOME IN LENALIDOMIDE TREATED NEWLY DIAGNOSED MULTIPLE MYELOMA

J. Krönke[1], F. Kuchenbauer[1], M. Kull[1], V. Teleanu[1], L. Bullinger[1], A. Greiner[1], S. Kolmus[1], S. Köpff[1], L.O. Mügge[2], C. Straka[3], F. Bassermann[4], M. Engelhardt[5], R. Bargou[6], H. Einsele[6], S. Knop[6], C. Langer[1,*]

[1]Internal Medicine III, Ulm University, Ulm, [2]Internal Medicine II, Friedrich Schiller University, Jena, [3]Hematology and Oncology, Schön Klinik Starnberger See, Berg, [4]Department of Medicine III, Klinikum Rechts der Isar, Munich, [5]Hematology and Oncology, University of Freiburg, Freiburg, [6]Department of Internal Medicine II, University Hospital of Würzburg, Würzburg, Germany

Background: Lenalidomide is an immunomodulatory drug (IMiD) with high activity in multiple myeloma (MM). IMiD binding to the CRBN E3 ubiquitin ligase results in targeted ubiquitination and degradation of the lymphoid transcription factors IKZF1 and IKZF3 and constitutes a unique mechanism of action for a class of drugs.
Aims: To determine whether expression levels of *CRBN*, *IKZF1*, and *IKZF3* are associated with outcome in lenalidomide treated patients (pts) with newly diagnosed MM.
Methods: We analyzed mRNA expression levels of *IKZF1*, *IKZF3*, and *CRBN* by real-time quantitative PCR (RQ-PCR) in CD138-selected pre-treatment samples from 60 pts with newly diagnosed MM uniformly treated within a phase II clinical trial of the German Myeloma Study Group (DSMM). Additionally, all pts were characterized for the presence of cytogenetic abnormalities using a comprehensive set of FISH probes. All patients received induction consisting of four cycles of lenalidomide, adriamycin and dexamethasone followed by high-dose melphalan (Mel-200) with autologous stem cell transplantation (aSCT). Genetically defined low- and intermediate risk patients received a second aSCT, while those pts with high-risk cytogenetics (presence of a del17p13, t(4;14) or t(14;16)) underwent allogeneic stem cell transplantation if a donor was available. All patients received lenalidomide maintenance for 12 months.

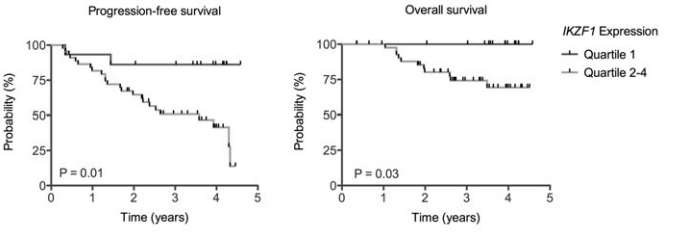

Figure 1.

Results: Median expression levels normalized to plasma cells from healthy volunteers of *CRBN*, *IKZF1*, and *IKZF3* were 0.66 (range, 0.12 - 2.86), 0.66 (0.16-2.92), and 0.52 (0.19-5.13), respectively. Expression levels of *CRBN*, *IKZF1*, and *IKZF3* were not affected by the presence of chromosomal aberrations (del13q14, del17p13, del9q34, +1q21, t(4;14), t(11;14), t(14;16)). Patients achieving a complete response (CR) or very good partial response (VGPR) had a trend towards a lower *IKZF1* expression than patients achieving a partial response (PR) (median *IKZF1* expression: 0.62 *vs* 0.84, p=0.07). Consistently,

lower *IKZF1* expression levels were associated with a better outcome: when segregating *IKZF1* expression levels into quartiles, pts with the lowest (Q1) quartile of *IKZF1* expression had a 3 year progression-free survival (PFS) of 86% compared to 51% in patients of the remaining quartiles (Q2-Q4)(Log rank test, p=0.01). This translated into a better overall survival (OS) (*IKZF1* Q1:100% *vs* *IKZF1* Q2-4:74% after 3 years, log rank p=0.03). In contrast, *CRBN* and *IKZF3* expression levels had no impact on response, PFS, or OS. Factors also associated with outcome included the presence of a del13q14 (PFS: p=n.s.; OS: p=0.04), del17p13 (PFS: p=0.001; OS=0.03), t(4;14) (PFS: p=0.009; OS: p=0.004) or +1q21 (PFS: p=n.s.; OS p=0.037).
Summary and Conclusions: In this cohort of uniformly treated newly diagnosed MM patients, *IKZF1* but not *IKZF3* or *CRBN* expression levels were associated with outcome. Low *IKZF1 m*RNA expression levels seem to identify a sub-group with a particularly good outcome.

S787

POST-TRANSPLANT CARFILZOMIB (KYPROLIS®), LENALIDOMIDE (REVLIMID®), AND DEXAMETHASONE (KRD) CONSOLIDATION IN NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM): EFFICACY AND TOLERABILITY OF EXTENDED TREATMENT

A. Jakubowiak[1,*] K. Griffith[2], J. Jasielec[3], C. Rosenbaum[1], K. McDonnell[1], J. Berdeja[4], R. Vij[5], N. Raje[6], D. Reece[7], D. Dytfeld[8], T. Zimmerman[1]
[1]The University of Chicago, Chicago, [2]University of Michigan, Ann Arbor, [3]Northshore University Health System, Evanston, [4]Sarah Cannon Cancer Center, Nashville, [5]Washington University, St. Louis, [6]Massachusetts General Hospital, Boston, United States, [7]Princess Margaret Cancer Centre, Toronto, Canada, [8]Poznan University Medical Science, Poznan, Poland

Background: In a previous phase 1/2 study, extended treatment for 24 months with KRd provided a high rate of stringent complete response (sCR) of 55% and durable disease control with a 3-year progression-free survival (PFS) of 79% and overall survival (OS) of 96% after extended treatment (Jakubowiak *et al.* Blood 2012; Jasielec *et al.* ASH 2013). In this Phase 2 study we evaluate post-transplant extended treatment with KRd in NDMM (NCT01816971).
Aims: To assess the efficacy and tolerability of extended post-transplant treatment with KRd in NDMM pts who have received KRd induction and ASCT.
Methods: Pts with symptomatic NDMM per IMWG criteria and transplant candidates were eligible for enrollment. After 4 cycles of KRd induction and ASCT, pts received KRd consolidation treatment (70—90 days post-transplant) as 28-day cycles for 4 cycles: CFZ 36mg/m^2 IV on Days 1, 2, 8, 9, 15, 16; LEN PO Days 1-21 starting at 15mg with option to escalate after 1 cycle of consolidation; DEX PO 20mg Days 1, 8, 15, 22. After consolidation, KRd was given for additional 10 maintenance cycles, with modified CFZ schedule on Days 1, 2, 15, 16. LEN single-agent was recommended off protocol at best tolerated dose after KRd maintenance. Dose modifications were permitted to manage toxicities. The primary endpoint was sCR rate at the end of Cycle 8; an improvement of sCR from 30%, the rate observed at the end of 8 cycles without transplant, to 50% in this study will be considered promising for strategy of combining KRd with transplant.
Results: As of Feb 1, 2015, 28 of a total 55 enrolled pts have completed at least 1 cycle of KRd consolidation: 25 pts have completed KRd consolidation and initiated maintenance; 7 pts have completed KRd maintenance and initiated LEN single-agent off protocol. After transplant prior to the initiation of KRd consolidation, ≥VGPR was 96%, ≥near CR (nCR) was 46%, and sCR was 29%. After 4 cycles of consolidation, ≥VGPR was 100%, ≥nCR was 88% and sCR was 72%. The rate of negative minimal residual disease by 9-color flow cytometry at the end of 8 cycles was 88%. Responses deepened in 25 pts treated beyond at least 4 cycles of KRd consolidation with an additional 1 pt converting to nCR and 3 to sCR, resulting in ≥nCR 96% and sCR 84%. After a median follow-up of 14 months from the start of the KRd treatment (range 8-24), all 28 pts were alive and progression free. There were no new or unexpected toxicities post-transplant compared to the referenced above phase 1/2 trial of KRd without transplant. Enrollment continues with a target of 70 pts; 55 have been enrolled and updated results of pts receiving at least one cycle post-ASCT will be reported during the meeting.
Summary and Conclusions: Based on this analysis, extended post-transplant treatment with KRd can be considered for future evaluation in pts who have received induction regimens other than KRd. The preliminary data suggest that KRd with transplant has high efficacy compared to standard single-agent maintenance therapy post-transplant.

S788

IMPACT OF STABLE DISEASE AS A RESPONSE TO POMALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE ON SURVIVAL OUTCOMES IN PATIENTS WITH REFRACTORY OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA IN THE MM-003 TRIAL

P. Moreau[1,*]K. Weisel[2]K. Song[3]C. Gibson[4]O. Saunders[5]L. Sternas[4]K. Hong[4]M. Zaki[4]M. A. Dimopoulos[6]
[1]University Hospital Hôtel-Dieu, Nantes, France, [2]University Hospital of Tuebingen, Tuebingen, Germany, [3]Vancouver General Hospital, Vancouver, Canada, [4]Celgene Corporation, Summit, United States, [5]BresMed Health Solutions, Sheffield, United Kingdom, [6]National and Kapodistrian University of Athens, Athens, Greece

Background: Patients (pts) with refractory or relapsed and refractory multiple myeloma (RRMM) have poor overall survival (OS) outcomes after failure of bortezomib and lenalidomide treatment (Tx) regimens. Pomalidomide plus low-dose dexamethasone (POM+LoDEX) has been demonstrated to significantly extend OS in this pt population compared with high-dose DEX (HiDEX; hazard ratio [HR]=0.74 [95% CI, 0.56-0.97]; *P*=0.0285; San Miguel et al, *Lancet Oncol,* 2013) in the phase 3 MM-003 trial (clinicaltrials.gov identifier NCT01311687). Secondary analysis of MM-003 showed that the survival benefit of Tx with POM+LoDEX extended to pts who achieved minor response or better (San Miguel et al, ASH, 2013).
Aims: This post hoc analysis of MM-003 investigated OS based on response status with a focus on pts who achieved stable disease (SD) but not a response by certain landmark points in time.
Methods: Kaplan-Meier methods and unadjusted Cox regression models were used for landmark analyses at the start of cycles (C) 3, 5, and 7. Response status was captured over time by time-dependent survival analyses. For both approaches, survival of pts with SD was compared with that of pts with progressive disease (PD) or overall response (OR; ≥partial response) at the same point in their treatment.
Results: 302 pts randomized to POM+LoDEX were included in the analysis. Response rates at C3 were 38.4% SD, 14.6% PD, and 19.2% OR, with no response data for 27.8% of pts (mostly due to early discontinuation). The median OS from randomization by response status at C3 was 15.3 mos for SD (n=116), 6.3 mos for PD (n=44; hazard ratio [HR]=3.83; *P* <0.0001 *vs* SD), and 17.5 mos for OR (n=58; HR=0.75; *P*=0.320 *vs* SD). Median OS at C5 was 16.6 mos for SD (n=57), 11.0 mos for PD (n=31; HR=2.81; *P*=0.004 *vs* SD), and 18.0 mos for OR (n=56; HR=0.74; *P*=0.462 *vs* SD). Median OS at C7 was not reached for SD (n=40), 16.4 mos for PD (n=18; HR=2.66; *P*=0.080 *vs* SD), and 18.0 mos for OR (n=47; HR=0.90; *P*=0.843 *vs* SD). The time-dependent survival model showed a lower risk of death for pts with SD or OR *vs* PD (HR=0.27 [95% CI, 0.17-0.44] and HR=0.06 [95% CI, 0.02-0.16], respectively). The HiDEX Tx arm exhibited a lower response rate and shorter OS, which in combination with a smaller number of pts overall resulted in response groups too small for meaningful analysis.
Summary and Conclusions: POM+LoDEX–treated pts with SD at C3, C5, and C7 had OS comparable to pts who achieved OR. The OS of pts with either SD or OR at these time points was significantly longer than for those with PD.

S789

A PHASE I/IIA STUDY OF THE HUMAN ANTI-CD38 ANTIBODY MOR202 (MOR03087) IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

M. Raab[1,*] H. Goldschmidt[1], H. Agis[2], I. Blau[3], H. Einsele[4], M. Engelhardt[5], B. Ferstl[6], M. Gramatzki[7], C. Röllig[8], K. Weisel[9], P. Klöpfer[10], D. Weinelt[10], S. Härtle[10], C. Peschel[11]
[1]University Hospital Heidelberg, Heidelberg, Germany, [2]University Hospital of Internal Medicine-AKH Wien, Vienna, Austria, [3]Charité Campus Benjamin Franklin, Berlin, [4]University Hospital Würzburg, Würzburg, [5]Medical University Hospital, Freiburg, [6]Fried-Alexander-University Erlangen-Nürnberg, Erlangen, [7]University Hospital Schleswig-Holstein Division of Stem Cell Transplantation and Immunotherapy, Kiel, [8]University Hospital Carl Gustav Carus, Dresden, [9]University Hospital of Tübingen, Tübingen, [10]MorphoSys AG, Martinsried, [11]Technical University of Munich, Munich, Germany

Background: MOR202 is a HuCAL-derived fully human immunoglobulin G1 (IgG1) anti-CD38 antibody, with high efficacy in preclinical models of multiple myeloma.
Aims: To evaluate the safety and preliminary efficacy of MOR202 in adult patients with relapsed or refractory multiple myeloma.
Methods: This is an open-label dose-escalation study (3+3 design). The data of patients previously treated with ≥2 prior therapies, including an immunomodulatory drug and a proteasome inhibitor, are presented. Patients received 2-hour intravenous MOR202 every 2 weeks (q2w; 8 dose levels from 0.01–16 mg/kg) without dexamethasone, or 4 or 8 mg/kg (dose levels 6 and 7) weekly (q1w)+/-dexamethasone. MOR202 16 mg/kg (dose level 8) q1w+/-dexamethasone, and combination cohorts with lenalidomide+dexamethasone and pomalidomide+dexamethasone, are planned, as well as confirmation cohorts.
Results: As of December 31 2014, 38 patients had been treated; 29 and 9 patients in the q2w and q1w dose levels, respectively. Median age was 70 (44–80) years. The median number of prior treatment lines was 4 (2–10) for all patients. A total of 36 patients (94.7%) developed adverse events. The most frequently reported adverse events (>10%) of any grade were anemia (31.6%), fatigue (28.9%), white blood cell count decreased (21.1%), lymphocyte count decreased (21.1%), diarrhea (21.1%), nasopharyngitis (18.4%), and leukopenia (13.2%). Grade ≥3 hematologic adverse events were lymphocyte count decreased (15.8%), white blood cell count decreased (7.9%), leukopenia (5.3%), thrombocytopenia (2.6%), and lymphopenia (2.6%). Infusion-related reactions occurred in 13 patients (34%) receiving MOR202 without dexamethasone, mainly during the first infusion. All were grade 1–2 except for 1

patient (grade 3). There have been no treatment-related deaths. Pharmacokinetic data demonstrate a significant target-mediated drug disposition effect for most patients treated q2w. In 4 out of 6 patients in the q1w 4 mg/kg cohort, MOR202 trough levels show the start of target saturation. Only 1 patient (MOR202 0.15 mg/kg q2w) generated a transient anti-drug antibody response to MOR202.

Summary and Conclusions: The maximum tolerated dose has not been reached. MOR202 is safe and well tolerated. Pharmacokinetic data show the potential for full target occupancy in the majority of patients receiving 8 and 16 mg/kg q1w. These latter dose levels of MOR202 will be tested as monotherapy or in combination with dexamethasone, lenalidomide+dexamethasone, and pomalidomide+dexamethasone, in the upcoming cohorts. Efficacy analyses are ongoing.

CLL: Refining outcomes

S790

SAFETY AND EFFICACY OF THE BRUTON TYROSINE KINASE INHIBITOR IBRUTINIB IN PATIENTS WITH HAIRY CELL LEUKEMIA: INTERIM RESULTS OF A PHASE 2 STUDY

J.A. Jones[1,*] L. Andritsos[1], F. Ravandi[2], R.J. Kreitman[3], C. Schiffer[4], T. Call[5], G. Lozanski[6], J. Sexton[7], P. Harris[8], M.R. Grever[1]
[1]Division of Hematology, Ohio State University, Columbus, OH, [2]Department of Leukemia, MD Anderson Cancer Center, Houston, TX, [3]Clinical Immunotherapy Section, National Cancer Institute, Bethesda, MD, [4]Department of Oncology, Karmanos Cancer Institute, Detroit, MI, [5]Department of Hematology, Mayo Clinic, Rochester, MN, [6]Department of Pathology, [7]Comprehensive Cancer Center, Ohio State University, Columbus, OH, [8]Cancer Therapy Evaluation Program, National Cancer Institute, Bethesda, MD, United States

Background: Effective therapy for classical hairy cell leukemia (c-HCL) refractory to purine nucleoside analog (PA) treatment is limited, and there is no accepted treatment standard for either treatment-naïve or relapsed variant hairy cell leukemia (v-HCL). Ibrutinib, an oral small molecule inhibitor of Bruton tyrosine kinase (BTK), has shown single-agent efficacy and acceptable tolerability in patients with various B-cell malignancies, including CLL, mantle cell lymphoma, and Waldenstrom macroglobulinemia. However, while BTK is expressed in HCL cells, the clinical activity of ibrutinib in this disease has not been previously assessed.
Aims: To characterize the overall response rate (complete+partial response) and safety of single-agent ibrutinib treatment for hairy cell leukemia.
Methods: This NCI/CTEP-sponsored, single-arm phase 2 study enrolled patients with c-HCL (unfit for or relapsed after PA) and v-HCL (relapsed or treatment-naïve). Eligible patients required treatment, had ECOG ≤2, no active infection, and preserved end-organ function. Patients received continuous oral ibrutinib (420 mg daily) in 28-day cycles. A second cohort at higher dose (840 mg daily) has been accrued after a pre-determined response endpoint was not initially met at the 420 mg dose. Response, including bone marrow biopsy with immunohistochemistry for minimal residual disease (MRD), is assessed after 8 and 12 cycles. Soluble interleukin-2 receptor levels (sIL2R) were measured serially and correlated with clinical outcome. Patients experiencing clinical benefit may continue ibrutinib indefinitely absent unacceptable toxicity or progressive disease.
Results: Data are presented for the initial 420 mg/day cohort (n=13). Enrolled subjects (1 treatment-naïve v-HCL, 1 relapsed v-HCL, 11 relapsed c-HCL) included 12 male and 1 female patients with median age 64 years (range: 43-76) and median 4 (range: 1-11) prior therapies. All relapsed patients had received prior PA, 5 (45%) were splenectomized, and 9 (82%) had prior rituximab. The most frequent (>20%) grade 3/4 adverse events (AEs) included lymphopenia (37%), hypophosphatemia (30%), neutropenia (23%), and infection (23%). Common grade 1/2 AEs included myalgias (61%), headache (38%), dizziness (38%), diarrhea (38%), arthralgias (30%), rash (30%), and fatigue (30%). Other hematologic AEs included grade 1/2 anemia (38%) and grade 1/2 thrombocytopenia (38%). In general, response has improved with continued treatment (Table). One MRD-negative complete response (c-HCL) and 5 partial responses have been observed (ORR 46%). Four additional patients (30%) with stable disease have experienced clinical benefit not meeting criteria for PR and continue on treatment. At median follow-up of 14.5 months, 9 patients (69%) remain progression-free on treatment, 3 patients (1 v-HCL, 2 c-HCL) have progressed and 1 patient (c-HCL) discontinued in cycle 8 after failing to resolve baseline neutropenia. Redistribution lymphocytosis (peaking at day 8) occurred in both v-HCL patients and 1 c-HCL patient with circulating disease at baseline. sIL2R levels were increased at baseline in all c-HCL patients for whom data were available and normalized in responders.

Tabella 1.

Response Category	Best Response (n=13)	Post-Cycle 8 (n= 11)	Post-Cycle 12 (n=11)
CR	1	0	1
PR	5	5	5
SD	6	6	4
PD	1	0	1

Summary and Conclusions: Ibrutinib is well-tolerated and can induce remissions, including MRD-negative complete remission, in hairy cell leukemia patients. The correlation between sIL2R levels and response will be investigated further. Accrual continues to the second cohort.

S791

THE INTERNATIONAL PROGNOSTIC INDEX FOR PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL-IPI)-AN INTERNATIONAL META-ANALYSIS

Background: Chronic lymphocytic leukemia (CLL) is a disease with a highly heterogeneous course, ranging from mild to aggressive. Therefore, prediction of outcome is important in clinical practice to avoid too aggressive treatment in patients with a rather mild course of disease and to identify patients in whom standard treatment is likely to fail. In the era of more effective treatments for CLL, the established clinical staging systems [Binet/Rai] do not accurately discriminate between prognostic subgroups. Despite the introduction of several new prognostic markers, there is no system integrating the major clinical, biological and genetic variables into one widely accepted prognostic system.
Aims: To develop an internationally applicable prognostic index for CLL patients [CLL-IPI], we performed a comprehensive analysis of 26 prognostic factors including clinical, biological and genetic markers.
Methods: The data from 8 prospective randomized phase III trials from France, Germany, UK, USA and Poland comprised our full analysis set including 3472 previously untreated patients at early and advanced clinical stage with a median age of 61 years (yr) (range, 27 - 86) and a median observation time of 80 months. First line therapies included Fludarabine (F), F+Cyclophosphamide (FC), FC+Rituximab, FC+Campath, C+Cladribine, Chlorambucil and watch & wait. The full analysis set was randomly divided into training [2308 (67%)] and internal validation dataset [1164 (33%)]. Methods of multivariable survival statistics were applied including proportional-hazards Cox regression analyses. The main end point of all statistical analyses was overall survival (OS). Handling of missing data was performed with complete case analysis using a 4 step-down procedure accounting for the degree of completeness of data. *C*-statistics were calculated to evaluate the discriminatory value of the model (c=1 indicates perfect discrimination; c=0.5 is equivalent to chance). Subsequently, the model was externally validated in a third dataset comprised of 845 newly diagnosed CLL patients from Mayo Clinic [median age 62 yr (range, 25 - 89); 63 months median observation time].
Results: Based on 1192 (52%) patients from the training dataset, 5 independent predictors for OS were identified: age [cut off, 65 yr], clinical stage [Binet A/Rai 0 *vs.* Binet B-C/Rai I-IV], del(17p) and/or *TP53* mutation, *IGHV* mutation status (MS) and serum β2-microglobulin (B2M) [cut off, 3.5 mg/L]. Applying weighted grading of the independent factors based on the regression parameters, a prognostic index was derived separating 4 different risk groups [low (score 0-1), intermediate (score 2-3), high (score 4-6) and very high risk (score 7-10)] with significantly different OS [93%, 79%, 64% and 23% OS at 5 yr for the low, intermediate, high and very high risk group respectively, p<0.001; *C*-statistic c=0.724 (95% confidence interval (CI), 0.69-0.76)] (figure 1A). This multivariable model was confirmed on the internal validation dataset [575 (49%) patients; 91%, 80%, 52% and 19% 5-yr OS, p<0.001; c=0.777 (95% CI, 0.73-0.82)] (figure 1B). In the external Mayo dataset the 5-yr OS for the CLL-IPI risk groups were 97%, 91%, 68% and 21% [p<0.001; c=0.790 (95% CI, 0.74-0.85)] (figure 1C). Further, the CLL-IPI provided accurate estimation regarding time to first treatment within this cohort [81%, 47%, 30% and 19% patients free from treatment at 5 yr, p<0.001].

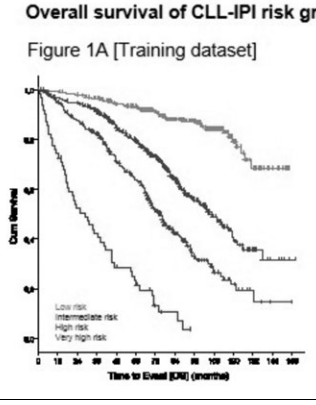

Figure 1A.

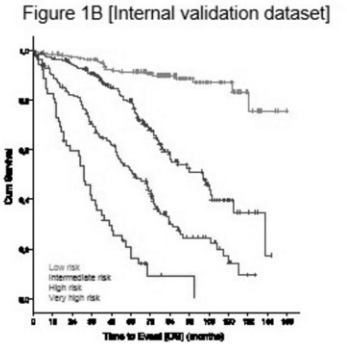

Figure 1B.

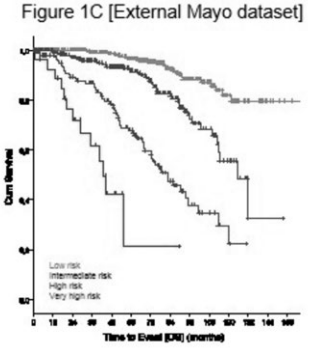

Figure 1C.

Summary and Conclusions: We report the development and validation of a weighted, integrated prognostic score and index derived from a broad number of established prognostic markers. The resulting CLL-IPI combines the most important genetic risk factors (*IGHV* MS, del(17p)/*TP53*) with traditional clinical stage, age, and B2M into an easily applicable prognostic index for CLL patients. Moreover, it both discriminates between prognostic subgroups and may help to inform current treatment recommendations in the future.

S792

THE LLR TAP ICICLLE TRIAL ASSESSING BIOLOGICAL RESPONSE TO IBRUTINIB IN CLL: IMMEDIATE DISEASE REDISTRIBUTION PRECEDES CELL CYCLE ARREST BY 2 WEEKS WITH REDUCED BONE MARROW INFILTRATION BY 6 MONTHS

A. Rawstron[1,*] T. Munir[1], S. Dalal[1], J. Thompson[1], C. Yap[2], K. Brock[2], F. Yates[2], E. Ogburn[2], C. Fox[3], D. MacDonald[4], C. Fegan[5], A. Bloor[6], P. Hillmen[7]
[1]St. James's Institute of Oncology, Leeds, [2]Cancer Research UK Clinical Trials Unit, Birmingham, [3]NHS Nottingham University Hospitals, Nottingham, [4]Imperial College at Hammersmith Hospital, London, [5]Cardiff and Vale UHB, Cardiff, [6]Christie Hospital NHS Trust, Manchester, [7]Leeds Insitute of Cancer and Pathology, Leeds, United Kingdom

Background: Ibrutinib is a Bruton's tyrosine kinase inhibitor with efficacy in CLL. The IcICLLe trial (ISRCTN 12695354) is a feasibility study to investigate the biological response to ibrutinib and inform the design of subsequent randomised phase II/III trial(s). Primary outcome measures include assessment of the CLL cell levels and protein expression profile, particularly in relation to cell cycle and other CLL treatment targets, in the peripheral blood (PB) and bone marrow (BM). Toxicity, categorical response and survival are secondary outcomes.
Aims: To understand the biological impact of ibrutinib treatment and identify changes that may impact the design of therapeutic strategies or affect disease monitoring.
Methods: 40 participants with CLL requiring treatment (20 treatment-naïve and 20 relapsed/refractory) received ibrutinib (420 mg once daily) from registration until either achievement of <0.01% residual disease in bone marrow or disease progression. PB & BM samples are taken -0.5 (screening), 1 & 6 months with additional PB samples at 0 (baseline), 4 hours, 1, 2, 7, & 14 days and 2, 9, & 12 months (M). Markers assessed at each time point include CD19, CD20, CD45, CD5, CD10, CD305, kappa, lambda, CD23, CD43, CD81, CD79b, ROR1, CXCR4, CD49d, Ki67, CD62L, and CD38 with an additional 30 markers (including BCL2, ZAP-70 and IRF4) samples with paired PB & BM.
Results: Absolute peripheral B-cell counts increased immediately after the first dose, peaking at two weeks, and returning to baseline by month 2 (median 1.25, 1.44, 2.1, 1.19 fold absolute B-cell count relative to baseline at 4hrs,

24hrs, 2 weeks and 2 months after first dose respectively). There was no difference in bone marrow infiltration after 1 month of treatment but after 6 months, 7/8 evaluable patients had more than 50% reduction in PB CLL counts relative to baseline and bone marrow involvement was reduced with 3/8 achieving <30% BM CLL and 1 treatment-naïve patient achieving a CR. The proportion of CLL cells expressing Ki67 at baseline was slightly lower in the peripheral blood (median 3.5%, range 0.3-22.3%) than the bone marrow (median 3.9%, range 0.8-42%) but the difference was not significant and blood was a suitable site for assessing proliferative capacity. Ki67 expression initially increased, peaking at 24 hours after first dose (PB CLL Ki67+median 5.1%, range 0.4-16.4%), after which the Ki67 expression declined below quantifiable levels (<0.5%) in 15% of patients by week 1 and in more than 90% of patients at subsequent time points. Similarly in the BM, CLL Ki67 expression was not detectable in most patients after 1 month of treatment. Other changes in protein expression during treatment, including decreases in markers associated with proliferation in CLL (CD5, CD23, CD38, CD49d and IRF4), and changes in molecules involved in CLL cell trafficking and adhesion (increased CXCR4 and CD24 expression; decreased CCR7, CD31 and CD11a) followed the same kinetics as cell cycle arrest, *i.e.* differences emerged after 1-2 weeks of treatment and then stabilised during subsequent treatment. Concerning molecules involved in disease monitoring, CD19, CD5 & CD43 expression were mildly reduced but overall expression remained strong; CD81/CD79b expression did not change significantly; CD20/CD22 expression decreased, potentially enhancing discrimination from normal B-cells but this may affect optimal timing of anti-CD20 therapy; CD200 expression was also consistently decreased and these changes need to be considered when assessing residual disease levels.
Summary and Conclusions: The redistribution of CLL cells during ibrutinib therapy happens much more rapidly than any changes in proteins associated with proliferation, cell trafficking or adhesion. The majority of changes in CLL cells correlate with the loss of the proliferative fraction, mostly stabilising after one month of treatment.

S793

OVERALL SURVIVAL ANALYSIS ADJUSTING FOR TREATMENT EFFECT AFTER CROSSOVER IN A PHASE 3 STUDY EVALUATING IDELALISIB IN COMBINATION WITH RITUXIMAB IN RELAPSED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

P. Ghia[1,*] P. Hillmen[2], Y. Kim[3], O. Gurtovaya[3], D. Li[3], T. Jahn[3], R. Perard[4], B. Coiffier[5]
[1]Università Vita-Salute San Raffaele and Istituto Scientifico San Raffaele, Milano, Italy, [2]The Leeds Teaching Hospitals, St. James Institute of Oncology, Leeds, United Kingdom, [3]Gilead Sciences, Foster City, United States, [4]Gilead Sciences Europe, Uxbridge, United Kingdom, [5]Lyon Sud University Hospital, Pierre-Bénite, France

Background: A Phase 3 trial evaluated idelalisib (IDELA)+rituximab (R) *vs* placebo (PBO)+R in patients (pts) with relapsed CLL (Furman, NEJM, 2014). Using an extension study design, pts on the control arm were allowed to receive IDELA after progression (PD). Estimating the true overall survival (OS) benefit of the active arm of randomized studies with such a crossover design represents a challenging statistical problem. Intent-to-treat (ITT) analyses considering data from pts after crossover as well as the approach of censoring subjects at the time point of crossover may significantly underestimate the OS benefit. Alternative analysis approaches like the rank-preserving structural failure time (RPSFT) model (Robins, 1991; Ishak, 2014) have successfully been used to estimate the true treatment effect in similar trials designs with crossover.
Aims: Estimate the treatment effect in OS adjusted for the impact of crossover
Methods: Three methods of OS analysis were compared (data cut-off date 01July2014): 1) ITT analysis calculating the OS according to initial randomization including data after crossover (as pre-specified), 2) Censoring subjects at the time point of crossover, and 3) RPSFT. Methods 1 and 2 commonly underestimate the true OS benefit. The RPSFT model estimates the counterfactual event time of the control arm that would have been observed without crossover and provides the estimate of treatment effect adjusted for the impact of crossover.
Results: 110 pts were randomized to each arm. 38% (n=42) of pts on PBO+R crossed over to receive single-agent IDELA following PD according to the initial study design. An additional 40% (n=44) of subjects on PBO+R crossed over to receive idelalisib in the absence of prior PD according to an amended protocol after the study was stopped due to overwhelming PFS efficacy. The median follow-up for the presented analyses was 12.5 months (mos) for pts initially on IDELA+R and 11.1 mos for PBO+R. There were 17 deaths in the IDELA+R group, and 40 deaths in the PBO+R group. Analysis results from each method are presented in the table below:

Tabella 1.

Method	HR (95% CI*)	Median OS (95% CI) in mos		p-value
		IDELA + R	PBO + R	
ITT	0.34 (0.19, 0.60)	NR (NR, NR)	20.8 (14.8, NR)	0.0001
Censoring at crossover	0.43 (0.20, 0.95)	NR (NR, NR)	NR (NR, NR)	0.0332
RPSFT	0.20 (0.10, 0.36)*	NR (NR, NR)	11.6 (8.2, NR)	<0.0001

NR=Not Reached; *95% CIs for hazard ratios were estimated by bootstrap method

Summary and Conclusions: IDELA+R demonstrated significant and consistent improvement in OS regardless of the analysis method. The median OS and HR as estimated by the RPSFT model reduced the bias associated with the idelalisib treatment effect compared to the ITT analysis or the censoring approach.

S794

BONE MARROW IS MORE SENSITIVE THAN PERIPHERAL BLOOD FOR DETECTION OF MRD IN CLL AND PROVIDES A MORE RELIABLE PREDICTION OF OUTCOME ACROSS DIFFERENT TREATMENTS

A. Rawstron[1,*] D. Cohen[2], R. de Tute[1], L. McParland[2], L. Collett[2], D. Phillips[2], A. Chalmers[2], A. Varghese[1], T. Munir[1], W. Gregory[2]P,. Hillmen[3]
[1]St. James's Institute of Oncology, [2]Clinical Trials Research Unit, [3]Institute of Cancer and Pathology, Leeds, United Kingdom

Background: Minimal residual disease (MRD) in CLL is an independent predictor of progression-free (PFS) and overall survival (OS) with a high, intermediate and low risk of disease progression seen in patients with >1%, 0.01-1%, or <0.01% MRD respectively. Evaluating novel treatments currently requires assessment of PFS/OS in randomised controlled trials but the prolonged duration of remission means that this approach is slow. Assessing MRD as a trial endpoint could greatly speed the process; using peripheral blood (PB) would be preferable but antibody therapies preferentially deplete circulating disease to a variable extent and bone marrow (BM) is the more sensitive site for MRD detection.
Aims: To compare PFS/OS according to MRD level in PB and BM for different treatment and patient groups and determine the optimum site for MRD assessment.
Methods: MRD was quantified using multi-parameter flow cytometry according to ERIC consensus protocols with a limit of quantification of 10-4 / 0.01% or better.
Results: The MRD level in 609 paired PB & BM samples taken during or within 6 months of treatment (446 in clinical trials, see table) was concordant in 443 (72.7%) at MRD thresholds <0.01% / 0.01-1% / >1%. In 391 cases with <0.01% PB MRD, 85/391 (21.7%) had 0.01-1% CLL and 14/292 (3.6%) had >1% CLL in the paired BM sample. In 118 cases with 0.01-1% CLL in the PB, the paired BM sample showed >1% CLL in 63/118 (53.4%). The PB MRD level would have assigned a higher risk category than BM in only 4 cases, all of which had detectable BM disease. Discrepancies between PB & BM MRD levels were not consistent across treatment and patient groups. Refractory patients treated with alemtuzumab-based therapies typically showed a high proportion of discrepant results with >1 log differences while patients in CR/PR receiving alemtuzumab consolidation had few discrepancies; during Ibrutinib monotherapy (IcICLLE trial) there have been no discordant cases to date. To determine whether discrepant results impact on outcome, PFS/OS was evaluated according to PB & BM MRD in different trials. In the ADMIRE/ARCTIC trials, PB & BM MRD levels were discordant in 66/312 evaluable cases, all with ≥0.01% BM but <0.01% PB MRD. After a median follow-up of 3 years, MRD level was confirmed as a strong predictor of PFS and OS, independent of categorical response, with the presence of ≥0.01% MRD conferring a significantly poorer outcome (PFS: HR 4.6, 95%CI 2.7 to 7.7, p=<0.001). For patients in CR, and with ≥0.01% MRD (n=70), 3 year PFS was 68.7% compared with 86.6% for patients with <0.01% MRD (n=176). There was no observable difference in the PFS or OS for patients with <0.01% PB but ≥0.01% BM MRD compared to those with <0.01% PB & BM MRD. However, for those patients with MRD detected in the BM only, there was a median of 0.08% CLL and this would be predicted to yield observable differences in PFS only after >3 years follow-up. The results contrast with the outcome for 47 evaluable patients in the CLL202 CAMFlud trial where patients with <0.01% MRD in PB but ≥0.01% disease in BM had a poor outcome that was similar to those with ≥0.01% in both PB & BM, and both groups had significantly poorer PFS/OS than patients with <0.01% MRD in both PB & BM (with median 55 months follow-up for patients with ≥0.01% in PB & BM / <0.01% PB but ≥0.01% BM / <0.01% MRD in both PB & BM patients respectively, median PFS was 1.6 / 6.5 / 44.7 months and OS was 7.5 / 14 / not reached, P<0.001).

Tabella 1.

						Discrepant results between PB and BM (% of total paired samples)			
Trial	Situation	Treatment	Patients	Final MRD assesment	Paired PB & BM samples	All discrepant cases	PB <0.01% BM >1%	PB<0.01% BM 0.01-1%	PB 0.01-1% BM >1%
CLL 201	Relapsed refractory	FCM ±R	52	3 months post-treatment	14	1 (7.1%)	0 (0%)	0 (0%)	1 (7.1%)
CLL 202 CAMFlud	Relapsed refractory	Alemtuzumab and Fludarabine	50	End of treatment	46	18 (39.1%)	5 (10.9%)	4 (8.7%)	9 (19.6%)
CLL 207	Consolidation in CR/PR	Alemtuzumab	47	End of treatment	49	7 (14.3%)	0 (0%)	7 (14.3%)	0 (0%)
IcICLLe	All patients	Ibrutinib	40	End of treatment	18	0 (0%)	0 (0%)	0 (0%)	0 (0%)
MO20927	Untreated, less fit	Chlorambucil Rituximab	100	3 months post-treatment	7	4 (57.1%)	1 (14.3%)	1 (14/3%)	2 (28.6%)
ADMIRE & ARCTIC	Untreated, fit	FCR, FCMR or FCM-miniR	415	3 months post-treatment	312	85 (27.2%)	2 (0.6%)	64 (20.5%)	19 (6.1%)

Summary and Conclusions: Patients achieving <0.01% CLL have a better outcome than those with detectable MRD but the power of peripheral blood MRD eradication to predict outcome varies widely according to the type of therapy received and is poor with more potent antibodies. The most robust tissue and time-point for MRD assessment to predict long-term outcomes in CLL is the bone marrow at 3 months post-treatment. Our work justifies the use of MRD eradication from the marrow post-treatment as a surrogate end-point in clinical trials.

AML: Molecular profile and targeting

S795

COMPREHENSIVE GENOMIC PROFILING OF A LARGE COHORT OF ACUTE MYELOID LEUKAEMIA TO DISSECT ITS GENOMIC AND PHENOTYPIC COMPLEXITY

E. Papaemmanuil[1,*] M. Gerstung[1], R. Schlenk[2], L. Bullinger[2], P. Paschka[2], G. Verena[2], N. Bolli[1], V. Teleanu[2], C.H. Köhne[3], G. Held[4], P. Brossart[5], M. Ringhoffer[6], H. Background: The characterization of recurrent chromosomal abnormalities in AML has paved the way for the incorporation of genetic lesions into clinical diagnostics and prognostication tools. However, clinical outcomes vary greatly and in the absence of informative lesions, a large proportion of patients are given an intermediate risk score. Recent profiling studies have characterized >50 recurrently mutated genes in AML. Considering the multitude of gene candidates, evaluations of the AML genomic landscape and its relationship to clinical trajectory must extend beyond single/few biomarkers studies and, importantly, involve large well-annotated datasets.
Aims: We sought to comprehensively evaluate the known driver mutations in AML; study molecular phylogenies that underpin AML transformation, and investigate how the composite genetic architecture determines phenotype and correlates to clinical response.
Methods: We study 1540 adult AML patients from three clinical trial cohorts of the AML-SG (HD98A, HD98B and 07-04) using a targeted re-sequencing approach. Taken together with cytogenetic analysis we identify 5,241 driver variants across 55 genes and 23 recurrent cytogenetic alterations. We incorporate these to diagnostic and clinical outcome data (median follow-up=2169 days), perform classification analysis to determine molecular subgroups, and apply variable selection models to characterize prognostic biomarkers.
Results: We find at least 1 driver mutation in 97% patients in the study, and importantly at least 2 in 85%. There was a long tail of infrequently mutated driver genes, with only 30% of the events seen in >10% of patients. The number of drivers increases with age and patients with normal karyotype have more mutations than patients with cytogenetic abnormalities. Using the fraction of reads reporting a gene mutation to distinguish subclonal from clonal mutations, we identify 690 samples with at least 2 driver mutations and subclonal heterogeneity and map recurrent preferences in order of mutation acquisition. We survey the composite genomic architecture and define 10 classes, which are broadly defined by inv(16); t(8;21), t(var;11q23), inv(3), t(6;9), bi-allelic CEBPA, NPM1/DNA hydroxymethylation, TP53/aneuploidies, chromatin/spliceosome and DNMT3A/IDH2 mutations, and collectively account for 85% of patients. The definition of each class extends beyond a single lesion and is rather determined by class-specific initiating events and co-operative lesions that are ordered in time. Many of these interactions extend to mutation clusters or hotspots within genes as evidenced by pairings between FLT3 TKD/ITD, NRAS c.12-13/c.61, IDH2 c.140/c.172 and CEBPA mono/bi-allelic mutations. As expected, evaluation of clinical phenotype and outcome associations identifies broad correlations between class, phenotype, response to induction chemotherapy and overall survival. Strikingly, we find that specific molecular contexts within each class (as defined by secondary and tertiary interactions) correlate with distinct and often opposing outcome trajectories and clinical phenotype ranging from excellent to highly adverse clinical outcomes. These relationships are underpinned by models of additive risk or suggestive of genetic epistasis. Using overall survival as a primary endpoint we evaluate the known landscape of driver mutations, and genetic interactions. We derive a comprehensive set of significant factors and identify at least three genetic interactions that retain significance ($q<0.01$) in the presence of other clinical and demographic variables. Importantly we identify at least one prognostic predictor in 70% of the patients and observe a three-fold increase in patients with 2 or 3 prognostic predictors relative to current molecular prognostication guidelines.
Summary and Conclusions: Taken together, we study an extended and well-annotated clinical cohort we demonstrate the potential of recent genetic findings to deliver improved classification and risk stratification algorithms that extend beyond single biomarker correlations, capture most AML patients and that are tailored to the individual patients genomic profiles.

S796

AKT PHOSPHORYLATION AT SERINE 473 IS A POWERFUL NOVEL BIOMARKER IN ACUTE MYELOID LEUKAEMIA, AND IS RELATED TO PROTEIN PHOSPHATASE 2A (PP2A) INHIBITION BY CIP2A AND SETBP1

C. Lucas[1], N. Carmell[1], L. Scott[1], A. Holcroft[1], R. Hills[2], R. Clark[1,*]
[1]Haematology, University of Liverpool, Liverpool, [2]Institute of Translation, Innovation, Methodology & Engagement, Cardiff University School of Medicine, Cardiff, United Kingdom

Background: Many malignancies are characterised by inappropriate substrate phosphorylation which causes aberrant proliferation and decreased apoptosis; this is often due to an overactive kinase *e.g.* BCR-ABL or FLT-3 in myeloid malignancy, or ERK or ErbB2 in solid tumours. What is less clear is why this effect is not simply countered by normal cellular phosphatases, of which the most important is protein phosphatase 2A (PP2A). PP2A is normally inhibited by SET, (which is stabilised by a binding protein SETBP1) and cancerous inhibitor of PP2A (CIP2A). We have shown that high CIP2A levels confer a poor outcome in chronic myeloid leukaemia (similar to findings in many solid tumours), and also that high CIP2A levels are associated with stabilisation of c-Myc and E2F1, as well as PP2A inactivation in CML. There are also data to suggest that high SETBP1 levels may confer a poor outcome in AML, presumably by PP2A inhibition via increased action of SET, though little is known of CIP2A in AML.
Aims: To investigate if CIP2A or network related proteins could predict clinical outcome in AML patients.
Methods: CIP2A and PP2A related proteins were investigated in 120 AML patient samples collected in the UK MRC/NCRI trials AML15, 16 and 17. These were stratified into intermediate or adverse risk, based on cytogenetics as previously defined (Grimwade *et al*, Blood. 1998: 92; 2322-33). Protein levels were studied in diagnostic mono-nuclear cells samples by flow cytometry. CIP2A levels in individual samples were then defined as either high or low based on receiver-operator characteristics analysis as previously described.
Results: Diagnostic CIP2A levels were significantly higher in younger intermediate than in adverse risk patients (p=0.004). In the intermediate risk group, overall survival was dominated by the survival from relapse. High diagnostic CIP2A was associated with high levels of c-Myc (p=0.003), inactive PP2A ($PP2A^{Y307}$, p=0.04) and activation of AKT as identified by its phosphorylation on serine 473 (AKT^{S473}) (p=0.0009). Interestingly, high diagnostic CIP2A was strongly associated with the presence of a FLT3-ITD mutation (p=0.009). For younger intermediate risk patients with high and low CIP2A levels, median survival from relapse censored at transplant was 56 days and 303 days respectively, and multivariate analysis adjusted for FLT3-ITD showed that a high CIP2A level predicted inferior survival from relapse (p=0.04, hazard ratio 4.02). Rates of high levels of CIP2A were lower in adverse risk patients but instead we found elevated levels of SETBP1, which acts via SET as an alternative inhibitor of PP2A. In younger patients with adverse cytogenetics, high SETBP1 levels predict for an inferior overall survival (p=0.02). High SETBP1 was also associated with secondary AML (p=0.06). In univariate analysis, high levels of AKT^{S473}were associated with poor survival in all patient groups. Multivariate analysis of known predictors of outcome (age, cytogenetics, white count, secondary leukaemia, FLT3-ITD) together with CIP2A and related proteins ($PP2A^{Y307}$, SET, SETBP1, c-Myc E2F1, AKT^{S473}, STAT5, and E2F1) was used to derive a prognostic model for survival. This ranked high levels of AKT^{S473} as the third most important predictor of outcome after age and cytogenetics.
Summary and Conclusions: AKT phosphorylation at S473 is a surrogate 'readout' of PP2A inhibition by either CIP2A (intermediate risk) or SETBP1 (adverse risk patients). The diagnostic AKT^{S473} level appears to be a novel biomarker for treatment outcome in AML. This should now be tested prospectively as part of a clinical trial.

S797

ASSOCIATION OF MIR29 RNA WITH RESPONSE AND SURVIVAL IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) TREATED WITH AZACITIDINE (AZA) OR CONVENTIONAL CARE REGIMENS (CCR)

K.J. MacBeth[1,*] L. Tang[1], J.F. Seymour[2], R.M. Stone[3], M.D. Minden[4], L.M. Lucy[1], C. Beach[1], H. Döhner[5]
[1]Celgene Corporation, Summit, United States, [2]Peter MacCallum Cancer Centre, East Melbourne, Australia, [3]Dana-Farber Cancer Institute, Boston, United States, [4]Princess Margaret Cancer Centre, Toronto, Canada, [5]Universitätsklinikum Ulm, Ulm, Germany

Background: DNA methyltransferases (DNMTs) mediate DNA methylation and contribute to epigenetic aberrancy in myeloid malignancies. The miR29 family of microRNAs directly inhibit the expression of DNMT-3A and -3B (Fabbri, *PNAS*, 2007). In a small study (N=23) of older patients (pts) with AML, higher levels of miR29b were significantly associated with response to decitabine (Blum, *PNAS*, 2010). The large (N=488) phase 3 randomized AZA-AML-001 study compared AZA and CCR treatment (Tx) in older pts with AML. AZA prolonged median overall survival (OS) by ~4 months (mos) (10.4 *vs* 6.5 mos; p<0.101) and improved 1-year survival (46.5% *vs* 34.2%) *vs* CCR (Dombret, EHA, 2014).
Aims: To investigate the relationship between miR29 family RNA levels and clinical endpoints (response and OS) in AZA-AML-001 pts.
Methods: Eligible pts were age ≥65 years with newly diagnosed AML (>30% bone marrow [BM] blasts) and had ECOG PS of 0-2, WBC count ≤15x10^9/L, and intermediate- or poor-risk cytogenetics. Pts received AZA (75mg/m^2/day [d] x7d/28d cycle) or a preselected CCR: intensive chemotherapy (standard 7+3 regimen), low-dose cytarabine (20mg SC BID x10d/28d cycle), or best supportive care only. RNA was isolated from BM mononuclear cells collected at screening from a subset of pts who gave informed consent for this exploratory biomarker analysis and had adequate BM mononuclear cells for analysis. Experimental miRNAs (miR29a, b, c) and control RNAs (RNU44, miR-16) were quantified by qRT-PCR. Associations between miR levels and response (IWG 2003) were assessed, defining responders as pts who achieved complete remission (CR) or morphologic CR with incomplete blood count recovery (CRi), and nonresponders as pts with partial response (PR), stable disease (SD), or progressive disease (PD) as their best response. Differences in baseline miRNA expression were compared by T-test within the AZA and CCR Tx arms. A 2-way ANOVA model was used to test the interaction between miR expression and Tx. miR expression as a continuous variable was also fit in a Cox model with and without strata in separate arms.
Results: The biomarker cohort comprised 156 of all 488 pts (32%; AZA n=83, CCR n=73). Baseline characteristics were well-matched in the biomarker *vs* non-biomarker groups, respectively, with median age 75 years in both groups, median BM blasts 50.5% *vs* 52.0%, and cytogenetic risks of intermediate 63.8% *vs* 66.5%, and poor 36.3% *vs* 33.5%. Baseline miR29a and miR29b expression levels were significantly higher in responders (CR+CRi) *vs* nonresponders (PR+SD+PD) with AZA Tx (p<0.004 & p<0.029, respectively), but not with CCR Tx (**Figure**). This difference for miR29a was confirmed in the 2-way ANOVA analysis of response and Tx (p<0.054). miR29a levels were also associated with OS (p<0.044) in the AZA arm, but not in the CCR arm, in stratified survival analysis. No significant associations between miR29b or miR29c levels and OS were seen in either Tx arm.

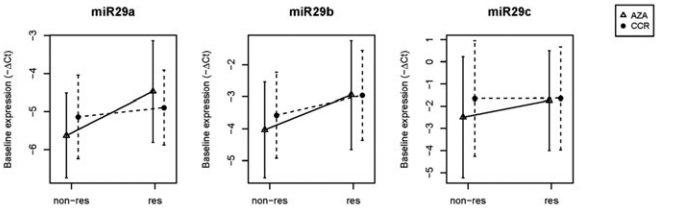

Figure 1. miR29a, b, c RNA expression levels (mean ±SD) in responders *vs* nonresponders.

Summary and Conclusions: In this exploratory analysis, higher expression levels of miR29a and miR29b were significantly associated with response to AZA Tx, and the association of miR29a levels with response was specific to AZA. Higher miR29a levels were also associated with improved OS in pts treated with AZA, but not in pts treated with CCR. As miR29a is implicated in regulating DNMT levels, an AZA target, these data are consistent with the concept that reduced pretreatment DNMT levels due to higher miR29a expression can improve response and survival with hypomethylating agents.

Background: FMS-like tyrosine kinase-3 (FLT3) mutations, including internal tandem duplication (ITD) and tyrosine kinase domain (TKD) mutations, are present in acute myeloid leukemia (AML) cells in up to 30% of patients. FLT3 inhibitors have shown promise as a therapeutic option for AML patients with

FLT3 activating mutations. *in vitro* analyses suggest that ASP2215 is a potent inhibitor of FLT3 and AXL tyrosine kinases and demonstrates activity against both FLT3-ITD and FLT3-TKD.
Aims: A Phase 1/2 trial investigated the safety, pharmacokinetics (PK), and clinical efficacy of ASP2215 in patients with relapsed or refractory (R/R) AML.
Methods: This open-label, first-in-human study, conducted in patients ≥18 years old with R/R AML, included 2 cohorts: dose escalation (Cohort 1) and dose expansion (Cohort 2). Cohort 1 was a modified 3+3 with accelerated titration design that evaluated ascending oral doses of ASP2215 (20–450 mg). Cohort 2 was a parallel multi-dose expansion cohort that was initiated based on the efficacy observed during dose escalation and patients were stratified by FLT3 mutation status. The primary endpoints included determination of the maximum tolerated dose (MTD) and the PK profile; clinical efficacy and FLT3 phosphorylation were evaluated as secondary endpoints. All patients provided informed consent. Data from an interim analysis are presented.
Results:: A total of 166 patients (Cohort 1, n=25; Cohort 2, n=141) with a median age of 64 years (range: 21–90) were enrolled between October 2013 and December 2014. ASP2215 MTD was determined to be 300 mg after 2 out of 3 patients dosed with ASP2215 treated at 450 mg experienced dose-limiting toxicities (grade 3 diarrhea and ALT/AST elevation). Plasma concentrations of ASP2215 increased with increasing dose, with t_{max} between 2 and 6 hours. Accumulation was observed following repeat dosing, with estimated $t_{1/2}$ values of 45 to 159 hours based on accumulation index. Approximately dose-linear PK parameters were observed over the dose range for both single and repeat dosing. Fatigue (13%), constipation (10%), anemia (8%), nausea (8%), diarrhea (7%), thrombocytopenia (6%), decreased platelet count (6%), vomiting (6%), dizziness (6%), peripheral edema (5%), increased transaminases (5%), and hypomagnesemia (5%) were the most commonly reported treatment-emergent adverse events considered "possibly" or "probably" related to drug. Further, no incidents of clinically significant QTc prolongation have been reported. Overall response rate (ORR, defined by composite complete and partial remissions) in patients with FLT3 mutations was 57% at doses between 20 and 300 mg, and 65% at doses of ≥80 mg; a lower ORR (11%) was observed in patients with wild type FLT3 (Table). In patients receiving doses ≥80 mg, a plasma inhibitory activity assay confirmed effective, consistent, and sustained FLT3 inhibition.

Tabella 1.

Response	FLT3 mutated		
	20–300 mg	≥80 mg	20–300 mg
	n=82	n=65	n=38
CR	4 (5%)	3 (5%)	0
CRp, incomplete platelet recovery	4 (5%)	4 (6%)	0
CRi, incomplete hematologic recovery	27 (33%)	25 (38%)	3 (8%)
PR	12 (15%)	10 (15%)	1 (3%)
Composite CR (CR+CRp+CRi)	35 (43%)	32 (49%)	3 (8%)
ORR (CRc+PR)	47 (57%)	42 (65%)	4 (11%)

All data presented as n (%).
Of the 166 enrolled patients, 120 patients (n=82 FLT3 mutations; n=38 FLT3 wild type) had evaluable efficacy data.
Abbreviations: CR, complete remission; CRc, composite complete remission; CRi, complete remission with incomplete hematologic recovery; CRp, complete remission with incomplete platelet recovery; ORR, overall response rate.

Summary and Conclusions: ASP2215, a potent oral inhibitor of FLT3/AXL, was well tolerated at doses of 20–300 mg/d in patients with R/R AML and showed a high degree of clinical activity in patients with FLT3-ITD and/or FLT3-TKD mutations. ASP2215 demonstrated a predictable PK profile consistent with once-daily dosing. Randomized phase 3 trials of ASP2215 dosed at 200 mg in newly diagnosed and R/R AML are planned.

S799

UPDATED RESULTS FROM THE SORAML TRIAL COMPARING SORAFENIB VERSUS PLACEBO IN ADDITION TO STANDARD THERAPY IN YOUNGER PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

Background: Sorafenib is a multi-kinase inhibitor with activity against several oncogenic kinases that may play a role in the pathogenesis of acute myeloid leukemia (AML). We present updated results from the randomized placebo-controlled SORAML trial (NCT00893373) testing sorafenib versus placebo as add-on to standard treatment in AML patients ≤60 years.
Aims: The data focus on treatment adherence, efficacy in cytogenetic subgroups and relapse pattern.
Methods: The trial enrolled 276 patients with newly diagnosed AML from 18 to 60 years and suitable for intensive therapy. The treatment plan for all patients included two cycles of induction with DA (daunorubicin 60 mg/m^2 days 3-5 plus cytarabine 100 mg/m^2 cont. inf. days 1-7) or HAM (cytarabine 3 g/m^2 b.i.d. days 1-3 plus mitoxantrone 10 mg/m^2 days 3-5), followed by three cycles of high-dose cytarabine consolidation (3 g/m^2 b.i.d. days 1, 3, 5). Allogeneic stem cell transplantation (SCT) was scheduled for all intermediate-risk patients in first complete remission (CR) with a sibling donor and for all high-risk patients with a matched related or unrelated donor. Patients were randomized to receive either sorafenib (800 mg/day) or placebo as add-on to standard treatment in a double blinded fashion. Study medication was given on days 10-19 of DA I+II or HAM, from day 8 of each consolidation until 3 days before the start of the next consolidation and as maintenance for 12 months after the end of consolidation.
Results: Out of 276 enrolled patients, 267 received study treatment, 134 in the sorafenib arm and 133 in the placebo arm. Demographic and disease characteristics were equally distributed between the two arms; the incidence of FLT3-ITD was 17%. Toxicity-related drop-outs were slightly more frequent in the sorafenib arm with 32% *vs* 25% of patients commencing maintenance. After a median observation time of 36 months, the median EFS was 9.2 months in the placebo arm and 20.5 months in the sorafenib arm (p=0.013). Induction mortality was 4% in both arms, but cumulative incidence of relapse was significantly higher in the placebo arm. Subgroup analyses on EFS suggest a beneficial effect of sorafenib already after induction treatment. In multivariate analysis, sorafenib exposure, favorable cytogenetics and NPM1 mutation were associated with superior EFS whereas FLT3-ITD remained a negative prognostic factor. Median RFS after standard treatment plus placebo was 23 months and not yet reached after sorafenib treatment (p=0.017). The median OS had not been reached in either arm; the 3-year OS was 56% with placebo versus 63% with sorafenib (p=0.382). More placebo patients (N=66; 50%) than sorafenib patients (N=39; 29%) received a SCT in relapse due to more and earlier relapses with placebo, whereas relative SCT rates among relapses were similar (sorafenib: 75%; placebo: 82%). Detailed subgroup analyses will be presented. The risk for fever, diarrhea, bleeding events, liver toxicity, hand-foot syndrome and rash was significantly higher in the sorafenib arm.
Summary and Conclusions: In younger AML patients, the addition of sorafenib to standard therapy is associated with significant EFS and RFS prolongation independent of FLT3-ITD status. After the current follow up, the RFS benefit does not translate into an OS benefit, most likely due to potent salvage strategies mainly based on SCT. Ongoing data collection on salvage treatments, second CR and molecular profiling plus additional follow up will contribute to further explain the mechanism of action of sorafenib in younger AML patients.

Stem cell transplantation: Clinical 3

MONOTHERAPY TREATMENT WITH A SINGLE DOSE OF THE CXCR4 ANTAGONIST BL-8040 AS A NOVEL METHOD FOR MOBILIZATION OF HUMAN HSPC AND MSC; RESULTS OF A PHASE I HEALTHY VOLUNTEERS STUDY

Y. Pereg[1,*] M. Abraham[2], B. Bulvik[2], O. Eizenberg[2], R. Golan[1], A. Vainstein[1], A. Aharon[1], Y. Caraco[3], R. Or[4], A. Peled[5]
[1]BioLineRx Ltd., Jerusalem, [2]Biokine Therapeutics Ltd, Ness Ziona, [3]Clinical Pharmacology Unit, [4]Cancer immunotherapy and immunobiology research center, Hadassah University Hospital, Jerusalem, [5]Biokine Therapeutics Ltd and Hebrew University Hospital, Ness Ziona, Israel

Background: Hematologic malignancies often require hematopoietic cell transplantation (HCT). Randomized trials demonstrated the advantages of hematopoietic stem/progenitor cells (HSPC) mobilized from the peripheral blood (PB) compared to bone marrow (BM) for HCT. The most commonly used mobilization regimen utilize G□CSF (-/+Plerixafor), which requires 4-5 treatment days and often involves several apheresis sessions. In addition, the graft composition; CD34+, mesenchymal stem cells (MSCs), NK and T cell subsets may influence recipient outcomes in terms of engraftment, anti-tumor activity, GVHD, morbidity and mortality. BL-8040 (BKT140) is a novel CXCR4 antagonist that binds the receptor with high affinity and long receptor occupancy. Studies in mice demonstrated that single BL-8040 injection mobilized long term repopulating cells sufficient for transplantation. Results from a study in multiple myeloma patients showed that BL-8040 when combined with G-CSF enabled the collection of high number of CD34+cells in a single aphaeresis procedure. The potential of BL-8040 monotherapy as a mobilizing agent and its derived graft composition and quality is currently evaluated in a phase I clinical study in healthy volunteers (NCT02073019).
Aims: To test the potential of BL-8040 monotherapy as a mobilizing agent and its derived graft composition and quality.
Methods: The first part of the study was randomized, double-blind, placebo-controlled dose escalation. Each cohort included 8 subjects in a 6+2 design (0.5, 0.75 and 1 mg/kg). After obtaining informed consent, BL-8040 was administered SC QD on 2 consecutive days. Frequent PB samples were tested for the number of WBC, CD34+, B, T, and NK cells, MSC, MSC colony forming cells and HPCs colony forming cells. In the second part, 8 subjects are receiving single injection of BL-8040 (1mg/kg) and 4 hours later undergo a standard leukapheresis (18 L) procedure. The composition of the collected graft is being tested for the number of CD34+cells per kg, number and type of MSCs per kg, number and type of T, B, NK and dendritic cells.
Results: BL-8040 was found safe and well tolerated at all doses tested (0.5-1 mg/kg). The primary treatment related AEs were mild to moderate transient injection site and systemic reactions. BL-8040 triggered substantial mobilization of WBC to the circulation. The mean WBC count, of all patients receiving BL-8040, rose from a baseline of 6.3 to 29.7 X 10^9/L at 4 hr post dose. Dramatic mobilization of HSPC (CD34+cells) was observed across all doses tested. Mean CD34+count at baseline was 5.8/μL; four hours post dose, the count rose to a mean of 8, 37, 31 and 35 cells/μL and four hours post the second dose of BL-8040, it further increased to 9, 38, 46 and 58 cells/μL (placebo, 0.5, 0.75 and 1 mg/kg, respectively). BL-8040 administration resulted in rapid mobilization of MSC and HPC colony forming, T, B and NK cells. Preliminary results from the second part of the study indicate the potential to collect sufficient amount of CD34+cells following single apheresis session. Long receptor occupancy and long pharmacodynamic effect (≥24 hours post dosing) were also observed.
Summary and Conclusions: The current data demonstrate that BL-8040 is safe and well tolerated and induces rapid mobilization of HSPC and MSC. These results support BL-8040 monotherapy as an effective strategy to shorten the procedure length required to collect sufficient cells for HCT. In addition, treatment with BL-8040 is expected to yield a potent hematopoietic graft with unique cells composition and may also serve as a novel approach to collect MSCs for diverse indications. The final study results will be presented.

IMMUNOMODULATORY EFFECT OF VITAMIN D AFTER ALLOGENEIC STEM CELL TRANSPLANTATION (ALLOSCT): RESULTS OF A PROSPECTIVE MULTICENTER CLINICALTRIAL. ALOVITA; EUDRACT: 2010-023279-25

T. Caballero Velázquez[1], I. Montero Cuadrado[1], F. Sánchez Guijo[2], R. Parody Porras[1], D. Valcárcel[3], O. López Godino[2], C. Ferra i Coll[4], R. Saldaña Moreno[5], M. Jurado[6], M. Cuesta[7], F. Márquez Malaver[1], A. Carrillo Vico[8], L.I. Sánchez-Abarca Bernal[2], L. López Corral[2], J.A. Pérez-Simón[1,*]
[1]Hematología y Hemoterapia, Hospital Universitario Virgen del Rocío, Institute of Biomedicine of Seville (IBiS), CSIC, Universidad de Sevilla, Sevilla, [2]Hematología y Hemoterapia, IBSAL-Hospital Universitario de Salamanca, Salamanca, [3]Hematología y Hemoterapia, Hospital Universitari Vall d´Hebrón, [4]Hematología y Hemoterapia, ICO Hospital Germans Trias i Pujol, Barcelona, [5]Hematología y Hemoterapia, Hospital de Especialidades, Jerez de la Frontera, [6]Hematología y Hemoterapia, Hospital Virgen de las Nieves, Granada, [7]Hematología y Hemoterapia, Hospital Carlos Haya, Málaga, [8]Bioquímica, Universidad de Sevilla, Sevilla, Spain

Background: Vitamin D receptor (VDR) is expressed on activated immune cells. Numerous preclinical studies, including models for solid organ transplantation, have shown that vitamin D (VitD) has a potent immunomodulatory effect although, by contrast, few reports have described an increased immune response upon exposure to vitD. In the alloSCT setting scanty information is available although an association between common polymorphisms of VDR and graft-versus-host disease (GVHD) has been described. In addition, different studies have also described the capability of vitD to induce differentiation of blasts in acute leukemia. In spite of these properties no clinical trial has been carried out to evaluate the role of VitD as an immunomodulatory agent after alloSCT.
Aims: Based on the potential benefit of vitD on the risk of GVHD but also considering previous studies describing an exacerbated immune response after exposure to the drug, the main aim was to determine the safety and to assess the effect of VitD supplementation after alloSCT on the incidence of GVHD.
Methods: We designed a multicenter prospective Phase I/II clinical trial with three consecutive cohorts of patients (n= 50 each group), receiving no vitD (control group, CG), 1000 IU/day po. VitD (low dose group, LDG) or 5000 IU/day (high-dose group, GDA) from day -5 to +100 post alloSCT. In addition, we measured plasma levels of VitD (on days -5, +1, +7, +14 and +21 after transplant), of serum th1/th2 cytokines (on days +1, +7, +14, +21, +56 and +100) and of WBC subpopulations including T cells (naive/memory/effector), activation markers for T cells, Treg, NK cells, B cells and dendritic cells by flow cytometry (on days +21, +56 and +100).
Results: Regarding characteristics of patients, we only observed significant differences between the 3 subgroups in terms of age, patients in LDG being slightly older. Calcineurin inhibitors plus methotrexate or MMF and FK506 plus rapamycin were used as GVHD prophylaxis. No T-cell depletion was allowed as GVHD prophylaxis. No significant differences were observed in terms of cumulative incidence of global and grade II-IV of acute GVHD (CG= 55.9% and 38.2%; LDG= 56.8% and 36.4% and HDG= 56.4% and 53.8%, respectively). By contrast, a significantly lower cumulative incidence of chronic GVHD (cGVHD) at 1 year was observed in LDG and HDG as compared to patients who did not receive VitD (33.7%, 25.9% and 66.7% for LDG, HDG and CG, respectively; p=0.04) (Figure 1). Multivariate analysis identified treatment with VitD as the only variable which significantly decreased the risk of cGVHD (p=0.03) (for LDG [HR=0.33, (95% CI=0.13-0.81), p=0.01] and for HDG [HR=0.42, (95% CI=0.16-1.1), p=0.07]. No significant differences were observed in terms of relapse or non-relapse mortality. With a median follow up of 1 year, overall survival was 70,6%, 74.2% and 70.4% for CG, LDG and HDG, respectively, p=0.76). Concerning the biological parameters monitored, plasma levels of vitD were higher among patients receiving the drug as compared to the control group, beyond day +21 (significantly for HDG). VitD modified the immune response after alloSCT for parameters evaluated, the most significant differences being a decreased percentage of B-cells for both LDG and HDG (p≤0.05), a markedly modified ratio of naïve/central memory/effector T cells, with a lower number of circulating naïve CD8 T cells for patients receiving vitD (10.1%; 9.61%; 16%, p=0.02 for LGC, HGD and CG respectively, p≤0.025) and a lower expression of CD40L as marker of activation upon exposure to vitD (24.4%, 39.5% and 49%, for LGD, HGD and CG, respectively, p≤0.02).

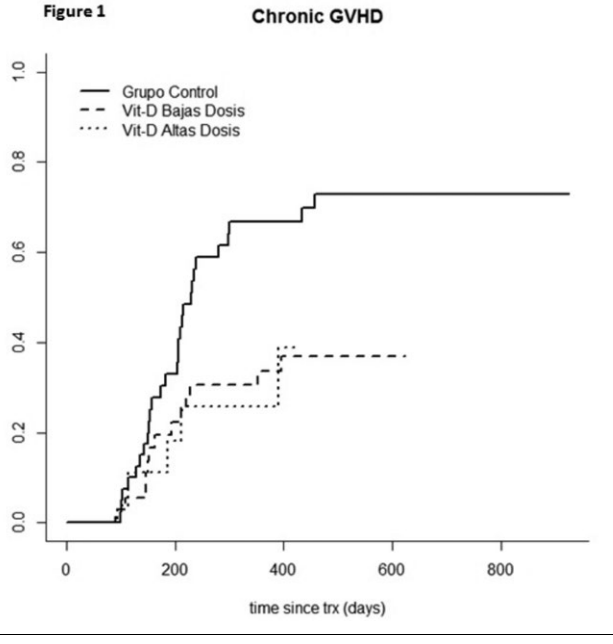

Figure 1.

Summary and Conclusions: This is the first prospective multicenter trial which analyzes the effect of vitamin D administration after alloSCT. A significantly lower incidence of cGVHD was observed among patients receiving vitD. Interestingly, vitD markedly modified the immune response after alloSCT.

DONOR-DERIVED, CD19-DIRECTED, CAR-MODIFIED T CELLS INFUSED AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION AS PRE-EMPTIVE DONOR LYMPHOCYTE INFUSION IN PATIENTS WITH CD19+MALIGNANCIES

P. Kebriaei[1,*] H. Huls[1], S. Ciurea[1], T. Liu[1], H. Singh[1], S. Su[1], C. Hosing[1], S. Olivares[1], M. Figliola[1], P. Kumar[1], B. Jena[1], S. Maiti[1], I. McNiece[1], D. Lee[1], P. Tewari[1], U. Popat[1], A. Alousi[1], B. Oran[1], N. Shah[1], K. Rezvani[1], M. Forget[1], S. Ang[1], R. Jackson[1], G. Rondon[1], H. Kantarjian[1], P. Hackett[2], E. Shpall[1], R. Champlin[1], L. Cooper[1]
[1]MD Anderson Cancer Center, Houston, [2]University of Minnesota, Minneapolis, United States

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) can be curative in a subset of patients with advanced B-lineage acute lymphoblastic leukemia (ALL), but relapse remains the main reason for treatment failure. Donor-derived, non-specific lymphocyte infusions (DLI) have been ineffectively infused and are associated with significant graft-versus-host-disease (GVHD). Chimeric antigen receptor (CAR)-modified T cells directed toward CD19 have demonstrated dramatic efficacy in patients with refractory ALL. However, responses are often associated with life-threatening cytokine release.
Aims: We hypothesized that infusing CAR-modified, CD19-specific T cells after HSCT as a directed DLI would be associated with less GVHD while providing cellular-based disease control, and may be associated with less cytokine released when administered in a minimal disease state.
Methods: We employed a non-viral gene transfer using the *Sleeping Beauty* (SB) transposon/transposase system to stably express a 2nd generation CD19-specific CAR (designated CD19RCD28 that activates via CD3z/CD28) in donor-derived T cells for patients with advanced $CD19^+$lymphoid malignancies. T cells were electroporated using a Nucleofector device to synchronously introduce two DNA plasmids coding for SB transposon (CD19RCD28) and hyperactive SB transposase (SB11). T cells stably expressing the CAR were retrieved over 28 days of co-culture by recursive additions of g-irradiated activating and propagating cells (AaPC) in presence of soluble recombinant interleukin (IL)-2 and IL-21. The AaPC were derived from K562 cells and genetically modified to co-express CD19 as well as the co-stimulatory molecules CD86, CD137L, and a membrane-bound version of IL-15.
Results: To date, we have successfully treated 16 patients with advanced $CD19^+$ALL (n=13) or NHL (n=3); 7 patients had active disease at time of HSCT. Donor-derived CAR^+T cells (HLA-matched sibling n=9; haplo-family n=5; double cord blood n=2) were infused at a median 64 days (range 42-91 days) following HSCT to prevent disease progression. Transplant preparative regimens were myeloablative, busulfan-based (n=8) or reduced intensity, fludarabine-based (n=8). All patients were maintained on GVHD prophylaxis at time of CAR infusion with tacrolimus, plus mycophenolate mofeteil for cord, plus post-HSCT cyclophosphamide for haplo donors. The starting CAR^+T-cell dose was 10^6 (n=7), escalated to 10^7 (n=6), and currently at $5x10^7$ (n=3) modified T cells/m^2 (based on recipient body surface area). Patients have not demonstrated any acute or late toxicity to CAR^+T cell infusions. Three patients developed acute grades 2-4 GVHD (liver n=1, upper GI n=1, skin=1) which was within the expected range after allogeneic HSCT. Eight patients have relapsed at a median of 90 days following HCT (range 68-185 days). Fifty percent of patients (n=8) remain alive and in complete remission (CR) at median 7.2 months (range 2.1-21.3 months) following HSCT.
Summary and Conclusions: We report the first human application of the SB and AaPC platforms to genetically modify clinical-grade cells. We demonstrate that infusing donor-derived CD19-specific CAR^+T cells in the adjuvant HSCT setting as pre-emptive DLI may provide an effective and safe approach for maintaining remission in patients at high risk for relapse. Modification of the CAR construct is underway in efforts to improve CAR T-cell *in vivo* proliferation and persistence.

S803

POLYMORPHISMS IN IMMUNOMODULATING GENES AND RISK OF INVASIVE ASPERGILLOSIS: RESULTS FROM THE ASPBIOMICS CONSORTIUM

Background: Invasive Aspergillosis (IA) is a life-threatening infection caused by *Aspergillus* that mainly affects acute myelogenous leukemia and allogeneic stem cell transplantation (allo-SCT) patients. Recent studies suggest that immunomodulating single nucleotide polymorphisms (SNPs) may influence on the risk of developing the infection.
Aims: The purpose of this study was to assess whether 36 SNPs within 14 immune-related genes (*IL4, IL4R, IL8, IL8RA, IL8RB, IL10, IL12A, IL12B, IL13, IFNg, IFNgR2, CCR5, MIF and VEGF*) are associated with the risk of IA and whether a predictive model built with these variants might help to predict the disease risk.
Methods: We conducted a three-stage case-control association study of 742 high-risk patients, 146 of whom were diagnosed with proven or probable IA. This is one of the largest populations recruited so far to conduct genetic association studies.

Tabella 1. Association of immunoregulatory polymorphisms and invasive aspergillosis

Variant_dbSNP	Gene	OR (95% CI)[a]	P_{value}	OR (95% CI)[b]	P_{value}	OR (95% CI)[c]	P_{value}

Abbreviations: OR, odds ratio; CI, confidence interval. Abbreviations: n/s, not specified; SNP, single nucleotide polymorphism; UTR, untranslated region. Estimates were adjusted for age, sex, country of origin, allo-SCT, and prophylaxis status (ever use of prophylaxis). P<0.05 in bold.
[a]Stage 1 (aspBIOmics population; N=330).
[b]Stage 1+2 (aspBIOmics + PCRAGA+Valencia+Salamanca populations; Phase 1+2; N=593 hematological patients).
[c]Overall (after extension with 149 non-HSCT patients; 48 of them with prophylaxis data).
[d]Estimates according a recessive model of inheritance.
[e]SNP also signifcantly associated with IA infection according a log-additive model of inheritance.
[f]Estimates calculated according a co-dominant model (homozygotes for the rare allele were not found).

Results: Overall, we found that the $IL4R_{rs2107356}$ and $IL8_{rs2227307}$ SNPs were associated with an increased risk of IA (P=0.007 and P=0.010, respectively) whereas the $IL12B_{rs3212227}$ and $IFNg_{rs2069705}$ variants were significantly associated with a decreased risk of developing the disease (P=0.046 and P=0.032; Table 1). Importantly, an allogeneic stem cell transplantation (allo-SCT)-stratified analysis revealed that the effect observed for the $IL4R_{rs2107356}$ and $IFNg_{rs2069705}$ SNPs was stronger in allo-SCT patients (P=0.0007 and$P$=0.0010, respectively) compared with those patients without transplantation. Although none of these associations remained significant after correction for multiple testing (P=0.0004), the association of$IL4R_{rs2107356}$ and $IFNg_{rs2069705}$ SNPs in allo-SCT patients remained marginally associated with the risk of IA infection. *In vitro* stimulation assays confirmed a relevant role of the $IL4R_{2107356}$ and $IL12B_{rs3212227}$SNPs in regulating *IL4R* and *IL12* levels. We found that $CD_{19}{}^+$B lymphocytes from carriers of the$IL4R_{2107356A/A}$ mutant genotype (n=7) tended to have an increased expression of *IL4R* protein when compared

with those B-cells from subjects harbouring the wild-type allele (n=7; *P*=0.08). Although carriers of the $IL4R_{2107356A/A}$ genotype also tended to have higher levels of *IL4R* in T-cells and monocytes, a substantial correlation could only be detected in B-lymphocytes, a cell subset where *IL4R* is highly expressed. We also confirmed that carriers of the $IL12B_{rs3212227C}$ allele showed an increased production of *IL12p70* after 24 and 48h of incubation with zymosan alone or in combination with LPS when compared with carriers of the $IL12B_{rs3212227A/A}$ genotype ($IL12B_{MUT\text{-}ZYM\text{-}24h}$=44.0±8.5 *vs.* $IL12B_{WT\text{-}ZYM\text{-}24h}$=30.1±2.2, *P*=0.087 and $IL12B_{MUT\text{-}ZYM\text{-}48h}$=81.9±9.4 *vs.* $IL12B_{WT\text{-}ZYM\text{-}48h}$=26.8±5.8, *P*=0.006 and $IL12B_{WT\text{-}ZYM+LPS\text{-}24h}$=34.6±3.0 *vs.* $IL12B_{MUT\text{-}ZYM+LPS\text{-}24h}$=73.3±4.0,*P*=0.0017). In addition, we found that patients harbouring the $IL12B_{rs3212227C}$ allele showed a substantially increased level of *IFNg* after 48h of incubation with Zymosan when compared with those subjects harbouring the wild type genotype ($IFNg_{MUT\text{-}ZYM\text{-}48h}$=501.4±38.1 *vs.* $IFNg_{WT\text{-}ZYM\text{-}48h}$=183.5±83.0, *P*=0.06). Finally, a predictive analysis also confirmed that a prediction model including SNPs significantly associated with IA showed a substantial improvement in the discriminatory ability to predict the disease when compared with a reference model including only demographic and clinical variables (AUC=0.659 *vs.* AUC=0.564; Figure 1).

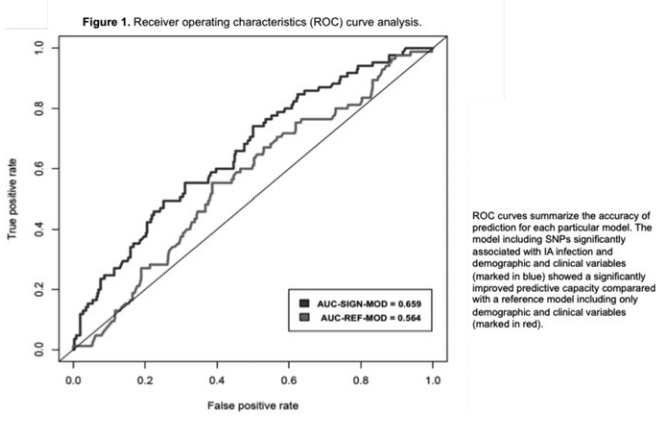

Figure 1. Receiver operating characteristics (ROC) curve analysis.

Summary and Conclusions: These findings suggest that SNPs within immuno-modulating genes influence on the risk of developing IA infection and might be used to predict the disease risk and to implement risk-adapted prophylaxis strategies.

Background: High-risk Follicular Lymphoma (FL) patients intensified with high dose therapy and autologous stem cell transplantation HDT/ASCT may achieve prolonged remissions. The best timing for the procedure remains controversial. Addition of rituximab to conventional chemotherapy has brought a significant development, with several phase III randomized trials proving a benefit in favor of a rituximab-containing chemotherapy up front. The vast majority of studies of HDT/ASCT in FL have been performed in the pre-rituximab era, and its value now remains to be elucidated.

Aims: To analyze the impact of previos Rituximab exposure in patients intensified with HDT/ASCT in a retrospective study from the Spanish Geltamo Registry.

Methods: All FL patients undergoing HDT/ASCT from 1989 to 2007 and reported to the Spanish GELTAMO registry (n=655, mean age 47 years, male sex 49,6%) were eligible for this study. 203 patients (31%) received HDT/ASCT after achievement of 1st CR, 43% of them requiring more than one therapy line to achieve CR; 26% in 2ndCR, 5% in 3rdCR, 21,5% in 1stPR, 12,5% in chemo sensitive recurrence, and 5% with active disease. Of the 312 cases who were evaluable for FLIPI, 125 (38%) were in the high-risk group. Of the 332 who were evaluable for FLIPI II, 125 (40%) were in in the high-risk group. Of the 640 assessable for Rituximab exposure previously to ASCT, 184 (30%) had been treated with the anti-CD20 monoclonal antibody (R+Group). Overall survival (OS) and progression free survival (PFS) probabilities were calculated using Kaplan-Meier estimates. The log rank test was used for univariate comparisons.

Results: Median follow-up from HDT/ASCT was 14, 5 years for the Rituximab-naïve (R- Group) patients and 9 years for the R+Group. In the R+Group, patients were older (*P*=0.01) and there were more with ECOG >1 (*P*=0.05), with high LDH (*P*=0.02), with poor risk FLIPI II *(P*=0.05) and had a shorter length of follow-up (*P*<0.0001). In patients transplanted in 1st CR, there were more patients who received more than one line of therapy to reach CR in the R+Group (P=0.02). Globally, R+Group showed a better outcome than R-Group (median PFS not reached *vs* 74 months (*P*=0.0006); median OS not reached *vs* 221 months, respectively; (*P*=0, 02)). For patients transplanted in 2nd/3rd CR the benefit of Rituximab was remarkable: median PFS not reached *vs* 92 months (P=0.002); OS at 5 years 91%, OS at 10 years 86%, in the R+Group *vs* OS at 5 years 76%, OS at 10 years 63% for the R- Group, respectively (*P*=0.01). Surprisingly this benefit did not occur in patients transplanted in 1st CR, where R- patients showed even a better outcome (no statistically differences on PFS and OS at 5 years 91% *vs* 83%, OS at 10 years 84% *vs* 72% for the R- Group and R+Group, respectively;(*P*=0.02)).

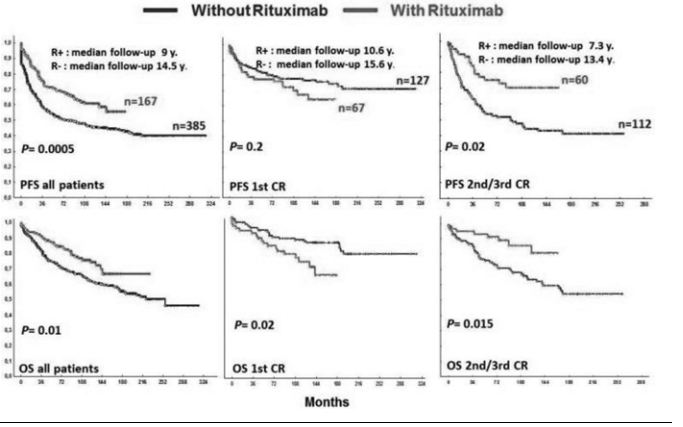

Figure 1.

Summary and Conclusions: Follicular lymphoma patients undergoing HDT/ASCT in 2nd / 3rd CR have a formidable outcome; treatment with rituximab seems to have a synergistic effect with HDT/ASCT in this population. R+Group transplanted in 1st CR, showed an excellent outcome, however it was no better than the obtained in R- Group. Worse initial prognostic factors in the R+Group, with more patients needing more than one line of therapy to reach the CR, could explain these data. In the Rituximab era, HDT/ ASCT should be considered in the therapeutic approach at first relapse for FL patients. Very high risk patients could, as well, benefit from a transplant in 1st CR. As well-balanced randomized studies are not easily feasible in this setting, we think that updating the results of the available studies could elucidate this question.

Progess in Hodgkin lymphoma therapy: Incorporation of novel agents and reduction of side effects

GERMAN HODGKIN STUDY GROUP PHASE I TRIAL OF DOXORUBICIN, VINBLASTINE, DACARBAZINE, AND LENALIDOMIDE (AVD-REV) FOR ELDERLY HODGKIN LYMPHOMA PATIENTS-FINAL ANALYSIS

B. Boell[1,*] A. Pluetschow[2], D. Eichenauer[2], B. von Tresckow[2], J. Atta[3], M. Pfreundschuh[4], F.B. Michaela[5], M. Vogelhuber[6], M. Sökler[7], M. Fuchs[2], A. Engert[2], P. Borchmann[2]

[1]Hematology, GHSG, University Hospital, [2]Hematology, GHSG, Cologne, [3]hematology, University Hospital, frankfurt, [4]Hematology, University Hospital, Homburg, [5]Hematology, University Hospital, Ulm, [6]Hematology, University Hospital, Regensburg, [7]hematology, University Hospital, Tuebingen, Germany

Background: About 30% of all Hodgkin Lymphoma (HL) patients are ≥60 years old. ABVD is standard of care for these patients, although outcome and feasibility are poor, one limitation being bleomycin-induced pulmonary toxicity.
Aims: We thus replaced bleomycin with lenalidomide (Revlimid®), and initiated the AVD-Rev phase-I trial (NCT01569204) for 60-75 year-old patients with 1st diagnosis of early unfavorable- or advanced-stage HL, good performance status (ECOG/WHO ≤2), and no severe organ dysfunction.
Methods: Depending on stage and response at interim staging, patients received 4-8 cycles of AVD-Rev followed by radiotherapy with prophylactic anticoagulation (ASA or heparin). The daily lenalidomide dose for the first patient was 5mg; possible dose levels ranged from 5 to 40mg. Thromboembolism ≥CTC II°, hematological toxicity as severe cytopenia (ANC<500/µl >7days with G-CSF and thrombocytopenia <25.000/µl), and complications as neutropenic fever and prolonged therapy delay were considered as dose limiting toxicities (DLT) if they occurred during the first 4 cycles.
Results: 25 patients (median age: 67, range 61-76) and a CIRS-G comorbidity score of up to 7 points (range 0-7) were assigned to dose levels 5mg (n=1), 10mg (n=1), 15mg (n=1), 20mg (n=6), and 25mg (n=16). 15 patients were male, 68% had advanced stage-HL, and 80% had B-symptoms. After DLT evaluation of 20 patients, a pre-specified stopping criterion was reached with a recommended dose for a phase II trial of 25mg. Dose delivery was high with a median relative dose intensity of 97% (range 49%>104%; mean 91%). However, CTC III°-IV° toxicities occurred in all 22 patients treated at the 20mg and 25mg dose levels. DLTs were observed in 1 of 6 and 5 of 16 patients at 20mg and 25mg, respectively, and were mainly hematologic but included 3 thromboembolic events despite ASA prophylaxis. No DLT occurred in patients receiving <20mg lenalidomide. Of note in these vulnerable patients, no treatment related deaths occurred. Overall response rates were 80% for all patients (20/25) and 86% (19/22) for patients receiving ≥20mg lenalidomide. At 19 months median observation time, 5 patients had disease progression and 4 patients died. The one-year estimates for progression-free (PFS) and overall survival (OS) are 75% [95%>CI: 53-88%] and 92% [95%>CI: 71-98%], respectively. Final results on PFS and OS with two years follow-up will be presented at the EHA congress 2015.
Summary and Conclusions: AVD-Rev is toxic but feasible and highly effective in this vulnerable population of elderly HL patients.

S806

BENDAMUSTINE-CONTAINING REGIMEN (BEGEV) AS INDUCTION CHEMOTHERAPY PRIOR TO ASCT FOR RELAPSED/REFRACTORY HODGKIN LYMPHOMA

R. Mazza[1,*] A. Pulsoni[2], G. Rossi[3], C. Carlo-Stella[1], A. Anastasia[3], M. Bonfichi[4], C. Rusconi[5], F. Salvi[6], S. Luminari[7], A. Re[3], M. Gotti[4], A.M. Liberati[8], N. Di Renzo[9], L. Giordano[10], A. Santoro[1]

Santa Maria, Terni, [9]Hematology, V.Fazzi Hospital, Lecce, [10]Department of Hematology, Oncology and Biostatistical Unit, Humanitas Cancer Center, Rozzano, Italy

Background: Salvage chemotherapy followed by high dose chemotherapy with autologous stem cell transplant (ASCT) is the standard of care for refractory/relapsed Hodgkin's lymphoma (HL r/r), leading to durable responses in approximately 50% of relapsed patients. The pre-transplantation achievement of CR is the strongest prognostic factor in this setting. The combination of gemcitabine and vinorelbine and ifosfamide (IGEV) demonstrated to be an highly active salvage regimen, with a high CR rate (48%) and low toxic profile. Bendamustine, as single agent, has been reported to induce objective responses in an high percentage of pts with HL recurring after autologous stem cell transplant (ASCT).
Aims: This study has been conducted with the aim of improving the CR rate of induction salvage chemotherapy in comparison to historical IGEV data by combining Bendamustine with Gemcitabine and Vinorelbine (BeGEV).
Methods: This was a Fleming's single-stage phase II multi-centric trial in HL r/r patients before ASCT. Aim of the study was to assess the activity of BeGEV in term of CR rate. Assuming an improvement of 15% (50 to 65%), with a 10% rejection error and a power of 85%, at least 35 CR out of 59 patients had to be observed. Secondary end points were overall response, cell mobilization, toxicity, progression free survival (PFS) and overall survival (OS). Patients were eligible if they had relapsed or refractory classic HL after first line chemotherapy. The treatment schedule was: Bendamustine (90 mg/sqm, days 2-3), Gemcitabine (800 mg/sqm, day 1 and 4) and Vinorelbine (25 mg/sqm, day) every 3 weeks for a total of 4 courses.
Results: Between August 2011 and March 2014, 59 consecutive patients with relapsed (45.8%) or refractory (54.2%) HL were enrolled. The median age was 33 years (range 18-68). Out of 59 enrolled patients, 43 (72.9%) achieved a CR, 6 (10.2%) a partial response (PR) for an overall response rate of 83.1%. The remaining 10/59 patients (16.9 %) were evaluated as non responders for: 1 (1.7%) stable disease, 8 (13.6 %), PD, 1 (1.7 %) toxicity. Adequate CD34+cell collection was achieved in 55 out of 57 (96.5%) mobilized patients. Considering the 49 responsive patients, 42 proceeded to ASCT (37/43 in CR, 5/6 in PR). The remaining 7 patients did not proceed to ASCT due failed mobilization (2 cases), allogenic transplant (1 case), physician's decision (2 cases), early relapse (1 case), and patient refusal (1 case). With a median follow up of 16 months, the PFS and OS at 2 years were respectively 50.9% and 68.8% for all series, without significant difference among relapsed and refractory patients. The 2-year PFS for the 49 responsive pts was 61% for CR and 63% for CR+PR, respectively. The 2-year OS reached 85.5% for CR+PR *vs* 14.3% induction failures (p value <0.001). Hematological and non-hematological side effects were acceptable. Out of 204 evaluated cycles, 23 (11%) had to be delayed and 4 (2%) reduced, respectively; only 1 patient stopped therapy for toxicity. Three non-hematologic G4 toxicity (2 infection and 1 hepatic failure unlikely related to treatment), were observed. No toxic death occurred.
Summary and Conclusions: The BeGEV regiment achieved a CR (72.9%) and overall response rate (83.1 %) overcoming the expected results. The study highlights the activity of this combination as well as the good toxicity profile and the high mobilizing potential. These data provide strong support for further development of BeGEV.

S807

MULTIVARIATE ANALYSIS OF PFS FROM THE AETHERA TRIAL: A PHASE 3 STUDY OF BRENTUXIMAB VEDOTIN CONSOLIDATION AFTER AUTOLOGOUS STEM CELL TRANSPLANT FOR HL

J. Walewski[1,*] A. Nademanee[2], T. Masszi[3], J. Holowiecki[4], M. Abidi[5], A. Chen[6], P. Stiff[7], S. Viviani[8], V. Bachanova[9], J. Sweetenham[10], S.Y. Lee[11], D. Huebner[11], E. Larsen[12], N. Hunder[12], C.H. Moskowitz[13]

Background: In the phase 3, randomized, placebo-controlled AETHERA trial, progression-free survival (PFS) was significantly improved with brentuximab vedotin (BV) *vs* placebo (HR=0·57, P=0·001) in Hodgkin lymphoma (HL) patients at risk of progression post-autologous stem cell transplant (ASCT).
Aims: A multivariate analysis was performed to determine which factors significantly influence PFS by investigator assessment.
Methods: After ASCT, 329 patients were randomized to receive BV 1.8 mg/kg q3wk (n=165) or placebo (n=164) for up to 16 cycles. The primary endpoint was PFS per independent review. Multivariate analysis using a Cox-proportional hazards model was developed on the following factors: treatment, age, sex, weight, geographical region, initial disease stage, time from diagnosis, no. of treatments pre-ASCT, chemosensitivity, response to frontline (FL) and salvage, type of FL therapy, prior radiotherapy, extranodal disease pre-ASCT, ASCT conditioning regimen, B symptoms at pre-ASCT relapse, number of risk factors, baseline ECOG, baseline lesions, and pre-existing peripheral neuropathy. Significant factors (p<0.05) were determined after a stepwise addition and elimination of nonsignificant factors from the model.
Results: Multivariate modeling indicated that factors significantly associated

with PFS by investigator assessment included: treatment (BV *vs.* placebo), salvage response, gender, number of treatments pre-ASCT, type of FL therapy, B symptoms pre-ASCT, and weight (see Table).

Tabella 1. Multivariate analyses of PFS by investigator assessment.

Effect	Hazard Ratio (95% CI)	P value
Treatment (BV vs Placebo)	0.44 (0.31, 0.62)	<0.001
Salvage response (CR vs PR/SD)	0.44 (0.30, 0.64)	<0.001
Gender (F vs M)	0.60 (0.43, 0.85)	0.004
No. treatments pre-ASCT (2 vs >2)	0.65 (0.47, 0.90)	0.010
FL therapy (ABVD vs BEACOPP/Other)	0.63 (0.44, 0.91)	0.013
B symptoms pre-ASCT (No vs Yes)	0.64 (0.45, 0.92)	0.015
Baseline weight (≤100 vs >100 kg)	0.58 (0.36, 0.94)	0.026

Summary and Conclusions: After adjustment for significant clinical factors in a multivariate regression analysis, consolidation treatment with BV significantly reduced the risk of treatment failure compared to placebo with a HR of 0.44. These results support the primary analysis.

S808

NIVOLUMAB IN PATIENTS WITH RELAPSED OR REFRACTORY LYMPHOID MALIGNANCIES AND CLASSICAL HODGKIN LYMPHOMA: UPDATED SAFETY AND EFFICACY RESULTS OF A PHASE 1 STUDY (CA209-039)

P. Armand[1,*] J. Timmerman[2], A. Lesokhin[3], A. Halwani[4], M. Millenson[5], S. Schuster[6], M. Gutierrez[7], E. Scott[8], D. Cattry[3], G. Freeman[1], B. Chapuy[1], A. Ligon[9], S. Rodig[9], L. Zhu[10], J. Grosso[10], J. Simon[10], M. Shipp[1], A. Cohen[6], D. Lebovic[11], M. Dhodapkar[12], D. Avigan[13], S. Ansell[14], I. Borrello[15]

Background: The PD-1 pathway functions as a checkpoint which limits T-cell mediated tumor immune responses. Nivolumab (NIVO), a fully human IgG4 monoclonal PD-1 blocking antibody, potentiates T-cell activity. Prior results from this study (median follow-up 40 weeks) showed that NIVO was tolerated and achieved an overall response rate of 87% in classical Hodgkin lymphoma (cHL), 40% in follicular B-cell lymphoma (FBL), 36% in diffuse large B-cell lymphoma (DLBCL) and 17% in T-cell non-Hodgkin lymphoma (T-NHL). The stable disease rate in multiple myeloma (MM) was 67%.
Aims: Herein, we report the updated follow-up and safety profile of this study.
Methods: Patients (Pts) were treated using a dose-escalation design (1 and 3 mg/kg) of NIVO administered every 2 weeks (wks) for 2 years. Responses were assessed using standard criteria. Primary endpoint was safety. The secondary endpoint was efficacy.
Results: 105 pts were enrolled (23 cHL, 31 B-NHL, 23 T-NHL, 27 MM and 1 chronic myelogenous leukemia). Pts were heavily pretreated with 88%, 78%, 68% and 66% of pts with cHL, T-NHL, B-NHL and MM, respectively, having received ≥3 prior regimens. Previous ASCT was reported for 75% of pts with cHL, 56% of MM, 13% of B-NHL and 9% of T-NHL. As of 1/8/2015, median duration of follow-up was 62 wks (range: 2 to 106+wks). Drug-related adverse events (DrAEs) occurred in 71 (67%) pts. The most common DrAEs occurring in ≥5% were fatigue (15%), rash (11%), diarrhea, pneumonitis, pruritus (each 9%), pyrexia (8%), thrombocytopenia, decreased appetite (each 7%), hypocalcemia, lipase increased, leukopenia, lymphopenia (each 6%) and nausea (5%). Serious DrAE in ≥5% of pts included pneumonitis (5%). Efficacy results shown below. The rate of stable disease in MM (n=27) was 63%. Among the 20 responding cHL pts, 10 discontinued NIVO; 6 (1CR and 5 PR) to undergo SCT, 3 for disease progression and 1 for toxicity (MDS, thrombocytopenia) and 10 (7 PR and 3 CR) continue to respond. Among responding B- and T-NHL pts, 1/4 DLBCL, 3/4 FL and 3/4 T-NHL pts remain in response. In this updated analysis, median duration of response has not been reached in cHL, B-NHL and T-NHL.

Tabella 1. Multivariate analyses of PFS by investigator assessment.

Tumor	Objective Response n (%)	Complete Response n (%)	Partial Response n (%)	Stable Disease n (%)	Median Weeks of Response Duration (range)	Ongoing Responders n (%)
cHL (n=23)	**20 (87)**	**4 (17)**	**16 (70)**	**3 (13)**	**NR (2 - 76+)**	**10 (50)**
B-NHL (n=31)	8 (26)	3 (10)	5 (16)	16 (52)	NR (6+ - 81+)	4 (50)
Diffuse Large B-cell Lymphoma (n=11)	4 (36)	2 (18)	2 (18)	3 (27)	22.1 (6 - 73+)	1 (25)
Follicular B-cell Lymphoma (n=10)	4 (40)	1 (10)	3 (30)	6 (60)	NR (23+ - 81+)	3 (75)
Other B-cell Lymphoma (n=10)	0	0	0	7 (70)	—	—
T-NHL (n=23)	4 (17)	0	4 (17)	10 (43)	NR (11 - 63+)	3 (75)
Cutaneous T-cell Lymphoma Mycosis Fungoides (n=13)	2 (15)	0	2 (15)	9 (69)	NR (24+ - 36+)	2 (100)
Peripheral T-cell Lymphoma (n=5)	2 (40)	0	2 (40)	0	NR (11 - 63+)	1 (50)
Other Cutaneous T-cell Lymphoma (n=3)	0	0	0	0	—	—
Other Non-Cutaneous T-cell Lymphoma (n=2)	0	0	0	1 (50)	—	—

Summary and Conclusions: Encouraging, durable objective responses were observed in cHL, DLBCL and FL, including CR and PR. NIVO treatment remains safe and tolerable with a safety profile similar to that in solid tumors, and further analysis is warranted in cHL and selected B-NHLs and T-NHLs.

S809

EFFECT OF BLEOMYCIN HYDROLASE GENE POLYMORPHISM ON LATE PULMONARY COMPLICATIONS OF TREATING HODGKIN LYMPHOMA

Á. Jóna[1,*] Z. Miltényi[1], S. Póliska[2], B. Bálint[2], Á. Illés[1]
[1]Department of Hematology, [2]Department of Biochemistry and Molecular Biology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

Background: Bleomycin induced pulmonary toxicity occurs in 20-46% of Hodgkin lymphoma (HL) patients, treated with ABVD (doxorubicin, bleomycin, vinblastin, dacarbasine) regimen. Bleomycin hydrolase (BLMH), an enzyme that inactivates bleomycin, may be a potential candidate that influences pulmonary function. Single nucleotide polymorphisms (SNP) of the BLMH gene have been investigated previously in testicular germ-cell cancer (TC) patients in parallel to survival data. Interestingly, homo- and heterozygous variants of BLMH gene SNP A1450G were found to significantly affect survival of TC patients. Yet, there is no available data of BLMH SNPs and bleomycin induced pulmonary toxicity in correlation with HL patients.
Aims: We hypothesized, that BLMH gene SNP A1450G (rs1050565) influences BLMH activity and by an altered metabolism of bleomycin, differences could be seen at the risk of bleomycin induced toxicity appearance.
Methods: Pulmonary functions of previously treated HL patients have been collected by using St. George Respiratory Questionnaire (SGRQ), dynamic inhalation lung scintigraphy and spirometry at the Department of Hematology, University of Debrecen, retrospectively. After informed consent of these patients genomic DNA was isolated from peripheral blood samples and TaqMan genotyping assay was used to determine genotype distribution. Local Research Ethics Committee approved this investigation.
Results: A total of 131 patient samples have been collected of previously treated HL patients, with a median age of 29 years (14-73), median time elapsed since treatment completion was 11 years (1-44). Genotype frequency was found as follows: A/A 55.0%, A/G 33.6%, G/G 11.5%, where A is the wild allele (71.8%) and G is the mutated allele (28.2%). Our results are comparable to the NCBI SNP database for SNP A1450G. Patients were subdivided into subgroups containing the mutated allele: A/G+G/G (45.1%) and those homogenous for the wild allele: A/A (55.0%). All bleomycin treated patients (n=102) had more favorable lung function test result in the wild A/A genotype group, with significant difference in the forced vital capacity results (FVC), p=0.041. When narrowing patients to those who received only ABVD regimen (n=68), significantly more favorable results were seen in the wild A/A genotype group with every investigated test method (SGRQ score: p=0.035, lung scintigraphy results: p=0.045, spirometry results: FVC: p=0.020; forced expiratory volume in 1 s (FEV1): p=0.028). Univariate analysis also confirmed these results. As control group (n=29), patients treated with agents excluding bleomycin were tested with no significant differences between the A/G+G/G and A/A groups. Other factors (smoking, age, bleomycin dose, chest irradiation, kidney function, use of colony stimulating factors) that could potentially affect lung function were equally represented in all investigated subgroups.
Summary and Conclusions: BLMH gene polymorphism significantly distinguished in retrospective pulmonary test results of ABVD treated patients. Based on these results prospective trials could be designed to further evaluate its role

in pulmonary toxicity of treating HL, and thus treatment could be adjusted individually. One of its potential roles could be to identify those cases even in the frontline setting, where brentuximab vedotin should be administered instead of bleomycin, either in the standard care or considering expense issues. Patients with multiple risk factors for lung toxicity should be particularly considered for this test method. Eventually, life expectancy and quality of life of HL patients wouldn't remarkably differ from the untreated healthy population.

Seràgnoli", University of Bologna, Bologna, Italy

Background: Imatinib mesylate (IM) has been for many years the standard of care for chronic myeloid leukemia (CML) in early chronic phase (CP). As first-line treatment, IM produce high probability of long-term survival, but few patients are able to achieve a stable deep molecular response ($MR^{4.0}$ or better), that is a pre-requisite to discontinue the TKI treatment. The treatment-free remission (TFR) is an emerging CML treatment goal. The identification of patients with higher probability of achieving a stable deep molecular response is important for the optimization of treatment strategy.
Aims: The aim of the present study was to investigate the predictors of $MR^{4.0}$ in CML patients treated frontline with imatinib.
Methods: We analyzed 559 patients enrolled within 3 multicentric prospective studies conducted by the GIMEMA CML WP (NCT00514488, NCT00510926, observational trial CML023). Definitions: major molecular response (MMR), BCR-ABL^{IS} ratio <0.1%; deep molecular response ($MR^{4.0}$), detectable disease ≤0.01% BCR-ABL^{IS} or undetectable disease with ≥10,000 ABL transcripts; stable $MR^{4.0}$: $MR^{4.0}$ lasting ≥24 months and ≥3 evaluable samples; unstable $MR^{4.0}$: unconfirmed occasional positive samples <0.1% BCR-ABL^{IS} in patients with a stable MR4.0 (Rousselot *et al.* J Clin Oncol 2014). The intention-to-treat population of each study was analyzed and all the 559 enrolled patients were included.
Results: Baseline demographics characteristics: median age, 52 years (extremes 18-84 years); male/female sex, 60%/40%; high Sokal, high Euro and high EUTOS scores, 22%, 7% and 7%, respectively; clonal chromosomal abnormalities (CCA) in Ph+cells, 4% (not evaluable in 32% of patients for insufficient number of metaphases); e13a2 BCR-ABL transcript, 36%. The median follow-up was 82 (60-105) months. The median time to MMR and MR^4 was 8 and 42 months, respectively. The rate of $MR^{4.0}$ at 24, 36, 48 and 60 months was 18%, 27%, 30% and 33%, respectively. Overall, 61% of patients achieved a $MR^{4.0}$ at least once. According to the previously detailed criteria, at the last contact 28% of patients had a stable $MR^{4.0}$ and 12% had an unstable $MR^{4.0}$ (stable+unstable $MR^{4.0}$=40%). The median duration of stable $MR^{4.0}$ was 36 months and the median duration of stable+unstable $MR^{4.0}$ was 40 months. In a multivariate Cox analysis including baseline variables, female sex, smaller spleen size and e14a2 transcript type resulted independent good prognostic factors on the probability to achieve a $MR^{4.0}$. Female sex was the only baseline variable able to predict a stable $MR^{4.0}$. The reduction of BCR-ABL1 transcript levels and the time to molecular response are influenced by baseline variables, so the impact of the dynamics of molecular response on the probability of $MR^{4.0}$ was analyzed separately: the time to MMR strongly predicted both the achievement and the stability of $MR^{4.0}$.
Summary and Conclusions: As suggested by a previous report (Branford *et al.* Blood 2013), in a large nationwide multicentric experience, the female sex was confirmed as a predictor of the achievement of a stable deep molecular response. Moreover, our results support strategies aimed to a rapid reduction of BCR-ABL1 transcript levels to optimize potential suitability for imatinib discontinuation studies.

EAC BCR-ABL1 ASSAY PERFORMANCE VALIDATION ON THE DPCR QS3D PLATFORM AND COMPARISON WITH OTHER DPCR PLATFORMS

M. Alikian[1,*] S. Akiki[2], K. Piechocki[2], A. Whale[3], S. Cowen[4], J. Huggett[3], L. Foroni[5]

[1]Haematology, Imperial College London, London, [2]haemato-oncology, Birm-

ingham Women's NHS Foundation Trust, Birmingham, [3]Science and Innovation, [4]Science and inovation, LGC, [5]Haematology, Imperial College, London, United Kingdom

Background: After the clinical success of TKIs in treating patients with CML, the clinical management of these patients became the core of patient care. RT-qPCR is the current gold standard for monitoring patients' response to therapy. Transcript levels are prognostic and capable of stratifying the patients in to risk groups as early as 3 month after therapy induction. Several molecular milestone have been introduced based on the log reduction of the transcript levels in response to therapy. Optimal response has been defined by the recently revised ELN guidelines as *BCR-ABL1* levels to be ≤10% by 3 month, <1% by 6 month, ≤0.1% by 12 month then ≤0.1% at any time. However, these percentages hugely vary from one centre to the other due to inherent limitations introduced by the gold standard method of quantification, unless expressed on the International scale. Recently, dPCR has been introduced as a method of quantification that promises simplified assay standardisation procedures mainly for being a method of absolute quantification as opposed to the relative quantification ascribed to the gold standard. In this study, we sought to optimize the use of such a platform, the QS3D, for our routine practice in addition to a performance comparison study with other dPCR platforms.
Aims: In this study, we sought to optimize the use of the dPCR platform, the QS3D, for our routine practice in addition to a performance comparison study with other widely used dPCR platforms, namely the Bio-Rad QX200 and RainDance.
Methods: For validating the EAC assay on the QS3D dPCR, we used the reference ERM-AD623 plasmid to assess the linearity metric of the platform by running a series of dilutions that fell within, below and above the sweet spot of the chip used. To assess the bias introduced to our measurements of BCR-ABL1 transcript ratios in patient material using our in-house generated Wessex plasmid, we ran a series of dilutions using the Wessex plasmid and compared it against the reference plasmid. To assess the limit of detection, we ran 6 categories of patient material at different disease ranges on the IS: 20%, 10%, 1%, 0.1%, 0.01%, and 0.001% (10 samples per category). These 60 patient material were also ran on the two other platform for comparing their performances.
Results: Linearity was maintained within the sweet spot and down to 3 molecules per chip. Inte and intra experimental variations were insignificant indicating excellent reproducibility (p=0.2). Linearity above the sweet spot was maintained, However a systematic underestimation was observed (p=0.05). There was a systematic bias introduce using out in-hour plasmid (p=0.001), and this bias was factored into the quantification of the cNDA molecules collected form the patients' samples. The limit of detection of the platform was concordant with that of the gold standard down to 0.1% IS (p=0.2); however dPCR demonstrated better precision in quantifying molecules in samples at the 0.01% IS level (p=0.07), and had improved sensitivity and precision in quantifying molecules in samples at the 0.001% IS level (p=0.06). Platform comparison showed reassuring concordance in sensitivity at all levels (p=0.16-0.4).

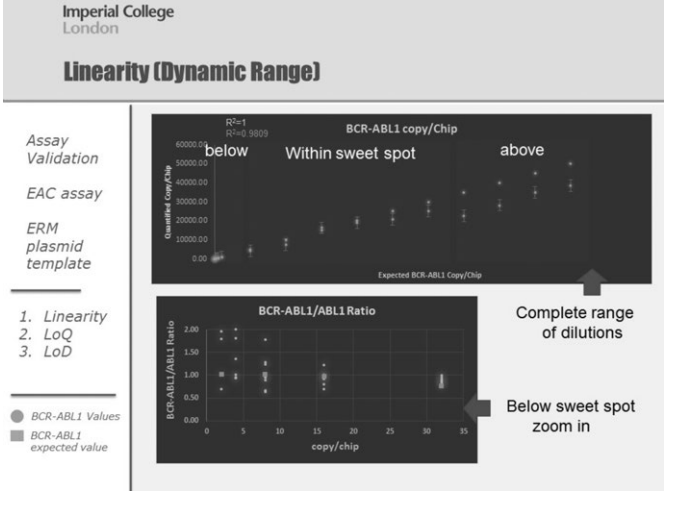

Figure 1.

Summary and Conclusions: In conclusion, our investigations demonstrate that the QS3D digital PCR platform demonstrates performance characteristics to favour its implementation in routine clinical use with a one log increased limit of detection compared to the gold standard.

S812

IMPACT OF MAJOR ROUTE VERSUS UNBALANCED MINOR ROUTE KARYOTYPES AT DIAGNOSIS ON PROGNOSIS OF CML

Background: Major route additional cytogenetic aberrations (ACA) at diagnosis of chronic myeloid leukemia (CML) indicate an increased risk of progression and shorter survival. Since all major route ACA are unbalanced it is unclear whether other unbalanced ACA at diagnosis also confer an unfavourable prognosis.
Aims: Since major route ACA are unbalanced aberrations and since patients with minor route ACA may also progress, the question arose whether a more generally defined group of chromosomal abnormalities such as unbalanced aberrations rather than only the specific major route ACA indicate progression.
Methods: On the basis of 1348 Philadelphia (Ph) chromosome positive chronic phase patients of the randomized CML-study IV we examined the impact of unbalanced minor route ACA at diagnosis in comparison to major route ACA on prognosis. Cytogenetic analyses of at least 20 Giemsa(G)-banded or Reverse(R)-banded bone marrow metaphases at diagnosis were interpreted according to the International System for Human Cytogenetic Nomenclature (2013). Patients with cytogenetic aberrations in Ph-negative clones at diagnosis were excluded from this analysis. Patients with constitutional changes were assigned to the group with standard translocation t(9;22)(q34;q11) or variant translocation t(v;22). In patients showing a complex aberrant karyotype G- or R-banding analysis was combined with m-FISH analysis. Cytogenetic remission was defined according to the ELN recommendations. Progression-free survival (PFS) was defined as the time from diagnosis until the beginning of accelerated phase, blast crisis, or death from any cause whatever event came first. For overall survival (OS), death from any cause was the only event. Probabilities of PFS and OS were calculated by the Kaplan-Meier method and compared by the log-rank test. Patients were censored at the date of last follow-up. P-values lower than 5% were considered significant. Due to the explorative character of this work, no adjustment of p-values was done and all p-values have to be interpreted descriptively.
Results: At diagnosis, 1175 patients (87%) had a translocation t(9;22)(q34;q11) and 74 (5.5%) a variant translocation t(v;22) only, while a loss of the Y-chromosome (-Y) was present in addition in 44 (3.3%), balanced or unbalanced minor route ACA each in 17 (1.3% each) cases and major route ACA in 21 (1.6%) cases. Patients with unbalanced minor route ACA achieved complete cytogenetic remission, major molecular remission, PFS and OS at similar rates as did patients with t(9;22), t(v;22), -Y, and balanced minor route karyotypes. In contrast, patients with major route ACA had a shorter OS and PFS than all other groups (p<0.005 for all pairwise comparisons with major route). Five year survival probabilities were for t(9;22): 91.4% (95% CI 89.5-93.1), t(v; 22): 87% (77.2-94.3), -Y: 89.0% (76.7-97.0), balanced: 100%, unbalanced minor route: 92.3% (72.4-100), major route: 52.2% (28.2-75.5).
Summary and Conclusions: We conclude that only major route, but not unbalanced minor route ACA at diagnosis have a negative impact on prognosis of CML. This observation may be of relevance also to other cancers.

S813

SECOND GENERATION TYROSINE KINASE INHIBITORS MITIGATE THE HIGH RISK OF DISEASE PROGRESSION IN CHRONIC MYELOID LEUKAEMIA PATIENTS WITH HIGH DIAGNOSTIC LEVELS OF CIP2A

C. Lucas[1], R. Harris[1], E. McDonald[1], F. Polydoros[2], R. Clark[1,*]
[1]Haematology, [2]CR-UK Liverpool Cancer Trials Unit, University of Liverpool, Liverpool, United Kingdom

Background: CML treatment has been significantly improved by the tyrosine kinase inhibitor (TKI) imatinib, but at least one-third of patients will eventually fail imatinib treatment[2,3] and a significant proportion of these will progress towards blast crisis (BC), which is usually rapidly fatal. Suppression of PP2A activity by the inhibitors SET and CIP2A is important in the pathogenesis and progression of chronic myeloid leukaemia (CML). We have previously shown that CML patients with a high diagnostic CIP2A protein level who then receive imatinib have a high risk of progressing to blast crisis.
Aims: The aim of this study was to investigate if high CIP2A also confers a high progression rate in patients receiving a second generation (2G) TKI dasatinib or nilotinib from diagnosis.
Methods: The diagnostic CIP2A protein level was assessed by flow cytometry

in 74 newly diagnosed chronic phase patients, who were subsequently treated with either imatinib or a 2G TKI. ROC analysis was used to define a CIP2A cut off level to stratify cases into high and low CIP2A groups. All have been seen since original diagnosis of chronic phase CML at our centre and have been followed for at least 9 months (median follow-up: 50 months).

Results: For patients with high diagnostic CIP2A level treated with imatinib, the overall and progression-free survival probability at 24 months was 41% and 17% respectively, compared to 100% for patients in any other group ($p<0.001$, Figure 1). Disease progression to blast crisis only occurred in those patients with a high diagnostic level of CIP2A and treated with imatinib. All progressions occurred within 32 months from diagnosis with the median time to progression being 12.5 months and disease progression was not associated with the development of BCR-ABL kinase domain mutations. The cumulative complete cytogenetic response (CCR) rate for low CIP2A level imatinib treated patients was 85% at 18 months. In contrast, only a single patient with a high diagnostic CIP2A level achieved CCR (cumulative CCR rate of 9% at 18 months; $p<0.001$); this patient subsequently progressed. This deleterious effect of high CIP2A was not seen if patients were treated with a 2G TKI from diagnosis, where the estimated cumulative CCR rate at 18 months was 86% and 56% for the low and high CIP2A 2G TKI patients respectively. The cumulative rate of MR4 (*BCR-ABL1/ABL* transcript ratio of ≤0.01%) for low CIP2A imatinib treated patients was 16% at 18 months. No patient with a high diagnostic CIP2A level and treated with imatinib achieved MR4 ($p=0.001$). High CIP2A patients treated with a 2G TKI have a lower rate of MR4 compared to low CIP2A 2G TKI treated patients, 11% and 48% respectively. High diagnostic CIP2A levels in patients treated with a 2G TKI predicts for poor molecular response. Early molecular response (EMR, *BCR-ABL1/ABL* ratio of <10% at 3 months) is an excellent predictor of clinical outcome in imatinib treated patients. 55% of imatinib treated low CIP2A patients achieved an EMR, compared to only 9% of high CIP2A patients ($p=0.01$). 90% of low CIP2A patients treated with a 2G TKI achieved an EMR compared to 44% of those with a high CIP2A level.

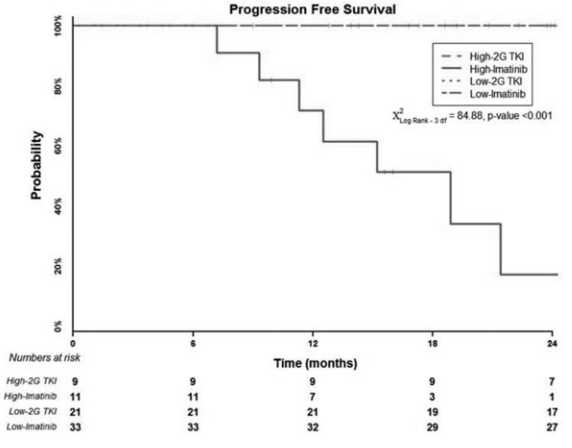

Figure 1. High CIP2A expressing patients do not progress if treated with a second generation TKI. All 74 patients involved in the study are included in the Kaplan-Meier estimate of progression free survival plots. The Log rank was used.

Summary and Conclusions: In summary, patients with high diagnostic CIP2A levels and treated with a 2G TKI at initial diagnosis do not progress to BC, suggesting that if a patient has a high CIP2A level at diagnosis then they should not be treated with imatinib due to the high risk of disease progression. A high diagnostic level of CIP2A in patients treated with a 2G TKI can predict an inferior deep molecular response. There is therefore now a case for routine CIP2A testing at diagnosis. Further study to determine the true incidence of high CIP2A patients in the general CML population is needed.

INTERNATIONAL CONTROL ROUND FOR DEEP SEQUENCING ANALYSIS OF BCR-ABL KINASE DOMAIN MUTATIONS IN 11 LABORATORIES FROM 7 EUROPEAN COUNTRIES

T. Ernst[1,*] J. Rinke[1], M. Stiens[2], S. Soverini[3], C. De Benedittis[3], K. Machova Polakova[4], V. Polivkova[4], S. Schnittger[5], C. Bär[5], M. Müller[6], C. Dietz[6], M. Füllgrabe[7], M. Medizinische Klinik, Universitätsklinikum Mannheim, Mannheim, [7]2nd Medical Department, University Hospital Schleswig-Holstein, Kiel, [8]Institute of Human Genetics, Hannover Medical School, Hannover, Germany, [9]IBSAL IBMCC (USAL-CSIC), Servicio de Hematología del Hospital Universitario de Salamanca, Salamanca, Spain, [10]Haemato Oncology Genetics, West Midlands Regional Genetics Laboratories, Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom, [11]Genetics Department, Institute of Experimental Medicine (DETAE), Istanbul University, Istanbul, Turkey, [12]Dept. of Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Point mutations in the BCR-ABL kinase domain are the most frequently identified mechanisms of acquired resistance towards tyrosine kinase inhibitors in chronic myeloid leukemia (CML). Although Sanger sequencing is still regarded as the gold standard technique for routine BCR-ABL mutation screening, next-generation sequencing (NGS) has evolved rapidly and is accessible to an increasing number of diagnostic laboratories. Thus far, data is limited on the technical performance of NGS for BCR-ABL mutation screening in a clinical diagnostic setting.

Aims: As an international consortium of 11 laboratories in 7 countries, we sought to investigate the robustness, precision, and reproducibility of NGS for BCR-ABL mutation analysis. The study was conducted as a subproject within the Interlaboratory Robustness of Next-generation sequencing (IRON)-II study.

Methods: Optimized PCR protocols and preconfigured 96-well plates containing lyophilized primer pairs targeting the entire BCR-ABL kinase domain were generated and distributed to each participating laboratory. To evaluate performance, 22 blinded control samples were sent to each laboratory (a total of 242 samples). Seventeen control samples contained cDNA of Ba/F3$^{BCR\text{-}ABL}$ cell lines harboring 12 different BCR-ABL kinase domain mutations that were mixed with non-mutated Ba/F3$^{BCR\text{-}ABL}$ to produce dilutions ranging from 1% to 100% of mutant alleles. Five control samples contained cDNA of non-mutated Ba/F3$^{BCR\text{-}ABL}$. All control samples were diluted into HL60 cells to simulate a BCR-ABL level of 10% on the International Scale. NGS was performed on 454 GS Junior sequencing instruments using 454 GS Junior Titanium chemistry for amplicon sequencing.

Results: Overall, a median of 104,732 high quality sequencing reads were generated across each of the 11 laboratories, where the number of sequencing reads ranged from 11,307 to 185,775. The mean read length obtained in all runs was 356 bases (range, 346 to 363), indicating a homogenous read length pattern across all centers. A combined number of % mixed and % dots filtered reads of less than 10% on average indicated a robust performance for each emulsion PCR (emPCR) reaction in this study. Concerning mutation analysis, 203 of 242 samples (84%) were evaluated correctly. Hereby, 9 laboratories showed an excellent performance with correct identification of 21 (2 laboratories), 20 (2 laboratories) and 19 (5 laboratories) of the 22 control samples including novel artificial variants (*e.g.* E282K) and five low-level mutations with less than 20% mutant alleles. The concordance of mutation quantification was high in all laboratories. All non-mutated control samples were reported correctly. The 1% T315I mutation dilution was not identified in any laboratory, a 5% M244V mutation was not detected in 7, and a 1% F311L mutation was not detected in 5 laboratories. Two laboratories failed to test 9 of the 22 control samples correctly, thereby reporting both false positive and false negative results.

Summary and Conclusions: This multicenter analysis demonstrated that amplicon-based deep sequencing is technically feasible, achieves a high concordance across multiple laboratories and allows a broad and in-depth characterization of BCR-ABL mutations in CML. However, data also illustrates that expertise in NGS performance and characterization of BCR-ABL mutations is advantageous and necessarily required for the report of accurate results.

Novel insights into the mechanisms involved in MPNs

S815

IDENTIFICATION OF FIP1L1-PDGFRA ASSOCIATING MOLECULE THAT LOCATES IN THE NUCLEUS AND AUGMENTS THE ACTIVITY OF FIP1L1-PDGFRA

T. Kondo[1,*] M. Ibata[1], J. Iwasaki[1], Y. Fujioka[2], K. Nakagawa[3], S. Darmanin[4], M. Onozawa[1], D. Hashimoto[1], Y. Ohba[2], S. Hatakeyama[5], T. Teshima[1]
[1]Hematology, [2]Cell Physiology, Hokkaido University Graduate School of Medicine, [3]Pathophysiology and Therapeutics, Hokkaido University Faculty of Pharmaceutical Sciences, Sapporo, Japan, [4]Medicine, Karolinska University Hospital, Huddinge, Sweden, [5]Biochemistry, Hokkaido University Graduate School of Medicine, Sapporo, Japan

Background: FIP1L1-PDGFRA is a fusion tyrosine kinase that plays a pathogenic role in chronic eosinophilic leukemia. This fusion kinase is constitutively active and its kinase activity is essential for the development of chronic eosinophilic leukemia. Therefore, a tyrosine kinase inhibitor, imatinib, is used to treat FIP1L1-PDGFRA-positive chronic eosinophilic leukemia. Although the C-terminal kinase portion of FIP1L1-PDGFRA is essential for activation of downstream substrates, the N-terminal FIP1L1 portion also plays a crucial role in cellular transformation. We have reported that the FIP1L1 portion directs FIP1L1-PDGFRA into the nucleus and is necessary for the higher proliferating activity (Iwasaki *et al.* Ann Hematol. 93:1473-81, 2014). However, little is known about the transforming pathway mediated by the FIP1L1 portion.
Aims: We tried to isolate a molecule interacting with FIP1L1-PDGFRA to elucidate the leukemogenic role of the FIP1L1 portion.
Methods: Yeast two-hybrid screening was performed, where FIP1L1-PDGFRA was used as bait. One of the positive clones encoded Protein inhibitor of activated STAT1 (PIAS1). Expression vectors of FIP1L1-PDGFRA and PIAS1 were constructed. Immunoprecipitation/immunoblotting analysis was performed to analyze the association of two molecules. Immunostaining was also performed to examine the intracellular localization of these molecules. In addition, a series of biochemical analysis was performed to analyze pathological significance of this association. Moreover, we established cells stably expressing FIP1L1-PDGFRA. Using this cell line, we analyzed whether PIAS1 contributes the FIP1L1-PDGFRA-dependent growth.
Results: PIAS1 was isolated as a FIP1L1-PDGFRA associating molecule by yeast two-hybrid screening. The association between two molecules was confirmed by immunoprecipitation/immunoblotting analysis. In addition, FIP1L1-PDGFRA associated with PIAS1 via the FIP1L1 portion. An immunostaining analysis revealed that FIP1L1-PDGFRA and PIAS1 co-localized in the nucleus. FIP1L1-PDGFRA, as a tyrosine kinase, and PIAS1, as a SUMO E3 ligase, catalyzed each other, and this enzymatic catalysis resulted in the stabilization of each molecule. Therefore, inhibition of PIAS1 activity by PIAS1-specific siRNA or a sumoylation inhibitor, ginkgolic acid, resulted in the destabilization of FIP1L1-PDGFRA. Ginkgolic acid and imatinib synergistically inhibit the kinase activity of FIP1L1-PDGFRA.
Summary and Conclusions: Our results revealed a novel pathway in the pathogenesis of chronic eosinophilic leukemia, where FIP1L1-PDGFRA associates with PIAS1 in the nucleus. The interaction of two molecules seems to be crucial for the pathogenesis of chronic eosinophilic leukemia. Moreover, sumoylation system could be a potential target in the treatment of chronic eosinophilic leukemia.

