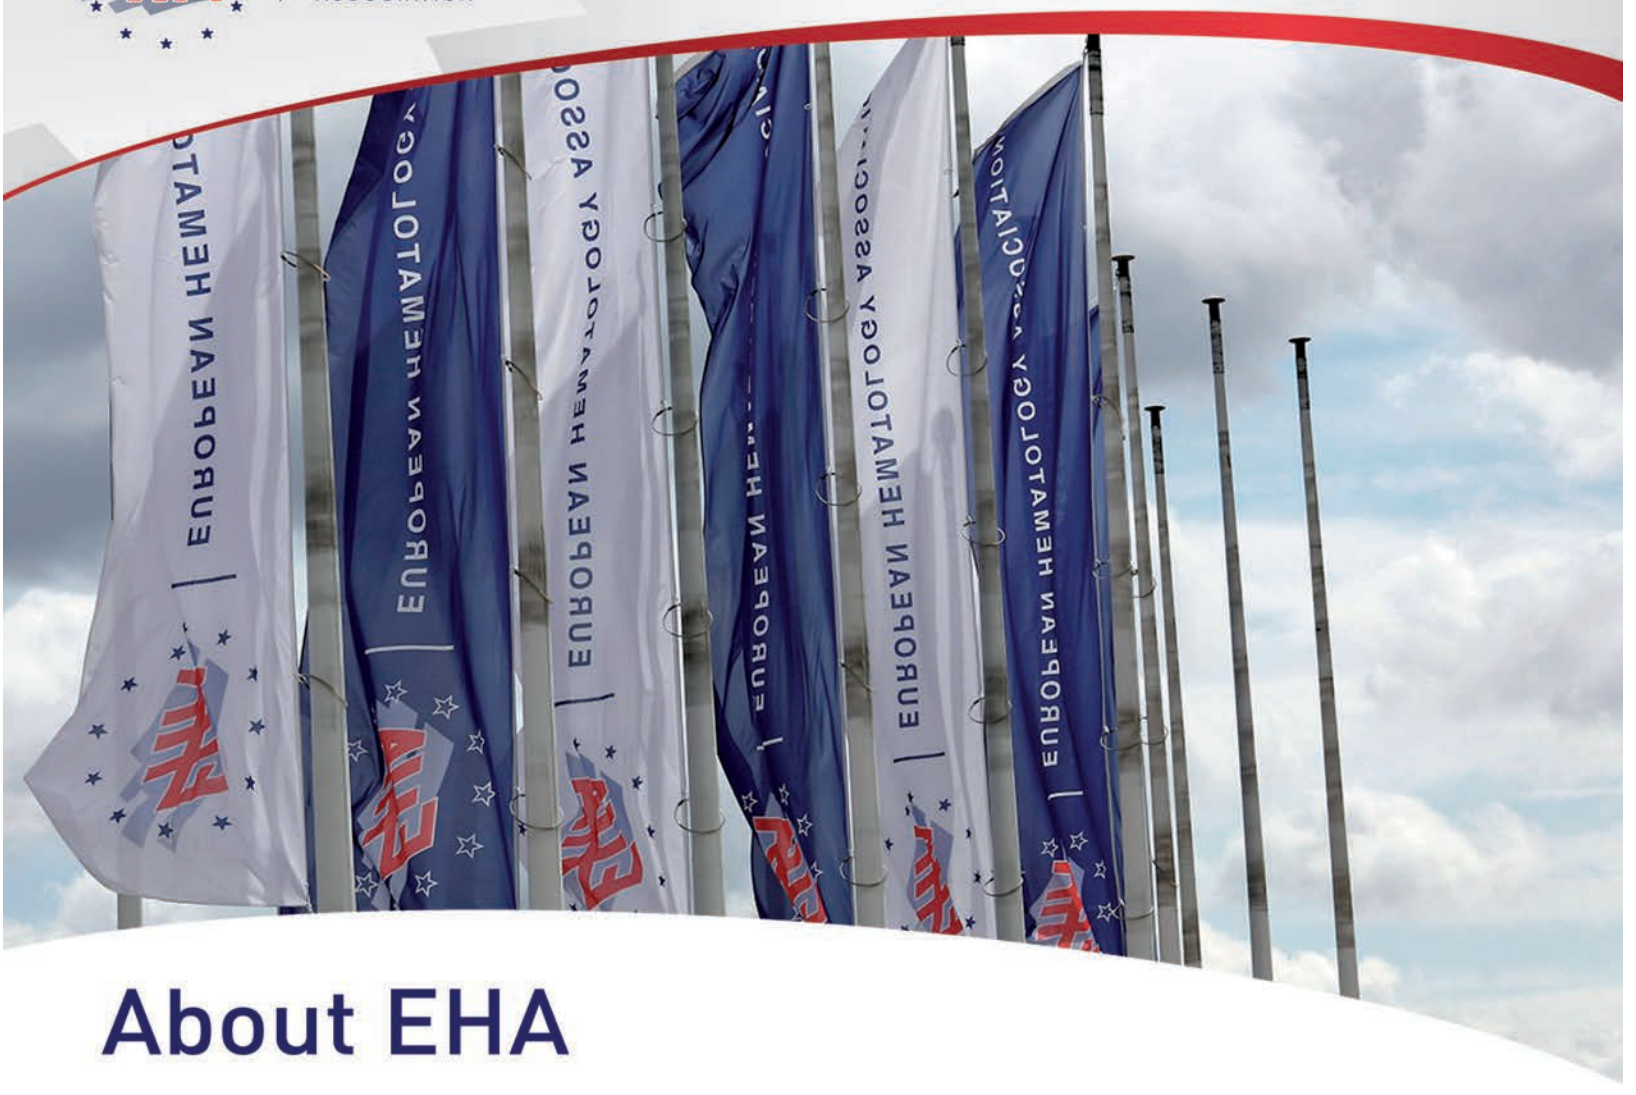
EUROPEAN
HEMATOLOGY
ASSOCIATION



About EHA

The European Hematology Association (EHA) is a non-profit scientific association that represents European medical professionals with an active interest in hematology.

The Annual Congress, organized in a major European City, offers the opportunity to learn about new data from basic, translational and clinical research and gives access to knowledge that directly impacts the clinical practice. Not only the size of the congress increased over the years but also the first steps towards creating an education and career development program were taken.

Educational needs are the focus of our continuing medical education program. Not only through live events, but also through the EHA Learning Center, a recently launched online platform. EHA supports high quality science: we encourage research by creating a network and sharing knowledge.

EHA offers education and training and supports the careers of hematologists in Europe and travelling to Europe through its fellowships and grants program. Different fellowships are available for basic, translational and clinical researchers both in their early or advanced career.

As the largest organization of hematologists in Europe, EHA has taken it upon itself to serve and further their political interests. We advocate for you on the EU level for more research funding, improved research environment and better access to hematology care.

More information about EHA activities can be found at ehaweb.org.

EUROPEAN HEMATOLOGY ASSOCIATION

NOW 50% DISCOUNT ON MEMBERSHIP FEES FOR THE REMAINDER OF 2016

Become a member of EHA for 2016!

Support our mission to promote excellence in patient care, research and education in hematology.

Join more than 4,000 members from over 100 countries worldwide and enjoy membership benefits for both professional and personal development within the field of hematology.

BECOME A MEMBER!

- Full Membership € 155
- Junior Membership € 20
- Health Care Affiliated Professional Membership € 90
- Emeritus Membership € 90

ENJOY OUR MEMBERSHIP BENEFITS ALL YEAR ROUND

ALREADY A MEMBER? RENEW YOUR MEMBERSHIP NOW!

EUROPEAN HEMATOLOGY ASSOCIATION

haematologica

Journal of the European Hematology Association
Owned & published by the Ferrata Storti Foundation

Word of Welcome

On behalf of the EHA Board and the Scientific Program Committee of the 21st Congress of EHA we are pleased to introduce this year's Abstract Program.

The Scientific Program Committee has compiled an exciting up-to-date program of Simultaneous Oral and Poster Sessions from over 2400 abstracts submitted. Selected posters will be presented during the traditional Poster Walks allowing more time for discussion of results and conclusions. To better promote basic research in hematology, we introduced a new special presentation type: the poster pitch! During selected oral sessions, 5-8 presenters will have the opportunity to pitch their abstract/poster to the attendees of the session.

There are also E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. All presented posters and E-posters can be viewed on the E-poster screens from Friday morning to Saturday evening. Posters will also be available on the EHA Learning Center, for which you have complimentary access after the congress: learningcenter.ehaweb.org.

The six Best Abstracts will be presented during the Presidential Symposium on Friday afternoon. One of them has been selected from the record number of "late breaking abstracts" with "hot" data. Only the most exciting results have been selected and will be presented in the Late Breaking Oral Session on Sunday morning. There are also late breaking posters that are included in a poster walk of the relevant topic.

On behalf of the EHA Board, the committees and all the people involved in this years' EHA congress, we thank you for coming to Copenhagen and wish you an exciting meeting.

Andreas Engert
Chair Scientific Program Committee 21st Congress

Information for readers, authors and subscribers

Haematologica (print edition, pISSN 0390-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), "Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making". The ad hoc journal's policy is reported in detail online (www.haematologica.org/content/policies).

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free.
For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, E-mail: info@haematologica.org).

Rates of the International edition for the year 2016 are as following:

	Institutional	*Personal*
Print edition	*Euro 500*	*Euro 150*

Advertisements. Contact the Advertising Manager, Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: marketing@haematologica.org).

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publisher, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer's own published literature.

The origin of a name that reflects Europe's cultural roots.

Ancient Greek

αἷμα [haima] = blood
αἵματος [haimatos] = of blood
λόγος [logos]= reasoning

Scientific Latin

haematologicus (adjective) = related to blood

Scientific Latin

haematologica (adjective, plural and neuter, used as a noun) = hematological subjects

Modern English

The oldest hematology journal, publishing the newest research results.
2014 JCR impact factor = 5.814

Haematologica, as the journal of the European Hematology Association (EHA), aims not only to serve the scientific community, but also to promote European cultural identify.

Background: Melphalan plus prednisone and bortezomib combination is the most frequent standard of care used upfront for newly diagnosed elderly myeloma (eNDMM). Despite significant improvements with bortezomib, such as subcutaneous administration and weekly schedule, safety profile issues remain with MPV, that only can be resolved with lowering the doses, albeit of the potential loss of efficacy. Carfilzomib, a novel generation proteasome inhibitor, has different safety profile with absence of neuropathy. Carmysap, a phase I/II trial of twice weekly Carfilzomib plus MP in eNDMM, demonstrated carfilzomib MTD at 36mg/m^2. The safety profile appeared otherwise good for this frail population.
Aims: We hypothesized that Carfilzomib can be used on a weekly schedule allowing to increase the dose of Carfilzomib given its positive safety profile.
Methods: IFM2012-03 (carmysap weekly) is a phase 1/2 multicenter open label single arm study to determine MTD during the phase 1 part and VGPR+CR rate (IMWG criteria) during the phase 2 part of KMP (Carfilzomib Weekly Plus Melphalan and Prednisone) regimen. The inclusion/exclusion criteria of interest were eNDMM (65 and older), with CRAB and measurable disease, with absolute neutrophils ≥1G/L, untransfused platelet count ≥75G/L, hemoglobine ≥8.5g/dL and clairance creatinine ≥30ml/min.
Induction comprised nine 5 weeks cycles. Carfilzomib is given 36, 45, 56 and 70 mg/m^2 on days 1, 8, 15, 22 IV route in combination to oral Melphalan 0.25mg/kg/j and oral prednisone 60mg/m2, both on days 1 to 4.
Maintenance: Carfilzomib. 36 mg/m^2 weekly, every two weeks IV route for 1 year. Melphalan and Prednisone is not pursued at maintenance. Analysis is done on an Intent to Treat. Recruitment was 6 patients per cohort, 3 DLTs meant MTD at the lower N-1 dose. The following are defined as DLTs: Any hematologic toxicity of grade 4 intensity or preventing administration of 2 or more of the 4 carfilzomib doses of the first treatment cycle; Grade ≥3 febrile neutropenia; Grade ≥3 gastrointestinal toxicities; Any other grade ≥3 nonhematologic toxicity considered related to CMP by the principal investigator; Grade ≥3 peripheral neuropathy persisting for more than 3 weeks after discontinuation of study drugs. We report herein the phase 1 part of the study with the 2 cohorts at 70mg/m^2.
Results: 32 NDMM recruited, 30 treated in the study, 6 per cohort at 36 mg/m² carfilzomib +MP, then 45, 56, and finally at 70mg/m². At the end of the first 70 cohort, the DSMB decided to add a second 70 cohort. The median age was 76 with 15 patients older than 75, sex ratio M/F 1.2, R-ISS 2 and 3 in 80%. There was one DLT at 36 mg/m² carfilzomib (grade 4 lymphopenia), one at 45 (lysis syndrome complicated with grade 4 renal insufficiency, two at 56 (cardiac insufficiency grade 3 and febrile neutropenia grade 3) and 2 at 70 (vomiting grade 3 and liver cholestase enzyme grade 3). As a whole for the study, the ORR is 87.5%, with 33% at least in CR. At data cut-off, with a median follow-up at 12 months, one patient had progressed and one patients had died of cardiac dysfunction considered related to Carfilzomib at the dose of 56mg/m^2. Along with the previous 2 patients, 2 other patients have stopped treatment for lysis syndrome (at 45) and pulmonary hypertension later in the disease course on cycle 5 at 56. Overall, there are 22 SAE reported for a total of greater than 200 cycles administered of KMP. An extra 3 patients have had Carfilzomib dose reduction, 2 patients at 36 from 45 and one at 45 from 56, for neutropenia grade 4, thrombocytopenia grade 4, and dyspnea grade 3, respectively.
Summary/Conclusions: IFM2012-03, the study of KMP, Carfilzomib (Kyprolis) plus Melphalan and Prednisone in elderly NDMM has not reached MTD up to 70mg/m^2 of carfilzomib. The RP2D could then be at 70 for carfilzomib. KMP appears feasible and manageable, the primary cause of AEs coming from dose adaptation of Melphalan in very elderly NDMM. Updated data will be presented at ASCO.

S101

IMPROVED EFFICACY AFTER INCORPORATING AUTOLOGOUS STEM CELL TRANSPLANT (ASCT) INTO KRD TREATMENT WITH CARFILZOMIB (CFZ), LENALIDOMIDE (LEN), AND DEXAMETHASONE (DEX) IN NEWLY DIAGNOSED MULTIPLE MYELOMA

A Jakubowiak[1,*], N Raje[2], R Vij[3], D Reece[4], J Berdeja[5], D Vesole[6], S Jagannath[7], C Cole[8], M Faham[9], J Nam[1], L Stephens[1], E Severson[1], A Revethis[1], B Wolfe[1], S Rosebeck[1], S Gurbuxani[1], C Rosenbaum[1], J Jasielec[10], D Dytfeld[11], K Griffith[8], T Zimmerman[1]

[1]University of Chicago, Chicago, IL, [2]Massachussetts General Hospital, Boston, MA, [3]Washington University, Saint Louis, MO, United States, [4]Princess Margaret Cancer Centre, Toronto, Canada, [5]Sarah Cannon Research Institute, Nashville, TN, [6]John Theurer Cancer Center, Hackensack, NJ, [7]Mount Sinai Medical Center, New York, NY, [8]University of Michigan, Ann Arbor, MI, [9]Adaptive Biotechnologies, Seattle, WA, [10]Northshore University Health System, Evanston, IL, United States, [11]NJ University of Medical Sciences, Poznan, Poland

Background: In a phase 1/2 trial (N=53), extended treatment with KRd without (w/o) ASCT was highly active in newly diagnosed myeloma (NDMM) with stringent complete response (sCR) 55% and 3-year progression-free survival (PFS) 79%.
Aims: In a subsequent phase 2 trial, we are evaluating whether extended KRd can be further improved by incorporating ASCT (KRd+ASCT). We report results from both trials after completion of enrollment into KRd+ASCT and after completion of KRd w/o ASCT (median follow-up [f/u] 4 years) as a historical control.
Methods: Both studies enrolled patients (pts) with NDMM based on similar eligibility criteria except KRd+ASCT excluded transplant ineligible pts. The treatment schemas were generally similar between studies. In KRd+ASCT, pts received: four 28-day cycles of induction with CFZ IV 36 mg/m^2 on Days (D) 1-2, 8-9, 15-16 (CFZ 20 mg/m^2 for D1-2, C1 only), LEN PO D121 at 25 mg, DEX PO 40 mg/wk; followed by stem cell collection (SCC), melphalan 200 mg/m^2 and ASCT; then KRd consolidation (C5-8) using the same doses and schedule except LEN 15 mg in C5 with the option to escalate to prior dose, and DEX reduced to 20 mg/wk; then KRd maintenance (C9-18) using the same doses as in C8 except CFZ on Days 1-2, 15-16 only. In KRd w/o ASCT, transplant-eligible pts underwent SCC after C4 then resumed KRd, and KRd maintenance was longer (C9-24). Both studies recommended single-agent LEN off study. The primary endpoint in KRd+ASCT is sCR at the end of C8. We hypothesized that an improvement of sCR from 30% at the end of C8 (historical KRd w/o ASCT) to >50% (KRd+ASCT) represents added benefit of ASCT with 5% type I error (2 sided) and supports further evaluation. Minimal residual disease (MRD) is evaluated by 10-color multiparameter flow cytometry (MFC, threshold 10^{-4}-10^{-5}) and by next-generation sequencing (NGS, LymphoSIGHT™, threshold at 10^{-6} for MRD negativity).
Results: The current KRd+ASCT study enrolled 76 pts with 72 evaluable. Baseline characteristics were comparable between the KRd+ASCT and KRd w/o ASCT study populations, including median age (59 and 59y) and high-risk IMWG cytogenetics (36% and 33%). In the ongoing KRd+ASCT, 69 pts proceeded to ASCT at data cut-off (Jan 1, 2016), 50 completed KRd consolidation, and 26 KRd maintenance, with remaining pts on treatment, except 1 patient who progressed prior to transplant. At the end of C8, sCR was 72% for KRd+ASCT (n=50) *vs* 30% for KRd w/o ASCT (n=44) and 88% (n=26) *vs* 51% (n=41) at the end of C18. At median f/u of 17.8 months, 2-year PFS was 99% for KRd+ASCT *vs* 92% for KRd w/o ASCT at median f/u of 47.5 months. In KRd+ASCT, MRD by MFC was negative in 94% of pts tested (n=31) at the end of C8 and 95% of pts tested (n=19) at the end of C18. In KRd w/o ASCT, 4-year PFS was 69% overall, 78% in MRD-negative pts *vs* 60% in positive/unknown pts by MFC, and 100% in pts with MRD negative status by NGS. Updated MRD analyses and outcomes based on MRD status by both MFC and NGS will be

presented at the meeting. The types and rates of adverse events (AEs) pre- and post-ASCT were comparable to AEs in KRd w/o ASCT.
Summary/Conclusions: Recognizing limitations of cross-study comparisons, KRd+ASCT shows superior outcomes *vs* historical KRd w/o ASCT, supporting further evaluation in the randomized setting. Both KRd studies compare favorably to other NDMM studies.

S102

WEEKLY CARFILZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE (WKCYD) FOLLOWED BY MAINTENANCE WITH WEEKLY CARFILZOMIB (WK) IN ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM)

S Bringhen[1,*], L De Paoli[2], A Larocca[1], S Ballanti[2], F Gentilini[2], AM Liberati[2], R Passera[3], A Bernardini[1], F Esma[1], P Galieni[2], M Offidani[2], P Corradini[2], G Gaidano[2], M Boccadoro[1], P Sonneveld[4], A Palumbo[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, [3]Divison of Nuclear Medicine 2, Azienda Ospedaliera Città della Salute e della Scienza di Torino, Torino, Italy, [4]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: Carfilzomib is a novel second-generation proteasome inhibitor approved as a single agent and in combination with lenalidomide and dexamethasone for the treatment of relapsed MM. The approved schedule of carfilzomib is twice-weekly, on days 1, 2, 8, 9, 15, and 16 of 28-day cycles. In a recent phase I/II study in relapsed/refractory patients (pts) a more convenient schedule of weekly Carfilzomib in combination with dexamethasone showed to be effective (77% overall response rate; ORR) and safe (ASH 2015). The ongoing phase III ARROW study compares weekly *vs* twice weekly Carfilzomib. In the newly diagnosed setting, no data about weekly Carfilzomib are available. We designed a phase 1/2 study of wKCyd for NDMM pts.
Aims: The primary objective was to determine the maximum tolerated dose (MTD) of weekly Carfilzomib. The secondary objectives were to determine the safety and the efficacy of wKCyd as induction and of wK as maintenance, including response rate, progression-free survival and overall survival.
Methods: NDMM pts not eligible for autologous stem cell transplantation due to age or co-morbidities were enrolled. Carfilzomib was administered intravenously on days 1,8,15; cyclophosphamide orally on days 1, 8, 15 and dexamethasone orally once weekly. Dose escalation used a standard 3+3 schema with dose-limiting toxicities (DLTs) assessed during cycle 1. Three dose levels were studied with Carfilzomib escalated from 45 to 70 mg/m^2 with the standard doses of cyclophosphamide 300 mg/m2 and dexamethasone 40 mg. After completion of 9 28-day cycles, patients receive 28-day maintenance cycles with Carfilzomib (days 1, 8, 15) at the MTD defined by the phase I study until disease progression or intolerance. Adverse events were graded by NCI-CTCAE v4. Response was assessed according to the modified International Uniform Response Criteria.

Table 1. Adverse events of any grade and grade ≥3 occurring in ≥5% of patients during induction and maintenance.

Adverse events	Induction (N=54)		Maintenance (N=29)	
	Any grade, n (%)	Grade ≥3, n (%)	Any grade, n (%)	Grade ≥3, n (%)
Anaemia	19 (35)	3 (6)	1 (3)	0
Thrombocytopenia	16 (30)	3 (6)	4 (14)	0
Neutropenia	13 (24)	10 (18)	3 (10)	0
Nausea/Vomiting	8 (15)	1 (2)	2 (7)	0
Hypertension	7 (13)	0	4 (14)	2 (7)
Fever	7 (13)	1 (2)	3 (10)	0
Bronchitis	6 (11)	2 (4)	0	0
Fatigue	4 (7)	0	0	0
Acute kidney injury	4 (7)	1 (2)	0	0
Pulmonary edema	4 (7)	4 (7)	0	0
Cardiac event	3 (6)	2 (4)	1 (3)	1 (3)
Diarrhea	3 (6)	0	0	0
Sepsis	2 (4)	2 (4)	0	0
Constipation	2 (4)	0	0	0

Results: Results of dose escalation phase 1 study have been previously reported (Palumbo A et al, Blood 2014), the MTD of weekly Carfilzomib was established as 70 mg/m^2. Results are presented for all patients treated with KCyd at the Carfilzomib MTD in both the phase 1 (n=3) and phase 2 (n=51) portions of the study. Among these 54 pts, median age was 72 years (range 60-85), 33% had ISS stage III, 49% had unfavorable FISH profile [t(4;14) or t (14;16) or del17p, del1 or amp1]. Median Carfilzomib treatment duration was 9.1 months (range 0.13-25.4). During induction, the ORR was 88%, the very good partial response (VGPR) rate was 71%, the complete response (CR) rate was 12%. Twenty-nine pts could be evaluated for maintenance. After a median duration of maintenance of 14.5 months, 7 pts (35%) improved response. During maintenance, the ORR was 95%, the VGPR rate was 80%, the CR rate was 40%, including a stringent CR rate of 20%. The 1-year progression-free survival was 79.4%. Ten pts (18%) discontinued treatment due to an adverse event. The most common adverse events of any grade and of grade ≥3 during induction and during maintenance are shown in the Table. Six pts died on study, cause of death included disease progression, pulmonary edema, pulmonary embolism, second primary malignancy, sudden death and pneumonia (1 each).
Summary/Conclusions: This is the first prospective study evaluating once weekly Carfilzomib in NDMM. wKCyd as induction and wK as maintenance appeared to be safe and effective. Responses became deeper with subsequent cycles and improved during maintenance. The response rate observed with weekly Carfilzomib compares favorably with similar studies with standard twice weekly Carfilzomib infusion.

S103

A META-ANALYSIS OF OVERALL SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA TREATED WITH LENALIDOMIDE MAINTENANCE AFTER HIGH-DOSE MELPHALAN AND AUTOLOGOUS STEM CELL TRANSPLANT

PL McCarthy[1,*], A Palumbo[2], SA Holstein[3], V Lauwers-Cances[4], MT Petrucci[5], PG Richardson[6], C Hulin[7], P Tosi[8], KC Anderson[6], D Caillot[9], V Magarotto[2], P Moreau[10], G Marit[11], Z Yu[12], M Attal[4]
[1]Blood and Marrow Transplant Program and Medicine Department, Roswell Park Cancer Institute, Buffalo, NY, United States, [2]University of Torino, Torino, Italy, [3]Roswell Park Cancer Institute, Buffalo, NY, United States, [4]Departments of Hematology and Biostatistics, Hôpital Purpan, Toulouse, France, [5]University La Sapienza, Rome, Italy, [6]Jerome Lipper Multiple Myeloma Center, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States, [7]Bordeaux Hospital University Center (CHU), Bordeaux, France, [8]Seràgnoli Institute of Hematology and Medical Oncology, Bologna University, Bologna, Italy, [9]Dijon University Hospital Center, Dijon, [10]University Hospital Hôtel-Dieu, Nantes, [11]Centre Hospitalier Universitaire, Bordeaux, France, [12]Celgene Corporation, Summit, NJ, United States

Background: Several studies demonstrate that lenalidomide (LEN) maintenance post autologous stem cell transplant (ASCT) reduces the risk of disease progression or death in patients with multiple myeloma (MM) by approximately 50% (Attal, *NEJM,* 2012; McCarthy, *NEJM,* 2012; Palumbo, *NEJM,* 2014). However, these studies were not powered for overall survival (OS).
Aims: To conduct a meta-analysis assessing the effect of LEN maintenance post ASCT on OS.
Methods: A prospectively planned meta-analysis assessed OS with LEN *vs* placebo/no maintenance (control) after ASCT. A search identified 17 randomized controlled trials (RCTs) using LEN post ASCT. Three RCTs (IFM 2005-02, CALGB 100104 [Alliance], GIMEMA RV-209) met prespecified inclusion criteria (had patient-level data, had a control arm, and achieved database lock for primary efficacy analysis of patients with newly diagnosed MM receiving LEN post ASCT). A March 2015 cutoff of the 3 RCTs enabled sufficient OS events to test treatment effect (hazard ratio [HR]=0.78).

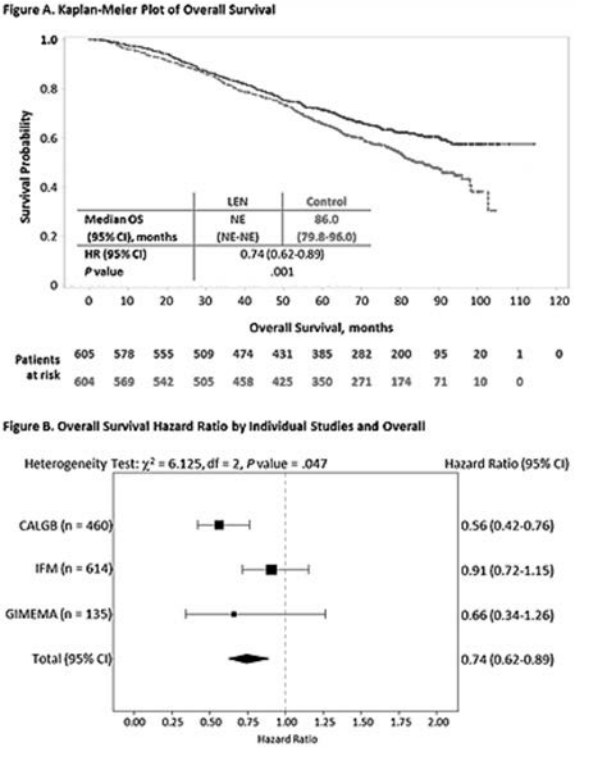

Figure A and Figure B.

Results: From 2005 to 2009, 1209 patients were randomized in the 3 RCTs to receive LEN (n=605) 10 mg/day on days 1-21 (GIMEMA) or 1-28 (IFM and CALGB) of 28-day cycles or control (n=604). With a median follow-up of 6.6

years, 491 patients (41%) had died. Baseline characteristics were generally balanced in the pooled data. After induction and single (82%) or tandem (18%) ASCT, 55% of patients achieved a complete response (CR) or very good partial response (VGPR). Median OS for the LEN maintenance group was not reached compared with 86 months for the control group (HR=0.74; 95% CI, 0.62-0.89; log-rank *P*=.001; **Figure A**), and 5-, 6-, and 7-year OS were longer in the LEN maintenance *vs* the control group (71% *vs* 66%, 65% *vs* 58%, and 62% *vs* 50%, respectively). Fisher's combination test confirmed the significant OS benefit in the meta-analysis (*P*=.001). Patients who achieved ≤PR post ASCT benefited from LEN maintenance (HR=0.86; 95% CI, 0.65-1.15) as did patients with CR/VGPR (HR=0.70; 95% CI, 0.54-0.90). OS benefit was generally consistent across subgroups. Based on a heterogeneity test (Pignon, *Lancet Oncol,* 2001), the OS study results from the efficacy meta-analysis were considered significantly heterogeneous (*P*=.047; **Figure B**) across studies for both the intention-to-treat post-ASCT population and for all patients randomized. Potential factors contributing to the heterogeneity between the clinical trials were explored and identified, including baseline/disease characteristics (such as International Staging System stage, cytogenetics), study conduct, and second-line therapy. Second primary malignancy data will be presented.

Summary/Conclusions: This large meta-analysis demonstrates that LEN maintenance significantly prolonged OS *vs* control (placebo/no maintenance) post ASCT, including in patients who achieved CR, demonstrating benefit in patients in all response categories.

UPFRONT OR RESCUE TRANSPLANT IN YOUNG PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: A POOLED ANALYSIS OF 529 PATIENTS

F Gay[1,*], V Magarotto[1], A Spencer[2], F Di Raimondo[3], L Pour[4], V Scudla[5], M Genuardi[1], AM Carella[3], AM Liberati[3], S Spada[1], A Evangelista[6], P Omedè[1], A Nagler[7], R Zambello[3], R Troia[1], G Rossi[3], M Offidani[3], S Oliva[1], A Malfitano[1], D Ben Yehuda[8], F Patriarca[3], M Salvini[1], P Corradini[3], R Foà[3], N Cascavilla[3], S Pulini[3], MT Petrucci[3], R Hajek[9], M Boccadoro[1], A Palumbo[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, [2]Alfred Health-Monash University, Melbourne, Australia, [3]Italian Multiple Myeloma Network, GIMEMA, Italy, [4]University Hospital Brno and Faculty of Medicine MU, Brno, [5]Department of Hemato-oncology, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Olomouc, Czech Republic, [6]Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy, [7]Division of Hematology and Bone Marrow Transplantation, The Chaim Sheba Medical Center, Tel-Hashomer, Ramat-Gan, [8]Dept. of Hematology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel, [9]Dept. of Hematooncology, University Hospital Ostrava and Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic

Background: In patients with newly diagnosed myeloma, upfront Melphalan 200 mg/m^2 followed by ASCT (MEL200-ASCT) prolongs progression-free survival-1 (PFS1) in comparison with chemotherapy plus lenalidomide (CC+R) but ASCT as salvage therapy at first relapse may still effectively rescue patients who did not receive upfront ASCT.

Aims: The primary aim was to evaluate the long-term benefit of upfront ASCT *vs* CC+R, including the impact of MEL200-ASCT *vs* CC+R in specific subgroups of patients with different prognostic features. The secondary aim was to evaluate the efficacy of salvage ASCT in patients receiving upfront CC+R.

Methods: We performed an individual patient data meta-analysis of patients enrolled in 2 phase III trials (RV-MM-209 and EMN-441) that randomized patients to MEL200-ASCT *vs* CC+R. Primary endpoints were PFS1, PFS2, overall survival (OS). Subgroup analyses according to baseline features, protocol and post MEL200-ASCT/CC+R maintenance were performed. We calculated the odds ratio (ORs) with 95% confidence intervals (CIs), as measure of association between the upfront and rescue therapy (MEL200-ASCT *vs* CC+R followed by rescue ASCT) with the 4-year risk of second progression/death (PFS2) and death (OS).

Results: In the pooled analysis, 268 patients were randomized to MEL200-ASCT and 261 to CC+R. Median follow-up was 46 months. MEL200-ASCT significantly improved PFS1 in comparison with CC+R (median 42 *vs* 24 months, HR 0.53; P<0.001), with a significant advantage in all the subgroups analyzed. In patients with R-ISS Stage I the 4-year PFS1 was 53% with MEL200-ASCT *vs* 36% with CC+R; in patients with R-ISS Stage II/III the 4-year PFS1 was 41% with MEL200-ASCT *vs* 23% with CC+R. 134 MEL200-ASCT patients and 176 CC+R patients experienced first progression. 125 patients in the MEL200-ASCT group and 174 in the CC+R group received second-line therapy. MEL200-ASCT significantly prolonged PFS2 in comparison with CC+R (4-year PFS2: 71% *vs* 54%, HR 0.53, p<0.001). The long-term advantage of MEL200-ASCT was evident in good and bad prognosis patients: in patients with R-ISS Stage I, the 4-year PFS2 was 83% with MEL200-ASCT *vs* 71% with CC+R; in patients with R-ISS Stage II/III the 4-year PFS2 was 67% with MEL200-ASCT and 48% with CC+R. The PFS1 and PFS2 advantage translated into a significant OS benefit for patients randomized to MEL200-ASCT in comparison with CC+R (4-year OS: 84% *vs* 70%, HR 0.51, P<0.001). Subgroup analyses of OS were limited by a lower number of events but the advantage with MEL200-ASCT was still evident in most of the subgroups analyzed. At data cut off, in the MEL200-ASCT group, 9% of patients received again ASCT, 68% bortezomib, 16% immunomodulatory agents (IMIDs), 7% other therapies. In the CC+R group, ASCT was recommended but not mandatory at relapse, and the choice of therapy was based on patient's will and physician discretion according to patient eligibility to ASCT: 53% of patients received ASCT, 38% bortezomib regimens, 6% IMIDs, and 3% other therapies. Upfront ASCT regardless of salvage therapy significantly reduced the risk of second progression/death (OR 0.31; P<0.001) and death (OR 0.41; P=0.003) at 4 years in comparison with CC+R followed by salvage ASCT.

Summary/Conclusions: MEL200-ASCT significantly improved PFS1, PFS2 and OS in comparison with CC+R in good and bad prognosis patients. Upfront ASCT significantly reduced the risk of death in comparison with CC+R and salvage ASCT. These data confirm the role of upfront ASCT as the standard approach for all young myeloma patients.

First-line treatment of Hodgkin Lymphoma

S105

BASELINE TOTAL METABOLIC VOLUME (TMTV) PREDICTS THE OUTCOME OF PATIENTS WITH ADVANCED HODGKIN LYMPHOMA (HL) ENROLLED IN THE AHL2011 LYSA TRIAL

Becquerel, Rouen, [10]Hematology, Hopital Henri Mondor, Creteil, [11]Hematology, CHU Caen, Caen, [12]Hematology, CHU Nantes, Nantes, [13]Hematology, Hopital Sud Francilien, Corbeille, [14]Hematology, CHU Bordeaux, Bordeaux, [15]Hematology, Centre L. Berard, Lyon, France, [16]Hematology, CHU Dinant Godinne, Yvoir, Belgium, [17]Hematology, CHU Nice, Nice, [18]Hematology, Institut Gustave Roussy, Villejuif, France

Background: The TMTV assessed on the baseline FDG-PET is a novel approach of tumor burden measurement quantifying the most active part of the tumor. It has been reported to influence HL outcome in a retrospective series (Kanoun et al, EJNM 2014; 41: 1735).
Aims: We designed a study evaluating the TMTV prognosis value in patients (pts) prospectively enrolled in a phase III randomized trial testing a treatment strategy driven by PET, compared to a standard treatment not monitored by PET.
Methods: Eligible pts for the present study had to be enrolled in the AHL2011 trial (NCT01358747) and to have a baseline PET (PET0) available for central review and TMTV calculation. Pts were 16-60 y, with a previously untreated advanced HL (Ann Arbor stage III, IV or high risk IIB) and were randomly assigned to a treatment strategy driven by PET after 2 escalated BEACOPP (BEA) cycles (PET2), delivering 4 cycles of ABVD for PET2 negative (PET2-) pts and 4 cycles of BEA for PET2 positive (PET2+) pts or a standard treatment not monitored by PET and delivering 6 cycles of BEA. PET2 were centrally reviewed and interpreted according to Deauville criteria. TMTV was computed on PET0 by summing the metabolic volumes of the individual lesions using the 41% SUVmax thresholding method already described in lymphoma (Meignan et al, EJNM 2014; 41: 113).
Results: 392 pts with a median age of 30 years were included: 64% were male, 89% had stage III/IV, and 59% an IPS≥3. Median TMTV was 200 ml (23-2149). Using a X-tile method a 350ml cut off value was firstly identified in a training set of patients (n=262; 67%) randomly obtained from the whole population, and found to predict PFS in both the training and validation sets of pts (n=130; 33%). With a median follow up of 16 months, 2y-PFS was 81% *vs* 93% in pts with high and low TMTV respectively in the whole population (p=0.0015; HR=3). PET2 positivity was also related to a lower 2y-PFS compared to PET2- pts (76% *vs* 92%; p<0.0001). Then 3 groups could be identified: pts with either [high TMTV and PET2+ (n=23; 6%)], or [high TMTV and PET2-, or low TMTV and PET2+ (n=103; 27%)], or [low TMTV and PET2- (n=261; 67%)] had a 61%, 88%, 94% 2y-PFS respectively (p<0.0001).
Summary/Conclusions: The TMTV predicts the outcome of young advanced HL pts independently of the early metabolic response to treatment. The combination of TMTV and PET2 allows identifying 3 subsets of HL pts with significantly different outcome that may help clinician to better tailor therapy.

S106

LONG-TERM FOLLOW-UP OF CONTEMPORARY TREATMENT IN EARLY-STAGE HODGKIN LYMPHOMA (HL): UPDATED ANALYSES OF THE GERMAN HODGKIN STUDY GROUP HD7, HD8, HD10 AND HD11 TRIALS

PJ Bröckelmann[*], H Görgen, A Plütschow, S Kreissl, C Bürkle, S Borchmann, M Fuchs, P Borchmann, A Engert
Department I of Internal Medicine and German Hodgkin Study Group (GHSG), University Hospital of Cologne, Cologne, Germany

Background: Combined modality treatment (CMT) is currently considered as standard of care in patients with early-stage HL. During the years, a gradual toxicity reduction through balancing extent and intensity of radiotherapy (RT) and chemotherapy was achieved.
Aims: We evaluated long-term follow-up (FU) of pivotal trials, to ensure the applied therapies are safe and beneficial for our patients.
Methods: We analyzed updated FU data of 4299 patients who were treated for primary early-stage HL in previously published GHSG trials between 1993 and 2003. Patients with favorable disease were randomized in HD 7 to either CMT with 2xABVD or to 40Gy extended-field (EF)-RT only, and in HD10 to either 4x or 2xABVD and 20 or 30Gy involved-field (IF)-RT, respectively. Patients with unfavorable HL in HD8 had received either 30Gy IF- or extended-field (EF)-RT after 2xCOPP/ABVD and in HD11 either 20 or 30Gy IF-RT after 4xABVD or 4x$BEACOPP_{bas}$. Progression-free (PFS) and overall survival (OS) were analyzed according to the Kaplan-Meier method. Cumulative incidences of secondary neoplasias (SN) were calculated and compared between groups using Pepe&Mori's test. Type of SN, salvage therapies and causes of death were analyzed descriptively.
Results: The median FU was 120 and 98 months for patients in HD7 (n=627) and HD10 (n=1190) and 153 and 106 months for patients in HD8 (n=1064) and HD11 (n=1395), respectively. New FU data beyond the last evaluation was available for only <50% of patients and last information was obtained from population registries in 18-30%. In HD7, CMT was superior to EF-RT with 15-year PFS estimates of 72.8% *vs* 52.2% and a hazard ratio (HR) of 0.45 (0.33-0.61). No significant differences were observed regarding OS (HR: 0.81 (0.56-1.18)) or the cumulative incidence of SN. In HD10, non-inferiority of 2xABVD+20Gy IF-RT to more intensive treatment was confirmed with HRs of 1.0 (0.6-1.5) and 0.9 (0.5-1.6) and 10-year estimates of 87.2% and 94.1% for PFS and OS, respectively. No significant differences in SN were observed. In HD8, non-inferiority of IF- compared to EF-RT was confirmed with HRs of 0.98 (0.76-1.25) and 0.88 (0.66-1.16) for PFS and OS, respectively. We observed a non-significant trend towards more SN (15-year cumulative incidence 17.1% and 14.2%, respectively, p=0.3) and deaths from SN after EF-RT. In HD11, no difference in PFS was found with intensified chemotherapy compared to standard ABVD with either 30Gy IF-RT (HR: 1.1 (0.7-1.5)) or 20Gy IF-RT (HR: 0.8 (0.6-1.1). In contrast, there was a significant difference in 10-year PFS rates estimated at 77.6% *versus* 83.3% to the detriment of ABVD-treated patients who had received 20Gy instead of 30Gy IF-RT with a HR of 1.5 (1.0-2.1). After $BEACOPP_{bas}$, 20Gy IF-RT was non-inferior to 30Gy IF-RT with a HR of 1.0 (0.7-1.5) for PFS. No differences in terms of OS or SN could be observed.
Summary/Conclusions: Long-term FU data of four large randomized GHSG phase III trials confirm the current risk-adapted therapeutic strategies in early-stage HL. Outcome in patients with early-stage favorable HL is optimal with CMT consisting of 2xABVD+20Gy IF-RT with 10-year PFS and OS estimates of 87.2% and 94.1%, respectively. 10-year PFS and OS estimates in early-stage unfavorable HL treated with 4xABVD+30Gy IF-RT leave room for improvement with 83.3% and 90.0%, respectively. Moderate intensification of chemotherapy does not improve efficacy outcome but might facilitate the reduction of IF-RT-dose. Continued FU is necessary to assess long-term effects of currently applied risk-adapted therapies.

ADJUSTMENT OF THERAPY FOR HODGKIN LYMPHOMA BASED ON INTERIM PET IS BENEFICIAL AND RADIOTHERAPY MAY BE SUBSTITUTED WITH CHEMOTHERAPY IN PATIENTS WITH NEGATIVE INTERIM STUDY: FINAL RESULTS OF H2 TRIAL

EJ Dann[1,*], O Bairey[2], R Bar-Shalom[3], T Mashiach[4], E Barzilai[4], A Korenberg[5], L Akria[6], T Tadmor[7], K Filanovsky[8], U Abadi[9], O Kagna[4], R Ruchlemer[3], R Abdah-Bortnyak[4], N Goldschmidt[10], R Epelbaum[4], NA Horowitz[4], D Lavie[10], D Ben-Yehuda[10], O Shpilberg[11], O Paltiel[10]
[1]Blood Bank and Apheresis Unit, RAMBAM HEALTH CARE CAMPUS, Haifa, [2]Rabin Medical Center, Petach Tikva, [3]Shaare Zedek Medical Center, Jerusalem, [4]RAMBAM HEALTH CARE CAMPUS, Haifa, [5]Assaf Harofeh Medical Center, Zerifin, [6]Galil Medical Center, Nahariya, [7]Bnai Zion Medical Center, Haifa, [8]Kaplan Medical Center, Rehovot, [9]Meir Medical Center, Kfar Saba, [10]Hadassah Medical Center, Jerusalem, [11]Assuta Medical Center, Tel-Aviv, Israel

Background: The main goal of therapy for Hodgkin lymphoma (HL) is to maximize response while minimizing long-term treatment-related toxicity.
Aims: The study aimed to explore the effect of therapy adjustment based on early interim PET/CT (PET-2) on the HL patient outcome.
Methods: This prospective multicenter study recruited patients (pts) between 9/2006-8/2013. Pts with classic HL aged 18-60 years, stages I-IV were eligible. Early HL (ED) was categorized into favorable (EF) and unfavorable (EU) disease. After 2 ABVD cycles, pts with EF and negative PET-2 underwent involved site radiation therapy (ISRT) and EU pts received 2 more ABVD cycles (total 4) followed by ISRT In pts with negative PET-2, ISRT could be substituted by two further ABVD courses. Pts with positive PET-2 received a total 4 or 6 ABVD courses for EF and EU, respectively, followed by obligatory ISRT. Pts with advanced HL (AD) (B symptoms or stages III/IV) were assigned to therapy based on IPS: those with IPS 0-2 initially received ABVDx2 while pts with IPS ≥3 received escalated BEACOPP (EB) x2. If PET-2 was negative, therapy was completed using ABVDx4. If PET-2 was positive, therapy was escalated to EB with ISRT given to bulky mediastinal masses. A dynamic visual score (DS) comparing PET-2 to baseline PET was used for decision-making regarding therapeutic changes (Dann et al, Haematologica, 2010).Briefly, for pts with an initial single site of uptake, PET-2 was considered positive if the intensity of residual uptake was ≥normal mediastinal or liver blood pool (the hottest of the two). For pts with multiple initial sites of HL, disappearance of uptake in all sites or a residual single site uptake with markedly lower intensity on PET-2

was considered a negative result. The Deauville score (performed post-hoc) less or equal to 3 was defined as negative.
Results: HL progression was documented in 50 out of 355 pts, of whom 42 relapsed and 8 had primary progressive disease. PET-2 was negative in 86% and positive in 7% of pts, according to both DS and Deauville score (93% concordance by both systems; kappa 0.627). At a median follow-up of 47 months (4-114), among 170 ED pts a highly significant difference in the 5-year progression-free survival (PFS) was demonstrated between those with negative and positive PET-2 [0.91 and 0.68, respectively; hazard ratio (HR) 3.66; 95% CI 1.4-9.7; p=0.009] by DS. The differences were even more marked after reassessment using the Deauville criteria (0.91 compared to 0.47,HR 7.6; 95% CI 2.7-21.4 P<0.001). The 5-year PFS for pts with a negative PET-2 who did not receive ISRT was 0.94 compared to 0.89 for the group receiving ISRT. In the AD group (n=185), 18% (n=33) of pts progressed and 15% (n=27) had a positive PET-2. The 5-year PFS for the whole group, PET-2 negative and positive subgroups was 0.80, 0.82 and 0.68, respectively (p=0.07). The 5-year OS for ED and AD groups was 0.99 and 0.97, respectively.
Summary/Conclusions: Seventy six percent of relapses still occur in pts with a negative PET-2. A positive PET-2 portends an adverse prognosis at all stages of HL. ED pts with positive PET-2 have a poor prognosis if their therapy is continued with ABVD followed by ISRT. ISRT does not appear to improve the outcome for ED pts with negative PET-2. The prognosis of AD patients with positive PET-2 could be improved with administration of 4 additional EB cycles. If PET-2 is negative, EB can be safely changed to ABVD in AD pts.

S108

PET-CT ADAPTED THERAPY AFTER 3 CYCLES OF ABVD TO ALL STAGES OF HODGKIN LYMPHOMA. GATLA TRIAL HL-05

A Pavlovsky[1,*], I Fernandez[1], N Kurgansky[2], V Prates[3], L Zoppegno[3], P Negri[4], G Milone[3], I Cerutti[5], S Zabaljauregui[1], R Mariano[4], H Fernandez Grecco[6], AL Basquiera[6], S Saba[3], S Rudoy[1], F Sackmann[1], V Castano[1], A Diaz[3], G Remaggi[1], L Valles[5], M Cabrejo[1], E Roveri[1], M Casale[1], C Campo[6], G Avila[6], V Cabanne[7], F Sackamoto[2], AI Varela[1], P Barreyro[1], M Riddick[3], S Pavlovsky[1]
[1]Hematología, GATLA, Buenos Aires, [2]Hematología, GATLA, Santa Fe, [3]Hematología, GATLA, La Plata, [4]Hematología, GATLA, Parana, [5]Hematología, GATLA, Rosario, [6]Hematología, GATLA, Cordoba, [7]Hematología, GATLA, Neuquen, Argentina

Background: Positron emission tomography using fluoro-2-deoxy-d-glucose (PET-CT) is an important tool for treatment response assessment in Hodgkin Lymphoma (HL) treated with ABVD.
Aims: Adapt therapy to all stage of Hodgkin Lymphoma to the result of PET-CT after 3 ABVD (PET-CT+3). Reduce therapy in pts. who achieve early CR with negative PET-CT. Intensify treatment, in pts. with positive PET-CT after 3 ABVD. Achieve CR, event free survival (EFS) and overall survival (OS), as good as in our historical control (LH -96), when we used 3-6 ABVD adapted to stage plus involved field radio therapy (IFRT) in all pts
Methods: Four hundred and one newly diagnosed pts. with HL Stages I-IV have been included (LH-05). All pts. received 3 ABVD and were evaluated with a PET-CT (PET-CT +3). Pts. with a negative PET-CT+3 were considered in CR and received no further therapy. Pts in partial response (PR) completed 6 ABVD and IFRT on PET-CT positive areas. Pts with less than PR received salvaje chemotherapy. Three hundred and seventy seven pts have been evaluated. With a median age of 35 yrs.and 38% age older than 59 years. Two hundred and twenty eight 860%9 presented with localized stage (I-IIA) and 144 (40%) presented with advanced stage (IIB-III-IV).

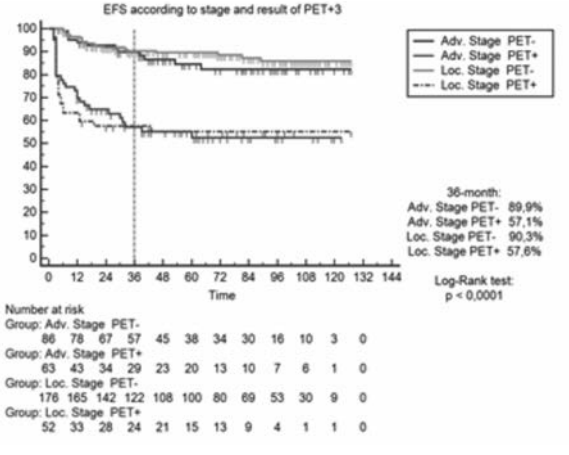

Figure 1.

Results: Of all pts. 260 (69%) achieved CR with negative PET-CT+3, 117 (31%) were PET-CT+3 positive, 101 pts. were in PR with chemo-sensitive disease and completed a total of 6 ABVD+IFRT in PET-CT positive areas. Eighty-two (81%) achieved CR. With a median follow up of 68 months the EFS and OS ***at 3 years*** is 80% and 96% respectively. Pts with negative PET-CT +3 had an EFS of 90% both for localized and advances stage, compared to 58% for pts. with positive PET-CT+3 and loc. stage and 5%for with a positive PET-TC+3 and adv. stage. We perform a multivariate analysis for EFS which included age, stage, IPS, bulky disease, extranodal areas and the result of the PET+3. This last parameter together with age were the only ones with statistical significance (p=0.001 and 0.046 respectively), finding stage at diagnosis not significant. When comparing the results LH-05 with our previous clinical trial (LH-96) there is no difference in EFS and OS at 36 months (83% *vs* 85% and 97 *vs* 96%) but in LH-05 only 30% received more than 3 cycles of ABVD and IFRT compared to 61% and 100% in LH-96. This reduces the exposure to chemo and radiotherapy.
Summary/Conclusions: With PET-CT adapted therapy for all stages of HL after 3 ABVD, 260 pts. received only 3 cycles of ABVD as initial therapy with an EFS and OS of 91% and 98% at 36 months. In the Cox regression model, PET-CT at completion of treatment was the most significant factor associated to EFS. Treatment with 3 cycles of ABVD can be adequate for pts. with negative PET-CT+3 regardless their stage at diagnosis

S109

OSTEONECROSIS AS A TREATMENT COMPLICATION IN HODGKIN LYMPHOMA PATIENTS: AN ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP (GHSG)

S Borchmann[1,*], H Müller[1], H Haverkamp[1], C Baues[2], J Marková[3], A Hüttmann[4], A Glunz[4], M Fuchs[1], A Engert[1]
[1]First Department for Internal Medicine, [2]Department of Radiooncology, University Hospital of Cologne, Köln, Germany, [3]Department for Internal Medicine and Haematology, University Hospital Kralovske Vinohrady and 3rd Faculty of Medicine, Charles University, Prague, Czech Republic, [4]Clinic for Hematology, Essen University Hospital, Essen, Germany

Background: Hodgkin Lymphoma (HL) is one of the best curable hematological malignancies. Therefore, a major focus for future improvements in the treatment of this disease will be a reduction of short- and long-term side effects. Osteonecrosis (ON) has been reported as an infrequent but sometimes debilitating late effect of HL therapy in a few case report series.
Aims: The aim of the present study is to provide a detailed analysis of ON as a late effect after multimodality treatment for HL.
Methods: A total of 12,083 patients treated within the GHSG trials HD10-15 and HD18 between 05/98 and 07/14 were evaluated. During the trial duration and prolonged follow-up, complications and late effects of trial participants are registered. Using a trial-database-aided search for ON and related symptoms as well as manual chart review, 66 incident cases of osteonecrosis were identified. Detailed information on patient characteristics, localizations, interventions and outcomes were collected. Risk factors for ON after HL therapy were analyzed by multivariate logistic regression.
Results: The cumulative incidence of ON was 0.16% [CI: 0.08-0.30] in early (favorable or unfavorable) stage HL (n=10) and 0.93% [CI: 0.71-1.21] in advanced stage HL (n=54). The majority of ON cases were male (75%). A total of 66 patients had a total of 140 ON. Most patients had more than one area affected (71%) and the most commonly affected location was the femoral head (73%). Most patients with available information needed surgical intervention (54%) and had continuing symptoms despite treatment (66%), including inability to walk and severe pain. Joint-saving interventions were attempted and successful in 6 of 8 patients. The first ON event occurred within the first 3 years after HL diagnosis in 83% of cases. Peak incidence was observed in the second year after diagnosis with 41% of cases occurring between 12 and 24 months after therapy. In a multivariate logistic regression including all patients, male gender (OR 2.1; CI: 1.2-3.7) and advanced stage (OR 3.9; CI: 2.3-6.9) were identified as risk factors for ON. Because ON was a very rare complication in early stage HL, the following results focused on survivors of advanced stage HL. The median cumulative prednisone dose in ON cases after advanced stage HL was 8,400mg (range: 3,920-10,800) *versus* 7,350mg (range: 0-16,800) in not affected patients. In a multivariate logistic regression model including only patients with advanced stage HL, young age (OR 0.7 for each additional 10 years of age; CI: 0.5-0.9) and a higher cumulative dose of prednisone during therapy (OR 1.3 for each additional 1gr; CI: 1.1-1.5) were identified as additional risk factors. Nodal pain after alcohol ingestion (p=0.78), radiotherapy (p=0.29), a large mediastinal tumor (p=0.13), international prognostic score (IPS) (p=0.09) and body-mass-index (BMI) (p=0.99) were evaluated as potential risk factors but did not significantly influence the risk for ON.
Summary/Conclusions: We provide the largest and most comprehensive analysis of ON after HL therapy performed so far. ON after HL therapy, despite being an infrequent event, often leads to significant disease burden in affected patients and sometimes has dramatic effects on mobility and quality of life. The described risk factors and peak incidence timeframe could be helpful in order to identify patients at high risk for ON. Early evaluation of these often young patients is recommended in case of symptoms suggestive of ON. This might help to identify affected patients early and attempt bone and joint saving interventions whenever possible. High prednisone doses were identified as a risk

factor for ON and future modifications of HL therapy leading to a decrease in the cumulative corticosteroid dose might be able to decrease the incidence of ON after HL therapy in the future.

Myeloproliferative neoplasms - Clinical 1

OUTCOMES OF 121 PREGNANCIES IN PATIENTS WITH POLYCYTHEMIA VERA (PV)

M Griesshammer[1,*], A Andreoli[2], S Schauer[3], M Gotic[4], T Barbui[5], K Döhner[3], JJ Kiladjian[6]
[1]Hematology and Oncology, Johannes Wesling Academic Medical Center, Minden, Germany, [2]CH Victor Dupouy, Argenteuil, Paris, France, [3]University Hospital of Ulm, Ulm, Germany, [4]Clinical Center of Serbia, Belgrade, Serbia, [5]Foundation for Clinical Research (FROM), Hospital Papa Giovanni XXIII, Bergamo, Italy, [6]Hôpital Saint-Louis, Paris, France

Background: Very limited data are available regarding pregnancy (preg) outcomes in patients with PV, less than 40 pregs being reported in the literature. Within the European LeukemiaNet we collected 121 pregs in 48 PV patients from 7 centers in France, Italy, Serbia, Romania, Switzerland and Germany.
Aims: Outcomes of pregancies in patients with polycythemia vera (PV).
Methods: Pregs were categorized in two groups. Group 1 consisted of pregs before the diagnosis of PV (n=39). Group 2 (n=82) included all pregs after the diagnosis of PV. Most patients in group 2 received low dose aspirin during preg and low molecular weight heparin after delivery until the 6th week postpartum. The target hematocrit during preg was 40% and therapeutic phlebotomy was performed, if needed. Iron supplementation was not advised during preg.
Results: Median age at diagnosis of PV was 29 yrs (range 18-40), median age at delivery 32 yrs (21-43). 13 out of 48 patients (27%) had high-risk PV due to severe thromboembolic complications either at the time of diagnosis or during follow up. These included 5 Budd Chiari syndromes, 4 portal vein thromboses, 2 *superior sagittal sinus thromboses*, 3 deep vein thromboses, and one pulmonary embolism. In group 2, a planned medical interruption was performed in 6/82 pregs due to patients´ choice. The outcome of another 6 pregs cannot be reported yet (still ongoing in 3 and missing in another 3). Thus, a total of 70 pregs are evaluable at time of abstract submission in group 2. In group 1 live birth was recorded in 19/39 pregs (49%), while 20 pregs were unsuccessful due to spontaneous abortion (n=9; 23%), stillbirth (n=8; 21%) or late fetal loss (n=3; 8%). In contrast, outcome was significantly better in group 2 with 54 live births out of 70 pregs (77%) [chi square, p=0,002]. In group 2 we observed 12 (17%) spontaneous abortions, one ectopic preg (1%) and 3 (4%) stillbirths. Interferon alpha was used in 12 high risk cases with 10 live births (83%) and 2 spontaneous abortions. Concerning maternal complications, the rate of severe thromboembolic events was similar between the two groups (group 1: one pulmonary embolism with cardiogenic shock (2,6%), group 2: two Budd Chiari syndromes in 3rd trimester (2,8%). There were no deaths. Of note, the bleeding rate was significantly higher in group 2 (8 minor and 3 major bleedings) which was probably due to the treatment with aspirin and low molecular weight heparin in this group while only one minor bleeding was observed in group 1 [chi square, p=0,036]. Most PV patients' hematocrit values spontaneously decreased during preg, thus phlebotomies were mainly performed during the first trimester. 6 twin pregs were managed in group 2, five of them resulted in live births, and one patient had a spontaneous abortion in the 22th week.
Summary/Conclusions: This is the largest series of PV pregs reported to date collected across the European LeukemiaNet network. The success rate of pregs was significantly better (49% *versus* 77%, respectively) for patients in whom the diagnosis of PV was known and appropriate management performed according to current guidelines. This high success rate of almost 80% is encouraging in this higher risk PV population. However, despite the use of aspirin and molecular weight heparin major thrombotic events still occur and an increased bleeding rate is observed.

S111

INCREASED RISK OF SECOND MALIGNANCIES IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS DIAGNOSED IN SWEDEN 1973-2009. A POPULATION-BASED COHORT STUDY OF 9,379 PATIENTS

A Ravn Landtblom[1,*], H Bower[2], TML Andersson[2], PW Dickman[2], M Björkholm[3], SY Kristinsson[3,4], M Hultcrantz[3,5]
[1]Department of Internal Medicine, Stockholm South Hospital and Karolinska Insititutet, [2]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, [3]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Insitutet, Stockholm, Sweden, [4]Faculty of Medicine, University of Iceland and Department of Hematology, Landspitali National University Hospital, Reykjavik, Iceland, [5]Myeloma Service, Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, United States

Background: The risk of developing acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS) in patients with myeloproliferative neoplasms (MPNs) is well established. Less is known, however, about the risk of non-hematologic malignancies in patients with MPNs.

Aims: To assess the risk of developing a wide range of second malignancies in a large population-based study of MPN patients compared to matched controls.
Methods: All patients diagnosed with MPNs and reported to the Swedish Cancer Registry or the Inpatient Registry between 1973 and 2009 were included. Four controls matched by age, sex, and region of residence were randomly selected from the Register of Total Population. End of follow-up was December 31st 2010. Patients and controls were excluded if they had any malignancy prior to the MPN diagnosis or corresponding time for controls. We identified incident cases of cancer during follow-up by cross-linking to the Swedish Cancer Registry. Hazard ratios (HRs) with 95% confidence intervals (CIs) were calculated using a Cox regression model. A landmark analysis was performed in order to reduce detection bias, where all patients with a new malignant diagnosis within one and two years respectively from the MPN diagnosis were excluded.
Results: In total, 9,379 MPN patients and 35,682 controls were identified. The MPN cohort included 4,502 males (48%) and 4,877 females (52%), and the median age at MPN diagnosis was 67.5 years. We found an overall significantly increased risk of non-hematologic cancer with an HR of 1.60 (95% CI 1.50-1.71). The relative risk of developing a second malignancy was similar across all MPN subtypes, men and women, and calendar periods of MPN diagnosis. The non-hematologic malignancies with the greatest observed risk increase included non-melanoma skin cancer (HR 2.92, 2.51-3.39), malignant melanoma (HR 1.85, 1.36-2.53), kidney cancer (HR 2.85, 2.01-4.03), brain cancer (HR 2.60, 1.76-3.86), and endocrine cancers including thyroid cancer HR 2.41, 1.59-3.64) (Table). MPN patients were also at a significantly increased risk of developing second malignancies of the lung, head and neck, pancreas, esophagus, and stomach compared to matched controls. The risk of developing a non-hematologic malignancy tended to increase with follow-up time after MPN diagnosis. The risk of developing a second hematologic malignancy was significantly increased, the HRs for lymphoproliferative malignancies (including acute lymphoblastic leukemia) were 2.62 (2.06-3.34) and for AML 47.04 (33.17-66.69). The relative risk of a second non-hematological and hematological malignancies in MPN patients remained similarly significantly elevated in the landmark analysis starting one and two years after the MPN diagnosis.

Table 1. Risk of different types of malignancies in patients with myeloproliferative neoplasms compared to matched controls. HR=hazard ratio, CI=confidence interval, ALL=acute lymphoblastic leukemia.

Type of malignancy	HR	95% CI
All non-hematologic cancer	1.60	1.50 - 1.71
Lung cancer	1.73	1.37 - 2.19
Non-melanoma skin cancer	2.92	2.51 - 3.39
Melanoma	1.85	1.36 - 2.53
Head and neck cancer	1.83	1.23 - 2.73
Breast cancer	1.35	1.09 - 1.67
Pancreas cancer	1.59	1.07 - 2.35
Esophagus and stomach cancer	1.71	1.26 - 2.32
Colon, rectum and anal cancer	1.13	0.94 – 1.36
Kidney cancer	2.85	2.01 - 4.03
Prostate cancer	1.26	1.08 - 1.48
Brain cancer	2.60	1.76 - 3.86
Endocrine cancer	2.41	1.59 - 3.64
Lymphoproliferative malignancies (including ALL)	2.62	2.06 - 3.34
Acute myeloid leukemia	47.04	33.17 - 66.69

Summary/Conclusions: This population-based study is, to our knowledge, the largest to date to support an increased risk of non-hematologic and hematologic malignancies in MPN patients. The reason behind the increased risk are not fully understood, but several possible factors exist; a genetic propensity to develop malignancies, acquired somatic mutations, an altered immune function and mutagenic cytoreductive treatments. Clinicians should be aware of the increased cancer risk and direct adequate attention to new symptoms in MPN patients.

S112

RUXOLITINIB PROVES SUPERIOR TO BEST AVAILABLE THERAPY IN PATIENTS WITH POLYCYTHEMIA VERA (PV) AND A NONPALPABLE SPLEEN: RESULTS FROM THE PHASE IIIB RESPONSE-2 STUDY

F Passamonti[1,*], M Griesshammer[2], F Palandri[3], M Egyed[4], G Benevolo[5], T Devo[6], J Callum[7], AM Vannucchi[8], S Sivgin[9], C Bensasson[10], M Khan[11], N Mounedji[10], G Saydam[12]

Background: PV is a myeloproliferative neoplasm characterized by erythrocytosis, burdensome symptoms, and increased risk of thrombosis. A key treatment goal is to maintain hematocrit (HCT) control. In the phase 3 RESPONSE study, the JAK1/JAK2 inhibitor ruxolitinib was superior to best available therapy (BAT) in maintaining HCT control without phlebotomy (PBT), normalizing blood cell count, reducing spleen volume, and improving symptoms in HU-resistant/intolerant PV patients (pts) with splenomegaly.
Aims: RESPONSE-2 is an open-label phase 3b study comparing RUX with BAT in HU-resistant/intolerant PV pts without palpable splenomegaly.
Methods: HU-resistant/intolerant pts without palpable splenomegaly who required PBT for HCT control were randomized 1:1 to RUX 10 mg bid or BAT. The primary endpoint was the proportion of pts who achieved HCT control at wk 28 (defined as the absence of PBT eligibility [HCT >45% and ≥3 percentage points from baseline, or HCT >48%] from wk 8 to 28, with ≤1 PBT eligibility from wk 0 to 8). The key secondary endpoint was the proportion of pts who achieved complete hematologic remission (CHR) at wk 28. Other endpoints included patient-reported outcomes and safety. The MPN-SAF TSS was used to assess 10 PV-related symptoms, each on a scale of 0 (absent) to 10 (worst imaginable). BAT pts could cross over to RUX from wk 28. Primary analysis occurred when all pts reached wk 28 or discontinued.

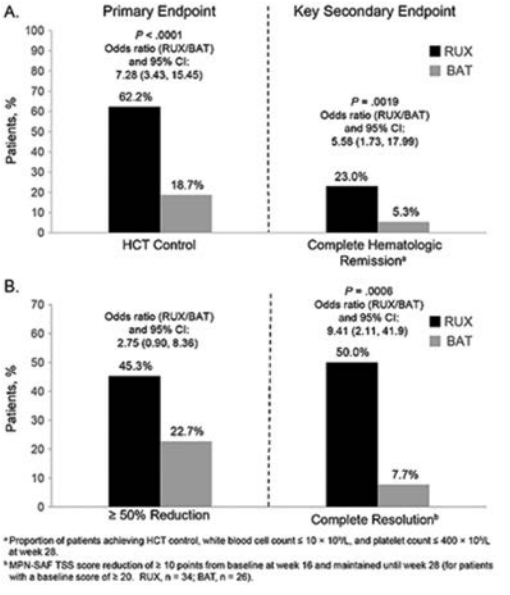

Figure. Percentage of Patients Achieving (A) the Primary and Key Secondary Endpoints and (B) Improvement in MPN-SAF TSS.

Results: 74 and 75 pts were randomized to RUX and BAT, respectively. The median time since PV diagnosis was 6.5 and 6.7 y; 28% and 24% of pts had a history of thromboembolic events; and 78% and 76% had ≥2 PBTs within 24 wk of screening, respectively. Overall, 29.5% of pts received >1 prior line of PV-directed therapy. By the cutoff date (29 Sep 2015), 2 (3%) RUX and 56 (75%) BAT pts had discontinued randomized treatment, of which 1.4% and 8.0% were due to adverse events (AEs), respectively; 51 (68%) pts crossed over to RUX. The median duration of exposure to RUX and BAT was 42 and 28 wk, respectively; median dose intensity for RUX was 20 mg/day. HCT control (primary endpoint) was achieved in 62% of RUX *vs* 19% of BAT pts (*P*<.0001); CHR (key secondary endpoint) was achieved in 23% and 5% of RUX and BAT pts, respectively (*P*=.0019; Fig A). At wk 28, 45% of RUX pts, *vs* 23% of BAT pts, had ≥50% improvement in MPN-SAF TSS; 50% *vs* 7.7% achieved complete symptom resolution (Fig B). RUX pts had improvements in individual symptoms; most symptoms worsened with BAT. Pruritus improved in RUX pts, but did not change in most BAT pts; 60% of RUX *vs* 5.3% of BAT pts had a much or very much improved condition in PGIC. Anemia or thrombocytopenia occurred in 16.2% and 2.7% of pts in the RUX arm *vs* 2.7% and 8.0% in the BAT arm. Corresponding grade 3/4 events were reported in 0% of RUX pts *vs* 1.3% and 4.0% of BAT pts, respectively. The most common nonhematologic AEs (>10% of pts) in either the RUX or BAT arm were headache (12.2%; 10.7%), constipation (10.8%; 5.3%), hypertension (10.8%; 4.0%), pruritus (10.8%; 20.0%), and weight increase (10.8%; 1.3%). All were grade 1/2, except hypertension (6.8%; 4.0%) and pruritus (0%; 2.7%). No deaths were reported in the RUX arm; 2 (2.7%) occurred in the BAT arm.
Summary/Conclusions: In this study, RUX was well tolerated and superior to BAT in controlling HCT without PBT, normalizing blood counts, and improving PV-related symptoms in pts with PV resistant to or intolerant of HU, thus extending the results from RESPONSE to pts without palpable splenomegaly.

S113

PHENOTYPIC DIFFERENCES AND TREATMENT RESPONSES IN MOLECULAR SUBGROUPS OF ESSENTIAL THROMBOCYTHEMIA FROM ANALYSIS OF THE PT1 COHORT

J Nangalia[1,*], A Jones[2], A Godfrey[1], C MacLean[3], P Beer[1], A Bench[4], F Nice[1], B Wilkins[5], W Erber[6], D Bareford[7], JJ Kiladjian[8], N Cross[2], MF McMullin[9], C Harrison[5], P Campbell[10], A Green[11]
[1]Haematology, Cambridge Institute for Medical Research, Cambridge, [2]Faculty of Medicine, Southampton, [3]University of Cambridge, [4]Haematology, Addenbrookes Hospital, Cambridge, [5]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [6]School of Pathology and Laboratory Medicine, The University of Western Australia, Crawley, Australia, [7]Russell's Hall Hospital, Dudley, United Kingdom, [8]Hopital Saint-Louis, Paris, France, [9]Queen's University, Belfast, [10]Wellcome Trust Sanger Institute, Hinxton, [11]Cambridge Institute for Medical Research, Cambridge, United Kingdom

Background: Somatically acquired mutations in JAK2, MPL or CALR are found in 85% of patients with essential thrombocythemia (ET) and 15% of patients are 'triple-negative' (TN). However, no prospective data exist on the disease characteristics or response to treatment of the different molecular subgroups of ET.
Aims: We aimed to characterise, in the prospective setting, whether baseline clinical characteristics, bone marrow histology, adverse outcomes, and response to treatment are influenced by mutation status in ET.
Methods: Patients aged 18 years or older with newly diagnosed or previously diagnosed ET were enrolled into low, intermediate or high-risk PT-1 studies depending on their risk of vascular complications. Median prospective follow-up duration was 36 months (range, 2-87 months). JAK2, MPL and CALR screening utilised PCR based methods. Clinical and laboratory features were compared between the four molecular subgroups. Time-to-event data was analyzed using Kaplan-Meier curves, log-rank analyses and Cox proportional hazards models. Response to treatment and drug dosage were analyzed using non-parametric regression and linear mixed effects modeling respectively.
Results: JAK2, MPL and CALR mutated ET represented 53%, 4% and 26% of patients and were mutually exclusive in most cases. 1% of patients harbored >1 mutation in these genes and analysis of such patients using individual hematopoietic colonies showed that JAK2, MPL or CALR mutations can be successively acquired within the same tumour subclone. Within the PT-1 cohort, CALR- and MPL-mutated subgroups affected males and females equally, in contrast to the female predominance observed in JAK2-mutated and TN subgroups wherein only 37% and 31% of patients respectively were male (p=0.0008, Chi-squared test). TN patients were significantly younger than any of the other molecular subgroups with a median age of 44 years (p<0.0001 for all comparisons, ANOVA). CALR-mutated patients were also significantly younger than JAK2- (p=0.003, ANOVA) and MPL-mutated (p=0.005, ANOVA) patients, with a median age of 54 years. *CALR*-mutated trephines had more prominent megakaryocyte atypia (increased cluster frequency, cluster size, tight clusters, paratrabecular megakaryocytes and fibrosis), and TN trephines had relatively milder megakaryocyte abnormalities. CALR-mutated ET patients presented with lower hemoglobin levels and total white cell counts, and higher platelet counts. Whilst the majority of venous thrombotic events occurred in the JAK2-mutated subgroup (21 of 27 events), CALR-mutated ET patients suffered increased rates of myelofibrotic transformation (hazard ratio 3.15 compared to the *JAK2*-mutated subgroup, p=0.03, Cox proportional hazards model correcting for age, gender and treatment received). No interaction was noted between treatment with either hydroxyurea or anagrelide and the incidence of these adverse outcomes. Patients with CALRins5 mutations presented with higher platelet counts than patients with CALRdel52 mutations but no other differences in disease features or outcome. Platelet control was equivalent between all molecular subgroups following treatment with either hydroxyurea plus aspirin or anagrelide plus aspirin in high-risk patients. However, CALR-mutated and MPL-mutated patients developed lower hemoglobin levels during anagrelide therapy. This observation was not due to differences in anagrelide dosage between molecular subgroups.
Summary/Conclusions: These results demonstrate that molecular testing identifies distinct biological subgroups in ET with different clinical outcomes and treatment responses.

S114

A GREATER UNDERLYING MUTATIONAL COMPLEXITY MAY CONTRIBUTE TO THE DIFFERENTIAL PROGNOSTIC IMPACT OF PHENOTYPIC-DRIVER MUTATION IN PRIMARY MYELOFIBROSIS

P Guglielmelli[1,*], G Rotunno[1], T Fanelli[1,2], A Pacilli[1], G Corbizi-Fattori[1,2], L Calabresi[1], A Pancrazzi[1], AM Vannucchi[1]
[1]1CRIMM-Center for Research and Innovation of Myeloproliferative Neoplasms, 2 Department of Experimental and Clinical Medicine, 1 AOU Careggi; 2 University of Florence, Florence, [2]University of Siena, Siena, Italy

Background: In primary myelofibrosis (PMF), *JAK2/CALR/MPL* mutational status is prognostically informative, with "triple-negative" (TN) patients (pts) displaying the worst survival (Rumi E, Blood 2014). Also, survival was significantly shorter in *CALR* type 2/like (Ty2) *vs* type 1/like (Ty1) mutated pts (Tefferi A, Blood 2014; Guglielmelli P, BCJ. 2015). A high-molecular risk category (HMR) identifies pts with reduced survival if harboring any one of *ASXL1, EZH2, IDH1/2* and *SRSF2* mutated genes (Vannucchi A, Leukemia 2013; Guglielmelli P, Leukemia 2014).
Aims: To analyze the molecular landscape of PMF pts categorized according to their driver mutation status and correlate with clinical endpoints and outcome.
Methods: All PMF pts (WHO-2008) provided informed consent. Established methods were used for JAK2, MPL and CALR mutations. NGS analysis with Ion Torrent platform was used to genotype 18 genes (referred as subclonal, SC): all coding sequence of c-KIT, TET2, RUNX1, NRAS, KRAS, DNAMT3A, IKZF1, EZH2, TP53; hot spot of IDH1/2 and SRSF2 and selected exons of CBL, IDH2, ASXL1, SF3B1, NFE2, SH2B3, U2AF1. The nonparametric Wilcoxon rank-sum test, Kaplan-Meier estimate of survival and log-rank test were used as appropriate.
Results: We analyzed 126 pts: 43 were *JAK2*+ (34.1%), 42 TN (33.3%) and 41 *CALR* mut (32.6%; 26 (63.4%) Ty1 and 15 (36.6%) Ty2. Overall, 17 pts (13.5%) progressed to AML. Death occurred in 69 pts (43.4%) after a median follow up of 3.8y. There was no difference between Ty1 and Ty2 for common hematologic and clinical variables; conversely, both Ty1 and Ty2 differed from *JAK2*+ counterpart for younger age, lower leukocyte and higher platelet counts; males were more represented among Ty1 pts that other genotypes. More deaths occurred among Ty2 (45.8%), *JAK2*+ (37.0%) and TN (72.7%) pts compared to Ty1 (20.0%) (P<.0001). Median survival of *CALR* Ty1 was 26.4y *vs* 8.59y for *CALR* Ty2, 10.3y for *JAK2*+ and 2.1 for TN (P<.0001). The corresponding hazard ratio, taking *CALR* Ty1 pts as reference, was 3.0 (95%CI, 1.2-7.6), 2.4 (95%CI, 1.0-5.7) and 11.1 (95%CI, 5.0-25.01) for *CALR* Ty2, *JAK2*+ and TN pts, respectively. HMR status was associated with shortened survival ((HR 3.3, 95%CI 1.9-5.8; P<.001) as it was the number of HMR mutations (HR 5.4, 95%CI 2.8-10.6; P<.001). Considering the individual mutations, only *EZH2, ASXL1* and *SRSF2* predicted for shorter survival (2.7y, 1.93y and 1.03y respectively; P=.001; P=.01 and P<.0001). Pts harboring any one of SC mutations were similarly distributed among groups: Ty1 61%, Ty2 67%, JAK2+ 77%, TN 74%; exceptions were *SRSF2* mutations (n=26) that were 0% Ty1, 6.7% Ty2, 14% JAK2+, 45% TN (P<.0001), and *SF3B1* that was mutated in 3 Ty2 (20%) *vs* 1 pts in both Ty1 (4%) and JAK2+ (2%) and no TN pt (P=.009). Conversely, the proportion of pts with ≥2 SC mutations was significantly higher in TN (52%) *vs* the others (Ty1 15%, Ty2 20%, JAK2+ 42%)(P=.02). The proportion of HMR was significantly higher in TN (67%) and JAK2+ (54%) pts compared with *CALR* subtypes (35% in Ty1, 27% in Ty2) (P=.01), as it was the percentage of pts having ≥2 HMR mutations (P=.006).
Summary/Conclusions: Overall, our findings support previous reports that the prognostic advantage of *CALR* mutation in PMF regards only Ty1 mutation; however, we did not find evidence that such difference might be ascribed to a greater molecular complexity of Ty2. Conversely, the dismal outcome of TN pts might be explained, at least in part, by occurrence of greater number of prognostically negative HMR mutations, particularly of *SRSF2* mutations.

CLL natural history and progression

INTEGRATIVE ANALYSIS OF GENE MUTATIONS AND CHROMOSOMAL ABNORMALITIES BY NEXT-GENERATION SEQUENCING AND FISH IN HEMATOPOIETIC PROGENITORS OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M Hernandez-Sanchez[1,*], M Quijada[1], C Robledo[1], JM Hernández-Sánchez[1], AE Rodríguez-Vicente[1], A Montaño[1], D Quwaider[1], MJ Del Pozo[1], R Benito[1], JÁ Hernández[2], JM Hernández-Rivas[1]
[1]IBSAL, IBMCC, University of Salamanca, CSIC, Cancer Research Center; Department of Hematology, University Hospital of Salamanca, Salamanca, [2]Department of Hematology, University Hospital Infanta Leonor, Complutense University of Madrid, Madrid, Spain

Background: Chronic lymphocytic leukemia (CLL) is a highly genetically heterogeneous disease. Although CLL has been traditionally considered as a mature B cell leukemia, few independent FISH and Next-Generation Sequencing (NGS) studies have shown that the genetic alterations may appear in CD34+ early hematopoietic progenitors. However, the presence of both chromosomal aberrations and gene mutations in CD34+ cells from the same patients has not been explored.
Aims: To analyze both chromosomal abnormalities and gene mutations in CD34+ hematopoietic progenitors from CLL patients to elucidate whether these genetic events appear previously during the B-cell differentiation process.
Methods: NGS and FISH studies were carried out in isolated CD19+ mature B cells from 57 CLL bone marrow samples to assess the presence of gene mutations and/or cytogenetic aberrations, respectively. Amplicon-based deep NGS (454 Life Sciences, Roche) was performed to study the mutational status of *TP53*, *NOTCH1*, *SF3B1*, *FBXW7*, *MYD88* and *XPO1*. The presence of genetic lesions on 11q, 12, 13q, 14q and 17p was studied by FISH. All cases with any mutations in CD19+ cells were also sequenced in their corresponding CD34+ early progenitors (coverage=1159X). Moreover, FISH was also performed in the CD34+ fraction of a subset of CLL patients with cytogenetic changes (n=9).
Results: NGS studies revealed a total of 28 mutations in 24 CLL patients (24/57, 42.1%). *NOTCH1* was the most frequently mutated gene (22.8%), followed by *XPO1* (8.8%), *SF3B1* (7%), *FBXW7* (5.3%), *TP53* (3.5%) and *MYD88* (1.8%). CLLs with mutations in any of these genes, except to *MYD88*, were associated with an unmutated *IGHV* status (*P*=0.001). Most of the patients showed the same mutations in their corresponding CD34+ cells (21/24, 87.5%). Comparing the mutations in both cell populations, two different patterns could be identified. In one group, the mutational burden remained similar between both cell fractions. Mutations in *NOTCH1* (11/13) and *XPO1* (5/5) were predominant in this group. By contrast, the other group showed a high decrease or even absence of these mutations in the CD34+ cells than the corresponding B lymphocytes being mutations in *TP53* (2/2), *FBXW7* (2/3) and *SF3B1* (3/4) the most recurrent in this group. FISH analysis revealed that 5 out of 9 CLL cases with cytogenetic alterations in B mature lymphocytes presented also the same aberrations on the CD34+ cells. Of note, *IGH* alterations did not appear in any of the CD34+ cases (0/2), whereas 11q- (2/2) and 13q- (3/5) were present in the CD34+ early progenitors. Gathering both techniques, 2 out of 9 CLLs had both chromosomal aberrations and mutations in their mature lymphocytes. Noteworthy, one of these cases showed an *IGH* alteration and *NOTCH1* mutation (altered cells=80% and 51%, respectively) on the CD19+ population. However, only *NOTCH1* mutation (31%) was found on the CD34+ cells. The other patient presented 13q- (93%), 11q- (64%) and *XPO1* mutation (39%) on the CD19+ B cells. The same alterations were also present in hematopoietic progenitors (72%, 49% and 31%, respectively).
Summary/Conclusions: Our data confirmed that chromosomal abnormalities and gene mutations are present not only in mature B lymphocytes, but also in the CD34+ early progenitors of CLL patients. Moreover, our findings shed light about the hierarchy existing in the appearance of these events: 11q-, 13q-, *NOTCH1* and *XPO1* mutations could be early hits on CLL pathogenesis, whereas *IGH* alterations, *TP53*, *SF3B1* and *FBXW7* mutations seemed to show in a later maturational level. **Funding:** PI15/01471; Junta de Castilla y León (MHS)

DISTINCT HOMOTYPIC B-CELL RECEPTOR INTERACTIONS SHAPE THE OUTCOME OF CHRONIC LYMPHOCYTIC LEUKEMIA

M Gounari[1], C Minici[2], R Übelhart[3], M Dühren-von Minden[3], D Schneider[4], A Tasdogan[4], A Alkhatib[4], A Agathangelidis[5], S Ntoufa[6], N Chiorazzi[7], H Jumaa[4], K Stamatopoulos[6,8], M Degano[9], P Ghia[1,5,10,*]

Background: Signaling initiated by antigen binding to the B-cell receptor immunoglobulin (BcR IG) is paramount for CLL development and evolution. Indeed, BcR signaling pathways are constitutively active in all CLL cases and recently, a cell-autonomous model of CLL cell activation has been proposed, whereby all CLL-derived BcR IGs could promote Ca^{2+} influx and NF-κB target gene transcription through the binding of a common internal epitope on the BcR IG.
Aims: We investigated the relevant molecular interactions underlying cell-autonomous signaling in CLL cases with distinct and opposite clinical outcome in order to understand the molecular basis of the clinical disease heterogeneity. We focused on CLL stereotyped subset #4 (IGHV4-34/IGKV2-30), a particularly indolent clinical subgroup with a characteristic anergic functional phenotype of the malignant cells, and stereotyped subset #2 (IGHV3-21/IGLV3-21), noted for a dismal prognosis, largely independent of p53 dysfunction.
Methods: We produced recombinant IG molecules from CLL leukemic cells. The BcR IGs were analyzed for self-association using analytical ultracentrifugation, and their structure was determined by x-ray crystallography. Recombinant BcRs were transfected in the RAG2/λ5/SLP65 triple knockout murine pre B-cell line (TKO cells) engineered to include a tamoxifen-inducible ERT2-SLP65 fusion protein. Addition of 4-hydroxy tamoxifen in the absence of exogenous antigen induces an increase in Ca^{2+} influx in case of autonomous signaling of the tested BcR.
Results: The BcR IGs of both subsets interact in the crystals in a geometry highly indicative of specific homotypic recognition, albeit with distinct features. In subset #4, the VH CDR3 binds to a conformational epitope spanning the Heavy chain (VH and CH1 domains), while in subset #2 the VL CDR1 and CDR2 loops contact a surface composed of residues from the Light chain (VL FR1 and the linker between the VL and CL domains). Using analytical ultracentrifugation, we confirmed that the contacts observed in the experimental crystal structures for both subsets were also occurring in solution. Interestingly, the association in solution of the receptors was markedly different for the two subsets with persistent binding in subset #4 cases with indolent disease, *versus* weaker interactions in subset #2 aggressive cases. For both subsets, using the TKO tamoxifen-inducible system and Ca^{2+} influx as a readout, we found that the observed interactions activate cell-autonomous intracellular signaling in the absence of exogenous antigen. Conversely, cells expressing epitope or paratope mutants of either receptor did not demonstrate significant variations in Ca^{2+} influx, confirming the relevance of the homotypic interactions revealed by the crystal structures.
Summary/Conclusions: We provide the first description to high resolution of a homotypic association process in BcRs that resembles antibody-antigen recognition and leads to intracellular signaling in CLL cells. BcR IGs from CLL cases with different prognosis bind homotypically via their combining sites to specific, diverse epitopes to initiate intracellular signalling. Our results suggest that the avidity of BcR self-recognition may directly underlie the clinical course of CLL, since tight, persistent binding was noted in cases with indolent disease whereas weaker interactions characterized the aggressive progressive cases.

[1]Cluster of Excellence on Cellular Stress Response in Aging-Associated Diseases (CECAD), University Cologne, [2]Department I of Internal Medicine, [3]Department of Radiology, Medical Faculty, [4]Center of Integrated Oncology (CIO), University Hospital Cologne, [5]Center of Molecular Medicine Cologne (CMMC), University Cologne, [6]Institute of Pathology, University Hospital Cologne, Cologne, Germany

Background: CLL is the most common leukemia in the Western world. During CLL development, incipient CLL cells undergo a multistep mutational process, during which they acquire a set of genetic and/or epigenetic lesions, which ultimately result in the leukemic state. CLL-associated mutations can be classified into so-called driver mutations, which are essential for malignant growth and passenger mutations, which are functionally less significant. Recent work has revealed the identity of early, so-called *trunk lesions* and later-occurring *subclonal mutations* that are associated with disease progression and (chemo-)therapy resistance. Prominent examples for subclonal additional genetic events are *ATM* and *TP53* mutations, which are both associated with resistance against genotoxic therapies.
Aims: We aimed at overcoming one of the biggest hurdles in preclinical CLL research-the lack of mouse models that faithfully mimic the genetic events leading to CLL development.

Methods: We combined the well established Eμ-*TCL1* CLL mouse model with a floxed *Tp53*- or *Atm*-allele. We made use of the *Cd19*-Cre mouse to specifically delete *Tp53* or *Atm* in the B cell compartment. The resulting Eμ-*TCL1*;*Cd19*$^{Cre/wt}$;*Tp53*$^{fl/fl}$ (TCP) and Eμ-*TCL1*;*Cd19*$^{Cre/wt}$;*Atm*$^{fl/fl}$ (TCA) mice were carefully characterized and subsequently used for treatment strategy testing.
Results: The increase of leukemic burden in the blood was significantly faster in TCP and TCA mice, when compared to the Eμ-*TCL1*;*Cd19*$^{Cre/wt}$ (TC) control. Thrombocytopenia and splenomegaly developed faster in the *Atm*- and *Tp53*-deficient models. In agreement with this faster disease progression, TCP and TCA mice succumbed faster to the disease than TC control animals (31.4 weeks, 36.9 weeks and 49.9 weeks, respectively). Despite faster diesase progression in TCP and TCA mice, splenomegaly at time of death was comparable in all three cohorts. Histologically, the three lines were indistinguishable. Richter's transformation, as defined by loss of Cd5 expression, a strong increase in cell size and a high proliferative index, was occassionally observed in TCP and TC mice, but not in the TCA cohort. Interestingly, TCA mice showed a significantly better response to cyclophosphamide when compared to TCP animals, but TC mice did not. Looking more closely at disease kinetics, we observed a significant increase in disease aggressiveness in the TC group up to the level of TCP mice, suggesting the selection of an aggressive clone under insufficient therapy. Lastly, we used the TCA model to investigate whether pharmacological inhibition of PARP, a treatment strategy proven to be effective in homologous recombination-deficient tumors of other entities, might be beneficial in *ATM*-deficient CLL as well. Indeed, we could show a strong and significant survival benefit by daily application of Parp inhibitor in our mice, an effect not observed in the *Atm*-proficient controls.
Summary/Conclusions: We have, based on the Eμ-*TCL1* allele, generated mouse models mimicking the genetic alterations found in high-risk CLL patients, namely the loss of *TP53* and *ATM*. These novel mouse models might be used as valuable tools for the development of new treatment strategies for these high risk groups. We have done so by assessing the effectiveness of Parp inhibition specifically in the *Atm*-deficient setting in this mouse model of CLL.

S118

AKT ACTIVATION IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS PROMOTES TRANSFORMATION TOWARDS AGGRESSIVE RICHTER'S SYNDROME LYMPHOMA

M Al-Maarri[1], N Nickel[2], A Roth[2], N Hövelmeyer[3], M Hallek[2], FT Wunderlich[4], C Pallasch[2,*]
[1]Max Planck Institute for Metabolism Research Cologne; Institute for Genetics, University of Cologne; Cologne Excellence Cluster on Cellular Stress Responses in Aging-associated Diseases (CECAD), University of Cologne, [2]Department I for Internal Medicine, Centre for Integrative Oncology CIO, University Hospital of Cologne, Cologne, [3]Institute for Molecular Medicine Mainz, University Hospital of Mainz, Mainz, [4]Max Planck Institute for Metabolism Research Cologne; Institute for Genetics, University of Cologne; Cologne Excellence Cluster on Cellular Stress Responses in Aging-associated Diseases (CECAD), University of Cologne, Cologne, Germany

Background: Richter's syndrome (RS) is an aggressive transformation of Chronic Lymphocytic Leukemia (CLL) refractory to current therapies with dismal prognosis. RS arises from CLL cells independent of common DLBCL-mutations. Frequently mutations in p53, CDKN2 or cMyc genes are involved, but a significant proportion displays no specifically acquired driver mutation.
Aims: Here we aim to elucidate the role of AKT in transformation towards Richter´s syndrome in human patients and functionally address constitutively AKT-activation *in vivo*. Ultimately, we aim to develop mouse models that can be used to develop novel treatment options towards Richter's syndrome.
Methods: FFPE sections of Richter syndrome patients were used for pAKT staining. We have developed a mouse model allowing for Cre-activatable expression of a myristoylated AKT constitutive active allele from the *Rosa26* locus (*AKT-C*). We crossed that mice with Cd19^{Cre}- and *Cg1*^{Cre}-mediated B cell-specific *AKT-C* expression in the *Eμ:Tcl1* CLL mouse model.
Results: In biopsies revealed from patients with RS one third of cases showed enhanced AKT activation. Strikingly, Richter's transformation was recapitulated when AKT was genetically over-activated in Eμ-Tcl-1 mice, where AKT-C expressing cells developed a high-grade lymphoma phenotype leading to significantly decreased survival. AKT-C expression in TCL1 mouse model CLL cells furthermore induced morphology changes displaying features of aggressive lymphoma such as large transformed B-cell phenotype and frequent mitotic figures, enhanced proliferation indicated by KI67. The phenotype of transformed aggressive lymphoma could be revealed independently in both Cd19^{Cre}- and *Cg1*^{Cre}-mediated activation of AKT. Thus, *Eμ:Tcl1* transformed CLL cells act in concert with constitutively active AKT to develop RS. Noteworthy, *Cd19*^{Cre};*AKT-C* double transgenic mice fail to develop leukemia and lymphoma, indicating that CLL development in *Eμ:Tcl1* mice is a precondition to transformation. As for the downstream mechanisms of AKT-mediated transformation we identified GSK-3b inhibition and subsequent cMyc and Mcl-1 stabilization. This might confer contribute to resistance of RS cells against DNA-damaging and PI3K-inhibiting compounds in this novel model of Richter´s syndrome.
Summary/Conclusions: Collectively, we have generated the first murine Richter's Syndrome model providing novel mechanistic insights into the molecular understanding of Richter's transformation as an AKT-driven disease. The new model is amenable to model therapeutic strategies and to address the efficacy of synergistic treatment combinations in transformed lymphoma.

AML Biology - Novel mechanisms of leukemogenesis

S119

FREQUENT RECURRING MUTATIONS DISRUPT THE ANTI-PROLIFERATIVE FUNCTION OF ZBTB7A IN ACUTE MYELOID LEUKEMIA WITH T(8;21) TRANSLOCATION

Background: The t(8;21)(q22;q22) translocation results in the *RUNX1/RUNX1T1* rearrangement and is one of the most frequent chromosomal aberrations in AML. However, *in vivo* models indicate the requirement of additional lesions, such as of *KIT* or *FLT3* mutations, for leukemogenesis as the RUNX1/RUNX1T1 fusion gene alone is not sufficient to induce leukemia.
Aims: We set out to identify cooperating mutations in AML patients with t(8;21) translocation.
Methods: Exome and targeted sequencing, DNA pull-down, transcription assay, immunofluorescence, retroviral transduction, gene expression profiling.

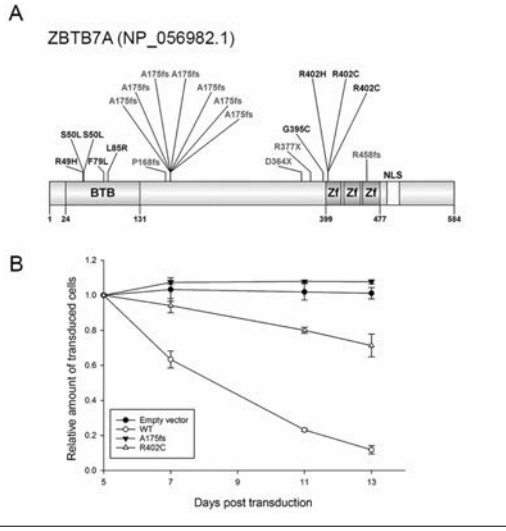

Figure A and Figure B.

Results: To identify additional cooperating mutations, we performed exome sequencing of matched diagnostic and remission samples from two AML patients with t(8;21) translocation. *ZBTB7A* was the only mutated gene identified in both patients. ZBTB7A is a member of the POZ/BTB and Krüppel (POK) transcription factor family. Previous studies suggested that ZBTB7A may act both as proto-oncogene and as tumor suppressor. Using targeted amplicon sequencing of *ZBTB7A* and 45 leukemia relevant genes, we screened 56 diagnostic AML t(8;21) samples. *ZBTB7A* mutations were identified in 13 of 56 patients (23%). Two recurring mutational hotspots (R402 and A175fs) in exon 2 were identified (Figure A). Variant allele frequency (VAF) ranged from 5.4-76.2% and 4 of 13 patients (31%) harbored two mutations of *ZBTB7A*. On the protein level, we confirmed the expression of a truncated ZBTB7A mutant (R377X) by Western blot for one patient with available material. In our cohort, *ZBTB7A* and *ASXL2* mutations occurred at similar frequencies and 5 of 13 patients carried mutations in both genes, however, there was no significant association of mutated *ZBTB7A* and mutations in *ASXL2* (Fisher's exact test, p=0.12) or any other recurrently mutated gene. On a functional level, the ZBTB7A mutants R402H, R402C, A175fs or R377X failed to repress a luciferase reporter containing ZBTB7A-binding elements derived from the ARF-promoter. Structural modeling revealed that Arginine 402 binds into the major groove of the DNA double helix and likely contributes to the affinity or sequence specificity of the DNA interaction of the zinc finger domain of ZBTB7A. Through DNA pull-down assays we confirmed impaired DNA binding of A175fs and R402H. The truncating ZBTB7A mutants A175fs and R377X showed altered cytoplasmic protein localization. In the t(8;21) translocation positive AML cell line Kasumi-1 retroviral expression of wild-type ZBTB7A inhibited cell growth, whereas this anti-proliferative effect was not observed upon expression of the A175fs ZBTB7A mutant. The R402C mutant expressing Kasumi1-cells showed a trend towards reduced cell growth, suggesting residual activity (Figure B). Based on this observation, we expressed *ZBTB7A* wild-type or its mutants together with the *RUNX1/RUNX1T1* fusion in lineage negative murine bone marrow cells and performed colony forming cell (CFC) assays. *ZBTB7A* expression led to a significant decrease in the number of colonies in primary CFC (87±12.6 *versus* 45±5.8, p<0.0001), while this effect was lost for both mutants A175fs and R402C. These findings support an oncogenic synergism between *RUNX1/RUNX1T1* and *ZBTB7A* mutations. We correlated *ZBTB7A* expression with clinical outcome in a large cohort of AML patients (GSE37642). Remarkably, in over 200 cytogenetically normal AML patients treated on clinical trial (NCT00266136), high expression of *ZBTB7A* was associated with a favorable outcome (p=0.0004), suggesting a relevance in AML beyond the t(8;21) subgroup.
Summary/Conclusions: In summary, we have identified *ZBTB7A* as one of the most frequently mutated genes in t(8;21) positive AML. Considering that *ZBTB7A* mutations result in loss of function, we suggest that *ZBTB7A* acts as a tumor suppressor in t(8;21) positive AML.

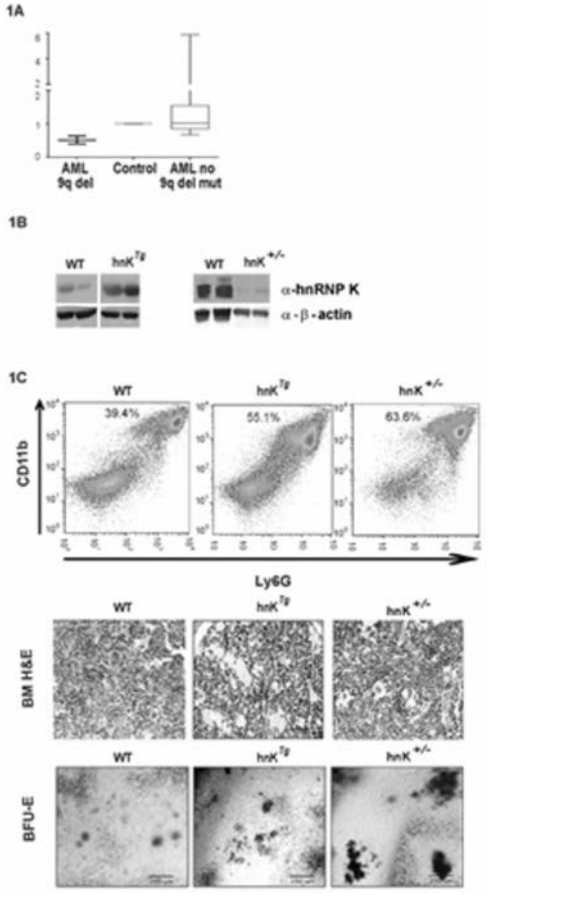
HNRNP K: AN ONCOGENE AND TUMOR SUPPRESSOR, TWO DISCRETE PATHS TO AML THROUGH ON GENE

M Gallardo[1,*], MJ Hornbaker[1], HJ Lee[2], X Zhang[1], C Bueso-Ramos[3], LR Pageon[4], M McArthur[4], A Multani[5], T Manshouri[1], J Parker-Thornburg[5], P Hu[3], I Rapado[6], A Quintas-Cardama[1], SM Kornblau[1], J Martinez-Lopez[6], SM Post[1]

[1]Leukemia, [2]Lymphoma and Myeloma, [3]Histopathology, [4]Veterinary Medicine & Surgery, [5]Genetics, MD Anderson Cancer Center, Houston, United States, [6]Hematology, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: We have recently demonstrated that *HNRNPK* is a critical haploinsufficient tumor suppressor residing at the 9q21.32 locus that is deleted in a subset of patients with AML (Gallardo et al, *Cancer Cell*, 2016). In this study, we generated a haploinsufficient *Hnrnpk* (*Hnrnpk*$^{+/-}$) mouse model that exhibited reduced survival and developed significant hematologic and myeloid malignancies. However, in addition to *HNRNPK* haploinsufficiency, we found that a large subset of AML patients without a 9q21.32 deletion, actually overexpress HNRNP K, resulting in poor prognoses. These data suggest that hnRNP K may have both tumor suppressive or oncogenic functions, depending on its expression levels.
Aims: This work will investigate the role of hnRNP K in AML, and to understand how *HNRNP K* behaves as an oncogene or as a tumor suppressor.
Methods: We analyzed copy number variations and aberrant expression of *HNRNPK* by FISH, qRT-PCR, and RPPA analyses in AML patients with and without 9q21.32 deletions. To directly examine the contribution of aberrant hnRNP K expression to malignant phenotypes, we generated two distinct cohorts of genetically engineered mice. One cohort was haploinsufficient for *Hnrnpk*, while the other specifically overexpressed hnRNP K in hematopoietic progenitors (*Hnrnpk*^{Tg}). Differences in survival, genomic stability, proliferation and differentiation potential, tumor formation, and molecular analyses were performed on hematological tissues using qRT-PCR, immunohistochemistry, colony formation assays, western blot analyses, and transplantation assays. Molecules of interest were further analyzed for interaction with hnRNP K via ChIP and RIP assays.
Results: Initial evaluation of *HNRNPK* expression levels in AML patients revealed that patients with the 9q21.32 deletion exhibited reduced hnRNP K levels, while many patients without this deletion had significant *HNRNPK* overexpression (Fig. 1A). This result was echoed in FISH analyses, as patients with the 9q21.32 deletion showed *HNRNPK* loss, while nearly 37% of AML (n=43) patients without the 9q deletion showed gene amplifications. In order to investigate the role of *HNRNP K* in AML, we generated both *hnRNP K*$^{+/-}$ and *hnRNP K*^{tg} mice. While these two mouse models have significant differences in hnRNP K expression compared to wild type (reduced *versus* overexpression), they surprisingly, had extremely similar phenotypes (Fig. 1B). Mice from each cohort suffered reduced survival, development of myeloid malignancies with high penetrance, genomic instability, enhancement in proliferation and differentiation potential in HSPCs, and the ability to generate myeloid hyperplasias following transplantation (Fig. 1C). Even though these opposite hnRNP K expression patterns result in extremely similar phenotypes, the molecular consequence of aberrant hnRNP K expression is facilitated through discrete molecular mechanisms. While hnRNP K haploinsufficiency directly decreased expression of anti-proliferation and differentiation genes likes *p21*, *C/EBPa*, and *C/EBPβ*, its over-

expression resulted in the direct activation of pro-growth genes like c-Myc. Given that hnRNP K expression is known to be tightly in all eukarotyic organisms, these data suggest that any alteration in hnRNP K expression may result in drastic cellular consequences.



Figures.

Summary/Conclusions: These data provide evidence that hnRNP K has the unique capacity to behave as an oncogene when overexpressed, or as a tumor suppressor when is its expression is reduced. In either case, these imbalances in hnRNP K expression are capable of directly contributing to the pathogenesis of AML.

S121

INTEGRATED ANALYSIS OF THE HUMAN HEMATOPOIETIC NON-CODING RNA LANDSCAPE REVEALS LNC-RNA STEM CELL SIGNATURE IN AML

S Emmrich[1], A Schwarzer[2], F Schmidt[1], M Ng[1], D Witte[1], FF Adams[2], C Reimer[1], A Maroz[1], D Reinhardt[3], JH Klusmann[1,*]
[1]Pediatric Hematology and Oncology, [2]Institute of Experimental Hematology, Hannover Medical School, Hannover, [3]Clinic for Pediatrics III, University Hospital Essen, Essen, Germany

Background: Long non-coding RNAs (lncRNAs) and miRNAs have emerged as crucial regulators of gene expression, epigenetics and cell fate decisions.
Aims: We sought to establish a comprehensive resource for the exploration of non-coding RNAs across the human hematopoietic hierarchy, to understand their role in the pathogenesis of acute myeloid leukemia (AML).
Methods: Here we present an integrated quantitative and functional analysis of the miRNA-, lncRNA- and mRNA-transcriptome of purified human hematopoietic stem cells (HSCs) and their differentiated progenies, including granulocytes, monocytes, T-cells, NK-cells, B-cells, megakaryocytes and erythroid precursors, which we correlated with the ncRNA expression profile of 46 pediatric AML samples to establish a core lncRNA stem cell signature in AML.
Results: For each blood cell population, RNA from 5 healthy donors was hybridized onto three microarray platforms (Arraystar lncRNA V2.0, NCode™-miRNA/-ncRNA), yielding a coverage of more than 40,000 lncRNAs, 25,000 mRNAs and 900 miRNAs on 146 arrays. Compared to mRNAs, the mean expression level of lncRNAs was nearly 2-fold lower ($p<2.2x10^{-16}$), highlighting the challenge for RNA-Seq to provide adequate coverage of these rare transcripts. T-distributed stochastic neighbor embedding (t-SNE) on lncRNA and miRNA genes robustly structured the dataset into groups of samples that matched the input populations, demonstrating their unique ncRNA expression profiles. Self-organizing maps revealed clusters of lncRNAs and mRNAs that were coordinately expressed in HSCs and during lineage commitment. To demonstrate their functionality, we knocked down LINC00173 from the granulocytic core signature using two independent shRNA constructs, which resulted in diminished granulocytic *in vitro* differentiation (2-fold reduction in percentage of $CD66b^+/CD13^+$ granulocytes, $p\leq0.05$), myeloid colony-formation (1.5-2-fold, $p\leq0.05$) and nuclear lobulation (MGG-staining). Accordingly, CRISPR-mediated transcriptional repression of nuclear localized *LINC00173* (RNA-FISH validated by qRT-RNA of fractionated RNA) using dCas9-KRAB and three sgRNAs per locus reduced proliferation of myeloid NB4 cells (2-3-fold, $p\leq0.01$). Having established a global human hematopoietic lncRNA expression resource, we extended our findings to malignant hematopoiesis. Linear (PCA) and nonlinear (t-SNE) dimensionality reduction of 46 pediatric AML samples including Down syndrome AMKL, core-binding factor AMLs (inv[16] or t[8;21]) and MLL-rearranged leukemias mapped most samples to a space between HSCs and differentiated cells together with the myeloid progenitors. A subset of AML-samples mapped closely to healthy HSCs, including most of the DS-AMKLs and MLL-AMLs. We identified a stem-cell associated lncRNA signature that was absent in healthy differentiated progenies, but upregulated in AML samples. A mesoscale CRISPRi screening in AML cell lines suggested the importance of the lncRNA stem cell core signature for the maintenance of leukemic growth.
Summary/Conclusions: The definition of a core lncRNA stem cell signature in normal HSCs and AML blasts will guide our way towards an improved understanding of self-renewal and the underlying transcriptional program, which is hijacked during malignant transformation.

S122

THE IMPACT OF CELLULAR AGE ON LEUKEMIC TRANSFORMATION

S Chaudhury[1,*], B Gibson[2], K Keeshan[1]
[1]Institute of Cancer Sciences, University of Glasgow, [2]Department of Hematology, Royal Hospital for Sick Children, Glasgow, United Kingdom

Background: Treatment of pediatric acute myeloid leukemia (AML) is largely extrapolated from adult trials despite age related disease heterogeneity. Indeed, during healthy ageing there are age related hemopoietic stem and progenitor (HSPC) cell proliferative and differentiative differences. We hypothesise that cellular age influences leukemic transformation, having implications for disease phenotype and response to therapy.
Aims: To determine if HSPC age affects oncogene-mediated leukemic transformation.
Methods: Murine HSPCs including $lin^-sca1^+cKit^+$ (LSK), common myeloid progenitor (CMP) and granulocyte-macrophage progenitor (GMP) cells from fetal liver (FL), 3 week(w), 10w and >60w adult bone marrow were isolated and transduced with the fusion oncogenes Nup98HoxA9 (NH9), AML1ETO (AE) and the mutant FLT3-ITD. Leukemic transformation was assessed *in vitro* by serial colony forming cell (CFC) assays, by growth in liquid culture and in stromal OP9 co-culture. *In vivo* leukemogenesis was assessed by transplantation of pre-leukemic LSKs transduced with NH9 after 2 rounds of colony formation (CFC2), into sublethally irradiated C57BL/6 mice. Gene expression was assessed by QPCR using fluidigm technology.
Results: NH9 transformed LSKs from all 4 ages *in vitro*. NH9 did not result in FL CMP and GMP transformation, while post-fetal (3w, 10w and >60w) CMPs and GMPs all transformed. Consistent with this, AE and FLT3-ITD transformed FL LSKs but not FL GMPs *in vitro*. This suggests that fetal transformation relies on specific features of the LSK that are absent from committed myeloid progenitors, independent from the oncogenic insult. To further assess age related transformation differences, NH9 transformed FL, 3w, 10w and >60w LSKs were assessed for AML *in vivo*. Older (10 and >60w) transformed cells led to a shorter latency with more penetrance than young (FL and 3w) transformed LSKs. Further, acute lymphoblastic leukemia (ALL) was observed in animals transplanted with FL and 3w transformed LSKs, but not 10w or >60w LSKs, suggesting young LSKs retain a lymphoid bias. As all NH9 transformed LSKs *in vitro* acquired self-renewal properties, the transformation differences observed *in vivo* may be cell autonomous or non-cell autonomous via the bone marrow microenvironment. Gene expression analysis of microenvironmental receptors and targets show the BMP pathway is upregulated in 10w and >60w LSK transformed cells suggesting the BMP pathway may have a role in age related transformation potential.
Summary/Conclusions: While LSKs from all 4 ages acquire self-renewal *in vitro*, progression to leukemia *in vivo* is slower and less penetrant in young compared to older transformed cells. This is in accordance with the lower incidence of AML in childhood compared to older adults. Activation of the BMP pathway has previously been associated with AML transformation, and our data suggest that the BMP pathway may play a role in the progression to AML specifically in older cells. The observation of ALL specifically in younger transformed LSKs suggests that young HSPCs retain lymphoid programs after myeloid oncogene expression, consistent with the higher incidence of ALL in childhood. Our findings support that age defined therapies are appropriate as HSPC age related biological differences are retained in leukemia and may impact not only disease phenotype but response to therapy.

Stem cell transplantation - Experimental

NBEA: A NOVEL REGULATOR OF HEMATOPOIETIC STEM CELL *IN VIVO* REPOPULATION

M Ganuza*, T Hall, S McKinney-Freeman
Hematology, St. Jude Children's Research Hospital, Memphis, United States

Background: Hematopoietic Stem Cells (HSCs) differentiate to generate all blood cells in a hierarchical manner. This has been exploited in HSC transplantation (HSCT) to treat hematologic diseases. Better understanding the molecular mechanisms implicated in HSCT should improve current transplant protocols. In our recently published work (Holmfeldt *et al.* J.Exp.Med. 2016), we have identified 17 new regulators of HSCT. Neurobeachin (*Nbea*) scored as a positive regulator of HSCT. NBEA protein is localized near the Golgi apparatus and regulates vesicular and protein trafficking. Patients with a disrupted NBEA allele present platelets with an abnormal morphology.
Aims: To understand the role of *Nbea* in HSCT and normal hematopoiesis.
Methods: *Nbea-/-* mice. Bone marrow (BM) transplant: Competitive congenic transplant into lethally irradiated recipients: Test cells (CD45.2+), competitor cells (CD45.1+), recipient mice (CD45.1+/CD45.2+). Flow Cytometry Analysis of Peripheral Blood (PB) and BM. RNA-microarray.
Results: Both adult BM Lineage-Sca-1+c-Kit+ (LSK) and E14.5 Fetal Liver (FL) LSK cells lentivirally transduced with shRNAs targeting *Nbea* (>70% transcript knockdown), and competitively transplanted within 40 hours post-infection into lethally irradiated recipient mice, suffer from a strong defect in short- and long-term repopulating activity, as measured by PB chimerism of recipient mice (>80% reduced). Thus, *Nbea* is required in LSK cells at different developmental stages for efficient HSCT. As transplanted *Nbea*-deficient cells are detected in the BM of recipients at 12 days post-transplantation, thus, a defect in homing or in LSK cell BM retention in recipients can be excluded. 4 months post-transplant, analysis of the major BM hematopoietic progenitor compartments (HPCs) of recipients showed a 50% decreased in the chimerism of *Nbea*-deficient cells in the HSC compartment. In contrast, *Nbea*-deficient cells were nearly absent from downstream progenitor compartments, suggesting a differentiation block. *Nbea-/-* mice die perinatally due to lack of synaptic transmissions There was no difference in the frequency of HPCs in the E14.5 FL of *Nbea-/-* and *Nbea+/+* littermates. *Nbea-/-* E14.5 FL-LSK cells showed no defect in engraftment ability compared to *Nbea+/+* controls, suggesting that embryonic plasticity has allowed for compensation. When CD45.2+ LSK cells derived from primary recipients of *Nbea-/-*E14.5 FL-LSK (CD45.2+) cells were isolated and transplanted into secondary recipients, a 25% reduction in repopulating activity was observed, supporting a role for *Nbea* in HSCT and HSC self-renewal. To understand how *Nbea* regulates HSC biology, we looked for differentially expressed genes using arrays on total RNA isolated from E14.5 FL-CD150+CD48- LSK cells sorted from both *Nbea+/+* and *Nbea-/-* embryos. Gene sets implicated in Snare interactions, vesicular transport, and Adherens junctions interactions were upregulated in *Nbea-/-* cells, supporting a role for *Nbea* in these processes.
Summary/Conclusions: *Nbea* is a *bona fide* regulator of HSC *in vivo* repopulation. Although Nbea is dispensable for native hematopoiesis, differences present in genes with a role in both vesicular trafficking and Adherens Junctions Interactions highlight the role of *Nbea* in these processes and how important they are for proper HSC interactions with the BM niche during HSCT.

ACUTE MYELOID LEUKEMIA (AML) PATIENTS CURED AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION GENERATE TUMOR-SPECIFIC CYTOTOXIC ANTIBODIES THAT KILL AML BLASTS

M Hazenberg[1,*], M Gillissen[2], M Kedde[3], G de Jong[2], E Yasuda[3], S Levie[3], A Bakker[3], Y Claassen[3], K Wagner[3], M Bohne[3], D Speijer[4], P Hensbergen[5], P van Helden[3], T Beaumont[3], H Spits[3]
[1]Hematology, AMC, [2]Hematology, Academic Medical Center, [3]AIMM Therapeutics, [4]Medical Biochemistry, Academic Medical Center, Amsterdam, [5] Center for Proteomics and Metabolomics, Leiden University Medical Center, Leiden, Netherlands

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) can cure acute myeloid leukemia (AML) when the donor immune system generates a potent graft *versus* leukemia (GvL) response. While the role of T cells and NK cells in GvL immune responses has been established, the contribution of B cells to GvL responses is less clear. Using SEREX and other techniques, the presence of antibodies directed against established tumor antigens following allogeneic HSCT has been demonstrated, but because these antibodies were not obtained in monoclonal format, the function of these antibodies could not be analyzed.
Aims: To investigate the role of antibodies produced by donor-derived B cells in GvL responses.
Methods: We selected five patients with high-risk AML who remained disease-free for more than 5 years after allogeneic HSCT and thus have mounted a potent GvL response. From the peripheral blood of these patients we isolated memory B cells that we transduced with Bcl-6 and Bcl-xL, to establish antibody-producing clonal B cell lines. Blood was obtained 2 years after allogeneic HSCT. B cell lines were screened for the production of antibodies that specifically bound to surface antigens on AML cell lines and AML blasts isolated from patients in our clinic. Target identification was performed by immunoprecipitation and mass-spectometry.
Results: We identified patient derived clonal B cell lines producing antibodies that recognized antigens expressed on the cell surface of AML cells, but not on normal hematopoietic and non-hematopoietic cells. Antibodies were donor-derived, and a number of these antibodies recognized the U5 snRNP200 complex. The U5 snRNP200 complex is a component of the spliceosome that in normal cells is located in the nucleus but that is exposed on the cell membrane of AML cells. U5 snRNP200 complex-specific antibodies were specific for allogeneic HSCT recipients with AML, as they were found in in 4 out of 5 AML patients screened, but were not found in multiple myeloma patients who received an allogeneic HSCT or in healthy individuals. Strikingly, U5 snRNP200 complex-specific antibodies induced death of AML cells *in vitro*, and, in a human AML mouse model, *in vivo*. Cell death was induced in the absence of cytotoxic leukocytes or of complement, through a non-apoptotic process that depended on destabilization of the cytoskeleton as cell death could be blocked by incubation of the target cells with cytochalasin D, an actin polymerization inhibitor. Cytotoxicity of the U5 snRNP200 antibodies was present at 4°C and 37°C, suggesting that cell death was induced by a passive process. Indeed, interaction of the antibodies with their target cells did not induce a calcium flux. Cytotoxicity of the antibodies depended on the Fc region of the antibody, since recombinant U5 snRNP200 complex-specific antibodies with a defective Fc region were not cytotoxic.
Summary/Conclusions: Allogeneic HSCT recipients with robust donor anti-AML immunity generate antibodies against a component of the spliceosome, the U5 snRNP200 complex, that is expressed on the membrane of AML blasts. U5 snRNP200 antibodies are cytotoxic *in vivo* and *in vitro*, demonstrating the potency of the humoral immune system in tumor immunology.

S125

INCREASED REACTIVE OXYGEN SPECIES AND EXHAUSTION OF QUIESCENT CD34-POSITIVE BONE MARROW CELLS MAY CONTRIBUTE TO POOR GRAFT FUNCTION AFTER ALLOTRANSPLANT

Y Kong[1,2,*], Y Song[2,3], Y Hu[2,3], MM Shi[2,3], XJ Huang[2,3]
[1]Collaborative Innovation Center of Hematology, Peking University, [2]Peking University Institute of Hematology, Peking University People's Hospital, [3]Academy for Advanced Interdisciplinary Studies, Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: Poor graft function is an important, often fatal complication following allogeneic hematopoietic stem cell transplantation. However, the underlying mechanism is unclear. In murine study, effective cross-talk between hematopoietic stem cells (HSCs) and the bone marrow microenvironment is important for normal hematopoiesis. Normal HSCs reside in a hypoxic bone marrow microenvironment protecting them from oxidative stress which would otherwise inhibit self-renewal resulting in bone marrow failure. We recently reported an impaired bone marrow endosteal and vascular microenvironment in subjects with poor graft function posttransplant. However, whether an increased level of reactive oxygen species (ROS) causes poor graft function following allotransplant remains to be elucidated.
Aims: The aim of our study is to determine whether quantitative and/or functional abnormalities of donor $CD34^+$ bone marrow cells result in poor graft function post-allotransplant.
Methods: In the current prospective case-pair study,apoptosis, cell-cycle state and colony forming capacity of $CD34^+$ bone marrow cells were quantified in subjects with poor or good graft function post-allotransplant. Moreover, expression of intracellular proteins including ROS, γ-H2AX, p53, phospho-p53, p21, phospho-p38, caspase-3 and caspase-9 were analyzed by flow cytometry. To study the effect of oxidative stress on post-allotransplant hematopoiesis, $CD34^+$ cells from subjects with good graft function were treated of H_2O_2 with and without N-acetyl-L-cysteine. Subsequently, the hematopoietic reconstituting activity of the donor $CD34^+$ bone marrow was evaluated using a NOD-$Prkdc^{scid}IL2rg^{null}$ xenograft assay by intra-bone marrow injection.
Results: Increased levels of ROS were identified in $CD34^+$ bone marrow cells in transplant recipients with poor graft function. This increase in ROS levels was associated with an elevated frequency of DNA double-strand breaks, apoptosis, exhaustion of quiescent $CD34^+$ cells and defective colony-forming unit plating efficiency, particularly in the $CD34^+CD38^-$ fraction. Up-regulated intracellular p53, phospho-p53, p21, caspase-3 and caspase-9 levels (but not phospho-p38) were detected in $CD34^+$ cells, particularly in the $CD34^+CD38^-$ fraction. To further study the potential role of ROS levels in post-transplant hematopoiesis, $CD34^+$ bone marrow cells from subjects with good graft function and normals were treated with H_2O_2. Treatment with H_2O_2 increased ROS levels, resulting in defective $CD34^+$ cells, an effect partially reversed by N-acetyl-L-cysteine. Moreover, $CD34^+$ bone marrow cells from the donors to subjects with poor or good graft function exhibited comparable hematopoietic reconstitution capacities in the xeno-transplanted NOD-$Prkdc^{scid}IL2rg^{null}$ mice.

Summary/Conclusions: Even if the transplanted donor's bone marrow CD34$^+$ cells are functionally normal pre-transplant, ROS-induced apoptosis may contribute to the exhaustion of CD34$^+$ bone marrow cells in subjects with poor graft function following allotransplant. This effect could be partially reversed by N-acetyl-L-cystine. Thus, our data suggest a potential approach for treating poor graft function post-allotransplant.

S126

MDSC (MYELOID-DERIVED SUPPRESSOR CELLS) DIFFERENTIATE UNDER GVHD (GRAFT-VERSUS-HOST DISEASE) CONDITIONS AND PREVENT GVHD BY INDUCING TYPE 2 T CELL RESPONSES

J Messmann[1], J Scheurer[1], F Leithäuser[2], KM Debatin[1], G Strauss[1,*]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, [2]Institute of Pathology, University of Ulm, Ulm, Germany

Background: Graft-*versus*-host disease (GVHD) still represents the major complication after allogeneic bone marrow transplantation (BMT) since allogeneic transplant-derived T cells attack and destroy recipient tissues. Therefore, a prerequisite for GVHD prevention is the interference with T cell activation, proliferation and functions. Myeloid-derived suppressor cells (MDSCs) are a population of immature myeloid cells, which inhibit T cell functions by versatile mechanisms.
Aims: Therefore, we tested whether co-transplantation of *in vitro*-generated MDSCs prevents GVHD and elucidated the influence of GVHD conditions on the differentiation of MDSCs.
Methods: MDSCs were generated *in vitro* by culturing BM cells in the presence of GM-CSF and G-CSF. After 4 days more than 90% exhibited a Gr-1$^+$CD11b$^+$ MDSC phenotype. To test whether and how MDSCs prevent allogeneic T cell functions, we co-transplanted MDSCs into lethally irradiated recipient mice together with allogeneic BM and spleen cells or we cultivated MDSCs in medium containing serum derived from GVHD developing mice.
Results: *In vitro*-generated MDSCs efficiently prevented T cell proliferation *in vitro*. If co-transplanted with allogeneic BM and spleen cells, MDSCs inhibited clinical GVHD and GVHD-associated death and attenuated histological GVHD. Interestingly, MDSCs did not predominantly reduce the numbers of allogeneic T cells but induced type 2 allogeneic T cells characterized by the expression of Th2 specific cytokines and transcription factors. *In vitro*-generated MDSCs represent a mixed population of CD11b$^+$CD11c$^-$ and CD11b$^+$CD11c$^+$ cells. To further investigate the Th2-inducing capacity of MDSCs, we cultured MDSCs in medium supplemented with GVHD serum, which induced an expansion of CD11b$^+$CD11c$^+$ cells. CD11b$^+$CD11c$^+$ cells expressed MHC class II^{high}, Gr-1^{med}, CD301b^{pos} while CD11b$^+$CD11c$^-$ cells were MHC class II^{low}, Gr-1^{high} and CD301b^{neg}. CD301 expression is associated with a Th2 inducing phenotype in dendritic cells just as the presence of transcription factors IRF4 and Klf4, whose expression was also higher in CD11b$^+$CD11c$^+$ cells. Similarly, MDSCs co-injected with the allogeneic transplant exhibited an expansion of CD11b$^+$CD11c$^+$ cells in spleen and GVHD target organs preferentially in mice developing GVHD. Comparable to the *in vitro* conditions, these CD11b$^+$CD11c$^+$ cells acquired a phenotype similar to antigen-presenting cells characterized by CD80, CD86, CD40, and MHC class II expression. Isolation of the different MDSC subpopulations *in vitro* and subsequent incubation with allogeneic spleen cells showed that CD11b$^+$CD1c$^+$ MDSCs induce the secretion of Th2 cytokine IL-5, while CD11b$^+$CD11c$^-$ cells provoked only a weak Th2 response.
Summary/Conclusions: In summary, we could show that transplantation of MDSCs prevents GVHD after allogeneic BMT by inducing type 2 T cells. Th2 inducing capacity, however, was preferentially mediated by a subpopulation of MDSCs. Further studies will elucidate the molecular mechanisms of Th2 induction and will clarify whether MDSC differentiation and functions are dependent on the type of inflammatory environment.

S127

INDUCTION OF NAÏVE T CELLS TRANSITION INTO AN EFFECTIVE CD4+CD25+FOXP3+CD127- REGULATORY T CELLS, *IN VITRO*, AS A POTENTIAL ORDNANCE IN THE PREVENTION OF GRAFT-VERSUS-HOST DISEASE

TJ Chiou[1,*], TH Chu[1], KH Chien[1], WH Wu[1], ST Chu[2], WF Tzeng[3]
[1]Division of Transfusion Medicine,Department of Medicine, Taipei Veterans General Hospital and National Yang-Ming University School of Medicine, [2]Institute of Biochemical Science, National Taiwan University, Taipei, [3]Department of Life Science, Fu-Jen University, New Taipei City, Taiwan, ROC

Background: Allogeneic haematopoietic stem cell transplantation (HSCT) has been used to treat some of haematological malignancies and inherited or acquired non-malignant diseases. Unfortunately, graft-*versus*-host disease (GVDH) occurred approximately 15% in transplant recipients and decreases the success of allogeneic HSCT. At present, no effective treatment can completely prevent the GVHD from allogeneic HSCT patients. CD4+CD25+FoxP3+ regulatory T cells (Tregs) have been shown to be important in maintaining immune homeostasis and preventing autoimmunity. However, 5% to 10% Tregs could be measured in human CD4+ T cells and few Tregs would convert to conventional activated T cells because of losing FoxP3 expression. It had been reported to correlate with the occurrence and severity of GVHD in some study.
Aims: In order to study the potential use of Treg cells for GVHD prevention, we attempt to evaluate the better method to increase the number of induced Treg cells (iTregs) in donor's PB and stabilize the FoxP3 in iTreg cells. To isolate the effective CD4+CD25+Foxp3+CD127-iTreg cells for clinical application and to establish a quick method to identify the functional iTreg cells is the study goal. Therefore, naïve T cells isolation for regulatory T cell induction is an important issue.
Methods: Mouse splenocytes were prepared from mouse spleen. Human PBSC were prepared from peripheral blood (PB) of healthy donors by Ficoll-Hypaque density gradient centrifugation. All T cells were isolated by negative selection; then CD4+naïve T cells were harvested. After that, the CD4+naïve T cells were activated by anti-CD3/CD28 beads in the presence of IL-2, TGF-β and retinoic acid (RA) containing RPMI1640 medium. The cells cultured with 3-day-nutrient-deprived medium (only 5% FBS), then refreshed the cells into the full nutrient supplement (10% FBS) for another 5 days. The harvested cells were analyzed by flow cytometry method with fluorescence-conjugated CD-antibodies, including CD4, CD25, CD127 and FoxP3. After trypanblue staining, the number of iTreg cell was counted by hemacytometer. The iTreg cells also harvested and the expression of functional marker genes in iTreg cells were analyzed via qPCR.
Results: In nutrient-deprived (5% FBS for 3 days in advance) culture system, we found the TGF-β triggered the mouse iTreg cells formation in a dose-dependent manner and increased iTreg cells formation efficiency under retinoic acid condition. Our data showed that we could induce the CD4+CD25+ Foxp3+CD127-iTreg cells more than 90%. The supplement of retinoic acid (0.1 and 0.5 nM) stabilized the *FoxP3*+ gene expression in iTregs during this incubation period; and the stability of FoxP3 expression and iTreg cell number could be maintained at least 12 days *in vitro*. The stability of iTreg cells is an important criterion for clinical use. Furthermore, we have analyzed the *FoxP3* gene and the bio-functional marker genes expression in iTreg cells to confirm the functional cells (Fig.1A). Based on these results, we consider the human T cells should be used. Therefore, we have investigated the human regulatory T cell induction. Human CD4+ naïve T cells were isolated from PB and activated via antibodies. The CD4+CD25+Foxp3+CD127-iTreg cells were induced to around 60~80% under IL-2 and TGF-β1 containing media, even without retinoic acid supplement (Fig.1B). It indicated we could harvest more iTreg cells under such condition. As we know, nTreg could suppress the induction of iTreg *in vivo*; further, we should remove the nTreg for improving the iTreg formation under cytokines supplement condition.

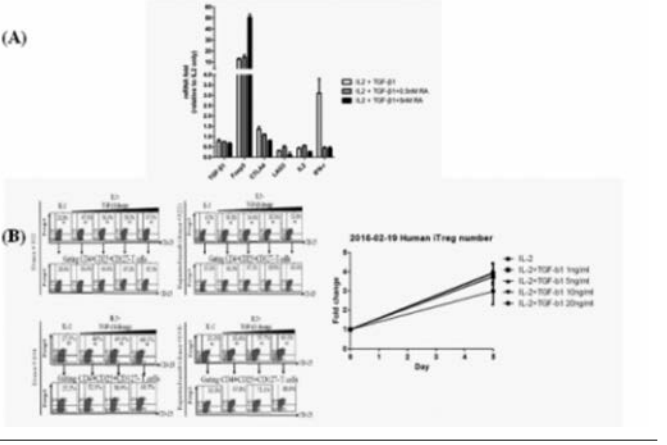

Figure 1. Functional iTreg cells induction. (A) The relative changes of gene expression in functional i Treg cells. (B) The human CD4+naïve T cells were isolated from human peripheral blood, and then activated with anti-CD3/CD28 antibodies. After TGF-β1 induction, the number of CD4+CD25+FoxP3+CD127- iTreg cells increased significantly in dose-dependent manner, even without retinoic acid supplement.

Summary/Conclusions: Our study showed that the combination of IL-2, TGF-β1 and RA in 3-day-nutrient-deprived medium could convert CD4+naïve T cells to CD4+CD25+FoxP3+CD127- iTreg cells and stabilize FoxP3 expression in the iTreg cells markedly. Further, we use the marker genes to clarify the biological function of iTregs *in vitro*. It may be to identify the functional iTreg cells quickly, after iTreg cells induction. Based on this method, we could harvest more and effective iTreg cells ready for use. It should be helpful for clinical application. GVHD mouse model will be established by using allogeneic HSCT to verify iTreg's function *in vivo*.

ARCADE (20090160): A PHASE 3 RANDOMIZED PLACEBO-CONTROLLED DOUBLE-BLIND TRIAL OF DARBEPOETIN ALFA IN THE TREATMENT OF ANEMIA IN PATIENTS WITH LOW OR INTERMEDIATE-1 RISK MYELODYSPLASTIC SYNDROMES (MDS)

U Platzbecker[1,*], A Symeonidis[2], E Oliva[3], JS Goede[4], M Delforge[5], J Mayer[6], S Badre[7], E Gasal[7], B Mehta[7], J Franklin[7]
[1]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik I, Dresden, Germany, [2]Division of Hematology, Department of Internal Medicine, University of Patras Medical School, Patras, Greece, [3]Division of Hematology, Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy, [4]Division of Hematology, University Hospital and University of Zürich, Zürich, Switzerland, [5]University Hospital Leuven, Leuven, Belgium, [6]Department of Internal Medicine-Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic, [7]Amgen Inc., Thousand Oaks, United States

Background: Although erythropoiesis-stimulating agents (ESAs) are recommended in clinical guidelines to treat anemia in patients with lower-risk MDS, ESAs are not widely approved for this indication.
Aims: To evaluate the efficacy and safety of darbepoetin alfa (DAR) in IPSS low / intermediate-1 (int-1) risk MDS patients with anemia, in a phase 3, randomized, placebo(PBO)-controlled trial (EudraCT#2009-016522-14, NCT# 01362140).
Methods: Patients were enrolled from Dec 21, 2011 to Aug 27, 2014 in 9 European countries. Eligible patients had low/int-1 MDS, anemia [hemoglobin (Hgb) ≤10 g/dL], low transfusion burden (<4 transfusion units in each of 2 consecutive 8-week periods prior to randomization), no previous treatment with ESAs or biologic response modifiers, and endogenous erythropoietin (EPO) levels ≤500 mU/mL. Patients were randomized 2:1 to receive 24 weeks of subcutaneous DAR 500 µg or PBO every 3 weeks (Q3W), stratified by IPSS status (low or int-1). The dose was reduced if Hgb was >12.0 g/dL or if Hgb increased by >1.5 g/dL in 3 weeks without transfusion. Investigational product (IP) was discontinued and the patient entered follow-up if >3 dose reductions were needed. Key efficacy endpoints included (1) transfusion incidence from weeks 5-24 and (2) erythroid response (HI E) per IWG 2006 criteria, ie, ≥1.5 g/dL increase from baseline in Hgb with a mean rise of ≥1.5 g/dL for 8 weeks without transfusions. Results from the 24-week double-blind period are reported here; patients could then receive open-label DAR 500 µg Q3W for 48 weeks and were followed up for survival and progression to AML status for up to 3 years (ongoing).
Results: A total of 147 patients were randomized; 50.7% of patients were IPSS low risk and 49.3% were int 1 risk, median Hgb levels were 9.3 (Q1:8.8, Q3:9.7) g/dL, median EPO levels were 69 (Q1:36, Q3:158) mU/mL, rates of good / intermediate / poor IPSS karyotype were 91% / 9% / 0%, respectively, and% WHO classifications were RA:15%, RARS:14%, RCMD:44%, del5q:9%, RAEB-1:16%, and MDS U/unknown:2%. There were 146 (97 DAR, 49 PBO) patients in the primary analysis set. Baseline demographic and disease characteristics were generally similar between the two arms. Transfusion incidence from weeks 5-24 was significantly reduced with DAR *vs* PBO (DAR:36.1% *vs* PBO:59.2%, p=0.008). The proportion achieving HI-E was significantly increased with DAR *vs* PBO; DAR:14.7% (11 of 75 evaluable) *vs* PBO:0% (0 of 35 evaluable), p=0.016. All patients with HI-E (n=11) had a baseline serum EPO level <100 mU/mL. Adverse events (AEs) occurring ≥5% more frequently in the DAR arm than the PBO arm were fatigue, pyrexia, headache, and myalgia. Safety results from this trial were consistent with the previous DAR phase 2 MDS trial (Gabrilove BJH 2008, 142:379-393).

Table 1.

	Placebo (N=48), n (%)	Darbepoetin alfa (N=98), n (%)
AEs leading to IP discontinuation	2 (4.2)	3 (3.1)
Grade ≥3 / grade ≥4	13 (27.1) / 6 (12.5)	15 (15.3) / 5 (5.1)
Fatal AEs (none treatment-related)	2 (4.2)	1 (1.0)
Serious AEs	8 (16.7)	11 (11.2)
Treatment-related serious AEs	0 (0)	1 (1.0)
Venous thromboembolic events	0 (0)	1 (1.0)
Progression to AML	1 (2.2)	2 (2.1)

Summary/Conclusions: In this phase 3, randomized, double-blind, PBO-controlled trial in low/int-1 MDS patients with anemia, 24 weeks of DAR Q3W significantly reduced transfusions and increased rates of erythroid response with no new safety signals.

S129

CC-486 (ORAL AZACITIDINE) IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS) WITH OR WITHOUT PRETREATMENT THROMBOCYTOPENIA

G Garcia-Manero[1,*], SD Gore[2], BL Scott[3], MR Savona[4], CR Cogle[5], TE Boyd[6], S Kambhampati[7], J Hetzer[7], Q Dong[7], K Kumar[7], SM Ukrainskyj[7], BS Skikne[7]
[1]University of Texas, MD Anderson Cancer Center, Houston, [2]Yale Cancer Center, New Haven, [3]Fred Hutchinson Cancer Research Center, Seattle, [4]Vanderbilt University Medical Center, Nashville, [5]University of Florida, Gainesville, [6]North Star Lodge Cancer Center, Yakima, [7]Celgene Corporation, Summit, United States

Background: The estimated prevalence of thrombocytopenia in MDS is 40-65% (Kantarjian, *Cancer*, 2007). Severe thrombocytopenia (platelet count <30x10^9/L) is one of the worst prognostic factors for patients (pts) with MDS (Garcia-Manero, *Am J Hematol*, 2015). It has been suggested that pts with IPSS Low or Intermediate (Int)-1 risk MDS with severe thrombocytopenia should be considered higher-risk and receive disease-modifying therapy (DMT) at diagnosis (Gonzalez-Porras, *Cancer*, 2011). Like other DMTs, azacitidine (AZA) is associated with transient exacerbation of cytopenias during early treatment (Tx), which improve as Tx continues (Santini, *Eur J Haematol*, 2010). CC-486, the oral formulation of AZA, is in clinical development for Tx of hematologic malignancies, including MDS.
Aims: Evaluate the safety and efficacy of CC-486 monotherapy in pts with MDS with or without pretreatment thrombocytopenia.
Methods: Pts with MDS from three phase 1/2 CC-486 studies, two of which included dose-finding periods, were included in these analyses. CC-486 dosing regimens were: 120-600mg x7 days (d) (following a single SC AZA 75mg/m^2 x7d/28d cycle), or (with no initial SC AZA cycle) 300mg QD or 200mg BID x14d or 21d. All dosing regimens were administered in repeated 28d cycles. Thrombocytopenia was defined as platelet count ≤75x10^9/L. Overall Response included complete remission (CR), partial remission (PR), hematologic improvement (HI), and transfusion independence (TI) (Cheson, *Blood*, 2006).
Results: In all, 137 MDS pts participated in the three studies, including 72 pts with platelet counts ≤75x10^9/L (LowPlt group). Median age of all pts was 72 years (range 31-91). Median platelet count at baseline in the LowPlt group was 32.5x10^9/L (range 2-75) and in pts with platelet counts >75x10^9/L (HiPlt group) was 162x10^9/L (78-593). At entry, pts in the LowPlt cohort were less likely to have WHO-defined refractory anemia (15% *vs* 42% of pts in the HiPlt group) and more likely to have higher-risk (IPSS Int-2 or high) MDS (31% *vs* 12%, respectively). Rate of CR+PR was 22% in the LowPlt cohort and 7% in the HiPlt cohort, and Overall Response was the same in both groups (42%, **Table**). In the LowPlt group, 2 pts (14%) attained platelet TI and 17 pts (24%) attained HI-P. The most frequent Grade 3-4 treatment-emergent adverse events were hematological; anemia, neutropenia, febrile neutropenia, and thrombocytopenia occurred in 17%, 13%, 18%, and 21%, respectively, of pts in the LowPlt group, and in 26%, 26%, 14%, and 14% of pts in the HiPlt group. Grade 3-4 bleeding events were infrequent (n=9, 6.6%) and did not occur more often in the LowPlt group (GI [n=2], vaginal or cerebral hemorrhage [n=1 each]) than in the HiPlt group (GI [n=4] or ear hemorrhage [n=1]). Six deaths occurred during CC-486 treatment, 4 in the LowPlt group and 2 in the HiPlt group, including a 93-yr-old HiPlt pt who died of GI hemorrhage related to a duodenal ulcer.

Table 1.

Hematologic Response	LowPlt ≤75x10^9/L (n=72) n/N (%)	HiPlt >75x10^9/L (n=64)* n/N (%)	All patients (n=136)* n/N (%)
Overall Response Rate (CR + PR + Any HI + Any TI)	30/72 (42)	27/64 (42)	57/136 (42)
CR†	8/36 (22)	2/29 (7)	10/65 (15)
PR†	0/24	0/28	0/52
Any HI	24/72 (33)	21/62 (34)	45/134 (34)
HI-E	12/65 (18)	16/55 (29)	28/120 (23)
HI-P	17/72 (24)	6/13 (46)	23/85 (27)
HI-N	4/37 (11)	4/21 (19)	8/58 (14)
Any TI	9/32 (28)	14/33 (42)	23/65 (35)
RBC TI	7/27 (26)	14/33 (42)	21/60 (35)
Platelet TI	2/14 (14)	0/0	2/14 (14)

n = number of pts with response / N = number of pts eligible for response
*No response assessment available for 1 pt
†CR and PR were investigator-assessed for 19 patients (1 CR, 0 PR)

Summary/Conclusions: CC-486 was generally well tolerated in these MDS pts, even in the LowPlt group with median pretreatment platelet counts bordering on severe thrombocytopenia. Grade 3-4 bleeding events were uncommon overall and occurred less frequently in the LowPlt group. Death was more frequent in the LowPlt cohort, consistent with the poor prognosis associated with marked thrombocytopenia. However, more than 20% of pts in the LowPlt group attained CR during CC-486 therapy and pts were equally likely to attain HI whether in the LowPlt or HiPlt group.

Background: Thrombocytopenia is a serious life-threatening complication in patients with advanced myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML). Eltrombopag (EPAG), an oral thrombopoietin receptor agonist, is approved for treatment of chronic immune thrombocytopenia, hepatitis C virus-related thrombocytopenia, and severe aplastic anemia. Preclinical studies showed that EPAG has potential antileukemic effects (Roth M *et al. Blood*. 2012;120:386–94). A randomized, placebo-controlled, Phase 1/2 study in advanced MDS/AML demonstrated an acceptable safety profile at EPAG doses up to 300 mg daily, with no disease progression, and a trend toward improved platelet pharmacodynamics (Platzbecker U *et al. Lancet Haematol*. 2015;2: e417–26).
Aims: To determine the effect of EPAG on reducing the number of clinically relevant thrombocytopenic events (CRTE) in patients with MDS or AML who have Grade 4 thrombocytopenia (platelets <25 Gi/L).
Methods: After 8 weeks of open-label, dose-defining EPAG treatment (Part 1 [Mittelman M *et al. Blood*. 2012;120(21): Abs 3822]), adult patients with advanced MDS or AML were randomized 2:1 in a double-blind fashion (Part 2) to 12 weeks of supportive care plus once daily EPAG (dose range 50–300 mg over the course of treatment) or placebo. Patients were stratified by baseline platelet count (<10 Gi/L *vs* ≥10 Gi/L) and disease severity (International Prognostic Scoring System intermediate-2/high-risk MDS *versus* AML). Eligibility included 10–50% baseline bone marrow blasts and a baseline platelet count of <25 Gi/L. The primary endpoint was reduction in CRTEs (a composite of platelet counts <10 Gi/L, platelet transfusions, and Grade ≥3 World Health Organization [WHO] bleeding scale events) during Weeks 5–12. Secondary endpoints included safety, platelet transfusion independence, maximum WHO bleeding, hematologic improvement, and MDS progression (increased blast percentage or leukemic transformation).
Results: At baseline, age ranged from 29–85 years (mean 72.3; n=98) in the EPAG group *vs* 44–87 (mean 70.6; n=47) in the placebo group. More patients had abnormal (53% *vs* 34%) or poor (34% *vs* 17%) karyotypes in the EPAG group. Fewer EPAG patients had baseline platelets <10 Gi/L (34% *vs* 45%) than placebo patients. Other baseline characteristics were similar. Efficacy results are described in the Table. EPAG-treated patients showed significantly lower CRTE than placebo (54% *vs* 69%; odds ratio=0.202, *P*=0.03). Proportionately fewer patients on EPAG than placebo experienced independent reviewer-assessed disease progression (42% *vs* 60%). The most frequent adverse events in this study were petechiae (42% *vs* 23%), epistaxis (28% *vs* 23%), pyrexia (24% *vs* 28%), diarrhea (21% *vs* 17%), and fatigue (25% *vs* 9%) on EPAG *versus* placebo, respectively. More EPAG (31.6%) than placebo (14.9%) patients discontinued due to AEs. During Part 2, 35% of EPAG and 28% of placebo patients died (*P*=0.287). The primary cause of death for both groups was the disease under study (EPAG 27%; placebo 23%).

Table 1. Efficacy results of 12-week, randomized, double-blind treatment in the ASPIRE study.

	Eltrombopag (n=98)	Placebo (n=47)	Statistics
Patients with weekly CRTE during Weeks 5–12, % (95% CI)	54% (43%, 64%)	69% (57%, 80%)	OR=0.202 (95% CI: 0.05, 0.87); *P*=0.03
Platelet transfusion independence,* days (SD)	26.3 (21.5)	25.4 (19.7)	—
Maximum WHO bleeding grade, n (%)			
WHO Grade 3	5 (5%)	3 (7%)	—
WHO Grade 4	1 (1%)	3 (7%)	—
Any hematologic improvement,† n (%)	10 (10%)	4 (9%)	OR=1.26 (95% CI: 0.37, 4.30); *P*=0.718
Disease progression,‡ n (%)	41 (42%)	28 (60%)	—
Progression from MDS to AML, n (%)	31 (62%)	16 (73%)	—
Overall survival, months	4.24	4.60	HR=0.971 (95% CI: 0.631, 1.496)

AML, acute myeloid leukemia; CI, confidence interval; CRTE, clinically relevant thrombocytopenic event; HR, hazard ratio; MDS, myelodysplastic syndromes; OR, odds ratio; SD, standard deviation; WHO, World Health Organization.
*Platelet transfusion independence was defined as the duration of time between two consecutive platelet transfusions.
†Hematologic improvement was defined as an improvement of >20 Gi/L and 2× baseline for patients with baseline platelets of <20 Gi/L or ≥50 Gi/L and 2× baseline for patients with baseline platelets of ≥20 Gi/L; ≥100% increase and absolute increase >0.5 Gi/L over baseline in neutrophils; and hemoglobin increase by ≥1.5 g/dL over baseline and red blood cell transfusions (given for hemoglobin <9.0 g/dL) reduced by ≥2 per 4 weeks from baseline.
‡Protocol-specific, modified International Working Group response criteria for MDS were applied to define disease progression in patients with MDS or AML.

Summary/Conclusions: Treatment of patients with advanced MDS or AML with the thrombopoietin receptor agonist EPAG *versus* placebo for 12 weeks resulted in fewer CRTEs and did not result in an increase of disease progression. Rates of WHO Grade 3/4 bleeding were lower with EPAG. EPAG did not demonstrate overall hematologic improvement in this study. This study (NCT01440374) was sponsored by GlaxoSmithKline; however, as of March 2, 2015, eltrombopag became an asset of Novartis AG.

S131

LUSPATERCEPT INCREASES HEMOGLOBIN AND REDUCES TRANSFUSION BURDEN IN PATIENTS WITH LOW-INTERMEDIATE RISK MYELODYSPLASTIC SYNDROMES (MDS): LONG-TERM RESULTS FROM PHASE 2 PACE-MDS STUDY

U Platzbecker[1,*], A Giagounidis[2], U Germing[3], K Götze[4], P Kiewe[5], K Mayer[6], J Chromik[7], M Radsak[8], T Wolff[9], E Donovan[10], D Wilson[10], X Zhang[10], A Laadem[11], M Sherman[10], K Attie[10]
[1]Universitätsklinikum Carl Gustav Carus, Dresden, [2]Marien Hospital Düsseldorf, [3]Universitätsklinikum Düsseldorf, Düsseldorf, [4]Technical University of Munich, Munich, [5]Onkologischer Schwerpunkt am Oskar-Helene-Heim, Berlin, [6]University Hospital Bonn, Bonn, [7]Universitätsklinikum Frankfurt, Goethe Universität, Frankfurt/Main, [8]Johannes Gutenberg-Universität, Mainz, [9]OncoResearch Lerchenfeld UG, Hamburg, Germany, [10]Acceleron Pharma, Cambridge, MA, [11]Celgene Corporation, Summit, NJ, United States

Background: Splicing factor mutations in MDS patients (pts), notably SF3B1, correlate with bone marrow ring sideroblasts (RS) and ineffective erythropoiesis (IE). Luspatercept (ACE-536), a fusion protein containing modified activin receptor type IIB, is being developed for treatment of anemia due to IE in MDS. Luspatercept binds GDF11 and other TGF-β superfamily ligands to promote late-stage erythroid differentiation and increase hemoglobin (Hgb) levels (Suragani R, Nat Med and Attie K, Am J Hematol, 2014).
Aims: This is an ongoing, phase 2, multicenter, open-label, dose-finding study followed by a long-term extension study to evaluate the effects of luspatercept in pts with low-intermediate risk MDS. Endpoints included erythroid response (IWG HI-E), RBC transfusion independence (RBC-TI, ≥8 weeks), duration of HI-E, pharmacodynamic and iron metabolism biomarkers, safety, and pt-reported QOL.
Methods: Inclusion criteria included age ≥18 yr, Hgb <10 g/dL (if <4U RBC/8 weeks), ESA refractory or EPO >500 U/L, no prior HMA, and no current lenalidomide or ESA. Luspatercept was administered SC every 3 wks for up to 5 doses in the base study, including 7 dose escalation cohorts (n=27 total, 0.125 to 1.75 mg/kg) and an expansion cohort (n=31, starting dose 1.0 mg/kg, max. 1.75 mg/kg). An amendment to the base study allows for additional pt subgroups (n=~50). A 2-year extension study (n=32 to date) is ongoing.
Results: Data (as of 31 Aug 2015) were available for 58 pts. Of these, 39 pts received ≥4U RBC/8 weeks (high transfusion burden, HTB) and 19 pts <4U RBC/8 weeks (low transfusion burden, LTB). Median age was 72 yr (range 27-90 yr) and 66% had prior ESA. Median RBC transfusion burden was 6U/8 weeks (range 4-18 units, HTB pts) and median Hgb was 8.7 g/dL (range 6.4-10.1 g/dL, LTB pts). 82% pts were RS+ (≥15% RS in bone marrow), including 19% RARS and 50% RCMD-RS.
LTB: IWG HI-E was achieved in 8/17 (47%) pts in the higher dose groups, compared with 0/2 in the lower dose groups in the base study. In the extension study, 9/13 (69%) pts achieved HI-E. Mean Hgb increase at Week 12 was 2.9 g/dL in HI-E responders and 1.3 g/dL in HI-E non-responders. 3/3 LTB pts who had 2U RBC/8 weeks at baseline became RBC-TI.
HTB: IWG HI-E was achieved in 16/32 (50%) in the higher dose groups (≥0.75mg/kg), compared with 2/7 (29%) in the lower dose groups, and 8/32 (25%) became RBC-TI in the base study. In the extension study, 13/19 (68%) achieved HI-E and 8/19 (42%) became RBC-TI (duration up to 50+ wks). IWG HI-E was achieved in 22/40 (55%) RS+ pts and 2/7 (29%) RS- pts. Response rates were 64% for EPO <200 U/L, 36% for EPO 200-500 U/L, 57% for ESA-naïve, and 46% for those refractory to prior ESA treatment. 18/30 (60%) pts with SF3B1 mutation responded; other potential predictors of response are being explored. Luspatercept was well tolerated, with 3 possibly related grade 3 adverse events of myalgia, worsening of general condition, and blast cell count increase. The most common possibly related AEs in the base study were diarrhea, fatigue (3 pts each), injection site erythema, bone pain, myalgia, and hypertension (2 pts each).
Summary/Conclusions: Luspatercept treatment was well tolerated and led to erythroid response in ~50% of low-intermediate risk MDS pts. Higher response rates were observed in RS+ and SF3B1mut pts, and responders included pts who were both ESA naïve and ESA-refractory, or with EPO up to 500 U/L. A Phase 3 study of luspatercept in regularly-transfused RS+ patients with lower-risk MDS according to IPSS-R is ongoing (MEDALIST study; clinicaltrials.gov NCT02631070).

Background: Health-related quality of life (HRQoL) has been introduced by authorities, stakeholders and clinicians as a relevant patient reported outcome. Description of HRQoL-profile in MDS-patients is essential for individualized treatment algorithms.
Aims: To analyze the impact of MDS on HRQoL at initial diagnosis as compared to sex- and age-matched reference populations and to define predictors of impaired HRQoL.
Methods: A prospective European Registry (EUMDS) for newly diagnosed IPSS low-/int-1 MDS was initiated by the European Leukemianet. The EQ-5D descriptive system was introduced in EUMDS at initial diagnosis. EQ-5D data from MDS-patients were compared with sex- and age-matched reference populations published by the Euroquol Group.
Results: 1985 EUMDS patients from 140 hematology centers in 15 European countries diagnosed between December 2007 to February 2016 were included. 1690 (85.1%) patients (median age 74; range 18 – 95 yrs) and 61.5% male, completed both EQ-5D descriptive system and EQ VAS at the time of inclusion. Demographic characteristics of patients who completed EQ-5D questionnaire did not differ substantially from the whole cohort. Overall, the HRQoL-data in the sample analyzed were likely missing at random. A significant proportion of MDS-patients were characterized by moderate/severe restrictions in the dimensions mobility in 41%, self-care 13.3%, usual activities 36.1%, pain/discomfort 49.5%, and anxiety/depression 37.9%, respectively. Overall, Wilcoxon signed ranks tests showed that in MDS a significantly higher proportion of patients reported problems in mobility (41.0 *vs* 33.5%), usual activities (36.1 *vs* 26.0%) and anxiety/depression (37.9 *vs* 14.9%) than in European norms (p<0.001). Similarly, both EQ-5D index and VAS were more unfavorable in MDS as compared to references (0.74 *vs* 0.76; p<0.05) (69.6 *vs* 71.8; p<0.05) (paired t-tests). Most impairments in HRQoL were significantly correlated with advanced age, female sex, a higher comorbidity burden (defined by HCT-CI or MDS-CI), low Hb-level (<10 *vs* ≥10 g/dl) and red blood cell transfusion need (0 *vs* ≥1))(p<0.001). In contrast the impact of WHO-diagnosis and IPSS-R on HRQoL was only marginal. Comparisons with European reference norms revealed pronounced impairments in MDS-patients in usual activities and anxiety/depression in all age groups (<60 *vs* 60-75 *vs* 75+ yrs) (p<0.001 for each subgroup) and in both sexes (p<0.001). The impact of MDS on mobility was most prominent in male (p<0.001) and elderly persons (60-75 (p<0.01) *vs* 75+ yrs (p<0.001)). VAS was more often diminished in women (p<0.05) and at advanced age (75+ yrs (p<0.001)), as compared to reference cohorts. A hierarchical multilevel analysis was preformed to assess whether there was a significant difference in HRQoL between groups with different demographic and clinical parameters. Based on univariate analyses advanced age, female gender, pronounced comorbidities, low Hb and transfusion need were major determinants, both of EQ-5D index and VAS (p<.001). In multivariate modeling there was a significant loss in HRQoL for elderly (-0.082 for EQ-5D index and -7.33 for VAS for those 75+ yrs), for advanced comorbidities (-0.059; -6.21 for MDS-CI int/high), low Hb-levels (-0.053; -5.56), transfusion need (-0.045; -4.02) and female sex (-0.077; -3.64).
Summary/Conclusions: This study demonstrates profound restrictions in distinct dimensions of the EQ-5D in MDS-patients at diagnosis as compared with age- and sex-matched reference populations and defines major predictors of HRQoL. This analysis forms the basis to address specific needs of MDS-patients and provides data for benchmark analyses.

Red blood cells and iron

S133

GENETIC LOSS OF ERYTHROID TFR2 STRONGLY AFFECTS THE THALASSEMIC PHENOTYPE IN MICE

A Nai[1,2,*], MR Lidonnici[2,3], I Artuso[1,2], G Mandelli[3], L Silvestri[1,2], G Ferrari[2,3], C Camaschella[1,2]
[1]Division of Genetics and Cell Biology, San Raffaele Scientific Institute, [2]Vita-Salute San Raffaele University, [3]SR-TIGET – San Raffaele Telethon Institute for Gene Therapy, Division of Regenerative Medicine, Gene Therapy and Stem Cells, San Raffaele Scientific Institute, Milan, Italy

Background: Transferrin receptor 2 (TFR2) is a multifaceted protein that in the liver activates hepcidin, the master regulator of iron homeostasis, while in erythroid cells is a component of the erythropoietin (EPO) receptor complex. We have shown that the lack of Tfr2 in the bone marrow (BM) increases the EPO sensitivity of erythroid cells and mimics iron-deficiency (Nai *et al.*, Blood 2015). β-thalassemias are recessive severe disorders of beta-globin gene, characterized by microcytic anemia, ineffective erythropoiesis, splenomegaly and secondary iron overload. Several studies demonstrated that iron restriction partially corrects the β-thalassemia phenotype in the *Hbb$^{th3/+}$* model of thalassemia intermedia.
Aims: In order to verify if the absence of Tfr2, mimicking iron-deficiency, could ameliorate the thalassemic phenotype we generated thalassemic animals with BM selective *Tfr2* inactivation.
Methods: We generated thalassemic mice with (*Hbb$^{th3/+}$*) or without BM *Tfr2* (*Tfr2^{BMKO}*/*Hbb$^{th3/+}$*) by transplanting BM cells from *Hbb$^{th3/+}$* or *Tfr2$^{-/-}$*/*Hbb$^{th3/+}$* mutants into lethally irradiated wild-type mice. Chimerism and hematological parameters were evaluated at 2 months. Mice were sacrificed 4 months after BM transplantation (BMT). At sacrifice blood was collected for hematological analysis, transferrin saturation (TS) and Epo levels; liver, spleen and BM cells were used for gene expression, tissue iron quantification, histology and flow cytometry analysis.
Results: Two months after BMT the engraftment of donor cells was 98-99%. *Tfr2^{BMKO}*/*Hbb$^{th3/+}$* and *Hbb$^{th3/+}$* animals appear viable and indistinguishable from one another. *Tfr2^{BMKO}*/*Hbb$^{th3/+}$* mice have greater red cells count and Hb levels as compared to *Hbb$^{th3/+}$* animals. On the contrary, 4 months after BMT *Tfr2^{BMKO}*/*Hbb$^{th3/+}$* mice are smaller and more anemic than *Hbb$^{th3/+}$*controls, have increased spleen size, TS and hepatic iron, but reduced spleen iron content. The alteration of body iron homeostasis is likely due to their lower hepcidin levels as compared with *Hbb$^{th3/+}$*mice. The ineffective erythropoiesis is exacerbated in the absence of Tfr2 and results in extramedullary spleen and liver erythropoiesis. Anemia is accompanied by increased Epo gene trascription in the kidney and by increased expression of Epo target genes, such as Epor, Bcl-xL and erythroferrone (Erfe) in BM.
Summary/Conclusions: Deleting erythroid Tfr2 in *Hbb$^{th3/+}$* animals has a transient beneficial effect, but is detrimental in long-term. Reasonably the loss of Tfr2 increases the sensitivity of thalassemic erythroid cells to Epo stimulation (as we demonstrated for normal cells), favouring erythroid reconstitution after BMT. However, when erythropoiesis reaches a steady state, increased stimulation becomes deleterious. We propose that this occurs through high and persistent production of erythroferrone, the soluble factor released by the erythroblasts in order to inhibit the hepcidin expression. This would increase iron absorption and release, causing iron overload, further impairing the thalassemic erythropoiesis and generating a "thalassemia major-like phenotype" in *Tfr2^{BMKO} Hbb$^{th3/+}$* mice. Further studies will better elucidate the mechanism of the observed biphasic effect on the phenotype and whether a time-controlled modulation of Tfr2 might improve β-thalassemia.

S134

HIGH SYSTEMIC IRON LEVEL IS A RISK FACTOR FOR CARDIOVASCULAR DISEASE

F Vinchi[1,*], A Simmelbauer[1], S Altamura[1], B Galy[2], MW Hentze[3], MU Muckenthaler[1]
[1]Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, [2]Infection, inflammation and cancer, German Cancer Research Center (DKFZ), [3]Molecular Medicine Partnership Unit (MMPU), European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

Background: Iron accumulates in atherosclerotic lesions but its role in atherogenesis is still debated. In the "iron hypothesis" (1981), Sullivan proposed that iron is detrimental for the cardiovascular system, promoting atherosclerosis progression. So far, epidemiological data and studies in animal models have provided conflicting evidence regarding a role of excess iron in atherogenesis and cardiovascular disease.
Aims: In this study we aimed to investigate the role of iron overload in the development of atherosclerosis.
Methods: To this purpose, a mouse model of type IV Hereditary Hemochromatosis, in which the hepcidin/ferroportin regulatory circuitry is disrupted due

to a point mutation in the iron exporter ferroportin (FPN^{C326S}; Altamura *et al.*, Cell Metabolism 2014), was interbred with ApoE-null mice(ApoE-/-), that show increased susceptibility to atherosclerosis. Plaque formation was analyzed in ApoE-/-FPN$^{wt/C326S}$ mice at 6 and 12 months of age.

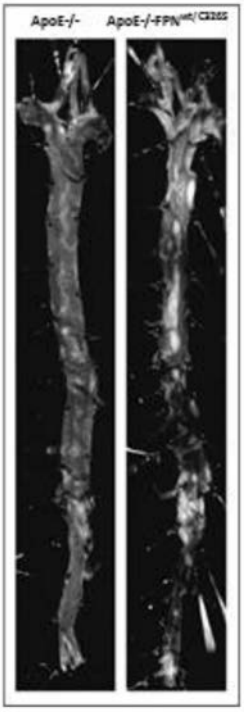

Figure 1.

Results: ApoE-/-FPN$^{wt/C326S}$ mice show high serum iron and cholesterol levels, as expected. Importantly, these mice show strongly increased lesion size and number at both 6 and 12 months of age compared to age-matched Apo-/- mice (6 months: 1.44±0.23 *vs* 5±0.53% aortic lesion area, P=0.0001; 12 months: 10.24±1.21 *vs* 20.44±2.69% aortic lesion area, P=0.0065). The atherosclerotic phenotype positively correlates with higher levels of circulating iron (12 months: 122.2±6.57 *vs* 337±19.22 mg iron/dl serum, P<0.0001) and oxidized LDLs (12 months: 2151±136.8 *vs* 3243±193.9 nmol oxLDL/ml serum, P=0.0002). Iron is deposited in the artery media layer, which correlates with vascular smooth muscle cell senescence, calcifications, vascular oxidative stress (12 months: 2.45±0.2 *vs* 4.33±0.32 nmol MDA/mg aorta protein, P=0.047) and DNA damage. We observe increased vascular permeability (6 months: 0.95±0.2 *vs* 3.11±0.51 mg aorta Evans Blue, P=0.0022), reduced nitric oxide availability and sustained activation and inflammation of the vascular endothelium (P<0.05). Within the atherosclerotic plaques, collagen deposition is reduced (P=0.0023) and lipid content is increased (P=0.0495), indicating enhanced plaque instability and faster disease progression. Plaque macrophages are significantly elevated and correlate with increased iron-induced CCL2 levels (12 months: 155.5±23.27 *vs* 305±38.39 pmol CCL2/ml serum, P=0.01), potentially contributing to increased lesion vulnerability (12 months: plaque vulnerability index P=0.0276). Ecocardiography in ApoE-/-FPN$^{wt/C326S}$ mice reveals an increased left ventricle mass and increased left ventricle area and volume in dyastole, plausibly as an attempt to compensate for increased arterial stiffness. Our mouse model further shows increased fibrinogen and pro-thrombin levels (P<0.05), suggesting a pro-thrombotic role for high systemic iron levels. Prolonged administration of a low-iron diet rescues the severe atherosclerotic phenotype, proving that iron is detrimental for this disease. Experiments are ongoing to test the effect of iron chelation therapy.
Summary/Conclusions: Our data suggest that high circulating iron levels strongly enhance the severity and promote the progression of atherosclerosis, indicating that systemic iron overload is a risk factor for atherosclerosis and predisposes to cardiovascular disease. Our findings have potential implications for those pathological conditions with elevated systemic iron levels, ranging from patients with hemochromatosis to anemic patients dependent on chronic blood transfusions, as well as for individuals subjected to intravenous iron administration (*e.g.* patients undergoing hemodialysis).

S135

THE PYRUVATE KINASE ACTIVATOR AG-348 IMPROVES MURINE B-THALASSEMIC ANEMIA AND CORRECTS INEFFECTIVE ERYTHROPOIESIS
A matte[1], E beneduce[1], A siciliano[1], P kosinski[2], A janin[3], C lebouef[3], A iolascon[4], L de falco[4], L dang[2], C kung[2], L De Franceschi[1,*]

[1]Medicine, University of Verona, verona, Italy, [2]development, agios, Cambridge, United States, [3]pathology, universite, Paris, France, [4]ceinge, University, naples, Italy

Background: β-thalassemias (β-thal) are worldwide distributed red cell disorders, characterized by ineffective erythropoiesis and reduced red blood cell (RBC) lifespan. Increased levels of reactive oxygen species (ROS) have been reported to play a key role in anemia of β thal, targeting both erythropoiesis and circulating RBCs. Pyruvate kinase (PK) is an important enzyme in the glycolytic pathway, responsible for conversion of phosphoenolpyruvate to pyruvate, with concomitant formation of the energy carrier adenosine triphosphate (ATP). As mature erythrocytes lack mitochondria, they rely almost exclusively on glycolysis to generate ATP, as well as the interlinked pentose phosphate pathway shunt to generate the reducing agent NADPH. The possible impact of PK activity on erythropoiesis is supported by evidence of ineffective erythropoiesis in human subjects with PK deficiency as well as mouse models of PK deficiency. The PK activator AG-348 has been evaluated in Phase I trials in healthy human subjects (NCT02149966) and is currently in Phase II studies in PK deficiency patients (NCT02476916). In the Phase I studies, AG-348 was shown to decrease levels of an upstream metabolite 2,3-diphosphoglycerate (2,3-DPG) and increased levels of ATP in whole blood, consistent with *in vivo* activation of PK.
Aims: To evaluate the impact of AG-348 on anemia and ineffective erythropoiesis in a mouse model of β thal intermedia.
Methods: Mouse strains C57B6/2J, as wildtype (WT) controls, and Hbb$^{th3/+}$, as a mouse model of β-thal intermedia, were used. Female mice aged between 2-3 months were treated with either vehicle or AG-348 at 50 mg/kg bid by oral gavage. Hematologic parameters, RBC indices, morphology, and reticulocyte count were evaluated at baseline, 7, 14, 21 days of treatment. Mouse erythropoiesis was studied using the CD44/TER119 gating strategy by FACS. ROS levels and the amount of Annexin-V+ cells were evaluated in erythroblast populations. Liver iron accumulation was evaluated by Pearl's staining and expression of liver hepcidin was measured by RT-PCR.
Results: In Hbb$^{3th/+}$ mice, 21 days of AG-348 treatment was associated with (i) a marked amelioration of anisopoykylocytosis; (ii) significantly increased Hb levels, MCV and MCH; (iii) a significant reduction in circulating erythroblasts (Es) and reticulocyte count; and (iv) reduction of ROS levels in circulating RBCs. In addition, AG-348 significantly decreased the amount of membrane precipitated α-globin chains and increased the amount of soluble Hb compared to the vehicle treated Hbb$^{3th/+}$ group. Consistent with these findings, we observed (i) a reduction of extramedullar erythropoiesis as indicated by both a decrease in spleen weight/mouse weight ratio and total Es (CD44TER119 Fsc high cells); (ii) a significant increase in pro-Es and basophilic Es, associated with reduction in orthochromatic Es; (iii) a reduction in ROS levels of Hbb$^{3th/+}$ Es and the amount of apoptotic orthochromatic Es compared to vehicle treated Hbb$^{3th/+}$ mice, suggesting an amelioration of β thal ineffective erythropoiesis. The amelioration of ineffective erythropoiesis was paralleled by a reduction in liver iron overload and up-regulation of hepcidin mRNA in liver from AG-348 treated Hbb$^{3th/+}$ mice.
Summary/Conclusions: Our data show that the PK activator AG-348 beneficially affects ineffective erythropoiesis in a mouse model of β thal and might represent a novel therapeutic tool in clinical management of anemia in β thalassemic syndromes.

S136

RAP-536 (MURINE ANALOG OF ACE-536/LUSPATERCEPT) INHIBITS SMAD2/3 SIGNALING AND PROMOTES ERYTHROID DIFFERENTIATION BY RESTORING GATA-1 FUNCTION IN A MURINE MODEL OF B-THALASSEMIA
P Martinez[1,*], M Bhasin[2], R Li[1], S Pearsall[1], R Kumar[1], R Suragani[1]
[1]Preclinical, Acceleron Pharma, Cambridge, [2]Genomics and Proteomics Center, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, United States

Background: Previously, we reported elevated Smad2/3 signaling in diseases characterized by ineffective erythropoiesis such as myelodysplastic syndromes (MDS) and β-thalassemia (Suragani *et al.* 2014). Luspatercept (modified ActRIIB receptor-Fc fusion protein), a Smad 2/3 ligand trap, has demonstrated efficacy in correcting ineffective erythropoiesis and the resulting anemia in murine models of MDS and β-thalassemia. RAP-536 (murine version of ACE-536/luspatercept) treatment also alleviated disease pathology in β-thalassemic mice.
Aims: In this study, we investigated the molecular mechanism of action of RAP-536 in a murine model of β-thalassemia.
Methods: Wildtype and β-thalassemic mice were used in this study. β-thalassemic mice (*Hbb$^{th3/+}$*) were administered a single bolus of vehicle (VEH) or RAP-536 (30 mg/kg, i.p) (N=2/group). At 16 hours, splenic basophilic erythroblasts (CD71^{+}Ter119^{+}FSC^{high}) were sorted by flow cytometry. RNA was isolated and subjected to genome wide transcriptome profiling using RNA sequencing analysis. Mouse erythroid leukemic (MEL) cells, primary fetal liver erythroid and β-thalassemic erythroid precursors were treated with GDF11 in the presence or absence of ACE-536 as described below.

Results: Transcriptome analysis of β-thalassemic erythroblasts identified 74 genes that were differentially expressed (absolute fold change >1.5, false discovery rate adjusted P value <0.05) in RAP-536 treated samples *vs* VEH treatment. To identify molecular mechanisms, we performed gene set enrichment analysis (GSEA) (Subramanian *et al.*, 2005) on these samples. The analysis depicted significant upregulation of target genes of multiple transcriptional regulators including GATA-1. Previously, multiple studies have established GATA-1 as a master transcriptional regulator of terminal erythroid differentiation. Further GSEA of GATA-1 activator signatures against RAP-536 treatment data revealed a significant up-regulation of 158 activated genes (Normalized Enrichment Score=2.7, P=0) involved in heme biosynthesis (such as Ppox, Fech, and Abcb10) and terminal erythroid differentiation (such as Fog1, Klf1 and Bcl-xl). ACE-536 is known to bind and inhibit Smad2/3 ligands such as GDF8, GDF11 and activin B but not activin A (Suragani et al 2014). Consistent with this data, treatment of MEL and fetal liver erythroid cells with GDF11 (50ng/mL) induced Smad2/3 phosphorylation and ACE-536 co-treatment inhibited the increase in pSmad2/3. In differentiating erythroid cells, GDF11 treatment displayed reduced nuclear GATA-1 protein levels by both western blotting and immunofluorescence studies. Additionally, reactive oxygen species (ROS) levels indicative of oxidative stress were elevated in MEL and primary fetal liver cells following GDF11 treatment. Consistent with the increase in ROS, we found decreased mitochondrial transmembrane potential (Δψm) indicative of unhealthy cells and increased caspase 3/7 activity in erythroid cells treated with GDF11. Importantly, treatment of erythroid cells with ACE-536 and GDF11 decreased ROS, restored Δψm and GATA-1 levels to control levels. Immunofluorescence studies demonstrated decreased GATA-1 levels in the nucleus of erythroid precursors from b-thalassemic cells compared to wild type mice. Treatment of these b-thalassemic erythroid precursors with ACE-536 prevented the decrease in GATA-1 levels.
Summary/Conclusions: Together, these data done with RAP-536 provide a potential mechanistic role for luspatercept as a novel treatment of β-thalassemia. By inhibiting pSmad2/3 signaling, RAP-536 treatment decreases ROS, prevents caspase 3/7 activation and GATA-1 cleavage. Thus by restoring GATA-1 availability and functional activity, RAP-536 treatment causes upregulation of genes involved in promoting terminal erythroid maturation, and consequently corrects anemia in b-thalassemia. Luspatercept currently completed phase 2 clinical trials and has initiated phase 3 studies in patients with MDS and b-thalassemia.

Thrombosis

S137

ETHNICITY AND THE EPIDEMIOLOGY OF VENOUS THROMBOEMBOLISM: A POPULATION-BASED STUDY

A Lazo-Langner[1,*], K Liu[2], S Shariff[2], A Garg[1], J Ray[3]
[1]Western University, [2]Institute for Clinical Evaluative Sciences, London, [3]University of Toronto, Toronto, Canada

Background: The epidemiology of Venous thromboembolism (VTE) has been largely studied in White populations, with much less known among non-Caucasians. Differences may exist in the biological predisposition to VTE but little is known about the epidemiology of VTE among immigrants or in relation to ethnicity.
Aims: To generate estimates of the incidence of VTE in immigrants to Ontario, Canada, grouped by their geographical region of origin as a proxy for ethnicity, and estimate risk ratios (RR) for different ethnic groups compared to Whites.
Methods: We conducted a population-based retrospective matched cohort study using linked health care and administrative databases in Ontario, Canada. These datasets were linked using unique, encoded identifiers and analyzed at the Institute for Clinical Evaluative Sciences (ICES) according to a pre-specified protocol that was approved by the research ethics board at Sunnybrook Health Sciences Centre (Toronto, Canada). We identified patients who immigrated to Ontario between Jan. 1, 2000 and Dec. 31, 2010. A non-immigrant comparison cohort was matched based on age, sex and place of residence. The main study exposure was an individual's ethnicity based on world geographical region of origin using a previously validated algorithm. Patients were divided in the following ethnic groups: 1) White, 2) Black, 3) Latin American, 4) Arab, 5) East Asian (including Chinese, Japanese, Korean, Filipino and other South East Asian), 6) South Asian, and 7) West Asian. Main study outcome was the occurrence of a first VTE. Secondary outcomes included deep vein thrombosis (DVT) and pulmonary embolism (PE). Patients were followed until the occurrence of an outcome, death, emigration from the province or end of follow up period (Dec. 31st, 2014). We calculated age-and sex specific incidence rates (IR) per 1000 person-years (PY). RR were calculated using Poisson regression models.
Results: We included 1,195,791 people in the immigrant and non-immigrant cohorts respectively, with a total period of observation >17,000,000 PY. Overall, the incidence rate for any VTE was 1.25 per 1000 PY (95% CI 1.23 to 1.27). For DVT the IR was 0.97 per 1000 PY (95% CI 0.96 to 0.99) and for PE it was 0.36 per 1000 PY (95% CI 0.35 to 0.37). The IR for VTE was lower among immigrants (0.87 per 1000 PY; 95% CI 0.85 to 0.89) than non-immigrants (1.59 per 1000 PY; 95% CI 1.56 to 1.61). Compared to white immigrants, the age-specific RR were consistently lower for both men and women of East Asian (RR 0.19-0.33) and South Asian (RR 0.29-0.65) ethnicity across all age groups. For patients of West Asian and Arab ethnicity the age-specific RR were also generally lower except for patients <30 or >80 years old. IR for immigrants of Black and Latin American ethnicity were no different across most age groups. RR for Black women less than 40 years old were higher compared to White immigrants. Among immigrants of Black, Arab and South Asian ethnicity who developed a VTE there was a higher prevalence of a previous delivery or C-section compared to White immigrants.
Summary/Conclusions: Incidence of VTE is lower among immigrants compared to non-immigrants in Ontario. Among immigrants, those of East and South Asian ethnicity have a lower risk of VTE compared to whites. *This study was supported by the Institute for Clinical Evaluative Sciences (ICES), which is funded by an annual grant from the Ontario Ministry of Health and Long-Term Care (MOHLTC). The opinions, results and conclusions reported in this paper are those of the authors and are independent from the funding sources. No endorsement by ICES or the Ontario MOHLTC is intended or should be inferred. AL-L was supported for this study by a grant from the Academic Medical Organization of South Western Ontario Opportunities fund and by the ICES Western Faculty Scholars program.*

DECODING THE RISK OF THROMBOEMBOLIC EVENTS IN LYMPHOMA PATIENTS

D Antic[1,*], N Milic[2], S Nikolovski[1], M Todorovic[1], J Bila[1], P Djurdjevic[3], B Andjelic[1], V Djurasinovic[1], A Sretetnovic[1], V Vukovic[1], J Jelicic[1], B Mihaljevic[1]
[1]Clinic For Hematology, Clinical Center Serbia, [2]Institute for Medical Statistics and Informatics, Belgrade, [3]Clinic For Hematology, Clinical Centre Kragujevac, Kragujevac, Serbia

Background: Considering data about increased incidence of thrombosis in lymphoma patients and the impact of thrombosis on the survival of lymphoma patients, the main question was "Which lymphoma patients are candidates for thromboprophylaxis after establishing the diagnosis of lymphoma and during chemotherapy?" Owing to risk of thrombocytopenia due to disease or chemotherapy, patients with hematologic malignancies are often excluded from thromboprophylaxis and those with nonhematologic malignancies are preferred.

Aims: The aim of this study was to develop the prognostic risk score based on individual clinical and laboratory parameters that would allow physicians to designate patients at risk for thromboembolic event.
Methods: We developed prognostic Thrombosis Lymphoma – *ThroLy* score based on the study population including 1820 lymphoma patients, who received at least one cycle of chemotherapy. The study population was divided based on a split-sample random method into the model developing and validation cohorts. The model was developed using data from a derivation, and further assessed in the validation cohort.
Results: 99 patients (5.4%) developed thromboembolic events. The variables independently associated with risk of thromboembolism were: previous venous and/or arterial events, mediastinum involvement, BMI>30 kg/m^2, reduced mobility, extranodal localization, development of neutropenia and hemoglobin level <100g/L. Based on the risk model score the population was divided into the following risk categories: low (score 0-1), intermediate (score 2-3), and high (score >3). For patients in the derivation cohort classified as *at risk* for TE (score >1), the model produced a negative predictive value (probability of not experiencing TE in patients designated low risk) of 98.5%, and the positive predictive value (probability of TE occurring in patient designated at risk) of 25.1%. The sensitivity (probability of being classified as at risk in patients experiencing TE) was 75.4%, and the specificity (probability of being classified as low risk in patients not experiencing TE) was 87.5%. Interestingly, a high-risk score ≥4 had a positive predictive value (probability of TE occurring in patient designated at high risk) of 65.2%. The risk model was then applied to the validation cohort (n=584) in which 34 patients (5.8%) developed TE. Similarly, in the validation cohort, the negative predictive value was 97.6%; the positive predictive value was 28.9%; the sensitivity was 64.7%; and the specificity was 90.2%.
Summary/Conclusions: ThroLy score is more specific for lymphoma patients than any other available score targeting cancer patients. Moreover, it is dynamic, can be changed during the different phases of therapy, does not require non-routine laboratory analysis and is not limited to hospitalized or outpatient settings.

S139

MAJOR BLEEDING IN PATIENTS ON TREATMENT WITH NOAC OR VKA IN REAL-LIFE: CLINICAL PRESENTATION, MANAGEMENT AND OUTCOME

L Franco[1,*], C Becattini[1], J Beyer-Westendorf[2], L Masotti[3], C Nitti[4], S Vanni[5], G Manina[6], S Cattinelli[7], R Cappelli[8], R Sbrojavacca[9], F Pomero[10], S Marten[2], G Agnelli[1]
[1]University Of Perugia, PERUGIA, Italy, [2]Technische Universität Dresden, Dresden, Germany, [3]Internal Medicine, Santa Maria Nuova Hospital, Firenze, [4]Emergency Medicine, Ospedali Riuniti Umberto I-Lancisi- Salesi, Ancona, [5]Emergency Medicine, Careggi University Hospital, Firenze, [6]Emergency Medicine, Policlinico Maggiore, Milano, [7]Emergency Medicine, Ospedale Cattinara, Trieste, [8]Internal Medicine, University of Siena, Siena, [9]Emergency Medicine, Santa Maria della Misericordia Hospital, Udine, [10]Internal Medicine, Santa Croce Hospita, Cuneo, Italy

Background: Limited data are available on major bleeding (MB) occurring during treatment with vitamin K (VKAs) or non-vitamin K antagonist oral anticoagulants (NOACs) outside clinical trials.
Aims: The aim of this study was to compare clinical presentation, management and outcome of MB in patients on treatment with VKA or NOAC in real-life.
Methods: Patients hospitalized for MB while on treatment with VKAs or NOACs were included in a multicenter study to compare clinical presentation, management and outcome of bleeding. The primary study outcome was in-hospital death.
Results: As for September 2015, 806 patients with MB were included in the study, 76% on VKAs and 24% on NOACs. MB was an intracranial hemorrhage in 51% and 21% patients on VKAs or NOACs, respectively (Odds Ratio [OR] 3.79; 95% confidence interval [CI] 2.59-5.54) a gastrointestinal bleeding in 46% and 25% patients on NOACs and VKAs, respectively (OR 2.62; 95% CI 1.87-3.68). In-hospital death occurred in 134 patients (17%), 19% of VKA and 10% of NOAC patients (OR 2.08; 95% CI 1.24-3.49, p=0.005). The rate of in-hospital death was similar in NOAC and VKA patients with intracranial hemorrhage (27% and 26% respectively; OR 1.02, 95% CI 0.49-2.12) and gastrointestinal bleeding (7% and 11%; OR 0.62, 95% CI 0.23-1.64) and lower in NOAC than VKA patients with other MBs (3% and 11%; OR 0.39, 95% CI 0.11-0.39).
Summary/Conclusions: Among patients hospitalized for MB while on treatment with anticoagulants, patients on NOACs are less frequently admitted for intracranial hemorrhage and more frequently for gastrointestinal bleeding as compared with patients treated with VKA. Mortality is lower in patients with MBs on NOACs than VKAs although this finding varies across the different types of MBs.

S140

PODOPLANIN EXPRESSION AND INTRAVASCULAR PLATELET AGGREGATES: THE MISSING LINK BETWEEN CANCER AND THROMBOSIS IN PRIMARY MALIGNANT BRAIN TUMORS

J Riedl[1,*], M Preusser[2], F Posch[1], PMS Nazari[1], S Panzer[3], C Marosi[2], P Birner[4], J Thaler[1], C Brostjan[5], D Lötsch[6], W Berger[6], J Hainfellner[7], I Pabinger[1], C Ay[1]
[1]Medicine I, Clinical Division of Hematology and Hemostaseology, [2]Clinical Division of Oncology, Department of Medicine I, [3]Department of Blood Group Serology and Transfusion Medicine, [4]Clinical Institute of Pathology, [5]Department of Surgery, [6]Institute of Cancer Research, Department of Medicine I, [7]Institute of Neurology, Medical University Of Vienna, Vienna, Austria

Background: Venous thromboembolism (VTE) is a common clinical problem in patients with primary malignant brain tumors, and underlying mechanisms are unclear.
Aims: In a prospective observational study, we explored the association of podoplanin, a sialomucin-like glycoprotein that has the ability to induce blood platelet activation and aggregation, with VTE in primary malignant brain tumors. Furthermore, we investigated the ability of primary human glioblastoma cells, isolated from a patient with glioblastoma and thrombotic complications, to activate human platelets *in-vitro*.
Methods: Immunohistochemical (IHC) staining against podoplanin and platelet surface protein CD61 was performed in brain tumor specimens of 213 adult patients (mostly high-grade gliomas [89%]) included in the Vienna Cancer and Thrombosis Study (CATS), a prospective observational cohort study of patients with newly diagnosed cancer or progressive disease. Primary endpoint was symptomatic VTE. *In-vitro*, co-incubation experiments were performed using primary glioblastoma cells isolated from a patient included in CATS who had developed pulmonary embolism (PE) during follow up and whose tumor stained positive for podoplanin in IHC. Activation and aggregation of human platelets upon co-incubation with different concentrations of cancer cells was investigated by light transmission aggregometry and macro- and microscopical visualization.
Results: During 2-year-follow-up, 29 (13.6%) patients developed VTE. In total, 151 (70.9%) tumor specimens stained positive for podoplanin (33 high expression, 47 medium expression, 71 low expression). Patients with podoplanin positive tumors had a lower blood platelet count (Median [25th-75th percentile], G/l: 227 [186-285] *vs* 286 [241-355]; p<0.001) and higher D-dimer levels (mg/ml: 0.85 [0.46-1.92] *vs* 0.42 [0.23-0.79]; p<0.001). Increasing podoplanin-staining intensity was associated with increasing levels of CD61-positive intravascular platelet aggregates in tumor specimens (p<0.001). In Cox regression analysis, high podoplanin expression was associated with increased risk of VTE (hazard ratio [HR] for high *vs* no podoplanin expression: 5.75, 95% confidence interval [CI]: 1.71-19.27; p=0.005). This association was independent of age, sex and tumor grade (HR 5.71, 95%CI: 1.52-21.26; p=0.010). Figure 1 shows cumulative incidence curves of VTE according to podoplanin expression levels. Podoplanin-positive glioblastoma cells induced platelet aggregation, measured by light transmission aggregometry, in a dose-dependent manner, which was not observed in a podoplanin-negative control glioblastoma cell line. Podoplanin-positive glioblastoma cells also induced marked macro- and microscopically visible blood coagulation upon co-incubation with whole blood from a healthy donor, while this was not observed for podoplanin-negative control cells.

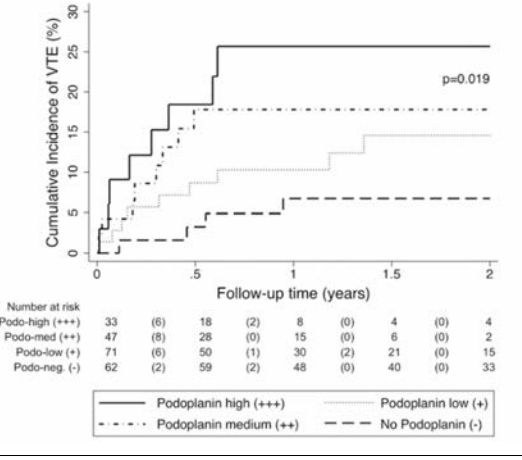

Figure 1. Cumulative incidence of venous thromboembolism (VTE) accounting for competing risk (death of any cause other than fatal VTE) according to expression levels of podoplanin. The probability of VTE significantly increased with increasing levels of podoplanin staining intensity (log-rank p=0.019).

Summary/Conclusions: High podoplanin expression in primary malignant brain tumors, which correlated with intravascular platelet aggregates, lower blood platelet counts and higher D-dimer levels, was associated with increased risk of VTE. *In-vitro*, podoplanin-positive cancer cells isolated from a glioblastoma patient who developed PE induced marked platelet activation and aggregation. Our study might provide a novel mechanistic insight into the pathogenesis of VTE in patients with primary malignant brain tumors.

HUMAN HEMATOPOIETIC STEM CELL DIFFERENTIATION FOLLOWS A CONTINUOUS WADDINGTON-LIKE LANDSCAPE

L Velten[1], S Haas[2], S Raffel[2], S Blaszkiewicz[2], C Lutz[3], E Buss[3], D Nowak[4], T Boch[4], WK Hofmann[4], A Ho[3], W Huber[1], A Trumpp[2], M Essers[2,*], L Steinmetz[1]
[1]EMBL, [2]HI-STEM gGmbH /DKFZ, [3]Department of Internal Medicine V, University of Heidelberg, Heidelberg, [4]Department of Hematology and Oncology, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany

Background: Blood formation is believed to occur via the step-wise progression of haematopoietic stem cells (HSCs) through a tree-like hierarchy of discrete progenitor cell types. Although several recent studies have challenged different aspects of this dogma, a comprehensive model of haematopoiesis and entry of HSCs into lineage commitment is currently lacking. Here, we mapped human bone marrow haematopoiesis by quantitatively integrating flow cytometric, transcriptomic and functional lineage fate data at the single-cell level.
Aims: Reconstruction of how individual HSCs enter lineage commitment by quantitatively integrating transcriptomic and functional single cell data that permits the reconstruction of developmental trajectories during HSC differentiation.
Methods: Healthy human BM HSPCs (Lin$^-$CD34$^+$) were individually sorted and surface marker fluorescence intensities of a panel of FACS surface markers commonly used to characterize these HSPCs were recorded to retrospectively reconstruct immunophenotypes. Index-sorted HSPCs were subjected to RNAseq ("index-omics", 379 cells) to determine their transcriptomes or individually cultured ex *vivo* ("index-culture", 1021 cells) to quantify lineage potential. Subsequently, the functional and transcriptomic data sets were integrated using commonly indexed surface marker expression to identify molecular and cellular events associated with the differentiation of human HSCs at the single cell level.
Results: We found that individual HSCs neither enter lineage commitment at binary branching points nor pass through discrete intermediate progenitor cell stages. In contrast, HSC lineage commitment occurs in a gradual manner best described by a continuous Waddington landscape with initially flat but progressively deepening valleys. Our data determine a detailed model of developmental trajectories within this landscape, as well as their underlying gene expression modules and biological processes.
Summary/Conclusions: Integration of transcriptomic and functional cell fate data at the single-cell level reveals that human hematopoiesis is not organized in a hierarchical "tree" of cell types, but follows a continuous differentiation flow within a Waddington-like landscape with initially flat and gradually deepening valleys.

S142

SINGLE-CELL PROFILING OF HUMAN MEGAKARYOCYTE-ERYTHROID PROGENITORS IDENTIFIES DISTINCT MEGAKARYOCYTE AND ERYTHROID DIFFERENTIATION PATHWAYS

B Psaila[1,2,3,*], N Barkas[1], D Iskander[2], A Roy[4], S Anderson[3], N Ashley[1], V Caputo[2], J Lichtenberg[3], S Loaiza[2], D Bodine[3], A Karadimitris[2], A Mead[1], R Irene[1,2,4]
[1]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford University, Oxford, [2]Department of Haematology, Imperial College, London, London, United Kingdom, [3]NHGRI, National Institutes of Health, Bethesda, United States, [4]Department of Paediatrics, Weatherall Institute of Molecular Medicine, Oxford University, Oxford, United Kingdom

Background: The conventional haematopoietic hierarchy proposes that megakaryocytes (MK) and erythroid cells (E) derive from a shared progenitor, the MEP. However, the MEP was defined using "bulk" assays and recent studies have suggested that MEP and other myeloid progenitor populations may be heterogeneous. Advances in single-cell techniques now provide the opportunity to dissect cellular heterogeneity within populations and to uncover rare cell types.
Aims: To integrate multiple different single-cell molecular and cell biology approaches to uncover heterogeneity in human MEP and to establish a new FACS strategy to prospectively purify and functionally validate the novel subpopulations.
Methods: Surface immunophenotype (10 markers) and gene expression profiles (GEP) of individual human MEP were correlated using index-FACS and parallel, targeted multiplex PCR using a specifically designed panel of 87 genes. Differentiation potential was tested in novel single-cell differentiation assays (Figure 1).
Results: A total of 681 single Lin-CD34+CD38+CD123-CD45RA-MEPs were analysed by index sorting and GEP. Principal component analysis of GEP data identified three distinct MEP subpopulations. Correlation with cell surface immunophenotype revealed how these novel populations could be prospectively purified using the additional cell surface markers CD44, CD71 and CD41. MEP Population 1 (CD44hi71-41-; ~43.6% of MEP) showed increased expression of CD34, CSF3R and FLT3 and lower expression of GATA1 in single-cell and population-based analyses. Population 2 (CD44mod CD71+CD41-; 37.4%) showed increased E-associated gene expression (*e.g.* KLF1, TMOD1, TAL1, LEF1). Population 3 (CD44mod CD71+CD41+; 5.1%) showed distinct expression of MK-associated genes (*e.g.* FLI1, VWF, NH1B, MPL). Single-cell *in vitro* differential assays demonstrated that the transcriptional profiles corresponded to functional differences in lineage potential: Population 1 (designated Pre-MEPs) contained almost all of the residual myeloid potential within the MEP compartment and showed frequent MK-E bipotent cells. In contrast, populations 2 (E-MEP) and 3 (MK-MEP) showed a marked lineage bias toward E and MK lineage commitment respectively. Pseudo-temporal ordering of the cells along their differentiation trajectory (Monocle analysis) was also compatible with a more primitive phenotype for Pre-MEP, and suggested that CD42 expression correlated with loss of E-associated gene expression, a finding confirmed in functional assays with high MK but absence of E potential in CD71+CD41+CD42+ MEPs, while CD71+41+42- MK-MEP retained residual low level capacity to generate E progeny.

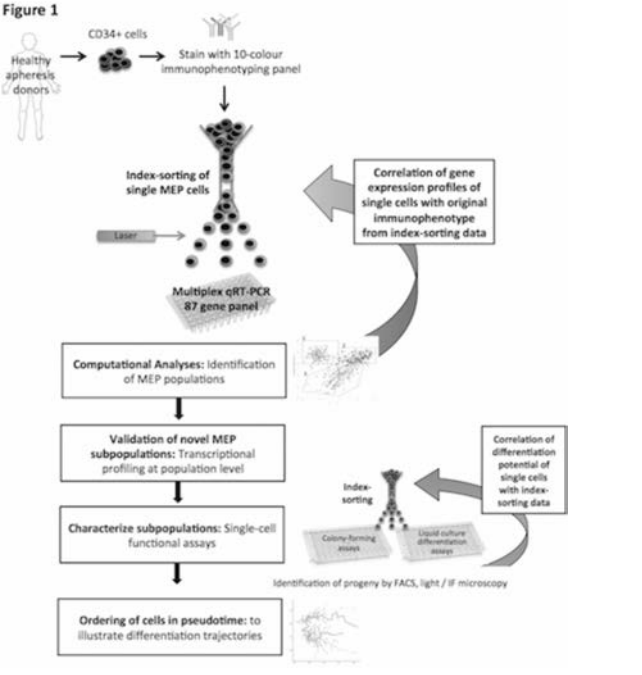

Figure 1.

Summary/Conclusions: This report illustrates the power of combining three single-cell techniques to interrogate cellular heterogeneity within populations, an approach that is applicable to many other systems. We show that classically defined MEP in fact contain three distinct subpopulations: (1)"Pre-MEP", enriched for E/MK progenitors but with residual myeloid differentiation capacity, (2)"E-MEP", strongly biased towards E differentiation, and (3)"MK-MEP", a rare population of bipotent cells that primarily generate MK progeny. Importantly, only a minority of classically defined MEP give rise to mixed E/MK colonies; the majority of the cells are transcriptionally-primed to generate cells of a single lineage. We believe that prospective identification of specific intermediate progenitor populations will allow for in-depth study of disorders of erythro-megakaryopoiesis, including myeloproliferative neoplasms and erythromegakaryocytic leukemias.

INTERFERON ALPHA MEDIATED REMODELING OF THE BONE MARROW STEM CELL VASCULAR NICHE

ÁM Prendergast[1,2,*], A Kuck[1,2], M van Essen[2], S Haas[1,2], S Blaszkiewicz[1,2], M Essers[1,2]
[1]Heidelberg Institute for Stem Cell Technologies and Experimental Medicine (HI-STEM), [2]Division of Stem Cells and Cancer, German Cancer Research Institute (DKFZ), Heidelberg, Germany

Background: Bone marrow endothelial cells (ECs) are a major part of the bone marrow (BM) vascular niche, regulating hematopoietic stem cell (HSC) function and fate. Furthermore, ECs significantly influence the response of an organism to infection, the primary response to which involves synthesis of immune-modulatory cytokines, such as interferon alpha (IFNα). In contrast to the anti-proliferative effect of IFNα on HSCs *in vitro,* we, and others, have shown that IFNα induces cell cycle entry of HSCs *in vivo*. Here we have investigated the result of acute IFNα treatment on the BM vascular niche *in vivo*.
Aims: To investigate the stimulatory effects of acute IFNα treatment on the BM stem cell vascular niche and its role in the chemotherapeutic response.

Methods: To characterize the response of the BM vascular niche to IFNα, wild-type mice were treated with recombinant IFNα or pI:C and were sacrificed 4h or 24h later. BM ECs were subsequently assessed for key inflammatory and EC-stimulatory markers by FACS. IFNα-mediated increased BM vascularity was quantified by *in vivo* labelling using Alexa 633. BM vessel integrity was assessed using the Evans blue assay. VEGF signalling was antagonized using the Anti-VEGF treatment, Avastin. Mice were co-treated with 5-FU and pI:C to evaluate the effect of IFNα-signalling of chemotherapeutic treatment.
Results: IFNα treatment induced a rapid stimulation of BM ECs *in vivo,* resulting in increased bone marrow (BM) vascularity and vascular leakage. IFNα-mediated activation of ECs involved the expression of key inflammatory and EC-stimulatory markers. Abrogation of BM EC activation *in vivo,* using the Anti-VEGF treatment, Avastin, linked VEGF signalling, mediated by BM cell types including HSCs, to IFNα-mediated activation of ECs. Finally, following a period of recovery, IFNα-signalling led to a rapid recovery of 5-FU-mediated cell activation and BM homeostasis.
Summary/Conclusions: Our data shows that IFNα stimulation *in vivo* leads to remodelling of the BM stem cell vascular niche, mediated by VEGF. These data increase our current understanding of the effect of IFNα and anti-VEGF treatment on HSCs and the stem cell niche *in vivo*. IFNα-mediated recovery from 5-FU treatment has obvious implications for therapy, and thus this effect may influence the clinical application of IFNα.

S144

CELL-EXTRINSIC HAEMATOPOIETIC IMPACT OF EZH2 INACTIVATION IN FOETAL LIVER ENDOTHELIAL CELLS

WH Neo[1,2,*], C Booth[1,2], E Azzoni[2], M de Bruijn[2], SE Jacobsen[1,2], A Mead[1,2]
[1]Haemopoietic Stem Cell Laboratory, Weatherall Institute for Molecular Medicine, [2]MRC Molecular Haematology Unit, University of Oxford, Oxford, United Kingdom

Background: The cell-intrinsic role of many different epigenetic factors in the regulation of normal haematopoiesis and development of blood cancers is well established. However, the possible role and function of epigenetic regulators in components of the haematopoietic niche remains largely unexplored. Ezh2, is a histone methyltransferase and key component of the polycomb repressive complex 2 (PRC2). Loss of function of PRC2 causes a cell-intrinsic defect in adult haematopoietic stem cells (HSCs) and block in T- and B-lymphopoiesis. Further, both increased and reduced PRC2 activity has been implicated in a range of blood cancers. However, the haematopoietic impact of Ezh2 inactivation in components of the niche has not been explored.
Aims: Recent evidence supports that vascular endothelial cells (VECs) are key components of the haematopoietic niche during foetal development and we therefore aimed to study the haematopoietic impact of Ezh2 depletion in foetal liver (FL) VECs.
Methods: Ezh2 was depleted in haematopoietic cells with or without deletion in VECs using Tie2-Cre (Tie2-KO) or Vav-iCre (Vav-KO) respectively, and the impact on foetal haematopoiesis was explored through phenotypic and functional assays.
Results: At E12.5, both Vav-KO and Tie2-KO embryos showed close to 100% recombination efficiency in haematopoietic cells, whereas only Tie2-KO showed high levels of recombination in VECs ($CD45^-Ter119^-CD31^+$). There was a striking difference in survival, with embryonic lethality at E13.5 in Tie2-KO embryos in contrast to Vav-KO which survived beyond E18.5. Numbers of phenotypic HSCs ($LSKCD48^-CD150^+$) were normal in Tie2-KO at E12.5 and expanded through to E18.5 in Vav-KO embryos, confirmed in functional (*in vivo* reconstitution) assays, excluding an impact of Ezh2 loss on FL HSCs. In contrast, there was a Tie2-KO specific loss of E12.5 FL cellularity (fc=0.44; p=0.0006) and reduction in progenitor cells ($LSKCD48^+CD150^-$; fc=0.33; p<0.0001) that was not present in Vav-KO embryos. Furthermore, Tie2-KO but not Vav-KO E12.5 FLs were severely anaemic, with a marked loss of $CD71^+Ter119^+$ erythroid precursors (fc=0.07; p=0.0010). We reasoned that depletion of Ezh2 in VECs was causing a cell-extrinsic suppression of FL progenitors, particularly those of erythropoietic lineage. This Tie2-KO phenotype was highly reminiscent of that seen in Steel mice, and although KitL mRNA expression was increased (fc=3.62; p=0.0291), immunofluorescence staining demonstrated an almost complete loss of the membrane bound form of KitL (mKL) in Tie2-KO FL. The loss of mKL was not VEC-specific, but also affected Tie2-KO hepatoblasts ($CD45^-Ter119^-CD31^-Alb^+$), which express KitL but are not targeted by Tie2-Cre. As mKL is a known target of Mmp9, and Mmp9 is a known target of Ezh2, we next examined Mmp9 mRNA expression and showed this was upregulated in Tie2-KO FLs (fc=12.41; p=0.0236). In order to confirm the mechanistic role of Mmp9, we demonstrated that Ezh2-depleted VECs from Tie2-KO FL had reduced capability to support erythropoietic colony formation *in vitro* in co-culture assays (fc=0.22; p=0.0036), which could be fully rescued with Mmp9 inhibitor treatment.
Summary/Conclusions: These data demonstrate a marked cell-extrinsic haematopoietic impact of PRC2 inactivation in VECs through loss of mKL expression caused by a marked upregulation of Mmp9 expression. This provides evidence that modulation of epigenetic regulators can have a major cell-extrinsic impact on haematopoiesis, of relevance for the development of epigenetic therapies, including Ezh2 inhibitors.

Medizinische Klinik, Medizinische Fakultät Mannheim, Universität Heidelberg, Mannheim, Germany

Background: The advent of tyrosine kinase inhibitors (TKI) has dramatically improved survival in chronic myeloid leukemia (CML) with a high percentage of patients reaching deep molecular responses (MR; Hehlmann 2014). In several studies, it could be shown that in a substantial part of patients with deep MR, TKI treatment can be safely and successfully stopped (Mahon 2010, Ross 2013). However, exact preconditions for stopping treatment in CML have not yet been defined.
Aims: The EURO-SKI study (European stop TKI study) was set up to define prognostic markers to increase the rate of patients in durable deep MR after stopping TKI. Already in an interim analysis the null hypothesis (relapse-free survival ≤40% at 6 months (m) could be discarded (Mahon ASH 2014, Saussele EHA2014).
Methods: Adult CML patients in chronic phase (CP) on TKI treatment for at least 3 years and in MR4 for at least one year, confirmed by 3 consecutive PCR results during the last 12 m prior to inclusion were eligible. Final MR4 confirmation was performed in a EUTOS standardized laboratory. Patients with a prior TKI failure were excluded. Primary endpoint is the assessment of molecular relapse-free survival after stopping TKI defined as survival without loss of major molecular remission (MMR) at one time point. We here, per protocol, report the results of all patients, with a minimum follow-up of 6 m. A further follow-up after 3 years is planned. Analyses were done on an intention-to-treat basis.
Results: From June 2012 to December 2014, 868 patients in CP CML from 11 countries were included. 96 were excluded (withdrawal of consent n=1, inclusion criteria violation n=23, atypical or unknown transcript n=8, pending cases n=64). Of the eligible 772 patients, 46.6% were female. Median age at diagnosis was 51.9 years (range 11.2 to 85.5); median age at stop was 60.3 years (range 19.5 to 89.9). 10% and 18% were high-risk according to EUTOS and Sokal Score, respectively. One patient decided not to stop therapy after inclusion. 390 patients were mostly pretreated with hydroxyurea prior to TKI therapy, and 87 patients received interferon before TKI. First-line TKI was imatinib in 94%, dasatinib in 2% and nilotinib in 4%. 115 patients switched to second-line TKI due to intolerance, 58 to dasatinib, 7 to imatinib, and 49 to nilotinib (one missing information). Time from diagnosis of CML to first day of stopping TKI varied from 36.7m to 270.7m, median time was 92.7m. Median duration of TKI treatment was 91m (range 36.3 to 170.3) and median duration of MR4 prior to TKI stop was 56.3m (range 12.6. to 159.8). MR4 was reached after a median time of 21.0m (only first-line patients, range 3.0 to 140.0). 717 patients had assessable molecular data for the estimation of molecular relapse-free survival. The median molecular follow-up is 10m. Of these patients, 331 lost MMR, 4 died in remission and 381 are still in MMR at last follow-up (range 1-36 months). This resulted in a molecular relapse-free survival of 62% (95% confidence interval (CI): 58%-65%) at 6m, 56% (CI: 52%-59%) at 12m and 51% (CI: 47%-55%) at 24m (see Fig.1). First univariate analyses in 401 patients with complete records on all prognostic variables confirmed statistically significant influence of duration of TKI treatment and of duration of MR4 on molecular relapse-free

survival up to 6m. Neither sex nor any of the variables part of any of the 2 scores (Sokal, EUTOS) showed a significant association with MMR status at 6m. Data will be completed and multivariate modelling will be presented at the meeting.

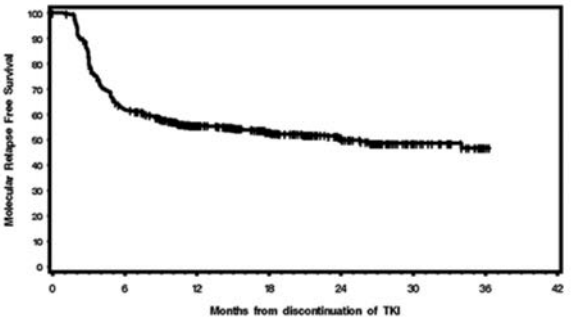

Figure 1.

Summary/Conclusions: In the setting of the EURO-SKI study, high molecular relapse-free remission rates are achievable. First univariate analysis demonstrated the importance of the duration of TKI treatment as well as of MR4 prior to stop. The EURO-SKI trial will further elucidate prognostic factors that improve the rate of patients in durable MMR after withdrawal of TKI.

S146

PERSISTENCE OF DRIVER MUTATIONS DURING COMPLETE REMISSION ASSOCIATES WITH SHORTER SURVIVAL AND CONTRIBUTES TO THE INFERIOR OUTCOMES OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

M Rothenberg-Thurley[1,*], S Amler[2], D Goerlich[2], MC Sauerland[2], S Schneider[1], NP Konstandin[1], S Schaaf[3,4], AM Nazeer Batcha[3,4], K Bräundl[1,3], B Ksienzyk[1], E Zellmeier[1], U Mansmann[3,4], M Fiegl[1], M Subklewe[1], SK Bohlander[5], A Faldum[2], W Hiddemann[1,3], K Spiekermann[1,3], J Braess[6], KH Metzeler[1,3]
[1]Laboratory for Leukemia Diagnostics, Department of Internal Medicine III, Ludwig-Maximilians-Universität, Munich, [2]Institute of Biostatistics and Clinical Research, University of Münster, Münster, [3]German Cancer Consortium (DKTK), German Cancer Research Center (DKFZ), Heidelberg, [4]Department of Medical Informatics, Biometry and Epidemiology, Ludwig-Maximilians-Universität, Munich, Germany, [5]Department of Molecular Medicine and Pathology, University of Auckland, Auckland, New Zealand, [6]Department of Oncology and Hematology, Hospital Barmherzige Brüder, Regensburg, Germany

Background: High-throughput sequencing techniques have shown that AML patients (pts) in complete morphological remission may harbor persistent preleukemic clones, which might be a source of leukemic relapse. Somatic mutations in epigenetic modifiers including *DNMT3A*, *TET2* and *ASXL1* occur in ageing-associated clonal hematopoiesis, and mutations in these genes are frequently present in preleukemic clones of AML pts. Previous studies demonstrated adverse outcomes of pts with persistent leukemia-associated mutations in remission (Klco *et al.*, JAMA 2015; PMID: 26305651).
Aims: We studied persistence of driver mutations in remission and clinical outcomes in a cohort of uniformly treated AML patients.
Methods: We studied 107 adult AML pts (median age, 53 years [y]; range 20-80y) who received intensive induction chemotherapy within the German multicenter AMLCG-2008 trial, and reached either complete remission (CR) (80/107, 75%) or CR with incomplete blood count recovery (CR_i) (27/107, 25%). Most patients (90%) had *de novo* AML, 5% had secondary AML and 5% had therapy-related AML. We analyzed bone marrow (BM) or peripheral blood (pB) specimens obtained at diagnosis (BM, n=96; pB, n=11) and during first remission (BM, n=101; pB, n=6). Ninety-two percent of remission samples were collected within 180 days after the start of induction therapy. We studied 68 genes recurrently mutated in myeloid neoplasms by multiplexed amplicon sequencing (Agilent Technologies), with a mean target coverage of 540x. Sequence alterations with a variant allele frequency (VAF) of ≥2% were classified as known/putative driver mutations, variants of unknown significance, or known germline polymorphisms based on published data including dbSNP, the Catalogue Of Somatic Mutations In Cancer (COSMIC) and The Cancer Genome Atlas (TCGA).
Results: At diagnosis, 426 driver mutations were detected in 42 genes (median, 4 mutations per patient; range, 0-10). In the paired remission samples, 66 mutations in 15 genes were still present (VAF, ≥2%) in 40/107 pts (37%), while 67 pts (63%) had no persistent mutation. Persistence of mutations during morphological remission was most commonly observed for *DNMT3A* (23/37 pts with mutations at diagnosis; 62%), *TET2* (9/13; 69%), *SRSF2* (5/8; 63%) and *ASXL1* (5/12; 42%). Mutations in other genes including *NPM1*, *FLT3*, *WT1*, and *NRAS* were no longer found in the remission samples. Sixty-nine percent of mutations detected in remission had VAFs >10%. Analyses of minimal residual disease (MRD) by flow cytometry or quantitative PCR for *NPM1* mutations or *MLL*-PTD showed similar MRD levels in remission specimens with and without persisting mutations. These findings suggest that mutations detected during remission are present in a pre-leukemic clone rather than in residual leukemic cells. Pts with ≥1 persisting mutation in remission were older (median, 63 years [y]) than pts without any persisting mutation (median, 48y; p<.001). Patients with non-*DNMT3A* persisting mutations tended to be older than those with persisting *DNMT3A* mutations (median, 66.5y *vs* 60y). Persistence of at ≥1 driver mutation in remission, in contrast to complete mutation clearance, associated with shorter relapse-free survival (RFS; median, 14.3 *vs* 58.0 months; p=.009) and shorter overall survival (OS; median, 39.6 *vs* >72 months; p=.005) (Figure A). Similar outcomes were observed for pts with persisting *DNMT3A* mutations and those with other persisting mutations (Figure B). In multivariate analyses adjusting for age, ELN genetic risk groups, and remission status (CR *vs* CR_i), detection of any persisting mutation remained associated with inferior RFS (hazard ratio, 2.2; p=.02) and OS (hazard ratio, 3.0; p=.008).

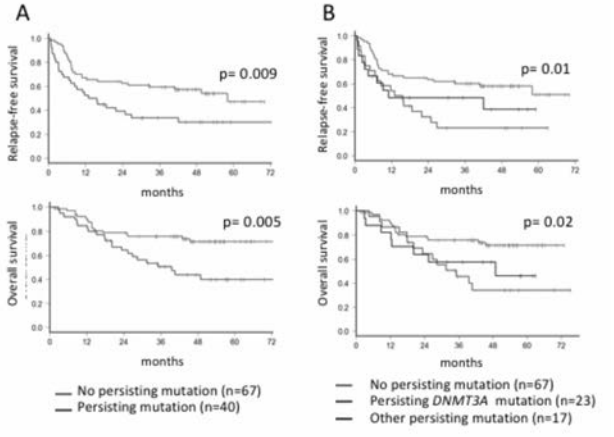

Figure 1.

Summary/Conclusions: Detection of persisting leukemia-associated driver mutations during first CR or CR_i is common in older AML pts and likely indicates persistence of a preleukemic clone. Mutation persistence associates with shorter RFS and OS and might contribute to the inferior outcomes of elderly AML pts.

DISSECTING THE CONTRIBUTION OF UNREGULATED MACROPHAGE IRON RECYCLING AND DIETARY IRON UPTAKE IN GENERATING SYSTEMIC IRON OVERLOAD IN HEMOCHROMATOSIS

J Glockenmeier[1,2], B Galy[3], M Hentze[1,4], M Muckenthaler[1,2], S Altamura[1,2,*]
[1]MMPU-Molecular Medicine Partnership Unit, [2]Pediatric Hematology, Oncology and Immunology, University of Heidelberg, [3]DKFZ-Deutsches Krebsforschungs Zentrum, [4]EMBL-European Molecular Biology Laboratory, Heidelberg, Germany

Background: Systemic iron levels are balanced by the hepatic iron hormone hepcidin and its "receptor" ferroportin (Fpn) to prevent the pathological consequences of iron overload or iron deficiency. Hepcidin binding to the iron exporter FPN reduces dietary iron export from duodenal enterocytes and iron recycling from aging erythrocytes in reticuloendothelial macrophages. Mutations as the Fpn(C326S), that disrupt the hepcidin/FPN regulatory loop, cause an uncontrolled iron export from spleen and duodenum resulting in systemic iron overload (Altamura et al, Cell Met. 2014).
Aims: The aim of this study is to quantify the individual contributions of macrophage iron recycling and dietary iron uptake to systemic iron levels. This knowledge is an important prerequisite to develop specific pharmacological strategies to limit iron export in iron-related disorders.
Methods: By applying cre/lox technology, we generated mouse lines expressing the Fpn(C326S) mutation only in duodenal enterocytes (Villin−Cre/FpnC326S) or in macrophages (Lyz−Cre/FpnC326S) to dissect the single contribution of these two iron exporting cell types in generating iron overload. 10−week old C57BL6/J congenic male mice have been analyzed in this study.
Results: Mice carrying the Fpn(C326S) mutation exclusively in the duodenum show identical hematological alterations as found both in hemochromatotic patients and in constitutive Fpn(C326S) mice: increased hemoglobin (Hb), hematocrit (HCT) and mean corpuscular volume (MCV). Serum iron content and transferrin saturation are strongly increased further consistent with the hemochromatotic phenotype. Hepatic iron measurement revealed severe iron deposition that correlates with increased hepcidin expression. Elevated hepcidin levels cause iron retention in reticuloendothelial macrophages of the spleen generating splenic iron overload. Interestingly, Lyz−Cre/FpnC326S mice that show hepcidin independent macrophage iron export failed to show alterations in hematological parameters and serum iron levels. However the spleen is iron depleted, in line with a constitutively expressed iron exporter. By contrast hepatic iron content and hepcidin expression are similar compared to control mice.

Summary/Conclusions: Our results show for the first time that increased duodenal iron export is the major if not the only contributor in the generation of systemic iron overload in hemochromatosis. This finding opens new insights in developing pharmacological strategies aimed to specifically limit dietary iron import for the treatment of primary and secondary iron overload diseases.

Background: ETV6-RT is an autosomal dominant IT recently identified in a few families and suspected to predispose to hematological malignancies.
Aims: To gain information on the clinical and laboratory picture of this new IT, in particular on predisposition to hematological malignancies.
Methods: 130 unrelated and consecutive patients with ITs were enrolled to the study: all of them had no definite diagnosis because they did not fit the criteria for any known IT. *ETV6* mutations were investigated by whole exome sequencing (84 probands) or Sanger sequencing (46 probands): whenever *ETV6* mutations were identified, all available relatives of probands were also investigated. 5 patients from 2 known *ETV6*-RT families already partially described (Noetzli L et al, Nat Genet 2015, 47:535) were also included. Each patient underwent to phenotypic characterization through the following investigations: complete blood count and platelet sizing, flow cytometry of platelet membrane glycoproteins, "*in vitro*" platelet aggregation, platelet activation, platelet adhesion and spreading, differentiation of human megakaryocytes (Mks) and morphological analysis, Mk flow cytometry, evaluation of proplatelet formation by *in vitro* differentiated Mks.
Results: Overall, 20 subjects from 7 families bearing 5 different *ETV6* mutations were identified. The bleeding tendency and the degree of thrombocytopenia were mild, but we found that 4 of 20 patients (20%) had childhood ALL, thus confirming that early leukemic transformation is a major risk of this IT. Moreover, one patient developed JAK2+ polycythemia vera at age 37, suggesting that this disease should be added to the list of malignancies to which the *ETV6*-RT predisposes. Clinical and laboratory findings (platelet aggregation, surface glycoproteins, activation and adhesion) did not identify any peculiar defect that can be used to suspect this disorder. *In vitro* studies revealed that patient Mks have defective maturation and proplatelet formation, while platelets have reduced ability to spread on fibrinogen. At variance with most ITs, platelet size was not enlarged: this finding is shared with ITs due to monoallelic mutations in *RUNX1* and *ANKRD26*, which also have normal platelet size and predispose to leukemia (the familial platelet disorder with predisposition to acute myeloid leukemia, and the *ANKRD26*-RT, respectively). Considering the possibility that patients with ITs have *ETV6*-RT is important both for the risk to develop hematological malignancies, and because this disorder is relatively frequent: in our series of 274 consecutive propositi, *ETV6*-RT was identified in 8 families and had, therefore, a relative prevalence of 2.9% in the whole case series, and of 6.1% in the series of patients with known ITs. In our experience, the frequency of *ETV6*-RT was lower only to that of monoallelic Bernard-Soulier syndrome (BSS, 12.2% in the whole series), *MYH9*-related disease (11.4%), *ANKRD26*-RT (9.4%), and biallelic BSS (5.7%).
Summary/Conclusions: Our study showed that monoallelic *ETV6* mutations cause one of the most frequent forms of ITs and confirmed that affected subjects have little bleeding tendency but high propensity to hematological malignancies, in particular childhood ALL. Since *ETV6*-RT is one of the few autosomal dominant forms of IT without platelet macrocytosis, the screening for *ETV6* mutations is recommended in all patients with these characteristics, along with the screening for *RUNX1* and *ANKRD26* mutations.

Background: Blinatumomab, a bispecific T-cell engager antibody construct, binds specifically to CD19 (B cells) and CD3 (T cells) to facilitate lysis of CD19-positive target B-lineage cells. Based on a single-arm phase 2 study, blinatumomab received approvals in the US (accelerated) and EU (conditional) for the treatment of Philadelphia chromosome-negative (Ph–) relapsed/refractory (r/r) B-cell precursor acute lymphoblastic leukemia (BCP-ALL).
Aims: This phase 3, randomized, open-label study investigated the effect of blinatumomab on overall survival (OS) compared with standard of care (SOC) chemotherapy in adult patients with Ph– r/r BCP-ALL.
Methods: Patients with r/r BCP-ALL (if first relapse, within 1 y) were randomized 2:1 to receive either blinatumomab or SOC chemotherapy (investigator's choice of 1 of 4 defined regimens). Randomization was stratified by age, prior salvage therapy, and prior allogeneic stem cell transplant (alloSCT). Blinatumomab was given in 6-week cycles of 4 weeks on (continuous infusion of 9 µg/d in week 1 of cycle 1, then 28 µg/d) and 2 weeks off; dexamethasone was given pre-dose to prevent cytokine release syndrome. Patients in remission after 2 induction cycles were eligible to continue therapy until relapse. OS was the primary efficacy endpoint. Complete remission (CR) and combined CR or CR with partial or incomplete hematologic recovery (CR/CRh/CRi) were secondary efficacy endpoints. The primary analysis was scheduled to occur after 330 deaths had accrued. This prespecified interim analysis for an independent data monitoring committee (DMC) occurred after 248 deaths (75%).
Results: A total of 405 patients were randomized to blinatumomab (n=271) or SOC (n=134) and analyzed for efficacy; 2% and 19%, respectively, elected to receive no study treatment. Baseline characteristics were balanced between treatment groups (blinatumomab, SOC): median age (37y, 37y); median bone marrow blasts (80%, 79%); prior salvage therapy (56%, 52%); and prior alloSCT (35%, 34%). Using results from the DMC analysis, median OS was 7.8 months (95%CI: 5.7, 10.0) for blinatumomab and 4.0 months (95%CI: 2.9, 5.4) for SOC (stratified log-rank test p=.011; hazard ratio=0.71), surpassing the prespecified O'Brien-Fleming boundary p value of 0.0183. Improvement in OS was consistent between subgroups based on age, prior salvage therapy, or prior alloSCT. Response rates were higher for blinatumomab *vs* SOC, including CR (39% *vs* 19%; p<.001) and CR/CRh/CRi (46% *vs* 28%, p=.001). A total of 373 patients received ≥1 dose of blinatumomab (N=266) or SOC (N=107; 47 FLAG±anthracycline; 19 HiDAC-based; 22 high-dose methotrexate-based; and 19 clofarabine-based) and were analyzed for safety; 57% and 25%, respectively, started at least 2 cycles. Safety outcomes were similar between blinatumomab and SOC (table 1).

Table 1. Incidence Rates of Adverse Events (AE), Regardless of Causality.

	Blinatumomab (N=266)	SOC (N=107)
Any AE, % (per 100 patient-months)	99% (631.3)	99% (764.4)
Any grade 3 AE, %	38%	34%
Any grade 4 AE, %	29%	40%
Any grade 5/fatal AE, %	19%	19%
Grade 5 infection, %	11%	12%
Any serious AE, % (per 100 patient-months)	62% (26.4)	45% (38.1)
Infection, %	28%	31%
Blood/lymphatic, %	14%	16%
Nervous system, %	7%	3%
Cytokine release syndrome, %	3%	0%

Summary/Conclusions: This prespecified interim analysis showed that blinatumomab, as compared with SOC chemotherapy, improved the primary endpoint of OS in the phase 3 TOWER study of adults with Ph– r/r BCP-ALL. Remission rates also were higher in the blinatumomab group. AEs in the blinatumomab group were consistent with previous studies. Based on these findings, the DMC recommended stopping the TOWER study for efficacy before the planned final analysis.

POSTER SESSION I

Acute lymphoblastic leukemia - Biology 1

P150

COMPARATIVE ANALYSIS OF GENE REGULATORY NETWORKS IN LYMPHOID LEUKEMIAS USING THE INTERACTIVE HEMAP RESOURCE

J Mehtonen[1,*], P Pölönen[1], J Lin[2], T Liuksiala[2,3], S Häyrynen[2], S Teppo[3], P May[4], V Hautamäki[5], K Granberg[2], O Lohi[3], M Nykter[2], M Heinäniemi[1]

Background: Acute lymphoblastic leukemia (ALL) is a paradigmatic example of a disease that can develop at an early age as a result of genetic lesions that impede lineage commitment. In normal development, cells commit to their lineage and differentiated phenotype state by the activation of transcription factors (TFs), or TF modules, in a series of decision points at which a choice is made between alternative lineage fates. In parallel, epigenetic regulation has emerged as an important mechanism that can corrupt the gene regulatory network.
Aims: We set out to examine whether patient expression profiles could be used to quantitatively detect the blocks to differentiation and to reveal aberrantly active TF loci. We further evaluated how amenable lymphoblastic leukemia cases may be to treatment with drugs acting on epigenetic modifiers.
Methods: We analyzed 1,304 pre-B-ALL, 385 T-ALL and 801 B-CLL transcriptomes as part of a curated set of 9,544 transcriptomes collected across 36 hematological malignancies to facilitate the characterization of mechanisms that can corrupt the regulatory network in lymphoblastic leukemias. Sample similarity was assessed using t-Distributed Stochastic Neighbor Embedding (t-SNE) maps that permitted detecting changes in gene expression at subtype resolution and association with specific TF translocations, epigenetic changes and aberrant enhancers. The expression of genes that encode epigenetic modifiers with existing small molecule drugs (list from ChEMBL) was compared between ALL and chronic lymphoblastic leukemia (CLL) and other hematological malignancies.
Results: We scored gene sets of blood cell type lineage-determining TFs across the transcriptome dataset and found that cancer samples lack the characteristic mutually exclusive lineage-restricted pattern of these TF sets. Analysis of stem cell similarity revealed predominant expression of a subset of hematopoietic stem cell TFs across all acute leukemias. Of these, *ERG* expression was highest in pre-B-ALL and correlated with high activity of a super-enhancer based on DNAse hypersensitivity and enhancer RNA expression. In addition, we found disease cluster-specific activation of transcription-regulating gene loci with low or undetectable expression in normal blood cell types. In the cluster of the common pre-B-ALL subtype carrying the t12;21 translocation (ETV6-RUNX1 fusion), four TFs (*IRX1*, *MYOCD*, *NR3C2* and *SOX11)* had a subtype-specific elevated expression level. We validated with overexpression and silencing of *ETV6-RUNX1* that the observed upregulation of *IRX1* occurs downstream of the fusion TF. Furthermore, high expression of epigenetic modifiers with existing small molecule drugs (available from ChEMBL) was significantly enriched in CLL, T-ALL, one pre-B-ALL and one AML cluster among the 9,544 hematological samples.
Summary/Conclusions: We demonstrate that there are recurrent patterns of aberrant TF expression in leukemia disease clusters. Misregulated expression of ERG in pre-B-ALL appears to be mediated by a stem cell super-enhancer based on the deep sequencing results presented. Moreover, elevated expression of drug targets that function as epigenetic modifiers was enriched in specific leukemia clusters. Their inhibition potentially restores expression of a larger repertoire of misregulated genes. Particularly in CLL, these genes represent promising treatment targets for the reconditioning of blast cells.

MEF2C DYSREGULATION IS ASSOCIATED WITH CDKN1B DELETIONS AND PREDICTS POOR GLUCOCORTICOID RESPONSE IN PEDIATRIC T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

S Colomer-Lahiguera[1,*], M König[1], M Pisecker[1], R Ullmann[2], MN Dworzak[3], A Attarbaschi[3], S Strehl[1]
[1]CCRI, Children's Cancer Research Institute, St. Anna Kinderkrebsforschung e.V., Vienna, Austria, [2]MPIMG, Max Planck Institute for Molecular Genetics, Berlin, Germany, [3]Department of Pediatric Hematology and Oncology, St. Anna Children's Hospital, Medical University of Vienna, Vienna, Austria

Background: T-cell acute lymphoblastic leukemias (T-ALLs) are aggressive hematologic tumors resulting from the malignant transformation of T-cell progenitors and account for 10 15% of pediatric ALL cases. T-ALL is a heteroge-

neous disease characterized by a number of specific genetic alterations, which define molecular subgroups associated with distinct gene expression signatures, including the *TAL/LMO*, *TLX1*, *TLX3*, *HOXA* clusters as well as the recently identified proliferative and immature subtypes, typically overexpressing *NKX2 1* or *NKX2 2* and *MEF2C*, respectively. The latter, at least in part, overlaps with early T-cell phenotype- (ETP-) like ALL. However, a number of recurrent abnormalities such as *CDKN1B* deletions occurring in about 12% of T-ALL have not as yet been assigned to any specific disease entity.
Aims: In this study we sought to characterize pediatric T-ALL patients with *CDKN1B* deletions, which represent one of the most frequent copy number alterations, in more detail.
Methods: Array comparative genomic hybridization (aCGH) of 102 pediatric T-ALL patients enrolled in the Austrian ALL-BFM 90, 95 or 2000 clinical trials was performed. Cytogenetic analysis and immunophenotyping were done as part of the routine diagnostic work-up. The presence of specific chromosomal abnormalities was furthermore determined by fluorescence *in situ* hybridization (FISH) and/or RT-PCR. Moreover, the samples were subjected to RT-qPCR for *MEF2C* expression.
Results: By aCGH analysis and quantitative genomic PCR we detected the presence of *CDKN1B* deletions in 14 cases. Further genetic characterization of these cases led to their classification into the major T-ALL subtypes: *TAL/LMO* (n=1), *TLX1* (n=1),*TLX3* (n=1), or *HOXA* (n=3). Since many of the cases did not fall into any of these groups, we determined whether they belonged to the immature cluster characterized by *MEF2C* expression and compared them to *CDKN1B* wild-type cases. Remarkably, while only 14% (4/28) of *CDKN1B* wild-type samples showed *MEF2C* dysregulation, this was observed in 54% (6/11) of the *CDKN1B*-deleted cases for which appropriate material for RT-qPCR was available (p=0.017), suggesting an association between loss of *CDKN1B* and *MEF2C* expression. Since *MEF2C* is considered as one of the driving oncogenes of immature/ETP-like ALL, we next evaluated whether the *MEF2C*-dysregulated cases displayed the immunophenotypic characteristics of ETP-ALL: CD1a/CD4/CD8 negative; absent or weak CD5, and expression of one or more myeloid and/or stem cell antigens. Notably, while all cases immunophenotypically defined as ETP-like cases showed upregulation of *MEF2C* expression, only 30% (3/10) of *MEF2C*-dysregulated cases showed an ETP-like phenotype. However, virtually all of them expressed myeloid or B-lineage-specific markers, suggesting a certain lineage plasticity. Furthermore, high *MEF2C* expression levels in primary leukemia samples were associated with a significantly higher proportion of the patients being resistant to glucocorticoid therapy (p=0.0033).
Summary/Conclusions: In summary, our data provide evidence that *CDKN1B* deletions are associated with immature/*MEF2C*-dysregulated T-ALL and that *MEF2C* overexpression, though associated with, is not exclusively found in ETP-like ALL. Furthermore, our results indicate that *MEF2C* expression is associated with or may even be predictive of the response to glucocorticoid treatment.

P152

HEDGEHOG PATHWAY ACTIVATION IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA PREDICTS RESPONSE TO SMO AND GLI1 INHIBITORS

J De Bie[1,*], A Dagklis[1], S Demeyer[1], E Radaelli[2], D Pauwels[1], S Degryse[1], O Gielen[1], C Vicente[1], E Geerdens[1], A Uyttebroeck[3], N Boeckx[4], CE De Bock[1], J Cools[1]
[1]Center for human genetics, VIB-KU Leuven, [2]Center for human genetics, KU Leuven, [3]Pediatric hematology and oncology, [4]Laboratory medicine, University Hospitals Leuven, Leuven, Belgium

Background: The hedgehog signaling pathway contributes to embryonic pattern formation and adult tissue homeostasis as it is important to regulate cell proliferation, survival and differentiation. Aberrant activation of the hedgehog pathway through overexpression of the ligands (SHH, IHH) or mutations in signaling components (PTCH1, SMO, SUFU, GLI1) has been described in various solid tumors. The Hedgehog pathway is important for normal T-cell development, but its potential role in the development of T-cell acute lymphoblastic leukemia (T-ALL) is poorly characterized.
Aims: Our aim was to investigate the role of the hedgehog pathway as an oncogenic factor and a potential target for therapy in T-ALL.
Methods: We analyzed gene expression profiles of human T-ALL samples from two independent cohorts. We determined the effects of hedgehog ligand stimulation, downregulation of critical signaling components or pharmacological inhibition of the pathway in T-ALL cell lines, a mouse T-ALL model and in patient derived xenografts.
Results: Gene expression data analysis of primary T-ALL samples revealed that about 25% of T-ALL cases show ectopic expression of the ligands of the hedgehog pathway. A strong correlation between the ligands SHH and IHH with the main transcriptional factors GLI1 and GLI2 and known GLI target genes was observed, indicative of hedgehog pathway activation through an autocrine loop. Pharmacological inhibition of the hedgehog pathway, or siRNA mediated knock-down of key signaling components caused a decrease of proliferation of a subset of T-ALL cell lines, and sensitized the T-ALL cell lines to chemotherapy. In our JAK3-dependent T-ALL mouse model expression of Shh or Ihh provided a growth advantage to the JAK3(M511I) leukemia cells. Finally, we tested if hedgehog pathway inhibition could inhibit the growth of primary T-ALL cells. For this reason patient derived T-ALL xenograft samples were treated with two hedgehog inhibitors *ex vivo* and *in vivo*. T-ALL samples with high GLI1 expression were sensitive in both *ex vivo* and *in vivo* experimental set up, while T-ALL samples with low or no GLI1 expression were insensitive.
Summary/Conclusions: We demonstrate that the hedgehog pathway is activated in a subset of T-ALL patients and that hedgehog pathway activation affects T-ALL cell proliferation and provides partial protection against chemotherapy. Data from patient derived xenograft T-ALL samples confirms that high GLI1 expression predicts sensitivity of T-ALL samples to hedgehog pathway inhibitors.

P153

IDENTIFICATION OF CANDIDATE ONCOGENES AND CHROMOSOMAL BREAKPOINT SEQUENCING BY TARGETED LOCUS AMPLIFICATION IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

E Vroegindeweij[1], T Lammens[2], K Canté-Barrett[1], E Splinter[3], A Uyttebroeck[4], J Buijs-Gladdines[1], W Smits[1], P Vandenberghe[4], R De Smedt[5], B De Moerloose[2], M van Min[3], R Pieters[1,6], P Van Vlierberghe[5], J Meijerink[1,*]
[1]Department of Pediatric Oncology/Hematology, ErasmusMC Rotterdam – Sophia Children's Hospital, Rotterdam, Netherlands, [2]Department of Pediatric Hematology-Oncology and Stem Cell Transplantation, Ghent University Hospital, Ghent, Belgium, [3]Cergentis B.V., Utrecht, Netherlands, [4]Center for Human Genetics, University Hospitals Leuven, Leuven, [5]Center for Medical Genetics, Ghent University, Ghent, Belgium, [6]The Máxima Center for Pediatric Oncology/Hematology, Utrecht, Netherlands

Background: T-cell acute lymphoblastic leukemia (T-ALL) is characterized by clonal and mutual exclusive chromosomal rearrangements that recurrently activate *TAL1*, *LMO2*, *TLX1*, *NKX2-1*, *TLX3*, *HOXA* or *MEF2C* oncogenes. Most of these translocations or chromosomal rearrangements occur as erroneous D-J or V-DJ rearrangement attempts of T-cell receptor beta (*TCRB*) or TCR alpha/delta (*TCRAD*) genes, positioning oncogenes under the transcriptional control of TCR enhancer elements. Alternatively, oncogenes can also be activated as consequence of *BCL11B* chromosomal rearrangements. Although many oncogenes are known in T-ALL, the driving oncogenic lesion in particular T-ALL cases remains unknown.
Aims: In this study, we aimed to clone reciprocal breakpoint sequences by Targeted Locus Amplification (TLA) to elucidate cellular mechanisms that lead to recurrent *BCL11B-TLX3* chromosomal translocations. Moreover, we want to identify oncogene candidates in various T-ALL patients with *BCL11B*-, *TCRB*- or *TCRAD*-translocations for which the candidate oncogenes have not been identified.
Methods: We used the TLA procedure, a recently developed method that relies on the crosslinking of DNA in live cells, DNA digestion and re-ligation to allow formation of circular DNA ligation fragment. Inverted polymerase chain reaction amplification from specific view-point loci that closely flank chromosomal rearrangement breakpoint followed by next generation sequencing allows for the identification of a 100kb genomic region.
Results: We resolved the nucleotide sequence of chromosomal breakpoints in 30 T-ALL patient samples that were previously characterized by FISH and/or QRT-PCR. For some cases, we confirmed classical chromosomal translocations or rearrangements for *TAL1*, *LMO2*, *TLX1*, *TLX3* or *NKX2-1* oncogenes to *TCRAD*, *TCRB* or *BCL11B* loci. We identified unusual translocations in 8 cases, including *SPI1-BCL11B* t(11;14)(p13;q32), *LMO2-BCL11B* t(11;14)(p13;q32), *TCL1-TCRAD* t(14)(q11;q32), *NKX2.5-BCL11B* t(5;14)(q35;q32), *TLX1-RPP30* t(10)(q32;q24), *TLX3-TCRB* t(5;7)(q35;q34) and *CENPP-TCRAD* t(9;14)(q22;q11). For *TLX3-BCL11B* translocations, most breakpoints were found in the close vicinity of the *TLX3* oncogene and the *BCL11B* enhancer region (major peak) and DNase hypersensitivity sites. However, one *TLX3-BCL11B* sample was not translocated to the major peak, pointing to other enhancer regions that may drive TLX3 expression.
Summary/Conclusions: Identification of chromosomal rearrangements by Targeted Locus Amplification reveals classic chromosomal rearrangements as previously detected by FISH or QRT-PCR in 30 selected patients. By TLA, breakpoint junctions were resolved in 22 patients. In addition, in 8 selected cases from which we were unable to identify a fusion partner by FISH, TLA led to the identification of genomic breakpoints for uncommon translocations. TLA therefore proved a useful tool to identify novel translocation partners from various loci such as the *TCR* or *BCL11B* genes that are recurrently involved in these chromosomal rearrangements in T-ALL. Cloning of molecular translocation breakpoints of diagnostic T-ALL patient samples may further provide excellent minimal residual disease markers for disease monitoring during the course of treatment.

P154

A PLATFORM FOR DETECTION OF FUSION GENES IN ALL FROM TARGET CAPTURE NEXT-GENERATION SEQUENCING OF DNA AND RNA

A Grioni[1,2,*], G Fazio[1], T Reigl[2], S Rigamonti[1], V Bystry[2], S Songia[1], A Biondi[1,3], N Darzentas[2], G Cazzaniga[1]

[1]Centro Ricerca Tettamanti, Monza, Italy, [2]Central European Institute of Technology (CEITEC), Brno, Czech Republic, [3]Clinica Pediatrica, Università di Milano-Bicocca, Monza, Italy

Background: Acute Lymphoblastic Leukemia (ALL), the most common leukemia in childhood, is characterized by genomic alterations, such as chromosomal translocations typically affecting a limited number of recurrent genes (targets) with several variable partner genes (partners). Fusion genes can be targeted by chemotherapy and/or new drugs, therefore genomic profiling of ALL has the potential to identify important new prognostic markers and potentially druggable targets.
Aims: Herein, we researched and developed a bioinformatic solution, 'BreakingPoint', for the robust detection of fusion genes. This was implemented in the context of an expert evaluation of Target Capture Next-Generation Sequencing (NGS-TC) protocols both at the DNA and RNA level on ALL samples. The platform will eventually be evaluated for routine clinical diagnosis.
Methods: 'BreakingPoint' has been developed to detect fusion genes from NGS-TC datasets from any sequencing technology and any biological material. Its distinctive feature is that it initially identifies all aligned reads indicating hypothetical breakpoints on the 'targets', then clusters these into longer (thus more informative) consensus sequences, which are then studied across the genome to identify the unknown 'partners'. We tested 'BreakingPoint' on NGS-TC datasets of: (i) DNA material from 10 patients with 7 known gene fusions (Illumina Nextera DNA capture); (ii) RNA material of 6 patients with 8 known gene fusions (NuGen Ovation RNA Fusion Panel); all on Illumina's MiSeq platform. We additionally compared our method to the popular 'Delly' tool (DNA) and the 'TopHat Alignment App' on the 'Illumina BaseSpace Cloud' (RNA).
Results: On the DNA dataset, 'BreakingPoint' identified 6/7 known fusion genes (*e.g.* BCR/ABL1, PAX5/AUTS2) plus one not previously known. The missing P2RY8/CRLF2 gene fusion was most probably due to the low complexity of chromosome X affecting the *in vitro* capture and *in silico* alignment steps. Our method also detected deletions affecting the IKZF1 'target', a gene prone to mutation in ALL patients. 'Delly' identified 5/7 known gene fusions, missing PAX5/AUTS2 and P2RY8/CRLF2. On the RNA dataset, 'BreakingPoint' identified all 8 known fusion genes, including P2RY8/CRLF2, plus a novel gene fusion (PAX5/ZCCHC7). Illumina's 'TopHat Alignment App' detected 5/8 known gene fusions and the novel PAX5/ZCCHC7 rearrangement; false negatives (BCR/ABL1; MLL/AF4;P2RY8/CRLF2) were most likely caused by low read numbers affecting 'targets' coverage. 'BreakingPoint' false positives showed a common pattern of low sequence complexity and few representative reads (less than 2), and in many cases breakpoints fell in long intron non-coding regions (LINC), making them easily recognizable when compared to true positives. Finally, we have implemented a graphical user interface to run 'BreakingPoint' (and other plug-in methods, including 'Delly', if the user so wishes) and browse the results.
Summary/Conclusions: These results indicate that our approach sensitively and reliably detects fusion genes, irrespective of biological material or protocol, even in cases of low reads coverage. This already provides the potential to identify novel and conventional targetable fusion genes. Eventually, after further validation and evaluation, and coupled with the user-friendly interface, we believe that the 'BreakingPoint' platform can be introduced in routine clinical diagnosis.

P155

THE NUP214-ABL1 FUSION COOPERATES WITH TLX1 IN THE DEVELOPMENT OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

M Vanden Bempt[1,2,*], CE de Bock[1,2], S Demeyer[1,2], R Vandepoel[1,2], N Mentens[1,2], E Geerdens[1,2], E Radaelli[1,2], J Cools[1,2]
[1]Center for Human Genetics, KU Leuven, [2]Center for the Biology of Disease, VIB, Leuven, Belgium

Background: The episomal NUP214-ABL1 fusion is observed in 6% of T-ALL patients. The resulting NUP214-ABL1 fusion protein is a constitutively activated tyrosine kinase, which activates STAT5 and ERK signalling, thereby stimulating proliferation and survival. Significantly, almost all T-ALL cases with the NUP214-ABL1 fusion also harbour chromosomal translocations resulting in the overexpression of the homeobox transcription factors TLX1 or TLX3.
Aims: To determine whether (i) co-expression of NUP214-ABL1 fusion and TLX1 cooperate together in leukemia development; and (ii) to understand the molecular mechanisms underlying any cooperation at the transcriptional level.
Methods: We have generated a conditional loxP-STOP-loxP NUP214-ABL1 knock-in mouse model, in which NUP214-ABL1 expression can be activated by Cre. We crossed these mice with *Tg(CD4-Cre) mice,* in which Cre is expressed in developing T-cells, and then subsequently with *Tg(Lck-TLX1)* mice, expressing TLX1 under control of the T-cell specific Lck promoter. These crossings resulted in a *Tg(CD4-Cre, NUP214-ABL1, Lck-TLX1)* mouse model. Using RNA-sequencing and ChIP-sequencing, we determined gene expression profiles and binding patterns of STAT5 and TLX1.
Results: The *Tg(CD4-Cre, NUP214-ABL1, Lck-TLX1)* mouse model developed a transplantable CD4+/CD8+ T-ALL with a significantly shorter latency (median survival of 193 days) compared to the *Tg(Lck-TLX1)* mouse model (median survival 385 days) or the *Tg(CD4-Cre, NUP214-ABL1)* mouse model (no disease), indicating true cooperation between NUP214-ABL1 and TLX1 during T-ALL development. Gene expression profiling revealed that there is significant upregulation of the JAK-STAT pathway, the mTOR signalling pathway and the Notch1 signaling pathway in the *Tg(CD4-Cre, NUP214-ABL1, Lck-TLX1)* mouse model, compared to the *Tg(Lck-TLX1)* mouse model. The cooperation between NUP214-ABL1 and TLX1 was also investigated in a human context using the T-ALL cell line ALL-SIL, which carries these two oncogenic alterations. ChIP sequencing results showed that STAT5 and TLX1 have overlapping binding patterns on genes that have been identified as STAT5 target genes. We are currently validating these results in our transgenic mouse model.
Summary/Conclusions: The NUP214-ABL1 fusion and TLX1 overexpression cooperate to drive T-ALL development.

P156

CLINICAL AND BIOLOGICAL LANDSCAPE OF DRIVER MUTATIONS IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

Background: B-progenitor acute lymphoblastic leukemia (B-ALLs) accounts for 85% of pediatric ALL and currently categorized into molecular subgroups according to their ploidy and recurrent translocations, such as *ETV6 -RUNX1* (*TEL-AML1*), *TCF3-PBX1 (E2A-PBX1), BCR-ABL1* or *MLL*-rearrangements. In addition, recent genetic studies using high-throughput sequencing have disclosed a number of novel gene mutations in each subgroup. However, the landscape of driver mutations and their relevance to clinical outcome have not been fully investigated in a large cohort of B-ALL patients.
Aims: The purpose of this study is to characterize the distribution of genetic alterations and their clinical relevance in pediatric B-ALLs using high-throughput sequencing in a large cohort of B-ALL patients.
Methods: A total of 524 pediatric B-ALL patients were enrolled in this study, who were uniformly treated according to the Japan Association of Childhood Leukemia Study (JACLS) ALL-02 protocol between 2002 and 2008. These patients were categorized into three risk groups, including standard risk, high risk, and extremely high risk. Infantile, *BCR-ABL1*–positive and Down syndrome–associated ALLs were not enrolled in this cohort. A total of 158 known or putative driver genes in pediatric ALL were analyzed for somatic mutations by targeted-capture deep sequencing using SureSelect (Agilent). Single nucleotide polymorphism-baits were also included, which were designed to allow for genome-wide copy number detection based on deep sequencing.
Results: The median age at diagnosis and observation period were 5.2 years (1-18.5) and 4.2 years (1.8-9), respectively. Sixty-six of the 524 patients (13%) had relapsed diseases and 47 patients (9%) were dead. Real-time RT-PCR and conventional cytogenetic analyses revealed *ETV6-RUNX1*, *TCF3-PBX1*, *MLL* rearrangements, hyperdiploidy (>50 chromosomes) and hypodiploidy (<44 chromosomes) in 113 (22%), 42 (8%), 10 (2%), 95 (18%), and 2 (0.4%) patients, respectively, and the remaining 262 patients (50%) had none of these abnormalities. The mean depth of the targeted sequencing was 569× across the entire cohort. In total, 74% of the patients harbored at least one mutation (median, 2 per patient; range, 0-9), and the mean number of mutations in *ETV6-RUNX1*, *TCF3-PBX1*, *MLL*-rearranged, hyperdiploid, hypodiploid ALLs were 0.63, 1.19, 1, 3.05 and 4, respectively. *CDKN2A*, *KRAS*, *NRAS*, *PAX5*, and *ETV6* were among the most frequently affected genes, which were mutated or deleted in 24%, 21%, 18%, 18%, and 15% of the cases, respectively. In terms of functional pathways, RAS pathway was most frequently affected and altered as many as 50% of the patients, followed by the pathways involved in epigenetic regulation, cell cycle, and B-cell development. Frequency of mutations showed a significant variation among B-ALL subtypes. For instance, RAS pathway mutations were detected in as many as 87% of hyperdiploid ALLs, compared to 3% of *TCF3-PBX1* ALLs. On the other hand, *IKZF1* mutations/deletions were only indentified in those without recurrent translocations, hyperdiploidy and hypodiploidy.
Summary/Conclusions: We revealed the landscape of driver mutations and copy number alterations in pediatric B-ALL and their diversity in B-ALL subtypes. Further analyses are underway to better clarify the prognostic significance of driver gene mutations.

P157

CHARACTERIZATION OF AN *EX VIVO* T-CELL CULTURE MODEL FOR THE STUDY OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

S Bornschein*, C de Bock, S Degryse, O Gielen, J Cools
KU Leuven Center for Human Genetics, VIB Center for the Biology of Disease, KU Leuven, Leuven, Belgium

Background: T-cell acute lymphoblastic leukemia is caused by the combined deregulation of various cellular functions, including NOTCH1 signaling, kinase signaling, and transcriptional regulation. Deregulated kinase signaling is often studied in the Ba/F3 pro-B cell line, but an easy T-cell system is lacking.
Early T cell progenitor cells undergo extensive expansion at the double negative two (DN2) stage *in vivo*, which allows for their expansion and culture *ex vivo*. Importantly, these cells maintain their potential to differentiate into mature T cells *in vivo*. This makes this culture method a suitable model to study T cell development and transformation events in pre-leukemic cells.
Aims: This study aimed to develop and characterize a T-cell model to dissect molecular mechanisms of T cell development and signalling pathways that are implicated in the development of T-ALL. We aimed to identify key transcriptional pathways and regulators during T cell differentiation and to study the effect of oncogenic mutations on these pathways.
Methods: Hematopoietic stem cells were cultured in the presence of SCF and IL7 on delta like ligand 4 (DLL4) coated plates, to induce differentiation into early T cell progenitors. Transcriptional profiling using RNA-sequencing of these pro-T cells was used to identify the key transcriptional pathways and genes induced by IL7, SCF or Notch signalling. Next, dominant oncogenic mutants of AKT, JAK3, NOTCH1 or KRAS were introduced with retroviral vectors, and Pten gene was inactivated using Crispr/Cas genome editing. These cells were analyzed for their possibility to grow in the absence of SCF, IL7 and/or DLL4.
Results: We identified transcriptional signatures, which were specific to IL7, SCF and DLL4 stimulation or induced in a synergistic manner. For example IL7, SCF and DLL4 by themselves were able to induce the expression of the transcription factor Myc. However, only Notch-signalling induced expression of Hey1, Dtx1, Hes1 or CCR7. Using computational tools, we identified transcription factors that mediated expression of these genes, specific to SCF and IL7 stimulation. Furthermore, SCF activated mainly the PI3K-Akt pathway and was unable to induce Stat5a/b phosphorylation. IL7 stimulation, on the other hand, resulted in activation of the Jak-Stat pathway, but provided less activation of Akt. In line with these observations, overexpression of the AKT(E17K) mutant or Crispr/Cas9 mediated Pten deletion resulted in SCF independent growth, whereas cells remained IL7 and DLL4 dependent. Furthermore, some, but not all, JAK3 mutants were able to transform cells to grow in the absence of IL7 and induced Stat5 phosphorylation. KRAS(G12D) mutants allowed the cells to grow in the absence of SCF and IL7. Upon transduction with ligand independent Notch1 mutants, cells became independent of DLL4 stimulation.
Summary/Conclusions: This model system for the SCF/IL7/DLL4 dependent *ex vivo* culturing of primary mouse T-cells enables the study of T-ALL oncogenic events in a T cell context.

FUNCTIONAL RESTORATION OF MUTANT P53 AND CELL DEATH SENSITIZATION IN ACUTE LYMPHOBLASTIC LEUKEMIA

S Demir[1,*], G Selivanova[2], E Tausch[3], L Wiesmüller[4], S Stilgenbauer[3], G te Kronnie[5], KM Debatin[1], LH Meyer[1]
[1]Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, [2]Department of Microbiology, Tumor and Cell Biology, Karolinska Institute, Stockholm, Sweden, [3]Department of Internal Medicine III, [4]Department of Obstetrics and Gynaecology, Ulm University Medical Center, Ulm, Germany, [5]Department of Women`s and Children`s Health, University of Padova, Padova, Italy

Background: In acute lymphoblastic leukemia (ALL), *TP53* alterations are rarely found at diagnosis but in about 12% of patients at relapse. *TP53* mutations (*TP53*mut) have been described to be associated with poor response to therapy and inferior outcome in ALL. Compounds targeting mutated p53 such as APR-246 demonstrated activity in different types of *TP53*mut malignancies. In ALL however, targeting mutant *TP53* has so far not been addressed.
Aims: To evaluate mutant *TP53* as target for directed anti-leukemia therapy in ALL.
Methods: Patient-derived primograft samples established in our NOD/SCID/huALL mouse model were analyzed for *TP53*mut by denaturating high-performance liquid chromatography and validated by Sanger sequencing. Sensitivities of ALL cells in response to different drugs and combinations were assessed analyzing half maximal inhibitory concentrations (IC50) and combination indices (CI). Apoptosis was detected by caspase-3 activation and Annexin-V/propidium iodide positivity. Activation of p53 was analyzed by phosphorylation of p53 (p53pSer15, flowcytometry), expression of p53 downstream molecules and confirmation of phosphorylation was carried out by western blot analysis. p53 deficient cell lines were generated by lentiviral shRNA mediated knock-down.
Results: Of 62 primograft samples, 4 cases with *TP53*mut (6.5%) were identified, corresponding to reported numbers in clinical studies. In parallel, we analyzed 6 BCP-ALL cell lines and identified 2 *TP53*mut and 4 wild type (*TP53*wt) lines. We analyzed the effects of the DNA damaging agent doxorubicin and the p53 targeting small molecule APR-246 (kindly provided by Aprea, Stockholm, Sweden) and observed an insensitivity to doxorubicin in *TP53*mut cell lines and primografts (mean IC50: 100 nM and >65 nM) compared to sensitive *TP53*wt cell lines and primografts (mean IC50: 9 nM and 7.4 nM). In contrast, *TP53*mut ALL cells were highly sensitive to APR-246 (mean IC50: 4.5 µM and 4.4 µM), compared to insensitivity of *TP53*wt cell lines and primografts (mean IC50: 58.3 µM and >90 µM). Increased Annexin-V/PI positivity and caspase-3 activity upon APR-246 exposure indicated apoptosis as mechanism of APR-246 mediated cell death. In order to investigate the specificity of APR-246 for p53, we investigated APR-246 mediated cell death induction in 2 genetically modified, p53 deficient ALL cell lines. No cell death induction could be detected upon p53 absence in contrast to high APR-246 sensitivity in the control transduced cell lines, clearly indicating dependency of APR-246 on the presence of mutant p53. Most importantly, a clear activation of p53 was identified upon APR-246 exposure in *TP53*mut but not *TP53*wt leukemias indicated by increased p53 phosphorylation and increased expression of the p53 target molecules NOXA and PUMA, pointing to restoration of p53 function and induction of downstream signaling in *TP53*mut ALL by APR-246. Moreover, we investigated the ability of APR-246 to re-sensitize *TP53*mut, DNA damage resistant ALL. Upon exposure of *TP53*mut ALL cell lines and primografts to combinations of APR-246 and doxorubicin, a strong synergism and re-sensitization to DNA-damage induced cell death was observed.
Summary/Conclusions: We provide evidence that APR-246 specifically targets *TP53*mut BCP-ALL leading to re-activation of p53, apoptosis induction, and re-sensitization of DNA-damage resistant *TP53*mut ALL cells. Thus, targeting mutated p53 provides a promising novel strategy for therapeutic intervention in this high-risk subtype of BCP-ALL.

P159

DETERMINING THE MUTATIONAL LANDSCAPE OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA REVEALS NR3C1 DELETIONS AND ACTIVATING MUTATIONS IN IL7R SIGNALING AS CAUSE OF STEROID RESISTANCE

Y Li[1], J Buijs-Gladdines[1], K Canté-Barrett[1], A Stubbs[2], E Vroegindeweij[1], W Smits[1], R van Marion[3], W Dinjens[3], M Horstmann[4,5,6], R Kuiper[7], R Buijsman[8], G Zaman[8], P van der Spek[9], R Pieters[10,11], J Meijerink[10,*]
[1]Department of Pediatric Oncology/Hematology, Eramus Medical Center/Sophia Children's Hospital, [2]Department of Bioinformatics, [3]Department of Pathology, Eramus Medical Center, Rotterdam, Netherlands, [4]Research Institute Children's Cancer Center Hamburg, [5]Co-operative Study Group for Childhood Acute Lymphoblastic Leukemia (COALL), [6]Clinic of Pediatric Hematology and Oncology, University Medical Center Hamburg-Eppendorf, Ham-

burg, Germany, [7]Department of Human Genetics, Radboud University Medical Center, Nijmegen, [8]Netherlands Translational Research Center B.V., Oss, [9]Department of Bioinformatics, Erasmus Medical Center, [10]Department of Pediatric Oncology/Hematology, Erasmus Medical Center/Sophia Children's Hospital, Rotterdam, [11]The Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands

Background: Response to therapy in children with acute lymphoblastic leukemia (ALL) including *in vitro* or *in vivo* steroid response is a strong predictor for survival and cure. T-ALL patients in particular have a high risk to relapse and are refractory to further treatment due to acquired therapy resistance. The mechanisms that underlie steroid resistance are poorly understood.
Aims: This study aimed to investigate the mutational landscape of pediatric T-ALL patients to identify molecular disease mechanisms underlying steroid resistance.
Methods: Whole-genome sequencing (WGS) of 13 T-ALL diagnostic tumor-remission pairs in the pilot group was performed by Complete Genomics to detect chromosomal rearrangements and somatic nucleotide variations. Targeted exome resequencing of 251 genes was performed in a validation cohort of 82 pediatric T-ALL samples, and mutation data was integrated with loss-of-heterozygosity data as obtained by array-comparative genomic hybridization for 53 T-ALL cases. Integrated data was related to clinical outcome and *in vitro* drug responses.
Results: WGS revealed intra-chromosomal (range of 5-25 per patient) and inter-chromosomal (range of 2-11) breakpoint junctions as consequence of deletions, duplications, inversions, translocations or complex rearrangements. Integrated mutation and copy-number data revealed 151 mutated genes (range of 0-51). Deletions in *NR3C1*—which are common in 5q chromosomal deletions in patients with the ALL subtype ETP-ALL (early thymus progenitor ALL)—are associated with steroid resistance. Moreover, we found that mutations in interleukin-7 receptor (IL7R) signaling molecules associated with steroid resistance while leaving cellular sensitivity levels to other chemotherapeutics unchanged. IL7R signaling mutations do not impair NR3C1 function, but activate MEK-ERK and PI3K-AKT pathways and downstream anti-apoptotic proteins BCL-XL and MCL1 while inhibiting GSK3B, a key regulator of steroid-induced pro-apoptotic BIM. Importantly, inhibitors of IL7R signaling reversed steroid resistance in T-ALL cells *in vitro*, whereas a GSK3B inhibitor conferred steroid resistance.
Summary/Conclusions: We revealed the mutational landscape of pediatric T-ALL patients. *NR3C1* deletions and IL7R signaling mutations were identified as cause for steroid resistance. This study supports the recommendation for the clinical application of IL7R signaling inhibitors to restore—or improve—steroid sensitivity of T-ALL cells.

P160

DEVELOPMENT OF A NOVEL FIRST-IN-CLASS ORAL INHIBITOR OF THE NOTCH PATHWAY

R Lehal[1,*], V Frismantas[2], V Reinmuller[3], G Turcatti[4], JP Bourquin[2], F Radtke[3]
[1]Cellestia Biotech AG, Basel, [2]University Children's Hospital, Zurich, [3]ISREC-EPFL, [4]Biomolecular Screening Facility, EPFL, Lausanne, Switzerland

Background: NOTCH signaling is a developmental pathway known to play critical roles during embryonic development as well as for the regulation of self-renewing tissues. Aberrant activation of NOTCH signaling leads to deregulation of the self-renewal process resulting in sustained proliferation, evasion of cell death, loss of differentiation capacity, invasion and metastasis, all of which are hallmarks of cancer. Over activation of NOTCH in human cancers can be a consequence of over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as chromosomal translocations leading to constitutive activation of the pathway.
Aims: Given the importance of Notch signaling in human cancers, several therapeutic approaches have been utilized to block NOTCH signaling. Two of these strategies are; a) the use of monoclonal blocking antibodies (Mabs) against NOTCH ligands and receptors and b) the use of small molecule □-secretase inhibitors (GSIs). However, these approaches can only be effective if tumor cells express full-length ligand or receptor molecules. On the contrary, in human cancers harbouring NOTCH gene fusion due to chromosomal translocations, the use of Mabs and GSIs will have very limited clinical benefits. A third, yet not fully explored approach could be the blockage of NOTCH signalling by targeting the most downstream event in the NOTCH cascade i,e NOTCH transcriptional activation complex using small molecule inhibitors.
Methods: Here we report discovery and identification of a novel, orally-active small molecule inhibitor, named CB-103, of the NOTCH pathway that blocks NOTCH signaling by targeting the NOTCH transcriptional activation complex in the nucleus.
Results: CB-103 has shown the ability to block NOTCH signalling in human T cell acute lymphoblastic leukemia cancer cell lines, induce neurogenic phenotype in drosophila, induce muscle cell differentiation and inhibit NOTCH dependent cellular processes in mice. Furthermore, CB-103 has shown a remarkable activity in *exvivo* and *invivo* patient derived models of human T-ALL harbouring activation of the NOTCH pathway. In addition, CB-103 exhibit anti-tumor efficacy in a xenograft model of human triple negative breast cancer resistant to GSIs and Mabs against NOTCH ligands/receptors.
Summary/Conclusions: Based on *in vivo* pharmacokinetic/ADME studies, CB-103 has been nominated as development candidate for further preclinical and clinical development.

P161

INTRINSIC AND SYNERGISTIC ACTIVITY OF ABT-199 AND OVERCOMING ABT-199 RESISTANCE BY THE CDK-INHIBITOR DINACICLIB IN B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

F Seyfried[1,*], S Demir[1], R Hörl[1], A Scheffold[2], S Köhrer[1], S Stilgenbauer[2], KM Debatin[1], LH Meyer[1]
[1]Department of Pediatrics and Adolescent Medicine, [2]Department of Internal Medicine III, Ulm University Medical Center, Ulm, Germany

Background: Therapy resistance and treatment failure in B-cell precursor acute lymphoblastic leukemia (BCP-ALL) are closely associated with deficient cell death pathways. Anti-apoptotic Bcl-2 family proteins are central apoptosis regulators, thereby serving as promising targets for novel, directed therapies. ABT-199 binds selectively to Bcl-2, inhibits its anti-apoptotic function and releases pro-death Bcl-2 family molecules leading to apoptosis induction. ABT-199 demonstrated activity in different hematological malignancies, pre-clinically and in early clinical trials. However, resistance for ABT-199 highlights the need for predictive markers and effective combination treatment strategies.
Aims: We addressed the effectivity of ABT-199 on BCP-ALL including pre-clinical *in vivo* evaluation and addressed resistance mechanisms and strategies to overcome ABT-199 insensitivity.
Methods: The effects of different drugs or combinations on BCP-ALL cell lines (n=6) and patient-derived BCP-ALL primografts (n=16) established by transplantation of primary patient ALL cells onto NOD/SCID mice were investigated analyzing half maximal inhibitory concentrations (IC50) and combination indices (CI). Anti-leukemic activity of ABT-199 was evaluated pre-clinically *in vivo*. Expression of apoptosis regulators was detected by western blot analysis. Mcl-1 deficient cell lines were generated by CRISPR/Cas gene engineering.
Results: A high sensitivity for ABT-199 was identified in 4 of 6 BCP-ALL cell lines with nanomolar IC50 values (mean 212 nM) in contrast to ABT-199 insensitivity in two other lines (IC50 >1μM). Similarly, a high sensitivity for ABT-199 was identified in the majority of ALL primografts (14 of 16, IC50 2 to 156 nM) with two insensitive cases (IC50 >1 μM). Of note, PBMCs from healthy donors also showed ABT-199 insensitivity. We assessed the expression of the apoptosis regulating molecules Bcl-2 and Mcl-1 and found high Bcl-2 levels in ABT-199 sensitive compared to low Bcl-2 levels in resistant ALL. In contrast, ABT-199 resistant leukemias showed high Mcl-1 expression and low levels were found in ABT-199 sensitive cases. Interestingly, CRISPR/Cas9-mediated knockout of Mcl-1 clearly sensitized ABT-199 insensitive cell lines for ABT-199 mediated cell death, indicating the role of Mcl-1 as mediator but also marker for ABT-199 resistance. Most interestingly, the CDK inhibitor dinaciclib induced rapid down-regulation of Mcl-1 at low nanomolar concentrations leading to sensitization for ABT-199 in resistant cell lines and primograft ALL. We also combined ABT-199 with chemotherapeutic agents used for remission induction in current therapy regimens. Co-exposure of ALL cells to vincristine, dexamethasone and asparaginase combined with ABT-199 showed a clear synergistic effect, both in cell lines and primograft ALL. Moreover, in a preclinical setting, recipient animals bearing a high-risk, t(11;19) leukemia were treated with ABT-199 or solvent. Importantly, a clear reduction of leukemia load was observed upon ABT-199 *in vivo* therapy compared to vehicle treated recipients ($p<0.01$).
Summary/Conclusions: Taken together, our data show apoptosis induction and high efficacy of ABT-199 as single compound, both *ex vivo* and pre-clinically *in vivo*, and synergy upon combination with conventional induction chemotherapy. Importantly, Mcl-1 was identified as mediator and indicator for ABT-199 resistance. Most importantly, the CDK-inhibitor dinaciclib was found to down-regulate Mcl-1 leading to sensitization for ABT-199 in previously resistant, Mcl-1 high expressing leukemia cells.

P162

LOSS OF PIGH EXPRESSION FREQUENTLY RESULTS IN A GPI-NEGATIVE SUBCLONE LACKING CD52 MEMBRANE EXPRESSION, CONFERRING ALEMTUZUMAB RESISTANCE TO B CELL ACUTE LYMPHOBLASTIC LEUKEMIA

F Loeff[1], K Rijs[1], E van Egmond[1], W Zoutman[2], M Vermeer[2], JF Falkenburg[1], S Halkes[1], I Jedema[1,*]
[1]Hematology, [2]Dermatology, Leiden University Medical Center, Leiden, Netherlands

Background: To improve treatment outcome of patients with B-cell acute lymphoblastic leukemia (B-ALL), several immunotherapeutic approaches have been developed in recent years. *E.g.*, direct targeting of CD19 or CD20 by (bispecific) antibodies or chimeric antigen receptors result in effective control of the disease. In contrast, introduction of alemtuzumab which targets the glycophosphatidylinositol (GPI)-anchored CD52 protein resulted in unsatisfactory clinical efficacy, potentially due to development of escape variants. Indeed, in previous studies (Nijmeijer et al, 2010) we have found outgrowth of CD52-neg-

ative escape variants following alemtuzumab treatment in a mouse model engrafted with human B-ALL. Further analysis showed that these variants expressed normal CD52 mRNA levels, but lacked CD52 membrane expression due to loss of GPI-anchor expression.
Aims: To unravel the mechanism underlying the loss of CD52/GPI expression in B-ALL
Methods: The presence and frequency of CD52/GPI-negative cells was analyzed by flowcytometry in peripheral blood (PB; n=10) and bone marrow (BM; n=8) samples taken with informed consent from B-ALL patients at diagnosis. Diagnosis samples of patients with chronic lymphocytic leukemia (CLL, n= 5), mantle cell leukemia (MCL, n=5) and hairy cell leukemia (HCL, n=6), and PB samples from 5 healthy donors were similarly analyzed in parallel. To investigate the mechanism of GPI loss, gene expression analysis was performed for the 26 genes that comprise the GPI anchor biosynthesis pathway in GPI positive and GPI negative B-ALL populations purified by flowcytometric cell sorting.
Results: To study the presence and frequency of CD52/GPI-negative cells at diagnosis, we analyzed PB and BM samples from B-ALL patients at diagnosis by flowcytometry. GPI-negative cells were present in 6/10 PB and 5/8 BM samples and comprised between 0.01% and 4.98% of the B-cell population. These obvious GPI-negative B-cell populations were not found in CLL (n=5), MCL (n=5), and HCL (n=6) diagnosis samples, or in healthy donors (n=5). To investigate the mechanism of GPI-anchor loss, gene expression analysis was performed for the 26 GPI biosynthesis pathway genes. In contrast to purified GPI-positive B-ALL populations, loss of PIGH mRNA expression, but not of any of the other genes, was found in all GPI-negative populations (n=9). To validate the relevance of this finding, GPI-negative and GPI-positive B-ALL cell cultures were generated from diagnosis material (n=2) and transduced with a retroviral construct encoding PIGH. Restored GPI-anchor expression and coinciding CD52 membrane expression was observed in the GPI-negative B-ALL cultures upon transduction with PIGH, but not empty vector. To explore the mechanism underlying the loss of PIGH mRNA expression in CD52/GPI-negative B-ALL cells, we performed DNA screening and assessed promoter CpG methylation, comparing GPI-negative with GPI-positive B-ALL cultures from the same individual (n=2). These analyses revealed that in GPI-negative cultures both alleles of the PIGH gene were present, unmutated and intact, but with a heavier methylated promoter region compared to the GPI-positive counterparts. Additionally, a 14 day treatment of GPI-negative B-ALL cultures with the demethylating agent 5-Azacitidine resulted in re-expression of the GPI-anchor
Summary/Conclusions: In conclusion, the majority of B-ALL patients presented a CD52/GPI-negative, alemtuzumab resistant, B-ALL population already at diagnosis. These cells lost PIGH expression, a key component in GPI-anchor synthesis. This is not due to genomic instability, but to epigenetic downregulation. Combining epigenetic modulatory drugs with alemtuzumab might be a promising therapeutic strategy to prevent outgrowth of CD52/GPI-negative escape variants in B-ALL.

P163

MUTATIONAL STATUS OF NRAS, KRAS AND PTPN11 GENES IS ASSOCIATED WITH GENETIC/CYTOGENETIC FEATURES IN CHILDREN WITH B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

DC Liang[1,*], SH Chen[2,3], HC Liu[1], CP Yang[2], TC Yeh[1], TH Jaing[2,3], IJ Hung[2], JY Hou[1], TH Lin[4], CH Lin[1], LY Shih[3,4]
[1]Mackay Memorial Hospital, Taipei, [2]Chang Gung Children's Hospital, [3]Chang Gung University, [4]Chang Gung Memorial Hospital-Linkou, Taoyuan, Taiwan, ROC

Background: The activating mutations in RAS signaling pathway including *NRAS*, *KRAS* and *PTPN11* genes have been described in B-precursor acute lymphoblastic leukemia (ALL). However, the correlation of RAS pathway gene mutations with recurrent genetic abnormalities was not addressed.
Aims: We aimed to investigate the frequencies, and the association with genetic/cytogenetic abnormalities as well as prognostic relevance of RAS pathway mutations in Taiwanese children with B-precursor ALL, the largest cohort in Asians.
Methods: Between 1995 and 2012, bone marrow samples at diagnosis from 538 children were studied. Mutations at codons 12, 13, and 61 in exons 1 and 2 of *NRAS* and *KRAS* genes, as well as the entire coding region of *PTPN11* were analyzed using PCR-based assay followed by direct sequencing. The mutational status of each gene was correlated with the clinico-hematological features, recurrent genetic abnormalities, and outcomes for those treated with TPOG-ALL-2002 protocol (n=348).
Results: The frequencies of *NRAS*, *KRAS*, and *PTPN11* mutations were 10.5% (56/533), 10.1% (54/533), and 3.4% (18/529), respectively. Mutations of *NRAS*, *KRAS*, and *PTPN11* were mutually exclusive with rare exception, including 4 co-occurrence of *NRAS* and *KRAS* mutations, and 2 co-existence of *KRAS* and *PTPN11* mutations. Together, 23.0% of B-precursor ALL patients had gene mutations involving RAS signaling pathway. No differences in age, Hb level, WBC or platelet counts were observed in patients with or without *NRAS* and *PTPN11* mutations. The frequency of *PTPN11* mutations was significantly higher in girls than in boys (1.4% *vs* 6.0%, *P*=0.006). Patients with *KRAS* mutations presented with significantly younger age (*P*=0.004) and lower platelet counts (*P*=0.007). Only one out of 21*BCR-ABL1* ALL had a mutation (*NRAS*) in RAS pathway. *ETV6/RUNX1* was associated with a lower frequency of *NRAS* mutations (2.2% *vs* 12.3%, *P*=0.002) and a trend of less *PTPN11* mutations (0% *vs* 4.1%, *P*=0.053); none of patients with *TCF3/PBX1* had *KRAS* mutation (*P*=0.024) whereas 2 of the 3 hypodiploid ALL had *KRAS* mutations (*P*=0.028); *KRAS* mutations occurred more frequently in patients with *MLL* rearranged (23.5% *vs* 9.2%, *P*=0.014, but the difference was not significant if we excluded infant ALL (n=30) (20% *vs* 8.7%, *P*=0.223). *NRAS* mutations were more commonly detected in hyperdiploid ALL (18.0% *vs* 9.5%, *P*=0.069). Patients without specific genetic/cytogenetic subtypes had a significantly lower frequency of *NRAS* mutations as compared to those without any of these recurrent genetic abnormalities (7.5% *vs* 13.2%, *P*=0.048) and a higher rate of *PTPN11* mutations (5.0% *vs* 1.6%, *P*=0.051). There were no differences in 5-year EFS and OS with regard to mutational status of *NRAS* (70.7% *vs* 79.0%, *P*=0.575; 89.6% *vs* 82.3%, *P*=0.863, respectively) and of *PTPN11* (80.8% *vs* 77.7%, *P*=0.490; 90.0% *vs* 82.2%, *P*=0.317, respectively). *KRAS* mutations were associated with inferior outcomes (66.0% *vs* 79.7%, *P*=0.039 for EFS and 74.8% *vs* 84.0%, *P*=0.058 for OS) but there was no difference in non-infant ALL (*P*=0.381 for EFS and *P*=0.635 for OS).
Summary/Conclusions: Patients with recurrent genetic abnormalities had rare occurrence of RAS pathway mutations in non-infant pediatric B-precursor ALL. *NRAS* mutations were more frequently detected in patients with hyperdiploidy, whereas *KRAS* mutations were highly associated with infant ALL with *MLL* rearranged. BABOON ENVELOPE PSEUDOTYPED LENTIVIRAL VECTORS: A HIGHLY EFFICIENT NEW TOOL TO GENETICALLY MANIPULATE T-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA INITIATING CELLS

G Hypolite[1], C Costa[2], O Bernadin[2], V Asnafi[1,3,4], E Macintyre[1,3,4], E Verhoyen[2,5], M Tesio[1,*]
[1]INEM, PARIS, [2]CIRI – International Center for Infectiology Research, Team EVIR, Université de Lyon, Lyon, France; Inserm, U1111; Ecole Normale Supérieure de Lyon, Lyon, France; Université Lyon 1; CNRS, UMR5308, Lyon, [3]Université Paris Descartes Sorbonne Cité, [4]Assistance Publique-Hôpitaux de Paris (AP-HP), Hôpital Necker Enfants Malades, Paris, [5]Inserm, U1065, Centre Méditerranéen de Médecine Moléculaire (C3M), équipe "contrôle métabolique des morts cellulaires", Nice, France

Background: T-Acute Lymphoblastic Leukaemia (T-ALL) is a heterogeneous and aggressive hematologic cancer arising from the malignant proliferation of T-cell progenitor cells, arrested at different stages of development. Although recently developed multi-agent chemotherapy protocols significantly improved the clinical outcome of this disease, the prognosis of patients undergoing relapse or therapy resistance remains poor. Since T-ALL chemo-resistance is linked to the activation of pathways that promote and sustain the self-renewal of leukemic initiating cells (LICs), it becomes imperative to develop novel therapies to eradicate these cells. To accomplish this objective it is necessary to perform pre-clinical, functional studies with primary T-ALL patient samples, a challenging task given that tools enabling an efficient genetic manipulation of primary T-ALL cells are still lacking.
Aims: To develop novel strategies to genetically manipulate T-ALL leukaemia initiating cells.
Methods: Fresh or thawed primary T-ALL samples were transduced with lentiviral vectors pseudotyped with a baboon envelop chmeric glycoprotein (BaEV). Two days post-transduction, 500.000-700.000 transduced cells were injected into cohorts of primary NSG(NOD.Cg-Prkdc(scid)Il2rg(tm1Wjll)/SzJ) mice to verify stable gene expression and T-ALL development from the transduced clones. The leukemic engraftment of the transduced cells was than evaluated by FACS analysis, based on GFP, CD45 and CD7 expression in the bone marrow, spleen and peripheral blood. To further assess the leukemic initiating ability of the transduced cells, 500.000-700.000 bone marrow cells issued from primary animals were injected into serial cohorts of NSG mice.
Results: Our work revealed that lentiviral vectors pseudotyped with a Baboon retroviral envelope glycoprotein (BaEV-LVs) are excellent tools to genetically modify T-ALL leukaemia initiating cells. These lentiviral vectors enabled high-level transduction rates (40-80%) at low multiplicity of infection (MOI=10) as they entered primary T-ALL blasts using ASCT1 and ASCT2, two aminoacid transporters that were highly expressed on all T-ALL subtypes. The transduced blasts engrafted cohorts of primary, secondary and tertiary mice, where they infiltrated bone marrow, spleen and peripheral blood, thus demonstrating that BaEV-LVs target leukemic-initiating cells. Importantly, this high performance was not linked to particular oncogenic features of the primary blasts not to a specific stage of maturation arrest. Competitive xenograft experiments, moreover, demonstrated the transduced clones did not acquire a selective growth advantage nor were outcompeted by the not-transduced clones, as evidenced by the relative ratio between GFP positive and GFP negative cells, which remained stable in all the mice serially transplanted. Hence, BaEV-LV mediated transduction does not alter LICs self-renewing pathways. This feature is an

essential pre-requisite to functionally investigate the signalling cascades involved in T-ALL initiation and development.
Summary/Conclusions: BaEV-LV vectors are essential and highly efficient tools to manipulate leukemic-initiating cells and to functionally investigate the molecular pathways involved in T-ALL development and clonal evolution.

P165

HIGH INCIDENCE OF PHILADELPHIA CHROMOSOME-LIKE ACUTE LYMPHOBLASTIC LEUKEMIA (PH-LIKE ALL) IN OLDER ADULTS WITH B-ALL

S Tasian[1], C Hurtz[2], G Wertheim[3], N Bailey[4], M Lim[5], R Harvey[6], IM Chen[6], C Willman[6], R Astles[2], S Reshmi[7], M Li[8], N Frey[2], S Luger[2], M Carroll[2], A Perl[2,*]
[1]Division of Oncology and Center for Childhood Cancer Research, Children's Hospital of Philadelphia, [2]Hematology/Oncology, University of Pennsylvania, [3]Pathology, Children's Hospital of Philadelphia, Philadelphia, [4]Pathology, University of Michigan, Ann Arbor, [5]Pathology, University of Pennsylvania, Philadelphia, [6]Department of Pathology and Hematologic Malignancies Research Program, University of New Mexico, Albuquerque, [7]Pathology and Laboratory Medicine, Nationwide Children's Hospital/Ohio State University, Columbus, [8]Genomic Diagnostics, Children's Hospital of Philadelphia, Philadelphia, United States

Background: Tyrosine kinase inhibitor (TKI) treatment of patients with Philadelphia chromosome-positive B-cell acute lymphoblastic leukemia (Ph+ B-ALL) improves response and survival in younger adults and has allowed de-escalation of conventional chemotherapy, particularly in older patients. Similar therapeutic approaches may also benefit patients with the Philadelphia chromosome-like (Ph-like) B-ALL subtype recently described in children and adolescents/young adults (AYA), as these leukemias are driven by activating mutations in kinase-associated signaling pathways. The frequency of adult Ph-like B-ALL is largely unknown, however.
Aims: We analyzed diagnostic B-ALL specimens from adult patients (range 18-88 years) by a validated, highly sensitive 15-gene low-density gene expression array (LDA) to determine the frequency of Ph-like ALL.
Methods: We analyzed 90 cryopreserved B-ALL samples from the institutional tissue banks at the University of Pennsylvania and University of Michigan by LDA to identify specimens with a kinase-active gene expression profile, as previously reported (Harvey, *et al. Blood* 2013, 123(21):826a). All samples were tested by reverse transcriptase-polymerase chain reaction (RT-PCR) for *BCR-ABL1* fusion. LDA signature-positive specimens without detected *BCR-ABL1* transcript (Ph-like ALL) were categorized as *CRLF2* (cytokine receptor-like factor 2)-overexpressing or non-overexpressing using LDA quantification of expression levels. *CRLF2*-overexpressing specimens were subsequently assessed for *IGH-CRLF2* and *P2RY8-CRLF2* rearrangements and *JAK1* and *JAK2* mutations via FISH, PCR, or RT-PCR with Sanger sequencing.
Results: By RT-PCR, 37.8% (34/90) of ALL specimens were *BCR-ABL1*+. Additionally, we identified a 20.0% (18/90) incidence of Ph-like ALL with a median age at diagnosis of 43 years (range 19-64). 77.8% (14/18) of the Ph-like ALL specimens harbored *CRLF2* rearrangements, including 7 patients with concomitant *JAK2* mutations. Using multiplexed RT-PCR, the 4 non-*CRLF2*-overexpressing Ph-like specimens were then evaluated for 39 published Ph-like kinase fusions; no recurrent gene fusions were identified. Correlative biology studies confirmed activation of JAK/STAT and/or ABL pathway signaling in primary Ph-like ALL specimens, as well as therapeutic efficacy of JAK or ABL kinase inhibition in adult Ph-like ALL patient-derived xenograft models.

	Ph-Like ALL (n=18)	Ph+ ALL (n=34)	KMT2A-R ALL (n=13)	Other B-ALL (n=25)
Mean WBC (10^3 cells/uL) +/- SEM	69.1 (+/- 29.7)	76.3 (+/- 16.8)	95.1 (+/- 21.7)	35.7 (+/- 10.3)
Median WBC (10^3 cells/uL)	28.6	37.7	90.2	11.6
Mean age in years (range)	43.2 (19-63)	54.6 (22-88)	45.8 (18-71)	42.3 (18-74)
% Male	66.7%	61.8%	36.4%	44 %
% Hispanic/Latino	16.7%	5.9%	0.0%	7.1%

Figure 1.

Summary/Conclusions: We identified a Ph-like gene expression signature in 20% of adults with B-ALL. Importantly, we also demonstrate for the first time that the majority of adult B-ALL is associated with activated kinase signaling. Unlike pediatric/AYA Ph-like ALL, in which kinase fusions occur frequently, *CRLF2* rearrangement is the predominant genetic lesion in adult Ph-like ALL. We propose that adult ALL diagnostic testing algorithms include flow cytometric assessment of surface CRLF2 (thymic stromal lymphopoietin receptor) expression, a surrogate marker for *CRLF2* rearrangement, with subsequent genetic confirmation. Finally, we demonstrate a substantial population of patients ≥40 years of age with non-Ph+ B-ALL who may also benefit from TKI therapies. The efficacy of such treatments should be evaluated via appropriate clinical trials, as clinical translation of our findings will potentially transform therapeutic approaches for adults with Ph-like ALL.

Background: In adults aged 18-60 years, many acute lymphoblastic leukemia (ALL) protocols have now incorporated L-asparaginase (ASPA) as part of induction regimen. As in children, adult patients are thus often exposed to pancreatitis, thrombosis, liver injury and allergic reactions. Thus some investigators do not use ASPA at all, like in the Hyper-CVAD regimen. In the GRAALL network, most of the centers started to use ASPA during induction when the pediatric-inspired GRAALL protocol was introduced in 2003.
Aims: The aim of this study was to report the real-life experience of the use of ASPA in the GRAALL-2005 trial and to identify factors associated with 1) main ASPA-related Adverse Events (AEs) and 2) the frequency and the impact of suboptimal ASPA dose administration.
Methods: Between 2006 and 2014, 787 adult patients with newly diagnosed Ph1-negative ALL were included in the multicenter French-Belgian-Swiss GRAALL-2005 trial. After a 7-day steroid prophase, patients received a 5-drug sequential induction including prednisone (PDN), vincristine (VCR), daunorubicine (DNR), cyclophosphamide (CPM) and ASPA (6000 IU/sqm/day for 8 days). Patients with induction failure received a high-dose cytarabine-based salvage course. AEs were assessed according to WHO classification. Four patients were excluded due to the lack of data.
Results: The median age of this cohort of 783 patients (505 BCP- and 278 T-ALL) was 36.1 years (range: 18.1-60.0). Median body mass index (BMI) was 23.6 kg/sqm (range: 15.7-46.3). Initial median WBC was 11.8 G/L (range: 0.4-645) and 55 patients had CNS involvement (7.0%). A complete remission (CR) was achieved in 720/783 (92.0%). A resistance to first induction phase was observed in 36/738 (4.9%) patients evaluable for CR. A grade 3-4 liver toxicity was observed in 272 patients (34.6%), a grade 3-4 pancreatitis in 43 patients (5.5%), and a cerebral venous thrombosis (CVT) in 25 patients (3.3%). An older age was significantly associated with an increased incidence of liver toxicity but a lower incidence of CVT. Pancreatitis was not associated with age. A high BMI was associated with liver toxicity and pancreatitis. In multivariate analysis, age, BMI, CNS involvement, and BCP-phenotype were associated with liver toxicity; BMI and female gender were associated with pancreatitis. During induction phase, patients received 97.8% of ASPA scheduled dose, 99.0% if younger than 45 years old but only 84.8% if older (p<.0001). In comparison, no difference in the administration of myelosuppressive drugs (DNR, CPM) was observed. In multivariate analysis, patient-related variables associated with less than 90% of scheduled ASPA administration (41% of patients) were older age, high BMI, and high ECOG score. In this model, center enrollment volume but also inclusion time period were statistically associated with a higher rate of ASPA administration, suggesting a learning effect. Finally, covariates independently associated with induction failure were higher WBC (OR 1.04 [95%CI, 1.01-1.07]), slower bone marrow clearance at D8 (OR 0.07 [95%CI, 0.02-0.20]), lower ASPA injection number (OR 0.72 [95%CI, 0.60-0.85]), and lower VCR injection number (OR 0.69 [95%CI, 0.55-0.88]), excluding all other induction drug dose variation.
Summary/Conclusions: During ALL induction, most ASPA-related toxicities seen in adult patients are correlated to age and BMI. Experience in the management of ASPA administration may enhance protocol compliance and thus contribute to reduce induction failure risk.

P167

EFFICACY AND SAFETY OF INOTUZUMAB OZOGAMICIN IN OLDER PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA ENROLLED IN THE GLOBAL PHASE 3 RANDOMIZED CONTROLLED INO-VATE TRIAL

EJ Jabbour[1,*], AS Advani[2], M Stelljes[3], W Stock[4], M Liedtke[5], N Goekbuget[6], G Martinelli[7], S O'Brien[8], K Wang[9], T Wang[10], ML Paccagnella[10], B Sleight[10], E Vandendries[11], DJ DeAngelo[12], HM Kantarjian[1]

[1]MD Anderson Cancer Center, Houston, TX, [2]Cleveland Clinic Main Campus, Cleveland, OH, United States, [3]Universitätsklinikum Münster, Münster, Germany, [4]University of Chicago, Chicago, IL, [5]Stanford Cancer Institute, Stanford, CA, United States, [6]Goethe University, Frankfurt, Germany, [7]University of Bologna, Bologna, Italy, [8]University of California, Irvine, Orange, CA, [9]Pfizer Inc, Pearl River, NY, [10]Pfizer Inc, Groton, CT, [11]Pfizer Inc, Cambridge, MA, [12]Dana-Farber Cancer Institute, Boston, MA, United States

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, has demonstrated superior response *vs* standard care for relapsed/refractory acute lymphoblastic leukemia (ALL) in the ongoing phase 3 INO-VATE trial (complete remission [CR]/CR with incomplete hematologic recovery [CRi], 81% [95% CI; 72–88]; minimal residual disease [MRD] negativity in responders, 78% [68–87]; median remission duration [DoR], 4.6 [3.9–5.4] months).
Aims: To assess the efficacy and safety of InO in patients with relapsed/refractory ALL aged ≥55 *vs* <55 years
Methods: Per protocol, the intent-to-treat analyses of CR/CRi included the first 218 of 326 patients randomized (ITT218). The safety population included 139 patients who received ≥1 InO dose (max 1.8 mg/m^2/cycle [0.8 mg/m^2 on day 1; 0.5 mg/m^2 on days 8 and 15 of a 21–28 day cycle for ≤6 cycles]). MRD negativity was assessed by central flow cytometry (<0.01%). Data as of October 2, 2014 are presented (trial ongoing). Informed consent was obtained from all patients.
Results: 109 patients in the ITT218 received InO (median age, 47 [range, 18–78] years; patients ≥55 years, 43 [39%]). Remission rates and DoR were similar whereas MRD-negativity rates in responders were numerically higher in older patients **(Table)**. In the safety population, grade ≥3 adverse events (AEs) were most frequently cytopenias (neutropenia, 46%; thrombocytopenia, 37%; febrile neutropenia, 24%); these grade ≥3 AEs were more common in patients ≥55 (n=53) *vs* <55 years (n=86): thrombocytopenia (49% *vs* 29%), neutropenia (53% *vs* 42%), febrile neutropenia (28% *vs* 21%). Patients ≥55 *vs* <55 years had similar discontinuation rates due to AEs (both 17%). For patients ≥55 *vs* <55 years, any grade hepatobiliary AE rates were similar (both 26%) and included, hyperbilirubinemia (both 15%), and veno-occlusive liver disease (VOD) including post-SCT VOD (both 11%; 2 fatal in patients <55 years [1 after second SCT]).

Table 1.

% (95% CI)*	<55 years (n=66)	≥55 years (n=43)
CR/CRi[b]	80 (69–89)	81 (67–92)
CR	35 (24–48)	37 (23–53)
CRi	45 (33–58)	44 (29–60)
MRD-negativity in responders	74 (60–85)	86 (70–95)
Median DoR, months	4.6 (2.8–5.4)[c]	4.4 (3.6–5.9)[d]

*ITT218; [b]Best response in 1–6 cycles; [c]n=51; [d]n=34

Summary/Conclusions: InO was highly effective in older patients with relapsed/refractory ALL for whom treatment options are currently limited; responses and safety profiles were generally similar to younger patients and the overall study population.

P168

THE COMBINATION OF BORTEZOMIB AND CHEMOTHERAPY IS AN EFFECTIVE TREATMENT TO RE-INDUCE REMISSION IN RELAPSED/REFRACTORY B-CELL PRECURSOR OR T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A Bertaina[1,*], S Gaspari[1], P Merli[1], V Ferruzzi[1], L Strocchio[1], F Del Bufalo[1], V Bertaina[1], R Caruso[1], B Lucarelli[1], L Vinti[1], F Locatelli[1,2]

[1]Hematology-Oncology, Ospedale Bambino Gesù, Roma, [2]Pediatrics, Univeristy of Pavia, Pavia, Italy

Background: Achievement of a new complete remission (CR) in relapsed/refractory pediatric acute lymphoblastic leukemia (ALL) is hampered by a low response rate and high toxicity, especially after second or subsequent relapses. Bortezomib, the first proteasome inhibitor approved by Food and Drug Administration for multiple myeloma and relapsed non-Hodgkin lymphoma, showed preclinical activity against ALL blasts. Moreover, a phase II study reported by the Therapeutic Advances in Childhood Leukemia & Lymphoma (TACL) study group demonstrated that the combination of bortezomib with vincristine, dexamethasone, pegylated asparaginase and doxorubicin carried acceptable toxicity and good efficacy in patients with relapsed B-cell precursor ALL who failed 2-3 previous regimens (Messinger, Blood 2012).
Aims: In order to improve the CR rate of children with relapsed/refractory ALL, we evaluated the use of bortezomib in combination with vincristine, dexamethasone, pegylated asparaginase and doxorubicin, as a salvage/re-induction

treatment in 24 and 7 children with B-cell precursor and T-cell ALL (2 ETP), respectively. Patient characteristics are reported in Table I.
Methods: Bortezomib (1.3 mg/m^2/dose) was administered intravenously on day 1, 4, 8, and 11. Dexamethasone 10 mg/m^2/day was given orally for 14 consecutive days. Doxorubicin 60 mg/m^2 was given intravenously on day 1. Vincristine 1.5 mg/m^2/dose (2 mg maximum dose) was administered intravenously on day 1, 8, 15, and 22. Pegylated asparaginase 2500 units/m^2/dose was given intravenously weekly for 4 doses. All patients received intrathecal (IT) cytarabine on day 1. Patients without CNS involvement were given IT methotrexate on day 15. Patients with CNS involvement at time of treatment were given IT methotrexate, methylprednisolone, and cytarabine on day 8, 15, and 22.
Results: Between February 2012 and July 2015, 24 pediatric patients with relapsed B-cell precursor and 7 with T-cell ALL were given the treatment detailed above at the Hematology/Oncology Department of the IRCCS Bambino Gesù Children's Hospital, Rome, Italy. Seventeen patients were males and 14 females, median age at diagnosis and at time of last leukemia relapse being 6.7 years (range 1-20.9) and 9.9 years (2.6-24.1), respectively. Four patients were CNS-positive at diagnosis, while 4/31 experienced a combined bone marrow (BM) and extramedullary relapse (2 CNS, 1 kidney and 1 gut, respectively). Fourteen children had previously received allogeneic hematopoietic stem cell transplantation (HSCT, see table 1 for details on the donor). Grade 3 (CTCAE v4.03) peripheral motor and sensory neuropathy developed in 5 (16%) patients. Six out of the 31 patients (19.5%) experienced severe infections (2 sepsis due to *Geotrycum*, 3 to *Candida* and 1 to multidrug resistant *Klebsiella Pneumoniae*). Despite the introduction of broad-spectrum antibacterial and antifungal therapy, 4 of them (13%) died (2 each with *Geotrycum and Candida* infection) without recovering neutrophils. Twenty patients achieved CR (10 with a MRD<0.1%), this leading to a 64.5% overall response rate. Interestingly, in our cohort, not only B-cell precursor patients had a good outcome (15/24, 62.5% CR rate), but also T-cell ALL responded well to this combination of drugs (5/7, 71.4% CR rate). Fifteen of these patients had a long-lasting CR allowing them to receive HSCT resulting in a 2-year Overall Survival (OS) of 37.1% (SE 13.2).

Table 1.

Sex	n (%)
Male	17 (55)
Female	14 (45)
Median age at diagnosis, years (range)	6.7 (1-20.9)

Days to platelets > 50 000/µL, median (range)	24 (14-43)
Neuropathy	5 (16)

* front-line therapy is not counted

Summary/Conclusions: In conclusion, the regimen of bortezomib combined with a 4-drug (vincristine dexamethasone, pegylated asparaginase and doxorubicin) re-induction therapy is effective for children with relapsed/refractory B-cell precursor or T-cell ALL. Considering the risk of life-threatening/fatal infections in a such vulnerable population, an intensive antibacterial and antifungal prophylaxis is strongly recommended.

P169

EFFICACY OF FRONT-LINE TREATMENT COMBINATIONS WITH PONATINIB *VERSUS* 1ST- AND 2ND-GENERATION TYROSINE KINASE INHIBITORS FOR PH+ ACUTE LYMPHOBLASTIC LEUKEMIA: A META-ANALYSIS AND META-REGRESSION

E Jabbour[1,*], M DerSarkissian[2], N McCormick[2], WY Cheng[2], LJ McGarry[3], A Souroutzidis[2], H Huang[3], MS Duh[2]
[1]University of Texas MD Anderson Cancer Center, Houston, [2]Analysis Group, Inc., Boston, [3]ARIAD Pharmaceuticals, Inc., Cambridge, United States

Background: The combination of a tyrosine kinase inhibitor (TKI) and either chemotherapy or corticosteroids is effective induction therapy in *de novo* Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL). Ponatinib is a multi-targeted TKI that is a more potent BCR-ABL1 inhibitor than previous generations of TKIs and selectively suppresses T315I resistance. However, evidence on the comparative effectiveness of ponatinib relative to other TKIs in *de novo* Ph+ ALL has not been well-established.
Aims: This study aims to evaluate the effectiveness, as measured by complete molecular response (CMR) and 2-year overall survival (OS), of front-line treatment combinations with ponatinib *versus* first- and second-generation TKIs (*i.e.*, imatinib, dasatinib, and nilotinib) in Ph+ ALL.
Methods: Nineteen Phase 2 through 4 trials and one retrospective analysis of front-line Ph+ ALL treatments were identified from a 2015 targeted literature review published by the American Society of Hematology. One study used ponatinib with chemotherapy and nineteen studies used a combination of first- or second-generation TKIs with either chemotherapy or corticosteroids. The proportions of patients achieving CMR and 2-year OS were extracted from all study arms and summarized by TKI group (ponatinib *vs* all other TKIs) using pooled estimates with 95% confidence intervals (CIs) from a random-effects meta-analysis. A binomial distribution was assumed to calculate the 95% CIs for the ponatinib trial. Multivariate logistic meta-regressions were conducted to examine the association between TKI groups and CMR rates as well as between TKI groups and 2-year OS, adjusting for age, gender, and in the OS model only, the proportion of patients receiving subsequent hematopoietic stem cell transplantation (SCT). P-values were calculated using non-parametric bootstrapping with 20,000 permutations.
Results: Across the 30 TKI-treatment arms from the 20 included studies, the median (range) age was 46 years (38-69 years), percent of male patients was 53% (40-67%), and percent of patients receiving subsequent SCT was 63% (0-100%). The pooled proportion of patients achieving CMR with ponatinib was 78% (95% CI: 62-90%) *vs* 30% (95% CI: 22-38%) with other TKIs. The pooled 2-year OS with ponatinib was 80% (95% CI: 65-92%) compared to 58% (95% CI: 53-63%) with other TKIs. The odds ratio (OR) for ponatinib *vs* other TKIs from the adjusted meta-regression for CMR (N=18) was 9.12 (95% CI: 1.59-52.21, p=0.025), and was 3.00 (95% CI: 0.63-14.43, p=0.136) for 2-year OS (N=19).
Summary/Conclusions: Our results support the hypothesis that ponatinib in combination with chemotherapy is associated with better clinical efficacy in newly diagnosed Ph+ ALL than combination therapy with older TKIs. In particular, compared to first- and second-generation TKIs, ponatinib was associated with a statistically significant 9-fold increase in the odds of CMR and a higher, though non-statistically significant, odds of 2-year OS. A limitation of our analysis is its reliance on study-level data from a small number of studies with heterogeneous therapy combinations; adjustment for heterogeneity across studies was limited to available covariates only. Nevertheless, our results suggest that ponatinib in combination with chemotherapy may represent a highly effective front-line treatment option for patients newly diagnosed with Ph+ ALL. Further prospective head-to-head clinical trials to confirm these results are warranted.

P170

RISK OF CEREBRAL VEIN THROMBOSIS (CVT) IN ADULT ALL PATIENTS IN FINLAND 1999-2012: SUGGESTION FOR A LEUKEMIA-RELATED PREDICTIVE SCORING MODEL

S Roininen[1,*], O Laine[2], M Kauppila[2], M Vesanen[3], M Sinisalo[2], E Jantunen[4], P Koistinen[5], M Säily[5], R Räty[1], E Elonen[1], U Wartiovaara-Kautto[1]
[1]Comprehensive Cancer Center, Department of Hematology, Helsinki University Hospital, Helsinki, [2]Dept. of Internal Medicine, Tampere University Hospital, Tampere, [3]Dept. of Internal Medicine, Turku University Hospital, Turku, [4]Dept. of Internal Medicine, Kuopio University Hospital, Kuopio, [5]Dept. of Internal Medicine, Oulu University Hospital, Oulu, Finland

Background: Thrombosis causes remarkable morbidity among patients with cancer and is the second leading cause of death after malignancy itself in this patient group. Khorana score estimates the risk of deep venous thrombosis (DVT) in solid tumor neoplasms, and may help physicians to prevent thrombotic complications. However, Khorana score is not applicable in acute leukemias and specific leukemia-related thrombosis risk score is still called for. Previous analyses focusing on thrombosis in ALL patients have mainly been conducted on pediatric study groups. Thrombotic risk profile in adult patients could, however, differ from children and these studies may not be converted straight-forward to adult setting.
Aims: To identify patient characteristics detectable at ALL diagnosis and possibly predisposing to CVT, which often represents with the most drastic consequences in patient's life.
Methods: We performed a population-based retrospective registry analysis on 186 adult-ALL patients treated with a national study protocol ALL2000 between years 1999-2012 in Finland.
Results: Of patients, 118 patients had pre-B ALL, 37 Philadelphia chromosome positive ALL and 31 T-ALL. Thirty-one patients (19%) suffered from a venous thrombosis (VT), whereof 9 (27%) from a CVT. Patients with CVT were thinner (p=0.018 and p=0.010) and had more T-ALL (Pearson Chi-Square values: 10.61, p=0.005 and 9.93, p=0.007), extramedullary leukemia (Pearson Chi-Square values: 5.167, p=0.023 and 5.412, p=0.046), and a higher pre-

chemotherapy CRP (p=0.033 and p=0.123) compared with both patients without VT and with other VTs, respectively (Table 1). A trend for younger age, higher pre-chemotherapy D-dimer, leukocyte and blood blast counts, and a lower platelet count was also detected in patients with CVT in this setting. CVT patients also presented with a higher pre-chemotherapy hemoglobin compared with patients without VT but this distinction did not reach statistical significance. Notably, most CVTs (n=5/9) occurred prior to the introduction of asparaginase, which is known to be the major factor predisposing ALL patients to thrombotic complications. None of the CVT patients had received intrathecal cytostatic treatment during the previous week before the thrombosis was diagnosed. Based on these results we constructed a risk model for CVT, which takes into account seven basic features detectable in patients at ALL diagnosis (Table 1). Patients scoring ≥5 points represented with a 20-fold risk for CVT compared with the low-risk (<5 points) patients (HR=20.841, p<0.0001, CI: 5.208-83.401) in our study group. The scoring model showed a very good specificity and satisfying sensitivity (NPV: 0.982, PPV: 0.375) in this study and is currently under validation in another patient cohort.

Table 1. Clinical and laboratory characteristics recorded at ALL diagnosis in patients obtaining CVT during the first three months of chemotherapy compared with other patient groups.

Variables	CVT vs. Without VT	n-fold	P-value	CVT vs. Other VT	n-fold	P-value
Leukocytes	↑	1.72	0.269	↑	1.16	0.675
Hb *1	↑	1.12	0.307	↔	0.99	0.659
Platelets *2	↓	0.63	0.309	↓	0.61	0.306
Bblast	↑↑	2.91	0.300	↑	1.65	0.497
CRP *3	↑↑	2.32	0.123	↑↑	3.58	**0.033**
D-dimer	↑	3.00	0.318	↑	2.25	0.236
Age *4	↓	0.66	0.166	↓↓	0.62	0.056
BMI *5	↓↓	0.84	**0.018**	↓↓	0.77	**0.010**
T ALL *6	↑↑	3.60	**0.005**	↑↑	4.10	**0.007**
Extramedullary leukemia *7	↑↑	2.50	**0.023**	↑↑	3.10	**0.046**

Parameters used in risk score model: *1 Hb > 100, *2 Platelets < 80, *3 CRP > 20, *4 Age < 41 years, *5 BMI < 24 kg/m2, *6 T-ALL = yes and *7 extramedullary leukemia = yes. A socre ≥ 5 points stands for over a 20-fold risk for CVT compared with patients in low-risk (< 5 points) group.

Summary/Conclusions: Thrombotic events and especially CVTs often have a major impact on patients with ALL during their course of leukemia treatment and after. Here, we present a set of laboratory and clinical characteristics identifiable at ALL diagnosis and associating with a very high risk of CVT during the first months of ALL treatment. These high-risk characteristics (*e.g.* low BMI and young age) are partly in contradiction to the acknowledged features predisposing patients to other forms of VT. This phenomenon hints for a distinctive mechanism of CVT in ALL patients possibly in linkage with ALL biology.

P171

INITIAL RESULTS FROM UKALL60+, A UK/HOVON COLLABORATIVE PHASE 2 STUDY IN ELDERLY PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA

N Morley[1,*], A Kirkwood[2], A Moorman[3], P Smith[2], C Rowntree[4], B Wrench[5], E Marwood[2], P Patrick[2], J Snowden[1], A Rijneveld[6], D Marks[7], A Fielding[8]
[1]Haematology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, [2]CR UK and UCL Cancer Trials Centre, UCL, London, [3]Leukaemia Research Cytogenetics Group, Newcastle University, Newcastle, [4]University Hospital Wales, Cardiff, [5]Barts Health NHS Trust, London, United Kingdom, [6]Erasmus MC, Rotterdam, Netherlands, [7]University Hospitals Bristol NHS Trust, Bristol, [8]UCL Cancer Institute, UCL, London, United Kingdom

Background: The outcome for older adults with acute lymphoblastic leukaemia (ALL) is generally poor. The UKALL12/ECOG2993 study reported a greater incidence of high risk cytogenetic abnormalities, increased toxicity (*e.g.* 18% Induction death rate) and poorer outcomes (CR rate 73% and 5 year overall survival 21%) in those 55- 65 years of age. There is a dearth of studies which focus on patients at the very oldest end of the age spectrum despite an increasing incidence with age.
Aims: We aimed to conduct a pragmatic study intended to establish baseline chemotherapy from which to design widely-applicable studies of novel agents in older people.
Methods: We established UKALL60+ as a collaboration between the UK National Cancer Research Institute Adult ALL Group and HOVON to study treatment choice and outcomes in patients aged 60 years and over (or 55 years and over with co-morbidities) with ALL. The study offers five 'arms' to be decided by investigator and patient choice; Non-intensive (designed to be delivered primarily out of hospital), Intensive, Intensive+, Philadelphia positive (Ph+) and Registration only (in which treatment is at investigators discretion, including no active therapy). Any elderly patient with newly diagnosed ALL is eligible. There are no exclusions for co-morbidities, including prior malignancies. Baseline characteristics of each group including Charlson index, ECOG, Karnofsky and CRASH scores are being collected with the aim of determining why each regimen was allocated. The primary endpoint is the rate of complete remission (CR) after 2 phases of induction. Secondary objectives include determination of MRD status at 3 time points, EFS and OS at 1 year, treatment related mortality and quality of life assessments.
Results: Since activation in December 2012 81 patients (84% of those screened) with a median age of 67 years (Range 55-83) have been enrolled. Median follow up is 9.4 months (Range 1 day to 29.8 months). ECOG performance status was 1 in 33 (40%), 2 in 37 (45%) and ≥3 in 13 (15%). Treatment allocation has been non-Intensive n=11, Intensive n=34, Intensive+ n=7, Ph+ n=18 and Registration only n=11 patients. It is too early to perform a full analysis of the reasons given for choosing each regimen but age appears to be a major factor for Ph-ve patients, with the average age 74 years (Range 64-82) in the non-Intensive arm compared with 66 years (Range 56-76) in the Intensive and Intensive+ arms. A total of 32/80 patients (40%) had high risk cytogenetics including *BCR-ABL1* (n=18), low hypodiploidy (n=10), complex karyotype (n=2) and *KMT2A-AFF1* (aka *MLL-AF4*) (n=1). So far forty-eight patients have completed 2 phases of induction chemotherapy with 37 of these attaining CR (77%). Failure to complete this was very common (n=17); reasons include inadequate response/relapse=8, death=5, clinician or patient decision=4. Baseline MRD samples were received for 62 patients, 43 of which have been evaluated to date by immunoglobulin heavy chain/T cell receptor re-arrangement quantification or BCR-ABL quantification. Only 3 of these patients were MRD negative following the first cycle of induction chemotherapy. Grade 3/4 AEs were seen in 54/58 assessable patients. The most common toxicities were haematological (71%) and infections (38%). To date 28 deaths have been reported; 18 patients died of ALL, 5 infection, 1 cardiac, 1 multi-organ failure and 3 data outstanding. Quality of life data has been collected and the results are anticipated.
Summary/Conclusions: ALL in older patients is difficult to treat with a delicate balance between efficacy and toxicity. Treatment choices currently vary widely. The goal of our trial is to provide a representative view of elderly ALL treatment, to identify a group where the current therapeutic approaches need improvement and to pave the way for older individuals to be at the forefront of development of novel approaches in *de novo* ALL.

P172

RELAPSE OF ACUTE LYMPHOBLASTIC LEUKAEMIA IN OLDER/ELDERLY PATIENTS - A SWEDISH POPULATION-BASED STUDY

E Bergfelt[1,*], P Kozlowski[2], L Ahlberg[3], P Bernell[4], E Hulegårdh[5], H Karbach[6], K Karlsson[7], B Tomaszewska-Toporska[7], M Åström[2], H Hallböök[1]
[1]Haematology, Dept of Medical Sciences, Uppsala University, Uppsala, [2]Haematology, Dept of Medical Sciences, Faculty of Medicine and Health, Örebro University, Örebro, [3]Dept of Haematology, University Hospital of Linköping, Linköping, [4]Div of Haematology, Dept of Medicine, Karolinska Institutet, Karolinska University, Stockholm, [5]Dept of Haematology and Coagulation, Sahlgrenska University Hospital, Göteborg, [6]Dept of Haematology, Cancer Centre, University Hospital of Umeå, Umeå, [7]Dept of Haematology, Skåne University Hospital, Lund, Sweden

Background: Knowledge about relapsed acute lymphoblastic leukaemia (ALL) in older/elderly patients is scarce.
Aims: To study the outcome of ALL relapse treatment in a population-based cohort of older/elderly patients.
Methods: Out of the Swedish ALL-registry and cause of death-registry patients 55-85 years (y) old diagnosed with B- and T-ALL from 2005 to 2012 were identified. Clinical, laboratory and treatment data were validated and supplemented from medical records. Informed consent was obtained and the study approved by the local ethical committee in accordance with the declaration of Helsinki. Proportions were compared with chi-square test. Overall survival (OS) was estimated by the Kaplan Meier method and distribution compared with log-rank test using IBM SPSS package (v 23). Confidence intervals (CI) of 95% were obtained.
Results: Of 103 patients with B- and T-ALL receiving intensive treatment with achieved first complete remission (CR1), 63 (61%) relapsed (28 males and 35 females). Median age at relapse was 67y (57-83). B-ALL was present in 57/63, T-ALL in 6/63, and Philadelphia-positive (Ph+) disease in 19 of 61 patients (31%) (two with unknown Ph-status). Bone marrow was the sole relapse local in 57 (91%) patients. Median time from CR1 to relapse (TTR) was 9 moths (range: 1-93) and seven relapsed after allogeneic hematopoietic stem cell transplantation (hSCT). Treatment with the goal of a second complete remission (CR2) was applied in 33 patients and the first course consisted of the Swedish protocol ABCDV (*n*=8), FLAG-Asp (*n*=6), FLAG-Ida (*n*=3), MEA (*n*=4), FLAG (*n*=1), Hyper-CVAD (*n*=3), NOPHO adult protocol (*n*=1), nelarabine (*n*=1) or other combinations (*n*=6). Regimens were supplemented with tyrosine kinase inhibitor (TKI) in six patients, DLI in one and CAR-T in one patient. hSCT in CR2 was performed in three patients (of 10 considered for the procedure). Two of them died of relapse and transplant related mortality respectively and one is still alive after seven years. Palliation was given to the 30 remaining patients with CHOP/COP (*n*=5, with rituximab added in 2), other intravenous chemotherapy combinations (*n*=5), TKI [alone (*n*=5), with chemotherapy/cortisone (*n*=3), radiotherapy (*n*=1) and DLI (*n*=1)], cortisone and/or oral chemotherapy combinations (*n*=7), no treatment (*n*=1) and unknown (*n*=2). Remission induction was given predominantly in late (>1y) relapse [18/27 (67%) *vs* 15/36 (42%); *P*=0.049]. In total, CR2 was achieved in 18 patients (29%) - 14/33 (42%) after remission induction and 4/30 (13%) after palliative treatment. Higher proportion of patients attained CR2 in late as compared with early relapse [13/27 (48%)

vs 5/36 (14%); *P*=0.003]. Median survival after relapse was 4 months (range: 0-95). The estimated 1 and 3y OS after relapse was 17 (CI: 7, 27)% and 7 (CI: 0, 14)%. There was no significant difference in OS between patients receiving remission induction and palliation. Age at relapse did not influence OS. Patients with late relapse had improved survival (*P*=0.001). CR2 achievement (as compared with treatment failure) enhanced survival in late [3y OS, CI: 34 (5, 64)% *vs* 7 (0, 21)%; *P*=0.001] but not early relapse (no survivors at 3y; *P*=0.22).

Summary/Conclusions: Intensive treatment can be considered in older ALL patients in case of late relapse. However, for the majority of the patients, the prognosis was poor, which supports alternative approaches such as immunotherapy or novel drugs.

Background: Compared with children, adults with acute lymphoblastic leukemia (ALL) have had inferior survival, when treated with traditional adult ALL regimens.

Aims: The aim of this study was to examine the event free survival (EFS) of children and adults with ALL (1-45 years) diagnosed, risk stratified, and treated uniformly according to the NOPHO ALL2008 protocol.

Methods: We collected information on 1509 patients from Sweden, Norway, Iceland (children only), Finland (children only), Denmark, Lithuania, and Estonia diagnosed 7/2008-12/2014 with Ph-negative ALL and treated according to the NOPHO ALL2008 protocol. Patients were registered in the NOPHO ALL2008 database upon diagnosis and subsequently followed systematically at three months intervals.

Results: Of 1509 patients, 1022 were children 1-9 years (484 female), 266 were 10-17 years (106 female) and 221 were adults 18-45 years (85 females). Adult patients more often had T-ALL (9% (1-9 years), 25% (10-17 years) and 32% (18-45 years), p<0.001), and *KMT2A* (a.k.a *MLL*) rearrangements (*KMT2A*-r, 3% (1-9 years), 5% (10-17 years) and 6% (18-45 years) , p<0.001), but lower median WBC when stratified by lineage (B-lineage 9.9 (1-9 years), 8.1 (10-17 years) and 6.8 (18-45 years) $x10^9$/L, p=0.01; T-lineage 134 (1- 9 years), 71.7 (10-17 years) and 38.8 (18-45 years) $x10^9$/L, p<0.001). Day 29 MRD was significantly higher for adults (p<0.001). Based on immunophenotype, WBC at diagnosis, MRD (discriminator 0.1%, FCM for BCP and PCR for T) at day 29 and 79, and presence of intermediate (dic(9:20) or iAMP21[*RUNX1*] or t(1;19)) or high risk cytogenetics (*KMT2A*-r or hypodiploidy (modal number <45)), patients were stratified into 4 risk groups (SR, IR, HR, and HR+hSCT, Table 1). Only MRD d29 ≥5% or d79>0.1% stratified to hSCT in 1st complete remission (CR1). Older patients were skewed towards higher risk group (Toft, Eur J Haematol 2013), but for each treatment arm severe toxicities (except for thrombosis and osteonecrosis) and intervals between treatment phases were almost identical for children and adults (Toft, Eur J Haematol 2015). After a median follow up for patients in CR1 of 4.0 years (75% range: 2.4-5.9 years), 16 patients (3 patients 18-45 years) had died during induction (induction failure), and 50 patients (12 patients 18-45 years) had died in first remission. A total of 123 patients relapsed (36 patients 18-45 years), and 12 children and 1 adult developed a second malignancy. The overall 5y-EFS for patients 1-9, 10-17 and 18-45 years was 88% (95%CI: 86; 90), 79% (95%CI: 73; 85) and 73% (95%CI: 67; 79), respectively, p <0.001. However, when stratified by risk group, the poorer EFS for adults was significant only for patients with intermediate risk ALL (Table 1).

Table 1.

Age group (Median age)		Total	1-9 (3 years)	10-17 (14 years)	18-45 (26 years)	p
Patients		N=1509	N=1022	N=266	N=221	
BCP/T		N=1278/231	N=929/93	N=199/67	N=150/71	<0.001
Induction failure		N=16 0.01(±0.01)	N=10 0.01(±0.00)	N=3 0.01(±0.01)	N=3 0.01(±0.01)	0.9
Death in 1. Remission		N=50 0.03(±0.00)	N=23 0.02(±0.00)	N=15 0.06(±0.02)	N=12 0.06(±0.02)	0.002
Relapse		N=123 0.10(±0.01)	N=60 0.08(±0.01)	N=27 0.12(±0.02)	N=36 0.19(±0.03)	<0.001
Event Free Survival (SE)						
EFS overall		0.84(±0.01)	0.88(±0.01)	0.79(±0.03)	0.73(±0.03)	<0.001
Standard risk (SR)	BCP & WBC<100K & d29 MRD <0.1%	N=673 0.92(±0.01)	N=546 0.92(±0.01)	N=83 0.90(±0.04)	N=44 0.87(±0.07)	0.20
Intermediate risk (IR)	BCP & WBC<100K & d29 MRD <0.1% or T a/o WBC≥100K & d29 MRD <0.1% or dic(9;20), t(1;19), iAMP21[RUNX1]	N=542 0.86(±0.02)	N=345 0.90(±0.02)	N=103 0.82(±0.04)	N=94 0.78(±0.05)	0.002
High risk (HR)	T a/o WBC≥100K & d29 MRD ≥0.1% or KMT2A-r hypodiploidy (<45 or DI<0.85)	N=176 0.66(±0.04)	N=85 0.65(±0.05)	N=46 0.68(±0.07)	N=45 0.66(±0.08)	0.9
High risk + hSCT (HR+hSCT)	d29 MRD ≥5% a/o d79 MRD (≥0.1%)	N=100 0.71(±0.05)	N=35 0.80(±0.08)	N=30 0.74(±0.09)	N=35 0.61(±0.09)	0.12

Table 1. Cumulative risk adjusted for competing events and event free survival.
16 patients with Induction failure and 2 patients not risk grouped due to severe toxicity (1-9 and 10-17 years) were excluded in survival analysis.
N number of patients, EFS event free survival. SE standard error, SR standard risk, IR intermediate risk, HR high risk, hSCT hematopoietic stem cell transplantation.

Summary/Conclusions: The EFS for adult ALL patients has improved markedly with NOPHO ALL2008 treatment compared with historical data. Although adult patients more often have higher risk ALL, their overall cure rates are close to those of children when stratified by risk group.

Acute myeloid leukemia - Biology 1

P173

MICRORNA-155 AND MICRORNA-708 ARE OPPOSING MODULATORS OF HOXA9 ACTIVITY IN ACUTE MYELOID LEUKEMIA

E Schneider[1,*], A Staffas[2], L Fogelstrand[2], S Yuan Wei[2], L Arabanian[2], L Röhner[1], J Ruschmann[3], M Mirkovic-Hösle[4], M Mulaw[5], A Scheffold[5], C Buske[1], H Döhner[5], L Bullinger[5], M Heuser[6], K Döhner[5], RK Humphries[3], A Rouhi[5], L Palmqvist[7], F Kuchenbauer[1]
[1]Department of Internal Medicine III, University Hospital Ulm, Ulm, Germany, [2]Department of Clinical Chemistry and Transfusion Medicine, Institute of Biomedicine, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, [3]Terry Fox Laboratory, Vancouver, Canada, [4]Terry Fox Laboratory, Vancouver, Sweden, [5]University Hospital Ulm, Ulm, [6]Hannover Medical School, Hannover, Germany, [7]Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

Background: In order to identify microRNAs (miRNA) relevant in acute myeloid leukemia (AML), we profiled global miRNA expression in a murine AML progression model based on Hoxa9 and Meis1 overexpression.
Aims: We found miR-155 and miR-708 as the most significantly upregulated miRNAs in leukemic Hoxa9/Meis1 cells compared to the preleukemic Hoxa9/ctrl cells (both p<0.01). Subsequent analysis of primary AML cases (n=38) comprising various AML subtypes showed significantly elevated levels of miR-155 and miR-708 in all samples compared to total bone marrow from healthy donors, indicating potential oncogenic roles for these miRNAs. We further investigated, *in vivo*, the role of miR-155 in AML by retroviral overexpression with Hoxa9 in murine bone marrow (mbm) cells followed by syngeneic transplantation. Overexpression of miR-155 in conjunction with Hoxa9 (Hoxa9/miR-155) caused a significantly accelerated onset of a myelomonocytic leukemia (p<0.001), but still a less aggressive course of disease compared to mice transplanted with Hoxa9/Meis1 (p<0.001). In order to assess if miR-155 is dispensable for the onset of AML, we transformed miR-155-/- and miR-155+/+ mbm with Hoxa9/Meis1 followed by syngeneic transplantation. No difference in onset of AML was observed. Further analysis revealed that absence of miR-155 impaired homing of Hoxa9/Meis1 cells but did not impact their proliferation rate, which eventually compensated for impaired engraftment in this AML model.
Methods: We then hypothesized that the combination of miR-155 and miR-708 could further replace the oncogenic potential of Meis1. Therefore, mbm cells were retrovirally transduced with Hoxa9, miR-155 and miR-708 (Hoxa9/miR-155/miR-708) or Hoxa9 and miR-708 (Hoxa9/miR-708) and functionally analyzed *in vitro* and *in vivo*. To our surprise, miR-708 abrogated the leukemogenic effect of Hoxa9, alone or in combination with Hoxa9/miR-155 *in vivo* (p=0.0117, p<0.0001), with little or no engraftment. Transcriptome analysis revealed that miR-155 and miR-708 have opposite effects on Hoxa9-induced transcription.
Results: To further understand why miR-708, a potent tumor suppressor miRNA, is upregulated in the highly aggressive Hoxa9/Meis1 AML cells, we explored the role of miR-708 in leukemia initiating cells (LIC). Hoxa9/Meis1 cell subpopulations enriched for LIC based on c-kit, Mac-1 and Gr-1 expression were FACS-sorted and transplanted into syngeneic mice. The c-kit$^+$Gr-1$^-$Mac-1$^-$ cells caused a significantly shorter survival of transplanted mice compared to the other sorted subpopulations (p=0.0072 and p=0.0021, respectively), with the c-kit$^-$Gr-1$^+$Mac-1$^+$ subpopulation resulting in the longest survival. This was mirrored by lower expression of miR-708 in the LIC-enriched c-kit$^+$Gr-1$^-$Mac-1$^-$ subpopulation compared to bulk (p=0.032), whereas there was no difference in miR-155 expression. Similar findings were made in human AML samples (n=7) sorted into LIC-enriched subpopulations using CD117, CD34 and CD38. Together, these results highlight the role of miR-708 as an orchestrator of the leukemic hierarchy through its tumor suppressor activity.
Summary/Conclusions: In conclusion, we demonstrate for the first time a functional role for miR-155 in homing of AML cells. In addition, we propose as a novel concept where miR-708, a tumor suppressor miRNA, stratifies the leukemic hierarchy.

P174

VENTX INDUCES EXPANSION OF PRIMITIVE ERYTHROID CELLS AND CONTRIBUTES TO THE DEVELOPMENT OF ACUTE MYELOID LEUKEMIA IN MICE

E Gentner[1,*], NM Vegi[1], MA Mulaw[1], T Mandal[1], A Tasdogan[2], L Quintanilla-Martinez[3], K Döhner[4], H Döhner[4], L Bullinger[4], T Haferlach[5], C Buske[1], VP Rawat[1], M Feuring-Buske[4]
[1]Institute of Experimental Cancer Research, CCC and University Hospital of Ulm, [2]Institute of Immunology, Ulm University, Ulm, [3]Institute of Pathology, University of Tübingen, Tübingen, [4]Department of Internal Medicine III, University Hospital of Ulm, Ulm, [5]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Homeobox genes are key factors in the development of acute leukemias. So far, little is known about the role of non-clustered homeobox genes such as *VENTX*. The Vent-like homeobox gene *VENTX* is a member of the Vent gene family in mammals and is the mammalian homolog of the *Xenopus xvent* gene. Our group has previously shown that the homeobox gene VENTX shows high and aberrant expression in human acute myeloid leukemia (AML) characterized by the AML1-ETO (AE) fusion (Rawat *et al.*, PNAS 2010).
Aims: With this study, we wanted to test the functional relevance of VENTX in the development of AE positive AML in mice.
Methods: To address this, mice were transplanted with bone marrow progenitor cells retrovirally engineered to express VENTX or AML1-ETO alone or in combination.
Results: Whereas none of the AML1-ETO mice developed any disease, all the recipients of AML1-ETO/VENTX double transduced cells succumbed to AML after a median latency of 334 days (range 19-403 days) post transplantation. Of note, induced AML cases were positive for erythroid markers such as CD71 and Ter119. Strikingly, VENTX alone induced a massive expansion of the primitive erythroid compartment in all transplanted mice. Furthermore, this massive perturbation in differentiation converted into an acute erythroleukemia in a fraction of mice. All leukemias in the AE/VENTX and the VENTX experimental arms were rapidly transplantable with a median latency of 40 days until leukemia induced death, characterized by high blast counts in the bone marrow (83%, range 55% - 92%). *Ex vivo*, leukemic cells grew permanently generating AE/VENTX positive cell lines. RNA-Seq analyses from CD34$^+$ cord blood transduced with VENTX documented 279 differentially expressed genes compared to the empty vector control, comprising pathways belonging to the categories “viral carcinogenesis”, “cytokine-cytokine receptor interaction”, “JAK-STAT signaling”, “cancer”, “signaling pathways in cancer”, “transcriptional misregulation in cancer” and “Huntington’s disease” in the KEGG analysis. Genes necessary for terminal erythroid differentiation such as the EPO-receptor and GATA1 were downregulated by constitutive VENTX expression. In line with the observation of VENTX induced primitive erythroid expansion in mice, VENTX was highly expressed in patients with primary human erythroleukemias and polycythemia vera. Knockdown of VENTX in the erythroleukemic HEL cell line significantly blocked growth *in vitro* and engraftment in NSG mice. Overexpression of VENTX impaired expression of genes linked to erythroid differentiation in human stem and progenitor cells.
Summary/Conclusions: In summary, these data indicate that aberrant expression of VENTX induces expansion of primitive erythroid cells and collaborates with AML1-ETO in inducing AML in mice.

P175

ABNORMAL INTRAGENIC TRANSCRIPTIONAL ACTIVATION IN MLL-AF9 AND KAT6A-CREBBP ACUTE MYELOID LEUKEMIA (AML)

AE Marneth[1,*], K Prange[2], SM Bergevoet[1], A Obulkasim[3], CM Zwaan[3], MM Van Den Heuvel-Eibrink[3], T Haferlach[4], M Fornerod[3], JH Jansen[1], J Martens[2], BA Van Der Reijden[1]
[1]Laboratory Medicine, Laboratory of Hematology, Radboudumc, [2]Department of Molecular Biology, Faculty of Science, Nijmegen Centre for Molecular Life Sciences, Radboud University, Nijmegen, [3]Pediatric Oncology/Hematology, Erasmus MC-Sophia Children’s Hospital, Rotterdam, Netherlands, [4]MLL Munich Leukemia Laboratory, Munich, Germany

Background: The mutated transcription factors AML1-ETO, CBFB-MYH11 and CEBPA cause unique pathogenic gene expression profiles (GEPs) in AML. Previously, we identified an AML subgroup with a unique GEP characterized by outlier high expression of the *BRE* gene. Most cases with this unique GEP harbor the oncogenic transcriptional regulator MLL-AF9. However, since ~50% of adult *MLL-AF9*$^+$ AML cases does not exhibit this unique GEP nor outlier high *BRE* expression, we postulated that another pathogenic mechanism besides the MLL-AF9 translocation causes this unique GEP.
Aims: We aimed at characterizing outlier high *BRE* expression and the associated unique GEP in *MLL-AF9*$^+$ AML, whether these phenomena were exclusive to *MLL-AF9*$^+$ AML and whether they associated with known oncogenic pathways.
Methods: AML samples were subjected to RNA-sequencing (n=4), H3K4me3 (n=7) and/or H3K27ac (n=3) ChIP-sequencing. Informed consent was obtained from all subjects prior to this study. 5’ Rapid Amplification of cDNA Ends (RACE) was performed to characterize the 5’ end of BRE transcripts. *BRE* gene expression was measured by qRT-PCR. Expression of an alternate BRE transcript was normalized to PBGD expression and a control sample without outlier high *BRE* expression. A normalized value >500 was considered high. Ingenuity pathway analyses were performed on the top 200 genes positively associated with *BRE* expression in MLL-AF9$^+$ AML.
Results: RNA-seq and qRT-PCR of *MLL-AF9*$^+$ patient samples showed a marked increase in *BRE* expression starting from exon 5, exclusively in samples with outlier high *BRE* expression. H3K4me3 and H3K27ac ChIP-sequencing revealed clear marks in *BRE* intron 4, 3 kb upstream of *BRE* exon 5, only in AML cases with outlier high *BRE* expression. To demonstrate that this region relates to active transcription, we performed 5’ RACE. A new transcript starting in *BRE* intron 4 near the H3K4me3/H3K27ac marks was identified, with sequences spliced to *BRE* exon 5. A qRT-PCR specific for the alternate BRE

transcript showed that it was frequently expressed in adult *MLL-AF9* samples and in samples with the *KAT6A-CREBBP* fusion gene (18/35, median expression high 8580, low 0.6). This is in line with published data showing that part of *MLL-AF9*$^+$ and *KAT6A-CREBBP*$^+$ samples share a common GEP. Also childhood *MLL*-rearranged and *KAT6A-CREBBP*$^+$ AML samples frequently expressed the alternate BRE transcript (31/43, median expression high 8172, low 26.9). Alternate *BRE* expression was generally low in patients with other types of AML (n=42, 1.4) and non-AML hematological malignancies (n=10, 0.4) or normal CD34$^+$ and bone marrow cells (n=14, 0.3). A polymorphism in BRE intron 5 revealed that alternate *BRE* transcription initiation is bi-allelic. Importantly, analysis of genome-wide H3K4me3 marks and RNA-seq data uncovered 98 potential intragenic transcriptional activation sites, several of which are in genes correlating with high *BRE* expression. Ingenuity pathway analyses using the top 200 genes positively associated with *BRE* expression, identified potential pathogenic pathways including p53 and protein kinase A signaling (p<0.03).
Summary/Conclusions: Alternate transcription initiation in the ALK gene was recently identified as oncogenic mechanism causing melanoma (Wiesner *et al.*, Nature, 2015). Our data show genome-wide alternate transcription initiation as new phenomenon in *MLL-AF9*$^+$ and *KAT6A-CREBBP*$^+$ AML cases that exhibit a unique GEP. Potential oncogenic pathways were identified in these AML subgroups. Further studies investigating the molecular mechanisms contributing to alternate transcription initiation in AML are warranted.

P176

HHEX TRANSFORMS PROMYELOCYTES AND COOPERATES WITH FACTOR INDEPENDENCE TO CAUSE PROMYELOCYTIC LEUKEMIA IN MICE

JT Jackson[1,*], A Ng[1], WS Alexander[1], S Haupt[2], Y Haupt[2], MP McCormack[1]
[1]Cancer & Haematology Division, The Walter & Eliza Hall Institute of Medical Research, Parkville, [2]Tumour Suppression Laboratory, The Peter MacCallum Cancer Centre, East Melbourne, Australia

Background: The transcription factor Hhex (Hematopoietically-expressed homeobox gene) is important for lymphoid commitment and causes T-cell leukemia when overexpressed. We have recently found that Hhex is overexpressed in human myeloid leukemias and maintains leukemia stem cell self-renewal in mouse models of AML via repression of Cdkn2a. However, whether Hhex overexpression also affects hematopoietic differentiation is not known.
Aims: The aims of this study are to investigate the effects of high levels of Hhex expression in growth factor independent hematopoietic progenitor cells and the roles of the functional domains of Hhex.
Methods: To study the effects of Hhex on haematopoietic progenitor differentiation, we immature Lin$^-$Sca$^+$Kit$^+$ (LSK) hematopoietic progenitors were transduced with retroviruses expressing wild-type and mutant forms of Hhex.
Results: Hhex overexpression in LSK cells caused serial replating of myeloid progenitors and to the rapid establishment of IL-3-dependent promyelocytic cell-lines. Structure function analysis demonstrated a requirement of the DNA binding domain and the N-terminal repressive domains of Hhex in promyelocytic transformation. This included a PML protein interaction domain, although loss of PML failed to prevent Hhex-induced promyelocyte transformation *in vitro*. RNA-Seq analysis showed that Hhex overexpression leads to repression of myeloid developmental genes including MPO. To test the leukemic potential of Hhex, Hhex-transformed promyelocyte lines were rendered growth factor-independent using a constitutively active IL-3 receptor common β subunit (βcV449E). The resultant cell-lines caused rapid promyelocytic leukemia in mice.
Summary/Conclusions: In addition to its role in repressing tumor suppressor pathways in myeloid leukemias, overexpression of Hhex causes a differentiation blockade and contributes to promyelocytic leukemia *in vivo*. As such, Hhex overexpression may contribute to human myeloid leukemias via multiple pathways.

P177

A SOMATIC MUTATION OF GFI1B IDENTIFIED IN LEUKEMIA ALTERS CELL FATE VIA A SPI1 (PU.1) CENTERED GENETIC REGULATORY NETWORK

E Anguita[1,*], R Gupta[2], V Olariu[3], PJ Valk[4], C Peterson[3], R Delwel[4], A Chaparro[1], WM Torres[1], T Enver[2]
[1]Hematology, Hospital Clínico San Carlos (IdISSC), MADRID, Spain, [2]Cancer Institute, UCL, LONDON, United Kingdom, [3]Computational Biology and Biological Physics, Lund University, Lund, Sweden, [4]Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

Background: Establishing a link between leukemia mutations and the malignant process requires functional assessment of their biological impact in the context of appropriate normal and malignant primary cells. Against this backdrop, we have identified a mutation (D262N) in the erythroid/megakaryocytic affliated transcriptional repressor GFI1B in acute myeloid leukemia (AML) and explored its biological properties.
Aims: Establishing a link between a *GFI1B* mutation and leukemia in the context of normal and malignant primary cells.
Methods: Human material and clinical information was obtained with informed consent and approval of institutional ethics committee from 69 patients with AML. Point mutation analysis: *GFI1B* coding regions were analyzed by DHPLC. Next generation sequencing performed with Hiseq2000 (Illumina) allowed the identification of a novel mutation. Cloning: *GFI1B* cDNA was amplified, cloned in pGEM-T easy vector and sequenced. Point mutation was introduced by PCR. Wild-type or mutated coding cDNA was cloned into pHRSINCSGW lentivirus vector, expressing green fluorescent protein (GFP). The *SPI1* hairpin was cloned into the SLX vector, with or without wild-type or mutant *GFI1B*. Enrichment of hematopoietic stem and progenitors: Enrichment of human CD34+ cells from mobilized peripheral blood was by magnetic selection (Miltenyi Biotec). Transduced GFP/CD34 positive cells were sorted. Methylcellulose Colony-Forming Cell (CFC) assays: CFC assays were performed with MethoCult H4436 (StemCell Technologies), 15 days. Liquid differentiation assays: CD34+ cells expressing mutant or wild type *GFI1B* were maintained under liquid culture conditions that support multi-lineage differentiation: Myelocult® H5100 with human cytokines, SCF, FLT3L (50 ng/ml); IL-3, GM-CSF, M-CSF (10 ng/ml); G-CSF (0.1 MUI); EPO (100 ng/ml) for 5-6 days. MDS cell culture: CD34+ cells were cultured in MyeloCult® H5100 with 10% (v/v) HS-5 conditioned medium, human SCF and IL-3 (both 50 ng/ml). AML patients gene expression profiling and data analysis: This has been published (www.ncbi.nlm.nih.gov/geo, GSE1159).
Results: We identified a *GFI1B* new mutation (D262N) in an AML patient with antecedent myelodysplastic syndrome (MDS). The GFI1B-D262N mutant functionally antagonizes the transcriptional activity of wild-type GFI1B. GFI1B-D262N promoted myelomonocytic *versus* erythroid output from primary human hematopoietic precursors and enhanced cell survival of both normal and MDS derived human precursors. Re-analysis of 285 AMLs transcriptome data revealed a significant subset of patients in which expression of wild-type *GFI1B* was inversely correlated with that of *SPI1* (*PU.1*). In delineating this GFI1B-SPI1 relationship we show (I) SPI1 is a direct target of GFI1B, (II) expression of GFI1B-D262N produces elevated expression of SPI1, (III) SPI1-knockdown restores balanced lineage output from GFI1B-D262N-expressing precursors, (IV) we also observed that *GFI1B* produced an increase in *MLLT3*, while expression of mutant *GFI1B* reduced *MLLT3* expression.
Summary/Conclusions: In conclusion, our data links GFI1B to both the myeloid and erythroid transcriptional networks by repressing SPI1 and increasing MLLT3 expression, helping to understand its role in lineage specification and its potential in promoting blood malignancy. In fact, our clinical findings and experimental data show that the GFI1B D262N mutant plays a role in AML in humans and does so primarily through the agency of master transcriptional regulator SPI1, reflecting GFI1B physiological function in *SPI1* regulation.

COMPARATIVE FUNCTIONAL ANALYSIS OF THE COMMON INTERACTORS OF 7 MLL FUSION PROTEINS

A Skucha[1,*], A César Razquin[1], A Stukalov[1], M Muhar[2], J Colinge[1], K Bennett[1], J Zuber[2], G Superti-Furga[1], F Grebien[3]
[1]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, [2]IMP, [3]Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria

Background: The Mixed Lineage Leukemia gene (MLL) is a frequent target of chromosomal rearrangements in human malignancies. Balanced translocations result in the fusion of the MLL gene to over 65 different fusion partner genes, leading to the production of novel chimeric proteins. Critical effectors of distinct MLL fusion proteins have previously been identified, and some of them were shown to hold great potential for targeted therapies. However, it is not clear if these effectors are conserved among all MLL fusion proteins or if different molecular mechanisms of transformation exist for distinct MLL fusion proteins.
Aims: We aimed to identify common critical effectors of 7 selected MLL fusion proteins (MLL-AF1p, MLL-AF4, MLL-AF9, MLL-CBP, MLL-EEN, MLL-ENL, MLL-GAS7), which have been presumed to employ different molecular mechanisms of oncogenic transformation.
Methods: Stable cell lines allowing for inducible expression of 7 different affinity-tagged MLL fusion proteins were prepared and transgene expression was verified by qRT-PCR and Western Blotting. Affinity purification coupled to mass spectrometry (AP-MS) identified novel interactors of the 7 MLL fusions. Functional annotation of the resulting interactome revealed significant enrichment of a large number of protein complexes. To assign functional information to a subset of 128 interactors, which were found to bind to ≥5 MLL fusions, we employed a RNAi screening approach. The MLL-AF9-positive MOLM-13 cell line was transduced with pools of viral vectors allowing for the expression of 6 shRNAs targeting the same candidate gene. We established a screening methodology that is suitable for positive and negative selection readouts. To confirm and further validate selected high-confidence candidates we performed additional RNAi screens in other MLL-rearranged- and MLL-wild-type leukemia cell lines and characterized RNAi-knock down efficiencies in various human and murine cell systems.
Results: Advanced statistical filtering using a novel, improved algorithm developed by us yielded a densely connected protein-protein interaction network of >950 proteins around 7 MLL fusions. Many protein complexes previously shown to be associated with MLL were significantly enriched, such as PAF-, SWI/SNF-

and the RNA Pol II containing coactivator complexes. 128 proteins were found to interact with ≥5 of the 7 MLL-fusions. This list of conserved MLL-interactors is highly enriched for proteins with known functions in chromatin metabolism and transcriptional control. Several RNAi screens in different human leukemia cell lines were used to functionally dissect the conserved MLL-fusion interactome. Our screening methodology identified known MLL interacting proteins such as Menin, DPY30 and HCFC1 as critical effectors of MLL fusion proteins, validating the approach. In addition, we selected a small set of novel interactors of MLL fusion proteins for further validation experiments, including a protein involved in cytoskeletal organization.
Summary/Conclusions: In conclusion, we developed a robust experimental pipeline allowing for the functional characterization of cellular effects of MLL fusion proteins in a comprehensive and comparative manner, which will contribute to further clarify the molecular mechanisms of MLL-fusion dependent leukemogenesis.

P179

TRANSFORMING ACTIVITY OF THE NUP98-MLL FUSION IN A CONDITIONAL TRANSGENIC MOUSE MODEL

A Thanasopoulou[1,*], M Mendez[1], S Juge[1], A Tzankov[2], A Peters[3], J Schwaller[1]
[1]Department of Biomedicine, Children's University Hospital, [2]Institute of Pathology, University Hospital Basel, [3]Friedrich Miescher Institute, Basel, Switzerland

Background: Genes encoding for mixed-lineage leukaemia (MLL) and nucleoporin 98 (NUP98) are both involved in multiple recurrent chromosomal rearrangements associated with haematological malignancies. Inv(11)(p15q23), present as a sole cytogenetic abnormality in patients with myelodysplastic syndromes (MDS) or acute myeloid leukaemia (AML), was reported to lead to the expression of a fusion containing the FG-repeats of NUP98 and almost the entire open reading frame of MLL but lacking the N-terminal menin/LEDGF interaction domain, known to be critical for transformation of all currently known MLL fusions through expression of critical downstream targets like the HOXA gene cluster.
Aims: To address the transforming potential of the NUP98-MLL fusion we established conditional transgenic mice.
Methods: The human NUP98-MLL fusion ORF of 13kb was integrated into the *Hprt* gene locus under the control of a *tetracycline (Tet) responsive element* in mouse ES cells harbouring a *reverse Tet transactivator* (*rtTA*) in the *Rosa26* locus and allowing conditional expression of the transgene by doxycycline (DOX) administration. The effects of conditional NUP98-MLL expression on the haematopoietic system were analysed.
Results: *Ex vivo* expression of NUP98-MLL in lineage-marker depleted bone marrow (BM) cells increased colony formation and replating in methylcellulose. In liquid cultures, NUP98-MLL increased proliferation and impaired differentiation of the cells shown by cell morphology and flow cytometric analysis for Gr-1, Mac-1, CD34 and c-Kit expression. *In vivo* induction of NUP98-MLL led to an MDS-like disease with progression to an AML phenotype after a median latency of 78 weeks. The pre-leukemic phenotype was characterized by the presence of dysplastic myeloid cells in the periphery, decreased Mac-1/Gr-1 expression in the BM, and extensive extramedullary haematopoiesis, especially erythropoiesis in the spleen. These mice also exhibited an increased number of haematopoietic stem and progenitor cells (HSPCs) that provided a significant competitive repopulation advantage when transplanted into irradiated syngeneic recipients. So far, 4 mice have progressed to AML characterized by increased white blood counts, presence of blasts in the periphery with infiltration of the BM, spleen, and other organs. The disease was transplantable into irradiated recipients and depended on NUP98-MLL expression since propagation of the disease was significantly impaired in the absence of DOX. As the fusion lacks the menin/LEDGF interaction domain we addressed the sensitivity to small molecules targeting this interface and expression of the HOX gene cluster. Interestingly, in contrast to cells immortalized by the MLL-AF9 or MLL-ENL fusions, NUP98-MLL expressing cells were resistant to the small molecule Mi2-2 menin inhibitor and did not express high levels of the HOX-A-B-C genes. In addition, treatment with the bromodomain inhibitor JQ-1 did not induce cell cycle arrest or significant cytotoxicity but increased the fraction of cells in >G2 phase suggesting alternative transforming mechanisms of NUP98-MLL implicating the cell cycle checkpoint control.
Summary/Conclusions: We show that transgenic NUP98-MLL expression in mice resulted in an "MDS-like" pre-leukemic state progressing to AML after a long latency. The transforming mechanisms of NUP98-MLL fusion differed from other MLL-fusions resulting in relative resistance to small molecules that are currently being explored for targeted AML therapy.

P180

CONDITIONAL DELETION OF THE HOXA CLUSTER IN MLL-AF9 IS INCOMPATIBLE WITH LEUKEMIA MAINTENANCE

LM Kettyle[1,*], CÉ Lebert-Ghali[2], IV Grishagin[1], GJ Dickson[3], JJ Bijl[4], KI Mills[1], A Thompson[1]
[1]Haematology, Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom, [2]Maisonneuve-Rosemont Hospital Research Center, Montreal, Canada, [3]Division of Cancer Studies, King's College London, London, United Kingdom, [4]Maisonneuve-Rosemont Hospital, Montreal, Canada

Background: Hox gene expression is high in hematopoietic stem/progenitor cells (HSPCs), decreases during normal differentiation but remains elevated in leukemia subtypes. Polycomb repressor complexes and histone modifiers, *e.g.* Mixed Lineage Leukemia (MLL), are key regulators of Hox expression. MLL rearrangements, frequent in acute leukemia, are associated high HOXA expression. However, necessity for the HoxA cluster in MLL-leukemia maintenance is not fully elucidated.
Aims: Determine the criticality of the HoxA cluster in MLL-AF9 leukemia maintenance.
Methods: Ectopic overexpression of MLL-AF9 (MA9) in HSPCs in conditional compound transgenic mouse backgrounds MxCre^{+}/HoxA$^{flox/flox}$ (MAFF) or HoxA$^{flox/flox}$ (AFlox) models resulted in increased colony formation and growth in liquid culture. Transformed colonies, serially re-plated (n=5) in methylcellulose and transplanted into sub-lethally irradiated recipient mice, resulted in primary leukemia. Initially, MAFF-MA9 leukemias were used to examine *in vivo* deletion of the HoxA cluster using intraperitoneal injections of Poly(I:C) to initiate an interferon response. To further examine the necessity for the HoxA cluster in disease maintenance, AFlox-MA9 leukemias were treated e*x vivo* with Cre-recombinase (MSCV-Cre-GFP) or vector control (MSCV-GFP), sorted based on GFP expression and used for gDNA-PCR, gene expression (Illumina NextSeq) and transplantation into sub-lethally irradiated recipient mice (500 cGy).
Results: Generation of MLL-AF9 leukemias in the MAFF background (MAFF-MA9) resulted in deletion of one HoxA cluster allele (HoxA$^{+/-}$), validated by genomic PCR and gDNA sequencing from expanded single colonies, presumably due to viral-induced activation of the Mx1 promoter. Poly(I:C) treatment of these mice resulted in a modest extension in survival (1-2 days) compared to controls. Direct treatment of MAFF-MA9 cells with interferon-α (*in vitro*) resulted in further deletion of the HoxA cluster (HoxA$^{-/hypo}$) and significant reduction in colony formation compared to controls. Although non-leukemic MAFF HSPCs retained colony forming ability after complete HoxA cluster deletion (HoxA$^{-/-}$) no HoxA$^{-/-}$ colonies were recovered from the interferon-α treated MAFF-MA9 cultures. Cre-recombinase-induced deletion of the HoxA cluster from AFlox-MA9 leukemia cells was confirmed by gDNA-PCR and sequencing. Transplantation of Cre-treated AFlox-MA9 cells resulted in significant increased survival ($P<0.002$) by up to 74 days in recipient mice, compared to controls. Further examination of the leukemias that developed from these Cre-treated AFlox-MA9 cells demonstrated retention of one allele of the HoxA cluster, as a result of escapees. To gain insight into the molecular mechanisms underlying the HoxA requirement for MLL-AF9 maintenance, matched Cre- or control treated AFlox-MA9 samples used for the transplantation were further examined for differential gene expression by Illumina NextSeq analysis. Gene expression signatures obtained from this analysis were submitted to the LINCS database to identify candidate small molecules that can mimic the HoxA deletion in MLL-AF9 leukemia.
Summary/Conclusions: Together these data support a fundamental role for the HoxA cluster in MLL-AF9 maintenance indicating dependency for this leukemia subtype which may be exploited for therapeutic benefit.

P181

TRIB2 TRANSFORMED GMP AS THE MYELOID LEUKEMIA INITIATING CELL

K Yalla[*], C O'Connor, J Campos, K Keeshan
Paul O'Gorman Leukemia Research Centre; Institute of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom

Background: TRIB2 is a member of the mammalian Tribbles family of serine/threonine pseudokinases. When ectopically expressed in hematopoietic stem and progenitor cell (HSPC) enriched bone marrow cells, TRIB2 was shown to induce acute myeloid leukemia (AML) in a murine transplant model dependent on C/EBPα degradation, showing it to be a potent myeloid oncogene. The cell of origin or leukemia initiating cell (LIC) refers to the cell from which a specific leukemia normally arises, and it is hypothesised that the LIC may influence the progression, disease phenotype and response to therapy. It remains unclear whether the LIC is a HSC or a more committed progenitor cell in TRIB2-driven AML.
Aims: Our current study focuses on identifying the LIC in TRIB2-driven AML and characterizing its role in disease potency and maintenance.
Methods: FACS sorted CD45.2^{+} stem and progenitor cell populations (HSC, MPP, CMP, GMP and MEP) transduced with a lentiviral vector encoding TRIB2 were cultured in methocult supplemented with cytokines that support myeloid cell growth and differentiation. Following the first plating (P1), GFP^{+} cells were sorted and serially replated. Cells which still formed colonies by the third replating (P3) implied acquisition of self-renewal ability and increased proliferation characteristic of myeloid transformation. These CD45.2^{+} cells from P3 were transplanted into sublethally irradiated CD45.1^{+} C57BL/6 recipient mice and chimeric animals were monitored for 1 year. Chemoresistance experiments were performed on the bulk bone marrow population (CD45.2^{+} cells

>95%) from the TRIB2 AML mice. Cells were treated with a range of concentrations of daunorubicin (DNR), followed by trypan blue cell counts to assess viability.
Results: Our study identified that while lentivirally transduced TRIB2 can transform all stem and progenitor cell populations of the hematopoietic system with variable efficiencies *in vitro*, the GMP subpopulation was identified as the LIC of TRIB2-driven AML. TRIB2 transformed GMP cells generated a more potent AML with complete penetrance and shortened latency compared to all other HSPC populations analysed. Indeed, phenotypically different diseases were propagated from TRIB2 expression in the HSC and GMP, with the former having a weakly penetrant, longer latency AML with a mixed lineage phenotype, whereas the later was a dominantly myeloid disease phenotype with a short latency. We next addressed the chemotherapeutic response of TRIB2 positive AML cells. We show that GMP-TRIB2 AML and bulk TRIB2 AML cells are chemoresistant. TRIB2 overexpression decreases DNR induced apoptosis, and knockdown of TRIB2 expression in AML cells leads to an increase in apoptotic gene expression. Our studies illustrate that TRIB2 expression is key in mediating the anti-apoptotic signals following DNR treatment.
Summary/Conclusions: We identify the GMP as the LIC in TRIB2 driven AML. Our findings are further supported by our previous work showing that degradation of C/EBPa is required for TRIB2-driven AML and the GMP population expresses the highest level of C/EBPa in hematopoiesis. We provide evidence for TRIB2 role in chemoresistance, and that the TRIB2 LIC is a highly chemoresistant cell. Our findings provide insight into the molecular events contributing to AML, and provide potential for novel avenues for therapeutic targeting.

P182

TRIB2 REGULATES THE CELL CYCLE UNDER STRESS CONDITIONS IN A MURINE CELL MODEL OF LEUKEMIA

M Salomè*, K Keeshan
Paul O'Gorman Leukaemia Research Centre, Institute of Cancer Sciences, MVLS, University of Glasgow, Glasgow, United Kingdom

Background: *TRIB2* is a known oncogene in different leukemias (AML, T-ALL) and can interact with different signalling pathways promoting the modulation of transcription factor and kinase proteins activation and expression in cancer. The expression level of TRIB2 is low in the myeloid lineage, but can be aberrantly increased in AML and other cancer types by different transcription factors (*e.g.* NOTCH1, MEIS1, E2F1, C/EBPα p30, PITX1 and TAL1). The tumorigenic mechanism of deregulated TRIB2 in myeloid cells has been elucidated, and involves degradation of the tumor suppressor C/EBPα p42. Far less is known about TRIB2 role in other AML oncogenic pathways. A link between TRIB2 and other key AML oncogenes has been documented, where *TRIB2* is one of the targets of Meis1 in NUP98/HOXD13/MEIS1-AML cells and HOXA9 has been shown to cooperate with TRIB2 to accelerate Trib2 driven AML. The mechanism of TRIB2 oncogenic cooperativity in AML is currently not known.
Aims: To assess the role of TRIB2 in the AML oncogenic pathways. In particular, we aimed to unravel the link between Trib2 and cell cycle progression after genotoxic stress.
Methods: To study the function of TRIB2, we utilised hematopoietic stem and progenitor cells (HSPCs) from WT and Trib2$^{-/-}$ mice. We generated an *in vitro* model of transformed leukemic cells by retrovirally expressing the fusion gene NUP98/HOXA9 (NH9) in murine HSPC and expanding them continuously in presence of IL3. Immortalized WT and Trib2$^{-/-}$ NH9 cell lines were challenged with the chemotherapeutic drug Daunorubicin (DNR) and apoptosis, cell cycle progression and DNA damage signalling pathways were analysed and compared between WT and Trib2$^{-/-}$ transformed cells using standard FACS, WB and qPCR techniques.
Results: Sensitivity to DNR is comparable between WT and Trib2$^{-/-}$ NH9 cells, as shown by AnnexinV-DNA double staining. Despite this, analysis of cell distribution within the cell cycle phases (GO, G1, S-G2-M) in the presence of DNR showed that Trib2$^{-/-}$ NH9 cells do not arrest in GO in response to the treatment as WT NH9 cells do, but rather continue to progress through to G2/M cell cycle phases. Moreover Trib2$^{-/-}$ NH9 cells exhibit higher expression of the mitotic marker Phospho-Histone H3 after the DNR treatment. Gene expression analysis revealed that Trib2$^{-/-}$ NH9 cells treated with DNR show evidence of DNA damage signalling pathways activation (with upregulation of p21, p16 and GADD45a). This response was higher than in the WT counterpart, suggesting a stronger or unresolved damage signalling in the Trib2$^{-/-}$ NH9 cells. MAPK p38 has a role in the activation of cell cycle check points after DNA damage, and is involved in cell cycle arrest to allow cells to repair the DNA before re-entering the cell cycle. WB analysis suggests that Trib2$^{-/-}$ NH9 cells have impaired phosphorylation of p38 in response to DNA insult consistent with the absence of a cell cycle arrest. Consistent with the absence of cell cycle checkpoint, p21 protein levels are also reduced in Trib2$^{-/-}$ NH9 cells compared to the WT cells after DNR treatment. Evidence for γH2Ax modification in Trib2$^{-/-}$ NH9 cells confirms that the damage was present and accumulated unresolved.
Summary/Conclusions: Our results show that Trib2 plays a role in the cell cycle checkpoint in transformed cells following DNA damage. The absence of Trib2 results in the loss of checkpoint controls including p38 MAPK and p21 activation and downstream activation of protective cell cycle mechanisms. These data suggest that the expression of Trib2 in AML may protect cells from genotoxic stress by preventing the accumulation of DNA damaged cells.

P183

CHROMOTHRIPSIS: A NEW MECHANISM OF CANCER INITIATION AND PROGRESSION IN ADULT ACUTE MYELOID LEUKEMIA

MC Fontana[1,*], G Marconi[1], JD Milosevic Feenstra[2], L Semerad[3], V Guadagnuolo[1], C Papayannidis[1], G Simonetti[1], A Padella[1], A Ferrari[1], E Franchini[1], S Soverini[1], S Paolini[1], S Parisi[1], MC Abbenante[1], C Sartor[1], M Manfrini[1], F Volpato[1], M Doubek[3], M Steurer[4], Z Racil[3], R Kralovics[2], G Martinelli[1]
[1]DIMES, Institute of Hematology, University of Bologna, Bologna, Italy, [2]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria, [3]Department of Internal Medicine - Hematology and Oncology, Masaryk University and University Hospital Brno, Brno, Czech Republic, [4]Division of Hematology and Oncology, Medical University of Innsbruck, Innsbruck, Austria

Background: Chromosomal abnormalities are predictive of response in Acute Myeloid Leukemia (AML) and guide therapeutic strategies. Chromothripsis, a one-step catastrophic mechanism of genomic instability, could represent a driving force in the development and progression of hematological diseases.
Aims: To discover the mechanisms underlying the pathogenesis, chromosomal instability and heterogeneity of AML, we used single-nucleotide polymorphism (SNP) microarrays to study chromothripsis in our cohort of patients (pts).
Methods: We performed classical cytogenetic karyotyping and microarray analysis using Genome-Wide Human SNP Arrays 6.0 or Cytoscan HD Arrays (Affymetrix) in 303 AML pts at diagnosis (both *de novo* and secondary). SNP Array data were analyzed by Nexus Copy Number™ v7.5 (BioDiscovery, v.7.5). The survival analysis was performed with Kaplan-Meier method using Mantel-Cox test.

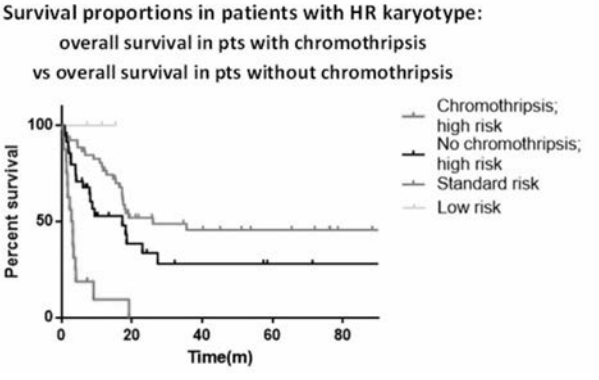

Figure 1.

Results: Twenty-three out of 303 pts (7.6%) showed chromothripsis events involving different chromosomes (2, 3, 4, 5, 6, 8, 9, 10, 11, 12, 13, 15, 16, 17 and 20), reflecting the random distribution of the one-step catastrophic event. By Nexus Copy Number we defined chromothripsis as a 2-3 variation of copy number (CN) state with at least 5 subsequent rearrangements, including CN gain and loss, interspersed with regions of diploid state and variable number of breakpoints. The pts affected by chromotripsis had a median age of 67.5 years, complex karyotype and high risk (HR) disease according to ELN definition. This group was screened for *FLT3*, *NPM1*, *IDH1*, *IDH2* and *TP53* mutational status. *TP53* was evaluated in 21/23 pts, displaying that the majority (17/21) of the pts with chromothripsis harbored a *TP53* mutation, while 4/21 pts were wild type for *TP53* but 2 of those had a single-copy loss of the gene. *TP53* mutation has a significantly higher incidence in chromothripsis pts than in others without chromothripsis ($p<0.001$). Chromothripsis defines a group of pts with poor prognosis compared with other in the cohort ($p<0.001$), with a median survival of 2.9 months and 19.1 months respectively. Remarkably, chromothripsis defines the group with the worst prognosis even if compared with pts harboring HR[JM1] karyotype features without chromothripsis ($p<0.001$) (Fig.1). Median survival was 2.9 months in pts with chromothripsis, 17.3 months in HR pts without chromothripsis, and 26.0 months for pts with standard risk features. Moreover, by comparing pts with (23/303) and without (280/303) chromothripsis, we identified several genes differentially altered between the 2 groups ($p<0.001$). The statistically most common deleted genes in chromothripsis are *RAD50*, *MARCH3*, *PRDM6*, *SSBP2*, *CDC23*, *HDAC3*, *CHD1*, *TBCA*, *LMNB1*, *JMY*, with 5q being the main altered chromosomic region. While the significant amplifications included *ZDPM2*, *RUNX2*, *RUNX1T1*, *FLT3*, *ERG*, *TTC3* and *GPC6*. The most significantly affected pathways in the chromothripsis group of pts are: regulation and extension of axon, canonical Wnt signaling pathway involved in regulation of cell proliferation, positive regulation of mitotic cell cycle, chromatin organization, telomere formation and maintenance ($p<0.001$).
Summary/Conclusions: Chromothripsis is a recurrent event in adult AML and independently defines a group of pts with poor prognosis. It is strongly associ-

ated with *TP53* mutations and losses, highlighting the importance of *TP53* for maintaining genomic stability in adult AML.

AN EVALUATION OF THE TYROSINE KINASE INHIBITOR PACRITINIB IN PATIENTS WITH RELAPSED FLT3-MUTATED ACUTE MYELOID LEUKAEMIA (THE UK NCRI AML17 STUDY)

S Knapper[1,*], A Grech[1], P Cahalin[2], H Kaur[3], P Mehta[4], D Richardson[5], D Taussig[6], R Hills[1], A Burnett[7], N Russell[8]
[1]Department of Haematology, Cardiff University, Cardiff, [2]Blackpool Teaching Hospitals NHS Foundation Trust, Blackpool, [3]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, [4]University Hospitals Bristol NHS Foundation Trust, Bristol, [5]University Hospital Southampton NHS Foundation Trust, Southampton, [6]The Royal Marsden Hospital NHS Foundation Trust, Sutton, [7]CTI Life Sciences Ltd, London, [8]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Background: Pacritinib (formerly SB1518) is a third generation tyrosine kinase inhibitor with activity against a number of targets of relevance to acute myeloid leukaemia (AML). Kinases with IC_{50} <50nM to pacritinib include JAK2 (6nM), JAK2V617F (9nM), FLT3 (15nM), interleukin-1 receptor-associated kinase (IRAK1) (14nM) and c-FMS / colony-stimulating factor-1 (CSF1R) (40nM). FLT3 remains of intense interest as a therapeutic target in AML; activating mutations of *FLT3* are associated with early relapse after chemotherapy and poor survival. Efficacy against JAK2 has motivated study of pacritinib in myelofibrosis. Although *JAK2* mutations are rare in AML, the JAK-STAT pathway is frequently activated and may represent a mechanism of resistance to FLT3 inhibitors. There is also pre-clinical evidence that activity against IRAK1 and CSF1R may overcome microenvironmental resistance mechanisms. For these reasons we undertook a preliminary assessment of pacritinib as part of the UK NCRI AML17 Trial (ISRCTN55675535).
Aims: To assess the safety and efficacy of pacritinib monotherapy in *FLT3*-mutated AML patients who had relapsed following chemotherapy.
Methods: Patients commenced pacritinib at an oral dose of 200mg bid with the option, if well-tolerated, of increasing to 300mg bid after 14 days of treatment. Clinical assessments included optional bone marrow at day 14 and formal response assessment including blood and bone marrow examination at day 28. Toxicity was assessed using NCI-CTC Version 3.0. Treatment beyond day 28 was at the investigator's discretion. Patients were permitted to continue on pacritinib for up to 12 months and/or proceed to salvage chemotherapy with or without allogeneic SCT.
Results: A total of 30 patients received pacritinib therapy. Median age was 54 years (16-68), median presenting WBC was $35.6x10^9$/l (1.2-182) and all had cytogenetically intermediate risk disease. 26 patients (87%) had *FLT3*-ITD mutations (median *FLT3*-ITD allelic burden 30% [7-94]) and 4(13%) had *FLT3*-TKD point mutations; 16 patients (53%) had concomitant mutated *NPM1*. Four patients had received previous TKI therapy, all with lestaurtinib (CEP701) alongside first-line chemotherapy. Eight patients had received prior allogeneic SCT. 28 of the patients had relapsed disease; median duration of first CR was 6.5 months (1-65). 23 patients were in first relapse (including 1 molecular relapse) and 5 in second relapse. Two patients had primary refractory disease. Patients received a median of 64 days pacritinib (3-200); all were dosed at 200mg bid with 1 patient escalating to 300mg bid. Most toxicities were minor (grade1/2). The most common toxicities were nausea/vomiting (53%), diarrhoea (33%) and raised ALT (30%). One patient stopped pacritinib after 3 days due to nausea (grade 2). 6 further patients were considered non-evaluable either due to early death (2 patients; infections), inadequate response evaluation sampling (2 patients) or the addition of salvage chemotherapy within the 28-day evaluation period (2 patients). In evaluable patients, the overall rate of response to pacritinib monotherapy at the day 28 assessment was 17% (4/23) including 3 CRi (2 CRp) and 1 PR; 3 of these patients were successfully bridged to allogeneic SCT with the fourth patient relapsing at day 60. 3 additional patients (13%) achieved >50% reduction in bone marrow blasts without evidence of peripheral count recovery, 2 going on to receive salvage chemotherapy with FLAG-Ida. 16 patients (70%) were considered non-responders. The 7 clinical responders included 6 patients treated in first relapse and 1 with primary refractory disease; all had *FLT3*-ITD mutations.
Summary/Conclusions: This is the first clinical experience of pacritinib in AML. Tolerability was encouraging and, in the challenging setting of relapsed/primary refractory FLT3-mutated AML where FLT3-directed monotherapy has seldom achieved complete remission, clinical responses were seen in one-third of evaluable patients. Importantly, several patients were successfully bridged to potentially-curative allogeneic SCT. Further clinical evaluation of pacritinib in this setting is warranted.

P185

ORAL THROMBOPOIETIN RECEPTOR AGONIST ELTROMBOPAG TREATMENT DURING INDUCTION CHEMOTHERAPY FOR ACUTE MYELOGENOUS LEUKEMIA (AML): RESULTS OF A RANDOMIZED, DOUBLE-BLIND, PHASE 2 STUDY

N Frey[1,*], S Strickland[2], J Szer[3], Á Illés[4], HJ Kim[5], R Ram[6], B Chong[7],

JM Rowe[8], E Borisenkova[9], J Liesveld[10], E Winer[11], A Cherfi[12], S Kalambakas[13], JH Jang[14]

Background: Thrombocytopenia is a significant problem for patients with AML due to the disease process and the side effects of its treatment. Eltrombopag is an orally bioavailable, small molecule, thrombopoietin receptor agonist that stimulates platelet production by a mechanism similar but not identical to endogenous thrombopoietin. A randomized, placebo-controlled, Phase 1 study suggested a benefit of eltrombopag treatment of up to 300 mg daily in patients with advanced myelodysplastic syndromes or AML (Platzbecker U, *et al. Lancet Haematol*. 2015;2:e417-26).
Aims: To assess the safety and tolerability of daily treatment with eltrombopag *versus* placebo in patients with AML receiving anthracycline-based induction treatment; these included rates of adverse events (AEs), changes in left ventricular ejection fraction (LVEF), and clinical laboratory parameters including effects on cytopenias.
Methods: In this randomized, double-blind, Phase 2 study, adult patients with AML of any subtype (except M3 and M7) (n=148), and who had not received previous treatment for AML, received standard induction chemotherapy with daunorubicin on Days 1-3 and cytarabine on Days 1-7 (Table 1), and eltrombopag 200mg (100mg for East Asians) or placebo daily, starting on Day 4. Study drug could be titrated to 100-300mg based on platelet counts. Randomization was stratified by antecedent malignant hematologic disorder (yes/no) and age (18-60 *vs* >60 years). Safety was the primary endpoint. The trial began in September 2013, enrollment is completed, and all patients completed induction/reinduction. Follow up for survival continues. This primary analysis represents results through June 2015.

Table 1. Primary safety and efficacy results of a randomized, placebo-controlled, Phase 2 study of the thrombopoietin receptor agonist eltrombopag in patients with AML receiving anthracyclines-based induction chemotherapy.

	Eltrombopag 100–300 mg Daily (Starting D4)* Daunorubicin 90 mg/m² IV D1–3 (60 mg/m² for patients >60 years) Cytarabine 100 mg/m² IV D 1–7 (n=74)		Placebo Daily (Starting D4) Daunorubicin 90 mg/m² IV D1–3 (60 mg/m² for patients >60 years) Cytarabine 100 mg/m² IV D1–7 (n=71)†

AE, adverse event; D, day; CI, confidence interval; EPAG, eltrombopag; HR, hazard ratio; IV, intravenous; LVEF, left ventricular ejection fraction; OR, odds ratio; MI, myocardial infarction; PBO, placebo.
*EPAG could be increased up to 300 mg once daily (100 mg starting dose for those with East Asian heritage, which could be increased to 150 mg) based on platelet count <100 Gi/L until a platelet count of at least 200 Gi/L is achieved, until remission is assessed by bone marrow biopsy, or for a maximum of 42 days from the start of the chemotherapy induction cycle.

Results: The eltrombopag *versus* placebo groups, respectively, were well matched at baseline: overall median (range) age 58.5 (23-77) *versus* 59.5 (21-75); median (range) platelet counts 51.5 (5-241) Gi/L *versus* 50.0 (9-232) Gi/L; 51% *versus* 42% females; and 22% poor karyotype in both groups. The frequency of AEs did not differ between treatment groups, but frequencies of serious AEs and deaths were greater in the eltrombopag group (with more deaths due to hemorrhage and cancer, which included disease under study and other malignancies) (Table 1). Deaths due to hemorrhage included pulmonary and intracranial/cerebral/brain hemorrhages, and occured during periods of thrombocytopenia. Thromboembolic events were similar between groups (7% *vs* 6% for eltrombopag *vs* placebo). Reductions in LVEF (a potential effect of drug-drug interaction between eltrombopag and daunorubicin) did not differ between groups (Table 1). Increases from baseline in Grade 3/4 laboratory AEs for thrombocytopenia, neutropenia, or anemia did not differ significantly between treatment groups. Time to platelet recovery, time to platelets >100 Gi/L, overall disease response, and survival also did not differ significantly between groups (Table 1).
Summary/Conclusions: The thrombopoietin receptor agonist eltrombopag did not significantly affect rates of thrombocytopenia during induction therapy with daunorubicin and cytarabine or disease response in adults with AML compared with placebo in this primary analysis. No statistically significant difference in LVEF events between eltrombopag and placebo was observed. *Funding:* This study (NCT01890746) was sponsored by GlaxoSmithKline; however, as of March 2, 2015, eltrombopag became an asset of Novartis AG.

SAFETY STUDY OF CRENOLANIB, A TYPE I FLT3 INHIBITOR, WITH CYTARABINE/DAUNORUBICIN OR CYTARABINE/IDARUBICIN INDUCTION AND HIGH-DOSE CYTARABINE CONSOLIDATION IN NEWLY DIAGNOSED FLT3+ AML

E Wang[1,*], R Stone[2], M Tallman[3], J Thompson[1], E Ontiveros[1], G Olson[1], I Galinsky[2], B Pond[4], A Uchida[5], V Urity[5], O Xhori[5], M Macaraeg[5], M Vusirikala[4], P Patel[4], R Walter[6], R Collins[4]
[1]Roswell Park Cancer Institute, Buffalo, [2]Dana-Farber Cancer Institute, Boston, [3]Memorial Sloan Kettering Cancer Center, New York, [4]University of Texas Southwestern, [5]Arog Pharmaceuticals Inc, Dallas, [6]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: Combining tyrosine kinase inhibitors (TKIs) of FLT3, such as midostaurin, with chemotherapy in FLT3+ mutant AML has improved CR rates (59% *vs* 53%) as well as overall survival (OS). Crenolanib is a novel, type I, oral pan-FLT3 TKI demonstrating encouraging single-agent activity against multiply relapsed FLT3-ITD and tyrosine kinase domain (TKD) mutant AML. We here report interim data from a Phase II trial to evaluate the safety and efficacy of crenolanib in combination with upfront chemotherapy (cytarabine plus idarubicin or daunorubicin) in patients (pts) with newly diagnosed FLT3+ AML.
Aims: To assess the safety and tolerability of crenolanib (100 mg TID) with induction and consolidation chemotherapy in newly diagnosed FLT3+ AML. Secondary objectives are to assess CR rate and relapse-free survival following crenolanib and chemotherapy.
Methods: Patients >18 years (y), with newly diagnosed FLT3+ AML (ITD and/or TKD mutants including secondary AML) are eligible. Crenolanib, 100 mg TID, is given daily from day (d) 9 following 7+3 induction (cytarabine 100 mg/m^2/d and either daunorubicin d1-3 (<60y: 90 mg/m^2; ≥60y: 60 mg/m^2) or idarubicin 12 mg/m^2 d1-3). Re-induction is permitted for inadequate leukemia cytoreduction on days 15-28. Consolidation with 6 doses of high dose cytarabine (HiDAC) (<60y: 3 g/m^2; ≥60y: 1g/m^2) is given with daily crenolanib (100 mg TID) starting d7. Eligible pts can proceed to allogeneic SCT. Crenolanib maintenance can be given for 1y post HiDAC or SCT. Crenolanib is held if total bilirubin is abnormal.
Results: 19 pts with newly diagnosed FLT3+ AML have so far been enrolled (11 females, 8 males) with a median age of 55y (range 23-74y). Median baseline WBC was 27,740/µL (range 1,760-248,800; 4 pts had WBC >100,000/µL). 13/17 (76%) of pts had normal karyotype, 2 pts had trisomy 8, 1 pt was pseudodiploid and 1 pt had complex karyotype. Majority of pts, 79% (15/19), were FLT3-ITD+ve with 10/15 also carrying NPM1 mutation. 4/19 (28%) pts were FLT3-D835+ve with 1 pt also carrying NPM1 mutation and 1 pt carrying D835Y and N841T mutations. 11/19 pts were tested for other mutations present at baseline: DNMT3A in 6/11 pts (55%), SF3B1, IDH1, TET2 and RUNX1 each in 2/11 pts (18%), and IDH2, MLL, SRSF2 and WT1 each in 1/11 pts (9%). All 19 pts have received induction chemotherapy: 13 received daunorubicin (8 pts at 90 mg/m^2, 5 pts at 60 mg/m^2) and 6 received idarubicin (12 mg/m^2) No pt has required a second induction. 2 pts died prior to starting crenolanib during induction 1 (due to sepsis and respiratory failure) and are not evaluable. Crenolanib 100 mg TID has been well-tolerated in combination with cytarabine/anthracycline induction with only 2 pts requiring dose reductions (due to rash and periorbital edema, respectively). Common AEs are consistent with what is seen with crenolanib monotherapy, including grade 1 or 2 nausea, vomiting, diarrhea and rash. Crenolanib did not appear to delay count recovery; median count recovery for WBC was 28d (range 16-43d) and platelet was 27d (22-46d). A high CR rate was seen in the 14 pts who are currently evaluable: 13/14 pts (93%) achieved CR with full count recovery, and all pts became FLT3-ve. Only 1 pt was refractory after first cycle of induction therapy and was taken off study. To date, 9 pts have received a total of 13 cycles of consolidation with HiDAC and crenolanib. 2 pts have undergone allogeneic SCT.
Summary/Conclusions: Crenolanib can be safely administered at full doses with cytarabine/anthracycline induction chemotherapy and HiDAC consolidation. Initial CR rates after just one cycle of induction with 7+3 and crenolanib are high. To date, no patients have relapsed. Accrual to this trial continues.

PHASE II STUDY OF CLADRIBINE AND LOW-DOSE ARAC ALTERNATING WITH DECITABINE IN OLDER PATIENTS WITH AML

T Kadia*, J Cortes, G Borthakur, E Jabbour, N Daver, N Pemmaraju, S Verstovsek, J Burger, A Ferrajoli, W Wierda, M Konopleva, C DiNardo, N Jain, M Brandt, C Tuttle, X Wang, F Ravandi, G Garcia-Manero, H Kantarjian
Leukemia, MD Anderson Cancer Center, Houston, United States

Background: Treatment of AML in older and unfit patients (pts) with intensive chemotherapy is complicated by increased toxicity and high early mortality. Additionally, many of these pts are not ideal candidates for stem cell transplant (SCT). Lower intensity approaches using hypomethylating agents (HMAs) are currently used for these pts, but more effective therapies are needed. Cladribine, which itself has hypomethylating properties, has been shown to improve survival in AML in combination with standard-dose araC (Holowiecki JCO 2012).
Aims: We developed a low-intensity, prolonged-maintenance treatment protocol studying the combination of cladribine and low-dose araC (LDAC) alternating with decitabine (DAC) in patients aged ≥60.
Methods: Pts with adequate organ function and newly diagnosed AML (excluding APL), including secondary- (s-AML) and therapy-related AML (t-AML), and high risk MDS were eligible. Induction was cladribine 5 mg/m^2 IV over 30 minutes on days 1-5 followed by araC 20mg SQ BID on days 1-10. Consolidation/maintenance consisted of 2 cycles of cladribine 5 mg/m^2 IV over 30 minutes on days 1-3 + araC 20 mg SQ BID on days 1-10 alternating with 2 cycles of DAC 20 mg/m^2 on days 1-5, for a maximum of 18 cycles. One cycle was 4 weeks and up to 2 cycles of induction were allowed.
Results: A total of 86 pts have been enrolled with a median age of 69 years (range, 49-85), including 37 pts (43%) ≥age 70. 49 pts (57%) had s-AML or t-AML and 16 pts (19%) had therapy for an antecedent hematologic disorder. Pt characteristics are listed in Table 1. Of the 86 pts evaluable for response, there were 52 CR (60%), 5 CRp (6%), 2 CRi (2%) and 1 PR (1%) for an overall response rate (CR/CRp/CRi) of 69% (59/86). Of the 49 pts who achieved a CR/CRp and had minimal residual disease (MRD) testing by flow cytometry at day 29, 24 pts (49%), achieved MRD negativity. However, MRD negativity at day 29 did not correlate with improved OS. 13 of the 57 pts (23%) who achieved a CR/CRp went on to SCT. With a median follow-up of 24+ months (m), the median OS is 13.8 m (16.5m in responders) and the median CR duration is 21.1m. (Figure 1a) The 1-year OS estimate is 57%. All pts had cytogenetic and molecular characterization of their AML prior to treatment, allowing correlation with outcomes (Figure 1b). Responses and median OS among different subgroups are shown in Table 1. The 4-week mortality was 1%. Grade ≥3 infections occurred in 16% of pts. There were no treatment-related grade 3/4 non-heme adverse events (AEs). Most common non-hematologic AEs were elevated bilirubin, nausea/vomiting, rash/itching, diarrhea and mucositis.

Table 1. Patient Characteristics (N=74).

Characteristic	N (%)	Outcomes by Genetic Subset (N)	CR/CRp	Median OS (m)
Median age [Range]	69 [49-85]	Diploid karyotype (27)	88%	16.4
Cytogenetics		Adverse karyotype (35)	46%	12.5
Diploid	27 (31)	Complex [> 2 abnl] karyotype (23)	43%	5.3
Adverse	35 (41)	TP53 mutated (12)	50%	16.2
Misc. other	18 (21)	DNMT3a mutated (9)	89%	12.6
Insufficient	6 (7)	FLT3-ITD (8)	100%	14.2
Median BM Blast [Range]	32 [8-95]	JAK2 mutated (7)	57%	7.5
Median WBC [Range]	2.7 [0.5-72.3]	NPM1 mutated (14)	100%	15.2
Median Platelets [Range]	41 [4-772]	RAS mutated (18)	61%	14.3
Median Creatinine [Range]	0.89 [0.46-1.94]			
Median Bilirubin [Range]	0.6 [0.2-2]			

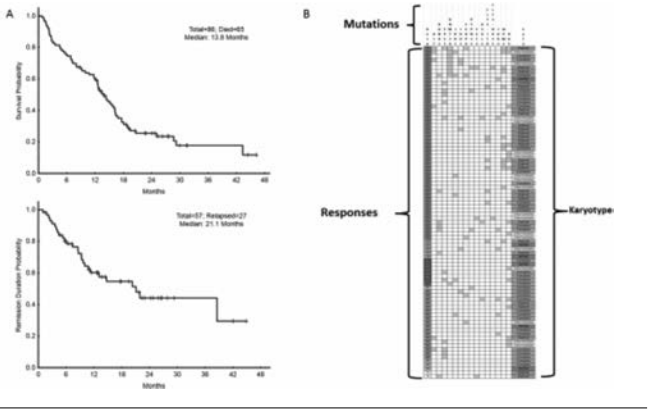

Figure 1.

Summary/Conclusions: The low intensity program of cladribine + LDAC alternating with DAC produces durable responses and is a well-tolerated ambulatory regimen for older patients, including those with unfavorable-risk features.

P188

DIFFERENTIATION RESPONSE TO GILTERITINIB (ASP2215) IN RELAPSED/REFRACTORY FLT3 MUTATED ACUTE MYELOID LEUKEMIA PATIENTS IS ASSOCIATED WITH CO-MUTATIONS IN NPM1 AND DNMT3A

J Canaani[1,*], B Rea[2], R Sargent[2], J Morrissette[2], D Lieberman[2], C Watt[2], M Carroll[1], A Perl[1]
[1]Division of Hematology and Oncology, Abramson Cancer Center at the University of Pennsylvania, [2]Clinical Pathology and Laboratory Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, United States

Background: FLT3 inhibitors show substantial clinical activity in relapsed/refractory *FLT3-ITD* mutated acute myeloid leukemia (AML). A subset of patients show a clinical response manifest by terminal differentiation of bone marrow blasts into granulocytes that contain *FLT3-ITD*. From clinical trials of the FLT3 inhibitor quizartinib (AC220), we observed this differentiation response predominantly among patients with a normal karyotype and mutated *NPM1* and/or *DNMT3A* (Nybakken, *et al.* Leukemia 2015).
Aims: To confirm whether observations from quizartinib trials reflect a common response pattern to FLT3 inhibitor treatment.
Methods: We performed analysis of the local institutional cohort of patients enrolled on a phase 1/2 study of gilteritinib (ASP2215) for relapsed/refractory AML (NCT02014558). All subjects were screened for 33 AML-associated mutations at study entry by next generation sequencing and all available histomorphologic, and cytogenetic material underwent an independent pathologist's blinded review.
Results: We restricted our analysis to the 25 *FLT3*-mutated subjects who received single-agent gilteritinib at ≥80 mg/day, as correlative pharmacodynamic data showed that this dose consistently generated continuous, potent FLT3 target inhibition (Levis MJ, *et al.* ASCO abstracts 2015). 2 subjects were withdrawn prior to the first treatment response assessment (refractory leukemia and lethal infection); 2 subjects had technically insufficient marrows. The remaining 21 subjects were evaluable for marrow response. Subjects had a median age of 61 years (range 22-86 years) and were relapsed or refractory after a median of 2 prior lines of chemotherapy (range 1-7). Subjects received gilteritinib at a median dose of 200 mg (range 80-300) for a median of 154 days (range 38-642). Baseline karyotype was normal in 9/20 (45%). 19/21 patients had *FLT3-ITD* mutation (3 had both *FLT3-ITD* and *FLT3-TKD*), and 2 had *FLT3-TKD* only. Gene mutations seen in >10% of subjects included *NPM1* (13, 62%), *DNMT3A* (11, 52%), *WT1* (8, 38%), *TET2* (7, 33%), and *IDH1/2* (4, 19%). All subjects treated for >28 days showed complete or near-total eradication of peripheral blood blasts. Thirteen subjects (62%) experienced a differentiation response defined by markedly left-shifted clonal granulocytic hyperplasia with persistent *FLT3-ITD:WT* allelic ratio, ≥50% reduction in overall blast percentage from baseline, and peripheral blood neutrophil recovery. 11/13 (85%) subjects with differentiation response had mutated *NPM1*, but only 6/12 (50%) had a normal karyotype. While 2/3 *NPM1* mutated subjects with WT *DNMT3A* did experience differentiation response, 10/11 subjects with *DNMT3A* mutation also had *NPM1* mutations, confounding our ability to associate differentiation response and *DNMT3A* mutation status alone. 3/21 subjects demonstrated both undetectable leukemic blasts from the marrow along with marked allelic ratio reduction or elimination of detectable *FLT3-ITD*, suggesting alternate mechanisms of treatment response (*e.g.* cytotoxicity or clonal selection without differentiation). Additionally, 5/21 evaluable subjects showed minimal to no reduction in marrow blasts. Considering the 8 non-differentiation responses plus the sole patient with growing AML prior to day 28, only 2/9 (22%) had an *NPM1* mutation, and 5/8 had abnormal karyotype.
Summary/Conclusions: Differentiation response to gilteritinib is strongly enriched among relapsed/refractory *FLT3*-mutated patients with *NPM1* and *DNMT3A* mutations. Our data inform response interpretation and may promote future trial enrichment strategies.

P189

PHASE IB/II STUDY OF NIVOLUMAB IN COMBINATION WITH 5-AZACYTIDINE (AZA) IN PATIENTS (PTS) WITH RELAPSED ACUTE MYELOID LEUKEMIA (AML)

N Daver[1,*], J Cortes[1], F Ravandi[1], S Basu[2], G Garcia-Manero[1], E Jabbour[1], N Pemmaraju[1], S Hendrickson[1], S Pierce[1], J Ning[3], G Gonzales[3], M Konopleva[1], M Andreeff[1], G Borthakur[1], C Bueso-Ramos[4], J Blando[2], J Allison[2], H Kantarjian[1], P Sharma[2]
[1]Department of Leukemia, [2]Immunotherapy Platform, [3]Department of Biostatistics, [4]Department of Hematopathology, University of Texas MD Anderson Cancer Center, Houston, United States

Background: PD1+ T-cells are significantly increased in the bone marrow (BM) of pts with relapsed AML as compared to healthy adult donor BM (*Daver et al., AACR 2016*). Epigenetic therapy upregulates PD1 and PD-L1 in MDS/AML and upregulation of these genes may be associated with the emergence of resistance and inferior survival (*Yang et al., Leukemia 2013*).
Aims: This single-center phase Ib/II study was conducted to determine the recommended phase 2 dose (RP2D), efficacy and safety of nivolumab in combination with AZA in pts with relapsed AML.

Methods: Pts are eligible if they have AML and failed prior therapy, have adequate performance status (ECOG ≤2), and organ function. The first six pts received AZA 75mg/m^2 days 1-7 with nivolumab 3mg/kg on Day 1 and 14. Courses were repeated approximately every 4-5 weeks. One of six pts had a dose limiting toxicity (grade 3 pneumonitis) and this dose was established as the RP2D. 24 additional pts have been treated at the RP2D.
Results: To date, 30 pts (15 *de novo*, 15 secondary AML) with a median age of 72 years (range, 45-76) have been enrolled. They included 9 (30%) pts with diploid, 14 (47%) with adverse, and 7 (23%) with miscellaneous cytogenetics. Median number of prior therapies was 2 (range, 1-4), including hypomethylating agent-based (n=17), high dose cytarabine-based (n=15), intermediate dose cytarabine-based (n=7), and targeted therapies (n=5). Median bone marrow blast%, WBC, hemoglobin, and platelet counts were 43% (13-90), 2.3x10^9/L (0.5-81), 9.3g/dL (7.4-12.7), and 28x10^9/L (8-145), respectively. Baseline bone marrow samples from all pts were analyzed for common myeloid mutations by next generation sequencing. The most frequently detected mutations were *DNMT3A* (n=9), *ASXL1* (n=6), *CEBPA* (n=4), *RAS* (n=4), *TP53* (n=3), and *TET2* (n=4). 22 pts are evaluable for response (Fig 1): 4 (18%) achieved complete remission (CR)/ complete remission with insufficient count recovery (CRi), 2 (9%) had hematologic improvement (HI) with blast reduction, 5 (23%) had HI only, and 5 (23%) had ≥50% BM blast reduction only. 6 pts had stable disease (n=2) or progression (n=4). 8 pts are too early for response assessment at this time. Median number of cycles to any response was 2 (1-4). The median follow-up is 3.6 months (1.5-8.7). Grade 3/4 and Grade 2 immune toxicities were observed in 6 (20%) and 5 (17%) pts, respectively. These included 6 pneumonitis, 2 nephritis, 1 skin rash, and 2 transaminitis. Time to onset of toxicities ranged from 4 days to 3.5 months. All toxicities responded rapidly to steroids and all pts were successfully rechallenged with nivolumab. No pts came off study due to immune toxicities. No association between toxicities and response was identifiable. The median progression free and overall survival for 22 evaluable pts was 3.5 and 5.9 months, respectively. These results compare favorably to a historical cohort of 99 relapsed AML pts treated on other hypomethylating agent combination protocols at our institution between 2005-2015 (Table 1). Identification of baseline and dynamic biomarkers of response and survival by sequential immunohistochemistry, flow-cytometry, and RNA-sequencing is currently ongoing.

Table 1. AZA+nivolumab *versus* historical HMA-combinations at MDACC

	AZA+nivolumab N=22	Hypomethylator-combination protocols N=99	*P*-value
CR/CRi	18%	11%	0.36
8-week mortality	5%	20%	0.08
Med PFS	3.5 m	2.2 m	<0.001
Med OS	5.9 m	4.1 m	0.25

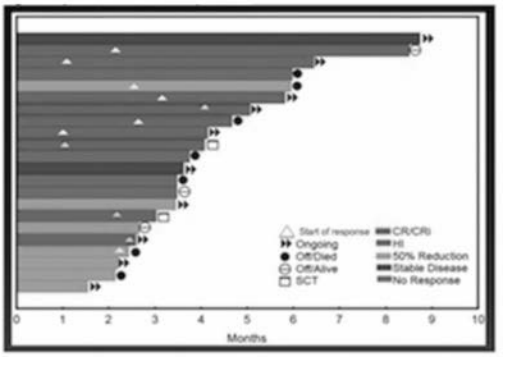

Figure 1. Response in 22 evaluable patients.

Summary/Conclusions: Combination of AZA and nivolumab is effective in pts with relapsed AML. Immune mediated toxicities occur and may be adequately managed with early recognition and systemic steroids.

P190

CLINICAL RESPONSE IN RELAPSED/REFRACTORY AML PATIENTS CORRELATES WITH LEUKEMIC BLAST MOBILIZATION AND DIFFERENTIATION INDUCED BY BL-8040, A POTENT CXCR4 ANTAGONIST; RESULTS OF A PHASE IIA STUDY

G Borthakur[1,*], MS Tallman[2], Y Ofran[3], J Foran[4], GL Uy[5], JF DiPersio[5], A Nagler[6], JM Rowe[7], MM Showel[8], JK Altman[9], A Peled[10], M Abraham[10], Y Pereg[11], A Vainstein[11], G Oberkovitz[11], A Aharon[11], C Bueso-Ramos[1], JE Cortes[1], M Andreeff[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]Memorial Sloan Kettering Cancer Center, New York, United States, [3]Rambam Health Care Campus, Haifa, Israel, [4]Mayo Clinic, Jacksonville, [5]Washington University Medical School, St. Louis, United States, [6]Chaim Sheba Medical Center, Tel Hashomer, [7]Shaare Zedek Medical Center, Jerusalem, Israel, [8]Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, [9]Robert H Lurie Medical Research Center, Chicago, United States, [10]Biokine Therapeutics, Rehovot, [11]BioLineRx Ltd., Modi'in, Israel

Background: The bone marrow (BM) niche protects acute myeloid leukemia (AML) cells from chemotherapy. BM retention of AML cells is dependent on CXCR4 and its ligand CXCL12 (SDF-1); high CXCR4 expression correlates with poor survival in AML patients. Blocking CXCR4 disrupts the interaction of AML blasts with the BM and augments the anti-leukemic effect of chemotherapy. BL-8040 (BKT140) is a high affinity CXCR4 inhibitor with long receptor occupancy. Recent clinical trials have demonstrated BL-8040's robust hematopoietic cell mobilization from the BM. BL-8040's anti leukemic effect is mediated through robust leukemic blast mobilization, induction of leukemia cell differentiation and apoptosis. Here we report results of a phase 2a study evaluating BL-8040 in combination with cytarabine (Ara-C) for the treatment of relapsed/refractory AML patients (NCT01838395).
Aims: To assess the safety, efficacy and PK/PD parameters of BL-8040 in combination with Ara-C in relapsed/refractory AML patients.
Methods: The study included a dose escalation phase (3+3 design) followed by an expansion phase. Each patient received a once daily SC dose of BL-8040 as monotherapy on days 1-2 followed by the same dose of BL-8040 plus Ara-C (1.5g/m^2 for patients ≥60; 3g/m^2 for patients <60) on days 3-7. Six BL-8040 doses (0.5-2.0mg/kg) were tested in the escalation phase with 1.5 mg/kg selected for the expansion phase. PD parameters such as extent of mobilization, induction of differentiation and apoptosis, CXCR4 expression and receptor occupancy were assessed by BM biopsy on day 3 and throughout the study. Remission was determined by BM biopsy on day 30.
Results: Forty five patients (median age, 61y; range, 23-75y) were treated with BL-8040 (including 3 patients treated on compassionate use basis). BL-8040 was escalated up to 2.0 mg/kg without reaching the MTD. Combination with Ara-C was safe and well tolerated at all doses. Three SAE's (Sweet's Syndrome, PCP pneumonia and allergic type reaction) were reported by the investigators as possibly related to BL-8040. Primary BL-8040 related AEs were transient, mild to severe injection site and systemic reactions, none of which were considered as DLT. The available composite complete remission (CR+CRi) rate is 38% in patients receiving BL-8040 doses of 1 mg/kg and higher (n=39). While baseline BM disease burden was comparable between responders (R) and non-responders (NR) (38% *vs* 40% BM blasts, respectively), responders demonstrated significantly lower levels of circulating blasts at baseline compared to non-responders (2.9% *vs* 19.3%, respectively). Furthermore, response to treatment was associated with higher mobilization of AML blasts following 2 days of BL-8040 monotherapy (CR=7.0, CRi=4.2, PD=1.1, SD=0.4, fold change) and with induction of granulocytic differentiation in the BM (R=3.2 *vs* NR=1.4, fold change). PD analysis further confirmed BL-8040's long receptor occupancy and its ability to induce apoptosis.
Summary/Conclusions: The results demonstrate that, in difficult to treat AML patients, sustained blockade of CXCR4 with BL-8040 combined with Ara-C may improve the clinical response rates achieved historically with Ara-C. In addition the data, for the first time, may suggest that better clinical responses are seen in patients with more efficient CXCR4 inhibition (reflected by higher mobilization and induction of granulocytic differentiation) and lower peripheral circulating blasts (despite comparable marrow blasts) at baseline. This finding may serve as a biomarker for patient selection in future BL-8040 studies in AML.

P191

RESULTS OF A PHASE I STUDY OF GMI-1271, A NOVEL E-SELECTIN ANTAGONIST IN COMBINATION WITH INDUCTION CHEMOTHERAPY IN RELAPSED/REFRACTORY AML: A NOVEL, WELL-TOLERATED REGIMEN WITH A HIGH REMISSION RATE

DJ DeAngelo[1,*], ME O'Dwyer[2], PS Becker[3], JL Liesveld[4], DL Bixby[5], JL Magnani[6], HM Thackray[6], BA Jonas[7]
[1]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, United States, [2]Department of Haematology, National University of Ireland, Galway, Ireland, [3]Department of Medicine, Division of Hematology, University of Washington, Seattle, [4]Department of Medicine, Hematology/Oncology, University of Rochester Medical Center, Rochester, [5]Department of Internal Medicine, Division of Hematology and Oncology, University of Michigan, Ann Arbor, [6]GlycoMimetics, Rockville, [7]Department of Medicine, Division of Hematology and Oncology, UC Davis Comprehensive Cancer Center, Sacramento, United States

Background: The treatment of patients with relapsed and refractory acute myeloid leukemia (AML) remains a significant challenge with poor outcomes primarily due to low remission rates as well as short remission duration. Although cytotoxic chemotherapy remains the standard approach for the treatment of patients with relapsed or refractory (R/R) AML, novel agents are urgently needed to improve clinical outcomes. The regimen consisting of mitoxantrone, etoposide, and cytarabine (MEC) is commonly used for patients with R/R AML, with remission rates of 25-30%. Binding of leukemic blasts to E-selectin, an adhesion molecule expressed constitutively in the bone marrow endothelium, activates leukemic cell survival pathways, thereby contributing to chemotherapy

resistance. GMI-1271 is a novel antagonist of E-selectin. Here we report initial results from a phase 1/2 trial of GMI-1271 with MEC for the treatment of patients with R/R AML.
Aims: To evaluate the safety, tolerability, pharmacokinetics (PK), and antileukemic activity of the combination of GMI-1271 plus MEC.
Methods: An open-label phase 1/2 trial enrolled patients with R/R AML receiving MEC induction chemotherapy. Eligible patients (ECOG 0–2) must have received ≤2 prior induction regimens, have no active CNS disease and adequate renal and hepatic function. Adjunctive treatment with GMI-1271 at increasing doses was administered concurrent with chemotherapy (24 hours prior, throughout, and 48 hours post MEC); MEC consisted of mitoxantrone 10 mg/m^2/d, etoposide 100 mg/m^2/d, and cytarabine 1000 mg/m^2/d IV for 5 days and supportive care given as per institutional guidelines. Dose limiting toxicity (DLT) was defined as either persistent neutropenia and/or thrombocytopenia beyond day 42 in the absence of disease or any grade 3 non-hematologic toxicity that did not resolve to Grade 2 by day 42.
Results: Two dose level cohorts have been completed, with 13 subjects treated (GMI-1271 at 5 mg/kg (N=6) and10 mg/kg (N=7)). The median age was 51 (range 26 –74) and 9 were male (69%). Seven patients (54%) had adverse cytogenetic risk (SWOG) and 6 patients (46%) had intermediate cytogenetic risk; none were favorable. Eight patients (62%) had relapsed disease and 5 (38%) were refractory to primary therapy. Two patients had relapsed within a year of hematopoietic cell transplant (HCT), 2/13 were FLT3-ITD mutated, 1 patient had extramedullary disease (EMD). All subjects tolerated GMI-1271+MEC well and completed study treatment without dose reduction or interruption; 30 day mortality was 0%. Mucositis developed in 5 subjects (4 at 5 mg/kg), of whom 2 required IV nutrition (both at 5 mg/kg). No DLTs were observed. Initial population PK analysis showed 28% lower clearance than healthy adults and overall similarity in PK profile. Seven of 13 subjects achieved CR (54%); one achieved CRi (transplanted before CR documented); one achieved morphologic leukemia-free state (inadequate count recovery); and four had persistent disease. CR/CRi rate was 8/13 subjects (62%). Of 5 with data post CR/CRi, 1 proceeded to HCT, one relapsed at 90 days, 3 remain in CR (4, 4, and 2 months duration). Responders include refractory AML (3), relapsed FLT3-ITD mutated (1) and EMD (1).
Summary/Conclusions: In early clinical assessment of the novel E-selectin antagonist GMI-1271, we report in a group of R/R AML patients a CR/CRi rate of 62%, higher than expected given the high risk cytogenetic features in this group. No DLTs have been observed. Enrollment in a third cohort is ongoing and will be reported. A Phase 2 expansion cohort is planned in both R/R AML as well as elderly *de novo* AML.

P192

RESULTS OF A PHASE 1B STUDY OF VENETOCLAX PLUS DECITABINE OR AZACITIDINE IN UNTREATED ACUTE MYELOID LEUKEMIA PATIENTS ≥65 YEARS INELIGIBLE FOR STANDARD INDUCTION THERAPY

DA Pollyea[1,*], C Di Nardo[2], M Thirman[3], A Letai[4], A Wei[5], BA Jonas[6], M Arellano[7], M Frattini[8], H Kantarjian[2], B Chyla[9], M Zhu[9], J Potluri[9], R Humerickhouse[9], M Mabry[9], M Konopleva[2], K Pratz[10]
[1]University of Colorado School of Medicine, Aurora, United Kingdom, [2]University of Texas MD Anderson Cancer Center, Houston, [3]University of Chicago Medical Center, Chicago, [4]Dana-Farber Cancer Institute, Boston, United States, [5]The Alfred Hospital and Monash University, Melbourne, Australia, [6]UC Davis Comprehensive Cancer Center, Sacramento, [7]Emory University, Atlanta, [8]Columbia University Medical Center, New York, [9]AbbVie, Inc., North Chicago, [10]Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, United States

Background: Venetoclax (VEN) is a potent, orally bioavailable BCL-2 inhibitor with single-agent activity in relapsed/refractory acute myeloid leukemia (AML) patients (pts), displaying synergistic activity with hypomethylating agents in preclinical studies. This trial evaluates VEN plus decitabine (DEC) or azacitidine (AZA) in treatment (Tx)-naive AML pts ≥65 y (NCT02203773).
Aims: The objectives of the study include safety, preliminary efficacy, and biomarker evaluations.
Methods: Tx-naive pts (ECOG PS ≤2, ≥65 y, intermediate- or poor-risk karyotype) not eligible for standard induction therapy received DEC (Arm A: 20 mg/m^2 iv) daily on days (D) 1-5 or AZA (Arm B: 75mg/m^2; subcutaneous or iv) daily on D 1-7 of each 28-D cycle in combination with once-daily continuous oral VEN. VEN dose escalation follows a 3+3 design; 1200 mg is the final dose level.
Results: As of 11/28/15, 39 pts (49% male; median age 74 y [65-85 y]) have been enrolled in Arm A (n=20) and Arm B (n=19). Median time on study is 111 D (6-375 D); 16 pts (41%) remain on therapy. Biomarker analysis and response evaluations have been completed in 34 pts with 400-mg and 800-mg VEN doses. As of 9/19/15, overall response rate (ORR; complete response [CR]/CR with incomplete marrow recovery [CRi]/partial remission [PR]) within this population was 76% (CR: 13/CRi: 11/PR: 2; 26/34 pts). Poor-risk cytogenetics and IDH1/2 mutations were reported in 24% (8/34) and 32% (11/34) of pts; ORR was 88% (7/8) and 82% (9/11), respectively. Median time to CR/CRi was 29.5 D (24-112 D). Most common treatment emergent adverse events (TEAEs) were nausea (54%), febrile neutropenia (41%), diarrhea (44%), decreased appetite (33%), and peripheral edema (31%). No dose-limiting toxicity was reported. Febrile neutropenia (41%) and neutropenia (33%) were the most common Grade 3/4 TEAEs. Most frequent serious AE was febrile neutropenia (28%). Four relapses occurred, all on Arm A. Six deaths occurred (3 disease progression, 1 sepsis, 1 respiratory failure, 1 bacteremia). MTD has not been reached.
Summary/Conclusions: Tx with VEN plus DEC or AZA shows a tolerable safety profile, with high response rates observed in Tx-naive AML pts ≥65 y, including those with adverse biologic disease features.

P193

A PHASE I TRIAL OF A PHARMACODYNAMICALLY-CONCEIVED DECITABINE/THIOGUANINE COMBINATION IN PATIENTS WITH ADVANCED MYELOID MALIGNANCIES

T Rosenblat[1], M Heaney[1], J Jurcic[1], A Raza[1], K Harwood[1], H Djaballah[2], J Scandura[3], A Letai[4], M Frattini[1,*]
[1]Columbia University Medical Center, New York, United States, [2]Institut Pasteur Korea, Seoul, Korea, Republic Of, [3]Weill-Cornell School of Medicine, New York, [4]Dana Farber Cancer Institute, Boston, United States

Background: Using a chemosensitivity screening assay, we previously demonstrated that decitabine and thioguanine combinations can rescue therapeutic efficacy in primary leukemia cells isolated from patients with relapsed and refractory acute myeloid leukemia (AML). Although decitabine and thioguanine have single-agent anti-leukemic activity, they have not previously been used concurrently.
Aims: To test the safety and preliminarily assess additive/synergistic activity of this combination, we performed a Phase I dose escalation trial of thioguanine given with standard dose decitabine.
Methods: Patients with AML >60 yrs not candidates for standard induction, relapsed/refractory AML, advanced MDS, and CMML were eligible. Two thioguanine dose levels were evaluated: 80 and 120 mg/m2/day, given on Days 1-12 of induction and Days 1-7 of maintenance. Decitabine at 20mg/m2 was administered on Days 3-12 during induction and on Days 3-7 during maintenance. Standard safety measures, clinical outcomes, and activity of decitabine and thioguanine was assessed by patient-specific pharmacodynamics including an *in vitro* chemosensitivity assay, genome-wide analysis of DNA methylation changes, and BH3 profiling in order to measure the degree to which samples were primed to undergo apoptotic cell death.
Results: Twelve patients (median age, 67) with denovo AML (1), transformed AML (6), relapsed/refractory AML (4), and CMML (1) were treated. DLT's were seen in two patients. One developed acute renal failure requiring hemodialysis (80mg/m2) and another persistent grade 4 leukopenia/thrombocytopenia (120mg/m2). Grade 3 infectious complications were common: neutropenic colitis, bacteremias, and pneumonias. 10 of 12 patients completed therapy with 4 undergoing Allogeneic-BMT (3 AML, 1 CMML), 4 removed for disease progression, and 2 for DLT. One patient relocated after induction, and another declined therapy after induction. Median cycles given was 3. Bone marrow blast reductions to <5% were seen in 6 of 7 evaluable patients with AML (1 CR and 3 CRi). The overall response rate in this high-risk patient population was 67%. The patient who achieved a CR (relapsed AML) received 4 previous cycles of single-agent decitabine, demonstrating that the decitabine and thioguanine combination regimen can rescue previous hypomethylating agent failure. The chemosensitivity assay results for thioguanine on pretreatment mononuclear cells directly correlated with clinical outcome in both response to therapy and clinical resistance. BH3 profiling was also performed on pre-treatment myeloblasts. Significant apoptotic priming corresponded to good initial clinical response. In addition, in the single patient who responded and subsequently relapsed, decreased apoptotic priming was observed in the relapsed sample, suggesting that the thioguanine/decitabine regimen applies selective pressure for reduction in apoptotic priming.
Summary/Conclusions: The decitabine and thioguanine combination was well-tolerated and showed surprising anti-leukemic activity. Importantly, chemosensitivity and BH3 profiling accurately predicted responses and confirmed the etiology of the loss of therapeutic response. A muti-center Phase II clinical trial is being planned.

Microenvironment and signaling in CLL

P194

GENOMIC CHARACTERIZATION OF HIGH-COUNT MBL INDIVIDUALS INDICATES THAT EARLY DETECTION OF DRIVER MUTATIONS AND SUBCLONAL EXPANSION ARE PREDICTORS OF ADVERSE CLINICAL OUTCOME

S Barrio[1,*], TD Shanafelt[2], J Ojha[1], KG Chaffee[3], C Secreto[2], MK Kortüm[1], SL Slager[3], R Fonseca[1], NE Kay[2], E Braggio[1]
[1]Hematology, Mayo Clinic, Scottsdale, [2]Department of Medicine, [3]Health Sciences Research, Mayo Clinic, Rochester, United States

Background: High-count monoclonal B-cell lymphocytosis (MBL) is an asymptomatic expansion of clonal B-cells with less than $5x10^9$/L B-cells in the peripheral blood and without other manifestations of chronic lymphocytic leukemia (CLL). Yearly, 1% of individuals with MBL evolve to CLL requiring therapy; thus it is critical to develop a better understanding of the biologic events that determine which MBLs progress to intermediate/advanced CLL stages. High-count monoclonal B-cell lymphocytosis (MBL) is an asymptomatic expansion of clonal B-cells with less than $5x10^9$/L B-cells in the peripheral blood and without other manifestations of chronic lymphocytic leukemia (CLL). Yearly, 1% of individuals with MBL evolve to CLL requiring therapy; thus it is critical to develop a better understanding of the biologic events that determine which MBLs progress to intermediate/advanced CLL stages.
Aims: We performed a longitudinal sequencing analysis on a cohort of high-count MBL, assessing the mutation profile, clonal heterogeneity and clonal dynamics over time and their impact on disease progression.
Methods: We performed targeted deep sequencing (TDS) on 48 high-count MBL individuals and explored the mutation status of 21 driver genes recurrently mutated in CLL. We analyzed the clonal evolution in 45 of these 48 MBLs by screening 2-4 sequential samples (average time between samples 56 months, range 10-119 months). At the last follow-up, 19 cases (39%) had progressed to Rai>0, and 10 cases (20%) required treatment. We analyzed 152 DNA samples from 48 cases (104 tumor CD5+/CD19+ samples and the 48 germ line CD5-/CD19- controls) using semiconductor-sequencing technology (IonTorrent PGM). Genetic information was integrated with relevant clinical and biological parameters. Subsequently, we evaluated the role of mutations and clonal evolution with progression to intermediate/advanced stage CLL (Rai stages I-IV) and time to treatment (TTT).
Results: We found somatic non-synonymous mutations in 25 MBLs (52%) at the initial time-point analyzed, including 13 (27%) with >1 mutated gene. Recurrent mutations were found in *SF3B1* (10% of cases), *BIRC3, DDX3X, CHD2* (8% each), *NOTCH1* (6%), and *ATM, BRAF, EGR2, FBXW7, KRAS, MED12, MYD88,* and *ZMYM3* (4% each). Furthermore, *BCOR*, *ITPKB, POT1, RIPK1* and *SAMHD1* were each mutated in one case. No mutations were found in *HIST1H1E, TP53* and *XPO1*. In cases that subsequently progressed to intermediate/advanced stage CLL, mutations were detected 41 months (median time) prior to progression. Except for *NOTCH1, TP53 and XPO1,* which have shown a lower incidence in MBL, driver genes were mutated with a similar prevalence to CLL, indicating the early origin of most driver mutations in the MBL/CLL continuum. Subclonal expansion of mutated drivers was found in 6 out of 10 (60%) cases who progressed to require treatment, compared with only 5 of 35 (14%) non-treated cases. Individuals with clonal expansion had both significantly shorter PFS (HR: 5.3 95% CI: 1.3-20.9; p=0.02), as well as significantly shorter TTT (HR: 6.4 95% CI: 1.8-23.2; p=0.005).
Summary/Conclusions: The findings of this study suggest that mutations in driver genes are an early event in the MBL-CLL continuum and predict progression to clinically significant CLL. Clonal heterogeneity and subclonal expansion is already found in individuals with high count MBL and its presence predicts an earlier development of CLL. Sequential genetic evaluation of individuals with MBL provides insights that add to our understanding of the events that contribute to progression from MBL to CLL and have potentially profound clinical implications.

P195

IDENTIFICATION OF NOVEL B CELL RECEPTOR ANTIGENS IN CHRONIC LYMPHOCYTIC LEUKEMIA

E Ten Hacken[1,*], T Oellerich[2,3], M Gounari[4], KT Pan[5], WG Wierda[1], A Ferrajoli[1], Z Estrov[1], MJ Keating[1], H Urlaub[5,6], P Ghia[4], JA Burger[1]

Background: B cell receptor (BCR) signaling is one of the main pathways activated in the Chronic Lymphocytic Leukemia (CLL) microenvironment. Nurselike cells (NLC), an important monocytic component of this microenvironment, spontaneously outgrow *in vitro* from high density CLL-PBMC cultures, and can expose proteins on their surface, which can be recognized by the CLL-BCRs and activate BCR signaling. CLL cases whose cells carry unmutated immunoglobulin heavy variable (*IGHV*) genes (U-CLL) generally experience an aggressive disease course, and U-CLL BCRs are highly polyreactive towards a variety of self-antigens, most of them still incompletely characterized.
Aims: The aim of this study was to characterize BCR signaling in the CLL-NLC co-culture system and to identify novel CLL-BCR antigens expressed by NLC.
Methods: CLL-PBMCs were cultured *in vitro* for 14 days until outgrowth of NLC, which was confirmed by phase contrast microscopy. CLL cells were then removed from the NLC co-culture and tested for BCR expression by flow cytometry and activation of BCR signaling by Western Blot. Chemokine secretion was tested in co-culture supernatants by ELISA. Concomitantly, NLC were harvested and lysed, followed by immunoprecipitation of protein lysates with recombinant monoclonal antibodies obtained by cloning of 4 U-CLL BCR sequences, all of them carrying 100% identity with the germline *IGHV* sequence. Protein lysates from the human mesenchymal stromal cell line hTERT were also tested, as control. Immunoprecipitated proteins were analyzed by label-free mass spectrometry followed by bioinformatic data analysis with the softwares Max Quant and Perseus.
Results: Down-modulation of IgM-BCR surface levels was observed after 14 days of co-culture of 10 CLL cases onto NLC. IgM levels recovered after 48 hours following *in vitro* culture in the absence of NLC, reaching pre-exposure levels after 72 hours. Activation of AKT and ERK kinases and induction of MYC protein were observed in 10 CLL cases after 14 days of CLL-NLC co-culture, and phosphorylation/expression levels of these proteins were reduced when CLL cells were removed from the NLC support. We also detected high levels of the BCR-related chemokines CCL3 and CCL4 in 18 CLL-NLC supernatants, in particular in the ones derived from U-CLL cases. Immunoprecipitation of 3 NLC lysates and the hTERT control with 4 recombinant U-CLL BCRs, followed by label-free mass spectrometry and bioinformatic data analysis, allowed the identification of 6 clusters of commonly recognized proteins (Figure 1). One cluster (Cluster 5) included 11 putative CLL-BCR antigens that were expressed by all 3 NLC samples, but not by hTERT, and included cytoskeletal proteins and membrane-associated proteins, some of them known autoantigens in other diseases.

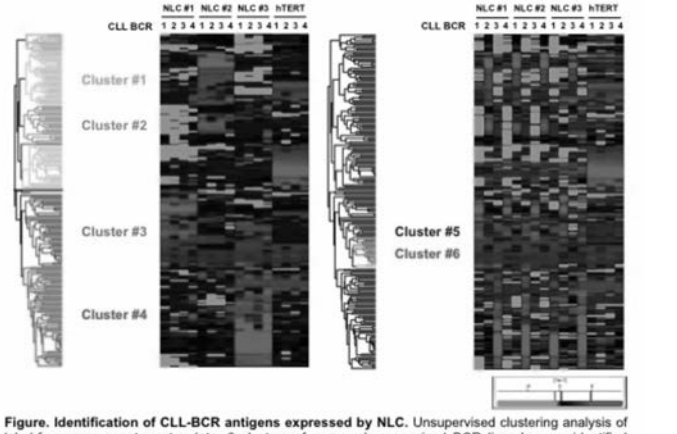

Figure. Identification of CLL-BCR antigens expressed by NLC. Unsupervised clustering analysis of label-free mass spectrometry data. 6 clusters of commonly recognized BCR ligands were identified through immunoprecipitation of NLC lysates derived from 3 CLL patients (NLC #1, NLC #2, NLC #3) or hTERT cells with 4 different U-CLL BCRs.

Figure 1.

Summary/Conclusions: The BCR signaling pathway is activated following co-culture of CLL cells with NLC, which can expose CLL-BCR ligands on their surface. By applying a novel mass-spectrometry based approach, we identified a number of putative CLL-BCR antigens expressed by NLC, which will be further validated for BCR binding and signaling activation properties, as well as for expression and localization in CLL-NLC co-cultures and lymph node sections from CLL patients. Overall, these results will allow a better characterization of the molecular mechanisms regulating BCR signaling in the CLL microenvironment and the identification of novel therapeutic targets for CLL therapy.

Background: The pathophysiology of chronic lymphocytic leukemia (CLL) depends on the interactions of the malignant B cells with the lymphoid tumor

microenvironment. The chemokine stromal cell-derived factor 1 (SDF-1, CXCL12) is constitutively secreted and presented by stroma under normal as well as malignant conditions. In CLL, binding of CXCL12 to its over-expressed classical receptor CXCR4 regulates cell migration and increases cell survival and cell adhesion-mediated therapy resistance, making this signaling axis a therapeutic target. Olaptesed pegol (NOX-A12), a PEGylated L-stereoisomer RNA aptamer, is a novel high-affinity CXCL12 antagonist. Using short term adoptive transfers of human leukemia cells into immune deficient mice, we recently demonstrated that olaptesed pegol antagonizes CLL cell homing to bone marrow.
Aims: Here, we aimed to determine the potential of olaptesed pegol to mobilize CLL cells from lymphoid organs and to antagonize disease progression *in vivo* using the murine Tcl transgenic (tg) CLL transplantation model.
Methods: Splenocytes from Tcl1 tg mice with overt leukemia were transplanted into the peritoneal cavity of C57BL/6J wildtype mice. Engrafted recipients with active leukemia (defined by a peripheral blood CD5+/CD19+ tumor cell concentration ≥10%) were randomized to treatment with olaptesed pegol or the CXCR4 antagonist AMD3100. CLL cell mobilization into peripheral blood was analyzed via flow cytometric detection of CD5+/CD19+ cells before substance application, and 1 h, 3 h, 6 h, and 24 h post application. Treatment studies of engrafted animals were performed using either olaptesed pegol or fludarabine, or ibrutinib followed by olaptesed pegol compared to ibrutinib alone. Readout parameters were tumor cell concentration and overall survival of mice.
Results: Olaptesed pegol induced a substantial mobilization of CLL cells into peripheral blood with an approx. 2-fold increased leukemic cell count compared to pre-application levels. Raised CLL cell counts in blood were observed within 1 hour, reached a peak upon 6 hours and were still visible at 24 hours post treatment while AMD3100 treatment did not result in consistent CLL cell mobilization. In long-term treatment experiments, olaptesed pegol prolonged overall survival of mice as efficient as fludarabine. Whereas ibrutinib followed by olaptesed pegol reduced blood tumor burden to a comparable extent as ibrutinib monotherapy, the combination had a stronger effect on median survival which was prolonged by 36% *vs* vehicle control and 18% *vs* ibrutinib alone.
Summary/Conclusions: Our data demonstrate the potential of olaptesed pegol as a CLL cell mobilizing and therapeutic agent. Further studies corroborating its efficiency as a single treatment using primary Tcl transgenic animals are ongoing.

THE PAN-PIM KINASE INHIBITOR LGB321 TARGETS APOPTOTIC PATHWAYS AND MICROENVIRONMENTAL INTERACTIONS IN CLL
S Decker[1,*], S Kissel[1], K Aumann[2], K Zirlik[1], C Dierks[1]
[1]Internal Medicine I, [2]Pathology, University Hospital Freiburg, Freiburg, Germany

Background: In recent years, the emergance of kinase inhibitors like Ibrutinib has drastically altered treatment strategies and improved outcomes in CLL patients, but lack of cure and resistance to therapy still remain serious problems. PIM kinases are involved in various important disease mechanisms in CLL, with PIM1 regulating CXCR4 surface expression impacting its interaction with the microenvironment, and PIM2/3 affecting the apoptotic machinery by regulating BAD. The Pan-PIM kinase inhibitor LGB321 (Novartis) targets all 3 PIM kinases and therefore affects both, CLL apoposis and its interaction with the microenvironment.
Aims: In the study presented here, we aimed to investigate the effect of the Pan-PIM inhibitor LGB321 on CLL *in vitro* and *in vivo*.
Methods: CLL patient samples: Peripheral blood samples were obtained with informed consent in accordance with the declaration of Helsinki from B-CLL patients who were either untreated or off therapy for at least 6 months. Immunoblotting: Protein expression of PIM1, PIM2, PIM3, CXCR4, pCXCR4, pBAD, BAD and beta-Actin was determined after Pan-PIM inhibitor treatment and was analyzed using the ImageJ software. Apoptosis Assay: PBMCs were plated with or without support of the murine stromal cell line M2-10B4 and treated with LGB321. After 24 and 48 h of incubation, cells were stained with a CD5-V450 and a CD19-APC antibody, followed by AnnexinV/7-AAD staining (BD) according to the manufacturer´s instructions. CLL cell homing into NOG mice: NOG mice were transplanted at 8 weeks of age. Primary human CLL cells were treated with LGB321 for 12 hours. CLL cells were resuspended in HBSS and mice received transplants via teil vein injection. Mice were analyzed 4 hours after transplantation. LGB treatment of CLL-Xenograft mice: PBMCs were transplanted using both retro-orbital and intraperitoneal application. Treatment started one week after transplantation and LGB321 was applied using oral gavage. After 2 weeks of treatment, mice were sacrificed, and spleen and bone marrow cells were harvested and stained for human CD5, CD19 and CD45 (BD).
Results: LGB321 was highly effective in inducing apoptosis in primary CLL cells, independent of risk factors like 17p deletions or the mutation status. Apoptosis induction correlated with reduced pBAD and BAD levels. Furthermore, LGB321 was also effective in the presence of protective stromal cells and could completely overcome the stroma protective effects. Mechanistically, we found that LGB321 treatment blocked the CXCR4/CXCL12 axis by dephosphorylating the CXCR4 receptor on Ser339, by reducing total CXCR4 protein levels and by blocking the externalization of the CXCR4 receptor. Concordantly, PIM inhibition blocked CXCR4 functions like migration towards a CXCL12 gradient (P<.0001), and reduced homing of LGB321-pretreated primary CLL cells towards the bone marrow (P=.0001) of NOG mice *in vivo*. *In vivo* experiments comfirmed the efficacy of LGB321 in 4 different CLL xenograft studies. Transplantation of primary human CLL cells into NOG mice and treatment with LGB321 for 2 weeks strongly reduced WBC counts, spleen size and spleen infiltration with human CLL cells (P=.0295) in all four CLL cases, and blocked BAD as well as CXCR4 phosphorylation also *in vivo.*
Summary/Conclusions: Our results demonstrate, that the Pan-PIM kinase inhibitor LGB321 might be an effective treatment option for CLL patients by impairing PIM2/3 mediated CLL-cell survival, and by blocking the PIM1/CXCR4-mediated interaction of CLL cells with their protective microenvironment *in vitro* and *in vivo*. Future clinical trials should be performed to validate its efficacy in human CLL.

***IN VIVO* CHARACTERIZATION OF LYN KINASE IN THE PATHOGENESIS OF CHRONIC LYMPHOCYTIC LEUKEMIA**
PH Nguyen[*], N Reinart, G Krause, M Hallek
Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: The introduction of therapeutics targeting B cell receptor (BCR) signaling such as the inhibitors of BTK and PI3K-δ has been changing the field of CLL therapy formidably. Inhibition of LYN, a central molecule of the BCR signaling, efficiently induced apoptosis *in vitro* but its effectiveness *in vivo* is still unclear. In CLL cells, LYN is found to be aberrantly expressed and highly activated. Not only the classical BCR molecules downstream of LYN such as SYK or PI3K, but also several other substrates such as HS1, procaspase-8, cortactin or PP2A have been indicated to be deregulated in CLL. These downstream molecules could support the aggressiveness and apoptosis resistance of the malignant cells. Besides, the expression levels of LYN mRNA was associated with treatment-free survival of CLL patients, providing further perspectives for LYN as a valuable therapy target. However, studies about the role of LYN in CLL have only been conducted from isolated cells *in vitro*, and modulations of Lyn activity in CLL were only performed using inhibitors with insufficient specificity. Thus, the contribution of LYN in CLL pathogenesis is far from being fully understood. We have demonstrated that Lyn kinase is essential for the development of CLL *in vivo* (Nguyen *et al.*, in revision). Interestingly, loss of Lyn in leukemic B cells results in higher proliferation rate, early malignant transformation and apoptosis resistance, and can potently induce CLL in immune competent syngeneic recipients. In stark contrast, our results suggest a striking role of Lyn for the formation of a tumor microenvironment that supports CLL expansion.
Aims: So far studies about the role of LYN in CLL have only been conducted from isolated cells *in vitro*, and modulations of Lyn activity in CLL were only performed using inhibitors with insufficient specificity. Thus, the contribution of LYN in CLL pathogenesis is far from being fully understood. Using the well-established mouse model for CLL, the Eμ-TCL1 mouse model, we investigated the functional contribution of LYN in the pathogenesis of CLL in on the *in vivo* level.
Methods: To better understand the physiological consequences of overexpressing LYN observed in human CLL cells, we generated a novel mouse model with constitutively active LYN mutation. The conditional knockin mice have a point mutation at the inhibitory phosphorylation tyrosine of the Lyn gene (Y508F), resulting in its constitutively active conformation that expresses specifically in B cells due to Cre-induced recombination under the CD19 promoter ($LYN^{up\text{-}B}$). This novel mouse model was intercrossed with the Eμ-TCL1 model ($TCL1^{+}LYN^{up\text{-}B}$) and monitored for CLL development.
Results: B cells isolated from $TCL1^{+}LYN^{up\text{-}B}$ mice exhibited remarkably enhanced activation of BCR-associated kinases such as SRC family kinases, SYK, AKT and ERK1/2 compared to control $TCL1^{+}LYN^{wt}$ B cells, particularly upon IgM stimulation. Our analysis also revealed a higher malignant transformation rate of $TCL1^{+}LYN^{up\text{-}B}$ B cells starting at six months of age, and a more progressive CLL burden in the peripheral blood of $TCL1^{+}LYN^{up\text{-}B}$ mice, particularly when the CLL clones had been well established at eight months of age. However, moribund mice from both cohorts showed similar infiltration of CLL cells in the lymphoid organs, and the slight increased CLL burden in peripheral blood did not affect overall survival of $TCL1^{+}LYN^{up\text{-}B}$ mice compared to $TCL1^{+}LYN^{wt}$ counterparts.
Summary/Conclusions: Our results suggest that constitutively active LYN and the hyperactive BCR signaling in leukemic cells contribute moderately to the progression of CLL in the Eμ-TCL1 mouse model.

MICROENVIRONMENTAL STROMAL CELLS TRIGGER HYPOXIASIGNALLING IN CLL CELLS – A MECHANISM THAT PROVIDES PROTECTION FROM APOPTOSIS AND CAN BE TARGETED THERAPEUTICALLY
D Mertens[1,2,*], I Idler[2], D Yosifov[1], M Reichenzeller[2], V Meyer-Pannwitt[1], A Scheffold[1], H Doehner[1], S Stilgenbauer[1]
[1]Internal Medicine III, University Ulm, Ulm, [2]Mechanisms of Leukemogenesis, DKFZ, Heidelberg, Germany

Background: Microenvironmental support protects malignant cells from apoptosis and cancer therapy, in part by induction of hypoxia-regulated pathways. Hypoxia-regulated pathways are conceivable as therapeutic targets in solid cancers, but not so much in leukemias.
Aims: Here we show that in chronic lymphocytic leukemia (CLL) cells hypoxia-regulated pathways are the most important mediators of support by bone marrow derived stromal cells (BMSC). These pathways can be targeted therapeutically.
Methods: We compared the transcriptomes of primary CLL cells protected by coculture with BMSCs to the transcriptomes of non-protected CLL cells that undergo apoptosis. To identify compounds that are active against the microenvironmental support, we determined the differential transcriptomic signature of CLL cells between *in vitro* co-culture and unsupported culture and compared it to a database of transcriptomes induced by bioactive compounds in cell lines ("connectivity map"). We tested emetine for efficacy in a syngeneic transplantation model of murine CLL, using three different treatment schedules - a short high dose intensity and two continuous lower dose intensity scheme.

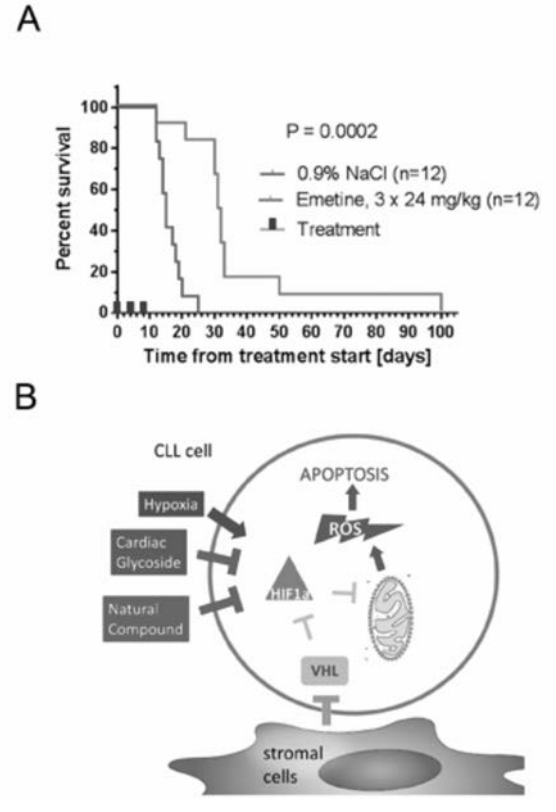

Figure 1.

Results: The cellular pathways most differentially regulated in primary CLL cells protected by coculture compared to unprotected CLL cells were involved in oxidative phosphorylation and mitochondrial function. Transcriptional differences were already evident at 6-8 h, directly before induction of apoptosis in unprotected cells. In line with this finding, the support of primary CLL cells by the BMSCs could be mimicked *in vitro* by hypoxia. By the comparison of the dysregulated CLL transcriptomic signature to the connectivity map database, we identified the cardiac glycoside ouabain and the ipecac alkaloid emetine as inducing the most correlated transcriptomic signatures. *In vitro*, these substances were highly active on primary CLL cells protected by coculture (IC50s 287 nM, 190 nM and 35 nM, respectively; the IC50 of fludarabine was 5 μM). *In vitro* characterization of the substances revealed suppression of HIF-1 alpha activity. This suppression coincided with a stronger oxidation of the mitochondrial and cytoplasmic redox homeostatic system compared to 20 redox-active compounds. We tested the efficacy of emetine *in vivo* using three different treatment schedules - a short one of high dose intensity (24 mg/kg every 4th day for 3 applications) and two continuous ones of lower dose intensity (3 or 8 mg/kg every 4th day). We transplanted murine CLL tumors induced by Eμ-driven overexpression of TCL1A into microenvironmentally intact wildtype syngeneic mice. Continuous low dose treatment did not lead to weight reduction in mice, whereas treatment with three high doses of emetine resulted in a significant loss of weight. However, while continuously administered low doses of emetine were not beneficial for survival of transplanted mice (Figure 1a), three high doses of emetine doubled median survival of diseased mice (31.5 days *vs* 15 days, p=0.0002, Figure 1b). This enhanced survival coincided with decreased numbers of CLL cells in peripheral blood, spleen and most pronounced in bone marrow (BM), which led to recovery of hematological parameters.

Summary/Conclusions: CLL cells are supported by bone-marrow derived stromal cells first of all through modulation of hypoxia-regulated pathways. This microenvironmental support can be therapeutically targeted by cardiac glycosides and ipecac alkaloids, both of which increase the intracellular oxidation of CLL cells even when they are protected by coculture. In a mouse model of CLL, this is reflected by doubled median survival of mice treated with emetine.

IBRUTINIB INHIBITS CD20 UP-REGULATION ON CLL B CELLS MEDIATED BY THE CXCR4/SDF-1 AXIS

G Pavlasova[1,2,*], M Borsky[2], V Seda[1,2], K Cerna[1,2], J Osickova[1,2], M Doubek[2], J Mayer[2], R Calogero[3], S Pospisilova[1,2], M Davids[4], J Brown[4], M Mraz[1,2]
[1]Molecular Medicine, CEITEC MU, [2]Dept. of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine MU, Brno, Czech Republic, [3]Dept. of Biotechnology and Health Sciences, University of Torino, Torino, Italy, [4]Dept. of Medical Oncology, Dana-Farber Cancer Institute, Boston, United States

Background: It was shown that BCR inhibitors such as ibrutinib interrupt microenvironmental interactions and mobilize CLL cells from lymph node niches and bone marrow into the blood stream. Therefore, it has been suggested that a combinatorial therapy of BCR-inhibitors with anti-CD20 or other antibodies might be an effective therapeutic combination.
Aims: The aim of this study was to test for the ibrutinib effect on the expression of selected CLL cell-surface molecules that could be potentially targeted by available monoclonal antibodies.
Methods: Peripheral blood samples were obtained from untreated CLL patients or patients treated with ibrutinib as a single agent (420 mg once daily). The study was approved by the institutional review board and samples were obtained with written informed consent.
Results: We performed gene expression profiling in samples obtained from CLL patients treated with ibrutinib as a single agent (pre-ibrutinib *vs* day 15 and/or week 5/12) and analyzed changes in >20 cell-surface molecules that could be potentially targeted by different available therapeutic antibodies. Surprisingly, we observed that CD20 mRNA had the most significantly changed expression (down-modulation of 3.4-fold; P<0.0001). This suggested that CD20 expression might be regulated by a yet unknown mechanism in the context of microenvironmental interactions impaired by ibrutinib. The co-culture of primary CLL cells with stromal cell line HS-5 induced higher CD20 surface levels on CLL cells, and ibrutinib inhibited this CD20 up-regulation. Then we assessed the CD20 expression on CLL cell populations defined according to CXCR4 and CD5 levels. CLL cells that have recently exited the lymph node microenvironment to the peripheral blood express lower levels of chemokine receptor CXCR4 and higher levels of activation marker CD5 ($CXCR4^{dim}CD5^{bright}$ cells) than those cells circulating in the blood stream for a long time ($CXCR4^{bright}CD5^{dim}$ cells). The $CXCR4^{dim}CD5^{bright}$ cells had 2-times higher CD20 surface as well as mRNA expression (P<0.01) suggesting that changes of CD20 levels within immune niches reflect the changes in its transcription. Moreover, CD20 expression gradually decreased with CLL cells' transition from $CXCR4^{dim}CD5^{bright}$ to $CXCR4^{bright}CD5^{dim}$ (P<0.01). This led us to hypothesize that CXCR4/SDF-1 is directly implicated in CD20 regulation. Indeed, *in vitro* treatment of CLL cells with SDF-1α (ligand for CXCR4 produced by stromal cells) up-regulated CD20 expression (P<0.01). The application of plerixafor (CXCR4 inhibitor) or ibrutinib abolished the SDF-1 mediated CD20 up-regulation (P<0.01). Altogether, this represents the first known mechanism of CD20 regulation in CLL cells. Notably, it has been shown that addition of rituximab to ibrutinib *in vivo* is able to eliminate CLL cells despite lower levels of CD20 suggesting that there must be other mechanism of ibrutinib action that allows for the effect of rituximab. The screening of anti-apoptotic molecules revealed that Mcl1 levels were significantly down-modulated after ibrutinib treatment *in vivo* (P=0.002), and ibrutinib also inhibited Mcl1 induction in CLL cells co-cultured with HS-5. As Mcl1 was described to directly protect CLL cells from rituximab-induced apoptosis and CDC, we suggest that ibrutinib-mediated Mcl1 reduction is a mechanism that facilitates rituximab efficacy.
Summary/Conclusions: We have described the first known mechanism of CD20 regulation in CLL cells. The CXCR4/SDF-1 axis up-regulates CD20 expression in CLL B cells, this is inhibited by ibrutinib. Supported by the Ministry of Education, Youth and Sports of the Czech Rep, project CEITEC 2020 (LQ1601); Ministry of Health of the Czech Rep, grant nr. 16-29622A; GACR (GA16-13334Y); TACR (TEO2000058/2014-2019); MUNI/A/1028/2015; MSMT COST CZ (LD15144); Horizon 2020 (No. 692298); and G.P. is a city of Ostrava scholarship holder.

FUNCTIONAL IMPACT OF BONE MARROW MESENCHYMAL STROMAL CELL-DERIVED EXTRACELLULAR VESICLES ON CHRONIC LYMPHOCYTIC LEUKEMIA B-CELLS: APOPTOSIS, MIGRATION, CHEMORESISTANCE AND GENE EXPRESSION MODIFICATION

E Crompot[1,*], M Van Damme[1], K Pieters[1], N Meuleman[2], D Bron[2], P Mineur[3], L Lagneaux[1], B Stamatopoulos[1]

[1]LTCC, Jules Bordet Institute/ULB, [2]Hematology, Jules Bordet Institute, bruxelles, [3]Grand Hopital de Charleroi, Charleroi, Belgium

Background: Chronic Lymphocytic Leukemia (CLL) is the most common leukemia in Western countries and is characterized by the accumulation of CD5/CD19+ monoclonal B-cells in peripheral blood and secondary lymphoid tissues. The interactions between CLL cells and the bone marrow (BM) microenvironment (notably composed by mesenchymal stromal cells - MSC) play an important role in promoting the increased survival of leukemic B-cells. Extracellular vesicles (EVs) produced by leukemic cells and the microenvironment may be implicated in this cross-talk. EVs, including microparticles and exosomes, are small plasma membrane fragments with sizes ranging from 0.01 to 1µm, and contain products specific to the original cell, such as microRNA, mRNA and proteins.
Aims: Our objective is to assess the role of EVs in the cross-talk between malignant cells and their microenvironment by functional studies and microarray analyzes.
Methods: Ultracentrifugation (150000g) was applied to isolate EVs from supernatant of BM-MSC. Different concentrations of EVs were added to CLL B-cells to evaluate their impact on cell survival, migration and chemoresistance. The gene expression change induced by EVs in CLL cells was also defined by microarray analysis (Affymetrix) after their incubation (24h) with BM-MSC-EVs. Some genes identified as differentially expressed were validated by real-time PCR.
Results: We demonstrated that BM-MSC EVs are able to enter in CLL-B-cells (PKH67 labeling): after 24h, >95% of CLL cells had integrated EVs. Apoptosis was assessed by flow cytometry: addition of increasing concentrations of EVs showed a protective effect on CLL-B-cells from spontaneous cell death (n=21/p-value<0.0001). CLL-B-cells pre-incubated with EVs (4h) displayed an increased spontaneous migration index and also in response to SDF1α (n=10/p-value=0.002). We also observed that EVs rescue CLL-B-cells from drug induced apoptosis. Microarray analysis reveals a significant effect on the expression of 987 genes after the integration of EVs in CLL-B-cells, notably implicated in apoptosis, epigenetic, adhesion, migration, cell activation, actin cytoskeleton regulation and immune pathways.
Summary/Conclusions: Here we show for the first time that BM-MSC-EVs protect CLL cells from spontaneous apoptosis and influence their migration and chemoresistance capacities. The implication of EVs in several cell functions was observed by microarray analyzes. This study demonstrates the existence of a powerful cross talk between BM-MSC and CLL-B-cells mediated by EVs. It provides new insight in the biology of CLL.

THE T-CELL/CLL/MACROPHAGE TRIAD SHAPES A SUPPORTIVE TUMOR MICROENVIRONMENT IN CLL

M Van Attekum[1,*], S Endstra[1], E Reinen[1], M Von Lindern[2], E Slinger[1], E Eldering[1], A Kater[3]
[1]Experimental Immunology, Academic Medical Center, [2]Hematopoiesis, Sanquin, [3]Hematology, Academic Medical Center, Amsterdam, Netherlands

Background: Survival of chronic lymphocytic leukemia (CLL) cells critically depends on signals from bystanders cells, such as T-cells and macrophages, within micro-environmental niches such as lymph nodes. The mechanisms of this intricate interplay are however unknown. Moreover, whether CLL cells actively participate in shaping their pro-survival niche is poorly understood.
Aims: 1) whether T-cell stimulation initiates active recruitment of monocytes by CLL cells, 2) whether CLL cells are able to differentiate these monocytes towards a supporting phenotype and 3) by which mechanism macrophages induce CLL survival.
Methods: migration assays with inhibitors, microarray, Luminex, flow cytometry, western blot, immunohistochemistry, survival assays, RNAi, polysome gradient fractionation
Results: 1) In *in vitro* migration assays we found that CLL cells can actively recruit monocytes after T-cell or CD40L stimulation. T-cell stimulation of CLL cells resulted in secretion of several chemokines, of which CCL2 was responsible for the enhanced monocyte migration. 2) We next examined and compared polarization patterns of monocytes after differentiation with serum derived from CLL patients (N=25) or pooled healthy donor serum and found that CLL serum was able to differentiate macrophages towards a tumor supporting M2 phenotype. This finding was confirmed *ex vivo* by IHC, as M2 marker CD206 co-localizes with CD68 cells in CLL LNs, while the majority of macrophages in non-CLL derived LNs are CD80+ (M1 type). 3) Lastly, we found that macrophages induce CLL cell survival and that this survival resulted from an AKT-dependent upregulation of pro-survival protein MCL-1, which was translationally stabilized. Interestingly, the mechanism of MCL-1 stabilization was independent of NF-κB signaling.
Summary/Conclusions: These studies shed light on reciprocal cellular interactions in the CLL LN that shape pro-tumor differentiation of supporting cells, that in turn cause survival by changing the apoptotic balance. These interactions can be targeted at different levels, creating new treatment venues for this still incurable disease.

P203

METABOLIC ALTERATIONS INDUCED BY IBRUTINIB IN CLL CELLS AS A BIOCHEMICAL BASIS FOR MECHANISM-BASED DRUG COMBINATION TO ENHANCE THERAPEUTIC ACTIVITY

H Pelicano[1,*], A Huang[1], F Li[1], J Liu[1], J Huang[1], WG Wierda[2], MJ Keating[2], P Huang[1]
[1]Translational Molecular Pathology, [2]Leukemia, UT MD Anderson Cancer Center, houston, United States

Background: Chronic lymphocytic leukemia (CLL) is the most common adult leukemia in the Western countries and is currently still incurable. Ibrutinib, a small molecule compound designed to target Bruton's tyrosine kinase (BTK) essential for CLL cell survival, exhibits impressive therapeutic activity in CLL, and significantly improves the clinical outcome of CLL patients. However, drug resistance and disease relapse may occur in a small percent of patients.
Aims: The main objectives of this study were to investigate the potential effect of Ibrutinib on CLL metabolism, and to develop novel strategies to enhance the therapeutic activity of Ibrutinib and reduce drug resistance.
Methods: Primary CLL cells were isolated from the peripheral blood samples of CLL patients for *in vitro* study. Metabolic alterations including changes in oxygen consummption (OCR) as an indicator of mitochondrial respiration and extracellular acidification rate (ECAR) as an indication of lactate production from glycolysis were measured by a Seahorse metabolic analyzer XF^{e}24. Cellular reactive oxygen species (ROS) were detected using a redoxsensitive fluorescence probe DCFH-DA.
Results: Since active generation of reactive oxygen species (ROS) is a metabolic feature of CLL cells, we first used DCFH-DA to test the potential effect of Ibrutinib on ROS production in primary CLL cells isolated from patients. We found that Ibrutinib induced a substantial increase of ROS as early as 90 min and lasted for up to 24 h. Mechanistic study suggests that the mitochondrial respiratory chain might be the major source of this abnormal ROS generation, since inhibition of the mitochondrial respiratory complex I by rotenone or suppression of flavoproteins (components of mitochondrial respiratory chain or NAD(P)H oxidase) by diphenyleneiodonium largely abrogated Ibrutinib-induced ROS generation. To further investigate the potential effect of Ibrutinib on mitochondria, we used the extracellular flux analyzer (XF^{e}24). In a CLL cells-stromal cells co-culture system (to maintain long-term viability of CLL cells), Ibrutinib induced little changes in OCR and ECAR during the first 48-72 h. However, prolonged drug exposure (up to 7 days) caused a consistent and significant decrease in OCR compared to the untreated CLL cells co-cultured with stromal cells for the same period. Importantly, CLL cells isolated from patients under Ibrutinib treatment for 7 days also exhibited a significant decrease in OCR compared to the pre-treatment samples from the same patients, suggesting that the impact of Ibrutinib on mitochondria occurred *in vivo*. Western blot analysis revealed that Ibrutinib induced a decreased expression of certain respiratory chain components. Functional analysis showed that Ibrutinib caused CLL cells to take up less glutamine but did not affect glucose uptake, suggesting that Ibrutinib might preferentially impact glutamine metabolism. Based on these new findings, we further tested the possibility that the metabolic alterations and mitochondrial dysfunction induced by Ibrutinib might render CLL cells vulnerable to compounds that impact mitochondria or inhibit glutamine metabolism. Indeed, our further study showed that combination of Ibrutinib with metformin (a drug that inhibits mitochondrial OXPHOS) or with C968 (a glutaminase inhibitor) had synergistic activity against CLL cells and induced massive leukemia cell death.
Summary/Conclusions: Overall, our study suggests that ibrutinib could induce metabolic alterations characterized by decreased mitochondrial respiration and attenuated glutamine metabolism. Such metabolic alterations provide a biochemical basis for mechanism-based drug combination to enhance the therapeutic activity of Ibrutinib. Since metformin is a diabetes drug with low toxicity, it is feasible to test its combination with Ibrutinib for treatment of CLL to potentially enhance therapeutic activity.

P204

BLOCKING ENDOTHELIN-1 SIGNALING DISRUPTS LEUKEMIC CELL HOMING AND B-CELL RECEPTOR PATHWAY IN CHRONIC LYMPHOCYTIC LEUKEMIA

R Maffei[1,2,*], S Fiorcari[1], S Martinelli[1], S Benatti[1], D Rossi[3], P Zucchini[1], G Gaidano[4], L Potenza[1], M Luppi[1], R Marasca[1]
[1]Department of Medical and Surgical Sciences, University of Modena and Reggio Emilia, [2]Department of Oncology, Hematology and Respiratory Track Diseases, Azienda Ospedaliero-Universitaria Policlinico di Modena, Modena, Italy, [3]Hematology, Oncology Institute of Southern Switzerland and Institute of Oncology Research, Bellinzona, Switzerland, [4]Department of Clinical and Experimental Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy

Background: Endothelin 1 (ET-1) is a 21-aa peptide that mediates its action by activating two G-protein-coupled receptor (GPCR) subtypes, ET_A and ET_B receptors. CLL cells secrete ET-1 and express ET_A and ET_B receptors on the cellular surface. ET-1 signaling improves CLL survival and proliferation and

reduces CLL sensitivity to phosphoinositide-3-kinase δ inhibitor idelalisib and fludarabine.
Aims: We asked whether ET-1 pathway may be involved in CLL homing and B-cell receptor (BCR) signaling pathway. Macitentan, a novel double inhibitor of ET_A and ET_B receptors, was tested in CLL in combination with the Btk inhibitor ibrutinib.
Methods: CD19+ CLL cells isolated from patients were treated *in vitro* with 100nM ET-1 with or without the addition of BQ-123, specific ET_AR inhibitor, BQ-788, specific ET_BR inhibitor or macitentan, a double ET_AR/ET_BR inhibitor. In some instances, CLL cells were pre-incubated with ibrutinib 0.5μM. We evaluated CLL migration, adhesion to stromal cells, calcium efflux and BCR signaling pathway. Moreover, the expression of ET-1, ET_AR and ET_BR in CD49d+ CLL *vs* CD49d- CLL as well as in $CXCR4^{high}$ CLL *vs* $CXCR4^{low}$ CLL was measured in peripheral blood of CLL patients by flow cytometry. We also evaluated big ET-1 level by ELISA in plasma samples from MBL, CLL patients at diagnosis and at first progression, in fludarabine resistant CLL and in CLL after ibrutinib treatment.
Results: First, we found that circulating $CXCR4^{high}$ CLL cells express higher levels of ET-1 and ET1 receptors than $CXCR4^{low}$ fraction ($p<0.05$). *In vitro*, ET-1 acts as a chemotactic factor for CLL cells. The blockage of ET receptors impairs CLL migration to ET-1 and also to other stimuli as CXCL12. In addition, ET-1 signaling is involved in CLL adhesion, as inferred on the basis of the following observations: (i) the blockage of ET receptors leads to CLL detachment from stromal cell supports; (ii) ET-1 stimulation promotes the phosphorylation of FAK, GSK3β, AKT and increases ILK expression in CLL cells and (iii) higher levels of ET-1 and ET receptors characterize CD49d+ CLL subset. Furthermore, we found that ET receptor triggering promotes calcium release in CLL. Blockage of both ET receptors by macitentan disrupts BCR signaling pathway and BCR-mediated calcium release in CLL cells in combination with ibrutinib. In plasma samples, big ET-1, the precursor of ET-1, was detectable in variable levels ranging from 0.6 to 67 pg/mL. Mean big ET-1 levels were equal to 2 pg/mL in MBL patients, 3.5 pg/mL in CLL at diagnosis, 7.9 pg/mL at first progression, 8.2 pg/mL at relapse, and 28.8 pg/ml in fludarabine-resistant CLL patients. In 4 CLL cases with plasma samples available before and after ibrutinib treatment, we found a significant decrease of big ET-1 in plasma from 10.8 to 3.9 pg/mL ($p<0.05$).
Summary/Conclusions: Collectively, our data describe for the first time an involvement of ET-1 signaling in CLL homing and BCR pathway. Moreover, ET-1 seems to accumulate in CLL patients with worse clinical features. Our results also envision the possibility to interfere with ET receptors activity using macitentan as a possible novel therapeutic strategy for CLL patients.

GENE EXPRESSION PROFILES OF PERIPHERAL BLOOD T AND NK-CELLS REVEALED DIFFERENT PATTERNS OF IMMUNE DYSFUNCTION IN CLL-LIKE MBL AND EARLY STAGE CLL

A Puiggros[1,2,*], G Blanco[1,2,3], M Rodríguez-Rivera[1,2], L Nonell[4], M Arnal[4], E Abella[5], E Gimeno[5], P Abrisqueta[6], M Bódalo[4], E Puigdecanet[4], M Salido[1,2], X Calvo[1,2], F Bosch[6], L Florensa[1,2], A Ferrer[1,2], B Espinet[1,2]
[1]Grup de Recerca Translacional en Neoplàsies Hematològiques, Cancer Research Program, IMIM-Hospital del Mar, [2]Laboratori de Citogenètica Molecular, Laboratori de Citologia Hematològica, Servei de Patologia, Hospital del Mar, [3]Department of Experimental and Health Sciences, Universitat Pompeu Fabra, [4]Microarray Analysis Service, [5]Servei d'Hematologia, IMIM-Hospital del Mar, [6]Servei d'Hematologia, Hospital Universitari Vall d'Hebron, Barcelona, Spain

Background: Immune evasion is important for the expansion of the tumoral clone in chronic lymphocytic leukemia (CLL). Impaired NK-cell activity and dysfunctional CD4+ and CD8+ T-cells with abnormal cytoskeletal dynamics and immune synapses have been reported in CLL. T and NK-cell dysregulation may be relevant in CLL-like monoclonal B-cell lymphocytosis (MBL) and initial stages of CLL, although it has not been studied in depth.
Aims: To compare the gene expression patterns of CD4+ and CD8+ T-cells and NK-cells from the peripheral blood of healthy controls, MBL subjects and CLL-A(0) patients. To assess the T and NK-cell dysfunction in these entities.
Methods: Samples from thirty-eight individuals (17M/21F, median age=72yrs) were collected: 9 healthy controls, 15 MBLs and 14 CLL-A(0) with an absolute lymphocyte count $<12x10^9$/L. T-cells (CD4+ or CD8+) and NK-cells (CD56+ CD3-) from all subjects were isolated by immunomagnetic methods (Miltenyi Biotec). Good quality extracted RNA (RIN>7) was hybridized to 113 Human Gene 2.0 ST arrays (Affymetrix). Differential gene expression between groups was evaluated employing linear models for microarrays in R. Genes with a P-value<0.05 and |logFC|>0.58 were considered as potentially relevant. Functional analysis was performed using Ingenuity Pathway Analysis (IPA). For the CD4+ T-cell fraction, expression results were validated by qPCR in the same and in an independent cohort composed by 10 MBL and 5 CLL-A(0) individuals.
Results: Unsupervised hierarchical clustering analysis clearly discriminated healthy controls from both MBL and CLL for CD4+ and NK-cells, where the major differences in the gene expression were found. Regarding CD4+, gene upregulation was notably predominant in MBL and CLL-A(0), mainly in terms of cytotoxicity (*GZMB, PRF1, GNLY, SERPING1, CLU, NKG7* and *FCRL6*) and signaling, cytoskeleton and membrane dynamics leading to an increased inflammatory response (*RAB31, VNN1, TNFSF4, ITGAM, TLR2*). Strikingly, MBL showed more upregulated networks and expressed genes with higher |logFC| values than CLL-A(0). Furthermore, some of the activated genes (*CCL5, MAP3K8, IL18RAP, NKG7, GZMH* and *PRF1*) have been previously described in Th1-cells, which points to a bias towards this T-cell subset in the Th1-Th2 axis. Additional qPCR analysis validated the expression results in this cell fraction. In contrast to previously described dysfunction of CD8+ T-cells in CLL, functional analysis did not reveal differences involving cellular migration, adhesion or cytotoxicity neither in MBL nor CLL-A(0). Regarding NK-cells, functional analyses showed a decrease of the NK function in both MBL and CLL-A(0), the latter showing higher number of differentially expressed genes and |logFC| values. The most relevant downregulated pathways were related to chemotaxis, adhesion and cell-to-cell binding (downregulation of *AMICA1, CCR4, CD4, FPR2, FPR3, KIT* and *XCL1*), as well as activation, cytotoxicity and cytoskeleton organization (down-regulation of *CD28, CD86, FCAR, FPR2, FPR3, ICOS* and up-regulation of *FCGR2B*).
Summary/Conclusions: 1. CD4+ T-cells show an unusual activation of cytotoxicity and inflammation that are higher in MBL than in CLL-A(0) patients. A Th1 expression pattern is also observed in these entities. 2. CD8+ T-cells dysfunction do not occur in our cohort of MBL and initial CLL. 3. NK-cell dysregulation in cytotoxicity and migration is already detectable in MBL, and increases progressively with the evolution of the disease. 4. These are preliminary results, validation and functional studies are ongoing.

Maria Misericordia, Udine, [5]Division of Hematology, Ferrarotto Hospital, Catania, Italy, [6]Department of Pathology and Cancer Center, University of New Mexico, Albuquerque, NM, United States, [7]Department with Hematology, Medical Oncology, Hemostaseology, Infectious Diseases and Rheumatology, Oncologic Center, Paracelsus Medical University Salzburg, Salzburg, Austria, [8]Division of Hematology, S. Eugenio Hospital and University of Tor Vergata, Rome, Italy

Background: Treatment with the B-cell receptor (BCR) signaling inhibitor ibrutinib (IB) has demonstrated high response rates and improved survival in chronic lymphocytic leukemia (CLL). IB treatment is associated with a highly variable degree of transient lymphocytosis, due to a reduction of CLL cell adhesion and efflux of CLL cells from tissue sites. CD49d, a strong negative prognosticator in CLL, is the alpha-chain of the integrin heterodimer CD49d/CD29 (VLA-4), a key molecule in CLL microenvironmental interactions. Inside-out activation of VLA-4 by BCR signals increases its adhesive properties, although the role of the BCR as a VLA-4 activator in CLL is unknown.
Aims: To correlate the kinetics of transient lymphocytosis with the expression and levels of activation of VLA-4.
Methods: Two cohorts of IB treated patients (IB-CLL) with data of absolute lymphocyte count (ALC) at pre-treatment and at different time points of IB treatment were available: 1) 28 refractory/relapsed CLL patients (15 CD49d+) treated with IB on a compassionate basis (IT cohort); 2) 26 CLL patients (14 CD49d+) enrolled in the investigator-initiated phase II study of ibrutinib NCT01500733 (US cohort).VLA-4 activation was assessed by flow cytometry using conformation sensitive anti-CD29 mAb HUTS-21 in conjunction with LDV-containing VLA-4 specific ligand. The levels of activated VLA-4 was measured as VLA-4 receptor occupancy (RO) in values ranging from 0.0 (no RO) to 1.0 (100% RO) as in Chigaev *et al.* (J Biol Chem, 2009): higher RO indicates a larger fraction of activated (*i.e.* with a higher affinity) VLA-4. BCR engagement was performed using goat F(ab')2 anti–human IgM. CD49d, CD29, IgM expression, and Ca^{++} release were cytometrically analysed. Adhesion assays were performed on VCAM-1-coated slides.
Results: Correlation between CD49d expression and IB-induced lymphocytosis was performed in both cohorts. Median ALC at baseline were $23x10^6$/mL and $29x10^6$/mL (IT cohort) and $67x10^6$/mL and $95x10^6$/mL (US cohort) for CD49d- and CD49d+ CLL, respectively. Despite these different baseline ALC, and although ALC data were available at slightly different timepoints, CD49d- CLL showed a more pronounced increase in ALC than CD49d+ cases in both cohorts (Figure 1). To explain the observed differences in ALC kinetics in CD49d+ and CD49d- CLL, VLA-4 inside-out activation upon BCR stimulation

was evaluated in CD49d+ CLL cells that were exposed in-vivo to IB. Cells collected from IB-CLL on t30 (n=7), showed slightly decreased (79-86%) CD49d, CD29, and IgM MFI levels compared to pre-treatment cells. Despite an overall impairment of BCR-dependent Ca^{++} signaling (mean Ca^{++} release: 12.4% at pre-treatment, 3.6% at t30), IgM stimulation increased both VLA-4 RO (mean 0.53-range 0.40-0.73-, compared to 0.36-range 0.22-0.52-, at pre-treatment, p=0.004; 0.53-range 0.41-0.84-, compared to 0.27-range 0.01-0.45-, at t30, p=0.010) and CLL cell adhesion (mean values of adherent cells/control= 4.6 *vs* 3.7 at pre-treatment and 4.5 *vs* 1.6 at day 30). Similarly, cells from IB-CLL on day 60-90 of treatment (n=3) kept showing an increased VLA-4 RO upon IgM stimulation (from 0.14, range 0.10-0.17 to 0.34, range 0.20-0.56), although Ca^{++} release was relevantly decreased.

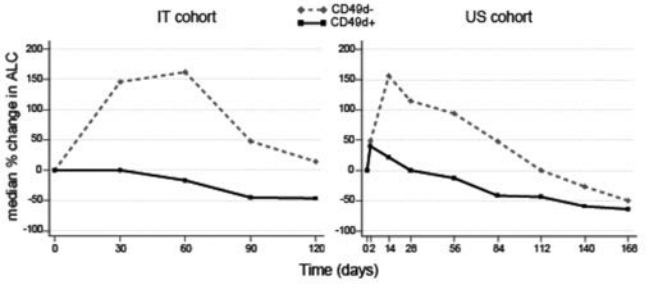

Figure 1.

Summary/Conclusions: BCR triggering in CLL cells activates VLA-4 via an inside-out pathway at least in part independent from IB binding to BTK. CD49d+ cells retain VLA-4 activation after IB treatment, with implications for CLL cell adhesion, and treatment-induced lymphocytosis. These observations should be considered in the design of IB therapies.

CLL - Efficacy and safety of new treatments 1

LONG-TERM FOLLOW-UP OF THE NEXT GENERATION PI3K-DELTA INHIBITOR TGR-1202 DEMONSTRATES SAFETY AND HIGH RESPONSE RATES IN CLL: INTEGRATED-ANALYSIS OF TGR-1202 MONOTHERAPY AND COMBINED WITH UBLITUXIMAB

A Mato[1,*], HA Burris III[2,3], I Flinn[2,3], M Lunning[4], J Vose[4], N Fowler[5], L Nastoupil[5], S O'Brien[6], MT Schreeder[7], MR Patel[2,8], TS Fenske[9], DM Brander[10], T Siddiqi[11], C Flowers[12], JA Burger[13], WG Wierda[13], JG Kuhn[14], P Sportelli[15], H Miskin[15], MS Weiss[15], OA O'Connor[16]

[1]Center for CLL (CCLL), Hospital of the University of Pennsylvania, Philadelphia, [2]Sarah Cannon Research Institute, [3]Tennessee Oncology, Nashville, [4]University of Nebraska Medical Center, Omaha, [5]Department of Lymphoma, MD Anderson Cancer Center, Houston, [6]University of California Irvine, Orange, [7]Clearview Cancer Institute, Huntsville, [8]Florida Cancer Specialists, Sarasota, [9]Division of Hematology/Oncology, Medical College of Wisconsin, Milwaukee, [10]Duke University Medical Center, Durham, [11]City of Hope National Medical Center, Duarte, [12]Emory University/Winship Cancer Institute, Atlanta, [13]Department of Leukemia, MD Anderson Cancer Center, Houston, [14]University of Texas Health Science Center at San Antonio, San Antonio, [15]TG Therapeutics, Inc., [16]Center for Lymphoid Malignancies, Columbia University Medical Center, New York, United States

Background: TGR-1202 is a novel, once-daily PI3Kδ inhibitor with a differentiated safety profile from other PI3Kδ inhibitors, and proven activity in patients (pts) with advanced hematologic malignancies. TGR-1202 is in clinical development as monotherapy and in combination with the glycoengineered CD20 mAb, ublituximab (UTX).

Aims: An integrated-analysis was conducted of pts dosed with TGR-1202 monotherapy or combined with ublituximab with a focus on outcomes in patients with CLL/SLL.

Methods: In both studies, there were no limits on prior therapies (Tx) and TGR-1202 was administered once-daily and escalated in 3 + 3 design with expansion cohorts explored. In the combo study, UTX was administered at a fixed dose of 900 mg per infusion. The primary endpoint was safety and efficacy was a secondary endpoint.

Results: Across both studies, a total of 152 pts (81 monotherapy/71 combined with UTX), including 40 CLL/SLL and 112 NHL patients were exposed to at least one dose of TGR-1202. Median age 65 yrs (22-86); 100 M/52 F; median # prior Tx=3 (1-14); 53% refractory to immediate prior Tx. Most frequent reported AE's (all grades; Gr 3/4): nausea (44%; 1%), diarrhea (42%; 2%), fatigue (36%; 3%), vomiting (23%; 0%) and neutropenia (19%; 16%). AST/ALT increase was 6% (3% Gr 3/4), pneumonia 6% (5% Gr 3/4) and pneumonitis 1% (<1% Gr 3/4). 64 pts received TGR-1202 for ≥6 mos, 33 for ≥1 year, with longest on >30 mos. Discontinuations due to AE's occurred in 8% of pts. Across both studies, 27 CLL/SLL pts received the therapeutic targeted dose of ≥800 mg (17 single agent, 10 combo with UTX) and were evaluable for efficacy. 48% of CLL patients exhibited high-risk cytogenetics (17p and/or 11q del). The combined ORR was 89% (4% CR) of which 22% had persistent lymphocytosis (all PR-L pts were on monotherapy). The median PFS in CLL was 24 mo (95% CI: 7.4, NR) as a single agent, and has not been reached for the TGR+UTX combo.