S816

THE THROMBOPOIETIN RECEPTOR SUPPORTS PROLONGED JAK2 V617F DIMERIZATION AND ACTIVATION AND IS MORE SENSITIVE TO LOW JAK2 V617F LEVELS DUE TO LONG HALF-LIFE WHEN COMPARED TO EPOR AND G-CSFR

V. Gryshkova[1,*] T. Balligand[1], S. Najjar[1], S.N. Constantinescu[1]
[1]Ludwig Institute for Cancer Research, Université catholique de Louvain, de Duve Institute, Brussels, Belgium

Background: The activating mutation V617F in the pseudokinase domain of JAK2 is prevalent in myeloproliferative neoplasms (MPN) such as Polycythemia Vera (PV), Essential Thrombocytosis (ET) and Myelofibrosis (MF). Low JAK2 V617F allele burdens in ET together with evidence from transgenic and retroviral mouse models established that low expression of mutated kinase specifically associates with an ET phenotype. The mechanism for this effect and how this single mutation promotes three distinct diseases still remains elusive.
Aims: Our aim was to investigate the differences in the interaction between JAK2 V617F and dimeric cytokine receptors for thrombopoietin (Tpo), erythropoietin (Epo) or granulocyte-colony stimulating factor (G-CSF) and to assess biochemical reasons to any possible distinctions in these interactions.
Methods: *Gaussia princeps* luciferase protein-fragment complementation was utilized to study interaction between JAK2 V617F and the cytokine receptors as well as dimerization of JAK2 V617F kinase co-expressed with these receptors. Signaling assays in transiently transfected HEK293 and γ2A cells as well as stably transduced Ba/F3 cells were used to validate the results of protein-fragment complementation assay.
Results: We have shown stronger interaction between JAK2 V617F and TpoR compared to EpoR or GCSFR at gradually decreasing dosages of the JAK2 V617F. Also, dimerization of JAK2 V617F appeared to be higher in presence of TpoR compared to other receptors tested. Interaction of the JAK2 V617F kinase with the cytokine receptors and its dimerization correlated with the half-lives of the receptors. The more stable TpoR supported prolonged JAK2 V617F and STAT5 activation compared to the less stable receptors EpoR or GCSFR. We have identified the intracellular domain in these receptors responsible for the distinction in their half-lives and made a shorter-lived TpoR and a longer-lived EpoR mutant by adding or removing a lysine, which triggers ubiquitination and degradation. As expected, the stability of the receptors was crucial for inducing pathologic signaling from JAK2 V617F with the less stable TpoR mutant losing its sensitivity to the low levels of JAK2 V617F, and, conversely, the more stable EpoR mutant becoming more sensitive to low JAK2 V617F levels.
Summary and Conclusions: Our results suggest that due to its natural long half-life in the cell and at the cell-surface, TpoR could support prolonged JAK2 V617F dimerization and activation even at the lower level of kinase expression explaining the *in vivo* JAK2 V617F gene dosage effect, where low JAK2 V617F levels are associated with thrombocytosis.

S817

CONSTITUTUIONAL GENETIC VARIATION AT HBS1L-MYB INFLUENCES WHETHER JAK2 V617F MUTATED MPN PRESENT WITH PV OR ET

W. Tapper[1,*] A. Jones[1], A. Chase[1], E. Chen[2], R. Kralovics[3], J. Ewing[4], K. Zoi[5], S. Schnittger[6], K. Dohner[7], C. Harrison[8], A. Green[2], A. Vannucchi[9], N.C. Cross[1]
[1]Human Genetics, University of Southampton, Southampton, [2]Department of Haematology, University of Cambridge, Cambridge, United Kingdom, [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria, [4]Birmingham Heartlands Hospital, Birmingham, United Kingdom, [5]Haematology Research Laboratory, Academy of Athens, Athens, Greece, [6]MLL Munich Leukemia Laboratory, Munich, [7]University Hospital of Ulm, Ulm, Germany, [8]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [9]University of Florence, Florence, Italy

Background: Polycythemia vera (PV) and essential thrombocythemia (ET) are characterized primarily by an excess production of erythrocytes and platelets, respectively. Whilst it is accepted that somatic mutations in *JAK2* and other genes drive clonal proliferation, less is known about the factors that determine the precise disease phenotype. Compared to ET, PV is characterized by higher levels of the *JAK2* V617F mutation and much more frequent outgrowth of homozygous mutant clones, however mutation burden alone cannot distinguish the two disorders and it is clear that other factors must also be important. The finding that leukocyte counts in murine *JAK2* V617F retroviral-mediated transfection/transplantation models differ in a strain-dependent manner was the first suggestion that host genetic factors may influence the disease phenotype.
Aims: Our aim is to identify inherited genetic factors that influence whether *JAK2* V617F positive MPN patients develop PV or ET.
Methods: We undertook a two stage genome-wide association study. At stage 1,556 ET patients and 556 PV patients that were positive for *JAK2* V617F and from the UK were genotyped. Following standard quality control, allelic chi-square tests were used to compare SNPs between ET or PV cases against controls (WTCCC2 n=5200). SNPs with subtype specific effects were identified by using Breslow-Day tests to assess the homogeneity of effect sizes. SNPs with significantly different effects in ET and PV cases were followed up at stage 2 by additional genotyping in two independent cohorts of *JAK2* V617F negative cases with either ET or primary myelofibrosis from the UK (n=524), Germany (n=187) and Austria (n=99). At stage 2, controls from the UK (WTCCC2 NBS n=2706) and Bavaria (KORA n=1805) were used for comparison. The final effect size and significance of SNPs was determined by a fixed effects meta-analysis of the 3 cohorts. To investigate SNP function, we used RT-qPCR to analyse gene expression in myeloid progenitors cultured *in vitro* from a series of healthy controls and MPN cases.
Results: After quality control, 490,755 SNPs were tested in 499 ET and 505 PV cases, and 5200 WTCCC2 controls at stage 1. Excluding the *JAK2* region due to recurrent aUPD in PV and to a lesser extent in ET, rs9376092 in the intergenic region between *HBS1L* and *MYB* was identified as having one of the strongest subtype specific effects (Breslow-Day test $p=4.4x10^{-5}$) which increases the risk of ET (allelic chi-square $p=6.1x10^{-7}$, OR=1.42) and may reduce the risk of developing PV (allelic chi-square p=0.068, OR=0.87). After testing stage 2 and using a fixed effects meta-analysis to combine evidence across stages, rs9376092 achieved genome-wide significance (meta-analysis $p=1.8x10^{-11}$, OR=1.35) without heterogeneity between cohorts (Cochran's Q test p=0.50). Using RT-qPCR we associated the rs9376092 risk allele with reduced expression of *MYB* (5.8-9.7 fold) and, less prominently, *HBS1L* (1.9-2.4 fold) in healthy individuals. We also found that *MYB* expression in ET was significantly lower in *JAK2* V617F-heterozygous BFU-E colonies compared to *JAK2*-wild type colonies from the same patient (Mann-Whitney test P=0.0009; q=0.01) but this difference was not seen in colonies from PV cases.

Summary and Conclusions: We conclude that constitutional genetic variation in the intergenic region between *HBS1L* and *MYB* influences whether *JAK2* V617F mutant MPN develop ET or PV. In *JAK2* V617F-negative MPN, the same variation predisposes to the development of ET. Our findings thus link constitutional differences in *MYB* expression to both predisposition to MPN and to MPN phenotype.

S818

CALCIUM INFLUX IS SHAPED BY THE MUTATIONAL STATUS IN CIRCULATING CD34+CELLS OF PATIENTS WITH MYELOFIBROSIS

V. Rosti[1,*] V. Poletto[1], I. Canobbio[2], L. Villani[1], E. Bonetti[1], M. Massa[3], R. Campanelli[1], G. Fois[1], M. Torti[2], F. Tanzi[2], F. Moccia[2], G. Barosi[1]
[1]Centro per lo Studio e la Cura della Mielofibrosi - L.S.R. Area Biotecnologie, Fondazione IRCCS Policlinico San Matteo, [2]Dipartimento di Biologia e Biotecnologie, Universita' di Pavia, [3]L.S.R. Area Biotecnologie, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Mutations of the JAK2, CALR, and MPL are detectable in the hematopoietic cells of about 90% of patients with myelofibrosis. Whereas JAK2 and MPL mutations are represented by point mutations resulting in a gain of function of the gene, CALR mutations are mainly represented by either a 52-bp deletion or a 5 bp insertion, resulting in a novel C-terminal peptide sequence. This domain regulates the Ca2+-binding activity of the protein and the two mutations are predicted to modify the Ca2+storage capacity in the endoplasmic reticulum (ER). The ER-Ca2+content of a cell depends on the balance between the so-called Store Operated Calcium Entry (SOCE) and the ER-dependent Ca2+release and, in turn, it regulates many important cell functions, such as proliferation, apoptosis and gene expression. In physiologic conditions, most of the ER-bound Ca2+is stored in the smooth-ER (s-ER). Little is known about the effects of the mutations on intracellular Ca2+homeostasis in CD34+cells of patients with myelofibrosis.
Aims: We have investigated the intracellular Ca2+release and SOCE in circulating CD34+cells of patients with MF with either the V617FJAK2 mutation (n=7) or a mutation of the CALR gene (n=7), and of healthy subjects (HS, n=4). We have also studied the ultrastructural extension of the s-ER of CD34+cells of the same subjects.
Methods: After loading CD34+cells with 4 mcM fura-2 acetoxymethyl ester, depletion of intracellular Ca2+stores was induced by adding 10 mcM cyclopiazonic acid (CPA) to a 0 Ca2+bathing medium. Ca2+was then added to the extracellular solution eliciting a rise in [Ca2+]i due to Ca2+influx through open store-operated Ca2+channels. The amplitude of the peak Ca2+response to CPA, was measured as the difference between the ratio at the peak and the mean ratio of 1 min baseline before the peak. SOCE amplitude was measured as the difference between the peak and the mean ratio of 1 min baseline recorded before the readdition of Ca2+. Extension of sER was assessed by electron microscopy (EM) followed by analysis by ImageJ software. Data are expressed as mean+/-SD.
Results: Resting levels of Ca2+of CALR-mutated CD34+cells were not statistically different from those of JAK2-mutated cells, but higher compared to those of HS. CALR-mutated CD34+cells released more Ca2+from ER stores compared to JAK2-mutated cells (60.6 nM±30.9 *vs* 26.7 nM±24.9, respectively, P=0.038) and compared to HS (27.6±19.8 nM, P=0.041 compared to CALR-mutated cells). SOCE of CALR-mutated CD34+cells (318.5 nM±206.1) was slightly increased compared to JAK2-mutated patients (242.8±146.8) and lower than SOCE of CD34+cells of HS (104.3 nM±66.5), without reaching a statistical significance. At EM evaluation, the extension of vescicles of the sER was higher in CALR-mutated CD34+cells compared to JAK2-mutated cells (0.82 *vs* 0.24 mcm, respectively, P=0.0001) and to HS-cells (0.101 mcm, P=0.0007).
Summary and Conclusions: Our results show that CALR mutation in CD34+cells of patients with PMF is associated with a rearrangement of intracellular Ca++balance, with a significant difference in Ca++release compared to that observed both in JAK2-mutated- and HS-CD34+cells. In keeping with the higher Ca2+release, we observed an increased extension of s-ER. Considering the pivotal role of Ca2+in regulating many cell functions, including proliferation and differentiation, these results seem to suggest that CALR mutation could be implicated in the myeloproliferative phenotype that characterizes PMF patients carrying CALR mutations by interfering with the signaling role of Ca2+.

S819

ROLE OF TREATMENT ON THE DEVELOPMENT OF SECONDARY MALIGNANCIES IN PATIENTS WITH ESSENTIAL THROMBOCYTEMIA

C. Santoro[1,*] I. Sperduti[2], J. Di Giandomenico[3], M. De Muro[4], N. Villivà[5], A. Di Veroli[6], M. Montanaro[7], R. Latagliata[1], B. Anaclerico[8], A. Giuseppe[4], M. Breccia[9], M. Background: Survival of essential thrombocytemia (ET) patients during the first 10 years of their disease is similar to that of the general population. While it is well known that alkylating agents (given alone or sequentially) increase the risk of transformation into an acute myeloid leukemia, the specific role of different therapies on the development of secondary malignancies (SM) in ET patients is still under investigation.
Aims: To retrospectively evaluate the role of different treatments on the development of SM in a large cohort of ET patients followed over a 30-year period.
Methods: Data from a series of 1026 ET patients diagnosed between 1980 and 2000, and followed at 11 Hematology Centers of the Lazio region in Central Italy, were collected. The median age at ET diagnosis was 62 years (range 17-93); there were 392 males, 634 females; the median follow-up of the entire population is 6.2 years (range 0.1–32). Among the whole population, 39% of patients carried the JAK2V617F mutation, while 27% were wild type; for 34% of cases, this datum is missing. With regard to adjunctive risk factors (smoke, diabetes, hypertension, dyslipidemia), 64% of patients presented at least one risk factor (42%, 1; 22% >1); 28% of patients did not present adjunctive risk factors and for 8% of cases this datum is missing. Smoke was present in 25% of cases, hypertension in 43%, diabetes in 7%, dyslipidemia in 15%. Sixty three of the 1026 patients (6%) developed 64 SM during the follow-up, after a median time of 50 months (range 2-158) from diagnosis. The observed SM were grouped as follows: genito-urinary 15, breast 14, non-melanoma skin cancer 5, lung 11, gastro-intestinal 8, hematologic 5, thyroid 3, central nervous system 1, soft tissue 1 and unknown 1. Taking into consideration the different treatment approaches, we divided our population into 5 different groups: group 0, untreated patients; group 1, patients treated with hydroxiurea (HU) alone or in combination/sequentially with interpheron α (IFN)/anagrelide (ANA); group 2, patients treated with alkylating agents (ALK) alone or in combination/sequentially with IFN/ANA; group 3, patients treated with ALK+HU sequentially; group 4, patients treated with ANA and/or IFN only.
Results: With regard to the exposure time to drugs, a statistically significant difference was found between the groups HU *vs* ALK (p=0.036), HU *vs* ALK+HU (p=0.006) and ALK+HU *vs* ANA/IFN (p=0.006). No differences were found for the groups HU *vs* ANA/IFN, ALK *vs* ALK+HU, ALK *vs* ANA/IFN. In univariate analysis, the following variables were considered: gender, age, different therapeutic approaches, exposure time, presence of adjunctive risk factors. A statistically significant difference was found only for gender (M *vs* F: p=0.035) and age (>60 years *vs* <60years: p=0.0001). In multivariate analysis, a statistically significant difference was maintained for both gender and age [gender HR1.7 (CI 95% 1.037-2.818) p 0.035; age HR 4.190 (CI 95% 2.308-7.607) p=0.0001)].

Table 1.

Groups	Number of patients	SM No	SM Yes	Median exposure time to drugs (years)	Median FU (years)
No therapy	220 (21.5%)	209 (95%)	11 (5%)	-	5 (0.1-23)
HU	641 (62.5)	599 (93%)	42 (7%)	4 (0.1-30)	6 (0.1-32)
ALK	26 (2.5%)	24 (92%)	2 (8%)	8 (0.4-23)	12 (1-30)
ALK+HU	86 (8.5%)	79 (92%)	7 (8%)	9 (0.6-24)	10 (2-26)
ANA/IFN	53 (5%)	51 (96%)	2 (4%)	4 (0.1-20)	8 (2-21)

Summary and Conclusions: In our series of 1026 ET patients followed over a 30-year period, the different therapies administered, comprising HU and ALK, do not appear to have impacted on the development of SM. A similar prevalence of SM was observed also in untreated patients. The only two variables which showed a statistical significance were male gender and age >60 years.

Towards targeted therapy in ALL

S820

A FUNDAMENTAL ROLE OF CXCR4 IN T-ACUTE LYMPHOBLASTIC LEUKEMIA

D. Passaro[1,2,*] M. Irigoyen[1], S. Gachet[1], C. Da Costa De Jesus[1], C. Lasgi[1], C. Tran Quang[1], J. Ghysdael[1]
[1]Hematology and Oncology, Curie Institute, Orsay, France, [2]Hematopoietic stem cell lab, CRUK, London, United Kingdom

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive malignancy resulting from the leukemic transformation of T-cell progenitors. Despite progress in intensive chemotherapy, 25% of pediatric and over 50% of adult patients with T-ALL show resistance to therapy and relapse. The pathophysiology of T-ALL suggests a significant deregulation of cell migration and tissue infiltration. Previously we showed that the serin-threonin protein phosphatase Calcineurin (Cn) regulates the physical and functional interaction that T-ALL cells establish with other cells in the tumor microenvironment, notably their adhesive and migratory properties, among other phenotypic traits including increased apoptosis, inhibition of cell proliferation and ultimately inhibition of Leukemia Initiating Cell (LIC) activity (Gachet *et al.*, 2013).
Aims: The aim of this study is to dissect the molecular mechanisms underlying the interactions between T-ALL cells and their microenvironment which are perturbed by Cn inactivation, and explore their therapeutic importance.
Methods: NOTCH-induced murine T-ALL in which Cn can be genetically inactivated were used to study the effect of Cn deletion on leukemic cells migration on stromal cells and on CXCR4 recycling. Retroviral mediated transduction of T-ALL cells was used to perform rescue experiments with both CXCR4 and Cortactin (Cttn). *In vivo* syngeneic transplantation studies were performed to analyse LIC activity of T-ALL cells, and two-photon confocal microscopy to study their homing ability. Sh-RNA lentiviral transduction of T-ALL cells was used to study the effect of CXCR4 knock-down on murine and human T-ALL.
Results: We identify CXCL12/CXCR4 as a highly deregulated pathway in T-ALL upon Cn deletion. Indeed, we demonstrate that Cn has a central role in CXCL12 signaling by regulating CXCR4 recycling at the cell surface. Farther, we link regulation of CXCR4 cell surface expression and CXCL12 responsiveness to the Cn-dependent expression of the actin binding protein Cttn in T-ALL. Moreover, we demonstrate that CXCL12/CXCR4 pathway not only regulates T-ALL migratory properties, but also their survival and proliferation *ex vivo*, and their homing and LIC activity *in vivo* both in NOTCH-induced mouse T-ALL and in human T-ALL xenografts.

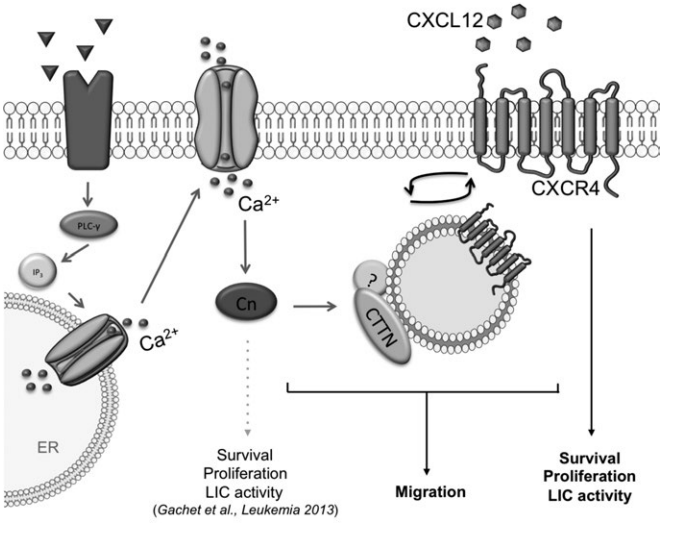

Figure 1.

Summary and Conclusions: Our results reveal a Cn-dependent regulation of CXCR4 surface expression and signaling, which plays a fundamental role in T-ALL migration. Moreover, our findings identify CXCR4 as an important regulator of T-ALL homing and transplantation and call for clinical trials targeting the calcineurin-CXCR4 axis to interfere with leukemogenesis and to improve current chemotherapy regimens in T-ALL.

MEK AND PI3K-AKT INHIBITORS SYNERGISTICALLY TARGET HYPERACTIVATING IL7-RECEPTOR SIGNALING MUTATIONS IN T-CELL ACUTE LEUKEMIA

K. Canté-Barrett[1,*] J. Spijkers-Hagelstein[2], J. Buijs-Gladdines[1], L. Zuurbier[1], J. Uitdehaag[2], W. Smits[1], M. Vuerhard[1], C. Kooi[1], J. van de Zwet[1], M. Irandoust[1], D. Geerts[1], M. Zwaan[1], R. Buijsman[2], G. Zaman[2], R. Pieters[3], J. Meijerink[1]
[1]Pediatric Oncology/Hematology, Erasmus MC-Sophia Children's Hospital, Rotterdam, [2]Netherlands Translational Research Center B.V., Oss, [3]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands

Background:
Pediatric T-cell acute lymphoblastic leukemia patients harbor mutations in *IL7Ra* or downstream molecules encoded by *JAK1*, *JAK3*, *N-RAS*, *K-RAS*, *NF1*, *AKT*, and *PTEN*. These mutated signaling molecules can contribute to leukemia by disturbing a multitude of cellular processes such as the cell cycle, epigenetics, apoptosis, or affecting other important signal transduction pathways.
Aims: We aimed to determine the overall incidence of mutations in *IL7Ra* and downstream signaling components in a large cohort of T-ALL patients. Additionally, we were interested to know whether these mutations occur in a mutually exclusive manner. In order to find better treatment options for patients with these mutations, we analyzed the effect of selected IL7Ra-pathway inhibitors—individually and in combinations—on downstream signaling and cytotoxicity for each of the mutations using our expression system in Ba/F3 cells.
Methods: We screened 146 pediatric T-ALL patient samples for mutations in the FERM, pseudokinase and kinase domains of the Janus kinase gene family (*JAK1-3, TYK2*) and hotspot regions of *N-RAS* and *K-RAS*. The three-dimensional JAK1 model was superimposed on the TYK2 pseudokinase-kinase crystallographic structure. We developed a doxycycline-inducible system by adapting the IL3-dependent Ba/F3 cell line to express mutant or wild type genes upon induction by doxycycline. Various IL7Ra-pathway inhibitors were tested using this system, and the synergy of combined inhibitors was determined by comparing the dose-response curve of different ratios of IC_{50}-based inhibitor concentrations to the curves for each of the single inhibitors. The Combination Index was calculated using Calcusyn™ software.
Results: *IL7Ra*, *JAK*, *RAS*, *AKT* and *PTEN* mutations are present in 44% of T-ALL patients and occur in a predominantly mutually exclusive fashion, suggesting they represent a single mutant signal transduction route. We found *JAK1*, *JAK3* and *RAS* mutations as previously reported, but also identified new *JAK1* mutations including V427M, L624YPILKV, E668Q, P815S, and T901G. Our novel three-dimensional model of JAK1 provides insight on how these JAK mutations result in constitutive kinase activity. Amino acid residues that regulate or facilitate direct interactions between the pseudokinase and the kinase domains are frequent targets of *JAK1* and *JAK3* mutations in T-ALL. In our doxycycline-inducible IL3-dependent Ba/F3 system, expression of mutant genes—in contrast to the wild type genes—transforms Ba/F3 cells by supporting IL3-independent growth, and by activating the RAS-MEK-ERK and PI3K-AKT pathways. We used this system to test the sensitivity to pharmacological inhibitors; IL7Ra and JAK mutant Ba/F3 cells are sensitive to JAK inhibition, so JAK inhibitors such as Ruxolitinib may offer therapeutic potential for IL7Ra, JAK1 or most JAK3 mutated T-ALL patients. However, IL7Ra and JAK mutants are relatively resistant to downstream RAS-MEK-ERK or PI3K-AKT-mTOR inhibition, indicating that inhibition of either of these downstream pathways alone is insufficient. Inhibitor combinations of both pathways completely block IL7R signaling irrespective of the level of activation by specific mutations. The RAS and AKT mutants respond to RAS-MEK and PI3K-AKT-mTOR inhibition, respectively, but are insensitive to JAK inhibition.
Summary and Conclusions: We show that the combined inhibition of MEK and PI3K/AKT leads to strong and synergistic cytotoxic effects in the IL7Ra and JAK mutants and efficiently blocks signaling downstream of both pathways. Since leukemia often depends on one or both pathways, the cytotoxic efficacy of synergistic MEK and PI3K inhibition should be further explored in clinical trials for IL7Ra mutant leukemia.

CONCURRENT CREBBP AND KRAS MUTATIONS ARE ASSOCIATED WITH A DISMAL OUTCOME IN CHILDREN WITH HYPERDIPLOID LEUKEMIA IMPLYING A SYNERGISTIC FUNCTION IN RELAPSE EVOLUTION

R. Panzer-Gruemayer[1,*] K. Malinowska-Ozdowy[2], C. Frech[2], C. Eckert[3], G. Cazzaniga[4], M. Stanulla[5], U. zur Stadt[6], A. Mecklenbräuker[2], A. Schönegger[7], M. Schuster[7], D. Kneidinger[2], A. von Stackelberg[8], F. Locatelli[9], M. Schrappe[10], M. Horstmann[6], A. Attarbaschi[11], C. Bock[7], G. Mann[11], O.A. Haas[2]
[1]Leukemia Biology Group, Children's Cancer Research Institute, [2]CCRI, Vienna, Austria, [3]Charité Universitätsmedizin Berlin, Berlin, Germany, [4]Centro Ricerca Tettamanti, Milan, Italy, [5]Hannover Medical School, Hannover, [6]University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [7]CeMM, Vienna, Austria, [8], Charité Universitätsmedizin Berlin, Berlin, Germany, [9]IRCCS Bambino Gesù Hospital, Rome, Italy, [10]Medical University of Schleswig Holstein, Kiel, Germany, [11]St. Anna Kinderspital, Vienna, Austria

Background: High hyperdiploidy (HD) denotes the largest B cell precursor acute lymphoblastic leukemia (BCP ALL) subgroup in children and adolescents. Patients usually present with low risk features and respond well to treatment. The relative proportion of relapses (up to 15%) is small but constitutes the largest genetically homogeneous fraction in the BCP ALL cohort. ≈50% of HD ALL harbor activating mutations in RTK/Ras pathway genes, which, however,

do not qualify as relapse predicting factor based on their high instability at relapse. By contrast, mutations in the transcriptional coactivator *CREBBP* (*CBP*) occur particularly in ALL relapsing cases, attenuate the function of the encoded protein and reduce acetylation of histone and non-histone proteins. Previous studies have focused on conventional sequencing of selected RTK/Ras pathway genes including small numbers of matched diagnosis and relapse samples only.

Aims: Our aim was, therefore, to investigate the mutational landscape of HD ALL using high throughput sequencing in a large cohort of such relapsing cases, in order to infer and compare the clonal composition of diagnostic and relapse samples, and test for clinical association.

Methods: We used whole exome sequencing (WES; n=19) and targeted sequencing in these and additional 81 relapsing cases (including 50 cases with matched diagnosis and relapse samples) as well as 51 non-relapsing ones. Cases were treated according to AIEOP/BFM-ALL95 and 2000, CoALL-08-09, and ALL-Rez BFM 2002 protocols.

Results: We detected at diagnosis 12 (median, range 3-23) and at relapse 25 (range 10-90) non-silent mutations per case. They target most frequently *KRAS*, *NRAS*, *PTPN11* and *FLT3* as well as *CREBBP*. Ras mutations were found in >80% of cases, frequently affecting only small clones with high inter- and intragenic heterogeneity at initial diagnosis; ≈50% were lost at relapse. RTK/Ras mutations were similarly frequent at relapse, when the vast majority of them define the major clone. *CREBBP* mutations were present in 18% of cases at diagnosis and 30% at relapse. They were already part of the major clone in >50% of cases at diagnosis, but were virtually always confined to the predominant relapse clone. Our most salient finding was the coexistence of *CREBBP* and *KRAS* mutations in the major clone of HD ALL relapses (P<0.001). Despite a similar frequency of *KRAS* and *NRAS* mutations, only the *KRAS* ones concurred with *CREBBP* mutations. This observation implies that these two mutations exert an interdependent function and cooperate in a RAS isoform-specific and synergistic fashion under the selective pressure of the applied chemotherapy. Clinically, RTK/Ras pathway and *CREBBP* mutated relapses showed only a slight prevalence of occurring early while *KRAS* mutated relapses usually did develop early; in line, relapses with concurrent *CREBBP* and *KRAS* mutations appeared earlier than those in the remaining cases (*P*=0.012*)*. While cases with *CREBBP* or *KRAS* mutations or double mutant leukemias had a significantly poorer outcome than wt cases, the cumulative incidence of relapses of the double mutant cases tended to be associated with an increased incidence of subsequent relapses.

Summary and Conclusions: *KRAS* and *CREBBP* double mutant HD ALL relapse cases are amongst those with the highest risk and are therefore suitable candidates for novel therapeutic approaches using histone deacetylase inhibitors and Ras pathway inhibitors. Since somatic *CREBBP* mutations are also present in a small number of non-relapsing HD ALL cases, they cannot be used as prognostic markers.

S823

MEK INHIBITION IS A PROMISING THERAPEUTIC STRATEGY FOR MLL-REARRANGED INFANT ALL PATIENTS CARRYING RAS MUTATIONS

M.J. Kerstjens[1,*] E.M. Driessen[1], M. Willekes[1], S. Mimoso Pinhancos[1], R. Pieters[2], R. W. Stam[1]

[1]Pediatric Oncology/Hematology, Erasmus MC - Sophia Children's Hospital, Rotterdam, [2]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands

Background: Acute Lymphoblastic Leukemia (ALL) in infants is characterized by a high incidence (~80%) of chromosomal rearrangements of the Mixed Lineage Leukemia (*MLL*) gene. *MLL*-rearranged (*MLL*-r) infant ALL patients are challenged by a very poor prognosis (*i.e.* 30-40% 5-year EFS), hence the need for better risk stratification and improved therapeutic solutions is evident. We recently screened a relatively large cohort (n=109) infant ALL patients (all enrolled in INTERFANT treatment protocols) for the presence of *KRAS* and *NRAS* mutations and found that the incidence of such mutations ranges between 14-24%, depending on the type of *MLL* translocation. Moreover, these mutations were found to represent independent predictors of exceedingly poor prognosis; all *RAS* mutation-positive *MLL*-r infant ALL patients deceased within 3 years from diagnosis.

Aims: We aimed to identify a therapeutic strategy to improve the prognosis of *MLL*-r infant ALL patients carrying *RAS* mutations.

Methods: 8 small molecule inhibitors against different RAS-pathway components were selected and tested for anti-leukemic activity against the *MLL*-r ALL cell lines SEM and RS4;11 (*RAS*^{wt}) and KOPN8 (*RAS*^{mut}) using MTS cell viability assays. Next, primary infant ALL samples (n=20) all carrying *MLL* translocation t(4;11) (giving rise to the MLL-AF4 fusion protein) either with (n=6) or without (n=14) *RAS* mutations were exposed to these inhibitors in MTT cytotoxicity assays. In addition, we assessed the RAS activity in *RAS* mutated and wild-type *MLL*-r infant ALL cells, and analysed downstream MEK and ERK activation both in the absence and presence of the MEK inhibitors. Furthermore, combination treatment of MEK inhibitors and prednisolone, the spearhead drug for ALL treatment regimes, was investigated in SEM and KOPN8 using the MTS assay.

Results: We found that the MEK inhibitors MEK162, Selumetinib, and Trametinib effectively reduced the viability of KOPN8 cells (*RAS*^{mut}), whereas SEM and RS4;11 cells (*RAS*^{wt}) largely remained unaffected. In line with this, MLL-AF4+infant ALL patient samples carrying *RAS* mutations were significantly more sensitive to these MEK inhibitors when compared with patients carrying wild-type *RAS* genes: LC_{50} values for MEK162 were 0.04 *vs.* 26.9 μM (p<0.01), for Selumetinib 0.04 and 23.7 μM (p<0.01), and for Trametinib 0.01 *vs.* 26.5 μM (p<0.01), respectively. Furthermore, the presence of *RAS* mutations in primary *MLL*-r infant ALL samples was associated with significantly increased RAS activity, as determined by immunoprecipitation of GTP-bound RAS. Remarkably, however, enhanced RAS activation was not demonstrated by increased downstream ERK phosphorylation, while a slight increase of MEK phosphorylation was observed. Yet, MEK inhibitor exposure in both KOPN8 and SEM cells resulted in nearly complete abrogation of ERK phosphorylation, without affecting total ERK protein levels, suggesting that the loss of ERK activation plays an important role in the observed anti-leukemic effects. Furthermore, MEK162 and Selumetinib, seemed to induce accumulation of phosphorylated MEK. Additionally, MEK inhibitor treatment in both SEM and KOPN8 synergistically enhanced sensitivity towards prednisolone. Interestingly, a subgroup of patient samples (n=5) with wild-type *RAS* also showed sensitivity towards MEK inhibition, similar to the primary cells with *RAS* mutations. However, this observation could not be explained by increased RAS activation, nor by the phosphorylation levels of either MEK or ERK.

Summary and Conclusions: Our data show that MEK inhibition represents a promising therapeutic approach for *MLL*-r infant ALL patients carrying additional *RAS* mutations. Furthermore, the mechanism of action provoked by these MEK inhibitors seems to involve abrogation of ERK phosphorylation, but the initial levels of ERK phosphorylation did not correlate with MEK inhibitor sensitivity, and has no predictive value. Moreover, the prednisolone sensitization induced by MEK inhibitor exposure, further illustrates the potential value of MEK inhibition for the treatment of *MLL*-r infant ALL. Currently we are in the process of testing the efficacy of the above mentioned MEK inhibitors *in vivo* using a xenograft mouse model, while further elucidation of the molecular mechanisms underlying the anti-leukemic effects of these inhibitors in *MLL*-r ALL cells are in progress.

S824

SMAC MIMETICS KILL REFRACTORY PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA THROUGH PARALLEL INDUCTION OF APOPTOSIS AND NECROPTOSIS

S. Mccomb[1,*] J. Aguade[1], G. Cario[2], M. Stanulla[3], C. Eckert[4], J.P. Bourquin[1], B. Beat[1]

[1]Department of Oncology and Children's Research Centre, Kinderspital Zurich, Zurich, Switzerland, [2]Department of General Pediatrics, University Hospital Schleswig-Holstein, Kiel, [3]Pediatric Hematology and Oncology, Hannover Medical School, Hannover, [4]Department of Pediatric Oncology/Hematology, Charité Medical University Berlin, Berlin, Germany

Background: Acute lymphoblastic leukemia (ALL) is the most common childhood cancer, and although current drug treatment is effective in most cases there are few effective second-line drugs available for drug-resistant disease. SMAC mimetics (SMs) are an emerging class of novel chemotherapeutics, which activate cell death by inhibiting key anti-apoptotic cellular inhibitors of apoptosis proteins (cIAP1, cIAP2, and xIAP).

Aims: To elucidate the potency and mechanisms of cell death induction by SMAC mimetics in pediatric ALL.

Methods: Using an *in vitro* screening approach, we assessed the sensitivity of 51 patient derived ALL xenografts to a preclinical SM compound (Birinapant). We applied specific inhibitors of apoptotic and necroptotic cell death as well as a CRISPR based genetic approach to map the mechanisms of cell death induction by SM treatment in patient derived ALL samples as well as ALL cell lines. Finally, we examined the ability of SM to selectively kill ALL cells in an *in vivo* xenograft model of refractory ALL.

Results: We show that a significant proportion of patient-derived ALL samples are highly sensitive to SM-induced death. SM sensitivity does not correlate with patient risk grouping and includes both relapsed and refractory samples. Pharmacological inhibition of distinct cell death pathways indicates that SM treatment induces both apoptotic and necroptotic cell death. While a minority of ALL samples showed either apoptotic or necroptotic features, a majority of cases had simultaneous induction of both cell death phenotypes. Examination of distinct cell death parameters such as DNA-fragmentation and loss of plasma membrane integrity by FACS and microscopy suggests that both apoptosis and necroptosis occur simultaneously within a given cell population after SM treatment. Lenti-CRISPR mediated gene disruption in ALL cell lines demonstrates that irrespective of the cell death phenotype, induction of death requires Rip1-kinase in all cases. Rip1 in turn activates Rip3-dependent necroptosis and/or Caspase-8-dependent apoptosis. Blockade of both death pathways through gene disruption or inhibitor treatment was required to restore cell viability after SM treatment. Strong anti-leukemic activity of SM was confirmed *in vivo* in a xenograft mouse model of refractory ALL. Treatment of transplanted

mice with SM not only delayed leukemia progression, but also completely eliminated leukemia burden in established disease for several weeks following treatment.

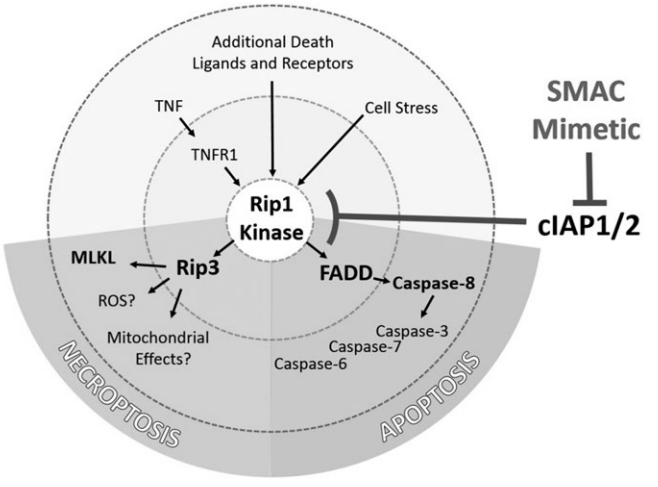

Figure 1.

Summary and Conclusions: This data shows that apoptotic and necroptotic cell death pathways are not mutually exclusive phenomena, but can be activated simultaneously in chemotherapy-resistant ALL. Because SM can induce both pathways of cell death in parallel, these agents have a strong potential for anti-leukemic therapy in refractory childhood ALL.

Biology and clinics of bone marrow failure syndromes and PNH

S825

CELLULAR AND MOLECULAR CHARACTERIZATION OF ERYTHROID DEFECTS IN DIAMOND BLACKFAN ANEMIA

D. Bodine[1,*] K.O'Brien[1], A. Vlachos[2], J. Farrar[3], L. Blanc[2], S. Anderson[1], S. Ellis[4], J. Lipton[2], N.I. Sequencing Center[1]
[1]NIH/NHGRI, Bethesda, [2]Feinstein Institute, New Hyde Park, [3]University of Arkansas, Little Rock, [4]University of Louisville, Louisville, United States

Background: Diamond-Blackfan anemia (DBA) is a rare, congenital bone marrow failure syndrome with severe anemia, congenital anomalies, predisposition to cancer and variable severity. Approximately 65% of DBA patients have heterozygous autosomal dominant mutations or deletions in one of >15 ribosomal protein (RP) genes encoding both large and small subunit proteins. In addition, recent studies have identified mutations in the *GATA1* gene in three DBA families. Despite targeted sequencing of all 80 RP genes, the causal abnormalities in the remaining ~35% of DBA patients are unknown as is the mechanism by which RP defects cause erythroid failure.
Aims: 1. To develop an *in vitro* system to culture erythroid cells from DBA patient peripheral blood CD34+cells. 2. To use transcriptional profiling of DBA erythroid cells to determine the disrupted pathways. 3. To perform whole exome sequencing on DBA patients without RP mutations to determine the genetic defects.
Methods: We developed a 2-step culture system that expands CD34+cells (7 days), then induces differentiation of erythroid cells (7 days). This system yields >10^7 CD235+erythroid cells from ~10^4 CD34+cells collected from 10 ml of healthy control peripheral blood. RNA isolated from CD235+erythroid cells was profiled on Affymetrix GeneChip Human Gene ST Arrays and by RNASeq. Whole exome sequencing (WES; Illumina HySeq; 80X coverage) was performed on DBA probands, an unaffected sibling and their parents. After filtering out common variants in the 1,000 Genomes and ClinSeq databases we used the VarSifter program to evaluate candidate causal variants for further study.
Results: In contrast to control cells, cells from 9 different DBA patients (5 RP mutations, 3 unknown, 1 with a *GATA1* mutation) exhibited a significantly reduced growth rate, generating ~100-fold fewer CD235+erythroid cells, with an ~2-day delay in the acquisition of the CD235 marker. Using flow cytometry, we isolated populations of CD235+erythroid cells from both control and patient cell cultures for RNA profiling. RNA from DBA patients showed a distinct transcriptional profile compared to control samples and the sample from the *GATA1* patient. Gene ontogeny analysis showed increased expression of genes associated with cellular stress and decreased expressed expression of genes associated with cell cycle progression and protein translation in the RP patients. The GATA1 patient's profile identified decreased expression of red cell structural genes as well as genes in the heme biosynthesis pathway. In one DBA family, we identified candidate autosomal recessive mutations in the *MCM2* and *POLR3B* genes. Normal CD34+progenitor cells expressing shRNAs targeting *MCM2* and *POLR3B* mRNA demonstrated 60-90% knockdown of each. *POLR3B* knockdown cells showed no inhibition of erythroid differentiation, indicating *POLR3B* is an unlikely DBA candidate gene. In contrast, knockdown of *MCM2* ddemonstrated a significant reduction in BFU-E (but not CFU-GM) colony formation. Similar to DBA patient cells, the proliferation of *MCM2* knockdown cells was reduced and the differentiation of CD235+erythroid cells was delayed. *MCM2* knockdown cells were arrested at the G_1/S checkpoint in the cell cycle. As confirmation, mice deficient in *Mcm2* have a severe bone marrow failure syndrome with erythroid defects.
Summary and Conclusions: Our *in vitro* differentiation system is a powerful tool to study erythropoiesis in DBA patients using small volumes of peripheral blood. We have used this system to demonstrate that the common forms of DBA, associated with defects in ribosomal genes, have defects in cell cycle and protein translation that differ significantly from the defects observed in the *GATA1* DBA patient. Finally, we have shown that mutation in the *MCM2* gene is associated with DBA in at least one family, which represents the first autosomal recessive mutation identified in DBA patients.

S826

ELTROMBOPAG ADDED TO STANDARD IMMUNOSUPPRESSION AS FIRST TREATMENT IN SEVERE APLASTIC ANEMIA

D. Townsley[1,*] B. Dumitriu[1], S. Phillip[2], R. Desmond[3], X. Feng[1], O. Rios[1], B. Weinstein[1], J. Valdez[1], T. Winkler[1], K. Keyvanfar[1], S. Sellers[1], M. Desierto[1], S. Soltani[1], H. Leuva[1], S. Valluri[1], C. Wu[1], K. Calvo[4], A. Larochelle[1], C. Dunbar[1], N. Young[1]
[1]National Institutes of Health, National Heart, Lung, and Blood Institute, Bethesda, United States, [2]Hospital Sao Jose - Hospital Beneficencia Portuguesa de Sao Paulo, Sao Paulo, Brazil, [3]Tallaght Hospital, Dublin, Ireland, [4]National

Institutes of Health, Clinical Center, Department of Laboratory Medicine, Bethesda, United States

Background: Immunosuppressive treatment (IST) for severe aplastic anemia (SAA) has a 60-65% rate of overall hematologic response (OR), of which only about 10% are complete (CR). Eltrombopag, a synthetic thrombopoietin receptor agonist (TPO-RA), has activity in refractory SAA, producing multilineage hematologic responses in about 40% of patients.
Aims: We conducted an investigator-initiated phase II, single-center trial to test the efficacy of adding eltrombopag to h-ATG/CsA (clinicaltrials.gov, NCT01623167).
Methods: Patients with treatment-naïve SAA were enrolled from July 2012 to November 2014. All subjects received standard h-ATG and CsA. To determine the optimum regimen, eltrombopag was administered at 150 mg daily to two consecutively enrolling cohorts (see Table). The primary endpoint was CR at 6 months. Both cohorts were powered to detect a ≥30% CR rate at 6 months for comparison with our historical rate of 10%. Our historical data suggest that CR is a surrogate for late events since it is associated with a low rate of evolution to monosomy 7/acute leukemia and correlates with excellent long-term survival.
Results: Thirty subjects enrolled in the first cohort had a median age of 39 years (12-72); thirteen (43%) had very severe disease (ANC<200/µl), and 8 (27%) had PNH clones ≥1%. Eltrombopag was well tolerated when combined with CsA, and only three patients discontinued treatment before 6 months. CR at 6 months was 33% (95% CI, 15-51%), significantly higher than our historical rate of 10% (p<0.001). OR at 6 months was 80% (CI, 65-95%), exceeding the historical rate of 60% (p=0.040). Median increases in blood counts among responders at 6 months (n=24) were: absolute neutrophil count (ANC) +1240/µl; hemoglobin +3.8 gm/dL; and platelets +87,000/µl. Median time to achieve transfusion independence was 32 days for platelets and 39 days for red cells. Serial BM biopsies showed improved cellularity in 25 cases without increased fibrosis. Median increase in BM CD34+cells, as measured by flow cytometry, was 34-fold from baseline to 3 months, and 23-fold from baseline to 6 months (p<0.0001). Primitive hematopoietic progenitors were serially measured in 4 patients, detecting HSC (CD34+CD38-CD45RA-CD90+CD49f+Rho^{lo}) and MPP (CD34+CD38-CD45RA-CD90-CD49f-) by flow cytometry. Undetectable at baseline, these cells constituted 4-48 HSC and 1-27 MPP per 100,000 CD34+cells 6 months after therapy. The first cohort has been followed for median 24 months (range 15-31m); there have been 3 clonal evolution events, all detected in responders: one patient had complex cytogenetics (t(3;3)(q21;q26)) with BM dysplasia followed by increased blasts, and deletion 13q in one subject and trisomy 15 in another, neither with BM dysplasia. Enrollment to the second cohort, in which eltrombopag is stopped at 3 months, is complete and 23 subjects are currently evaluable at 6 months. OR at 6 months is 87% (20/23) and CR rate at 6 months is 22% (5/23) confirming results observed in the first cohort. One clonal evolution event (deletion 7p) occurred at 6 months in a responder and relapse of pancytopenia soon followed.

Tabella 1. Hematologic Response.

	3 months *N (%)*	6 months *N (%)*
Cohort 1	30	30
OR	23 (77)	**24 (80)**
PR	18 (60)	14 (47)
CR	5 (17)	**10 (33)**
Cohort 2	31	23
OR	24 (77)	**20 (87)**
PR	16 (52)	15 (65)
CR	8 (26)	**5 (22)**

Cohort 1: eltrombopag d14 - 6mos.
Cohort 2: eltrombopag d14 - 3mos.

Overall response (OR) = blood counts no longer meeting criteria for SAA
Partial response (PR) = blood counts not meeting criteria for SAA or CR
Complete response (CR) = ANC ≥1,000/µl, hemoglobin ≥10 gm/dL, and platelets ≥100,000/µl.

Summary and Conclusions: The addition of eltrombopag to IST increases overall and complete hematologic response rates. Marked increase in CD34+cells, the appearance of multipotent progenitor cells, and rapid blood count recovery support a mechanism of action of direct stimulation of stem and progenitor cells by eltrombopag.

S827

COMBINATION OF MINOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONES AND LYMPHOCYTE TELOMERE LENGTH PREDICT RESPONSIVENESS TO IMMUNOSUPPRESSIVE THERAPY IN PEDIATRIC APLASTIC ANEMIA

A. Narita[1,*] H. Muramatsu[1], Y. Sekiya[1], Y. Okuno[1], H. Sakaguchi[2], N. Nishio[1], N. Yoshida[2], X. Wang[1], Y. Xu[1], N. Kawashima[1], S. Doisaki[1], A. Hama[1], Y. Takahashi[1], K. Kudo[3], H. Moritake[4], M. Kobayashi[5], R. Kobayashi[6], E. Ito[7], H. Yabe[8], S. Ohga[9], A. Ohara[10], S. Kojima[1]

[1]Department of Developmental Pediatrics, Nagoya University Graduate School of Medicine, [2]Department of Hematology and Oncology, Children's Medical Center, Japanese Red Cross Nagoya First Hospital, Nagoya, [3]Department of Pediatrics, Fujita Health University School of Medicine, Toyoake, [4]Department of Reproductive and Developmental Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, [5]Department of Pediatrics, Hiroshima University Graduate School of Biomedical and Health Sciences, Hiroshima, [6]Department of Pediatrics, Sapporo Hokuyu Hospital, Sapporo, [7]Department of Pediatrics, Hirosaki University Graduate School of Medicine, Hirosaki, [8]Department of Cell Transplantation and Regenerative Medicine, Tokai University School of Medicine, Isehara, [9]Department of Pediatrics, Yamaguchi University Graduate School of Medicine, Ube, [10]Department of Pediatrics, Toho University School of Medicine, Tokyo, Japan

Background: Acquired aplastic anemia (AA) is characterised by a hypo-cellular marrow and peripheral blood cytopenias. Unfortunately, allogeneic bone marrow transplantation is limited by the availability of human leukocyte antigen (HLA)-matched donors. Most AA patients receive immunosuppressive therapy (IST) combining anti-thymocyte globulin (ATG) and cyclosporine A (CyA). The presence of minor paroxysmal nocturnal hemoglobinuria (PNH) clones and a short telomere length (TL) were identified as predictive biomarkers of IST responsiveness.
Aims: To assess whether combining minor PNH clones and TL could predict IST response with greater accuracy.
Methods: We enrolled 118 children (67 boys and 51 girls) diagnosed with acquired AA in Japan between July 2001 and November 2013. Fifty-three patients received horse ATG (Lymphoglobulin, 15mg/kg/day for 5 days) and 65 received rabbit ATG (*Thymoglobulin*, 2.5−3.75 mg/kg/day for 5 days). All patients received CyA (6 mg/kg/day) starting on day 1 for at least 180 days. The dose of CyA was adjusted to maintain trough levels of 100–200 ng/ml. Written informed consent was obtained from the parents of all patients. This study was approved by the ethics committee of Nagoya University Graduate School of Medicine. A flow cytometry assay was used to detect PNH-type granulocytes and red blood cells (RBCs). The presence of >0.005% $CD13^+CD55^-CD59^-$ granulocytes and/or >0.010% glycophorin $A^+CD55^-CD59^-$ RBCs was defined as PNH clones positive (PNH^+). Cut-off values were determined using receiver operator characteristic (ROC) analysis. The telomere length of peripheral lymphocytes was measured by flow-fluorescence *in situ* hybridization (flow-FISH). According to ROC analysis, we defined −1.21 SD of age-adjusted controls as the cut-off value.
Results: Patients' median age when IST was administered was 9.7 years (range, 0.9–16.0 years), disease was moderate-to-very severe, and all three categories of disease severity were well represented. The causes of AA were idiopathic in 103 patients and hepatitis-associated in 15 patients. Forty-eight patients (41%) carried PNH^+clones. The median TL of AA patients was −1.08 standard deviation (SD) (range, −4.01–+3.01 SD). Overall, 63 patients (53%) responded to IST after 6 months. Multivariate logistic regression analysis identified WBC ≥2.0 × 10^6/L (OR, 2.82; 95% CI, 1.13–7.03; p=0.026), absence of PNH^+clones (OR, 4.66; 95% CI, 1.81–12.00; p=0.001), and a shorter TL (OR, 4.10; 95% CI, 1.66–10.10; p=0.002) as independent unfavorable predictors of response to IST at 6 months. Accordingly, the cohort was stratified into unfavorable group (PNH^- and a shorter TL, n=41) and favorable group ($PNH^+$and/or a longer TL, n=77). The response rate at 6 months of the unfavorable group was significantly lower (22%) compared with that of the favorable group (70%) (p <0.001). Five-year transplantation free survival (TFS) and failure free survival (FFS) were significantly lower in the unfavorable group compared with those in the favorable group [TFS, 53% (95% CI, 34%–68%) *vs.* 73% (95% CI, 60%–82%); p=0.010; FFS, 24% (95% CI, 11%–39%) *vs.* 53% (95% CI, 40%–65%); *p* <0.001]. However, no difference was observed in 5-year overall survival (OS) between groups [unfavorable group, 98% (95% CI, 84%–100%) *vs.* favorable group, 96% (96% CI, 88%–99%); p=0.743], possibly because of effective salvage hematopoietic stem cell transplantation (HSCT).
Summary and Conclusions: The current study reveals that PNH^- patients with shorter TL are less likely to respond to IST. Our findings suggest that combining these two markers may help to provide the appropriate treatment option to the patients and prevent adverse events due to unnecessary treatment. Despite the risk of complications, unrelated or mismatched related donor transplantation may be considered as a front-line therapy for patients in the unfavorable group lacking HLA-matched sibling donors.

S828

A SUBCUTANEOUSLY ADMINISTERED RNAI THERAPEUTIC (ALN-CC5) TARGETING COMPLEMENT C5 FOR TREATMENT OF PNH AND COMPLEMENT MEDIATED DISEASES: INTERIM PHASE 1 STUDY RESULTS IN HEALTHY VOLUNTEERS

B. Sorensen[1,*] J. Taubel[2], J. Bush[3], A. Hill[4], A. Borodovsky[1], N. Kawahata[1], L. Melton[1], J. Cehelsky[1], C. Powell[1], K. Yucius[1], R. Hutabarat[1], P. Chaturvedi[1], G. Warner[1], A. Vaishnaw[1], P. Garg[1]

[1]Alnylam Pharmaceuticals, Cambridge, United States, [2]Richmond Pharmacology Ltd, London, [3]Covance, [4]Department of Haematolog, Leeds Teaching Hospitals, Leeds, United Kingdom

Background: Uncontrolled complement activation plays a pivotal role in a variety of disorders such as PNH and aHUS.
Aims: ALN-CC5 is a subcutaneous (S.C.) investigational RNAi therapeutic targeting complement C5 (C5) with the purpose of decreasing terminal complement activity and thereby protects against intravascular hemolysis and complement mediated tissue damage.
Methods: Preclinical studies in rat and non-human primate (NHP) models were used to investigate the ability of ALN-CC5 to reduce complement C5, inhibit complement-mediated hemolytic activity and complement alternative- and complement classic pathway (CAP and CCP). Furthermore, ALN-CC5 was investigated in a rat membranous nephropathy model, the anti-collagen antibody induced arthritis model and in a passive myasthenia gravis model. A placebo controlled double blind phase 1 clinical study in healthy volunteers and patients with PNH is ongoing. Several cohorts in part A, a single ascending dose study have been completed and Part B, a multiple ascending dose study is currently ongoing. Part C will be a multiple dose study in patients with PNH. Primary endpoints are safety and tolerability. Secondary endpoints are pharmacokinetics, reduction of circulating C5, reduction in hemolytic and CAP as well as CCP activity.
Results: Pre-clinical studies demonstrated that ALN-CC5 resulted in mean 98.4±0.7% reduction of C5 levels in NHPs, mean 88±6.1%% reduction in hemolysis and mean 95.1±0.93% reduction in CAP with every-other week or monthly S.C. dosing. Furthermore, ALN-CC5 significantly reduced proteinuria in a rat membranous nephropathy model, reduced disease activity in the mouse arthritis model and reduced clinical disease score and improved grip strength in the myasthenia gravis model. ALN-CC5 reduced disease manifestation comparable to treatment with C5 monoclonal antibody. In Part A of the phase 1 study, human volunteer subjects were randomized (3:1) to placebo or a starting single subcutaneous dose of 50 mg ALN-CC5 and followed for at least 70 days. Following safety review, additional single ascending dose cohorts were authorized. Part B multiple ascending cohorts are planned to start in parallel to Part A. Up-to-date results on safety, tolerability and C5 knockdown, changes in CAP, CCP and hemolytic activity from study will be presented.
Summary and Conclusions: Collectively, these data suggest that the use of a novel RNAi therapeutic targeting C5 is a promising approach for inhibiting complement in PNH, aHUS and other complement mediated diseases. The subcutaneous route of administration and infrequent dosing make this a particularly encouraging potential therapy.

S829

ACUTE AND CHRONIC RENAL FAILURE IN A PATIENT COHORT FROM THE SPANISH PNH REGISTRY

A.M. Villegas[1,*] R. Nuñez[2], A. Gaya[3], M.V. Cuevas[4], J.M. Bosch[5], A. Carral[6], B. Arrizabalaga[7], M.D.C. Fernández[8], R. Córdoba[9], P. Bravo[10], E. Lavilla[11], C. Monteserin[12], B. Hernández[13], P. Martinez Barranco[14], I. Jarque[15], F.A. Gonzalez[1], Á. Urbano[3]
[1]Hospital Clínico San Carlos, Madrid, [2]Hospital Virgen del Rocío, Sevilla, [3]Hospital Clínic Barcelona, Barcelona, [4]Hospital General Yagüe, Burgos, [5]Hospital Universitario Materno-Insular, Las Palmas de Gran Canaria, [6]Hospital de Sagunto, Valencia, [7]Hospital de Cruces, Bilbao, [8]Complejo Hospitalario de Toledo, Toledo, [9]Fundación Jiménez Diaz, [10]Hospital de Fuenlabrada, Madrid, [11]Hospital Lucus Agusti, Lugo, [12]Hospital de Getafe, Madrid, [13]Hospital General de Ciudad Real, Ciudad Real, [14]Hospital Fundación Alcorcón, Madrid, [15]Hospital la Fe, Valencia, Spain

Background: Paroxysmal Nocturnal Hemoglobinuria (PNH) is a rare, genetic, and life-threatening blood disease. This illness is characterized by the destruction of red blood cells and hemolytic anemia [1]. The consequent intravascular hemolysis, hypercoagulability, and bone marrow failure may result in several clinical sequels as thrombosis or renal failure [2]. Although its treatment was usually symptomatic, Eculizumab has recently shown efficient results for this disease world-wide [3] and specifically in Spanish cohorts [4].
Aims: This study was planned to describe Acute and Chronic Renal Failure (ARF and CRF) related values in PNH-patients and to assess how Eculizumab affects these parameters.
Methods: From 128 registered patients (PNH Spanish Registry; April 2014), 60 were diagnosed with classic PNH (47%). 27 of these cases (45%) also suffered ARF or CRF and were included in this retrospective and descriptive study.
Results: PNH studied patients were 12 males and 15 females with a mean age of 48.5 (±16.2) y/o whom were diagnosed with PNH when they had a mean age of 38.6 (±13.8) y/o. PNH clone values for analyzed patients was 71.7 % (±23.4) granulocytes, 76.6 % (±28.1) monocytes and 42.3 % (±23.6) erythrocytes. All 27 patients presented renal failure. Specifically, 5 (18.5%) patients were diagnosed with CRF without any previous ARF, 8 (29.6%) were diagnosed with CRF and suffered ARF and 14 (51.9%) only presented ARF. In 20 cases, ARF diagnosis was coincident with a hemolytic crisis. In addition, a patient presented 5 ARF episodes and 4 patients presented 2 episodes. ARF patients showed these mean values at diagnosis: 3880.3 (±2253) UI/L for LDH, 8.1 (±1.9) g/dL for Hemoglobin (Hb), 7.6% (±7.2) Reticulocytes, 117.3 (±46.7) mg/dL for Urea, 4.4 (±2.3) for Creatinine, 26.8 (±17.3) ml/min/1.73 m2 for Glomerular filtrate and 534.8 (±492.1) mg/24 h for Proteinuria. In addition, 21 out of 22 patients showed Hemoglobinuria, 15 out of 16 Hemosideruria and 9 out of 15 Urinary casts. Finally, 6 ARF patients required dialyses and there were 18 complete recoveries and 4 partial recoveries, with a mean time of 13.3 (±7.6) days. Values for CRF-diagnosed patients were 41.7 (±27.2) mg/dL for Urea, 1.3 (±0.4) mg/dL for Creatinine, 56.8 (±14.0) ml/min/1.73 m2 for Glomerular filtrate and 814.4 (±614.0) mg/24 h for Proteinuria. After PNH diagnosis, estimated probability to evade ARF at 5 years was 56.5% (IC 95%; 35.1, 73.3) and median time without an ARF episode was estimated to be 7.3 (IC 95%; 2.2, 14.9) years. Likewise, estimated probability to avoid CRF at 5 years was 60.9% (IC 95%; 37.8, 77.7) and median time without CRF diagnosis was estimated to be 14.5 (IC 95%; 3.8, ND) years. Finally, from 23 Eculizumab treated patients, 20 were still continuing with a mean extent of 3.9 (±2.2) years. Creatinine and Glomerular filtrate values for treated CRF patients were still very preliminary to statistical evaluation. However, recorded data showed a trend towards improvement after 18 months. Considering all treated patients, only 1 (5.3%) suffered a septic shock coincident ARF episode after treatment. All patients were alive at the end of the study.
Summary and Conclusions: This study described ARF and CRF values of Spanish PNH patients and estimated the probabilities to present these diseases after PNH diagnosis. Also, preliminary results suggested that there might be a low ARF incidence in Eculizumab treated patients and CRF related clinical values might have a positive development in time.

LB2067

APL OF ALL RISK GROUPS IS HIGHLY CURABLE WITH A CHEMO-FREE COMBINATION OF ATTENUATED ARSENIC TRIOXIDE AND ATRA

A. Burnett[1,*] N. Russell[2], R. HillsA. Khwaja[3], D. Bowen[4], J. Cavenagh[5], L. Friis[6], J. Kell[7], S. Knapper[7], Y. Morgan[8], J. Lok[9], G. Jones[10], A. Hunter[11], M.F. McMullin[12], R. Clark[13], D. Grimwade[14]
[1]NCRI AML Study Group, Arran, [2]Department of Haematology, Nottingham University Hospitals NHS Trust, Nottingham, [3]Department of Haematology, University College Hospitals, London, [4]Department of Haematology, St James Hospital, Leeds, [5]Department of Haematology, Barts & the London NHS Trust, London, United Kingdom, [6]Department of Haematology, Odense Hospital, Odense, Denmark, [7]Department of Haematology, University Hospital Wales, Cardiff, [8]Guy's and St Thomas's Hospital, [9]Guy's and St Thomas NHS Trust, London, [10]Department of Haematology, Newcastle Hospitals NHS Trust, Newcastle, [11]Department of Haematology, Leicester Royal Infirmary, Leicester, [12]Department of Haematology, Belfast City Hospital, Belfast, [13]Department of Haematology, Royal Liverpool Hospital, Liverpoll, [14]Kings College, London, United Kingdom

Background: Survival for patients with APL has improved in the last 20 years. The MRC AML15 trial delivered 80% 5 year survival using anthracycline and All-trans retinoic acid (ATRA) and the exclusion of cytarabine and maintenance which has become standard of care. Arsenic Trioxide (ATO) and Gemtuzumab Ozogamicin (GO) are effective as single agents with the former approved for relapsed disease. The next stage in de-intensification in this disease is the "chemo-free" combination of ATO+ATRA. In low risk disease (WBC<10x10^9/L) the GIMEMA-AMLSG-SAL trial, using a daily schedule of ATO+ATRA, indicated this was at least as effective as chemotherapy containing protocols (Lo Coco *et al*., NEJM 2013;369: 111-21).
Aims: The NCRI AML17 Trial compared Anthracycline/ATRA (AIDA) *vs* the chemo-free combination of ATO (in an attenuated schedule) +ATRA. Importantly high risk patients (presenting WBC>10x10^9/L) were also included with the option to add a single dose of GO (6mg/m^2) in induction.
Methods: From May 2009 to October 2013, 235 patients aged>16 who entered the AML17 trial with molecularly confirmed APL were randomised to either **ATRA+ATO** (8 week induction 0.3mg/kg d1-5 w1, 0.25mg/kgx2/w w2-8, followed by 4 consolidation courses of 0.3mg/kgx2 w1, 0.25mg/kgx2/w w2-4 (63 ATO doses) **OR AIDA** schedule: Idarubicin (Ida)12mg/m^2 d2,4,6,8 +ATRA to d60) (induction) then Ida 5mg/m^2 d1-4 +ATRA d1-15 (Course 2); Mitox. 10mg/m^{2}d1-4 +ATRA d1-15 (course 3); Ida 12mg/m^2 d1 +ATRA d1-15 (Course 4). ATRA was 45mg/m^2/d**.** Follow-up is complete to 1/1/2014.
Results: The median age was 47y (16-77); 57 had WBC>10x10^9/L (27 AIDA, 30 ATRA+ATO) and 49 (24 AIDA, 25 ATRA+ATO) were >60y. 90% entered morphological CR; overall day 30, 60 mortality was 5%, 7%. When a landmark analysis is performed from day 30, 4-year OS is 96%. 20 patients have relapsed. Survival at 4 years is 91%. For patients with a high WBC OS was 86%, and for patients >60 years OS was 77%. There was no significant difference in CR rate between the arms (Chemo 89%, Chemo-free 94%; OR 0.54 (0.21-1.34), p=0.18). The day 30, 60 mortalities were 6% *vs* 4% (p=0.6) and 9% *vs* 5% (p=0.2). One patient on ATRA+ATO experienced frank relapse compared with 12 on AIDA plus a further 7 molecular relapses on this arm (cumulative incidence of frank relapse 13% *vs* 1%, HR 0.16 (0.05-0.48) p=0.001). Among patients who achieved molecular negativity cumulative incidence of molecular relapse was 27% *vs* 0%. The OS at 4 years is 89% (Chemo) *vs* 93% (Chemo-free), HR 0.60 (0.26-1.42) p=0.2, but EFS was significantly superior with ATRA+ATO (91% *vs* 74%, HR 0.36 (0.19-0.70) p=0.003) due to the lack of relapse after CR. There was significantly less alopecia, grade 3,4 liver and GI toxicity on the chemo-free arm. Significantly fewer blood and platelet transfusions were used and there were fewer days on antibiotics and in hospital. The QoL and HADS assessments did not differ significantly. There was no heterogeneity of treatment effect by subgroup. Importantly, when considered by WBC risk, for low risk patients (WBC<10x10^9/l) cumulative incidence of frank relapse was 5% *vs* 1% (p=0.03) with 4-year survival of 90% *vs* 95% (p=0.17). In high risk patients (WBC>10^9/L) CIR was 26% *vs* 0% (p=0.008), and OS 87% *vs* 84% (p=0.8). Of 30 high risk patients allocated to the chemo-free arm, 28 received GO as per protocol. The OS at 4 years for high risk patients given GO was 89%. Of the 2 patients not treated with GO, one died on d12. Compared with the GIMEMA-AMLSG-SAL trial, results were similar, but with less liver toxicity (<10% *vs* 63%); less frequent dosing of ATO (63 *vs* 140); less ATO required (151 vials *vs* 280 vials for a 70kg patient, which at an acquisition cost of £350/vial represents a cost reduction of £46k/patient).
Summary and Conclusions: The combination of ATO and ATRA represents a new standard of care resulting in a very low risk of relapse resulting in significantly better EFS and excellent survival. The attenuated dosing approach is safe and effective in high risk patients particularly if combined with a single dose of GO, is less toxic and less costly.

LB2068

IMPACT OF A GAIN-OF-FUNCTION MUTATION OF CXCR4 ON HAEMATOPOIESIS IN MICE

C. Freitas[1,2,*] M. Wittner[3], J. Nguyen[1,2], V. Biajoux[1,2], M.L. Aknin[4], F. Gaudin[1,2,4], S. Beaussant-Cohen[5], Y. Bertrand[6], F. Bachelerie[1,2], A. Dalloul[1,2], J. Donadieu[7], F. Louache[3], K. Balabanian[1,2]

Background: The Warts, Hypogammaglobulinemia, Infections and Myelokathexis Syndrome (WS) is a rare immuno-haematological disorder characterized notably by a chronic pan-leukopenia. It is mostly caused by inherited heterozygous autosomal dominant gain-of-function mutations in *CXCR4*, which engender a distal truncation in the carboxyl-terminal tail (C-tail) domain and lead to a desensitization-resistant receptor. CXCR4 is widely expressed on non-haematopoietic cells and virtually all leukocytes. Thus, we hypothesized that WS-associated circulating lymphopenia arises from altered CXCR4-mediated signalling that skews tissue distribution and differentiation of lymphocytes. We recently produced major breakthroughs in the pathophysiology of the WS by generating a knock-in mouse strain (*Cxcr4$^{+/1013}$*) harbouring a WS-linked heterozygous *Cxcr4* mutation. Mutant mice displayed *in vitro* lymphocytes with enhanced migration to Cxcl12, the sole ligand of Cxcr4, and phenocopied severe circulating pan-lymphopenia. Analyses of primary lymphoid organs (*i.e.* bone marrow [BM] and thymus) have unveiled defects in early stages of B- and T-cell development, *i.e.* B-cell progenitors and Early T-cell progenitors. The mechanisms underlying deregulation of lymphopoiesis process, and the resulting chronic blood lymphopenia, are still unknown.
Aims: Here we explore the biological impact of a gain-of-Cxcr4-function on haematopoiesis in both BM and extra-medullary sites.
Methods: We took advantage of our original knock-in model to investigate BM and splenic haematopoietic stem and progenitor cells (HSPC) distribution, clonogenicity, quiescence and *in vivo* migration by flow cytometry and clonogenic assays. We further examined the capacity of mutant HSC to repopulate the BM in long-term BM reconstitution experiments. To exclude any interference of the *Cxcr4$^+$*(WT) allele, we produced and investigated homozygous *Cxcr4$^{1013/1013}$* mice in parallel.
Results: We showed that the total number and homing properties of HSC, as well as the clonogenicity of progenitors, were not altered in the BM of mutant mice as compared to WT littermates. The quiescence status of LSK SLAM was increased, whereas the total number of multipotent and common lymphoid progenitors was decreased in an allele dose-dependant manner. Long-term BM reconstitution experiments indicated that these defects were cell-autonomous and further revealed a decreased capacity of *Cxcr4$^{1013/1013}$* HSC to repopulate the BM. Based on clonogenic assays, we reported a decrease in the total number of HSPC in the blood of mutant mice, an anomaly also found in four WS patient carrying a heterozygous *CXCR4* mutation. This suggested an abnormal HSPC circulation that was strengthened by the increased extramedullary haematopoiesis observed in the spleen of mutant mice. This phenomenon was allele dose-dependent, cell autonomous and associated with an increased expression of Cxcl12 in the red pulp area.
Summary and Conclusions: These results provide new details about haematopoiesis by establishing the C-tail in Cxcr4-mediated signalling as a pivotal regulator of such process. Our current activities consist in investigating *in vitro* the lymphoid differentiation of mouse and human HSPC and characterizing BM and spleen HSC niches.

LB2069

ASSESSMENT OF INTRAVENOUS FERRIC CARBOXYMALTOSE VERSUS ORAL IRON SULPHATE IN THE MANAGEMENT OF PREOPERATIVE ANAEMIA: A PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

A. Khalafallah[1,2,3,*] C.R. Chilvers[4], M. Sexton[3], E. Ingram[5], C.M. Chilvers[3], M. Vialle[4], B. Kirkby[6], B. Einoder[6], T. Brain[7]
[1]Menzies Research Institute, [2]Faculty of Human Health Sciences, University of Tasmania, [3]Haematology, [4]Anaesthesia, Launceston General Hospital, [5]School of Medicine, University of Tasmania, [6]Surgery, [7]Pathology, Launceston General Hospital, Launceston, Australia

Background: Both pre and postoperative anaemia are highly prevalent in surgical patients. Depending on the type of surgery, underlying disease and the definitions of anaemia, about 14% up to 76% of surgical patients may present with pre-operative anaemia according to different studies. Recently, there has

been increasing evidence to suggest that pre-operative anaemia can lead to an increased risk of peri-operative adverse outcomes such an increase in the requirement for blood transfusion, increase of hospital Length of Stay (LoS) and increased overall morbidity and mortality. In addition, evidence has shown that pre-operative anaemia increases the chance of receiving unnecessary allogeneic blood transfusion with its consequences when compared to patients with a normal haemoglobin level, preoperatively.

Aims: Assessment of safety of a single intravenous iron carboxymaltose dose versus standard oral iron sulphate and the subsequent effect on the perceived quality of life (QoL) in both treatment groups.

Methods: We conducted a prospective randomised controlled trial with two different iron therapies for the treatment of iron deficiency anaemia (IDA) patients who were undergoing elective surgery. During the period between January 2012 and August 2014 at our tertiary referral Hospital for Northern Tasmania, Australia, we recruited 125 patients 2-4 weeks preoperatively who were randomized to a single intravenous ferric carboxymaltose (FCM) infusion (1000 mg standard dose) versus oral daily iron sulphate (325 mg, equivalent to 105 elemental iron) until the time of the surgery. Median age was 71 years (range, 38-94) with a male to female ratio of 67:58. The vast majority of patients were Caucasian. All patients gave an informed consent according to Helsinki guidelines. There were 70 patients who underwent major orthopaedic surgery, 23 abdominal surgery, 27 genitourinary surgery and 5 patients underwent general surgery.

Results: Average Hb level at recruitment was 113 g/L in the FCM intervention group versus 120 g/L in the oral iron group that increased respectively to an average of 122 g/L versus 124 g/L immediately prior to surgery and was maintained at 126 g/L versus 123 g/L at 3 months after treatment respectively. The median baseline ferritin in the FCM group was 32 mcg/L versus 76 mcg/L that increased immediately prior to surgery to 544 mcg/L in the FCM versus 107 mcg/L in the oral iron group and was maintained for 3 months at 176 mcg/L versus 90 mcg/L respectively (p<0.001). Average LoS in the hospital was reduced by 1 day in the FCM group as compared to the oral iron group. FCM was well tolerated by all patients without serious adverse events.

QoL assessment using SF36 at baseline, immediately preoperative, and 3 months post operatively showed improvement in physical function, energy and general health in favour of the FCM group.

Summary and Conclusions: Our data suggest that IV FCM was well tolerated and was associated with improvement of both immediate preoperative Hb and ferritin levels compared to oral iron. Accordingly, there was a reduction of length of hospital stay and improvement of perceived QoL after surgery. Further trials that aim to improve and optimize preoperative and postoperative Hb are warranted.

Trial registration: This study was registered prospectively in the Australian New Zealand Clinical Trials Registry:
(http://www.ANZCTR.org.au/ACTRN12611001256965) and the World Health Organization:
(http://apps.who.int/trialsearch/trial.aspx?trialid=ACTRN12611001256965*).*

Background: Massively parallel whole-exome sequencing (WES) studies have uncovered cancer drivers in CLL and have provided new insights in disease pathogenesis, evolution and prognostication.

Aims: To overcome limitations in size and the clinical heterogeneity of previous cohorts, we performed WES on pretreatment tumor and matched germline samples of 278 CLLs enrolled in the CLL8 trial of the GCLLSG treated with FC/FCR and with full clinical annotation and mature follow up time. We enhanced the power to detect putative drivers through integration with previously published WES data for a total discovery cohort of 538 CLL exomes.

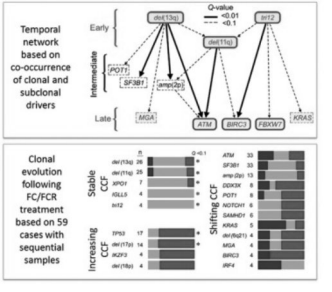

Figure 1.

Results: This resulted in detection of 55 putative CLL driver events (44 sSNVs, 11 sCNVs), many of which have not been previously associated with CLL. At least one potential driver event was found in 91.1% of samples, with 65.4% harboring 2 or more. These putative drivers appeared to affect 8 major cellular processes, including the MAP-ERK pathway (KRAS, NRAS, BRAF, MAP2K mutations; affecting 5.6% of cases), and the MYC pathway (MGA, FUBP1, PTPN1, IRF4 mutations; 8% of cases). For the majority of samples, two driver events were found within the same sample, one at clonal and the other at subclonal frequency. Such cases enabled us to infer a temporal sequence of acquisition and built a network based on significantly recurrent temporally directed events. Thus we found distinct points of origin restricted to few events such as del13q and tri12, with early convergence to del11q and subsequent divergence in diverse late-occurring driver events including mutated TP53 and KRAS. We assessed the clinical impact of driver events in 278 patients from CLL8 in the context of front line therapy. Mutated TP53 and SF3B1 cases had significantly shorter PFS and OS. XPO1 (HR 2.02, *P* =0.02), BRAF (HR 2.05, *P* =0.05) and EGR2 (HR 2.14, *P* =0.05) mutations were associated with reduced OS and trend towards shorter PFS. ATM and BIRC3 mutations had no significant impact on outcome. Both the presence of a pre-treatment subclonal driver (66.5% of subjects) and clonal driver (84.2%) were associated with a significantly shorter PFS (HR 1.64, p=0.003 and HR 1.78 p=0.009) with only subclonal drivers achieving significance in the FCR arm. To directly observe clonal evolution following FC/FCR, we compared the cancer cell fractions (CCFs) of the putative driver alterations in 59 of 278 samples for which a matched relapse samples was available. We observed clonal shifts in 57 of 59 cases of which 21 showed linear and 36 branched evolution with the latter significantly associated with

FCR treatment. Neither type of evolution nor presence of the relapsed clone at baseline (n=18) had an impact on outcome. Notably events inferred as early events by our temporal network were stably clonal over time. Late events demonstrated either increasing (*i.e.* in TP53) or shifting (*i.e.* in SF3B1, ATM) CCFs after FC/FCR suggesting evolution in relation to therapy (figure). In addition, this temporal map suggests that the copy number loss in 11q precedes point mutations in ATM or BIRC3 in cases with biallelic loss. By contrast, TP53 and 17p show a concordant rise of both events suggesting that biallelic inactivation of TP53 is typically required for fitness advantage.

Summary and Conclusions: WES of a large, uniform cohort revealed several novel putative drivers in CLL, enabled their categorization into 8 major functional pathways and investigation of their prognostic impact within the CLL8 trial cohort. Furthermore we developed a network model of CLL evolution with earlier initiating and late accelerating events.

LB2071

CARFILZOMIB AND DEXAMETHASONE IMPROVES PROGRESSION-FREE SURVIVAL AND RESPONSE RATES VS BORTEZOMIB AND DEXAMETHASONE IN PATIENTS (PTS) WITH RELAPSED MULTIPLE MYELOMA (RMM): THE PHASE 3 STUDY ENDEAVOR

M. Dimopoulos[1,*] P. Moreau[2], A. Palumbo[3], D. Joshua[4], L. Pour[5], R. Hájek[6], T. Facon[7], H. Ludwig[8], A. Oriol[9], H. Goldschmidt[10], L. Rosiñol[11], J. Straub[12], A. Suvorov[13], C. Background: Bortezomib and dexamethasone (Vd) is a standard-of-care regimen for RMM. Carfilzomib (20/27 mg/m^2; 2–10 min intravenous [IV] infusion) is approved in Argentina, Israel, Mexico, and the United States for relapsed and refractory multiple myeloma and significantly improved progression-free survival (PFS) when given with lenalidomide and dexamethasone for RMM in the phase 3 study ASPIRE (NCT01080391; Stewart et al, *N Engl J Med*, 2015). In study PX-171-007 (NCT00531284), carfilzomib (20/56 mg/m^2; 30-minute infusion) and dexamethasone (Kd) had promising activity in pts with RMM (Papadopoulos et al, *J Clin Oncol*, 2015).

Aims: ENDEAVOR (NCT01568866) compares Kd with Vd in pts with RMM. Results from a prespecified interim analysis are presented.

Methods: Adults with RMM (1–3 prior treatments) were eligible. Pts were randomized 1:1 and stratified by prior K or V (yes *vs* no), prior lines of treatment (1 *vs* 2–3), International Staging System stage (1 *vs* 2–3), and intended route of V (IV *vs* subcutaneous [SC]). The Kd arm received K (30-min IV infusion) on days (D) 1, 2, 8, 9, 15, 16 (20 mg/m^2 on D1, 2 [cycle 1]; 56 mg/m^2 thereafter) and dexamethasone (20 mg) on D1, 2, 8, 9, 15, 16, 22, 23 of a 28-day cycle. The Vd arm received V (1.3 mg/m^2; IV or SC) on D1, 4, 8, 11 and dexamethasone (20 mg) on D1, 2, 4, 5, 8, 9, 11, 12 of a 21-day cycle. Cycles were repeated until disease progression or unacceptable toxicity. The primary end point was PFS assessed by an independent review committee. Secondary end points include overall survival (OS), overall response rate (ORR), duration of response (DOR), rate of peripheral neuropathy (PN), and safety.

Results: In total, 929 pts (Kd: 464; Vd: 465) were randomized. In the Vd arm, 83.6% of pts received SC bortezomib. Median treatment exposure was 39.9 weeks (Kd) and 26.8 weeks (Vd). Kd led to a 47% decrease in the risk of progression or death (hazard ratio, 0.53; 95% confidence interval [CI], 0.44–0.65; *P*<.0001), with a median PFS of 18.7 months (95% CI, 15.6–not estimable) in the Kd arm *vs* 9.4 months (95% CI, 8.4–10.4) in the Vd arm. OS data were immature (deaths: Kd=75; Vd=88); pts continue to be followed. Best overall responses are presented in the table. The median DOR was 21.3 months (Kd) and 10.4 months (Vd). Treatment discontinuation due to an adverse event (AE) occurred in 14.0% (Kd) and 15.7% (Vd) of pts. An AE led to dose reductions of K or V in 22.9% and 47.8% of pts, respectively; 61.9% of dose reductions in the Vd arm were due to neuropathy-related AEs *vs* 6.6% in the Kd arm. Rates of grade ≥2 PN (grouped term) were 6.0% in the Kd arm vs 32.0% in the Vd arm (P<0001). The most common hematologic AEs (preferred terms; all grades) in the Kd and Vd arms, respectively, included anemia (39.3% *vs* 27.0%) and thrombocytopenia (20.5% *vs* 17.1%); the most common nonhematologic AEs (preferred terms; all grades) included diarrhea (30.9% *vs* 38.4%), fatigue (29.4% *vs* 28.5%), and dyspnea (28.5% *vs* 13.2%). Grade ≥3 AEs of interest in the Kd and Vd arms, respectively, included hypertension (preferred term; 8.9% *vs* 2.6%), dyspnea (preferred term; 5.4% *vs* 2.2%), cardiac failure (grouped term; 4.8% *vs* 1.8%), and acute renal failure (grouped term; 4.1% *vs* 2.6%). A total of 3.9% of pts in the Kd arm and 3.4% of pts in the Vd arm died on study owing to AEs.

Tabella 1. Best overall responses.

	Kd (N=464)	Vd (N=465)
Best overall response, n (%)[a]		
Stringent complete response	8 (1.7)	9 (1.9)
Complete response	50 (10.8)	20 (4.3)
Very good partial response	194 (41.8)	104 (22.4)
Partial response	104 (22.4)	157 (33.8)
ORR[a]		
n	357	291
ORR, % (95% CI)[b]	76.9 (72.8–80.7)	62.6 (58.0–67.0)
Odds ratio (Kd/Rd) (95% CI)[c]	2.03 (1.52–2.72)	
P value (1-sided)[c]	<.0001	

[a]Determined by independent review committee according to International Myeloma Working Group Uniform Response Criteria. ORR includes patients with a best overall response of partial response or better. One patient in each arm was not evaluable for best overall response owing to censoring but was included in the ORR calculation since they achieved a partial response prior to being censored.
[b]Clopper–Pearson interval.
[c]The odds ratio and 95% CI and *P* values were calculated using the stratified Cochran–Mantel–Haenszel method.

Summary and Conclusions: Carfilzomib and dexamethasone demonstrated statistically significant and clinically meaningful superiority over bortezomib and dexamethasone in RMM, with a 2-fold improvement in median PFS and a favorable benefit–risk profile. These data suggest that carfilzomib could be a best-in-class agent for RMM.

LB2072

PATIENT-REPORTED OUTCOMES (PROS) IN PERSIST-1: A RANDOMIZED, MULTI-COUNTRY PHASE III TRIAL OF THE JAK2 INHIBITOR PACRITINIB (PAC) VS. BEST AVAILABLE THERAPY (BAT) IN MYELOFIBROSIS (MF)

R. Mesa[1,*] A. Vannucchi[2], A. Mead[3], L. Wang[4], Y. Yang[5], C. Harrison[6]

[1]Mayo Clinic, Scottsdale, United States, [2]University of Florence, Florence, Italy, [3]Oxford University, Oxford, United Kingdom, [4]CTI BioPharma Corp., Seattle, [5]Baxter Healthcare Corporation, Deerfield, United States, [6]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: MF is a serious, life-threatening disease characterized by splenomegaly and debilitating symptoms such as fatigue, night sweats, pruritus, weight loss, and abdominal pain. MPN-SAF TSS is a PRO tool designed to measure the burden of MF-related symptoms. The instrument was developed and validated at Mayo Clinic for utilization in clinical practice. In agreement with the FDA, the instrument was modified (MPN-SAF TSS 2.0) for use in PERSIST-1 and PERSIST-2, both, international, phase 3 randomized clinical trials to support a PRO endpoint.

Aims: Compare symptom reduction of PAC *vs* BAT in the open-label PERSIST-1 (NCT01773187) trial in primary myelofibrosis (PMF), post-polycythemia vera (PV-MF), and post-essential thrombocythemia (PET-MF).

Methods: JAK inhibitor naïve patients (pts) were randomized 2:1 to oral PAC 400 mg once daily or BAT stratified by DIPSS risk (Int-1/Int-2 *vs* High) and platelet (plt) count (<50,000/μL *vs* 50,000 to <100,000/μL *vs* ≥100,000/μL). Pts had baseline total symptom score (TSS) ≥13 using MPN-SAF TSS. Each symptom is rated on a scale from 0 (absent) to 10 (worst imaginable) using MPN-SAF TSS and MPN-SAF TSS 2.0 with core symptoms tiredness, night sweats, early satiety, itchiness, bone pain, and abdominal pain. Other PROs included Patient Global Impression of Change (PGIC), EORTC QLQ-C30, and EQ-5D-5L.

Results: 327 pts were enrolled (PAC: 220, BAT: 107), 62% with PMF; 32% had plt counts <100,000/μL and 16% had plt counts <50,000/μL. 24.5% of pts treated with PAC and 6.5% treated with BAT achieved a ≥50% decrease in TSS at Week 24 (WK24; Figure; p<0.0001) in the intent-to-treat population. In pts with baseline plt count <100,000/uL, 25.0% of pts treated with PAC and 8.8% treated with BAT achieved a ≥50% decrease in TSS at WK24 (p=0.0677). There were significant reductions from baseline to WK24 in fatigue, early satiety, abdominal discomfort, inactivity, night sweats, itching, and bone pain (MPN-

SAF TSS), and tiredness, early satiety, abdominal discomfort, night sweats, and pain under ribs on left side (MPN-SAF TSS 2.0). In the PAC group, 81% of pts rated the change in their overall condition as very much improved, much improved, or minimally improved by PGIC in pts who completed questions, *vs* 21% for pts in the BAT group (p<0.001). Among those with improvement in PGIC, 40% had ≥50% reduction of TSS at WK24. On the EQ-5D-5L, overall health scores were higher on average in patients treated with pacritinib and a greater proportion reported improvement in the usual activities, pain/discomfort, and anxiety/depression dimensions. Pacritinib-treated patients also reported higher scores on functioning (physical, role and social) scales and lower scores on symptom scales including fatigue, pain, insomnia, and loss of appetite on the EORTC QLQ-C30.

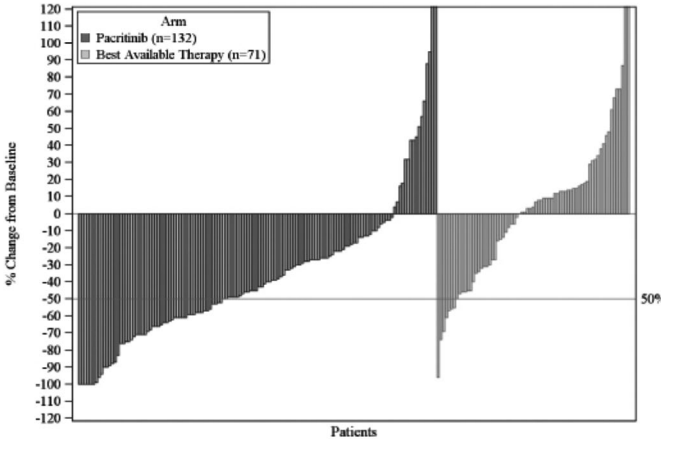

Figure 1.

Summary and Conclusions: PAC treatment improved PROs across several measures. Specifically, it resulted in significantly higher response rates based on TSS which were associated with better PGIC and QoL.

LB2073

EFFICACY AND SAFETY OF INOTUZUMAB OZOGAMICIN (INO) VS STANDARD OF CARE (SOC) IN SALVAGE 1 OR 2 PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): AN ONGOING GLOBAL PHASE 3 STUDY

D.J. DeAngelo[1,*] M. Stelljes[2], G. Martinelli[3], H. Kantarjian[4], M. Liedtke[5], W. Stock[6], N. Goekbuget[7], K. Wang[8], L. Pacagnella[9], B. Sleight[9], E. Vandendries[8], A.S. Advani[10]

[1]Dana Farber Cancer Institute, Boston, MA, United States, [2]Universitätsklinikum Münster, Münster, Germany, [3]Institute Seragnoli, University of Bologna, Bologna, Italy, [4]MD Anderson Cancer Center, Houston, TX, [5]Stanford Comprehensive Cancer Center, Stanford, CT, [6]University of Chicago, Chicago, IL, United States, [7]Goethe University, Frankfurt, Germany, [8]Pfizer Inc, Cambridge, MA, [9]Pfizer Inc, Groton, CT, [10]Cleveland Clinic, Cleveland, OH, United States

Background: The majority of cases of B-cell ALL express CD22. InO, a humanized anti-CD22 antibody conjugated to calicheamicin, a potent cytotoxic antibiotic, showed initial efficacy and safety in ALL (Kantarjian. *Cancer.* 2013;119:2728).
Aims: To assess antitumor activity and safety of InO *vs* SOC (intensive chemotherapy) in adults with relapsed/refractory ALL
Methods: In this phase 3 trial (NCT01564784), patients (pts) were randomized to InO (starting dose 1.8 mg/m^2/cycle [0.8 mg/m^2 on d1; 0.5 mg/m^2 on d8 and 15 of a 21–28 d cycle [≤6 cycles]) or SOC (either fludarabine/cytarabine [ara-C]/granulocyte colony-stimulating factor [FLAG], ara-C plus mitoxantrone, or high-dose ara-C). A split-α design was used for 2 primary endpoints: 1) complete remission (CR) or CR with incomplete hematologic recovery (CRi) assessed in 218 pts; and 2) overall survival (OS) to be assessed in all 326 pts enrolled. Secondary endpoints: duration of remission (DOR), minimal residual disease negativity (MRD-neg; <0.01% by central flow cytometry) in pts with CR/CRi, stem cell transplant (SCT) rate. Data as of October 2, 2014 are presented, except for survival (not mature at this date).
Results: Per protocol, the first 218 of 326 pts randomized were included in the primary intent-to-treat (ITT) analysis (for InO *vs* SOC [n=109 each]: CR1 duration ≥12 mo, 43% *vs* 35%; age <55 y, 61% *vs* 63%; Salvage 1, 67% *vs* 63%); CR/CRi rate was significantly better in the InO *vs* SOC arm (see **Table** for efficacy). Safety was assessed in 259 pts who received ≥1 dose of study drug; pts received InO (n=139) for median 8.3 (range, 0.1–26.4) wks *vs* SOC (n=120) for median 0.9 (0.4–15.1) wks; 83% *vs* 89% discontinued, primarily due to CR in InO (35%) *vs* resistant ALL in SOC (40%) arms. Most common grade (Gr) ≥3 AEs were hematologic cytopenias. For InO *vs* SOC, Gr≥3 hepatobiliary AEs occurred in 9% *vs* 3% pts; any grade veno-occlusive liver disease (VOD) occurred in 15 *vs* 1 pts (Gr≥3, 13 *vs* 1 pts). More patients proceeded to allogeneic SCT with InO (n=48) *vs* SOC (n=20); in the InO arm, 5 VOD cases (2 in pts with prior SCT) occurred during treatment and 10 after subsequent SCT (2 fatal).

Tabella 1. Best overall responses.

% (95% CI)	InO (n=109)	SOC (n=109)	1-sided *P*-Value
CR/CRi[a]	80.7 (72–88)	33.3 (24–44)	<0.0001
S1	87.7	31.3	<0.0001
S2	66.7	37.9	0.0104
Median DOR, mo	4.6 (3.9–5.4)	3.1 (1.4–4.9)	0.0169
MRD-neg in pts with CR/CRi	78.4 (68–87)	28.1 (14–47)	<0.0001

[a]Modified ITT analysis excluding 13 untreated SOC pts; assessed per independent endpoint adjudication committee

Summary and Conclusions: CR/CRi, DOR, and MRD-neg rates were significantly greater with InO *vs* SOC. InO safety profile is consistent with previous studies; liver toxicities and VOD were more common with InO; additional VOD analyses characterizing risk factors and management considerations will be presented. Trial is ongoing to allow survival data to mature.

FISH-BASED SCREENING FOR TYROSINE KINASE-ACTIVATING FUSION GENES IN CHILDHOOD HIGH-RISK B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (BCP-ALL)

K. Nebral[1,2,*] M. König[2], A. Attarbaschi[3], G. Mann[3], O.A. Haas[1,2,3], S. Strehl[2]
[1]medgen.at GmbH, [2]CCRI, Children's Cancer Research Institute, [3]St. Anna Children's Hospital, Medical University, Vienna, Austria

Background: Tyrosine kinase (TK)-activating gene fusions define a biologically and clinically distinct class of apparently high-risk BCP-ALL in children and adolescents (Roberts et al, New Engl J Med 371:1005;2014). Because they provide unique targets for therapeutic interventions with various fusion type-specific tyrosine-kinase inhibitors, these abnormalities attain considerable interest. Consequently, there is also a pressing need to identify all the respective lesions in a fast and cost efficient way.
Aims: In consideration of these demands, we devised a hierarchical FISH-based screening algorithm that enables the detection of the vast majority of all relevant alterations. We used this approach to examine a careful selected group of high-risk patients that were enrolled in the Austrian BFM-ALL 2000 treatment study with the aim to identify the respective TK-activating fusion genes in order to determine their type, frequency and clinical relevance.
Methods: Our strategy consists of several hierarchical steps of FISH screening, the first of which is required to define and exclude the preponderant proportion (>60%) of cases with all known specific abnormalities, such as those with an *ETV6/RUNX1, BCR1/ABL1, KMT2A, TCF3* and *IGH* rearrangement as well as those with a hyper- or hypodiploid karyotype, iAMP21 and dic(9;20), because cases with the TK fusions of interest are almost exclusively found in the remaining so-called "B-others" cohort. Next, we exploit the fact that one of the respective fusion partners is always one of a few TK-activating hub genes, namely *ABL1, ABL2, CRLF2, CSF1R, JAK2, PDGFRB* or *EPOR.* The potential involvement of the one or the other of these genes is then assessed with the respective 3'-5' dual-color split apart FISH probes.
Results: So far, we have analyzed 50 high-risk "B-others" patients that were selected according to the above criteria. These cases were screened for the presence of TK-activating gene fusions with all currently available commercially *PDGFRB/CSF1R, JAK2, CRLF2* and (the non-TK) *PAX5* split-apart FISH probes. We identified specific rearrangements in 13/50 (26%) cases. Three had a *PDGFRB/CSF1R,* two a *JAK2,* seven a *CRLF2* and one an *ABL1* gene rearrangement, the latter of which became apparent during screening with a *BCR/ABL1* FISH probe. Moreover, with the help of metaphase FISH, CGH array and RT-PCR analyses we were also already able to identify the fusion partner in 11/13 of these cases. Six of the 13 patients were transplanted, two of them in second remission, five experienced a late relapse and three died, two because of septicemia and one after experiencing a third relapse after transplantation.
Summary and Conclusions: The results of our analyses confirm the efficiency and validity of our FISH screening approach, which currently is supplemented also with additional assays, in particular those identifying *ABL1* and *ABL2* gene rearrangements. The presented strategy can be easily adopted in an analogous fashion to identify such TK-activating gene fusions also in other forms of hematologic malignancies. Their unambiguous identification is an essential requirement for choosing a suitable TK inhibitor, an option that is increasingly required for the appropriate disease-specific treatment.

E850

CUSTOMIZED NEXT-GENERATION SEQUENCING PANEL FOR IMPROVED CLINICAL DIAGNOSTICS OF HIGH-RISK B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA OF CHILDHOOD

U. Zur Stadt[1,*] G. Escherich[2], D. Indenbirken[3], M. Adao[1], M. Alawi[4], M.A. Horstmann[25]
[1]Center for Diagnostic, [2]Clinic of Pediatric Hematology and Oncology, University Medical Center Hamburg Eppendorf, [3]Virus Genomics, Heinrich-Pette-Institute for Experimental Virology, [4]Bioinformatics Core Facility, University Medical Center Hamburg Eppendorf, [5]Research Institute Children's Cancer Center, Hamburg, Germany

Background: Next generation sequencing (NGS) applications have recently identified various recurrent kinase and cytokine receptor mutations in a subgroup of B-cell precursor acute lymphoblastic leukemia (BCP-ALL) that is characterized by a Ph-like gene expression signature. Combined genome, exome or transcriptome analyses have identified recurrent genetic alterations of kinases and cytokine-receptors/adaptors, which often result in ligand-independent, constitutive activation of downstream signalling pathways. The diversity of mutation types including complex genomic rearrangements demands new strategies for cost-effective, time-saving routine clinical diagnostics.
Aims: We report a feasible approach for the identification and characterization of kinase and kinase-dependent pathway aberrations in BCP-ALL utilizing a customized sequence enrichment capture panel for NGS.
Methods: Thirteen BCP-ALL patients with a high minimal residual disease (MRD) level (≥1x10^{-2}) after induction therapy from COALL studies 07-03 or 08-09 were applied to the panel. Four positive controls with known rearrangements (*BCR-ABL1* and *ID4-JH*) were included to test the general applicability of the method. Genomic capture probes were specific for exonic and intronic regions of *ABL1, JAK2, PDGFRB, CRLF2* and for the *IgH-JH* region on chromosome 14. These predefined genomic regions from recurrently mutated or rearranged kinase and cytokine receptor genes were enriched from 50 ng of initial genomic DNA without gene specific PCR amplification steps, followed by paired end sequencing of the captured genomic fragments (Nextera Rapid Capture Custom enrichment protocol with paired end sequencing on a MiSeq benchtop sequencing platform; Illumina).
Results: All breakpoints from 4 positive controls were successfully identified and verified by patient specific amplification of the genomic fusion sites. *ABL1* and *JH* specific capture probes allowed the "fishing" of the genomic fusion partner gene, here *BCR* and *ID4*, by paired end sequencing of overlapping, breakpoint spanning reads. This approach also allowed the identification and exact mapping of the genomic breakpoint for *CRLF2 (P2RY8-CRLF2; CRLF2-JH*), *PDGFRB (EBF1-PDGFRB)* or *EPOR (IgH-EPOR)* in 7/13 BCP-ALL with high level of post-induction MRD.
Summary and Conclusions: Rapid identification of kinase- or cytokine receptor rearrangements in BCP-ALL offers new therapeutic options for the treatment with target specific tyrosin kinase inhibitors (TKI's). Our approach is applicable for routine clinical applications with short turnaround times of less than 2 weeks. Up to 12 samples can be processed in parallel on one MiSeq run. Bioinformatical analysis follows a standardized, automated workflow. Despite limitations in target gene selection, the method allows the identification of unknown fusions partners from frequently rearranged kinase genes, providing the exact breakpoint location. MRD guided NGS panel analysis is a feasible strategy for identification of patients suitable for targeted TKI intervention, which may reduce the high risk for therapeutic failure/relapse.

E851

THE LNCRNAS MEG3 AND LINC-PINT REGULATE THE EXPRESSION OF HMOX1 IN ALL, SHOWING A POTENTIAL AS A THERAPEUTIC TARGETS FOR THIS DISEASE

A. Garitano Trojaola[1], X. Agirre[1], A. Vilas[1], V. Segura[2], P. Fortes[3], F. Prosper[1,*]
[1]Oncology, [2]Bioinformatics, [3]Hepatology and Gene therapy, Centre for Applied Medical Research (CIMA), Pamplona, Spain

Background: Long non-coding RNAs (lncRNAs) are functional RNAs longer than 200 nucleotides in length. Compared to mRNAs, most lncRNAs are localized preferentially to the nucleus, are more cell type specific and are expressed at lower levels. The function of lncRNAs in the cell is primarily regulatory and they have a clear impact in cell behavior. Furthermore, several lncRNAs are deregulated in human diseases including several cancers.
Aims: we aimed to analyze the expression and function of lncRNAs in ALL.
Methods: In order to identify aberrantly expressed lncRNAs in ALL, we used the SurePrint G3 Human Gene Expression array that detects 27956 coding genes and 7419 lncRNAs. The transcriptomes of primary ALL cells, ALL cell lines and control samples were compared.
Results: In this analysis, we detected 37 lncRNAs differentially expressed, 24 of them down-regulated and 13 up-regulated in ALL cells compared to healthy controls. We analyzed the expression of 21 deregulated lncRNAs by quantitative RT-PCR (q-PCR) and we validated the data obtained by expression arrays in 18 out of the 21 genes tested. We focused our study in *MEG3* and *linc-PINT*, and by q-PCR, we observed a decreased expression of these 2 lncRNAs in 10 ALL-derived cell lines compared with B and T cells obtained from healthy donors. Also, we detected a direct correlation between an inappropriate DNA methylation and the decreased expression of *MEG3* in ALL cell lines. Interestingly, we observed that re-expression of *MEG3* or *linc-PINT* in ALL cells led to a decrease in cell proliferation, due to cell cycle arrest in G2 phase and induction of apoptosis. The transcriptome analysis of ALL cell lines after overexpression of *MEG3* or *linc-PINT*, showed an increase expression of *HMOX1*. Interestingly, the overexpression of *HMOX1* on its own also decreased cell proliferation, suggesting that HMOX1 could be a mediator of the phenotype observed after re-expression of *MEG3* or *linc-PINT*. Finally, we observed that different drugs that affect proliferation of ALL cells, such as curcumin or panobinostat, induced drastically the expression of *linc-PINT* and *HMOX* in these cell lines. These results indicate that *linc-PINT* and *HMOX1* could be interesting therapeutic targets for improving the treatment of ALL patients.
Summary and Conclusions: The expression of several lncRNAs is altered in primary samples and cell lines of ALL. In some cases, altered expression is due to inappropriate DNA methylation. *MEG3* and *linc-PINT* are decreased in ALL cells and their re-expression affects cell cycle progression and induces apoptosis in these cells. These effects could be mediated by HMOX. Curcumin and panobinostat also induce *linc-PINT* and *HMOX,* which could drive their effects in cell proliferation. Therefore, *linc-PINT* and *HMOX1* could be therapeutic targets for improving the treatment of patients with ALL.

E852

THE ROLE OF NRARP IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA PATHOGENESIS AND CHEMOTHERAPY SENSITIVITY

M.L. Oliveira[1], R. Cabrita[1], J.T. Barata[1], R. Fragoso[1,*]
[1]Cancer Biology Unit, Instituto de Medicina Molecular, Lisboa, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy. Although the outcome of T-ALL patients has improved over recent years, the poor prognosis of patients with resistant or relapsed disease is still a major concern. Even though NOTCH is a known driver in T-ALL, its inhibition cannot be efficiently achieved with the drugs currently available, due to their weak therapeutic effects and severe toxicity. Thus, a better understanding of the mechanisms downstream of NOTCH oncogenic signaling in T-ALL is necessary in order to develop NOTCH targeting therapies more effective and less toxic. We have shown that loss of *mir-181ab1* blocks Notch-induced T-ALL development partly by de-repressing the expression of NRARP (NOTCH regulated ankyrin repeat protein)(Fragoso R., PLOS Genetics 2012), a transcriptional target of NOTCH and a negative regulator of NOTCH signaling. Interestingly, NRARP over-expression in murine hematopoietic stem cells impairs T-cell differentiation. Since T-ALL originates from a block during T-cell development, these results suggest that de-regulation of NRARP expression can contribute to the pathogenesis of T-ALL. Importantly, over-expression of NRARP in thymoma cells displaying NOTCH-induced glucocorticoid resistance was shown to sensitize the cells to this drug. This suggests that targeting NRARP may further tackle chemotherapy-resistance in T-ALL.
Aims: To investigate the role of NRARP in human T-ALL cell growth and survival and its potential to sensitize T-ALL cells to commonly used chemotherapeutic agents.
Methods: NRARP mRNA and protein expression was determined by real time-PCR and western blot analyses. *in vitro* functional evaluation of NRARP in T-ALL cell lines was performed by flow cytometry analysis of proliferation and viability upon NRARP over-expression. To determine the effects of NRARP in chemotherapy sensitivity and resistance, T-ALL cells were exposed to Dexamethasone (Dex), Asparaginase (APR) and Methotrexate (MTX).
Results: We started by quantifying *NRARP* expression in human T-ALL cell lines (n=10) and compared it with the expression of *NRARP* in human thymocytes (n=10). We observed that *NRARP* expression is significantly decreased in T-ALL cells (p=0.05). Moreover, quantification of NOTCH1 in the same cells showed that *NRARP* expression is inversely correlated with *NOTCH1* levels. Of note, although NRARP is a downstream target of NOTCH signaling, which is constitutively active in T-ALL patients, it is also a target of *mir-181ab1*, which is highly expressed in T-ALL cells. Next, we over-expressed NRARP in human T-ALL cell lines. Remarkably, NRARP over-expression results in a block in leukemia cell expansion (4 out of 5 cell lines). Proliferation and viability analyses revealed that NRARP over-expression affects T-ALL cell proliferation (CEM and Jurkat cells) and survival (Molt4 and DND41 cells). Importantly, NRARP overexpression sensitizes leukemia cells to APR (CEM cells), MTX (CEM and DND41 cells) and Dex (CEM and DND41). Moreover, over-expression of NRARP partly re-sensitizes Molt4 Dex-resistant cells to this drug.
Summary and Conclusions: Taken together our preliminary results suggest that NRARP plays an important role in T-ALL pathogenesis and chemotherapy resistance.

E853

THE INHIBITION OF CHECKPOINT KINASE 1 INCREASES THE EFFECTIVENESS OF CONVENTIONAL CHEMOTHERAPY IN B-/T-ACUTE LYMPHOBLASTIC LEUKEMIA

A. Ghelli Luserna Di Rora[1,*] I. Iacobucci[1], E. Imbrogno[1], E. Derenzini[1], A. Ferrari[1], V. Robustelli[1], V. Guadaguolo[1], M. Abbenante[1], C. Papayannidis[1], M. Cavo[1], G. Martinelli[1]
[1]Department of Hematology and Medical Sciences "L. and A. Seràgnoli, Bologna, Italy

Background: During the last few years the efficacy of many Checkpoint Kinase (Chk)1/Chk2 inhibitors has been assessed for the treatment of different type of cancers but only few studies have been performed to evaluate their effectiveness on hematological diseases.
Aims: In this study we evaluated the *in vitro* efficacy of the Chk1 inhibitor, LY2606368, as single agent and in combination with other tyrosine kinase inhibitors (imatinib and dasatinib) or chemotherapy drugs (clofarabine) in B-/T-ALL cell line and in primary blasts.
Methods: Human B (BCR-ABL1-positive: BV-173, SUPB-15; BCR-ABL1-negative: NALM-6, NALM-19, REH) and T (MOLT-4, RPMI-8402, CEM) leukemia cell lines were incubated with increasing concentrations of drug (1-100 nM) for 24 and 48 hours and the cell viability was evaluated using WST-1 reagent. The effect of the inhibition of Chk1 on cell cycle profile was analyzed using Propidium Iodide (PI) staining. To deeply understand the effect of the compound on the pathway of Chk1, different western blots analyses were performed on specific downstream targets of Chk1. The Chk1 inhibitor LY2606368 was purchased by ApexBio Technology.
Results: LY2606368 deeply reduced the cell viability in a dose and time dependent manner in all the cell lines treated, with the BV-173 (6.33 nM IC50 24hrs) and RPMI-8402 (8.07 nM IC50 24hrs) cell lines being the most sensitive while SUP-B15 (61.4 nM IC50 24hrs) and REH (96.7 nM IC50 24hrs) cell lines being the less sensitive. In addiction the sensitivity was no correlated with the different sub-type of ALL or with the mutational status of p53. The cytotoxic activity was confirmed by the significant increment of the number of apoptosis cells (Annexin V/Propidium Iodide), by the increment of γH2AX foci and by the activation of different apoptotic markers (Parp-1 and pro-Caspase3 cleavage). To better understand the relationship between the activation of apoptosis and the effect on cell cycle, different cell cycle analyses were performed. The inhibition of Chk1, even with a high heterogeneity among the different cell lines, deeply changed the cell cycle profile. In all the cell lines the percentage of cells in G1 phase and in G2/M phase were reduced by the treatment while the numbers of cells in sub-G1 and S phase were increased. Furthermore the cytotoxicity of LY2606368 was evaluated in combination with imatinib, dasatinib or the purine nucleoside antimetabolite clofarabine. The combination strongly reduced the cell viability when compared to the cytotoxic effect of the single drugs. Moreover the combination showed an additive efficacy in term of induction of DNA damages as showed by the increase number of γH2AX foci and the activation of phospho-Chk1 (ser 317).
Summary and Conclusions: LY2606368 as single agents showed a strong cytotoxic activity on B-/T-All cell lines. Furthermore the compound was able to increase the cytotoxic effect of imatinib, dasatinib and clofarabine in all the cell lines treated. In our opinion this data are the basis for a future clinical evaluation of this compound in the treatment of leukemia. Supported by ELN, AIL, AIRC, progetto Regione-Università 2010-12 (L. Bolondi), FP7 NGS-PTL project.

LEUKEMOGENICITY OF RCSD1-ABL1 OF PH-LIKE ACUTE LYMPHOBLASTIC LEUKEMIA VARIES BETWEEN FUSION SITES

H. Tamai[1,*] H. Yamaguchi[1], K. Miyake[2], M. Takatori[3], T. Kitano[4], K. Dan[5], K. Inokuchi[1]
[1]Hematology, [2]Biochemistry and Molecular Biology, [3]Research Center for Advanced Medical Technology, [4]Research Center for Life Science, Nippon Medical School, Tokyo, [5]Medical Education Center, Ryotokuji University, Urayasu, Japan

Background: The RCSD1 gene, located at 1q23 involved in t(1;9)(q23;q34) translocation in acute lymphoblastic leukemia (ALL)ALL is known as a novel gene fusion partner of ABL1 gene. RCSD1-ABL1-positive ALL is included in Philadelphia chromosome-like (Ph-like) ALL. The leukemogenicity of RCSD1-ABL1 are undefined. We found two types of fusion gene in a case of RCSD1-ABL1-positive ALL—the first involved fusion of exon 2 of RCSD1/exon 4 of ABL1 (R2A4; 2952 bp) and the other involved fusion of exon 3 of RCSD1/exon 4 of ABL1 (R3A4; 3042 bp).
Aims: The aim of this study is examine the leukemogenicity of two kinds of fusion genes of RCSD1-ABL1.
Methods: We generated retroviral vectors expressing R2A4 or R3A4, which we used to transduce Ba/F3 cells, and examined the IL-3 dependency of each transduced Ba/F3 cell line. Secondly we examined the multiplication activity and the IL-3 dependency of each Ba/F3. Thirdly we injected $2x10^8$ of each Ba/F3 to SCID mice and examined the overall survivals (OS) and histopathology of each mice. Fourthly we examined phosphorylation receptor tyrosine kinase activity of each Ba/F3 under no IL3 by Phosphorylation Antibody Array. Based on the result of Phosphorylation Antibody Array, we examined the mechanisms of leukemogenicity of RCSD1-ABL1 by Western Blotting. Finally we examined the response of leukemogenicity of RCSD1-ABL1 to Tyrosine Kinase Inhibitors
Results: Only R3A4-Ba/F3 showed significant independence from IL3 (Control *vs.* R3A4, $P = 0.001$; Control *vs.* R2A4, $P = 0.90$). *In vivo*, R3A4-Ba/F3-injected mice showed significantly shorter survival times than Control or R2A4-Ba/F3-injected mice (42 *vs.* > 100 days, respectively, $P = 0.0009$). Leukemic changes were observed only in R3A4-Ba/F3-injected mice. Phosphorylation Antibody Array showed that Tyk2 were activated only in R3A4-Ba/F3. Western Blotting showed that the leukemogenicity of R3A4 consists of Tyk2-STAT2 pathway. R3A4-Ba/F3 was resistant to Imatinib and Dasatinib but sensitive to pan-JAK family including Tyk2 inhibitor.
Summary and Conclusions: Previous study reported that another R3A4 fusion activated STAT5, which was inhibited by Dasatinib. Our findings, together with this previous report, suggest that leukemogenicity of RCSD1-ABL1 of Ph-like ALLvaries between fusion sites.

TRD/TRA REARRANGEMENTS OCCUR INFREQUENTLY IN EARLY THYMIC PRECURSOR SUBTYPE OF T LYMPHOBLASTIC LEUKEMIA BY HIGH-THROUGHPUT SEQUENCING

A. Sherwood[1,*] B. Wood[2], K. Choi[1], S. Winter[3], K. Dunsmore[4], M. Loh[5],

M. Rieder[1], D. Wu[2], H. Robins[6]
[1]Adaptive Biotechnologies, [2]University of Washington, Seattle, [3]University of New Mexico Health Sciences Center, Albuquerque, [4]University of Virginia, Charlottesville, [5]University of California, San Francisco, San Francisco, [6]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: High-throughput sequencing (HTS) of T-cell receptor genes may be useful for detecting minimal residual disease (MRD) in acute lymphoblastic leukemia. We previously demonstrated application of high-throughput sequencing for the detection of minimal residual disease in T-lineage acute lymphoblastic leukemia (T-ALL) (Sci. Transl. Med. 4(134):134ra63. 2012), and showed that early thymic precusor T-ALL and a subtype which we termed "near-ETP" with variable low CD5 expression frequently lacked a complete clonal rearrangement of *TRB*. The absence of a pre-treatment clonal rearrangement of *TRB* limits the potential for molecular monitoring by next-generation sequencing of this T-cell receptor gene rearrangement for minimal residual disease in these subtypes of leukemias. *TRD* gene rearrangements are expected to occur earlier in T cell development than *TRB*, suggesting they are an attractive marker.
Aims: Given TRD is the first T-cell receptor to rearrange during T lymphocyte development, we evaluated the feasibility of amplifying and sequencing of *TRD* gene rearrangements to monitor MRD in ETP and "near-ETP" subtypes of T-ALL.
Methods: We sequenced the *TRD* and *TRA* of residual samples from 33 patients enrolled in Children's Oncology Group AALL0434 using an amplification bias-controlled multiplex PCR. These 33 samples included 11 cases of early thymic precursor (ETP) subtype, 12 so-called near-ETP sample (which have similar immunophenotype with ETP but differences in CD5 expression) and 10 non-ETP samples. We defined high-frequency clones as probable neoplastic if they exceeded 15% of the repertoire.
Results: We find that clonal *TRD* and *TRA* rearrangements can be identified in only 2 of 11 of pre-treatment samples of ETP-TALL, using a cut-off of 15% for defining clonality. By comparison, in a cohort of 12 "near-ETP" samples, samples with leukemic blasts that have some but not all of the immunophenotypic features of ETP, we found 5 of 12 cases with *TRD* gene rearrangement. Lastly, typical, "non-ETP" T-ALL subtypes showed evidence of clonal rearrangement in 7 of 10 cases.
Summary and Conclusions: Our data suggest that clonal rearrangements in ETP subtype of T-ALL are infrequent, suggesting that molecular monitoring of *TRD* and *TRA* T-cell receptor gene rearrangements does not substantially enhance the ability to follow ETP- clones through treatment for post-therapy MRD detection.

PROGNOSTIC VALUE OF DELETIONS AND PROMOTER METHYLATION OF CDKN2A AND CDKN2B IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Braun[1,*] A. Pastorczak[1], J. Madzio[1], J. Taha[1], M. Ramiszewska[2], M. Matysiak[2], K. Derwich[3], M. Lejman[4], J. Kowalczyk[4], W. Badowska[5], B. Kazanowska[6], T. Szczepanski[7], J. Styczynski[8], J. Trelinska[1], B. Zalewska-Szewczyk[1], N. Irga-Jaworska[9], W. Mlynarski[1]
[1]Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Lodz, [2]Department of Pediatric Hematology and Oncology, Medical University of Warsaw, Warsaw, [3]Department of Pediatric Hematology, Oncology and Transplantology, University of Medical Sciences, Poznan, [4]Department of Pediatric Hematology and Oncology, Medical University of Lublin, Lublin, [5]Department of Pediatric Hematology and Oncology, Olsztyn, [6]Department of Pediatric Hematology, Oncology and Transplantology, Wroclaw Medical University, Wroclaw, [7]Department of Pediatric Hematology and Oncology, Medical University of Silesia, Zabrze, [8]Collegium Medicum, Bygdgoszcz, [9]Department of Pediatric Hematology, Gdansk Medical University, Gdansk, Poland

Background: Alterations in *CDKN2A* and *CDKN2B* are the most common molecular patterns in pediatric acute lymphoblastic leukemia (ALL). Deletions in these genes occur in 30% of cases and are the leading mechanism in inactivation of these genes. The available data for promoter methylation of *CDKN2A* and *CDKN2B* is discrepant and the importance of this mechanism needs to be answered.
Aims: To assess the prevalence and size of deletions and promoter methylation of *CDKN2A* and *CDKN2B* and to ascertain the impact of these aberrations on clinical and biological features in children with ALL.
Methods: We analyzed copy number variations in selected genomic loci using MLPA (Multiplex Ligation dependent Probe Amplification; P202, P335, ME028 kits) on DNA extracted from bone marrow samples collected from patients at diagnosis of childhood ALL. Promoter methylation of *CDKN2A* and *CDKN2B* was examined by using Methylation-specific MLPA (MS-MLPA) method. Data mining analysis technique was used for evaluation of coexistence of non-random patterns of factors. We analyzed overall survival and event-free survival with respect to genetic alterations as well as clinical features of these patients.
Results: Six hundred fifty two samples were analyzed. In 185 (28.4%) samples deletions in 9p21 region were detected: 29 (4.4%) were positive for deletions of *CDKN2A*, 151 (23.2%) of *CDKN2A* and *CDKN2B* and 5 (0.8%) of *CDKN2B*. In 85 (13%) patients deletions of *CDKN2A* were homozygous. Methylation status was determined in 208 samples. P15 promoter was methylated in 49 (23.5%) samples, p14 and p16 promoters were methylated in 9 (4.3%) and 11 (5.3%) cases, respectively. The deletion of *MIR31* was significantly associated with the deletion of both *CDKN2A* and *CDKN2B* (p<0.001). We detected associations between deletions in 9p21 region and *ETV6, IKZF1* and *PAX5*: concurrent deletions in 9p21 and *ETV6* were found in 42 (7.0%) cases (p=0.04), in 9p21 region and *IKZF1* were found in 41 (6.3%) cases (p=0.008) and in 9p21 region and *PAX5* were found in 44 (7.0%) cases. Homozygous deletions in *CDKN2A* and *CDKN2B* genes were associated with worse event free survival (p=0.03), but there was no significant impact on overall survival. Methylation of p15, p14 and p16 promoters were not associated with other molecular alterations. Methylation of p15 worsened overall survival (p=0.003) and the tendency was seen regarding shortening event free survival.
Summary and Conclusions: Deletions in *CDKN2A* and *CDKN2B* are commonly associated with deletions of *ETV6*, *PAX5* and *IKZF1* genes. The co-occurrence with deletions in *IKZF1* may explain the fact of worse prognosis in terms of both EFS and OS in patients with homozygous deletions of *CDKN2A*. We found that the deletion of *MIR31* is a valid indicator of large deletions in 9p21. Methylation of p15 promoter seems to be a frequent and biological important occurrence in childhood ALL.

E857

MAJOR IMPACT OF AN EARLY CHECKPOINT FOR MINIMAL RESIDUAL DISEASE IN FLOW CYTOMETRY IN CHILDHOOD ALL: A BICENTRIC STUDY

M. Eveillard[1,*] N. robillard[1], I. arnoux[2], R. garand[1], F. rialland[3], C. thomas[3], M. strullu[3], N. blin[3], G. michel[4], C. fossat[2], M.C. béné[1], M. loosveld[2]
[1]Hematology Laboratory, Centre Hospitalier Universitaire, Nantes, [2]Hematology Laboratory, Centre Hospitalier Universitaire, Marseilles, [3]Oncopediatry department, Centre Hospitalier Universitaire, Nantes, [4]Oncopediatry department, Centre Hospitalier Universitaire, Marseilles, France

Background: Although childhood acute lymphoblastic leukemia (ALL) is of good prognosis, about 15 to 25% of the patients relapse. The early persistence of positive minimal residual disease (MRD) is considered as a poor prognostic factor indicative of chemoresistance.
Aims: We report a study on the level of MRD assessed by multiparameter flow cytometry (MFC) in the bone marrow samples used for morphologic assessment of chemosensitivity at day 21 (D21) post induction.
Methods: This study enrolled 123 children (median age 5 years, range 6 months-21 years), treated between 2006 and 2014 in Nantes and Marseilles University Hospitals with a median follow up of 30 months. On D8, 85 children were corticosensitive and 21 were unassessable (<1G/L blasts at diagnosis). On D21, 109 patients with less than 5% bone marrow blasts were considered chemosensitive. Sixteen relapses were observed and 5 patients died.MRD was investigated at D21 (MRD0) in MFC and at day 35 by RT-qPCR for IGH/TCR rearrangements (MRD1). Antibody combinations (5 to 10) corresponding to the specific Leukemia Associated ImmunoPhenotypes of the blasts at diagnosis was used. A minimum of 10 clustered events allowed to assess a positive result. Acquisition of at least 100,000 events were required for a negative result. A median of 537 816 events were analyzed per patient.Event-free survival (EFS) and overall survival (OS) were studied according to the log-rank test. A Chi2 test was performed to compare MRD0 to MRD1.
Results: Early MRD defines three risk groups: three risk groups were established according to the level of MRD0 by MFC at D21: Level 1 (high risk, n=25)>10^{-2}, Level 2 (intermediate risk, n=46) 10^{-2} to 10^{-4} and Level 3 (low risk, n=50) <10^{-4}.OS (p=0.048) and EFS (p=0.00017, Figure 1) were significantly different between the three MRD0 risk groups. These subgroups also allowed to reclassify patients at high cytogenetic risk, those reaching level 3 presenting no relapse (p=0.02). Early MRD levels are more discriminating than classically defined early responses to therapy: evolution of the 14 corticoresistant patients appeared to strongly depend on their MRD0 level (p=0.004), all low-risk level 3 patients still being in complete remission 1 (CR1) at 4 years while all high-risk level 1patients had relapsed. Similarly, chemosensitive patients had a significantly different evolution according to their level of MRD0, both for EFS (p=0.004) and OS (p=0.02). MRD0 has more prognostic value than MRD1: MRD0 and MRD1 levels were compared for 112 patients. Consistent results (-/- or +/+) were observed in 57.2 % of the cases. Four patients had a low level of MRD1 but undetectable MRD0. By contrast, the 44 MRD0+/MRD1- patients had a significantly worse EFS (p=0.004) than the 33 with undetectable MRD at both MRD0 and MRD1.Multivariate analysis for EFS, using the Cox model analysis with age, corticosensitivity, chemosensitivity, MRD0 and MRD1, only retained a significant prognostic value for age (p=0.01) and MRD0 (p=0.0001).

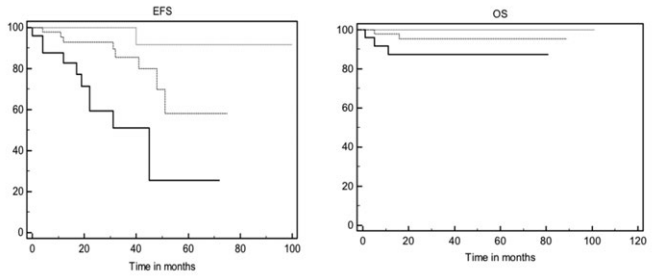

Figure 1. Comparative EFS and OS according to MRD levels in MFC at day Level 1, solid line, level 2 dashed line, level 3 dotten line.

Summary and Conclusions: This study confirms the usefulness and superiority of MRD detection by MFC in day21 bone marrow in order to better discriminate patients with less than 5% blasts in cytomorphology at this time point. In addition, MFC MRD0 identifies a subgroup of patients with poorer prognosis (MRD0+/MRD1-) who would be missed with MRD only performed on D35. MFC thus provides valuable early information on the actual chemosensitivity of these children.

E858

TARGETING THE P53–MDM2 INTERACTION BY THE SMALL-MOLECULE MDM2 ANTAGONIST NUTLIN-3A IN ADULT PHILADELPHIA POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

S. Trino[1,*] I. Iacobucci[2], D. Erriquez[3], I. Laurenzana[1], L. De Luca[1], A. Ferrari[2], A. Ghelli Luserna Di Rorà[2], C. Papayannidis[2], E. Derenzini[2], A. Lonetti[4], C. Venturi[2], F. Cattina[5], E. Ottaviani[2], M.C. Abbenante[2], D. Russo[5], G. Perini[3], P. Musto[6], G. Martinelli[2]
[1]Laboratory of Pre-clinical and Translational Research, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture (Pz), Rionero in Vulture (Pz), [2]Institute of Hematology "L. and A. Seràgnoli", Department of Experimental, Diagnostic and Specialty Medicine, [3]Department of Pharmacy and Biotechnology, [4]Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, [5]Chair of Hematology and BMT unit, University Of Brescia, Brescia, [6]Scientific Direction, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture (Pz), Rionero in Vulture (Pz), Italy

Background: The human p53 tumor suppressor is functionally impaired in nearly 50% of human cancers. Although its alterations are relatively infrequent in B-ALL, wild-type *TP53* remains dysfunctional due to overexpression of MDM2 and also to deletion of *CDKN2A* gene.
Aims: In testing novel therapeutic approaches activating p53, we investigated the preclinical activity of the MDM2 antagonist, Nutlin-3a, in Philadelphia positive (Ph^+) and negative (Ph^-) leukemic cell line models, and primary Ph^+B-Acute lymphoblastic leukemia (ALL) patient samples.
Methods: Ph^+(BV-173 and SUP-B15) and Ph^- (NALM-6, NALM-19 and REH) cell lines and primary Ph^+ALL cells were incubated with increasing concentrations of Nutlin-3 for different times. Methanethiosulfonate test was used to evaluate cell viability and flow cytometry was performed to analyze the apoptosis. Gene expression profile (GEP) was performed using Affymetrix GeneChip Human Gene 1.0 ST platform. p53, BMI-1, p21, caspase-3 and caspase-7 protein expression was evaluated by Western Blot (WB). *BMI-1* mRNA expression was measured by quantitative real time PCR in ALL patient samples.
Results: In order to investigate the effects of Nutlin-3a treatment, we examined cell viability of $Ph^+$and Ph^- cell lines and primary Ph^+ALL cells. Nutlin-3a efficiently reduced cell viability of Ph^+(BV-173 and SUP-B15) and Ph^- (NALM-6 and NALM-19) ALL cells with wild-type p53, in dose-dependent manner. In contrast, no significant changes in cell viability were observed in chronic myeloid leukemia p53-null cell line K562 and in Ph^- ALL p53-mutated cell line REH after incubation with MDM2 inhibitor. Next, we observed that Nutlin-3a treatment, at 5 μM concentration for 24 hours, induced a reduction of cell viability, ranging from 25% to 40%, on primary ALL cells compared to their untreated counterpart. Notably, the dose-dependent reduction in cell viability was confirmed in primary blast cells from two Ph^+ALL patients with the T315I BCR-ABL kinase domain mutation. MDM2 inhibitor treatment increased p53 protein expression in wild-type p53 cell lines activating p53 pathway, as demonstrated by increasing expression of p53 downstream target, p21, and activation of the cleaved caspase-7 apoptotic marker. Nutlin-3a also induced a dose- and time-dependent apoptosis in BV-173, SUP-B15 and NALM-6 cell lines, with wild-type p53. By contrast, REH cells were not sensitive to Nutlin-3a. In order to better elucidate the implications of p53 activation and to identify biomarkers of clinical activity, GEP analysis in sensitive cell lines showed 621 genes (48% down-regulated and 52% up-regulated) differentially expressed ($p<0.05$) upon treatment. We found a strong down-regulation of *BMI-1*, repressor of INK4/ARF and p21, after treatment as compared to control cells (fold-change -1.11; p=0.03). This was validated in BV-173 and SUP-B15 cells after Nutlin-3a treatment. Noteworthy, *BMI-1* mRNA expression was down-regulated in Ph^+ALL patients after treatment ($p<0.05$), if compared with their untreated counterparts.
Summary and Conclusions: Inhibition of MDM2 efficiently reduces cell viability and induces p53-mediated apoptosis in ALL cells. Therefore, targeting p53-MDM2 could be able to overcome or synergize with conventional therapies in Ph^+ALL patients with wild-type p53. Our results suggest a new possible therapeutic strategy in resistant T315I mutated ALL patients. These findings provide a strong rational for further clinical investigation of Nutlin-3a in $Ph^+$and Ph^-ALL.

CHARACTERIZATION OF IMMUNOPHENOTYPING AND MOLECULAR PROFILE OF FLT3 MUTATIONS IN CHILDHOOD T-CELL LEUKEMIA

E. Noronha[1,*] E. Pina[1], F. Andrade[1], M.S. Pombo-de-Oliveira[1]
[1]Programa de Hematologia e Oncologia pediatricos, Instituto Nacional de Câncer, Rio de Janeiro, Brazil

Background: T-cell Acute Lymphoblastic Leukaemia (T-ALL) in childhood is an aggressive and biological heterogeneous malignancy. T-cell immature immunophenotype might identify settings of T-ALL with gene mutations. The FMS-like kinase-3 (FLT3/CD135) and the stem cell factor receptor (cKit/CD117) are members of the receptor tyrosine kinase family that contribute to normal differentiation and proliferation of hematopoietic cells. Mutations in *FLT3* -internal tandem duplication (ITDs) and single mutations in the tyrosine kinase domain (TKD), results in constitutive activation of the FLT3 receptor in the absence of ligand.
Aims: To identify *FLT3* mutations in a cohort of childhood T-ALL at diagnosis at any point in time and in relapses; to test the possible correlation between *FLT3* mutation with cellular expression of CD135 and CD117
Methods: A cohort of 178 T-ALL (≤18 years) was evaluated throughout flow cytometry and molecular techniques. Diagnostic samples (DS, n=157) prior to any oncotreatment, and relapsed samples (RS, n=23) were selected. The levels of cellular surface of CD135 and CD117 were quantified by multiparametric flow cytometry (M-FCM). The monoclonal antibodies anti-CD135; CD117; CD135;CD34; CD127 were included in four or 6 colours to M-FCM analysis. These variables were categorized by percentage of cell positivity and median intensity fluorescence. Positivity was evaluated in CD45 intermediate/low gate in≥20% of blasts cells. DNA and RNA were extracted from BM aspirate or PB blast cells to perform molecular tests (*SIL-TAL1, HOX11L2, IL7R* and *FLT3* mutations); *FLT3*-D835 mutations were tested in exon 17 by restriction fragment length polymorphism PCR assay, whereas, *FLT3*-ITD was examined by the amplification of the juxtamembrane domain in exons 11 and 12. To compare the distribution of categorical variables Fisher`s exact test was used and Mann-Whitney U test comparing two groups (positive/negative) and Kruskal Wallis test comparing more than two groups to test differences in continuous variable. P-values of <0.05 were considered statistically significant.
Results: Fifteen out of 176 (8.5%) cases presented mixed phenotype- T / Myeloid lineage. Early T cell precursors (ETP-ALL) were identified in 20 cases (11.4%). Amongst the remaining 141 T-ALL cases, 30 T-II (18.6%), 78 T-III (48.4%) and 33 T-IV (20.5 %) cases were found. CD127 was expressed in 55 out of 70 (78.6%) cases tested; whereas CD117 was expressed in 19 out of 86 (22%) and CD135 found in 10 out of 85 (11.7%) cases tested. *FLT3*-ITD were founds in 8 out of 157 (5%) of DS and in 2 out of 23 (8.7%) in RS. There were no statistical differences regarding demography (gender and age at the diagnosis), and clinical features (mediastinal mass, high white blood cell count or SNC involvement) in T-ALL with *FLT3-ITD.* The frequencies of somatic aberrations of *SIL-TAL1, HOX11L2, IL7R* and *FLT3* mutations were 24.8%, 12%, 10% and 7%, respectively. Besides *FLT3* and *IL-7R* mutation were also mutually exclusive. No association was observed in CD127 and CD135 cellular expression and T-ALL subtypes, nor association with *IL7R* mutation (p=0.64). The percentage of CD117 positive cells was greater in the ETP-ALL than other subtypes (T II, T-III and T-IV) (p <0.001); The variation of CD117 expression according to *FLT3* and/or *IL7R* mutations demonstrated that high expression level of CD117 were associated with FLT3 mutation (p=0.02), whereas CD117 lower expression with *IL7R* mutation (p=0.03). The higher expression of CD135 was associated with *HOX11L2* alteration (p=0.012) and with *FLT3* mutation (p=0.03). The CD127 expression was higher in cases with *SIL-TAL1* rearrangement (p=0.04) and in cases with mutated *FLT3* had a lower expression (p=0.04).
Summary and Conclusions: *FLT3-ITD* is important in the pathogenesis of T-ALL and it seems to contribute to disease progression in cooperation with other alterations. Preliminary results demonstrated that CD117 and CD127 could predictive molecular aberrations in some T-ALL settings.

E860

IMPACT OF SMALL MOLECULE INHIBITORS OF SKP2 IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

S. Colomer-Lahiguera[1,*] S. Strehl[1]
[1]CCRI, Children's Cancer Research Institute, St. Anna Kinderkrebsforschung e.V., Vienna, Austria

Background: T-cell acute lymphoblastic leukemia (T-ALL) accounts for 10-

15% of pediatric leukemias. NOTCH1 activating mutations are found in more than 50% of T-ALLs and have been shown to induce transcription of the S phase kinase-associated protein 2 (*SKP2*), which in turn decreases CDK inhibitor $p27^{KIP1}$ levels, thereby promoting cell cycle progression. During the last years, efforts have been directed towards therapeutically targeting the ubiquitin-proteasome system in order to reduce protein degradation. Recently, small molecule inhibitors of SKP2, which showed different specificities, have been developed. Compound C1 has been described to specifically target the interface between SKP2 and CKS1, an accessory protein responsible for the recognition of Thr187-phosphorylated $p27^{KIP1}$ (Wu *et al.*, 2012). A second compound, C25, interacts with SKP2 and prevents its binding to SKP1, thus inhibiting SKP2-SCF E3 ligase activity (Chan *et al.*, 2013)

Aims: The purpose of this study was to evaluate the effects of these new small molecule inhibitors of SKP2 in T-ALL.

Methods: To assess the impact of SKP2 inhibitors, we treated four different T-ALL cell lines (Jurkat, DND-41, TALL-1, and Loucy) with the compounds C1 or C25 for 24 and 48 hours. Trypan blue exclusion assay was used to determine the number of viable cells. Apoptosis (Annexin V/PI double staining) and cell cycle distribution were analyzed by flow cytometry. Equal amounts of cell lysates were subjected to immunoblot analysis in order to evaluate the protein levels of the main cell cycle regulators.

Results: As has been previously shown by others, we, too, observed that SKP2 is up regulated in T-ALL, suggesting that SKP2 inhibitors may hold promise for therapeutic intervention. Applying compound C1 resulted in a decrease of cell proliferation in a dose- and time-dependent manner in all cell lines. In contrast, when using C25, only TALL-1 showed a slight reduction in cell growth. To evaluate whether the observed growth inhibition was related to cell death, we performed Annexin-V/propidium iodide staining and flow cytometry analysis. Depending on the cell line used, compound C1 showed different effects with a tendency towards a faster cell death in Loucy, as compared to Jurkat, and no impact at all on the other cell lines. This observation was confirmed by western blotting for cleaved PARP. In marked contrast, cells treated with the C25 inhibitor did not show any induction of apoptosis and cell death. Notably, in TALL-1 and DND-41 cells, neither C1 nor C25 induced major changes in viability, which - together with the observed growth inhibition - suggests an effect on the cell cycle as the main impact of the inhibitors. To further substantiate this notion, we assessed the influence of the two compounds on cell cycle progression. On the one hand, in TALL-1 and DND-41 C25 treatment resulted in an accumulation of G0/G1-phase cells, reflected by an increase in $p27^{KIP1}$ protein levels, which inversely correlated with SKP2 expression. However, no effects at all were observed in Loucy or Jurkat. On the other hand, treatment with C1 induced a significant accumulation of G2/M-phase in a dose- and time-dependent fashion in all cell lines. Quite unexpectedly, also the cell line Loucy, which lacks $p27^{KIP1}$ expression, showed a decrease in cell proliferation, increased cell death and achieved a G2 arrest, suggesting that cell cycle arrest occurs independent of $p27^{KIP1}$.

Summary and Conclusions: Our results indicate that T-ALL cell lines show different sensitivities towards SKP2 inhibitors and that the two compounds tested have distinct effects on the cell cycle, apoptosis, and cell death. Furthermore, they raise the question whether the compounds C1 and C25 may have so far unrecognized (off-target) effects.

E861

ANTI-CD47 AND METHOTREXATE INDUCE CELL DEATH BY PHAGOCYTOSIS – PHAGOPTOSIS – OF LEUKAEMIA CELLS, SUGGESTING NOVEL WAYS OF TARGETING CANCER

L. Metayer[1,*] G. A. Burke[2] G. Brown[1]
[1]Biochemistry, [2]Paediatrics, University of Cambridge, Cambridge, United Kingdom

Background: Antibodies to CD47 have been shown to increase clearance of many types of cancer cells *in vitro* and *in vivo*, but the means by which they cause cell death and clearance is not yet clear.

Aims: To explore the mechanism of action of anti-CD47 in a model of B-ALL/B lymphoblastic lymphoma.

Methods: U937 cells were treated with 10 ng/mL PMA for 24 hours, then allowed to mature for a further 48 hours. Phagocytosis was assayed with a 1:1 target:effector ratio, using either flow cytometry (2 hour co-incubation), or fluorescent microscopy for live/dead cell phagocytosis of propidium iodide stained target cells (1 hour co-incubation). Live cell imaging of the mitochondrial membrane potential measured with JC-1 stained target cells was performed over 3 hours. The blocking CD47 antibody clone B6H12 was used at 2 µg/mL, with $F(ab')_2$ blocking in a 1:5 molar ratio. CD19 at 2-10 µg/mL, 4N1K at 0.12 nM-30 µM, thrombospondin at 1.2-12 nM, methotrexate at 0.01 µM and 6-mercaptopurine (6MP) 5 µM (24 hours for phagocytosis assays, up to 72 hours for direct cell death).

Results: Anti-CD47 strongly increased the phagocytosis of 697 cells, a pre-B ALL cell line, by U937 macrophages. The leukaemia cells were alive when phagocytosed by macrophages as indicated by their exclusion of propidium iodide and their intact mitochondrial membrane potential. However, death rapidly followed as shown by mitochondrial depolarisation of leukaemia cells after their engulfment. 2 µg/mL anti CD47 was sufficient to clear all leukaemic cells within 3 hours. Inhibition of phagocytosis prevented clearance and death of leukaemic cells, indicating that cell death was by phagoptosis. Phagocytosis required the Fc domain of the anti CD47 antibody as blocking this domain with $F(ab')_2$ prevented the phagocytosis. However, an antibody against CD19, a B cell marker, did not increase phagocytosis, indicating that phagocytosis required both antibody binding with an available Fc domain and blocking/activation of CD47. Alternative ligands for CD47, low dose 4N1K and thrombospondin, had little effect on phagocytosis, suggesting that activation of CD47 is not sufficient for phagocytosis. Finally, low doses of the maintenance phase treatment methotrexate increased the phagocytosis and subsequent death of live 697 cells. The same doses induced little or no death of the lymphoblasts in the absence of macrophages.

Summary and Conclusions: CD47 is an exciting treatment for lymphoid malignancies, and does induce death of live cells by phagocytosis (phagoptosis). This finding may explain the mechanism of action of the little understood requirement for prolonged low dose maintenance phases, and this could potentially be shortened by utilising the more effective pro-phagocytic treatment anti-CD47.

E862

CD22 AS A TARGET FOR ELIMINATION OF THE LEUKEMIC BLASTS IN B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

V. Kanderova[1,*] D. Kuzilkova[1], M. Vaskova[1], T. Kalina[1], O. Hrusak[1], E. Mejstrikova[1]
[1]Department of Pediatric Hematology and Oncology, CLIP-Cytometry, 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic

Background: Epratuzumab is a humanized anti-CD22 monoclonal antibody (mAb) derived from LL2 clone. Its B-cell suppressive effect was demonstrated in autoimmune diseases (systemic lupus erythematosus), and some hematological malignancies (non-Hodgkin lymphoma). In current IntReALL study of iBFM group, epratuzumab is included in post-induction treatment phase in relapsed B-cell precursor acute lymphoblastic leukemias (BCP-ALL). CD22 function in mature B cells is partly known, the exact mechanism of action of epratuzumab is not completely understood. Furthermore, the effect of the concomitant and proceeding chemotherapy on CD22 expression remains unknown.

Aims: Optimize the detection of CD22 before and during epratuzumab treatment. Assessment of the level of CD22 expression on leukemic blasts and its correlation with BCP-ALL genetic subtype. Monitor CD22 expression on leukemic blasts in BCP-ALL patients during treatment. Determine the effect of epratuzumab to leukemic cell proliferation, cell cycle, apoptosis, and intracellular signaling.

Methods: CD22 was detected with 2 different antibody clones (S-HCL-1 and epratuzumab) by flow cytometry. Proliferation was determined by cellular counting. Changes in cell cycle were monitored with Pyronine Y/Hoechst 33342 staining. Apoptosis was checked with Annexin V/propidium iodide or DAPI staining. Intracellular signaling (phosphorylation of Syk, Akt and Erk1/2) was measured by single cell phospho-flow cytometry.

Results: For optimal detection of CD22 three temperatures (4, 25, and 37°C) and two antibody clones were tested. We observed reduction of epratuzumab binding to cells with decreasing temperature (n=3): 41% at 25°C and 2% at 4°C. In contrast, S-HCL-1 binding did not differ at low temperature (34% at 25°C and 40% at 4°C). This reduction of LL2 affinity at 4°C was previously described (Mattes et al, 1997). Moreover epratuzumab and S-HCL-1 partially competed for CD22 binding but we were able to detect CD22 by S-HCL-1 at 25°C well when the cells were pre-incubated with epratuzumab. *In vitro* experiments did not show any anti-proliferative effect of epratuzumab on leukemia cell lines (n=5) probably due to their partial growing independence on external stimuli. In contrast, we detected reduced numbers of viable B-cells isolated from healthy peripheral blood after epratuzumab treatment (n=3, $p<0.05$). In addition, cell cycle transition from G0 to G1 phase was inhibited after 24h (n=2, $p<0.05$) and intracellular signaling led via phosphorylation of Syk and Erk1/2 in healthy B-cells (n=4). Deeper proteomic profiling is in progress. In our so far limited cohort of patients with BCP-ALL where the CD22 expression was quantified with the two mAb clones (n=16), the CD22 levels varied greatly. In contrast, CD22 expression on mature B cells was comparable among healthy individuals (n=8). The only cases without detectable CD22 expression were found among patients with pro-B BCP-ALL.

Summary and Conclusions: CD22 is detected by both clones of antibodies at 25°C at diagnosis and relapse. During the epratuzumab treatment, CD22 can be monitored by S-HCL-1 clone. CD22 expression varies on leukemic blasts among individuals. CD22 negativity is found within pro-B BCP-ALLs. BCP-ALL cell lines are frequently resistant to epratuzumab treatment and cannot be used as *in vitro* model. In healthy B-cells, epratuzumab partially inhibits cell cycle and proliferation *in vitro*, the signaling occurs via B-cell receptor associated kinase Syk and via kinase Erk1/2. *Supported by FP7 IntReALL, IGA NT13462, UNCE 204012.*

E863

BONE MARROW STROMAL PRECURSOR CELLS OF THE ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED ACCORDING TO THE ALL-2009 PROTOCOL RESTORE THEIR FUNCTIONAL AND BIOLOGICAL POTENTIAL DAMAGED BY THE DISEASE

T. Sorokina[1,*] I. Shipounova[2], A. Bigildeev[2], N. Petinati[2], N. Drize[2], L. Kuzmina[1], E. Parovichnikova[1], V. Savchenko[3]
[1]High dose chemotherapy, depressions of hematopoiesis and bone marrow transplantation, [2]Physiology of Hematopoiesis laboratory, [3]General director, National Research Center for Hematology, Moscow, Russian Federation

Background: Stromal microenvironment essential for normal hematopoiesis, as it forms niches for hematopoietic precursors, suffers during leukemia development. High dose chemotherapy affects not only hematopoietic cells but also stromal precursor cells.
Aims: The goal of this study was to analyze the alterations in the characteristics of human multipotent mesenchymal stromal cells (MSC) and their more differentiated progeny – fibroblastic colony forming units (CFU-F), derived from the bone marrow (BM) of acute lymphoblastic leukemia (ALL) patients at the moment of diagnosis and during treatment according to the protocol ALL-2009.
Methods: Fourteen newly diagnosed cases (8 B-ALL and 6 T-ALL) were involved in the study after informed consent. BM was aspirated prior to any treatment and at days 37, 100 and 180 since the beginning of the protocol. MSC were cultured in aMEM with 10% fetal calf serum. Cumulative MSC production was counted after 3 passages. CFU-F concentration was analyzed in standard conditions. The ability of MSC to maintain hematopoietic precursor cell was assessed by cobble-stone area forming cells (CACF-1-2 wk) method. As a reference control MS5 cell line was used. The relative expression level (REL) of different genes was measured by TaqMan RQ-PCR. As a control MSC and CFU-F from 88 healthy donors of BM for alloHSCT were used.
Results: The CFU-F concentration in the BM of patients at the moment of ALL diagnostics was about 1/7 of the donor's (table, p<0.0001). BM blasts count did not correlate reversely with CFU-F concentration in the BM of each patient, thus the dramatic decrease in CFU-F concentration is caused by the damage of this stromal precursor cells by leukemic cells. The treatment of patients resulted in the restoration of CFU-F concentration in as little as 37 days. Cumulative MSC production at the disease manifestation did not differ from donor's, while their ability to maintain normal hematopoietic cells had the tendency to decrease. At the same moment in MSC the REL of PDGFRA and PDGFRB increased in 3 and 2 fold correspondingly (p=0.01 and 0.03), while REL of TGFB2 decreased 3 fold (p=0.002). Chemotherapy did not affect MSC production and during treatment their ability to maintain CAFC 1-2wk normalized. Table Main characteristic of stromal precursor cells from the BM of ALL patients.

Tabella 1.

	CFU-F per 106 BM cells	Cumulative MSC production per 3 passages, x106	Frequency of CAFC 1-2wk, proportion to MS5
Donor	25.4±3.0	7.1±1.0	74.9±9.5
Before treatment	3.8±1.6	7.9±2.4	57.5±11.4
37 days of ALL-2009	30.3±6.8	9.7±2.5	62.1±8.2
100 days of ALL-2009	31.5±1.0	11.1±2.4	74.4±16.6

Summary and Conclusions: It was demonstrated that Protocol ALL-2009 was highly effective for treatment adult ALL patients. Such treatment restores the functional and biological characteristics of stromal microenvironment initially damaged by leukemic cells.

E864

THE PAN-BCL-2-TARGETING DRUG OBATOCLAX (GX15-070) AND THE PI3-KINASE/MTOR-INHIBITOR BEZ235 PRODUCE SYNERGISTIC GROWTH-INHIBITORY EFFECTS ON LEUKEMIC CELLS IN PATIENTS WITH PH+AND PH- ALL

G. Stefanzl[1,*] D. Berger[1], K. Blatt[1], G. Eisenwort[1,2], W.R. Sperr[1], A. Hauswirth[1], U. Jäger[1], S. Cerny-Reiterer[1,2], P. Valent[1,2]
[1]Internal Medicine I, [2]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, Austria

Background: Acute lymphoblastic leukemia (ALL) is a life-threatening stem cell disease defined by abnormal expansion of lymphoblasts in hematopoietic tissues. Despite improved therapy only a subfraction of patients can be cured. Therefore, current research is attempting to identify new drug targets and novel targeted drugs to improve therapy in these patients. A number of previous and more recent data have shown that members of the BCL-2 family and components of the PI3-Kinase/mTOR pathway are critically involved in the regulation of growth and survival of leukemic cells in ALL.
Aims: We examined the effects of the pan-BCL-2-targeting drug obatoclax (GX15-070) and the dual PI3-Kinase/mTOR blocker BEZ235 on growth and survival in ALL cells.
Methods: The effects of obatoclax and BEZ235 on proliferation were examined by ^{3}H-thymidine-uptake, and drug-induced apoptosis was determined by flow cytometry and Western blotting.
Results: Both drugs were found to suppress the *in vitro* proliferation of leukemic cells obtained from patients with Ph+ALL (n=4) and Ph- ALL (n=9) in a dose-dependent manner (obatoclax $IC_{50:}$ 0.05-0.1 µM; BEZ235, IC_{50}: 0.01-0.5 µM). In addition, obatoclax and BEZ235 suppressed the proliferation in the Ph+ALL cell lines BV-173 (obatoclax IC_{50}: 0.08-0.3 µM; BEZ235, IC_{50}: 0.01-0.03 µM), NALM-1 (obatoclax IC_{50}: 0.1-0.5 µM; BEZ235, IC_{50}: 0.05-0.1 µM), TOM-1 (obatoclax IC_{50}: 0.1-0.3 µM; BEZ235, IC_{50}: 0.01-0.03 µM), and Z119 (obatoclax IC50: 0.05-0.1 µM; BEZ235, IC50: 0.03-0.05 µM) as well as in the Ph- cell lines RAJI, RAMOS, REH, and BL-41 (IC_{50}: <1 µM). The growth-inhibitory effects of both drugs were accompanied by apoptosis in all cell lines examined, as evidence by Western blotting using an antibody against cleaved caspase 3 as well as by AnnexinV/PI-staining and staining for active-caspase 3 by flow cytometry. We also confirmed that BEZ235 counteracts phosphorylation of pAkt and pS6 in all cell lines tested. Since obatoclax and BEZ235 interact with a different spectrum of molecular targets, we also determined drug-combination effects. In these experiments, obatoclax was found to cooperate with BEZ235 in inhibiting the growth of all Ph+ALL cell lines and all Ph- cell lines tested. Finally, we were able to show that primary ALL cells, CD34+/CD38- leukemic stem cells and all cell lines tested express major drug targets, including members of the BCL-2 family (BCL-2, MCL-1, BCL-xL), the PI3-Kinase and mTOR.
Summary and Conclusions: Obatoclax and BEZ235 effectively counteract growth and survival in ALL cells. Both agents exert synergistic anti-leukemic effects on ALL cells which may have clinical implications.

E865

GDF15 MODULATES HEPCIDIN-FERROPORTIN AXIS IN LYMPHOBLASTIC LEUKEMIC CELLS

J. Gao[1,*] J.-R. Wu[1], L.X. Yuan[2], Z. Wan[3], Y.P. Zhu[3]
[1]Department of Pediatric Hematology and Oncology,West China Second University, [2]Public Laboratory, West China Second University Hospital, [3]Department of Pediatric Hematology and Oncology, West China Second University Hospital, Sichuan University, Chengdu, China

Background: Being a novel pleotrophic member of TGF-beta family, growth differentiation factor 15(GDF15) is intimately involved in cancer development and prognosis, and has been documented recently as an upstream negative regulator of the iron regulatory hormone hepcidin, with its expression upregulated remarkably in a variety of anemias characterized by ineffective erythropoiesis.
Aims: To investigate the expressions of GDF15, key iron regulators and transporters, and oxygen sensing molecule hypoxic inducible factor 1 alpha (Hif1alpha) in lymphoblastic leukemic cells, exploring roles of GDF15 on modulation of iron homeostasis in lymphoblastic leukemic cells.
Methods: Sixty newly diagnosed children with ALL and 19 age-and-sex matched control children were enrolled in this study, together with 5 types of leukemic cell lines. mRNA expressions of target genes were assayed by Eva-Green real-time RT-PCR in triplicates. Relative gene expression was represented by the mean of target gene against housekeeping gene by delatdeltaC$_t$ method. suppressed in ALL group as against controls (P=0.000) and was positively correlated both to hepcidin and GDF15. (4) There was no significant difference in terms of Hif1alpha expression in the two groups.
Results: (1) Hepcidin was expressed in both leukemic cell lines and clinical sample of primary lymphoblastic cells. GDF15 expression in ALL group was significantly increased as compared to controls(p=0.026), with median of expression being 0.5 and 0.005 in ALL and control groups respectively; (2) Expression of GDF15 was significantly higher in ALL group than that in controls (p=0.003) and was positively correlated to hepcidin(P=0.000); (3) Expression of ferroportin was remarkably suppressed in ALL group as against controls (P=0.000) and was positively correlated both to hepcidin and GDF15. (4) There was no significant difference in terms of Hif1alpha expression in the two groups.
Summary and Conclusions: We demonstrated that GDF15 is remarkably upregulated in ALL cells independent of Hif1alpha signaling pathway. More importantly, we found that hepcidin is expressed by both leukemic cell lines and primary cells. In addition, ferroportin, the only cellular iron exporter, is significantly downregulated in lymphoblastic leukemic cell, which is consistent with reduced expression in breast cancer cells (cell lines). And GDF15 expression is positively correlated both to hepcidin and ferroportin. Taken together, our study strongly indicates that upregulation of GDF15 stimulates induction of hepcidin by leukemic cells themselves, with in turn mediates enhanced ferroportin internalization and degradation, resulting in reduced iron efflux from leukemic cells, providing more iron available for leukemic cell proliferation. Further studies are urgently needed to explore interrelationship between regulations of cellular and systemic iron homeostasis in patient with lymphoblastic leukemia.

E866

PROGNOSTIC SIGNIFICANCE OF THE CYTOGENETIC EVOLUTION AFTER THE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC ACUTE LEUKEMIA

T.L. Gindina[1,*] N. Mamaev[1], N. Stancheva[1], O. Slesarchuk[1], E. Nikolaeva[1], I. Petrova[1], A. Alyanskiy[1], L. Zubarovskaya[1], B. Afanasyev[1]
[1]R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, FIRST PAVLOV SAINT PETERSBURG STATE MEDICAL UNIVERSITY, Saint-Petersburg, Russian Federation

Background: Cytogenetic abnormalities at diagnosis have significant impact on disease outcome and clonal evolution at cytogenetic level is considered to be associated with relapse and refractoriness to chemotherapy. Relapse of acute leukemia was reported to be associated with cytogenetic clonal evolution in 40% of patients who have received chemotherapy. The cytogenetic clonal evolution in post-transplant relapse has been recently studied in adult acute myeloid leukemia (AML) by Yuasa *et al.*,2013. They showed that the cytogenetic clonal evolution is an important predictor of resistance to therapy after allogeneic hematopoietic stem cell transplantation (alloHSCT).
Aims: To study karyotypic changes in post-transplant relapses of pediatric acute leukemia in order evaluate a prognostic impact of the cytogenetic clonal evolution on survival.
Methods: We retrospectively reviewed children and adolescents with diagnosis of AML or ALL who underwent allo-HSCT at our institute from 2009 to 2014 and analyzed the cytogenetic evolution patterns in patients (pts) at relapse of acute leukemia after HSCT.
Results: Thirty children and fifteen adolescents with post-transplant relapse were included in this study. The bone marrow karyotypic changes were analyzed before and after allo-HSCT. Twenty six (58 %) pts were male, and median age at alloHSCT was 10 years (range, 1,2-21). Seventeen (38 %) pts are still alive. Thirteen (29 %) pts received related transplantation, 15 (33 %) did unrelated HSCT, and 17 (38 %) did haploidentical HSCT. Four (9 %) pts had normal karyotype, 22 (49 %) had one chromosomal abnormality, 4 (9 %) had two abnormalities, and 15 (33 %) had more than three abnormalities before HSCT. Median follow-up after HSCT was 500 days (40-861). Twenty-eight (62 %) pts showed gain or loss of chromosomal abnormalities from original one (group 1), 16 (36 %) showed no karyotypic change between HSCT, and 1 (2 %) showed totally different karyotype. We defined the cytogenetic evolution group as group 1, and others as group 2. Median time from transplantation to relapse was not different between group 1 and 2. Shorter survival after relapse was observed for group 1 (8,9 % *vs* 51,5 % at 2-year post-relapse survival, P=0,041)(Figure1). Moreover, survival after relapse was inferior for pts with 2 or 3 cytogenetic subclones (n=10) compared to pts with 1 cytogenetic clone (n=35) (0% *vs* 32,5 % at 2 year post-relapse survival, P=0,016).

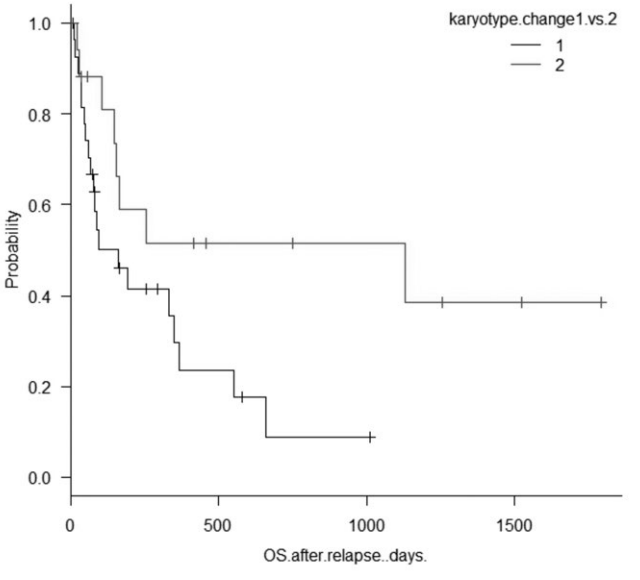

Figure 1.

Summary and Conclusions: Survival time of pediatric acute leukemia pts was similar with those of the above-mentioned adult AML being significantly shorter for group 1 than group 2. It supports that cytogenetic clonal evolution may be an important predictor of resistance to therapy after allo-HSCT, and needs novel therapeutic approaches.

E867

SEQUENCE ANALYSIS OF CLONAL IMMUNOGLOBULIN REARRANGEMENTS IN ACUTE LYMPHOBLASTIC LEUKEMIA: PATHEGENESIS AND MECHANISM

K. Katsibardi[1,*] M. Braoudaki[2], M.P. Le Franc[3], F. Tzortzatou-Stathopoulou[4], A. Kattamis[5], G. Chrousos[5]
[1]Hematology/Oncology Unit, First Department of Pediatrics, University of Athens, "Aghia Sophia" Children's Hospital, [2]University Research Institute for the Study and Treatment of Childhood and Malignant Diseases, University of Athens, "Aghia Sophia" Children's Hospital, Athens, Greece, [3]International imMunoGeneTics Information System, Université Montpellier 2, Laboratoire d'ImmunoGénétique Moléculaire LIGM, Institut de Génétique Humaine IGH, Montepellier, France, [4]University Research Institute for the Study and Treatment of Childhood and Malignant Diseases, University of Athens, "Aghia Sophia" Children's Hospital, [5]1Hematology/Oncology Unit, First Department of Pediatrics, University of Athens, "Aghia Sophia" Children's Hospital, Athens, Greece

Background: Clonal immunoglobulin rearrangements are assembled from the joining of (V) variable, (D) diversity and (J) joining gene segments (VDJ rearrangement). This process takes place during the maturation of B-cells.
Aims: Aim of the present study was to evaluate the clonal immunoglobulin rearrangements in children with B-cell acute lymphoblastic leukemia (ALL), in order to describe the underlying mechanism and ascertain whether it is influenced by the stage of leukemogenesis and the clonal evolution. Furthermore, characteristics of the VDJ rearrangement were evaluated as novel prognostic factors.
Methods: DNA extracted from 80 bone marrow samples at diagnosis of ALL patients was amplified by Polymerase Chain Reaction. Direct sequencing for PCR products was carried out on a MJ Research PTC-225 Peltier Thermal Cycler. The V, D and J segments were identified using the ImMunoGeneTics Information System (IMGT, European Bioinformatics Institute, Montpellier, France) and the software algorithm JOINSOLVER in order to characterize the closest matching human germline counterparts. The rearranged IGH V-D-J sequences were characterized as productive or non-productive.
Results: V region was identified in all VDJ rearrangements, involving 21 different gene segments, while 45% were in the 3' terminus of chromosome 14. V3 family (V3-13, V3-15, V6-1, V3-11) was the most common (55%). In pre-B-ALL patients, V3-11 and V6-1 regions were used frequently (67%). D identification was feasible at 84% rearrangements, distinguishing totally 24 different sections. In 73% sequences, segments of the 3' end of region D were associated with gene segments of the 5' end of J region. In 9.7% cases, D irregular recombination (DIR) signal sequences were recognized. In patients with pre-B-ALL only J4 and J6 areas were observed. In 90% of the rearranged VDJ sequences the CDR3 region was short. Insertion of N regions was recorded in 95% of rearrangements with a greater number of nucleotides in the region between V and D. Most sequences (75.5%) were non-productive and were associated with better prognosis, which means 97% of relapse-free events. On the other hand, productive rearrangements counted for 24.5% of cases and were linked to worse outcome that is 75% of relapse-free episodes.
Summary and Conclusions: The selective involvement of the V gene fragments depending on their position on chromosome 14 reinforces the theory of D-proximal model. The association of D and J for the creation of DJ complex is selective depending on the stage of maturation of B-cells. The superiority of V3-11 and V6-1 rearrangements in immature B-lymphocytes suggests that possibly the leukemogenesis occurs at the initial stages of B-lymphocytes maturation. Furthermore, the small size of the CDR3 region shows that malignant transformation occurred in the early stages of differentiation of B-cell. The increased risk of relapse in patients with productive VDJ rearrangements is based on the fact that they are completed at the advanced phases of B-cell maturation, which means they are more prone to mutations. Concluding, gene rearrangements are subject to the influence of molecular mechanisms, the discovery of which might give more information regarding leukemogenesis and subsequently serve as a therapeutic target in acute lymphoblastic leukemia of childhood.

E868

NUDT15 GENE POLYMORPHISM RELATED TO MERCAPTOPURINE INTOLERANCE IN TAIWAN CHINESE CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

D.C. Liang[1,*] C.P. Yang[2], H.C. Liu[1], T.H. Jaing[2,3], S.H. Chen[2,3], I.J. Hung[2], T.C. Yeh[1], T.H. Lin[4], C.L. Lai[4], C.Y. Lai[3], L.Y. Shih[3,5]
[1]Mackay Children's Hospital and Mackay Medical College, Taipei, [2]Chang Gung Children's Hospital, [3]Chang Gung University, [4]Chang Gung Memorial Hospital, Taoyuan, [5]Chang Gung Memorial Hospital, Taipei, Taiwan, ROC

Background: It is well known that the European descent have higher risk allele frequency of thiopurine methyltransferase (*TPMT*) gene than that of East Asian. However, this can not explain why the East Asian are more intolerable to mer-

captopurine than the European descent. A recent study identified a variant of the *NUDT15* gene (rs116855232 C>T) associated with intolerance to thiopurine in Korean patients with Crohn's disease.
Aims: We aimed to determine the prevalence of *NUDT15* variant in a Taiwan Chinese population and sought to clarify the reason why the East Asian tolerate mercaptopurine poorly.
Methods: Four hundred and four Taiwan Chinese children with acute lymphoblastic leukemia (ALL) at achieving complete remission and 100 adult patients with normal bone marrow (BM) were examined. Pyrosequencing for *NUDT15* (rs116855232) c.415 C>T (NM_018283.1) and genotyping for *TPMT* (rs1142345) c.719 A>G (NM_0003673) by use of TaqMan assay were performed.
Results: Of 404 ALL patients, 224 were boys and 180 girls. Five (3 boys and 2 girls), were homozygous for *NUDT15* rs116855232 (TT), 84 (42 boys and 42 girls), were heterozygous (TC), and the remaining 315 were wild-type (CC), with a risk allele frequency of 11.6 %. In 100 normal adult BM, one was homozygous, 29 were heterozygous, and the remaining 70 were wild-type *NUDT15*, with an overall risk allele frequency of 15.5%. There was no statistical difference between pediatric ALL patients and normal adult BM in *NUDT15* variant (*P*=0.154). By contrast, of the 404 ALL patients, none was homozygous for *TPMT* (GG), 13 were heterozygous (AG), and the remaining 391 were wild-type (AA), with an overall risk allele frequency of 1.6%. In the 100 normal adult BM samples, none was homozygous, one was heterozygous, and the remaining 99 were wild-type *TPMT*, with an overall risk allele frequency of 0.5%. No difference in the variant frequency of *TPMT* genotype was observed between children with ALL and adults with normal BM (*P*=0.325).The high risk *NUDT15* variant was closely associated with the intolerance to mercaptopurine in children with ALL. The maximal tolerable daily doses of mercaptopurine, in which a patient could maximally tolerated for at least several months, in *NUDT15* TT, TC and CC groups were 9.4±3.7 mg/m^2 (mean±SD), 30.7±11.7 mg/m^2, and 44.1±15.3 mg/m^2, respectively (*P*<0.0001). The maximal tolerable dose of mercaptopurine in *TPMT* AG and AA were 31.4±10.2 mg/m^{2}and 41.2± 15.8 mg/m^2, respectively (*P*=0.034). The maximal tolerable daily dose of mercaptopurine in double heterozygous for both *NUDT15* and *TPMT* (n=4) was 32.7±14.3 mg/m^2/day compared with single heterozygous for *NUDT15* or *TPMT* of 30.0±11.7 mg/m^2/day *(P* =0.655*)*, the latter was significantly different from the dose 44.6±15.3 mg/m^2/day in wild-type for both *NUDT15* and *TPMT* (*P*<0.0001). The 5-years event-free survival (EFS) was 87.6%, 90.2%, and 50.0%, for *NUDT15* CC, TC, and TT genotype, respectively (*P*=0.0118). The patients with homozygous for *NUDT15* (TT) had inferior EFS compared with heterozygous TC (*P*=0.034). Neither heterozygous *NUDT15* nor *TPMT* variant alone affected EFS of children with ALL.
Summary and Conclusions: The high frequency of *NUDT15* risk variant, but not the low frequency of *TPMT* risk variant, was closely associated with the intolerance to mercaptopurine in children with ALL in Taiwan.

HTS COUPLED WITH A BIOINFORMATICS ANALYSIS IN ROUTINE HOSPITAL PRACTICE FOR MULTICLONAL DIAGNOSIS AND MRD FOLLOW-UP IN ALL

Y. Ferret[1,*] N. Grardel[1], M. Salson[2,3], A. Caillault[1], M. Duez[2,4,5], S. Sebda[1], C. Villenet[6], C. Roumier[1], M. Figeac[6], B. Nelken[7], B. Quesnel[8], C. Preudhomme[1], M. Giraud[2,3]
[1]Hématologie, Centre de Biologie Pathologie CHRU Lille, [2]INRIA Lille, [3]Laboratoire d'Informatique Médicale de Lille (LIFL), [4]Laboratoire d'Informatique Médicale de Lille, UMR CNRS 8022, Université Lille 1, [5]SIRIC OncoLille, [6]Functional Genomic Platform, Cancer Research Institute, [7]Hôpital Jeanne de Flandre, [8]Service des Maladies du Sang, CHRU Lille, Lille, France

Background: The molecular diagnosis in ALL allows, by the research of V(D)J rearrangements on lymphoblast DNA, to find clonal markers in 95% of the cases. These markers are also used to quantify the minimal residual disease (MRD) by real time Q-PCR to adapt treatments. This strategy fails in some cases: Absence of initial marker, failure of sequencing or emergence at relapse time of a clone which was not observed at diagnosis time or in minority. Several studies have asserted the usefulness of high-throughput sequencing (HTS). It enables deep sequencing of a whole lymphoid population, bypassing some of these problems. However, the huge amount of data raises two challenges. First, hospitals must be able to store and process terabytes of data per year. Second, the data must be nicely synthesized to ease clinician interpretation.
Aims: Here we report the use of HTS in a hematology lab for diagnosis and follow-up of ALL, combined with a bioinformatics analysis and visualization of the results with the new dedicated Vidjil software (Giraud, Salson, et al, BMC Genomics 2014, http://www.vidjil.org).
Methods: In a first work we retrospectively studied the clonality of 8 pediatric patients (5 B-ALL and 3 T-ALL, 2w-6m, 2-14 years) at diagnosis and follow-up (37 follow-up time points). Since January 2015 we lead a prospective study of pediatric ALL clonality at diagnosis in a routine hospital practice (15 patients in mid-February: 11 B-ALL and 4 T-ALL, 2-22 and 10-25 years). 500ng of bone marrow DNA are extracted on Qiagen® Kit and amplified by PCR systems for TRG, TRD, IGKB and IGH targets (compared to only TRG and IGH for the retrospective study). These systems are described or derived from the BIOMED-2 works. The libraries are done with Ion Fragment Plus® Kit and sequenced with an Ion Torrent® 318 or 316-V2 Chip system on PGM™. The Vidjil platform clusters reads in clones, names the clones based on their V(D)J rearrangement and tracks them along the time. Sequences can be aligned, merged and sent to IMGT/V-QUEST or IgBlast. It exports medical results tailored to general laboratory computer system or to a printable file.
Results: We identified a number of clones in the diagnosis samples and observed their evolution at different follow-up time points. All the clones detected by classic methods were also found by Vidjil. Moreover the software allows us to look deeper at other clones appearing at lower concentrations. This way we could easily notice emergence of minority clones or clones that were not detected at diagnosis: Relapses were detected, and for one patient two emerging clones were observed. (See FIGURE 1 below.). No sequencing failure occurred in the 15 prospective analyses compared to one Sanger failure in the usual protocol. The whole analysis from the receipt of the sample to the end of the validation by the clinician was several days faster than the current protocol, with equal resources.

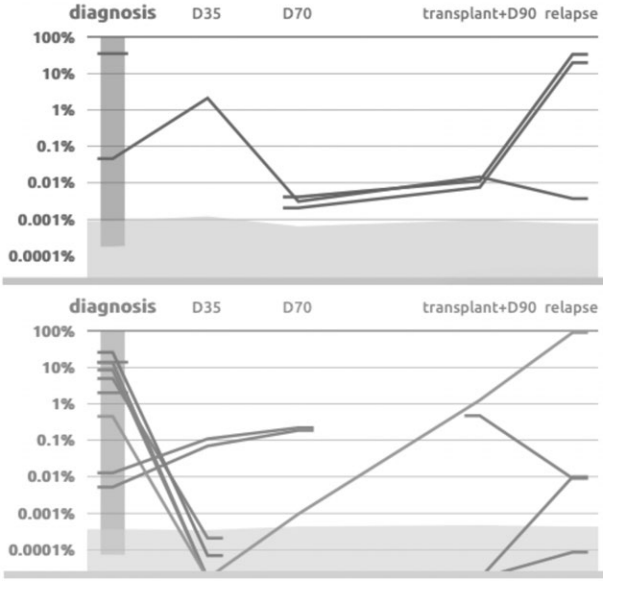

Figure 1.

Summary and Conclusions: Vidjil has been designed and tested for two years in Lille and is now being tested in other French hospitals involved in ALL-MRD. It opens the floodgates to the use of HTS in routine hospital practice. Now all diagnosis samples received in Lille are analyzed both with the usual and the HTS protocols.

A NOVEL HOTSPOT FOR IKZF1 WHOLE GENE DELETIONS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

B.A. Lopes[1], C. Meyer[2], T.C. Barbosa[1], U.Z. Stadt[3], M.S. Pombo-de-Oliveira[1], R. Marschalek[2], M. Emerenciano[*]
[1]Pediatric Hematology-Oncology Program, Instituto Nacional de Câncer, INCA-RJ, Brazil, Rio de Janeiro, Brazil, [2]Diagnostic Center of Acute Leukemia, Goethe University, Frankfurt am Main, [3]Center for Diagnostic, University Medical Center Hamburg Eppendorf, Hamburg, Germany

Background: B-cell precursor acute lymphoblastic leukemia (BCP-ALL) is characterized by chromosomal translocations. Genome-wide studies have revealed additional alterations, such as *IKZF1* deletions (*IKZF1*del). The gene is located at 7p12 and encodes the transcription factor Ikaros, which is involved in the development of the B cell lineage. *IKZF1*del is independently associated with relapse and dismal outcome in BCP-ALL. They are mainly characterized by absence of exons 2-3, 2-8, 4-7, and 4-8. In a recent study, a multiplex PCR

approach was able to detect the most frequent *IKZF1*del on chromosome 7p, which could be used as markers for minimal residual disease monitoring. However, precise data concerning *IKZF1* whole-gene Δ1-8 deletions, which account for approximately 30% of all *IKZF1del*, are still lacking.
Aims: We aimed at characterizing *IKZF1* whole-gene deletions at the genomic level in order to improve the current PCR methods for the analysis of the most frequent *IKZF1* deletions in pediatric patients with BCP-ALL.
Methods: Samples of BCP-ALL with *IKZF1* whole-gene deletions (n=30) were included. Deletions of exons 1-8 were first identified by the multiplex ligation-dependent probe amplification (MLPA) kit (P335-A4), and confirmed using specific *IKZF1* MLPA kit (P202). Six samples were analyzed with CytoScan HD array (Affymetrix. Inc., Santa Clara, CA, USA), and the breakpoints were confirmed by multiplex PCR. Afterwards, 24 samples were screened for the hotspot identified by the array (located within *COBL* gene) with a long distance PCR (LDI-PCR) and sequencing approach.
Results: According to the comparative genome analysis, 2 out of 6 samples with BCP-ALL (33.3%) and *IKZF1* whole-gene deletions had a breakpoint on *COBL* intron 5. They presented a ~1.7 Mb and ~18.8 Mb deletion (7p12.2-*COBL* and 7p14.3-*COBL*). Further screening of 24 samples within *COBL* intron 5 led to the verification of three molecular alterations: a 1.1 Mb inversion of *COBL* that also compromised *IKZF1*; and two chromosomal translocations (Xp21.3-*COBL* and C20orf194-*COBL*). In sum, a hotspot on *COBL* intron 5 was found in 16.7% of the samples (five of thirty samples) with *IKZF1* Δ1-8.
Summary and Conclusions: This study identified chromosomal translocations, deletions, and inversions involving *COBL* intron 5 on samples with *IKZF1* whole-gene deletions. This clearly indicates that *COBL* intron 5 is a new hotspot for *IKZF1* whole-gene deletions. Genetic alterations starting on *COBL* intron 5 also promote *IKZF1* deletions due to the proximity between *IKZF1* and *COBL* (~800 Mb). Further analyses covering a larger genomic area within *COBL* are ongoing in order to unravel novel regions associated with DNA breaks and *IKZF1* deletions.

EXPRESSION ANALYSIS OF GENES LOCATED IN THE COMMON REGION OF AMPLIFICATION IN PEDIATRIC B CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA WITH INTRACROMOSSOMAL AMPLIFICATION OF CHROMOSOME 21

J.C. Santoro[1], G. Fuka[1], M.S. Pombo-de-Oliveira[1], M. Emerenciano[*]
[1]Pediatric Hematology-Oncology Program, Instituto Nacional de Câncer, INCA-RJ, Brazil, Rio de Janeiro, Brazil

Background: B-cell precursor acute lymphoblastic leukemia (BCP-ALL) cases frequently present high hyperdiploidy (>50 chromosomes) or chromosomal translocations resulting in chimeric gene fusions (*ETV6-RUNX1, BCR-ABL1, TCF3-PBX1*, and *KMT2A-AFF1*). Recently, molecular cytogenetic studies defined a subgroup among BCP-ALL with cryptic intrachromosomal amplification features on chromosome 21 (iAMP21). The iAMP21 has been described in 1.5-3% of BCP-ALL and is associated with a higher relapse risk when patients are treated under standard regimens. Genomic analysis demonstrated the presence of a common region of amplification (CRA), including genes such as *IFNGR2, GART, SON DSCR1, RUNX, DYRK1A, ERG*, and *ETS*. These genes are described to be involved in the leukemogenesis and/or in the therapeutic response of some leukemia subtypes. Our hypothesis is that aberrant expression of these genes could also contribute to the particularities of iAMP21-BCP-ALL.
Aims: We aimed to identify genes that could be potentially relevant in the leukemogenesis of iAMP21-BCP-ALL by evaluating the expression of genes with functions previously described in leukemia and located in the CRA.
Methods: From 368 bone marrow (BM) samples of patients with BCP-ALL diagnosed between 2002 and 2012, 74 were suggestive for chromosome 21 copy number alterations by *Multiplex Ligation-dependent Probe Amplification* (MLPA). In 9 patients an iAMP21 was confirmed by Fluorescence *in situ* hibridization (FISH). Gene expression analysis of these samples was performed by reverse transcriptase quantitative PCR (qPCR) and CT values of the selected genes among BCP-ALL samples either with or without an iAMP21 were calculated. The non-iAMP21 subgroups were: *ETV6-RUNX1* fusion (n=9), hyperdiploid karyotypes (n=3), no recurrent gene fusions (n=7), and non-leukemic controls (n=7). Statistical analysis was performed using *Student's t-tests,* p values <0.05 were considered statistically significant (*Unpaired t-test*), using the GraphPad Prism 1.5 software.
Results: Patients with iAMP21-BCP-ALL had higher expression of *IFNGR2* (*p=0.0331; **p=0.0147; ***p=0.0023), *ERG* (*p=0.0284; ***p=0.0115), *ETS2* (*p=0.0343; **p=0.0058; ***p=0.0021) and *DYRK1A* (***p=0.0008) genes when compared with *ETV6-RUNX1* (*p), no recurrent gene fusions (**p), or with hyperdiploid karyotypes (***p) groups.

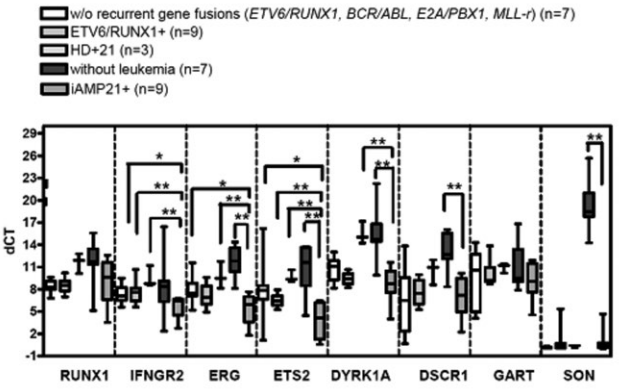

Figure 1.

Summary and Conclusions: Our results suggest that there is a differential expression of some genes in the CRA of samples from patients with iAMP21-BCP-ALL. Thus, these data allow further studies in order to evaluate the contribution of these genes in leukemogenesis and therapeutic response of iAMP21-BCP-ALL.

AKT REGULATION OF ONCOGENIC NOTCH PATHWAY IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

N. Platonova[1,2,*], E. Vigolo[1], G.C. Cermisoni[1], D. De Simone[1], M. Colombo[1], S. Garavelli[1], E. Lazzari[1], S. Galletti[2], A. Paoli[1], A. Neri[2], R. Chiaramonte[1]
[1]Department of Health Sciences, [2]Department of Clinical Sciences and Community Health, Università degli studi di Milano, Milano, Italy

Background: Notch and PI3K/AKT signaling are two key oncogenic pathways closely associated in T-cell acute lymphoblastic leukemia (T-ALL). These pathways collaborate in controlling proliferation, survival and migration of T-ALL cells and are deregulated in ~60% (Notch pathway) and 48% (PI3K/AKT) of T-ALL patients. Recent evidences indicate that in T-ALL cells, Notch and PI3K/AKT pathways collaborate through a reciprocal control.
Aims: of this work was to investigate the molecular mechanisms of PI3K/AKT-dependent Notch1 activity regulation.
Methods: T-ALL cell line, Molt4, and HEK293T cell line were grown in RPMI-1640 and DMEM respectively, supplemented with 10% heat-inactivated FBS. 1 mg RNA isolated from cells was retro-transcribed in 20 ml by M-MuLV reverse transcriptase using random hexamer primers. RT-PCR analysis was performed using primers for Notch1, HES1, preTCRa, GAPDH. Apoptotic cells were identified by Annexin-V and propidium iodide staining. Protein expression was detected by Western blot analysis of whole cell lysates. HEK293T cells were transfected with expression plasmid encoding the dominant negative mutant form of AKT (DN-AKT) and with plasmid encoding full length Flag-tagged NOTCH1 using the DMRIE-C reagent (Invitrogen), according to manufacturer's instructions. Molt4 cells were electroporated with 20 μg of pcDNA3.1 DN-AKT or mock pcDNA3.1 using the Neon Transfection System (Invitrogen) according to the manufacturer's guidelines. After 72 h cells were harvested to prepare protein lysates. Immunoprecipitation of ubiquitin-conjugated proteins was performed using the UbiQapture-Q Kit (Biomol, Exeter, UK), as described by the manufacturer. Co-immunoprecipitation analysis was performed using Protein G Agarose beads, eluted immunoprecipitates were analyzed by Western blot. Immunofluorescent staining was done on HEK293T cells incubated with anti-Flag or anti-c-Cbl primary antibodies and the appropriate AlexaFluor-conjugated secondary antibodies. Images were acquired with a Leica TCS SP2 confocal microscope. A colocalization area was determined based on a 2D cytofluorogram and density analysis performed by Multicolor Analysis Leica Confocal software.
Results: Both LY294002-mediated chemical inhibition of PI3K/AKT signaling and transient transfection of a DN-AKT mutant strongly reduced Notch1 protein level and activity, without affecting Notch1 transcription. We showed that downstream AKT regulator, GSK-3β, did not mediate the effect of PI3K/AKT withdrawal on Notch1 protein. We demonstrated that Notch1 protein decrease upon PI3K/AKT inhibition was due to lysosomal degradation of the Notch1 membrane-bound form. IP and Co-IP analyses revealed that PI3K/AKT withdrawal in Molt4 cells resulted in an increased tyrosine phosphorylation of Notch1 and monoubiquitination of Notch1 as detected by ubiquitin capture assay. Co-immunoprecipitation assay and co-localization analysis further showed that E3 ubiquitin ligase, c-Cbl, interacted with Notch1 in order to direct it into the lysosome for degradation.
Summary and Conclusions: To our knowledge, our results provide the first evidence of mechanism by which AKT pathway controls Notch1 activity reduc-

ing the amount of protein undergoing to lysosomal degradation. Given the crucial role of Notch1 in T-ALL, our findings suggest that hyperactive AKT signaling in T-ALL may contribute to increase the oncogenic Notch signaling in T-ALL independently from mutations in Notch1. Therefore a therapeutic strategy directed to PI3K/AKT signaling in T-ALL could provide advantages to inhibit the dysregulated NOTCH signaling.

EVALUATION OF INOSINE TRIPHOSPHATE PYROPHOSPHOHYDROLASE 94 C>A, IVS2 +21 A>C POLYMORPHYSMS IN ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED WITH 6-MP AND PREDICTION OF ITS MYELOSUPPRESSIVE EFFECTS

Y. Mortazavi[1,*] F. Azimi[2], A. Ramazani[3], M. Khalili[2], S. Faghihzadeh[4]
[1]Pathology, [2]molecular medicine, [3]Biotechnology, [4]Biostatistics, Zanjan University of Medical sciences, Zanjan, Iran

Background: 6- Mercaptopurine (6-MP) plays an importante role in treatment of ALL. ITPA is one of the enzymes which is involved in 6-MP metabolism pathway, catalyzes the pyrophosphohydrolysis of inosine triphosphate (ITP) to inosine monophosphate (IMP) and prevents accumulation of toxic ITP metabolits.
Aims: Our objective was to evaluate the *ITPA 94 C >A, IVS2 +21 A >C* gene polymorphisms in patients with ALL under treatment with 6-MP and prediction of its myelosuppressive effects.
Methods: In this case series study the population consisted of 70 patients diagnosed with ALL in the Division of Hematology-Oncology of Tehran Mofid Hospital. PCR was carried out to amplify exon 2, exon 3, intron 2 and intron 3 of *ITPA* gene. All the amplified fragments were subjected to directional sequencing, then association between genotype and 6-MP toxicity was studied.
Results: In this study two exonic variants including *94 C>A* and *138 G>A* showed a prevalence of 8.5% and 36.4% respectively and two intronic variants, *IVS2 +21 A>C* and *IVS3 +60 G>A* were found in 13.5% and 7% of the samples respectively. The rate of myelosuppression in the presence of mutant homozygote and heterozygote alleles (*94 C>A, 138 G>A, IVS2 +21 A>C* and *IVS3 +60 G>A*) was higher compared to wild type (CC, AA and GG) alleles during the use of 6-MP (P<0.05). Hepatotoxicity in individuals with mutant homozygote and heterozygote *94 C>A* and *IVS3 +60 G>A* alleles was higher than individuals with wild type alleles (CC and GG) during the use of 6-MP (P<0.05).
Summary and Conclusions: Our results indicate that individuals who have aberrant ITPase genotype (mutant homozygous or heterozygous), more likely to have myelosuppression and hepatotoxicity during the use of 6-MP. This results also suggest that pre-therapeutic screening of *ITPA 94 C>A*, *IVS2 +21 A>C* and *IVS3 +60 G>A* may help in minimizing the myelosuppression and hepatotoxicity induced by 6-MP in ALL patients.

E871

COMPARISON OF THREE DIFFERENT PRIMING REGIMENS BASED ON IDARUBICIN, ACLACINOMYCIN OR PIRARUBICIN FOR REFRACTORY/ RELAPSE ACUTE LYMPHOBLASTIC LEUKEMIA

K. Miao[1,*] H. Zhu[1], W. Shen[1], S. Wang[1], H. Wu[1], J. Li[1], G. He[1]
[1]the first affiliated hospital of Nanjing Medical University, Nanjing, China

Background: Refractory/relapse acute lymphoblastic leukemia (ALL) has very poor clinical outcome for the resistance to routine chemical agents. Priming regimen was a promissing choice for refractory/relapse ALL, especially for those eldly patients.
Aims: We were interested and analyzed three different priming regimens based on idarubicin, aclacinomycin or pirarubicin for refractory/relapse ALL. Both the effectiveness and safety were investigated.
Methods: A total of 43 refractory and/or relapsed ALL patients were enrolled in this study. These patients composed of 31 male and 12 female, with the medial age of 26(8~ 85) years old. The salvage regimen was idarubicin, aclacinomycin or pirarubicin combined with cytarabine (Ara-C) and granulocyte colony-stimulating factor (G-CSF). The detailed three regimens were performed as, IAG (idarubicin 10mg/d, d1,4,8,11; Ara-C 10 mg/m^2 twice daily, d1-14; G-CSF 200 mg /m^2 d0~14), CAG(Acla 10mg/d, d1-8; Ara-C 10 mg/m^2 twice daily, d1-14; G-CSF 200 mg /m^2 d0~14) and TAG(pirarubicin 10mg/d, d1,4,8, 11; Ara-C 10 mg/m^2 twice daily, d1-14; G-CSF 200 mg /m^2 d0~14). There were 13 cases in IAG group, 18 cases in CAG group and 12 cases were assigned to TAG group. Effectiveness was measured using objective response and safety was measured using the NCI classification system of common toxicity criteria for adverse events. Some parameters which may influence the clinical outcome, such as age, immunophenotype and white blood cell (WBC) count were also explored.
Results: The overall complete remission (CR) rate for all patients in three groups was 46.5% (20 cases), partial remission (PR) rate was 16.2% (7 cases), and 16 cases (37.2%) got no remission (NR). The overall response rate (ORR) was 62.8%. In IAG group, the ORR was 69.2%, and the CR rate as well as PR rate was 53.8% and 15.4%, respectively. There were 8 patients (44.4%) got CR, 3 patients (16.6%) got PR, and ORR was 61% in CAG group. In group TAG, a total of 5 cases (41.7%) got CR, and 2 cases (16.6%) got PR, with ORR 58.3%. The response rate in three groups had no statistical difference (P=0.837). Compared with patients □35 years old (ORR 71.4%), the ORR for ≤35 years old group was 54.5%, and no statistical difference was found between two groups (P=0.347). There was also no significance about ORR between T-

ALL and B-ALL groups (T-ALL group 68.4% *Vs* B-ALL group 54.1%, P=0.542). No significance could be found between WBC decreased group and WBC normal or increased group (ORR, WBC decreased group 65% *Vs* WBC normal or increased group 60.9%, P=1.000). ORR in >60 years old group and ≤60 years old group did not show any significant difference (ORR, >60 years old group 60% *Vs* ≤60 years old group 54.3%, P=0.272).If we define WBC≥100×10^9/L in T-ALL or WBC≥30×10^9/L in B-ALL as high WBC group, there was also no significance between high WBC group and non high WBC group (ORR, 50% *Vs* 64.9%, P=0.808). Further more, it was analyzed in every two chemotherapy regimen groups, and no significance was found for response rate. Some common adverse events occurred during and after chemotherapy, including fever, bone marrow suppression, gastrointestinal tract reaction and liver function damage. These events were all well tolerated.
Summary and Conclusions: Three different priming regimen based on idarubicin, aclacinomycin or pirarubicin for refractory/relapse ALL showed high remission rate, good tolerance, and the non hematological toxicity was mild and could be well tolerated. These regimens did not show any significance in both response rate and side effects.

E872

INVESTIGATING THE PROGNOSTIC SIGNIFICANCE OF MICRORNA-335 EXPRESSION IN ADULT ACUTE LYMPHOBLASTIC LEUKAEMIA

J.S.X. Lee[1,*] B.H. Lin[1], W.J. Chng [1]
[1]Department of Haematology-Oncology, National University Cancer Institute, Singapore / National University Health System, Singapore, Singapore, Singapore

Background: Acute lymphoblastic leukaemia (ALL) accounts for approximately 15% of all leukemias in adults. Unlike paediatric ALL, which has a 90% five-year event-free survival, adult ALL tend to fare poorly, with a 20-30% five-year event-free survival rate. While some of the issues related to poor outcome may be due to host conditions, most patients die of refractory disease rather than treatment-related complications. Prognostic factors and the treatment regimen for adult ALL have not evolved in more than 15 years; it is therefore critical that we try to identify better prognostic factors that not only identify high-risk patients, but may also provide insight into the use of therapeutic agents that can improve prognosis. MicroRNA has been shown to be dysregulated in cancer cells, and to be more powerful prognostic factors in leukaemia. Low levels of miR335 have previously been found to result in higher MAPK1-mediated survival of paediatric ALL and is associated with prednisolone resistance. The use of MAPK inhibitors could overcome this resistance. miR335 has not been studied in adult samples.
Aims: We aimed to determine the level of miR335 in samples of newly diagnosed Adult ALL patients. Our hypothesis is that low expression of miR335 in adult ALL is associated with a poorer outcome. We also hoped to determine miR335 association with known poor prognostic factors as well as the need for Stem Cell Transplants.
Methods: We determined the level of miR335 in 37 newly diagnosed Adult ALL patients who were treated uniformly on our institutional protocol over the past 5 years. Mononuclear cells were separated and harvested at diagnosis using Ficoll-Paque density gradient centrifugation. Total RNA was extracted using TRIzol Reagent and subsequently purified. cDNAs was then synthesized from total RNA with miR335 specific primers and qRT-PCR quantification of miR335 was performed of the samples. Using the median expression of miR335 as a cut off, we compared a number of parameters between the 2 populations, including complete response rates, survival, known poor prognostic factors and need for stem cell transplantation. The t-test is used for comparison of continuous values, chi-square test for categorical values and log-rank test for survival.
Results: Those with a high level of miR335 were noted to have more poor prognostic factors (94%) as compared to the group with a low level of miR335 (71%, p=0.04). Despite this, those with a high level of miR335 had a higher rate of remission after induction chemotherapy (71% *vs* 41%, p=0.046). Although fewer patients with low miR335 had poor prognostic factors, they required more stem cell transplants (47% *vs* 11%, p=0.03) compared to the high miR335 group. This was mainly due to poor response to induction chemotherapy with 78% of them not achieving remission then. Although the overall survival is the same in both groups (High miR335 39%, Low miR335 42%, p=0.66), it is largely confounded by the high rate of stem cell transplant in the low miR335 group.
Summary and Conclusions: This data supports the hypothesis that miR335 in adult ALL confers a poorer outcome which is independent of traditional poor prognostic factors. This may allow us to identify poor risk patients for which we can tailor treatment using MAPK1 inhibition to overcome therapeutic resistance as we have shown previously, at the beginning of treatment rather than at a later stage based on minimal residual disease measurement.

Background: Acute lymphoblastic leukemia (ALL) is the major malignancy in childhood. Patients with high hyperdiploid (HeH) chromosome constellation represent the largest genetic subgroup. Despite its generally favorable prognosis, patients show heterogeneous clinical outcome.
Aims: The eight most commonly gained chromosomes (4, 6, 10, 14, 17, 18, 21, X) were investigated by correlated way at single-cell level using multicolor interphase fluorescence *in situ* hybridization (iFISH) in order to explore genetic heterogeneity and identify subgroups of patients with distinct prognostic features.
Methods: After exclusion of children with t(9;22)(q34;q11.2), t(v;11q23), t(12;21)(p13;q22) or t(1;19)(q23;p13.3) a complete multi-target iFISH analysis was successfully performed on bone marrow samples of 168 patients with pre-B ALL. A minimum of 300 nuclei were aimed to be fully evaluated in each sample. Modal number (iMN_8), defined as the chromosome number of the largest subclone by iFISH, has been identified for each leukemia.
Results: iMN_8 indicated a HeH ≥51 chromosome set in 28.5% (48/168) of cases. As compared to non-HeH patients higher DNA index (p<0.001), lower WBC at presentation, higher proportion of patients in the standard risk group, somewhat younger age and longer survival were all indicators of better prognosis in the iMN_8 ≥51 group. A subgroup of patients (n=20) with the highest modal number, iMN_8 55-56, had an excellent 5-year pOS (95.2%) which was not only higher compared to all other patients involved in the study (p=0.019) but also considering HeH patients exclusively (p=0.046). iMN_8 55-56 patients had significantly lower WBC at diagnosis (p=0.010), more patients belonged to the standard risk arm (p=0.007) and none of them had central nervous system involvement at diagnosis. We scrutinized whether the pattern of specific numerical chromosome aberrations has an association with the outcome heterogeneity observed in the HeH group. Improved survival was achieved by patients gaining chromosome(s) 4, 4-6, 4-10, 4-17, 4-18 and 4-10-17. and 4-10-17. Patients with 4-10-17 triple trisomy, a feature previously reported to be associated with the best prognosis, showed a better pEFS but not pOS. The multi-target iFISH approach allowed us to determine the copy number status of 8 chromosomes in single nuclei. Cells sharing identical alterations were grouped during clonality identification and subclonal composition was then analyzed to assess chromosomal heterogeneity. Amongst patients with iMN_8 55-56 on average 23.0 (SE 9.24) subclones were detected, which was significantly lower (P=0.028) compared that in the iMN_8 51-54 group.
Summary and Conclusions: We successfully performed a screening for whole chromosome copy number changes at single-cell level using an extensive panel of FISH probes on unselected leukemic cells of patients with childhood pre-B ALL. We were able to identify patients with HeH ALL with high reliability as well as to explore chromosomal heterogeneity, reveal cytogenetic patterns as predictors of outcome and classify HeH ALL patients into prognostically distinct subgroups.

EARLY CLEARING OF PERIPHERAL BLOOD BLASTS IS AN INDEPENDENT PROGNOSTIC FACTOR IN ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

L. Monteiro[1], J. Schuh[1,*] R. Gerivaz[1], S. Leocádio[1], A. Tomé[1], M. Fevereiro[1], N. Almeida[1], F. Costa[1], J. Caldas[1], C. Gaspar[1], M. Silva[1], L. Checa[1], A. Monteiro[1], G. Ferreira[1], M.H. Sousa[1], P. Ribeiro[1], E. Cruz[1], M. Prata[1], I. Poças[1], A. Botelho de Sousa[1]
[1]Serviço de Hematologia, Hospital dos Capuchos, Lisboa, Portugal

Background: Although therapeutic regimens for acute lymphoblastic leukemia (ALL) in use for adult patients achieve complete remission (CR) rates over 80%, most patients eventually relapse and long-term mortality is high. Steroid resistance is known to be associated with aggressive disease in children, but it has not been routinely evaluated as a prognostic factor in adults.
Aims: In order to evaluate the impact of steroid sensitivity at diagnosis, we retrospectively analyzed the day 7 peripheral blood blast count (d7BC) in adult patients treated in our department over a period of 11 years with the hyperCVAD regimen, which includes a 7-day pre-induction phase with dexamethasone.
Methods: We evaluated 131 consecutive patients treated from January 2003 to December 2013 for the influence of the following variables on disease-free survival (DFS) and overall survival (OS): age, sex, immunophenotype, hyperleukocytosis (defined as >30,000/ul for B and >100,000 for T subtypes), central nervous system or testicular involvement at diagnosis, unfavorable cytogenetics [t(9;22) or *MLL*rearrangements] and d7BC.
Results: Median age was 40 years (15-69) with 18% (23 patients) >60 years; 53% were male. The phenotype was B in 79% (104) patients and T in 21% (27). Hyperleukocytosis was present at diagnosis in 22% of B and 30% of T-ALL; median leukocyte count at diagnosis was 13300/ul. The CR rate was 88%. With a median follow-up of 60 months, DFS was 25,7 months and OS

was 30 months. Among the 108 evaluable patients for circulating blasts, 36% (39) had persisting d7BC. This subgroup of patients had a shorter OS (17,1 *vs* 38,8 months, P <0,01). In multivariate analysis, the Hazard Ratio was 2,0 for persisting d7BC.

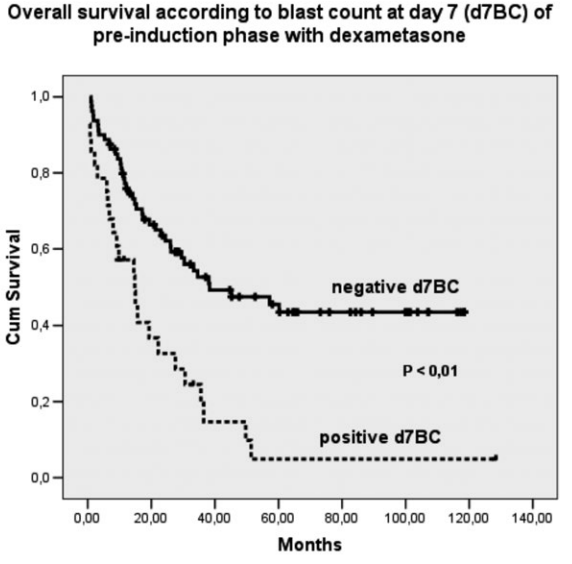

Figure 1.

Summary and Conclusions: Our results show that d7BC is an independent risk factor, suggesting that early clearance of blasts has a major impact on the outcome of ALL in adults. The potential of emerging novel therapies should be explored in this particular group of patients.

PHILADELPHIA CHROMOSOME MAY NOT BE AN ADVERSE PROGNOSTIC FACTOR IN THE OLD-AGE B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS IN THE ERA OF TYROSINE KINASE INHIBITOR

J.Y. Lee[1,*] J. Jang[1], J.J. Lee[2], I. Kim[3], J.C. Jo[4], S.K. Sohn[5], J.S. Ahn[2], D.Y. Shin[6], Y. Choi[4], J.H. Moon[5], J.W. Cheong[1], Y.H. Min[1]
[1]department of internal medicine, Yonsei University College of Medicine, Seoul, [2]Department of Hematology and Oncology, Chonnam National University Hwasun Hospital, Hwasun, [3]Department of Internal Medicine, Seoul National University Hospital, Seoul, [4]Division of Hematology-Oncology, Ulsan University Hospital, University of Ulasan College of Medicine, Ulsan, [5]Department of Hematology/oncology, Kyungpook National University Hospital, Daegu, [6]Department of Internal Medicine, Korea Cancer Center Hospital, Korea Institute of Radiological and Medical Sciences, Seoul, Korea, Republic Of

Background: Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL) is approximately comprised of 25% of adult ALL, and has been characterized by poor clinical outcomes, especially in the elderly patients. However, the prognosis in these patients might be improved with the advent of tyrosine kinase inhibitors (TKIs) as combination therapy to various chemotherapeutic regimens.
Aims: The aim of this study is to analyze the prognostic significance of Ph+B-cell precursor (BCP) old-age ALL treated with TKIs and compare its clinical outcomes with Ph- BCP old-age ALL.
Methods: The clinical outcomes of 41 elderly patients with BCP, who were treated at 5 university hospitals in Korea from Sep 2005 to Nov 2013, were retrospectively analyzed.
Results: In this study, the median age of the patients was 65 (range, 60 to 82) and median follow up duration was 58.3 months (range, 1.5 to 115.4 months). Twenty-one patients (51%) were Ph+and treated with TKI combined chemotherapy. Patients with Ph- ALL were treated with conventional chemotherapy identical to those for the Ph+patients. There were no differences in the patient characteristics including age, white blood cell count, immunophenotype, extramedullary involvement, and lactic dehydrogenase level according to the presence of Philadelphia chromosome. Complete remission (CR) rate was significantly higher in the Ph+ALL compared to the Ph- ALL elderly patients (80.0% *vs* 50.0%, *P*=0.047). There was no difference in the treatment-related mortality rate between two groups. Median overall survival was not different between the Ph- and Ph+ALL (5.4 months *vs* 7.5 months). Among Ph+patients, Bcr/abl subtypes at diagnosis and quantitative PCR analysis after induction therapy did not show any prognostic values. Multivariate regression analysis demonstrated that Charlson comorbidity score of less than 4 at diagnosis (Hazard ratio (HR) 0.186, *P*=0.05), CR achievement after the first induction chemotherapy (HR 0.188, *P*=0.001) and negative CD20 expression (HR 0.271, *P*=0.007) remained as the independent prognostic factors predicting higher overall survival rate. In contrast to Ph- ALL patients (HR 1.462, *P*=0.481), CD20 expression level on the leukemic blasts was significantly associated with low overall survival rate in the Ph+old-age ALL (HR 5.338, *P*=0.008).

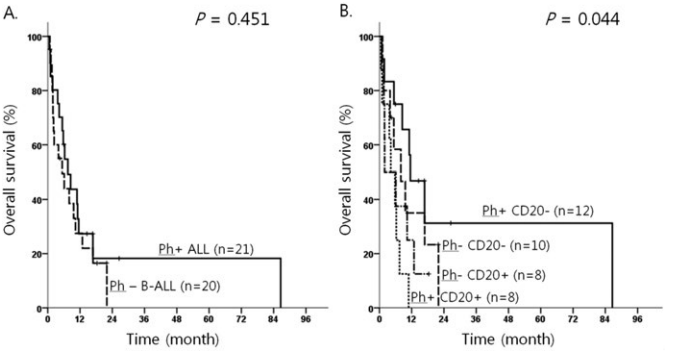

Figure 1.

Summary and Conclusions: In this study, the survival rates of elderly BCP ALL patients were very low as expected. However, no additive poor prognostic value of the presence of Philadelphia chromosome was observed in the elderly ALL patients treated with TKI-combined chemotherapy. In addition, the prognostic relevance of CD20 antigen expression should be further evaluated for the large number of elderly Ph+ALL patients.

E876

NELARABINE IN CHILDREN WITH REFRACTORY AND RELAPSED T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

N. Myakova[1,*] Y. Diakonova[1], O. Bydanov[2], N. Ponomareva[3], L. Fechina[4], E. Boychenko[5], A. Karachunsky[2], A. Shamardina[6]
[1]oncohematology, [2]Federal Center for Pediatric Hematology,Oncology, Immunology named by D.Rogachev, Moscow, Russia, [3]Russian Children Hospital, Moscow, [4]Ekarinburg Childrens Oncological Center, Ekaterinburg, [5]Medical University Hospital, Saint-Petersburg, [6]Regional Chinldren Hospital, N.Novgorod, Russian Federation

Background: Nelarabine is a pro-drug of the deoxyguanosine analogue ara-G. Accumulation of ara-GTP in leukemic blasts allows for incorporation into deoxyribonucleic acid (DNA), leading to inhibition of DNA synthesis and cell death. It is indicated for patients with T-cell acute lymphoblastic leukemia (T-ALL) and T-cell lymphoblastic lymphoma whose disease has not responded to or has relapsed following treatment with at least two chemotherapy regimens. This use is based on the induction of complete responses by Nelarabine alone. We used Nelarabine in combination with other agents in treatment of children with refractory T-ALL.
Aims: To assess rational use of Nelarabine in children with T-ALL
Methods: In multicenter studies ALL-MB from 1991 to 2014 yy there were registered 506 pts with T-ALL, 81 of them (16%) didn't respond to induction therapy and were classified as high-risk group (HRG). There were no significant differences between responders and non-responders in terms of initial characteristics, except immunophenotype – significantly more patients with CD1a expression <25% were refractory (p,0,01). Nelarabine was used in 26 cases – for 21 patients (80,8%) as postinduction therapy and for 5 pts (19,2%) with early relapses as second-line treatment. For both groups we used two 5-days courses of Nelarabine 650mg/m^2, combined with Dexa, Cph, PEG-asp in the 1st block and with Dexa, VP-16 and Ara-C in second.
Results: Among high-risk patients 16 (76,2%) responded after one or two blocks. 13 of them were transplanted from MUD, MSD or haploidentical donor. Among 5 relapsed T-ALL patients nobody responded to therapy. We also compared those, who were treated by standard chemotherapy for HRG (12 pts) with those with Nelarabine. There was no difference in initial data, and also in remission achievement rate (47% *vs* 34%, p=0,2). Patients with T3-ALL responded significantly worse in Nelarabine group(p<0,0001). Severe reversible neuropathy was observed in 2 patients, who achieved remission.
Summary and Conclusions: Nelarabine didnt show an advantage over standard HR-blocks in our non-randomized study. But the groups were small, and we need further research to establish optimal dose regimen, possible drug combinations and reasons for refractoriness in T3-variant of ALL.

E877

DAUNORUBICIN INDUCED EARLY CARDIAC DYSFUNCTION IN ACUTE LYMPHOBLASTIC LEUKEMIA - A PROSPECTIVE STUDY

M. Aggarwal[1,*] P. Mishra[1], A. Saxena[2], S. Gupta[2], S. Tyagi[1], S. Venkatesan[1]

[1]Hematology, [2]Cardiology, All India Institute Of Medical Sciences, New Delhi, India, New Delhi, India

Background: Anthracyclines are effective agents used in the treatment of hematological malignancies and form important part of induction chemotherapy in Acute Lymphoblastic leukemia (ALL). However, they cause progressive chronic cardiotoxicity resulting in heart failure and acute toxicity manifesting as arrhythmia and diastolic dysfunction. This is due to irreversible cardiac myocyte damage caused by topoisomerase II inhibition and iron free radical induced DNA damage. The early detection of cardiotoxicity is important as it may be useful in the prevention of heart failure. Left ventricular ejection fraction (LVEF) has been the main indicator of cardiac dysfunction and a powerful predictor of mortality. However, impairment in LVEF is often detected only after considerable myocyte loss has taken place. However, Doppler parameters and tissue Doppler parameters can detect early cardiac changes and may help predict later overt LVEF decline.
Aims: To study the acute cardiac toxicity of anthracycline infusion in ALL patients by serial echocardiographic parameters during induction chemotherapy.
Methods: The study was conducted on newly diagnosed acute lymphoblastic leukemia without any history of previous anthracycline exposure for any reason. Patients were treated as per Augmented BFM protocol and during induction, they were administered daunorubicin 25 mg/m^2/week for 4 weeks, vincristine 1.4 mg/m^2/week for 4 weeks, Prednisone 60 mg/m^2/day for 28 days and L- asparaginase 6000 U/m^2 on alternate day for 9 doses. Echocardiography was done in all the patients before start of chemotherapy (baseline) and at end of induction chemotherapy (post). One more echo was done after 2 weekly doses of anthracycline (mid echo). Various parameters on 2D mode, Doppler and tissue Doppler were recorded and ejection fraction and myocardial performance index calculated.
Results: A total of 20 patients of acute leukemia were enrolled in the study. Median age was 16.5 year (4-42 year), with 17 males (85%). Baseline leucocyte count was 6910/ul (range: 600-788,250), with 3 patients having high risk cytogenetics and two having CNS 3 status. Changes in echocardiographic parameters occurring during baseline, mid chemotherapy and post chemotherapy are shown in table. 2 D Parameters: LVIDes/BSA showed a decreasing trend from baseline to mid echo (p value 0.07). It returned to near baseline value in post echo. LA dimensions, IVS thickness was not significantly altered at any point of time as was the case with LVPW. Doppler Parameters: E velocity was showing overall significant changes in ALL patients (p value 0.031). A velocity showed trends towards overall changes during induction (p value 0.07), attaining significant difference in mid and post echo (p value 0.048). E/A ratio showed statistical significant difference in post chemotherapy echo (p value 0.049). Deceleration time showed a non significant dip after chemotherapy cycle and reverted back to some extent in ALL patients. Tissue Doppler Parameters: Sm lateral was insignificant during chemotherapy. Sm septal showed a significant dip from baseline to mid echo (p value 0.02). Em lateral had significant decrease (p value 0.045). Em septal had non-significant decreasing trend (p value 0.08). Am septal and lateral showed non- significant changes. Iso-volumetric relaxation and contraction time did not show significant variation during chemotherapy at any time. Left ventricular ejection fraction did not show significant changes. Myocardial performance index was also almost unchanged during induction.

Tabella 1. Changes in echocardiographic parameters during ALL induction.

Parameter	Baseline (B) Mean ± SD (n=20)	Mid chemo(M) Mean ± SD (n=18)	Post chemo(P) Mean ± SD (n=17)	P value B vs M	B vs P	M vs P
LVIDes /BSA(mm)	2.1±0.4	1.9±0.3	2.1±0.5	0.07	0.4	0.2
LVIDed /BSA(mm)	3.3±0.7	3.0±0.5	3.2±0.6	0.1	0.4	0.2
LA (cm)	2.7±0.5	2.8±0.5	2.8±0.4	0.9	0.9	0.9
Aorta (cm)	2.3±0.6	2.4±0.5	2.5±0.6	0.9	0.1	0.4
IVS (cm)	0.8±0.1	0.8±0.1	0.8±0.1	0.8	0.9	0.5
LVPW (cm)	0.8±0.1	0.8±0.1	0.8±0.1	0.9	0.9	0.2
E vel (cm/s)	94.0±23.0	82.0±17.7	84.0±18.7	0.09	0.2	0.9
A vel (cm/s)	52.0±14.3	49.5±12.2	60.8±18.9	0.5	0.8	0.048
E/A	1.9±0.7	1.7±0.4	1.5±0.4	0.9	0.2	0.3
Deceleration time (msec)	175.1±66.0	146.8±38.1	156.5±35.9	0.2	0.8	0.9
Sm(lateral) (cm/s)	10.1±1.8	10.3±1.9	10.0±2.2	0.9	0.9	0.9
Sm (septal) (cm/s)	9.3±1.9	8.3±1.4	8.7±1.7	0.02	0.4	0.9
Em(lateral) (cm/s)	15.4±3.4	14.1±3.8	13.9±3.7	0.2	0.09	0.9
Em(septal) (cm/s)	11.3±2.6	10.1±1.6	10.1±2.6	0.2	0.3	0.9
Isovolumetric contraction time(msec)	60.1±17.9	55.9±10.6	51.4±10.0	0.9	0.3	0.6
Isovolumetric relaxation time(msec)	68.4±15.0	70.2±15.8	64.1±15.9	0.9	0.9	0.3
Am(latera) (cm/s)	7.6±2.1	7.6±2.6	8.7±1.6	0.9	0.6	0.8
Am(septal) (cm/s)	7.9±2.6	8.5±2.7	9.0±1.8	0.9	0.7	0.9
Ejection time(msec)	267.8±36.6	252.9±34.7	249.3±33.7	0.8	0.2	0.9
LVEF (%)	60.3±15.9	58.9±16.8	60.4±16.5	0.5	0.9	0.9
MPI	0.49±0.1	0.48±0.1	0.48±0.08	0.9	0.9	0.9

Summary and Conclusions: Daunorubicin induced early cardiac toxicity causes predominantly diastolic dysfunction, as is reflected by changes in various Doppler and tissue Doppler indices. Systolic function of the heart as assessed by LVEF is relatively preserved. Myocardial performance index (Tei index), proposed as sensitive indicator of cardiac dysfunction, does not change either during induction. These changes in echo parameters remain sub- clinical during induction. Patients with changes in echocardiographic parameters need to be followed up with repeated echo to find improvement or worsening of these changes and their relation to clinical symptoms due to heart failure.

E878

APPLICATION OF SYSTEMS PHARMACOLOGY MODELING FOR EVALUATION OF THERAPIES EFFECT ON BLAST DYNAMICS IN ACUTE LYMPHOBLASTIC LEUKEMIA

A. Nikitich[1,*] O. Demin Jr[1]
[1]Institute for Systems Biology Moscow, Moscow, Russian Federation

Background: Acute lymphoblastic leukemia (ALL) is an acute form of cancer of the white blood cells, characterized by the overproduction of cancerous, immature white blood cells. ALL is most common in childhood with a peak incidence at 2–5 years of age, and another peak in old age. About 80% of ALL patients will have complete remission, but the question about the most effective therapy remains open.
Aims: The aim of this work is to reproduce dynamics of ALL progression and compare efficacy of several clinically accepted and potential treatments.
Methods: Systems pharmacology model of ALL progression and treatment was developed. The model is a system of ordinary differential equations. It includes description of B-lymphoblasts proliferation and distribution between cell cycle phases with and without treatment, B-lymphoblasts and other blood cells dynamics during ALL progression, pharmacokinetics of several compounds (vorinostat, sorafenib) and its effect on B-lymphoblasts dynamics in ALL patients. Parameters of the model were calculated on the basis of the literature data or fitted against published experimental data. Treatment was simulated for two types of virtual patients: with slow and high rate of disease progression.
Results: Model satisfactory reproduces *in vitro* data on B-lymphoblasts cell lines proliferation and distribution between cell cycle phases with and without drug treatment and *in vivo* blasts levels in blood measured during ALL progression. The model was validated against blast dynamics during treatment with sorafenib. Model shows that for virtual patients with slow ALL progression vorinostat is more effective than sorafenib. For virtual patient with fast ALL progression both compounds are ineffective.

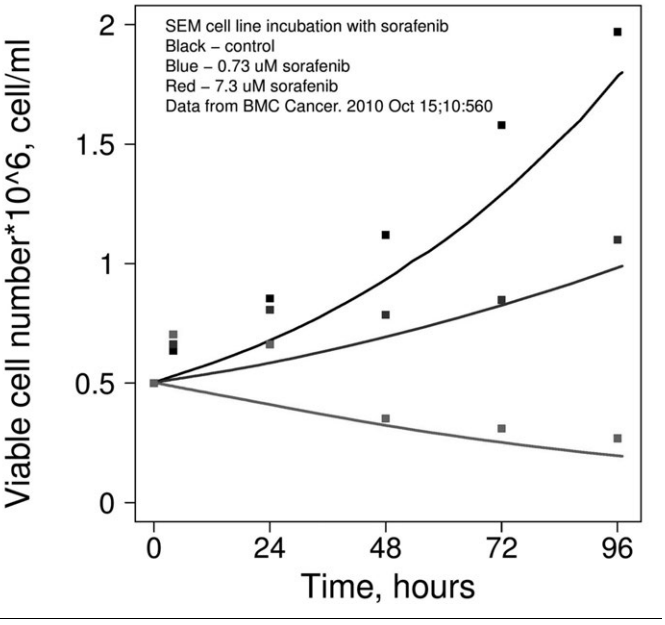

Figure 1.

Summary and Conclusions: Model predicts that slow progression rate patients have better respond to the therapy. Systems pharmacology model of ALL progression and treatment could be used as a tool to compare different clinically accepted and potential treatments.

E879

LACK OF PROGNOSTIC IMPACT OF ABERRANT MYELOID ANTIGEN EXPRESSION IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

M. Alpoim[1,*] G. Brás[1], R. Pinto[1], A. Carneiro[1], F. Príncipe[1], J.E. Guimarães[1]
[1]Serviço de Hematologia Clínica, Centro Hospitalar de São João, Porto, Portugal

Background: A subset of adult acute lymphoblastic leukemia (ALL) patients have blast cells which coexpress myeloidassociated markers. The expression

of aberrant myeloid antigen (MyAg) in ALL differs considerably in independent studies and its prognostic value is still controversial.
Aims: To analyze the incidence of MyAg in a group of adult ALL and its correlation with clinical features, prognostic factors and outcome.
Methods: We retrospectively analyzed the expression of MyAg CD13 and/or CD33 of 79 adult patients with *de novo* ALL in a single center, between 2006 and 2014.
Results: The median age at diagnosis was 44 years [17-70]. The median white blood count (WBC) was 9.6 x10^9/L [0.2-254] and 24 (30.4%) patients had high WBC (>30x10^9/L in B-ALL and >100x10^9/L in T-ALL). Physical examination revealed hepatomegaly in 30 (38%) and splenomegaly in 27 (34.2%) patients. The central nervous system (SNC) was involved in 9 (11.4%) and 31 (39.2%) had serum lactate dehydrogenase (LDH) >4xULN. Sixty-nine (87.3%) patients had a B-lineage ALL (common-B ALL 63.8%, pre-B ALL 29%, pro-B ALL 7.2%), while only 10 (12.7%) patients had T-lineage ALL (Thymic ALL 60%, mature-T ALL 40%). MyAg expression (CD13 and/or CD33) was documented in 25 (31.6%) patients. No differences were found between the MyAg +and MyAg- groups with regard to median age, median WBC, high WBC, high LDH (>4xULN), hepatomegaly and/or splenomegaly or involvement of SNC at diagnosis. MyAg expression was only found in B-ALL and none of the 10 cases of T-ALL showed aberrant phenotype (31.6% vs. 0%; p=0.017). According to immunophenotypic subtype B, no difference was observed (p=0.275). Karyotype was evaluated in 71 of 79 patients and 34 (47.9%) had an unfavorable karyotype: t(9,22) in 32 (45.1%) patients, t(4,11) in 1 (1,4%) and hypodiploidy in 1 (1.6%) patient. Fifty-one (64.6%) patients fulfilled criteria for High Risk (HR) group, while the remaining 28 (35.4%) were classified as Standard Risk (SR) group. In B-lineage ALL, the MyAg+group was more frequently associated with unfavorable karyotype (47.1% *vs* 25%; p= 0.074) and with HR group (41.3% *vs* 26.1%; p=0.215) but these differences were not statistically significant. Patients were treated with the Hyper-CVAD protocol or HOVON 100 ALL/EORTC 06083 protocol (nonexperimental arm). Seventy-seven (97.5%) patients achieved complete remission (CR) after induction therapy. The two patients with resistant disease had MyAg+expression but this difference was not statistically significant (p=0.097). The 5-year overall survival rates for MyAg+group *vs* MyAg- group were 26.7% *vs* 39.7%, respectively, but again, the difference was not statistically significant (p=0.555). The 5-year disease free survival (DFS) rates were 29.5% for MyAg+group and 43.5% for MyAg- group, difference not significant (p=0.567). We separately analyzed B-lineage ALL cases and we found no differences in DFS (p=0.460) and OS (p=0.464) between MyAg+and MyAg- cases. Additionally when cases with unfavorable karyotype were analyzed as a separate group, we failed to observe any statistical difference between the two groups in terms of DFS (p=0.978) and OS (p=0.888). Again, when the HR group was evaluated as a separate group, no differences were recorded between the two groups (DFS p=0.587; OS p=0.583).
Summary and Conclusions: In our study we have found that there was no prognostic impact of aberrant myeloid antigen expression in adult acute lymphoblastic leukemia. However, the evaluation of the expression of these antigens remains valuable, as for example, in the monitoring of minimal residual disease.

E880

OUTCOME OF OLDER ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH HYPERCVAD

J. Schuh[1,*] N. Almeida[1], L. Monteiro[1], S. Leocádio[1], R. Gerivaz[1], A. Tomé[1], M. Fevereiro[1], F. Costa[1], J. Caldas[1], A. Botelho de Sousa[1]
[1]Serviço de Hematologia, Hospital dos Capuchos, Lisboa, Portugal

Background: Older patients with acute lymphoblastic leukemia (ALL) have a poorer outcome. Due to assumptions about a higher risk of complications and toxic death, they are often denied potentially curative treatment approaches.
Aims: To address the impact of known prognostic factors in older fit patients offered intensive chemotherapy, we retrospectively analyzed the outcome of patients ≥55 years of age who received HyperCVAD as a first-line treatment.
Methods: We compared the outcome of 35 consecutive older patients (age 55-69) who were treated in our center from January 2003 to December 2013, and of the 96 younger patients (age 15-54) treated in the same period with the same regimen. We evaluated the complete remission (CR) rate, the disease-free survival (DFS) and the overall survival (OS) of these 2 groups, and we analyzed the influence of age, performance status, immunophenotype, leukocyte count at diagnosis (≤ or >50000/uL), presence of hyperleukocytosis (defined as >30000/uL for B and >100000/uL for T subtypes) and unfavorable cytogenetics (*BCR-ABL1* or *MLL* rearrangements).
Results: Disease characteristics were similar in older and younger patients (*BCR-ABL1* being non-significantly more frequent in the former, 32% *vs* 20%). The CR rate was lower in older patients (82% *vs* 90%). At a median follow-up of 60 months (m), DFS was worse in older patients (7,8m *vs* 32,8m), as was OS (9,8m *vs* 36,4m, p<0,01). In older patients, a T phenotype had a strong negative impact on OS (1,8m *vs* 17m, p<0,05). In multivariate analysis, the 2 independent prognostic parameters for OS were a T phenotype (Hazard Ratio 2,1) and older age (Hazard Ratio 2,25).

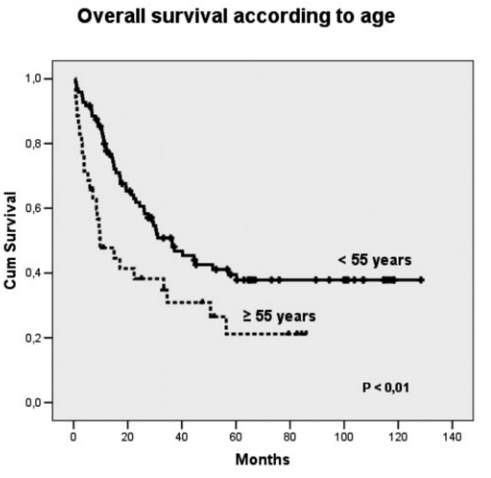

Figure 1.

Summary and Conclusions: Older patients easily achieve CR, but CR duration and OS remain highly unsatisfying (in particular for T-ALL) even with an intensive regimen such as HyperCVAD, underscoring the need for novel strategies.

Background: Retinoic acid (RA), a metabolite of Vitamin A (retinol), is a known regulator of cell growth and differentiation, inducing expression of multiple genes such as retinoic acid receptor responder 1 (RARRES1/TIG1). RARRES1, and its associated binding partners such as AXL kinase, have been shown to promote tumor growth and drug resistance in multiple tumor types. RA has been used as a single-agent treatment in patients with acute promyelocytic leukemia (APL) with roughly 90% of patients attaining a complete remission. However, remissions can be transient and resistance arises within a few months following treatment. This resistance is thought to develop through increased RA metabolism through upregulation of CYP26, a cytochrome P450 enzyme that plays a key role in the metabolism of RA.
Aims: We have sought to understand the role of AXL inhibition as a means of restoring sensitivity to RA treatment. We hypothesize that treatment with our AXL inhibitor, TP-0903, would disrupt RA metabolism by CYP26.
Methods: RT-PCR was used to measure mRNA expression of CYP26 in cells induced with RA and treated with TP-0903. Following treatment, changes in CYP26 expression was assessed at the protein level, using standard western blotting techniques. Endogenous RA levels were measured using a competitive ELISA technique. To determine the effect of TP-0903 on tumor growth in an *in vivo* model, we tested TP-0903 treatment in a MV4-11 xenograft mouse model.
Results: Consistent with prior reports, we observe a robust induction in mRNA expression levels of CYP26 following 1 mM RA treatment in MV4-11 leukemia cells, reaching nearly 4.3-fold after 6 hours of treatment. However, treatment of cells with TP-0903 at levels as low as 100 nM inhibited RA-mediated induction of CYP26 mRNA levels by 88.9% in MV4-11 cells at 6 hours. Interestingly, TP-0903 also inhibited basal mRNA levels of CYP26 by 94.1% at 6 hours. Similar trends are observed in additional cell lines (HL60, A549, and H1650), and with an alternative AXL inhibitor, R428, although only at higher concentrations. At time points greater than 24 hours, and without re-treatment with TP-0903, CYP26 expression exceeded levels observed in induced samples. In TP-0903-treated cells, we observed that RA levels are maintained at time points where CYP26 expression is suppressed. TP-0903 strongly inhibited tumor volumes by up to 100% at multiple dose levels and treatment schedules. Analysis of CYP26 expression in fixed tissues, and RA levels in plasma will be assessed to determine the effects of TP-0903 on physiological levels of CYP26 and RA.
Summary and Conclusions: Our observations support our hypothesis that inhibition of AXL kinase by TP-0903 disrupts RA metabolism by suppressing CYP26. Taken together, our data suggest that AXL may serve as a suitable therapeutic target for addressing cellular responses mediating RA resistance.

AN EFFICIENT COMPUTATIONAL APPROACH TO EVALUATE THE EXPRESSION PROFILE OF INDIVIDUAL ACUTE LEUKEMIA PATIENTS

M.C. Hansen[1,*] C.G. Nyvold[1], T. Haferlach[2], M.O. Henriksen[1,3], A.S. Roug[1], P. Hokland[1]
[1]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark, [2]MLL Munich Leukemia Laboratory, Munich, Germany, [3]Department of Hematology, Aalborg University Hospital, Aalborg, Denmark

Background: Microarray and sequencing studies have been instrumental in the mapping of genome wide associations in hematological diseases. Thus, the MILE Study (Haferlach *et al*, J Clin Oncol 2010) has taught us that it is possible to robustly classify and predict leukemia subgroups. However, several factors have impeded the general use of such data and methods in the everyday clinical setting: *(i)* technical expertise may not be available and, *(ii)* inter-study variations have hampered direct comparison of results between centers. As a consequence, *(iii)* the practical implications of analyzing single patient samples have to some extent been overlooked. Tools, which enable *the singular patient omics* to be addressed in a clinically relevant fashion, are thus much needed. We hypothesized that combining data from MILE Study and data mining at the single patient level by novel scripts could delineate the unique expression signature.
Aims: *(1)* To develop an algorithm for implementing results from large profiling studies (microarray or RNA-seq) without the need for normalization between sample sets *(2)* to predict leukemia subtype of single samples in a timely fashion, thus *(3)* enabling informative exploration within the private expression profile of genes of interest.
Methods: We accessed the MILE Study data (2096 samples from Stage I study), to generate a single compressed dataset for individual leukemia prediction of 21 separately run samples (Aarhus, DK) derived from microarray analysis (HG-U133A arrays, Affymetrix Inc., CA, USA) of bone marrow aspirates (Figure 1A). This resulted in a reference matrix, which covered 2181 predictor genes in total and 15 leukemia subtypes, denoting genes as upregulated, unaltered or downregulated (discrete values of 1, 0, -1), evaluated via the Leukemia Gene Atlas (Hebestreit *et al*, PLoS One 2012). The patient samples were comprised of three clinically defined subtypes (6 AML inv(16), 8 t(8;21) and 7 ALL t(12;21)). The evaluation of individual molecular subtypes was subsequently performed by entry-wise matrix multiplication followed by scoring. Data mining was performed by coupling external sources and results, utilizing Wolfram Mathematica as computational platform (Hansen *et al*, Br J Haematol 2015, in press).
Results: Prediction of leukemia subtype matched clinical diagnoses in all cases (21/21). Consecutive data mining enabled us to evaluate and emphasize individual expression patterns, which were otherwise masked by attempts to draw parallels between samples. Setting an arbitrary threshold of *e.g. eightfold* expression difference, the *common* gene set for each subgroups was low compared to the total number of genes observed (Figure 1B). In contrast, evaluating combinations of samples in each subtype showed a higher number of common differentially expressed genes in-between patients. At the individual level a substantial part of the genes with increased or decreased expression was leukemia associated (median values of 17–62 in sets of 74–230 genes, evaluated through DisGeNET database, Bauer-Mehren *et al*, PLoS One 2011). Of these sets each genes was found to have two or more MeSH term associated references in the PubMed database (within the three clinically defined subtypes: $^{74}/_{138}$, $^{97}/_{178}$, $^{181}/_{376}$). It was also observed that the vast majority of biological gene functions matched potentially malignant functions, *i.e.* cell cycle, migration, defense response and signal transduction.

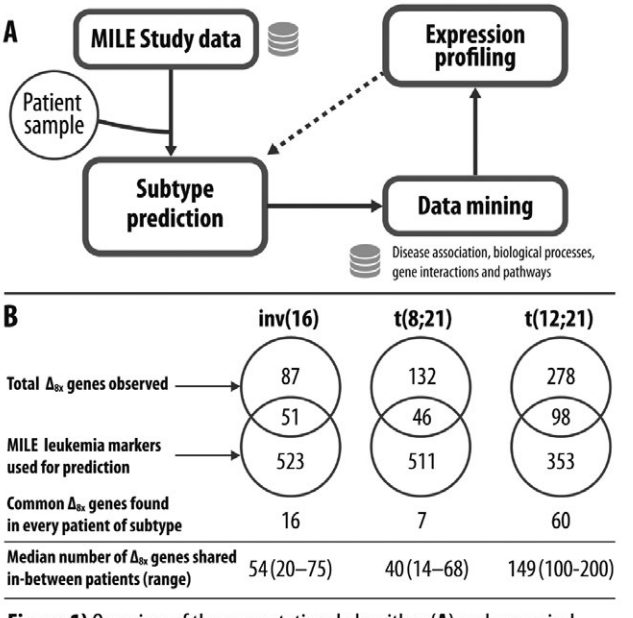

Figure 1) Overview of the computational algorithm (**A**) and numerical evaluation of the 8-fold differentially expressed genes (Δ_{8x}) shared in subtypes and with MILE Study markers (**B**) and a low number of common genes

Figure 1.

Summary and Conclusions: We have recently described how genomic analysis on the single patient level can be utilized in the setting of exome sequenced samples (Hansen *et al*, Br J Haematol 2015, in press). Here we show that this data mining approach can also be utilized for expression profiling of single patients. Hopefully, with shortened lab turn-over time for *omic* studies, the present approach, which involves minimal computational effort, taken together with standard molecular screening in acute leukemia patients, should result in speedy information flow from research to the clinic with much more detailed characterization of the single patient. Ultimately, this should in turn enable more focused personalized medicine.

E883

MOLECULAR CORRELATES AND DRUG RE-PURPOSING SCREENING IN HYPOMETHYLATING AGENT FAILURE IN AML AND MDS

R. Tibes[1,*] J. Bogenberger[1], R. Hlady A.[2], M.D. Champion[3], L. Padrnos[1], J. Petite[3], J. Foran[4], A. Al-Kali, [2]T. Ho[1], M. Patnaik[2], K.D. Robertson[2], N. Meurice[3]
[1]Hematology and Medical Oncology, Mayo Clinic, Scottsdale, [2]Mayo Clinic, Rochester, [3]Mayo Clinic, Scottsdale, [4]Mayo Clinic, Jacksonville, United States

Background: After initial response to the hypomethylating agents (HMA)/DNMT inhibitors 5-Azacitidine (AZA) and Decitabine, ultimately all patients with Myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) progress/fail treatment. Subsequent therapies and outcomes are dismal. Developing novel therapeutic approaches in HMA failure MDS and AML patients is one of the largest clinical needs in this field.
Aims: The mechanisms of HMA failure are still poorly understood and effective novel regimens are lacking. To address these deficiencies, we pursued several approaches in parallel including extensive genomic characterization of AZA resistant cells as well as *in vitro* drug re-purposing screens of FDA approved small molecule libraries with the goal to define the molecular landscape and novel therapeutic targets in HMA failure MDS/AML, as well as to identify novel drugs that could be immediately translated into clinical use.
Methods: Over a 2-year period AZA resistant (RES) cell lines (TF-1, HEL) were generated including non-clonal (NC, requiring continuous AZA exposure) and clonal (C) sub-lines with 20-50 fold AZA resistance. Lines were extensively profiled by various next generation assays including exome sequencing, RNA-seq, Illumina 450K methylome and miRNA arrays; to identify differences in molecular changes in resistant vs. parental (PAR) cells mimicking clinical scenarios cells were either AZA treated or left untreated prior to performing assays. A 1,489 RNAi gene silencing screen for molecular vulnerabilities is available as well. A ~ 2,216 drug library (*i.e.* Prestwick, Mayo customized selected approved drugs) was run on RES and PAR cells. Lastly, we performed targeted sequencing and RNA-seq in HMA failure MDS/AML patients to assess clonal evolution and correlate findings with *in vitro* models.
Results: In RES cells no actionable new mutation were identified by exome sequencing. RNA-seq showed several genes and regulators of the MAPK and specifically RAS pathway activated in RES cells. Methylation analysis showed shared genes with loss of methylation following AZA in PAR and RES cells. Further, genes with methylation changes only in RES or PAR cells as well as genes that were unmethylated at baseline in RES vs. PAR cells but became methylated following AZA treatment, indicate a loss of response to epigenetic regulation upon chronic HMA exposure. These genes represent novel genomic therapeutic vulnerabilities and depict resistance mechanism. From the 2,216 compound screen, only 4 compounds were overlapping in >3 of 6 cell lines, these 4 drugs are formally being validated now including primary HAM resistant patient samples. In parallel we tested putative HMA/DNMT inhibitors based on structural bioinformatics knowledge mining in the HMA resistance context. Several drugs, including known drug entities such as antihypertensives, showed similar activity in sensitive and resistant lines. Lastly, we have generated a mutational landscape of HMA resistant clinical samples (Foundation Medicine Heme Panel) and RNA-seq has been performed.
Summary and Conclusions: At the meeting our efforts and data will be presented to give an overview of our translational research platform and our approach at HMA failure. We present and highlight results and data of our combined integrated platforms of elucidating molecular mechanisms of HMA resistance while providing drugs and therapeutic avenues for MDS and AML patients who have failed AZA or Decitabine.

E884

ABSOLUTE QUANTIFICATION OF EVI1 OVEREXPRESSION IN ACUTE MYELOID LEUKEMIA BY RQ-PCR ANALYSIS: A STUDY OF THE ALFA GROUP

T. Smol[1,*] A. Renneville[1], O. Nibourel[1], A. Marceau-Renaut[1], K. Celli-Lebras[2], C. Berthon[3], B. Quesnel[3], N. Boissel[4], C. Terré[5], X. Thomas[6], S. Castaigne[7], H. Dombret[4], C. Preudhomme[1]
[1]Hematology Laboratory, Biology and Pathology Center, Lille University Hospital, Lille, [2]ALFA Coordination, Saint-Louis Hospital, Paris, [3]Hematology Department, Lille University Hospital, Lille, [4]Hematology Department, Saint-Louis Hospital, Paris, [5]Cytogenetic Laboratory, Versailles Hospital, Le Chesnay, [6]Hematology Department, Edouard Herriot Hospital, Lyon, [7]Hematology Department, Versailles Hospital, Le Chesnay, France

Background: The *Ecotropic viral integration site 1* (*EVI1*) gene is located on chromosome band 3q26.2, and is composed of 16 exons. At diagnosis, *EVI1* overexpression has been implicated in approximately 8% of patients harboring acute myeloid leukemia (AML) and confers a poor prognosis. It is often associated with adverse cytogenetic abnormalities, but can be found in normal karyotypes. Quantification of *EVI1* expression is complex due to its various splice variants and its 5 alternative mRNA 5'-ends. *EVI1* mRNA expression has been mainly assessed by real-time quantitative PCR (RQ-PCR) using the housekeeping genes *Abelson* (*ABL*) and the ΔCt method. The technique currently used in our laboratory is based on the relative quantification of the *EVI1-1D* alternative splice form. Although this assay provides good results at AML diagnosis, it is not powerful enough to monitor MRD.
Aims: In the present study, we developed a RQ-PCR assay to perform the absolute quantification of *EVI1* expression covering the different *EVI1* splice variants. This assay was applied in control samples to define threshold values in normal bone marrow (BM) and peripheral blood (PB), and in AML diagnostic and follow-up samples.
Methods: This study focuses on 64 patients with *EVI1* overexpression included in the ALFA-0701 and ALFA-0702 trials. BM and PB samples were collected at AML diagnosis (n=67) and during follow-up (n=152). Using relative quantification, *EVI1* was considered as overexpressed at AML diagnosis if the ΔCt value between *EVI1* and the housekeeping gene *ABL* was less than 10. Reference values of normalized *EVI1* levels in normal PB and BM were established by analyzing a total of 31 PB and 17 BM samples collected from healthy volunteers. To achieve absolute quantification, we cloned a sequence of *EVI1* localized on exons 14 and 15, framing primers and TaqMan probe previously described by Gröschel *et al.* The sequence was integrated into plasmids that were used to determine the standard curve for the RQ-PCR. In parallel, the expression of the housekeeping gene *ABL* was evaluated by RQ-PCR for each sample. The results were expressed as a percentage of *EVI1* copies by *ABL* copies.
Results: The median value of *EVI1* expression in normal PB samples was 0.11% (range, 0.01 to 0.49%) and was 0.36% (0.01 to 0.96%) in normal BM samples. The overexpression threshold was set at 0.5% for PB and at 1% for BM. At diagnosis, we confirmed *EVI1* overexpression for 62 samples out of 67 selected samples. We observed a good correlation between absolute and relative quantification, only 5 PB samples considered as low positive in relative quantification were discordant. The median *EVI1* expression was 23.3% (4.1 to 614.1%) in BM and 3.6% (0.53 to 80.7%) in PB samples. Patients with unfavorable cytogenetics (n= 42) had a significantly higher *EVI1* expression level compared to patients with intermediate cytogenetics (n= 20) (*P=.004*), with an average *EVI1* expression of 43.1% *versus* 6.8%, respectively. The highest *EVI1* overexpression was found in the AML subgroup with *MLL* rearrangement (n= 11), with an average *EVI1* expression of 91.4% *versus* 18.3% in the absence of *MLL* rearrangement (*P=.006*). MRD monitoring by *EVI1* mRNA level quantification was performed in diagnostic and follow-up samples from 48 patients. *EVI1* expression in BM varied from 21.6% in diagnostic samples to 3.56% in post-induction samples. *EVI1* expression in PB varied from 4.0% at diagnosis to 0.22% in post-induction. Although reduction was significant (*P <.001*), it remained insufficient for MRD follow-up on this parameter. Finally, among the 44 patients who achieved CR1, we observed a trend of higher *EVI1* expression in relapse group with an average expression of 163.1% in BM (n=6) and 11.5% in PB (n=12) against 26.8% in BM (n=12) and 4.4% in PB (n=15) in relapse free group (*P=0.1*).
Summary and Conclusions: We developed a model of absolute quantification of *EVI1* expression correlating with routine relative quantification. Nevertheless, the basal expression of *EVI1* is high and variations are weak between diagnosis and follow-up. However at diagnosis, we observed higher expression in patients with *MLL* rearrangements, and thus, a trend of higher *EVI1* expression in patients who relapsed after having achieved CR1.

E885

THE D816V C-KIT MUTATION HAS HIGHER ABILITY OF JAK-STAT AND SRC FAMILY KINASE THAN N822K C-KIT MUTATION, AND THEREFORE PROLIFERATION ACTIVITY IS HIGH IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA

I. Omori[1,*] H. Yamaguchi[1], T. Kitano[1], N. Miyake[2], K. Miyake[2], D. Kazuo[3], K. Inokuchi[1]
[1]Hematology, [2]Biochemistry and Molecular Biology, Division of Gene Therapy Research Center for Advanced Medical Technology, Nippon Medical School, Tokyo, [3]Medical Education Center, Ryotokuji University, Urayasu, Japan

Background: Acute myeloid leukemia (AML) with the t(8;21) or inv(16)/t(16;16) is defined as core-binding factor AML (CBF-AML) and has been considered an AML group with favorable prognosis. In recent years, it has been reported that CBF-AML with *c-kit* mutations show poor prognosis. Among these mutations, D816V in exon 17 is the most frequent mutation in CBF-AML and confers higher tumor growth and anti-apoptotic potential compared to other mutations of exon 8, 10 and 11. Interestingly N822K in exon 17 is reported at frequency similar to D816V mutation in Asia. Our previous report (Leukemia. 2011;25(9):1423) suggested the possibility that the prognosis of CBF-AML with the N822K mutation was different from D816V and that D816V and N822K may differ functionally even if this mutation is also in the same A-loop.
Aims: The aim of this study is to clarify a difference of the molecular biologic function for leukemogenesis between D816V and N822K.
Methods: To analyze the molecular function of D816V and N822K, we generated amphotropic retroviral vector expressing *c-kit* (wild type, D816V, and N822K). After transduction with human Interleukin 3 (IL-3) dependent TF-1 cells, we established *c-kit* expressed TF-1 cells (TF-1^{WT},TF-1^{D816V}, and TF-1^{N822K}). In these three cells, we analyzed the proliferation rate by cell growth assay and the erythropoietin (EPO)-related induction of differentiation by fluorescence activated cell sorting. We also analyzed the signal pathways by Western blotting, and examined responsiveness to protein kinase (PTK) inhibitors which were Imatinib, Dasatinib, and CP690550 (JAK inhibitor).
Results: Cell growth assay showed IL-3 independent proliferation in TF-1^{D816V} and TF-1^{N822K} but not TF-1^{WT}. The proliferation rate of TF-1^{D816V} was significantly higher than that of TF-1^{N822K} (18610±6269 cells *vs* 4354±1109 cells in day 10, p=0.026). The erythroid differentiation assay showed TF-1^{D816V} inhibited differentiation to erythroblast as compared with TF-1^{N822K} and TF-1^{WT} with or without EPO. (The rates of $CD71^{+}CD235a^{+}$cells 72 hours after EPO addition:

TF-1^{D816V} 22.1%, TF-1^{N822K} 84.6%, TF-1^{WT} 82.8%) Subsequently, we investigated the difference of signal pathway for cell proliferation by Western blotting. Under the condition starved from IL-3, the same levels of constitutive phosphorylation of c-kit protein were observed in the TF-1^{D816V} and TF-1^{N822K}, but the TF-1^{WT} hardly induced phosphorylation of it. We investigated about the downstream of phosphorylated c-kit protein in the TF-1^{D816V} and TF-1^{N822K}. We observed a strong phosphorylation of STAT3 and Src proteins in the TF-1^{D816V}, but phosphorylation of ERK protein in the TF-1^{N822K}. Finally, we examined responsiveness to PTK inhibitors. Imatinib could inhibit cell proliferation of TF-1^{N822K}, but not inhibit it of TF-1^{D816V}. In contrast, Dastinib could inhibit cell proliferation of both TF-1^{N822K} and TF-1^{D816V}. We could demonstrate these findings by Western blotting that half maximal inhibitory concentration (IC50) of Dasatinib more strongly inhibited phosphorylation of c-kit and Src proteins as compared with Imatinib in the TF-1^{D816V}. CP690550 could also inhibit cell proliferation of both TF-1^{N822K} and TF-1^{D816V}. We could also demonstrate these findings by Western blotting that IC50 of CP690550 inhibited phosphorylation of STAT3.

Summary and Conclusions: We conclude that the D816V *c-kit* mutation confers higher proliferation activity by JAK-STAT and Src family kinase compared to N822K *c-kit* mutation. These findings suggest that biological functions of *c-kit* mutations differ depending on the mutation site, which may affect responsiveness to treatments.

E886

FREQUENCY AND PROGNOSTIC RELEVANCE OF HTERT SPLICED VARIANTS IN AML

P. Bernasconi[1,*] B. Rocca[1], C. Calvello[1], C. Klersy[2], M. Boni[1], R. Zappatore[1], I. Dambruoso[1], P.M. Cavigliano[1], I. Giardini[1], M. Caresana[1], A. Orlando[1]
[1]Hematology, [2]Biometry Unit and Epidemiological Studies, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Telomeres shortening, a pro-apototic cellular event that occurs at every round of DNA replication is prevented by human telomerase. This last consists of two components, hTERT, a telomere specific reverse transcriptase that catalyzes the addition of telomeric repeats, and hTERC, the RNA component used as a template. Thus, telomerase activity mostly relies on hTERT which activity depends on the spliced variant produced by an alternative splicing process. This last can generate not only the full-length hTERT transcripts (+α+β), but also transcripts carrying α and/or β deletions (transdominant negative isoform -α+β, inactive products +α-β and -α-β). Recent data provided evidence that in AML hTERT over-expression may be associated with a poor clinical outcome, but up to now no study has examined the frequency and prognostic significance of spliced variant transcripts.

Aims: Our objectives were to estimate the frequency of hTERT isoforms in a series of de novo AML patients (pts) and to establish whether the expression of these isoforms varied between pts with a normal and a complex karyotype and had any influence on clinical outcome.

Methods: The one-hundred and nine de novo AML patients included in the present study came to our observation in the period January 2010 and January 2014. They were forty-three females and sixty-six males; their median age was 59 years (range 18-84). According to WHO classification 8 (7.3%) patients were classified as M0/M1, 51 (46.7%) as M2, 42 (38.5%) as M4, 7 (6.4%) as M5 and one as M6. Cytogenetic studies revealed a normal karyotype (NK) in sixty-two (56.8%) pts, whose median age was 56 years (range 24-84), and a complex chromosomal pattern (CK) with ≥3 defects in forty-seven (43.2%), whose median age was 60 years (range 33-84). The two patients groups were comparable by age. An internal tandem duplication (ITD) of the FLT3 gene and a NPM1 mutation were revealed in 15 and 2 chromosomally normal patients. No CK presented a FLT3 ITD. All patients received standard induction chemotherapy followed by two courses of consolidation treatment. At the time of the study 41 patients achieved a complete remission (CR) and 39 died. Median follow-up was 22.7 months (range: 13.5-60.2). hTERT isoforms expression was determined in bone marrow samples by real-time reverse transcriptase polymerase chain reaction, using SYBR Green I. hTERT transcript (+α+β) primers design was made using BLAST (http://www.ncbi.nlm.nih.gov/BLAST/), while for the other primers we referred to Capraro *et al.* 2011. Specific amplifications were confirmed by sequences analysis. In order, to estimate hTERT isoforms expression levels in normal mononuclear cells, twenty-three umbilical cord bloods (UCB) were examined (control group).

Results: At first, the expression of hTERT isoforms of NK pts was compared to that of CK pts by applying the Kruskal-Wallis rank test, but no significant difference was observed (P=0.39, P=0.77; +α+β, -α+β respectively). Instead, Cox univariate analysis revealed that independently from karyotype response to treatment was significantly better in pts presenting an over-expression of the trans-dominant negative isoform (-α+β) (P=0.03, HR=2.11; 95% CI:1,13-3,93). In addition, leukemia-free survival was significantly worse in pts who over-expressed inactive products (-α-β) (first group) than in those who presented a low expression of these same products (second group) (P=0,003, HR=3,26; 95% CI:1,33-7,96). Pts who over-expressed the full-length hTERT transcript (+α+β) and the trans-dominant negative isoform (-α+β) presented only a trend towards significance. Moreover, the first group of pts presented a worse overall survival (HR=1,66; 95% CI:0.94-2,91), whereas the second group a better overall survival (HR=0,58; 95% CI:0,33-1,02).

Summary and Conclusions: Thus, in our study the over-expression of the hTERT trans-dominant negative isoform identified low-risk AML pts, whereas the over-expression of the hTERT inactive product (-α-β) identified high-risk AML pts. Interestingly, this last isoform might control the expression of its trans-dominant negative isoform. In conclusion, our results suggest an intriguing link between the control of hTERT isoforms expression and AML outcome.

E887

COMPLEMENTARY DYNAMIC BH3 PROFILES PREDICT INDUCTION OF APOPTOSIS BY THE MULTI-KINASE INHIBITOR TG02 IN COMBINATION WITH THE BH3 MIMETIC ABT-199 IN AML CELLS

F. Burrows[1], M. Pallis[2,*] J. Ryan[3], C. Seedhouse[2], A. Abdul-Aziz[2], J. Montero[3], A. Letai[3], N. Russell[2]
[1]Oncology Biology, Tragara Pharma, Carlsbad, United States, [2]Department of Haematology, Nottingham University Hospitials, Nottingham, United Kingdom, [3]Department of Medicine, Dana-Farber Cancer Institute, Boston, United States

Background: The heterogeneity of MCL1 and BCL2 expression in primary AML samples, and likely even within individual patient isolates, suggests that it would be difficult to establish cut-off points that would enable the clinician to select patients for either MCL1 or BCL2-directed targeting, so the use of complementary agents may offer an ideal solution.TG02 is a novel CDK9-selective multi-kinase inhibitor that down-regulates RNA Polymerase II causing the depletion of the labile BCL2-family pro-survival protein MCL1, but not its stable paralogs BCL2 or BCLX_L. ABT-737 and ABT-199 are BH3 mimetics that inhibit BCL2.

Aims: We investigated whether ABT-737 and/or ABT-199 would co-operate with TG02 to kill AML cells, and we studied the mechanisms of their interactions.

Methods: Cytotoxicity was measured by alamar blue in AML lines and flow cytometry in patient samples. Apoptosis was determined using flow cytometric assays for Annexin V binding, and active epitopes of BAX, BAK and caspase 3. In dynamic BH3 profiling assays, cells were treated with TG02 or ABT-199 for 4 hours and probed with BH3 peptide mimetics for a further hour. Mitochondrial outer membrane permeabilisation was then determined by Cytochrome C release assays.

Results: In CD34+CD38- KG1-a cells, TG02 was strongly synergistic with ABT-737 or ABT-199 with combination indices as low as 0.13. In a cohort of 18 patient samples treated *in vitro*, 50 nM TG02 +50 nM ABT-199 or ABT-737 was significantly more toxic than 100 nM of each agent individually. Whereas the agents were synergistic in some samples, others showed enhanced apoptotic responses to TG02 but not to ABT-199/737 and vice versa. Normal CD34+cells from stem cell harvests were not sensitive. In AML cells all three agents exposed activation-specific epitopes of BAX, BAK and caspase 3. The sensitiser protein BAD binds to BCL2, which can then release the apoptosis-activator protein BIM, whereas the sensitiser NOXA releases BIM from MCL1. Following treatment of AML cells with TG02 or ABT-199, the resultant dynamic BH3 profiles were found to be complementary: both agents sensitised cells to BIM, TG02 sensitised to BCL2-targeting BAD and ABT-199 sensitised to MCL1-targeting NOXA. Drug priming altered patient cell BH3 peptide sensitivity in a manner that corresponded closely to the cells' *in vitro* demise.

Summary and Conclusions: We conclude that this combinatorial approach broadens the therapeutic potential of anti-survival signalling drugs in AML and that dynamic BH3 profiling is a sensitive methodology for investigating complementary mechanisms of chemoresponsiveness.

E888

COMBINED INHIBITION OF HEDGEHOG AND FLT3 SIGNALLING LEADS TO EFFECTIVE ANTI-LEUKEMIC EFFECTS IN ACUTE MYELOID LEUKEMIA

E. Latuske[1,*] H. Stamm[1], M. Klokow[1], G. Vohwinkel[1], M. Kebenko[1], C. Bokemeyer[1], M. Jücker[1], W. Fiedler[1], J. Wellbrock[1]
[1]Hematology and Oncology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: The interaction of leukemic stem cells with the bone marrow niche is dependent on stem cell activators implicated in normal stem cell biology including the Hedgehog pathway. Recently, we revealed that expression of the Hedgehog downstream transcription factors GLI1 and GLI2 represents a negative prognostic marker for patients with acute myeloid leukemia (AML) and that targeted inhibition of GLI1/2 mediates anti-leukemic effects *in vitro* and *in vivo*. Furthermore, the expression of GLI2 was correlated to the occurrence of FLT3 mutations in AML patients. Activating FLT3 mutations represent one of the most frequent aberrations in AML resulting in a constitutively activated downstream signalling including the PI3K cascade. In addition to the Hedgehog ligand-mediated, a non-canonical GLI activation via PI3K, TGF-β or Ras has been described. Therefore, we propose also FLT3 as a non-canonical inducer of GLI transcription in AML.

Aims: The aim of our study was to analyze the therapeutic potential of combined GLI and FLT3 signaling inhibition in AML.

Methods: FLT3 mutated AML cell lines MV4-11 and MOLM-13 as well as the non-mutated cell line OCI-AML5 were treated with combinations of the GLI inhibitor GANT61, the FLT3 inhibitor sunitinib or the PI3K inhibitor PF-04691502

and analyzed for cell proliferation. MV4-11 cells were also analyzed in colony formation and apoptosis induction assays. Specific shRNA knockdown of all targets have been performed to confirm the results.
Results: In proliferation assays, single agent treatment with sunitinib, PF-04691502 or GANT61 was significantly less effective than double and especially triple combinations. Growth inhibition of FLT3-mutated MV4-11 and MOLM-13 cells occurred at lower concentrations compared to non-mutated OCI-AML5 underlining the potential role of a non-canonical activation of GLI via FLT3-PI3K. Investigating the induction of apoptosis in MV4-11 cells, combinations of two inhibitors were more effective compared to the single agent treatments while the triple combination of GANT61, sunitinib and PF-04691502 induced the highest apoptosis rate after 48h. Similar effects were observed in colony formation assays of MV4-11 cells. The double combinations induced a slightly stronger inhibition compared to the single agent treatments while the triple combination resulted in most drastically reduced colony numbers. The impact of combined treatment on colony numbers was also analyzed in CD34 positive hematopoietic progenitor cells isolated from healthy donors. Interestingly, the reduction of colonies upon double or triple inhibitor combinations was only slightly, but not significantly increased compared to the single agent treatments possibly opening up a therapeutic window for combination therapy. Targeted knockdown of GLI, FLT3 and PI3K in MV4-11 cells using specific shRNA lentiviral constructs could confirm our observations. The cells transduced with all shRNAs showed the poorest proliferation rates and colony formation capacities. Upon transduction with the FLT3 shRNA alone the mRNA expression of GLI2 was also reduced supporting our hypothesis of GLI2 activation by FLT3 signaling in AML.
Summary and Conclusions: We propose that the Hedgehog pathway members GLI1/2 are non-canonically activated by FLT3. Therefore, the combined inhibition of FLT3, PI3K and GLI could represent a more effective, therapeutic approach than targeting FLT3 alone in patients with FLT3-mutated AML.

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare subtype of leukaemia/lymphoma, whose diagnosis can be difficult to achieve due to its clinical and biological heterogeneity, as well as its overlapping features with other hematologic malignancies.
Aims: In this study we investigated whether the maturational stage of tumour cells could be associated with particular clinico-biological and prognostic features of the disease.
Methods: 46 BPDCN cases were analysed and classified into three maturation-associated subgroups according to the expression of CD34 and CD117: 1) immature BPDCN (expression of CD34 in at least a fraction of blasts); 2) intermediate BPDCN (partial positivity for CD117 in the absence of CD34), and; 3) mature cases ($CD34^-$ $CD117^-$ blasts).
Results: Blasts from cases with an immature plasmacytoid dendritic cell (pDC) phenotype exhibited an uncommon $CD56^-$ phenotype, coexisting with $CD34^+$ non-pDC tumour cells, typically in the absence of extramedullary (*e.g.* skin) disease at presentation. Conversely, patients with a more mature blast cell phenotype more frequently displayed skin/extramedullary involvement and spread into secondary lymphoid tissues. Despite the dismal outcome, acute lymphoblastic leukaemia-type therapy (with central nervous system prophylaxis) and/or allogeneic stem cell transplantation appeared to be the only effective therapies.
Summary and Conclusions: Overall, our findings indicate that the maturational profile of pDC blasts in BPDCN is highly heterogeneous and translates into a wide clinical spectrum -from acute leukaemia to mature lymphoma-like behaviour-, which may also lead to variable diagnosis and treatment.