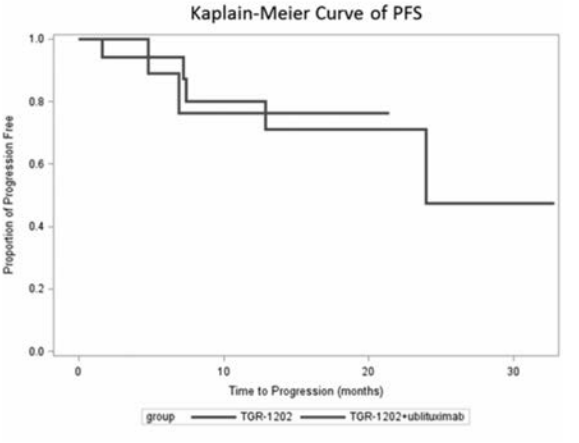

Figure 1.

Summary/Conclusions: TGR-1202 has exhibited a markedly differentiated safety profile from other PI3Kδ inhibitors to date with few discontinuations due to AE's and limited G 3/4 events. In particular we highlight the minimal rates of transaminitis / pneumonitis / colitis events across a large CLL/NHL population. Robust activity was observed in CLL, leading to a global Phase 3 trial evaluating

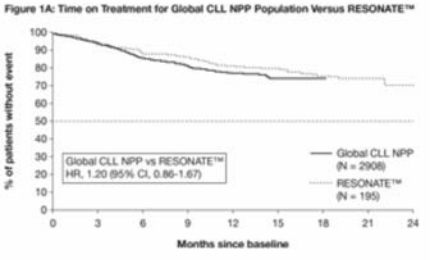
TGR-1202 in combination with UTX in treatment naïve and relapsed CLL. Based on the safety profile observed to date, combination Phase 1 & 2 trials exploring TGR-1202+ibrutinib, and the triple combinations of TGR-1202+ UTX+ibrutinib, and TGR-1202+UTX+pembrolizumab are ongoing. TGR-1202 is also being evaluated in a Phase 2 study in CLL patients intolerant to a BTK or PI3K delta inhibitor.

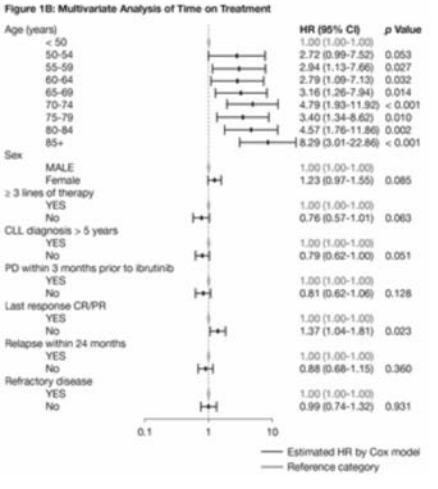
P208

REAL-WORLD EXPERIENCE OF IBRUTINIB IN >2900 CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS: DATA FROM A GLOBAL NAMED PATIENT PROGRAM

P Hillmen[1,*], J Diels[2], N Healy[3], W Iraqi[4], J Aschan[5], M Wildgust[6]
[1]The Leeds Teaching Hospitals, St. James Institute of Oncology, Leeds, United Kingdom, [2]Janssen EU HEMAR Statistics & Modeling, Beerse, Belgium, [3]Janssen-Cilag EMEA Medical Affairs, Dublin, Ireland, [4]Janssen Pharmaceuticals, Paris, France, [5]Janssen-Cilag EMEA Medical Affairs, Sollentuna, Sweden, [6]Janssen Research & Development, Raritan, United States

Background: A global named patient program (NPP) was opened in numerous countries worldwide in order to allow access to ibrutinib for eligible patients with relapsed/refractory chronic lymphocytic leukemia (CLL) prior to approval in those countries. This program provides real-world data on estimated outcomes with ibrutinib across a large, global CLL population.
Aims: To use real-world data from the ibrutinib CLL NPP to investigate whether treatment benefits reported in randomized clinical trials are reflected in outcomes observed in clinical practice.
Methods: In an analysis of ibrutinib ordering/reordering, we estimated patient time on treatment in order to provide a conservative approximation of progression-free survival (PFS) using Kaplan-Meier analysis and Cox proportional hazards regression. Reordering data were censored at the date of last ibrutinib supply or resupply (ibrutinib was resupplied every 1-3 months depending on stage of the NPP). Patients transferring to commercial ibrutinib after approval were censored at the time of NPP closure in their country.





Figures.

Results: Overall, 2908 patients with CLL from 30 countries participating in the global NPP were included in this analysis; median age was 69 years, and 66.3% were male. After 12 months, 77.3% (95% CI, 74.7-79.6%) of the global population remained on treatment. This estimate is similar to the 12-month time on treatment (81.5% [95% CI, 75.3-86.3%]) and PFS (83.8% [95% CI, 77.8-88.3%]) rates observed in the phase 3 RESONATE™ study of ibrutinib for relapsed/refractory CLL (inclusion criteria were similar for the CLL NPP and the RESONATE™ trial). Moreover, Kaplan-Meier curves for time on treatment for the global CLL NPP population and the RESONATE™ study were not statistically different (Figure 1A; CLL NPP *versus* RESONATE™: HR, 1.20 [95% CI, 0.86-1.67]). Limited baseline demographic information collected at NPP enrollment allowed an exploration of time on treatment via multivariate analysis (Figure 1B). Younger patients or those achieving complete/partial response to prior therapy had significantly longer time on treatment. Strong trends indicating longer time on treatment were observed for patients who had received fewer prior lines of therapy, as well as for male patients, those who were diagnosed with CLL within the last 5 years, and those with a progression-free interval of ≥3 months prior to ibrutinib treatment. Neither refractory disease (defined as no response to prior therapy [ie, stable disease or progression]) nor duration of response to prior therapy additionally impacted time on treatment. In total, 332 patients (11.4%) discontinued treatment during the observation period, the most common reasons being death (4.2%), disease progression (1.9%), and adverse events (1.7%).
Summary/Conclusions: Although NPP data are based on physician declarations and are unmonitored, this analysis provides a real-world estimate of time on treatment, which can be considered a conservative proxy for PFS. The estimates, determined from a large, global CLL population, were similar to those reported for RESONATE™, suggesting that results observed in ibrutinib clinical trials are reproducible in clinical practice.

P209

IMPACT OF ADDING RITUXIMAB TO VENETOCLAX ON THE RATE, QUALITY, AND DURATION OF RESPONSE IN PATIENTS WITH RELAPSED/ REFRACTORY CHRONIC LYMPHOCYTIC LEUKAEMIA: A CROSS-STUDY MULTIVARIABLE ANALYSIS

AW Roberts[1,*], S Ma[2], D Brander[3], TJ Kipps[4], JC Barrientos[5], MS Davids[6], MA Anderson[1], M Choi[4], C Tam[7], LL Lash[8], M Verdugo[8], SY Kim[8], M Zhu[8], JF Seymour[7]
[1]Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Cancer and Hematology Division, Melbourne, Australia, [2]Northwestern University, Chicago, [3]Duke University Medical Center, Durham, [4]University of California San Diego, San Diego, [5]Hofstra Northwell School of Medicine, Hempstead, [6]Dana-Farber Cancer Institute, Boston, United States, [7]Peter MacCallum Cancer Centre, Melbourne, Australia, [8]AbbVie Inc., North Chicago, United States

Background: Venetoclax (VEN) is a selective, potent, orally bioavailable BCL-2 inhibitor. High overall response rates (ORR, 79%) and complete response rates (CR, 20%) were attained in a first-in-human dose-escalation study (M12-175) of VEN monotherapy in patients (pts) with relapsed/refractory (R/R) chronic lymphocytic leukaemia (CLL) or small lymphocytic lymphoma (SLL). The addition of monthly rituximab (R; months 1-6) in combination with VEN is being evaluated in an ongoing phase 1b dose-escalation study (M13-365) and as of 28Oct2015, the observed ORR is 86% and the CR rate is 47%. Entry criteria for the two studies were similar, but distribution of pt demographic and disease characteristics differed.
Aims: To assess the effect of adding R to VEN on response rate as well as on the quality and duration of the response, relative to VEN monotherapy using post hoc exploratory multivariable analyses.
Methods: Analyses used a cutoff of 25 Aug 2015 for M12-175 and 28 Oct 2015 for M13-365. The median follow-up was 17 and 21 months for M12-175 and M13-365, respectively. Demographic and disease characteristics were analyzed if their distribution differed between the studies and/or they had been identified as VEN response-modifiers in prior exploratory analyses (Roberts et al, NEJM 2016). Included variables were: age, number of prior therapies received (<3 *vs* ≥3), maximum lymph node diameter (≤5 *vs* >5cm), 17p status by FISH (not deleted *vs* deleted), and VEN dose (evaluated using assigned dose cohort in each study: 400 *vs* <400mg [150, 200, 300mg] or >400 mg [500, 600, 800mg]). Pt inclusion required available data for all variables analyzed. Forward stepwise selection was applied for the model, starting with therapy (VEN plus R *vs* VEN monotherapy); a significance threshold of $p<0.2$ was used to add or remove variables to/from the model. Logistic regression analyses were performed for ORR (responder *vs* non-responder) and CR (CR/CRi *vs* all other pts). A Cox proportional hazards model was applied to evaluate differences in duration of response (DoR).

Table 1.

	ORR, Odds Ratio (95% CI); p-value	CR, Odds Ratio (95% CI); p-value	DoR, Hazard Ratio for Progression (95% CI); p-value
VEN plus R vs. VEN	1.142 (.433 – 3.015); p=.79	3.292 (1.527 – 7.097); p=.002	.235 (.078 – .703); p=.01
Prior therapies <3 vs ≥3	4.579 (1.624 – 12.908); p=.004	NS	NS
Lymph node size ≤5 cm vs >5 cm	NS	3.921 (1.807 – 8.506); p=.0005	.406 (.163 – 1.009); p=.052
17p status not deleted vs deleted	NS	NS	.452 (.193 – 1.058); p=.067
Age continuous variable	NS	NS	NS
Dose of VEN <400 mg vs 400 mg	NS	NS	3.129 (1.025 – 9.551); p=.045
>400 mg vs 400 mg	NS	NS	1.365 (.447 – 4.171); p=.59

NS, not included in the final model.

Results: Final models from stepwise regression analyses are summarized in the table. Following selection of the final model, 157 pts were evaluated for ORR (84, M12-175; 45, M13-365), 156 for CR (83, M12-175; 45, M13-365), and 105 for DoR (66, M12-175; 39, M13-365). Combination therapy did not influence ORR relative to VEN monotherapy (odds ratio: 1.142 [95% CI: 0.433-3.015]; *p*=0.79). Responses of CR/CRi were more likely with combination therapy (odds ratio: 3.292 [95% CI: 1.527-7.097]; *p*=0.002) and they were more durable, with longer DoR with combination *versus* VEN monotherapy (hazard ratio for progression: 0.235 [95% CI: 0.078-0.703]; *p*=0.01). When analyzed across both studies, pts who received <3 prior therapies were more likely to achieve a response. Confirming prior exploratory analyses, pts with maximum nodal diameter ≤5 cm were more likely to achieve CR. Pts receiving <400 mg VEN (400 mg is the phase 2 dose of VEN combined with R or monotherapy) had shorter DoR. The effects of other variables were not significant.
Summary/Conclusions: Results of these exploratory, cross-study, post hoc analyses support the choice of 400 mg VEN dosing and indicate higher CR rates and longer DoR with the combination of VEN plus R after adjusting for pt demographics and disease characteristics. VEN combined with R is currently being evaluated in the ongoing, phase 3 MURANO study randomized against bendamustine with R.

P210

PRELIMINARY RESULTS OF A PHASE II STUDY OF IBRUTINIB IN COMBINATION WITH FCR (IFCR) IN PREVIOUSLY UNTREATED, YOUNGER PATIENTS WITH CLL

MS Davids[1,*], HT Kim[1], J Bsat[1], A Savell[1], K Francoeur[1], JM Hellman[1], DM Brander[2], CA Jacobson[1], EP Hochberg[3], RW Takvorian[3], JS Abramson[3], DC Fisher[1], JR Brown[1]
[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, [2]Medical Oncology, Duke University Medical Center, Durham, [3]Medical Oncology, Massachusetts General Hospital, Boston, United States

Background: FCR is a standard initial therapy for younger patients (pts) with CLL; however, only about 20% of pts will achieve complete response (CR) with bone marrow minimal residual disease negativity (BM MRD-neg) (Boettcher *et al.*, 2012), which is likely a prerequisite for cure. Ibrutinib is an oral BTK inhibitor with an excellent efficacy and safety profile in CLL. We report on the preliminary results of an investigator-initiated, phase II study of ibrutinib plus FCR (iFCR) as upfront treatment for young, fit CLL pts (NCT02251548).
Aims: The primary aim of this open-label, single arm, multicenter phase II study is to determine the rate of CR with BM MRD-neg in younger CLL pts treated upfront with iFCR. Secondary aims are to assess response rates and safety/tolerability.
Methods: Ibrutinib 420 mg daily monotherapy is given for 7 days, and FCR per standard dosing is added on day 8. Up to 6 cycles of FCR are given concurrently with daily ibrutinib; growth factor support and antimicrobial prophylaxis are mandatory. Responders continue on ibrutinib maintenance until time of progression or unacceptable toxicity. Eligibility criteria include: age ≤65, requiring initial treatment by IW-CLL criteria, ECOG PS ≤1, and adequate organ function. CTCAE v4 and IW-CLL criteria are used to evaluate toxicity and efficacy, with response evaluations after 3 cycles, 2 mos. after final FCR, and q6 mos. thereafter. MRD is assessed by 4-color flow cytometry (10^{-4} sensitivity).
Results: As of 22 February 2016, 27 pts were enrolled. The median age at enrollment was 55 yrs (range 43-65). 7/25 (28%) had del (11q) and 1/25 (4%) had del (17p) with *TP53* mutation. Unmutated *IGHV* was present in 11/17 (65%), ZAP-70 was positive in 17/23 (74%), and 1/16 (6%) patient had *NOTCH1* mutation. In a 10 patient safety lead-in, there was no unexpected toxicity. Of the 27 total pts, hematologic toxicity includes neutropenia (26%; 15% gr 3-4), thrombocytopenia (56%; 19% gr 3-4), and anemia (19%, 4% gr 3-4). All grade non-hematologic toxicities occurring in ≥15% of pts include gr 1/2 nausea (63%), fatigue (33%), bruising (33%), rash (19%), and gr 1 diarrhea (15%). The only bleeding event was gr 1 epistaxis in 1 pt. SAEs include gr 4 febrile neutropenia, gr 3 atrial fibrillation, and gr 3 transaminitis in 1 patient each. In the 17 pts who have undergone re-staging after completing the iFCR combination, the ORR is 100%, including 8/17 (47%) with CR or CRi, all of whom are BM MRD-neg, and 9/17 (53%) with PR. The rate of MRD-neg in the BM is 13/17 (76%), including 5 patients in PR. 8/9 pts with PR have residual lymph nodes <2.5 cm in long axis by CT imaging. The median duration of therapy is 7.7 months (range 0.5-16.2), and 25 of the 27 pts remain on treatment. A pt who completed 6 cycles of iFCR and achieved CR with BM MRD-neg declined ibrutinib maintenance and remains in CR on observation, and the pt with del(17p) achieved PR and elected to pursue allogeneic stem cell transplant.
Summary/Conclusions: iFCR is a highly active combination for young, fit pts with CLL, with toxicities similar to FCR and ibrutinib given as individual therapies. Although the ORR and CR rates are similar to FCR historical controls, the 47% rate of CR with BM MRD-neg compares favorably to the 20% rate observed on the FCR arm of the CLL8 study. Additionally, several pts who achieved PR are BM MRD-neg, have small residual lymph nodes, and will be monitored for conversion to CR while on ibrutinib maintenance in this ongoing trial.

P211

PRESENCE OF MULTIPLE UNMUTATED IGHV REARRANGEMENTS IN CLL PATIENTS IS ASSOCIATED WITH A VERY SHORT TREATMENT-FREE SURVIVAL: RESULTS FROM 2 INDEPENDENT COHORTS

B Stamatopoulos*, D Bruce, A Timbs, H Dreau, A Schuh
Molecular Diagnostic Center, University of Oxford, Oxford, United Kingdom

Background: The immunoglobulin heavy-chain gene (IgHV) mutational status is considered the gold standard of prognostication in CLL and is currently determined by Sanger Sequencing (SSeq) that only allows for analysis of the major clone. Next-generation sequencing (NGS), in the other hand, is able to highlight multiple rearrangements within a patient. However, the prognostic significance of multiple subclones in CLL is still unknown.
Aims: The aim of the present work was to investigate the prognostic impact of multiple IgHV rearrangements on treatment-free (TFS) and/or overall (OS survival).
Methods: Using NGS, we sequenced the IgHV gene from 2 independent cohorts: (I) 270 unselected CLL patient samples obtained at diagnosis with a median follow-up of 83 months (range, 1-397) and (II) 227 patients from the UK Arctic-Admire FCR-based clinical trial with a median follow-up of 24 months (range, 0.1-215). The data were after correlated with TFS and/or OS.
Results: The presence of multiple rearrangements was confirmed by fluorescence electrophoresis of DNA fragments. We also showed that some IgHV biclonal patients had multiple clones by flow cytometry using a CD5/CD19/Kappa/Lambda staining. Accuracy of sequences obtained by NGS was validated by SSeq. In order to control for potential PCR/sequencing errors, only the most abundant sequences with a median depth of 32631 reads (range, 639-354763) were used to calculate the IgHV mutational status allowing a perfect concordance between SSeq and NGS. Reproducibility of results was confirmed by independent duplicate experiments. Based on IgHV-NGS subclonal profiles, we were able to define 5 different categories: patients with (a) multiple M clones, (b) 1M clone, (c) a mix of M-UM clones, (d) 1UM clone, (e) multiple UM clones. In the population obtained at diagnosis (composed of treated and untreated patients), IgHV-NGS classification stratified patients into 5 different subgroups with median TFS of >280 (a), 131 (b), 61 (c), 29 (d), 18 (e) months (P<0.0001) and a median OS of >397 (a), 292 (b), 196 (c), 137 (d), 106 (e) months (P<0.0001). The subgroups were associated with well-known prognostic factors such as ZAP70, CD38, LPL, lymphocyte doubling time or cytogenetic abnormalities. In the clinical trial population (composed only of treated patients), IgHV-NGS classification stratified patients into 5 different subgroups with median TFS of >38 (a), 37 (b), 17 (c), 19 (d) and 4 (e) months (P=0.0017). The very favorable prognosis of patients with multiple mutated rearrangements was not confirmed in the clinical trial population: indeed, this subgroup is composed of 85% of untreated patients in population (I) who were excluded in trial population (II) which by definition only contains treated patients. On the contrary, the very short median TFS of patient with multiple unmutated rearrangements was confirmed in both populations: patients with multiple unmutated IgHV have a significantly shorter TFS than patients with only one unmutated rearrangement (I. P=0.0190 and II. P=0.0359). In addition, their chance of requiring a treatment within the 4 first years after diagnosis is associated with a positive predictive value of 94% (I) and 90% (II).

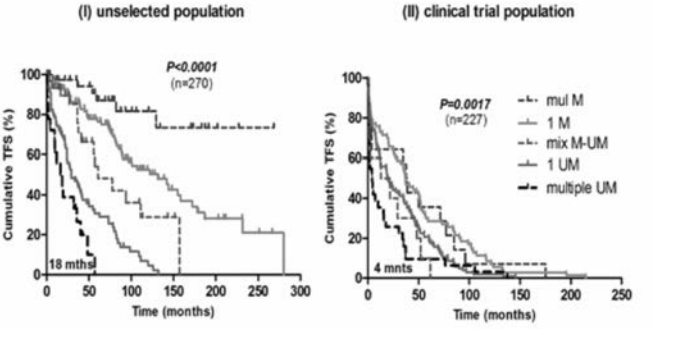


Figure 1.

Summary/Conclusions: Here, we showed for the first time that patients with multiple unmutated IgHV rearrangements determined by deep NGS have very aggressive disease with a very short TFS compared to patient with only one unmutated rearrangement. These finding will help identify patients at diagnosis who will require early treatment and consequently closer follow-up.

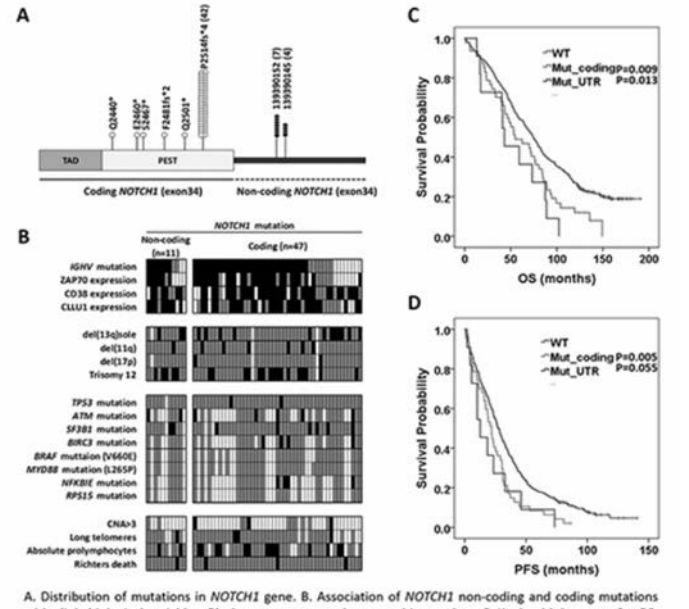
P212

NON-CODING NOTCH1 MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKAEMIA; THEIR CLINICAL IMPACT IN THE CLL4 CLINICAL TRIAL

M Larrayoz[1], MJ Rose-Zerilli[1], H Parker[1], SJ Blakemore[1], J Forster[1], Z Davis[2], AJ Steele[1], M Else[3], D Catovsky[3], DG Oscier[2], JC Strefford[4,*]
[1]Cancer Sciences Unit, Faculty of Medicine, University of Southampton, Southampton, [2]Department of Molecular Pathology, Royal Bournemouth Hos-

pital, Bournemouth, [3]Haemato-oncology Research Unit, Division of Pathology, The Institute for Cancer Research, Sutton, [4]Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom

Background: *NOTCH1* is recurrently mutated in approximately 10% of patients with Chronic Lymphocytic Leukaemia (CLL) and associates with reduced survival and Richters transformation. Whilst mutations were initially localized to exon 34 (termed 'coding'), recent whole genome sequencing analysis (Nature 2015, 526:519) showed additional mutations in the 3' UTR of *NOTCH1* (termed 'non-coding') resulting in in the same constitutive activation of Notch1. However, the clinical impact of these mutations on patients requiring therapy, enrolled into a clinical trial has not been ascertained.
Aims: To assess the incidence of *NOTCH1* non-coding mutations in the UK CLL4 trial and identify any associations with clinico-biological characteristics, progression free- (PFS) and overall survival (OS).
Methods: 489 CLL patients with available material were included in this study. High-resolution melt analysis, Sanger and high-throughput sequencing were employed to identify *NOTCH1* mutations.
Results: We identified 47/489 (9.6%) and 11/489 (2.2%) coding and non-coding mutations, respectively, with the latter being the those previously reported [139390152 A>G (n=7) and 139390145 A>G (n=4), Nature 2015, 526:519] (**Figure 1A**). The non-coding variants constituted 19% of the total *NOTCH1* mutations, with 11.8% of CLL4 patients carrying either *NOTCH1* mutation. *NOTCH1* non-coding mutations were mutually exclusive of *TP53, MYD88, RPS15* and *NFKBIE* mutations (**Figure 1B**). When considering all 58 mutations together, mutant *NOTCH1* was associated with unmutated *IGHV* genes (OR:2.93, 95%CI:1.38-6.23, P=0.005), CD38 (OR:4.48, 95%CI:2.30-8.72, P<0.001) and ZAP70 positive expression (OR:3.11, 95%CI:1.52-6.37, P=0.002) and the presence of trisomy 12 (OR:4.00, 95%CI:2.16-7.38, P<0.001). For non-coding mutations in isolation, only the association with trisomy 12 remained significant (OR:5.55, 95%CI:1.64-18.83, P=0.006). We analysed the impact of the two types of *NOTCH1* mutations on survival. Considered together, coding and non-coding mutations were associated with a significant reduction in OS and PFS with medians of 53.4 months *versus* 74.7 months (HR:1.63, 95%CI:1.22-2.17, P=0.001) and 19.3 *versus* 27.7 (HR:1.59, 95%CI:1.20-2.11, P=0.001), respectively, compared to wild-type patients. Considered separately, *NOTCH1* non-coding and coding mutations presented a significantly shorter OS than wild-type patients (median 43.2, 54.8 and 74.6 months to death, respectively, P=0.012 and P=0.013, respectively) (**Figure 1C**). Only coding *NOTCH1* mutations were significantly associated with reduced PFS compare to wild-type (median 22.0 *versus* 27.7 months, respectively, P=0.005) (**Figure 1D**). However, whilst not statistically significant, UTR mutations did exhibit reduced PFS (median 12.72, P=0.055) compared to wild-type patients. Cases with non-coding *NOTCH1* mutations were 80% (HR: 1.80, 95%CI: 0.99-3.28, P=0.055) more likely to progress and two-fold more likely to die (HR: 2.14, 95%CI: 1.17-3.92, P=0.013) than wild-type patients at last follow-up. When non-coding and coding mutations were combined, two additional features were noted: 1) combined *NOTCH1* status captured 11 more of both PFS and OS events compared to coding mutations alone, and 2) a trend was observed between the presence of *NOTCH1* mutations and death from Richters transformation (P=0.062).



A. Distribution of mutations in *NOTCH1* gene. B. Association of *NOTCH1* non-coding and coding mutations with clinic-biological variables. Black:presence, grey: absence, white:no data. C. Kaplan-Meier curve for OS. D. Kaplan-Meier curve for PFS.

Figure 1.

Summary/Conclusions: *NOTCH1* non-coding mutations constitute 19% of the total *NOTCH1* truncating mutational burden in patients requiring treatment in the UK CLL4 trial. Importantly, these non-coding mutations have a comparable impact on OS after first-line treatment with chemotherapy. This work supports the detection of non-coding *NOTCH1* mutations in patients requiring therapy.

P213

UPDATED RESULTS OF A PHASE 3 RANDOMIZED, CONTROLLED STUDY OF IDELALISIB IN COMBINATION WITH OFATUMUMAB FOR PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

T Robak[1,*], J Jones[2], M Wach[3], J Brown[4], A Menter[5], E Vandenberghe[6], L Ysebaert[7], N Wagner-Johnston[8], J Polikoff[9], F Awan[2], X Badoux[10], S Coutre[11], S Spurgeon[12], J Loscertales[13], G Xing[14], R Dubowy[14], I Flinn[15], C Owen[16]

Background: Idelalisib (IDELA) is an oral PI3Kδ inhibitor approved within the EU for use with rituximab in pts with relapsed CLL and as first-line treatment of CLL with either del(17p) or *TP53* mutation in patients unsuitable for chemoimmunotherapy. This open-label study (NCT01659021) compared IDELA + ofatumumab (OFA) *vs* OFA in pts with relapsed CLL. Results of the primary endpoint analysis were previously reported (Robak et al, EHA 2015) and are updated here with an additional 8.5 mos of follow-up. In the primary analysis, the combination yielded superior PFS and the KM estimated median OS was 20.9 and 19.4 mos in the IDELA + OFA and OFA arms, respectively.
Aims: To evaluate the safety and efficacy of IDELA + OFA *vs* OFA alone in patients with relapsed CLL.
Methods: Pts with CLL progressing ≤24 mo from last therapy, who had received ≥2 cycles of a purine analogue or bendamustine, were randomized 2:1 to either Arm A (IDELA 150 mg BID continuously plus OFA, 300 mg IV wk 1, then 1 g IV q wk x 7 and q 4 wk x 4) or Arm B (OFA, same as Arm A except 2 g was substituted for 1 g dosing) with stratification factors relapsed *vs* refractory, del(17p) and/or *TP53* mutation, and *IGHV* mutation. The primary endpoint was PFS as determined by an Independent Review Committee using modified IWCLL 2008 criteria.
Results: Pt characteristics were balanced in the 2 arms: med age 67; Rai II/III/IV 18/13/51%, med no. prior regimens 3, refractory 49%, del(17)p/*TP53*mut 40%, *IGHV* unmut 78%. Exposure, disposition, and efficacy are shown in the table. Results were consistent across risk groups. Gr ≥3 AEs in Arm A included diarrhea/colitis (23.1%), pneumonia (19.7%), and pneumonitis (4.6%).

Table 1.

	Arm A (IDELA/OFA)	Arm B (OFA)	HR / OR[2]
Pts randomized/dosed	174/173	87/86	-
Months on study (range)	16.1 (1.1 - 28.5)[1]	5.8 (0 - 25.4)	-
Reason for study D/C, n (%)			
PD[3]	52 (29.9)	44 (50.6)	-
Death	26 (14.9)	6 (6.9)	-
AE/Physician decision	29 (16.7)	19 (21.8)	-
Withdrew consent/other	15 (8.6)	17 (19.5)	-
Med PFS[4], mo	16.4	8.0	HR = 0.27, p < 0.0001
ORR, %	75.3	18.4	OR = 15.9, p < 0.0001
Q1[5] of OS[4] (95% CI), mo	18.2 (12.3, 22.7)	12.7 (6.0, 19.3)	-
Med OS[4] (95% CI), mo	NR (25.8, NR)	NR (21.7, NR)	HR = 0.75, p = 0.27
Del(17p)/*TP53*mut: Med OS[4] (95% CI), mo	25.8 (22.7, NR)	19.3 (10.7, NR)	HR = 0.52, p = 0.03

[1]IDELA med exposure 12.3 mo (0.2-23.9); [2]odds ratio; [3]per physician; [4]KM estimation; [5]1st quartile

Summary/Conclusions: With >8 mos longer follow-up, IDELA + OFA *vs* OFA continues to show superior PFS and ORR, and now demonstrates superior OS in pts with del(17p)/*TP53*mut and a trend of improvement of OS in the ITT population.

P214

AN EVALUATION OF THE CLL-IPI SCORE AND COMPREHENSIVE PROGNOSTIC FACTOR ANALYSIS IN PATIENTS WITH R/R CLL IN IDELALISIB PHASE 3 RANDOMIZED STUDIES

JD Soumerai[1,*], JC Barrientos[2], M Hallek[3], TJ Kipps[4], JA Jones[5], G Xing[6], NS Yao [6], L Ysebaert[7], S Stilgenbauer[8], AD Zelenetz[1]
[1]Memorial Sloan-Kettering Cancer Center, New York, NY, [2]Hofstra North Shore-

LIJ School of Medicine, Hempstead, NY, United States, [3]Department of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital, Cologne, Germany, [4]University of California San Diego Moores Cancer Center, La Jolla,CA, [5]Ohio State University, Columbus, OH, [6]Gilead Sciences, Inc., Foster City, CA, United States, [7]Department of Haematology, Institut Universitaire du Cancer de Toulouse - Oncopôle, Toulouse, France, [8]University of Ulm, Ulm, Germany

Background: The International Prognostic Index for patients (pts) with chronic lymphocytic leukemia (CLL-IPI) is a scoring system with prognostic value for overall survival (OS) in untreated CLL (Bahlo J *et al. Haematologica* 2015; 100: 313), but has not been studied in relapsed/refractory (R/R) CLL or in the context of novel agents. The CLL-IPI is a risk-weighted model consisting of 5 risk factors: age (relative weight, 1), stage (1), β2-microglobulin (2), IGHV mutation status (2), and del(17p)/TP53 mutation (17p-/TP53M) (4). Since IDELA is active in CLL with 17p-/TP53M, which is a major contributor to the CLL-IPI, we hypothesized that IDELA would overcome the negative impact of a high CLL-IPI.
Aims: 1) To assess the prognostic utility of CLL-IPI in R/R CLL in IDELA phase 3 randomized trials; 2) To determine if IDELA overcomes the negative impact of a high CLL-IPI; 3) To identify independent risk factors for OS in pts with R/R CLL and in pts treated with IDELA
Methods: The CLL-IPI was analyzed among 460 pts with R/R CLL requiring treatment who received IDELA+rituximab (R) *vs* placebo+R (NCT01539512), or IDELA+ofatumumab (O) *vs* O (NCT01659021). Subgroup analyses were conducted in 274 pts treated with IDELA+R or IDELA+O (IDELA cohort) and 186 pts treated with R or O (Control). Median OS was estimated using the Kaplan-Meier method for the 4 CLL-IPI risk groups: low (score 0-1), intermediate (2-3), high (4-6), and very high (7-10). The log-rank test was used to compare survival distributions across CLL-IPI risk groups. Multivariate analyses of prognostic factors for OS were performed. Factors with a p-value of <0.1 in the univariate analysis (log-rank test) were included in the multivariate analyses (Cox proportion hazards model).
Results: Most pts with R/R CLL have very high (40.9%) and high risk CLL-IPI (49.6%), and intermediate (8.3%) and low risk CLL-IPI (1.3%) are rare. Notably, only 0.6% pts with R/R CLL were Rai 0/Binet A. At a median follow-up of 14.7 months, the CLL-IPI score was validated in pts with R/R CLL with significant differences in OS across CLL-IPI risk groups (p=0.0001). In subgroup analyses, the CLL-IPI was prognostic for OS in the Control (p=0.0007) but not in the IDELA cohort (p=0.086). In the multivariate analyses: 17p-/TP53M, B2M, LDH and Karnofsky performance status (KPS) were independently prognostic for OS in pts with R/R CLL. While B2M, KPS and 17p-/TP53M were independently prognostic for OS in the Control cohort, only LDH and age were independently prognostic for OS in the IDELA cohort.

Table 1.

Multivariate analyses:	R/R CLL		IDELA Cohort		Control Cohort	
Overall Survival	HR (95% CI)	P value	HR (95% CI)	P value	HR (95% CI)	P value
B2M ≥3.5	2.29 (1.09, 4.8)	0.0283	1.69 (0.64, 4.45)	0.2912	3.29 (1.01, 10.69)	0.0482
LDH elevated	1.65 (1.15, 2.36)	0.0064	1.73 (1.03, 2.89)	0.0376	1.63 (0.97, 2.74)	0.0665
Age ≥65	1.44 (0.97, 2.15)	0.074	2.01 (1.11, 3.62)	0.0202	0.94 (0.54, 1.65)	0.8333
KPS ≤70	1.93 (1.33, 2.8)	0.0005	1.47 (0.86, 2.52)	0.161	2.91 (1.71, 4.93)	0.0001
17p-/TP53M	1.63 (1.15, 2.32)	0.0066	1.41 (0.86, 2.3)	0.1732	1.88 (1.12, 3.15)	0.0161
IGHV unmutated	1.45 (0.88, 2.37)	0.1448	1.48 (0.76, 2.86)	0.2475	1.32 (0.61, 2.85)	0.4764

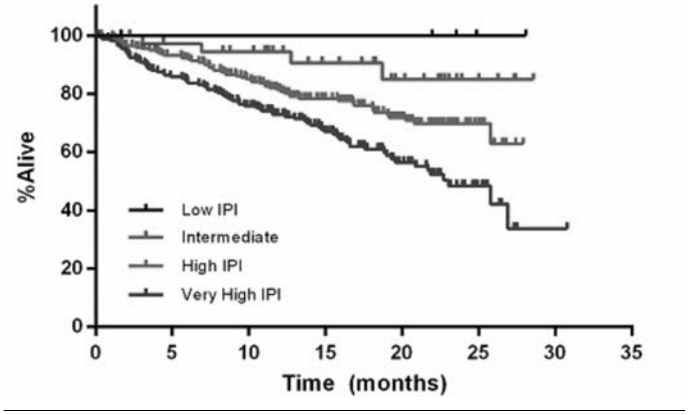

Figure 1.

Summary/Conclusions: Although low/intermediate-risk CLL-IPI is uncommon in R/R CLL, the CLL-IPI may be prognostic for OS in this population. These data suggest that IDELA overcomes the negative impact of high-risk CLL-IPI. While 17p-/TP53M, B2M, LDH and KPS were prognostic for OS in pts with R/R CLL, the current analysis indicates that only age and LDH may be prognostic for OS in pts treated with IDELA in combination with an anti-CD20 monoclonal antibody. Additional work is needed to develop adjusted risk models for pts with R/R CLL and for pts treated with targeted agents.

P215

DISCONTINUATION OF IDELALISIB TREATMENT DUE TO DISEASE PROGRESSION IN PATIENTS WITH RELAPSED AND REFRACTORY CLL: AN EVALUATION OF OUTCOMES

JR Brown[1,*], P Ghia[2], JA Jones [3], AR Pettitt[4], JP Sharman[5], L Ysebaert[6], Y Kim[7], T Newcomb[7], NS Yao[7], RR Furman[8], S Stilgenbauer[9]
[1]Dana-Farber Cancer Institute, Boston, United States, [2]Universita Vita-Salute San Raffaele and IRCCS San Raffaele Scientific Institute, Milan, Italy, [3]Ohio State University, Columbus, United States, [4]Department of Molecular and Clinical Cancer Medicine, University of Liverpool, Liverpool, United Kingdom, [5]US Oncology Network/Willamette Valley Cancer Institute, Springfield, Oregon, United States, [6]Department of Haematology, Institut Universitaire du Cancer de Toulouse - Oncopôle, Toulouse, France, [7]Gilead Sciences, Inc., Foster City, CA, [8]Weill Cornell Medical College, New York, NY, United States, [9]University of Ulm, Ulm, Germany

Background: There have been reports of rapid decline leading to death in patients with CLL following discontinuation of B-cell receptor pathway-targeted therapy (Jain, *et al. Blood*. 2015;125(13):2062-7). Idelalisib (IDELA) is a first in class PI3Kδ inhibitor which inhibits multiple signaling pathways, including those downstream of the B-cell receptor, CXCR4, and CXCR5. It is administered orally until disease progression or intolerance. Outcomes of patients with CLL who discontinued IDELA treatment either due to progressive disease (PD) or adverse events (AEs) have not been described comprehensively.
Aims: The objective of this post hoc analysis was to examine the outcomes of patients with R/R CLL who discontinued IDELA.
Methods: Data were pooled for patients with R/R CLL who were randomized to treatment with either IDELA+ofatumumab (n=173) in Study 119 or IDELA+rituximab (n=110) in Study 116 (including long-term follow up in extension Study 117). Time-dependent endpoints were calculated from the dates of IDELA discontinuation, including: time to next therapy (TTNT), and time to death (TTD). Kaplan-Meier analysis was used to estimate overall survival (OS) from the date of randomization. Subgroup OS analyses were performed using the integrated safety data set.
Results: Of 283 patients in the safety population, 124 (44%) remained on IDELA, 28 (10%) discontinued due to PD (22 CLL progressions and 6 Richter's transformations (RT), and 131 (46%) discontinued for reasons other than PD. Presence of -17p/TP53 mutation at baseline was reported for 54% of patients who discontinued due to PD, 41% of patients who discontinued due to AEs, and 37% of patients who remained on IDELA treatment. The clinical outcomes for those patients who discontinued IDELA treatment due to PD are tabulated.

Table 1.

	IDELA D/C due to PD (n=28)
OS, mos	
Median (95% CI)	18.8 (15.5, NR)
OS at 24 months, %	44.4%
TTNT, mos	
n	7
Median (95% CI)	0.9 (0.2, 3.7)
TTD, mos	
n	9
Median (95% CI)	2.4 (0.1, 9.9)

Summary/Conclusions: In contrast to reports for other B-cell receptor pathway inhibitors, discontinuation of IDELA due to progression of CLL does not appear to be associated with shortened survival.

P216

ASSOCIATION BETWEEN KIR/HLA GENOTYPE AND OUTCOME IN THE CLL11 STUDY OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS RECEIVING CHLORAMBUCIL ALONE OR IN COMBINATION WITH OBINUTUZUMAB OR RITUXIMAB

G Terszowski[1,*], N Crompton[2], V Goede[3], K Humphrey[2], G Lei[2], C Klein[4], K Mundt[5], M Stern[1,4]
[1]University Hospital Basel, Basel, Switzerland, [2]Roche Products Ltd, Welwyn, United Kingdom, [3]Dept. I of Internal Medicine, University of Cologne, Cologne, Germany, [4]Roche Innovation Center, Zurich, [5]F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background: Interaction between killer cell immunoglobulin-like receptors (KIRs) and HLA class I molecules results in negative regulation of natural killer (NK) cells. Depending on an individual's KIR/HLA genotype, the number of possible inhibitory KIR/HLA interactions can range from 1-3. Previous analyses suggest a negative correlation between response to monoclonal antibody therapy and number of KIR/HLA interactions, with a lower number resulting in increased NK cell activation and a stronger response to treatment. Findings from in-vitro studies suggest that inhibitory signaling through KIRs observed with the conventional anti-CD20 antibody rituximab (R) may be overridden by the enhanced NK-cell activation associated with the glycoengineered anti-CD20 antibody obinutuzumab (GA101; GAZYVA/GAZYVARO; G).
Aims: To analyze the association between KIR/HLA genotype and treatment outcome using data from the CLL11 study (NCT01010061) comparing chlo-

rambucil (Clb), R plus Clb (R-Clb), and G plus Clb (G-Clb) as first-line treatment in patients (pts) with CLL.
Methods: Pts with available DNA who provided informed consent for genomic analysis were included. Genotyping was performed for the inhibitory KIR genes *2DL1*, *2DL2/3* and *3DL1* and their respective HLA ligands *HLA-C2*, *HLA-C1* and *HLA-Bw4*. Multivariate Cox regression analysis was performed to determine the association between number of KIR/HLA interactions (based on the presence of a receptor-ligand pair) and progression-free survival (PFS). Overall response rate (ORR) and minimal residual disease (MRD) negativity at end of treatment by number of KIR/HLA interactions was also evaluated. In the main analysis, pts carrying genes for 1 or 2 interactions (1-2i) were compared with pts carrying genes for all 3 interactions (3i). As this was an exploratory analysis, p-values were not adjusted for multiple testing.
Results: In total, 489 pts were included in the analysis (Clb, n=74; R-Clb, n=203; G-Clb, n=212). The number of KIR/HLA interactions was: 1 in 104 pts (21%); 2 in 221 pts (45%); and 3 in 164 pts (34%). In the Clb arm, KIR/HLA genotype did not significantly influence PFS (median PFS: 1-2i, 11.1 months [mo]; 3i, 10.6 mo; adjusted HR 0.75, 95% CI 0.42-1.34, p=0.33). The impact of KIR/HLA genotype on PFS tended to be stronger in pts treated with R-Clb (median PFS: 1-2i, 18.0 mo; 3i, 14.7 mo; HR 0.79; 95% CI 0.56-1.10; p=0.16) or G-Clb (median PFS: 1-2i, 29.6 mo; 3i, 22.9 mo; HR 0.69, 95% CI 0.47-1.00, p=0.05). A similar effect was seen for ORR, although differences were not statistically significant (Clb: 1-2i, 31% *vs* 3i, 39%; R-Clb: 1-2i, 70% *vs* 3i, 59%; G-Clb: 1-2i, 79% *vs* 3i, 71%). MRD negativity appeared higher for 1-2i pts in the G-Clb arm (39% *vs* 3i, 26%), but not in the R-Clb arm (3% *vs* 3i, 2%); p>0.05 for both arms. No pt achieved MRD negativity in the Clb arm. Analysis of pts with 1i *vs* 2i *vs* 3i suggested a trend of association between the KIR/HLA interaction number and PFS in G-Clb pts (median PFS: 33.5 mo *vs* 29.1 mo *vs* 22.9 mo, respectively; HR 1i *vs* 3i 0.60, 95% CI 0.36-1.00, p=0.05; HR 2i *vs* 3i 0.73, 95% CI 0.49-1.10, p=0.13).
Summary/Conclusions: Pts with a lower number of KIR/HLA interactions appeared to have a consistently better outcome across a number of efficacy parameters when treated with anti-CD20 antibodies; the strongest effect was observed in the G-Clb arm. These findings warrant investigation of combined KIR-blockade with anti-CD20 antibody treatment in pts with CLL to decrease the impact of these inhibitory interactions on antibody-dependent cell-mediated cytotoxicity.

CLL - Efficacy and safety of new treatments 2

Background: CLL primarily affects older pts who often have comorbidities and disease-related immunosuppression. Improvement of health-related quality of life (QOL) is an important therapy endpoint. In pts with CLL, QOL per EORTC QLQ-C30 is significantly compromised (Holtzer-Goor Qual Life Res 2015). Ibr is the first-in-class, once-daily, oral inhibitor of Bruton's tyrosine kinase approved for CLL pts with ≥1 prior therapy. Ibr was associated with improvement in QOL in R/R CLL pts on RESONATE study (Barrientos ASH 2014). The recent phase 3 PCYC-1115 trial (RESONATE-2) showed superior PFS, OS, response, and hematologic improvement with ibr *vs* clb in older TN pts with CLL, with a favorable safety profile (Burger NEJM 2015).
Aims: To evaluate outcomes associated with pt well-being from RESONATE-2 in 1st-line CLL.
Methods: After informed consent, TN pts ≥65 years (yrs) received 420 mg ibr once daily until progression or clb for up to 12 cycles. Patient-reported QOL was measured by change from baseline to each assessment time for FACIT-Fatigue (F) and QLQ-C30 in the ITT population.

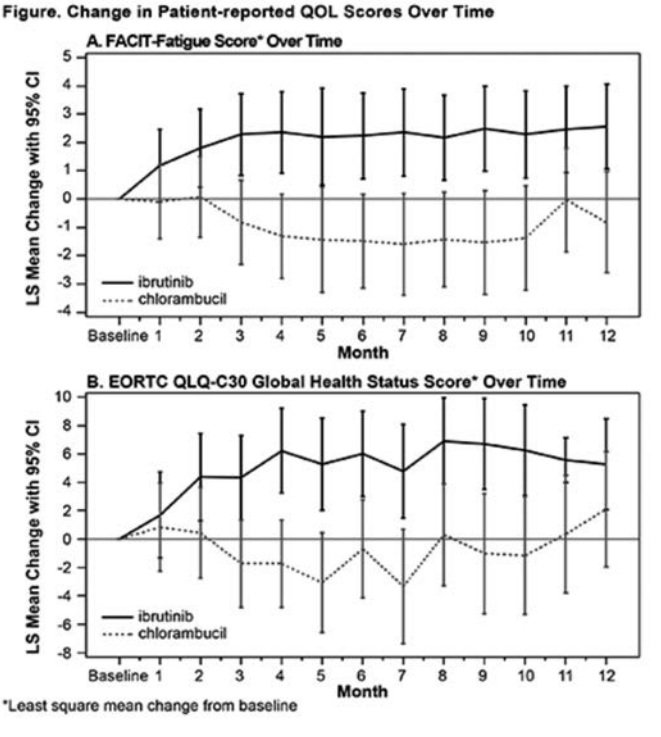

Figure 1.

Results: In 269 randomized pts, median age was 73 yrs (≥70 yrs in 70%) and 69% had comorbidities (CIRS score >6, reduced creatinine clearance, or ECOG status 2). Median follow-up was 18.4 mo. Ibr resulted in greater improvements over time compared to clb in FACIT-F (P=0.0004) and QLQ-C30 global health (P=0.0002) by repeated measures (Figure 1). Baseline hemoglobin (Hb) correlated with FACIT-F; Hb improvement was associated with meaningful improvement in fatigue. Sustained improvement in hematologic function occurred in 84% of ibr pts with baseline anemia and 77% with baseline thrombocytopenia (vs 45% and 43% for clb), both occurring earlier with ibr; median time to first sustained improvement in Hb was 4 mo (vs 12 mo with clb; P=0.0003) and in platelets was 3 mo with ibr (vs 11 mo with clb; P=0.0269). Lymph node (LN) and spleen reductions ≥50% occurred in 95% and 95% of ibr pts *vs* 40% and 52% with clb, with complete resolution in lymphadenopathy and splenomegaly in 42% and 56% *vs* 7% and 22%, respectively. At first assessment (4 mo), median reductions of 73% in LN and 72% in spleen occurred with ibr *vs* 17% and 17% with clb. Disease symptoms including fatigue, night sweats, and weight loss improved more frequently with ibr *vs* clb. No decrement in median IgG or IgM levels was observed for ibr, with relative increase in IgA. Median exposure for ibr was 17.4 mo *vs* 7.1 mo for clb. Most frequent ibr adverse events (AEs) were largely mild (grade 1) including diarrhea, fatigue, cough and nausea. Atrial fibrillation occurred in 8 pts on ibr (6 within the first 6 mo), which was largely grade 1-2 with 2 grade 3 events. Anticoagulants and antiplatelet agents were frequently used (53% of pts), most commonly aspirin. Major hemorrhage was observed in 6 ibr pts including 2 within first 6 mo, 3 during mo 6-12, and 1 during mo 12-18. Clb arm had 2 major hemorrhages, 1 each in first 6 mo and 6-12 mo. The exposure-adjusted infection rate for pts treated with ibr *vs* clb was 7.5 *versus* 10.1 per 100 patient-mo. Grade ≥3 infections decreased with time for ibr. AEs leading to ibr discontinuation were infrequent with most occurring during first 6 mo. 87% of pts continued ibr.

Summary/Conclusions: In TN CLL pts, ibr compared with clb was associated with greater improvements in QOL and hematologic function, as well as reduction in disease burden. The safety profile was favorable allowing for 87% of this elderly population with frequent comorbidity to continue therapy after median 1.5 yrs of follow-up.

P218

ULTRA DEEP TARGETED NEXT GENERATION SEQUENCING FOR THE DETECTION OF SUBCLONAL TP53 ABERRATIONS IN CLL

C Brieghel[1,*], LB Pedersen[1], L Jönson[2], CW Yde[2], C da Cunha-Bang[1], CU Niemann[1]

[1]Department of Haematology, [2]Center for Genomic Medicine, Copenhagen University Hospital, Rigshospitalet, Copenhagen O, Denmark

Background: *TP53* aberrations (del(17p) and/or *TP53* mutations) are well-characterized as a prognostic marker in chronic lymphocytic leukemia (CLL). However, subclonal *TP53* aberrations as low as 0.3% allelic burden has been demonstrated to result in as poor survival as for patients (pts) with clonal *TP53* aberrations (Rossi *et al. Blood.* 2014, Nadeau *et al. Blood*. 2016). As low allelic burden *TP53* mutations are expected to influence choice of treatment for pts with CLL, it is of the outmost importance to develop a robust, reproducible, and sensitive assay. We here describe the development of an assay refining the detection of subclonal levels of *TP53* as low as 0.1% based on algorithms combined with a dilution step.

Aims: To establish a clinical tool to evaluate very small subclonal *TP53* aberrations.

Methods: Purified DNA from four CLL pts with known clonal levels of *TP53* mutations (detected by Sanger) were diluted with wild type (wt)-TP53 DNA to 10%, 1%, and 0.1%. wt-TP53 DNA was used as reference. Twenty-one amplicons of approximately 180 base pairs (bp) lengths covering *TP53* exons 2-10 were generated and in order to minimize the error rate of nucleotide incorporation a proofreading DNA polymerase was used. Amplicons were purified, adaptor ligated, and sequenced using targeted next generation sequencing (tNGS). All sequences were trimmed 5' and 3' to remove primer DNA *in silico*. To diminish background noise, variants were only called if a minimum of 10 reads of the aberration were detected, and only if variants were also present in a dilution at the expected frequency. The same method was applied with four breast cancer pts with known clonal levels of *TP53* insertions or deletions (INDELS), to test performance of our algorithm with INDELS. These samples were first diluted with wt-TP53 DNA into subclonal levels (5% patient DNA) and then further diluted in a 1:3 and 1:10 ratio. We further optimized our test by reducing the number of 180-220 bp amplicons needed to cover *TP53* exons 2-10.

Results: With a median coverage of 30,587x (range: 0-94,696x, with 85% >13,331x) and 41,465x (range: 134-113,468x, with 85% >14,116x) for the pts with CLL and breast cancer respectively, we were able to detect the known mutations in all eight samples (3 substitutions, 3 deletions, and 2 insertions). One CLL sample also contained a previously unknown subclonal substitution. All background noise could be clearly eliminated *in silico* with the inclusion of the dilution step. Including a 1:3 or a 1:10 dilution step showed same results. The current detection level for the assay is approximately 0.1% allelic burden (Figure 1). However, mutations were still detectable as low as 0.02% allelic burden. One single variant call within the tested eight samples was above 0.3% allelic burden but discarded as background noise (163 reads at 51,000x) based on our novel dilution algorithm. This false positive aberration would have been called as a true mutation with the cut-off based on statistical algorithms used by other groups in previous publications.

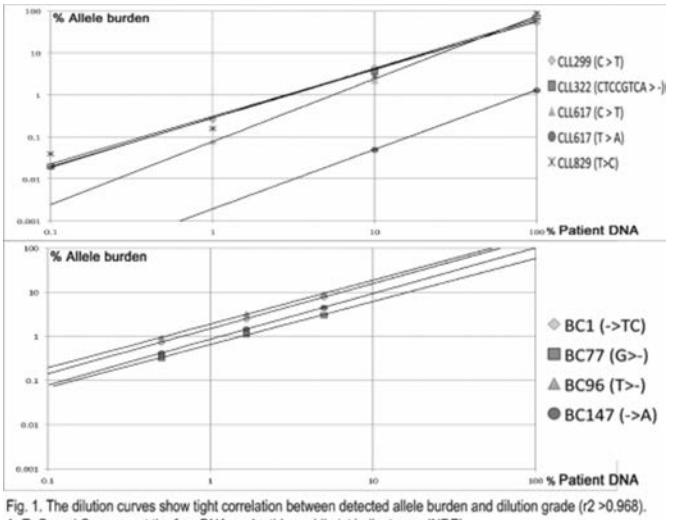

Fig. 1. The dilution curves show tight correlation between detected allele burden and dilution grade (r2 >0.968). A, T, G, and C represent the four DNA nucleotides, while '–' indicates an INDEL.
A) All four CLL TP53 mutations diluted in wt-TP53 DNA to 10%, 1%, and 0.1% were detected. Sample CLL617 show excessive dilution with an allelic burden of less than 0.1% at 1% dilution, thus not detectable at the highest dilution. Sample CLL617 also harbored a subclonal T>A substitution at chr17:7579394 (hg19), which was detected for the first time by our assay.
B) All four breast cancer TP53 INDELS diluted to 5%, 1.67%, and 0.5% in wt-TP53 DNA were detected. There were no differences between including a 1:3 or a 1:10 dilution step, when calling the variants, indicating a lower level of detection of only 0.06% allele burden with the inclusion of a 1:3 dilution step.

Figure 1.

Summary/Conclusions: We here describe for the first time the development of a more robust tNGS assay enabling the detection of very low allelic burden *TP53* mutations. At the same time, false positive variant calls can be discarded based on the inclusion of a dilution step, while the sensitivity for both substitutions and INDELS is as low as 0.1%. The assay is undergoing further validation in a retrospective cohort of pts with CLL. The assay will subsequently be implemented as part of the diagnostic tools available at Copenhagen University Hospital, Rigshospitalet.

P219

COMPARABLE OUTCOMES IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS TREATED WITH REDUCED DOSE IBRUTINIB: RESULTS FROM A MULTI-CENTER STUDY

R Banerjee[1,*], C Timlin[2], D Fitzpatrick[2], C Howlett[3], CS Ujjani[4], M Fanning[2], SJ Schuster[2], J Svoboda[2], DL Porter[2], EA Stadtmauer[2], BD Cheson[4], AP Skarbnik[3], T Feldman[3], A Goy[3], C Dorsey[2], DL Capozzi[2], DJ Landsburg[2], S Nasta[2], AR Mato[2]

[1]Department of Medicine, Hospital of the University of Pennsylvania, [2]Center for CLL, Abramson Cancer Center, University of Pennsylvania, Philadelphia, [3]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, [4]Lombardi Comprehensive Cancer Center, Georgetown University, Washington, DC, United States

Background: Ibrutinib (Ibr) is a first-in-class oral covalent inhibitor of Bruton's tyrosine kinase (BTK). Ibr is dosed according to guidelines for chronic lymphocytic leukemia (CLL) patients at 420mg daily to achieve >90% BTK occupancy (≥2.5mg/kg/day). Although fewer patients achieve >90% occupancy at <420mg daily, it is unknown whether lower Ibr doses translate into inferior outcomes. To address this question, we conducted a multi-center study to capture experiences of CLL patients treated with Ibr below suggested starting doses.

Aims: This study evaluated survival outcomes for CLL patients treated with Ibr at reduced doses.

Methods: We conducted a multi-center, IRB approved, retrospective study of all Ibr-treated CLL patients between 1/2010 and 10/2015. Demographics, Ibr dose, clinical responses, and outcomes were recorded. Reduced Ibr dose was defined as sustained (≥2 months) dosing at <420mg/day, either at treatment initiation or within 3 months of initiation. The primary study endpoints were progression-free survival (PFS) and overall survival (OS), estimated by the Kaplan Meier method and stratified by Ibr dose (standard dose *versus* reduced dose). For comparison, log rank tests and Cox regressions were performed.

Results: 197 Ibr-treated CLL patients were identified (83% with relapsed or refractory disease). 37 patients (19%) received reduced dose Ibr. Median follow-up time was 13.5 months. For reduced dose patients, median dose was 4.3mg/kg/day (4% <2.5mg/kg/day). The most common reasons for reducing

Ibr dose were GI toxicity, bleeding, rash, cardiotoxicity, and pre-existing renal insufficiency. 5% of patients in the reduced dose group were taking a mild-moderate CYP3A4 inhibitor. The best overall response rate (CR+PR+PR-L) for the entire cohort was 85%, *versus* 84% in the reduced dose group. Median PFS for standard dose and reduced dose cohorts were 37.4 months and not reached, respectively (p=0.6, LR test). Median OS for standard dose and reduced dose cohorts were both not reached (p=0.5, LR test). Ibr dose did not impact PFS (1.2, 95% CI 0.5-2.6) or OS (0.6, 95% CI 0.14-2.7).

Figure 1.

Summary/Conclusions: We describe the largest real-world experience of reduced dose Ibr in CLL patients. Reduced Ibr doses do not appear to affect clinical outcomes. Most patients treated with doses <420mg/day achieve a dose of >2.5mg/kg/day, and therefore adequate BTK occupancy. Weight-based dosing should be considered in future studies and pharmacoeconomic analyses. Comparative analyses of toxicity profiles stratified by Ibr dose are underway.

Background: Cytogenetic abnormalities detected by FISH define prognostic groups in chronic lymphocytic leukemia (CLL). Complex karyotypes (CK) confer poor prognosis in patients treated with chemoimmunotherapy and novel agents. However, only 28-50% of patients with CK carry *TP53* deletions [delTP53]. The relationship between delTP53 and CK, and its clinical impact, remain to be elucidated.
Aims: 1. To describe the clinico-biological profile of CLL and monoclonal B-cell lymphocytosis (MBL) patients regarding the karyotype complexity by chromosome banding analysis (CBA) 2. To compare the clinical outcome of patients with CK lacking high-risk FISH deletions (HR-FISH), *TP53* and/or *ATM,* and those with HR-FISH and non-CK.
Methods: Our database comprising 2756 MBL and CLL patients from Grupo Cooperativo Español de Citogenética Hematológica and Grupo Español de Leucemia Linfática Crónica was screened for patients with CBA results available at diagnosis or prior to treatment. The clinico-biological data and outcome of patients with CK (≥3 abnormalities) were compared with those with normal or <3 abnormalities [non-CK]. Time to first treatment (TFT) and overall survival (OS) were assessed according to both karyotype complexity and HR-FISH deletions.
Results: CBA results were available for 1149 patients (703M/446F, median age 67), 199 MBL and 1050 CLL. Most karyotypes (75%) were assessed on peripheral blood TPA-based cultures. 438/1149 (38.1%) patients displayed abnormal karyotypes, 82 showing a CK. CK cases showed features of more advanced and aggressive disease than non-CK: more Binet B/C stages (23 *vs* 12%; P=0.008), higher LDH (379 *vs* 304 IU/L; P<0.001) and β2-microglobulin (2.8 *vs* 2 mg/L; P<0.001), higher positivity rates for CD38 (38% *vs* 21%; P<0.001) and ZAP70 (50% *vs* 33%; P<0.001) and increased +12 (32% *vs* 18%; P<0.001), delATM (19% *vs* 7%; P=0.001) and delTP53 (42% *vs* 6%; P<0.001) by FISH. Indeed, patients with CK showed a shorter median TFT (119m *vs* 43m, P<0.001) and OS (163m *vs* 93m; P<0.001). Although the CK group was significantly enriched in delTP53, only 29/78 (37.2%) patients with delTP53 showed CK. Of note, CK negatively impacted on OS even among patients with delTP53 (132m *vs* 38m; P<0.001). Categorization of patients regarding HR-FISH and CK allowed stratification in terms of TFT (Figure). Nonetheless, while patients with both HR-FISH and CK showed the worst OS (39m) being clearly distinct from those non-CK and non-HR-FISH (not reached), survival analysis did not show significant differences between patients with only one high-risk cytogenetic marker (CK or HR-FISH) (Figure). Similarly, no differences in OS for CK patients lacking delTP53 and those with delTP53 and non-CK were observed (209m *vs* 133m; P=0.795). In the multivariate analysis for TFT and OS, both CK and del*ATM* or del*TP53* remained statistically significant (OS HR: 2.6, 2.1 and 2, respectively; P<0.001).

Figure. Kaplan Meier plots for TFT and OS and presence of CK and/or HR FISH

Figure 1.

Summary/Conclusions: 1. CK is associated to advanced disease and poor prognostic markers; however, only 42% of them carry delTP53. 2. Patients with CK lacking delTP53 show an equivalent impaired clinical evolution as those with delTP53 and non-CK. 3. Other mechanisms than *TP53/ATM* dysfunction could be responsible for the outcome of CK. A better characterization of CK patients is needed to elucidate if they could benefit from new therapeutic strategies.

Background: Ibrutinib is an oral once-daily first-in-class covalent Bruton's tyrosine kinase inhibitor approved in Europe for adult patients with CLL who have received at least one prior therapy, or in first line in the presence of 17p deletion or TP53 mutation in patients unsuitable for chemo-immunotherapy. We report here the largest series of real-world results in 428 patients receiving ibrutinib through a temporary authorization for use (ATU) granted by the French National Agency for Medicines and Health Product Safety (ANSM).

Aims: Herein we describe key baseline characteristics and initial outcomes for all patients with CLL/SLL submitting an access-to-ibrutinib form throughout the period of the ATU (December 2013-November 2014).

Methods: Data reported herein represent the final report. As a real-world analysis, all data are declarative in nature (by physicians in charge of the patients), and medical files were not monitored.

Results: Among 428 CLL/SLL patients, most were male (67.1%) with a median age of 70 years (range 33-93, 35%>75y). Median time from diagnosis was 8.1 years. 50.4% of patients had lymph nodes ≥5 cm. Binet stage was A for 7,1%, B for 36.2% and C for 56.7%. Cytogenetic data were reported for 381 patients, among which 45.1% had del17p and/or TP53 mutation, and 24.6% had del11q. A median of 3 prior therapies was reported (range 0-10), including fludarabine-cyclophosphamide-rituximab (63.6%), bendamustine-rituximab (59.8%), and alemtuzumab (27%). Thirty seven patients had undergone prior stem cell transplantation (22 allo, 15 autoSCT). At least one concomitant disease was reported for 232 patients (54.2%), including 24.5% with vascular disorder, 16.6% with metabolism/nutrition disorder, and 11.2% with cardiac disorder. At least one other co-medication was reported in 66.1% of cases (including antithrombotic agents (14%)). The risk of grade 3-4 haemorrhages were 1.6% *vs* 2.6%, respectively for taking these drugs. (no or yes). After a median follow-up of 3 months (range 1-279 days), investigator-assessed ORR was 88.5% including 44.1% PR with lymphocytosis and 1.5% had progressive disease (out of 340 patients with assessable disease). The median PFS, OS and DOR have not been reached. Definitive discontinuation of ibrutinib was reported in 14.5% of 372 evaluable patients, with main reasons including adverse drug reaction (n=20), death (n=19), disease progression (n=8), contra-indication to pursuit of ibrutinib (n=3), and allogeneic transplantation (n=4). In the analysis for safety, 73.4% had at least one AE, 33.2% at least one SAE (among 150 patients above 75y: 34%). Of note, frequency of SAE either in total (34% *vs* 33.2%) or of special interest, infections (11.2% *vs* 10.7%), gastrointestinal disorders including diarrhoea (1.9% *vs* 2%), and cardiac disorders including atrial fibrillation (6.3% *vs* 9.3%), were not statistically increased in elderly patients.

Summary/Conclusions: This is the largest real-world analysis on ibrutinib given for 17p deletion or relapsed/refractory CLL, covering a vast territory (France), both in public/private practice. Efficacy and adverse events profiles were similar to those reported from published clinical trials, especially the RESONATE trial (with the acknowledged limitations inherent to such programs, declarative nature of the data and lack of patient monitoring).

P223

DURABLE TREATMENT-FREE REMISSION AND EFFECTIVE RETREATMENT IN PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA WHO ACHIEVED A DEEP RESPONSE WITH VENETOCLAX COMBINED WITH RITUXIMAB

D Brander[1,*], AW Roberts[2], JF Seymour[3], TJ Kipps[4], JC Barrientos[5], MS Davids[6], MA Anderson[2], M Choi[4], C Tam[3], B Prine[7], C Cornejo[7], M Zhu[7], LL Lash[7], S Ma[8]

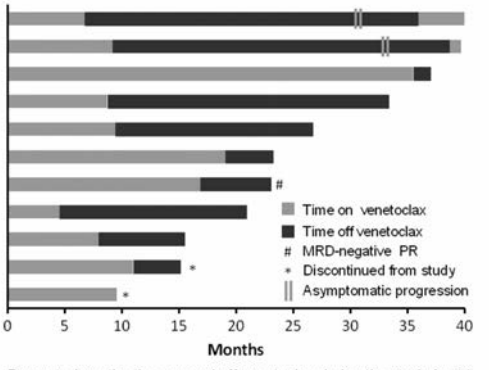
Background: Venetoclax (VEN) is a selective, potent, orally bioavailable BCL-2 inhibitor. VEN monotherapy induces rapid, deep, and durable responses, with a 79% ORR (20% CR) for patients (pts) with relapsed/refractory (R/R) chronic lymphocytic leukemia (CLL) or small lymphocytic lymphoma (SLL). Based on preclinical evidence of synergy, combination therapy of VEN plus rituximab (R) is being assessed in an ongoing Phase 1b study. In this study, pts with CR/CRi or MRD-negative (neg) PR may stop VEN, remain on study, and be retreated upon disease progression by iwCLL criteria.

Aims: To assess outcomes in pts with R/R CLL who had CR/CRi or MRD-neg PR and stopped therapy per study protocol.

Methods: Pts who achieved CR/CRi or MRD-neg PR could stop therapy and remain on study with clinical monitoring and peripheral blood (PB) counts every 3 months. Pts who then progressed could re-initiate VEN once daily with weekly ramp-up at 20, 50, 100, 200 to 400 mg. R could be added at month 4 or earlier per investigator's discretion. Responses and progression were assessed by iwCLL criteria with CT scan and bone marrow (BM) biopsy. MRD was assessed in blood and BM aspirates using ≥4 color flow cytometry (min sensitivity: 0.01%).

Results: 49 pts (48 CLL/1 SLL) were enrolled. Median number of prior regimens was 2 (range: 1-5); 45 (90%) received prior R (14 [29%] R-refractory) and 28 (57%) received fludarabine (9 [18%] fludarabine-refractory). 15/45 (33%) pts had del(17p) and/or *TP53* mutation. Common adverse events (AEs) were mild diarrhea, neutropenia, upper respiratory tract infection, and nausea. As of 28Oct2015, ORR was 86% (47% CR/CRi), with 55% MRD-neg (17 CR/CRi; 10 PR). While on therapy, disease progression was observed in 7 pts, with 4 occurring after PR, 1 after SD, and 2 had primary PD. 11 pts elected to stop therapy after achieving MRD-neg CR/CRi (8), MRD-pos CR/CRi (2), or MRD-neg PR (1); 9 remain in active follow-up and 2 discontinued from the study with no evidence of progression. Demographics and disease characteristics of these 11 pts were similar to the total study population and median time on VEN was 9 (range: 5–36) months. As of 28Oct2015, 7/9 pts have not progressed (all MRD-neg) and remain in follow-up for a median of 8 (range: 2-25) months off VEN. 2 pts with MRD-pos CR/CRi as best response had subsequent asymptomatic progression off VEN. The first pt stopped VEN plus R at month 7 and had asymptomatic progression (lymphocytosis, BM infiltrate, and splenomegaly) 24 months later. This pt was retreated with VEN monotherapy, achieved PR after 4 months of VEN, and remains in response with ongoing treatment. AEs reported during retreatment were all Grade 1/2 and similar to those seen during first treatment. The second pt stopped VEN at 9 months and had asymptomatic progression (lymphocytosis) 24 months later (PB MRD levels increased after 14 months off VEN). This pt recently reinitiated VEN monotherapy and has not yet had disease reassessment.



Presented are the time on and off venetoclax during the study for 11 patients who stopped venetoclax treatment after achieving CR/CRi or MRD-negative PR, with rows representing each patient. Two patients with MRD-pos CR/CRi as best response had asymptomatic progression after approximately 24 months off therapy. Both patients have reinitated venetoclax treatment.

Figure 1.

Summary/Conclusions: The combination of VEN plus R induced deep responses, with 47% pts achieving CR/CRi and 55% reaching MRD negativity in BM. The rate of disease progression was low for pts continuing VEN with current follow-up. Pts achieving deep responses who stop VEN per study protocol do not relapse rapidly, and treatment-free remissions can be durable, as 7 MRD-neg pts still off VEN maintain remission to date. Progression has been observed after 24 months off VEN in two pts whose best response was MRD-pos; preliminary data suggest that ongoing retreatment is well tolerated and effective.

Background: Supraventricular tachyarrhythmias, particularly atrial fibrillation (AF), are an adverse effect of ibrutinib. In 3 phase 3 CLL studies, AF incidence was 5-7.7%, significantly higher than seen in control arms (0.5-2.4%). AF is

associated with deleterious effects on cardiac function and with risk of arterial thromboembolism, particularly stroke; patients receive prophylactic anti-platelet or anticoagulant medication according to individual thromboembolic risk (eg. CHADS2-VASC score). The clinical consequences of tachyarrhythmias and their optimal management in CLL patients treated with ibrutinib are unclear; in particular, the anti-platelet effect of ibrutinib may increase bleeding risk from thromboembolism prophylaxis.

Aims: We characterized clinical course and management of 59 CLL patients who received ibrutinib and developed supraventricular arrhythmia (AF/flutter 56, SVT 3).

Methods: We retrospectively reviewed data from 59 patients treated from 2010-2015 with ibrutinib 420mg/d (n=53) or ibrutinib plus rituximab (n=6): 31 patients were treated at FILO centers (France/Belgium), 22 at MD Anderson Cancer Center and 6 at Peter MacCallum Cancer Centre, Australia.

Results: Median age was 70. Median time to onset was 3.8 months. Baseline risk for AF was not increased: mean HATCH score (a risk index for AF) was 1.39, similar to an age-matched population. Hypertension requiring treatment was present in 63% cases, similar to an age-matched population; mild-moderate mitral regurgitation or aortic stenosis was present in 9/36 (25%) of cases with available echocardiogram results; LVEF was <50% in 10/36 (28%) and <35% in 5/36 (14%), with clinical congestive heart failure in 7/59 of all patients (12%) and angina in 7 cases (12%). Recent infection (<1 month) was present 10 cases (17%). Fifteen of 56 (27%) patients with AF/flutter had a previous history of AF/flutter; all were in sinus rhythm when ibrutinib treatment was started. 90% of the patients received an antiarrhythmic medication and/or procedure. Pharmacological antiarrhythmic therapy was: amiodarone in 19 cases (32%), flecainide in 5 (8%), beta-blockers in 40 (68%) and calcium channel blockers in 4 cases (6%). Seven patients underwent cardioversion; sustained conversion to sinus rhythm was achieved in 2/7. Tachyarrhythmias were persistent in 35/59 (59%) cases despite treatment, whether Ibrutinib was discontinued or not. 71% of patients with atrial fibrillation/flutter had a CHADS2-VASC score ≥2, considered an indication for anticoagulation: 48% of patients with AF/flutter received anticoagulation, 34% received anti-platelet therapy and 27% received neither therapy. Median CHADS2/VASC score was 2 in patients who received or did not receive thromboembolism prophylaxis. Clinical consequences of tachyarrhythmias were: 3 episodes of severe cardiac failure (one fatal); 1 stroke; 8 non-thrombocytopenic patients (13.5%) experienced grade 3-4 bleeding, including 2 subdural hemorrhages and 2 cases of hemorrhagic cardiac tamponade. Figure 1 outlines the management of ibrutinib dosing in patients with tachyarrhythmias. Altogether, Ibrutinib was permanently discontinued due to arrhythmia in 23/59 cases (39%), limiting effective antineoplastic therapy.

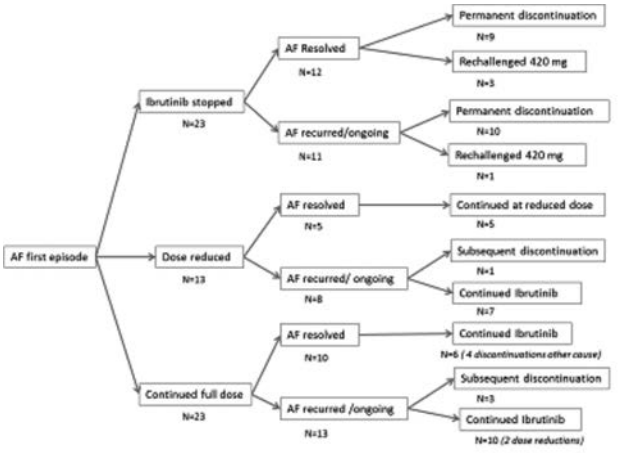

Figure 1.

Summary/Conclusions: AF in ibrutinib-treated patients with CLL is frequent and associated with significant consequences. Management, even in academic centers, was variable. Guidelines for prevention and management of AF in patients receiving ibrutinib are urgently required, particularly as ibrutinib use increases in community practice.

P225

INTEGRATED SAFETY ANALYSIS OF VENETOCLAX MONOTHERAPY IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

MS Davids[1,*], J Gerecitano[2], J Potluri[3], E Cerri[3], SY Kim[3], M Steinberg[3], M Verdugo[3], T Busman[3], S Heitner Enschede[3], M Mobasher[4], A Best[3], M Desai[3], WG Wierda[5]

[1]Dana-Farber Cancer Institute, Harvard Medical School, Boston, [2]Memorial Sloan Kettering Cancer Center, New York, [3]AbbVie, Inc., North Chicago, [4]Genentech, Inc., South San Francisco, [5]MD Anderson Cancer Center, Houston, United States

Background: Venetoclax is a potent, selective, oral BCL-2 inhibitor that has activity in patients (pts) with relapsed/refractory (R/R) CLL, with an objective response rate of >70%.

Aims: Here we report the aggregated venetoclax monotherapy safety analysis from 3 pooled trials in R/R CLL.

Methods: An integrated safety analysis was conducted for pts with R/R CLL who received venetoclax monotherapy in a phase 1 dose escalation and two phase 2 trials (N=328). Pts who received the recommended phase 2 dose of 400mg once daily (QD) were analyzed for incidence and timing of adverse events (AEs) and are reported here.

Results: Pts receiving 400 mg QD (n=279) included 181 pts with del 17p and 75 pts with previous B cell receptor inhibitor failure. As of Aug 25, 2015, the median duration on treatment was 10.3 months and 65.6% of pts were still on study. Discontinuation occurred in 96 pts, with 24 pts discontinuing due to adverse events (AEs). The most common (>20% pts) AEs of any grade (Gr) were neutropenia (38%), diarrhea (38%), nausea (36%), anemia (26%), fatigue (24%), and upper respiratory tract infection (21%). The most common (>10% pts) Gr 3/4 AEs were neutropenia (36%), anemia (15%), and thrombocytopenia (13%). Cytopenias occurred early and rates decreased over time. Serious AEs (>2% pts) were pneumonia (5%), febrile neutropenia (5%), pyrexia (3%), and autoimmune hemolytic anemia (3%). There were 41 deaths, 11 due to AEs not associated with disease progression. Under the most recent tumor lysis syndrome (TLS) mitigation guidelines, which align prophylactic measures with the pt's relative risk, 4/105 pts (4%) experienced laboratory TLS, all Gr 3. All TLS events were observed within the initial 5-wk dose ramp-up and were managed with hydration, electrolyte correction, and dose interruption. All pts were able to resume dosing without clinical sequelae.

Summary/Conclusions: Venetoclax 400mg QD has an established and manageable safety profile for the treatment of R/R CLL pts, including those who may not be appropriate candidates for other approved treatments.

MANAGEMENT OF TRANSAMINASE ELEVATIONS ASSOCIATED WITH IDELALISIB

P Ghia[1,*], S Coutre[2], IW Flinn[3], AK Gopal[4], SM O'Brien[5], GA Salles[6], T Newcomb[7], CC Waldapfel[7], W Ye[7], AD Zelenetz[8], WG Wierda[9]

[1]Universita Vita-Salute San Raffaele and IRCCS San Raffaele Scientific Institute, Milan, Italy, [2]Stanford University, Stanford, [3]Hematologic Malignancies Research Program, Sarah Cannon Research Institute, Nashville, TN, [4]Medical Oncology Division, University of Washington School of Medicine, Seattle, WA, [5]Irvine Chao Family Comprehensive Cancer Center, University of California–Irvine, Orange, CA, United States, [6]Hematology Department, Hospices Civils de Lyon, University Claude Bernard, Pierre Benite, France, [7]Gilead Sciences, Inc., Foster City, CA, [8]Memorial Sloan-Kettering Cancer Center, New York, NY, [9]Department of Leukemia, Division of Cancer Medicine, University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: Idelalisib (IDELA), a first-in-class, selective oral PI3Kδ inhibitor, has been associated with increased alanine transaminase (ALT) and aspartate transaminase (AST) elevations in clinical trials. These transaminase elevations typically occur early during treatment (median onset of 8 weeks) and are generally asymptomatic. Currently recommended management of grade ≥3 (>5-20X ULN AST/ALT) elevation involves dose interruption with re-initiation of therapy possible following resolution to grade ≤1.

Aims: This post hoc analysis evaluated outcomes following treatment-emergent grade ≥3 ALT/AST in IDELA clinical trials.

Table 1.

n (%)	IDELA Alone (n=485)	IDELA Combination (N=588)	Total (N=1073)
Patients with any grade ALT/AST elevation	237/485 (49)	306/588 (52)	543/1073 (51)
Grade 1 (3 to < 5 × ULN)	136/485 (28)	193/588 (33)	329/1073 (31)
Grade 2 (5 to < 10 ULN)	31/485 (7)	38/588 (6)	69/1073 (6)
Grade 3 (10 to < 20 ULN)	49/485 (10)	63/588 (11)	112/1073 (10)
Grade 4 (≥ 20 × ULN)	19/485 (4)	14/588 (2)	33/1073 (3)
Patients with any grade ≥3 ALT/AST elevation	68/485 (14)	77/588 (13)	145/1073 (14)
Resolved to grade ≤1	64/68 (94)	69/77 (90)	133/145 (92)
Rechallenged	47/68 (70)	63/77 (82)	110/145 (76)
Recurrence of grade ≥3 ALT/AST	15/47 (32)	19/63 (30)	34/110 (31)
Recurrence resolved to grade ≤1	14/15 (93)	18/19 (95)	32/34 (94)

ULN=upper limit of normal

*pts were rechallenged at the discretion of the treating physician

Methods: An integrated analysis of safety was conducted for 1073 patients across 9 studies: 538 with previously treated chronic lymphocytic leukemia (CLL), 105 with untreated CLL or small lymphocytic lymphoma (SLL), and 430 with other relapsed/refractory B-cell malignancies (indolent non-Hodgkin lymphomas, mantle cell lymphoma, diffuse large B-cell lymphoma, Hodgkin lymphoma, acute myeloid leukemia, and multiple myeloma) who received IDELA alone (doses=50 mg BID to 350 mg BID) or as part of a combination regimen (IDELA doses=100 or 150 mg BID). Clinical laboratory findings were evaluated for highest grade of ALT/AST elevation and summarized according to MedDRA

and Common Terminology Criteria for Adverse Events (CTCAE) liver-related laboratory tests and categories. Those with grade ≥3 ALT/AST elevation were evaluated for rate of resolution to grade ≤1 ALT/AST, and recurrence of the event at any time on study. Patients were grouped by use of IDELA alone or as part of a combination regimen.
Results: Among patients with any disease type or regimen (N=1073), the incidence of any grade ALT/AST elevation was 51%, and the incidence of grade ≥3 ALT/AST elevation was 14% (Table). Of patients with transaminase elevation, 73% (398/543) experienced grade 1 or grade 2 events. The incidences of grade ≥3 ALT/AST elevations, and outcomes for patients with grade ≥3 ALT/AST elevation (Table) were comparable whether IDELA was used alone or in combination. 92% of patients with grade ≥3 ALT/AST elevation were managed with dose interruption and achieved resolution to grade ≤1. The majority (69%) of patients with subsequent IDELA rechallenge experienced no recurrence of the event; of events that did recur, the vast majority (94%) resolved in the analysis time period.
Summary/Conclusions: These data support the management of ALT/AST elevation with IDELA using dose interruption at grade 3 with reintroduction after resolution at the discretion of the treating physician. Studies Included in this Analysis: 101-02: NCT00710528; 101-07: NCT01088048; 101-08: NCT01203930; 101-09: NCT01282424; 101-10: NCT01306643; 101-11: NCT01393106; 101-99 (extension): NCT01090414; GS-US-312-0116: NCT01539512; GS-US-312-0117 (extension): NCT01539291; GS-US-312-0119: NCT01659021

Chronic myeloid leukemia - Clinical 1

P227

DE-ESCALATION OF TYROSINE KINASE INHIBITOR THERAPY IS SAFE IN CHRONIC MYELOID LEUKAEMIA IN DURABLE MOLECULAR RESPONSE (≥ MR3 FOR ≥12 MONTHS): INITIAL RESULTS IN THE BRITISH DESTINY STUDY

R Clark[1,*], F Polydoros[2], J Apperley[3], C Pocock[4], G Smith[5], R Salim[6], T Coffey[2], S O'Brien[7], L Foroni[3], M Copland[8]
[1]Haematology/MCCM, [2]Liverpool Clinical Trials Unit, University of Liverpool, Liverpool, [3]Haematology, Hammersmith Hospital, London, [4]Haematology, Kent & Canterbury Hospital, Canterbury, [5]Clinical Haematology, St James University Hospital, Leeds, [6]Haematology, Royal Liverpool University Hospital, Liverpool, [7]Northern Institute for Cancer Research, University of Newcastle, Newcastle, [8]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, United Kingdom

Background: Some chronic myeloid leukaemia (CML) patients with prolonged and deep molecular remissions on tyrosine kinase inhibitor (TKI) therapy can discontinue treatment. However, study of this has been restricted to patients in stable MR4 (BCR-ABL1<0.01%), and it is not known whether some patients in stable major molecular response (MR3; BCR-ABL<0.1%) but not MR4 can discontinue treatment. In addition, it is plausible that while some patients might not be able to completely discontinue TKI therapy, they may be able to maintain good molecular remissions on TKI doses that are less than standard, with concurrent improvement in any TKI-related adverse events; this has not been previously investigated.
Aims: The British DESTINY study is examining the safety and efficacy of initially de-escalating therapy to half the standard TKI dose (*i.e.* imatinib 200mg daily, nilotinib 200mg twice daily, or dasatinib 50mg daily) for 12 months, then stopping altogether.
Methods: Entrants must be in stable MR3 or better, on all PCR results (minimum of 3) in the preceding 12 months, and must have received TKI for at least 3 years, and not switched TKI (except that a single switch was permitted if solely due to intolerance). The primary endpoint is loss of MR3; monthly molecular monitoring is carried out centrally.
Results: During 16 months recruitment to April 2015, 174 patients (male 98; female 76) were recruited after giving informed consent by 20 sites. At entry, 125 (72%) were in MR4 and 49 (28%) in MR3 but not MR4; 148 were receiving imatinib, 16 on nilotinib and 10 on dasatinib. During 12 months of de-escalation in the first 100 patients, no deaths, disease progressions or losses of cytogenetic response have been seen, though 7 serious adverse events have occurred (6 Grade 3+), all unrelated to TKI. Thirteen patients reported 14 new events of musculoskeletal disorders since decreasing TKI therapy (all Grade 1), comprising pain, stiffness or cramps in the joints, legs, chest, neck and/or back (13) with one additional event of arthritis. Individual side effects (lethargy, diarrhoea, rash, nausea, periorbital oedema, hair thinning) all improve in the first 1-2 months of de-escalation but not significantly thereafter, though the FACT-BRM or EQ-5D Quality of Life data are already optimal at trial entry, suggesting that TKI side effects in entrants do not impact Quality of Life. During the de-escalation phase in the first 100 patients there have been 7 molecular relapses (defined as loss of MR3 on 2 consecutive samples), occurring during the second (1 case), third (2), seventh (1) and eighth (3) month of de-escalation. Four of these were in the 31 patients in MR3 but not MR4 at trial entry, giving a relapse rate of 12.9%; similarly 3 of 69 patients (4.3%) relapsed in the 'MR4 at entry' group. No relapses have occurred in the quartile with the shortest duration of prior TKI treatment (less than 4.8 years), while 3 of the 7 relapses have occurred in the quartile with the longest pre-entry TKI treatment (>10.2 years). All 7 patients have regained at least MR3 within 4 months of resumption of standard dose TKI. Overall, 26 (84%) 'MR3 but not MR4' and 64 (93%) 'MR4 at entry' patients have proceeded to the stopping phase.
Summary/Conclusions: In this first DESTINY trial report focussed on de-escalation, halving the standard TKI dose for 12 months in CML patients in at least MR3 appears safe, does not compromise disease control, and is associated with a rapid improvement in side effects. Mild musculoskeletal symptoms may occur in about 13% of patients.

P228

LONG-TERM EFFICACY AND SAFETY OF PONATINIB IN HEAVILY PRETREATED LEUKEMIA PATIENTS: 4-YEAR RESULTS FROM THE PIVOTAL PHASE 2 PACE TRIAL

JE Cortes[1,*], J Pinilla-Ibarz[2], PD le Coutre[3], R Paquette[4], C Chuah[5], FE Nicolini[6], JF Apperley[7], HJ Khoury[8], M Talpaz[9], M Baccarani[10], S Lustgarten[11], FG Haluska[11], F Guilhot[12], MW Deininger[13], A Hochhaus[14], TP Hughes[15], NP Shah[16], HM Kantarjian[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL, United States, [3]Charité Universitätsmedizin Berlin, Berlin, Germany, [4]Ronald Reagan UCLA Medical

Center, University of California, Los Angeles, CA, United States, [5]Singapore General Hospital and Duke-National University of Singapore Graduate Medical School, Singapore, Singapore, [6]Centre Hospitalier Lyon Sud, Pierre Bénite, Lyon, France, [7]Centre for Haematology, Imperial College, London, United Kingdom, [8]Winship Cancer Institute of Emory University, Atlanta, GA, [9]Comprehensive Cancer Center, University of Michigan, Ann Arbor, MI, United States, [10]S. Orsola-Malpighi University Hospital, Bologna, Italy, [11]ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States, [12]Inserm CIC 1402, CHU de Poitiers, Poitiers, France, [13]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, United States, [14]Jena University Hospital, Jena, Germany, [15]Institute of Medicine and Veterinary Science, Adelaide, Australia, [16]University of California San Francisco, San Francisco, CA, United States

Background: The approved tyrosine kinase inhibitor (TKI) ponatinib is potently active against native and resistant BCR-ABL, including T315I.
Aims: The pivotal phase 2 PACE trial (NCT01207440) evaluated the efficacy and safety of ponatinib.
Methods: Patients with chronic myeloid leukemia (CML) or Philadelphia-positive acute lymphoblastic leukemia (Ph+ALL) refractory to dasatinib or nilotinib, or with T315I, were enrolled in PACE (starting dose 45 mg once daily). All patients gave informed consent. Dose reductions were recommended in October 2013 due to observed arterial occlusive events (AOEs). Efficacy and safety at 4 years, as well as by year for chronic phase (CP) CML patients are reported (data as of 3 August, 2015). Exposure-adjusted incidence rates of new AOEs are reported as the number of events/100 patient-years.
Results: Of 449 patients, 59% received ≥3 prior TKIs. At analysis, 30% (133/449) of patients (median follow-up 37.3, range 0.1–58.5 months) and 41% (110/270) of CP-CML pts (48.2, 0.1–58.5 months) remained on study. Primary reasons for discontinuation were disease progression (22.5% overall, 10.4% CP-CML) and adverse events (AEs) (16.0% overall, 18.5% CP-CML). Responses continued to deepen over time (Table 1**,** CP-CML patients) despite dose reductions. Among CP-CML patients, estimated 4-year rates for PFS, OS, and maintenance of major cytogenetic response (MCyR) and major molecular response (MMR) were 56%, 77%, 82% and 61%, respectively. For accelerated phase patients, the estimated 4-year OS was 51%; median OS for blast phase/Ph+ALL patients was 6.9 months (95% CI, 5.0-9.2). Common (in ≥30% of patients) treatment-emergent AEs were thrombocytopenia 44%, abdominal pain 43%, rash 42%, constipation 37%, headache 37%, dry skin 36%, fatigue and hypertension 30%. AOE rate/serious AOE rate was 23%/19%, including cardio- 13%/9%, cerebro- 9%/7%, and peripheral-vascular 9%/7%. Of patients with AOEs (n=104), 38% remained on study. Exposure-adjusted incidence rates of new AOEs fell after the first 2 years: 15.5 Year 1, 15.7 Year 2, 10.4 Year 3, and 9.6 Year 4. Nearly 2 years after recommended dose reductions, 87% (114/131) and 74% (70/95) of CP-CML pts were estimated to maintain MCyR and MMR, respectively, and 8% (6/75) of all dose-reduced pts without a prior AOE on trial had an AOE.

Table 1.

Percentage cumulative response rates with ponatinib in CP-CML pts (n=267, efficacy evaluable)

	MCyR	CCyR	MMR / MR4.5
Year 1	55	51	30 / 9
Year 2	58	53	36 / 16
Year 3	59	53	39 / 22
Year 4	59	54	39 / 23

Summary/Conclusions: After 4 years, heavily pretreated patients continue to show deep and lasting responses on ponatinib, and approximately 2 years post recommended dose reductions, maintenance of response is high, and the incidence of newly occurring AOEs has decreased.

Background: Nilotinib is a second-generation tyrosine kinase inhibitor (TKI) that exhibits significant efficacy as first- or second-line treatment in patients with chronic myeloid leukemia (CML). Superior rates of deeper molecular responses (DMR) were achieved with nilotinib *vs* imatinib in patients newly diagnosed with CML in chronic phase (CML-CP) in the ENESTnd trial. Recently, treatment free remission (TFR) is one of the goals in CML treatment. Indeed, prospective trials suggest that imatinib therapy may be safely and successfully discontinued in 40% of CML patients with DMR (Mahon et al, Lancet Oncol 2010, Ross et al, Blood 2013).
Aims: The purpose of this study is to evaluate the efficacy of two-year consolidation by nilotinib for successful TFR in patients with CML-CP who had achieved $MR^{4.5}$ with imatinib.
Methods: Patients with CML-CP who had achieved $MR^{4.5}$ (BCR-ABL1 ≤0.0032% on the International Scale [IS]) by real- time quantitative polymerase chain reaction (RQ-PCR) on imatinib were eligible. At study entry, patients treatment was switched from imatinib to nilotinib and nilotinib was taken twice daily (600mg/day) for 2 years as a consolidation phase. Patients who had sustained $MR^{4.5}$ for 2 years after initiation of the study were able to stop nilotinib in TFR phase. Thirty-three institutions in STAT study group participated. The study was conducted in accordance with the principles of the Declaration of Helsinki. Informed consent was written by all patients according to institutional guidelines. The study was approved by all institutional review boards and registered with ClinicalTrials.gov (number UMIN000005904). The primary objective of this multicenter phase II, single-treatment arm, open-label clinical study was to identify the $MR^{4.5}$ rate at 12 months after discontinuation of nilotinib treatment in patients who have sustained $MR^{4.5}$ for 2 years after initiation of the study. The molecular response was evaluated using IS-PCR (Molecular MD One-Step qRT-PCR BCR-ABL kit) at a central laboratory (BML, Inc., Kawagoe, Japan) upon study entry, every 3 months during the consolidation phase, every month the first year in TFR phase, every 2 months the second year in TFR phase, and every 3 months the third year in TFR phase thereafter. Molecular recurrence of CML was defined as confirmed loss of $MR^{4.5}$ (2 consecutive BCR-ABL1 IS >0.0032%) according to STIM criteria (Mahon Lancet Oncol 2010).
Results: Between July, 2011 and December, 2012, 96 Japanese patients were enrolled, and 75 patients who had sustained $MR^{4.5}$ during the consolidation phase were eligible to discontinue nilotinib. The median age was 56 years. The ratio of men to women was 60:36 and the risk groups according to Sokal Score were low: 56, intermediate: 20, high: 18, respectively. Sixteen patients were treated with interferon prior to imatinib therapy. All patients showed $MR^{4.5}$ at the time of entry into the study and the median time to DMR on imatinib therapy was 50.8 months. Median follow up duration in TFR phase of STAT2 trial was 16 month (range: 3 - 30 months). Among the 75 patients who entered the TFR phase, 52 patients (69.4%, 95%CI: [58.9% to 79.8%]) remained without molecular recurrence the first 12 months (Figure 1). TFR rate at 12M was 69.4%, which was superior to the previous reports, although we have to carefully validate that the population baseline characteristics are similar to those from other trials. Furthermore, the 23 patients with molecular recurrence who were treated with nilotinib again achieved $MR^{4.5}$ within 6 months.

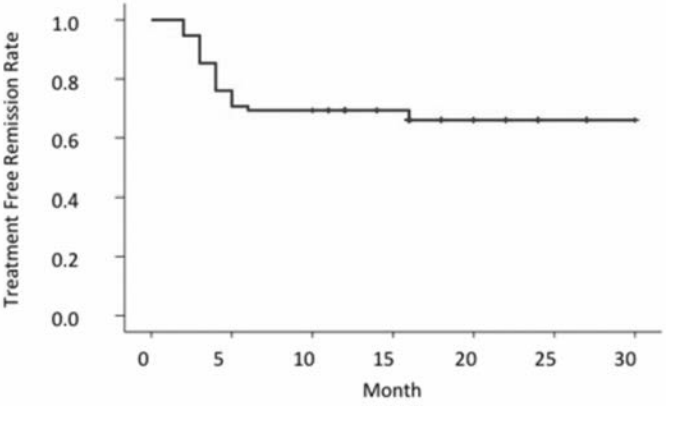

Figure 1.

Summary/Conclusions: 2-year consolidation by nilotinib is associated with successful TFR in CML patients with $MR^{4.5}$ on imatinib.

P230

IMPACT OF SECOND DECLINE RATE OF BCR-ABL1 TRANSCRIPT BETWEEN M3 AND M6 ON CLINICAL OUTCOME FOR CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH IMATINIB: PRACTICAL ASPECT FOR THE TRUE LIFE

S Dulucq[1,*], G Etienne[2], S Morisset[3], C Chollet[1], F Robbesyn[1], B Turcq[2], F Nicolini[4], FX Mahon[2]
[1]Laboratory of Hematology, Molecular biology, Hopital Haut Leveque, PESSAC, [2]INSERM U1218, Bergonie Cancer Institute, BORDEAUX, [3]Lieu-Dit la caillatte, Chazey sur Ain, [4]Hematology 1G, CHU LYON Sud, Pierre Benite, France

Background: Early molecular response (*BCR-ABL1* level at 3 months) has been associated with clinical outcome in chronic phase chronic myeloid leukemia (CML) patients treated with tyrosine kinase inhibitors (TKI). However, a single measurement of *BCR-ABL1* transcript levels does not seem enough to define failure and the European Leukemia Net (ELN) recommendations define first line-failure only at 6 months if *BCR-ABL1* transcript level is above 10%. The transcript rate decline from baseline has been demonstrated to be more predictive than a single *BCR-ABL1* level at 3 months however it cannot be used routinely because *ABL1*, as an internal gene control reliable for *BCR-ABL1* quantification is above 10%.
Aims: This study aimed to compare clinical outcome and molecular response of CML patients, depending on the percentage of decrease of *BCR-ABL1* transcript from M3 to M6 using *ABL1* as an internal control gene, used by most laboratories that provide results on the International Scale.
Methods: The first CML patient cohort (University Hospitals of Bordeaux n=116) was used to develop the model and the second one (University Hospitals of Lyon n=107) was taken to confirm and validate the predictive model. All patients were in chronic phase from September 2000 to October 2014, treated by frontline imatinib 400 mg, and for whom M3 and M6 molecular data were available. Event-free (EFS), failure-free (FFS), progression-free (PFS) and overall survivals (OS) defined according to ELN, were measured from M6 to the date of event or death. Survival differences estimated by Kaplan-Meier analysis were assessed using a log-rank test. The analysis of the area under the time-dependent ROC curve (AUC) using the inverse probability of censoring weighting (IPCW) approach was used to define the best cut-off for the percentage of decline. The cut-off was obtained by the closest "top left" method. Associations with MR^4 or $MR^{4.5}$ and multivariate analysis including Sokal, age and *BCR-ABL1* level ≤ or >10% at 3 months were assessed by Cox regression. Significant results obtained in the first cohort were validated in the second cohort.
Results: The percentage of *BCR-ABL1* decline from M3 to M6 was significantly linked to the EFS and the PFS (p=0.002). A common cut-off of 72% of decline at 24, 36 and 60 months after M6, predicted the better risk of having an event with respectively a sensibility of 0.69, 0.72, 0.56 and a specificity of 0.74, 0.80, 0.82 for each time point. Patients with a percentage of decrease below 72% have worse EFS as compared to those having a higher decrease (p<0.001 cohort 1; p=0.028 cohort 2; figure1). The estimated 5-years EFS are 60.75% and 51.76% for patients with less than 72% of decline *vs* 84.78% and 71.63% for patients with a higher decline, for cohort 1 and 2 respectively. The impact was maintained in the first cohort if we remove from all events treatment cessation for toxicity (p=0.017). However, only a trend is observed in the second cohort (p=0.073). The impact is independent of the Sokal score, age and *BCR-ABL1* level ≤ or >10% at 3 months.

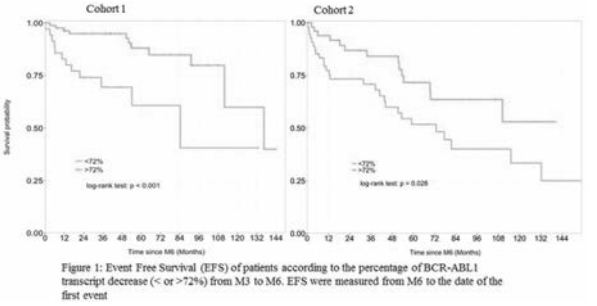

Figure 1: Event Free Survival (EFS) of patients according to the percentage of BCR-ABL1 transcript decrease (< or >72%) from M3 to M6. EFS were measured from M6 to the date of the first event

Figure 1.

Summary/Conclusions: Since the slope between diagnosis and 3 months cannot be reliable using *ABL1* as an internal gene control, the second decline rate of *BCR-ABL1* transcript between M3 and M6 could efficiently identify patients at higher risk of presenting an event and could help physicians to manage CML patients treated with imatinib or generic imatinib and to decide to switch to another TKI in the true life.

P231

EFFICACY AND SAFETY OF FIRST-LINE TREATMENT WITH NILOTINIB IN ELDERLY CHRONIC MYELOID LEUKEMIA PATIENTS

Background: In chronic phase (CP) chronic myeloid leukemia (CML) nilotinib has shown better efficacy compared to imatinib, but it has been associated to a higher incidence of arterial thrombotic events (ATEs). Considering that aging is linked to a higher cardiovascular risk, elderly patients treated with nilotinib may experience more ATEs, which ultimately may impact on their outcome.
Aims: To investigate the efficacy and safety, particularly the cardiovascular safety, of nilotinib in elderly chronic phase chronic myeloid leukemia patients.
Methods: We analyzed 345 patients with CP CML enrolled in clinical trials of the GIMEMA CML WP investigating nilotinib as first-line treatment. Patients were treated with: nilotinib 400 mg BID (n=73); rotation of nilotinib 400 mg BID / imatinib 400 mg OD (3-month periods for each drug)(n=123); nilotinib 300 mg BID (n=149). The median follow-up was 58 months. The median age was 53 years. We analyzed in detail the response rates, events and outcome of 89 patients ≥65 years of age; these patients were also compared to the 245 patients <65 years. Definitions: Major molecular response (MMR): BCR-ABL≤0.1% (IS), with >10.000 ABL copies; MR4: BCR-ABL≤0.01% (IS), with >10.000 ABL copies. Events: permanent discontinuation of nilotinib for adverse events, progression to accelerated/blast phase (AP/BP), or death for any reason. ATEs: peripheral arterial obstructive disease (PAOD), acute coronary syndrome, chronic ischemic heart disease, significant carotid stenosis and ischemic stroke.
Results: In elderly patients, the Sokal risk distribution was: low, 9%; intermediate, 69%; high, 22%. The median age was 71 years. Males were 49%. Molecular response rates were as follows: BCR-ABL/ABL <10% at 3 months, 89%; MMR at 12 months, 54%; MR4 at 12 months, 25%; cumulative incidence of MMR by 5 years, 93%; cumulative incidence of MR4 by 5 years, 75%. These response rates were similar to those observed in patients <65 years (all p >0.05). Overall, events leading to permanent discontinuation of nilotinib were observed in 38% of elderly patients, a proportion significantly higher than that of patients <65 years (23%; p=0.005). ATEs occurred in 15 (16.9%) elderly patients, and were the reason of permanent nilotinib discontinuation in 12 (13.4%) of them. As expected, the rate of ATEs in younger patients was significantly lower (5.8%; p=0.0035). Nine (10%) elderly patients died during the follow-up: a patient after progression to AP/BP (the only progression observed in patients ≥65 years), while the others died in CP for concomitant diseases / age-related conditions (2 patients had a previous ATE). The 6-year progression-free survival and overall survival in elderly patients were 85%.
Summary/Conclusions: Nilotinib as first-line treatment of newly diagnosed CP CML patients showed high efficacy in patients ≥65 years, with molecular response rates comparable to those observed in younger patients. However, a significantly higher proportion of elderly patients discontinued nilotinib, partially because of the occurrence of ATEs. Even though a relevant morbidity was associated to some ATEs, they did not significantly impacted on the long-term outcome of elderly patients.

P232

LATE RELAPSES, UP TO 45 MONTHS AFTER IMATINIB DISCONTINUATION: RESULTS FROM THE ISAV STUDY

Background: As already demonstrated in different trials, it is possible to safely discontinue imatinib treatment in patients (pts) affected by Chronic Myeloid Leukemia (CML) who achieve a durable complete negativity by Q-RT-PCR. However a variable fraction of them become PCR positive but never loose Major Molecular Response (MMR). Here we report an update of the Imatinib Suspension And Validation (ISAV) study at 52 months (mts) of follow-up (FUP).
Aims: The ISAV study is aimed at validating the capability of digital PCR (dPCR) to predict relapses after imatinib discontinuation in CML pts with negative Q-RT-PCR results and to evaluate relapse rate, time of recurrence, survival and the impact of imatinib treatment on Quality of Life (QoL).
Methods: This study involves 15 sites worldwide. CML pts (Chronic or Accelerated Phase) under imatinib therapy since more than 2 years and in complete molecular remission (CMR) were eligible. Patients had to be in CMR for at least 18 mts, with a minimum of 3 Q-RT-PCR performed at their own sites. After discontinuation of imatinib therapy, Q-RT-PCR was performed monthly (mts 1-6), bimonthly for 36 mts and then every 6 months for additional 2 years, to assess the maintenance of the molecular remission. The loss of molecular remission was defined as two consecutive positive Q-RT-PCR tests with at least one BCR-ABL/ABL value above 0.1%. Patients losing molecular remission resumed imatinib treatment at the same dosage used before interruption. Patients' QoL during imatinib discontinuation/resumption was evaluated through the EORTC QLQ–C30 questionnaire.
Results: The ISAV study enrolled 112 pts with a median FUP time of 35.5 mts [95% CI: 33.5-36.0]. The cumulative probability of survival at 3 years is 94.7% [95% CI: 81.4-98.6]. dPCR results showed that 23.1% of pts were positive and 75.9% negative at the time of discontinuation, with a Negative Predictive Value ratio (dPCR/Q-RT-PCR) of 1.01 [95% CI: 1.22-0.99]. At 52 mts from imatinib discontinuation, 55 pts (50.9%, 95% CI: 41.1-60.7) of the 108 eligible ones relapsed and resumed imatinib; 70.9% of them relapsed in the first 9 mts. Of the 53 not-relapsed pts, 39 (36.1% of the total) regained Q-RT-PCR positivity without losing MMR. The median time to Q-RT-PCR positivity was 3.0 mts [95% CI: 2.1-3.1] in the relapsed pts and 4.8 mts [95% CI: 2.9-7.8] in pts who developed only PCR positivity. In this latter group 2 pts experienced late relapses, at 30.5 and 45.5 mts respectively (Fig. 1). No case of CML progression or resistance to imatinib was observed. No significant correlation between relapse and previous duration of imatinib treatment, use of interferon, time to CCyR, Sokal score or duration of CMR was identified, while an inverse relationship between pts age and risk of relapse was evident. The analysis of QoL evidenced a statistically significant improvement in the general well-being and symptoms scales at 1 month after imatinib discontinuation and in particular nausea, diarrhea and fatigue (p<0.01). An inverse and transient trend toward increased pain emerged at mts 1 and 3.

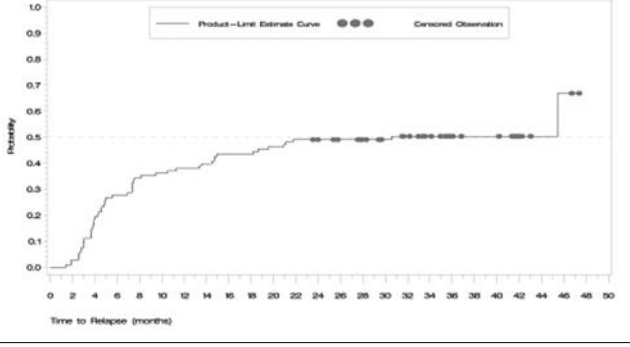

Figure 1. Time to Relapse (months) Kaplan-Meier curve evaluable patients

Summary/Conclusions: At 52 mts from the beginning of the study, with a median FUP of 35.5 mts, 50.9% of pts relapsed; the majority of relapses developed in the first 9 mts after imatinib discontinuation but late relapses also occurred, up to the 4th year. Therefore pts who discontinue imatinib should be monitored for a long period of time, especially if they showed positive PCR values after imatinib discontinuation.

P233

ASSESSMENT OF THERAPY RESPONSE IN CHRONIC MYELOID LEUKEMIA VIA 1 MONTH BCR-ABL1 TRANSCRIPT DECLINE

M El Missiry[1,*], H Hjorth-hansen[2,3], J Richter[4], U Olson-Strömberg[5], L Stenke[6], K Porkka[1], A Kreutzmann[1], S Mustjoki[1,7]
[1]Hematology Research Unit Helsinki, Department of Hematology, University of Helsinki and Helsinki University Central Hospital Comprehensive Cancer Center, Helsinki, Finland, [2]Department of Hematology, St Olavs Hospital, [3]Department of Cancer Research and Molecular Medicine, St Olavs Hospital, Norwegian University of Science and Technology (NTNU), Trondheim, Norway, [4]Department of Hematology and Vascular Disorders, Skåne University Hospital, Lund, [5]Department of Hematology, Uppsala University Hospital, Uppsala, [6]Department of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [7]Department of Clinical Chemistry, University of Helsinki, Helsinki, Finland

Background: The majority of chronic myeloid leukemia (CML) patients achieve excellent therapy responses to tyrosine kinase inhibitors (TKIs). However, a proportion of patients still fail to respond to the assigned first-line TKI. Currently, treatment responses are usually assessed first time at the 3 months time-point. As the treatment responses to TKIs are in general very fast, we hypothesized that the prediction of overall treatment response could be done at an earlier time-point than 3 months especially with emerging of newer TKIs.
Aims: To evaluate the feasibility of using the reduction of *BCR-ABL1* levels after one month of TKI treatment to predict therapy response.
Methods: 52 first-line TKI treated chronic phase CML patients were included (imatinib n=26, dasatinib n=21, nilotinib n=5). *BCR-ABL1* transcript levels were measured at diagnosis, 1, 3, 6, 12, 18, 24, and 36 months in EUTOS standardized laboratories. The patients were divided into groups based on the decline of *BCR-ABL1* at 1 month compared to the diagnostic values. The patients with a fold change (FC) higher than 1 (*i.e.* no decrease in *BCR-ABL1* values during the first month [FC>1]) were named *non-responders*, while those lower than 1 (FC<1) were *responders*. The median FC for the *responders* was 0.31, and this group of patients was further divided into *intermediate responders* (FC 0.31-1) and *good responders* (FC<0.31)
Results: One fifth (n=11, 21% of total) of patients had no decrease in *BCR-ABL1* after 1 month and were identified as *non-responders*. All *non-responders* had used full doses of their assigned TKIs according to their drug accountability logs in the clinical trial records and therefore the lack of response was not due to non-compliance. Surprisingly, at the diagnosis, the *non-responders* had lower *BCR-ABL1* compared to the *responders* (31% *vs* 48%, p=0.0083). Further, the *non-responders* had significantly more often enlarged spleen (55% *vs* 15%; p<0.01), lower hemoglobin levels (median 105g/L, range 88-122g/L *vs* 128g/L, range 82-154g/L; p<0.001), and higher percentage of Ph+ CD34+CD38- cells in the bone marrow (91% *vs* 75%, p<0.05). These three factors might be a better reflection of the total tumor load in the body than the initial level of *BCR-ABL1*, and therefore explain the slower response to therapy. In addition, the eradication of leukemic stem cells was slower in the *non-responders* in comparison to the *responders*. The *non-responders* had a modest decrease in Ph+CD34+CD38- after 1 month (medians at dg 91.3% *vs* 56.2% at 1m; p<0.05), while the decrease was quite dramatic in *responders* (at dg 75.3% *vs* 11.1% at 1m; p<0.0001). Similarly for Ph+CD34+CD38+ progenitor cells, the *non-responders* still had high percentages at 1 month (median at dg 99% and at 1m 86.5%; p<0.05,) while they were rapidly decreased in the *responders* (at dg 94.7% and at 1m 32.0%, p<0.0001). Long-term follow-up of molecular responses showed that the major molecular response (MMR) rates were inferior in the *non-responders* when compared to the *responders* (at 12m 18% *vs* 64%, p<0.01; 18m 27% *vs* 75%, p<0.01, 24m 55% *vs* 87%, p<0.01). In the latest ELN recommendations the 3 month BCR-ABL<10% is a marker for good response. In our patients, we observed that *BCR-ABL1* was <10% at 3 months in all *good responder* cases (n=17), while 24% (5/21 cases) of the *intermediate group* and 36% (4/11 cases) of the *non-responder* group had *BCR-ABL1* >10% at 3 months (p<0.01).
Summary/Conclusions: The early 1 month treatment response analysis defines a biologically distinct patient subgroup with less satisfactory long-term response.

P234

DEVELOPMENT AND EVALUATION OF A MR1 – MR4.5 SECONDARY LYOPHILIZED CELL REFERENCE PANEL FOR BCR-ABL1 QUANTIFICATION ON THE INTERNATIONAL SCALE

N Cross[1,2,*], H White[1,2], T Ernst[3], L Welden[4], G Saglio[5], FX Mahon[6], C Wong[7], D Zheng[7], S Wong[7], SS Wang[7], M Müller[8], A Hochhaus[3], S Branford[4]
[1]Wessex Regional Genetics Laboratory, Salisbury NHS Foundation Trust, Salisbury, [2]Faculty of Medicine, University of Southampton, Southampton, United Kingdom, [3]Hematology/Oncology, Universitätsklinikum Jena, Jena, Germany, [4]Department of Genetic and Molecular Pathology, SA Pathology, Adelaide, Australia, [5]Department of Clinical and Biological Sciences, San Luigi Hospital, University of Turin, Orbassano, Turin, Italy, [6]Bergonie Institute Cancer Center Bordeaux, INSERM U1218, University of Bordeaux, Bordeaux, France, [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States, [8]III. Medizinische Klinik, Medizinische Fakultät Mannheim, Universität Heidelberg, Mannheim, Germany

Background: Frequent molecular monitoring of chronic myeloid leukemia patients using high quality *BCR-ABL1* tests standardized to the International Scale (IS) is recommended for proper disease management, especially when

treatment cessation is considered. Currently, many laboratories standardize to the IS by exchanging patient samples with reference laboratories, an expensive and time-consuming process. A *BCR-ABL1* reference panel accredited by the World Health Organization (WHO) has been developed as a primary standard for IS calibration (MR^1-MR^4), but access to the material is restricted.
Aims: (1) To develop a secondary reference panel that is traceable to and faithfully replicates the WHO panel in manufacturing materials and methods, with an additional $MR^{4.5}$ level. (2) To assess the secondary panel in an international multi-center study.
Methods: As with the WHO panel, the secondary panel was manufactured by lyophilizing K-562 and HL-60 cell mixtures. Reverse-transcription droplet digital polymerase chain reaction (RT-ddPCR) was used to quality assess and calibrate the secondary panel to the WHO panel. The secondary panel was subsequently evaluated by 44 laboratories to determine the optimal sample input for each assay, and to assess assay performance including PCR efficiency, IS accuracy, sensitivity, linearity and precision.
Results: A secondary panel with *BCR-ABL1* levels of MR^1, MR^2, MR^3, MR^4 and $MR^{4.5}$ was successfully developed and IS calibrated to the WHO panel using RT-ddPCR against *ABL1*, *BCR* and *GUSB*. Quality control assessments indicated that the secondary panel had minimal residual moisture, excellent vial-to-vial homogeneity and >2.5 years real-time stability. The multi-center evaluation of the panel demonstrated compatibility with >44 *BCR-ABL1* assays of different configurations. Interestingly, in a standard curve experiment, we found that >40% of *BCR-ABL1* assays showed signs of inadequate optimization such as poor linearity and suboptimal PCR efficiency. When optimized sample inputs were used, 60% of tests achieved mean%BCR-ABL1 values within 2-fold of the panel's assigned values. Furthermore, 84% achieved good precision (≤0.25 log standard deviation) from MR^1 to MR^4, and 76% achieved a 100% detection rate at $MR^{4.5}$. Finally, 58% obtained IS conversion factors from the secondary panel equivalent to their current ones, most of which were obtained via sample exchange. Correlation analysis indicated that better PCR optimization was associated with better assay performance, and increased sample input improved detection rate and precision at $MR^{4.5}$. Different assay configurations were not found to be correlated with alterations in%BCR-ABL1 results.
Summary/Conclusions: We successfully developed the first secondary panel that is traceable to and fully replicates the WHO primary standards, with an additional $MR^{4.5}$ level. The panel was shown to be compatible with *BCR-ABL1* assays of different configurations in an international multi-center study. Importantly, once assay conditions were optimized, a high degree of precision and $MR^{4.5}$ sensitivity were achievable, yet IS accuracy was demonstrated in only 60% of cases. These findings indicate that there remains an unmet need for a simple and broadly available calibration mechanism, such as this secondary panel, to ensure IS accuracy is maintained in laboratories over time. The secondary panel and its derivatives can also be used as reference samples for assay analytical validation, optimization and quality assessment.

Background: In the last 10 years different studies analyzed the outcome of patients (pts) with sustained complete molecular remission (CMR) who discontinued imatinib, reporting rates of treatment-free remission (TFR) ranging from 33 to 66% depending on the definition of molecular relapse. On these bases it is judged safe to discontinue treatment with tyrosine-kinase inhibitors (TKIs) in experimental contexts.
Aims: To evaluate TFR in the setting of clinical practice according to the Italian experience where most of the pts who discontinued TKIs were not included in prospective protocols.
Methods: We retrospectively analyzed the outcome of pts treated in 23 Divisions of Hematology in Italy, who discontinued TKIs in deep molecular response (MR). General and clinical information such as TKI at discontinuation, line of treatment, type of MR at discontinuation, reasons for discontinuation were collected. We estimated TFR with the Kaplan-Meier method. Prognostic factors for TFR were assessed by univariate Cox regression model analysis.
Results: We analyzed a total of 208 pts who discontinued TKIs from June 2003 to October 2015. Median age was 59 years (Interquartile Range, IQR, 46-72). 102 were male, 106 female; 52%, 35% and 13% were low, intermediate and high Sokal score respectively. 168 pts (81%) discontinued in first line; 38 pts in second line (63% for intolerance to prior TKIs) and 2 pts in third line. 153 pts (74%) were on treatment with imatinib (all frontline), 26% with either nilotinib or dasatinib. Median duration of treatment with the last TKI was 75.2 mos (IQR 50-114); median time to CMR (undetectable transcript or MR4/MR4.5/MR5) with the last TKI was 23.3 mos (IQR 11.1-45.2). Median duration of CMR was 23 mos (IQR 11-45) before stop. At 3 mos of last TKI 28% of pts were in MR3, 26% were in PCyR and/or had a transcript <10%, 45% were in CCyR and/or had a transcript <1%, and 1% had no response. 184 pts had a response defined according to molecular standardization: 8% were MR3, 30% were MR4, 36% were MR4.5, 26% were MR5. Reasons for discontinuation were: toxicity for 28% of pts, pregnancy for 10%, pt request for 56%, enrollment in ISAV protocol for 10 pts. After a median follow-up of 11 mos (IQR 1-149), estimated TFR was 71% (95%CI 64.6%>78.1%) (figure 1). 69 pts restarted treatment. Reasons for restarting were: loss of MR4 for 20% of pts, loss of MR3 for 55%, loss of CCyR for 12%, other reasons for 13%. Median time to restart treatment was 6 mos (IQR 4-11). We assessed age, sex, Sokal score, type of transcript, previous IFN therapy, duration of TKI therapy, response at 3 mos, time to CMR, CMR duration, line of therapy at stop, depth of MR, reasons for stop as potential prognostic factors for TFR, but no statistically significant association were found, with the exception of response MR5 at stop (MR5 *vs* MR4, HR: 0.43, 95%CI 0.21-0.87, p=0.02) and age [HR 0.62 (95%CI 0.42-0.93, p=0.02), *i.e.* a decreased risk in older *vs* younger pts (difference of age=26 years)]. Pts who had to restart therapy were treated with imatinib (57), nilotinib (10), dasatinib (2). All of them regained at least MR3. No pts progressed. All pts were alive at the last follow up with the exception of 7 who died for reasons unrelated to CML.

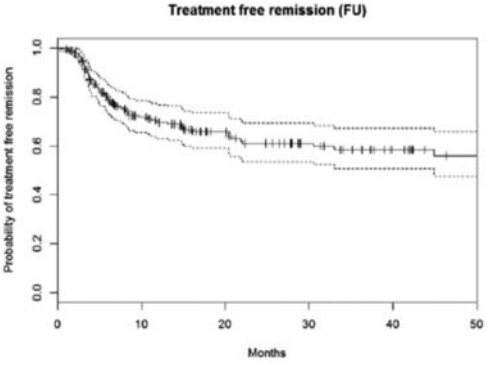

Figure 1. TFR of patients who discontinued TKIs in Italy.

Summary/Conclusions: Although our population is heterogeneous and worthy of specific sub-analysis, our experience confirms that discontinuation of imatinib, nilotinib and dasatinib is feasible and safe in the clinical practice. No progressions occurred, considering that 1/4 of our population had a follow-up longer than 12 years.

Background: Background The European LeukemiaNet (ELN) has produced recommendations for monitoring and assessing the response to tyrosine kinase inhibitors (TKI) at particular time points. Response criteria hve been developed and revised by ELN over the years and have been validated in adults with chronic myeloid leukemia (CML). In 2014, de La Fuente et al (BJH,2014) proposed the modified ELN guidelines for the management of children and young adults with CML treated with imatinib (IM). To date, both the 2013 ELN guideline and the modified ELN recommendations have not been yet validated in children with CML.
Aims: The aims of this study were: a) to analyze treatment results in patients less than 18 years of age at initial diagnosis of chronic phase CP-CML, treated and monitored according to local guidelines designed to standardize disease management in pediatric patients; b) to evaluate the 2013 ELN recommendations and the modified ELN guidelines in this pediatric population.
Methods: CML patients in CP, diagnosed between March 2001 and March 2014 and followed for at least 18 months were included in this analysis. The local guidelines provided cytogenetics on bone marrow (BM) cells before and every 3 months during IM therapy as well as molecular analysis on peripheral blood (PB) monthly and on BM every 3 months. Allogeneic stem cell transplantation (SCT) was considered for children who failed IM. Quantitative RT-PCR (qPCR) was assessed according to the ELN recommendations. BCR-ABL1 kinase domain mutation analysis was planned in patients with IM failure. Cytogenetic and molecular monitoring at planned time points, as well as treatment response according to the 2013 ELN recommendations and modified ELN guidelines were evaluated in this cohort of patients managed according to the local guidelines.
Results: Fifty-one CP-CML patients, 19 females and 32 males, median age at diagnosis: 11.2 years (range: 3.1-17,9), were managed at 11 Italian pediatric centers according to the local guidelines. Assessments of response at 3, 6, 12 and 18 months were carried out in 92%, 91%, 91%, 95% and 92% of patients, respectively. Figure 1 shows the response rates according to the 2013 ELN and modified ELN guidelines (B). The response rates at 3, 6, and 12 months were higher according to the modified ELN guidelines compared to the 2013 ELN criteria, owing to the high number of not evaluable (NE) patients using the modified ELN guideline. IM was discontinued in 29.5% of patients, due to toxicity (8%) or failure (21.5%), that occurred after a median of 24 months. Patients who failed IM had an optimal (82%) or a suboptimal response (18%) at 3 months. BCR-ABL35INS and no mutations were found in 45.5% and 54.5% of patients who failed IM, respectively. Fifteen% of patients with optimal response at 3 months underwent a SCT, all before 2009. IM was successfully discontinued in 8% of patients showing a durable deep molecular response. All patients are alive at a median follow-up of 75 months (range: 21-151.3).

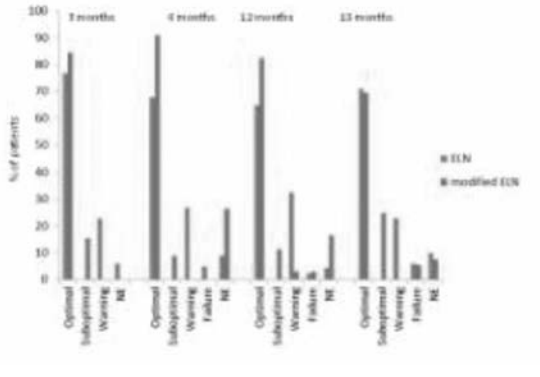

Figure 1.

Summary/Conclusions: Our experience confirms that collaborative studies have been useful to better manage children and adolescents with CML. Taking into account the rarity of the condition and the differences in the biology, clinical presentation, progression and response to treatment in adults compared tochildren, international collaborative studies and a shared clinical database for pediatric CML will be useful to address unanswered questions and issues.

Background: Prior clinical studies of imatinib (IM) have demonstrated proof of concept for TFR; in the STIM trial, TFR (no loss of deep molecular response [MR]) was maintained 1 y after treatment discontinuation by ≈40% of pts with sustained deep MR on long-term frontline IM. In ENESTcmr, pts who did not achieve deep MR ($MR^{4.5}$; *BCR-ABL1* ≤0.0032% on the International Scale [IS]) with IM were more likely to achieve this response with a switch to NIL.
Aims: To present results from the single-arm phase 2 ENESTop study (NCT01698905) evaluating the ability to maintain TFR in pts who achieve and sustain $MR^{4.5}$ on NIL following a switch from IM to NIL treatment.
Methods: Eligible pts had CML-CP, received prior tyrosine kinase inhibitor (TKI) treatment for ≥3 y (including IM for >4 wk followed by NIL for ≥2 y), and achieved $MR^{4.5}$ with NIL. All pts provided informed consent. Upon enrollment, pts continued NIL for 1 y (consolidation phase; RQ-PCR assessments every 12 wk). Pts without confirmed loss of $MR^{4.5}$ (consecutive *BCR-ABL1*^{IS} >0.0032%) during the consolidation phase were eligible to stop NIL (TFR phase; RQ-PCR assessments every 4 wk for the first 48 wk). NIL was reinitiated (ReRx phase) upon confirmed loss of MR^4 (consecutive *BCR-ABL1*^{IS} >0.01%) or loss of MMR (*BCR-ABL1*^{IS} >0.1%). The primary endpoint was the proportion of pts with ongoing TFR 48 wk after stopping NIL. This analysis was conducted when all pts who entered the TFR phase had completed 48 wk of TFR, entered the ReRx phase, or discontinued from the study (data cutoff, 26 Nov 2015).
Results: A total of 163 pts were enrolled and entered the consolidation phase; 126 entered the TFR phase. Median age at baseline was 56 y; prior to entering the TFR phase, median durations of TKI and NIL treatments were 88 (range, 49-171) and 53 (range, 37-109) mo, respectively. Of 126 pts, 57.9% (95% CI, 48.8-66.7%) remained in TFR at wk 48 (primary endpoint); 53.2% (95% CI, 44.1-62.1%) of pts had $MR^{4.5}$ at wk 48. Of 53 pts who discontinued from the TFR phase, 51 entered the ReRx phase (loss of MMR, n=34; confirmed loss of MR^4, n=17), and 2 permanently discontinued from the study (1 with confirmed MR^4 loss did not enter ReRx phase due to investigator decision; 1 was found to have atypical transcripts). In the ReRx phase, 50 pts (98.0%) regained MMR or better by the data cutoff, and 48 (94.1%) and 47 (92.2%) regained MR^4 and $MR^{4.5}$, respectively; median times to regain MR^4 and $MR^{4.5}$ were 12.0 and 13.1 wk, respectively. No new safety signals were observed with NIL. Adverse event rates were 77.0% *vs* 73.8% in the consolidation *vs* the TFR phase (full analysis set). Events in the musculoskeletal pain grouping (defined as musculoskeletal pain, myalgia, pain in extremity, arthralgia, bone pain, and/or spinal pain) were reported in 42.1% (n=53) of pts (grade 3/4, 1.6%) in the first 48 wk of the TFR phase; most of these pts (37 of 53; 69.8%) had no history of musculoskeletal pain. In the TFR phase, the majority of events (46 of 54) in this grouping occurred during the first 24 wk; most events were still ongoing.
Summary/Conclusion: ENESTop provides the largest set of prospective TFR data to date in pts with CML-CP who achieved sustained deep MR after switching from IM to NIL. After stopping NIL, 58% of pts remained in TFR at 48 wk. The results of ENESTop, together with those from ENESTcmr showing that a higher proportion of pts switching to NIL reach deep MR, suggest that a higher proportion of pts switching to NIL will achieve TFR compared with pts continuing on IM.

Myelodysplastic syndromes - Biology

P237

IMPACT OF MUTATION-DERIVED ANTIGENS IN IMMUNE RECOGNITION OF HEMATOLOGICAL MALIGNANCIES, SPECIFICALLY MYELOID DYSPLASTIC SYNDROMES (MDS)

SK Saini[1], S Dorfmüller[1,2,*], AM Bjerregaard[3], AK Bentzen[1], AC Eklund[3], H Medyouf[4], SR Hadrup[1]
[1]Section for Immunology and Vaccinology, National Veterinary Institute, Technical University of Denmark, Frederiksberg C, Denmark, [2]Institue for Immunology, Witten/Herdecke University, Witten, Germany, [3]Center for Biological Sequence Analysis, Department of Systems Biology, Technical University of Denmark, 2800 Lyngby, Denmark, [4]Georg-Speyer-Haus, Institut für Tumorbiologie und experimentelle Therapie, Frankfurt, Germany

Background: Mutation-derived neoepitopes have been suggested as a major component for immune recognition of solid tumors with a high mutational load, *e.g.* Melanoma and Non-Small-Cell Lung Cancer (NSCLC). Myelodysplastic syndromes (MDS) are a heterogeneous group of myeloid neoplasms characterized by increasing bone marrow failure due to clonal expansion of immature dysplastic cells in the bone marrow. Compared to Melanoma and NSCLC, these dysplastic cells carry low numbers of point mutations, but high levels of frameshifts, indels, splice variations or epigenetic changes. All of which may contribute to the generation of tumor-specific neoepitopes.
Aims: Assess if immune recognition of tumor specific neoepitopes is evident in MDS. Such neoepitopes may serve a potential important novel targets for immune therapy in hematological malignancies.
Methods: We identified personalized tumor specific mutations based on whole exome sequencing of MDS blasts and corresponding germline DNA. HLA binding regions covering these mutation sites were characterized by prediction of peptide-HLA binding using a specially designed program (MuPeXI, the Mutant Peptide Extractor and Informer), including state-of-the-art prediction tools based on netMHC.
Results: We identified 60-250 peptides per patients, for 6 MDS patient. These neoepitopes covered point mutations (70%) and indels/frameshifts (30%). Peptide-MHC multimer reagents where generated for each of these peptides, matching the HLA expression of the patient. We screened bone-barrow-derived T cells for recognition of these large pMHC libraries using a novel multiplex technology based on DNA barcode labeled MHC multimers. This technique allows screening for T cell recognition of >1000 different pMHC complexes in a single sample.
Summary/Conclusions: Potential neoepitopes where identified from all 6 MDS patients included. Bone marrow-derived T cells where successfully analyzed both directly ex-vivo and following in-vitro expansion. Data analyses are currently ongoing. This study proves the feasibility for identification of neoepitopes in MDS and confirms the barcode-labeled MHC multimer complexes as a strong tool to discover the T cell recognition of mutation derived neoepitopes.

P238

VITAMIN C INCREASES VIRAL MIMICRY INDUCED BY 5-AZA-2'-DEOXYCYTIDINE

AD Ørskov[1,*], M Liu[2], W Zhou[2], H Ohtani[2], J Charlet[3], H Shen[2], SB Baylin[2,4], G Liang[3], K Grønbæk[1], PA Jones[2]
[1]Department of Hematology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [2]Van Andel Research Institute, Grand Rapids, [3]Department of Urology, Keck School of Medicine, University of Southern California, Los Angeles, [4]Department of Oncology, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, United States

Background: Cancer patients are often deficient in vitamin C, which is an essential cofactor for the ten-eleven translocation (TET) enzymes. Since TET enzymes initiate DNA demethylation by oxidation of 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC), restoring vitamin C to physiological levels might raise the levels of 5hmC in cancer cells. DNA methyltransferase inhibitors (DNMTi's), 5-aza-2'-deoxycytidine (5-aza-CdR) and 5-azacytidine (5-aza-CR), are drugs of choice in higher risk myelodysplastic syndromes (MDS) and have shown efficiency in the treatment of acute myeloid leukemia (AML). Our group recently showed that low dose DNMTi causes upregulation of endogenous retroviruses (ERVs) that induce the viral defense pathway to elicit an interferon response, which may play an important role in the efficiency of DNMTi's.
Aims: The aim of this study was to explore if vitamin C would enhance growth inhibition and apoptosis induced by DNMTi via; 1) improved activation of TET enzymes and the formation of 5hmC and 2) enhanced induction of ERVs and activation of the viral defense pathway.
Methods: We measured the blood levels of vitamin C in 24 patients with hematological malignancies using high performance liquid chromatography (HPLC). Next, we explored the synergy between physiological doses of vitamin C and low doses of 5-aza-CdR in five cell lines measuring growth inhibition by CellTiter-Glo luminescent cell viability assay and apoptosis by annexin V affinity assay using flow cytometry. Upregulation of ERVs and viral defense genes were determined by RT-qPCR, gene expression microarrays and RNA sequencing. Finally, to detect global 5hmC changes we performed dot blot analysis using a specific antibody against 5hmC as well as Illumina Infinium HM450 DNA methylation assay to detect global 5mC changes. Bisulfite sequencing and a Hydroxymethyl Collector kit were used for detection of 5mC and 5hmC at the long terminal repeat (LTR) regions of the ERVs.
Results: We first document that hematological cancer patients are indeed vitamin C deficient. By adding vitamin C at physiological concentrations to low doses of 5-aza-CdR *in vitro*, we showed a synergistic inhibition of cancer cell proliferation and enhanced apoptosis. These effects are associated with enhanced immune signals including increased expression of bi-directionally transcribed ERV transcripts, increased presence of cytosolic double stranded RNAs (dsRNA), and activation of an interferon induced cellular response to these transcripts. In addition, we show that the TET product, 5hmC, is enriched both globally and locally at the LTR regions, which initiates transcription of ERVs.
Summary/Conclusions: Our work shows a remarkable synergy between physiological doses of vitamin C and 5-Aza-CdR, and the combination enhances a "viral mimicry" response by upregulation of ERVs, including dsRNA production and induction of an innate immune response. This may be essential for the responses of patients to this class of drugs. Since patients with hematological cancers are markedly vitamin C deficient, the addition of vitamin C to treatment protocols may therefore be a straightforward way to increase the clinical efficacies of these drugs in MDS/AML patients. A.D.Ø., M.L., W.Z. and H.O. contributed equally to this work.

Background: Studies on germline mutations responsible for cancer predisposition provide an important clue to the pathobiology and potentially the management of relevant cancers. Within acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS), only a handful of genes, including *RUNX1, CEBPA, GATA2, ETV6,* and *ANKRD26*, have been implicated in early onset familial cases, with germline mutations rarely seen in sporadic cases. Recently, we have identified novel germline variants of the *DDX41* gene that predispose to AML/MDS, using whole exome sequencing (WES) of familial cases with MDS/AML. In contrast to the variants of other MDS/AML-predisposing genes, germline *DDX41* variants are associated with a late onset disease typically diagnosed at the age of over 60, which could obscure their genetic predisposition, raising a possibility that germline *DDX41* variants might be found in apparently sporadic cases with MDS/AML.
Aims: This study was designed to assess the impact of germline DDX41 mutations on the AML/MDS development in Asian and Caucasian cohorts of sporadic AML/MDS.

Methods: We performed WES (N=55) or targeted-capture sequencing (N=1,035) in patients from the Asian cohort of sporadic AML/MDS (N=1,090), where the germline or somatic origin of the detected mutations was determined by using paired tumor and matched germline DNA if available. These results were compared to those from the Caucasian cohort of AML/MDS (N=1,034). The effect size of each variant for AML/MDS development was estimated by using the data from healthy populations in Asian countries (N=6,434) (BioBank Japan, Tohoku Medical Megabank Organization, and Exome Aggregation Consortium (ExAC) database) and in Caucasian countries (N=33,364)(ExAC database).
Results: In the Asian cohort of AML/MDS, germline *DDX41* variants were found in 42 patients (3.9%), of whom 15 (1.4%) also harbored a somatic *DDX41* mutation. In Caucasians, 8 patients (0.8%) had germline variants, and 2 (0.19%) for simultaneous germline and somatic mutations. Asian patients with germline variants had a median age of 56.6 (21-89), which was almost similar with that of the whole Asian cohort of AML/MDS {55 (6-93)}. In total, 8 and 1 recurrent germline variant alleles were observed in the Asian and Caucasian cohorts, respectively. Among them, the most predominant variants were p.A500fs (n=23; 55%) and p.Y259C (n=6; 14%) in the Asian cohort and p.D140fs (n=6; 75%) in Caucasians. Notably, no variants were shared by both populations, except for p.E256K, which are thought to be derived from a common ancestor. In contrast, a prominent hotspot mutation involving a highly conserved amino-acid within the helicase domain (p.R525H) was observed in both cohorts, accounting for 67% of second-hit *DDX41* somatic mutations. As a whole, these germline variants showed significant enrichment in AML/MDS cases compared to the respective control populations: odds ratio (OR)=18, {95% confidence interval (CI): 10-33} for Asian variants, and OR=10.8 (4.9-24) for Caucasian variants. As for individual variants, the enrichment in AML/MDS also showed various effect sizes: OR=19 (8.5-46) for p.A500fs, 8.9 (2.5-32) for p.Y259C in Asians, and 19.5 (7.1-54) for p.D140fs in Caucasians.
Summary/Conclusions: Germline *DDX41* variants are found in 0.8% to 3.9% in sporadic cases with MDS/AML depending of different ethnic populations. These germline *DDX41* alleles are present in the general population at low frequencies but account for the largest genetic predisposition to MDS/AML with high absolute risks. Second-hit mutations are common and show a prominent hotspot within the catalytic domain (p.R525). Given the high prevalence of *DDX41* germline variants and the late onset of associated MDS/AML, their detection may help clinicians to better manage patients with AML/MDS and to find other family members at risk, even when no family history is known.

P240

IDENTIFICATION OF ALTERED AND CRYPTIC-SPLICING IN SF3B1 MUTANT MYELODYSPLASTIC SYNDROMES AND ISOGENIC MODELS OF SF3B1-K700E MUTATION

F Liberante*, K Lappin, K Savage, K Mills
CCRCB, Queen's University Belfast, Belfast, United Kingdom

Background: In recent years, mutations in the SF3B1 gene have been discovered in a variety of cancers, especially myelodysplastic syndromes (MDS), acute myeloid leukemia (AML) and chronic lymphocytic leukemia (CLL). The majority are a single A>G transition resulting in a K700E codon change within the HEAT repeats. Very recent data have demonstrated that this mutation drastically alters the branch point preference of the SF3B1 protein. The high prevalence of mutations in SF3B1 in MDS alludes to an important role in the disease. In terms of clinical utility, identifying therapies which target cells harbouring mutant SF3B1 would be of great benefit, as there is pressing need to improve available therapies for MDS, a disease of the elderly.
Aims: To identify the downstream effects of mutant SF3B1 in primary MDS and assess the sensitivity of SF3B1 mutant cells to standard and advanced molecular therapies; using isogenic pre-clinical models of SF3B1 mutant MDS and AML.
Methods: An RNA-Seq data set from $CD34^+$ cells from a panel of SF3B1 wild-type and mutant MDS together with normal donors was analysed. More specifically, the dSpliceType tool was used to identify differential and cryptic-splicing between both SF3B1 mutant and wildtype MDS samples or SF3B1 mutant MDS and normal donors. In addition to analysis of primary material, we used genome-editing via CRISPR/Cas9 nucleases to create isogenic models for *in vitro* comparisons. The generated SF3B1 mutant cell lines have been validated by mass spectrometry and profiled by numerous assays. In order to ascertain the effects of SF3B1 mutation on both splicing and the wider transcriptome, we are currently validating RNA-Seq from these isogenic clones.
Results: The analysis of primary MDS RNA-Seq characterised nearly 3,000 differentially-spliced transcripts. Perhaps unsurprisingly, there was an enrichment of genes with roles in RNA processing, suggesting a possible feedback or compensatory mechanism in SF3B1 mutant cells. Of the altered transcripts, only around 150 were related to alternative 3' splice site recognition, which is likely to be directly attributable to $SF3B1^{K700E}$. Interestingly, this set of genes was enriched for phosphoproteins, which may suggest an impact of $SF3B1^{K700E}$ on kinase cascades within the cell. The isogenic models were successfully created by introducing the A>G transition at the K700 codon in one allele of the endogenous SF3B1 gene. The expression of the mutant was confirmed both by sequencing and mass spectrometry. The mutant cells do show a slightly slower growth rate, but are generally similar to wildtype cells. Altered splicing in these clones was validated using qPCR, which targeted transcripts identified in the primary samples. Further studies comparing differentiation and clonogenic potential, together with response to a wide range of therapeutics, are starting to yield interesting differences.
Summary/Conclusions: This study has shown that SF3B1 mutation leads to an altered transcriptome in primary MDS samples and many atypical transcripts. Furthermore, it has identified a potential role for SF3B1 in modulating the splicing of phosphoproteins representing a potential source of clinical targets that could be employed in the clinic. In addition, the successful creation of an isogenic model that recapitulates the altered splicing seen in the primary disease provides an opportunity for the screening of therapeutics for MDS or secondary AML.

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative therapy for patients with myelodysplastic syndromes (MDS), but its benefit is often offset by high mortality and morbidity accompanied. During the past decade, substantial advances have been made in our understanding of the genetic basis of myelodysplastic syndromes (MDS), through which a full spectrum of major mutational targets was delineated and their impacts on disease phenotypes and clinical outcome have been intensively studied. However, few studies addressed the effects of these mutations and other genetic alterations in the setting of allo-HSCT in a large series.
Aims: We aimed to elucidate the effect of genetic alterations on the clinical outcome of allo-HSCT for MDS based on a large scale-genotyping.
We aimed to elucidate the effect of genetic alterations on the clinical outcome of allo-HSCT for MDS based on a large scale-genotyping.
Methods: We performed targeted deep sequencing of genomic DNA from 865 MDS patients who received unrelated bone marrow transplantation via Japan Marrow Donor Program between 1998 and 2013, through which somatic mutations in the major drivers in MDS (68 genes) and other copy number abnormalities(CNAs) and their association to clinical outcomes were interrogated.
Results: The median age at HSCT and observation period were 52 years (1-66) and 1121 days (48-5,747), respectively. At the diagnosis, 5%, 26%, 20%, and 8% of the patients were classified into low, intermediate-1, intermediate-2, and high risk categories based on the International Prognostic Scoring System, respectively (42% were not informative). At HSCT, 28%, 35%, 19%, 4%, and 15% were diagnosed with low-risk MDS, refractory anemia with excess blasts (RAEB), secondary acute myeloid leukemia (sAML), myelodysplastic/ myeloproliferative neoplasms (MDS/MPN), and MDS not specified, respectively. In total, 79% of the patients had either somatic mutations (75%) or CNAs (45%). *RUNX1*, *U2AF1*, *ASXL1*, and *TP53* were among the most frequently mutated genes and mutated in >10% of the cases. Complex karyotype, -7/del(7q), del(5q), and trisomy 8 were identified in 17.4, 16.3, 9.6, and 6.7%, respectively. In univariate analysis, mutations in *TP53* (hazard ratio (HR):2.76), *CBL* (2.15), *PHF6* (2.06), *NRAS* (1.85), *PTPN11* (1.83), *EZH2* (1.65), *FLT3* (1.63), and *RUNX1* (1.39) showed negative effect on overall survival. In multivariate analysis combining these mutations, CNAs and clinical parameters, mutations in *CBL* (HR:2.72), *KRAS* (2.60), *EZH2* (2.37), *PHF6* (2.29), and *TP53* (1.95) were independently associated with significantly poor survival, together with red blood cell transfusions before HSCT (2.99), multiple HSCTs (1.91), 3≥points of Hematopoietic Cell Transplantation-Comorbidity Index (1.72), male recipients (1.62), serological HLA mismatch (1.59), grade II-IV of acute graft *versus* host disease (GVHD) (1.50), and diagnosis of RAEB, sAML and MDS/MPN (HR:1.66, 1.76, and 2.08, respectively). We also analyzed the impact of mutations on relapse in cases who achieved complete response (CR) after HSCT (n=765; 88.4%). Multivariate analysis revealed mutations in *TP53* (HR:9.66), *ATRX* (7.12), *CUX1* (5.60), *ETV6* (5.15), *RUNX1* (2.71), del(11q) (11.7), loss of heterozygosity of 6p (5.03), disease status of relapse (7.89), refractory disease (2.69), CR (2.98), and partial response (2.69) at HSCT (compared to treatment naive cases), and diagnosis of sAML (2.85) significantly correlated with unfavorable outcomes, whereas *PTPN11* (0.04) mutations predicted a favorable prognosis.

Summary/Conclusions: This large study of MDS cases treated by unrelated HSCT demonstrated that somatic mutations of specific driver genes could predict clinical outcomes of MDS patients treated by HSCT and better guide therapy.

17P DELETIONS AND TP53 MUTATIONS IN PATIENTS WITH MDS/AML AND COMPLEX ABERRANT KARYOTYPE

R Schaab[1,*], C Ganster[1], S Dierks[1], M Tallo Parra[1], R Martin[1], U Germing[2], U Platzbecker[3], K Shirneshan[1], F Lange[4], N Kröger[5], K Döhner[6], B Glaß[7], U Bacher[1], D Haase[1]
[1]Clinics of Hematology and Medical Oncology, University Medicine Göttingen, Göttingen, [2]Department of Hematology, Oncology and Clinical Immunology, Heinrich-Heine University Düsseldorf, Düsseldorf, [3]Medical Clinic and Polyclinic I, University Hospital, Technical University Dresden, Dresden, [4]Hufeland Klinikum, Mühlhausen, [5]Department of Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, [6]Department of Internal Medicine III, University Hospital of Ulm, Ulm, [7]Department of Hematology, Oncology and Stem Cell Transplantation, Asklepios Hospital St Georg, Hamburg, Germany

Background: Alterations of the *TP53* gene, either by molecular mutations or by cytogenetic deletions of the 17p13 region (where *TP53* is localized), are frequent in patients (pts.) with myelodysplastic syndromes (MDS) with complex aberrant karyotypes (≥3 clonal cytogenetic aberrations (CA)). Both, molecular as well as cytogenetic alterations of *TP53* were shown to be prognostically adverse in pts. with MDS.
Aims: This study investigates the interrelations between mutational status (hetero- *vs* homozygous, cytogenetic deletion *vs* molecular mutation) of *TP53* with the extent of (cyto)genetic instability and with prognosis of MDS/AML pts. with complex aberrant karyotypes.
Methods: We included 123 pts. with MDS (N=91), sAML after MDS (N=15) and *de novo* AML (N=17) all with complex aberrant karyotypes (≥3 clonal cytogenetic aberrations). Pts. were comprehensively characterized by chromosomal banding analysis (CBA), interphase fluorescence *in situ* hybridization (FISH) including 17p13/*TP53*, multicolor FISH (mFISH), sequencing of *TP53* and molecular karyotyping (MK, SNP-array analysis). The extent of genetic imbalances was quantified by the number of CA, the number of fusions as shown by mFISH and the size of total genomic aberrations (TGA) measured by MK.
Results: We identified molecular *TP53* mutations in 62/123 (50.4%) pts. from our study cohort (all with complex aberrant karyotypes). FISH/CBA revealed deletions of *TP53* on 17p in 31/89 (34.8%) pts. Combining the different aberration types a total of 50/89 pts. (56.2%) showed molecular and/or cytogenetic changes of *TP53*. In detail, a total of 28/89 pts. (31.5%) showed any alteration (chromosomal or molecular) of one allele (corresponding to a heterozygous status of *TP53*), two *TP53* aberrations (corresponding to a homozygous state) were found in 22/89 pts. (24.7%). In 39/89 (43.8%) pts. we could not identify any *TP53* mutation. Pts. with a molecular *TP53* mutation showed a higher number of CA (median 7; range 1-41; *vs* 4; 3-23; p=0.014), a tendency for larger TGA size (median 362 Mb; range; 97-981; *vs* 163 Mb; 64-600 Mb; p=0.135) and for a higher number of fusions (median 2; range, 0-17; *vs* 3.5; 0-13; p=0.093) as compared to pts. without a molecular *TP53* mutation. Likewise the number of CA and fusions was significantly higher in pts. with a homozygous mutational status of *TP53* (CA: median 8; range 3-41; fusions: 5; 0-13) and those with a heterozygous *TP53* mutational status (CA: 8; 1-25; fusions: 3; 0-10) in comparison to pts. with no aberration of *TP53* (CA: 4; 3-23; p=0.001; fusions: 2; 0-17; p=0.012). Preliminary follow-up analysis suggests an additional impact of the number of CA on survival outcomes of complex aberrant pts. with molecular *TP53* mutations. Currently, we are collecting further survival data for additional validation of this observation.
Summary/Conclusions: We were able to confirm a high proportion of molecular and/or cytogenetic aberrations of *TP53* in 56.2% of pts. with cytogenetically complex aberrant MDS/AML. Complex aberrant pts. with evidence of molecular and/or cytogenetic *TP53* aberrations showed higher levels of genetic instability as measured by the number of CA, genetic fusions and TGA size as compared to those without any *TP53* aberration. The extent of cytogenetic complexity may be prognostically relevant for complex aberrant MDS/AML pts. with molecular *TP53* mutations. We aim to collect further data to prove this observation. Those 43.8% of MDS pts. with a complex aberrant karyotype but without any *TP53* aberration raise the question whether other genes of the *TP53* pathway might be involved causing a "TP53-like" phenotype.

P243

TP53 AND EZH2 MUTATIONS PREDICT POOR SURVIVAL IN PATIENTS TREATED WITH HYPOMETHYLATING AGENTS IN MDS

MT Cedena[1,*], I Rapado[1], RM Ayala[1], E Onecha[1], M Abáigar[2], E Such[3], F Ramos[4], JV Cervera[5], JM Hernández-Rivas[2,6], G Sanz[3], J Martínez-López[1]
[1]Hematology, H. Universitario 12 Octubre, Madrid, [2]Cancer Research Center, IBSAL, University of Salamanca, Salamanca, [3]Hematology, H. Universitario La Fe, Valencia, [4]Hematology, H. Virgen Blanca, León, [5]Genetic Unit, H. Universitario La Fe, Valencia, [6]Hematology, H. Universitario de Salamanca, Salamanca, Spain

Background: Azacitidine (AZA) is a hypomethylating drug, which obtains a 40 to 50% of overall responses in MDS. Blast<15%, normal karyotype and no previous treatment seem to be independent factors for better response. However, the potential value of the gene mutations has not been extensively explored.
Aims: To evaluate the impact of gene mutations detected by next generation sequencing (NGS) on treatment response to hypomethylating agents in MDS patients; and to define predictive factors of survival.
Methods: Eighty-four MDS patients were included. According to WHO classification the diagnosis was: RA (1%), RCMD (22%), RAEB1 (25%), RAEB2 (23%), MDS isolated del5q (2%), CMML (8%), MDS/AML 20-30% blasts (13%) and unclassified MDS (6%). Very low, low, intermediate, high and very high-risk categories according to IPSS-R were found in 2%, 18%, 24%, 27%, and 25% of patients, respectively. For NGS, *Ion Torrent Proton (Life Technologies, Palo Alto, CA)* system was used. We selected a panel of 34 genes related to myeloid pathologies. An optimal depth of coverage, median about 2000, was reached, contributing to a high sensitivity. Additionally, clinical characteristics were considered: sex, age, WHO classification, cytogenetic risk, IPSS-R, response to AZA (IWG response criteria) and outcome.
Results: The median age was 69 years (range: 49-99). The median follow-up time was 17 months (range: 1-93). Mean numbers of cycles received per patient were 9 (range 1-55). Overall response to AZA was 42%, included complete remission 17%, partial remission 5% and hematologic improvement 20%. A total of 181 somatic mutations were found in 78 out of 84 patients (93%). The more frequent mutations involved *TET2* (25%), *TP53* (20%), *RUNX1* (18%), *DNMT3A* (18%), *EZH2* (14%), *ASXL1* (13%), *U2AF1* (12%), *SF3B1* (11%), *ZRSR2* (10%), and the remainder had frequencies of <10%. Considering clinical characteristics and mutational status in the univariate analysis of the impact on response, the number of AZA cycles (*p=0.003*), and the number of mutations per patient (*p=0.032*) were associated with overall response. Taking into account genes related to DNA methylation pathway (*TET2, DNMT3A, IDH1* and *IDH2*), the presence of at least 1 mutation in any of these genes was associated with complete remission (*p=0.031*). In the multivariate analysis, these parameters remained significant for overall response after adjusting by IPSS-R and age: number of AZA cycles (*p=0.006*; OR=1.2; 95%CI 1.1-1.4), number of mutations per patient (*p=0.042*; OR= 0.6; 95%CI 0.3-0.9), and mutations in methylation pathway genes (*p=0.024*; OR=4.4; 95%CI 1.2-15.7). In univariate analysis of survival, platelet counts, cytogenetic risk, IPSS-R, WHO classification, response to AZA and *TP53*, *RUNX1*, and *EZH2* mutational status were associated with overall survival. By contrast, in multivariate analysis, considering these clinical and molecular variables significant, only *TP53* and *EZH2* mutations remained as independent adverse prognostic factors for overall survival (HR=3.9; 95% CI: 1.9-7.8; *p*<0.001 for *TP53*, and HR=2.5; 95% CI: 1.2-5.1; *p*=0.012 for *EZH2*), regardless of the response to AZA (figure 1).

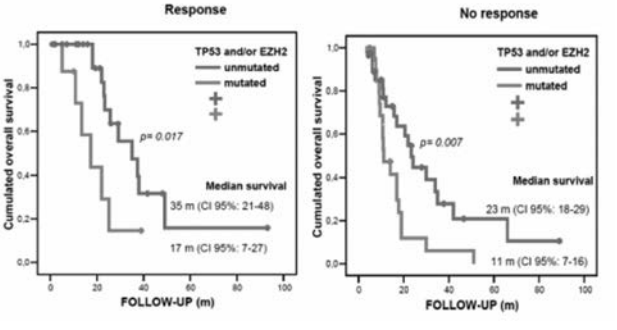

Figure 1.

Summary/Conclusions: In our series of patients treated with AZA, we found than more number of AZA cycles, less number of mutations per patient and the presence of at least 1 mutation in genes related to DNA methylation (*TET2, DNMT3A, IDH1, and IDH2*) were predictive factors for AZA response. However, a lower overall survival was associated with *TP53* and *EZH2* mutations regardless of this response.

AZACYTIDINE RESTORES THE ABNORMAL STAT SIGNALING BIOSIGNATURE OF FOXP3+ T REGULATORY CELLS (TREGS) IN RESPONDING MDS PATIENTS

E Lamprianidou[1,*], TP Vassilakopoulos[2], A Galanopoulos[3], SG Papageorgiou[4], M Papoutselis[1], Z Topouzoglou[1], E Spanoudakis[1], C Tsatalas[1], I Kotsianidis[1]
[1]Hematology, Democritus University of Thrace, Alexandroupolis, [2]Hematology,

Laikon General Hospital, National and Kapodistrian University of Athens, [3]Hematology, Department of Clinical Hematology, G. Gennimatas Hospital, Athens, [4]Hematology, Second Propedeutic Department of Internal Medicine, Attikon University General Hospital, Athens, Greece

Background: Tregs are expanded in late-stage MDS and may compromise tumor immunity. Signal transducer and activator of transcription (STAT) proteins regulate Treg differentiation, while aberrant immune signaling via STATs drives disease pathobiology in various malignancies. We have previously shown that, compared to RAEB-2 and AML/MDS patients, the CMML-2 ones display a distinct STAT signaling profile in Tregs which is also differentially modulated by azacytidine (AZA).
Aims: We have now updated our work by including more patients and normal donors and an extended panel of signaling nodes.
Methods: Peripheral blood mononuclear cells of 41 patients were obtained before, 15 days after AZA initiation and after the 6th cycle. According to WHO, 20 (48,7%) patients had RAEB-2, 12 (29,2%), 12 (29,2%) CMML-2, 7 (17%) AML/MDS and 2 (4,8%) RCMD. Based on the IWG criteria patients were divided into responders (CR and hematologic improvement, n=17) and non-responders (stable disease and failure, n=24). We applied phospho-specific flow cytometry to measure either basal or potentiated phospho-STAT1, STAT3 and STAT5 levels with simultaneous staining for FOXP3. The following potentiated, *i.e.* target/stimuli, signaling nodes (SN) were studied: IFNα/pSTAT1, IFNα/pSTAT5, IL-6/pSTAT1, IL-6/pSTAT3 and IL-2/pSTAT5. Clustering of SNs was performed with hierarchical cluster analysis and was correlated with response, disease subtype, transfusion burden, IPSS-R and cytogenetics by using χ^2 or Fisher Exact tests.
Results: Treg levels decreased in responders after cycle 6 (p=0.04), whereas non-responders showed a nonsignificant increase (p=0.17). Also, non-responders upregulated significantly the transcription factor Helios at 6 months (p=0.02), whereas responders retained stable levels. Unsupervised clustering of pretreatment SNs demonstrated that patients bear a different Treg STAT biosignature from age-matched normal donors (p=0.003), characterized by blunted response in cytokine stimulation and higher basal levels of STAT3. Normal donors still formed a separate cluster on day 15 (p=0.03), but clustering after cycle 6 separated two main clusters (figure 1). Cluster 1 encompassed all normal donors and was enriched in responders (p=0.04), whereas non-responders segregated in cluster 2 which was characterized by weak potentiated responses. Clustering of the fold-change of SNs in Tregs after the 6th cycle (MFI *cycle 6 – MFI pretreatment/MFI pretreatment*) discriminated responders from non-responders in 2 clusters (p=0.03). The first group upregulated both basal and potentiated nodes, while the second downregulated most SNs and upregulated pSTAT1 responses in IL-6 and IFNα.

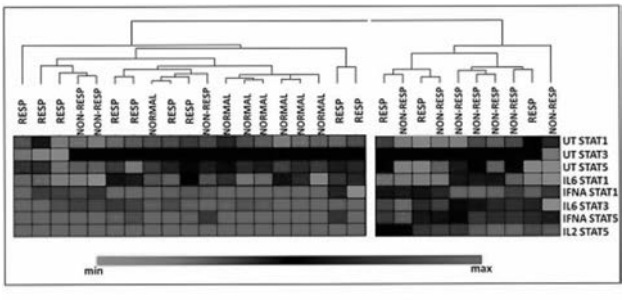

Figure 1. Hierarchical clustering of STAT signaling profiles in Tregs after 6 cycles of azacytidine. Resp=CR+HI; Non-Resp=Failure+stable disease

Figure 1.

Summary/Conclusions: Collectively, we demonstrate for the first time that the STAT signaling biosignature of Tregs in late-stage MDS patients is pathological, characterized by blunted response to cytokines. AZA induced a disparate effect in Tregs which was linked with clinical response; Responders decreased Treg numbers and normalized their STAT biosignature by restoring Treg responsiveness to cytokines, while non-responders tend to increase Tregs, displayed a marked increase in Helios expression and retained the abnormal STAT biosignature as they upregulated only pSTAT1 responses. Our results are suggestive of a clinically relevant immunomodulatory effect of AZA by modifying the cytokine/STAT signaling axis in Tregs. Further elucidation of the pathobiological significance of alterations in individual nodes will provide novel insights in the mechanisms of action and resistance to AZA.

A CULTURE MODEL MIMICKING THE BM-NICHE ALLOWS FOR STUDYING THE DYSREGULATED ERYTHROPOIESIS OF SF3B1 MUTATED MYELODYSPLASTIC SYNDROME WITH RINGED SIDEROBLASTS

EM Elvarsdóttir[1,*], T Mortera-Blanco[1], M Dimitriou[1], S Conte[1], B Sander[2], M Jansson[1], I Douagi[1], SE Jacobsen[1,3], E Hellström-Lindberg[1]

[1]Medicine, [2]Department of Laboratory Medicine, [3]Cell and molecular biology, Karolinska Institutet, Stockholm, Sweden

Background: The bone marrow (BM) constitutes a complex microenvironment that maintains and regulates hematopoiesis, and promotes differentiation. Little is known about the microenvironment of myelodysplastic syndrome with ringed sideroblasts (MDS-RS), of which >80% of patients harbor splice factor *SF3B1* mutations. We recently showed that MDS-RS erythropoiesis fails in particular during its terminal phase, a process that normally requires the formation of erythroid islands (Conte *et al*, BrJH 2015). Currently available culture models remain inefficacious to simultaneously support the formation of erythroid islands, enucleation of erythroblasts, and ring sideroblast development in MDS-RS, hence we lack adequate systems to model and target terminal erythropoiesis in MDS.
Aims: Our aim was to develop an *in vitro* culture model to study normal and MDS-RS hematopoiesis under conditions simulating the human *in vivo* BM microenvironment, and for the first time to be able to generate an MDS-RS phenotype *in vitro*.
Methods: Mononuclear cells including autologous stromal cells (MNC+) and CD34+ cells were isolated from 8 MDS-RS patients and 9 healthy individuals, and seeded into scaffolds made out of collagen-coated polyurethane (3D culture), or into previously established suspension cultures. The *in vitro* conditions were optimized for erythropoiesis by testing different cytokines and media. Cells were extracted weekly to evaluate proliferation, cellular composition and enucleation by flow cytometry, and ringed sideroblast quantification using morphological assessments by Perl´s Prussian blue staining. Self-renewal potential of cultured cells was assessed by long-term culture initiating cell assays (LTC-ICs) and allelic burden of *SF3B1* mutations with pyrosequencing. Scaffolds were sectioned for morphological assessment.
Results: The optimal medium composition included an initial phase aiming for erythroid progenitor enrichment followed by a high concentration of iron loaded human transferrin and EPO to induce erythroid maturation. Both MNC+ cultures and CD34+ 3D cultures maintained proliferation for up to 4 weeks. Interestingly, self-renewal potential, as assessed by LTC-ICs, was also maintained following this culture period. By contrast, conventional CD34+ cultures lost proliferative capacity after 2 weeks and did not give rise to LTC-ICs. The allelic burden of *SF3B1* was maintained in the 3D cultures (with MNC+ and CD34+ cells), but decreased within 4 weeks in suspension cultures. The MNC+ cultures were able to retain different lineages of hematopoiesis (including myeloid, lymphoid and erythroid) although primarily facilitating erythroid cells, while the CD34+ cultures (3D and suspension) only generated cells of the erythroid lineage. We identified enucleated erythroid cells from all cultures except for CD34+ suspension cultures. Importantly, erythroid islands carrying central macrophages were formed during week 3 and 4 in the MNC+ 3D culture. Morphologic quantification confirmed that 9-50% of the erythroblasts extracted at the end of the MNC+ cultures (3D and suspension) and CD34+ in 3D cultures were ringed sideroblasts.
Summary/Conclusions: We report for the first time that a 3D culture model seeded with BM MNC including autologous stromal cells is able to mimic hematopoiesis of healthy and MDS-RS BM *in vitro*, and provide support for formation of terminal erythropoiesis both from normal and *SF3B1* mutated bone marrow cells. This novel *in vitro* system should enable studies of MDS associated erythroid maturation defects *in vitro*.

Background: The increasing resolution of modern molecular genetics technologies has recently enabled the discovery of a novel phenomenon of genome instability that plays a role in cancer genesis and its progression. This phenomenon, termed chromothripsis, affects single chromosomes and/or chromosome regions that are shattered into many small pieces in a single catastrophic event. Chromothripsis was first described in 2011 by Stephens and colleagues. Since then, the occurrence of chromothripsis was detected in a wide range of tumor entities including hematologic malignancies. According to the published data it can be seen in approximately 2%–3% of all human cancers and is strongly associated with complex karyotypes. However, the real frequency of chromothripsis is likely to be much higher than was originally suspected.
Aims: The aim of the study was to assess the incidence and clinical significance of chromothripsis in bone marrow cells of the previously untreated patients with myelodysplastic syndromes (MDS) and complex chromosomal aberrations (CCAs).

Methods: A detailed retrospective genome-wide analysis of fixed bone-marrow cells from adults with CCAs (³3 aberrations) identified with conventional G-banding at the diagnosis of MDS was performed. The CCAs were studied through FISH with Vysis DNA probes (Abbott, Des Plaines, IL) and mFISH/mBAND methods using the 24*X*Cyte and the *X*Cyte color kits (MetaSystems, Altlussheim, Germany). Genomic imbalances were identified with CytoChip Cancer SNP 180K (BlueGnome, Cambridge, UK) or with Illumina Human CytoSNP-12 arrays (Illumina, San Diego, CA).
Results: We examined a large group of 222 patients with MDS and CCAs (104 females, 118 males; median age 68 years). The chromothripsis signature was revealed in 66.7% cases, both in the main clones as well as in one or more subclones. On the cytogenetic level, chromothripsis was manifested by multiple deletions, insertions, ring chromosomes, amplification of individual genes or chromosomal regions, and/or by the formation of chaotically reassembled marker chromosomes. The fragmentation or shattering of chromosomes into many pieces was observed as well. The most frequently shattered were chromosomes 5, 7, 17, and 12. In cases with signs of chromothripsis a higher frequency of the loss of heterozygosity (LOH) of 17p and/or the copy number neutral LOH (cnLOH) of 17p was observed (p=0.05). It is usually associated with homozygous mutations of *TP53* gene. Patients with chromothripsis had significantly worse overall survival (median OS, 3 months).
Summary/Conclusions: The results of this study confirmed chromothripsis as a frequent finding in patients with MDS and CCAs. This phenomenon was associated with a higher frequency of LOH/cnLOH 17p, very poor prognosis and rapid disease progression. The poor outcome could be explained by the fact that the function of many important genes becomes affected. The early identification of chromothripsis in patients with MDS can help with prognostication. Moreover, a better understanding of the mechanistic basis of chromothripsis could lead to the development of new treatment strategies based on drugs targeting genes present in amplified or deleted regions, and/or the DNA damage response pathways.

MODEST EPIGENETIC EFFECT OF AZACITIDINE IN GENOME-WIDE MAPPING OF DNA METHYLATION, H3K9ME3, H3K18AC AND GENE EXPRESSION IN MDS PROGENITORS

M Tobiasson[1,*], H Abdulkadir Ali[2], A Lennartsson[3], S Katayama[4], F Marabita[5], M Karimi[2], K Khrjutskhov[4], E Einarsdottir[4], M Jansson[2], A Ben Azenkoud[2], K Ekwall[4], J Kere[4], E Hellström-Lindberg[1], J Ungerstedt[1]
[1]Center for Hematology and Regenerative Medicine, Department of medicine Huddinge, division of Hematology Karolinska Institutet, Karolinska University Hospital Huddinge, [2]Center for Hematology and Regenerative Medicine, Department of medicine Huddinge, [3]Department of Biosciences and Nutrition, [4]Department of Biosciences and Nutrition, Center for Innovative Medicine, [5]Center for molecular medicine, Karolinska institutet, Stockholm, Sweden

Background: Azacitidine (Aza) is first-line treatment for patients with higher risk MDS. Since Aza is an inhibitor of DNMT1, demethylation of tumor suppressor genes has been proposed as the principal mechanism of action. Demethylation of specific genes has however been difficult to link to increased gene expression and a more comprehensive mapping of epigenetic and transcriptional effects of Aza on stem / early progenitor cells is warranted.
Aims: To comprehensively map epigenetic and transcriptional effects of Aza in primary MDS progenitors.
Methods: We selected 11 consecutive patients with higher-risk MDS (n=6), AML with 21-29% marrow blasts and multilinear dysplasia (n=4) and CMML type II (n=1). The patients were well characterized with regard to clinical data and mutations in recurrently mutated genes. CD34+ cells from these patients were cultured with or without Aza(1µM). Cells were harvested after 24h and 48h; treated and untreated cells were compared with regards to genome-wide DNA methylation using the Illumina 450k array (n=9), transcription levels using RNA sequencing (n=4), enrichment of the repressive chromatin mark H3K9me3 (n=6) and the activating mark H3K18ac (n=2) by ChIP seq.
Results: Cell growth and viability over 48 h showed little variation between untreated and treated cells. Gene expression increased over time in the control culture, while methylation changes patterns remained unchanged over time. We observed a strong correlation between gene expression, DNA promotor methylation (p=1.57e−22) and promotor H3K18ac (p=2.72e−61) in the untreated samples. Exposure to Aza for 24 h resulted in global DNA demethylation, with 18 657 and 908 promotors being demethylated and hypermethylated, respectively. The absolute change in methylation was however very modest with a median reduction in beta-value of 0.015 per gene. Similarly, the effects of Aza on the histone modifications H3K9me3 and H3K18ac were modest with 12 718 and 13 091 differentially enriched genes, respectively, whereof 52% and 44% being positively enriched in the Aza samples,; median fold change were 1.03 and 0.94, respectively. By contrast, the effect of Aza on gene expression was substantial with 8596 up- and 1804 downregulated; median fold change per gene was 1.61. Figure 1 illustrates global effects on gene expression and epigenetic changes with all genes plotted as bars on the X-axis sorted from most decrease to most increase. The relatively large changes observed in gene expression could not be explained by corresponding changes in promotor DNA methylation (p=1.88e−01), H3K9me3 (p=6.09e−01) or promotor H3K18ac (p=5.02e−01). GO analysis of the upregulated genes display enrichment in pathways involved in gene expression, protein synthesis and protein localization. Principal component analyses of epigenetic data displayed clustering based on patient identity while Aza-treatment had minor impact on clustering pattern.

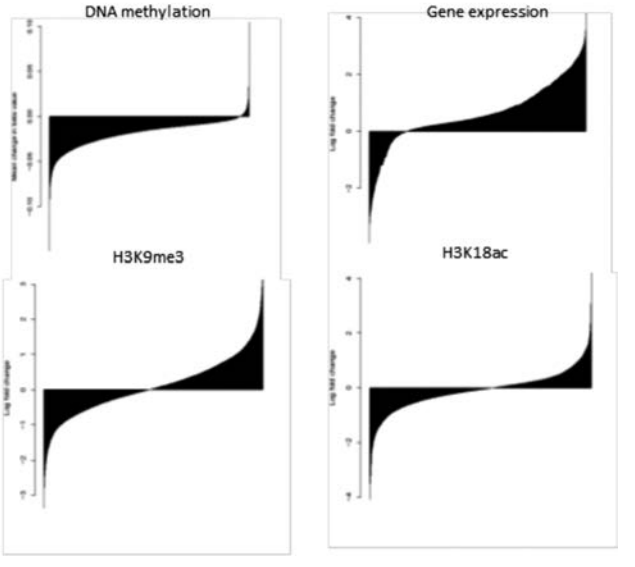

Figure 1.

Summary/Conclusions: *in vitro* Aza-treatment induces modest epigenetic changes in primary MDS progenitors. There are more pronounced effects on gene expression but since there is no correlation with changes in DNA methylation, H3K9me3 or H3K18ac, these effects must be a result of other mechanisms such as modulation of transcription factors. The limited epigenetic effect observed in the progenitor cells might be an explanation why Aza fails to achieve long-term remissions and the short-term remissions may be due to epigenetic effects on more differentiated cells.

Myelodysplastic syndromes - Clinical 1

P248

RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, MULTICENTER STUDY EVALUATING EPOETIN ALFA *VERSUS* PLACEBO IN ANEMIC PATIENTS WITH IPSS LOW- INT1 RISK MDS

P Fenaux[1,*], V Santini[2], MA Aloe Spiriti[3], A Giagounidis[4], R Schlag[5], A Radinoff[6], L Gercheva-Kyuchukova[7], A Anagnostopoulos[8], E Oliva[9], A Symeonidis[10], A Potamianou[11], H Haralampiev[11], R Wapenaar[11], I Milionis[11], U Platzbecker[12]

Background: Erythropoiesis stimulating agents (ESA) are first choice for treating anemia in lower-risk MDS patients (pts), but no ESA is approved for this indication. This international, Phase 3, randomized, double-blind, placebo (PBO)-controlled, multicenter study assessed the efficacy and safety of epoetin-alfa (epoetin-a; Eprex®) in pts with IPSS Low- or Int-1 risk MDS suffering from anemia.
Aims: To evaluate whether epoetin-a improves anemia (by erythroid response [ER]; IWG 2006) *vs* PBO over 24 weeks (w) of treatment. Duration of ER,% of pts maintaining ER up to w48, time to 1st RBC transfusion, transfusion-free interval, # of RBC transfusions, changes in PROs/ QoL and safety were also assessed.
Methods: Pts with *de novo* IPSS Low or Int-1 MDS with Hb ≤10.0 g/dl, transfusions ≤4 RBC units within 8-w before randomization, baseline serum EPO level <500 mU/mL, adequate iron and vitamin stores were eligible. The study included 3 phases: 3-w screening, 24-w double-blind treatment, and 24-w double-blind treatment extension in responders. Pts were randomized 2:1 to receive either epoetin-a 450 IU/kg (max tot. starting dose 40k IU) or matching PBO, once weekly sc, stratified according to transfusion need (yes/no) & serum EPO level (<200 mU/mL *vs* ≥200 mU/mL). Dose adjustments driven by ER and weekly Hb levels, included increase up to 1050 IU/kg (max tot. dose 80k IU) and dose reduction/withhold according to weekly Hb regardless of ER status. Primary endpoint was ER during first 24-w based on IWG 2006 criteria by investigators and an independent Response Review Committee (RRC). An *ad hoc* analysis was conducted in subjects who responded at any time of the study, regardless the IWG 2006 criteria, to allow assessment following dose adjustments and a longer period of observation.
Results: 130 pts were randomized, 85 to epoetin-a group; 54.6% were male; median age was 75 years. Baseline characteristics were comparable between groups. 70 (82.4%) epoetin-a pts completed the 24-w treatment; 39 (45.9%) epoetin-a pts entered the extension phase *vs* 1 (2.2%) PBO pt. 31.8% of epoetin-a pts achieved primary endpoint *vs* 4.4% of PBO pts, $p<0.001$. In the *ad hoc* analysis, 45.9% of epoetin-a pts *vs* 4.4% of PBO pts achieved ER, $p<0.001$. Median ER duration for epoetin-a pts was 197 days. Within 8-w prior to baseline, 51.8% of epoetin-a pts needed transfusions; this decreased to 24.7% by w-24. Transfusion need remained unchanged in the PBO pts (48.9% - 54.1%). Time to 1st transfusion was longer in the epoetin-a group ($p=0.046$). In a post-hoc analysis improvement in QoL scores was observed at w-24 in the epoetin-a arm in responders *vs* non responders (FACT-An p=0.025, EQ-5D p=0.007, EQ VAS p=0.037). Safety data were comparable up to w24; 77.6% of pts on epoetin-a reported ≥1 treatment-emergent adverse event (TEAE) *vs* 88.9% with PBO. Drug discontinuation due to AE was 10.6% in epoetin-a *vs* 13.3% in PBO. 4 pts in the epoetin-a arm (4.7%) and none in PBO reported ≥1 TVE. There were 4 TEAEs with fatal outcome in the epoetin-a arm *vs* 1 in PBO arm; none was reported to be related to the study drug. During the study progression to AML was similar between groups (3.5% in epoetin-a; 4.4% in PBO).
Summary/Conclusions: Epoetin-a significantly improved anemia by increasing Hb and reducing transfusion requirement in patients with Low or Int-1 MDS. Improved QoL was observed in responders. No new safety signals were detected in this study. These results confirm experience from clinical practice.

P249

OVERALL SURVIVAL (OS) AND SUBGROUP RESULTS FROM A RANDOMIZED PHASE 2 STUDY OF SGI-110 (GUADECITABINE) IN PREVIOUSLY TREATED MYELODYSPLASTIC SYNDROMES (MDS)

G Garcia-Manero[1,*], GJ Roboz[2], MR Savona[3], PL Kropf[4], CL O'Connell[5], KJ Walsh[6], S Lunin[7], R Tibes[8], TL Rosenblat[9], EA Griffiths[10], J Mace[11], NA Podoltsev[12], JP Issa[13], V Ahanonu[14], Y Hao[14], M Azab[14], HM Kantarjian[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]Weill Cornell/NY Presbyterian Medical Center, New York, [3]Vanderbilt University Medical Center, Nashville, [4]Fox Chase Cancer Center, Philadelphia, [5]University of Southern California, Keck School of Medicine, Los Angeles, [6]The Ohio State University, Columbus, [7]Florida Cancer Specialists, Inglewood, [8]Mayo Clinic Arizona, Scottsdale, [9]New York-Presbyterian/Columbia University Medical Center, New York, [10]Roswell Park Cancer Institute, Buffalo, [11]Florida Cancer Specialists, St. Petersburg, [12]Yale University School of Medicine, New Haven, [13]Fels Institute, Temple University, Philadelphia, [14]Astex Pharmaceuticals Inc., Pleasanton, United States

Background: Guadecitabine (formerly SGI-110) is a next generation small volume subcutaneous (SC) hypomethylating agent (HMA) with a differentiated PK profile and clinical activity reported in previously treated MDS and AML patients (pts) in Phase 1 (Issa et al, Lancet Oncology 2015). Responses were also seen in a Phase 2 study in both newly diagnosed and previously treated MDS and chronic myelomonocytic leukemia (CMML) pts randomized to guadecitabine SC 60 mg or 90 mg/m^2 QDx5 with no significant differences between the 2 dose groups (Garcia-Manero et al, ASH 2014).
Aims: To report the clinical activity, safety, long term OS, and subgroup analyses results for guadecitabine in previously treated MDS and CMML pts.
Methods: Intermediate (Int), or High Risk (HR) MDS by IPSS score, and CMML pts who were previously treated with azacitidine (AZA) and/or decitabine (DAC) were randomized to either 60 mg/m^2 or 90 mg/m^2 QDx5 every 28 days in this Phase 2 study. Clinical responses were assessed using the IWG 2006 criteria. Safety was assessed using CTCAE grades.
Results: 53 relapsed/refractory (r/r) MDS or CMML pts were randomized to either guadecitabine 60 mg/m^2 (26 pts) or 90 mg/m^2 (27 pts). There were no major differences between the 2 dose groups so data from both groups were combined for this report. Median age was 72 y (range 52-88y); ECOG PS was 0/1/2 in 21, 58, and 21% of patients. Patients were previously treated with AZA (77%) and/or DAC (32%) with 75% of patients receiving at least 6 months of prior treatment; 19% of patients had CMML, 47% had HR MDS; and 66% were transfusion-dependent. The median baseline bone marrow (BM) blasts were 8% (range 0-19%), baseline median Hb was 9.3 g/dL (range 7.1-13.5), median neutrophils were 0.81 x10^9/L (range 0.1-15.6), and median platelets count was 37 x10^9/L (range 7-328). Patients received a median number of 5 cycles of guadecitabine (range 1-29). Complete Response (CR) was achieved in 2 pts (4%), marrow CR in 15 pts (28%), and Hematological Improvement (HI) in 11 pts (21%). Median OS was 11.7 months (m). Patients who achieved a clinical response (CR, mCR, or HI) had longer OS than those with no response (p=.006). Median OS was 19.8 m for CMML; 12.3 m for Int MDS; and 10.1 m for HR MDS. Baseline BM blasts >5% and transfusion dependence predicted poor OS (p=0.07 and 0.06 respectively), with the worst OS in pts with both BM blasts >5% and transfusion dependence (p=0.007). Treatment was reasonably well tolerated. The most common Grade ≥3 AEs regardless of relationship to treatment were thrombocytopenia (55% of patients), anemia (51%), neutropenia (45%), febrile neutropenia (38%) and pneumonia (32%). All-cause 60-day mortality was reported in only 1 patient (1.9%).
Summary/Conclusions: SC guadecitabine (SGI-110) is a well-tolerated novel HMA with clinical activity and OS of almost 12 months in heavily HMA treated r/r Int and HR MDS and CMML pts that warrants further development. Clinical responses were associated with improved OS, and pts with both baseline BM blasts >5% and transfusion-dependence had the worst OS.

P250

MUTATIONS OF COHESIN COMPLEX GENES IN MYELODYSPLASTIC SYNDROME: DISTINCT CLINIC-BIOLOGICAL FEATURES AND PROGNOSTIC RELEVANCE

LH Chen[1,*], HA Hou[1], WC Chou[1,2], YY Kuo[3], JL Tang[1], CY Liu[4], CC Lin[1,2], MH Tseng[1], YC Chiang[1], MC Liu[5], CW Liu[5], LI Lin[6], W Tsay[1], M Yao[1], CC Li[1,7], SY Huang[1], BS Ko[1], SC Hsu[2], CY Chen[1], CT Lin[1,7], SJ Wu[1], HF Tien[1]
[1]Division of Hematology, Department of Internal Medicine, [2]Department of Laboratory Medicine, National Taiwan University Hospital, [3]Graduate Institute of Oncology, College of Medicine, National Taiwan University, [4]Biostatistics Consulting Laboratory, School of Nursing, National Taipei University of Nursing and Health Sciences, [5]Department of Pathology, National Taiwan University Hospital, [6]Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, National Taiwan University, [7]Tai-Cheng Stem Cell Therapy Center, National Taiwan University, Taipei, Taiwan, ROC

Background: Cohesin, a multimeric protein complex, is essential for chromosomal stability and transcriptional regulation. Perturbation of cohesin complex genes may contribute to malignant transformation and clonal evolution of hematopoietic cells. Recently, mutations within the cohesin complex were found in patients with myeloid neoplasms, but the reports concerning their clinical implications in myelodysplastic syndrome (MDS) are limited.
Aims: We aimed to elucidate the clinic–biological features and prognostic relevance of cohesin mutations in a large cohort of *de novo* MDS patients.
Methods: The mutational status for cohesin complex genes, including *RAD21, STAG1, STAG2, SMC1A* and *SMC3*, and 18 other molecular genetic alterations were analyzed in 420 patients with *de novo* MDS based on the FAB classification. Among them, the disease of 324 patients fulfilled the criteria of MDS

according to the 2008 WHO classification. The clinical features, cytogenetics, molecular alterations, and treatment outcomes were compared between patients with and without cohesin mutations.
Results: Cohesin mutations were identified in 31 (7.4%) of 420 patients, including two (0.5%) with *STAG1* mutations, 27 (6.4%) with *STAG2* mutations, and 2 (0.5%) with *SMC1A* mutations, respectively. The patients with cohesin mutations were older (P=0.0368), and had lower absolute neutrophil counts (P=0.0361) at diagnosis. Cohesin mutations occurred frequently in patients with refractory anemia with excess blasts (RAEB1/RAEB2), those with higher-risk International Prognostic Scoring System (IPSS) and revised IPSS (P=0.0107, P=0.0207 and P=0.0011, respectively). Clonal chromosomal abnormalities were detected in 168 (42.5%) of 395 patients who had chromosomal data. There was no difference in the distribution of karyotypes between patients with cohesin mutations and those without. Twenty-seven (87.1%) of the cohesin-mutated patients had concurrently other gene mutations. The patients with cohesin mutations had significantly higher incidences of concurrent *RUNX1* (25.8% *vs* 11.3%, P=0.0403), *IDH1* (12.9% *vs* 0%, P<0.001), *ASXL1* (61.3% *vs* 19.5%, P<0.001), and *SRSF2* mutations (45.2% *vs* 11.1%, P<0.001), but a trend of lower incidence of *TP53* mutation (0% *vs* 10.5%, P=0.0587) than those with wild type cohesin. With a median follow up duration of 42.9 months, there was a close correlation between cohesin mutations and acute leukemia transformation (3-year leukemia transformation rate, 78.5% *vs* 25.1%, for patients with and without cohesin mutations; P<0.001). MDS patients, based either by the FAB or 2008 WHO classification, had a significantly shorter overall survival if they harbored cohesin mutations than those who did not (median, 22.5 months *vs* 34 months, P=0.004 and 28.3 months *vs* 48.1 months, P=0.003, respectively). The difference remained significant when the analysis was performed in the subgroup of patients with lower risk MDS defined by the FAB classification (including RA and RARS), the WHO classification (other than RAEB, subtypes with blasts <5%), IPSS (including low- and intermediate 1-risk groups) or IPSS-R (including very low-, low- and intermediate–risk groups). However, there was no prognostic impact of cohesin mutations in the patients with higher risk MDS.
Summary/Conclusions: Cohesin mutations can be detected in a portion of MDS patients and are closely associated with mutations of *RUNX1, IDH1, ASXL1* and *SRSF2.* The presence of cohesin mutations predicts shorter survival, especially in the patients with lower risk MDS.

P251

MOLECULAR PROFILING IN A POPULATION BASED COHORT OF NORDIC MYELODYSPLASTIC SYNDROME PATIENTS

M Karimi[1,*], V Ljungström[2], J Werner Hansen[3], A Olsnes Kittang[4], M Skov Holm[5], I Dybedal[6], J Maxwell Nøgraad[5], F Ebeling[7], G Walldin[1], M Jädersten[1], C Ladenvall[2], L Cavelier[2], R Rosenquist[2], K Grønbæk[3], E Hellström-Lindberg[1]
[1]Dept. Medicine Huddinge, Karolinska Instutet, Stockholm, [2]Dept. of Immunology, Genetics and pathology, Uppsala University, Uppsala, Sweden, [3]Dept. of Hematology, Bartholin Institutet, Copenhagen, Denmark, [4]Dept. of Medicine, Haukeland University Hospital, Bergen, Norway, [5]Dept. of Hematology, Aarhus University Hospital, Aarhus, Denmark, [6]Dept. of Hematology, Oslo University Hospital, Oslo, Norway, [7]Dept. of Hematology, Helsinki University Central Hospital, Helsinki, Finland

Background: High through-put sequencing studies have revealed a large number of mutated genes in patients with myelodysplastic syndromes (MDS), of which RNA splicing factors and epigenetic factors constitute the two most frequent groups. Several studies have suggested that mutational screening may be beneficial to predict prognosis and clinical outcome of MDS patients.
Aims: In the present study we investigated molecular profiles in Nordic MDS patients, asking the question whether these population-based cohorts differ from that of previously published patient materials.
Methods: A total of 495 consecutive samples from Sweden, Denmark, and Norway were included in this study, encompassing all MDS subgroups, CMML, mixed MDS-MPN and RARS-T. The respective regional ethical committees approved the study, and all patients provided informed consent. Clinical data was collected based on national health registry systems.
Fresh bone marrow MNCs were isolated using gradient centrifugation and genomic DNA was extracted using column based DNA purification kits. Targeted enrichment of protein coding genomic regions of 42-75 frequently mutated genes were carried out and analyzed by next generation sequencing.
Results: Samples were successfully sequenced with an average coverage over 500 reads, allowing us to set the mutation detection to an allelic burden of ≥3%. In addition, we set the detection limit to 1% for TP53, considering the putative prognostic role of mutations in this gene. In our cohort, only 28 patients (6%) showed no mutations. We found that eleven genes; TET2, SF3B1, ASXL1, SRSF2, DNMT3A, TP53, RUNX1, U2AF1, EZH2, IDH2 and ZRSR2 were mutated in more than 5% of the patients (Fig.1), as compared to 7 genes, in the study by Papaemmanuil, et al, (Blood, 2013, 122(22): 3616-3627). Correspondingly, 7 genes showed a mutation rate >10%, compared to 4 in that study. Although our top gene list was similar to those reported in previous large studies we noted some interesting differences. Mutations in AXSL1 (15%), RUNX1 (10%), and TP53 (10.7%) were more frequent than in the study reported by Papaemmanuil (12%, 6% and 5%, respectively). The higher TP53 mutation rate can to some extent be attributed to the higher sensitivity, since 7 mutations had an allelic burden between 1% and 5%. Moreover, 34% (174 Patients) of our cohort had ≥3-mutated genes, compared to 20% in the Papaemmanuil paper.

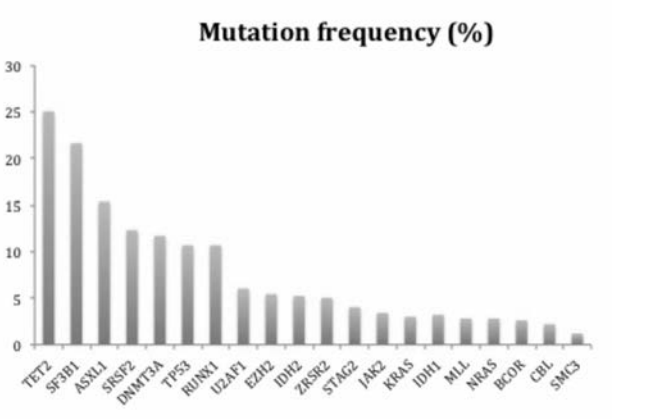

Figure 1.

Summary/Conclusions: The representativeness of reported studies based on selected patient cohorts constitutes a concern. Here, we show evidence that the mutational spectrum of a consecutive population-based Nordic cohort has an overall higher risk profile than previously published patient materials. This is valuable information, as mutation profiling will be soon part of standard clinical practice. In addition we believe that screening for TP53 mutations in MDS patients should be performed with sensitive methods, allowing for detection also of small subclones.

P252

CLINICAL BENEFIT AMONG LENALIDOMIDE (LEN)-TREATED PATIENTS (PTS) WITH RBC TRANSFUSION-DEPENDENT (RBC-TD) LOW-/INT-1-RISK MYELODYSPLASTIC SYNDROMES (MDS) WITHOUT DEL(5Q)

G Garcia-Manero[1,*], A Almeida[2], P Fenaux[3], N Gattermann[4], A Giagounidis[5], S Goldberg[6], K Ozawa[7], J Weaver[8], MM Sugrue[8], V Santini[9]
[1]MD Anderson Cancer Center, Houston, TX, United States, [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal, [3]Service d'Hématologie Séniors, Hôpital Saint-Louis, Université Paris 7, Paris, France, [4]Heinrich-Heine-Universität, [5]Marien Hospital Düsseldorf, Düsseldorf, Germany, [6]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NY, United States, [7]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, [8]Celgene Corporation, Summit, NJ, United States, [9]AOU Careggi, University of Florence, Florence, Italy

Background: In the phase 3 MDS-005 study of LEN in RBC-TD lower-risk (LR) non-del(5q) MDS pts ineligible for/refractory to erythropoiesis-stimulating agents (ESAs), a statistically significant and clinically relevant higher proportion of LEN-treated pts achieved RBC transfusion independence (RBC-TI) ≥8 wks *vs* placebo (PBO) (*P* <0.001); other measures of efficacy collected included erythroid improvement and cytogenetic response (CyR).
Aims: To evaluate the relationship between LEN and clinically meaningful measures of response in pts from MDS-005.

Table 1.

Response, n (%)	LEN (n = 160)	PBO (n = 79)	OR (95% CI)
Clinical benefit	51 (31.9)	3 (3.8)	11.85 (3.57–39.38)
RBC-TI ≥ 8 wks	43 (26.9)	2 (2.5)	
Transfusion reduction ≥ 4 pRBC units ≥ 8 wks[1]	34 (21.3)	0	
Hb increase ≥ 1.5 g/dL (IWG 2006)	31 (19.4)	2 (2.5)	
CyR	9 (5.6)	0	

[1] Data normalized to 8 wks using data from a 112-day assessment period divided by 2.

Methods: Pts were randomized 2:1 to LEN 10 mg/day (n=160) or PBO (n=79) once daily. Clinical benefit ≥8 wks was defined as the composite endpoint of RBC-TI ≥8 wks, or transfusion reduction of ≥4 units packed RBCs (pRBCs) ≥8 wks, or hemoglobin (Hb) increase ≥1.5 g/dL at 8 wks (IWG 2006), or CyR. The rate of transfusion reduction was calculated using data collected during a 112-day assessment period to account for on-study differences in transfusion burden. CyR was also evaluated separately.

Results: Clinical benefit was higher in pts treated with LEN *vs* PBO (Table 1). In evaluable pts with ≥1 follow-up assessment (n=43), CyR with LEN was reported in 9 (33.3%) pts (major: n=5; minor: n=4). No CyR occurred in the PBO group. Among pts with CyR, 5 (55.6%) also achieved RBC-TI ≥8 wks.
Summary/Conclusions: In RBC-TD pts with LR non-del(5q) MDS ineligible for or refractory to ESAs, LEN was associated with significantly greater clinical benefit, as measured by this newly defined composite endpoint, *vs* PBO. This analysis provides evidence that other measures of response in addition to RBC-TI may be valuable in the management of LR non-del(5q) MDS. Clinically meaningful responses to LEN in non-del(5q) pts include CyR, decrease in transfusions, and increased Hb, in addition to RBC-TI.

P253

PHASE 1 DOSE-ESCALATION STUDY OF ORAL ASTX727, A COMBINATION OF ORAL DECITABINE WITH A CYTIDINE DEAMINASE INHIBITOR (CDAI) E7727, IN SUBJECTS WITH MYELODYSPLASTIC SYNDROMES (MDS)
MR Savona[1,*], O Odenike[2], P Amrein[3], D Steensma[4], A DeZern[5], L Michaelis[6], S Faderl[7], A Oganesian[8], J Lowder[8], P Taverna[8], M Azab[8], G Garcia-Manero[9]
[1]Vanderbilt University Medical Center, Nashville, [2]University of Chicago, Chicago, [3]Massachussetts General Hospital, [4]Dana Farber Institute, Boston, [5]Johns Hopkins University Hospital, Baltimore, [6]Medical College of Wisconsin, Milwaukee, [7]Hackensack University Medical Center, Hackensack, [8]Astex Pharmaceuticals Inc., Pleasanton, [9]UT MD Anderson Cancer Center, Houston, United States

Background: Hypomethylating agents (HMA) are typically administered parenterally and adjusted to body surface area (BSA) in order to achieve target pharmacokinetic (PK) parameters associated with response. Much of the variation associated with administration of HMAs is related to the intrinsic variability of the activity of cytidine deaminase (CDA) an enzyme with highest levels in the gut and liver which rapidly metabolizes HMAs.
Aims: To assess PK comparability with the aim of matching PK parameters of BSA adjusted dosing with IV decitabine (DAC) with a novel fixed-dose oral combination (ASTX727), of DAC and E7727, a CDA inhibitor. Preliminary safety and clinical activity were previously reported (Savona M, Blood:126(23); 1683,2015).
Methods: Adult patients with Int-1/Int-2 or HR MDS or Chronic Myelomonocytic Leukemia (CMML) were enrolled in a Phase I, dose-escalation trial, aiming to achieve a mean AUC of DAC following oral ASTX727 comparable to IV DAC at the approved dose of 20mg/m^2. In the first cycle, each patient received an IV DAC dose of 20mg/m^2 on Day 1 as an internal comparator followed by oral ASTX727 on Days 2-5 escalated by cohort. Only one component at a time was escalated in each cohort and oral doses were not adjusted for weight or body surface area. Full PK assessments were performed on Days 1, 2 and 5.
Results: 43 patients were treated in 5 cohorts of 6 patients each plus a dose confirmation cohort of 13 patients. In cohorts 1-3 ASTX727 was given as a fixed oral DAC dose of 20mg with escalating doses of oral E7727 at 40, 60, and 100mg, respectively. In cohort 4, the oral DAC dose was escalated to 40mg while E7727 was kept at 100mg and Cohort 5 evaluated 30 mg DAC and 100mg E7727. DAC AUC increased with increasing doses of E7727. The AUC on Day 5 of dosing was higher than that on Day 2 of dosing due to residual levels of inhibitor E7727 present systemically 24 hours post dosing. Thirty patients were male, 13 female, their median weight was 87.8kg (range=51.1-204.1) and median BSA was 2.0m^2 (range 1.28-2.67). The Day 1 AUC for IV DAC 20mg/m^2 over all 5 cohorts was 188(+/-76) ng*hr/mL, CV= 41%. The Day 5 mean DAC AUC for ASTX727 increased with dose escalation from 31 to 148% of the Day 1 IV DAC AUC. (Table 1) Cohort 5 achieved ~90% oral DAC AUC exposures to IV with the acceptable variability of CV=50%. Linear regression between weight and DAC AUC for cohort 5 showed no correlation (p=0.7887).

Table 1. Mean Plasma DAC AUC and SD by Cohort for the Study afterASTX727 and IV DAC.

Cohort Dose mg/d DAC/E7727 (Days 2-5)	20/40 N=5	20/60 N=6	20/100 N=6	40/100 N=6	30/100 N=19	Total N=43
	AUC ng*h/mL	AUC ng*h/mL	AUC ng*h/mL	AUC ng*h/mL	AUC ng*h/mL	AUC ng*h/mL
IV DAC (20 mg/m^2) Day 1						188(76)[41%]
Oral DAC Mean(SD) [CV]	60.1(21.7) [36%]	79.8(28.2) [35%]	112(53.7) [48%]	285(149) [52%]	169(84.4) [50%]	
Weight (Kg) Mean(SD) [CV]	82.6(7.2) [9%]	88.5(11) [12.4%]	107.9(43) [40%]	117.2(55.4) [47%]	93.5(31.8) [34%]	96.6(34) [35%]
BSA (m^2)	1.85(0.31) [17%]	2.1(0.12) [5.7%]	1.9(0.34) [18%]	2.0(0.32) [16%]	2.0(0.23) [11.5%]	2.0(0.26) [13%]

Summary/Conclusions: Despite wide ranges in weight and BSA, oral ASTX727 administered in a fixed low dose of decitabine and E7727 delivers an AUC comparable to BSA adjusted IV decitabine in both exposure and variation. The low PK variability is attributed to the elimination of variations due to CDA activity through CDA inhibition by E7727 which appears to compensate for body mass disparities. An ongoing randomized cross-over Phase 2 trial is currently studying the PK and pharmacodynamic effects of full 5-day cycles of IV DAC and ASTX727.

P254

THE USE OF A HIGH DENSITY, 2.6 MILLION MARKER, SNP ARRAY AS THE PRIMARY GENETIC TEST FOR MYELODYSPLASTIC SYNDROME AT DIAGNOSIS: INTERIM FINDINGS OF THE WEST MIDLANDS, UK STUDY
N Trim[*], E Huxley, P Wojtowicz, L Osland-Jones, J Caddick, L Ford, S Jeffries, M Griffiths
West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom

Background: Myelodysplastic syndrome (MDS) prognosis, risk stratification and management is currently dictated by the IPSS-R with metaphase chromosome analysis being the only current contributing genetic factor. The UK NHS genetic service offers metaphase cytogenetics (MC) as the only routine test, which is not only time consuming but ultimately only detects an abnormal karyotype in approximately 45% samples. Although there is no single technology that can identify the various genomic and genetic aberrations observed in MDS in a single test, the cytogenetic aberrations seen in MDS are mostly copy number changes (with the exception of 3q26 *MECOM* gene rearrangements) and therefore microarray analysis offers an alternative approach to MC. High density single nucleotide polymorphism microarrays (SNP-A) offer genome wide copy number analysis at a resolution beyond that of MC analysis, and often down to the single gene, and even exon, and can identify regions of copy number neutral loss of heterozygosity (CN-LOH) that may harbour biallelic gene mutations. Consequently microarray analysis has the potential to increase genetic abnormality detection rates thereby improving diagnosis.
Aims: The West Midlands Regional Genetic Laboratory has undertaken a two year study to use SNP-A analysis as a complementary tool to MC in patients with confirmed or highly suspected MDS both at presentation and during the disease course. The aim of the first arm of the study is to determine the utility of high density SNP-A as the primary test for MDS patients to replace MC analysis at diagnosis. This includes comparison of abnormal karyotype detection rate and aberrational yield.
Methods: SNP-A analysis was performed on DNA extracted from marrow samples of 102 MDS patients. All 102 patients' samples were, in parallel, subjected by MC analysis. DNA was interrogated using Affymetrix CytoScan HD SNP arrays which contain 2.6 million markers including approximately 750,000 SNPs. Data was analysed using Affymetrix Chromosome Analysis Suite (ChAS).
Results: Forty four cases (43%) were found to have no reportable abnormalities by both MC and SNP-A analysis, and 40 cases (39%) were found to be abnormal by both techniques. The remaining 18 cases (15%) were discrepant: 15 cases were found to be abnormal by SNP-A but normal by MC analysis, whereas 3 cases were found to be abnormal by MC analysis but normal by SNP-A analysis. The karyotype of 33 cases were discrepant between MC and SNP-A. A total of 39 additional abnormalities in 30 cases were detected by SNP-A that were not seen or identified by MC analysis, including: 18 regions of CN-LOH; gain of chromosome 4; loss of chromosome 7; loss of 7q; two *TET2* deletions, two *CUX1* deletions; a partial deletion of *RUNX1*; and a partial tandem duplication of *KMT2A*. Regions of CN-LOH (>10 Mb, extending to the telomere) were found in 17 patients (18%), with 7q being the region most affected (5 patients). Three aberrations were identified by MC that were not detected by SNP-A: a low level trisomy 8 clone (~1% clone); an insertion resulting in a *RUNX1* rearrangement as the sole abnormality; and a 3q translocation resulting in a *MECOM* rearrangement as part of a complex karyotype.
Summary/Conclusions: SNP array analysis increased the number of cases identified as genetically abnormal from 43% to 54% and identified an additional 39 aberrations compared to MC analysis. Additional aberrations detected by SNP array, including gene deletions and CN-LOH, have the potential to refine risk stratification and prognosis in MDS. The detection of cytogenetically cryptic and potentially prognostically significant abnormalities in these MDS patients highlights the need for higher resolution genomic detection methods in the diagnosis of this disease.

P255

PHASE 1B STUDY OF GLASDEGIB (PF-04449913) IN COMBINATION WITH AZACITIDINE IN PATIENTS WITH HIGHER RISK MYELODYSPLASTIC SYNDROME, OLIGOBLASTIC ACUTE MYELOID LEUKEMIA, OR CHRONIC MYELOMONOCYTIC LEUKEMIA
U Borate[1,*], BD Smith[2], S Gore[3], A Zeidan[3], M Savona[4], ML Savoie[5], N Zhu[6], D Breems[7], X Zhang[8], MN Shaik[9], A Rampersad[8], G Chan[10], A Woolfson[8], M Sekeres[11]
[1]University of Alabama, Birmingham, AL, [2]Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD, [3]Yale University School of Medicine, New Haven, CT, [4]Vanderbilt-Ingram Cancer Center, Nashville, TN, United States, [5]Tom Baker Cancer Centre, Calgary, [6]University of Alberta, Edmonton, Canada, [7]ZNA Stuivenberg, Antwerpen, Netherlands, [8]Pfizer Oncology, New York, NY, [9]Pfizer Oncology, La Jolla, CA, [10]Pfizer Oncology, Collegeville, PA, [11]Cleveland Clinic, Cleveland, OH, United States

Background: The Hedgehog signaling pathway (HhP) is known to be aberrantly activated in leukemias and myelodysplastic syndrome (MDS), promoting cancer stem cell maintenance. Glasdegib is a potent, selective, oral HhP

inhibitor which acts by inhibition of Smoothened (SMO), with activity in preclinical models and antitumor efficacy *in vivo*. A Ph.1 study of glasdegib monotherapy in patients (pts) with hematologic malignancies suggested the drug is well tolerated and active. When glasdegib was combined with low-dose cytarabine, decitabine or standard induction chemotherapy in 7 previously untreated high-risk MDS pts, 2 achieved complete responses (CR) and 3 had marrow (m)CRs. Further, blocking the HhP with SMO inhibitors in combination with azacitidine (aza) demonstrated synergy *in vitro* and inhibited primary malignant myeloid cells *ex vivo*.

Aims: Primary objective of the open-label Ph.1b part of this study (NCT02367456) was to assess the safety of combining glasdegib with aza in pts with previously untreated higher risk MDS (IPSS score risk: high or Int-2), oligoblastic acute myeloid leukemia (oAML) with 20-30% blasts and multi lineage dysplasia (WHO 2008 criteria), or non-proliferative chronic myelomonocytic leukemia (NP-CMML) with white blood cells <13x10^9/L.

Methods: Adult pts gave informed consent and received glasdegib 100mg once daily in combination with standard aza 75mg/m^2 days 1-7 every 28 days for as long as pts received clinical benefit. Patients were assessed for safety, tolerability and efficacy.

Results: As of Dec 30, 2015, 12 pts (7 males) with a mean age of 72 years (range 59-89) were enrolled. Primary baseline diagnosis was MDS: 7 (IPSS-risk Int-2: 5, high risk: 2), oAML: 3, NP-CMML: 1, other (erythroleukemia): 1. Across all cycles the median dose intensity was 80% for glasdegib and 97% for aza. At data cutoff, 8 pts (67%) discontinued treatment due to an adverse event (AE) (n=5), physician decision (n=2) or patient decision (n=1). Plasma exposure of both agents was unchanged when coadministered. The most common, all-cause AEs included anemia and constipation (75% each), nausea (67%), fatigue (58%), dysgeusia and neutropenia (50% each). Non-hematologic grade (G)3-4 AEs of sepsis occurred in 2 pts (17%); additional G3-4 AEs occurring in 1 pt (8%) are listed in the Table 1. Eight pts (67%) experienced serious AEs (SAEs); SAEs occurring in 2 pts (17%): cellulitis, febrile neutropenia, and pyrexia. Four of the 12 pts had an investigator-assessed response by IWG criteria: 3 CR and 1 mCR; 4 pts had stable disease. Three pts died from disease progression, sepsis with multi-organ failure, and myocardial infarction due to underlying CAD. Six-month survival was 67%.

Table 1. Non-hematologic G3-4 AEs (n=1).

G3: Fatigue, prolonged QT, muscle spasms, hyponatremia, urinary tract infection, hematoma, hypophosphatemia, hypoxia, bacteremia, diverticulitis, hemarthrosis, hypokalemia, lung malignancy, mental status changes, musculoskeletal chest pain, neutropenic sepsis, osteomyelitis, procedural hypotension, respiratory tract infection, and tachycardia
G4: Dyspnea, cellulitis, hypotension, pneumonia, acute kidney injury, acute respiratory distress syndrome, ischemic hepatitis, respiratory distress, and septic shock

Summary/Conclusions: The addition of glasdegib to standard-of-care aza in the treatment of pts with MDS, CMML or oAML appears to have an acceptable safety profile. The number of CRs observed so far appears favorable in the context of the 15-17% CR rate seen with aza alone. A randomized trial of glasdegib in combination with aza is planned in MDS.

P256

RESULTS FROM PHASE I/II STUDY OF THE COMBINATION OF ORAL RIGOSERTIB AND AZACITIDINE IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

S Navada[1], G Garcia-Manero[2], K Hearn[2], R Odchimar-Reissig[1], E Demakos[1], Y Alvarado[2], N Daver[2], C DiNardo[2], M Konopleva[2], G Borthakur[2], P Fenaux[3,*], S Fruchtman[4], P Zbyszewski[4], L Silverman[1]

[1]Tisch Cancer Institute, Division of Hematology/Oncology, Icahn School of Medicine at Mount Sinai, New York, [2]MD Anderson Cancer Center, Houston, United States, [3]Hospital St Louis, Paris, France, [4]Onconova Therapeutics, Inc., Newtown, United States

Background: Rigosertib is a Ras-mimetic (Athuluri-Divakar, Cell 2016, in press) that inhibits the PI3K and PLK cellular signaling pathways by binding directly to the Ras-binding domain found in Ras effector proteins. *In vitro*, the combination of rigosertib with azacitidine synergistically inhibits growth and induces apoptosis of leukemic cells in a sequence-dependent fashion (rigosertib administered prior to azacitidine) (Skidan, AACR 2006). Phase I results of this study in pts with MDS or AML showed the combination of oral rigosertib and standard-dose azacitidine to be well-tolerated with evidence of efficacy (Navada, Blood 2014).

Aims: Phase II was initiated to further study the combination in pts with MDS.

Methods: Oral rigosertib was administered twice daily on Day 1-21 of a 28-day cycle at the recommended Phase II dose (560 mg qAM and 280 mg qPM). Azacitidine 75 mg/m^2/d was administered SC or IV for 7 days starting on Day 8. A complete blood count was performed weekly and a bone marrow aspirate and/or biopsy at baseline, Day 29, and every 8 weeks thereafter.

Results: Pts with MDS previously untreated with an HMA or progressing/failing to respond to a prior HMA are presented. Oral rigosertib/azacitidine was administered to 40 pts with MDS. Demographic data are available on 37 pts, among whom 73% were male; median age was 64 years (range: 25-85); ECOG performance status was 0, 1, and 2 in 24%, 73%, and 3%, respectively. Fourteen pts (38%) had received prior HMA therapy: 10 (27%) azacitidine, 3 (8%) decitabine, and 1 (3%) both. Patients received 1-27+ months of treatment with the doublet, with a median duration of 4 months. Seven pts have been treated >1 year and 1 for >2 years. Thirty pts were evaluable for response: Phase I (N=8) or Phase II (N=22). Among these 30 pts, hematologic response per the International Working Group (IWG: Cheson, Blood 2006) criteria was seen in 23 (77%) of pts in Phase I/II: 6 (20%) with complete remission (CR), 16 (53%) marrow CR (mCR), and 1 (3%) hematologic improvement (HI). Six (20%) pts had stable disease (SD) and 1 (3%) had progressive disease (PD). Among the 27 of 30 pts with sufficient follow-up for a peripheral blood lineage response evaluation (3 were too early to evaluate), 13 (48%) had an HI: 11 erythroid, 12 platelet, 7 neutrophil. The table shows response by International Prognosis Scoring System (IPSS-R; Greenberg, Blood 2012) risk categories for the 30 evaluable MDS pts. Among the 11 evaluable pts with MDS who had failed to respond/progressed/relapsed on prior treatment with an HMA, 7 (64%) had a response after rigosertib was added: CR (1), mCR (4), mCR plus HI (2). For HMA-naïve patients (N=19); 16 (84%) responded per IWG. The most frequent adverse events (AEs) in Cycle 1 were nausea and fatigue (27% each) and pyrexia and thrombocytopenia (24% each). The most frequent AEs for ≥Cycle 2 were constipation and neutropenia (22% each). Three deaths due to adverse events have been reported.

Table 1.

	IPSS-R Risk Category			
	Low/ Intermediate	High	Very High	Unknown
Hematologic response*				
N = 30	6	9	10	5
CR	2 (33)	1 (11)	3 (30)	0
mCR	3 (50)	4 (44)	6 (60)	3 (60)
SD	1 (17)	2 (22)	1 (10)	2 (40)
PD	0	1 (11)	0	0
HI**	0	1 (11)	0	0
Hematologic improvement*				
N = 27	6	8	9	4
Erythroid response	3 (50)	3 (38)	5 (56)	0
Platelet response	3 (50)	3 (38)	6 (67)	0
Neutrophil response	0	2 (25)	5 (56)	0

*Per 2006 IWG
**HI based on peripheral blood only; no bone marrow response

Summary/Conclusions: The combination of oral rigosertib and standard-dose azacitidine was well tolerated in repetitive cycles in pts with MDS. Among the 30 evaluable MDS pts in Phase I/II, hematologic response was seen in 23 (77%), with responses seen in 64% of patients who failed HMA therapy. These results suggest potential synergistic interaction of the combination and the capability to reverse clinical HMA resistance, and supports continued study of this unique combination in pts with MDS.

P257

FREQUENT MUTATIONS IN EPIGENETIC REGULATORS IN CYTOPENIA OF UNDETERMINED SIGNIFICANCE: ASSOCIATION WITH RISK OF PROGRESSION TO MYELODYSPLASTIC SYNDROME

JW Hansen[1,*], MK Westman[2], LD Sjö[3], L Saft[4], LS Kristensen[1], AD Ørskov[1], M Treppendahl[5], MK Andersen[2], K Grønbæk[2]

[1]Department of Hematology, [2]Department of Clinical Genetics, [3]Department of Pathology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [4]Department of Pathology, Karolinska University Hospital, Solna, Stockholm, Sweden, [5]Hematology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark

Background: Peripheral blood cytopenia is a common finding in the elderly population, and an extensive diagnostic work up is often done trying to unravel its causality. Next generation sequencing may be a valuable new diagnostic tool in these patients, and clonal cytopenia of undetermined significance (CCUS) has recently been introduced to describe patients with cytopenia of unknown significance who carry a mutation characteristic of myeloid malignancies.

Aims: The purpose of the present study was to investigate the frequency of mutations in patients with persistent cytopenia and an undetermined diagnosis after routine workup.

Methods: We included 60 patients between 2008-2015, who all had persistent cytopenia for more than six months, and an undetermined diagnosis after routine workup. Median (range) age was 70 years (25-89) (Table). Diagnosis according to bone marrow morphology was reviewed in a blinded fashion by two hematopathologists. Patients with aberrant cytogenetics, except deletion of the Y-chromosome, were excluded. DNA from peripheral neutrophils or from mononuclear cells from the bone marrow were sequenced with a targeted 20 gene panel, including genes frequently mutated in myelodysplastic syndrome (MDS).

Results: Twenty-one (35%) patients had only one cytopenia, 30 (50%) had two cytopenias and nine(15%) had pancytopenia. Patients with a mutation had a lower level of neutrophils compared to non-clonal patients, otherwise the characteristics were very similar between the two groups (Table). At time of inclusion mutations in 15 of the 20 genes included in the sequencing panel was identified. Thirty-seven (62%) patients carried at least one mutation. *TET2* was the most frequently mutated gene, found in 26 (43%) patients. There was no association with the number of cytopenias and the risk of having a mutation detected at time of inclusion. Follow-up was 1-8 years and during this period six patients (10%) progressed to MDS or chronic myelomonocytic leukemia (CMML). Among these patients, five had mutations at the time of inclusion. At time of progression to MDS or CMML four had a new co-occurring mutation in *NRAS*, *TP53, GATA2* or *ASXL1*.

Table 1.

CHARACTERISTICS	TOTAL (n=60)	CCUS (n=37)	Cytopenia – non-clonal (n=23)	P-value
Sex Women Men	 22 38	 14 23	 8 15	0.81
Age, years (range)	70 (25-89)	70 (60-75)	70 (60-80)	0.89
Hemoglobin mmol/l, median (IQR)	7.0 (6.2-7.8)	6.9 (6.1-7.8)	7.3 (6.2-8.1)	0.51
Leukocytes 10^9/L, median (IQR)	4.3 (1.7-22.4)	3.9 (3.2-6.1)	5.5 (2.9-7.8)	0.32
Neutrophils, median 10^9/L (IQR)	2.3 (0.5-18.1)	1.93 (1.1-3.55)	3.3 (1.7-6.8)	0.025
Thrombocytes 10^9/L, median (IQR)	110 (30-383)	111 (78-163)	103 (88-142)	0.96
MCV, median (IQR)	92 (87-99)	93 (87-102)	89.5 (85-98)	0.34
Ferritin µg/L, median (IQR)	246 (77-420)	283 (91-542)	138 (59-340)	0.037
LDH U/l, median (IQR)	183 (161-222)	186 (161-236)	180 (164-219)	0.565
One Cytopenia, n (%)	21 (35)	12 (33)	9 (39)	0.597
Two Cytopenias, n (%)	30 (50)	19 (51)	11 (48)	0.791
Pancytopenia, n (%)	9 (15)	6 (16)	3 (13)	0.738

IQR=inter quartile range
CCUS=clonal cytopenia of undetermined significance
MCV=mean corpuscular volume
LDH=lactate dehydrogenase

Summary/Conclusions: Patients with persistent cytopenia and an undetermined diagnosis often carry mutations in genes associated with myeloid malignancies. Next generation sequencing is a promising supplement in the diagnostic workup as it may identify patients with increased risk of disease progression.

Molecular characterization of MM

P258

MOLECULAR AND CLINICAL TYPES OF PLASMA CELL DYSCRASIAS ARE ASSOCIATED WITH DISTINCT EXPRESSION PATTERNS OF LONG NONCODING RNAS

M Manzoni[1,2,*], D Ronchetti[1,2], L Agnelli[1,2], E Taiana[1,2], S Galletti[1,2], L Nobili[1,2], M Lionetti[1,2], C Vinci[1,2], K Todoerti[3], P Musto[3], F Strozzi[4], A Neri[1,2]
[1]Department of Oncology and Hemato-Oncology, University of Milano, [2]Hematology Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, [3]Laboratory of Pre-Clinical and Translational Research, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture, Potenza, [4]Bioinformatics Core Facility, Parco Tecnologico Padano, Lodi, Italy

Background: Multiple myeloma (MM) is a malignant proliferation of antibody-secreting bone marrow plasma cells (PCs) characterized by a wide clinical spectrum ranging from the presumed pre-malignant condition called monoclonal gammopathy of undetermined significance (MGUS), to smoldering MM (SMM), truly overt and symptomatic MM, and extra-medullary myeloma/plasma cell leukemia (PCL). Although many efforts have recently contributed to improve our knowledge of molecular pathogenesis of MM, the role and significance of long non-coding RNAs (lncRNAs) in PC malignancies remains virtually absent.
Aims: We investigated the lncRNA expression profiles in a large and representative cohort of PC dyscrasia, with the aim of identifying deregulated lncRNAs putatively associated with MM pathogenesis and possibly linked to the multi-step process underlining the different stages of the disease.
Methods: We developed a custom annotation pipeline on Gene 1.0 ST microarray data, to investigate lncRNA expression in highly purified bone marrow PCs from 20 MGUS, 33 SMM, 170 MM, 36 PCL and 9 healthy donors, collected from proprietary and publicly available datasets.
Results: Our study identified 31 lncRNAs deregulated in pathological samples compared to the healthy condition. In particular, the upregulation of MALAT1 in symptomatic patients was associated with molecular pathways involving cell cycle regulation, p53-mediated DNA damage response, and mRNA maturation processes. Furthermore, we found 21 lncRNAs whose expression was progressively deregulated trough the more aggressive stages of PC dyscrasia, suggesting a possible role in the progression of the disease. In the context of molecular heterogeneity of MM, we identified a transcriptional fingerprint in hyperdiploid (HD) patients, characterized by the upregulation of lncRNAs/pseudogenes related to ribosomal protein genes. These findings are in line with the global up-regulation of the translational machinery, including genes involved in protein biosynthesis, characterizing HD group. To gain evidences of lncRNAs that may potentially act on gene expression, we evaluated the correlation of each of the differentially expressed lncRNAs with all the transcripts unambiguously detectable by the arrays. By focusing on high correlation coefficient, we identified five lncRNAs suggestive of an *in cis* rather than an *in trans* interaction. Finally, based on several evidences that have suggested the interplay of the various non-coding species, we investigated the liaison between lncRNAs and miRNAs in 125 samples out of our series for which miRNA expression profiling was available. We identified 290 lncRNA-miRNA couples significantly anti-correlated in our database. Hence, to add confidence to the anti-correlation connection, we inspected which of the 290 lncRNAs anti-correlated to miRNAs could also be miRNAs targets. Based on RNA22 prediction algorithm, we identified nine lncRNA-miRNA couples with transcripts resulting anti-correlated and for which lncRNA is a predicted miRNA target. Particularly interesting is lnc-MAP1LC3B2-2, found upregulated in MM with MAF translocation and anti-correlated with miR-222 and miR-221.
Summary/Conclusions: Our study reported many lncRNAs deregulated in different forms of PC dyscrasia, providing an important source for future functional studies on lncRNAs in MM disease.

Background: Deletions of chromosomal region 1p22 are found in ~20% of multiple myeloma patients and have been identified as a negative prognostic

factor for progression-free survival (PFS) and overall survival (OS) in newly diagnosed patients (Hebraud *et al.*, Leukemia, 2013). These findings suggest the presence of an unidentified tumor suppressor gene on 1p22.
Aims: We aimed to delineate a minimal deleted region (MDR) on 1p22 to identify potential tumor suppressor genes in this region. Additionally, we were interested in the clinical relevance of lowered expression of genes in the MDR on 1p22.
Methods: We investigated 1p22 deletions using high resolution copy number arrays in a cohort of 35 multiple myeloma patients. The expression of the genes in the MDR and their correlation with clinical outcome was further investigated in data of the MMRC, the phase III HOVON-65/ GMMG-HD4 trial and the APEX trial. *In vitro* experiments in mouse B-cells were done to investigate the correlation between expression levels of one of the genes (*RPL5*) in the MDR with sensitivity to proteasome inhibitors.
Results: Using high resolution genomic profiling, we delimit a 58 kb minimal deleted region on 1p22.1 encompassing two genes: ectopic viral integration site 5 (*EVI5*) and ribosomal protein L5 (*RPL5*). Although mutations in 1p22 genes are rare in multiple myeloma, a tumor suppressor role for *EVI5* and *RPL5* may also be supported by the fact that these genes show the highest frequency of mutations predicted to impair protein function on 1p22. Interestingly, inactivation of *RPL5* was also recently described in T-cell acute lymphoblastic leukemia (T-ALL) and glioblastoma. We also found that 1p22 deleted patients have significantly lower levels of *EVI5* and *RPL5* mRNA expression. Whereas 1p22 deletion status correlates well with *EVI5* expression in all patients, it is a bad predictor of *RPL5* expression level in some, suggesting that other mechanisms besides 1p22 deletion can downregulate *RPL5* expression in multiple myeloma. In agreement with what is known for deletion of 1p22, we saw that low mRNA expression of *EVI5* and *RPL5* is associated with worse PFS and OS in diagnostic patients. Interestingly, reduction of *RPL5* expression in B-cells caused 2-fold sensitization to the proteasome inhibitors bortezomib and carfilzomib. In addition, *RPL5* but not *EVI5* mRNA expression levels were significantly lower in multiple myeloma patients showing clinical response to bortezomib compared to patients that are not responding. Furthermore, PFS of newly diagnosed patients with low *RPL5* expression was significantly longer when they were treated on a bortezomib containing protocol (median PFS bortezomib protocol 29.8 months *versus* 18.7 months for non-bortezomib, p=0.03, data phase III HOVON-65/ GMMG-HD4 trial). In contrast, PFS of *RPL5* high patients was not influenced by bortezomib. These associations between *RPL5* expression level and bortezomib response were confirmed when performing the same analyses on the PFS data from relapse patients in the APEX trial. For low *EVI5* expressing patients, there was a non-significant trend towards benefit from bortezomib which was not present in the *EVI5* high cases.
Summary/Conclusions: We provide genetic data that point towards a tumor suppressor role for *EVI5* and *RPL5* on 1p22. Although the exact role of these genes in promoting MM progression remains to be determined, we identify *RPL5* mRNA expression as a relevant biomarker for initial response to bortezomib and subsequent survival benefit after long-term treatment.

Background: A deletion of chromosome 17p (del17p) is detected in 10% of multiple myeloma (MM) patients at diagnosis and is associated with a dismal prognosis, classifying it as high-risk disease. Moreover, its prevalence is known to increase during disease progression. Even though this suggests that it may be a driver of disease, little is known about the genetic defects that are involved in its pathology. Del17p in MM usually involves a hemizygous loss of a commonly deleted region (CDR) on 17p13.1, in which several potential tumor suppressor genes reside that could be bi-allelically inactivated by the deletion itself and a concomitant mutation. Of these, *TP53* is the most studied gene in del17p MM, but previous targeted sequencing efforts failed to identify a high prevalence of mutations herein. We therefore hypothesized that relevant genetic lesions might have been missed in either *TP53* itself, in other genes in the CDR on chromosome 17p (Chr17p), or in disease-relevant pathways, that could explain the aggressive clinical behavior of this type of MM.
Aims: With this study, we sought to systematically analyze the genomes of del17p MM tumors, in order to identify recurrent genetic aberrations and to assess their prognostic significance within this disease subgroup.
Methods: DNA was isolated from peripheral blood and CD138+ enriched bone marrow mononuclear cells from chemotherapy-naive MM patients with a del17p in ≥50% of plasma cells, as detected with fluorescent *in situ* hybridization (FISH). Libraries were generated using a custom capture (SeqCap EZ Exome Plus, Nimblegen) of 111 Mb, comprising the whole exome, Chr17p and the *IgH*, *Igk*, *IgL* and *MYC* regions. Paired-end sequencing was performed on a HiSeq2500 platform, followed by data analysis using an in-house bioinformatics pipeline at Erasmus MC, including SNPExpress, MutSigCV and GISTIC2. Single nucleotide variants in *TP53*, *FAM46C*, *KRAS*, *NRAS*, *DIS3* and *BRAF* were validated using a custom amplicon panel (TruSeq Custom Amplicon Assay v1.5, Illumina), followed by deep sequencing on a MiSeq System.
Results: We captured and sequenced tumor and germline DNA from 44 patients, which resulted in an average coverage of 90x and overall coverage of 94%. Clinical data were available from 40/44 patients, with a median follow-up time of 18 months. We identified a CDR on Chr17p of 235 kb, in which one or more somatic, nonsynonymous aberrations in *TP53* were detected in 25/44 (57%) patients (adj. $p<1x10^{-10}$; n=17 missense, n=9 nonsense, n=2 splicing). All other genes in the CDR on Chr17p lacked any nonsynonymous mutations. Besides *TP53*, we found *FAM46C* and *KRAS* to be significantly mutated. *RB1*, *TRAF3* and *FAM46C* were significantly deleted in our patient cohort. *TP53* mutated patients had a worse overall survival (OS) than *TP53* wildtype patients (p=0.008). Patients with *TP53* missense mutations showed the worst OS ($p<1x10^{-3}$), as well as progression-free survival (PFS) (p=0.015).
Summary/Conclusions: (1) *TP53* is somatically mutated in the majority of del17p MM patients; others lack any nonsynonymous somatic event in the CDR on Chr17p. (2) Particularly *TP53* missense mutations have a significantly negative impact on both OS and PFS in del17p MM patients. (3) The rest of the genomic landscape of del17p MM is characterized by significant mutations in *FAM46C* and *KRAS*, as well as deletions of *RB1*, *TRAF3* and *FAM46C*.

DEPENDENCE ON GLUTAMINE UPTAKE OF MYELOMA CELLS DELINEATES A NEW ATTRACTIVE THERAPEUTIC STRATEGY

M Bolzoni[1,*], M Chiu[2], F Accardi[1], P Storti[1], I Airoldi[3], K Todoerti[4], L Agnelli[5], G Missale[6], R Andreoli[1], MG Bianchi[2], M Allegri[2], A Barilli[2], D Toscani[1], F Costa[1], V Marchica[1], F Aversa[1], O Bussolati[2], N Giuliani[1]
[1]Clinical and Experimental Medicine, [2]Biomedical, Biotechnological and Translational Sciences, University of Parma, Parma, [3]"Laboratorio di Oncologia", "Istituto Giannina Gaslini", Genoa, [4]Lab. of Pre-clinical and Translational Research, IRCCS, Referral Cancer Center of Basilicata, Rionero in Vulture, [5]Oncology and Hemato-oncology, University of Milan, Milan, [6]Infectious Disease Unit and Hepatology Unit, "Azienda Ospedaliero-Universitaria di Parma", Parma, Italy

Background: The importance of glutamine (Gln) metabolism in multiple myeloma (MM) cells and its potential role as a therapeutic target are still under investigation, although it has been reported several years ago that human myeloma cell lines (HMCL)s are highly sensitive to Gln depletion. Moreover, MM cells produce an excess of ammonium (NH_4^+) in the presence of Gln and hyperammonemia is a possible rare clinical manifestation in relapsed/refractory MM patients.
Aims: The aim of this study was to investigate the relationship between NH_4^+ production and Gln-dependence in MM cells, as well as the mechanisms involved therein, actually unknown, in order to identify a new potential target in MM patients.
Methods: A total cohort of 64 patients with Plasma cell (PC) disorders were included in the study: 6 patients with monoclonal gammopathy of undetermined significance (MGUS), 12 with smoldering myeloma (SMM), and 46 with active MM including 28 newly diagnosed MM (ND-MM) and 18 relapsed MM (R-MM). NH_4^+ levels in bone marrow (BM) plasma and produced by HMCLs (JJN3, OPM2, RPMI 8226, XG1, KMS-12-BM) and primary $CD138^+$ cells purified from BM aspirates in the presence or in the absence of Gln were assessed by the Roche Cobas NH3 Ammonia assay. BM plasma content of amino acids was determined by HPLC. The expression of the main enzymes involved in Gln metabolism (Glutaminase (GLS); Glutamine Synthetase (GS) and Asparaginase) and Gln transporters were evaluated. The effect on MM cell viability of *E. chrysanthemi* L-Asparaginase (ASNase), with glutaminolytic activity, was tested alone or in combination with Bortezomib (0-10 nM). The intracellular levels of Gln, Glutamate (Glu), and 2-oxoglutarate (2-OG) were measured with mass spectrometry. Furthermore, gene expression profiles of glutamine transporters were evaluated in two PC dyscrasia datasets, generated using 3 proprietary (GSE13591, GSE6205 and GSE66293) and 3 publicly available (GSE6477, GSE6691 and GSE47552) datasets. Anti-SLC1A5 shRNA lentiviral vector was used for ASCT2 stable knockdown in HMCLs, whereas the scramble lentiviral vector was used as control. For the *in vivo* experiment 8 SCID-NOD mice for group were injected subcutaneously with JJN3 stably transfected with anti-SLC1A5 containing plasmid vectors or with JJN3 stably transfected with the empty vector and then tumor growth was monitored.
Results: We found that both HMCLs and primary BM $CD138^+$ cells produced large amounts of NH_4^+ in the presence of Gln. Active MM patients have higher BM plasma NH_4^+ and Glu and lower Gln levels in comparison with patients with indolent monoclonal gammopathies. Interestingly, HMCLs expressed GLS and were sensitive to its inhibition with BPTES and CB-839, while exhibited negligible

expression of GS. High GLS and low GS expression were also observed in primary CD138+ cells. Gln-free incubation or treatment with the glutaminolytic enzyme ASNase depleted the cell contents of Gln, Glu and the anaplerotic substrate 2-OG, inhibiting MM cell growth. Moreover, ASNase effect on HMCL viability was potentiated in the presence of Bortezomib. In line with the dependence of MM cells on extracellular Gln, the gene expression profile analysis showed an increased expression of the Gln transporters SNAT1, ASCT2, and LAT1 by CD138+ cells across the progression of monoclonal gammopathies. Interestingly, among these transporters, only ASCT2 inhibition in HMCLs caused a marked decrease in Gln uptake. Consistently, ASCT2 stable down-regulation inhibited HMCL growth both *in vitro*. Finally, in the *in vivo* mouse model we found that mice inoculated with the ASCT2-silenced cells developed significantly smaller plasmacytomas than animals injected with the scramble-transfected cells.
Summary/Conclusions: In conclusion, MM cells strictly depend upon extracellular Gln and show features of Gln-addiction. Therefore, the inhibition of Gln uptake is a new attractive therapeutic strategy for MM.

LOSS OF PRIMING OR MCL-1 DEPENDENCY CONFERRED ACQUIRED RESISTANCE TO VENETOCLAX IN MULTIPLE MYELOMA
M Amiot[1,*], C Dousset[1], S Maiga[1], P Gomez-Bougie[1], J Le Coq[1], C Touzeau[2], P Moreau[2], S Le Gouill[2], C Pellat-Deceunynck[1], A Moreau-Aubry[1]
[1]Inserm U892 CNRS 6299, Centre de recherche en cancérologie Nantes/Angers, [2]CHU Nantes, Nantes, France

Background: Venetoclax/ABT-199 is the first in class Bcl-2 specific BH3 mimetic and among the most promising targeted therapy in oncology. Venetoclax has already demonstrated its efficacy in chronic lymphoid leukemia and is currently under investigation in multiple myeloma. Multiple myeloma is heterogeneous and includes patients with translocation of the IgH locus on chromosome 14 with different chromosomes (4, 6, 11 or 16) and patients with a hyperdiploidy involving odd chromosomes. Venetoclax induces apoptotic cell death in a subgroup of myeloma patients that carried the t(11;14) translocation and expressed a high Bcl-2/Mcl-1 gene expression ratio. In contrast, resistance to venetoclax is mediated by a high Mcl-1 expression in other myeloma subgroups.
Aims: The expected use of venetoclax alone or in combination with other agents in the treatment of myeloma leads us to explore the mechanisms of acquired venetoclax resistance. We investigated whether the acquired resistance to venetoclax might be different from the intrinsic resistance.
Methods: We derived resistant sublines from initially KMS12-PE and XG5 t(11;14) myeloma venetoclax highly sensitive cell lines (LD50 15 and 5nM respectively). Cell lines were cultured during several months with increasing venetoclax concentrations until cells were able to maintain viability with 2mM venetoclax. Patterns of Bcl-2 family gene and protein expression were compared between parental and resistant sublines by quantitative PCR and western blotting analysis. BH3 profiling approach by flow cytometry was used to analyze the mitochondrial priming of parental and subline.and their dependence on individual anti-apoptotic family member. Bax exon sequencing was performed to analyze potential mutations.
Results: We first provided evidence that venetoclax resistant sublines (XG5-199R and KMS12PE-199R) displayed cross-resistance to bortezomib. We then demonstrated that both resistant sublines exhibited a strong increase in both Mcl-1 mRNA and protein levels. Beside Mcl-1, the other Bcl-2 anti-apoptotic proteins were not significantly modified. Strikingly, a total lack of both Bax and Bak effector proteins characterized the XG5-199R subline. According to its strong sensitivity to venetoclax, XG5 cells exhibited a primed Bcl-2 profile. In contrast, we found that XG5-199R cells were unprimed. The XG5-199R unprimed status could be explained by the absence of Bax and Bak effector proteins. Finally, by sequencing *BAX* gene, we identified a mutation at position Q52 leading to a stop codon, which resulted in a very short Bax truncated protein missing all the BH domains. KMS12PE-199R was characterized by a decline in several pro-apoptotic proteins (*i.e.*, Bak, Bim, Bik and Puma). Like XG5, KMS12-PE had a primed Bcl-2 profile. Of interest, a switch in the dependence on Bcl-2 in KMS12PE cells towards Mcl-1 was demonstrated in KMS12PE-199R cells. Finally, we found that KMS12PE-199 acquired resistance could be overcome by A1210477, a recently discovered potent Mcl-1 inhibitor.
Summary/Conclusions: The XG5199R and KMS12PE199R acquired models of venetoclax resistance in myeloma reflect two main ways to escape to apoptosis, either by a reduction of BH3 only proteins or by a loss of effector multidomain proteins both being accompanied by an increase of Mcl-1 level of expression. Both models of acquired resistance affect the mitochondrial priming and/or the dependency on individual anti-apoptotic protein of the cells.

LOSS OF THE INHIBITORY RECEPTOR CD85J/LILRB1 ON MALIGNANT PLASMA CELLS: FROM MGUS TO SYMPTOMATIC MULTIPLE MYELOMA
E Lozano[1,*], T Diaz[1], MP Mena[1], X Calvo[1], M Calderon[1], B Martin-Antonio[1,2], MT Cibeira[1], L Rosinol[1], J Bladé[1,2], C Fernandez de Larrea[1,2]
[1]Hematology Department, Hospital Clínic-IDIBAPS, [2]Josep Carreras Leukaemia Research Institute, University of Barcelona, Barcelona, Spain

Background: Immune regulation may control proliferation of aberrant plasma cells (PCs) in the asymptomatic monoclonal gammopathy of undetermined significance (MGUS). Loss of inhibitory pathways could lead to progression from MGUS to active multiple myeloma (MM). CD85j (LILRB1) molecule is an inhibitory immunoreceptor containing four immunoreceptor tyrosine-based inhibitor motifs (ITIM). Binding of HLA-G to CD85j suppresses B cell responses. The role of CD85j in MM pathogenesis remains to be elucidated.
Aims: The aim of this study was to investigate CD85j contribution to immune regulation in monoclonal gammopathies and its role in progression from MGUS to MM.
Methods: CD138+ PCs from bone marrow (BM) aspirates from individuals with MGUS (n=20) and patients with active MM (n=20) were isolated with immunomagnetic beads. Both fractions CD138+ and CD138^{neg} were analyzed by real-time PCR. CD85j expression and cell proliferation assays were assessed by multi-parameter 8-color flow cytometry. Effects of ligation of CD85j with specific anti-CD85j monoclonal antibodies were analyzed on myeloma cell lines and *ex vivo* BM functional assays.
Results: Gene expression of CD85j (*lilrb1*) and its ligand S100A9 was significantly downregulated in BMPCs from patients with MM compared to PCs from individuals with MGUS. Consistently, flow analysis showed that the inhibitory molecule CD85j was mainly expressed on the BMPCs and B cells in MGUS. In contrast, patients with MM showed significantly lower levels of CD85j compared to those with MGUS. On the other hand, the expression of this inhibitory checkpoint was recovered in patients in complete remission but not in progression (Fig.1). In asymptomatic MGUS, flow cytometry analysis identified PCs at distinct stages of the malignant transformation: (i) normal PCs were CD85j^{high}, (ii) PCs positive for CD85j and with abnormal expression of CD56 or CD117 and, finally, (iii) PCs expressing CD56 or CD117 that lost CD85j expression like malignant PCs observed in MM. In MGUS, CD85j expression was significantly decreased when the proportion of aberrant PC was higher than 40%, suggesting that loss of CD85j may be an early event promoting tumor immune escape. Furthermore, our functional assays showed that ligation with anti-CD85j antibody decreased the number of normal *ex vivo* BMPCs from patients with MGUS. In contrast, malignant PCs from patients with MM and MM cell lines were resistant to treatment with anti-CD85j. Finally, we wanted to investigate whether other inhibitory members of the LILRB family were also downregulated in MM. Consistent with our results on CD85j expression, *lilrb2* (CD85d) and *lilrb3* (CD85a) were significantly decreased in PCs from patients with MM compared to PCs from individuals with MGUS.

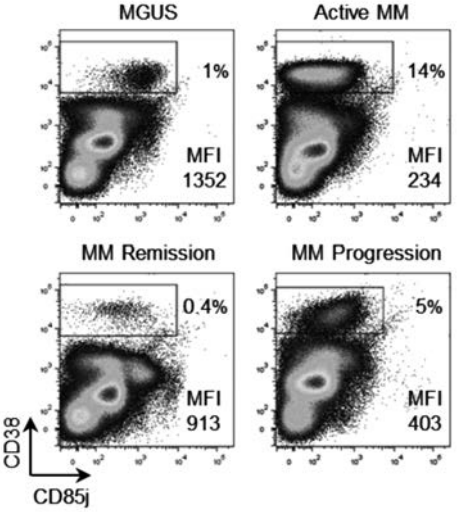

Figure 1. Flow cytometry analysis of bone marrow samples. Frequency of plasma cells and CD85j MFI are shown.

Summary/Conclusions: Similar to loss of tumor suppressor function, loss of inhibitory immune checkpoints such as CD85j may provide a selective advantage for malignant cell clones promoting immune escape and tumor survival. In this emerging era of cancer immunotherapies, it is crucial to better understand relevant immune checkpoint signaling playing a role in tumor progression. Further investigation is needed to discover whether downregulation of inhibitory receptors on malignant PC may provide a novel mechanism of immune escape associated with myeloma progression.

PROTEIN KINASE CK1A INACTIVATION IN MULTIPLE MYELOMA EMPOWERS LENALIDOMIDE INDUCED CYTOTOXICITY AND CELL CYCLE ARREST
S Manni[1,2,*], M Carrino[1,2], S Canovas Nunes[1,2], K Gianesin[1,2], P Macaccaro[1,2], L Quotti Tubi[1,2], A Cabrelle[2], G Semenzato[1,2], F Piazza[1,2]

[1]Department of Medicine, Hematology and Clinical Immunology Branch, University of Padova, [2]Venetian Institute of Molecular Medicine, Padova, Italy

Background: Multiple myeloma (MM) is a malignant plasma cell neoplasm, accounting for about 10% of all blood tumors. Despite the introduction of proteasome inhibitors and immunomodulatory drugs (such as lenalidomide) in the therapy of MM, it remains still incurable. Recently, it was shown in myelodysplastic syndromes that lenalidomide determines the degradation of Protein Kinase CK1α. CK1α is a serine/threonine kinase essential for the function of signaling pathways that could be involved in MM pathobiology: the canonical Wnt/β-catenin cascade, the Hedgehog and the NF-κB pathways and the p53-driven response (here by stimulating the binding to Mdm2 and p53 inhibition). Recent evidence indicates that protein kinase CK1α may play a key role in myeloma cell growth and its inactivation determines MM cell death.
Aims: In this study we have investigated CK1α expression, cellular localization and its contribution to MM survival. We investigated the therapeutic potential of the combination of lenalidomide and CK1α inactivation analyzing whether lenalidomide could cause CK1α degradation and whether CK1α could take part in lenalidomide-induced MM cell apoptosis and cell cycle arrest. We next studied whether blocking CK1α αcould influence pro-survival signalling pathways, accounting for resistance to lenalidomide.
Methods: CK1α expression and activity were evaluated in MM cells and controls; the consequences of CK1α inhibition, with a small ATP-competitive compound (D4476) or by RNA interference in association with lenalidomide, on MM cell survival and proliferation were investigated with Annexin V/PI and Ki-67/PI staining and FACS analysis or PARP and caspase cleavage, p21 and Mdm2 protein expression level detection. CK1a-dependent signalling events were analyzed by WB.
Results: We found that CK1α is overexpressed in a fraction of MM patient and cell lines. CK1α inactivation caused MM apoptosis and cell cycle arrest. Treatment of cells with lenalidomide not only caused MM death and cell cycle impairment, but strikingly determined a time-and dose-dependent reduction of CK1α expression and activation (monitored with a reduction of its target Ser 45 β-catenin). A therapeutic potential of the combination of lenalidomide and CK1α inactivation was established. Remarkably, the association of lenalidomide and D4476 increased MM cell apoptosis and reduced the S-G2/M and G1 phases of the cell cycle, suggesting a cooperative effect of the two compounds. Ki-67 staining showed a clear reduction of active proliferating cells in the combination therapy. Activation of apoptosis and derangement of the cell cycle were also confirmed by the raise of p21 with concomitant decline of Mdm2 protein levels (indicating an activation of p53 axis) in the combination treatment compared to the single treatments. Most importantly these results were confirmed by RNA interference using siRNAs targeting the α isoform of CK1.
Summary/Conclusions: Our findings suggest that the combination of lenalidomide and CK1α inactivation could be a promising therapeutic approach for MM therapy. The identification of the exact mechanism of action and of the pathways targeted by CK1α/lenalidomide in MM plasma cells is the subject of future research.

QUANTIFICATION OF CYCLIN D1, CYCLIN D2, IKAROS, AIOLOS AND CEREBLON PROTEINS BY CAPILARY IMMUNOASSAY IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA AND ANALYSIS OF THEIR IMPACT ON PATIENT SURVIVAL

I Misiewicz-Krzeminska[1,2,*], E Rojas[1,2], L Corchete[1,2], V Gutierrez[3], T Prieto[3], I Isidro[3], J Martinez-Lopez[4], R Garcia-Sanz[2,3], A Oriol[5], J Bladé[6], JJ Lahuerta[4], J San Miguel[7], MV Mateos[2,3], NC Gutierrez[2,3]
[1]Centro de Investigacion del Cancer, [2]IBSAL, [3]Hospital Universitario de Salamanca, Salamanca, [4]Hospital 12 de Octubre, Madrid, [5]Hospital Universitari Germans Trias i Pujol, [6]Hospital Clinic, IDIBAPS, Barcelona, [7]Clínica Universidad de Navarra, Pamplona, Spain

Background: Multiple myeloma has been comprehensively analyzed using high-throughput genomic technologies. Although a large number of biomarkers have been described, most of them were not subsequently validated at the protein level. In fact, the unresolved difficulties in studying the proteome have made the quantification of messenger RNA (mRNA) an indirect measure of protein expression. However, many studies have shown that levels of mRNA cannot be used as surrogates for protein levels. The amount of myeloma cells obtained after purification of patient samples is usually very limited, which precludes the posibility of quantify protein levels using standard Western Blot analysis.
Aims: To quantify the steady state levels of cyclin D1, cyclin D2, ikaros, aiolos and cereblon proteins, and correlate them with the corresponding gene expression (mRNA). To analyze the impact of the protein expression compared to gene expression on MM prognosis.
Methods: Bone marrow aspirates from 64 newly diagnosed MM patients treated with lenalidomide- and bortezomib-containing regimens were included in the study. Myeloma cells were purified by anti-CD138 magnetic microbeads using the AutoMACs separation system (purity was above 90%) and next, were stored in RLT+ buffer at -80^{0}C. We developed and optimized a protocol for extraction of DNA, RNA and proteins from the same single sample. Total protein quantification and particular proteins expression analysis were performed using the capillary electrophoresis with immunoassay methodology (patented by the ProteinSimple company as WES system). mRNA expression was quantified using Taqman assays by q-RT-PCR.
Results: After the analysis of total protein content, 61 MM samples fulfilled the quantity and quality requirements. Cyclin D1 protein levels were strongly correlated with mRNA levels (R^2 *0.804, p<0.01)*. The highest cyclin D1 protein expression was found in MM samples with t(11;14), whereas intermediate cyclin D1 levels were observed in those patients with polysomy 11. Lower correlations between protein and mRNA levels were observed for cyclin D2/*CCND2* (R^2 *0.409, p<0.01),* aiolos/*IKZF3* ($R^2$0.383, p<0.01) and ikaros/*IKZF1* (R^2 *0.337, p<0.01).* On the contrary, no significant correlation was seen for cereblon protein levels and the corresponding *CRBN* expression. Higher protein levels of cereblon and ikaros were significantly associated with longer progression free survival (PFS) and overall survival (OS). Interestingly, no impact on prognosis was observed when survival analysis was carried out using the mRNA levels of *CRBN, IKZF1* and *IKZF3.*

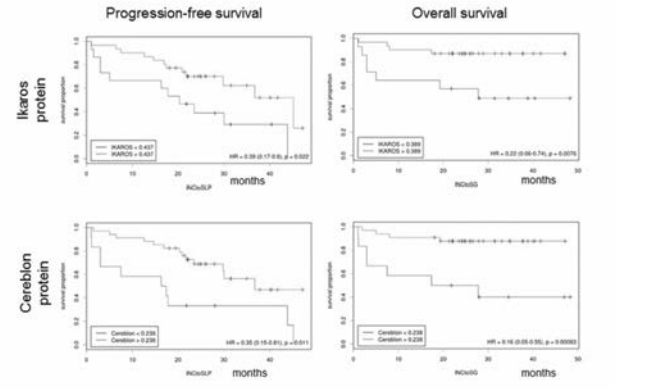

Figure 1.

Summary/Conclusions: The capillary electrophoresis with immunoassay methodology allowed us to analyze the steady state expression of mRNA and protein obtained from the same one MM sample. The preliminary results showed that protein measurement of cereblon and ikaros discriminate prognosis of patients with MM better than mRNA levels. The Capilary Immunoassay offers the novel opportunity to automatically analyze, for the first time, the expression of proteins encoded by key genes in the development of MM, with high levels of sensitivity and reproducibly.
Acknowledgement: This work is funded by a grant from the International Myeloma Foundation's Black Swan Research Initiative®. WES platform was acquired thanks to INNOCAMPUS Program (CEI10-1-0010).

DEFERASIROX INDUCES APOPTOSIS THROUGH INHIBITION OF ONCOGENIC PYK2/BETA-CATENIN SIGNALING IN MULTIPLE MYELOMA CELLS

K Takada*, Y Kamihara, T Sato, Y Kawano, K Murase, Y Arihara, S Kikuchi, N Hayasaka, M Usami, S Iyama, K Miyanishi, M Kobune, J Kato
Medical Oncology and Hematology, Sapporo Medical University School of Medicine, Sapporo, Japan

Background: Iron is an element essential for many indispensable cellular functions, including proliferation and DNA synthesis. Accumulating evidence suggests that abnormal iron metabolism plays an important role in carcinogenesis and in the progression of many cancers. In cancer cells, the demand for iron increases in response to sustained, accelerated cell proliferation and DNA synthesis. Multiple myeloma (MM) is characterized by clonal proliferation of long-lived plasma cells within the bone marrow. Despite recent advances in its treatment, MM remains an incurable disease, underlining the need to continue exploring its molecular characteristics. Recently, two independent groups reported that serum ferritin, which is used as a marker for iron overload, can be a negative prognostic indicator in MM. However, the underlying mechanisms of this effect have not been clarified, and the significance of iron metabolism in MM cells remains unclear.
Aims: Our study was aimed to investigate iron metabolisms and iron chelation therapy with deferasirox (DFX) in MM cells.
Methods: We analyzed the prognostic relevance of iron metabolism-related genes by integrating a data set in the public domain (MAQC-II Project MM data set). We also evaluated mRNA expression of iron metabolism-related genes in MM cell lines and primary cells. Intracellular iron concentrations were measured with fluorescent probes FeRhoNox-1. The effect of DFX, an orally active, long-acting iron chelator approved for iron overload, on MM cell lines was examined using a WST-1 cell proliferation assay. To elucidate the cytotoxic mechanism of DFX, immunoblotting and flow cytometry analysis were performed. To clarify

the mechanisms of DFX-induced apoptosis in MM, we analyzed the phosphoinositide 3-kinase (PI3K)/Akt signaling pathway using PCR arrays. Subsequently, Pyk2 downstream target molecules were analyzed with immunoblotting and qPCR. To test the therapeutic potential of DFX, we evaluated its ability to suppress tumor growth *in vivo* using the subcutaneous RPMI8226 murine xenograft model of human MM.
Results: Overall survival was significantly longer MM patients with high ferroportin levels, a cellular iron exporter. qRT-PCR studies showed lower *ferroprtin* expression in both cell lines and primary cells compared to control cells. Increased intracellular iron concentrations were noted in MM cells. DFX induced apoptosis in MM cells and overcame the survival advantage conferred by the bone marrow microenvironment. The FAK transcript was substantially suppressed following DFX treatment in PCR array. However, no expression of FAK protein in three of four MM cell lines was observed. Next, we investigated Pyk2, which is a member of the FAK family and has a 48% amino acid sequence identify with FAK. We assessed Pyk2 activation after treatment with DFX. DFX significantly reduced phosphorylation of Pyk2(Tyr402), resulting in inactivation of Pyk2 activity. beta-catenin protein levels were decreased by DFX treatment, accompanied by decreased levels of phosphorylated-GSK-3beta (inactive form). Treatment with DFX reduced the mRNA levels of *Axin2* and *c-Myc*, which are Wnt target genes; in particular, *Axin2* is a robust and specific Wnt target gene. We detected an increase in apoptotic tumor cells in animals treated with DFX compared to vehicle-treated mice, as evaluated by Cleaved PARP staining and immunoblotting.
Summary/Conclusions: This study has demonstrated that low expression of *ferroportin* is associated with a poor prognosis in MM, and had been revealed that increased intracellular iron contributes to MM pathogenesis. Our results suggest the potential clinical application of DFX for iron overloaded and/or Pyk2/beta-catenin driven MM treatment.

DEVELOPMENT AND IMPLEMENTATION OF A HIGH-THROUGHPUT SEQUENCING BASED, CLINICALLY-FOCUSED, COMPREHENSIVE GENOMIC CHARACTERISATION OF MYELOMA WITHIN A MOLECULAR DIAGNOSTIC SERVICE

P Blombery[1,*], K Jones[1], J Markham[1], G Mir Arnau[1], M McBean[1], A Papenfuss[1,2], D Westerman[1,3], M Prince[1,3], M Dickinson[1,3]
[1]Peter MacCallum Cancer Centre, [2]The Walter and Eliza Hall Institute of Medical Research, [3]University of Melbourne, Melbourne, Australia

Background: In the genomic context, treatment decisions in patients with myeloma are currently influenced by (i) the presence of copy number changes (*e.g.* TP53) and balanced chromosomal translocations (*e.g.* t(4;14)) (ii) response to therapy as assessed by minimal residual disease (MRD) testing (*e.g.* with IGVH MRD) and (iii) the presence of potentially targetable mutations (*e.g.* BRAF V600E). In addition, there are numerous novel genomic factors that may influence treatment including gene expression based prognostic scores, gene expression signatures indicating sensitivity to novel therapeutics and response to therapy as measured by circulating tumour DNA (ctDNA) monitoring.
Aims: We aimed to develop, validate and implement a suite of molecular tools and workflow in a molecular diagnostic laboratory setting to enable comprehensive molecular characterisation of multiple myeloma biosamples, prioritising genetic lesions that now or may in the future influence patient management. Moreover, we aimed to utilise this molecular workflow to establish a local compendium of genomic data on cases of myeloma.
Methods: DNA and RNA is extracted from CD138+ MACS selected plasma cells from patients undergoing bone marrow biopsies for either newly diagnosed or relapsed myeloma at Peter MacCallum Cancer Centre (Melbourne, Australia). Amplicon library preparation is performed using a Fluidigm Access Array IFC. Whole transcriptome RNA-seq RNA libraries are prepared using Illumina TruSeq RNA. Low-coverage Whole Genome Sequencing (LC-WGS) is performed using DNA libraries prepared by Kapa Hyper Library Prep (Kapa Biosystems). Sequencing is performed on an Illumina NextSeq (RNA-seq and LC-WGS) and an Illumina MiSeq (amplicon panel).
Results: Targeted amplicon sequencing is performed using an in-house designed panel which includes the most frequently mutated genes in myeloma (BRAF, NRAS, KRAS and TP53). This provides relatively rapid feedback to clinical teams on the presence of genetic lesions which may direct management. Assessment of myeloma samples is aligned with other next-generation sequencing amplicon assays within the laboratory in order to minimise turnaround times and achieve efficiencies in laboratory workflow. Whole transcriptome RNA-seq is performed and used for (i) variant calling to correlate with the mutations identified from the targeted-amplicon panel and also as a discovery platform for novel mutations (ii) assessment against established gene expression profile classifiers for cytogenetic lesions and prognosis (*e.g.* GEP70) and (iii) assessment of expression of therapeutic targets (*e.g.* CD38, SLAMF7, CRBN). LC-WGS is then used to detect copy number changes. During the validation phase, findings from RNA-seq and LC-WGS were validated using orthogonal methods including conventional metaphase cytogenetics and FISH. Novel bioinformatics and clinical informatics tools including a copy number calling pipeline, RNA-seq variant calling and differential expression pipeline, copy number browser and an IGVH analysis interface have been developed to analyse and report samples. Approximately 50 samples have been processed with this workflow to date with the results used to inform patient management.
Summary/Conclusions: We have successfully developed and implemented a suite of molecular testing for multiple myeloma within a molecular diagnostic laboratory to detect key genomic lesions which affect patient management as well as establishing a local discovery-level data set to answer future research questions.

P268

DYNAMIC EVOLUTION OF COPY NUMBER ABERRATIONS ACCOMPANIES DISEASE RELAPSE IN MULTIPLE MYELOMA

D Begum[1], S Ellis[1], C Smith[1], A Price[1], A Sherborne[1], P Proszek[1], D Johnson[1], B Walker[2], J Jones[1], C Pawlyn[1], M Jenner[3], M Drayson[4], R Owen[5], R Houlston[1], D Cairns[6], W Gregory[7], G Cook[8], F Davies[2], G Morgan[2], G Jackson[9], M Kaiser[1,*]
[1]The Institute of Cancer Research, London, United Kingdom, [2]University of Arkansas Medical School, Little Rock, United States, [3]University Hospital Southampton, Southampton, [4]University of Birmingham, Birmingham, [5]St. James' University Hospital, [6]Clinical Trials Research Unit, University of Leeds, [7]Clinical Trials Research Unit, [8]University of Leeds, Leeds, [9]Newcastle University, Newcastle Upon Tyne, United Kingdom

Background: Despite novel and effective therapies, the clinical course of multiple myeloma is that of a relapsing-remitting disease. In general, remission times shorten with each subsequent therapy, finally resulting in refractory disease. Changes in the predominance of molecular subclones have been implicated in disease relapse.
Aims: To identify the longitudinal changes in predominant copy number aberrations in myeloma patients from new diagnosis to first relapse.
Methods: Matched presentation and relapse CD138 immunomagnetically selected bone marrow tumour material from 69 patients treated in the NCRI Myeloma XI trial were analysed. Median time between samples was 19 months (range 2 – 39 months). Cases were molecularly profiled using a combination of MLPA and qRT-PCR (Boyle EM, *et al.* Gen Chrom Canc 2015; Kaiser MF, *et al.* Leukemia 2014). Copy number by MLPA is inferred by comparison of target regions against control regions.
Results: Three regions showed frequent changes in copy number from diagnosis to relapse: TP53 at 17p, CKS1B at 1q, and MYC at 8q. In 20% of cases, copy number of at least one of the regions changed between the timepoints. The frequency of predominant clones with TP53 deletion increased from 10.1% at presentation to 15.9% at relapse with five patients showing a novel TP53 deletion at first relapse. Copy number of CKS1B changed in 16% of cases between presentation and relapse: eight cases demonstrated novel gain or amplification of CKS1B, whereas in three cases copy number gain of CKS1B reverted to normal at relapse. The frequency of gain(1q) was 34.7% at presentation and 42.0% at relapse. A novel, predominant clone with gain of MYC was detected in four cases at relapse. Gain of MYC reverted to normal in three cases from presentation to first relapse.
Summary/Conclusions: We found dynamic changes in predominant clones between presentation and first relapse. Deletion of TP53/del(17p) and gain(1q) were more frequent at relapse than at presentation, indicative of clonal advantage under therapeutic selective pressure early in the disease course. Although novel gains of 8q suggest a clonal advantage for MYC, this appears to be context-dependent and further longitudinal studies are required to assess its impact over time.

Innovative therapies for MM 1

Hospital, Brzozow, Poland, [12]Hematology Division, Chaim Sheba Medical Center, Tel Hashomer, Israel, [13]Mayo Clinic, Rochester, United States, [14]Hadassah Medical Center, Kiryat Hadassah, Jerusalem, Israel, [15]Division of Hematology, Mayo Clinic, Rochester, United States, [16]Clinica Universidad de Navarra, Centro Investigación Medica Aplicada (CIMA), Pamplona, Spain, [17]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States, [18]University Hospital Hôtel Dieu, Nantes, France, [19]Dana-Farber Cancer Institute, Boston, United States

Background: The phase 3 TOURMALINE-MM1 study (NCT01564537) showed a significant 35% improvement in progression-free survival (PFS) with IRd *vs* placebo-Rd (hazard ratio [HR] 0.742, p=0.012) in 722 patients (pts) with relapsed/refractory multiple myeloma (RRMM) (Moreau et al, ASH 2015). Data from this study led to the approval by the US FDA of ixazomib, in combination with Rd, for the treatment of pts with MM who have received at least one prior therapy.
Aims: A key secondary endpoint was overall survival (OS) in patients with del(17p), and another secondary endpoint was outcome in patients with high-risk cytogenetic abnormalities. Here, we analyze the efficacy and safety of IRd *vs* placebo-Rd by cytogenetic risk status.
Methods: Pts with RRMM were randomized 1:1 to receive IRd or placebo-Rd (ixazomib 4 mg or matching placebo on days 1, 8, and 15, plus lenalidomide 25 mg on days 1–21 and dexamethasone 40 mg on days 1, 8, 15, and 22, in 28-day cycles) until disease progression or unacceptable toxicity. Stratification factors were number of prior therapies (1 *vs* 2 or 3), proteasome inhibitor-exposed *vs* -naïve status, and ISS stage I or II *vs* III. Cytogenetic risk status was assessed using FISH at a CLIA-certified central laboratory. High-risk abnormalities were defined as del(17p), t(4;14) or t(14;16); cut-off values for these abnormalities were, per protocol, based on the false-positive rates (technical cut-offs) of the Kreatech FISH probes used, which were 5%, 3%, and 3% positive cells, respectively. The standard-risk group consisted of all other patients with known baseline cytogenetics. Post-hoc analyses were performed using different cut-off values for del(17p) and t(4;14).

Table 1.

	Median PFS, mos		
Pts	IRd	Placebo-Rd	HR
All (N=722)	20.6	14.7	0.742
Standard-risk cytogenetics (n=415)	20.6	15.6	0.640
High-risk cytogenetics (n=137)	21.4	9.7	0.543
del(17p) alone or with t(4;14) and/or t(14;16) (n=69)	21.4	9.7	0.596
t(4;14) alone (n=61)	18.5	12.0	0.645

Using cut-offs of 5% positive cells for del(17p), 3% for t(4;14), and 3% for t(14;16)

Results: A total of 552 patients (76% of the 722 pts enrolled) had cytogenetic results (97% central laboratory-confirmed), of whom 137 had high-risk abnormalities, 75 in the IRd arm and 62 in the placebo-Rd arm. After a median follow-up of ~15 mos, PFS was improved with IRd *vs* placebo-Rd in both pts with high-risk and pts with standard-risk cytogenetics (Table); in high-risk pts, the median PFS with IRd was similar to that in all pts and in standard-risk pts. The PFS benefit with IRd *vs* placebo-Rd was consistent using different cut-off values for defining del(17p) and t(4;14) positivity. For del(17p), median PFS with IRd *vs* placebo-Rd was 21.4 *vs* 6.7 mos (HR 0.611) with a 20% cut-off (n=59), and 15.7 *vs* 5.1 mos (HR 0.49) with a 60% cut-off (n=33). For t(4;14) alone using a cut-off of 10% (n=59), median PFS was 18.5 *vs* 12.0 mos (HR 0.444) with IRd *vs* placebo-Rd. Median time to progression with IRd *vs* placebo-Rd was 21.4 *vs* 12.0 mos and 20.6 *vs* 15.9 mos in high-risk and standard-risk pts. Overall response rate with IRd *vs* placebo-Rd was 79% *vs* 60% in high-risk pts and 80% *vs* 73% in standard-risk pts, including CR+VGPR rates of 45% *vs* 21% and 51% *vs* 44%, respectively. At data cut-off, OS data were not mature, with 8 (11%) deaths in the IRd arm *vs* 13 (21%) in the Rd arm for high-risk pts, and 21 (11%) deaths in the IRd arm *vs* 32 (15%) in the Rd arm for standard-risk pts. At a 23-month analysis, rates of grade ≥3 adverse events (AEs) with IRd *vs* placebo-Rd were 66% *vs* 73% in high-risk pts and 75% *vs* 65% in standard-risk pts; rates of serious AEs were 42% *vs* 52% and 45% *vs* 47%, respectively.
Summary/Conclusions: IRd showed substantial benefit *vs* placebo-Rd in RRMM pts with high-risk cytogenetic abnormalities, irrespective of the cut-offs used, with limited additional toxicity. Molecular studies, including analyses of the impact of p53 mutation on outcomes, will also be presented.

P270

HIGH CUT-OFF HAEMODIALYSIS (HCO-HD) DOES NOT IMPROVE OUTCOMES IN MYELOMA CAST NEPHROPATHY: RESULTS OF EUROPEAN TRIAL OF FREE LIGHT CHAIN REMOVAL BY EXTENDED HAEMODIALYSIS IN CAST NEPHROPATHY (EULITE)

M Cook[1,2,*], C Hutchison[3], L Fifer[4], J Gillmore[5], N Heyne[6], K Weisel[6], J Bradwell[7], P Cockwell[2,4]

[1]Department of Haematology, [2]Institute for Translational Medicine, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom, [3]Department of Nephrology, Hawke's Bay District Health Board, Hawke's Bay, New Zealand, [4]Department of Renal Medicine, Queen Elizabeth Hospital Birmingham, Birmingham, [5]National Amyloidosis Centre, University College London, Royal Free Campus, London, United Kingdom, [6]Department of Medicine, University of Tuebingen, Tuebingen, Germany, [7]School of Medicine, University of Birmingham, Birmingham, United Kingdom

Background: Severe acute kidney injury (AKI) secondary to myeloma cast nephropathy (MCN) and requiring acute dialysis is associated with poor patient survival. MCN is caused by the pathogenic (involved) immunoglobulin serum free light chain (sFLC). High cut-off haemodialysis (HCO-HD) can remove large quantities of sFLC and retrospective uncontrolled clinical trials using HCO-HD have reported renal function recovery (from dialysis) in over 60% of patients. This is compared to historic reports of 20% renal recovery. Recovery of renal function is associated with improved survival. However, it is not known if these better outcomes were associated with HCO-HD or novel chemotherapy regimens. There have been no RCTs of the efficacy of HCO-HD or the efficacy of bortezomib based chemotherapy in patients with MCN and severe AKI requiring dialysis treatment.
Aims: To carry out a prospective multi-centre RCT in patients with newly diagnosed MM and associated MCN who required acute dialysis treatment, comparing HCO-HD to standard high flux (HF)-HD, and using bortezomib based chemotherapy as the standard of care.
Methods: Ninety patients with a first diagnosis of MM & MCN confirmed by kidney biopsy, sFLC levels of the involved LC >500 mg/l (Freelite™), and a requirement for acute dialysis, were randomised to receive HCO-HD or standard HF-HD. HCO-HD was carried out with two 1.1 m^2 Baxter-Gambro HCO 1100 dialyser in series. The dialysis regimen was based on studies that identified an optimal protocol for FLC removal. All patients received bortezomib, doxorubicin, and dexamethasone chemotherapy to a maximum of 8 cycles. Primary outcome was independence of dialysis at 3-months. Patients were followed for 2-years. Other pre-defined outcomes included; 3-week sFLC levels, overall renal recovery, stem-cell transplantation, 2-year OS. All results are reported as intention to treat (ITT). Where statistical tests are not stated the chi-squared test is reported.

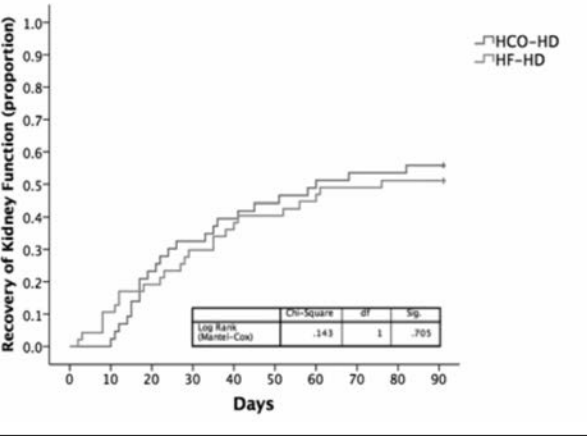

Figure 1.

Results: There was no difference between groups for sFLC levels (mg/L, median, range (Mann-Whitney test)) by isotype at randomisation. These were: kappa LC; HCO- HD 12000 (1839-61900), HF-HD 11800 (1200-76322), lambda LC; HCO-HD 6031 (1950-33196), HF-HD 8400 (574-38400). There was no difference at randomisation between HCO-HD and HF-HD for age, ethnicity, gender, myeloma type (light chain only *vs* intact Ig). Serum FLC levels levels on the first full protocol dialysis decreased for kappa LC and lambda LC by 75.6% and 71.2% for HCO-HD, and 20.2% and 9.1% for HF-HD, respectively (P<0.001). However, there was no difference in the percentage reduction of sFLC level from baseline at 3 weeks between HCO-HD and HF-HD. 24/43 patients (55.8%) in the HCO-HD group and 24/47 patients (51.6%) in the HF-HD group recovered renal function by 3 months (not significant, NS). Kaplan–Meier analysis is shown in the figure. Overall recovery of renal function was 62%; 58.1% in the HCO-HD group, 66% in the HF-HD group (NS). 35% in the HCO-HD group and 32.2% in the HF-HD received a stem-cell transplant (NS). OS at 2-years was 24 (55.8%) in the HCO-HD group and 36 (76.6%) in the HF-HD group (P=0.037; odds ratio (95% confidence interval), 1.583 (1.048-2.392)). There were more lung infections in the first 3-months in the HCO-HD group (12 *vs* 3, P=0.014).

Summary/Conclusions: In this RCT, where all patients received bortezomib based chemotherapy, 62.2% of patients recovered renal function and overall survival at 2-years was 66.7%. HCO-HD, compared to HF-HD, did not improve renal recovery rates in patients with severe AKI secondary to MCN. There was worse overall survival in the HCO-HD group.

P271

OPROZOMIB, POMALIDOMIDE, AND DEXAMETHASONE (OPOMD) IN PATIENTS (PTS) WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA (RRMM): INITIAL RESULTS OF A PHASE 1B STUDY (NCT01999335)

J Shah[1,*], R Niesvizky[2], E Stadtmauer[3], RM Rifkin[4], J Berenson[5], J Berdeja[6], J Sharman[7], R Lyons[8], Z Klippel[9], H Wong[9], YL Chang[9], S Usmani[10]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]Weill Cornell Medical College/New York Presbyterian Hospital, New York, [3]University of Pennsylvania Abramson Cancer Center, Philadelphia, [4]US Oncology Research and Rocky Mountain Cancer Centers, Denver, [5]Institute for Myeloma & Bone Cancer Research, Los Angeles, [6]Sarah Cannon Research Institute, Nashville, [7]US Oncology Research and Willamette Valley Cancer Institute, Springfield, [8]US Oncology Research and Cancer Care Centers of South Texas, San Antonio, [9]Amgen Inc., South San Francisco, [10]Levine Cancer Institute/Carolinas Healthcare System, Charlotte, United States

Background: Oprozomib (OPZ), an irreversible proteasome inhibitor has demonstrated activity in pts with RRMM (Vij, *Haematologica* 2015;100[suppl 1]:abst P646; Hari, *Haematologica* 2015;100[suppl 1]:abst P653).

Aims: The primary objective of the phase 1b portion of this study was to determine the maximum tolerated dose (MTD) and recommended phase 3 dose (RP3D) of OPZ in the OPomd regimen and to evaluate safety and tolerability. Secondary objectives included estimating overall response rate (≥partial response) and clinical benefit rate (≥minimal response), and evaluating OPZ pharmacokinetics (PK).

Methods: Pts with RRMM (≥2 prior regimens) were eligible; pts must have received ≥2 consecutive cycles of both bortezomib and either lenalidomide or thalidomide. Prior carfilzomib (CFZ) was allowed if CFZ was not discontinued due to an adverse event (AE). Pts received OPZ orally once-daily on days (D) 1-5 and 15-19 (*i.e.*, 5/14 schedule) or on D1, 2, 8, 9, 15, 16, 22, 23 (*i.e.*, 2/7 schedule) of 28-day cycles. Pts received pomalidomide (POM) orally on D1–21 and dexamethasone (DEX) 20 mg orally on D1, 2, 8, 9, 15, 16, 22, 23. The starting OPZ dose in the 5/14 schedule was 150mg/day and in the 2/7 schedule was 210mg/day; subsequent escalation was in a standard 3+3 dose-escalation schema. The starting POM dose for both schedules was 4mg.

Results: Thirty-one pts were enrolled (5/14 schedule, n=4; 2/7 schedule, n=17 and n=10 for the expansion arm). In the 5/14 schedule, pts received OPZ 150 mg/day + POM 4 mg/day (n=3); or OPZ 150 mg/day + POM 2 mg/day (n=1). In the 2/7 schedule, pts received OPZ 210 mg/day + POM 4 mg/day (n=17 including expansion arm patients); or OPZ 240 mg/day + POM 4 mg/day (n=10). Median age was 57 yr (5/14 schedule), 61 yr (2/7 schedule OPZ 210 mg/d) and 71 yr (2/7 schedule OPZ 240 mg/d). Pts received a median (range) of 7 (3-22) prior regimens in the 5/14 schedule, 3 (2-8) in the 2/7 schedule OPZ 210 mg/d and 3.5 (1-11) in the 2/7 schedule OPZ 240 mg/d. At data cutoff (10/26/15), pts in the 5/14 and 2/7 schedules had been on treatment for a median duration of 17.8 wk (range, 3.3-38.6) and 19.3 wk (range, 3.3-50.9) for all study drugs, respectively. Three dose-limiting toxicities (DLTs) were reported in 2 pts in the 5/14 schedule: 1 pt grade (Gr) 3 mucositis and rash; 1 pt Gr 3 abdominal distention and impaired cognitive function. One DLT occurred in the 2/7 schedule (OPZ 210 mg/d): Gr 3 gastric hemorrhage with severe erosive gastritis identified in endoscopy. One pt in the 5/14 schedule (25%) and 1 pt (5.9%) in the 2/7 schedule OPZ 210 mg/d discontinued treatment due to an AE. No pts died on study. The most common hematologic and of clinical interest AEs (any Gr and Gr ≥3) are shown in the table. In the 2/7 schedule, a partial response or better was reported in 71% of the OPZ 210 mg/d patients (and in 4 of 5 CFZ-refractory patients) and 50% of the OPZ 240 mg/day patients; 50% of patients in the 5/14 schedule also achieved partial response or better. Considering current measures of variability and sample size, the PK of OPZ, when given in combination with POM and DEX, were generally consistent with previous OPZ studies.

Table 1. Adverse events of any grade occurring in >25% and grade ≥3 adverse events occurring in ≥10% of patients.

AE, n (%)	5/14 Schedule OPZ150 mg/d (n= 4)		2/7 Schedule OPZ 210 mg/d (n= 17)		2/7 Schedule OPZ240 mg/d (n= 10)

AE, adverse event; OPZ, oprozomib

Summary/Conclusions: Initial results from this ongoing phase 1b study suggest that the combination of OPomd has significant anti-myeloma activity, is active in a highly refractory patient population, and is generally well tolerated. The most common grade ≥3 AEs observed were anemia (47%) and diarrhea (11%) with 210 mg OPZ in the 2/7 schedule. The MTD of OPZ in combination with POM/DEX was not reached on either schedule.

P272

PHASE 1B STUDY OF VENETOCLAX COMBINED WITH BORTEZOMIB AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

P Moreau[1,*], A Chanan-Khan[2], AW Roberts[3], A Agarwal[4], T Facon[5], S Kumar[2], C Touzeau[1], S Diehl[6], J Cordero[6], J Ross[6], W Munasinghe[6], M Zhu[6], AH Salem[6], J Leverson[6], P Maciag[6], M Verdugo[6], SJ Harrison[7]

Background: BCL-2 and MCL-1 promote multiple myeloma (MM) cell survival. Bortezomib (BTZ) inhibits MCL-1 activity, and venetoclax (VEN), an oral, selective BCL-2 inhibitor, enhances its efficacy in MM xenograft models.

Aims: The objectives of the study are to evaluate safety and preliminary efficacy of VEN with BTZ and dexamethasone (Dex) in relapsed/refractory (RR).

Methods: Patients received daily VEN, per assigned dose escalation cohorts (50-1200mg), combined with BTZ (1.3mg/m^2 SC) and Dex (20mg PO) for 11 cycles, and then VEN alone thereafter.

Table 1.

Best response by prior B status, n (%)	B Naïve (n=6)	B Sensitive (n=17)	B Refractory (n=18)	All (n=41)

MR	0	0	2 (11)	2 (5)
SD	0	2 (12)	4 (22)	6 (15)
PD	0	3 (18)	8 (44)	11 (27)
DC before assessment	0	0	1 (6)	1 (2)
Median (range) time on study*, months	9.8 (0.6–16.5)	5.5 (0.5–18.3)	1.3 (0.3–13.5)	4.9 (0.3–18.3)

*All patients (n=45): 1st dose to cut-off (active patients) or last dose (DC patients)

Results: 45 patients were enrolled as of 9/17/15. Median age was 65, with 29 males and 16 females; 24 patients had ISS stage II/III. The median (range) number of prior lines of therapy was 4 (1-13). 38 patients received prior BTZ (19 refractory), 36 had lenalidomide (26 refractory), and 32 had prior SCT. Adverse events occurring in ≥30% of patients were constipation (40%), diarrhea (38%), thrombocytopenia (33%), and insomnia (29%). Grade 3/4 adverse events in ≥10% were thrombocytopenia (22%), and anemia (16%). Serious adverse events in ≥2 patients were pneumonia (n=3), cardiac failure, embolism, pyrexia, respiratory failure, sepsis, and thrombocytopenia (n=2 each). One dose limiting toxicity was observed, and maximum tolerated dose was not reached. 30 patients discontinued (DC): 24 related to disease progression (3 died), 2 due to adverse events, and 4 withdrew consent. Dose-normalized PK for VEN with BTZ+Dex was similar to VEN monotherapy. 41 out of45 patients were evaluable for efficacy (Table 1). Preliminary results also indicate that

patients who had received 1-3 prior lines of therapy (N=18) had higher ORR (83.3%) as compared to patients who had received 4-6 (N=13, 38.5% ORR) or ≥7 prior lines of therapy (N=10, 10% ORR).
Summary/Conclusions: Venetoclax with bortezomib and dexamethasone has an acceptable safety profile and evidence of anti-tumor activity in RR MM; response rates were highest in patients who were naïve or sensitive to prior bortezomib, or had received 1–3 prior therapies. Currently, dose escalation is complete and safety expansion is ongoing at 800 mg.

P273

A PHASE IB STUDY OF THE AKT INHIBITOR AFURESERTIB IN COMBINATION WITH BORTEZOMIB AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: FINAL RESULTS WITH LONG TERM FOLLOW-UP

S Trudel[1,*], A Spencer[2], H Sutherland[3], M O'Dwyer[4], SY Huang[5], AK Stewart[6], A Chari[7], M Rosenzwieg[8], A Nooka[9], C Rosenbaum[10], CC Hofmeister[11], N Callander[12], BR Bengoudifa[13], B Gadbaw[14], M Reyes[13], F Su[14], P Voorhees[15]

Background: The PI3K/AKT pathway is constitutively active in multiple myeloma (MM), providing proliferative and anti-apoptotic signals, and contributing to drug resistance in preclinical models. Afuresertib is an orally bioavailable, ATP-competitive, reversible inhibitor of all 3 AKT kinases. Single-agent activity has been seen in patients (pts) with heavily pretreated MM. Preclinical studies have shown that combining afuresertib with bortezomib results in downstream target inhibition and synergistic cell death in myeloma cell lines.
Aims: The aims of the current study were to determine the safety, tolerability, and MTD of afuresertib when dosed in combination with bortezomib and dexamethasone for pts with relapsed/refractory (R/R) MM. Secondary endpoints included pharmacokinetics (PK), pharmacodynamics (PD), and clinical activity.
Methods: In this Phase Ib open-label study, pts (aged ≥18 years, ECOG PS ≤2) with MM who had failed ≥1 line of systemic therapy were enrolled into the dose escalation part of the study (part 1). The initial dose of afuresertib (75 mg QD) was increased in 25 mg increments until the MTD was reached. Bortezomib was dosed at 1.0 mg/m^2 IV in the first cohort and 1.3 mg/m^2 IV for all other cohorts. Dexamethasone was administered at 20 mg (40 mg for the MTD cohort) on the same days as bortezomib. Pts received induction with afuresertib, bortezomib, and dexamethasone for eight 21-day cycles, and then continued single-agent afuresertib until treatment discontinuation criteria were met. Pts were enrolled into the dose expansion part of the study (part 2) at the MTD. Two cohorts were explored in part 2: a PK/PD and a safety/efficacy cohort. Pts with bortezomib-refractory disease were eligible for part 1, but were excluded in part 2.

Table 1. Clinical activity of afuresertib in combination with bortezomib category.

Cohort	Summary of overall response rate by prior bortezomib category			
	Bortezomib naïve (n=17)	Bortezomib relapsed (n=49)	Bortezomib refractory (n=24)	All patients (N=90)

Part 2 safety/efficacy cohort (N=46)	- sCR: 0/14 - CR: 2/14 (14%) - VGPR: 3/14 (21%) - PR: 3/14 (21%) sCR+CR+VGPR+PR: 8/14 (57%), 95% CI: [28.9%,82.3%]	- sCR: 1/32 (3%) - CR: 3/32 (9%) - VGPR: 6/32 (19%) - PR: 12/32 (38%) sCR+CR+VGPR+PR: 22/32 (69%), 95% CI: [50.0%,83.9%]	NA	- sCR: 1/46 (2%) - CR: 5/46 (11%) - VGPR: 9/46 (20%) - PR: 15/46 (33%) sCR+CR+VGPR+PR: 30/46 (65%), 95% CI: [49.8%,78.6%]

CI, confidence interval; CR, complete response; NA, not available; PD, pharmacodynamics; PK, pharmacokinetics; PR, partial response; SCR, stringent complete response; SD, stable disease; VGPR, very good partial response.

Results: 90 pts were enrolled (34 in part 1, 10 in the PK/PD cohort, and 46 in the safety/efficacy cohort). Pts had a median age of 64 years and had received a median of 3 prior lines of treatment (range: 1-10). Pts received a median of 105 days (range: 5-1050) of afuresertib treatment and a median of 5 cycles (range: 0-8) of bortezomib plus dexamethasone. In the safety/efficacy cohort, median time on study was 119 days (range: 5-757). DLTs were reported in the 100 mg cohort (Grade [G] 2 ALT elevation, n=1), the 125 mg cohort (G3 erythema multiforme, n=1), and the 175 mg cohort (G3 rash, n=1; G3 rash/G3 diarrhea/G3 thrombocytopenia, n=1). The MTD and recommended dose for Phase 2 was established as 150 mg QD afuresertib plus 1.3 mg/m^2 bortezomib and 40 mg dexamethasone on Days 1, 4, 8, and 11. In the part 2 safety/efficacy cohort, the most common AEs were diarrhea (65%), fatigue (59%), nausea (52%), thrombocytopenia (37%), constipation (35%), hyperglycemia (35%), and anaemia (35%). G3/4 AEs occurring in >10% of pts were thrombocytopenia (26%), diarrhea (22%), hyperglycemia (15%), and orthostatic hypotension (13%). The overall response rate across all cohorts was 53% (95% CI: 42.5%,63.9%) and 65% (95% CI: 49.8%,78.6%) in the safety/efficacy cohort. Responses were observed in 8/24 pts who were refractory to prior bortezomib (Table 1). Afuresertib PK profiles were generally dose proportional and mean afuresertib exposure was similar alone or in combination with bortezomib and dexamethasone. Survival data will be presented at the meeting.
Summary/Conclusions: Treatment of R/R MM with afuresertib plus bortezomib and dexamethasone demonstrated a manageable safety profile and showed promising clinical activity. The PK profile of afuresertib was not affected by bortezomib or dexamethasone.

P274

UPDATED DATA FROM A PHASE II DOSE FINDING TRIAL OF SINGLE AGENT ISATUXIMAB (SAR650984, ANTI-CD38 MAB) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

Background: Isatuximab (ISA) is a humanized anti-CD38 monoclonal antibody with multiple modes of action for killing tumor cells through direct tumor targeting and immune cell engagement. We report updated data from an ongoing Phase II dose finding study of ISA monotherapy in patients with RRMM (NCT01084252).
Aims: Primary objective: evaluation of ISA activity (overall response rate [ORR; IMWG]).
Methods: Patients with RRMM (≥3 lines of anti-MM therapy or refractory to immunomodulatory drugs [IMiDs] and proteasome inhibitors [PIs]) were randomized to ISA 3 mg/kg Q2W, 10 mg/kg Q2W x 2 cycles then Q4W, or 10 mg/kg Q2W. Randomization stratified by prior pomalidomide and/or carfilzomib therapy. Emerging PK data prompted enrollment of a 4th treatment arm at 20 mg/kg QW x 4 doses then Q2W. 1 cycle=28 days. All patients signed an IRB approved informed consent.
Results: 97 patients treated: median age, 62.5 (38-85) y; median time from diagnosis, 5.9 (1.2-24.1) y; ISS stage 3, 37%; median prior lines of therapy, 5 (2-14); 86%, 61%, 80%, 57%, 88% refractory to lenalidomide, pomalidomide, bortezomib, carfilzomib, or IMiD+PI, respectively. 24/56 cytogenetics-evaluable patients (43%) had t(4;14) and/or del(17p). Median treatment duration, 13.1 wks; 22 patients remain on treatment (cut-off Nov 2015). ORR: 9% (2/23), 20% (5/25), 29% (7/24) & 24% (6/25) at ISA 3 Q2W, 10 Q2W/Q4W, 10 Q2W, & 20 mg/kg QW/Q2W, respectively; 14/20 responders continue without progression. At ≥10 mg/kg: ORR was 24% (18/74), similar in subgroups (age, CrCl, prior lines of therapy), and 44% (8/18) in patients with abnormal cytogenetics. Median time to 1st response, 1.35 mo; median duration of response at data cut-off, 6.6 mo. Most common adverse events (AEs) were nausea (33%), fatigue (30%), dyspnea (26%), and cough (24%), which were typically grade ≤2. Infusion-associated reactions (IARs) occurred in 49% of patients, mostly grade ≤2, 94% during the 1st infusion. 6 patients discontinued therapy due to AEs, 2 due to IARs.
Summary/Conclusions: ISA monotherapy is active and generally well tolerated in heavily pretreated RRMM, with efficacy greatest at ≥10 mg/kg (ORR

24%). ORR was similar in subgroups, including high-risk cytogenetics. Progression-free survival and overall survival data will be presented.

P275

CARFILZOMIB, LENALIDOMIDE, AND DEXAMETHASONE VS LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA: ANALYSIS OF RESPONSE AND PROGRESSION-FREE SURVIVAL HAZARD RATIO OVER TIME

MA Dimopoulos[1,*], AK Stewart[2], M Wang[3], V Maisnar[4], J Minarik[5], WI Bensinger[6], MV Mateos[7], D Ben-Yehuda[8], V Kukreti[9], M Obreja[10], S Aggarwal[10], P Moreau[11], A Palumbo[12]

[1]National and Kapodistrian University of Athens School of Medicine, Athens, Greece, [2]Mayo Clinic, Scottsdale, [3]The University of Texas MD Anderson Cancer Center, Houston, United States, [4]Charles University Faculty Hospital and Faculty of Medicine, Hradec Králové, [5]University Hospital Olomouc, Olomouc, Czech Republic, [6]Fred Hutchinson Cancer Research Center, Seattle, United States, [7]University Hospital of Salamanca/IBSAL, Salamanca, Spain, [8]Hadassah-Hebrew University Medical Centre, Jerusalem, Israel, [9]Princess Margaret Cancer Centre, Toronto, Canada, [10]Amgen Inc., South San Francisco, United States, [11]University of Nantes, Nantes, France, [12]University of Torino, Torino, Italy

Background: As previously reported, treatment with carfilzomib, lenalidomide, and dexamethasone (KRd) significantly improved progression-free survival (PFS) and treatment responses *versus* lenalidomide and dexamethasone (Rd) in patients (Pts) with relapsed multiple myeloma (ASPIRE; NCT01080391). Per trial protocol, carfilzomib (CFZ) was discontinued after 18 cycles (28 days/cycle) so optimal duration of KRd treatment was not determined; all Pts continued to receive Rd treatment until disease progression.
Aims: To evaluate post hoc the time to cumulative complete response or better (≥CR) and PFS hazard ratio (HR) at 18 months from randomization for KRd *vs* Rd treatment.
Methods: Cumulative rates of ≥CR overtime were evaluated from start of treatment for KRd (CFZ starting dose 20 mg/m^2 and target dose 27 mg/m^2, lenalidomide 25 mg, and dexamethasone 40 mg) *vs* Rd (same doses lenalidomide and dexamethasone) arms This analysis was done on treated patients. PFS HR at 18 months for the intent-to-treat population was evaluated using piecewise Cox regression analyses based on the method of Collett (2003).
Results: KRd (n=396) and Rd (n=396) Pts were followed for a median of 31 and 30 months for PFS, respectively. A total of 126 and 37 Pts in the KRd and Rd groups achieved ≥CR with sample median time from treatment start to ≥CR of 6.7 and 8.3 months, respectively. The increase in rate of ≥CR Pts over time was greater in the KRd group than the Rd group, most notably in the first 15 months; cumulative ≥CR rates increased steadily thereafter (Table). The overall PFS HR in ASPIRE for KRd *vs* Rd was 0.69 (95% CI, 0.57 to 0.83). For the first 18 months, the PFS HR was 0.58 (95% CI, 0.46 to 0.72).

Table 1.

	Cumulative ≥CR rates* (% Pts)		
Treatment (Months)	KRd (n=392)	Rd (n=389)	KRd-Rd
3	3.1	0.8	2.3
6	13.5	3.1	10.4
9	20.9	4.9	16.0
12	24.2	6.7	17.5
15	27.3	7.2	20.1
18	28.6	7.7	20.9
21	29.6	8.2	21.4
24	30.6	9.0	21.6
27	31.1	9.3	21.9
30	31.9	9.3	22.6

*Safety population: time from treatment start

Summary/Conclusions: CFZ combined with Rd provides greater response and improvements/benefits in PFS compared with Rd alone. Cumulative ≥CR rates increased over time in the KRd arm with rates rising rapidly in the first 15 months. The 18 month PFS HR was lower than the overall study PFS HR, possibly related to KRd Pts receiving CFZ for a maximum of 18 months.

P276

THE SKY92 PROGNOSTIC MARKER IS VALIDATED IN EIGHT MULTIPLE MYELOMA CLINICAL DATASETS

M Van Vliet[1,*], R Kuiper[1], J Ubels[1], B Dumee[1], L Bosman[1], E van Beers[1], L de Best[1], A Waage[2], S Zweegman[3], G Morgan[4], J Levy[5], D Auclair[5], R Fonseca[6], H Goldschmidt[7], M van Duin[8], P Sonneveld[8]

[1]SkylineDx BV, Rotterdam, Netherlands, [2]Norwegian University of Science and Technology, Trondheim, Norway, [3]VU University medical center, Amsterdam, Netherlands, [4]Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, [5]MMRF, Norwalk, [6]Mayo Clinic, Scottsdale, United States, [7]GMMG and Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany, [8]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Prognostic markers for Multiple Myeloma (MM) are recommended in most guidelines and consensus papers for clinical use and for risk stratified trials. A prognostic marker is considered suitable for clinical use when it identifies a reasonable fraction of all patients with sufficiently differential outcome (hazard ratio), and is reproducible in multiple independent clinical studies. SKY92 risk stratification was performed in eight independent clinical datasets for which gene expression profiling was available along with overall survival (OS). Three datasets also had progression free survival (PFS), which is an important measure to identify the patient's response to therapy and which is often a relatively early indication of the severity of the disease. Patients with a shorter PFS require care at a higher frequency, possibly a different treatment strategy and likely need higher intensity treatment than patients with longer progression free survival. It would therefore be useful to reliably identify patients that are expected to have a shorter OS and PFS in an early stage. The SKY92 signature has been reported to be a robust predictor for OS as well as PFS (Kuiper *et al.* 2012, Kuiper *et al.* 2015).
Aims: To validate the prognostic value for PFS and OS of the SKY92 high risk marker in newly diagnosed and relapsed refractory Multiple Myeloma across a wide variety of clinical trial datasets.
Methods: OS data and gene expression profiling (GEP) data, either publicly available or obtained by analysis of the CE IVD MMprofiler assay (that includes the SKY92 signature), of eight clinical datasets (Figure 1) were used to evaluate the proportion of cases, hazard ratios and *p*-values associated with the SKY92 risk marker. The datasets included both newly diagnosed MM (TT2, TT3, MRC-IX, MMGI, HOVON87) and relapsed refractory MM (APEX and TT6) and also elderly (>65 yrs) MM (HOVON87 and about half of MRC-IX). The Cox proportional hazards model was used to calculate Hazard Ratios (HR), and associated p-values.
Results: Figure 1 shows Kaplan Meier curves for eight datasets comparing cases that are high risk for SKY92 *versus* those that are standard risk for SKY92. The proportion of high risk cases was very similar in all cohorts (range 15.4% - 20.7%). For OS the (high risk) / (standard risk) hazard ratios range from HR=2.2 (MRC-IX) to HR=10.3 (TT6) and are all significant, see Figure 1A, including the relapsed stage cohorts TT6 and APEX. For PFS, the hazard ratios range from HR=1.7 (APEX) to HR=2.2 (HOVON87) and are all significant, see Figure 1B. The hazard ratios for OS (Figure 1A) are larger than for PFS (Figure 1B), which seems to suggest that the SKY92 signature is prognostic beyond the first line of treatment.

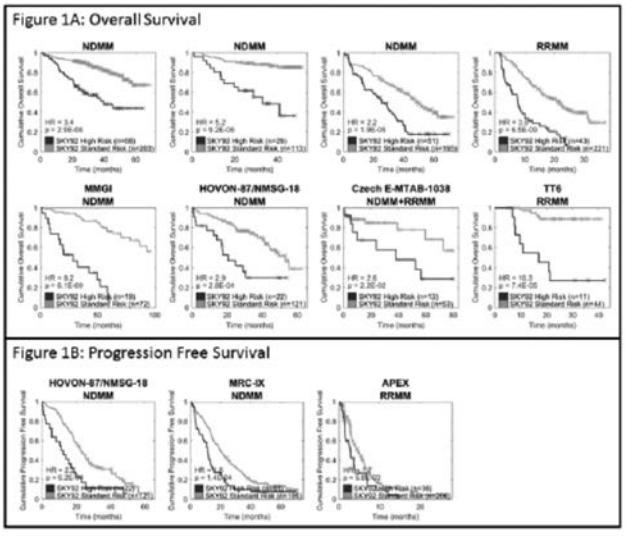

Figure 1. A) Prognostic value for OS of SKY92 in eight clinical datasets including NDMM and RRMM; B) for PFS (bottom) in three clinical datasets including NDMM and RRMM. TT2 |n=351|, TT3 |n=139|, MRC-IX |n=246|, APEX |n=264|, MMGI |n=91|, HOVON-87/ NMSG-18 |n=143|, Czech E-MTAB-1038 |n=66|, TT6 |n=55|. Note that follow up time (x-axis) differs between studies.

Summary/Conclusions: SKY92 is a powerful and robust prognostic marker, not only for OS but also for PFS in younger, elderly, newly diagnosed, relapsed (refractory) MM patients across various treatments including transplant, thalidomide, lenalidomide and bortezomib. It can therefore be used reliably as a predictor for survival to optimize follow-up and treatment strategies in an early stage.

P277

A PHASE 1B/2 STUDY OF SELINEXOR IN COMBINATION WITH BACKCONE THERAPIES FOR TREATMENT OF RELAPSED/REFACTORY MULTIPLE MYELOMA

N Bahlis[1,*], C Chen[2], M Sebag[3], C Venner[4], T Kouroukis[5], H Sutherland[6], R LeBlanc[7], D Bergstrom[8], A McCurdy[9], M Lalancette[10], C Choe-Juliak[11], C Picklesimer[11], JR Saint-Martin[11], J Jeha[11], M Kauffman[11], S Shacham[11], R Kotb[12]

[1]Southern Alberta Cancer Research Institute, Calgary, [2]Princess Margaret Cancer Center, Toronto, [3]Royal Victoria Hospital, Montreal, [4]Cross Cancer Institute, Edmonton, [5]Juravinski Cancer Centre, Hamilton, [6]Vancouver General Hospital, Vancouver, [7]Hôpital Maisonneuve-Rosemont, Montreal, [8]Memorial Hospital of Newfoundland, St. John's, [9]The Ottawa Hospital, Ottawa, [10]Hotel-Dieu de Québec, Québec, Canada, [11]Karyopharm Therapeutics, Newton, United States, [12]Cancer Care Manitoba, Winnipeg, Canada

Background: The nuclear export protein exportin 1, (XPO1) is overexpressed in a wide variety of cancers including multiple myeloma (MM). Selinexor is an oral Selective Inhibitor of Nuclear Export (SINE), specifically a XPO1 antagonist. Selinexor forces nuclear retention and reactivation of tumor suppressor proteins (TSPs; NF-κB, p53 and FOXO) and reduction of many proto-oncogenes, including MDM2, MYC and Cyclin D. Preclinical activity for selinexor has been demonstrated in combination with pomalidomide (pom), bortezomib (bort) or lenalidomide (len). There is *in vitro* and *in vivo* evidence of selinexor synergy with bort (*e.g.* proteasome inhibitors) through repression of NF-κB pathway and induction of autophagy in MM. In MM xenografts model, selinexor in combination with IMiDs have shown synergy in tumor growth inhibition and increased overall survival when compared to single agents alone. In addition, phase 1 and 2 clinical studies demonstrated selinexor single agent anti-myeloma efficacy.
Aims: To independently assess the efficacy and safety of three combination therapies for the treatment of patients (pts) with relapsed/refractory MM. The combinations are selinexor + dexamethasone (dex) + either Pom (SdP), Bort (SdB), or Len (SdL).
Methods: The dose escalation phase, conducted via the standard 3+3 design, consists of 3 treatment arms (SdP, SdB, and SdL), each arm including two treatment cohorts (once-weekly (80 mg, 100 mg) *vs* twice-weekly (60 mg, 80 mg) selinexor dosing). These 3 treatment arms are evaluated in parallel. Pom (4 mg), len (25mg) and dex (20mg with each selinexor dose) will not be dose escalated. For the SdB arm, bort (1.3mg/m^2 given SC) will be dose escalated from once-weekly to twice-weekly dosing (consistent with its approved, labeled dose).
Results: As of 10-Feb-2016, 4 pts (2M/2F, median of 8 prior regimens, median age 61 yrs) have been enrolled in the SdP arm. Ten pts (5M/5F, median of 8 prior regimens, median age 65 yrs) have been enrolled in the SdB arm. Common grade 1/2 adverse events (AEs) in the SdP arm are nausea (2 pts, 50%) and dysgeusia (2 pts, 50%). One grade 4 AE, neutropenia, was reported in the SdP arm. The most common related grade 1/2 AEs in the SdB are fatigue (2 pts, 20%), nausea (1 pt, 10%), and diarrhea (1 pt, 10%). Thrombocytopenia (5 pts, 50%) is the only Grade 3 AE reported in the SdB arm. Two pts were evaluable for response in SdP arm and achieved a very good partial response (VGPR, n=1) and a minor response (MR, n=1). Seven pts were evaluable for responses in the SdB arm including 3 partial responses (PR, 2 pts were bort refractory and 2 with del17p in >60%), 2 MR, 1 stable disease and 1 progressive disease.
Summary/Conclusions: Significant responses are observed in both treatment combinations of selinexor + dex + pom and selinexor + dex + bort, even in heavily pretreated patients with del17p and/or prior refractoriness to bortezomib. In patients with relapsed/refractory MM whose disease has progressed after PI and/or IMIDs based regimen, the addition of selinexor to bortezomib or pomalidomide is well tolerated. The early response rate observed is promising given the history of extensive pretreatment in this patient group. Updated results from this ongoing phase I/II trial will be presented at the meeting. (clinicalTrials.gov #NCT02343042)

Innovative therapies for MM 2

Background: Isatuximab (ISA), a humanized anti-CD38 monoclonal antibody, has demonstrated activity in patients with RRMM in combination with lenalidomide and dexamethasone (Len/Dex) in an ongoing Phase 1b study (NCT01749969). Overall response rate (ORR) was 63% at ISA 10 mg/kg Q2W (n=24). Here, we report data from 2 new cohorts evaluating a higher ISA dose and a different administration schedule.
Aims: Primary objective: to determine the maximum tolerated dose (MTD).
Methods: Patients with RRMM (≥2 prior MM therapies) were sequentially enrolled to ISA 10 or 20 mg/kg (weekly × 4 doses, then every 2 wks; initial infusion rate 175 and 250 mg/h at 10 and 20 mg/kg, respectively) plus Len 25 mg (days [D]1-21) and Dex 40 mg (D1, 8, 15, and 22), in 28-day cycles. All patients signed an IRB approved informed consent.
Results: An additional 26 patients were treated in the 2 cohorts: median age 65 (42-76) yrs; median yrs from diagnosis 4.5 (1.8-16.6). Median 4.5 (1-8) & 6 (3-10) prior lines of therapy at 10 & 20 mg/kg, respectively; Len-refractory (67% & 86%), pomalidomide+carfilzomib-refractory (25% & 64%), immunomodulatory drug+proteasome inhibitor-refractory (50% & 86%). At data cut-off (Dec 2015), median duration of dosing was 21.5 wks (10 mg/kg) and 9.9 wks (20 mg/kg); 13 patients remain on treatment. 4 patients discontinued therapy due to adverse events (AEs) (grade [Gr] 3 infusion-associated reactions [IARs] [n=3], dose-limiting toxicity of Gr 3 pneumonia [n=1]), all at 20 mg/kg in Cycle 1; these patients were excluded from the efficacy analysis. Most frequent AEs were fatigue (46%), pyrexia (35%) and diarrhea (31%). IARs occurred in 65% of patients, mostly Gr ≤2, and >90% during 1st infusion. MTD has not been reached. In evaluable patients, ORR (IMWG criteria; confirmed responses) was 50% in both cohorts (10 mg/kg [n=12]: VGPR 25%; PR 25%. 20 mg/kg [n=10]: VGPR 20%; PR 30%). Clinical benefit rate (≥MR) was 83% and 50% in the 10 and 20 mg/kg cohorts, respectively. Median time to 1st response was 4 (4-16) wks.
Summary/Conclusions: The combination of ISA ≥10 mg/kg and Len/Dex was generally tolerated and clinically active in heavily pretreated RRMM. Responses were observed after approximately 4 wks. PK, biomarker, and longer term follow-up data will be presented.

MOR202 ALONE AND IN COMBINATION WITH POMALIDOMIDE OR LENALIDOMIDE IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA: DATA FROM CLINICALLY RELEVANT COHORTS FROM A PHASE I/IIA STUDY

M Raab[1,*], M Chatterjee[2], H Goldschmidt[1], H Agis[3], I Blau[4], H Einsele[2], M Engelhardt[5], B Ferstl[6], M Gramatzki[7], C Röllig[8], K Weisel[9], P Klöpfer[10], D Weinelt[10], J Endell[10], R Boxhammer[10], C Peschel[11]

[1]Department of Medicine V, University Hospital Heidelberg, Heidelberg, [2]Department of Internal Medicine II, University Hospital of Wuerzburg, Wuerzburg, Germany, [3]Department of Medicine I, University Hospital of Internal Medicine – AKH Wien, Vienna, Austria, [4]Department of Internal Medicine III, Charité Campus Benjamin Franklin, Berlin, [5]Hematology & Oncology Department, Medical University Hospital, Freiburg, [6]Department of Internal Medicine 5 - Hematology and Oncology, Friedrich-Alexander-University Erlangen-Nuernberg, Erlangen, [7]Department of Medicine, University Hospital Schleswig-Holstein Division of Stem Cell Transplantation and Immunotherapy, Kiel, [8]Department of Medicine I, University Hospital Carl Gustav Carus, Dresden, [9]Department of Hematology, Oncology, Immunology, Rheumatology and Pulmonology, University Hospital of Tuebingen, Tuebingen, [10]MorphoSys AG, Martinsried, [11]Department of Internal Medicine III, Technical University of Munich, Munich, Germany

Background: MOR202, a HuCAL-derived, human IgG1 CD38 monoclonal antibody induces potent ADCC and ADCP; preclinical models show high activity of single-agent MOR202 and synergy in combination with immunomodulatory drugs (IMiDs), lenalidomide (LEN) or pomalidomide (POM). Unlike other CD38 antibodies, MOR202 does not induce complement-dependent cytotoxicity thought to be a major contributor to infusion-related reactions (IRRs).
Aims: The primary objectives of the study were to evaluate the safety, maximum tolerated dose (MTD)/recommended phase II dose of MOR202 in patients with relapsed or refractory multiple myeloma.

Methods: This is an interim analysis of a multicenter, dose-escalation phase I/IIa study of MOR202. Preliminary safety and efficacy data from 3 cohorts of patients treated with MOR202 alone or with an IMiD are presented: MOR202 4, 8 and 16 mg/kg weekly; MOR202 8 or 16 mg/kg weekly with either LEN or POM.
Results: As of January 29, 20 patients were treated: 11 patients with MOR202 alone, 5 patients with MOR202+LEN and 4 patients with MOR202+POM. Patients receiving MOR202 alone or with POM were relapsed or refractory to prior bortezomib and LEN with a median of 4 prior regimens. Patients given MOR202 with LEN had a median of 2 prior regimens, mainly bortezomib, cyclophosphamide and autologous stem cell transplant. The MTD has not been reached. MOR202 alone or with an IMiD was well tolerated with mainly hematological toxicity. No MOR202-related study discontinuations or deaths were recorded. A 2-hour MOR202 infusion was feasible in all patients. IRRs (grade 1) were seen in only 1/20 patients. Responses were reported in 8/18 evaluable patients: 3/10 responses (1 very good partial response [VGPR] and 2 partial responses [PR]) in the MOR202 alone, 3/4 responses (all PR) in the MOR202+LEN and 2/4 responses (1 complete response and 1 VGPR) in the MOR202+POM cohorts. In total, 7/8 responses were still ongoing, the longest duration of response was >10 months in a patient given MOR202 alone. Preservation of high CD38 levels on MM cells under MOR202 therapy was shown.
Summary/Conclusions: In this analysis, MOR202 given as a 2-hour infusion showed excellent infusion tolerability and overall safety profile. Promising preliminary efficacy and long-lasting tumor control was seen for MOR202 +/- IMiDs.

P280

ELOTUZUMAB + LENALIDOMIDE/DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: ELOQUENT-2 POST-HOC ANALYSIS OF PFS AND TUMOR REGROWTH BY TIME FROM DIAGNOSIS AND PRIOR LINES OF THERAPY

MA Dimopoulos[1,*], A Palumbo[2], K Weisel[3], P Richardson[4], MV Mateos[5], P Moreau[6], M Gupta[7], J Sheng[7], C Passey[7], O Sy[7], J Katz[7], S Lonial[8]
[1]National and Kapodistrian University of Athens, Athens, Greece, [2]A.O.U. San Giovanni Battista di Torino - Ospedale Molinette, Torino, Italy, [3]University of Tubingen, Tubingen, Germany, [4]Dana-Farber Cancer Institute, Boston, United States, [5]Complejo Asistencial Universitario de Salamanca-IBSAL, Salamanca, Spain, [6]University Hospital, Nantes, France, [7]Bristol-Myers Squibb, Princeton, [8]Winship Cancer Institute, Emory University, Atlanta, United States

Background: Elotuzumab, an immunostimulatory monoclonal antibody targeting SLAMF7, kills myeloma cells by both directly activating natural killer cells and mediating antibody-dependent cell-mediated cytotoxicity. ELOQUENT-2 (NCT01239797) is a Phase 3 study comparing elotuzumab plus lenalidomide and dexamethasone (ELd) with lenalidomide and dexamethasone (Ld) in patients (pts) with relapsed/refractory multiple myeloma (RRMM). Pts had a median time from diagnosis of 3.5 yrs. In a 3-yr follow-up, ELd showed a 27% reduction in the risk of disease progression/death (hazard ratio [HR] 0.73; 95% CI 0.60–0.89; p=0.0014), with durable efficacy across key subgroups.[1] Pts in the ELd group also demonstrated a delay of 1 yr in time to next treatment (TTNT) *vs* the Ld group, with a median (95% CI) TTNT of 33 (26.2–40.2) months in the ELd group *vs* 21 (18.1–23.2) months in the Ld group (HR 0.62; 95% CI 0.50–0.77).[1] Interim overall survival (OS) analysis indicated a strong trend in favor of long-term benefit of ELd *vs* Ld.[1]
Aims: To examine the effect of time from diagnosis and number of prior lines of therapy on progression-free survival (PFS), and to assess tumor shrinkage/regrowth, indicated by serum M protein, via dynamic modeling.
Methods: RRMM pts with 1–3 prior therapies were randomized to ELd or Ld in 28-day cycles until disease progression/unacceptable toxicity. PFS was a co-primary endpoint. An exploratory, post-hoc Kaplan-Meier analysis evaluated the impact of time from diagnosis and prior lines of therapy on PFS. Serum M protein dynamic, non-linear, mixed-effect modeling assessed the rate of serum M protein suppression as well as tumor regrowth, based on longitudinal serum M protein data from baseline.
Results: 646 RRMM pts were randomized (ELd n=321; Ld n=325). Baseline demographics: median age 66 yrs; 32% of pts had del(17p), 9% had t(4;14); 35% of pts were refractory to their last therapy. In pts with ≥median time from diagnosis, median PFS in the ELd group was 26.0 months *vs* 17.3 months in the Ld group (HR 0.60; p=0.0004). In the ELd group, pts with ≥median time from diagnosis and 1 prior line of therapy (n=48) had a 53% reduction in the risk of progression/death (HR 0.47; p=0.013) *vs* the Ld group (n=61). PFS HR in pts with ≥median time from diagnosis and >1 prior line of therapy was 0.59 (p=0.004; ELd n=111; Ld n=96). Serum M protein dynamic modeling showed the pattern of tumor regrowth; specifically, regrowth rate was slower for pts in the ELd *vs* the Ld group regardless of whether pts had ≥or <median time since diagnosis. The slowest rate of tumor regrowth (0.00145 g/dL.Day^{-1}) was in pts in the ELd group with ≥median time from diagnosis (vs 0.00234 g/dL.Day^{-1} in Ld group; <median time from diagnosis: ELd, 0.00279 g/dL.Day^{-1}; Ld, 0.00389 g/dL.Day^{-1}).
Summary/Conclusions: ELOQUENT-2 data show a PFS benefit with elotuzumab plus Ld *vs* Ld across key subgroups. Data from the current analyses indicate that PFS is favorable for ELd *vs* Ld across pt subgroups according to time from diagnosis, including in pts with a longer time from diagnosis and with either 1 or >1 prior therapy. This finding is further supported by serum M protein dynamic modeling, which suggests that elotuzumab may differentially slow the rate of tumor regrowth, thus providing sustainable and long-term survival benefits for pts, as an immuno-oncology agent. Further investigations to identify pt subgroups with increased PFS and OS benefit from elotuzumab are ongoing.

FINAL PHASE 2 STUDY DATA OF MELFLUFEN AND DEXAMETHASONE FOR PATIENTS WITH RELAPSED-REFRACTORY MULTIPLE MYELOMA (RRMM)

A Palumbo[1,*], V Magarotto[1], P Sonneveld[2], T Plesner[3], C Paba-Prada[4], P Voorhees[5], UH Mellqvist[6], C Byrne[7], J Harmenberg[8], E Nordström[9], H Zubair[8], PG Richardson[4]
[1]University of Torino Oncology Department, Myeloma Unit Division of Hematology, Torino, Italy, [2]Erasmus MC, Rotterdam, Netherlands, [3]Hematology, Vejle Hospital, Vejle, Denmark, [4]Dana Farber Cancer Institute, Boston MA, [5]University of North Carolina, Chapel Hill, NC, United States, [6]Södra Älvsborgs Sjukhus, Borås, Sweden, [7]Oncopeptides AB, Miami FL, United States, [8]Oncopeptides AB, [9]Oncopeptides AB, Clinical, Stockholm, Sweden

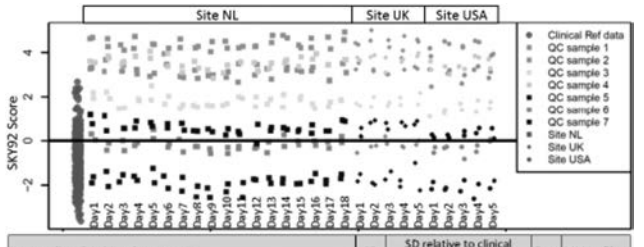
Background: Melflufen is a peptidase potentiated therapy with an alkylating payload, designed for efficient targeting of tumor cells with a unique mechanism of action. As a highly potent anti-angiogenic compound, melflufen triggers rapid, robust and irreversible DNA damage and exerts its cytotoxicity through alkylation of DNA. The lipophilicity of melflufen leads to rapid and extensive distribution into cells where it is readily metabolized by intracellular peptidases (often over-expressed in malignant cells) into hydrophilic alkylating metabolites leading to 50-fold enrichment in MM cells of these metabolites.
Aims: To study the efficacy and safety of melflufen in combination with dexamethasone (dex) in patients (pts) with RRMM.
Methods: 40 mg melflufen was given in 28-day cycles in combination with 40 mg weekly dex in RRMM pts with ≥2 prior lines of therapy, including lenalidomide and bortezomib, and who progressed on or within 60 days of last therapy.
Results: As of 11 Feb 2016, recruitment was complete (N=40). Median time from initial diagnosis to first dose of melflufen was 5.0 years (range 1-20) and the median number of prior therapies was 4 (range 2-9). 12 patients had ISS stage I, 16 stage II, 10 stage III and 2 unknown. 12 pts (30%) had high cytogenetic risk (del17p, t(4;14) or t(14;16)). 62% were double-refractory and 56% alkylator-refractory. Median duration of treatment was 4.0 months (m), (range 0.7-15) with 4 pts still ongoing. The best response achieved in the 30 efficacy evaluable pts (defined as received ≥2 cycles with appropriate assessments) was VGPR in 3 and PR in 9 for an overall response rate (ORR, ≥PR) of 40%. An additional 7 pts achieved MR for a clinical benefit rate (≥MR) of 63%. 10 pts achieved SD and 1 PD. Similar results were seen regardless of refractory status with an ORR of 35% in double-refractory pts and 53% in alkylator-refractory pts. The ORR was 33% in pts with high-risk cytogenetics. Time to first response (≥MR) was rapid with a median of 1.0 m (range 0.6-5.5). ORR in all 40 treated pts was 30%. The median Progression-Free Survival (PFS) was 8.0 m (95% conf. int. [CI] 4.1-13.6) based on 21 events in 30 pts in the efficacy evaluable population. Median PFS was 4.5 m (95% CI 3.7-11.0) based on 30 events in all 40 treated pts. Median duration of response was 8.8 m and overall survival was not yet measurable. Hematologic toxicity was common but manageable with cycle prolongations, dose modifications and supportive therapy. Melflufen treatment-related Grade 3/4 adverse events (AE) were reported in 85% of patients; thrombocytopenia 63%, neutropenia 58%, anemia 43% and neutrophil count decreased 10% followed by febrile neutropenia, asthenia, pyrexia, fatigue and pneumonia that each occurred in 5% of patients. 16 patients (40%) experienced serious AEs and 12 patients (30%) had melflufen treatment-related serious AEs. 58% of the pts required RBC transfusions, 43% platelet transfusions and 53% G-CSF.
Summary/Conclusions: Melflufen produces rapid and durable responses in MM pts refractory to the major classes of therapy and with high-risk cytogenetics. Clinical benefit (≥MR) was achieved among 63% of these advanced and heavily pretreated pts. Median PFS was 8.0 m in efficacy evaluable pts. Hematological AEs were common but manageable and non-hematological AEs were infrequent. Results support continued development of melflufen with its unique mechanism of action. Recruitment continues to a cohort of single-agent melflufen. Updated information will be presented at the time of the conference.

P282

PRECISION AS PART OF THE ANALYTICAL VALIDATION OF THE SKY92 HIGH RISK SIGNATURE AND THE MMPROFILER ASSAY

M Van Vliet[*], B Dumee, L Bosman, D Huigh, E van Beers, L de Best
SkylineDx BV, Rotterdam, Netherlands

Background: The SKY92 signature is a tool to identify high risk Multiple Myeloma (MM) patients. This signature has been clinically validated on eight independent cohorts, spanning patients from newly diagnosed to the relapsed/refractory setting. For clinical application and patient management, analytical validation is required on top of the clinical validation. That is, the precision should be such that given the technical variability of the assay its prognostic value can be guaranteed. Here the results of the MMprofiler precision studies, Repeatability, Intermediate Precision, and Reproducibility are reported.
Aims: To demonstrate the precision as part of the analytical validation of the SKY92 high risk signature and the MMprofiler assay.
Methods: The CE-IVD MMprofiler assay employs an Affymetrix Gene Expression Profiling (GEP) microarray, and standardized reagents and lab procedures. The assay reports the qualitative SKY92 result, *i.e.* an MM patient can either be standard risk or high risk. This result depends on an underlying quantitative SKY92 score and cut point, which was therefore used to assess the precision. Seven standard QC samples were created using representative samples covering the entire detection range of the SKY92 score. The repeatability (successive measurements of the same sample under the same conditions, also known as within run precision) and intermediate precision were assessed at the site in The Netherlands, by performing 18 runs of the seven samples in duplicate, while alternating three microarray lots, three reagent lots, three technicians, and two Affymetrix DX2 machines, providing a total of 252 MMprofiler analyses. For the reproducibility study, two external sites (UK, and USA) performed five runs of the same seven samples in duplicate (70 MMprofilers per site). In accordance with CLSI standard EP5-A2, the precision close to the cut point was estimated as the 95% confidence interval upper limit of the standard deviation (SD). Prior to the execution of the precision studies, the maximal tolerable SD at which the SKY92 signature would remain prognostic was established to be 0.80.
Results: A total of 392 MMprofiler assays were performed at three different sites (UK, USA, NL), for which the SKY92 scores were plotted, see Figure 1. The variation due to Repeatability was found to be SD=0.22, and the other sources of variation amount to SD=0.19. Combined, the Intermediate Precision, was found to be SD=0.28, which is only 4.4% of the range of SKY92 scores seen in a reference cohort of samples. Next, the Reproducibility was assessed across the three participating sites (SD=0.34), which corresponds to 5.4% of the reference range. All SD estimates were well below the acceptance criterion of 0.80, and thus the prognostic value of the SKY92 signature can be guaranteed.



Intermediate Precision Component	SD	SD relative to clinical reference samples range	Days	MMprofilers
Intermediate Precision (95% Confidence Interval Upper Limit)	0.28	4.4%	18	252
Intermediate Precision	0.25	3.9%		
Variation due to days, reagents, machines, microarrays, operators	0.19	3.0%		
Repeatability	0.22	3.5%		

Reproducibility Site (for all sites 95% Confidence Interval Upper Limits are reported)	SD	SD relative to clinical reference samples range	Days	MMprofilers
Site NL (* day 1 to 5 from the Intermediate Precision reused here)	0.33	5.2%	5	70*
Site UK	0.34	5.4%	5	70
Site USA	0.29	4.6%	5	70
Sites combined	0.34	5.4%	15	210

Figure 1. Scatterplot showing the SKY92 scores from seven QC samples performed on 18 days using alternating reagent lots/machines/technicians at the NL site. An additional five runs have been performed at two external sites in the UK and USA. The Tables below shows the SDs, also expressed relative to the range of SKY92 scores observed in a clinical reference cohort.

Summary/Conclusions: The precision estimates of the SKY92 signature and MMprofiler were found to be small, at most 5.4% of the range of SKY92 scores seen in a clinical reference cohort. This shows that the MMprofiler SKY92 marker provides reliable results for determination of prognosis across different sites. This allows worldwide comparison of the MMprofiler results for clinical (research) purposes.

P283

RISK STRATIFICATION BY SKY92+ISS OUTPERFORMS IFISH MARKERS T(4;14) AND DEL(17P) IN MULTIPLE MYELOMA

M Van Vliet[1,*], R Kuiper[1], J Ubels[1], B Dumee[1], L Bosman[1], E van Beers[1], L de Best[1], A Waage[2], S Zweegman[3], G Morgan[4], H Goldschmidt[5], P Sonneveld[6]
[1]SkylineDx BV, Rotterdam, Netherlands, [2]Norwegian University of Science and Technology, Trondheim, Norway, [3]VU University Medical Center, Amsterdam, Netherlands, [4]Myeloma Institute for Research and Therapy, University of Arkansas for Medical Sciences, Little Rock, AR, United States, [5]GMMG and Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany, [6]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Multiple Myeloma (MM) is a disease with a heterogeneous genetic makeup across patients, and differing survival. Various prognostic markers have been identified, which may be employed in risk stratified treatment paradigms. A large comparison has unveiled that the combination of SKY92 + ISS is the best prognostic marker for identifying high risk and low risk patients. However, a recurring question is how this marker model relates to the currently established iFISH abnormalities such as t(4;14), and del(17), which have earlier been associated with poor overall survival (OS). Here, we demonstrate that iFISH is outperformed by the SKY92 + ISS marker combination for risk stratification.
Aims: To show the prognostic relevance of iFISH markers in perspective of the SKY92 + ISS risk stratification model for prognosis of MM patients.
Methods: Four datasets were gathered, HOVON-65/GMMG-HD4 (n=329), HOVON-87/NMSG-18 (n=143), MRC-IX (n=246), and a Czech cohort (E-MTAB-1038, n=66). Pooled, this provided n=559 MM patients for which GEP data, iFISH annotation, Overall Survival (OS), and ISS were available. The pooled dataset was split into three risk strata as previously proposed (Kuiper *et al.*, 2015): SKY92 standard risk (SR) and ISS1 (low risk), SKY92 Standard Risk and ISS2/3 (intermediate risk), SKY92 high risk (HR). Subsequently, each of these three risk strata were further refined into two groups: those that had either iFISH t(4;14) and/or del(17p) characteristics and those without. The Cox proportional Hazards model was applied to those two groups in each of the three strata separately, to calculate hazard ratios and associated *p*-values. Since groups would become too small, splitting the groups into all possible FISH subgroups was not performed, *i.e.* positive for both t(4;14) and del(17p), and those positive for one and negative for the other.
Results: The four datasets were pooled and then split into three risk strata, providing n=140 low risk (25.0%, SKY92 SR and ISS1), n=289 intermediate risk (51.7%, SKY92 SR and ISS2/3), and n=130 high risk (23.3%, SKY92 HR) MM patients, see Figure 1A. Out of the 140 low risk patients 28 (20%) had a t(4;14) and/or del17, whose survival was equivalent to those without iFISH aberrations (HR=2.4, p=0.054, see Figure 1B). Moreover, their survival was much longer than those in the SKY92 HR group, signifying that they would be at risk for overtreatment when iFISH would be used for risk stratification. Similarly, 55 (19%) out of 289 intermediate risk patients were found to harbor either iFISH t(4;14) or del(17p), but with no impact on their survival (hazard ratio=1.3, *p*=0.17, see Figure 1C). Finally, the group of SKY92 high risk patients were clearly overrepresented for t(4;14) and del(17p), with 65 out of 130 cases (50%). However, those 50% of patients that did not bear a t(4;14) and/or del(17p) aberration (*i.e.* non high risk by iFISH) had the same poor OS as those with them (hazard ratio=1.0, *p*=0.82, see Figure 1D). As a consequence, applying the current prognostic models using iFISH, those 50% HR patients not detected by iFISH would be at risk of undertreatment.

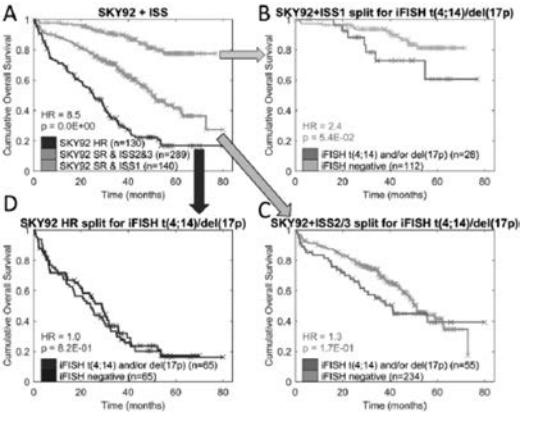


Figure 1. Kaplan Meier plots for the SKY92 + ISS risk stratification scheme on the four pooled datasets (top left). Each of the three strata were subsequently split based on the presence of at least one of the iFISH markers t(4;14) or del(17p) or absence thereof.

Summary/Conclusions: Risk stratification based on SKY92 and ISS is a powerful tool to identify both high risk MM patients and low risk MM patients. Patients identified to be iFISH t(4;14) and/or del(17p) are only high risk when they co-occur with SKY92 HR. Moreover, when they are SKY92 SR, their prognosis is better defined by their ISS stage.

P284

CONSOLIDATION WITH BORTEZOMIB AND LENALIDOMIDE POST-ASCT WITHOUT DEXAMETHASONE AND BISPHOSPHONATES: FINAL ANALYSIS OF A PROSPECTIVE STUDY IN NEWLY DIAGNOSED MYELOMA PATIENTS

E Terpos[*], E Kastritis, D Christoulas, E Eleutherakis-Papaiakovou,

M Gavriatopoulou, D Fotiou, I Panagiotidis, D Ziogas, E Kafantari, M Migkou, M Roussou, MA Dimopoulos
Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Consolidation therapy with the combination of bortezomib, lenalidomide and dexamethasone (VRD) is an effective therapy in patients with multiple myeloma (MM) post autologous stem cell transplantation (ASCT). Bisphosphonates (BPs) are given for at least for 12 months after diagnosis in these patients.
Aims: The primary endpoint of the study was to explore the efficacy of VR consolidation, without dexamethasone, in newly-diagnosed MM patients who received bortezomib-based induction treatment and then underwent ASCT. Secondary endpoints included: safety, time to progression (TTP), time to next treatment (TtNT), overall survival and effects of VR on bone metabolism, in the absence of BPs.
Methods: Patients who achieved at least stable disease post-ASCT were eligible for participation in the study. Consolidation consisted of 4 cycles of VR, which started on day 100 post-ASCT. Bortezomib was given at a dose of 1.3 mg/m^2, on days 1, 4, 8 and 11 of a 21-day cycle, while lenalidomide was given at a dose of 25 mg, on days 1-14. Patients did not receive any BP during or post-ASCT and during VR consolidation. The following bone remodeling markers were measured on the day of SC collection, before and after VR consolidation: i) osteoclast regulators RANKL and OPG, ii) osteoblast inhibitors Dkk-1 and sclerostin, iii) bone resorption markers CTX and TRACP-5b and iv) bone formation markers bALP and osteocalcin (OC).
Results: Fifty-nine patients (30M/29F, median age 54 year, range 37-68 years) participated in the study. After induction, one (1.7%) patient achieved sCR, one (1.7%) CR, 30 (50.8%) vgPR, 22 (37.3%) PR, while 5 (8.5%) patients had stable disease. After ASCT, 34 (57.6%) patients improved their status of response; in total, 14 (23.7%) achieved sCR, one (1.7%) CR, 35 (59.3%) vgPR and 9 (15.3%) PR. After VR consolidation, 23/59 (39%) patients further improved their response; overall, 30 (50.8%) patients achieved sCR, one (1.7%) CR, 26 (44.1%) vgPR and two (3.4%) PR. The most common adverse events included neutropenia (68%, grade 3/4 23%), thrombocytopenia (59%, grade 3/4 7%), peripheral neuropathy (56%, grade 3/4 2%), anemia (50%, grade 3/4 4.5%) and skin rash (34%, grade 3/4 9%). Fifteen patients (34.1%) experienced at least one infectious episode (grade 1 and 2). Post-VR consolidation there was a reduction of sRANKL/OPG ratio and sclerostin ($p<0.001$) in all patients. Patients who achieved at least vgPR showed higher reductions of sRANKL/OPG and sclerostin compared to all others ($p<0.01$). There was no reduction of bone resorption markers throughout the study period, possibly due to the dramatic reduction of these markers during induction therapy, when zoledronic acid was given. Furthermore, there were no alterations in Dkk-1, bALP and OC, despite the use of bortezomib which has bone anabolic effects. This may be due to the enhanced expression of Dkk-1 caused by lenalidomide and the short period of observation. No skeletal-related events (SREs) were observed during the study period. The median follow-up after ASCT was 35 months and 54% of patients have progressed. The median TTP after ASCT was 42 months (95% CI 29-54 months). There was a trend for longer TTP in patients achieving sCR (48 *vs* 35 months, p=0.145). The median TtNT has not been reached.
Summary/Conclusions: Four cycles of VR consolidation without dexamethasone improves the quality of response in approximately 40% of patients and produces long TTP. In the absence of bisphosphonates, VR consolidation has beneficial effects on bone metabolism and is related with no SREs.

P285

LOW INCIDENCE OF SKELETAL-RELATED EVENTS AT THE TIME OF FIRST RELAPSE IN PATIENTS WITH MULTIPLE MYELOMA WHO RECEIVED BORTEZOMIB-BASED REGIMENS AS FIRST LINE TREATMENT

E Terpos[1,*], N Kanellias[1], LA Moulopoulos[2], D Christoulas[1], M Gavriatopoulou[1], M Migkou[1], A Koureas[2], T Bagratuni[1], V Koutoulidis[2], E Kastritis[1], MA Dimopoulos[1]
[1]Department of Clinical Therapeutics, [2]Department of Radiology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: Skeletal-related events (SREs) which include pathological fractures, spinal cord compression (SCC) and need for radiotherapy or surgery to bone are frequent complications of multiple myeloma (MM)
Aims: The aim of the study was to evaluate SRE rate in MM patients who received frontline therapy with bortezomib or IMiD-based therapies and explore possible correlations with disease or genetic features
Methods: We studied MM patients who received frontline therapy with novel agents in a single center, since 2007. All patients had a whole body skeletal survey using conventional radiography (WBXR) at diagnosis and then at the time of relapse or whenever clinically indicated; MRI of the spine and pelvis at diagnosis was recorded if available. SNPs in genes that are involved in bone destruction were also evaluated: LRP5 (rs4988321), GC vitamin D (rs4588), TNFRSF11A (rs3018362), DKK1 (rs1569198), RANKL (rs9594759), OPG (rs6469804) and ERS1 (rs1038304).
Results: Since 2007, 463 consecutive patients with symptomatic MM (237M/226F, median age: 68 years) were studied. At diagnosis, the skeletal survey detected osteolytic disease in 328 (71%) patients. MRI was available in 243 patients: 36% of patients had focal, 40% diffuse, 20% normal, and 4% variegated pattern of marrow involvement. SREs were observed in 194 (42%) patients at diagnosis: 120 (26%) patients presented with pathological fractures (89 with vertebral fractures, 21 with rib fractures and 17 with fractures of the long bones; 28 patients had both vertebral and long bone or rib fractures), while 22 (4.7%) patients needed surgery to bone, 21 (4.5%) radiotherapy and 20 (4.3%) patients presented with SCC. The incidence of SREs was higher in patients with osteolytic lesions (52% *vs* 19%, $p<0.001$) or abnormal MRI pattern (51% *vs* 22%, p=0.001). However, we noted that approximately 1/4 patients without lytic lesions in WBXR or with normal MRI pattern presented with a SRE at diagnosis. No correlation was found between the presence of SREs and a specific polymorphism of those studied. Frontline therapy with IMiD-based regimens was given in 38% of patients; 36% patients received bortezomib-based regimens and 26% both IMiD and bortezomib (VTD or VRD). BPs were given in all but 86 patients (18.5%) at diagnosis, mainly due to renal insufficiency; however, almost 60% of them (n=51) received BPs later in the course of their therapy. The vast majority (91%) of patients received zoledronic acid. During first line treatment, 8 (1.7%) patients developed a SRE: 2 on bortezomib- and 6 on IMiD-based regimens. The rate of SREs was higher in patients who did not receive upfront BPs (5% *vs* 1%; p=0.021). The median follow-up was 63 months. At the time of first relapse (data available for 218 patients), 12 patients presented with fractures and 35 patients required local radiotherapy to bone (SRE rate: 21.5%). Patients who had received only bortezomib-based regimens had lower SRE rate (8% *vs* 24%, p=0.06). In total, during the course of their disease, 52.8% of the patients presented with at least one SRE. Presentation with SREs at diagnosis did not predispose for SREs during the disease course.
Summary/Conclusions: Our data, from the first systematic report on the incidence and characteristics of SREs in the era of novel agents, indicate that SREs remain a significant complication in MM at diagnosis. Importantly, despite high response rates after first line therapy more than 20% of patients develop an SRE, which was lower in patients who received first line therapy with bortezomib-based regimens

PHARMACODYNAMIC RELATIONSHIP BETWEEN NATURAL KILLER CELLS AND DARATUMUMAB EXPOSURE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

T Casneuf[1,*], XS Xu[2], H Adams III[3], A Axel[3], B Verbist[1], K Liu[3], I Khan[2], T Ahmadi[3], X Yan[2], S Lonial[4], T Plesner[5], H Lokhorst[6], NW van de Donk[6], PL Clemens[3], AK Sasser[3]
[1]Janssen Research & Development, Beerse, Belgium, [2]Janssen Research & Development, LLC, Raritan, NJ, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Department of Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA, United States, [5]Vejle Hospital, Vejle, Denmark, [6]Department of Hematology, VU University Medical Center, Amsterdam, Netherlands

Background: Daratumumab (DARA), a human IgG1 monoclonal antibody that targets CD38, was recently approved in the United States for patients with relapsed/refractory multiple myeloma (RR MM) who have received ≥3 lines of prior therapy, including a proteasome inhibitor (PI) and immunomodulatory drug (IMiD), or who are double refractory to PI/IMiD. High levels of CD38 are expressed on MM cells, and to a lesser extent on immune cells, including natural killer (NK) cells. We assessed the exposure-response relationship of DARA and NK cells, and the impact on clinical outcomes of RR MM patients treated with DARA.
Aims: To characterize the relationship between DARA exposure, NK cell kinetics, and patient clinical outcomes.
Methods: ADCC and CDC assays were performed following DARA treatment of NK cells isolated from peripheral blood mononuclear cells of normal, healthy donors. Samples were pooled from 2 DARA monotherapy studies in patients with RR MM (GEN501, N=104; SIRIUS, N=124). We explored the kinetics of total NK cells ($CD16^+CD56^+$) and activated NK cells ($CD16^+CD56^{dim}$) after DARA infusion. Associations between changes in NK cells post-treatment and DARA exposure, safety, and efficacy were evaluated.
Results: High levels of CD38 were expressed on the surface of NK cells, making these cells sensitive to DARA-mediated ADCC and CDC *in vitro*. After infusion of DARA in patients, the numbers of total and activated NK cells were rapidly and significantly reduced in a dose-dependent manner in whole blood and bone marrow, but recovered post-treatment (Figure 1). A hyperbolic maximum effect (E_{max}) dose- or concentration-response relationship was observed for the maximum reduction in NK cells in the peripheral blood. While baseline levels of NK cells (total or activated) between responders and nonresponders were similar, a trend towards higher overall response rate was associated with greater reduction in NK cells following DARA treatment, suggesting that depletion of NK cells did not interfere with the clinical activity of DARA. No correlations were observed between reductions in the number of NK cells and onset of grade ≥3 adverse events (AEs), infections of any grade, grade ≥3 infections, or herpes zoste.

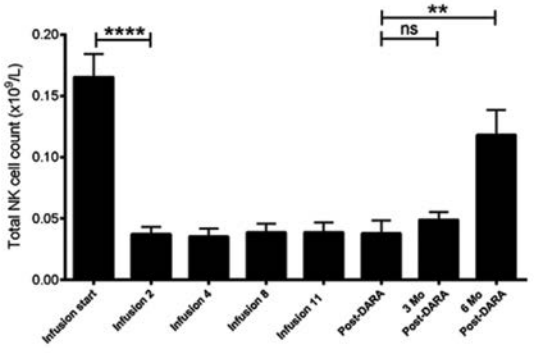

Figure 1. Rapid reduction of total NK cell counts and recovery after DARA treatment.

Summary/Conclusions: CD38 is expressed on NK cells, which are sensitive to DARA treatment. The peripheral NK cells decreased with increasing DARA exposure, exhibiting an E_{max}-type exposure-response relationship. This finding suggests that NK cells can be used as a pharmacodynamic marker for DARA. However, no apparent relationship was observed between NK cell reduction during treatment and incidence of grade ≥3 AEs or infections of any grade.

Myeloproliferative neoplasms - Biology

P287

CONCURRENT INHIBITION OF PI3K/MTOR AND JAK1/JAK2 PATHWAYS PROMPTS COMPLETE DEPHOSPHORYLATION OF STAT5 PROVIDING SYNERGISTIC ACTIVITY IN MPN MODELS

M Balliu[1,*], N Bartalucci[1], L Calabresi[1], S Martinelli[1], C Bogani[1], JL Villeval[2], F Annunziato[1], P Guglielmelli[1], AM Vannucchi[1]
[1]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, [2]INSERM, Gustave Roussy, Villejuif, France

Background: The constitutive activation of the JAK/STAT pathway by JAK2V617F (VF) and other driver mutations in myeloproliferative neoplasms (MPN) on turn promotes deregulation of other intracellular signaling pathways including the PI3K/mTOR. We previously reported that drugs targeting the PI3K pathway induce cell cycle arrest and attenuate dissemination of JAK2VF cells infused in immunodeficient mice (JCellMolMed 2013;17:1385). Also, the mTOR inhibitor RAD001 demonstrated clinical efficacy in a phase I/II trial in MPN patients (Blood 2011;118:2069).
Aims: Herein we have addressed the molecular mechanisms of the efficacy of PI3K inhibitors, using as relevant drugs the pan-PI3K inhibitor BKM120 and the mTORC1 complex inhibitor RAD001, that were employed as single agents or combined with the JAK1/JAK2 inhibitor Ruxolitinib (Ruxo).
Methods: As MPN models, we used *in vitro*, JAK2VF-mutated SET2 and HEL cell lines, *ex vivo*, the primary $CD34^+$cells from MPN patients and *in vivo*, JAK2V617F knock-in (KI) mice (Blood 2013;122:1464).
Results: Treatment of JAK2VF SET2 and HEL cell lines and JAK2V617F KI mice with BKM120 caused a marked decrease of p-mTOR and its target p-4EBP1, that were accompanied by reduction of p-STAT5 levels. We found that cells treated with BKM120 showed marked dephosphorylation of serines (Ser) residues of STAT5, specifically Ser193/Ser731, while p-tyrosine (Tyr) residues, particularly p-Tyr694, were unaffected. Conversely, Ruxo caused reduction of p-Tyr694 with irrelevant effects on Ser residues. To understand the mechanisms of BKM120-induced Ser dephosphorylation, we sought to identify involved protein phosphatases. We found that only the downregulation of serine/threonine protein phosphatase 2A (PP2A) effectively abrogated drug-induced dephosphorylation of Ser residues. In addition, the mRNA and protein levels of the cancerous inhibitor of protein phosphatase 2A (CIP2A) were strongly reduced by PI3K-inhibitors both in cell lines and primary samples from patients who showed responsiveness to RAD001 treatment. Also, downregulation of the PI3K downstream effector SNAI1 induced by BKM120 treatment leads to upregulation of miR-375, which is involved in the stability of CIP2A mRNA (MolBiolCell 2013;24:1638-48). Therefore, inhibition of p-STAT5 by PI3K inhibitors in MPN cells results from a microcircuit involving miR-375, CIP2A and PP2A overall controlling phospho status of STAT5 Ser residues. Owing that PI3K/mTOR and JAK2 inhibitors induced dephosphorylation at different STAT5 residues, we evaluated the combination of BKM120, RAD001 and Ruxo to induces complete STAT5 inactivation, both *in vitro* and *in vivo* models. *In vitro,* triple drug combination showed the highest synergic activity (CI<0.25; Chou and Talalay combination index) in reducing proliferation of JAK2VF cell lines and colonies formation from patients' cells, as compared to double combinations (BKM120+Ruxo CI<0.65; RAD001+Ruxo CI<0.3). Immunoblots of cells treated with triple-combo showed a concomitant dephosphorylation of both Tyr694 and Ser193/Ser731 reflecting stronger STAT5 inhibition. *In vivo,* JAK2V617F KI mice treated with triple-combo showed dramatic reduction of splenomegaly and control of blood cell counts much more effectively than single-drug treated ($p<0.5$) and control ($p<0.1$) animals.
Summary/Conclusions: Overall, these data reinforce the functional cross-talk between the JAK/STAT and PI3K/mTOR pathways in MPN cells and, by providing evidence of drug synergism mediated by differential targeting of STAT5 phosphoresidues, supporting the combined use of JAK1/2 and PI3K/mTOR inhibitors for the treatment of MPN.

P288

ACE-1332 (TGFB LIGAND TRAP) INHIBITS ELEVATED TGFB1 SIGNALING AND REDUCES FIBROSIS IN A MURINE MODEL OF MYELOFIBROSIS

NVSR Suragani[1,*], P Martinez[1], R Li[1], SR Pearsall[1], R Kumar[2]
[1]Pre Clinical Pharmacology, [2]Biology, Acceleron Pharma, Cambridge, United States

Background: Myeloproliferative neoplasms (MPN) are group of clonal stem cell disorders that originate from acquired mutations in the hematopoietic lineage cell leading to abnormal kinase signaling, cell proliferation, cytokine expression, splenomegaly and bone marrow (BM) fibrosis. Primary myelofibrosis (PMF), post-polycythemia vera (PV) MF and post-essential thrombocythemia MF are categorized under myelofibrosis (MF) with overlapping disease phenotypes including progression to BM fibrosis. Mutations in JAK2 have been highly correlated with MF and currently, JAK2 kinase inhibitor therapy is

the only available treatment that offers symptomatic benefit, but does not alter the natural history of the disease or improve BM fibrosis. It is known that TGFβ1 is a critical regulator of fibrosis in many disease states and may be an important therapeutic target for improving bone marrow fibrosis in MPN.
Aims: Elevated TGFβ1 levels were reported to be important for fibrosis in patients with MF. We hypothesize that inhibition of TGFβ1 signaling may prevent fibrosis and help reduce secondary morbidities associated with disease in MF patients. Therefore, we evaluated this hypothesis using ACE-1332 in a murine model of MF.
Methods: Transgenic JAK2 (*V617F*) mutant mice (MF model) and age matched wild-type controls were used in the studies. Mice were dosed with RAP-1332 (murine ortholog of ACE-1332) twice weekly (10 mg/kg) by subcutaneous injection. Expression of TGFβ and inflammatory cytokines at different ages (2-12 months) during disease progression was determined by serum ELISA and qRT-PCR. Bone marrow and spleen cells were analyzed for different cell lineages by flow cytometry. BM sections were stained with H&E and reticulin to determine cellularity or degree of fibrosis respectively.
Results: To understand the onset and progression of MF disease in JAK2 (*V617F*) mice, we initially analyzed the complete blood counts and degree of fibrosis at various ages (2, 3, 4, 5, 8, 10 and 12 months) compared to wild-type mice. These data were then correlated with the expression of TGFβ and inflammatory cytokines. As expected, red blood cells (RBC) and platelets were elevated in JAK2 mutant mice at all ages compared to wild-type mice, although a trend towards a progressive increase was observed between 2 to 5 months followed by a decrease from 8 to 14 months. BM fibrosis was detected starting at 5 months and worsened with age. JAK2 mutant mice also displayed splenomegaly that increased as the disease progressed. Interestingly, serum levels of TGFβ1 and TGFβ3 increased at earlier ages (2-5 months) compared to the latter ages, a trend similar to RBC levels. These levels peaked during the initiation of fibrosis at 5 months. In contrast, inflammatory cytokines (such as IL6, IL-1β, and TNFα) were elevated at later ages consistent with disease progression. We initiated treatment with RAP-1332 in JAK2 (*V617F*) mice (N=8/treatment group) at 4 months of age, the age corresponding to elevated serum TGFβ1 levels and prior to the onset of fibrosis (at 5 months of age). Following 6 months of treatment, vehicle (VEH) treated JAK2 mutant mice displayed elevated RBC (+37.1%, P<0.001), platelets (+74.5%, P<0.001) and spleen weights (+9.5 fold, P<0.001) compared to wild-type mice. BM and spleen sections from VEH treated JAK2 mutant mice revealed severe fibrosis. TGFβ1 antagonism by RAP-1332 treatment of JAK2 mice displayed moderate effect on RBC (-8.4%, N.S) without any effect on platelet counts compared to VEH treatment. Flow-cytometry identified a reduced proportion of $Ter119^+$ erythroid precursors in BM and spleen (-15%, P<0.05) and no change in $CD41^+$ megakaryocytes. RAP-1332 treated mice displayed reduced spleen weights (-29%, P<0.01), and marked reduction in bone marrow (Figure) and spleen fibrosis compared to VEH. Consistent with the reduction in fibrosis, RAP-1332 treated JAK2 mice displayed reduced IL-6 levels (-48.9%, P<0.05) compared to VEH treatment.

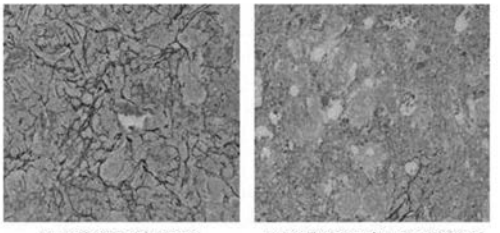

Figure 1.

Summary/Conclusions: These data demonstrate that TGFβ1 levels were correlated with bone marrow fibrosis in a murine model of MF disease. Inhibition of TGFβ1 using RAP-1332 reduces fibrosis, splenomegaly and inflammation in this the JAK2 V617Fmurine model of myelofibrosis.

P289

TARGETING OF BRD4 AS A NOVEL THERAPEUTIC CONCEPT IN JAK2 V617F+ MPN

A Keller[1,2,*], B Peter[1,2], J Zuber[3], D Berger[2], PB Staber[2], P Bettelheim[4], P Valent[1,2], E Hadzijusufovic[1,2,5]
[1]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, [2]Medical University of Vienna, [3]Research Institute of Molecular Pathology, Vienna, [4]Elisabethinen Hospital Linz, Linz, [5]University of Veterinary Medicine Vienna, Vienna, Austria

Background: Myeloproliferative neoplasms (MPN) are characterized by clonal expansion and accumulation of myeloid cells, erythrocytes, and/or platelets in the bone marrow (BM) and peripheral blood. Classical MPN are polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). In patients with MPN, the *JAK2* V617F mutation is frequently detected. Although MPN are chronic and indolent diseases in most patients, fatal progression may occur. So far, the only curative approach for these patients is hematopoietic stem cell transplantation. Therefore, current research is evaluating new therapeutic targets. The epigenetic reader bromodomain-containing protein 4 (BRD4) has recently been identified as a promising target in acute myeloid leukemia.
Aims: The aim of the present study was to investigate the potential value of BRD4 as a molecular target in MPN.
Methods: We employed two *JAK2* V617F+ cell lines, SET-2 and HEL, as well as BM samples obtained from 19 patients with *JAK2* V617F+ MPN (ET: n=6; PV: n=7; PMF: n=6). Three BRD4 inhibitors were applied: JQ1, BI2536, and BI6727.
Results: As assessed by qPCR, SET-2, HEL, and primary MPN cells were found to express BRD4 mRNA and mRNA of the BRD4-downstream target MYC. In ^{3}H-thymidine uptake experiments, all three BRD4 blockers were found to suppress the proliferation of both cell lines and all tested MPN patient samples (7/7). The effects of these drugs were dose-dependent with reasonable IC_{50} values (Table 1). In addition, we analyzed the effects of the BRD4 inhibitors on the putative (neoplastic) stem cells (CD34+/CD38-). In one PMF and one PV patient, exposure to JQ1 was followed by a decrease in the percentage of CD34+/CD38- cells (PMF: control: 0.16% *vs* JQ1: 0.045%; PV: control: 0.078% *vs* JQ1: 0.056%). In the PV patient, the effects of BI2536 and BI6727 were also tested and found to be comparable to JQ1. To confirm the role of BRD4 as a potential target in MPN cells, we performed target-knockdown experiments in SET-2 and HEL cells using two different BRD4 shRNAs. Knockdown of BRD4 was found to block proliferation in transfected cells when compared to untransfected or random shRNA-transfected cells. In a next step, we examined the effects of the BRD4 inhibitors on cell cycle progression. BI2536 and BI6727 were found to induce a G2/M phase arrest in both cell lines. In contrast, JQ1 induced a G1-arrest in HEL cells, but did not show a significant effect in SET-2 cells. In addition, we found that all three BRD4 blockers induced apoptosis in SET-2 and HEL cells in a dose-dependent manner (ED_{50} values: Table 1). Finally, we examined whether exposure to BRD4 inhibitors is associated with modulation of MYC mRNA expression. JQ1, BI2536, and BI6727 were found to downregulate MYC mRNA levels in SET-2 and HEL cells after 2 hours. As assessed by Western blotting, protein levels of MYC were found to be reduced in the MPN cell lines after 24 hours of treatment with BRD4-targeting drugs.

Table 1.

		JQ1	BI2536	BI6727
IC_{50} (nM)	SET-2	50 - 100	20 - 40	50 - 75
	HEL	100 - 500	20 - 40	30 - 50
	primary cells	500 - 1000	500 - 1000	500 - 1000
ED_{50} (nM)	SET-2	100 - 250	10 - 25	25 - 50
	HEL	250 - 500	10 - 25	10 - 25

Summary/Conclusions: In conclusion, our data show that BRD4 is expressed in *JAK2* V617F+ MPN cells and that BRD4 inhibition is associated with decreased proliferation and survival of neoplastic cells. The clinical value of BRD4 as a therapeutic target in *JAK2*-mutated MPN remains to be determined in clinical trials.

P290

LNK MUTATIONS IN FAMILIAL MYELOPROLIFERATIVE NEOPLASMS

E Rumi[1,2,*], A Harutyunyan[3], D Pietra[1], C Cavalloni[2], E Roncoroni[1], I Casetti[2], M Bellini[2], C Milanesi[1], C Astori[1], R Kralovics[3,4], M Cazzola[1,2]
[1]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, [2]Department of Molecular Medicine, University o Pavia, Pavia, Italy, [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, [4]Department of Internal Medicine I, Division of Hematology and Blood Coagulation, Medical University of Vienna, Vienna, Austria

Background: Myeloproliferative neoplasms (MPN), including polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) have in most instances a sporadic occurrence. However, familial clustering of MPN has been reported. Common mutations involved in the pathogenesis of MPN such as *JAK2* V617F, *CALR*, and *MPL* mutations are not inherited, but somatically acquired also in familial cases. The SH2B adaptor protein 3 (SH2B3) gene, also known as *LNK* gene, encodes a negative regulator of cytokine signaling: Lnk negatively regulates erythropoietin receptor signaling and thrombopoietin receptor signaling, by attenuating Jak2 activation and thus reducing erythropoiesis and megakaryopoiesis, respectively. *LNK* mutations have been described in some patients with sporadic MPN and in a small number of cases with idiopathic erythrocytosis and subnormal Epo levels. The majority of mutations occur in exon 2 and is acquired although rare cases of germline *LNK* mutations have been reported. To date, there are no data regarding the occurrence of *LNK* mutations in familial myeloproliferative neoplasms.
Aims: In an attempt to identify the germline genetic factors that underlie familial clustering of MPN we applied next generation sequencing to our MPN families.
Methods: Our cohort of 94 MPN families was analyzed with two strategies. First we applied whole exome sequencing (Illumina instrument) in a subgroup of 16 families with MPN. As this approach resulted in the identification of a exon 2 *LNK* mutation in one family, next we screened for exon 2 *LNK* mutations by Sanger

sequencing the remaining 93 families. Variants were validated by Sanger sequencing. All samples were collected after subjects gave their written informed consent.
Results: Exome sequencing resulted in the identification of an E208Q *LNK* mutation in a patient with familial PV belonging to family 36. Then we screened for exon 2 *LNK* mutations the remaining 93 families. Of 149 patients affected with familial MPN, two patients (1.4%) showed E208Q *LNK* mutation (including the initial case, identified through exome sequencing). The pedigrees and the *LNK* sequences of the two mutated cases (MeF and MPC12_294, belonging to family 36 and family 38 respectively) are reported in Figure 1. Both patients were affected with *JAK2* V617F mutated polycythemia vera. Unfortunately DNA from healthy relatives of family 36 and 38 was not available. The two patients carried the mutation both in granulocyte and T lymphocyte DNA, thus suggesting a germline mutation. In both families the other family member affected with MPN (MeR and MPC07_24) did not carry any mutation of the *LNK* gene, thus excluding segregation of the E208Q mutation with the disease phenotype. This raised the suspicious that the mutation might be an early mutation occurred in the hematopoietic system instead of a real germline mutation. To test this hypothesis we recalled patient MeF to collect DNA from his hair. E208Q mutation was found also in DNA from hair roots, thus confirming that the E208Q mutation was a real germline mutation.

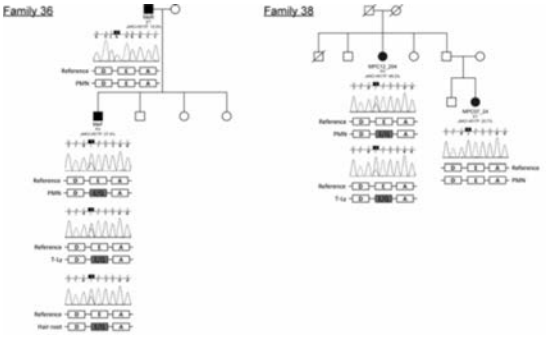

Figure 1.

Summary/Conclusions: *LNK* germline mutations may rarely occur in familial MPN, also in the presence of *JAK2* V617F mutation, but do not segregate with the disease phenotype.

P291

HOMOZYGOUS CALRETICULIN MUTATIONS IN PATIENTS WITH MYELOFIBROSIS LEAD TO ACQUIRED MYELOPEROXIDASE DEFICIENCY
AP Theocharides[1,*], L Pontus[2], AK Lakkaraju[3], V Lysenko[1], R Myburgh[1], A Aguzzi[3], RC Skoda[2], MG Manz[1]
[1]Division of Hematology, University Hospital Zurich and University of Zurich, Zurich, [2]Department of Biomedicine, Experimental Hematology, University Hospital Basel and University of Basel, Basel, [3]Institute of Neuropathology, University Hospital Zurich and University of Zurich, Zurich, Switzerland

Background: The pathogenesis of acquired myeloperoxidase (MPO) deficiency, a rare phenomenon observed in patients with Philadelphia chromosome-negative myeloproliferative neoplasms (MPN), is unknown. MPO is a glycoprotein chaperoned by Calreticulin (CALR) in the endoplasmic reticulum. Mutations in *CALR* are frequently found in patients with myelofibrosis (MF) and essential thrombocythemia (ET) with nonmutated *Januskinase 2* (*JAK2*).
Aims: We aimed to determine whether acquired MPO deficiency in MPN is associated with the presence of *CALR* mutations.
Methods: A cohort of 317 MPN patients (142 polycythemia vera (PV), 94 ET and 81 MF) was screened for MPO deficiency using an ADVIA hematology analyzer. Molecular and cell biological analyses were performed in order to determine the underlying mechanism implicated in cases with MPO deficiency.
Results: MPO deficiency was observed in 6/81 MF patients (7.4%), but not in PV or ET patients. Susceptibility to infections had been documented in 2/6 (33%) MPO deficient patients. Five out of six patients with MPO deficiency carried a homozygous *CALR* mutation and were also deficient in eosinophilic peroxidase (EPX). In contrast, one MF patient with a *JAK2*-V617F mutation and MPO deficiency carried two previously reported *MPO* mutations and showed normal EPX activity. Importantly, we did not find patients with homozygous *CALR* mutations and normal MPO activity or patients with heterozygous *CALR* mutations and MPO deficiency in our cohort. Although additional MPN-associated mutations were detected in patients with homozygous *CALR* mutations, none of them was recurrent within these patients. Patients with homozygous *CALR* mutations had reduced MPO protein, but normal *MPO* mRNA levels supporting a post-transcriptional defect in MPO production. Finally, we demonstrate *in vitro* that in the absence of CALR immature MPO protein precursors are degraded in the proteasome.
Summary/Conclusions: Four decades after the first description of acquired MPO deficiency in MPN we provide the molecular correlate associated with this phenomenon and evidence that *CALR* mutations can affect the biosynthesis of glycoproteins.

P292

CHARACTERISATION OF THE INFLAMMATORY MICROENVIRONMENT IN MYELOPROLIFERATIVE NEOPLASMS AND ITS FUNCTIONAL IMPACT ON STEM AND PROGENITOR CELLS
NF Øbro[1,*], J Grinfeld[1,2], MS Shepherd[1], OB Harris[1], JC Prick[1], AL Miller[1], EJ Baxter[2], AR Green[1,2], DG Kent[1]
[1]Department of Haematology, University of Cambridge, [2]Department of Haematology, Addenbrooke's Hospital, Cambridge, United Kingdom

Background: The immune microenvironment in the bone marrow can have tumor-promoting activity in leukaemia. However, the role of the microenvironment in the initiation and evolution of early myeloid malignancies in not well understood.
Aims: The aim of this study is to characterise the inflammatory microenvironment in chronic myeloproliferative neoplasms (MPNs), including essential thrombocythaemia (ET), polycythaemia vera (PV), and myelofibrosis (MF). We undertook a cell surface marker screen and secreted molecule screen in an effort to identify disease biomarkers and to functionally characterise their impact on pre-malignant stem and progenitor cells.
Methods: We performed a screen of cell surface markers (n=244 markers in 7 patients, followed by 7 candidate markers in 18 patients) and cytokine levels (n=38 cytokines, 193 patients) in MPN patient mononuclear cells and peripheral blood serum (and in 12 normal controls). Statistical analyses to identify candidates for disease subtype and/or progression was undertaken. Colony assays were performed in patient samples with and without candidate cytokines.
Results: A cell surface marker screen of 244 antigens identified an increase in the frequency of markers associated with activated T- and NK-cells in myelofibrosis patients. We therefore undertook a screen of inflammatory cytokines in the serum of 193 patients to determine if specific cytokines were driving disease progression. Using multi-plexed cytokine bead arrays (Millipore) with 38 analytes, we identified a range of serum cytokines that displayed differential serum concentration across the MPN subtypes. Higher levels of IL-8, IP-10, IFN-gamma and TNF-alpha all associated with myelofibrosis. Distinct cytokine profiles were also seen for PV and ET, incl. increased EGF in ET and increased TGF-alpha in PV patients. In colony assays, a direct effect on the growth of stem and progenitor cells was observed with IFN-gamma treatment. Single HSCs from ET, PV and MF patients were treated with IFN-gamma, and progenitor expansion was decreased in ET, unaffected in PV and increased in MF. Further analyses are now underway to determine the longitudinal changes in serum cytokines over the course of disease and transformation as well as additional functional data in single stem and progenitor cell assays.
Summary/Conclusions: Together these data implicate the immune microenvironment as a major player in MPN biology with several cytokines showing differential levels across subtypes of MPN.

P293

MESENCHYMAL STROMAL CELLS (MSC) FROM HIGH-GRADE BONE MARROW FIBROSIS PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS (PH-NEG MPN) DISPLAY REDUCED CLONOGENICITY AND PROLIFERATION CAPACITY
B Rambaldi[1,2,*], A Pievani[2], E Diral[2,3], IM Michelozzi[2], L Antolini[4], P Pioltelli[3], A Biondi[5], EM Elli[3], M Serafini[2]
[1]Unit of Blood Disease and Stem Cell Transplantation, University of Brescia, AO Spedali Civili of Brescia, P.le Ospedali Civili 1, 25123, Brescia, [2]Department of Pediatrics, Dulbecco Telethon Institute at Centro Ricerca Tettamanti, University of Milano- Bicocca, [3]Hematology Division, San Gerardo Hospital, University of Milano-Bicocca, [4]Centro di Biostatistica per l'Epidemiologia Clinica, School of Medicine, University of Milano-Bicocca, [5]Department of Pediatrics, Pediatric Hematology-Oncology Department and "Tettamanti" Research Centre, Milano-Bicocca University, "Fondazione MBBM," San Gerardo Hospital, Monza, Italy., Monza, Italy

Background: MSC play an important role in the structure of the bone marrow (BM) niche and regulation of stem cells homeostasis. In Ph-neg MPN, including Polycythemia Vera (PV), Essential Thrombocythemia (ET) and Myelofibrosis (MF), there is a substantial alteration of the BM niche, characterized by massive deposition of fibrous tissue, neoangiogenesis and osteosclerosis, with concomitant loss of the hematopoietic tissue.
Aims: The aim of this work is to study possible alterations in the mesenchymal compartment in Ph-neg MPN in relationship to the BM fibrosis grade.
Methods: MSC were characterized after isolation from BM biopsies of 23 patients with Ph-neg MPN and BM harvests of 6 healthy donors (HD), from washouts of transplant bags, as previously described (Pievani A. *et al.* Cytotherapy. 2014 Jul;16(7):893-905). BM fragments were digested using collagenase

soltion and repeatedly washed with a syringe with 25-Gauge needle using fresh PBS, in order to collect mononuclear cells (MNC). Patients were classified in 3 groups according to diagnosis of Ph-neg MPN and grade of BM fibrosis (WHO criteria): low fibrosis (0-1) no MF (LF-NOMF), low fibrosis MF (LF-MF) and high fibrosis (2-3) MF (HF-MF), respectively formed by 11, 4, and 8 patients. Mutations of JAK2, CALR and MPL genes were present respectively in 65%, 22% and 9% of cases. A triple negativity was documented only in one case (4%).
Results: The median age at the time of cell collection was 54 years (range: 38-77) for the patients and 50.5 years (44-58) for the HD group. A remarkably different number of MNC was harvested from biopsies digestion in different patients groups with a median value of 0.70x10^{6}cells/mm (0.23-2.88) for HF-MF and 2.27x10^{6}cells/mm (1.75-3.18) for LF-MF (p 0.028). LF-NOMF cellularity was 1.44x10^{6}cells/mm (0.40-2.78). No difference was noted between the two group with LF (p 0.131) (Fig.1A). Median value of CFU per 10^2 plated cells was 10.70 (0-14.50) for HF-MF, significantly reduced compared to the other groups: LF-MF 31.50 (11.70-36.30; p 0.042), LF-NOMF 36.70 (9.30-59.70; p 0.0049) and HD 32.50 (25.30-38.00; p 0,0012) (Fig.1B). The proliferation capacity was investigated by the population doubling (PD) assay. The median cumulative PD value at passage 5 for HF-MF was 5.78 (0.43-8.14), significantly reduced compared to other groups: LF-MF 8.31 (5.66-8.42; p 0.05), LF-NOMF 7.83 (5.68-10.26; p 0.0097) and HD 8.71 (6.90-9.46; p 0.014) (Fig.1C). All patient's MSC lines express the typical markers of mesenchymal cells (CD90, CD105, CD73, CD146), similarly to HD. Regarding trilineage differentiation potential, Ph-neg MPN-MSC showed a normal differentiation capacity into adipogenic tissue and the up-regulation of key adipogenic differentiation genes (*FABP4, LPL, PPARG*), with a similar trend compared to HD. In the same patients, MSC were efficiently differentiated into osteogenic lineage with a comparable up-regulation of key osteogenic differentiation genes (*RUNX2, ALPL, COL1A2, SPP1, SPARC, BGLAP*) with respect to the HD group. Ph-neg MPN-MSC were also able to differentiate into cartilagineous pellets, showing an up-regulation of key differentiation genes (*COL2A1, COL10A1, SOX9, ACAN*) similar to HD. No evident differences were observed between the 3 groups of patients. Finally, MSCs were tested for the presence of the respective HSC mutations (JAK2, MPL, CALR) and no one harbored them.

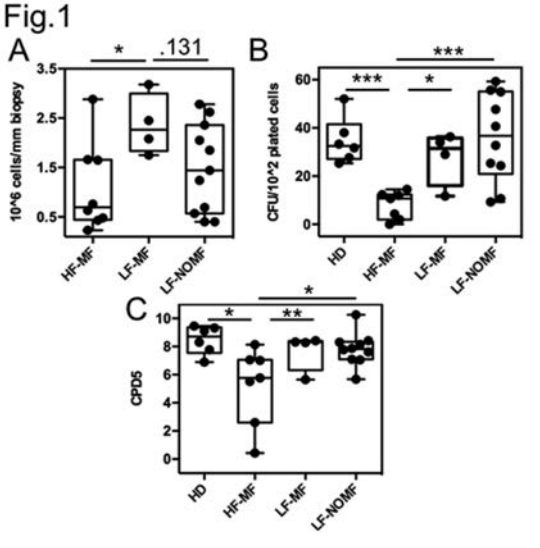

Figure 1.

Summary/Conclusions: Ph-neg MPN-MSC with HF showed a reduced clonogenicity and proliferation capacity compared to the LF groups, independently from the type of disease. These data suggest an alteration of MSC of Ph-neg MPN restricted to the MSC derived from patients who already have a HF in the BM.

P294

NEXT-GENERATION SEQUENCING IDENTIFIES MPL-TET2 MUTATED CLONES IN A SUBSET OF PATIENTS WITH JAK2V617F-POSITIVE MYELOFIBROSIS

S Schulze[1,*], R Stengel[2], N Jaekel[1], SY Wang[1], K Hubert[3], M Roskos[2], M Schneider[2], G Franke[1], D Niederwieser[1], HK Al-Ali[1]
[1]University Hospital of Leipzig, Leipzig, [2]Oncoscreen, Synlab, Jena, [3]University of leipzig, Leipzig, Germany

Background: Phenotype driver mutations (mut.) in *JAK2, CALR*, and *MPL* are present in ~90% of patients (pts) with myelofibrosis (MF). As these mut. are considered mutually exclusive, the diagnostic workup via PCR or melting analysis is limited to analyzing exon 14 of *JAK2*, exon 10 of *MPL*, and exon 9 of *CALR*.

Aims: Next-generation sequencing (NGS) is likely to enter clinical practice in near future. We compared an NGS-based approach to standard PCR techniques in detecting driver mut. in MF.
Methods: Genomic DNA was isolated according to standard procedures from whole-blood samples of 129 pts with MF (68 males; median age 60 y). *JAK2*, *MPL*, and *CALR* mut. analysis via PCR were performed as published. Next, NGS was performed: Coding regions and adjacent intronic sequences of 23 selected genes were amplified by multiplex PCR with a primer panel (692 primer pairs). PCR products were purified and ligated to adapters specific for NGS using the Ion AmpliSeq workflow (Thermo Fisher Scientific). DNA libraries were used for templating the sequencing particles. For sequencing, the semiconductor-sequencing technology of the Ion Torrent PGM sequencing platform (Thermo Fisher Scientific) was used. Sequencing reads were aligned to the human genome (hg19) with the Torrent Suite Software, variants were called using the Torrent Variant Caller, and variant annotation was done with the Ion Reporter Software (Thermo Fisher Scientific) according to the HGVS nomenclature.
Results: Standard PCR detected *JAK2*V617F, *MPL*W515L, and mutated *CALR* in 81 (63%), 1 (0.8%), and 25 (19.4%) pts respectively. One patient (0.8%) harboured both mutated *JAK2* and *CALR*. NGS identified *JAK2* mut. at positions R1063H [exon 24; (n=6)] and R893T [exon 20; (n=1)] in *JAK2*V617F+ pts and in *MPL* at positions W515L ± E335K, E259K, Y591D (n=3), and Y591D (n=2). *TET2* and *ASXL1* mut. were found in 27 (21%) and 25 (19%) pts respectively. None of the pts with *JAK2*R1063H or *JAK2*R893T mut. carried a *TET2* or *ASXL1* mut. *JAK2–TET2* double-mutant cells were present in 16 (12%) pts. Interestingly, 4 of 5 *MPL* mut. were found in the *JAK2–TET2* mutated group and non in the *CALR* mutated or triple negative cohorts. Patients with the *JAK2–MPL-TET2* mut. were older, had a higher *JAK2*V617F allele burden, larger spleens, and a more proliferative disease in terms of WBC and peripheral blasts compared to the *JAK2*V617F+ "only" cohort. Except for age and peripheral blasts, the clinical phenotype of *JAK2–MPL-TET2* and *JAK2–TET2* mutated pts was similar (table).

Table 1. Patients characteristics (n=129).

Variable	*JAK2*V617F+ "only" N=65	*JAK2 -TET2* double mutated N=12	*JAK2-MPL-TET2* triple mutated N=4
Median age (years)	60	64	69
Median *JAK2*V617F allele burden, (%)	77	93	86
Allele burden <50%, (%)	36	17	0
Palpable spleen >5cm, (%)	69	83	75
Median palpable spleen, (cm)	8	12	12
Median WBC x10^9/L	9.3	20	16.5
WBC >25x10^9/L, (%)	17	42	25
Median peripheral blasts, (%)	1	0.5	4
Hb < 100 g/L (%)	37	33	50
DIPSS (Int-2/high-risk), (%)	42/15	33/42	25/25

Summary/Conclusions: With NGS, additional activating mut. such as *MPL*Y591D (a gain of function mut. in exon 12 of *MPL*) could be detected through the inclusion of all coding exons of *JAK2* and *MPL*. Our data provide evidence that driver mutations are not always mutually exclusive as was the case in 4% of pts and imply that combination of mut. could have a specific effect on clinical phenotype. Analysis of larger cohorts will provide accurate estimates of the frequency of concomitant *JAK2* and *MPL* mut. Serial NGS permits the study of the chronology of mut. which might influence the biology of the disease and/or response to therapy.

THE INNATE AND ADAPTIVE IMMUNE SYSTEM IS SIGNIFICANTLY DYSREGULATED IN MYELOFIBROSIS: EVIDENCE OF A CENTRAL ROLE OF MUTATIONAL STATUS

M Romano[1,2], D Sollazzo[2], S Trabanelli[3], N Polverelli[2], M Perricone[2], D Forte[2], F Lapi[2], S Fatica[2], S Luatti[2], M Cavo[2], N Vianelli[2], C Jandus[3], F Palandri[2], L Catani[2,*]
[1]Immunoregulation and immune intervention department, King's College, London, United Kingdom, [2]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Institute of Hematology "L. e A. Seragnoli", Bologna, Italy, [3]Ludwig Center for Cancer Research, Lausanne, Switzerland

Background: Myelofibrosis (MF) is a clonal neoplasia associated with myeloproliferation, extramedullary haematopoiesis and bone marrow fibrosis. MF patients have severely reduced life expectancy, with infectious complications constituting more than 10% of all causes of death. Besides molecular abnormalities (Janus Kinase 2 (JAK2), Calreticulin (CALR) and myeloproliferative leukemia protein (MPL) genes mutations), chronic inflammation has emerged as a key-player in MF pathogenesis and progression. However, thus far, few and incomplete studies focused on the contribution of the innate and adaptive immunity to MF pathogenesis.
Aims: To better understand MF pathogenesis and the mechanisms involved in infectious events, we studied key immune-cells and plasma cytokine levels in MF patients according to their mutational status. We evaluated circulating dendritic cells (DCs) and monocytes, focusing on their DCs differentiation capacity.

DCs promote T cell polarization into different subsets of T-helper cells (Th) responsible for the clearance of intra and extracellular pathogens. For these reasons, we analysed the percentages of Th1, Th2 and Th17 cells; in addition, the role of natural regulatory T cells (Tregs) was investigated. Due to the aberrant cytokine compartment in MF, we also evaluated Innate Lymphoid Cells (ILCs), a novel family of immune effector cells with a critical role in inflammation and immunosurveillance.
Methods: Mutations were monitored using RT-PCR (JAK2 and MPL genes) and exon 9 Next Generation Sequencing approach (CALR gene). Circulating Th1, Th2 and Th17 cells (identified as $CD3^+CD4^+CD45RO^+CXCR3^+CRTH2^-CCR6^-$, $CD3^+CD4^+CD45RO^+CXCR3^-CRTH2^+$ and $CD3^+CD4^+CD161^+CCR6^+$ cells, respectively), myeloid and plasmacytoid DCs (identified as $Lin^-HLA\text{-}DR^+/CD11c^+$ or $CD123^+$ cells, respectively) from 36 untreated patients and 10 healthy subjects were evaluated by flow cytometry. Percentages and function of total Tregs and ILCs (identified as $CD3^+CD4^+CD25^{high}CD127^{neg}$ and Lin^-CD127^+) plus their cognate subpopulations were analysed as well. After immunomagnetic isolation, we tested phenotype of circulating monocytes and their capacity to differentiate into DCs. Cytokines plasma levels were measured by ELISA.
Results: We demonstrated that in MF specific crucial subsets of the immune system show quantitative and/or qualitative abnormalities identifying a mutation-driven immunological signature. Th17, mDCs and Tregs Population II reduction, associated with an increase in ILC1 is specific of JAK2 mutated patients. Alternatively, CALR mutated patients are characterised by increased ILC3 population, diminished Th1 compartment together with reduced monocyte capacity to mature *in vitro* into DCs. Of note, Tregs from CALR mutated patients were less suppressive than the normal counterpart. This may be due to the increased *in vitro* proliferative capacity of responder T cells carrying CALR mutation. Nevertheless, irrespective of mutation status, ILC1 and 2 were hypofunctional. Finally, patients showed a reduced plasma levels of interleukin (IL) -4, -5 and Interferon-γ with concomitant increased levels of IL-1β, -6, -12, -13, -17, and Tumor Necrosis Factor-α.
Summary/Conclusions: This study shows that MF patients are characterized by a mutation-driven state of immunosuppression, with key cellular components of the immune system showing defective number/function. This state of immune deficiency may play a role in disease pathogenesis and explain, in part, the susceptibility of MF patients to infectious complications.

THE H3K4 METHYLTRANSFERASE SETD1B IS ESSENTIAL FOR HAEMATOPOIETIC STEM CELL HOMEOSTASIS IN MICE

K Schmidt[1,*], A Kranz[1], A Tasdogan[2], HJ Fehling[2], F Stewart[1], K Anastassiadis[1]
[1]Biotechnology Center Dresden, Dresden, [2]Institute of Immunology, University Clinics Ulm, Ulm, Germany

Background: Lineage- and cell-specific transcription programs are established and maintained by a complex network of epigenetic modifications. Pertubations of epigenetic regulation are associated with many human diseases such as cancer. All expressed genes are trimethylated at histone 3 lysine 4 (H3K4me3) on promoter nucleosomes. The responsible enzymatic machinery belongs to the trithorax group of proteins and comprises six different enzymes: MLL1, MLL2, MLL3, MLL4, SETD1A and SETD1B. The founding member MLL1 has been identified due to frequent involvement in chromosomal translocations that are commonly found in human 'mixed-lineage leukaemias'. On the other hand, hardly anything is known about the specific roles of the other H3K4 methyltransferases in haematopoiesis.
Aims: The present study specifically addresses the function of Setd1b in the haematopoietic system of the adult mouse. Since the constitutive deletion of Setd1b turned out to be embryonic lethal before E11.5, we generated a conditional knockout mouse strain that relies on the tamoxifen-inducible Rosa26-CreER(T2) technology.
Results: Upon deletion of Setd1b mice progressively weaken, develop splenomegaly and do not survive beyond 30 weeks after tamoxifen treatment. Blood count analysis reveals general cytopenias in knockout mice, however both neutrophil granulocytes and monocytes are significantly increased in peripheral blood. Cytospin preparations and histological stainings further confirm an increased abundance of more immature myeloid cells that infiltrate both bone marrow and splenic tissue. Subsequent flow cytometric analysis of haematopoietic stem and progenitor cells (HSPCs) reveals an increased LSK fraction (Lin^- $Sca\text{-}1^+$ $c\text{-}Kit^+$) and an abnormal ratio among individual stem cell types. One very prominent observation relates to an accumulation of short-term HSCs ($CD34^+$ $Flt3^-$) that are more myeloid-biased based on higher expression of key myeloid transcription factors such as Pu-1. Both *in vivo* - by BrdU incorporation - and *in vitro* - by methylcellulose replating assays - we were able to demonstrate an enhanced self-renewal capacity in Setd1b-deficient HSPCs. Finally, to rule out any putative effects derived from the stem cell niche, we performed bone marrow transplantations and additionally bred our mice to the haematopoietic-specific Vav-Cre deleter. In either case a comparable neoplastic phenotype was generated highlighting the intrinsic requirement of Setd1b in the haematopoietic compartment.
Summary/Conclusions: In conclusion, these findings strongly support an essential function of Setd1b to maintain haematopoietic homeostasis and provide a new model to study epigenetic changes that accompany myeloid malignancies. Given the known role of Mll1 in haematopoiesis, this study further highlights the importance of epigenetic regulation in both steady-state and malignant haematopoiesis. Future investigations will focus on the specific molecular pathways that depend on Setd1b function. In this respect, expression profiling data was recently generated and will be of great use.

Background: STAT5 is a recognized driver of myeloproliferative neoplasms (MPNs), STAT1 is promoting megakaryopoiesis and STAT3 plays dual roles, reducing megakaryopoiesis, but promoting inflammation. No information exists for STAT2 role in MPN.
Aims: To determine the role of STAT2 in MPNs knowing that STAT2 is key for interferon action and is activated also by Tpo.
Methods: We used a combination of *in vivo* models and biochemical studies to determine what is the impact of STAT2 on MPN phenotype induced by JAK2V617F, and on gene expression induced via TpoR.
Results: Here we show that ablation of STAT2 enhances the thrombocytosis phenotype in a knock-in model of JAK2 V617F MPN. Furthermore, we show that STAT2 exerts a negative effects on thrombopoiesis. In addition to STAT5/1/3, Tpo can activate in also STAT2, resulting both STAT1/STAT2/IRF9 complexes, which are hallmarks of type I interferon signaling for anti-proliferative and anti-viral activities and other STAT2-containing complexes. We show that STAT2 activation by Tpo is globally defective in MPN patient platelets. Tpo activated STAT2 induces both common genes with type I interferon via STAT1/STAT2/IRF9, as well as distinct genes that are regulated by STAT2. The gene expression response varies with the amount of expressed JAK2 and STAT2.
Summary/Conclusions: Our results identify a novel regulator of the MPN phenotype and indicate that the cross-talk between Tpo and interferon pathways might be essential for the MPN phenotype. Given than type I interferon is effective in MPNs, we suggest that basal TpoR-mediated induction of STAT2 activity primes stem and progenitor cells for type I interferon action.

Myeloproliferative neoplasms - Clinical 1

Bianchi-Melacrino'-Morelli, Reggio Calabria, Italy, [12]St. Paul's Hospital, University of British Columbia, Vancouver, British Columbia, Canada, [13]Novartis Pharma AG, Basel, Switzerland, [14]Novartis Pharmaceuticals Corporation, East Hanover, United States, [15]Universidade Federal de Goiania, Goiania, Brazil

Background: Ruxolitinib (RUX) is a potent JAK1/JAK2 inhibitor that has shown improvements in splenomegaly and symptoms and prolonged overall survival (OS) in patients (pts) with intermediate (Int)-2– and high-risk MF by the International Prognostic Scoring System (IPSS) in the phase 3 COMFORT studies. JUMP is a phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with IPSS Int-1 MF. Unlike the IPSS, which is used at diagnosis, the Dynamic IPSS (DIPSS) has been validated for use over the disease course and allows for comparisons with other MF populations.
Aims: To assess the safety and efficacy of RUX in pts with DIPSS Int-1 MF (N=700).
Methods: Pts with IPSS high- or Int-2–risk MF, or Int-1 MF and a palpable spleen (≥5 cm) were eligible for JUMP. Starting dose was based on baseline platelet (PLT) count (5 mg bid [≥50 to <100×10^9/L], 15 mg bid [100-200×10^9/L], or 20 mg bid [>200×10^9/L]) and was titrated during treatment. The primary endpoint was safety. OS data were investigated along with Int-1 pts in the DIPSS database who received standard therapy (N=74; Passamonti *Blood* 2010).

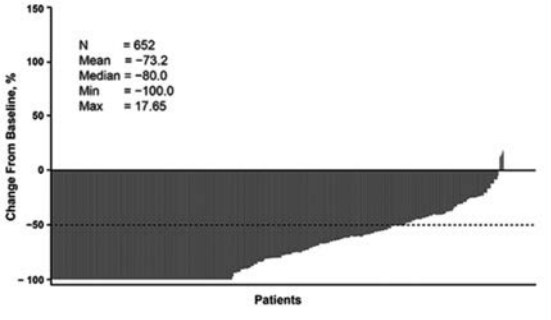

Figure 1. Best percent change from baseline in palpable spleen length at any time by week 72.

Results: JUMP includes 700 Int-1 pts (primary MF, 57%) who started treatment ≥1 y before data cutoff (01 Jan 2015). At baseline, median age was 64 y (range, 18-88); mean spleen length, 13 cm (SD, 6.6); time since diagnosis, 50 mo (SD, 61.4). DIPSS parameters (% of pts): >65 y, 43%; Hb <10 g/dL, 3%; ≥1% peripheral blasts, 19%; constitutional symptoms, 82%; WBC >25×10^9/L, 8%. The majority of pts started at 20 mg bid (n=468) or 15 mg bid (n=190); median exposure, 15.4 mo (range, 0.2-37.5). At time of data cutoff, most pts either remained on treatment (46%) or completed per protocol (27%). Main reasons for treatment discontinuation included adverse events (AEs; 14%) and disease progression (6%). The most common hematologic grade 3/4 AEs were anemia (22%) and thrombocytopenia (10%), which led to discontinuation of treatment in 1% and 2% of pts. Rates of nonhematologic grade 3/4 AEs were low (<2%). Infections (≥5%) included urinary tract infection (all grade, 6% [grade 3/4, 0.7%]), herpes zoster (6% [0.4%]), and nasopharyngitis (5% [0%]). At wk 24, 62% (339/547) of pts had a ≥50% reduction from baseline in spleen length, and 21% (117/547) had 25-50% reductions; rates were similar at wk 48 (68% [276/407] and 19% [78/407]), respectively. Best response in spleen length by wk 72 is shown in the **Figure 1**; 78.5% of pts achieved ≥50% reductions, including 192 (29%) with complete resolution of splenomegaly. Median time to response was 4.7 wk (0.1-75.0), and the estimated probability of maintaining a response was 0.92 (95% CI, 0.89-0.94) at 48 wk. From wk 4 to 48, 40-50% of pts achieved a clinically meaningful response on the FACT-Lym TS (wk 4, 46% [295/641]; wk 48, 44% [171/388]) and FACIT-Fatigue (wk 4, 51% [327/644]; wk 48, 43% [164/382]). The Kaplan-Meier estimated OS probabilities at wk 48 were similar between JUMP (median follow-up, 65 wk) and the DIPSS database (0.98 [95% CI, 0.97-0.99] *vs* 0.987 [0.96-1.00]), as expected in Int-1 pts given the short time period.
Summary/Conclusions: JUMP is the largest study of pts with MF treated with RUX and includes the largest cohort of DIPSS Int-1–risk pts, a risk group not included in the COMFORT studies. Pts with DIPSS Int-1–risk MF achieved spleen size reduction and symptom improvement similar to those seen in pts with Int-1 MF by IPSS and the overall JUMP population. The safety and efficacy of RUX in Int-1 pts in JUMP are consistent with that in the phase 3 COMFORT studies.

P297

PHASE 3 TRIAL TEAM-ET IN 106 HIGH-RISK ESSENTIAL THROMBOCYTHEMIA PATIENTS, DEMONSTRATING NON-INFERIORITY OF ANATHROMB, A NOVEL, EXTENDED-RELEASE ANAGRELIDE FORMULATION, TO THE LICENSED COMPARATOR

Background: Anathromb (AR) is a novel, extended-release formulation of anagrelide hydrochloride (ana), a well-known compound used to selectively normalize platelet counts (plc) by inhibiting megakaryocyte development and maturation in high-risk patients suffering from the myeloproliferative neoplasm Essential Thrombocythemia (ET). Common side-effects of licensed formulations may be largely due to ana and its 3OH-metabolite peak plasma concentrations, whereas efficacy is proportional to AUC. Moreover, licensed formulations need to be dosed twice daily.
Aims: The aim of this study was to demonstrate the non-inferiority of Anathromb in comparison to the licensed comparator in a phase 3, randomized, active-control, double-blind, parallel group non-inferiority setting.
Methods: AR was compared to a commercially available ana formulation, Thromboreductin (TR) in a phase 3, randomized, active-control, double-blind, parallel group non-inferiority trial in high-risk ET patients, either ana-naïve or ana-experienced. After a 6 to 12 weeks titration period, the primary endpoint was the mean plc in the maintenance phase (3 consecutive measurements, centrally assessed, each 2 weeks apart).
Results: 106 patients (91 ana-naïve) were randomized and treated. All patients fulfilled the WHO 2008 diagnostic criteria, the median age was 61, roughly two-thirds were female, and both treatment arms were well balanced. The mean plc at screening was 821 for AR and 797 for TR groups, during the maintenance phase mean plc was 283 for AR and 316 for TR. Thus, both treatments were highly effective in normalizing plc, and the primary endpoint was met formally demonstrating non-inferiority of AR to the licensed TR (p<0,0001). Time from randomization to maintenance phase and number of responders were similar in both treatment arms. Results were consistent between ana-naïve and –experienced patients. Importantly, plc normalization was achieved in three-quarters of patients with a dosing corresponding to 1-2 tablets AR once daily, whereas >90% of the patients required 3 or more capsules TR per day divided in two doses morning and evening. Treatment was well-tolerated, in line with the known side effect profile of ana, the most frequent adverse events were cardiac, CNS and GI disorders. There was no statistically significant difference between the two treatment arms, numerically cardiac disorders occurred less frequently in the AR arm, whereas the opposite trend was observed for CNS and GI. Evaluation of potential differences between AR and TR regarding tolerability requires additional studies with more patients and longer exposure.
Summary/Conclusions: In summary, the novel extended-release formulation AR was well tolerated and equally effective as the licensed comparator TR in

normalizing plc. AR provides a more convenient once-daily dosing schedule and may offer an alternative to licensed immediate-release ana formulations in particular for patients not well tolerating ana side effects.

P298

CLINICAL IMPACT OF ONCOGENETIC PROFILES IN SYSTEMIC MASTOCYTOSIS WITH AN ASSOCIATED HEMATOLOGICAL NON-MAST CELL DISEASE

C Fernandez[1,*], C Teodosio[2], S Matarraz[3], A López[3], M Jara-Acevedo[3], A Mayado[3], I Álvarez-Twose[4], L Sánchez-Muñoz[4], A García-Montero[3], ML Gutierrez[3], L Escribano[4], A Orfao[3]
[1]Flow Cytometry Core, University of Salamanca, Salamanca, Spain, [2]Leiden University Medical Center, Leiden, Netherlands, [3]University of Salamanca, Salamanca, [4]Instituto de Estudios de Mastocitosis de Castilla La Mancha, Hospital Virgen del Valle, Toledo, Spain

Background: In a substantial fraction of systemic mastocytosis (SM) patients, SM coexists with an associated clonal hematological non-mast cell (MC) lineage disease (AHNMD). Most SM-AHNMD patients carry *KIT* mutations and AHNMD-associated genetic alterations; however, there is limited information about the frequency and clinical impact of the coexistence of both types of genetic/molecular alterations in distinct bone marrow (BM) cell compartments.
Aims: we report on the clinic-biological, immunophenotypic, genetic and prognostic features of 65 SM-AHNMD patients classified into three different ontogenetic groups based on the pattern of involvement of BM MC, AHNMD tumor cells and other residual BM cells, by both the KIT mutation and AHNMD-associated cytogenetic/molecular alterations
Methods: Here we studied 65 SM-AHNMD patients grouped into SM-AHNMD cases with: i) unrelated genetic alterations; ii) shared KIT mutation in BM MC and AHNMD tumor cells, in the absence of AHNMD-associated genetic alterations in BM MC, and; iii) shared AHNMD-associated genetic alterations. Cell Purification. Purification of specific BM cell populations was performed using a FACSAria flow cytometer (BD). Interphase fluorescence *in situ* hybridization (iFISH) and human androgen receptor assay (HUMARA) studies. iFISH studies aimed at detection of t(9;22), t(8;21), inv(16), 11q abnormalities, -5/del(5q), -7/del(7q), del(20q), trisomy 8, nulisomy Y, trisomy 12, del(17p13.1), del(13q14), t(14q32), t(18q21), t(11;14), t(3q27) and del(6q21) were performed on interphase nuclei from different FACS-purified and methanol/acetic fixed 3/1 (v/v) cell populations. KIT mutational analysis. The KIT D816V mutation was assessed in genomic DNA from FACS-purified cell populations, using a previously described polymerase chain reaction and peptide nucleic acid-clamping technique.

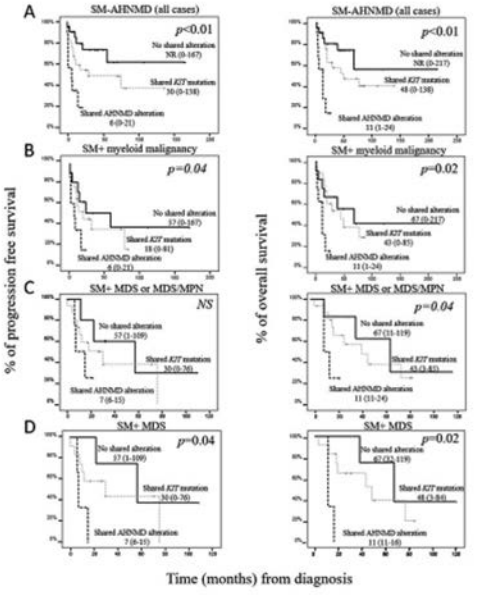

Figure 1.

Results: Overall, patients with shared AHNMD-associated genetic alterations showed a significantly poorer progression-free survival (PFS) and overall survival (OS) *vs* the other two groups (p<0.01). In addition, the pattern of involvement of BM cell compartments other than MC by the *KIT* mutation and the subtypes of SM and AHNMD, were also relevant prognostic factors in the univariate analysis (p<0.01). Multivariate analysis confirmed that the best combination of independent prognostic factors for OS and PFS were the pattern of involvement of BM cells by the *KIT* mutation (p<0.001 and p<0.01, respectively) and the oncogenetic subgroup of AHNMD (p=0.02 and p<0.01, respectively) together or not with the type of AHNMD (HR, 27.9; p<0.001), respectively.

Summary/Conclusions: Overall, patients with shared AHNMD-associated genetic alterations showed a significantly poorer progression-free survival (PFS) and overall survival (OS) *vs* the other two groups (p<0.01). In addition, the pattern of involvement of BM cell compartments other than MC by the KIT mutation and the subtypes of SM and AHNMD, were also relevant prognostic factors in the univariate analysis (p<0.01). Multivariate analysis confirmed that the best combination of independent prognostic factors for OS and PFS were the pattern of involvement of BM cells by the KIT mutation (p<0.001 and p<0.01, respectively) and the oncogenetic subgroup of AHNMD (p=0.02 and p<0.01, respectively) together or not with the type of AHNMD (HR, 27.9; p<0.001), respectively. SM-AHNMD patients show different oncogenetic profiles with an impact on disease outcome. Coexistence of the KIT mutation and AHNMD-associated genetic markers in BM MC andAHNMD cells is an adverse prognostic factor in SM-ANMD.

Background: Myelofibrosis (MF) is a clonal myeloproliferative neoplasm characterized by the presence of *JAK2 V617F* and *MPL* mutation in 65% and 10% of cases, respectively. *CALR* mutations have been described recently in most cases of *JAK2*-/*MPL*- myelofibrosis. In the last years other gene mutations have been identified, some of them with a probably prognostic value.
Aims: Investigate the frequency and clinical significance of mutations determined by massive sequencing (NGS) in patients with MF.
Methods: We retrospectively studied 155 patients diagnosed with primary MF (PMF) (n=98, 63%) or secundary MF: post-ET MF (n=29, 19%) or post-PV MF (n=28, 18%), according to the WHO 2008 (see table "clinical characteristics"). Sequencing was performed on a MiSeq NGS (Illumina) system using a panel of 99 genes previously related to myeloid malignancies. Sequencing results were analyzed by using the VariantStudio software package (Illumina), the threshold for mutation calling was set to 5%.

Table 1.

CLINICAL CHARACTERISTICS (N=155)	N (%)	Median (ratio)
Median age at diagnosis (years)		71 (30-87)
Sex:		
- Male	103 (66.5%)	
- Female	52 (33.5%)	
Diagnosis:		
- PMF	98 (63.2%)	
- post-ET MF	29 (18.7%)	
- post-PV MF	28 (18.1%)	
Median time between ET/PV and MF development (years)		10.6 (1.2-31.2)
IPSS:		
- Low/Int-1	60 (38.7%)	
- Int-2/High	95 (61.3%)	
DIPSS-plus:		
- Low/Int-1	54 (34.8%)	
- Int-2/High	101 (65.2%)	
Cytogenetic abnormalities	29 (18.7%)	
AlloHCT	10 (6.5%)	
AML transformation	22 (14.2%)	
Median time between AML and MF diagnosis (months)		30 (3-154)
Death	79 (51%)	
Causes of death (N=77):		
- MF progression	22 (28.6%)	
- AML transformation	20 (26%)	
- Infection	15 (19.5%)	
- Haemorrhage	4 (5.2%)	
- Thromboembolic events	1 (1.3%)	
- Others	15 (19.5%)	

Results: We found mutations in 153 patients (98.7%). A total of 465 gene variations were detected in 64 different genes. The median number of mutated genes by case was 3 (1-10). *JAK2 V617F* mutation was present in 98 patients (63.2%), *CALR* in 25 (16.1%) and *MPL* in 13 (8.4%), with 19 triple negative cases (12.3%). The most prevalent mutated genes were: *JAK2*, *ASXL1* (n=38, 24.5%), *TET2* (n=35, 22.6%), *CALR*, *SRSF2* (n=20, 12.9%), *RUNX1* and *U2AF1* (n=15, 9.7%), *MPL*, *DNMT3A* (n=11, 7.1%), *TP53* (n=10, 6.5%), *KMT2D*, *PTPN11* and *EZH2* (n=9, 5.8%), and *SETBP1* (n=8, 5.2%). Only 5 cases (3.2%) showed *IDH1* mutations while *IDH2* was mutated in 3 patients

(1.9%). The mutation profile was similar in PMF and post-ET/PV MF. We observed relationship between LMA transformation and mutation in *EZH2* (p=0.007), *IDH1* (p=0.003), *SF3B1* (p=0.026), *TET2* (p=0.026) and *CDH13* (p=0.010). In the multivariate analysis, only *EZH2* (p=0.008 [1.72-37.44]) and *IDH1* mutations (p=0.008 [2.01-114.93]) remained statistically significant. The 3-years overall survival (OS) was 68.5% with a median follow-up of 37 months (1.6-219.4). The presence of int-2/high risk IPPS was associated with a shorter OS (p=0.000). Moreover, ≥4 mutated genes by case was also related to a worse outcome (median OS: 39 *vs* 83 months) (p=0.005). Mutations associated to a bad prognosis such as *ASXL1*, *SRSF2*, *EZH2*, *IDH1* and *IDH2* (n=58, 37.4%) showed a shorter OS (p=0.000). In contrast, *CALR* mutated cases had a better outcome (median OS: 147 *vs* 52 months) (p=0.001). In addition, a shorter OS was observed in patients showing mutations in *U2AF1* (p=0.004), *TP53* (p=0.029), *SETBP1* (p=0.000), *PHF6* (p=0.015) and *ETV6* (p=0.000). However, the presence of *DNMT3A* mutations showed a trend of a long OS (p=0.049). In the multivariate analysis, the variables showing a worse prognosis in terms of OS were: int-2/high risk IPSS (p=0.000, HR 3.53 [2.02-6.16]), mutations in *ASXL1*, *SRSF2*, *EZH2*, *IDH1* and *IDH2* (p=0.003, HR 2.12 [1.28-3.49]), *TP53* mutation (p=0.022, HR 3.1 [1.18-8.19]), and *SETBP1* mutation (p=0.014, HR 3.34 [1.27-8.72]); while the presence of *CALR* (p=0.015, HR 0.33 [0.13-0.81]) or *DNMT3A* mutations (p=0.019, HR 0.22 [0.06-0.77]) were associated to a better outcome.

Summary/Conclusions: The presence of mutations in *ASXL1*, *SRSF2*, *EZH2*, *IDH1, IDH2, TP53* and *SETBP1* is associated to a bad prognosis in MF. By contrast, *CALR* and *DNMT3A* mutated cases have a better outcome. There is a relationship between LMA transformation and mutation in *EZH2* and *IDH1*. The use of NGS should be explored in addition to characterization of MF prognosis.

P300

PHASE II STUDY OF LCL161, A SMAC MIMETIC, IN PATIENTS WITH PRIMARY MYELOFIBROSIS (PMF), POST-POLYCYTHEMIA VERA MYELOFIBROSIS (POST-PV MF) OR POST-ESSENTIAL THROMBOCYTOSIS MYELOFIBROSIS (POST-ET MF

N Pemmaraju*, H Kantarjian, J Cortes, T Kadia, C DiNardo, Z Estrov, S Pierce, L Zhou, K Salinas, C Tuttle, PY Mak, BZ Carter, S Verstovsek
Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: There is no standard therapy for patients (pts) with intermediate (int)-2 or high risk myelofibrosis (MF) who have failed or are intolerant to Janus kinase (JAK) inhibitors such as ruxolitinib. Second mitochondria-derived activator of caspases (Smac) mimetics, also known as, inhibitors of apoptosis (IAP) antagonists, lead to increased apoptotic cancer cell death, especially in high TNFα-expressing tumor models.
Aims: Primary objective: to determine efficacy (IWG-MRT, 2013) of LCL161 as monotherapy for pts with MF. Secondary objectives: to determine safety, durability of response, and change in symptom burden [Myeloproliferative Neoplasm (MPN)-Total Symptom Score (TSS)]. Exploratory objectives: to assess *JAK2*V617F and *CALR* allele burden; 28-gene panel for molecular mutations via next-generation sequencing; and LCL161 target inhibition.
Methods: We conducted an investigator-initiated, single-center, phase II study of LCL161 for pts with MF in a Simon's Optimal two-stage design. Pts age ≥18, PS=0-2, int-2 to high risk MF, who were intolerant to, ineligible for, or relapsed/refractory to JAK inhibitors were eligible. There was no threshold requirement for spleen size or platelet (plt) count, and pts with prior allogeneic stem cell transplant (SCT) were eligible. LCL161, an oral (po) drug, was given at starting dose 1500mg po once weekly. Each cycle=28 days. After 3 cycles, bone marrow exam and objective response assessments were performed.

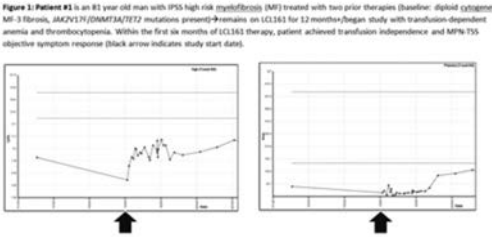

Figure 1.

Results: From January 2015 to January 2016, 13 pts have been enrolled. Baseline pt characteristics are listed in Table 1. *JAK2*V617F mutations were present in 7(54%), *CALR* mutations in 3(23%), and *MPLW*515L mutation in 1(8%) pt. Additionally, the most common other molecular mutations were: *DNMT3A*(n=2); *TET2*(n=2); *RAS*(n=2); *EZH2*(n=1). 10(77%) had ≥2 prior therapies. 2 pts had prior SCT. By IPSS, 11(85%) were high risk MF; 2(15%) were int-2. Median number of cycles received=5[1-13], median treatment duration=4.4 months (mos)[1-11.8]. All 13 pts are alive, with median follow-up of 4.7 mos[1-11.8]. 4 pts had 5 objective responses (1 pt: 2 separate IWG-MRT responses, Figure 1): Clinical improvement (CI) (anemia) in 2 pts; CI (Symptom) in 2 pts; CI (Spleen) in 1 pt. Grade 3/4 non-hematologic adverse events: syncope, n=2. No pts had cytokine release syndrome. Most common grade 1/2 non-hematologic toxicities: fatigue (n=7), nausea (n=6), dizziness/vertigo (n=3). Dose reductions: 6 pts, all to dose -1 level (1200 mg po once weekly); most common reason: grade 2 fatigue (n=5). 7 pts are now off study [n=3 pt request; n=2 progression of MF; n=1 progression to extramedullary AML (74 year old pt with high risk MF, 4 prior therapies, and prior SCT); n=1 proceeded to SCT]. Preliminary, ongoing correlative studies demonstrate significant on-target inhibition (by Western blot) of CIAP1 in 3/3 responding pts with available samples.

Table 1.

Table 1: Baseline Patient Characteristics

Patient Characteristic (N=13)	[Range] (%)
Age, median	74 [58-81]
ECOG Performance Status (PS)	
PS=1	11(85)
PS=2	2(15)
Median Baseline CBC	
Hemoglobin (g/dL)	9[6.3-11.4]
WBC (K/uL)	5[1.1-19]
Platelets (K/uL)	36[6-1365]
Spleen size (n=5), cm	12 [4-20]
Molecular mutations	
JAK2V617F	7 (54)
CALR	3 (23)
MPLW515L	1(8)
Prior treatment history	
Prior treatment, ≥2	10(77)
Prior JAK inhibitor	8 (62)
Prior IMID (Thalidomide, Lenalidomide, or Pomalidomide)	4(31)
Prior allogeneic stem cell transplant (SCT)	2(15)
IPSS (baseline)	
Intermediate-2	2 (15)
High risk	11 (85)

Summary/Conclusions: In this study, in an older group of pts with MF, 85% IPSS high risk, with median plt count of 36 at study entry, in whom 77% had received ≥2 prior therapies, we observed 5 objective responses in 4 pts among the first 13 pts enrolled. LCL161 has a convenient (po, weekly) dosing schedule, represents a novel target for pts with MPNs, and is able to be administered to pts who have failed or intolerant/ineligible for JAK inhibitor therapy. This study has met criteria for the pre-planned analysis for efficacy (Simon Stage 1) and therefore is able to proceed to Simon Stage 2. This clinical trial is registered at www.clinicaltrials.gov/ct2/show/NCT02098161.

Background: Hematocrit control below 45% is associated with a lower rate of thrombosis in polycythemia vera (PV).
Aims: To assess if patients treated with hydroxyurea plus phlebotomies have the same risk of thrombosis than those controlled with hydroxyurea alone.
Methods: The Spanish Registry of Polycythemia Vera is a live ambispective study including, by February 2016, 1353 patients in which baseline characteristics, therapies and complications during follow-up are periodically updated. From this cohort, a total of 533 patients treated with hydroxyurea were selected for the present study. Data from the first 60 months of therapy with hydroxyurea were retrospectively recovered including Hematocrit, WBC, platelet count and number of phlebotomies. Hematocrit response was defined as a hematocrit <45% (with or without phlebotomy requirement) and complete hematological response (CHR) as the presence of hematocrit <45%, WBC <10x10^9/L and platelet count <400x10^9/L. Hematocrit response and CHR were assessed at months 6, 12, 18, 24, 36, 48 and 60. Sustained response was defined as a response lasting more than 50% of follow-up. Intermittent response was defined as a response lasting less than 50% of follow-up. Phlebotomy requirement during the time of study was recorded. Patients requiring ≥4 phlebotomies per year while they received therapy with Hu were categorized as phlebotomy dependent.
Results: Median follow-up was 36 months (range: 6-60). One or more phlebotomies were performed in 304 (57%) patients, 24% of patients were phlebotomy dependent. Hematocrit response and CHR was more frequently achieved in patients without phlebotomy dependency. Hydroxyurea dose was

similar among both groups of patients. A total of 36 thrombotic events (22 arterial, 14 venous) were recorded resulting in a 3 and 5-year probability of thrombosis of 6.9% and 11%, respectively. Phlebotomy dependent patients showed a higher rate of thrombosis than the reminder (19.3% *versus* 4.4% at 3 years, p<0.0001). Adjusting phlebotomy requirement by response in the hematocrit showed a higher risk of thrombosis for phlebotomy dependent patients (HR: 3.9, 95%CI: 1.9-8.1, p<0.0001) whereas sustained hematocrit response did not (HR: 0.98, 95%CI: 0.5-1.98, p=0.9). Multivariate analysis including sex, cardiovascular risk factors, thrombosis at PV diagnosis and need for phlebotomies showed a higher risk of thrombosis in phlebotomy dependent patients (HR: 3.5, 95%CI: 1.7-6.9, p<0.0001) whereas time in hematocrit response or in CHR were not associated with a lower risk of thrombosis. Twenty five bleeding events (6 major, 19 minor) were registered resulting in a 3- and 5-year probability of 4.4% and 7.2%, respectively. The 3-year probability of bleeding was higher in phlebotomy dependent patients than in the remainder (10% *versus* 3.2%, respectively, p=0.01). In multivariate analysis, dependency for phlebotomies showed a higher risk of bleeding (HR: 2.6 95%CI: 1.1-5.9, p=0.028) after adjusting for age and treatment with antiplatelet agents and oral anticoagulants.

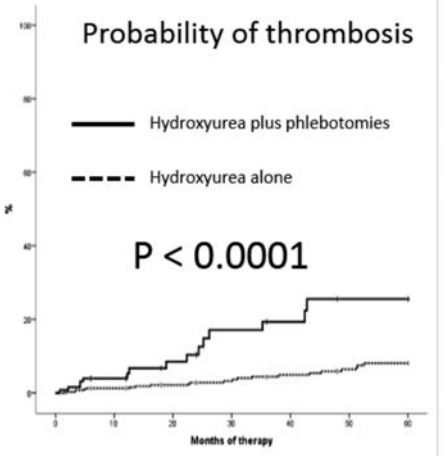

Figure 1.

Summary/Conclusions: Patients treated with Hu who remain dependent on phlebotomies have a higher risk of thrombosis and bleeding than those controlled with Hu alone.

P302

RATE OF MALIGNANT TRANSFORMATION IN HIGH RISK ET DURING 5 YEARS OF FOLLOW-UP OF CYTOREDUCTIVE THERAPY

G Birgegård[1,*], Y Folkvaljon[2], H Garmo[2], C Besses[3], M Griesshammer[4], L Gugliotta[5], C Harrison[6], M Hamdani[7], J Wu[7], H Achenbach[8], JJ Kiladjian[9]
[1]Department of Haematology, Uppsala University, [2]Regional Cancer Centre, Uppsala, Sweden, [3]Department of Haematology, Hospital del Mar-IMIM, Barcelona, Spain, [4]Hematology and Oncology, Johannes Wesling Medical Center, Minden, Germany, [5]Department of Haematology, 'L e A Seragnoli', St Orsola-Malpighi Hospital, Bologna, Italy, [6]Department of Haematology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [7]Global Biometrics, Shire Pharmaceuticals, Lexington, United States, [8]Research & Development, Shire GmbH, Zug, Switzerland, [9]APHP, Hôpital Saint-Louis, Centre d'Investigations Cliniques, Paris, France

Background: First line therapy for essential thrombocythemia (ET), hydroxycarbamide (HC), has mutagenic properties and there is a concern for possible leukemogenicity. The issue has not been conclusively settled in previous studies.
Aims: To assess risk of acute leukemia and non-hematological malignancies in patients treated with HC or anagrelide (ANA) in the EXELS study.
Methods: EXELS, a prospective 5-year study, recruited 3649 high risk ET patients, on or needing cytoreductive therapy, given at the discretion of the treating physician. Previous exposure to ANA and HC was based on patient history. All subjects were followed until death or end of study. Risk of acute leukemia (AL) after study enrolment was estimated by the cumulative incidence. Disease progression may be confounding, influencing therapy choice, so a minimum exposure time of 6 months was used to account for this. The relative risk of AL transformation and non-hematologic malignancies was estimated as age-, gender- and country- standardized incidence ratios (SIRs) with 95% confidence intervals based on background cancer incidence in enrolling European countries. The relative risk ratio of AL for HC *vs* ANA was assessed using the ratio of SIRs. To estimate a 95% confidence interval around this, non-parametric bootstrapping with 10,000 samples was used.
Results: At registration, 481 patients had ANA treatment, 2305 had HC and 656 had been exposed to a combination of the two. Together these treatments included 94% of the patients. The median age in patients on ANA was 51 years, in the HC group 71 years. The SIR for all malignancies was close to 1 for all groups (table 1), indicating no increased risk for ET patients. In skin cancer, the SIR for patients on HC was higher than expected (1.14) and higher than for patients on ANA and patients with neither(1.15 *vs* 0.41 and 0.50). Due to the low number of events, the CIs were wide, and no statistically significant differences could be shown (table 1). A total of 67 cases of AL and 19 cases of myelodysplastic syndrome (MDS) were observed. With a minimum exposure time of 6 months, 62 cases of AL indicated a markedly increased risk for ET patients compared with a normal population, with high SIRs for all groups (table 1). Due to the low number of cases in the ANA group the CIs were wide and no statistically significant difference could be seen for HC *vs* ANA (table 1). Assessing the ratio of SIRs for HU and ANA did not reveal any significant differences; RR 0.91, 95% CI 0.52-3.27.

Table 1. Relative risks in each treatment category, as standardized incidence ratios (SIR) with 95% confidence intervals (CI), using a lag time of 180 days for exposure.

	Observed	Expected	Person-years	SIR	95% CI
Acute myeloid leukemia (ICD code C92.0)					
ET without hydroxycarbamide/anagrelide	3	0.16	1956	18.6	(3.74-54.4)
ET with hydroxycarbamide	42	0.88	8265	47.7	(34.4-64.5)
ET with anagrelide	5	0.10	2091	52.3	(16.9-122)
ET with hydroxycarbamide and then anagrelide	10	0.13	1711	77.2	(37-142)
ET with anagrelide and then hydroxycarbamide	2	0.03	582	58.2	(6.53-210)
Skin cancer (ICD code C43-44)					
ET without hydroxycarbamide/anagrelide	2	4.04	1956	0.50	(0.06-1.79)
ET with hydroxycarbamide	25	21.8	8265	1.15	(0.74-1.69)

ET with anagrelide and then hydroxycarbamide	6	6.41	579	0.94	(0.34-2.04)

Summary/Conclusions: EXELS data enables a comparison of malignant transformation with treatments for ET. We previously showed that the AL event rate per 100 years of exposure for ANA was 0.07 compared with 0.28 for other cytoreductive treatment, and transformation to MDS only occurred in the HC group (event rate 0.12) Higher event rates for other malignancies were also shown (Birgegård et al). However, the age difference between treatment groups was large. This difference was accounted for in this study by estimating SIRs using country-specific cancer registry data. For non-hematologic malignancies the SIRs were close to 1, indicating no increased risk for any group. An increased risk of AL was seen for all patients. Most AL occurred in patients on HC, but likely due to a low event number there was no statistically significant difference between HC and ANA. The concern over risk of leukemia and skin cancer due to HC remains but could not be substantiated, probably due to the low number of events within the time frame of the study. There was no increased risk of other malignancies.

MIDOSTAURIN (PKC412) IN INDOLENT SYSTEMIC MASTOCYTOSIS: A PHASE 2 TRIAL

B Van Anrooij[1,*], J Oude Elberink[1], L Span[2], J de Monchy[1], S Rosati[3], A Mulder[4], J Kluin-Nelemans[2]
[1]Allergology, [2]Hematology, [3]Pathology, [4]Laboratory Medicine, University Medical Centre Groningen, Groningen, Netherlands

Background: Indolent systemic mastocytosis (ISM) is characterized by mast cell infiltration of several organs, notably the skin and bone marrow, without evidence of organ dysfunction. Although ISM patients have a near normal life expectancy, in some the disease is associated with severe mediator-related symptoms such as anaphylaxis, fatigue, flushing, pruritus, osteoporosis and depression. The activating mutations (typically *KIT*D816V) in the cKIT receptor of mast cells hinder inhibition by most tyrosine kinase inhibitors. Midostaurin, a multiproteinase inhibitor that inhibits the tyrosine kinase activity of *KIT*D816V, showed in a large phase II trial impressive activity in patients with aggressive mastocytosis (Blood 2014;124, abstract 636). The drug appeared safe and showed rapid symptom reduction.
Aims: Because of this, we felt justified to investigate the potential therapeutic effect of Midostaurin on symptom severity, quality of life and mast cell burden in ISM patients.
Methods: In this investigator-initiated single center phase II study 20 patients with *KIT*D816V$^+$ ISM, elevated tryptase levels, and severe refractory symptoms were enrolled after written informed consent. They received oral Midostaurin 100 mg twice daily for 24 weeks with the option for continuation after a 2 month wash-out period. Midostaurin was supplied by Novartis Pharmaceutical Cor-

poration, which offered additional financial support. The primary endpoint was symptom response, defined as a reduction in the Mastocytosis Symptom Assessment Form (MSAF) sumscore at week 12. Secondary endpoints were improvements at week 12 and 24 of skin and bone marrow mast cell infiltration, serum tryptase levels, and disease-related quality of life. Study recruitment is closed; patient treatment and follow-up are ongoing. The study is registered with Clinical Trials.gov, NCT01920204.

Results: Three patients dropped out due to adverse events (all nausea) before week 12. Analysis is based on intention-to-treat. At week twelve 16 (80%) patients had significant median 35% (p=0.002; IQR: 16% - 56%%) reduction in symptom severity that further improved to an average 38% reduction at week 24 and was accompanied by a significant median 25% (p=0.001, IQR 12% - 47%) improvement of disease related quality of life. After 4 weeks all patients showed a statistically significant (P<0.000) reduction in tryptase levels (from 36.0 to 15.5 ug/l, P<0.001) that remained stably reduced for all but 1 patient throughout the study. At 24 weeks, 8 out of 16 histologically assessable bone marrow biopsies showed a reduction in mast cell infiltration, 2 an increase and 6 no change. Urticaria pigmentosa improved in 12 (80%) of the 15 patients with skin symptoms with the strongest reduction seen in the intensity of lesions. Grade 1-2 adverse events were reported by all patients; the most common being nausea (n=14), diarrhea (n=11) and headache (n=9). There was one SAE deemed to be probably not treatment related and 3 grade 3-4 adverse events (anaphylaxis, syncope and elevated AST). Notably, there were no hematological adverse events. After stopping of the drug at week 24 according to protocol, 16 patients showed a rapid relapse of symptoms objectified by an increase in tryptase levels. From them, 10 patients strongly favored restarting of Midostaurin.

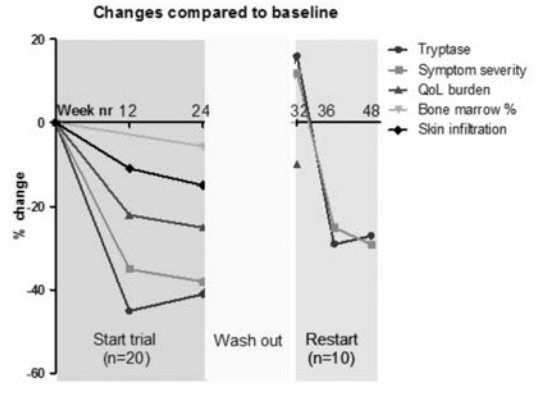

Figure 1.

Summary/Conclusions: In conclusion, Midostaurin is effective in symptom-reduction and even mast cell infiltration in patients with indolent mastocytosis. Despite side effects, most patients favor continuation of the drug.

LB304

RUXOLITINIB COMPARED WITH BEST AVAILABLE THERAPY FOR ESSENTIAL THROMBOCYTHAEMIA PATIENTS RESISTANT OR INTOLERANT TO HYDROXYCARBAMIDE IN MAJIC - AN INVESTIGATOR LEAD RANDOMIZED TRIAL

C Harrison[1,*], A Mead[2], A Panchal[3], S Fox[3], C Yap[3], A Houlton[4], S Aliman[1], M Wood[5], F Chen[6], J Coppell[7], N Panoskaltsis[8], R Scherber[9], H Geyer[10], A Dueck[11], R Mesa[12], MF McMullin[13]

[1]Guy's and St Thomas' NHS Foundation Trust, London, [2]Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, [3]Cancer Research UK Clinical Trials Unit, [4]Cancer Research UK Clincal Trials Unit, University of Birmingham, Birmingham, [5]Colchester Hospital University NHS Foundation Trust, Colchester, [6]Centre for Clinical Haematology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, [7]Royal Devon and Exeter NHS Foundation Trust, Exeter, [8]Department of Haematology, London North West Healthcare NHS Trust, London, United Kingdom, [9]Department of Hematology and Oncology, Oregon Health and Sciences University, Portland, [10]Division of Hospital Medicine, [11]Section of Biostatistics, [12]Division of Hematology and Medical Oncology, Mayo Clinic, Scottsdale, United States, [13]Centre for Cancer Research and Cell Biology, Queen's University, Belfast, United Kingdom

Background: Ruxolitinib (RUX), a Janus kinase (JAK) 1 & 2 inhibitor has significant clinical benefits in myelofibrosis (MF) & those patients with polycythaemia vera whom are resistant or intolerant to Hydroxycarbamide (HC). We conducted a randomized, phase II, trial of RUX *vs* Best Available Therapy (BAT) in patients with essential thrombocythemia (ET) who were resistant or intolerant to HC.

Aims: To evaluate the activity & safety of RUX treatment of patients with ET who met modified European LeukaemiaNet (ELN) criteria for resistance or intolerance to HC. The primary end-point was rate of achievement of complete hematological response within 1 year (according to ELN guidelines); secondary endpoints included partial hematological response, safety, thrombosis, hemorrhage, transformation (adjudicated by central review), as well as symptom & quality of life assessment.

Methods: Patients with ET were recruited over 30 months (2012-2015), stratified by JAK2V617F status & randomized to receive 25mg bd of RUX or BAT. Post-ET MF was excluded at trial entry. Patients eligible for the modified intention to treat (mITT) analysis were those who commenced study treatment & received at least one response assessment. Patient reported outcome & quality of life were assessed using EQ5D, MDASI & MPN Symptom Assessment Form (MPN10). Symptom response was defined as ≥ 50% reduction in MPN10 total symptom score (TSS) & compared between arms using a linear mixed model of post-baseline scores through month 12 adjusting for baseline.

Results: Overall 116 patients were recruited, 110 were eligible for mITT analysis, 58 (52%) & 52 (48%) in RUX & BAT arms respectively, comprising 44 males, 66 females, mean age 64.2ys, who were resistant (24.5%), intolerant (51.8%) or both (22.7%) to HC. Baseline characteristics at randomization were balanced, (Table 1). The primary end point was achieved in 27 (46.6%) of the patients in the RUX arm *vs* 23 (44.2%) in the BAT arm (p= 0.81). Partial response occurred in 26 (44.8%) & 27 (51.9%) of those treated with RUX & BAT respectively. The median dose of RUX received was 15mg bd, & median follow-up at this analysis was 1.8 years. No new pattern of safety events for RUX was noted: grade 3 or 4 anemia occurred in 19% and 0% of RUX patients *vs* 0% in the BAT arm, grade 3 or 4 thrombocytopenia in 5.2% & 1.7% of RUX *vs* 0% of BAT patients respectively, & grade 3 and 4 infections occurred in 10.3% of patients in the RUX arm compared to 3.6% in the BAT arm. Overall 2 patients discontinued for anemia & none discontinued for thrombocytopenia. In RUX treated patients, thrombotic or hemorrhagic events were experienced by 9 patients (10 events) & 1 patient respectively *vs* 5 thrombotic and 5 hemorrhagic events in BAT patients (adjusted following central review). Transformations to post-ET MF occurred in 8 RUX *vs* 3 BAT treated patients, 1 RUX patient developed acute myeloid leukemia. There were 2 patient deaths in each arm, due to 1 each of multiple organ failure, cerebral hemorrhage in the BAT arm, bowel infarction due to adhesions, & ischemic cardiomyopathy in the RUX arm. Mean MPN-10 TSS for early satiety, itching, & weight loss during the first 12 months were all significantly lower for RUX *vs* BAT (all p<0.05).

Table 1. Baseline characteristics for ET patients.

Characteristics		BAT (52)	RUX (58)	Overall (110)
Age (years)	Median (SD)	65.6 (13.5)	62.9 (12.3)	64.2 (12.9)
	Range	37.2-85.4	34.5-90.5	34.5-90.5
Gender (%)	Female	30 (57.7)	36 (62.1)	66 (60)
	Male	22 (42.3)	22 (37.9)	44 (40)
JAK2V617F (%)	Negative	26 (50)	30 (51.7)	56 (50.9)
	Positive	26 (50)	28 (48.3)	54 (49.1)
Resistant*/Intolerant	Resistant	24 (46.2)	28 (48.3)	52 (47.3)
* Patients with both classed as resistant	Intolerant	57 (51.9)	30 (51.7)	57 (51.8)
	Missing	1 (1.9)	0 (0)	1 (0.9)
Time from diagnosis years	Mean (SD)	6.9 (5.9)	10.4 (6.7)	8.8 (6.5)
Prior thrombosis (%)	Yes	18 (34.6)	17 (29.3)	35 (31.8)
Prior hemorrhage (%)	Yes	4 (7.7)	2 (3.4)	6 (5.5)
Known diabetes (%)	Yes	4 (7.7)	6 (10.3)	10 (9.1)
Known hypertension (%)	Yes	19 (36.5)	23 (39.7)	42 (38.2)
Known angina (%)	Yes	3 (5.8)	0 (0)	3 (2.7)
Blood count				
Hemoglobin (g/L)	Mean (SD) Range	126 (17) 90-160	119 (17) 87-152	122 (17) 87-160
Hematocrit	Mean (SD) Range	.38 (.051) .27-.49	.36 (.051) .27-.46	.37 (.051) .27-.49
White blood cell count (x 10^9/L)	Mean (SD) Range	6.8 (2.7) 2.8-15	7.5 (4.8) 1.7-30	7.3 (3.9) 1.7-30
Platelet count (x 10^9/L)	Mean (SD) Range	572 (227) 166-1406	545 (215) 89-1139	558 (220) 89-1406
Splenomegaly	Yes	9 (17.3)	14 (24.1)	23 (20.9)
	No	37 (71.2)	37 (63.8)	74 (67.3)
	Missing	1 (1.9)	1 (1.7)	2 (1.8)

Summary/Conclusion: We report primary results from the ET arm of the MAJIC study, the first randomized study of RUX in ET, 110 patients were eligible for the mITT analysis. The results suggest that there is no significant difference in complete hematological response rates between RUX & BAT therapy. Partial hematological responses, transformation, thrombosis & hemorrhage rates appear similar. However symptom scores for early satiety, itching & weight loss were significantly improved by RUX. The side effect profile of RUX was as previously reported.

Hodgkin lymphoma - Clinical

P304

RISK FACTORS (RF) FOR RELAPSE IN PATIENTS WITH RELAPSED OR REFRACTORY HODGKIN LYMPHOMA (RRHL) AFTER AUTOLOGOUS STEM CELL TRANSPLANT (ASCT): A REAL-WORLD ANALYSIS IN GERMANY AND THE UNITED KINGDOM (UK)

EA Zagadailov[1,*], S Corman[2], M Hagan[3], V Chirikov[2], C Johnson[2], C Macahilig[3], MR Dalal[1], PJ Bröckelmann[4]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Pharmerit International, Bethesda, MD, [3]Medical Data Analytics, Parsippany, NJ, United States, [4]Department I of Internal Medicine and German Hodgkin Study Group, University Hospital of Cologne, Cologne, Germany

Background: With the advance of novel therapeutic options, RFs for post-ASCT outcomes in patients with RRHL are of immediate interest. Several risk factors for relapse have been previously documented; however, there are limited data with respect to the prevalence and distribution of RFs in post-ASCT RRHL patients who have and have not had a subsequent relapse.
Aims: We aimed to describe the prevalence and distribution of RFs after ASCT in patients with RRHL in a sample of real-world patients in Germany and the UK.
Methods: We included patients who were ≥18 years old at the time of HL diagnosis, received ASCT between 1 January 2008 and 30 June 2014, were not enrolled in an HL-related clinical trial and treated under real-world setting at 45 clinical sites in Germany and the UK. This analysis included randomly selected post-ASCT patients, and was augmented by patients who relapsed post-ASCT. Patient characteristics including RFs for relapse were analyzed descriptively. RFs of interest included patient age; sex; B symptoms, extranodal disease, bulkiness, clinical stage, and/or ECOG performance status at the time of ASCT; number of salvage regimens prior to ASCT; response to salvage treatment; and time to relapse.
Results: A total of 350, predominantly male patients, with a median follow-up of 2.2 years post-ASCT were included (196 in Germany, 154 in the UK). The mean age at diagnosis was 42 years. In total, 267 (76%) had a relapse during the follow-up period. A similar proportion of patients who did and did not relapse had B symptoms at the time of ASCT, extranodal disease at the time of ASCT, and less than a partial response to salvage chemotherapy (Table). A greater proportion of patients who relapsed were male and ≥45 years old. Among the patients who relapsed, 83% had ECOG ≥1 at the time of first relapse relapse, 31% had stage IV disease, and 16% had bulky disease. The median number (range) of RFs present was 2 (0-7) in patients who relapsed and 0 (0-1) in patients who did not relapse.

Table 1. Prevalence of risk factors in patients who did and did not relapse after ASCT.

Risk factor, N (%)	Relapsed N=267	Did not relapse N=83
Male	153 (57.3)	48 (57.8)
Age ≥45 years	133 (49.8)	19 (22.9)
B symptoms at the time of ASCT	29 (10.9)	7 (8.4)
Extranodal disease at the time of ASCT	43 (16.1)	18 (21.7)
≥2 salvage regimens prior to ASCT	13 (4.9)	0 (0)
Non-response to salvage therapy (stable or progressive disease)	13 (4.9)	1 (1.2)
Bulkiness (>5 cm) at relapse	43 (16.1)	N/A
Clinical stage at relapse		N/A
I	8 (3.1)	
II	91 (35.1)	
III	79 (30.5)	
IV	81 (31.3)	
ECOG status ≥1 at relapse	221 (83.7)	N/A
Time to relapse <3 months	10 (3.7)	N/A

Summary/Conclusions: This real-world study demonstrates the prevalence and distribution of a myriad of RFs in patients post-ASCT RRHL. RF profiles are different in patients who did and did not have a subsequent relapse, and, as such, clinical evaluation of RFs is critical to identify patients at increased risk of subsequent relapse.

P305

BRENTUXIMAB VEDOTIN (BV) IN PATIENTS WHO ARE INELIGIBLE FOR AUTOLOGOUS STEM CELL TRANSPLANT (ASCT) WITH RELAPSED OR REFRACTORY HODGKIN LYMPHOMA (RRHL): A UK AND GERMANY RETROSPECTIVE STUDY

PJ Bröckelmann[1,*], EA Zagadailov[2], S Corman[3], M Hagan[4], V Chirikov[3], C Johnson[3], C Macahilig[4], MR Dalal[2]
[1]Department I of Internal Medicine and German Hodgkin Study Group, University Hospital of Cologne, Cologne, Germany, [2]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [3]Pharmerit International, Bethesda, MD, [4]Medical Data Analytics, Parsippany, NJ, United States

Background: BV is an anti-CD30 antibody-drug conjugate indicated for the treatment of CD30+ RRHL following ASCT or following at least two prior therapies in patients who are ASCT-ineligible. Clinical outcomes in the ASCT-ineligible population have not yet been evaluated in a real-world study.
Aims: We aimed to describe outcomes in real-world ASCT-ineligible patients with RRHL in two countries known to have different practice patterns in RRHL.
Methods: This was a retrospective medical chart review study that enrolled patients at 45 clinical sites representative of routine clinical practice in Germany and the UK. The study included patients ≥18 years old at the time of HL diagnosis, who progressed after ≥2 multi-drug chemotherapy regimens between 1 January 2008 and 30 June 2014 and were not ASCT candidates as identified by their clinicians, were subsequently treated with BV, and were not enrolled in an HL-related clinical trial. Patient demographics (eg, age, gender), clinical characteristics (disease stage, type, ECOG status, reason for ASCT ineligibility), and treatment characteristics (dose and duration of treatment) were described. Clinical outcomes included best response to treatment, progression-free survival (PFS), and overall survival (OS). All outcomes were descriptive, and reported in the full study population and by country.
Results: A total of 125 patients were included in this analysis (69 in Germany and 56 in the UK). The median age of study patients at HL diagnosis was 70 years, and 60% were male. Nearly all patients had had classical HL (96%), and over half had non-bulky (<5 cm) disease (55%). The most common reasons for ASCT ineligibility were comorbidities (74%), age (57%), and disease progression (11%). Coronary artery disease (41%), diabetes (25%), and chronic pulmonary disease (14%) were the most common comorbidities among study patients. Eighty-six percent of patients received at least 2 lines of treatment prior to initiating BV. At the time of BV initiation, 24% of patients had stage IV disease and 22% had extranodal involvement. The median duration of follow-up was 3.1 years from the time of HL diagnosis. Nearly three fourths of patients had a partial or complete response (Table). Other outcomes of interest included leukopenia (12%; of which 47% were serious), neuropathy (10%; all serious), and anemia (8%; 40% serious).

Table 1. Treatment, Response, and Survival in ASCT-Ineligible Patients Receiving Brentuximab Vedotin.

Outcome	ASCT-Ineligible Patients Receiving BV N=125
Median cycles administered (range)	8 (1-16)
Response	
Complete response	34%
Partial response	38%
Stable disease	15%
Progressive disease	12%
PFS from start of BV (months), median (95% CI)	12.3 (8.8-18.9)
OS from start of BV (months), median (95% CI)	15.6 (13.7-24.4)

Summary/Conclusions: Progression-free and overall survival in ASCT-ineligible patients receiving brentuximab vedotin were 12.3 and 15.6 months, respectively, after initiation of treatment.

P306

REAL-WORLD EFFECTIVENESS OF BRENTUXIMAB VEDOTIN (BV) *VS* OTHER TREATMENTS IN PATIENTS WITH RELAPSED/REFRACTORY HODGKIN LYMPHOMA (RRHL) POST AUTOLOGOUS STEM-CELL TRANSPLANTATION (ASCT)

EA Zagadailov[1,*], S Corman[2], M Hagan[3], V Chirikov[2], C Johnson[2], C Macahilig[3], MR Dalal[1], PJ Bröckelmann[4]
[1]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Pharmerit International, Bethesda, MD, [3]Medical Data Analytics, Parsippany, NJ, United States, [4]Department I of Internal Medicine and German Hodgkin Study Group, University Hospital of Cologne, Cologne, Germany

Background: BV is an anti-CD30 antibody-drug conjugate indicated for the treatment of CD30+ RRHL following ASCT or following at least two prior therapies in patients who are ASCT-ineligible. While no randomized trials have been conducted in the post-ASCT RRHL setting, patients receiving BV have been shown to have higher complete response rates and longer overall survival (OS) compared to historical control groups.
Aims: We aimed to compare effectiveness in post-ASCT patients with RRHL receiving BV to those receiving other treatments or no treatment in clinical settings in Germany and the UK.
Methods: A retrospective medical chart review study was conducted that enrolled patients at 45 clinical sites in Germany and the UK. The study included patients ≥18 years old at the time of HL diagnosis, who received ASCT between

1 January 2008 and 30 June 2014, had at least 12 months of available clinical data from the initiation of post-ASCT treatment, and were not enrolled in an HL-related clinical trial. This analysis included randomly selected post-ASCT patients who subsequently relapsed, and an augmented sample of patients who relapsed post-ASCT and were treated with BV or another treatment regimen after relapse. Patients were grouped according to the first line of therapy received after post-ASCT relapse (BV, salvage chemotherapy, or no treatment). Patient demographics (eg, age, gender), clinical characteristics (disease stage, type, ECOG status), and treatment characteristics (dose and duration of treatment) were described for BV and non-BV patients. Clinical outcomes included progression-free survival (PFS), OS, and best response. Median PFS and OS were calculated using Kaplan-Meier methods; all other outcomes were summarized using descriptive statistics, by treatment (BV and non-BV) and country.

Results: A total of 267 patients were included in the study (131 Germany, 136 UK). Of these, 163 received BV (88 Germany, 75 UK), 87 received other treatments, (39 Germany, 48 UK), and 17 received no treatment for post-ASCT RRHL (4 Germany, 13 UK). The groups were similar in median age at diagnosis (42, 46, and 50 years, respectively), gender (56%, 59%, and 65% male), and type of HL (>96% classical HL in all groups). The most common salvage chemotherapy regimens in the non-BV group were gemcitabine-based regimens (41% and 42% in Germany and UK) and CHOP (13% in both countries). Patients in the BV group received a median of 7 of the potential 16 cycles of treatment (Table). The median duration of follow-up was approximately 2 years in all groups. Median PFS was 8.6 months longer in patients receiving BV compared to those receiving salvage chemotherapy. Median OS could not be estimated because <50% of patients died during the follow-up period. Other events of interest included anemia (12%) and leukopenia (12%) in the BV group and leukopenia (12%) and thrombocytopenia (6%) in the salvage chemotherapy group.

Table 1. Treatment and Survival Outcomes in Patients with RRHL after ASCT relapse.

Outcome	Brentuximab vedotin	Salvage chemotherapy
Median cycles administered (range)	7 (1-16)	4 (1-8)
Best response to therapy		
Complete response	45%	41%
Partial response	34%	22%
Stable disease	12%	6%
Progressive disease	8%	29%
PFS from start of post-relapse therapy (months), median (95% CI)	22.0 (19.3-NE)	13.4 (6.7-28.0)

NE, not estimable

Summary/Conclusions: In this observational, real-world study, patients receiving BV as the first post-relapse line of therapy after RRHL had longer PFS than patients receiving salvage chemotherapy; however, confidence intervals were wide.

Gaslini, Genova, [17]Radiology Unit, Radiology Department, A.R.N.A.S. Ospedali Civico, Di Cristina e Benfratelli, Palermo, Italy

Background: Cancer incidence and use of computed tomography (CT) and positron emission tomography (PET) in childhood have been increasing over time and in some studies an association between pediatric CT and cancer risk was found. The risk linked to overuse of diagnostic radiation has recently inspired 2 different international campaigns, "Image Gently" and "Eurosafe," both aimed at understanding what are the most careful practices and in 2013 the American Society of Hematology, included "*surveillance CT scans in asymptomatic patients after curative-intent treatment for aggressive lymphoma*" among tests not well supported by evidence.

Aims: Based on the evidence that the majority of HL presentation is in the mediastinum and/or in a superficial lymphadenopathy (abdomen/pelvis disease is present in 39.0% in the present series) we decided to determine if abdomen/pelvis CT can be safety omitted in the staging of a subgroup of children with Hodgkin Lymphoma (HL). Since it is well known that the measurement accuracy of US is inferior to CT, a randomized trial would be addressed as not ethical, and so we organized a complex study with a centralized revision of CT images.

Methods: Every participating center sent *local* staging reports of PET and abdominal ultrasound (US) along with digital images of staging CT to the investigation center where the CT scans were evaluated by an experienced pediatric radiologist. The *local* radiologist who performed the US was unaware of local CT and PET reports (both carried out after US), and the *reviewer* radiologist examining the CT images was unaware of local US, PET and CT reports. A *Final Staging* (FS) of 123 patients performed on the basis of *local* US and PET reports and *centralized* CT report was compared to a *Test Staging* (TS) based on *local* US and PET. US/PET evaluation of lymphonodes (LNs), spleen and liver (no other site was affected) was based on criteria adopted in the Euronet-PHL-C1 trial and could be *positive* (involved), *negative* (not involved) or *doubtful* (table 1 and 2). Also the TS (table 3) could result *positive*, *negative* or *doubtful* (cases where CT was mandatory to assess the involvement).

Results: There were 71/123 patients with a negative TS: no new lesion was diagnosed by CT. In 27/123 patients the TS was positive: no site was added or withdrawn by CT, and specifically in the group of isolated US positivity (or concordant US/PET positivity) in spleen + concordant US/PET negativity in LNs no additional information was provided by CT. In 25/123 patients the TS was doubtful: in 21 (84%) the FS was positive, and in 4 (16%) negative. According to the study methods, in doubtful TS cases at least one technique (US and/or PET) was doubtful or positive: if we consider these cases positive, the analysis in terms of sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) shows these results: 1)Sensitivity: 1.00 (CI: 0.89-1.00); 2)Specificity: 0.95 (CI: 0.87-0.99); 3)PPV: 0.92 (CI: 0.81-0.98); 3)NPV: 1.00 (CI: 0.93-1.00).

Table.

Table 1 - US/PET evaluation of lymph nodes

Lymph nodes		
US	PET	US/PET evaluation
Negative	Negative	Negative
Positive	Positive	Positive
Positive	Negative	Doubtful
Negative	Positive	Doubtful
Doubtful	Positive or Doubtful or Negative	Doubtful
Positive or Negative	Doubtful	Doubtful

Table 2 - US/PET evaluation of spleen/liver

Spleen or Liver		
US	PET	US/PET evaluation
Negative	Negative	Negative
Negative	Positive or Doubtful	Doubtful
Doubtful or Positive	Positive or Doubtful or Negative	Positive

Table 3 – Test staging

US/PET evaluation	Test staging
Negative in lymph nodes and spleen/liver	Negative
Positive in at least one site	Positive
Doubtful in at least one site (and no positive site)	Doubtful

Summary/Conclusions: We think CT remains useful in whatever type of LN positivity in PET and/or US since CT can better assist the choice as to radiotherapy planning. At the same time, we think that, with the strictest approach, it is possible to omit CT at least in PET/US negative patients (57.7%) even though it seems that CT could be safely omitted also in cases of isolated US positivity (or concordant US/PET positivity) in spleen + concordant US/PET negativity in LNs (9.7%). Avoiding abdomen/pelvis CT would have some positive effects in patients in whom it is deemed possible: 1)Reducing radiation exposure. 2)Cutting possible side effects and adverse/allergic reactions of contrast materials and of general anesthesia (in the minority of patients needing it).3)Cutting the costs. All these advantages would be present even compared to an initial staging performed through combined PET/CT (where usually a CT scan with iodine contrast media is performed after PET) or, apart from the radiation risk, through chest CT and abdomen/pelvis MRI, which is a much more complicated approach.

P308

INCREASED CORONARY ARTERY CALCIUM SCORE AFTER RADIOTHERAPY IN HODGKIN LYMPHOMA SURVIVORS

E Van Leeuwen-Segarceanu[1,*], J Bijl[2], J van der Heyden[2], B Rensing[2], WJ Bos[1], D Biesma[1]
[1]Internal Medicine, [2]Cardiology, St. Antonius Hospital, Nieuwegein, Netherlands

Background: Coronary artery disease (CAD) is a well know complication of mediastinal radiotherapy (MRT). Long term survivors of Hodgkin Lymphoma have an increased risk of myocardial infarction compared to the general population. Pre-clinical CAD, detected using modern imaging techniques, has been rarely described in these patients.
Aims: The aim of this study is to compare computer tomography (CT) detected CAC-scores in HLS treated with and without MRT. Furthermore we tried to identify risk factors (RFs) predisposing HLS to develop coronary artery calcifications.
Methods: In this cross-sectional study we describe 82 Hodgkin Lymphoma survivors (HLS) with a mean current age of 47.8 years and mean follow-up time from diagnosis of 13.4 years. Fifty patients were treated with MRT with or without chemotherapy. Seventy-five patients underwent coronary artery calcium (CAC) score measurements.
Results: Significantly increased CAC-scores (*i.e.* CAC-score >75th percentile for age and gender) were more frequently observed in HLS treated with MRT 41.3%, than in HLS treated without MRT 10.3% (p=.004). In multivariable analysis, HLS treated with MRT ≥10 years ago had an odds ratio of 12.1 of having a CAC-score >75th percentile compared to HLS treated without MRT. HLS irradiated <10 years ago had a similar incidence of significantly increased CAC-scores compared to the no-MRT group. HLS treated with MRT and CAC-score >75th percentile had more traditional cardiovascular risk factors (median 3) than HLS treated with MRT with a CAC-score <75th percentile (median 2), p=.036. Five HLS treated with MRT and one treated without MRT had already developed symptomatic CAD before screening. During four years follow-up after screening, two more patients developed CAD for which revascularisation therapy was needed.

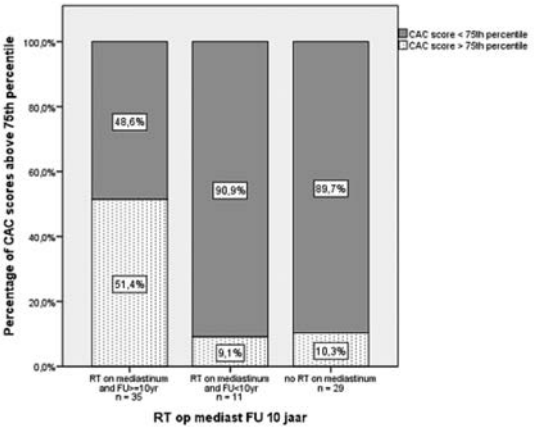

Figure 1.

Summary/Conclusions: We therefore recommend that screening HLS by CAC-score measurements should begin 10 years after MRT and that traditional cardiovascular risk factors should be addressed in this high risk population.

P309

THE LYMPHOMA ASSOCIATED MACROPHAGES-HODGKIN/REED-STERNBERG CELLS RATIO IS A POOR PROGNOSTIC FACTOR IN CLASSIC HODGKIN LYMPHOMA PATIENTS

V Prochazka[1,*], T Papajik[1], T Dyskova[2], M Dihel[2], Z Prouzova[3], E Kriegova[2]
[1]Dept. of Hemato-Oncology, [2]Dept. of Immunology (OLGEN), Faculty of Medicine and Dentistry, Palacky University Olomouc, Czech Republic., Olomouc, [3]Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic

Background: Classical Hodgkin lymphoma (cHL) is the most common lymphoid malignancy under the age of 30. Despite the relatively high curability, about 20-30% of patients relapse after front-line therapy. Recent years have brought novel information about close Hodgkin/Reed-Sternberg (HRS): lymphoma associated macrophages (LAM) cross-talk promoting tumor growth and resistance to therapy.
Aims: To assess the prognostic role of LAM to HRS ratio in lymph node biopsies using a novel automated system for scanning large tumor sample areas in cHL patients.
Methods: High-quality tissue samples obtained from 38 patients at time of diagnosis were analyzed. The median age at diagnosis was 35 (17.5-93) years; the male-to-female ratio was 0.66:1. The lymphoma subtypes were nodular sclerosis (NS) in 25 (66%) and mixed cellularity (MC) in 13 (34%) patients. German Hodgkin Study Group stages were: limited in 4 (12%), intermediate in 8 (23%) and advanced in 23 (66%) patients. Chemotherapy was given to 35 patients (92%): BEACOPP in 20 (57.1%), ABVD in 6 (17.1%), Stanford V in 4 (11.4%) and other (COPP, COPP/ABV) in 5 (14.3%) cases. Involved-field radiotherapy was applied in 11 (29%) cases. Tissue array analyses were performed using the TissueFAXS (TissueGnostics, Austria). Data were analyzed with TissueQuest software. Paraffin-embedded biopsies were prepared from diagnostic samples stained with anti-CD30 and anti-CD68. Analyzed areas were reviewed by pathologist and fibrotic (≥10%), necrotic or residual lymphatic structures were excluded.
Results: After treatment, 31 (82%) patients achieved complete remission, three partial remission, one stable disease and three patients progressed. After a median follow-up of 64.3 months, 9 (24%) patients relapsed or progressed and 7 (18%) died. Five-year overall survival (5-y OS) reached 81.0%; 5-year progression survival (PFS) was 68.3%. The mean sample scanned area covered 27.2±13.5 mm^2 with the mean total number of cells 461,504±286,491. The means (medians) of HRS and LAM densities were 279±232 (181) and 1724±1115 (1317) cells per mm^2, respectively. Mean and median number LAM per HRS cell (LAM to HRS ratio, LHR) achieved 13.1 and 7.48, respectively. LHR did not correlate with sex (p=0.44), age (p=0.19), systemic symptoms (p=0.68), tumor bulk (p=0.35) or Ann Arbor stage (p=0.59). High LHR (>7.48) correlates with lower probability of CR achievement (63% *vs* 95%, p=0.02). High LHR was associated with inferior 5-y PFS (41.1% *vs* 94.7%, p<0.001) and OS (62.2% *vs* 100%, p=0.004). Multivariate Cox regression identified high LHR as an unfavorable prognostic factor for PFS (p=0.01, HR=13.3) independent of age, sex, disease stage and lymphoma subtype.

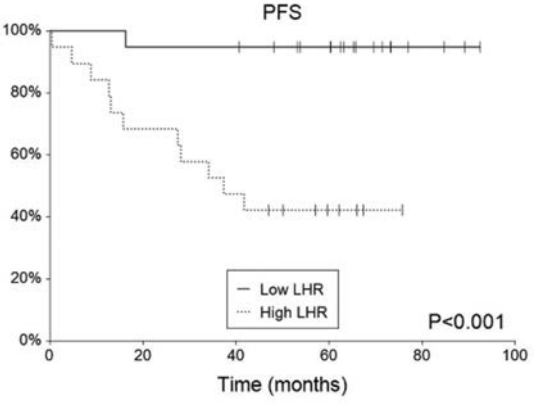

Figure 1.

Summary/Conclusions: This is the first evidence about the possible predictive role of LAM to HRS ratio in cHL patients. High LHR at diagnosis is associated lower probability of CR and higher risk of lymphoma progression or death. Automated image analysis is a new tool overcoming technical limitations caused by small (microarray) samples in lymphomas with high intra-tumor heterogeneity. Further analyses will define the role of HRS and LAM density analysis in cHL in the context of risk-adapted and CD30-targeted therapies.

P310

THE PROGNOSTIC ROLE OF BCL-2 EXPRESSION IN PATIENTS WITH CLASSICAL HODGKIN LYMPHOMA ASSESSED FOR CD68+ CELL COUNT

A Cuccaro[1,*], M Martini[2], S Annunziata[3], E Cupelli[1], T Cenci[2], E Galli[1], ML Calcagni[3], V Rufini[3], F D'Alò[1], A Giordano[3], LM Larocca[2], S Hohaus[1]
[1]Institute of Hematology, [2]Institute of Pathology, [3]Institute of Nuclear Medicine, Catholic University of the Sacred Heart, Rome, Italy

Background: Risk stratification in classical Hodgkin Lymphoma (cHL) is largely based on clinical, radiological and laboratory findings. In the last years, interim PET-CT has added important prognostic information for therapy stratification. Among risk factors that reflect tumor biology, Bcl2 expression in Hodgkin/Reed-Sternberg cells (HRS) has been reported to be an adverse prognostic factor in HL. More recently, studies using genome-wide expression data have identified the number of tumor-infiltrating macrophages (TAMs) as an important tissue biomarker. Several studies have shown that patients with TAMs over 5% identified by immunohistochemical staining for the CD68 antigen had an inferior outcome.
Aims: The aim of this study was to evaluate Bcl-2 expression in HRS cells, analyze for associations of Bcl-2 expression with clinical characteristics, interim PET-CT and in particular, the CD68+ cell count and clinical outcome.

Methods: We studied 122 patients with cHL (58 females, 64 males, median age 38 years), diagnosed at our Institution between 2004 and 2016, and treated with ABVD (95 patients), BEACOPP (21 patients) or COPP (6 patients). Tissue sections of patients were stained for Bcl-2, and cases were considered positive if any HRS cell expressed Bcl-2 (Rassidakis, Blood 2002; 100;3935). CD68+ cells were assessed by staining with the PGM-1 antibody. PET was performed after 2 cycles of chemotherapy in 95 patients and evaluated according to the 5-point Deauville scale (5p-DS). Primary endpoint was event-free survival (EFS), defined as time from date of diagnosis to date of first relapse, disease progression, or death from any cause.
Results: Bcl-2 was expressed in HRS cells of 60/122 (49%) cases. CD68 count was >5% in 66/122 (54%) cases. We found a significant association between Bcl-2 expression and the CD68+ count >5% (p=0.04). Both Bcl-2-positivity and CD68+ cell count >5% were associated to elevated levels of LDH (p=0.006; p=0.02 respectively) and the nodular sclerosis type 2 according to BNLI criteria (p=0.002; p=0.005 respectively). Using a score of >3 as cut to define a positive interim PET-CT, 83 patients had a negative interim PET, 12 patients were PET-positive. No association was found between Bcl-2-positivity and the PET result; instead we observed a direct correlation between CD68+ count and 5p-DS (p<0.002). Bcl-2 expression was associated only with a trend for poor EFS (p=0.07), while the CD68+ count >5% was a strong predictor for reduced EFS (p<0.001). In a multivariate analysis adjusted for the type of chemotherapy, CD68+ count and interim PET retained their independent prognostic significance (p<0.001, and p<0.001, respectively).
Summary/Conclusions: Our study suggests that BCL-2 expression in HRS cells does not provide prognostic information in addition to the CD68+ cell count and interim PET-CT that remain strong and independent outcome predictors in cHL.

P311

AUTOLOGOUS STEM CELL TRANSPLANTATION (AUTO-SCT) IS HIGHLY EFFECTIVE IN RELAPSED NODULAR LYMPHOCYTE-PREDOMINANT HODGKIN LYMPHOMA (NLPHL): A RETROSPECTIVE STUDY BY THE EBMT LYMPHOMA WORKING PARTY

S Akhtar[1,2], A Boumendil[2], H Finel[2], T Masszi[2], P Jindra[2], D Nemet[2], H Baurmann[2], Y Begiun[2], L Castagna[2], F Ferrara[2], R Foa[2], R Malladi[2], JM Moraleda[2], A Bloor[2], G Salles[2], J Meissner[2], A Sureda[2,*], P Dreger[2,3]
[1]Oncology Center, King Faisal Specialist Hospital, Riyadh, Saudi Arabia, [2]Lymphoma Working Party, EBMT, Paris, France, [3]Medicine V, University of Heidelberg, Heidelberg, Germany

Background: NLPHL is a rare CD20-positive subtype of Hodgkin lymphoma (HL). Although long term survival is better than in classical HL, frequent relapses are common and progression / transformation to aggressive non-Hodgkin lymphoma (NHL) may happen. Whilst high-dose therapy (HDT) with auto-SCT is considered as standard treatment for relapsed / refractory classical HL, information on auto-SCT in relapsed / refractory NLPHL is sparse.
Aims: We report a registry study of auto-SCT for NLPHL using the EBMT database, representing the largest sample analyzed to date.
Methods: Eligible for this study were patients 18 years or above with NLPHL who underwent auto-SCT between 2003 to 2013 and were reported to the EBMT. Baseline patient, disease, and transplant data were collected from EBMT MED-A standard forms. Centers with potentially eligible patients were contacted to provide additional treatment and follow-up information including a written histopathology report for central review. *Statistical analysis* was descriptive and employed log rank comparisons for univariate assessment of the impact of baseline characteristics on survival endpoints.
Results: Altogether, 92 patients met the inclusion criteria and had a full data set including written diagnostic report available. Of these, 36 patients had to be excluded after histopathology report review (17 classical HL, 2 NHL, 17 no sufficient information), leaving 56 patients in the final study sample. There was a predominance of male patients (88%), and the median age was 36 (interquartile range (IQR) 29-50) years. Prior to auto-SCT, 71% had 2, 20% had 3, and the remainder more than 3 lines of treatment (median 2 lines), containing rituximab in 62% of the patients. Median time from diagnosis to auto-SCT was 21 (IQR 14-51) months. At auto-SCT, 54% of the patients were in complete remission (CR), and 43% in partial remission (PR). BEAM was used as HDT in the vast majority of patients (84%), with additional rituximab in 13%. With a median follow-up of survivors of 5.0 (IQR 3.6-6.6) years, the 5-year progression-free and overall survival were 67% (95%CI 55-82), and 86% (95%CI 77%>96%). 5-year incidence of relapse was 32% (95%CI 20-46). There were no transplant-related deaths. Univariate comparisons considering age, time from diagnosis to transplant, number of pretreatment lines, disease status at auto-SCT and rituximab use during induction, salvage and/or HDT failed to identify significant predictors of any survival endpoint.
Summary/Conclusions: Patients with relapsed NLPHL undergoing auto-SCT have an excellent outcome, even after failing many lines, comparing favorably with historical data on auto-SCT for relapsed classical HL. In this retrospective analysis, a significant effect of rituximab treatment prior to and/or during HDT did not emerge.

Non-Hodgkin & Hodgkin lymphoma - Novel agents

P312

BIOLOGICALLY MEANINGFUL CHANGES IN CYTOKINE AND CHEMOKINE PRODUCTION FOLLOWING IBRUTINIB THERAPY IN WALDENSTROM'S MACROGLOBULINEMIA

J Vos[1,2,*], N Tsakmaklis[3], K Meid[3], J Castillo[3], P Brodsky[3], T Ganz[4], L Xu[3], G Yang[3], S Treon[3], Z Hunter[3]
[1]Interal medicine-Hematology, Sint Antonius Ziekenhuis, Nieuwegein, Netherlands, [2]Bing Center for WM, Dana Farber Cancer Insitute, [3]Bing Center for WM, Dana Farber Cancer Institute, Boston, [4]Department of Medicine, David Geffen School of Medicine at University of California, Los Angeles, United States

Background: Waldenström's macroglobulinemia (WM) is characterized by bone marrow (BM) infiltration of lymphoplasmacytic lymphoma along with a serum IgM monoclonal protein. Recently, MYD88 and CXCR4 activating somatic mutations were identified in approximately 90% and 35% of WM patients, respectively. CXCR4 mutations occur almost exclusively in MYD88 mutated patients. Ibrutinib is an oral BTK inhibitor and the only drug specifically approved for WM by the European Medical Association. Ibrutinib is highly active in previously treated WM patients with the best responses in MYD88 mutated CXCR4 wild-type (WT) patients. The serum cytokine profile for WM based on MYD88 and CXCR4 genotype has yet to be defined and the serum cytokine response to ibrutinib based therapy has not been previously studied in WM.
Aims: The aim of this study is to define cytokines that correlate with WM clinical characteristics, MYD88 and CXCR4 mutation status, and response to ibrutinib therapy.
Methods: A total of 137 peripheral blood derived plasma samples were tested, obtained from 52 previously untreated WM patients and 34 previously treated and symptomatic WM patients who received ibrutinib therapy as part of a prospective clinical trial (Treon et al, NEJM 2015). The untreated group included 23 patients that were MYD88 mutated and CXCR4 wild type, 20 patients that were both MYD88 and CXCR4 mutated, and 9 patients that were MYD88 and CXCR4 wild type. The patients participating in the ibrutinib trial were tested just before and one year after initiation of ibrutinib therapy. Twenty age and gender matched healthy controls were included for comparison. Cytokines were tested using magnetic multiplex enzyme- linked immunosorbent assays (R&D Systems Inc., Minneapolis, MN). The following 27 cytokines were tested: TNF, IL6, IFNG, CXCL10, IL10, CCL2, IL8, IL1b, IL7, IL1RA, CCL3, CCL4, CCL5, IL17A, IL4, IL5, IL2, GMCSF, IL2RA, CXCL9, IL12, IL15, IL13, CCL11, CXCL12, CXCL13 and CD27. Statistical analysis was performed with R statistical computing software. Clinical parameters and cytokine levels were analyzed following log transformation. Correlation between variables was tested using Spearman's rho and when appropriate Holm-Bonferroni multiple hypothesis correction was applied. Adjusted p-values <0.05 were deemed significant for this analysis.

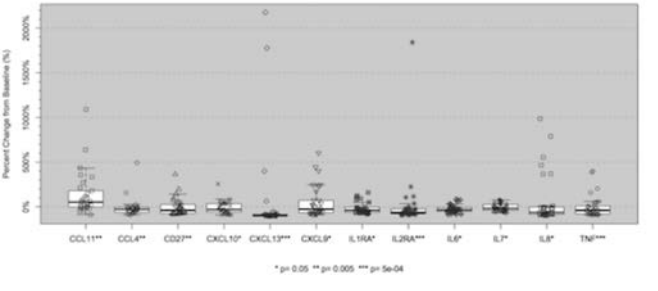

Figure 1.

Results: CXL10, IL10, IL2RA, CXCL13 and CD27 were significantly higher between WM patients *versus* controls. At baseline CXCL13, IL2RA and CD27 strongly correlated with HGB levels (p<0.001 for all) with correlation coefficients of -0.55, -0.55, and -0.47, respectively. CXCL13 (rho=0.56; p<0.001) and CD27 (rho=0.46; p<0.001) correlated with BM infiltration. None of the cytokines showed significant correlated with IgM levels. Based on CXCR4 mutation status within MYD88 mutated patients, IL2RA (p=0.025), IL1RA (p=0.003), CXCL10 (p=0.026) and CD27 (p=0.016) were higher in CXCR4 WT patients. No significant difference in cytokine levels based on MYD88 mutation status was noted though this was due to MYD88 WT cytokine levels being similar to those found in CXCR4 mutated patients. Twelve cytokines were significantly changed after 1 year on ibrutinib (Figure 1). Only the change in CXCL13 was significantly correlated to achieving at least at least a partial response (PR; >50% decrease in serum IgM; p=0.019). Baseline CXCL13 levels were significantly higher in patients that subsequently reached at least a partial response (PR; >50% decrease in serum IgM) after 1 year (p=0.048). This was also true using logistic regression to account for age, gender, MYD88/CXCR4 mutation status, and baseline BM involvement (p=0.035).
Summary/Conclusions: CXCL13 is a strong biomarker of BM tumor involvement in WM and baseline levels are predictive of achieving a major response

to ibrutinib. These data suggest a role of CXCL13 in WM tumor biology and warrants further study.

P313

A PHASE III STUDY OF OFATUMUMAB VS RITUXIMAB IN INDOLENT B-CELL NON-HODGKIN LYMPHOMA RELAPSED AFTER RITUXIMAB CONTAINING THERAPY (HOMER): RESULTS OF THE INTERIM ANALYSIS

DG Maloney[1,*], N Fukuhara[2], M Ogura[3,4], JF Larouche[5], O Tournilhac[6], M Coleman[7], X Hong[8], M Fennessy[9], M Cota[10], M Woessner[10], K Tobinai[11]
[1]Fred Hutchinson Cancer Research Center, Seattle, United States, [2]Tohoku University Hospital, Miyagi, [3]Nagoya Daini Red Cross Hospital, Aichi, [4]Tokai Central Hospital, Gifu, Japan, [5]CHU Québec, Enfant-Jésus, Québec, Canada, [6]CHU Estaing, Clermont-Ferrand Cedex 1, France, [7]Clinical Research Alliance, Lake Success, NY, United States, [8]Cancer Hospital Affiliated to Fudan University, Shanghai, China, [9]Novartis Pharmaceuticals, Basel, Switzerland, [10]Novartis Pharmaceuticals, East Hanover, NJ, United States, [11]National Cancer Center Hospital, Tokyo, Japan

Background: Rituximab, (R) as a single agent or in combination, is standard therapy for untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL). Due to the ubiquitous use of R in the treatment of iNHL and the invariable relapse of patients with iNHL, there remains an unmet need for novel therapies in relapsed iNHL. Ofatumumab (OFA) is an anti-CD20 human monoclonal antibody (mAb) that binds to a membrane-proximal epitope of the CD20 molecule.
Aims: The study aimed to evaluate the efficacy and safety of treatment with OFA compared with R in iNHL patients who had relapsed following R-containing treatment. Here we report the results of the interim futility analysis.
Methods: In this Phase III, multicentre, open-label study, patients (aged ≥18 years) who had relapsed following R-based therapy were randomized to receive either 1000 mg OFA or 375 mg/m^2 R every week for 4 weeks, followed by every 2 months for four additional doses. All patients provided informed consent and were R-sensitive: a complete or partial response to their last prior R-containing therapy lasting at least 6 months beyond the end of R treatment was required. Randomization was stratified by FLIPI score (0–2 *vs* 3–5), disease type (FL *vs* non-FL), and prior R (monotherapy *vs* combination). The primary endpoint was progression-free survival (PFS), as assessed by an independent radiology reviewer (IRR). An interim futility analysis was reviewed by an independent data monitoring committee (IDMC) when 50% of the 373 planned events for the primary endpoint analysis had been reported. A recommendation to stop the study would occur if the IRR-assessed PFS had a conditional power ≤30%.
Results: A total of 409 patients (205 in the OFA arm and 204 in the R arm) were enrolled and evaluated in the interim analysis. The majority of patients (98%) had follicular lymphoma. Patient and disease characteristics were similar between the treatment arms. Just under a third of patients (31% OFA, 27% R) discontinued from study treatment, with the most common reason being disease progression (21%). The IRR-assessed median PFS was 16.2 months in the OFA arm and 21.2 months in the R arm (Table 1). IRR-assessed response rates were 50% and 63% in the OFA and R arms, respectively. Investigator (INV)-assessed median PFS was 16.1 months and 17.9 months in the OFA and R arms, respectively. INV-assessed response rates were 47% for OFA and 58% for R. Median overall survival and median time to next therapy appeared to be similar between arms. Infusion-related adverse events appeared higher in the OFA arm *vs* R arm (any grade: 87% *vs* 58%; grade 3/4: 22% *vs* 5%), and mostly affected the first infusion administered. Incidences of gastrointestinal disorders appeared higher in the OFA arm *vs* R arm (38% *vs* 27%), whereas neutropenia (OFA: 3% *vs* R: 7%) and pyrexia (OFA: 4% *vs* R: 10%) appeared to be more frequent in the R arm.

Table 1. Efficacy endpoints of the HOMER study.

	R (N=204)	OFA (N=205)	HR (95% CI)
Median IRR-assessed PFS, mo (95% CI)	21.2 (16.3–25.2)	16.2 (15.7–21.5)	1.32 (0.99–1.76)
Median INV-assessed PFS, mo (95% CI)	17.9 (16.1–21.6)	16.1 (15.5–18.5)	1.14 (0.89–1.48)
Median overall survival, mo (95% CI)	47.1 (45.5–NA)	45.9 (39.2–NA)	1.18 (0.61–2.30)
Median time to next therapy, mo (95% CI)	31.8 (25.8–35.5)	28.6 (24.2–33.7)	1.05 (0.77–1.44)
IRR-assessed response rate, n (%)			
CR+PR (95% CI)	128 (63) (55.7–69.4)	103 (50) (43.2–57.3)	
INV-assessed response rate, n (%)			
CR+PR (95% CI)	119 (58) (51.2–65.2)	96 (47) (39.8–53.9)	

CI, confidence interval; CR, complete response; HR, hazard ratio; INV, investigator; IRR, independent radiology reviewer; mo, months; NA, not available; OFA, ofatumumab; PFS, progression-free survival; PR, partial response; R, rituximab.