INVOLVEMENT OF HISTONE ACETYLTRANSFERASES IN DEVELOPMENT OF ACUTE PROMYELOCYTIC LEUKEMIA AND RESPONSE TO DIFFERENTIATION-INDUCING COMPOUND

Y. Sunami[1,*] M. Araki[2], A. Ito[3], Y. Hironaka[1], A. Ohsaka[2], M. Yoshida[3], N. Komatsu[1]
[1]Department of Hematology, [2]Department of Transfusion Medicine and Stem Cell Regulation, Juntendo University school of medicine, Tokyo, [3]Chemical Genetics Laboratory, RIKEN, Saitama, Japan

Background: In a model of acute promyelocytic leukemia (APL) development, PML-RARA fusion protein suppresses transcription of RARA regulated genes through recruitment of histone dedyacetylase (HDAC), which blocks granulocytic differentiation. Differentiation-inducing compound all-*trans* retinoic acid (ATRA) that is used for APL treatment induces granulocytic differentiation in APL cells by modulating PML-RARA structure and subsequently dissociating HDAC from PML-RARA. Although the HDAC involvement in APL development and ATRA response is well documented, roles of histone acetyltransferases (HAT) remain elusive.
Aims: This study aims to uncover involvement of HAT in APL development and ATRA-induced granulocytic differentiation in APL cells.
Methods: mRNA expression levels of major HAT such as PCAF, GCN5, and p300 were assessed in APL patients' bone marrow by quantitative PCR (q-PCR) at onset and complete remission of APL. RNA expression profiles in APL and other hematologic malignancies were further analyzed with public databases. Differential expression of HAT upon ATRA treatment was further examined *in vitro* with cell lines such as HL-60 and NB4, and primary cells from APL patients. The protein levels of HAT were finally examined by immunoblot analysis. For functional characterization, a loss-of-function assay was performed using lentivirus vectors system with 3 independent shRNA sequences against PCAF or GCN5, and a non-target shRNA. Granulocytic differentiation was defined by CD11b expression.
Results: PCAF and GCN5 but not CBP/p300 showed differential expression between onset and complete remission of APL. PCAF expression was suppressed in APL bone marrow, while GCN5 expression was significantly elevated. When leukemic cells were induced for cellular differentiation by ATRA, dynamic change of PCAF and GCN5 mRNA expression was observed in culture cells NB4 and HL-60, and primary cells from APL patients. In cultured cells, levels of PCAF and GCN5 proteins followed those of mRNA. In public databases, reduced level of PCAF-expression in patients' bone marrow compared to healthy individuals was observed in not only APL but also other acute leukemia such as acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) (healthy individuals; n=74, AML; n=505, ALL; n=750). While, the reduction of PCAF-expression was not evident in chronic myeloid leukemia (CML) and myelodysplastic syndrome (MDS). In Contrast, GCN5-expression in AML and ALL was increased compared to that in the healthy individuals, and even in chronic hematologic malignancies. These data suggest that in malignant cells GCN5 expression was generally upregulated whereas PCAF expression is coupled with normal differentiation, which was preferentially blocked in acute leukemia cells. Potential of contradictory roles between PCAF and GCN5 in leukemia cells were assessed by a loss-of-function assay. Knocking down GCN5 induced massive apoptosis in HL-60 cells, suggesting that GCN5 harbors oncogenic property. In contrast, when knocking down PCAF, cells failed to differentiate into granulocytes after ATRA treatment. Furthermore, primary APL blasts of which PCAF was knocked down became resistant to ATRA-induced granulocytic differentiation, which implies that PCAF possesses a tumor suppressor function.
Summary and Conclusions: Despite that functional redundancy between PCAF and GCN5 in normal development was proposed, our data strongly suggest that PCAF and GCN5 have opposing roles in the APL development and ATRA-induced granulocytic differentiation in APL cells. More detailed understanding of HAT involvement in leukemogenesis and ATRA-induced cell differentiation in APL may lead to a development of novel treatment strategy against not only APL but also other AML.

E891

EFFECTS OF ARSENIC TRIOXIDE ON EVI-1 IN ZEBRAFISH AND IN LEUKEMIA CELLS

F. Chen[1,*] L. Shen[1]
[1]Hematology department, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: The *ecotropic viral integration site-1* (Evi-1) was first identified as the integration site of the ecotropic retrovirus leading to myeloid leukemia in murine model systems. In humans, Evi-1 is located on chromosome 3q26, and rearrangements on chromosome 3q26 often activate EVI-1 expression in myeloid malignancies. Arsenic trioxide (ATO), used in some traditional Chinese remedies for a very long history, has been found to be an effective treatment for acute promyelocytic leukemia (APL) and is being tested for treating other malignancies. Therefore, in our study we chose Tg(*EVI*-1:HSE:EGFP) zebrafish model (zebrafish embryos) and leukemia cells (both primary leukemia cells and leukemia cell line THP-1) to examine the effect of ATO on Evi-1 gene expression and clarify the mechanisms.
Aims: High expression of oncogene Evi-1 is an independent negative prognostic indicator of survival in leukemia patients. The present study investigates the effects of ATO on Evi-1 in zebrafish and in leukemia cells via apoptosis.
Methods: Embryos of Evi-1 transgenic zebrafish, tagged with Enhanced green fluorescent protein (EGFP),were treated with different concentrations of ATO

(50, 100 and 150μM) *in vivo* from 24 hours post fertilisation (hpf) to 72 hpf prior Evi-1 mRNA quantification by RT-PCR. Meanwhile, we measured the Evi-1 expression in bone marrow mononuclear cells treated with 1 μM ATO for 24h, 72h or 120h *in vitro*, the specimen was donated by a patient diagnosed with acute monocytic leukemia with high Evi-1 expression. Furthermore, THP-1 cell line, the highest expression of Evi-1 out of four leukemia cell lines (K562, HL-60, U937, THP-1),were treated with different concentrations of ATO (1, 3 and 5μM), or with a novel selective inhibitor of c-Jun N-terminal kinase (JNK), named as SP600125 (10μM),for 24h, 48h or 72h, tested for cell viability by CCK-8 kit, cell morphology by cytospin smear, cell apoptosis by flow cytometry, Evi-1 mRNA expression by RT-PCR, protein quantity by western blot.
Results: ATO downregulated Evi-1 mRNA in zebrafish *in vivo* and in primary leukemia cells *in vitro*. ATO treatment was shown to inhibit proliferation, induce apoptosis, downregulate both Evi-1 mRNA and Evi-1 oncoprotein expression, increase the expression of pro-apoptosis protein JNK, p-JNK, p-P53, PUMA, Bax, caspase-9 and caspase-3, and decrease the expression of anti-apoptotic protein Bcl-2 and Bcl-xL in THP-1 cell line *in vitro*. The pro-apoptotic activity of ATO in THP-1 cells could be inhibited by SP600125 (a specific JNK inhibitor), whereas SP600125 had little effect on the expression of EVI-1 protein.

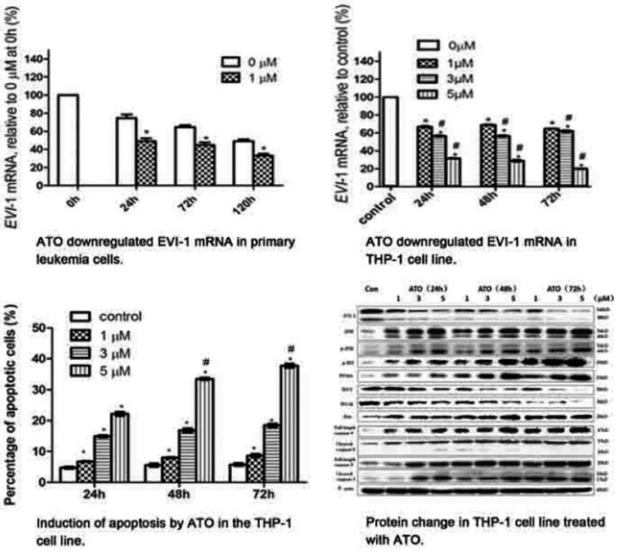

Figure 1.

Summary and Conclusions: Together, the study results reveal that ATO can downregulate Evi-1 mRNA as well as oncoprotein and block the repression of Evi-1 to JNK pathway, so the JNK apoptotic pathway is activated, giving rise to apoptosis of Evi-1 positive cell line THP-1. These novel findings provide theoretical basis for developing personalized medicine strategy to improve the therapeutic efficacy of the treatment of Evi-1 positive leukemia.

E892

CLINICAL CHARACTERISTICS AND PROGNOSTIC IMPLICATIONS OF DNMT3A MUTATIONS IN ACUTE MYELOID LEUKEMIA

E. Petrova[1,*] I. Martynkevich[1], L. Polushkina[1], L. Martynenko[1], M. Ivanova[1], N. Cybakova[1], E. Kleina[1], E. Shabanova[1], A. Chechetkin[1], K. Abdulkadyrov[1]
[1]Molecular genetics, Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Saint-Petersburg, Russian Federation

Background: Gene mutations and epigenetic changes have been shown to play a significant role in the pathogenesis of acute myeloid leukemia (AML). The components of epigenetic machinery such as DNA methylation plays an essential role in development, differentiation, genomic instability, specific regulation of gene expression and may contribute to leukemogenesis. Recently, researchers have been interested in investigating *DNMT3A*, because of the high frequency of mutations of this gene in AML. Also, *DNMT3A* mutations are considered to be independently associated with an unfavourable prognosis in adults with *de novo* AML, however, there are still ongoing debates on this topic.
Aims: The aim of the research was to investigate the frequency and prognostic impact of *DNMT3A* mutations in AML patients and to analyze its interaction with other prognostic markers.
Methods: This retrospective study was performed in 143 previously un-treated adult patients (135 pts with de novo and 8 pts with secondary AML). There were 65 males and 78 females with a median age of 55 years (18-86). According to the results of cytogenetic analyses pts were separated in the following groups: with favourable (9.8%), unfavourable (14.0%) prognosis, with normal karyotype (NK) (49.0%) and other aberrations (27.2%). Mutation analysis of *DNMT3A* R882 was performed by high-resolution melting curve analysis. Mutations in *FLT3* and *NPM1* were analysed by PCR and in *NRAS* by sequencing. Metaphase chromosomes were banded with the trypsin-Giemsa technique.
Results: Mutations of *DNMT3A* R882 were found in 23 (16.1%) de novo AML patients: R882H (16 pts), R882C (6 pts) and R882S (1 pts). All but one pts (with mutation R882S) were heterozygous and retained a wild-type allele. *DNMT3A* mutations were detected in all morphologic variants (except M0 and M3, extremely rare in M2 (p=0.006)) and were frequently noted in patients with M5 (7/17, p=0.003) and M4 (11/38, p=0.012). It was revealed, that none of the patients with favourable karyotype harboured *DNMT3A* R882 and only 1/20 pts with adverse karyotype had *DNMT3A* mutation. 17/23 pts (24.3%) with $DNMT3A_{mut}$ had tumors with normal cytogenetic profiles (of a total of 70 NK samples) (p=0.009). Patients with isolated *DNMT3A* mutations were seen in 5 cases; all 3 patients with genotype $DNMT3A_{mut}/NRAS_{mut}$ had the R882C variant of the mutation; 6 pts had genotype $DNMT3A_{mut}/FLT3\text{-}ITD_{mut}/ NPM1_{mut}$. *DNTM3A* mutations were significantly more prevalent in *NPM1* positive cases when compared to *NPM1* wild type cases (p=0.005). *DNTM3A* mutations were also more dominant in *FLT3*-ITD positive pts than wild type (p=0.001). Patients who harbored the mutations in *DNMT3A* had a higher white blood cell count (p=0.001) and platelets count (p=0.020) in peripheral blood, and blasts in bone marrow (p=0.099) at diagnosis. There was no statistical correlation with other parameters, including sex, age and hemoglobin between patients with and without *DNMT3A* mutations (p>0.05). There was statistically significantly correlation between overall survival (OS) and relapse-free survival (RFS) of AML pts with $DNMT3A_{mut}$ and $DNMT3A_{wt}$ (p=0.031 and p=0.045, respectively). Medians of OS and RFS were: 5.2 and13.0 months; 4.8 and10.0 months, respectively.
Summary and Conclusions: AML with *DNMT3A* mutations represent a group, which is homogeneous on a number of clinical and laboratory parameters, associated with adverse prognosis and a high risk of relapse. Therefore, the discovery of highly recurrent mutations in *DNMT3A* may provide a new tool for the classification of intermediate-risk AML.

E893

CRITICAL ROLE OF SOX12 IN LEUKEMOGENESIS IN AML

H. Wan[1,*] H. Zhong[1], B. Ni[1], J. Cai[1], F. Chen[1]
[1]Hematology, Renji Hospital, Shanghai Jiaotong University School of Medicien, Shanghai, China

Background: The SOX (Sry-related HMG box) genes belong to a family of transcription factors containing a High-Mobility-Group box domain. In an initial screen of SOX genes in human leukemias, SOX12 is uniquely up-regulated in acute myeloid leukemia, myelodysplastic syndrome and chronic myelogenous leukemia but down-regulated in most cases of normal individuals.
Aims: The study is to examine the expression and function of SOX12 in acute myeloid leukemia (AML).
Methods: Mononuclear cells (MNCs) were isolated from AML and fractionated by immunomagnetic selection and fluorescence activated cell sorting (FACS). SOX12 expression in different leukemia subsets was evaluated by RT-PCR. To examine its function, SOX12 siRNA was nucleofected to K562 cells and gene knock-down was confirmed by RT-PCR and Western Blot. Apoptosis and cell cycle were analyzed by Annexin V/7AAD assay and flow cytometry. To examine the leukemia stem cell (LSC) function in AML, SOX12 was knocked down with siRNA, and K562 cells transduced with siRNA were subjected to *in vitro* colony forming assay, and injected into NOD/SCID mice as well. 2 weeks later, the number of colonies were enumerated, and 8 to 12 weeks later, the mice were euthanized and bone marrow cells from the mice were analyzed.
Results: SOX12 was preferentially expressed in $CD34^+$cells ($CD34^+$*vs* $CD34^-$: P<0.015) but not $CD34^+CD38^-$ cells which were considered stem/progenitor cells in normal hematopoiesis. SOX12 knockdown in K562 cells with siRNA could reduce the cell proliferation (scramble *vs* SOX12 at day 3, p=0.025), induce the increase of cells in G1 phase (SOX12 *vs* scramble at day 3, p=0.03), but had no effect on apoptosis. *in vitro* colony number was reduced with siRNA transduced K562 cells compared to control group (P=0.032). Engraftment of transduced K562 cells in NOD/SCID mice were significantly reduced 8 to12 weeks after transplantation (p=0.04).
Summary and Conclusions: SOX12 is preferentially expressed in human $CD34^+$cells of AML. SOX12 knock-down reduced cellular proliferation by arresting the AML cells in G1 phase of the cell cycle. SOX12 knock-down could also reduce the repopulating ability of AML in NOD/SCID mice, indicating SOX12 was involved in the regulation of leukemogenesis in AML. Its mechanism of action would have to be further evaluated.

E894

THE SYK INHIBITORS R788, R406 AND P505-15 COUNTERACT NEOPLASTIC CELL SURVIVAL AND SYNERGIZE WITH MIDOSTAURIN IN PRODUCING GROWTH ARREST IN AML CELL LINES AND PRIMARY AML BLASTS

R. Gaupmann[1,*] B. Peter[1], K. Blatt[1], I. Sadovnik[1], D. Berger[1], G. Stefanzl[1], W. Sperr[1], P. Valent[1], K. Gleixner[1]

[1]Internal Medicine I, Medical University of Vienna, Vienna, Austria

Background: In acute myeloid leukemia (AML), relapse after high-dose chemotherapy is frequent and the overall outcome is poor. Therefore, new therapeutic strategies are warranted. Currently, the effects on leukemic cells of novel targeted drugs, including signal-transduction inhibitors, have been examined. Syk is a tyrosine-kinase that has been shown to play a key role in oncogenic signaling in AML cells.
Aims: In this study, we evaluated the effects of the Syk-inhibitors Fostamatinib (R788), its active metabolite R406 and the more specific inhibitor P505-15 on proliferation and survival of AML cells.
Methods: The inhibitors R788 and R406 were purchased from Selleck (Houston, TX), and P505-15 from Exon Medchem (Groningen, NL). The multikinase inhibitor PKC412 (midostaurin; active against Flt-3) was purchased from Chemietek (Indianapolis, IN). In this study, the Flt-3-ITD positive AML cell lines MOLM-13 and MV4-11 were used. Primary AML blasts were isolated from the peripheral blood or bone marrow from 13 AML patients. Neoplastic cells were exposed to various concentrations of Syk-inhibitors alone or in combination with PKC412. Thereafter, cell proliferation was measured by ^{3}H-thymidine-uptake. Cell cycle progression and induction of apoptosis were analyzed by flow cytometry. Apoptosis was confirmed by light microscopy and by Western blot analysis of cleaved caspase-3. Drug interactions (additive, synergistic) were qualified with Calcusyn software. The enzymatic activity of Syk was evaluated by detection of autophosphorylated tyrosine on the position 348 by flow cytometry.
Results: In a first step, MOLM-13 and MV4-11 cells were exposed to the three Syk-inhibitors. As assessed by ^{3}H-thymidine-uptake, all tested drugs were found to inhibit proliferation in both cell lines in a dose-dependent manner (IC_{50}: 0.1-5 μM). The underlying mechanisms of growth-inhibition were induction of cell-cycle arrest in G0/G1 phase and induction of apoptosis, as assessed by light microscopy, flow cytometry and Western blot analysis of cleaved caspase-3. These effects were accompanied by a dose dependent decrease of the enzymatic activity of Syk. We next incubated primary AML-blasts (n=13 patients) with R406, R788 and P505-15. Again, all compounds tested were found to inhibit cell-proliferation with IC_{50} -values ranged between 0.1 μM and 5 μM in all tested samples, including in primary cells expressing Flt-3-ITD. No difference in IC_{50} -values were seen between samples isolated from newly diagnosed patients and heavily pretreated patients, suggesting, that Syk-inhibition may exert antileukemic effects even in relapsed patients. Finally, we combined the Syk-inhibitors with the Flt-3-inhibitor PKC412 at suboptimal concentrations and were able to demonstrate synergistic effects of these targeted drugs in producing growth-inhibition in Flt-3-ITD+AML cell lines.
Summary and Conclusions: Altogether, Syk-inhibitors act antineoplastic in AML cell lines and primary AML blasts, including in samples isolated from patients with relapsed AML. Further, Syk-inhibitors synergize with the Flt-3-inhibitor PKC412 in blocking leukemic cell expansion. Our data suggest that Syk-inhibitors may be implicated in the therapy of relapsed AML. However, the therapeutic value of these agents alone or in combination with other drugs remains to be investigated within the frame of clinical trials.

E895

ACCUMULATION OF THE NPM-1 SPLICE VARIANT R2 ACCOMPANIES AML DEVELOPMENT

M. Zajac[1,*] J. Zaleska[1], O. Jankowska-Lecka[2], M. Hus[2], L. Bullinger[3], K. Giannopoulos[12]
[1]Experimental Hematooncology Department, [2]Department of Hematooncology and Bone Marrow Transplantation Unit, Medical University of Lublin, Lublin, Poland, [3]Department of Internal Medicine III, University of Ulm, Ulm, Germany

Background: The relevance of differential splicing in human cancer is an evolving area of cancer biology. The recent findings of frequent mutations of the splicing pathways in MDS provide insight into the mechanism of alternative splicing, which has been long associated with the development of cancer. The genome-wide microarray analysis using Exon arrays discovered significantly differentially spliced genes in AML. Moreover, the AML specific "splicing profile" was normalized in remission and reappears with patient relapse, thereby supporting a role of deregulated splice variants in the process of leukemogenesis. A close cytogenetic and molecular deregulation between *de novo* MDS and AML of elderly people suggests a common pathogenic mechanism for these conditions. Although the full spectrum of leukemic progression has not yet been completely clarified, recent clinical and biological studies indicate that MDS and AML could be considered as part of the same continuous disease spectrum rather than as distinct disorders. Recently, we found that high expression of the *NPM-1* splicing variant R2 may provide prognostic value for CN-AML patients. As the R2 splicing variant represents a truncated form of *NPM1* gene this isoform mostly localizes in the nucleoplasm, and thus might also have a biological impact in the malignant cells.
Aims: Assuming the common origin of MDS and AML we aimed to characterize the *NPM1* R2 splice variant expression as well as the influence of R2 expression on NPM1 localization in groups with MDS, sAML and AML patient samples.
Methods: Since we found prognostic significance of the expression level of R2 for the AML cohort of patients, therefore we decided to evaluate its significance for MDS and sAML cases. For 61 samples (25 AML, 30 MDS and 6 samples with sAML) qRT-PCR was performed. Expression level of *NPM-1* R2 was assessed. To investigate whether R2 might disrupt localization of the NPM1 wild type protein, immunohistochemistry analysis for NPM1 in 23 AML bone marrow smears was performed.
Results: We found significant differences in *NPM-1* R2 expression levels between cytogenetically normal (CN-AML), sAML, MDS and healthy volunteer (HV) groups. Interestingly, expression of *NPM-1* R2 tended to be elevated in CN-AML compared to MDS (median 0.022 *vs* 0.015, p=0.061). The expression of R2 was significantly increased in the CN-AML, sAML and MDS groups compared to HVs (median 0.022 *vs* 0.005, p<0.001, 0.015 *vs* 0.005, p<0.001, and 0.022 *vs* 0.005, p<0.001, respectively). Moreover, we stratified MDS and AML patients according to IPSS and genetic risk classification, respectively and found significant differences in *NPM-1* R2 expression between those groups. The IHC stainings for AML samples revealed that in cases with high *NPM-1* R2 expression we were able to determine a cytoplasmic localization of NPM1 even in the absence of a concomitant *NPM1* mutation. Therefore, we provide further evidence that the cytoplasmic localization of NPM1 might depend not only on its mutational status, but might also be influenced by the distribution of its splice variants.
Summary and Conclusions: In our study we found that the expression levels of *NPM-1* R2 were elevated in AML, sAML and MDS groups compared to HVs suggesting that *NPM-1* R2 might play some role in the process of the tumorigenesis not only in AML cases but also in early stages of development of this disease. As the *NPM-1* R2 splice variant represents a truncated form of *NPM1* gene this isoform mostly localizes in the nucleoplasm, and thus might also have a biological impact in the malignant cells. The *NPM-1* R2 might interact with cellular proteins affecting signal pathways and by this have influence on outcome or modulate treatment response. In summary, the expression of *NPM-1* R2 might be of biological importance for CN-AML as well as for sAML and MDS patients. This work was supported by National Centre for Science Grant HARMONIA (UMO-2013/10/M/NZ5/00313).

NEXT GENERATION SEQUENCING OF MYELOID MALIGNANCIES IDENTIFIED A SPECTRUM OF NOVEL MUTATIONS IN EPIGENETIC REGULATORS – CENTER FOR INDIVIDUALIZED MEDICINE CLINIC EXPERIENCE

M. Damlaj[1,*] H. Alkhateeb[2], R. Tibes[3], G. Nowakowski[2], T. McAllister[4], A. Pardanani[2], D. Viswanatha[5], K. Lazaridis[6], A. Feldman[5], E. Wieben[7], J.B. Egan[8], A. Bryce[3], M.E. Fernandez-Zapico[9], M. Patnaik[1]
[1]Hematology, Blood and Marrow Transplant, [2]Hematology, Mayo Clinic, Rochester, [3]Hematology and Oncology, Mayo Clinic, Scottsdale, [4]Center for Individualized Medicine, [5]Laboratory Medicine and Pathology, [6]Gastroenterology and Hepatology, [7]Medical Genetics, Mayo Clinic, Rochester, [8]6Comprehensive Cancer Center, Mayo Clinic, Scottsdale, [9]Medical Oncology, Mayo Clinic, Rochester, United States

Background: Next generation sequencing (NGS) studies have been instrumental in identifying novel and recurrent mutations in hematologic malignancies. FoundationOne Heme© is a comprehensive NGS platform designed to provide targeted assessment of the genomic landscape of hematologic neoplasms. It interrogates the entire coding sequence of many genes, described to be somatically altered.
Aims: We wished to report the frequency of somatic mutations and variants of unknown significance (VUS) in myeloid neoplasms and their impact on clinical care including timing of testing.
Methods: After due IRB approval, patients with myeloid malignancies who underwent FoundationOne Heme© analysis at Mayo Clinic Rochester were identified. The complete coding DNA sequence of 405 genes, selected introns of 31 genes as well as the RNA sequence (cDNA) of 265 genes was interrogated. Mutations identified were stratified as having prognostic or actionable clinical impact. Actionable mutations were defined as potentially leading to a treatment decision with clinical trials or off label therapies, whereas prognostic mutations were those that helped with risk stratification. All data was retrospectively abstracted.
Results: A total of 45 patients were included in this analysis. The distribution of underlying conditions was: AML (27), ALL (5), acute undifferentiated leukemia (2), MDS (4), MPN (3), MDS/MPN overlap syndrome (3) and others (3). At last follow up, 19 (42%) patients were alive. A. Somatic mutations: A total of 164 somatic mutations were identified with a median of 4 per patient (range: 0-8). Of therapeutic relevance, the following mutations were most common: *DNMT3A* (8%), *RUNX1* (6%), *TET2* (5%), *FLT3* and *KRAS* (4% each), whereas *TP53* (10%) and *ASXL1* (8%) were the most common prognostic mutations. A total of 58 (35%) aberrations were actionable; 53 via clinical trials and 38 through off label therapeutics. Median number of potential therapies and clinical trials

identified after testing were 2 (0-6) and 3 (0-7) per patient, respectively. Among patients who succumbed to their disease, median time to death from sample acquisition was 68 days (6-375), and 7 patients (16%) died within 1 month of testing, 5 of whom died before results were available. In Patients surviving beyond 2 weeks of available results, testing changed clinical management in 7/38 (18%); 5 received off label therapy and 2 were enrolled in phase I/II clinical trials. B. Variants of unknown significance (VUS): A total of 286 somatic variants were identified; 215 in AML and 71 in other myeloid neoplasms, with 29 overlapping variants. Most common variants observed were in the following genes; *MLL2* (3%), *DNMT3A, EP300, FLT1, LRP1B, LRRK2, MAP2K6, PDCD11* and *ROS1* (2% each) in AML and *HDAC7* (4%), *ATRX, CRKL, DOT1L, EP300, FLT1, FOXO3, MLL2, RICTOR, SPEN* and *STAT6* (3% each) in other myeloid neoplasms.

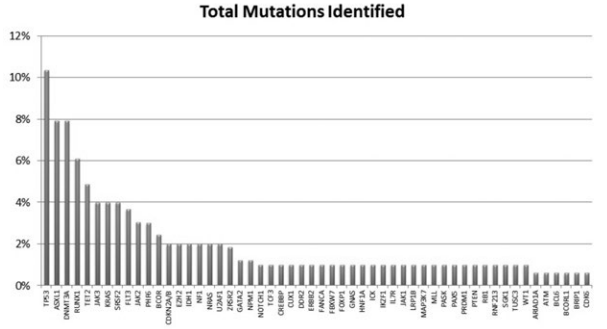

Figure 1.

Summary and Conclusions: Targeted use of NGS potentially yields prognostic and therapeutic information about somatic mutations in Hematologic malignancies. This permitted the use of novel targeted therapies including clinical trials in some patients. However, delayed testing until exhaustion of therapeutic options limits the utility of this tool. Utilizing a larger cohort with functional studies is required to comprehensively investigate the potential pathologic nature of recurrent VUS.

A COMPREHENSIVE ANALYSIS OF ACCESSIBLE BONE MARROW PROTEINS FOR ANTIBODY-BASED THERAPY OF ACUTE MYELOID LEUKEMIA

L. Angenendt[1,*] S. Reuter[2], D. Kentrup[2], A. Benk[3], C. Schwöppe[1], T. Kessler[1], C. Zerbst[1], J.H. Mikesch[1], W.E. Berdel[1], R.M. Mesters[1], C. Rösli[3], C. Schliemann[1]
[1]Department of Medicine A, [2]Department of Medicine D, University Hospital Münster, Münster, [3]HI-STEM gGmbH, German Cancer Research Center, Heidelberg, Germany

Background: Immunoconjugates are targeted agents that combine the tumor homing properties of monoclonal antibodies with the cancer killing capacity of effector molecules such as drugs, cytokines, toxins or radionuclides. There is no therapeutic antibody approved for the treatment of AML to date, but several are under clinical investigation. Well characterized antigens like CD33 and CD123 are leukemia-selective, but lack true leukemia-specificity. New targets are usually identified by comparison of the expression of membrane-bound proteins in leukemic cells and their normal hematopoietic counterparts.
Aims: Here, we used a general chemical proteomics approach based on *in vivo* protein biotinylation to identify bloodstream-accessible proteins as they exist natively in the bone marrow in AML, a disease that is, despite therapeutic improvements of the last decades, still lethal to the majority of patients.
Methods: Brown Norway (BN) rats bearing the syngeneic BNML acute myeloid leukemia model and healthy control rats were subjected to *in vivo* protein biotinylation by vascular perfusion with an aqueous solution of sulfo-NHS-LC-biotin, a reactive ester derivative of biotin, that enables the covalent labeling of proteins readily accessible from the blood-stream. Biotinylated proteins from the perfused bone marrow were purified on streptavidin-resin, trypsinized and subjected to LC-MALDI-TOF/TOF mass spectrometry and bioinformatic processing for identification and relative quantification. The most promising AML-associated targets were validated by APAAP-immunohistochemistry (IHC) on rat and human AML bone marrow specimens.
Results: In total, almost 1500 bloodstream-accessible proteins were identified in healthy and leukemic bone marrow. Among them, 181 proteins were more than 100-fold up-regulated in AML as compared to normal bone marrow. Fifteen of the most differentially expressed proteins were selected for further validation by IHC. Of these, ECM1, Nucleolin, COL6A1 and AP3B2 showed the most differential expression in rat and human AML as compared to normal bone marrow.
Summary and Conclusions: We provide an atlas of circulation-accessible AML-associated bone marrow proteins that could serve as potential targets for a site-specific antibody-mediated pharmacodelivery of cytotoxic drugs, cytokines or radionuclides to the leukemia-infiltrated bone marrow in AML.

E899

IMPACT OF DEVELOPMENTAL STAGE AND AGE ON GENE EXPRESSION IN CHILDHOOD AND ADULT ACUTE MYELOID LEUKAEMIA

A. Stevens[1,*] L. Bullinger[2], M. van der Heuvel-Eibrinck[3], P. Clayton[1], S. Meyer[4]
[1]Institute of Human Development, University of Manchester, Manchester, United Kingdom, [2]Internal Medicine, Ulm University, Ulm, Germany, [3]Department of Pediatric Hematology and Oncology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, [4]Centre for Paediatric, Teenage and Young Adult Cancer, Institute of Cancer, Manchester, United Kingdom

Background: Acute myeloid leukaemia (AML) is a heterogeneous disease with a sharp rise in incidence after the 3rd decade. A strong correlation between specific genetic changes and gene expression patterns is well established, and individual cytogenetic subtypes of AML, in particular t(8;21), t(15;17) and inv(16) display distinct gene expression patterns[1]. Chronological age of the patient is one of the most important markers for prognosis and clinical outcome[2]. The impact of age on leukaemia prognosis is not understood in detail. Differences in gene expression patterns between AML in younger and older patients have been described, and suggests differential oncogenic pathway activation in older patients (>55 years of age)[3]. We have recently defined distinct gene expression patterns associated with the developmental stages in childhood; infancy, early and late childhood, and puberty. These gene expression patterns discriminate stages of childhood development and imply that developmental stage impacts on gene transcription in a tissue-independent manner[4]. We propose that age will affect gene expression patterns independent and dependent on cytogenetic subtype in children and adults.
Aims: I) Identify genes and gene expression patterns that are age dependently regulated in childhood and adult AML independent of cytogenetic subtype. **II)** Delineate expression patterns that are regulated by age according to cytogenetic subtype.
Methods: We have used transcriptomic data from the age annotated dataset of childhood AML (0 – 19 years of age n=237)[5,6], normal children (0 – 19 years of age, n=87)[4] and from adult patients (16-84 years of age, n=436)[7]. We identified genes that showed age-related regulation in expression both dependently and independently of cytogenetic subtype [focussing on t(8;21), inv(16), t(15;17)]. The Isomap dimensional reduction approach to principal component analysis (PCA) was used to define age and cytogenetic relationships within AML patient data (Qlucore Omics Explorer software) using unsupervised time-series clustering. Cross-validation of the PCA by sample exclusion was used to identify robust relationships. Rank regression was used to define age-related gene expression.
Results: The *TPM1* gene, producing an actin binding protein involved in calcium signalling, had differentially phased variation during childhood in AML subtypes and normal children, but displayed age dependent variation only in AML with t(15;17) (p<0.01). *SPIRE2*, a protein kinase involved in cytoskeleton organisation, transcripts showed age dependent variation in normal children and childhood AML (p<0.01) with patterns that suggest differential phasing in adult AML; age-dependent variation was independent of karyotypic subtype. *TSPAN2*, a component of the integrin signalling pathway, transcripts showed different levels of expression in different phases of childhood in normal children (p<0.01), however in AML age dependent regulation was differentially phased dependent on cytogenetic subtype.
Summary and Conclusions: We have identified three examples of individual transcripts where age and karyotype display very different effects. These data imply that some age dependent changes in AML are karyotype specific.

NEXT-GENERATION SEQUENCING AS A TOOL FOR ASSESSING MINIMAL RESIDUAL DISEASE IN AML PATIENTS WITH CEBPA MUTATIONS

L. Zejskova[1,*] R. Plachy[1], L. Sedlackova[1], O. Mazal[1], M. Ondrackova[1], A. Zavrelova[2], P. Zak[2], V. Petecukova[3], J. Novak[3], T. Kozak[3], S. Pekova[1]
[1]Laboratory synlab genetics s.r.o., synlab genetics s.r.o., Prague, [2]4th Department of Internal Medicine – Hematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, [3]Internal Clinic of Hematology, University Hospital Kralovske Vinohrady, Prague, Czech Republic

Background: Mutations in the CCAAT/enhancer binding protein alpha (*CEB-*

PA) gene occur approximately in 5 – 10 % of acute myeloid leukemia (AML) patients and can be used as molecular markers for monitoring of minimal residual disease (MRD). However, detection of MRD using quantitative real-time PCR (qPCR) is complicated due to GC-rich regions and thus validation of leukemia-specific and sensitive MRD assay can be technically difficult.
Aims: The goal of our work was the application of next-generation amplicon-based deep sequencing (NGS) as a quantitative detection method for MRD monitoring.
Methods: Since 2010, we have performed mutational analysis of the *CEBPA* gene coding region in 411 AML patients at the time of diagnosis using Sanger sequencing. In patients with the *CEBPA* mutation/s as the only detected mutation/s, *i.e.* the examined patients did not have other available MRD markers after standard molecular analysis of fusion transcripts and mutations in hematological prognostic genes, we designed leukemia-specific assays using qPCR. However, in 5 patients the assay did not provide sufficiently sensitive and specific detection of residual leukemic cells. In these cases MRD was monitored by NGS technology (GS Junior System, Roche). For MRD analysis starting at first diagnosis and following the course of the treatment we analyzed bone marrow (n=36) or peripheral blood (n=2) samples. The result of the MRD assessment was evaluated as a percentage of the mutated reads from all reads (reads with mutation/all reads). 20 000 reads per sample was considered as a minimum for valid MRD analysis.
Results: From January 2013 to February 2015 we examined 38 samples from 5 AML patients. *CEBPA* mutations found in these patients and used as a marker for MRD analysis were short insertions or deletions. The median of reads per sample was 58 376 (mean 58 076, range 27 829 - 110 564). The assay detection sensitivity achieved the threshold of 10^{-4} to 10^{-5} (1 leukemic cell in 10 000 cells to 1 leukemic cell in 100 000 cells). The MRD levels of residual leukemic cells correlated with clinical outcome. In patients with relapse (three out of five patients), the occurrence of the *CEBPA* mutation/s was also confirmed by conventional Sanger sequencing.
Summary and Conclusions: Quantitative assessment of *CEBPA* mutations using next-generation amplicon-based deep sequencing enabled MRD monitoring in AML patients, where the design of quantitative real-time PCR assay didn not achieve sensitivity of at least four orders of magnitude. NGS technology represents another approach for MRD assessment of the mutated *CEBPA* gene.

E901

GRANULOCYTE COLONY-STIMULATING FACTOR INHIBITS CXCR4/SDF-1A SIGNALING AND OVERCOMES STROMAL-MEDIATED DRUG RESISTANCE IN HL-60 CELL LINE

H. Zhong[1,*] X.F. Sheng[1], H.X. Wan[2], F.Y. Chen[1], J.H. Zhong[2]
[1]Hematology, [2]Ren Ji Hospital, Shang Hai, China

Background: The outcome of acute myeloid leukemia in older and relapsed/refractory patients is dismal, which is partially due to drug resistance. The cytarabine, aclarubicin and granulocyte colony-stimulating factor (G-CSF) protocol has been widely used in these patients and has been achieved dramatic therapeutic efficacy, while the underlying mechanisms are still not very clear. Interaction with stromal cells may protect leukemia cells from spontaneous and drug-induced apoptosis.
Aims: We tried to clarify the potential ability of G-CSF to overcome stromal-mediated drug resistance through CXCR4/SDF-1α axis regulated by miR-146a expression in the leukemia cells.

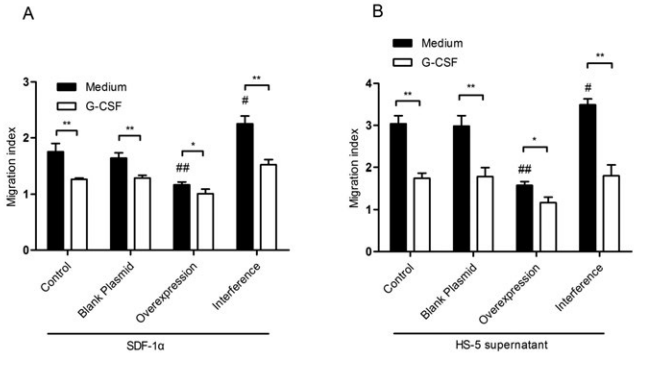

Figure 1.

Methods: HS-5/HL-60 co-culture model was established to imitate the interactions between stromal and leukemia cells. The ability of G-CSF sensitize HL-60 cells to chemotherapy through G-CSF→microRNA-146a (miR-146a)→CXCR4 pathway was investigated. For all experiments, HL-60 cells were divided into four groups: control group, blank plasmid, miR-146a over-expression group and miR-146a interference group.
Results: An obviously inverse correlation between miR-146a expression and CXCR4 expression was observed. In over-expression group, miR-146a was significantly up-regulated and CXCR4 mRNA was decreased. In interference group, miR-146a was down-regulated and CXCR4 mRNA was increased. The levels of surface and total CXCR4 protein were also reduced in over-expression group, while increased in interference group. Then we verified that G-CSF clearly up-regulated the levels of miR-146a in all groups compared with medium, along with down-regulated CXCR4 mRNA and protein expression. In function assays, we firstly found that HL-60 cells can be attracted and adhered to HS-5 cells. The migration index and adhesion was decreased in over-expression group, but increased in interference group compared with control group. Then we also observed that G-CSF disturbed HL-60 cell migration and adhesion. Lastly, we observed that HL-60 cells were protected from apoptosis (both spontaneous apoptosis and drug-induced apoptosis) when co-cultured with HS-5 cells in all groups, while G-CSF partially inhibited this protective effect. We also observed that the protective effect was more apparent in interference group and less apparent in over-expression group than control group.
Summary and Conclusions: Our data suggest that interfering with the CXCR4/SDF-1α signaling axis by using G-CSF inhibited HL-60 cell migration, adhesion and stromal-mediated protective effects. Our study also indicate that G-CSF reduced CXCR4 expression by miR-146a up-regulation, that is to say, there may be exist a G-CSF→miR-146a→CXCR4 pathway to explain how G-CSF inhibits CXCR4/SDF-1α signaling and overcomes stromal cell-mediated drug resistance in acute myeloid leukemia.

E902

THE ROLE OF CYBB IN MAINTENANCE OF MLL-REARRANGED LEUKEMIA

C.F. Lam[1,*] R.K. Ng[1]
[1]Biochemistry, The University of Hong Kong, Hong Kong, Hong Kong

Background: *MLL* (*mixed lineage leukemia*)-rearranged leukemia is caused by the chromosomal translocation of the *MLL* and partner genes. Previous studies demonstrated that the *Cytochrome b beta chain* (*Cybb*) gene is severely down-regulated in *Mll*-rearranged leukemia. *Cybb* encodes the catalytic subunit of NAPDH oxidase 2 (Nox2) complex and its expression is closely associated with the reactive oxygen species (ROS) level. ROS has been shown to influence stem cells maintenance and progenitors differentiation in hematopoietic system. The down-regulation of *Cybb* may suppress intracellular ROS level and therefore enhance stemness of *Mll*-rearranged leukemia.
Aims: To investigate the function of *Cybb* and Nox2-generated ROS in the maintenance of *MLL*-rearranged leukemic cells.
Methods: We have established a novel Mll-Een cell line from an Mll-Een knock-in mouse model. We compared the expression level of *Cybb* in the Mll-Een cells and wild-type bone marrow cells isolated from C57BL/6 mice by qPCR analysis. Intracellular ROS level was quantified by CellRox staining. Overexpression of *Cybb* in Mll-Een cells was done by lentiviral transduction. The ROS level and leukemic features of *Cybb* overexpressing Mll-Een cells were assessed by CellRox staining, colony forming assay and proliferation assay.
Results: We found that *Cybb* expression was severe down-regulated in the Mll-Een cell line when compared with the wild-type bone marrow cells. Besides, the intracellular ROS level of Mll-Een cells was also reduced. Overexpression of *Cybb* in Mll-Een leukemia cell increased the intracellular ROS level by over 30%. The colony forming number of *Cybb* overexpressing cells was sharping decreased by 89%, indicating that *Cybb* expression attenuates the colony forming potential of Mll-Een cells. Importantly, the colony morphology of *Cybb* overexpressing cells consists of mainly terminally differentiated cell colonies, which are 5 times higher in number than the control sample (57% *vs* 11%). These results suggested *Cybb* reduces self-renewal potential and promotes myeloid differentiation of Mll-Een leukemia. Furthermore, proliferation ability of *Cybb* overexpressing Mll-Een cells was greatly reduced by 87%, implying an impaired proliferative potential.
Summary and Conclusions: Overexpression of *Cybb* in Mll-Een cells increases ROS level and attenuates leukemic feature, such as the self-renewal potential and proliferative ability. *Cybb* also promotes myeloid differentiation in *Mll*-rearranged leukemia cells.

E903

ANALYSIS OF ASXL1 MUTATIONS AND CORRELATION WITH CHROMOSOMAL ALTERATIONS IN ACUTE MYELOID LEUKEMIA

K. Kakosaiou[1], A. Daraki[1], P. Apostolou[1], S. Zachaki[1], M. Pagoni[2], C. Sambani[1], G. Dimitriadis[3], V. Pappa[3], K. Manola[1,*]
[1]NCSR "DEMOKRITOS", [2]Evangelismos Hospital, [3]University General Hospital "Attikon", Athens, Greece

Background: Additional sex comb-like 1 (*ASXL1*) is an enhancer of Trithorax and Polycomb family, which is necessary for the maintenance of stable repression of homeotic and other loci. Recently, mutations of the *ASXL1* gene were identified in the hematopoietic cells from patients with a variety of myeloid malignancies, including acute myeloid leukemia (AML). The vast majority of these mutations, which are frameshift and nonsense, have been associated with an aggressive phenotype and detrimental effects on overall survival, especially in patients with a normal karyotype.

Aims: The purpose of this study is the identification of the *ASXL1* mutations in *de novo* and secondary AML (s-AML) patients and their correlation with the cytogenetic findings.
Methods: Our study included 275 AML patients (184 *de novo* AML and 91 s-AML) and 10 healthy donors. Conventional cytogenetic analysis was performed on unstimulated bone marrow cells. In order to detect *ASXL1* exon 12 mutations, molecular analysis was performed by PCR and subsequent direct Sanger sequencing in all patients' and controls' samples.
Results: A successful karyotypic analysis was performed in all AML samples at diagnosis. Among them, 201 patients (73.1%) exhibited clonal karyotypic aberrations and 74 (26.9%) showed a normal karyotype. *ASXL1* mutations were detected in 50 out of 275 patients (18.2%) while none *ASXL1* mutation was observed in the control group. A significantly higher frequency of *ASXL1* mutations was found in s-AML compared to *de novo* AML patients (26.4% *vs* 14.1%, respectively; p=0.013). The most frequent *ASXL1* mutation was the c.1934dupG (43/50, 86.0%). *ASXL1* mutations were more frequently found in males than in females (19.8% *vs* 15.8%, respectively), while stratification of patients according to age revealed a higher frequency of *ASXL1* mutations in patients ≥61years than in patients <60years (*p*=0.003). Among the 50 AML patients with *ASXL1* mutations, 28% exhibited a normal karyotype, 22% had trisomy 8 either as a sole abnormality or in combination with others, 4% t(8;21), 4% trisomy 13, 4% -7/del(7q), 2% t(15;17), 2% t(9;22) and 26% other chromosomal abnormalities. Moreover, 8% of *ASXL1* mutated patients revealed complex karyotypes.
Summary and Conclusions: These results suggest that *ASXL1* mutations are frequent in AML, especially in s-AML and are highly correlated with older age, male sex and specific karyotypic aberrations. The most common chromosomal abnormality associated with *ASXL1* mutations is trisomy 8, followed by t(8;21) and trisomy 13. *ASXL1* mutations are present in all AML cytogenetic risk groups with good, intermediate and poor prognosis.

E904

TARGETED NEXT GENERATION SEQUENCING (NGS) IN PARALLEL ANALYSES OF CHILDHOOD (CAML) AND ADULT ACUTE MYELOID LEUKEMIA (AAML) PATIENTS

I. Glumac[1,*] J. Kostic[1], B. Stanic[1], N. Pejanovic[1], B. Lucic[1], T. Karan-Djurasevic[1], D. Janic[2,3], L. Dokmanovic[2,3], S. Jankovic[2,3], N. Suvajdzic Vukovic[3,4], D. Tomin[3,4], M. Popovic[5], I. Bogicevic[5], S. Pavlovic[1], N. Tosic[1]
[1]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, [2]University Children's Hospital, Belgrade, Serbia, [3]School of Medicine University of Belgrade, Belgrade, Serbia, [4]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia, [5]Seven Bridges Genomics, Belgrade, Serbia, Belgrade, Serbia

Background: The existence of age-specific differences in the genetic mechanisms of myeloid leukemogenesis has long been observed and has been the subject of numerous studies. However, only the introduction of new NGS technology has allowed us to obtain, in a relative simple manner, a large amounts of mutation data.
Aims: The aim of this study was to facilitate our understanding of the similarities and differences in molecular pathogenesis between cAML and aAML by application of parallel targeted NGS technology.
Methods: We analyzed DNA isolated from the bone marrow mononuclear cells from 20 childhood (cAML) and 20 adult AML (aAML) unselected patients, using TruSeq Cancer Panel with the MiSeq platform (Illumina) for the detection of somatic mutations, consisting of 212 amplicons targeting mutational hotspots in 48 cancer-related genes. Filtering and variant calling were performed using GATK UnifiedGenotyper and VariantFiltration tools. Resulting data were mapped against human genome b37. The average coverage of high-quality sequences was 2981 × per amplicon. Nine genes were discarded due to insufficient coverage, therefore a total of 188 amplicons from 39 genes was used for subsequent analysis. FLT3/ITD and IDH2 mutations were screened using PCR followed by direct sequencing.
Results: We identified 939 (467 cAML, 472 aAML) different mutations in both coding and non-coding targeted regions, with substantial variation from patient to patient. A total of 527 (260 cAML, 267 aAML) mutations in the non-coding regions and 412 (207 cAML, 205 aAML) mutations in the coding regions was detected, out of which only 122 (62 cAML, ranging from 0 –7 mutations per patient; and 60 aAML, ranging from 1 –5 mutations per patient) were potentially protein-changing, *i.e.* nonsense (N), frameshift (F) and missense (M) mutations. Seven genes were found to have more than 5 NFM mutations, namely *NRAS*, *KIT*, *KDR*, *NPM1*, *MET*, *FLT3*, and *TP53*. Out of these, *TP53* and *KDR* were found to have more than 20 mutations in over 50% of AML patients. Finally, the number of patients who harbored at least one mutation in *TP53* gene was 17 of 20 in cAML and 19 of 20 in aAML. As expected, the prevalence of the most AML associated mutations including *FLT3/ITD*, *NPM1*, *IDH1* and *IDH2* gene, differed in cAML and aAML patient cohorts. *IDH1* (0% cAML, 5% aAML), *IDH2* (0% cAML, 10% aAML), *NPM1* (10% cAML, 35% aAML), *FLT3/ITD* (0% cAML, 10% aAML). This discrepancy in prevalence in leukemia associated genes highlights the differences in the pathogenesis of cAML versus aAML at the genetic level.
Summary and Conclusions: Our results confirm that AML contains relatively small number of genetic alterations, suggesting that for the development of AML fewer genetic alterations are required than for other malignancies. In our study in which we used samples from unselected AML patients, we were not able to determine previously unknown prevalence of some gene alterations. Our results merely confirmed existing prevalence AML specific mutations in aAML. Many of them are well known (*FLT3*, *NPM1*, *CEBPA*) and their detection has already entered standard clinical practice. Given that AML is extremely heterogeneous in its clinical and genetic characteristics, more definite results regarding similarities and differences in pathogenesis of these two entities will be obtained in a parallel NGS analysis of the morphological and cytogenetic homogeneous groups of cAML and aAML patients.

E905

PROGNOSTIC SIGNIFICANCE OF CD34$^+$CD38$^{LOW/-}$CD123$^+$ LEUKEMIC STEM CELLS IN ACUTE LEUKEMIA - A PROSPECTIVE COHORT STUDY

P.K. Singh[1,*] R. Maiwall[2], R. Sharma[1], P.C. Misra[1], T. Seth[1], M. Mahapatra[1], R. Saxena[1]
[1]Hematology, All India Institute of Medical Sciences, [2]Hepatology, Institute of Liver and Biliary Sciences, New Delhi, India

Background: It is believed that acute leukemia arises from stem cells called Leukemic Stem Cells (LSC) and they are usually resistant to chemotherapy. These are also implicated in relapse of the disease. They can easily be quantified by flow cytometry by the presence of CD34$^+$CD38$^{low/-}$CD123$^+$ clone.
Aims: To study the prognostic significance of CD34$^+$CD38$^{low/-}$CD123$^+$ leukemic stem cells in terms of response to induction therapy and survival at induction.
Methods: Prospective single-centre cohort study which included 76 patients of acute leukemia. Bone marrow samples at diagnosis were analysed by flow cytometry to quantify the LSC clone. Patients of both ALL and AML were given the usual induction chemotherapy. Response was assessed by peripheral blood blast clearance, interim bone marrow blast assessment, CR (complete remission) status and survival at induction.
Results: All enrolled patients of acute leukemia were followed during the induction chemotherapy phase. Of these 43% were ALL (median age 23 years; 70% males) and 57% were AML (median age 32 years; 61% males). Fever (97%) and anemia (97%) were the major symptoms followed by bleeding (40%). Amongst the clinical signs presence of lymphadenopathy (40% versus 5%; p<0.001), hepatomegaly (64% versus 12%; p<0.001) as well as splenomegaly (64% versus 12%; p<0.001) were more commonly seen in patients with ALL as compared to AML. Leucocyte counts at baseline and blasts in the peripheral blood were also higher in the ALL group compared to AML group (median of 29,000/mm^3 versus 8900/mm^3; p=0.06). Mortality was significantly more in the AML group as compared to ALL group (49% versus 24%; p=0.03). There was a significant correlation of LSC clone size with ALL type (p=0.002, r^2=0.512), blast clearance (p=0.02, r^2=0.397) and day 7 BM blasts (p=0.01, r^2=0.557). B-ALL had significantly higher LSC clone size compared to T-ALL (5.2 versus 0.004; p=0.002). In patients with ALL, higher LSC clone size was significantly associated with delayed blast clearance in peripheral blood (p=0.02) and less number of patients having M2 or M3 bone marrow (p=0.013). Patients with high LSC clone had higher days of peripheral blood blast clearance and had lesser number of patients clearing blast within 5 days. Similarly, in patients with AML, there was a significant correlation of LSC clone size with AML cytogenetics risk group (p=0.02; r^2=0.352), blast clearance (p=0.03; r^2=0.328) and mortality (p=0.002; r^2=0.452). High risk AML had higher percentage of LSC clone. Patients with high LSC clone had not only delayed clearance of blasts in the peripheral blood (P=0.03) but also higher risk of death (P=0.002).
Summary and Conclusions: Both ALL and AML had presence of LSC clone expressed as CD34$^+$CD38$^{low/-}$CD123$^+$ leukemic stem cells. Presence of high LSC clone is associated with poor blast clearance in peripheral blood and bone marrow and poor survival in patients with acute leukemia

E906

COOPERATIVE MUTATION STUDY IN KOREAN PATIENTS WITH MLL-REARRANGED ACUTE MYELOID LEUKEMIA USING TARGETED NEXT GENERATION SEQUENCING

S.Y. Kim[1,2,*] J.J. Yang[3], T.S. Park[3], W.I. Lee[3], E.H. Cho[4], C. Meyer[5], R. Marschalek[5], S.T. Lee[6], H.J. Kim[6], S.H. Kim[6], Y.U. Cho[7], S. Jang[7], C.J. Park[7]
[1]LabGenomics, Seongnam, [2]Department of Medicine, Graduate School, Kyung Hee University, [3]Department of Laboratory Medicine, School of Medicine, Kyung Hee University, Seoul, [4]Green Cross Genome, Yongin, Korea, Republic Of, [5]Institure of Pharmaceutical Biology, ZAFES, Diagnostic Center of Acute Leukemia, Goethe-University of Frankfurt, Frankfurt, Germany, [6]Department of Laboratory Medicine and Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, [7]Department of Laboratory Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of

Background: Recent advancements of technologies including next generation sequencing (NGS) have led to discovery of molecular pathogenesis of malignant diseases of hematological malignancies, and these discoveries are now enabling the beginning of molecular targeted therapy. The *MLL*-rearranged fusion gene is among the main leukemogenic mutations which is found in both acute myeloid leukemia (AML) and acute lymphoblastic leukemia with a frequency of about 5-10%, and is associated with a poor clinical prognosis. Systematic studies analyzing cooperative genetic events of *MLL*-rearranged leukemia based on NGS technology has mainly been conducted in western populations, and has not yet been carried out in Asian ethnicity, such as the Korean population.
Aims: The aims of this study are to evaluate the cooperative mutation profiles of Korean *MLL*-rearranged acute myeloid leukemia patients using targeted next generation sequencing and to determine the ethnic difference of molecular basis of AML.
Methods: This study includes total of 24 *MLL*-rearranged AML patients who visited two separate tertiary care hospitals between the period of January 2009 and May 2014. The patient group included twelve men and twelve women (M:F=12:12), and also twelve children and twelve adult patients (A:C=12:12). The number of each *MLL* fusion genes are as follows; *MLL/MLLT3* n=12; *MLL/MLLT4* n=6; *MLL/ELL* n=2; other *MLL* fusion genes n=4. Mutation profile study for 19 candidate genes for cooperative mutation (*TET2, DNMT3A, IDH1, IDH2, NPM1, FLT3, CEBPA, ASXL1, BRAF, CBL, KIT, KRAS, NRAS, PTPN11, RUNX1, TP53, WT1, SETD2, JAK2*) was carried out using a MiSeq sequencer (Illumina, San Diego, CA).
Results: Among the twenty-four *MLL*-rearranged patients, 17 patients had no additional mutations (~70%) found. Only 7 patients (29.2%) had positive results for more than 1 gene mutations which were analyzed for (Table 2). Positive gene mutations found were in order of their frequency; *ASXL1* (n=4), *FLT3* (n=2), *CEBPA* (n=2), *KRAS* (n=1), *NRAS* (n=1) and *PTPN11* (n=1). Interestingly, 4 out of 6 patients harboring *MLL/MLLT4* were found to have additional gene mutations. Two patients had multiple gene mutations while one patient had four concurrently detected gene mutations (Table).

Tabella 1. Results of detected cooperative mutations by targeted sequencing in this study.

Patient	RT PCR	NGS	Chromosome	Exon	Position	reference>variant	mutation

Abbreviations: RT-PCR, reverse transcriptase polymerase chain reaction; NGS, next generation sequencing;

Summary and Conclusions: This is the first cooperative mutation study on *MLL*-rearranged AML patients of Asian ethnicity using targeted NGS technology. Small number of cases was a limitation in assuming the general mutational spectrum of the representing population, however a higher incidence of gene mutation among *MLL/MLLT4* patient group (4/6) and relatively higher incidence of *ASXL1* mutation (4/24) being found could be carefully suspected as an ethnical difference in molecular basis of AML. Further study requires a larger number of *MLL*-rearranged *MLL* patients of equal ethnicity and additional mutation profile study with ethnical comparison.

E907

ASSOCIATION BETWEEN CD117 (C-KIT) AND CD135 (FLT3) RECEPTOR TYROSINE KINASES AND MUTATIONAL STATUS AND CLINICAL FEATURES IN ADULT AML PATIENTS UNDER 60 YEARS

S. Bellesi[1,*] F. Corrente[1], E. Metafuni[1], P.L. Puggioni[1], A.M. Ciminello[1], F. D'Alò[1], D.G. De Ritis[1], S. Giammarco[1], L. Laurenti[1], F. Sorà[1], S. Sica[1], V. De Stefano[1], P. Chiusolo[1]

[1]Hematology, Policlinico A. Gemelli UCSC, Rome, Italy

Background: Proliferation is one of the mechanism for AML pathogenesis. Receptor Tyrosine Kinases have significant contribution in leukemogenesis because of their proliferative role. For this reason we have evaluated CD117 (c-kit receptor) and CD135 (FLT3 receptor) in the setting of AML.
Aims: The purpose of this study was to investigate the association between CD117 and CD135 expressions and FLT3-ITD, NPM1 mutations and clinical features.
Methods: Percentages of expression and Median Fluorescence Intensity (MFI) of CD117 and CD135, tagged with phycoerythrin (PE), were obtained from flow-cytometric AML definition panels acquired on FACSCanto cytometer using BDFACSCanto software. Levels of NMP1 mutation (NPM1m) and internal tandem duplications of FLT3 (FLT3-ITD) were quantified in a RT-PCR assay. Comparison between two groups were performed using the Mann–Whitney *U* (MWW) and Chi-square tests (CSQ) or Fisher exact test (FET) for continuous and dichotomic variables, respectively; for comparison among different groups Kruskal Wallis test (KW) was performed. Measure of association was expressed by Odds Ratio (OR). Cut-off value for the marker was selected using receiver operating curves (ROC). P values lower than 0.05 were considered statistically significant (SPSS 15.0 version).
Results: 106 AML patients (pts) under 60 years with median age of 48 ys (range 15-65; M/F 62/44), diagnosed in our lab from 2007 to 2015, were included in this study. The incidence of FLT3-ITD and NPM1m was 28.9% and 42.0%, respectively. Double FLT3-ITD/NPM1m was present in 18.8% of cases. Pts with FLT3-ITD had higher median WBC (36.4 *vs* 10.5 x 10^9/L, MWW, P=0.004), median percentage of bone marrow blasts (80% *vs* 43%, MWW, P <0.001), peripheral blood blasts (72% *vs* 29%, MWW, P <0.001) and median LDH value (761 *vs* 401 UI/L, MWW, P=0.010) than in FLT3 wild type (FLT3wt) pts. FLT3-ITD cases showed a greater median percentage of CD135 expression (86% *vs* 65%, MWW, P=0.009) than counterpart. NPM1m pts did not exhibit significant differences in clinical features, but showed a lower expression of CD117, both in percentage (61% *vs* 88%, MWW, P=0.001) and MFI (298 *vs* 1458, MWW, P <0.001). By calculating ROC, a MFI cut off value of 1125 provided a best sensitivity (89%) and specificity (63%). Higher median MFI of CD117 were present in FAB M0 (1189), M1 (832), M2 (986) and lower in FAB M4 (394) and M5 (89) (KW, P=0.044). The association between CD117 expression (categorized by ROC) and FAB M5 (FET, P=0.046) showed an OR of 0.14 (95% CI from 0.02 to 0.97) No differences were observed for CD135 expression levels in FAB subtypes. The favorable NPM1m/FLT3wt status (48% of all NPM1m) was associated with FAB M5 (FET, P=0.011), with an OR of 8.33 (95% CI from 1.68 to 41.29). Adverse FLT3-ITD/NPM1 wild type (12% of all FLT3-ITD) correlated with FAB M0 (FET, P=0.006) with an OR of 31.8 (95% CI from 2.77 to 365.53). Any association was found between double NPM1m/FLT3-ITD status and FAB subtypes. Pts with refractory AML were associated with an higher level of CD117 expression (categorized by ROC) (CSQ, P=0.003, OR 4.47, CI 95% from 1.57 to 12.72) and an adverse FLT3-ITD/NPM1wt status (FET, P=0.042, OR 5.87, CI 95% from 1.13 to 30.45).
Summary and Conclusions: High percentage of CD135 expression in pts with the adverse FLT3-ITD status and high level of CD117 expression in refractory AML pts suggested a possible role of this combination for a bad prognosis. In opposite, the strong correlation of CD117 low expression with the presence of the favorable NPM1m can be predictive of a good prognosis.

E908

ROLE OF DNMT3A MUTATIONS IN INTERMEDIATE-RISK ACUTE MYELOID LEUKEMIA PATIENTS: ASSOCIATION WITH PROGNOSIS AND TREATMENT STRATEGIES

M.I. Prieto-Conde[1,*] M. Alcoceba[1], C. Jiménez[1], M. García-Álvarez[1], M.E. Sarasquete[1], A. Balanzategui[1], M. Hernández-Ruano[1], E. Sebastián[1], R. Corral[1], L. Marín[1], F. Ramos[2], P. Giraldo[3], A. Bárez[4], N. C. Gutiérrez[1], R. García-Sanz[1], M.C. Chillón[**1], M. González-Díaz[**1]

[1]Hematology Department, University Hospital of Salamanca-IBSAL, Salamanca, [2]Hematology Department, Hospital de León and Ibiomed, Universidad de León, León, [3]Hematology Department, Hospital Miguel Servet, Zaragoza, [4]Hematology Department, Hospital Nuestra Señora de Sonsoles, Ávila, Spain

Background: Mutations impacting epigenetic mechanisms, such as *DNMT3A* mutations, are recurrent in acute myeloid leukemia with intermediate-risk karyotype (AML-IR), although their prognostic value remains unclear. The prospective determination of *DNMT3A* mutations may provide an important step forward individualized therapies using hypomethylating agents or high-dose daunorubicin. However, the clinical benefit of allogeneic stem cell transplantation (HSCT) has not been established.
Aims: 1) To evaluate the incidence of *DNMT3A* mutations, their prognostic impact as well as the interaction with other molecular markers in AML-IR patients; 2) To determine if allogeneic HSCT in first remission improves the outcome of patients with somatic mutations in the *DNMT3A* gene.
Methods: A cohort of 74 patients with AML-IR (median age 54 years) (PETHE-

MA AML-99-2010). Analyses of *DNMT3A* mutations (exons 10 to 23) were characterized by direct sequencing in diagnostic bone marrow (BM) samples. Sixty-four patients achieved complete remission (CR) and 30 of them underwent an allogeneic bone marrow HSCT.
Results: Of the 74 patients included in this study, 31% (23/74) had mutations in *DNMT3A* (78% had R882 mutations and 22% other missense mutations). *DNMT3A* mutations were frequently detected in *FLT3*-ITD mutated patients (48% vs. 19%, p=0,013). No significant differences were found in both groups with regard to age, WBC counts or BM blast percentages. The median follow-up time was 543 days (range, 20-2678). AML-IR patients with *DNMT3A* mutations had shorter overall survival (OS) (36% vs. 54%, p=0,024) and relapse-free survival (RFS) (23% vs. 53%, p=0,018) at 5 years than the non-mutated subgroup. These differences were more evident when older patients (>65 y.) were excluded (RFS: 15% vs. 55%, p=0,005) or only *DNMT3A* R882 mutations were considered (RFS: 20% vs. 54%, p=0,012). In multivariate analysis, *DNMT3A* R882 mutations (p=0.039) were independent factors for shorter OS, and only *FLT3*-ITD mutations (p=0.004) had a negative prognostic impact on RFS. We next examined the relapse risk after allogeneic HSCT in first CR in order to elucidate if poor outcome of *DNMT3A*mutations was overcome. Again, *DNMT*3A mutations identified a population of patients with substantially shortened RFS at 5 years (37% vs. 70%, p=0,020).
Summary and Conclusions: Mutations in *DNMT3A*, especially R882 mutations, identify a subgroup with poor prognosis in the intermediate-risk group. Although based on small numbers of patients, these data suggests that mutations in *DNMT3A* identify a significant fraction of HSCT recipients with poor survival, for whom alternatives to standard transplantation options should be considered. **Equal senior contribution. FINANCIAL SUPPORT: Grants PI12/02321 from the Instituto de Salud Carlos III, BIO/SA44/14 from the Consejería de Sanidad (JCYL), RD12/0036/0069 and Asociación Española Contra el Cáncer (AECC).

ACUTE MYELOID LEUKEMIA DISEASE MODELING VIA RNA-GUIDED CRISPR–CAS9 SYSTEM INDUCED SOMATIC MUTATIONS

O. Brabetz[1,*] L. Angenendt[1], W.E. Berdel[1], M.F. Arteaga[1], J.H. Mikesch[1]
[1]University of Münster, Münster, Germany

Background: Acute myeloid leukemia (AML) is a genetically heterogeneous clonal disorder characterized by the accumulation of acquired somatic genetic alterations in hematopoietic progenitor cells that alter normal mechanisms of self-renewal, proliferation and differentiation. In the majority of AML patients chromosomal aberrations and/or gene mutations that are involved in disease development are detectable in the leukemic blasts. Disease models (incl. retroviral/lentiviral overexpression, transgene mouse models etc.) have largely contributed to reveal key mechanisms of AML leukemogenesis and progression. However, the current models face severe limitations since most of them induce unphysiological gene expression and depend on external promoters for regulation of gene expression/repression. Moreover, a significant proportion of AMLs is based on gene mutations rather than chromosomal rearrangements or up/down regulation of gene expression levels.
Aims: We sought out to develop a new effective methodology to reproduce precise leukemia associated mutations required for improved disease modeling and to gain insight into AML development. IDH2 mutations that occur frequently in AML and are related with poor prognosis for the patients were chosen for acute myeloid leukemia cell genome editing.
Methods: Using the clustered, regularly interspaced, short palindromic repeats (CRISPR)/Cas9 system we induced specific DNA double strand breaks in the IDH2 gene of K562 myeloid leukemia cells and introduced IDH2 R140Q point mutation via homologous recombination introducing a specific DNA template. Thus, integrated IDH2 R140Q mutation was regulated by the endogenous IDH2 gene promoter.
Results: Correct insertion of the mutation was confirmed performing targeted integration PCR as well as genomic DNA sequencing. K562 cells carrying IDH2 R140Q mutation showed significantly enhanced *in vitro* cell proliferation and colony forming capacity as compared with controls carrying wt IDH2 introduced analogously. *in vivo* studies in NSG mouse model are currently underway to confirm differences in human leukemia development upon introduction of IDH2 mutation in leukemia cells.
Summary and Conclusions: Our data present a new strategy for generating leukemia-related gene mutations at defined positions and under endogenous gene promoters. Using this approach for leukemic cells as well as normal hematopoietic progenitor cells will provide a promising new methodology for leukemia disease modeling.

E910

VSTM-V1 IS A POTENTIAL MYELOID DIFFERENTIATION ANTIGEN GENE THAT IS DOWNREGULATED IN BONE MARROW CELLS FROM PATIENTS WITH MYELOID LEUKEMIA

J. Zhou[1,*] M. Xie[1], T. Li[2], N. Li[1], J.L. Li[1], Q.M. Yao[1], W.L. Han[2], G.R. Ruan[1]
[1]Peking University People's Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [2]Peking University Center for Human Disease Genomics, Department of Immunology, Key Laboratory of Medical Immunology, Ministry of Health, School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China

Background: Myeloid leukemia is a myeloid blood cell malignancy that shows great heterogeneity. Leukocyte differentiation antigens often represent important markers for the diagnosis, classification, prognosis and therapeutic targeting of these malignancies. To find novel leukocyte differentiation antigens, we used an immunogenomics approach and VSTM1 (V-set and transmembrane domain containing 1) was selected as a candidate.
Aims: To find novel leukocyte differentiation antigens and new targets for the diagnosis and treatment of leukemia.
Methods: VSTM1 expression in cell lines, bone marrow samples from healthy donors and myeloid leukemia patients were analyzed by qRT-PCR, western blotting and flow cytometry. The promoter methylation of VSTM1 was assessed by methylation-specific PCR (MSP) and bisulfite genomic sequencing (BGS). All-trans retinoic acid (ATRA) was used to induce APL cell line NB4 and bone marrow cells from APL patients to investigate the relationship between VSTM1 expression and cell differentiation *in vitro*. To explore the effect of VSTM1-v1 on leukemic cell growth, VSTM1-v1 was overexpressed in K562 and MEG-01 cells and performed viable cell counting assays. Additionally, it was tested for correlations between VSTM1 expression and patient characteristics.
Results: Herein, we report that the expression level of VSTM1 is downregulated by qRT-PCR in bone marrow cells from leukemia patients (Table 1) and showed a high degree of promoter methylation. The predominant splice variant encoded by the gene, VSTM1-v1, encodes an ITIM-bearing type I membrane molecule. By flow cytometry, we could divide bone marrow cells into subpopulations by immunophenotyping and showed that VSTM1-v1 expression levels were positively correlated with the maturation state of the myeloid cells (Table 2). Additionally, *in vitro* ATRA treatment could restore VSTM1-v1 expression in both bone marrow cells from APL patients and NB4 cells. The overexpression of VSTM1-v1 in K562 or MEG-01 leukemia cells led to an inhibitory effect on cell growth. When analyzing correlations between VSTM1 expression and the clinical features of AML patients, we detected a higher expression level of VSTM1 in the AML1-ETO-positive group.

Tabella 1. The expression level of VSTM1 in bone marrow cells from leukemia patients and healthy donors.

Groups	MIC[a]	Sample size	Mean ratio, *VSTM1/ABL*	*P*-value[b]
HD[c]		36	17.358±17.904	
Untreated-AML		145	4.333±7.895	<0.001
	M1	3	0.374±0.619	n.a.[d]
	M2	72	5.292±10.171	<0.001
	M3	29	2.884±3.960	<0.001
	M4	24	4.814±5.293	0.001
	M5	14	3.052±4.867	<0.001
	M6	3	1.417±2.205	n.a.[e]
Untreated-ALL[d]		40	0.381±0.755	<0.001
Untreated-CML		57	5.479±8.266	<0.001
	CP	38	7.743±9.312	0.001
	AP/BC	19	0.950±1.367	<0.001

[a] MIC denotes morphological, immunological and cytogenetic classifications.
[b] The P-value was calculated using Wilcoxon signed ranks test as compared to the HD grou
[c] HD denotes healthy donors.
[d] ALL denotes acute lymphoic leukemia patients.
[e] n.a. indicates not available due to a small sample size.

Table 2. The expression of VSTM1-v1 at various stages of myelocytic differentiation.

	Myeloblasts	Promyelocytes	Myelocytes	Metamylocytes
CD markers	CD34+	CD34-CD117+CD16-	CD34-CD117-CD16-CD13+	CD16+
VSTM1-v1-positive cells (%)	5.69±2.69	11.48±4.58	35.02±11.58	61.63±8.53
P-valuea	<0.001	<0.001	<0.001	

[a] *The P-value was calculated using Wilcoxon signed ranks test as compared with the next stage.*
Summary and Conclusions: VSTM1-v1 could represent an important myeloid leukocyte differentiation antigen and might provide a potential target for the diagnosis and treatment of leukemia.

E911

THE PI3K GAMMA/DELTA INHIBITOR, IPI-145 (DUVELISIB) INHIBITS ACUTE MYELOID LEUKEMIA BLAST PROLIFERATION AND ADHESION

G. Pillinger[1,*] R. Piddock[1], M. Lawes[2], S. Rushworth[1], K. Bowles[1,2]
[1]Molecular Hematology, University of East Anglia, [2]Hematology, Norfolk and Norwich University Hospital Trust, Norwich, United Kingdom

Background: A number of non-receptor tyrosine kinases have been identified as functionally important in the biology of acute myeloid leukemia including protein kinase B (AKT), phosphatidylinositol 3-kinase (PI3K), signal transducer and activator of transcription 5 (STAT5), mitogen-activated protein kinase (MAPK) and Bruton's tyrosine kinase (BTK), have all been shown to be constitutively activated in AML. Tyrosine kinase inhibition is clinically effective and well tolerated in chronic myeloid leukemia, chronic lymphocytic leukemia and mantle cell lymphoma. Inhibition of selected tyrosine kinases seems an attractive strategy to assess in AML. PI3K is an enzyme group that generates phosphatidylinositol 3, 4, 5-triphosphate which provides membrane docking site for the tyrosine kinase AKT. AKT itself is responsible for activation of the mammalian target of rampamycin (mTOR) pathway which plays an essential role in the growth of malignant cells, stimulating glycolysis, driving cells to consume glucose and promoting cell survival and cell-cycle progression. PI3K is known to be constitutionally active in patients with AML. Recently PI3K/mTOR inhibition has been shown to delay tumor progression, reduce tumor load and prolong survival in MLL-AF9$^+$/FLT3-ITD$^+$xenograft mouse models. PI3K has different isoforms, α β δ and γ.
Aims: To determine the functional effects of PI3K δ/γ inhibition on AML signalling, survival and adhesion.
Methods: To investigate the role of PI3K p110δ and p110γ isoforms in the regulation of AML survival, proliferation, migration and adhesion we inhibited PI3K using different doses of IPI-145 (Duvelisib) (δ/γ inhibitor), CAL-101 (Idelalisib) (δ inhibitor), and LY294002 (pan PI3K inhibitor). We used AML cell lines and AML primary cells as well as primary bone marrow stromal cells derived from AML patients to determine the role of PI3K inhibition in AML proliferation and adhesion. We assessed survival using CellTiter-Glo and adhesion by Calcein AM staining of AML cultured on fibronectin or bone marrow stromal cell (BMSC) coated plates. Western blot analysis was used to assess phosphoAKT and phosphoMAPK expression. The concentration range of IPI-145 used covers the plasma steady-state concentration of 0.9uM for patient treated at a dose of 25mg twice a day.
Results: PI3K inhibition with IPI-145, CAL-101 and LY294002 inhibited proliferation in 5/6 AML cell lines. We also observed similar anti-proliferative activity in primary AML cells. Furthermore, we show that inhibition of PI3K with IPI-145, CAL-101 and LY294002 results in a decrease in the activity of phospho-AKT, but has no effect of the activity of phosphoMAPK, indicating that MAPK is activated via a separate signalling pathway. Finally we report that pre-treatment of AML cells with IPI-145 inhibits adhesion of both AML cell lines and primary AML cells to primary BMSC at nanomolar concentrations.
Summary and Conclusions: Here we report that IPI-145 (Duvelisib) inhibits AML proliferation and adhesion through effects on downstream survival signals including inhibition of AKT phosphorylation at concentrations achievable in patients. Our results provide biological rationale for further evaluation of PI3K δ/γ inhibitors in AML.

E912

IDENTIFICATION OF CYTOGENETIC AND MOLECULAR SUBGROUPS OF ACUTE MYELOID LEUKEMIAS SHOWING L-ASPARAGINASE IN VITRO SENSITIVITY

S.N. Bertuccio[1,*] S. Serravalle[1], A. Astolfi[1,2], A. Pession[1], F. Melchionda[1]
[1]Pediatric Hematology and Oncology, O.U. Pediatrics, S.Orsola-Malpighi Hospital Univeristy of Bologna, [2]Giorgio Prodi Cancer Center, University of Bologna, Bologna, Italy

Background: L-Asparaginase catalyzes the hydrolysis of L-Asparagine to L-aspartic acid and ammonia and sustains reduction in serum asparagine, which is required for rapid proliferation of leukemic cells. The gene coding for L-Asparagine synthetase (*ASNS*) is located in 7q21.3 and its increased expression is correlated with resistance to L-Asparaginase in Acute Lymphoblastic Leukemia (ALL). Monosomy of Chromosome 7, or partial deletion involving its long arm [del(7q)], are recurrent aberrations in myeloid disorders, and it was shown that these events lead to a significant down-regulation of the genes located in the deleted regions, including *ASNS*. Moreover, methylation of CpG islands in the promoter region is one of the epigenetic mechanisms for silencing of genes, and some studies demonstrate that *ASNS* gene is often methylated in ALL cells, thus explaining why ALL cells may be sensitive to L-Asparaginase.
Aims: The aim of the study is to analyze the *in vitro* sensitivity to L-Asparaginase of human AML cell lines with different *ASNS* gene expression levels and to identify cytogenetic and/or molecular events involved in the *in vitro* response to L-Asparaginase. In particular this study investigates if the cytogenetic status of chromosome 7q or, more generally the expression level of *ASNS* gene, could predict the efficacy of L-Asparaginase in Acute Myeloid Leukemia.
Methods: FISH (Fluorescent *in situ* Hybridization) of Chromosome 7 was performed with specific probes D7S522/CEP7 (Abbott Molecular) located at chromosome 7q31 and 7p11.1-q11.1. In order to measure drug sensitivity we used the WST-1 assay (Roche Applied Science, Monza, IT), testing eight concentrations of L-Asparaginase (Erwinia chrysanthemi, Jazz Pharmaceuticals). The expression level of *ASNS* gene was evaluated with quantitative RT-PCR (Roche LightCycler 480 instrument). For methylation analysis DNA was modified with bisulfite, amplified by PCR and sequenced with specific primers.
Results: FISH analysis identified 3 out of 10 AML cell lines displaying Chr 7monosomy (UCSD, FKH-1, OCI-AML6). AML cell Lines carrying Chr 7 monosomy were more sensitive than the other AML cell lines to L-Asparaginase, with P value <0.01 (Figure A, B). Moreover AML cell lines with Chr 7 monosomy showed a statistically significant lower expression of ASNS gene when compared to the other AML cell lines. The four ALL cell lines (DND41, HPB-ALL, MOLT-4 and RPMI-8402) displaying by WST-1 assay the highest sensitivity to the drug, also showed a lower expression of *ASNS* gene with respect to the other three ALL cell lines, that however did not display Chr. 7 abnormalities. We therefore analyzed the methylation status of the promoter region of *ASNS* gene, as an alternative mechanism for gene silencing. ALL cell lines DND41, HPB-ALL, MOLT-4 and RPMI-8402, that had a low expression of *ASNS* gene indeed show hyper-methylation of the *ASNS* gene promoter region. On the contrary none of the AML cell lines showed hyper-methylation of the *ASNS* gene.

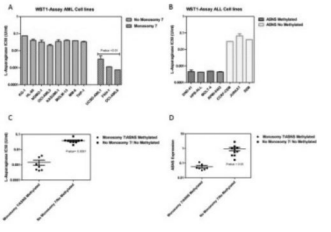

Figure 1.

Summary and Conclusions: The low expression of *ASNS* gene, found in AML cell lines carrying Chr 7 monosomy and in ALL cell lines with hyper-methylation of *ASNS* CpG island, significantly correlates with higher sensitivity to L-Asparaginase *in vitro* (Figure C, D). The study was supported by a research grant from EUSAPHARMA (Europe) Ltd.

E913

AZACITIDINE FOR THE TREATMENT OF MDS, AML AND CMML: THE SOUTH WALES (UK) EXPERIENCE

A.J. Mahdi[1,*] J. George[1], G.A. Pitchers[1], R. Al-meshhedani[1], E.M. Bretherton[1], S. Seppings[1], R. Jones[1], S. Al-Ismail[1], U. Mohite[1]
[1]ABM University Health Board, Swansea, United Kingdom

Background: The management of elderly patients with myelodysplastic syndrome (MDS) and Acute Myeloid leukaemia (AML) poses significant challenge to the haematologist. Azacitidine (AZA) is a first-in–class hypomethylating agent with activity in MDS and has shown significantly improvement in survival compared with conventional care regimens. AZA was approved by the UK regulatory body, the National Institute for Clinical Excellence (NICE) in 2011. Approval was granted in non-transplant eligible patients with AML with 20-30% marrow blasts, CMML with 10-29% marrow blasts and intermediate-2/ high risk MDS.
Aims: We report the results of the treatment with AZA at our centre in patients with MDS, AML and CMML in a "real life" setting. We investigate the characteristics and outcome of patients receiving AZA including tolerability, efficacy and overall survival.
Methods: We conducted a retrospective analysis of patients receiving AZA between 1st Jan 2011 to 31st Dec 2014 over 4 year period from three hospitals in South Wales, UK within the Abertawe Bro Morgannwg University Health Board (ABM UHB). Patients were included if they received one cycle of AZA. Patients were identified from our electronic prescribing system (Chemocare) and correlated with clinical notes. Disease status was defined by the World Health Organisation (WHO) classification system. Patients with MDS were risk stratified using the IPSS-R. Statistical analysis was conducted using SPSS. Overall survival (OS) was estimated using Kaplan-Meier estimates.
Results: A total of 90 patients with AML and MDS were treated in ABM UHB. Out of this 26 patients received AZA representing 28% of all patients with MDS and AML. A median age 73.9 years (range 66-84 years) was observed. Median follow up was 12.2 months (2-36 months). A male predominance (73.1%) and a range of indications were seen (MDS n=14, 54 %; AML n=9, 35%; CMML n=3, 11%). AZA was used outside NICE indications in 3 (11%) cases. AZA was used as first line therapy in 17 cases (65%) and beyond second line therapy in 9 cases (35%). Out of those receiving 2nd line therapies, 3 (11%) had received previous high dose therapy, 4 (15%) previous low dose therapy and 2 (7%) were on only transfusion support. The median number of cycles received was 6.9 (range 1-26). Most patients tolerated AZA well. Grade I-2 skin toxicity was observed in 9 patients (34%). Grade 1-2 gastrointestinal was common but did

not prompt discontinuation of AZA treatment. At least one hospital admission was required in 9 patients (35%) during treatment. Overall response including stable disease was achieved in 17 patients (65%) out of which complete remission was achieved in 7 patients (26%) and cytogenetic remission in 2 cases (8%). At present 7 patients (26%) are alive and continuing on AZA therapy. Median overall survival (OS) was 8 months. No difference was observed between disease (p=0.92) and IPSS-R classification in MDS patients (p=0.806). Patients receiving >6 cycles (n=14, 54%) obtained transfusion independence and blood count responses with significantly improved overall survival (5 months vs. 20 months, p=0.001).
Summary and Conclusions: AZA is well tolerated and deliverable in our institution. Patients receiving >6 cycles were most likely to achieve transfusion independent, improvement in blood counts and have improved median OS comparable to published data. Persistence with AZA is therefore vital to obtaining a response.

MIRNA SIGNATURES ASSOCIATED WITH MOLECULAR MARKERS IN ACUTE MYELOID LEUKEMIA
M. Llop[1,*] F. Lluch[1], C. Alonso[1], M. Ibáñez[1], E. Such[1], I. Gómez[1], M. López[1], J. Cervera[1], S. Palanca[1], I. de Juan[1], R. Murria[1], P. Bolufer[1], M.Á. Sanz[1], E. Barragán[1]
[1]Hospital La Fe, Valencia, Spain

Background: Genomic characterization of normal karyotype acute myeloid leukaemia (NK-AML) has provided in the last years novel molecular markers (such as DNMT3A, IDH1/2 or TET2) that help refine classification and risk assessment. miRNA profiling can also define new biological subtypes and therefore it could complement NK-AML diagnosis and risk stratification.
Aims: Our aim is to identify a miRNA profile in NK-AML, to find miRNA signatures associated with established molecular markers (FLT3, NPM1, DNMT3A and CEBPA), and to determine whether altered miRNA expression has prognostic value in NK-AML.

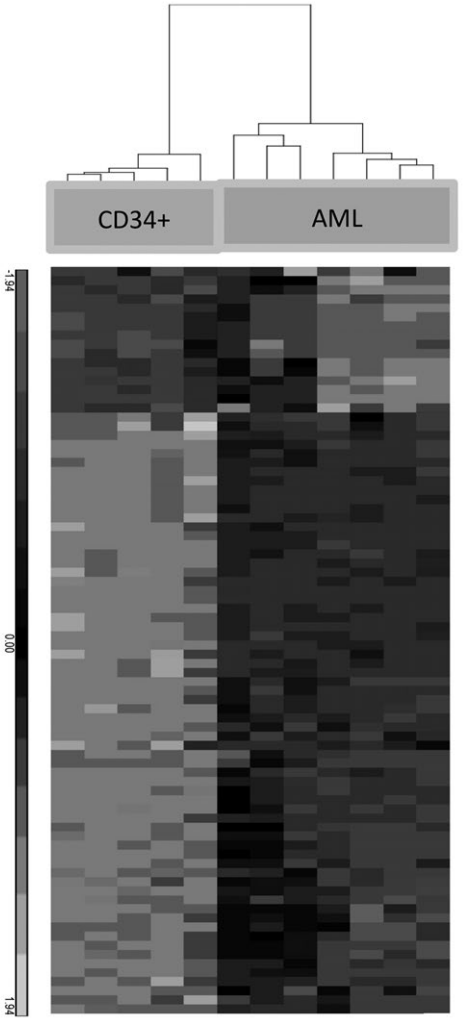

Figure 1.

Methods: Five CD34+samples from cord blood obtained from healthy donors and 7 *de novo* NK-AML samples (>70% blast count, CD34+and no mutations in FLT3, NPM1, DNMT3A or CEBPA) were hybridized onto an array miRNA 3.0 chip (Affymetrix). Deregulated miRNAs in NK-AML were determined with a hierarchical cluster analysis set at 10-fold change (FC) and p<0.001. The most up- and down- regulated miRNAs were validated by qRT-PCR (miScript system) in a cohort of 60 NK-AMLs. Mann-Withney U-test was used to determine differentially expressed miRNAs according to molecular alterations
Results: We found a miRNA signature characterized by 6 up- and 61 downregulated mature miRNAs in NK-AML compared with CD34+controls (Figure 1). By y qRT-PCR we validated 9 miRNAs in a cohort of 60 samples. MiR-20b (p<0.001), miR-99a (p=0.006), miR-126 (p= 0.009), miR-146b and miR-151b (both p=0.012) were downregulated; and miR-4668 and miR-494 were upregulated (p=0.004 and 0.005, respectively). NPM1 and/or FLT3 mutations significantly reduced miR-126, miR-424 and miR-4668 expression. CEBPA and DNMT3a mutations did not modify any of the miRNAs expression. WT1 overexpression was accompanied by a significant reduction of miR-424 expression. We are currently increasing our patient series to establish the prognostic value of the altered miRNAs/miRNA profile. Interestingly, miR-126 (downregulated) targets PI3K (protooncogene), and miR-494 (upregulated) targets PTEN (turmor suppressor gene). These two genes catalyze opposite reactions in cell signalling pathways. We are currently analyzing the involvement of these two miRNAs in PI3K/PTEN expression regulation in NK-AML.
Summary and Conclusions: In conclusion, NK-AML has a defined miRNA profile that is altered by the presence of NPM1 and FLT3 mutations. miR-424 and miR-126 expression is altered in AML and they are predicted to target PTEN and PI3K, respectively, so these miRNAs could be modulating their function in NK-AML

VPA AND SAHA TREATMENT DIFFERENTIALLY IMPACT PROTEOME AND ACETYLOME OF ACUTE MYELOID LEUKEMIA HL60 CELLS
X. Zhu[1,*] X. Liu[2], J. Yan[1], Q. Wu[1], Z. Sun[1]
[1]Hematology, [2]ANHUI PROVINCIAL HOSPITAL, Hefei, China

Background: Valproate(VPA) and Suberoylanilide hydroxamic acid (SAHA) are both HDAC inhibitors. Previous studies indicated that both inhibitors showed therapeutic effects on acute myeloid leukemia(AML), while the differential impacts of the two different HDACi on AML treatment still remain elusive.
Aims: The aim of this study was to analyze the impact of VPA and SAHA treatment on histone lysine acetylation and proteome in AML HL60 cells and explore the differential impacts of the two different HDACi on AML treatment.
Methods: In AML HL60 cells, by using 3-plex stable isotope labeling for cell culture (SILAC)-based quantitative proteomics, biochemistry assay, and bioinformatic analysis, here we for the first time comprehensively identified and quantified proteome and acetylome profiling on AML HL60 cells in response to VPA or SAHA treatment.
Results: In total, we identified 5,775 proteins with 3,227 quantifiable proteins in AML HL60 cells in response to VPA or SAHA treatment. Taking advantages of anti-acetyllysine antibody based affinity enrichment followed by Nano-HPLC/MS/MS analysis, we identified 1124 Kac sites in 702 Kac proteins in response to VPA or SAHA treatment, among which 1,089 quantifiable Kac sites in 686 Kac substrates were screened. Intensive bioinformatic analysis clearly showed that VPA and SAHA treatment differently induced proteome and acetylome profiling in AML HL60 cells.
Summary and Conclusions: This study therefore for the first time revealed the differential impacts of VPA and SAHA on proteome/acetylome in AML cells, deepening our understanding of HDAC inhibitor mediated AML therapeutics.

PIVOTAL BIOMARKER ALTERATIONS IN CYTARABINE-RESISTANT ACUTE MYELOID LEUKEMIA CELL LINES
L.I. Lin[1], J.W. Lu[1,*] P.P. Lim[1], Y.L. Lai[1], C.Y. Chen[2], H.F. Tien[2]
[1]Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, [2]Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, ROC

Background: Cytarabine is the backbone of acute myeloid leukemia (AML) therapy. However, the majority of patients succumb to disease relapses. Although several reports tried to unveil the mechanisms of cytarabine resistance, such as diminished cytarabine import, increased cytarabine degradation, decreased formation of active metabolized form of cytarabine, these mechanisms failed to fully explain cytarabine resistance. Recent studies indicated that molecules of signal transduction and apoptosis may be involved.

Aims: To establish cytarabine-resistant leukemia cell lines, and further characterize the pivotal biomarker alterations, on which future treatment may be developed.
Methods: We established a resistant derivative of the human leukemic line MV4-11 by using stepwise dose-escalation method. The parental and resistant MV4-11 cells were named MV4-11-P and MV4-11-R, respectively. Further, pivotal biomarker alterations were characterized by using human phospho-kinase array, human apoptosis array, and human phospho-RTK array. Western blotting was used to confirm those changes. Sanger's sequencing and pyrosequenicng were used to study the mutation status of p53.
Results: MV4-11-P and MV4-11-R showed cytarabine IC_{50} of 0.26μM and 3.37μM, respectively. MV4-11-R cells also showed higher IC_{50} to idarubicin and CI-1040 (an MEK inhibitor). In contrast, they displayed no remarkable difference in response to MK-2206 (an allosteric AKT inhibitor), sorafenib (a multikinase inhibitor inhibits BRAF and VEGFR) and XL-184 (a multikinase inhibitor inhibits c-MET, VEGFR, and FLT-3). There were no detectable differences between MV4-11-P and MV4-11-R cells morphologically and immunophenotypically. By using human phospho-kinase array, there were significant differences between MV4-11-P and MV4-11-R cells in phosphorylated form of several molecules, such as increased phosphorylated ERK1/2 and p53, as well as decreased phosphorylated CREB. Slightly increased phosphorylation in MV4-11-R included p38, JNK, and Akt; on the contrary, slightly decreased phosphorylation of STAT5 was noted in MV4-11-R. By using human apoptosis array, substantial increased phosphorylation of p53 was found in MV4-11-R cells. In addition, slight increase in HSP27 was found; on the contrary, slight decrease in SMAC, survivin, TNF-R and XIAP were found in MV4-11-R cells. By using human phospho-RTK array, increased phosphorylation of EGFR, AXL, HGF-R, Tie-2 and Dtk were found in MV4-11-R cells; on the contrary, decreased phosphorylation was only found in VEGFR. Western blotting confirmed these changes. Exon sequencing revealed that a secondary p53 mutant (D281G) in MV4-11-R cells in addition to the pre-existing p53 mutant (R248W) of MV4-11-P cells. By using pyrosequencer analysis, no significant change of R248W burden was noted, but D281G emerged from 1% to 41%.
Summary and Conclusions: We established a cytarabine-resistance cell line MV4-11-R. This cell line possesses substantial higher phosphorylation of AKT, ERK, MEK, p53 and lower phosphorylation of CREB and STAT5. Of them, an emerging secondary p53 mutant (D281G) was noted. Further characterization of the biologic significance of these molecular alterations may lead to the development of novel therapeutics for AML.

E918

THE EXPRESSION OF THE DNA REPAIR GENE SETMAR IS HIGHLY CORRELATED TO THE LEVEL OF THE MINIMAL RESIDUAL DISEASE IN ACUTE MYELOID LEUKEMIA THROUGHOUT THE DISEASE

J.L. Jensen[1,*] H.B. Ommen[1], P. Hokland[1], C.G. Nyvold[1]
[1]HemoDiagnostic Laboratory, Aarhus University Hospital, Aarhus, Denmark

Background: Acute Myeloid Leukemia (AML) is characterized by accumulation of malignant white blood cells in blood and bone marrow. The human fusion protein *SETMAR* is interesting in the context of the disease, as high expression in AML cells has shown inhibitory effects on Topoisomerase IIa (*TOPO2A*) inhibitors that form a cornerstone as drug in this disease entity. *SETMAR* promotes DNA double strand break (DSB) repair in the non-homologous end joining pathway, thereby reducing migration of DNA fragments and suppressing chromosomal translocation. We have previously shown that *SETMAR* is higher expressed in patients without a chromosomal translocation compared to patients with a translocation[1].
Aims: The aim of this study is to explore the correlation of the expression of *SETMAR* and the level of minimal residual disease (MRD) in patients with AML. Furthermore the expression level of *TOPO2A* is correlated to the expression of *SETMAR* to investigate whether a high expression of *SETMAR* has an up regulating effect on the expression level of *TOPO2A*.
Methods: Blood samples from 28 patients diagnosed with AML and treated with *TOPO2A* inhibitors were collected from diagnostic samples and from subsequent follow-up samples (n=82). For 10 patients the follow-up samples were drawn up to seven years from diagnosis (n=28) while samples were drawn shortly after treatment for 18 patients (n=54). The cell line K562 was used as a positive control for the quantification of *SETMAR* and *TOPO2A* expression. A quantitative PCR (qPCR) assay including primers and probes targeting transcript variant 1 of *SETMAR* was used as previously published [1]. Furthermore a qPCR assay targeting *TOPO2A*, established prior to the study, was used for the quantification of *TOPO2A* expression level (forward primer: CCCAAGAGCTTTGGATCAAC, reverse primer: AACTTCACCCAGTTTAGTATGC, TaqMan probe: ATCAAAGCTGCCATTGGCTGTGGT). b-*glucoronidase* (*GUS*) and b-*2-microglobulin* (b2*m*) were used as reference genes. The MRD level was routinely quantified for diagnostics purpose and correlated to the *SETMAR* and *TOPO2A* expression levels. The MRD target was either *WT1*, *inv(16)*, or *t(8;21)*.
Results: We observed a close correlation (Sperman's rho=0.57, P<0.01) between the expression of *SETMAR* and the level of MRD for all 28 patients. This is shown in Figure 1A. Likewise we found a trend towards a positive correlation between *SETMAR* and *TOPO2A* expression (Spearman's rho=0.1753, P=0.0671, Figure 1B). When correlating the expression of *SETMAR* and *TOPO2A* to the level of MRD only for the 18 patients with samples drawn shortly after diagnosis a tighter correlation between the expression of *SETMAR* and MRD level was observed (Sperman´s rho=0.6167, P<0.001). Longitudinally sampling showed excellent correlation between variations in *SETMAR* expression level and disease state from time of diagnosis to follow up. This is depicted in Figure 1C-D where two representative patient courses are shown. The expression of *SETMAR* followed the pattern for MRD at time of relapse suggesting a close relationship between *SETMAR* level and degree of disease in patients with AML. For the 18 patients with samples drawn at three specific time points 15 of these showed expression levels of *TOPO2A* that corresponded to the changes in gene expression levels of *SETMAR* and the MRD level.

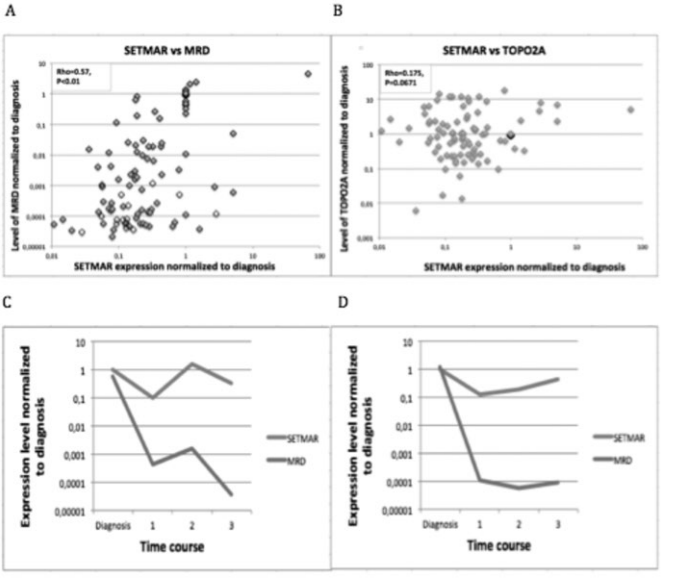

Figure 1. Correlation between *SETMAR*, *TOPO2A*, and *MRD*. A: The expression of *SETMAR* is positively correlated to the *MRD* level (Sperman's rho=0.57, P<0.01). B: The expression of *SETMAR* versus the expression of *TOPO2A* (Spearman's rho=0.1753, P=0.0671). C-D: *SETMAR* and *MRD* during treatment for two representative patient courses. The levels are normalized to the diagnostic samples.

Figure 1.

Summary and Conclusions: We identified a positive correlation between the expression of *SETMAR* and the MRD level as well as a positive correlation between the expression of *SETMAR* and *TOPO2A*. Interestingly there seemed to be very high concordance between the kinetics of *SETMAR* and MRD target during follow-up. This might indicate that *SETMAR* is present in the malignant compartment of the neoplastic cells. The mechanisms behind this remains to be further explored but we speculate that the need for DNA repair in the malignant population might be an issue here. The level of *SETMAR* followed the level of *TOPO2A* over time in the majority of cases indicating that the inhibitory effect of *TOPO2A* inhibitors could be an important subject to be considered in choice of treatment strategy.

CORRELATION OF GENOMIC ANALYSIS BY MYAML™ WITH IN VITRO HIGH THROUGHPUT DRUG SENSITIVITY TESTING IN NEW DIAGNOSIS AND RELAPSED ACUTE MYELOID LEUKEMIA

P.S. Becker[1,2,*] M. Schmitt[3], L. Loeb[4], W. Gu[5], Q. Wei[5], Z. Xie[6], A. Carson[6], T. Martins[7], C.A. Blau[8], V. Oehler[2], K.Y. Yeung[9]
[1]Division of Hematology, University of Washington, [2]Clinical Research Division, Fred Hutchinson Cancer Research Center, [3]Hematology and Medical Oncology, [4]Pathology, [5]University of Washington, Seattle, [6]Invivoscribe, San Diego, [7]Institute for Stem Cell and Regenerative Medicine, [8]Institute for Stem Cell and Regenerative Medicine and Center for Cancer Innovation, University of Washington, Seattle, [9]Institute of Technology, University of Washington, Tacoma, United States

Background: Whole genome sequencing has demonstrated tremendous heterogeneity in the mutations and chromosomal translocations associated with acute myeloid leukemia (AML), yet we remain quite limited in our ability to predict specific chemotherapy drug sensitivity based on genomics with the exception of a few selected mutations or translocations, such as FLT3-ITD or PML-RARA. The overall survival in AML remains poor, especially for patients who are refractory to ≥2 regimens, or for those with brief duration of first complete remission.
Aims: 1. To categorize the mutations identified by MyAML™ in new diagnosis and relapsed AML, and correlate with clinical features.
2. To determine if specific mutations or patterns of mutations will correlate with results of *in vitro* high throughput drug sensitivity testing in AML.
Methods: MyAML™ uses next generation sequencing to analyze the coding

regions and potential genomic breakpoints within known somatic gene fusion genomic breakpoints of 194 genes known to be associated with AML. Fragmented genomic DNA is captured (3.4Mb) with a customized probe design, and sequenced with 300bp paired end reads on an Illumina MiSeq instrument to an average depth of coverage >1000x. Using a custom bioinformatics pipeline, MyInformatics™, single nucleotide variants (SNVs), indels, inversions and translocations are identified, annotated, characterized, and allelic frequencies calculated. Commonly associated variants in dbSNP and 1000 genomes were eliminated, as well as variants with allele frequencies less than 5%. High throughput drug sensitivity testing was performed against a panel of 160 drugs, of which 56 are FDA approved and 104 are investigational. De-identified samples from 12 patients with de novo AML and 12 patients with relapsed AML were analyzed. For 2 patient samples, Duplex Sequencing was also performed to detect sub-clonal mutations below the detection limit of conventional next-generation DNA sequencing. Statistical analysis was performed to examine relationships between gene mutations and drug sensitivity profiles. Specifically, we computed the Pearson's correlation between all possible pairs of genes containing missense mutations and the *in vitro* cytotoxicity response across the same set of 24 patients.

Results: From the 24 patient samples analyzed to date, an average of 129 missense mutations were identified in each sample with an allelic frequency >5%. Of these, an average of over 21 missense variants were observed in COSMIC and less than 3 were novel (not in dbSNP). These samples also contained an average of over 12 coding indels (~5 frameshift and 7 inframe indels per sample). In addition, MyAML™ identified 3 samples with inv(16) and 6 samples with translocations, including the cryptic NUP98-NSD1 t(5;11) that was not detected by karyotyping. For 2 of the samples, Duplex Sequencing was performed at a depth of at least 6000X, and showed concordance of some of the mutations, with each method identifying additional mutations not observed by the other, an expected finding, as each method targeted distinct regions, and Duplex Sequencing had a greater depth of coverage. The correlative studies between mutations and the results of the high throughput drug sensitivity testing are in progress.

Summary and Conclusions: Data from disease focused genomics and *in vitro* chemotherapy sensitivity testing of individual patient AML samples will likely lead to innovation in treatment, identification of novel targeted agents, and improved outcomes in AML.

ANALYSIS OF GENETIC POLYMORPHISMS IN DNA REPAIR GENES IN ASSOCIATION WITH ACUTE MYELOID LEUKEMIA AND ITS SPECIFIC CHROMOSOMAL ABNORMALITIES

A. Daraki[1,2,*] D. Koumbi[1], P. Masoura[2], S. Samara[2], C. Sambani[1], V. Aleporou-Marinou[2], K. Manola[1], P. Kollia[2]
[1]Laboratory of Health Physics, Radiobiology & Cytogenetics, NCSR "Demokritos", [2]Department of Genetics & Biotechnology, Faculty of Biology, National and Kapodistrian University, Athens, Greece

Background: DNA damage repair mechanisms are vital to maintain the functions of normal cells and genomic integrity. Alterations and a variety of polymorphisms in DNA repair genes have been associated with increased risk of developing acute myeloid leukemia (AML). DNA double-strand break repair pathway (DSB) represents the main pathway in maintaining genome stability and is distinguished into two distinct and complementary pathways homologous recombination (HR) and non-homologous end-joining (NHEJ), while the nucleotide excision repair (NER) pathway constitutes the primary mechanism for removal of bulky adducts from DNA. Essential components of the above pathways represent the XPD23 proteins which participate in the opening of the damaged DNA during NER, the Rad51 proteins in HR and Lig4 proteins which are central components of the NHEJ. The genes that encode the above proteins are subjected to a single-nucleotide polymorphism (SNPs) and have been associated with hematological malignancies.

Aims: The aim of this study was to assess the role of $A^{23927}C$, $G^{135}C$ and $C^{26}T$ germline polymorphisms of *XPD23*, *RAD51* and *LIG4* genes as genetic risk factors for AML and its specific chromosomal abnormalities.

Methods: Genotyping was performed in 83 AML patients and 91 controls by PCR-RFLPs. Cytogenetic analyses were performed on unstimulated bone marrow cells cultured for 24 and 48 hours.

Results: Concerning the polymorphic sites $A^{23927}C$ of *XPD23* gene and $G^{135}C$ of *RAD51* gene, our analysis showed the same allelic and genotypic frequency between patients and controls. However, the genotypic distribution for $C^{26}T$ polymorphism of *LIG4* gene revealed a statistically higher frequency of the variant genotypes in patient's group compared to controls (C/T: 50.6% *vs* 30.8%, T/T: 10.8% *vs* 6.6%, respectively, p=0.006). Allele frequency distribution analysis showed that AML patients exhibited an almost 2-fold increased risk of carrying at least one variant T allele compared to controls (p=0.004, OR [95% CI]=2.100 [1.253-3.224]). After stratification of patients according to karyotype, no statistically significant associations were found between the above polymorphisms and the cytogenetic subgroups. Nevertheless, an increased frequency of the variant genotypes of $C^{26}T$ polymorphism of *LIG4* gene (CT+TT) was observed in patients with +8 (80.0%), -7/del(7q) (76%) and -5/del(5q) (66.7%) compared to healthy donors.

Summary and Conclusions: Our results showed that AML risk is not significantly associated with *RAD51* and *XPD23* polymorphisms. However, our data provide evidence for a possible role of the $C^{26}T$ polymorphism of *LIG4* gene in AML development and its specific chromosomal abnormalities.

EXPOSURE TO ROS INDUCES DNA DAMAGE AND INFLUENCES DNA METHYLATION IN NORMAL AND MALIGNANT HEMATOLOGICAL CELL LINES

A.C. Gonçalves[1,2,3,4,*] R. Alves[1,2,3,4], A. Pires[1,2], J. Jorge[1,2], L. Mota-Vieira[5,6,7], J.M. Nascimento-Costa[8,9], A.B. Sarmento-Ribeiro[1,2,3,4,10]

Background: The pathogenesis of myeloid neoplasias is complex and involves multiple genetic and epigenetic events. The oxidative stress and abnormal DNA methylation have been implicated in some types of cancer, namely in myelodysplastic syndromes (MDS), chronic myeloid leukemia (CML) and acute promyelocytic leukemia (APL). Since both mechanisms are observed in some of these patients, we hypothesize that oxidative stress may influence DNA methylation.

Aims: In this context, the present work aimed to analyze the influence of acute and chronic exposure to OS in global and localized methylation, as well as in the gene expression levels of epigenetic modulators and antioxidant enzymes.

Methods: In this study, normal lymphocytes (IMC cell line) and several hematological neoplasia cell lines, the K-562 cells (CML), the F36P cells (MDS), the NB-4 and the HL-60 cells (APL with and without t(15;17), respectively), were exposed acutely (48h) and chronicle (± six months) to oxidative stress inducers (hydrogen peroxide and menadione). Cell proliferation and death were analyzed by trypan blue assay. ROS and GSH levels were analyzed using fluorescent probes (DCFH2DA, DHR123, DHE, DAF, and MO, respectively) by flow cytometry. DNA damage was analyzed through 8-hydroxy-2'-deoxyguanosine (8-OHdG) levels (ELISA). The localized methylation status was analyzed through *p15*, *p16*, *DAPK,* and *KEAP1* methylation profile (MSP). Global methylation status was assessed by 5-methylcytosine (5mC), 5-hydroxymethylcytosine (5hmC) levels, and LINE-1 methylation. Gene expression levels of epigenetic modulators (*DNMT1, DNMT3a, DNMT3b, p300, EZH2, MBD1, MBD2, MECP2*, and *TET2*), oxidative stress genes (*GPX1, GSTM1, NQO1, GSR, HMOX1, SOD1, KEAP1*, and *TXN*), transcription factors (*NF-KB* and *NRF2*), as well as tumor suppressors (*p15, p16, p53*, and *DAPK*), were analyzed by real time PCR. The statistical analysis was carried out by variance analysis ($p<0.05$).

Results: Acute and chronic exposure to hydrogen peroxide (H_2O_2) and menadione (MND) increased intracellular ROS levels in all tested cells lines. Under acute exposure to ROS, GSH content decrease, while in chronic exposure it was increased, probably reflecting an adaptation to OS. Moreover, acute exposure to ROS induces a significant increase of DNA damage, however chronic exposure only significantly increases DNA damage in IMC cells. This oxidative damage is followed by an increase in 5-mC levels and a decrease in LINE-1 methylation. Moreover, OS also conduced to hypermethylation of *p15*, *p16,* and *KEAP1* promoter genes in a cell type- and exposure-dependent manner. In all cells lines, we observed that chronic exposure to H_2O_2 and MND induced an increase in *DNMT1*, *DNMT3a*, *GSR*, *GSMT1,* and *NQO1* gene expression and a decrease in *KEAP1*, *p15* and *p16* genes. In cells, acutely exposed to theses compounds, gene expression levels were cell line-dependent.

Summary and Conclusions: In summary, exposure to hydrogen peroxide and menadione (a superoxide donor), especially chronic exposure, lead to DNA damage, global hypomethylation and localized hypermethylation. These findings suggest a relationship between oxidative stress and aberrant methylation status, two common mechanisms involved in the development of hematological neoplasias. *This work was supported by CIMAGO and R. Alves is supported by the FCT fellowship FRH/BD/51994/2012.*

POLYMORPHISM OF FOLATE AND METHIONINE METABOLISM GENES IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROME

Z. Sidorova[1,*] I. Kostroma[2], S. Gritsaev[2], S. Kapustin[1]
[1]Laboratory of biochemestry, [2]FSBI "Russian Research Institute of Hematology and Transfusiology of FMBA", Saint-Petersburg, Russian Federation

Background: Abnormal DNA methylation is often seen in patients with acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). Polymorphism of folate and methionine metabolism (FMM) relating genes can influence the methylation processes and, therefore, modify the risk of AML and MDS development.
Aims: The aim of this study was to assess the features of alleles and genotypes distributions of the FMM genes in MDS and AML patients.
Methods: Forty-eight patients with MDS (21 men and 27 women, mean age 61.3 yrs), 71 patients with AML (25 men and 46 women, mean age 51.2 yrs) and 121 healthy controls (HC) (cancer-free 73 men and 48 women, mean age 54.1 yrs) were genotyped for the MTHFR C677T, MTHFR A1298C, MTR A2756G, MTRR A66G and MTHFD G1958A polymorphisms by PCR-RFLP technique. The differences in allele and genotype frequencies between patients and HC groups were assessed by Fisher's exact test with computation of odds ratios (OR), their 95% confidence intervals (CI) and p-values.
Results: The frequency of the MTHFR 1298AC genotype was decreased in MDS patients and increased in AML patients, when compared to HC group (33.3% vs. 43.8% and 55.7% vs. 43.8%, respectively). The difference between MDS and AML patients was statistically significant (33.3% vs. 55.7%, OR=0.4, 95%CI: 0.2-0.9, p=0.025). At the same time, the MTR 2756 GG variant was present in 2 (4.2%) patients with MDS, none of AML patients (0.0%) and 8 (6.6%) controls. The latter observation also was statistically significant (0.0% *vs* 6.6%, OR=0.09, 95%CI: 0.01-1.6, p=0.027). It is interesting, that the MTR 2756 GG genotype was detected in none of the male patients in MDS and AML groups compared to men in the HC group (0.0% vs. 11.0%, respectively, OR=0.08, 95%CI: 0.01-1.5, p=0.023). The simultaneous presence of the MTHFD 1958GG and MTRR 66GG genotypes was more often detected in MDS group than in HC (14.6% vs. 4.1%, OR=4.0, 95%CI: 1.2-13.2, p=0.04), and in AML group compared to HC group (8.5% vs. 4.1%, OR=0.5, 95%CI: 0.14-1.6, p=0.33).
Summary and Conclusions: We conclude that polymorphism of the FMM genes could have an important role in pathogenesis of both MDS and AML.

Background: *All-trans* retinoic acid and arsenic trioxide have revolutionized management of acute promyelocytic leukemia. Right now targeting epigenetic modifiers, such as histone deacetylases, bromodomain and extraterminal domains or methyltransferases and differentiation-inducing agents are rising hopes for development of effective therapeutic strategies for other types of acute myeloid leukemia (AML). Numerous proteins involved in tumor development have so-called allosteric disulfide bonds amenable to modifications affecting protein structure and function (*Hogg P, Nat Rev Cancer 2013*). Targeting allosteric disulfide bonds becomes a novel approach to cancer treatment. Our interest in this field focuses on proteins with thioredoxin fold such as protein disulfide isomerase (PDI). We have developed SK053, a small molecule inhibitor of thioredoxin/thioredoxin reductase system (*Klossowski S, Muchowicz A et al., J Med Chem 2012*) that is not a target-specific, but mechanism-selective inhibitor of allosteric disulfide bonds formation that blocks the enzymatic activity of PDI
Aims: The aim of this project was to evaluate anti-leukemic and differentiation-inducing effects of SK053 and investigation of the potential mechanisms of its activity.
Methods: We evaluated the biological effects on proliferation and differentiation and the transcriptome changes determined by SK053 in the human myeloid cell lines: HL60, NB4, KG1 and MOLM14
Results: Our results show that SK053 reduces cell proliferation evaluated by trypan blue exclusion. SK053 induces cell differentiation along the monocytic and granulocytic lineages as evidenced with May-Grünwald-Giemsa staining, nitro blue tetrazolium reduction assay and flow cytometry analysis of CD11b, CD14 and CD15 expression. Accordingly relative gene expression calculation and RNA sequencing showed the up-regulation differentiation-related genes. RNA-seq analysis revealed that 5 day incubation of HL60 cells with SK053 down-regulates mRNA for MYC and ID1 oncogenes as well as for histone proteins. Expression of other genes of mature myeloid lineage such as adhesion molecules (collagen type XV, fibronectin I, MAC-1), hydrolytic enzymes (carboxypeptidase, proteinase 3, CA12 anhydrase, ADAM19 metalloprotease), proteoglycan 2 (core of eosinophilic granules) and PGLYRP3 (peptidoglycan recognition protein 3) was significantly up-regulated. Moreover, the transcripts for histone proteins: HIST1H3J, HIST1H2AB, HIST1H1B, HIST1H3H, HIST1H2AH were strongly down-regulated. Drugs that disrupt histone modifiers are in clinical trials with promising results but very little is known about direct targeting of histone proteins. We also plan to analyze transcriptome of HL60 cells incubated for shorter time with SK053 using RNA-seq techniques to estimate an early response to that compound. Figure 1) Differential expression assesed with RNA-seq after 5-day treatment of HL60 cells with SK053. HL60 cells were incubated with 10 μM SK053, next RNA from control and SK053-treated cells was transcribed to cDNA library using Illumina kit. Next-Generation Sequencing was performed with Illumina HiSeq 1500. Transcriptome RNA-seq dataset was analyzed using Spliced Transcripts Alignment to a Reference (STAR) software and HTseq software (short-read counts). The y-axis presents negative log of the p-value from differential gene expression.

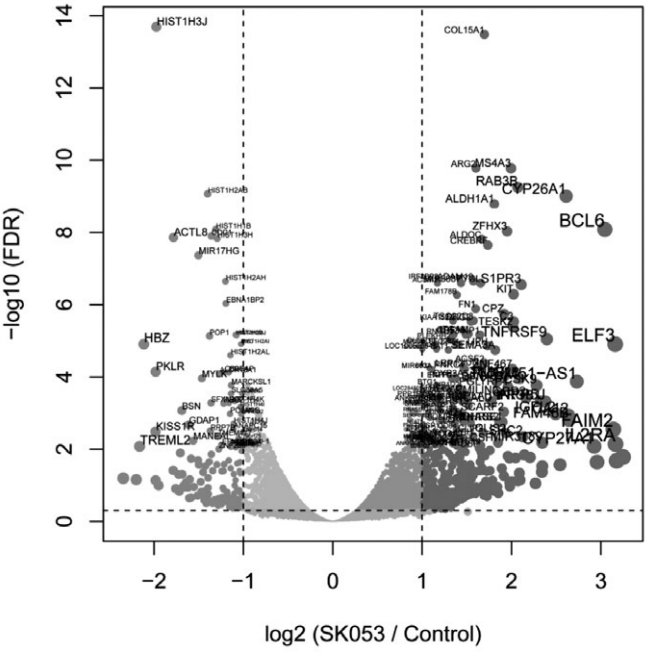

Figure 1.

Summary and Conclusions: We propose a new approach in AML treatment, *i.e.* targeting of enzymes involved in formation of allosteric disulfide bonds which has already been reported as novel promising strategy in other cancer types.

Background: The intake of anthracyclines in blast cells could be affected by several transporters, including influx transporters (SLC22A16 and SLCO1B1) and efflux pumps of the ABC family.
Aims: Previous studies have suggested that single nucleotide polymorphisms (SNPs) of genes coding for anthracyclines transporters may influence their effectiveness or toxicity, although their impact in acute myeloid leukemia (AML) induction therapy remains undetermined.
Methods: The SNPs of anthracycline transporter genes (ABCB1: rs1128503, rs1045642, rs2032582 and haplotype; ABCC1: rs4148350; ABCC2: rs8187710; ABCG2: rs2231142, rs2231137; SLCO1B1: rs4149056; SLC22A16: rs12210538, rs714368) were evaluated in 149 adult patients at initial diagnosis from AML using a Sequenom (iPLEX) mass spectrometry–based multiplex

genotyping assay (Sequenom, San Diego, CA). All patients received induction chemotherapy consisting of idarubicin plus cytarabine (PETHEMA-LMA 99, 2007 and 2010 trials). Genotypes were grouped as dichotomous variables (dominant and recessive model). Efficacy of first induction cycle was evaluated comparing complete remission (CR) vs. partial remission or resistance. Patients dying during induction were considered as no evaluable for efficacy. Based on the WHO grading scale, toxicities were grouped as binary variables (grade 0-1 vs. grade 2-4). The grade of toxicity assigned to an organ group was the maximum grade of all the specific toxicities within that group. Overall toxicity was grouped with grade 3-4 assessment. Hematologic toxicity was measured with the time to neutropenia and thrombocytopenia recovery since first day of chemotherapy. Categorical and continuous variables were assessed using $\chi 2$ test with Yates correction if needed and Mann–Whitney U test, respectively. Significant values were reanalyzed with logistic regression (covariables: age, gender, ECOG, leukocyte and platelet count).

Results: The median age of patients was 51.7 years (17-78 years). There were lower CR rates among patients harboring ABCB1 G2677T variant allele (rs2032582, GG: 60.0% vs. GT/TT: 78.6%, P=0.03; OR: 2.44; IC95%:1.08-5.55; P=0.033), genotype previously associated with lower activity of ABCB1 pump, and lower anthracycline clearance. Cardiotoxicity was related with wild type ABCB1 haplotype (32.0% vs. 11.3%, P=0.013; OR: 3.42; IC95%:1.19-9.85; P=0.023) and variant allele of ABCG2 (rs2231142, CC: 17.0% vs. CA/AA: 50.0%, P=0.008; OR: 6.87; IC95%:1.89-24.96; P=0.003). Neurotoxicity was associated with wild type ABCB1 haplotype (24.0% vs. 11.4%, P=0.041; OR: 3.00; IC95%:0.97-9.28; P=0.057). Skin toxicity was higher in wild genotypes of ABCB1 G2677T (rs2032582 GG: 44.0% vs. GT/TT: 24.5%, P=0.015; OR: 0.41; IC95%:0.20-0.85; P=0.017) and ABCB1 haplotype (45.7% vs. 18.9%, P=0.007; OR: 2.44; IC95%:1.02-5.88; P=0.046), as well as mucositis with variant allele of ABCC1 (rs4148350 GG: 34.8% vs. GT/TT: 7.1%, P=0.037; OR: 0.14; IC95%:0.02-1.09; P=0.060). Regarding hematologic toxicity, time to neutropenia recovery was delayed with variant allele of SLCO1B1 (TT/CT: 26.8 vs. CC: 29.9 median days, P=0.033).

Summary and Conclusions: This study shows a prognostic impact of transporter genes polymorphisms in adult AML patients regarding induction chemotherapy efficacy and toxicity. Further studies with larger population are needed to validate these associations, which could be useful biomarkers in clinical practice.

NQO1 C609T VARIANTS ARE ASSOCIATED WITH TYPE I AND II MUTATIONS IN PEDIATRIC ACUTE MYELOID LEUKEMIA

F.G. Andrade[1], G.D. Brisson[1], F.V.D.S. Bueno[1], E. Pina[1], E.P. Noronha[1], B.A.A. Gonçalves[1], M.S. Pombo-de-Oliveira[1,*]

[1]Pediatric Hematology-Oncology Program, Instituto Nacional de Câncer, Rio de Janeiro, Brazil

Background: Acute myeloid leukemia (AML) has long been recognized for its biological heterogeneity, as well as the diversity of genetic and epigenetic modifications. The broad range of abnormalities across different subtypes is important to stratify AML cases to different prognostic groups and choosing of an appropriate therapy for the disease. However, there has been no recent comprehensive overview of the type I (*FLT3*, *RAS*) and II [*RUNX1-RUNX1T1*, *CBFb-MYH11*, *MLL* rearrangements (*MLL*-r), *PML-RARa*] genetic alterations in one large cohort of pediatric AML cases and examining the potential contribution of inherited susceptibility to AML development.

Aims: The purpose of this study is to evaluate the association of *NQO1* rs1800566 polymorphism with pediatric AML risk presenting *RAS* and *FLT3* gene mutations as cooperating events with the mainly fusion genes related to AML in children.

Methods: Samples from 601 AML cases aged ≤21 years-old ascertained from 2000-2014 prior to any treatment were included. Variables of reference were type I/II mutations and *NQO1* rs1800566 (C609T). Restriction fragment length polymorphism and/or direct sequencing were used to screen *FLT3* and *K/N-RAS* mutations. RT-PCR and/or FISH were performed to identify the most common partners of *MLL* gene, and the fusion transcripts *RUNX1-RUNX1T1*, *CBFb-MYH11*, and *PML-RARa*. *NQO1* polymorphism was detected by real-time allelic discrimination technique.

Results: Overall, type I mutations were identified in 42.2% of cases and type II mutations in 45.5% (*KRAS*=6.9%; *NRAS*=11.6%; *FLT3*=23.7%; *RUNX1-RUNX1T1*=16.9%; *CBFb-MYH11*=4.5%; *MLL*-r=12.4%; *PML-RARa*=11.7%). Higher rate of *KRAS* mutation was found in AML with *MLL*-r (42.9%) compared with cases without this abnormality, as well *NRAS* in *RUNX1-RUNX1T1* positive cases (50.0%) and *FLT3* with *PML-RARa* (56.7%), suggesting a non-random association among these alterations. Children aged >2-10 years-old with at least one *NQO1* variant allele were at higher risk for developing AML with *PML-RARa* than cases with no type II mutation (odds ratio (OR) 3.67, 95 % confidence interval (CI) 1.01-13.40). Interestingly, we observed a reverse association for those cases *PML-RARa* positives aged >10 years-old (OR 0.18, 95%CI 0.04-0.87). The presence of at least one *NQO1* variant allele also provided an increased risk for cases presenting *RUNX1-RUNX1T1* or *CBFb-MYH11* and concomitant *FLT3* mutations (OR 6.08, 95%CI 1.15-32.29).

Summary and Conclusions: The identification of genetic subgroups in pediatric AML may assist to improve the molecular-epidemiology, risk stratification and etiopathology of AML worldwide. The *NQO1* rs1800566 (C609T) polymorphism modified risk depending on genetic subtype and age range, suggesting that lower NQO1 enzyme activity may play a synergistic effect with genetic alterations and environmental exposures for leukemogenesis.

Acute myeloid leukemia - Clinical

E924

FAVORABLE PROGNOSTIC IMPACT OF NMP1 MUTATION IN ELDERLY PATIENTS WITH NORMAL KARYOTYPE ACUTE MYELOID LEUKEMIA

M. Virijevic[1,*] I. Djunic[1], N. Suvajdziv-Vukovic[2], N. Tosic[3], A. Novkovic[4], M. Mitrovic[5], N. Colovic[2], A. Vidovic[2], S. Pavlovic[3], D. Tomin[2]
[1]Department of acute leukemias, Clinic for Hematology, Clinical Center of Serbia, [2]Department of acute leukemias, Clinic for Hematology, Clinical Center of Serbia, Medical Faculty Of Belgrade University, [3]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade,, [4]Clinical Hospital Center "Zemun", [5]Clinic for Hematology, Clinical Center of Serbia, Medical Faculty Of Belgrade University, Belgrade, Serbia

Background: The prognosis of acute myeloid leukemia (AML) in elderly patients is poor. The prognostic impact of molecular mutations in these patients is still unknown. Recent studies showed that NPM1 mutation have a favorable prognostic impact in elderly patients with de novo AML.
Aims: The aim of this study was to investigate the impact of NPM1 and FLT3 internal tandem duplication (ITD) mutations as prognostic factors for overall survival (OS), complete remission (CR) rate and disease-free survival (DFS) in elderly patients with normal karyotype (NK) AML.
Methods: Diagnostics bone marrow samples from 138 *de novo* AML patients aged ≥65years diagnosed between 2009 and 2014 were analyzed for NPM1 and Flt3 mutations by DNA PCR amplification/sequencing. Chemotherapy received 110 patients and 28 patients treated by supportive care only. Co morbidities were evaluated by using the hematopoietic cell transplantation-specific comorbidity index (HCT-CI). Performance status (PS) was evaluated by Eastern Cooperative Oncology Group (ECOG), ranged 0-4. Cytogenetic risk group was assessed by recommendation of European LeukemiaNet. The following parameters were estimated as the risk factors for CR rate, DFS and OS: leukocytes count (<30x10^9/L vs. ≥3010^9/L), level of serum lactate dehydrogenase (LDH) more than 1.5 x upper limit of normal, ECOG PS (<2 vs. ≥2), ELN cytogenetic risk group, HCT-CI (<2 vs. ≥3) and NPM1 and FLT3-ITD mutations. Risk factors were identified using the univariate and multivariate analysis.
Results: NPM1 and/or FLT3-ITD mutations detected in 43.5% (60) of patients. Patients with NPM1 mutations (NPM1+) and without FLT3-ITD mutation (FLT3-ITD-) had higher CR rate than NPM1- patients (p=0.015). Also, NPM+/ FLT3-ITD- patients had longer DFS than NPM- patients (p=0.023). Nevertheless, in NPM1+/FLT3- patients multivariate analysis indicated HCT-CI <3 as the most important risk factor for longer OS: p=0.02, relative risk (RR)=2.486; 95% confidental interval (CI)=1.156-5.346.
Summary and Conclusions: NPM1 mutation was associated with higher CR rate and longer DFS in elderly patients with NK-AML and without FLT3-ITD mutation, but comorbidity remained to be the most important risk factor for OS of its patients.

E925

STUDY OF PLASMA ENDOSTATIN LEVEL IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

R. Haggag[1,*] O. Hussein[2], H. Abd El Moaty[2], A. Omran[2], H. Ebian[2]
[1]Medical Oncology, [2]Clinical Pathology, faculty of medicine/ Zagazig Univerisity, Zagazig, Egypt

Background: Endostatin is a naturally-occurring 20-kDa C-terminal fragment derived from type XVIII collagen. It serves as an anti-angiogenic agent. Endostatin is a broad spectrum angiogenesis inhibitor and may interfere with the pro-angiogenic action of growth factors such as basic fibroblast growth factor (bFGF/FGF-2) and vascular endothelial growth factor (VEGF).
Aims: To evaluate the role and prognostic value of endostatin in AML patients
Methods: Sixty subjects were included in this study, 30 apparently healthy adult subjects as control (group 1) and 30 adult patients with newly diagnosed de novo AML(group2). Estimation of serum endostatin level by ELIZA, at the onset of the disease and after 1 month of induction treatment
Results: Serum endostatin levels varied widely from 2.1 ng/mL to 7.1 ng/mL (median, 4.1ng/mL), and the median level was higher in patients with AML compared with patients in the control group (2.6 ng/mL; *P =0.001*). No significant difference was found between pre-and post-treatment in group 2 (0.23).
Median overall survival of group 2 was 7 months (1 to 16 months), while the disease free survival ranged from 2 to 15 months with a median of 8.5 months. The overall survival of patients who had pre-treatment endostatin level ≤50% percentile was significantly longer than patients with pre-treatment endostatin level >50% percentile (p=0.007). According to change of endosatin levels, the overall survival of patients with increased endostatin level was significantly longer than patients with decreased endostatin (p=0.03). Also there were significant association between change of endosatin level and age, performance status, cytogenetics, response to treatment and the disease outcome.
Summary and Conclusions: Inhibition of the angiogenesis may have a role in remission of AML patients. Levels of endostatin in patients with AML may be effective in predicting the survival

E926

LONG TERM EFFICACY OF CONSOLIDATION TREATMENT WITH COURSES OF HIGH-DOSE CYTARABINE AND LIMITED AUTOLOGOUS PBSC SUPPORT IN A SERIES OF ADULTS WITH ACUTE MYELOID LEUKEMIA NOT AT HIGH BIOLOGICAL RISK

E. Borlenghi[1,*] C. Pagani[1], E. Cerqui[1], A. Belotti[1], C. Bottelli[1], D. Dalceggio[1], S. Ferrari[1], I. Nardiello[1], A. Passi[1], F. Schieppati[1], M. Chiarini[2], C. Lamorgese[2], G. Giuliani[1], M. Enrico[1], G. Ruggeri[3], C. Cattaneo[1], G. Rossi[1]
[1]UO Ematologia, [2]Centro di Ricerca Emato-oncologico AIL (CREA), [3]UO Laboratorio di Analisi, Spedali Civili, Brescia, Italy

Background: In adult acute myeloid leukemia (AML) consolidation treatment after complete remission (CR) is mandatory to improve remission duration. Allogeneic stem-cell-transplantation (allo-SCT) is considered standard for young pts but repeated cycles of high-dose cytarabine (HDAraC) or autologous SCT may be as effective in standard risk (SR) pts. In these pts, the AML-00 NILG program (Bassan, ASH 2003) called for 3 consolidation cycles of idarubicin (8 mg/sqm for 2 days) and HDAraC at 2g/sqm/bid for 5 days (A20). Small doses (1-2x10^6/kg) of autologous CD34+peripheral blood stem cells (PBSC) were reinfused after each A20 to minimize toxicity.