Summary/Conclusions: Based on the reported observations of efficacy, the IDMC recommended stopping the study for futility, as there was little likelihood of OFA demonstrating superiority over R, and accrual was terminated.

P314

A PHASE IB STUDY EVALUATING THE SAFETY AND CLINICAL ACTIVITY OF ATEZOLIZUMAB COMBINED WITH OBINUTUZUMAB IN PATIENTS WITH RELAPSED OR REFRACTORY NON-HODGKIN LYMPHOMA

ML Palomba[1,*], BG Till[2], SI Park[3], F Morschhauser[4], G Cartron[5], R Marks[6], E Penuel[7], S Chitra[7], JCH Byon[7], L Popplewell[8]
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Fred Hutchinson Cancer Research Center, Seattle, WA, [3]University of North Carolina, Chapel Hill, NC, United States, [4]Lille University Hospital Center, Lille Cedex, [5]University Hospital Center of Montpellier, Montpellier, France, [6]Universitätsklinikum Freiburg, Freiburg, Germany, [7]Genentech Inc, South San Francisco, CA, [8]City of Hope, Duarte, CA, United States

Background: Even with modern chemo-immunotherapy regimens, outcomes for patients (pts) with relapsed or refractory diffuse large B-cell lymphoma (DLBCL) or follicular lymphoma (FL) remain poor. Atezolizumab (atezo), a humanized engineered IgG1 monoclonal antibody (mAb) against programmed death-ligand 1 (PD-L1), blocks the interaction between PD-L1 and its receptors PD-1 and B7.1, thereby preventing inhibition of T-cell activity. Atezo monotherapy has demonstrated clinical activity in multiple types of cancers, including non-Hodgkin lymphoma (NHL). Increased PD-L1/PD-1 expression has been reported in DLBCL and FL on cancer cells, stromal cells and tumor-infiltrating immune cells and may represent escape from immune surveillance. Obinutuzumab (obi) is a next-generation anti-CD20 mAb with enhanced ADCC.
Aims: To determine whether the combination of atezo and obi can activate both innate and adaptive immunity to enhance anti-tumor responses in lymphoma.
Methods: This multicenter, open-label Phase Ib study (NCT02220842) is assessing atezo combined with obi in pts with relapsed or refractory DLBCL or FL. Primary endpoints are safety and tolerability; secondary endpoints are pharmacokinetics and clinical activity. Key eligibility criteria were measurable disease and treatment with ≥1 prior chemo-immunotherapy regimen. Prior autologous stem cell transplant was allowed but not allogeneic stem cell transplant. In cycle 1, pts received obi intravenously (IV) alone on days 1 (100 mg), 2 (900 mg), 8 and 15 (1000 mg). From cycles 2–8, atezo (1200 mg) and obi (1000 mg) were administered IV on day 1 q3w. Atezo consolidation followed (1200 mg q3w) for an additional 6 mo. Objective response rate (ORR) was assessed by IWG NHL criteria. Pretreatment biopsies and on-treatment samples were collected to determine PD-L1 expression levels and examine other biomarkers of response and resistance.
Results: As of Feb 5, 2016, 31 pts (17 DLBCL; 14 FL) were evaluable for safety. Median age was 60 yrs (range 26–90) and 58% of pts were male. Median disease burden at baseline was 3027.9 mm^2 (range 598.0–31400.0). Median duration of therapy was 43 days (range 2–387) for DLBCL and 117 days (range 2–211) for FL. 1 potentially atezo-related adverse event (AE) (Grade 2 myalgia) led to treatment discontinuation. AEs led to study drug interruptions in 7 pts. 26 pts experienced ≥1 treatment emergent (TE) AE (Gr 1–4). The most common Gr 3–4 TEAEs were neutropenia (12.9%) and abdominal pain (6.5%). 4 deaths (3 due to disease progression; 1 unknown cause) were reported. 20 pts with ≥1 imaging assessment were evaluable for efficacy and had a median of 3 prior therapies (range, 2–7). At the first response assessment (after cycle 4), the ORR was 15%; 2 FL pts achieved a complete response, and 1 FL pt had a partial response. 6 pts had stable disease (1 with DLBCL; 5 with FL). PD-L1 expression was detected in DLBCL and FL; corresponding measurements of biomarkers associated with immune activity including infiltration by CD8+ T cells were seen. Updated safety, efficacy and biomarker data will be presented.
Summary/Conclusions: Preliminary results indicate that atezo combined with obi is well tolerated with evidence of clinical activity in pts with heavily pretreated relapsed or refractory DLBCL and FL.

P315

LONG-TERM FOLLOW-UP OF THE NEXT GENERATION PI3K-DELTA INHIBITOR TGR-1202 DEMONSTRATES SAFETY AND HIGH RESPONSE RATES IN NHL: INTEGRATED-ANALYSIS OF TGR-1202 MONOTHERAPY AND COMBINED WITH UBLITUXIMAB

OA O'Connor[1,*], I Flinn[2,3], M Lunning[4], J Vose[4], N Fowler[5], L Nastoupil[5], S O'Brien[6], MT Schreeder[7], MR Patel[2,8], TS Fenske[9], DM Brander[10], T Siddiqi[11], C Flowers[12], JA Burger[13], WG Wierda[13], JG Kuhn[14], HP Miskin[15], P Sportelli[15], MS Weiss[15], HA Burris III[2,3]
[1]Center for Lymphoid Malignancies, Columbia University Medical Center, New York, [2]Sarah Cannon Research Institute, [3]Tennessee Oncology, Nashville, [4]University of Nebraska Medical Center, Omaha, [5]Department of Lymphoma, MD Anderson Cancer Center, Houston, [6]University of California Irvine, Orange, [7]Clearview Cancer Institute, Huntsville, [8]Florida Cancer Specialists, Sarasota, [9]Division of Hematology/Oncology, Medical College of Wisconsin, Milwaukee, [10]Duke University Medical Center, Durham, [11]City of Hope National Medical Center, Duarte, [12]Emory University/Winship Cancer Institute, Atlanta, [13]Department of Leukemia, MD Anderson Cancer Center, Houston, [14]University of Texas Health Science Center at San Antonio, San Antonio, [15]TG Therapeutics, Inc., New York, United States

Background: TGR-1202 is a novel, once-daily PI3Kδ inhibitor with a differentiated safety profile from other PI3Kδ inhibitors, and proven activity in patients (pts) with advanced hematologic malignancies. TGR-1202 is in clinical development as monotherapy and in combination with the glycoengineered CD20 mAb, ublituximab (UTX).
Aims: An integrated-analysis was conducted of pts dosed with TGR-1202 monotherapy or combined with ublituximab with a focus on patients with indolent and aggressive NHL.
Methods: In both studies, there were no limits on prior therapies (Tx) and TGR-1202 was administered once-daily and escalated in 3 + 3 design with expansion cohorts explored. In the combo study, UTX was administered at a fixed dose of 900 mg per infusion. The primary endpoint was safety and efficacy was a secondary endpoint.
Results: Across both studies, a total of 152 pts (81 monotherapy/71 combined with UTX) were exposed to at least one dose of TGR-1202, including 40 CLL/SLL and 112 lymphoma patients. Among patients with lymphoma, histologies included 41 Follicular (FL), 38 DLBCL, 11 Marginal Zone (MZL), 9 Hodgkins (HL), 8 Mantle Cell (MCL) and 5 other. Median age 65 yrs (22-86); 100 M/52 F; median # prior Tx=3 (1-14); 53% refractory to immediate prior Tx. Most frequent reported AE's (all grades; Gr 3/4): nausea (44%; 1%), diarrhea (42%; 2%), fatigue (36%; 3%), vomiting (23%; 0%) and neutropenia (19%; 16%). AST/ALT increase was 6% (3% Gr 3/4), pneumonia 6% (5% Gr 3/4) and pneumonitis 1% (<1% Gr 3/4). 64 pts received TGR-1202 for ≥6 mos, 33 for ≥1 year, with longest on >30 mos. Discontinuations due to AE's occurred in 8% of pts. Across both studies, 74 NHL pts received the therapeutic targeted dose and were evaluable for efficacy. Amongst 37 patients with indolent NHL (FL and MZL), the ORR was 49% (11% CR), and amongst 37 patients with aggressive NHL (DLBCL, MCL, and Richter's), the ORR was 24% (8% CR). Notably, greater activity was observed in patients treated with the combination of TGR-1202 + UTX, with an ORR of 71% (24% CR) in indolent NHL and an ORR of 32% (16% CR) in aggressive NHL patients treated with the combination. The majority of DLBCL responses were observed with the combination of TGR-1202 + UTX, including 3 CR's and were mostly of GCB subtype. The median PFS for TGR-1202 monotherapy in indolent NHL was 27 mo, and has not been reached for patients treated with the TGR+UTX combo.
Summary/Conclusions: TGR-1202 has exhibited a markedly differentiated safety profile from other PI3Kδ inhibitors to date with few discontinuations due to AE's and limited G 3/4 events. In particular we highlight the minimal rates of transaminitis / pneumonitis / colitis events across a large CLL/NHL population. A global Phase 3 trial evaluating TGR-1202 in combination with UTX is ongoing in patients with treatment naïve and relapsed CLL. Registration directed Phase 2 and Phase 3 studies in patients with DLBCL and indolent NHL are planned.

P316

THE COMBINATION OF IBRUTINIB AND VENETOCLAX (ABT-199) RAPIDLY ACHIEVES COMPLETE REMISSIONS IN PATIENTS WITH RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA: PRELIMINARY RESULTS OF THE PHASE II AIM STUDY

C Tam[1,*], A Roberts[2], MA Anderson[2], SJ Dawson[1], R Hicks[1], C Pott[3], D Westerman[1], G Burke[1], S Kamel[4], M Dreyling[5], M Dawson[1], J Seymour[1]
[1]Peter MacCallum Cancer Centre, East Melbourne, [2]Melbourne Health, Parkville, Australia, [3]University Hospital Schleswig-Holstein, Kiel, Germany, [4]St Vincent's Hospital, Melbourne, Australia, [5]University of Munich, Munich, Germany

Background: The targeted agents ibrutinib & venetoclax (ABT-199) individually achieve response rates of 68-75% in patients (pts) with relapsed/refractory (R/R) mantle cell lymphoma (MCL). However, individually both drugs are associated with complete remissions (CR) in <25%, and median remissions <18 months. Multiple preclinical models showed synergy between ibrutinib and venetoclax.
Aims: We report the first-in-human experience with the combination of ibrutinib and venetoclax in the ongoing phase II, investigator-initiated AIM study.
Methods: Pts gave written consent, have R/R MCL, ECOG ≤2, and adequate marrow and organ function. The treatment plan comprises of 4 weeks ibrutinib induction at 560mg daily, followed by a 4 week ramp-up of venetoclax (to a target dose 400mg daily) with tumour lysis syndrome (TLS) monitoring, and continuation of both drugs thereafter. At full recruitment (n=24), the AIM study is powered to show improvement in CR rate after 4 months (primary endpoint) from a historic 9% for ibrutinib alone, to ≥30%. Pts are restaged using FDG PET/CT scans & minimal residual disease (MRD) by flow cytometry, ASO-PCR and circulating tumor DNA.
Results: As of 29-Jan-2016, 8 pts were enrolled: median follow-up was 38 days (range, 1-188), median age was 72 years (53–77), median prior therapies was 2 (1–7); 63% of pts had high MIPI scores. The most common adverse events (AE, all grade 1-2) were nausea (n=4), diarrhea (n=2) and oral candidiasis (n=2). Six serious AE have occurred: none were related to study drugs. Response to 4 weeks of ibrutinib induction were 2 partial responses (PR), 2 stable disease and 1 progressive disease; 3 pts were still receiving induction. The full dose of 400mg was reached in all 4 pts entering venetoclax ramp-up, without occurrence of laboratory or clinical TLS. Three pts have completed primary staging at 4 months (1 month of ibrutinib and 3 months of ibrutinib & venetoclax): 2 subjects were in CR with normalization of PET±endoscopy, and complete clearance of previous marrow involvement, including flow cytometry at $>10^{-4}$ sensitivity (Figure). The remaining pt had uninvolved marrow and non-FDG avid, small volume disease following ibrutinib induction that was inadequately visualized on the 4-month PET/CT scan, and was thus classified as PR. Updated safety, efficacy & MRD data (available in at least 8 pts) will be presented at the meeting.

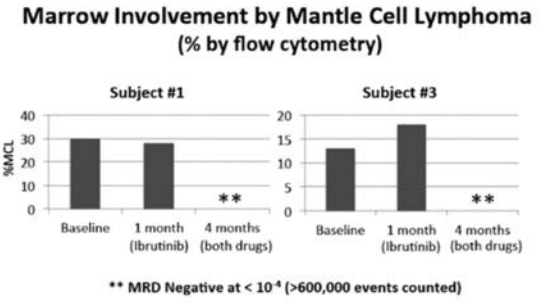

Figure 1.

Summary/Conclusions: The early experience with ibrutinib and venetoclax in combination shows no unexpected safety signals, and indicates promising efficacy.

P317

IDELALISIB MONOTHERAPY IN RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA (FL): EXPERIENCE THROUGH AN EARLY ACCESS PROGRAM IN EUROPE AND AUSTRALIA

JJ Li[1], M Breuleux[1], C Smith[1], A Davies[2,*]
[1]Gilead Sciences, Inc., Foster City, CA, United States, [2]Cancer Sciences Unit, Cancer Sciences Unit, Faculty of Medicine, University of Southampton, United Kingdom

Background: Idelalisib (IDELA) is an oral first-in-class selective PI3Kδ inhibitor approved in EU for use as a monotherapy in patients (pts) with FL who are refractory to two prior lines of treatment. Pts with FL of any grade (grade 1, 2, or 3a) who were refractory to two prior lines of treatment were eligible for this post-authorization, pre-national reimbursement early access program (EAP). Refractoriness required 2 out of the following criteria to be confirmed: (i) refractory to rituximab with chemotherapy; (ii) refractory to alkylating agent (administered with or without rituximab) or (iii) refractory to rituximab without chemotherapy. IDELA data outside clinical trials and in the real-world is limited.
Aims: The objective of this analysis was to characterize the baseline characteristics of refractory FL pts treated with IDELA monotherapy, in a real-world setting. The serious adverse events (SAE) reported are also presented.

Table 1.

Baseline Demography	Total (n=66)

0	24 (36.4)
1	32 (48.5)
2	10 (15.2)
3	0
Number of prior regimens, median (range)	4 (2-13)

**Indicates mandatory information collected upon enrolment*

Methods: This analysis only included pts with refractory FL treated with IDELA monotherapy within the EAP, in Australia, Belgium, Greece and Spain. This

program began enrollment from March 2015 and the data cut off was January 15, 2016. Available data were collected from de-identified pt registration data, follow-up resupply data and SAEs reports. This analysis summarizes the baseline pt characteristics reported which were either mandatory or optional on the pt enrolment form. SAEs were reported whilst the pts were on treatment. The proportion of missing data where information was unreported or unrecoverable is also shown in the table. Of 66 pts with refractory FL who had documented prior treatment regimens (60 pts with specific treatment documented and 6 with number of prior regimens only), the most common prior agents included rituximab (98.4%), cyclophosphamide (96.7%), prednisolone (95%), vincristine (95%), doxorubicin (76.7%) and etoposide (46.7%). A total of 12 pts (20%) had received a prior autologous stem cell transplant. With a median follow up of 109 days (range: 3-309), IDELA monotherapy was well-tolerated with 6/66 pts (9.1%) reporting an SAE. Reported SAEs, regardless of causality, include 1 (1.5%) each of febrile neutropenia, neutropenia, diarrhea, gastrointestinal inflammatory disorder, pancytopenia, progressive disease, liver enzyme elevation, hypotension and colon adenocarcinoma.

Results: Of 66 pts with refractory FL who had documented prior treatment regimens (60 pts with specific treatment documented and 6 with number of prior regimens only), the most common prior agents included rituximab (98.4%), cyclophosphamide (96.7%), prednisolone (95%), vincristine (95%), doxorubicin (76.7%) and etoposide (46.7%). A total of 12 pts (20%) had received a prior autologous stem cell transplant. With a median follow up of 109 days (range: 3-309), IDELA monotherapy was well-tolerated with 6/66 pts (9.1%) reporting an SAE. Reported SAEs, regardless of causality, include 1 (1.5%) each of febrile neutropenia, neutropenia, diarrhea, gastrointestinal inflammatory disorder, pancytopenia, progressive disease, liver enzyme elevation, hypotension and colon adenocarcinoma.

Summary/Conclusions: The results of this large real-world cohort of pts with FL who are refractory to 2 prior lines of therapy treated by IDELA monotherapy outside of the clinical trial setting confirm the acceptable tolerability profile of IDELA.

P318

PHASE 2A STUDY OF THE PHOSPHATIDYLINOSITOL-3-KINASE (PI3K) INHIBITOR COPANLISIB IN PATIENTS WITH RELAPSED/REFRACTORY, INDOLENT OR AGGRESSIVE LYMPHOMA

M Dreyling[1,*], F Morschhauser[2], K Bouabdallah[3], D Cunningham[4], D Bron[5], K Linton[6], S Assouline[7], G Verhoef[8], C Thieblemont[9], U Vitolo[10], J Garcia-Vargas[11], I Gorbatchevsky[11], M Neves[12], J Grunert[13], F Hiemeyer[14], BH Childs[11], PL Zinzani[15]

[1]Klinikum der Universität München-LMU, Munich, Germany, [2]CHRU - Hôpital Claude Huriez, Lille, [3]University Hospital of Bordeaux, Bourdeaux, France, [4]The Royal Marsden Hospital, Sutton, United Kingdom, [5]Institute Jules Bordet (ULB), Brussels, Belgium, [6]The Christie NHS Foundation Trust, Manchester, United Kingdom, [7]Jewish General Hospital, Montreal, Canada, [8]University Hospital Leuven, Leuven, Belgium, [9]APHP-Hôpital Saint-Louis, Paris, France, [10]Città della Salute e della Scienza di Torino, Torino, Italy, [11]Bayer HealthCare Pharmaceuticals, Whippany, United States, [12]Bayer HealthCare, Sao Paulo, Brazil, [13]Bayer Pharma AG, Wuppertal, [14]Bayer Pharma AG, Berlin, Germany, [15]Institute of Hematology "Seragnoli" University of Bologna, Bologna, Italy

Background: Copanlisib (BAY 80-6946) is a potent and selective pan-class I PI3K inhibitor with preferential activity against the δ- and α-isoforms. In an expansion cohort of a phase I study, promising activity was seen in patients with non-Hodgkin lymphoma (NHL), with 6 of 6 responses in follicular lymphoma (FL) patients [2 of which were durable (>3 years) complete responses per post-hoc radiologic review (Patnaik et al, submitted)] and 1 of 3 diffuse large B-cell lymphoma (DLBCL) patients achieving a partial response (PR).

Aims: We therefore investigated the efficacy and safety of copanlisib in subjects with relapsed/refractory indolent or aggressive NHL or chronic lymphocytic leukemia (CLL). (NCT01660451)

Methods: Patients with histologically confirmed indolent or aggressive lymphoma or CLL, relapsed or refractory to ≥2 prior lines of treatment were enrolled. Copanlisib (0.8 mg/kg) was administered intravenously on days 1, 8 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) as assessed by independent radiology review according to the response criteria for lymphoma (Cheson et al, JCO 1999) or the guidelines for diagnosis and treatment of CLL (Hallek et al, Blood 2008). Secondary endpoints included progression-free survival (PFS) and duration of response (DOR), safety and tolerability.

Results: A total of 20 patients with indolent NHL (iNHL; 16 FL, 3 marginal zone lymphoma, 1 small lymphocytic lymphoma), 13 CLL and 48 with aggressive NHL [15 DLBCL, 14 peripheral T-cell lymphoma, 11 mantle cell lymphoma (MCL), 6 transformed, 1 mediastinal, and 1 Grade 3b FL] were treated; median age 67 years; 53% male; median 3 (range 1-10) number of previous lines of treatment and prior rituximab in 80% of patients. At the time of analysis, the ORR was 47% (90% CI 27-68) and stable disease (SD) was 47% (CI 27-68) in patients with iNHL, 38% (CI 17-65) and 46% (CI 22-71) in CLL, and 26% (CI 16-39) and 17% (CI 9-29) in aggressive NHL, respectively. For patients with FL, the ORR was 40% (CI 19-64), with 1 CR, 2 uCRs, and 3 PRs; SD in 53% (CI 30-76). The ORR in the MCL patients was 64% (CI 35-86; 2 uCR and 5 PRs). The median DOR was 390 days in the indolent group and 166 days in the aggressive group. The most common treatment-related adverse events (AEs) of all grades (G) were hyperglycemia (59%), hypertension (54%), diarrhea (33%), and fatigue (28%). G3-4 treatment-related AEs occurring in >10% of patients included hypertension (39%) and hyperglycemia (25%). Treatment-related AEs leading to dose reduction were observed in 4%, interruption in 36%, interruption and reduction in 7%, or permanent discontinuation in 17% of patients, respectively. There were 4 treatment-related grade 5 events: meningitis, respiratory failure and 2 lung infections.

Summary/Conclusions: Copanlisib is active as a single agent in heavily pretreated patients with a variety of relapsed/refractory indolent or aggressive lymphoma subtypes, with promising CR activity in FL and MCL. Copanlisib exhibited a manageable toxicity profile. Final results of survival rates will be presented. Based on these encouraging results, phase II studies in patients with FL, MCL, and DLBCL are ongoing.

P319

PRELIMINARY SAFETY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF DUVELISIB PLUS RITUXIMAB OR OBINUTUZUMAB IN PATIENTS WITH PREVIOUSLY UNTREATED CD20+ FOLLICULAR LYMPHOMA

C Casulo[1,*], E Jacobsen[2], K Van Eygen[3], HE Holmes[4], JP Lemmens[5], K Allen[6], L Steelman[6], V Campbell[6], J Nevejans[6], J Pearlberg[6], A Goy[7]

[1]James P. Wilmont Cancer Center Strong Memorial Hospital, Rochester, [2]Partners Cancer care, Dana-Farber Cancer Institute, Boston, United States, [3]AZ Groeninge, Kortrijk, Belgium, [4]Texas Oncology PA, Dallas, United States, [5]Medcl Inst St Augustinus, Wilrijk, Belgium, [6]Infinity Pharmaceuticals Inc, Cambridge, [7]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, United States

Background: Duvelisib (IPI-145), a dual PI3K-δ,γ inhibitor, is being evaluated as an oral therapeutic for hematologic malignancies as a monotherapy or in combination with anti-CD20 antibodies.

Aims: We report herein results for the CONTEMPO (NCT02391545) study, an ongoing 2-part, 2-arm, Phase 1b/2 study that evaluates the safety, pharmacokinetics, pharmacodynamics and efficacy of duvelisib combined with the anti-CD20 antibodies rituximab (DR) or obinutuzumab (DO) in patients with previously untreated CD20+ follicular lymphoma.

Methods: Duvelisib is administered at 25 mg BID continuously in 28-day treatment cycles combined either with rituximab (375 mg/m^2 for 4 weekly doses, then 1 dose every 2 cycles) or obinutuzumab (1000 mg for 4 weekly doses, then 1 dose every 2 cycles). We report results from Part 1 which evaluated the safety of the combinations by monitoring adverse events (AEs) and dose limiting toxicities (DLTs).

Results: Twelve patients were treated in Part 1 of the study (6 DR and 6 DO). At the time of data cut-off, patients had received duvelisib for a median of 2.5 (DR) and 1.9 (DO) months. No DLT occurred with DR. One DLT of treatment-related Grade 3 elevated lipase occurred with DO (Cycle 1). No serious AEs occurred on either arm, and no patient discontinued treatment. Four patients (1 DR; 3 DO) had ≥Grade 3 AEs (DR: amylase increased, lipase increased; DO: neutropenia, ALT increased, lipase increased). Duvelisib was rapidly absorbed (t_{max}~1 hour; C_{max}~910 ng/mL; single dose); after multiple doses, plasma steady state levels were ~500-540 ng/mL and approximately half of the duvelisib was transformed into its metabolite IPI-656. Postdose serum cytokine levels were decreased by Cycle 1 Day 8 compared to baseline. Preliminary activity will be reported at the time of the meeting.

Summary/Conclusions: Combination of duvelisib 25 mg BID with rituximab or obinutuzumab was well tolerated in these patients, with one DLT observed. Both DR and DO arms were continued to Part 2 of the study, which is ongoing.

P320

SAFETY AND EFFICACY PROFILES OF CLARITHROMYCIN MONOTHERAPY IN 55 PATIENTS WITH EXTRANODAL MARGINAL ZONE LYMPHOMA (EMZL)

AJ Ferreri[1,*], C Cecchetti[1], B Kiesewetter[2], M Sassone[1], T Calimeri[1], L Scarfò[1], M Raderer[2]

[1]Department of OncoHematology, San Raffaele Scientific Institute, Milano, Italy, [2]Dept. of Internal Medicine I, Medical University of Vienna, Wien, Austria

Background: Macrolides have been proposed as new anticancer agents. In particular, clarithromycin displays different immunomodulatory effects on several pathways, and is active in different tumor models. Two phase II trials have demonstrated that clarithromycin monotherapy is safe and active in patients (pts) with relapsed/refractory EMZL (Govi *et al.* BJH 2010; Ferreri *et al.* Ann Oncol 2015), but the best administration schedule of this antibiotic as antineoplastic agent remains to be defined.

Aims: To address tolerability, activity and efficacy of clarithromycin monotherapy in a large retrospective series of pts with EMZL. Results with three different administration schedules were analyzed.

Methods: 55 pts with EMZL and at least one measurable/parametrable lesion treated with single-agent clarithromycin between 2003 and 2015 were analyzed. Clarithromycin was used with three different schedules: a 6-month regimen at 500 mg twice a day, every day (n=13); three courses of 500 mg twice a day, days 1-21, every 35 days (n=19); or four courses of 2.000 mg/d, days 1-14, every 21 days (n=23).
Results: Median age of analyzed pts was 65 years (range 30-88), with a M:F ratio of 0.57. EMZL affected a single organ in 40 pts, and was multifocal in 15: the most commonly involved organs were ocular adnexae (n=30), stomach (n=9) and lung (n=7). International Prognostic Index (IPI) score was 0-1 in 40 pts and 2-4 in 15; the IELSG risk score (age, LDH and stage) was 0 in 25 pts, 1 in 23 and >1 in 7. A prior history of chronic infection was recorded in 20 pts: HBV/HCV, *H. pylori* and *C. psittaci* in 5 pts each, with multiple combinations of these micro-organisms in 5. Clarithromycin was the first treatment line in 8 pts, the second in 24, the third in 15, and the 4^{th}-6^{th} in 8. Tolerability was excellent: only 2 pts had grade-3 toxicity (nausea); the main side effects were grade 1-2 nausea (17 pts), dysgeusia (7), dizziness (4), headache (3), arthralgia (2), and rash (2). Five pts interrupted treatment due to nausea (3), rash or dysgeusia. There were no differences in feasibility and tolerability among different treatment schedules, but nausea was significantly more common when a daily dose of 2.000 mg was used (52% *vs* 25%; Fisher exact, p=0.03). Objective response after clarithromycin treatment was complete in 13 (24%) pts and partial in 13, with an overall response rate (ORR) of 47% (95% CI= 34-60). Responses were more common among pts with gastric MALT lymphoma (7/9 *vs* 19/46; p=0.04). ORR was not associated with prior treatment, IPI, IELSG score, and clarithromycin dose. At a median follow-up of 33 months (range 7-137), 29 pts remain progression-free, with a 3-year PFS of 52±7%. Pts with lymphoma refractory to prior treatment and pts with IPI score ≥2 had a significantly and independently poorer PFS. Conversely, clarithromycin dose was not associated with outcome, with a 3-year PFS of 60±9% and 42±10% (log-rank test; p=0.47) for pts treated with a daily dose of 1 g and 2 g, respectively. Fifty-two pts are alive, with a 3-year OS of 96±3%; causes of death were liver failure, stroke and lung cancer.
Summary/Conclusions: Clarithromycin monotherapy is active in pts with EMZL, and exhibits an excellent safety profile when used at a dose of up to 2 g/d for 4-6 months. The recommended daily dose of clarithromycin in pts with EMZL is 1 g as it is associated with a lower incidence of nausea and similar efficacy than 2 g. Further investigation of clarithromycin, alone or associated with immunomodulators, in lymphoma pts is warranted.

P321

A PHASE I STUDY IN T CELL LYMPHOMA PATIENTS TREATED WITH ANTI-CD70 SIMPLE ANTIBODY™ ARGX-110

JM Michot[1,*], K Silence[2], M Maerevoet[3], P Aftimos[3], S Rottey[4], C Rolfo[5], F Offner[4], L Van Rompaey[6], M Moshir[6], H de Haard[6], M Bagot[7], P Pauwels[5], K Zwaenepoel[5], A Awada[3], D Bron[3], V Ribrag[8]
[1]Gustave Roussy, Cancer Campus Grand Paris, Paris, France, [2]argenx bvba, Zwijnaarde, [3]Institut Jules Bordet-Université Libre de Bruxelles, Bruxelles, [4]Ghent University Hospital, Gent, [5]Universitair Ziekenhuis Antwerpen, Antwerpen, [6]argenx bvba, Gent, Belgium, [7]Saint-Louis Hospital Assistance Publique des Hopitaux de Paris, [8]Institut Gustave Roussy, Paris, France

Background: CD70 is a cell surface marker transiently expressed on activated B, T and dendritic cells. The interaction via its receptor CD27 results in survival, proliferation and lymphocyte differentiation. In a large number of solid tumours types CD70 is overexpressed, but without receptor co-expression. The CD70/CD27 axis appears critical for proliferation and survival of malignant cells in T-cell lymphoma. Indeed, overexpression of CD70 is paralleled by high expression of its receptor CD27 in TCL.
Aims: ARGX-110 is a novel glycoengineered monoclonal antibody targeting CD70 and blocking CD27 signaling, leading to a direct mode of action lysing $CD70^+$ tumor cells (via CDC, ADCP and enhanced ADCC) and indirect anti-tumor restoring immune surveillance. (NCT01813539) A phase I trial was initiated with ARGX-110, dose escalated to investigate safety, clinical pharmacology and determine the RP2D, in refractory or relapsed solid tumors and hematological malignancies.
Methods: Patients with >10% $CD70^+$ expression on the tumor in immunohistochemistry were included in the study. ARGX-110 was given to 65 patients at doses from 0.1 to 10 mg/kg intravenously every 3W. In TCL patient's biomarkers were measured during the course of treatment.
Results: Immunohistochemistry on TCL patient samples confirmed overexpression of CD70 (>10% CD70+ tumor cells) in 40/73 PTCL (55%) and 15/21 CTCL (71%) samples. In 68% of these samples CD70 and CD27 were simultaneously expressed. Serum soluble CD27 levels were elevated in TCL patients compared to healthy subjects (670±1096 *vs* 192±44 IU/ml, respectively, p=0.0062). Nine patients TCL patients were included in the study (3 Cutaneous TCL (CTCL) and 6 Peripheral TCL (PTCL)). ARGX-110 was well tolerated with no grade >3 adverse events related to the study drug. A clinical and/or biological response was observed in 4/9 of T-cell Lymphoma cohort patients; CTCL (n=3) and PTCL-AITL (n=1) patients. The activity in 2 patients with Sezary syndrome (treated at 0.1 and 10 mg/kg, respectively) resulted in a >90% reduction in the circulating malignant clone and a clinical partial response in the skin in one patient. The patient with CTCL T_{FH} lymphoma (T_{FH}L; 5 mg/kg) achieved a PR. One patient with AITL reached a PR (5 mg/kg dose) and had a resolution of lymphoma associated auto-immune hemolytic anemia.
Summary/Conclusions: In the TCL patients treated with ARGX-110, we observed a clinical and/or biological response in 4/9 patients. These preliminary results support further investigation of ARGX-110 in TCL.

Stem cell transplantation - Experimental

P322

TO SCREEN BIOLOGICAL MARKER GENE ASSOCIATED WITH B CELL IN CHRONIC GRAFT-VERSUS-HOST DISEASE (CGVHD) PATIENTS

L Liu*, X Li, Q Qu, Y Yao, M Zhu, L Dai, W Shen, Y Xu, X Wu, G Chen, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a widely used therapy for a lot of malignant and nonmalignant hematologic diseases. Graft-*versus*-host disease (GVHD) remains one of the major barriers to a more widespread and successful application of allo-HSCT. Despite immune-suppressive prophylaxis, most survivors develop chronic GVHD (cGVHD). Identification of biologic markers of the syndrome could facilitate significant advances in understanding to help guide prevention and treatment approaches. Data in humans support a role of both T- and B-cells in a highly complex network leading to cGVHD. However, there was no report about biological marker gene associated with B cell in cGVHD patients.
Aims: So we screened biological marker gene associated with B cell in cGVHD patients. Microarrays were used to detect expressed gene profiles of peripheral blood mononuclear cells total RNA from subjects in the mild-moderate cGVHD, severe cGVHD, non-cGVHD, immune tolerance and healthy donors groups.
Methods: Microarrays were used to detect expressed gene profiles of peripheral blood mononuclear cells total RNA from subjects in the mild-moderate cGVHD, severe cGVHD, non-cGVHD, immune tolerance and healthy donors groups. Found out the genes associated with B cell in cGVHD patients reached statistical significance after a false discovery rate (FDR) correction was applied to the data. Real-time quantitative RT-PCR was used to confirm the B cell genes.
Results: Found out the genes associated with B cell in cGVHD patients reached statistical significance after a false discovery rate (FDR) correction was applied to the data. Real-time quantitative RT-PCR was used to confirm the B cell genes. 284 genes were found by microarrays between cGVHD patients and patients without cGVHD, 5 genes (CDKN2A, SOX4, ZBTB32, CD70, IL21R) associated with B cell. 800 genes were found by microarrays between immune tolerance patients and patients without cGVHD, 3 genes (NFAM1, CD27, BST1) associated with B cell. Real-time quantitative RT-PCR confirmed significantly lower expression of CDKN2A in cGVHD relative to without cGVHD patients (P=0.001). Significantly higher expression of CD27 and lower expression of BST1 in immune tolerance relative to without cGVHD patients (P=0.038, P=0.022).
Summary/Conclusions: The preliminary results indicated that CDKN2A gene had significantly lower expression in cGVHD relative to without cGVHD patients, CD27 gene had significantly higher expression and BST1 gene had significantly lower expression lower expression in immune tolerance patients relative to without cGVHD patients. The changes of these genes may be potential biomarkers for cGVHD and immune tolerance.

P323

MITOCHONDRIAL INHIBITION BY NICOTINAMIDE RIBOSIDE POTENTLY STIMULATES HEMATOPOIESIS AFTER TRANSPLANTATION VIA THE MITOCHONDRIAL UNFOLDED PROTEIN RESPONSE

N Vannini[1,*], V Campos[1], M Girotra[1], E Stefanidis[2], A Semilietof[2], Y Yersin[1], L Tauzin[3], E Pirinen[1], D Vanhecke[2], G Coukos[1], J Auwerx[1], M Lutolf[1], O Naveiras[1]
[1]Institute of Bioengineering, Ecole Polytechnique Federale de Lausanne, [2]Ludwig Center for Cancer Research, UNIL, [3]Flow Cytometry Core Facility, Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland

Background: The slow nature of blood regeneration from hematopoietic stem cells (HSCs) severely compromises the survival of patients upon primary bone marrow failure, intensive ablative chemotherapy or HSC transplantation. Current strategies to accelerate HSC regeneration and shorten the time of bone marrow aplasia, including treatment with granulocyte colony stimulating factor (G-CSF), are insufficient to avoid severe and often lethal infections during the time of aplasia. Indeed, HSCs are predominantly quiescent during homeostasis. The proliferative stress imposed on HSCs to reconstitute the full hematopoietic system in the 4-6 weeks following HSC transplantation entails activation of oxidative phosphorylation within mitochondria, interfering with pyruvate dehydrogenase kinase (PDK) and hypoxia-inducible factor (HIFa)-driven metabolic checkpoints of HSC self-renewal and thus induces premature HSC aging. In turn, activation of the mitochondrial unfolded protein response (UPR^{mt}) enhances mitochondrial health and prolongs lifespan from *C. elegans* to mice, mostly due to the activation of the Sirtuins and their convergence into DAF-16/FOXO3 signaling, also shown to regulate HSCs maintenance.
Aims: We set to test whether mitochondrial inhibition and/or activation of UPRmt in HSCs would lead to accelerated recovery from aplasia after bone marrow transplantation in mice.
Methods: Wildtype C57BL/6 mice or NOD-SCID mice reconstituted with human CD34+ cells were treated with Nicotinamide Riboside for 7 days during homeostasis, and from day -7 to 35 in the context of HSC transplantation.
Results: Here we show that distinct hematopoietic progenitor compartments show specific increases in mitochondrial activity during commitment, and that mitochondrial activity is a functional predictor of HSC engraftment both *in vivo* and *in vitro*. We have shown that modulating mitochondrial potential through the use of uncouplers can displace the long-term (LT)/short-term (ST) -HSC equilibrium *in vivo* by maintaining LT-HSCs while increasing the ST-HSC pool. Dietary supplementation in NAD^+-boosting agent Nicotinamide Riboside (NR) inhibits mitochondrial activity via UPRmt and activation of autophagy within long-term HSCs, resulting in the expansion of functional short-term HSCs without HSC exhaustion in mice. Indeed, NR treatment dramatically improves survival and accelerates blood recovery after murine HSC transplantation, also increasing the production of human blood cells in humanized mice.
Summary/Conclusions: Our work establishes a novel link between UPRmt and autophagy in self-renewing HSCs, demonstrates for the first time an effect of NAD+ boosting strategies at the level of the most primitive blood stem cells, and unveils the potential of NR to improve the outcome of patients suffering from bone marrow insufficiency.

MESENCHYMAL STROMAL CELLS STIMULATE THE PROLIFERATION AND IL-22 PRODUCTION BY TYPE 3 INNATE LYMPHOID CELLS

M Hazenberg[1,*], V van Hoeven[1], M Munneke[1], A Cornelissen[2], S Omar[1], M Spruit[1], J Bernink[3], H Spits[3], C Voermans[2]
[1]Hematology, Academic Medical Center, [2]Sanquin, [3]Academic Medical Center, Amsterdam, Netherlands

Background: Graft-*versus*-host disease (GvHD) remains a challenging complication after allogeneic hematopoietic stem cell transplantation (HSCT). Mesenchymal stromal cells (MSCs) are increasingly applied to treat steroid-refractory GvHD. The therapeutic effect of MSCs is mainly ascribed to their ability to suppress the proliferation of (alloreactive) lymphocytes and to enhance the tissue repair activity of endothelial cells, fibroblasts, and epithelial cells. However, only about half of the GvHD patients actually respond to MSC therapy, and which determinants are related to MSC responsiveness remains to be elucidated. We recently found an inverse association between the proportion of circulating, activated type 3 innate lymphoid cells (ILC3s) before allogeneic HSCT and susceptibility to GvHD development, which may be related to the ability of ILC3s to produce tissue-protective interleukin 22 (IL-22).
Aims: To investigate the potential interaction between MSCs and ILC3s *in vitro*. In particular we aimed to test whether MSCs can induce ILC3s to produce the tissue protective cytokine IL-22.
Methods: ILC3s isolated from human tonsils were CellTrace-labeled and co-cultured with bone-marrow derived MSCs for 5 days in the presence of IL-2. Following co-culture, we determined ILC3 proliferation and cytokine production, and analyzed surface-marker expression on MSCs by flow cytometry.
Results: Co-culture with MSCs significantly enhanced the proliferation of ILC3s and resulted in an increased production of IL-22. ILC3s proliferated slightly better in the presence of MSC culture supernatant compared to IL-2 only, and addition of IL-7 blocking antibodies to MSC-ILC3 co-cultures had an inhibitory effect on ILC3 proliferation in MSC-ILC3 co-cultures. These findings suggest that the MSC-driven stimulation was at least partly mediated via IL-7. In transwell experiments, however, proliferation of ILC3s was significantly reduced when ILC3s and MSCs were cultured in separate compartments, showing that cell-cell proximity or cell-cell contact is important for the stimulation of ILC3s by MSCs. Reciprocally, ILC3s also influenced the MSCs, as ICAM1 and VCAM1 expression was upregulated in co-cultures. Addition of blocking antibodies against ICAM1, VCAM1, or the integrin subunits these adhesion molecules bind to, did not affect the proliferation of ILC3s.
Summary/Conclusions: We here show that MSCs can interact with ILC3s *in vitro*, resulting in enhanced proliferation and cytokine production of ILC3s. These results suggest that MSCs may have a dual mechanism by which they contribute to the control of GvHD: (1) by inhibiting the proliferation of (alloreactive) T lymphocytes and NK cells, and (2) by promoting expansion and IL-22 production of tissue-protective ILC3s.

P325

GRANULOCYTE COLONY-STIMULATING FACTOR MOBILIZATION INCREASES THE PROPORTION OF REGULATORY GAMMA DELT T CELLS

L Xuan[1,*], X Wu[2], L Gao[1], Z Fan[1], Z Jin[2], X Wang[2], Y Li[2], Q Liu[1]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, [2]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background: The immune modulatory effect of granulocyte colony-stimulating factor (G-CSF) on T cells resulted in an unexpected low incidence of graft-*versus*-host disease (GVHD) in allogeneic peripheral blood stem cell transplantation. Our previous studies demonstrated that G-CSF mobilization influenced

the distribution and clonality of TRGV and TRDV repertoire (T cell receptors of γδ T cells). Regulatory γδ T cells (γδ Tregs), which express Foxp3 and primarily belong to $CD27^{+}CD25^{high}$ phenotype, are a novel subset of cells with immunosuppressive function. However, whether G-CSF mobilization could influence the expression and immunosuppressive function of γδ Tregs remains unknown.
Aims: To explore the effect of G-CSF mobilization on γδ Tregs, the expression and immunosuppressive function of γδ Tregs before and after G-CSF mobilization were compared.
Methods: Peripheral blood $γδ^{+}$ T cells were sorted by magnetic activated cell-sorting (MACS) from 10 donors before and after G-CSF mobilization, respectively. MACS-sorted γδ T cells were used as effector cells in the carboxylfluorescein diacetate succinimidyl ester (CFSE) assays and cell immunophenotyping was analyzed by flow cytometry. Autologous $CD4^{+}$ T cells were purified by MACS, labeled with CFSE, used as responder cells, and finally co-cultured with effector cells. After 5 d incubation, cells were harvested and analyzed for flow cytometry by gating on the CFSE-labeled cells. The percentages of divided responder T cells before and after G-CSF mobilization were compared.
Results: Compared with that before mobilization, the proportions of $Foxp3^{+}γδ$ T, $Foxp3^{+}$ Vδ1 T and $Foxp3^{+}$ Vδ2 T cells were significantly increased in sorted γδ T cells after G-CSF mobilization (P=0.035, P=0.017 and P=0.004). The proportions of $CD27^{+}γδ$ T, $CD27^{+}$Vδ1 T and $CD27^{+}$Vδ2 T cells were also significantly increased in sorted γδ T cells after G-CSF mobilization (P=0.035, P=0.026, P=0.037). The proportions of $CD25^{+}γδ$ T, $CD25^{+}$ Vδ1 T and $CD25^{+}$Vδ2 T cells were similar in sorted γδ T cells before and after mobilization (P=0.252, P=0.126, P=0.237). We then compared the inhibitory effect of sorted γδ T cells before and after G-CSF mobilization on the proliferation of autologous $CD4^{+}$ T cells. We found that MACS-sorted γδ T cells before and after G-CSF mobilization both exerted certain suppression on proliferation, whereas γδ T cells after G-CSF mobilization had a more significant suppressive effect on $CD4^{+}$ T cells than γδ T cells before mobilization (P=0.002).
Summary/Conclusions: G-CSF mobilization could increase the proportions of regulatory T cells in sorted γδ T cells, thus having a higher suppressive effect on $CD4^{+}$ T cells.

P326

PREACTIVATED MESENCHYMAL STROMAL CELLS IMPROVE T-CELL REGENERATION AFTER THEIR COTRANSPLANTATION WITH HEMATOPOIETIC STEM CELLS

S Kuci*, Z Kuci, B Eising, K Michel, H Kreyenberg, T Klingebiel, P Bader
University Hospital Frankfurt Department for Children and Adolescents, Frankfurt am Main, Germany

Background: Mesenchymal stromal cells (MSCs) are known to support hematopoiesis both *in vitro* and *in vivo*. However, there is scant evidence on the effect of preactivated MSCs with inflammatory cytokines on the engraftment of hematopoietic stem/progenitor cells.
Aims: The aim of this study was therefore to investigate whether preactivation ("licensing") of subsets of MSCs with inflammatory cytokines (IFN-gamma, TNF-alpha) may affect regeneration of T-cells after hematopoietic cell transplantation.
Methods: MSCs were generated from positively selected $CD271^{+}$ bone marrow mononuclear cells (CD271-MSCs) by using the MSC Research Tool Box–CD271 (LNGFR)-APC (Miltenyi Biotec GmbH), according to manufacturer's instructions. $CD34^{+}$ hematopoietic stem/progenitor cells (HSCs) were cotransplanted with either resting or preactivated ("licensed") CD271-MSCs with IFN-γ or TNF-α in immunodeficient NSG-mice.
Results: Flow cytometric analysis of peripheral blood (PB) of NSG-mice 4 weeks after cotransplantation of $CD34^{+}$ cells with CD271-MSCs demonstrated that $CD34^{+}$ HSCs differentiated in B and NK-cells, but not in T-cells. However, FACS analysis of PB at week 14, showed a 6.6-fold increase of T-cells in the cotransplanted group *versus* the group transplanted with CD34+ HSCs only (control group). Moreover, cotransplanted mice with "licensed" CD271-MSCs with TNF-α or IFN-γ showed a significantly increased number of T-cells (23- or 30-fold, respectively) compared to control group. All regenerated T-cells (helper and cytotoxic) had a naïve (CD3+CD4+CD45RA+CCR7+ or CD3+CD8+ CD45RA+CCR7+) but not an effector phenotype. Both, resting and preactivated CD271-MSCs normalized the CD4/CD8 ratio from 0.8 (control group) to 1.3. TREC-analysis of the thymus cells revealed no difference between cotransplanted groups and control. However, Vβ spectratyping (23 Vβ-subgroups) of spleen cells showed an increased T cell repertoire complexity (Vß2, Vß3, Vß4, Vß9, Vß17 und Vß21) in the group cotransplanted with IFN-γ preactivated CD271-MSCs and $CD34^{+}$HSCs. T-cell regeneration was also confirmed by immunohistochemistry of the spleen.
Summary/Conclusions: Cotransplantation of preactivated CD271-MSCs with IFN-γ appears to be a novel strategy to improve T-cell regeneration and development of T-cell receptor repertoire after hematopoietic transplantation.

P327

EVIDENCE OF COMPLEMENT DYSREGULATION IN TRANSPLANT ASSOCIATED THROMBOTIC MICROANGIOPATHY

E Gavriilaki[1,2,*], P Imus[3], X Yuan[2], A Baines[2], R Jones[3], R Brodsky[2]
[1]Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece, [2]Division of Hematology, Department of Medicine, [3]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, United States

Background: Transplant-associated thrombotic microangiopathy (taTMA) is a devastating complication occurring in 10-39% of patients undergoing hematopoietic cell transplantation (HCT) with a high mortality rate. However, our understanding of the pathophysiology which is strongly related to diagnosis and treatment options is limited. Recent evidence has linked taTMA with atypical hemolytic uremic syndrome (aHUS), a disease of excessive activation of the alternative pathway of complement (APC) that is successfully treated by terminal complement inhibition with eculizumab. We have recently developed the modified Ham test as a functional assay that can reliably distinguish APC activation observed in aHUS from other TMAs.
Aims: We aimed firstly to detect evidence of increased APC activation by the modified Ham test in taTMA and secondly to test the *in vitro* ability of eculizumab to inhibit APC activation in taTMA.
Methods: Patients were enrolled in a prospective fashion from December 2014 to April 2015 as all patients admitted to our service with taTMA according to clinical judgement, in keeping with the current diagnostic criteria (BMT-CTN or IWG). Patients with graft-*versus*-host-disease / GVHD and transplanted patients with neither complication / controls were enrolled during the same timeframe. APC activation was detected in the modified Ham test, a cell proliferation assay that measures complement-mediated cell killing caused by patient serum, and was compared to a previously described marker of complement activation, serum C5b-9 levels. Eculizumab containing serum (ECU) was collected from a patient with paroxysmal nocturnal hemoglobinuria (PNH) within 60 minutes after the infusion and used to test complement blockade by eculizumab in the modified Ham test.
Results: We studied 5 patients with taTMA, 4 patients with GVHD and 6 transplanted patients with neither complication. We first measured C5b-9 levels as a biomarker of terminal complement activation. There was no difference in serum C5b-9 levels among patients with taTMA, patients with GVHD and controls (57.8±28.1, 49.2±25.5 and 53.4±31.9 ng/ml respectively, p=0.913). We next utilized the modified Ham test, which detected increased APC activation in taTMA. Serum from patients with taTMA caused significantly increased complement-mediated killing compared to patients with GVHD and controls (Figure 1). As previously described, increased complement activation was also found in taTMA patients while on eculizumab (grey symbols in Figure 1). In the ROC curve analysis, a cutoff of 23.5% identified taTMA with 100% sensitivity and specificity in this small cohort. Then, we evaluated the efficacy of complement inhibition by eculizumab in the modified Ham test. Mixing eculizumab serum (ECU) with taTMA sera demonstrated a dose-killing relationship that was consistent across the three patients.
Summary/Conclusions: Our results confirm recent suggestions that complement dysregulation is involved in the pathophysiology of taTMA. If confirmed in larger series, the modified Ham test may also form the basis for therapeutic trials based upon complement inhibition.

Background: Cord blood transplantation (CBT) from a related family member is an effective therapy for patients with Sickle Cell Disease (SCD) resulting in encouraging outcomes with similar or superior survival to adult donor transplant. Efforts to implement family-directed umbilical cord blood (UCB) banking have been developed in the past two decades for siblings requiring stem cell transplantation (SCT).
Aims: Public umbilical cord blood banks are faced with the challenge regarding the units to be stored or to be discarded or used for other endeavors such as research. To this end, we report our 20-year experience of family-directed UCB banking for SCD and review the characteristics of the UCB units collected between 1995 and 2014.

Methods: Families were eligible if they had a child with SCD, and expecting the birth of a sibling. Participation was voluntary and free of charge. All mothers underwent a panel of serologic blood donor screening assays. UCB units were collected in remote sites, cryopreserved and stored in a single bank. UCB testing included viral serology, bacterial cultures and cell counts. HLA typing on the UCB were not routinely performed unless requested by the transplant physician.
Results: 189 families from 27 different centers were enrolled. 17 (10%) families had >1 UCB unit stored, due to multiple pregnancies. Potential recipients had a median age of 6 years (range 11 months - 12 years) at time of UCB harvest. 14 families had >1 affected child. A total of 210 UCB units were collected from 189 mothers. All UCBs were negative for HIV and 64 UCBs (30%) had positive anti-HBs and/or anti-HBc with negative HBsAg. Median UCB volume at cryopreservation was 92.5 mL (range 33-194).Median total nucleated cell (TNC) count at cryopreservation was 9.2 $x10^8$ (range 1-75.3). The median collected CD34+ and CFU-GM cell counts were 4.5 $x10^6$ (range 0.18-61) and 4.5 $x10^5$ (range 0.14-67) respectively. The hemoglobin status of the UCB units was assessed through the neonatal screening. Data were available for 179 UCBs (85%) including 64 (30%) hemoglobin AA, 85 (40%) hemoglobin AS, 25 (14%) hemoglobin SS, 3 (<1%) hemoglobin AC, 1 S-beta+-thal and 1 beta-thal. Eight (4%) out of the 210 banked UCB units were released for CBT with a median TNC count of 7.0$x10^8$ (3.0$x10^8$ - 21.8$x10^8$). Five patients were transplanted using a single UCB and 3 patients with the sibling's bone marrow and UCB. Post-transplant data were available for 6 patients: all of them had stable engraftment of donor cells and are alive, free of SCD.
Summary/Conclusions: Our data showed that family-directed UCB banking is feasible and yields good quality cord blood units for sibling transplantation. However, the number of CBT performed is disappointing despite the good results of sibling transplantation in SCD. Therefore, we must think about the cost-effectiveness of this approach when HLA identical sibling donor is available.

Stem cell transplantation - Clinical 1

P329

CONSOLIDATION BY ALLOGENEIC STEM CELL TRANSPLANTATION IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN CR1 AGED 40-69 YEARS: A COMPARISON OF MYELOABLATIVE AND REDUCED INTENSITY CONDITIONING

A Szabo[1,*], A Dinmohamed[1,2,3], B van der Holt[4], J Versluis[1], M de Groot[5], S Zeerleder[6], H Schouten[7], M Schaap[8], E Meijer[9], E Petersen[10], F Falkenburg[11], A Rijneveld[1], J Cornelissen[1]
[1]Hematology, Erasmus University Medical Center Cancer Institute, Rotterdam, [2]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [3]Public Health, Erasmus University Medical Center, [4]HOVON Data Center, Department of Hematology, Erasmus University Medical Center Cancer Institute, Rotterdam, [5]Hematology, University Medical Center Groningen, Groningen, [6]Hematology, Academic Medical Center, Amsterdam, [7]Hematology, University Hospital Maastricht, Maastricht, [8]Radboudumc, Nijmegen, [9]Hematology, VU University Medical Center, Amsterdam, [10]Hematology, University Medical Center, Utrecht, [11]Hematology, Leiden University Medical Center, Leiden, Netherlands

Background: While survival in ALL patients<40 years has improved with the introduction of pediatric regimens, outcome in patients ≥40 years is still disappointing. Complete remission (CR1) rates upon induction therapy estimate 70-80%, but inferior survival is caused by both enhanced relapse and a higher incidence of treatment-related mortality (TRM). Reduced intensity conditioning (RIC) allogeneic stem cell transplantation (alloSCT) was developed as a less toxic but effective type of consolidation therapy and applied as from 2000 in several centers in the Netherlands, while some centers continued to apply myeloablative (MAB) alloSCT.
Aims: We set out to retrospectively compare RIC alloSCT and MAB alloSCT as consolidation therapies in patients with ALL aged 40-69 years in CR1.
Methods: 151 patients (age: 40-67 years) with ALL in CR1 receiving consolidation by alloSCT between 2001 and 2013 were included. Data were provided by the Dutch Stem Cell Transplantation Working Group of HOVON. The median follow up was 68 months for MAB alloSCT (n=62) and 56 months for RIC alloSCT recipients (n=89). MAB was predominantly applied by the combination of total body irradiation (TBI) and cyclophosphamide, while RIC by the Seattle regimen (fludarabin and 2 Gy TBI). Univariable and multivariable Cox-regression analysis were performed with endpoints overall survival (OS), relapse free survival (RFS), TRM and relapse. Cox-regression was adjusted for age, white blood cell count at diagnosis, cytogenetic risk, interval from diagnosis to alloSCT, year of treatment, donor type.
Results: Statistically significant differences between RIC and MAB recipients were found with respect to age (median 55 *vs* 47 years, p<0.001) and year of transplantation (median 2009 *vs* 2006, p=0.001). Although not statistically significant, RIC alloSCT patients had higher EBMT scores (score 3-4: 62% *vs* 45%, p=0.105) and more alternative donors were used in RIC alloSCT patients (48% *vs* 35%, p=0.071). Underlying ALL risk parameters did not differ between either type of alloSCT. The relapse rate at 5 years was significantly higher after RIC alloSCT as compared to MAB alloSCT (47% *vs* 20%, p=0.001, Figure). TRM was predominantly affected by age and interval from diagnosis to transplantation. By univariate analysis, improved OS was found in recipients of MAB alloSCT as compared to RIC alloSCT, which appeared significantly affected by age and type of conditioning. Multivariable analysis showed again that RIC alloSCT was associated with a significantly higher relapse rate (HR: 3.47 [95% CI: 1.70-7.11] p=0.001) and significant reduction of TRM (HR: 0.42 [95% CI: 0.18-0.97] p=0.043). These opposing effects, however, resulted in a non-significant difference between RIC and MAB as regards RFS (HR: 1.47 [95% CI: 0.88-2.47] p=0.144) and OS (HR: 1.27 [95% CI: 0.74-2.19] p=0.392).

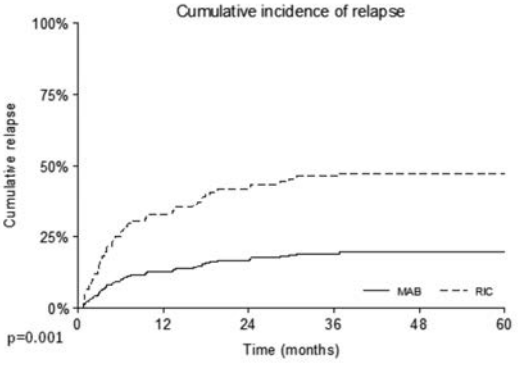

Figure 1.

Summary/Conclusions: Recipients of RIC and MAB conditioning appeared to differ for a number of variables, which hampered an unbiased comparison. Nevertheless, RIC alloSCT was associated with a significantly higher relapse rate, while these patients did not exhibit more high-risk ALL features. Due to less TRM, that difference did not translate into a significant difference in RFS and OS. Collectively, these results suggest that MAB alloSCT may provide a more effective type of consolidation therapy for reduction of relapse and that RIC alloSCT may especially be applied in patients at higher risk for TRM because of age, EBMT score and/or comorbidities.

P330

RELAPSED/REFRACTORY HIGH GRADE B CELL NON-HODGKIN LYMPHOMA: SHOULD ONGOING PET POSITIVITY PRECLUDE AUTOLOGOUS TRANSPLANTATION IN PATIENTS ATTAINING A CT RESPONSE TO SALVAGE CHEMOTHERAPY?

N Elmusharaf[1,*], MH Iqbal[1], V Trainer[2], AJ Mahdi[1], D Davies[1], P Fielding[2], S Al-Ismail[3], W Ingram[1], K Wilson[1]
[1]Haematology, [2]Radiology, University Hospital of Wales, Cardiff, [3]Haematology, Singleton Hospital, Swansea, United Kingdom

Background: High dose chemotherapy and autologous stem cell transplantation (ASCT) have been shown to increase overall (OS) and event-free survival (EFS) in patients with chemo-sensitive relapsed or refractory high grade B cell Non-Hodgkin lymphoma (NHL) as assessed by computerized tomography (CT). Positron Emission Tomography (PET) scanning, when compared to CT, has been shown to upstage disease both at diagnosis and assessment of treatment response and can help to predict outcome. However, the positive predictive value for end of treatment PET scans varies widely, especially for patients treated with rituximab. It is therefore unclear whether CT responders who have residual PET positive lesions will benefit from ASCT since this has not been evaluated in a randomized controlled trial. This question is important since historically (prior to PET) these patients will do poorly when treated with conventional dose chemotherapy alone. We therefore assessed whether ongoing PET positivity adversely affected outcome in chemo-sensitive patients with high grade B cell NHL who received ASCT by the South Wales Blood and Marrow Transplant (SWBMT) Programme.
Aims: To compare outcome in patients who had ASCT for chemo-sensitive relapsed/refractory high grade B cell NHL (as defined by CT) according to the presence or absence of residual PET positive lesions.
Methods: The prospectively maintained database of the SWBMT programme which serves 77% of the Welsh population (mid-2014 census estimate) was interrogated to identify patients with high grade B cell NHL who received ASCT between January 1999 and December 2014 to allow a minimum of 12 months follow up. All patients with a pre-ASCT PET were assessed by the Deauville criteria to define their response with patients being considered to have achieved a complete metabolic response (CMR) if lesions demonstrated uptake of grade 3 or less. The data was analyzed according to patients achieving CMR, less than CMR or no prior PET.

Table 1.

Parameter	No PET	PET Negative	PET Positive	TOTAL
Number	61	22	18	101

Relapsed	17 (28%)	05 (23%)	05 (28%)	27 (27%)
Dead	29 (48%)	06 (27%)	04 (22%)	39 (39%)
Alive	32 (52%)	16 (73%)	14 (78%)	62 (61%)
Follow up:				
Years, median (range)	7.8 (1.5-15.1)	4.2 (2.1-11.8)	3.8 (1.8-15.2)	5.0 (1.5-15.2)

Results: A total of 101 patients received ASCT for chemo-sensitive refractory or relapsed high grade B cell NHL between 1999 and 2014. Patient characteristics are summarised in the Table. The median age was 54 (range 17-69) years and there was an overall male predominance (62%). The most common subtype was DLBCL (76%) and the majority had stage IV disease. Two-thirds of patients had primary refractory disease and a median of 3 (range 1-7) lines of therapy were administered prior to ASCT. Forty-two of 61 (69%) patients with no PET received rituximab compared with 37/40 (93%) of the PET group. Of the 40 patients with a pre-ASCT PET, 22 had achieved a CMR (PET NEG) and 18 had residual lesions (PET POS). Relapse occurred in 28% of the No PET and PET POS groups compared to 23% in the PET NEG group. With a median follow-up of 5.0 (1.5-15.2) years 62 (61%) of patients are alive: No PET 52% v PET NEG 73% v PET POS 78%.
Summary/Conclusions: This study with relatively long follow-up beyond the typical relapse interval of 2 years, shows that residual PET positivity did not adversely affect outcome in chemo-sensitive relapsed/refractory patients undergoing ASCT for high grade B cell NHL. This may be explained by the fact that the majority of the PET group (93%) received rituximab, a known association with false PET positivity. In addition, patients with residual PET lesions did not routinely undergo biopsy to evaluate the significance of the lesions. The older No PET group which used CT to assess response, experienced survival similar to the pivotal Parma Trial (Philips et al, NEJM 1995) with 52% being alive at 7.8 years compared to 53% 5 year survival. In the more recently treated PET POS group, which is the current equivalent of the No PET group, survival had improved to 78% at 3.8 years follow-up. Given the similarity in relapse rate, this probably reflects improved supportive care. However, given that survival was not inferior to the contemporaneous PET NEG group it is probably premature to exclude these patients from ASCT solely on the basis of residual PET lesions. We suggest that patients with chemo-sensitive relapsed/refractory high grade NHL should not be denied ASCT on the basis of residual PET lesions and that randomized trials are needed to further address this question.

P331

MARAVIROC CONCENTRATIONS ARE HIGHLY PREDICTIVE OF ACUTE GRAFT-VERSUS-HOST DISEASE IN REDUCED-INTENSITY ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

A Ganetsky[1,*], LM Crisalli[1], AP Huffman[2], EP Acosta[3], JK Mangan[1], SM Luger[1], AW Loren[1], EO Hexner[1], NV Frey[1], EA Stadtmauer[1], JA Hoxie[1], RH Vonderheide[1], DL Porter[1], R Reshef[2]
[1]University of Pennsylvania, Philadelphia, [2]Columbia University, New York, [3]University of Alabama at Birmingham, Birmingham, United States

Background: We previously published favorable results with the use of maraviroc (MVC), a CCR5 antagonist, as a prevention strategy against acute graft-*versus*-host disease (GVHD) (Reshef *et al.* NEJM 2012). Various genetic and physiologic factors affect the pharmacokinetic (PK) profile of MVC, which leads to significant interpatient variability in MVC exposure. Whether variability in MVC PK affects the protective activity of MVC against GVHD is unknown.
Aims: We sought to identify whether a relationship exists between MVC trough concentrations and clinical outcomes in hematopoietic stem cell transplantation (HCT) recipients.
Methods: We evaluated the associations between MVC trough concentrations and clinical outcomes in a *post hoc* analysis combining data from two prospective clinical trials that tested the addition of MVC to tacrolimus/methotrexate in 67 patients (pts) undergoing their first allogeneic HCT at the University of Pennsylvania between 2009 and 2015. All pts received a uniform reduced-intensity conditioning (RIC) regimen consisting of fludarabine (120mg/m^2) and busulfan (6.4mg/kg), followed by infusion of peripheral-blood stem cells. Most pts were at high-risk for HCT-related complications given their age (median 62, range 21-74 years), donor source (matched unrelated 72%; single-antigen mismatch unrelated 16%; matched related 12%), and HCT-comorbidity index (low 30%, intermediate 34%, high 36%). The most common underlying diseases were acute myeloid leukemia (55%) and myelodysplastic syndromes (18%). All pts included in this PK analysis received MVC 300mg twice daily (BID) except for 4 pts in the first trial that received MVC 150mg BID as part of a dose-finding phase. The primary endpoint was cumulative incidence (CI) of acute grade 2-4 GVHD by day 180. Univariate analyses were performed using cumulative incidence and Cox regression models. Multivariate models were constructed using the backward elimination method.
Results: The median MVC trough concentrations (range) at days 0, 7, and 14 were 64.9 (11.7-315.7), 72.7 (7.9-555.0), and 142.0 (10.9-1064.0) ng/mL, respectively. The day-180 CI (±SE) of acute grade 2-4 GVHD and acute grade 3-4 GVHD were 24.7±5.1% and 11.3±3.8%, respectively. Pts with a day 0 MVC trough concentration ≤ median had a higher incidence of acute grade 2-4 GVHD compared with pts > median (38.7±8.6% *vs* 6.1±4.2%; *P*=.001). In multivariate analysis, day 0 MVC concentration remained an independent predictor of acute grade 2-4 GVHD (HR 0.35; 0.13-0.95; *P*=.039), as shown in Figure 1. We also observed a nonsignificant trend towards a higher incidence of acute grade 3-4 GVHD in pts with day 0 MVC trough concentrations ≤ median (12.2±5.9% *vs* 3±3%; *P*=.20). In addition, no pt (n=20) with day 0 MVC trough concentration >100ng/mL developed GVHD by day 180. The CI of relapse at 1 year was 42.5±5.9%. Interestingly, pts with a day 0 MVC trough concentration ≤ median had a higher relapse incidence (62.4±8.7% *vs* 21.7±7.4%; *P*=.001). Day 0 MVC concentrations were not significant predictors of chronic GVHD or survival. No

associations between clinical outcomes and MVC concentrations on day 7 or 14 were noted. We repeated the same analysis including only pts who received MVC 300mg BID and observed similar results.

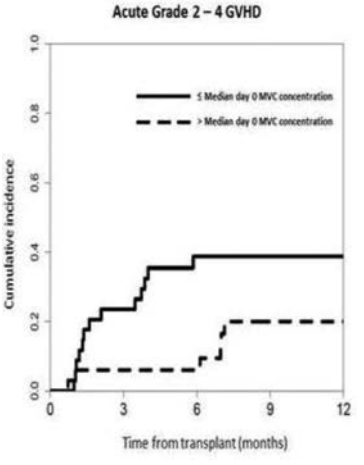

Figure 1.

Summary/Conclusions: Higher MVC concentrations on day 0 of RIC HCT were associated with significantly reduced risk of both acute grade 2-4 GVHD and relapse. These data highlight the importance of optimizing initial dosing of MVC in RIC HCT recipients.

P332

HYPERACUTE GRAFT *VERSUS* HOST DISEASE: RISK FACTORS, OUTCOMES AND IMPACT OF TACROLIMUS/SIROLIMUS PROPHYLAXIS

O Lopez Godino[1,*], E Pérez López[1], L López Corral[1], R Pérez López[2], S Alonso[1], M Cabrero[1], J Labrador[1], L Vázquez[1], D Caballero[1]
[1]Hematology department, [2]Pharmacology department, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Hyperacute graft *versus* host disease (haGVHD) is associated with poor prognosis in the context of acute GVHD due to its severity and to its worse response to steroids. Most reports include majority patients receiving calcineurin inhibitors/MTX prophylaxis.
Aims: Analysis of patients with haGVHD *vs* patients who developed other acute GVHD comparing clinical characteristics, outcomes, response to treatment and risk factors in both groups, specially in those with tacrolimus/sirolimus prophylaxis in our Unit.
Methods: We prospectively analysed 627 patients consecutively transplanted in our Unit between 1995-2014 excluding paediatrics and 2ndallo-HSCT. HaGVDH was defined as that occurring within 14 days after HSCT.

Table 1.

	All patients	Value n (%/range) II-IV haGVHD	II-IV oaGVHD
	n = 627	n = 70	n = 264
Male sex	365 / 58%	50 / 71%	143 / 54%
• Sex mismatch	137 / 22%	27 / 38%	51 / 19%
Median age patient	49 (16-69)	49 (17-65)	50 (16-69)
Donor			
• Sibling	412 / 66%	26 / 38%	161 / 62%

• FluMelThiotepa	6 / 1%	1 / 4%	3 / 1%
• BuCy+/- Thiotepa	78 / 13%	6 / 9%	32 / 12%
• CyTBI	68 / 11%	16 / 23%	28 / 11%
• Others	53 / 9%	3 / 4%	18 / 7%
PB cell source/ Median CD34x106/kg	526 (84%) / 5,3 (0,9-22)	58 (83%)/ 5,1 (1,2-9,6)	217 (82%) / 5,5 (1,3-16,3)
GVHD prophylaxis			
• CSA + MTX	329 / 53%	18 / 26%	130 / 49%
• Tacrolimus + MTX	76 / 12%	10 / 15%	35 / 14%
• Calcineurin inhibitor + MMF	64 / 10%	8 / 11%	28 / 11%
• Tacrolimus + Sirolimus	141 / 22%	32 / 45%	64 / 24%
• Others	17 / 3%	2 / 3%	5 / 2%
In vivo T cell depletion	69 / 11%	4 / 6%	21 / 8%

Results: 70 patients (11%) developed II-IV haGVHD, 264 (42%) other acute II-IV GVHD (oaGVHD). Median of days to haGVHD and oaGVHD were +10 (4-14) and +35 (12-362) respectively. Patient's characteristics are shown in table 1. Differences between haGVHD and oaGVHD include a higher skin involvement and a higher proportion skin III-IV grades in haGVHD: 75 *vs* 45%, p=0,00 and 44% *vs* 18%, p=0,03 respectively. In multivariate analysis, risk factors associated with haGVHD include sex mismatch (p=0,004; OR 2,1; IC95% 1,02-4,4), conditioning regimen other than Fludarabina-Busulfan (p=0,00), Tacrolimus-Sirolimus prophylaxis (p=0,001; OR 2,1; IC95% 1,4-3,4) and unrelated donor +/- mismatch (p=0,004, OR 3,2, IC95% 1,4-7,1), whereas only mismatch unrelated donor was associated with a higher risk of oaGVHD (p=0,003, OR 3,2, IC95% 1,4-7,1). Steroids resistance was similar in both groups (haGVHD 23% *vs* 17% in oaGVHD). Factors influencing higher risk of steroid resistance in the multivariate analysis were HLA mismatch (p=0,04; OR 5,9; IC95% 1,05-33,7) and grade III-IV (p=0,004, OR 11,7, IC95% 2,2-62) in haGVHD and grades III-IV (p=0,00, OR 21, IC95% 9,2-48) in the group of oaGVHD. With a median follow-up of 38 months, OS and TRM for the whole series is 57% and 19%. Comparing haGVHD *vs* oaGVHD, haGVHD hadn't impact neither in OS (56% *vs* 51%; p=0,5) and TRM (33% *vs* 25%; p=0,17). While Tacrolimus/sirolimus prophylaxis was associated with a higher risk of haGVHD, this scheme was also associated with a better OS in the global series (p=0,002, HR 0,38, IC95% 0,2-0,7). Although we investigated the role of serum immunosuppressive levels in this group, we failed to demonstrate that infratherapeutic levels had a role in the haGVHD development.
Summary/Conclusions: According to our centre experience, haGVHD is characterized for a higher skin preference; it was not associated with a poorer outcome neither with a higher steroid resistance as compared with oaGVHD; althought tacrolimus/sirolimus is one of the risk factors to develop haGVHD, this regimen is also associated with a better OS.

P333

REDUCED INTENSITY CONDITIONING TRANSPLANTATION (RIC) AS PART OF FIRST LINE THERAPY FOR MANTLE CELL LYMPHOMA: RESULTS FROM THE PHASE II MINI ALLO TRIAL (CRUK: C7627/A9080)

S Rule[1,*], K Peggs[2], N Russell[3], G Cook[4], A Hunter[5], N Morley[6], A Sureda[7], P Smith[8], P Patrick[8], N Braganca[8], L Stevens[8], T Adedayo[8], A Kirkwood[8], S Robinson[9]
[1]Derriford Hospital, Plymouth, [2]UCH, London, [3]City Hospital, Nottingham, [4]University Hospital, Leeds, [5]Royal Infirmary, Leicester, [6]Royal Hallamshire, Sheffield, [7]Cambridge University Hospitals, Cambridge, [8]University College, London, [9]Bristol Royal Infirmary, Bristol, United Kingdom

Background: For young patients with MCL, standard therapy comprises high dose cytarabine based chemotherapy which is usually consolidated by autologous stem-cell transplantation (ASCT). Although the median overall survival with this approach is impressive (>10 years in some series) no plateau is observed, whereas at relapse, allogeneic transplantation can lead to long term disease-free survival in some individuals. Up front allogeneic stem cell transplantation is rarely used in this condition due to concerns over the associated mortality and morbidity, however it is the treatment of choice following relapse.
Aims: This was a prospective study evaluating reduced induced conditioning allogeneic transplantation (RIC allo) as part of first consolidation for patients responding following front line chemotherapy. The primary endpoint was a progression free survival (PFS) improvement from 45% to 70%, (15/25 patients) after 2 years.
Methods: This study evaluated the role of RIC-Allo in first remission for MCL. The induction chemotherapy adopted was at the physicians discretion but patients required at least a partial response to be able to receive the transplant. Eligible patients received a BEAM-C (BCNU, etoposide, Ara-C, melphalan and alemtuzumab) conditioned sibling or unrelated donor allograft in first remission. Donor lymphocyte infusions (DLI) were administered for persistent, mixed chimerism or at relapse.
Results: Twenty-five patients were recruited from 8 centres (January 2010 - September 2013). The median age was 54 (34-70) and 22 (88%) were male. Eleven (44%) were in CR and 14 (56%) PR at registration. Eleven (44%) donors were siblings and 15 (56%) were unrelated. All 25 patients engrafted by day 100. Toxicity was as expected: grade 3-4 adverse events in 96%; the treatment related mortality (TRM) rate was 8% (2/25). GvHD incidence was low, in keeping with T cell depletion: acute GvHD (12%); chronic GVHD (24%). Fifteen patients were alive and progression free at 2 years (with 2 more yet to reach this point). The 2 year PFS estimate was 68% (95% CI: 46.1 - 82.5%). Of those alive and in remission, 14/16 (88%) have reached full donor T-cell chimerism, 5 after DLI.
Summary/Conclusions: RIC-Allo is a feasible option for consolidation of first remission in MCL. In this study, the target endpoint for PFS was achieved and further exploration of RIC-Allo in patients identified to be at high risk of disease progression with ASCT is warranted.

P334

THE ROLL OF HYPOMETHYLATING AGENTS IN MYELOID RELAPSES AFTER ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANT

F López Cadenas[1,*], M Cabrero Calvo[2], AA Martin López[2], O López Godino[2], E Pérez López[2], O Ferré Bermejo[2], L García Martín[2], J Labrador Gómez[3],

F Ramos[4], L Vázquez López[1], L López corral[1], M Díez-Campelo[1], MC Del Cañizo[1], MD Caballero Barrigón[1]
[1]Department of Hematology, [2]Department of Hematology, Hospital Clínico Universitario de Salamanca, Hospital Clínico Universitario De Salamanca (Sanidad Castilla y León), Salamanca, [3]Department of Hematology, Hospital Universitario de Burgos, Burgos, [4]Department of Hematology, Complejo Asistencial Universitario de León, León, Spain

Background: Allogenic hematopoietic stem cell transplant (HSCT) remains the only curative treatment for high-risk hematological malignancies and post-HSCT relapses confer a particularly bad prognosis. Optimal therapy in this situation keeps unclear; hypomethylating agents (HMA) such as 5-azacitidine (5Aza) or decitabine (Dec) can be feasible therapy in this set of patients.
Aims: Analyze the outcome of patients receiving HMA for acute myeloid leukemia (AML) or myelodysplastic syndromes (MDS) relapsing after HSCT.
Methods: From 355 AML/MDS patients who underwent HSCT in our institution from November 1995 to December 2015, relapse occurred in 112 (32%), and 45 of them (40%) were treated with HMA. From the total of these patients, we selected 40 patients with a follow-up period longer than 30 days and we analyzed them in terms of response rate (RR) and overall survival (OS).
Results: Median age was 54 years (25-71) and 19 (47%) were male. Diagnoses were AML in 30 (75%) and MDS in 10 (25%), with high risk cytogenetic in 43%. Peripheral blood was the stem cell source in 36 patients (90%) and donor was related in 70%. Reduced-intensity conditioning was used in 75%. Mean number of previous therapies was 2 (1-5); 5-azacitidine had been used before HSCT in 15 (37%), with 87% of patients responding. Patients relapsed after a median of 98 days (20-524), 56% with <10% blast, 22% with 10-20% blast and 22% with >20% blast. 5Aza was the HMA used in 39 patients (97%) and Dec in 1. Median number of HMA courses was 3 (1-19). Together with this strategy, the immune effect was enhanced in 38 patients (95%), tapering immunosuppressive treatment in 30 (75%) and with donor lymphocyte infusion (DLI) in 8 (21%). Chronic or acute graft *versus* host disease (GVHD) occurred in 21 patients (52%). Overall response rate (ORR) was 60% (n=24), including 19 CR (47%) (17 of them with negative minimal residual disease (MRD) by flow cytometry). Median time to best response was 91 days (21-209) and it was reached after a median of 2 cycles (1-8). Thirteen out of 24 responding patients (54%) progressed or relapsed after a median of 214 days (84-729). With a median follow up of 174 days (34-1779) from time of relapse, estimated OS was 55% at 6 months and 37% at 1 year post-relapse. Variables with significant influence on OS in univariate Kaplan-Meier analysis were: response to HMA [6 months OS: 82.5% for those responding *vs* 14% for non-responders; *p*=0.000], blast percentage at time of relapse considering >10% [6m OS: 48% *vs* 64%; *p*=0.05] and >20% blast [29% *vs* 65%; *p*=0.0014], developing GVHD after relapse [6m OS: 71% *vs* 36%; *p*=0.015]. Early relapses considered as <120 days after HCST was also associated with a better OS [6m OS: 62% *vs* 52%; *p*=0.078] although did not achieved statistical significance in univariate analysis. In a Cox multivariate regression model, all these variables (response to HMA, tumor burden at relapse, development of GVHD and early *vs* late relapse) showed to be independent factors with influence in OS.
Summary/Conclusions: 5-Azacitidine is an effective treatment for AML/MDS patients who relapse after HCST, especially for those with lower tumor burden and late relapses. In addiction enhancement of graft *versus* tumor effect together with HMA is a capital strategy to achieve longer OS.

P335

IMPROVED CLINICAL OUTCOMES OF GBM/GPB MIXTURE HAPLOIDENTICAL TRANSPLANTATION WHEN COMPARED TO A PROPENSITY SCORE-MATCHED GPB HAPLOIDENTICAL TRANSPLANTATION: A MULTICENTER STUDY

X Zhao[1], F Gao[2], X Zhang[1], Y Wang[1,3], L Xu[1], K Liu[1], X Zhao[1], Y Chang[1], H Wei[1], H Chen[1], Y Chen[1], Z Jiang[4,5], X Huang[1,3,5,*]
[1]Peking University People's Hospital & Institute of Hematology, Beijing Key laboratory of Hematopoietic Stem Cell Transplantation, Beijing, [2]North china university of science and techinology affiliated hospital, Hebei, [3]Peking University Qinghe Hospital, [4]State Key Laboratory of Protein and Plant Gene Research, Key Laboratory of Cell Proliferation and Differentiation of the Ministry of Education, School of Life Sciences, Peking University, [5]Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: The effects of haploidentical(H) rhG-CSF-mobilized blood(B) and marrow(M) transplantation (HBMT) on hematological malignances are well established. Previous prospective single-center studies have demonstrated better survival after HBMT *vs* haploidentical rhG-CSF-mobilized peripheral blood stem cells transplantation (HPBSCT) for acute leukemia (AL) not in remission (NR) or in more than second complete remission (>CR2).
Aims: The aim of this study was to test the hypothesis that HBMT would still be a superior method for patients with AL, multiple myeloma (MM), and Non-Hodgkin lymphomas(NHL) in CR1/CR2 and patients with chronic myeloid leukaemia in first and second chronic phase lacking a matched donor as compared to HPBSCT.
Methods: We designed a propensity score method based multicenter study.
Results: Hematopoietic recovery, acute graft-*versus*-host disease (aGVHD), chronic GVHD was comparable between HBMT group(n=168) and HPBSCT group (n=42). No significant differences were found in the non-relapse mortality (20.17%±3.58% and 27.24%±7.16%, P=0.18) rates and relapse rates (19.96%±3.72% and 28.49%±8.25%, P=0.32) between HBMT group and HPBSCT group. HBMT recipients had better overall survival (65.0%±4.2% and 54.2%±8.3%, P=0.037) and disease free survival (59.9%±4.6% and 44.3%±8.7%, P=0.051). Multivariate analysis showed that HPBSCT was associated with poorer DFS (HR(95%CI), 1.639(0.995-2.699), P=0.052).
Summary/Conclusions: Our comparisons showed that HBMT was superior compared to HPBSCT as postremission treatment for patients lacking an identical donor.

P336

TREATMENT OF CHRONIC GRAFT *VERSUS* HOST DISEASE WITH A COMBINATION OF B-CELL DEPLETION AND TYROSINE KINASE INHIBITION

L Van Der Wagen[1,*], L te Boome[1,2], I Nijhof[1], M Schoordijk[3], D Buter[1], E Meijer[3], J Kuball[1]
[1]Hematology, University Medical Center Utrecht, Utrecht, [2]Internal Medicine, MC Haaglanden, The Hague, [3]Hematology, VU Medical Center Amsterdam, Amsterdam, Netherlands

Background: Chronic Graft *Versus* Host Disease (cGVHD) still has a large impact on morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HSCT). Affected patients require long term use of immunosuppressive drugs, mainly corticosteroids, which lead to development of severe side effects. Therapeutic approaches for cGVHD are limited. Generally recommended first line therapy consists of glucocorticoid therapy combined with a calcineurin inhibitor. Options for second line therapy are numerous but no consensus on the most favourable choice of agents has been reached.
Aims: Both monotherapy with rituximab and monotherapy with tyrosine kinase inhibitors have shown to be effective in reducing cGVHD symptoms. We aimed to test whether the sequential therapy of the anti CD20 antibody rituximab followed by a 6 month treatment period with the tyrosine kinase inhibitor nilotinib is a good treatment strategy for patients with sclerotic cGVHD (EudraCT nr 2008-004125-42).
Methods: We treated patients with sclerotic cGVHD with 4 infusions of rituximab (375mg/m2 i.v. once weekly) followed by six months of nilotinib (start dose 300mg b.i.d.). Patients were followed up monthly for 13 months.
Results: We included 29 patients, 4 patients went offstudy, 13 patients have currently completed the follow up. Of these 13 patients, 1 patient reached a complete response, 8 patients showed a partial response and 4 patients remained in stable disease. Moreover, 2 out of 5 patients who suffered from severe ulcerations at the start of the study had a complete resolution of ulcers at the end of the treatment period. There is a significant decrease in cGVHD affected body surface area (Figure 1). Patients with a (partial) response also show a decrease in self attributed severity of cGVHD and their immunosuppressive drugs could be tapered. Sixty percent of responding patients could taper >50% of prednisolone dose.

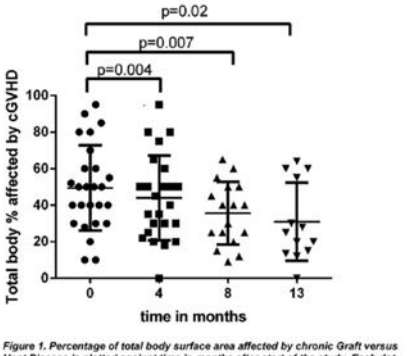

Figure 1. Percentage of total body surface area affected by chronic Graft versus Host Disease is plotted against time in months after start of the study. Each dot represents 1 patient. P-values are calculated by means of Wilcoxon matched-pairs signed rank test.

Figure 1.

Summary/Conclusions: The sequential therapy of B-cell depletion and tyrosine kinase inhibition provides a new and interesting alternative treatment option for this difficult and heavily pretreated patient category. Approximately 70% of patients achieve a (partial) response that results in a significant reduction in use of corticosteroids.

Background: Acute graft-*versus*-host disease (aGVHD) is a major complication of allogeneic hematopoietic cell transplantation (HCT), and glucocorticoids are typically used as first-line treatment.
Aims: The aim of our study was to evaluate the effect of ECP +/- steroid therapy in order to reduce the incidence of infections and toxicity.
Methods: From December 2010 to November 2015, 47 of 179 pts (26%), were diagnosed with aGVHD grade ≥2 following alloSCT and 33 (70%) pts were treated with ECP +/- steroid as first-line therapy. 8 (25%) pts were treated with ECP only, 24 (75%) pts with ECP + steroid 1 or 2 mg/kg/day, with a total of 32 pts evaluated for aGVHD response. Conditioning regimen was myeloablative (MAC) n=7, nonmyeloblative (NMA) n=14 or reduced-intensity (RIC) n=11. Acute GVHD diagnosis was performed using Keystone criteria and scored by Seattle and IBMTR criteria. ECP was performed using the offline technique. ECP was started as soon as possible with a treatment schedule consisted of 4 rounds of two procedures per week, 3 rounds of two procedures every other week and finally two procedures every month until clinical improvement and/or immunosuppressive therapy (IST) tapering.
Results: The median follow-up time was 20 (range: 5-60) months. The median age was 51 (20-71). 17 pts were affected by lymphoma, 8 by AML, 3 by MM, 2 by ALL, 1 by CLL and 1 by MDS. Donors were: haploidentical (n=21), HLA-identical (n=5), matched unrelated (n=5) and cord blood (n=1). Stem cell source was: peripheral blood (PBSC, n=17) and bone marrow (BM, n=14). aGVHD was diagnosed after a median time of 39 days (13-150) from alloSCT. aGVHD grade was 2 in 28 (88%), 3 in 2 (6%) and 4 in 2 (6%) pts. Visceral involvement was reported in 5 (15%) pts: gut (n=4) and liver (n=1). ECP was started after a median of 4 (0-30) days from aGVHD diagnosis. The median duration of steroid therapy was 29 days (3-104) and every patient underwent a median of 19 (2-83) ECP procedures, during a median time of 6 months. At 30 days from GVHD diagnosis, 21 (66%) pts achieved complete remission and 6 (19%) pts partial remission, with an overall response rate of 85%. At univariate analysis, we found a trend towards higher risk of GVHD progression for pts receiving PBSC and with visceral involvement (Table 1). Among responders, 6 (22%) pts had aGVHD relapse during steroid tapering or discontinuation. Overall, not responders patients were 11 (34%), and 10 pts received second-line therapy (1 pt not included for early death). From GVDH diagnosis, 17 (53%) had cytomegalovirus reactivation, 12 (38%) had a bacterial infection and 3 (9%) fungal pneumonias were reported. The cumulative incidence of chronic GVHD was 26.5% (95% CI: 12.2-43.3), the 1-yr cumulative incidence of relapse and non-relapse mortality were 16.4% (95% CI: 5.8-31.8) and 22.7% (95% CI: 9.8-38.9), respectively. The 1-yr overall survival and GVHD-free/relapse-free survival were 70.0% (95% CI: 53.5-86.5) and 34.7% (95% CI: 17.6-51.8), respectively.

Table 1. Univariate analysis of variables predicting lack of response to first-line therapy.

Variables	HR	95% CI	p-value
Haploidentical donor	1.67	0.17-16.16	0.66
PBSC source	3.30	0.34-32.01	0.30
aGVHD grade >2	1.61	0.17-15.51	0.68
Visceral involvement	3.32	0.46-23.71	0.23
ECP only	0.88	0.09-8.44	0.91

Summary/Conclusions: This observational study suggests that ECP +/- steroids is safe and effective first-line treatment for aGVHD after alloSCT. The response rate is high with a low cumulative dose of steroids. However, the duration and speed of steroid tapering needs to be further assessed, in order to maintain a sustained response, when patients received PBSC and had visceral GVHD involvement.

P338

EFFICACY OF HOST-DENDRITIC CELL VACCINATIONS WITH AND WITHOUT MINOR HISTOCOMPATIBILITY ANTIGEN LOADING, COMBINED WITH DONOR LYMPHOCYTE INFUSION IN MULTIPLE MYELOMA PATIENTS

R Oostvogels[1,2,*], E Kneppers[1,3], M Minnema[1], R Doorn[4], L Franssen[1,2], T Aarts[4], M Emmelot[4], E Spierings[5], I Slaper[6], K Westinga[6], E Goulmy[7], H Lokhorst[1,2], T Mutis[2,4]
[1]Hematology, University Medical Center Utrecht, Utrecht, [2]Hematology, VU Medical Center, Amsterdam, [3]Hematology, Isala Clinics, Zwolle, [4]Clinical Chemistry and Hematology, [5]Immunology, [6]Clinical Pharmacy, University Medical Center Utrecht, Utrecht, [7]Immunohematology and blood bank, Leiden University Medical Center, Leiden, Netherlands

Background: Donor lymphocyte infusions (DLI) can induce durable remissions in multiple myeloma (MM) patients, but this occurs only in a fraction of the patients. The T cell-mediated graft-*versus*-tumor (GvT) effect of DLI depends on the presence of host dendritic cells (DC), but these are rapidly replaced by donor DC after allogeneic stem cell transplantation (alloSCT).
Aims: We tested in a prospective phase I/II trial whether the efficacy of DLI in MM patients could be improved by simultaneous vaccination with *ex vivo* generated host DCs. As the donor T cells involved in GVT are mainly directed at mismatched minor histocompatibility antigens (mHags), we also analyzed the possibility to further improve the GvT effect by loading the host-DCs with peptides of mismatched hematopoietic cell-specific mHags.
Methods: Eleven MM patients, not responding to a first DLI, were treated with a second equivalent dose DLI combined with DC vaccinations, generated from host-monocytes (moDC). In four of these patients the DCs were loaded with mHag peptides.
Results: Toxicity was limited and no acute graft-*versus*-host disease (GvHD) occurred. Most patients developed objective but temporary anti-host T cell responses however, with only modest clinical effects. In a patient vaccinated with mHag ACC-1 peptide-loaded DCs, a distinct ACC-1 specific T cell response accompanied a temporary clinical response.
Summary/Conclusions: These findings confirm that DLI combined with host-DC vaccination, either unloaded or loaded with mHag peptides, is feasible, safe and capable of inducing host-specific T-cell responses. The limited clinical effects observed in some patients may be improved by developing more immunogenic DC products or by combining this therapy with immune potentiating modalities like immune checkpoint inhibitors.

Stem cell transplantation - Clinical 2

TRACING OF URINARY EXCRETION OF BKV AND JCV BY QUANTITATIVE PCR IN RECIPIENTS OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTS (ALLO-HSCT) TO ANTICIPATE THE DEVELOPMENT OF HEMORRHAGIC CYSTITIS (HC)

J Zanabili Al-Sibai, MDP Palomo Moraleda, AP González Rodríguez*, T Arias Fernández, LF Ávila Idrovo, L Morais Bras, S Melón, AJ González Huerta, S González Muñiz
Hematology, HUCA, Oviedo, Spain

Background: BK virus (BKV) and JC virus (JCV) are frequently identified in the urine of HSCT pts with hemorrhagic cystitis (HC). However, viruria is common even in asymptomatic pts, making difficult to establish a direct causative role of these viruses.
Aims: Many studies have identified an association between polyomaviruses and late HC and the studies have noted that viruria preceded or coincided with the onset of disease. Some of these studies indicate that some factors, such as conditioning regimen intensity, unrelated donor, etc contribute to the development of HC and others, like receiving prophylaxis with quinolones could protect for this disease.
Methods: We conducted a prospective monitorization of urinary BK and JC shedding by qPCR in 968 urine samples from 128 pts who underwent 135 allo-HSCT between January 2010 and December 2014. BKV and JCV quantitative polymerase chain reaction (qPCR) were performed in urine samples collected at admission for transplant and weekly until discharge. Seventy-seven were male (57%). Median age was 49 years old (range: 1-68). Most frecuent baseline disease was acute leukemia (n=53). Seventy-two (53.3%) received cells from unrelated donor, 58 (43%) from matched siblings and the remainder haploidentical-HSCT. Stem cell source were bone marrow (n=59), peripheral blood (n=27) and umbilical cord (n=9).

Table 1.

Median	HC(+)	HC(-)	*p* Value	Quinolones(+)	Quinolones(-)	*p* Value
Time for first BKV	3.5	8.5	NS	10	-1	NS
Duration of BKV excretion	77	16.5	0.001	14	31	NS
First BKV detection	3.07	2.69	NS	2.69	3.08	NS
Maximum BKV load	8.3	5.13	0.004	4.28	7.98	NS
log increase in BKV copies/mL	1.96	0.62	0.012	0.53	3.48	0.048
Time for first JCV	55	-6.5	NS	-6	-6	NS
Duration of JCV excretion	46.5	27.5	NS	28	27.5	NS
First JCV detection	3.05	4.64	NS	3.43	5.18	NS
Maximum JCV load	9	5.4	NS	5.86	5.79	NS
log increase in JCV copies/mL	2.5	0.00	NS	0.00	0.00	NS

Results: BK viruria was demonstrated in 85 pts (63%), JCV in 56 patients (41.5%) and both viruses in 36 pts (19.2%). BKV was excreted at day +5.5 as a median (range: -12 to +167) during 20 days (range: 1-554). There was a significant correlation between the first and maximum BKV load and intensity of hematuria (R=.242; p=.026 and R=0.408; p<.001). Also, we observed a direct correlation between the maximum BKV load and the number of lymphocytes (R=0.248; p=.022) and an inverse with the quantity of immunoglobulins (R=-0.28; p=.01). JCV was excreted in 56 pts (41.5%) at day -6 (range: -12 to +347) for 27.5 days (range: 1-535). At maximum viral load of JCV, there was an inverse correlation with the immunoglobulins and platelets (R=-0.378; p=.005 and R=-0.289; p=.033) and a direct correlation with the intensity of hematuria (R=.387; p=.004). Only one patient receiving stem cell source from umbilical cord blood had urinary JCV excretion. Eighty-four percent of pts who excreted JCV had received a fludarabine-based conditioning regimen (p=.046). Fifteen patients (11.1%) developed HC, 13 out of 15 excreted BKV (86.7%), 8 JCV (53.3%) and 6 (40%) both. Patients who excreted BKV had more risk to developed HC (p=.044). The development of HC was correlated to excretion of at least one polyomavirus in all cases (p=.018). Patients who had clinical HC showed higher BK viral load at maximum detection (log10 8.3 *vs* 5.13copies/mL; p=.004), more log copies/mL increase (1.96 *vs* 0.62, p=.012) and virus shedding for a longer time (77 *vs* 16.5 days; p=.001). JCV maximum load detection and days of excretion were higher in pts who develop HC but it is not significant. Eighty-seven pts (64.4%) received prophylaxis with quinolones and 10.3% of them developed HC. Further, 60.9% and 73.25% of them excreted BKV and JCV respectively, without differences with patients who did not get prophylaxis.
Summary/Conclusions: BK and JC excretion were frequent in our series of allo-HSCT recipients. High viral load is correlated with more hematuria. Higher increase in log BKV urine qPCR copies/mL, higher BKV load and longer shedding were associated with risk of HC. We could not demonstrate that prophylaxis with quinolones impact on duration of excretion, amount of polyomavirus shedding or protection of development of HC.

OUTCOMES AFTER AUTOLOGOUS AND ALLOGENEIC STEM CELL TRANSPLANTATION (SCT) IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PATIENTS WITH MYC/BCL2 CO-EXPRESSION, DOUBLE-HIT LYMPHOMA, OR MYC COPY GAIN

AF Herrera[1,*], L Low[2], G Griffin[3], M Mei[1], R Merryman[4], J Song[2], V Bedell[2], H Sun[3], T Paris[5], T Stiller[5], E Alyea[6], J Brown[6], E Budde[1], R Chen[1], YB Chen[7], WC Chan[2], C Cutler[6], M Davids[6], A Freeman[6], D Fisher[6], V Ho[6], E Jacobsen[6], C Jacobson[6], J Koreth[6], A LaCasce[6], J Murata-Collins[2], J Murata-Collins[2], A Nademanee[1], S Nikiforow[6], J Palmer[5], G Pihan[8], R Pillai[2], T Siddiqi[1], A Sohani[9], L Popplewell[1], J Zain[1], L Kwak[1], D Weinstock[6], R Soiffer[6], J Antin[6], S Forman[1], D Weisenburger[2], S Rodig[3], Y Kim[2], A Krishnan[1], P Armand[6]
[1]Hematology/HCT, [2]Pathology, City of Hope, Duarte, [3]Pathology, [4]Medicine, Brigham and Women's Hospital, Boston, [5]Information Sciences, City of Hope, Duarte, [6]Hematologic Malignancies, Dana-Farber Cancer Institute, [7]Bone Marrow Transplantation, Massachusetts General Hospital, [8]Pathology, Beth Israel Deaconess Medical Center, [9]Pathology, Massachusetts General Hospital, Boston, United States

Background: Double-hit lymphomas (DHL) - DLBCL with rearrangements of *MYC* and *BCL2* and/or *BCL6* - and double expressing lymphomas (DEL) - DLBCL with co-expression of MYC and BCL2 by immunohistochemistry (IHC) - are associated with poor outcomes after upfront therapy. Data are limited regarding outcomes of patients with rel/ref DHL who undergo SCT, and no study to date has examined SCT outcomes in patients with DEL.
Aims: Evaluate the prognostic impact of DHL and DEL status on SCT outcomes in patients with rel/ref DLBCL.
Methods: We studied patients with rel/ref DLBCL or transformed indolent lymphoma (TIL) who underwent autologous SCT (autoSCT) at Dana-Farber Cancer Institute (DFCI) or City of Hope between 1/2000 and 7/2013. We also studied patients with rel/ref DLBCL or TIL who underwent allogeneic SCT (alloSCT) at DFCI or Massachusetts General Hospital during the same period. In the autoSCT cohort, IHC for MYC, BCL2, and BCL6 were performed and cutoffs of ≥40% MYC-positive and ≥50% BCL2-positive cells were used to define DEL. Cell-of-origin (COO) classification was determined by Hans criteria. In both cohorts, FISH for *MYC* was performed using dual-color break-apart probes; cases with *MYC*-rearrangement or copy gain (CG) also had *BCL2* and *BCL6* FISH performed. Rearrangement was defined as ≥10% nuclei with break-apart signals, and CG was defined as ≥30% nuclei with extra signals. DHL had rearrangement of *MYC* and *BCL-2* and/or *BCL-6*, and "atypical DHL" had at least 3+ *MYC* CG and *BCL2* and/or *BCL6* CG or rearrangement.

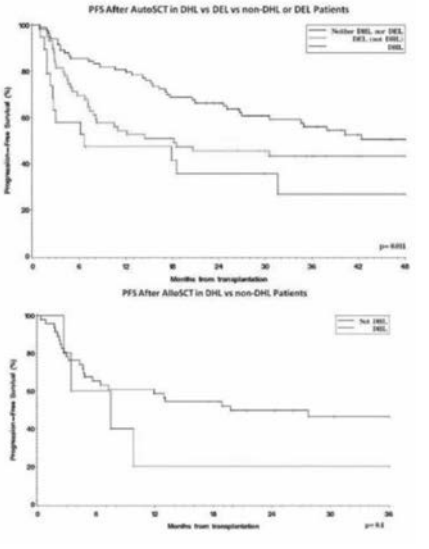

Figure 1.

Results: Cohort Characteristics AutoSCT cohort: 201 patients; median age 60y (range 30-77); 26% TIL; median 2 prior therapies; 99% prior rituximab; 53% primary refractory disease/relapse <6 mo; 59% CR at ASCT; median follow-up 53 months. AlloSCT cohort: 61 patients; median age 55y (range 28-69); 33% TIL; median 4 prior therapies; 64% prior autoSCT; 72% chemosensitive; 80% reduced intensity conditioning; 30% matched related, 54% matched unrelated, 6% mismatched unrelated, 5% haploidentical, 5% cord; median follow-up 41 months. Overall, 4y progression-free survival (PFS)/overall survival (OS) in the autoSCT were 44%/61%, and 3y PFS/OS in the alloSCT cohort were 42%/47%, respectively. Outcomes AutoSCT: Of 184 autoSCT patients with IHC data, 40% were DEL. 4y PFS in DEL v non-DEL patients was 37% v 52% (p=0.001), 4y OS was 52% v 69% (p=0.007). Of 167 autoSCT patients with FISH and IHC data, 13% were DHL, 38% had atypical DHL with 3+ *MYC* CG, and 8% had atypical DHL with 4+ *MYC* CG. 4y PFS in DHL v non-DHL patients was 24% v 48% (p=0.005), 4y OS was 31% v 62% (p=0.002) [Figure]. In a multivariable model, only DEL (PFS HR 2.1, p=0.0005; OS HR 1.8, p=0.022), DHL (HR 1.9, p=0.039; HR 2.4, p=0.012), and SD/PD at autoSCT (HR 3.1, p=0.02; HR 3.4, p=0.014) were associated with inferior PFS and OS. Neither PR *vs* CR status at autoSCT, isolated MYC, BCL2, or BCL6 expression, atypical DHL with 3+ or 4+ *MYC* CG, nor COO were associated with outcome

when DHL/DEL status was taken into account. AlloSCT: 51 alloSCT patients had complete FISH data – 10% had DHL, 29% had atypical DHL with 3+ *MYC* CG, and 10% had atypical DHL with 4+ *MYC* CG. 3y PFS/OS in DHL v non-DHL patients were 20% v 47% (p=0.4) and 20% and 53% (p=0.24) [Figure]. Atypical DHL was not associated with outcome.
Summary/Conclusions: Rel/ref DEL and DHL are associated with inferior PFS and OS after autoSCT, independent of other prognostic factors. Rel/ref DHL appears to also have a worse outcome after alloSCT, but the sample size is not large enough to draw definitive conclusions.

P341

BTLA GENOTYPE AND CLINICAL OUTCOME AFTER HLA-IDENTICAL SIBLING STEM CELL TRANSPLANTATION
N Santos[1,*], R Rodríguez-Romanos[2], S Brunet[3], R de la Camara[4], JB Nieto[5], JB Nieto[6], C Martínez[7], I Buño[8], C Vallejo[9], A Jiménez-Velasco[10], M González[11], C Solano[12], C Ferrá[13], A Sampol[14], J Pérez-Simón[15], J López-Jiménez[16], JL Díez[8], D Gallardo[1]
[1]Institut Català d´Oncologia, [2]Institut d'Investigació Biomèdica de Girona Dr. Josep Trueta (IDIBGI), Girona, [3]Hospital de la Santa Creu i Sant Pau, Barcelona, [4]Hospital La Princesa, Madrid, [5]Hospital Morales Maseguer, [6]Hospital Morales Meseguer, Murcia, [7]Hospital Clínic, Barcelona, [8]Hospital Gregorio Marañón, Madrid, [9]Hospital Universitario Central de Asturias, Oviedo, [10]Hospital Universitario Regional de Málaga, Málaga, [11]Hospital Universitario de Salamanca, Salamanca, [12]Hospital Clínico, Valencia, [13]Institut Català d´Oncologia, Badalona, [14]Hospital Son Espases, Palma de Mallorca, [15]Hospital Virgen del Rocío, Sevilla, [16]Hospital Ramón y Cajal, Madrid, Spain

Background: The co-inhibitory receptor B and T lymphocyte attenuator (BTLA) is thought to negatively regulate the proliferation and differentiation of T-cells modifying immune response. The BTLA genotype has been associated with the development of some autoimmune diseases. However, various *in vivo* models have showed that BTLA could have dissimilar roles in controlling immune responses depending on the tissue examined. The BTLA gene is located on chromosome 3 in q13.2 and consists of five exons
Aims: Here, we focus on the relevance of the rs9288953 BTLA C>T polymorphism on the clinical outcome after allogeneic stem cell transplant (allo-HSCT).
Methods: We carried out a retrospective analysis of 1060 allo-HSCTs from HLA-identical sibling donors performed between 1991 and 2013. Patients who received a T-depleted graft HSCT were not included. BTLA genotyping was made by allelic discrimination assays and detection system Life Technologies on DNA samples obtained from peripheral blood of the donors. Written informed consent was obtained from patients and donors. Statistical cumulative incidence was estimated for aGVHD, relapse and transplant related mortality (TRM) according to BTLA donor's genotype. TRM was defined as death due other causes but relapse. The Kaplan Meier method was applied to analyze overall survival (OS) and relapse-free survival (RFS), comparing curves by the log-rank test. Multivariate analysis was performed using the Cox regression model.
Results: BTLA allele and genotype frequencies were similar to the previously described in Caucasian populations. The homozygous BTLA CC genotype was the predominant in 44.3% of cases. Homogeneity in clinical variables between genotype groups was confirmed. There were not statistical differences in cumulative incidence of aGVHD grades II-IV (p: 0.367) and the secondary clinical endpoints OS (p: 0.500), TRM (p: 0.597) or RFS (p: 0.143), but we detected higher cumulative incidence of relapse between BTLA CC *versus* TT/CT genotypes (p: 0.015). Multivariate analysis identified BTLA genotype, stage of the disease, and acute leukemia diagnosis as independent risk factors for relapse (p: 0.038; HR1.3; 95%CI: 1 to 1.7; p<0.001; HR2.5; 95%CI: 1,9 to 3.2 and p: 0.03; HR1.6; 95%CI: 1.2 to 2.3 respectively).
Summary/Conclusions: The BTLA genotype of the donor seems to be independent risk factor for relapse. There were no statistically differences in other clinical endpoints, suggesting that BTLA should be relevant in the prevention of relapses, but not in the initial process of allorecognition. These preliminary results should be confirmed by other studies. This work has been financed by grants PI11/01690 and PI14/01646 from the Instituto de Salud Carlos III, co-financed by FEDER (Fondo Europeo de desarrollo regional) and by grant MTV3 Fundació Marató TV3.

P342

HIGH-DOSE *VERSUS* STANDARD-DOSE RITUXIMAB WITH BEAM IN AUTOLOGOUS STEM CELL TRANSPLANTATION (SCT) FOR RELAPSED AGGRESSIVE B-CELL NON-HODGKIN'S LYMPHOMAS (NHL)
SA Srour[*], S Lozano, Y Nieto, AM Alousi, UR Popat, MH Quazilbash, P Anderlini, P Kebriaei, E Shpall, RE Champlin, C Hosing
Stem Cell Transplant and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Background: High-dose rituximab (HD-R) combined with carmustine, cytarabine, etoposide, and melphalan (BEAM) and SCT was effective and tolerable in a single-arm study for relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) and other aggressive B-cell NHLs. This prospective randomized phase 2 study compared the efficacy and safety of HD-R *vs* standard-dose rituximab (SD-R) combined with BEAM in R/R-NHL.
Aims: 1. To determine the disease-free survival (DFS) for patients with R/R aggressive B-cell lymphomas in the two study arms: HD-R *vs* SD-R plus BEAM. 2. To compare the safety of the two treatment arms.
Methods: Patients with R/R-NHL (44 DLBCL, 49 other aggressive B-cell lymphomas) were randomized to HD-R or SD-R using Bayesian adaptive algorithm. HD-R (1,000 mg/m^2) or SD-R (375 m^2) were administered on days +1 and +8 after stem cell infusion. Primary endpoint: DFS, defined as time from SCT to disease progression or death. Overall survival (OS) and safety analysis were secondary endpoints. Planned sample size was 100 patients; however, the trial was closed to new patient entry by the Data and Safety Monitoring Board after 93 patients were enrolled because it was considered extremely unlikely that either treatment arm would be found significantly superior. Intention-to-treat Kaplan-Meier estimator (DFS & OS) and Cox proportional hazards regression were used. An informed consent was granted from patients before study enrollment.
Results: 93 patients (29% females) with a median age of 63 years (6-75) were randomized to HD-R (n=42) or SD-R (n=51). No significant differences in patient demographic and clinical characteristics. With a median follow-up of 7.92 years, the 5-year DFS and OS were 42% and 48% for the whole study population, respectively. We found no statistically significant differences between the HD-R and SD-R arms in 5-year DFS (37% *vs* 47%; p=0.2) and OS (42% *vs* 52%; P=0.4) (Figure 1). In multivariate analyses, only disease status at the time of SCT [complete remission (CR) *vs* no CR] (HR 0.57, 95% CI: 0.35-0.95) and number of prior treatment lines (a line of treatment is defined as any active treatment before BEAM and transplant, using chemotherapy and/or chemoimmunotherapy as single agent or in combination), (≤2 *vs* >2) (HR 0.53, 95% CI: 0.32-0.89) were associated with worse DFS. Similarly, these were found to be significant poor prognostic factors for OS: HR 0.56 (95% CI 0.33-0.95, p=0.03) for CR at time of SCT, and HR 0.53 (95% CI 0.24-0.74, p=0.002) for ≤2 lines of treatment. Patients transplanted in CR had better 5-year DFS (50% *vs* 30%, P=0.026) and OS (57% *vs* 35%; P=0.02). Similarly, those with ≤2 prior lines of treatment had significantly better 5-year DFS (45% *vs* 30%, P=0.006) and OS (54% *vs* 30%, P=0.001). No differences in Grade 3-4 toxicities, infection rates or engraftment were seen between both arms.

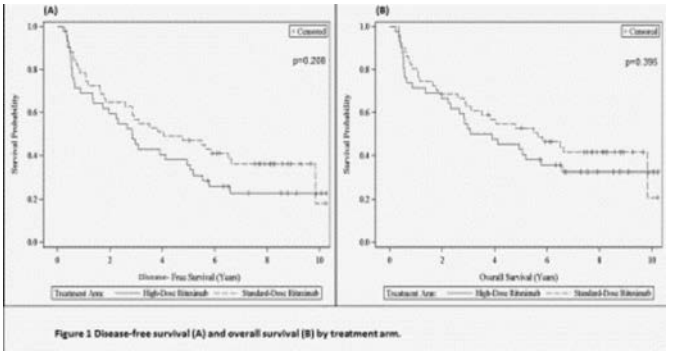

Figure 1.

Summary/Conclusions: SD-R is not significantly different from HD-R when combined with BEAM in B-cell aggressive R/R-NHL in terms of DFS and OS. Pre-transplant disease status (CR *vs* no CR) and numbers of treatments prior to transplant (≤2 *vs* >2) were the only significant predictors for prognosis. Patients with CR and those with ≤2 prior lines at time of SCT have the best outcomes.

P343

INTERFERON GAMMA (IFN-GAMMA) NEUTRALIZATION AS A VALUABLE THERAPEUTIC TARGET IN PRIMARY HLH
F Locatelli[1,*], M Jordan[2], C Allen[3], S Cesaro[4], F Fagioli[5], M Henry[6], MC Putti[7], C Rizzari[8], C Rossig[9], J Sevilla[10], M Ballabio[11], W Ferlin[11], C De Min[11]
[1]Pediatric Hematology and Oncology, Ospedale Pediatrico Bambino Gesu', Roma, Italy, [2]Cincinnati Children's Hospital, Cincinnati, [3]Texas Children's Hospital, Houston, United States, [4]Policlinico GB Rossi, Verona, [5]A.O. Regina Margherita, Torino, Italy, [6]Phoenix Children Hospital, Phoenix, United States, [7]University Hospital, Padova, [8]Ospedale S. Gerardo, Monza, Italy, [9]University Children's Hospital, Muenster, Germany, [10]Hospital Universitario Nino Jesus, Madrid, Spain, [11]Novimmune sa, Plan-Les-Ouates, Switzerland

Background: Primary HLH (pHLH) is a rare immune regulatory disorder which is lethal if untreated. High production of IFNγ has been shown to play a critical role in the pathophysiology of the disease. Immune-chemotherapy, primarily etoposide-based regimens, is currently used to control HLH and bring patients to allogeneic hematopoietic stem cell transplant (HSCT). In spite of recent

attempts to further intensify treatment regimens, mortality and morbidity remain high, also due to drug-related toxicities. NI-0501 is a fully human, high affinity, anti-IFNγ monoclonal antibody that binds to and neutralizes human IFNγ, offering a novel and targeted therapeutic approach for HLH.
Aims: To evaluate the safety and efficacy of NI-0501 in children with pHLH.
Methods: We have evaluated patients enrolled in the Phase 2 international study or who, although fulfilling the study criteria, were treated in Compassionate Use since not transferrable to study sites. NI-0501 was administered at an initial dose of 1 mg/kg every 3 days, possibly adjusted during treatment, along with dexamethasone dosed between 5-10 mg/m^2/day that could be tapered depending on clinical evolution. HLH response to treatment, NI-0501 safety profile and survival were assessed.
Results: A total of 20 patients (18 in the study, 2 in CU) have been evaluated so far: 10F/10M, median age 1.0 yr (range 2.5 mo-13 yr), mostly at the severe end of the HLH spectrum, and carrying significant toxicities from previous HLH treatments. Eighteen patients received NI-0501 as second line treatment and 2 as first line. In 18 patients a known HLH genetic defect was documented (6 FHL2, 4 FHL3, 1 FHL4, 1 FHL5, 3 GS-2, 1 XLP1, 2 XLP2). Eight patients started NI-0501 treatment in the presence of an active infection (mostly EBV and CMV), likely to be the disease trigger. Five patients had CNS signs and symptoms prior to NI-0501 administration requiring intrathecal therapy. To date, 11 patients received HSCT (2 also with additional HLH therapies), 4 achieved HLH control and are awaiting for HSCT, and 3 are at week 2 of treatment. Two patients died of HLH/MOF prior to HSCT. HLH parameters were positively impacted by NI-0501 treatment, in particular platelet and neutrophil counts, abnormal at baseline in 13 and 11 patients, normalized in 8 and 9, respectively, at end of treatment (EoT, Fig.1). CNS signs and symptoms resolved in the 4 evaluable patients. Dexamethasone dose could be at least halved in 60% of patients during the first 4 weeks of treatment. After transplantation, 9/11 patients (82%) are alive with a median follow-up of 4 mo (1 wk-2.5 yrs) Two patients died from HSCT complications (GvHD and graft rejection). IFNγ neutralization was demonstrated by a sharp decrease in CXCL9, an IFNγ-induced chemokine. NI-0501 was well tolerated and no safety concerns were identified. All infections present at start of treatment resolved upon appropriate treatment. Infections occurred during NI-0501 treatment only in patients who previously received chemotherapy. None of the infections were caused by pathogens known to be favored by IFNγ neutralization.

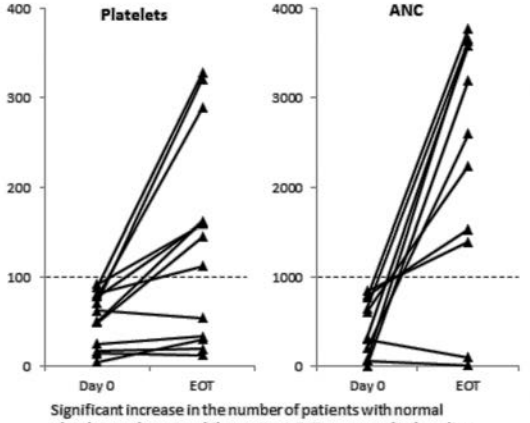

Figure 1. Response to NI-0501 treatment.

Summary/Conclusions: NI-0501 has shown to be safe and effective in patients with pHLH both in second and in first line. Efficacy of NI-0501 seems to be independent of the presence and type of causative mutations, as well as the presence and type of an infectious trigger. None of the typical etoposide-based regimen toxicities were observed, while a significant positive impact on cytopenia was noted. Based on the data available to date, IFNγ neutralization is proposed as a valuable pHLH therapy, and may be considered as first-line approach for HLH.

P344

BIDIRECTIONAL RELATIONSHIP BETWEEN CMV-R AND AGVHD: CMV-R HAS A BETTER OVERALL SURVIVAL AND T CELL RECONSTITUTION

P R Varanasi[1,2,3,*], J Ogonek[2,4], S Luther-Wolf[2], P Schweier[2], M Stadler[2], A Ganser[2,3], M Messerle[3,5], C Falk[1,6], S Borchers[2,3], L Hambach[1,2], E Mischak-Weissinger[1,2,3,4]
[1]Integrated Research and Treatment Centre Transplantation, [2]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, [3]German Centre for Infection Research, [4]Marie Curie Celleurope, [5]Institute of Virology, [6]Institute of Transplant Immunology, MEDICAL SCHOOL HANNOVER, Hannover, Germany

Background: Cytomegalovirus reactivation (CMV-R) and acute graft *versus*-host disease (aGvHD) are early complications after hematopoietic stem cell transplantation (HSCT). Multiple (m)CMV-Rs lead to an increased risk for development of aGvHD and vice-versa. Nevertheless, the interaction between aGvHD, CMV-R and their respective outcomes post HSCT is not well understood.
Aims: In a bidirectional approach we investigated the interaction of CMV-R and aGvHD on overall survival and T cell reconstituion
Methods: CMV-seropositive (R+) patients transplanted with hematopoietic stem cells derived from CMV-seropositive donors (D+) between 2006 and 2013 at Medical School Hannover were included in this analysis (n=145). All patients were monitored regularly for the development of T cells (CD8+, CD4+ T cells and CMV-CTLs) from day +25 to 1 year post-HSCT. In this study, T cell analysis was performed on day +50 and overall survival (OS) was evaluated at 2 years after HSCT.
Results: Based on the sequence of single or (m)CMV-R and aGvHD we analysed the influence of both CMV-R and aGvHD on OS. We observed that patients with aGvHD grade II-IV prior to CMV-R had a ten-fold increased risk to die (RR: 10.21, p=0.007), which was about the same as patients with aGvHD grade II-IV only (RR: 9.30, p=0.026) when compared to patients without either of these complications or to patients with CMV-R alone. Interestingly, patients with CMV-R prior to aGvHD grade II-IV (RR: 4.18, p=0.04) had only a four-fold risk to die, when compared to the patients without these complications. Patients with CMV-R alone had no increased mortality when compared to those without complications. We observed a rapid engraftment of CD8+ T cells and increased inflammatory cytokine secretion (*e.g.* IL1Ra, IL18, Hu TRAIL, MIP-1b and TNF-a) in the plasma of patient's post-CMV-R which led to the progression of aGvHD.
Summary/Conclusions: Our data suggest that the rapid reconstitution of CD8+ T cells in concert with the secretion of inflammatory cytokines post-CMV-R leads to the progression/development of aGvHD grade II or more. We could also show that CMV-R itself is not a risk factor worse OS in the R+/D+ patient group. However, as expected, aGvHD grade II-IV and CMV-R post-aGvHD grade II-IV are associated with a higher risk to die after HSCT.

P345

HIGH DOSE CHEMOTHERAPY WITH AUTOGRAFT MAY IMPROVE THE POOR PROGNOSIS OF NAIVE DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS WITH MYC/BCL2 CO-EXPRESSION

F Maura[1,*], A Pellegrinelli[2], A Dodero[1], A Guidetti[1,3], M Pennisi[1], C Caprioli[1], L Farina[1], LF Devizzi[1], A Cabras[2], P Corradini[1,3]
[1]Department of Hematology, [2]Department of Pathology and Laboratory Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, [3]Department of Oncology and Hemato-Oncology, University of Milan, Milan, Italy

Background: The concurrent immmunohistochemical (IHC) expression of MYC and BCL2 has recently emerged as one of the strongest and most unfavorable prognostic factor among naïve DLBCL patients after R-CHOP therapy, with a 3-year event free survival (EFS) and overall survival (OS) of 27-39% and 30-43% respectively. Nevertheless, Horn et al (Leukemia 2015) have recently suggested that the MYC/BCL2 co-expression is not strongly associated with inferior survival among young DLBCL patients treated with more intense chemotherapy regimens. This discordant result may be explained either by the lower prognostic relevance of MYC/BCL2 among young DLBCL patients, but also by the ability of more intense chemotherapy regimens to overcome the negative prognostic features of MYC/BCL2 co-expression.
Aims: We investigated the clinical impact of MYC/BCL2 co-expression among naive DLBCL patients treated with high dose chemotherapy followed by autologous stem cell transplantation in first line.
Methods: We analyzed a consecutive series of 71 naïve DLBCL patients treated with high-dose sequential chemotherapy integrated with monoclonal antibody Rituximab (R-HDS) between 2000 and 2015 at the Istituto Nazionale dei Tumori Milano. R-HDS schedule is a typical ASCT-based program, including the delivery of high-dose drugs from the start of treatment, the collection of PBSC and a final autograft. Tumor samples from all enrolled patients were analyzed for MYC and BCL2 expression by ICH with a 40% and 70% threshold, respectively.
Results: All patients had an IPI score ≥1 and 65/71 (91%) had an Ann Arbor stage ≥3. Among patients younger than 60 years, 30/47 (63%) were characterized by an age adjusted IPI≥2. No differences for IPI, ECOG score ≥2, Ann Arbor stage >2, age, extranodal sites ≥2 and LDH levels were observed between double expressor and non double expressor patients. The treatment schedule was interrupted, and the transplant was not performed, in 16 (22.5%) patients due to refractory and/or progressive disease (n=12) and adverse events (n=4), including 2 patients who died of infection during treatment. After a median follow up of 92 months (range 4-200), the overall 5-year EFS and OS were 65.2% (95% CI, 59.4-71%) and 83.5% (95% CI, 78.7-88.3%) respectively. MYC and BCL2 expression on IHC was observed in 31 (44%) and 37 (52%) patients respectively. Among them, 20 (28%) were classified as MYC/BCL2 double expressors. The Ki-67 expression, MYC or BCL2 expression alone were not associated with inferior outcome. Conversely the co-expression of

MYC/BCL2 was associated with a trend of worse outcome: 5-year EFS 49.4% (95% CI, 37.7-61.5%) *vs* 71.5% (95% CI, 65-78%); p=0.06 (Figure1a). However, this higher relapse risk did not affect final 5-year OS [76.7 (95% CI, 66.4-87) *vs* 83.4 (78-88.8)] (Figure 1b). When only the 55 transplanted patients where considered, MYC/BCL2 co-expression was not associated with any significant difference in term of EFS and OS (Figure 1c-d). By multivariate analysis (including age, bulky disease, ECOG≥2, Extra nodal sites≥2, IPI score≥2) MYC/BCL2 co-expression retained its independent prognostic value for EFS without affecting the final OS.

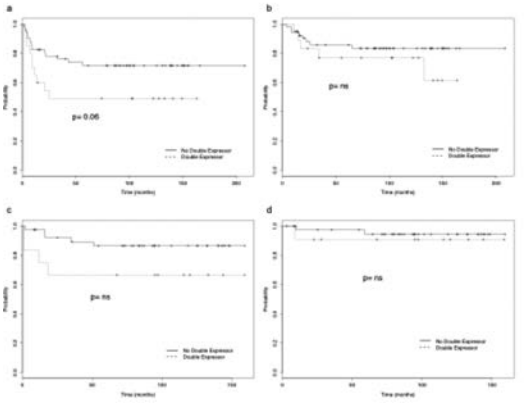

Figure 1.

Summary/Conclusions: In our R-HDS cohort the 5-year EFS and OS of double expressor patients compared better with previous reports of different DLBCL series treated with R-CHOP. This improvement was especially evident in transplanted patients, where R-HDS seems to be able to overcome the poor clinical outcome associated with MYC/BCL2 co-expression. Finally, the double expressor higher relapse risk did not affect the final whole series survival, suggesting that a significant fraction of relapsed/refractory young patients may be rescued with other intensive salvage therapies.

BIOMARKERS PREDICTING ACUTE GRAFT-VERSUS-HOST DISEASE IN ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANT RECIPIENTS: A PROSPECTIVE STUDY IN 120 PATIENTS

LC Vaccari[1,2,*], MC Barbanti[2], F Giglio[2], M Morelli[2], D Mannina[2], T Perini[2], L Lazzari[2], S Mastaglio[2], S Piemontese[2], F Lorentino[2], A Forcina[2], A Assanelli[2], S Marktel[2], M Carrabba[2], L Vago[2,3], C Corti[2], M Bernardi[2], MT Lupo Stanghellini[2], J Peccatori[2], F Ciceri[2,4], R Greco[2]

[1]College of Medicine and Veterinary Medicine, University of Edinburgh, Edinburgh, United Kingdom, [2]Haematology and Bone Marrow Transplant Unit, [3]Unit of Immunogenetics, Leukemia Genomics and Immunobiology, IRCCS San Raffaele Scientific Institute, [4]Università Vita-Salute San Raffaele, Milano, Italy

Background: Allogeneic haematopoietic stem cell transplantation (allo-HSCT) is the only curative treatment for many haematological diseases. Despite advances in supportive therapies, acute Graft-*versus*-Host Disease (aGvHD) remains the leading cause of morbidity and mortality. There are shortcomings in the prediction of aGVHD, indicating the urgent need for non-invasive and reliable laboratory tests to allow a precision-medicine tailored prophylactic approach.
Aims: We conducted a prospective observational study to ascertain the potential usefulness of the levels of ten biomarkers, measured pre-transplant and at +7 days post-transplant, in predicting the development and severity of aGvHD in allo-HSCT patients. These time-points were chosen as early risk stratification may provide a window for additional prophylactic measures.
Methods: We collected data from 120 consecutive patients (41 female and 79 male; median age 52, range 19-77 years) who underwent allo-HSCT at our institute between 2014 and 2015. Most patients were affected by acute myeloid leukaemia (n=62; 52%). Disease status at HSCT was "active disease" in 58% of patients (n=70). Stem cell donors were unrelated (n=39, HLA matching 9/10 in 14 and 10/10 in 25), family haploidentical (n=56), HLA-identical sibling (n=22), or cord blood (n=3). Post-transplant GvHD prophylaxis was with PT-Cy in 65 patients, ATG in 28 patients, both agents in 18 cases whilst 9 patients received neither. Additionally, sirolimus-based GvHD prophylaxis was used in 95 patients, while a CSA-based prophylaxis in 25 cases according to institutional guidelines. The following biomarkers were measured 7 days pre- and post-transplant: interleukin-6 (IL6), Ceruloplasmin (CER), Cholinesterase (CHE), Albumin, Immunoglobulin A, Gammaglutyl-transferase (GGT), White Blood Cells, Neutrophils, Haemoglobin and Platelets.
Results: In this cohort of 120 patients, 77 developed GvHD, of which 69 were aGvHD. Of the aGvHD cases, 49 had skin, 12 had liver and 19 had gut involvement. 39 of 120 patients died: 3/39 deaths were attributable to aGvHD. We looked for associations between in-range and out-of-range levels of our ten biomarkers with presence of aGvHD. At baseline, lower CHE concentrations were significantly related to the risk of developing aGvHD and to some of its main characteristics, such as severity (p=0.009), grade II-IV liver involvement (p=0.016), and gut involvement (p=0.036). At 7 days after HSCT, concentrations of IL6 were increased in patients who later developed grade II-IV gut GvHD (p=0.03). We found that baseline albumin concentrations were reduced in patients with subsequent liver aGvHD (p=0.027). Similarly, raised baseline GGT values were correlated with liver involvement (p=0.05). Moreover, we assessed the correlation of laboratory tests with non-relapse mortality (NRM: death from any non-relapse complication) disease relapse and overall survival (OS) at 100 days. Baseline albumin and CHE concentrations, together with post-transplant IL6 levels, were correlated to OS and TRM. Disease relapse was associated with baseline levels of albumin and IL6.
Summary/Conclusions: Pre-transplant CHE and GGT levels are predictors of aGvHD, especially with regards to grade III-IV aGvHD and liver involvement. Lower albumin levels were associated with liver aGvHD development, while raised IL6 concentration 7 days after HSCT represented a risk factor for gut aGvHD. These biomarkers will be incorporated in a treatment algorithm to increase primary GvHD prophylaxis in patients at risk of severe aGVHD after allo-HSCT.

P347

BONE MARROW WT1 LEVELS IN ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANT (HCT) FOR ACUTE MYELOID LEUKEMIA AND MYELODYSPLASIA STUDY TIME POINTS AND THRESHOLDS WITH CLINICAL RELEVANCE

J Nomdedeu[1,*], A Esquirol[1], M Carricondo[1], M Hoyos[1], M Pratcorona[1], A Garrido[1], MA Rubio[2], E Bussaglia[1], I Garcia Cadenas[1], C Estivill[1], S Brunet[1], R Martino[1], J Sierra[1]

[1]Hematology, Hospital de la Santa Creu i Sant Pau, [2]Diagnostic Hematology, IIB Sant Pau, Barcelona, Spain

Background: WT1 mRNA is overexpressed in most myeloid malignancies. Standardized methods of quantitation have been developed and succesfully used in minimal residual disease (MRD) assessment. The uncertaintity about the levels with prognostic and/or therapeutic impact has precluded a more widespread use of WT1 monitoring in HCT patients.
Aims: To investigate the WT1 levels and time points with clinical relevance in patiens with myeloid malignancies who received a HCT.
Methods: Prospective collection of samples from consecutive patients with acute myeloid leukemia (AML) and myelodysplasia (MDS) recipients of an allogeneic HCT in a University hospital. Normalized WT1 levels were obtained using the ELN protocol and the Ipsogen© plasmid. Statistical correlations with survival, relapse and other clinical variables were established.
Results: One hundred and ninety three consecutive allogeneic HCT recipients with myeloid malignancies (148 AML, 45 MDS) treated from 2003 to 2014 were included in the study. The analysis of pretransplant samples (n=177) showed that with WT1 levels below 100 copies had better post-transplant outcome in terms of overall survival at 5 years (OS:40±1 *vs* 29±6, p:0.004), disease-free survival (DFS:35±9 *vs* 26±6, p:0.002) and cumulative incidence of relapse (CIR:29±7 *vs* 37±6 p:0.051) than those patients with WT1>100 copies. When we analyzed the marrow samples obtained just after the neutrophil recovery (n=182), and using again the 100 copies threshold we also identified differences in OS (40±7 *vs* 31±9 p:0.025), DFS (36±7 *vs* 30±8, p:0.004) and CIR (29±6 *vs* 54±9, p<0.001). In 104 cases four consecutive follow-up samples were available. Those patients with sustained WT1 levels below 100 copies had a significantly better outcome than those with one or more determination higher than 100 copies (OS: 68±11 *vs* 26±7, p<0.001; DFS: 63±11 *vs* 20±8, p<0.001; CIR:20±8 *vs* 71±8, p<0.001).
Summary/Conclusions: Normalized bone marrow mRNA levels of WT1 provided useful information in patients with AML and MDS treated with HCT. In patients with more than 100 copies pre and/or postransplant further therapeutic interventions after the procedure are needed to avoid disease recurrence.

P348

TRANSPLANTATION FROM MATCHED UNRELATED AND HAPLOIDENTICAL DONOR IN PEDIATRIC SEVERE APLASTIC ANEMIA: EXPERIENCE WITH TCR ALPHA/BETA AND CD19 DEPLETION AS GRAFT PROCESSING METHOD

D Shasheleva[1], L Shelikhova[1], M Ilushina[1], Z Shekhovtsova[1], D Balashov[1], E Boyakova[2], Y Skvortsova[1], E Kurnikova[3], P Trakhtman[3], E Gutovskaya[1], Y Muzalevsky[3], A Kazachenok[3], A Abrosimov[1], A Livshits[1], S Blagov[1], G Novichkova[4], A Maschan[4], M Maschan[4,*]

[1]HSCT, [2]Laboratory of biology of HSCT, [3]Laboratory of Transplant Processing and Cell Preparations, [4]Dmitry Rogachev Federal Research Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: Hematopoietic stem cell transplantation from non-sibling donors

remains the only curative option for severe aplastic anemia patients refractory to ATG/CsA immunosuppression.
Aims: Although the results of MUD and haploidentical transplantation in SAA have improved significantly, graft-*versus* host disease (GVHD) remains a serious problem, associated with significant morbidity and mortality. We investigated the role of new method of graft processing - TCR alpha/beta depletion as a way to improve the results of MUD and haploidentical transplants in SAA.
Methods: Thirty seven patients with SAA were treated since November 2012 till November 2015. Median age at HSCT was 11(3-22) years, 22 male/15 female. All pts were refractory/relapsed after at least two courses of ATG/CsA, 2 pts had concurrent severe hemolytic PNH. Time from diagnosis to transplant was 4,3(1-10) years. Donors were unrelated volunteers in 29 cases, haploidentical parent in 8 cases. Preparative regimen included cyclophosphamide 100-150 mg/kg, fludarabine 150mg/kg, ATG and 2-6Gy thoraco-abdominal irradiation, in haplo transplants patients additionaly recieved thiophosphamide at 10mg/kg. Two patients recieved alemtuzumab instead of ATG because of anaphylaxis. Post-transplant GVHD prophylaxis included Tacro and Mtx on days +1,+3,+6. PBSC grafts were depleted of TCRalpha/beta cells and CD19 cells with CliniMACS device as recommended by the manufacturer. Patients recieved a median of 8,6(6,8-13,5)x10^6 CD34 per kg, 3(1-30) x10^4 TCRalpha/beta per kg.
Results: All patients engrafted with a median of 14 days for WBC and 13 days for platelets. In 4 patients after MUD transplantation secondary graft failure (rejection) developed, two of them were successfully retransplanted. Cumulative incidence of aGVHD 2-4 was 3% (95% CI: 1-17%) and 50%(95% CI: 28-89%) in MUD and haplo respectively. Cumulative incidence of aGVHD 3 was 0% and 12%(95% CI: 3-58%) in MUD and haplo respectively. Cumulative incidence of cGVHD was 3%(95% CI: 0-25%) and 37%(95% CI: 15-92%) in MUD and haplo respectively. A median follow up was 18 months. Six patients died. The reasons of death were: viral infection (3 pts), viral infection plus GVHD (one pt), and 2 pts died after second transplantation (1 – toxoplasmosis, 1 – viral infection plus GVHD). Overall survival was 81%(95% CI: 65-96%) and 87%(95% CI: 65-100%) respectively. Prolonged mixed chimerism in T-cells was detected in recipients of MUD grafts in contrast to haploidentical grafts.
Summary/Conclusions: TCR alpha/beta depletion is a robust platform for allogeneic transplantation from MUD and haploidentical donors in severe aplastic anemia. Results can be further improved by additional measures to control viral infections and prevent rejection in MUD transplants.

Stem cells and the microenvironment 1

P349

THE PRC2 COMPONENT JARID2 IS DISPENSABLE FOR HEMATOPOIETIC STEM CELLS BUT CRITICAL FOR THE MAINTENANCE OF LEUKEMIC STEM CELLS

AK Frank[1,2,3,*], A Willer[2,3,4], TL Jensen[1,2,3], N Rapin[1,2,3], FKB Lauridsen[1,2,3], T D'Altri[1,2,3], A Wilhelmson[1,2,3], Y Ge[1,2,3], S Pundir[1,2,3], M Hasemann[1,2,3], K Helin[2,3,5], B Porse[1,2,3]
[1]The Finsen Laboratory, Rigshospitalet, Faculty of Health Sciences, University of Copenhagen, [2]Biotech Research and Innovation Centre (BRIC), [3]Danish Stem Cell Centre (DanStem), Faculty of Health Sciences, University of Copenhagen, [4]Finsen Laboratoriet, Rigshospitalet, [5]Centre for Epigenetics, University of Copenhagen, Copenhagen, Denmark

Background: Hematopoietic stem cells (HSCs) are under tight transcriptional regulation and erroneous regulation can confer unwanted properties to the cells and ultimately lead to malignant transformation. Several studies have implicated the epigenetic modulator Polycomb Repressive complex 2 (PRC2), which is responsible for the deposition of the H3K27me3 mark associated with transcriptional repression, in preserving correct HSC maintenance.
Aberrant function of PRC2 is shown to influence malignant transformation and propagation of disease. A number of PRC2 auxiliary factors has been identified, one being JARID2, which is involved in modulating the activity of the complex by regulating binding to target genes.The role of JARID2 in the hematopoietic system is essentially unknown.
Aims: To characterize the functional consequences of *Jarid2* deletion in both normal and malignant hematopoiesis.
Methods: Using a conditional knock out (KO) mouse model we have investigated the loss of *Jarid2* in the normal hematopoietic system. We also assayed leukemic development and maintenance in our KO model using a Notch1 induced T cell acute lymphoblastic leukemia (T-ALL) model. Both settings were studied by immunophenotypic analyses by FACS, RNAseq and micro array based gene expression profiling, and ChIPseq analyses of histone marks. Multi-lineage reconstitution and self renewal capacity of the hematopoietic stem cells were assayed by competitive and serial transplantations. Leukemic development, maintenance, and frequency of leukemic stem cells (LSC) were assessed by serial transplantation and limiting dilution transplants. Serially transplanted T-ALL was further analysed by exome sequencing to identify mutations altering LSC frequency.
Results: We found that JARID2 is dispensable for the numbers and function of adult hematopoietic stem cells and observed only mild changes for the down stream progenitor cells. These findings were further supported by a lack of changes in gene expression and H3K27me3 levels in these cells. Through transplantation assays, we found that the self-renewal capacity of normal HSCs also remained intact after loss of JARID2. These findings are in stark contrast to the requirement for JARID2 in the leukemic setting. In a model of T-ALL we observed an initial acceleration of leukemic onset, possibly explained by improved homing abilities of the *Jarid2* KO cells. However, KO T- ALL showed a marked decrease in the ability to propagate leukemia in secondary recipients, and the increased latency was reflected in a dramatic reduction in leukemic stem cells (LSC) frequency. Furthermore, gene expression profiles for these cells were inversely correlated with relapse signatures for childhood T-ALL. Surprisingly, the latencies were reverted upon re-transplantation into tertiary recipients, and this corresponded to a rise in LSC numbers. To study this further we performed exome sequencing of serially transplanted T-ALL and identified mutations in *Pten* and *Ikzf1*. These are likely candidates responsible for rescuing the LSC deficiency observed for JARID2 depleted T-ALL.
Summary/Conclusions: JARID2 is, contrary to other PRC2 components, dispensable for normal HSC function, but plays a key role in LSC maintenance in NOTCH1 induced T-ALL. Loss of *Jarid2* leads to a marked loss of LSCs but their numbers can recover as a consequence of secondary mutations.
Thus, this study provides new insights into the function of PRC2 in normal and malignant hematopoiesis as well as into mechanisms governing the behavior of LSCs in T-ALL.

HHEX PROMOTES HSC SELF-RENEWAL AND STRESS HEMATOPOIESIS VIA REPRESSION OF CDKN2A

JT Jackson[1,*], BJ Shields[1], W Shi[2], L Di Rago[1], D Metcalf[1], N Nicola[1], MP McCormack[1]
[1]Cancer & Haematology Division, [2]Bioinformatics Division, The Walter & Eliza Hall Institute of Medical Research, Parkville, Australia

Background: The Hematopoietically-expressed homeobox transcription factor (Hhex) is important for the maturation of definitive hematopoietic progenitors and B-cells during development. We have recently shown that in adult hematopoiesis Hhex is dispensable for maintenance of hematopoietic stem cells (HSCs) and myeloid lineages but essential commitment of common lym-

phoid progenitors to diverse lymphoid lineages. However, whether Hhex plays a role in HSC self-renewal and myeloid expansion during hematopoietic stress is unknown.
Aims: The aim of this is to determine the roles of Hhex in HSC self-renewal and emergency hematopoiesis.
Methods: We employed inducible knock out mice for Hhex to assess the requirement of this transcription factor in adult haematopoiesis. Serial bone marrow transplantation was used to test the effect of Hhex deletion on HSC self-renewal. In addition, the bone marrow response to myeloablation was tested using 5- fluorouracil (5-FU) treatment, and the proliferation of immature blast colony-forming units was tested *in vitro* using soft agar cultures.
Results: Here we show that Hhex-deleted HSCs are progressively lost during serial bone marrow transplantation, revealing an intrinsic defect in HSC self-renewal. Moreover, Hhex-deleted mice show markedly impaired hematopoietic recovery after myeloablation using 5-FU. *In vitro* cultures demonstrated that although Hhex-null donor bone marrow contained elevated numbers of hematopoietic progenitors, immature blast colonies were specifically incapable of replating. Thus, Hhex is essential for HSC self-renewal and immature myeloid progenitor expansion *in vitro* and *in vivo*. RNAseq analysis of Hhex-null LSK cells showed Hhex deletion led to the dysregulation of cell cycle regulators, including an upregulation of Cdkn2a-encoded $p16^{Ink4a}$ and $p19^{Arf}$. Consequently we crossed Hhex inducible knock-out mice with those lacking Cdkn2a. Loss of Cdkn2a completely restored the expansion of Hhex-null progenitors and blast colony replating *in vitro*, as well as hematopoietic reconstitution following myeloablation *in vivo*.
Summary/Conclusions: These finding show that Hhex is a key transcriptional mediator of HSC self-renewal and stress hematopoiesis, mediating these effects by regulation of cell cycling via repression of Cdkn2a.

P351

WNT5A FROM THE NICHE REGULATES THE ACTIN REGULATORY PATHWAY IN HEMATOPOIETIC STEM CELLS
C Schreck[1], R Istvanffy[1], C Ziegenhain[2], T Sippenauer[1], Á Prendergast[3], N Mende[4], F Gärtner[5], S Massberg[5], M Essers[3], C Waskow[6], C Peschel[1], W Enard[2], R Oostendorp[1,*]
[1]III. Medizinische Klinik, Klinikum rechts der Isar der TU München, [2]Anthropology and Human Genetics, Ludwig-Maximilians University, München, [3]Hi-STEM, Heidelberg, [4]Institure of Immunology, TU Dresden, Dresden, [5]Medizinische Klinik und Poliklinik I, Ludwig-Maximilians University, München, [6]Institute of Immunology, TU Dresden, Dresden, Germany

Background: The niche regulates the quality of hematopoietic stem cells (HSCs) that are regenerated under conditions of stress, such as transplantation. We found earlier, that WNT5A is overexpressed in stromal cells capable of maintaining HSC activity in an *in vitro* model of culture stress.
Aims: We here wished to delineate the role of stromal WNT5A in hematopoietic processes *in vivo*.
Methods: For this purpose, we performed transplantation experiments in which wild-type (WT) HSCs were transplanted into a WNT5A haploinsufficient environment. After trasnplantation the regenerated HSCs were subjected to rigorous molecular and cellular asessment, as well as transplanted into secondary WT recipients.
Results: We find that although HSCs efficiently find and lodge in the Wnt5a-deficient niche, the reduced level of WNT5A in the niche regenerates HSCs, which do not successfully engraft secondary recipients. In particular, RNA sequencing shows a dysregulated Zeb1- and Nfatc-associated gene expression of multiple genes involved in the small GTPase- dependent actin polymerization pathway. Misexpression of these genes results in reduced ability to direct polarized F-actin localization, leading to defects in adhesion, migratory behavior and homing to the bone marrow of secondary recipients. Our study also shows that the Wnt5a-deficient environment similarly affects p185-BCR-ABL cells, which, in 42% of the studied recipients, fail to generate leukemia and, in the remaining cases, fail to transfer leukemia to secondary hosts.
Summary/Conclusions: Thus, we show that Wnt5a in the niche is required to regenerate HSCs and leukemic cells with functional ability to rearrange the actin cytoskeleton which is required for successful engraftment.

P352

NPM1 IS REQUIRED FOR NORMAL HEMATOPOIESIS
CH Ang[1,2,*], Z Xu[2], W Alexander[1,2], S Glaser[1,2]
[1]Department of Medical Biology, Univerisity of Melbourne, [2]Cancer and Haematology, Walter and Eliza Hall Institute for Medical Research, Parkville, Australia

Background: The NPM1 gene encodes a multifunctional protein that shuttles between nucleus and cytoplasm and is frequently mutated in hematological malignancies. Recurrent mutations of NPM1 occur in 30% of acute myeloid leukemia (AML) patients, causing a frame-shift in exon 12 that results in aberrant localization of the mutated protein, designated NPMc+, to the cytoplasm. Although NPM1 is the most frequently mutated gene in AML, its role in leukemogenesis is poorly understood, given its multiple cellular functions and attribution as a proto-oncogene and a tumour suppressor. Previous studies showed that constitutive homozygous deletion of NPM1 in mice is embryonic lethal due to aberrant organogenesis and defects in primitive hematopoiesis, whilst heterozygous loss of a single NPM1 allele causes a hematological condition resembling human myelodysplastic syndrome (MDS), a preleukemic condition often progressing towards AML.
Aims: We aim to study the role of NPM1 in adult hematopoiesis.
Methods: We describe a conditional mouse model using Tamoxifen-inducible Cre recombinase to delete *NPM1* in adult hematopoiesis.
Results: We found that deletion of the *NPM1* gene in adult mice resulted in multiple hematopoietic abnormalities. Loss of *NPM1* compromised hematopoietic stem and progenitor cell (HSPCs) function, causing depletion of progenitors and mature lineages, particularly the erythroid lineage. *NPM1*-null HSPCs exhibited aberrant cell cycle status with increased number of cells in the synthesis phase. Competitive transplantation and *in vitro* differentiation assays revealed that *NPM1*-null HSPCs had reduced capacity to engraft and produce mature hematopoietic lineages, including B-cells, T-cells, and myeloid cells compared to wild-type controls, indicating impaired self-renewal and differentiation of the stem cells. Phenotypically, *NPM1*-null mice were anemic and leukopenic with splenomegaly, symptoms that resemble human MDS.
Summary/Conclusions: In summary, this mouse model highlights the important role of *NPM1* in adult hematopoiesis. Knowledge of the role of *NPM1* in normal hematopoiesis is likely to improve our understanding of AML pathogenesis associated with mutations in *NPM1*.

PLZF MUTATION ALTERS MOUSE HEMATOPOIETIC STEM CELL FUNCTION AND CELL CYCLE PROGRESSION
C Vincent-Fabert[1,*], N Platet[1], A Vandevelde[1], M Poplineau[1], M Koubi[1], P Finetti[2], Am Imbert[3], F Bertucci[2], E Duprez[1]
[1]CRCM Inserm U1068 CNRS 7258, Institut Paoli-Calmettes, [2]CRCM Inserm U1068 CNRS 7258, Department of Medical Oncolgy, Institut Paoli-Calmettes, [3]CRCM Inserm U1068, Inserm CBT-1409 CIC Biothérapies, Institut Paoli-Calmettes, Marseille, France

Background: Hematopoietic stem cells (HSCs) give rise to all blood populations due to their long-term self-renewal and multipotent differentiation capacities. Because they have to persist throughout an organism's life span, HSCs tightly regulate the balance between proliferation and quiescence. As with most tissues that have a high cellular turnover, hematopoietic tissue is sensitive to aging, which results in multiple functional defects that accumulate in HSCs from older individuals. Aging HSCs have a reduction in their regenerative capacity and support decreased lymphoid lineage output together with increased myeloid output. Surprisingly, the number of phenotypically-defined HSCs increases with age; while it has long been known that aging has a major impact on the frequency and cell-cycle kinetics of hematopoietic cell compartments, mechanisms underlying this phenomenon remain poorly understood.
Aims: Here we investigated the role of the transcription factor, plzf in HSC fate using the Zbtb16lu/lu mouse model, harboring a natural spontaneous mutation that inactivates plzf.
Methods: We used the Zbtb16lu/lu mouse model in order to study the role of plzf in HSCs. We performed serial and competitive transplantation assays to evaluate Zbtb16lu/lu HSC function. Effect of Zbtb16lu/lu mutation at the genomic level was addressed by transcriptomic analyses and plzf role on cell cycle regulation was studied through a combination of flow cytometry and BrdU injection.
Results: Regenerative stress revealed that Zbtb16lu/lu HSCs had a lineage skewing potential from lymphopoiesis towards myelopoiesis, an increase in the long-term-HSC pool and a decreased repopulation potential. Comparison of young Zbtb16lu/lu HSCs with one-year-old HSCs for their competitive repopulation ability showed that the Zbtb16lu/lu HSCs have a myeloid competitive advantage and contribute more to the LT-HSC compartment relatively to ST-HSC and MPP1 fractions. Furthermore, old plzf-mutant HSCs present an amplified aging phenotype. Comparative microarray-based gene expression data from Zbtb16lu/lu and control HSCs revealed that Zbtb16lu/lu HSCs harbor a transcriptional signature associated with a loss of stemness and cell-cycle deregulation suggesting changes in HSC cell cycles induced by plzf mutation. Indeed, cell-cycle analyses revealed an important role for plzf in the regulation of the G1-S transition of HSCs. We also demonstrated a significant increase in apoptosis in Zbtb16lu/lu HSC in comparison to WT cells that could account for the limited accumulation of Zbtb16lu/lu HSCs in young PLZF-mutant. Interestingly, apoptosis was not as increased in transplanted Zbtb16lu/lu HSCs.
Summary/Conclusions: These results suggest that Zbtb16lu/lu promotes premature-aging-like syndrome in mice after regenerative stress and imply a role for plzf in the control of age-related mechanisms in HSC. Our study reveals a new role for plzf in regulating HSC function that is linked to cell-cycle regulation and positions plzf as a key player in controlling HSC homeostasis.

P354

IL-1 INDUCED ACTIVATION OF QUIESCENT HEMATOPOIETIC STEM CELLS *IN VIVO*

U Demel[1,2,*], S Sujer[1,2], S Blaszkiewicz[1,2], A Kuck[1,2], M Essers[1,2]
[1]Heidelberg Institute for Stem Cell Technology and Experimental Medicine (HI-STEM gGmbH), [2]Hematopoietic Stem Cells and Stress Group, Division of Stem Cells and Cancer, Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany

Background: The pro-inflammatory cytokines IL-1α and IL-1β play important roles in the acute inflammatory response to infection and injury. Intracellular IL-1α protein is highly expressed in endothelial cells and platelets, suggesting that its release may function as a danger signal. In contrast, IL-1β is highly secreted by monocytes and macrophages upon infection to initiate a systemic pro-inflammatory response. In addition, IL-1 is involved in a variety of autoinflammatory diseases, which are often associated with hematopoietic dysfunctions. However, thus far the effect of IL-1α and IL-1β on hematopoietic stem cells (HSCs) remains unclear.
Aims: To investigate the effect of the pro-inflammatory cytokines IL-1α and IL-1β on quiescent HSCs *in vivo*.
Methods: To analyze the effect of IL-1α or IL-1β on quiescent HSCs, wild-type (wt) or IL-1R$^{-/-}$ (IL-1 receptor knock-out) mice were injected with IL-1α or IL-1β. HSC number, proliferation and cell cycle status were analyzed by FACS 18 hours following treatment. HSCs from treated mice were also isolated and transplanted into lethally irradiated recipients to analyze the function of these HSCs.
Results: Here, we could show that IL-1α and IL-1β efficiently induced the activation of quiescent HSCs *in vivo*. Within 18 hours after treatment of mice, HSCs exited G_0 phase and entered an active cell cycle. This effect was abrogated in mice lacking the IL-1 receptor (IL-1R$^{-/-}$), demonstrating the requirement of the IL-1 receptor. Competitive bone marrow (BM) transplantations and serial transplantation assays showed no functional impairment or reduced self-renewal potential of HSCs upon short-term IL-1 treatment. Moreover, forward and reverse BM chimeras showed that IL-1 signaling via the IL-1R in cells of the BM niche is dispensable for the IL-1 effect on HSCs. Interestingly, mixed BM chimeras with wt and IL-1R$^{-/-}$ HSCs indicated a direct effect of IL-1α on HSCs, whereas the effect of IL-1β on HSCs was both direct and indirect via other cells of the hematopoietic system. Furthermore, we could link the effect of IL-1 on HSCs *in vivo* to NFkB signaling.
Summary/Conclusions: Our data show a strong effect of IL-1α and IL-1β on quiescent HSCs *in vivo.* In addition to previous studies on other pro-inflammatory cytokines, our data indicate that *in vivo* activation of HSCs by pro-inflammatory cytokines is a more general phenomenon, strongly linking the host response to systemic inflammation to activation of quiescent HSCs.

P355

SFRP2 FROM THE NICHE IS REQUIRED TO MAINTAIN THE REGENERATION OF THE HEMATOPOIETIC STEM CELL POOL

F Ruf, C Schreck, S Grziwok, T Sippenauer, C pagel, A Wagner, K Götze, C Peschel, R Istvanffy, R Oostendorp*
III. Medizinische Klinik, Klinikum rechts der Isar der TU München, München, Germany

Background: We previously found that *Sfrp2* was overexpressed in stromal cells, which maintain hematopoietic stem cells (HSCs) in *in vitro* culture.
Aims: Here, we determined the relevance of Sfrp2 expression by niche cells for the maintenance of hematopoiesis under stress conditions *in vivo*.
Methods: To determine the role of Sfrp2 in HSC responses under stress conditions, we studied *in vitro* cultures, 5-FU treatment *in vivo*, and HSC engraftment in transplantation experiments.
Results: In in-vitro co-cultures with sh*Sfrp2* stromal cells, the number lineage-negative Kit+ Sca-1+ (LSK) and progenitors increased. The LSK cells showed higher levels of Ki-67 expression, BrdU incorporation, and catenin-dependent Wnt signaling. Yet, total repopulating activity of these cultures was diminished, suggesting exhaustion of HSCs. These *in vitro* results were mirrored in *in vivo* models of stress, such as aging, 5-FU treatment and hematopoietic regeneration in *Sfrp2*-/- recipients. In all three *in vivo* situations of stress, we noted an increase of LSK cells, which in accompanied by increased levels of ®- catenin and cyclin D1. In the transplantation experiments, the increase in LSK cells was accociated with a progressive loss of HSCs in serial transplantation recipients. Similarly, genotoxic stress in 5-FU-treated *Sfrp2*-/- mice showed LSK cells with a higher cycling activity than wild-type (WT) littermates, as shown by higher levels BrdU incorporation, and a higher expression of Ki-67 and canonical Wnt signaling mediators. Importantly, increased cycling of LSKs was accompanied with stress-induced senescence-associated DNA damage response as indicated by ©H2A.X staining and depolarized localization of acetylated H4K16.
Summary/Conclusions: Our experiments are consistent with the view that *Sfrp2* expression in the niche is required to limit stress-induced DNA damage and canonical Wnt-mediated HSC activation, thus preventing HSC exhaustion.

P356

CLEC-2 EXPRESSION IS A NEW MARKER FOR A SUBSET OF HEMATOPOIETIC STEM/PROGENITOR CELLS THAT CONTRIBUTES TO INFLAMMATION-INDUCED EMERGENT MEGAKARYOPOIESIS

T Kumode*, H Tanaka, S Rai, Y Taniguchi, I Matsumura
Hematology and Rheumatology, Kinki University Faculty of Medicine, Osaka, Japan

Background: Recent studies have suggested that megakaryocytes can be generated from multiple pathways, through some processes bypassing multipotent common myeloid progenitor (CMP) and/or bipotent megakaryocyte/erythrocyte progenitor (MEP) stages. Furthermore, a recent research demonstrated the presence of a subset of megakaryocyte-committed cells within hematopoietic stem cell (HSC) compartment that are activated by inflammatory stress. However, the immunophenotype of these megakaryocyte-biased HSCs remains poorly understood. Here, we show that the authentically identified HSC population includes a functionally distinct subset expressing the C-type lectin-like receptor 2, CLEC-2, which contributes to inflammation-induced emergent megakaryopoiesis.
Aims: The present experiments were designed to characterize biological significance of CLEC-2$^+$ cells within the immunophenotypically defined HSC compartment.
Methods: Bone marrow (BM) cells were obtained from femurs and tibias of 6-8 weeks old C57BL/6J mice. To induce inflammation, we injected a single dose of 5 mg/kg pI:C into mice intraperitoneally. HSCs and stem/progenitor cells were isolated by staining unfractionated BM cells. In this experiment, we defined Lin$^-$Sca1$^+$c-Kit^{high} (LSK) CD150$^+$CD34$^-$ cells as HSCs, Lin$^-$Sca1$^-$c-Kit$^+$IL-7Rα$^-$FcRII/III^{low}CD34$^+$ cells as CMP, and Lin$^-$Sca1$^-$c-Kit$^+$IL-7Rα$^-$FcRII/III$^-$CD34$^-$ cells as MEP, respectively.
Results: We first evaluated the expression of CLEC-2 on unfractionated BM cells. CLEC-2 expression was significantly high on CD41(Itga2b)$^+$ megakaryocytes and endothelial cells, but very low on multi- and bipotent committed precursors, such as CMPs and MEPs, that were sequentially placed downstream of HSCs. On the other hand, we found that LSK CD150$^+$CD34$^-$ HSCs fraction contained a substantial number of CLEC-2$^+$ cells. Interestingly, the treatment with pI:C significantly augmented CLEC-2$^+$ fraction from 0.6% to 4.9% in the HSCs compartment, while it reduced CLEC-2$^-$ population. Cell cycle analysis revealed that most CLEC-2$^+$ HSCs are in G0/G1 and only a small population are in S/G2/M phase of the cell cycle before stimulation with pI:C, indicating that this population is also in a quiescent state as well as CLEC-2$^-$ HSCs without stimulation. Although CLEC-2$^+$ HSCs didn't express CD41 protein, an early marker of megakaryocytic maturation, before stimulation with pI:C, its expression was induced by pI:C treatment drastically on CLEC-2$^+$ HSCs, suggesting that inflammatory signals efficiently activated quiescent CLEC-2$^+$ HSCs and imposed commitment to the megakaryocyte lineage on these cells. To assess whether CLEC-2 distinguished functionally different subpopulations of HSCs, we evaluated colony types yielded from CLEC-2$^+$ and CLEC-2$^-$ HSCs after 14-day *in vitro* semiliquid cultures. While CLEC-2$^-$ HSCs produced numerous CFU-Mix, CFU-GM/G/M, BFU-E colonies, CLEC-2$^+$ HSCs were less potent to produce these colonies. On the other hand, CLEC-2$^+$ HSCs had great potential to produce CFU-Meg. Furthermore, qRT-PCR analysis revealed that CLEC-2$^+$ HSCs exhibited a differential lineage profile from CLEC-2$^-$ HSCs, with increased expression of megakaryocyte/platelet genes such as *CD41*, *pf4*, and *vwf*, as well as transcription factors *gata1, Fog-1*, and *klf1*.
Summary/Conclusions: We identified viable megakaryocytes-biased HSCs in the most primitive hematopoietic cell fraction of adult BM with a new marker CLEC-2, which contributes to emergent megakaryopoiesis upon inflammatory stimulation. Our findings provide a new insight into the hematopoietic hierarchy.

P357

IN VITRO AND *IN VIVO* STEM CELL PROPERTIES OF HIGHLY ENRICHED HUMAN BONE MARROW MESENCHYMAL STROMAL CELLS

R Ghazanfari[1,*], H Li[1], D Zacharaki[1], HC Lim[1], S Scheding[1,2]
[1]Stem Cell Center, University of Lund, [2]Hematology Department, University Hospital Lund, Lund, Sweden

Background: Human bone marrow contains a rare population of non-hematopoietic stem/progenitor cells, the so-called mesenchymal stromal cells (BM-MSCs). BM-MSCs are essential constituents of the hematopoietic niche and give rise to skeletal tissues and the hematopoietic stroma. Although BM-MSCs have been suggested to be stem cells, it has thus far not been thoroughly investigated, whether or not BM-MSCs fulfill stringent cell properties, *i.e.* self-renewal and differentiation *in vitro* and, importantly, *in vivo*.
Aims: Based on our recent finding that BM-MSCs were highly enriched in lin$^-$/CD45$^-$/CD271+/CD140a$^-$ BM cells (Li et al, Stem Cell Reports 2014), the current study aimed to study the stem cell properties of this putative stem cell population.
Methods: BM aspirates were obtained from healthy donors. Following lineage depletion, mononuclear cells were antibody-labeled, FACS sorted (single-cell and bulk), analyzed for single cell gene expression (Fluidigm), differentiation potential, and propagated as either CFU-F in standard adherent MSC cultures

or as non-adherent mesenspheres, the latter of which has been reported to better conserve immature MSC features. Adherently-cultured and sphere-derived cells were then compared side-by-side for their self-renewal and differentiation potential *in vitro* and *in vivo* by serial xenotransplantation into NSG mice.
Results: Single cell Fluidigm analysis of lin$^-$/CD45$^-$/CD271+/CD140a$^-$ BM-MSCs showed homogeneous mRNA expression levels of MSC associated genes, such as VCAM1, BMP5, CXCL12, LEPR, and others. Furthermore, similar progenitor cell frequencies and *in vitro* self-renewal capacities were observed under CFU-F and mesensphere assays conditions. CFU-Fs and mesenspheres displayed similar surface marker profiles and comparable *in vitro* tri-lineage differentiation potential towards osteogenesis, adipogenesis and chondrogenesis. *In vivo* self-renewal and differentiation potential of primary BM-MSC were assessed by s.c. transplantation of lin$^-$/CD45$^-$/CD271+/CD140a$^-$-derived CFU-Fs and spheres into NSG mice. Whereas CFU-F numbers decreased after transplantation, mesensphere *in vivo* self-renewal was documented by increasing numbers of spheres recovered after primary and secondary transplantation. Additionally, lin$^-$/CD45$^-$/CD271+/CD140a$^-$ -derived spheres displayed full *in vivo* differentiation capacity in primary and secondary transplantations.
Summary/Conclusions: Our data provide definite evidence that primary human lin$^-$/CD45$^-$/CD271+/CD140a$^-$ cells fulfill stringent stem cell criteria, *i.e. in vitro* and *in vivo* self-renewal and differentiation. However, BM-MSCs stem cell properties were preserved only when cells were propagated as non-adherent cells, but not under standard adherent culture conditions.

P358

GENOME WIDE DYSREGULATION OF GENE EXPRESSION BY TRISOMY 21 IN FETAL LIVER HAEMATOPOIETIC STEM AND PROGENITOR CELLS
A Roy[1,*], B Liu[1], K Goudevenou[2], G Bohn[2], S Filippi[3], N Elliott[1], G Cowan[2], D O'Connor[2], N Bhatnagar[2], S Chou[4], M Weiss[5], P Vyas[6], A Karadimitris[2], I Roberts[1,6]
[1]Department of Paediatrics, University of Oxford, Oxford, [2]Centre for Haematology, Imperial College London, London, [3]Department of Statistics, University of Oxford, Oxford, United Kingdom, [4]Division of Hematology, The Children's Hospital of Philadelphia, Philadelphia, [5]Hematology, St. Jude Children's Research Hospital, Memphis, United States, [6]MHU, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Trisomy 21 (T21) causes multilineage perturbation of fetal and neonatal haematopoiesis. We have previously demonstrated that 2nd trimester Down Syndrome (DS) fetal liver (FL) samples have increased numbers of immunophenotypic haematopoietic stem cells (HSC) and megakaryocyte erythroid progenitors (MEP) together with a severe reduction in committed B progenitors (CBP). Functional studies and Fluidigm gene expression assays support lineage bias favouring megakaryocyte-erythroid over B lymphoid differentiation and proliferation but did not identify causative genes on chromosome 21 (Hsa21) reflecting the limited number of Hsa21 genes which can be included on the panel[1]. Determining the mechanisms underlying these defects is likely to be important for understanding why young children with DS are more prone to myeloid and lymphoid leukaemias.
Aims: To investigate the impact of the additional copy of chromosome 21 (Hsa21) on the transcriptome of primary FL HSC and progenitor cells (HSPC). Specifically, to determine (a) whether there is a T21 'gene expression signature' and whether this is consistent across all HSPC types and samples and (b) whether T21 causes consistent patterns of genome-wide dysregulation of gene expression in HSPC.
Methods: Genome-wide transcriptome profiling was performed by RNA sequencing of 8 flow-sorted FL HSPC populations (immunophenotypic HSC, MPP, LMPP, CMP, MEP, GMP, ELP and CBP as previously described[1]) from 7 gestation-matched 2nd trimester FL samples: DS (n=4) and normal (n=3). Indexed cDNA libraries were multiplexed and sequenced using Illumina HiSeq2500. Raw reads generated were subjected to an in house RNASeq analysis pipeline including adaptor trimming, QA, filtering and alignment of genome and transcriptome using TopHat2. Read-count based expression analysis was performed using DESeq2, and HTSeq-count; and differential expression compared in each HSPC population between the DS and normal FL samples. LOESS (Local polynomial regression fitting) was used for up/down regulated chromosomal domains. Data analysis and visualisation was performed with R.
Results: Using ANOVA, ~2700 genes were differentially expressed (DE) between HSPC populations from all 7 samples (FDR<0.001). Principal Component Analysis (PCA) showed good spatial segregation of HSPC into distinct lineage-specific populations in both normal and DS FL. The best spatial segregation was found using the top 300 DE genes which also showed that while PC1 separated normal and T21 HSPC equally, PC2 accounted for a greater segregation of T21 than normal FL HSPC. Although lineage-specific gene expression patterns were largely maintained in DS HSPC, there were differences in levels of gene expression between DS and normal HSPC with the number of significantly (FDR<0.05) DE genes ranging from 10 in CMP to 1225 in CBP. Perturbation of lineage-associated gene expression was particularly prominent in CBP, HSC, MPP and MEP. More than half of all protein coding Hsa21 genes (154/243) were expressed in both DS and normal FL HSPC. Within each HSPC population, a consistent Hsa21 gene expression profile was seen in all 7 samples and most of the differences in Hsa21 gene expression between DS and normal HSPC were an exaggeration of the 'normal' HSPC profile rather than an aberrant expression of a different set of Hsa21 genes or a single Hsa21 gene. Using Loess smoothing, Hsa21 gene expression was consistently higher in DS HSPC compared to normal HSPC along the entire length of Hsa21 rather than in clearly defined domains. Finally, the majority of DE genes in all HSPC populations were located on chromosomes other than Hsa21.
Summary/Conclusions: These data show that global perturbation of fetal haematopoiesis by T21 is matched by genome-wide dysregulation of gene expression affecting most chromosomes in all HSPC, particularly lymphoid progenitors. Although DS FL HSPC populations all showed a 'T21 gene expression signature', this reflected more pronounced expression of the same Hsa21 genes as in normal HSPC rather than being driven by aberrant expression of a small subset, or single, Hsa21 gene(s).

GPR56: A NOVEL MOLECULE INVOLVED IN HEMATOPOIETIC STEM CELL GENERATION
E De Pater[1,*], P Solaimani Kartalaei[2], C Vink[2], R van der Linden[2], E Dzierzak[3]
[1]Hematology, [2]Cellbiology, Erasmus MC, Rotterdam, Netherlands, [3]The Queen's Medical Research Institute College of Medicine and Veterinary Medicine, Edinburgh, United Kingdom

Background: Knowledge of the key factors that drive hematopoietic stem cell (HSC) generation is of particular importance for current hematopoietic regenerative approaches and reprogramming strategies. At mouse embryonic day (E)10.5, the permanent adult hematopoietic system initiates with the formation of HSCs in clusters lining the major embryonic vasculature (aorta, vitelline and umbilical arteries) in a process called endothelial-to-hematopoietic transition (EHT). From all hemogenic endothelial cells (HECs) only few generate an HSC.
Aims: We aime to find novel regulators of EHT and possibly a new and more faithful HSC marker.
Methods: By CRISPR Cas9 genome editing we have generated a Gpr56 knockout zebrafish model to study its function during embryonic development
Results: A comparative RNA sequencing analysis of HEC *versus* HSCs from mouse tissue by our lab has resulted in the identification of several candidate regulatory genes of EHT. The top candidate, *gpr56,* showed a 4.88 log fold (30x) increase during endothelial to HSC transition and was recently implicated in HSC function in the adult mouse. Upon *gpr56* knockdown, zebrafish embryos showed severe reduction of *cmyb* expressing cells (HSC marker, a reduction in CD41 expressing cells (expressed in HSCs and progenitors) and a reduction in EHT events, showing a requirement for Gpr56 in HSC generation. Rescue with both *gpr56* zebrafish and mouse RNA resulted not only in the restoration of *cmyb* expressing cells, but in an expansion and ectopic expression of *cmyb* expressing cells to the axial vein. This shows that Gpr56 is sufficient for HSC generation and suggests that the function of Gpr56 is conserved between mouse and zebrafish.
Summary/Conclusions: Since Gpr56 is required for HSC generation and functions at the membrane, it is a perfect target for manipulation by bioactive compounds. Therefore, we want to identify the direct binding partners of Gpr56 (both its ligand and downstream signaling partners) and identify bioactive compounds which regulate Gpr56 function and thus manipulate HSC generation for possible therapeutic regenerative purposes.

Gene therapy, cellular immunotherapy and vaccination

DENDRITIC CELL THERAPY FOR MALIGNANT PLEURAL MESOTHELIOMA (MPM): FINAL RESULTS OF A PHASE I/II CLINICAL TRIAL

K Saevels[1,*], S Anguille[1], A Van de Velde[1], A Snoeckx[2], J Van Meerbeeck[3], T Van den Wijngaert[4], E Lion[5], B Stein[5], G Nijs[5], M Huizing[6], V Van Tendeloo[5], P Germonpré[3], E Smits[5], Z Berneman[1]
[1]Haematology, [2]Radiology, [3]Thorax Oncology, [4]Nuclear Medicine, [5]Center for Cell therapy and Regenerative Medicine, [6]Oncology, University Hospital Antwerp, Edegem, Belgium

Background: Cellular therapies, including the use of dendritic cells, are gaining momentum as a therapeutic option in cancer patients, especially in light of recent data showing that such therapies have the potential to improve survival often without causing significant toxicity. Except for a small group of long-term survivors (*i.e.* survival beyond 36m), patients with Malignant Pleural Mesothelioma (MPM) face little prospect of survival by any of the mainstream treatments.
Aims: The aim of this study was to establish the potential utility of dendritic cell therapy for immune modulation in MPM patients.
Methods: Ten MPM patients with non-resectable disease (median age 62 years, stage 1-2, PS 0-1) were included in this open-label phase I/II clinical trial (NCT01291420) after completion of frontline platinum/pemetrexed-based chemotherapy. Autologous DCs were propagated *in vitro* from fresh peripheral blood monocytes obtained by leukapheresis, according to our previously published protocol (Van Tendeloo *et al*. PNAS 2010). Antigen loading of the DCs was performed by electroporation of mRNA encoding the mesothelioma-associated tumor antigen Wilms' tumor-1 (WT1). DCs ($10x10^6$ cells per injection) were administered 4 times on a biweekly basis, after which response evaluation was performed by various immunological assays and imaging studies.
Results: All patients completed the intended treatment schedule of 4 biweekly DC vaccinations; most patients continued to receive DC vaccinations with a mean number 18 vaccines administered per patient (range 5-44). The vaccinations were well tolerated; none of the patients showed overt signs of systemic toxicity. All patients except one demonstrated a significant delayed-type hypersensitivity skin reaction, providing evidence of vaccine-elicited immunity *in vivo*. Progression-free survival, determined by repeated imaging studies, was 5 months. Median overall survival calculated from start of chemotherapy was 36 months. After exclusion of 4 long-term survivors, median overall survival was corrected to 32 months.
Summary/Conclusions: DC therapy in chemotherapy-treated MPM patients is feasible, safe and immunogenic. Overall survival data of this study compare favorably to the 22-month overall survival reported for a similar cohort of patients (Hillerdal *et al.* J Thorac Oncol 2008). This is in line with other recent studies showing that DC therapy can confer overall survival benefit to cancer patients.

EXPLORING CHIMERIC NATURAL KILLER RECEPTOR NKP30 EXPRESSING HUMAN T LYMPHOCYTES FOR ADOPTIVE IMMUNOTHERAPY TO ACUTE LEUKEMIA

P Ploch, S Khan, A Bhatti, L Krebs, M Theobald, UF Hartwig[*]
III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR)-reprogrammed T cells has advanced as a valuable personalized and effective immunotherapy for leukemia and solid tumors. In particular, clinical trials on $CD19^+$ lymphomas using CD19 CAR expressing T lymphocytes have revealed highly promising results. However, suitable antigens for an effective and specific CAR-mediated therapy to acute myeloid leukemia (AML) are still warranted as *e.g.* CD33 and CD123 CAR expressing T cells induce potent immune responses not only to AML blasts but also recognize normal hematopoietic stem cells (HSC). In contrast, B7H6, a member of the B7 family, is frequently expressed on various tumor cells including AML blasts but not constitutively expressed on normal tissues and recognized by the natural killer (NK) cell activating receptor NKp30. Moreover, NKp30 recognizes human leukocyte antigens (HLA)-B-associated transcript 3, a nuclear factor that is secreted and translocated to the cell surface in stressed and transformed cells.
Aims: In the current study, we therefore explored human T cells redirected by retroviral transduction of a NKp30-based CAR for effective antileukemic immunity *in vitro* and adoptive immunotherapy to AML *in vivo* using humanized mice.
Methods: Peripheral blood mononuclear cells (PBMC) or immunomagnetically purified human T cells were polyclonally stimulated and reprogrammed with a CAR based on the external region of the NKp30 receptor fused to the CD3ζ chain signaling domain (kindly provided by Dr. S. Klobuch, Dept. of Internal Medicine 3, Medical University Regensburg, Germany) by retroviral gene transfer. Transduced cells were further selectively expanded utilizing puromycin resistance. NKp30 expression was determined by flow cytometry. IFN-γ ELISPOT analyses and cytotoxicity assays were performed to assess antileukemic responses to acute leukemia lines and primary AML blasts *in vitro* and *in vivo* by adoptive transfer of redirected T cells into leukemia engrafted NSG mice. Expression of B7H6 in target cells was examined by RNA-based RT PCR.
Results: Following transduction and puromycin selection ≥90% of $CD3^+$ T cells expressed the NKp30 CAR. Upon coculture with B7H6 expressing targets such as K562 and HL-60 (myelogenous leukemia cell lines), NALM 16 (pre-B-ALL) and AML MZ987 NKp30-redirected T cells elicited potent IFN –γ release and exhibited cytolytic activity to both leukemia lines and primary AML blasts. These responses were specific as no reactivity to the B7H6 negative myeloma line U266 was observed. Furthermore, Mock transduced T cells used as controls did not reveal significant alloreactive responses. To test for antitumor immunity *in vivo*, we first examined reactivity of NKp30-redirected T cells to K562 cells engrafted into NSG mice and observed clear reduction of tumor burden. Moreover, first studies revealed, that adoptive transfer of 1 - $5x10^6$ HLA-matched, NKp30-redirected $CD3^+$ T cells into NSG mice engrafted with patient derived AML blasts for up to 5% thus resembling minimal residual disease at time of transfer resulted in significant leukemia regression. Further experiments to elaborate the therapeutic efficacy and what extent $CD4^+$ and CD8 T cells contribute to this antileukemic immunity are in progress.
Summary/Conclusions: These studies demonstrate that human T lymphocytes can be successfully redirected to acute leukemia by NK cell activating receptor based CARs such as the NKp30-CAR. As its ligand B7H6 has not been reported to be expressed on $CD34^+$ HSC, this antigen might be an interesting target for adoptive immunotherapy to AML.

P362

TARGETING CD123+ ACUTE MYELOID LEUKEMIA CELLS WITH REDIRECTED NATURAL KILLER CELLS

M Morgan[1,*], J Dahlke[1], O Oberschmidt[2], S Kloess[2], K Vu[1], J Wenzl[1], C Neudoerfl[3], A Kloos[4], M Heuser[4], U Koehl[2], C Falk[3], A Schambach[1]

Background: The utility of immune cell modification via chimeric antigen receptors (CARs) has been demonstrated clinically for T cells (*e.g. versus* $CD19^+$ lymphatic leukemia) and is also currently investigated for natural killer (NK) cells. The observation that CD123 is highly expressed on the surface of many primary human acute myeloid leukemia (AML) cells makes CD123 a clinically interesting target.
Aims: The aim of this work was to engineer NK92 cells to express a CAR that detects and eradicates $CD123^+$ AML cells.
Methods: NK92 cells, an NK cell line, were transduced with state-of-the-art alpharetroviral self-inactivating (SIN) vectors encoding EGFP alone as control or a third generation CAR engineered with an anti- CD123 single chain variable fragment (scFv) (with or without an HA-tag) and containing the CD28 transmembrane domain, the 4-1BB costimulatory domain, the CD3ζ signaling domain and an internal ribosomal entry site (IRES) element for EGFP expression. EGFP, CD123-CAR and HA-CD123-CAR protein expression were quantified by flow cytometry and verified by immunoblotting after separation by SDS-PAGE. The kinetics of cytotoxicity elicited by modified NK92 cells was monitored over 48 hours at effector:target ratios of 5:1 and 10:1 and quantified by flow cytometry.
Results: Transduction efficiencies were 76% for the EGFP control vector at multiplicity of infection (MOI) of 0.3, 25% for the CD123-CAR vector at MOI of 0.3 and 30% for the HA-CD123-CAR vector at MOI of 1. Transduced NK92 cells were enriched to >95% purity by flow cytometric sorting based on EGFP expression and sorted NK92 cell populations were used for the following experiments. Using an anti-HA antibody, the HA-CD123-CAR was detected in >85% of sorted NK92 cells modified with the HA-CD123-CAR but not in the EGFP controls or in cells modified with the CD123-CAR lacking the HA-tag. The CD123-CAR was detected with a goat-anti-human IgG antibody (approximately 60% of sorted cells), but the HA-CD123-CAR was less efficiently recognized with this antibody (approximately 30% of sorted cells). Untransduced NK92 and EGFP-transduced NK92 cells served as negative controls for antibody detection. Flow sight analysis provided evidence that the HA-CD123-CAR was expressed on the surface of NK92 cells. SDS-PAGE and immunoblotting experiments further demonstrated HA-CD123-CAR and EGFP transgene expression in the respective samples. Transduced populations were stably cultivated and expanded for several months. Compared with the EGFP-modified NK92 cells used as a control, CD123-CAR- and HA-CD123-CAR-modified NK92 cells exhibited greatly enhanced cytotoxicity against the $CD123^+$ AML target cell line KG1a upon coincubation at effector:target ratios of 5:1 and 10:1. The AML-specific cytotoxicity of NK92-CD123-CAR cells is currently being confirmed with primary AML cells.
Summary/Conclusions: We demonstrate efficient modification of NK92 cells with a clinically relevant CAR designed to target CD123-expressing cells. Importantly, CD123-CAR modified NK92 cells exhibited greatly improved ability to eliminate $CD123^+$ AML cells. Thus, our results support the continued investigation of NK cell redirection with molecules designed to target AML-specific antigens.

PRECLINICAL EVALUATION OF CHIMERIC ANTIGEN RECEPTOR LYMPHOCYTES MODIFIED BY SLEEPING BEAUTY TRANSPOSON FOR THE TREATMENT OF ACUTE LYMPHOBLASTIC LEUKEMIA

CF F Magnani[1,*], C Cappuzzello[1], C Mezzanotte[1], F Benedicenti[2], A Calabria[2], E Tenderini[2], S Tettamanti[1], LJ Cooper[3], A Aiuti[2], E Montini[2], A Biondi[1], E Biagi[1]
[1]Department of Pediatrics, University of Milano-Bicocca, San Gerardo Hospital/Fondazione MBBM, Tettamanti Research Center, Monza, [2]San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Milan, Italy, [3]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Chimeric antigen receptor (CAR)-modified T-cell adoptive immunotherapy is an emerging therapeutic option proven effective in the treatment of hematological malignancies. However, the success of CAR-engineered T cells strictly depends on the optimization of several critical parameters related to cell manufacturing and gene therapy.
Aims: We sought to develop a novel gene-modification protocol to engineer cytokine-induced killer cells (CIKs) with CD19 CAR using the *Sleeping Beauty* (SB) transposon system.
Methods: With an improved SB transposon platform, we genetically modified CIK cells to express the CAR specific for acute lymphoblastic leukemia (ALL) CD19+ blasts and evaluated their preclinical efficacy and safety.
Results: The non-viral transduction protocol combined to the large scale production process minimally affected the phenotype of the CD19 CAR CIK-cell final product. Stable expression of CD19 CAR (average 60%) was achieved together with an efficient T cell expansion suitable for clinical application. Furthermore, modified cells displayed persistence of cell subsets with memory phenotype, specific and effective anti-tumor activity. Upon comparison with conventional T-SB platforms, our method achieved superior results in terms of expansion, CAR expression and functionality. Adoptive transfer of CD19.CAR lymphocytes led to a significant antitumor response *in vivo*. CD19.CAR CIK cells also controlled leukemia in xenograft models of human ALL, bearing the high-risk features of MLL–ENL and Ph-like (PAX5/AUTS2) gene rearrangements. Frozen/thawed CD19.CAR CIK cells remained active *in vitro* and *in vivo* with efficacy comparable with that of fresh CIK cells. Furthermore, NOD-SCID-γchain-/- (NSG) mice were treated with CD19.CAR CIK cells to evaluate general toxicity, tissue damage, and biodistribution. Notably, we found no evidence of integration enrichment near cancer-related genes and transposase expression in the final cell product.
Summary/Conclusions: Taken all together, our findings describe a novel donor-derived non-viral CAR approach characterized by efficient cell transfection and expansion that may widen the range of applications of T cell-based immunotherapy. We are currently designing a phase I/II study for relapsing and remitting ALL after Hematopoietic Stem Cell Transplantation (HSCT).

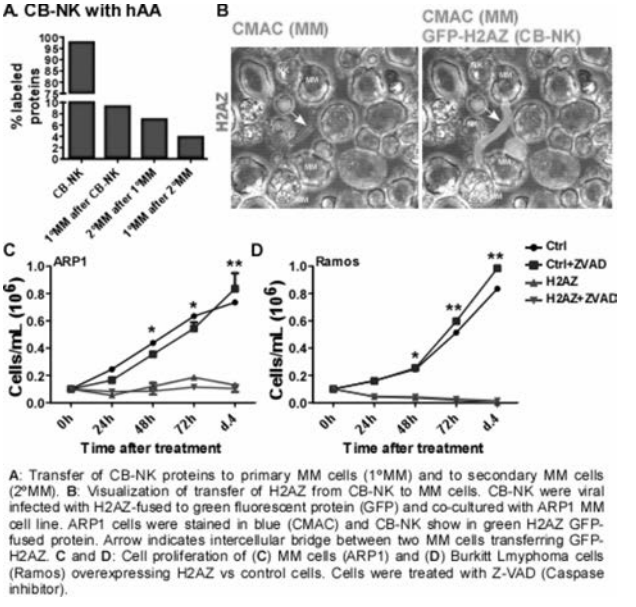
CORD BLOOD DERIVED NK CELLS TRANSFER HISTONE H2AZ TO MULTIPLE MYELOMA CELLS CAUSING DIRECT AND INDIRECT CYTOTOXICITY

B Martín-Antonio[1,*], G Suñe[1], A Najjar[2], L Perez[1], E Lozano[3], C Bueno[4], J Estanyol[5], A Urbano-Ispizua[1]
[1]Hematology, Hospital Clinic/IDIBAPS/Josep Carreras Leukemia Research Institute, Barcelona, Spain, [2]Cancer Systems Imaging, MD Anderson Cancer Center, Houston, United States, [3]Hematology, Hospital Clinic/IDIBAPS, [4]Hematology, Josep Carreras Leukemia Research Institute, [5]Proteomics, University of Barcelona, Barcelona, Spain

Background: Cord blood derived natural killer cells (CB-NK) are a feasible source of NK cells to use in immune cell therapy for hematological malignancies. We previously showed that CB-NK exert a transmissible cytotoxicity towards multiple myeloma (MM) cells, which involves lipid-protein vesicle transfer between initial MM cells exposed to CB-NK (primary MM cells) and the recipient MM cells exposed to primary MM cells (secondary MM cells).
Aims: We aimed to determine which proteins with cytotoxic activity were transferred from CB-NK to primary MM cells, and from primary to secondary MM cells.
Methods: CB-NK and MM cells (ARP1) were labeled with heavy aminoacids (hAA) in independent experiments, then they were co-cultured and FACS sorted before we performed TRANS-SILAC proteomics to identify proteins transferred from CB-NK to MM cells and from MM to CB-NK. Transfer of these proteins was validated by confocal fluorescence microscopy. Functional assays by lentiviral overexpression of these proteins were performed to evaluate cytotoxic effects in CB-NK and MM cells.
Results: We demonstrated CB-NK protein transfer between primary and secondary MM cells, which represents a dilution of the cytotoxic CB-NK material from primary to secondary MM cells (Figure 1A). Interestingly, under the presence of CB-NK, primary MM cells transfer a high amount of their own proteome to CB-NK and to secondary MM cells. A high number of Histone proteins were on the list of transferred proteins. We focused on the functional role of Histone *H2AZ* variant 1 which was transferred from CB-NK to primary and then to secondary MM cells. Time lapse *in vivo* confocal microscopy showed the direct and secondary transfer of H2AZ between MM cells associated to cell death. This transmission occurred either through vesicles or large intercellular structures (Figure 1B). H2AZ overexpression in CB-NK increased CB-NK cytotoxicity against MM cells. Consistently, H2AZ induced overexpression was lethal not only in MM cells but also in Burkitt Lymphoma (Ramos) and acute promyelocytic leukemia (HL60) cell lines. This cell death was caspase independent (Figure 1C-D). H2AZ-mediated cytotoxicity was also transmissible from H2AZ-overexpressing MM cells to neighboring MM cells causing cell death in this secondary MM population.



A: Transfer of CB-NK proteins to primary MM cells (1°MM) and to secondary MM cells (2°MM). **B**: Visualization of transfer of H2AZ from CB-NK to MM cells. CB-NK were viral infected with H2AZ-fused to green fluorescent protein (GFP) and co-cultured with ARP1 MM cell line. ARP1 cells were stained in blue (CMAC) and CB-NK show in green H2AZ GFP-fused protein. Arrow indicates intercellular bridge between two MM cells transferring GFP-H2AZ. **C** and **D**: Cell proliferation of (**C**) MM cells (ARP1) and (**D**) Burkitt Lmyphoma cells (Ramos) overexpressing H2AZ vs control cells. Cells were treated with Z-VAD (Caspase inhibitor).

Figure 1.

Summary/Conclusions: Our findings reveal a novel mechanism of malignant cell cytotoxicity performed by NK cells which is caspase independent and mediated by histones. We demonstrate the relevance of cell-cell communication mediated by intercellular structures as a mechanism leading to MM cell death. Molecules transferred from CB-NK to MM cells can lead to the discovery of novel therapeutic targets such as H2AZ in hematological malignancies.

P365

ALLOGENEIC TCRA/CD38 DOUBLE KNOCKOUT T-CELLS BEARING AN ANTI-CD38 CHIMERIC ANTIGEN RECEPTOR: AN IMPROVED IMMUNOTHERAPY FOR THE TREATMENT OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA AND MULTIPLE MYELOMA

M Dusseaux[*], D Le Clerre, A Gouble, J Smith
Cellectis, Paris, France

Background: Adoptive immunotherapy with autologous T-cells expressing chimeric antigen receptors (CARs) targeting CD19 has achieved long-term remissions in patients with B-cell leukemia, pointing out that CAR technology may become a game changer in cancer treatment.
Aims: In the present study we have assessed the feasibility of CAR-mediated targeting of the CD38 antigen, which is highly expressed on tumors cells from most patients with acute lymphoblastic leukemia (T-ALL) and multiple myeloma (MM). However, expression of CD38 on normal activated T-cells is a significant hurdle for the development of CAR T-cells against this protein, since antigen-expressing T-cells will be targeted, potentially preventing the efficient production of anti-CD38 CAR T-cells.
Methods: To circumvent this issue we have used Transcription Activator-Like Effector Nuclease (TALEN®) gene editing technology to inactivate the CD38 gene (CD38 KO) in T-cells, prior to transduction with a lentiviral vector encoding an anti-CD38 CAR. To validate this approach, we have examined the capacity of CD38 KO cells expressing an anti-CD19 CAR to eliminate CD19+ cells in order to determine if the absence of CD38 has an impact on T-cell activity. Experiments in an orthotopic Burkitt's lymphoma mouse model showed that CD38 disrupted T-cells expressing anti-CD19 CAR were able to mediate an *in vivo* anti-tumor activity similar to unmodified T-cells expressing an anti-CD19 CAR. These results demonstrate that T-cells lacking CD38 are capable of mediating efficient *in vivo* anti-tumor activity.
Results: Gene editing technology can also be used to manufacture T-cells from healthy donors to generate allogeneic "off-the-shelf" engineered CAR+ T-cell-based frozen products. We have previously demonstrated that TALEN® mediated inactivation of the TCRa constant (TRAC) gene can be achieved at high frequencies and eliminates the potential for edited T-cells to mediate Graft

versus Host Disease (GvHD). Furthermore, multiplex genome editing can lead to the production of double KO (TRAC and CD38) T-cells, allowing large scale manufacturing non allo-reactive CD38 specific T-cells. We will present data demonstrating that such gene-edited anti-CD38 CAR T-cells can be efficiently produced and display high cytotoxic activity.
Summary/Conclusions: Thus, large-scale manufacturing of allogeneic, non-alloreactive CD38 specific T-cells from a single healthy donor could offer the possibility of an off-the-shelf treatment that would be immediately available for administration to a large number of T-ALL and MM patients.

OPTIMIZED AAV-MEDIATED HUMAN FACTOR VIII GENE THERAPY IN HEMOPHILIA A MICE AND CYNOMOLGUS MACAQUES

JA Greig[1,*], Q Wang[1], AL Reicherter[1], E Bote[1], D McMenamin[1], C Draper[1], SJ Chen[1], AL Hanlon[2], T Goode[1], KR Clark[3], S Wadsworth[3], L Wang[1], JM Wilson[1]
[1]Gene Therapy Program, Department of Medicine, [2]School of Nursing, University of Pennsylvania, Philadelphia, [3]Dimension Therapeutics, Cambridge, United States

Background: Hemophilia A is an X-linked bleeding disorder driven by a deficiency in human coagulation factor VIII (hFVIII), which occurs at a frequency of 1 in 5,000 live male births. The bleeding manifestations of hemophilia, which directly correlate with circulating FVIII activity, can result in significant disability or even death. Protein replacement therapy is effective in maintaining a mild or moderate phenotype. However, infusion frequency remains burdensome to patients. AAV-based gene therapy has the potential to provide long-term improvement of the disease phenotype following a single administration of vector.
Aims: In an effort to optimize expression of hFVIII for the treatment of hemophilia A, an extensive study was performed combining liver-specific promoter and enhancer elements with a codon-optimized human B-domain-deleted hFVIII transgene.
Methods: Due to the large size of the FVIII coding sequence, it is critical for gene expression control elements to be as short as possible while retaining hepatocyte-restricted transcription. Therefore, several strong liver-specific promoters were shortened and combined, with combinations consisting of up to three liver-specific enhancer sequences, to generate 42 enhancer/promoter combinations. These 42 liver regulatory gene cassettes were then packaged into the AAVrh10 capsid and tested in FVIII KO mice. Following intravenous (IV) administration of 10^{10} genome copies (GC), mice were bled every 2 weeks to follow hFVIII activity and antibody generation to the transgene.
Results: At week 2 post-injection, mice showed a range in hFVIII activity from 0.12-2.12 IU/ml. FVIII KO mice developed antibodies to hFVIII at week 4, and by week 8, mice in most of the 42 vector groups had detectable anti-hFVIII IgG levels. Based on the FVIII KO mouse studies and a small pilot rhesus macaque study, 2 of the original 42 enhancer/promoter combinations were selected for further evaluation in cynomolgus macaques, using 2 different Clade E capsids for expression. Each of the 4 vector combinations were administered IV at a dose of $1.2x10^{13}$ GC/kg into 5 macaques per group. With one capsid plus enhancer/promoter combination, peak expression of 37% of normal FVIII levels was seen at week 2 post-vector administration, which then plateaued at 20% of normal. While antibodies to the hFVIII were detected in the majority of macaques by week 8, antibodies remained undetectable in 2 animals at week 30 post-vector administration.
Summary/Conclusions: The use of an AAVrh10 vector to deliver a codon-optimized, B-domain-deleted hFVIII transgene results in a substantial increase in FVIII expression in both FVIII KO mice and cynomolgus macaques. The majority of animals generated an anti-FVIII antibody response by week 8 post vector delivery. However, 2 of the macaques dosed were free of a detectable antibody response through week 30. Overall, our study supports the continued development of AAV-based gene therapeutics for hemophilia A.

A DOSE-ESCALATING PRECLINICAL STUDY TO DETERMINE THE SAFETY, EFFICACY, AND MINIMUM EFFECTIVE DOSE OF A CLINICAL CANDIDATE VECTOR IN A MOUSE MODEL OF HEMOPHILIA B

L Wang[1,*], J White[1], Z He[1], T Goode[1], D McMenamin[1], C Draper[1], C Brown[1], L Kattenhorn[2], G Wilmes[2], R Clark[2], S Wadsworth[2], JM Wilson[1]
[1]Gene Therapy Program, Department of Medicine, University of Pennsylvania, Philadelphia, [2]Dimension Therapeutics, Cambridge, United States

Background: While safe and effective recombinant FIX therapeutics are currently available, patients with Hemophilia B may gain additional clinical benefit from longer-acting therapeutic options. The use of rAAV-based gene therapy to obtain long-term expression of a human FIX (hFIX) transgene may be ideal in this setting. In recent years, academic institutions have begun to generate promising clinical data in this area. However, there is an ongoing need to replicate and extend these results in a commercial setting in order to allow such new therapies to become broadly available to patients.
Aims: Dose-dependent inflammatory responses that impact transgene expression have been reported in clinical trials with rAAV FIX vectors. This highlights the need for clinical rAAV vectors to have the highest possible potency, allowing the overall vector dose to be reduced. The goal of this study is to investigate the potential of a clinical candidate AAV vector to achieve potent, safe, and effective levels of hFIX expression in a mouse model of Hemophilia B, while also mapping the vector's minimum effective dose (MED).
Methods: We have developed a potent AAV serotype rh10 vector containing codon-optimized human FIX (hFIXco) cDNA under the control of a highly active liver-specific promoter with the goal of achieving approximately 10% of normal FIX levels in patients. In preparation for a clinical trial, we tested this AAVrh10.hFIXco vector for aspects of efficacy and safety in the factor IX knockout (FIX-KO) mouse model of Hemophilia B.
Results: A dose-dependent increase in FIX protein expression and activity was observed following intravenous administration at vector doses between $1.6x10^{10}$ and $5.0x10^{13}$ GC/kg. FIX-KO mice that received AAVrh10.hFIXco at $1.6x10^{10}$ GC/kg achieved between 5% and 8% of normal hFIX expression by 2 weeks after dosing and maintained this level for the 90-day study period. In comparison, with a dose of $5.0x10^{10}$ GC/kg, FIX-KO mice achieved between 30% and 42% of normal hFIX expression by day 14, which was also maintained for the 90-day study period. From these results, we can estimate that the vector dose required to achieve the stated goal of 10% of normal FIX expression levels would be between $1.6x10^{10}$ GC/kg and $5.0x10^{10}$ GC/kg. Levels of hFIX antigen expression correlated well with measured hFIX activity levels, where doses between $1.6x10^{10}$ GC/kg and $5.0x10^{10}$ GC/kg corresponded with 8% to 35% of normal hFIX activity. FIX-KO mice also provide an excellent model to examine the effects of AAVrh10.hFIXco on hemophilia B-related complications, where mice are prone to spontaneous bleeds and often suffer from fatal hemorrhages after handling or trauma. In this study, 4 out of 7 animals in the Day 90 control group succumbed to hemophilia-related complications. In contrast, FIX-KO mice receiving a single dose intravenous administration of AAVrh10.hFIXco at doses of $1.6x10^{10}$, $5.0x10^{10}$, $1.6x10^{11}$, $5.0x10^{11}$, $5.0x10^{12}$, and $5.0x10^{13}$ GC/kg showed no test article-related mortality, clinical pathology, gross pathology, or histopathologic findings.
Summary/Conclusions: Overall, our study demonstrates the safety, efficacy, and MED for a clinical candidate AAVrh10.hFIXco vector in FIX-KO mice. These findings support the progress of a gene therapy based treatment for Hemophilia B in its transition to clinical use.

P368

THE LCR-FREE GAMMA-GLOBIN LENTIVIRAL VECTOR COMBINING TWO HPFH ACTIVATING ELEMENTS CORRECTS MURINE THALASSEMIC PHENOTYPE *IN VIVO*

P Antoniou[*], E Papanikolaou, M Georgomanoli, E Drakopoulou, N Anagnou
Cell and Gene Therapy, U. Athens and Biomedical Research Foundation of the Academy of Athens, Athens, Greece

Background: The β-thalassemias result from reduced or absent expression of the β-chain of adult hemoglobin (HbA;$\alpha_2\beta_2$) causing precipitation of excess α-chains and eventually apoptosis. Thus, factors that reduce the degree of chain imbalance such as an innate ability to increase fetal hemoglobin (HbF;$\alpha_2\gamma_2$), as in the HPFH phenotype, have an ameliorating effect on the disease. Hence, gene therapy of β-thalassemia based on γ-globin addition via viral vectors, displays a considerable advantage.
Aims: In this study, we assessed the efficiency of our previously generated LCR-free γ-globin self-inactivating vector GGHI (Papanikolaou *et al.* Hum Gene Ther 23:15-31, 2012) to correct the thalassemic phenotype *in vivo* in the $Hb^{th3/+}$ C57BL/6J mouse model (thal3 model).
Methods: Recipient mice aged about 12 weeks, were treated with the myelosuppresant factor busulfan, while donor mice, of the same age and of the opposite gender, were treated with 5-fluorouracil, prior to transplantation. Total bone marrow was isolated from 5-fluorouracil–treated donors and was transduced with GGHI in X-VIVO™ medium containing cytokines (mIL-1a, mIL-3, mIL-6 and mSCF) at an MOI=30, employing the spinoculation method. The transduced cells were then transplanted via tail vein intravenous injection to the recipients. To evaluate the therapeutic effect of GGHI, blood was collected from recipient mice prior and post transplantation for 4 months, hemoglobin levels (g/dl), hematocrit and total red blood cell count were assessed by a hematological analyzer. The expression of human γ-globin in peripheral blood was assessed by flow cytometry using an anti-HbF monoclonal antibody.
Results: Our results documented that transplanted thalassemic mice (n=4) with GGHI-corrected hemopoietic stem cells, exhibited an increase in hematocrit values by 22.3% (ranging from 24.5% to 35.7%, p=0.02) with a concomitant increase in hemoglobin levels, reaching an average of 11.1 g/dl in transplanted mice *vs* 8.8 g/dl to those prior to transplantation, which corresponds to a 25.5% increase (p=0.008). Human γ-globin was detected in the peripheral blood of all transplanted animals by flow cytometry and ranged from 20 to 45%. Transduction efficiency in these experiments was estimated to be 35-50% as assessed *in vitro* in CFUs by PCR for vector-specific sequences.
Summary/Conclusions: In summary, these results demonstrate for the first time that viral-mediated globin gene transfer via an LCR-free γ-globin lentiviral vector in hemopoietic stem cells effectively corrects a severe hemoglobin disorder.

P369

BALANCE OF ANTI-CD123 CHIMERIC ANTIGEN RECEPTOR (CAR) BINDING AFFINITY AND DENSITY IN AN *IN VITRO* MODEL OF ACUTE MYELOID LEUKEMIA

S Arcangeli[1,*], M Bardelli[2,3], MC Rotiroti[1], L Simonelli[2,3], CF Magnani[1], A Biondi[1], E Biagi[1], S Tettamanti[1,2], L Varani[3]
[1]Pediatrics Department, M. Tettamanti Research Center, University of Milano Bicocca, Monza, Italy, [2]USI Università della Svizzera italiana, Lugano, [3]Institute for Research in Biomedicine, Bellinzona, Switzerland

Background: Chimeric Antigen Receptors (CARs)-redirected T lymphocytes are a promising novel immunotherapeutic approach, nowadays object of accurate preclinical evaluation also for the targeting of Acute Myeloid Leukemia (AML). In this context, we recently developed a CAR against the CD123, overexpressed on AML blasts and leukemic stem cells (LSCs). However, the potential recognition of low CD123-positive healthy tissues, through the so called "on-target-off-organ" effect, limits the safe clinical employment of CAR-redirected T cells. In order to address this issue, among the CAR design variables under investigation, it has been found that CAR-T cell functional profiles can be modulated by tuning the binding affinity to the target antigen, in an extremely context-dependent manner.
Aims: We aimed therefore to unravel how the interplay existing between CAR affinity, antigen density and CAR expression could impact on anti-CD123 CAR-redirected effector cells efficacy against leukemic cells and safety towards healthy cells.
Methods: We developed a novel integrated model for the functional screening of *in silico*-selected CAR mutants, starting from predicted antibody binding properties, that are then *in vitro* validated based on CAR-redirected T cell related biological requirements. We therefore generated and tested anti-CD123 lower CAR affinity mutants by single residues substitution on the wt CAR. In this way, the affinity mutants produced should provide the same binding site as the original molecule, representing the binding properties variation the only variable in the system.
Results: In particular, exploiting a panel of anti-CD123 CAR affinity mutants, we defined both "lytic" and "activation" antigen thresholds showing that, while the early cytotoxic activity is not affected neither by CAR expression nor by CAR affinity tuning, the CAR expression represents the main variable impairing later effector functions. In view of a future clinical translation of this approach, the lowest affinity mutant suggested a potential threshold of affinity below which, even if the safety profile is preserved, the antileukemic efficacy could be impaired.
Summary/Conclusions: Overall, the full dissection of all these variables offers additional knowledge for the proper design of suitable anti-CD123 CAR-based approaches for the treatment of AML.

PHARMACOKINETICS (PK) AND PHARMACODYNAMICS (PD) OF GBT440, A NOVEL HEMOGLOBIN S (HBS) POLYMERIZATION INHIBITOR FOR THE TREATMENT OF SICKLE CELL DISEASE (SCD), IN HEALTHY VOLUNTEERS AND SCD PATIENTS

M Patel[1,*], A Hutchaleelaha[1], V Siu[1], A Silva-Garcia[1], D Oksenberg[1], J Lehrer-Graiwer[2], T Mant[3], E Ramos[2]
[1]Biology, [2]Clinical, Global Blood Therapeutics, South San Francisco, United States, [3]Quintiles Drug Research Unit at Guy's Hospital, London, United Kingdom

Background: SCD is caused by a point mutation in the β-globin gene producing hemoglobin S (HbS) that polymerizes upon deoxygenation with subsequent formation of sickled red blood cells (RBCs). GBT440 is a novel, orally bioavailable small molecule that inhibits HbS polymerization by increasing the affinity of O_2 to hemoglobin (Hb). Based on this mechanism, a left-shift of the oxygen equilibrium curve (OEC) at p20 or p50 (partial pressure of oxygen that results in 20% or 50% saturation of Hb with oxygen, respectively) can potentially be used as a PD marker of GBT440.
Aims: To determine PK of GBT440 in healthy volunteers (HV) and SCD patients and correlate the GBT440 concentrations in RBCs to p20 and p50 values in these two populations.
Methods: A Phase 1/2, randomized, placebo-controlled, double-blind, single and multiple ascending dose study of the tolerability and PK of GBT440 was conducted in HV and SCD patients (6 treated and 2 placebo subjects in each cohort). Part A of the study consisted of a single ascending dose evaluation in healthy subjects (100 to 2800 mg) and SCD patients (1000 mg). Part B consisted of a multiple ascending dose evaluation for up to 15 days in HV (300 to 900 mg QD) and up to 28 days in SCD patients (700 mg QD). Whole blood and plasma concentrations of GBT440 were analyzed by LCMS. Samples were obtained pre-dose and at various time points post-dose. OECs were measured by a TCS Hemox analyzer and p20 and p50 values were determined.
Results: Both the maximum concentration (C_{max}) and the area under the curve (AUC) increased dose proportionally following single and multiple doses. When a single dose of 1000 mg GBT440 was administered to HV and SCD patients, GBT440 exposure was lower and the half-life ($T_{1/2}$) was significantly shorter in SCD patients relative to HV (Table 1). RBC/plasma ratio were 95:1 and 75:1 for HV and SCD subjects, respectively. The difference in PK is likely due to a lower total Hb in SCD patients to which GBT440 binds, and possibly the more rapid turnover of RBCs. Inter-subject variability at steady state was low in the intended dose range (%CV <15%). A linear relationship between concentrations of GBT440 in RBC ($[GBT440]_{RBC}$) and p20 and p50 for both HV and SCD patients was observed. Due to the biphasic nature of GBT440's OECs, p20 appears to be a more sensitive parameter and has better correlation than p50 within the expected target therapeutic range (<40% Hb modification). p20 correlated well with $[GBT440]_{RBC}$ at ≥0.25 mM (~5% Hb modification; r^2=0.83 and 0.55 for HV and SCD, respectively) and p50 at ≥0.5 mM (~10% Hb modification; r^2=0.48 and 0.40 for HV and SCD, respectively) (Image/Pictures).

Table 1

PK Parameters	HV	SCD
Cmax (µg/mL)	58.2	36.0
AUC0-∞ (µg hr/mL)	6730	2480
T1/2 (hr)	69.1	38.8

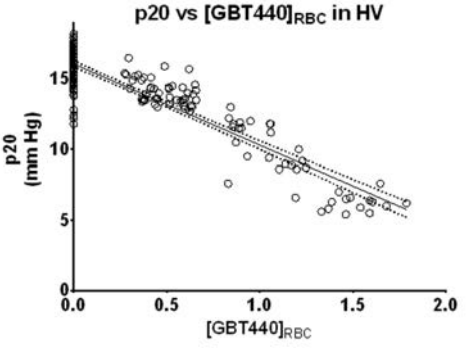

Figure 1.

Summary/Conclusions: GBT440 is an orally bioavailable compound that has potential to be used to treat SCD by once daily administration. The exposure of GBT440 increased proportionally with dose. There was a linear relationship between $[GBT440]_{RBC}$ and the degree of left-shifting of the OEC curve which

demonstrates that GBT440 enhances O_2 affinity of Hb. The high correlation between $[GBT440]_{RBC}$ and the p20 indicates that the change in Hb-O_2 affinity can be used as a PD marker for GBT440.

GBT440, A NOVEL HBS POLYMERIZATION INHIBITOR, INCREASES HB OXYGEN AFFINITY AND RESULTS IN A RAPID IMPROVEMENT IN HEMOLYSIS AND ANEMIA

J Lehrer-Graiwer[1], C Hemmaway[2], J Howard[3], P Telfer[4,*], M Layton[5], M Awogbade[6], J Porter[7], M Roberts-Harewood[8], T Mant[9], K Dufu[1], A Hutchaleelaha[1], D Oksenberg[1], M Patel[1], M Tonda[1], E Ramos[1]
[1]Global Blood Therapeutics, South San Francisco, United States, [2]Haematology, Queens Hospital, Romford, [3]Haematology, Guy's and St. Thomas NHS Trust, [4]Haematology, The Royal London Hospital, [5]Haematology, Imperial College Healthcare NHS Trust, [6]Haematology, King's College Hospital, [7]Haematology, University College London Hospital, [8]Haematology, North Middlesex University Hospital, [9]Quintiles Drug Research Unit at Guy's Hospital, London, United Kingdom

Background: Sickle cell disease (SCD) is caused by polymerization of Hemoglobin S (HbS), resulting in hemolysis and vaso-occlusion. No therapy achieving pancellular, direct inhibition of HbS polymerization is available. GBT440 is a novel small molecule which increases hemoglobin oxygen affinity and inhibits HbS polymerization and prevents sickling *in vitro*.
Aims: This study explored safety, pharmacokinetics (PK) and pharmacodynamics (PD) of GBT440 in healthy volunteers (HV) and subjects with SCD and anti-hemolytic and anti-sickling effects in SCD subjects.
Methods: This randomized, placebo-controlled, double-blind, phase I/II study enrolled HV and HbSS and HbSB^0 SCD subjects. GBT440 was dose orally. The study was conducted in three parts: Part A, single ascending doses, Part B multiple ascending doses for 28 days and Part C 90-day dosing (ongoing). The primary endpoint was safety. Secondary endpoints included PK, PD and hematologic response.

Table 1. Biomarker Results

Day 28, or change from baseline	GBT440 500 mg (n=10)	GBT440 700 mg(n=12)	Placebo (n=8)
Hb Modification, d28 (%, mean)	~13	~17	NA
p50 d28 (mmHg, mean)	30	29	34
Hb (g/dL)	0.5	0.7	-0.1
Unconjugated Bilirubin (%)	-31	-43	2
LDH (%)	-20	-12	-7
Reticulocytes(%)	-31	-37	7
P-Selectin(%)	ND	-19	20
Erythropoietin (mU/mL)	-9	-18	28
Sickle Cells Counts (%)	-56	-46	14

ND=Not yet done, data still to be analyzed, NA=not applicable, LDH=lactate dehydrogenase

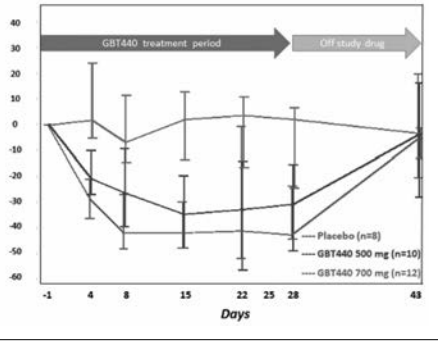

Figure 1. Relative chenge in unconjugated bilirubin from baseline (Median and 25th and 75th percentile).

Results: As of 22 February 2016, 30 SCD subjects had completed Part B (10 at 500 mg; 12 at 700 mg; 8 received placebo [pbo]). The 1000 mg (28 days) and 700 mg (90 days) cohorts in Parts B and C, respectively, were still under evaluation; 60% were male, 40% were female; 20% were on hydroxyurea (HU); 80% had 0-1 painful crisis in the prior year (range 0-7); median age was 32 yrs. GBT440 was well tolerated; there were no drug-related severe or serious adverse events and the most common AEs were headache and pain. PK exposures increased dose-proportionally; mean GBT440 blood half-life after a single dose was 1.6 days in SCD subjects and RBC:Plasma ratio was 75:1. GBT440-treated subjects demonstrated increased hemoglobin oxygen affinity (p50 moved towards the normal range) and a sustained decrease in unconjugated bilirubin, a marker of hemolysis, during the treatment period, with return to baseline by day 43 (Table 1, Figure 1). Other markers of hemolysis, hemoglobin level, sickle cell counts, and erythropoietin levels improved concordantly, as did the inflammatory marker P-Selectin (Table 1, change to day 28). At the EHA conference, additional results, including hemolysis markers and exploratory markers of RBC function, will be presented from Part B 1000 mg and Part C 700 mg cohorts.

Summary/Conclusions: GBT440 was well tolerated with dose-proportional PK and increases in hemoglobin oxygen affinity. GBT440 resulted in a marked and sustained reduction in clinical markers of hemolysis, an increase in hemoglobin, and decreases in erythropoietin, circulating sickle cells, and the inflammatory marker P-Selectin. These results are consistent with inhibition of HbS polymerization leading to decreased RBC damage, improved RBC lifespan, improvement in inflammation and tissue oxygen delivery, and support further investigation of GBT440 as a potential disease-modifying therapy for SCD.

P372

CEREBROVASCULAR RESERVE IN SICKLE CELL DISEASE ASSESSED WITH PERFUSION MAGNETIC RESONANCE IMAGING

L Vaclavu[1,*], HJ Mutsaerts[1], CB Majoie[1], ET van Bavel[2], AJ Nederveen[1], BJ Biemond[3]
[1]Radiology, [2]Biomedical Engineering & Physics, [3]Internal Medicine, Haematology, Academic Medical Center, Amsterdam, Netherlands

Background: Arterial Spin Labelling (ASL) MRI is a non-invasive perfusion MRI technique that circumvents the need for PET-or-SPECT evaluations of cerebral tissue viability, and allows us to assess haemodynamics in relation to stroke risk in Sickle Cell Disease (SCD). SCD is a hereditary form of anaemia leading to red blood cell damage, hampered oxygen transport and neurovascular tissue damage. Local deficits in perfusion lead to silent ischaemic infarcts as a result of impaired cerebrovascular reserve (CVR).
Aims: Our aim was to gain understanding of cerebral haemodynamics in SCD by utilising ASL MRI. We investigated the acute cerebral blood flow (CBF) response to an administration of acetazolamide (ACZ)-a potent vasodilator-in order to probe CVR in patients with SCD who were in a steady-disease state. We hypothesised that patients would have impaired CVR due to pre-existing increased vasodilation and elevated resting CBF[1].
Methods: 23 SCD patients (aged 33±13y) with HbSS/HbSß^0-thalassaemia, and 6 age- and ethnicity-matched healthy controls (aged 30±14y; Wilcoxon rank sum, p=0.38) were recruited from an outpatient clinic and invited to undergo MRI. Blood samples were drawn from an antecubital vein prior to MRI. ASL-MRI was performed prior to and 10 minutes after ACZ on a 3.0Tesla Philips Ingenia system (Philips Healthcare, Best, the Netherlands). To avoid overestimation of CBF, T1 of blood – a parameter used in the quantification of CBF from ASL, and which is influenced by blood haematocrit(Hct) - was measured in the sagittal sinus with a separate MRI sequence. ASL data were processed with in-house developed software and CBF was quantified using a single-compartment flow model[2]. Wilcoxon rank-sum tests were performed to compare groups on CBF at baseline, and CVR. CVR was calculated as $(CBF_{ACZ}–CBF_B)/CBF_B*100\%$, where CBF_B is baseline and CBF_{ACZ} is post-ACZ CBF. Pearson's correlation was performed between baseline CBF, and Hct and CVR. P<0.05 was considered statistically significant.
Results: Whole brain CBF was significantly higher in patients (mean 55±12 mL/100g/min) compared to controls (mean 31±3 mL/100g/min) at baseline (p<0.001) and was significantly correlated with Hct in all subjects (R=-0.83, p<0.001) and patients alone (r=-0.63, p=0.002). Mean CVR in patients (24±13%) was significantly lower than in controls (69±11%; p<0.001). Figure 1 shows the inverse relationship between CBF and CVR.

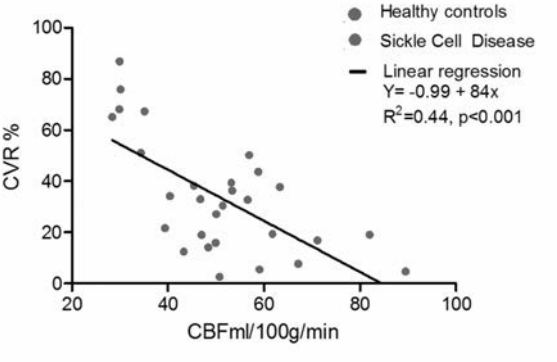

Figure 1.

Summary/Conclusions: The finding that patients had higher CBF at baseline compared to controls complements previous studies in which CBF increases are associated with anaemia in SCD[3]. The finding that Hct was inversely correlated with CBF confirms previous findings in which perfusion increases compensate for anaemia to cater for adequate oxygen delivery. The relatively low CVR in SCD patients is in line with literature suggesting that maximum vasodilation has been reached in SCD. Since this was observed in SCD patients in a steady-state disease course, it is very imaginable that the CVR will become exhausted during times of increased metabolic demand. The results show that CVR could potentially be a cerebrovascular biomarker in SCD for treatment

stratification in the future. In conclusion, ASL-based CBF measurements with ACZ show robust CVR results and indicate that cerebral haemodynamics may be impaired in SCD.

RESTING STATE FUNCTIONAL MRI SHOWS HOW COGNITIVE PERFORMANCES COULD BE PRESERVED IN CHILDREN WITH SICKLE CELL DISEASE

R Colombatti[1,*], M Lucchetta[2], M Montanaro[1], P Rampazzo[2], M Ermani[2], G Talenti[2], A Favaro[2], C Baracchini[2], G Basso[1], R Manara[3], L Sainati[1]
[1]Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, [2]Department of Neurosciences, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, [3]Deparment of Neuroradiology, University of Salerno, Salerno, Italy

Background: Sickle cell disease (SCD) is the most common genetic disorder worldwide. Cerebrovascular complications are frequent events in children with SCD. Overt ischemic stroke occurs in 11% of untreated children and cerebral silent infarcts (CSI) affect 40% of children by the age of 14. In the past years improvements have been made in the management of stroke and CSI and algorithms for screening, prevention and management based on Transcranial Doppler (TCD) and Magnetic Resonance Imaging/Angiography (MRI/MRA) are routinely used. Less progress has been made in the management of cognitive dysfunction, a major morbidity among children with SCD. Impairment of cognitive function is reasonable in children who experienced an overt stroke or present CSIs, due to the anatomical damage of the brain. But the pathophysiology of cognitive impairment in children with normal neuroimaging is less clear. Functional MRI allows the evaluation of resting state brain networks. The Default Mode Network (DMN) is a brain network involving the precuneus and posterior cingulate, the bilateral inferior–lateral–parietal and ventromedial frontal cortex and is invoolved in the cognitive impairment of various diseases
Aims: We aimed at evaluating DMN connectivity by means of resting state functional MRI hypothesizing that neurocognitive scores and parameters linked to cognition in SCD, such as mean steady state hemoglobin and Oxygen saturation (SatO2), could be related to brain connectivity in the DMN.

Table 1

	N° of Patients

Hemoglobin (g/dL)	
≥8	30
<8	10
02 pulse oxymetry	
≥97%	31
<97%	9

Methods: In this cross-sectional study 40 children with SS-Sβ° (mean age 8 years) underwent neurocognitive evaluation and comprehensive brain imaging assessment with TCD, MRI, MRA, Resting State (RS) Functional MRI with evaluation of the DMN. Sixteen healthy age-matched controls underwent MRI, MRA and RS functional MRI. Brain connectivity was compared between patients and controls and analyzed in patients according to TCD, MRI/MRA results, haemoglobin and SatO2 values
Results: Patients characteristics are displayed in Table 1. Children with SCD displayed increased brain connectivity in the DMN compared to controls, even in the absence of alterations in standard imaging techniques. Patients with low neurocognitive scores presented higher brain connectivity compared to children without cognitive impairment or controls, suggesting an initial compensatory mechanism to maintain performances. In our cohort steady state haemoglobin level was not related to increased brain connectivity, but SatO2<97% was (Fig. 1 Functional MRI group analysis. (A) Increased connectivity in the DMN, in the posterior precuneus, in patients *versus* controls; (B) Increased connectivity in the DMN, in the medial prefrontal regions, in patients with normal Verbal IQ compared to controls; (C) Increased connectivity in the DMN, in the right prefrontal region, in patients with normal MRI compared to controls; (D) Increased connectivity in the posterior calcarine region in patients with SatO2≤97% compared to patients with higher SatO2).

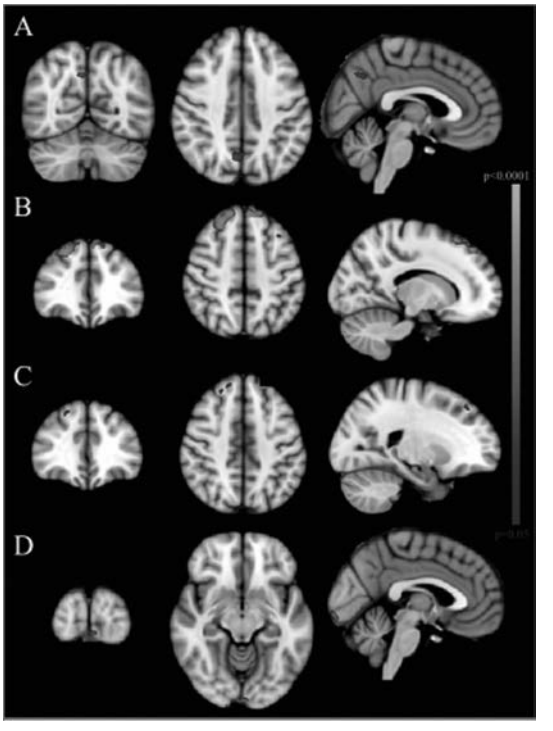

Figure 1.

Summary/Conclusions: Our findings provide novel evidence that SCD is characterized by functional abnormalities in brain connectivity that are independent from the known mechanisms of cerebral vasculopathy and are thus not revealed by routinely used imaging techniques. fMRI might represent a useful complimentary analysis for investigating the disease natural course in studies linking physiopathology, anatomical and functional changes.

istry of Health, Korle Bu Teaching Hospital, Accra, Ghana, [15]Pediatric Hematology Oncology, University of Michigan, Ann Arbor, Ann Arbor, United States

Background: The Consortium for the Advancement of Sickle Cell Research is an international, multi-institutional group evaluating clinical severity of adults and children with SCD through a validated questionnaire and medical chart review. Sites include academic centers in Italy, U.S., and Ghana. Chawla *et al* published on the clinical phenotype of underweight pediatric SCD patients in a U.S. cohort and revealed male gender, older age, lower hemoglobin and SS phenotype were statistically associated with being underweight. Although malnutrition and SCD are both relatively common in parts of Ghana, the impact of comorbid malnutrition on the SCD phenotype has not been published in an international cohort.
Aims: The aim of this study was to determine the relationship between underweight status (<5th percentile body mass index (BMI)) and clinical markers of SCD severity in the CASIRE cohort.
Methods: Subjects were enrolled following informed consent/assent. Categories for underweight, normal, overweight and obese were calculated using the formula: weight (kg)/[height (m)]^2. BMI alone was used to classify adults into weight categories. For children, weight categories were determined using gender- and age-associated BMI percentile charts. Demographic data included age, gender, and country of residence. Clinical data included room air oxygen saturation, hemoglobin phenotype (SS, Sβ0, Sβ+, SC), hemoglobin level, leukocyte count, urine microalbumin, pain crisis frequency, emergency department (ED) utilization frequency, as well as history of leg ulcers, acute chest syndrome (ACS), priapism, stroke, and avascular necrosis (AVN). The relationship between BMI and both demographic and clinical data was analyzed using SPSS statistical software.
Results: There were 676 patients in the study and 56% were under age 18. Patients were equally distributed between developed and developing countries (48% U.S./Italy *vs* 52% Ghana). 16% of the patients were underweight (n=109). Compared to normal, overweight and obese patients, underweight SCD patients were more likely to be male (79% *vs* 52%, *p<0.001*), Ghanaian (83% *vs* 47%, *p<0.001*), report less frequent pain crises/ year (<3/year 82.2% *vs* 64.6%, *p<0.001*), have higher ED utilization for pain (>3/year 34.8% *vs* 21.6%, *p=0.01*), have no prior history of acute chest syndrome (35.5% *vs* 18.7%, *p=0.001*), have a history of leg ulcers (11% *vs* 4.4%, *p=0.005*), higher leukocyte count (12.2 *vs* 10.5 x1000/ul, *p=0.007*), and lower hemoglobin (8.1 *vs* 9.2 g/dL, *p<0.001*). In the U.S./Italy cohort only, underweight BMI was associated with greater microalbuminuria (60.8 *vs* 25.2 mg/gm, *p=0.04*). In the SS and Sβ0 thalassemia group only, underweight patients were more likely to have AVN of hips (25% *vs* 13%, *p=0.02*) or humeral head (13.8% *vs* 4.3% *p=0.03*) compared to non-underweight patients. There was no significant relationship between underweight BMI and age, hemoglobin phenotype, stroke, priapism, or room air oxygen saturation.
Summary/Conclusions: We are the first to describe the clinical severity markers of an underweight SCD patient cohort that includes adults as well as individuals from both developed and developing nations. We have identified that underweight SCD patients demonstrate a distinct clinical phenotype. Although less likely to experience pain crises and develop ACS, they are more likely to have far less clinically apparent complications such as AVN and early signs of kidney damage. The strikingly high prevalence of underweight BMI in the Ghanaian cohort is particularly noteworthy and also warrants further investigation.

P375

IMPROVEMENT IN CARE QUALITY FOLLOWING DEVELOPMENT OF A NEW ADULT SICKLE CELL DISEASE CENTER WITHIN AN ACADEMIC CANCER CENTER

B Andemariam*, S Jones
Hematology/Oncology, University of Connecticut, Farmington, United States

Background: In the United States, a national shortage of specialized centers with expertise in the management of adults with sickle cell disease (SCD) remains a concerning public health disparity. As a result, poor quality of care is delivered to this vulnerable population as the emergency department emerges as the primary mode of care delivery with little emphasis on chronic disease management. Yet, across the country there is an abundance of cancer centers whose operational infrastructure is not only well-suited to the treatment of the cancer patient, but also can provide medical and procedural care essential to the management of SCD. In light of this, a new adult SCD center was formally established within our academic hospital-based cancer center in 2009.
Aims: To describe the development of the new center and measure its impact on patient volume, acute care utilization patterns, and quality of care delivered.
Methods: A single-institution retrospective chart review was conducted of all SCD patient encounters occurring five years pre- and six years post-SCD center establishment (2004-2015). Programmatic, demographic, clinical as well as hospital utilization and care quality data were compared.
Results: Following establishment of the SCD center, the adult SCD population grew from 22 to 193 patients over six years. Total visits increased from 153 to >2500 per annum. The center was staffed by one primary academic hematologist, shared cancer center nursing staff, and a full-time dedicated social worker. Patients received both preventative visits for chronic disease management including hydroxyurea, scheduled blood transfusions where appropriate, as well as treatment for acute painful episodes with intravenous opioids. Additionally, four programs were developed to enhance care: a formal transition program with the affiliated children's hospital, a specialized red blood cell apheresis program, a fast-track emergency department pain management protocol, and a day hospital for individualized management of acute painful episodes. Post-SCD center establishment, patients experienced increased average annual outpatient preventative visits for chronic disease management (1 *vs* 5) and fewer average hospitalizations yearly (2.4 *vs* 0.8). There was a decrease in hospitalization rates for management of acute pain (50% *vs* 15%), average hospitalization length of stay (12 *vs* 4.95 days), and the proportion of hospital discharges resulting in readmission within thirty days (60% *vs* 26.5%). Ninety percent of children were successfully transitioned to adult care. Hydroxyurea use among eligible patients increased from 30% to 90%.
Summary/Conclusions: We conclude that embedding adult SCD centers within existing cancer center infrastructures can improve patterns of health care utilization and positively impact the delivery of quality care.

P376

KLOTHO GENE POLYMORPHISMS AND THEIR ASSOCIATION WITH CLINICAL MANIFESTATIONS IN PATIENTS WITH SICKLE CELL ANEMIA

J Batista[1], D Martins[1], R Medeiros[1], L Laranjeira[1], D Falcao[1], I Domingos[1], B Hatzlhofer[1], M Souza[1], A Cunha[2,*], F Ferreira Costa[3], A Araujo[4], AR Lucena-Araujo[1], MA Bezerra[1]
[1]Universidade Federal de Pernambuco, Recife, [2]Universidade Federal de São Carlos, São Carlos, [3]Universidade Estadual de Campinas, Campinas, [4]Hematology and Hemotherapy Foundation of Pernambuco, Recife, Brazil

Background: Sickle cell anemia (SCA) is the most common genetic disease worldwide. Although patients with SCA present the same genotype, the clinical course may significantly vary among patients. Several evidence suggest that such heterogeneity occurs due to environmental, social, and genetic factors. Therefore, several studies aim to identify molecular markers that might explain the different clinical courses of patients with SCA. An important gene to be evaluated in these patients is *KLOTHO*. This gene encodes for a transmembrane and secreted proteins involved in many important processes in vascular homeostasis, such as suppression of expression of adhesion molecules, nitric oxide production and suppression of oxidative stress. These points are important in the pathophysiology of SCA, justifying the importance of studying *KLOTHO* on these patients.
Aims: The aim of this study was to investigate the clinical impact of two tag single nucleotide polymorphisms (rs211239, G>A and rs685417, G>A) in *KLOTHO* gene of the 703 patients with SCA followed in a single reference center in northeast Brazil.
Methods: Patients with SCA were divided into two groups: cases (incidence of osteonecrosis, priapism, leg ulcers, stroke, heart disease and/or acute chest syndrome) and controls (patients without occurrence of such events). The entire cohort were genotyped by PCR-RFLP.
Results: The recessive genotype (AA) of polymorphism rs211239 was associated with the number of clinical complications of patients: only 2% of patients with wild type genotype (GG) or heterozygous (GA) had three or more complications and 5% with genotype AA showed this phenotype (P=0.036). For the other variables, no association was found. In contrast, for the polymorphism rs685417, the wild genotype (GG) was significantly associated with higher frequency of vaso-oclusion crises (P=0.009) and heart disease (P=0.033). In addition, heterozygous genotype (GA) was significantly associated with the occurrence of leg ulcers (P=0.006), osteonecrosis (P=0.038) and priapism (P=0.02).
Summary/Conclusions: Our results showed that the over dominant model (GA genotype) of rs685417 is associated with priapism, leg ulcers and osteonecrosis, while the dominant model (GG genotype) is associated with heart disease and higher frequency of vaso-oclusion. Futhermore the recessive model (AA genotype) of rs211239 is associated with the number of complications in SCA patients.

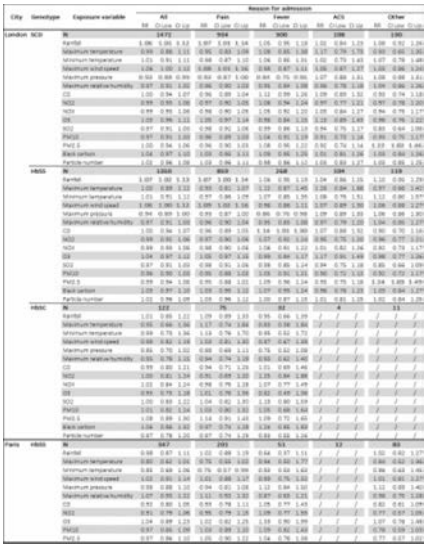
P377

ASSOCIATION BETWEEN ENVIRONMENTAL FACTORS AND HOSPITAL ADMISSIONS FOR SICKLE CELL DISEASE: A RETROSPECTIVE TIME SERIES ANALYSIS

S Tewari[1,*], F Piel[2], V Brousse[3], A Analitis[4], V Ghersi[5], S Menzel[1], S Chakravorty[6], B Inusa[7], P Telfer[8], M De Montalembert[3], G Fuller[1], K Katsouyanni[9], D Rees[1]
[1]King's College London, [2]Imperial College London, London, United Kingdom, [3]Pediatric Department, Hopital Universitaire Necker-Enfants Malades, Paris, France, [4]University of Athens Medical School, Athens, Greece, [5]AIRPARIF, Surveillance de la Qualite de l'Áir en Ile-de-France, Paris, France, [6]King's College Hospital NHS Trust, [7]Evelina Children's Hospital, [8]Royal London Hospital, [9]University of Athens Medical School, King's College London, London, United Kingdom

Background: The clinical severity of sickle-cell disease (SCD) is extremely variable. Genetic and genome wide association studies does not entirely account for phenotypic variability. Investigations of the impact of environmental factors, including climate and air quality, on the severity of the disease conducted across a range of countries have provided inconsistent results. Accurate identification of environmental factors triggering clinical complications in urban settings could lead to better prevention measures, which could result in improved quality of life for patients with SCD and their relatives as well as in reductions in hospital admissions and health care costs.
Aims: To investigate the impact of climate change and air quality on the rate of hospital admissions in urban European cities.
Methods: We extracted anonymised daily hospital admission records over 5 years (2008-2012) for patients with (SCD) less than 18 years living within a radius of ten kilometres from each of the following hospitals: Kings College Hospital (Camberwell), Evelina London Children's Hospital (Lambeth) and Royal London Hospital (Whitechapel) in London, and the Necker Hospital for Sick Children in Paris. Recorded reasons for hospital admissions were pain, fever, acute chest syndrome and other. Information on the genotype of patients, either HbSS or HbSC, was available for the three London hospitals, but not in Paris. Official meteorological data of daily rainfall (mm); air temperature (°C), relative humidity (%), wind speed (knots) and pressure (hPa) were extracted from the British Atmospheric Data Centre for several monitoring stations, including Heathrow– the reference station in London - and St James Park– the nearest station to the three hospitals. Data were purchased from Météo France only for one meteorological station, Paris Montsouris (48°49'18"N, 2°20'12"E).
Official daily air quality data on carbon monoxide (CO, mg/m^3), nitrogen dioxide (NO2, µg/m^3), sulphur dioxide (SO2, µg/m^3), ozone (O3, µg/m^3), particulate matter ≤10 µm in diameter (PM_{10}, µg/m^3) and particulate matter ≤2.5 µm in diameter ($PM_{2.5}$, µg/m^3), black carbon (µg/m^3) and particle number (µg/m^3) were extracted from the London Air Data and AirParif websites. Missing data were an issue: we kept only data from the most complete monitoring stations (records available for ≥80% of days) and filled the gaps using an expectation–maximization imputation algorithm for multivariate normal time series implemented in the *mnimput* function of the *mtsdi* R package. Pollutant's measurement data were normalised using a log transformation. Cross-validation based on a left-out sample of 100 daily records were conducted and the root mean squared error (RMSE) and normalised root mean square error (NRMSE) were calculated. All meteorological and air quality data were normalised for the analyses. Statistical differences between admission rates per year, season, month and day of the week were identified by ANOVAs with Tukey's significant difference (HSD) test.
Results: Over the five-year study period, 1,887 and 346 hospital admissions for SCD were recorded in London and Paris, respectively. In London, increased admissions for acute pain in children with SCA was associated with increased rainfall and wind speed, although no such pattern was seen in Paris, where temperature had a significant effect. No air quality effects were seen in either city, and there were no clear environmental effects on admissions for ACS or in children with HbSC disease.

Table 1.



Summary/Conclusions: Using high-quality data from London and Paris, combined with rigorous time-series analysis methods, our results do not support associations between hospital admissions for SCD and temperature. Environmental factors, which consistently appeared significant throughout our analyses, were rainfall, wind speed and pressure. A better understanding of the environmental factors triggering clinical complications in patients with SCD could provide insight into prevention of acute events in SCD.

Background: Febrile neutropenia, one of the most serious complications that can occur during the treatment of hematological malignancies, is sometimes caused by fungal pathogens. Prospective, randomized studies indicated the utility of liposomal amphotericin B or caspofungin as empirical antifungal therapy. Itraconazole is a broad spectrum triazole antifungal agent, effective against *Candida*, *Aspergillus*, *Trichosporon* and *Mucorales*; however, its oral capsules are poorly absorbed in the intestines, which makes it difficult to achieve a stable serum drug concentration. An intravenous formulation of itraconazole has been developed to allow a sufficient serum concentration to be achieved, which may, therefore, offer a potentially safer and effective alternative.
Aims: The aim of this multicenter, open-label, randomized, non-inferiority trial was to confirm the safety and efficacy of intravenous itraconazole *versus* liposomal amphotericin B as empirical antifungal therapy in patients with hematological malignancies aged 20-79 years, who developed fever refractory to broad-spectrum antimicrobial agents during neutropenia.
Methods: Patients were recruited from 19 institutes in Japan and randomly assigned to either liposomal amphotericin B 3.0 mg/kg once daily group or intravenous itraconazole 200 mg per dose group with five stratification factors (risk, previous antifungal prophylaxis, age, sex and institute). The primary endpoint was defined as success of all components of a five-part composite secondary endpoint (overall favorable response), consisting of successful treatment of baseline infection by the end of treatment, absence of breakthrough infection, no discontinuation of the antifungal treatment due to drug-related toxicity, resolution of fever during neutropenia (axillary temperature <37.5 °C for at least 48 hours), and survival 7 days after termination of the antifungal treatment. The non-inferiority margin for the difference between the experimental and control arms for an overall favorable response was -10%, implying that intravenous itraconazole is non-inferior if the lower limit of the 90% confidence interval of the difference is larger than -10%.
Results: Between April 2011 and February 2015, 103 patients were registered. The study was terminated early due to low patient recruitment. There were no baseline fungal infections in both groups. The mean duration of antifungal therapy was 14.4 days for liposomal amphotericin B (52 patients) and 14.0 days for intravenous itraconazole (50 patients). Overall favorable response rates were 32.7% for liposomal amphotericin B and 36.0% for intravenous itraconazole, with a difference of 4 percent (90% confidence interval, -12% to 20%), which doesn't fulfill the statistical criterion for non-inferiority of intravenous itraconazole. These rates were independent of the antifungal prophylaxis or risk. All patients survived until 7 days after termination of the antifungal treatment. The outcomes were similar between liposomal amphotericin B and intravenous itraconazole with respect to documented breakthrough fungal infections (3.8% *vs* 0.0%, P=0.50), discontinuation of treatment due to drug-related toxicity (19.2% *vs* 10.0%, P=0.26), and resolution of fever during neutropenia (38.5% *vs* 42.0%, P=0.84). Five patients who received liposomal amphotericin B were later diagnosed with probable invasive fungal disease, while none of the patients who received intravenous itraconazole developed fungal infections (P=0.06). Significantly fewer patients in the intravenous itraconazole (14

patients) than the liposomal amphotericin B (29 patients) group had events associated with grade 3-4 hypokalemia (P<0.01). The incidence rates of other adverse events were similar.
Summary/Conclusions: Intravenous itraconazole showed similar efficacy and better safety outcomes compared to liposomal amphotericin B as empirical antifungal therapy in hematological malignancy patients with persistent fever and neutropenia, although its non-inferiority could not be demonstrated due to the small sample size.

P379

PREVALENCE, STRUCTURE, AND PUTATIVE MECHANISM FOR TEMPLATED INSERTIONS IN VDJ RECOMBINATION

MT Koning[1], CA van Bergen[1], IJ Trollmann[1], U Scherer[2], M Griffioen[1], R Toes[2], H Veelken[1,*]
[1]Department of Hematology, [2]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Background: Functional immunoglobulin heavy chain genes are assembled in pre-B cells by genetic VDJ recombination. Random N nucleotides are inserted at the junctions of the participating gene segments by terminal desoxynucleotidyl transferase. Together, combinatorial and junctional diversity create an extremely diverse B-cell repertoire. Recently, insertion of long sequences of a LAIR1 exon template at the V-D junction was described as a novel mechanism to generate broadly neutralizing antibodies to parasital RIFIN antigens on *P. falciparum*-infected erythrocytes (Tan *et al.*, Nature 2016). In these antibodies, the binding specificity of the LAIR1 element was shifted from its natural ligand collagen to RIFINs by extensive somatic hypermutation, indicating passage through a germinal center reaction and antigenic selection.
Aims: To investigate whether templated insertions (TI) occur in healthy donor B-cell repertoires and to elucidate the mechanism behind these insertions.
Methods: We searched for TI in BCR repertoires from 6 healthy donors comprising >32,000 unique VDJ sequences. These repertoires were generated by ARTISAN PCR, an anchored RT-PCR primed on constant immunoglobulin regions and employing a template-switching reverse transcriptase. ARTISAN amplicons were barcoded and analysed as full-length single molecules by PacBio massive parallel sequencing. With its unbiased amplification and an error rate of $0.126x10^{-3}$, ARTISAN PCR in combination with PacBio sequencing accurately displays the entire repertoire of VDJ sequences in complex biological samples (Koning *et al.*, EHA 2015). VDJ sequences (n=719) belonging to the highest percentile with respect to total length, length of the CDR3 region, or combined length of N1 and N2 regions as identified by IMGT V-QUEST were selected. Predicted N regions were submitted to BLAST search with an E cut-off value of 0.00139 to correct for multiple testing.
Results: We searched for TI in BCR repertoires from 6 healthy donors comprising >32,000 unique VDJ sequences. These repertoires were generated by ARTISAN PCR, an anchored RT-PCR primed on constant immunoglobulin regions and employing a template-switching reverse transcriptase. ARTISAN amplicons were barcoded and analysed as full-length single molecules by PacBio massive parallel sequencing. With its unbiased amplification and an error rate of $0.126x10^{-3}$, ARTISAN PCR in combination with PacBio sequencing accurately displays the entire repertoire of VDJ sequences in complex biological samples (Koning *et al.*, EHA 2015). VDJ sequences (n=719) belonging to the highest percentile with respect to total length, length of the CDR3 region, or combined length of N1 and N2 regions as identified by IMGT V-QUEST were selected. Predicted N regions were submitted to BLAST search with an E cut-off value of 0.00139 to correct for multiple testing.
Summary/Conclusions: TI is a novel mechanism of antibody diversification for which we propose the term "T region". Unlike suggested by Tan *et al.*, T regions appear not to originate through repair of double-stranded DNA breaks introduced by activation-induced deaminase in germinal center reactions. Their presence in unmutated VDJ sequences that are presumably derived from naïve B-cells, their exclusive positioning in V-D, D-J, or V-J junctions, and the universal presence of cryptic RSS sites rather point to primary VDJ recombination as the generating event. The combined evidence also suggests that certain loci (*e.g.* the LAIR1 exon) and certain individuals are more prone to generate antibody T regions. We speculate that juxtaposition of IGHV and T region templates is mediated by RAG1/RAG2 via RSS binding during VDJ recombination, followed by introduction of a double-strand break on the IGHV allele only and aberrant repair by using the template in *trans*. As shown by Tan *et al.*, VTDJ sequences may be selected by antigenic stimulation if undergoing somatic hypermutation, and may participate in protective immune responses.

FLUOROQUINOLONE PROPHYLAXIS SIGNIFICANTLY AFFECTS BACTERIAL EPIDEMIOLOLOGY AND ANTIBIOTIC RESISTANCE BUT DOES NOT IMPACT ON INCIDENCE AND MORTALITY OF BLOODSTREAM INFECTIONS IN ACUTE LEUKAEMIA

C Cattaneo[1,*], P Zappasodi[2], S Ferrari[3], F Pavesi[4], N Fracchiolla[5], A Ferrario[6], E Todisco[7], A Passi[1], M Da Vià[2], C Pagani[1], V Mancini[3], M Petullà[1], C Basilico[6], E Borlenghi[1], C Annaloro[5], A Nosari[3], G Rossi[1]
[1]Spedali Civili, Brescia, [2]Policlinico S. Matteo, Pavia, [3]Niguarda Ca' Granda Hospital, [4]Ospedale S. Raffaele, [5]Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, [6]Azienda Ospedaliera Universitaria, Ospedale di Circolo e Fondazione Macchi, Varese, [7]Humanitas Cancer Center, Milan, Italy

Background: The efficacy of fluoroquinolones (FQ) prophylaxis in neutropenic patients, including those with acute leukaemia (AL), has been demonstrated more than ten years ago (Bucaneve 2005). With the recent emergence of multiresistant Gram-negative (G-neg) bacteria its usefulness has been challenged. Indeed, FQ have been associated to an increased incidence of Extended Spectrum Beta-lactamases producing (ESBL+) enterobacteria and carbapenem-resistant (CR) G-neg.
Aims: In order to better understand the impact of FQ prophylaxis on recent bacterial epidemiology, we analyzed all BSI occurring during chemotherapy-induced neutropenia in AL patients treated in 7 centres participating to the regional network Rete Ematologica Lombarda (REL).
Methods: From Dec-12 to Dec-14, all febrile/infectious episodes were prospectively recorded. Data concerning incidence, bacterial epidemiology and resistance, and outcome of BSI occurring during neutropenic phases of chemotherapy cycles were analysed according to the administration or not of FQ prophylaxis (FQ cycles and nFQ cycles, respectively). The number of treatment cycles delivered to AL patients during the period of observation was also requested to each participating centre.
Results: During the period of observation, 472 AL (376 myeloid and 96 lymphoblastic) patients underwent 1356 chemotherapy cycles. FQ prophylaxis was administered in 946 (69.8%) of all cycles. Overall incidence of BSI did not differ with or without FQ prophylaxis, as BSI occurred in 258/946 (27.3%) and in 121/410 (29.5%), respectively (p=0.43). Gram-positive (G-pos) BSI were significantly more frequent with prophylaxis (FQ: 53.1% *vs* nFQ: 38.3%, p=0.0075), whereas G-neg BSI were less frequent, although not significantly (FQ: 37.2% *vs* nFQ: 44.6%, p=0.169), as well as polymicrobic (PMB) BSI (FQ: 9.3% *vs* nFQ: 15%, p=0.1). Fungaemia was rare in both groups (FQ: 1/258, 0.4%; nFQ: 3/121, 2.5%, p=0.06). Among G-pos strains, coagulase-negative staphylococci (CoNS) showed a trend to a higher frequency with FQ (FQ:33.7% *vs* nFQ:24.8%, p=0.07). Considering G-neg, FQ significantly reduced the frequency of Enterobacteria other than *E. coli* (Enterob n/coli) BSI (FQ:5% *vs* nFQ:16.5%; p=0.0002), as well as of *P. aeruginosa* (FQ: 5% *vs* nFQ: 15.7%; p=0.0005). Considering resistant strains among G-neg, FQ significantly increased the proportion of ESBL+ Enterobacteria (FQ: 29.2% *vs* nFQ: 14,8%; p=0.048) whereas the frequency of CR G-neg BSI remained similar in the two groups (FQ:8.3% *vs* nFQ:11.1%; p=0.57). Overall 30-day mortality was 23/379 (5.8%); it was 13/258 (5%) in FQ BSI and 10/121 (8.3%) in nFQ (p=0.22). However, Enterob n/coli and/or *P. aeruginosa* BSI were fatal in 5/10 cases in nFQ group (50%) (15,4%) as compared to 2/13 in the FQ (p=0.07). The 30-day fatality rate of ESBL+/CR G-neg BSI were similar in the two groups (FQ 5/13, 38.5% *vs* nFQ 4/10, 40%).
Summary/Conclusions: Our study shows that FQ prophylaxis did not influence the overall incidence of BSI but it markedly affected bacterial epidemiology. G-pos BSI, particularly CoNS, were significantly increased whereas G-neg BSI by Enterob n/coli and *P. aeruginosa* were significantly decreased, although ESBL+ strains became relatively more common. Overall 30-day mortality was similar in both groups. However, a worrisome 50% mortality due to Enterob n/coli and/or *P. aeruginosa* BSI among nFQ patients suggests extreme caution and the need for close epidemiologic surveillance and controlled studies when considering FQ prophylaxis discontinuation.

VIRAL ENCEPHALITIS AFTER HAPLO-IDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION: CAUSATIVE VIRAL SPECTRUM, CHARACTERISTICS AND RISK FACTORS

XH Zhang[*], JM Zhang, H Chen, YH Chen, W Han, FR Wang, JZ Wang, YY Zhang, XD Mo, Y Chen, Y Wang, YJ Chang, LP Xu, KY Liu, XJ Huang
Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Hematopoietic stem cell transplantation (HSCT) is increasingly used to treat hematologic, oncologic, autoimmune, immunodeficiency, and genetic diseases. Up to 70% of patients develop neurological complications after an allogeneic HSCT, of which approximately 25% of patients suffer from more severe neurological complications involving the central nervous system (CNS) and frequent infections, which are associated with high morbidity and mortality. With an allo-HSCT, a recipient's immunocompromised state and the potential for donor-transmitted infections can result in a unique epidemiology of encephalitis, including infection by certain uncommon causative viruses, whichfeatures an increased risk of high morbidity and mortality due to encephalitis regardless of the specific cause compared with immunocompetent individuals. Currently, most reports focus on HHV-6 and limited data are available on the characteristics and independent risk factorsfor viral encephalitis (VE) in patients after a haplo-identical HSCT.
Aims: To retrospectively identify characteristics and risk factors of VE in patients who underwent a haplo-identical HSCT.

Methods: A nested case-control study was designed. Cases with VE and controls matched for years of HSCT and length of follow-up were identified from a cohort composed of 1274 patients who underwent a haplo-identical HSCT from 2012 to 2015.
Results: VE was identified in 30 patients (2.4%, 95% confidence interval 1.6%>3.2%).The median time from HSCT to diagnosis was 144.5 days (range 24–1077 days), but the onset times were lowest in patients with human herpesvirus-6 encephalitis and greatest in patients in which more than one virus was detected.The viruses detected included RSV-B (43.3%), BKV (23.3%), more than one virus (10%), CMV (6.7%), RSV-A (6.7%), HSV (3.3%), HHV-6 (3.3%) and CVB3 (3.3%). Seizures and alterations of consciousness were the most frequently presented symptoms, followed by symptoms, including fever (13 patients, 43.3%), tremor (8 patients, 26.7%), delirium (5 patients, 16.7%), dysesthesia (4 patients, 13.3%), headache (4 patients, 13.3%), paralysis (4 patients, 13.3%), vomiting (2 patients, 6.7%), apathy (1 patient, 3.3%), and irritability (1 patient, 3.3%).Neuroimaging detected abnormalities in 19 (76%) patients,9 of whom showed focal white matter hyperintensity in T2-weighted images and FLAIR, which is consistent with CNS demyelinating diseases. These demyelination abnormalities were detected in encephalitis caused by RSV-B or BKV, with especially high incidence in RSV-B encephalitis (63.6%). The CSF cell count, protein and glucose concentration were elevated in 8 (26.7%), 18(60%), and 9 (30%) patients, respectively. Multivariate analyses revealed that acute GVHD (grad III-IV), CMV viremia and engraftment syndrome were significantly and independently associated with VE. The probability of a sustained response to treatment was 76.7%, but the treatment efficacy and prognoses varied considerably based on the different causative viruses. The cumulative mortality for patients suffering with viral encephalitis was significantly higher than in the controls (p=0.003). Of the 22 patients who survived, 3 (14.3%) continued to exhibit prosopoplegia, spastic paralysis and anterograde amnesia at the last follow-up.
Summary/Conclusions: Acute GVHD (grad III-IV), CMV viremia and engraftment syndrome were associated with an increased risk of viral encephalitis after a haplo-identical HSCT. Characteristics, such as onset time, response to treatment and outcome, varied based onthe different causative viruses.

COMPREHENSIVE MONITORING OF GUT MICROBIOTA DURING THERAPY FOR ACUTE LEUKEMIA

M Aichholzer*, M Rau, H Einsele, A Geier, L Rasche
Department of Internal Medicine II, University Hospital Würzburg, Würzburg, Germany

Background: Colonization and infection by multi-resistant bacteria increasingly challenges the treatment of critical ill patients as well as the infrastructure of care giving facilities. Especially patients with leukemia, where intensive antibiotic therapy is necessary to manage infectious complications during disease and treatment associated cytopenias, are at high risk for acquiring resistant pathogens.
Aims: In this study we longitudinal analyzed stool microbiota of patients with acute leukemia beginning from admission to hospital to obtain insights in the development of dysbiosis and correlated findings with clinical parameters.
Methods: We used a comprehensive strategy including 16s sequencing, quantitative (q) PCR, and cultivation techniques. A total number of 108 stool samples were collected from 3 cohorts: (1) patients undergoing treatment for acute leukemia (n=56), (2) outclinic patients with known multi-resistant bacteria colonization in anal swab (n=26) and (3) healthy controls (HC) (n=26).
Results: All leukemia patients experienced infectious complications requiring antibiotic treatment with at least three different antibiotic regimens. Four out of 14 patients established multiresistent gram-negative bacteria (MRGN) and/or vancomycin-resistent enterococcacae (VRE) in cultures from anal swab during their course of disease. Considering quantitative assessment leukemia patients displayed a significant decreased bacterial load when compared to HC or outclinic patients (5 *vs* 75 *vs* 43ng bacterial DNA /mg stool; p<.001) indicating a decreased colonization resistance as risk factor of acquiring multi-resistant bacteria. Dysbiosis in acute leukemia was characterized by a shift towards enterococcacae including cases with >90% colonization. In contrast outclinic patients and HC showed no relevant enteroccocacae fraction. Furthermore, gram-negative bacteria increased during treatment of leukemia as it was also observed in outclinic patients. Both, enterococcacae and gram-negative pathogens were responsible for infectious complications with proof of the respective bacteria in primary sterile liquids such as blood cultures. In 6/10 positive blood cultures the causative organism was found in gut microbiota before. Interestingly, morbidity of enteroccocacae was only seen in patients with >50% intestinal colonization whereas gram-negative infections also occurred in patients with significant reduced proportion thereof. In some samples collected late during leukemia treatment staphylococcus aureus as well as other staphylococcacae were found. On the other hand protective bacteria such as blautia or prevotella disappeared. In general, a dramatic loss of diversity could be observed. Outclinic patients with known multi-resistant bacteria particularly showed a gram-negative fraction of intestinal bacteria as expression of a sustained dysbiosis.
Summary/Conclusions: During treatment of leukemia a clinically relevant dysbiosis was observed responsible for infectious complications.

INVASIVE FUNGAL INFECTIONS IN LYMPHOPROLIFERATIVE DISORDERS: REVISION OF INCIDENCE IN THE "MODERN TREATMENT" ERA

MC Tisi[1,*], S Hohaus[1], A Cuccaro[1], I Innocenti[1], E De Carolis[2], T Za[1], G Dragonetti[1], L Laurenti[1], L Fianchi[1], S Sica[1], M Sanguinetti[2], V De Stefano[1], L Pagano[1]
[1]Institute of Hematology, [2]Institute of Microbiology, Catholic University Rome, Rome, Italy

Background: Invasive fungal infections (IFIs) are serious, life-threatening complications of hematological malignancies. While epidemiological data on patients (pts) with acute myeloid leukemia have been updated during the past few years, little information is available on IFIs in lymphoproliferative malignancies.
Aims: Aim of the study was to identify the incidence and variety of IFIs, risk factors, prognosis and outcome of IFIs in lymphoproliferative disorders.
Methods: We performed a monocentric retrospective analysis on 1191 adult pts affected by lymphoproliferative disorders [Chronic lymphocytic leukemia (CLL), n=305; Hodgkin lymphoma (HL), n=188; diffuse large B cell lymphoma (DLBCL), n=350; follicular non Hodgkin lymphoma (FL), n=100; and multiple myeloma (MM), n=248] diagnosed and treated in our hospital from 2006 to 2014. We included only probable or proven IFI (*De Pauw, CID 2008*). Data were collected from routine clinical practice in order to provide information regarding fungal infections and in particular epidemiology, diagnosis, treatment and outcome. Clinical data were matched with microbiological (fungal culture or serology) and radiological data.
Results: Thirty-eight patients (3.2%) developed a proven/probable IFI. Invasive Aspergillosis (IA) was the most frequent fungal infection (31 cases, 2.6%), while the other 7 infections were caused by yeasts (0.6%) (Table 1). Fever was present in 84% of patients with IFI and upper respiratory tract symptoms in 47% of patients. Lung was the most frequent organ involved (76%). We recorded five proven infections affecting the gastrointestinal system, blood and urinary tract. IFI was the cause of death in only one patient (2.6%), while 7 patients died from the hematological disease with a concomitant IFI. The prevalence of IFI was highest in pts with MM (5.6%), followed by HL (3.7%) and DLBCL (3.1%). Patients with FL and CLL patients were at lower risk for IFI (2% and 1.3%, respectively) (Table 1) The majority of IFI (25/38, 66%) occurred during first-line treatment, while 13 (34%) IFI occurred in patients treated with salvage regimens for progressive or relapsed disease. Treatment-related factors that were frequently present in patients with IFI were: HSCT within 100 days (47% of pts), corticosteroid treatment (50% of pts) and neutropenia (47% of pts). Restricting the analysis to patients with DLBCL, we observed that the majority of patients (7/11) who developed IFI had a high-risk international prognostic index (IPI) and developed IFI during consolidation phase including HSCT that was our standard approach in these years for patients with young patients with high-risk DLBCL. In a logistic regression analysis, this group of patients had a 6.1-fold risk (OR; 95% CI 1.2-30, *p=0.02*) for IFI with respect to young standard risk DLBCL (<65 years, treated with R-CHOP). In the same line, the group of younger MM pts (<65 years) undergoing HSCT as part of their first-line treatment were at higher risk for IFI than older patients (>65 years) treated without HSCT (OR 15.4; 95% CI 1.9-127.4, *p<0.01*). In contrast, IFI were rare during first-line treatment in patients with FL and CLL who developed IFI more often during salvage treatment for relapsed/progressive disease.

Table 1. Incidence of fungal infections in lymphoproliferative disorders.

UNDERLYING DISEASE	Patients (n)	Incidence IFI (n)	Molds (all IA) (n) Probable/Proven	Yeasts (n) Probable/Proven
CLL	305	4 (1.3%)	1(0.3%) 1/0	3 (1%) 1/2*
HL	188	7 (3.7%)	6 (3.2%) 6/0	1 (0.5%) 0/1*
NHL aggressive	350	11 (3.1%)	8 (2.3%) 8/0	3 (0.8%) 1/2*
NHL Indolent	100	2 (2%)	2 (2%) 2/0	0 (0%) 0/0
MM	248	14 (5.6%)	14 (5.6%) 14/0	0 (0%) 0/0
Overall incidence	1191	38 (3.2%)	31 (2.6%)	7 (0.6%)

* Proven IFI:
Rhodotorula mucilaginosa sepsis (CLL-relapse)
Candida Tropicalis cystitis (CLL-onset)
Candida Norvegensis peritonitis (HL-onset)
Candida Parapsilosis sepsis (NHL-ASCT)
Candida Albicans colitis (NHL-ASCT)

Summary/Conclusions: Treatment strategies in lymphoproliferative disorders that include HSCT in addition to combined treatments of cytotoxic and immunomodulating and immunosuppressive agents can increase the risk of mycoses and require continuous monitoring and revision of the specific risk factors for fungal infections.

P384

INFECTIOUS AND THROMBOTIC COMPLICATIONS IN PERIPHERALLY INSERTED (PICCS) COMPARED TO SHORT TERM CENTRAL VENOUS CATHETERS IN ONCOHEMATOLOGIC PATIENTS: A REL GROUP (RETE EMATOLOGICA LOMBARDA) STUDY

NS Fracchiolla[1,*], E Todisco[2], A Bilancia[2], S Gandolfi[2], V Mancini[3], L Marbello[3], M Bernardi[4], A Assanelli[5], N Orofino[1], F Guidotti[1], R Cairoli[6], F Ciceri[4], A Santoro[2], G Rossi[7], A Cortelezzi[8]
[1]Oncohematology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, [2]Hematology Unit, Humanitas Cancer Center, Rozzano, [3]Hematology and Oncology, A.O. Ospedale Niguarda Cà Granda, [4]Hematology and Bone Marrow Transplantation Unit, San Raffaele Hospital Scientific Institute, [5]Hematology and Bone Marrow Transplantation Unit, San Raffaele Hospital Scientific Institute, [6]Department of Hematology and Oncology, A.O. Ospedale Niguarda Cà Granda, Milan, [7]Department of Hematology, Spedali Civili, Brescia, [8]Oncohematology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Milan, Italy

Background: PICCs are vascular devices inserted in a peripheral vein providing a central venous access with an intermediate duration between jugular or subclavian short term central venous catheters (STCVCs), and long term ones (port-a-caths). Few clinical data from large oncohematologic patients (pts) series are available on infectious and thrombotic complications occurring in PICCs *versus* STCVCs.
Aims: To analyze the results of a large multicenter, retrospective study of the REL group (Rete Ematologica Lombarda-Lombardy Hematologic Network, Italy) aimed at comparing infectious and thrombotic complications in PICCs *vs* STCVCs in oncohematologic pts management.
Methods: Four REL Hematology Centres participated to the study. The clinical data of implanted PICCs and STCVCs from January 2010 to June 2015, were retrospectively collected.
Results: 464 PICCs and 441 STCVCs were compared. Total *in situ* days were 48293 for PICCs and 9471 for STCVCs. Median age PICC *vs* STCVCs: 61 (range 10-88) *vs* 53 years (range 18-99). Underlying diseases in PICCs *vs* CVCs: 199/133 non-Hodgkin's lymphoma, 10 chronic lymphocytic leukemia (PICCs), 110/203 acute myeloid leukemia, 46/54 acute lymphoblastic leukemia, 36/5 Hodgkin's lymphoma, 40/22 multiple myeloma, 11/10 myelodysplastic/ myeloproliferative syndrome, 10 miscellaneous/14 severe aplastic anemias. The median PICC *vs* STCVC life-span was 76/19 days (range 1-800; 1-78; p<.0001). Complications (PICC *vs* STCVC) occurred in 185 *vs* 316 cases (40%, 3.8/1000 cath days *vs* 71.6%, 33.3/1000 cath days); in detail: 97 *vs* 284 infectious (21%, 2/1000 cath days; 64.4%, 30/1000 cath days), 38 *vs* 6 thrombotic (8%, 0.8/1000 cath days; 1.36%, 0.63/1000 cath days), 44 *vs* 24 mechanical (9.5%, 1/1000 cath days; 5.4%, 2.5/1000 cath days) and 6 *vs* 2 miscellaneous (1.2%, 0.1/1000 cath days; 0.5%, 0.2/1000 cath days). Among infectious complications in PICC *vs* STCVC, we reported 18 *vs* 122 cases (3.8%, 0.37/1000 cath days *vs* 27.6%, 13/1000 cath days) of fever of unknown origin (FUO) and 79 *vs* 125 cases (17%, 1.6/1000 cath days *vs* 28%, 13.2/1000 cath days) of BSI. Globally 400/463 (86%) PICCs were removed. Catheter related complications was the cause of PICC removal in 132/464 (28.4%) *vs* 154/441 (35%) STCVC cases. In 55/97 (56.7%) PICCs and in 124/284 (50%) STCVCs (86 infectious and 38 local inflammation), the infectious episode led to catheter removal. Thromboses caused removal in 28/38 (73%) PICCs and 6/6 (100%) STCVCs. Comparing PICCs and STCVCs outcomes, PICCs presented a longer duration (p<.0001), lower total complications rate (p<.0001), lower removal rate for complication (p=.0363), fewer infectious complications (p<.0001), more thromboses (p<.0001).
Summary/Conclusions: Our data suggest that PICCs, as an alternative to STCVCs, are safe and effective in patients at high risk of hemorrhagic and infective complications. In particular PICCs, compared to STCVCs, presented a lower rate of infections (21%, 2/1000 cath days *vs* 64.4%, 30/1000 cath days), and a higher rate of thrombotic complications (8%, 0.8/1000 catheter days *vs* 1.36%, 0.63/1000 catheter days). In particular, in terms of cath days, STCVCs increase in infection complications largely overcome PICCs increase in thrombosis (30 *vs* 2/1000 cath days for infections compared to 0.63 *vs* 0.8/1000 cath days for thrombosis). Therefore we conclude that PICCs compare favorably with STCVCs in terms of complications (in particular infections), and facilitate the proper management of complex and prolonged therapeutic programs in oncohematologic patients.

P385

USEFULNESS OF SERUM 1,3-B-D-GLUCAN FOR DIAGNOSIS OF INVASIVE FUNGAL DISEASE IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A RETROSPECTIVE ANALYSIS

B Weinbergerova[1], I Kocmanova[2], M Rolencova[1], J Mayer[1], Z Racil[1,*]
[1]Dept. of Internal Medicine - Hematology and Oncology, [2]Dept. of Clinical Microbiology, Masaryk University and University Hospital Brno, Brno, Czech Republic

Background: Serologic detection of circulating 1,3-b-D-glucan (BG) fungal biomarker shows promise for improving the diagnosis of invasive fungal diseases (IFDs). Numerous studies have evaluated the diagnostic performance of BG and proved its suboptimal sensitivity when used alone for early diagnosis of IFDs. Moreover, the major limitation of this test mainly in hematological patients (pts.) is the high frequency of false positive results.
Aims: We have evaluated the usefulness of the serum BG assay in real practice for the diagnosis of IFDs in pts. with hematological malignancies.
Methods: We retrospectively analyzed serum BG samples collected from patients with hematological malignancies in high risk of IFDs treated at our department between 2010 and 2014. The Fungitell assay was used for detection of BG. We performed retrospective cross check of probable and proven IFDs recorded in the Fungal INfection Database - FIND. BG results were not used for the diagnosis of IFDs.
Results: Fungitell assay was performed on 1912 serum samples from 630 patients with hematological malignancy (3.0 samples/pt.). Depending on the cut-off used (≥60; ≥80; ≥100; ≥150pg/ml) there were 231 positive BG samples in 78 pts.; 185 samples in 64 pts.; 155 samples in 52 pts. and 108 samples in 33 pts, respectively. Proven and probable cases of IFD occurred only in 49 (21.2%) out of 231 positive samples (in 19 out of 78 patients) with BG ≥60 pg/ml - 11 probable invasive aspergillosis (IA), 4 proven IA, 3 invasive candidiasis and 1 invasive fusariosis. Eight pts. (1.5%) from the group with negative BG samples (<60pg/ml) developed any IFD (6 probable IA, 1 proven IA and 1 invasive trichosporonosis). Depending on the criterion of positivity of BG used (≥60/ ≥80/ ≥100/ ≥150pg/ml) sensitivity was 67.1/63.6/63.1/53.9%, specificity was 90.1/92.9/93.6/95.4%, negative predictive value (NPV) was 98.6/98.6/ 98.6/98.6% and positive predictive value (PPV) was 21.2/21.3/26.5/25.9%, respectively.
Summary/Conclusions: Our study proved high specificity and NPV of serum BG allowing to exclude patients with IFD. On the other hand we confirmed limited sensitivity and mainly very low PPV of the test as its major limitations. We didn't observe any significant differences in sensitivity and PPV between groups with different cut-offs. Thus positive BG assay results in high risk hematological patients should be carefully evaluated together with other clinical and microbiological findings. This work was supported by grant MUNI/A/1028/2015.

DIFFERENT ISOFORM LOCALIZATION GOVERNS SIGNALING QUALITY OF DECTIN-1 IN THE REGULATION OF ANTI-FUNGAL IMMUNITY

M Fischer[1], J Müller[2], B Spies-Weisshart[1], C Gräfe[1], A Hochhaus[1], S Scholl[1], U Schnetzke[1,*]
[1]Klinik für Innere Medizin II, Abteilung Hämatologie und Internistische Onkologie, [2]Institut für Molekulare Zellbiologie, CMB, Universitätsklinikum Jena, Jena, Germany

Background: Dectin-1, a C-type-lectin-like receptor, is recognized as a major receptor for fungal ß-glucans and contributes to anti-fungal immunity. Two major human isoforms (isoform A and B) are expressed in human monocyte populations by alternative splicing. They differ by the presence of a stalk region and its N-linked glycosylation site.
Aims: The incidence of invasive fungal infections (IFI) in hematological patients has substantially increased during the last decades. Thus, there is a need for a better understanding of antifungal immunity. Here, we focus on dissecting the specific characteristics of Dectin-1 isoform A and B concerning subcellular localization, ligand binding capacity and protein signaling.
Methods: Expression of Dectin-1 isoform A and B was analyzed in monocyte-derived cells. Cell lines stably expressing Dectin-1 isoform A or B were created and characterized concering localization using flow cytometry and confocal laser scanning microscopy and signaling quality using immune blotting.
Results: While glycosylated isoform A of Dectin-1, was found to be predominantly localized at the cell surface, Dectin-1 isoform B missing a N-glycosylation site was retained intracellularly and remained unglycosylated. Inhibition of using Tunicamycin resulted in efficient abrogation of surface expression of Dectin-1 isoform A. Binding of Zymosan and Syk- and p38- dependent signaling quality of Zymosan stimulated cells expressing Dectin-1 isoform B was drastically reduced compared to cells expressing Dectin-1 isoform A.
Summary/Conclusions: Glycosylation of Dectin-1 plays an important role for surface expression and consequently Zymosan mediated signal transduction. Different expression profiles of human Dectin-1 isoforms on monocyte-derived cells may indicate distinct isoform usage as a cell-type specific mechanism of regulating anti-fungal immunity.

Background: In the era of mold active azoles prophylaxis, the incidence of invasive fungal infections has varied.
Aims: We evaluated characteristics and outcome of patients (pts) with fungal bloodstream infections (FBSI) during treatment of hematological malignancies (HMs) on a retrospective/prospective study.
Methods: We gathered all consecutive documented FBSI diagnosed between January 2011 and December 2015 in 29 Italian Hematology Departments (both adults and pediatrics), referring to SEIFEM (Sorveglianza Epidemiologica Infezioni Fungine Emopatie Maligne).
Results: We collected 198 cases: M/F 116/82, median age 55 y.o. (range 3-88). FBSI were detected in 82 AML pts (41.4%), 53 (26.8%) NHL, 24 (12.1%) ALL, 14 (7.1%) MM, 13 (6.5%) MDS, 4 (2.1%) MPN, 5 (2.5%) CLL and 3 (1.5%) HL. Regarding the underlying malignancies' treatment at FBSI onset, 64 pts (35.3%) experienced the first cycle of chemotherapy, 55 pts (43.9%) salvage treatment for refractory/relapsed HMs, 21 pts (20.7%) subsequent treatment after complete or partial remission; 58 pts (29.3%) underwent HSCT (16 autologous and 42 allogeneic). Central venous catheter had been placed in 182 pts (92%), urinary catheter in 75 pts (37.8%) and nasogastric tube in 8 pts (4%); 76 pts (38.3%) were supported with parenteral nutrition. Among 114 (57.6%) neutropenic pts at FBSI diagnosis (neutrophils count <500/mmc), 45 (39.5%) recovered at the end of observation period, (median duration of neutropenia 13 days, range 1-100). Use of steroids was reported in 105 pts (53%), with a median duration of 12 days (range 3-106). In 43 pts (21.7%) a skin, oral and/or rectal fungal colonization was detected. FBSI was most frequently caused by yeasts: 158 (79.8%) *Candida* spp. (49 *albicans* and 109 *non albicans*), 10 (5.1%) *Geotrichum*, 5 (2.5%) *Trichosporon*, 6 (3%) *Rhodotorula*, 4 (2%) *Saprochaeta* and 1 (0.5%) *Blastoschizomyces*. Molds have been detected rarely: 12 (6%) *Fusarium*, 1 each (0.5%) *Scedosporium* and *Mucor*. Antifungal prophylaxis was administered in 121 pts: 11 received only topic antifungals. In 101 pts systemic antifungals were administered as follow: 38 (37.6%) posaconazole, 38 (37.6%) fluconazole, 8 (7.9%) itraconazole, 6 (5.9%) liposomal amphotericin B (L-AmB), 8 (7.9%) echinocandins (6 caspofungin and 2 micafungin), 3 (3%) voriconazole. The median duration of prophylaxis was 15 days (range 4-120). The residual 86 pts (43.5%) did not received any antifungals. In 20 pts (10%) no systemic antifungal therapy was administered: 14 of them experienced early mortality. The residual 178 pts were treated as follow: 89 (44.9%) echinocandins (77 caspofungin, 6 anidulafungin, 6 micafungin), 50 (25.2%) L-AmB, 31 (15.5%) azoles (20 fluconazole, 1 posaconazole, 7 voriconazole, 3 itraconazole) and 9 (4.4%) combo therapy (4 posa+L-AmB, 4 caspo+L-AmB, 1 vori+caspo). The median duration on treatment was 12 days (range 2-180). At 30 days from FBSI diagnosis 81 pts (40.9%) were dead: 37 (18.6%) from fungal infection, 19 (9.6%) from HMs, 11 (5.5%) from other causes; in 14 pts (7.1%) we cannot discriminate the cause of death (FBSI *vs* HMs). Of note, 33 dead pts (16.6%) received no antifungal prophylaxis and 6 (3%) received neither prophylaxis or therapy.
Summary/Conclusions: Our study confirms the rarity of FBSI in hematological pts. The most frequently identified strains are *Candida* spp, especially *non albicans*, yet molds are identified not so rarely, *i.e. Fusarium* spp. Although the wider use of broad spectrum azoles prophylaxis and the early institution of antifungal therapy, overall mortality in this setting is still high.

P388

PROGNOSTIC FACTORS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES ADMITTED TO THE INTENSIVE CARE UNIT: EXPERIENCE WITH 335 PATIENTS FROM A SINGLE CENTER

A Rivas-Delgado[1,*], C Fernandez de Larrea[1], M Rinuaudo[2], P Castro[2], M Suárez-Lledo[1], S Fernández[2], MT Cibeira[1], JM Pericas[2], D Monzon[2], M Rovira[1], JM Nicolás[2], J Esteve[1]
[1]Hematology, [2]Medical Intensive Care Unit, Hospital Clinic, Barcelona, Spain

Background: In the last years, the prognosis of patients with hematological malignancies has improved substantially due to the availability of more effective treatments and better management of complications associated with the disease and treatments, including stem cell transplantation (SCT). Despite this progress, patients with hematologic malignancies still have serious complications that requires admission to the intensive care unit (ICU).
Aims: The aim of this study is to analyze the survival outcomes and identify the prognostic value of different variables of patients with haematological malignancies requiring admission to the ICU at our institution during the past fourteen years.
Methods: Three hundred thirty-five patients (140 F/195 M) with a diagnosis of hematologic malignancy that required admission to the ICU from January 2000 to September 2013 were included. Thirthy-nine percent of patients had undergone SCT, mostly allogenic (73%), and approximately one half of the patients were receiving front-line treatment. The main causes of admission were septic shock (45.7%) and acute respiratory failure (37.6%). The most common hematologic malignancy was acute myeloid leukemia (29.3%).
Results: Overall ICU and hospital mortality were 37.6% and 54.6%, respectively, and a decrease in ICU mortality beyond 2005 (52% 2000-2004, 31% 2005-2008 and 32% 2009-2013, p <0.001) was observed (Figure 1). The variables associated with a worse overall survival in the ICU were being admitted to ICU from the hematological unit, relapsing disease, severe thrombocytopenia, allogeneic SCT, high APACHE II (>19 points) and SOFA (>8 points) score, previous use of antibiotics, use of vasopressors, non-invasive and invasive mechanical ventilation (IMV) and renal replacement therapy. By contrast, the potential myelotoxicity of previous chemotherapy as well as neutropenia had no significant impact. In the multivariate analysis the need of IMV (HR 16.3; p <0.001), renal replacement therapy (HR 3.28; p=0.003), previous use of antibiotics (HR 2.08; p=0.022) and APACHE II score greater than 19 points (HR 1.99, p=0.024) retained their independent prognostic value. Allogeneic SCT was also associated with a shorter overall survival compared to other therapeutic modalities (p<0.001); however the characteristics associated with the transplant (donor type, source of stem cells, conditioning regimen intensity or the development of graft-*versus* host disease) had no effect on survival. The prognosis of patients undergoing acute leukemia induction was similar to those treated with autologous SCT.

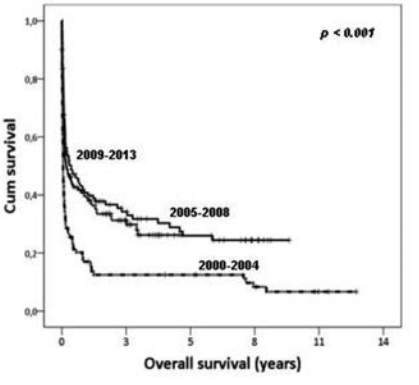

Figure 1. Overall survival of patients admitted to ICU according to the period.

Summary/Conclusions: The survival of patients with hematological malignancies admitted to the ICU has improved in the last years. A previous allogeneic SCT transplantation, the need for mechanical ventilation and renal replacement therapy, prior use of antibiotics and high APACHE II score are factors associated with a worse prognosis in this group of patients.

SAFETY AND EFFICACY OF HUMAN T-LYMPHOTROPIC VIRUS 1 (HTLV-1) HYPERIMMUNE GLOBULIN AGAINST HTLV-1 INFECTION IN A HUMANIZED MOUSE MODEL

T Mizukami[1,*], K Nojima[1], W Kuribayashi[1], E Sasaki[1], M Kuramitsu[1], K Ohkuma[1], S Matsuoka[1], K Furuhata[1], R Sobata[2], C Matsumoto[2], M Satake[2], K Tadokoro[2], K Yamaguchi[1], I Hamaguchi[1]
[1]Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, [2]Central Blood Institute, Japanese Red Cross, Tokyo, Japan

Background: Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus 1 (HTLV-1). Prevention of HTLV-1 infection is the most effective strategy for eradicating ATL. However, there is currently no effective vaccine or anti-viral agent for HTLV-1.
Aims: In this study, we aimed to develop a safe and effective HTLV-1 hyperimmune globulin (HIG) by using donations from HTLV-1-positive carriers that were screened at the Japanese Red Cross. Additionally, we assessed the viral safety of HIG during the manufacturing process by spiking the samples with HTLV-1.
Methods: First, we developed two *in vitro* screening methods to evaluate and characterize the anti-viral effect of HTLV-1-positive plasma. We modeled HTLV-1 infection by using an HTLV-1-infected cell line, MT-2, along with Jurkat or SLB-1 cells. We then purified HIG from 30 typical HTLV-1-positive serum samples from the excluded blood donations to the Japan Red Cross, and we evaluated its effect in a humanized mouse (Hu-PBL NOG) model to assess its ability to prevent HTLV-1 infection *in vitro*. Hu-PBL NOG (NOD.Cg-*Prkdc*^{scid} *Il2rg*^{tm1Sug}/Jic) mice were treated with HIG for 5 days before HTLV-1 infection by injection with mytomicine C-treated MT-2 cells ($1x10^5$) 3 days after the mice received human peripheral blood mononuclear cells ($1x10^7$). To observe the viral clearance ability throughout the HIG manufacturing process, we performed a viral clearance study in which we purified HIG from HTLV-1-negative or -positive plasma that had been spiked with $1x10^5$ MT-2 cells.
Results: We found that HTLV-1-positive plasma, defined as plasma isolated from an HTLV-1 carrier with a proviral load above four, can effectively block both HTLV-1 infection and syncytia formation *in vitro*. In *in vivo* experiments, HTLV-1 was detected in the untreated HTLV-1-infected mice, but not in the HIG-treated HTLV-1-infected mice on days 11 and 38 post-infection. HTLV-1-infected cells ($CD3^+/CD4^+/CCR4^+/CD25^+/CD30^+$) could be seen in the spleen, liver, and lungs of the untreated HTLV-1-1infected mice, but no HTLV-1-infected cells were observed in these tissues in the HIG-treated mice, even though their normal T cells ($CD3^+/CD4^+$ and $CD8^+$) were observed. We were still able to detect the inhibitory effect of HIG treatment on HTLV-1 infection when we treated mice with HIG 20 days after the HTLV-1 infection. The results of a viral clearance study show that high log reduction values were obtained during the HIG manufacturing process. We were unable to detect any HTLV-1 genomes in the purified HIG, and there was no HTLV-1 infectivity in the HIG purified from source plasma spiked with $1x10^5$ MT-2 cells.
Summary/Conclusions: We found that HTLV-1 HIG may be an effective and safe therapy for the prevention of HTLV-1 infection.

P390

STABLE AND FULL PRODUCTION OF FETAL HAEMOGLOBIN AFTER BONE MARROW TRANSPLANT FAILURE IN PATIENTS WITH THALASSAEMIA MAJOR AND CLINICAL REMISSION: THE GENETIC BACKGROUND

K Paciaroni[1,*], N Bianchi[2], G De Angelis[3], C Gallucci[3], C Alfieri[3], M Ribersani[3], P Sodani[3], J Gaziev[3], A Isgrò[3], M Marziali[3], F Agostini[4], G Lucarelli[3], R Gambari[2]
[1]Policlinic of "Tor Vergata" University, Rome, Italy, International Centre for Transplantatin in Thalassemia and Sickle Cell Anaemia, Mediterranean Institute of Haematology, Rome, [2]Department of Life Sciences and Biotechnology, Ferrara, [3]International Centre for Transplantatin in Thalassemia and Sickle Cell Anaemia, Mediterranean Institute of Haematology, [4]Department of Biomedicine and Prevention, Policlinic of "Tor Vergata" University, Rome, Italy

Background: High fetal haemoglobin (HbF) levels ameliorate morbidity and mortality in Sickle Cell Anaemia (SCA) and β-thalassaemia. The variability of HbF levels is genetically controlled by multiple genes and recent studies provide new insight into the molecular mechanisms in order to induce the HbF production in adult haemopoietic cells as a promising therapeutic approach to ameliorate the severity high levels of HbF ameliorate the severity of the β -disorders. A strong support to such novel approaches comes from recent clinical observations carried out by our group
Aims: To study the fetal haemoglobin levels and genetic background of three thalassemic patients who underwent bone marrow transplant (BMT) and exhibited high HbF level after BMT failure and autologous reconstitution.
Methods: Out of 292 consecutive patients with β-haemoglobin disorders undergoing allogeneic Bone Marrow Transplant at our institution, we observed 3 BMT recipients who developed the reactivation of HbF synthesis after BMT failure. We analyzed the blood samples of three patients for the genetic polymorphisms associated to increased level of HbF, genomic DNA sequencing, western blotting, electrophoretic mobility shift assays, surface plasmon resonance (SPR) biospecific interaction analysis, bioinformatics analyses based on docking experiment.
Results: Three patients with β°-thalassaemia major underwent BMT and rejected at +40, +90 and +18 days after transplant respectively. The autologous recovery was documented (0% residual donor cells) in all cases. Transfusion therapy was required to support anaemia until +118, +162 and +178 days after transplant respectively. Afterwards the Hb levels were steadily over 10.2 g/dl (range 10.2-11.8 gr/dL) without the use of transfusion support and the Hb electrophoresis revealed HbF 99.8% in all 3 cases. At +93, +82 and +17 months respectively of ongoing follow-up after graft failure, all 3 patients maintain the sustained and full (99.8%) production of HbF and are transfusion-free. (See the table).The genetic analysis documented that all patients were carrier of the non-deletion form of hereditary persistence of HbF. The 3 thalassaemic patients exhibit the homozygosity for the –158 (C->T) point mutation in the G γ promoter sequence and we found in all three a novel polymorphism of the Aγ-globin gene at position +25(G→A). This region belongs to a sequence recognized by DNA-binding protein complexes, including LYAR (Ly-1 antibody reactive clone), a zinc-finger transcription factor previously proposed to be involved in down-regulation of the expression of γ-globin genes in erythroid cells decreasing the efficiency of the interaction between this sequence and specific DNA binding protein complexes.
Summary/Conclusions: Our study showed that the reactivation of HbF synthesis can occur in the adult age and the high levels of HbF provide a therapeutic benefit to the β-disorders. We found a novel polymorphism of the Aγ-globin gene in all three thalassemic patients who failed BMT and developed high levels of HbF. It is likely that the favorable genetic background in these patients concurred the full HbF production.

P391

AUDIT OF TRANSFUSION PRACTICES IN PATIENTS RECEIVING AUTOLOGOUS STEM CELL TRANSPLANTATION AT UNIVERSITY HOSPITALS BIRMINGHAM

A Burke[1,*], K Fordwor[1], M Cook[1], S Morton[2]
[1]Department of Clinical Haematology, University Hospitals Birmingham, [2]NHS Blood and Transplant, Birmingham, United Kingdom

Background: Autologous stem cell transplantation (autoSCT) is an effective consolidation therapy, improving outcomes in a number of haematological conditions. Blood product support is often required to treat anaemia and reduce risk of haemorrhage. However many patients undergoing autoSCT have previously been treated with chemotherapy regimens that do not routinely require support with blood products.
Aims: We examined transfusion practice at our transplant centre to investigate whether patients undergoing autoSCT were receiving potentially avoidable transfusions.
Methods: 121 consecutive patients who underwent autoSCT at University Hospitals Birmingham between 01/09/14 and 31/10/15 were identified using the Bone Marrow and Stem Cell Transplant registry.
Of the 26 patients receiving their pre transplant treatment in our centre, 16 (58%) received their first transfusion during the transplant period. Clinical and laboratory data was collected from these patients from the electronic patient record, and paper records when necessary.
Results: 69% were male, median age 60 years (range 31 to 68 years). Myeloma was the most frequent indication for transplant (81%). There were 40 platelet transfusions delivered to 16 patients, median 3 per patient (range 1-6). Of these, 29 were apheresis and 11 were pooled doses. All were single unit transfusions. There were 13 units of red cells transfused in 6 episodes to 5 patients, median 2 per patient, with one single unit transfusion. Transfusions were delivered a median of 3 days before engraftment (range day -12 to day +53), with 15%, 45% and 75% being delivered within 1, 3 and 5 days of engraftment respectively and a median of 4 days before discharge (range day -9 to day +56), with 15%, 37% and 59% occurring within 1, 3 and 5 days respectively.
23 (57.5%) doses of platelets were assessed to be clinically justified based on the available information. Of these, 11 were for platelet count less than or equal to $10x10^9$/L, 3 were for minor bleeding and the remaining 9 were for prophylaxis during a septic episode to maintain platelet count greater than $20x10^9$/L. The 16 platelet transfusions where no clinical justification was evident amounted to 28 potentially unnecessary donor exposures in 12 patients. 3 of the 6 red cell episodes were justified by haemoglobin less than 80g/L. Two episodes were not assessable due to lack of clinical noting. There were 3 patients who only had a single platelet transfusion, involving 6 donors, and there was no apparent clinical justification in any of these.
Summary/Conclusions: In conclusion we found transfusion practice during autoSCT to be liberal, resulting in high donor exposures, of which at least 39% were potentially avoidable. 12 (75%) patients (who were previously transfusion naïve) were exposed to at least one transfusion which we believe was not clinically justified. The median potentially avoidable donor exposures in these

patients was 1.5 (range 1-6). Strict adherence to recent NICE guidelines and local policy is expected to improve the donor exposure rate in autoSCT, particularly in those not previously transfused.

P392

COAGULATION PROFILE AND OUTCOME OF BLOOD COMPONENT THERAPY IN SNAKE BITE VICTIMS

AM Rafi*, S Innah
Transfusion Medicine & Immunohematology, Jubilee Mission Medical College & Research Institute, Thrissur, India

Background: Bites from poisonous snakes cause substantial human morbidity and mortality in tropical and subtropical countries. Hemotoxic envenoming is quite common in many parts of India, but only limited data exist on its accurate incidence in the country, and clinical effects. Herein we present findings from an observational study on coagulation profile and outcomes of blood component therapy in patients with hemotoxic snake bites
Aims: To assess the coagulation profile and outcome of blood component therapy in snake bite victims
Methods: We undertook an observational study between January 2013 and June 2014, on patients admitted to the medical ICU of our tertiary hospital, with a history of snake bite and satisfying the inclusion criteria. The patients underwent detailed evaluation of envenoming by clinical and laboratory investigations. The patients were screened by a standard, 20-minute Whole Blood Clotting Time (WBCT) test (repeated four times at 30 min. intervals) and prolongation of at least one test result indicated hemotoxic envenoming. Routine blood counts, Bleeding Time (BT), Prothrombin Time (PT), International Normalized Ratio (INR), activated Partial Thromboplastin Time (aPTT), fibrinogen and D-dimer levels were also monitored. Samples of plasma separated from a citrated blood sample collected at the occurrence of deranged WBCT were flash frozen and assayed for coagulation factors. Blood component therapy and its outcomes were also monitored in the patients.
Results: Among 595 patients reporting with snake bites, 445 were adults. Absence of signs of envenoming suggested non-venomous bites 282 patients. One hundred and sixty three patients manifested features of envenoming, and received Anti-Snake Venom (ASV). Species identification of the biting snake was not possible in 50% of cases. Among the rest, Russel's viper and Pit viper accounted for 66 and 9 cases, respectively. Only the cases where the biting species could be identified were studied further. Delayed treatment resulted in severe local and systemic manifestations in patients. Hematological manifestations developed following bites from Russel's viper, pit viper and unidentified species as well. Acute Renal Failure (ARF) due to Disseminated Intravascular Coagulation (DIC) and capillary leak syndrome developed only in patients with bites from Russels viper, and necessitated hemodialysis. Coagulopathies occurred in most patients with bites from Russel's viper and pit viper. Patients bitten by Russel's viper manifested severe deficiency of Factor V and Factor X, while it did not occur in pit viper bites. Qualitative testing for Factor XIII revealed its deficiency specifically in cases of Russel's viper bite. Most patients with hemotoxic envenomation received transfusion of fresh frozen plasma (FFP), 24 hours after administration of ASV. Severe thrombocytopenia necessitated the administration of platelet concentrate in seven patients. Packed Red Blood Cells (PRBC) was administered in 4 patients with anemia. Blood component therapy significantly increased hospital stay of the patients. No statistically significant complications or mortality occurred after transfusion therapy.
Summary/Conclusions: Rural areas had higher incidence of snake bites. Though BT and CT were sufficient to identify hemotoxicity, costlier and time-consuming assessment of PT, aPTT, serum fibrinogen and D-dimers had more sensitivity. Hematological manifestations occurred following bites from Russel's viper and pit viper, while the former produced major bleeding diatheses and a higher incidence of DIC and ARF. The public need to be made aware of the need for early identification and appropriate treatment of snake bites

P393

IMPACT OF PROTHROMBIN COMPLEX CONCENTRATE (PCC) USE ON TRANSFUSION REQUIREMENTS AND BLOOD LOSS IN CARDIAC SURGERY

A Mo[1,*], G Matalanis[2], F Hong[3], C Smith[3]
[1]Haematology, Monash Hospital, Clayton, [2]Cardiothoracic surgery, [3]Laboratory Haematology, Austin Health, Heidelberg, Australia

Background: Cardiac surgery is associated with significant coagulopathy and bleeding. This has led to off-label Prothrombin Complex Conccentrate (PCC) use, despite minimal data regarding its efficacy in this setting. There have been retrospective studies investigating use of four-factor PCCs in Europe showing variable efficacy, however the only PCC available in Australia is Prothrombinex-VF, a three-factor PCC containing factors II, IX and X.
Aims: We aimed to retrospectively review the perioperative off-label use of PCCs during cardiac surgery in our institution, to evaluate if PCC use reduced postoperative bleeding or transfusion requirements, and its effect on other clinical and laboratory parameters compared to patients who did not receive PCC.
Methods: A retrospective audit was performed, with the approval of the hospital Research Ethics Committee, of all patients undergoing cardiac surgery from 1st June 2012 to 31st December 2012. Data was collected via the hospital's cardiac surgery database and medical records.
Results: 193 patients underwent cardiac surgery during the study period. 66 (34%) received PCC at a median dose of 22 IU/kg. There was a significant reduction in the INR (medain INR reduced from 1.5 pre-PCC to 1.3 post-PCC), with the change in INR greatest for patients with the highest pre-PCC INRs), but no change to APTT following PCC use. Post-operative blood loss, as measured by the 4-hour chest drain output, was comparable to international studies and did not decrease significantly with PCC (290mL *versus* 270mL, p=0.29). The PCC group also had higher transfusion requirements, including more red blood cells (median 4 units *versus* 0 units), more platelet transfusions (median 2 bags *versus* 0), more Fresh Frozen Plasma (both receiving a median of no units however the PCC group had a greater IQR of 0-2 units), and more cryoprecipitate transfusions (median 3.5 units *versus* 0) (p <0.0001). These results were, however, potentially confounded by longer median cardiopulmonary bypass time and a greater proportion of aortic surgeries in the PCC group.
Summary/Conclusions: A substantial proportion of patients undergoing cardiac surgery are treated off-label with PCCs. This is associated with a reduction in the INR, but no significant difference in the post-operative blood loss or blood product transfusion rate.

P394

COMBINED PLASMA EXCHANGE AND ERYTHROCYTAPHERESIS FOR TREATMENT OF MULTIORGAN FAILURE DUE TO SUSPECTED FAT EMBOLISM SYNDROME IN SICKLE CELL DISEASE

D Avenoso*, S Deplano, B Sevillano, A Luqmani, N Cooper, L Eccersley, S Thomas, R Haynes, L Alexander, M Layton
Haematology, Hammersmith Hospital - Imperial College NHS Trust, London, United Kingdom

Background: Fat embolism syndrome (FES) as a consequence of bone marrow necrosis during a vaso-occlusive crisis is a devastating complication of sickle cell disease (SCD) that affects all age groups and phenotypes with a high mortality. Clinically FES is characterised by acute respiratory failure, neurological impairment, cutaneous/mucosal petechiae, acute kidney injury, and hepatic dysfunction. Additional markers that aid diagnosis include hyponatraemia, thrombocytopenia and coagulopathy. Retrospective case reviews of FES in SCD have highlighted the role of red cell exchange transfusion in improving clinical outcome though mortality remains ~30%. These have not differentiated between manual and automated red cell exchange. Previous studies have shown reduction in inflammatory mediators after manual exchange transfusion. Such an effect would not be expected from selective removal of red cells during automated erythrocytapheresis (aRCE) increasingly the modality of choice in specialist haemoglobinopathy centres. Since inflammatory mediators are likely to play a role in its pathogenesis we reasoned that combined plasma exchange (PEX) and erythrocytapheresis could improve the outcome of FES in SCD.
Aims: To report the outcome in adult SCD patients who developed multiorgan failure and met diagnostic criteria for FES treated with combined aRCE and PEX.

Table 1. Clinical details at the onset of MOFS.

	Case 1	Case 2	Case 3
Gender	F	F	F
Age	60	47	33
Genotype	HbS-beta thal	HbS-O Arab	HbSS
WC x10^6/L	2,41	7	11
Hb g/l	66	68	65
Plt x10^6/L	64	48	50
Creatinine (umol/L)	112	122	>110
ALT (iU/L)	72	113	>40
Arterial pO2 (kPa)	7.7	8.2	6.5
Glasgow Coma Score Before PEX	11	9	8
HbS%	28	23	25
Courses of PEX	3	2	1
Outcome at 2 months	Alive	Alive	Alive
Recovery (days)	9	18	16

Methods: A retrospective analysis of 3 SCD patients aged 33-67 years with suspected FES treated at Hammersmith Hospital. Clinical details of the patients are summarized in table 1. Apheresis was performed using the Spectra Optia Apheresis System according to our standard operating procedure with a target HbS of <30% and plasma volume exchanged of 3L. Consecutive aRCE and PEX were performed initially and a decision to repeat PEX subsequently based on clinical response (median number PEX 2;range 1-3). Time to recovery was defined by reversal of neurological and respiratory impairment and normalisa-

tion of platelet count, liver and renal function and coagulation parameters. Overall survival (OS) was assessed 2 months post-treatment with a median follow up of 16 months (range 2-21).
Results: All patients exhibited features of multiorgan failure compatible with the diagnosis of FES. OS was 100% at 2 months. Rapid improvement in neurological status was seen with normalisation of Glasgow Coma Scale within 24 hours of completing PEX. No long-term neurological sequelae were observed. Median time to recovery as defined above was 16 days (range 9-18).
Summary/Conclusions: Based on these favourable preliminary results in SCD patients with multiorgan failure due to suspected FES it is recommended combined aRCE/PEX is evaluated in a larger cohort of patients to determine its efficacy in treatment of this life-threatening complication.

P395

REDUCTION OF ABO GLYCOSYLTRANSFERASE CAUSED BY SYNONYMOUS VARIATION IN B309 ALLELE

JG Shin[1], SH Oh[1,*], HS Kim[2], S Lee[2], TS Park[3], JY Lee[1], HR Kim[1], JN Lee[1]
[1]Laboratory Medicine, Inje University College of Medicine, BUSAN, [2]School of Life Science and Biotechnology, Kyungpook National University, Daegu, [3]Laboratory Medicine, School of Medicine, Kyung Hee University, Seoul, Korea, Republic Of

Background: Non-synonymous single-nucleotide polymorphism in the *ABO* gene can affect the enzyme characteristics and protein quantity producing many kinds of ABO blood type subgroups. B3 phenotype including 11 variant alleles reveals characteristic mixed field agglutination. Synonymous variations, formerly called 'silent' mutation, can result in aberrant protein expression and protein folding. Interestingly, *B309* variant (*255C>T* on exon 6 in the background of *B101*) was recently reported to have synonymous SNP (sSNP). We found B309 alleles recurrently in Korean B3 phenotype individuals.
Aims: B309 allele's effect on B antigenic expression was investigated in patients and confirmed by the experimental model.
Methods: Individuals with mixed field agglutination with anti-B were tested by direct sequencing. *B309* allele were isolated and confirmed by TA cloning. cDNAs from exon 5 to exon 7 were amplified and sequenced in B309 individuals to exclude out the possibility of splice variant. *B101* and *B309* coding sequence with *255C>T* were cloned, inserted to the vectors with fluorescent tags and transduced into the HeLa cells that have O/O genotype. The protein expression and antigenic changes by sSNP were evaluated with fluorescent protein expression and flowcytometric analysis.
Results: We found two unrelated Korean individuals and three family members in one pedigree who have *B309* alleles and all of them revealed B3 phenotypes. Exon 6 of ABO transferese gene was not spliced out in their cDNAs. Protein expression and antigenic expression were reduced in B309 variant (the median MFI: 36.85) compared to B101 (MFI: 50.03).

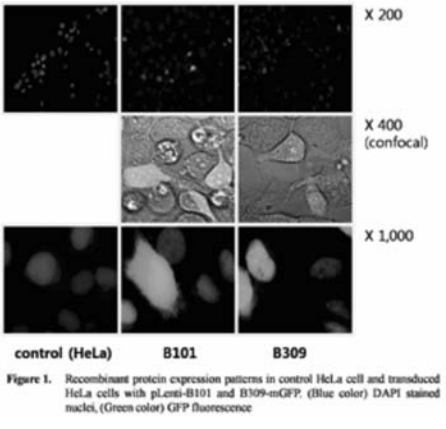

Figure 1. Recombinant protein expression patterns in control HeLa cell and transduced HeLa cells with pLenti-B101 and B309-mGFP. (Blue color) DAPI stained nuclei, (Green color) GFP fluorescence

Figure 1.

Summary/Conclusions: Individuals with *B309* allele revealed B3 phenotypes and their *255C>T* synonymous polymorphism didn't contribute to the alternative splicing. *255C>T* polymorphism was experimentally proven to cause the reduced expression of ABO transferase and the subsequent weakening of B antigens. This phenomenon implies that sSNP could also affect the expression and function of the protein, and finally alter the immunohematologic reactions.

P396

EFFECTS OF IMPLEMENTATION OF A MASSIVE TRANSFUSION PROTOCOL IN A TERTIARY REFERRAL HOSPITAL

I Giannoutsos[1,*], E Tegg[2], H Keenan[3], JA Greaves[3]
[1]Haematology, Nepean Hospital, Kingswood, [2]Haematology, [3]Transfusion, ICPMR, Westmead Hospital, Westmead, Australia

Background: Following the study in 2007 of Borgman et al regarding early plasma product support in trauma patients receiving massive transfusion, the implementation of massive transfusion protocols (MTPs) has become the norm.Aims of utilising a MTP include pre-emptive transfusion with plasma products platelets in an effort to be proactive and overcome the effects of transfusing mostly large amounts of packed red cells on coagulation, in patients with critical bleeding.
Aims: The effect of implementing a MTP in a tertiary referral hospital, for both trauma and non-trauma–related critical bleeding was examined. Parameters include the number of MTP 'episodes' or 'activations', the proportion of 'true' critical bleeding episodes, the ratio of blood products transfused (Red Blood Cells:Fresh Frozen Plasma:Cryoprecipitate:Platelets) and blood product wastage.The appropriateness of platelet transfusion and 28-day mortality were of interest.
Methods: Data regarding the issuing of blood products which was collected by Blood Bank staff at the time of the MTP, as well as computer records regarding laboratory parameters and blood product use was assessed retrospectively.The first dataset period, denoted Period 1(P1), was prior to the implementation of the MTP and the second period (P2) post-implementation.
Results: During P1 (16.5 months), the total number of massive transfusion 'episodes' was 53 and during P2 (7.5 months) there were 59 MTP 'activations'.During P1 the average number of Red cells (RBC), Fresh Frozen Plasma (FFP), Cryoprecipitate(Cryo) and Platelets (Plt) transfused per patient were:15.1, 13.3, 13.6 and 1.5 respectively.4 RBCs or less were transfused in only 3 episodes during P1.During P2 (7.5 months), the total number of activations included 57, and the corresponding average numbers of RBC, FFP, Cryo and Plt per patient were 7.9, 6.9, 7.4 and 0.5.4 RBCs or less were transfused in 27 episodes during P2.The proportion of deaths for the 53 patients during P1 was 28% and during P2 the proportion of deaths was 31.6%.The RBC:FFP ratio in P1 was 1.13:1 and in P2 it was 1.18:1. RBC:Cryo ratio was 1.11:1 for P1 and 1.09:1 for P2. RBC:Plt ratios for P1 and P2 were 10.06:1 and 16.2:1.
Summary/Conclusions: The 2 periods contain similar numbers of patients, however the time periods during which the 'critical bleeding' episodes were recorded differ markedly (16.5/12pre *vs* 7.5/12post).This is mainly due to a large number of MTP activations in which 4 or less RBC units were transfused in the post-implementation period.The high proportion of patients who did not have truly 'massive bleeding' but for whom the MTP was activated (47%), is similar to that previously reported.Correspondingly, the number of blood products transfused per patient was much higher in the pre-MTP protocol period. A cardinal reason for the wastage of blood products is that in patients who are severely injured, the MTP is activated after they have undergone an initial assessment and plasma products are thawed, however they succumb to their injuries before receiving these.Patient mortality did not differ in the periods before and after the MTP implementation (28.3% v 31.6%).The ratio of RBC to plasma products is similar in the pre- and post-MTP implementation periods.Fewer platelets were transfused per patient in the post-MTP period than pre-implementation (0.5 v 1.5);this is most likely because the 1st MTP 'shipment' of blood products containing 4 RBCs, 4 FFPs and 4 Cryo, would not normally include platelets.In summary, implementation of a formal MTP protocol has resulted in more 'activations' than had been the case before, an increased number of 'false' activations, increased wastage of blood product, no significant changes in mortality or ratio of plasma product to RBCs transfused.Possible ways to mitigate plasma product wastage could include alteration of MTP activation criteria, extending the lifespan of thawed products and the use of lyophilised fibrinogen.

P397

LOW PREVALENCE OF ALLOIMMUNIZATION AFTER RED BLOOD CELL TRANSFUSION IN 182 CHILDREN WITH SICKLE CELL DISEASE

S Allali[1,*], T Peyrard[2], D Amiranoff[3], M Chalumeau[1], V Brousse[1], M de Montalembert[1]
[1]Department of Pediatrics, Necker Hospital for Sick Children, [2]Centre National de Référence pour les Groupes Sanguins, Institut National de la Transfusion Sanguine, [3]Etablissement Français du Sang, Necker Hospital for Sick Children, Paris, France

Background: A high prevalence (around 30%) of red blood cell alloimmunization has been reported in patients with sickle cell disease (SCD), but few studies have focused on children.
Aims: Our objectives were to study prevalence and risk factors of red blood cell alloimmunization in a population of children affected with SCD.
Methods: We analyzed the medical and transfusion files of 245 children with SCD, hospitalized in our center in 2014, and identified 182 patients aged 1 to 18 years who received at least one red cell concentrate in their lifetime. The main clinical and immuno-haematological characteristics of alloimmunized and non-alloimmunized patients were compared.
Results: The 182 patients received 1 to 339 red blood cell units with a median of 10 (IQR: 4-46.7) units per patient. Six patients out of the 33 in whom a red cell genotyping was performed (18.2%) had a partial antigen in the Rh blood group system. Five patients (2.7%) had a S-s- rare blood type (either $U+^{var}$ or U-). Excluding autoantibodies and the naturally-occurring antibodies identified before any transfusion, the prevalence of alloimmunization was 13.7% (95% CI [8.6-18.6]). After excluding the probable irregular natural antibodies (anti-M, anti-Le^a, anti-Le^b), the prevalence dropped to 7.4% (95% CI [3.5-11.3]) and the alloimmunization rate was 0.17/100 units received. These antibodies were

directed against antigens of Rh (D, C, Ce and C^w), Kell (Kp^a), Duffy (Fy^a, Fy3), MNS (S, U) and Colton (Co^b) blood group systems. Two anti-D alloimmunizations involving partial antigens could have been prevented by systematic *RHD* genotyping. Main risk factors for alloimmunization were a higher number of red blood cell units (median of 65 *vs* 10 units per patient; p=0.01) and the presence of one or more red cell autoantibodies (46.2 *vs* 4.7%; p<0.0001).
Summary/Conclusions: The relatively low frequency of alloimmunization in our study is probably due to the fact that it is a pediatric population exclusively transfused with blood systematically matched for C, c, E, e and K antigens, and probably also for other blood group antigens as the number of donors of African-Caribbean origin is high in the Paris region. The prevalence of red blood cell alloimmunization is relatively low among SCD patients followed in our pediatric center but it could still very likely be lowered by the implementation of a systematic genotyping for the major blood group systems. The presence of red cell autoantibodies appears to be a major risk factor for alloimmunization and could justify specific transfusion guidelines.

P398

INTRAUTERINE BLOOD TRANSFUSIONS IN FETAL ANEMIA CAUSED BY PARVOVIRUS B19 INFECTION

K Cadren[1,*], M Falcón Rodriguez[1], M Negrín López[1], R García Delgado[2], R García Rodriguez[2], M Medina Castellano[2]
[1]Hematology, [2]Obstetrics and Gynecology, Hospital Insular de Gran Canaria, Las Palmas de Gran Canaria, Spain

Background: Parvovirus B19 has an affinity for hematopoietic system cells, including erythroid progenitor cell. The virus attacks cells of the red blood cell lines in the bone marrow, causing hemolysis and red blood cell aplasia. Fetal anemia is a serious complication in pregnancy associated with perinatal mortality and morbidity. The immaturity of the fetal immune system asociated to its inability of overproducing red blood cells leads to a physiological immunodeficiency that can be life threathening producing serial fetus conditions such as non inmune hydrops fetalis and spontaneous abortions. We present 8 cases of fetal anemia induced by Parvovirus B 19 (PV19) infection diagnosed during routine prenatal ultrasounds examination using the measurement of the middle cerebral artery peak systolic velocity (MCA-PSV) and their subsequent treatment by intrauterine blood transfusions (IBT).
Aims: To determine the impact of intrauterine blood transfusions on the correction of fetal anemia in fetal PV19.
Methods: A retrospective descriptive study was performed of all intrauterine blood transfusions for PV19 between January 2014 and December 2014. The study was carried out in the Complejo Hospitalario Materno- infantil de Las Palmas de Gran Canaria. The patient's clinical, laboratory and transfusion data were obtained from hospital records. Incidental findings at routine second trimester ultrasounds concerning an increase of the MCA- PSV>1.5 MoM correlated with fetal anemia. MCA-PSV is a sensitive, noninvasive means to determine the degree of fetal anemia that can be used accurately to time the first and subsequent intrauterine transfusions. Pregnant women at risk were assessed for the presence of PV19 infection by determining their IgM anti Parvovirus status and PCR. The primary management tool was cordocentesis to assess fetal hemoglobin and performing IBT. Serial hematocrit determinations were taken and IBT where performed until the resolution of anemia.
Results: In 2014, an outbreak of parvovirus B19 infection occurred. Eight asymptomatic pregnant women were diagnosed. Their median gestational age at diagnosis was 20.5 weeks. Five of eight pregnant women were transfused. Out of the five transfused fetus, three survived. The overall survival rate was 60% *(Table 1)*.

Table 1.

	Gestational age (weeks)	Ultrasound indirect signs of anemia	MCA-PSV	Hemogram Pre- IBT	Hemogram final Post IBT	Number of IBT	Final outcome
Case 1	21 + 2	Hydrops, IUGR *	>1,5 MoM	1,1 gr/dl	-	1	Severe pancytopenia Fetal Death
Case 2	20+6	Hydrops Cardiomegaly, pericardial effusion	<1,5 MoM	3,2 gr/dl	-	2	Fetal death at 25 weeks
Case 3	21+1		>1,5 MoM	4 gr/dl	13,8 gr/dl	4	Eutocic birth
Case 4	21+1		>1,5 MoM	2,8 gr/dl	11 gr/dl	3	Instrumented birth
Case 5	21+2	Hydrops	>1,5 MoM	****		Expectant management	Fetal death at 23 +2 weeks
Case 6	20+5	Hydrops, cardiomegaly	>1,5 MoM	8 gr/dl	12 gr/dl	1	Eutocic birth
Case 7	12+5	Hydrops	Not done	****	-	-	Spontaneous abortion
Case 8	25	Nuchal oedema, pericardial effusion	< 1,5 MoM	-	-	Expectant management	Eutocic birth

** IUGR: Intrauterine growth restriction.*

Summary/Conclusions: The development of an acute PV19 infection during pregnancy can cause prenatal complications ranging from early pregnancy loss to nonimmune hydrops and intrauterine death. Measurements of MCA-PSV represent a non invasive procedure to diagnose fetal anemia, thus leading to an early correction of anemia trough IBT and reducing prenatal mortality.

Background: Sickle cell anaemia (SCA) is an inherited red cell disorder characterised by haemolytic anaemia, recurrent painful vaso-occlusive crises and end organ damage. There are few treatment options. Platelets, activated by ADP released through haemolysis, contribute to vaso-occlusion by forming multi-cellular aggregates and promoting inflammation. Prasugrel is an oral, third-generation thienopyridine inhibitor of ADP-mediated platelet activation and aggregation. Prior studies showing a reduction in markers of platelet activation, as well as the rate and intensity of pain suggested a potential therapeutic benefit of prasugrel in SCA.
Aims: To assess the efficacy of prasugrel in children with SCA, as measured by reduction in the rate of vaso-occlusive crisis (VOC).
Methods: The DOVE trial was a phase 3 double-blind, placebo-controlled, parallel-group, multinational trial of children with SCA, ages 2 to <18 years, who were randomly assigned to receive oral prasugrel or placebo, dose titrated to achieve a pre-specified reduction of platelet reactivity, for 9 to 24 months. The primary endpoint was the rate of VOC, a composite of painful crisis or acute chest syndrome (ACS). Secondary endpoints included electronic diary-documented rate and intensity of sickle cell related pain, analgesic use and school attendance; rates of sickle cell related RBC transfusion; and rates of hospitalisation for VOC, painful crisis and ACS.

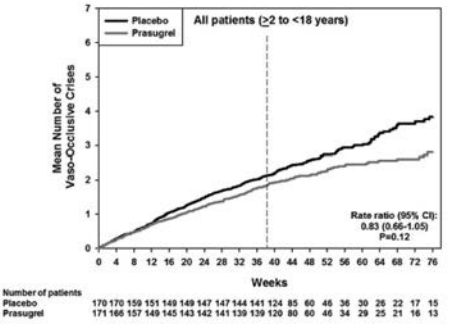

Figure 1.

Results: A total of 341 patients with SCA were randomized at 51 sites in 13 countries across the Americas, Europe, Asia, and Africa. Of these, 308 (90.3%) had HbSS and 153 (45%) were receiving stable dose hydroxyurea (HU); 275 patients completed the 9 month visit, of which 266 continued beyond 9 months and 9 discontinued prior to locking the database. A total of 736 VOC events occurred in the study: 328 among 115 (67.3%) patients in the prasugrel group and 408 among 123 (72.4%) patients in the placebo group. The rate of VOC trended lower in the prasugrel compared to the placebo groups but did not reach

significance: 2.30 per person-year and 2.77 per person-year, respectively (rate ratio, 0.83; 95% CI, 0.66-1.05; P=0.12) (Figure). There were no significant differences between groups in the secondary diary-reported outcomes. Pre-specified subgroup analyses identified a modest treatment effect in two subgroups; the oldest age (≥12 to <18 years) group (0.72; 95% CI, 0.51-1.02; P=0.06) and patients not on concomitant HU (0.74; 95%CI 0.54-1.01; P=0.06). Safety endpoints, including frequency of bleeding events requiring medical intervention, treatment emergent adverse events, both haemorrhagic and non-haemorrhagic, and discontinuations due to study drug did not significantly differ between groups.
Summary/Conclusions: In children with SCA, prasugrel did not significantly reduce the rate of the primary composite endpoint of VOC at the levels of platelet inhibition attained in this study. Prasugrel treatment had no impact on secondary outcomes. The overall adverse event rate, including haemorrhagic and non-haemorrhagic events, did not differ between the treatment groups. A trend towards an effect of prasugrel on VOC in the ≥12 to <18 year age group and in patients who were not receiving HU suggest that anti-platelet agents may have a therapeutic role as part of a multi-drug approach toward the complex pathophysiology of SCA. The DOVE study is the first multinational interventional trial in children with SCA and provides valuable guidance for future multi-continental SCA clinical trials. (Funded by Daiichi Sankyo, Ltd and Eli Lilly and Company; DOVE ClinicalTrials.gov number, NCT01794000).

P401

ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA: A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

M Tarantino[1,*], J Bussel[2], V Blanchette[3], J Despotovic[4], C Bennett[5], A Raj[6], B Williams[7], D Beam[8], J Morales[9], M Rose[10], N Carpenter[11], M Eisen[12]
[1]The Bleeding and Clotting Disorders Institute, Peoria, [2]Department of Pediatrics, Division of Hematology, Weill Medical College of Cornell University, New York, United States, [3]Hospital for Sick Children, Toronto, Canada, [4]Texas Children's Hematology Center, Houston, [5]Emory University, Atlanta, [6]Pediatric Blood and Cancer Disorders Clinic, Louisville, United States, [7]Lady Cilento Children's Hospital, South Brisbane, Australia, [8]Cook Childrens Medical Center, Forth Worth, [9]Louisiana State University Health Sciences Center, New Orleans, [10]Nationwide Children's Hospital and The Ohio State University College of Medicine, Columbus, United States, [11]Amgen Ltd, Uxbridge, United Kingdom, [12]Amgen Inc., Thousand Oaks, United States

Background: Romiplostim could be a treatment option for symptomatic children with ITP.
Aims: This was a phase 3, double-blind study designed to evaluate weekly romiplostim or placebo (randomized 2:1) given for 24 weeks to children with ITP for ≥6 months.
Methods: Dose was adjusted weekly from 1-10 μg/kg to target platelet counts of 50-200×10^9/L. Platelet response was defined as platelet counts ≥50×10^9/L any week of weeks 2-25 (excluding 4 weeks after rescue medication). The primary endpoint, durable platelet response, was defined as ≥6 weekly responses during the final 8 weeks, weeks 18-25. Overall platelet response was defined as ≥4 weekly responses weeks 2-25.

Table 1.

		Romiplostim (N = 42)	Placebo (N = 20)	
Durable platelet response, all patients		22/42 (52%)	2/20 (10%)	p<0.002
By baseline age	1 to <6 years	3/8 (38%)	1/4 (25%)	
	6 to <12 years	10/18 (56%)	1/9 (11%)	
	12 to <18 years	9/16 (56%)	0/7 (0%)	
Overall platelet response, all patients		30/42 (71%)	4/20 (20%)	p=0.0002
By baseline age	1 to <6 years	5/8 (63%)	2/4 (50%)	
	6 to <12 years	15/18 (83%)	1/9 (11%)	
	12 to <18 years	10/16 (63%)	1/7 (14%)	

Results: Patients (n=62) had median (min-max) age 9.5 (3-17) years, ITP duration 2.1(0.5-10.7) years, and baseline platelet counts 18 (1-94)×10^9/L and 44% were male; 66% were Caucasian, 13% African American, and 8% Asian. For the primary endpoint, measured in the final 8 weeks after 16 weeks of dose titration, the proportions of patients with a durable platelet response were romiplostim: 52% and placebo: 10% (p<0.002). The proportions of patients with overall platelet response were romiplostim: 71% and placebo: 20% (p=0.0002), and with any platelet response were romiplostim: 81% and placebo: 55% (p=0.03). For romiplostim, the median (min-max) time to first platelet response was 4.5 (1-20) weeks and the median average weekly dose was 3.9 (0.9-8.1) μg/kg. Median platelet counts with romiplostim were ≥50×10^9/L from week 8 on. When the number of bleeding events was divided by exposure time, duration-adjusted rates per 100 patient-weeks of any bleeding (30.9 *vs* 47.3, p<0.0001), CTCAE grade ≥2 bleeding (5.9 *vs* 17.9, p=0.0006), and composite bleeding episodes, ie CTCAE grade ≥2 bleeding and/or rescue medication use (8.1 *vs* 18.4, p <0.0001), were all significantly lower with romiplostim than placebo. No patients withdrew due to adverse events (AE). Incidence rates of serious AEs (SAEs) were romiplostim: 23.8% (10 patients) and placebo: 5.3% (1 patient). SAEs with romiplostim consisted of 2 cases each of contusion, epistaxis, and headache, and 1 case each of petechiae, thrombocytosis, nephrotic syndrome, nausea, vomiting, bronchiolitis, fever, urinary tract infection, and seizure. Only one headache SAE and the thrombocytosis SAE (same patient) were considered treatment-related by the investigator. There were no thrombotic events, no malignancies observed, and no findings indicating bone marrow dysplasia or fibrosis in the only bone marrow biopsy performed (in a placebo-treated patient).

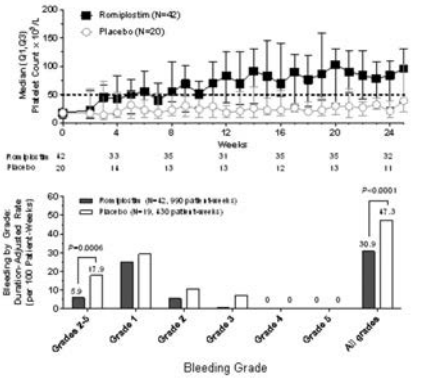

Figure 1.

Summary/Conclusions: In children with symptomatic ITP of ≥6 months duration, romiplostim was effective in inducing durable and overall platelet responses and reducing bleeding. There were no new safety signals. Romiplostim may be a treatment option for children with symptomatic chronic ITP.

P402

NEW MUTATION C.-140C>G IN 5'UTR OF ANKRD26 GENE IN PATIENTS WITH MILD FORM OF INHERITED THROMBOCYTOPENIA ASSOCIATED WITH MALIGNANCIES

S Ferrari[1,*], A Bertomoro[1], AM Lombardi[1], I Cortella[1], I Barzon[1], MC Putti[2], F Fabris[1]
[1]Department of Medicine, [2]Dipartimento di Salute della Donna e del Bambino, University of Padua, Padua, Italy

Background: The identification of ANKRD26 as the gene responsible for a mild form of inherited thrombocytopenia stimulated revealed that this disorder exposes subjects to the risk of haematological neoplasm. A similar pattern is present in subject with platelet disorder due to mutations in RUNX1 and ETV6 related familial thrombocytopenia. A recent study about paediatric inherited thrombocytopenia show a presence in the 5' UTR of ANKRD26 gene of a new mutation c.-140C>G, not previously described in the Italian population
Aims: Screening of 5'UTR of ANKRD26 gene in patients with mild form of inherited thrombocytopenia
Methods: We studied 50 patients with mild form of inherited thrombocytopenia lacking a definite genetic characterization followed at the 1st Clinical Medicine of the University City Padua Hospital. Molecular analysis in the 5'-UTR of the ANKRD26 was carried out to investigate the presence of the gene mutations.
Results: We identified 6 patients belonging three family trees and three sporadic cases with single nucleotide substitutions in the 5'-UTR region of the ANKRD26 gene: one family presented with c. -128C>G mutation, one family presented with c. -140C>G mutation, one family presented with c. -140C>G and c. -134G>A mutations, three sporadic patients presented with c. -140C>G mutation. The clinical features of the patients are mild thrombocytopenia (>90×109/l), normal mean platelet volume (MPV), autosomal dominant transmission and absence of haemorrhagic symptoms. One patient was first diagnosed as immune thrombocytopenia. Cases of malignancies registered in the subjects with mutations are breast cancer, prostate cancer, kidney cancer and acute myeloid leukaemia.
Summary/Conclusions: Thrombocytopenia with 5'UTR ANKRD26 gene mutation must be considered in case of a mild thrombocytopenia with a low bleeding tendency, associated with autosomal dominant transmission, normal platelet size and history of malignancies. This newly described pathology is very probably under diagnosed. The new mutation c. -140C>G in the 5'-UTR region of the ANKRD26 gene, recently described by Boutroux *et al.* in 2015, must be investigated in patients with these clinical features.

Background: The treatment of chronic/relapsing immune thrombocytopenia purpura (ITP) is not well established due to the lack of evidence-based data, and is particularly challenging in children who are more at risk of severe side-effects secondary to prolonged steroid therapies. Mychofenolatemofetile (MMF) is an immunosuppressor which reduces T and B-cells proliferation by inhibiting the inosine monophosphate dehydrogenase. It has been shown to be safe and effective in some series of patients with ITP, and in few cases of Evans Syndrome secondary to ALPS. In the largest reported cohort of 46 adults with ITP, 52% achieved a response, which was complete in 33%. However, data from larger group of children and details on timing of response still have to be investigated.
Aims: The aim of this study is to evaluate the outcome, timing of response and toxicity of children treated with MMF for ITP.
Methods: We collected data of children undergoing MMF treatment for ITP, with or without involvement of other cell lineages, in 8 Italian Centers. Patients showing other signs of autoimmunity or with ITP secondary to an ALPS-related disorder, defined as the presence of at least one absolute or primary additional criterion for ALPS, were included in the study. Patients with ALPS were excluded. Complete response (CR) and partial response (PR) were defined as a platelet count >/= $100x10^9$/Land >$30x10^9$/L and at least 2 fold increase of the baseline count, respectively.
Results: 56 children with primary ITP (37, 66%) or secondary to an ALPS-like disorder (19, 34%), were treated with MMF. 16/56 (28%) patients had also an Evans syndrome (ES) due to the association of leukopenia (6), autoimmune haemolytic anemia (5) or both (5). All patients but 2 who were treated as first line therapy, received MMF as second (35), third (15) or fourth (2) line treatment. 35/54 (65%) evaluable patients responded to the treatment and achieved a CR and PR in 25 (46%) and 10 (18%) cases, respectively. PR and CR were obtained after 20 (range 7-137) and 37 (range 7-192) days of treatment, respectively. 14/19 (73%), and 21/35 (60%) evaluable children with signs of autoimmunity/ALPS-like syndromeand primitive disease achieved a response, respectively. Patients with ES and with monolinear thrombocytopenia responded in13/16 (81%) and in 22/38 (58%) cases, respectively. Six out of 37 (16%) responding children relapsed at median of 283 days (range 189-1036) from the response. Four patients (7%) reported mild toxicity consisting of nausea/vomit (2), asthenia (1), skin hyperpigmentation (1) that didn't require the interruption of the treatment. Median duration of treatment and follow-up were 7 months (range 1-42,8) and 12.7 months (range 1-92), respectively.
Summary/Conclusions: To the best of our knowledge this is the largest cohort of patients treated with MMF for ITP or Evans Syndrome confirming its safe profile and showing that children seem to have a better overall response compared to what has been reported in adults, in particular a higher rate of CR. It also shows, for the first time, that MMF represents a valid option also for children with ES other than ALPS, who showed a better, although not statistically significant, response compared to the ones with monolinear thrombocytopenia. Thanks to the relatively short time of response, MMF can be considered as second-line option before the use of more aggressive and expensive treatments as Rituximab or splenectomy. Clinical trials are needed to confirm these results.

P404

SAFETY AND EFFICACY OF ELTROMBOPAG IN SPLENECTOMIZED AND NONSPLENECTOMIZED PATIENTS WITH IMMUNE THROMBOCYTOPENIA: RESULTS FROM THE EXTEND STUDY

RS Wong[1,*], J Bussel[2], A Khelif[3], A El-Ali[4], J Han[5], MN Saleh[6]
[1]Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, Hong Kong, [2]Weill Cornell Medicine, New York, United States, [3]Hôpital Farhat Hached, Sousse, Tunisia, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharmaceuticals Corporation, East Hanover, [6]The University of Alabama at Birmingham, Birmingham, United States

Background: Although splenectomy remains an appropriate treatment for ITP, it is associated with adverse events (AEs). The most recent guidelines for ITP indicate that splenectomy should be designated a second-line treatment and delayed for 6-12 months. Eltrombopag is an oral thrombopoietin receptor agonist (TPO-RA) approved in Europe for treatment of splenectomized adult chronic ITP patients who are refractory to other treatments, and as a second-line treatment for adult nonsplenectomized patients in whom surgery is contraindicated. The EXTEND study assessed long-term safety and efficacy of eltrombopag in ITP patients previously enrolled in 6-week or 6-month placebo-controlled trials.
Aims: To compare the safety and efficacy of long-term eltrombopag treatment in patients with or without splenectomy in the EXTEND trial.
Methods: Eltrombopag was started at 50 mg weekly and titrated to maintain platelet counts 50–200 Gi/L.
Results: Among patients enrolled in EXTEND (N=302), 115 splenectomized (38%) and 187 nonsplenectomized (62%) patients had similar characteristics at baseline, except that more splenectomized patients were receiving ITP medications at baseline (47% *vs* 25%) and more had a history of bleeding (23% *vs* 13%). Greater than half of both groups received eltrombopag for ≥24 months. After eltrombopag treatment, a greater proportion of nonsplenectomized patients achieved platelets ≥50 Gi/L than splenectomized ones, and was consistent by age group (Table). Nonsplenectomized patients experienced proportionately fewer serious bleeding AEs (Table). Rates of any bleeding AE were experienced by 49 (26%) and 35 (30%) nonsplenectomized and splenectomized groups, respectively. Events occurring in ≥4% of patients in the splenectomized and nonsplenectomized groups, respectively, included mouth hemorrhage (4% and 1%), epistaxis (14% and 6%), petechiae (8% and 2%), ecchymosis (2% and 4%), contusion (3% and 4%), and hematuria (2% and 4%). In each group, 13% had a sustained reduction or permanently stopped at least one concomitant ITP medication without having received any on-treatment rescue medication. Splenectomized patients had higher rates of Grade 1-4 World Health Organization bleeding at baseline (64% *vs* 52%), but rates declined in both groups over time.

Table 1. Results of the EXTEND eltrombopag study by baseline splenectomy status.

	Not Splenectomized (n=187; 62%)	Splenectomized (n=115; 38%)	Total (N=302)
Platelet count ≥50 Gi/L, n (%)			
Post-baseline	167 (89)	92 (80)	258 (85)
>50% of assessments	126 (67)	59 (51)	185 (61)
>75% of assessments	90 (48)	36 (31)	126 (42)
Platelet count ≥50 Gi/L by age group (years), n/N (%)			
18 to 49	76/87 (87)	46/62 (74)	122/149 (82)
50 to 64	58/62 (94)	36/41 (88)	94/103 (91)
≥65	33/38 (87)	10/12 (83)	43/50 (86)
Bleeding adverse events, n (%)*	(n=187)	(n=115)	(N=302)
Any event	49 (26)	35 (30)	84 (28)
Serious AEs	7 (4)	11 (10)	18 (6)
Discontinuations	1 (<1)	2 (2)	3 (<1)

*Number of patients with an event.

Summary/Conclusions: Long-term treatment with eltrombopag increased platelets in both nonsplenectomized and splenectomized patients, with numerically higher response rates in the former. Rates of AEs were similar to those in patients with splenectomy.
Funding: This study (NCT00351468) is/remains sponsored by GlaxoSmithKline; however, as of March 2, 2015, eltrombopag is an asset of Novartis AG.

P405

CHARACTERIZATION OF PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP) ENTERING REMISSION IN A ROMIPLOSTIM BONE MARROW STUDY

A Janssens[1,*], L Cervinek[2], M Tejeda Romero[3], X Wang[4], M Eisen[4]
[1]Department of Hematology, University Hospitals Leuven, Leuven, Belgium, [2]University Hospital Masaryk University, Brno, Czech Republic, [3]Hospital Juarez de Mexico, Mexico City, Mexico, [4]Amgen Inc., Thousand Oaks, United States

Background: The thrombopoietin receptor agonist romiplostim is approved for use in adults with chronic ITP. In this study, patients with ITP (N=169) had bone marrow biopsies performed at baseline and after 1, 2, or 3 years of romiplostim; 24 patients discontinued romiplostim and entered remission.
Aims: To examine remission in patients with ITP receiving romiplostim in a bone marrow study.
Methods: Patients with ITP entering the bone marrow study had a platelet count <50x109/L and ≥1 prior ITP therapy. Romiplostim, received weekly for up to 3 years, was adjusted from 1 10 µg/kg to target platelet counts of 50-200x109/L; doses were reduced for platelet counts >200x109/L for 2 consecutive weeks and no romiplostim was given for platelet counts >400x109/L. A post hoc analysis was conducted of those who entered remission, ie platelet counts ≥50×109/L for ≥6 months with no ITP therapy, including romiplostim.
Results: The median years since ITP diagnosis for those who did (N=24) and did not (N=145) enter remission (1.66 years *vs* 5.16 years) had overlapping ranges [not significant (NS)], as did the median average weekly dose (1.1µg/kg *vs* 3.5µg/kg, NS, included zero doses prior to last non-zero dose) (Table 1). Adverse events (AEs) occurred at similar rates. A *post hoc* analysis examining the association between remission and baseline factors including age, gender, platelet count, prior splenectomy, ITP duration, and number of prior treatments indicated that ITP duration ≤1 year could be a potential predictor for remission

(hazard ratio 2.46, 95% CI: 1.04, 5.79, p=0.04); however, this association could be due to multiple comparisons (ie, type I error). Median time of onset for remission was 52 weeks (range, 6-124 weeks) and median duration of remission during the study was 88 weeks (range, 29-154 weeks); 21 of the 24 patients were still in remission at the last observation on study.

Table 1.

Characteristic	Remission (N=24)	No Remission (N=145)
Women, n (%)	12 (50)	102 (70)
Age, y, median (Q1, Q3)	45.5 (31.0, 58.0)	51.0 (37.0, 64.0)
Years since ITP diagnosis, median (Q1, Q3)	1.66 (0.46, 7.75)	5.16 (1.62, 12.84)
Prior splenectomy, n (%)	7 (29.2)	53 (36.6)
Platelet count at screening, $\times 10^9$/L, median (Q1, Q3)	20.9 (7.5, 35.0)	23.0 (11.0, 35.0)
Time to first platelet response, n, weeks, median (Q1, Q3)	24, 3.5 (2.0, 14.0)	131, 2.0 (2.0, 6.0)
Treatment duration, weeks, median (Q1, Q3)	62.5 (14.1, 82.1)	155.7 (66.0, 156.0)
Average weekly dose, µg/kg, median (Q1, Q3)	1.1 (1.0, 2.2)	3.5 (1.9, 7.2)
Splenectomy on study, n (%)	0	3 (2.1)
Any treatment-related AE, n (%)	9 (37.5)	51 (35.2)
Serious AE / Treatment-related serious AE, n (%)	8 (33.3) / 0	48 (33.1) / 6 (4.1)
Fatal AE, n (%)	0	7 (4.8)
Bone marrow changes (increased reticulin ≥2 grades or collagen), n (%)	0	9 (6.2)
On-study bleeding AE, n (%)	15 (62.5)	84 (57.9)
On-study grade ≥2 bleeding AE, n (%)	4 (16.7)	34 (23.5)
On-study serious bleeding AE, n (%)	1 (4.2)	13 (9.0)

Summary/Conclusions: In this *post hoc* analysis, 14% (24/169) of patients in a romiplostim ITP bone marrow study were able to enter remission following standard dosing rules; more studies are needed to confirm whether shorter ITP duration is a predictor of remission.

P406

THE IMMUNOMODULATORY EFFECTS OF RETINIC ACID IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIA

Q Feng[1,*], M Xu[2], YX Sun[1], Y Hou[1], YY Yu[1], XH Zhang[3], M Hou[1], J Peng[1]
[1]Department of Hematology, Qilu Hospital, Shandong University, Jinan, China, [2]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, Canada, [3]Department of Hematology, Peking University People's Hospital, Beijing, China

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder in which platelets are destroyed by macrophages. Macrophages can polarize into pro-inflammatory M1 or anti-inflammatory M2 phenotypes in response to different environmental stimulation. Previous study showed that all-trans retinic acid (ATRA) combined with IL-4 induced M2 differentiation in mice. However, the effect of ATRA on macrophage polarization in ITP patients has not yet been reported.
Aims: To investigate the immunomodulatory effects of retinic acid in adult ITP patients.
Methods: Human spleens were obtained from 5 ITP patients and 5 patients with traumatic spleen rupture. The M1/M2 ratio of splenocytes was evaluated by immunofluorescence. Peripheral blood mononuclear cells (PBMCs) were isolated from 18 untreated ITP patients and 12 steroid-resistant ITP patients who were responsive to the ATRA therapy (10mg once, 3 times per day; median time to response, 63 days). Human monocyte-derived macrophages were induced and polarized into M1 or M2 by LPS plus IFN-γ or IL-4 respectively, in the presence or absence of ATRA. The phenotypes of M1 or M2 were analyzed by flow cytometry. The concentration of IL-10 and IL-12 in the culture supernatant was assayed by ELISA. CFSE-labeled $CD4^+$ or $CD8^+$ T cells were co-cultured with allogeneic M1, M2, ATRA-M1 or ATRA-M2. The proliferation of T cells and the proportion of $CD4^+CD49b^+LAG3^+$ regulatory T (Tr1) cells were analyzed by flow cytometry. The secretion of IL-12, IL-10, IL-1β, IFN-γ, IL-2, IL-4, IL-5, IL-6, TNF- a, GM-CSF and IL-18 in the co-culture supernatants were detected with ProcartaPlex assays. The expression of transcription factor cAMP response element-binding protein 1 (CREB1) was measured by RT-PCR.
Results: Our data demonstrated that there was a preferred polarization of macrophages towards M1 in the spleens of ITP patients compared with controls. In monocyte-derived macrophages induced from the 18 untreated ITP patients, the expression of M1 markers (CD80, CD86, TNF-α and IL-12) was dramatically increased and the expression of M2 markers (IL-10 and CD209) decreased compared to those from healthy controls. Macrophages induced from ITP patients displayed a higher ability to promote both $CD4^+$ T cell and $CD8^+$ T cell proliferation and a lower ability to induce Tr1 cells than those from controls. In both M1 and M2 macrophages, ATRA effectively down-regulated the expression of CD80, CCR7 and IL-12 while increased the expression of CD209 and IL-10. ATRA also inhibited the expression of CD86 and HLA-DR in M2 macrophages. ATRA-modulated macrophages (both M1 and M2) showed suppressive function on T cell proliferation compared with the untreated macrophages. Moreover, ATRA-modulated M2 macrophages expanded Tr1 cells but no effect was observed on M1. The concentration of IL-12, IL-2, TNF-α, IFN-γ and IL-1β was decreased while IL-4 and IL-10 increased in the co-culture supernatants with ATRA-modulated macrophages and T cells compared with unmodulated systems, indicating that ATRA-modulated macrophages could affect Th1/Th2 polarization by promoting Th2 responses. ATRA modulation was associated with the elevated expression of CREB1 in macrophages. *In vivo* ATRA therapy could correct the M1 deviation of macrophages and induce a M2 phenotype in the 12 steroid-resistant ITP patients.
Summary/Conclusions: Our findings demonstrate that an aberrant macrophage polarization is involved in the pathogenesis of ITP, while ATRA could correct this imbalance, thus being able to be used as a potential therapy for ITP.

P407

STUDIES ON PLATELET FUNCTION IN A GROUP OF CLL AND MCL PATIENTS TREATED WITH IBRUTINIB - PRELIMINARY RESULTS

B Sokolowska[*], D Jawniak, A Nowaczynska, A Szymczyk, E Wasik-Szczepanek, E Drab-Urbanek, W Tomczak, J Kozinska, M Hus
Department of Hematooncology, Medical University, Lublin, Poland

Background: Ibrutinib, an inhibitor of Bruton's tyrosine kinase (BTK) has a significant activity in chronic lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL). Although the treatment is well tolerated, some clinical studies reported mucocutaneous bleeding complications. Such complications may be caused by platelet or vessel abnormalities.
Aims: The aim of the study was to evaluate platelet function before and during the ibrutinib therapy.
Methods: We examined 24 patients: 21 with CLL and three with MCL (11 females and 13 males, median age 68 (48-83).The majority of patients received 420 mg Ibrutinib. Two patients received the dose of 140 mg because of atrial fibrillation. We performed platelet aggregation studies in whole blood samples using Multiplate technology, in which platelets were activated by: adenosine diphosphate (ADPtest), arachidonic acid (ASPItest), collagen (COLtest), TRAP-6 (TRAPtest). Platelet function was evaluated three times: before Ibrutinib treatment, after 1 or 2-4 months. The control group (CG) consisted of 20 healthy persons: 6 males and 14 females, median age 44(26-59).
Results: We detected statistically significant impaired platelet function [p<0.0001] in all the patients in COLtest in all points compared to the control group [CCL patients COLtest 1 Median (M) 35.41,6-75; COLtest2 M18.89, 4-35; COLtest 3 M:19.73,7-37; CG M 70.5, 49-107]. What is more, we observed exacerbation of this platelet defects during the treatment. COLtest after 2-4 months was statistically significantly diminished compared to the value before the treatment [COLtest 1: M: 35.41,6-75; COLtest 3 M: 19.73, 7-37, p=0,016]. We also detected statistically significant [p<0.0001] impaired platelet function in ADP test in all points compared to the control group (CLL patients: ADP 1median(M) 30.45; 0-74; ADP2 M: 35.11; 1-80; ADP3 M: 38.91; 6-87, CG:M: 84.5; 54-102]. In other two tests: ASPItest and TRAPtest, platelet function was statistically significantly impaired compared to the CG in all three points but a very interesting tendency appeared. The value of the third point was raised indicating some improvement in arachidonic acid and TRAP induced platelet aggregation. This tendency was the most pronounced in ASPItest but not statistically significant. We observed bleeding complications in five patients: in two patients there occurred nose bleeding, in three patients skin petechiae was reported. Platelet function in these patients was impaired, all test values were lower than in the patients without bleeding complication. However, this tendency did not achieve statistical significance. In three out of five patients lower platelet count (75-85G/l) was detected just before Ibrutinib therapy. In one patient because of atrial fibrillation a new oral anticoagulant-pradaxa was introduced causing aggravation of the skin petechiae. After diminishing the dose of pradaxa the skin changes disappeared.
Summary/Conclusions: We detected impaired platelet aggregation measured by Multiplate technology in all the patients. The impairment of collagen induced platelet aggregation was exacerbated during ibrutinib treatment. On the other hand, arachidonic acid and TRAP induced platelet aggregation tended to improve during the treatment. Only 21% of ibrutinib patients presented some mild bleeding complications.

P408

CLINICAL CHARACTERISTICS AND TREATMENT PATTERN OF NEWLY DIAGNOSED PRIMARY IMMUNE THROMBOCYTOPENIA CASES IN THE UNITED KINGDOM IMMUNE THROMBOCYTOPENIA (ADULT) REGISTRY

IU Doobaree[*], K Conway, R Nandigam, A Newland, D Provan
Haematology, Barts and the London School of Medicine and Dentistry, London, United Kingdom

Background: Primary immune thrombocytopenia purpura (ITP) is a rare autoimmune bleeding disorder. In a platelet depleted state, ITP patients present with bleeds or are at risk to bleeding. Treatment decisions may vary according to the clinical profile at presentation and patients' choice. This study sought to understand how newly diagnosed ITP patients are treated with newer treatment options becoming available.
Aims: To describe the demographic and clinical characteristics of newly diagnosed ITP patients and how these influence treatment choice.
Methods: The UK ITP Registry is a collaborative effort of 70 centres throughout the UK, coordinated at the Royal London Hospital (RLH), to permit adequate data collection on a rare disease. In this study, data collected on adults (≥18 years) up to July 2015 were analysed using various statistical techniques.
Results: A cohort of 1618 ITP patients [median age at diagnosis 49.3 (IQR 31.1, 64.2) years; 58.2% female; 76.2% European) contributed data for this

study. Age distribution at diagnosis resembled an 'M-shaped' pattern with peaks at 18 to 30 years (18%) and 50 to 70 years (17%) of age. The RLH (12.2%) and Castle Hill Hospital (6.2%) had highest recruitment. The most prevalent history of comorbidities before ITP were hypertension (16.7%), depression/anxiety (5.0%), diabetes (4.4%) osteoarthritis (4.1%) and arterial thromboembolism (4.0%). The cohort's median platelet count around diagnosis was 23.0 x10^9/L ([IQR 7-61 years]; 56.1% had platelet count <30 x10^9/L). Of those who received treatment within 3 months of ITP diagnosis, 96.9% had 1st line treatment [including prednisolone (86.1%) IVIg (34.3%), Anti-D (2.5%)], 19.8% had 2nd line treatment [including rituximab (6.3%); splenectomy (1.8%) and others (<1% to 4%)], and 11.9% had blood product transfusion [(platelet (8.8%), red blood cells (4.7%)]. Throughout the entire cohort history, common treatments were prednisolone (70.3%), IVIg (39.2%), splenectomy (12.8%), romiplostim (9.24%), Anti-D (6.5%) and eltrombopag (6.1%), whereas 19.5% had no treatment. For those with platelet counts <50 x10^9/L and bleed within 3 months of diagnosis, there was a significant association with use of both 1st and 2nd line treatment. A similar pattern of treatment was found for platelet counts ≥50 x10^9/L but to a lesser extent. Bleed from the respiratory system (*e.g.* haemoptysis), gastrointestinal system (exc. oral) and obstetric/gynaecological-related ones were associated with receiving transfusion (including platelet). The median time from ITP diagnosis to having a splenectomy was 1.4 (IQR 0.5-3.9) years; 77.1% were diagnosed below the age of 50. Fifteen individuals had this procedure within 3 months of diagnosis, of which 60% were before 2010. Over the last 2 decades there has been a decrease in the overall number of splenectomies carried out [and in relation to the year that the splenectomised patients were diagnosed (1990-99: 30.1%; 2000-09: 12.7%)], and for those diagnosed within the last five years, 4.4% had this procedure. The same time periods saw increased use of newer therapeutic agents (figure).

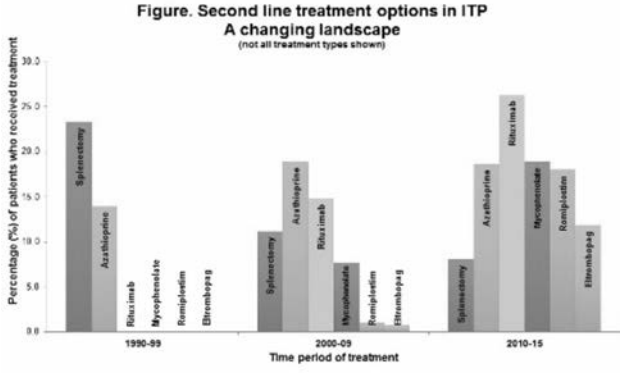

Figure 1.

Summary/Conclusions: Patients with low platelet and bleeding within the 1st three months of ITP diagnosis were likely to receive both 1st and 2nd line treatment options. Notable, is the decline of splenectomy as 2nd line treatment, while there are different drug options available. It would be important to increase the cohort size, including expanding internationally, to obtain more treatment data on higher number of patients who received 2nd line treatment options and long-term follow up data.

Coagulation - Clinical Research

P409

EFFICACY AND SAFETY OF RIVAROXABAN FOR NON-VALVULAR ATRIAL FIBRILLATION IN PATIENTS WITH SEVERE RENAL IMPAIRMENT

S Ali*, LA Wakefield, K Saja
National Health Service, London, United Kingdom

Background: Patients with atrial fibrillation and severe renal impairment (CrCL <30ml/min) were excluded from the ROCKET-AF study and, indeed, most of the seminal phase 3 DOAC studies in atrial fibrillation. However, the summary of product characteristics states that rivaroxaban may be used at a reduced dose of 15mg OD for anti-coagulation management of atrial fibrillation in patients with severe renal impairment (CrCl 15-29 ml/min). This recommendation was solely based on pharmacokinetic analyses and has not been validated in a clinical study.
Aims: Assess safety and efficacy of rivaroxaban (15mg OD) in patients with atrial fibrillation and severe renal impairment (CrCl 15 – 29 ml/min). The primary safety point is occurrence of bleeding complications.
Methods: Retrospective cohort analysis of 30 patients with non-valvular atrial fibrillation and severe renal impairment who were commenced on rivaroxaban (15mg OD) in our anti-coagulation clinic between October 2012 and March 2015. Medical notes were reviewed and general practitioners were contacted by telephone or fax. Information collected included age, weight, CHA2DS2-Vasc and HAS-BLED scores, baseline blood investigations (CrCl, FBC, LFT and clotting screen) and where available blood investigations at the time of the bleeding event.
Results: A total of 30 patients were retrospectively followed up for a minimum of 10 months. The majority of patients were female (83.3%) with a median age and weight of 89.5 years and 54 kilograms respectively. Median CHA2DS2-Vasc score was 5, giving an estimated annual stroke risk of 6.7%, and approximately 76% of patients had a HAS-BLED score ≤2. Creatinine clearance was calculated using the Cockcroft-Gault formula, and the median CrCl was 26.39 ml/min. During the follow up period, 11 patients died (37%), one of whom died of massive gastrointestinal bleeding after being switched from rivaroxaban to warfarin due to worsening renal function. The cause of death for one patient could not be obtained, however there were no documented deaths due to rivaroxaban as a primary or contributing cause. A total of 6 rivaroxaban related bleeding events were identified with two events occurring in one patient. Bleeding sites included nasal (epistaxis), gastro-intestinal and genitourinary tracts but there were no incidents of intracranial haemorrhage or major bleeding as defined by the International Society on Thrombosis and Haemostasis. A patient who discontinued rivaroxaban due to haematuria later developed acute limb ischemia requiring embolectomy. Although compliance to treatment could not be assessed, a further patient developed an ischemic stroke whilst on rivaroxaban.
Summary/Conclusions: Clinically relevant bleeding events occurred in approximately 17% of our small cohort of very elderly patients with severe renal impairment receiving rivaroxaban (15mg) as anti-coagulant therapy for non-valvular atrial fibrillation. The event rate is almost identical to that in the Rocket-AF study (16.7%) and there were no major bleeding events. Our findings indicate that the use of rivaroxaban in this group of patients is feasible and relatively safe.

P410

ORAL DIRECT ANTICOAGULANTS IN THE TREATMENT OF NONVALVULAR ATRIAL FIBRILLATION. RESULTS OF THE DAILY CLINICAL PRACTICE

B Perez Villardon[1,*], AM Garcia Bellon[2], C Jimenez Rubio[1], A Rubio Alcaide[1], L Perez Benito[1], MA Ramirez Marrero[2], M De Mora Martin[2], E De Teresa Galvan[3]
[1]Cardiology, Hospital Comarcal Axarquia, Velez-Malaga, [2]Cardiology, Hospital Regional Carlos Haya, [3]Cardiology, Hospital Clinico Universitario Virgen de la Victoria, Malaga, Spain

Background: Atrial fibrillation (AF) is the most common arrhythmia. It leads to significant morbidity and mortality. The new oral anticoagulants (NOAC) represent an improvement compared with standard treatment (vitamin K antagonists (AVK)) in the prevention of thromboembolic complications in patients with non-valvular AF.
Aims: The aim of this study is to analyse the clinical characteristics of the patients (p) anticoagulated with NOAC and compared these with those taking AVK, as well as to assess their effectiveness and safety. The primary study outcome was the composite of stroke, systemic embolism, pulmonary embolism, myocardial infarction or death (MACE). The primary safety outcome was major haemorrhage.
Methods: We studied 688 p with a diagnosis of NVAF between November-2011 and November-2014. We made a prospective analysis, with a median follow-up of 14 months.
Results: A total of 688 p were included with a mean age of 73.4±7.9 in the AVK group *vs* 73.9±8.3 in the NOAC group (p=0.432). In the NOAC group,

hypertension was significantly more common (82.3% *vs* 92.2%, p<0.001), with more frequent history of heart failure (15.3% *vs* 30.4%, p<0.001), and more history of stroke or transient ischemic attack (10% *vs* 15.9%, p=0.022). Mean scores for thromboembolic and bleeding risk indices are shown in Table 1.

Table 1.

SCORE	ACENOCOUMAROL	NOAC	p
CHADS2	1.9±1.0	2.3±1.1	P<0.001
CHA2DS2VASc	3.5±1.3	3.9±1.5	P<0.001
HASBLED	1.3±0.7	1.4±0.7	P=0.086

The primary outcome occurred in 12 p receiving AVK (2.9%) and 11 p receiving NOAC (4.1%) (p=0.413) (HR acenocoumarol *vs* NOAC 1.737; IC 95%: 0.760-3.969, p=0.190). MACE were more common in patients with poor INR control (58.3% *vs* 41.8%, p=0.037). In the univariate analysis, the factor associated with MACE in the AVK group was the poor INR control (4.009 (1.266-12.696), p=0.018), showing the sex female category a strong trend to be a protective factor (0.228 (0.050-1.043), p=0.057). In the NOAC group, valvulopathy ≥moderate (3.840 (1.166-12.652), p=0.027) and renal insufficiency (7.197 (1.743-29-772), p=0.006) were significantly associated with MACE. The rate of major bleeding was 3.51% with AVK, as compared with 0.6% per year in the group that received NOAC (17 events -4.1% >vs. 2 events, 0.7%, p=0.009) (figure 1; HR acenocoumarol *vs* NOAC 0.252; IC 95%: 0.058-1.101, p=0.067). In the univariate analysis, the factors associated with bleeding in the AVK group were age ≥75 years (3.187 (1.028-9.882), p=0.045) and HASBLED score (2.106 (1.072-4.136), p=0.031). The rate of intracranial bleeding was 1.02% with AVK compared with 0.34% per year in NOAC group (5 events – 1.2% *vs* 1 event – 0.4%, p=0.248). There were no significantly differences in the rates of gastrointestinal bleeding (1.02% with AVK *vs* 0.94% per year, p=0.902) neither minor bleeding (4.88% with AVK *vs* 3.51% per year, p=0.309). There was a significantly higher rate of discontinuation with AVK (17.14% *vs* 6.68% per year, p<0.001).

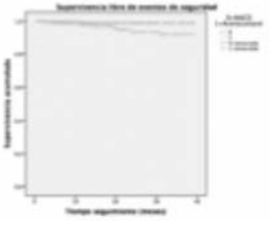

Figure 1.

Summary/Conclusions: Patients with NVAF anticoagulated with NOAC have higher embolic risk than those that receive acenocoumarol. No differences were found in efficiency. Patients anticoagulated with NOAC show a trend to lower bleeding risk. In the multivariate analysis, the predictors of events in the acenocoumarol group were the male category, poor INR control, ≥75 years, anemia and HASBLED score. The predictors of events in the NOAC group were valvulopathy≥moderate, renal insufficiency and anaemia.

P411

SWITCH FROM VKA, LMWH OR FONDAPARINUX TO DOACS IN THE CLINICAL PRACTICE

F Cortiula*, U Venturelli, A Bertone, G Barillari
University Hospital of Udine, Center for Hemorrhagic and Thrombotic Diseases, Udine, Italy, Udine, Italy

Background: New oral anti-coagulant drugs (NOACs) are largely used both in AF (Atrial Fibrillation) and in VTE (Venous Thromboembolism) and, due to their important advantages over older drugs, many patients have been switched from VKA (Vitamin K antagonists), LMWH (Low Molecular Weight Heparin) or Fondaparinux to NOACs. Current recommendations by scientific society suggest switching from VKAs to NOACs according to the INR test result. Regarding how to switch from Fondaparinux or LMWH to NOACs the suggested wash out period is 24 hours.
Aims: Evaluate safety and efficacy of switching anticoagulant therapy from old to new anticoagulant drugs without monitoring the INR. Safety outcomes were major and minor bleeding rate. Effectiveness outcomes were VTE events. We also evaluate the tolerability of the new treatment.
Methods: We switched patients, affected by AF or DVT, from VKAs or LMWH or Fondaparinux to NOACs regardless from the INR. We follow current recommendations for switching from LMWH and Fondaparinux; we applied to the VKAs-DOACs switch the same schedule prescribed by current guidelines for bridging therapy from VKAs to LMWH. Therefore, we began the NOACs treatment after 24 hours since the last previous anticoagulant intake, if the patient has been switched from LMWH, Fondaparinux or Acenocumarol. We began the NOACs treatment after 48 hours if Warfarin was the patient's therapy. We checked the platelet count and the Creatinine Clearance collecting these laboratory measurements within 30 days before the end of VKA treatment. We collected outcomes measures until 30 days from the switch. Data are presented as mean±standard deviation (SD).
Results: We enrolled in the present study 603 patients: 458 have been switched to NOACs from VKAs, 101 from LMWH and 44 patients from Fondaparinux. 179 patients were affected by AF and 424 by VTE. Thirty days after the switching 99% of the patients were still on NOACs. Three patients complained about nausea, dyspepsia and abdominal pain. Two of them came back to VKAs and one patient change Rivaroxaban with Apixaban, without further side effects. Two patients reported minor bleedings: gingival hemorrhage and hematuria. One of them remained on NOACs treatment and another switch to acetylsalicylic acid. There were no VTE recurrence and no bleedings in the whole cohort.

Table 1.

Population	n	Age (y)	ClCr (ml/min)	CHA2DS2-VASc	HAS-BLED	Major Bleeding	Minor Bleeding	TEV recurrences
AF (from VKA)	179	75.3±7.4	69±29	4.5	3	0	0	0
VTE	424	62.5±15.3	84.4±31.3	/	/	0	2(0.0047%)	0
p value		<0.00001	<0.00001				0.85	
from VKA	279	62.7±15,1	83.8±31	/	/	0	0	0
from LMWH	101	63.1±14.2	86.2 ± 32	/	/	0	1(0.001%)	0
from Fondaparinux	44	58.8 ±18.3	83.3 ± 26.6	/	/	0	1(0.022%)	0
p value		0.25	0.81	/	/		0.37	

Summary/Conclusions: Safety and efficacy of switching anticoagulant therapy in our center are really satisfying compared to the studies that closely monitored INR to adjust anticoagulant therapy switching, suggesting that monitoring INR may not be routinely needed for the switch. Further studies are needed to confirm these findings.

P412

HIGH HEMOGLOBIN CONCENTRATIONS AND RISK OF THROMBOSIS: CAUSALITY OR CONFOUNDING?

S Rögnvaldsson[1,*], SH Lund[1], M Hultcrantz[2,3], G Eiríksdóttir[4], TB Harris[5], V Guðnason[4], SY Kristinsson[1,2,6]
[1]Faculty of Medicine, University of Iceland, Reykjavík, Iceland, [2]Dept. of Hematology, Karolinska Institutet, Uppsala, Sweden, [3]Myeloma Service, Dept. of Medicine, Memorial Sloan Kettering Cancer Center, New York, United States, [4]The Icelandic Heart Association, Kópavogur, Iceland, [5]Laboratory of Epidemiology and Population Science, National Institute on Aging, Bethesda, United States, [6]Dept. of Hematology, Landspítali University Hospital, Reykjavík, Iceland

Background: Patients with polycythemia vera are known to have an increased risk for thrombotic events. This effect has also been observed among those with high as well as low concentrations of hemoglobin (Hgb) in the general population. However many of the earlier studies lack sufficient clinical data to account for underlying disease or causes of high Hgb.
Aims: To assess whether high concentrations of Hgb is an independent risk factor for thrombotic events.
Methods: Hgb measurements and baseline characteristics were obtained from participants in the Reykjavik-AGES study at enrollment in 2002. The Reykjavik-AGES study, a nationwide screening study of 5755 elderly individuals, includes thorough medical history, physical examination, and blood measurements. Lifetime incidents of thrombotic events were recorded up to 2015 in the Icelandic National Health Service and linked to the participants of the study through the National Registry. Primary outcomes of arterial and venous thrombosis were considered separately 10 years before and after enrollment. Hgb measurements at enrollment were used to determine exposure, both as a continuous variable in steps of 10g/L and stratified into five strata (<130, 130-144,145-159,160-175 and >175g/L for men and <120, 120-134,135-149,150-159, >160g/L for women). Men with Hgb concentrations of 120-144g/L and women with Hgb concentration of 120-134g/L were used as reference. Cox proportional hazard regression was used for the statistical analyses and adjusted for confounders (gender, age, body mass index (BMI), diabetes mellitus, smoking, hypertension, and statin use) in three different models.
Results: Analysis of Hgb concentration as a continuous variable in steps of 10 g/L revealed increased risk of arterial and venous thrombosis with increasing Hgb concentration (hazard ratio (HR) 1.06 95% confidence interval (CI) [1.04-1.09] p<0.001 and HR 1.08 95% CI [1.05-1.106] p<0.001). Adjustment for confounders revealed a reverse effect (HR 0.92 95% CI [0.89-0.94] p<0.001 and HR 0.89 95% CI [0.87-0.92] p<0.001). After excluding anemic patients (Hgb <130g/L for men and <120g/L for women) there was however, no association (Table 1). Crude analysis, using stratified Hgb levels, revealed increased risk of arterial and venous thrombosis associated with high Hgb (Hgb: 160-175g/L for men and 150-159g/L for women. HR 1.10 95% CI [1.02-1.20] p=0.02 and HR 1.17 95% CI [1.07-1.29] p<0.001). After adjusting for gender, age, and BMI, this association was no longer evident. There was however marginally increased risk of venous thrombosis in those with slightly higher Hgb concentrations than the reference group (Hgb: 145-

159 g/L for men and 135-149 g/L for women. HR 0.91 CI [0.85-0.98] p=0.01). Anemic participants had a decreased risk of both arterial and venous thrombosis (HR 0.76 CI [0.70-0.83] p<0.001 and HR 0.74 CI [0.68-0.81] p<0.001) (Table).

>175/>160 (n=14)	0.95 [0.74-1.22]	0.92 [0.72-1.18]	0.89 [0.68-1.17]	0.85 [0.65-1.12]

*: <0.05, **: <0.01, ***: <0.001, Hgb: hemoglobin
Model 1: Adjusted for gender, age and BMI
Model 2: Adjusted for gender, age, BMI, diabetes, pack years, hypertension and statin use
Model 3: Censored at diagnosis of malignant neoplasm and adjusted for gender, age, BMI, diabetes, pack years, hypertension and statin use

Summary/Conclusions: In this large population based cross sectional cohort study, including detailed clinical information on elderly individuals, we observed that high concentrations of Hgb were not associated with risk of thrombosis after adjusting for confounding factors. Furthermore, we found that low concentration of Hgb was associated with a lowered risk of thrombosis. This is contradictory to many of the previous studies done with less extensive clinical data and suggests that previous studies expressed association by confounding rather than causality.

P413

HEMOSTATIC BIOMARKERS BASED PREDICTIVE MODEL FOR METASTATIC DISEASE, PROGRESSION AND MORTALITY IN CANCER PATIENTS

E A Beleva[1,*], T Deneva[2], S Stoencheva[2], V Popov[1], Z Grudeva-Popova[1]
[1]Division of Medical Oncology, Department of Clinical Oncology, Medical Faculty, [2]Department of Clinical Laboratory, Faculty of Pharmacy, Medical University - Plovdiv, Plovdiv, Bulgaria

Background: Hemostatic factors have been implicated as effectors in key processes of tumor biology. Exploratory clinical studies of plasma hemostatic components as potential tumor biomarkers with putative predictive and prognostic potential could provide useful information for monitoring of cancer patients and justifying novel anti-tumor strategies.
Aims: To determine the predictive utility of TF-dependent microparticle activity (MPTF), tissue factor antigen (TFAg), angiopoietin-2 (ANG-2) and soluble urokinase activator receptor (suPAR) for metastatic disease at onset, disease progression and death in cancer patients undergoing chemotherapy.
Methods: MPTF, TFAg, ANG-2 and suPAR were measured in 128 patients with various cancer types and in 82 healthy controls. MPTF was determined with the Zymuphen MPTF kit; TFAg, ANG-2 and suPAR were measured by ELISA. Conventional coagulation parameters: thrombin time, prothrombin time, fibrinogen and mean platelet volume were determined and VTE score calculated for all patients as well. Patients were followed up prospectively for two years (2013-2015) from chemotherapy initiation until metastatic progression and/or death. Predictive value of the tested variables, including age and sex, was analyzed by retrograde logistic regression. The study has been IRB approved and written informed consent was obtained from all participants.
Results: MPTF activity was significantly decreased in cancer patients compared to controls, while TFAg levels, ANG-2 and suPAR were significantly elevated, p<0.0001. There was no significant association of MPTF, TFAg, ANG-2 with any of the VTE risk groups, however suPAR levels correlated significantly with VTE score (ρ=0.235, p<0.05). Significant predictor variables were determined by logistic regression and the final model included VTE score, MPTF, TFAg, ANG-2 and suPAR. The model tested significant regarding its ability to determine presence of metastatic disease at onset (χ=16.779, p=0.01), disease progression (χ=14.347, p=0.026) and death (χ=17.282, p=0.008). Elevated levels of ANG-2 are associated with increased probability of metastatic disease (OR_{ANG-2}=15.795, p=0.041), TFAg levels are associated with higher probability of disease progression (OR_{TFAg}=1.224, p=0.03), VTE score is associated with mortality (OR=13.488, p=0.041).
Summary/Conclusions: The probability of primary metastatic disease, progression of disese and death in cancer patients increases with higher VTE score, elevated levels of TFAg, ANG-2, suPAR and decreased MPTF procoagulant activity.

P414

ANNEXIN A5 M2 HAPLOTYPE: TO BE OR NOT TO BE, THAT'S THE QUESTION!

R Tenreiro[1,*], AL Pinto[1], Â Rodrigues[2], P Martinho[1], T Fidalgo[1], C Godinho[2], C Barata[2], R Salvado[1], L Ribeiro[1]
[1]Hematology Department, Cento Hospitalar e Universitario de Coimbra, [2]Obstetrics Department, Maternidade Bissaya Barreto - Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Hereditary thrombophilias are known to impair placental function and cause adverse pregnancy outcomes (APO) such as recurrent pregnancy loss, pre-term labour, intrauterine growth restriction or small for gestacional age newborns. Mutations in blood coagulation factors II and V, alterations in protein C and its co-factor protein S are commonly accepted as hereditary thrombophilias. Furthermore alterations resulting in reduced fibrinolysis have also been associated with APOs. More recently conflicting data on the possible involvement of M2 Annexin A5 (ANXA5) haplotype have been published, with evidence that supports its involvement in embryonic-induced anticoagulation. So far consensus on its role in APO has not been achieved.
Aims: Assess the presence of M2 ANXA5 haplotype in a population of women with a previous history of APO.
Methods: Retrospective case-control study including women referred to the Pregnancy and Thrombophilia Consultation in our Center, between January 2012 and May 2015, with a previous history of APO including recurrent miscarriages (early and late), fetal death, pre-eclampsia and HELLP syndrome. Detailed previous medical history was reviewed. Patients with hereditary thrombophilias, antiphospholipid syndrome or autoimmune diseases were excluded. The genotyping for the presence or absence of carriage of the M2 ANXA5 promoter haplotype was assessed. The possible relationship between M2 and APO was evaluated by comparing our case-group with two independent control groups. Odds ratio (OR) with 95% confidence intervals (CI) and chi-squared tests were calculated. Statistical significance was defined as p<0.05.
Results: The case group included 110 women with a previous history of unexplained APO. They had a mean (range) age of 33.2 years (17-41), median gravidity of 2 (0-7) and median parity of 1 (0-2). Forty-nine women had experienced a total of 108 pregnancy losses (median 2, range 1-5), 91% in the first trimester. Cardiovascular (CV) risk factors were distributed as follows: smoking habit 12.7% (n=14), dyslipidemia 10.9% (n=12), hypertension 2.7% (n=3), only 1 had previous history of diabetes. Mean body mass index (BMI) was 24.62±3.98 kg/m^2. All but one were Caucasians. Eight patients had prior history of thrombotic events (75% venous events). Presence of M2 ANXA5 promoter haplotype was observed in 30% (n=33) of our case group individuals. When comparing our case group with a general control population we found statistically significant association between the presence of M2 haplotype and the presence of unexplained APO (OR 2.35, 95% CI 1.47-3.77; p<0.001). When comparing with a group of fertile female controls we also found a significant association (OR 4.80, 95% CI 2.86-8.05; p<0.0001). No other differences in age, BMI, CV risk factors were identified when comparing carriers of M2 *versus* non-carriers. No association between carriage status for M2 haplotype and subtype of APO was identified.
Summary/Conclusions: A higher frequency of the M2 ANXA5 haplotype was found in our case group when compared with two independent control populations, suggesting a possible relationship between this specific genotype and unexplained APO. Genotyping ANXA5 M2 status seems to be a well oriented approach in the diagnostic of a subset of women with unexplained APO.

P415

IRON METABOLISM IN PATIENTS WITH PORTAL THROMBOSES

E Lukina*, A Dezhenkova, E Sysoeva, K Lukina
Department of Orphan Diseases, National Research Center for Hematology, Moscow, Russian Federation

Background: Portal thrombosis (of portal, splenic or superior mesenteric vein) is the most common cause of prehepatic portal hypertension. Bleedings from esophageal and/or gastric varices are the frequent complication of prehepatic portal hypertension. Posthemorrhagic anemia is diagnosed in 58% of patients with prehepatic portal hypertension and is usually considered to be an indication for iron therapy.
Aims: To study iron metabolism in patients with prehepatic portal hypertension due to portal thrombosis and recurrent bleedings from esophageal and/or gastric varices.
Methods: The study group included 70 patients (31 males and 39 females aged from 22 to 73 years, median age 45 years) with prehepatic portal hypertension and portal thromboses diagnosed by abdominal Doppler ultrasonography or computed tomography. Thirty seven patients (53%) of the study group

had recurrent bleedings from esophageal and/or gastric varices. Patients were divided into 2 groups based on the results of hematological examination (blood count and bone marrow morphology): 43 patients with chronic myeloproliferative disorders and 27 patients with cytopenias associated with other disorders (antiphospholipid syndrome, paroxysmal nocturnal hemoglobinuria, inherited thrombophilia). The following parameters were studied to characterize iron metabolism: ferritin, transferrin, iron concentration and total iron binding capacity. In patients previously treated with iron parameters of iron metabolism were investigated not less than 2 weeks after termination of iron therapy.
Results: Anemia was revealed in 34 (48%) patients of the study group. Only 4 (12%) patients with anemia had laboratory signs of iron deficiency. Other 30 (88%) patients with anemia had laboratory signs of functional iron deficiency, which is a key feature of anemia of chronic disease. All patients of the study group were divided in 2 groups: 1) patients who received iron therapy in the past (34 patients) 2) patients who never received iron treatment (36 patients). Frequency of new thrombotic events (*i.e.*, pulmonary embolism, mesenteric thromboses, arterial thromboses, thromboses of jugular vein, myocardial infarction, transient ischemic attack) or portal rethromboses was 35% in the first group of patients and 6% - in the second group. Frequency of recurrent bleedings from esophageal and/or gastric varices was 79% in the first group of patients and 28% - in the second group.
Summary/Conclusions: 88% of pts with prehepatic portal hypertension due to portal thrombosis had anemia of chronic disease. Iron therapy in such patients was associated with higher incidence of new thrombotic events or portal rethromboses and recurrent bleedings.

P416

PERIPHERALLY INSERTED CENTRAL VENOUS CATHETER-RELATED VENOUS THROMBOSIS IN PATIENTS WITH HEMATOLOGICAL DISEASES

A Boban[1,*], D Dujmovic[1], A Ostojic[2], S Zupancic-Salek[3], D Pulanic[3], I Aurer[1], S Basic-Kinda[2], R Serventi-Seiwerth[2], R Vrhovac[1], N Durakovic[1], D Sertic[2], D Nemet[3]
[1]Division of Hematology, Department of Internal Medicine, Medical School, University Hospital Center Zagreb, [2]Division of Hematology, Department of Internal Medicine, University Hospital Center Zagreb, [3]Division of Hematology, Department of Internal Medicine, Medical School, University Hospital Center Zagreb, Faculty of Medicine Osijek, Zagreb, Croatia

Background: The use of peripherally inserted central venous catheters (PICCs) has been markedly increased during the last decade due to their advantages over conventional central venous catheters, such as a reduced risk of complications during insertion and durable venous access. These characteristics make PICC suitable for use in patients with hematological malignancies. Catheter-related deep venous thrombosis (DVT) has been described as the late complication of PICC. The incidence of PICC-related DVT in patients with hematological disorders is however unknown.
Aims: The aim of this study was to establish the risk factors and evaluate the incidence of the PICC-related DVT in patients with hematological disorders.
Methods: We performed a retrospective cohort study evaluating the thrombotic complication of PICCs placed in a single center between 2011 and 2015 to the patients with hematological malignancies or aplastic anemia with the need of the prolonged venous access. Symptomatic catheter-related DVT was determined by Doppler ultrasound. The following information was retrieved for each patient: type of disease, therapy applied through PICC, serum creatinine level, hemoglobin (Hb) level, white blood counts (WBC) and platelet (Plt) number at the time of PICC placement, and position of the tip of the catheter determined by the chest x-ray. All data were retrieved from the medical records.
Results: A total of 182 patients (104 men/78 women, median age of 50,2 years (range 17-82)) with hematological disorders were included, with 201 catheters and total of 27056 catheter-days. 163 patients had one, and 19 patients had two catheters inserted. Hematological disorders included 53 acute myeloid leukemias, 35 acute lymphoblastic leukemias, 63 malignant lymphomas, 9 multiple myelomas, 9 aplastic anemias and 13 patients in the miscellaneous group consisting of chronic myeloid leukemia, chronic lymphoid leukemia, chronic myelomomocyctic leukemia and osteomyelofibrosis. Indication for the PICC placement included necessity for venous access due to the need for a long-term chemotherapy (129 catheters) and supportive treatment in case of difficult venous access (72 catheters). The incidence of PICC-related venous thrombosis was 11,9% (0,88/1000 PICC days). The median duration form insertion to diagnosis of catheter-related thrombosis was 17 days (range 1-241), with 45% of the events described within the first 7 days from the PICC insertion. WBC count and catheter malposition were found as significant risk factors for PICC-related DVT (p=0,007 and 0,008, respectively) in univariate analysis and only catheter malposition in multivariant analysis (p=0,002, OR 4,37, CI 95% 1,69-11,33).
Summary/Conclusions: The study found catheter-related DVT as important complication of PICC in patients with hematological malignances. Also, catheter malpositioning was identified as s significant risk factor for developing thrombosis. Moreover, our study speaks in favor of the hypothesis suggesting that thrombogenicity of PICC could be related to endothelial injury and phlebitis following the insertion of the catheter, since almost 50% of thrombosis happened within the first seven days from the catheter placement. This study highlights the need of vigilant evaluation of thrombosis risk previous to PICC insertion in patients with malignant hematological diseases and careful monitoring of the patient during the first week of the catheter dwelling. Also, better clinical outcomes could be achieved by recognition of the catheter malposition, and the correction of its position.

P417

EQUATIONS FOR ESTIMATING GFR: COMPARING RENAL FUNCTION CATEGORISATION IN THE CATCH STUDY

MS Janas[1,*], LC Hiort[1], R Bauersachs, on behalf of the CATCH Investigators[2]
[1]LEO Pharma, Ballerup, Denmark, [2]Department of Vascular Medicine, Darmstadt Hospital, Darmstadt, Germany

Background: The CATCH study was a randomized, multicenter study (NCT01130025) of 900 patients comparing tinzaparin 175 IU/kg once daily with dose-adjusted warfarin for 6 months in patients with active cancer and acute, symptomatic venous thromboembolism. Only patients with very severe renal impairment at baseline (estimated glomerular filtration rate [eGFR] below 20 mL/min) were excluded from the study. Over time, the recommendations for estimating renal function have changed, reflecting that improved tools for screening for renal impairment have been developed and validated in broader patient populations. These tools have further standardized the estimation of renal function, as they are based on results from isotope dilution mass spectrometry (IDMS) standardized assaying of serum creatinine.
Aims: To compare three different validated equations for estimating renal function in a population of patients with cancer-associated thrombosis, older age and multiple ethnicities.
Methods: eGFR was evaluated in a patient population with cancer-associated thrombosis. Creatinine was determined at baseline, and monthly during the 6-month study. All samples were analyzed centrally using a validated (IDMS) assay. Renal function was estimated using three different equations: the Modification of Diet in Renal Disease (MDRD) study equation, the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation and the Cockcroft-Gault (CG) equation, using SI units only.
Results: During the CATCH study, 5238 samples were taken from which eGFR could be calculated in 896 patients. Mean age was 59 years; 40% were male; 55% had metastatic cancer at baseline; 53% received anticancer treatment at any time during the study. The racial distribution was: 50% White, 34% Asian, 2% Black, 14% Multiple or Other. The equations provided largely consistent findings when eGFR estimations were below 60mL/min, with an overall agreement between MDRD and CKD-EPI of 97%, between MDRD and CG: 88%, and between CKD-EPI and CG: 89%. The CKD-EPI and MDRD equations had similar results in eGFR range 60-90 mL/min, but whereas MDRD had eGFR estimations ranging up to 350 mL/min, CKD-EPI yielded no eGFR estimations beyond 200mL/min. When MDRD and CKD-EPI were compared with CG, the eGFR above 60 mL/min varied to a much higher degree (Fig. 1). The MDRD/CG comparison covered ranges up to 350–400 mL/min, whereas the CKD-EPI/CG comparison tapered off, limited by CKD-EPI not yielding any values above 200mL/min. Categorisation of severe renal impairment (eGFR below 30 mL/min) differed in only four samples (0.1%) when comparing MDRD and CKD-EPI, whereas when these were compared with CG, 63 and 64 samples (1.2%), respectively, were discrepant.

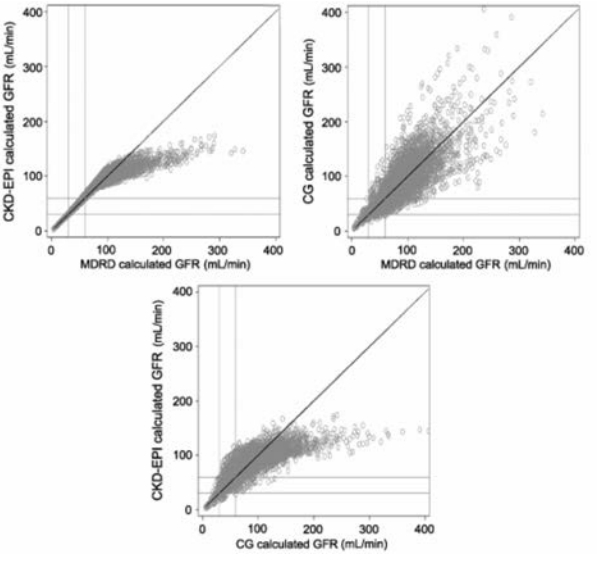

Figure 1. Scatter plots to show the comparsion of equations for estimating renal function, including x=y reference line.

Summary/Conclusions: Overall, there was a strong agreement between MDRD and CKD-EPI for estimating renal function when eGFR estimations were below 60 mL/min. Estimating the eGFR using CG yielded results that diverged to a greater degree from both MDRD and CKD-EPI. CKD-EPI had an added limitation of yielding no eGFR estimations above 200mL/min.

LB418

IMPACT OF CAPLACIZUMAB TREATMENT ON MORTALITY AND MAJOR THROMBOEMBOLIC EVENTS IN ACQUIRED TTP: PHASE II TITAN STUDY RESULTS

F Peyvandi[1], M Scully[2], JA Kremer Hovinga[3], P Knöbl[4], S Cataland[5], K De Beuf[6], F Callewaert[6], H De Winter[6], RK Zeldin[6,*]
[1]Angelo Bianchi Bonomi Hemophilia and Thrombosis Center, IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy, [2]Department of Hematology and the National Institute for Health Research Biomedical Research Centre, University College London Hospital, NHS Foundation Trust and University College London, London, United Kingdom, [3]University Clinic of Hematology & Central Hematology Laboratory, Inselspital, Bern University Hospital and the University of Bern, Bern, Switzerland, [4]Medical University of Vienna, Department of Medicine 1, Div. Hematology and Hemostasis, Vienna, Austria, [5]Department of Internal Medicine, Ohio State University, Columbus, United States, [6]Ablynx Nv, Zwijnaarde, Belgium

Background: Acquired thrombotic thrombocytopenic purpura (TTP) is a potentially life-threatening thrombotic microangiopathy in which aggregation of platelets to von Willebrand Factor (vWF) leads to profound thrombocytopenia, hemolytic anemia, and systemic microvascular thrombosis. In spite of treatment with plasma exchange and immunosuppression, the current standard of care, mortality from an episode of acquired TTP is approximately 20% and patients remain at risk for thrombotic complications until remission is achieved[1]. Caplacizumab is an anti-vWF Nanobody® in development for the treatment of acquired TTP. The efficacy of caplacizumab in conjunction with standard of care in reducing the time to confirmed platelet count normalization was demonstrated in the Phase II TITAN study of patients with acquired TTP[2].
Aims: To report the results of a post-hoc analysis which assessed the impact of treatment with caplacizumab on the incidence of major thromboembolic events during the study drug treatment period and the incidence of TTP-related mortality during this Phase II study.
Methods: The occurrence of treatment-emergent major thromboembolic adverse events was investigated in the Phase II clinical study database, using the Standardized MedDRA Query (SMQ) for 'embolic and thrombotic events'. The proportion of subjects with at least one of these events together with the total number of events were summarized and reported per treatment group. Transient episodes were not considered major thromboembolic events and were, therefore, not included in this analysis. TTP-related mortality during the study was evaluated based on adverse events reporting, with relatedness to TTP as judged by the Investigator.
Results: The safety population consisted of 35 caplacizumab-treated and 37 placebo-treated subjects. Four major thromboembolic events were reported in 4 subjects in the caplacizumab group (1 pulmonary embolism and 3 TTP exacerbations). In the placebo group, 20 major thromboembolic events were reported in 14 subjects (2 acute myocardial infarctions, 1 ischemic and 1 hemorrhagic stroke, 1 pulmonary embolism, 1 deep vein thrombosis, 1 venous thrombosis and 13 TTP exacerbations). Two TTP-related deaths occurred during the study, both in the placebo treatment group (causes of death: refractory TTP and cerebral hemorrhage). In total, 11.4% of caplacizumab-treated subjects *versus* 43.2% of placebo-treated subjects experienced one or more thromboembolic events or died (Table 1).

Table 1. Treatment-emergent major thromboembolic events during the treatment period and overall TTP-related mortality in the Safety Population of the Phase II TITAN study.

	Caplacizumab (N=35)			Placebo (N=37)		
	# Events	# Subjects	% of subjects	# Events	#Subjects	% of subjects
Embolic and thrombotic events (SMQ)						
Acute myocardial infarction	0	0	0	2	2	(5.4%)
Deep vein thrombosis	0	0	0	1	1	(2.7%)
Venous thrombosis	0	0	0	1	1	(2.7%)
Pulmonary embolism	1	1	(2.9%)	1	1	(2.7%)
Ischemic stroke	0	0	0	1	1	(2.7%)
Hemorrhagic stroke	0	0	0	1	1	(2.7%)
Thrombotic thrombocytopenic purpura [1]	3 [2]	3 [2]	(8.6%)	13	11	(29.7%)
TTP-related mortality						
Deaths related to TTP	0	0	0	2	2	(5.4%)
TOTAL	4	4 [3]	(11.4%)	22	16 [3]	(43.2%)

[1] this preferred term consisted of recurrences of TTP during the treatment period, defined in the protocol as exacerbations of TTP
[2] one adverse event reported as 'Thrombocytopenia' was not considered in this analysis, as this event was reported as part of the presenting disease
[3] a subject may have experienced more than one event

Summary/Conclusions: Compared to subjects who received placebo and standard of care treatment, a lower proportion of those treated with caplacizumab and standard of care had one or more major thromboembolic adverse events or died. The results of this post-hoc analysis suggest that treatment with caplacizumab has the potential to reduce the significant morbidity and mortality associated with acquired TTP. A phase III confirmatory study is ongoing and will include a prospectively defined assessment of this clinically meaningful endpoint.

Background: Red blood cell (RBC) transfusion support is standard of care in the majority of patients with myelodysplastic syndromes (MDS). Despite that, there is a dearth of information regarding its impact on patient quality of life (QoL).
Aims: The main objective of this study was to investigate the burden of transfusion dependency, by comparing patterns of QoL over time between transfusion dependent (TD) *versus* transfusion independent (TI) patients.
Methods: Analysis is based on 280 newly diagnosed IPSS intermediate-2 or high risk (*i.e.*, higher risk) MDS patients who were consecutively enrolled in an international prospective cohort observational study. Quality of life was assessed at baseline (*i.e.*, before treatment) with the well validated EORTC QLQ-C30 questionnaire and thereafter at week 4 and week 8 after the first treatment start. Transfusion dependency at baseline was defined as having received at least one red blood cell transfusion every 8 weeks over a period of 4 months (Malcovati L, et al, *J Clin Oncol*. 2007; 25: 3503-10). Differences were assessed at baseline between TD and TI by Fisher exact and Wilcoxon-Mann-Whitney tests as appropriate. Trajectories over time of QoL outcomes were estimated for TD and TI patients by a linear mixed model with an unstructured covariance structure which accounted for treatment received (hypomethylating agents and intensive chemotherapy *vs* lower intensity therapies). An overall F test was used to test the significance of possible differences of estimated QoL patterns over time between TD and TI groups. No adjustment was performed for multiple testing thus statistical significance was set as α=0.05.
Results: Median age was of 71 years and there were 176 men (63%) and 104 (37%) women. Mean Hb level for the overall population was 9.3 g/dl (range 4.1-15.8). There were 224 patients (68%) considered as TI and 56 (32%) considered as TD. At baseline, there were no statistically significant differences between TD and TI patients with regard to age, gender, IPSS risk score (int.-2 *vs* high risk) and comorbidity. With regard to functional limitations at baseline, worse statistically significant differences for TD patients were found for physical functioning (P=0.003), role functioning (P=0.013), social functioning (P=0.039) as well as for global QoL (P=0.012). Greater symptom severity for TD patients were found for fatigue (P=0.020), pain (P=0.034) and dyspnea (P=0.008). After baseline assessment, treatment with hypomethylating agents was the most common one being received by 165 patients (59%). Investigation of QoL trajectories over time between groups, since treatment start, revealed that patterns of QoL changes was different between groups regardless of type of therapy. QoL of the overall population generally deteriorated during the first two months of therapy. However, the magnitude of this change was worse in TD patients. This latter group, compared to TI patients, deteriorated to a greater extent with regard to physical functioning (P=0.019) and role functioning (P=0.009). The same pattern was observed for fatigue (P=0.019) and pain (P=0.014).
Summary/Conclusions: This study indicates that transfusion dependency not only impairs QoL of MDS patients at baseline, but also limits recover over time compared to patients who are not transfusion dependent at the start of therapy. Future longer follow-up studies are needed.

P419

EFFECT OF LENALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE TREATMENT UNTIL PROGRESSION ON HEALTH-RELATED QUALITY OF LIFE OVER TIME IN TRANSPLANT-INELIGIBLE PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

DT Vogl[1,*], M Delforge[2], K Song[3], S Guo[4], CJ Gibson[5], A Ervin-Haynes[5], T Facon[6]

[1]Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA, United States, [2]Universitair Ziekenhuis Leuven, Campus Gasthuisberg, Leuven, Belgium, [3]Vancouver General Hospital, Vancouver, BC, Canada, [4]Evidera, Lexington, MA, [5]Celgene Corporation, Summit, NJ, United States, [6]Service des Maladies du Sang, Hôpital Claude Huriez, Lille, France

Background: The FIRST trial established a progression-free survival and overall survival benefit for transplant-ineligible patients with newly diagnosed multiple myeloma (NDMM) treated with lenalidomide plus low-dose dexamethasone (Rd) until disease progression (Rd continuous) *vs* melphalan, prednisone, and thalidomide (Benboubker et al, *NEJM*, 2014). Furthermore, treatment with Rd improved health-related quality of life (HRQoL) over the first 18 months of treatment (Delforge et al, *Haematologica*, 2015). HRQoL data were not collected past 18 months.
Aims: The aim of this analysis was to examine the effect of Rd continuous on HRQoL beyond 18 months by identifying predictors of change in HRQoL scores using data from the FIRST trial.
Methods: Univariate linear mixed-effects regression analyses (n=535) identified variables collected until progression as predictors of 7 preselected HRQoL domains of interest: global QoL, physical functioning, fatigue, and pain (EORTC QLQ-C30), disease symptoms and side effects of treatment (EORTC QLQ-MY20), and health utility (EQ-5D). Variables with univariate $P<.1$ were combined into multivariate models for each HRQoL domain; variables with $P<.1$ were retained for final models. Modeled HRQoL domain score changes were validated against observed score changes prior to 18 months and extended to extrapolate HRQoL changes from baseline based on observed predictor values beyond 18 months for patients still receiving Rd at 24, 30, 36, 42, and 48 months.
Results: Key time-varying determinants of final mixed models of HRQoL domains included: eastern Cooperative Oncology Group performance status: all domains; ongoing hospitalization: global QoL, fatigue, side effects of treatment, health utility; serum albumin: global QoL, physical functioning, fatigue, pain, side effects of treatment, health utility; red blood cell transfusion within 30 days: fatigue, pain, disease symptoms; ongoing adverse events: global QoL; ongoing grade ≥3 pain: physical functioning, fatigue, pain, disease symptoms, side effects of treatment, health utility; ongoing grade ≥2 fatigue: fatigue; ongoing grade 3/4 anemia: physical functioning, side effects of treatment. Nearly all observed changes in HRQoL scores from baseline fell within the 95% confidence interval of the final predictive models, including the final EQ-5D health utility model (Figure 1). Exceptions were month 1 of the global QoL and fatigue models and month 3 of the disease symptoms model.

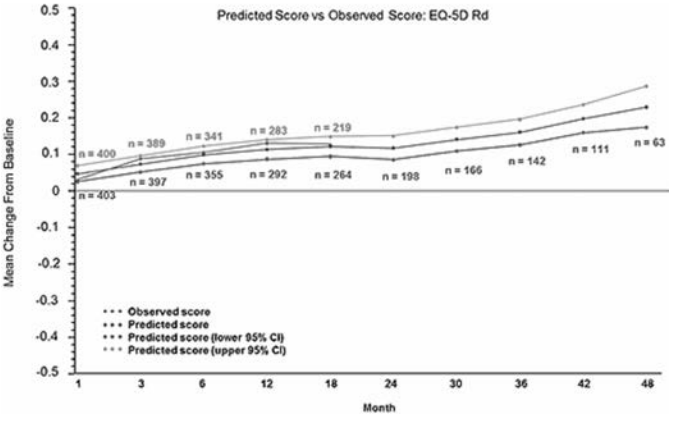

Figure 1.

Summary/Conclusions: Our results suggest that the gains in HRQoL over the first 18 months in Rd-treated patients with NDMM are maintained for patients on treatment up to 48 months. The analysis is exploratory in nature; further research is needed to better define the impact of continuous therapy on HRQoL compared to a fixed duration of therapy followed by a period of observation.

P420

HEALTHCARE COSTS AMONG NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) PATIENTS UNDERGOING FRONTLINE STEM CELL TRANSPLANTATION IN THE U.S. COMPARISON OF OUTPATIENT *VERSUS* INPATIENT-BASED CARE

R Dorothy[1,*], S Dacosta Byfield[2], JS Schwartz[3], L Becker[2], M Jhaveri[1], B Seal[1]
[1]Takeda Pharmaceuticals, Cambridge, MA, [2]Optum, Eden Prairie, MN, [3]Wharton School of the University of Pennsylvania, Philadelphia, PA, United States

Background: The use of stem cell transplantation (SCT) in the U.S. in patients (pts) with MM has increased from 5.1% to 25.1% between 1994 and 2005 (McCarthy 2013), with inpatient (inpt) costs increasing from $684 million in 2004 to $1.3 billion in 2007 for SCT procedures overall (Strangers 2009). However, improved supportive care has enabled a shift of SCT to the outpatient (outpt) setting. Prior research in small cohorts suggests that this shift may produce substantial cost savings (Rizzo 1999; Frey 2002) but these studies were based on single-institutional experiences and focused on short-term costs only.
Aims: The goal of this study was to compare short- and long-term costs of outpt- *vs* inpt-based SCT among MM pts in a large, national, U.S. healthcare claims database receiving SCT within 300 days post-initiation of initial MM-directed therapy (frontline SCT).
Methods: Adult pts with newly diagnosed MM were identified between 1/2008 and 3/2015 from among commercially insured and Medicare Advantage beneficiaries. Pts with continuous enrollment (CE) from 12 months (mos) prior to the first observed claim for MM were included. Pts with frontline SCT were identified and stratified according to SCT setting (inpt *vs* outpt). Short- and long-term costs were estimated from 14 days prior to SCT through 100 days and 12 mos after SCT, respectively, among pts with CE (including pts who died). Total healthcare costs (payer + patient paid) during each time period were calculated. Baseline characteristics and costs were compared using univariate analysis (chi-square test for categorical and t-test for continuous variables). Generalized linear models compared 100-day and 12-mos costs for the outpt *vs* inpt groups.
Results: Of 607 MM pts with frontline SCT, 97% received autologous SCT; 67% (n=407) underwent SCT during an inpt stay. Compared to pts receiving outpt SCT, the inpt SCT group was older (median age: 58 *vs* 60 years old, P=.02), but baseline Charlson Comorbidity index score and gender distributions were similar across cohorts. In the inpt SCT group, initial hospitalization length of stay was 17 days (IQR: 3). Post-SCT hospitalizations in the outpt SCT cohort were more common than either rehospitalizations within 100 days (50% *vs* 20%, p<0.001, n=536) or within 12 months (58% *vs* 40%, p<0.001, n=390) in the inpt SCT cohort. Overall, the mean 100-day and 12-mos costs were $133,215 and $228,497, respectively. Total mean 100-day costs were higher among the inpt *vs* outpt SCT group (adjusted: $139,269 *vs* $121,313, p=0.004). Mean difference in 12-mos costs remained higher among inpt *vs* outpt SCT (adjusted: $238,184 *vs* $211,734, p=0.059) but did not reach statistical significance (Table 1).

Table 1. Costs associated with frontline SCT among MM patients.

		Overall (N=607)	Inpatient Transplant (N=407)	Outpatient Transplant (N=200)	p-value
Costs (2014 US$)					
Total unadjusted cost					
Within 100 days[a]	mean (SD)	133,215 (69,316)	139,007 (71,811)	121,760 (62,731)	0.004
	median	120,397	125,587	113,149

Within 100 days[a]	predicted mean	-	139,269	121,313	0.004
Within 12-months[b]	predicted mean	-	238,184	211,734	0.059
Inpatient unadjusted cost					
Within 100 days[a]	mean (SD)	75,138 (67,933)	103,188 (62,485)	19,663 (37,286)	<0.001
	median	79,288	93,966	0.00	
	IQR	91,921	43,975	24,488	
Within 12-months[b]	mean (SD)	89,783 (109,152)	123,708 (117,445)	27,133 (49,247)	<0.001
	median	51,965	102,567	4,584	
	IQR	103,225	58,456	31,085	
Outpatient unadjusted cost					
Within 100 days[a]	mean (SD)	49,049 (47,738)	29,532 (27,584)	87,650 (55,194)	<0.001
	median	32,577	22,334	87,142	
	IQR	63,376	29,537	56,522	
Within 12-months[b]	mean (SD)	91,129 (84,014)	66,534 (65,087)	136,548 (95,581)	<0.001
	median	69,571	52,203	117,690	
	IQR	80,347	53,357	68,901	

IQR: interquartile range; SD: standard deviation;
[a]14 days prior through 100 days post SCT
[b]14 days prior through 365 days post SCT
[c]adjusted for age, CCI, gender, days from diagnosis to transplant, transplant year

Summary/Conclusions: Total short-term costs were lower in pts undergoing outpt SCT compared with the inpt SCT group. A trend towards lower long-term total costs was noted in the outpt *vs* inpt SCT groups at 12 months. However, in both time frames, the initial cost savings associated with outpt SCT were partially offset by higher hospitalization rates both in the first 100 days and the first 12 months after transplant. Future work will examine cost drivers, including post-transplant complications.

COST-EFFECTIVENESS OF OFATUMUMAB FOR MAINTENANCE IN RELAPSED CHRONIC LYMPHOCYTIC LEUKEMIA

A Davies[1,*], D Zou[2], M Hurry[3], V Bal[4]
[1]ICON plc, Oxford, United Kingdom, [2]ICON plc, Vancouver, [3]Health Policy and Patient Access, Novartis Pharmaceuticals Corporation, Dorval, Canada, [4]Global Market Access and Policy, Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Chronic lymphocytic leukemia (CLL) is incurable disease and patients eventually relapse after lines of therapies. Ofatumumab (OFA) is the first therapy approved by the Food Drug Agency as extended treatment in relapsed CLL. PROLONG was phase III trial where 474 subjects in remission after second- or third-line therapy for CLL were randomized 1:1 to OFA or observation (OBS). OFA showed lengthened progression free survival (PFS) by 14.2 months (median 29.4 *vs* 15.2; hazard ratio [HR] 0.49, p<0.0001) and longer time to next treatment (median 38.0 *vs* 31.1 months; HR 0.623, p=0.005). The estimated median overall survival (OS) was not reached in either arm (HR 0.85; p=0.517). In addition to clinical efficacy, economic evaluation of novel health care technologies is important for decision making in both Europe and North America.
Aims: To evaluate the cost-effectiveness of OFA compared to OBS as maintenance treatment in patients with relapsed CLL who are in remission after induction therapy.
Methods: A partitioned survival model, commonly adopted in economic evaluations based on randomized clinical trials in oncology, was developed with three health states: progression free, post-progression, and death. Parametric survival functions for PFS, OS, and time to treatment discontinuation were developed based on the PROLONG individual patient data. Model fit was assessed by Akaike Information Criteria and Cox-Snell residual plots. Resource use was modelled adopting a Canadian public health care system perspective. Costs (2015 CAD) included drug acquisition and administration, medical care for adverse events, and pre- and post-progression routine care including follow up therapies (a variety of mono and combo therapies) based on the PROLONG data. Utilities were sourced from the literature, and used to calculate quality-adjusted life years (QALYs) based on modeled PFS, OS, and adverse events (grade 3 or 4 events occurring in at least 2% of the PROLONG patients). Cost-effectiveness was evaluated as the incremental cost per QALY gained, and uncertainty was explored through deterministic and probabilistic sensitivity analyses.
Results: Lognormal functions were selected to model PFS and OS. The former included a treatment effect (acceleration factor) that was applied for two years (whilst patients remained progression free and on-therapy), consistent with the trial; due to the immaturity of the OS data and the availability of effective salvage treatments following relapse, no impact of OFA on OS was assumed. Over patients' modelled lifetime, OFA provided an additional 1.26 progression free life years. After applying utilities and discounting (at 5% per annum), this translated into 0.44 QALYs gained. OFA was associated with approximately an additional cost of CAD $30,000 over patients' lifetime. Incremental cost/QALY was CAD $68,600 (95% confidence interval 49,900-107,600), with a 96% probability of being cost-effective at a threshold of 100,000 CAD/QALY. Deterministic sensitivity analyses suggested OFA's cost-effectiveness was most sensitive to shorter time horizons and quality of life weights for post-progression, but was largely insensitive to alternative scenarios regarding PFS and OS functions, including direct use of Kaplan-Meier survival estimates.
Summary/Conclusions: In the PROLONG trial OFA demonstrated substantial gains in terms of PFS and time to next therapy. OFA may represent a cost-effective addition to the management of relapsed CLL patients who have responded to induction therapy.

PATIENT PREFERENCES - SURVEY OF HODGKIN LYMPHOMA SURVIVORS ON TREATMENT-ASSOCIATED BURDEN AND SIDE EFFECTS

C Buerkle[*], H Goergen, H Müller, P Bröckelmann, S Kreissl, M Fuchs, A Engert, P Borchmann, K Behringer
German Hodgkin Study Group, University hospital of Cologne, Cologne, Germany

Background: Hodgkin lymphoma (HL) survivors often report impaired quality

of life due to side effects such as organ failure, fatigue or second malignancies. Patient's experiences, needs and worries related to therapy-associated and social burden are mostly unclear.
Aims: To evaluate the relevance of efficacy outcomes and side effects from the patient's point of view, we created a questionnaire for long-term HL survivors. In addition, the impact of treatment efficacy was put into perspective with long-term side effects of treatment.
Methods: The questionnaire was developed by an interdisciplinary team of physicians, psychologists and statisticians. It consists of six blocks of questions, each containing multiple aspects to be rated on four-point Likert scales. We sent the questionnaire to randomly selected 150 male and 150 female patients of each of our 5th generation trials (HD13, HD14, HD15) with no documented refractory disease or relapse (rrHL) (N=900) and to all candidates with documented rrHL (N=249).
Results: 52% of eligible patients returned the questionnaire (N=484 without rrHL, N=97 with rrHL) with a median follow up from study entry of 107 months. Chemotherapy was a substantial burden for 76% of the participants, independent of stage, treatment and study. Patients in early favorable (HD13) and unfavorable (HD14) stages, received standard radiotherapy (RT) with 30 Gy and for 64% of them, this was a great or very great burden. In advanced stages (HD15), RT was only performed in patients with PET-positive residual tissue after chemotherapy. 26% of them rated RT as great or very great burden. Fatigue was the most frequent side effect, reported by 87% during and 41% after treatment, and considered as a great or very great burden by 75% of the affected patients. Other acute side effects frequently considered as a burden were related to social aspects such as strain for the family and loss in productivity. Most long-term side effects were significantly more frequent in patients with rrHL. Socioeconomics aspects such as financial problems are considered a very great burden. At the time of first diagnosis, >50% of participants had concerns about acute and long-term side effects, relapse and death due to HL. However, concern about relapse was mentioned most frequently. At the time of survey, 25% of patients without rrHL still worried much or very much about side effects of therapy and death from HL and 40% worried much or very much about long-term effects and relapse. In participants with rrHL, concern of side effects or death from HL was still present in 35%, whereas the percentage of patients worrying about long-term effects or another relapse increased to about 60%. Cure of HL was rated as the most important treatment goal by 72% of patients. Retrospectively, only 9 participants (2%) would have chosen a slightly less effective therapy to avoid side effects. Overall, >80% of patients felt well informed about their disease and therapy but 35% felt uninformed regarding potential late effects.
Summary/Conclusions: HL patients frequently consider chemotherapy as a great burden independent of duration and intensity of the administered regimen. HL survivors are more concerned about relapsing than dying from HL, which could be interpreted as fear of another treatment. The results suggest that avoidance of relapse should be the primary therapy goal, and cure is more relevant than possible side effects. Our results imply that progression-free survival is a very important patient-relevant outcome in clinical studies in HL.

P423

UNDERESTIMATED IMPACT OF MILD COGNITIVE IMPAIRMENT IN "CLINICALLY FIT" OLDER PATIENTS WITH MALIGNANT HEMOPATHIES ADMITTED TO RECEIVE CHEMOTHERAPY

S Dubruille[1], Y Libert[2], A Ruiz[3], M Roos[4], A Collard[4], N Meuleman[3], M Maerevoet[3], D Razavi[2], D Bron[3,*]
[1]Dpt of Hematology - Clinic of Psycho-Oncology, [2]Clinic of Psycho-Oncology, [3]Dpt of Hematology, [4]Onco-geriatry Unit, Institut Jules Bordet (ULB), Brussels, Belgium

Background: We reported recently that neither the G8 screening tool nor the CGA total score (≥2 impairments) seem to predict chemotherapy completion and overall survival (OS) among *clinically fit* older patients with malignant hemopathies (1). Regarding survival, we found in a multivariate analysis that only mild cognitive impairment (MCI) (MMSE<27 and/or MoCA<26) in the CGA had a predictive value for one-year OS (1). However, this study did not investigate the relationship between MCI and other specific, clinical and biological parameters of the CGA.
Aims: 1) To determine the predictive value of MCI, clinical and biological parameters in terms of chemotherapy completion and two-year OS. 2) To further investigate whether MCI is correlated with specific clinical and biological parameters and two-year OS.
Methods: CGA were proposed to 117 consecutive patients (65-89yrs) with malignant hemopathies assessed by their physicians as *clinically fit* to receive chemotherapy, meaning no geriatric syndromes and/or irreversible comorbidities significantly impairing their daily function. Biological parameters, chemotherapy completion and causes of deaths were extracted from medical records.
Results: One hundred and two patients were evaluable. Eighty-six percent had a favorable prognosis (CLL, Lymphoma or Multiple Myeloma) and 69% received a full dose of chemotherapy at the time of treatment initiation. Non-completion of chemotherapy (38%; n=39) was predicted only by polypharmacy (drugs ≥5) at the time of treatment initiation (OR=2.83, 95%CI: 1.16-6.91; p=0.023). After adjusting for established prognostic factors, two-year OS (54%, n=52) was predicted by disease recurrence (HR=4.28, 95%CI: 1.42-12.88; p=0.010); MCI (MoCA <26) (HR=4.83, 95%CI: 1.34-17.41; p=0.016), low albumin (HR=1.11, 95%CI: 1.01-1.22; p=0.040) and elevated potassium level (HR=0.32, 95%CI: 0.11-0.89; p=0.030). MCI was associated with a reduced-dose of chemotherapy at the time of treatment initiation (p=0.007), higher age (p=0.025), loss of functional autonomy (p=0.002), a higher number of comorbidities (p=0.036).
Summary/Conclusions: In our selected population of clinically fit patient with malignant hemopathies 1) polypharmacy predicted the non-completion of chemotherapy 2) in addition to classical prognostic factor (advanced disease), MCI, poor nutritional status and severe ionic impairment appear to be powerful prognostic factors. The presence of MCI in *clinically fit* older patients with malignant hemopathies may be a marker of an unsuspected vulnerability. Moreover, MCI seems to be a risk factor for under-treatment of *clinically fit* older patients with malignant hemopathies. Prospective trials are required to further determine whether better identification and management of MCI in *clinically fit* older patients with malignant hemopathies could improve survival.

WHAT DO PATIENT EXPERIENCE DATA REVEAL ABOUT THE DIAGNOSTIC JOURNEY FOR MYELOMA PATIENTS? FINDINGS FROM SECONDARY ANALYSIS OF NATIONAL CANCER PATIENT SURVEY DATA

S Richard*, E Low, C Shaw
Myeloma UK, Edinburgh, United Kingdom

Background: Despite improvements in long-term survival myeloma remains one of the most difficult cancers to diagnose. In 2010 34% of myeloma (MM) patients in England were diagnosed through an emergency route, one of the highest rates of all cancers. While 78% of MM patients are now surviving >1 year after diagnosis this drops to 51% for patients diagnosed as an emergency. Dealing with a diagnosis of a rare and complex cancer can be a major challenge for patients. It is critical that MM patients receive clear and accurate information during testing and subsequent diagnosis. To date there is little evidence derived directly from MM patients to assess the current state of the myeloma diagnostic journey. Such evidence is crucial for developing strategies for policy makers, professionals and patient groups to improve patient experiences and outcomes.
Aims: The study aimed to explore patient experiences of the myeloma diagnostic journey from symptom presentation to receiving a diagnosis and compare MM patient experiences during diagnosis with the all cancer (AC) average.
Methods: Myeloma UK obtained data from the National Cancer Patient Experience Survey (NCPES) 2014 to conduct secondary analysis of MM patients' reported experiences of diagnosis. The NCPES is the largest NHS patient experience survey of its kind, covering a comprehensive journey through care. In 2014, 70,141 cancer patients responded across England, a response rate of 64%, including 4,023 MM patients. The large sample size provides a reliable basis from which to draw conclusions about MM patients' experiences of diagnosis. We compared MM patient responses to questions covering diagnosis with those for AC patients using +/-5% to indicate practical significance.
Results: Our comparative analysis with the cancer average found MM patients reported significantly worse diagnosis-related experiences than AC patients, from length of time in primary care before referral to receiving information about their tests and diagnosis. The data showed MM patients made significantly more visits to their GP with symptoms than the AC average. Of those MM patients who visited their GP with symptoms before their diagnosis 20% made ≥5 visits before being referred to hospital compared to just 9% of AC patients. Only 31% of MM patients were referred after just one visit compared to 54% of AC patients. There were also significant differences in how long it took patients to see a hospital doctor after first suspecting something might be wrong, with 28% of MM patients reporting a wait of ≥3 months before seeing a hospital doctor compared to 19% of AC patients. More MM patients (37%) said that their health got worse during this time than AC patients (20%). In relation to information provision, MM patients scored significantly worse than the AC average on receiving easy-to-understand written information before their diagnostic test(s) (MM 80%, AC 87%) and their test results being explained in a way they completely understood (MM 72%, AC 78%). Only 52% of MM patients said they understood the explanation of their subsequent diagnosis compared to 73% of AC patients.
Summary/Conclusions: The analysis confirms that diagnosis is a particular challenge in myeloma, right through from initial symptom presentation, testing and receiving information following diagnosis. These data emphasise a critical need to increase understanding of the barriers to early diagnosis in myeloma and identify ways to tackle them. Follow-up qualitative research with patients would be useful to explore their experiences of symptom presentation in primary care in more depth. Myeloma UK will raise awareness of these findings and

use them to further develop our Myeloma Diagnosis Pathway and other educational resources for general practitioners. Through targeted information provision and initiatives such as our Clinical Service Excellence Programme we will continue to work with primary and secondary care professionals to ensure every myeloma patient is given quality information at critical time-points through their diagnosis journey.

P425

STREAMLINING OF THE CHEMOTHERAPY SERVICE WITH FOCUS ON DRUG SUPPLY AND PATIENT SAFETY

H Reinhardt[1,*], R Trittler[2], S Wöhrl[2], T Epting[3], S Kaiser[1,4], P Otte[1,4], M Szymaniak-Vits[1,4], M Buck[5], K Opeker[1], B Lieberwirth[6], S Kaiser[5], M Ruch[6], D Jonas[5], J Duyster[1,4], M Jung[7], MJ Hug[2], M Engelhardt[1]
[1]Department of Hematology and Oncology, [2]Pharmacy, [3]Department of Clinical Chemistry, [4]Comprehensive Cancer Center Freiburg, [5]Environmental Health Sciences and Hospital Infection Control, University Medical Center Freiburg, [6]MPS GmbH, [7]Institute of Pharmaceutical Sciences, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany

Background: In times of increasingly complex requirements for preeminent patient (pt) care accompanied by high pt turnover, organisational, safety, quality and financial aspects play a pivotal role. In an interdepartmental, cross functional cooperation, we are investigating the feasibility and benefits of implementing dose-banding in chemotherapy (CTx) at our university center. The dose-banding concept very elegantly and efficiently allows the preproduction of frequently used doses for CTx substances with adequate stability data, offering potential to substantially improve the process of drug supply for pts. As part of the CTx service at Freiburg university medical center, CTx prescriptions are generated via an e-database (Chemo-AS) by the physicians and clinically checked by a surveillance team: the Clinical Cancer Research Group (CCRG) in close cooperation with pharmacy. Any detected error is instantly reported, corrected and recorded electronically. This system has now been established for over 10 years resulting in an interception of 99.9% of the CTx related errors (Lohfert award 2015).
Aims: a) Identify CTx substances suitable for dose banding from a practical and stability point of view and to implement dose banding into clinical practice. b) Gain insight into causes and potential consequences of CTx prescribing errors. c) Design a next generation software with improved safety features.
Methods: Analysis of local prescribing practice via the pharmacy database (Zenzy) applying the banding model described by Zavery et al *(Clin Pharm 2011; 3:116-18)*. In order to simulate the worst case, microbiological stability tests were performed using liquid media instead of CTx: samples were stored for 3 months and incubated at different time points. In an additional container integrity test, the stored infusion bags and syringes were inserted into a highly contaminated broth for 1 hour, incubated and analysed for sterility. Physical and chemical stability tests (colour, particles, pH-changes) for a maximum storage period of 3 months of the respective CTx preparations at relevant concentrations were performed. A quantitative assay was conducted by HPLC analysis. We also performed a detailed analysis of 406 CTx prescribing errors prevented by CCRG initiative using SPSS. The data had been collected prospectively over 2 years (2013/2014) via Chemo-AS by the CCRG. In an interdisciplinary approach, in cooperation with IT specialists, the causes of the errors were analysed for effective future preventability.

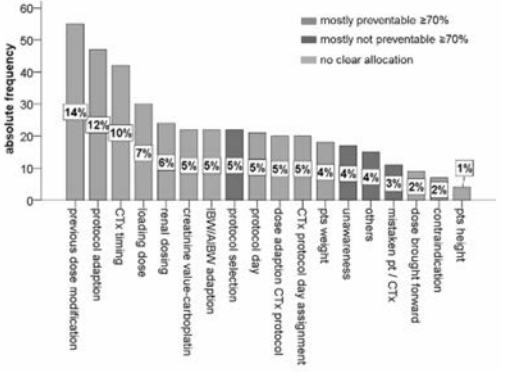

Figure 1. Analysis of CTx error preventability software engineering.

Results: Gemcitabine, 5-FU bolus and carboplatin were identified as most suitable CTx preparations for dose banding by statistical analysis. Microbiological stability could be demonstrated over the complete storage period and all preparations passed the container integrity test. For the selected substances physical and chemical stability over 3 months was shown. In line with international guidelines, we determined a gemcitabine content of ≥95% at 12 weeks storage. The 406 prescribing errors of 18.823 CTx orders were affecting 375 (2%) orders, 303 (12,4%) tumor pts and 508 (1,3%) CTxs. Errors were divided into categories of potential consequences: overdose 203 (51%), underdose 59 (15%), incorrect length of cycle/CTx timing 56 (14%), wrong CTx 40 (11%), CTx not ordered 38 (10%) (with 10 errors additive in consequence). 256 CTxs were affected by the 203 overdosed CTx orders: 110 (43%) were overdosed ≤25%, 66 (26%) with 26-50%, 63 (25%) with 51-100% and 17 (7%) >100%. Of all errors analysed, 61% were identified as avoidable by specific software improvements. Results of the assessment of error preventability by program engineering are shown in Figure 1.
Summary/Conclusions: This analysis shows that dose banding is feasible for gemcitabine and possibly other CTx preparations taking into account statistical and stability aspects. Our "error analysis" was very useful for pinpointing areas, where CTx error reduction by software engineering is possible. However as, according to our analysis, 30-40% of errors are not electronically avoidable, the CCRG, ward pharmacists or other surveillance teams remain indispensable. Dose banding, together with an upgraded CTx prescribing software tool, bear high potential for moving towards standardisation and considerable improvement of the CTx service at Freiburg university hospital. This contributes to a very safe therapy and reduces waiting time for pts as well as ensuring support for doctors and pharmacy staff. Moreover, our new CTx software will be available to other external hospitals, resulting in shared benefit for a large number of pts and healthcare staff.

P426

INTERIM QUALITY OF LIFE RESULTS WITH VENETOCLAX (ABT-199/GDC-0199) MONOTHERAPY IN PATIENTS WITH RELAPSED/REFRACTORY DEL(17P) CHRONIC LYMPHOCYTIC LEUKEMIA

W Wierda[1], M Cifaldi[2], LI Hsu[2,*], E Cerri[2], ME Verdugo[2]
[1]The University of Texas MD Anderson Cancer Center, Houston, [2]AbbVie, North Chicago, United States

Background: Chronic lymphocytic leukemia (CLL) is associated with reduced health-related quality of life (HRQoL) with progressive severe fatigue being a particularly relevant burden. Additionally, treatment can further reduce HRQoL, based on a recent study from Netherlands (Holtzer-Goor KM *et al.* QLR 2015). Recently, deep and durable responses to the oral BCL-2 inhibitor venetoclax (VEN) were achieved in patients with relapsed/refractory (R/R) CLL with deletion of chromosome 17p [del(17p)] in a phase 2 study (NCT01889186, Stilgenbauer S *et al.* ASH 2015).
Aims: To evaluate changes in HRQoL in patients with VEN monotherapy treatment based on interim results from this study.
Methods: In this single-arm trial, patients ≥18 years of age with R/R del(17p) CLL received VEN monotherapy. Patient-reported HRQoL measures were an exploratory endpoint for this study and included the EORTC-QLQ-C30 and EORTC-QLQ-CLL16. The mean changes from Baseline (BL) to visit Weeks 4, 12, 24, 36, and 48 were reported. Clinical relevance was based on minimum important difference (MID) of values from BL at different assessment points. The lower bound of 5–10 point changes, previously considered a "little" change for EORTC-QLQ-C30 (Osoba D *et al.* JCO 1998 and Osoba D *et al.* QLR 1994) was used for MID acceptance for this and EORTC-QLQ-CLL16.

Table 1.

Table 1. Clinically relevant changes in EORTC-QLQ-C30 and EORTC-QLQ-CLL16 parameters with VEN monotherapy treatment.

EORTC-QLQ-C30 parameter (N)	BL Mean	Visit Mean	Mean change from BL (95% CI)
Global Health Status			
Week 4 (70)	55.2	64.4	9.2 (4.3, 14.1)
Week 24 (73)	58.6	67.9	9.4 (3.3, 15.5)
Emotional functioning			
Week 4 (73)	72.0	81.2	9.2 (5.4, 12.9)
Week 24 (76)	74.6	82.4	7.9 (3.6, 12.1)
Role functioning			
Week 4 (70)	64.3	73.6	9.3 (3.7, 14.8)
Week 24 (74)	68.0	79.1	11.0 (3.8, 18.2)
Social functioning			
Week 4 (73)	64.6	71.5	6.8 (0.5, 13.2)
Week 24 (76)	69.1	80.9	11.8 (5.6, 18.1)
Fatigue			
Week 4 (74)	42.4	35.7	-6.7 (-11.7, -1.7)
Week 24 (77)	37.1	30.6	-6.5 (-11.6, -1.3)
EORTC-QLQ-CLL16 parameter (N)	**BL Mean**	**Visit Mean**	**Mean change from BL (95% CI)**
Future health			
Week 4 (73)	56.6	39.7	-16.9 (-23.4, -10.4)
Week 24 (73)	54.8	32.9	-21.9 (-30.1, -13.7)
Fatigue			
Week 4 (75)	34.0	24.0	-10.0 (-16.1, -3.9)
Week 24 (77)	29.7	21.2	-8.4 (-14.3, -2.6)

Results: Clinically relevant gains in global health status and role, social, and emotional functioning of the EORTC-QLQ-C30 occurred from Week 4 to Week 24 (Table 1). Furthermore, early and sustained improvements in fatigue were shown in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1). Associated with these positive HRQoL results was considered as a large effect (>20 points) in patient EORTC-QLQ-CLL16 future health views at Week 24 (Table 1) (Osoba D *et al.* JCO 1998 and Osoba D *et al.* QLR 1994). These clinically relevant improvements were seen in patients having generally lower BL HRQoL than patients in a recent Netherlands study using similar measures.
Summary/Conclusions: Understanding the effect of therapy on HRQoL and patient well-being is an important factor when making treatment choices. These interim results showed that in this very symptomatic and difficult to treat patient population, VEN improved HRQoL and patients' view of their future health.

SIMULTANEOUS SESSIONS II

Innovative therapies in CLL

S427

PRELIMINARY SAFETY DATA FROM THE PHASE 3B GREEN STUDY OF OBINUTUZUMAB (G) ALONE OR COMBINED WITH CHEMOTHERAPY FOR PREVIOUSLY UNTREATED OR RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

V Leblond[1,*], MS Dilhuydy[2], R Foà[3], W Knauf[4], M Montillo[5], S Robinson[6], S Stilgenbauer[7], E Gresko[8], S Lasserre[8], F Bosch[9]
[1]AP-HP Hôpital Pitié-Salpêtrière, UPMC, Paris, France, [2]Hôpital du Haut-Lévèque, Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France, [3]'Sapienza' University, Rome, Italy, [4]Onkologische Gemeinshaftspraxis, Frankfurt, Germany, [5]Niguarda Ca' Granda Hospital, Niguarda Cancer Center, Milan, Italy, [6]QEII Health Sciences Centre, Halifax, Canada, [7]University of Ulm, Ulm, Germany, [8]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [9]University Hospital Vall d'Hebron, Barcelona, Spain

Background: GREEN (NCT01905943) is an ongoing phase 3b, open-label trial of G alone or with chemotherapy in pts with previously untreated (1L) or relapsed/refractory (R/R) CLL; the primary outcome is safety.
Aims: To assess the frequency, type and severity of AEs in all pts in GREEN, based on a 6-month safety review (data cut-off for analysis, 26 August 2015).
Methods: Enrolled pts are aged ≥18 yrs with documented CLL, ECOG PS 0-2 and adequate hematologic function. Pts receive G 1000mg IV, alone or with chemotherapy (at investigator's discretion), on days 1 (dose split over 2 days [25+975mg or 100+900mg]), 8 and 15 of cycle (C)1, and day 1 of C2-6 (six 28-day cycles). Chemotherapy options were: fludarabine and cyclophosphamide (FC) for fit pts only (CIRS ≤6 and CrCl ≥70mL/min); chlorambucil (Clb) for unfit pts only (CIRS >6 and/or CrCl <70mL/min), or bendamustine (B) for any pt. Pts refractory to previous G monotherapy had to receive G with chemotherapy. All pts gave informed consent.
Results: In 825 pts analyzed (1L, 485; R/R, 340), median age was 66.0 (33-90) yrs, 63.4% were male, 434 (52.6%) were at risk of tumor lysis syndrome (TLS; tumor burden ≥10cm or ≥5cm but <10cm with lymphocytes ≥25x10^9/L) and 41.1%/33.5% were Binet stage B/C. Median observation time was 12.7 (0.1-22.1) months and median exposure time was 20.3 (0.1-33.1) weeks. AEs, grade ≥3 AEs and SAEs occurred in 96.1%, 72.0% and 43.1% of 1L pts, and 96.5%, 73.8% and 46.5% of R/R pts, respectively (results by treatment group in Table 1).

Table 1.

N (%)	Total (n=825)	G alone (n=106)	G-FC (n=159)	G-Clb (n=97)	G-B (n=463)
Any AE	794 (96.2)	98 (92.5)	157 (98.7)	97 (100)	442 (95.5)
TLS	51 (6.2)	6 (5.7)	7 (4.4)	3 (3.1)	35 (7.6)
Grade ≥3 AEs	600 (72.7)	66 (62.3)	133 (83.6)	63 (64.9)	338 (73.0)
Neutropenia	369 (44.7)	26 (24.5)	93 (58.5)	41 (42.3)	209 (45.1)
TCP	131 (15.9)	11 (10.4)	34 (21.4)	19 (19.6)	67 (14.5)
Grade ≥3 infections	123 (14.9)	17 (16.0)	17 (10.7)	16 (16.5)	73 (15.8)
Grade ≥3 IRRs	152 (18.4)	25 (23.6)	33 (20.8)	19 (19.6)	75 (16.2)
Any SAE	367 (44.5)	44 (41.5)	61 (38.4)	39 (40.2)	223 (48.2)
Any fatal AE	32 (3.9%)	4 (3.8%)	4 (2.5%)	3 (3.1%)	21 (4.5%)

The most common grade ≥3 AEs were neutropenia (44.7%), thrombocytopenia (TCP; 15.9%), anemia (9.0%), febrile neutropenia (6.9%), and leukopenia (6.2%). AEs were considered related to G treatment in 83.0% pts, most commonly neutropenia (36.0%), TCP (23.0%), pyrexia (21.7%), nausea (17.5%), chills (15.3%) and anemia (10.4%). AEs of particular interest (any grade) were: cardiac events, 8.7%; hemorrhagic events, 6.2%; TCP, 32.4%; and secondary malignancies, 4.1%. Other AEs of interest (any grade) were: infusion-related reactions (IRRs, *i.e.* events occurring during or within 24h of G infusion and treatment-related), 63.3% (most common: pyrexia, 17.7%; chills, 14.8%; nausea, 12.5%; causing G discontinuation, 2.8%); infections, 45.2% (most common: pneumonia, 7.0%; bronchitis, 5.0%; URTI, 5.0%); neutropenia, 58.4% and TLS, 6.2%. In the G-B arm, TLS was more common in unfit pts (23; 10.0%) than fit pts (12; 5.2%). AEs caused G discontinuation in 111 (13.5%) pts. In 43 pts who died (1L fit, 9 [3.4%]; 1L unfit, 10 [4.5%]; R/R, 24 [7.1%]), primary causes were AEs (n=32) and disease progression (n=11); 15 were related to underlying cancer. One pt in the G-B arm (1L unfit) died of TLS before data cut-off.
Summary/Conclusions: Preliminary safety data from GREEN are in line with the known safety profile of G in similar populations.

S428

QUANTITATIVE MRD IS PROGNOSTIC FOR PROGRESSION-FREE & OVERALL SURVIVAL IN ELDERLY PATIENTS RECEIVING CHLORAMBUCIL ALONE OR WITH OBINUTUZUMAB/RITUXIMAB: A PROSPECTIVE ANALYSIS OF THE GCLLSG CLL11 STUDY

[1]University of Schleswig-Holstein, Kiel, Germany, [2]Erasmus University Medical Center, Rotterdam, Netherlands, [3]German CLL Study Group (GCLLSG), Department I of Internal Medicine and Center of Integrated Oncology (CIO), Cologne, Germany, [4]Medical University of Innsbruck, Innsbruck, Austria, [5]Charles University Hospital, Prague, Czech Republic, [6]Royal North Shore Hospital, University of Sydney, Sydney, Australia, [7]Kantonsspital Graubünden, Chur, Switzerland, [8]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [9]Roche Products Ltd, Welwyn, United Kingdom, [10]University of Ulm, Ulm, Germany, [11]Cologne Center of Excellence for Cellular Stress Response and Aging Related Diseases (CECAD), University of Cologne, Cologne, Germany

Background: The CLL11 study (NCT01010061) is an ongoing open-label, randomized, three-arm study in patients (pts) with previously untreated chronic lymphocytic leukemia (CLL), comparing the efficacy and safety of obinutuzumab (GA101; GAZYVA/GAZYVARO; G) plus chlorambucil (Clb; G-Clb) with rituximab (R) plus Clb (R-Clb) or Clb alone.
Aims: To determine the prognostic value of minimal residual disease (MRD) quantification with respect to clinical risk factors, treatment regimen, and MRD-source tissue in an advanced-age CLL population.
Methods: In total, 781 patients with treatment-naïve CLL, a median age of 73 years and a Cumulative Illness Rating Scale total score of >6 were included and randomized to receive Clb, G-Clb or R-Clb. Peripheral blood (PB) samples were taken at repeated timepoints during and up to 12 months (mo) after treatment. Bone marrow (BM) aspirate was taken 3 mo after end of treatment (EOT) to confirm complete response (CR). MRD was analyzed by quantitative immunoglobulin allele-specific real-time PCR. MRD results at EOT (PB or BM) were available in 73% of pts. Outcome was analyzed according to known MRD risk groups, *i.e.* MRD-positive (+ve; ≥1%), MRD intermediate (int; <1% and ≥0.01%) and MRD-negative (-ve; <0.01%), and other known risk factors.
Results: At EOT, combination treatment with either G-Clb or R-Clb achieved higher MRD negativity rates in PB and BM compared with Clb alone (PB: G-Clb 35.8% *vs* R-Clb 3.3% *vs* Clb 0%; BM: G-Clb 18.2% *vs* R-Clb 2.6% *vs* Clb 0%). Due to the absence of MRD negativity in the Clb arm, all further MRD analyses were restricted to the comparison of G-Clb *vs* R-Clb. When measured in PB, MRD risk groups significantly correlated with progression-free survival (PFS; median PFS: MRD-ve 49.3 mo; MRDint 23.9 mo; MRD+ve 13.9 mo; p<0.001) and overall survival (OS; median OS not reached in any group; p<0.001; see Figure 1 for KM curves). When MRD was measured in PB, three-year OS rates were: MRD-ve 94.3%; MRDint 87.3%; and MRD+ve 69.5%. When comparing G-Clb with R-Clb, median PFS in the MRD-ve group was not significantly different (p=0.15). Results were similar for MRD measured in PB after 3 cycles of treatment (interim staging [IST]; median PFS: MRD-ve not reached; MRDint 27.3 mo; MRD+ve 15.2 mo; p<0.001). A total of 53/417 (12.7%) pts converted from PB MRD+ve or MRDint at IST to MRD-ve at EOT across the G-Clb/R-Clb arms. In multivariate analysis (including various baseline markers), MRD in PB at EOT was an independent prognostic factor for PFS (HR 5.29, 95% CI 3.48-8.04, p<0.001) and OS (HR 3.04, 95% CI 1.53-6.03, p=0.002), with the highest weight in the model. When analyzing MRD in PB at EOT in conjunction with clinical remission status, MRD-ve/CR and MRD-ve/PR pts had similar PFS (median PFS 49.3 mo *vs* 56.4 mo, HR 1.74, 95% CI 0.79-3.86, p=0.17), whereas MRD+ve/CR pts had a worse outcome than MRD-ve/CR pts (median PFS 32.7 mo *vs* 49.3 mo, HR 3.6, 95% CI 1.64-7.99, p=0.001).

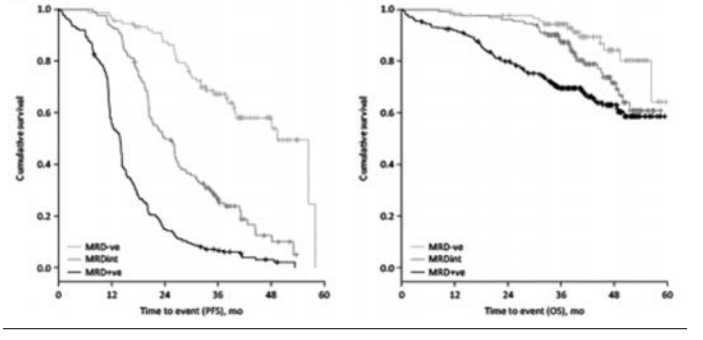

Figure 1. Kaplan Meier curves for PFS (A) and OS (B) according to MRD risk groups in PB at EOT.

Summary/Conclusions: Data presented are consistent with the CLL8 study and confirm that, when measured in PB or BM, MRD is prognostic in elderly

pts with comorbidities, with G-Clb achieving a much higher rate of MRD negativity than R-Clb and Clb alone. In this cohort, pts achieving MRD-ve status at IST had a similar outcome to pts with later conversion (at EOT). Although MRD measurement in BM seems to be more sensitive, MRD measurement in PB, at least in this trial, is sufficient to identify MRD based risk groups.

Background: Patients (pts) with deletion 17p (del17p) chronic lymphocytic leukemia (CLL) have aggressive disease and poor outcomes with chemoimmunotherapy. Ibrutinib (ibr), a once-daily oral inhibitor of Bruton's tyrosine kinase, is approved for pts with CLL after ≥1 prior therapy and for pts with del17p CLL in the US (including first-line) and first-line with del17p or *TP53* mutation unsuitable for chemoimmunotherapy in the EU. Ibr trials that enrolled pts with del17p CLL include a phase 2 study in treatment-naïve (TN) or relapsed/refractory (R/R) CLL (PCYC-1102) with extension (PCYC-1103), phase 3 RESONATE study of pts with R/R CLL (PCYC-1112), and phase 2 RESONATE-17 study in pts with R/R CLL (PCYC-1117).
Aims: This study evaluated efficacy and safety outcomes in an integrated analysis of pts with del17p CLL/SLL across 3 ibr clinical trials, including outcomes with complex karyotype (CK) in 1 longstanding extension trial.
Methods: All pts gave informed consent. Del17p was determined by FISH in a central laboratory (PCYC-1102/1117) or by local laboratory (PCYC-1112). Pts received once-daily oral ibr 420 (n=232) or 840 mg (n=11) until progressive disease (PD) or unacceptable toxicity. Sustained hematologic improvement over baseline was defined as ≥56 days without transfusion support and included platelet (PLT) or absolute neutrophil count (ANC) increase ≥50% and/or hemoglobin (Hgb) increase ≥2 g/dL. In PCYC-1102, CK was defined as ≥3 unrelated chromosomal abnormalities by stimulated cytogenetics as assessed by a reference laboratory.
Results: 243 CLL pts with del17p (241 R/R and 2 TN) were evaluated, with median age 65 y (37% ≥70 y). At baseline, 63% had Rai stage III-IV disease, and 53% had bulky disease ≥5 cm; cytopenias were observed in 68%. With median 2 prior therapies (range, 0-12), del11q was observed in 18% of 239 pts and unmutated *IGHV* in 80% of 201 pts. The median time on study was 28 mos; 66% received ibr for >2 y. ORR (including PR-L) was 84%; estimated median PFS was 32 mo (95% CI: 28, 40), and estimated 30-mo landmark OS was 67% (95% CI: 59, 74) (Figure 1).

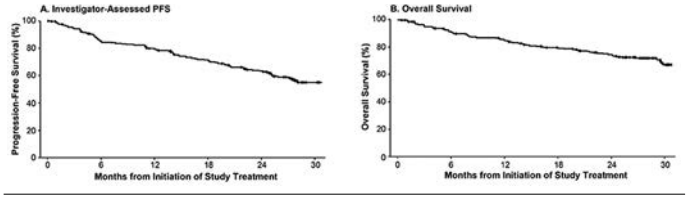

Figure 1. PFS (A) and OS (B) in ibrutinib-treated Del17p Patients.

Sustained hematological improvement in Hgb, PLT, and ANC occurred in 61%, 68%, and 68% of pts with baseline cytopenias, respectively. For pts with PD, Richter transformation tended to occur earlier at a median of 253 d (range, 31-786) *vs* CLL progression at median 594 d (range, 26-1572). Of 36 pts with del17p on PCYC-1102/1103, median time on study was 42 mo; baseline CK was observed in 22 pts. Median number of prior therapies was 2.5 *vs* 4 in pts without *vs* with CK, respectively. ORR was 80% in del17p pts without CK and 82% with CK. Estimated median PFS was 52 mo for pts without CK and 25 mo in those with CK. Estimated median OS was not reached for pts without CK and 32 mo with CK. Across all 243 pts with del17p, grade (Gr) ≥3 adverse events occurring in ≥5% of pts over the >2 y median treatment period were neutropenia (Gr 3/4, 5/14%), pneumonia (Gr 3/4/5, 9/1/2%), hypertension (Gr 3/4, 11/0%), thrombocytopenia (Gr 3/4, 5/5%), and anemia (Gr 3/4, 7/1%). Gr 3/4 atrial fibrillation occurred in 2/1% of pts. Gr ≥3 hemorrhage occurred in 6/1% (Gr 3/4). 110 pts (45%) remain on study treatment.
Summary/Conclusions: In this analysis of 243 pts, the estimated median PFS and 30-mo OS for ibr surpass those of other therapies for del17p CLL. Results from pts with central karyotype information suggest those without CK experience more favorable PFS/OS outcomes. These results provide further evidence of ibr's robust clinical activity and survival outcomes in difficult-to-treat CLL populations.

Background: The international, double-blind, placebo-controlled, phase 3 HELIOS study evaluated ibrutinib (ibr)+bendamustine and rituximab (BR) *vs* placebo (plb)+BR in patients with previously treated CLL/SLL. At 1st analysis (median follow-up, 17.0 months), progression-free survival (PFS) was significantly improved for ibr+BR *vs* plb+BR (HR [95% CI], 0.203 [0.15-0.28]; $p<0.0001$). Prior studies have shown deepening responses with continued once-daily ibr treatment; thus, long-term follow-up assessing durability and depth of response is important, as is evaluating safety and tolerability over time.
Aims: The 1st HELIOS study results were reported with a median follow-up of 17 months. 2-year data are now available with additional safety follow-up. Because minimal residual disease negativity (MRD-ve) represents a lower disease burden and an endpoint that can potentially affect patient outcomes, we focus on these data to better understand the benefit of ibr over time in previously treated CLL patients.
Methods: 578 patients received BR (≤6 cycles) and were randomized 1:1 to ibr (420 mg/d) or plb (N=289 per arm). Patients with del17p (≥20% of cells) were excluded. The primary endpoint was independent review committee (IRC)-assessed PFS. Key secondary endpoints were investigator (INV)-assessed PFS, overall survival (OS), overall response rate (ORR; IRC and INV), and rate of MRD-ve response. With continued follow-up, we report INV-assessed clinical endpoints. At 1st analysis, overall concordance between IRC and INV assessments for progressive disease (PD) was 90% in the ibr group and 85% in the plb group.
Results: Median follow-up is now 25.4 months. Ibr+BR continues to show improvement in PFS *vs* plb+BR (INV-assessed median, not reached *vs* 14.2 months; HR [95% CI], 0.199 [0.15-0.26]; p<0.0001; 2-yr rate, 74.8 *vs* 20.9%). Median PFS2 (randomization to PD corresponding to the next line of treatment, or death) is unreached in both arms but PFS2 was significantly longer for patients assigned to ibr+BR *vs* plb+BR, despite crossover (HR [95% CI], 0.62 [0.42-0.92]; p=0.016). Median OS is still unreached in either arm (HR [95% CI], 0.67 [0.44-1.02]; p=0.058; 2-yr rate, 86.2 *vs* 81.5%); 142 patients (49.1%) in the plb+BR arm with confirmed PD have crossed over to receive ibr. The updated INV-assessed best ORR (at any time point) is 87.2% for ibr+BR *vs* 66.1% for plb+BR (p<0.0001); updated rates of complete response (CR)/ CR with incomplete bone marrow recovery (CR/CRi) are 33.9 *vs* 7.2% (rates at 1st analysis, 21.4 *vs* 5.9%). Rates of MRD-ve response for the intent-to-treat population are 18.0% (52/289) for ibr+BR *vs* 4.8% (14/289) for plb+BR (p<0.0001) (rates at 1st analysis, 12.8 *vs* 4.8%). Among patients who were evaluated for MRD status post-BR, ibr showed a more sustained PFS over plb whether or not MRD-ve response was achieved, though patients in the ibr arm who achieved MRD negativity had a longer PFS than those who did not (Figure 1). There were no new or unexpected safety signals reported in this update.
Summary/Conclusions: Ibr+BR continues to demonstrate superiority *vs* plb+BR, with significantly longer PFS and higher ORR. Moreover, responses continue to deepen with continuous ibr therapy, with rates of CR/CRi and MRD-ve response increasing over time. Patients on the ibr arm demonstrate a more sustained PFS at each MRD level (<0.01% and ≥10%) than those on the plb

arm. Ibr maintains the same degree of safety as previously observed in CLL patients. These 2-year follow-up data further confirm the important role of ibr in patients with previously treated CLL.

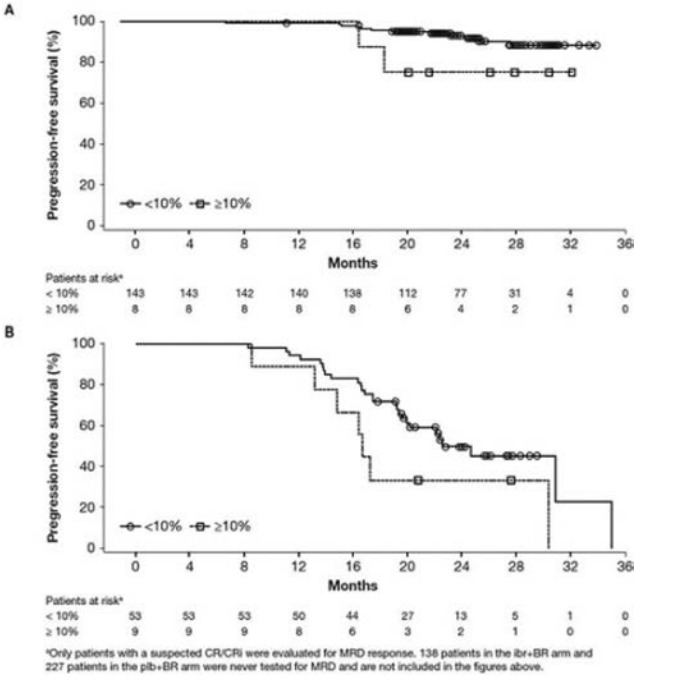

Figure 1. PFS by MRD level for (A) ibr+BR and (B) plb+BR.

ACALABRUTINIB, A SECOND-GENERATION BRUTON TYROSINE KINASE (BTK) INHIBITOR, IN PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

W Wierda[1,*], J Jones[2], R Furman[3], D Stephens[4], S Devereux[5], J Brown[6], P Hillmen[7], A Hamdy[8], M Fardis[8], M Tawashi[8], MH Wang[8], P Patel[8], D Mittag[9], F Krantz[8], W Rothbaum[8], R Izumi[8], S O'Brien[10], J Byrd[2]
[1]University of Texas MD Anderson Cancer Center, Houston, United States, [2]The Ohio State University, Columbus, United States, [3]Weill Cornell Medical College, New York, United States, [4]Univ of Utah Huntsman Cancer Inst, Salt Lake City, United States, [5]College Hospital, London, United Kingdom, [6]Dana-Farber Cancer Institute, Boston, United States, [7]St. James's University Hospital, Leeds, United Kingdom, [8]Acerta Pharma, Redwood City, United States, [9]Acerta Pharma, Oss, Netherlands, [10]University of California–Irvine, Irvine, United States

Background: Btk is a kinase involved in B-cell receptor signaling and a critical therapeutic target in CLL. Acalabrutinib—an irreversible, selective Btk inhibitor has demonstrated clinical efficacy in relapsed CLL (Byrd NEJM 2015).
Aims: Here, we present preliminary results from an ongoing Phase 1-2 study of acalabrutinib monotherapy in patients (pts) with previously untreated CLL.
Methods: Pts with previously untreated CLL who met IWCLL 2008 criteria for treatment were eligible, irrespective of any cytopenias. Pts received oral acalabrutinib at 100 mg BID (n=37) or 200 mg QD (n=37). Pts had a median age of 64 (48-85) years, bulky lymph nodes ≥5 cm (47%) and unmutated IGHV gene (57%, 38/67). CLL responses were assessed per modified IWCLL criteria.
Results: Results are presented through 07Dec2015 for the first 74 treated pts, including 72 evaluable for response. Median time on study (N=74) was 11 (1-15) months. Acalabrutinib was well tolerated with 97% (72/74) of pts continuing on study drug. Most AEs were Grade (Gr) ≤2. The most common Gr 1-2 AEs (≥15% pts) were headache (42%), diarrhea (35%), arthralgia (22%), contusion (18%), nausea (18%) and increased weight (18%). Gr 3-4 AEs that occurred in ≥2 pts were syncope (n=2, both Gr 3) and hypertension (n=2, both Gr 3). One Gr 5 event (pneumonia) has occurred. One Gr 3 upper GI bleed due to a gastric ulcer and aspirin use has occurred. No atrial fibrillation was reported. Clinical activity was observed with both dose schedules; Btk occupancy was highest with BID dosing (98% *vs* 93% predose at Day 28). All pts had a rapid reduction in lymphadenopathy. Treatment-related lymphocytosis occurred in 53% (39/74) of pts and resolved in 97% (38/39) of these pts. In general, lymphocytosis peaked at a median of 1 week and resolved by a median of 7 (3-15) weeks. Best ORR was 96% (PR=86%, PR+L=10%, SD=4%, PD=0%). Median time to response was 2 (2-8) months. No CLL progression or Richter's transformation have occurred.
Summary/Conclusions: In pts with previously untreated CLL, a favorable safety profile and high response rates that appear durable were observed with acalabrutinib therapy. Based on these results, a Phase 3 trial has commenced (NCT02475681).

Chronic myeloid leukemia - Clinical

Background: Imatinib generics could substantially decrease costs of CML therapy, however there is a lack of data regarding the efficacy and safety of its use in larger populations of CML patients.
Aims: The aim of the study was to evaluate the efficacy and safety of imatinib generics in patients suffering from chronic phase CML treated *de novo* with generics (…*de novo*" patients), and in the group of patients switched from glivec to imatinib generics (…switched" patients) during a one-year therapy period.
Methods: In …*de novo*" group the rate of BCR/ABL1 reduction to <10% at 3 months and to <1% at 6 months of therapy, the rate of optimal response, and failure according to current ELN guidelines, the rate of CCyR,MMR,MR4, and MR4,5 achieved at 12 months of therapy, and the rate of patients switched to second generation TKI have been assessed. In the …switched" group the rate of sustained, improved and worsened molecular response, the rate of CCyR, MMR, MR4, and MR4,5 loss have been estimated. To assess the safety of imatinib generics in both groups the rate of hematologic (3rd or 4th grade), and of non-hematologic adverse events (all grades according to CTCAE criteria) have been evaluated. In current report the results of one-year, "real-life" observation started on 03.APR.2014 in 501 patients treated in 12 Polish Hematology Centers are presented. Polish Adult Leukemia Group imatinib generics registry records approximately 900 patients, in the current report only patients who completed 12-month observation (all patients with available RQ-PCR result at 12 month), with MMR achieved before start of therapy with generics, and treated for more than 12 months with generics (…switched" patients) have been analyzed.
Results: Forty patients started *de novo* treatment with generics (24 Nibix, 16 Meaxin), and 461 patients were switched from Glivec to imatinib generics (343 to Nibix, 118 to Meaxin). Early molecular response (BCR/ABL1 <10% at 3 months) was achieved in 75%, and the reduction of BCR/ABL1 to <1% at 6 months in 68% of …*de novo*" patients. Optimal response (MMR at 12 months) was achieved in 75% of …*de novo*" patients. Two patient from this group were switched to 2GTKI due to simultaneously occurred resistance and non-hematological toxicity. Hematologic toxicity (grade 3 or 4) was observed in 2 patients (therapy was not changed), non-hematologic toxicity occurred in 17 patients (2 patients were switched to 2GTKI). In the …switched" group the molecular response under therapy with generics was sustained, improved and worsened in 47.0%, 27.3%, and 25.5% of patients respectively. MMR was lost in 2.4%, CCyR in 0.4% and MR4.5 in 4.5% of patients switched to imatinib generics. During a one-year observation 4.5% of patients were switched to 2GTKI; 3,8% for intolerance (non-haematologic toxicity only), 0.8% for resistance, and 0.6% for intolerance+resistance.
Summary/Conclusions: This is the first report on "real life" imatinib generics effectiveness and safety in a big cohort of CML patients. Two tested generics of imatinib (Meaxin and Nibix) seem to be not less effective as Glivec in therapy of patients with CML CP, safety profile of both generics is acceptable – no increased switching rate between 1st and 2GTKI was noted.

mouc, Czech Republic, [6]Dept. of Adult Hematology and INSERM-UMR 1160, Hôpital Saint-Louis, APHP, Paris, France, [7]Dept. of Biochemistry, University Hospital Brno, [8]Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, [9]Dept. of Internal Medicine - Hematology and Oncology, University Hospital Brno, Brno, Czech Republic

Background: Our pilot study on 10 CML patients demonstrated fast development of hyperinsulinaemia, peripheral insulin resistance, hypoadiponectinaemia and hypercholesterolemia during nilotinib (NILO) therapy.
Aims: The aim of this multicenter ENIGMA 2 study was to confirm these results and to compare data obtained during NILO therapy with control groups of patients treated with imatinib (IMA) and dasatinib (DASA).
Methods: Patients received intensive laboratory workup before the start of tyrosine kinase inhibitor (TKI), after 3 and 12 months of therapy. This included oral glucose tolerance test, fasting insulin, glucose, adiponectin and serum lipid concentration. Patients with diabetes mellitus, TKI treatment interruption for >2 weeks (start-month 3) or >4 weeks (month 4-12) or TKI dose reduction for >25% were excluded.
Results: Between 2/2011-11/2015 87 CML patients in 6 centers initiated TKI therapy – 48 NILO (1st line - 25; 2nd line - 23), 24 with IMA (all 1st line) and 15 with DASA (1st line - 5; 2nd line - 10). After 3 months of NILO treatment patients evolved significant hyperinsulinaemia and hyperglycaemia (presented in 75% of patients) as result of fast development of peripheral insulin resistance. This was proved by significant increase in HOMA-2 index during this period (appeared in 73% of patients). Moreover, total and LDL cholesterol concentration significantly increased already after this short NILO treatment (developed in 92% and 87% of patients, respectively). All these abnormalities were significant also after 12 months of therapy (Table 1). A separate analysis of patients treated with NILO either 1st or 2nd line confirmed these metabolic changes after 3 months of treatment. On the contrary – none of these abnormalities were detected in the control group of patients treated with IMA and DASA, including any change in insulin resistance measured by HOMA-2 index.
Interestingly, previously described decrease in adiponectin (major insulin sensitizer) concentration during NILO administration was confirmed subsequently when all NILO treated patients were analyzed together. However, in separate analysis decrease in adiponectin was proved only in patients with the 2nd line NILO therapy (median concentration at baseline *vs* month 3 – 14.3 *vs* 7.1 mg/l, p<0.001; at baseline *vs* month 12 – 14.3 *vs* 10.5 mg/l, p<0.001), but not in the 1st line NILO patients (median concentration at baseline *vs* month 3 – 7.3 *vs* 7.3 mg/l, p=0.875; at baseline *vs* month 12 – 7.3 *vs* 7.8 mg/l, p=0.917). While in the control IMA group (but not DASA) adiponectin concentration was significantly and persistently increased. Thus hypoadiponectineamia observed in the whole NILO group was caused by spontaneous decrease in adiponectin after the stop of IMA in the subgroup of the 2nd line NILO-treated patients.

* Possible role of limited number of patients

Summary/Conclusions: We proved fast and persisting development of peripheral insulin resistance during NILO therapy as underlying cause of glucose and lipid metabolism impairment during NILO treatment. This was not proved for patients treated with IMA and DASA. IMA administration significantly increases serum adiponectin (major insulin sensitizer) concentration, which spontaneously declines after discontinuation of IMA and start of 2nd line NILO therapy.

Seràgnoli", University of Bologna, Bologna, Italy

Background: The outcome of BCR-ABL+ chronic myeloid leukemia (CML) has been significantly improved by the introduction of tyrosine kinase inhibitors (TKIs) and, actually, many patients die of reasons unrelated to CML. A new scoring system, the EUTOS long-term survival (ELTS) score, based on the analysis of a large cohort of CML patients treated frontline with IM and aimed to discriminate the probability of dying of CML, has been recently published by the European LeukemiaNet (ELN). The relevant variables included were: age, peripheral blasts, spleen size and platelet count (Pfirrmann *et al.* Leukemia 16). Nilotinib (NIL) is a 2nd generation TKI approved as frontline therapy of CML in many countries.
Aims: To investigate the prognostic value of the ELTS score in a cohort of CML patients in early chronic phase treated with NIL-based regimens as first-line therapy.
Methods: Three hundred and forty-five adult patients were included. The patients were enrolled in three multicenter studies (ClinicalTrials.gov NCT00481052, NCT00769327 and NCT01535391) conducted by the GIMEMA CML WP, or treated at the University Hospital of Bologna, Italy. The initial treatment was NIL 300 mg BID or NIL 400 mg BID. The intention-to-treat population of each study was analyzed. Definitions: risk scores were defined according to Sokal, EUTOS and ELTs formulations; major molecular response (MMR): BCR-ABL1^{IS} ratio <0.1%; MR$^{4.0}$: BCR-ABL1^{IS} ratio <0.01% with >10,000 ABL1 copies; progression: transformation to advanced phases according to ELN criteria; leukemia-related death (LRD): death after progression.
Results: The median age was 53 years (range 18-86). The patient distribution according the different scoring systems was as follows: 41% low, 40% intermediate and 19% high Sokal score, 94% low and 6% high EUTOS score, 59% low, 30% intermediate and 10% high ELTS score, respectively. The median follow-up was 59 months (range: 24-82 months). The cumulative incidence of MMR and MR$^{4.0}$ was 83% and 69%, respectively; the 6-year progression-free survival (PFS), overall survival (OS) and cumulative incidence of LRD were 91%, 92% and 4%, respectively. All the 3 scores were associated with significantly different probabilities of MMR (cumulative incidence of MMR according to ELTS score: 90%, 77% and 61% in low, intermediate and high risk patients, respectively; p<0.001), but only the ELTS score was able to predict the achievement of MR$^{4.0}$ (cumulative incidence of MR$^{4.0}$: 75%, 63% and 53% in low, intermediate and high ELTS score patients, respectively; p=0.013). Interestingly, both the Sokal score and the ELTS score, but not the EUTOS score, predicted the OS (p=0.021 and p=0.037, respectively), while only the ELTS score predicted a significantly different PFS (p=0.038); the 6-year cumulative incidence of progression was 2%, 7% and 6% in patients with low, intermediate and high ELTS score, respectively. Probably due to the low number of deaths related to CML, all the 3 scores failed to predict LRD, but comparing patients with low ELTS score *versus* patients with intermediate and high ELTS risk the difference became significant.
Summary/Conclusions: In a cohort of CML patients treated with NIL-based regimens as frontline therapy, the prognostic predictive ability of ELTS score resulted superior to Sokal and EUTOS score.

HIGH GENE EXPRESSION OF HIST1H2AG AND HIST1H4A REDUCES IMATINIB UPTAKE INTO CML CELLS AND PREDICTS POOR RESPONSE TO FRONTLINE IMATINIB THERAPY

CH Kok[1,2,*], D Watkins[1,2], J Wang[1,2], V Saunders[2], J Goyne[2], I Pagani[2], P Dang[2], J McLean[2], D Yeung[1,2,3], T Hughes[1,2,3], D White[1,2]

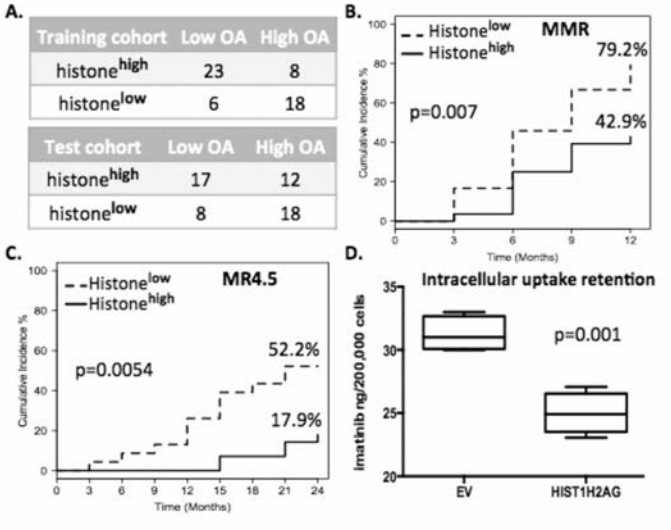
Background: Imatinib (IM), the first generation tyrosine kinase inhibitor (TKI), remains standard frontline treatment for newly diagnosed patients with chronic-phase chronic myeloid leukaemia (CP-CML). None of the second generation TKIs have shown an overall survival advantage over IM. We have previously demonstrated that the OCT-1 activity (OA) assay, (which measures the cellular uptake of IM at diagnosis), is highly predictive of subsequent treatment outcomes. To derive an assay more readily adaptable for other labs, and to understand the biological basis of this functional assay we performed gene-expression profiling (GEP) of low and high OA patients.
Aims: To identify a set of genes measured at diagnosis that predicts patients who have high IM uptake (high OA) and favourable clinical outcome.
Methods: RNA was isolated from total white cells collected from patients on TOPS, TIDEL-I and TIDEL-II trials. The OA associated genes were identified based on a pilot microarray study (n=14). Subsequently the identified genes were validated by qRT-PCR in 110 diagnostic CP-CML samples also obtained from these trials. Patients were divided into low and high gene expression groups using the recursive partitioning and regression trees (rpart) with 10-fold cross validation in the training cohort (n=55), and validation in an independent cohort (n=55).
Results: Previous studies have associated low expression of histone genes with higher rates of complete cytogenetic response (CCyR) by 12 months in IM treated patients. We have measured the expression levels by qRT-PCR of 7 histone genes that demonstrated significant association with OA based on our GEP. Importantly, we identified that low expression of 2 histone genes (*HIST1H2AG* and *HIST1H4A* based on ΔCt 11.7 and 13.0 cutoff respectively) was significantly associated with high OA in the training cohort, and this was also validated in the independent patient test cohort by both Student's t-test and rpart statistical methods (Figure 1A). Significantly, in the validation cohort, patients with low expression of these 2 histone genes (histone^{low}) demonstrated superior rates of major molecular response (MMR: 79% *vs* 43%, p=0.007) by 12 months, and superior rates of MR$^{4.5}$ (52% *vs* 18%, p=0.005) by 24 months compared to patients with high expression of these genes (histone^{high}; Figure 1B-C). There were 26 patients in the validation cohort with histone^{low} based on the cut-offs above, and of these 18 were high OA patients and 8 low OA patients. Although 8/26 (31%) patients were low OA, 7 of these 8 patients achieved MMR by 12 months. There were 6 patients with blast crisis (BC) progression and/or mutations that classified as low OA, and all 6 were in the histone^{high} group. The histone^{high} group is significantly associated with high blast counts in our study compared to histone^{low} group (p=0.01), consistent with a previous study that demonstrated BC patients have higher histone GEP compared to CP patients. Furthermore, overexpression of *HIST1H2AG* using lentiviral transduction significantly reduced the IM cellular uptake in K562 cells compared to empty vector control (p=0.001, Figure 1D), supporting our clinical data observation.
Summary/Conclusions: Histone gene expression likely plays a role in regulating the uptake of imatinib, and possibly BC progression. Patients with low expression of *HIST1H2AG* and *HIST1H4A* are highly likely to achieve good molecular responses and excellent clinical outcomes on imatinib.



(A.) Patients were divided into low and high *HIST1H2AG* and *HIST1H4A* gene expression group using the classification tree method in the training cohort (n=55). Histone^{low} patient group was significantly associated with high OA (p=0.0003). This result was validated in an independent test cohort (p=0.038). **(B-C.)** In the test cohort, histone^{low} patient group (dotted line) demonstrated superior rates of MMR and MR4.5 compared to histone^{high} patient group (solid line). **(D.)** Overexpression of *HIST1H2AG* gene significantly reduced cellular uptake of imatinib compared to empty vector control (EV) in K562 cells.

Figure 1. Low *HIST1H2AG* and *HIST1H4A* gene expression predicts high OCT-1 activity (OA) and favorable clinical outcomes.

S436

ALLELES OF SNPS IN REGULATORY REGIONS OF SLC22A4 AND SLC22A5 GENES ARE SIGNIFICANTLY ASSOCIATED WITH STABLE MAJOR MOLECULAR RESPONSE TO IMATINIB FIRST LINE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

M Jaruskova[1,2], N Curik[1,3], R Hercog[4], V Polivkova[1,5], E Motlova[1], V Benes[4], H Klamova[1,2], K Machova Polakova[1,2,*]
[1]Institute of Hematology and Blood Transfusion, [2]Institute of Clinical and Experimental Hematology of the 1st Medicine Faculty, Charles University and Institute of Hematology and Blood Transfusion, [3]Institute of Pathophysiology, 1st Medicine Faculty, Charles University, Prague, Czech Republic, [4]Genomics Core Facility, Heidelberg, Germany, [5]Faculty of Science, Charles University, Prague, Czech Republic

Background: The bioavailability of imatinib (IM) in leukemic cells at a curative concentration is an important pharmacokinetic factor influencing the response to the treatment of chronic myeloid leukemia (CML) with IM. Pharmacogenetics represents a potential source of molecular markers as patients with inherited haplotype associated with the key genes encoding drug transporters, have genetic predisposition to respond optimally or non-optimally. IM transport was confirmed for transporters encoded by some genes from SLC and ABC families.
Aims: The aim of this study was to screen polymorphisms in the promoter regions of selected SLC and ABC genes and to identify SNPs associated with the response to the first line IM therapy of CML patients.
Methods: Using NGS we screened promoters of 15 SLC and 4 ABC genes on testing cohort of 83 CML patients with optimal (n=42) and non-optimal (n=41) response to IM. Patients were treated with 400mg/day of IM during the minimal follow-up of 24 months. SNPs confirmation in SLC22A4 and SLC22A5 promoters were performed by Sanger Sequencing in the validation cohort of 42 patients. Linkage disequilibrium analysis of genotyped SNPs on European population and proxy identification with the regulatory function in SLC22A4 and SLC22A5 non-coding regions were performed using LDlink1.1. The Fisher´s exact probability test and Chi-square test were used for allele frequency analysis. Cumulative achievement of stable major molecular response (MMR) was calculated using XLSTAT. Kaplan-Meier method was applied for event free survival calculation. Events were defined as loss of MMR, loss of cytogenetic response, TKI switch, BCR-ABL1 mutations, death, hematological relapse and progression.
Results: Among 1486 NGS evaluated sequences we identified 95 SNPs. In the merged cohort of patients from testing and validation cohorts (n=125) we revealed significant differences in the frequencies of rs460089-GC and rs460089-GG (SLC22A4) genotypes among rs2631365-TC (SLC22A5) genotype carriers associated with optimal and non-optimal response, respectively. We found that loci rs460089 and rs2631365 are in highly significant linkage disequilibrium with another 12 regulatory loci (R^2=0.98-1.0; P=0.0) located in introns of SLC22A4 and SLC22A5 encoding OCTN1 and OCTN2 IM transporters, respectively. Based on the genotypes association analysis with the response to IM we revealed that rs460089-GC genotype carriers had significantly higher probability to achieve stable MMR (P =0.001) and this was enhanced in rs460089-GC_rs2631365-TC genotypes carriers (Figure 1; P=0.000). Consequently, patients with rs460089-GC genotypes have higher probability to survive without event in contrast to patients with rs460089-GG (P=0.003), when the contrast was higher in patients with rs460089-GC_rs2631365-TC genotypes in comparison to rs460089-GG_rs2631365-TC (P<0.0001).

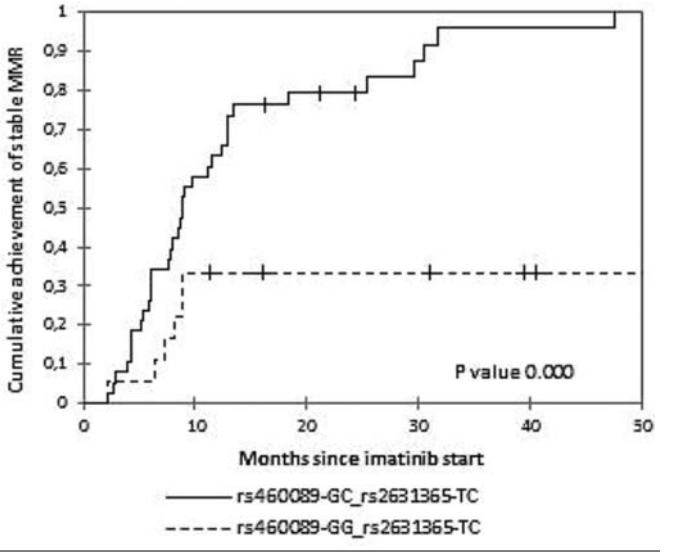


Figure 1.

Summary/Conclusions: We found that SNPs rs460089 and rs2631365 may represent important genetic markers for European population of CML patients by predicting response to the IM therapy at the time of diagnosis. Patients with rs460089-GC_rs2631365-TC genotype would likely respond optimally, in contrast, rs460089-GG_rs2631365-TC genotype represents a risk factor for IM failure and disease progression. This risk factor maybe associated with sublethal concentration of IM, which may lead to resistant clone development and disease progression. Patients with high-risk genotype rs460089-GG_rs2631365-TC may profit from therapy with tyrosine kinase inhibitors that are independent on OCTN1 and OCTN2 carriers.