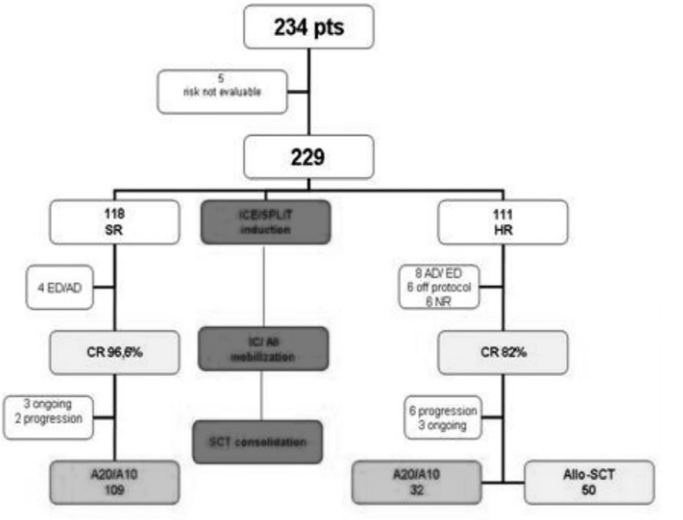

Figure 1.

Aims: To analyze, by intention to treat and according to cytogenetic/molecular characteristics, the very long term outcome of SR pts who received A20 consolidation with PBSC support according to the AML-00 NILG program, adopted as standard at our Institution. High risk (HR) pts, identified by high-risk cytogenetics, secondary AML, late CR or FLT3-ITD positivity, were addressed to allo-SCT and analyzed separately.
Methods: Induction treatment consisted of ICE (3-7-5) followed by IC (2-7) consolidation if CR was achieved, or by SPLIT (HD-AraC and HD-Idarubicin) in patients refractory to ICE. AraC 1g/sqm/bid for 4 days (A8) was then given to all patients achieving CR to allow collection of 3-6x10^6/Kg PBSC in three aliquots. SR pts were treated with 3 cycles of A20 followed by reinfusion of 1-2x10^6/Kg CD34+PBSC, at 1-2 months intervals upon hematologic recovery. Pts with insufficient CD34 +PBSC yield received 2 courses of A10 (HD-AraC 1g/sqm/bid for 5 days +idarubicin 10mg/sqm day 1). HR pts received A20/A10 waiting for donor availability and allo-SCT. From January 2001 to December 2014, 234 consecutive AML pts were diagnosed at our Institution, (median age 53, range 15-65). According to molecular/cytogenetic data, available in 229 (97.8%), 118 were SR (51,5%) and 111 HR (48,5%). The CR rate after ICE induction was 78,6% (180/229) and increased to 89,5% (205/229) after SPLIT (SR 96,6% and HR 82%). Early/aplastic death rate was 3,9%. A8 course was administered to 196/205 pts, and 160 (82%) successfully collected CD34+PBSC (Fig1).
Results: Of 118 SR pts, 109 actually received A20 (86,2%) or A10 (13,7%). Of 111 HR pts, 50 actually received allo-SCT and 32 A20/A10 consolidation only. The TRM at 100-days after A20/A10 was 2/141 (1,4%) (*Ps aeruginosa* sepsis and toxic megacolon). Neutrophil recovery occurred at a median of 10 days after reinfusion. After a median of 20 mo., the median OS of the entire population was 37.8 mo.; 45+/-6% (IC 95%) of pts were alive 5 years and 42+/-7% 8 years after diagnosis. Focusing on SR pts, median OS was 131 months and 62+/-6% were alive after 5 years. According to ELN risk, 5y-OS was 86+/-4% in CBF+, 100% in CEBPA+, 80+/-10% in NPM+, 54+/-15% in ELN Int-1, and 30+/-12% in Int-2 risk groups, respectively. OS at 8 years did not change except in NPM+pts, where it dropped to 53+/-18% because of late relapses (Fig2). In HR pts, 5y-OS was 24+/-5% by intention to treat. It was 45+/-8% in the 50 pts actually receiving allo-SCT and 25+/-9% in 32 patients actually completing A20/A10 because of allo-SCT refusal or lack of donor.

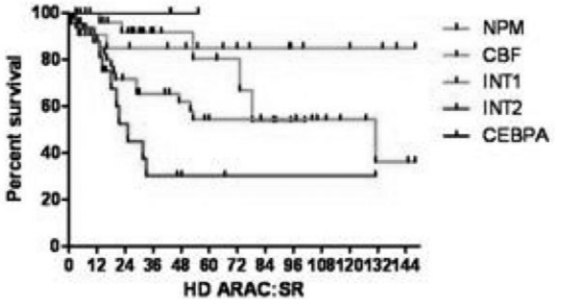

Figure 2.

Summary and Conclusions: Repeated courses of HD-AraC with limited PBSC support as consolidation was feasible, well tolerated and very effective in non HR adult AML. After long term follow up, 86% of CBF+, and more than 50% of NPM+and ELN int-1 risk pts appear to be cured. In NPM+pts late relapses can occur even after 5 years from diagnosis.

E927

HIGH CURE RATE OF YOUNGER AML PATIENTS WITH FLUDARABINE, CYTARABINE AND IDARUBICINE INDUCTION AND RISK ORIENTED CONSOLIDATION: TEN- YEARS REAL LIFE EXPERIENCE

P. Minetto[1,*] F. Guolo[1], M. Clavio[1], L. Giannoni[1], D. Lovera[1], D. Guardo[1], J. Agnelli[1], S. Bagnasco[1], F. Trovato[2], M. Bado[2], N. Colombo[1], R. Grasso[1], B. Rebesco[2], F. Ballerini[1], M. Miglino[1], R.M. Lemoli[1], M. Gobbi[1]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Pharmacology Division, IRCSS AOU San Martino-IST, Genoa, Italy

Background: Conventional induction therapy of acute myeloid leukemia (AML) is still largely based on the combination of cytarabine (ARA-C) and daunorubicin. In the last two decades alternative drug combinations have been tested in order to improve complete remission (CR) rate and quality of remission. Fludarabine has been shown to enhance ara-CTP accumulation in leukemic blasts and to inhibit DNA repair mechanisms, thus providing a rationale for combination with DNA damaging agents.
Aims: In our institution a fludarabine containing induction regimen (FLAI-5) is being used since more than 15 years. The aim of present study was to critically rewiev feasibility and efficacy of our strategy.

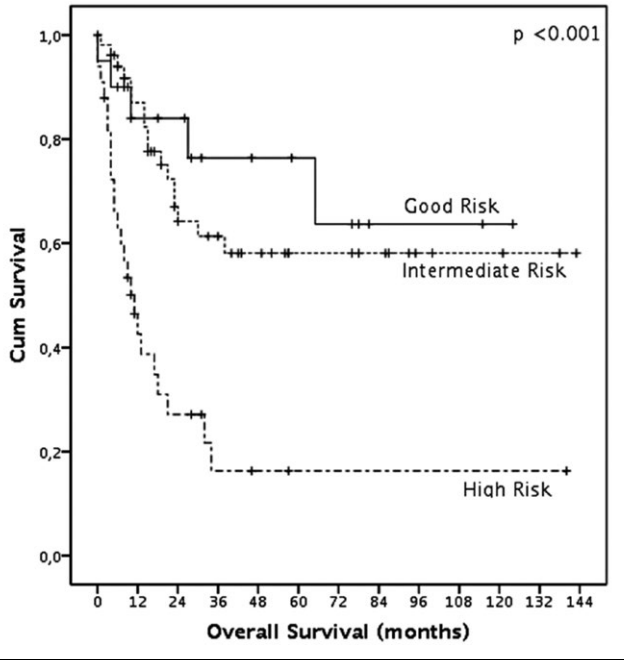

Figure 1. Overall Survival according to risk group.

Methods: One hundred-five consecutive non M3 AML patients (age 17-72 years) treated in our center between 2004 and 2013 were retrospectively analyzed. Median age was 45 yy; 90/105 patients (86%) were de-novo AML while 15 (14%) had secondary disease. Fifteen patients (14%) had high risk karyotype; 35 patients had NPM-1 mutation (33%), and 24/105 (23%) carried FLT3-ITD. Median follow-up was 48 months. Induction regimen included fludarabine 30 mg/sqm and ARA-C 2g/sqm on days 1 to 5 plus idarubicin (IDA) 10 mg/sqm on days 1-3-5, with or without gemtuzumab ozogamicin (3mg/sqm) on day 6. Patients achieving complete remission received a second course including ARA-C 2g/sqm on days 1 to 5 and IDA at an increased dose of 12 mg/sqm on days 1-3-5. Patients were stratified in prognostic risk groups according to a comprehensive score based on karyotype, de-novo or secondary disease, NPM and FLT3 status. High-risk and selected intermediate-risk patients underwent allogeneic bone marrow transplantation (BMT) in first CR if a donor was available. The other patients were scheduled to receive at least 2 and up to 4 courses of consolidation therapy with 4 days of ARA-C (2g/sqm, daily).
Results: Five (4.8%) and nine patients (8.6%) died during the first 30 and 60 days, respectively, mainly because of infective or hemorrhagic events**.** After 1st induction cycle 83 patients achieved CR (79%) and 17 did not respond (16%). After cycle 2, CR rate was 84% (88/105). FLAI-5 was generally well tolerated, with negligible non-hematological toxicity; median time to neutrophil and platelets recovery was 18 and 17 days, respectively. Most patients were able to receive subsequent therapy at full dose and in a timely manner; 29/88 CR patients underwent BMT in first CR whereas 41 out of the 59 not scheduled for an early transplant (70%) received the full programmed therapy. In the whole cohort, 3 years DFS and OS were 42.8% and 48.3% (median 34 and 35 months, respectively). Patients not undergoing early allo-BMT and receiving the full planned dose had a very good outcome, with a 3-year DFS of 56.7% (median 63 months). The outcome was further improved if a third consolidation cycle was given, with a 3-years DFS and OS of 71.2% and 100%, median not reached.
Summary and Conclusions: In a large randomized trial Burnett et al showed that FLAG-Ida favorably compared with other induction schedule. However the longer disease free survival and the lower relapse rate observed in the FLAG-Ida arm did not translate in a higher OS mostly due to the severe hematological toxicities following the second FLAG-Ida course. Our results are comparable to those recently published and show that delivering only one fludarabine containing regimen may significantly reduce hematological toxicity therefore allowing patients to proceed along the risk tailored consolidation program in a good performance status.

E928

IMPACT OF CYTOGENETICS ON CLINICAL OUTCOME IN PATIENTS WITH FIRST RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA TREATED WITH VOSAROXIN PLUS CYTARABINE VS PLACEBO PLUS CYTARABINE: RESULTS FROM VALOR

N. Vey[1,*] F. Ravandi[2], E.K. Ritchie[3], H. Sayar[4], M.D. Craig[5], R.K. Stuart[6], J.E. Lancet[7], S.A. Strickland[8], R. Ward[9], J.A. Smith[9], T.A. Crowley[9], H.A. Horst[10], A. Pigneux[11]
[1]Institut Paoli-Calmettes, Marseille, France, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, United States, [3]Weill Cornell Medical Center, New York, NY, United States, [4]Indiana University Cancer Center, Indianapolis, IN, United States, [5]West Virginia University, Morgantown, WV, United States, [6]Medical University of South Carolina, Charleston, SC, United States, [7]Moffitt Cancer Center, University of South Florida, Tampa, FL, United States, [8]Vanderbilt-Ingram Cancer Center, Nashville, TN, United States, [9]Sunesis Pharmaceuticals, Inc., South San Francisco, CA, United States, [10]II. Medizinische Klinik und Poliklinik im Städtischen Krankenhaus, Kiel, Germany, [11]Hôpital Haut Lévêque-CHU de Bordeaux, Pessac Cedex, France

Background: Diagnostic karyotype is one of the most important predictors of outcome in acute myeloid leukemia (AML). VALOR, a large phase 3 trial of vosaroxin plus cytarabine (vos/cyt) *vs* placebo plus cytarabine (pla/cyt) in patients with relapsed or refractory (R/R) AML [NCT01191801], provided the opportunity to evaluate the impact of karyotype on clinical outcomes in this difficult-to-treat patient population.
Aims: The aim of this posthoc analysis was to assess efficacy outcomes by cytogenetic risk category and treatment arm in a large cohort of patients with R/R AML.
Methods: Patients were randomized 1:1 to receive cyt (1 g/m^2 IV over 2 hr, d 1-5) plus either vos (90 mg/m^2 IV over 10 min, d 1 and 4; 70 mg/m^2 in subsequent cycles) or placebo. Complete remission (CR) rates, overall survival (OS), and 30-day and 60-day mortality were assessed by treatment arm in R/R AML patients based on cytogenetic risk category (an optional entry in the case report form at screening) per NCCN guidelines.
Results: Overall, cytogenetic data were available for 479 of 711 (67%) of patients on the VALOR study, of whom 133 (28%) had unfavorable risk, 330 (69%) had intermediate risk, and 16 (3%) had favorable risk karyotype as reported at screening. CR rates by cytogenetic group were: 12.0% for unfavorable, 27.0% for intermediate, and 56.3% for favorable risk patients. Median OS was 4.0 mo, 8.1 mo, and 15.6 mo for unfavorable, intermediate, and favorable risk groups, respectively. On the vos/cyt treatment arm, there were 58 patients with unfavorable risk, 175 patients with intermediate risk, and 7 patients with favorable risk. For the pla/cyt arm, there were 75 patients with unfavorable risk, 155 patients with intermediate risk, and 9 patients with favorable risk (test for association, p=0.16). When CR was examined by treatment arm, there were improved rates in the vos/cyt treatment arm compared with the pla/cyt arm for

each cytogenetic risk group: 15.5% *vs* 9.3% for unfavorable, 34.3% *vs* 18.7% for intermediate, and 71.4% *vs* 44.4% for favorable risk. In the intermediate risk group, the difference in CR rate was statistically significant (P=0.0015, chi-square test). Forest plots of OS hazard ratios (HR) reflected treatment benefit for all categories of cytogenetic risk (Figure). When median OS was reported by treatment arm, patients with unfavorable and intermediate cytogenetics who received vos/cyt had improved survival compared with patients who received pla/cyt (for unfavorable group: 5.0 mo *vs* 3.8 mo, respectively [HR 0.79; P=0.20]; for intermediate group: 8.3 mo *vs* 7.1 mo, respectively [HR 0.88; P=0.32]). Between cytogenetic risk groups there were no clinically meaningful differences between treatment arms with respect to 30-day and 60-day mortality.

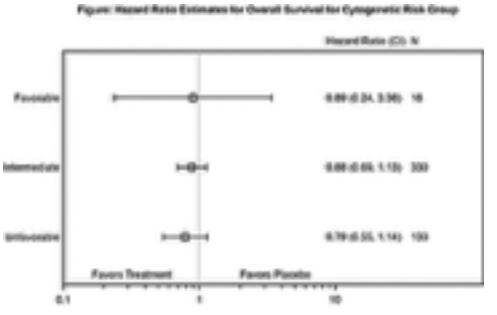

Figure 1.

Summary and Conclusions: These data further validate previous reports of important prognostic value of cytogenetics in R/R AML. Improvement in CR rate and OS benefit was observed for vos/cyt-treated patients with the poorest prognosis, those with intermediate or unfavorable cytogenetics, without an increase in early mortality. CLOFARABINE AND HIGH-DOSE CYTARABINE ARABINOSIDE (CLARA) FOR PRIMARY REFRACTORY OR RELAPSED ACUTE MYELOID LEUKAEMIA – A PROSPECTIVE FOLLOW-UP STUDY OF 60 PATIENTS

H. Gill[1,*] T. Chan[1], Y.Y. Hwang[1], A. Leung[1], E. Tse[1], Y.L. Kwong[1]
[1]Medicine, The University of Hong Kong, Hong Kong, Hong Kong

Background: Relapsed or refractory acute myeloid leukaemia (AML) is associated with a poor prognosis with a remission rate ranging between 10 to 40 percent with conventional salvage regimens. Clofarabine was designed to incorporate the anti-leukaemic properties of fludarabine and cladribine, both of which are active against AML.
Aims: The aim of this study was to prospectively evaluate the efficacy and tolerability of the salvage regimen combining clofarabine and high-dose cytarabine in patients with primary refractory or relapsed AML in the real-world scenario.
Methods: Patients with primary refractory or relapsed AML were prospectively recruited between 1 June 2009 and 31 December 2013. All data was censored on 30 June 2014. Patients were treated with **Cl**ofarabine at 40mg/m^2/day from day 1 to day 5) in combination with cytarabine arabinoside (**Ara**C) at 2g/m^2/day from day 1 to day 5 (**CLARA**). Clinicopathologic features, treatment response and survivals were determined. Prognostic factors for response and survivals were determined using logistic regression and cox regression.
Results: 60 patients with primary refractory or relapsed AML were recruited (primary refractory,N=18; first relapse,N=31, second relapse,N=10, third relapse,N=1). 29 men and 31 women with a median age of 48.5 (range: 18-66) were recruited. They received a median of 2 (range:1-5) prior induction/re-induction regimens for AML. 36 patients (40%) had normal karyotype at diagnosis while 24 patients (60%) had abnormal karyotype. 8 patients had fms-like tyrosine kinase 3-internal tandem duplication (*FLT3*-ITD) and 5 patients had mutated nucleophosmin 1 (*NPM1*). 8 patients achieved complete remission (CR) and 25 patients achieved a complete remission with incomplete haematopoietic recovery (CRi) making the CR/CRi rate of 55%. 17 patients progressed after initial remission. 15 patients (25%) underwent allogeneic haematopoietic stem cell transplantation (HSCT) after remission. Grade 3/4 haematological toxicity was seen in all 60 patients. Febrile neutropenia occurred in 24 patients (40%) and grade 3/4 hepatotoxicity was seen in 5 patients (8%). With a median follow-up of 6.5 months (range: 1-43), the median overall survival was 8 months (95% confidence interval: 5.04-10.96). The overall survival at 12 and 24 months was 38.9% and 29.7% respectively. Patients who were successfully bridged to allogeneic HSCT had a significantly better overall survival (P<0.001). The overall survival at 36 months in patients who underwent HSCT was 62.2%. The median progression-free survival following CLARA was 6 months.
Summary and Conclusions: Clofarabine in combination with high-dose cytarabine was effective in inducing a response in a significant proportion of patients with heavily-pretreated primary refractory or relapsed AML. Successful bridge to subsequent curative allogeneic HSCT was the major determinant of overall survival.

E930

IDH1 (BUT NOT IDH2) MUTATIONS CAUSE INFERIOR OUTCOME IN PATIENTS WITH AML WITH AN INTERMEDIATE-RISK CYTOGENETICS

J. Marková[1,*] P. Michková[1], C. Šálek[1], J. Březinová[1], J. Soukupová Maaloufová[1], P. Soukup[1], P. Cetkovsky[1], K. Michalová[1], J. Schwarz[1]
[1]Institute Hematology and Blood Transfusion, Prague 2, Czech Republic

Background: IDH1 and IDH2 are enzymes that catalyze the oxidative carboxylation of isocitrate to α-ketoglutarate in the Krebs cycle. Heterozygous mutations at *IDH1* Arg132, *IDH2* Arg140 and *IDH2* Arg172 were found to cause loss of normal enzymatic function. *IDH1* mutations are described in 6-16% of patients with cytogenetically normal AML, incidence of *IDH2* mutations is slightly higher (15-20%). *IDH2* mutations, particularly Asp140 are considered to have an unfavourable prognostic impact.
Aims: Patients: Presence of *IDH1* and *IDH2* mutations was analysed in 296 patients with AML with an intermediate-risk cytogenetics (defined according to Grimwade *et al.*, Blood, 2010) diagnosed between years 1998-2012. Median age at diagnosis was 55.1 years (range 16.0-81.7), the initial median WBC count was 22.3 x 10^9/L (range 0.4-483.7). The male/female ratio was 147/149 and the median of follow-up was 10.8 months.
Methods: Exons 4 of both *IDH1* and *IDH2* genes were amplified by RT-PCR; PCR products were treated by ExoSAP-IT reagent and directly sequenced. Obtained sequences were compared with wild type ones and mutations were identified.
Results: *IDH1/2* mutations were detected in 81 (27.4%) from 296 patients, all but one mutations were heterozygous. *IDH* mutations were more frequent in female patients (P=0.055) and independent of age (P=0.395). *IDH* mutations were associated with mutated *DNMT3A* (P=0.0008), but not with *FLT3*/ITD (P=0.124). *IDH1* mutations were found in 28 (9.5%) patients; 14/28 (50.0%) patients had Arg132His mutation, 9/28 (32.1%) Arg132Cys, 4/28 (14.3%) Arg132Ser and the remaining one had a Arg132Gly change. 6 of *IDH1*-positive patients had also *FLT3*/ITD. 53/296 (17.9%) cases carried mutations in *IDH2* gene; the majority of them (39/53; 73.6%) had Arg140Gln mutation, 13/53 (24.5%) harboured Arg172Lys change and one patient carried a previously undescribed alteration Gly145Trp. 11/53 cases were *FLT3*/ITD positive. None of the *IDH* mutations influenced WBC counts at diagnosis. Neither *IDH1*, nor *IDH2* mutation worsened the chance for reaching complete remission (CR): 15/27 (55.5%) *IDH1*-positive cases receiving standard induction treatment achieved CR as well as 30/47 (63.8%) cases with *IDH2* mutation and 126/208 (60.6%) without any *IDH* alteration. 10/15 (66.7%) patients harbouring *IDH1* mutation suffered a relapse, while only 59/125 (47.2%; P=0.362) cases without any *IDH* mutation and 9/30 (30.0%; P=0.009) carrying *IDH2* change relapsed. The difference was more obvious, when *FLT3*/ITD positive cases were excluded from analysis (66.7% patients with *IDH1* mutation relapsed vs. 37.5% relapsing cases with wt *IDH* and 26.1% of *IDH2*-positive ones). Patients with mutated *IDH1* had significantly shorter overall survival (OS) than cases without this mutation (P=0.048) or cases with *IDH2* mutation (P=0.026). OS 2 years after the diagnosis was 18.8% in cases with mutated *IDH1*, compared with 35.2% and 39.3% in patients without any *IDH* mutation and *IDH2*-positive ones, respectively.
Summary and Conclusions: We detected *IDH* mutations in 27.4% of patients with intermediate-risk cytogenetics. *IDH1*-positive patients had significantly shorter OS in comparison with *IDH* negative ones as well as comparing to *IDH2*-positive cases. This may result from a slightly lower CR rate on one hand and higher incidence of relapses in *IDH1* group on the other. *IDH2* mutations did not influence the prognosis of AML patients whatsoever. Supported by Research project 00023736 of Ministry of Health of Czech Republic and grant RVO VFN64165.

DISTINCT EPIDEMIOLOGIC EXPOSURES AND PROGNOSTIC FACTORS FOR SURVIVAL IN OLDER ADULTS AGE ≥70 YEARS RECEIVING LOW INTENSITY THERAPY FOR ACUTE MYELOID LEUKEMIA (AML)

J. Foran[1,*] M. Heckman[2], L. Sproat[3], L.J. Jiang[4], R. Ketterling[5], R. Tibes[3], L. Finn[6]
[1]Mayo Clinic Cancer Center, [2]Biostatistics, Health Services Research, Mayo Clinic Florida, Jacksonville, [3]Division of Hematology & Medical Oncology, Mayo Clinic Arizona, Phoenix, [4]Hematopathology, Mayo Clinic Florida, Jacksonville, [5]Cytogenetics, Mayo Clinic Rochester, Rochester, [6]Division of Hematology & Medical Oncology, Mayo Clinic Florida, Jacksonville, United States

Background: Many older adults age ≥70 years with AML were not previously candidates for intensive remission induction therapy and consequently the epidemiology and prognostic factors for overall survival (OS) have not been studied systematically in this population. However many now receive lower intensity treatment strategies, with distinct patterns of OS. We sought to study prognosis, clinical outcome and role of epidemiologic risk factors for AML development in this population.

Aims: The primary study aim was to evaluate prognostic factors for overall survival after AML and the incidence and contribution of epidemiologic exposures in older (≥70yrs) versus younger adults, and following intensive vs. low intensity therapy.
Methods: Epidemiologic exposures associated with AML development [including family history of hematologic malignancy (FHx); prior myelodysplasia (MDS); secondary AML (sAML); obesity (BMI ≥30kg/m^2); smoking; history of farm habitat or toxin exposure; and medical history, medications and prior immunosuppressive therapy (IST)] and clinical risk factors associated with OS were studied in a well characterized and non-selected cohort of n=295 consecutive AML patients diagnosed and treated at Mayo Clinic Florida & Arizona from 2002-12. Patients were treated in accordance with existing institutional algorithms, and central cytogenetics testing was performed at Mayo Clinic in all cases. Single variable Cox proportional hazards regression models, testing interaction p-values between groups (Age ≥70 vs. ≤69 yr.; intensive therapy vs. non-intensive or supportive care), was performed to evaluate differences in associations with OS. Fisher's exact test (or Wilcoxon rank sum test) was used for comparisons of patient characteristics.
Results: Older patients had a lower incidence of favorable risk cytogenetics, and were more likely to have prior MDS (p=0.032); sAML (p=0.026); a comorbidity index score (HCTCI) ≥3 (p<0.001); ECOG performance status (PS) >1 (p<0.001); and history of aspirin (p=0.001), statin (p=0.004) and metformin use (p=0.047) (but not acetaminophen). No other major difference in the incidence of epidemiologic exposures was observed between groups. Older patients were significantly less likely to receive intensive therapy (38% vs. 90%, P<0.001). Significant differences in prognostic factors for OS were observed. sAML was strongly associated with inferior OS in younger (Hazard Ratio (HR) 2.00, 95% Confidence Intervals (CI) 1.32-3.03) but not older adults (HR 1.09, 95%CI 0.75-1.58) (p interaction =0.030). In contrast, ECOG PS >1 was associated with OS in older (HR 2.39, 95%CI 1.67-3.43) but not younger patients (HR 0.97, 95%CI 0.60-1.56) (p interaction =0.003). Intensive therapy had a similar effect on OS in both groups (<70yr, HR 0.17, 95%CI 0.07-0.40; ≥70 yr, HR 0.21, 95%CI 0.13-0.33) (p interaction =0.77). Poor risk cytogenetics was associated with inferior OS in both groups, however cytogenetically normal AML was adverse in older (HR 5.71, 95%CI 1.35-24.12) but not younger (HR 1.69, 95%CI 0.58-4.90) adults. Other epidemiologic exposures (smoking, obesity, acetaminophen, IST, Farm habitat) did not affect OS, with the exceptions of FHx and Toxin exposure both associated with inferior OS after intensive therapy (HR 1.5, 95%CI 0.88-2.54 and HR 2.33, 95%CI 1.30-4.15, respectively) but not after low intensity/supportive care (HR 0.53, 95%CI 0.23-1.22 and HR 0.70, 95%CI 0.22-2.21, respectively) (p interaction =0.047 and =0.085, respectively).
Summary and Conclusions: Patients age ≥70 years and those receiving lower intensity therapy demonstrate a distinct profile of epidemiologic exposures, and prognostic factors for OS differ from younger adults. This suggests that prognostic factors in younger patients receiving intensive therapy cannot be directly extrapolated to this population, and prospective studies are needed to evaluate unique etiologic and prognostic factors for older adults.

E932

CHARACTERISTICS OF ACUTE MYELOGENOUS LEUKEMIA PATIENTS WITH GATA2 MUTATIONS

H. Maeng[1,*] M. Routbort[2], J. Jorgensen[2], T. Kadia[1], K. Bhalla[1], J. Cortes[1], H. Kantarjian[1], C. DiNardo[1]
[1]Leukemia, [2]Hematopathology, the University of Texas MD Anderson Cancer Center, Houston, United States

Background: The zinc-finger transcription factor GATA2, located on chromosome 3q21, serves an essential role in the development and regulation of hematopoietic stem cells and myeloid differentiation. Acquired and inherited GATA2 mutations leading to decreased GATA2 transcription have been described in patients with myeloid malignancies, often in the setting of a hypocellular marrow with atypical megakaryocyte morphology. In addition to a predisposition to myeloid malignancies, GATA2 deficiency is characterized by deficiencies in B-lymphocyte, monocyte, NK and dendritic cells and a propensity for mycobacterial, fungal and viral infections, as well as lymphedema and pulmonary disease and propensity for venous thromboembolic disease among other described clinical manifestations.
Aims: The aim of our present study was to investigate the frequency, characteristics and outcome of acute myelogenous leukemia (AML) patients with GATA2 mutations.
Methods: We performed a database search for GATA2 mutations in AML patients from 2013 to 2014; conveyed as part of our institutional Next-Generation Sequencing (NGS) platform. All patients signed an informed consent form approved by the University of Texas MD Anderson Cancer Center institutional review board. Medical records were retrospectively reviewed.
Results: Among 233 patients with AML, 16 patients were identified to have GATA2 sequence variations. Six patients with previously reported non-pathogenic population polymorphisms (2 P161A, 1 G237D and 3 P250A) were excluded from further analysis. Data from 10 (4.3%) patients were collected and analyzed; clinicopathologic characteristics of these 10 patients are provided in Table 1. Median age was 53 (range 22-79) years old, with 4 patients under the age of 35 years. No patient had a prior known diagnosis or family history of GATA2 syndrome or clinical history of frequent infections. Complete blood count at diagnosis demonstrated a median WBC 29.3x10^3 (3.3-215.9x10^3)/uL, peripheral blast 37(0-95) %, Hemoglobin 9.25 (5.8-11.30) g/dL and platelet 72.5x10^3 (8-181x10^3)/uL. By bone marrow morphology, 4 patients were classified as AML without differentiation, 3 as AML with differentiation, 1 myelomonocytic leukemia and 2 as AML with MDS-related changes. Patient 4 with dysplastic changes had GATA2 L359V that was previously reported to cause myelomonocytic differentiation in blastic transformation of chronic myelogenous leukemia. Cytogenetics revealed a diploid karyotype in all evaluable patients except one patient with isolated deletion 5(q22q35) in 10 out of 20 metaphases. GATA2 mutations were always found in the presence of other somatic mutations, with a median number of 3 (range 2-6) mutations. Of significant interest, CEBPA mutations were identified in 6 (60%) of patients with double-CEBPA mutations in 5 of the 6 patients. With a median of 9.5 (2-14) months, 7 patients are alive in first complete remission status post high-dose cytarabine based induction chemotherapy; Patient 9 was additionally consolidated with a stem cell transplant in CR1. Patient 4 is alive 10 months into decitabine therapy with stable disease not requiring transfusion. Two patients have died; one of infectious complications after a cord-blood stem cell transplant in remission and the other had multiorgan failure in the setting of relapsed disease.

Tabella 1.

Table 1. Clinical characteristics of the AML patients with GATA2 mutations.

	Age	Sex	Family Cancer History	Presenting event	AML	Follow Up (months)	Outcome	Infectious Episodes	cytogenetics	GATA 2 mutation exon	GATA 2 mutation amino acid	CEBPA	FLT3	DNMT 3A	RAS	NPM 1	WT1	ASXL 1	MLL	TET2	IDH1 IDH2	IDH2 R140
1	52	F	father-kidney	sinusitis	M2	10+	CR	influenza A	diploid	3	S152N					○						
2	22	F		fatigue	M1	7+	CR	perirectal cellulitis	N/A	4	G320C	double										
3	59	F	father: pancreas cousin leukemia	abnormal CBC on annual exam	M1	2+	CR	neutropenic fever	diploid	4	L321H	double								○	IDH1	
4	79	M	daughter-breast mother-breast	bacteremia after vascular procedure	dysplastic	10+	SD	klebsiella, E coli bacteremia stenotrophomonas pneumonia	del5	5	L359V							○				
5	59	F	sister-colon	pharyngitis	M4	10	CR died post SCT	Stomatococcus bacteremia, pneumonia, Pseudomonas cellulitis	diploid	5	R362Q			○	KRAS NRAS	○						
6	33	M		pharyngitis	M2	2+	CR	Streptococcal pharyngitis neutropenic fever	diploid	5	R362Q	double			NRAS							
7	29	M	mother-breast	cellulitis	M2	10+	CR	Corynebacterium bacteremia cellulitis	diploid	5	R362_N363insV	double		ITD		○						
8	54	F		back pain	dysplastic	9	Relapsed, died of sepsis	Staphylococcus bacteremia	diploid	5	A372T	○		ITD	○	NRAS						○
9	58	M	mother-CLL	DVT	M1	14+	CR, SCT	CMV reactivation	diploid	5	A372T			D835			○			○		
10	24	M		pharyngitis	M1	7+	CR	pharyngitis	diploid	5	L375I	double										

Summary and Conclusions: We identify the presence of GATA2 mutations in approximately 4% of newly diagnosed AML patients. GATA2 mutations are associated with younger age at AML diagnosis, diploid cytogenetics, an apparently favorable outcome, and notably a strong correlation was seen with concomitant CEBPA mutations suggesting cooperativity. Evaluation for familial inheritance of the presumed somatic GATA2 and/or CEBPA mutations is ongoing in select families.

E933

DAY-14 LAIP ON BONE MARROW PREDICTS COMPLETE RESPONSE AND DRIVE EARLY SALVAGE CHEMOTHERAPY IN AML: RESULTS OF MULTIPARAMETER FLOW CYTOMETRY AND WT1-RNA QUANTIFICATION

C. Messina[1,*] M.G. Carrabba[1], E. Sala[1], P. Ronchi[2], C. Tresoldi[3], M. Tassara[3], F. Pavesi[1], B. Gentner[1], L. Vago[1], F. Ciceri[1], R. Milani[2], M. Bernardi[1]
[1]Department of Onco-Ematology, Unit of Hematology and Bone Marrow Transplantation, [2]Immuno-hematology and Transfusion Medicine, [3]Unit of Molecular and Functional Immunogenetics, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: In acute myeloid leukemia (AML) response to induction chemotherapy (CT) is evaluated by bone marrow (BM) morphology and cytogenetics. Real-time quantitative PCR (RQ-PCR) and multiparametric flow citometry (MFC) are sensitive techniques to assess minimal residual disease (MRD). Early evaluation of response at day14 (d14) predicts the achievement of complete remission (CR). Most studies rely on BM morphology at d14 but this timepoint is often not evaluable for cytological blast count. Few data on BM blast clearance by MFC and/or RQ-PCR are available; the correlation between these two assays is unknown in this setting. Moreover, it is to be established if early intensification with a second CT cycle could increase CR rate or reduce the time to achieve CR in pts with disease persistence at d14 BM.
Aims: Objective of the study were i) to compare the two assays to identify the more sensitive/specific assay; ii) to compare the outcome of pts who received or did not receive an early intensification for d14 disease persistence, if in appropriate clinical conditions.
Methods: We retrospectively evaluated 33 newly diagnosed AML pts who received induction CT at our Center between 02/2009 and 02/2015, and for whom analysis of BM both at d14 and after hematologic recovery was available. We evaluated MFC (d14-LAIP) and WT1 quantification by PCR (d14-WT1) to predict the response to induction at d14, in particular when morphologic blast count is not evaluable.
Results: 25 pts received "3+7" and 8 pts the ICE induction regimen. After d14 BM evaluation, 6 pts received early reinduction CT (FLAG-Ida) starting at d16 (median), 27 pts did not receive further therapy before d28 BM evaluation. Overall CR rate was 64% (21 pts), PR/NR 36% (12 pts), d60 treatment related mortality (TRM) 3% (1 pt). At d14, morphologic blast count was not evaluable in 13 (39%) cases due to marrow aplasia, in 1 case (3%) blasts were <5%, in 5 (16%) <20%, in 14 (42%) ≥20%; by MFC (33 evaluable), in 15 pts (45%)

blasts were ≤2%, in 18 (55%) >2%; by PCR (27 evaluable), in 7 pts (26%) WT1 was <250cp/10^4ABL, in 20 (74%) ≥250cp/10^4ABL. At d28 of the 13 pts with d14 aplastic marrow, 10 (77%) achieved CR and 3 (23%) PR/NR, all the 6 pts with d14 blasts 5-19% achieved CR, of the 14 pts with d14 blasts ≥20%, 5 (36%) achieved CR and 9 (64%) PR/NR. Analysis of the paired results from nadir to recovery revealed that d14-LAIP 2% had a positive predictive value (PPV) of 83% and negative predictive value (NPV) of 93%, with 90% sensitivity and 87% specificity; d14-WT1 250 had a PPV of 53% and NPV of 86%, with 89% sensitivity and 46% specificity. The d14-LAIP was strongly associated with CR after induction (p=0.00007). Considering the 14 pts with d14 blasts ≥20%, 5/6 (83%) who received d14 FLAG-Ida obtained CR after a median time of 43 days, 3 pts did not receive further therapies, 3/5 (60%) who received d30 reinduction CT obtained CR after a median time of 54 days (p=0.23).

Summary and Conclusions: D14-LAIP proved to be superior to morphology and d14-WT1 in terms of feasibility and predictive value of subsequent CR. Even in one-third of pts who had an early morphologic response not evaluable due to marrow aplasia MFC proved to be a useful tool with a 100% applicability. Correlation between the two assays was >90%. Our data confirm the prognostic value of d14 BM evaluation and suggest that MRD detection, also in aplasia, could drive early salvage CT. Our results with early intensification are promising; clinical impact of this strategy will be investigated in larger studies.

E934

IDENTIFICATION OF PROGNOSTIC FACTORS RELATED TO THERAPEUTIC OUTCOMES OF CHEMOTHERAPY AND ALLOGENEIC STEM CELL TRANSPLANTATION IN 120 ACUTE MYELOID LEUKEMIA PATIENTS WITH MONOSOMAL KARYOTYPE IN KOREA

H. Cho[1,*] J. Jang[1], J. Yoon[2], I. Kim[3], J.H. Lee[4], C.W. Jung[5], H.J. Shin[6], W.S. Lee[7], J.H. Lee[8], D.S. Hong[9], H.J. Kim[10], H.J. Kim[2], S. Park[3], J.H. Jang[5], J.S. Chung[6], S.M. Lee[7], J. Park[8], J.S. Ahn[10], W.S. Min[2], J.W. Cheong[1], Y.H. Min[1]

Background: Monosomal karyotype (MK) was known to be associated with a dismal prognosis in acute myeloid leukemia (AML) and provide additive prognostic value in AML patients with complex karyotype.

Aims: In this study, we evaluated the prognostic significances of clinical characteristics and additive chromosomal abnormalities, which are associated with therapeutic outcomes of chemotherapy and allogeneic stem cell transplantation in ML AML.

Methods: Clinical data on AML in Korea has been collected through AML registry managed by the AML/MDS Working Party of the Korean Society of Hematology, and a total of 3,041 AML patients were registered at the time of analysis. From Jan. 2007 to Dec. 2011, 184 patients who met the definition of MK-AML were selected for this study, and 120 of 184 received induction therapy were retrospectively analyzed.

Results: The MK-AML accounted for 6.1 % of total AML in our registry, and the median age of was 56 years (range, 17-82 years). Median follow up duration for 120 patients was 40.5 months. The most frequent cytogenetic abnormality was -7/7q deletion (46.7%), and -5/5q deletion (40.8%) and 17p abnormality (17.5%) followed. MK defined by one single autosomal monosomy with at least one structural chromosomal abnormality was shown in 45 patients (37.5%), and MK defined by equal or more than two autosomal monosomies in 75 patients (62.5%). Fifty-two patients (46%) achieved complete remission (CR) after 2 cycled of induction chemotherapy, and early mortality rate was 16% (19 patients). Univariate and multivariate analysis revealed that ≥10% cells with normal metaphase was an independent good prognosis factor for CR achievement. Older age (≥60) and 17p abnormality were significant risk factors for early mortality. The 3-years overall survival (OS) and progress-free survival (PFS) for all patients was 20.8% and 7.9%, respectively. Univariate and multivariate analysis revealed that single monosomy, achievement of CR, and ≥10% cells with normal metaphase were independent good prognostic factors for PFS and OS. De novo type of AML and absence of 17p abnormality were another good prognostic factors for PFS and OS, respectively. Total 44 patients were finally received allogeneic hematopoietic stem cell transplantation (alloHSCT). Thirty-three of 44 patients were in CR1 or CR2 status, and 11 in relapsed or refractory status at alloHSCT. The 3-years overall survival (OS) and progress-free survival (PFS) for these transplanted patients was 38.6% and 24.1%, respectively. For 52 patients achieving CR, single monosomy, de novo type of AML, and alloHSCT at CR1 were significant good prognostic factors for relapse-free survival. Interestingly, as shown in Figure 1, MK-AML with one single monosomy receiving alloHSCT at CR1 showed better prognosis (3-yr OS and DFS rate was 64.6% and 48.1 %, respectively)

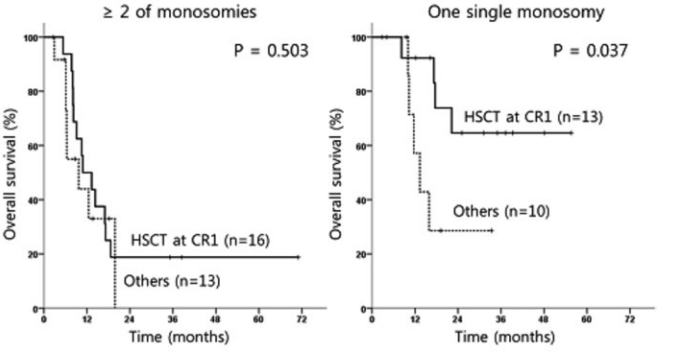

Figure 1. Overall survival according to type of MK and treatment modalities.

Summary and Conclusions: MK-AML, one of subtypes of AML accounting for about 6 % of AML in Korea, showed dismal prognosis with lower CR rate, PFS, and OS. However, compared to patients showing equal or more than 2 monosomy or <10% cells of normal metaphase, MK showing single monosomy or ≥10% cells with normal metaphase showed better prognosis in our analysis. AlloHSCT at the first CR should be strongly recommended to MK-AML patients with better prognostic factors, and for those without, more prudent decision is required. Furthermore, biologic mechanism of these better prognostic cytogenetic features should be investigated.

E935

NO INCREASE IN LEVEL OF FATIGUE AMONG LONG-TERM SURVIVORS WITH ACUTE MYELOID LEUKEMIA

Å. Derolf[1,*] M. Hultcrantz[1], E. Brånvall[1], K. Bergmark[2], E. Johansson[1], M. Björkholm[1]

[1]Division of Hematology, Karolinska University Hospital, [2]Department of oncology and pathology, Karolinska Institutet, Stockholm, Sweden

Background: At least 60% of patients <40 years and about 40% of patients 41-60 years of age can expect to become long-term survivors if diagnosed with acute myeloid leukemia (AML). These survivors are at risk of potential long-term disease- and treatment-related side complications due to intensive chemotherapy treatment and hematopoietic stem-cell-transplantation (HSCT). Most studies on long-term survivors have been performed in the HSCT population. Impaired sexual function, increased fatigue and psychological distress have been described among patients treated with HSCT when compared to patients receiving conventional chemotherapy only. There are few comparisons between AML survivors and the general population.

Aims: The aim of this study was to assess the impact of AML and its treatment on fatigue in long-term survivors in a population-based setting and with a matched control population.

Methods: Adult AML patients diagnosed 1973-2003 within the area of the Leukemia Group of Middle Sweden were identified in the Swedish Cancer Registry and those who died within 5 years of their diagnosis were excluded from the study using theCauses of Death Registry. Survivors were invited to participate by letter. Participants for the comparison group were identified through Statistics Sweden. For each survivor, 3 controls matched for sex, year of birth and residence were identified. Fatigue was measured using the Multi-dimensional Fatigue Inventory (MFI-20), a validated instrument consisting of five subscales of fatigue: general fatigue, physical fatigue, reduced motivation, reduced activity, and mental fatigue.

Results: 161 survivors were invited to participate; 100 accepted and were included (response rate 62%; 55 women). 150 controls accepted participation (response rate 31 %); 96 women. 27 patients had been treated with HSCT. AML survivors did not report a higher level of fatigue than the comparison group. We investigated whether there were any differences in the reported fatigue levels associated with the treatment applied. Radio therapy (*i.e.* total body irradiation as part of conditioning treatment prior to HSCT) was associated with an increased level of reduced motivation (p=0.044). When adjusting for age and co-morbidities using a linear regression analysis, radio therapy was associated with reduced motivation (p=0.010) and mental fatigue (p=0.044). We did not find any association between allogeneic HSCT and increased fatigue level in any dimension, neither in crude analyses or when adjusting for age and co-morbidities. Presence of chronic graft versus host disease (GvHD) or previous recurrence of AML was not associated with a higher level of fatigue. Among patient characteristics, we found a strong association between the presence of co-morbidities and general fatigue, physical fatigue and reduced activity. All five fatigue

dimensions were also associated with anxiety and depressive symptoms. There was no difference between male and female AML survivors.

Table 1. Five dimensions of fatigue among AML survivors and comparison group.

	AML survivors median (range)	Comparison group median (range)	p-value*	Crombach's
General fatigue	11.00 (4-20)	10 .00 (4-20)	0.826	0.84
Physical fatigue	10.33 (4-20)	8.00 (4-20)	0.186	0.90
Reduced activity	9.00 (4-20)	9.00 (4-20)	0.637	0.89
Reduced motivation	7.00 (4-19)	7.00 (4-18)	0.362	0.72
Mental fatigue	8.00 (4-19)	9.00 (4-20)	0.800	0.76

Summary and Conclusions: In this cohort of long-term AML survivors, most patients were treated with chemotherapy only. After more than five years after diagnosis, this group of survivors did not experience increased fatigue when compared to the general population.

E936

LONG-TERM REPORT OF A PILOT STUDY EVALUATING CLOFARABINE COMBINED WITH INTERMEDIATE-DOSE CYTARABINE AS CONSOLIDATION THERAPY IN PATIENTS WITH NON-FAVORABLE ACUTE MYELOID LEUKEMIA IN FIRST REMISSION

L. Roulin[1,*] N. Boissel[1], K. Celli-Lebras[1], M. El-Amhri[2], X. Thomas[2], H. Dombret[1], E. Raffoux[1]
[1]Maladies Du Sang, Hopital St Louis, Paris, [2]Hematology, CHU Lyon, Lyon, France

Background: In younger patients with AML in first complete remission (CR), a standard consolidation option relies on repeated cycles of high-dose cytarabine (HDAC), according to the CALGB schedule (Mayer, NEJM, 1994). Nevertheless, relapse incidence remains high, especially in those with non-favorable AML. Combination of 40mg/m^2/d clofarabine d2-6 with 1000 mg/m^2/d cytarabine d1-5 has been associated with promising response rate in high-risk AML patients (Faderl, Blood 2005 & 2006).
Aims: We conducted a pilot study to assess the feasibility of this "CLARA" combination as first CR consolidation in younger patients with non-favorable AML and no identified donor for allogeneic stem cell transplantation (SCT). We report here on long-term outcome and safety of this experimental approach.
Methods: Between 2004 and 2007, 23 patients aged 22 to 63 years (median, 50) with non-favorable AML in first CR (10 intermediaire I, 2 intermediaire II, and 11 adverse risk, according to ELN classification) received 3 CLARA cycles as consolidation, without further maintenance. All had previously received remission induction according to ALFA-9802 protocol (Thomas, Blood). All received oral antibacterial prophylaxis with levofloxacin or amoxicillin, but none received anti-fungal prophylaxis.
Results: Eight patients received the planned 3 CLARA cycles; 13 patients received only 1 or 2 cycles because either they became eligible for SCT (5 patients) or presented severe complications (8 patients). Two patients received a reduced clofarabine dose (30 mg/m^2/d) from the first cycle. Six patients are still in CR1 (26%) with a median follow up of 59 months, including 3 non-transplanted patients. In addition, 2 patients are still in CR2 with a median follow-up of 51 months. Infectious adverse events were frequently reported: 10 non documented infections, 7 sepsis documented with Gram-negative bacteria, 12 sepsis documented with coagulase-negative staphylococcus, 2 clostridium colitis, 3 viral reactivation (CMV), 7 pulmonary invasive aspergillosis (4 possible and 3 probable, according to EORTC classification) and 1 candidemia. Two patients required ICU hospitalization and 1 patient died from infection after the second CLARA cycle. Liver cytolysis was also frequently reported (7 Grade III and 7 Grade IV episodes) in 12 patients.
Summary and Conclusions: Administration of repeated CLARA consolidation cycles is a promising approach in younger patients with non-favorable AML in first CR. Nevertheless high rate of infections (especially pulmonary aspergillosis) led us to reduced the clofarabine dose from 40mg/m^2/d to 30mg/m^2/d and to introduce systematic anti-fungal prophylaxis in the following and not yet reported randomised ALFA-0702 trial, which compared prospectively CLARA to HDAC consolidation in similar patients.

E937

RETRO-TRANSCRIPTION LOOP MEDIATED ISOTHERMAL AMPLIFICATION (RT-Q-LAMP) AS A RAPID AND ROBUST MOLECULAR ASSAY FOR THE DIAGNOSTIC DETECTION OF PML-RARA FUSION TRANSCRIPTS

F. Lo Coco[1], G. Minnucci[2], M.D. Divona[3,*] F. Rigo[2], E. D'Agostini[2], A. Brisci[2], C. Montrasio[4], G. Amicarelli[2], L. Cicconi[5], C. Ciardi[6]
[1]Dipartimento di Biomedicina e Prevenzione, Università Tor Vergata, Roma, [2]Molecular Diagnostics, Diasorin Spa, Gerenzano, [3]Policlinico Universitario Tor Vergata Roma, Roma, [4]Molecular Diagnostics, 4Università degli Studi Milano-Bicocca Milano, Milano, [5] Dipartimento di Biomedicina e Prevenzione, [6]Dipartimento di Biomedicina e Prevenzione Roma, Università Tor Vergata, Roma, Italy

Background: The accurate and timely molecular identification of the Acute Promyelocytic Leukemia (APL) associated PML-RARa fusion gene is mandatory to confirm the morphologic suspect of APL and rapidly initiate tailored therapy, thus reducing the risk of potentially fatal hemorrhagic complications. The molecular analysis is currently based on RT-PCR or RQ-PCR assays, which can suffer from poor quality or insufficient amount of the extracted RNA, thus delaying the diagnosis.
Aims: Improvement of the molecular diagnosis of APL by introducing a novel ultra rapid and reliable screening test, robust for suboptimal RNA samples.
Methods: RT-Q-LAMP PML-RARa is an innovative, isothermal, non-PCR-based method for direct RNA amplification, extremely sensitive and specific. It consists of two fluorescent multiplex assays: one specific for the most frequent transcript isoforms (bcr1 and bcr3) and one for the infrequent bcr2 type. The reaction mix of both assays contains also additional primers to detect the endogenous GUSb housekeeping RNA as internal control. The reaction is performed in 40 minutes, with the amplification of positive samples requiring about 15 minutes, into the Liaison IAM instrument (DiaSorin) at constant temperature with a real-time monitoring of fluorescence. The data obtained are directly elaborated by the instrument that returns objective results and the proper discrimination of the transcript type.
Results: The triplex (bcr1-bcr3-GUSb) and duplex (bcr2-GUSb) RT-Q-LAMP assays have been tested on 33 PML-RARa positive and 20 PML-RARa negative clinical samples. In all cases RNA was extracted with the phenol-chloroform method and RT-PCR for PML-RARa was performed according to the Europe Against Cancer (EAC) protocol. All RNA samples presented heavy chemical contamination (ratio of 260/230 in the range of 0.29-0.99). In addition we tested 7 clinical samples that didn't produce an acceptable amplification result for the RT-PCR, due to strong RNA degradation (n=3), inhibition (n=2), and very low RNA amount availability (5ng/ul, n=2).The RT-Q-LAMP PML-RARa assays correctly amplified all the 53 samples with low 260/230 ratio, giving concordant results with those of conventional RT-PCR. Moreover, the 7 samples for which RT-PCR analysis was not possible, were all successfully amplified with RT-Q-LAMP in less than 30 minutes.
Summary and Conclusions: The fluorescent RT-Q-LAMP assays for PML-RARa fusion transcript detection is highly specific, sensitive and rapid. The rapidity and specificity of RT-Q-LAMP associated with the robustness for low concentrated and degraded samples, allow to reach a timely diagnosis in all cases, avoiding the need for analysis repetition or new sample extraction, as actually required by conventional RT-PCR. In addition, RT-Q-LAMP PML-RARa assays demonstrated to be not affected by the common PCR inhibitors, allowing the rapid amplification of samples presenting chemical contamination. These features increase the confidence in the results and make the assays suitable for even not highly specialized laboratories.

E938

THE ROLE OF AZACITIDINE IN THE TREATMENT OF ELDERLY PATIENTS WITH AML - RESULTS OF A RETROSPECTIVE MULTICENTER STUDY

A. Tombak[1,*] M.A. Ucar[1], A. Akdeniz[1], E.N. Tiftik[1], D. Sahin[2], O.M. Akay[2], M. Yildirim[3], O. Nevruz[3], C. Kis[4], E. Gurkan[4], S. Medeni Solmaz[5], M.A. Ozcan[5], R. Yildirim[6], I. Background: Older patients with AML have significant comorbidities, poorer performance status.Overall results of intensive chemotherapy remain poor.Azacitidine (AZA) has significant activity in MDS.Use of AZA was associated with improved OS when compared to low dose cytarabine in patients with high risk MDS, including those with marrow blast counts ranging from 20 to 30%. In untreated or relapsed/refractory AML, few studies have also shown significant response rates of AZA.However, there is limited data showing efficacy of AZA in AML patients with >30% bone marrow (BM) blasts.
Aims: In this retrospective multicenter study, we aimed to investigate the efficacy and safety of AZA in elderly patients with AML (including patients with >30% BM blasts) defined according to WHO.
Methods: Between 2009-2014,≥60 year-old patients with AML from 16 centers

in Turkey were included.Eligibility criteria included ≥60 years-old AML patients treated with at least one dose of AZA.Demographic data, comorbidities, ECOG status, transfusion-dependency, cytogenetic risk status, blast ratios, treatment prior to AZA, adverse events, treatment responses were recorded.Assessment of response was performed after 4 cycles.
Results: 130 patients (72 men) receiving AZA were included into study.Median age was 73 (60-88 years).ECOG performance status (ECOG-PS) was ≥2 in 54.6%, there were comorbidities in 66.2% of cases (89.5% had <3 comorbidities).LDH was ≥225 IU/L in %75.4 and 40.8% had WBC count>10x109/L/mm3. 80 patients (61.5%) had >30% BM blasts.112 patients were transfusion-dependent. 50.8% had an intermediate karyotype.Patients received AZA for a median of 4 cycles (range 1-21). Initial ORR (including complete remission CR/CRi/PR) was 36.2%. Any hematologic improvement (HI) was documented in 37.7%.HI was also documented in 27.1% of patients who were unresponsive to treatment.Median overall OS was 18 months for responders, 12 months for non-responders (p=0.005).In unresponsive patient group, any HI has also improved OS compared to patients without any HI (median OS was 14 months versus 10 months, p=0.068).In univariate analysis of following parameters had significant effect on both treatment response and OS: ECOG-PS, number of AZA cycles and any HI. ECOG-PS≥2 was associated with a worse response to AZA (29.7% versus 53.2%, p=0.012) and with a worse OS (10 [95% CI 8.1-11.9] months versus 14.1 [95% CI 7.8-20.3] months,p=0.034).In patients receiving ≥5 courses of AZA versus <5 courses, response rate and OS were higher (61.9% versus 28%, p<0.001 and 14.1 [95% CI 8.5-19.6] months versus 9 [95% CI 4.0-14.0] months,p=0.011, respectively).Response rate and OS increased with any HI versus without any HI (59.6% versus 27.1%,p<0.001 and 18 [95% CI 10.0-26.0] months versus 10 [95% CI 5.1-14.9] months,p=0.002).OS was higher in patients with LDH<225 IU/L compared to patients with LDH≥225 IU/L (19 [95% CI 12.1-25.9] months and 11 [95% CI 8.6-13.4] months, respectively,p=0.018), but LDH level had no impact on treatment response (ORR is 38.5% versus 41.9% for LDH</≥225 IU/L, respectively,p=0.758).Transfusion-dependence prior to AZA was associated with a worse response to AZA (36.3% versus 66.7%,p=0.025) and with reduced OS, which was however not statistically significant (12.3 [95% CI 9.8-14.8] months versus 20 [95% CI 4.2-35.9] months,p=0.077).ECOG<2, increasing number of AZA cycles (≥5 courses) and any HI predicted better OS (Figure1). Age, AML type, BM percentage had no impact.Grade 3-4 neutropenia, thrombocytopenia anemia were documented in 34.6%,40.8%,39.2% of patients, respectively.Non-hematologic toxicities were mild;most common adverse events being mucositis, injection site pain, nausea.

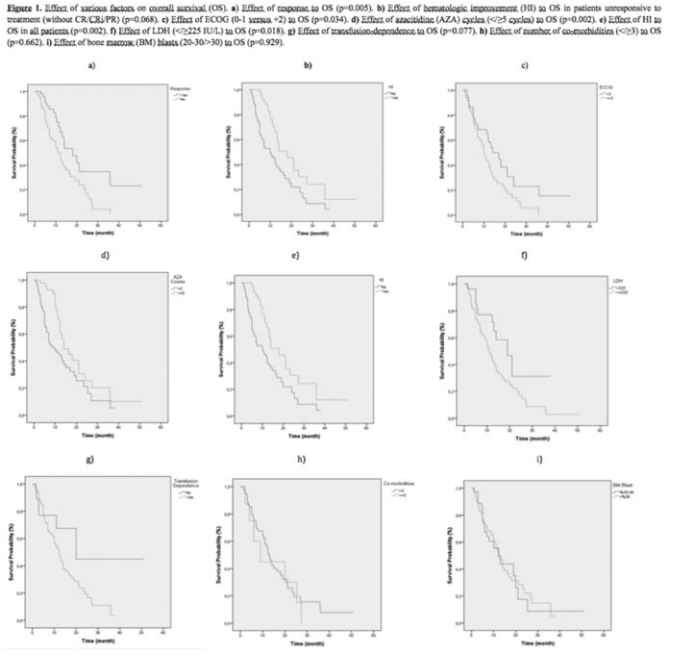

Figure 1.

Summary and Conclusions: In conclusion; AZA is effective and well tolerated in elderly, comorbid AML patients with fewer required erythrocyte and platelet transfusions, irrespective of BM blast count. And HI should be considered sufficient response to continue treatment and treatment should not be interrupted since OS and response to treatment increase with the increasing number of AZA cycles.

E939

CORE-BINDING FACTOR IN CHILDHOOD ACUTE MYELOID LEUKEMIA

O. Kassar[1,*] M. charfi[1], F. kallel[1], M. ghorbel[1], M. mdhaffar[1], N. abdejellil[2], H. bellaaj[1], S. hdijji[1], T. ben othmen[2], M. elloumi[1]
[1]Hematology, University Sfax, Sfax, [2]Bone Marrow Transplantation Center, University Tunis, Tunis, Tunisia

Background: Core-binding factor-acute myeloid leukemia (CBF-AML) (t[8;21] or inv[16]/t[16;16]) represents a favorable cytogenetic AML subgroup and have favorable prognosis
Aims: We reported the results of therapeutic and prognostic pediatric AML with rearrangement of CBF genes in a single center from Tunisia.
Methods: Our study is retrospective; it concerned patients under 20 years with AML with rearrangement of CBF genes de novo during the period between January 2006 and December 2013.The treatment protocol includes: a course of 7 +3 induction (Arac200mg/m2/day+DNR60mg/m2/day) followed in case of complete remission (CR) by 3 courses of consolidation: *1st course: Arac 6g/m^2/day (3d) +Mitoxantrone12mg/m2/day(3d), 2nd course: Arac200mg/m^2/day (7d) +DNR50mg/m^2/day VP16100mg/m2/day (5d) * 3rd course: Arac 6g/m2/day (3d) +L-asparaginase 6000UI/m2 in day 5. Allogenic bone marrow transplantation is indicated for patients who have a HLA-compatible family donor. Kaplan-Meier method is used to estimate overall survival (OS) and event-free survival (EFS).
Results: Of the 33 patients under 20 year with acute myeloid, 10 patients (33%) enrolled in our study with CBF genes. The sex ratio is 1,5. The mean age is 12 years [6 -18 years]. Distribution according to the FAB classification is as followed: 8 patients with AML2, 1 patient with AML4 and 1 patient with AML6. Cytogenetic abnormalities are found in 9 cases and 1 case have normal karyotype. Eight patients (80%) have t(8,21), one patient has inv 16 and one case has normal karyotype with positive CBF tanscript. Complete remission rate (RC) is 100%, relapse rate is 30 %. The bone marrow transplantation was performed in one patient in RC1. A second remission is achieved in 2 patients (67%). Overall survival, event-free survival and relapse-free survival at 5 years are respectively 89% and 65,5%.
Summary and Conclusions: The cytogenetic t(8;21) is predominant in CBF AML in our series (80%). Childhood CBF- AML are associated with a high CR rate and a good long-term prognosis in our series similar the literature.

E940

PROGNOSATIC RISK SCORE FOR HAEMORRHAGIC EARLY DEATH IN ACUTE PROMYELOCYTIC LEUKEMIA

M. Mitrovic[1,2,*] N. Suvajdzic[1,2], A. Novkovic[3], I. Djunic[1], A. Vidovic[1,2], M. Virijevic[1], N. Colovic[1,2], I. Elezovic[1,2], D. Tomin[1,2]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]3. Clinical Hospital Center Zemun,, Belgrade, Serbia

Background: Hemorrhagic early death (HED), w
ith reported rates between 5 and 26.52%, is a major impediment in the managing of acute promyelocytic leukemia (APL). Although previous studies identified several prognostic factors for HED such as poor performance status (PS), high white blood cell (WBC) count, high peripheral blast count, serum lactate dehydrogenase (LDH), low fibrinogen level, platelet count and prolonged prothrombin time (PT), a predictive model for HED has not yet been elaborated.
Aims: To identify factors predictive of HED and to develop prognostic scoring system.
Methods: We analyzed data on HED in 85 newly diagnosed PML-RARA positive APL patients (median age 45 years, range 18-78; 36/49 female/male ratio) managed in the Clinic of Hematology from 2004 to 2014 with all-trans retinoic acid combined with anthracyclines. Central nervous system (CNS), retinal, pulmonary or gastrointestinal haemorrhages were considered a severe bleeding event. HED was defined as death from hemorrhage from the first day of hospitalization up to the end of the induction treatment. The following parameters were evaluated as risk factors for HED: age, ECOG PS, patient's (time from the first symptoms to seeking medical care), medical (time from the first medical contact to ATRA initiation) and treatment delay (time from hospitalization to ATRA initiation), severe bleeding, WBC count, peripheral blast count, platelet count, fibrinogen level, PT, D dimer, ISTH DIC score, morphological disease type, CD15 and CD56 positivity, additional cytogenetic abnormalities, PML-RARA isoforms and *FLT3-ITD* mutation. Pearson chi test and Fisher test were used to analyze differences for categorical data. For multivariate analysis a binary logistic regression model was constructed for EHD adjusting for 6 variables. A backwards elimination procedure was used to exclude redundant or unnecessary variables. Integer weights for the risk score were derived from logistic regression model. Prognostic score was validated via 10-fold cross validation.
Results: HED occured in 12/85 (14.12%) patients. Predictors of HED in univariate analysis were: ECOG PS ≥2 (P=0.010), severe bleeding at diagnosis (P=0.023), WBC >20x10^9/L (P=0.015), fibrinogen level <2 g/L (P=0.05), PT <50% (P=0.005), and ISTH DIC score ≥7 (P=0.031) as the most statistically significant cutoff points. Independent risk factors in multivariate analysis were: severe bleeding at diagnosis (P=0.041), WBC >20x10^9/L (P=0.018) and ISTH DIC score ≥7 (P=0.024). A clinical prognostic scoring system was then developed: absence of severe bleeding at diagnosis, WBC <20x10^9/L, ISTH DIC score <7=0, WBC ≥20x10^9/L=1 point and ITSH DIC score ≥7=2 points. Accordingly patients were classified in three groups: low risk=0 points, intermediate=1-

2 points and high risk ≥3 points. The HED rate between these groups (low 2.4%, intermediate 26.1% and high 100%) was significantly different (p<0.001).
Summary and Conclusions: The prognostic model developed in this study allows for the identification of the patients at high risk for HED, needing more aggressive supportive measures. Further large population-based studies for testing new score systems and refinements therapeutic approaches for APL patients in high HED risk are needed.

E941

THERAPY-RELATED ACUTE MYELOID LEUKEMIA IN ADULTS: IS AGE YOUNGER THAN 40 CLINICALLY RELEVANT?

F. Rosenblum[1], V. Parekh[1], V. Reddy[1], D. Peker[1,*]
[1]University of Alabama at Birmingham, Birmingham, United States

Background: Therapy-related myeloid neoplasms (t-MN) occur as the complication of chemotherapy (CT) and/or radiation therapy (RT), and account for approximately 10 to 20% of all cases of myeloid neoplasm in adults. t-MN represent distinct clinical entities, confer a worse prognosis when compared to de novo counterparts and have a high prevalence of adverse-risk karyotypes. One of the most serious entities comprising t-MN is therapy-related acute myeloid leukemia (t-AML).
Aims: Most of the studies published in the past have focused on elder patients, so we aim to investigate the features of t-AML in patients younger than 40 years of age as compared to their older counterparts.
Methods: A retrospective review of cases encountered between 2003 and 2013 was performed following IRB approval. All cases of AML with a prior history of CT/RT were included in the study (n=70). The clinical data including age, sex, medical history and the time interval between the treatment for prior solid or hematologic malignancy and the development of t-AML were recorded. Cytogenetic, molecular and/or FISH data for t-AML were available for sixty-one patients. The cases were divided into two groups. Group 1 consisted of t-AML patients 40 years of age or younger and Group 2 consisted of patients older than 40. A survival analysis was performed.
Results: Table 1 shows the summary of characteristics for groups 1 and 2. Group 1 included 12 cases with a median age of 32 (20-40 years) and the M:F ratio of 0.5. In this group, the most frequent prior malignancy was hematologic cancers (n=5, 42%); Hodgkin lymphoma being the most common, followed by sarcomas majority of which are Ewing sarcomas (n=3, 25%). Cytogenetic findings were abnormal in 10 of 12 patients (83%), with MLL gene anomalies being the most common finding (n=5, 42%), followed by 7q deletion (n=4, 33%). Group 2 consisted of 58 cases with a median age of 61 (41-86 years) and the M:F ratio of 0.7. In this group, the most frequent prior solid and hematologic malignances were breast cancer (n=19, 33%) and follicular lymphoma (n=9, 16%), respectively. Cytogenetics and FISH (combined) revealed 7q deletion as the most frequent abnormality (n=16, 28%) followed by *MLL* gene abnormalities (n=9, 16%). NPM1 and FLT3 internal tandem duplications were found in 5% of cases. The median interval between the last CT/RT and diagnosis of t-AML for groups 1 and 2 were not significantly different; 47 and 36 months, respectively. There was no significant difference in cell counts or bone marrow blast counts. The OS in two groups were significantly different; 28 vs. 9 months in Groups 1 and 2, respectively (p <0.05) (Figure 1). There was no significant difference in OS between patients >60 and =<60 years old; 8 vs. 9 months, respectively (p=0.225).

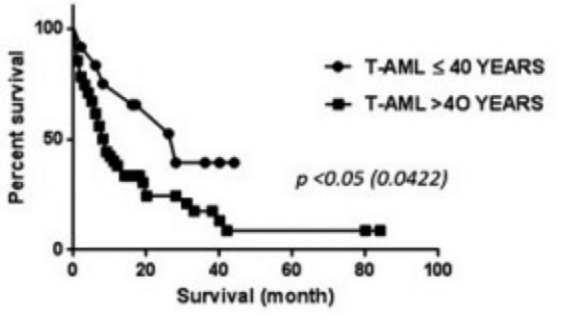

Figure 1. Survival analysis between Group 1 and Group 2.

Summary and Conclusions: The results of the current study show that age is an important prognostic factor regardless of the karyotypic abnormalities. In the two groups we analyzed, group 1 (=<40 years) showed more frequent association with poor prognostic karyotype when compared to group 2 (>40 years). There was no significant difference between two groups with regards to interval between prior treatment and t-AML, cell counts or blast count. t-AML being a dire complication in patients treated with cytotoxic therapy, prognostication is important to accurately predict the outcome in this group. Large scale studies are warranted to investigate other prognostic factors in addition to cytogenetic sub-classifications.

Tabella 1. Summary of patient char acter ist ics and outcomes.

	t-AML (Age =<40 years) (n= 12)	t-AML (Age >40 years) (n=58)
Age at diagnosis (median)	32 (20-40 years)	61 (41-86 years)
Prior radiation therapy	7 (58%)	27 (45%)
Prior chemotherapy	12 (100%)	53 (91%)
Prior malignancy		
Solid organ tumors	2 (17%)	33 (57%)
Hematologic malignancies	5 (42%)	22 (37%)
Germ cell tumors	1 (8%)	1 (2%)
Sarcomas	4 (33%)	0
Melanoma	0	1 (2%)
Other	0	1 (2%)
Interval between treatment and diagnosis of t-AML, median (months)	47	36
White blood cell count at diagnosis, median ($x10^3/\mu L$)	3.0	4.65
Absolute Neutrophil count at diagnosis, median ($x10^3/\mu L$)	0.15	0.85
Hemoglobin at diagnosis, median (g/dL)	7.9	8.6
Platelet count at diagnosis median ($x10^3/\mu L$)	44.5	43.5
Bone marrow blast count, median (%)	60	65
Molecular/karyotypic abnormalities at diagnosis (%)		
MLL	5 (42%)	9 (16%)
Del 7q	4 (33%)	16 (28%)
t(15;17)	0	2 (3%)
t(8;21)	0	2 (3%)
inv(16)	0	1 (2%)

E942

AZACYTIDINE THERAPY IN PREVIOUSLY UNTREATED ELDERLY AML PATIENTS: COMPARISON WITH CONVENTIONAL CHEMOTHERAPY IN A MATCHED-PAIRED ANALYSIS

P. Minetto[1,*] F. Guolo[1], M. Clavio[1], L. Giannoni[1], D. Guardo[1], F. Ballerini[1], L. Mitscheunig[1], L. Del Corso[2], A. Bellodi[2], E. Balleari[2], M. Miglino[1], R.M. Lemoli[1], M. Gobbi[1]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]Chair of Internal Medicine, Department of Internal Medicine (DiMI), University of Genoa, IRCSS AOU San Martino-IST, Genoa, Italy

Background: The hypomethylating agent azacytidine (AZA) is increasingly used in acute myeloid leukemia patients (AML) with low marrow blast count or in elderly patients who are not eligible for intensive chemotherapy. We recently performed a retrospective analysis of AZA front line treatment in elderly AML patients and reported its efficacy and feasibility.
Aims: The aim of the present study was to compare the outcome of untreated elderly AML patients receiving AZA or conventional chemotherap by performing a matched-paired analysis.
Methods: We retrospectively analyzed the outcome of 42 elderly AML patients who received AZA as front line treatment in our Centre from June 2010 to December 2014. A control series of patients treated with conventional chemotherapy was selected through a matched-paired analysis. Matching variables were white blood cells count at diagnosis, age, karyotype, disease onset and sex. No significant differences were appreciable for those variables, whereas median age was significantly higher in AZA cohort than in FLAI-3 cohort (74 yy and 70 yy, respectively, p <0.05). Relevant comorbidities (diabetes mellitus, heart disease, hypertension, liver or lung diseases) were present in 70% of patients receiving AZA. AZA was delivered at the dosage of 75 mg/sqm s.c. with a 5+2 days schedule. Patients were given a median of 4 courses of treatment (range 1-27). Twenty-five patients (75%) received concomitant recombinant alpha erythropoietin therapy (40000 U once weekly). AZA therapy was continued until unacceptable toxicity or disease progression, regardless of response achieved. Conventional treatment consisted in a fludarabine-containing regimen with age-adjusted doses (FLAI-3 schedule: fludarabine 25 mg/mq, cytarabine 1000 mg/mq, idarubicin 5 mg/mq, days 1,2,3).
Results: Major infection during therapy were observed in 20/42 (47.6%) patients in AZA group and 15/42 (35.7%) in FLAI-3 group (p=0.356). Four and two patients died during induction in AZA and FLAI-3 group, respectively. Complete remission (CR) rates were significantly lower in AZA-treated patients (7/38, 18%), compared

to FLAI-3 (21/40, 53%) (p=0.002). Sex, disease onset, karyotype, WBC count and age did not significantly influence CR rates in neither of the two cohorts. Of note, none of the nine patients treated with AZA who presented with leukocytosis achieved CR, compared with 6/15 (40%) patients in the FLAI-3 cohort. However, this did not translate in a significant lower OS for patients with leukocytosis treated with AZA (2yy OS 50.4% and 24.2% for patients with WBC count lower or higher than 10.000/mmc, respectively, p=0,120). After a median follow-up of 25 months, 2-years overall survival (OS) was 36.2% in AZA group (median 14 months), significantly higher than FLAI-3 group (11.2%, median 9 months, p=0.048, Figure1). OS duration was significantly influenced only by achievement of CR in FLAI-3 cohort (p=0.000), whereas in AZA cohort was influenced only by younger age at diagnosis (p=0.048). Achievement of CR had only a borderline effect on OS duration in AZA cohort (p=0.050).

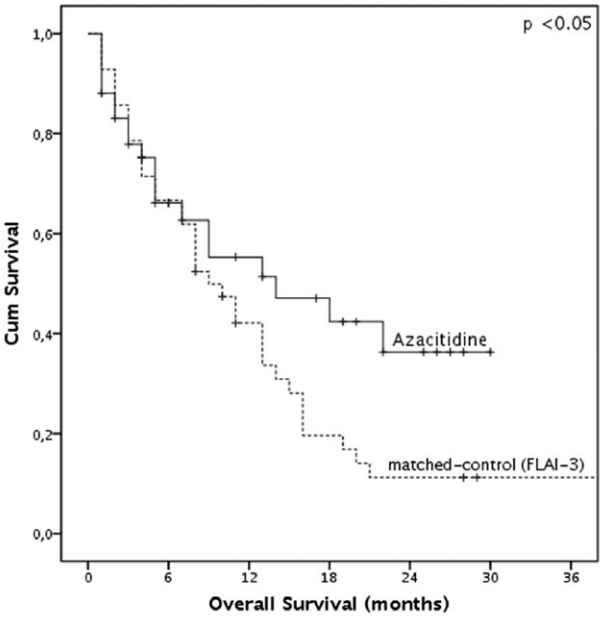

Figure 1. Overall survival according to treatment.

Summary and Conclusions: AZA was generally well tolerated, with acceptable toxicity profile, even in our cohort of very frail untreated AML patients. Even if CR rates were significantly lower when compared to a matched-paired cohort of conventionally-treated patients, OS rate were not inferior. Our data suggest that Azacytidine is a safe first-line therapy for frail AML patients, with comparable effectiveness with conventional intensive chemotherapy.

E943

COMBINATION OF CLOFARABINE AND CYTARABINE IN THE TREATMENT OF REFRACTORY OR RELAPSED ACUTE MYELOID LEUKEMIA

B. Spassov[1,*] G. Balatzenko[2], S. Angelova[2], S. Toshkov[2], M. Guenova[3], G. Arnaudov[4], G. Mihaylov[1]
[1]Department of Clinical Hematology, [2]Laboratory of Cytogenetics and Molecular Biology, [3]Laboratory of Hematopathology and Immunology, [4]Department of Stem Cell Transplantation, National Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: The use of combination chemotherapy is effective and curative in some patients with acute myeloid leukemia (AML). However, some of the newly diagnosed AML patients fail to achieve complete remission (CR) because of resistance to treatment and 40% of CR patients will relapse within 2 years. The prognosis of patients with primary refractory or relapsed AML is generally unfavourable, with salvage chemotherapy giving a remission rate of merely 10–40%. Clofarabine is a new generation deoxyadenosine analog that has shown some activity in relapsed or refractory AML. Because of the structural similarity between purine analogues, a putative synergism between clofarabine and cytarabine has been postulated. However data regarding efficacy and safety of clofarabine and cytarabine combination therapy in refractory and relapsed AML patients is limited.
Aims: To examine the efficacy and safety of sequential clofarabine and high dose cytarabine in adult patients with relapsed or refractory AML.
Methods: Data from 35 refractory or relapsed AML patients, at a median age of 39.4 years (range, 21-60 years), diagnosed between 2010 and 2014, were evaluated retrospectively. Clofarabine was administered as a 1-hour intravenous infusion at a dose of 40 mg/m^2 daily for 5 consecutive days on days 2 through 6 followed 4 hours later by cytarabine at a dose of 1 or 2 g/m^2 as a 2-hour intravenous infusion daily for 5 consecutive days on days 1 through 5. On day 1, only cytarabine was administered, and on day 6, only clofarabine was given. Patients who achieved CR received further consolidation chemotherapy with intermediate- (1.5 g/m2 every 12 h for six doses) or high-dose cytarabine (3 g/m2 every 12 h for six doses) or allogeneic hematopoietic stem cell transplantation (HSCT).
Results: All the patients had received at least one prior regimen. There were 29 primary refractory and 6 relapsed cases. Cytogenetic analysis was performed in 91.4% (32/35) of the patients. Twenty one patients (65.6%) had intermediate cytogenetic risk, whereas favorable and unfavorable cytogenetic findings were detected in 3 (9.4%) and 8 (25%), respectively. Internal tandem duplications of *FLT3* gene (FLT3-ITD) were found in 8 patients (22.9%). Eighteen patients (51.4%) achieved CR, whereas thirteen patients (37.1%) had resistant disease, and 4 (11.4%) died during induction. CR was achieved in 9 (60%) patients with diploid cytogenetics whereas CR was observed in 3 (100%) and 1 (12.5%) patient with favorable and unfavorable cytogenetic findings, respectively. Patients with FLT3-ITD achieved CR in 50% (4/8) of the cases. In patients with CR, 55.6% (10/18) were able to proceed to allogeneic HSCT. The 24 month overall survival (OS) for the whole patients' cohort was 28.8%. For CR patients, the 24 month OS and disease-free survival (DFS) were 33.8% and 40.8%, respectively.
Summary and Conclusions: Clofarabine in combination with cytarabine is effective in refractory and relapsed AML patients. In addition, it represents a useful remission induction strategy to serve as a bridge to transplantation in these patients.

E944

PROGNOSTIC IMPACT OF WT1 GENE EXPRESSION QUANTIFICATION DURING MINIMAL RESIDUAL DISEASE MONITORING OF ACUTE PROMYELOCYTIC LEUKEMIA

M. Mitrovic[1,2,*], N. Tosic[3], N. Suvajdzic[1,2], I. Djunic[1], A. Vidovic[1,2], M. Virijevic[1], N. Colovic[1,2], I. Glumac[3], T. Kostic[3], S. Pavlovic[3], I. Elezovic[1,2], D. Tomin[1,2]
[1]Clinic of Hematology, Clinical Center of Serbia, [2]Faculty of Medicine, University of Belgrade, [3]Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia

Background: Acute promyelocytic leukemia (APL) is characterized by the highest Wilms tumor gene 1 (WT1) expression levels in comparison to other types of acute myeloid leukemia (AML). Several studies have reported the usefulness of WT1 expression assessment as a molecular marker of minimal residual disease (MRD) in AML patients. However, data on prognostic significance of WT1 gene expression during MRD monitoring of APL is lacking.
Aims: To quantify WR1 gene expression during MRD monitoring of APL patients
Methods: Data on WT1 expression in 22 *de novo PML-RARA* positive APL patients were analyzed prospectively (median age 42 years; female/male ratio 12/10; median WBC count 1.5 x10^9/L (range: 0.4-88), median follow-up of 27 months (range: 5-78)). The patients were managed with all-trans retinoic acid combined with anthracyclines. Fresh bone marrow (BM) samples were collected at diagnosis, after the first consolidation and after that every six months. WT1 expression levels were quantified by RQ-PCR method, using TaqMan chemistry. Abl served as a housekeeping gene. Relative quantification analysis was performed using comparative Ct method (2-ddCt), where ddCt=dCt(sample) - dCt(healthy(median)). A WT1 level of at least twice the maximum assessed in healthy controls was defined as WT1 overexpression (≥18.00).
Results: A total of 89 BM samples were collected during diagnosis and follow-up. Initially WT1 level was significantly higher in APL patients compared to healthy controls (mean 3765.99, range 13.64-13988.95vs. 1.95±1.18, range 0.06-8.77, p<0,001), with overexpression in 21/22 (95.45%) of patients. After first consolidation all patients reached molecular remission (MR). In 15/22 (68.18) patients MR was accompanied by WT1 levels ≥3 log reduction, in 4/22 (18.18%) by ≥2 log reduction and 1/21 (4.54%) <1 log reduction. Median WT1 gene expression after first consolidation was 24.34 (range: 0.95-72), with overexpression in 6/22 (27%) patients. Six relapses (5 molecular) was observed in 4/22 (18.18%) patients. The increase in WT1 expression was observed in all samples during relapse (>1.5 log in 2/6 relapses (30%), >1 log in 3/6 (50%) and <1 log in 1/6 (16.67%)) with mean level of 274.07 (range: 11.93- 1327.96). Increased WT1 expression was combined with PML-RARA positivity in 5/6 (83.3%) samples. In one case WT1 level increment was registered 6 months before PML-RARA positivity. Mean WT1 expression in patient with persistent MR was 21.17 (range: 3.34-59.76), with high level of variability and overexpression in 11/30 (36.7%) samples. However WT1 expression increment >1 log wasn't seen in patients with persistent MR. APL relapses were significantly associated with WT1 overexpression after first consolidation (3/4 (75%) *vs* 3/18 (16.67%), p=0,003), and >1 log WT1 expression increment during follow-up (5/6 (83.3%) *vs* 0, p=0,0001). No correlation was found with initial WT expression level (2471/7 *vs* 3994/51, p=0,516).
Summary and Conclusions: 1. WT1 decreased rapidly after induction but maintained residual levels in MR 2. WT1 expression was able to detect patients at high risk of relapse 3. Quantitative analysis of WT1 as post-remission control enables early detection of relapse. Further large prospective trials should eval-

uate whether this parameter should be included in risk stratification and MRD monitoring.

E945

CCAAT/ENHANCER BINDING PROTEIN ALPHA (CEBPA) NEW MUTATIONS IDENTIFIED BY THE HEMATOLOGY OF FLORENCE

V. Ponziani[1,*] F. pancani[2], F. mannelli[2], B. scappini[2], S. di lorenzo[1], A. bosi[1]
[1]hematology, [2]careggi hospital, florence, Italy

Background: CCAAT/enhancer binding protein alpha *(*CEBPA) is a transcription factor involved in lineage specification; it is crucial for the development of myeloid progenitors to differentiated neutrophils. Mutations in CEBPA gene are specific to AML and are not reported in other cancers. They are detected in 5-14% of cytogenetically normal AML patients (CN-AML). Typical alterations affect either the N-terminus with nonsense mutations leading to a dominant negative protein, and/or C-terminus resulting in decreased DNA binding of basic leucine zipper (bZIP) region. Several studies show that a single mutation in CEBPA (CEBPAsm) is prognostically neutral, whereas double mutations (CEBPAdm) have been associated with a relatively favourable outcome and therefore are emerging as a prognostic marker at the diagnosis. In the majority of CEBPAdm AML, the mutations are typically on different alleles and involve a combination of a N-terminal and a C-terminal mutation.
Aims: In order to obtain a better insight into the distribution of the various types of CEBPA mutations and evaluate their impact on clinical outcome, we screened for CEBPA a cohort of 230 de novo AML patients.
Methods: We analysed the entire coding region of CEBPA using three overlapping PCR primer pairs designed by Pabst *et al.* (2001) with minor modifications. PCR products were sequenced in both directions on ABI-3100 Genetic Analyzer (Applied Biosystems).
Results: By sequencing the entire CEBPA coding region, we identified a total of 33 mutations in 23 patients (10%) in our cohort of 230 patients de novo CN-AML. Within them, 10 patients had biallelic mutations (CEBPAdm) while 13 patients had single CEBPA mutation. Among these 33 mutations detected, 16 were already identified in previous studies, while the others (listed in table 1) had not been described before. The results can be summarized as follows: 8 of the 17 alterations described were frameshift mutations, 8 were insertions/duplications in-frame, 1 was a missense point mutation. According to literature data, insertions/deletions mutations (3n+1 bp) out-of-frame were concentrated in N-terminal region causing frameshift in the reading sequence and involving the formation of a new stop codon. All new mutations identified in the C-terminal region were in-frame and occurred between AA 301 and AA 318. We observed in four cases a "de novo" nucleotides insertion, while all the other patients showed long existing sequences duplication to 36 bp. Patient # 9 showed a nonsense nucleotide substitution in position 992 of the C-terminus, in which an thymine was replaced by a cytosine, corresponding to an Isoleucine Proline amino acid substitution (I with P), creating a novel stop codon.
Summary and Conclusions: In this analysis on a cohort of 230 de novo AML we identified 18 new CEBPA mutations not described before. Due to the relevant role of CEBPA in leukemogenesis, the identification of novel mutations aids to get more insight into the biology and prognosis of CEBPA-mutated AML subset. A longer follow up is necessary to evaluate the impact of CEPBAdm and particularly of these new mutation on the clinical outcome.

E946

CENTRAL NERVOUS SYSTEM INVOLVEMENT AT DIAGNOSIS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA: RISK FACTORS, TREATMENT AND OUTCOME

I. Djunic[1,*] N. Suvajdzic-Vukovic[2], M. Virijevic[1], N. Kraguljac-Kurtovic[3], V. Knezevic[3], M. Mitrovic[2], A. Novkovic[4], N. Colovic[5], A. Vidovic[5], D. Tomin[5]
[1]Department of acute leukemias, Clinic For Hematology, Clinical Center Of Serbia, [2]Clinic For Hematology, Clinical Center of Serbia, Medical Faculty of Belgrade University, [3]Laboratoty for imunoflowcytometry, Clinic For Hematology, Clinical Center Of Serbia, [4]Clinical Hospital Center "Zemun", [5]Department of acute leukemias, Clinic For Hematology, Clinical Center of Serbia, Medical Faculty of Belgrade University, Belgrade, Serbia

Background: Central nervous system (CNS) involvement at diagnosis of acute myeloid leukemia (AML) occurs in less then 5% of patients. It is rare but serious complication of AML with significant influence on poor outcome of these patients. Due to infrequency of CNS involvement (CNS+) in AML there is a paucity of literature on the optimal management of CNS disease.
Aims: The aims of this investigation were to estimate the incidence of CNS+at diagnosis AML, to determine risk factors for its occurrence and to define influence of CNS+on outcome of these patients: rate of complete remission (CR) and remission of CNS+, relaps-free survival (RFS) and overall survival (OS).
Methods: This single-center study involved 402 adult patients with nonpromyelocytic *de novo* AML during follow-up of 72 months. The following parameters were estimated as risk factors for CNS+at diagnosis of AML: age, WBC ($<30x10^9$/L *vs* $\geq 30x10^9$/L), serum lactate dehydrogenase (LDH) concentration >1.5x the upper limit of normal, expression of CD56 antigen on leukemic blasts (<20% *vs* ≥20%), AML subtype according to the French-American-British (FAB) Cooperative Group and cytogenetic risk group (assessed according to European LeukemiaNet recommendations). The presence of leukemic cells in cerebrospinal fluid (CSF) detected by cytomorphological and/or flow cytometric analysis of CSF is considered as CNS involvement. Patients were treated according with follow chemotherapy (CT): induction CT (daunorubicin 60 mg/m^2 three days and 7 days cytarabin 200 mg/m2) following three CT of consolidations (high dose of cytarabine, eg. 3 g/m2 every 12 h on day 1,3,5). In patients aged >60 years doses of induction CT were reduced for 50% and as consolidations CT were applied cytarabine in intermediate dose (1.5 g/m2 day 1 to 3). Patients aged >75 years treated with paliative therapy (Hydroxiurea or 6-mercaptopurine per os). Patients with CNS+treated with intrathecal (i.t.) CT: cytarabine 100 mg 2 x/week until clear of CSF. Patients who no achived remission of CNS+treated with radiotherapy of CNS with 18-24 Gy in total dose. Assesment of remission of CNS+was performed after 8 i.t. CT.
Results: The CNS+was recorded in 4.7% (19 pts) of AML patients at diagnosis. The mean age of CNS+patiens was 48 years (range 26-71 years) while the mean age of CNS negative (CNS-) patients was 58 years (range 19-85 yeras). Multivariate analysis identified CD56+as the most important risk factor for CNS+at diagnosis in AML patients: p=0.001, relative risk (RR)=18.241; 95% confidental interval (CI)=3.305-100.675. In group of CNS+patients, the CR rate was 68% (13 pts) while CNS remission rate was 16% (3 pts). RFS was significance different among CNS+and CNS- patients: 8 *vs* 20 months (p=0.001), as well as OS: 6 *vs* 18 months (p=0.002). Multivariate analysis indicated CNS+as the most significant independent predictor of poor RFS: p=0.002, RR=1.806, CI=1.241-2.628, and OS: p=0.008, RR=1.592, CI=1.130-2.243.
Summary and Conclusions: AML patients with CNS involvement at diagnosis have a poor prognosis and further studies need to improved and optimized their treatment.

E947

PHASE 1 STUDY: SAFETY AND TOLERABILITY OF INCREASING DOSES OF CB-839, AN ORALLY-ADMINISTERED SMALL MOLECULE INHIBITOR OF GLUTAMINASE, IN ACUTE LEUKEMIA

M.Y. Konopleva[1,*] I.W. Flinn[2], E.S. Wang[3], C.D. DiNardo[1], M.K. Bennett[4], C.J. Molineaux[4], M.H. Le[4], M.B. Maris[5], O. Frankfurt[6]
[1]Dept of Leukemia, Div of Cancer Medicine, MD Anderson Cancer Center, Houston, TX, [2]Hematologic Malignancies Research Program, Sarah Cannon Research Institute, Nashville, TN, [3]Leukemia Service, Dept of Medicine, Roswell Park Cancer Institute, Buffalo, NY, [4]Research & Development, Calithera Biosciences, Inc., South San Francisco, CA, [5]Transplant Physician, Colorado Blood Cancer Institute, Denver, CO, [6]Dept of Medicine-Hematology/Oncology, Northwestern University Feinberg School of Medicine, Chicago, IL, United States

Background: Glutaminase is a proposed tumor metabolism target implicated in the growth and survival of a variety of tumor types. The enzyme is essential to the utilization of glutamine by many tumor cells, converting incoming glutamine to glutamate for use in the TCA cycle and for production of glutathione and many other cellular constituents. Glutaminase is highly expressed in primary tumors, including acute myeloid leukemia (AML). CB-839 is a highly selective, reversible, allosteric inhibitor of glutaminase. Preclinial studies have demonstrated *in vitro* and *in vivo* anti-tumor activity across a broad array of solid and hematological tumor types and the compound was well tolerated in animals.
Aims: CX-839-003 is an ongoing Phase 1 study of escalating doses of CB-839 in acute leukemia patients to evaluate safety and tolerability, and to identify a recommended Phase 2 dose (R2PD) of the compound. Pharmacokinetics (PK) and pharmacodynamics (PD) of CB-839, as well as an exploration of biomarkers of tumor sensitivity, are being evaluated.
Methods: CB-839 was administered orally continuously in 21-day treatment cycles from 100 to 1000 mg three times daily (TID) to patients with relapsed and/or treatment-refractory acute leukemia. The plasma pharmacokinetics of CB-839 was determined after the first dose given on Days 1 and 15. At the RP2D, 11 patients will be enrolled in disease-specific treatment cohorts including AML; additional patients will be added if there are responses.
Results: 15 patients enrolled during dose escalation have received CB-839 with doses up to 1000 mg TID. The steady state plasma concentration of CB-839 on Day 15 was found to be above 250 nM continuously in most patients using doses of 600 mg TID and higher. In a companion solid tumor trial, CX-839-001, this plasma concentration was determined to result in >85% inhibition of glutaminase activity in platelets and 75% in solid tumors. Peripheral blood mononuclear cells (PBMCs) from three patients treated with 600, 800, and 1000 mg TID on the current trial were found to have between 10 and 58% leukemic blast counts and showed >94% inhibition of glutaminase activity.
CB-839 has been administered TID 1 hr before breakfast, at 3 pm, and prior to bedtime in all patients thus far. An increase in exposure was demonstrated with increasing dose. When CB-839 was administered at 600 mg BID with food in CX-839-001, the C_{max} was reached in 2-6 hr; trough drug levels exceeding 450 nM in all patients. This schedule of administration will be employed for all

patients going forward in this trial. There were no DLTs identified in this trial and treatment-related AEs (all grades) that occurred in >10% of patients were limited to increases in transaminases (4 patients) and bilirubin (2 patients). There were no Grade ≥3 AEs that were considered treatment-related in >10% of patients. Stable Disease (SD) for 4 – 10 cycles was observed in 5 (33%) of 15 efficacy-evaluable AML patients across all dose levels, with patients remaining on study for an average of 134 days (>6 cycles). One of these patients achieved a Complete Response in the bone marrow with incomplete recovery of peripheral counts (CRi) after 6 cycles of dosing; therefore, enrollment will continue with additional patients in the expansion cohort. All of these patients with SD or better were >65 years of age and not eligible for high dose therapy.
Summary and Conclusions: The glutaminase inhibitor CB-839 is well tolerated in AML patients using doses up to 1000 mg TID. One CRi was observed and 33% of patients enrolled during dose escalation showed stable disease that was prolonged for 4-10 cycles. This trial will continue to enroll at the expansion phase.

E948

PHARMACOKINETIC/PHARMACODYNAMIC (PK/PD) EVALUATION OF AG-221, A POTENT MUTANT IDH2 INHIBITOR, FROM A PHASE 1 TRIAL OF PATIENTS WITH IDH2-MUTATION POSITIVE HEMATOLOGIC MALIGNANCIES

B. Fan[1,*] Y. Chen[1], F. Wang[1], K. Yen[1], L. Utley[1], C. Almon[1], K. Straley[1], E. Attar[1], C. Bowden[1], S. Biller[1], S. Agresta[1], H. Yang[1]
[1]Agios Pharmaceuticals, Cambridge, United States

Background: The isocitrate dehydrogenase 1/2 (IDH1/2) enzymes catalyze the production of alpha-ketoglutarate (α-KG) from isocitrate. Mutant IDH1/2 enzymes are capable of novel enzymatic production of D-2-hydroxyglutarate (2-HG) from α-KG. 2-HG is an oncometabolite implicated in cancer initiation and progression that is found at highly elevated levels in several cancer types expressing mutant IDH, including acute myeloid leukemia (AML). AG-221 is a first-in-class, oral, selective, potent inhibitor of mutant IDH2. *In vitro* studies have shown that AG-221 reduces 2-HG levels by >90%, reverses histone and DNA hypermethylation, and induces cellular differentiation in leukemia cell models. In *in vivo* xenograft mouse models using U87MG and primary human AML cells, oral AG-221 also demonstrated robust 2-HG inhibition. These pharmacokinetic/pharmacodynamic (PK/PD) correlations between AG-221 exposure and 2-HG inhibition were used to project the efficacious dose in humans. Here we present updated PK/PD analyses from the ongoing, first-in-human, phase 1 trial of AG-221 in patients with IDH2 mutation-positive advanced hematologic malignancies (NCT01915498).
Aims: To model the human PK/PD profile of AG-221, to compare these results with *in vitro* as well as pre-clinical studies, and to assess the PK/PD profile of AG-221 across different IDH2 mutations.

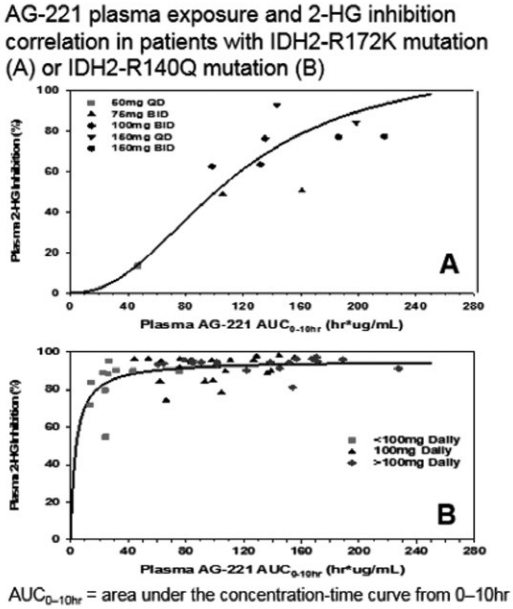

Figure 1.

Methods: In the phase 1, open-label, dose-escalation trial, patients who provided informed consent received oral AG-221 once (QD) or twice daily (BID) in continuous 28-day cycles. Dosing began at 30 mg BID and increased in subsequent cohorts. Blood and bone marrow samples were collected at multiple time points after a single dose at Day –3 and after multiple doses. AG-221 and 2-HG concentrations were measured using a qualified LC-MS/MS method for PK/PD analysis, which was performed with WinNonLin®. *In vitro* activity was assessed in cell lines carrying IDH2 mutations. Efficacy of oral AG-221 and PK/PD relationships were also evaluated in U87MG and primary human AML xenograft mouse models carrying the IDH2-R140Q mutation.
Results: Patients in this analysis received AG-221 at doses of 30, 50, 75, 100, and 150 mg BID and 50, 75, 100, 150, and 200 mg QD (total N=64). Patients bearing the two dominant IDH2 mutations, R140Q (88%) or R172K (12%), were enrolled. AG-221 demonstrated excellent dose-dependent plasma exposure with high accumulation after multiple doses and a half-life >40 hours. After multiple AG-221 doses, substantial, sustained reduction of 2-HG in plasma and bone marrow was observed. 2-HG inhibition in plasma was dose- and exposure- dependent, with up to 98% inhibition in IDH2-R140Q and 93% inhibition in -R172K mutation-positive patients. More than 30-fold different PD responses were modeled for each of the mutations (**Figure**), with an AG-221 free fraction 50% inhibitory concentration (IC_{50}) of 5 ng/mL for IDH2-R140Q (E_{max} model) and 160 ng/mL for IDH2-R172K (sigmoidal E_{max} model). This correlates with PK/PD analysis from *in vitro* studies, in which lower IC_{50} values were observed in IDH2-R140Q cells than in IDH2-R172K cells.
Summary and Conclusions: AG-221 demonstrates a favorable PK profile that supports oral QD dosing, based on the high plasma exposure and long half-life observed in this study. AG-221 inhibition of 2-HG production was more potent in IDH2-R140Q than in -R172K mutants, however, AG-221 reduces plasma 2-HG in patients with both IDH2-R140Q and -R172K mutations to within the normal range seen in healthy volunteers, in a dose- and exposure-dependent manner. The PK/PD findings translate well from *in vitro* to *in vivo* studies and from pre-clinical to human studies.

E949

REDUCED MEDICAL COSTS AND HOSPITAL DAYS WITH ORAL ARSENIC PLUS RETINOIC ACID COMPARED WITH INTRAVENOUS ARSENIC PLUS RETINOIC ACID AS THE FRONT-LINE TREATMENT OF ACUTE PROMYELOCYTIC LEUKEMIA

H.H. Zhu[1], J. Hao[1], G.W. Liang[2], Q. Jiang[1], S. Han[2], L.W. Shi[2], X.J. Huang[1,*]
[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Department of Pharmacy Administration and Clinical Pharmacy, Peking University Health Science Center, Beijing, China

Background: We recently demonstrated that oral arsenic (Realgar-*Indigo naturalis* formula,RIF) plus all-trans retinoic acid (ATRA) is not inferior to intravenous arsenic trioxide (ATO) plus ATRA as the front-line treatment of acute promyelocytic leukemia (APL). However, the cost-effectiveness of oral arsenic-based treatment has never been reported.
Aims: We aimed to compare the cost-effectiveness of between oral and intravenous arsenic.
Methods: we analyzed the results of 60 patients (30 patients in each group) involved in a randomized controlled trial at our center. The direct medical costs and hospital days for each patient were calculated.
Results: The median total medical costs were ¥83056 in the RIF group compared with ¥152063 in the ATO group (p<0.0001). This difference primarily resulted from the differential costs of induction therapy (p=0.016) and maintenance treatment (p<0.0001). The hospitalization length for the RIF group was significantly lower compared with the ATO group (24 *vs.* 31 days, p<0.0001) during induction therapy. During maintenance treatment, the estimated medical costs were ¥12897 for each patient in the RIF group treated at home compared with ¥71025 for each patient in the ATO group treated in an outpatient setting (p<0.0001).
Summary and Conclusions: We concluded that oral RIF plus ATRA significantly reduced the medical costs and length of hospital stay during induction and maintenance therapy compared with ATO plus ATRA in APL patients. Oral arsenic plus ATRA should be incorporated into the front-line treatment of patients with APL for medical and economic reasons.

E950

CLINICAL COURSE OF LEPTOMENINGEAL INVOLVEMENT OF ACUTE MYELOID LEUKEMIA: 14-YEARS SINGLE CENTER EXPERIENCE

J.H. Kwon[1,2,*], J. Park[1,3], Y.I. Koh[1], I.H. Kim[1], S.S. Yoon[1], S. Park[1]
[1]Seoul National University, College of Medicine, Seoul, [2]Chungbuk National University Hospital, Cheongju, [3]Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, Korea, Republic Of

Background: The leptomeningeal involvement of acute myeloid leukemia is known to be rare in adult, and its prognostic importance is controversial.
Aims: We investigated risk, clinical course and outcome of acute myeloid leukemia patients with leptomeningeal involvement.
Methods: We examined medical records of the patients who were diagnosed with acute myeloid leukemia (AML) at Seoul National University Hospital from January 2000 to November 2013. Leptomeningeal involvement was defined as the presence of atypical or malignant hematopoietic cells in cerebrospinal

fluid. Molecular risk group was classify into three categories; good (t(8;21), t(15;17), inv(16) & NPM1), Poor (t(9;22), MLL rearrangement, MDS-related change, complex karyotype, FLT3-ITD) and Standard (normal karyotype and other abnormalities). Information about demographical data, treatments and outcomes, survival was also collected.
Results: Among 943 patients with acute myeloid leukemia, 155 patients (16.4%) have had lumbar puncture and cerebrospinal fluid examination. Leptomeningeal involvement of AML was confirmed in forty-three patients (4.6%). Most common symptom was headaches (15 patients, 34.9%). Median age was 51 years old and 27 patients (62.8%) were male. Patients in good risk group were fifteen (34.9%). Among these patients, t(15;17) was founded in 6 patients (40%). Fifteen were standard and eleven were high risk group. Twenty-three patients (53.5%) had involvements of extramedullary site except leptomeninges, and sixteen patients (37.2%) had chloromas in their brain parehchyma or spinal cord. Twelve patients (27.9%) discovered leptomeningeal involvement simultaneously with the initial diagnosis of leukemia. Among these patients, 3 (25.0%) belonged to good risk group. Thirty-one patients (72.1%) developed leptomeningeal involvement at the relapsed or refractory status, twelve (38.7%) of them were in good risk group. Thirty-six patients (83.7%) received intrathecal chemotherapy, then leukemic cells were eliminated from cerebrospinal fluid in thirty-one patients (86.1%). Whole-brain or spinal radiotherapy was performed in 13 patients (30.2%). The complete remission-rate of bone marrow after the first induction chemotherapy was 67.4%, and allogeneic hematopoietic stem cell transplantation was performed in 14 patients (35.5%). Median overall survival was 10.8 months. Radiotherapy and complete remission after the first induction chemotherapy were independent prognostic factors for overall survival in multivariate analysis.

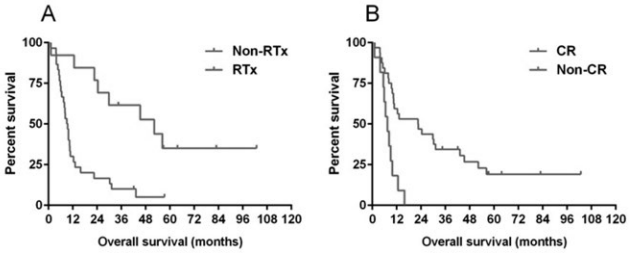

Figure 1. Overall survival. A; radiotherapy, B; Complete remission after 1st induction chemotherapy.

Summary and Conclusions: Leptomeningeal involvement in acute myeloid leukemia is rare condition, which are relatively common in relapsed or refractory status. Whole-brain radiotherapy and complete response to induction chemotherapy were thought to have contributed to improve their prognosis. Active treatment using intensive induction chemotherapy and leptomeninges-directed treatment including radiotherapy might be helpful improving their survival.

E951

A PHASE IB/II STUDY TO EVALUATE THE SAFETY AND EFFICACY OF VISMODEGIB IN RELAPSED/REFRACTORY ACUTE MYELOGENOUS LEUKEMIA

R. Noppeney[1,*] D. Bixby[2], T. Lin[3], J. Cortes[4], J. Krauter[5], K. Yee[6], B.C. Medeiros[7], A. Krämer[8], S. Assouline[9], W. Fiedler[10], S. Williams[11], B. Simmons[12], T. Riehl[12], D. Colburn[12]
[1]Universitätsklinikum Essen Klinik für Hämatologie, Essen, Germany, [2]University of Michigan, Ann Arbor, [3]University of Kansas Cancer Center, Westwood, [4]MD Anderson Cancer Center, Houston, United States, [5]Klinikum Braunschweig, Braunschweig, Germany, [6]Princess Margaret Hospital, Toronto, Canada, [7]Stanford University, Stanford, United States, [8]Universitätsklinikum Heidelberg, Heidelberg, Germany, [9]Hospital Maisonneuve-Rosemont, Montreal, Canada, [10]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [11]Roche Products LTD, Welwyn Garden City, United Kingdom, [12]Genentech Inc., South San Francisco, United States

Background: Vismodegib is a small molecule inhibitor of the hedgehog (Hh) signaling pathway currently approved for treatment of advanced basal cell carcinoma. Increased expression of Hh ligand leading to activation of the Hh pathway is thought to play a key role in the maintenance of the leukemic stem cell in myeloid leukemias. Specifically, the Hh ligand may contribute to leukemic stem cell self-renewal properties. Inhibiting the ability of leukemic stem cells to self-renew by targeting the Hh pathway could eradicate the malignant clone.
Aims: To assess the safety and efficacy of vismodegib in the treatment of relapsed/refractory acute myelogenous leukemia (AML) patients with a primary endpoint of overall response rate at week 8 of study treatment.
Methods: Patients (pts) with relapsed or refractory AML who gave informed consent were enrolled in a single arm treatment of vismodegib 150mg PO daily for 8 weeks or until progression evaluated by using the International Working Group criteria. Eligibility criteria included pts with documented relapsed/refractory AML (excluding APL), ≥18 years, ECOG ≤2, with adequate renal and hepatic function. Pts were stratified by the following factors: poor risk cytogenetics (based on NCCN guidelines), FLT3+mutation, or neither (patients who were not poor risk or FLT3+).
Results: 38 pts were enrolled (poor-risk karyotype n=15, FLT3+n=4, and neither n=19). Most pts had relapsed AML (60.5%), were white (89.5%) and male (55.3%) with a median age of 68.5 years. The ORR was 5.3% (1 CRi, 1 PR). Both of the responders were in the "neither" group with no identified cytogenetic abnormalities or other risk factors. The median duration of vismodegib therapy was 49 days, with a range of 5 – 225. 37 patients (97.4%) had at least one adverse event. The most common adverse events were pyrexia (39.5%), nausea (39.5%), dysgeusia (31.6%), epistaxis 26.3%), febrile neutropenia (23.7%), fatigue (23.7%), muscle spasms (23.7%), decreased appetite (23.7%), and peripheral edema (21.1%). Serious adverse events occurred in 26 patients (68.4%). The majority of serious adverse events were infections (53.8%). Most patients died due to disease progression on study, 27 of 33 pt deaths.
Summary and Conclusions: Single agent vismodegib treatment produced minimal clinical efficacy in pts with relapsed/refractory AML. However, this is the first documented single-agent response in a disease thought to be driven through the Hh ligand as opposed to a mutation in the pathway. The adverse event profile was most likely driven by the underlying AML. Serious adverse events were typically infections, which are common in relapsed/refractory AML.

E952

PHASE I/II STUDY OF DFP-10917 GIVEN BY CONTINUOUS INFUSION IN PATIENTS WITH RELAPSED OR REFRACTORY ACUTE LEUKEMIA: PHARMACOKINETIC, PHARMACODYNAMICS AND PHARMACOGENOMICS PROPERTIES

W. Plunkett Jr.[1,*] E. Jabbour[1], G. Garcia-Manero[1], T. Kadia[1], N. Daver[1], N. Jain[1], G. Borthakur[1], C. DiNardo[1], J. Cortes[1], B. Anderson[2], K. Iizuka[3], C. Jin[3], H. Kantarjian[1]
[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, [2]Theradex, Princeton, United States, [3]Delta-Fly Pharma, Inc., Tokushima, Japan

Background: DFP-10917 is activated by deoxycytidine kinase (DCK) and inactivated by cytidine deaminase (CDA) similar to the deoxycytidine analogs, cytarabine and gemcitabine. Upon low dose administration DFP-10917 is converted to its nucleotide form and incorporated into tumor DNA causing DNA strand breaks and G2/M phase-arrest by cell-checkpoint regulators and ultimately tumor cell apoptosis.
Aims: To determine the maximum tolerated dose (MTD), the recommended phase II dose (RP2D) and dose-limiting toxicity (DLT) of DFP-10917 given by continuous infusion (CI) in patients with relapsed or refractory acute leukemia. To perform pharmacokinetic (PK), pharmacodynamic (PD) and pharmacogenomic (PGx) analyses.
Methods: In phase I, DFP-10917 was administered by 7-day CI followed by 21 days rest (stage 1) or 14-day CI followed by 14 days rest (stage 2) in pts with relapsed or refractory acute leukemia to determine the MTD. PK analysis was performed to measure DFP-10917 (CNDAC) and the primary metabolite at days 7 and 14. PD assessment utilized the comet assay to quantify DNA strand breaks in whole blood and bone marrow samples. PGx assessment was performed by DNA genotyping of CDA and DCK.
Results: In stage 1, twenty-seven pts received a 7-day CI of DFP-10917 at eight escalating doses ranging from 4 to 35 mg/m^2/day. At the 35 mg/m^2 dose level, one patient experienced a DLT of grade 3 diarrhea during cycle 1. The starting dose for stage 2 was calculated as two-thirds the cumulative 7-day DFP-10917 dose at the MTD of 30 mg/ m^2/day divided by 14-day resulting in a dose of 10 mg/m^2/day x 14 days. The 10 mg/m^2/day x 14-day CI dose resulted in DLTs of prolonged hypo-cellularity in 2 of 4 pts. At the 6 mg/m^2/day x 14-day dose level, 1 of 6 evaluable pts experienced a DLT of prolonged hypo-cellularity, and the MTD/RD was defined as 6 mg/m^2/day x 14-day CI. Initial efficacy assessments include leukemia responses observed in 7 of 10 AML pts (70%) receiving the 14-day DFP-10917 CI (3 bone marrow complete responses, 4 partial responses). PK data indicates dose-proportionality for steady state concentration (Css) of DFP-10917 and its primary metabolite. 2 of the 3 patients with prolonged hypo-cellularity DLTs demonstrated CNDAC Css of >10 ng/ml (0.0346 nM). The comet assay results indicate DNA strand breakage increased following the 7 and 14 day CI of DFP-10917; however, the 14-day CI was associated with a lower level of DNA strand breakage. DNA genotyping did not detect genetic mutations associated with CDA and DCK.
Summary and Conclusions: The MTD/RP2D of DFP-10917 in relapsed AML was established for 14-day CI at 6 mg/m^2/day, and the phase II study is ongoing. Prolonged myelosuppression was associated with CNDAC Css >10 ng/ml among 2 of 4 pts treated at 10 mg/m^2/day x 14 days of DFP-10917. PD data demonstrated DNA strand breakage at the doses tested. No genetic mutations associated with CDA or DCK were detected among leukemia patients treated in the Phase 1 study.

E953

EFFICACY AND TOXICITY OF FLUDARABINE BASED INDUCTION REGIMENS IN ACUTE MYELOID LEUKEMIA PATIENTS YOUNGER THAN 65 YRS

A. Candoni[1,*] S. Vassallo[1], D. Lazzarotto[1], E. Simeone[1], G. Ventura[1], M.E. Zannier[1], F. Zanini[1], C. D'Odorico[1], E. Lucchini[1], R. Fanin[1]
[1]Hematology and BMT, Division of Hematology, University Hospital, Udine, udine, Italy

Background: Fludarabine (Fluda)–Cytarabine combinations are commonly used as salvage chemotherapy in Acute Myeloid Leukemia (AML). The role and efficacy of Fluda based induction regimens in high risk AML younger than 65 yrs are still poorly understood.
Aims: To evaluate efficacy and toxicity of Fludarabine based induction regimens in patients with AML and younger than 65 yrs.
Methods: We retrospectively evaluated the efficacy and toxicity following induction chemotherapy with Fluda based regimens in 286 pts, with previously untreated Acute Myeloid Leukemia, followed over a 10 years period (2002-2012) at our Center. All patients were younger than 65 with a median age of 52 years. Diagnosis of AML was confirmed in all cases and Cytogenetic, Multidrug Resistance, FLT3 mutation analysis, were performed in all patients; 73% of these were poor-risk at diagnosis [high risk factors: BC >30x10^9/L, secondary AML, FLT3 ITD mutation, poor-risk karyotype]. The 286 Fluda based induction courses included: 235 FLAI courses (Fludarabine, Cytarabine, Idarubicine) and 51 FLAIE courses (FLAI course plus Etoposide). Patients were evaluated for response rate and treatment related adverse events. Toxicity was evaluated and graded according to National Cancer Institute criteria.
Results: After Induction with a Fluda based regimen 213/286 (74%) of patients achieved a Complete Remission (CR). Only a 3% of Death During Induction (DDI) was reported. Non hematologic toxicity was acceptable with 54% of pts presented FUO, 48 % bacteremia or sepsis and 20% grade II-III oral mucositis. As expected, all pts experienced grade IV hematological toxicity and (in CR pts) the median time to PMN (>1000/ml) and platelet (>50.000/ml) recovery was 24 (range 17 to 40) and 26 days (range 18-43), respectively. Supportive treatment consisted of a median of 13 RBC (range 5-26) and 7 platelet units (range 3-18). Median time to hospital discharge was 31 days (range 22-61). 1 yrs Overall Survival and DFS was 68% and 64%, respectively.
Summary and Conclusions: This data, from a large serie of cases, confirm that Fluda based induction regimens are effective and well tolerated in poor risk AML patients younger than 65 yrs with a high CR rate, favourable safety profile and very low DDI.

E954

OVERALL SURVIVAL (OS) AND CLINICAL OUTCOMES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) TREATED WITH AZACITIDINE (AZA) OR LOW-DOSE CYTARABINE (LDAC) IN THE AZA-AML-001 STUDY

J.F. Seymour[1,*] H. Döhner[2], R. Kumar[3], R.M. Stone[4], A. Wierzbowska[5], T. Bernal del Castillo[6], J. Falantes[7], J. Delaunay[8], M. Sabloff[9], M.T. Voso[10], I. Kim[11], R. Ram[12], J.P. Gau[13], S. Songer[14], L.M. Lucy[14], C. Beach[14], H. Dombret[15]
[1]Peter MacCallum Cancer Centre, East Melbourne, Australia, [2]Universitätsklinikum Ulm, Ulm, Germany, [3]Cancer Care Manitoba, Winnipeg, Canada, [4]Dana-Farber Cancer Institute, Boston, United States, [5]Medical University of Lodz, Lodz, Poland, [6]Hospital Central de Asturias, Oviedo, [7]Hospital Universitario Virgen del Rocio/Instituto de BioMedicinia de Sevilla, Sevilla, Spain, [8]CHU Nantes Hôtel Dieu, Nantes, France, [9]University of Ottawa and Ottawa Hospital Research Institute, Ottawa, Canada, [10]Universita' Tor Vergata, Rome, Italy, [11]Seoul National University Hospital, Seoul, Korea, Republic Of, [12]Rabin Medical Center, Petach Tikva, Israel, [13]Taipei Veterans General Hospital, Taipei, Taiwan, ROC, [14]Celgene Corporation, Summit, United States, [15]Hôpital Saint Louis, Institut Universitaire d'Hématologie, University Paris Diderot, Paris, France

Background: There is no standard treatment (Tx) for older patients (pts) with AML, who have especially poor OS due to adverse risk factors such as unfavorable karyotypes and poor performance status (PS). Older pts may be unfit for high-intensity induction chemotherapy (IC); such pts are often treated with LDAC or best supportive care (BSC) alone, which are associated with very poor outcome (Dombret, *Semin Oncol,* 2008). The international phase 3 AZA-AML-001 study compared AZA with conventional care regimens (CCR) in older pts with AML. Before randomization, investigators selected their preferred Tx option for each pt from 3 commonly used CCR for AML Tx: IC, LDAC, or BSC only. Pts were then randomized to receive AZA or CCR and received their preselected Tx.
Aims: To compare effects of AZA *vs* LDAC on OS and clinical outcomes in the subgroup of pts in AZA-AML-001 preselected to receive LDAC before randomization.
Methods: Pts aged ≥65 years with newly diagnosed *de novo* or secondary AML (>30% bone marrow [BM] blasts by local assessment), ECOG PS 0-2, WBC count ≤15x10^9/L, and intermediate- or poor-risk cytogenetics were enrolled. AZA dose was 75mg/m^2/day SC x7 days/28-day cycle and LDAC dose was 20mg SC BID x10 days/28-day cycle. OS and 1-year survival were estimated using Kaplan-Meier methods. OS was compared between Tx groups by log-rank test. An unstratified Cox proportional hazards model generated hazard ratios (HRs) and 95% CIs. Overall response rate (ORR) included complete remission (CR) +CR with incomplete blood count recovery (CRi) (IWG 2003). Proportions of pts with grade 3-4 infections and hematologic treatment-emergent adverse events (TEAEs), and TEAE incidence rates (IR) per 100 pt-years of Tx exposure, are reported.
Results: Of all pts in AZA-AML-001, most (312/488, 64%) were preselected to receive LDAC (AZA n=154, LDAC n=158). Median number of Tx cycles received was 7 (range 1–28) for AZA and 4 (1–25) for LDAC. At baseline in the AZA and LDAC groups, respectively, median ages were 76 (range 64–90) and 75 (65–88) years; 25% and 22% had ECOG PS of 2; centrally read median BM blasts were 70% (2–100) and 74% (4–100); and 29% and 34% of pts had poor-risk cytogenetics. Median OS in the AZA and LDAC groups was 11.2 *vs* 6.4 months (mon), respectively (HR=0.90 [95%CI 0.70, 1.16], p=0.43; Figure), indicating a 4.8-mon (95%CI 1.7, 7.9) longer median OS with AZA. The OS difference was not statistically significant due to convergence of the OS curves at ~20 mon. One-year survival rate was 48.5% with AZA *vs* 34.0% with LDAC, a difference of 14.5% (95%CI 3.5%, 25.5%). ORR was 27% with AZA and 26% with LDAC. Proportions [IRs] of AZA and LDAC pts, respectively, with grade 3-4 TEAEs were: anemia 19% *vs* 23% [26 *vs* 42]; neutropenia 25% *vs* 25% [33 *vs* 46]; febrile neutropenia 27% *vs* 30% [36 *vs* 56]; thrombocytopenia 25% *vs* 28% [34 *vs* 51]; and infections 49% *vs* 46% [66 *vs* 84].

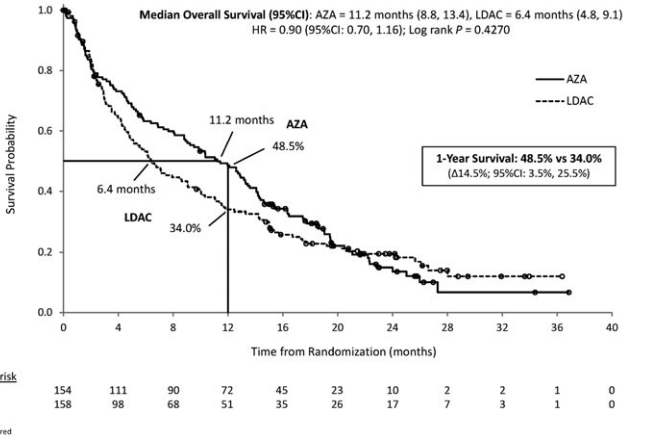

Figure 1. Overall survival in patients preselected to LDAC.

Summary and Conclusions: Analyzing outcomes within preselection groups allows assessment of Tx effects in pts with generally similar prognoses and clinical features, as preselection of the preferred CCR occurred before randomization. AZA was associated with a longer median OS of 11.2 mon *vs* 6.4 mon with LDAC, in pts with similar features at study entry. At 1 year, almost one-half of AZA-treated pts were alive, compared with approximately one-third of LDAC-treated pts. Quality of life outcomes during Tx with AZA or LDAC in this pt group are now being evaluated. AZA may offer potential advantages over LDAC as first-line low-intensity Tx in difficult-to-treat older pts with AML and high blast counts.

E955

RETROSPECTIVE ANALYSIS OF OUTCOMES BETWEEN PATIENTS WITH ACUTE MYELOID LEUKEMIA WHO ARE TREATED WITH HEPARIN AND RECOMBINANT HUMAN THROMBOMODULIN THERAPY

N. Takezako[1,*] N. sekiguchi[1], A. nagata[1], A. miwa[1]
[1]Hematology - National Hospital Organization Disaster Medical Center, DISASTER MEDICAL CENTER OF JAPAN, Tachikawa, Japan

Background: Recombinant thrombomodulin (rTM) is a promising anticoagulant and rTM therapy more significantly improves disseminated intravascular coagulation (DIC) and relieves bleeding complications in DIC patients, when compared with unfractionated heparin therapy. However, it is unknown as to whether or not the treatment with rTM affects acute myeloblastic leukemia (AML) patient's outcome.
Aims: we retrospectively analyzed 103 patients with AML (except adult acute promyelocytic leukemia), and compared outcomes between patients treated with low-molecular-weight heparin and rTM.
Methods: We retrospectively analyzed 103 patients with AML and compared the outcomes between the patients with low molecular weight heparin therapy and with rTM. The diagnostic criteria for DIC previously proposed by the Japanese Ministry of Health and Welfare. Comparisons between the qualitative variables were carried out using the χ^2 test. The survival probabilities were estimated by the Kaplan-Meier method, and differences in the survival distributions

were evaluated using the log-rank test.
Results: 47 developed DIC in association with chemotherapy or disease status. Fourteen patients were treated by rTM, and 33 patients were treated by low molecular weight heparin (LMWH). The overall survival was worse in the DIC group compared with the non- DIC group on the log-rank test (P=0.003). The overall survival was superior in the rTM group compared with LMWH group according to the log-rank test (P=0.016).

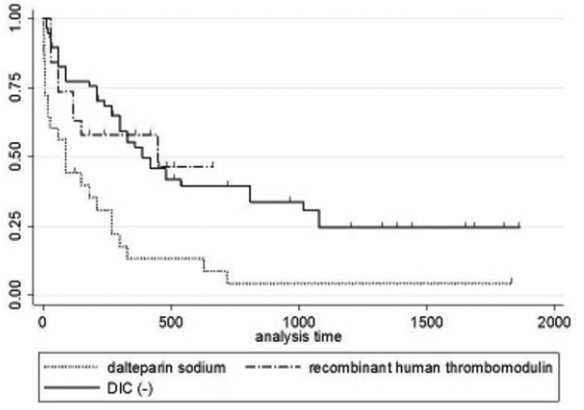

Figure 1.

Summary and Conclusions: Treatment with rTM is efficient compared with LMWH because of improvement of overall survival.

E956

POST REMISSION MONITORING OF MINIMAL RESIDUAL DISEASE BY WT1 AND LEUKEMIA ASSOCIATED IMMUNOPHENOTYPE PREDICTS RELAPSE IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS

M. Malagola[1,*] C. Skert[1], E. Borlenghi[2], E. Morello[2], M. Chiarini[3], V. Giustini[3], F. Comini[3], A. Turra[1], F. Cattina[1], V. Cancelli[1], E. Cerqui[1], C. Pagani[1], A. Passi[1], R. Ribolla[1], F. Schieppati[1], S. Brenardi[3], S. Perucca[3], A. Di Palma[3], G. Ruggeri[4], G. Rossi[2], L. Caimi[4], D. Russo[1]
[1]Experimental and Clinical Sciences, Chair of Hematology, Bone Marrow Transplant Unit, University of Brescia, AO Spedali Civili Brescia, [2]Division of Hematology, [3]Centro di Ricerca Emato-oncologico AIL (CREA), AO Spedali Civili Brescia, [4]Department of Molecular and Translational Medicine, Laboratorio Analisi, AO Spedali Civili di Brescia, Brescia, Italy

Background: Although a complete remission (CR) can be achieved in 70-80% of newly diagnosed acute myeloid leukemia (AML) patients, relapses occur in up to the 50% of cases. Minimal residual disease (MRD) monitoring is a major issue for early detection of patients at high-risk of treatment failure and relapse.
Aims: to perform a comparative sequential monitoring of MRD by RT-qPCR on WT1 and by Multiparametric Flow Cytometry (MFC) on Leukemia Associated Immunophenotypes (LAIPs).
Methods: 104 newly diagnosed AML patients consecutively treated between 2010 and 2013 were monitored with RT-qPCR WT-1 from bone marrow (BM) and peripheral blood (PB) and with MFC on the LAIP on BM at baseline, after induction, after the first consolidation course and after the first intensification course.
Results: All the patients were studied at diagnosis for a LAIP and this was available in 80/104 (77%) cases. BM and PB-WT1 level at diagnosis was available in 92/104 (88%) and 70/104 (67%), respectively. Eighty-eight out of 104 patients (85%) achieved a complete remission (CR) after induction, 30/88 (34%) relapsed during follow up and 33/104 (32%) were addressed to allogeneic stem cell transplantation (allo-SCT). Univariate and multivariate analysis on relapse free survival (RFS) were conducted, censoring allotransplanted patients at the time of allo-SCT. By univariate analysis, after induction BM-WT ≥295x10^4/ABL (HR 7.8; p<0.0001) significantly identified patients at high risk of relapse. After 1st consolidation BM-WT1 ≥121x10^4/ABL (HR 5.2; p>0.0001), PB-WT1≥18x10^4/ABL (HR 7.9; p<0.0001), LAIP ≥0.2% (HR 3.3; p=0.002) and LAIP-decrease <85% (HR 3.6; p=0.001) were significantly correlated with adverse RFS. After 1st intensification cycle (before allo-SCT), BM-WT1 ≥150x10^4/ABL (HR 7.8; p<0.0001), PB-WT1 ≥16x10^4/ABL (HR 12.2; p<0.0001) ,and LAIP decrease <85% (HR 4.5; p=0.006) significantly affected the RFS. By multivariate analysis, after 1st consolidation BM-WT1 ≥121x10^4/ABL (HR 4.1; p=0.02) and LAIP decrease <85% (HR 3.0; p=0.0001) and after 1st intensification PB-WT1 ≥16x10^4/ABL (HR10.2; p=0.0001) were independently associated with averse outcome. Within the different ELN-risk categories, BM-WT1 ≥121x10^4/ABL after the 1st consolidation cycle significantly dissected the patients at high risk of relapse both in the ELN Int-1 [HR 14.4; 95% CI 1.7-118.6); p=0.01] and Int-2 risk category [HR 11.7; 95% CI 1.1-124.9); p=0.04]. Similarly, LAIP decrease <85% after the 1st consolidation cycle significantly identified the patients at high risk of relapse in the ELN Int-2 risk group only [HR 10.1; 95% CI 1.1-93.9); p=0.04]
Summary and Conclusions: Our data, although retrospectively collected, show that WT1 and LAIP MRD monitoring is useful to predict the relapse in AML patients and may help to guide the post-remission treatment strategy.