Follicular and Mantle Cell Lymphoma - Clinical

S437

15-YEAR FOLLOW-UP OF THE NORDIC MCL2-TRIAL: DESPITE LONG-TERM RESPONSES LATE RELAPSES STILL OCCUR

CW Eskelund[1,*], A Kolstad[2], A Laurell[3], M Jerkeman[4], R Räty[5], S Husby[1], NS Andersen[1], LB Pedersen[1], M Eriksson[4], M Nordström[6], E Kimby[6], H Bentzen[7], O Kuittinen[8], GF Lauritzsen[2], H Nilsson-Ehle[9], E Ralfkiær[10], M Ehinger[4], C Sundström[3], J Delabie[2], ML Karjalainen-Lindsberg[5], P Brown[1], E Elonen[5], K Grønbæk[1], CH Geisler[1]

[1]Dept. of Hematology, Rigshospitalet, Copenhagen, Denmark, [2]Norwegian Radium Hospital, Oslo, Norway, [3]Uppsala University Hospital, Uppsala, [4]Lund University Hospital, Lund, Sweden, [5]Helsinki University Central Hospital, Helsinki, Finland, [6]Karolinska Institute, Stockholm, Sweden, [7]Aarhus University Hospital, Aarhus, Denmark, [8]Oulu University Hospital, Oulu, Finland, [9]Sahlgrenska Hospital, Gothenburg, Sweden, [10]Rigshospitalet, Copenhagen, Denmark

Background: Until recently, Mantle Cell Lymphoma (MCL) was associated with an exceedingly poor prognosis with a median overall survival (OS) of 3-5 years (Herrmann, JCO, 2008). However, during the last 15 years the outcome has improved substantially by an intensified Ara-C-containing induction regimen, addition of rituximab and consolidation with high-dose therapy and autologous stem cell transplantation (ASCT). One such regimen was introduced by the MCL2 trial, conducted by the Nordic Lymphoma Group (NLG), and showed a projected 10-year OS and PFS of 58% and 43%, respectively, after a median follow-up time of 6.5 years (Geisler, BJH, 2012).

Aims: The MCL2 regimen is still the 1-st-line regimen of choice for younger patients in many centers worldwide. Here we present the updated results after a median follow-up of 11.4 years of the MCL2 trial.

Methods and Patients: Between 2000 and 2006, 160 untreated stage II-IV MCL patients younger than 66 years were enrolled in Denmark, Norway, Sweden and Finland. Patient characteristics have previously been described elsewhere (Geisler, Blood, 2008). Histological diagnoses were confirmed by a central pathology review board. An informed consent was obtained from all patients.

Treatment: Six alternating cycles of maxi-CHOP and high-dose Ara-C, with rituximab after cycle 3, followed by BEAM/BEAC and ASCT in responders (n=145). Patients who subsequently developed solely molecular relapse detected by clonal IGHV or t(11;14) PCR received 4 weekly cycles of rituximab (Andersen, JCO, 2009).

Results: With a median follow-up of 11.4 years, the median OS and PFS were 12.7 and 8.5 years, respectively (Figure 1A,B). The median response duration (RD) of the 145 patients who underwent ASCT was 12.4 years (Figure 1C). The MCL international prognostic index (MIPI) and the biological index (MIPI-B) significantly divided patients into three risk groups according to OS, PFS and RD (Figure 1D,E, data only shown for PFS). The median OS and PFS were 4.0 and 2.5 years in the MIPI high-risk group, 11.0 and 8.0 years in the intermediate risk group, and not reached and 12.8 years in low risk group, (Figure 1D). Interestingly, 17 patients relapsed after 5 years or more in CR, and 6 patients beyond 10 years, primarily from the intermediate and low risk groups. Meanwhile, the MIPI high risk group reached a plateau at 24% (n=9) after 7 years. We recently proposed an improved prognosticator including expression of micro-RNA-18b (MIPI-B-miR) based on the same patient cohort (Husby, Blood, 2016). In the present update, it remains highly significant and identifies a high-risk group of an exceedingly poor prognosis with OS and PFS of only 1.6 and 1.0 years, respectively (n=10) (Figure 1F), while still separating the low- and intermediate risk groups.

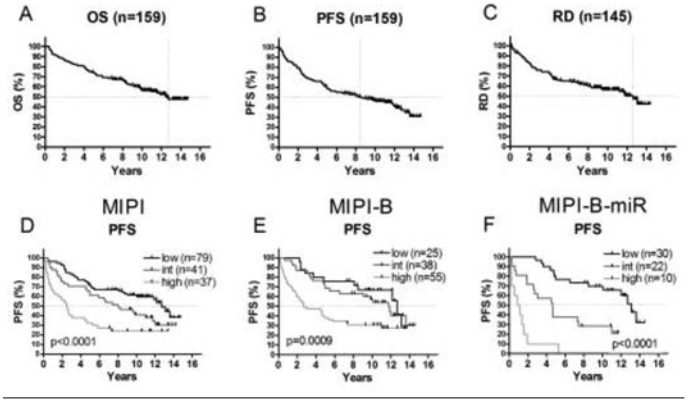

Figure 1.

Summary/Conclusions: After an extended median follow-up of 11.4 years, the outcome of the Nordic MCL2 trial is still good. However, a pattern of continuing relapse is observed, seemingly precluding cure. MIPI, MIPI-B and, in particular,

MIPI-B-miR remain valid prognosticators that clearly separate patients into risk groups with different outcomes. All risk groups might benefit from addition of novel agents, and such approaches are underway in large randomized trials.

S438

OVERALL SURVIVAL OUTCOMES IN PATIENTS WITH MANTLE-CELL LYMPHOMA (MCL) TREATED WITH IBRUTINIB IN A POOLED ANALYSIS OF 370 PATIENTS FROM 3 INTERNATIONAL OPEN-LABEL STUDIES

S Rule[1,*], M Dreyling[2], G Hess[3], R Auer[4], B Kahl[5], N Cavazos[6], B Liu[7], F Clow[6], J Goldberg[8], D Beaupre[6], J Vermeulen[9], M Wildgust[8], M Wang[10]
[1]Derriford Hospital, Plymouth, United Kingdom, [2]Department of Medicine III, Klinikum der Universität München, München, [3]Department of Hematology, Oncology and Pneumology, University Medical School of the Johannes Gutenberg-University, Mainz, Germany, [4]Haemato-Oncology, St.Bartholomew's Hospital, Barts Health NHS Trust, London, United Kingdom, [5]Washington University School of Medicine, St. Louis, [6]Pharmacyclics, Sunnyvale, United States, [7]Biostatistics, J&J Medical China, Shanghai, China, [8]Janssen Research & Development, Raritan, United States, [9]Janssen Biologics Europe, Leiden, Netherlands, [10]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: MCL is a rare, aggressive B-cell lymphoma with a poor prognosis. For patients who fail initial therapy, conventional chemotherapy achieves only short-term remissions. Ibrutinib is a first-in-class, once-daily, oral, covalent inhibitor of Bruton's tyrosine kinase shown to be highly active for patients with MCL. The current pooled analysis from 3 ibrutinib studies (PCYC-1104, MCL2001 [SPARK] and MCL3001 [RAY]) assessed the impact of baseline factors on overall survival (OS) in patients with relapsed/refractory (R/R) MCL.
Aims: To explore baseline factors impacting OS in patients with MCL receiving ibrutinib.
Methods: Patients with R/R MCL were enrolled across 3 studies to receive ibrutinib 560 mg orally once daily until progressive disease or unacceptable toxicity. Inclusion and exclusion criteria were similar in all 3 studies; however, patients in SPARK were required to have received both rituximab and bortezomib. Patient-level data from all 3 studies were combined into one database. Simple descriptive statistics were used, and exploratory analyses were conducted using Kaplan-Meier estimates for progression-free survival (PFS) and OS. Univariate and multivariate analyses were also conducted with hazard ratios to allow for comparisons of variables. All patients provided written informed consent.
Results: Overall, 370 patients were included in this analysis (PCYC-1104, n=111; SPARK, n=120; RAY, n=139); median age was 67.5 years, 94% had ECOG 0-1, 45% and 32% had intermediate and high-risk sMIPI, most patients had 1-3 prior lines of therapy (27%, 29%, 22% had 1, 2, 3 prior lines of therapy, respectively), 49% had bulky disease (>5 cm) and 88% had non-blastoid histology. Overall response rate (ORR) was 66% (20% CR; 46% PR), with a median DOR, PFS and OS of 18.6, 12.8 and 25.0 months, respectively. ORR (CR) for patients with 1, 2 and ≥3 prior lines of therapy was 77.8% (34%), 71% (24%) and 64% (16%). Of patients who achieved a CR, 70% were progression-free and 90% were alive at 2 years. Univariate analyses showed that patients with 1 *vs* >1 prior line of therapy had significantly longer OS, with longer OS also observed in those who were younger and had non-blastoid histology (Figure 1), non-bulky disease or better sMIPI score. Patients with blastoid and non-blastoid histology had similar ORR (55 *vs* 72%) and time to best response (2.2 *vs* 2.1 months); however, DOR (8.6 *vs* 18.8 months), PFS (5.1 *vs* 14.6 months) and OS (12.8 *vs* not reached) were significantly shorter in patients with blastoid histology. Multivariate analyses identified ECOG, sMIPI, bulky disease and blastoid histology as impacting OS, and sMIPI, bulky disease, blastoid histology and 1 prior line of therapy as impacting PFS.

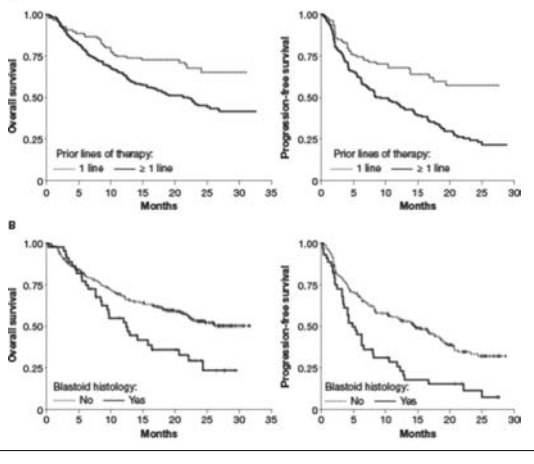

Figure 1. Kaplan-Meier Curves of OS and PFS by Baseline Factors: 1 *vs* >1 Prior Line of Therapy and Blastoid Histology.

Summary/Conclusions: Here we show that OS is significantly longer in ibrutinib-treated patients who are younger and who have fewer prior lines of therapy, better sMIPI scores, non-bulky disease and non-blastoid histology. While PFS and OS in patients with blastoid *vs* non-blastoid histology are shorter, these rates are higher than seen with other agents, indicating that ibrutinib is an effective agent to achieve a response and potentially provide a bridge to transplant. Multivariate analyses indicate that traditional poor prognostic factors adversely impact OS, suggesting that worsening OS in later lines of therapy is associated with disease characteristics rather than an impact of ibrutinib on postprogression survival. Data support the preferential use of ibrutinib after initial *vs* later relapse, as PFS and OS are longer in patients receiving 1 *vs* >1 prior line of therapy.

S439

SEQUENCE VARIANTS IN PATIENTS WITH PRIMARY AND ACQUIRED RESISTANCE TO IBRUTINIB IN THE PHASE 3 MCL3001 (RAY) TRIAL

G Lenz[1,*], S Balasubramanian[2], J Goldberg[3], A Rizo[3], M Schaffer[2], C Phelps[3], S Rule[4], M Dreyling[5]
[1]Translational Oncology, Münster University Clinic, Münster, Germany, [2]Janssen Research & Development, Spring House, [3]Janssen Research & Development, Raritan, United States, [4]Derriford Hospital, Plymouth, United Kingdom, [5]Department of Medicine III, University Hospital Grosshadern/LMU, Munich, Germany

Background: The phase 3 MCL3001 (RAY) study compared the efficacy and safety of ibrutinib with that of temsirolimus in patients with relapsed or refractory mantle-cell lymphoma (MCL). Ibrutinib significantly prolonged progression-free survival (PFS) *versus* temsirolimus (14.6 *vs* 6.2 months; p <0.0001) and increased overall response rate (ORR) (72 *vs* 40%; p <0.0001). The current study explores underlying molecular mechanisms of resistance to ibrutinib in patients from the RAY study.
Aims: To identify specific mechanisms underlying ibrutinib resistance in MCL, and to correlate potential genetic signatures with patient response.
Methods: The clinical results of the RAY study are reported elsewhere (Dreyling 2015). Patients were grouped by best ORR+PFS: Durable Responder: complete response or partial response (PR)+PFS ≥4 months; Moderate Clinical Benefit: PR+PFS <4 months or stable disease; and Primary Resistant Disease. For mutational analysis, the Durable Responder group was compared with the Poor/Non-responders group (Moderate Clinical Benefit+Primary Resistant Disease combined) using Fisher's exact test for comparisons between the 2 groups. For primary resistance analysis, baseline variant differences between groups were compared. For acquired resistance analysis, initial samples and samples obtained at progression after response were compared. Deep sequencing was performed on DNA from tumor cells (Illumina HiSeq instrument) using a custom gene panel. Sequences were aligned to hg19 reference genome, variants were described using SAMtools, and germline filters were applied to identify possible somatic mutations. All patients provided written informed consent.
Results: Mutations associated with primary resistance to ibrutinib were identified in NF-kB signaling pathways, both canonical (*e.g.*, A20) and noncanonical (*e.g.*, BIRC2). Other mutations were found in epigenetic modifiers and in the EGFR family. To explore acquired resistance, 34 paired samples (11 ibrutinib; 23 temsirolimus) were analyzed. Two PLCg2 mutations were found in patients with durable PRs (18.5 and 8.5 months); a CARD11 mutation after PR was found in 1 patient (after 12 months). Mutations in epigenetic modifiers and alternate NF-kB or PI3K/mTOR pathways were found after a short treatment duration (<4 months). No primary or acquired Bruton's tyrosine kinase (BTK) C481S mutations were detected.
Summary/Conclusions: Mutations in the NF-kB pathway bypassing BTK appear to be a common mechanism of resistance in this population with MCL. The similarity between primary and acquired mutations, as well as the lack of BTK C481S mutations to date, may possibly be explained by the short follow-up and shorter response duration compared with chronic lymphocytic leukemia. Some mutations seen in the acquired setting (*e.g.*, CARD11, PLCg2) have been associated with ibrutinib resistance. Understanding both primary and acquired resistance patterns is key in order to improve outcomes and define the populations that benefit from ibrutinib treatment.

OBINUTUZUMAB PLUS BENDAMUSTINE *VERSUS* BENDAMUSTINE ALONE IN PATIENTS WITH RITUXIMAB-REFRACTORY FOLLICULAR LYMPHOMA: RESULTS FROM THE GADOLIN STUDY

M Trněný[1,*], K Bouabdallah[2], G Dueck[3], J Gribben[4], P Lugtenburg[5], O Press[6], G Salles[7], L Sehn[8], C Berge[9], G Fingerle-Rowson[9], E Wassner-Fritsch[9], B Cheson[10]
[1]Charles University, Prague, Czech Republic, [2]University Hospital of Bordeaux, CHU Haut-Leveque, Bordeaux, France, [3]British Columbia Cancer Agency, Vancouver, Canada, [4]Queen Mary University of London, London, United Kingdom, [5]Erasmus MC Cancer Institute, Rotterdam, Netherlands, [6]Fred Hutchinson Cancer Research Center, Seattle, United States, [7]Hospices Civils de Lyon, Université Claude Bernard Lyon-1, Lyon, France, [8]British Columbia Cancer

Agency and the University of British Columbia, Vancouver, Canada, [9]F. Hoffmann-La Roche Ltd, Basel, Switzerland, [10]Georgetown University Hospital, Washington, United States

Background: Limited treatment options are available for patients (pts) with rituximab-refractory (R-R) indolent non-Hodgkin lymphoma (iNHL). GADOLIN (NCT01059630) is an open-label, randomized, phase 3 trial comparing the efficacy and safety of obinutuzumab (GA101; GAZYVA/GAZYVARO; G) plus bendamustine (B; G-B) induction, followed by G maintenance, with B standard of care in this pt group. In the primary analysis (median observation time: 21 months [mo]) of iNHL pts, median Independent-Review Committee (IRC)-assessed progression-free survival (PFS) was longer in the G-B arm (194 pts; median not reached) than in the B arm (202 pts; 14.9 mo), with a 45% reduction in risk of progression or death (HR 0.55; 95% CI 0.40-0.74; p=0.0001). Safety profiles were comparable.
Aims: To evaluate efficacy and safety in the follicular lymphoma (FL) subset of GADOLIN pts considered in the primary analysis.
Methods: GADOLIN pts were aged ≥18 years with documented R-R iNHL and an Eastern Cooperative Oncology Group performance status of 0-2. Pts received either G 1000mg intravenously (IV) (days [D] 1, 8 and 15 of cycle (C) 1 and D1 of C2-6) plus B 90mg/m^2/day IV (D1 and 2 of C1-6) or B monotherapy (120mg/m^2/day IV D1 and 2 of each cycle for up to six cycles); each cycle was 28 days. Following induction, pts in the G-B arm without evidence of progression received G maintenance (1000mg IV every 2 mo for 2 years or until disease progression). Endpoints included IRC-assessed PFS (primary), investigator (INV)-assessed PFS, response and safety. All pts gave informed consent.
Results: 321 (81%) of 396 iNHL pts enrolled had FL (G-B, 155; B, 166). Baseline characteristics of the FL population were balanced between arms. Median number of prior therapies was 2. Most pts were refractory to their last prior rituximab (R)-containing regimen (G-B, 94%; B, 93%) and double-refractory to R and an alkylating agent (G-B, 77%; B, 80%). IRC-assessed end of induction (EOI) and best overall response were similar in the G-B and B arms (p>0.05 for comparison; Table 1). Median IRC-assessed PFS was not reached in the G-B arm and was 13.8 mo in the B arm (Figure 1), while median INV-assessed PFS was more than twice as long in the G-B arm than in the B arm (Table 1); in both instances, the advantage corresponded to a 52% reduction in risk of progression or death relative to B (Table 1). Survival data were immature at the time of analysis. Safety profiles were comparable. Of note, grade 3-5 adverse events (AEs) and grade 5 AEs (fatal outcome) occurred in 65.8% and 5.2% pts in the G-B arm and 58.9% and 6.1% pts in the B arm, respectively.

Table 1.

Parameter	FL subpopulation	
	G-B (n=155)	B (n=166)
Median observation time (range), mo	22.08 (0.4-48.5)	20.27 (0.0-50.0)
PFS (IRC)		
Pts with event, n (%)	54 (34.8)	90 (54.2)
Median (mo)	Not reached	13.8
HR [95% CI]; stratified*	0.48 [0.34-0.68]	
PFS (INV)		
Pts with event, n (%)	62 (40.0)	102 (61.4)
Median (mo)	29.2	13.7
HR [95% CI]; stratified*	0.48 [0.35-0.67]	
Response† (IRC)		
EOI response (%): overall‡/CR	70.5/9.4	62.6/13.5
Best response (%): overall‡/CR	79.7/15.7	77.0/19.3

**Stratification factors for FL population were refractory type (R vs R-chemo) and prior therapies (≤2 vs >2); †During treatment and within 12 mo after start of treatment; ‡Complete response (CR) or partial response.*

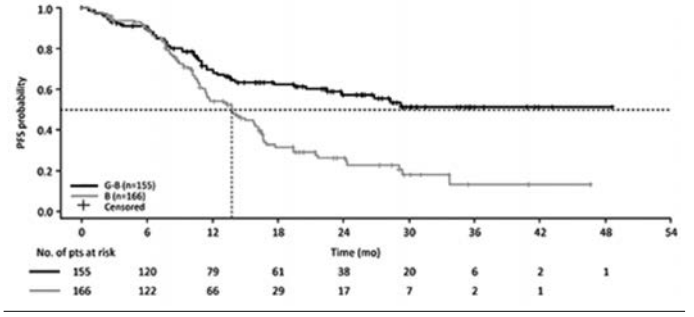

Figure 1. Kaplan Meier plot of IRC-assessed PFS in patients with FL.

Summary/Conclusions: In the FL subset of GADOLIN pts, PFS was significantly longer in the G-B arm compared with the B arm, corresponding to a 52% reduction in risk of progression or death. No unexpected safety signals were identified. G-B is an effective therapy for pts with R-R FL.

Background: High dose therapy supported by autologous stem cell transplantation (HDT/ASCT) has been a treatment frequently indicated in follicular lymphoma (FL) patients and has contributed to modify the natural history of the disease, however secondary neoplasia is one of the concerns after HDT/ASCT with a reported incidence very variable among studies due in part to cohort different in terms of age, pre-ASCT treatments, used of total body irradiation (TBI)-based conditioning regimen or length of follow-up rather than to the procedure itself.
Aims: To evaluate the cumulative incidence and characteristics of myelodysplastic syndromes and acute myeloid leukemia (sMDS/sAML) and solid tumors after HDT/ASCT in a very long-term follow-up analysis of FL patients.
Methods: A total of 655 FL patients reported to the Spanish GELTAMO registry and intensified with HDT/ASCT between 1989 and 2007 were analyzed. Baseline characteristics and therapeutic-related data are listed in the Table 1. Standardized Incidence Ratios (SIR) were calculated to assess the risk of a second malignancy by dividing the number of observed second malignancies with the number of expected sex matched incidence using the 2008 crudes rates in the Spanish population (*M.J Sánchez, Annals oncology 2010*).

Table 1. Main clinical Features at Diagnosis and Treatment Variables of the Series.

Characteristics		No. [a]	%
All patients		655	100
Median age, years (range)		47 (18-73)	
Sex: Male/ Female		330/ 325	50.4/ 49.6
FLIPI Score	Low	108	33
	Intermediate	120	36
	High	102	31
FLIPI 2 Score	Low	69	22
	Intermediate	118	38
	High	125	40
Disease Status at ASCT	CR	405	62
	PR	221	34
	Refractory disease	29	4
Anthracycline-containing first line therapy		460	76
Fludarabine-containing first line therapy		36	6
Only one therapy line before HDT/ASCT		183	28
Rituximab previous HDT, Yes/ No		184/ 436	30/ 70
Conditioning Regimen TBI based, Yes/ No		109/ 504	17/ 83
PBPC, Yes/ No		517/87	14.5/ 85.5

Abbreviations: BM: Bone Marrow, FLIPI: Follicular Lymphoma prognostic index, CR: Complete Response,PR: Partial Response, ASCT: Autologous Stem Cell Transplantation, HDT: High Dose Therapy, TBI: Total Body Irradiation, PBPC: Peripheral Blood Progenitor Cells.
a There are some missing data for several variables. No. of missing values can be directly derived for each variable by the equation: 655-(sum of available results)

Results: At a median follow-up of 12 years from HDT/ASCT and 14.2 years from diagnosis of FL the median OS were 21.3 years from HDT/ASCT and 22.6 years from the time of FL diagnosis. Of the 645 evaluable patients; 80 (12.5%) developed a second malignancy: solid tumors (38 cases; 47.5%; of them 5 were skin cancers), sMDS/sAML (34 cases; 42.5%), ALL (2 cases),

CML (1 case), Hodgkin lymphoma (1 case) and not specified (4 cases). The accumulated incidence at 5, 10 and 15 years was 1.8%, 3.5% and 4.9% for solid tumors and 2.6%, 4.3% and 5% for sMDS/sAML, respectively. sMDS/sAML and solid tumors were documented with a median time of occurrence since HDT/ASCT of 4.2 years (0.3-15.5) and 8.3 years (0.5-24.4), respectively. The SIR for second neoplasia was 2.8.Male sex (*P*=.1) and the use of BM as stem cell source (*P*=.1) tended to be associated with an increased number of second neoplasia. There were no differences according to the use of anthracycline, fludarabine or rituximab previously to HDT/ASCT, number of therapy lines before HDT/ASCT, time from diagnosis to HDT/ASCT, status of the disease at HDT/ASCT or conditioning regimen. Median OS for patients with second neoplasia is 11.8 years from the time of FL diagnosis, 9.4 years from ASCT [14.5 y. for solid tumors and 8 y. for sMDS/sAML (*P*=.01)] and 1.4 years from the time of diagnosis of second neoplasia [2.7 y. for solid tumors and 1.3 y. for sMDS/sAML (*P*=.01)], respectively.

Summary/Conclusions: Our results, from the longest follow-up study in FL including a large number of cases from the rituximab era, indicate that FL patients undergoing and ASCT are at an increased risk of developing a second malignancy, however, the incidence is not higher than that reported in other series without transplantation (*Rummel, Lancet 2016; Ardeshna, Lancet 2003*). Low percentage of patients conditioned with TBI and a considerable number of patients been transplanted soon during the disease, could explain these good results. Once a secondary neoplasia is diagnosed prognosis is dismal, and consequently a carefully selection of patients candidates to ASCT is necessary. For all that, we suggest that, given the favorable survival obtained by HDT/ASCT makes not evident to what extent incidence of secondary neoplasia will diminish the benefit of HDT/ASCT in FL.

Background: The development and progression of cancer are shaped by dynamic alterations of clonal architecture, characterization of which in terms of gene mutations is essential for the understanding of the pathogenesis of cancer. However, the clonal architecture in myelodysplastic syndromes (MDS) has been only inferred from the allelic burden of a limited number of driver mutations at a single time point. Comprehensive mutation profiling of serial samples has been performed only for a small number of patients.

Aims: We aimed to delineate the impact of clonal dynamics on disease phenotypes, progression to secondary acute myeloid leukemia (sAML), and clinical outcomes in a large cohort of fully genotyped MDS patients.

Methods: Clonal architecture and dynamics were investigated by whole exome sequencing (WES) and/or targeted sequencing of 779 patients with MDS and sAML, of whom 97 were analyzed longitudinally. Combined with published data sets (N=2,133), the data were also used to interrogate differential roles of driver mutations in disease progression.

Results: Higher-risk MDS was characterized by a higher number of mutations with increasing diversity and a larger clone size. The number of cases with heterogeneity was significantly higher in sAML compared to lower-risk MDS (*P*=0.03). In WES analysis of serial samples, evolution of a new dominant clone that swept out other subclones was common during disease progression and frequently accompanied by newly emerging subclones. Leukemic transformation was heralded by acquisition of new mutations in most cases without clone sweeping. To clarify the relationship between driver mutations and disease progression or phenotype, we compared frequencies of major driver mutations between disease subtypes within a large cohort of patients. In total, data from samples with lower- (n=1,157) and higher-risk (n=672) MDS, as well as sAML (n=304), were subjected to analysis of 27 driver genes mutated in more than 2% of the entire cohort. Mutations in genes designated as Type-1 (*FLT3, PTPN11, IDH1, CBL,* and *NRAS*) were significantly enriched in sAML compared to higher-risk MDS. When compared between higher- and lower-risk MDS, we observed a skewed enrichment of certain driver mutations in higher-risk MDS, designated here as Type-2 (*TP53*, *GATA2*, *RUNX1*, *IDH2*, *STAG2, ASXL1*, and *NPM1*). In longitudinal samples, Type-1 mutations were more likely to be newly acquired or to increase in clone size ($P=1.94\times10^{-4}$, trend test). In contrast, more Type-2 and other mutations decreased in their clone size or were even lost in the second sampling. Patients with Type-1 mutations (Group-I) had a significantly shorter time to progression to sAML compared to other patients (hazard ratio (HR)=5.7, 95% confidence interval (CI)=3.4−9.6; *P* <0.001). Time to sAML in Group-I patients was also significantly shorter than that in patients who had Type-2 mutations but lacked Type-1 mutations (Group-II) (HR=3.0, 95% CI=1.7−5.4; *P* <0.001). Despite the significant difference in the rate of progression to sAML between patients in Group-I and Group-II, both had a similar overall survival. Accordingly, in Group-II patients more deaths occurred before progression to sAML, compared to Group-I patients.

Summary/Conclusions: Dynamics of clonal architecture strongly correlates with distinct types of mutations, which are significantly associated with leukemia-free survival and non-leukemia death, suggesting that screening of these specific mutations might be useful for the prediction of clinical outcome.

S443

INTEGRATIVE GENOMICS IDENTIFIES THE MOLECULAR BASIS OF RESISTANCE TO AZACITIDINE THERAPY IN MYELODYSPLASTIC SYNDROMES

Background: Myelodysplastic Syndrome (MDS) and Chronic Myelomonocytic Leukaemia (CMML) are haematological disorders that develop in haematopoietic stem or progenitor cells (HSPCs) and are characterised by ineffective haematopoiesis. 5'-Azacitidine (AZA), a DNA demethylating agent, is the primary drug for the treatment of high-risk MDS and CMML and response is associated with improved survival benefits. However, only half of treated patients will ever respond to AZA and the molecular basis for poor response is currently unknown. Additionally, AZA response is rarely sustained and a substantial fraction of responders will eventually relapse.
Aims: We aimed to: 1.) understand the molecular basis for poor response to AZA, and 2.) characterise the *in vivo* effect of AZA therapy on dysplastic cells in responders, as a first step towards understanding eventual relapse.
Methods: We enrolled 18 high-risk MDS and CMML patients on a compassionate access program for AZA in Australia. Bone marrow was collected at seven different points – before treatment; through 6 cycles of treatment; and at up to two years after initiation – and we isolated high-purity CD34$^+$ HSPCs (Figure 1 A). 10 patients had a complete response while 8 were poorer responders. We performed RNA-seq to query the transcriptomes and deduced the clonal evolution in the bone marrow in response to AZA therapy by whole exome-sequencing and single-cell genotyping.

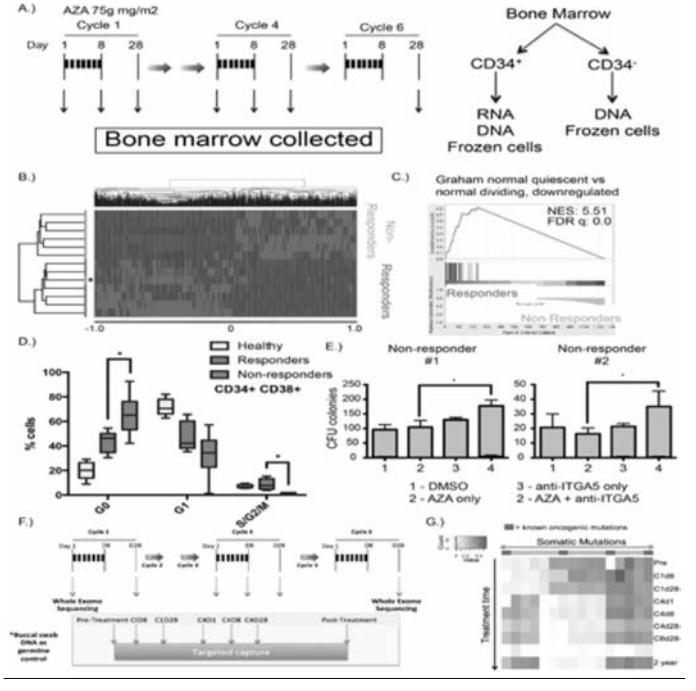

Figure 1.

Results: We hypothesised that primary AZA resistance would be driven by pre-existing molecular differences between responders and non-responders. Analysis of the pre-treatment RNA-seq data revealed differential gene expression between responders and non-responders (Figure 1 B). Pathway analyses of these genes indicated that cell cycle was relatively up-regulated in responders compared to non-responders (Figure 1 C). We validated these gene expression differences in independent patient cohorts. We then adapted a flow cytometry based assay, amenable to prospective use in a clinical diagnostic setting, to directly detect the increased quiescence of CD34$^+$ CD38$^+$ haematopoietic progenitors in unsorted bone marrows of non-responders (Figure 1 D). Finally, to reverse the quiescence of progenitor cells of non-responders, we developed a stromal co-culture drug testing platform and discovered that inhibiting integrin-linked signalling combinatorially with AZA improved the functionality of dysplastic cells (Figure 1 E). To trace the fate of dysplastic cells upon AZA therapy, we performed whole exome sequencing of all patients (Figure 1 F). Using the mutations as "molecular barcodes", we deduced the clonal architecture in each individual. We have discovered that although AZA alters the sub-clonal contribution to different lineages, founder clones are not eliminated and continue to drive hematopoiesis even in complete responders (Figure 1 G). Lastly, we have also discovered that AZA response is associated with an up-regulation of inflammation-associated pathways *in vivo*.
Summary/Conclusions: Our findings, across independent cohorts and relevant to both MDS and CMML, have immediate clinical utility not simply to prospectively identify AZA non-responders but also by suggesting combinatorial therapies that could improve response. Finally, elucidating the *in vivo* effects of AZA therapy lay the foundation for developing more durable treatments.

S444

HEDGEHOG SIGNALING PATHWAY INHIBITOR, PF-04449913 LIMITS THE SELF-RENEWAL OF MDS-DERIVED INDUCED POTENT STEM CELLS (IPSC): MOLECULAR MECHANISMS

T Tauchi*, S Okabe, S Katagiri, Y Tanaka, K Ohyashiki
Haematology, Tokyo Medical University, Tokyo, Japan

Background: Myelodysplastic syndromes (MDS) are clonal hematopoietic disorders characterized by no efficient hematopoiesis and frequent progression to acute myeloid leukemia (AML). Even in low risk MDS, clonal hematopoiesis already dominates at diagnosis, and clones found in secondary AML originate from the MDS stage of disease, highlighting the need to specifically target the MDS-initiating clone. PF-0449913 is a potent and selective hedgehog pathway inhibitor that act by binding Smoothened (SMO) and blocking signal transduction. In xenograft models of human coloirectal and pancreatic cancer, treatment with PF-04449913 in combination with other anticancer agents reduced the tumor growth. Furthermore, PF-04449913 demonstrated preliminary antitumor activity in a phase I trial, when given as monotherapy in patients with several hematopoietic malignancy.
Aims: In the present study, we investigated the molecular mechanisms by which PF-04449913 regulate the self-renewal of MDS-derived iPS cells (iPSCs) *in vivo*.
Methods: We generated iPSCs from bone marrow mononuclear cells of two MDS patients (RAEB1 and RAEB2 by WHO clssification) with complex karyotypic abnormalities. Karyotyping analysis revealed that MDS-derived iPSCs have identical abnormalities to primary MDS cells. We also generated iPSCs from bone marrow mononuclear cells of normal volunteer as control. To investigate the effects of PF-04449913 on self-renewal and the relevance as a therapeutic target in MDS initiating cells, NOD/SCID mice were injected sucutaneously with MDS-derived iPSCs or normal iPSCs then treated with PF-04449913 (100 mg/kg; p.o.) from day 10 for 28 days. We also used MDS-L, a myelodysplastic cell line establised from MDS patient with del(5q) and complex karyotypic abnormalities for *in vitro* studies.
Results: Both MDS-derived iPSCs transferred NOD/SCID mice and normal iPSCs transferred NOD/SCID mice demonstrated the engraftment of CD34+CD38- positive cells by flow cytometry. However, the treatment with PF-04449913 reduced the population of CD34+CD38- positive cells in MDS-derived iPSCs transferred NOD/SCID mice. We isolated human CD45+ cells from the spleen of mice from each treatment group and injected equivalent numbers of CD45+ cells into secondary recipients. Following 50 days, all mice treated with vehicle engrafted with CD34+CD38- positive cells. In contrast, CD34+CD38- positive cells engraftment was not detected in recipient mice (n=3) from PF-04449913-treated donors. These results demonstrate the persistent effects of PF-0449913 on long term self-renewing MDS-initiating cells. We further examined the effects of Nanog pathway modulation on *in vitro* clonogenic growth. CD34+CD38- cells from MDS-derived iPSCs transferred NOD/SCID mice and MDS-L cells were treated with 2 mM of PF-04449913 for 72 hrs, washed free of drugs, and plated in quadruplicate in methylcellulose. At 14 days, colonies were counted as initial plating. The representative plate was then washed and cells were re-suspended and re-plated. After an additional 14 days, colonies were counted as secondary re-plating. Clonogenic recovery of untreated cells was normalized to 100% and plating results from all treatment groups were expressed as % control. PF-04449913 had only minimum effects on colony formation after initial plating over control cells. However, upon serial re-plating, secondary colony formations were significantly inhibited by PF-04449913 ($p<0.001$). Also reduced expression of Nanog by shRNA also supressed the secondary colony formations.To identify the mechanisms that limit the self-renewal of MDS-initiating ells by PF-04449913, NOD/SCID mice engrafted with CD34+CD38- fractions from MDS-derived iPSCs were treated

with PF-04449913 (100 mg/kg; p.o.) for 14 days. PF-04449913 induced the expressions of p21Cip1, cleaved PARP and reduced the expression of BMI-1, c-Myc, Nanog, and Bcl-XL.
Summary/Conclusions: Our preclinical results indicate that PF-04449913 have potential as an important option for controlling the drug-resistant MDS-initiating cells. It is expected that the PF-04449913 may become extremely useful therapeutic interventions in a number of hematological neoplasms, including MDS, where the persistence of cancer stem cells.

[1]Center for Hematology and Regenerative Medicine, Karolinska University Hospital Huddinge, Stockholm, Sweden, [2]Haematopoietic Stem Cell Biology Laboratory, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, [3]Cancer Genome Project, Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Background: Mutations in the RNA splicing gene *SF3B1* are found in more than 80% of patients with myelodysplastic syndrome with ring sideroblasts (MDS-RS), and predict for a stable clinical course and a favourable survival (Malcovati L. *et al., Blood* 2015 126(2):233-41). Little is known about the cellular origin of these mutations or their hierarchy in relation to other somatic mutations.
Aims: To establish the origin of *SF3B1* mutations within the bone marrow (BM) hematopoietic stem and progenitor cell compartment (HSPC) in MDS-RS.
Methods: We investigated BM mononuclear cells (MNC) from 13 MDS-RS patients (6 RARS and 7 RCMD-RS) and 4 healthy controls for mutational spectrum by targeted sequencing, and quantified HSPC subsets using flow cytometry. Functional analysis of the purified populations was performed *in vivo*, using xenotransplantation in NOD scid gamma (NSG) mice to establish repopulating and self-renewal ability, and *ex vivo* using clonogenic progenitor assays: colony forming-unit (CFU) and long-term culture initiating cell (LTC-IC). Hierarchy of molecularly and functionally distinct stem and progenitors cells was established using pyrosequencing.
Results: Screening for recurrently mutated genes in the MNC fractions revealed mutations in *SF3B1* in 12/13 cases, combined with *TET2* and *DNMT3A* in 4 and 2 patients, respectively. The frequencies of phenotypically defined MDS-RS HSPC in the BM did not differ from that of normal controls, whereas pro-B cells were significantly reduced ($p<0.005$) in MDS-RS. We tracked back all the mutations identified in the MNC fractions to each purified MDS-RS stem and progenitor population, and in all LTC-IC and CFU colonies generated *in vitro*. Importantly, we identified the *SF3B1* mutation at the BM pro-B level in 5 investigated patients, and also in a smaller fraction, in purified peripheral blood B-cells from these patients. Analysis of peripheral blood B cells from the same patients 2-3 years after the first sampling showed an increase in *SF3B1* allelic burden in all cases. Importantly, co-mutations including *DNMT3A* and *B-COR* were not detected in peripheral B cells. This demonstrates that the origin of *SF3B1* mutation arises in the very primitive lymphoid-myeloid multipotent stem cell compartment. We transplanted purified hematopoietic stem cells (HSC) and lineage restricted cell populations: CMPs, GMPs and MEPs from 4 *SF3B1* mutated MDS-RS patients into NSG mice; 2 of which also carried *TET2* mutations. Engraftment, as defined by ($hCD45^+CD19^+$, $hCD45^+CD33^+CD66b^+CD15^+$ or GPA^+CD71^+) of all four HSC samples was detected, while all more mature cell populations failed to engraft. Importantly, morphological development of ring sideroblasts was observed in mice transplanted with HSCs from all 4 patients, proving that the self-renewal potential as well as commitment to the RS erythroid phenotype is restricted to MDS-RS HSC.
Summary/Conclusions: Our findings provide evidence of a multipotent stem cell origin of the *SF3B1* mutation in MDS-RS patients and propose the existence of a mixed B-cell population formed by abnormal cells derived from the MDS-RS clone and a normal "pre-clonal" population. Stem cell potential and reproduction of the MDS-RS erythroid phenotype was restricted to MDS-RS stem cells only.

CLONAL ORIGIN OF THERAPY-RELATED MYELOID NEOPLASMS

K Takahashi[*], F Wang, H Kantarjian, D Denaha, K Khanna, E Thompson, K Patel, S Neelapu, C Gumbs, C Bueso-Ramos, C DiNardo, S Colla, F Ravandi, S Xingzhi, J Zhang, X Wu, F Samaniego, G Garcia-Manero, A Futreal
UT MD Anderson Cancer Center, Houston, United States

Background: Therapy-related myeloid neoplasms (t-MNs) are secondary malignancies that develop in patients treated with chemotherapy and/or radiation therapy (C/RT). Previously, it was thought that genotoxic stress from C/RT induced driver mutations in hematopoietic stem cells leading to the development of t-MNs. However, a recent study suggested that pre-leukemic *TP53* mutations could pre-exist in t-MN patients years before t-MN development. Further, hematological driver mutations have been detected in peripheral blood (PB) from apparently healthy individuals or patients with solid tumors, a phenomenon referred to as clonal hematopoiesis of indeterminate potential (CHIP).
Aims: To test the hypothesis that pre-leukemic driver mutations are detectable in t-MN patients at the time of primary cancer diagnosis and prior to C/RT exposures.
Methods: We identified 14 patients with t-MNs who were found to have paired samples of diagnostic bone marrow (BM) at the time of t-MN diagnosis and PB obtained after the diagnosis of their primary cancers but prior to C/RT. Targeted gene sequencing of the 280 leukemia-related genes was performed on the 14 t-MNs diagnostic BM to detect driver mutations. We then assessed presence of the same driver mutations in the patients' matched PB samples taken at the time of primary cancer diagnosis. Because pre-leukemic driver mutations in the PB samples were expected to have very low variant allele frequency (VAF), we performed molecular barcoding deep sequencing of 32 genes that were reported as CHIP-associated mutation.
Results: Of the 14 t-MN patients, 5 (36%) had t-AML and 9 (64%) had t-MDS. The median age at primary cancer diagnosis and at t-MNs diagnosis was 62 years (range: 25-74) and 66 years (range: 28-77), respectively. The median latency from primary cancer to t-MNs was 3 years (range: 1-8). In the t-MN BM, 3 patients (21%) had normal karyotype and 7 (50%) had del 7q/-7, 4 (29%) had del 5q/-5 and 5 (36%) had complex karyotypes. Targeted gene sequencing of t-MN BM (median 289x): revealed 21 canonical hematological driver mutations in 14 t-MNs patients: mutations in *TP53* (29%), *DNMT3A* (21%), *TET2* (21%), *RUNX1* (21%), *IDH2* (14%), *SRSF2* (7%), *EZH2* (7%), *FLT3* (7%), *NRAS* (7%), *PTPN11* (7%) and *GATA2* (7%). Molecular barcoding deep sequencing of the PB samples (median 3,000x) taken at the time of primary cancer diagnosis revealed that pre-leukemic driver mutations were detected in 10 out of 14 (71%) patients. Figure 1 shows the model of clonal evolution from pre-leukemic driver mutations to t-MN in 3 representative cases. For example, Case UID6982 had limited stage small cell lung cancer and received concurrent chemo-radiation therapy with carboplatin and etoposide. He developed t-AML 3 years after C/RT and was found to have an *IDH2* p. R140Q (VAF 25%) and *SRSF2* p.P95fs (46%) mutations in the diagnostic BM. His PB samples obtained before C/RT showed the same *IDH2* p.R140Q and *SRSF2* p.P95fs mutations with VAF of 16.4% and 9.8%, respectively. By genes, 75% of *TP53*, 67% of *DNMT3A*, 100% of *TET2*, 67% of *RUNX1*, 50% of *IDH2,* 100% of *SRSF2*, 100% of *FLT3,* 100% of *NRAS*, and 100% of *PTPN11* mutations were detected as pre-leukemic driver mutations at time of primary cancer diagnosis. We did not detect *EZH2* and *GATA2* mutations as pre-leukemic mutations. The median VAF of the detected pre-leukemic driver mutations was 7.6% (range: 0.5-23%). There was no statistical difference between patients with and without detectable pre-leukemic mutations in terms of age at primary cancer diagnosis or latency time to t-MN development (P=0.73 and 0.54, respectively).

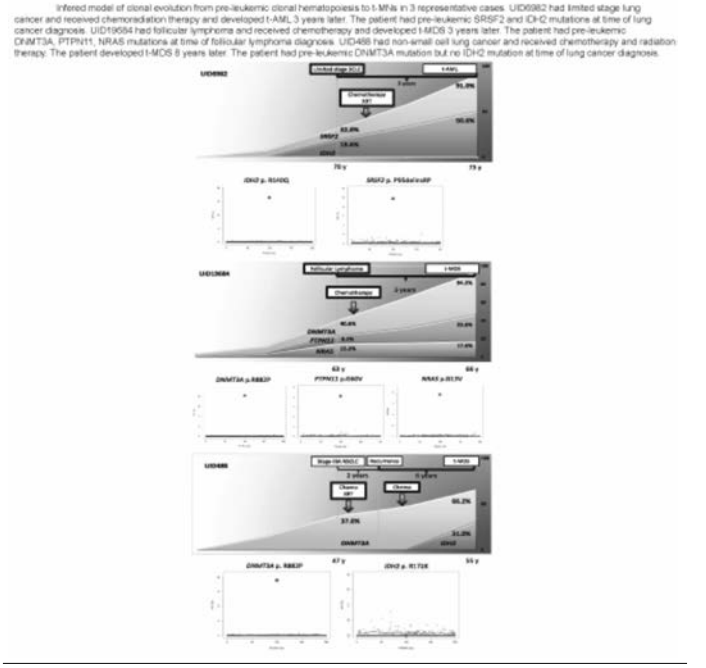

Figure 1.

Summary/Conclusions: In this study we have demonstrated evidence of detectable pre-leukemic driver mutations in multiple leukemia driver genes at time of diagnosis and before therapy of primary cancer in patients whose subsequent t-MNs also harbored identical driver mutations. These data suggest the potential to develop a risk stratification model based on presence of CHIP with canonical driver mutations at the time of primary cancer diagnosis. Determining predictive value of pre-leukemic driver mutations in t-MN development is currently undergoing.

New biological markers in MM

A TARGETED SEQUENCING APPROACH IN MULTIPLE MYELOMA REVEALS A COMPLEX LANDSCAPE OF GENOMIC LESIONS THAT HAS IMPLICATIONS FOR PROGNOSIS

N Bolli[1,*], G Biancon[1], S Gimondi[1], Y Li[2], S Vijitha[2], F Maura[1], C Carniti[3], M Fulciniti[4], R Szalat[4], KC Anderson[4], S Minvielle[5], M Attal[6], P Moreau[7], PC Campbell[2], H Avet-Loiseau[6], NC Munshi[4]
[1]University of Milan, Milan, Italy, [2]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [4]Dana-Farber Cancer Institute, Boston, United States, [5]Université de Nantes, Nantes, [6]Institut Universitaire du Cancer Toulouse, Toulouse, [7]CHU Nantes, Nantes, France

Background: Next-generation sequencing (NGS) studies have shown that multiple myeloma is a heterogeneous disease with a complex subclonal architecture and few recurrently mutated genes. The analysis of smaller regions of interest in the genome ("targeted studies") allows interrogation of recurrent genomic events with reduces complexity of downstream analysis at a lower price.
Aims: Here, we performed the largest targeted study to date in multiple myeloma to analyze gene mutations, deletions and amplifications, chromosomal copy number changes and immunoglobulin heavy chain locus (IGH) translocations and correlate results with biological and clinical features.
Methods: We used Agilent SureSelect cRNA pull down baits to target: 246 genes implicated in myeloma or cancer in general in a mixed gene discovery/confirmation effort; 2538 single nucleotide polymorphisms to detect amplifications and deletions at the single-gene and chromosome level; the IGH locus to detect translocations. We sequenced unmatched DNA from CD138-purified plasma cells from 418 patients with multiple myeloma at diagnosis, with a median follow-up of 5.3 years. We sequenced at an average depth of 337x using Hiseq2000 machines (Illumina Inc.). We applied algorithms developed in-house to call genomic events, filtering out potential artifacts and germline variants. We then ranker each event on its likelihood of being "oncogenic" based on clustering, recurrence and cross-reference with the COSMIC database.
Results: We identified 2270 gene mutations in 412/418 patients, and of those 688 were oncogenic. 342 patients harbored at least one oncogenic mutation. 215/246 genes showed at lease one likely somatic mutation, but only 106 showed at least one oncogenic mutation. 63% of oncogenic mutations were accounted for by the top 9 driver genes previously identified (KRAS, NRAS, TP53, FAM46C, BRAF, DIS3, TRAF3, SP140, IRF4), implying our gene discovery effort did not identify novel mutated genes. We included deletion of tumor suppressors, amplification of oncogenes, chromosomal copy number changes and IGH translocations for a total of 76 variables, so that 413/418 patients showed at least one informative driver genomic event, (median 4/patient). We investigated pairwise associations between events and found significant correlations, such as TP53 mutations and del(17p), CYLD mutations and del(16), FAM46C mutations and del(1p), SF3B1 mutations and t(11;14). Hotspots mutations of IRF4 lysine p.123 showed an inverse correlation with a hyperdiploid karyotype and del(16) as opposed to other missense mutations scattered along the gene, which has pathogenic implications. Survival was negatively affected by the cumulative burden of lesions in an almost linear fashion, with median survival of 10.97 and 4.07 years in patients with <=2 or >=7 lesions respectively, and this was independent of the nature of the genomic events. Given the heterogeneity and complex interplay of the variables we fitted a cox-proportional hazard model to predict survival. We found that mutations in TP53, amplifications of MYC, deletions of CYLD, amp(1q), del12p13.31 and del17p13 where the only significant events, all promoting shorter survival. In particular, TP53 mutations and deletions, often co-occurring, had an additive effect so that carriers of both showed a dismal survival of 17 months (Figure 1).

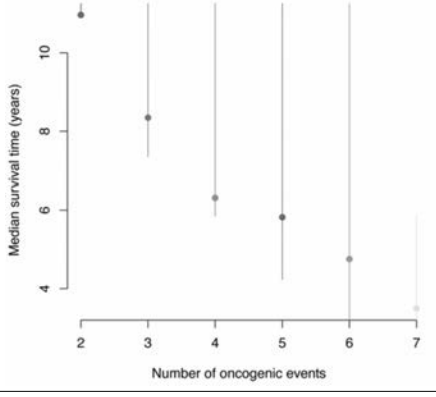

Figure 1.

Summary/Conclusions: Due to the complex genomic landscape in MM, a discovery effort still requires large studies to derive significant associations. We conclude that a targeted sequencing approach may provide prognostic models and give insights into myeloma biology.

S448

A NEW MULTIPLE MYELOMA CLASSIFICATION SYSTEM THAT CORRELATES TO DISEASE STAGE AND PROGNOSIS - INDICATION OF REVERSIBLE PHENOTYPIC PLASTICITY AS A HALLMARK

Background: Today's diagnostic tests for multiple myeloma (MM) reflect the criteria of the updated WHO classification based on biomarkers and clinicopathologic heterogeneity.
Aims: To that end, we propose a new biological subtyping of myeloma plasma cells (mPC) by B-cell subset associated gene signatures (BAGS), from the normal B-cell hierarchy in the bone marrow (BM). Here we document the prognostic and biological value of subtyping, as shown for DLBCL (JCO 2015 Apr 20; 33:1379).
Methods: We combined FACS and GEP to generate BAGS classifiers for the normal BM subsets: PreB-I, PreB-II, immature (Im), naive (N), memory (M) and PC. Construction was based on median-centred probe sets from the BM data using regularized multinomial regression with six discrete outcomes representing BAGS, by a total of 55 genes varying from 15-24 per subtype. Each patient underwent BAGS assignment according to the highest predicted probability score above 0.45 or was otherwise unclassified. The impact of BAGS was analyzed using six clinical cohorts, gathered across geographical regions, time eras, and sampling methods. The analysis estimated subtype frequencies and included a prognostic meta-analysis of 926 patients treated with high dose melphalan as first line therapy in 3 prospective trials: UAMS, HOVON65/GMMG-HD4, MRC Myeloma IX data with the Affymetrix U133 plus 2.0 microarray data available from myeloma PC samples. To compensate for cohort-wise technical batch effects, each cohort was median centred and adjusted probe set-wise to have same variance as the BM data.
Results: *Validation of the normal B-cell subset phenotypes.* Normalized histograms of the fluorescence intensities (FI) of CD markers based on merged multiparametric flow cytometry reanalysis of pure sorted populations resulting from seven independent sorting procedures documented high purity. Principal component analysis (PCA) of the FI for each sorted cell in all samples documented specificity. Surface markers, transcription factors, and B-cell differentiation–specific genes were identified through a literature review, and their expression across subsets was evaluated. The most varying probe sets were included in an unsupervised hierarchical clustering analysis, supporting the biological differences. *Validation of MM patients subtyping by prognosis.* The resultant tumor assignments exhibited very similar BAGS subtype frequencies, across 1302 individual MM cases from 4 different cohorts. The 5 BAGS subtypes of 926 MM cases were significantly associated with overall ($P=5.2x10^{-8}$) and progression free ($P=1.5x10^{-6}$) survival in a meta-analysis of patients in the 3 clinical trials. The major impact was observed within the PreB-II and M subtypes conferred with significant increased ISS stage III and inferior prognosis compared to the Im, N and PC subtypes. Cox proportional hazard meta-analysis showed that the five BAGS subtypes added significant and independent prognostic information to the TC classification system and plasma Beta-2 microglobulin level. In parallel we found significant correlation between the PreBII subtypes and the proliferation index, risk profiling ($P<0.0001$) and Beta-2 microglobulin ($P<0.001$).
Summary/Conclusions: We have documented patient specific mPC differences with prognostic impact in support of reversible phenotypic plasticity in MM. This observation provides a new model for generating insight into the stages of clonal plasticity associated with oncogenesis and dedifferentiation.

S449

DEFINING NEW THERAPEUTIC AGENTS THAT TARGET THE ONCOGENIC TRANSLATION PROGRAM IN MULTIPLE MYELOMA

S Manier[1,2,3,*], D Huynh[3], K Salem[3], R Ebright[3], J Park[3], S Glavey[3], J Shi[3], A Sacco[3], A Roccaro[3], J Snyder[4], L Brown[4], T Facon[1], L Whitesell[5], J Porco[4], I Ghobrial[3]
[1]Department of Hematology, Lille Hospital, [2]INSERM U1172, University Lille 2, Lille, France, [3]Medical Oncology, Dana-Farber Cancer Institute, [4]Center for Molecular Discovery, Boston University, Boston, [5]Whitehead Institute, Cambridge, United States

Background: Despite significant therapeutic advances, Multiple Myeloma (MM) remains an incurable hematological malignancy. Therefore, there is a need for the development of new therapeutic options with novel mechanisms of action that have not been previously explored in MM.
Aims: To identify new potential therapies in MM, we screened a library of small molecules against lymphoid cell lines and defined the mode of action for the most active class of hits that we found. These compounds act as potent, highly selective inhibitors of translation initiation and therefore inhibit the oncogenic translation program of MM.
Methods: A chemically diverse small-molecule drug screen of over 3,000 compounds from the Boston University Center for Molecular Discovery was performed using H929 and NAMALWA cell lines. Follow-up validation and structure-activity relationship (SAR) studies were performed in several cell lines including H929, MM1S, MM1R, U266, RPMI and OPM2. RNA sequencing was performed using the NEBNext kit and Illumina HiSeq 2500. Quantitative proteomic analysis was performed by Tandem Mass Tag (TMT) with mass spectrometry (MS). For animal studies, SCID mice were injected with $5x10^6$ MM1S luc-GFP cells and followed by blood cell count, body weight, bioluminescence imaging (BLI) and survival.
Results: A primary screen of over 3,000 small-molecules identified 45 compounds with potent activity on H929 and NAMALWA. Further validation of these hits in 6 cell lines highlighted 3 compounds of the rocaglate class as by far the most effective. A follow-up SAR screen including 40 rocaglate derivatives identified a compound called CMLD10509 with an IC50 below 10nM against several MM cell lines, but no cytotoxicity on human PBMCs, suggesting a useful therapeutic window for this agent in MM. To define the mode of action for CMLD10509 against MM, we performed RNA-seq on drug- *vs* DMSO-treated cell lines. By GSEA analysis, the most enriched pathways were regulators of transcriptional activation and translation inhibition. To validate these findings we queried our compound's signature against the LINCS Cloud database - a large catalog of gene-expression profiles collected from human cells exposed to chemical and genetic perturbations - and identified a positive correlation between our drug signature and translation inhibitors as well as KD of ribosome subunits. To better define the consequences of CMLD10509-induced translation inhibition, we performed a quantitative proteomic MS experiment. We identified 7312 proteins of which 54 were significantly down-regulated by CMLD10509 exposure ($p<0.05$ and FC>2), among them key oncoproteins in MM such as MYC, MDM2, CCND1, MCL1 and MAF (Figure 1). Strikingly, down-regulated proteins were strongly associated with KEGG cancer pathways, representing the oncogenic translation program in MM. Correlation between TMT and RNA-seq (confirmed by immunoblot and qRT-PCR) validated a purely translational mechanism as responsible for their depletion in MM cells. Importantly, increased expression of these same rocaglate-sensitive genes was significantly enriched in MM patients in several datasets. Finally, CMLD10509 was both active and well tolerated in a xenograft model of MM (n=10 per group), with significantly lower BLI counts ($p<0.001$) and prolonged survival (median OS 35 *vs* 47 days, $p<0.001$).

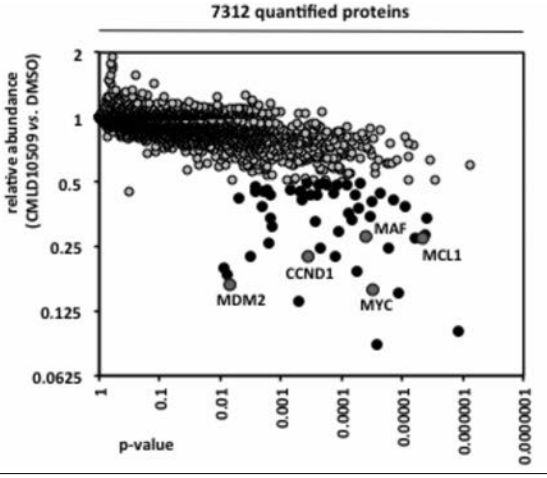

Figure 1. TMT mass spectometry of NCIH929 treated with CMLD10509 or vehicle (DMSO). Triplicate analysis, two tailed *t*-test.

Summary/Conclusions: From a large-scale small molecule screen, we identified CMLD10509 as a potent compound, which selectively inhibits the translation initiation and impairs an oncogenic translation program supporting MM cells that includes MYC, MDM2, CCND1 and MCL1. As proof of concept for the potential of CMLD10509 as a novel therapeutic strategy, we found it to be highly active and well tolerated in a mouse model of MM.

S450

PD-1 BLOCKADE ENHANCES THE EFFICACY OF ELOTUZUMAB IN MOUSE TUMOR MODELS

N Bezman[1,*], A Jhatakia[1], A Kearney[1], T Brender[1], M Maurer[1], C Sum[1], M Lei[1], K Waggie[1], J Postelnek[1], K Henning[1], M Jenkins[2], A Rogers[2], P Neeson[2], A Korman[1], M Robbins[1], R Graziano[1]
[1]Bristol-Myers Squibb, Princeton, United States, [2]Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Elotuzumab is a humanized monoclonal antibody (mAb) that binds specifically to human SLAMF7 (hSLAMF7) and has been approved by the US Food and Drug Administration for use in combination with lenalidomide and dexamethasone for the treatment of patients with multiple myeloma (MM) who have received one to three prior therapies. Previous preclinical models demonstrated that elotuzumab inhibited the growth of SLAMF7-expressing human myeloma xenografts in immune-compromised mice. These models, however, lacked adaptive immune cells and therefore could not assess the mechanism of elotuzumab anti-tumor activity in the setting of a fully intact immune system.
Aims: To model elotuzumab mechanism of action, alone or in combination with PD-1 blockade, using human natural killer (NK) cells *in vitro* and mouse tumor models *in vivo*.
Methods: We evaluated elotuzumab-mediated anti-tumor activity alone or in combination with a mAb to PD-1 using mouse cell lines that stably express human SLAMF7 (A20-hSLAMF7 and EG7-hSLAMF7). The effect of treatment on the phenotype and functionality of tumor-infiltrating lymphocytes (TILs) using flow cytometry and immunohistochemistry was evaluated. In addition, the effects of elotuzumab on the phenotype of human NK cells isolated from either healthy donors or patients with MM treated with elotuzumab plus lenalidomide and dexamethasone was assessed.
Results: A murine IgG2a version of elotuzumab (elotuzumab-g2a) inhibited growth of hSLAMF7-expressing mouse tumor cells *in vivo*. Tumor-bearing mice treated with elotuzumab-g2a, anti-PD-1, or elotuzumab-g2a plus anti-PD-1 had significantly improved survival over those treated with control IgG2a (Figure 1). Anti-tumor activity mediated by elotuzumab-g2a required an Fc fragment that was able to interact with activating Fc receptors, was partially dependent on both NK cells and CD8+ cells, and synergized with anti-PD-1 treatment. TILs taken from mice treated with elotuzumab-g2a plus anti-PD-1 had increased numbers of activated tumor-specific and total CD8+ T cells. Elotuzumab-g2a and anti-PD-1 combination treatment also promoted NK cell activation and cytokine and chemokine release within the tumor. *In vitro* co-cultures of human NK cells, elotuzumab, and SLAMF7-expressing tumor cell lines led to NK cell degranulation, upregulation of inflammatory cytokines, and enhanced expression of activation markers. Similarly, NK cells isolated from bone marrow aspirates from patients treated with elotuzumab showed an enhanced activation state compared with NK cells isolated prior to treatment.

Kaplan–Meier curve showing survival in A20-hSLAMF7-bearing mice treated with control mIgG2a (n=9), elotuzumab-g2a 10 mg/kg (n=9), anti-PD-1 3 mg/kg (n=9), or elotuzumab 10 mg/kg plus anti-PD-1 3 mg/kg on Days 10, 14, and 17. Differences between survival curves were analyzed using Mantel-Cox test.

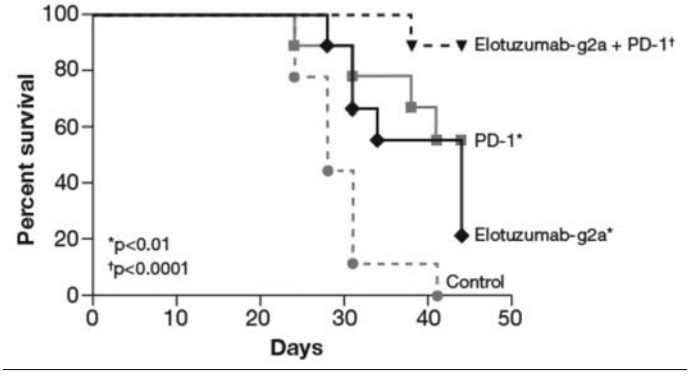

Figure 1.

Summary/Conclusions: The combination of the tumor-targeted antibodies elotuzumab-g2a and anti-PD-1 showed enhanced anti-tumor efficacy in mouse tumor models. The strong control of tumor growth observed with combination treatment was due to activation of both adaptive and innate immune cells local-

ized to the tumor microenvironment. These *in vivo* findings support the suggested mechanism of action of elotuzumab and PD-1 blockade and provides rationale for the clinical investigation of elotuzumab and anti-PD-1 combination therapy in patients with MM.
Study support: Bristol-Myers Squibb.

THERAPEUTIC IMPACT OF TAK-1 INHIBITION ON TUMOR GROWTH AND BONE DESTRUCTION IN MYELOMA

J Teramachi[1,2], M Hiasa[2,3], A Oda[2], H Tenshin[2,4], R Amachi[2,4], T Harada[2], S Nakamura[2], H Miki[5], I Endo[2], T Haneji[1], T Matsumoto[6], M Abe[2,*]
[1]Histology and Oral Histology, [2]Hematology, Endocrinology and Metabolism, [3]Biomaterials and Bioengineering, [4]Orthodontics and Dentofacial Orthopedic, Tokushima University, [5]Transfusion and Cell Therapy Medicine, Tokushima University Hospital, [6]Fujii Memorial Institute of Medical Sciences, Tokushima University, Tokushima, Japan

Background: Multiple myeloma (MM) is still incurable with progressive bone loss. The development of novel therapeutic options yielding better survival outcomes with bone restoration is urgently needed. We have reported that Pim-2 is overexpressed in MM cells and their surrounding cells, namely bone marrow stromal cells (BMSCs) and osteoclasts, in bone lesions, and that treatment with Pim inhibitors markedly suppressed MM tumor growth while preventing bone destruction in MM-bearing animal models, indicating Pim-2 as an important therapeutic target in MM (Leukemia 2011, 2015). We recently found TGF-β-activated kinase-1 (TAK-1) as an upstream mediator responsible for Pim-2 up-regulation.
Aims: We therefore aimed to clarify the role of TAK-1 in tumor growth and bone destruction in MM and therapeutic impact of TAK-1 inhibition.
Methods: TAK-1 and Pim-2 expression and TAK-1 phosphorylation was analyzed by Western blotting. Osteoclastogenic activity was analyzed by TRAP staining as well as resorptive pit formation. Osteoblastogenesis was estimated with mineralized nodule formation by MC3T3-E1 preosteoblastic cells. The TAK-1 inhibitor LLZ1640-2 and TAK-1 siRNA were used to block TAK-1 activation and reduce TAK-1 expression, respectively. To create MM animal models, murine 5TGM1 MM cells were inoculated into the tibia in SCID mice.
Results: TAK-1 was constitutively over-expressed and phosphorylated in MM cells while only marginally in normal peripheral blood mononuclear cells. The TAK-1 inhibitor LLZ1640-2 dose-dependently suppressed cell growth, and induced caspase-dependent apoptosis in MM cells. Although TNF-α and IL-6 upregulated Pim-2 expression in MM cells, LLZ1640-2 abolished TNF-α-induced NF-κB, p38MAPK and ERK activation and IL-6-induced STAT3 activation in MM cells, leading to Pim-2 suppression. The TAK-1 inhibition also reduced the transcription factor Sp1 expression upregulated in MM cells. Because Sp1 induces the expression of various factors responsible for MM cell growth and survival, Sp1 reduction by the TAK-1 inhibition appears to cause efficaciously suppression of MM cell survival. LLZ1640-2 as well as TAK-1 knock-down decreased VCAM-1 expression and IL-6 production in BMSCs, and MM cell adhesion to BMSCs to impair BMSC support of MM cell growth. Interestingly, phosphorylation of TAK-1 was induced in BMSCs and MC3T3-E1 preosteoblastic cells by addition of cytokines known as inhibitors of osteoblastogenesis in MM, including IL-3, IL-7, TNF-α, TGF-β and activinA, as well as MM cell conditioned media (MMCM), suggesting TAK-1 as a common mediator to suppress osteoblastogenesis in MM. Furthermore, LLZ1640-2 abolished up-regulation of Pim-2, an inhibitory mediator of osteoblastogenesis, in BMSCs and MC3T3-E1 cells by MMCM to restore mineralized nodule formation. Moreover, the TAK-1 inhibition up-regulated in MC3T3-E1 cells phosphorylation of Smad1/5 and p38MAPK by BMP-2 while suppressing Smad2/3 phosphorylation by TGF-β suggesting potentiation of BMP-2-mediated anabolic signaling. TAK-1 was also up-regulated in osteoclastic lineage cells along with osteoclastogenesis. Treatment with LLZ1640-2 suppressed the induction of c-fos and NFATc1 in RAW264.7 preosteoclastic cells as well as their osteoclastogenesis by RANK ligand. Finally, treatment with LLZ1640-2 potently suppressed MM growth in murine MM models.
Summary/Conclusions: TAK1 plays a pivotal role in MM tumor growth and bone destruction in MM. TAK1 may become an efficacious therapeutic target in MM to suppress tumor burden while restoring bone.

Background: The JAK1/JAK2 inhibitor RUX has demonstrated rapid and durable improvements in splenomegaly and symptoms and improved survival in the two phase 3 COMFORT studies in pts with MF.
Aims: To report final long-term efficacy and safety results after 5 years (y) of RUX treatment in COMFORT-I.
Methods: In COMFORT-I, 309 pts were randomized (1:1) to RUX or placebo (PBO). RUX starting dose was based on baseline platelet count (100–200×10^9/L: 15 mg BID; >200×10^9/L: 20 mg BID). Pts receiving PBO could crossover to RUX after the primary analysis (when all pts completed week [wk] 24 and half completed wk 36) or at any time if they had prespecified worsening of splenomegaly. The primary endpoint was the proportion of pts achieving ≥35% reduction in spleen volume (SV) at wk 24. Overall survival (OS) was estimated by Kaplan-Meier analysis according to randomized treatment (intent-to-treat analysis).
Results: Median follow-up was 268 wk at the time of this analysis. Of 155 pts randomized to RUX, 43 were still on treatment at the time of study termination. Of 154 pts randomized to PBO, 111 crossed over to RUX; median time to crossover was 41.1 wk; 28 were still on treatment at the time of study termination. At wk 24, pts originally randomized to RUX had a mean SV reduction from baseline of 31.6%; this response was durable for pts who continued on RUX with a mean SV reduction of 37.6% at wk 264. At wk 264, 18.5% of pts randomized to RUX had a ≥35% reduction from baseline in spleen volume. Median duration of spleen response (≥35% SV reduction) was 168.3 wk for RUX (range, 107.7–NE; n=92 pts). OS favored RUX (HR=0.69; 95% CI: 0.50, 0.96; *P*=0.025), with 69 and 82 deaths among pts originally randomized to RUX and PBO, respectively. Median OS has not been reached for pts in the RUX group. Median OS was approximately 108 wk for pts randomized to PBO censored at crossover, and approximately 200 wk for PBO pts. Mean platelet count and hemoglobin (Hgb) initially decreased through 3 mo. Mean Hgb gradually increased toward baseline. After wk 24, mean Hgb and platelet count generally remain stable through 5 y. New onset grade 3 or 4 anemia was 25.2% for the RUX arm and 26.1% for PBO crossover; grade 3 or 4 thrombocytopenia occurred in 12.3% and 13.5% of pts, respectively. Notable AEs included herpes zoster (10.3% and 13.5% of RUX and PBO crossover pts, respectively); basal cell carcinoma (7.7% and 9.0%, respectively); acute myeloid leukemia (5 pts in each arm). The rate of leukemic transformation was 0.01 per pt-year for pts randomized to RUX and 0.02 per pt-year for the PBO crossover pts (Figure 1).

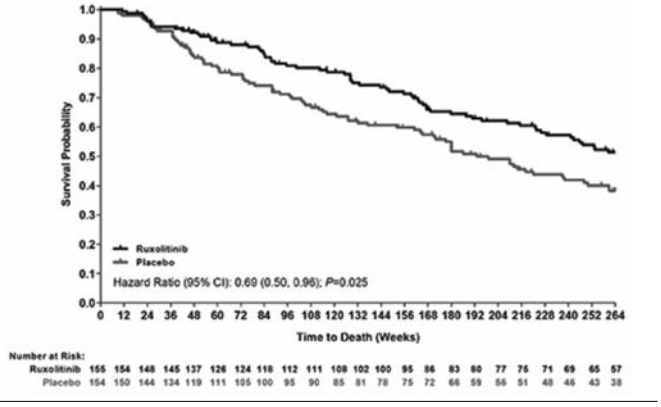

Figure 1.

Summary/Conclusions: After a median follow-up of 268 wk, the hazard ratio for OS favored pts randomized to RUX over those randomized to PBO, and SV reductions were sustained with long-term therapy. Collectively, these data support the durable efficacy and long-term safety of RUX in pts with MF.

S453

IMPACT OF THE MOLECULAR PROFILE ON THE RISK OF ACUTE MYELOID TRANSFORMATION IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA

A Senín[1], C Fernández[1], B Bellosillo[2], E Arellano-Rodrigo[3], M Gómez[4], F Ferrer-Marín[5], J Martínez[6], L Camacho[2], S Reyes[5], D Colomer[7], F Cervantes[8], C Besses[1], JC Hernández-Boluda[4], A Alvarez-Larrán[1,*]
[1]Hematology, Hospital del Mar-IMIM, UAB, [2]Pathology, Hospital del Mar-IMIM, UPF, [3]Hemotherapy and Hemostasis, Hospital Clínic-IDIBAPS, Barcelona, [4]Hematology, Hospital Clínico, Valencia, [5]Hematology, Hospital Morales Messeguer-IMIB, UCAM, Murcia, [6]Hematology, Hospital 12 de Octubre, Madrid, [7]Hematopathology Unit, [8]Hematology, Hospital Clínic-IDIBAPS, Barcelona, Spain

Background: Polycythemia vera (PV) and essential thrombocythemia (ET) are myeloproliferative neoplasms (MPN) associated with driving mutations in *JAK2*, *CALR* or *MPL* genes that can evolve into acute myeloid leukemia (AML). Older age, abnormal cytogenetics and sequential exposure to cytoreductive agents have been associated with higher risk of AML.
Aims: To analyze the influence of the genotype on the risk of myeloid transformation in patients with PV and ET. In addition, the somatic mutational profile in paired samples from the chronic and the leukemic phases was studied.
Methods: A total of 1095 patients (PV n=371, ET n=724) were included. The risk of myeloid transformation according to age, sex, type of disease (PV or ET), leukocyte count at diagnosis, cytogenetics, cytoreductive treatment, and genotype (*JAK2*, *CALR*, *MPL,* and triple negative) was evaluated by Cox regression. Next generation sequencing (NGS) analysis of 66 AML-related genes was performed in paired samples from the chronic and leukemic phases, whenever possible. Supported by grants from the Instituto de Salud Carlos III, Spanish Health Ministry: PI13/00557, PI1300393 and PI1300636.
Results: Median age at MPN diagnosis was 63 years (females: 59%). An abnormal karyotype was documented in 30 (2.7%) out of 583 evaluable patients. Genotype was available in 806 patients: 92.5% of PV patients were *JAK2*-mutated, whereas 64%, 18%, 3%, and 15% of ET patients were *JAK2*+, *CALR*+, *MPL*+ or triple negative, respectively. Hydroxyurea plus P32, busulphan or melphalan was administered in 10% of patients. With a median follow-up of 8 years, 35 cases of AML and 5 cases of myelodysplastic syndrome (MDS) were diagnosed, resulting in a 10-year probability of myeloid transformation of 3.9%. There were no significant differences in transformation rate according to MPN type (10-year probability of 4.7% and 3.5% for PV and ET, respectively, p=0.8). In multivariate analysis, an increased risk of AML/MDS transformation was observed for patients older than 60 years (HR: 4.3, 95%CI: 1.6-11.6, p=0.004), with leukocytes >10x109/L (HR: 2.2, 95%CI: 1.01-4.7, p=0.048) and those treated with hydroxyurea plus leukemogenic agents (HR: 2.5, 95%CI: 1.2-5.4, p=0.02). An abnormal karyotype was associated with an increased risk of transformation in PV (HR: 5.1, 95%CI: 1.2-22.1, p=0.03) but not in ET. In ET patients, the 10-year probability of AML/MDS according to genotype was 25% for *MPL*+, 6.6% for triple negative, 4.6% for *JAK2*V617F+, and 0% for *CALR*+ (p=0.007). When the genotype was included in the multivariate model, the *MPL* mutation was an independent risk factor for higher risk of AML/MDS (HR: 6.1, 95%CI: 1.2-30.2, p=0.028), whereas *JAK2*V617F, *CALR* or triple negative genotypes lacked prognostic significance. NGS was performed in 24 post-MPN AML/MDS samples. Somatic mutations in genes other than *JAK2*, *CALR* or *MPL* were seen in 20 (83%) patients. Five (21%) patients have one, 7 (29%) two, 3 (12.5%) three and 5 (21%) four or more additional mutations. Mutational frequencies were: *TP53* 42%, *TET2* 21%, *RUNX1* 21%, *DNMT3A* 17%, *IDH1/2* 17%, *SRSF2* 12%, *ASXL1* 12%, *SETBP1* 8%, *SH2B3* 8%, and <5% for *SF3B1*, *NRAS*, *KRAS*, *NOTCH1*, *PTPN11, CBL, NPM* and *FLT3*. At time of submission, NGS molecular studies were performed in 10 paired samples at PV/ET diagnosis and AML/MDS transformation being 52% of the mutations present in both samples.
Summary/Conclusions: *MPL* genotype is associated with higher risk of AML/MDS transformation. Somatic mutations in genes other than *JAK2, CALR or MPL* are frequently observed at time of transformation, with 50% of them being already present at ET/PV diagnosis. TP53 is the gene most frequently mutated at time of transformation.

RUXOLITINIB (RUX) REDUCES JAK2V617F ALLELE BURDEN (AB) IN PATIENTS (PTS) WITH POLYCYTHEMIA VERA (PV) ENROLLED IN THE RESPONSE STUDY

AM Vannucchi[1,*], S Verstovsek[2], P Guglielmelli[1], M Griesshammer[3], TC Burn[4], A Naim[4], D Paranagama[4], M Marker[5], E Tiecke[5], B Gadbaw[5], JJ Kiladjian[6]
[1]CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Florence, Italy, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, United States, [3]Johannes Wesling Clinic, Minden, Germany, [4]Incyte Corporation, Wilmington, DE, [5]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States, [6]Hôpital Saint-Louis, Paris, France

Background: The *JAK2*V617F mutation leads to constitutive activation of downstream JAK/STAT signaling in pts with PV. In the phase 3 RESPONSE study evaluating Rux (an oral JAK1/JAK2 inhibitor) *vs* best available therapy (BAT) in pts with PV who had an inadequate response to or unacceptable side effects from hydroxyurea, Rux was superior to BAT in controlling hematocrit, reducing spleen volume, and improving symptoms. Rux also decreased *JAK2*V617F AB steadily over time up to Week 112.
Aims: This follow-up exploratory analysis of the RESPONSE study evaluated the effect of long-term Rux treatment on *JAK2*V617F AB in pts with PV.
Methods: 211 pts with the *JAK2*V617F mutation at Baseline were evaluable for this analysis. AB was defined as the percent of mutant allele relative to total (wild-type and mutant). Changes from Baseline in *JAK2*V617F AB among Rux-randomized pts and those who crossed over from BAT to Rux were reported up to Week 208. Baseline AB for the crossover cohort was defined as last observation before receiving Rux. Complete and partial molecular remission (CMR, PMR) were defined using the IWG-MRT/ELN consensus criteria. An exploratory analysis was performed to identify any potential relationship between reductions in AB and spleen volume.
Results: Pts randomized to Rux (n=104) experienced consistent AB reduction (mean percent change from Baseline, –12.2%, –18.3%, –22.0%, –30.0%, –38.1%, –34.9%, and –40.0% at Weeks 32, 56, 80, 112, 144, 176, and 208, respectively). On average, BAT-randomized pts did not experience AB improvements at Week 32 (mean percent change from Baseline, 1.2%); those who crossed over to Rux (n=80) had markedly reduced AB over time (–6.3%, –6.7%, –10.4%, –15.7%, –17.8%, and –13.0% at 32, 56, 80, 112, 144, and 176 weeks after crossover, respectively). Mean baseline AB for pts who did and did not have prior interferon (IFN) therapy was as follows: Rux: IFN=72.1%, no IFN=74.5%; BAT: IFN=88.2%, no IFN=72.0%. All BAT pts who received IFN (n=13) at randomization crossed over to Rux; mean maximal AB reduction in evaluable BAT pts receiving IFN was –6.6% before crossover and –25.6% after crossover. The average maximal percent reductions in AB (median time to maximal reduction) in Rux-randomized and Rux crossover arms were –35.9% (25.9 mo) and –21.2% (18.2 mo), respectively (Figure 1). Among evaluable pts, 2/102 (2.0%) Rux-randomized pts achieved CMR at Weeks 143 and 144 *vs* 1/94 (1.1%) Rux crossover pts at Week 123. Pts who achieved PMR included 33/101 (32.7%) evaluable Rux-randomized pts and 20/92 (21.7%) evaluable Rux crossover pts, after median times of 112 and 92 weeks, respectively. Seven pts had ≥90% AB reduction from Baseline (Rux-randomized, n=6; Rux crossover, n=1). Based on tertiles of maximal AB reduction for the Rux-randomized arm, there was no relationship between mean maximal change in AB (tertile 1, –72.2%; tertile 2, –29.1%; tertile 3, –5.7%) and mean PV duration (mo) from diagnosis (tertile 1, 81.6; tertile 2, 126.2; tertile 3, 105.2). No linear relationship was observed at last visit between percent change in AB from Baseline and corresponding clinical outcomes in terms of spleen volume reduction.

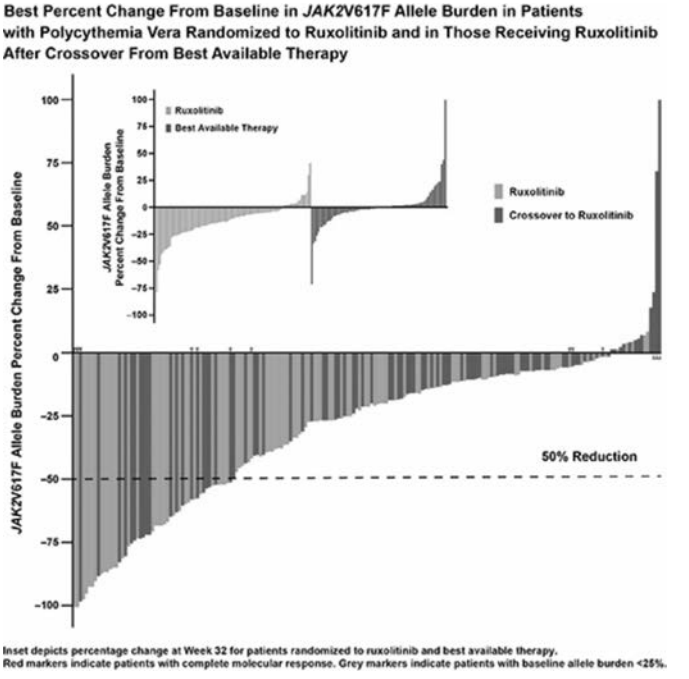

Figure 1.

Summary/Conclusions: Rux treatment (randomized and post-crossover) reduced *JAK2*V617F AB in RESPONSE study pts after up to 4 years of treat-

ment. Some pts may experience molecular responses with Rux treatment regardless of initiation timing during the disease course or previous IFN treatment. No clear relationship between AB reduction and spleen volume reduction was observed.

S455

HSC GENETIC HETEROGENEITY DETERMINES CLONAL DYNAMICS IN PMF

I Triviai[1,*], S Zeschke[1], V Panagiota[2], M Heuser[2], C Stocking[1], N Kroeger[1]
[1]KMT, UKE, Hamburg, [2]Hematology, Hemostasis, Oncology and SCT, MHH, Hannover, Germany

Background: Primary Myelofibrosis (PMF) is a myeloproliferative neoplasm of stem cell origin, characterized by sequential distinctive waves of aberrant myeloid differentiation. Atypical erythroid-megakaryocytic progenitors expand at the initial stages of PMF and perish in the course of PMF development and/or the expansion of pre-leukemic clones. The continuum of clonal dynamics dominating the chronic phase disease, as exhibited in the variability of divergent myeloid progeny in PMF progression, reflects the molecular heterogeneity of malignant HSCs that sustain fluctuations in clone propagation.
Aims: In our previous work, we described a CD133+ stem cell population circulating in PMF patient peripheral blood, which exhibits multi-lineage differentiation capacity *in vivo* and *in vitro* and induces the PMF phenotype in the first xenotransplantation model of PMF. Single cell analysis of CD133+ patient-derived HSCs revealed multi-clonal lineage restricted differentiation potential of the stem cell pool in PMF. The correlation of the molecular burden of individual stem cells with their differentiation potential sheds light on the order of genetic lesions orchestrating the sequence of impaired stem cell function.
Methods: CD133+ HSCs from 100 PMF patients were molecularly characterized by whole exon sequencing. Sorted HSC cells were functionally analyzed at a single cell level for variable myeloid colony formation. 2230 colonies were phenotypically characterized and isolated. Analysis of the PMF HSC clonogenic potential indicates that the presence of mutations in the epigenetic regulator EZH2 correlates with granulo/monocytic differentiation but limited erythroid colony formation potential (0-0,05%), as determined in three different patient samples (2 JAK2-V617F+, 1 CALR-fs*+). Transplantation of these patient samples gave the highest engraftment in our mouse model and in one case, $EZH2^{mu}JAK2^{wt}$ leukemic transformation.
Results: CD133+ HSC-derived single colony analysis indicated 8 different genotypic clones of HSC, which exhibit variable granulo/monocytic differentiation capacity *in vitro*. From a total of 569 formed colonies, 538 were CFU-GM,-G,-M and 31 BFU-E. PCR analysis of colonies for JAK2-V617F and Sanger sequencing for EZH2-D265H and EZH2-Y733C mutations indicates that the presence of JAK2-V617F in hetero- or homozygosity can occur in the EZH2-D265H background without influencing the granulo/monocytic commitment of these mutated HSCs. Interestingly, the limited BFU-Es that arose contained only single JAK2-V617F mutations in the same patient. Moreover, the presence of single EZH2-D265H heterozygous clones, single JAK2-V617F hetero- or homozygous clones, as well as double mutated clones indicate two independent mutational events affecting the same locus and nucleotide have occurred in this patient. In view of the overall high frequency of JAK2-V617F mutations, we predict that the EZH2 mutation was the first mutation in double mutant clones in this patient. The presence of homozygous EZH2-Y733C mutations in other patients was detected irrespectively of JAK2-V617F mutation and is correlated with granulocytic-monocytic committed progenitors.
Summary/Conclusions: Our results indicate that mutations in epigenetic regulators precede the expanding mutations of the chronic phase PMF (JAK2, CALR). Thus, they confer the genomic instability connected with subsequent emergence of following mutations and they shape the genomic landscape supporting the expansion of pre-leukemic clones.

ACTIVATION OF THE THROMBOPOIETIN RECEPTOR BY MUTANT CALRETICULIN IN CALR-MUTANT MYELOPROLIFERATIVE NEOPLASMS

M Araki[1,*], Y Yang[2], N Masubuchi[2,3], Y Hironaka[2], H Takei[2], S Morishita[1], Y Mizukami[2,4], S Kan[2,5], S Shirane[2], Y Edahiro[2], Y Sunami[2], A Ohsaka[1], N Komatsu[2]
[1]Blood Transfusion and Stem Cell Regulation, [2]Hematology, [3]Research Institute for Disease of Old Age, [4]Center for Genomic and Regenerative Medicine, [5]Leading Center for the Development and Research of Cancer Medicine, Juntendo University School of Medicine, Tokyo, Japan

Background: Recurrent somatic mutations of *Calreticulin (CALR)* have been identified in patients harboring myeloproliferative neoplasms; however, their role in tumorigenesis remains to be elucidated.
Aims: We aim to elucidate the oncogenic property of mutant CALR and molecular mechanism of its action.
Methods: To examine whether mutant CALR exhibits oncogenic properties, its capacity to induce factor-independent growth was examined in a human megakaryocytic cell line UT-7/TPO that proliferates only in the presence of thrombopoietin (TPO). The genetic and biochemical interactions between mutant CALR and TPO receptor c-MPL were examined using a loss-of-function assay with shRNA and a co-immunoprecipitation assay, respectively. The functional and structural differences between mutant and wild-type CALR were examined using a domain analysis of CALRs for the c-MPL interaction. Mutant-CALR activation of c-MPL was determined by examining the phosphorylation status of c-MPL-downstream molecules using an immunoblot analysis. To demonstrate this activation process in more physiological circumstances, a loss-of-function assay for c-MPL was performed in iPS-derived hematopoietic stem cells that harbor the CALR mutation and exhibit TPO-independent megakaryopoiesis.
Results: We found that the expression of mutant, but not wild-type, CALR induced TPO-independent growth of UT-7/TPO cells. We demonstrated that c-MPL was required for this cytokine-independent growth. Mutant CALR preferentially associated with c-MPL that is bound to JAK2 over the wild-type protein. Furthermore, we demonstrated that the mutant-specific C-terminus portion of CALR interfered with the P-domain of CALR to allow the N-domain to interact with c-MPL; thus, providing an explanation for the gain-of-function property of mutant CALR. We showed that mutant CALR induced the phosphorylation of JAK2 and its downstream signaling molecules in UT-7/TPO cells and that this induction was blocked when the cells were treated with a JAK2 inhibitor. Finally, we demonstrated that c-MPL is required for TPO-independent megakaryopoiesis in iPS-derived hematopoietic stem cells harboring the CALR mutation.
Summary/Conclusions: These findings imply that mutant CALR activated the JAK2 downstream pathway via its association with c-MPL. Considering these results, we propose that mutant CALR promotes the development of myeloproliferative neoplasms by activating c-MPL and its downstream pathway.

AML Biology Mutant FLT

NPM1 AND FLT3-ITD MUTATIONS SINERGISTICALLY INDUCE GATA1 EPIGENETIC SILENCING IN A AML MOUSE MODEL

P Sportoletti[1,*], E Varasano[1], L Celani[1], R Rossi[1], C Rompietti[1], F Strozzini[1], B Del Papa[1], D Cecchini[1], O Bereshchenko[2], T Haferlach[3], MP Martelli[1], F Falzetti[1], B Falini[1]
[1]Institute of Hematology-Centro di Ricerche Emato-Oncologiche (CREO), [2]Section of Pharmacology Toxicology and Chemotherapy, University of Perugia, Perugia, Italy, [3]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Mutations in *NPM1* and *FLT3*-ITD are frequently associated in human AML and were also reported to induce leukemia in mice. However, the molecular consequences of this oncogenic cooperation in the development of AML still remain elusive.
Aims: We generated an *NPM1*/*Flt3*-ITD AML mouse model to address the following issues: i) to characterize the cellular origin of leukemia; ii) to identify the epigenetic/transcriptional signature in AML pathogenesis; iii) to analyze AML therapeutic response *in vivo*; and iv) to validate mouse data in human AML.
Methods: We crossed our *NPM1* mutant and *Flt3-ITD* mice and used: 1) FACS analysis to study the HSC/progenitor cell compartments in bone marrow (BM); 2) real-time PCR and Western blot analysis to measure GATA1 mRNA and protein expression; 3) bisulfite conversion followed by DNA sequencing to study methylation; 4) 5-Aza-dC and the FLT3 inhibitor AC220 for treatment experiments.
Results: *NPM1/Flt3-ITD* double mutated mice progressed to AML recapitulating *features of the human disease*. The AML phenotype was preceded by a preleukemic stage of variable length that inversely correlated with the burden of the mutant alleles. Pre-leukemic mice displayed leukocytosis (WBC 20.8±18x10^9/L) and macrocytosis (MCV 58.74±5.6 fl). In *NPM1*/*Flt3-ITD* mice, FACS analysis revealed expansion of multipotent and granulocyte-macrophage progenitor compartments. Conversely, long-term hematopoietic stem cells and immature megakaryocytic/erythroid compartments were significantly reduced as compared to other genotypes combinations. Strikingly, we found that the key regulator of normal myelo-erythroid differentiation GATA1 was transcriptionally silenced in *NPM1*/*Flt3-ITD* mice. Similarly, AML patients with *NPM1*/*FLT3*-ITD mutations displayed a significantly lower mean GATA1 expression compared to patients with a different genotype (0.42±0.09 *vs* 5.3±1.3 respectively, p<0.05). Genomic bisulfite sequencing of the GATA1 promoter revealed more than 80%±0.12 methylated CpGs in BM cells from double mutated mice as compared to only 53%±0.22 methylation in other genotypes, thus clearly implicating epigenetic changes as the cause of GATA1 transcriptional silencing. *In vivo* treatment of leukemic mice with the DNA methyltransferase inhibitor 5-aza-deoxycytidine (5-Aza-dC) reactivated GATA1 expression determining the normalization of leukocytosis and preventing a drop in platelets counts. Strikingly, real-time PCR analysis revealed a significant 3.45±1.01 upregulation of GATA1 mRNA levels in BM samples from *NPM1*/*FLT3*-ITD mutant AML patients that underwent 5-Aza-dC treatment (p<0.001). Finally, we assessed the sensitivity of *NPM1/Flt3*-ITD mice AML to targeted FLT3 inhibition. *In vitro* treatment with the FLT3 inhibitor AC220 significantly reduced the viability of BM cells isolated from *NPM1*/*Flt3-ITD* preleukemic or leukemic mice. *In vivo*, AC220 induced a reduction of WBC counts accompanied by a partial GATA1 re-expression in peripheral blood cells without improving mice survival. In a xenotransplant model of human *NPM1*/*FLT3*-ITD AML, the FLT3 inhibitor induced significant reduction in size of subcutaneous AML tumors with GATA1 upregulation.
Summary/Conclusions: We demonstrated that epigentic modification abrogated a GATA1-dependent transcriptional program and represented a prerequisite for *NPM1*/*Flt3*-ITD leukemogenesis. Mouse data are further supported by low GATA1 expression found in human AML samples and *in vivo* treatments rescues. Therefore, GATA1 represents a target for new tailored therapies in AML with *NPM1* and *FLT3*-ITD mutations.

S458

FLT3-D835Y AND NPM1C ONCOGENES COOPERATE TO INDUCE AN AGGRESSIVE MPN IN MICE

A Rudorf[1,*], T Mueller[1], C Klingeberg[1], GS Vassiliou[2], A Bradley[2], J Duyster[1], AL Illert[1]
[1]Dept. of Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, Germany, [2]Haematological Cancer Genetics, Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom

Background: Activating mutations in FLT3 and NPM1 are most common alterations in AML and frequently coincidental. The exon 12 mutation of *Npm1* (NPM1c) leads to a mislocalization of the protein from the nucleus to the cytoplasm. Two types of mutations are present in FLT3: Tandem duplication of the juxtamembraneous domain (ITD) and point mutations of the tyrosine kinase domain (TKD). In murine models, both NPM1c and FLT3-ITD induce an MPN, while FLT3-TKD leads to a lymphoid disorder. Co-expression of NPM1c and FLT3-ITD rapidly induces an AML in mice.
Aims: In the present study, we investigated the impact of co-expression of NPM1c with the TKD mutation FLT3-D835Y in a mouse model.
Methods: For this purpose a heterozygous conditional *Npm1c* knockin mouse model was used where *Npm1c* can be induced via the Mx1Cre-system. Donor bone marrow was harvested from these mice and cells were retrovirally infected with the MiG-*Flt3-D835Y* vector. Infected bone marrow cells were injected into lethally irradiated C57Bl/6 wt recipient mice. The *Npm1c* expression was induced by p(I:C) injection post transplantation resulting in the activation of IFN-α and thereby Cre recombinase induction under the control of the Mx1 promotor. Control mice received no p(I:C) injection. Lymphatic/Leukemic organs of moribund mice were analyzed for lineage-specific cell surface markers by flow cytometry.
Results: Strikingly, *Npm1c Flt3-D835Y* mice rapidly developed a myeloproliferative neoplasia and succumbed after a median latency of 33 days. In contrast, *Flt3-D835Y Npm wt* control mice did not develop a leukemic disease. Detailed analysis *Npm1c Flt3-D835Y* mice revealed a high leukemic burden in the peripheral blood as well as in the bone marrow and a pronounced splenomegaly. Flow cytometry analysis revealed a myeloid phenotype in the peripheral blood, spleen and bone marrow of moribund mice, characterized by a high frequency of FLT3-D835Y$^+$/CD11b$^+$and Gr1$^+$ cells, whereas *Flt3-D835Y* control mice showed a normal immune phenotype. Interestingly, immunoblot analysis of spleen extracts from moribund mice indicated that Flt3-D835Y in combination with NPM1c induces STAT5 but not STAT3 signaling. These results suggest that the MPN induction in this model might be due to STAT5 activation. Previously, it has been shown that the myeloid leukemia of *Npm1c Flt3-ITD* mice is retransplantable. To discover whether the myeloid phenotype of *NPM1c Flt3-D835Y* mice is retransplantable as well, 1x10^5 and 1x10^6 spleen cells of an *Npm1 Flt3-D835Y* mouse were injected into sublethally irradiated C57Bl/6 wt recipient mice. Indeed, we were able to show retranplantability of *Npm1c Flt3-TKD* disease in the group transplanted with high cell numbers, whereas the retranplantability was not only partial inducible (15-30% of the mice) in the group transplanted with lower spleen cell numbers (1x10^5).
Summary/Conclusions: In summary, our data show that co-expression of NPM1c and FLT3-D835Y results in the development of a rapidly fatal MPN whereas FLT3-D835Y-expression alone is not sufficient to cause a myeloproliferative disease in C57Bl/6 mice. Moreover, the myeloid phenotype is retransplantable with 1x10^6 donor spleen cells in C57Bl/6 mice. Interestingly, myeloproliferative disease induction might be due to aberrant STAT5 activation by FLT3-D835Y in the background of NPM1c mutant.

Background: Acute myeloid leukemia (AML) is a heterogeneous disease with diverse leukemogenic driver lesions. The genetic understanding of AML has resulted in major improvements in diagnosis, classification, prognostication, and outcome prediction. However, these insights have not yet translated into molecular mechanism-based therapies in the majority of cases, because AML cells are able to rapidly escape attempts at therapeutic targeting such as small-molecule inhibition of FLT3 internal tandem duplication (ITD) mutants, which occur in up to 30% of cases and confer a poor prognosis.
Aims: Given the propensity of AML to develop resistance to single-agent small-molecule therapy, we aimed to identify potential new targets for combinatorial treatment approaches.
Methods: We performed a series of large-scale RNA interference screens, using a subgenomic short hairpin RNA (shRNA) library targeting kinases, phosphatases, and known cancer-related genes, in a panel of AML cell lines.
Results: We identified that the RET receptor tyrosine kinase (RTK), which has not previously been implicated in AML pathogenesis, is critical for the viability and proliferation of cell lines representing various AML subtypes. Validation experiments demonstrated that depletion of RET by shRNA knockdown or CRISPR/Cas9-mediated knockout leads to cell cycle arrest in the G0/G1 phase, increased apoptosis, and reduced clonogenic activity. Moreover, transcriptome analysis identified elevated *RET* mRNA levels in 35 of 260 (13.5%) primary human AML samples. RTK profiling using ELISA-based antibody arrays demonstrated that RET is highly phosphorylated in RET-dependent AML cell lines. Analysis of known RET ligand/co-receptor pairs (GDNF/GFRA1, NRTN/GFRA2, ARTN/GFRA3, PSPN/GFRA4) by quantitative real-time PCR and shRNA knockdown suggested that RET signaling is facilitated mainly through NRTN/GFRA2 or ARTN/GFRA3. Interrogation of various signaling pathways known to promote myeloid leukemogenesis showed that RET knockdown resulted in decreased

phosphorylation of p70S6K (Ser371), S6RP (Ser240/244), and ULK1 (Ser758), pointing to mTORC1-mediated protein synthesis and/or suppression of autophagy as important effects of RET signaling in AML cells. Based on recent data showing that FLT3-ITD mutants can be autophagically degraded (Larrue *et al.* Blood 2016), we reasoned that the RET-mTORC1 signaling axis promotes AML through protection of FLT3-ITD mutants from autophagic degradation. Consistent with this hypothesis, RET knockdown or pharmacologic RET inhibition with vandetanib and danusertib predominantly affected FLT3-dependent AML cell lines and were accompanied by upregulation of autophagy and destabilization of FLT3, as evidenced by p62 degradation, increased numbers of autophagic vacuoles, and decreased FLT3 protein levels. Finally, we are currently investigating whether Ret is required for AML development and propagation *in vivo* using a murine bone marrow transplantation model.

Summary/Conclusions: Combined, our results indicate that in a proportion of AML, RET-mTORC1 signaling promotes cell viability and proliferation through suppression of autophagy, suggesting that targeting RET or, more broadly, depletion of critical leukemogenic drivers via induction of autophagy may provide a therapeutic opportunity in this subset of patients.

Background: In acute myeloid leukemia (AML) about 20-30% of patients possess a FLT3-internal tandem duplication (ITD) associated with a poor prognosis and a higher propensity for relapse after remission. Tyrosine kinase inhibitors (TKI) such as PKC412 have been developed for therapy of FLT3-ITD-positive AMLs. So far, resistance to tyrosine kinase inhibitors has been demonstrated to occur by point mutations in FLT3 whereas further mechanisms that render leukemic cells drug resistant remain incompletely understood.

Aims: We utilized a PKC412-resistant model of FLT3-ITD-positive MV4-11 cells to (1) identify novel mechanisms of drug resistance, (2) to analyze cross resistance to the standard chemotherapeutics cytarabine and daunorubicin and translate our findings to FLT3-ITD-negative AMLs and (3) to develop strategies to reverse chemoresistance in AML.

Methods: Drug resistance mechanisms were analyzed *in vitro* by immunohistochemistry, Western blot, shRNA-mediated mRNA knockdown, lentiviral overexpression, immunoprecipitation, label-free- and SILAC (Stable isotope labeling by amino acids in cell culture)- mass spectrometry, ChIP-seq and ex-vivo- culture of patient samples. For *in vivo* analysis xenograft mouse models were applied.

Results: We identified loss of the histone methyltransferase EZH2 with subsequent reduction of histone H3K27 trimethylation in PKC412- resistant MV4-11 cells which led to cross-resistance to cytarabine and daunorubicin. In AML patients, the absence of EZH2 protein expression was closely associated with poor overall survival (p=0.008), poor event-free (p=0.005) and poor relapse-free survival (p=0.047) as analyzed by tissue microarrays. The reduction of EZH2 protein levels via treatment with H3K27 methyltransferase inhibitors or lentiviral knockdown was sufficient to induce chemoresistance of Normal Karyotype (NK)- AML blasts and cell lines *in vitro* and in a xenograft mouse model. The loss of EZH2 in drug resistant MV4-11 cells was regulated by posttranslational mechanisms. Immunoprecipitation of EZH2 revealed a 2.6-fold increased phosphorylation of residue T487 in resistant cells (p=0.014) and the cyclin-dependent kinase 1 (CDK1) was associated with EZH2 specifically in resistant MV4-11. Several ubiquitin-E3-ligases such as TRIM21 were increasingly bound to EZH2 in resistant compared to sensitive cells resulting in a strong ubiquitination of EZH2 and subsequent degradation. Pharmacological inhibition of CDK1 and treatment with the proteasome inhibitor bortezomib, respectively, increased EZH2 protein and restored drug sensitivity in resistant cells. Functionally, reduction of EZH2 directly induced upregulation of *HOX* genes and the drug transporter MRP1, suggesting a stem-cell-like signature to be associated with the resistance phenotype, which could be reverted by proteasome inhibitors. In primary AML samples sensitivity to cytarabine was specifically increased in samples with elevated EZH2 protein levels upon bortezomib exposure whereas no change was observed in patient samples without EZH2 increase upon bortezomib treatment (p=0.0079, Fisher´s exact test).

Summary/Conclusions: In summary, our findings identify a novel epigenetic resistance mechanism that can be induced by prolonged exposure to PKC412 or cytotoxic drugs. EZH2 protein restoration by proteasome inhibitors in combination with established therapy approaches may be a promising therapy concept to restore drug sensitivity in AML.

S461

LOSS OF FUNCTION SETD2 MUTATIONS LEAD TO RESISTANCE TO DNA DAMAGING CHEMOTHERAPY IN LEUKEMIA

J Kahn[1,*], B Mar[2], H Chu[3], P Graumann[1], R Zon[1], K Boettger[1], S Chu[3], S Armstrong[3], B Ebert[1]

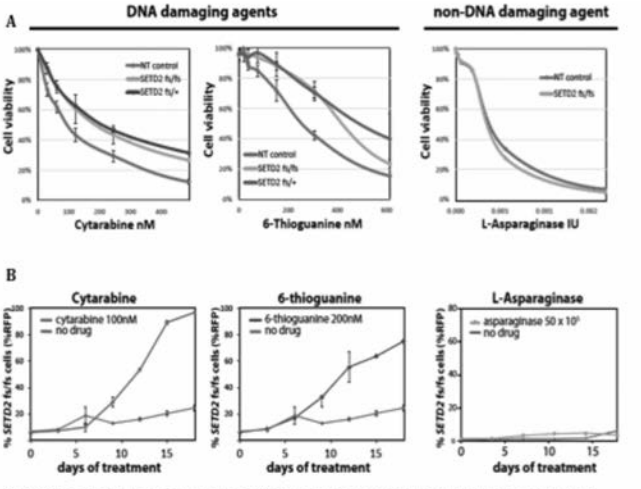
[1]Brigham and Women's Hospital, [2]Boston Children's Hospital, Boston, [3]Memorial Sloan Kettering Cancer Center, New York, United States

Background: Relapsed leukemia has a poor survival, which can be attributed to the relative chemotherapy resistance of this disease entity. While the consequences of chemotherapy resistance are clear, the genetic alterations underlying resistance remain poorly understood. We recently identified somatic mutations that are specifically enriched in relapsed leukemia, including a novel loss of function mutation in the epigenetic regulator *SETD2*. SETD2 is the only known mammalian Histone 3 Lysine (H3K36) trimethyltransferase and its role in DNA mismatch repair was recently established. In view of the presence of *SETD2* mutations in relapsed leukemia, and the role of SETD2 in DNA repair, we hypothesized that SETD2 plays a role in chemotherapy resistance in relapsed leukemia.

Aims: To investigate the role of *SETD2* loss of function mutations in chemotherapy resistance and identify therapeutic targets for *SETD2* mutant leukemia.

Methods: We employed two different models to study the role of SETD2 in chemotherapy resistance, which include an isogenic human leukemia model engineered with CRISPR-Cas9 and a murine leukemia with *Setd2* conditional knockout and retroviral expression of *MLL-AF9*. We studied the presence and mechanism of chemotherapy resistance in both models.

Results: We demonstrate that loss of function *SETD2* mutations cause resistance to chemotherapy. The resistance is specific to DNA damaging chemotherapies, including the commonly used agents 6-thioguanine and cytarabine. In contrast, no resistance to the non-DNA damaging agent L-asparaginase was observed. In addition to causing an increase in IC50 values, loss of SETD2 results in a strong competitive advantage in the presence of DNA damaging agents, mimicking the selective pressure of SETD2 mutant clones during treatment in patients (Figure 1). We further establish that the resistance is caused by an abrogated DNA damage response as demonstrated by a decreased phosphorylation of CHK1 and CHK2 and a reduced apoptotic response after treatment with DNA damaging therapies. In our conditional knockout model, we show that, in addition to causing a significant acceleration of leukemia, SETD2 loss causes resistance to cytarabine and doxorubicin treatment *in vivo*. Finally, we show that WEE1 inhibition specifically targets *SETD2* mutant cells and re-sensitizes to chemotherapy, hereby providing a treatment option for *SETD2* mutant, chemotherapy resistant leukemia.



SETD2 loss leads to resistance to DNA damaging chemotherapy. (A) Viability assays in Molm13 CRISPR Cas9 cells transduced with an sgRNA targeting *SETD2*, or a non-targeting control (NT control). *SETD2* heterozygous (fs/+), compound heterozygous (fs/fs) or *SETD2* WT control cells (NT control) were exposed to increasing concentration of Cytarabine, 6-Thioguanine or L-Aspargainase for 72 hours. **(B)** Molm13 *SETD2* mutant (fs/fs) cells were mixed in a 1:20 ratio with Molm13 control cells and exposed to Cytarabine, 6-Thioguanine or L-Asparaginase treatment for 18 days. Molm13 *SETD2* mutant cells were marked by RFP.

Figure 1.

Summary/Conclusions: While relapsed leukemia is known to be chemotherapy resistant, the mechanisms of resistance remain poorly understood. This study is the first to show that loss of function *SETD2* mutations confer chemotherapy resistance in leukemia. In addition, we show that treatment with a WEE1 inhibitor – which is currently in clinical trials - is able to specifically target *SETD2* mutant leukemia and reverse chemotherapy resistance. Hence, this study supports a prominent role for loss of function *SETD2* mutations in disease progression and chemotherapy resistance in leukemia, as well as providing evidence for a potential therapy to treat *SETD2* mutant, chemotherapy resistant leukemia.

RESULTS OF TRANSCRANIAL DOPPLER ULTRASOUND SCREENING FROM THE POST-STOP STUDY

J Kanter[1,*], J Kwiatkowski[2], J Voeks[3], H Fullerton[4], E Debenham[3], R Adams[3]
[1]Pediatrics, Medical University of South Carolina, Charleston, [2]Pediatrics, Childrens Hospital of Philadelphia, Philadelphia, [3]Neurosciences, Medical University of South Carolina, Charleston, [4]Neurology, University of California at San Francisco, San Francisco, United States

Background: The Stroke Prevention Trial in Sickle Cell Anemia (STOP) and Optimizing Primary Stroke Prevention in Sickle Cell Anemia (STOP 2) established that routine transcranial Doppler ultrasound (TCD) screening could identify children with sickle cell disease (SCD) at high risk of stroke. Furthermore, these studies demonstrated that patients with abnormal TCD require indefinite chronic red cell transfusions (CRCT) as standard of care. Thus, annual TCD screening is recommended from ages 2 to 16 years, with more frequent monitoring if the result is abnormal. Patients with abnormally high TCD who were started on CRCT had reductions in ischemic strokes compared to patients not receiving transfusions as shown in several clinical series and analyses utilizing large hospital databases when comparing rates before and after the publication of the STOP study in 1998.
Aims: This study sought to evaluate the outcomes of patients identified with abnormal TCD who had previously participated in the STOP and/or STOP 2 trials.
Methods: Between 1995 and 2005, STOP and STOP 2 (STOP/2) were conducted at 26 sites in the US and Canada. These studies included 3,835 children, ages 2 to 16 y with SCD type SS or S-beta-0-thalassemia. Participation in STOP/2 ranged from a single screening TCD to randomization. STOP 2 also had an observational arm for children on CRCT for abnormal TCD who's TCD had not reverted to normal. The Post-STOP study was designed to follow-up the outcomes of children who participated in one or both trials. 19 of the 26 original study sites participated in Post-STOP, contributing a total of 3,539 (92%) of the STOP/2 subjects. After exit from STOP/2, these children received TCD screening and CRCT (or other treatment) according to local practices. Data abstractors visited each clinical site and obtained retrospective data from STOP/2 study exit to 2012-2014 (depending on site) including follow-up TCD and brain imaging results, clinical information, and laboratory results. Two vascular neurologists, blinded to STOP/2 status and prior TCD and neuroimaging results, reviewed source records to confirm all ischemic and hemorrhagic strokes, discordant opinions were resolved through discussion.
Results: The two (STOP and STOP-2) study databases contained unique records for 3854 children at 26 sites. Nineteen of those original sites participated in post stop accounting for 3539 subjects (92%). Of these 3539, records of care at enrolling states were located for 2851 subjects (81% of possible). The mean age at the start of Post-STOP was 10.5 y and mean duration of follow-up after exiting STOP/2 was 9.1 y. During the STOP or STOP2 period, 333 (11.7%) patients had an abnormal TCD and 12 patients suffered acute stroke (included the post-STOP encounters). During the Post-STOP period, an additional 122 (4.34%) of children where identified with abnormal TCD. Of these patients identified with abnormal TCD in the Post-STOP period, 25 (20%) patients suffered an ischemic event only 15 (60%) of which were receiving appropriate CRCT prevention. An additional 7 patients (5.7%) identified with abnormal TCD suffered a hemorrhagic event, only 1 of whom was on CRCT therapy (4 patients were on HU and 2 patients had unknown treatment). The remaining 90 (74%) patients with abnormal TCD had no reported negative neurologic outcomes despite variations in compliance with CRCT during the post-stop period (or were lost to follow-up).
Summary/Conclusions: The Post-STOP study included 81% of the original STOP and STOP-2 patients. In total, 455 of those patients (16%) were identified with an abnormal TCD. While many of these patients were continued on CRCT, many individuals were treated with Hydroxyurea, had no preventative therapy or were lost to follow-up. Future prospective trials are needed to better evaluate which patients identified at high risk for stroke by TCD do not require lifetime CRCT.

Background: Stroke is one of the leading causes of death in both children and adults with sickle-cell disease (SCD) most often related to a specific large-vessel vasculopathy. Prevention of stroke is based on blood exchange transfusion if stenosant vasculopathy is confirmed. However magnetic resonance angiography or angio scanner are not easily available in many AFrican countries instead of Doppler ultrasound which is the main diagnosis strategy in SCD children. Doppler ultrasound has never been demontrated to be effecient in SCD adults.
Aims: The objective of this study was to assess whether Doppler ultrasound is sensitive and specific to identify SCD adult patients with vasculopathy, compared with magnetic resonance angiography.
Methods: 80 adult SCD patients likely to have brain attempt were referred to our center for vasculopathy screening. 77 patients could benefit from our protocol including both a 3T brain MR imaging with a 3D time-of-flight MR angiography and a Doppler-Ultrasound examination performed on the same day. 3 patients presented contraindication to MRI.
On MR imaging, patients were categorized according to the grade of the highest stenosis and to the presence of Moya-Moya. On EchoDoppler-Utrasound examination, time-averaged mean of the maximum velocity (TAMMx) was measured and a TAMMx ratio was established using the highest TAMMx value recorded on one axis, divided by the TAMMx value of the ipsilateral extracranial internal carotid artery. Presence of Moya-Moya was also recorded.
Results: Among the 38 patients with an intracranial vasculopathy (stenosis >=50% on MR imaging, presence of an occlusion or Moya-Moya), 33 had a severe vasculopathy according to EchoDoppler criteria defined as a TAMMx ratio >=3 (n=5) or presenting an occlusion (n=11) or a Moya-Moya (n=17). Sensitivity and specificity of EchoDoppler to identify patients with >=50% vasculopathy on MRA is respectively of 87%, 90%. Positive and negative predictive values are respectively of 86% and 87%.
Summary/Conclusions: Doppler ultrasound may be used to identify SCD adult patients with vasculopathy.

Background: Patients with sickle cell anemia (SCA) are known to have cognitive deficiency. However, only a comparison with non-SCA siblings allows true appreciation of the disease impact.
Aims: The aims of the present study were to compare the cognitive performances of SCA-children on long-term transfusion programs due to a history of abnormal transcranial Doppler (TCD) velocities with those of their siblings, and to assess the relation to neuroimaging data.
Methods: *Drepagreffe* is a French national multicenter prospective trial (APHP, NCT 01340404) involving SCA-children, younger than 15 years of age, placed on chronic transfusion for abnormal-TCD (TAMMX ≥200 cm/sec), and comparing the outcome of cerebral vasculopathy following transfusions or hematopoietic stem cell transplant. We present here, the results of cognitive testings done at enrollment in SCA-children and non-SCA siblings, and patient neuroimaging data. The MRI scoring was: 3=territorial, 2=borderzone (cortical and subcortical), 1=white matter or basal ganglia infarcts, 0 to 3=atrophia, and MRA scoring was: 1=mild stenosis (25-49%), 2=moderate stenosis (50-74%), 3=severe stenosis (75-99%), 4=occlusion for each artery and 0 to 2 for Moya presence. Cognitive testing, performed in patients and in siblings when possible, included WPPSI-3 (3-6 yr), WISC-4 (7-16 yr) or WAIS-3 (>16 yr) scales, depending on the subject age.
Results: Sixty-seven SCA-children (36F/31M) were included. Seven had a history of overt stroke. *At abnormal-TCD detection and chronic transfusion initiation*, the mean age (SD) was 5.5yr (2.5) and velocities≥200/cm/sec were found in right/left middle (n=29/22), anterior (n=7/5), internal carotid (n=10/7) and extracranial internal carotid (n=7/7) arteries, as abnormal velocities were observed in more than one artery in several patients. *At enrollment*, following a mean duration of chronic transfusion of 2.8 years, the mean age was 8.1yr (3.1), and mean(SD) maximum velocities had significantly decreased from 219 (26) to 169 (46) cm/s *(p<0.001)*. MRI/MRA data were available in 66/67 patients. Ischemic lesions were present in 25 patients and 18 of them had silent lesions. Stenoses were present in 35/66 patients in right/left middle (n=7/10), anterior (n=11/16), internal carotid (n=7/12) and extracranial internal carotid (n=11/12) arteries, as stenoses were observed in more than one artery in several patients. Cognitive testing was obtained in 64/67 patients (parental refusal for 3 patients), and in 56 siblings (8 were too young for testing). Paired analysis with siblings showed significant differences in Verbal Comprehension Index (VCI) with a mean difference of 7.6±14.5 (p<0.001), Processing Speed Index (PSI) 6.3±20.5 (p=0.04), and Full Scale IQ (FSIQ) 7.3±15.0 (p=0.001). Patient cognitive performance indexes were correlated negatively and significantly with the MRI and MRA scores. After exclusion of the 7 patients with stroke history, significant differences were still observed in VCI (p=0.013) and FSIQ (p=0.019), but were not correlated with the presence of silent cerebral infarcts.
Summary/Conclusions: SCA-children on transfusions for history of abnormal cerebral velocities had significantly lower cognitive performances than their siblings, even in the absence of stroke history. In the no-stroke patients, the differences observed with their siblings were not correlated with the presence of silent cerebral infarcts. These data suggest that stroke and silent infarcts are not the only underlying cause of cognitive deficiency in SCA children.

A PHASE I/II STUDY OF AUTOLOGOUS HEMATOPOIETIC STEM CELLS GENETICALLY MODIFIED WITH GLOBE LENTIVIRAL VECTOR FOR THE TREATMENT OF TRANSFUSION DEPENDENT BETA-THALASSEMIA

S Marktel[1,2,*], F Giglio[1], MP Cicalese[3], M Casiraghi[3], S Scaramuzza[2], A Aprile[2], MR Lidonnici[2], C Rossi[2], J Peccatori[1], F Ciotti[3], S Gattillo[4], R Milani[4], M Coppola[4], G Viarengo[5], E Cassinerio[6], G Graziadei[6], L Naldini[2], MD Cappellini[6], A Aiuti[2], F Ciceri[1], G Ferrari[2]
[1]Haematology and BMT Unit, [2]San Raffaele Telethon Institute for Gene Therapy, [3]Pediatric Immunohematology, [4]Blood Transfusion Service, San Raffaele Scientific Institute, Milan, [5]Immunohematology and Transfusion Medicine Service, Fondazione IRCCS Policlinico S. Matteo, Pavia, [6]Rare Disease Center, Fondazione IRCCS Ca' Granda, Milan, Italy

Background: A clinical trial was initiated in April 2015 at Scientific Institute San Raffaele to evaluate safety and efficacy of autologous hematopoietic stem cells (HSCs) genetically modified with the GLOBE lentiviral vector for the treatment of transfusion dependent beta thalassemia (TIGET-BTHAL; EudraCT number 2014−004860−39).
Aims: The financial sponsor is the Italian charity organization Fondazione Telethon. The manufacture is MolMed S.p.A. The therapeutic potential of GLOBE was validated in thalassemic mice (Miccio *et al.*, PNAS 2008; Miccio *et al.* PlosONE, 2011) and human thalassemic cells (Roselli *et al.*, EMBO MolMed 2010) showing persistent transgene expression and disease correction. Preclinical GLP studies included a toxicology and tumorigenicity study in th3/+ mice and a biodistribution study of human of CD34+ cells in NSG mice demonstrating safety of the approach.
Methods: The clinical protocol will treat 3 adults followed by 7 minors, with a staggered enrolment strategy based on evaluation of safety and preliminary efficacy in adult patients by an independent data safety monitoring board before inclusion of pediatric subjects. Inclusion criteria: transfusion dependent beta thalassemia, age 3-65 years, adequate cardiac, renal, hepatic and pulmonary functions, absence of severe liver or cardiac iron overload, absence of severe liver fibrosis or cirrhosis. Exclusion criteria include active hepatitis, HIV infection or a previous allogeneic BMT and for pediatric patients availability of a well matched donor. The HSC source is mobilized peripheral blood stem cells (PBSCs) obtained after administration of lenograstim and plerixafor. PBSCs are transduced after apheresis and kept frozen in 10%DMSO until administration to the patient. Conditioning: treosulfan and thiotepa for adult and elderly children (≥8years), busulfan for younger children (age 3-7yrs old). The chosen route of administration of thawed and washed gene modified cells is intraosseous in the posterior-superior iliac crests, bilaterally. The aim of intraosseous infusion is to enhance engraftment and minimize first-pass intravenous filter. Autologous lymphocytes (previously cryopreserved from apheresis or phlebotomy) are re-infused at a target dose of 5x10^7 CD3+ cells/kg on day+3 to speed adaptive immune recovery.
Results: Between May and October 2015 three patients were included. As of March 2016, one patient is 6 months post gene therapy, one 1.5 months and one has completed mobilization. Age at enrollment: 31, 35, 35 years. Stem cell harvest was $30x10^6$ CD34+/kg, $21.3x10^6$ CD34+/kg and $23.5x10^6$ CD34+/kg, respectively. Cell dose of gene modified cells of the 2 treated patients: $19.4x10^6$ CD34+/kg and $18.4x10^6$ CD34+/kg. Adverse events recorded as of March 2016 were mild, reversible and related to the conditioning regimen and transplant procedure. The first patient had a neutrophil engraftment (>500 ANC/µl) on day+21 and platelet engraftment (>20.000/µl unsupported) on day+16. The second patient had a neutrophil engraftment on +25 and platelet engraftment on +21. The first patient treated showed multilineage engraftment of gene corrected cells with higher levels in erythroid lineage and received the last red blood cell transfusion 2 months after gene therapy. At 6 months follow up the patient was transfusion-free and conducting a normal working activity with a haemoglobin of 9.2 g/dL.
Summary/Conclusions: In conclusion, preliminary data on adult patients showed a good yield of PBSCs, a high number of cells infused, good tolerability of the procedure overall with reversible adverse events and preliminary positive efficacy data.

S466

EFFECTS OF AG-348, A PYRUVATE KINASE ACTIVATOR, ON ANEMIA AND HEMOLYSIS IN PATIENTS WITH PYRUVATE KINASE DEFICIENCY: EARLY DATA FROM THE DRIVE PK STUDY

RF Grace[1,*], C Rose[2], DM Layton[3], W Barcellini[4], JL Kwiatkowski[5], B Silver[6], E Merica[7], C Kung[7], M Cohen[8], H Yang[7], J Hixon[7], PA Kosinski[7], L Silverman[7], L Dang[7], ZJ Yuan[7], AJ Barbier[7], S Agresta[7], B Glader[9]
[1]Dana-Farber Boston Children's Cancer and Blood Disorder Center, Boston, United States, [2]Hôpital Saint Vincent de Paul, Lille, France, [3]Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom, [4]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [5]The Children's Hospital of Philadelphia and Perelman School of Medicine, Philadelphia, [6]Bruce A Silver Clinical Science and Development, Dunkirk, [7]Agios Pharmaceuticals, Inc., Cambridge, [8]MBC Pharma Solutions, Newtown, [9]Stanford School of Medicine, Palo Alto, United States

Background: Pyruvate kinase (PK) deficiency is a congenital hemolytic anemia caused by deficiency of the glycolytic enzyme red cell PK (PK-R), required for maintenance of adenosine triphosphate (ATP) in red blood cells. AG-348 is an orally-available, small molecule, allosteric activator of PK-R that activates wild-type and a range of mutated PK-R enzymes *in vitro* and increases PK-R activity and restores ATP levels in red blood cells from patients with PK deficiency *ex vivo*.
Aims: To describe early data from the ongoing DRIVE PK study (NCT02476916), an open-label, dose-ranging trial of AG-348 in transfusion-independent adults with PK deficiency.
Methods: After providing informed consent, patients are randomized to AG-348 50 mg or 300 mg orally twice daily (BID) for 6 months. Transfusion independence is defined as no more than 3 units of red blood cells transfused in the 12 months preceding first dose and no transfusions in the 4 months preceding first dose. Patients are followed weekly for Weeks 1–3, then every 3 weeks until Week 12, and then monthly until Week 24. Hormone and iron status are evaluated at Baseline, Week 12 and End of Study.
Results: As of 15 Jan 2016, 10 patients have received treatment for between 1 and 24 weeks. Adverse events (AEs) have been mild-to-moderate, with nausea (CTCAE Grade 1–2) the most commonly reported AE: 2 out of 5 (40%) patients in the 50 mg BID arm and 3 out of 5 (60%) patients in the 300 mg BID arm. No serious AEs have been reported. There have been no dose modifications for AEs. A single patient has had dose modifications for an increase in hemoglobin (Hb) above the protocol mandated maximum. Dosing was temporarily interrupted and reduced twice (100 mg BID, then 50 mg BID) and the patient has since been maintained on 50 mg BID for several weeks. Pharmacokinetic data showed exposure in line with expectations from earlier healthy volunteer studies with AG-348 for both doses. At data cutoff, pharmacodynamic analysis of 2,3-diphosphoglycerate (2,3-DPG) and ATP was available for 5 patients. Baseline 2,3-DPG levels were elevated in 4 of 5 patients, as expected. All patients with a Hb response of ≥1.5 g/dL also showed a substantial decrease in 2,3-DPG levels. Further data are being collected to evaluate relationships between hematological parameters and pharmacodynamic markers (2,3-DPG and ATP). Genotype–response relationships are also being assessed.
Summary/Conclusions: Early clinical data from DRIVE-PK indicate that AG-348 is well tolerated. Data on all patients (n~15–20), including safety, hematological responses, pharmacodynamic effects and genotype–response relationships will be presented.

FIRST RESULTS FROM A DOSE-ESCALATING STUDY WITH AAV5 VECTOR CONTAINING WILD TYPE HUMAN FACTOR IX GENE THERAPY IN PATIENTS WITH SEVERE OR MODERATELY-SEVERE HAEMOPHILIA B

F Leebeek[1,*], J Schwaeble[2], K Meijer[3], M Coppens[4], P Kampmann[5], S Krekeler[2], H Bonig[2], E Seifried[2], W Miesbach[2]
[1]Erasmus MC, Rotterdam, Netherlands, [2]Universitätsklinikum Frankfurt, Frankfurt, Germany, [3]University Medical Center Groningen, Groningen, [4]Academic Medical Center, Amsterdam, Netherlands, [5]Rigshospitalet, Copenhagen, Denmark

Background: Gene therapy for haemophilia B offers the potential to convert the disease severity from severe to a mild phenotype through continuous endogenous production of FIX. Adeno-associated viral (AAV) vectors of serotypes 2 and 8 (AAV2 and AAV8) containing the human factor IX (hFIX) gene have been used in previous clinical trials.[1-3] A single infusion with AAV8 vector resulted in dose dependent FIX expression for up to 4 years.[4] AMT-060 (AAV5-hFIX) consists of an AAV5 vector with an LP1 liver specific promotor, containing a codon-optimised wild type hFIX gene. A potential advantage of AAV5 is the lower prevalence of neutralising antibodies compared to other serotypes.
Aims: This study aims to investigate the safety and efficacy of AMT-060 in adult patients with severe or moderately severe haemophilia B.
Methods: This is an open-label, single dose escalating study in patients with FIX activity ≤1-2% of normal, and a severe bleeding phenotype. Five patients were enrolled in the first cohort of AMT-060 5×10^{12} gc/kg and a subsequent 5 patients will be enrolled in the second cohort of 2×10^{13} gc/kg. Patients receive AMT-060 via IV infusion over 30 minutes in an in-hospital setting. Safety assessments include treatment related adverse events (AEs) and serious AEs (SAEs). Efficacy assessments include FIX activity, rFIX usage and annualized bleeding rates. We report here preliminary results of the 5 patients treated in the first dose cohort. All patients gave informed consent.
Results: The age of the patients ranged from 35 to 72 years. None of the patients had pre-existing AAV5 antibodies. Four patients had documented FIX activity of <1% and one patient had 1.5%. Four patients had documented haemophiliac arthropathy. All patients were receiving rFIX prophylaxis weekly or twice-weekly prior to treatment with AMT-060. As expected, all 5 patients developed anti-AAV5 antibodies in response to study drug. None of the patients have developed inhibitory antibodies against FIX. Two SAEs have occurred. One patient had an asymptomatic, mild, transient elevation of ALT (peak level at week 10, 61 IU/L; upper limit of normal, 40 IU/L) that resolved after rapid institution of a tapering regimen of prednisolone. Another patient had a self-resolving febrile episode within the first 24 hours of AMT-060 administration. During the first 12 weeks post-gene therapy, 4 out of the 5 patients achieved FIX activity levels that allowed them to discontinue rFIX prophylaxis. FIX activity and other efficacy outcome measures for a minimum of 30 weeks follow-up of the 5 patients in the first dose cohort will be presented.
Summary/Conclusions: Treatment of haemophilia B with a single infusion of AMT-060 was well tolerated, and clinically relevant FIX activity has been achieved in the first dose cohort, relieving 4 out of 5 patients from rFIX prophylaxis. The study will continue with enrolment of the second dose cohort as planned.

RESPONSIVENESS OF HEMOPHILIA B-CAUSING NONSENSE MUTATIONS TO RIBOSOME READTHROUGH-INDUCING DRUGS STRICTLY DEPENDS ON THE NUCLEOTIDE AND PROTEIN CONTEXT

A Branchini[*], M Ferrarese, S Lombardi, M Baroni, M Campioni, F Burini, F Bernardi, M Pinotti
Department of Life Sciences and Biotechnology, University of Ferrara, Ferrara, Italy

Background: Nonsense mutations, caused by premature termination codons, are relatively frequent in Haemophilia (>10%) and are considered as "null mutations". However, they have been found also in moderate/mild Haemophiliacs

and, as compared with large gene deletions, are associated with lower risk for developing inhibitors. This observation point to the presence of residual expression levels arising from "ribosome readthrough" over nonsense triplets, whose sequence context has an impact on readthrough efficiency, as we have shown in a very small cohort of Haemophilia B (HB) patients. Drugs inducing readthrough such as aminoglycosides are proposed as potential therapy.
Aims: To investigate residual secreted and functional levels of factor IX (FIX) produced by an extended panel of HB nonsense mutations.
Methods: Recombinant FIX (rFIX) nonsense variants were expressed in HEK293 cells, and secreted and intracellular protein levels, as well as protein isoforms, were evaluated by ELISA and Western Blotting analysis. Residual activity was assessed by coagulant assays.
Results: We investigated a panel of *F9* mutations (R75X, L103X, R162X, W240X, R294X, R298X, Y330X, Q370X, R379X, R384X), associated to severe/moderate HB, representing the vast majority of patients with nonsense mutations in HB (324 patients out of 467, corresponding to ~70%). Appreciable levels of secreted FIX were detected for the R162X, W240X, R294X, R298X, Y330X mutants, with truncated isoforms being the large predominance. Truncated forms for Q370X, R379X and R384X were observed in cell lysates only, which suggests misfolding and intracellular retention. Noticeably, the full-length FIX form was appreciable for the R162X variant, indicating the occurrence of spontaneous readthrough, which was significantly increased by the use of aminoglycosides. Moreover, aminoglycosides promoted the synthesis of full-length FIX in the presence of the R75X, Y330X, Q370X, R379X, R384X mutations, not undergoing appreciable spontaneous readthrough. Intriguingly, we investigated the peculiar W240X nonsense mutation, caused by two different termination codons, which showed a differential impact of readthrough in restoring the full-length protein depending on the sequence context. Preliminary coagulant and functional assays revealed that only a few variants were prone to undergo efficient readthrough in terms of secretion and coagulant function.
Summary/Conclusions: These data demonstrate that nonsense mutations can be associated to residual FIX levels through a mechanism of "productive" readthrough. The identification of "leaky" nonsense mutations, and thus of patients with trace FIX levels and potentially "high responders" to readthrough-inducing drugs, might help diagnosis and treatment.

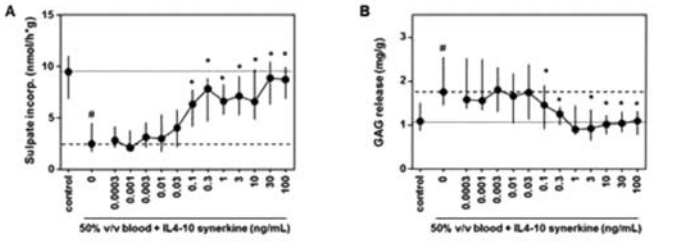
A FUSION PROTEIN OF INTERLEUKIN-4 AND INTERLEUKIN-10 PROTECTS AGAINST BLOOD-INDUCED CARTILAGE DAMAGE *IN VITRO* AND *IN VIVO*

L van Vulpen[1,2,*], R Schutgens[2], K Coeleveld[1], C Steen-Louws[3], C Hack[3], J Popov-Celeketic[1], S Mastbergen[1], F Lafeber[1]
[1]Rheumatology & Clinical Immunology, [2]Van Creveldkliniek, [3]Laboratory for Translational Immunology (LTI), University Medical Center, Utrecht, Netherlands

Background: Joint damage upon bleeding causes significant morbidity in patients with hemophilia, and adds to joint degeneration after trauma and major joint surgery. Interleukin (IL)-4 and IL-10 have been demonstrated to protect cartilage from blood-induced damage independently. Recently a novel fusion protein of both cytokines, IL4-10 synerkine, has been developed.
Aims: To evaluate whether IL4-10 synerkine protects against blood-induced joint damage similarly as the combination of the individual components, both *in vitro* as well as *in vivo*.



Healthy human cartilage (n=5) was cultured for 4 days in the absence (control: dotted line) or presence of 50% blood (dashed line). During blood-exposure, the IL4-10 synerkine was added in a broad concentration range. Proteoglycan synthesis rate (A), -release (B) and -content (C) are depicted as median ± IQR.
 # P<0.05 compared with control values, ** P<0.05* compared with blood-exposed cartilage without addition.

Figure 1. Concentration dependent effect of the IL4-10 synerkine.

Methods: *In vitro*, human cartilage explants were exposed to 50% v/v whole blood for 4 days and simultaneously to a broad concentration range (0-100ng/mL) of the IL4-10 synerkine. Effects of 10 ng/mL IL4-10 synerkine were compared to the same concentrations of the individual cytokines and the combination. Cartilage matrix proteoglycan turnover (proteoglycan synthesis, release, and content) was assessed after a recovery period of 12 days. Moreover, the influence of IL4-10 synerkine and its individual components on levels of IL-1β and IL-6 were investigated in a 4 days 50% v/v whole blood culture.
In hemophilia A mice, a joint bleed was introduced on day 0 and 14. Mice were randomized between intra-articular treatment with synerkine (7pmol), IL-4&IL-10 (both 7pmol) or PBS on day 0, 2,14 and 16. After 5 weeks, joint damage was evaluated by the Valentino score for synovitis (hematoxylin and eosin-stained sections) and the modified OARSI score for cartilage damage (Safranin O-stained sections).
Results: *In vitro,* the synerkine prevented blood-induced cartilage damage in a dose-dependent manner up to normalization already at a concentration of 1 ng/mL (see Figure 1). At 10ng/mL, the synerkine was equally effective as the combination of the separate cytokines. IL-1β and IL-6 release in whole blood cultures was suppressed. *In vivo*, treatment with the synerkine attenuated cartilage damage upon joint bleeding (difference between experimental and contralateral joint in synerkine group p=0.201; IL-4&IL-10 p=0.008; PBS p=0.001). In all groups, synovial inflammation was statistically significantly increased in the experimental paw, none of the treatments affected this (p<0.005 in all groups).
Summary/Conclusions: The IL4-10 synerkine fully prevented blood-induced cartilage damage in a human cartilage tissue *in vitro* model and ameliorated cartilage degeneration upon a repeated joint bleed in haemophilic mice when injected intra-articularly. These data support the need for further investigation of the potency of the IL4-10 synerkine in the treatment of blood-induced arthropathy.

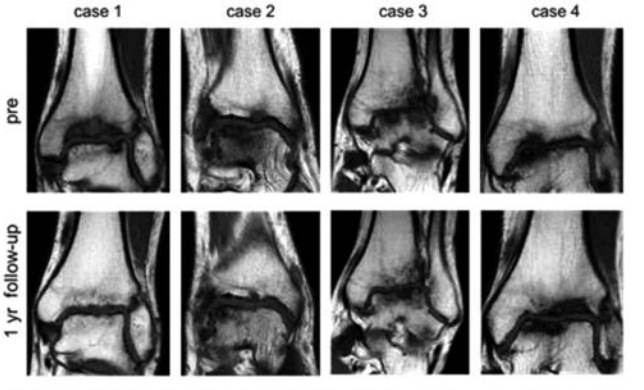
FIRST PROSPECTIVE RESULTS OF JOINT DISTRACTION IN SEVERE HEMOPHILIC ANKLE ARTHROPATHY

L Van Vulpen[1,*], HC Vogely[2], G Roosendaal[1], P de Kleijn[1], P van Roermund[2], R Schutgens[1], S Mastbergen[3], F Lafeber[3]
[1]Van Creveldkliniek, [2]Orthopaedic Surgery, [3]Rheumatology & Clinical Immunology, University Medical Center, Utrecht, Netherlands

Background: The ankle joint is the most affected joint in youngsters with hemophilia. Joint distraction, an effective treatment in ankle osteoarthritis, has the advantage of preservation of the original joint without compromising subsequent conservative surgeries like arthrodesis, if still needed. In three cases evaluated in retrospect, good clinical and structural efficacy in hemophilic ankle arthropathy was demonstrated.
Aims: The aim of the current study is to prospectively investigate the clinical effectiveness of ankle joint distraction in hemophilia.
Methods: Hemophilia patients (n=10; ≥18 and <55 years) were eligible in case of severe complaints of arthropathy in the tibiotalar joint causing functional limitations, despite analgesics and conservative treatment. Ankle joint distraction using an Ilizarov external fixator was performed during 10 weeks. Clinical effectiveness was evaluated using standard questionnaires and physical examination. Functional tests, X-ray and MRI examination were performed at baseline and 1-year follow-up.
Results: At the moment, a 12 months follow-up is available in 4 patients, three severe hemophilia A patients and one severe hemophilia B patient. Age at time of surgery ranged from 21 to 33 years. During distraction, none of the patients experienced bleeding. Pin tract infection, commonly seen with external frame use, occurred in 3 patients, and was treated effectively with oral antibiotics.
Pain (visual analogue scale) decreased from 67 (47-79)mm at inclusion to 27 (7-84)mm at 6 months and 15 (1-43)mm at 12 months follow-up. Functional limitations, measured by the Haemophilia Activities List and the Ankle Osteoarthritis Scale, improved in three patients at 6 months, and in all four patients at 12 months. Functional tests improved considerably in all patients at 1-year follow up (*e.g.* 6-minutes walking test increased from 497 (434-560) to 621 (560-688) meters). Range of motion of the ankle was slightly decreased after 6 months due to stiffness of the ankle, but regained at 12 months in all patients. MRI revealed a decrease in volume of subchondral cysts and bone edema in all patients, and slight improvement of the joint space width in two patients (see Figure 1).



Note the decrease in volume of the subchondral cysts, and bone edema in all cases. Improvement of joint space width is visible in case 3 and 4.

Figure 1. Structural improvement after ankle distraction on MRI.

Summary/Conclusions: This first prospective study investigating the efficacy of joint distraction in haemophilic ankle arthropathy, showed clear clinical and structural improvement in all patients at 1 yr follow-up. Although preliminary, these data indicate that joint distraction may be a promising treatment postponing more rigorous surgery like ankle arthrodesis in those patients not benefitting from conservative therapy.

THALIDOMIDE FOR HEREDITARY HEMORRHAGIC TELANGIECTASIA: EFFICACY AND SAFETY OF LONG-TERM TREATMENT

R Invernizzi*, F Quaglia, C Klersy, F Pagella, F Chu, E Matti, G Spinozzi, C Olivieri, R Bastia, C Danesino, M Benazzo, CL Balduini
IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: Hereditary hemorrhagic telangiectasia (HHT) is a genetic disease that leads to multiregional angiodysplasia. Severe recurrent epistaxis is the most common presentation often leading to severe anemia. In a previous open label, phase 2, non-randomized, single-centre study, we have shown that low-dose thalidomide (Thal) was safe and effective in reducing epistaxis in HHT patients, providing a rapid, long-lasting clinical improvement without serious adverse events (Lancet Haematol 2015; e465-73). However, the effect of Thal was not permanent. After the end of therapy, most patients relapsed at various time points.
Aims: To assess the effects of Thal on the severity of epistaxis in subjects with HHT who relapse after a first successful treatment with the drug; to evaluate safety and tolerability. The main purpose of our study is to obtain clinical data useful for the identification of a regimen for long-term prevention of HHT epistaxis by Thal.
Methods: Our study is the extension of a previous clinical trial (THALI-HHT, EudratCT 2011-004096-36, ClinicalTrials.gov Identifier: NCT01485224). HHT patients, successfully treated with Thal according to this protocol, may receive again Thal providing that eligibility criteria are still met and they relapsed at least 4 weeks after the end of previous therapy. Twenty-nine patients are potentially recruitable. Thal is given orally for 8 weeks at the same dosage that induced remission (50 or 100 mg/day, off label use). Thal courses may be repeated at most 3 times; in case of relapse occurring within 4 weeks from the end of a previous treatment course, Thal is permanently discontinued. Monthly follow-up evaluates the epistaxis severity according to well defined criteria (Am J Rhinol Allergy 2009;23:52-58) and the transfusion need, with adverse events being reported.
Results: Fourteen HHT patients for whom informed consent was obtained, 9 M and 5 F, aged 48-84 years (median 64), with mutations in either ACVRL1 (12 cases) or ENG gene (2 cases) who relapsed at 10-68 weeks (median 32) after the end of Thal induction therapy, have been retreated so far, 9 patients with 50 mg/day of Thal and 5 patients with 100 mg/day. Eight-week courses of Thal were effective in 13 (93%) patients with a significant reduction of nose bleeding and a concomitant increase of hemoglobin levels and decrease of the transfusion need. At a median follow-up of 81 weeks (range 39-117) after the end of the first course of retreatment, 3 (22%) patients maintained a response, whereas 10 (71%) relapsed again (median relapse-free survival 28 weeks). Eight patients were successfully retreated with a second 8-week course of Thal and 5 patients, who relapsed again, with an additional third course. Median relapse-free survival was 28 weeks after the end of the second course and 24 weeks after the end of the third course. Only nonserious, grade 1, drug-related adverse effects, including constipation, drowsiness, and peripheral edema were observed during Thal courses.
Summary/Conclusions: These preliminary results strongly support the hypothesis that repeated administrations of Thal maintain their efficacy and can be used for long-term treatment of HHT epistaxis. Recruiting a suitable group of patients and following them carefully is expected to confirm this suggestion and contribute to identifying maintenance treatment schedules that permanently reduce epistaxis.

DYSREGULATED MIR34A/DIACYLGLYCEROL KINASE Z INTERACTION ENHANCES T-CELL ACTIVATION IN ACQUIRED APLASTIC ANEMIA

Y Sun*, H Li, Q Feng, Y Yu, X Li, J Peng
Qilu hospital of Shandong University, Jinan, China

Background: As a paradigm of bone marrow failure syndrome, acquired aplastic anemia (AA) was thought to be a specific autoimmune disease for the aberrant T-cell immune homeostasis. MicroRNAs (miRNAs) down-regulate gene expression by binding to target messenger RNAs and play important roles in various immune processes. We screened for differentially expressed miRNAs in T-lymphocytes of sever AA (SAA) patients by miRNA genechip assays and found miR34a overexpressed in SAA. MiR34a has been demonstrated to directly and functionally target diacylglycerol kinase (DGK) ζ to promote T-cell response. There was no data referred to the role of miR34a or DGKζ in AA.
Aims: To investigate the role of miR34a and DGKζ in T-cell activation in AA.
Methods: Human bone marrow mononuclear cells (BMMCs) were isolated from 25 SAA patients, 16 moderate AA (MAA) patients and 20 healthy volunteers. Affymetrix miRNA genechip assays on $CD3^+$ T-cells purified from BMMCs of three SAA patients and three healthy controls were undertaken. Then the relative expression of miR34a and DGKζ in BMMCs from the 41 AA patients and 20 healthy controls was quantified by real time polymerase chain reaction. The BMMCs from AA patients were transfected with miR34a inhibitor sponge in lentivirus and the level of T-cell activation marker CD69 on the transfected cells was analyzed by flow cytometry. The lymphocytes isolated from lymph nodes (LN) of wild-type (WT) and miR34a-knockout (KO) mice were labeled with CFSE and left unstimulated or stimulated with McAbs to CD3 and CD28. The cell division and the CD69 and CD25 expression was analyzed by flow cytometry. A murine model of bone marrow failure was created in which LN cells from WT or miR34a-KO mice (C57/B6 background) were transferred into CB6F1 mouse recipients preirradiated with 5 Gy total body irradiation. After euthanasia on Day 12, $CD4^+$,$CD8^+$ and $Lin^-Sca1^+CD117^+CD34^-$(LSKCD34$^-$) BM cells were analyzed by flow cytometry.
Results: The microarray analysis demonstrated that miR34a expression increased 2.1-fold in T-cells from SAA patients compared with that in healthy controls. The significantly higher expression of miR34a was confirmed by PCR in BMMCs from the 41 AA patients compared with that from the 20 normal controls. The miR34a expression showed a negative correlation with peripheral blood neutrophil or reticulocyte counts in AA patients, and was higher in SAA than in MAA groups. The mRNA level of DGKζ in AA patients was much lower than that in controls, and was negatively correlated with the level of miR34a. The protein level of CD69 on T-cells transfected with miR34a inhibitor lentivirus was lower than that on cells transfected with control lentivirus. In murine models, upon stimulation with McAbs to CD3 and CD28, the $CD4^+$ and $CD8^+$ LN cells from miR34a-KO mice expressed much lower levels of CD69 and CD25 than those from WT mice, and proliferated less vigorously than the cells from WT mice. Consistently, the DGKζ expression in LN cells from miR34a-KO mice decreased to a less extent after stimulation than that in cells from WT mice. *In vivo*, the mouse recipients transferred with miR34a-KO lymphocytes demonstrated lower mortality on Day12 after irradiation, fewer $CD8^+$ T-cells in BM and increased BM LSKCD34$^-$ cells compaired to those transferred with WT cells.
Summary/Conclusions: The data demonstrated that miR34a/DGKζ was dysregulated in AA, which resulted in enhanced T-cell activation and bone marrow failure. Our study indicated that miR34a/DGKζ played a critical role in T-cell immunity in AA and might be a new therapeutic target for AA.

S473

BONE MARROW FAILURE IN PAROXYSMAL NOCTURNAL HEMOGLOBULINURIA IS ASSOCIATED WITH EXPANSION OF ANTIGEN-SELECTED T CELLS: HIGH-THROUGHPUT EVIDENCE

E Stalika[1,*], K Gemenetzi[1], L Gargiulo[2], N Maglaveras[1,3], I Chouvarda[1,3], K Stamatopoulos[1], A Hadzidimitriou[1], A Karadimitris[2], M Papaioannou[2,4]
[1]Institute of Applied Biosciences, CERTH, Thessaloniki, Greece, [2]Centre for Haematology,Department of Medicine, Hammersmith Hospital, Imperial College London, London, United Kingdom, [3]Laboratory of Medical Informatics, Medical School, [4]1st Dept Internal Medicine, Hematology Unit, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Paroxysmal nocturnal hemoglubinuria (PNH) is an acquired clonal disease of hematopoietic stem cells caused by somatic mutation of the *PIG-A* gene that is essential for the biosynthesis of the glycolipid molecule glycosylphosphatidylinositol (GPI). The clinical phenotype of PNH consists of hemolysis, thrombophilia and bone marrow failure (BMF). While hemolysis and thrombosis are largely due to deficiency of the GPI-linked complement inhibitors, the pathogenesis of BMF remains unknown. Previous studies have indicated that CD1d-restricted, GPI-specific T cells are present in PNH patients and might underlie BMF. Interestingly, these cells display a heavily biased T cell receptor

repertoire with enrichment for T cell receptor (TR) α chains encoded by the TRAV21/TRAJ31-1 genes and frequently carrying a distinctive complementarity-determining region 3 (CDR3: AVNNNARLM) combined by TR β chains encoded by the TRBV19 gene, often with restricted CDR3 as well, strongly alluding to selection by common (auto)antigen(s).
Aims: Prompted by these findings, here we sought to obtain more evidence about the nature of the implicated immune response through detailed analysis of the repertoire of GPI-specific T cell populations.
Methods: Our study included samples from 11 patients and 9 normal donors. TRAV21 gene rearrangements were RT-PCR amplified on RNA from T cell subsets sorted from peripheral blood mononuclear cells on the basis of: (i) expression of CD48, [positive in GPI+ cells] and vice versa; and, (ii) expression of TR β chains encoded by the TRBV19 gene *versus* TRBV19 negative. Both criteria applied to PNH patients, whereas the sole criterion used for normal donors was TRBV19 expression. PCR products were sequenced on 454 GS Junior (Roche) platform. Sequences were submitted to IMGT/HighV-QUEST, and metadata was processed by an in-house bioinformatics pipeline. Since all studied rearrangements utilized the same TRAV gene, we defined as clonotypes TRA rearrangements with identical TRA joining (TRAJ) gene usage and amino acid CDR3 sequence.
Results: Overall, significant differences ($p<0.05$) were identified in PNH patients *vs* normal controls for 13 of 50 functional TRAJ genes, the most pronounced concerning the TRAJ39, TRAJ57 and TRAJ58 genes. Similarly, significant differences ($p<0.05$) emerged when comparing the TRAJ gene repertoire between T cell subsets in PNH patients. In particular, (i) the TRAJ15 and TRAJ4 genes were over-represented amongst CD48+ cells; while the TRAJ24 and TRAJ33 were over-represented amongst CD48- cells, (ii) the "GPI-specific" CDR3 sequence (AVNNNARLM) was identified with higher frequency in CD48+ *versus* CD48- cells, however it was also present, with statistically significant lower frequency ($p<0.05$) amongst healthy donors ; (iii) the frequency of the "GPI-specific" CDR3 sequence was identified in GPI- positive up to 73.8% and in GPI-negative T – cell fractions up to 25.6%. When comparing the CDR3 length in i) patients *versus* healthy individuals, and ii) GPI-positive *versus* GPI-negative T cells, we noted a significant ($p<0.05$) bias to longer CDR3s in patients *vs* healthy donors; and, CD48- *vs* CD48+ cells. Cluster analysis of the CDR3 sequences of all PNH cases identified 21 different clonotypes that were shared by PNH patients but not by healthy individuals.
Summary/Conclusions: The present study documents noteworthy restrictions in the TR repertoire in PNH, indicative of antigen selection. The existence of clonotypes shared between different patients suggests that common antigen driven immune responses may be implicated in the pathogenesis of BMF.

A SUBCUTANEOUSLY ADMINISTERED INVESTIGATIONAL RNAI THERAPEUTIC (ALN-CC5) TARGETING COMPLEMENT C5 FOR TREATMENT OF PNH AND COMPLEMENT-MEDIATED DISEASES: INTERIM PHASE 1 STUDY RESULTS

A Hill[1,*], A Gava[2], J Taubel[3], J Bush[4], A Borodovsky[5], N Kawahata[5], H McLean[6], CH Soh[5], A Partisano[5], B Sorensen[5], N Najafian[5], A Urbano-Ispizua[7]
[1]St James' Institute of Oncology, Leeds Teaching Hospitals, Leeds, United Kingdom, [2]Hospital Clínic of Barcelona, Barcelona, Spain, [3]St George's University of London, London, [4]Covance Clinical Research Unit, Leeds, United Kingdom, [5]Alnylam Pharmaceuticals, Cambridge, United States, [6]Alnylam Pharmaceuticals, Uxbridge, United Kingdom, [7]Hospital Clinic Barcelona, IDIBAPS, Institute of Research Josep Carreras, Barcelona, Spain

Background: Uncontrolled complement activation plays a pivotal role in a variety of disorders such as paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic-uremic syndrome (aHUS). Despite the availability of eculizumab, treatment challenges, including heterogeneity in clinical response combined with inter-individual variation in clearance of eculizumab, remain. ALN-CC5 is a subcutaneous (SC) investigational RNA interference (RNAi) therapeutic targeting complement C5 (C5).
Aims: The aim of this abstract is to report safety, pharmacodynamics (PD) and clinical activity of ALN-CC5 in normal healthy volunteers as well as initial results in patients with PNH.
Methods: A phase 1/2 single-ascending dose (Part A) and multiple-ascending dose (Part B) study of ALN-CC5 in healthy adult volunteers and patients with PNH (Part C) is ongoing. Enrollment of several cohorts of healthy volunteers in both Part A and Part B has been completed. Part C is a 39-week multiple dose study in patients with PNH. Primary endpoints are safety and tolerability. Secondary endpoints include: pharmacokinetics (PK), reduction of circulating C5 and complement activity as measured by CAP/CCP Wieslab ELISA assays and sheep erythrocyte hemolysis assay as well as reduction in LDH (in PNH patients). ALN-CC5 is administered SC at a concentration of 200 mg/mL.
Results: Part A enrolled 32 healthy volunteers who were randomized (1:3) to placebo or a single SC dose of 50, 200, 400, 600 or 900 mg of ALN-CC5. Part B enrolled 24 healthy volunteers who were randomized (1:3) to placebo or up to 13 weekly doses of 100, 200, 400 or 600 mg of ALN-CC5. Among the initial healthy volunteers enrolled, (Part A: n=20; Part B: n=12) ALN-CC5 was considered generally well tolerated with no serious adverse events (SAEs), study discontinuations or clinically significant laboratory findings. Preliminary data showed C5 knockdown up to 99% with nadir residual C5 values as low as 0.6 mcg/mL; complement activity inhibition (CAP & CCP) up to 97% with mean max inhibition of 95±1% for CAP and 96±0.9% for CCP and reduction of serum hemolytic activity up to 98% with mean max inhibition of 84±7.6%, suggesting potentially clinically meaningful complement inhibition following ALN-CC5 administration. Notably, an up to 97.8% knockdown (KD) of serum C5 at day 98 after a single dose in the top dose cohort and up to 98.3% KD at day 112 after five weekly doses in the 200 mg cohort was maintained. Based on these initial findings, Part C was initiated. In Part C, patients with PNH receive 200 mg weekly doses of ALN-CC5. Updated safety, pharmacodynamics (PD) and clinical activity for all study participants, will be presented.
Summary/Conclusions: ALN-CC5 was shown to be generally well tolerated, with no clinically significant, drug-related adverse events to date in healthy volunteers. The PD effects of ALN-CC5 were found to be durable, with clamped C5 knockdown and complement activity inhibition supporting a less frequent as well as SC dose regimen. Collectively, these initial results suggest that the use of a novel RNAi therapeutic targeting C5 is a promising approach for inhibiting complement in PNH, aHUS and other complement-mediated diseases.

S475

NEXT GENERATION TARGETED SEQUENCING IMPROVED THE PRECISE DIAGNOSIS OF PEDIATRIC APLASTIC ANEMIA /INHERITED BONE MARROW FAILURE SYNDROMES

W An[*], Y Guo, Y Chen, Y Zou, X Chen, W Yang, L Chang, Y Wan, X Zhu
Pediatric blood diseases center, Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Inherited bone marrow failure syndromes (IBMF) is a group of diseases with heterogeneous clinical and genetic characteristics and overlapping symptoms. Diagnosis of IBMFS depend on classic clinical manifestation like early onset, physical anomalies associated, family history of cancer and/or bone marrow history, and abnormal laboratory test including chromosome breakage testing (MMC and/or DEB), mutation analyses and bone marrow chromosome analyses. At present, more than 70 pathogenic gene mutations had been identified. However, in some patients, physical anomalies is absent or delayed, and were diagnosed as acquired bone marrow failure. Therefore, precise genetic analysis is very important for establish a specific diagnosis, predict cancer risk, direct treatment and genetic counseling.
Aims: In this study, we focus on the application of next generation targeted sequencing in precise diagnosis of pediatric aplastic anemia (AA)/IBMF, and compared the results with clinical manifestation and chromosome breakage testing.
Methods: We designed a targeted capture next generation sequencing (NGS) assay to test a panel of 417 blood disease genes. Pediatic patients (≤14 year old) with suspected diagnosis of AA/IBMF were enrolled. Peripheral blood (PB) was used to genetic analysis and oral epithelia cells or PB from the parents were used to identify whether the gene mutations were somatic mutations or not. The results were validated by Sanger sequencing.
Results: We validated the assay using 30 samples with known mutations. The mean depth for targeted sequencing was 200×, 93.28% of targeted regions were covered with >10×.288 patients with pediatric IBMF were enrolled including 177 subjects were clinically diagnosed as acquired AA, 49 Fanconi anemia (FA), 26 DBA, 8 DC, 15 SCN, 4 congenital thrombocytopenia, 1 Shwachman-Diamond syndrome (SDS). Totally, 66 (23.6%) subjects have IBMF related genetic mutations. In subjects clinically diagnosed as acquired AA, 17 (9.6%) subjects have IBMF related gene mutations, including 10 subjects finally genetically diagnosed as FA, 3 DC, 2 Epstein syndromes, 1 Wiskott-Aldrich syndrome (WAS). In subjects clinically diagnosed as FA, 21 (42.1%) have FANC related gene mutations and 3 (6.9%) have other IBMF related gene mutations. In subjects clinically diagnosed as DC, 7 (85.7%) have telomere related gene mutations. In subjects clinically diagnosed as DBA, 11(37.9%) have ribosomal protein related gene mutations and 1 FA. In subjects clinically diagnosed as SCN, 5 (33.3%) have SCN-related gene mutations, 1 DC, 1 FA and 1 WHIM syndrome, 1 AKT, 1 GFI1 mutation. In subjects clinically diagnosed as congenital thrombocytopenia, 1 CAMT. In subjects finally genetically diagnosed as AA, FA or DC, 4.4%, 18.2% and 9.1% have family history of BMF or malignant blood diseases respectively, and 3.8%, 9.1%, 0% have family history of solid tumor respectively. In subjects finally genetically diagnosed as AA, FA or DC, 8.8%, 66.75%, 63.3% have physical anomalies respectively. Compared to subjects with AA, subjects with FA or DC are more likely to have physical anomalies of short stature and development retardation, Cafe au lait spots of the skin and finger(toe) malformation (24.2% *vs* 0%, P=0.000; 21.2% *vs* 1.2%, P=0.021; 36.4% *vs.*1.2%, P=0.000). Moreover, 8.1% subjects present physical anomalies before or at the same time with bone marrow failure. In subjects finally diagnosed as FA or DC, only 27% and 14% have positive MMC respectively.
Summary/Conclusions: Compared to traditional diagnostic methods, the targeted NGS analysis is economic, convenient, easy to update and very important for differential diagnosis, personal treatment and follow-up and genetic counselling, especially for make differential diagnosis between acquired and congenital BMF. Moreover, the targeted NGS can be used to make precise

diagnosis between IBMFs which have overlapping clinical symptoms. In subjects with IBMF, the positive rate of MMC is low. Therefore, further gene mutation analysis is necessary for highly suspicious subjects with IBMF who have negative result of MMC.

S476

THREE CASES OF CYCLIC NEUTROPENIA WITH ACQUIRED CSF3R MUTATIONS, ONE DEVELOPING AML

C Zeidler[1,*], M Klimiankou[2], S Mellor-Heineke[3], E Reinel[2], M Uenalan[4], S Kandabarau[3], K Welte[5], J Skokowa[2]
[1]SCNIR, Medical School Hannover, Hannover, [2]Department of Hematology, Oncology, Immunology, Rheumatology and Pulmonology, University Hosppital Tuebingen, Tuebingen, [3]Medical School Hannover, Hannover, Germany, [4]Department of Experimental Hematology, Medical School Hannover, Hannover, [5]Dept of Pediatrics, University Hosppital Tuebingen, Tuebingen, Germany

Background: We recently reported a 17-year-old female with cyclic neutropenia (CyN) harboring *ELANE* mutations presenting with cycling hematopoiesis involving neutrophils, platelets and reticulocytes who developed AML (FAB M2) (presented at ASH 2015, Blood 126 (23) abstract 885). At the time of AML diagnosis, all *CSF3R*-expressing BM leukemic blasts were positive for the p.Gln741X mutation. We tested the patient's BM MNCs, obtained at the time of leukemia development, for *RUNX1* mutations, finding that the *RUNX1* mutation p.Asp171Asn was present at an allele frequency of 10%. So far, *CSF3R* mutations have been reported in congenital neutropenia patients (CN) only but never in patients with CyN.
Aims: Our aim was to determine whether other CyN patients harbor *CSF3R* mutations.
Methods: We performed deep sequencing of *CSF3R* in 19 additional CyN patients.
Results: Out of these 19 patients we identified two additional patients harboring acquired *CSF3R* mutations. One CyN patient aged 15.4 years and her sister inherited the *ELANE* mutation from their father. Time-course analysis of the acquisition of *CSF3R* mutations in this patient showed that 2.6% of the *CSF3R* alleles in BM MNCs were obtained at the age of 13 years possessing the p.Gln749X mutation. After additional 1.5 and 2.4 years, respectively, the mutant allele frequency increased to 9% and 8%. A third CyN patient, a 7 year old girl, harboring spontaneous *ELANE* mutations and revealing typical cycling of neutrophils, platelets, and monocytes was treated with G-CSF at a dose of 4.5 µg/kg/day and recently acquired *CSF3R* mutation (p.Gln739X) in approx. 30% of the *CSF3R* allele. The latter two CyN patients have not yet developed AML or myelodysplastic syndrome (MDS).
Summary/Conclusions: Taken together, these findings suggest that CyN patients with typical CyN-associated *ELANE* mutations may also acquire *CSF3R* mutations and are therefore at risk for leukemic development. Long-term data of the Severe Chronic Neutropenia International Registry (SCNIR) have shown that the risk of acquisition of *CSF3R* mutations and of myeloid transformation is low but not absent in patients with CyN compared to patients with CN. This new knowledge is important for prognostic counseling and long-term management of *ELANE*-CyN patients.

Diffuse large B-cell lymphoma

Background: Rituximab (R)-CHOP is standard treatment for patients with diffuse large B-cell lymphoma (DLBCL). The optimal R dose and schedule is not known. In a small series of 20 patients serum levels of R, measured during the R-CHOP-14 regimen in elderly patients with DLBCL increased slowly up to cycle 5, reaching plateau thereafter (Reiser M, *et al.* J Clin Oncol 2006). We hypothesized that R serum levels might be suboptimal, especially early during treatment, and that the treatment outcome might improve through intensification of R during the first 4 cycles. In this study designed for both young and elderly DLBCL patients we compared standard treatment of R-CHOP-14 with the same regimen combined with 4 extra R administrations during the first 4 cycles. Patients in complete remission after induction treatment were randomized for a second time between observation and R maintenance. Here we report the efficacy and safety results of the first randomization.
Aims: This phase III, open-label randomized study was designed to detect superior metabolic complete remission rates of early intensification of R combined with CHOP-14+G-CSF *versus* no intensification of rituximab in patients with DLBCL of all age groups.
Methods: Patients with previously untreated DLBCL, CD20 positive, stage II-IV, ages between 18-80 years, were randomized 1:1 between standard R-CHOP-14 and an experimental arm with R-CHOP-14 combined with extra R 375 mg/m^2 IV on day 8 of the first 4 cycles. Prephase treatment of prednisone 100 mg orally for 5 days was mandatory in elderly patients. All patients received pegfilgrastim 6 mg sc on day 2. All patients underwent restaging after 4 cycles of therapy and at the end of induction therapy. Response was evaluated using PET-CT scans according to the Lugano criteria 2014. A Deauville score of ≤3 was considered as a complete response. The primary endpoint of the first randomization was metabolic complete remission rate after induction treatment. This trial was registered at www.trialregister.nl as NTR1014. All patients gave written informed consent.
Results: 575 patients were randomized (standard arm 286 patients, experimental arm 289 patients). Median age was 65 years (range, 18-80), 50% of patients were 66 years or older and 52% were male. The majority of patients (57%) had a high-intermediate or high aa-IPI score. Baseline patient and disease characteristics were well balanced between treatment arms. No significant difference in CR rate was observed between the two treatment arms, standard arm 84% CR and experimental arm 82% CR (odds ratio=0.83, 95% CI 0.54-1.28, p=0.40). The observed CR rates in patients ≤or >65 years were identical. With a median follow-up of 49 months (maximum 90 months), 3- and 5- year progression free survival (PFS) were 74% and 68% in the standard arm and 71% and 61% in the experimental arm (hazard ratio=1.23, 95% CI 0.92-1.63, p=0.16). No significant improvement in PFS was noted in subgroups by age (≤or >65 years) or gender. The frequencies of hematological and non-hematological adverse events were similar in both treatment arms.
Summary/Conclusions: In patients with DLBCL treated with R-CHOP-14 rituximab intensification early during treatment did not improve the CR rate or the 3-year PFS. No clinical subgroup benefited from rituximab intensification in this study.

Background: Communicating prognosis in a plain language to patients with diffuse large B-cell lymphoma (DLBCL) and their relatives can be challenging. Survival of DLBCL patients relative to a matched background population (MBP) represents a relevant measure of prognosis.
Aims: The purpose of this study was to investigate the post-treatment survival of DLBCL patients in CR/CRu relative to an MBP and to examine the duration of CR/CRu needed to obtain similar survival to the MBP.
Methods: This retrospective study utilized the nationwide Danish Lymphoma Registry (LYFO). We included patients fulfilling the following criteria: a) newly diagnosed DLBCL in the period 2003-2011, b) ≥15yrs of age at diagnosis, and c) achieving CR or CRu after 1st line R-CHOP(-like) therapy. Survival curves were generated using the Kaplan-Meier method and survival of the MBP was established from lifetime tables.
Results: In total, 1632 Danish DLBCL patients met the inclusion criteria and the baseline characteristics were similar to that seen in previous studies. The median follow-up from diagnosis was 85 months. The 5-year OS of the MBP was superior to that of the DLBCL patients (88% *vs* 78%, p<0.001). In analyses restricted to patients in continuous CR/CRu for >2 and 5 years, the OS of DLBCL patients remained inferior to that of an MBP (p<0.001 for 2 years; p<0.001 for 5 years). Age-stratified analyses (<50yrs *vs* ≥50yrs) showed, the OS of patients <50yrs became identical to that of an MBP after only two years in continuous CR/CRu (p=0.90). For DLBCL patients ≥50yrs, however, the OS remained inferior past 5 years of continuous CR/CRu. The OS of DLBCL patients ≥50 years were still inferior after censoring patients with relapses (p<0.001) (Figure 1).

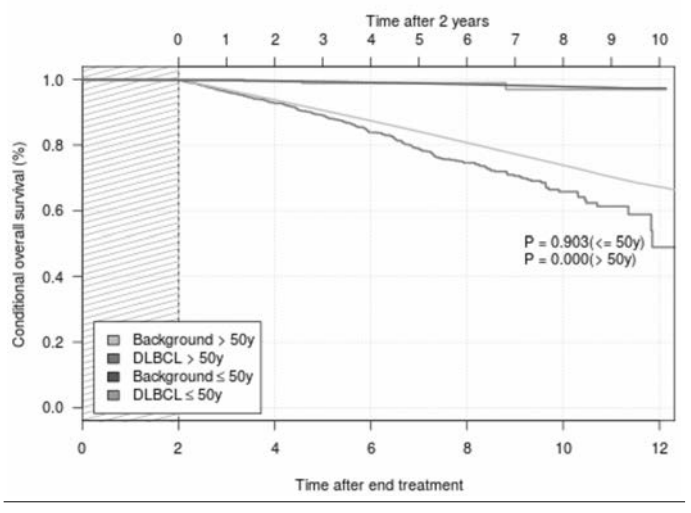

Figure 1.

Summary/Conclusions: The OS of DLBCL patients in CR/CRu after R-CHOP(-like) therapy was inferior to that of an MBP, but the differences were gradually reduced for patients with durable remission. Interestingly, the OS of young DLBCL patients (<50yrs) quickly became identical to that of an MBP. However this was not the case for patients ≥50yrs, even after excluding those with relapse. This suggests that the residual life expectancy of this subgroup of patients may be reduced due to late toxicities or other causes not directly related to DLBCL.

S479

A BIOCLINICAL PROGNOSTIC MODEL INCORPORATING MYC AND BCL2 PREDICTS OUTCOME TO SALVAGE THERAPY IN RELAPSED/ REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA: AN NCIC CTG LY12 CORRELATIVE SCIENCE STUDY

D Stewart[1,*], B Chen[2], A Mansoor[3], A Akhter[3], D Lebrun[2], M Crump[4], L Shepherd[2], M Bosch[5]
[1]Oncology and Medicine, University of Calgary and Tom Baker Cancer Centre, Calgary, [2]Queen's University, Kingston, [3]University of Calgary, Calgary, [4]University of Toronto, Toronto, [5]University of Saskatchewan, Saskatoon, Canada

Background: Less than 50% of patients (pts) with relapsed/refractory diffuse large B-cell lymphoma (rrDLBCL) achieve long-term event-free (EFS) and overall (OS) survival with salvage therapy. Better predictors of outcome are needed for these pts.
Aims: To determine clinical and molecular predictors of EFS and OS for rrDLBCL pts treated with rituximab (R) and either gemcitabine, dexamethasone, cisplatin (R-GDP) or dexamethasone, cytarabine, cisplatin (R-DHAP) followed by autologous stem-cell transplantation (ASCT) on the Canadian Cancer Trials Group LY12 study.
Methods: In total, 91 pts had DLBCL and sufficient histologic material to create tissue microarrays and undergo immunohistochemical (IHC) testing for CD10, BCL6, MUM1, FOXP1, LMO2, BCL2, CMYC, P53, pySTAT3 expression. In addition, 97 formalin-fixed, paraffin-embedded tissue samples underwent gene expression profiling (GEP) using NanoString to evaluate Cell of Origin (COO) by the Lymph2Cx assay, as well as BCL2, MYC, P53, STAT3, PDL1 and PD1 expression. Survival analysis was performed using the Kaplan-Meier method and Cox regression.
Results: COO was not associated with EFS or OS, according to the Hans IHC algorithm or the Lymph2Cx assay. Expression of py-STAT3 (≥50%), P53 (≥30%), MYC (≥40%), and BCL2 (≥70%) by IHC was found in 7.6%, 19.8%, 36.3%, 63.7%, of patient samples respectively. Expression of MYC was associated with lower 3-year (y) EFS rates (10% *versus* (*vs*) 42%, p=0.007) and OS rates (29% *vs* 56%, p=0.002) compared to MYC- patients. Similarly, 3y EFS rates were 25% *vs* 41% (p=0.029) and OS rates were 37% *vs* 63% (p=0.020) for BCL2+ *vs* BCL2- cases, respectively. The 22 pts with IHC-based dual expressing (DE) lymphomas (MYC+/BCL+) had significantly worse 3y EFS (0% *vs* 40%, p=0.0009) and OS rates (20% *vs* 54%, p=0.0004) relative to the 69 pts with without DE phenotype. In addition, p53+ *vs* p53- lymphomas had 3y EFS rates of 11% *vs* 36% (p=0.034). STAT3 was not associated with EFS or OS. Similar to IHC, both MYC and BCL2 expression using NanoString GEP (>1.5xmean) were significantly associated with inferior OS and EFS, and no patient who expressed both markers achieved 2y EFS or OS. For the 82 lymphomas with samples for both IHC and GEP, a concordance rate of 79% was seen for MYC and 57% for BCL2. Expression of PD1 (p=0.03) but not PDL1 (p=0.41) by GEP was associated with inferior EFS. In multivariate analyses, 4 factors were adversely associated with EFS and OS: primary refractory DLBCL, elevated serum LDH at relapse, MYC expression and BCL2 expression (assessed by either IHC or GEP). Using these 4 factors, a bio-clinical score predicted EFS and OS from initiation of salvage chemotherapy. Using IHC to assess MYC and BCL2, 3y EFS was 55% for 34 pts with 0-1 factor *vs* 16% for 53 patients with 2-4 factors (p<0.0001). Similarly, using GEP to assess MYC and BCL2, the 3y EFS was 46% for 58 pts with 0-1 factor *vs* 5% for 39 pts with 2-4 factors (p<0.0001, see Figure 1). The same 4 factor model predicted EFS for the 54 pts who received ASCT: 3y EFS 68% for 0-1 factor *vs* 34% for 2-4 factors (p=0.013) assessing MYC and BCL2 by IHC, or 53% for 0-1 factor *vs* 18% for 2-4 factors (p=0.008) when assessing MYC/BCL2 by GEP.

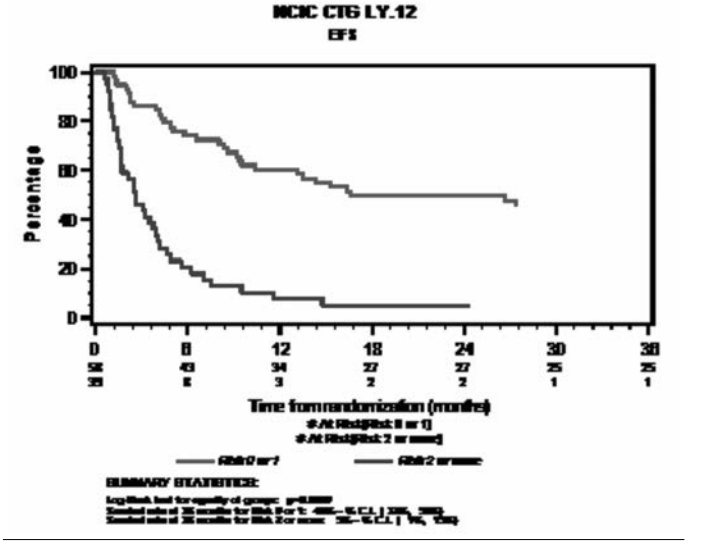

Figure 1.

Summary/Conclusions: In conclusion, MYC and BCL2 expression, determined by IHC or Nanostring GEP, are independent poor prognostic factors for rrDLBCL, and dual expression predicts dismal prognosis. Combining MYC and BCL2 expression, primary refractory disease and elevated LDH results in a robust bio-clinical model strongly associated with EFS and OS for rrDLBCL, including chemosensitive patients who proceed to ASCT.

PHASE 1 TRIAL OF CUDC-907, A NOVEL, ORAL DUAL INHIBITOR OF HDAC AND PI3K: UPDATED ASSESSMENT OF PATIENTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA, INCLUDING DOUBLE EXPRESSOR LYMPHOMA

A Younes[1,*], J Berdeja[2], M Patel[3], K Kelly[4], I Flinn[2], J Gerecitano[1], S Neelapu[5], A Copeland[1], J Wang[3], L Gong[6], M Clancy[6], A Ma[6], K Sun[6], J Wang[6], J Viner[6], Y Oki[5]

[1]Department of Medicine, Lymphoma Service, Memorial Sloan Kettering Cancer Center, New York, [2]Sarah Cannon Research Institute, Nashville, [3]Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, [4]University of Southern California Keck School of Medicine, Los Angeles, [5]Department of Lymphoma/Myeloma, The University of Texas MD Anderson Cancer Center, Houston, [6]Curis, Inc, Lexington, United States

Background: Diffuse large B-cell lymphoma (DLBCL), the most common lymphoid malignancy in adults, is an aggressive form of non-Hodgkin lymphoma with significant heterogeneity in terms of gene expression, prognosis and response to treatment. Certain histone modifications and HDAC expression patterns have been implicated in the pathobiology of DLBCL and other cancers. Aberrant PTEN/PI3K/AKT signaling is also frequently observed in a variety of human cancers including DLBCL, where loss of PTEN and/or activating mutations in PI3K have been shown to inhibit apoptosis and promote tumor cell proliferation. Synergistic anti-tumor effects achieved with HDAC and PI3K inhibitor combinations in DLBCL xenograft models have provided a strong rationale for testing a highly potent dual HDAC and PI3K inhibitor, CUDC-907. Significant anti-tumor effects have been observed across a wide range of DLBCL models exposed to CUDC-907, including the U2932 ABC DLBCL model that harbors BCL2 amplification and over-expresses cMYC and BCL6, and the double hit WSU-DLCL-2 GCB DLBCL model that harbors *MYC* and *BCL2* translocations. These disease mechanisms and preclinical data have led to testing of CUDC-907 in an ongoing Phase 1 trial in patients with various hematologic cancers.
Aims: This study is evaluating the effect of CUDC-907 on treatment-related toxicity and efficacy in patients with relapsed or refractory (RR) lymphoma and multiple myeloma (MM).
Methods: Seventy-five heavily pre-treated patients with RR lymphoma or MM have received CUDC-907 in 21-day cycles according to once daily (QD), intermittent (BIW or TIW), or five days on/two days off (5/2) dosing schedules. CUDC-907 was escalated in 30 mg increments such that patients received 30-60 mg QD, 60-150 mg intermittently, or 60 mg 5/2. Dose expansion investigating the 60 mg 5/2 dose and schedule as monotherapy and in combination with rituximab is ongoing. To date, a total of 29 patients have been treated with the 5/2 dosing schedule, including 4 patients who were assigned to concomitant standard of care dosing of rituximab on day 1 of the first 6 cycles of treatment.
Results: The most common treatment-related adverse events (AEs) were Grade 1-2 diarrhea (56%; 4% Grade ≥3), fatigue (33%; 4% Grade ≥3), nausea (29%), thrombocytopenia (27%; 17% Grade ≥3), and neutropenia (12%; 9% Grade ≥3), with dose limiting toxicities of hyperglycemia (QD and BIW schedules) and diarrhea (QD and TIW schedules). Side effects were reversible and manageable. The AE profile for patients who received CUDC-907 on the 60 mg 5/2 dosing schedule, including those who received concomitant rituximab, was commensurate with that of the overall safety population. Among 20 response-evaluable patients with RR DLBCL, 9 (45%) achieved objective responses (3 CRs and 6 PRs); lasting a median of 2.6 months (range: <1-14+). Three response evaluable patients were found to overexpress MYC (≥40%) and BCL2 (≥70%) by IHC, meeting criteria applied to "double-expressor" (DE) DLBCL. Two of these patients attained objective responses: 1 CR (followed by autologous stem cell transplant) and 1 PR (lasting 4 months). The third patient has experienced lengthy disease stabilization (5.7+ months). Interestingly, all 3 CRs observed on this study occurred in patients with MYC gene copy number gain, including the patient who also had DE DLBCL.
Summary/Conclusions: Signals emerging from preclinical and clinical studies suggest that patients with DLBCL, including those with MYC-altered and therefore particularly aggressive disease, may derive benefit from treatment with CUDC-907. A Phase 2 trial examining CUDC-907 60 mg 5/2 as monotherapy and in combination with rituximab in RR MYC-altered DLBCL is currently ongoing. Patients are being enrolled based on locally reported MYC status, defined as gene translocation or copy number gain by FISH and/or protein expression ≥40% by IHC. Tumoral tissue will be assessed centrally to confirm MYC status of enrolled patients. Other genetic aberrations, such as BCL2 and BCL6, will also be evaluated for correlation with clinical outcomes (NCT02674750).

RESULTS FROM SCHOLAR-1: OUTCOMES IN PATIENTS WITHREFRACTORY AGGRESSIVE DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL)

C Gisselbrecht[1,*], AE Hay[2], SS Neelapu[3], U Farooq[4], E Van Den Neste[1], MA Ahmed[3], BK Link[5], M Crump[2], JR Cerhan[5], L Zhu[2], S Boussetta[1], L Feng[3], MJ Maurer[5], L Navale[6], JS Wiezorek[6], WY Go[6], J Kuruvilla[2]

[1]LYSARC, Pierre-Bénite, France, [2]NCIC Clinical Trials Group at Queen's University, Kingston, Canada, [3]The University of Texas MD Anderson Cancer Center, Houston, [4]Mayo Clinic/University of Iowa Carver College of Medicine, [5]Mayo Clinic/University of Iowa Hospitals and Clinics, Rochester/Iowa City, [6]Kite Pharma, Inc., Santa Monica, United States

Background: Non-Hodgkin lymphoma (NHL) is the most prevalent hematologic malignancy in the US and the fifth most deadly cancer with nearly 19,790 deaths/year in the US. DLBCL is the most common NHL subtype, representing 25-35% of new cases annually. Although five-year survival rates in the first-line setting range from 30-50%, approximately 1 in 3 of these patients will be refractory to or relapse post treatment. Diverse therapeutic outcomes are observed in these patients with relapsed/refractory aggressive DLBCL. The international, multi-cohort Retrospective Non-Hodgkin Lymphoma Research (SCHOLAR-1) was designed to study outcomes in patients with refractory DLBCL.
Aims: The aim of SCHOLAR-1 was to retrospectively evaluate response rate and overall survival in patients with refractory DLBCL to serve as a benchmark for future clinical trials in this underserved population.
Methods: Eligibility criteria included refractory DLBCL, which was defined as progressive disease (PD) or stable disease (SD) as best response to chemotherapy (duration of SD <12 months and at least 4 cycles of first-line or 2 cycles of later line therapy) or relapse ≤12 months after autologous stem cell transplantation. All patients must have received an anthracycline as part of a prior regimen. In addition, all patients with CD20-positive disease must have received prior treatment with an anti-CD20 monoclonal antibody. SCHOLAR-1 included data from 2 phase 3 studies (LYSARC-CORAL and Canadian Cancer Trials Group (CCTG)-LY.12) and 2 observational cohorts (MD Anderson Cancer Center [MDACC] and Mayo Clinic/University of Iowa [MC/IA] Specialized Program of Research Excellence). Response rates and overall survival were estimated from the time that salvage therapy was initiated.
Results: Among 861 patients with DLBCL, 597 patients with refractory disease were identified. Response rates ranged from 19% to 36% (complete responses from 2% to 18%). Median survival was poor, ranging from 4.6 months to 6.9 months across cohorts. Data for each study or cohort are shown in the Table 1.

Table 1.

Relapsed ≤ 1 yr after ASCT (n = 149)	21	11	NA	35
Median OS, months (Q1, Q3)	6.9 (5.8, 8.2)	4.6 (3.9, 5.8)	6.8 (5.8, 8.2)	6.7 (5.6, 8.8)

[a]CORAL included subjects 18 - 65 years of age; CCTG LY.12 included subjects ≥ 16 years; subjects > 65 years were not recommended for inclusion.

ASCT, autologous stem cell transplantation; CR, complete response; NA, not applicable (based on study design); OS, overall survival; PR, partial response; RR, response rate; tx, treatment.

Summary/Conclusions: This is the first study to define patient outcomes for those with refractory DLBCL in a large group of patients. Outcomes were similar across cohorts. Our results suggest that patients with refractory, aggressive DLBCL represent a homogenous population with a response rate of 20% - 30% and median overall survival of approximately 6 mos. These consistently poor outcomes represent a significant unmet need in patients with refractory DLBCL.

Standard Treatment Results in AML

S482

IMPROVED SURVIVAL IN PEDIATRIC ACUTE MYELOID LEUKEMIA: A REPORT FROM AML-BFM TRIALS 1987-2011

M Rasche[1,*], M Zimmermann[2], L Kellerstrass[1], U Creutzig[2], D Reinhardt[1]
[1]Department of Pediatric Hematology-Oncology, University of Duisburg-Essen, Essen, [2]Hannover Medical School, Hannover, Germany

Background: Prognosis of children with acute myeloid leukemia (AML) improved within the recent decades. Study groups worldwide performed prospective randomized trials to select more effective and/or less toxic drugs. Several approaches such very high dosages of cytarabine *versus* high cumulative dosages of anthracyclins or performance of allogeneic stem cell transplantation (HSCT) *versus* chemotherapy only led to rather similar results in terms of event-free (EFS) and overall survival (OS).
Aims: Therefore we asked if the improvement of survival is dependent from particular therapy elements identified in randomized trials or rather a correlation with time. This would implicate that factors such as intensity, supportive care or risk group stratification have a much higher impact than the selection of a specific drug.
Methods: In total, 1873 children (0 to 18 yrs) enrolled to the AML-BFM trials from 1987 until 2011 were included (excluding Down's Syndrome and acute promyeloblastic leukemia). The AML-BFM Study group recruited on population-based trials all children with AML from Germany and since 1998 from Czech Republic, Austria and Switzerland. Outcome data were analyzed not only per trial but per 2- and 3-year-periods respectively (Kaplan-Meier).
Results: The 5–year EFS and OS (1987 to 2011) increased from 41±3% to 51±2% and 49±3% to 72±2%, respectively. The Table 1 shows EFS and OS of 3 year periods. The comparison to the AML-BFM trial episodes indicate that a stepwise increase in long-term survival was achieved –according to protocols- by more intensive chemotherapy from 1987-1997. Analysis of 2 and 3-yr-periods shows changes within these study protocols dependent on particular therapy elements and amendments (Figure 1). After 1998 the following years rather show a continuous improvement but only in OS. An increasing gap between EFS and OS (period 1987-1989: 9%; 2008-2010: 24%) was observed. A relevant and unexpected increase in OS was observed in 2001/02. At this time point there was no change in first line protocol, but in addition an international relapse protocol was implemented. The survival after relapse increased from 17±3 up to 44±3%.

Table 1.

3-yr-period	[n]	EFS±SE [%]	OS±SE [%]
1987-1989	134	43±4%	52±4%
1990-1992	161	39±4%	47±3%
1993-1995	249	52±3%	58±3%
1996-1998	284	48±3%	58±3%
1999-2001	250	50±3%	64±3%
2002-2004	246	51±3%	65±3%
2005-2007	245	52±3%	74±4%
2008-2010	232	46±4%	70±3%
AML-BFM 87 (1987-1992)	295	41±3%	49±3%
AML-BFM 93 (1993-1997)	488	50±2%	57±2%
AML-BFM 98 (1998-2003)	465	49±2%	63±2%
AML-BFM 2004 (2004-2011)	625	51±2%	72±2%

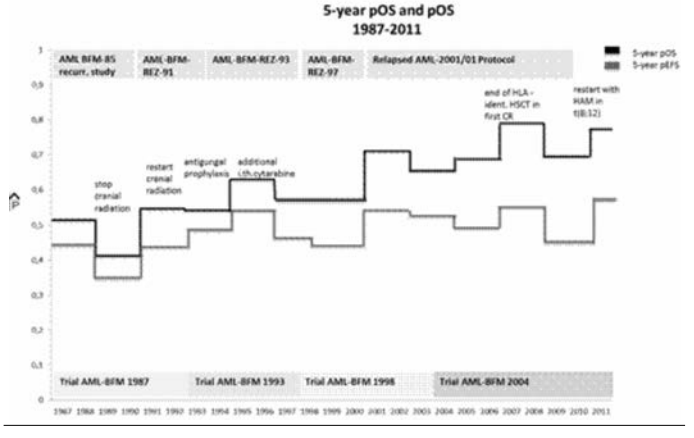

Figure 1.

Summary/Conclusions: Since 1987, several changes influenced AML therapy. The intensity of treatment increased until the AML-BFM 98 trial, in supportive care mainly the general introduction of antimycotics (recommendation 1993) might be the most relevant change. Since 1995 OS improved continuously until 2008, whereas EFS did not change significantly. Although, the slightly reduced relapse rate might suggest that 2nd line treatment becomes more difficult due to the selection of the more resistant AML, from the data it is clear that the efficacy of 2nd line therapy improved.

S483

MONOSOMAL KARYOTYPE AND TRISOMY 8 ARE POOR PROGNOSTIC FACTORS IN PEDIATRIC AML: AN AML-BFM 2004 TRIAL REPORT ON GENOTYPE-OUTCOME CORRELATIONS

M Rasche[1,*], C von Neuhoff[1], M Dworzak[2], JP Bourquin[3], J Bradtke[4], G Göhring[5], G Escherich[6], G Fleischhack[1], B Gruhn[7], T Klingebiel[8], B Kremens[1], T Lehrnbecher[8], Z Zemanova[9], N von Neuhoff[1], M Zimmermann[5], U Creutzig[5], D Reinhardt[1]
[1]Department of Pediatric Hematology-Oncology, University of Duisburg-Essen, Essen, Germany, [2]Medical University of Vienna, Vienna, Austria, [3]University Children's Hospital Zurich, Zurich, Switzerland, [4]University Hospital, Giessen and Marburg, [5]Hannover Medical School, Hannover, [6]University Medical Center, Hamburg-Eppendorf, [7]Jena University Hospital, Jena, [8]University Children's Hospital of Frankfurt/Main, Frankfurt, Germany, [9]General University Hospital and First Faculty of Medicine, Prague, Czech Republic

Background: Conflicting data on poor risk factors in pediatric acute myeloid leukemia (AML) hamper risk stratification systems and the improvement of risk-adapted therapeutic strategies.
Aims: We aimed to unravel the prognostic impact of specific chromosomal aberrations including complex and hypodiploid as well as monosomal karyotypes and trisomy 8 in pediatric patients with AML.
Methods: Karyotypes of a population-based cohort of 643 patients <18 years with *de novo* AML treated on the AML-BFM 2004 study protocol (excluding Down's Syndrome and patients with t(15;17)/PML-RARA fusion gene) were analyzed. For cytogenetic definitions see Table 1.
Results: Our analysis revealed overlapping groups of patients with monosomal (MK+), complex (CK+) or hypodiploid (HK+) karyotypes. Multivariate regression confirmed MK+ (n=25) as new independent poor risk factor for event-free survival (EFS) with a reduced EFS of 23±9% (p=0.008), even after exclusion of monosomy 7 (MK^{no-7}; n=19; EFS 25±10%, p=0.007). As expected, Monosomy 7 (n=8; pEFS 13%±12%; p=0.0026) was associated with poor outcome and resistance to induction chemotherapy. Importantly, after exclusion of MK, patients with CK did not experience a significantly worse outcome (n=47; 42±7%, p=0.12), while CK+/MK+ patients did poorly (n=11; EFS 24±14%, p =0.04). Similarly, hypodiploid karyotype (HK) did not predict worse outcome overall (n=38; EFS 43±8%, p=0.26). However, after exclusion of HK+ patients with concurrent t(8;21) (n=21; pEFS 70±10%), the remaining HK+ patients showed very poor prognosis (n=17, pEFS 9±8%, p=<0.0001). Finally Trisomy 8 without additional cytogenetic aberrations was associated with poor outcome (n=16; EFS 25±11%; p=0.009).

Table 1.

	Pts n (%)	5y pEFS (SE) %	p-value (Logrank)*	5ypOS (SE)%	p-value (Logrank)*
monosomal karyotype† (MK+)	**25(4)**	**23(9)**	**0.0008**	**43(10)**	**0.0008**
monosomal karyotype†excl. -7	19(3)	25(10)	0.0066	47(12)	0.0070
MK+/CK+	11(2)	24(14)	0.041	36(15)	0.0013
MK+/CK-	14(2)	21(11)	0.0047	50(13)	0.070
MK+/HK+	11(2)	9(9)	<0.0001	36(15)	0.0031
MK+/HK-	14(2)	34(13)	0.22	49(14)	0.057
hypodiploid karyotype¬ (HK+)	**38 (6)**	**43(8)**	**0.26**	**62(8)**	**0.27**

complex karyotypes+(CK+)	**58(9)**	**42(7)**	**0.12**	**62(7)**	**0.30**
CK+/MK-	47(7)	47(7)	0.33	68(8)	0.94

**in comparison to other patients with cytogenetic data,+3 or more aberrations, at least one structural aberration; without favorable genetics; without MLL rearrangement; †Two or more autosomal monosomies or one autosomal monosomy with at least one structural abnormality. No favorable cytogenetics (t(15;17)(q22;q21); (t(8;21)(q22;q22); inv(16)(p13q22)/t(16;16)(p13;q22)); ¬ <46 chromosomes, SE=standard error, pOS=probability of OS, pEFS=probability of ES.*

Summary/Conclusions: Our study identified monosomal karyotype and isolated trisomy 8 for the first time as strong and independent prognostic factors in a pediatric AML cohort that are associated with poor outcome. In contrast, complex karyotype alone without MK or hypodiploidy per se does not seem to confer dismal prognosis. These results have important implications for risk stratification including the indication for stem cell transplantation and should be validated in ongoing pediatric trials.

RISK ADAPTED THERAPY FOR ACUTE MYELOID LEUKEMIA (AML) BASED ON GENETIC DATA AND MINIMAL RESIDUAL DISEASE: RESULTS OF THE AML12 TRIAL OF THE CETLAM GROUP IN ADULTS UP TO THE AGE OF 70 YEARS

J Sierra[1,*], A Garrido[1], S Vives[1], MP Queipo de LLano[1], R Guardia[1], M Diaz Beya[2], M Calabuig[1], M Pratcorona[1], M Arnan[1], O Salamero[1], M Cervera[1], MA Sampol[1], A Garcia[1], C Pedro[1], JM Marti[1], J Bargay[1], L Font[1], JF Nomdedéu[1], M Hoyos[1], L Escoda[1], M Batlle[1], B Merchan[1], I Sanchez Ortega[1], M Tormo[1], D Gallardo[1], JM Ribera[1], J Esteve[1], S Brunet[1]
[1]Hematology, Spanish CETLAM Group, [2]Hematology, Spanish CETLAM Group, Barcelona, Spain

Background: Refinement of the AML risk stratification based on genetic data (cytogenetics and molecular characteristics) and minimal residual disease (MRD) assessment may optimize the post-remission allocation to consolidation chemotherapy only or hematopoietic cell transplantation (HCT).
Aims: To evaluate the feasibility and results of an ongoing prospective phase II trial of intensive chemotherapy followed or not by HCT depending on genetics of AML and levels of MRD after consolidation.
Methods: Patients 18 to 70 years old with primary AML treated at 15 academic hospitals between February 2012 and November 2015 were enrolled in the trial. The number of patients included and the outcomes will be updated on May 1, 2016. Induction consisted of idarubicin 12 mg/m^2 days 1-2-3 as intravenous bolus and cytarabine 200 mg/m^{2}as continuous infusion days 1 to 7. Consolidation courses were the high-dose cytarabine schedule of the CALGB with reduction of cytarabine from 3 g/m^2 to 1.5 g/m^2 in patients older than 60 years. The number of consolidation courses was based on AML risk allocation: three in the low-risk category (CBF, NPM1mut/FLT3-ITDwild or ratio<0.5, CEBPA biallelic mutation, all of them with low MRD after consolidation (by flow cytometry and/or quantitative PCR of the specific transcripts); two in the intermediate risk category (intermediate cytogenetics without favorable or unfavorable mutations (these patients subsequently received an autologous or allogeneic transplantation depending on MRD levels and availability of an HLA matched donor); and one consolidation followed by mandatory allogeneic transplantation from any stem cell source available (identical sibling, unrelated, cord blood, haploidentical) in the high-risk group (adverse genetics and/or MRD persistence on high levels).
Results: In 372 patients enrolled so far, the median age (range) was 55 (18-70) years and 53% were male. MRC cytogenetic distribution was: CBF AML 12%, intermediate-risk 66% and poor risk 22%. FLT3-ITD was detected in 22% of 348 cases studied (29% in intermediate risk cytogenetics) group and NPM1 mutation was evident in 57% of patients with a NK.Complete remission (CR) rate in 365 evaluable patients was 74% (n=272), Induction death occurred in 9% and 19% in patients up to and above 60 years, respectively; 10% of patients had refractory leukemia in the two age categories. Two hundred forty patients completed the consolidation phase and were risk allocated; 104 (43%) to the genetics-MRD favorable category, 73 (30%) to the intermediate and 65 (27%) to the high-risk group; in the latter, 80% of patients received an allogeneic HCT. Median follow-up of the surviving patients is 16 months. Overall survival (OS) of the whole series was 47±3% at 30 months; disease-free survivals at that time point were 74±5% in the favorable risk group, 44±5% in the intermediate and 29±7% in the in the high-risk group (Figure 1), due to significantly difference in the relapse incidence (23%, 41% and 56%, respectively). Remarkably, we confirmed our previous finding that patients with intermediate-risk MRC cytogenetics with NPM1 mutation and FLT3-ITDwild had comparable outcomes to those with NPM1 mutation and an allelic ratio below 0.5.

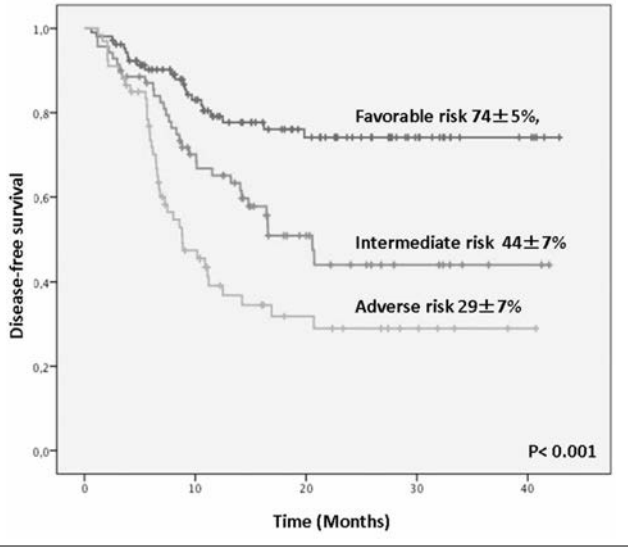

Figure 1.

Summary/Conclusions: Risk adapted therapy for primary AML based on genetics and MRD is feasible in a cooperative group setting. The proportion of patients in whom the risks of an allogeneic HCT in first CR may be avoided is higher than 40% when considering not only cytogenetics but also molecular and MRD information. Allogeneic HCT in high-risk patients was feasible in most instances but further approaches to decrease relapses such as novel agents and immune therapies are needed.

S485

SEQUENTIAL HIGH-DOSE CYTARABINE PLUS IDARUBICIN IMPROVES REMISSION RATE AND SURVIVAL DURATION IN ADULT ACUTE MYELOGENOUS LEUKEMIA (AML): RANDOMIZED TRIAL OF THE NORTHERN ITALY LEUKEMIA GROUP (NILG)

Maurizio, Bolzano, [23]Medicine, Section of Hematology and Clinical Immunology, University of Perugia, Perugia, [24]Clinical Sciences and Community Health, University of Milan, Milano, Italy

Background: AML is curable in the fraction of patients who achieve complete remission (CR) and do not relapse following consolidation or allogeneic stem cell transplantation (ASCT). Therefore new strategies are continuously developed to overcome the risk of primary resistant or recurrent disease.
Aims: In NILG trial 02/06 [ClinicalTrials.gov Identifier: NCT00495287]a sequential high-dose (SHD) regimen was compared to standard induction, having CR rate as primary study objective. CR patients were eligible to risk-specific treatment.
Methods: Study patients were stratified by age 60 years and randomized to ICE (idarubicin 12 mg/m^2/d iv. dd1-3, cytarabine 100 mg/m^2/bd iv. dd 1-7, etoposide 100 mg/m^2/d iv. dd1-5) or SHD (cytarabine 2 g [1 g if age >65]/m^2/bd iv. dd 1-2 and 8-9, idarubicin 18 mg/m^2/d iv. dd 3 and 10), plus G-CSF from d11. Postremission consolidation consisted of IC (cycle 2), intermediate-dose cytarabine 1 g/m^2/bd iv. dd 1-4, with harvest of CD34+ blood stem cells (cycle 3), and allogeneic SCT if high-risk or second randomization to BUCY2-conditioned autograft or repetitive HD cycles (cytarabine 2 g/m^2/bd iv. dd 1-5 and idarubicin 8 mg/m^2/d dd 1-2, cycles 4-6) supported by 1-2 x10^6/kg CD34+ cells. The high-risk class was defined by cytogenetics, selected risk factors in intermediate/normal cytogenetic risk group (FLT3 ITD+, WBC >50, minimally differentiated/megakaryo-/erythro-blastic,secondary or MDS-related AML), and late CR. Results were analyzed by treatment intention and, to detect late survival differences, compared using the Kaplan-Meier estimate with weighted log-rank tests according to Fleming and Harrington.
Results: Between 2006-2012, 572 patients were enrolled (median age 52 years, range 16-73; 74% high-risk; 286 with comparable characteristics in each arm). After induction course, CR rate was 69.2% in ICE arm and 81.5% in SHD arm (*P* .001), due to lower resistance rate (25.2% *vs* 11.2%, *P* <.0001) without increased mortality (5.6% *vs* 7.3%, *P* .39). The benefit was confirmed in high-risk AML (n=201 *vs* 218: CR 64.2% *vs* 77.6%; *P* .002) and in patients aged ≤60 years with *de novo* AML (n=190 *vs* 189: CR 74.2% *vs* 86.2%; *P* .003). Overall CR rate after cycle 2/other salvage was 82.5% *vs* 86.0% (*P* .25). SHD increased the time to neutrophil/platelet recovery (*P* <.0001), the risk of infections (bacterial, *P* .0001; fungal, *P* .003) and hepatic, metabolic and cutaneous toxicity (*P* <.05), and was associated with longer intercycle intervals (P<.0001), lower feasibility of cycle 3 (*P* <.0001) and poorer stem cell mobilization (n=123 *vs* 93). One-hundred ninety-three patients (41%) had an allograft in CR1 (175 high-risk [96 in ICE arm and 79 in HDS arm] and 18 standard-risk [6 in ICE arm and 12 in HDS arm]). Median and 5-year overall survival (OS) were 2.14 years

and 38% in ICE arm compared to 4.51 years and 48% in SHD arm (*P* .0125), improving sensibly in the standard-risk subset (5-year OS 55% *vs* 72%, *P* .0068) and patients aged ≤60 years with *de novo* AML (5-year OS 43% *vs* 58%; *P* .0026). Median and 5-year DFS were 1.48 years and 36% compared to 3.41 years and 48% (*P* .0030), again improving in the standard-risk subset (5-year DFS 40% *vs* 64%; *P* .0064) and patients aged ≤60 years with *de novo* AML (5-year DFS 38% *vs* 54%; *P* .0023) (Figure 1).

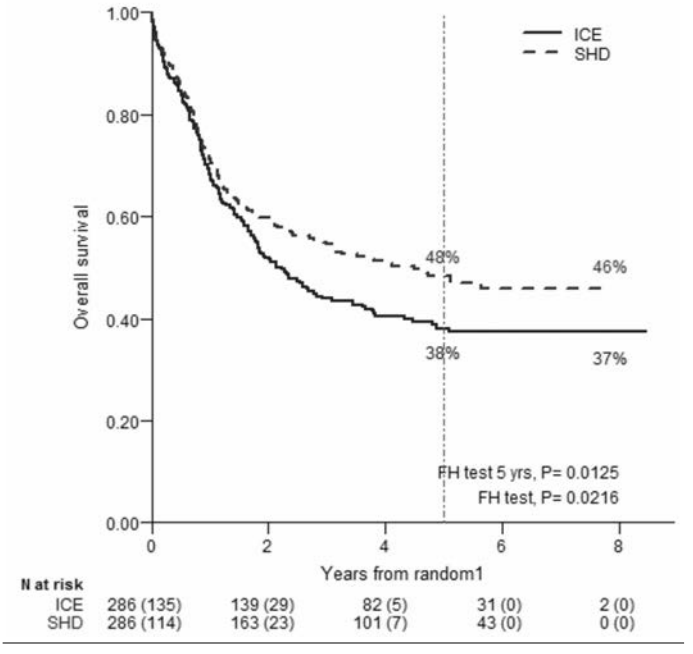

Figure 1.

Summary/Conclusions: The current SHD schedule, albeit proving more toxic than standard ICE did not increase the risk of induction death and improved the CR rate and 5-year OS and DFS results, particularly in patients with standard-risk AML and aged ≤60 years with *de novo* AML.

S486

LONG-TERM OUTCOME OF ELDERLY PATIENTS WITH ACUTE PROMYELOCYTIC LEUKEMIA TREATED WITH ANTHRACYCLINE MONOTHERAPY AND ATRA-BASED PETHEMA PROTOCOLS

Background: Outcomes of elderly patients with acute promyelocytic leukemia (APL) have been reported as less effective than in younger patients because of lower compliance and higher mortality rate related to toxicity of the treatment. This fact has led to design the risk-adapted and age-adapted PETHEMA LPA2005 protocol, in which the anthracycline dose in second consolidation was reduced with respect to previous protocols.
Aims: This study aims at comparing elderly patients (age ≥60 years old) who were treated according to PETHEMA LPA2005 schedule and those who were included in the more intensive previous protocols (LP96&LP99 trials).
Methods: Elderly patients (age equal or greater than 60) who were reported to the multicenter PETHEMA APL registry, diagnosed with APL and demonstration of the t(15;17) or *PML/RARA* rearrangement were included in this study. They were excluded if they met any of the following criteria: 1) Eastern Cooperative Oncology Group (ECOG) performance status at presentation of more than three, 2) severe medical comorbidities limiting the administration of chemotherapy in opinion of the treating physician, 3) antecedents of primary malignancy or previous therapy with leukemogenic agents, and 4) protocol violation. Elderly patients who received treatment according to the risk and age-adapted protocol LPA2005 were compared to those included in LPA96&LPA99 protocols.
Results: From November 1996 to November 2014, 389 elderly patients were reported to PETHEMA APL registry and 268 (69%) were considered as eligible. Causes of ineligibility were secondary APL (19%), ECOG 4/unfit for intensive chemotherapy (11%), and protocol violation (1%). Median age of eligible patients was 67 years (range, 60-84), and the distribution of relapse-risk categories was low (29%), intermediate (50%), and high (21%). Two-hundred sixteen out of 268 eligible patients (81%) achieved complete remission and 52 (19%) died during induction treatment due to hemorrhage and infection, mainly. Leukemic resistance was not observed. Comparing patients according to protocol, no differences in biological and clinical characteristics at diagnosis were identified between the LPA96&99 and LPA2005 cohorts. The median follow-up of patients alive was 62 months (range 2-191). Patients treated with the less intense schedule (LPA2005 trial) had lower toxicity, with a lower duration of neutropenia and thrombocytopenia during the second consolidation and fewer days of hospitalization, resulting in reduced 5-year non-relapse mortality compared with the LPA96&99 trials (5% *vs* 18%, *P*=0.02). At 5 years, patients treated according to LPA2005 protocol had higher overall survival (74% *vs* 60%, *P*=0.02), and higher disease-free survival (87% *vs* 69%, *P*=0.009) than patients who received LPA96&99 protocols. There were no differences in the cumulative incidence of relapse between the two groups (*P*=0.25) (Figure 1).

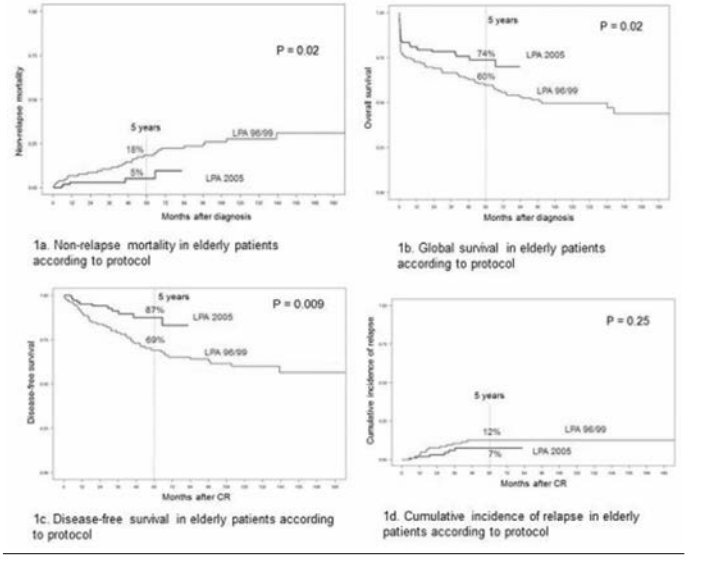

Figure 1.

Summary/Conclusions: Anthracycline dose reduction during consolidation for elderly patients with APL treated with the PETHEMA LPA2005 trial resulted in lower toxicity and non-relapse mortality, while maintaining a high antileukemic activity.

Background: Primary central nervous system lymphoma (PCNSL) is a rare subtype of non-Hodgkin lymphoma, of which approximately 95% are diffuse large B-cell lymphomas (DLBCLs). However, PCNSL shows very different biological and clinical characteristics from systemic DLBCL, and our knowledge about the molecular pathogenesis of PCNSL is still incomplete.
Aims: The purpose of this study is to delineate the entire spectrum of gene mutations, copy number alterations (CNAs) and structural variants (SVs) in PCNSL to better understand its pathogenesis.
Methods: We first analyzed paired tumor/normal DNA from 37 PCNSL cases by whole-exome sequencing (WES). Significantly mutated genes identified by WES and previously known mutational targets in PCNSL and systemic DLBCL were further screened for mutations using targeted sequencing in an extended cohort of PCNSL cases (N=92). CNAs have been also investigated using SNP array-karyotyping (N =56). Whole-genome sequencing (WGS, N=9) was also performed to identify the recurrent mutations in non-coding regions and S*Vs.*
Results: The mean number of nonsynonymous mutations identified by WES was 183 per sample, which was comparable to the figure in systemic DLBCL. A higher representation of C>T transition involving CpG dinucleotides and hotspot mutations within the WRCY motif targeted by somatic hypermutations (SHMs) suggested the involvement of activation-induced cytidine deaminase (AID) in the pathogenesis of PCNSL. We found 12 genes significantly mutated in PCNSL (q <0.1), including *MYD88*, *PIM1*, *HLA-A*, *TMEM30A*, *B2M*, *PRDM1*, *UBE2A*, *HIST1H1C*, *GRB2* as well as several previously unreported mutational targets in systemic DLBCL or PCNSL, such as *SETD1B*, *ITPKB*, *EIF4A2*. Copy number analysis identified recurrent genomic segments affected by focal deletions (N=27) and amplifications (N=10), most of which included driver genes targeted by recurrent somatic mutations or known targets of focal CNAs such as *CDKN2A* and *FHIT*. Subsequent targeted sequencing finally identified a total of 107 significantly mutated genes, of which 43 were thought to be targeted by SHM according to their mutational signature. Most cases with PCNSL (98%) had mutations and CNAs involving genes that are relevant to constitutive NF-κB/Toll-like receptor (TLR)/B-cell receptor (BCR) activity, including those in *MYD88*, *CD79B/A*, *CARD11*, *TNFAIP3*, *GRB2* and *ITPKB*. Genetic alterations implicated in escape from immunosurveillance were also frequently identified in as many as 76% of cases, including mutations of *HLA-B*, *HLA-A*, *HLA-C*, *B2M* and *CD58* as well as CNAs in 6p21.32 (HLA class II), 1p13.1 (*CD58*) and 15q15.2 (*B2M*), suggesting the importance of immune escape in the pathogenesis of PCNSL. SHMs were observed in most cases (98%), which affected not only known non-immunoglobulin targets of AID including *PIM1*, *IGLL5* and *BTG2* but also previously unreported genes involved in cell proliferation, apoptosis, or B cell development. WGS identified 52 loci in which somatic mutations were enriched, including 5'-region of *BCL6*, *RHOH*, *BACH2*, genes known to undergo SHM. Furthermore, breakpoints clusters of S*Vs* included *IG* loci (*IGK*, *IGH* and *IGL*), *CDKN2A/B* as well as known targets of AID, such as *BCL6, BTG2* and *PIM1*.
Summary/Conclusions: Comprehensive genetic analyses of a large cohort of PCNSL cases revealed the genetic landscape of PCNSL, which was characterized by constitutive NF-κB/TLR/BCR signaling, escape from immunosurveillance, as well as SHMs/S*Vs* caused by AID.

Background: Mantle cell lymphoma (MCL) ranges from cases with rather indolent clinical behavior to very aggressive tumors with poor survival rates. Aggressive cases seem to be associated with low levels of somatic hypermutation (SHM) in the Immunoglobulin Heavy Chain (*IGHV)* gene, and *de novo* expression of SOX11. In contrast, indolent MCLs have high levels of IGHV somatic mutation and lack SOX11. Although many studies have focused on biological and clinical features of MCL, its methylome remains largely unknown. As recent studies have suggested a relationship between dynamic methylation during normal differentiation and neoplastic transformation, we hypothesized that a similar link exists in MCL.
Aims: We aimed to explore the DNA methylation landscape in MCL in light of the methylome in the entire B-cell lineage in order (i) to generate new insights into the biological and clinical aspects of MCL and (ii) to further understand the link between the dynamic methylation during normal differentiation and neoplastic transformation.
Methods: We generated genome-wide DNA methylation profiles of 86 MCL samples using the HumanMethylation450 BeadChip and we sequenced the DNA methylome of two representative MCLs by whole genome bisulfite sequencing (WGBS). As normal controls, we used samples (n=67 for BeadChip and n=12 for WGBS) from different B-cell subpopulations (n=10 for BeadChip and n=6 for WGBS). We applied a principal component analysis and consensus clustering to define epigenetic MCL subgroups and to determine their normal counterparts. Furthermore, to tackle the high individual epigenetic variation in MCL, we compared the DNA methylation profile of each individual MCL to a fixed reference point, the hematopoietic progenitor cells, and further analyzed the observed changes in the context of DNA methylation changes observed during B-cell differentiation. To understand the functional and clinical impact of DNA methylation changes we have linked our data with histone modification profiles (chIP-seq), the three-dimensional chromatin structure (4C-seq), the mutational landscape (whole genome/whole exome sequencing) and clinical data in MCL.
Results: First of all, we identified two epigenetic MCL subgroups that carry epigenetic imprints of pre- *versus* post-germinal center B cells.
Secondly, we observed that the majority of individual DNA methylation changes in MCL also occur during normal B-cell differentiation and that pure tumor-specific changes are rare; most (89-99%) DNA methylation alterations in MCL are within or in close proximity to those regions showing dynamic methylation in normal B cells. Thirdly, several thousand differentially methylated regions in MCL show differential enhancer-associated histone modifications, including a region 650 Kb away from *SOX11*. In SOX11 expressing MCL cells, this distant region is hypomethylated and shows high contact frequencies with the *SOX11* promoter in three-dimensional space, suggesting that we have identified a new regulatory element of SOX11 in MCL. Lastly, at the clinical level we observed that epigenetic and genetic changes co-evolve during MCL progression and that the magnitude of epigenetic changes is associated with overall survival of MCL patients.
Summary/Conclusions: Our results (i) provide new insights into the cellular origin, pathogenetic mechanisms and clinical behavior of MCL, (ii) show that pure tumor-specific DNA methylation changes in MCL are rare and (iii) highlight that differential methylation in cancer can target potential epigenetic drivers at distant regulatory elements of key oncogenes.

Research Center, Moscow, Russian Federation, [10]Institute of Neuropathology, University Hospital Cologne, Cologne, [11]Interfaculty Institute for Cell Biology, Department of Immunology, Univeristy of Tübingen, Tübingen, [12]Department of Hematology/Oncology, [13]Department of Pathology, Charité - Univeristy Medical Center, Berlin, [14]Center of Integrated Oncology (CIO), University Hospital Cologne, [15]Center of Molecular Medicine (CMMC), University of Cologne, Cologne, [16]Max-Delbrück-Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany

Background: The adaptor protein MYD88 is critical to relay activation of Toll-like receptor signaling to NF-κB activation. *MYD88* mutations, particularly the *p.L265P* mutation, have been described in numerous distinct B cell malignancies, including diffuse large B cell lymphoma (DLBCL). 29% of activated B cell (ABC)-type DLBCL, which is characterized by constitutive activation of the NF-κB pathway, carry the *p.L265P* mutation. In addition, ABC-DLBCL frequently displays focal copy number gains affecting *BCL2*.
Aims: Here, we aimed to investigate the potential role of the *Myd88$^{p.L265P}$* point mutation in lymphomagenesis.
Methods: We generated a novel mouse model (termed *Myd88$^{c\text{-}p.L252P}$*), in which Cre-mediated recombination, specifically in B cells, leads to the conditional expression of *Myd88$^{p.L252P}$* (the orthologous position of the human *MYD88$^{p.L265P}$* mutation) from the endogenous locus. More precisely, the endogenous exons 2 to 6 of *Myd88* (which consists of 6 exons) were flanked by *loxP*-sites. Downstream of the last exon, a second set of exons 2 to 6 was inserted, harboring the point mutation *p.L252P*. Cre-mediated recombination leads to the excision of the endogenous exons 2 to 6 and expression of the inserted, mutated set of exons. This system very closely mimicks the situation observed in the clinic, as it allows for the heterozygous expression of *Myd88$^{p.L252P}$* from the endogenous locus.
Results: To assess the functionally of our allele, we generated mouse embryonic fibroblasts (MEFs) homozygous for the *Myd88$^{c\text{-}p.L252P}$* allele, recombined them *in vitro* by lentiviral transduction. After puromycin selection, cDNA was sequenced and only the mutant transcript was detected. Western blotting verified the expression of this mutant transcript and increased phospho-p65 levels as a marker for NF-kB activation. We activated our allele B cell-specifically by crossing it to the *Cd19-Cre* mouse. The resulting *Myd88$^{c\text{-}p.L252P}$;Cd19$^{Cre/wt}$* animals had a lifespan of around 500 days, significantly shorter than that of the *Cd19$^{Cre/wt}$* control. Magnetic resonance imaging and autopsy showed the development of splenomegaly and lymphadenopathy starting at around 60 weeks of age. Further histological and immunohistochemical investigation revealed the existence of lymphoproliferative disease and the sporadic emergence of large B cell lymphoma with an Bcl6$^-$/Mum1$^+$/B220$^+$/Cd138$^-$ immunotype. Analysis of V(D)J recombination by southern blotting showed clonal populations in samples from animals diagnosed with lymphoma by histology. BCL-2 is highly expressed in most ABC DLBCL cases. To potentially enhance lymphomagenesis in our mice, we aimed to combine the *Myd88$^{p.L252P}$* mutation with *Bcl-2* overexpression by making use of a newly genrated *LSL.BCL2* allele, where human *BCL2* expression is driven by the *CAGGs* promoter. Indeed, all *Myd88$^{c\text{-}p.L252P}$;LSL.BCL2;Cd19$^{Cre/wt}$* mice die of aggressive large B cell lymphoma at a median of 36 weeks. All animals showed splenomegaly and/or lymphadenopathy, accompanied by infiltration of the liver. Bone marrow involvement was only detected once and was locally restricted, indicating a secondary lesion. Clonality analysis by southern blot showed oligoclonality, suggesting a strong oncogenic potential of *Myd88$^{p.L252P}$* in combination with *BCL2* overexpression. Interestingly, lymphoma cells were of a Bcl6$^-$/Mum1$^+$/B220$^-$/Cd138$^+$ immunotype, in accordance with the plasmoblastic morphology that was histologically observed.
Summary/Conclusions: In summary, we generated a mouse model that enables Cre-mediated expression of *Myd88$^{p.L252P}$* from the endogenous locus. *Myd88$^{c\text{-}p.L252P}$;Cd19$^{Cre/wt}$* mice develop and eventually die of lymphoproliferative disease. The emergence of diffuse large B cell lymphoma (DLBCL) was observed. Combination of B cell-specific *Myd88$^{p.L252P}$* with *BCL-2* overexpression results in the development of an aggressive lymphoma with plasmoblastic features, most reminiscent of ABC-type DLBCL.

BET INHIBITORS SUPPRESS PD-L1 TRANSCRIPTION TO ENHANCE ANTI-TUMOUR IMMUNITY AND IMMUNOTHERAPEUTIC APPROACHES

S Hogg[1,2,*], J Shortt[3], R Johnstone[1,2]
[1]Peter MacCallum Cancer Centre, [2]Sir Peter MacCallum Department of Oncology, The University of Melbourne, [3]School of Clinical Sciences at Monash Health, Monash University, Melbourne, Australia

Background: Bromodomain and Extra-Terminal (BET) proteins are a highly conserved family of epigenetic 'readers' that recognise and bind acetylated lysine residues on histones and other proteins to modulate gene expression. BET proteins are enriched at enhancer regions regulating oncogenic transcription and inhibitors (BETi) displace BET proteins from chromatin leading to suppression of oncogenes (*e.g. cMYC*). BETi elicit a heterogeneous range of tumour cell responses including apoptosis, growth arrest, differentiation, and senescence. However, responses to single agent BETi are self-limited *in vivo* and drug resistance uniformly emerges in preclinical modelling. As BET-inhibitors (BETi) are now being clinically evaluated in both haematological and solid malignancies, the focus is now shifting to the design of effective combination strategies for phase II studies.
Aims: BETi have potent anti-inflammatory properties, including chromatin-independent downregulation of NFkB signalling. However, broader mechanisms of immunomodulation by BETi in the context of anti-tumour responses remain poorly defined. Having previously discovered NK- and T-cell immunostimulatory activity of an acetyllysine mimetic fragment (n-methylpyrrolidone), we sought to evaluate the immunomodulatory activity of the prototypical theinodiazapine BETi, JQ1.
Methods: Utilising the syngeneic model of transplanted Eμ-*Myc* aggressive 'Burkitt-like' lymphoma we first compared the efficacy of JQ1 in wild-type (immunocompetent) and immunodeficient RAG1$^{-/-}$ or RAG2$^{-/-}$cγ$^{-/-}$mice. To interrogate the functional interaction between JQ1 and the immune system, we profiled changes in tumour cell immunogenicity following drug exposure by flow cytometry.
Results: We observed a 50% reduction in the survival advantage conveyed by JQ1 in mice deficient in T- and/or B-lymphocytes compared to immunocompetent controls. Notably, tumour-infiltrating lymphocytes (TILs) and peripheral blood T-cells from wild-type mice failing JQ1 therapy expressed high levels of PD-1, suggesting suppression of an endogenous anti-lymphoma immune response during disease progression. Having previously identified recurrent copy number amplification of PD-L1 (universally juxtaposed to the Eμ-*Myc* transgene), we hypothesised this endogenous host response may be dampened by the PD-L1/PD1 axis and further modulated by JQ1. Strikingly, JQ1 rapidly and potently suppressed PDL1 transcription in Eμ-*Myc* lymphoma cells *in vitro* and *in vivo*. ChIP assays revealed significantly reduced BRD4 occupancy of the PDL1 promoter/enhancer within 2 hours of JQ1 exposure (with 90% suppression of PD-L1 mRNA levels). shRNA knockdown of BRD4 likewise downregulated PD-L1 transcription. Moreover, JQ1 treatment suppressed both constitutive and IFNγ-inducible PD-L1 expression in human myeloma, Burkitt and Hodgkin cell lines. Finally, treatment of mice bearing Eμ-*Myc* lymphoma with JQ1 in combination with a checkpoint inhibitor (anti-PD1) or immune stimulating antibody (anti-4-1BB) was highly synergistic responses despite minimal single-agent activity of these therapeutic antibodies.
Summary/Conclusions: We suggest that oncogenic PD-L1 transcription (including IFNγ-induced expression) is directly regulated by BRD4 and can be suppressed for therapeutic gain by BETi leading to augmented anti-tumour immunity, particularly in the context of immune checkpoint inhibitors. BETi/anti-PD1 combination studies should be evaluated in genetically leveraged (*e.g.* cMYC positive) aggressive lymphoid malignancy.

Children Hospital, Los Angeles, CA, [5]City of Hope Coprehensive Cancer Ctr., Duarte, CA, United States, [6]University of Prague, Prague, Czech Republic, [7]University of Montreal, Montreal, Canada, [8]Aarhus University Hospital, Aarhus, Denmark, [9]University of Utah, Salt Lake City, UT, [10]University of Alabama Birmingham, Birmingham, AL, United States, [11]University of Milano-Bicocca, Monza, Italy, [12]Imperial College of London, London, United Kingdom, [13]Microbiology and Immunology, The University of Maryland Baltimore and Greenebaum Cancer Center, Baltimore, United States

Background: Nanostring arrays and RNAseq analysis of total, $CD34^+$, $CD34^+CD38^-$ bone marrow (BM) cells from healthy individuals (n=6) and CML patients (n=16) showed gradual inhibition of miR-300 expression (CML-$CP^{miR-300}$>CML-$BC^{miR-300}$). MiR-300 is a human intergenic microRNA predicted to target multiple components of the BCR-ABL1/JAK2/hnRNPA1/SET/PP2A/β-catenin pathway that, as reported is essential for survival/self-renewal of leukemic progenitors and quiescent TKI-resistant Ph^+ hematopoietic stem cells (HSCs).
Aims: This work is aimed at understanding the mechanisms regulating miR-300 in CML and assessing the importance of its downregulation for proliferation, survival and self-renewal of CML (CP and BC) cells.
Methods: Lentiviral-mediated modulation of miR-300 expression was used in CML cells and cell lines to assess effect of miR-300 on its mRNA targets, and on the clonogenic potential, LTC-IC, and number of quiescent leukemic stem and/or progenitor cells, and on the leukemogenic potential in animal models of CML. MSC-derived exosomes and conditioned medium, hypoxic/normoxic conditions and BCR-ABL1 inhibition were used to determine the mechanisms of regulation of miR-300 expression.
Results: MiR-300 transduction in CML^{CD34+} cells and BCR-$ABL1^+$ cell lines decreased JAK2, β-catenin, hnRNPA1 and SET expression and increased PP2A activity. Targets were confirmed by miR-300 expression in BCR-$ABL1^+$ cells expressing Flag-tagged miR-300-targets lacking or carrying a wild-type or mutated 3'UTR. Restored miR-300 expression in CML^{CD34+}cells and/or BCR-$ABL1^+$ cell lines impaired proliferation and clonogenic potential, markedly reduced LTC-ICs, and increased TKI sensitivity. Notably, miR-300 expression was inhibited by BCR-ABL1 in proliferating cells. Accordingly, imatinib restored miR-300 expression in $CD34^+$ dividing progenitors and BCR-$ABL1^+$ cell lines without altering miR-300 levels in quiescent ($CFSE_{MAX}$) CML^{CD34+}cells (n=3), consistent with the BCR-ABL1 kinase-dependent activation of the Jak2/SET/PP2A/β-catenin pathway in CML progenitors but not quiescent Ph^+ HSCs. Surprisingly, miR-300 levels were increased in $CD34^+CD38^-$ compared to $CD34^+CD38^+$ CML cells, and >20-fold higher in $CFSE_{MAX}$ compared to dividing CML^{CD34+}cells (n=4). Furthermore, it appears that forced miR-300 expression decreases engraftment of BCR-ABL^+ cells (32D-BCR-ABL) in immunocompromised mice. Bone marrow transplant experiments in NSG mice with miR-300-transduced human CD34+ CML-BC cells, and with miR-300-transduced Lin^- and LSK cells from SCL-tTA-BCR-ABL mice are ongoing and will allow us to determine the role of miR-300 on leukemic HSC engraftment and ability to propagate disease. To determine whether enhanced miR-300 expression in quiescent cells depends on cell autonomous events or is induced by the BM microenvironment, we exposed BCR-ABL^+ cells to conditioned medium (CM) of HS-5 or hTERT mesenchymal stem cells (MSC). CM strongly decreased proliferation, induced imatinib but not FTY720 (PP2A activator) resistance, increased miR-300 levels, decreased BCR-ABL1 activity and Jak2 expression but not its activity, and did not alter b-catenin levels or PP2A activity. Interestingly, miR-300 was found in MSC-derived exosomes, and its expression increased in BCR-$ABL1^+$ cells exposed to exosomes. Accordingly, proliferation of CML-$BC^{CD34+}$and LAMA-84 cells was strongly reduced upon exposure to MSC-derived exosomes. These effects were abolished when we used CM from MSCs transduced with a miR-300 antagomir. Interestingly, culturing of leukemic cells in hypoxic conditions dramatically induced miR-300 expression that, in turn, impaired proliferation of primary $CD34^+$ CML cells and BCR-ABL cell lines.
Summary/Conclusions: Altogether our results indicate that downregulation of miR-300 appears necessary for the activation of JAK2/SET/PP2A/b-catenin survival signals in CML progenitors. Conversely, increased miR-300 levels (endogenous and MSC-derived) seem to be required for HSC quiescence.

S492

IDENTIFYING, TRACKING AND VISUALIZATION CML BLAST CRISIS STEM/PROGENITORS CELLS BASED ON SINGLE-CELL MASS CYTOMETRY ANALYSIS

H Zhou[1,2,*], PY Mak[2], H Mu[2], DH Mak[2], Z Zeng[2], J Cortes[3], Q Liu[1], M Andreef[2], BZ Carter[2]
[1]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China, [2]Section of Molecular Hematology and Therapy, Department of Leukemia, [3]Department of Leukemia, The University of Texas M.D. Anderson Cancer Center, Houston, TX, United States

Background: Tyrosine kinase inhibitor (TKI) has dramatically improved the outcome of CML, but it could not eliminate leukemia stem cell (LSC). Self-renewal is a key characteristic for LSC. Emerging evidence indicates that β-catenin, the Wnt pathway's central effector molecule, is required for development and maintenance of LSC in CML.
Aims: We hypothesize that the combination of β-catenin and tyrosine kinase inhibition could represent a promising strategy for preventing the development of TKI resistance as well as a novel approach in the therapy of BC CML by targeting CML-BC LSC.
Methods: Aided with single-cell mass cytometry analysis and data visualization with SPADE and viSNE, we investigated the activity of the combination of TKI with a Wnt/b-catenin signaling modulator C82 *in vitro* and with the C82 prodrug PRI-724 *in vivo* in a xenograft murine model.
Results: Primary CML-BC cells were stained with multiple cell surface markers and intracellular survival signaling molecules and subjected to CyTOF analysis. It revealed that β-catenin expression was high in various CML stem/progenitor cells and particularly highest in $CD34^+CD38^+CD123^+Tim3^+$ subset. viSNE visualization demonstrated that β-catenin overexpression was associated with high levels of pCRKL, c-Myc, pAKT, pTyr, pSTAT3, and pSTAT5. Primary CML-BC cells from were then treated with C82, nilotinib, and both. viSNE visualization and SPADE tree analysis revealed that C82 and the combined regimen more significantly decreased various stem/progenitor cells, especially $CD34^+CD38^+CD123^+Tim\text{-}3^+$ cells, which represents for the candidate for CML-BC LSC. Next, NSG mice engrafted with CML-BC^{T315I}cells were treated with PRI-724, nilotinib, or the combination. At the end of treatment, cells were collected from the mice and subjected to CyTOF analysis. viSNE visualization showed that PRI-724 and combination strikingly reduced $CD34^+$b-$catenin^{high}$, $CD34^+CD38^-$, and $CD34^+CD38^+$ different CML-BC stem/progenitor subsets. Furthermore, SPADE tree analysis revealed the combination more profoundly than PRI-724 alone reduced $CD34^+CD38^-$, $CD34^+CD38^+$ and Tim-3^+GMP progenitor cells in NSG mice, which was confirmed by flow cytometry.Furthermore, PRI-724 and the combination induced CD11b expression, suggesting PRI-724 and the combination promoted CML-BC stem/progenitor cell differentiation. Notably, PRI-724 and nilotinib combination significantly inhibited CD44 in $CD34^+CD38^+CD123^{high}$ and $CD34^+CD38^+CD123^{high}Tim\text{-}3^{high}$ subsets, and Tim-3 in $CD34^+CD38^+CD123^{high}Tim\text{-}3^{high}$ subset, respectively. Finally, PRI-724 and the combination significantly improved the overall survival of CML-BC-loaded NSG mice, as compared to control and the nilotinib treatment.
Summary/Conclusions: Collectively, by identifying, tracking and visualization CML-BC LSC based on CyTOF analysis, our results show that inhibition of β-catenin effectively targets CML-BC stem/progenitor cells and prolongs survival of CML-BC-loaded NSG mice, which is further enhanced by combination with inhibition of Bcr-Abl.