E957

TREATMENT WITH LOW-DOSE CYTARABINE (LD-ARAC) IN ELDERLY PATIENTS (AGE 70 YEARS OR OLDER) WITH ACUTE MYELOID LEUKEMIA (AML): A SINGLE INSTITUTION EXPERIENCE

M. Heiblig[1,*] M. El Ahmri[1], I. Tigaud[2], A. Plesa[3], F. Barraco[1], H. Labussière-Wallet[1], S. Ducastelle-Leprêtre[1], M. Michallet[1], F.E. Nicolini[1], C. Plesa[4], E. Wattel[1], G. Salles[1], X. Thomas[1]
[1]Hematology Department, [2]Laboratory of Cytogenetics, [3]Laboratory of Cytology and Immunology, Centre Hospitalier de Lyon Sud, [4]Hematology Department, Trarieux Clinic, Lyon, France

Background: The treatment outcome for patients with AML aged 70 years or older is unsatisfactory and has not improved significantly over the last two decades. Most of these patients do not receive intensive chemotherapy either because they decline or because they are not considered fit enough for such therapy. LD-AraC is still regarded as the standard of care in elderly patients with AML 'unfit' for intensive chemotherapy, against which novel drugs may be compared.
Aims: In this study, we compared the efficacy of LD-AraC with that of intensive chemotherapy (IC), best supportive care (BSC), or lower intensity therapy (LIT) based on hypomethylating agents in a single institution experience.
Methods: Three hundred and sixty six patients (aged 70 years or older) with newly diagnosed AML have been seen in our institution between 2000 and 2014. Among them, 60 patients (16%) received LD-AraC at 20 mg once or twice daily by subcutaneous injection for 10 consecutive days. Subsequent courses were administered after intervals of 4 to 6 weeks.
Results: They were compared to 85 patients treated by IC (anthracycline- and cytarabine-based chemotherapy), 34 patients treated by LIT (12 received decitabine and 22 azacitidine), and 43 patients receiving only BSC. The overall complete remission (CR) rate with LD-AraC was 7% (4/60 patients). The median number of courses to CR was 4 courses (3-9 courses). The CR rate was better in patients treated by IC (144/280 patients; 51%) and in patients treated by LIT (7/34 patients; 21%). Median OS of patients treated with LD-AraC was 9.6 months (95% CI, 5.8-13.5 months) with 3-year OS of 12%. Survival with LD-AraC was better than with BSC only (median OS: 9.6 months *vs* 3.4 months; *P*=0.001). Although not statistically significant, IC tended to be better than LD-AraC in terms of OS (median OS: 12.4 months *vs* 9.6 months; 3-year OS: 27% *vs* 12%; *P*=0.07). However, differences in favor of IC were only confirmed for patients aged less than 75 years (median: 12.7 months *vs* 9.2 months; 3-year OS: 28% *vs* 10%). In patients aged >or=75 years, median OS was better with LD-AraC (9.6 months *vs* 2.8 months). No significant differences were observed between LIT and LD-AraC (median OS: 16.1 months *vs* 9.6 months; 3-year OS: 22% *vs* 12%; *P*=0.1). There was no clear evidence that a beneficial effect of LD-AraC was restricted to any particular subtype of patients, except for cytogenetics (favorable and intermediate-risk *vs* unfavorable-risk) (median OS: 11.4 months *vs* 4.3 months; *P*=0.03). Of the patients who received LD-AraC, 24 patients were treated inside clinical trials, while 36 patients were not. Median OS was 13.2 months for the first ones *vs* 7.8 months for the others; 3-year OS: 18% *vs* 9%; *P*=0.21.
Summary and Conclusions: Overall, despite a trend in favor of IC and LIT over LD-AraC, no real significant advantage could be demonstrated, while LD-AraC showed a significant advantage comparatively to BSC. This tends to confirm that LD-AraC can still represent a baseline against which new promising agents may be compared either alone or in combination.

E958

CLINICAL SIGNIFICANCE OF THE DAY 5 PERIPHERAL BLASTS CLEARANCE RATE IN THE EVALUATION OF EARLY TREATMENT RESPONSE AND THE PROGNOSIS FOR AML PATIENTS

B. Chen[1,*] C. Yu[1], Q. L. Kong[1], Y.X. Zhang[1], S.J. Chen[1]
[1]State Key Laboratory of Medical Genomics,Shanghai Institute of Hematology, Rui Jin Hospital, affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Acute myeloid leukemia (AML) is a group of clinically and genetically heterogeneous diseases. In spite of the landmark progress in treating acute promyelocytic leukemia (M3), current treatment of AML is still largely based on chemotherapy. The standard induction chemotherapy consists of anthracycline and cytarabine ("3+7" regimen) could achieve the complete remission (CR) rate about 75%, but due to the variability of individual genetic profile and drug sensitivity, the outcome is uncertain. Monitoring of the minimal residual disease (MRD) could reflect the treatment response in time, and then become the essential reference for AML patients to optimize chemotherapy strategy. In the past decades, multiparameter flow cytometry (MFC) method

has been used as a standard technique to track MRD in leukemia patients.
Aims: For AML patients, the MRD detection of bone marrow was usually performed after one course of induction chemotherapy. To optimize the chemotherapy strategies, it is essential to establish an earlier and easier method to monitor the early treatment response during induction period. Peripheral blood (PB) blasts clearance rate might serve as such a monitoring marker.
Methods: PB blasts were monitored using flow cytometry, the absolute counts were calculated before treatment (D0) and on the 3rd, 5th, 7th, 9th days (D3, 5, 7, 9) of induction chemotherapy. The cut-off value of Day 5 peripheral blasts clearance rate (D5-PBCR) was defined by a receiver operating characteristic (ROC) analysis. Prognostic effect was compared between the different patient groups according to D5-PBCR cut-off value.
Results: The D5 peripheral blasts clearance rate (D5-PBCR) cut-off value was determined as 99.55%. Prognostic analysis showed that patients with D5-PBCR≥99.55% were more likely to achieve CR (94.6% vs. 56.1%, *P*<0.001) and maintain the relapse-free status (80.56% vs. 57.14%, *P*=0.027). In survival analysis, both relapse-free survival (RFS) and overall survival (OS) were longer in the D5-PBCR≥99.55% patients group (2-year OS: 71.0% vs. 38.7%, *P*=0.011; 2-year RFS: 69.4% vs. 30.7%, *P*=0.026). Moreover, in cytogenetic-molecular intermediate-risk group, a subgroup with worse outcome could be further distinguished by D5-PBCR level (<99.55%) (OS: *P*=0.033, RFS: *P*=0.086).
Summary and Conclusions: In conclusion, our work established an effective early treatment response evaluation method by monitoring PB blasts using flow-cytometry. The D5-PBCR value (99.55%) could be a reliable reference to predict the treatment response and outcome in very early stage of chemotherapy, which may offer the opportunity of induction regimen modification, and help in optimizing the current cytogenetic-molecular prognostic risk stratification.

E959

PROPHYLACTIC USE OF SORAFENIB IN PATIENTS WITH FLT3-ITD-POSITIVE ACUTE MYELOID LEUKEMIA UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Q. Liu[1,*] L. Xuan[1], Z. Fan[1], Q. Jiang[1], M. Dai[1], P. Shi[1], C. Yin[1], J. Sun[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Internal tandem duplication of FMS-like tyrosine kinase 3 (FLT3-ITD) mutations have been reported in 20%>30% of patients with acute myeloid leukemia (AML). FLT3-ITD-positive AML patients have an inferior survival, primarily due to lower complete remission (CR) rate and higher relapse rate. Although allogeneic hematopoietic stem cell transplantation (allo-HSCT) improves the outcomes of a proportion of FLT3-ITD-positive AML, a significant number will suffer disease recurrence after allo-HSCT. Sorafenib, an inhibitor of multiple kinases including FLT3, has shown promising activity in FLT3-ITD-positive AML. Recent studies have shown that sorafenib monotherapy or in combination with chemotherapy are effective in attaining CR, but they do not have significant improvement in relapse. Currently, prophylactic use of sorafenib after allo-HSCT has been rarely reported, and whether it can improve outcomes of FLT3-ITD-positive AML remains unclear.
Aims: To assess the feasibility and efficacy of prophylactic use of sorafenib in FLT3-ITD-positive AML after allo-HSCT for preventing relapse.
Methods: A total of 18 patients with FLT3-ITD-positive AML undergoing allo-HSCT from January 2012 to March 2014 at our single institute were enrolled in this retrospective study. The median age was 29 years (range 16-51 years), with 10 males and 8 females. Thirteen patients received related (9 sibling and 4 family donors), 5 unrelated donor transplants; 8 received HLA locus matched, 10 mismatched transplants. Seven patients were in first CR at the time of transplantation and all received standard conditioning. Eleven patients were not in CR (NR) at the time of transplantation and all received intensified conditioning. Sorafenib was used from day 30 to day 180 post-transplantation. The initial dose of sorafenib was 400 mg orally twice daily and was adjusted in case of suspected toxicity or resistance (dose range, 200-800 mg daily).
Results: Of the 18 patients, 7 patients received prophylactic sorafenib, including 3 in CR and 4 in NR pre-transplantation; 11 did not receive prophylactic sorafenib, including 4 in CR and 7 in NR pre-transplantation. The eleven patients in NR at the time of transplantation all achieved CR and had complete chimerism by day +30 post-transplantation. Of the 7 patients with prophylactic sorafenib, one developed grade II acute graft-versus-host disease (aGVHD) and 3 developed chronic GVHD (cGVHD, limited in 2 and extensive in 1). Of the 11 patients without prophylactic sorafenib, 3 patients developed aGVHD (grade II in 2 and III in 1) and 7 developed cGVHD (limited in 3 and extensive in 4), including 1 grade III aGVHD and 2 cGVHD after donor lymphocyte infusion (DLI). With a median follow up of 433 (range, 124-765) days post-transplantation, 7 patients with prophylactic sorafenib all had no recurrence and survived. Of the 11 patients without prophylactic sorafenib, 5 experienced leukemia relapse at a median time of 92 (range, 49 to 335) days post-transplantation, including hematologic in 4 and central nervous system (CNS) in 1. The patient with CNS relapse achieved CR after radiotherapy and DLI, and was still alive now. Of the 4 patients with hematologic relapse, one abandoned treatment and 3 received treatment, including sorafenib combined with chemotherapy and DLI. Two of the three patients achieved short CR after treatment and finally all of them died of relapse within half a year. With a median follow up of 343 (range, 135-863) days post-transplantation, 6 patients survived and 5 died in the 11 patients without prophylactic sorafenib. Causes of death included leukemia relapse (n=4) and cGVHD (n=1). The main side effect of sorafenib was rash, and none of patients experienced bone marrow suppression. Of the 10 patients with sorafenib treatment, 6 had hand-foot skin reaction and/or rash. Anti-allergy therapy was ineffective, and glucocorticoid was usually required. In 4 of the 6 patients, the skin rash covered gradually after reducing the dose of sorafenib and the use of glucocorticoid. Other two patients even required drug discontinuation, but sorafenib was tolerated after the reuse although the rash reappeared.
Summary and Conclusions: Early prophylactic use of sorafenib has an acceptable toxicity profile and could reduce relapse of FLT3-ITD-positive AML.

E960

COMPARISON OF DIFFERENT COMORBIDITY INDICES FOR PREDICTING OUTCOME IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

F. Hitz[1,*] C. Müller-Tidow[1], L.P. Müller[1], M. Wass[1]
[1]Department of Internal Medicine IV, University Hospital Halle, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany, Halle (Saale), Germany

Background: Age is a dominant predictor of outcome in acute myeloid leukemia (AML). It is unclear to which extent comorbidities contribute to this effect. Unfortunately, data regarding the impact of pretreatment comorbidities on prognosis and outcome are limited.
Aims: The object of this study was to determine the effect of relevant comorbidities on the survival of patients with AML and compare three validated comorbidity indices in predicting outcome.
Methods: In a single-center retrospective study 194 AML patients aged older than 18 years treated between 1996 and 2012 were included. The Hematopoietic stem cell transplantation comorbidity index (HCT-CI), the Adult Comorbidity Evaluation-27 (ACE-27) score and the Cumulative Illness Rating Scale for Geriatrics (CIRS-G) at the time of initial AML diagnosis were evaluated to assess the degree of pretreatment comorbidity conditions. Data on demographics, cytogenetics, treatment and outcome were collected. Kaplan-Meier methods and Cox regression were used to assess survival.

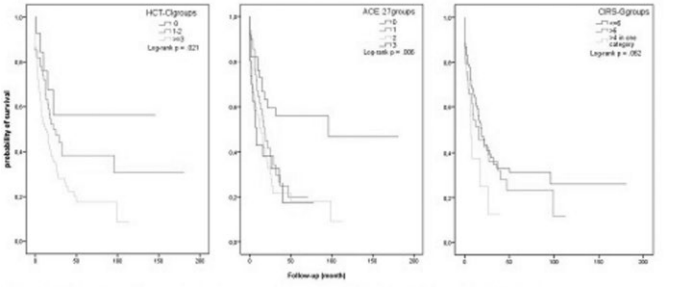

Figure 1. Survival curves according to HCT-CI, ACE-27 and CIRS-G.

Results: The study included 102 male and 92 female with median age at diagnosis of 60.9 years (range, 18-90). Median duration of follow-up was 9 month. One hundred twelve (57.7%) patients died, and 173 (89,2%)received intensive chemotherapy. Overall median survival was 17 month (range, 0-180). The most frequent comorbidities included cardiovascular disease (59.8%), infection (57.7%), hepatic disorders (45.9%) and prior malignancy (39.2%). In univariate analysis, presence of cardiovascular disease, severe hepatic disease and renal impairment were associated with inferior survival (26 *vs* 12 month, p=.005; 19 *vs* 4 month, p=.013; 17 *vs* 7 month, p=.016). Also, older age (≥60 years), poor cytogenetics and higher ECOG score (≥2) were significantly associated with reduced overall survival (25 *vs* 13 month, p=.003; 29 *vs* 12 month, p=.008; 21 *vs* 4 month, p=.000). For each index, the highest comorbidity burden was associated with poorer overall survival (Figure 1). However, in Cox-analysis the impact on overall survival was only significant for the ACE-27 score and the HCT-CI. Median survival by ACE-27 score was 96, 18, 14 and 8 month for patients with none, mild, moderate and severe comorbidities, respectively (p=.006). Median survival by HCT-CI was not reached, 22 and 12 month for patients in the lower- (0 points), intermediate- (1-2 points) and high- (≥3 points) risk groups, respectively (p=.021). Although the HCT-CI appeared to separate the risk groups better, in multivariate models only the ACE-27 score was significantly associated with overall survival. Adjusted hazard ratios were 1.9, 2.3 and 4.2 for mild, moderate and severe comorbidities, respectively, compared with no comorbidities (p=.004). Exploratory evaluations of the multivariate analysis suggested that higher ECOG (≥2), poor cytogenetics and presence of severe comorbidities according to ACE-27 had a significant impact on overall survival. Interestingly, higher age (i. e. ≥60 years) had no significant impact in multivariate analysis.
Summary and Conclusions: Comorbidities have a significant impact on survival of patients with AML. Patients with severe comorbidity had a greater than

50% decrease in survival, independent of age, ECOG and cytogenetics. A pre-treatment assessment of severity of comorbidities by comorbidity indices may help to identify patients with poor outcome. It appears that age at least partially impacts survival as a marker for comorbidities. Our data suggest that the ACE-27 score is a suitable index to predict survival in patients with AML.

Dept. with Hematology and Medical Oncology, Hemostaseology, Rheumatology and Infectious Diseases, Laboratory for Immunological and Molecular Cancer Research, Oncologic Center, Paracelsus Medical University Hospital Salzburg, and Center for Clinical Cancer and Immunology Trials at Salzburg Cancer Research Institute, Salzburg, Austria

Background: Acute erythroleukemia (AML-M6) accounts for 4% of all AML and is often associated with high risk karyotypes and poor prognosis, with a median survival of 3-9 months from diagnosis. When treated with intensive chemotherapy (ICT), remissions last less than one year (Santos et al, Leukemia 2009). Azacitidine (AZA) prolongs overall survival (OS) in patients with MDS and AML who are not candidates for ICT (Fenaux et al, Lancet Oncology 2009) but there is limited data of its efficacy in AML-M6 (Almeida, Leuk Res Reports 2013).
Aims: We report the clinical outcomes of 88 AML-M6 patients treated with AZA.
Methods: Data were pooled from registries and/or clinical files from multiple nations. Survival was estimated using the Kaplan-Meyer method and log-rank test for group comparison.

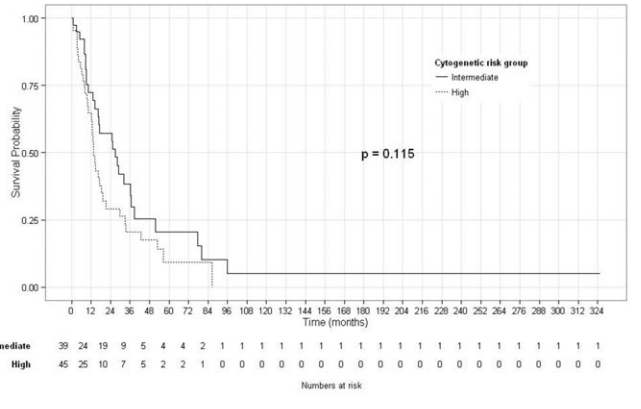

Figure 1.

Results: AZA was used as first line treatment in 41 patients (47%) and as ≥2nd line treatment in 51% (treatment line unknown in 2%).
Median age was 69 (range 28-88) years. MRC cytogenetic risk was intermediate in 44% and poor in 51%. The median time from diagnosis to treatment start was 21.9 days (1-552) and patients received a median number of 5 cycles (1-37). At the time of last follow-up 22 patients were still alive, of which 9 were still on AZA treatment; the main reasons for treatment discontinuation were disease progression (52%), infection/toxicity (12%), death (11%) and allogeneic transplantation (17%). At the time of writing, 66 patients had died from disease progression (48%), infectious complications (12%), and other (12%) or unknown causes (21%). Recorded grade 3-4 toxicities were predominantly hematological, and only 32 hospital admissions due to toxicities were reported. Overall marrow response was 34%, with 23% complete responses and 11% partial responses (assessed according to IWG criteria). Time to first and best response was 2.6 and 3.9 months, respectively. Progression free survival (PFS) in the whole AZA cohort was 5.1 months (range 3.4-9.2), and 9.4 months (range 4.3-14.5) in those treated with AZA first line. The median OS was 16.8 months (13.3-28.3) from diagnosis, 12.3 months (9.8-14.3) as of treatment start with AZA. Median OS from start of treatment for patients treated with AZA 1st line was 14.2 months (12.6-25.2) months, and 9.8 months (4.6 to 13.5) for those receiving AZA ≥2nd line. Response to AZA showed a significant impact on OS: 18.3 months in patients achieving CR/PR/HI, 16.2 months in patients with marrow SD and 9.1 months in patients with PD (p=0.008) Of importance, patients with poor-risk cytogenetics did not have an inferior survival when treated with AZA (Fig1). The median OS from start of treatment in a group of AML-M6 patients (n=34) treated with ICT alone was 7.6 months (5.4-20.3).
Summary and Conclusions: AZA demonstrates efficacy and shows promising response and survival results in our cohort of AML-M6 patients, not inferior to that seen with ICT. The median OS of 14.2 months for those treated with AZA 1st line compares favorably with data for WHO-AML patients treated with AZA 1st line in a randomized trial (10.4 months; Dombert H, EHA 2014, LB-2433) or from established patient registries (12.8 months; Pleyer L *et al.*, ASH 2014, #943). In addition, the observed median OS of 9.8 months in relapsed or refractory AML-M6 patients which generally confers a dismal prognosis (~3 months; Ferrara F, Haematologica 2004;998; Roboz G, JCO 2014;1919), is promising. Thus, AZA is a treatment option for 1st line treatment of AML-M6 patients ineligible for IC approaches, and also as salvage therapy for AML-M6 patients with relapsed/refractory AML.

E962

CLINICAL FEATURES AND OUTCOMES OF HYPOCELLULAR ACUTE MYELOID LEUKEMIA IN ADULTS: KOREAN AML REGISTRY DATA

I.C. Song[1,*] D.Y. Jo[1], H.J. Kim[2], Y.H. Min[3], D.S. Hong[4], W.S. Lee[5], H.J. Kim[6], J.H. Lee[7], J. Park[8], H.J. Shin[9]
[1]Internal medicine, CHUNGNAM NATIONAL UNIVERSITY HOSPITAL, Daejeon, [2]Hematology-oncology, Chonam National Univesity Hwasun Hospital, Hwasun, [3]Internal medicine, Yonsei University College of Medicine, Seoul, [4]Hematology-oncology, Soon Chun Hyang University Hospital, Bucheon, [5]Internal medicine, Inje University Busan Paik Hospital, Busan, [6]Internal medicine, Catholic Blood and Marrow Transplantation Center, [7]Hematology, Asan Medical Center, Seoul, [8]Hematology-oncology, Gachon University Gil Hospital, Incheon, [9]Internal medicine, Pusan National University Hospital, Pusan, Korea, Republic Of

Background: The hypocellular variant of acute myeloid leukemia (AML) is defined as the presence of <20% of cellular bone marrow in a biopsy specimen at presentation.
Aims: We performed a retrospective analysis to determine the clinical features and survival outcomes of hypocellular AML in a Korean population.
Methods: We reviewed the medical records of all patients with AML who were diagnosed from 2006 to 2012 at 9 hospitals participating in the AML registry. Overall survival and event-free survival were calculated from the time of diagnosis until death or an event, respectively. An event was defined as relapse after remission, failure to respond or death from any cause.
Results: In total, 2110 patients were enrolled, and 102 (4.8%) were identified as having hypocellular AML. Patients with hypocellular AML were older than those with non-hypocellular AML (median age, 59 *vs. 49* years, respectively; p <0.001) and more frequently presented with leukopenia (mean white blood cell count, 5,810/μL *vs.* 40,549/μL, respectively; p <0.001). There were no differences in the presence of antecedent hematologic disorders (5.9% *vs.* 5.3%, respectively; p=0.809). No differences were seen between the hypocellular and non-hypocellular AML groups with respect to the complete remission rate (53.9% *vs*. 61.3%, p=0.139), early death rate (defined as any death before 8 weeks, 14.7% *vs.* 13.0%, p=0.629). Overall survival (OS) and event-free survival (EFS) were not different between two groups (median OS, 16 *vs.* 23 months, respectively; p=0.169; median EFS, 6 *vs.* 9 months, respectively; p=0.215).
Summary and Conclusions: Hypocellular AML is more frequently observed in older age, but the clinical outcomes of hypocellular AML do not differ from that of non-hypocellular AML.

E963

REDUCED-INTENSITY TRANSPLANTATION AS A PART OF STANDARD TREATMENT STRATEGY IN PATIENTS AGED 60 TO 70 YEARS WITH ACUTE MYELOID LEUKEMIA – SINGLE CENTRE EXPERIENCE

M. Karas[1,*] K. Steienrova[1], D. Lysak[1], S. Vokurka[1], M. Hrabetova[1], A. Jungova[1], P. Jindra[1]
[1]Hematology and Oncology dpt., Charles University Hospital Pilsen, Pilsen, Czech Republic

Background: Outcome of patients (pts) over 60 years of age with acute myeloid leukemia (AML) treated only with intensive chemotherapy is poor. To improve treatment results reduced-intensity transplantation (RIT) was establish as a part of standard treatment strategy for pts aged 60 to70 years with AML (except of pts with prognostically favourable AML) in our centre from 2003.
Aims: With the aim to evaluate transplant feasibility and the role of RIT in the treatment of pts aged 60 to 70 years with AML we analysed outcome of such pts in our centre from 2003.
Methods: From 1/2003 to 11/2014 AML was diagnosed in 188 pts aged 60 to 70 years. 120 pts were intensively treated and 61 pts with median of age 63 years (range, 60-68 years) with AML in 1st CR (35 pts), in 2nd CR (5pts), with primarily resistant AML (9 pts) and with AML beyond CR (12 pts) underwent RIT (30% HLA identical related, 41% HLA matched unrelated, 26% HLA mismatched unrelated, 3% haploidentical related). Source of stem cells was in 85% peripheral blood and in 15% bone marrow with the median of infused CD 34+cells 4,8x10^6/kg (range, 1,7-14,9x10^6/kg). The conditioning regimen consisted of fludarabine (30mg/m2 for 4 days) and melphalan (140mg/m2 for 1 day), in 14 pts with ATG (ATG Fresenius 15mg/kg). CsA and methotrexate were used as GVHD prophylaxis except haploidentical RIT where posttransplant CPA and combination of CsA and MMF was used.
Results: The main reasons of impossibility to implement RIT in treatment of older pts with AML were death during remission induction treatment (39%), resistant or progressive AML (24%), non-availability of donor (16%), severe comorbidities (12%) and refusal of RIT (9%). However 51% of intensively treated pts with AML eventually underwent RIT. All pts fully engrafted and achieved complete remission (CR). 37 pts (60%) developed aGVHD (6 pts grade III-IV) and among 50 evaluable pts 22 (44%) of them developed chGVHD (9 limited, 13 extensive). With median follow-up 46 months (range, 4-123 months) 27 pts (44%) are alive (26 pts in CR). 14 pts (23%) relapsed and 13 of them died. 21 pts (34%) died due to NRM, 2 (3%) of them till day 100 after RIT and 11 (18%) of them till day 365 after RIT. The estimated probabilities of 3-years EFS and OS are 44% and 47%. 3-years OS for all intensively treated elderly pts was 38%.
Summary and Conclusions: Our data show that half of intensively treated pts aged 60 to 70 years with AML were able to undergo RIT and that RIT even in case of unrelated or HLA mismatched donor is associated with acceptable NRM and encouraging disease control of unfavourable AML (3-years OS 47%). The relatively high percentage of transplanted pts undoubtedly influenced the overall results of the group of intensively treated elderly patients with AML with a median survival of 15 months and estimated 3-year OS of 38%. RIT should be considered as standard treatment option for consolidation therapy in elderly patients with AML.

HUMAN MYELOID INHIBITORY C-LECTIN (HMICL): A NOVEL ACUTE MYELOID LEUKEMIA MARKER

E. kandeel[1,*] D. samir[2], A. mohy eldin[3], T. el kerdany[4]
[1]clinical pathology, National Cancer Institute Cairo University, [2]clinical pathology, Faculty of medicine Ain shams University, Cairo, [3]clinical pathology, Misr University For Science And Technology, Giza, [4]clinical pathology, Faculty of medicine Ain shams University, Cairo, Egypt

Background: Acute myeloid leukemia (AML) is the most frequent acute leukemia affecting adults and its incidence increases with age. Leukemogenic mutations affect hemopoietic stem cells resulting in leukemic clones. It has been proven that leukemic stem cells reside in CD34+CD38- compartment of the bone marrow. Several studies were conducted to include different markers *e.g.* CD44, CD123, CD90 and CD133 for discriminating leukemic stem cell during treatment (minimal residual disease) or for targeted therapy. The human myeloid inhibitory C-type lectin-like receptor (hMICL) (also named CLL-1) was reported as possible leukemic stem cell marker and for targeted therapy.
Aims: The aim of this work is to determine the diagnostic impact and the applicability of the Human Myeloid Inhibitory C-Lectin (hMICL) in routine clinical flow cytometry (FCM) in the diagnosis of AML in Egyptian patients.
Methods: Bone marrow samples were drawn from 40 de novo AML and 20 de novo ALL patients. Mobilized peripheral blood was drawn from healthy donors after granulocyte colony-stimulating factor (G-CSF) stimulation. An informed consent in accordance with the Declaration of Helsinki was obtained. Bone marrow samples were stained with hMICL PE (clone: 687317, R&D systems, Minneapolis, USA) in combination with CD45 PE-PC5,CD34 ECD and CD38 FITC (Bechman Coulter,Maiami, USA) analysis done within 24 hours of sampling. Sample analysis was done by multicolor flow cytometry (Coulter Epics XL, Hialeah, USA). Gating strategy was applied using dim CD45/side scatter. Data analysis was done on Winlist 6 (Verity Software House, Topsham, ME).
Results: In AML cases, hMICL was expressed in all studied patients ranging from 20% to 95% (mean 60.3±19.9). This was found to be significantly higher compared to the healthy control subjects who ranged from 0.8% to 9.5% (mean 3.5±2.4) ($p<0.0001$) and to ALL patients who ranged from 0.9% to 7.2% (mean 3.3±1.9) ($p<0.0001$). In different FAB subtypes, expression of hMICL percentage was heterogeneous. The highest percentage was 95% in M1 and the lowest was 20% in M4. This heterogeneity of hMICL % expression was found to be significant ($p=0.02$). An interesting finding is that hMICL expression was also found in all CD 34- cases with percentage that reached 87% which pave the way for improved leukemia associated immunophenotype (LAIP) characterization and minimal residual disease (MRD) detection and quantification by multicolour FCM in the otherwise poorly described CD34- AML cases. hMICL expression has no statistical significance regarding age, gender, hemoglobin, platelet count, total leukocyte count, blast percentage, CD34, cytogenetic profile, and FLT3 ITD mutation. Using the receiver operating characteristic (ROC) curve, cut-off values for hMICL% and hMICL-MFI were identified which allow the most significant separation and differentiation between AML cases and normal subjects. The hMICL % cut-off value was 9.5% showing sensitivity of 95% and specificity of 100%. The hMICL MFI cut-off value was 2.3 showing sensitivity of 100%, specificity of 85%
Summary and Conclusions: hMICL is unique novel discriminator of AML reliable for diagnosis and MRD detection and it is considered a goal for targeted therapy.

E965

CLINICAL OUTCOMES OF AML PATIENTS TREATED WITH AZACITIDINE IN PORTUGAL: A RETROSPECTIVE MULTICENTER STUDY

A. Almeida[1,*] A.R. Ferreira[2], M.J. Costa[3], S. Sofia[3], K. Alnajjar[1], B. Isabel[1], F. Pierdomenico[1], A. Mafalda[4], G. Braz[4], E. Cortesão[5], R. Pinto[4]
[1]IPO Lisboa, [2]Centro Hospitalar Universitário de Coimbra, [3]Centro Hospitalar Lisboa Norte - Hospital Santa Maria, Lisbon, [4]Hospital São João, Porto, [5]Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal

Background: Acute myeloid leukemia (AML) in elderly patients has a poor prognosis when treated with intensive chemotherapy (IC) and there is a need for new treatment options. Regardless of the blast count, elderly patients often display more indolent disease behaviour, resembling that seen in high risk myelodysplastic syndromes (MDS). Several studies have demonstrated the efficacy of Azacitidine (AZA), approved for use in MDS, in patients with AML unfit for IC.
Aims: We present a multi-centre retrospective analysis of efficacy of azacitidine in AML patients unfit for IC or relapsed/refractory to IC.
Methods: Retrospective data collection from clinical files was carried out following ethical committee approval. Survival was estimated using the Kaplan-Meyer method, post-hoc pairwise comparisons using log-rank test were performed and the p-values adjusted for multiple comparison using Hochberg method. Responses were assessed according to the IWG-MDS-2006 response criteria. [F1]Avaliação de resposta de acordo com que critérios.
Results: One-hundred and twenty three AML patients treated with AZA were identified. Median age at diagnosis was 69 years; 67% were men. At diagnosis, 75% of patients were anemic, 38% neutropenic and 46% thrombocytopenic. Secondary AML was diagnosed in 45% of patients. Karyotypes were normal in 40%, intermediate risk in 23% and poor risk in 21%. Patients started azacitidine a median of 1.5 months following diagnosis. It was first line therapy in 57% and second line following IC in 28%, unknown in 15%. Patients were treated until progression, toxicity or bone marrow transplant and received a median number of 5 cycles. Overall response rate was 27.6%, with 19.5% complete and 8.1% partial responders. Stable disease at time of assessment was seen in 17.9% and progression in 17.1%. Haematological improvement was achieved in 44.7% of patients. Of the whole population, 4 (3.3%) were not evaluable for survival. During the study period 86 deaths were reported. The main cause of death was disease progression (64%). The other main identified cause was infectious (12%). Median overall survival was 15.7 months. Response of any quality to AZA had a significant impact in overall survival. The median survival observed in patients achieving CR or PR was 19.2 months, in patients with SD was 24.6 months and in patients with PD was 6.4 months ($p=0.006$). Pairwise comparisons show a significant difference in overall survival between PD and CR+PR and between PD and SD but not between CR+PR and SD. The median survival was significantly higher in patients with haematological improvement (17 *vs* 13 months, respectively; log rank test: $p=0.048$).
The survival of the cohort treated with AZA was compared to that of a matched pair group treated with IC. The median time from diagnosis to start of IC in this comparator group was 0.13 months (range: 0-9.2 months). The median follow-up was 5.4 months (range: 0.1-43.4). There were 48 deaths and only 2 patients were still alive at the time of last follow-up. Median overall survival observed in this comparator cohort was 5.4 months. This was significantly inferior to that observed in the cohort treated with AZA ($p<0.0001$).
Summary and Conclusions: These results support the efficacy of AZA in AML in a similar fashion to that demonstrated in high risk MDS, increasing treatment options in these patients.

THE DNMT3A R882 MUTATION WITH FLT3-ITD POSITIVITY IS AN EXTREMELY POOR PROGNOSTIC FACTOR IN PATIENTS WITH NORMAL KARYOTYPE AML AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

J.S. Ahn[1], H.J. Kim[1,2,*] Y.K. Kim[1], S.H. Jung[1], D.H. Yang[1], J.J. Lee[1], N.Y. Kim[2], S.H. Choi[2], C.W. Jung[3], J.H. Jang[3], H.J. Kim[4], J.H. Moon[5], S.K. Sohn[5], J.H. Won[6], S.H. Kim[7], D.D.H. Kim[8]

Background: The prognostic relevance of epigenetic modifying genes (*DNMT3A*, *TET2*, and *IDH1/2*) in patients with acute myeloid leukemia (AML) has been investigated extensively.
Aims: However, the prognostic implications of these mutations following allogeneic hematopoietic cell transplantation (HCT) have not been evaluated comprehensively in patients with normal karyotype (NK)-AML.
Methods: A total of 121 patients who received allogeneic HCT for NK-AML were evaluated for the *FLT3*-ITD, *NPM1. CEBPA, DNMT3A, TET2*, and *IDH1/2* mutations in diagnostic samples and analyzed for long-term outcome following allogeneic HCT.
Results: The prevalence rates for the mutations were: *FLT3*-ITD^{pos}(32.2%), *NPM1*^{mut} (43.8%), *CEBPA*^{mut} (double) (29.2%), *DNMT3A*^{mut} (32.2%), *DNMT3A* R882^{mut} (19.8%), *TET2*^{mut} (8.3%), and *IDH1/2*^{mut} (15.7%). The 5-year overall survival (OS) and event-free survival (EFS) rates were 57.9% and 56.2%, respectively, with a median follow-up duration of 69.2 months. A multivariate analysis revealed that *FLT3*-ITD^{pos} (hazard ratio, [HR], 2.122; p=0.009) and *DNMT3A R882*^{mut} (HR, 2.198; p=0.012) were unfavorable prognostic factors for OS. In addition, both mutations were significant risk factors for EFS and relapse risk. *DNMT3A* R882^{mut} had high coincidence with *FLT3*-ITD^{pos} (p=0.038). Additionally, patients with both mutations showed the worst OS, EFS, and higher relapse rates than those with the other mutations, which were confirmed in a propensity score matching analysis.
Summary and Conclusions: These results suggest that the *DNMT3A* R882^{mut}, particularly when accompanied by *FLT3*-ITD^{pos}, is a significant prognostic factor for inferior transplant survival outcome by increasing relapse risk, even afterallogeneic HCT. Thus, the association between *DNMT3A R882*^{mut}and *FLT3*-ITD^{pos} will clarify the prognosis in the patients with NK-AML after allogeneic HCT.

LOW-DOSE CYTARABINE AFTER FAILURE OF 5-AZACITIDINE AS PALLIATIVE TREATMENT FOR ELDERLY PATIENTS WITH AML OR HIGH-RISK MDS INELIGIBLE FOR INTENSIVE CHEMOTHERAPY. A RETROSPECTIVE SINGLE CENTER ANALYSIS

C. Jakob[1,*] S. Peinert[2], F. Breywisch[1], B. Guenther[1], K. Dittberner[1], L. Boger[1], F. Rothmann[1], G. Maschmeyer[1]
[1]Hematology, Oncology and Pallaitive Care, Klinikum Ernst von Bergmann, Potsdam, [2]Practice for Hematology/Oncology, Aurich, Germany

Background: The demethylating agents 5-azacitidine (5-AZA) or decitabine recently became a standard of care for first line treatment of elderly or unfit patients with high-risk myelodysplastic syndrome (MDS) or acute myeloid leukemia (AML) who are not eligible for intensive induction chemotherapy or allogeneic stem cell transplantation. Although there is an improvement in overall survival with epigenetic therapies, almost all patients eventually develop disease progression, for which no standard therapeutic option is available.
Aims: The aim of our retrospective analysis was to evaluate the clinical benefit of low-dose cytarabine (ARA-C) treatment compared to best supportive care (without chemotherapy) as second-line palliative treatment options after failure of 5-AZA.
Methods: From 2009 to 2014 we treated 48 consecutive patients, 10 with newly diagnosed high-risk MDS and 38 with de novo AML, with 5-AZA (75mg/m2 s.c. d1-7, q-d29) as first-line therapy until progression. After failure of 5-AZA, 15/31 patients received a 2nd-line treatment with subcutaneous low-dose cytarabine (ARA-C, 2x 10 mg/m2/d, d1-10) and 16 patients received best supportive care only, without chemotherapy.
Results: After first-line 5-AZA 37/48 (76%) patients achieved a partial hematologic response (n=23) or stable disease (n=14). Median duration of response was 14 (2-52) months. After a median follow-up of 18 months, 31 patients had a disease progression, as defined by worsening of peripheral blood counts, increase of blasts or increase in transfusion frequency. Four of 15 patients, who were treated with ARA-C as second line therapy, achieved a partial hematologic response and 5/15 had stable disease with a median response duration of 4 months. The median overall survival from the time of progression on 5-AZA (OS-2) was 6 months, with a trend for longer survival in patients achieving at least a partial remission. There was no correlation between response and cytogenetic risk. In comparison to the ARA-C group, in 16 patients who received best supportive care only, the median OS-2 was 2.9 months and no objective responses were observed.
Summary and Conclusions: In conclusion, our analysis show that second-line treatment with ARA-C may add a survival benefit of approximately 3 months compared to best supportive care alone. The second overall survival (OS-2) of 6 months is within the range achieved with low dose ARA-C as primary treatment for this patient population. Our data indicate that ARA-C can be considered as a reasonable therapeutic option after failure of 1st-line treatment with demethylating agents like 5-AZA. This clinical observation is supported by recent pre-clinical data, showing that epigenetic modifications in AML cells can have a sensitizing effect for the subsequent administration of ARA-C.

Background: *FLT3* internal tandem duplication (*FLT3*-ITD) is present in nearly 25% of patients with normal karyotype acute myeloid leukemia (NK-AML) and have been associated with poor prognosis. Because of inferior outcome of *FLT3*-ITD^{+} NK-AML patients when treated with standard chemotherapy regimens like daunorubicin (DNR)-cytarabine (AraC) 3+7 induction (DA), this group prompts the use of investigational therapy. Targeting the *FLT3* receptor signaling has recently become particularly attractive. However, so far clinical experience failed to demonstrate efficacy of such approach.
Aims: We retrospectively evaluated the effect of the addition of cladribine to induction regimen on patients outcome according to presence or absence of *FLT3*-ITD.
Methods: 227 patients with NK-AML either enrolled in clinical trials or treated with the same protocols outside prospective studies were included in the analysis. 103 patients were treated with daunorubicine-cytarabine-cladribine (DAC) while 124 patients received daunorubicine-cytarabine (DA).
Results: Among *FLT3*-ITD^{+} patients the use of DAC was associated with increased rate of complete remission rate (CR; 86% *vs* 61% in DA group; p=0.04) and improved overall survival (OS; 37% *vs* 14%, respectively; p=0.05). The effect on OS was most prominent when observations were censored at time of allogeneic hematopoietic stem cell transplantation. In multivariate analysis, DAC independently improved CR rate and predicted longer OS in the group of *FLT3*-ITD^{+} patients after adjusting for age and *NPM1* mutations (p=0.07 for CR rate; p=0.009 for OS). Such an effect could not be demonstrated for *FLT3*-ITD^{-} patients.
Summary and Conclusions: Thus, our results suggest that DAC regimen can abolish negative effect of *FLT3*-ITD on the prognosis of NK-AML patients.

ELEVATED PIM-2 GENE EXPRESSION IS ASSOCIATED WITH POOR SURVIVAL OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

K. Kapelko-Slowik[1,*] T. Owczarek[2,3], K. Grzymajlo[2], D. Urbaniak-Kujda[1], B. Jazwiec[1], M. Slowik[4], K. Kuliczkowski[1], M. Ugorski[2,3]
[1]Haematology, Wroclaw Medical University, [2]Department of Biochemistry, Pharmacology and Toxicology, Wroclaw University of Environmental and Life Sciences, Wroclaw Poland, [3]Biochemistry, Ludwik Hirszfeld Institute of Immunology and Experimental Therapy Polish Academy of Sciences, Wroclaw, Poland, [4]Ophthalmology, Wroclaw Medical University, Wroclaw, Poland

Background: *PIM-2* gene belongs to the *PIM* family which encodes the serine/threonine kinases involved in cell survival and apoptosis. While *PIM-1* is described as an antiapoptotic protein in acute myeloid leukemia (AML), much less is known about the importance of *PIM-2*. The relations between *PIM-2* gene expression and AML outcome have not been fully defined
Aims: The aim of the presented study was to evaluate *PIM-2* gene as marker of AML malignancy. We also examined the role of *PIM-2* expression in apoptosis and proliferation of blastic cells isolated from patients with AML.
Methods: Ninety-one patients were enrolled in this study: aged 18-84, median age 50. Forty-eight patients reached complete remission (CR). For all patients, bone marrow samples were collected at the time of diagnosis, only samples with blastic cells for more than 80% of total cellularity were examined. In 20

patients bone marrow in CR phase was assessed. The control group consisted of 24 hematologically healthy bone marrow donors. External validation was performed on TCGA AML dataset. *PIM-2* expression levels assessed by RNAseq and represented as z-score were downloaded from cBioPortal. Expression of *PIM-2* gene was assessed by TaqMan RQ-PCRassay. Apoptosis was measured using FITC-Annexin V and propidium iodide staining. The BrdU staining was performed using FITC BrdU Flow Kit. Inhibition of *PIM-2* was performed with RNAi and apoptosis rate of HL-60/PAC-GFP and HL-60/PAC-GFP-shPIM-2 cells was analysed by standard methods. Expression of PIM-2, BAD, 4E-BP1 p-BAD, p-4E-BP1 proteins was assessed by Western blot. All statistical analyses were performed using GraphPad Prism 5 software.
Results: Median *PIM-2* gene expression in AML patients was significantly higher than in healthy control group. AML patients with high expression levels of *PIM-2* gene (above median) had significantly shorter leukemia free survival (LFS) than patients with low *PIM-2* expression (p=0.0082). External data from TCGA AML dataset was utilized to farther validate these observations. For patients with AML, Kaplan-Mayer analysis of overall survival confirmed that high *PIM-2* gene expression level is associated with poor prognosis (p=0.038). In addition, it was found that patients who achieved CR had significantly lower expression of the *PIM-2* gene than patients with no CR (p=0.0083). Importantly, elevated *PIM-2* gene expression assessed at presentation was restored to normal level in all patients in CR. Moreover we revealed overexpression of the PIM-2 kinase and its downstream effectors: native BAD and 4E-BP1 proteins as well as p-BAD (Ser112) and p-4E-BP1 (Ser65) in AML samples in comparison to controls. Negative, moderate correlation between *PIM-2* gene expression and the percentage of blastic cells in a total apoptosis was found (r^2=0.4332, p<0.0001). Cytometric analysis of HL60/PAC-GFP and HL60/PAC-GFP-shPIM2 cells revealed increase in the number of spontaneously apoptotic cells after inhibition of *PIM-2* gene.
Summary and Conclusions: In summary, we showed that elevated expression of the *PIM-2* gene in blastic cells is associated with poor prognosis of AML patients and their resistance to induction therapy, what can be linked with increase resistance of leukemic cells to apoptosis. We hypothesize that anti-apoptotic effect of the PIM-2 kinase is mediated, at least in part, by increased phosphorylation of BAD and 4E-BP1 proteins. Based on obtained data, we speculate that AML patients with elevated *PIM-2* expression more likely develop resistance to induction therapy, what may negatively affect their survival.

RITUXIMAB MAINTENANCE VERSUS WW AFTER R-DHAP PLUS AUTOLOGOUS STEM CELL TRANSPLANTATION IN UNTREATED PATIENTS WITH MCL: INTERIM ANALYSIS OF THE LYMA TRIAL, A LYSA STUDY

S. Le Gouill[1,*] E. Deconinck[2], H. Ghesquieres[3], M. Mertault[4], B. Audhuy[5]W. [6], E. Jourdan[7], L. Sanhes[8], R. Bouabdallah[9], A. Van Hoof[10], A. Delmer[11], O. Hermine[12]
[1]CHU de Nates, Nantes, [2]CHU de Besançon, Besançon, [3]Centre Léon Berrard, Lyon, [4]CH de Lens, Lens, [5]CH Colmar, Colmar, [6]CH Meaux, Meaux, [7]CHU de Nimes, Nimes, [8]CH Perpignan, Perpignan, [9]IPC, Marseille, France, [10]CH Bruges, Bruges, Belgium, [11]CHU de Reims, Reims, [12]AP-HP Necker, Paris, France

Background: The LyMa (ClinicalTrials.gov, NCT00921414) is a prospective randomised phase III trial conducted by the LYSA group. The study assessed the potential benefit of Rituximab maintenance after autologous stem cell transplantation (ASCT) in young previously untreated Mantle Cell Lymphoma (MCL) patients (<66y).
Aims: The primary endpoint was EFS at 4 years after randomization, EFS being defined as death of any cause, disease progression, severe allergic reaction or severe infection to Rituximab. PFS and OS were secondary objectives. Herein, we present the first planned interim analysis. Analysis was performed by intention to treat.
Methods: Patients were enrolled at times of diagnosis. All patients received 4 courses of R-DHAP followed by ASCT (4 additional courses of R-CHOP was given to patients who did not reach at least a PR after R-DHAP). The conditioning regimen of ASCT was Rituximab (500mg/m2) plus BEAM. Patients achieving a complete or partial response after ASCT were randomly assigned between 3 years of Rituximab maintenance therapy (375mg/m2, one injection every two months) versus wait and watch (WW) (1:1).
Results: From September 2008 to August 2012, 299 patients were included (one patient withdrawn his consent, data of one patient with incomplete data at time of the present analysis). Median age at registration was 57y (27-65) and 236 (78,9%) patients were male. MIPI score was low in 53,2% (n=159), intermediate in 27,4% (n=82) and high in 19,4% (n=58). In all, 257 (86%) patients proceeded to ASCT. The CR/CRu rates before and after ASCT were 81,4% and 92.7%, respectively. Last update was performed in November 2014. Median follow-up calculated from time of inclusion is 40.6 months. For all patients, median PFS and OS are not reached. The estimates 3y-PFS and -OS are 75% (95%CI ; 69.5-79.6) and 83.4% (95%CI ; 78.5-87.3), respectively. Last randomization was done in February 2013. Two hundred and thirty eight patients were randomised: 119 patients were assigned to rituximab maintenance and 120 to WW. The mFU (n=238) calculated from date of randomization is 34.3 months. The 3y-EFS is 88.1% (95%CI, 79.5-93.2) in the Rituximab maintenance arm versus 73.4% (95%CI, 62.6- 81.6) in the WW arm (p=0.0057). The 3y-OS does not differ between the two groups (85.5 in the WW arm *vs* 93.1% in the maintenance arm ; p=0.7175).
Summary and Conclusions: This planned interim analysis of the LyMa trial shows that a 3 years of rituximab maintenance after R-DHAP plus ASCT as first-line treatment for young patients with MCL significantly improves EFS and PFS.

E969

CLINICO-BIOLOGICAL CHARACTERISTICS AND OUTCOME OF PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) CARRYING HEPATITIS B VIRUS OR C VIRUS RECEIVING IMMUNOCHEMOTHERAPY

M.Á. Torrente Marchante[1,*] I. Dlouhy[1], S. Lens[2], L. Magnano[1], E. Gine[1], J.G. Correa[1], J. Rovira[1], K. Karube[3], G. Roué[4], L. Colomo[3], A.S. Martínez[1], D. Julio[1], F. Xavier[2], J.M. Sánchez Tapias[2], E. Campo[3], A. López Guillermo[1]
[1]Hematology, [2]Hepatology, [3]Pathology, Hospital Clinic, [4]IDIBAPS, Barcelona, Spain

Background: DLBCL patients carrying hepatitis B virus (HBV) or hepatitis C virus (HCV) are a management challenge in the clinical setting, particularly since rituximab-based treatments became the gold standard.
Aims: The aim of this study was to assess the HBV and HCV incidence and their clinical and prognostic impact in a series of DLBCL patients treated with immunochemotherapy.
Methods: 321 patients (161M/160F; median age 66) diagnosed with DLBCL in a single center between 2002 and 2013. Primary central nervous system lymphoma, primary mediastinal lymphoma and plasmablastic lymphoma were excluded, as well as transformed cases from other lymphomas, post-transplant lymphoproliferative disorders and HIV+patients. HCV+and HBV+were defined by the presence of IgG anti-HCV and HBV core-antibodies, respectively. Main clinico-biological characteristics and outcome were analyzed according to the viral status.

Results: 265 patients were virus negative, 32 HBV+(10%) and 29 HCV+(9%). 5 of the latter had HBV/HCV co-infection. Main initial features and outcome are detailed in the table. Elevated basal bilirubin correlated with higher liver toxicity during treatment (85% *vs* 40%, p<.001) and shorter overall survival (OS). After a median follow up of 49 months (range 2-146), median OS was not reached for patients without hepatitis, and was of 55, 38 and 14 months for HBV+, HCV+and HBV+/HCV+patients, respectively (p=.005). HCV+patients without liver cirrhosis showed an almost identical OS compared to hepatitis negative patients. When the analysis was restricted to patients receiving curative intention regimens, 5 year OS for hepatitis negative, HBV+, HCV+and HBV+/HCV+was 69%, 62%, 63% and 25%, respectively (p=NS).

Tabella 1. Summary of patient char acter ist ics and outcomes.

	No hepatitis (n=265)	HBV (n=32)	HCV (n= 29)	HBV/HCV (n=5)#
Gender (male) (%)	54	34*	35*	60
Age ≥60 years (%)	60	66	83*	80
Cell of origin $				
Germinal center (%)	45	57	38	0
Activated (%)	51	14	25	50
Undetermined (%)	4	29	38	50
Extranodal involvement (%)	70	63	59	40
Spleen (%)	14	29*	38**	60*
Liver (%)	8	13	24*	0
Ann-Arbor stage III-IV (%)	57	53	66	60
IPI risk high intermediate or high (%)	46	31	62*	40
Serum albumin <35 g/L (%)	18	31	44*	50
Serum LDH ≥450 UI/L (%)	49	47	72*	100
Serum B2m ≥2.3 mg/L (%)	53	73*	77*	100
Curative-intent treatment (%)	91	69**	76*	80
Liver toxicity grade ≥2 WHO	6	14	39**	75**
Complete remission (%)	73	61	55	40
5-year FPS (%)	53	39	37	20
5-year OS (%)	65	43*	42**	20

These patients are also included in HBV and HCV columns;*p<,05; **p<,005; $n= 64 patients

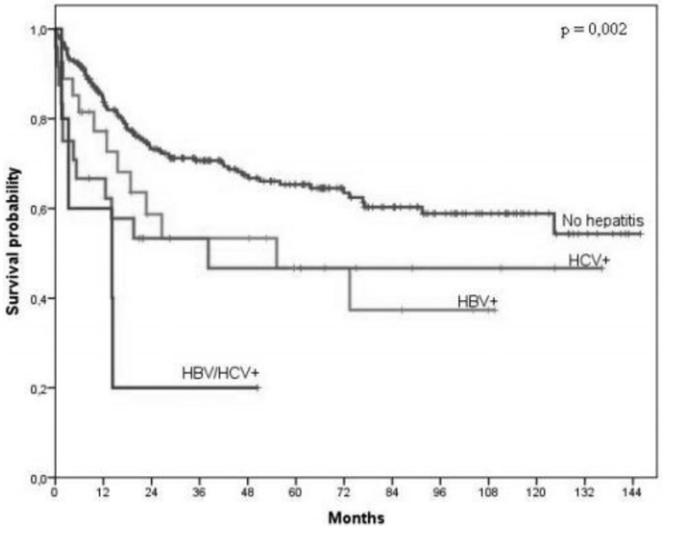

Figure 1.

Summary and Conclusions: The presence of HBV or HCV in DLBCL patients entails higher number of complications; however, liver impairment and not the hepatitis viral status is the key feature in the outcome of the patients.

E970

SIL INDEX IS A SIMPLE AND OBJECTIVE PROGNOSTIC INDICATOR IN DIFFUSE LARGE B-CELL LYMPHOMA

N. Tomita[1,*] T. Suzuki[2], K. Miyashita[3], W. Yamamoto[4], K. Motohashi[5], T. Tachibana[1], H. Takasaki[4], R. Kawasaki[3], M. Hagihara[5], C. Hashimoto[6], S. Takemura[7], H. Koharazawa[8], E. Yamazaki[1], J. Taguchi[8], K. Fujimaki[3], H. Fujita[9], R. Sakai[4], S. Fujisawa[5], S. Motomura[4], Y. Ishigatsubo[1]
[1]Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, Yokohama, [2]Hematology, Yokosuka City Hospital, Yokosuka, [3]Hematology/Immunology, Fujisawa City Hospital, Fujisawa, [4]Medical Oncology, Kanagawa Cancer Center, [5]Hematology, Yokohama City University Medical Center, Yokohama, [6]Hematology/Oncology, Yamato Municipal Hospital, Yamato, [7]Internal Medicine, Yokohama Ekisaikai Hospital, Yokohama, [8]Hematology, Shizuoka Red Cross Hospital, Shizuoka, [9]Hematology, Saiseikai Yokohama Nanbu Hospital, Yokohama, Japan

Background: Rituximab (R) plus CHOP (R-CHOP) is the standard of care for patients with diffuse large B-cell lymphoma (DLBCL). The International Prognostic Index (IPI) and revised IPI were reported as prognostic indicators for DLBCL in 1993 and in 2007, respectively. Although they are widely accepted, the performance status (PS) factor is sometimes ambiguous or subjective. Therefore, we developed a new prognostic index, SIL, that includes only three objective prognostic factors: clinical stage (S), soluble interleukin-2 receptor level >2,500 U/mL (I), and elevated lactate dehydrogenase level (L) (Cancer Sci. 2012).

Aims: To compare the SIL index with other risk factors that comprise the IPI and to evaluate its utility in the risk stratification of patients with DLBCL.

Methods: Between 2003 and 2012, we registered and treated 781 consecutive patients with DLBCL, excluding those with mediastinal large B-cell lymphoma, intravascular large B-cell lymphoma, and primary effusion lymphoma. All the included patients were scheduled to undergo primary therapy with six cycles of full-dose R-CHOP. Patients in whom the initial therapy dose was reduced by >20% were excluded. Finally, 572 of 781 patients were retrospectively analyzed. Patients with partial remission (PR) after the initial four cycles underwent eight R-CHOP cycles in total, whereas those who did not achieve PR after the initial four R-CHOP cycles or those who exhibited disease progression at any given time received salvage therapy. If deemed necessary by the attending physician, additional local irradiation was performed in patients with PR or complete remission.

Results: The median age at diagnosis was 63 years (range, 18-89 years). The median number of therapy cycles was 6 (range, 1-8), and 90% of the patients received ≥6 cycles. Sixty-one patients (11%) received radiation therapy as primary treatment, which was often used to treat sites of residual masses at the end of chemotherapy. The median observation time for survivors was 55 months (range, 1-131 months). For the 572 patients, the 5-year progression-free survival (PFS) and 5-year overall survival (OS) rates were 70% and 81%, respectively. According to the SIL index, 367 patients (64.2%) and 205 patients (35.8%) were classified as having standard (SIL index: 0 or 1) and high (SIL index: 2 or 3) risks, respectively. Five-year PFS rates in the standard and high risk groups were 79% and 53%, respectively (*P* <0.0001). Five-year OS rates in the standard risk and high risk groups were 90% and 66%, respectively (*P* <0.0001) (Figure). Cox regression analysis of the SIL index, age (>60 years), PS (2-4), extranodal involvement sites (>1), and sex showed that the SIL index (*P* <0.0001; hazard ratio [HR]: 2.38) and PS (*P*=0.005; HR: 1.73) were independent risk factors for PFS. Similarly, the SIL index (*P* <0.0001; HR: 2.62) and PS (*P*=0.006; HR: 1.89) were independent risk factors for OS. When the patients were divided into two groups by age (≤60 years and >60 years), the SIL index was a good prognostic indicator for PFS and OS in both groups. When they were divided by the number of extranodal involvement site (0-1 and >1), and sex, the SIL index was still a good prognostic indicator for PFS and OS in both groups. Lastly, when they were divided by PS (0-1 and 2-4), the SIL index was effective in the good PS group. In the poor PS group however, the SIL index showed a statistically significant difference in the OS, but not in the PFS.

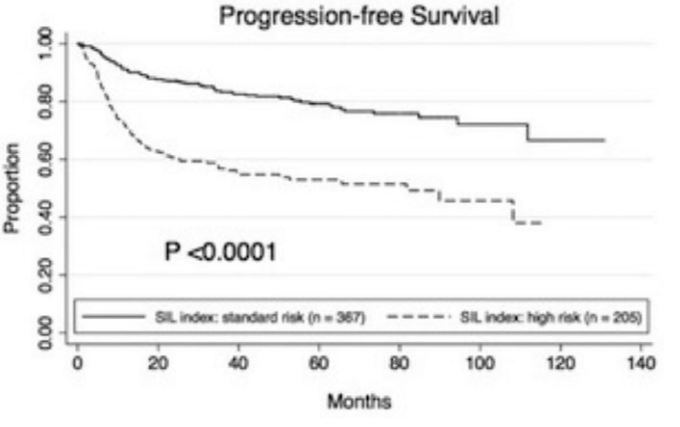

Figure 1.

Summary and Conclusions: The SIL index is a simple and objective prognostic indicator for DLBCL patients treated with R-CHOP.

E971

CLINICAL FEATURES AND OUTCOMES IN PATIENTS WITH PRIMARY TESTICULAR LYMPHOMA

Y. Nakajima[1,*] N. Tomita[1], T. Suzuki[2], M. Itabashi[3], K. Miyashita[4], A. Numata[3], Y. Hattori[5], W. Yamamoto[5], T. Miyazaki[1], H. Takasaki[5], R. Kawasaki[4], C. Hashimoto[6], H. Koharazawa[7], J. Taguchi[7], K. Fujimaki[4], H. Fujita[8], R. Sakai[5], S. Fujisawa[3], Y. Ishigatsubo[1]
[1]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, Yokohama, [2]Department of Hematology, Yokosuka City Hospital, Yokosuka, [3]Department of Hematology, Yokohama City University Medical Center, Yokohama, [4]Department of

Hematology/Immunology, Fujisawa City Hospital, Fujisawa, [5]Department of Medical Oncology, Kanagawa Cancer Center, Yokohama, [6]Department of Hematology, Yamato City Hospital, Yamato, [7]Department of Hematology, Shizuoka Red Cross Hospital, Shizuoka, [8]Department of Hematology, Ssai-seikai Yokohama Nanbu Hospital, Yokohama, Japan

Background: Primary testicular lymphoma (PTL) is a rare type of extranodal non-Hodgkin lymphoma. Because of its rarity, clinical features, and optimal treatments remain uncertain.
Aims: To assess clinical features, outcomes and prognostic factors in patients with PTL.
Methods: In total, 62 patients were diagnosed with PTL at 8 institutions of the Yokohama City University Hematology Group from 1998–2014. Of 62 patients, 57 (92%) were diffuse large B-cell lymphoma (DLBCL). Our retrospective analysis included these 57 patients with PTL-DLBCL. We defined stage IE as mono or bilateral involvement of the testis, and stage IIE as the stage IE lesion with concomitant regional lymph node involvement. Stage III or IV, although undistinguishable from a nodal lymphoma in advanced stage, was defined as testicular involvement with distant lymph nodes and/ or extra-nodal sites involvements.
Results: The median age at diagnosis was 68 years (range, 42–85 years). The clinical stage of PTL was stage I, II, III, and IV in 25, 15, 7, and 10 patients respectively. The median observation period in the surviving patients was 53 months (range, 7–124 months). Fifty-five patients underwent orchiectomy. Fifty-five patients received systemic chemotherapy; 46 with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) therapy, 7 with CHOP therapy, and 2 with other regimens. Of the remaining 2 patients, 1 had orchiectomy and radiation, and 1 had best supportive care (BSC). Thirty-two patients received contralateral testicular irradiation in addition to systemic chemotherapy. Prophylactic intrathecal methotrexate (IT) or high-dose intravenous methotrexate (HdMTX) for central nervous system (CNS) relapse was administered in 40 patients; IT for 32, and HdMTX for 8. Among the 56 patients who underwent treatments other than BSC, 48 (86%) achieved complete remission, and 3 (5%) partial response. The 4-year progression-free survival (PFS) and overall survival (OS) rates of all patients were 57% and 59%, respectively. Twenty-one patients had disease progression after treatment for PTL. Extranodal recurrence was reported in 18. CNS was the most common site of extranodal relapse observed in 6 patients, although 5 of them had prophylactic IT. In total, 21 patients died: 13 of lymphoma, 2 of infection during chemotherapy, 1 of pneumonia in remission, 2 of secondary malignancy, and 2 of cardiopulmonary arrest from unknown cause. Absence of B symptoms, normal levels of serum lactate dehydrogenase, good performance status (PS), and addition of contralateral testicular irradiation to chemotherapy were associated with better PFS and OS at univariate analysis. Patients that received chemotherapy plus contralateral testicular irradiation had a tendency to be in earlier stages (P=0.03), and in better PS (P=0.008) than those who received chemotherapy alone. However, even when the analysis was limited to the patients with stage I and II, the benefit of radiation therapy added to chemotherapy remained statistically significant for PFS (P=0.015), and OS (P=0.002). The impact of additional radiation therapy diminished in advanced stages. In the multivariate analysis, any prognostic factors were significant for OS, whereas only additional contralateral testicular irradiation was associated with better PFS (HR 0.29; 95%CI 11-83; P=0.02).

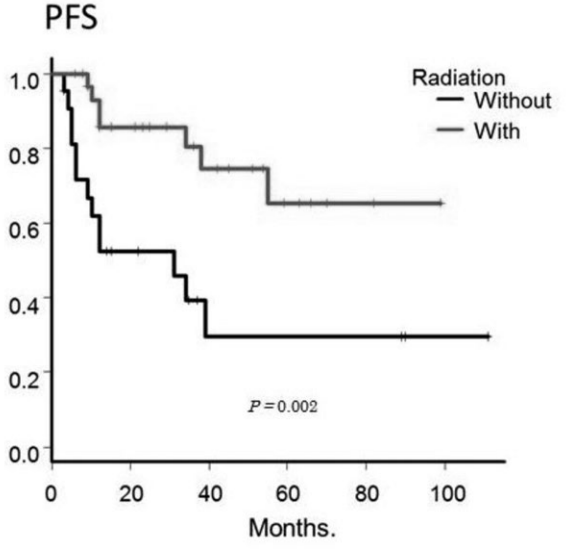

Figure 1. PFS according to contralateral testicular irradiation.

Summary and Conclusions: PTL-DLBLC had poor outcomes, and a high frequency of extranodal relapse, especially in CNS. Our study showed that chemotherapy with contralateral testicular irradiation may improve the outcomes.

E972

STATIN ADMINISTRATION AND THE RISK FOR NON-HODGKIN LYMPHOMA: A NATIONWIDE POPULATION-BASED CASE-CONTROL STUDY

S.F. Cho[1,*] Y.C. Liu[1], H.H. Hsiao[1], C.H. Wu[1], Y.F. Tsai[1], H.C. Wang[1], T.C. Liu[1]
[1]Division of Hematology & Oncology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan, ROC

Background: 3-Hydroxy-3-methylglutary–coenzyme A reductase (HMG-CoA) inhibitors, also known as statins, are common cholesterol-lowering medications that are widely used for the primary and secondary prevention of cardiovascular disease and stroke. In addition to their cholesterol-lowering effects, several *in vitro* and *in vivo* studies have suggested that statins may have anticancer properties via various mechanisms.
Aims: The purpose of this study was to investigate whether statin administration was associated with a decreased risk of non-Hodgkin lymphoma (NHL).
Methods: This nationwide population-based case–control study was conducted retrospectively using the National Health Insurance Research Database (NHIRD) of Taiwan. The NHL group consisted of the patients with a first-time diagnosis of NHL between 2005 and 2008. The cases of the control group were pair-matched to the NHL group by sex, year of birth and index date. The usage of statins was analyzed retrospectively in both groups since January 1, 1996 to the index day. The cumulative defined daily dose (cDDD) was estimated to evaluate the statin exposure. Usage of other lipid-lowering agents, aspirin, non-steroidal anti-inflammatory drugs, cyclooxygenase-2 inhibitors and angiotensin-converting enzyme inhibitors was also identified. Adjusted odds ratios (ORs) and 95 % CIs (95 % confidence intervals) were estimated using multiple logistic regression.
Results: This study enrolled 1715 cases with NHL and 17150 controls for the analysis. Compared with the group without the statin administration, the group with any previous statin usage had an adjusted OR of 0.54 (95% CI=0.46-0.64). In addition, the chemo-preventive effect of the statins was exerted in a dose-response manner. The adjusted ORs were 0.69 (95% CI= 0.51-0.94), 0.56 (95% CI=0.42-0.76), 0.55 (95% CI=0.42-0.71), and 0.37 (95% CI=0.26-0.54) for statin administration of fewer than 28, 28 to 90, 91 to 365, and more than 365 cumulative defined daily doses (cDDDs), respectively, relative to the group without the statin administration.
Summary and Conclusions: The results of this study suggest that the administration of statins may reduce the risk of NHL.Further studies, especially prospective randomized trials, to confirm our findings are warranted.

E973

HIGHLY SUSPECTED LYMPHOMA ASSOCIATED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS WITHOUT PATHOLOGICAL EVIDENCE: PET-CT FEATURES AND TREATMENT OUTCOME

J. Wang[1,*] H. Qiu[1], S. Zhang[1], D. Wang[1]
[1]Department of hematology, The first affiliated hospital of Nanjing medical university, Nanjing, China

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life threatening syndrome of hyper-inflammation, caused by uncontrolled activation and proliferation of lymphocytes and antigen-presenting cells. Up to now, few researches have described the characteristic findings of PET/CT in patients with HLH, especially for those with out known pathological evidences. Further studies about identifying the causative agents and finding efficacious regimens to lymphoma associated HLH patients are seldom reported.
Aims: The aims of the present study were to: (1) investigate the characteristics of PET-CT image in patients with sHLH; (2) find out the differences of PET-CT characteristics between lymphoma associated HLH (LAHLH) and non-lymphoma associated HLH (non-LAHLH); (3) discuss the diagnostic performance of PET-CT for the detection of underlying lymphoma, especially when pathological evidences were unavailable; (4) compare the efficacy of different regimens for sHLH without pathological basis.
Methods: A total of 44 adult patients first diagnosed with HLH who had undergone F-18 FDG PET-CT scanning before clinical treatment were enrolled in this retrospective analysis. Their clinical manifestations, laboratory findings, PET-CT characteristics, and received therapies or survival data were collected and compared. PET-CT parameters were comparatively analyzed between LAHLH patients and non-LAHLH patients. Moreover, the efficacies of initial therapies to highly suspected lymphoma were compared by OS analysis.
Results: All of the patients had at least 3 organs involved, including 37 cases (82.2%) showing splenomegaly, 35 cases (77.8%) with bone lesions, 34 cases (75.6%) lymphadenopathy, 35 cases (77.8%) inflammatory changes in the lung including pneumonia and/or atelectasis, 29 cases (64.4%) serous effusions, 26 cases (57.8%) pleura thickening and/or pleura adhesion, 17 cases (37.8%) cholecystitis or cholelithiasis, 16 cases (35.6%) sinusitis, 15 cases (33.3%) heart lesions, 13 cases (28.9%) brain tissue or cerebrovascular lesions, 10 cases (22.2%) hepatomegaly, 8 cases (17.8%) pericardium thickening. The maximum SUV levels of the spleen (SUV_{Sp}), bone marrow (SUV_{BM}), lymph node (SUV_{LN}), SUV_{max}, $SUV_{LN/Li}$ and $SUV_{max/Li}$ in LAHLH group were signif-

icantly higher than those in non-LAHLH group (p= 0.002, p=0.042, p=0.001, p<0.001, p=0.041, p=0.022, respectively). However the level of SUV_{Li}, $SUV_{Sp/Li}$, $SUV_{BM/Li}$ in two groups revealed no significant difference. HLH patients with an absolute SUV_{max} value >5.5, absolute SUV_{LN} value >2.6, and an absolute SUV_{sp} value >4.8 were more like to be LAHLH (p<0.001, sensitivity=92.9% and specificity=82.4%, AUC=0.933; p=0.001, sensitivity=85.7% and specificity=70.6%, AUC=0.851; p=0.001, sensitivity=71.4% and specificity=100%, AUC=0.836). The incidence of multiple lymphadenopathys with increased FDG uptake in LAHLH patients was significantly higher than those in non-LAHLH group (p=0.004); the incidence of multiple bone lesions in LAHLH patients was significantly higher than those in non-LAHLH group (p=0.016). Furthermore, OS analysis revealed that highly suspected LAHLH patients treated with lymphoma-chemotherapy had better prognosis (365 days) than those treated with non-lymphoma therapy (35 days) (p=0.003).

Figure 1.

Summary and Conclusions: PET-CT may play an important role in confirming the diagnosis of LAHLH without pathologic evidence. Patient in LAHLH group had remarkablely higher levels of SUV_{Sp}, SUV_{BM}, SUV_{LD}, SUV_{max}, $SUV_{LD/Li}$, and $SUV_{max/Li}$ than those in non-LAHLH group. In addition, sHLH patients who presented in PET-CT images with multiple lymphadenopathys and/or multiple bone lesions accompanied by increased FDG uptake were more like to be LAHLH. For the initial treatment of these highly suspected LAHLH, lymphoma chemotherapy, rather than HLH-2004 protocol or immunosuppressive/cytokine-regulating therapy, may have a relatively favorable effect and better clinical outcomes.

E974

HIGH THROUGHPUT TCR SEQUENCING PROVIDES ADDED VALUE IN THE DIAGNOSIS OF CUTANEOUS T-CELL LYMPHOMA

I. Kirsch[1,*] D. Williamson[1], J. Krueger[2], J. Teague[3], M. Tavallaee[4], C. Elco[3], R. Clark[3], J. Kim[4], Y. Kim[4], T. Kupper[3], H. Robins[5]
[1]Adaptive Biotechnologies, Seattle, [2]Rockefeller University, New York, [3]Brigham and Women's Hospital, Boston, [4]Stanford University, Palo Alto, [5]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: Diagnosis of early-stage CTCL can be challenging because skin lesions contain a mixture of both diverse benign and clonal malignant T cells. High throughput sequencing (HTS) of the TCR gamma (TCRG) and TCR beta (TCRB) CDR3 regions provide markers of the total repertoire of T cell clones in a specimen, the breadth of repertoire diversity, and an exact quantitation of individual T cell clones.
Aims: Two independent sample cohorts from two different institutions have been analyzed by HTS in an attempt to validate this approach and discriminate benign from malignant skin disease.
Methods: The two independent studies together involve the analysis of >100 patients with CTCL and approximately 100 patients with benign skin disease. Skin biopsies were studied from patients with histopathologically and clinically suspicious or diagnostic CTCL (over 80% Stage I or Stage II), treated CTCL patients, patients with benign inflammatory diseases, and normal skin. Genomic DNA was extracted from FFPE or OCT sections of skin biopsy specimens of patients. T cell receptor gamma (TCRG) and beta (TCRB) chain sequences were then independently amplified using multiplex PCR with optimized primer sets. Following HTS, a bioinformatics pipeline clusters the sequences into distinct clonotypes to determine overall frequencies and to identify diagnostic clones. V, (D), and J genes are also identified for each clonotype.
Results: The assays defined the dominant clonal sequences in the majority of malignant cases and distinguished likely gamma/delta from alpha/beta T cell lymphoma. Using the fraction of the top two TCRG sequences divided by two as a fraction of the total nucleated cell population defined a cut off of approximately 1/1000 above which the assay approached 100% specificity for malignant disease and below which the assay approached 100% specificity for non-malignant or treated malignant disease. TCR PCR was negative in a significant fraction of lesions suspicious of CTCL—most of these were among those determined to be clonal by HTS. There was also a significant false positive rate for TCR PCR.
Summary and Conclusions: HTS analyses of DNA extracted from skin biopsies of patients with skin disorders can provide important quantitative data of T cell number, clonality, repertoire, and frequency and in so doing provide a useful discriminator of benign versus malignant disease, extent of disease, and disease response.

E975

THE CLINICAL IMPLICATION OF THE ACTIVATION OF NF-KB SIGNALING PATHWAY IN DIFFUSE LARGE B CELL LYMPHOMA: PRE- AND POST-RITUXIMAB ERA

L. Lee[1,*] J.H. Liu[2], C.H. Tzeng[2], J.P. Gau[2], P.M. Chen[2], T.J. Chiou[2]
[1]Hematology-oncology, Veteran General Hospital of Taipei, Taoyuan branch, [2]Hematology-oncology, Veteran General Hospital of Taipei, Taipei, Taiwan, ROC

Background: The nuclear factor-κB (NF-κB) comprises a family of transcription factors that control genes implicated in the activation, proliferation and resistance to apoptosis in normal B lymphocyte and malignant lymphoma cells, especially diffuse large B cell lymphoma (DLBCL). Gene expression studies on DLBCL lines have discovered that several genes which are targets of NF-κB are expressed on a subgroup of DLBCL (activated B-cell subtype). However, the clinical implication of activated NF-κB was not fullly elucidated, especially in the Rituximab era.
Aims: The aim of this study is through antibodies against the members of NF-κB family to delineate the activation of NF-κB, and to evaluate the clinical implication of this signaling pathway.

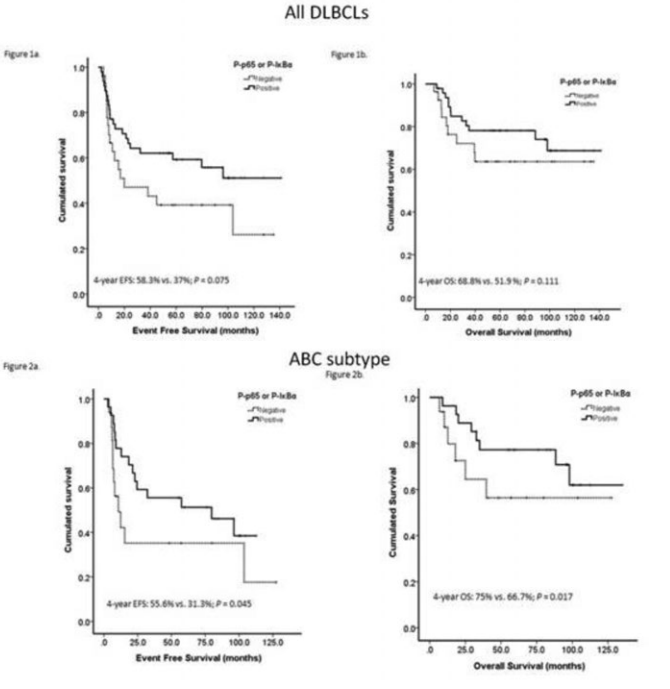

Figure 1.

Methods: Seventy-six DLBCLs diagnosed between 2002~2009, treated with antracycline containing regimen with (n=40; 53%) or without Rituximab (n=36; 47%) were evaluated with antibodies against phosphorylated p65(P-p65), phosphorylated IκBα (P-IκBα), p52, BCL-2, BCL-6, CD10, MUM-1 and c-MYC. IκB phosphorylation and degradation results in liberation of NFκB dimers (p65/p50) and its activation. Besides, there is evidence that phosphorylation of p65 on

serine 536 leads to NFκB activation, independently of IκB degradation. Therefore, activation of NFκB was defined as presence of positive P-p65 or P-IκBα. The impact of activated NF-κB was analyzed comparing clinical features and outcome including 4-year event free survival (4-year EFS) and 4-year overall survival (4-year OS) of DLBCL patients. We also evaluate the association between activated NF-κB and DLBCL subtypes, clinical features or other IHC stain markers (includes BCL-2, BCL-6 and C-MYC).

Results: Seventy-six DLBCLs were enrolled, and 48 cases had activated NF-κB. In the group with activated NF-κB, one case cannot be subdivided into GCB or ABC subtype. Twenty (20/47; 43%) belonged to GCB subtype and twenty-seven (27/47; 57%) belonged to non-GCB subtype (*P*=0.743). There were no difference betweent NFκB activation (+) and NFκB activation (-) in Ann Arbor stage, international prognosis index (IPI ≥3 vs. <3), and age (≥60 vs. <60). Treatments (with or without Rituximab) given to patients with NFκB activation (+) or NFκB activation (-) also had no difference.

With a median follow-up of 58 months, the group of activated NF-κB had trend toward better 4-year EFS(58.3 vs. 37%, P=0.075). 4-year OS was also better in the group with activation of NFκB but with no significance (68.8% vs. 51.9%, P=0.111). Because the gene expression studies on DLBCL cell lines suggested NFκB is preferentially activated in ABC-like DLBCL. Subgroup analysis revealed that in the no-GCB group, patients with activated NFκB had better 4-year EFS (55.6% vs. 31.3%; P=0.045) and 4-year OS (75% vs. 66.7%; P=0.017). We further analyzed if addition of Rituximab to chemotherapy could affect the clinical outcome according to the activation status of NFκB. We found that patients with activated NFκB who also received treatment with Rituximab containing regimen had the best 4-year EFS and 4-year OS (P=0.036 and P=0.058, respectively). Similarly, in non-GCB subgroup, patients with activated NFκB who received treatment with Rituximab containing regimen also had the best 4-year EFS (P=0.024). In multivariate analysis, activated NFκB was correlated with trend for better 4-year EFS (HR 0.521, P=0.056) and trend for better 4-year OS (HR 0.479, P=0.062).

Summary and Conclusions: NFκB activation through classical pathway can be detected through immunohistochemical stain of P-p65 or P-IκBα. Activation of NFκB is associated with good prognosis. Besides, patients with activated NFκB also had better outcome to Rituximab containing regimen. Subgroup analysis revealed that in non-GCB DLBCL, patients with activated NFκB also had better prognosis which is not observed in GCB DLBCL. NFκB activation is not confined to non-GCB subgroup and is not correlated with other IHC markers (BCL-6, BCL-2 or c-MYC).

E976

HISTOLOGICAL DISTRIBUTION, TREATMENT AND PROGNOSIS OF PERIPHERAL T-CELL LYMPHOMAS: AN ANALYSIS OF 505 PATIENTS IN TAIWAN

H.W. Kao[1,*] L.Y. Shih[1,2], M.C. Kuo[1], P.N. Wang[1], T.L. Lin[1], T.C. Tang[1], H. Chang[1], Y.S. Hung[1], P. Dunn[1,2], J.H. Wu[1], T.T. Kuo[2,3]
[1]Division of Hematology-Oncology, Chang Gung Memorial Hospital, [2]College of Medicine, Chang Gung University, Taoyuan, [3]Department of Pathology, Chang Gung Memorial Hospital, Taipei, Taiwan, ROC

Background: Peripheral T-cell lymphomas (PTCL) are a heterogeneous group of lymphoid malignancies. The distribution of pathological subtypes differs in different geographic areas and the prognostic factors, optimal therapy and roles of stem cell transplantation (SCT) remain to be defined.

Aims: We aimed to determine the clinical characteristics of PTCL in Taiwan.

Methods: We examined histological subtypes, patient characteristics, treatment, and outcome among 505 consecutively newly diagnosed adult PTCL patients from 1998 to 2014.

Results: PTCLs represented 14.3% (505/3539) of all non-Hodgkin lymphomas (NHL). PTCL subtypes included NK/T-cell lymphoma (NKTCL) (21.0%), angioimmunoblastic T-cell lymphoma (AITL) (20.2%), PTCL, not otherwise specified (PTCL-NOS) (17.0%), anaplastic large cell lymphoma (ALCL) (15.6%), adult T-cell leukemia/lymphoma (ATLL) (overall 7.3%, acute type 4.5%), others (3.0%), and cutaneous T-cell lymphomas (CTCL) (15.9%) including mycosis fungoides (7.3%), primary cutaneous ALCL (4.6%), subcutaneous panniculitis-like T-cell lymphoma (3.2%), and rare subtypes of CTCL (0.8%). Median age was 56 (range 20-90) years, 53% had stage III/IV disease, 53% had international prognostic index (IPI) ≥2, and 38% had prognostic index for T-cell lymphoma (PIT) ≥2. 391 patients received chemotherapy: CHOP (77%), COP (23%), proceeding to high-dose chemotherapy (ESHAP, VPBBM, MINE, ICE or EPOCH regimen) (22%) and SCT (6%). The overall response rate was 61%, complete response (CR) rate was 51%, and 37% had primary refractory disease. With a median follow-up of 63.7 months, 3-year progression free survival (PFS) and overall survival (OS) rates were 38% and 45% for all patients. The 3-year OS rate for each subtype was 77% (CTCL), 63% (ALK-positive ALCL), 52% (NKTCL), 39% (AITL), 39% (ALK-negative ALCL), 28% (PTCL-NOS), 18% (ATLL), and 9% (others). Both IPI (HR 3.9, *P*<0.001) and PIT (HR 3.8, *P*<0.001) had significant impact on OS. In multivariate analysis, age ≥60 (HR 1.7, *P*<0.001), ECOG performance status ≥2 (HR 1.9, *P*<0.001), extranodal sites ≥2 (HR 1.6, *P*=0.006), bone marrow involvement (HR 1.5, *P*<0.018), elevated LDH (HR 1.4, *P*=0.017), and hypoalbuminemia (HR 1.5, *P*=0.02) were independent poor pre-treatment prognostic factors for OS. OS benefit was observed in patients who received CHOP-like compared to COP regimen (HR 0.6, *P*=0.004), and in patients who achieved CR (HR 0.2, *P*<0.001) or received SCT (HR 0.5, *P*=0.052).

Summary and Conclusions: The overall frequency of PTCL among NHL and the frequencies of NKTCL and ATLL in our cohort were higher compared to western countries. The distribution of PTCL subtypes are mostly in line with other Asian series except for a lower frequency of ATLL and higher frequencies of ALCL and CTCL compared to Japanese series. IPI and PIT predicted OS. Hypoalbuminemia was a poor prognostic factor for OS. Patients who received CHOP-like regimen or achieved CR survived longer. SCT provided a trend of improved OS in PTCL patients.

E977

THE INFLUENCE OF TREATMENT FACILITY VOLUME ON SURVIVAL OF DIFFUSE LARGE B-CELL LYMPHOMA

R. Go[1,*] M. Al-Hamadani[2], N. Shah[3], E. Habermann[3]
[1]Hematology, Mayo Clinic, Rochester, [2]Medical Research, Gundersen Medical Foundation, La Crosse, [3]Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, MAYO CLINIC, ROCHESTER, United States

Background: Diffuse large B-cell lymphoma (DLBCL), the most common form of non-Hodgkin lymphoma, is a relatively uncommon cancer with annual incidence of ~21,000 cases in the US.

Aims: The goal of this study was to determine the extent to which the number of DLBCL patients treated annually in a facility (facility volume) affects overall survival (OS).

Methods: We included DLBCL patients identified from the US National Cancer Data Base (NCDB) from 1998 to 2011. NCDB, a joint program of the American College of Surgeons and the American Cancer Society, is a nationwide oncology outcomes database for more than 1,500 cancer programs in the US and Puerto Rico capturing about 70% of all newly diagnosed cases of cancer in the US. We classified treatment facilities by quartiles based on facility volume (mean DLBCL patients/year): Quartile 1 (Q1; ≤2), Quartile 2 (Q2; 3-6), Quartile 3 (Q3; 7-11) and Quartile 4 (Q4; >11).

Results: 116,615 DLBCL patients were cared for in 1,547 facilities. The distribution of patients according to facility volume was Q1 (2.0%), Q2 (14.3%), Q3 (23.0%) and Q4 (60.7%) and according to facility type was academic (30.3%), comprehensive community (11.0%), community (54.1%) and other (4.6%). The unadjusted median OS by facility volume was: Q1: 27.5 months, Q2: 38.5 months, Q3: 49.1 months and Q4: 61.3 months. After multivariable analysis adjusting for demographic (sex, age, race, ethnicity), socioeconomic (education, income, primary payor), geographic (area of residence), disease-specific (NHL subtype, stage) and facility-specific (type and location) factors, we show that facility volume remains an independent predictor of OS. Compared to patients treated at Q4 facilities, patients treated at lower quartile facilities had a worse OS (Q3HR: 1.03 [95% CI, 1.06-1.13]; Q2HR: 1.09 [1.06-1.13]; Q1HR: 1.21 [1.314-1.29]). We performed sensitivity analyses removing primary payor and facility type (collinearity with age and facility volume, respectively) as well as adjusting for Charlson-Deyo co-morbidity score (available for patients diagnosed after 2003) in secondary models and found similar results.

Summary and Conclusions: Patients who receive treatment at higher volume facilities for DLBCL are likely to have longer OS than those who are treated at facilities with a lower volume.

E978

CLINICAL SIGNIFICANCE OF CO-EXPRESSION OF MYC AND BCL2 PROTEIN IN AGGRESSIVE B-CELL LYMPHOMAS TREATED WITH A SECOND LINE IMMUNOCHEMOTHERAPY

K. Miura[1,*] M. Nakagawa[1], H. Takahashi[1], Y. Hatta[1], M. Sugitani[2], S. Otake[1], M. Sakagami[1], Y. Uchino[1], S. Kiso[1], H. Kodaira[1], N. Iriyama[1], S. Kobayashi[1], A. Hojo[1], M. Yagi[1], D. Kurita[1], Y. Kobayashi[1], M. Takei[1]
[1]Department of Hematology and Rheumatology, [2]Department of Pathology, Nihon University School of Medicine, Tokyo, Japan

Background: Recent studies have shown that concurrent expression of MYC and BCL2 protein evaluated by immunohistochemistry (IHC) in *de novo* diffuse large B-cell lymphoma (DLBCL) is associated with worse survival when standard R-CHOP is applied. However, little is known about the clinical significance of concurrent expression of MYC/BCL2 protein in aggressive B-cell lymphomas which failed to benefit from conventional, upfront immunochemotherapies.

Aims: We show the clinical impact of co-expression of MYC and BCL2 protein among patients with relapsed or refractory aggressive B-cell lymphomas, who were uniformly treated with a second line immunochemotherapy.

Methods: This is a retrospective analysis of patients with relapsed and refractory aggressive B-cell lymphomas, who were consecutively treated with the R-IVAD regimen consisting rituximab (375 mg/m^2, day 1), ifosfamide (1500 mg/m^2 on day 3-7), etoposide (150 mg/m^2, day 3-5), cytarabine (100 mg/m^2, day 3-5) and dexamethasone (40 mg/body, day 3-5) followed by consolidative high-dose chemotherapies at Nihon University Itabashi Hospital from 2001 to 2009. MYC

and BCL2 protein were analyzed by IHC assay using formalin-fixed paraffin-embedded tissue specimens for all available cases. Cut-off values of positivity for MYC and BCL2 protein were set as 40% and 50% of stained tumor cell, respectively. Lymphomas showing concurrent positivity for MYC and BCL2 protein were defined as "Double expresser lymphoma (DEL)".
Results: A total number of 27 patients with a median 61 years (range 38-79) of age were analyzed. Nineteen patients were relapsed and the other eight patients were refractory to upfront immunochemotherapies. Histological subtypes consisted of 20 cases of DLBCL and seven cases of grade 3/transformed follicular lymphoma. Totally, 12 cases (44%) were categorized into DEL. Clinical characteristics such as risk factors consisting IPI or relapsed/refractory status were generally balanced, whereas a histological form of DLBCL was more common in the DEL group as compared with the non-DEL group (100% *vs* 53%, *P*=0.008). The overall response (OR) and the complete response (CR) rate to R-IVAD for all patients was 70% and 56%, respectively. The DEL group was less likely to respond to R-IVAD, as compared with the non-DEL group (OR: 50% *vs* 87%, *P*=0.087, CR: 33% *vs* 73%, *P*=0.057). The numbers of patients proceeding to consolidative therapies in the DEL group and the non-DEL group was 4 (33%) and 9 (60%) (*P*=0.252), respectively. Within a median 47 months (range 2-152) of observation period, the 2-year EFS and the OS rate for all patients was 33% and 59%, respectively (Figure a, b). As for the status of MYC/BCL2 protein, both the 2-year EFS and the OS rate were significantly lower in the DEL group than in the non-DHL group (Figure c, d). Multivariate analysis revealed that the negative impact of MYC/BCL2 expression on OS was still significant (HR 3.05, 95%CI 1.05-9.65, *P*=0.040), after it was adjusted for the other prognostic factors (*i.e.* high/high-intermediate risk for IPI, and refractory disease).

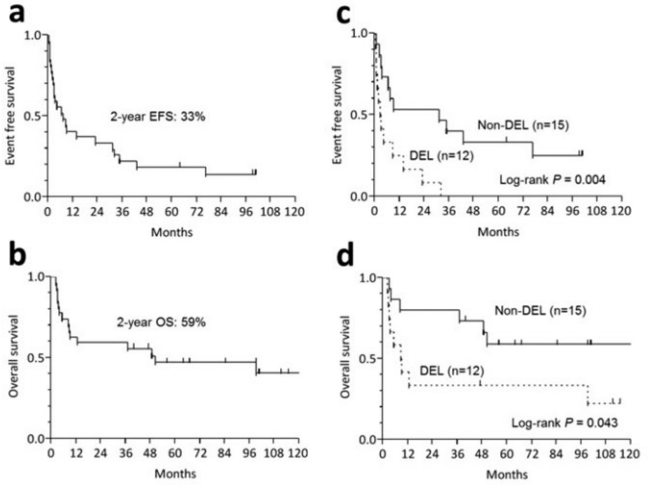

Figure 1.

Summary and Conclusions: This analysis confirmed that dual expression of MYC/BCL2 protein in IHC among relapsed/refractory aggressive B-cell lymphomas was common especially in DLBCL, and strongly associated with worse clinical outcome. Our findings suggest that MYC/BCL2 related high-risk aggressive B-cell lymphomas need highly discreet strategies in the context of second line setting as well as upfront therapies. The standardization of diagnostic procedures for DEL should therefore be established.

E979

OUTCOMES OF SPLENECTOMY IN NON-HODGKIN'S LYMPHOMAS COMPLICATED BY IMMUNE CYTOPENIAS

Y. Yevstakhevych[1,*] Y. Vygovska[1], I. Yevstakhevych[1], O. Vygovska[1], V. Loginsky[1]
[1]Hematology, SI "Institute of Blood Pathology and Transfusion Medicine, NAMS of Ukraine", Lviv, Ukraine

Background: Autoimmune hemolytic anemia (AIHA) and immune thrombocytopenia (ITP) complicate the clinical course of Non-Hodgkin's lymphomas (NHL) in 15-25% of patients. In cases of ineffective steroid- and chemotherapy and in the presence of massive splenomegaly, such patients undergo splenectomy (SE).
Aims: To retrospectively analyze the efficacy of splenectomy in patients with NHL associated with AIHA and/or ITP.
Methods: Ninety seven patients with NHL underwent SE during 1986-2014. In 49 out of them (50.5%), immune cytopenias were diagnosed. Warm-type AIHA was observed in 7 (7.2%) patients: mantle cell lymphoma (MCL) in one, splenic marginal zone lymphoma (SMZL) in 2, diffuse large B-cell lymphoma (DLBCL) in 4. ITP was found in 28 (28.9%) patients: SMZL in 8, DLBCL in 13, diffuse large T-cell lymphoma (DLTCL) in one, hepatosplenic T-cell lymphoma (HCTCL) in one, and in 5 patients NHL were classified according to the Working Formulation (WF). NHL with AIHA and ITP was diagnosed in 14 (14.4%) patients: MCL in 2, follicular lymphoma (FL) in one, SMZL in 6, while one of them had splenic lymphoma with villous lymphocytes (SLVL), DLBCL in 4, and DLTCL in one. Splenomegaly was revealed in all patients, some of them developed a giant-size spleen weighing 6-8 kg. Patients were followed up to 1-270 months after splenectomy.
Results: SE has been effective in 25 (89%) out of 28 patients suffering from NHL with ITP: a large tumor mass was removed, the platelet count was normalized, and signs of hemorrhagic syndrome disappeared. In 3 patients (DLBCL – 1, DCTCL – 1, and HCTCL – 1), splenectomy proved ineffective. They died within 4 months following surgery due to a thrombocytopenia relapse and disease progression. Mean post-splenectomy survival of patients with NHL with ITP reached 67.3 months. SE performed in 14 patients with NHL associated with AIHA and ITP proved effective in 9 (64%) patients: abdominal discomfort was relieved, hemolysis was reverted, and the platelet count was normalized. One patient died immediately after operation due to acute adrenal insufficiency, and four patients died within 1-6 months following SE (DLBCL – 1, DLTCL – 1, and SMZL with SLVL – 1 patient). Mean survival after SE reached 50.5 months. The worst long-term outcomes of SE were observed in patients with NHL and AIHA: 6 patients survived 2-22 months after operation, whereas only one has been living for 270 months following SE. Mean survival after SE is 46.2 months.
Summary and Conclusions: SE remains to be an effective treatment option in NHL associated with splenomegaly and immune cytopenias. The worst long-term outcomes of SE are observed in NHL with AIHA. SE proved to be ineffective in DLTCL and HCTCL.

E980

LONG-TERM RESULTS OF TREATMENT OF DIFFUSE LARGE CELL LYMPHOMA ASSOCIATED WITH HEPATITIS C (DLBCL+C)

S. Lepkov[1,*] I. subortseva[2], S. kosyura[1], G. Storojakov[1], A. Kovrigina[2], P. Zeynalova[3], O. kolomyetsev[3], J. Rybuchina[3], G. Tumyn[3], N. kokosadze[3], T. Bulik[3]
[1]Therapy, Russian Research Medical University Moscow, [2]hematology, Hematology Research Center, [3]oncology, Cancer Research Center NN Blokhin, Moscow, Russian Federation

Background: Materials. 94 patients with diffuse large cell lymphoma and markers of hepatitis C (DLBCL +C) and 72 patients with diffuse large cell lymphoma without markers of hepatitis C (DLBCL - C) were included in the study. All the patients were under the supervision of an oncohematologist and therapist from 2003 to 2013.
Aims: The age of patients with DLBCL +C ranged from 21 to 76 years (mediana 47). In control group age ranged from 23 to 81 years (mediana 55) (p=0.02). The ratio of men and women in the two groups was equal - in DLBCL +C -1:1.3 in the group DLBCL-C-1:1.7. Stage I and II were in 11% of patients in group DLBCL +C, and 48% of patients in the control group; III and stage IV were in 89% of patients in the DLBCL +C, 52% in the control group (p=0.00002). Extranodal lesions were 72% of patients in the DLBCL +C, 46% of patients with DLBCL - C (p=0.006).
Methods: In the group of patients with GCB DLBCL+C was 55% non-GCB was 45%; in the control group GCB DLBCL-C was 36%, non-GCB was 64% of patients (p=0.001).
Results: In the group of patients with DLBCL+C antibodies to hepatitis C were positive in all 94 patients. Positive PCR HCV was 78% (74 patients). Median viral load at the start of chemotherapy was 2x104 copies / mL. 15 patients with viral load was high - more than 1 x106 copies / mL. All patients received chemotherapy CHOP / R-CHOP. After treatment in patients with DLBCL+C and DLBCL-C complete remission was achieved in 60% and 63% respectively. Disease free survival in patients with DLBCL+C was 25 months in the control group - 61 months. The median overall survival in DLBCL+C group was 40 months in the control group it was 71 months (p=0.0003). Median progression free survival in patients with GCB DLBCL+C was 40 months in the patients with GCB DLBCL-C - 60 months (p=0.003). Median overall survival in the group of patients with GCB DLBCL+C was 45 months in the control group to 70 months (p=0.002). Median progression-free survival in patients with non-GCB DLBCL+C was 10 months in the control group non-GCB DLBCL-C -60 months (p=0.00001). Overall survival in the group of patients with non-GCB DLBCL+C was 18 months in the patients with non-GCB DLBCL-C overall survival was 70 months (p=0.00001).
Summary and Conclusions: DLBCL with markers of viral hepatitis C is a separate group of lymphomas with characteristic clinical, morphological features. This allows us to separate of a hepatitis C-associated DLBCL. Despite the lack of differences in the effectiveness of the therapy, long-term results of therapy was significantly worse in patients DLBCL+C.

E981

INTERIM 18F-FGD PET/CT MAY NOT PREDICT THE OUTCOME IN PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA PATIENTS TREATED WITH INTENSIVE METHOTREXATE AND CYTARABINE

J.C. Jo[1,*] D.H. Yoon[2], J. Huh[3], J.S. Ryu[4], J.H. Kim[5], C. Suh[2]

[1]Hematology and Oncology, Ulsan University Hospital, Ulsan, [2]Oncology, [3]Pathology, [4]Nuclear Medicine, [5]Neurosurgery, Asan Medical Center, Seoul, Korea, Republic Of

Background: ^{18}F-fluoro-2-dexoy-*D*-glucose-positron emission tomography (PET)/computed tomography (CT) is a useful imaging technique for monitoring treatment response in cases of malignant lymphoma.
Aims: We investigated the value of interim brain PET/CT (I-PET/CT) for monitoring the response to intensive methotrexate chemotherapy in primary central nervous system lymphoma (PCNSL) patients with diffuse large B cell lymphoma (DLBCL).
Methods: Of 94 PCNSL patients treated with intensive methotrexate and cytarabine chemotherapy between September 2006 and December 2012, 66 PCNSL patients with DLBCL underwent brain PET/CT at diagnosis, during therapy (I-PET/CT), and at the end of therapy (final [F]-PET/CT) and were included in this study.
Results: The patient cohort consisted of 66 individuals (43 men and 23 women), with a median age of 59 years (range, 17–75 years). During chemotherapy, 36 patients (54.5%) showed a negative metabolism in the scan of I-PET/CT, and 47 patients (71.2%) showed a negative F-PET/CT at the end of therapy. The baseline characteristics were similar between I-PET/CT-negative (n=36) and I-PET/CT-positive patients (n=30). After a median follow-up of 27.5 months, there was no difference in the progression-free survival (PFS; P=0.701) or overall survival (OS; P=0.620) between the I-PET/CT-negative and I-PET/CT-positive groups. However, PFS in the F-PET/CT-negative group was significantly longer than in the F-PET/CT-positive group (P <0.001) without significant difference in OS (P=0.892)
Summary and Conclusions: Our findings suggest that I-PET/CT might not predict the survival outcome of PCNSL patients with DLBCL treated with intensive methotrexate and cytarabine chemotherapy. Prospective trials are required to fully evaluate the role of I-PET/CT.

E982

CLINICAL RELEVANCE OF BONE MARROW HEMOPHAGOCYTOSIS IN THE DIAGNOSIS OF HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN ADULTS: A SINGLE CENTER, RETROSPECTIVE ANALYSIS

S.H. Lim[1,*] S. Park[1], J.H. Jang[1], K.H. Kim[1], H.J. Kim[2], S.H. Kim[2], W.S. Kim[1], C.W. Jung[1], S.J. Kim[1]
[1]Medicine, [2]Laboratory Medicine, Samsung Medical Center, Seoul, Korea, Republic Of

Background: Hemophagocytic lymphohistiocytosis (HLH) is an immune-mediated life-threatening condition diagnosed by the diagnostic criteria for HLH (HLH-2004). However, the clinical relevance of HLH-2004 criteria is still not clear in adult patients because it was mainly based on clinical experience in pediatric patients. Thus, we analyzed bone marrow hemophagocytosis in adult patients presenting suspicious hemophagocytic syndrome.
Aims: The primary objective was to analyze underlying causes, clinical features and outcomes of adult patients with bone marrow hemophagocytosis, and the secondary objective was to explore the feasibility and clinical usefulness of HLH-2004 criteria in adult patients.
Methods: We reviewed the electronic data base of medical records at the Samsung Medical Center, and selected 264 patients who had evidence of hemophagocytic histiocytosis in bone marrow aspiration and biopsy between January 2000 and June 2014.
Results: All patients had bone marrow hemophagocytosis, and their median age was 53 years (range, 18-83). Malignant disorders were predominant underlying causes of adult HLH (n=170, 64%), especially aggressive T/NK-cell (n=82) and B-cell non-Hodgkin lymphomas (n=45). Among non-malignancy associated HLH (n=94, 36%), infectious disease (n=48) and idiopathic HLH (n=17) were more common than autoimmune disease. There was no primary/familial HLH in these patients. Fever (68%) and splenomegaly (55%) were most common clinical manifestations, and more than 80% of patients had increased level of serum ferritin and lactate dehydrogenase (89% and 84%, respectively) whereas the frequency of hypofibrinogenemia, hypertriglyceridemia, and bicytopenia were less common findings (<40%). Thus, only 45% of patients who had bone marrow hemophagocytosis could be diagnosed with HLH based on the current diagnostic criteria (≥five positive criteria). However, the remaining patients also had clinically significant hemophagocytic syndrome. Malignancy was more common cause of HLH than non-malignant disorders in patients who fulfilled the diagnostic criteria (63% vs. 37%). After a median follow-up of 30 months, the median overall survival (OS) was significantly worse in patients with malignancy (9.0 months, 95% CI: 5.6-12.5) than patients without malignancy (71.8 months, 95% CI: 56.5-87.1, p <0.001). The presence of bi-cytopenia, splenomegaly, and hypertriglyceridemia was not associated with poor OS (p >0.05). However, the presence of fever, elevation of ferritin, and hypofibrinogenemia was significantly associated with poor OS in malignancy-associated hemophagocytosis. Especially, patients with very high ferritin level (>10,000 ng/mL) showed extremely worse OS than patients who did not.
Summary and Conclusions: Bone marrow hemophagocytosis might be a crucial finding in the diagnosis of HLH in adult patients regardless of other diagnostic clues. Considering high incidence of malignancy, especially lymphoma as predisposing disorders for HLH in adults, immediate evaluation and management should be done in adult patients with bone marrow hemophagocytosis.

E983

TOTAL BODY SURFACE AREA (TBSA) AS A NEW PROGNOSTIC VARIABLE IN MYCOSIS FUNGOIDE AND SÉZARY SYNDROME

S. Novelli[1,*] P. Garcia-Muret[2], A. Mozos[3], J. Sierra[1], J. Briones[1]
[1]Hematology, [2]Dermatology, [3]Pathology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Mycosis fungoides and Sézary syndrome (MF/SS) are the most common forms of primary cutaneous T cell lymphomas. There is no standard chemotherapy regimen for advanced stages of disease. The only curative option is allogeneic stem cell transplantation but it is limited to eligible patients. Currently, it is still difficult to establish prognosis taking into account clinical and biological features at diagnosis.
Aims: Our aim is to analyze the applicability of cutaneous lymphoma international prognostic index (CLIPi) in our population with MF/SS and also evaluate the total body-surface area (TBSA) at diagnosis and the type of skin lesions.
Methods: A retrospective analysis identified in our center 134 patients diagnosed with MF/SS between 1976 and 2013. (see table 1)

Tabella 1. Characteristics of MF/SS patients (n=134).

Table 1. Characteristics of MF/SS patients (n=134)		
Gender	Male: 59.7% (n=80)	Female: 40.3% (n=54)
Age	Median: 61 years (range: 9-90 years)	
Histological subtype of MF/SS	Classic: 79.1%	(n=106)
	Folliculotropic Follicular: 6.7%	(n=9)
	Pagetoid: 0.7%	(n=1)
	Granulomatous: 0.7%	(n=1)
	Sézary: 12.7%	(n=17)
ISCL/EORTC Stage	Ia - IIb: 82.8%	(n=111)
	IIIa - IVb: 17.2%	(n=23)
TBSA score	< 40% score: 38%	(n=51)
	≥40% score: 62%	(n=83)
B symptoms	No: 64.4%	Yes: 33.6%
Median time of follow up	96 months (range: 0 – 450 months)	

Results: The overall survival (OS) at median time of follow up (96 months) was 75.6% (CI 95%, 62.0-98.5%). In the univariate analysis, OS was analyzed by age (≤60 vs. >60 years), advanced disease (<IIb *vs* ≥IIb) according to ISCL/EORTC, presence of erythroderma, type of skin lesions and TBSA (<40% *vs* ≥40%) at diagnosis; all showed differences in OS (p<0.01) (see figure 1). In the multivariate analysis there was a significant increased relative risk of survival (p<0.05) in those patients younger than 60 years, with TBSA less than 40% and early stage (<IIb).

Tabella 2. Independent prognostic factors for survival.

Table 2. Independent prognostic factors for survival			
Prognostic factors	Hazard ratio	95% confidence interval	P-value
Age ≤ 60 years	5.481	2.572 – 11.679	<0.0001
TBSA < 40%	2.971	1.372 – 6.433	<0.006
Stage < IIb	4.862	1.653 – 14.301	<0.004
Lesions with patch	1.281	0.540 – 3.040	0.573
Erythroderma	0.647	0.215 – 1.947	0.439

CLIPi was calculated for both early and advanced disease. There were differences in probabilities of survival in early and advanced disease, but patients with CLIPi 0 and 1 in both groups were poorly discriminated.

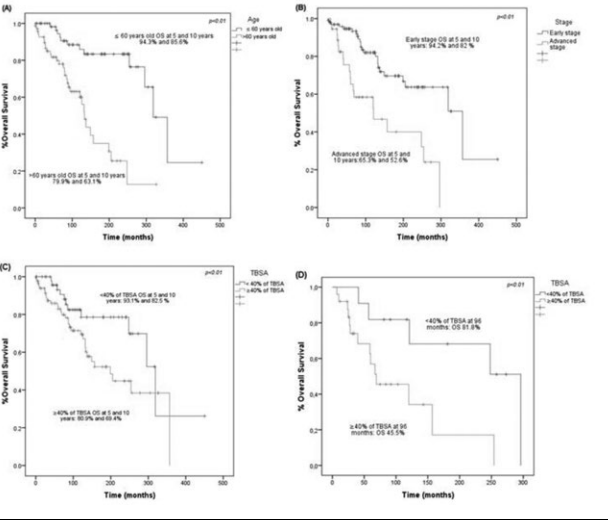

Figure 1. Overall Survival at 5 and 10 years: (A) OS by Age. (B) OS by Stage. (C) OS by TBSA. (D) OS in advanced.

Summary and Conclusions: In conclusion, the CLIPi is a reliable tool to identify poor prognostic patients, but those with initially early stages were not fully discriminated. The addition of the TBSA data is a simple, ready-to-use method in the daily clinical practice that could improve the prognostic classification of those patients with early-stage disease. This combined score, CLIPi plus TBSA, may be used to identify early-stage patients that may benefit from new systemic therapies.

E984

DIRECT ANTIGLOBULIN TEST POSITIVITY IS A PROGNOSTIC MARKER IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS

J. Tobin[1], B. Shadbolt[2], S. Jain[3], Y. Gonzalez[4], D. Talaulikar[4,5,*]
[1]Australian National University, [2]Canberra Hospital, Canberra, Australia, [3]Anatomical Pathology, [4]Haematology, Canberra Hospital, [5]Haematology, Australian National University, Canberra, Australia

Background: The revised International Prognostic Index (r-IPI) is conventionally used for prognostication of DLBCL patients but has limited ability to stratify patients with a probability of survival less than 50%. There is thus a need to identify readily available biomarkers to ifurther classify prognostic groups within this category.
Aims: We investigated the prevalence of, and prognostic value of subclinical autoimmunity directed against red blood cells [demonstrated by a positive direct antiglobulin test (DAT)] in DLBCL
Methods: Eligibility criteria for inclusion in the study were: patients aged >18 years, histological diagnosis of DLBCL at the Canberra Hospital from 2004-14, DAT performed at the time of diagnosis, and availability of relevant clinical and laboratory data. In addition to descriptive statistics and Kaplan-Meier curves, Cox proportional hazard regression (SPSSv22.0) was used to calculate the prognostic effect of DAT positivity on progression free survival (PFS) at 5 years and overall survival at 3 years (OS) controlling for R-IPI, gender, and anaemia.
Results: Of the 96 cases that fulfilled the eligibility criteria for inclusion in the study, 77 were DAT negative (80.2%) and 19 DAT positive (19.8%). DAT positivity resulted in a poorer 5-year PFS (HR=2.3, p= 0.046) and 3-year OS (HR=2.605, p=0.035). This effect was accentuated in the 'poor prognosis' subset of patients identified by an r-IPI score of 3 or higher (OR=5.630, p=0.004).
Summary and Conclusions: The findings of this study demonstrate that the prevalence of DAT positivity is much higher in DLBCL than the background reported rate of 1:10,000. Further, it is a strong negative prognostic marker in DLBCL and may be particularly useful in identifying patients with a very poor prognosis. It is likely that the impact of subclinical autoimmunity on survival is mediated by effects on the tumour microenvironment and further studies are required to understand this epiphenomenon.

E985

FEATURES OF EBV VIREMIA AND OUTCOMES IN PATIENTS RECEIVED ALLOGENEIC STEM CELL TRANSPLANTATION: A CHINESE MULTICENTER SURVEY

J. Chen[1,*] T. Song[1], F. Chen[1], Y. Xu[1], Y. Wang[1], Z. Zhu[1], J. Xu[2], X. Li[3], C. Ye[2], X. Bao[3], A. Sun[1], D. Wu[1]
[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, [2]Loufeng Hospital of Suzhou Industrial Park, [3]Guangci Oncology Hospital, Suzhou, China

Background: EBV reactivation and associated diseases have been well recognized as one of the life threatening complications after SCT, which leads to the establishment of prophylactic and preemptive treatment for EBV viremia. However since then, few epidemic data was shown in SCT recipients, especially in China.
Aims: An observational data base study was conducted in patients with hematological disorders who received allo-SCT from Jun 2011 through Jun 2014.
Methods: EBV-negative status was confirmed before transplant for both donors and recipients. EBV-DNA was screened weekly until Day 100 post SCT by qPCR, and then every 2-4 weeks until 1 year. Additional tests were carried out when clinically indicated. All patients received ganciclovir during conditioning regimen, and then switched to acyclovir or valaciclovir after stem cell infusion until 1 year post SCT. Ganciclovir and/or foscarnet were used when DNAemia developed, as well as rituximab for high risk patients such as high viral load or persistent DNAemia.
Results: This study recruited 892 evaluable cases, including 91 cases of benign diseases and 801 cases of malignancies. EBV-DNA was detected in 165 cases with a median duration of 55 days (16-618days) post SCT, and the long-term cumulative incidence of DNAemia was 21.3±1.5%. Totally 7 patients developed probable or proven PTLD. Log-rank test showed EBV-DNAemia had impact on neither 2 year-OS (67.2±6.3% *vs* 66.2±1.9%, P=0.341) nor 2 year-NRM (19.4±4.0% *vs* 25.1±1.8%, P=0.272). Cox model analysis revealed that haploidentical donor (RR 1.973 [95%CI 1.383-2.814], P<0.001) and the use of ATG/ALG (RR 4.831 [95%CI 2.469-9.524], P<0.001) were independent risk factors (Figure 1). While focusing on leukemia patients, RIC regimen was identified as an additional risk factor (RR 3.378 [95%CI 1.058-10.870]), with a weaker association (P=0.040).
Summary and Conclusions: Reported EBV viremia incidence post SCT ranged from 0.6 to 26%. A relatively higher incidence in this study was probably due to higher proportion of haploidentical donor SCT. Fortunately, OS and NRM were comparable between EBV-positive and EBV-negative patients, and PTLD was rarely observed, which implied the efficacy of preemptive treatment. Previously described risk factors of EBV reactivation include unrelated or HLA-mismatched donor, use of T cell depletion *in vivo* and onset of GVHD. Our results were partially in accordance with those literatures. Acute GVHD had not been identified as an independent risk factor, and a probable reason is that physicians paid more attention to virus infection during the treatment of GVHD. For haploidentical donor SCT recipients, the EBV prophylactic strategy needs to be further explored.

E986

A MODIFIED-INTERNATIONAL PROGNOSTIC INDEX INCLUDING PRETREATMENT HEMOGLOBIN LEVEL FOR EARLY STAGE EXTRANODAL NK/T CELL LYMPHOMA

L. Wang[1,*] Z.J. Xia[1], Y.J. Zhang[2]
[1]Hematologic Oncology, [2]radiation oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Anemia is a common finding in cancer patients, even before patients have received radiotherapy or chemotherapy and even when there is no bone marrow infiltration. Recent studies have found that pretreatment anemia status is correlated with shorter survival in patients with several hematological malignancies.
Aims: We aimed to define the relationship between pretreatment hemoglobin level and survival outcomes in patients of extranodal NK/T cell lymphoma, nasal type (ENKTL).
Methods: We retrospectively investigated the prognostic role of pretreatment hemoglobin level in 352 patients with stage I/II ENKTL.
Results: Of 352 patients, 67% had stage I disease, and 79.8% had international prognostic index (IPI) scores between 0 to 1. There were no significant correlations between baseline hemoglobin level and age, ECOG performance status score, lactate dehydrogenase (LDH) level, and Ann-Arbor stage. The complete response rate in patients with anemia was 64.7%, slightly lower than that in patients without anemia (75.6%, P=0.076). The overall response rate in both groups were similar (84.1% and 88.7%, P>0.05). At a median follow-up time of 83.8 months, the 5-year and 10-year PFS rate were 48.0% and 40.0%, respectively, and the 5-year and 10-year OS rate were 63.0% and 60.0%, respectively. Patients with pretreatment hemoglobin level<120g/L had significantly inferior PFS and OS than those with hemoglobin level≥120g/L (P<0.05). In a multivariate Cox regression model, age, ECOG performance status, LDH level, Ann-Arbor stage, and pretreatment hemoglobin level were all independent prognostic factors for PFS and OS (P<0.05). Using these five parameters, a modified-IPI model (mIPI) was constructed and three prognostic groups were classified: group 1, no adverse factors; group 2, one or two factor; group 3, three or more factors. This mIPI could categorize three groups with significantly different PFS and OS (both P<0.0001). Using the cohort of patients who received asparaginase-based therapy as a validation set, this mIPI retained its prognostic value.
Summary and Conclusions: This large-cohort retrospective study confirmed the independent prognostic role of pretreatment hemoglobin level in early stage ENKTL, and a newly modified IPI including pretreatment hemoglobin level could be used to further optimize treatments for patients with stage I/II ENKTL, even in the era of asparaginase.

E987

CARBOPLATIN, ARACTYIN PLUS DEXAMETHASONE WITH OR WITHOUT RITUXIMAB (DHAC+/-R) IS A FEASIBLE AND EFFECTIVE TREATMENT FOR LYMPHOMA PATIENTS

B. Tessoulin[1,*] E. Deslandes[2], J. Moynard[2], T. Gastinne[1], H. Maisonneuve[3], N. Blin[1], B. Mahé[1], V. Dubruille[1], M. Voldoire[1], P. Gallas[1], P. Moreau[1], P. Thomaré[2], S. Le Gouill[1]
[1]Clinical Hematology, [2]Clinical Pharmacy Oncology Unit, Nantes University Hospital, Nantes, [3]Clinical Hematology, Hospital, La Roche sur Yon, France

Background: Salt platins (cisplatin, oxaliplatin, carboplatin) are used in relapsed/refractory (R/R) lymphomas. The so-called DHAP regimen with or without Rituximab (R) combines dexamethasone, cisplatin plus high-dose cytarabin (AraC-HD). However, cisplatin-induced nephrotoxicity is a major concern: 10-20% of tubular complication sometimes leading to persistent reduced glomerular filtration that jeopardizes autologous stem cell transplantation (ASCT). Oxaliplatin may replaces cisplatin but it is associated with neuropathy toxicity. Carboplatin is widely used in solid tumours and combined with ifosfamide (ICE regimen) in lymphomas. However, the carboplatin plus AraC-HD and dexamethasone (DHAC+/-R) regimen has never been evaluated.

Aims: Taken into account the potential benefice of carboplatin, we investigated this regimen. Herein, we report the toxicity and efficacy of DHAC+/-R in lymphomas patients.
Methods: From September 2008 to September 2014, all R/R lymphoma patients treated in our institution received DHAC+/R instead of DHAP+/-R. Only patients with Mantle Cell Lymphoma (MCL) or contra-indication to anthracycline was allowed to receive upfront DHAC+/-R. Rituximab (375mg/m^2) was administrated only in CD20+lymphoma entities. DHAC consisted of: Carboplatin (targeted AUC =5, Calvert's formula [Dose (mg)= AUC x (GFR +25)]), AraC-HD 2g/m^2 two times a day (day 2) and IV or oral dexamethasone from day 1 to 4. Interval between courses was 21 days. Number of cycles was adapted to patients and therapeutic program including or not ASCT.
Results: 182 patients received DHAC+/-R. Diagnoses were as followed: Diffuse Large B Cell Lymphoma (DLBCL) in 97 cases (53%), Follicular Lymphoma (FL) in 24 cases (13%), Hodgkin Disease (HD) in 22 cases (12%), MCL in 22 cases (12%), Peripheral T Cell Lymphoma (PTCL) in 6 cases (3%) and 7 cases presented with low grade B lymphomas and 3 patients had plasmablastic lymphomas. Twenty-two patients received upfront DHAC+/-R while 54 were in relapse (n=54, 30%), 61 in partial response (PR) (34%), 19 in stable disease/refractory (SD) (11%) and 23 patients had progressive disease (PD) (13%). The median number of treatments line before DHAC+/-R was 1 (range, 1-4). At time of first cycle, median age was 53 years (range, 18-75). Before start of DHAC+/-R, ASCT was planned for 133 patients (73%). 48% of patients received DHAC+/-R with overnight stay and 38% in day care hospital. For all patients, a median of 3 cycles of DHAC+/-R was administrated. Median dosing of carboplatin at cycle 1, 2, 3, 4, 5 and 6 were (mg/m²) 350, 350, 350, 350, 310, 315, respectively. Median dosing of AraC-HD was 4g/m² through all cycles. 78% of patients with advanced disease completed the scheduled number of cycles. Major cause of arrest of DHAC+/-R was PD or SD (32 out of 41). In term of toxicity, Grade >=3 haematological toxicities were reported mainly thrombopenia (n=53) and anaemia (n=41). Transfusion support was used in 106 patients (58%), with a median of 2 red blood cell units (2-14) and 2 platelets units (1-27) during the treatment period. 11 sepsis were reported. One patient died of septic shock at day 8 of first cycle of DHAC. No grade >= 3 renal (4 cases of grade 1/2), and only one grade 3 neurological toxicities were reported. In term of response, Percentage of response after DHAC was as followed: complete remission (CR) in 27%, PR in 42%, SD in 11% and 20% PD. 60% of the patients at diagnosis reached CR, while 72% of patients with relapsed lymphoma reached PR. For the entire cohort, the median follow-up was 24m (range, 2-71), median OS was not reached (estimated 2-year OS was 74%), and median PFS was 46m. According to lymphoma entities, median PFS were 3.6m for PTCL, 21m for DLBCL, NR for FL, NR for MCL and 51m for HD. When focusing on DLBCL with insufficient response before ASCT, the 2y OS was 85% and the 2y PFS was 64% (41-77). Among the 133 patients scheduled for ASCT, 96 were in response after DHAC+/-R and they all underwent ASCT.
Summary and Conclusions: Herein, we show that DHAC+/-R is a safe chemotherapy regimen associated with good clinical response in all lymphoma entities and does not jeopardize ASCT when PR is reached.

E988

C-MYC AND BCL2 TRANSLOCATION FREQUENCY IN DIFFUSE LARGE B CELL LYMPHOMAS

B. Akkaya[1,*] O. Salim[2], H. Akkaya[3], M. Ozcan[1], O.K. Yucel[2], R. Erdem[2], U. Iltar[2], L. Undar[2]
[1]Pathology Dept., [2]Hematology Dep., Akdeniz University School of Medicine, [3]Pathology Dept., Baskent University Alanya Hospital, Antalya, Turkey

Background: Diffuse large B-cell lymphomas (DLBCLs) are a biologically heterogeneous group with varied clinical courses, histology, molecular and cytogenetic characteristics.
Aims: DLBCLs have been associated with multiple cytogenetic abnormalities including *MYC* with *BCL6* or *BCL2* rearrangement. Three antibody panel of immunohistochemical stains can be used to subclassify DLBCL into prognostically significant germinal center B-cell like (GCB) DLBCL and activated B-cell like (ABC) DLBCL subtypes. Both CD 10 and BCL6 are considered as germinal center markers while MUM 1 is expressed in activated B-cells and plasma cells.The aim of this study was to investigate the frequency and prognostic impact of BCL2 and MYC rearrangements.
Methods: In the present study, we evaluated the expression patterns of CD 10, BCL6 and MUM 1 by immunohistochemistry on contructed 121 cases (62; GCB, 59 ABC), (60; female, 61; male) of DLBCL in tissue microarray. MYC, BCL2 rearrangements were investigated by interphase fluorescence *in situ* hybridization (FISH) on tissue microarrays in 97 DLBCLs.
Results: Mean age of patients was 54.8 year. There were 60 women (49,58%) and 61 men (50,41%) patients. Tumors were located at lymph nodes in 59 patients (48,76%). Mean of survival time was 65,74 months. FISH was successfully performed in 97 cases. No significant differences were observed with regard to age (<60 *vs* -60years), sex, primary site of presentation (nodal *vs* extranodal), stage (I-II *vs* III-IV) among GCB and ABC subgroups. MYC rearrangements were observed in 11 (11,3%) of 97 DLBCL patients. There was no association with other clinical features, including age, sex, nodal/extranodal disease. MYC rearrangement was associated with significantly worse overall survival (p=.00). MYC rearrangement was more common in cases with GCB phenotype (9 cases GCB; 2 cases ABC). BCL2 rearrangements were observed in 14 (14,4%) of 97 DLBCL patients. Six of them were extranodal lymphoma, eight cases were nodal lymphoma. BCL2 rearrangements were more common in nodal than in extranodal presentations. There was no association with other clinical features, including age, sex. BCL2 rearrangement had prognostic impact on outcome (p= .00). No significant differences were observed with regard to age (<60 *vs* -60years), sex, primary site of presentation (nodal *vs* extranodal), stage (I-II *vs* III-IV) among GCB and ABC subgroups.No significant differences were observed with regard to BCL2 rearrengement among GCB and ABC phenotype. MYC and BCL2 rearrangements were observed in 3 (3,09%) of 97 cases. There was no significant difference between GCB and ABC phenotype cases with regard to MYC and BCL2 rearrangements. Three cases were 53 (female), 53, 63 years years old, respectively. Two of them were GCB type of DLBCL. The patients were died in 24.,18. and 35. months after diagnosis. Double-hit lymphoma patients included one female and two males with a median age of 56 years (range, 53-63). Two cases had primary nodal and one case primary extranodal presentations. The majority of patients had stage IV disease.
Summary and Conclusions: Cases in which clinical, morphological and immunohistochemical diagnosis are not adequate to discriminate DLBCL-BL, cytogenetic studies are beneficial. In this way, not only the patient will be able to reach the correct diagnosis but also get the effective treatment. We concluded that C-MYC and BCL2 may contribute to aggressive transformation, and more mechanism-based therapy should be explored. Analysis of MYC gene rearrangement along with BCL2 is critical in identifying high-risk patients with poor prognosis.

E989

R-DA-EPOCH VS R-CHOP IN PATIENTS WITH PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA: INTERIM RESULTS OF RANDOMIZED (PROSPECTIVE) MULTICENTER STUDY

I. Kryachok[1,*] I. Stepanishyna[1], K. Filonenko[1], O. Novosad[1], I. Tytorenko[1], T. Skrypets[1]
[1]Oncohematology, National Cancer Institute, Kiev, Ukraine

Background: The standard frontline therapy of primary mediastinal large B-cell lymphoma (PMBL) does not establish. Different anthracycline–based regimens are applied. Therefore, the effort to determine the most effective and well-tolerated treatment of such category of patients is reasonable.
Aims: To compare the treatment efficacy and toxicity of R-da-EPOCH and R-CHOP regimens in patients with PMBL.
Methods: 57 patients with newly diagnosed PMBL from five Ukrainian centers were included into the study. Median age was 30 years (range 17-45), 39 females (68.4%) and 18 males (31.6%). 70.2 % of patient had early stage (I-II) of disease, 80.7 % of patients had greatest size of the tumor mass in mediastinum more than 10 cm. The tumor pleurisy, pericarditis were revealed in 40.3% and 42.1%, respectively. Patients were randomized in two groups to receive R-da-EPOCH (32 patients) or R-CHOP (25 patients). Primary and post treatment assessment of disease included PET-CT or CT of the whole body. The treatment efficacy in both groups was evaluated according to Cheson criteria 1999, 2007 and Deauville criteria. All patients received 6 cycles of R-chemo±mediastinal radiation therapy (30-36 Gy).
Results: The ORR was 100% in the group of R-da-EPOCH and 78% in group of R-CHOP, p<0.01. CR rate (including CR unconfirmed) was 75% and 48%, respectively, p<0.05. Primary refractory disease was diagnosed in 3 pts (12%) of R-CHOP group. 1 patient from R-da-EPOCH-group had early relapse up to 6 months after treatment. All 57 patients had manifestations of treatment toxicity. 54 (94.7%) patients completed full treatment plan. There was no significant difference in toxicity rate in both groups. Treatment was complicated by anemia grade 3-4 in one case in R-da-EPOCH group *vs* two cases in R-CHOP group. FN was detected in 4 pts (12.4%) *vs* 3 pts (12%), respectively. Thrombocytopenia grade 3-4 was not observed. All cases of non-hematological toxicity were grade 1-2.
Summary and Conclusions: The treatment of patients with PMBL with both regimens was quite efficient, but ORR and CR rate was significantly higher in R-da-EPOCH group. The treatment toxicity rate was comparable in both groups. The study should be continued to evaluate and analyze long-term results.

E990

A PHASE IIA STUDY OF SINGLE-AGENT MOR208, AN FC-OPTIMIZED ANTI-CD19 ANTIBODY, IN PATIENTS WITH RELAPSED OR REFRACTORY B-CELL NON-HODGKIN'S LYMPHOMA

W. Jurczak[1,*] P. L. Zinzani[2], A. Goy[3], M. Provencio[4], Z. Nagy[5], T. Robak[6], K. Maddocks[7], C. Buske[8], R. Korolkiewicz[9], M. Winderlich[9], K. Blum[7]
[1]Jagiellonian University, Kraków, Poland, [2]University of Bologna, Bologna, Italy, [3]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, United States, [4]University Hospital Puerta De Hierro, Madrid, Spain, [5]Semmelweis University, Budapest, Hungary, [6]Medical University of Lodz, Lodz, Poland, [7]The Ohio State University Comprehensive Cancer Center,

Columbus, United States, [8]University of Ulm, Ulm, [9]MorphoSys AG, Martinsried, Germany

Background: A number of second-generation monoclonal antibodies (mAbs) that target the antigens CD20 and CD19 have been evaluated across a range of non-Hodgkin's lymphoma (NHL) subtypes combined with chemotherapy, as a single agent, or as maintenance therapy. Although these agents are usually well tolerated and have demonstrated clinical activity in patients (pts) with NHL, there remains a high unmet medical need for new therapies for pts with relapsed or refractory (R-R) B-cell NHL. MOR208 is an Fc-engineered, humanized mAb that targets the B-cell-specific antigen CD19 and which possesses significantly enhanced antibody-dependent cell-mediated toxicity, a key mechanism for tumor cell killing.
Aims: To evaluate the preliminary efficacy and safety of MOR208 in adult pts with relapsed or refractory NHL.
Methods: This is a non-randomized, open-label, multicenter, two-stage, phase IIa study of MOR208 in pts with R-R NHL previously treated with rituximab who were not candidates for high-dose chemotherapy with stem cell support. Adult pts with diffuse large B-cell lymphoma (DLBCL), mantle cell lymphoma (MCL), follicular lymphoma (FL), or other indolent NHL (iNHL), were treated with single-agent MOR208, at an intravenous dose of 12 mg/kg, weekly, over two 28-day cycles. Pts with at least stable disease according to the 2007 International Response Criteria were to continue treatment with MOR208 for another cycle. Pts achieving a complete or partial response (CR or PR) could then receive maintenance MOR208 every two or four weeks, depending on the investigator's decision, until progression. Overall response rate (ORR=CR +PR) was the primary endpoint.
Results: By 17 November 2014, all pts (N=89) had been enrolled (DLBCL, n=35; FL, n=31; MCL, n=12; iNHL, n=11); median age was 67 (range 35–90) years. Of these pts, 88% had stage III–IV disease and the median number of prior therapies was 2 (range 1–4). The mean number of cycles completed was 2.2 (0–3). The investigator-assessed responses across all NHL subtypes are shown in Table 1; the highest ORR was recorded in the DLBCL cohort (26%). Preliminary median duration of response was 7.7 months in the DLBCL group and 2.6 months in the FL group. Grade ≥3 non-hematologic treatment-emergent adverse events (TEAEs) were recorded in 30 pts (34%); disease progression, reported in 10 pts (11%), was most common. Grade ≥3 hematologic TEAEs were recorded in 8 pts (9%); neutropenia, reported in 5 pts (6%), was most common. Infusion-related reactions, reported in 8 pts (9%), were all grade 1–2 except for one case of dyspnea, which was grade 4. There were no treatment-related deaths.

Tabella 1. Investigator-assessed responses in HHL subtypes (safety population).

	NHL cohort				
Response, n	DLBCL N = 35	FL N = 31	MCL N = 12	iNHL N = 11	Overall N = 89
CR	2	1	0	1	4
PR	7	6	0	3	16
SD	5	14	6	3	28
PD	11	4	5	3	23
NE	10	6	1	1	18
ORR, n (%)	**9 (26)**	**7 (23)**	**0 (0)**	**4 (36)**	**20 (22)**

CR, complete response; DLBCL, diffuse large B-cell lymphoma; FL, follicular lymphoma; MCL, mantle cell lymphoma; NE, not evaluable; iNHL, indolent non-Hodgkin's lymphoma; ORR, overall response rate; PD, progressive disease; PR, partial response; SD, stable disease.

Summary and Conclusions: MOR208 demonstrated encouraging single-agent efficacy with CRs observed in pts with R-R DLBCL, FL, and iNHL. MOR208 is well tolerated without significant infusional toxicity. Protocols are being developed to investigate MOR208 in combination with other agents.

E991

PROPOSED PROGNOSTIC MODEL FOR PERIPHERAL T-CELL LYMPHOMA: PSU-PROGNOSTIC INDEX FOR T-CELL LYMPHOMA (PSU-PIT) SCORE

J. Julamanee[1,*] P. Viboonjuntra[1], D. Kongkabpan[1], P. Saelue[1], A. Lekhakula[1]
[1]Department of Internal Medicine, Prince of Songkla University, Songkhla, Thailand

Background: Peripheral T-cell lymphoma (PTCL) is an uncommon lymphoma entity which is composed of various histological subtypes and unfavorable outcomes. Compared with Western countries, the prevalence of PTCL is higher in the Asian population and accounts for 15-20%.
Aims: This objective of the study was to identify prognostic factors and to propose a new prognostic model for PTCL patients.
Methods: The clinical characteristics, histopathology, treatment outcomes, and survival of 182 newly diagnosed PTCL patients from 2001 to 2014 in Songklanagarind Hospital were retrospectively reviewed. The clinical and outcome data were analyzed to define the factors associated with the response rate and survival outcomes.
Results: The histological subtypes of our patients included PTCL, NOS (33.5%), AITL (17.6%), nasal NKTCL (15.4%), CTCL (12.6%), SPTCL (12.1%), ALCL (4.4%), and others (4.4%). Overall clinical characteristics of the patients included a median age of 53 years (range 15-89 years), 70.3% male, 87.4% ECOG score 0-1, 80.2% extranodal lesions with 28.1% extranodal lesions >1, 48.4% Ann Arbor stage III-IV, 50% had B symptoms, 63.7% had high LDH level, 23.5% had bone marrow (BM) involvement, and 10.4% had thrombocytopenia (platelet count $<150x10^9$/l). Eighty-five percent of the patients were treated with chemotherapy and CHOP regimen was used in 77.4%. Of the 148 patients evaluated, the overall response rate was 69.6% with 47.3% complete remission (CR). With the median follow-up time of 18 months, the median overall survival (OS) was 23.9 months and the 3-year OS was 43.8%. From multivariate analyses, 6 factors were significantly associated with poor OS including the ECOG score 2-4 (p=0.000), extranodal >1 (p=0.013), Ann Arbor stage III-IV (p=0.005), B symptoms (p=0.003), BM involvement (p=0.003), and platelet count $<150x10^9$/l (p=0.001). A new prognostic (PSU-PIT) model was constructed by combination of these prognostic variables: score 0-1 as low-risk group, score 2-3 as intermediate-risk group, and score >3 as high-risk group. The PSU-PIT score was able to differentiate 3 risk-groups of PTCL patients with significantly different response rates (p=0.016) and survival outcomes (p=0.000) as the table.

Tabella 1.

PSU-PIT risk group	N (%)	CR rate (%)	Median OS (mo)	3-year OS (%)
Low	101 (55.5)	50	47	54.6
Intermediate	47 (25.8)	34	13	38.5
High	34 (18.7)	12	9	13.8
p value		0.016	0.000	0.000

Summary and Conclusions: A new prognostic model for PTCL was proposed. The PSU-PIT score efficiently predicted the CR rate and 3-year OS among the three risk groups of our PTCL patients.

E992

RESULTS OF TREATMENT OF LYMPHOBLASTIC LYMPHOMA AT THE CHILDREN CANCER HOSPITAL EGYPT- A SINGLE CENTER EXPERIENCE

H. Abdelrahman[1,*] M. Sedky[2], A. Hamoda[1], N. El Kenaie[3], M. El Wakeel[4], D. Hesham[5]
[1]Pediatric Oncology, National Cancer Institute, Cairo University, [2]Pediatric, National Research Center, [3]Pathology, [4]Radiodiagnosis, National Cancer Institute, Cairo University, [5]Clinical Research, Children Cancer Hospital, Cairo, Egypt

Background: Lymphoblastic lymphoma (LL) and acute lymphoblastic leukemia (ALL) and are neoplasms of immature B or T-cell precursors. They are considered as a unique biological entity in the 2008 World Health Organization Classification of Hematologic Neoplasm. Both entities are arbitrarily separated by a cut-off point of 20-25% of blast cells in the bone marrow. Treatment of LL has evolved over time from conventional high-grade NHL schedules to ALL- derived protocols.
Aims: The aim of this work is to estimate the EFS, OS, and common chemotherapy toxicities of LL patients treated at the Children Cancer Hospital Egypt during 5.5 years period.
Methods: A Retrospective review of patients charts diagnosed and treated as LL during the period between July 2007 till end of December 2012 was done. Patients were treated according to St. Jude Children Research Hospital ALL Total Therapy XV protocol, standard risk arm.
Results: This study included 77 patients. T- cell LL patients were 87%, while B-cell were 13%. The median age at diagnosis was 9 years (range 1–17 years). The majority were males (70.1%). Stage III was the most common at presentation (74%). Two patients were excluded from analysis as they died before receiving chemotherapy. Complete remission post induction chemotherapy was seen in 25.3% of the patients, partial remission in 72%. Progressive disease was the event in 6.6% of the patients, while 5.3% suffered from a disease recurrence. The most common chemotherapy toxicities were cerebral venous thrombosis (20%), followed by bone infarcts ((10.6%), and avascular necrosis of head of femur (9.3%). One patient developed secondary AML after 3 years of FU. Disease recurrence was local in 4% and systemic in 5% of the patients. By the end of the study, 84% of the patients were alive, 16% were dead. Mean duration of follow up was 48.6 months (range 1-89 months). The 4 years overall survival was 82.7% while event free survival was 82.2%.
Summary and Conclusions: Disease progression and chemotherapy related toxicity are the main causes of death in pediatric LL patients. While cerebral vascular thrombosis and steroids induced musculoskletal complications are the major chemotherapeutic adverse events.

E993

VALIDATION OF THE NCCN IPI IN 70 YEARS AND ABOVE AGGRESSIVE PATIENTS TREATED WITH R-COMP

[1]Hematology, MD Anderson CC Madrid Spain, Madrid, [2]Hematology, H. Vega Baja Oriuela, Oriuela, [3]Fundacion MD Anderson, MD Anderson CC Madrid Spain, [4]Hematology, H. Quiron, Madrid, [5]Hematology, ICO-H.U. Germans Trias i Pujol, Badalona, [6]Hematology, Son Espases, Palma de Mallorca, [7]Hematology, Sanitas Zarzuela, Madrid, [8]Hematology, H. U. Guadalajara, Guadalajara, [9]Hematology, H. U. Central de Asturias, Oviedo, [10]Hematology, H. Virgen de la Luz, Cuenca, [11]Hematology, H. Lozano Blesa, Zaragoza, [12]Hematology, H. del Tajo, Aranjuez, [13]Hematology, H. U. Principe de Asturias, [14]Hematology, H. U. Puerta de Hierro, Madrid, Spain

Background: The new NCCN IPI has been suggested as a better outcome predictor than the classic IPI in patients with DLBCL in the Rituximab era (blood 2014). The MDA-LNH-2011-01 study analyzed the effectiveness and toxic profile of R-COMP in patients 70 and above with diagnosis of DLBCL and grade 3 Follicular Lymphoma, G3FL (EHA 2013).
Aims: The aim of this study is to evaluate the new NCCN IPI in 70 yr old and above aggressive lymphoma patients treated with R-COMP (Rituximab 375 mg/m2/day1, Ciclofosfamide 750 mg/m2/day1, Vincristine 2 mg/day1, Liposomal non pegilated Doxorubicin 50 mg/m2/day1 and Prednisone 60 mg/m2/days 1-5).
Methods: We performed the analysis of the ORR, CRR (as *Revised-Response-Criteria-for-Malignant-Lymphoma v2007)*, OS and PFS (Kaplan meier) using the new NCCN IPI as well as the classic IPI in the patients included in the MDA-LNH-2011-01 study. This study was approved by the Spanish Medicines Agency (AEMPS).
Results: The MDA-LNH-2011-01 study included 100 patients from 15 Spanish sites, data to perform the new NCCN IPI were available in 84 pt. Mean age 77.3 (70-91), age >75yr 52pt (62%), M/F 46/38pt, DLBCL/G3FL 74/10pt, Ann Arbor III/IV 54pt (64%), extranodal involvement 52pt (62%), ECOG≥2 38pt (45%), LDH 1-3 49pt (58%), LDH>3 8pt (9.5%). NCCN IPI: int-low 14pt, int-high 36pt, high 34pt. Classic IPI: low 10pt, int-low 23pt, int-high 19pt, high 32pt. Effectiveness: CRR 55pt (65.5%), mean OS 24.6 months, mean PFS 22.7 months. Toxicity: Febrile neutropenia (FN) 29pt (34%). In the univariate analysis ECOG≥2 predicts OS and PFS (p<0.01 and p 0.02) and extranodal involvement predicts PFS (p0.02). The NCCN IPI index results in statistical significant differences for OS (p0.01), classic IPI don't (p0.07). Both index predict OS (p<0.01) and have correlation with FN incidence, if we make two groups, low and int-low versus int-high and high. We didn't observed correlation between other clinical baseline characteristics, age >80 yr, creatinine >1.3 mg/dL, Hb <10g/dL and OS.
Summary and Conclusions: In our experience NCCN IPI is useful to predict OS in 70 and above aggressive lymphoma patients treated with R-COMP. Making two groups (low and int-low versus int-high and high) both index are useful to predict OS and FN.

E994

PROSPECTIVE PHASE II TRIAL OF LENALIDOMIDE IN ASSOCIATION WITH CHOP IN ELDERLY PATIENTS WITH ANGIOIMMUNOBLASTIC T CELL LYMPHOMA (AITL): INTERIM ANALYSIS OF A LYSA STUDY

V. Safar[1,*] L. De Leval[2], M. Meignan[3], E. Bachy[4], G. Cartron[5], M.P. Moles-Moreau[6], A. Delmer[7], R. Bouabdallah[8], L. Voillat[9], B. Corront[10], O. Casasnovas[11], V. Cacheux[12], R. Background: Angioimmunoblastic T-cell lymphoma (AITL) is one of the most frequent subtypes of T-cell lymphoma encountered in Western countries. Its optimal first-line treatment remains ill-defined with only 30% of patients experiencing long-term disease free survival when treated with anthracycline-based regimens. This disorder derives from the "follicular helper T cells" (TFH) subset developing within a unique malignant microenvironment. Owing to the importance of this microenvironment and given the promising activity of lenalinomide in a relapsed/refractory setting in AITL, we postulated that AITL patients might benefit from a treatment with lenalinomide combined with a classical CHOP regimen.
Aims: This multicenter, open label, phase 2 trial (NCT01553786) investigates the combination of lenalidomide with CHOP in previously untreated elderly patients with AITL.
Methods: Patients older than 59 years were treated with 8 cycles of lenalidomide +CHOP 21 (lenalidomide 25 mg/day (d), d1 to 14 - cyclophosphamide 750 mg/m², d1- doxorubicin 50 mg/m², d1- vincristine 1.4 mg/m², d1-prednisone 40 mg/m², d1 to 5, with pegfilgrastim at day 6) and received intrathecal methotrexate as central nervous system prophylaxis with the first 4 cycles. A thrombosis prophylaxis was mandatory. A dose adjustment of lenalidomide was planned according to related toxicities. A PET was performed at diagnosis and at the end of treatment. Histologic samples and PET were centrally reviewed. The primary objective was to evaluate the complete response (CR) rate based on a visual interpretation (Deauville five points scale) of PET according to the Lugano 2014 Classification. Secondary endpoints were safety, progression free survival and overall survival. Based on a Simon two-stage design comparing a CR rate of 60% with treatment to an unacceptable CR rate of 45% (CHOP alone), 17 or more CR out of 37 evaluable patients were required to declare the treatment worthy of further testing.
Results: Between November 2011 and July 2014, 19 LYSA centers enrolled 38 patients, of whom 37 were evaluable. Median age at diagnosis was 68 (59-79), 47 % were male, 68% had a performance status of 0 to 1, 97% an Ann Arbor stage ≥III, 84% IPI≥3 and 82% a PIT score≥2. The mean number of cycles delivered was 5.9. A total of 21 patients received the 8 planned cycles. A metabolic CR was obtained in 17 patients (46% [IC95%:29.5-63.1]) and 3 patients achieved a partial response, providing an overall response rate of 54%, 12 patients progressed and 5 could not be evaluated (one death of a septic shock after cycle 1, one withdrawal of consent, 2 patients with a major protocol violation retrieved after one cycle and one patient who refused to continue lenalidomide after one cycle). Toxicity was in the range of CHOP regimen with 70% and 30% grade 4 neutropenia and thrombocytopenia, respectively. Four episodes of thrombosis occurred during treatment. No second cancer was reported.
Summary and Conclusions: This pre-planned interim analysis shows that a combination of 25 mg of lenalidomide for 14 days with CHOP cycles gives acceptable activity and toxicity in AITL elderly patients. The study will continue as planned for a total of 70 evaluable patients.

E995

SUVMAX ON 18F-FLUORODEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY SCAN IS ASSOCIATED WITH CLINICOPATHOLOGICAL FACTORS AND PROGNOSIS IN NEWLY DIAGNOSED PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

H. Huang[1,*] F. Xiao[1], F. Chen[1], H. Zhong[1], X. Han[1], L. Zhong[1], L. Xu[1], J. Zhu[1], B. Ni[1], J. Lu[1], M. Zhang[1], L. Shen[1], T. Wang[1], T. Yin[1], L. Zheng[2], T. Chen[3]
[1]Dept. of Hematology, [2]Dept. of Pathology, [3]Dept. of Nuclear Medicine, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China

Background: Although 18F-fluorodeoxyglucose positron emission tomography (PET) imaging for diffuse large B cell lymphoma (DLBCL) have been widely utilized to evaluate the staging and response assessment after treatment with high sensitivity, the relevance of the maximum standard uptake value (SUVmax) on pretreatment PET scan to disease outcome has been poorly studied.
Aims: The aim of this study was to investigate relationships between SUVmax on pretreatment PET scan and clinicopathological factors, and the prognostic value of baseline SUVmax in patients with newly diagnosed DLBCL.
Methods: In the present study, 140 patients with newly diagnosed DLBCL who had undergone pretreatment PET scan from 2004 to 2014 in single institute using an identical protocol were reviewed and analyzed. Correlations between SUVmax at the predominant lesion on PET scan and patient clinical features, immunohistochemical parameters of glucose transporter-1 (Glut-1), Glut-3 and Ki-67 reactivity were evaluated. SUVmax were evaluated for their association with progression-free survival (PFS) and overall survival (OS).
Results: The median SUVmax was 12.2 (1.7–42.7). The median follow-up time was 30 months (range, 4-124months). There was significant association between high SUVmax and patient characteristics, including Ann-Arbor stage, B symptoms, number of extranodal involvement, serum lactate dehydrogenase level, and Prognostics Index (R-IPI). High SUVmax was significantly associated with high expression of Glut-3 (immunoreactive score ≥6 *vs* <6: 16.7±10.1 *vs* 9.7±5.8 *P*=0.008) and Ki-67 (%expression ≥50% *vs* <50%: 15.1±10.0 *vs* 9.4±4.9 *P*=0.001), but not with Glut-1 (*P*=0.668). The 3-year PFS rates in patients with low SUVmax (SUVmax≤9) and those with high SUVmax (SUVmax>9) were 92.2 and 63.6%, respectively (*P*=0.000). The 3-year OS rates were 95.5 and 78.3%, respectively (*P*=0.003). This outcome advantage was demonstrable in patients with very good prognosis group and poor prognosis group according to the R-IPI categories (PFS, *P*=0.044 and *P*=0.011, respectively). Multivariate analysis revealed that high SUVmax is a significant poor prognostic factor for PFS (hazard ratio (HR) 4.784 [1.429–16.022], *P*=0.011), independent of R-IPI. The combination of SUVmax and R-IPI risk group provided a powerful discriminator of outcome.

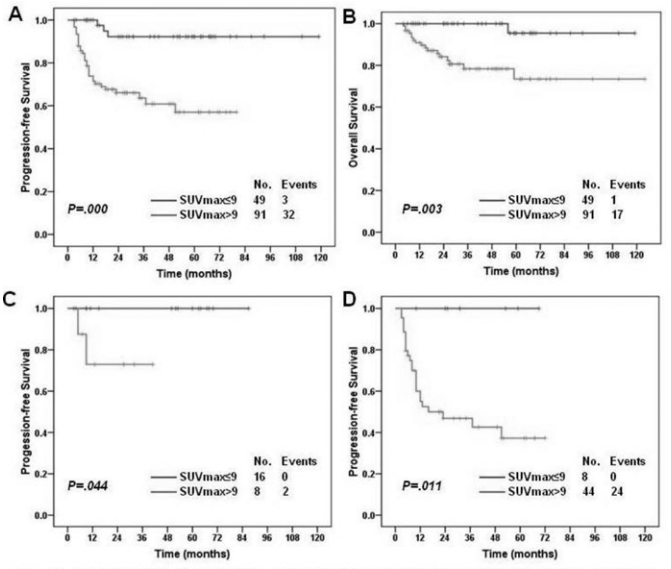

Fig. PFS (A) and OS (B) of all patients according to SUVmax using cut off value of 9;PFS of of patients in the "very good" prognosis group by R-IPI according to SUVmax (C), and of patients in the "poor" prognosis group according to SUVmax (D).

Figure 1.

Summary and Conclusions: In conclusion, for newly diagnosed patients with DLBCL, there was significant relationship between SUVmax on pretreatment PET and clinicopathological factors including R-IPI, Glut-3 and Ki-67. SUVmax can provide prognostic information in DLBCL beyond that which can already be obtained by the R-IPI. Therefore, the baseline SUVmax is an important prognostic tool of disease progression in DLBCL.

E996

PROGNOSTIC VALUE OF INTERIM POSITRON EMISSION TOMOGRAPHY-COMPUTED TOMOGRAPHY IN 377 PATIENTS WITH NON-HODGKIN LYMPHOMA: A SINGLE INSTITUTIONAL ANALYSIS OVER THE 8 YEARS

K. Fukumoto[1,*] Y. Suehara[1], M. Fujisawa[1], H. Sugihara[1], M. Takeuchi[1], K. Matsue[1]
[1]Division of Hematology/Oncology, Department of Medicine, Kameda Medical Center, Kamogawa city, Japan

Background: Positron Emission Tomography combined with computerized tomography (PET-CT) is increasingly used in non-Hodgkin lymphoma (NHL), and its availability of a staging also improves the accuracy of subsequent response assessment. Recently, interim PET-CT (iPET) that is often used to assess the early response and to guide the subsequent treatment, although its role is still controversial other than in Hodgkin disease.
Aims: The present study was performed to evaluate the prognostic value and clinical significance of iPET with regard to NHL in assessment of early response, and the usefulness for guiding subsequent treatment.
Methods: Between June 2006 and December 2014, 377 patients with NHL who was had iPET after two to four courses of treatment and end of treatment at Kameda Medical Center, Kamogawa-shi, Japan were retrospectively analysed. All of the patients with CD20-positive B-cell lymphoma received rituximab combined treatment. iPET was performed just before the next cycles of treatment to avoid the post chemotherapeutic change due to previous chemotherapy. A negative interim scan was defined as FDG uptake less than or equal to liver uptake at any site of FDG-positive disease identified in the baseline study. A positive scan was defined as any FDG uptake greater than liver background activity with a corresponding structural abnormality on CT scan. Overall survival (OS) and progression free survival (PFS) differences between curves were calculated by two-sided log-rank test. OS and PFS were compared between the patients with negative and positive results on iPET.
Results: The study population consisted of 219 males and 158 females with a median age of 63 years. The most frequent lymphoma diagnoses were diffuse large cell lymphoma (DLBCL; n=225), followed by indolent lymphoma (n=83) and T-cell lymphoma (n=69). Percentage of patients whose treatment was modified by iPET results were 13% in patients with DLBCL, 39% with T-cell lymphoma, and 5% of indolent lymphoma. iPET and at the end of treatment PET-CT status correlated with conventional response criteria. With a median follow up of 34 months, 2-year progression free survival rate was 81.2% for iPET negative versus 45.7% for iPET positive (P<0.001). Percentage of patients who became iPET negative was 70% (157/225), 71% (59/83), and 48% (33/69) in patients with DLBCL, indolent lymphoma and T-cell lymphoma, respectively. iPET status was associated with high serum LDH and soluble interleukin 2 receptor by Fisher's exact test (p<0.01 and P<0.001, respectively). On the whole, the patients who achieved the iPET negative showed significantly longer OS and PFS compared to those with positive (P<0.001). In the analysis of lymphoma subtypes, patients with DLBCL and T-cell lymphoma who had iPET negative showed significant longer PFS and OS (P<0.001), however, iPET did not have a predictive values in patients with indolent lymphoma (P=0.7 for OS and P=0.22 for PFS). We also analyzed maximal standardized uptake value reduction (ΔSUVmax) at baseline and iPET. Using the receiver operating characteristic (ROC) curve, ΔSUVmax between baseline and iPET of >85% was predictable for better PFS and OS (sensitivity 55.2%, specificity 85.7%, area under curve 0.719, 95% confidence interval=0.667-0.771).

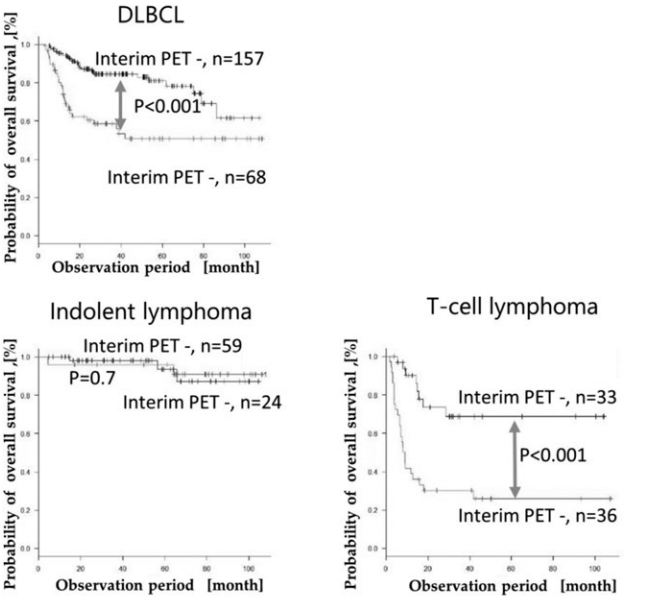

Figure 1. Impact of interim PET-CT negative on OS.

Summary and Conclusions: iPET effectively predict outcomes of patients with DLBCL and T-cell lymphoma, but it appeared to have a limited predictive value in patients with indolent lymphomas. ROC analysis revealed theΔSUVmax between baseline and iPET>85% is also predictable for better survival in both PFS and OS.

E997

LONG-TERM OUTCOME OF ADULTS WITH FIRST-RELAPSED OR REFRACTORY SYSTEMIC ALCL: A LYSA STUDY

A. Morel[1,*] J. Brière[2], L. Lamant[3], M. Loschi[4], C. Haioun[5], B. Coiffier[6], S. Bologna[7], P. Morel[8], A. Sonet[9], C. Gisselbrecht[10], G. Delsol[3], P. Gaulard[11], H. Tilly[4], D. Sibon[1]
[1]Hematology, Necker University Hospital, [2]Pathology, Saint Louis Hospital, Paris, [3]Pathology, CHU de Toulouse, Toulouse, [4]Hematology, Centre Henri Becquerel, Rouen, [5]Hematology, Henri Mondor Hospital, Créteil, [6]Hematology, CHLS, Pierre Bénite, [7]Hematology, CHU de Nancy, Nancy, [8]Hematology, CH de Lens, Lens, France, [9]Hematology, CHU Dinant Godinne UCL Namur, Yvoir, Belgium, [10]Hematology, Saint Louis Hospital, Paris, [11]Pathology, Henri Mondor Hospital, Créteil, France

Background: Long-term outcomes of adults with first-relapsed or refractory (R/R) systemic anaplastic large-cell lymphoma (ALCL) are not definitively established and should be evaluated.
Aims: To evaluate long-term outcomes of adults with first R/R systemic ALCL.
Methods: We previously reported the long-term outcomes of adult patients treated at first diagnosis of systemic ALCL in three LYSA prospective clinical trials (Sibon D et al, J Clin Oncol 2012). All patients had confirmed systemic ALCL after immunohistopathologic review and defined ALK expression status. Here we report the long-term outcomes of these patients with R/R systemic ALCL.
Results: Among the 138 (64 ALK+and 74 ALK-) adult patients treated at first diagnosis in clinical trials, 40 (14 ALK+and 26 ALK-) had R/R systemic ALCL after the frontline chemotherapy and their long-term outcomes were analyzed. Median follow-up of R/R patients was 12.5 years (ALK+13.6 years; ALK- 12.1 years). The median age at first relapse/progression was 35 (19-76) years for ALK+patients and 61 (34-82) years for ALK- patients. All patients relapsed/progressed after polychemotherapy with an anthracycline-based regimen. Five (4 ALK+and 1 ALK-) patients relapsed/progressed after planned high-dose therapy/autologous stem-cell transplantation as first-line treatment consolidation. Median time from initial inclusion in clinical trials to relapse/progression after primary therapy was 6 months (46 days – 2.8 years) for ALK+patients and 11

months (32 days – 5.6 years) for ALK- patients. Median progression-free survival (PFS) after the first relapse/progression (second PFS) was 5 months for ALK+patients and 4 months for ALK- patients. Median overall survival (OS) after the first relapse/progression was 11.9 months for ALK+patients and 7.7 months for ALK- patients, and 10-year OS rates were 14% for ALK+patients and 15% for ALK- patients, without significant difference (p=0.99; figure). ALCL was the main cause of death. Impact of treatments will be presented.

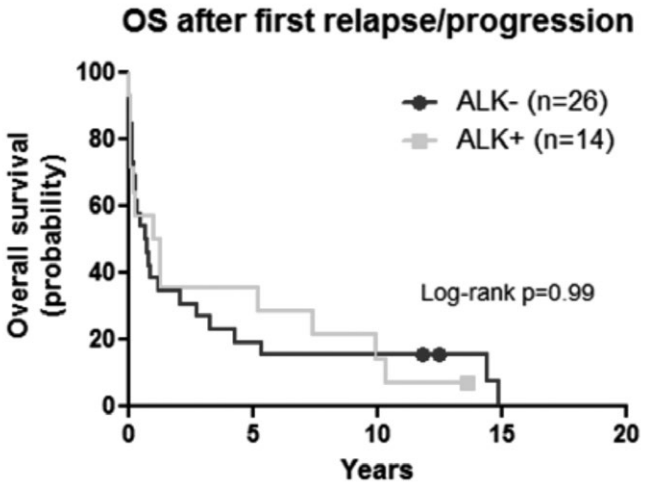

Figure 1.

Summary and Conclusions: Most patients with first R/R ALCL have poor outcomes with short survival, without significant difference between ALK+and ALK- patients. These results could be used as reference in the evaluation of new drugs for R/R ALCL.

E998

HIGH-THROUGHPUT SEQUENCING OF BOTH IMMUNOGLOBULIN LIGHT AND HEAVY CHAIN GENE REARRANGEMENTS IMPROVES DETECTION OF NEOPLASTIC CLONES IN MATURE B-CELL LYMPHOMAS

A. Sherwood[1,*] J. Fromm[2], D. Hospodsky[1], H. Robins[3], R. Emerson[1], M. Rieder[1], B. Wood[2], D. Wu[2]
[1]Adaptive Biotechnologies, [2]University of Washington, [3]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: The detection of recurrent/persistent disease in mature B-cell lymphomas is important for individualized patient care. Amplification and high-throughput sequencing (HTS) of CDR3 sequences to describe the repertoire of B-cell and T-cell receptors is emerging as a low-invasive and sensitive method to identify and monitor minimal residual disease (MRD), and we have previously applied this technology to MRD monitoring in precursor T- and B-lineage acute lymphoblastic leukemias (Sci. Transl. Med. 2012; 4: 134ra63, Clin. Cancer Res. 2014; epub). However applying this technology to mature B-cell lymphomas present a unique challenge; some germinal-center derived mature B-cell lymphomas may have somatic hypermutation (SHM) of the *IGH* locus that may limit primer binding and amplification of these rearrangements. Prior work suggests that analysis of multiple gene rearrangements, IGH, IGK, and IGL, may increase the likelihood of identifying a tractable clone (Biol Blood Marrow Transplant. 2014; S1083-8791(14)00257-2).
Aims: Here we evaluate the potential of sequencing immunoglobulin heavy and light chains (*IGH* and *IGK/IGL*) in mature B-cell lymphomas by testing if we could identify tractable B-cell clones using HTS of the IGH and IGK/IGL repertoire.
Methods: First we defined tractable clones by defining the normal proportion of reactive clones in lymphoid tissues and peripheral blood by measuring the relative abundance of B-cell clones in healthy controls. We amplified the *IGH* and *IGK/IGL* repertoire of 20 control samples using an amplification bias-controled multiplex PCR assay and HTS sequencing. We defined clones as abnormal and representing a neoplastic population in patient samples, if the clones occurred at a proportion of >5 standard deviations above mean frequency of the most abundant rearranged IGH, IGK/IGL in control samples. Next we used the same assay to amplify the IGH and IGK/IGL repertoire of a cohort of 60 mature B-cell lymphomas assembled from residual material. This set included cased from: 20 diffuse large B-cell lymphoma (DLBCL), 10 mantle cell lymphoma (MCL), 20 follicular lymphoma (FL), and 10 chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). As described, we then used the distribution of abundant clonal IGH and IGK/IGL CDR3 sequences in healthy controls to define probable neoplastic clones.
Results: We detected a clonal IgH gene rearrangement suitable for disease tracking in all MCL and CLL/SLL samples. By contrast, for many follicular lymphoma samples (11 of 20) and for some DLBCL samples (3 of 20), a clonal *IGH* gene rearrangement was not detected, most likely due to SHM. Additional high-throughput sequencing analysis of *IGK* or *IGL*, however, allowed a tractable clone to be detected in nearly all samples (18 of 20 for follicular lymphoma and 19 of 20 for DLBCL). Taken together, in this cohort, ninety-five percent of samples (57 of 60 cases) had at least one tractable clonal, immunoglobulin gene rearrangement.
Summary and Conclusions: We conclude that high-throughput sequencing of *IGH* is suitable for the majority of mature B-cell lymphomas. Lymphomas that may undergo somatic hypermutation, such as diffuse large B-cell lymphoma and follicular lymphomas, benefited most from additional immunoglobulin light chain gene sequencing. As high-throughput sequencing of antigen receptors can describe the breadth of the B-cell repertoire and simultaneously quantify the proportion of individual clones, this technology could contribute to the clinical monitoring of recurrent/persistent disease in these patients.

E1000

AN INHERITED MUTATION OF THE NOD2 GENE IS ASSOCIATED WITH POOR SURVIVAL OF PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

M. Zawartko[1,*] W. Kluźniak[2], D. Wokołorczyk[2], C. Cybulski[2], K. Safranow[3], J. Lubiński[2], B. Zdziarska[1]
[1]Department of Hematology, [2]Department of Genetics and Pathology, [3]Department of Biochemistry and Medical Chemistry, Pomeranian Medical University, Szczecin, Poland

Background: The *NOD2/CARD15* gene is involved in the regulation of immune function through activation of the transcription nuclear factor – kappaB (NF-kappaB). A single truncating mutation of *NOD2/CARD15* gene, 3020insC is present in the Polish population with a frequency of approximately 7%. This allele has been shown to be associated with chronic inflammatory disease such as Crohn's disease and also with increased risk of colorectal cancer. The mutation has also been found to confer an increased risk of gastric MALT lymphoma, but not of other subtypes of lymphoma.
Aims: In the current study we analysed whether or not this mutation is associated with the risk of diffuse large B cell lymphoma (DLBCL), disease progression and survival among patients with DLBCL.
Methods: We genotyped 141 patients diagnosed with DLBCL between the November 2000 and the August 2009 for the 3020insC allele using PCR-RFLP. We compared the frequency of this allele in DLBCL patients to that reported previously in the general population of Poland using Fisher exact test. The patients were followed from date of diagnosis (November 2000 to August 2009) to the date of death (for deceased patients) or the date of last follow up (for alive patients). The mean follow up time was 4.4 years (range 0.04 – 12.9 years). For clinical evaluation we used a retrospective analysis of: International Prognostic Index (IPI) and its modifications, first full blood count (FBC) parameters at diagnosis (absolute lymphocyte count (ALC), presence of anemia or thrombocytopenia), progression incidence. Progression free survival rates, overall survival and disease specific survival were compared between carriers of the allele and non-carriers.
Results: The 3020insC allele was present in 11 of 141 (7.8%) patients with DLBCL, compared to 140 of 1910 (7.3%) population controls and the difference was not significant (OR=1.1, 95%CI=0.6 - 2.0, p=0.9). In the univariate Cox proportional hazards model carriers of the NOD2 mutation were found to have 2.7-fold increased risk of DLBCL progression (95%CI=1.1 - 6.5, p=0.02) and 3.1-fold increased risk of death because of the lymphoma (95%CI=1.1 - 9.4, p=0.03), but association with death of any cause was not significant (HR=2.0, 95%CI=0.8 - 4.6, p=0.12). The analysis of survival curves showed that the presence of 3020insC was associated with both a shorter progression-free survival (log-rank p=0.04) and disease-specific survival (log-rank p=0.045), but not with overall survival (log-rank p=0.15). In multivariate Cox regression analysis where age of onset, sex, aaIPI and thrombocytopenia at the time of diagnosis were included as covariates, the 3020insC mutation was associated with increased risk of DLBCL-related death (HR=7.7, 95%CI=1.8 - 32.9, p=0.006).
Summary and Conclusions: Our study suggests that an inherited mutation of the *NOD2* gene is an independent factor associated with poor disease-specific survival in patients with diffuse large B cell lymphoma, however, further studies are needed in this regard.

E1001

MYC/BCL2 DOUBLE EXPRESSION INCREASES A RISK OF RELAPSE OR PROGRESSION IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS TREATED WITH INTENSIVE CHEMOTHERAPY M-NHL-BFM-90 PLUS RITUXIMAB

A. Misyurina[1,*] A. Kovrigina[1], E. Baryakh[2], V. Misyurin[3], S. Kravchenko[1], A. Misyurin[3,4], S. Kulikov[1], T. Obukhova[1], N. Denisov[5], J. Denisova[5],

A. Magomedova[1], V. Vorobiev[2], Y. Mangasarova[1], E. Gemdzhian[1]
[1]National Research Center for Hematology, [2]State clinical hospital №52, [3]FSSI "Blokhin Russian Cancer Research Center", [4]GeneTechnology LLC, [5]Dialab, Moscow, Russian Federation

Background: Diffuse large B-cell lymphoma (DLBCL) represents a highly aggressive type of lymphoma. A potential role of MYC and BCL2 synergetic interaction continues to be widely discussed in context of tumor chemoresistance. Previously it was reported that MYC/BCL2 double expressor (DE) DLBCL had a poor prognosis in patients, treated with CHOP plus rituximab (R) and in pts with non-GCB DCBCL who underwent R-(DA)-EPOCH chemotherapy.
Aims: To investigate a prognostic significance of MYC/BCL2 double expression in DLBCL patients treated with intensive chemotherapy m-NHL-BFM-90+R.
Methods: 62 DLBCL patients (35 males and 27 females) which underwent modified protocol of intensive chemotherapy – m-NHL-BFM-90+R in National Research Center for Hematology (Moscow) between 2004 and 2013 years were included in current study. Hans algorithm was used to determine GCB or non-GCB immunohistochemical subtypes of DLBCL. Tumor samples were stained with antibody to BCL2 (clone 124, Dako) and MYC (clone Y69, Epitomics). We used a previously reported cut off for MYC expression ≥40% and BCL2 ≥50% (N. Johnson *et al.*, 2012). G-banding data were available in 19 patients. 1 patient had a translocation t(8;14)(q24;q32). In all other cases FISH didn't reveal *c-MYC* or *BCL2* rearrangements with DNA probes Vysis LSI MYC Dual color, Break Apart Rearrangement Probe, Vysis LSI BCL2 Dual color, Break Apart Rearrangement Probe. We used Kaplan-Meyer and Cox regression analysis to estimate treatment results (SAS 9.3).
Results: By clinical characteristics patients corresponded to a high-risk group according IPI (3-5) in 48 (78%) cases. According to MYC and BCL2 expression status patients were divided into 4 groups: MYC+/BCL2- -9 (14,5%), MYC+/BCL2+- 15 (24%), MYC-/BCL2+- 21 (34%), MYC-/BCL2- 17 (27,5%) patients. All patients had comparable clinical characteristics, except of age. Median age of DE MYC/BCL2 patients were statistically higher - 61 (25-73) years old than in others - 47 (15-73) years old, (P<0,05). MYC/BCL2 double expression was revealed more frequently in non-GCB (29%) than in GCB subtype (17%), (P=0,18). 45 (78%) of patients achieved a complete remission, 4 from them had second remission. Relapses and progression of DLBCL developed in 9 (15%) and 7 (11%) patients, respectively. 5 (8%) patients died because of other reasons. There wasn't significant differences in 4-year OS depending on MYC and BCL2 expression: MYC+/BCL2- - 100%, MYC-/BCL2 – 78%, MYC+/BCL2+- 57%, MYC-/BCL2+- 53% (P=0,09). Although DE DLBCL patients had a statistically higher risk of relapse or disease progression within 4 years: MYC+/BCL2- - 14%, MYC-/BCL2 – 14%, MYC+/BCL2+- 65%, MYC-/BCL2+- 24% (P=0,02) (Picture 1). If compare DE patients with all others statistical significance increased (65% *vs* 15%, P=0,003). GCB/non-GCB subtype increases a probability of DLBCL relapse or progression within 4 years (17% *vs* 39, P=0, 07). In multivariate analysis MYC/BCL2 double expression had an independent prognostic power (HR 4,717, P=0,0024) from IPI, GCB/non-GCB subtype.

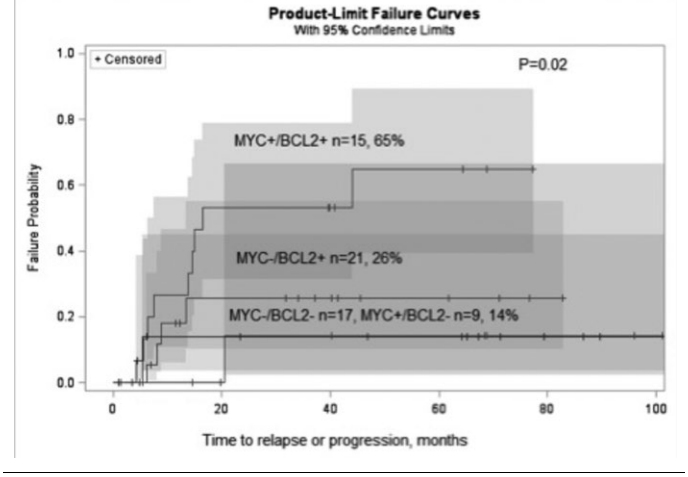

Figure 1.

Summary and Conclusions: MYC/BCL2 double expression is an independent risk factor of DLBCL relapse or progression in patients treated with intensive chemotherapy m-NHL-BFM-90+R, independently of IPI, GCB/non-GCB subtype.

CLINICAL FEATURES AND OUTCOMES OF PATIENTS WITH EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE: A PROSPECTIVE MULTICENTER STUDY FROM THE THAI LYMPHOMA REGISTRY

T. Numbenjapon[1] K. Prayongratana[1], J. Julamanee[2], A. Lekhakula[2], K. Chansung[3], C. Sirijerachai[3], L. Norasetthada[4], W. Nawarawong[4], A. Khuhapinant[5], N. Siritanaratkul[5], U. Bunworasate[6], T. Intragumtornchai[6], N. Kanitsap[7], P. Nipharuck[8], S. Chuncharunee[8], T. Suwanban[9,*]
[1]Medicine, Phramongkutklao Hospital and College of Medicine, Bangkok, [2]Medicine, Faculty of Medicine, Prince of Songkhla University, Songkhla, [3]Medicine, Faculty of Medicine, Khon Kaen University, Khon Kaen, [4]Medicine, Faculty of Medicine, Chiang Mai University, Chiang Mai, [5]Medicine, Faculty of Medicine, Siriraj Hospital, Mahidol University, [6]Medicine, Faculty of Medicine, Chulalongkorn University, [7]Medicine, Faculty of Medicine, Thammasart University, [8]Medicine, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, [9]Medicine, Rajvithi Hospital, Ministry of Public Health, Bangkok, Thailand

Background: Extranodal NK/T-cell lymphoma (ENKTL), nasal type is a rare subtype of lymphoma with a strong geographic predilection for Asian and South American populations. At diagnosis, most of ENKTL, nasal type patients present with destructive lesions in the nasal cavity and paranasal sinuses.
Aims: This study aims to describe the clinical features and treatment outcomes of Thai patients with ENKTL, nasal type.
Methods: A clinical review of patients with ENKTL, nasal type according to WHO 2008 classification obtained from The Thai Lymphoma Registry between 2002 to 2014 was performed.
Results: Among 4,019 cases of lymphoma, there were 81 cases (2%) of ENKTL, nasal type. The median age was 45 years old (range, 21-91). The male: female ratio was 2.5: 1. At diagnosis, approximately half of the patients had stage I/II disease (55.6%), International Prognostic Index (IPI) score of ≤1 (51.9%), B symptoms (54.0%), and elevated serum LDH (54.0%). A majority of the patients (92.6%) presented with good ECOG performance status. The patients were treated with chemoradiotherapy in 34.6%, chemotherapy alone in 35.8%, and radiotherapy alone in 11.1%. Fifteen patients (18.5 %) did not receive any treatment. The most common first-line induction chemotherapy regimen was CHOP (92.9%). Of the 66 evaluable patients, the overall complete remission (CR) rate and overall partial remission (PR) rate was 39.4% and 6.1%, respectively. The CR rate was achieved in 71.4%, 27.6%, and 22.2% of the cases treated with chemoradiotherapy, chemotherapy alone, and radiotherapy alone, respectively. With the median follow-up time of 9.7 months (range, 0.5-316.2), the median overall survival (OS) and progression-free survival (PFS) for the whole group was 10.8 months (95% CI: 0.2-21.5) and 8.2 months (95% CI: 3.0-13.5), respectively. The median OS of the patients treated with chemoradiotherapy was significantly higher than those treated with chemotherapy alone (5.8 years [95% CI: 1.2-10.4] vs. 0.4 year [95% CI: 0.1-0.7]; *P*=0.002) and radiotherapy alone (5.8 years [95% CI: 1.2-10.4] vs. 0.3 year [95% CI: 0.1-0.5]; *P*=0.021). The median PFS of the patients treated with chemoradiotherapy was significantly higher than those treated with chemotherapy alone (17.1 months [95% CI: 8.7-25.5] vs. 4.1 months [95% CI: 2.2-5.9]; *P*=0.014) and radiotherapy alone (17.1 months [95% CI: 8.7-25.5] vs. 3.1 months [95% CI: 1.6-4.6]; *P*=0.024). Furthermore, the IPI score was of prognostic significance to predict the median OS (IPI score=0 [6.4 years] vs. IPI score ≥1 [0.4 year]; *P*=0.016) and 5-year OS (IPI score=0 [56.9%, 95% CI: 30.8-76.3] vs. IPI score ≥1 [25.2%, 95% CI: 14.5-37.5]; *P*=0.012) in this cohort.
Summary and Conclusions: ENKTL, nasal type is rare among Thai population. At presentation, approximately half of the patients had early stage diseases, B symptoms, elevated serum LDH, and low IPI score. Chemoradiotherapy was the most effective treatment. In this cohort, the IPI score significantly predicted the OS.

E1003

CD30 EXPRESSION IN DE NOVO DIFFUSE LARGE B-CELL LYMPHOMA: CLINICAL FEATURES AND OUTCOME

F. Gaudio[1,*] F.E. Laddaga[1], T. Perrone[1], P. Pinto[1], M.S. De Candia[1], G. Ingravallo[2], G. Specchia[1]
[1]Hematology, University of Bari, [2]Patology, University of Bari, Bari, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common and one of the most heterogeneous lymphomas. Therefore, it is critical to further stratify cases of DLBCL into biologically similar and clinically meaningful subgroups, which will not only guide prognostic assessment and facilitate therapeutic decisions, but also stimulate further research to understand the pathogenesis and develop potential novel treatments. One promising candidate is brentuximab vedotin, an antibody-drug conjugate targeting CD30-expressing cells. Previous observational studies have suggested that CD30 may be expressed in 10 to 20% of DLBCLs.
Aims: The aim of this study was to determine the prevalence of CD30 expression in DLBCL by immunohistochemistry, and to explore possible relationships with outcome.
Methods: We retrospectively identified cases of DLBCL diagnosed between January 2010 and January 2013 at our Institution. The following large B cell lymphoma subtypes were excluded from this analysis: post-transplant lymphoproliferative disorders with a DLBCL morphology, Primary Mediastinal large cell lymphoma and unclassifiable lymphomas with intermediate features between either DLBCL and Burkitt's lymphoma or DLBCL and Hodgkin's lymphoma. Immunohistochemistry was performed as part of the routine workup

and CD30 was considered positive when ≥30% of neoplastic cells stained positive. A total of 82 cases of de novo DLBCL treated with R-CHOP were included in the training set for further analysis There were 45 men and 37 women with a median age of 57 years (range, 16-84); 35 patients (43%) presented with B symptoms, and 49 (60%) had advanced Ann Arbor stages. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0- 1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0-2, 63%). Involvement of multiple extranodal sites (>=2) was seen in 22% of cases, and bulky disease in 32% of cases.
Results: The median follow-up time was 47 months. Among the 82 cases in the training set, CD30 was positive in 24 cases (29%). No difference in response rate was observed between CD30 positive and CD30 negative patients. Patients with CD30+DLBCL showed a significantly superior OS and PFS compared with those with CD30–. The 3-year OS was 79% in patients with CD30+vs 59% in CD30– (P <0.05); 3-year PFS was 73% in patients with CD30+vs 57% in CD30– (P<0.05).
Summary and Conclusions: CD30 is expressed in approximately 29% of all DLBCL and defines a novel subgroup of diffuse large B-cell lymphoma with a more favorable prognosis. The advent of brentuximab vedotin and its well-established effectiveness in other types of relapsed lymphomas opens the possibility of its application in this subset of patients.

E1004

PHASE II STUDY OF SMILE CHEMOTHERAPY FOR RELAPSED/ REFRACTORY PERIPHERAL T-CELL LYMPHOMA

R. Suzuki[1,*] R. Hyo[2], W.S. Kim[3], N. Tsukamoto[4], Y. Maeda[5], Y. Masaki[6], R. Sakai[7], T. Masunari[8], N. Niitsu[9], F. Ishida[10], S. Nakamura[11], J. Suzumiya[1]
[1]Cancer Center, Shimane University, Izumo, [2]HSCT Data Management and Biostatistics, Nagoya University, Nagoya, Japan, [3]Hematology, Samsung Medical Center, Seoul, Korea, Republic Of, [4]Hematology, Gunma University, Maebashi, [5]Hematology, Okayama University, Okayama, [6]Hematology, Kanazawa Medical University, Kanazawa, [7]Medical Oncology, Kanagawa Cancer Center, Yokohama, [8]Hematology, Chugoku Central Hospital, Fukuyama, [9]Hematology, Saitama Medical University, Saitama-ken, [10]Hematology, Shinshu Medical University, Matsumoto, [11]Pathology, Nagoya University, Nagoya, Japan

Background: We previously reported that SMILE (Steroid, Methotrexate, Ifosfamide, L-asparaginase and Etoposide) regimen is effective for newly-diagnosed stage IV, relapsed or refractory extranodal NK/T-cell lymphoma, nasal type (J Clin Oncol 2011; 29: 4410-6). Because of the many similarities in extranodal NK/T-cell lymphoma, nasal type and peripheral T-cell lymphoma (PTCL), the SMILE regimen was applied for PTCL.
Aims: The aim of this study is to examine the efficacy and safety of SMILE regimen for relapsed/refractory PTCL.
Methods: The phase II study of SMILE for PTCL was carried out according to the Simon's two-stage design. Patients with relapsed or refractory PTCL after first-line chemotherapy, aged 15-69 years old, and with a performance status of 0-2 were eligible. Eight subtypes of PTCL were subjected, comprising PTCL, not otherwise specified (PTCL-NOS), angioimmunoblastic T-cell lymphoma (AITL), ALK-positive and -negative anaplastic large cell lymphoma (ALCL), hepatosplenic T-cell lymphoma, enteropathy-associate T-cell lymphoma (EATL), primary cutaneous gamma-delta T-cell lymphoma (PCGDTL), and primary cutaneous CD8+aggressive epidermotropic cytotoxic T-cell lymphoma. The primary endpoint was overall response rate (ORR) after 2 cycles of SMILE chemotherapy.
Results: From November 2009 to February 2014, a total of 42 patients were enrolled. The median age was 56 years (range, 28 to 69 years), and the male:female ratio was 33:9. The diagnosis was PTCL-NOS in 19, AITL in 14, ALK-positive ALCL in 1, ALK-negative ALCL in 4, EATL in 3, and PCGDTL in 1. Twenty-six were relapsed PTCL, and 16 were refractory to initial treatment with anthracycline-containing regimen. Complete and partial response was achieved in 6 and 13 patients, respectively, with an ORR of 48% (90% confidence interval, 34-62%). The response was stable disease in 6, progressive disease in 15, but was not evaluable in 2. The ORR was 64% (90% confidence interval, 46-80%) for relapsed PTCLs, but was 27% (90% confidence interval, 10-51%) for relapsed patients, and the difference was statistically significant (P=0.048). One patient died of sepsis and another patient died of disease in the treatment period.
Summary and Conclusions: These results indicate that SMILE regimen is effective for relapsed or refractory PTCL. The efficacy was lower than that for extranodal NK/T-cell lymphoma, but the present T-SMILE study included more relapsed patients. Further follow-up defined in the protocol is required to determine the duration of response and long-term efficacy.

E1005

GASTROINTESTINAL TRACT POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER (PTLD) AFTER KIDNEY TRANSPLANT: A 17-YEAR BRAZILIAN SINGLE-CENTRE EXPERIENCE

E.M. Cavalcante[1,*] J. Garibaldi Jr[1], A.M.D. Penna[1], G.F. Perini[1], J.O.M. Pestana[2], O.C.G. Baiocchi[1]
[1]Clinical and Experimental Oncology, UNIFESP - Federal University Of São Paulo, [2]Hospital do Rim e Hipertensão, São Paulo, Brazil

Background: Post-Transplant Lymphoproliferative Disorder (PTLD) is a well recognized complication following both solid organ and allogenic hematopoietic stem cell transplantation. This condition is characterized by the development of lymphoid or plasma cell neoplasms in the setting of post-transplant immunossupression. Epstein-bar virus is considered the most important causative factor, with EBV positivity observed within up 90% of tumor lymphocytes. Gastrointestinal (GI) involvement of PTLD is a relatively common life-threatening condition, usually associated with aggressive presentation and high mortality rates.
Aims: To analyze the cases of PTLD with Gastrointestinal involvement dignosed between 1998 and 2014 on our center.
Methods: From 1998 to 2014, a total of 11,284 kidney transplants were performed at Hospital do Rim e Hipertensão/UNIFESP (Federal University of São Paulo). We retrospectively analyzed cases of PTLD with GI tract involvement diagnosed over the past 17 years. Only confirmed cases of PTLD with available clinical and epidemiological data were included.
Results: PTLD was reported in 94 recipients. GI tract involvement was present in 39% of the cases (37 patients). Two patients were excluded from the analysis due to incomplete data. The median age at diagnoses was 41 (range 4 to 64). The M:F ratio was 1,92:1. The median time from transplant to PTLD was 57 months. Twelve (32%) of our cases received induction therapy either with antithymocyte globuline (ATG) (50%) or Basiliximab (50%) at the time of transplant. The immunossupressive regimen the patients were receiving at the time of diagnosis of PTLD were: Prednisone (100%), azathioprine (88%), tacrolimus (62%), cyclosporine (37%), mycophenolate mofetil (8%) and 1 patient received FTY720. Regarding EBV positivity, 28 patients (76%) were EBV positive, 4 patients (11%) were EBV negative and 5 patients (13%) were not tested or had inconclusive results. Monomorphic PTLD was present in 32 patients (86%), the majority (90%) was diagnosed as diffuse large B-cell non-Hodgkin lymphoma, Polymorphic PTLD corresponded to only 4 cases (11%) and 1 patient could not be classified. Eight (22%) patients had multiple gastrointestinal tract involvement, 11 (31%) patients had only small intestine involvement, followed by 9 (24%) patients with stomach involvement, 8 (22%) with hepatic involvement and 1 patient had esophageal involvement. Seventeen (46%) had concomitant non GI tract extranodal involvement (lung/pleura, CNS, bone marrow, bone, skin and ovaries). After diagnosis, all patients had their immunossupression regimens reduced or suspended. Twenty-eight (76%) patients received anti-CD20 based therapy with 21 (75%) patients receiving R-CHOP, 5 patients (13.5%) did not received chemo/immune therapy, eleven patients (30%) required surgery (gastrectomy or enterectomy) and in 4 (11%) cases surgery was the only treatment. Nineteen (51%) of our patients achieved complete remission (CR). 17 patients (46%) died, most of them (10 patients) from infectious complications, 3 patients due to GI perforation, 2 patients from pulmonary embolism and 2 from undetermined causes. At total, 6 (16%) cases of GI perforation were observed.
Summary and Conclusions: In our population, GI tract was the most common PTLD involved site. EBV was positive in the majority of cases. Although 19 patients achieved CR, a high number of deaths were observed, mostly due to infection. This unique condition should be considered in every transplant recipient presenting with abdominal symptoms.

E1006

THE ROLE OF UPFRONT AUTOLOGOUS STEM CELL TRANSPLANTATION FOR HIGH-RISK PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

H. Cho[1,*] S.J. Kim[1], H. Park[1], J.Y. Lee[1], J.E. Jang[1], Y. Kim[1], J.W. Cheong[1], Y.H. Min[1], J.S. Kim[1]
[1]Severance Hospital, Seoul, Korea, Republic Of

Background: Primary central nervous system lymphoma (PCNSL) is an aggressive extranodal non-Hodgkin lymphoma. The patients with International Extranodal Lymphoma Study Group (IELSG) score of more than one or those who did not achieve complete remission (CR) after two courses of high-dose methotrexate (HD-MTX)-based chemotherapy (non-CR1) have been shown inferior treatment outcomes. Upfront autologous stem cell transplantation (ASCT) as consolidation after HD-MTX-based chemotherapy has shown better efficacy compared to whole brain radiotherapy consolidation.
Aims: To investigate the role of upfront ASCT for high-risk PCNSL patients
Methods: We retrospectively analyzed a total of 66 newly diagnosed high-risk PCNSL patients between February 2003 and December 2014 in Severance Hospital. Patients who were younger than 65 years of age with IELSG score ≥2 (n=56) and/or non-CR1 (n=37) were included in this study. All the patients (n=66) were HIV negative, received HD-MTX-based chemotherapy as initial treatment and achieved at least partial response (PR) after initial treatment.
Results: The median age at diagnosis was 52 (range 21-64) years and 43 (65.2%) patients were male. Median follow-up for surviving patients was 22 (range 2-123) months. The upfront ASCT group included more patients aged 50 or less (68.4% vs. 31.9%, *P*=0.007). Nineteen (28.8%) patients have received upfront ASCT, and all of them received busulfan-based conditioning regimens including busulfan plus thiotepa (n=18). The disease status at the

time of upfront ASCT was CR in 17 (89.5%) patients and PR in 2 (10.5%) patients. Transplant-related mortality occurred in 1 (5.3%) patient after upfront ASCT. In non-upfront ASCT group (n=47), 28 (59.6%) patients achieved CR after completion of therapy and 16 (34.0%) patients received whole-brain radiotherapy as consolidation. Twelve patients in the non-upfront ASCT group underwent ASCT after relapse. Non-upfront ASCT was associated with shorter overall survival (OS) and progression-free survival (PFS) in multivariate analysis (hazard ratio (HR) 8.24; 95% CI 1.31-51.99; *P*=0.025, and HR 4.26; 95% CI 1.49-12.14; *P*=0.007, respectively). The 2-year OS and 2-year PFS of all patients were 65.9% and 39.9%, respectively. The upfront ASCT group showed superior OS and PFS compared to the non-upfront ASCT group (*P*=0.022 and *P*=0.005, respectively). Among the 56 patients with IELSG score ≥2, upfront ASCT was performed in 17 (30.4%) patients and showed survival benefit for OS and PFS (*P*=0.036 and *P*=0.005, respectively). OS and PFS between the upfront and the non-upfront ASCT group also showed similar results in patients with 37 non-CR1 patients (*P*=0.009 and *P*=0.021, respectively).

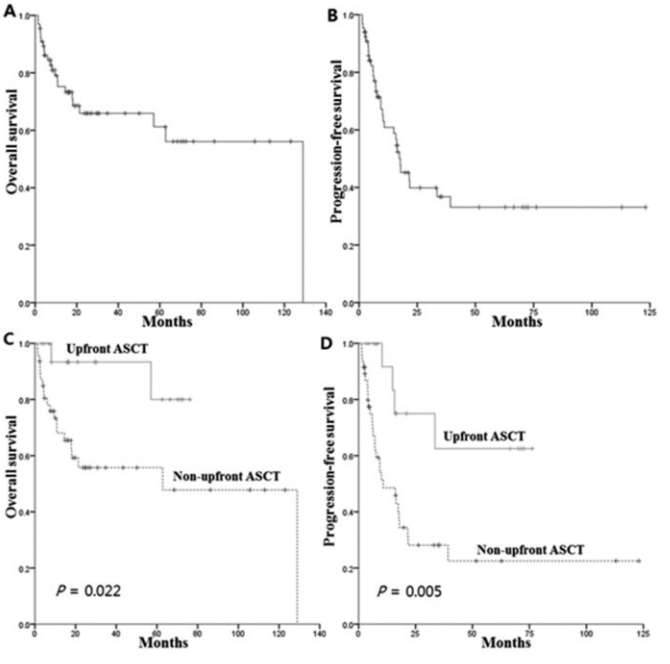

Figure 1.

Summary and Conclusions: Upfront ASCT as consolidation after HD-MTX-based induction chemotherapy in high-risk PCNSL showed better survival results with acceptable toxicities. Upfront ASCT overcomes a negative impact of IELSG score ≥2 and/or non-CR1 in PCNSL.

E1007

FAVORABLE OUTCOME IN PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA IN A SINGLE CENTRE: THE PADUA EXPERIENCE

S. Imbergamo[1,*] A. Visentin[1], S. Bonetto[1], C. Gurrieri[1], F. Piazza[1,2], C. Boso[3], R. Zambello[1,2], G. Semenzato[1,2], L. Trentin[1,2]
[1]Department of Medicine, Hematology and Clinical Immunology Branch, [2]Venetian Institute of Molecular Medicine, Padua, Italy, Padua University School of Medicine, [3]Department of Radiotherapy, Veneto Istitute of Oncology, IOV-IRCCS, Padova, Italy

Background: Primary mediastinal large B-cell lymphoma (PMBCL) is a distinct clinical, pathological and molecular subtype of diffuse large B-cell lymphoma. The optimal management of PMBCL is still unknown, however several retrospective analyses showed an improvement of outcome with dose-intensive chemotherapy regimens and radiotherapy on residual mass.
Aims: In this study we evaluate activity, feasibility and safety of the third generation regimen R-VACOP-B and mediastinal radiotherapy (RT) in the treatment of PMBCL.
Methods: We retrospectively evaluated data from 34 previously untreated patients with PMBCL between September 2002 and January 2014, referred to the Hematology and Clinical Immunology Unit of Padua University Hospital. Patients were treated with R-VACOP-B+RT according to Todeschini G. et al Br J Cancer 2004. Progression free survival (PFS) and Overall survival (OS) were calculated as date of initial presentation to progression (event) or death for any cause (event), respectively, or last known follow-up (censored). Survival analyses were performed by Kaplan-Meier method and Log-rank test to compare survivals. p values <0.05 were considered significant.
Results: Among recruited patients 50% of them were female, the median age at diagnosis was 33 years, 79% had a mediastinal-limited disease, 88% had IPI 0 or 1 and ECOG 0 or 1, and the median follow-up was 69 months. All patients completed the planned 8 cycles R-VACOP-B followed by RT. Treatment was well tolerated; neutropenia G3-4 occurred in 38% of patients, anemia G3-4 in 3% but no piastrinopenia G3-4 was observed. 38% of subject underwent a major infective event. Extrahematological toxicity mainly consisted in transient neuropaty (21%) and catheter related thrombosis (12%). Focusing on late cardiac toxicity, a decrease in left ventricular ejection fraction (EF) was observed in 18% of the cohort but an EF<40% was reported only by 1 patients. Considering pulmonary toxicity 50% of subjects had a slight to moderate reduction of CO diffusion, but none of them developed a life threatening interstitial pneumonia. Finally, hypothiroidism and mammarian nodule was observed in 6% of patients. Interim PET-CT was performed in 23 patients (68%) and for 18 (78%) of them it was negative. Interestingly, all of these 18 subjects achieved a complete remission (CR) at the end of therapy. 14 patients (41%) had partial response at interim analysis, 10 of them covered to CR after the eighth cycle, the remaining 4 developed a relapse-refractory (R/R) disease. The median PFS was not reached during the follow-up and the 5-year PFS and OS were 82% and 100% respectively. 6 patients (18%) had a R/R disease and all progressed within the first 15 months. All these 6 patients were successfully saved by R-DHAP followed by autologous stem cell transplantation. 1 (3%) patient required allogenic bone marrow transplant due to acquired bone marrow failure. All 34 subjects were still alive after 10 years of follow-up. Furthermore, we observed that IPI and staging at diagnosis significantly correlated with PFS (IPI 0-1 *vs* >1, 86% *vs* 50%, p=0.0385 and Stage II *vs* III-IV, 89% *vs* 50%, p=0.0234).
Summary and Conclusions: In this single center retrospective study, R-VACOP-B+RT induced a very-high remission rate with an acceptable toxicity profile. IPI and ECOG correlated with PFS and all patients were still alive after a follow-up of more than 10 years. We provide evidence that R-VACOP-B is a safe and effective radio-chemo-immunotherapeutic protocol for the treatment of patients with PMBCL. In the next future, we will compare R-VACOP-B+RT *vs* R-DAEPOCH.

E1008

HUMAN T-LYMPHOTROPIC VIRUS TYPE I TAX SPECIFIC CYTOTOXIC T-LYMPHOCYTE ANALYSIS OF AGGRESSIVE TYPES OF ADULT T-CELL LEUKEMIA/LYMPHOMA PATIENTS WITH LONG-TERM SURVIVAL AND COMPLETE REMISSION

T. Jo[1,*] K. Horio[1], K. Shigematsu[2]
[1]Hematology, [2]Pathology, Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki, Japan

Background: Adult T-cell leukemia/lymphoma (ATLL) is a peripheral T-cell malignancy caused by human T-lymphotropic virus type I (HTLV-I). Most ATLL cells are CD4 and CCR4 positive, and CD8 negative. ATLL is classified into 4 clinical subtypes: smoldering, chronic, acute, and lymphoma. Acute and lymphoma type ATLLs, which are aggressive types, have a very poor prognosis.
Aims: We report here the extremely interesting results of aggressive ATLL patients with long-term survival and complete remission (CR) after activation of cellular immunity against ATLL cells.

Tabella 1. A summary of HTLV-I tax specific CTL analysis and HTLV-I provirus load in the peripheral blood.

Patient No.	HLA		CTL (%)	HTLV-I provirus (copies/1000 cells)	Mainly used TCR VB (%)
1	A02:01	2012	0.11	35.4	VB3 (71.0)
		2014	0.13	61.9	
2	A02:01	2012	0.78	24.4	VB2 (4.1)
		2014	1.56	14.7	VB8 (6.0)
					VB17 (5.4)
					VB22 (6.8)
3	A02:01	2012	1.06	7.1	VB1 (12.53)
		2014	1.31	13.3	VB3 (7.95)
	A24:02	2012	0.03		
		2014	0.03		
4	A24:02	2012	2.07	26.4	VB17 (12.2)
		2014	3.64	27.9	VB20 (13.5)

Methods: We retrospectively evaluated 46 patients with aggressive ATLLs diagnosed at our hospital between January 2001 and August 2011. Of these, 7 patients had long-term survival greater than 3 years with complete remission (CR) after intensive chemotherapies. Four of these 7 patients had HLA-A02:01

or HLA-A24:02, and were investigated using cytotoxic T-lymphocyte (CTL) analysis. T-cell receptor (TCR) V beta (VB) repertoire and the HTLV-I provirus load in peripheral blood were also analyzed.
Results: The Table summarizes the results. HTLV-I specific CTL analysis and HTLV-I provirus load in the peripheral blood were performed twice, once in 2012 and once in 2014. HTLV-I tax specific CTLs were detected in all 4 patients. Although all patients maintained CR, HTLV-I proviruses were detected in the peripheral blood in all patients. This phenomenon was observed both in 2012 and in 2014. TCR VB repertoire was analyzed using flow cytometry in January 2015. Clonal dominance was present in all patients. In particular, HTLV-I tax specific CTL expressing VB3 was found in a high percentage (71%) in Patient No. 1.
Summary and Conclusions: The findings from this study suggest that HTLV-I specific CTLs can be induced with clonal dominance in patients with aggressive types of ATLL. In patients having long survival with CR, these CTLs can contribute to treatment and may play a roll inhibiting the relapse of ATLL. The development of efficacious methods to induce HTLV-I specific CTLs in individual ATLL patients may leads to improved outcomes for aggressive types of ATLL.

E1009

PROPHYLACTIC USE OF ACETAZOLAMIDE REDUCES WEIGHT GAIN AND AMELIORATES RENAL COMPLICATIONS ASSOCIATED WITH HIGH DOSE METHOTREXATE

M. Ku[1,*] A. Bazargan[1], S. O'Connor[2], C. Tam[1,3,4]
[1]Haematology, [2]Pharmacy, St Vincent's Hospital, Fitzroy, [3]Haematology, Peter MacCallum Cancer Centre, East Melbourne, [4]Medicine, University of Melbourne, Parkville, Australia

Background: High dose methotrexate (HDMTx) is an effective drug in the treatment of lymphoid malignancies such as CNS lymphoma, especially combined with high dose cytarabine or radiotherapy. Adequate MTx levels in the CSF require rapid infusion, with 2 - 4 hours deemed the optimal duration. HDMTx toxicities include mucositis, hepatotoxicity, renal impairment and myelosuppression. HDMTx-induced acute kidney injury (HDMTx-AKI) is a rare complication; it can range from asymptomatic serum creatinine (Cr) rise to life-threatening AKI. HDMTx-AKI can increase the risk of other MTx related toxicities, and cause a reduction of the optimal MTx dose administered. HDMTx-AKI is attributed to tubular obstruction due to precipitation of MTx and its metabolite (crystal nephropathy), which may be exacerbated by acidic urinary pH and hypovolemia. Acetazolamide (AZL) is a carbonic anhydrase inhibitor in the renal proximal convoluted tubule. It causes increased bicarbonate excretion and therefore urine alkalinization. Shamash et al found AZL 500 mg QID effectively alkalinized urine in patients treated with HDMTx, with satisfactory plasma MTx elimination. Prophylactic intravenous fluids are also essential in preventing HDMTx-AKI, and hence fluid overload is a common complication of HDMTx therapy.
Aims: We conducted a dual centre, retrospective cohort study examining AZL's renoprotection effect in patients receiving HDMTx for haematological malignancies. Parameters examined included AKI incidence, days of elimination and urinary pH. Since 2010, the use of prophylactic AZL was recommended for patients undergoing HDMTx therapy at our institutions.

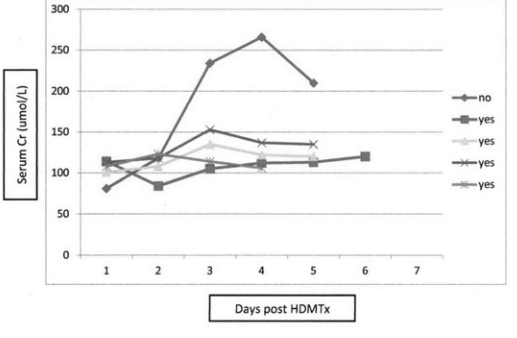

Fig 1. A graph of a patient's serial serum creatinine (Cr) in 4 cycles of HDMTx is shown, depicting much higher serum Cr without acetazolamide (blue line) versus serum Cr levels with acetazolamide in subsequent cycles.

X axis - days post HDMTx
Y axis - serum Cr levels (umol/L)

Figure 1.

Methods: Data of patients who had HDMTx from 2007 to 2012 was analysed. In total, 92 patients were given HDMTx, resulting in 256 cycles. The AZL group (250mg q8h) and non-AZL group were comparable in the majority of variables that could have impacted on the incidence of HDMTx-AKI. The primary endpoint was AKI (Cr>100umol/L) or prolonged MTx elimination (>5 days).
Results: 1. AZL showed a strong trend in preventing either AKI (Cr>100umol/L) or prolonged MTx elimination (>5 days). a) AKI or MTx elimination>5 days occurred in 24/164 (14.6%) of the non AZL group, versus 4/68 (5.9%) of the AZL group, p=0.063. There is a strong trend that AZL use reduced renal complications. A graph of a patient's serial Cr in 4 cycles of HDMTx is shown (Fig 1), depicting much higher Cr without AZL versus Cr levels with AZL. b) HDMTx induced AKI was correlated with increased days of elimination (mean 6.5 days for AKI versus 4.0 days for non AKI, p=0.001). c) AZL benefit on HDMTx-AKI or prolonged MTx elimination was more obvious in males, who were more prone to these effects. In the non AZL group, 4/64 (6.3%) females had either AKI or prolonged MTx elimination, versus 20/100 (20%) males, p=0.015. AZL abolished this gender disadvantage, with 2/29 (6.9%) females versus 2/39 (5.1%) males, p=0.759. 2. AZL use resulted in significantly less weight gain and less acidic urinary pH (pH<7) and was tolerated well a) weight gain - median weight gain of 3.0kg (range 0 - 13, n=151) in the non AZL group, compared to 1.0kg (0 - 6, n=85) in the AZL group, Mann-Whitney p<0.001. b) urine pH <7.0 - 40/166 (24.1%) in the non AZL group had at least one episode of urinary pH<7, versus 10/86 (11.6%) in the AZL group, Chi-square p=0.029. c) AZL was well tolerated, with mild hypokalaemia being the only common complication (48.5% of AZL group). This was preventable by prophylactic oral potassium use.
Summary and Conclusions: This retrospective, dual centred cohort study examined AZL's renoprotection effect during HDMTx. AZL showed a strong trend in preventing either AKI or prolonged MTx elimination, especially in males, who appeared to be at higher risk. A larger patient sample is required to confirm the significance of this finding. AZL use also resulted in significantly less weight gain and less acidic urinary pH (pH<7) during HDMTx; these factors could influence patient management and length of hospital stay. In summary, this study demonstrated that AZL could be used as an adjunct renoprotective treatment in HDMTx regimens.

E1010

CD30 EXPRESSION IN DLBCL, INCIDENCE AND PROGNOSIS VALUE: A SINGLE-INSTITUTION EXPERIENCE

L. García-Sanchis[1,*] C. Martinez-Ciarpanglini[2], A. Ferrández[2], A. Teruel[1], J.L. Piñana[1], C. Solano[1], M.J. Terol[1]
[1]Hemathology, [2]Pathology, Hospital Clinico de Valencia, Valencia, Spain

Background: DLBCL is the most common subtype of NHL, with R-CHOP, the standard of treatment, we obtain CR and 5 years PFS in more than 50% of patients. It has been identified biological markers with impact on the outcome of these patients. CD30 is a cell-surface marker expressed by several types of NHL, including a subset of DLBCL (±15%). A better outcome has been suggested for CD30 positive patients.
Aims: The aim of this study is to analyze the incidence of CD30 in DLBCL and to evaluate the prognostic impact and the possible correlation with clinical and biological characteristics.
Methods: We carried out a single institution study with DLBCL samples from patients diagnosed in the period 1994-2011 and treated with chemotherapy or R-chemotherapy. DLBCL diagnosis was reconfirmed. Tissue fixation and processing were performed using standard methods. Tissue microarrays (TMAs) that contained two representative 2-mm cores from each tumor were prepared. Internal control cores were present in each TMA. Immunohistochemical stainings were performed using fully automated protocols. Sections were subjected to staining protocols with the antibody CD 30(Dako). CD30 expression was evaluated by an anatomopathologist and a hematologist and was considered positive 20% and above. CD30 expresion was also evaluated using computerized image analysis with Image Pro Plus 6.0. A mean number of 1000 cells were evaluated per case. Both readings were compared and scoring discrepancies (differences >10%) were resolved using a multi-head microscope. Correlation with clinical and biological characteristics were analyzed with chi-square test and OS and PFS with kaplan Meier (SPSS19). This study has been approved by local ethic committee.
Results: Samples from 140 DLBCL patients (95/45pt R-chemo/chemo) were analyzed, median age 70 (23-76), male/female 73/67pt, Ann Arbor stage III or IV: 73pt (52%), high LDH 72pt (51%), high β2-microglobullin 62pt (44%) IPI low 53 pt, int-low 26pt (19%), int-high 31pt (23%), high 28pt (20%) IPI ≥3: 59pt (42.1%). All patients ORR 79pt (58%), CRR 53pt (39%). We observed CD30 overexpressed (>20%) in 14pt (10%). In univariate analysis patients with CD30 overexpression had better CRR, 91% versus 68% (p0.08). CD30 also appears to predict a better outcome, OS p 0.1 and PFS p0.1. We didn't observed correlation between CD30 overexpression and clinical baseline characteristics.
Summary and Conclusions: In our experience the incidence of CD30 expression seems lower than the previous reported (10% versus 15%), these CD30 positive patients have a higher CRR, better OS and better PFS.

E1011

PROPOSAL OF NEW PROGNOSTIC INDEX FOR PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN THE RITUXIMAB ERA

S. Yoon[1,*] D.H. Yoon[1], S. Kim[1], K. Lee[1], E.H. Kang[1], S.W. Lee[2], C.J. Park[3], C.S. Park[4], J. Huh[4], C. Suh[1]
[1]Department of Oncology, [2]Department of Radiation Oncology, [3]Department

of Laboratory Medicine, [4]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: The International Prognostic Index (IPI) has been useful prognostic tool to predict prognosis of aggressive non-Hodgkin lymphoma in the last 20 years. Since the advent of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone) chemotherapy for diffuse large B-cell lymphoma (DLBCL), its utility has been challenged and other prognostic index including revised IPI and National Comprehensive Cancer Network (NCCN)-IPI were proposed, which are not popularly used yet.
Aims: We aimed to develop new prognostic model for DLBCL in rituximab era.
Methods: Between March 2004 and June 2012, patients with DLBCL treated with R-CHOP were identified in the database of the Asan Medical Center (AMC) Lymphoma Registry. Primary end point was to devise a new prognostic index for DLBCL. Secondary end point was to validate the NCCN-IPI in our cohort. We tested new prognostic index model in the training set of AMC cohort consisted of randomly selected 80% of the sample (503 patients). The remaining 20% (118 patients) was used as an internal validation set.
Results: The AMC cohort consisted of 621 patients. Median follow-up duration was 43.3 months (6.2-122.5 months). Median age was 57 years (range, 16-85 years). Median β-2 microglobulin (β-2 MG) was 2.10 mg/L (range, 1.0-66.0 mg/L). The univariate analysis of baseline characteristics revealed that age (≤60 vs. >60 years), LDH (within normal vs. increased), ECOG performance (0 or 1 vs. ≥2), advanced stage (Ann Arbor stage I/II vs. III/IV), extra-nodal involvement (≤1 vs. >1), B symptoms (no vs. yes), and β-2 MG (≤2.5 vs. >2.5) could predict overall survival (OS), whereas bulky disease and gender did not (p value 0.140, 0.621, respectively). In the multivariate analysis, age, LDH, ECOG performance status, and β-2 MG were significantly associated with OS (p value 0.001, <0.001, 0.004, and 0.019, respectively), while stage, extra-nodal involvement, and B symptom did not (p value 0.057, 0.233, and 0.577, respectively). We developed a new prognostic model with these 4 significant factors in the multivariate analysis. One point is assigned for each of the risk factors without refined categorization. Four risk groups were composed as followings: low (0 point), low-intermediate (1 point), high-intermediate (2-3 points), and high (4 points). The new prognostic model showed better discriminative power compared with classic IPI (Figure 1A). Five-year OS of low- and high-risk subgroup in new scoring model and classic IPI model in AMC cohort were 95% and 32% versus 89% and 45%, respectively. Our model was validated in an internal validation set (Figure 1B). NCCN-IPI also could stratify four risk groups (Figure 1 A and B).

Figure 1. IPI versus NCCN IPI versus new prognostic index model

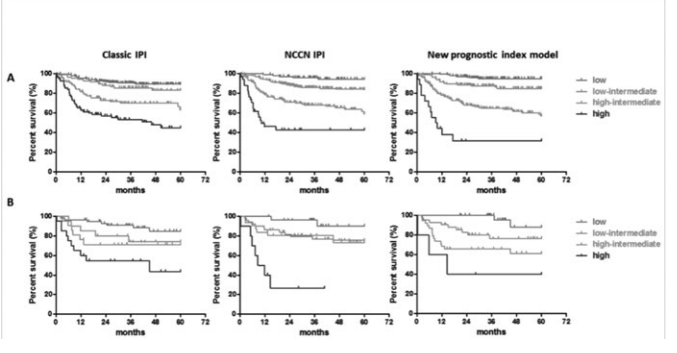

Figure 1.

Summary and Conclusions: We propose a new prognostic index model for DLBCL in rituximab era with age, LDH, ECOG performance and β-2 MG, which has good discriminative power and convenient to apply. It warrants further validation using an independent cohort.

E1012

AN INVESTIGATION OF RADIATION THERAPY FOR DLBCL AFTER CHEMOTHERAPY FOR ACHIEVING COMPLETE REMISSION: A SINGLE INSTITUTION EXPERIENCE

A. Ouchi[1,*] M. Yokoyama[2], M. Oguchi[3], K. Takeuchi[4], Y. Kusano[2], H. Nitta[2], K. Ueda[2], N. Nishimura[2], N. Tsuyama[4], Y. Terui[2], N. Usui[1], K. Aiba[1], K. Hatake[2]
[1]Department of oncology and hematology, Jikei university school of medicine, [2]Department of hematology and oncology, [3]Department of radiation oncology, Cancer institute hospital, [4]Department of pathology, Japanese foundation of cancer research, Tokyo, Japan

Background: Radiation therapy (RT) for localized- refractory or -relapsed diffuse large B cell lymphoma (DLBCL) after chemotherapy is a sort of standard therapy. Some cases can achieve complete remission (CR) after RT for local residual disease, but others cannot. If we can distinguish more radioactive DLBCL from radio-resistant DLBCL in advance, more appropriate care could be possible.
Aims: To clarify which cohorts of patients (pts.) are more radiosensitive and which cohorts aren't.
Methods: We analyzed DLBCL receiving RT on the purpose of achieving remission after chemotherapy at Cancer Institute Hospital from October 2005 to January 2014. All pts.' histopathology samples were reviewed by expert hematopathologists, according to the WHO classification. All 3-dementional conformal RT were planned by an expert lymphoma radiation oncologist.
Results: A total of 180 pts. were included in this study. Baseline pts.' characteristics were as follows; a median age of 65.2 years (range, 17.3-88.1 years), 105 male and 75 female. We classified them into four categories; 87 pts. (48.3%) received RT as an adjuvant therapy after CR by R-CHOP therapy, 43 pts. (23.9%) received RT after partial metabolic response (PMR) at positron emission tomography-computed tomography (PET-CT)-based response of the Lugano classification by R-CHOP therapy, 38 pts. (21.1%) received RT for no metabolic response (NMR) at the PET-CT-based response by R-CHOP therapy, and 12 pts. (6.7%) received for progressive metabolic disease (PMD) after previous chemotherapy. The median dose of RT for CR settings was 30.6Gy (range, 16.2-45.0Gy), for PMR setting was 40.0Gy (range, 30.0-54.0Gy), and for NMR/PMD were 40.0Gy (range, 20.0Gy-50.4Gy). Disease progression rates within RT field were 0% of CR group, 2.3% (5 pts.) of PMR group, 43.2% (13 pts.) of NMR group, and 16.7% (2pts.) of PMD group. Disease progression outside of the radiation fields were 5.8% (5 pts.) of CR group, 11.6% (5 pts.) of PMR group, 50% (19 pts.) of NMR group, and 83.3% (10pts.) of PMD group. There was no treatment related mortality during RT. At a median follow-up time of 48.2 months (range, 6.5-78.8), the 2 year progression free survival (PFS) after RT and overall survival (OS) rates of all the pts. are 75.9%, 83.0%, respectively. In CR group, PFS and OS were 95.1%, 96.4%, in PMR group, 89.9%, 90.4%, in NMR group, 37.3%, 47.5%, and in PMD group, 16.7%, 72.7%, respectively.
Summary and Conclusions: RT as an adjuvant therapy resulted in a good prognosis as previously reported in the literature. RT for PMR after chemotherapy also resulted in a good prognosis. However, RT for NMR and PMD after previous chemotherapy showed poor prognosis and also revealed high rates of disease progression outside the RT field, suggesting the limitation of localized treatment for DLBCL. Because RT causes few severe adverse events, it is tolerable even for elderly people and pts. with long history of chemotherapy. Though such an advantage, it might be desirable for DLBCL of NMR and PMD after chemotherapy to treat with a systematic therapy if their health conditions allow for achieving remission.

E1013

UNDERWEIGHT AND LOW BODY SURFACE AREAS FOR CHEMOTHERAPY DOSING ARE ASSOCIATED WITH INFERIOR SURVIVAL IN MALE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A STUDY OF 658 R-CHOP TREATED PATIENTS

P. Svenssen Munksgaard[1,*] M. Tang Severinsen[1], E. Bekric[2], C. Brieghel Mortensen[3], K. Buchardi Jensen[4], M. Bøgsted[5], M. Dahl Bendtsen[5], T. Christoffer El-Galaly[1]
[1]Department of hematology, Aalborg University Hospital, Aalborg, [2]Department of hematology, Odense University Hospital, Odense, [3]Department of hematology, Copenhagen University Hospital, Copenhagen, [4]Department of hematology, Holstebro Hospital, Holstebro, [5]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark

Background: Chemotherapeutic drugs are usually dosed according to patient weight or body surface area (BSA). Therefore, anthropometrics may influence survival in patients with diffuse large B-cell lymphoma (DLBCL).
Aims: To examine the impact of body mass index (BMI) and BSA on overall survival (OS) in DLBCL patients.
Methods: This retrospective study included adult patients with newly diagnosed DLBCL seen at the hematology centers of Aalborg (2003-2010), Holstebro (2006-2012), Odense (2006-2012), and Copenhagen (Rigshospitalet, 2010-2012). All patients had been treated with R-CHOP/CHOP-like regimens. Patient lists were obtained from the Danish Lymphoma registry (LYFO). All medical records were reviewed for information about weight and height at diagnosis, disease-related weight loss (≤5kg, >5kg), and BSA values used for chemotherapy dosing. Patients were grouped according to the WHO defined BMI categories for underweight (<18.5), normal weight (≥18.5, <25), overweight (≥25, <30) and obesity (≥30). The 3-year overall survival (OS) fractions were estimated using the Kaplan-Meier method. Cox regression analyses were used to assess the prognostic impact of BMI and BSA.
Results: A total of 658 DLBCL patients were included in the present study. The median age was 67 years (range 16-95 years) and the male:female ratio was 1.3. Patients with full international prognostic index (IPI) scores (n=615) were categorized as low-risk (27%), low-intermediate (26%), intermediate-high (27%) and high-risk (20%). By the time of first chemotherapy, 4% of the patients were underweight, 46% were normal weight, 34% were overweight, and 16% were obese. BSA values used for chemotherapy dosing were <1.8 m^2, 1.8-2.0 m^2, and >2,0 m^2 in 36%, 31%, and 33% of the patients, respectively. The used BSA value was not reported in five patients. The Table shows the prognostic impact of BMI and BSA on OS. There were no significant differences in the

BMI-specific 3-year OS estimates with the exception of inferior OS for underweight patients vs. overweight patients. In the sex-stratified analyses, underweight was associated with a higher risk of death in male patients, but not in female patients. BSA values between >1.8 m^2were associated with a better OS for male patients, but only BSA values ≥2.0 m^2 retained significance in multivariate analysis.

Tabella 1.

	3-year OS (95% CI)			Crude HR (95% CI)		Adjusted HR (95% CI)*	
	All	Men	Women	Men	Women	Men	Women
Normal weight	70% (64-75)	67% (59-75)	72% (63-79)	1 (ref)	1 (ref)	1 (ref)	1 (ref)
Underweight	57% (37-73)	33% (5-68)	63% (40-80)	3.85 (1.39-10.70)	1.50 (0.70-3.23)	5.67 (1.96-16.39)	1.86 (0.80-4.28)
Overweight	74% (67-79)	74% (66-81)	73% (61-82)	0.85 (0.55-1.31)	0.99 (0.58-1.70)	0.80 (0.49-1.28)	1.33 (0.73-2.43)
Obesity	69% (59-77)	67% (53-78)	72% (55-83)	1.02 (0.59-1.76)	1.02 (0.53-1.97)	1.29 (0.71-2.34)	1.15 (0.54-2.45)
BSA<1.8 m^2	66% (59-72)	52% (36-66)	70% (62-76)	1 (ref)	1 (ref)	1 (ref)	1 (ref)
BSA ≥1.8, <2.0 m^2	73% (66-79)	72% (63-79)	76% (64-84)	0.50 (0.29-0.86)	0.76 (0.44-1.29)	0.60 (0.33-1.08)	1.05 (0.58-1.90)
BSA ≥2.0 m^2	72% (65-78)	72% (65-78)	66% (34-85)	0.46 (0.28-0.77)	0.83 (0.33-2.09)	0.55 (0.32-0.96)	0.77 (0.24-2.50)

*Adjustment for IPI risk groups and weight loss>5 kg. HR=hazard ratio

Summary and Conclusions: Consistent with previous reports, being underweight at the time of diagnosis was associated with an inferior survival in male DLBCL patients. Lower BSA values were also associated with a worse outcome in male patients, which highlights the ongoing discussion of a possible inadequate dosing of immunochemotherapy in these patients.

E1014

18-F FDG PET/CT VERSUS BONE MARROW BIOPSY FOR ASSESSMENT BONE MARROW INVOLVEMENT IN PATIENTS WITH NON-HODGKIN LYMPHOMA

D. Vassileva[1,*] B. Spassov[2], J. Dimitrov[3], M. Guenova[3], S. Toshkov[4]
[1]Laboratory of Nuclear Medicine, [2]Department of Clinical Hematology, [3]Laboratory of Hematopathology and Immunology, [4]Laboratory of Cytogenetics and Molecular Biology, National Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: Bone marrow involvement is an important parameter that affects the stage, prognosis and management of lymphoma patients. Bone marrow involvement in patients with non-Hodgkin lymphoma (NHL) shows extensive stage of the disease. The bone marrow biopsy (BMB) is the method of choice for the detection of bone marrow infiltration, despite its technical limitations. BMB may demonstrate high false negative results. In last years 18-F FDG PET/CT imaging has become a very useful technique for diagnosis, staging and therapy control in NHL patients.
Aims: To evaluate the value of 18-F FDG PET/CT and its concordance with BMB in determining the bone marrow involvement in patients with NHL.
Methods: Data from 70 patients (39 men and 31 women), aged 21- 69 years, with histologically verified non-Hodgkin lymphoma were analyzed retrospectively. All the patients were investigated by 18-F FDG PET/CT, according to the accepted protocol. Iliac crest BMB was performed according to standard procedure. The 18-F FDG PET/CT results were compared with the BMB results in order to evaluate the bone marrow involvement.
Results: Both 18-F FDG PET/CT and BMB were negative in 52 (74%) patients. In 18 patients (26%) 18-F FDG PET/CT was positive for bone marrow infiltration. The focal and diffuse bone marrow involvement was detected in 13 and 5 patients respectively. Of the eighteen 18-F FDG PET/CT positive patients, both methods gave concordant data in 5 (28%) patients. Thirteen patients of the 18-F FDG PET/CT positive patients showed a negative BMB. These patients had multifocal 18-F FDG uptake but excluding the iliac crest biopsy site.
Summary and Conclusions: 18-F FDG PET/CT has a complementary role with BMB for the detection of bone marrow involvement in patients with non-Hodgkin lymphoma, especially in the focal bone marrow infiltration. 18-F FDG PET/CT positive results may change the treatment in patients with negative BMB.

E1015

INTRAPLEURAL RITUXIMAB FOR THE TREATMENT OF MALIGNANT PLEURAL EFFUSION DUE TO CD20-POSITIVE LYMPHOMA

M. F. Law[1,*]H. N. Chan[2]H. K. Lai[2]C. Y. Ha[2]C. Ng[2]Y. M. Yeung[2]S. F. Yip[2]
[1]Medicine, Prince of Wales Hospital, Shatin, [2]Medicine, Tuen Mun Hospital, Tuen Mun, Hong Kong

Background: Pleural effusion due to lymphoma can be massive and resistant to chemotherapy treatment. When systemic therapy fails, local therapy has to be considered. Rituximab was proven effective for the treatment of CD20-positive B cell lymphoma when given intravenously. The intrapleural route of administration was not explored. The intrapleural route might allow achievement of a high enough concentration of the antibody for lymphoma cell killing in the pleural cavity.
Aims: We assess the use of intrapleural rituximab in controlling malignant pleural effusion due to CD20-positive lymphoma.
Methods: Patients with malignant pleural effusion due to lymphoma were identified. Immunophenotyping study of the pleural fluid was performed to confirm CD20 positivity. They were given systemic chemotherapy and pleural tapping. Those with persistent pleural effusion were recruited and given intrapleural rituximab. Rituximab (50-100mg in 50ml saline as a bolus) was given intrapleurally and the chest tube was clamped for two hours and then released.
Results: Two patients with refractory pleural effusion were given intrapleural rituximab. The first patient was a 61-year-old man with stage IV mantle cell lymphoma. There was bone marrow and pleural involvement by lymphoma with massive left pleural effusion. Immunophenotyping study of the pleural fluid showed malignant B cell (CD20+) involvement. He was given two cycles of standard R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine and prednisolone) chemotherapy three weeks apart but the pleural effusion persisted. At the third cycle of chemotherapy, rituximab (100mg in 50ml saline as a bolus) was added and given intrapleurally. Repeat chest X-ray on day two showed resolving pleural effusion. There was no untoward side effect. After the fourth cycle of R-CHOP, the patient had lymphoma progression with central nervous system involvement. Further salvage chemotherapy including high dose methotrexate and cytarabine was given. The lymphoma did not respond to salvage chemotherapy. Despite this, there was no recurrence of the pleural effusion. The second patient was a 44-year-old man suffering from marginal zone B-cell lymphoma. He presented with extensive lymphadenopathy and left massive pleural effusion. Immunophenotyping study of the pleural fluid also confirmed malignant B cell (CD20+) involvement. Two cycles of R-CHOP chemotherapy at standard dosing was given but there was persistent massive effusion that required repeated chest drainage. Rituximab (50mg in 50ml saline as a bolus) was then administered intrapleurally together with the first day of intravenous chemotherapy and rituximab at the third cycle of chemotherapy. Two more doses of rituximab (100mg in 50ml saline) were given intrapleurally three weeks apart in subsequent cycles. The patient tolerated the intrapleural rituximab and the effusion subsided gradually.
Summary and Conclusions: Intrapleural rituximab has an adjuvant role in the control of malignant pleural effusion due to CD20-positive lymphoma. Our patients demonstrated a good response to rituximab given through this route, with resolution of the effusion. This route of administration was well tolerated. It is worthwhile exploring further this novel route of administration.

Bleeding disorders (congenital and acquired)

E1016

LOCALLY ADMINISTERED HAEMOSTATIC DRUG TREATMENT OF DIFFUSE LIFE-THREATENING PULMONARY BLEEDS, REFINING TECHNICAL APPROACH

A. Selmeczi[1,*] A. Szücs[2], M. Udvardy[1]
[1]Department of Haematology, [2]Intensive care Unit, Debrecen Medical University, Debrecen, Hungary

Background: Fulminant diffuse, critically severe pulmonary bleedings, particularly diffuse alveolar haemorrhage (DAH) might be treated with iv. recombinant Factor VIIa (rFVIIa) and quickly stopped by intratracheal application of suitable sized haemostatic compounds, including rFVIIa (Orphan Drug Status in DAH: Europe, UK and FDA).
Aims: DAH is well known, sometimes critically severe complication of bone marrow (or organ) transplantation and might also be the consequence of systemic pulmonary vasculitis. There is limited, anecdotic experience on intrapulmonary rFVIIa administration, which had been summarised by Hesley, 2012 (Biologics 6:37). Intratracheal rFVIIa might powerfully stop DAH bleeding, without unwanted systemic coagulatory effects. However, the optimal dose, applied volume, way of application is far from being elucidated. Limited data are available on systemic or intrapulmonary tranexamic acid in DAH. Our aim was first of all stop life-threatening DAH bleeds, and try to improve our skills in intrapulmonary haemostatic drug delivery (timing, combinations and sequence).
Methods: Three fulminant DAH cases will be presented on the poster. All three cases received intrapulmonary rFVIIa and or tranexamic acid first iv, but due to refractoriness locally, by bronchoscopy or inhalation or both. The dose of intrapulmonary rFVIIa was 50 ug/kg and tranexamic acid was applied as 500 mg in 5 ml. Bronchoscopic administration was followed, if needed by a second inhalatory administration one day later. The control of bleeding was assessed by bronchoscopic lavage, and measuring respiratory parameters, along with haemodynamics and haemostasis monitoring.
Results: Pulmonary bleeding was stopped or significantly decreased in all of our cases, within a few minutes. The most complex and relapsing case was a young male patient, in whom DAH developed following autologous bone marrow transplantation therapy of AL amyloidosis. His fulminant DAH needed complex systemic therapy including repeated iv 40 ug/kg rFVIIa and tranexamic acid, which measures could not stop the progression of DAH. Following that intrapulmonary rFVIIa administration (with quick cessation of bleeding), but later, when restrictive heart failure became even more serious it turned to be refractory and the patient died. In the other two patients (case 2: liver failure with DAH, case 3: DAH following acute leukaemia chemotherapy) intrapulmonary rFVIIa +tranexamic acid proved to be effective quite promptly, achieving durable responses. We used the recommended rFVIIa dosing schedule (50ug/kg), however, we found critical over flood phenomenon if we applied the originally suggested 50 ml volume –divided into the two lungs, so at the end we reduced the volume to 5-10 ml/lung. We did not observe any systemic haemostatic changes or thrombotic events following our intrapulmonary treatments.
Summary and Conclusions: Careful intrapulmonary administration of rFVIIa or probably tranexamic acid is safe and effective way to stop otherwise refractory, massive pulmonary haemorrhage and DAH. This form of treatment is safe, feasible, but needs well trained and instrumented intensive care unit, and should be available and applicable in transplant and larger oncohaematological centres. However, the optimal technique, mode of application, dosage seems to be uncertain, *e.g.* the volume recommended by the literature seemed to be critically oversized. It is not clear weather intrapulmonary administration could be the first approach instead of iv route or not. It would be important to collect and summarise anecdotic experiences, until then each treating unit should develop an own protocol and improve skills.

E1017

THE USE OF PROTHROMBIN COMPLEX CONCENTRATE FOR INDICATIONS OTHER THAN VITAMIN-K ANTAGONIST REVERSAL: AN ALTERNATIVE AND EFFECTIVE MEANS OF CORRECTING ACQUIRED COAGULOPATHIES

M. Scott[1,*] R. Ramsey[2], J. Thachil[3]
[1]Department of Haematology, Central Manchester NHS Foundation Trust, [2]University of Manchester School of Medicine, [3]Central Manchester NHS Foundation Trust, Manchester, United Kingdom

Background: In accordance with a number of national guidelines, prothrombin complex concentrate (PCC) is widely used for the emergency reversal of the anticoagulant effect induced by vitamin-K antagonists. The licenced use also includes the treatment and prophylaxis of bleeding in all situations where there may be an acquired deficiency of coagulation factors. Despite this, fresh frozen plasma (FFP) is preferentially used in these scenarios, partly because of clinician familiarity, but also because of lack of data supporting PCC use in this context.
Aims: To determine the frequency of PCC utilisation at Central Manchester NHS Foundation Trust (CMFT) for indications other than the emergency reversal of vitamin K antagonists; the indications for this use and it's efficacy in terms of correction of routine coagulation parameters.
Methods: Data was collected retrospectively for two 13-month periods, January 1st 2012 – January 31st 2013 and January 1st 2014 – January 31st 2015. Using electronic records held by the CMFT transfusion laboratory, all patients that had been issued PCC during these periods were identified. These records were cross-referenced with electronic request forms and discharge documentation to determine which patients had been anticoagulated with vitamin K antagonists at the time of PCC issue and excluded. Besides laboratory results and demographic information, the following data was collected: Patient sex; coagulopathy aetiology; Liver function test and albumin results; PCC indication; dose issued; pre and post-PCC administration PT and APTT.
Results: A total of 41 patients were identified to have received PCC for indications other than vitamin-K antagonist reversal. This included 20 males and 21 females. The average PCC dose issued was 2463 iu (equivalent to 35iu/kg for a 70kg patient). 18 patients (44.0%) had evidence of significant liver impairment (at least grade A, according to Childs-Pugh classification). All patients had baseline coagulation parameters available; 32 patients (78%) had a repeat measurement within 24 hours of receiving PCC. Of those that had a repeat measurement, the PT and APTT corrected to within 0.5 seconds of the reference range in 34.4% and 4.0% of patients, respectively. With the less stringent target of correction to within 1.5x reference range, the PT and APTT corrected in 75.0% and 71.9%, respectively.
Summary and Conclusions: In comparison to FFP, there are a number of advantages to using PCC to correct coagulation abnormalities. It can be administered rapidly and, relative to FFP, incurs a low volume fluid load. These are issues particular pertinent in the management of critically ill and decompensated patients. Our data suggests that, at therapeutic doses, PCC is effective, correcting routine coagulation parameters to with 1.5x of reference range in the majority of patients. In combination with its clinical advantages, we suggest this data supports wider advocacy of PCC use in acquired coagulopathies.

E1018

VON WILLEBRAND FACTOR DEFICIENCY CORRECTED BY LUNG TRANSPLANTATION.

A. Lario[1,*] R. Forés[1], S. Gil[1], J.L. Campo-Cañaveral[2], D. Gomez-de-Antonio[2], R. Laporta[3], M. Martín[4], G. Anze[1], N. Dorado[1], J.L. Bueno[1], R. Abad[1], C. Fernández[1], A. Vázquez[1], R. Cabrera[1]
[1]Hematology, [2]Thoracic Surgery, [3]Pneumology, Hospital Universitario Puerta de Hierro Majadahonda (Madrid), Majadahonda (Madrid), [4]Hematology, Hospital Universitario La Paz, Madrid, Spain

Background: In experimental models with von Willebrand disease (vWD) pigs, plasma von Willebrand factor (vWF) was significantly increased after lung transplantation because lung endothelial cells strongly express vWF. However these findings have not been confirmed in human beings.
Aims: To confirm that bilateral lung transplantation could correct a mild von Willebrand defect.
Methods: A 26-year-old man, with mild bleeding episodes (epistaxis) and family history (mother with menorrhagia), was diagnosed in November 2012 with type 1 vWD (FvW:Ag 39 IU/dL; FvW:RCo 44 IU/dL; FVIII 99%). The patient was referred to our institution for lung transplantation as a result of cystic fibrosis. The vWF deficiency was confirmed by low levels of vWF and a normal multimeric plasma vWF pattern. Bilateral lung transplantation was performed in April 2013. The mechanical ventilation time was 48 hours and PaO2/FiO2 was 358. Ischemic times were 315 minutes (right lung) and 435 minutes (left lung). *Ex vivo* lung perfusion was performed with Organ Care System (preservation time 120 minutes). FVIII/vWF concentrate was administered both during and after surgery, without any relevant bleeding events. The patient developed primary lung graft dysfunction grade 2 although he was extubated on the second postoperative day with good oxygenation. However he developed progressive lung infiltrates with respiratory failure and extracorporeal membrane oxygenation (ECMO) was administered for 10 days. At hospital discharge in June 2013 he was taking immunosuppression with oral tacrolimus, prednisone and mycophenolate mofetil, which has continued until the present day (+22 months).

Tabella 1.

	APTT (s) (29.2-40.0)	FVIII (%) (60-150)	FvW:Ag (IU/dL) (50-160)	FvW:RCo (IU/dL) (55-140)	PFA 100 COL/EPI (s) (94-193)
At diagnosis		99	39	44	
Month -5	46.6	85	48		158
Day 0 (surgery)	43.3	69	74	Not detected	
Day +2	40.9	169	203	157	
Month +1	38.7	227	206	151	
Month +5	36.9	122	101	89	125
Month +11	40.9	97	111	85	167
Month +14	40.0	95	85	73	174
Month + 22	41.0	123	96	84	103

Results: Plasma vWF level increased during the postoperative days, presumably due to endothelial injuries and the infusion of vWF concentrate. Laboratory

tests post-lung transplantation demonstrated sustained normalization of all parameters.
Summary and Conclusions: In the present case, bilateral lung transplantation resulted in a sustained increase of plasma vWF levels produced by normal lung endothelial cells that corrected the defect. To our knowledge, this is the first case of von Willebrand deficiency corrected through lung transplantation.

E1019

PREDICTING BLEEDING RISK IN PATIENTS ON VITAMIN K ANTAGONISTS TREATMENT.
D. Benlaldj[1,*] A. Kamel[1], M.A. Moueden[1], F. Seghier[1]
[1]Hemobiologie, CHU ORAN, Oran, Algeria

Background: The patients on vitamin k antagonists, anticoagulant treatment (VKA) have a high risk of bleeding which is difficult to evaluate and to predict.
Aims: Assess the bleeding risk in patients on VKA using the ISTH/SSC scoring system. And evaluated the efficiency of the scores: OBRI, HAS-BLED, HEMORR2HAGES and ATRIA in predicting the risk of bleeding.
Methods: We have studied and evaluated the bleeding history of 57 patients on VKA treatment. For each patients we calculate ISTH/SSC, OBRI, HAS-BLED, HEMORR2HAGES and ATRIA score; this score was correlated with biological and clinical data.
Results: 52% of the patients have a low bleeding risk (ISTH average score after VKA treatment: 1.27), 39% of the patients have an intermediate bleeding risk (ISTH average score after VKA treatment: 5.59), and 9% of the patients have a high bleeding risk (ISTH average score after VKA treatment: 9.8). 79% of the patients have a labile INR with a bleeding incidence estimated at 48.1% per year, the incidence become 20% when the INR is not labile, whereas the Major bleeding incidence is estimated at 2.5% per year. The scores: OBRI, HAS-BLED, HEMORR2HAGES and ATRIA; have a low sensibility and specificity (sensibility <41% and specificity between 20% and 50%).
Summary and Conclusions: Good correlation was found between the high score results (ISTH/SSC) and bleeding risk in the patients with Atrial fibrillation on VKA treatment (INR [2-3]). The scores: OBRI, HAS-BLED, HEMORR2HAGES and ATRIA have a limited ability to predict the bleeding risk.

E1020

THE P2Y12 H1 HAPLOTYPE IS ASSOCIATED WITH IMPAIRED ADP INDUCED AGGREGATION IN TWO PATIENTS WITH PLATELET-TYPE BLEEDING DIATHESIS.
G. Soufla[1,*] E. Iliopoulou[1], M. Katafygioti[1], N. Matoula[1], A. Angelidis[1], E. Melissari[1]
[1]Department of Haematology, Blood Transfusion Unit and and Haemostasis, Onassis Cardiac Surgery Center, Athens, Greece

Background: At least two platelet receptors are required for full platelet activation and aggregation in response to ADP: P2Y1 that mediates a rapidly reversible wave of aggregation and P2Y12 that is responsible for slowly progressive and sustained platelet aggregation. Markedly reduced and reversible aggregation in response to (4μM) ADP (≈10%) was observed in two patients free of any antiplatelet treatment with a bleeding diathesis suggesting an underlying molecular defect in P2Y12 receptor.
Aims: To investigate the above patients for molecular defects in the P2Y12 gene.
Methods: DNA & RNA extracted from patients' whole blood were subjected to PCR and RT-PCR respectively, followed by sequencing and real-time PCR.
Results: Both subjects had normal coagulation tests (fibrinogen, prothrombin time and activated partial thromboplastin time), vonWillebrand factor antigen and ristocetin cofactor activity but prolonged bleeding time (≥15min). Patient KG had low platelet count (≈120x10^3/μL). Sequencing analysis of P2Y12 gene revealed patient KG to be heterozygous for a non coding G-to-T transversion (G52T) in exon 2 and an intronic T-to-C transition (i-T744-C). Therefore patient KG carries both H1/H2 P2Y12 haplotypes. Patient DT exhibited no polymorphic variation in these sites or at positions i-ins801A and i-C139T, indicating that the patient carries two H1 alleles (H1/H1). Platelet P2Y12 mRNA, quantified by real-time PCR in both patients, was expressed similarly to healthy blood donors' platelets exhibiting normal aggregation in response to ADP. Sequencing analysis of the P2Y12 cDNA revealed no sequence variations.
Summary and Conclusions: In conclusion, no loss of function mutation or transcriptional defect in the P2Y12 gene has been found in our patients. However, it has been published that the H2 and H1 haplotypes of P2Y12 gene are associated with higher and lower maximal aggregation respectively in response to ADP in healthy subjects. Therefore we can speculate that the presence of the H1 P2Y12 haplotype could be associated with a poor ADP response leading to bleeding diathesis in these subjects.

E1021

PREGNANCY MANAGEMENT IN VON WILLEBRAND'S DISEASE
M. Vinogradova[1,*] T. Fedorova[1], R. Shmakov[2]
[1]transfusiology, [2]obstetrics, Federal State Budget Institution «Research Center for Obstetrics, Gynecology and Perinatology», Moscow, Russian Federation

Background: Pregnancy and childbirth are considered as the situations predisposing to a high risk of bleeding in women with von Willebrand disease (VWD). A clinical vigilance and a treatment if necessary minimize the number of complications during pregnancy and postpartum.
Aims: Establishment of algorithms for a management of pregnancy, delivery and postpartum in VWD is crucial to pregnancy outcomes. We have been optimizing strategies for the management of pregnant patients with VWD.
Methods: Since 2010 we have analyzed 24 pregnancies in 22 women with VWD (previously diagnosed VWD-20, determined during pregnancy-2). VWD Type 1 established in 16 patients, type 2 in 5 patients, type 3 in 1 case. All of them underwent monitoring and a preventive treatment when necessary. The laboratory assessment included complete blood count, activated partial thromboplastin time, prothrombin time, fibrinogen, von Willebrand panel (FVIII, VWF:Ag, VWF:RCo), platelet aggregation studies and thromboelastography. In addition, we examined the newborns to detect VWD.
The preventive treatment administered if analyses revealed hypocoagulation signs or a clotting factor levels reduction. We used DDAVP during pregnancy in type 1 on demand, a clotting factor concentrate (CFC) containing VWF until the levels were above 40-50 IU/dl and a tranexamic acid.
Results: No bleeding events registered during pregnancy. Most women with VWD type 1 developed an increase of clotting factor levels as a physiological response to pregnancy. Only 4 (16,7%) cases required a regular CFC treatment throughout pregnancy, including the patient with VWD type 3 received CFC all observation time. Therapy on demand was performed in 9 (37,5%) cases. The CFC preventive treatment during labour was performed in 8 (33,3%) cases, a postpartum therapy - in 17 (70,8%) cases. Pregnancies resulted in a birth of the full-term newborns in all 24 cases. No spontaneous miscarriage or neonatal mortality has occurred. Caesarean sections were performed in 3 (12,5%) of births. We detected VWD in 9 (37,5%) newborns. Despite the preventive treatment, we observed one intraoperative hemorrhage in the case of placenta previa and non-severe secondary postpartum hemorrhage (PPH) in 3 cases. Close monitoring was conducted over 4-6 weeks postpartum for preventing delay PPH.
Summary and Conclusions: The risk of hemorrhagic complications during pregnancy and postpartum in VWD may be minimized by applying the management algorithm including a preventive treatment. For women with low factor levels the preventive treatment with CFC is necessary. Women with VWD need pregnancy planning, clinical vigilance and observation by multidisciplinary team during pregnancy, puerperium and postpartum.

E1022

EFFICACY AND SAFETY PROFILE OF RIVAROXABAN FOLLOWING HIP AND KNEE ARTHROPLASTY
A. Hua[1], V. Loganathan[1], J. Berger[1], S. Patel[1,*] H. Kurunadalingam[1], S. Deplano[1], M. Vizcaychipi[1]
[1]Chelsea and Westminster NHS Foundation Trust, London, United Kingdom

Background: The incidence of venous thromboembolism (VTE) after hip and knee arthroplasty has been quoted as 1.1% and 0.53% respectively despite thromboprophylaxis. Furthermore, the incidence of myocardial injury after non-cardiac surgery is 8.0%[1]. There is a burden of thromboembolic events in orthopaedic patients during the perioperative period. Rivaroxaban is recommended as thromboprophylaxis following total hip and knee replacement surgery.
Aims: To investigate the efficacy and safety profile of rivaroxaban in patients undergoing hip and knee arthroplasties.
Methods: Patients who underwent total hip or knee replacement surgery between April 2013 and August 2014 were included in the retrospective study, carried out in accordance with the UK Good Clinical Practice. Data regarding patient characteristics and postoperative morbidity were collected using medical records. Patients were followed up with telephone surveys to investigate any bleeding events/adverse effects experienced. Primary efficacy was defined as composite of pulmonary embolism (PE), deep vein thrombosis (DVT), myocardial infarction (MI) and stroke. Safety profile was defined as major or minor bleeding. Data analysis was performed using IBM SPSS statistical software.
Results: 445 patients were included in the study. Preliminary results are presented for a sub-cohort of 99 patients. PE occurred in three (3%) patients, of which one patient died, and is higher compared to other studies[1]. No incidences of DVT, MI or stroke were reported. One major bleeding event and seven minor bleeding events occurred in five patients. The major bleeding event followed a lobectomy and required blood transfusion. Minor bleeding events included epistaxis, wound, gastrointestinal and skin bleeds. There was a statistically significant association between diabetes and PE (p=0.02), and ischaemic heart disease and bleeding events (p=0.04) according to Fisher's exact test.
Summary and Conclusions: Prophylactic management of VTE should be individualised according to patients' risk factors for thrombosis and bleeding. A small percentage of patients experienced bleeding events and strategies for reversal of rivaroxaban remain limited as there is no specific antidote currently available. Future work includes long-term follow up of orthopaedic patients initiated on rivaroxaban and preventative strategies of VTE events.

FACTOR V DEFICIENCY IN WEST OF ALGERIA: SINGLE CENTER EXPERIENCE

M. Mohamed Amine[1,*] B. driss[1], H. wassila[1], S. fatima[1]
[1]Pharmacy Oran, Hemobiology Service, Oran, Algeria

Background: Factor V deficiency is one of the rare inherited bleeding disorders the frequency in world is 1/ 10^6. But in algeria the high consanguinity rates have increased the number of patients with Rare Bleeding Disorders (RBDs)
Aims: -It was established a clinical and biological classification of patients with rare deficiency disorders. It was explored the relationship between coagulation factor activity level and bleeding severity for this patients.
Methods: A retrospective study conduct from 2008 to 2014. It was concerned 63 patients with a mean age 29 years (range1 year to 73 years) and Sex ratio ♂/♀=1.17. We use assigned categories of clinical bleeding severity of The European Network of Rare Bleeding Disorders (EN-RBD): **1. Asymptomatic**: No documented bleeding episodes. **2. Grade I:** bleeding Bleeding that occurred after trauma or drug ingestion (antiplatelet or anticoagulant therapy). **3. Grade II**: bleeding Spontaneous minor bleeding:bruising, ecchymosis, minor wounds, oral cavity bleeding, epistaxis and menorrhagia. **4. Grade III**: bleeding Spontaneous major bleeding: hematomas*, hemarthrosis, central nervous system,gastrointestinal and umbilical cord bleeding.
Results: 15 patients (23.8%) of RBDs were diagnosed with Factor V deficiency, the coagulation factor activity levels that were necessary for patients to remain asymptomatic were: (39.58±13.56) %. Grade 1: (27.50±21) %. Grade 2: 12 %. Clinical bleeding showed that the most common symptoms in patients with FV deficiency were oral cavity bleeding followed by hemarthrosis.
Summary and Conclusions: There was no association between coagulation factor activity level and clinical bleeding severity for FV. R^2=0.143. Results of the literature review suggest that the severity of symptoms is variable and correlates poorly with laboratory phenotype. Platelets provide a concentrated supply of FV: although most FV is present in plasma, approximately 20–25% of the circulating FV is found within platelet a-granules. After a granule release upon platelet activation, FV can presumably bind immediately to surface receptors optimizing prothrombinase complex activity. This probably protects some patients with FV deficiency from severe life-threatening bleeding, and may explain the weak association between laboratory phenotype and clinical severity.

E1024

COMPOUND FACTOR V AND FACTOR VIII DEFICIENCY IN ALGERIA

D. Benlaldj[1,*] M.A. Moueden[1], W. Homane[1], F. Seghier[1]
[1]Hemobiologie, CHU ORAN, Oran, Algeria

Background: The frequency of the compound Factor V and factor VIII deficiency is 1/1000000. The gene is located on chromosome 18. Level factor are variable between 5% and 25%.
Aims: To assess the relationship between factor level and bleeding severity.
Methods: Retrospective study conducted for 7 years (2008 to 2014) in the west of Algeria, 63 patients has been tested for diagnosis of rare bleeding disorder. We use the Assigned categories of clinical bleeding severity of European Network of Rare Bleeding Disorders (EN-RBD): 1. Asymptomatiqc (no documented bleeding episodes). 2. Grade I bleeding (bleeding that occurred after trauma or drug ingestion). 3. Grade II bleeding (spontaneous minor bleeding; bruising, ecchymosis, minor wounds, oral cavity bleeding, epistaxis and menorrhagia). 4. Grade III bleeding (spontaneous major bleeding ; hematomas, hemarthrosis, central nervous system, gastrointestinal and umbilical cord bleeding).
Results: 16 patients (25.4%) diagnosed with compound Factor V and factor VIII deficiency, 11 patients have factor level <20 % classified with severe form and 05 patients had factor level betwene 20 and 40 % classified with moderate form. According the proposition of europen network of rare bleeding disorder. Regarding the clinical severity 3 are asymptomatic (factor level between 25 and 30%), 9 patients classified on grade 1 (factor level between 10 and 25%) and 4 on grade 2 (factor level between 5 and 10%).
Summary and Conclusions: A good corelation was found between factor level (factor V and VIII) and the clinical severety (R^2=0.83). Factor level **<**10% is associated with severe bleeding, and a level factor > 25 % are asymptomatic.

E1026

IN VITRO FACTOR VIII ACTIVITY AFTER RECONSTITUTION WITH DILUENT FLUID FOR CONTINUOUS INFUSION

K. Lee[1,*] S. Hyun, [2]Y. Shim[3], J. Kim[1]
[1]Pediatrics, Kyungpook National University School of Medicine, Daegu, [2]Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, [3]Pediatrics, Keimyung University Dongsan Medical Center, Daegu, Korea, Republic Of

Background: Major surgery for hemophilia patients is very critical situation for one's life. For the successful result one's blood coagulation factor level during and after surgery is important. Continuous infusion method has merit of saving product as much as 30%. Because the drug activity will be decreased gradually after dilution even *in vitro* the latter portion of infusion will have decreased activity also.
Aims: We evaluate *in vitro* factor VIII activity after reconstitution with diluent fluid for continuous infusion.
Methods: We checked the *in vitro* activities on 0, 8, 16 and 24 hours after dilution with one commercial plasma derived FVIII product. And three commercial FVIII products (2 recombinant FVIII and 1 plasma derived concentrates) were used for *in vitro* FVIII:C activities at 0, 2, 4, 6, and 8 hours after reconstitution in both the exposure to indoor light group and the light shield group.
Results: *In vitro* activity was gradually decreased to 91±5.3%, 80±6.9%, and 56±6.7% at 8 hr, 16 hr and 24 hr on room temperature and on room light exposure respectively. Better results of 94±4.8%, 89±6.5% and 73±6.4% on light shield were observed (p<0.001). In the three drugs, *in vitro* FVIII:C was decreased from 0 to 8 hours after reconstitution (p <0.001). The decline of FVIII:C followed linear model (p<0.001). *in vitro* FVIII:C was 95.3±1.91% and 90.6±2.53% at 4 and 8 hours after reconstitution, respectively, in exposure to room light group. On light shield group, FVIII:C was 95.4±1.12% and 90.9±1.67% at 4 and 8 hours, respectively (p=0.849).
Summary and Conclusions: We aware the longer *in vitro* dilution state the lower factor activity. So, we have to adjust the required amount according to the frequency of changing bottle for the best bleeding control during and after surgery. Reconstitution of lyophilized powder with diluent every 4 hours is desirable to maintain effective blood factor level.

E1027

FREQUENCY AND CHARACTERISTICS OF FACTOR VIII INHIBITORS IN TUNISIAN HEMOPHILIA A: EXPERIENCE OF A SINGLE CENTER

O. Kassar[1,*] M. charfi[1], M. ghorbel[1], C. kallel[2], M. elloumi[1]
[1]hematology, [2]laboratory of hematologie, Habib Bourguiba Hospital, university sfax, sfax, Tunisia

Background: Development of an inhibitory antibody to factor VIII is a rare but serious complication of hemophilia treatment of patients with hemophilia A.
Aims: The aim of this study is to determine the prevalence of inhibitors in hemophiliacs patients and to analyse their characteristics in our center.
Methods: From May 2008 to May 2013, 75 patients with severe hemophilia A admitted in department of hematology in Sfax from Tunisia were evaluated. Those who had abnormal mixing study, antibody against FVIII were measured. High titer inhibitor was defined as having a titer of >5 BU/ mL at any time. Data were collected and analyzed. Our patients received treatment on-demand with plasma-derived or recombinant FVIII and or cryoprecipitate.
Results: Of the 74 with hemophilia A enrolled in our study, 50 patients (68%) were with severe form, 16 patients (21%) were with moderate form and 8 patients (11%) mild form. From this group, sixteen (21%) were developed inhibitors. Frequency of inhibitors in severe, moderate and mild form were respectively 26%, 19% and 0%. The mean age of patients at inhibitor development was 15 years (3 -31years). Seven patients (44%) were high responders while 9 patients (56%) were low responders. All low inhibitors have disappeared spontaneously despite continued treatment with FVIII. One patient died by severe bleeding and one patient developed compressive spinal hematoma and keeps a flaccid paraplegia.
Summary and Conclusions: In our series the incidence of inhibitors in Haemophilia A (21%) is similar to the literature (20 à 30 %). Inhibitors are more frequently encountered in persons with severe hemophilia compared to those with moderate or mild hemophilia. The median age of inhibitor development in our series is higher than in developed countries (three years or less). Development of an inhibitory remains a major problem in the management of hemophilia threatening the vital and functional prognosis in our patient population

E1028

12 NOVEL MUTATIONS IDENTIFIED IN PATIENTS OF CONGENITAL AFIBRINOGENEMIA IN PAKISTAN.

T. Nafees Sonia Khan[1,*] A. Naz[1]
[1]Coagulation and Hemostasis, National Institute of blood diseases and bone marrow tranplantation, karachi, Pakistan

Background: Consanguinity is a hot issue in multiple cultures around the globe. Pakistan is included in the list where interfamilial wedlock is highly preferential and enriched source of inherited bleeding disorders.
Aims: This study focuses to detect the mutation in fibrinogen gene (*(FGA, FGB &FGG)* by DNA sequencing in Pakistani patients.
Methods: This descriptive and cross sectional study was conducted in Karachi and Lahore and fully complied with the Declaration of Helsinki. Patients with fibrinogen deficiency (tested by Fibrinogen functional assay from Laboratoire Stago, Asnieres, France) were screened for mutations in the Fibrinogen gene alpha (FGA), beta (FGB) and gamma (FGG) genes by direct sequencing.
Results: Total 17 mutations have been identified in 13 patients. 10 mutations were novel and identified in *FGA*, 4 in *FGB* and three in *FGG*. *FGA* gene mutation is seemingly the most commonly occurring mutation in our population with 8 novel mutations followed by 2 novel mutations identified in *FGB* and two novel mutations in *FGG*. Results were matched with wild type of *FGA,FGB* & *FGG* using HGMD*(http://www.hgmd.cf.ac.uk/ac/index.php)*.
Summary and Conclusions: Congenital afibrinogenemia is a rapid growing problem in countries such as Pakistan where consanguinity is frequently practiced. In this study amongst 8 novel mutations in *FGA* gene, five are identified as Missense mutation in *FGA* in our population which has not been reported yet in literature. This study transpires the fact that mutations in *FGA* frequently exist in local population followed by *FGB and FGG* mutations.

E1029

EFFICACY AND SAFETY OF PROPHYLAXIS IN PREVIOUSLY UNTREATED PATIENTS WITH SEVERE HEMOPHILIA A IN IRAN

M. Karimi[1,*] P. Eshghi[2], S. Haghpanah[1], Z. Zahedi[1], B. Habibpanah[2]
[1]Hematology Research Center, Shiraz University Of Medical Sciences, Shiraz, [2]Pediatric Congenital Hematologic Disorders Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background: Hemophilia is an inherited bleeding disorder that is associated with wide range of bleeding episodes. Primary prophylaxis is the best method of treatment to save the health and quality of life especially in children. Recently the low dose tailoring method of primary prophylaxis has been introduced for Previous Untreated Patients (PUP).
Aims: To evaluate the efficacy and safety of low dose tailoring method of primary prophylaxis in PUPs with severe hemophilia A.
Methods: In this pre-post interventional study, 16 patients with severe hemophilia A (activity <1%) were included. All patients were attending at the two main comprehensive care centers in Iran. Primary continuous modified prophylaxis was used for patients with age less than 3 years old, after first and before the second episode of obvious clinical bleeding in large joints or large soft tissue hematoma or major bleedings. All the hemophilic subjects in our study were previously untreated patients and randomly selected into two groups receiving recombinant factor 8 concentrate (Kogenate Bayer) and plasma derived (Emoclot Kedrion). Prophylaxis was started by 25-30 IU/kg once per week and increased to twice or three per week if necessary according to defined bleeding events for at least 50 exposure days (ED) or one year, each of occurred later. None of the patients had positive titer of inhibitor at the beginning of study. Descriptive data were presented as median and interquartile range (IQR) and also summarized at table 1.
Results:: Median and IQR for age were 3 and 2.7 years respectively. Median and IQR for age at diagnosis and age of starting prophylaxis were: 6 (5.7) and 9.5 (12) months respectively. Median and IQR for Annual Bleeding Rate (ABR) of patients after prophylaxis were 1 and 2.75 episodes per year respectively. Inhibitor was present in 5 patients (31%) after prophylaxis (patients number 2, 3 and 5: inhibitor titer =4; number 12: inhibitor titer =400; and number 13: inhibitor titer =32).

Table 1. Clinical characteristics of previously untreated patients with severe hemophilia A

	Age (Year)	Age at diagnosis (Month)	Age of starting Prophylaxis (Month)	Bleeding episode/year after prophylaxis	Bleeding type after prophylaxis	Dose of prophylaxis IU/kg	Dose of prophylaxis number/week
Patient N 1	1	At birth	6	0	No	25	1
Patient N 2	2	4	4	2	hematoma	25	2
Patient N 3	3	7	8	1	hematoma	25	1
Patient N 4	5	8	9	1	hematoma	25	1
Patient N 5	3	6	6	0	No	25	1
Patient N 6	5	2	30	0	No	25	1
Patient N 7	6	9	10	3	hemarthrosis	30	1
Patient N 8	1	7	7	3	Hematoma, ICH*	25	2
Patient N 9	7	6	35	1	hematoma	25	1
Patient N 10	4	6	6	0	No	25	1
Patient N 11	3	9	18	1*	hemarthrosis, gum bleeding	25	1
Patient N 12	1	5	7	1	hematoma	25	1
Patient N 13	2	2	17	0	No	25	1
Patient N 14	3	1	16	1	hematoma	25	1
Patient N 15	3	9	18	2	Hematoma, hemarthrosis	25	1
Patient N 16	3	At birth	10	3	Hematoma, tongue bleeding	25	1

Summary and Conclusions: Our study showed modified prophylaxis once per week can be cost- benefit in comparison with other known protocols and leads reduced morbidity in patients with severe hemophilia A comparing with On Demand treatment. On the other hand, incidence of inhibitor was 31% in our study which is comparable with previously published data (5-39%).

E1030

DISTRIBUTION OF THE ALLELES HLA II CLASS IN UKRAINIAN HEMOPHILIA A PATIENTS, DEPENDING ON THE INHIBITORS

O. Stasyshyn[1,*] V. Krasivska[2], H. Makuch[3]
[1]Surgery, 1SI "Institute of blood pathology and transfusion medicine NAMS of Ukraine", [2]Surgery, SI 'Institute of Blood Pathology and Transfusion Medicine of UNAMS", [3]Diagnosis of Hereditary Pathology, "Institute of hereditary pathology NAMN of Ukraine", Lviv, Ukraine., Lviv, Ukraine

Background: The development of neutralizing antibodies against factor VIII and IX is the major complication in haemophilia care today. The antibodies neutralize the biological activity of FVIII and FIX and render replacement therapies ineffective. Antibodies against infused FVIII affect 20–30% of patients with severe HA and usually occur in childhood within the first 20-50 exposure days (ED) of therapy Antibodies are generated as a result of a cascade of tightly regulated interactions between different cells of the innate and the adaptive immune system located in distinct compartments. Candidates for immunogenetic investigation are genes involved in the immune response such as human leucocyte antigen (HLA) alleles. The HLA class II molecules are of particular interest because they present extracellular antigens (*e.g.* exogenous FVIII) to the patient's immune system. Previous immunogenetic studies in severe HA have shown the implication of HLA alleles in inhibitors formation.
Aims: The aim of our study was to investigate a possible link between the alleles HLA II class and the inhibitor and its type in Ukrainian haemophilia A patients (pts)
Methods: The study included 47 haemophilia A pts, aged 3 to 65 years (13 children and 34 adults) who were divided into 3 groups: I - HA pts without inhibitors (n=13); II –HA permanent inhibitor pts (n=20); III – HA transient inhibitor pts (n=14). All non-inhibitor pts had more than 150 ED; Informed consent was obtained from pts, children's parents or adolescents. To measure the FVIII activity and establish haemophilia diagnosis, the one-stage clotting assay was performed. To detect inhibitors against FVIII, the Bethesda method was applied. Genomic DNA was extracted from peripheral blood leukocytes by salting. Genotyping DRB1, DQA1 and DQB1 performed using PCR. Investigated 16 gene allele HLA-DRB1, 10 alleles of the gene HLA-DQA1 gene alleles and 19 HLA-DQB1.
Results: Statistical analysis of the results allowed to distinguish alleles associated with inhibitor in patients with haemophilia A in Ukraine. To significantly increase set for alleles DRB1*15:01 (χ^2=4,61, p <0,0), DQB1*06:02 (χ^2=4,61, p <0,05), and is likely to significantly reduce DQB1*0302 (χ^2=6,14, p <0,05). This means that the alleles DRB1*15:01 and DQB1 *06:02 can be seen as alleles - aggressors, and allele DQB1*03:02 rather as protectors allele. The calculation showed that carriers of allelic groups DRB1*15:01 and DQB1*06:02 and increases the risk of inhibitor in patients with haemophilia 10 times each (OR=10,7; CI 95%: 0,58-198,91) as opposed to carrier DQB1*03:02, which reduces the risk of inhibitor 5 times (OR=5,5; CI 95%: 1,29-23,17).
Summary and Conclusions: The majority of associations of immune response genes to the production of inhibitors in Ukrainian HA pts are related to HLA class II alleles HLA- DRB1*15:01, DQB1*06:02 and DQB1*03:02 haplotype. Further research must continue in a large group to determine the possible characteristic of certain groups alleles and investigate their role in the development of the FVIII inhibitor.

E1031

THE RATIO OF LEUKOCYTE AND RED BLOOD CELL CLONES IN PATIENTS WITH AA/PNH AND THEIR CORRELATION WITH LDH LEVEL

E. Shilova[1,*] T. Glazanova[2], Z. Chubukina[2], O. Rozanova[2], K. Abdulkadyrov[1], L. Bubnova[2]
[1]Hematological department, [2]lab. immunohematology, Russian Research Institute of Hematology and Transfusiology of the FMBA of Russia, St-Petersburg, Russian Federation

Background: It is known that patients with AA in 70% and more can have PNH-clone of various size: from minor clones to clones of considerable size with the development of severe hemolysis. There are cases of discrepancy of granulocyte and monocyte PNH-clone sizes in the same patients. In addition relationship of leukocyte PNH-clone size with a level of LDH as indicators of hemolysis is understood not enough.
Aims: Aim was to examine the ratio of granulocytic and monocytic PNH-clones of patients with aplastic anemia associated with the PNH (AA/PNH) and assess the relationship between the level of LDH and PNH-clone size among the different types of blood cells.
Methods: We heve examined 33 patients with AA/PNH, including 23 patients in dynamics (total 78 analyses) with the definition of the size of PNH-clone among white blood cells and red blood cells (RBC) using highly sensitive method of 4-colour flow cytometry. The PNH-clone size, defined among the granulocytes, was equal to or higher than 10% in 12 patients (Group 1) and was less than 10% at 21 (Group 2).
Results: In most of the examined patients (19 of 33) the sizes of granulocyte and monocyte PNH-clones did not significantly differ among themselves in the same person. 13 patients have shown a higher percentage of monocyte PNH-clone, including more than 10% difference in 5 patients: 4 in Group 1 and 1 – in Group 2. The predominance of granulocytic PNH-clone was observed in 1 patient with a clone size within 20-30%. In a survey of the dynamics in the absolute majority of patients trends persisted. In the whole group of patients there were observed highly reliable correlation values of granulocyte and monocyte PNH-clone size with LDH level ($r=0.62$ and $r=0.74$, respectively, $p<0.01$), mostly due to the patients of Group 1. In Group 2 there persisted a correlation between monocyte PNH-clone size and LDH level ($r=0.61$, $p<0.01$) and there was no correlation between the granulocyte clone size and LDH level ($r=0.07$). Worthy of note is the fact that in one third of this group of patients the size of the monocyte PNH-clone was significantly higher than that among the granulocytes. Indicators of pathological clone size among RBC and ratio of type II and III RBC could be variable in the same patient, depending on the presence and intensity of hemolysis. But examination outside the periods of active hemolysis in patients with clinical manifestation of PNH-clone identified general trends. There was reliable correlation between the level of LDH and total RBC PNH-clone ($r=0.51$, $p<0.01$) in the whole group of patients, mainly due to RBC type III ($r=0.51$, $p<0.01$), whereas the relationship between the level of LDH and RBC type II was much weaker ($r=0.24$). The relationship between the size of granulocyte and total RBC PNH-clone was stronger in patients of Group 1 compared with that of Group 2 ($r=0.53$ and 0.46, respectively). On the contrary, the relationship between the sizes of RBC clones type II and III was more pronounced in patients of Group 2, compared to one in Group 1 ($r=0.36$ and 0.24, respectively).
Summary and Conclusions: 1. In examined AA/PNH patients we have revealed variability of the ratios PNH-clone sizes among granulocytes, monocytes and different types of RBC. Noted more frequent prevalence of monocyte PNH-clone compared to granulocyte one in patients with PNH-clone <10%.
2. In cases with the amount of granulocytic PNH-clone >10% there was a clear correlation between the level of LDH (the primary intravascular hemolysis indicator) with the value of the granulocyte and monocyte PNH-clone and RBC type III (with an absolute deficiency of GPI-linked proteins). In cases of small PNH clone (<10%) LDH correlated only with monocyte and RBC clones.

E1032

VITAMIN D LEVELS OF CHILDREN WITH FANCONI ANEMIA

C. Albayrak[1,*] D. Albayrak[1]
[1]Pediatric Hematology Department, Samsun Ondokuz Mayis University Faculty Of Medicine, Samsun, Turkey

Background: Fanconi anemia (FA) is a congenital syndrome associated with chromosomal fragility and aplastic anemia. Conflicting data exist regarding whether low bone mineral density is associated with FA. Factors that contribute to development of peak bone mineral during critical periods of childhood and adolescence include adequate calcium and vitamin D intake, general nutritionaladequacy, exercise, and normal hormonal and pubertal progression, along with genetic factors. Severe vitamin D deficiency may cause myelofibrosis in some children.
Aims: The aim of this study was to determine the frequency of vitamin D deficiency and insufficiency in children with FA.
Methods: None of the patients had previously received vitamin D supplementation. No patient had clinical or radiologic findings of rickets or seropositivity of hepatitis C virus or HIV or had been made bone marrow transplantation. Age, gender, serum level of ferritin, hemoglobin F, peripheric blood count, ALT, AST, calcium, phosphor, alkaline phosphatase, 25-OH vitamin D, and parathormon level were recorded. 25-OH vitamin D levels have measured by HPLC. 25-OH vitamin D level below 10 ng/ml is accepted as severe vitamin D deficiency and between 10 and 19.99 accepted as vitamin D deficiency, 20 and 29.99 was vitamin D insufficiency.
Results: Seventeen children with FA were included in the study. The median age of the patients was 13 (range, 4–20) years. The median vitamin D level was 11.73 ng/ml (range, 4.23–35.00). Vitamin D levels were below 10 ng/ml (severe vitamin D deficiency) in 4 cases (23%), between 10 and 19.99 ng/ml (vitamin D deficiency) in 10 cases (59%), between 20 and 29.99 ng/ml (vitamin D insufficiency) in 2 cases (12%), and above 30 ng/ml (normal vitamin D level) in 1 cases (6%).
Summary and Conclusions: A majority of our patients with Fanconi anemia (94%) had low vitamin D levels. Vitamin D levels will be different in different geographic regions even in the same country. Our study is from the north region of Turkey. New studies are therefore required from different regions. All centers should determine the frequencies themselves and develop a prophylaxis policy based on this data. We advise routine checking of vitamin D levels twice a year and vitamin D supplementation to maintain its level between 30 and 100ng/ml.

Bone marrow failure syndromes incl. PNH - Clinical

E1033

A PROPOSAL OF CLASSIFICATION FOR PAROXYSMAL NOCTURNAL HEMOGLOBINURIA.

A. Gaya[1,*] S. Brunet[2], S. Piernas[3], L. Armando[4], A.C. Oliveira[5], A. Rodriguez[6], D. Beneitez[7], J.D.N. Ferreira[8], N. Martinez-Cibrian[1], U. Álvaro[1]
[1]Hematology, Hospital Clinic, [2]Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, [3]Hematology, Hospital Parc Taulí, Sabadell, [4]Hematology, Hospital Arnau de Vilanova, Lleida, [5]Hematology, Hospital Duran i Reynals, ICO, Hospitalet de Llobregat, [6]Hematology, Hospital Germans Trias i Pujol, ICO, Badalona, [7]Hematology, Hospital Vall d'Hebron, Barcelona, [8]Hematology, Hospital Joan XXIII, Tarragona, Spain

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a hematopoietic stem cell disorder characterized by hemolysis, thrombosis and a frequent association with bone marrow failure syndromes. The size of the GPI deficient clone (PNH clone) and the intensity of the hemolysis and pancytopenia vary widely among patients and during the evolution of the disease. There is a general agreement that the current PNH classification does not cover the spectrum of these clinical manifestations and should be updated, especially in the eculizumab era.
Aims: We propose a new PNH classification based on the clinical characteristics of the patients and introducing the concept of "evolving PNH" in order to allow a better identification of the differences in prognostic and treatment of each subgroup.
Methods: We propose to define four main PNH groups. (a) **Predominantly hemolytic with or without mild cytopenias**, defined by: LDH>3 x ULN, reticulocytes >150 x10^9/L, neutrophils >1.5 x10^9/L, platelets count>100 x10^9/L. (b) **Predominantly hemolytic with significant cytopenias**, defined by: LDH>3 x ULN, reticulocytes >150 x10^9/L, neutrophils <1.5 x10^9/L, platelets <100 x10^9/L. (c) **Predominantly hypoplastic with mild hemolysis**, defined by LDH high but<3 x ULN, reticulocytes high but <150 x10^9/L, and patients may have hypoplastic bone marrow with significant cytopenias (as defined above). (d) **Subclinical**, characterized by a PNH clone with no evidence of hemolysis, in general in the context of a severe aplastic anemia (2 of the following 3 values: neutrophils count<0.5 x10^9/L, platelets count<20 x10^9/L, reticulocytes<80 x10^9/L and bone marrow cellularity<25%) or a normal hemopoiesis.
Results: Thirty two patients (median age 35, range 6-71, years; males 63%) diagnosed with PNH at 7 institutions between July 1979 and August 2013 have been studied. At diagnosis, 12 (37.5%) patients were predominantly hemolytic, 7 (22%) predominantly hemolytic with significant cytopenias, 4 (12.5%) predominantly hypoplastic with mild hemolysis, and 9 (28%) subclinical PNH. Of the 32 patients, 17 (53%) experienced an evolution of the disease along the time, with clinical changes that modified their initial classification. Thus, 9 (28%) patients presenting at diagnosis with severe aplastic anemia or with significant cytopenias normalized the peripheral neutrohil and platelet values and evolved into a more hemolytic disease, while 2 (6%) patients showed the opposite, a progressive trend to an aplasia with decreasing hemolysis. Two (6%) patients developed a myelodysplasia with 7q deletion, 2 (6%) patients evolved to a subclinical PNH with normal neutrophil and platelet values and without hemolysis, and 2 (6%) patients achieved a complete response after receiving a bone marrow transplantation.
Summary and Conclusions: The proposed PNH classification was able to classify all 32 PNH patients in four groups. It constitutes a dynamic classification, showing that more than 50% of the patients change of category along the time. Furthermore, this classification could be used to better define treatment indications, according the predominance of hemolysis or aplasia, among different hospitals and groups interested in PNH.

E1034

RABBIT ANTITHYMOCYTE GLOBULIN AT >3,5 MG/KG/DAY/X 5 DAYS FOR TREATMENT OF ACQUIRED APLASTIC ANEMIA

C. Vallejo[1,*] A.J. González[2], B. Xicoy[3], Á. Bendaña[4], B. Cuevas[5], C. García[6], M.J. Requena[7], O. Salamero[8], L. Yáñez[9]
[1]Hematology, Hospital Universitario de Donostia, Donostia/San Sebastián, [2]Hematology, Hospital Universitario Central de Asturias, Oviedo, [3]Hematology, Hospital Universitari Germans Trias i Pujol, Badalona, [4]Hematology, Complejo Hospitalario Universitario de Santiago, S. Compostela, [5]Hematology, Hospital Universitario de Burgos, Burgos, [6]Hematology, Hospital General Universitario de Alicante, Alicante, [7]Hematology, Hospital Universitario S. Ochoa, Leganés, [8]Hematology, Hospital Universitari Vall d'Hebron, Barcelona, [9]Hematology, Hospital Universitario M. Valdecilla, Santander, Spain

Background: Aplastic anemia (AA) is a life-threatening hematological condition that can be cured with prompt and correct management, including combination of the rabbit ATG Thymoglobuline (TG) plus cyclosporine A (CsA). However, optimal dose of TG is still unknown.
Aims: To analyze outcome of a large series of patients treated with TG at >3,5 mg/kg/day/5 days plus long-term CsA (>1 year) (TG-3,5).
Methods: Sixty-three AA patients (36 male, 27 female) treated with TG-3,5 were included in this retrospective analysis, across 22 centers. Median age was 45 yo (2-78). Infection prophylaxis and dose of steroids used to prevent serum sickness (SS) were administered according to each local center's policy. Response (complete [CR] plus partial [PR]) was assessed at days +90, +180 and at 1 year.
Results: Early (≤4 months) mortality rate was 15,9% (10 patients from 6 centers, 7 of them due to infections). Late mortality (>4 months) was 0%. If we excluded the 12 alive patients with follow-up <1 year, the overall response was 76,5% (39 out of 51). Five patients with no response at day +90 reached response at day +180 or 1 year (late responders).
Summary and Conclusions: Our series of AA patients treated with TG at >3,5 mg/kg/day/5 days plus long-term CsA showed: 1) Infectious early mortality in around 1 out of 10 patients, which highlight the need to focus on infection prophylaxis and limit the total dose of steroids employed after the 5 days of ATG administration in patients who do not develop SS, as steroids may significantly increase infectious complications. 2) 1-year overall response (CR plus PR) superior to 75%. 3) An increase in response rate over time in a cohort of patients (late responders). 4) Prospective randomized studies, as the ongoing Asia-Pacific study, are warranted to find out the ideal dose of TG to treat AA patients.

E1035

A STUDY OF THE MARKERS OF THROMBIN GENERATION AND INFLAMMATION IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA IN A SUBSET OF PATIENTS SEEN AT A TERTIARY CARE CENTRE IN NORTH INDIA

R. Dhawan[1,*] S. Varma[1], P. Malhotra[1], N. Varma[2], J. Ahluwalia[2]
[1]Internal Medicine, [2]Hematology, Post Graduate Institute of Medical Education and Research (PGIMER), Chandigarh, India

Background: Data from studies on PNH patients from western countries and few Asian countries suggest more hemolytic and thrombotic manifestations in Caucasians compared to Asians. There is limited data reported on PNH from the Indian subcontinent.
Aims: Study of clinical features and outcomes of PNH in Indian population and to measure the markers of thrombin generation and inflammation in PNH patients presenting to our centre.
Methods: We studied disease characteristics, with emphasis on thromboembolic complications in 18 patients with PNH who were registered in our department between January 2004 and January 2014. Patients were sampled for markers of hemostatic activation; thrombin-antithrombin complex (TAT), D-Dimers, soluble P-Selectin (Sp-Selectin) and inflammatory cytokine Interleukin-6 (IL-6). The samples were also collected for these assays from 35 age and sex matched healthy control individuals in order to determine the cut off values in Indian population. Plasma TAT, Sp-Selectin and IL-6 levels were measured using commercial enzyme-linked immunoassays (Abcam TAT ELISA, Abcam Inc, MA, USA; Human sP-selectin/CD62P ELISA & Human IL-6 Quantikine HS ELISA, R & D Systems Inc, Minneapolis, MN, USA respectively). D Dimer was measured with automated STA LIATEST immunoturbidimetric D-dimer assay performed on the STA-Compact analyzer (Diagnostica Stago, France).

Table 1.

Patient characteristics	Present study	Hillmen P et al	International PNH registry Schrezenmeier et al	French data de Latour et al	Chinese data Ge et al

Pancytopenia	17%	N/A	N/A	39.1%	49.5%
Median Lactate Dehydrogenase X ULN	11	N/A	1.96	N/A	N/A
Haemoglobin (Median)	58 g/L	N/A	106 g/L	N/A	63 g/L
Median Absolute neutrophil count	2 x 10^9/L	N/A	1.7 x 10^9/L	N/A	0.75 x 10^9/L
Platelet count (Median)	125 x 10^9/L	N/A	131 x 10^9/L	N/A	21x10^9/L
Median Granulocyte clone	85%	N/A	68.1%	N/A	N/A
Classical PNH	85%	N/A	83%	46%	39.1%
PNH/AA	52%	N/A	35%	20%	23.5%

*: Diagnosis of AA preceded the diagnosis of PNH in 29% of the patients in this study

Results: Thromboembolism was present in three (17%) PNH patients in our study (two cerebral venous thrombosis and one portal vein thrombosis). All the patients with thromboembolism had PNH clone size more than 85% at presentation. The majority of the patients in our study (95%) fit criteria for classical PNH. Bone marrow examination findings were correlated with clinical presentation in 13 patients. Five (28%) patients had peripheral blood cytopenias fulfilling the IAAAG criteria for aplastic anemia. However only one patient with PNH/AA had decreased bone marrow cellularity and normal ME ratio. Peripheral blood cytopenias with increased BM cellularity were present in 4 (22%) of patients. One of the two patients with anemia and thrombocytopenia had massive splenomegaly with hypersplenism secondary to portal vein thrombosis. Two patients with pancytopenia had myeloid hypoplasia in addition to erythroid hyperplasia in BM. The optimal cut-off values for TAT (2.9 ng/ml) & sP-Selectin (58.41 ng/ml) were determined in our study population using Youden's index. IL-6 levels were not significantly elvated in PNH patients as all the patients were on prednisolone therapy at the time of study. We found significant elevation of markers of thrombin generation (TAT and D-Dimer) and endothelial and platelet activation (sP-Selectin) in patients with PNH in our study. A positive correlation of TAT levels with sP-selectin and D-Dimer levels was observed in our study suggesting a contributory role for platelet and endothelial activation in activation of thrombosis in PNH. There was no correlation of hemolysis (LDH) with markers of thrombin generation (D-Dimer, TAT) or platelet and endothelial activation (sP-Selectin) in our study.
Summary and Conclusions: The prevalence of thromboembolism in PNH reported in our study is similar to that reported from other Indian studies and is comparable to the rates of thromboembolism reported in the western PNH patients. We found significantly elevated markers of thrombin generation and endothelial and platelet activation in PNH patients in our study. Further, there was a lack of correlation between serum LDH and markers of thrombin generation suggesting that thrombin generation in patients with PNH occurs may be through pathways independent of hemolysis.

E1036

ELTROMBOPAG IS BENEFICIAL IN THE TREATMENT OF CHILDREN WITH ACQUIRED APLASTIC ANEMIA

E. Atmatzidou[1,*] A. Vlachou[1], K. Katsibardi[1], N. Tourkantoni[2], S. Kostaridou[3], A. Kattamis[4]
[1]Pediatrics Hematology-Oncology Unit, First Department of Pediatrics, University of Athens, [2]Pediatrics Hematolgy-Oncology Unit, First Departmemt of Pediatrics, University of Athens, [3]Pediatrics Hematolohy-Oncology-Unit, [4]Pediatrics Hematology- Oncology Unit, First Department of Pediatrics, University of Athens, Athens, Greece

Background: Acquired Aplastic Anemia (AA) in children is a rare disorder characterized by peripheral blood pancytopenia and hypocellular bone marrow, caused by immune-mediated processes. The first line treatment is allogeneic bone marrow transplantation from an HLA-matched sibling donor. Patients not eligible for bone marrow transplantation receive immunosuppressive treatment (IST), with the most commonly used schema consisting of antithymocyte globulin, cyclosporine, and methylprednisolone with the optional addition of Granulocyte colony-stimulating factor (G-CSF). Eltrombopag is an oral thrombopoietin mimetic, licensed for chronic immune thrombocytopenic purpura in adult patients. Treatment of adult patients with AA with eltrombopag has been shown to be beneficial. The use of eltrombopag in pediatric patients with AA has not been reported.
Aims: To evaluate the hematologic response following eltrombopag use in children with AA.
Methods: We report the use of eltrombopag in 4 children diagnosed with AA treated in our unit during the past two years. The patient received the medication as off-label compassionate use and after having received approval from regulatory authorities and Ethics committee. The patients were 3 males and 1 female, with their age being 6, 10, 15 and 16 years old, respectively. Possible identifiable cause for AA was the use of non-steroid anti-inflammatory drugs in one patient, while two patients presented with elevated transaminases, suggestive of infectious or auto-immune etiology. All patients fulfilled criteria for severe AA (absolute neutrophil count <500, platelet count (PLT) <20.000 /μL). As they had no HLA-matched sibling donor, they received IST. Eltrombopag was started at a dose of 100 mg daily per os, as they continued to have suboptimal platelet response, within 2 months after IST in the 3 patients, while the 4th patient started at 15 months after IST for persistent suboptimal response and parental hesitation. Treatment was continued until they reach optimal platelet count levels.
Results: Hematological response to the treatment with eltrombopag was observed within the first weeks of treatment. All of the patients increased their PLT levels at a percentage of >50%, and became platelet independent with PLT counts>20.000/μL within the first month of treatment. Continuation of therapy was related to continuous platelet improvement (figure 1). Neutrophil count and hemoglobin levels paralleled platelet response. Duration of treatment was at least for 6 months. One patient ended treatment after 6 months and is currently off Eltrombopag for 8 months with stable PLT counts>100.000/μl. The other 3 patients continue to be on therapy, in 6, 7 and 8 months respectively. Discontinuation of eltrombopag in one patient resulted in drop in the platelet count. When the drug was restarted, the platelet count rose again. This observation verifies the direct effect of eltrombopag. No adverse events related to eltrombopag use were observed.

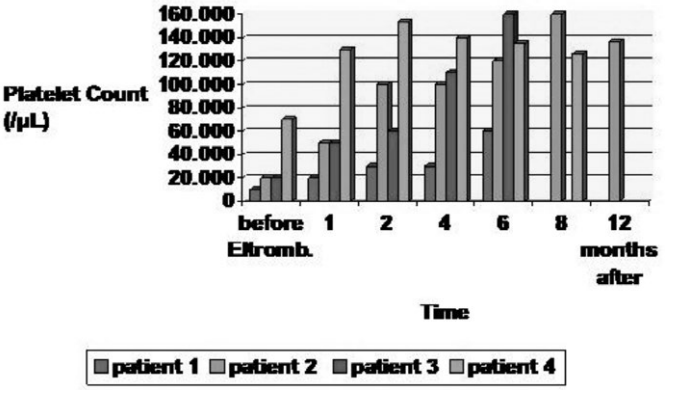

Figure 1.

Summary and Conclusions: Eltrombopag use was clearly associated with an increase in platelet count and possibly with a multilineage clinical response. Addition of Eltrombopag should be considered in pediatric patients with AA.

Chronic lymphocytic leukemia and related disorders - Biology

E1037

CHARACTERIZATION OF THE DNA-DAMAGE RESPONSE DOWNSTREAM OF B-CELL RECEPTOR SIGNALING IN CLL

N. Nickel[1,*] A. Roth[1], C.P. Pallasch[1]
[1]Innere Med. I - CECAD Research Center, Uniklinik Köln, Cologne, Germany

Background: Despite the considerable efforts which have been undertaken to develop new treatment strategies, the classical chemotherapy is still indispensable for the treatment of B-cell chronic lymphocytic leukemia (B-CLL). Chemotherapeutic agents damage the genome of neoplastic cells which triggers the DNA damage response (DDR) to either halt the cell cycle and repair the damage or, if the extent of damage is beyond repair capacity, to send the cell into apoptosis. However resistance against chemotherapy sooner or later occurs and leads to a relapse of the disease. In order to develop new strategies to overcome this resistance, a better understanding of the pro-survival signaling cascades in CLL and their link to the DDR machinery is necessary. One important pro-survival pathway in CLL is the PI3K/AKT pathway, which is activated through B-cell receptor (BCR) signaling. Since the literature states several links between AKT and the DDR, we hypothesize that AKT signaling downstream of BCR activation interacts with the DDR also in B-CLL.
Aims: In the presented study we aim to clarify the importance of BCR signaling and subsequent AKT activation for the resistance of CLL cells to classical chemotherapy and try to identify molecular targets involved in DDR signaling which respond to BCR activation.
Methods: We either stimulate the BCR by cross linking with soluble anti-IgM antibodies or inhibit the receptor signal by blocking BTK (Ibrutinib) or PI3K (Cal-101) in primary CLL cells to analyze the impact of BCR signaling on cellular resistance towards genotoxic stress. We measure cellular survival by flow-cytometry and activation of DDR signaling by immunofluorescence staining of γ-H2AX as well as immunoblotting of p53, Chk2 and DNAPK.
Results: We observed no induction of DDR signaling by BCR stimulation alone, but a clear activation of the investigated signaling molecules in response to DNA damage induced by bendamustine. Stimulation with anti-IgM antibodies clearly protects CLL cells from cell death induced by bendamustine and this protective effect is abandoned by inhibition of BCR signaling with Ibrutinib or Cal-101. However, the investigated DDR molecules show a very diverse activation pattern when genotoxic stress is combined with BCR stimulation. This diversity became even more pronounced when also Cal-101 was added.
Summary and Conclusions: In CLL the BCR generates a distinct pro-survival signal which protects the cells from apoptosis caused by genotoxic stress, however the activation of DDR signaling in response to BCR activation is not that clear-cut. Since CLL is a very heterogeneous disease, our results potentially reflect the existence of different CLL subgroups. We are currently subdividing our patient samples according to different criteria, *e.g.* mutational status of the immunoglobulin heavy chain, cytosolic calcium signaling in response to BCR stimulation, deletion of chromosomes 11q or 17p or clinical response to treatment in order to identify a correlation to the DDR patterns observed.

E1038

CD69 EXPRESSION POTENTIALLY PREDICTS RESPONSE TO BENDAMUSTINE IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Montraveta[1,*] E. Lee-Verges[1], J. Roldan[1], L. Jimenez[1], S. Cabezas[2], G. Clot[3], M. Pinyol[4], S. Xargay-Torrent[1], L. Rosich[1], C. Arimany-Nardi[5], M. Aymerich[6], N. Villamor[6], A. Lopez-Guillermo[7], P. Perez-Galan[1], G. Roué[1], M. Pastor-Anglada[5], E. Campo[6], M. Lopez-Guerra[8], D. Colomer[8]
[1]Experimental Therapeutics in Lymphoid Malignancies Group, IDIBAPS, [2]Hematopathology Unit, Hospital Clinic, [3]IDIBAPS, Barcelona, Spain, [4]Genomics Unit, IDIBAPS, [5]Departament de Bioquímica i Biologia Molecular, Institut de Biomedicina, Universitat de Barcelona and Oncology Program, CIBEREHD, [6]Hematopathology Unit, [7]Hematology Department, [8]Experimental Therapeutics in lymphoid malignancies group, Hematopathology Unit, Hospital Clinic, IDIBAPS, Barcelona, Spain

Background: Bendamustine, a drug that combines the properties of an alkylator and a nucleoside analogue, is currently being used for the treatment of chronic lymphocytic leukemia (CLL). Clinical responses are very heterogeneous and no specific markers to predict drug sensitivity have been reported.
Aims: The purpose of this study was to identify suitable biomarkers useful to predict bendamustine response in CLL patients.
Methods: The *in vitro* response to bendamustine 25 μM at 24 hours was determined in peripheral blood mononuclear cells from 80 CLL cases by Annexin V/PI labeling and flow cytometry. A gene expression profile was done in 38 CLL samples in order to identify the differentially expressed genes (DEGs) between the bendamustine-sensitive and the -resistant samples. Most relevant genes were validated by qPCR in a larger cohort of 77 CLL cases and the correlation of gene expression with bendamustine cytotoxicity was analyzed. The protein levels of the genes showing the strongest correlation with bendamustine response were then validated by flow cytometry. The effect of the microenvironment was also analyzed by co-culture with stromal cell lines.
Results: We found 416 DEGs between bendamustine-sensitive and -resistant cases. The biological functions of these genes included cell-to-cell signaling and interaction, cellular development, cellular growth and proliferation and cell death and survival. According to the fold change, we selected 66 genes for validation by qPCR, including 21 that showed a significant correlation with the *in vitro* response to bendamustine. The combination of *CD69 (*CD69*)* and *ITGAM* (CD11b) genes was the best predictor mRNA signature of response. When we interrogated the predictive value of the cell surface protein expression of these two molecules, we showed that the single expression of the activation marker CD69 was the most reliable predictor of bendamustine sensitivity in CLL cells. Importantly, a multivariate analysis revealed that the prognostic value of CD69 was independent from other biological and clinical CLL features, including Binet stage, mutational *IGHV* status, previous treatment, deletions on 17p and 11q and expression of ZAP-70, CD38 and CD49d. We also confirmed that the chemoresistance mediated by the microenvironment was accompanied by an upregulation of CD69 protein levels when CLL cells were cocultured with the stroma. Likewise, tissue-derived CLL cells expressed higher CD69 levels than their respective peripheral blood cell counterparts and, concordantly, were less sensitive to bendamustine.
Summary and Conclusions: We have identified CD69 as a maker of bendamustine resistance in CLL patients. Thus, CD69 quantification by flow cytometry may be useful to stratify patients who may receive bendamustine alone or in combination regimens. Acknowledgements: This work has been funded by Mundipharma Research.

SERUM CHEMOKINES AND CYTOKINES IN CLL PATIENTS TREATED WITH DUVELISIB, AN ORAL DUAL INHIBITOR OF PI3K-DELTA,GAMMA

M. Douglas[1,*] K. Allen[1], J. Sweeney[1], S. O'Brien[2], I. Flinn[3], S. Horwitz[4], J. Byrd[5], M. Patel[6], B. Kahl[7], F. Foss[8], P. Porcu[9], V. Kelly[1], H. Stern[1]
[1]Infinity Pharmaceuticals, Cambridge, [2]MD Anderson Cancer Center, Houston, [3]Sarah Cannon Research Institute, Nashville, [4]Memorial Sloan Kettering Cancer Center, New York, [5]The Ohio State University Medical Center, Columbus, [6]Florida Cancer Specialists, Sarasota, [7]University of Wisconsin, Madison, [8]Yale Medical Group, New Haven, [9]The Ohio State University, Columbus, United States

Background: PI3K-δ and PI3K-γ play complementary roles in malignant B-cells and the tumor microenvironment. Inhibition of PI3K-δ blocks cytokine-mediated CLL proliferation, while inhibition of PI3K-γ blocks M2 macrophage polarization and T-cell migration *in vitro*. Duvelisib, a dual oral inhibitor of PI3K-δ,γ, has shown clinical activity in a phase 1 study in patients with hematologic malignancies (Study IPI-145-02), including patients with relapsed/refractory (R/R) CLL (O'Brien, ASH 2014).
Aims: Examine changes in serum chemokines and cytokines from patients with R/R CLL following treatment with duvelisib.
Methods: Serum from 52 patients with R/R CLL and 30 healthy subjects was analyzed for 72 analytes (cytokines, chemokines, and matrix metalloproteinases) using Luminex xMAP^{O} technology at baseline, Cycle 1 Day 8 (C1D8), C2D1, and C3D1. Median change from baseline was analyzed for statistical significance using a paired t-test with Bonferroni correction for multiple hypotheses; threshold for reduction was ≤50% of baseline and for increase was ≥150% of baseline. Comparison between CLL and healthy subjects utilized a 2-sample t-test with Bonferroni correction.
Results: Following treatment with duvelisib, the median serum levels of 12 analytes decreased to ≤50% of baseline ($p < 0.0002$) by C1D8. These included CCL1, CCL3, CCL4, CCL17, CCL22, CXCL10, CXCL13, IL-6, IL-10, IL-12p40, MMP-9 & TNFα. All of these were significantly elevated ($p < 0.0042$) at baseline in CLL patients compared to healthy subjects and reduced towards normal range following duvelisib treatment. In addition, MMP1 was the only analyte for which median serum levels increased above the threshold of ≥150% of baseline ($p < 0.0002$). Together, these 13 analytes were further explored for potential associations with clinical efficacy. TNFα was significantly elevated ($p < 0.0013$) at C2D1 & C3D1 in patients who did not exhibit a nodal response.
Summary and Conclusions: Most of the analytes reduced following duvelisib treatment are known to be involved in the communication between CLL cells and the tumor microenvironment. Furthermore, one of these analytes (TNFα) exhibited elevated levels at C2D1 and C3D1 in patients who did not achieve a nodal response. Together, these data indicate that modulation of the tumor microenvironment via PI3K-δ,γ inhibition may be an important mechanism of action in supporting clinical activity of duvelisib in patients with CLL.

Background: Chronic lymphocytic leukemia (CLL) is a lymphoid malignancy which is derived from monoclonal B-lymphocytes. Tumor reactive T cells were determined in patients with CLL especially in early stages and it was suggested that immunosuppressive mechanisms allow CLL cells to escape from immunosurveillance. Regulatory T cells (Treg cells) are defined as a subgroup of T cells which express the markers CD4, CD25 and FOXP3. It was shown that Treg cells can prevent autoimmune and inflammatory diseases and inhibit antitumor responses. The numbers of Treg cells increase in other malignancies and CLL. Possible mechanisms about Treg cells' effects in immunoregulatory activity include cell-cell contact dependent suppression, secretion of anti-inflammatory cytokines like interleukin 10, transforming growth factor beta, and accumulation of pericellular adenosine. CD39 is another marker of Treg cells which has ectoenzyme- ectonucleoside triphosphate diphosphohydrolase activity for producing adenosine monophosphate (AMP). After production of AMP, another ectoenzyme (CD73) hydrolyses this substrate for accumulating pericellular adenosine which contributes to Treg cells' suppressor activity and by binding to its receptors on cytotoxic T cells (CTL) they can also suppress anti tumor activity of CTLs.
Aims: In our study we have measured Treg cells in the peripheral blood of 39 CLL patients and 21 healthy controls (HCs) by using flow cytometry. We have also evaluated the anti-proliferative effect of Treg cells on effector CD4 positive T cells with co-culture.
Methods: Peripheral blood CD4+CD25+and CD4+CD25-T cells from patients and HCs isolations were performed. Cells were co-cultured triplicate in anti-CD3 coated 96 well plates at a ratio of 1:1 ($5x10^3$cells: $5x10^3$cells) for 5 days and medium supplemented with soluble CD28 at 5µl/ml concentration. Cross mixing experiments were performed by co-culturing patients' and HCs' Treg cells with the autologous and the converse CD4+CD25- cells either HCs or patients. On the first day and the fifth day of culture WST-1 was performed in order to measure proliferation. The measurements were performed in triplicate. The results were evaluated according to the unpaired T-test by using SPSS statistical program. The difference were indicated as statistically significant if $p<0.05$ and highly significant if $p<0.01$.The proliferation index was calculated according to the formula mentioned as $[(\text{Cell \#})_{last}-(\text{Cell\#})_{initial}]/ [(\text{Cell\#})_{initial}]$
Results: As demonstrated in the table the percentages of CD4+CD25+and CD4+CD25+FOXP3+cells were not different between patients and HCs. However the expressions of CD39 on CD4+CD25+cells are significantly higher in patients than HCs. In addition, the cell percentage of CD39+cells in the population of lymphocytes was found approximately equal to those of CD4+CD25+cell population. The effect of Treg cells on effector T cells are shown in figures We evaluated the proliferation index for CLL patients and HCs. In this context, first, we compared proliferation index of 1:1($CD4^+CD25^{high}$: $CD4^+CD25$-) autologous cell co-culture versus 0:1 ($CD4^+CD25^{high}$: $CD4^+CD25$-) cell culture in patients and HCs separately. We demonstrated that patient $CD4^+CD25^{high}$ Treg cells could not inhibit proliferation of autologous $CD4^+CD25$- cells. In contrast, $CD4^+CD25^{high}$Treg cells from HCs supressed the proliferation of their own $CD4^+CD25$- significantly (p=0,018). Second, we performed a cross-mixing experiment in which patient and control regulatory $CD4^+CD25^{high}$cells were co-cultured with the converse $CD4^+CD25$- cells from either controls or patients. We compared proliferation index of A) Patient $CD4^+CD25^{high}$:HCs $CD4^+CD25$- (1:1) versus HCs $CD4^+CD25$- (0:1) B)HCs $CD4^+CD25^{high}$:Patient $CD4^+CD25$- (1:1) versus patient $CD4^+CD25$- (0:1). We found that while patients Treg cells have no inhibitor effect on HCs' $CD4^+CD25$- cells, in contrast HCs' Treg cells could inhibit the proliferation of patient $CD4^+CD25$- cells however the difference was not significant.

	CD4+CD25+ (min-max) (%)	CD4+CD25+ FOXP3+ (min-max) (%)	CD4+CD25+CD39+ (min-max) (%)	CD39+ (min-max) (%)
Patients	0,74 (0,07-8,889)	5,71 (1,07-50,48)	20,62(0,10-77,33)	21,46 (0,20-80,60)
Healthy Control	1,37(0,10-18,21)	7,91(0,30-52,33)	6,34(0,19-12,62)	3,68(0,09-13,51)
P value	0,114	0.963	<0,01	<0,01

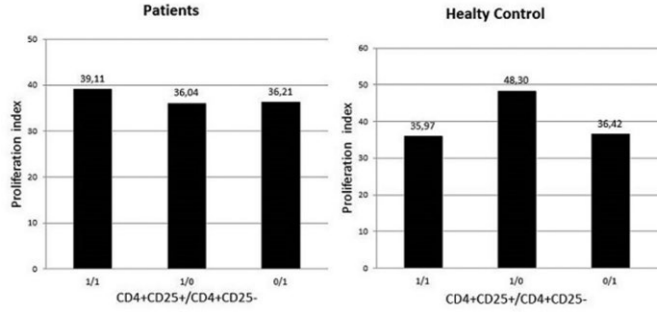

Figure 1.

Summary and Conclusions: CD4+CD25+cells are sensitive to toxicity induced by ATP, high expression of CD39 on these cells can reduce this sensitivity and this mechanism can provide survival advantage for Treg cells. In addition, it can be possible that high expression of CD39 on Treg cells in CLL can serve more AMP for CD73 which can result pericellular accumulation of adenosine. It is probable that by this mechanism, inhibition of anti tumor activity of CTL can be resulted as enhanced surveillance of malign CLL cells. On the other hand we demonstrated defective function of Treg cells in co cultures in CLL. An increased incidence of autoimmunity is a known entity in CLL. The question is whether this defective cell-cell contact dependent suppression can be responsible from this increased incidence.

E1041

ELIMINATION OF MUTATED P53 PROTEIN AND INDUCTION OF P53 DOWNSTREAM GENES IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS USING PRIMA-1MET

Z. Jaskova[1,2,*], J. Malcikova[1,2], J. Smardova[3], Y. Brychtova[1], J. Mayer[1], M. Trbusek[1,2]
[1]Department of Internal Medicine - Hematology and Oncology, University Hospital, [2]Centre of Molecular Medicine, Central European Institute of Technology, Masaryk University, [3]Department of Pathology, University Hospital, Brno, Czech Republic

Background: In chronic lymphocytic leukemia (CLL), *TP53* mutations represent the most adverse predictive and prognostic factor. As we have reported, particularly poor prognosis is associated with missense mutations located in DNA-binding motifs of the p53 protein. These alterations frequently lead to accumulation of mutated p53 protein with presumably oncogenic properties. Thus, the affected patients could potentially benefit from innovative therapy targeted directly to the mutated p53 protein. PRIMA-1^{MET}(Tocris Bioscience) is a small molecule currently tested in clinical trials, which has been declared to be able to change mutated p53 to wild-type (wt) conformation and rescue its activity.
Aims: To test a possibility of subtle molecular manipulation with accumulated mutated p53 in CLL cells using small molecule PRIMA-1^{MET}.
Methods: CLL patients' peripheral blood mononuclear cells (leukemic cells' proportion over 85%) used for reactivation study were chosen from the cohort characterized for *TP53* status by FASAY and direct sequencing. The samples were analyzed for p53 protein level by western blot (WB). A metabolic activity (viability) after PRIMA-1^{MET} treatment was determined by WST-1 assay. Impact of 48 h PRIMA-1^{MET} exposure on p53 protein level was analyzed by WB. The p53 downstream genes' induction was assessed by qRT-PCR.
Results: Firstly, the impact of PRIMA-1^{MET} on CLL cells' viability was assessed to determine appropriate concentration range for the reactivation. We observed clear concentration-dependent curve of viability in all studied samples (n=5) between 0.5 and 4µM. Therefore, 2µM and 4µM were further applied for the testing of reactivation at molecular level. Five out of eleven mutated samples with high baseline p53 level showed clearly diminished or even absent p53 protein after 4µM PRIMA-1^{MET} treatment and four other samples manifested partially reduced level. The effects at 2µM were also apparent, but less pronounced. The best response was observed for mutations p.Y205H, p.R248W, and p.C275R, in which the p53 protein was completely eliminated even at 2µM concentration. The p53 downstream genes' expression was heterogeneous among the samples, with the induction of *CDKN1A* (*p21*) and *GADD45* being much more prominent compared to *PUMA*. The expression induction reached up to 11800% (*p21*) and 4500% (*GADD45*) in comparison with untreated control set at 100%. The *BAX* and *MDM2* genes' expression was not increased after treatment. This indicates that observed elimination of mutated p53 is not probably caused through the induction of the p53 basic negative regulator MDM2. Concerning the specificity of observed effects with respect to *TP53* status, we noted the following: (i) in line with other studies, we noted similar impact of PRIMA-1^{MET} on both p53-wt and p53-mut samples' viability, and (ii) certain induction of p53 target genes was also evident in p53-wt samples. In addition, we also analyzed 10 samples with *TP53* mutation, but without p53 protein stabilization, for induction of the downstream genes. Again, the effects of PRIMA-1^{MET} were apparent, especially in case of *p21* and *GADD45*.
Summary and Conclusions: We have been able to demonstrate that PRIMA-1^{MET} can significantly diminish or even completely eliminate p53 protein accumulated due to the high-risk mutations in *TP53* gene. It still remains to be elucidated, what is the specificity of the p53 pathway activation with respect to *TP53* status. Supported by grants NT/13519-4/2012 and MUNI/A/1180/2014.

Heart, Rome, [4]Hematology Unit, "Pugliese Ciaccio" Hospital, Catanzaro, [5]Scientific Direction, IRCCS Centro di Riferimento Oncologico della Basilicata, Rionero in Vulture, [6]CEINGE, Advanced Biothecnology, University "Federico II", Naples, Italy

Background: Normal and malignant cells secrete extracellular microvesicles (MV), usually defined as shedding membranous vesicles (50-1,000 nm diameter) that are produced by budding from the plasma membrane. It has been demonstrated that elevated levels of circulating MV in chronic lymphocytic leukemia (CLL) are able to activate bone marrow stromal cells and, in turn, to enhance production of VEGF, a pro-survival factor for CLL B-cells
Aims: We analyzed serum from untreated CLL patients searching for the number of circulating MV in order to test their possible prognostic role when evaluated at diagnosis.
Methods: Sera from 101 CLL patients (mean age 70 years, range 41 – 89; 60 M, 41 F; 52 patients with A, 36 with B, and 13 with C Binet clinical stage, respectively) were collected at diagnosis. Briefly, 1 ml of serum was processed with serial centrifugations using Optima XE ultracentrifuge (Beckman Coulter): 2,000 x g for 15 min; 10,000 x g for 30 min; 100,000 x g for 70 min. Resulting pellets were washed with pre-filtered (0.22 µm) phosphate buffer saline (PBS) and centrifuged at 100,000 x g for 70 min. Pellets were suspended in 200 µl of pre-filtered PBS. All steps of MV isolation were performed at 4°C. MV enriched pellets were analyzed by a FACSCalibur (Becton Dickinson) cytometer using Cell Quest software. Standard micro beads (0.3 – 0.9 – 3 µm) were used to define the size limit for MV and their size assessment. Pre-filtered PBS was also used to set the lower limit of MV gate. TruCOUNT beads (BD) were also added immediately prior to analyze samples by flow cytometry to determine the number of MV/µl. To identify and characterize MV, allophycocyanin-conjugated anti-CD19 monoclonal antibody and isotype-matched controls were used.
Results: A higher mean number of MV was found in CLL patients with respect to 28 control healthy subjects (991.8±768.4/µl *vs* 270±325/µl; p <0.001). Of interest, in CLL patients about 15% of MV were found to be CD19+. A higher number of MV was found in patients with advanced clinical stage (Binet A+B 950/µl±770 *vs* C 1,234/µl±661, p 0.02), while a trend was observed with surface expression of CD38, (p 0.06). No correlation was found according to CD49d and ZAP-70 expression, IgVH mutational status and cytogenetics abnormalities detected by FISH. A correlation was also found with respect to the number of circulating B-lymphocytes, with either total and CD19+MV (r=0.23 and r=0.25, respectively, p<0.05). Overall, patients who required therapy showed a more elevated number of MV at diagnosis (1,333/µl±941) with respect to those who did not (764/µl±565) (p 0.003). The time to treatment was longer in patients with lower number of both total (p 0.05) and CD19+MV (p<0.05). Finally, overall survival was shorter in patients with higher levels of total MV (p 0.001), while the number of CD19+MV was not significant.
Summary and Conclusions: Our study suggests a possible prognostic relevance of the circulating MV number detected at diagnosis in CLL patients. Interestingly, it has been previously reported that: i) the majority of circulating MV is platelet-derived (about 80%), while only a minority of them directly belongs to endothelium (about 10%) or leukocytes (about 10%); ii) a phenotypic shift from predominantly platelet/megakaryocyte-derived CD61+MV occurs in early stages ,while more "leukemic" CD19+B-cell derived MV are seen in advanced clinical stages; iii) *in vitro* stimulated CLL cells generate MV which preferentially express CD52, but not CD19 antigen. In light of these observations, we are currently evaluating the complete phenotype of the CD19-negative MV.

CHANGES IN LYMPHOCYTE SUBSETS, ANGIOGENIC FACTORS AND PLASMA CYTOKINES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA DURING TREATMENT WITH OFATUMUMAB AND LENALIDOMIDE

C. Vitale[1,*] E. ten Hacken[1], H. Gao[2], M.J. Keating[1], S. O'Brien[1], W.G. Wierda[1], L. Falchi[1], J. Reuben[2], J. Burger[1], G. Calin[3], A. Ferrajoli[1]
[1]Department of Leukemia, [2]Department of Hematopathology, [3]Department of Experimental Therapeutics, UT MD Anderson Cancer Center, Houston, United States

Background: Chronic lymphocytic leukemia (CLL) is characterized by a complex immune dysregulation. In CLL, lenalidomide exerts both a direct antitumor effect and a pleiotropic activity on the immune system. The addition of an anti-CD20 monoclonal antibody to lenalidomide is associated with improved clinical responses in patients with CLL.
Aims: The aim of this study was to analyze the *in vivo* effects of the combination of ofatumumab and lenalidomide on circulating T and NK cell numbers, and on plasma levels of angiogenic factors, chemokines and cytokines.
Methods: Thirty-two patients with relapsed or refractory CLL were treated in a phase II clinical study with ofatumumab and lenalidomide. Peripheral blood mononuclear cells (PBMC) and plasma samples were collected at baseline and after 3, 6, 9, and 12 months of therapy. Lymphocyte subsets were defined by the expression of CD3, CD4, CD5, CD8, CD16, CD19, CD20, CD25, CD56, CD57, and Forkhead box protein P3 (FoxP3) by flow cytometry. PBMC from 34 age-matched healthy individuals were used as controls. A multiplex bead-based immunoassay was used to quantify plasma concentration of bFGF, VEGF, Trombospondin-1, IFN-γ, CCL2, CCL3, CCL4, IFNα2, and IL-12p70. Clinical responses to therapy were assessed according to the 2008 International Workshop on CLL criteria.
Results: Treatment with ofatumumab and lenalidomide decreased the number of circulating T and NK cells. The greatest decrease was observed after 3 months of therapy as compared to baseline (median $CD3^+$T cells 950/µl vs. 1830/µl, $CD4^+$T cells 460/µl vs. 790/µl, $CD8^+$T cells 460/µl vs. 700/µl, Tregs 50/µl vs. 80/µl, $CD16^+CD56^+$NK cells 120/µl vs. 160/µl, and $CD57^+CD56^+$NK cells 32/µl vs. 70/µl; p≤0.02 for all comparisons). We hypothesized that T cell number could impact the response to therapy, and therefore compared T and NK cell populations in patients who achieved a complete response (CR) versus those seen in non-responders (NR). We found that the baseline number of $CD4^+$T cells and $CD57^+CD56^+$NK cells was higher in CR patients as compared to NR patients (median absolute number 1595/µl vs. 715/µl, p=0.04, and 358/µl vs. 70/µl, p=0.02). We also compared baseline T and NK cell populations of CR patients to healthy donors, and found that the former had significantly higher numbers of $CD16^+CD56^+$and $CD57^+CD56^+$NK cells (median 356/µl vs. 80/µl, p=0.03, and 358/µl vs. 29/µl, p=0.0008). Interestingly, baseline numbers of $CD16^+CD56^+$and $CD57^+CD56^+$NK cells were comparable between NR patients and healthy individuals. Plasma levels of bFGF, VEGF and IFN-γ were also significantly decreased at month 3 compared to baseline in all analyzed patients (p≤0.02 for all comparisons). No modulation of Trombospondin-1 levels was detected. Consistently with our previous report in patients treated with lenalidomide as monotherapy, we observed significantly lower levels of circulating CCL2, CCL3, CCL4, IFNα, and IL-12p70 during treatment in patients who achieved CR, compared to NR (p <0.05 for all comparisons).
Summary and Conclusions: Patients with CLL achieving CR to treatment with ofatumumab and lenalidomide have higher baseline numbers of CD4+T cells and CD57+CD56+NK cells, suggesting that these cells play a key role in response to therapy. The *in vivo* effect of this combination in modulating the interactions between the microenvironment and the CLL clone is supported by the induced changes in plasma angiogenic factors and cytokine levels.

E1044

CD49D EXPRESSION IN TRISOMY 12 CLL HAS LITTLE PROGNOSTIC POWER FOR SHORTER OVERALL SURVIVAL

P. Bulian[1,*] T.D. Shanafelt[2], C. Fegan[3], A. Zucchetto[4], L. Cro[5], H. Nuckel[6], L. Baldini[5], A.V. Kurtova[7], A. Ferrajoli[7], J. Burger[7], G. Gaidano[8], G. Del Poeta[9], C. Pepper[3], D. Rossi[8], V. Gattei[1]
[1]Clinical and Experimental Onco-Hematology Unit, IRCCS Centro di Riferimento Oncologico, Aviano, Italy, [2]Mayo Research Center, Rochester, United States, [3]Cardiff University, Institute of Cancer and Genetics, Cardiff, United Kingdom, [4]IRCCS Centro di Riferimento Oncologico, Aviano, [5]Ospedale Maggiore, IRCCS Ca Granda, Milano, Italy, [6]University of Duisburg-Essen, Essen, Germany, [7]University of Texas, MD Anderson Cancer Center, Houston, United States, [8]Amedeo Avogadro University, Novara, [9]Tor Vergata University, S. Eugenio Hospital, Roma, Italy

Background: Trisomy 12 CLL cells have increased expression of many integrins, including CD49d, compared with non trisomy 12 CLL. CD49d is one of the most powerful prognostic markers in CLL and CD49d positive cases have an average 23% reduction in OS at 10 years. The high fraction of CD49d positive cases would predict an high risk disease, in contrast with the intermediate risk category assigned to the generic case bearing trisomy 12.
Aims: To verifiy if the high fraction of CD49d positive cases in trisomy 12 CLL is still significantly correlated to shorter overall survival.
Methods: We performed a multi-center pooled analysis on 2157 untreated CLL cases all evaluated by FISH for the common cytogenetic aberrations. Cases were classified according to the hierarchical model of Dohner in the following subgroups: 41% del13q (n=892), 28% negative (n=599), 14% trisomy 12 (n=303), 17% high risk (n=363, del17p or del11q). The following prognostic variables were evaluated: IGHV mutational status, CD49d, CD38 and ZAP-70 expression. The endpoints overall survival (OS) and treatment free survival (TFS) were correlated with prognostic variables by Kaplan-Meyer plots and Cox regression analysis.
Results: The rate of death across cytogenetic subgroups was as expected: 10.5% in del13q cases, 14.3% in negative cases, 15.8 in trisomy 12, 26% in high risk cases. By comparing low risk cytogenetic subgroups (del13q, negative and trisomy 12) we found in trisomy 12 a remarkable higher fraction of cases expressing CD49d, CD38, ZAP-70 and UM IGHV. This was most evident for CD49d (78% of cases CD49d positive), one of the most powerful prognostic markers in this setting. We compared the hazard ratio (HR) for death in trisomy 12 and negative cytogenetics subgroups, which shared a similar rate of death and median follow-up (3.5 year trisomy 12, 4.7 years negative). By univariate analysis all the variables had a significant HR, however, in trisomy 12 cases the HR magnitudo and its statistical significance were lower for CD49d, CD38 and ZAP-70, with a barely significant p-value for CD49d (p=0.0489). By contrast, UM IGHV had a slight higher HR with the same level of statistical confidence. By Kaplan-Meyer analysis, the 10-years OS rate of the few CD49d negative cases (84%) was superimposable to that of del13q/negative subgroups

(82% and 76%). However, in multivariate analysis only UM IGHV remained a significant predictor for shorter OS.
Summary and Conclusions: Our data suggest that in trisomy 12 CLL IGHV mutational status may still be used for prognostic assessment, on the contrary CD49d, CD38 and ZAP-70 expression lose their usual prognostic power. These features, toghether with other characteristics, support the idea that CLL bearing trisomy 12 constitute a CLL subgroup with a different biology from all other CLLs.

E1045

MESENCHYMAL STROMAL CELLS IMPROVE SURVIVAL OF B-CLL CELLS: ROLE OF CELL-CELL CONTACT AND SOLUBLE FACTORS IN THE MICROENVIRONMENT

V. Trimarco[1,*] G. Chiodin[1], E. Ave[1], C. Gattazzo[1], F. Frezzato[1], V. Martini[1], F. Severin[1], S. Imbergamo[1], A. Cabrelle[1], A. Visentin[1], M. Facco[1], G. Semenzato[1], L. Trentin[1]
[1]Department of Medicine, University of Padua, Padua, Italy

Background: The malignant behavior of chronic lymphocytic leukemia (CLL) cells can be ascribed to intrinsic features involving an abnormal signal transduction mediated by B Cell Receptors (BCR) and to factors originating from the surrounding microenvironment in which CLL B cells engage complex interactions with stromal cells. Mesenchymal Stromal Cells (MSCs) represent the dominant population in CLL-marrow stroma and are involved in supporting leukemic B cell survival and conferring drug-resistance. During last years, several molecules have been developed to inhibit a variety of kinases in the BCR signaling that are essential not only for activation of multiple survival pathways, but also for migration and adhesion of B cells in the microenvironment.
Aims: The aim of this work was to evaluate how MSCs influence CLL B cell behavior and whether Bafetinib, CAL-101 and Ibrutinib kinase inhibitors could affect the MSC-CLL B cell cross-talk.
Methods: MSCs isolated from the BM of 50 CLL patients were expanded *ex vivo* and characterized through flow cytometry analysis and differentiation cultures (adipocytes and osteocytes). Freshly isolated CLL peripheral blood B cells were co-cultured with MSCs. For experiments using kinase inhibitors, B cells were treated with 5μM Bafetinib, 5μM CAL-101 and 5μM Ibrutinib. Apoptosis was measured by Annexin V test and western blotting analysis. Chemokines and cytokines released in culture supernatants were collected for the human Bio-Plex™ 27 plex Cytokine Assay.
Results: In presence of MSCs, we observed an extended survival of leukemic B cells (60%±17.3 with MSCs *vs* 14%±11.7 with *medium* alone). Through a transwell system to avoid lymphocyte-MSC direct contact, CLL B cell survival in presence of MSCs was minimally reduced (60%±17.3 with MSCs *vs* 52.4%±23.5 with MSCs in transwell system), suggesting that the anti-apoptotic effect is mainly ascribed to soluble factors produced by MSCs. In order to identify soluble factors responsible for the pro-survival effect, MSCs secretion profile was evaluated before and after CLL B cells exposure. We observed a stronger increase of IL-8, IL-15, CCL11 and CXCL10 production under co-culture conditions, suggesting their potential involvement in leukemic B cell survival. Moreover, we found that MSCs were not able to rescue CLL B cells from apoptosis induced by kinase inhibitors. In fact, CLL B cell viability co-cultured with MSCs was: 84.7%±4.9% without inhibitors, 57.2%±14.9% with Bafetinib ($p<0.01$), 49%±16.5% with CAL-101 ($p<0.01$), and 38.2%±10.8% with Ibrutinib ($p<0.001$).
Summary and Conclusions: We demonstrate that MSC-CLL B cell co-culture represents a reproducible *in vitro* system mimicking the *in vivo* bone marrow conditions, pointing out that the heterogeneity of the disease is reflected also by CLL B cell ability to respond to MSCs signals. Therefore, to identify patients who may benefit from treatments targeting the cross-talk with supportive cells, it is mandatory to test the effect of new therapeutic agents in the context of the microenvironmental influence. For this reason, in our co-culture system we tested the effect of Bafetinib, CAL-101 and Ibrutinib kinase inhibitors involved in BCR pathway, finding that all the molecules were able to reduce CLL B cell viability despite the MSCs presence. As a result of the ability of kinase inhibitors to inactivate BCR signaling pathway, leukemic B cells lose not only their ability to proliferate and survive but also their ability to home in, invade, and persist in the lymphoid tissue, a necessary condition to pursue the eradication of the disease.

E1046

QUANTITATIVE AND QUALITATIVE ANALYSIS OF REGULATORY T CELLS (TREGS) IN B CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL)

E.D. Ioannidou[1,*] V. Bakou[1], M. Vikentiou[1], E. Konsta[1], F. Kontsioti[1], C. Kontos[2], D. Vasilatou[1], A. Mpouchla[1], K. Gontopoulos[1], C. Roubakis[1], G. Stavroulaki[1], N. Papanikolaou[1], M. Atta[1], E. Mpazani[1], S. Papageorgiou[1], S. Kokkori[3], E. Kyriakou[3], G. Dimitriadis[1], V. Pappa[1]
[1]Second Department of Internal Medicine and Research Institute, Attikon University General Hospital, [2]Department of Biochemistry and Molecular Biology, University of Athens, [3]Hematology Laboratory, Attikon University General Hospital, Athens, Greece

Background: T regulatory cells are immunosuppressive cells considered to play an important role in cancer biology and autoimmunity by suppressing host immune response and autoreactive lymphocytes respectively. Accumulated data indicate a significant role of T cell dysfunction in the pathogenesis of CLL.
Aims: The scope of this study is the analysis of numerical and functional abnormalities of Tregs in B-CLL with the view to elucidate their role in the pathogenesis of the disease.
Methods: Treg cells derived from 28 untreated B-CLL patients with a median age of 62 and 17 healthy donors were analyzed by Flow cytometry. Peripheral blood was obtained from 15 patients with B-CLL. Mononuclear cells were isolated using Ficoll-Paque gradient centrifugation. $CD4^+CD25^+$(Treg cells), $CD4^+CD25^-$ (T effector cells, Teff), $CD5^+CD19^+$(B-CLL) and $CD5^-CD19^+$(Normal B, NB) cells were separated using magnetic antibody cell sorting. To test the functionality of the assayed Tregs, the isolated cell populations were cultured in a 96-well plate (Tregs, Teff, B-cll, NB cells, B-cll: Tregs in 1:20 ratio, B-cll: Teff in 1:20 ratio, NB cells: Tregs in 1:20 ratio, NB cells: Teff in 1:20 ratio) and their proliferative capacity was measured using the BrdU assay. To further analyze the functional role of Tregs, peripheral blood was obtained from 12 patients with B-CLL and 12 healthy donors. Mononuclear cells were isolated using Ficoll-Paque gradient centrifugation. $CD4^+CD25^+CD127^{dim/-}$ (Treg cells), $CD5^+CD19^+$(B-CLL) and $CD5^-CD19^+$(Normal B, NB) cells were separated using magnetic antibody cell sorting and were co-cultured in a 96-well plate in a 1:10 ratio. The apoptosis of B cells was determined by the Annexin V/PI method.
Results: FACS analysis of the Treg cells resulted at the following observations: The Treg absolute cell number (cells/μL), estimated either as the number of $CD4^+CD25^+CD127^-$ cells or as the number of $CD4^+CD25^+FoxP3^+$cells, was significantly higher in patients' samples than in controls ($CD127^-$ $p=0.047$, $FoxP3^+p= 0.036$). Annexin V expression in Treg cells from BCLL patients was significantly lower compared to controls ($p=0.027$). The functional analysis of Treg cells through BrdU assay and Annexin V/PI method indicated that CLL Tregs were able to suppress the proliferation of Teff cells ($p=0.002$) and that Teff cells were in turn able to significantly suppress the proliferation of B-CLL cells ($p=0.05$). After the co-culturing of NB cells with Treg CLL cells, the apoptosis of NB cells was significantly increased compared to NB cells (16.10 *vs* 6.22, $p<0,005$). Likewise, when B-CLL cells were co-cultured with Treg CLL cells, their apoptosis was significantly increased compared to control (24.06 *vs* 12.66, $p<0,01$). Interestingly, no significant alterations were observed after culturing NB or B-CLL cells with Tregs from healthy donors.
Summary and Conclusions: In CLL patients, Treg cells are significantly higher and present with lower apoptotic levels compared to healthy donors. The functional analysis indicates that Teff cells suppress the proliferation of B-CLL cells whereas they are suppressed by Tregs, indicating that increased Tregs observed in CLL contribute indirectly to the proliferation of the CLL clone. Moreover, CLL Tregs, unlike Tregs from healthy donors, enhance the apoptosis of both NB and B-CLL cells, suggesting the existence of distinct functional differences between CLL Tregs and their normal counterparts, which need to be further elucidated.

E1047

FCGAMMARIIB HOMMOAGREGATION CAN INDUCE A PROSURVIVAL STATE IN CHRONIC LYMPHOCYTIC LEUKAEMIA CELLS

R. Bosch[1,2,*], G. Ferrer[3], R. Damle[3], S. Gorlotov[4], K. Rai[5], E. Montserrat[6], J. Sierra[1,2], N. Chiorazzi[7], C. Moreno[1,2]
[1]Oncology/Hematology and Transplantation Laboratory, Biomedical Research Institute Sant Pau (IIB-Sant Pau), [2]Department of Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Experimental CLL Research and Treatment Program, The Feinstein Institute for Medical Research, Manhasset, NY, [4]MacroGenics, Rockville, MD, [5]Hematology/Oncology, Oncology LIJ Medical Center, Lake Success, NY, United States, [6]Department of Hematology, Institute of Hematology and Oncology, Hospital Clínic, Barcelona, Spain, [7]Experimental CLL Research and Treatment Program, The Feinstein Insitute for Medical Research, Manhasset, NY, United States

Background: FcγRIIb is a low-affinity receptor that regulates B-cell activation by inhibiting signalling from the B-cell receptor (BCR) in murine and normal B cells. This inhibitory capacity depends on the colligation of FcγRIIb with BCR and it is mediated by phosphorylation of SHIP and inhibition of the AKT pathway. Besides this BCR-dependent inhibitory effect, in murine B-cells FcγRIIb has been also implicated in delivering pro-apoptotic signals upon homoaggregation. However, the effects of FcγRIIb hommoagregation have not been extensively investigated in human normal-B cells and CLL cells.
Aims: To evaluate the effects of FcγRIIb signalling on viability, activation, and proliferation of human CD19+normal B-cells and CLL cells. Also, to investigate whether the SHIP/AKT pathway is involved in FcγRIIb hommoagregation signalling in these cells.
Methods: B-cells were isolated from cryopreserved PBMCs from 31 patients with CLL (14 *IGHV* mutated, M-CLL, and 17 *IGHV* unmutated, U-CLL) and 10 healthy donors, cultured in RPMI 10% FBS in the presence or absence of the novel and specific anti-human FcγRIIb mAb from Macrogenics. At 48 hours, cell viability was determined as the percentage of AnnexinV/TO-PRO®-3 double negative cells by flow cytometry, and cell activation was determined as the percentage of CD69+cells. Cell proliferation was determined at 72 hours by

using the Click-iT® EdU Alexa Fluor® 488 Imaging Kit. For signaling analyses, reactions were stopped after 5 minutes of exposure, and total protein extracts were performed to analyze the expression of phosphorylated SHIP and AKT by western blot.
Results: In human CD19+normal-B cells and CLL cells, the hommoagregation of FcγRIIb did not induce changes in B-cell viability nor in activation as compared to basal levels. However, the FcγRIIb hommoagregation induced an increase in proliferation at 72h in CLL cells from 15 out of 31 CLL samples and in CD19+normal B-cells from 2 of 10 healthy donor samples (48.4% *vs* 20%, p=0.152). Within CLL subgroups, 9 of 14 U-CLL and 6 of 17 M-CLL cases responded with an increase in proliferation after FcγRIIb hommoagregation (64.3% *vs* 35.3%, p=0.156). At the molecular level, we found that in 17 of 20 patients with CLL analyzed by western blot, CLL cells did respond to FcγRIIb hommoaggregation with an increase in AKT phosphorylation, while in CD19+normal-B cells, only 1 of 10 healthy donor samples did respond to FcγRIIb crosslink with a slight increase of AKT phosphorylation (p<0.01). No significant differences were observed between U-CLL and M-CLL cases, both groups showing an increase AKT phosphorylation in 90% and 80% of cases, respectively. SHIP protein did not appear to be involved in FcγRIIb hommoaggregation signalling in CD19+normal-B cells and in CLL cells.
Summary and Conclusions: In contrast to what has been described in murine B cells, the homaggregation of FcγRIIb in human normal B-cells and CLL cells did not trigger B-cell apoptosis. Moreover, in CLL cells FcγRIIb hommoagregation induced AKT-phosphorylation activating signals, an effect that was not observed in CD19+normal-B cells. Further experiments are needed to investigate whether FcγRIIb stimulation may enhance CLL cells survival and thereby contributing to the progression of the disease.

CHRONIC LYMPHOCYTIC LEUKEMIA CELLS ARE HIGHLY SUSCEPTIBLE TO DIRECT INHIBITION OF CHECKPOINT KINASE 1

J. Zemanova[1,2,*], K. Paruch[3,4], L. Krejci[3,5], K. Souček[3,6], O. Hylse[3,4], M. Boudny[1], M. Borsky[2], J. Osickova[2], P. Khirsariya[3,4], L. Sebejova[1], V. Navrkalova[1], J. Malcikova[1], E. Diviskova[2], Y. Brychtova[2], J. Mayer[2], M. Trbusek[1]
[1]Department of Molecular Medicine, CEITEC, [2]Department of Internal Medicine - Hematology and Oncology, University Hospital Brno, [3]Center of Biomolecular and Cellular Engineering, ICRC, [4]Department of Chemistry, [5]National Centre for Biomolecular Research, Masaryk University, [6]Department of Cytokinetics, Institute of Biophysics, Brno, Czech Republic

Background: Chronic lymphocytic leukemia (CLL) is incurable disease with as yet no optimal treatment options, particularly for patients with mutations in *TP53* or *ATM* genes. Checkpoint kinase 1 (Chk1) is involved in molecular pathways preserving genome integrity in all cell cycle checkpoints (G1/S, intra-S, G2/M) and also in non-dividing cells. SCH900776 (Schering-Plough) is highly specific Chk1 inhibitor currently tested in clinical trials for selected solid tumors and leukemia. We have prepared its potentially more metabolically stable analog OH209EN1, which possesses highly unusual N-trifluoromethyl pyrazole moiety. OH209EN1 phenocopies short interfering RNA-mediated Chk1 ablation and greatly sensitizes tumor cells to nucleoside analogs.
Aims: (1) to assess the impact of direct Chk1 inhibition on CLL cells´ viability using our innovative inhibitor, and (2) to correlate observed effects with the presence of *TP53* and *ATM* defects.
Methods: *TP53* and *ATM* mutations were identified by next-generation sequencing and Sanger sequencing. Deletions 17p and 11q were detected by I-FISH. Peripheral blood mononuclear cells (CLL cells´ proportion over 85%) were treated in 96-well plates using 500 000 cells/well. Cell lines were tested the same way using 50 000 cells/well. The final viability after 72h inhibitor exposure was assessed using metabolic WST-1 assay. Apoptosis (Annexin-V/PI) was measured by flow-cytometry in full blood samples in lepirudin treated with OH209EN1 for 24 h at 37ºC, 5% CO_2.
Results: Firstly we determined appropriate concentration range of OH209EN1 for viability testing using cell lines with known genetic status and healthy cells. The LC50 values after 72h treatment were following: 80 nM for GRANTA-519 (MCL, ATM mutation), 250 nM for MEC-1 (CLL/PL, p53 mutation), and 300 nM for NALM-6 (B-cell precursor leukemia, ATM/p53-wt). Negligible effect on three healthy PBMNC cultures and three non-cancerous fibroblast cell lines was noted up to 400 nM of the inhibitor. Further, Chk1 autophosphorylation on Ser-296 (Chk1 activation marker) was readily eliminated (on western blot) using 200 nM OH209EN1 in the cell line with high baseline autophosphorylation level (NALM-6). According to these results, we used concentrations 100, 200, 300 and 400 nM of OH209EN1 for the testing in CLL cells. Fifty-four CLL cultures were used and a clear concentration-dependent decrease of viability was noted in the very most of them. At the highest concentration 400 nM, the final median viability in individual genetic categories was following (listed according to sensitivity): 33% in samples with ATM inactivation (mutation and 11q-; n=15), 44% in samples with sole 11q- (n=10), 46% in samples with p53 inactivation (mutation with/without 17p-; n=13), and 62% in samples having no *ATM* or *TP53* abnormality (n=16). Interestingly, the inhibitor SCH900776 tested in parallel in 44 cultures showed substantially weaker effects with final median viability 80%. The concentration-dependent (OH209EN1, 100-400 nM) induction of apoptosis was clearly noted in two full blood samples from CLL patients, while no apparent effect was observed in one tested healthy control blood.
Summary and Conclusions: Although CLL cells from peripheral blood are non-dividing and exhibit rather low Chk1 expression, they manifest surprisingly high intrinsic sensitivity to specific Chk1 inhibitor. This good response concerning also *ATM* and *TP53* mutated samples seems to be in contrast to non-cancerous cells and thus provides potential clinical utility. E1050

REGULATION OF CD38 BY IRF4 IN CHRONIC LYMPHOCYTIC LEUKAEMIA

H. Marr[1,*] L. Gaughan[1], S.J. Tudhope[1], J.M. Allan[1]
[1]Northern Institute of Cancer Research, Newcastle University, Newcastle on Tyne, United Kingdom

Background: Chronic lymphocytic leukaemia (CLL) typically follows a very heterogeneous course in different patients. A number of prognostic markers have been determined in CLL, of which CD38 surface expression is one of the most widely used, with positivity indicating a poorer outcome. Interferon regulatory factor 4 (IRF4) is a transcription factor with vital roles in B cell differentiation. A single nucleotide polymorphism (defined by rs872071) in the 3'UTR region of the *IRF4* gene has been identified in genome wide association studies as defining a strong common risk allele for development of CLL (OR=2.72 [1.93-3.82 95% C.I.]). Interestingly, it is also significantly associated with CD38 positivity (p=0.004).
Aims: Given that the promoter and first intronic region of *CD38* both carry perfect consensus binding sites for IRF4, we hypothesised that IRF4 plays a role in the regulation of CD38 expression.
Methods: Chromatin immunoprecipitation (ChIP) was used to investigate binding of IRF4 to *CD38* in a panel of immortalised B cell lines (TK6, MEC-1, SU-DHL-6) and primary CLL samples. Primary cells were cultured on a CD40 ligand-expressing fibroblast layer in order to mimic the tumour microenvironment, prior to ChIP. Short interfering RNA (siRNA) was used in B cell lines to generate cells with transient knockdown of IRF4 protein. B cell lines were also transduced with short hairpin RNA (shRNA) and then cloned on sloppy agar to generate cell clones with constitutive IRF4 knockdown. Protein knockdown was confirmed by Western blotting. CD38 expression in knock down and wild type cells was determined by flow cytometry, and the effects on cell proliferation and sensitivity to cytotoxic agents were investigated by growth inhibition assay.
Results: ChIP demonstrated binding of IRF4 at *CD38* in two out of three cell lines (SU-DHL-6 and MEC-1). In both cases, binding at *CD38* intron 1 was consistently greater than the binding at the *CD38* promoter, and this reached significance in SU-DHL-6 (p=0.02). In contrast, binding at the *CD38* intron 1 was negligible in TK6 cells. IRF4 knockdown slowed proliferation in TK6 cells (p=0.02) and sensitized them to fludarabine-induced cytotoxicity. These effects were not observed in the other cell lines. In addition, despite evidence of IRF4 knockdown confirmed by western blotting, there was no effect on surface CD38 expression in any of the cell lines. Co-culture of primary cells on a fibroblast monolayer was associated with upregulation of IRF4 protein expression. ChIP in these primary cells did not show consistent evidence of binding at the *CD38* promoter or first intron. In separate experiments, IRF4 upregulation in primary cells cultured on the fibroblast layer was not associated with any change in CD38 expression.
Summary and Conclusions: These data suggest that IRF4 binds to *CD38*, specifically at the first intron. IRF4 is known to bind its target genes as a heterodimer with Ets family transcription factors, and the cell-line specificity of the IRF4-*CD38* binding demonstrated here, suggests that the expression of IRF4 binding partners in cell lines may be relevant. Despite evidence of IRF4-*CD38* interaction however, we were unable to demonstrate any impact of altered IRF4 expression (knockdown or upregulation) on surface CD38 expression. While CD38 remains a potential therapeutic target in CLL, these data suggest that IRF4 plays a relatively minor role in the functional regulation of surface CD38 in CLL.

Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background: In Chronic lymphocytic leukemia (CLL) four recurrent cytogenetic aberrations with different prognostic impact are routinely tested: deletions 11q, 13q, 17p and trisomy 12. Their prognostic impact is generally described using Dohner's hierarchy: del17p >del 11q >tris 12 >normal >del 13q. The aberrations are usually tested once at the diagnosis but their spectra can change during disease evolution.
Aims: Repeated analysis of the four recurrent CLL cytogenetic aberrations was aimed to monitor the changes in aberration distribution in the different disease stages.
Methods: Four common cytogenetic aberrations (deletions 11q, 13q, 17p, and trisomy 12) were detected using interphase FISH analysis.
Results: Based on the disease course and therapy administration, CLL patients were stratified into two groups: (A) patients with indolent disease – 16 % (52/335), no treatment required, median follow-up 75 months; (B) patients with progressive disease requiring therapy intervention either after an inactive phase (56 %; 186/335; median time to first treatment 35 months; median follow-up 74 months), or soon after diagnosis (28 %; 97/335; median time to first treatment 14 months, median follow-up 54 months). In total, newly acquired cytogenetic aberration was detected in 33 % (109) from 335 repeatedly tested patients. In the indolent group A, 23 % (12/52) of patients gained a new aberration during follow-up. In almost all cases (92 %; 11/12) the newly acquired aberration was deletion 13q. In the progressive group B, patients were tested repeatedly before the first therapy and during relapse where possible. 11 % (30/283) of patients gained a new aberration already before therapy - 20 % (6/30) at inactive phase and 80 % (24/30) at active phase of CLL. Del 13q comprised 83% (5/6) of aberrations gained at inactive phase. The distribution of aberrations gained at active phase of CLL was following: del 13q in 63 % (15/24), del 17p in 17 % (4/24), del 11q in 13 % (3/24), and tris 12 in 7 % (2/24) of cases. 71 % (200/283) of CLL patients were tested again in progression after therapy. New chromosomal aberration was detected in 34 % (67/200) of cases: del 13q in 61 % (41/67), del 17p in 28 % (19/67), del 11q in 16 % (11/67), and tris 12 in 1 % (1/67).
Summary and Conclusions: In our study we showed that 33 % of repeatedly tested patients acquired additional cytogenetic aberrations during the CLL course. The most frequently acquired aberration was 13q deletion (66 %). Regarding the disease activity, deletion 13q comprised 92 % newly acquired aberrations among patients with indolent CLL without clinical manifestation of the disease progression. Surprisingly, 13q deletion comprised 60 % of all aberrations acquired before therapy and 61 % of all aberrations acquired after therapy also in the group with progressive disease. Our data suggests that the proportion of the deletion 13q among newly acquired aberrations appears independent on the disease activity and therapy intervention. In contrary, 17p deletion acquisition increases with disease activity and foregoing therapy, 13 % before vs. 28 % cases after treatment in progressive group. NOVEL NO-ASA DERIVATIVES ARE NEW PROMISING AGENTS IN THE THERAPY OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AND SOLID CANCERS

H. Flamme[1,*] M. Krüger[2], A. Berkessel[2], M. Hallek[1], K.A. Kreuzer[1]
[1]Klinik I für Innere Medizin | Universitätsklinikum Köln, [2]Department Chemistry, University Cologne, 50937 Cologne, Germany

Background: CLL is characterized by an accumulation of B cells in the peripheral blood, bone marrow and lymphatic tissues. Patients harbouring inferior prognostic markers as the 17p deletion or the *TP53* mutation show high resistance to standard therapy in CLL. It is well known that NO-ASA (Nitric-oxide donating acetylsalicylic acid) is a potential drug for the treatment of diverse cancers by inducing apoptosis *in vitro* & *in vivo*.
Aims: Our main objectives were to determine whether NO-ASA is a specific therapeutic substance in high risk CLL and further solid cancers. Further we intend to illuminate the mechanism of its cytotoxic effect.
Methods: A group of 22 new developed NO-ASA derivatives were tested for their efficacy to induce apoptosis on primary CLL cells and PBMCs of healthy donors via Annexin V/7AAD assay. The anti-tumor effect analysis of the most promising derivatives (B9, B12, B13) was enlarged to the analysis of diverse cancer cell lines (SW480, MelJuso, HCC-44, SH2, COLO-407). In addition the *in vivo* effect of B1 (para-NO-ASA), B9, B12 and B13 were analyzed via JVM3-xenograft mouse model. To elucidate the biological mechanism of the derivatives we performed a kinase array, Western Blots and immunofluorescence analyses with a fluorescence coupled B9 (B20).
Results: The effective dose (and therefore the toxicity) in most of the NO-ASA derivatives were significant lower in CLL cells compared to healthy PBMCs (*e.g.* EC_{50} CLL: B9 1.3 µM, B12 1.05 µM, B13 1.08 µM; EC_{50} PBMCs: B9 93.4 µM, B12 55.4 µM, B13 77.2 µM). We detected a strong reduction of cell viability in all tested cell lines and a cytotoxic effect even on *TP53* mutated and pretreated CLL with the highest effects by B9 and B12. Derivative B9 and even B12 demonstrated a strong anti-tumor efficacy in the xenograft mouse with a maximal tumor inhibition rate of 65-70%. Cell imaging assumes that B20 might be localized and acts in structures near the endoplasmatic reticulum. The human phosphor kinase array and Western Blot analyses showed preliminary results of the impact of the NO-ASA derivatives on the cell cycle checkpoint signaling and the MAPKinase signaling pathway. After 3 h NO-ASA treatment (B9, B12) on primary CLL cells the phosphorylation of the kinases p38 alpha, MKK3/ MKK6, Chk2 and CREB were induced.
Summary and Conclusions: We showed that our new developed NO-ASA derivatives (especially B9 and B12) are novel potential therapeutic drugs in the treatment of CLL patients including these with bad prognosis. For the first time we identified the three NO-ASA derivatives B9, B12 and B13 as potential drugs for diverse solid cancers.

E1053

A RETROSPECTIVE CASE CONTROL STUDY ASSOCIATING CHRONIC LYMPHOCYTIC LEUKEMIA AND ITS SPECIFIC ABERRATIONS WITH CERTAIN RISK FACTORS

M. Karakosta[1], E. Delicha[1], G. Kouraklis[2], K. Manola[1,*]
[1]NCSR "DEMOKRITOS", [2]Medical School, University of Athens, Athens, Greece

Background: The role of environmental or occupational genotoxic exposure in the development of Chronic Lymphocytic Leukemia (CLL) is limited and inconclusive. In addition, no investigation has been conducted to elucidate the putative role of lifestyle and occupational factors in the formation of CLL specific chromosomal aberrations.
Aims: Regarding the above, the present study examines through detailed questionnaires the potential environmental and occupational chemical exposure as well as the lifestyle and cancer family history of cases and healthy controls to assess the contribution of specific risk factors to CLL incidence. Moreover, these postulated risk factors are evaluated for the first time in respect to CLL specific chromosomal abnormalities.
Methods: A total of 138 unselected patients diagnosed with CLL and 141 unrelated healthy men and women, age and sex matched to CLL cases, were enrolled in this study. Face-to-face interviews were conducted on the study participants using a standardized and structured questionnaire to obtain a lifetime demographic, occupational and medical history as well as other risk factor information. In addition, cytogenetic analysis was performed on unstimulated and stimulated bone marrow cells of all CLL patients at the time of diagnosis so as to associate CLL chromosomal abnormalities with specific risk factors. Study results were analysed using univariate and multivariate statistical analysis to control the overall influence of risk factors.
Results: CLL was positively associated with certain lifestyle and medical/clinical risk factors such as smoking (P=0.005), family history of CLL or other malignancy (P<0.0001), episodes of pneumonia (≥1) within 5 years before CLL diagnosis (P=0.016) and exposure to medical radiation (P=0.003). Similarly positive associations were revealed between CLL and occupational/environmental chemical exposures including exposure to petroleum (P<0.0001), metals (P=0.024), pesticides/chemical fertilizers (P<0.0001) and detergents (P<0.0001). It was also observed that if someone is exposed to more than two risk factors in lifetime, he/she is at ~1.5 fold greater risk of developing CLL compared to those who have experienced only one toxic exposure (OR=1.42, 95% CI=1.17-1.73, P<0.0001). Analyses by specific risk factors and CLL chromosome abnormalities showed that del(11q) and del(13q) were found more frequent in patients having been exposed to pesticides (P=0.050) and rubber (P=0.044) respectively while patients who had a father suffering from CLL or other malignancies tended to carry more often del(11q), del(13q) and +12.
Summary and Conclusions: Our study provides evidence for the involvement of genetic predisposition and exposure to specific occupational and lifestyle risk factors in the onset of CLL. Moreover, it was indicated that the more different risk factors one has been exposed to, the greater is the risk of developing CLL. Notably, the association of certain risk factors with CLL specific chromosomal aberrations for the first time revealed positive correlations between deletions of 11q and 13q and exposure to pesticides and rubber respectively. The above results reinforce the idea that the interaction between specific exposures and genetic predisposition may be a possible cause for the development of CLL and its specific chromosomal abnormalities.

HIGH RESOLUTION MELT (HRM) CURVE ANALYSIS OF P53 MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS

E. Elhassadi[1,2,*] P. Browne[1,2], D. O'Brien[2], J. Kelly[3], F. Quinn[4], E. Vandenberghe[1,2]
[1]Haematology, Trinity College, The University of Dublin, [2]Haematology, St.James's Hospital, [3]Cytogenetics, Our Lady's Children's Hospital, [4]Cancer Molecular Diagnostics, St.James's Hospital, Dublin, Ireland

Background: Disruption of p53 by deletion, mutation or both occurs in at least 10% of patients with chronic lymphocytic leukaemia (CLL) prior to first-line treatment and is associated with both chemo-refractoriness and a short median survival of 3-5 years. Del (17p) detected by FISH analysis identifies up to 80% of p53 disrupted patients, but the remainder can only be confirmed by Sanger sequencing, which is not feasible in a diagnostic molecular laboratory. p53 disrupted patients follow a specific treatment pathway with alemtuzumab and allogeneic transplantation if <65 years, but more recently the novel, effective agents ibrutinib and idelalisib have been licensed. The European research initiative on CLL (ERIC) recommended screening all patients for evidence of p53 disruption prior to therapy.
Aims: To develop a pre-sequencing screening assay for p53 mutations, using a high resolution melt (HRM) analysis to detect sequence alterations in exons 5-8 which harbour ≥95% of p53 mutations in CLL prior to confirmatory sequencing.
Methods: Consensus p53 PCR programme was employed to amplify exons 5-8 and optimise HRM analysis. The HRM predictive value and sensitivity were evaluated using the cell lines (K-562 and JURKAT) and DNA from known del(17p) patients of whom 80% will have a mutated second allele. We performed HRM screening on 45 CLL patient blood samples (12 treatment–naïve and 33 relapsed / refractory) and lymph node (LN) DNA from 4 patients with Richter's transformation (RT). Samples with an aberrant melt curve suggestive of sequence alteration, was confirmed by bidirectional Sanger sequencing and p53 mutation bioinformatics (COSMIC / Polyphen database) were used to establish mutation frequency and its deleterious impact.
Results: The HRM assay sequence alteration detection sensitivity was 15%. HRM analysis detected aberrant melt curves in 16/45 samples; 8/10 samples (80%) had a del(17p) and 8/35 (23%) had no FISH-detectable deletion and all cases were confirmed by sequencing. p53 mutations were detected in 8% (1/12) of treatment-naïve and 33% (11/33) of relapsed / refractory patients respectively. The 4 Richter's patients had no mutations detected in blood; however, 3 of them had a mutation in LN DNA. Missense mutations affecting the DNA binding site accounted for 83% of the p53 mutations and all were both common and deleterious when compared to the COSMIC and Polyphen database respectively.
Summary and Conclusions: We developed a consensus PCR amplification and HRM protocol for p53 mutation detection. HRM methodology is a sensitive, rapid and cost-effective pre-sequencing screening assay which reduces the numbers of samples requiring sequencing with a sensitivity of 15%. Our p53 mutation detection results are comparable with reported data in the literature.

E1055

ENDOSTEAL AND VASCULAR STRUCTURES OF BONE MARROW STROMA IN CLL

N. Semenova[1,*] B. Stanislav[1], R. Victor[1]
[1]Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: Normal hematopoiesis is carried out in close association with stromal microenvironment, which forms the hematopoietic niche. Endosteal and vascular elements of bone marrow stroma regulate the development of HSC and lymphoid differentiation. The study of endosteal-vascular niche structural organization of the bone marrow allows to clarify the role of these entities in the malignancy of hemolymphopoiesis.
Aims: To determine the morphofunctional features of stromal elements of hematopoietic microenvironment that form hematopoietic niches in CLL.
Methods: Bone marrow core biopsies of 96 patients with CLL at the age 49-73 years obtained before therapy were researched. Histological, histochemical, morphometric and immunohistochemical methods were used. The statistical significance was considered with p≤0,05 (Student criterion).
Results: On the bases of CLL patients spongy bone research, in bone marrow parenchyma 3 types of lymphoid infiltration were detected: nodular (18 cases - 18,8%), interstitial (26 cases - 27%), and diffuse (52 cases - 54,2%). The distribution of bone marrow infiltration types by Rai stages was determined. So, 3-4 stage was characterized by a predominance of cases with diffuse infiltration of the bone marrow, while 0-1 stage - by a predominance of nodular infiltration. Interstitial infiltration was observed at all Rai stages (0 stage - 3 cases, 1 stage – 7 cases, 2 stage – 16 cases, 3 stage – 10 cases, 4 stage – 5 cases). Morphological signs of bone marrow stroma disorders were established at all types of infiltration. Silver impregnation showed the increase number of reticulin fibers and the formation of reticular sclerosis foci in interstitial and diffuse types of infiltration, including endosteal bone marrow areas. Microvessels density increased with the progression of bone marrow infiltration. Vessels area in diffuse infiltration increased by almost 2 times in comparison with the control group (17,9±3,7% instead of 9,1±1,2% in the control group), in interstitial infiltration increased by 1,5 (13,1±1,2%), in nodular infiltration statistically significant changes were not found (12,3±2,5%), and, what is especially important, the increase of vessels' number in subendosteal spaces was noted. Dependance of prognostic protein marker Zap70 expression from the density of microvessels was evaluated and statistically significant correlation between these parameters (R=0,7, p <0.05, N=96) was noticed. The Zap70 expression also correlated with the type of bone marrow infiltration: in all cases of diffuse infiltration of bone marrow (n=52) most leukemic cells were positive (>65%), in nodular infiltration (n=18) expression in the majority of cases was not detected, interstitial infiltration of bone marrow (n=26) differed by variable expression of Zap70. 6 cases of interstitial infiltration with lack of expression of Zap70 (less than 15%), 4 cases with high expression (50-65%), 16 cases with moderate expression (30-45%) were noted. Analysis of endosteal cells showed an increase in cells number per area unit in interstitial (1,8±0,4 against 1,4±0,2 in the control group) and diffuse (2,3±0,7) infiltration. The change of endosteal cells morphology was established too. The number of cellular elements with elongated flattened nuclei shapes was decreased, while increase in endosteal and subendosteal areas of stromal cells with large light nucleus was noticed. Expression of the molecule CD146, which marks the stromal cells endosteal and perivascular areas in diffuse infiltration was also increased and was present in subendosteal areas almost everywhere (10,2±1,3% vs. 2,5±0,3% in the control group).
Summary and Conclusions: Defects of endosteal-vascular structures of bone marrow stroma testify to the participation of the hematopoietic niche in the neoplastic transformation of B-lymphocytes in CLL.

NEW PROGNOSTIC MARKER IN CHRONIC LYMPHOCYTIC LEUKEMIA: PLASMA CCL3 (MIP-1A)

D. Keskin[1], S.N. Esatoglu[2], M. Kutnu[3], T. Elverdi[1], A. Salihoglu[1,*] A.E. Eskazan[1], M.C. Ar[1], S. Ongoren[1], Z. Baslar[1], Y. Aydin[1], N. Tuzuner[4], H. Uzun[3], T. Soysal[1]
[1]Hematology, [2]Internal Medicine, [3]Biochemistry, [4]Pathology, Istanbul Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Chronic lymphocytic leukemia (CLL) is one of the most common hematologic malignancies in adulthood. Prognostic markers are still needed to aid therapy decision making. In response to BCR (B-cell receptor) activation, CLL cells secrete the chemokine CCL3 (MIP-1α) [C-C motif Ligand 3/Macrophage Inflammatory Protein-1α], which affects tumor cell-microenvironment interactions. It is found that plasma CCL3 level is a useful prognostic marker for risk assessment in CLL.
Aims: We aimed to determine if there is any correlation between CCL3 plasma levels and other prognostic markers in CLL patients, and if CCL3 has an impact on overall survival (OS).
Methods: Between May 2012-2014, 99 CLL patients and 25 control cases were included in the study. Peripheral blood samples were collected from both groups. Age, gender, Rai, Modified Rai and Binet stages, lymphocyte count, LDH level, β-2 microglobulin, CD38 expression, ZAP70 expression, del 17p status, bone marrow involvement pattern and plasma CCL3 levels were reported in the patient group. Age, gender and plasma CCL3 levels were reported in control group. Plasma CCL3 level was measured by enzyme-linked immunosorbent assay (ELISA).
Results: The median follow-up time was 18 months in both groups. Median age was 62.91±10.52 in CLL group and 67.92±12.28 in the control group. We established that plasma CCL3 levels in CLL patients were higher than in the control group (p=0.001). We divided CLL patients into two groups according to high and low CCL3, based on ROC analysis (cut off value >35 pg/ml). We found a positive correlation between high CCL3 level and β2-microglobulin (r=0.220, p=0.042). Six patients in the CLL group with high CCL3 were dead by the time of analysis, whereas no deaths occurred in the low CCL3 group. Patients lost to follow-up had higher plasma CCL3 (p=0.047). OS of patients with high CCL3 levels was found shorter. It was statistically determined that OS decreased with increased CCL3 levels (r=-0.201, p=0.046). No correlations were found between other prognostic markers. There was not any difference in CCL3 levels between the treated and not treated patients (p<0.2). In subgroup analysis, we noticed that splenomegaly was more common among patients with high CCL3 level (p=0.025).
Summary and Conclusions: Plasma CCL3 level is an important prognostic marker and is correlated with OS. The exact level of this chemokine in defining disease course is not determined yet. Further studies are warranted to confirm cut-off values of this chemokine and to make it one of the prognostic markers in CLL. CCL3/MIPI-α might also have a role in the follow-up of the targeted therapies of CLL.

E1057

IMMUNOPHENOTYPE OF CLL CASES WITH STEREOTYPED BCR IS CHARACTERIZED BY DECREASED CD23 EXPRESSION

V. Strugov[1,*] E. Stadnik[1], T. Silina[1], Y. Virts[1], Y. Mirolubova[1], A. Rumyantsev[1], P. Butylin[1], A. Zaritskey[1,2]
[1]Hematology Institute, Federal North-West Medical Research Centre, [2]Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation

Background: About 1/3 of CLL cases is characterized by stereotyped motifs in BCR structure apparently representing common antigen-driven selection of malignant clones. It is conceivable that continuous antigenic stimulation would

lead to certain surface immunophenotype changes in cases with BCR stereotypy. To the best of our knowledge no studies have tested this hypothesis so far.
Aims: To compare surface marker expression in CLL cases with or without BCR stereotypy.
Methods: Out of 148 treatment-naïve participants of NORMA trial (id: NCT02110394) 89 pts with diagnosis confirmed in a single centre by standardized flow cytometry protocol and known IGHV/IGHD/IGHJ sequences were analyzed. Most of these cases had typical CLL immunophenotype with bright CD5, high CD23 (median 83,8%) and CD200 (median 98,8%) expression. In few cases with low CD23 expression (N=3) mantle cell lymphoma was further excluded by FISH with IGH/CCND1 t(11;14) probe. BCR stereotypy was determined according to ERIC recommendations. Levels of expression of surface markers (in %) in stereotyped *vs* non-stereotyped cases were compared with Mann-Whitney U test.
Results: Among 89 pts IGHV-UM cases prevailed (N=61; 68,5%). 19 (~21%) pts had stereotyped BCRs. Most common subsets included #2 (N=6), #7 (N=4), #8 (N=3) and #1 (N=2). Statistical analysis showed no differences in surface expression of such markers as CD20, CD22, CD38, CD43, CD79b, CD200, kappa or lambda among stereotyped and non-stereotyped cases. However, BCR stereotypy was associated with significantly lower % of CD23 positivity (median 64,55% *vs* 87,15%, p=.041).
Summary and Conclusions: Decreased surface expression of CD23 in CLL cases with stereotyped BCR is shown for the 1st time. Ongoing antigenic stimulation or increased TLR signaling could be possible explanations for this observation as published previously[1,2]. It is still unknown, whether underlining mechanism is downregulation of CD23 protein synthesis or increased shedding. Other B-cell activation markers, sCD23 and, possibly, IgE levels should be examined in the same manner.

Background: Chronic lymphocytic leukemia (CLL), the most common adulthood leukemia, is characterized by the accumulation of abnormal $CD5^+$B lymphocytes, which results in a progressive failure of the immune system. Despite intense research efforts, drug resistance remains a major cause of treatment failure in CLL, particularly in patients with dysfunctional *TP53*.
Aims: The objective of our work was to identify potential approaches that might overcome CLL drug refractoriness by examining the pro-apoptotic potential of targeting the cell surface receptor CD47 with serum-stable agonist peptides.
Methods: We performed *in vitro* cellular and molecular biology assessments in primary $CD5^+$B lymphocytes obtained from a cohort of 80 CLL patients, and we assessed, in a CLL-xenograft mouse model, the *in vivo* capacity of the CD47 agonist peptides to reduce tumor burden.
Results: Our *in vitro* approach shows that the CD47 peptide agonists enable a Ca^{2+}-mediated, caspase-independent PCD pathway that, sparing the normal T and B lymphocytes, efficiently kills CLL B cells, including those from drug-refractory patients (*e.g.*, with dysfunctional *TP53*). This PCD pathway, molecularly described here for the first time, involves a sequence of events initiated by the triggering of CD47 by serum-stable peptide agonists and the subsequent activation and phosphorylation at tyrosine 783 of the signal transduction protein PLCγ1, an over-expressed protein in CLL. Further, PLCγ1 activation leads, by means of the second messenger IP_3, to ER stress, cellular Ca^{2+}overload, mitochondrial damage, and B cell death. The *in vivo* data obtained in the CLL-xenograft mouse model demonstrated that, by inducing PLCγ1-mediated, caspase-independent PCD, the injection of CD47 agonist peptides significantly reduced tumor burden.
Summary and Conclusions: Our work provides substantial progress in (i) the development of serum-stable CD47 agonist peptides that are highly effective at inducing PCD in CLL, (ii) the understanding of the molecular events regulating a novel PCD pathway that overcomes CLL apoptotic avoidance, (iii) the identification of PLCγ1 as an over-expressed protein in CLL B cells, and (iv) the description of a novel peptide-based strategy against CLL.

E1059

FREQUENCY OF CLL-LIKE MONOCLONAL B LYMPHOCYTOSIS IN JAPANESE PEOPLE LIVING IN SAO PAULO, BRAZIL
M. Ferreira de Faria[1,*] J. Almeida[2], E. Kimura[1], E. Koulieris[2], M. Cavalcante Andrade Silva[1], F. Borges[1], I. C Garcia[2], F. Pinotti Guirao[1], M. Pitombeira Lacerda[1], G. Dighiero[3], C. Arrais Rodrigues[1], A. Orfao[2], M. Yamamoto[1]
[1]Hematology, Universidade Federal de São Paulo (EPM-UNIFESP), Sao Paulo, Brazil, [2]Cytometry Service and Department of Medicine, University of Salamanca, Salamanca, Spain, [3]Intitut Pasteur of Montevideo, Montevideo, Uruguay

Background: Monoclonal B-cell lymphocytosis (MBL) is defined by the presence of <5x109/L circulating clonal B cells in healthy individuals. In the general population, the frequency of MBL varies from 5% to 12% in Western countries, depending on the sensitivity of the method. High-count MBL (MBLhi) with chronic lymphocytic leukemia (CLL)–like phenotype has been related to the progression to CLL at frequency of 1%/ per year. CLL shows clinical and epidemiological differences among different ethnic groups including a low incidence in Asian populations, even in those living in Western countries. MBL assessment in individuals of Asian ancestry might contribute to clarify the pathogenesis of CLL and its relationship with MBL.
Aims: To evaluate the frequency of MBL in healthy Japanese individuals living in São Paulo.
Methods: 195 healthy adults without racial miscegenation were studied (median 66 years; range: 40-88 years; 57% female). Peripheral blood samples collected in EDTA were analyzed in an 8-color flow cytometer. Cells were stained after "bulky-lysed" using the following antibody combinations: sIgl & CD8/ sIgk &CD56/ CD5/ CD19/ CD3/ CD38/ CD45 CD4 &CD20 and CD23/ CD10/ CD79b/ CD19/ CD5/ CD43/ CD45/ CD20. Median acquisition was of 5,000,000 events (648,250 to 7,933,086 events). A MBL clone was defined by the presence of >30 clustered events.
Results: The mean values were: hemoglobin 14.6±1.3 g/dL (11.2-18.5 g/dL), platelets 230±61x10^9/L (121-492x10^9/L), WBC 5.9±1.6x10^9/L (3.1-14.0x10^9/L), lymphocytes 1.7 ±0.5 /L (0.6-4.0x10^9 /L), T lymphocytes 1.1±0.5x10^9/L (0.3-3.4x10^9 /L), T CD4+0.7±0.4 x10^9 g/L (0.2-3.3 x10^9 g/L) and T CD8+0.3±0.2 x10^9 g/L (0.07-1.4 x10^9 g/L), CD4/CD8 ratio 2.7±1.6 (0.5 to 12.6), B cells 0.19±0.12x10^9/L (0.003-0.84x10^9 /L), sIgk/sIgl ratio 1.4±0.2 (0.6 to 3.5) and plasma cells 0.005±0.015 x10^9/L (0-0.2 x10^9). MBL was detected in 7.7 % of individuals (15/195), including 8.2% (10/122) of those cases where ≥5,000,000 cells were measured. All detected MBL clones had a CLL-like phenotype (in 9 cases a single clone was identified while 6 were biclonal). The median size of the MBL clone was of 0.06% (0.01-19.8%) of B cells and 38.1x10^3 / L (2.0x10^3-19.1x10^6/L). The frequency of MBL clones progressively increased with age: 4.6% (4/87) in individuals <65 years (GI); 6.2% (4/65) in subjects between 65 and 74 years (GII) and 16.3% (7/43) ≥75 years (GIII), while total B cells progressively decreased (mean x10^9/L) (GI=0.222±0.161, GII= 0.203±0.118 and GIII=0.144±0.09) (p≤0.002 for GIII *vs* the other groups). The oldest individuals (GIII) presented a higher frequency of MBL as compared to the others (16.3 *vs* 5.4%) and significantly lower number of total B cells (0.144±0.09 *vs* 0.214±0.144 x10^9 / L, respectively, p ≤0.001). Plasma cells also showed a tendency to be reduced with age >75 years (0.0036±0.0039 *vs* 0.0052±0.018; p=0.06). Additionaly, a trend to a positive correlation was also observed between the size of the MBL clone and age (r=0.49, p=0.07).
Summary and Conclusions: The frequency of MBL in the Japanese individuals living in Brazil is similar to that reported for Western populations but inferior to that reported by Nieto et al (12%) using a technique with a similar sensitivity. Of note, all cases corresponded to CLL-like MBL and showed a significant increased frequency (as well as clone size) with age, most cases (13/15) having clone sizes below the <0,5X109/L cutoff associated with risk of progression to CLL. (Acknowledgments: FAPESP-proc n.2010/17668-6; CAPES; Hospital Sta. Cruz and IOP/GRAACC).

E1060

CHARACTERIZATION OF NORMAL AND PATHOLOGICAL LYMPHOID POPULATIONS: VALIDATION OF A 10-COLORS FLOW CYTOMETRY PROTOCOL FOR ROUTINE DIAGNOSIS
L. Rigollet[1,*] J. Stagnara[1], A. Milhau[1], L. Pellegrina[1]
[1]Laboratoire Biomnis, Lyon, France

Background: Multiparametric flow cytometry (MFC) has developed over last years and 10-colors techniques are becoming routine, providing a great level of information. Using markers of mutually exclusive expression, one can design panels with even more markers than detectors available on the cytometer. Neverthe-

less MFC remains a complex technique needing a thorough validation before it can be used as a routine-test for diagnosis in hematology or immunology.
Aims: We developed a panel of only two tubes for screening and characterization of lymphoid abnormalities in blood or marrow samples. The "screening" tube contained 11 markers in 9 colors: CD8+kappa-FITC / CD56+lambda-PE / CD3-ECD / CD5-PC5.5 / CD2-APC / CD7-AA700 / CD20+CD4-PacB / CD45-KrO. The second tube, designed for B-cell malignancies, contains CD200-PE / CD23-ECD / CD5-PC5.5 / CD19-PC7 / CD10-APC / CD22-AA700 / CD38-AA750 / FMC7-PacB / CD45-KrO. The aim of our study was to validate the technical performances of these tubes, compared to our previous 5-colors technique, for correct characterization of lymphoid abnormalities.
Methods: The results obtained with this panel were compared with our previous method which consisted in a 3 tubes screening panel: CD45-FITC / CD4-PE / CD8-ECD / CD3-PC5 / CD2-PC7, CD45-FITC / CD56+CD16-PE / CD19-ECD / CD3-PC5 / CD7-PC7 and kappa-FITC / lambda-PE / CD19-ECD / CD5-PC5 / CD20-PC7, and 2 tubes for B-cells malignancies: CD22-FITC / CD10-PE / CD19-ECD / CD5-PC5 / CD38-PC7 and FMC7-FITC / CD23-PE / CD19-ECD / CD5-PC5. All antibodies were provided by Beckman Coulter except kappa and lambda light chains (Dako) and CD200 (BD Biosciences). Almost 100 samples were tested including normal cases, benign unbalanced lymphoid populations (*eg* HIV) and various pathological contexts: CLL, other B-cell malignancies, T-cell malignancies (*eg* Sézary cells, prolymphocytic T-cell leukemia) and blastic infiltrations. Quality assessment samples were also assayed. We used a Navios* (Beckman Coulter) cytometer and data were analyses with Kaluza* software (Beckman Coulter).
Results: The results obtained with this 2-tubes method showed no discordance with our previous technique. In addition, this new method provided a higher level of information, as more markers could be assessed together. This allowed a more accurate analyze of the lymphoid sub-populations, particularly in pathological samples. The sensibility and specificity were thereby better with this technique than with our previous 5-colors protocol. Although not expressly designed for, the screening tube detected CD45- immature cells efficiently.
Summary and Conclusions: This 10-colors technique with one 11-markers screening tube and one "Matutes"-tube for lymphocyte exploration provided very satisfying results. Hence it was adopted in our lab for routine-use and submitted to accreditation. In addition to these technical issues, it is to note that this technique saves human resources (less manipulations), cytometer resources (faster acquisition) and reagents (no marker repeated in iterative tubes), medico-economical cost being also of importance nowadays.

Chronic lymphocytic leukemia and related disorders - Clinical

E1061

CHEMOTHERAPY EXPOSURE AND SURVIVAL AMONG PATIENTS DIAGNOSED WITH CHRONIC LYMPHOID LEUKEMIA

J. Kuiper[1,*] P. Musingarimi[2], C. Tapprich[3], F. Penning-van Beest[1], M. Gaudig[4]
[1]PHARMO Institute for Drug Outcomes Research, Utrecht, Netherlands, [2]Janssen Health Economics & Market Access EMEA, High Wycombe, United Kingdom, [3]Janssen Medical Affairs EMEA, [4]Janssen Health Economics & Market Access EMEA, Neuss, Germany

Background: Chronic lymphoid leukemia (CLL) accounts for approximately 30% of all lymphoid neoplasms and 12% of nodal lymphomas and is largely a disease of older people. Currently, there are around 650 new cases of CLL per year in the Netherlands.
Aims: To describe chemotherapy exposure, overall survival (OS) and progression-free survival (PFS) among patients diagnosed with CLL.
Methods: Data from the Eindhoven Cancer Registry (ECR), including data on all newly diagnosed cancer patients, was linked on an anonymized patient-level with the PHARMO Database Network that combines data from multiple linked healthcare databases including in- and out-patient drug dispensing, hospitalizations and clinical laboratory measurements. The PHARMO-ECR cohort represents approximately 10% of the Dutch population. Patients diagnosed with CLL between January 1, 1998-December 31, 2011 were included in the source population. For a subset of patients with in-patient pharmacy data available, chemotherapy exposure after initial diagnosis was assessed. OS after initial diagnosis was determined in the source population. For patients receiving chemotherapy, OS was also determined after chemotherapy treatment as well as PFS. Progression was defined based on 1) start of a different type of chemotherapeutic agent and for a subset of patients also on 2) increase in the number of blood lymphocytes by 50%, 3) decrease in Hgb level by >2 g/dl or a Hgb of <10 g/dl, 4) decrease in platelet counts by >50% or a platelet count of <100.000/ul. Survival was analyzed by the Kaplan-Meier method.
Results: In total, 624 patients were diagnosed with CLL in the study period. Mean (±SD) age was 68 (±11) years and 62% was male. For 393 of the CLL patients (63%), in-patient pharmacy data was available. Of these, 125 patients (32%) received chemotherapy: 52 patients (42%) started chemotherapy within 6 months after initial diagnosis and 73 patients (58%) started chemotherapy more than 6 months after initial diagnosis. Overall, median time from initial diagnosis until start of chemotherapy was 282 days. About 50% of the 125 patients had one treatment line and about 25% had two lines of treatment. The most common type of chemotherapy received as first and second line chemotherapy was chlorambucil (71% and 48% for 52 patients starting chemotherapy within 6 months after initial diagnosis and 75% and 58% for 73 patients starting chemotherapy more than 6 months after initial diagnosis). The second most common type of chemotherapy received as first and second line chemotherapy was R-CVP for patients starting chemotherapy within 6 months after initial diagnosis (13% and 15%) and fludarabine among patients starting chemotherapy more than 6 months after initial diagnosis (10% and 17%). Five years after initial diagnosis, 79% of all patients in the source population were still alive. The highest mortality rate was observed within the first three months (9.2 (95% CI: 5.0-15.5) per 100 person-years). Among patients receiving chemotherapy, 78% were still alive one year after chemotherapy treatment. The median PFS from end of the first treatment line was 27.4 months for patients starting chemotherapy within 6 months after initial diagnosis, and 16.8 months for patients starting chemotherapy more than 6 months after initial diagnosis.
Summary and Conclusions: About one third of CLL patients received chemotherapy, which mostly was chlorambucil. At 5 years, the majority of CLL patients were still alive (79%). Among those receiving chemotherapy, the median PFS ranged from 17 to 27 months, depending on the timing of chemotherapy.

E1062

REAL-WORLD OUTCOMES OF PATIENTS WITH RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA WITH 17P DELETION

N. Lamanna[1,*] D. Hurst[2], D. Latremouille-Viau[3], R. Ionescu-Ittu[3], A. Guerin[3], Y.M. Yim[2], C. Reyes[2]
[1]Hematologic Malignancies Section/Herbert Irving Comprehensive Cancer Center, New York-Presbyterian/Columbia University Medical Center, New York, [2]Genentech, Inc., South San Francisco, United States, [3]Analysis Group, Inc, Montreal, Canada

Background: Patients (pts) with relapsed and refractory (R/R) chronic lymphocytic leukemia (CLL) and 17p deletion (del 17p) studied in clinical trials had poor outcomes after standard CLL treatment (tx).
Aims: To describe best response, progression free survival (PFS), and overall survival (OS) outcomes of R/R del 17p CLL pts receiving salvage tx in clinical practice.

Methods: An online medical chart review was used to collect data from 120 US oncologists/hematologists from 79 community and 41 academic sites on 408 adults with R/R del 17p CLL who started salvage tx from 2009 to 2014. Pts characteristics were collected at R/R CLL diagnosis (dx). As reported by physicians, del 17p was detected by FISH, and minimal residual disease (MRD) by bone marrow aspirate and flow cytometry or PCR. Best response on 1st and 2nd salvage tx, assessed according to local practice standards, and response duration up to response loss or end of follow-up were reported. Kaplan-Meier analyses from salvage tx initiation were used to estimate PFS and OS rates. A sensitivity analysis was conducted among the subgroup of pts who started salvage tx ≥1 year prior to study data collection (n=134).
Results: Of 408 R/R del 17p CLL pts, 54% were relapsed and 46% were refractory to primary CLL tx. Median age was 64 years and 62% were male. Among pts with reported information at R/R CLL dx, 72% had Rai stages III/IV (292/406; 78% in relapsed, 65% in refractory pts), 21% had beta-2 microglobulin ≥6 mg/L (69/322; 22%, 21%), 69% had unmutated IGHV (180/262; 71%, 66%), 27% had ≥20% cells with del 17p (98/362; 35%, 19%), and 28% had ECOG ≥2 (114/403; 29%, 28%). Median time from R/R CLL dx to salvage tx initiation was 0.4 month (range 0.0-39). Follow-up data after salvage tx initiation was available for a median of 6 months (range 0.6-71). Outcomes are presented in the table.

Table 1.

6-month (95% CI)	100% (97-100)		92% (87-95)	
1-year (95% CI) overall; subgroup analysis	97% (90-99);95% (86-98)		80% (71-87);72% (60-81)	
CR/PR=complete/partial response; CCR= complete clinical remission (i.e., no evidence of disease without bone marrow confirmation); CCRi= CCR with incomplete bone marrow recovery.				

Summary and Conclusions: In this large study describing real-world outcomes of salvage tx in R/R del 17p CLL pts, refractory pts ppeared to have lower physician-reported overall response rate, PFS, and OS after 1st salvage tx as compared to relapsed pts. Despite CRs, response durations appeared limited. Tx analyses are ongoing.

OUTCOMES OF ANTICOAGULANT OR ANTIPLATELET USE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA OR INDOLENT NON-HODGKIN'S LYMPHOMA IN IDELALISIB TRIALS

S. Stilgenbauer[1], J. Barrientos[2], P. Ghia[3], J. Pagel[4], G. Salles[5], J. Sharman[6], O. Gurtovaya[7], Y. Kim[7], B. Philip[7], A.D. Zelenetz[8], P. Hillmen[9,*]
[1]University of Ulm, Ulm, Germany, [2]Hofstra North Shore–LIJ School of Medicine, Hempstead, United States, [3]Universita' Vita-Salute San Raffaele and Instituto Scientifico San Raffaele, Milano, Italy, [4]Fred Hutchinson Cancer Research Center and University of Washington, Seattle, United States, [5]Hospices Civils de Lyon and University Claude Bernard, Pierre Benite, France, [6]Willamette Valley Cancer Institute and Research Center/US Oncology Research, Springfield, [7]Gilead Sciences, Foster City, [8]Memorial Sloan Kettering Cancer Center, New York, United States, [9]St. James's University Hospital, Leeds, United Kingdom

Background: Idelalisib (IDELA), a selective oral PI3Kδ inhibitor, is approved for use in relapsed chronic lymphocytic leukemia (CLL; in combination with rituximab [R]) and indolent non-Hodgkin's lymphoma (iNHL; as monotherapy). Both diseases occur mainly in the elderly, who have comorbidities that increase thrombotic risk.
Aims: This post hoc analysis characterized the use and outcomes of anticoagulant (AC)/antiplatelet (AP) therapy, which was allowed in IDELA registrational clinical trials.
Methods: In the phase 3 Study 312-116 (NCT01539512), frail patients with relapsed CLL (including those with any degree of thrombocytopenia) were randomized to receive a combination of continuous IDELA 150 mg BID or placebo (PBO) with 8 R doses. In the phase 2 Study 101-09 (NCT01282424), patients with refractory iNHL received IDELA 150 mg BID until disease progression or unacceptable toxicity. All patients provided informed consent. Grade 1, 2, and ≥3 bleeding events were analyzed using MedDRA preferred terms and CTCAE.
Results: The 2 trials included 343 patients. In the CLL study, 18 patients (16%) on IDELA +R and 31 (29%) on PBO +R had grade ≥3 thrombocytopenia at baseline. Concomitant AC/AP use was frequent (45% in each study); the most common were aspirin, enoxaparin, and warfarin. AC/AP use was more frequent in patients treated with IDELA +R *vs* PBO +R. The incidence of bleeding events was similar with IDELA, IDELA +R, and PBO +R. Of the 28 patients receiving warfarin, 9 had bleeding events (3 IDELA +R [all grade 1]; 2 PBO +R [all grade 1]; 4 IDELA patients [grade 1, n=3; grade 2, n=1). Grade ≥3 bleeding events occurred in 1 IDELA +R, 1 PBO +R, and 3 IDELA patients.

Table 1.

	CLL		iNHL
n (%)	IDELA + R n=110	PBO + R n=108	IDELA Monotherapy n=125
Patients receiving AC/AP	60 (55)	38 (35)	56 (45)
Aspirin	42 (38)	21 (19)	30 (24)
Enoxaparin	11 (10)	6 (6)	19 (15)
Warfarin	8 (7)	9 (8)	11 (9)
Patients with ≥1 bleeding event (any grade)			
Overall	15 (14)	20 (19)	17 (14)
Grade 1/2	14 (13)	19 (18)	14 (11)
Patients on AC/AP	n=60	n=38	n=56
Received AC	9	4	13
Received AP	5	3	6
Event at any time	10 (17)	6 (16)	14 (25)
Event on AC/AP	7 (12)	5 (13)	8 (14)
Patients not on AC/AP	n=50	n=70	n=69
Event at any time	5 (10)	14 (20)	3 (4)

Summary and Conclusions: AC/AP use involved 45% of the IDELA registrational trial population. Overall, rates of bleeding events were moderate and similar with IDELA +R *vs* IDELA +PBO; grade ≥3 events were uncommon. There was no specific trend with regard to AC/AP and bleeding events in the 2 arms of the CLL study. Funded by Gilead Sciences.

MODELING THE EPIDEMIOLOGY OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) AND WALDENSTROM'S MACROGLOBULINEMIA (WM) IN FRANCE

X. Troussard[1,*] A. Herrera[2], E. Cornet[1], P. Solal-Céligny[3]
[1]Laboratoire d'hématologie biologique, CHU Caen - Hôpital de la Côte de Nacre, Caen, [2]Médecine interne immunologie, Hôpital Antoine-Béclère Clamart, Clamart, [3]Service d'Oncologie médicale, ICO site Paul Papin / ICO site René Gauducheau, Angers / Saint Herblain, France

Background: Chronic lymphocytic leukemia (CLL) is a slowly progressing but incurable disease and Waldenstrom's Macroglobulinemia (WM) is a rare disease, representing 6% of lymphoproliferative diseases in France. Furthermore, CLL and WM patients will eventually relapse after multiple lines of treatment, leading to a high unmet medical need.
Aims: In 2014, there were few reliable publication sources of epidemiological data for CLL and WM in France, particularly with regard to advanced stages. In addition, epidemiology registries generally provide data on disease incidence; however, no information can be directly obtained for the relapsed patient population. At the same time, several new and effective therapies will be made available to the Hematologist/Oncologist community and thus, there will be an increase in the complexity of therapeutic algorithms. To address this, we undertook an innovative modeling approach to answer the need of a greater understanding of the number of relapsed patients in need of new therapies. The objective of the model was to determine the yearly incidence of first line and later lines of therapy between 2015 and 2018 in CLL and WM patients; thus, the model provides relevant data to determine the patient population size that will be eligible for the new compounds and that could be implemented into a prospective economic model.
Methods: First, we used the "Registre Régional des Hémopathies Malignes de Basse-Normandie" (RRHMBN) to collect real world patient characteristics, such as patient subgroups and tumor staging. The RRHMBN is dedicated to Hematological malignancies and supported by official Health Authorities: "Institut National du Cancer"(INCA) and "Institut National de Veille Sanitaire" (INVS). Then, we applied these findings to the French National Network of Registers "FRANCIM" incidence and survival data. The analysis showed that in 2015, the total number of patients estimated with stage A, B or C CLL is 3612, 671 and 384 respectively. In 2018, it is expected to reach 3778, 702 and 403 patients respectively. In 2015, the total number of patients with symptomatic (20%) or asymptomatic +monoclonal gammopathy of undetermined significance (80%) WM is estimated at 252 and 1008 respectively. In 2018, it is estimated to reach 254 and 1018 patients respectively.
Results: The table below shows the yearly number of CLL and WM patients eligible for treatment in first and subsequent lines of therapy as produced by the model.

Table 1.

Category	Line of Therapy	2015	2016	2017	2018
CLL					
< 65 years (27.6%)	1st line (L)	583	589	595	600
	≥ 2nd L	463	477	485	491
	Sub-total	1 046	1 066	1 080	1 091
> 65 years Unfit (36.2%)	1st line (L)	484	489	493	498
	≥ 2nd L	323	327	326	315
	Sub-total	807	816	819	813
> 65 years Fit (36.2%)	1st line (L)	1 128	1 139	1 150	1 162
	≥ 2nd L	749	757	769	770
	Sub-total	1 877	1 896	1 919	1 932
Total	1st line (L)	2 195	2 217	2 238	2 260
	≥ 2nd L	1 535	1 561	1 580	1 576
	Total CLL population	3 730	3 778	3 818	3 836
WM					
Asymptomatic	1st line (L)	0	0	0	0
	≥ 2nd L	0	0	0	0
	Sub-total	0	0	0	0
MGUS	1st line (L)	0	0	0	0
	≥ 2nd L	0	0	0	0
	Sub-total	0	0	0	0
Symptomatic	1st line (L)	252	253	254	254
	≥ 2nd L	162	162	162	162
	Sub-total	414	415	416	416
Total	1st line (L)	252	253	254	254
	≥ 2nd L	162	162	162	162
	Total WM population	414	415	416	416

Summary and Conclusions: Our modeling approach compensates for a lack of real world information on relapsed CLL and WM. We have shown that there is a significant number of relapsed patients who are in need of new treatments in France. The model produces estimates for the number of patients in later lines in need of novel therapies by 2018 and provides efficient prospective data that can be integrated into medico-economic model development. Furthermore, these data address a current medical need for the development of new CLL and WM treatment algorithms that are required for the upcoming therapies in the relapsed setting.

MICRO-RNAS ASSOCIATED WITH PROGNOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) DO NOT IMPACT OVERALL SURVIVAL IN PATIENTS WHO RECEIVE NONMYELOABLATIVE ALLOGENEIC STEM CELL TRANSPLANT (NMAT)

I. Khouri[1,*] S. Anfossi[2], R. Saliba[1], J. Khoury[2], L. St John[1], J. Molldrem[1], J. Reuben[2]
[1]Stem Cell Transplantation and Cellular Therapy, [2]Hematopathology, MD Anderson Cancer Center, Houston, United States

Background: Noncoding RNAs play an important role in the pathogenesis of CLL. Recent studies have shown that higher miR-155 levels (>56th percentile) are associated with a lower overall survival (OS) (P= 0.0122) in CLL patients treated with conventional chemotherapy regimens (Ferrajoli *et al.* Blood 2013; 122:1891). Others revealed that expression of miR-29b or miR-181b inhibits the *TCL1* oncogene (Pekarsky *et al.* Cancer Res 2006; 66:11590), whereas high Tcl1 expression correlates with aggressive CLL phenotype showing unmutated immunoglobulin variable region genes and ZAP70 positivity. However, the clinical impact of the expression of these miRs in CLL patients who undergo NMAT is unknown.
Aims: To assess the impact of miRs on overall survival in CLL patients undertaking NMAT.
Methods: We identified 28 patients with relapsed/refractory CLL who had received NMAT at our center between 2000-2010 and in whom pre-transplant serum samples collected before initiating allogeneic conditioning were available. We measured the serum levels of miR-155, miR-15a/16-1 cluster, miR-29b, and miR-181b. Total RNA was isolated from 100 µL of serum using the Total RNA Purification Kit and miRNA levels were measured by qRT-PCR (TaqMan MicroRNA assays). Twenty fmol of synthetic *C. elegans* miRNA (cel-miR-39) was spiked into each serum samples to normalize the experimental qRT-PCR data (cel-miR-39 Ct mean±SD=17.777± 0.628). Relative miR levels were calculated using the equation $2^{-\Delta Ct}$, where ΔCt=mean Ct_{miRNA} – mean $Ct_{cel\text{-}miR\text{-}39}$, and Ct=threshold cycle.
Results: Patients had a median age of 59 years (range, 45-70). Median number of prior therapies was 3 (range, 2-8). Eleven (39%) patients had a beta-2 microglobulin level of >3 mg/L. Ten of 12 (83%) patients with data that could be evaluated had unmutated immunoglobulin variable-region heavy-chain gene, and 4/19 (21%) had 17p13.1 deletion. At transplantation, 46% of patients had refractory disease. The proportion of patients who received a matched related and a matched unrelated donor was 68% and 32%, respectively. All patients received nonmyeloablative conditioning with fludarabine, cyclophosphamide, and rituximab as published previously (Khouri *et al.* Cancer 2011; 117:4679). Graft-versus-host-disease prophylaxis consisted of tacrolimus and methotrexate. Median follow-up time was 68 months (range, 43-141). The OS from the time of NMAT was evaluated as a function of tiered relative miR levels (low, below median; high, above median). Notably, none of the relative levels of the miRs evaluated were associated with 5-year OS following NMAT (Table).

Table 1.

Micro-RNA	OS associated with low-level	OS associated with high-level	P-value
miR-155	63%	50%	0.4
miR-15a	57%	57%	1.0
miR-16	43%	71%	0.2
miR-29b	52%	61%	0.7
miR-181b	60%	53%	0.9

Summary and Conclusions: Our data suggest that serum levels of miR-155, miR-15a/16-1 cluster, miR-29b, and miR-181b do not impact 5-year OS in relapsed/refractory CLL following NMAT. As such, other prognostic biomarkers are needed in this patient group.

E1068

THE OCCURRENCE OF OTHER MALIGNANCIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M. Todorovic Balint[1,*] A. Sretenovic[1], V. Kecman[2], D. Antic[1], J. Jelicic[1], A. Bogdanovic[1], J. Bila[1], B. Andjelic[1], V. Djurasinovic[1], V. Vukovic[1], M. Smiljanic[1], B. Mihaljevic[1]
[1]Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, Belgrade, [2]Department of Internal Medicine, General Hospital, Pancevo, Serbia

Background: Chronic lymphocytic leukemia (CLL) is related with an increased risk of developing different malignancies due to immunologic defects associated with disease or therapy-related immunosuppression.
Aims: The aim of this study was to determine in patients with CLL type and frequency of previously diagnosed malignanat disease MD (pMD), concomitant MD (cMD), afterwards secondary MD (sMD), as well as patient's outcome.
Methods: We have retrospectively analyzed clinical data of CLL patients who were diagnosed at our institution from 1994 to 2010. Disease stage and treatment were established after collecting clinical, laboratory, and pathological data. Immunophenotypic diagnosis was verified by applying of CLL scoring system. The study involves 471 patients (311 males/ 160 females) with median age at diagnosis 64.3 (39-80).