DYNAMICS OF SOMATIC MUTATIONS COMMONLY DETECTED IN OTHER MYELOID NEOPLASMS BEYOND THE BCR-ABL GENE REARRANGEMENT IN RESPONSE TO TYROSINE KINASE INHIBITOR THERAPY IN CHRONIC MYELOID LEUKEMIA

T Kim[1,2,*], MS Tyndel[3], HJ Kim[4,5], JS Ahn[4,5], SH Choi[5], HJ Park[5], YK Kim[4], SY Kim[5], SS Lee[4], H Gook[6], JH Lipton[7], Z Zhang[1,2,8], DDH Kim[7]
[1]Donnelly Centre for Cellular and Biomolecular Research, [2]Computer Science, [3]The Edward S. Rogers Sr. Department of Electrical and Computer Engineering, University of Toronto, Toronto, Canada, [4]Department of Hematology-Oncology, [5]Genome Research Center for Hematopoietic Disease, Chonnam National University, [6]Department of Pediatrics, Chonnam National University, Hwasun, Korea, Republic Of, [7]Department of Medical Oncology, [8]Department of Molecular Genetics, University of Toronto, Toronto, Canada

Background: Chronic myeloid leukemia (CML) is mainly characterized by a translocation event t(9;22)(q34;q11.2) which fuses the *ABL1* gene and the *BCR* gene, yielding a *bcr-abl* onco-protein. Despite remarkable improvement in the treatment of CML via tyrosine kinase inhibitors (TKIs), a portion of patients show resistance to these treatments and have a much higher risk of progression to accelerated phase (AP) or blastic phase (BP) as a result. The survival of patients who progress to BP is comparable to the pre-TKI era, even with other salvage treatment modalities such as allogeneic stem cell transplantation. Using high-throughput sequencing technologies, extensive investigations in other myeloid malignancies have discovered commonly mutated genes and the biological pathways they effect. Other than *ABL1* kinase domain (KD) mutations,

very little is known about the origins and dynamics of relevant somatic variants, as well as their associations with *BCR-ABL* transcript changes and their clinical implications on TKI response in CML.
Aims: We aimed to determine whether patterns of mutation acquisition, persistence, and clearance can provide insight into treatment outcomes in CML.
Methods: 100 CML patients were included for deep sequencing targeting 92 genes that are recurrently mutated in other myeloid neoplasms. Treatment failure was estimated to be 10.2% at 3 years while PFS at 5 years was 91.0%. The OS at 5 years was 92.6%. Based on ELN criteria, 74 patients were determined to have optimal response, 18 failed but remained in CP, and 8 had progressed to accelerated or blast phases. For each patient, samples taken at the initial diagnosis (prior to TKI therapy) and after TKI treatment, as well as T-cell samples, were sequenced in this study.
Results: In total, 64 variants from 32 genes in 37 patients were detected in 300 serial samples from 100 CML patients. *ASXL1*, *ABL1*, and *TET2* were the 3 genes most frequently mutated (n=9, n=6, and n=6, respectively). Unsupervised hierarchical clustering of the 51 non-silent mutations across all serial samples revealed 5 distinct pattern of mutation dynamics throughout the course of CML (Figure 1). A majority of cases with mutations only had mutations from one pattern. Pattern 1 mutations arise at diagnosis and persist at follow-up. Despite this, all patients with Pattern 1 mutations were TKI-responsive. Since these mutations were not cleared in spite of significant reduction of *BCR-ABL* transcript level at the time of follow-up, they are likely to be indicative of abnormal and clonal *Ph*-negative hematopoiesis that existed prior to *Ph*-positive clones. Pattern 2 mutations are acquired during TKI treatment. This pattern included a high portion of *ABL1* KD mutations (7/13 mutations in 6 patients). Perhaps unsurprisingly, all patients with Pattern 2 mutations failed TKI therapy. Pattern 3 mutations rise at the time of diagnosis and vanish or substantially decrease following TKI therapy. Patients with these mutations showed mixed patterns of clinical outcomes. Interestingly, Pattern 3 mutations were frequently within genes associated with chromatin modification and DNA methylation, which are epigenetic regulation pathways (11/17, 64.7%). Patients with Pattern 4 and 5 mutations showed evidence of preleukemic mutations in CML. Too few cases had these mutations to assess their association with treatment outcomes.

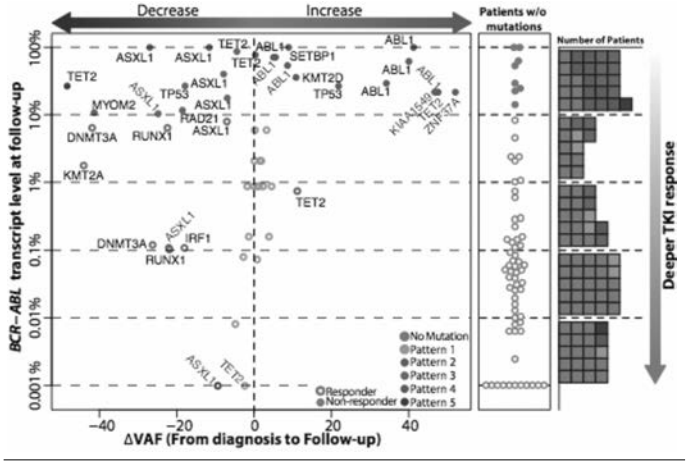

Figure 1. BCR-ABL level indicated on a log10 percentage scale for both subplots. Each circle in the left-hand plot represents a variant. Filled circles indicate TKI treatment failure. The right-hand plot shows patients without extra mutations. Each dot indicates an individual patient. The boxes on the right indicate the number of patients within each decade on TKI response coloured by pattern.

Summary/Conclusions: Overall, this study demonstrates that patterns of mutation acquisition, persistence, and clearance vary but have a number of interesting correlations with clinical outcomes. Our data show that mutation burden often persists despite successful TKI response in CML, particularly in mutations that are likely in persistent *Ph*-negative clones, while mutation clearance is not associated with particular outcomes. Patients that acquired new mutations during treatment all failed TKI therapy. We found evidence of preleukemic mutations in some CML patients. These patterns show that CML mutation dynamics following TKI therapy are markedly distinct from other hematologic malignancies.

S494

THE ADVERSE EFFECTS OF CANCEROUS INHIBITOR OF PROTEIN PHOSPHATASE 2A, ARE LINKED WITH REDUCTION OF FUNCTIONAL B56GAMMA, A REGULATORY SUBUNIT OF PROTEIN PHOSPHATASE 2A, IN CHRONIC MYELOID LEUKAEMIA

JA Austin*, CM Lucas, L Scott, A Holcroft, L Wang, RE Clark
Molecular & Clinical Cancer Medicine, University of Liverpool, Haematology, Liverpool, United Kingdom

Background: Protein phosphatase 2A (PP2A) is an important phosphatase which opposes the deregulated kinase activity that typifies many malignancies. It comprises a scaffold (A) subunit linked to a catalytic (C) and regulatory (B) subunit; the latter dictates activity, substrate specificity and intracellular localisation and has 26 isoforms. Of these, B56γ confers a PP2A nuclear localisation signal, and mutations interfering with its PP2A binding are reported in solid tumours. We have shown that a high diagnostic level of CIP2A, a key PP2A inhibitor, is a predictive biomarker of poor outcome in both acute and chronic myeloid leukaemia (CML), and ~30 studies in non-haematological tumours all also show a similar association with poor outcome. PP2A is known to dephosphorylate MYC at serine 62, thus destabilising it and shortening its half-life. PP2A also regulates mTORC1, MAPK/ERK, AKT, P53 and NfKB pathways which are associated with malignancy, but whether CIP2A involvement is direct or indirect is not understood; furthermore the detailed molecular and biochemical consequences of high CIP2A levels in malignant cells remain elusive.
Aims: We aim to test whether CIP2A binding to PP2A is dependent on which regulatory subunits are attached in the PP2A heterotrimeric complex. This will help to explain how CIP2A can mediate some but not all of PP2A's specific functions on pathways involved in cancer progression.
Methods: The CML cell line K562 expresses high levels of CIP2A. Its CIP2A levels and those of MYC, S62 MYC, and PP2A components were assessed by flow cytometry. Primary CML cells, both mononuclear and $CD34^+$, with either low or high levels of CIP2A were also studied, after obtaining informed consent. CML cells and cell-lines were used in fractionation (to seperate into distinct cellular compartments), western blotting, co-immunoprecipitation and qPCR.
Results: CIP2A co-immunoprecipitates not only with PR65, the heat repeat scaffold (A) subunit of PP2A, but also with B56γ, one of the B regulatory subunits of PP2A, though not with the alternative B subunits PPP2R4, B56α, B56β, PPP2R5E or B72/130. In primary CML cells with high CIP2A levels, B56γ mRNA expression is lower than in either control or CML samples with low CIP2A levels, to suggest it has an inhibitory effect on B56γ protein levels. In high CIP2A K562 cells, CIP2A is predominantly cytoplasmic, as is B56γ. In addition, S62 MYC is almost entirely cytoplasmic. CIP2A knockdown by transient transfection of siRNA will increase the level of B56γ and vice versa, suggesting that expression is negatively correlated.
Summary/Conclusions: These data suggest that CIP2A reduces the active PP2A-B56γ associated complex and is compatible with the following model: In normal cells (which have very little CIP2A present) and malignant cells with low CIP2A, the PP2A scaffold plus C unit complex moves freely around the cell with full activity, getting access to the nucleus by the nuclear localisation signal obtained on binding B56γ. CIP2A is at too low a level to interfere with this. Cytoplasmic PP2A is also fully active and can thus regulate important cytoplasmic pathways such as MAPK/Jun which can promote proliferation. If CIP2A is high (exclusively a feature of some malignant cells), it binds B56γ as part of the PP2A complex. This results in the specific loss of function performed by the PP2A-B56γ attached complex. This could be achieved by CIP2A in a number of ways, including interfering with PP2A- B56γ nuclear transport, by restricting access of the nuclear localisation signal (NLS) or a direct inhibitory effect on function (*i.e.* blocking of the active site). Concurrently, a reduction in B56γ mRNA is observed. Overall, these effects reduce the amount of PP2A- B56γ phosphatase function, leading to deregulation of known pathways that require functional B56γ; these include the P53 tumour suppressor function and MAPK/ERK in uncontrolled cell proliferation. The effect on S62 MYC may also be affected by reducing total nuclear levels of PP2A or causing a misbalance of other active B regulatory subunits that compete to bind PP2A. Thus, high CIP2A results in a specific deregulation of PP2A function likely to promote clonal progression, with potential overlap in other haematological malignancies.

S495

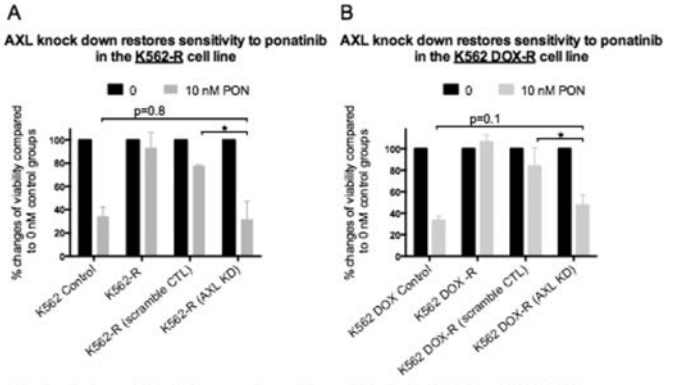
MODELLING PONATINIB RESISTANCE IN BCR-ABL1+ CELL LINES: IMPLICATIONS FOR PONATINIB THERAPY

L Lu[1,2,*], V Saunders[2], C Kok[1,2], T Leclercq[1,2], T Hughes[1,2,3], D White[1,2]
[1]School of medicine, The university of Adelaide, [2]Cancer Theme, South Australian Health and Medical Research Institute, [3]Department of haematology, SA pathology, Adelaide, Australia

Background: Ponatinib overcomes TKI resistance (imatinib, nilotinib and dasatinib) that develops due to *BCR-ABL1* kinase domain (KD) mutations including T315I. Besides KD mutations, there are several identified TKI resistance mechanisms, such as *BCR-ABL1* overexpression, regulation of the expression of TKI transporters, and Bcr-Abl independent Axl kinase overexpression. However, little is known about the mechanisms that may cause ponatinib resistance. Here, modes of ponatinib resistance have been investigated in TKI naïve and pre-treated *BCR-ABL1*+ cell lines.
Aims: To characterise ponatinib resistance mechanisms in *BCR-ABL1*+ cell line models.
Methods: Ponatinib resistance was generated by using four *BCR-ABL1*+ cell-lines: 1) K562, 2) K562-DOX (ABCB1 overexpressing variant) 3) K562 DOX-55D (resistant to 55 nM dasatinib) and 4) K562 T315I (resistant to 200 nM dasatinib, harbouring the T315I mutation). The average steady state of ponatinib plasma concentration in patients is 101 nM for dosage at 45 mg/day.

Hence, the resistant cells were exposed to increasing concentration of ponatinib to 100 nM (if higher concentration could not be achieved) or 200 nM, as these concentrations are close to clinically relevant. Parental ponatinib naïve controls were maintained in parallel. R indicates ponatinib resistant variants.

Results: Four resistant cell lines were established. All of the four cell lines were cross-resistant to other TKIs (2000 nM imatinib, 1000 nM nilotinib and 200 nM dasatinib). The two dasatinib pre-treated resistant cell lines developed *BCR-ABL1* KD mutation(s). The level of T315I in the K562 T315I-R line (survived in 100 nM ponatinib) increased from 44% to 66%, and the expression level of *BCR-ABL1* increased 6-fold compared to the naïve line ($p<0.05$). The K562 DOX 55D-R (survived in 200 nM ponatinib) developed compound mutations G250E/E255K (54%). However, KD mutations were not observed in the cell lines with no prior exposure to TKI. The ponatinib resistance in K562-R and K562 DOX-R cell lines (both survived in 200 nM ponatinib) were Bcr-Abl independent: active Bcr-Abl and CrkL (surrogate marker of Bcr-Abl activity) levels were reduced, while Axl protein and *AXL* mRNA expression levels were increased significantly (all $p<0.05$). After incubation with Axl inhibitors, 1 μM R428 or 12.5 μM BMS-777607, the K562-R and K562 DOX-R cell lines were re-sensitised (approximately 50% reduction in viability) to 200 nM ponatinib while the controls remained resistant to the drug (both $p<0.05$). Next, retroviral vector was used to reduce *AXL* gene expression in the K562-R and K562 DOX-R cell lines. This *AXL* gene reduction in the two cell lines resulted in re-sensitisation to 10 nM ponatinib (Figure 1A-B), while controls remained resistant to 200 nM ponatinib. These results suggested that Axl overexpression is critical for Bcr-Abl independent ponatinib resistance.



The knock-down of AXL (A-B) restored ponatinib sensitivity in the K562-R and K562 DOX-R resistant cell lines to the same degree as the ponatinib naïve control cell lines. Error bars represent mean+SD. *$p<0.05$.

Figure 1.

Summary/Conclusions: We show that in the setting of prior-TKI exposure, *BCR-ABL1* KD mutations are likely to cause ponatinib resistance. In the TKI naïve setting, Bcr-Abl independent modes of resistance may be more likely, suggesting combination therapeutic approaches may be required in this setting. In addition, ponatinib resistance are unlikely to be overcome by the use of the first or second generation TKIs.

Acute lymphoblastic leukemia - Clinical

HIGH THROUGHPUT SEQUENCING AS A MEASURE OF EARLY RESPONSE TO THERAPY IN CHILDHOOD ALL

I Kirsch[1,*], B Crossley[1], D Williamson[2], C Gawad[3], B Wood[4], M Borowitz[5], M Devidas[6], K Maloney[6], E Larsen[6], N Winick[6], P Marin[6], S Hunger[7], M Loh[8], H Robins[9]
[1]Translational Medicine, [2]Client Services, Adaptive Biotechnologies, Inc., Seattle, [3]Oncology, St. Jude Children's Research Hospital, Memphis, [4]Laboratory Medicine, University of Washington, Seattle, [5]Laboratory Medicine, Johns Hopkins University Medical Center, Baltimore, [6]Children's Oncology Group, University of Florida, Gainesville, [7]Pediatric Oncology, Children's Hospital of Philadelphia, Philadelphia, [8]Pediatric Oncology, University of California at San Francisco, San Francisco, [9]Adaptive Biotechnologies, Seattle, United States

Background: Early response to induction chemotherapy has been demonstrated to be a highly significant prognostic factor in the outcome of children with acute lymphoblastic leukemia. Multiparametric flow cytometry (mpFC) has been the routinely used methodology in the US for determination of this response. New high throughput sequencing (HTS) technologies of rearranged immune receptor (TCR and Ig) genes have raised the possibility of a more accurate, sensitive, and standardizable approach to determination of early response to therapy in ALL patients.

Aims: In this study, we investigated whether the Adaptive Biotechnologies assay of IgH and TCRG would be able to quantify residual disease at the end of induction therapy for children with ALL and be of prognostic value with regard to outcome (event free survival) in these patients.

Methods: The first study involved a total of 480 patients enrolled on Children's Oncology Group (COG) clinical trials AALL0331 and AALL0232 for whom mpFC measurement of residual disease and outcome data are available. A second study involved samples from 73 patients enrolled in a former Pediatric Oncology Group trial, POG 9905, who were mpFC negative at d29. For increased statistical power the patients in POG 9905 were selected for analysis so that ~50% had relapsed disease determined in follow-up monitoring. MpFC was performed at COG reference laboratories the University of Washington or Johns Hopkins Hospital as part of the evaluation for MRD. Genomic DNA was extracted from frozen bone marrow specimens collected at diagnosis and at day 29 post the start of induction therapy. High throughput sequencing of CDR3 regions of IGH and TCRG was performed on all samples, with the testing laboratory blinded to patient outcome. Diagnostic and d29 matched samples from a given patient were sequenced and dominant clonal CDR3 sequences from diagnosis were searched for in the corresponding d29 sample. Both the presence and the frequency of the MRD clone relative to the total IGH repertoire and total nucleated cell population were determined.

Results: The assays defined the dominant clonal sequences in 93% of the patients. 70% of this subgroup was found to have residual disease present at d29. Clones from some of the patients demonstrated a single "trackable" sequence while clones from other patients demonstrated multiple trackable sequences either within or between the two immune receptor loci being assessed. 60% of the residual disease detected by HTS was previously reported as MRD negative by mpFC. For "standard risk" patients, 53% were positive for MRD by HTS and negative by mpFC. With the combined COG data, using a MRD cutoff of 10^{-4}, HTS was able to define a correlation with event-free survival ($p=0.0003$). Furthermore, for the "standard risk" patients, being MRD positive or negative as determined by the more sensitive HTS assay was also correlated with outcome ($p=0.02$). In addition, a correlation was noted between poorer outcome and a "germline" or TCRG only (*i.e.* IgH loci retained in the germline configuration) genotype ($p=0.04$). In the second study of patients enrolled in the POG 9905 trial, the more sensitive HTS cut-off of $10^{-5}$was correlated with outcome ($p=0.0228$).

Summary/Conclusions: This is the largest patient cohort studied to date for which mpFC, HTS, and outcome data are available. This work suggests that HTS is an accurate and standardized assay whose increased sensitivity compared to mpFC is relevant to determination of patient outcome.

S497

DURABLE REMISSIONS AFTER MONOTHERAPY WITH CD19-SPECIFIC CHIMERIC ANTIGEN RECEPTOR (CAR)-MODIFIED T CELLS IN CHILDREN AND YOUNG ADULTS WITH RELAPSED/REFRACTORY ALL

S Maude[1,*], D Teachey[1], S Rheingold[1], P Shaw[2], R Aplenc[1], D Barrett[1], C Barker[1], C Callahan[1], N Frey[2], F Nazimuddin[2], S Lacey[2], Z Zheng[2], B Levine[2], J Melenhorst[2], L Motley[1], D Porter[2], C June[2], S Grupp[1]
[1]The Children's Hospital of Philadelphia, [2]University of Pennsylvania, Philadelphia, United States

Background: Targeted immunotherapy with chimeric antigen receptor (CAR)-modified T cells can produce potent anti-tumor responses. We previously reported complete remissions (CR) and prolonged persistence in children and adults

with relapsed/refractory acute lymphoblastic leukemia (ALL) treated with CD19-specific CAR-modified T cells (CTL019). We now report on outcomes and longer follow-up of 59 children and young adults with relapsed/refractory ALL enrolled on the pediatric phase 1/2a trial of CTL019.
Aims: Determine the safety and efficacy of CTL019 in pediatric patients with relapsed/refractory CD19+ ALL. Determine the safety and efficacy of CTL019 in pediatric patients with a history of CNS involvement of ALL. Assess relapse-free survival (RFS) and overall survival (OS) after CTL019.
Methods: After informed consent, patient-derived T cells were transduced with a lentiviral vector encoding a CAR composed of anti-CD19 scFv, CD3z, and 4-1BB domains, activated/expanded *ex vivo* with anti-CD3/CD28 beads, and then infused at a dose of 10^7 to 10^8 cells/kg with a transduction efficiency of 2.3-45%. 54/59 patients received lymphodepleting chemotherapy the week prior to cell infusion.
Results: Of 59 patients aged 20mo-24y with CD19+ ALL, 44 had detectable disease prior to CTL019 cell infusion, while 15 were minimal residual disease (MRD)-negative. 39 were treated for relapse after prior stem cell transplant (SCT). 15 patients had CNS disease within a year of infusion. At assessment 1 month after infusion, 55/59 (93%) were in CR. MRD <0.01% by flow cytometry was achieved in 52 patients. CTL019 cells were detected in the CSF, all patients achieved CR in the CNS (including 4 patients with CSF blasts detected the day prior to infusion), and no CNS relapses have been seen. With median follow-up 12 mo (1-43 mo), 34 patients had ongoing CR, with only 6 receiving subsequent therapy (5 SCT, 1 donor lymphocyte infusion), RFS was 76% (95% CI, 65-89%) at 6 mo and 55% at 12 mo (95% CI, 42-73%), and OS was 79% (95% CI, 69-91%) at 12 mo. 20 patients subsequently relapsed, 13 with CD19-negative disease. CTL019 persistence was accompanied by B cell aplasia, which continued up to last assessment (1-39 mo) in 24/34 patients with ongoing CR. Cytokine release syndrome (CRS) was seen in 88% of patients. Severe CRS requiring hemodynamic or respiratory support occurred in 27%, was associated with high disease burden, and was reversed with the anti-IL6R agent tocilizumab. We could predict development of severe CRS through regression modeling using IFNγ, sgp130, and IL1RA measured in the first 72h (sensitivity 86%, specificity 89%, AUC 0.93).
Summary/Conclusions: Single-agent CTL019 immunotherapy can induce potent responses in patients with relapsed/refractory ALL and can control CNS leukemia. Durable remissions were observed without subsequent SCT. Phase 2 multisite and global registration trials of CTL019 are in progress.

S498

IMPACT OF DISEASE BURDEN ON LONG-TERM OUTCOME OF CD19-TARGETED CAR MODIFIED T CELLS IN ADULT PATIENTS WITH RELAPSED B-ALL

J Park*, I Riviere, X Wang, M Sadelain, R Brentjens
Memorial Sloan-Kettering Cancer Center, New York, United States

Background: We have previously reported high response rates in adult patients with relapsed or refractory (R/R) B-cell ALL following CD19-targeted 19-28z chimeric antigen receptor (CAR) modified T cells regardless of the disease burden at the time of T cell infusion. However, the impact of disease burden on toxicity and long-term clinical outcome in patients who received 19-28z CAR modified T cells has not been examined in detail.
Aims: In order to better understand the association between pre-treatment disease burden and tolerability and long-term efficacy of 19-28z CAR T cells, herein we report the result of of a focused analysis from the phase I clinical trial of 19-28 CAR T cells in adults patients with R/R B-ALL (NCT01044069).
Methods: Adult patients with R/R B-ALL were enrolled to the phase I clinical trial. All patients underwent bone marrow (BM) biopsy immediately prior to 19-28z CAR T cell infusion, and were divided into two cohorts based on the blast % in BM: minimal disease (<5% blasts) *vs* morphologic disease (≥5% blasts). Subsequently, patients received lymphodepleting chemotherapy followed by 19-28z CAR T cell infusion.
Results: Of 46 patients treated, 21 patients had minimal disease and 25 patients had morphologic disease at the time of CAR T cell infusion. Baseline disease and treatment characteristics were similar between the two cohorts, except less HSCT in the minimal disease cohort (29 *vs* 48%). Complete response (CR) and minimal residual disease-negative CR (MRD-CR) rates were 91% and 71% in the minimal disease cohort, and 75% and 65% in the morphologic disease cohort, respectively. Severe cytokine release syndrome exclusively occurred in patients with morphologic disease (44% *vs* 0%) but grade 3/4 neurotoxicity was observed in 14% of patients with minimal disease *vs* 40% with morphologic disease. Although overall relapse rates did not differ between the two cohorts, no relapse or death occurred in the minimal disease cohort beyond 12 months. At a median follow-up of 12.0 months (range, 1-45), the estimated 6-month overall survival (OS) rates for all patients in the minimal disease and morphologic disease cohorts were 73% and 57%, respectively. Among the patients who achieved MRD-CR, the estimated 6-month OS rates were 92% for the minimal disease cohort with remissions extending beyond 3 years, and 65% for the morphologic disease cohort.
Summary/Conclusions: These data confirm the potent anti-tumor efficacy of 19-28z CAR T cells (JCAR015) in adult patients with R/R ALL regardless of pre-treatment disease burden. Patients with minimal disease appear to have more favorable toxicity profile and long-term survival rates. These findings support the use of 19-28z CAR T cells in earlier lines of ALL treatment, such as in a frontline setting.

S499

INOTUZUMAB OZOGAMICIN FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA IN THE GLOBAL PHASE 3 RANDOMIZED CONTROLLED INO-VATE TRIAL: EFFICACY AND SAFETY BY PRIOR THERAPY

DJ DeAngelo[1,*], EJ Jabbour[2], M Stelljes[3], M Liedtke[4], W Stock[5], N Goekbuget[6], G Martinelli[7], S O'Brien[8], K Wang[9], T Wang[10], ML Paccagnella[10], B Sleight[10], E Vandendries[11], AS Advani[12], HM Kantarjian[2]
[1]Dana-Farber Cancer Institute, Boston, MA, [2]University of Texas MD Anderson Cancer Center, Houston, TX, United States, [3]Universitätsklinikum Münster, Münster, Germany, [4]Stanford Cancer Center, Stanford, CA, [5]The University of Chicago Medicine, Chicago, IL, United States, [6]University Hospital Frankfurt, Frankfurt, Germany, [7]University of Bologna, Bologna, Italy, [8]University of California, Irvine, Orange, CA, [9]Pfizer Inc, Pearl River, NY, [10]Pfizer Inc, Groton, CT, [11]Pfizer Inc, Cambridge, MA, [12]Cleveland Clinic Main Campus, Cleveland, OH, United States

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, showed superior response *vs* standard care for relapsed/refractory acute lymphoblastic leukemia (ALL) in the ongoing phase 3 INO-VATE trial.
Aims: To assess the effects of prior therapy on response and toxicities in patients with relapsed/refractory ALL receiving InO in the phase 3 trial
Methods: Per protocol, intent-to-treat analyses of complete remission [CR]/CR with incomplete hematologic recovery [CRi] included the first 218 of 326 patients randomized (ITT218). The safety population included 139 patients who received ≥1 InO dose (max 1.8 mg/m^2/cycle [0.8 mg/m^2 on day 1; 0.5 mg/m^2 on days 8 and 15 of a 21–28 day cycle for ≤6 cycles]). Minimal residual disease (MRD) negativity was assessed by central flow cytometry (<0.01%). Data as of October 2, 2014 are presented (trial ongoing). Informed consent was obtained from all patients.
Results: 109 patients in the ITT218 received InO (CR/CRi rate, 81% [95% CI, 72–88]; MRD negativity rate in responders, 78% [95% CI, 68–87]; median remission duration [DoR], 4.6 [95% CI, 3.9–5.4] months). 67% and 32% of patients received InO as salvage (S) 1 and S2 (missing, n=1). For S1 *vs* S2, response was numerically higher, MRD-negativity was similar, and DoR was numerically longer (Table 1). CR/CRi rate was numerically lower for patients with (n=17) *vs* without (n=92) prior SCT (77% [95% CI, 50–93] *vs* 82% [72–89]). In the safety population, grade ≥3 febrile neutropenia rates were similar for S1 (n=95) *vs* S2 (n=43) (both 23%) and for patients with (n=24) *vs* without (n=115) prior SCT (29% *vs* 23%). Any grade hepatobiliary AE rates were significantly higher in S2 *vs* S1 (47% *vs* 17%; P<0.001) and numerically higher for patients with *vs* without prior SCT (42% *vs* 23%). For S1 *vs* S2, 36 *vs* 11 patients had poststudy SCT. Veno-occlusive liver disease (VOD) including post-SCT VOD occurred in 8% of S1 *vs* 16% of S2 patients (2 fatal in S1); in 21% with *vs* 9% without prior SCT (1 fatal in each cohort).

Table 1.

% (95% CI)[a]	S1 (n=73)	S2 (n=35)
CR/CRi[b]	88 (78–94)	69 (51–83)
CR	43 (31–55)	23 (10–40)
CRi	45 (34–57)	46 (29–63)
MRD-negativity in responders	78 (66–88)	79 (58–93)
Median DoR, months	5.2 (3.0–5.8)[c]	4.2 (3.2–4.6)[d]

[a]ITT218; [b]Best response (1–6 cycles); [c]n=62; [d]n=23

Summary/Conclusions: InO may provide clinical benefit in patients with relapsed/refractory ALL for both S1 and S2 therapy; hepatotoxicity risk increases with number of prior therapies and prior SCT.

S500

EARLY IMMATURE T-ALL AS DETERMINED BY ABSENCE OF BI-ALLELIC DELETION AT THE TCR GAMMA LOCUS IS NOT AN ADVERSE PROGNOSTIC FACTOR ON THE MRC UKALL2003 TRIAL

N Farah[1,2,*], AA Kirkwood[3], S Rahman[1], T Leon[1], S Jenkinson[1], RE Gale[1], K Patrick[4], S Samarasinghe[5], DC Linch[1], A Moorman[6], N Goulden[5], A Vora[4], MR Mansour[1]
[1]Haematology, UCL Cancer Institute, [2]Developmental Biology and Cancer Program, Institute of Child Health, UCL, [3]Cancer Research UK and UCL Cancer Trials Centre, UCL, London, [4]Haematology, Sheffield Children's Hospital, Sheffield, [5]Haematology, Great Ormond Street Hospital, London, [6]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle, United Kingdom

Background: Despite a marked improvement in the survival of children with T-cell acute lymphoblastic leukaemia (T-ALL), a significant proportion of patients will experience refractory disease or relapse. Previous studies using immunophenotyping and gene expression profiling identified the early T-cell precursor (ETP) phenotype as a subgroup of T-ALL with an inferior outcome. However, the diagnosis of ETP by immunophenotyping remains difficult to standardise, and gene expression profiling on T-ALL cases is not widely utilised. An alternative marker of immature T-ALL is Absence of Bi-allelic Deletion (ABD) at the TCRγ locus which has been shown to be associated with a very poor outcome. It is a marker that can potentially be standardised and assessed in real time for clinical use.
Aims: To investigate whether ABD status at the TCRγ locus adds prognostic information to paediatric T-ALL patients treated on the MRC UKALL2003 trial.
Methods: After informed consent, diagnostic DNA from 152 paediatric patients with T-ALL on the UKALL2003 trial was analysed by qPCR to amplify the region between the most 3' V region (*TRGV11)* and the most 5' J region (*TRGJP1)* of the TCRγ locus. Presence of an undeleted sequence in this region would indicate developmental arrest of the thymocyte at an early immature stage prior to V-J recombination. Patients were assigned to the ABD and non-ABD groups if fold change was ≥0.5 and <0.25 respectively. The undetermined group (fold change 0.25-0.5) were excluded from further analysis. Results were validated using the Illumina CytoSNP-850K array. Overall Survival (OS) and Relapse-free Survival (RFS) were plotted using Kaplan-Meier survival analysis. Cox regression and the log rank test were used to compare groups.
Results: Of 152 patients analysed by qPCR, 23 (15%) had ABD, 110 (72%) were non-ABD, and 19 (13%) were undetermined. Of the 133 informative patients, 118 had SNP array data that was consistent with the qPCR findings. There was no statistical difference in OS by ABD group (HR for ABD 1.34 (0.37–4.79); p=0.65). RFS was also very similar between the two groups (HR for ABD 1.68 (0.54-5.22); p=0.36) (Fig 1). MRD results were available for 102 patients. Median MRD levels were higher in the ABD group than the non-ABD group (2.5% positive cells at day 29 *vs* 0.02% respectively, p=0.031). The proportion of patients with indeterminate MRD was also higher in the ABD group (n=13, 57%) than in the non-ABD group (n=18, 19%) (p<0.0001). All eight ABD patients with high risk MRD received regimen C compared to 29 of 53 (55%) MRD high risk non-ABD patients (p=0.01). The good OS in ABD patients could not be attributed to coincidence of a favourable–risk NOTCH/FBXW7 genotype, as only 9% (2/23) of ABD patients were double mutant as compared to 31% (34/110) of non-ABD patients (p=0.03) (Figure 1).

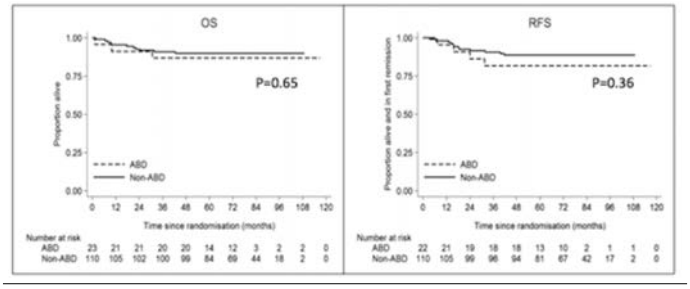

Figure 1. Kaplan-Meier curves for OS and RFS for T-ALL patients according to ABD status treated on the UKALL2003 trial.

Summary/Conclusions: We found no evidence that the molecular marker ABD added further prognostic value to the outcome of paediatric patients with T-ALL treated on the UKALL2003 trial. Therefore escalation of treatment to more intensive regimens based on ABD status is not justified on this protocol. Our failure to confirm previous reports of a poor outcome for the ABD patients could be due to the fact that this trial employed MRD risk directed therapy.

New Compounds in AML Treatment

S501

PHASE III RANDOMIZED TRIAL OF VOLASERTIB PLUS LOW-DOSE CYTARABINE (LDAC) *VERSUS* PLACEBO PLUS LDAC IN PATIENTS AGED ≥65 YEARS WITH PREVIOUSLY UNTREATED AML, INELIGIBLE FOR INTENSIVE THERAPY

KG, Biberach, [28]Goethe University, Frankfurt/Main, Germany

Background: Volasertib (V) is a potent and selective cell cycle kinase inhibitor that induces mitotic arrest and apoptosis by targeting polo-like kinase. In a randomized, open label, Phase II trial in patients (pts) with previously untreated AML, ineligible for intensive therapy, V+LDAC *vs* LDAC improved remission rate (31% *vs* 13%; p=0.052), event-free survival (EFS; HR 0.57 [95% CI 0.35–0.92]) and overall survival (OS; HR 0.63 [95% CI 0.40–1.00]; Döhner *et al.,* Blood 2014).
Aims: A Phase III trial (NCT01721876) was conducted to confirm the Phase II results.
Methods: Pts were randomized 2:1 (stratified by ECOG [0/1 *vs* 2] and type of AML [*de novo vs* secondary]) to receive LDAC (20 mg s.c. BID Days 1–10 Q4W) and either V (350 mg; 1-hr iv infusion Days 1 and 15 Q4W) or placebo (P). The primary analysis was performed after completion of recruitment (Nov 2014) and focused on efficacy in pts randomized ≥5 months before clinical cut-off. Objective response (OR; complete response [CR]+CR with incomplete hematological recovery [CRi]; blinded central review) was the primary endpoint, and OS was the key secondary endpoint. An additional OS analysis was performed in all randomized pts (Nov 2015).
Results: 666 pts were treated (444 V+LDAC; 222 P+LDAC). The primary analysis included 371 pts (246 V+LDAC; 125 P+LDAC); pt characteristics were balanced: median age, 75/75 yrs; secondary AML, 47%/49%; adverse genetics, 32%/32%, respectively. The percentage of pts with OR was not statistically significantly higher with V+LDAC *vs* P+LDAC (25.2% *vs* 16.8%; Odds ratio 1.66 [95% CI 0.95–2.89; p=0.071]), and thus the primary endpoint was not met. A negative OS trend was seen for V+LDAC *vs* P+LDAC (median OS: 4.8 *vs* 6.5 mos; HR 1.26 [95% CI 0.95–1.67; p=0.113]). Adverse event severity increased with V+LDAC *vs* P+LDAC, with fatal infection frequency of 16.6% *vs* 5.1%, considered to be the main reason for the negative OS trend. Consequently, the study was unblinded, and investigators/pts could stop/continue treatment based on individual benefit-risk evaluations. Additional exploratory analyses were conducted. The protocol allowed doses to be missed or delayed for medical reasons; this dosing flexibility resulted in differences of overall treatment intensity, and a better outcome for pts treated in the V+LDAC arm at lower-dose density *vs* higher-dose density was shown. Competing risk modeling of survival endpoints (events resulting from lack of efficacy or non-tolerability) confirmed the antileukemic effect of V+LDAC. An additional OS analysis was performed on all randomized pts from a Nov 2015 snapshot. The HR for OS was 1.06 (95% CI 0.88–1.28; p=0.552); these OS results may be affected by the communication of primary analysis results, unblinding and subsequent treatment decisions.
Summary/Conclusions: This Phase III trial did not meet the primary endpoint and did not confirm the promising efficacy results from the randomized Phase II study. Pts treated with V+LDAC had higher risk for fatal infections compared with P+LDAC, resulting in a negative OS trend at the primary analysis. Pt management/medical decision making (dose density) influenced the outcome and might have been affected by the blinded trial design. Updated results one year after unblinding show largely overlapping OS for both treatment arms. Com-

peting risk modeling of survival endpoints confirmed the antileukemic effect of V+LDAC and supports investigation of modified V doses and schedules to improve tolerability. The trial is still ongoing; updated/final results will be presented at the meeting as available.

S502

CPX-351 TREATMENT OF PREVIOUSLY UNTREATED OLDER AML PATIENTS WITH HIGH RISK AML MARKEDLY INCREASES THE RESPONSE RATE OVER 7+3 IN PATIENTS WITH FLT3 MUTATIONS

Background: CPX-351 is a nano-scale liposomal formulation of 5:1 molar ratio cytarabine and daunorubicin that exhibits marked efficacy improvements among poor risk AML patients. A phase III study of CPX-351 *vs* 7+3 treatment in older high-risk (*e.g.* secondary) AML patients is nearing completion (NCT01696084).
Aims: This report correlates induction response (CR+CRi) with baseline FLT3 ITD/TKD+, NPM1+, and CEBPA+ mutations from the Phase III study.
Methods: Patients 60-75 years of age with t-AML, $_{MDS}$AML, $_{CMML}$AML and *de novo* AML with MDS cytogenetic abnormalities were eligible for this open label randomized study. 153 patients were randomized to CPX-351 (100units/m^2, days 1, 3, and 5) and 156 patients to 7+3 (cytarabine 100mg/m^2/dayx7 days, daunorubicin 60mg/m^2 days 1, 2, and 3) induction. Data for response was reviewed independently and in a blinded manner by the study's hematopathologist. Patients were assessed at baseline for FLT3, NPM1, and CEBPA mutations.
Results: Mutation status was determined in 278/309 (90%) patients for FLT3 ITD, 275/309 (89%) for FLT3 TKD, 282/309 (91%) for NPM1, and 270/309 (87%) for CEBPA. FLT3 mutations (ITD+ and/or TKD+) were found in 44 (16%) patients. Mutations occurred in 26 pt (9%) for NPM1, and 15 pt (6%) for CEBPA. The complete remission data stratified by FLT3 ITD+, FLT3 TKD+, NPM1+, and CEBPA+ status are presented in the Table 1. Compared to control, CPX-351 treatment produced higher response rates among all patients (47.7% *vs* 33.3%), all FLT3 mutated patients (68.2% *vs* 27.3%, p=0.148), FLT3 ITD+ patients (12/19 (63.2%) *vs* 3/14 (21.4%)), FLT3 TKD+ patients (5/6 (83.3%) *vs* 4/11 (36.4%)), and NPM1+ patients (92.3% *vs* 53.9%). Most FLT3 ITD+ patients were NPM1- (26/33, 78.8%) with responses in 8/15 (53.3%) CPX-351 *vs* 2/11 (18.2%) in 7+3 patients.
Summary/Conclusions: Treatment with CPX-351 appears to be associated with improved response rates in patients with common AML mutations, including those associated with poor outcomes, such as FLT3 ITD mutations. Preliminary findings from cytotoxicity assays using fresh AML patient blasts suggest that AML blasts exhibiting FLT3 ITD mutations were more sensitive to CPX-351 than FLT3 WT blasts. Moreover, increased cytotoxicity was associated with increased uptake of CPX-351 liposomes by AML blasts. While the clinical findings are based on small patient numbers, the remission data presented here, combined with the early preclinical data provide a provocative hypothesis for how CPX-351 might be advantageous for specific types of AML mutations and provide a rationale for expanded trials of CPX-351, particularly in the FLT3 ITD mutated population, which is expected to respond poorly to conventional treatment regimens.

Sammons Cancer Center, Dallas, [14]Seattle Genetics, Inc., Bothell, [15]Gehr Family Center for Leukemia Research, City of Hope, Duarte, United States

Background: Many older patients with AML are treated with hypomethylating agents (HMAs) or other low-intensity therapy (Dombret 2015, Kantarjian 2012). SGN-CD33A (vadastuximab talirine; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine (PBD) dimer. Upon binding, 33A is internalized and transported to the lysosomes where PBD dimer is released via proteolytic cleavage of the linker, crosslinking DNA, and leading to cell death. Enhanced cytotoxicity was observed in preclinical studies combining 33A+HMA (azacitidine or decitabine), with HMA priming upregulating CD33 and increasing incorporation of PBD dimer (Sutherland 2015).
Aims: A combination cohort in a phase 1 study (NCT01902329) was designed to evaluate the safety, tolerability, pharmacokinetics, and antileukemic activity of 33A in combination with an HMA.
Methods: Eligible patients (ECOG 0– 1) must have previously untreated CD33-positive AML, and have declined intensive therapy. 33A (10 mcg/kg) was administered via outpatient IV every 4 weeks on the last day of HMA (azacitidine or decitabine [5-day regimen], standard dosing). Patients with clinical benefit could continue treatment until relapse or unacceptable toxicity. Investigator assessment of response was per IWG criteria; CRi required either platelet count of ≥100,000/μL or neutrophils of ≥1,000/μL (Cheson 2003).
Results: Fifty-three patients (64% male) with a median age of 75 years (range 60 – 87) were treated with the combination therapy. Nineteen patients (36%) had adverse cytogenetic risk (MRC) and 30 patients (57%) had intermediate cytogenetic risk. Forty-eight patients (91%) were treatment naïve and 5 patients (9%) had received prior low-intensity therapy for MDS. At baseline, patients had a median of 45.9% BM blasts. Patients were on treatment for a median of 15.6 weeks (range 2 – 68) and 27 patients (51%) remain on study treatment; no DLTs were reported. Grade 3 or higher adverse events (AE) reported in ≥20% of patients were febrile neutropenia (47%), thrombocytopenia (42%), anemia (34%), and neutropenia (28%). Other common treatment-emergent AEs regardless of relationship to study treatment were fatigue (55%), nausea (43%), constipation (38%), decreased appetite (36%), and peripheral edema (36%). Thirty- and 60-day mortality rates were 2% and 8% respectively with no treatment-related deaths reported. Thirty-seven of the 49 efficacy evaluable patients (76%) achieved CR (17), CRi (19), or PR (1), with a median time to remission of 2 cycles (range 1 – 4); the median relapse-free survival in CR/CRi patients is currently 6.9 months (range 0+ – 11+). Thirteen of 17 patients (76%) with adverse cytogenetic risk achieved remission. Of the responding patients, 14 of 33 (42%) achieved MRD negativity by local or central flow cytometry.

Thirty-seven patients (70%) were alive at the time of this data cut with a median follow-up of 4.7 months (range 0.5-15.6). Survival trends appear similar in patients ≥75 years as in patients <75 years.

Summary/Conclusions: The combination of 33A with HMA was well tolerated and capable of inducing deep and durable remissions. In ~50 treated patients, activity with the combination appeared greater and occurred more rapidly than what is historically expected from HMA alone in this patient population. The observed low early mortality rate and the 76% overall remission rate in AML patients with poor risk factors are particularly encouraging. A global phase 3 randomized trial of 33A+HMA *vs* HMA alone is planned for 2016.

S504

PHASE 1B RESULTS OF IDASANUTLIN+CYTARABINE (ARA-C) IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS (PTS)

Background: Idasanutlin is a potent, oral MDM2 antagonist. A Phase 1b study was conducted to assess the safety and efficacy of idasanutlin+ara-C in relapsed/refractory (R/R) AML pts.

Aims: The primary endpoint was to identify the maximum tolerated dose and/or recommended dose and safety profile of idasanutlin+ara-C. Secondary endpoints included complete remission (CR) rate, complete remission with incomplete platelet (CRp) or hematologic recovery (CRi), morphologic leukemia free state (MLFS), composite complete remission (CRc, CR+CRp+CRi) rate, pharmacokinetics (PK), and exploratory analyses of predictive/prognostic biomarkers.

Methods: In the dose escalation phase, R/R AML pts or those not considered candidates for standard induction therapies were treated with escalating doses of the initial idasanutlin formulation dailyx5 days (d)+ara-C 1 g/m^{2}x6d. After identification of the recommended dose, an expansion cohort in R/R AML pts treated with ≤2 prior regimens was enrolled. A bridging arm was added to characterize the safety and PK of a spray dried powder (SDP) formulation of idasanutlin. CRs were confirmed ≥28d after initial assessment. TP53 mutation and flow cytometry of MDM2 expression in blasts were assessed as potentially predictive/prognostic by association with CRc.

Results: A total of 76 pts (1 pt was subsequently identified to have CMML and not AML) were treated with the combination therapy. Dose escalation patients (n=23) were treated with 400 mg qd (n=10), 400 mg bid (n=7), or 600 mg bid (n=6) of idasanutlin with ara-C. While not meeting protocol specified DLT criteria, diarrhea incidence and grade tracked with increasing dose and thus the recommended dose was 600 mg bid. Twenty-one pts were subsequently treated in an expansion cohort with 600 mg bid idasanutlin+ara-C. Thirty-two pts were enrolled in the bridging arm with either 300 mg bid (n=19) or 400 mg bid (n=13) of SDP idasanutlin+ara-C. Demographics and best responses are noted in the Table 1. The CR proportion was 25% (19/75 pts); the CRc proportion was 29% (22/75 pts), and the CR+CRp+CRi+MLFS proportion was 33% (25/75). Patients with CRc were followed until relapse or until 1 year (yr) from start of therapy; median duration of response is ~6.4 months (range 1.1 to 11.9 mos). Five pts remain in CR and continue in the 1 yr follow up period; 4 pts were in CR at the final visit ~1 yr from start of treatment. PK exhibited C_{max} at ~6h, $t_{1/2}$ of 1d, and dose proportionality. The SDP formulation doubled relative bioavailability. MDM2% positivity in CD45dim AML blasts by flow cytometry suggests that higher levels of MDM2 expression are associated with response (p=0.00049). TP53 mutation status was not associated but did trend with response (p=0.08) as predictive/prognostic association derives from negative predictive value of the small proportion of mutant patients. By contrast, MDM2 protein expression by flow cytometry displayed pronounced association with CRc when analyses were restricted to TP53 WT-only patients (p=0.0021).

Summary/Conclusions: Treatment with idasanutlin+ara-C resulted in durable CRs. Five of the 22 pts who achieved a CRc (23%) proceeded to transplant following therapy, demonstrating that this combination is a promising therapeutic option in R/R AML. Biomarker data suggests that identifying pts in which TP53 activity may be therapeutically enhanced may provide for improved outcomes. A Phase 3 trial is open and accruing.

PHASE I/II STUDY OF VOSAROXIN AND DECITABINE IN NEWLY DIAGNOSED OLDER PATIENTS (PTS) WITH ACUTE MYELOID LEUKEMIA (AML) AND HIGH-RISK MYELODYSPLASTIC SYNDROME (MDS)

N Daver[1,*], H Kantarjian[1], G Garcia-Manero[1], E Jabbour[1], G Borthakur[1], S Pierce[1], K Vaughan[1], K Vaughan[1], J Ning[2], G Gonzalez[2], N Pemmarjau[1], T Kadia[1], M Konopleva[1], M Andreeff[1], C DiNardo[1], J Cortes[1], R Ward[3], A Craig[3], F Ravandi[1]

[1]Department of Leukemia, [2]Department of Biostatistics, University of Texas MD Anderson Cancer Center, Houston, [3]Sunesis Inc., San Francisco, United States

Background: Vosaroxin, is a first-in-class anti-cancer quinolone derived (AQD) DNA topoisomerase II inhibitor currently under evaluation for the treatment of pts with AML and high-risk MDS.

Aims: To determine the overall response rate including complete response (CR)+CR without platelet recovery (CRp)+CR with insufficient hematological recovery (CRi), safety and early mortality of vosaroxin and decitabine in newly diagnosed older pts with AML.

Methods: Pts were eligible if they had untreated AML or high-risk MDS (≥10% blasts), were 60 years of age or older, had adequate performance status (ECOG ≤2) and organ function. In the phase I the first six pts received vosaroxin 90 mg/m^2 daily on Days 1 and 4 with decitabine 20 mg/m^2 daily for 5 days repeated in approximately 4 to 5 week intervals for up to 7 cycles. This dose was well tolerated in the 6 pts. However, due to occurrence of 8 episodes of grade 3/4 mucositis in the subsequent 16 pts the induction dose of vosaroxin was reduced to 70 mg/m^2. 40 subsequent pts received vosaroxin 70mg/m2 in induction..

Results: 62 pts (55 AML, 7 high-risk MDS) with a median age of 69 years (range, 60 - 78) have been enrolled. They included 23 (37%) with diploid, 22 (35%) with adverse, and 17 (27%) pts with miscellaneous cytogenetics. 18 (33%) pts with AML had antecedent hematological disorders (AHD) including 9 (16%) with MDS, 5 (9%) with MDS/MPN, and 1 (2%) with CLL. Four pts with AHD had received prior therapy including 5-azacytidine (n=1), decitabine (n=1), ruxolitinib+5-azacytidine (n=1), lenalidomide (n=1). Additionally, 10 (16%) pts had therapy-related disease. Median bone marrow blast %, median white blood cell, hemoglobin, & platelet counts were 36% (9-97), 3.6x10^9/L (0.4 - 57.0), 9.4 g/dL (6.8 - 13.1), and 33x10^9/L (7 - 333), respectively. All 62 pts were evaluable for response. The overall response rate was 74% including CR in 31 (50%), CRp in 10 (16%), and CRi in 5 (8%). Minimal residual disease by 19 color flow-cytometry was not detectable in 21 of 38 (55%) evaluable responders. The median number of cycles to response was 1 (1-4). Response by baseline characteristics is shown in Table 1.

	IDH1	9	33%	33%
	RAS	11	64%	18%

Eleven (18%) pts have proceeded to allogeneic stem cell transplant. The median follow-up is 11.0 months (2.8 - 27.5). The main therapy related grade ≥3 toxicities were mucositis in 11 (18%) and liver enzyme elevation in 8 (13%) pts.

The median overall survival (OS) for all pts is 9.8 months. Four-week and 8-week mortality for all pts were 0 and 13%, respectively. The induction dose of vosaroxin was 90 mg/m^2 in 22 pts and 70 mg/m^2 in 40 pts. The lower dose of vosaroxin was associated with reduced 8-week mortality (8% *versus* 23%), similar overall response (75% *versus* 73%), and improved OS (Figure 1).
Summary/Conclusions: Combination of vosaroxin and decitabine is effective in older pts with AML and high-risk MDS. The lower dose of vosaroxin 70 mg/m2 on days 1 and 4 is associated with improved outcomes.

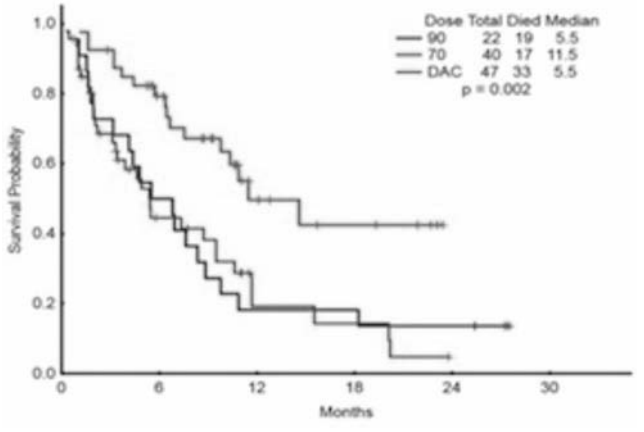

Figure 1. OS with vosaroxin and decitabine compared to historical cohort of pts treated with single agent decitabine at MDACC.

S506

GENETIC VARIATION AT HBS1L-MYB AND GFI1B-GTF3C5 INFLUENCES WHETHER JAK2 V617F MUTATED MPN PRESENT WITH ET OR PV

N Cross[1,*], J Score[1], A Chase[1], J Baxter[2], J Ewing[3], L Wallis[4], J Chacko[4], P Guglielmelli[5], D Colomer[6], B Bellosillo[7], B Navarro[8], M Gomez[8], JC Hernández-Boluda[8], C Besses[7], F Cervantes[6], S Koschmieder[9], A Reiter[10], A Green[2], C Harrison[11], A Vannucchi[5], W Tapper[1]
[1]University of Southampton, Southampton, [2]University of Cambridge, Cambridge, [3]Birmingham Heartlands Hospital, Birmingham, [4]Royal Bournemouth Hospital, Bournemouth, United Kingdom, [5]University of Florence, Florence, Italy, [6]Hospital Clinic, IDIBAPS, [7]Hospital del Mar, Barcelona, [8]Hospital Clínico Universitario, INCLIVA, Valencia, Spain, [9]Aachen University, Aachen, [10]Universitatsmedizin Mannheim, Mannheim, Germany, [11]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background: Evidence from epidemiological, familial and genetic studies indicate that common, low penetrance variants present in the general population contribute to the risk of developing MPN and also contribute to the phenotypic pleiotropy observed in these disorders. In a recent genome wide study we found that genetic variation at MECOM, TERT, JAK2 and HBS1L-MYB predisposes to JAK2-unmutated MPN. Furthermore, focused analysis of these four variants demonstrated that rs9376092 at HBS1L-MYB and the JAK2 46/1 haplotype specifically influence whether JAK2 V617F mutated cases present with PV or ET.
Aims: It is likely that variation at other genetic loci influence disease phenotype in MPN. Our aim was to identify inherited genetic factors on a genome wide basis that influence whether JAK2 V617F positive MPN patients present with PV or ET.
Methods: We undertook a two stage genome-wide association study. At stage 1,556 ET and 556 PV patients with JAK2 V617F were genotyped using Illumina Human OmniExpressExome v1.2 BeadChips. Following standard quality control, allelic chi-square tests were used to compare ET and PV cases. At stage 2, significant SNPs were genotyped in four additional JAK2 V617F-positive ET/PV cohorts from the UK (n=180), Spain (n=664), Italy (n=547) and Germany (n=74). The final effect size and significance of SNPs was determined by a fixed effects meta-analysis. The relationship with disease subtype was determined by comparison of either ET or PV cases against healthy controls (stage 1; WTCCC2 n=5200) and linear regression was used to assess the relationship with JAK2 V617F mutation burden following normalisation using Blom transformation.
Results: After quality control and excluding the p arm of chromosome 9 due to recurrent aUPD in PV and to a lesser extent in ET, 650,386 SNPs were tested in 499 ET and 505 PV cases at stage 1. Using a combination of significance, clustering of significant linked SNPs and functional evidence, 163 SNPs were tested at stage 2. Meta-analysis of ET *versus* PV cases identified one SNP, rs9399137 43kb upstream of HBS1L and 83kb upstream of MYB, that achieved genome-wide significance (p_{META}=2.91x10^{-9}) without heterogeneity between cohorts (Cochran's Q test, p=0.31). One additional SNP, rs3011271 16kb downstream of GFI1B and 22kb upstream of GTF3C5, with moderate significance for ET *versus* PV (p_{META}=3.00x10^{-5}) and without heterogeneity between cohorts (p=0.18) also reached genome-wide significance (p_{META}=2.36x10^{-8}) when compared to V617F mutation level. In comparison with healthy controls, the HBS1L-MYB SNP predisposes to ET (p=2.01x10^{-6}, OR=1.41) while the GFI1B-GTF3C5 SNP predisposes to PV (p=1.66x10^{-7}, OR=1.49). Stratifying PV cases by 9p aUPD, showed that the association with GFI1B-GTF3C5 is restricted to PV cases with 9p aUPD (p=1.95x10^{-11} in cases with aUPD; p=0.67 in cases without aUPD). We found no evidence that previously reported SNPs at NR3C1 (glucocorticoid receptor), TET2, ATM, SH2B3, ERCC2 or CHEK2 influenced the development or phenotype of JAK2 V617F-mutated MPN.
Summary/Conclusions: On a genome wide level (excluding chromosome 9p), we have found that germline variation in the intergenic regions between HBS1L and MYB exerts the strongest influence on JAK2 V617F mutated MPN phenotype. In addition, variation between GFI1B and GTF3C5 predisposes to PV and in particular to cases with high JAK2 V617F mutation burden associated with 9p aUPD. Our findings indicate a complex interplay between somatic and germline genetics in MPN, and provides pointers towards the functional basis of the phenotypic pleiotropy of these disorders.

S507

TUMOR NECROSIS FACTOR RECEPTOR 2 MAY BE REQUIRED FOR CLONAL DOMINANCE OF JAK2 V617F MUTANT OVER JAK2 WILDTYPE CELLS

M Deininger*, W Heaton, A Senina, A Pomicter, J Marvin, S Swierczek, A Eiring, J Prchal, T O'Hare
University of Utah/Huntsman Cancer Institute, Salt Lake City, United States

Background: The JAK2^{V617F} mutation is detected in large subsets of patients

with myeloproliferative neoplasms (MPNs). The presence of JAK2^{V617}in a hematopoietic stem (HSC) or progenitor cell confers a proliferative advantage over native JAK2 counterparts. Several inflammatory cytokines are elevated in MPN patients and in murine models of JAK2^{V617F}-driven MPN, including tumor necrosis factor alpha (TNF-α). We have previously shown that JAK2 kinase activity regulates TNF-α expression, which in turn imparts a competitive advantage on JAK2^{V617F} expressing cells over their normal counterparts (Fleischman *et al.* Blood. 2011;118(24):6392-8).

Aims: 1. To identify the cellular source of TNF-α generation in JAK2^{V617} expressing hematopoietic cells.

2. To deliniate whether TNFR1 *vs* TNFR2 mediates TNF effects in MPNs.

Methods: We used FACS/intracellular staining to measure TNF-α expression in murine and human hematopoietic cells. Blocking antibodies or shRNA knockdown were used to specifically probe the role of TNFR1 *vs* TNFR2 for MPN colony formation. Colonies were genotyped by FACS (GFP) or DNA sequencing. TNFR1/R2 null hematopoietic cells were used in competitive repopulation experiments to interogate the functional relevance of TNFR1 *vs* TNFR2 for MPN pathogenesis.

Results: TNF-α was low in unstimulated hematopoietic cells. However, when cells were treated with lipopolysaccharide (LPS), TNF-α expression was 16-fold higher in HSCs of MF patients compared to normal controls ($p<0.005$), with significant but less pronounced differences in more mature populations. In a murine model of JAK2^{V617F} driven MPN, where JAK2^{V617F} cells are identified by GFP, TNF-α expression was 3-fold higher in JAK2^{V617F}-expressing hematopoietic stem cells (HSCs; GFP$^+$) compared to GFP$^-$ controls ($p<0.005$), irrespective of LPS stimulation. We initially treated JAK2^{V617F} mice with etanercept, a soluble TNF receptor fusion protein that binds and inactivates TNF-α, but found that etanercept did not significantly restrain JAK2^{V617F}-associated WBC or hematocrit increases over a 10-week period, despite suppression of plasma TNF-α activity. As TNF-α may activate pro-apoptotic (predominantly through TNFR1) and pro-survival pathways (predominantly through TNFR2), we reasoned that global (etanercept) blockade of TNF-α may not shift the balance in favor of normal hematopoiesis. To investigate this we sorted primitive (Lin$^-$, cKit$^+$) cells from mice with JAK2^{V617F}-induced MPN by TNF receptor expression. TNFR2$^+$ cells showed significantly increased colony formation compared to TNFR1$^+$ cells, demonstrating that TNFR2 expression is associated with increased clonogenic potential. Next we treated these primitive cells with specific antibodies blocking TNFR1 or TNFR2 and assessed colony formation. Blocking TNFR2 resulted in decreased colony formation, while blocking TNFR1 increased colony formation. Analogous results were seen in CD34$^+$ cells from MF patients. Additionally in samples heterozygous for JAK2V617F, TNFR2-blocking antibodies selected JAK2 wild type over V617F mutant colonies. Preliminary results from murine TNFR1 and TNFR2 null models and shRNA knockdown of TNFR1 and TNFR2 suggest that lack of TNFR2 but not TNFR1 favors outgrowth of wild type cells.

Summary/Conclusions: Our data suggest that TNF-α generated by primitive MPN cells promotes their survival through activation of TNFR2, suggesting that selective inhibition of TNFR2 may shift the equilibrium from MPN toward normal hematopoiesis and that TNFR2 blockage may be useful to treat MF and other myeloproliferative neoplasms.

THE JAK2V617F MUTATION IS A POTENTIAL TARGET FOR CANCER IMMUNE THERAPY

MO Holmström[1,2,*], MD Hjortsø[2], SM Ahmad[2], Ö Met[2], E Martinenaite[2], C Riley[1], PT Straten[2], IM Svane[2], HC Hasselbalch[1], MH Andersen[2]

[1]Department of Hematology, Roskilde Sygehus, University Hospital Copenhagen at Roskilde, Roskilde, [2]Center for Cancer Immune Therapy, Department of Hematology, Herlev Hospital, Herlev, Denmark

Background: More than 50% of patients with Philadelphia chromosome negative chronic myeloproliferative neoplasia (MPN) harbor the *JAK2*V617F mutation. This is an acquired somatic mutation, and is found exclusively in myeloid malignancies, rendering it a cancer specific antigen and thus an attractive target for cancer immune therapy.

Aims: By this study we wish to clarify if the *JAK2*V617F mutation is recognized by the immune system, hereby proving the potential of cancer immune therapy as a whole new treatment modality for the *JAK2*V617F mutated MPNs.

Methods: We used the database www.syfpeithi.de to identify epitopes in the mutated JAK2 peptide with high affinity for HLA-A2. We chose the HLA-A2 restricted nonamer peptide JAK201 containing the V617F valine to phenylalanine substitution as the most promising candidate. A specific T cell culture was established from peripheral blood mononuclear cells (PBMCs) from an HLA-A2 positive healthy donor by stimulating with autologous dendritic cells, JAK201 peptide and cytokine as previously described[1]. Enzyme Linked ImmunoSPOT (ELISPOT), intracellular cytokine staining (ICS) and Cr51 cytotoxicity assays were used to analyze the reactivity of the specific T cells. The T cells were either stimulated with JAK201 peptide, T2 cells, HLA-A2 or HLA-A3 positive K562 cells or non-HLA K562 cells. T2 cells are unable to present endogenous peptides and thus only present exogenous peptide – in our experiments the JAK201 peptide. The HLA-A2 positive cancer cell lines UKE1 and SET2, which both harbor the *JAK2*V617F mutation, were used as target cells for the analyses of the T cells' reactivity against *JAK2*V617F mutated cancer cells.

Results: First we analyzed the capacity of the specific T cells to release TNF-α and IFN-γ upon stimulation with JAK201 peptide. Release of both cytokines upon stimulation with JAK201 peptide was confirmed by ELISPOT (Figure 1A and B) and ICS (data not shown). Next we showed, that the specific T cells were able to kill T2 cells pulsed with JAK201 peptide (data not shown). K562-A3 cells pulsed with JAK201 peptide were not killed, whereas K562-A2 cells were killed, demonstrating that killing by the specific T cells is HLA-A2 restricted (Figure 1D). Next we wanted to investigate, if stimulation of T cells with cancer cells carrying the *JAK2*V617F mutation induces cytokine release and killing of the cancer cells. We thus stimulated T cells with the HLA-A2 and *JAK2*V617F positive cancer cell line UKE1. The JAK201 specific T cells released IFN-γ (Figure 1C) and TNF-α (data not shown) in response to stimulation with UKE1. The target cells were stimulated with IFN-γ 48 hours before assaying to increase their antigen presentation, and the T cells showed an enhanced release of IFN-γ upon stimulation with IFN-γ treated UKE1 cells (Figure 1C). Furthermore, T cells were able to kill UKE1 cells in a cytotoxicity assay, and in line with the above, we demonstrated an increased killing of the UKE1 cells after treatment with IFN-γ (Figure 1E). Initially the HLA-A2 and *JAK2*V617F positive cancer cell line SET2 was not killed in a cytotoxicity assay, but after stimulation with IFN-γ, the SET2 cells were readily killed by the JAK201 specific T cells (data not shown). Finally, transfection with *JAK2*V617F siRNA into UKE1 cells abrogated T cell mediated killing, whereas mock transfected UKE1 cells were killed by the T cells (Figure 1F). By this experiment we demonstrated, that killing of target cells is dependent upon the presence of the *JAK2*V617F mutation.

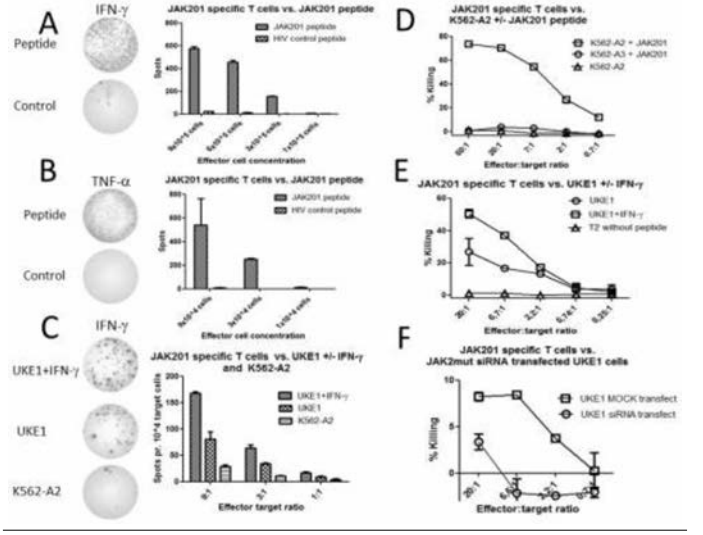

Figure 1.

Summary/Conclusions: By establishing a T cell culture specific for the *JAK2V*617F mutation we have shown that the immune system is able to effectively target cells carrying the *JAK2*V617F mutation. Thus cancer immune therapy in the form of adoptive T cell therapy and/or vaccination could prove to be new treatment modalities for MPN in the future.

CALRETICULIN MUTANT PROTEINS INDUCE MEGAKARYOCYTIC SIGNALING TO TRANSFORM HEMATOPOIETIC CELLS AND UNDERGO ACCELERATED DEGRADATION AND GOLGI-MEDIATED SECRETION

L Han, C Schubert, J Köhler, M Schemionek, S Isfort, T Brümmendorf, S Koschmieder, N Chatain*

Department of Hematology, Oncology, Hemostaseology, and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany

Background: Somatic calreticulin (CALR), Janus kinase 2 (JAK2) V617F, and thrombopoietin receptor (MPL) mutations are essentially mutually exclusive in myeloproliferative neoplasms (MPN), suggesting that they activate common oncogenic pathways. CALR mutants are confined to MPNs with aberrant megakaryopoiesis, such as essential thrombocythemia and myelofibrosis. Recent data showed that MPL is essential for CALR mutant-driven MPN. However, the characteristics of CALR mutants and their mechanisms of action are still poorly understood.

Aims: Our study was aimed at the elucidation of MPL-dependent and -independent mechanisms of CALR frameshift mutants to drive megakaryocytic dif-

ferentiation and oncogenic transformation. Furthermore, we investigated the cause of low cellular protein abundance of the CALR mutants.
Methods: The murine myeloid cell line 32D and human HL60 cells stably expressing the most frequent CALR mutants (del52 and ins5) were generated to analyze growth factor-independent growth, as the first steps of cellular transformation, in the presence and absence of MPL expression. Additionally, using brefeldin A, MG132, and tunicamycin treatment as well as generation of further mutants (*i.e.* YFP-fusion proteins), CALR mutant protein degradation and secretion were examined.
Results: In this report, we demonstrate that the most frequent CALR mutants, type 1 (del52) and type 2 (ins5), increase critical megakaryocytic transcription factors such as NF-E2 and GATA1. Interestingly, this occurred in an MPL-independent but AKT-dependent fashion, leading to the upregulation of *Mpl* and CD41 expression. These effects were also confirmed by the observation of spontaneous outgrowth of CALR mutant-transduced 32D cells, showing increased NF-E2, CD41, and *Mpl* expression as well as constitutive STAT5 activation and response to JAK inhibitor treatment. Interestingly, we found high cellular levels of mutated CALR and loss of downstream signaling after blockage of the secretory pathway and protein glycosylation. Hence, we demonstrate that low CALR mutant protein abundance is a result of accelerated secretion as well as ubiquitin- and proteasome-independent degradation. CALR mutant degradation was attenuated by MPL expression.
Summary/Conclusions: Together, our data illustrate how CALR mutants may initiate abnormal megakaryopoiesis, even in the absence of MPL, by a mechanism that most likely involves activated AKT. In addition, our findings show enhanced secretion, MPL-driven protein stabilization, and importance of Golgi signaling of the MPL receptor for CALR-mutant mediated transformation.

S510

EXPRESSION, REGULATION, AND FUNCTIONAL ROLE OF HERMES ADHESION RECEPTOR CD44 IN NEOPLASTIC MAST CELLS IN SYSTEMIC MASTOCYTOSIS

N Mueller[1,*], D Wicklein[2], G Eisenwort[1,3], A Boehm[1,4], H Herrmann[1,3], G Stefanzl[1,3], G Hoermann[3,5], WR Sperr[1,3], M Arock[6], U Schumacher[2], P Valent[1,3]
[1]Internal Medicine I, Division of Hematology and Hemostaseology, Medical University of Vienna, Vienna, Austria, [2]Institute of Anatomy and Experimental Morphology, University Cancer Center, University Medical-Center Hamburg-Eppendorf, Hamburg, Germany, [3]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, [4]Elisabethinen Hospital, Linz, [5]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria, [6]LBPA CNRS UMR8113, Ecole Normale Supérieure de Cachan, Paris, France

Background: The Hermes receptor CD44 is a multifunctional adhesion molecule that plays an essential role in the homing and expansion of neoplastic stem- and progenitor cells in various myeloid malignancies. Although mast cells (MC) are known to express CD44, little is known about the regulation and function of this receptor on neoplastic stem cells and MC in patients with systemic mastocytosis (SM).
Aims: The aim of this study was to define the expression and function of CD44 on neoplastic MC.
Methods: CD44 expression on primary neoplastic MC and various human MC lines was analyzed by immunocytochemistry and flow cytometry.
Results: CD34+/CD38- stem cells, CD34+/CD38+ progenitor cells, and KIT+/CD34- MC invariably expressed CD44 in all patients with indolent SM (ISM, 12/12), SM with associated hematologic non-MC-disease (SM-AHNMD, 4/4), aggressive SM (ASM, 3/3), and MC leukemia (MCL, 6/6). In addition, all human MC lines examined, including HMC-1.1, HMC-1.2, ROSA^{KITwt}, and ROSA^{KITD816V}, were found to express cytoplasmic CD44 and cell surface CD44. We next examined the regulation of expression of CD44 in neoplastic MC. Incubation with the MEK inhibitor RDEA119 (0.1-5 µM) or the STAT5 blocker pimozide (2.5-10 µM) for 48 hours resulted in a dose-dependent and significant downregulation of surface expression of CD44 compared to control medium (100%) in all MC lines examined (RDEA119, 2.5 µM: 71±9% surface staining intensity in HMC-1.1; 82±3% in HMC-1.2, 33±13% in ROSA^{KITwt}, and 31±3% in ROSA^{KITD816V}cells; pimozide, 7.5 µM: 59±7% surface staining intensity in HMC-1.1; 68±3% in HMC-1.2, 62±16% in ROSA^{KITwt}, and 80±3% in ROSA^{KITD816V} cells, p<0.05). In contrast, incubation with the demethylating agents decitabine (0.1-5 µM) or azacitidine (0.1-5 µM) for 96 hours resulted in a dose-dependent and significant upregulation of CD44 expression compared to control medium (100%) in all MC lines examined (decitabine, 5 µM; 210±50% surface staining intensity in HMC-1.1; 282±78% in HMC-1.2, 236±56% in ROSA^{KITwt}, and 198±55% in ROSA^{KITD816V} cells; azacytidine, 5 µM: 379±103% surface staining intensity in HMC-1.1; 429±105% in HMC-1.2, 412±135% in ROSA^{KITwt}, and 292±136% in ROSA^{KITD816V} cells; p<0.05). We were also able to detect soluble CD44 in the sera of patients with ISM, SM-AHNMD, ASM, and MCL as well as in the supernatants of neoplastic MC lines. In order to define a functional role for CD44 on MC, an *in vivo* xenotransplantation model using severe combined immunodeficient (SCID) mice, HMC-1.2 cells, and shRNA against CD44, were employed. In this model, the shRNA-mediated knock-down of CD44 in HMC-1.2 cells was found to lead to reduced MC expansion, reduced tumor formation, delayed ulceration, and prolonged survival compared to cells transduced with control shRNA (median survival in the CD44 shRNA group: 110 days *vs* 97 days in the control group; p<0.05). In these experiments, the formation of lung metastasis, quantified by human Alu-sequence-specific qPCR, was found to be particularly decreased (15-fold) in the CD44 knock-down group compared to controls.
Summary/Conclusions: CD44 is a relevant MC homing molecule that is expressed in neoplastic MC as well as in neoplastic stem- and progenitor cells in advanced SM. Our data also suggest that CD44 may serve as an interesting new target of therapy in patients with advanced SM.

Gene therapy, cellular immunotherapy and vaccination

S511

TUMOR-SPECIFIC GLYCOSYLATED CD43 IS A NOVEL AND HIGHLY SPECIFIC TARGET FOR ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROME

M Hazenberg[1,*], M Gillissen[1], M Kedde[2], E Yasuda[2], G de Jong[1], S Levi[2], A Bakker[2], P Hensbergen[3], T Beaumont[2], P van Helden[2], H Spits[2]
[1]Hematology, AMC, [2]AIMM Therapeutics, Amsterdam, [3] Center for Proteomics and Metabolomics, LUMC, Leiden, Netherlands

Background: Acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) are high-risk diseases with a poor prognosis. Even with intensive treatment regimens less than 50% of patients can be cured, and for the majority of patients - those over 65 years of age and/or patients with comorbidities - such intensive regimens are not feasible. Novel therapeutic approaches such as immunotherapy directed against a highly specific tumor target are highly needed.
Aims: The aim of our study was to identify novel therapeutic antibodies that are highly specific for AML and to discover novel tumor-specific antigens, widely expressed on AML and MDS but not on healthy hematopoietic and non-hematopoietic cells.
Methods: For this we made use of the oldest human tumor immunology model with proven efficacy available: an allogeneic HSCT patient with a potent graft *versus* AML allo-immune response. From this patient we isolated CD27+ IgG+ memory B lymphocytes and transduced these cells with Bcl-6 and Bcl-xL, thereby generating pre-plasmablast B cell clones that produce abundant antibodies. Supernatants of these B cell clones were used to screen for binding to surface antigens on the AML cell line THP-1.
Results: We identified an IgG1 antibody, AT14-013, that specifically interacted with AML cell lines THP-1, MOLM-13, SH-2 and others, and with leukemic blasts isolated from newly diagnosed AML and MDS patients from our clinic. AT14-013 did not interact with healthy hematopoietic and non-hematopoietic cells. This antibody was of donor origin and was antigen experienced as it contained 26/11 somatic hypermutations in the heavy and light chains, respectively. Target identification using mass spectrometry analysis and epitope mapping strategies with FLAG-tagged truncated variants of CD43 expressed by THP-1 that we created revealed CD43 as the target. CD43 is expressed by all hematopoietic cells, but AT14-013 targeted a specific, sialylated epitope on CD43 that is uniquely and widely expressed on all types of AML, as illustrated by its reactivity with blasts of each of 48 randomly selected AML and MDS patients in our clinic. AT14-013 induced antibody-dependent cell-mediated cytotoxicity and complement dependent cytotoxicity of AML cell lines and primary blasts.
Summary/Conclusions: We have identified onco-sialylated CD43 ($CD43^{os}$) as a novel tumor-specific target that is widely expressed on AML and MDS blasts. Antibodies against this target have high potential as therapeutic antibodies, either as a naked antibody or manufactured into an antibody-drug conjugate, bispecific T cell engager or CAR (chimeric antigen receptor) T cell.

S512

THE HIGHLY CLINICAL EFFICACY AND SAFETY OF THE AUTOLOGOUS ANTI-CD19 CHIMERIC ANTIGEN RECEPTOR T CELLS IMMUNOTHERAPY FOR 26 CASES WITH HEAVILY TREATED REFRACTORY B ACUTE LYMPHOBLASTIC LEUKEMIA

J Pan[1,*], J Yang[1], B Deng[2], X Zhang[1], Y Wu[2], Y Lin[1], C Tong[1]
[1]Department of Hematology, [2]Department of immunotherapy, Yanda Lu Daopei Hospital, Langfang, China

Background: the patients with refractory B-ALL are almost incurable by chemotherapy or allo-HSCT. Many data has demonstrated that anti-19-CART cell immunotherapy can result in CR and bridge to allo-HSCT for these patients.
Aims: to evaluate the clinical efficacy and safety of the second generation of anti-CD19-CART cells immunotherapy.
Methods: leukapheresis products from the patients themselves were cultured in the serum free medium containing antibodies to CD3, CD28, and IL2, IL7, IL15, IL21, transduced with the lentivirus encoding anti-CD19-CD3ξ-4-1BB CAR (Figure 1) for 7 days. After leukapheresis, patients received chemotherapy containing fludarabine 30mg/ m^2 per day IV and cyclophosphamide 250mg/ m^2 per day IV for 3 days except one patient who had persistent cytopenia. On day 7 or/and day 8, the cultured CART cells were infused. Between Jun. 31 2015 to Feb. 20 2016, total 26 cases with chemotherapy refractory B-ALL were treated with CART. After infusion of CART, the patients were followed until die, or relapse, or at least 15 days. In the included cases, the median age was 9 years old (2-59 years old), the median observation period was 100 days (19-204 days), and the median prior chemotherapy period was 14 months (1-36 months). 19/26 cases were hematological relapse, with 10/19 complicated extramedullary relapse, 7/26 cases remained minimal residual disease detected by flowcytometry (FCM-MRD) over 3 months although by alternative chemotherapy. Before CART therapy, all patients relapsed during chemotherapy or hadn't responded to 1 or more cycles of chemotherapy after relapsed except one patient suffered from severe infective pneumonia because she carried inherited immune related gene deficiency (LYST c.6031A>G/p.I2011V gene mutation) and was intolerated to chemotherapy. Before CART therapy, the median percentage of blasts in BM was 67% (11.5-96%) in the cases with hematological relapse, the FCM-MRD were 0.01-1.53% in the MRD+ group. The median infused total CD19- CAR T cells was $10x10^4$/kg (0.5-$140x10^4$/kg), the median cells transfection efficiency is 19% (1.2- 53.6%), the median cells viability is 85% (43-99.4%).
Results: On day 16 after CART infusion, 15/19 hematological relapse cases achieved CR or CRi (83.3%), 14/15 cases achieved CMR (FCM-MRD negative). 6/7(85.71%) FCM-MRD positive cases achieved CMR (FCM-MRD negative). During the first month, 1 case died from CRS, 2 cases died from leukemia progression. 2/16 who have achieved CR and been follow up for ≥60 days relapsed again, 1 is CD19- relapse. 6/6 cases who have achieved CR and bridged to allo-HSCT remain CCMR to now with median follow up period 40 days (24-106 days) after allo-HSCT. The median appearance of CRS was at day 6 (day 1-11), the median CRS grade was 1 (0-5). All MRD+ patients before CART therapy only developed ≤1 grade of CRS. The IL6 and INFγ elevates in PB and CSF in all detected patients (n=4).

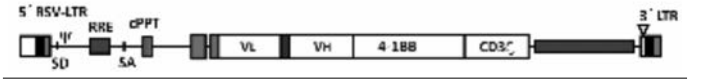

Figure 1.

Summary/Conclusions: Our anti-CD19-CAR T cells immunotherapy can result in high CR/CRi /CMR rate (including extramedullary leukemia) and low TRM for the heavily treated refractory B-ALL, which provide an opportunity to cure these advanced patients by allo-HSCT. The infused CART number in our patients is lower than many reports, which can dramatically reduce the cost of the therapy. The major complication is CRS. CRS grade is associated with the number of malignant B cells in PB. CD19-relapse has been observed.

S513

REGENERATION OF WT1 SPECIFIC CTLS UTILIZING IPSC TECHNOLOGY

T Maeda[1,2,*], S Nagano[1,2], K Masuda[1], T Kitawaki[2], A Takaori-Kondo[2], H Kawamoto[1]
[1]Department of Immunology, Institute for Frontier Medical Science Kyoto University, [2]Department of Hematology and Oncology, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Background: Current cancer immunotherapies mainly aim to activate and expand tumor antigen specific cytotoxic T lymphocytes (CTLs) *in vitro* or *in vivo*, but these methods are not so successuful because of the difficulty in preparing sufficient number of CTLs.
Aims: For successful cancer immunotherapy, we are trying to expand tumor antigen specific cytotoxic T lymphocytes (CTLs) by utilizing the iPS cell technology. When iPSCs are produced from antigen specific T cells, the rearranged configurations of T cell receptor (TCR) genes are inherited to the iPSCs, and when T cells are regenerated from such iPSCs, all of them should come to express the same TCR as the original one. Therefore it will become possible to obtain *de novo* generated tumor specific CTLs almost unlimitedly. In line with this concept, we have succeeded in regenerating MART-1 specific T cells (Vizcardo *et al.,* Cell Stem Cell, 2013).
Methods: We firstly established iPSCs from CTLs specific for WT1, expanded from healthy volunteers. CD4/8 DP cells were generated by culturing these T-iPSCs on Op9/DLL1 cells. By stimulating these DP cells by agonist peptide or anti CD3 Ab, CD8 T cells expressing CD8 alpha-beta heterodimers were formed. They can be expanded more than ten thousand fold by repeated TCR stimulation.
Results: Regenerated CD8 T cells exhibited very high antigen specific killing activity comparable to the original CTLs and were able to kill some leukemia cell lines and primaly leukemia cells which express endogenous WT1 protein and HLA A2402. In *in vivo* leukemia treatment model regenerated CD8 T cells elongated the survival of treated mice.
Summary/Conclusions: We have succeded in regenerating CD8 T cells with high antigen specific cytotoxic activity. This method could bring about a breakthrough in cancer immuno-therapy.

S514

MESENCHYMAL STROMAL CELLS GENERATED FROM POOLED MONONUCLEAR CELLS OF MULTIPLE BONE MARROW DONORS AS A RESCUE THERAPY FOR SEVERE STEROID-REFRACTORY GRAFT *VERSUS* HOST DISEASE: A MULTICENTER SURVEY

Z Kuci[1,*], H Bönig[2], H Kreyenberg[1], M Bunos[2], A Jauch[3], J Janssen[3], M Skific[4], K Michel[2], B Eising[1], G Lucchini[5], S Bakhtiar[1], J Greil[6], P Lang[7], O Basu[8], I von Luettichau[9], A Schulz[10], KW Sykora[11], A Jarisch[1], J Soerensen[1], E Salzmann-Manrique[1], E Seifried[2], T Klingebiel[1], P Bader[1], S Kuci[1]

[1]University Hospital Frankfurt, Department for Children and Adolescents, [2]Institute of Transfusion Medicine and German Red Cross Blood Center, Frankfurt am Main, [3]Institute of Human Genetics, University of Heidelberg, Heidelberg, Germany, [4]University Hospital Centre Zagreb, Clinical Department of Transfusion and Transplantation Biology, Zagreb, Croatia, [5]Great Ormond Street Hospital, Department of Hematology/Oncology, London, United Kingdom, [6]University Children's Hospital Heidelberg, Heidelberg, [7]University Children's Hospital Tuebingen, Tuebingen, [8]University Children's Hospital Essen, Essen, [9]University Children's Hospital München-Schwabing, Munich, [10]University Children's Hospital Ulm, Ulm, [11]Children's Hospital, Medizinische Hochschule Hannover, Hannover, Germany

Background: Mesenchymal stromal cells (MSCs) represent a heterogeneous cell population concerning their proliferative, differentiation and allosuppressive potential.
Aims: To circumvent donor-to-donor heterogeneity which may lead to inconsistent results after treatment of acute graft-*versus*-host disease (aGvHD) with mesenchymal stromal cells (MSCs) generated from a single or several individual donors, we developed a novel approach by generating MSCs from pooled bone marrow mononuclear cells (BM-MNCs) of eight healthy "third-party" donors.
Methods: BM-MNCs of 8 healthy "third-party" donors were isolated and frozen separately in cryobags. After thawing, BM-MNCs of 8 donors were pooled and cultured for 14 days in DMEM+5% platelet lysate (PL). Generated MSCs were frozen in 209 cryovials à 1.5x10e6 MSCs, representing the MSC-bank. Several vials were expanded for 12-14 days in DMEM+10% PL till the end of passage 2 and frozen as MSC-end products (MEPs). These products were evaluated for proliferative, differentiation and allosuppressive potential as well as genomic stability. Eighty-one MEPs generated from aliquots of the MSC bank were administered on a compassionate-use basis after approval of the regulatory authorities to 26 patients with steroid-refractory acute GvHD at a target dose of 1-2×10^6 MSCs/kg BW in 7 transplantation centers.
Results: MEPs exhibited typical MSC phenotype, trilineage differentiation potential and replicative senescence after 13 passages, as determined by increased expression of senescence-related markers such as p21 (CDKN1A) and p16 (CDKN2A). Chromosomal analysis of MEPs demonstrated a normal karyotype, whereas FISH analysis demonstrated a normal diploid pattern, indicating their genomic stability. Importantly, MEPs exerted a significantly higher allosuppressive potential than the mean allosuppressive potential of MSCs generated from the same donors individually. Administration of 81 MEPs to 26 patients with severe steroid-resistant aGvHD in 7 stem cell transplant centers who were refractory to many lines of treatment, induced a 77% overall response at the primary endpoint (day 28). Remarkably, although the cohort of patients was highly challenging (92% grade III/IV and only 8% grade II GvHD), after treatment with MEPs the overall survival rate at 2 years follow-up was 71±11% for the entire patient cohort, compared to 51.4±9.0% in GvHD clinical studies, in which MSCs were derived from single donors.
Summary/Conclusions: To our knowledge this is the first serum-free MSC bank generated from pooled BM-MNCs of multiple donors as a source for bulk production of clinical-grade MSCs with a predictable potency. Importantly, clinical data presented in this study demonstrated the *in vivo* safety and efficacy of MEPs, which may provide a novel therapeutic tool for the effective treatment of severe aGVHD.

S515

GENERATION OF CHIMERIC ANTIGEN RECEPTOR - MODIFIED MEMORY STEM CELL CD8+ T LYMPHOCYTES FROM NAIVE PRECURSORS BY MODULATION OF WNT/BETA-CATENIN PATHWAY OR INHIBITION OF AKT-SIGNALING

A Berger[1], I Weber[1], S Khan[1], M Chiemlewski[2], H Abken[2], M Theobald[1], UF Hartwig[1,*]
[1]III. Dept. of Medicine - Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, [2]Dept. of Internal Medicine I & Center for Molecular Medicine, University of Cologne, Cologne, Germany

Background: Adoptive cellular therapy (ACT) of chimeric antigen receptor (CAR)-reprogrammed T cells has advanced as a personalized and effective immunotherapy for leukemia and solid tumors. However, ACT, especially to solid tumors is often hampered by limited T cell engraftment and limited capability of terminally differentiated, high avidity effector T cells (T_{EFF}) to establish sustained antitumor immunity. Recently, long-living stem cell memory T cells (T_{SCM}) with an enhanced capacity for self-renewal and plasticity to differentiate into central memory (T_{CM}), effector memory (T_{EM}) and T_{EFF} could be shown to elicit potent antitumor responses, prolonged survival and memory. Moreover, modulating the Wnt/ß-catenin or PI3K-Akt-mTOR signaling pathways in T cells using inhibitors of glycogen-sythase-kinase-3β (TWS119) or Akt (inhibitor VIII) have emerged as promising approaches to block $CD8^+$ effector T cell differentiation and to facilitate the *in vitro* generation of T_{SCM} and T_{CM}.
Aims: In the present proof of concept study, we therefore investigated the generation of CD19 CAR expressing $CD8^+$ T_{SCM} from naive $CD8^+$ T lymphocytes by modulating T-cell differentiation using TWS119 or Akt inhibitor VIII to be used for ACT.
Methods: Naive $CD8^+CD45RA^+$ T cells isolated from PBMC by MACS® were polyclonally stimulated with CD3/CD28 Dynabeads in the presence of various cytokines and retrovirally transduced with a second generation CD19 CAR three days after activation. To promote a $T_{SCM/CM}$ phenotype transduced cells were either polyclonally restimulated or co-cultured with $CD19^+$ B-ALL (NALM16) together with TWS119 or Akt inhibitor VIII. CD19 CAR expression was determined by flow cytometry. IFN-γ ELISPOT and ^{51}chromium-release-cytotoxicity assays were used to analyze effector functions of CD19 CAR expressing T_{SCM} and T_{CM}. Adoptive transfer studies of redirected T cells into NALM-16 engrafted NSG mice were performed to evaluate antileukemic responses *in vivo*.
Results: Upon repetitive restimulation and TWS119/Akt inhibitor VIII treatment we obtained strong expansion of T cells with a $T_{SCM/CM}$ phenotype. In contrast, this effect was less pronounced by naive T cells cultured in the sole presence of interleukin (IL)-12 followed by IL-2, IL-7, IL-15, and IL-21, confirming that both Wnt/ß-catenin and PI3K-Akt-mTOR pathways play a key role in T cell differentiation. In addition, $CD8^+CD45RA^+CD45RO^-CD95^+CD62L^+CCR7^+T_{SCM/CM}$ showed high expression levels of CD19 CAR, elicited strong IFN-γ release and cytolytic activity to $CD19^+$ NALM-16 cells when compared to mock transduced controls. This effect was also seen in CD19 CAR positive total $CD8^+$T cells although less pronounced. First studies to evaluate the therapeutic efficacy of CD19-CAR redirected $T_{SCM/CM}$ revealed that upon adoptive transfer of 1-5x10^6T cells into NSG mice engrafted with NALM-16 B-ALL significant regression of leukemia could be observed in spleen and bone marrow. Again, antileukemic responses were also seen with CD19 CAR transduced T_{EM} and T_{EFF} but $T_{SCM/CM}$ appeared to be more effective when applied at lower numbers (1 x10^6 cells/mouse). Further studies are in progress to elucidate the functional properties of CD19 CAR $T_{SCM/CM}$ in more detail.
Summary/Conclusions: In conclusion, these proof of concept studies demonstrate that *ex vivo* generated $T_{SCM/CM}$ redirected to acute leukemia by retroviral transfer of optimized leukemia- or tumor-reactive CARs may be a promising approach to improve ACT.

S516

DISREGULATED MEGAKARYOCYTE MIGRATION AND MATURATION IS POSSIBLY DUE TO IMPAIRED BONE MARROW SYMPATHETIC NERVETHROUGH NESTIN+ MESENCHYMAL STEM CELL IN CHRONIC IMMUNE THROMBOCYTOPENIA

M Wang, LL Xu, JM Zhang, FE Feng, QM Wang, XS Zhao, Y Kong, XY Zhao, YJ Chang, LP Xu, KY Liu, XJ Huang, XH Zhang*
Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Impaired megakaryocyte maturation and reduced platelet production is a most important mechanism responsible for immune thrombocytopenia (ITP).Megakaryocyte (MK) maturation in the bone marrow microenvironment (BMME) is accompanied by increased expression of CXCR4 andits migration from the endosteal niche to the vascularniche, where MKs intrude proplatelets into the bone marrow (BM)sinus to release platelets.Thrombopoietin(TPO) is the major physiological regulator of the proliferation and differentiation of MKs,whereas MK migration is regulated by sympathetic nerves and the chemokine CXCL12, which is mainly produced by nestin+ mesenchymal stem cells (MSCs) in the BM.There is no information regarding MK migration or BMME in ITP.
Aims: We sought to investigate the migration and maturation status of MKsin chronic ITP, to measure the sympathetic nervous response, which regulates the migration and maturation of MKs, and to assess the variationin nestin+ MSCs, which produce the potent chemokine CXCL12 under the regulation and protection of sympathetic nerves.
Methods: BM samples were obtained from chronic ITP patients and healthy haematopoietic stem cell donors.The distribution of MKs, sympathetic nerve fibres, Schwann cells and nestin+ MSCs in BMME was analysed by immunohistochemistry and/or immunofluorescence, and quantitative analyses were conducted using confocal microscopy. BM nestin+ MSCs were sorted by flowcytometry. The quantity and apoptosis of nestin+ MSCs and the surface markers CXCR4 and β3-adrenergic receptor (adrb3)on nestin+ MSCs and CXCL12+ nestin+ MSCs were further analysed by flowcytometry.The expression levels of CXCL12 and adrb3 in nestin+ MSCs wereanalysed by real-time quantitative PCR.
Results: The percentage of CD41+ MKs adjacent to the CD34+ BM sinus and CXCR4+CD41+MKs in the BM were both strikingly reduced in chronic ITP patients compared with normal controls.The concentration of CXCL12 was also significantly lower in the BM of ITP patients,and the percentage of CD41+ MKs in the vascular niche and of CXCR4+CD41+MKs correlated with the concentration of BMCXCL12. The percentage of nestin+ MSCs among CD45-CD31-CD235a- stromal cellsin normal controls was 3.8 times higher than that in chronic ITP patients.Consistently, the percentage of live nestin+ MSCs in normal controls was also significantly increased, whereas apoptosis of nestin+ MSCs in ITP patients was significantly increased compared with normal controls. The proportion of CXCL12+nestin+ MSCs in normal controls was much higher than that in ITP patients, which was correlated with the concentration of CXCL12 in the BM.Sympathetic nerve fibres and Schwann cells adjacent todistinctive nestin+ MSCs and vasculature weremarkedlyreduced in the BMof ITP patients, andthe neurotransmitternorepinephrine and adrb3 in nestin+ MSCs were both significantly reduced in ITP patients.
Summary/Conclusions: This isthe first report to describe BMME and megakaryocyte migration in chronic ITP. Our research suggests that reduced activity of BM sympathetic nervesis associated with impaired MK migration and maturation, resulting in reduced plateletproduction. With reducedBM sympathetic nerves innervation, nestin+ MSCs arefunctionally compromised and reduced due to increased apoptosis, enhancing the dysregulatedmigration and maturation of MKsvia diminished CXCL12 signalling through CXCR4 on MKs. Protection of sympathetic nerves that prevent MSCapoptosis may provide a potentially powerful strategy to promotethrombopoiesis.

S517

FINAL SAFETY AND EFFICACY RESULTS FROM THE EXTEND STUDY: TREATMENT WITH ELTROMBOPAG (EPAG) IN ADULTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP)

J Bussel[1,*], MN Saleh[2], A Khelif[3], B Meddeb[4], A Salama[5], M Socorro O. Portella[6], P Burgess[7], RS Wong[8]
[1]Pediatric Hematology/Oncology, Weill Cornell Medicine, New York, [2]Comprehensive Cancer Center, The University of Alabama at Birmingham, Birmingham, United States, [3]Hôpital Farhat Hached, Sousse, [4]Hôpital Aziza Othmana, Tunis, Tunisia, [5]Charite-Universitätsmedizin, Berlin, Germany, [6]Novartis Pharmaceuticals Corporation, East Hanover, United States, [7]Novartis Pharma AG, Basel, Switzerland, [8]Sir YK Pao Centre for Cancer & Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, NT, Hong Kong

Background: EPAG increased platelets and reduced bleeding in 6-week and 6-month placebo-controlled trials in previously treated cITP patients. Adult patients with cITP initially enrolled in 4 EPAG studies could continue treatment in the open-label extension study, EXTEND.
Aims: To present the final long-term safety and efficacy results from EXTEND (Jun 2006 to Jul 2015).
Methods: EPAG was started at 50 mg and titrated to 25-75 mg/day or less often, based on platelet counts. Maintenance dosing continued after minimization of concomitant ITP medication and optimization of EPAG dosing. Patients who received 2 years of EPAG and transitioned off due to commercial availability of EPAG were considered to have completed EXTEND, whether or not they continued treatment with commercial EPAG.
Results: Of 302 patients enrolled, 67% were females and 38% were splenectomized; 45% (n=135) completed and 55% (n=167) withdrew. The most common reasons for withdrawal were adverse events (AEs; 14%), patient decision (13%), lack of efficacy (11%), and other (13%). The overall median duration of exposure was 2.4 years (range, 2 days to 8.8 years) and mean average daily dose was 50.2 (range, 1-75) mg/day. Median platelet counts increased to 50 Gi/L by Week 2. Overall, 86% (259/302) of patients achieved platelets 50 Gi/L in the absence of rescue therapy and 61% achieved platelets 50 Gi/L for 50% of on-treatment assessments; 126/248 (51%) patients maintained continuous platelet counts ≥50 Gi/L for at least 31 weeks (Figure 1). Incidence of bleeding symptoms (WHO grades 1-4) decreased from baseline (57%; 171/302) to 1 year (16%; 13/80). Proportionately more patients with platelet counts <10 Gi/L had grades 2-4 bleeding compared with those with higher platelet counts (59% *vs* ≤40%). Of 101 patients receiving concomitant ITP treatment at baseline, 34 stopped at least one ITP medication, and 39 had a sustained reduction or permanently stopped at least one ITP medication taken at baseline. The most frequently discontinued/reduced ITP medications were corticosteroids (n=34), danazol (n=5), azathioprine (n=4), and other (n=1). AEs occurred in 277 (92%) patients. Serious AEs (SAEs) occurred in 96 (32%) patients, and 24 (8%) patients had SAEs considered possibly drug-related. Drug-related SAEs occurring in 2 patients were cataracts (n=8), increased alanine aminotransferase (ALT) (n=4), deep vein thrombosis (n=2), increased aspartate aminotransferase (n=2), increased bilirubin (n=2), myocardial infarction (n=2), and pneumonia (n=2). AEs leading to withdrawal occurred in 41 (14%) patients. 28 (9%) patients experienced SAEs. The most frequent AEs leading to withdrawal were increased ALT (n=5), increased bilirubin (n=4), cataracts (n=4), and DVT (n=3). Nineteen patients (6%) reported thromboembolic events (TEEs), and 37 reported hepatobiliary laboratory abnormalities (HBLAs). Ocular-related events started on-therapy occurred in 80 (26%) patients; the most frequently occurring events were cataract (n=28; 9%) and conjunctivitis (n=12; 4%). At baseline, 192 patients had at least one cataract risk factor.

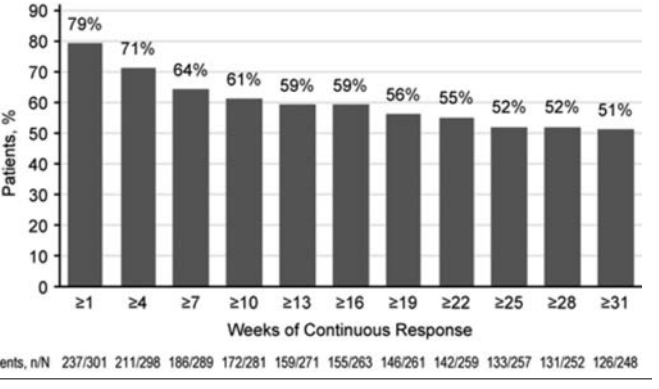

Figure 1. Maximum continuous weeks of maintaining platelets ≥50 Gi/L without rescue therapy.

Summary/Conclusions: Sustained platelet increases and reduced bleeding symptoms were observed in EPAG-treated patients with cITP throughout the study. Concomitant ITP medications were reduced without requiring rescue medications. EPAG was well tolerated with exposures 6 years. Monitoring of HBLA and cataracts is appropriate, even with long-term treatment. *Funding:* Study (NCT00351468) is/remains sponsored by GlaxoSmithKline; EPAG is an asset of Novartis AG as of March 2, 2015.

S518

IDENTIFYING THE GENETIC BASIS OF RARE BLEEDING AND PLATELET DISORDERS USING SYSTEMATIC PHENOTYPING AND GENOME SEQUENCING

E Turro[1,2,3,*], S Sivapalaratnam[1,2], D Greene[1,2,3], W Ouwehand[1,2,4]
[1]Haematology, University of Cambridge, [2]NHS Blood and Transplant, [3]MRC Biostatistics Unit, Cambridge Institute of Public Health, Cambridge, [4]Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Background: The majority of rare bleeding, thrombotic and platelet disorders (BPDs) do not have an identified genetic basis. Whilst whole genomic sequencing is now an affordable approach, small family sizes, variable penetrance and phenotypic variability are barriers to identifying the responsible genetic variants.

We have used a systematic phenotyping approach combined with novel clustering analyses to identify implicated genes and candidate causal mutations called by next generation sequencing (NGS).
Aims: Detection of novel genetic causes of BPDs.
Methods: A total of 848/1247 index cases and 78/87 affected relatives have been sequenced/phenotyped. The Human Phenotype Ontology (HPO) has been expanded to better capture clinical and laboratory data. Genes known to harbour variants responsible for BPDs have been screened. New algorithms have been developed to identify patients with similar phenotypes and a potentially shared genetic basis of disease.
Results: In 115 cases a definitive or likely genetic explanation has been identified and in 13 a partial genetic explanation. Four genes harbouring variants responsible for platelet abnormalities including *DIAPH1*, *SRC* and *TRPM7* have been identified. Variants responsible for atypical presentations of previously known syndromes, including *MYH9*-related disease and Hermansky-Pudalk syndrome, have also been identified. Finally, we have shown that large numbers of cases are explained by variants in recently reported genes, *e.g.* 27 by variants in *ACTN1*, eight by variants in the 5'UTR of *ANKRD26* and two by variants in *STIM1*. In total a long list of 45 genes have been identified as harbouring variants responsible or possibly responsible for BPDs in our collection and many are under further investigation.
Summary/Conclusions: A systematic method of detailed phenotyping and NGS has formed the basis of screening and clustering analysis. We have identified genes harbouring variants responsible for BPDs and have confirmed previous findings. Syndromic phenotypes have been better defined and a large number of candidate variants remain to be explored. Having used WGS as the main method of DNA sequencing will now allow these methods to be extended to regulatory regions of the genome.

S519

LONG-TERM HEMATOLOGIC, BIOMARKER, AND BONE RESPONSE TO ORAL ELIGLUSTAT IN PATIENTS WITH GAUCHER DISEASE TYPE 1: RESULTS FROM A PHASE 2 AND TWO PHASE 3 TRIALS

E Lukina[1,*], T Cox[2], P Mistry[3], N Weinreb[4], J Angell[5], S Gaemers[5], MJ Peterschmitt[5]
[1]National Research Center for Hematology, Moscow, Russian Federation, [2]University of Cambridge, Addenbrooke's Hospital, Cambridge, United Kingdom, [3]Yale University School of Medicine, New Haven, [4]University Research Foundation for Lysosomal Storage Disorders, Coral Springs, [5]Sanofi Genzyme, Cambridge, United States

Background: Gaucher disease is caused by deficient activity of lysosomal acid β-glucosidase, leading to glucosylceramide accumulation in macrophages and resultant hepatosplenomegaly, pancytopenia, and skeletal disease. Despite well-characterized symptoms and treatment availability, disease awareness is low. Diagnostic delays are common and can result in irreversible disease manifestations. As thrombocytopenia, anemia, and splenomegaly are common in Gaucher patients, hematologists often identify, evaluate, and manage the disease. Eliglustat, a substrate reduction therapy, is a first-line oral treatment for adults with Gaucher disease type 1 (GD1) who have a compatible CYP2D6 metabolizer phenotype (>90% of patients).
Aims: Summarize hematologic, bone, and Gaucher biomarker outcomes (chitotriosidase and others) in 3 clinical trials of eliglustat in adults with GD1.
Methods: Data were evaluated from 3 Sanofi Genzyme-sponsored trials: Phase 2 in treatment-naïve patients (NCT00358150, N=26); ENGAGE, a randomized, placebo-controlled Phase 3 trial in treatment-naïve patients (NCT00891202, N=40); and ENCORE, a Phase 3 imiglucerase-controlled trial in patients previously stabilized on ≥3 years of enzyme replacement therapy (NCT00943111, N=159).
Results: Primary endpoints were met in all 3 trials (Lukina *Blood* 2010; Mistry *JAMA* 2015; *Cox Lancet* 2015). In the Phase 2 study after 4 years, mean hemoglobin increased by 2.3±1.5 g/dL relative to baseline (BL) (BL=11.3±1.5 g/dL), mean platelet count increased by 95% (BL=69±21x10^9/L), spleen and liver volumes decreased, and mean lumbar spine bone mineral density went from the osteopenic to the normal range with corresponding reductions in biomarkers. In ENGAGE after 18 months, mean hemoglobin levels, platelet counts and spleen and liver volumes improved in placebo patients switched to eliglustat and continued to improve in patients continuing on eliglustat, with corresponding improvements in mean bone marrow burden (BMB) score and biomarkers. In former placebo patients, mean hemoglobin increased by 0.79±0.82 g/dL (BL=12.2±2.0 g/dL), mean platelet count increased by 40%±37 (BL=71.5±25.2x10^9/L) and mean BMB score decreased by 0.9 after 9 months on eliglustat. In patients on eliglustat for 18 months, mean hemoglobin increased by 1.02±0.84 g/dL (BL=12.1±1.8 g/dL), mean platelet count increased by 58%±41 (BL=75±14x10^9/L), and mean BMB score decreased by 2.2. In ENCORE after 2 years, stability with respect to hemoglobin, platelets, spleen, liver, bone, and biomarkers was maintained in former imiglucerase patients switching to eliglustat and in patients continuing on eliglustat. In former imiglucerase patients, 100% maintained stable hemoglobin (mean change: 0.04±0.78 g/dL) and 90% maintained stable platelets after 1 year of eliglustat (mean change: 1.46±31.7x10^9/L). In patients continuing on eliglustat, 97% maintained stable hemoglobin (mean change: 0.10±0.77 g/dL) and 94% maintained stable platelets (mean change: 2.27±17.6x10^9/L) after 2 years. Mean bone values, all in the normal range at baseline, remained normal after 1-2 years of eliglustat. In all 3 trials, eliglustat was generally well tolerated; 90% of patients overall elected to continue on eliglustat. Most adverse events were non-serious, considered unrelated to eliglustat, and mild or moderate in severity.
Summary/Conclusions: Long-term use of eliglustat in adults with GD1 was associated with continued improvements in clinical parameters in previously untreated patients and clinical stability in patients previously stabilized on enzyme replacement therapy.

S520

ROMIPLOSTIM IN SPLENECTOMIZED (SPLNX) AND NONSPLENECTOMIZED (NONSPLNX) PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP)

D Cines[1,*], J Wasser[2], F Rodeghiero[3], B Chong[4], M Steurer[5], D Provan[6], R Lyons[7], J Garcia Chavez[8], N Carpenter[9], X Wang[10], M Eisen[10]
[1]Perelman-University of Pennsylvania School of Medicine, Philadelphia PA, [2]University of Connecticut Health Center, Farmington CT, United States, [3]San Bortolo Hospital, Vicenza, Italy, [4]University of New South Wales, Sydney, Australia, [5]Innsbruck Medical University, Innsbruck, Austria, [6]Barts and the London School of Medicine and Dentistry, London, United Kingdom, [7]Texas Oncology, San Antonio TX, United States, [8]Unidad Médica de Alta Especialidad, Mexico City, Mexico, [9]Amgen, Uxbridge, United Kingdom, [10]Amgen Inc., Thousand Oaks CA, United States

Background: ITP is an autoimmune disorder with increased platelet destruction and insufficient platelet production. Romiplostim, a thrombopoietin receptor agonist, improves ITP outcomes compared with control (placebo or standard of care). Splenectomy removes a major site of sequestration of antibody-coated platelets, which might alter responsiveness to romiplostim or increase the risk of thrombosis or other complications. The efficacy and safety of romiplostim in splnx *versus* nonsplnx patients are not fully characterized.
Aims: This analysis evaluated safety and efficacy for splnx *vs* nonsplnx patients across 13 completed clinical studies of romiplostim in adults with ITP.
Methods: Data up to June 2014 were pooled. Informed consent was obtained in each ITP study. Safety was analyzed after ≥1 dose of romiplostim or control. Adverse event (AE) rates were adjusted for time of exposure. Efficacy included platelet response (any ≥50x10^9/L) and sustained platelet response (≥50x10^9/L ≥9 of 12 consecutive weeks). Four dose-finding studies that employed off-label doses were excluded from efficacy analyses.
Results: Safety was analyzed for 1111 patients (395 splnx; 716 nonsplnx). At baseline, splnx (*vs* nonsplnx) patients had longer median ITP duration (8.7 [95%CI: 7.7, 9.7] *vs* 1.6 [1.4, 2.0] yr), lower median platelet count (14.0 [12.0, 15.3] *vs* 19.3 [18.0, 21.0] x10^9/L), and a higher proportion with >3 prior ITP treatments (38% [33.2%, 43.0%] *vs* 12% [9.5%, 14.3%]). Splnx patients used more rescue medications (263.4 [95%CI: 251.5, 275.7] *vs* 153.3 [125.3, 138.8] per 100 pt-yr). Exposure-adjusted AE rates are provided in the Table 1. AE rates per 100 pt-yr in the control group for both splnx (1861.1 [95%CI: 1616.9, 2132.2]) and nonsplnx (1052.6 [989.3, 1119.0]) patients were higher than in the respective romiplostim group. Efficacy data were analyzed for 1024 patients (376 splnx; 648 nonsplnx). Median platelet counts increased with romiplostim and platelet responses were stable over time in both subgroups. For romiplostim, rates of platelet response (≥50x10^9/L at least once) were 82% (95%CI: 78%, 86%) for splnx and 91% (89%, 93%) for nonsplnx patients (p<.0001), and rates of sustained platelet response (≥50x10^9/L ≥9 of 12 consecutive weeks) were 68% (63%, 72%) and 80% (77%, 83%), respectively (p<.0001).

Table 1. Duration-adjusted AE Rate per 100 pt-yr (95% CI).

	Splnx (702.0 pt-yr)	Nonsplnx (1129.7 pt-yr)
Any AE	1226.4 (1200.6, 1252.5)	851.9 (835.0, 869.1)
Hemorrhage AEs	266.1 (254.2, 278.4)	140.8 (134.0, 147.9)
Infection AEs	156.7 (147.6, 166.2)	124.8 (118.4, 131.5)
Thrombotic AEs	6.3 (4.6, 8.4)	4.6 (3.4, 6.0)
Reticulin AEs*	0.4 (0.2, 7.4)	0.6 (0.2, 1.3)
Any serious AE	68.1 (62.1, 74.5)	44.1 (40.3, 48.1)
Any fatal AE	1.6 (0.8, 2.8)	2.7 (1.9, 3.9)
Any treatment-related AE	123.1 (115.0, 131.6)	82.1 (76.9, 87.6)

**AEs reported as bone marrow reticulin fibrosis, myelofibrosis, or reticulin increase across 12 studies; excluded 1 ITP study specifically designed for bone marrow assessment (reported separately).*

Summary/Conclusions: Removing a major site of platelet sequestration increased neither responsiveness nor toxicity of the thrombopoietin receptor agonist, romiplostim. In splnx patients, platelet response rates were lower, use of rescue medications was higher, and exposure-adjusted rates of hemorrhage AEs and infection AEs were higher. Differences between splnx and nonsplnx patients in disease duration/severity may have influenced concomitant treatments and safety/efficacy results. In conclusion, romiplostim safety generally was comparable between splnx and nonsplnx patients and platelet response rates were high in both populations.

Background: Both T cell receptor (TCR) and co-signalling molecules are required for T cell activation. Programmed death 1 molecule (PD-1) triggers an immune checkpoint and co-inhibitory signalling that leads to peripheral tolerance. Some PD-1 polymorphisms (SNPs) have been described and associated with autoimmune disease or cancer predisposition. Monoclonal antibodies target co-inhibitory molecules enhance the immune response against malignancies.
Aims: Establish the relevance of the PD-1 SNPs on the clinical outcome after allogeneic-hematopoietic stem cell transplantation (allo-HSCT).
Methods: We accomplished a retrospective analysis of the SNPs PD-1.1G/A (promoter) and PD-1.3G/A (4 intron) genotypes of the donor in a cohort of 1485 HLA-identical sibling transplants (SIB) from Spanish transplant centers performed between 1991 and 2013. T-cell depleted graft recipes were not included. PD-1 genotyping determined by allelic discrimination assays and detection system Life Technologies on DNA samples obtained from peripheral blood. Written informed consent was obtained. Statistical cumulative incidence was estimated for aGVHD, relapse and transplant related mortality (TRM) according to PD-1 donor's genotype. TRM was defined as death due other causes but relapse. Overall survival (OS) and relapse-free survival (RFS) were analyzed through Kaplan Meier method comparing curves by the log-rank test. Multivariate analysis was performed by Cox regression model.
Results: PD-1 allele and haplotype frequencies were comparable to other Caucasian populations. The haplotype PD-1.1G/PD-1.3G was the predominant (86.3%). There were statistical differences on age and gender demographic features in donors genotyped as PD-1AG or AA. The remaining clinical variables were comparable between these both genotype groups and between PD-1.3AA or PD-1.3AG/GG cohorts as well, except for the high proportion of myeloablative transplants on the last one. The aGVHD grades II-IV cumulative incidence was higher in recipes receiving grafts from homozygous PD-1.1G (p: 0.027) and PD-1.3A (p: 0.003) donors. Both genotypes were independent risk factors in multivariate analysis for grades II-IV aGVHD (p:0.033; HR2.2; 95%CI: 1.1 to 4.8 and p<0.001; HR4.5; 95%CI: 2 to 10.1 respectively). PD-1.3AA remained as independent risk factors for sever III-IV aGVHD (p<0.001; HR7.22; 95%CI: 2.6 to 19.7). The cumulative incidence for aGVHD grades II-IV was 64% in patients with "high risk" genotypes (PD-1.1GG/PD1.3AA), 32.6% for PD-1.1GG/PD-1.3AG or GG genotypes and 18% in those with of at least one A-allele at PD-1.1 position (p:0.001 and p:0.029). Despite the increased risk of aGVHD, we did not detect any influence of the PD-1 genotype and the secondary clinical endpoints (chronic GVHD, TRM, OS and relapse). We inferred the relative frequencies of genotypes and haplotypes for CTLA-4/PD-1 combinations so, on 883 donors we found that the most frequent matched observed (42.6%) involves the A alleles at both CTLA-4 SNPs coexisting with G allele at PD-1.1 and PD-1.3, without any association between CTLA-4 and PD-1 SNPs.
Summary/Conclusions: PD-1 genotypes carrying with the "high risk" alleles are independent risk factors for grades III- IV aGVHD. Other genotypes seem to be protective as it has been describe in other autoimmune mediated diseases. There were no statistically differences with the other clinical endpoints, suggesting that PD-1 should be relevant in the initial process of allorecognition, but not on prevention of relapses. These preliminary results should be confirmed by other studies. Financed by PI11/01690 and PI14/01646 and MTV3/120210.

Background: Management of patients with grade I acute graft *versus* host disease (GvHD) (a skin rash covering less than 15% of the body surface), is a matter of individual preference: some would treat with steroids, most clinicians would probably not treat. We hypothesized that treatment of grade I GvHD would significantly reduce the proportion of patients progressing to grade II GvHD.
Aims: To test whether steroid treatment of acute GvHD grade I, protects patients from progressing to grade II GvHD.
Methods: Nine Centers of the Italian Group for Bone Marrow Transplantation (GITMO), randomized 171 patients with acute grade I skin GvHD, to an *observation arm (n=85) or to* a *treatment arm (n=86)*- prednisolone 1 mg/kg/day for 5 days and then taper and discontinue on day +30. Patients in the *observation* arm, could be treated when GvHD grade II developed, at whatever interval from randomization. The primary end point of the study was progression to acute GvHD grade II. Secondary end points were: transplant related mortality (TRM), survival, infections and chronic GvHD.The two groups were balanced for diagnosis (p=0.9), disease phase (p=0.4) and donor type (p=0.4) The median age for the *observation* arm, was borderline higher than the *treatment arm (*46 *vs* 38 years, p=0.08).
Results: The cumulative incidence of progression to acute GvHD grade II, was 50% in the *observation* and 35% in the *treatment* arm (p=0.02). This difference was 58% *vs* 35%, (p=0.05) for HLA identical siblings (n=70) and 45% *vs* 36% for alternative donors (n=101) (p=0.3). Grade III-IV GvHD was diagnosed in 11 *observation vs* 12 *treatment* patients (13% *vs* 14%, p=0.8); the incidence was comparable in the two arms, also when stratified in HLA identical siblings (17% *vs* 18%) or alternative donor grafts (10% *vs* 11%). Moderate/severe chronic GvHD was comparable in the two groups (17% *vs* 19%). Patients in the *observation* arm had less bacterial infections (11 *vs* 23, p=0.05) less CMV reactivation episodes (66 *vs* 95, p=0.01), and comparable fungal infections (6 *vs* 8, p=0.4). Severe adverse events (SAE) were recorded less frequently in the *observation* arm (n=18) than in the *treatment* arm (n=31)(p=0.1). Cumulative incidence of transplant related mortality (TRM) was 20% (*observation*) *vs* 26% (*treatment*) (p=0.2). Relapse related death (RRD) was 25% *vs* 21%. Actuarial 1 year survival was 86% (*observation*) *vs* 82% (*treatment*) (p=0.3). Main causes of death in *observation/treatment* arms, were as follows : acute GvHD 7% -12%; chronic GvHD 4%>2%; infection, 6%>11%; and leukemia relapse 21% -17%.
Summary/Conclusions: In conclusion, steroid treatment of grade I GvHD prevents progression to grade II GvHD, however, it does not protect patients against GvHD grade III-IV, nor against chronic GvHD, and exposes patients to a higher risk of infections. For this reason there is no beneficial effect on TRM, relapse related death and survival. Based on this prospective trial, patients with grade I GvHD should be left untreated, untill GvHD resolves spontaneously or progresses to grade II.

S523

INFUSION OF BPX-501 (DONOR T CELLS TRANSDUCED WITH THE IC9 SUICIDE GENE) AFTER A/B T-CELL DEPLETED HAPLO-HSCT IN CHILDREN WITH ACUTE LEUKEMIA: PRELIMINARY RESULTS OF A PHASE I-II TRIAL

A Bertaina[1,*], B Lucarelli[1], P Merli[1], LP Brescia[1], V Bertaina[1], GM Milano[1], G Li Pira[1], S Ceccarelli[1], MG Cefalo[1], V Cirillo[1], V Trevisan[1], F Del Bufalo[1], A Moseley[2], F Locatelli[1,3]
[1]Hematology-Oncology, Ospedale Bambino Gesù, Roma, Italy, [2]Bellicum Pharmaceuticals, Houston, United States, [3]Pediatrics, University of Pavia, Pavia, Italy

Background: We recently conducted a prospective study (NCT01810120) which showed that haploHSCT after depletion of α/β T cells is a suitable and effective option for those children in need of an allograft and lacking an immediately available HLA-identical donor. However, recovery of adaptive T-cell immunity remains suboptimal and some patients experienced either relapse of the original disease or severe viral infections.
Aims: In light of these considerations, strategies aimed at accelerating early recovery of adaptive T-cell immunity are desirable.
Methods: We designed a phase I/II trial aimed at testing the safety and efficacy of post-transplant infusion of donor-derived T cells transduced with the new iC9 suicide gene (BPX-501) in children with either malignant or non-malignant disorders (NCT02065869); enrollment started in December 2014. Cells are administered within 14±4 days after haploHSCT. The phase I portion of the trial consisted of a classical 3+3 design with 3 cohorts, receiving escalating doses of BPX-501 cells of $2.5x10^5$, $5x10^5$, and $1x10^6$ cells/kg, respectively. Patients included in the phase II portion received the highest tolerated/recommended dose identified during the phase I portion of the study. As of February 15th 2016, 13 children with acute leukemia either in first or second complete remission (CR1/CR2) have been transplanted; 7 were males and 6 were females.

Median age at HSCT was 6.5 years (range 0.9-16.1); 10 pts had acute lymphoblastic leukemia (ALL) and 3 acute myeloid leukemia (AML). All pts transplanted in CR1 had either poor cytogenetic/molecular characteristics or high levels of minimal residual disease (MRD) at the end of induction therapy. All children received >10x10^6 CD34+ cells/Kg and <1x10^5 αβ+ T cells/Kg. A myeloablative regimen was given to all children, who also received as prophylaxis of graft-*versus*-host disease (GVHD) anti-thymocyte globulin (12 mg/kg over 3 days, from -5 to -3). Rituximab (200 mg/m^2) was administered on day -1 to further prevent EBV-related lymphoproliferative disorders. No pharmacological GvHD prophylaxis was employed after HSCT.

Results: Sustained primary engraftment occurred in all pts. The median time to infusion of BPX-501 cells was 16 days (range 13-18) after HSCT; median cell viability was 91% (range 65-97). Only one child developed gut and liver acute GVHD requiring infusion of AP1903, which controlled the disease. Five pts experienced skin-only grade I-II acute GVHD, this leading to a cumulative incidence (CI) of 38%. None of the patients at risk developed chronic GVHD. No patient died for transplant-related complications. One pt relapsed at 4 month after HSCT, the CI of disease recurrence being 12%. With a median follow-up of 6 months (range 3-12), the Kaplan Meier estimate of leukemia-free survival (LFS) is 88% (95% CI 38.7-98.1) compared to 76.6% (95% CI 65.4-84.5) in the 77 CR1/CR2 ALL/AML patients included in our previous study (Figure 1). BPX-501 cells progressively expanded over time after the infusion and are persisting, contributing to the recovery of adaptive T-cell immunity.

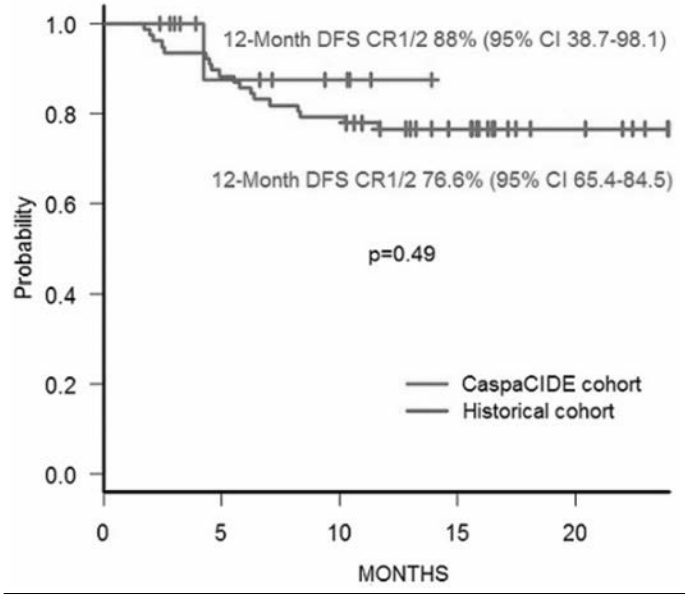

Figure 1.

Summary/Conclusions: These data indicate that the infusion of BPX-501 cells in children with acute leukemia given selectively manipulated haploHSCT results in the absence of transplantation-related mortality and chronic GVHD. Although the median observation time is still limited, the CI of disease recurrence is promising.

TRENDS IN THE USE OF HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA: A REPORT FROM THE ACUTE LEUKEMIA WORKING PARTY OF EBMT

S Giebel[1,*], E Beohou[2], M Labopin[3], A Seesaghur[4], F Baron[5], F Ciceri[6], J Esteve[7], NC Gorin[8], B Savani[9], C Schmid[10], S Wetten[4], M Mohamad[8], A Nagler[11]

[1]Cancer Centre & Institute of Oncology, Gliwice, Poland, [2]European Society for Blood and Marrow Transplantation, [3] Department of Hematology and Cell Therapy, Hôpital Saint Antoine, Paris, France, [4]Amgen Ltd., London, United Kingdom, [5]University of Liège, Liège, Belgium, [6]Ospedale San Raffaele, Milan, Italy, [7]Hospital Clínic, Barcelona, Spain, [8]Hôpital Saint Antoine, Paris, France, [9]Vanderbilt University, Nashville, United States, [10]Klinikum Ausberg, Ausberg, Germany, [11]Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: Indications for hematopoietic stem cell transplantation (HSCT) for adults with acute lymphoblastic leukemia (ALL) evolve over time and vary among countries as well as the methodology of the procedures.

Aims: The goal of this study was to assess general trends in the number of various types of HSCTs performed between years 2001 and 2012 in Europe.

Methods: Data reported to the European Society for Blood and Marrow Transplantation (EBMT) registry were used for this analysis. In addition, we evaluated HSCT rates with respect to the incidence of ALL in selected European countries.

Results: Altogether, 11602 first allogeneic (n=9938) or autologous (n=1664) HSCTs were performed in the period 2001-2012. Comparing years 2010-2012 and 2001-2003, the number of alloHSCTs performed in first CR increased by 108%, most prominently for transplantations from unrelated (219%) and mismatched related donors (89%). The number of HSCTs from matched sibling donors increased by 43%, while the number of autoHSCTs decreased by 71% (Table 1). The increase of the use of alloHSCT, irrespective of the disease stage, was stronger for Ph-pos (108%) than Ph-neg ALL (21%) while similar for B- and T-ALL. Among patients aged >55 years, the number of alloHSCT increased by 386% while among younger adults (18-55 years), by 48%. Between 2001 and 2003, peripheral blood was used as source of stem cells in 69% cases of alloHSCT, compared to 93% between 2010-2012 (p<0.0001). The use of bone marrow decreased from 30% to 6%, respectively (p<0.0001). The proportion of alloHSCT with reduced-intensity conditioning (RIC) increased from 6% to 19% (p<0.0001). Among myeloablative transplantations, regimens based on total body irradiation were the preferable option (app. 80% over the whole study period, p=NS). In contrast, among RIC regimens, the use of chemotherapy predominated (75% between 2010-2012, p=0.006). In most of analyzed individual countries, the estimated rates of alloHSCT (no. HSCT per 100 newly diagnosed ALL) for patients in CR1 increased over time. However, the values for a period 2010-2012 varied strongly, being highest in the Netherlands (42.2), followed by the UK (32.3) and France (32.2) while lowest in Russia (0.8). HSCT rates correlated with socio-economic status of a country as defined by the Human Development Index (R=0.71, p=0.046).

	YEAR			
Type of HSCT	2001-2003	2004-2006	2007-2009	2010-2012
Total alloHSCT	1005	1344	1811	2093
MSD-HSCT	604 (60%)	736 (55%)	819 (45%)	862 (41%)
URD-HSCT	363 (36%)	581 (43%)	956 (53%)	1159 (55%)
MMRD-HSCT	38 (4%)	27 (2%)	36 (2%)	72 (3%)
AutoHSCT	459	327	163	134

MSD, matched sibling donor; URD, unrelated donor;
MMRD, mismatched related donor
% refer to proportions of various donor types among alloHSCT

Table 1. Numbers of HSCT procedures for ALL in first CR by donor type.

Summary/Conclusions: Results of our analysis indicate a continuous trend for an increased use of alloHSCT for adults with ALL, which may be attributed to increasing availability of unrelated donors. However, it may also be speculated that the introduction of tyrosine kinase inhibitors allowed higher proportion of patients with Ph-pos ALL proceeding to transplantation. Finally, the implementation of RIC regimens contributed to wider use of alloHSCT among older adults. Limitations of the analysis include any assumptions made regarding ALL incidence for the specified time period and possible variation in reporting to the EBMT registry from different countries over time.

S525

FIRST ANALYSIS OF THE MULTICENTRE, BLINDED, PLACEBO-CONTROLLED PRE-GVHD CLINICAL-TRIAL FOR PREDICTION AND PRE-EMPTIVE TREATMENT OF ACUTE GVHD IN 210 OF 260 PATIENTS

E M Weissinger[1,*], J Metzger[2], M Schleuning[3], C Schmid[4], G Beutel[1], A Rank[4], E Wagner[5], J Schetelig[6], F Stölzl[6], K Schäfer-Eckhard[7], W Bethge[8], D Bunjes[9], D Heidenreich[10], E Holler[11], D Niederwieser[12], H Kreipe[13], K Westphal[7], D Wolff[11], C Rothmann[3], P Schweier[1], I Tueruechanow[1], D Ihlenburg-Schwarz[1], A Durban[2], J Raad[2], M Dakna[2], D Jonigk[13], I Hamwi[1], L Hambach[1], J Krauter[1,14], M Stadler[1], A Ganser[1]

[1]Hannover Medical School, [2]mosaiques GmbH, Hannover, [3]Helios Kliniken, Wiesbaden, [4]Klinikum Augsburg, Augsburg, [5]Universitätsklinikum Mainz, Mainz, [6]Universitätsklinik Dresden, Dresden, [7]Klinikum Nürnberg, Nürnberg, [8]Universität Tübingen, Tuebingen, [9]Universitätsklinik Ulm, Ulm, [10]Uniklinik Heidelberg, Heidelberg, [11]Universitätsklinikum Regensburg, Regensburg, [12]Universitätsklinik Leipzig, Leipzig, [13]Pathology, Hannover Medical School, Hannover, [14]Klinikum Braunschweig, Braunschweig, Germany

Background: The success of allogeneic stem cell transplantation (HSCT) is limited by acute graft-*versus*-host disease (aGvHD), one of the major and life-limiting complications. A proteomic urine pattern "aGvHD_MS17" capable to predict aGvHD grade II or more has been developed (Weissinger *et al.,* 2007 and 2014). In 2008 a multicenter, randomized, placebo-controlled, double blind clinical trial to evaluate the proteomic-based prediction of aGvHD as well as possibilities of pre-emptive therapy was initiated. Patients after the first allogeneic HSCT could be included in this trial. Ten centers in Germany contributed 267 patients to this trial and 90 were randomized according to the positivity of proteomic urine pattern aGvHD-MS17 to receive either prednisolone or placebo. To date, data of 210 (89 randomized) patients have been analysed for incidence of acute GvHD grade II or more and overall survival for the first year post HSCT.

Aims: The aim of this clinical trial was to evaluate the predicitve potential of

aGvHD_MS17 for the development of aGvHD grade II to IV. In additioan we analysed the possibility of 2mg/kg body weigth prednisolon for pre-emtptive therapy of aGvHD diagnosed by the positivity of aGvHD_MS17.
Methods: Urine was collected on days +7, +14, +21,+28, +35, +50 and +80 (all +/-3 days) after allogeneic HSCT frozen, shipped to Hannover and analysed within 72h as described (Weissinger *et al.*, 2007). Positivity of aGvHD_MS17 was achieved, when the dimensionless classification factor (CF) was +0.1 or more. Upon positivity of a sample for aGvHD_MS17, patients were randomized and received either prednisolone (2mg/kg BW for 5 days) or placebo. The majority of the patients had acute leukaemia prior to transplantation (n=120), were not in CR/CP (n=126; 60%) and were transplanted from matched (n=184; 84%). One hundred fifty one (71%) received reduced intensity conditioning regimens and the majority (84%; n=177) received immunosuppressive antibodies as GVHD-prophylaxis prior to transplantation and a calcineurin-inhibitor (CSA/MTX n=78; CSA/MMF n=93) based GvHD-prophylaxis afterwards.
Results: Prospective and blinded evaluation of aGvHD_MS17 revealed in this first analysis the correct classification of patients developing aGvHD grade II or more with a sensitivity of 71.17% and a specificity of 80%. The best CF (criterion) for the prediction of acute GvHD was at 0.16, which is between the previously published discriminatory CF of 0.2 (Weissinger *et al.,* Blood 2007) and 0.11 (Weissinger *et al.,* Leukemia 2014). The aGvHD-MS17-pattern turns positive about 7 days (range: 1 to 21) prior to the prior to clinical or biopsy based diagnosis of aGvHD. Patients in the aGvHD-MS17-positve group developed aGvHD grades II to IV in 49.5% while 19% of patients with aGvHD-MS17 negative samples developed acute GvHD grade II to IV. Interestingly, aGvHD_MS17 positivity between day +5 to +35 indicated pending aGvHD II-IV very accurately. Pattern-negative patients developed aGvHD II-IV later namely between days +20 and +40. Both groups reach a plateau around day +50. Patients with aGvHD_MS17-positive samples have a 2.76 fold risk of developing severe acute GvHD ($p<0.0001$). In addition, overall survival is significantly different for patients with samples positive for aGvHD_MS17, 40% of those die within the 1st year after HSCT (day +80 and +250). In contrast, 90% of patients who never had aGvHD_MS17-positive samples survive the first year ($p<0.0001$).
Summary/Conclusions: Our first analysis of the Pre-GvHD-trial implicates that aGvHD_MS17 is highly reproducible in the early prediction of aGvHD development, especially shortly after HSCT (up to day +25). Additionally, univariate analysis suggests that aGvHD_MS17 accurately separates patients with high and low overall survival after allogeneic HSCT.

Acute lymphoblastic leukemia - Biology 3

P526

IN VIVO ROLE OF ACTIVATION INDUCED CYTIDINE DEAMINASE (AID) EXPRESSION IN THE DEVELOPMENT OF PRECURSOR B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

F Auer[1,*], D Ingenhag[1], A Martín-Lorenzo[2], I Sánchez-García[2], A Borkhardt[1], J Hauer[1]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, Center for Child and Adolescent Health, Heinrich Heine University, Düsseldorf, Germany, [2]Instituto de Biologia Molecular y Celular del Cancer (IBMCC), CSIC/Universidad de Salamanca, Salamanca, Spain

Background: AID is essential for somatic hypermutation and class switch recombination in mature B-cells, while its role in precursor B-cells is controversially discussed. Since recently there is *in vitro* experimental evidence that AID is upregulated in precursor B-cells after exposure to LPS and contributes to the clonal evolution of pB-ALL.
Aims: Our rational was to establish an *in vivo* model to investigate the effect of AID in precursor B-cells independent of BCR-signaling and/or Rag1 induced oncogenic alterations. In this study we elucidate its role *in vivo* using a $Rag1^{-/-}$ tumor-prone model, which is AID deficient or AID competent. Therefore we are able to study the relevance of the *Aicda* gene in a dose dependent manner in pro-B cells.
Methods: The $p19Arf^{-/-}/Rag1^{-/-}$ mouse model (Hauer *et al.*, 2011) was crossed back on an AID deficient background ($p19Arf/Rag1/AID^{-/-}$). Healthy and leukemic mice were characterized by FACS analysis, immunohistochemistry, and molecular genetics. Preleukemic pro-B-cells were analyzed for IL7 sensitivity. Three pB-ALL tumors were further subjected to whole exome sequencing on a HiSeq2500 (Illumina) platform.
Results: $P19Arf/Rag1^{-/-}$ deficient mice develop pB-ALL at an incidence of 26% with evidence of AID expression. Surprisingly, additional loss of AID in these mice accelerates the pB-ALL incidence to 96% (43/45, median disease onset 25 weeks). Moreover we show that this effect is AID dose dependent, since AID heterozygous animals on the same background displayed a significant disease reduction (83%, 15/18, median disease onset 33 weeks). The leukemias displayed blast infiltration through spleen and peripheral blood with a cell surface phenotype of $CD19^+B220^+ckit^+IgM^-CD25^-$ and were able to engraft in secondary recipients with a phenotype identical to the primary disease. Whole exome sequencing of murine tumors additionally revealed an accumulation of recurrent somatic Jak3 mutations (R653H, V670A), highlighting the relevance of the IL7R signaling in these cells. AID expression was verified in preleukemic pro-B cells ($CD19^+B220^+ckit^+IgM^-$) of $p19Arf/Rag1^{-/-}$ and $P19Arf/Rag1^{-/-}AID^{+/-}$ animals by qRT-PCR. The importance of an intact IL7-signaling pathway was further shown by an increased sensitivity to IL-7 withdrawal in AID deficient preleukemic pro-B cells of these mice.
Summary/Conclusions: This work provides evidence for an *in vivo* role of AID in precursor-B cells and that absent AID expression as well as overexpression of AID can promote leukemia.

P527

UNFAVORABLE PROGNOSTIC VALUE OF BCR-ABL1-LIKE IS INDEPENDENT OF AN INTEGRATED GENETIC RISK SCORE IN PEDIATRIC BCP-ALL

JM Boer[1,*], G Escherich[2], HA de Groot-Kruseman[3], R Pieters[3,4], ML den Boer[1]
[1]Department of Pediatric Oncology/Hematology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, [2]COALL, German Cooperative Study Group for Childhood Acute Lymphoblastic Leukemia, Hamburg, Germany, [3]DCOG, Dutch Childhood Oncology Group, The Hague, [4]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands

Background: Pediatric B cell precursor acute lymphoblastic leukemia (BCP-ALL) is characterized by cytogenetic aberrations and deletions of B cell development genes. Patients with cytogenetic aberrations *ETV6-RUNX1*, high hyperdiploidy (51-65 chromosomes) and *TCF3-PBX1* have a good prognosis, whereas *BCR-ABL1*, *MLL*-rearranged, iAMP21 and haploid/near-triploid BCP-ALLs have a poor prognosis. Cases without these established chromosomal abnormalities are called B-other ALL and have an intermediate prognosis. Within the B-other group a novel high-risk subtype, *BCR-ABL1*-like, was discovered based on similar gene expression to *BCR-ABL1*-positive BCP-ALL and a similar poor outcome (Den Boer *et al.* 2009; Mullighan *et al.* 2009). Recently, Moorman *et al.* developed an integrated genetic risk score combining cytogenetic data and deletion profile of B cell differentiation genes which was predictive for outcome of pediatric BCP-ALL patients treated on UK protocols (Moorman *et al.* 2014).
Aims: We aimed to evaluate the independent prognostic value of the integrated genetic risk score in B-other and *BCR-ABL1*-like ALL of a Dutch/German pediatric cohort.

Methods: This study comprised 170 children with BCP-ALL including 78 previously described *BCR-ABL1*-like cases identified by hierarchical clustering and 92 non-*BCR-ABL1*-like B-other cases (Van der Veer *et al.* 2013). Patients with Down syndrome were excluded because of increased risk for treatment-related toxicity. Copy number of 8 commonly deleted genes was measured by the SALSA MLPA kit P335, a ratio <0.75 was considered a deletion. Using the described MLPA profiles (Moorman *et al.* 2014) the genetic risk score was determined for each sample. Briefly, genetic good risk is defined by no deletion of *IKZF1*, *CDKN2A/B*, *PAR1*, *BTG1*, *EBF1*, *PAX5*, *ETV6* or *RB1*; isolated deletions of *ETV6*, *PAX5* or *BTG1*; *ETV6* deletions with a single additional deletion of *BTG1*, *PAX5* or *CDKN2A/B*. Genetic poor risk is defined by any deletion of *IKZF1*, *PAR1*, *EBF1* or *RB1,* and all profiles not mentioned above. Event-free survival (EFS) was estimated using the actuarial Kaplan-Meier method, survival data between groups were compared using Cox regression.
Results: Among 170 cases negative for sentinel cytogenetic aberrations, we identified 126 genetic poor risk and 44 genetic good risk cases. The 5-year EFS in the genetic poor risk cases was 74% compared with 83% in the genetic good risk group (p=0.1). Genetic poor risk was more frequent in *BCR-ABL1*-like than in B-other (86% *vs* 64%, Fisher p=0.001). The prognosis of B-other/genetic poor risk (5-yr EFS 81%, p=0.3) and *BCR-ABL1*-like/genetic good risk (5-yr EFS 73%, p=0.3) cases was worse, but not significantly worse, from that observed for B-other/genetic good risk (5-yr EFS 86%), whereas the *BCR-ABL1*-like/genetic poor risk cases had poorer outcome (5-yr EFS 68%, p=0.03; Figure 1). *IKZF1* deletion, known to be associated with poor outcome, occurred in 54% of *BCR-ABL1*-like/genetic poor risk and 36% of B-other/genetic poor risk cases. After removing *IKZF1*-deleted cases, outcome of the *BCR-ABL1*-like/genetic poor risk cases remained poor (5-yr EFS 57%, p=0.01), while outcome of the B-other/genetic poor risk cases (87%) did not differ from that observed for B-other/genetic good risk cases (86%). In multivariate analyses including subtype and genetic risk score, the *BCR-ABL1*-like subtype was independently prognostic in the total group of *BCR-ABL1*-like and B-other cases (HR 1.8, p=0.06) and upon exclusion of *IKZF1*-deleted cases (HR 3.0, p=0.01) whereas genetic risk score was not independently prognostic of these subtypes. About 80% of both *BCR-ABL1*-like and B-other genetic poor risk *IKZF1*-wild type cases carried *CDKN2A/B* and/or *PAX5* aberration, however intragenic amplification of *PAX5* was more frequent among *BCR-ABL1*-like than B-other genetic poor risk group (16% *vs* 3%, p=0.08).

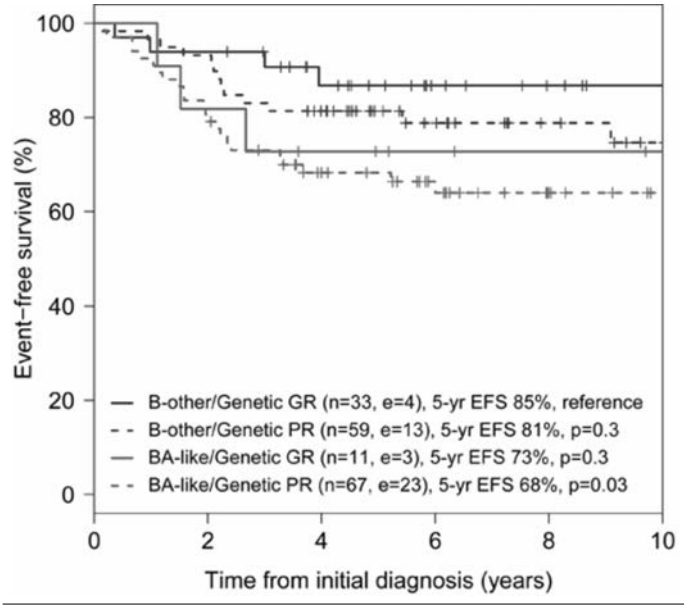

Figure 1.

Summary/Conclusions: The genetic risk score developed in the UK identified a group of *BCR-ABL1*-like patients at higher risk of treatment failure in a Dutch/German pediatric BCP-ALL cohort. The outcome of B-other/genetic poor risk and *BCR-ABL1*-like/genetic good risk cases showed a trend for a worse outcome compared with B-other/genetic good risk. The genetic poor risk group largely overlapped with the *BCR-ABL1*-like group, and only the latter independently predicted for an adverse clinical outcome.

P528

THE HISTONE DEACETYLASE INHIBITOR GIVINOSTAT (ITF2357) HAS A POTENT ANTI-TUMOR ACTIVITY AGAINST CRLF2 REARRANGED LEUKEMIA

AM Savino[1], J Sarno[1], L Trentin[2], M Vieri[1], G Fazio[1], M Bardini[1], C Bugarin[1], G Fossati[3], K Davis[4], G Gaipa[1], L Meyer[5], G Nolan[4], A Biondi[1], T te Kronnie[6], C Palmi[1], G Cazzaniga[1,*]

[1]Centro Ricerca Tettamanti, Fondazione Tettamanti, Monza, [2]Department of Women's and Children's Health, University of Padova, Padova, [3]Preclinical R&D Department, Italfarmaco S.p.A., Cinisello Balsamo, Italy, [4]Baxter Laboratory in Stem Cell Biology, Department of Microbiology and Immunology, Department of Pediatrics, Stanford University, Stanford, United States, [5]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, Ulm, Germany, [6]Department of Women's and Children's Health, University ofPadova, Padova, Italy

Background: The cure rate for B Cell Precursor Acute Lymphoblastic Leukemia (BCP-ALL) approaches 90% with current treatment regimens, however only a third of patients with relapse are cured. Therefore, there is an urgent need to focus on subgroups of patients with hallmarks of bad prognosis that could benefit from novel therapeutic approaches. Alterations of *Cytokine Receptor-like Factor 2 (CRLF2)*, a negative prognostic factor in pediatric BCP-ALL, have been identified in up to 10% of patients representing half of the high risk Ph-like ALL and of Down Syndrome-associated BCP-ALL. Rearrangements of *CRLF2* resulting in its overexpression are associated with activating mutations of the JAK-STAT pathway, causing the hyperactivation of JAK/STAT and PI3K/mTOR signaling. Inhibition of CRLF2/JAK2 signaling has the potential to become a therapeutic targeted intervention for this subgroup of poor prognostic patients. Previous studies have shown that the HDAC inhibitor Givinostat/ITF2357 has potent anti-tumor activity against JAK2V617F mutated myeloproliferative neoplasms (MPN), for which it has already a clinic application and established safety profile.
Aims: We studied the *in vitro* and *in vivo* efficacy of Givinostat in cases with *CRLF2* rearrangements.
Methods: The effect of Givinostat in proliferation and apoptosis was tested on MHH-CALL4 and MUTZ5 cell lines positive for exon 16 *JAK2* mutations and in patient derived CRLF2-rearranged blasts expanded in xenograft mouse models (PDX) and co-cultured on OP9 stroma.
Results: Givinostat inhibited proliferation and induced apoptosis of BCP-ALL *CRLF2*- rearranged MHH-CALL4 and MUTZ5 cell lines, with IC50 values lower than those for the SET2 cell line bearing JAK2V617F mutation, both for proliferation (IC50: 0.08±0.05μM *vs* 0.14±0.03μM) and apoptosis (IC50: 0.17±0.03μM *vs* 0.22±0.04μM). Consistently, after 72 hours of co-culture on OP9 stroma, Givinostat (0.2μM) was able to kill up to >90% of PDX cells (Annexin V/Sytox negative), in contrast with the vehicle-treated samples which showed 25-60% of blasts still alive after treatment. Moreover, in primary samples from diagnostic BM, CyTOF analyses showed that CD10+/CRLF2+ blasts were preferentially killed by the drug whereas the normal residue remained unaffected. At low doses (0.2 μM), Givinostat downregulated genes of the JAK/STAT pathway (*STAT5A*, *JAK2*, *IL7Rα*, *CRLF2, BCL2L1* and *cMYC)* and inhibited the basal and ligand induced signaling, reducing the phoshporylation of STAT5 in all tested samples (mean fold decrease of pSTAT5: 2.4±0.6). The down modulation of CRLF2 protein was also observed by flow cytometry (mean fold decrease 3.55±1.38). Furthermore, Givinostat augmented the effect of chemotherapy in inhibiting proliferation and inducing apoptosis in CRLF2 rearranged cell lines and in primografts, *in vitro*. After 72 hours, the combined treatment reached considerable reduction in viable blasts than single treatments (*e.g.* 6.3-35.3% viable cells in chemotherapy-treated samples *vs* 1.4-4.3% of combination). *In vivo*, Givinostat significantly reduced engraftment of human blasts in xenograft models of CRLF2 positive BCP-ALL.
Summary/Conclusions: In conclusion the HDAC inhibitor Givinostat efficiently kills CRLF2 rearranged leukemia by inhibiting JAK/STAT pathway and synergizes with current chemotherapy. Givinostat may represent a novel and effective tool, in combination with current chemotherapy, to treat this subsets of ALL with poor prognosis and chemotherapy-related toxicity. These data strongly argue for the translation of Givinostat in combination with conventional therapy into human trials.

P529

INSIGHTS INTO THE MOLECULAR EVOLUTION OF BCR-ABLP190 MEDIATED PRECURSOR B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

F Auer[1,*], A Martín-Lorenzo[2], C Vicente-Dueñas[2], I García-Ramírez[2], G Rodríguez-Hernández[2], J Hauer[1], A Borkhardt[1], I Sánchez-García[2]
[1]Department of Pediatric Oncology, Hematology and Clinical Immunology, Center for Child and Adolescent Health, Heinrich Heine University, Düsseldorf, Germany, [2]Instituto de Biología Molecular y Celular del Cáncer, CSIC/ Universidad de Salamanca, Salamanca, Spain

Background: Although, the genetic aberration associated with BCR-ABL^{p190}-positive leukemia is already well characterized, the link between the BCR-ABL^{p190} fusion protein and precursor B-cell acute lymphoblastic leukemia (pB-ALL) development is only insufficiently understood.
Aims: By applying a combination of tyrosine kinase inhibitors (TKI) and chemotherapy, significant improvements have been made in fighting the poor prognosis of Ph$^+$ ALL, but there is still no long term survival achieved in 30-50% of pediatric and adult ALL cases. Thus for the development of individual disease based treatments, further insights are needed to identify the underlying mechanism that shape BCR-ABL^{p190} pB-ALL development.
Methods: We generated a mouse model, restricting BCR-ABL^{p190} expression to hematopoietic stem/progenitor cells (HS/PCs), by placing the *BCR-ABL*^{p190}

cDNA under the control of the Sca1 promoter (Sca1-BCR-ABL^{p190}). This model was further crossed back with Pax5$^{+/-}$ mice (Sca1-BCR-ABL^{p190}+*Pax5*$^{+/-}$). PB-ALL tumors of both strains were subjected to whole exome and genome sequencing (HiSeq2500 - Illumina). Reporter gene assays containing copies of a CD19 promoter derived high affinity binding site were used to assess the transcriptional functionality of the detected Pax5 variants.
Results: Here we show that pB-ALL development can be established in mice (13%, 5 out of 36, starting at 13 months), when BCR-ABL^{p190} oncogene expression is restricted to HS/PCs (Sca1-BCR-ABL^{p190}). These leukemias are a phenocopy of the human disease with respect to clinical, pathology and genomic lesions. All pB-ALLs displayed clonal immature BCR rearrangement and the cell surface phenotype (CD19^{-}B220^{+}IgM^{-}), suggested a reduction of Pax5 activity. Therefore, Sca1-BCR-ABL^{p190}+*Pax5*$^{+/-}$ mice were generated, which almost exclusively developed pB-ALL (CD19^{-}B220^{+}IgM^{-}Mac1$^{+/-}$) with shorter latencies (93%, 27 out of 29, first disease onset at 6 months). In order to identify the second hit related to pB-ALL disease we next performed whole exome (n=13) and whole genome (n=3) sequencing of Sca1-BCR-ABL^{p190}+*Pax5*$^{+/-}$ tumors, which further revealed alterations of the remaining wild-type *Pax5* allele (6/13 point mutations; 1/3 deletions). All point mutations were shown to confer reduced transcriptional Pax5 activity by luciferase assay.
Summary/Conclusions: Thus, we shed further light on Ph+ ALL disease evolution on a molecular level, by presenting first proof that expression of the BCR-ABL^{p190} oncogene is not necessary in the leukemic cell, but is sufficient in HS/PCs to induce pB-ALL. Moreover we show an essential function of Pax5 in BCR-ABL^{p190} mediated pB-ALL development.

P530

THE ROLE OF CNOT3 AND THE ENTIRE CCR4-NOT COMPLEX IN TUMOR DEVELOPMENT

C Vicente[1,*], R Stirparo[1], S Demeyer[1], R Vandepoel[1], O Gielen[1], B Hassan[1], T Kureha[2], T Yamamoto[2], J Cools[1]
[1]KU Leuven, Center for Human Genetics and VIB, Center for the Biology of Disease, Leuven, Belgium, [2]Cell Signal Unit, Okinawa Institute of Science and Technology, Kunigami, Okinawa, Japan

Background: CNOT3 is a subunit of the evolutionary conserved CCR4-NOT complex, mediating RNA degradation through deadenylation of mRNA. We recently discovered loss-of-function mutations in CNOT3 in patients with T-cell acute lymphoblastic leukemia (T-ALL) and CNOT3 has also been found to be mutated in chronic lymphocytic leukemia. These finding suggests a role for CNOT3 as tumor suppressor gene. However, the role of CNOT3 in normal and malignant T-cell development remains largely unknown.
Aims: We used mouse and fly (Drosophila melanogaster) models to investigate the role of CNOT3/Not3 and other members of the CCR4-NOT complex in normal T-cell development and in tumor development.
Methods: RNAi mediated down-regulation of *Not3* and other subunits of the CCR4-NOT complex was performed in the fly eye cancer model (based on NOTCH hyper-activation). In mice, we conditionally deleted *Cnot3* in lymphoid lineage cells by crossing *Cnot3*$^{fl/fl}$ mice with the *CD2*-iCre strain.
Results: In the fly model, reduction of *Not3* expression resulted in a significant increase in tumor incidence. The knockdown of other subunits of the CCR4-NOT complex (Not1, Not2, Twin and Pop2) also enhanced tumor formation, indicating that the entire complex and its deadenylase activity are required for tumor suppression. Overexpression of *Not3* suppressed formation of eye tumors. Gene expression profiling (RNA-seq) showed that suppression of *Not3* expression leads to the stabilization of a set of transcripts that might support tumor growth and development. In the mouse, we confirmed that CNOT3 and other subunits of the CCR4–NOT complex are expressed in normal T-cells during T-cell development. A single *Cnot3* allele was sufficient to support normal T-cell development. However, in mice with deletion of both *Cnot3* alleles, CD4+ and CD8+ cells were greatly reduced in spleen, bone marrow and peripheral blood. Analyses of thymi revealed that cells were blocked at the DN2-DN3 developmental stages. Thus, CNOT3 is essential for the normal development and differentiation of T cells.
Summary/Conclusions: Our results show that CNOT3 is important for proper T-cell development and establish the entire CCR4-NOT complex as a tumor suppressor complex.

P531

CAPTURE-BASED NEXT GENERATION SEQUENCING (NGS) IDENTIFIES ALSO RARE IG/TCR REARRANGEMENTS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

ML Guinea Montalvo[1,*], M Paris[1], M Tosi[1], S Lilliu[1], B Peruta[1], R Cavagna[1], C Belotti[1], P Zanghì[1], L Elidi[1], S Salmoiraghi[1], T Intermesoli[1], R Bassan[2], A Rambaldi[1], O Spinelli[1]
[1]Hematology and Bone Marrow Transplant Unit, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, [2]Hematology, Ospedale dell'Angelo, Mestre-Venezia, Italy

Background: Minimal Residual Disease (MRD) has been demonstrated as the most important prognostic factor in Acute Lymphoblastic Leukemia (ALL). To date, allele-specific oligonucleotide quantitative PCR (ASO-QPCR) has been considered the gold standard for MRD analysis. This approach requires the identification of clonal markers at diagnosis starting from PCR amplification of the most frequent IG/TCR gene rearrangements. However, in a proportion of cases it fails to identify clonality and suitable markers for MRD evaluation. Recently, a Next Generation Sequencing (NGS) approach, similarly based on selected rearrangements amplification, has been described to identify clonal markers at diagnosis and to monitor MRD in lymphoid malignancies.
Aims: To apply a novel capture-based NGS approach for the identification of IG/TCR clonal markers at diagnosis possibly overcoming limits of an amplicon-based approach.
Methods: A capture-based NGS panel was designed targeting coding V, D and J genes in the IG/TCR loci. Libraries were prepared using Nextera Rapid Capture Enrichment protocol (Illumina) and pair-end sequenced on the MiSeq platform (v3 chemistry, 2x300bp, Illumina). NGS experiments were performed on 10 diagnostic bone marrow samples of adult ALL patients (6 B- and 4 T-lineage) already studied for clonality following the EuroMRD guidelines within the NILG 09/00 clinical trial (ClinicalTrials.gov Id: NCT02067143). We also included 2 Human Umbilical Vein Endothelial Cells (HUVEC) and 2 mesenchimal cord blood cells as negative controls for IG/TCR rearrangements. NGS data were analyzed by the Vidjil software (Giraud, Saison *et al.,* BMC Genomics 2014, http://www.vidjil.org).
Results: In the 10 studied diagnostic samples, capture NGS detected all the fifty clonal rearrangements previously identified by standard clonality assessment and Sanger sequencing. Only one IGH rearrangement was not revealed because of low coverage of the V, D and J genes involved in this specific rearrangement. Furthermore, this novel approach allowed to identify 24 additional clonalities that were subsequently confirmed: (i) 3 corresponded to low represented clones that were finally revealed by standard method only after an additional amplification round and sequencing; (ii) 10 corresponded to oligoclonal rearrangements in which Sanger sequencing did not allow the discrimination of single clones that was only possible thanks to single sequences deriving from NGS; (iii) 11 were characterized by uncommon V/DJ combination that were amplified and sequenced only after NGS based oligonucleotide design. HUVEC and mesenchimal cells capture NGS data analysis did not reveal any rearrangement in IG/TCR genes.
Summary/Conclusions: Our capture-based NGS approach for IG/TCR loci allowed to identify known as well as low represented and uncommon rearrangements not previously isolated by conventional methods. This technology offers the opportunity to identify at diagnosis minor leukemia clones so preventing unexpected relapse in patients proved negative for major clones. Furthermore, capture NGS can be of high value in patients with rare rearrangements in which standard procedures could not identify molecular markers suitable for MRD evaluation. In fact these patients could not benefit from a MRD driven treatment. In the future, we aim to retrospectively apply this technology on samples where standard clonality assessment failed in order to redefine patients molecular MRD risk classification and to correlate the new assignment with clinical outcome.

MIR-126 DRIVEN LEUKEMIA: A MURINE MODEL TO UNDERSTAND HUMAN B-ALL PATHOGENESIS

MM Naldini[1,2,3,*], C Caserta[1,2,3], S Nucera[1], G Desantis[1], A Cosentino[1,2], J Garcia-Manteiga[4], JE Dick[5], A Lombardo[1], F Ciceri[2,6], B Gentner[1,7]
[1]San Raffaele Telethon Institute for Gene Therapy, [2]Vita Salute San Raffaele University, Milan, [3]Co-First Authors., [4]Centre for Translational Genomics and Bioinformatics, Milan, Italy, [5]Princess Margaret Cancer Centre, University Health Network and Dept. of Molecular Genetics, University of Toronto, Toronto, Canada, [6]Hematology and Bone Marrow Transplantation Unit, IRCSS Ospedale San Raffaele, [7]Hematology and Bone Marrow Transplantation Unit, IRCSS Ospedale San Raffaele, Milan, Italy

Background: Deregulated miR activity can contribute to hematologic malignancy. We have shown that miR-126 regulates HSC quiescence, and its ectopic expression induces a monoclonal leukemia in mice. By engineering a Doxycycline(doxy)-repressible miR-126 overexpression cassette (Tet.126), we showed that spontaneous B-ALL development was prevented, and full-blown disease regressed when miR-126 was turned off.
Aims: We sought to further investigate the mechanism behind miR-126-driven leukemia in our mouse model and explore its relevance in human B-ALL.
Methods: We performed RNAseq of murine B-ALL blasts before and after turning miR-126 off. We then functionally validated involved pathways by phosphoflow and performed *in vivo* rescue experiments by lentiviral (LV) overexpression of candidate factors. We then transduced human B-ALL blasts with miR-126 reporters-, knockdown- or overexpressing L*Vs* and transplanted them into NSG mice for characterization.
Results: Transcripts changing in our murine B-ALL model upon miR-126 withdrawal clustered into 3 main categories: (1) up-regulation of p53-dependent pathways and negative cell cycle regulators; (2) induction of B-cell differentiation genes including the transcription factors Myb, Mafb, Ebf1, Ikzf1/3, Pbx1 and pre-BCR-type signaling; (3) down-regulation of oncogenic/prosurvival pathways

typically associated with stem and progenitor cells (Kit, Wnt, Thy1, Jak/Stat, Bcl2). Further proof of miR-126-dependent activation of Stat5 and Akt pathways, two key signaling axes in leukemia, was obtained by phosphoflow analysis. To explore the functional relevance of these pathways in our mouse B-ALL model, we transduced Tet.126 ALL blasts with LV expressing dominant negative p53 (GSE56), Ikaros (IK6) or BCRABL (p210), engrafted them in mice and turned off miR-126 expression by doxy when mice had full-blown leukemia. Doxy treatment cured mice transplanted with Tet.126 ALL. However, GSE56 delayed early blast clearance, and this effect was further enhanced when combined with IK6 or BCRABL, confirming a relevant role of these pathways in our model. We are currently knocking out direct miR-126 targets by Crispr/Cas9 technology in B-ALL blasts in order to identify the components that render this model fully independent from miR-126 expression. To test the relevance of the model for human B-ALL, we focused on Philadelphia (Ph)+ B-ALL, which share some of the molecular features encountered in our model. Most patient Ph+B-ALL expressed to various levels miR-126. To measure biological miR-126 activity, we transduced primary blasts (n=10 Ph+ALL) with a miR-126 reporter LV and successfully engrafted 7 of them in NSG mice. In all 7 diseases, we detected substantial miR-126 activity that was stable and disease-specific over serial transplantation, suggesting a fine-tuned regulation of miR-126 expression in B-ALL. We then over-expressed or knocked down miR-126 in primary Ph+B-ALL. Both perturbations negatively affected engraftment in NSG mice and increased apoptosis, further confirming that human B-ALL depend on a precisely set level of miR-126 expression. Interestingly, miR-126 knock-down and Imatinib treatment showed a less than additive effect on B-ALL burden in the mice (n=2 different diseases), suggesting that miR-126, at least in part, maintains active kinase signaling in human Ph+B-ALL. Our murine miR-126 B-ALL model shows similarities to Ph+B-ALL.

Summary/Conclusions: We propose that miR-126 constitutes part of the armamentarium of B-ALL cells to counteract apoptosis and differentiation thereby permanently maintaining them in an otherwise unstable progenitor cell state.

Acute lymphoblastic leukemia - Clinical 2

Background: B-cell precursor Acute Lymphoblastic Leukemia (B-ALL) is a malignancy of lymphoid progenitor B-cells, characterized by a marked heterogeneity. The identification of hidden genomic lesions that could be associated with treatment failure and relapse is still a challenge.

Aims: To determine the frequency and prognostic impact of mutations in a panel of genes in both children and adults with B-ALL, treated according to PETHEMA and SEHOP protocols.

Methods: The mutational status of *TP53, JAK2, PAX5, LEF1, CRLF2* and *IL7R,* genes was investigated in 340 newly diagnosed patients with B-ALL, 211 were children while 129 were adults. Mutation analyses were performed using oligonucleotide primer plates designed as part of the IRON-II collaborative network applying 454 massively parallel amplicon next-generation sequencing technology (454 Life Sciences, Branford, CT, USA). 19 exons (E) were sequenced by case: *TP53* (E4-E11), *JAK2* (E12-E16), *PAX5* (E2-E3), *LEF1* (E2-E3), *CRLF2* (E6) and *IL7R* (E5).The variant analysis was performed using Amplicon Variant Analyzer (AVA-Roche 454) and Sequence Pilot (JSI Medical Systems) software. A cut-off 2% was applied to define variants.

Results: A mutation rate of 12.1% (41 of 340) was identified. Eleven (26.8%) patients with mutations concomitantly harbored 2 or 3 mutations. The mutations were more frequent in adult than in children (20.2% *vs* 7.1%, p<0.0001). *TP53* was the most frequently mutated gene (4.1%), while mutations in *CRLF2* (2.9%), *JAK2* (3.5%), *PAX5* (2.4%), *IL7R* (0.3%) and *LEF1* (0.6%) were less frequent. All mutations observed in the childhood cohort of B-ALL, were exclusively observed in the subgroup of patients without *ETV6-RUNX1* translocation (p=0.045) while in the adults all mutations were exclusively detected in *BCR-ABL1* negative cases (p<0.0001). In the whole cohort of patients, the presence of mutations in *TP53* (*TP53*mut) (p=0.007) and *JAK2* (*JAK2*mut) (p=0.003) was associated with poor response to frontline therapy. The univariate survival analysis in whole B-ALL cohort showed that, *CRLF2*mut was associated with shorter RFS (p=0.023) and EFS (p=0.027), *JAK2*mut with a decreased RFS (p<0.0001) and EFS (p=0.001), while *TP53*mut was associated with poorer OS (p<0.0001), RFS (p=0.001) and EFS (p<0.0001). In the multivariate analysis, *TP53*mut was an independent risk factor associated with shorter OS (HR, 3.4; p=0.032). *TP53*mut (RFS:HR, 3.2; p=0.04 and EFS:HR, 3.2; p=0.04) and *JAK2*mut (RFS: HR,4.0;p=0.01 and EFS: HR,3.9;p=0.01) were independent markers of poor prognosis for RFS and EFS respectively. In the group of children with B-ALL, a significantly shorter OS (p=0.002), RFS (p=0.04), and EFS (p=0.009) was observed in patients with *TP53*mut. *TP53*mut was an independent risk factor associated with significantly shorter RFS (HR, 4.5; p=0.04). In adult B-ALL patients, *TP53*mut was associated with a shorter OS (p=0.02) and RFS (p=0.03), and *JAK2*mut was related with poorer RFS (p=0.002) and EFS (p=0.03).The presence of *TP53*mut was an independent risk factor associated with significantly shorter OS (HR, 2.3; p=0.03). Moreover, *TP53*mut (HR, 5.9; p=0.03) and *JAK2*mut (HR, 5.6; p=0.04) retained their independent prognostic significance in multivariate analysis regarding for RFS.

Summary/Conclusions: The mutations in *TP53* and *JAK2* genes could be considered as a novel biomarkers associated with poor prognostic in B-ALL patients.

Background: *NBN* gene encodes nibrin which is a part of the MRN complex responsible for DNA double-strand brakes (DSB) repair. Homozygous mutation in *NBN* gene leads to rare autosomal recessive immunodeficiency associated with chromosomal instability and increased predisposition to lymphoproliferative disorders, called Nijmegen breakage syndrome (NBS). Although the role of homozygous deletion (657del5) of *NBN* gene in ALL development has been established, the impact of heterozygous variants of *NBN* gene on clinical course of childhood ALL remains undefined.
Aims: To determine clinical course and biological features of childhood ALL in homo- and heterozygous carriers of 657del5 mutation in *NBN* gene.
Methods: In total, 593 children (median age 6.48±4.64 years, median follow-up 3.31 years) with newly diagnosed BCP-ALL treated in 15 centers of the Polish Pediatric Leukemia/Lymphoma Study Group were enrolled in the study. We detected 657del5 mutation in *NBN* gene using PCR with fluorescent primer and capillary electrophoresis. Positive results were subsequently confirmed by Sanger's sequencing. Targeted copy number screening of selected 23 loci was performed on available DNA samples (n=366) using the P335-B2 SALSA MLPA kit (MRC-Holland, Netherlands). *IKZF1* deletions were additionally identified using multiplex-PCR with breakpoint-specific primers. Survival analysis with estimation of the probability of overall survival (OS), event-free survival (EFS) and relapse-free survival (RFS) was performed with respect to cytogenetic and molecular features of ALL, clinical characteristics at diagnosis (WBC, age, gender, risk group, CNS involvement) as well as response to treatment (steroidoresistance and minimal residual disease at day 15).
Results: In total, we identified n=23 patients (3.88%) with 657del5 in *NBN* gene, four of them (17.39%) harbouring biallelic deletions (Nijmegen breakage syndrome) while the remaining n=19 were heterozygous carriers (82.61%). Carriers of 657del5 in *NBN* had shorter EFS compared to wild type patients (median 2.05 years, IQR: 1.52-3.82 years *vs* 3.16 years, IQR:1.89-4.79 years; p=0.082). No significant differences in OS were observed. Interestingly, we found that CNS relapse of BCP-ALL was significantly more frequent in 657del5 carriers as compare to wild-type patients (17.65% *vs* 1.87%; p=0.002). In the multivariate analysis we found that steroidoresistance (OR=15.82, 95%CI 2.44-102.37, p=0.004) and being a carrier of 657del5 in *NBN* (OR=38.46, 95%CI 5.69-259.22, p<0.001) are independent risk factors increasing the risk of CNS relapse.
Summary/Conclusions: We report for the first time the association between *NBN* gene variants and biological and clinical features of childhood ALL. In our study cohort, carriers of 657del5 in *NBN* gene who were diagnosed with BCP-ALL had increased risk of CNS relapse regardless CNS involvement at diagnosis. Carriers of 657del5 have worse prognosis (shorter EFS) comparing to wild-type patients.

P535

TARGETED LOCUS AMPLIFICATION & NEXT GENERATION SEQUENCING FOR THE DETECTION OF RECURRENT AND NOVEL GENE FUSIONS FOR IMPROVED TREATMENT DECISIONS IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

M den Boer[1,*], S van Reijmersdal[2], E Splinter[3], M Simonis[3], J Yu[2], E Sonneveld[4], S Blanca[5], J Boer[1], A Boeree[1], M Yilmaz[3], P Hoogerbrugge[6], F van Leeuwen[5], M Van Min[3], R Kuiper[2]
[1]Department of Pediatric Oncology/Hematology, Erasmus MC - Sophia Children's Hospital, Rotterdam, [2]Department of Human Genetics, Radboud university medical center, Nijmegen, [3]Cergentis, Utrecht, [4]Dutch Childhood Oncology Group, The Hague, [5]Laboratory of Pediatric Oncology, Radboud university medical center, Nijmegen, [6]Prinsess Máxima Center for Pediatric Oncology, De Bilt, Netherlands

Background: Despite developments in targeted and whole genome gene sequencing, the robust detection of all genetic variation, including structural variants, in and around genes of interest and in an allele-specific manner remains a challenge. Targeted Locus Amplification (TLA) [de Vree *et al.*, Nature Biotechnology 2014;32:1019-25] is a strategy to selectively amplify and sequence entire genes on the basis of the crosslinking of physically proximal sequences. Unlike other targeted re-sequencing methods, TLA works without detailed prior locus information, as one or a few primer pairs are sufficient for sequencing tens to hundreds of kilobases of surrounding DNA. This enables robust detection of single nucleotide variants, structural variants and gene fusions in genes of interest.
Aims: We describe the use of TLA and NGS to detect fusion genes and sequence mutations relevant for stratification of B-cell precursor acute lymphoblastic leukemia (BCP-ALL). Genomic profiling of BCP-ALL in the last few years has substantially extended the number of risk factors that can be used for risk stratification. However, conventional tests provide incomplete sequence information and can therefore miss clinically relevant information. In addition the opportunities TLA presents in the detection of breakpoint sequences promise to empower breakpoint specific minimal residual disease tests.
Methods: A total of 31 primer sets targeting 19 recurrently affected genes were designed and multiplexed, including the 'classical' players *MLL*, *RUNX1*, *TCF3*, and *IKZF1*, the tyrosine kinase genes *ABL1*, *ABL2*, *PDGFRB*, *CSF1R*, *JAK1*, *JAK2*, *JAK3*, *FLT3*, and *TYK2*, and the cytokine signaling genes *CRLF2*, *EPOR*, *IL7R*, *TSLP*, *SH2B3*, and *IL2RB*. Primer sets were chosen such that the most relevant regions were sufficiently covered. Viable cells from 47 selected BCP-ALL samples were analysed. TLA prep was performed, TLA amplicons were library prepped using Nextera and sequenced on an Illumina NextSeq.
Results: All 20 rearrangements known to be present in these samples were detected by TLA, including rearrangements in *ETV6-RUNX1* (n=5), *MLL* (n=2), *TCF3-PBX1* (n=3), *CRLF2* (n=3), *EBF1-PDGFRB* (n=2), *BCR-ABL1* (n=1), *RCSD1-ABL2* (n=1), *SSBP2-CSF1R* (n=1) and iAMP21 (n=2). For 14 of the fusions sequencing depth was sufficient to extract breakpoint-spanning sequences directly. For two cases with known *JAK2* fusions with an unknown partner, the fusion gene was identified (*TERF2* and *BCR*), as was the case for an unknown ABL1 fusion (*FOXP1*). New fusions were identified in 8 cases, including previously described *IGH@-EPOR*, *TCF3-ZNF384*, *MLL,* and *CRLF2* fusions, and novel gene fusion of *TCF3-CD163L1* and *HDAC9-FLT3.* In addition we identified multiple deletion breakpoints in *IKZF1*, and sequence mutations in *JAK2*.
Summary/Conclusions: We conclude that TLA is an effective method for the reliable detection of sequence mutations and structural variations that are relevant for disease prognosis and/or improved treatment decisions.

P536

TARGETING BET FAMILY PROTEINS IMPROVES THE THERAPEUTIC EFFICACY OF BCL-2 INHIBITION IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

S Peirs[1,*], V Frismantas[2], F Matthijssens[1], B Lintermans[1], T Pieters[1,3,4], N Vandamme[3,4], W Van Loocke[1], G Berx[3,4], B Poppe[1], JP Bourquin[2], P Van Vlierberghe[1]
[1]Center for Medical Genetics Ghent, Ghent University, Ghent, Belgium, [2]Pediatric Oncology, Children's Research Centre, University Children's Hospital Zurich, Zurich, Switzerland, [3]Unit for Molecular and Cellular Oncology, VIB Inflammation Research Center, [4]Department of Biomedical Molecular Biology, Ghent University, Ghent, Belgium

Background: More effective and less toxic therapies are required for the treatment of T-cell acute lymphoblastic leukemia (T-ALL). Recently, we and others reported promising therapeutic activity for ABT-199, a highly specific inhibitor of the anti-apoptotic BCL-2 protein, in immature subtypes of human T-ALL. Nevertheless, ABT-199 sensitivity is variable between different T-ALL patient samples and the emergence of therapy resistance together with the occurrence of dose-limiting toxicities provides a rationale for the evaluation of ABT-199 as part of combination therapies. Indeed, previous studies have shown that ABT-199 can synergize with conventional chemotherapeutic agents in human T-ALL.
Aims: In this study, we aimed to identify novel synergistic drug combinations with the BH3 mimetic ABT-199 in the context of human T-ALL.
Methods: A drug-screening platform was used to identify promising drug combinations of ABT-199 with a panel of 21 drugs, including approved anticancer drugs and emerging investigational and preclinical compounds, in a panel of primary T-ALLs. Subsequently, *in vitro* synergism was analyzed by determination of the combination index (CI) based on cell viability. Moreover, *in vivo* drug treatment assays were performed using xenografts of luciferase-labeled T-ALL cells. Finally, microarray-based gene expression analysis, RT-qPCR, Western blot and co-immunoprecipitation assays were used to obtain additional insights in the molecular mechanisms of drug synergism.
Results: A drug screening in 6 primary human T-ALLs (5 diagnostic and one relapse specimen) revealed strong anti-leukemic effects for the combination of ABT-199 with BET bromodomain inhibitors, including JQ1 and OTX-015. *In vitro* drug synergism between these molecules was confirmed in a panel of 13 human T-ALL cell lines and the degree of synergism was significantly correlated with BCL-2 expression levels. Furthermore, *in vivo* drug treatment experiments using xenografts of luciferase-positive LOUCY cells confirmed the synergistic activity of the JQ1/ABT-199 combination therapy as evaluated by bioluminescence, percentage of leukemic blasts in blood or bone marrow and spleen size.

Finally, to better understand the molecular mechanism by which BET bromodomain inhibition enhances the anti-leukemic properties of ABT-199, we defined the transcriptional consequences of JQ1 in synergistic T-ALL cell lines. Notably, *BCL2L11* expression was rapidly induced after short-term JQ1 exposure. As a result, BET bromodomain inhibition triggered an enhanced binding of BIM to BCL-2 in synergistic T-ALL cell lines, providing a putative explanation for the improved therapeutic efficacy of ABT-199 and JQ1 in human T-ALL.
Summary/Conclusions: BET bromodomain inhibition can sensitize BCL-2-positive human T-ALL to ABT-199 treatment by interfering with the balance of pro- and anti-apoptotic BCL-2 family members.

P537

PATIENT-REPORTED OUTCOMES FROM A GLOBAL PHASE 3 RANDOMIZED CONTROLLED TRIAL OF INOTUZUMAB OZOGAMICIN *VERSUS* STANDARD CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA

HM Kantarjian[1,*], Y Su[2], H Bhattacharyya[2], E Yan[3], M Shapiro[4], JC Cappelleri[5]
[1]University of Texas MD Anderson Cancer Center, Houston, TX, [2]Pfizer, Inc, New York, NY, [3]Pfizer, Inc, La Jolla, CA, [4]Pfizer, Inc, Cambridge, MA, [5]Pfizer, Inc, Groton, CT, United States

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, has demonstrated superior clinical activity *versus* standard care (SC; intensive chemotherapy) for relapsed/refractory acute lymphoblastic leukemia (ALL) in the ongoing phase 3 INO-VATE trial (DeAngelo, European Hematology Society 2015 meeting [abstract: LB2073])
Aims: To assess quality of life (QoL), functioning, and symptoms in patients with relapsed/refractory ALL receiving InO *versus* those receiving SC, based on patient-reported outcomes (PROs) from this phase 3 trial.
Methods: Patients were randomized to InO (max 1.8 mg/m^2/cycle [≤6 cycles]) or SC (fludarabine/cytarabine [ara-C]/granulocyte colony-stimulating factor, ara-C+mitoxantrone, or high-dose ara-C [≤4 cycles]) and completed the European Organization for Research and Treatment of Cancer Quality of Life Core Questionnaire (EORTC QLQ-C30) and EuroQoL 5 Dimensions questionnaire (EQ-5D) at baseline, day 1 of each cycle, and end of treatment. Treatment differences in PRO measures over time were assessed in the intent-to-treat population using longitudinal mixed-effects models with random intercepts and slopes. Analyses were supportive and no multiplicity adjustments were made. Informed consent was obtained from all patients.
Results: 141 and 138 patients were randomized to InO or SC; PROs completion rates were 85% and 64%, respectively. Overall, patients receiving InO reported numerically better quality of life (QoL), functioning and symptom scores at each cycle *versus* SC, with statistically significant differences in least squares mean Physical and Role Functioning (7.6 and 11.5, respectively; $P<0.02$). Mean treatment differences in favor of InO in EQ-VAS, Global Health Status/QoL, Social Functioning, Dyspnea, Appetite Loss, and Fatigue exceeded or approached 5 (generally considered the minimally important difference [MID] to be clinically meaningful), although without statistical significance. Other dimensions directionally favored InO, except Emotional Functioning, Constipation, and Pain, but none approached MID.
Summary/Conclusions: This is the first time that PROs are reported in a large randomized controlled trial of ALL. QoL, functioning, and symptoms in relapsed/refractory ALL patients receiving InO appeared generally better than those receiving SC. These data support the favorable benefit risk ratio of InO for relapsed/refractory ALL treatment, with superior clinical efficacy that does not compromise patients' QoL.

P538

DELETIONS OF IKZF1 GENE, BUT NOT GENETIC RISK GROUPS, DEFINED BY COPY-NUMBER ALTERATIONS, ARE PROGNOSTICALLY SIGNIFICANT FOR PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA ON ALL-MB 2008 PROTOCOL

G Tsaur[1,2,*], A Druy[1,2], A Solodovnikov[2,3], A Popov[4], T Riger[1,2], T Verzhbitskaya[1,2], O Streneva[1,2], E Shorikov[5], L Saveliev[1,2,3], L Fechina[1]
[1]Regional Children's Hospital N 1, [2]Research Institute of Medical Cell Technologies, [3]Ural State Medical University, Ekaterinburg, [4]Federal Research Institute of Pediatric Hematology, Oncology and Immunology named after D. Rogachev, [5]Morozov pediatric municipal hospital, Moscow, Russian Federation

Background: Recently *A. Moorman et al* introduced new stratification strategy for pediatric B-cell precursor ALL (BCP-ALL) based on cytogenetic risk groups and copy-number alterations (CNAs) detected by single multiplex ligation probe amplification (MLPA) kit (*Blood. 2014; 124(9):1434-1444*).
Aims: To test refined diagnostic strategy on independent cohort of childhood BCP-ALL enrolled into Russian multicenter trial ALL-MB 2008.
Methods: 142 BCP-ALL patients with median age of 3.1 years (range 1-16 years) were included in the current study based on availability of genomic DNA obtained at the time of diagnosis. Median of follow-up period was 4.2 years. Ph-positive ALL was revealed in 2 patients; both of them were allocated into high risk group (HRG) and included in the study. MRD was evaluated by multicolor flow cytometry with sensitivity non-less than 0.01%. CNAs were estimated by SALSA MLPA P335 ALL-IKZF1 probemix, all revealed *IKZF1* deletions were confirmed by SALSA MLPA P202 IKZF1 (IKAROS) probemix (both MRC-Holland, The Netherlands). Informed consent was obtained in all cases.
Results: *IKZF1* deletions were found in 15 (10.6%) patients, deletions of *CDKN2A/B* was detected in 44 (31.0%) cases, *BTG1* deletions in 12 (8.4%), *EBF1* in 2 (1.4%), *PAX5* in 46 (32.4%), *ETV6* in 39 (27.5%), *RB1* in 11 (7.7%), *PAR1* region was deleted in 9 (6.3%) cases. Based on cytogenetic risk and CNA group assessment 111 (78.2%) patients allocated to the genetic good risk (GGR) group, 31 (21.8%) to the genetic poor risk (GPR) group. Patients referred to the GGR group had higher EFS than patients in GPR group (0.89±0.03 *vs* 0.59±0.11, p=0.002) and lower cumulative incidence of relapse (CIR) (0.07±0.03 *vs* 0.39±0.11, p<0.001). Although in multivariate analysis the relation between genetic risk group stratification and EFS as well as relapse risk was not statistically significant. While *IKZF1* deletions (HR 5.214 (95% CI 2.045-13.292), p=0.001), WBC count at diagnosis more than $50*10^9$/L (HR 3.273 (95% CI 1.264-8.476), p=0.015) and M3 status of bone marrow (BM M3) at day 15 (HR 2.711 (95% CI 1.612-4.559), p<0.001) were significantly associated with decreased EFS. Presence of *IKZF1* deletions also led to higher relapse risk (HR 15.175 (95% CI 3.676-62.643), p<0.001) and it was independent of other risk factors. After that we estimated the role of *IKZF1* deletions, solely. Patients with *IKZF1* deletions were older (9.7 *vs* 3.2 years, p=0.007) and more frequently stratified to HRG (53.3% *vs* 5.5%, p<0.001) than the 127 cases without *IKZF1* deletions. *IKZF1* deletions were associated with delayed blast clearance, assessed by BM M3 status at day 15 (p=0.003), lack of hematological remission at day 36 (p<0.001). As a result, the *IKZF1*-positive cases more often had MRD levels ≥10% at day 15 (45.4% *vs* 12.4%, p=0.014), ≥0.1% at day 36 (66.7% *vs* 13.1%, p<0.001) and ≥0.01% at day 85 (41.7% *vs* 6.6%) than those with normal status of *IKZF1. IKZF1* deletions led to significantly worse outcome in the whole cohort of patients (EFS 0.30±0.15 *vs* 0.89±0.03, p<0.001, CIR 0.67±0.18 *vs* 0.07±0.02 P<0.001). Additionally, *IKZF1* deletions retained their prognostic significance in different subsets of patients: in the 'B-other' group, in BM M3 as well as in BM M1+M2 groups at day 15, in MRD-defined risk groups at day 15, day 36 and day 85, in ALL-MB 2008 ImRG patients, but not in SRG or HRG. Notably, all 2 SRG patients with *IKZF1* deletions remained in the first CCR.
Summary/Conclusions: We could not confirm that stratification for genetic risk groups was independent of other factors. It might be protocol-dependent. In contrast, *IKZF1* deletions led to unfavorable outcome in the whole cohort of patients, various subgroups and appeared to be MRD-independent.

P539

LACK OF PROGNOSTIC SIGNIFICANCE OF CD20 EXPRESSION IN ADULTS WITH PHILADELPHIA CHROMOSOME-NEGATIVE, B-CELL PRECURSOR ALL TREATED ACCORDING TO MRD-ORIENTED PROTOCOLS

Josep Carreras Leukemia Research Institute, Barcelona, [7]Hospital General de Alicante, Alicante, [8]ICO-Hospital Duran i Reynals, L'Hospitalet de Llobregat, [9]Hospital Universitario Central de Asturias, Oviedo, [10]ICO-Hospital Joan XXIII, Tarragona, [11]Hospital Universitario General de Castellón, Castellón de la Plana, [12]ICO-Hospital Josep Trueta, Girona, [13]Hospital Vall d'Hebron, Barcelona, [14]Hospital Morales Meseguer, Murcia, [15]Hospital Universitario Marqués de Valdecilla, Santander, [16]Hospital Son Llàtzer, Palma de Mallorca, [17]Hospital Clínico Universitario Virgen de la Victoria, Málaga, [18]Hospital Universitario 12 de Octubre, Madrid, [19]Hospital Clínico Universitario de Salamanca, Salamanca, [20]Hospital Gregorio Marañón, Madrid, [21]Hospital San Pedro de Alcántara, Cáceres, Spain

Background: Several studies have reported a poorer prognosis for patients with Ph-negative, B-cell precursor (BCP) ALL expressing CD20 in ≥20% blasts. This has led to perform phase II and III studies demonstrating an improvement in prognosis with the addition of anti-CD20 monoclonal antibodies to the initial treatment. However, little is known about the prognostic value of CD20 expression in BCP ALL patients treated according to MRD-oriented protocols.
Aims: To analyze the frequency and prognostic impact of CD20 expression in adult patients (18 - 59 yr) with Ph-negative, BCP ALL treated with the MRD-oriented protocols ALL-HR-03 and ALL-HR-11 (for patients with high risk ALL) and ALL-SR-08 (for patients with standard risk ALL) from the Spanish PETHEMA Group.
Methods: Immunophenotypic reports of adult patients with Ph-negative, BCP

ALL included in the above referred protocols were reviewed. CD20 expression ≥20% was considered to define CD20 positivity (CD20+) as this cut-off level has been selected in some studies performing treatment with antiCD20 MoAb. MRD was assessed by multiparameter flow cytometry. High-risk (HR) Ph-negative, BCP ALL patients were defined according to one of the following criteria: age (≥30 years), WBC count (>30x10^9/L) or cytogenetics (11q23/MLL gene rearrangements), whereas patients lacking all these features were considered as standard-risk (SR) ALL. HR-ALL patients included in ALL-HR-03 and ALL-HR-11 protocols received intensive induction and consolidation therapy followed by allogeneic HSCT if the MRD clearance was poor, whereas SR-ALL cases received a pediatric-based protocol, allogeneic HSCT being also indicated if persistent MRD positivity.

Results: Overall 308/362 patients included in the three protocols were evaluable for CD20 expression, of whom 111 (36%) were CD20+. Compared with patients with CD20 level ≤20%, CD20+ cases showed a trend towards lower WBC count (X[SD] 33[76] *vs* 46[77]x10^9/L, P=0.05) and a higher frequency of common+pre-B phenotypes (107/111 *vs* 148/197, P<0.001). No differences in outcomes (CR rate, CIR, DFS and OS) were observed on comparison of CD20+ patients with the other cases, neither for the whole series nor for the different risk groups (Table 1). Similar results were observed after censoring the follow-up of patients at the time of HSCT. The lack of prognostic impact was observed after stratification (cut-off) for age (30 yr.) and WBC count (30x10^9/L).

Table 1.

	CD20	CR rate	4-yr CIR (CI95%)	4-yr DFS (CI95%)	4-yr OS (CI95%)
Whole series (n=308)	≥20% (n=111)	103 (93%)	35% (24;47)	40% (28;52)	50% (39;61)
	<20% (n=197)	180 (91%)	44% (35;53)	42% (33;51)	48% (39;57)
HR ALL (n=250)	≥20% (n=92)	84 (91%)	36% (24;48)	35% (22;48)	43% (31;55)
	<20% (n=158)	144 (91%)	47% (37;56)	36% (26;46)	40% (31;49)
SR ALL (n=58)	≥20% (n=19)	19 (100%)	39% (0;68)	61% (22;100)	88% (65;100)
	<20% (n=39)	36 (92%)	32% (8;50)	68% (47;89)	82% (67;97)

Summary/Conclusions: One third of adult patients (18-59 yr) with Ph-negative, BCP ALL treated with MRD-oriented PETHEMA protocols expressed CD20 ≥20%. CD20 expression ≥20% did not show prognostic significance in this study.

Supported in part with the grants PI10/01417 from Fondo de Investigaciones Sanitarias and RD12/0036/0029 and RD12/0036/0048 from RTICC, Instituto de Salud Carlos III and 2014SGR225(GRE), Generalitat de Catalunya and La Caixa Foundation, Spain.

Acute myeloid leukemia - Biology 2

P540

PROTEIN PHOSPHATASE 4 REGULATORY SUBUNIT 2 (PPP4R2) IS RECURRENTLY DELETED IN ACUTE MYELOID LEUKEMIA (AML) AND REQUIRED FOR EFFICIENT DNA DOUBLE STRAND BREAK REPAIR

JK Herzig[1,*], L Bullinger[1], A Tasdogan[2], FH Heidel[3], V Teleanu[1], HJ Fehling[2], C Buske[4], H Döhner[1], K Döhner[1], VI Gaidzik[1]

[1]Internal Medicine III, University Hospital of Ulm, [2]Institute of Immunology, Ulm University, Ulm, [3]Leibniz-Institute for Age Research, Fritz-Lipmann-Institute, Jena, [4]Institute of Experimental Cancer Research, University Hospital of Ulm, Ulm, Germany

Background: We have previously identified a commonly deleted region (CDR) at chromosomal band 3p14.1-p13 in cytogenetically normal (CN) and complex karyotype (CK) AML. This CDR has also been described in solid tumors like cervix and prostate cancer. Within the CDR, *PPP4R2* is one of eight affected genes. As part of the protein phosphatase 4 (PPP4) complex, PPP4R2 was shown to be involved in the DNA repair of double-strand breaks (DSBs) by dephosphorylation of DNA damage response (DDR) proteins like phosphorylated histone H2AX (γH2AX) or KRAB-domain associated protein 1 (pKAP1) in osteosarcoma or cervix carcinoma cells.

Aims: To investigate the role of *PPP4R2* in hematopoiesis and leukemogenesis.

Methods: Gene expression of *PPP4R2* was analyzed by qRT-PCR in a cohort of AML patients (pts, n=63), that is 3p CDR within CN-AML (n=10), 3p CDR within CK-AML (n=26), CN-AML (n=24), CK-AML (n=3), and healthy bone marrow (BM) controls (n=8). Lentiviral transduction with *PPP4R2*-ORF was used to overexpress (OE) *PPP4R2* in the human myeloid leukemic cell line MEG-01 with a homozygous deletion of *PPP4R2*. Knockdown (KD) of *Ppp4r2* was performed by lentiviral delivery of *Ppp4r2*-shRNA in murine pre-leukemic MLL-AF9 and normal Lineage negative (Lin^-) BM cells. We determined the effects on proliferation by MTS-Assay, clonogenic growth in methylcellulose, and apoptosis and DDR by flow cytometry and Western blot analysis.

Results: Compared to healthy BM, *PPP4R2* expression was significantly lower in AML pts with lowest expression levels in CN-AML 3p CDR cases and CK-AML 3p CDR cases (p=0.007; p<0.0001, respectively). *PPP4R2* OE in MEG-01 cells considerably reduced proliferation (p=0.007), as well as colony forming potential (p=0.07). On the other hand, apoptosis caused by DSBs upon ionizing radiation (IR) was not induced in *PPP4R2* OE MEG-01 cells, suggesting a restoration of DDR. In line, *PPP4R2* OE in MEG-01 cells showed a significant decrease of pKAP1 (S824), reduced γH2AX (S139) [0.5 h post (p.) IR: p=0.01, p=0.4; 2 h p. IR: p=0.0001, p=0.8, respectively] and less P53 (S15) activation. Next, we determined loss-of-function effects upon *Ppp4r2* KD in murine MLL-AF9 transformed BM cells. In this leukemia model, *Ppp4r2* KD significantly decreased cell proliferation (p<0.0001) as well as colony forming potential (p=0.0002), but enhanced repopulating capacity (p=0.04). IR caused enhanced apoptosis in *Ppp4r2* KD cells (48 h p. IR: p=0.009) that was accompanied by significant accumulation of pKAP1, γH2AX (0.5 h p. IR: p=0.005, p=0.0002; 2 h p. IR: p=0.004, p<0.0001, respectively), and activated P53, indicating constitutive DNA damage and less efficient DNA repair. Furthermore, we assessed the effect of *Ppp4r2* KD in Lin^- BM cells. *Ppp4r2* KD reduced proliferation (p=0.3), but not clonogenic growth (p=0.6). In response to IR, *Ppp4r2* KD in Lin^- BM cells resulted in a higher amount of apoptotic cells (48 h p. IR: p=0.07), which was associated with elevated DDR protein pKAP1 and γH2AX levels (0.5 h p. IR: p=0.02, p=0.6, respectively).

Summary/Conclusions: As candidate gene of a CDR on 3p in AML pts, *PPP4R2* displayed lowest expression in CN-AML with 3p CDR. Furthermore, we identified *PPP4R2* as a critical regulator of DDR in both normal hematopoietic and leukemic cells via deregulation of the PPP4 complex. While impaired DNA repair and constitutive DNA damage might contribute to the pathogenesis of AML, further studies are warranted to determine potential additive effects of *PPP4R2* deletion to leukemogenesis.

P541

PRELEUKEMIC CLONES IN NPM1-MUTATED AML MAY BE ASSOCIATED WITH EVOLUTION TO MYELODYSPLASTIC SYNDROME (MDS) OR MYELOPROLIFERATIVE NEOPLASM (MPN)

S Morin[1,*], A Renneville[2], A Marceau-Renaut[2], M Sebert[1], T Braun[3], C Bally[1], C Preudhomme[2], P Fenaux[1], L Adès[1]

[1]Hematology, Hôpital Saint Louis-Assistance publique Hôpitaux de Paris, Paris, [2]Laboratory of Hematology, Biology and Pathology Center, CHRU of Lille, Lille, [3]Hematology, Hôpital Avicenne-Assistance Publique Hôpitaux de Paris, Paris, France

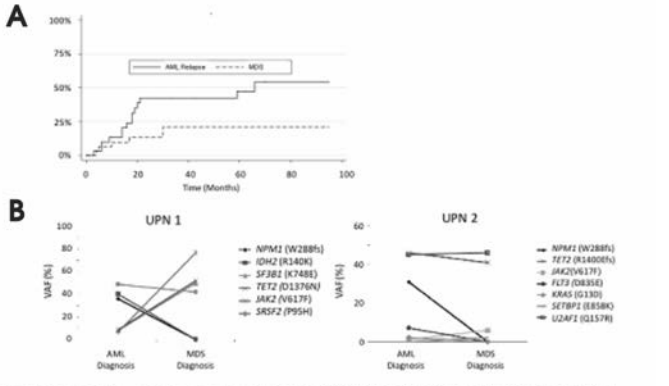
Background: Nucleophosmin 1 gene (*NPM1*) mutations account for 30% of AML and 50% of cytogenetically normal (CN) AML. *NPM1* mutated AML without *FLT3*-ITD (NPM 1^+FLT3 ITD^-) is classified in the favorable risk group. Recent studies, including from our group, showed that most *NPM1*$^+$*FLT3*-ITD^-AML also carry mutations in other genes such as *DNMT3A, IDH1, IDH2, TET2* muta-

tions which may constitute "preleukemic" clones, as suggested by the fact that those mutations often persist in patients with undetectable *NPM1* minimal residual disease (MRD) after intensive chemotherapy (Peterlin Haematologica 2015, Corces-Zimmerman PNAS 2014). On the other hand, a recent report showed that virtually all relapses in *NPM1*$^+$AML carried *NPM1* mutation, arguing against the fact that relapse can emerge from those preleukemic clones, independently of the presence of *NPM1* mutation (Hills NEJM 2016).

Aims: To better understand the genetic mechanisms underlying disease evolution in patients with *de novo* CN *NPM1*$^+$ *FLT3*-ITD$^-$AML in complete remission (CR).

Methods: Over a 10-year period, 34 *de novo* CN *NPM1*$^+$ *FLT3*-ITD$^-$AML (median age 55 years) were treated with intensive chemotherapy at our center, and 32 achieved CR. 12 (37%) remained in hematological CR with undetectable *NPM1*-MRD, 14 (44%) relapsed with the same *NPM1* mutation, and 6 (19%) developed MDS or MPN while still in molecular CR for NPM1 (Figure 1A). 12 of the relapsing patients and all 6 patients with MDS or MPN evolution had sequential molecular analysis using NGS of PCR-amplified exons of a panel of the 26 genes most frequently mutated in myeloid malignancies.

Results: The 6 patients who developed MDS or MPN with undetectable *NPM1*-MRD, after a median of 14 months (range: 4-30), were all aged >55 years, and included 2 RARS, 2 RCMD, 1 CMML type 1 and 1 primary myelofibrosis (PMF). In all 6 cases, a "preleukemic" clone with at least 1 mutation in *TET2 (n=4), JAK2 (n=2), ASXL1 (n=1), IDH2 (n=3)* or spliceosome genes (SRSF2, SF3B1, U2AF1, (n=3)) was found at AML diagnosis, and was still present (with stable or increasing variant allele frequency) at the time of MDS or MPN diagnosis (Figure 1B). In the 12 relapsing patients, "preleukemic" mutations were also present at AML diagnosis in 10/12 cases. However, they possibly differed between the 2 groups: At AML diagnosis, *TET2* mutation was identified in 4/6 (66%) patients who developed MDS or MPN, *versus* 2/12 (16%) patients who relapsed, p=0.1). Conversely, 8/12 patients who relapsed had mutations in *DNMT3A* or *IDH1*, *versus* 0/6 patients who developed MDS or MPN (p=0.025). At AML relapse, mutations co-occurring with *NPM1*mutation were identical to those observed at AML diagnosis.



a. Cumulative incidence of relapse and evolution to MDS/MPN in 32 patients with *NPM1*$^+$, *FLT3*-ITD$^-$ cytogenetically normal AML in first CR.
b. Evolution of Variant Allele Frequency in mutated genes at AML diagnosis and MDS/MPN diagnosis in 2 patients who developed PMF (UPN 1, left) or MDS (UPN 2, right), with undetectable *NPM1* MRD.

Figure 1.

Summary/Conclusions: Our study suggests that a significant proportion of patients with *de novo NPM1*$^+$*FLT3*-ITD$^-$ CN-AML (19% in our series) may subsequently develop MDS or MPN in the absence of *NPM1* mutation recurrence, and that this type of hematological evolution seems to be related to the persistence and expansion of preleukemic clones. The high incidence of such evolution may be related to the relatively advanced age of our patient cohort, due to our hospital unit recruitment (mostly elderly AML). Interestingly, in most patients with AML relapse, preleukemic clones were also observed at AML diagnosis but with a different mutational pattern, possibly pointing out different pathophysiological mechanisms. If those findings are confirmed in a larger number of patients, *NPM1*$^+$ AML patients may have to be closely followed-up after CR achievement even when *NPM1* MRD remains undetectable, due to the relatively high risk of MDS or MPN, at least in elderly patients.

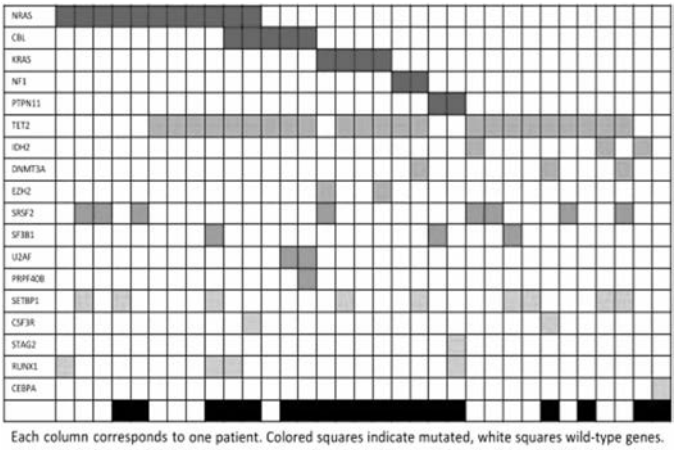
Background: Little is known about factors contributing to the transformation of CMML into secondary AML. In the "Austrian Biodatabase for Chronic Myelomonocytic Leukemia (ABCMML)" we retrospectively and prospectively collect clinical, biologic and molecular information of patients with CMML from different centers in a real life setting. Up to now 355 patients have been included, cytogenetic data are available in 186 patients, targeted next-generation sequencing (NGS) data in 138 patients, and *in vitro* culture data in 120 patients, respectively.

Aims: Our aim was to characterize the clinical, molecular and biologic features of patients with CMML who develop AML.

Methods: Clinical, hematological and cytogenetic data were obtained from patients records. For molecular characterization we used NGS with amplicon-based target enrichment of 39 CMML associated genes. Only mutations with an allele burden of 10% or higher were considered positive in this analysis. Since increased spontaneous myeloid colony formation is an *in vitro* characteristic of RAS pathway hyperactivation *(Wang et al., Blood 2010)* colony-forming units granulocyte/macrophage (CFU-GM) growth in the absence of exogenous cytokines was assessed using semisolid cultures as previously described (*Geissler et al., J Exp Med 1996)*. Transformation into AML was defined as a blast cell percentage of at least 20% in the peripheral blood and/or bone marrow.

Results: Of the 355 CMML patients studied, we identified 47 who had already CMML derived AML at the time of inclusion (group A), 80 patients who later had documented transformation into AML (group B) and 228 patients, in whom no transformation was recorded (group C).

Characteristics (median values, ranges) [p-values] of CMML patients who developed AML (group A+B) *vs* CMML patients without AML (group C) were: age (years): 70 (34-88) *vs* 73 (45-92) [0.14]; WBC (G/l): 14.0 (0.7-360) *vs* 14.2 (1.6-156) [0.818]; hemoglobin (g/dl): 9.8 (6.0-16.7) *vs* 11.0 (5.1-12.2) [0.000]; platelets (G/l): 89 (5.0-435) *vs* 90 (2.0-709) [0.435]; PB blasts (%): 14 (0-79) *vs* 0 (0-18) [0.000]; LDH (U/l): 294 (106-3685) *vs* 259 (102-1912) [0.013]; OS (months): 23.1 *vs* 38.7 [0.004]; CFU-GM per 10^5 PBMNC: 333 (0-4533) *vs* 13 (0-1009) [0.002]; (range in normal individuals 3.5 – 8.5). Thus, CMML patients who developed AML had a significantly inferior survival, lower hemoglobin value, higher LDH, and higher spontaneous CFU-GM formation than patients who did not develop secondary AML. The incidence of RAS pathway mutations in group A+B (67%; 22/33) was significantly higher than in group C (37%; 39/105), [p=0.003]. The detailed pattern of mutations in RAS pathway, epigenetic regulator and spliceosome components in CMML patients who developed AML (group A+B) is shown in Figure 1.



Each column corresponds to one patient. Colored squares indicate mutated, white squares wild-type genes. The colores of mutant genes indicate the most affected functional categories. Red, green, blue and yellow represent the RAS pathway, epigenetic regulators, spliceosome, and other components, respectively. At the bottom of the graph black squares indicate patients who had AML at the time of sampling and open squares patients who later developed AML.

Figure 1. Mutation status of genes in CMML patients who developed AML.

RAS pathway mutations were found in 15 of 19 (79%) CMML patients in whom molecular profiles were studied at the time of AML and in 7 of 14 (50%) CMML patients who later developed AML. The incidence of TET2 mutations was 70% (23/33) in group A+B which was not significantly different from the incidence in

group C (63%; 66/105), [p=0.474]. There was also no significant difference in the incidence of mutations with regard to other epigenetic modulators and to components of the spliceosome. Other mutations were rare and were also not significantly different. The most common cytogenetic abnormalities were+8 (12%), -7/del(7q) (6%), and –Y (4%), respectively, without significant differences in the two groups.
Summary/Conclusions: Our data show that patients with CMML who transform into AML have an unfavorable prognosis. In the majority of them the transformation process seems to be associated with hyperactivation of the RAS pathway. In order to improve outcome RAS pathway inhibitors should be studied in this high risk cohort.

P543

MOLECULAR CLASSIFICATION AND COMPARATIVE ANALYSIS OF ACUTE MYELOID LEUKEMIA MULTI-OMICS DATA USING THE INTERACTIVE HEMAP RESOURCE

P Pölönen[1], J Mehtonen[1], J Lin[2,*], T Liuksiala[2], S Häyrinen[2], S Teppo[3], P May[4], V Hautamäki[5], K Granberg[2], O Lohi[3], M Nykter[2], M Heinäniemi[1]
[1]Institute of Biomedicine, University of Eastern Finland, Kuopio, [2]Institute of Biosciences and Medical Technology, University of Tampere, [3]Tampere Center for Child Health Research, University of Tampere and Tampere University Hospital, Tampere, Finland, [4]Luxembourg Center for Systems Biomedicine, University of Luxembourg, Luxembourg, Luxembourg, [5]School of Computing, University of Eastern Finland, Joensuu, Finland

Background: Collections of genome-wide data can facilitate the characterization of disease states. The current challenge is to unify pre-existing patient molecular data to allow i) subtype-specific mechanisms to be distinguished from common mechanisms that underlie the departure from healthy states and ii) to evaluate disease contexts for promising drug targets.
Aims: The first goal in this study was to determine the robustness of molecular stratifications in acute myeloid leukemia (AML) by comparing them across different datasets and clinical annotations. We further focused on characterization of acute myeloid leukemia (AML) cases with normal or complex karyotypes and develop methodology for *in silico* evaluation of drug specificity.
Methods: The unsupervised dimensionality reduction method t-Distributed Stochastic Neighbor Embedding (t-SNE) was used to stratify a heterogeneous collection of 1,713 AML transcriptomes. We developed bioinformatics methodology for inclusion of new samples and unsupervised discovery of their cytogenetic type. Additional multi-omics datasets of 99 patients from The Cancer Genome Atlas were integrated to gain insight into disease biology. *In silico* screening of drug target expression was combined with chemical screen data of target specificity to compare two FLT3 inhibitors that are in ALL and AML clinical trials (Lestaurtinib and Tandutinib, respectively). A larger collection of 9,544 transcriptomes from 36 hematological malignancies and healthy blood cell type controls was utilized for this purpose.
Results: The current clinical classification of AML distinguishes between fusion-gene-positive categories. Unsupervised clustering in the t-SNE space yielded a performance comparable to that of robust and reproducible classifiers. Furthermore, we found additional clusters using t-SNE maps that corresponded to a distinct mutational pattern (CEBPA, NPM1 or RUNX1/TP53). CEBPA-mutated cases were found to exhibit elevated expression of S-adenosylmethionine-dependent methyltransferase pathway and we could show that this leads to globally elevated DNA methylation levels genome-wide. Expression patterns of targets inhibited by Lestauritinib revealed that it has the potential to act on considerably more genes (in addition to *FLT3*), of which several targets with low Kd values are also expressed in normal cell types, thus having potential to lead to side effects. Comparison of AML and other malignancies showed that the more specific Tandutinib may also be a promising drug for lymphoma trials, based on the multiple low Kd targets associated with this disease context.
Summary/Conclusions: Our results revealed molecular phenotypes that distinguish normal karyotype AML samples. The generated interactive resource, Hemap, is available online for investigating the molecular states of hematological malignancies and expediting therapeutic innovations. The FLT3 inhibitor currently evaluated in AML clinical trials, Tandutinib showed highly AML-specific expression profile of its low Kd targets and has potential for drug repositioning in lymphoma.

P544

SOMATIC DDX41 P.R525H MUTATION CAUSES GROWTH DEFECT IN HEMATOPOIETIC CELLS

H Matsui[1,*], M Kadono[2], A Kanai[2], A Nagamachi[2], T Inaba[2], T Ichinohe[3]
[1]Department of Molecular Laboratory Medicine, Kumamoto University, Kumamoto, [2]Department of Molecular Oncology and Leukemia Program Project, Research Institute for Radiation Biology and Medicine, Hiroshima University, [3]Department of Hematology and Oncology, Research Institute for Radiation Biology and Medicine, Hiroshima, Japan

Background: The *DDX41* gene, encoding a DEAD-box type ATP-dependent RNA helicase, is rarely but reproducibly mutated in myeloid diseases. The acquired mutation in *DDX41* is highly concentrated at c.G1574A (p.R525H) in the conserved motif VI located at the C-terminus of the RecA-like helicase core domain where ATP interacts and is hydrolysed. Therefore, it is likely that the p.R525H mutation in the DDX41 protein perturbs the ATPase activity in a dominant-negative manner.
Aims: This study was aimed at elucidating the molecular functions of DDX41 protein and the role of p.R525H DDX41 mutant in leukemogenesis.
Methods: In this study, we first screened for the *DDX41* mutation of CD34-positive tumour cells based on mRNA-sequencing and identified the p.R525H mutation in three cases among 23 patients. Then we analyzed changes in gene expressions and phenotype of hematopoietic cells transduced with the DDX41 mutant.
Results: We initially found that the patients harboring the p.R525H DDX41 mutation commonly exhibited AML with peripheral blood cytopenias and low blast counts, suggesting that the mutation inhibits growth and differentiation of hematopoietic cells. To address molecular functions of DDX41, we clarified the localization of DDX41 protein. Ectopically expressed Myc-tagged DDX41 was mostly nuclear regardless of the p.R525H mutation. In addition, the majority of the endogenous DDX41 protein was also mostly nuclear. In the nucleus, DDX41 protein was localized both in the nucleoplasm and in the nucleolus, implying that DDX41 plays a role in the nucleoplasm as well as in the nucleolus. We then transduced cord blood-derived CD34-positive cells with DDX41 wild type (WT) or p.R525H. After a 30-day culture, p.R525H cells showed decreased proliferation compared with WT cells, with a certain ribosomopathy phenotype as suggested by GSEA analysis. This finding and the highly conserved DEAD-box type RNA helicase domain of DDX41 led us to speculate that the enzyme might be involved in the pre-rRNA processing. Northern blot analysis probing internal spacer (ITS) 1 and 2 of pre-rRNA showed that signals of 47S and 41S pre-rRNAs were increased, whereas the 21S signal was decreased in THP-1 cells expressing DDX41 p.R525H. Although the precise phase at which DDX41 takes part in the pre-rRNA processing has not been elucidated yet, this series of experiments suggests a role for DDX41in the trimming of 5' external spacer and/or ITS2. Recent studies on ribosomopathies including 5q- syndrome revealed an activation of the MDM2-p53 pathway in the pathogenesis of the diseases. Although p53 activation was not evident in the p.R525H DDX41 expressing cells, GSEA instead revealed a negative enrichment of cell cycle-promoting genes regulated by the RB-E2F axis in p.R525H DDX41 cells. Cell cycle inhibition through E2F suppression was also detected in patient-derived samples. In our study, we further found increased RPL5 and RPL11 bound to MDM2 in p.R525H DDX41 cells. It is likely that the mutant DDX41 increased free ribosomal proteins that are not incorporated into the 60S ribosome and that these proteins eventually formed a complex with MDM2, thus the degradation of RB by MDM2 might be compromised.
Summary/Conclusions: In summary, we propose a mechanism of growth defect in haematopoietic cells triggered by p.R525H DDX41 occurring in the following order: (i) p.R525H mutant inhibits pre-rRNA processing;, (ii) compromised ribosomal biogenesis as a result of impaired rRNA synthesis causes a release of ribosomal proteins that bind to MDM2; (iii) MDM2-mediated RB degradation is suppressed, thus eventually activating the RB pathway and resulting in the inhibition of E2F activity. Considering late occurrence of AML in patients harbouring the mutation, it might require age-dependent epigenetic alterations or other somatic changes for this mutation to fully transform haematopoietic cells.

P545

WHOLE EXOME SEQUENCING REVEALS NOVEL CANDIDATE GENES IN FAMILIAL MDS/AML

A Rio-Machin[1,*], S Cardoso[2], K Tawana[1], J Wang[3], C Chelala[3], V Plagnol[4], Y Wallis[5], G Ryan[5], A Ellison[2], A Al Seraihi[1], A Walne[2], H Tummala[2], J Fitzgibbon[1], I Dokal[2], T Vulliamy[2]
[1]Centre for Haemato-Oncology, Barts Cancer Institute, Queen Mary University of London, [2]Centre for Genomics and Child Health, Blizard Institute, Queen Mary University of London, [3]Centre for Molecular Oncology, Barts Cancer Institute, Queen Mary University of London, [4]UCL Genetics Institute, London, [5]Cancer Programme, West Midlands Regional Genetics Laboratory, Birmingham Women's NHS Foundation Trust, Birmingham, United Kingdom

Background: Myelodysplastic syndrome (MDS) and acute myeloid leukaemia (AML) are related heterogeneous haematopoietic stem cell clonal disorders characterised by defective haematopoiesis and premature mortality in many patients. The majority of MDS and AML cases are sporadic but there are also rare cases (<5%) where two or more affected individuals are found within the same family (familial MDS/AML). Familial MDS/AML patients represent a high-risk population who require unique follow-up and treatment strategies to achieve cancer risk reduction, prevention and best management. To date, heterozygous germline mutations in 10 disease genes (*ACD, ANKRD26, CEBPA, DDX41, ETV6, GATA2, RUNX1, SRP72, TERC* and *TERT*) have been associated with the inherited predisposition in these families, but explain only 50-60% of cases.
Aims: To identify new germ-line mutations in families with MDS/AML of unknown aetiology
Methods: Bone marrow or peripheral blood samples were collected from 78 families, where two or more members have been diagnosed with a haematological disease (AML, MDS, aplastic anaemia or thrombocytopenia) but including at least one with MDS or AML. Each index case of these families was tested for mutation in the 10 known disease genes using deep targeted sequencing.

Whole exome sequencing (WES) was performed in families with still unknown aetiology. Exome libraries were prepared using Illumina Nextera reagents and sequenced on the HiSeq2000. Germline variant calling was performed using GATK and all functional variants were selected. We used the following criteria to enrich for genes with pathogenic relevance: (i) recurrent genes (those with mutations in at least two families); (ii) novel variants or genetic lesions, not described in dbSNP137, ExAC, HAPMAP or the 1000 Genomes projects; (iii) functional annotation based on both PolyPhen scores (>0.850) and the MutationTaster algorithm (*disease causing*) to assess pathogenicity.
Results: 46 of the 78 families in our cohort (59%) have mutations in 8 of the 10 known loci (*ACD, CEBPA, DDX41, GATA2, RUNX1, SRP72, TERC* and *TERT*). In 32 families of unknown aetiology, whole exome sequencing (WES) was performed and a mean of 422 non-synonymous variants were found per sample. The chosen criteria have allowed us to limit the search to the most relevant germline mutations in our cohort, reducing the number of new candidate disease genes to nine with shared nonsynonymous variants: *ATP13A4, COL2A1, DNAJC10, GLDC, LRP2, MAN1C1, PDCD4, SEC23B* and *TFIP11*.
Summary/Conclusions: We have identified nine new potential candidate disease genes in familial MDS/AML. However, a single unifying candidate gene has not been identified, suggesting genetic heterogeneity. Further studies will establish which of these can be assigned as true 'familial MDS/AML' disease genes.

P546

CLONAL EVOLUTION IN NPM1 MUTATED ACUTE MYELOID LEUKEMIA (AML)

S Cocciardi[1,*], S Kapp-Schwoerer[1], S Hirsch[1], A Dolnik[1], TJ Blätte[1], J Krönke[1], A Corbacioglu[1], VI Gaidzik[1], P Paschka[1], V Teleanu[1], K Holzmann[2], G Göhring[3], F Thol[4], M Heuser[4], A Ganser[4], RF Schlenk[1], H Döhner[1], L Bullinger[1], K Döhner[1]
[1]Department of Internal Medicine III, [2]Genomics Core Facility, University Hospital of Ulm, Ulm, [3]Institute of Cell & Molecular Pathology, [4]Department of Haematology, Haemostasis, Oncology, and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Mutations in the *nucleophosmin 1* (*NPM1*) gene are considered a key event in the pathogenesis of AML. Recently, we gained insights into clonal architecture and clonal evolution of *NPM1 mutated (NPM1*^{mut}*)* AML. While *DNMT3A* mutations (*DNMT3A*^{mut}) showed the highest stability suggesting *DNMT3A*^{mut} to be an early event in leukemogenesis, we also observed an increase in genomic complexity at the time of relapse.
Aims: To validate our previous results on clonal evolution in a larger cohort of *NPM1*^{mut} AML patients (pts), to define relapse specific mutation patterns as well as to identify the impact on gene expression.
Methods: Paired samples at diagnosis and relapse from 129 *NPM1*^{mut} AML pts were assessed for additional mutations by comprehensive mutation analysis (*FLT3*-ITD, *FLT3*-TKD, *DNMT3A*, *IDH1/2*, *NRAS, ASXL1*, *TP53*, *MLL*-PTD). In addition, AML cases with loss of *NPM1*^{mut} at the time of relapse and with persisting *NPM1*^{mut} were subjected to whole exome sequencing (WES; n=20) and RNA-Seq was performed on selected paired *NPM1*^{mut} loss diagnosis and relapse cases (n=6).
Results: At diagnosis, concurrent gene mutations were found at the following incidence: *FLT3*-ITD 32% (40/126), *FLT3*-TKD^{mut}19% (22/118), *DNMT3A*^{mut} 69% (78/113), *NRAS*^{mut} 19% (22/117), *IDH1*^{mut} 21% (26/123) and *IDH2*^{mut} 18% (22/118). None of the pts analyzed exhibited a *TP53*, *MLL*-PTD or *ASXL1* mutation. At relapse, we found a significant shift in the genetic pattern of 74 pts (59%) with the most frequent changes seen for *FLT3*-ITD, which was lost in 10 and newly acquired in 24 pts. Additional changes affected *FLT3*-TKD^{mut}, *DNMT3A*^{mut}, *NRAS*^{mut}, *IDH1*^{mut}, *IDH2*^{mut}, *ASXL1*^{mut} and *TP53*^{mut}. Notably, gain of *MLL*-PTD (n=4) was restricted to pts with loss of *NPM1*^{mut} at the time of relapse. Based on these findings we calculated the following stabilities for the most frequent mutations: *FLT3-TKD*^{mut}27%, *NRAS*^{mut}45%, *FLT3-ITD* 75%, *IDH1*^{mut} 88% and *IDH2*^{mut} 90%, and *DNMT3A*^{mut} 97%, thereby confirming our previous findings for *DNMT3A*^{mut}. Similarly, *NPM1*^{mut} was lost at relapse in 10 pts (8%) of which 9 pts showed a stable *DNMT3A*^{mut} at relapse. By WES we could confirm persistence of mutations known to be involved in clonal hematopoiesis, such as *DNMT3A* and *TET2* mutations. These were usually seen during all analyzed time points (diagnosis, remission and relapse). Otherwise, we found distinct mutational patterns at the time of relapse compared to the time of diagnosis for *NPM1*^{mut} loss cases, while mutational profiles of cases without *NPM1*^{mut} loss at relapse remained more stable. For example, while the mutational pattern of diagnostic samples showed an enrichment for mutations affecting MYC signaling, at the time of relapse in *NPM1*^{mut} loss cases there was a significant enrichment of mutations in the MAPK signaling cascade. RNA-Seq for selected diagnosis/relapse pairs further supported a switch in signaling cascades at the time of relapse in *NPM1*^{mut} loss pts with differentially expressed genes being significantly enriched for MAPK signaling genes.
Summary/Conclusions: In total, 59% of *NPM1*^{mut} AML pts showed clonal evolution at the time of relapse. In accordance with our previous findings, *DNMT3A*^{mut} demonstrated the highest stability constituting early events that persist in preleukemic hematopoietic stem cells. While some relapse cases evolve from clones already forming the tumor bulk at diagnosis, *NPM1*^{mut} loss relapse cases possess almost no relationship to the paired diagnosis sample, apart from preleukemic mutations, and demonstrate a switch in major signaling cascades.

POOR PROGNOSIS MONOSOMIC AND TRISOMIC ACUTE MYELOID LEUKEMIA ASSOCIATES WITH CHECKPOINTS AND CDC20 DEREGULATION: A NOVEL LEUKEMOGENIC MECHANISM AND THERAPEUTIC TARGETS

G Simonetti[1,*], A Padella[1], M Manfrini[1], LF do Valle[2], C Papayannidis[1], C Baldazzi[1], A Ferrari[1], MC Fontana[1], V Guadagnuolo[1], E Zago[3], M Garonzi[4], A Astolfi[5], A Laginestra[1], G Marconi[1], E Zuffa[1], E Franchini[1], I Iacobucci[1], M Cavo[1], E Ottaviani[1], N Testoni[1], A Ferrarini[4], M Delledonne[34], T Haferlach[6], D Remondini[2], G Martinelli[1]
[1]Department of Experimental, Diagnostic and Specialty Medicine, [2]Department of Physics and Astronomy, University of Bologna, Bologna, [3]Personal Genomics, [4]Department of Biotechnology, University of Verona, Verona, [5]Centro Interdipartimentale per la Ricerca sul Cancro "G. Prodi", University of Bologna, Bologna, Italy, [6]Munich Leukemia Laboratory, Munich, Germany

Background: Chromosome number alteration, aneuploidy, causes unfitness in eukaryotic cells and is generally not sufficient to induce malignant transformation. However, it is a hallmark of cancer and 10-15% of acute myeloid leukemia cases are aneuploid.
Aims: Aim of the study was to investigate the molecular mechanisms activated by A-AML cells to tolerate an abnormal chromosome number and overcome the unfitness barrier, in order to define potential druggable targets.
Methods: We performed whole exome sequencing of 42 aneuploid (A-) AML (isolated trisomy and monosomy, complex and monosomal karyotype) and 34 euploid (E-) AML (100 bp, paired-end, Illumina platform). Variants were called by MuTect and Varscan 2.0. Gene expression profiling was obtained from bone marrow cells of 22 A-AML and 27 E-AML with 80-100% blasts (HTA 2.0, Affymetrix). Data were analyzed using Transcriptome Analysis Console 3.0 (Affymetrix) and Gene Set Enrichment Analysis (Broad Institute).
Results: In a cohort of 166 AML patients (80 A-AML and 86 E-AML) treated at our Institute, aneuploidy was associated with poor overall survival (median survival: 13 and 26 months in A-AML and E-AML, respectively; p<.01). A-AML showed reduced expression of RAD50 and ATR compared with E-AML (p<.001), suggestive of an impaired DNA damage response and checkpoint arrest, despite normal levels of CHK1 and CHK2 kinases. These defects hampered the activation of p53, the guardian of ploidy and its transcriptional program, which were disrupted both at functional and genomic levels. A-AML was not only enriched for *TP53* mutations, which were common in complex and monosomal karyotype cases and absent in E-AML, but also for genomic lesions targeting p53-related genes, including those involved in p53 activation (*APAK*, *FATS*, *PIAS4*) and stability (*USP10*, *DDX31*) and known p53 targets (*RBM38*, *DDR1*). Overall, 42% A-AML had a mutation in *TP53* or its related genes, compared with 15% E-AML (p=.01). Moreover, a gene expression signature of p53 downregulation was enriched in A-AML, irrespective of the mutational status (p<.05). Upregulation of PLK1 contributed to functional inactivation of p53 in A-AML (p<.01). PLK1 also forced entry and progression through mitosis in A-AML by cooperating with overexpression of CDC20 (p<.001), which is sufficient to overcome the spindle-assembly checkpoint, leading to the formation of daughter cells with an aberrant chromosome number. The spindle assembly machinery and additional cell cycle-related genes involved in DNA replication, centrosome dynamics, chromatid cohesion and chromosome segregation were frequently mutated (p<.05) or deregulated at transcriptional level (p<.01) in A-AML, suggesting a role in promoting and maintaining genomic instability, which was highlighted by a higher number of genomic alterations in A-AML. The mutations mostly targeted chromatin modifiers, splicing, DNA methylation and signaling genes. In parallel, a KRAS transcriptional signature was upregulated in A-AML (p<.05), irrespective of the mutational status, to sustain cell survival and proliferation.
Summary/Conclusions: We depicted here for the first time the complex molecular mechanisms promoting and maintaining the aneuploid phenotype in AML, which include deregulated checkpoint response and cell cycle machinery, inactivated p53 and hyperactivated KRAS pathway. This evidence suggests that pharmacological reactivation of p53, inhibition of cell cycle checkpoints and KRAS signaling, which are under investigation, may be valuable therapeutic strategies for aggressive A-AML.

IN ACUTE MYELOID LEUKEMIA WITH COMPLEX KARYOTYPE CHROMOTHRIPSIS IS LINKED TO TP53 ALTERATION AND CELL CYCLE IMPAIRMENT

F Rücker[*], A Dolnik, H Kett, R Schlenk, H Döhner, K Döhner, L Bullinger
University Hospital of Ulm, Ulm, Germany

Background: The single catastrophic event "chromothripsis", uncovered by

genome sequencing, is a phenomenon of genomic instability. It is characterized by extensive genomic rearrangements reflected by an oscillating pattern of DNA copy number levels in one or few chromosomes as assessed by *e.g.* single-nucleotide polymorphism (SNP) microarray analysis. The prevalence of chromothripsis across tumor entities is very heterogeneous, and despite several studies linking chromothripsis with *TP53* alterations, the underlying mechanisms are still largely unknown. In acute myeloid leukemia (AML), *TP53* alterations (loss and/or mutation) are almost exclusively found in cases with complex karyotype (CK-AML).

Aims: Our aim was to gain further insight into the role of chromothripsis in AML.

Methods: We performed integrative analysis using genomic SNP microarray profiling, global gene expression profiling as well as *TP53* mutation screening in 103 CK-AML and correlated our findings with clinical data of 55 age-adjusted intensively treated study patients (HD98A, AMLSG 07-04, and AMLSG 06-04).

Results: SNP profiling identified rearrangement patterns consistent with chromothripsis (defined as at least ten switches between two or three copy-number states on an individual chromosome) in 36 of 103 CK-AML (35%). The most frequent affected chromosome (chr) was chr 7 (14%) followed by chr 3, 5, 17, 21 (11% each), and 6, 8, 10, 11, and 12 (5% each). Cases with chromothripsis were characterized by a higher degree of genomic complexity, as measured by total number of copy number alterations per case (mean±SD 23±10 *versus* 11±10, P<.0001), and by the association with specific genomic alterations, that is, monosomy 5 or losses of 5q (-5/5q-) (P=.003), -7/7q- (P=.02), -16/16q- (P=.009), and the cytogenetic category "monosomal karyotype" (P=.0002). Genetically, as previously reported chromothripsis was correlated with *TP53* alteration (30/36 chromothripsis-positive CK-AML *vs* 37/67 chromothripsis-negative CK-AML, P=.005). Clinically, CK-AML patients with chromothripsis were slightly older (median age, 62 *versus* 58 years, P=.02) and showed in trend lower bone marrow blast counts (median 45% *versus* 80%, P=.07). Whereas *TP53* alteration predicted for lower complete remission (CR) rate (*TP53*^{altered} 25% *vs TP53*^{unaltered} CK-AML 68%, P=.005), chromothripsis had no impact on CR, but predicted for inferior survival; the 2-year estimated survival rates for chromothripsis-positive and chromothripsis-negative patients were as follows: event-free survival (EFS), 0% *versus* 12% (P=.01); relapse-free survival (RFS), 0% *versus* 35% (P=.06); and overall survival (OS), 0% *versus* 26% (P=.02), respectively. Since chromothripsis is associated with *TP53* alteration, which is the most important prognostic factor in CK-AML outweighing all other known prognostic variables in multivariable analysis, chromothripsis does however not provide additional independent prognostic information. On the other hand, gene expression profiling comparing chromothripsis-positive *vs* –negative *TP53*^{altered} CK-AML cases showed a distinct gene signature pointing to mechanisms underlying chromothripsis. For example, in addition to *TP53* alteration chromothripsis-positive cases showed a significant deregulation of genes associated with genomic instability (*e.g.* Fanconi anemia pathway genes), mitotic regulation (*e.g. CCNA1*) as well as transcriptional regulation (*e.g. CEBPA*).

Summary/Conclusions: Detailed molecular profiling links chromothripsis to impaired *TP53* in CK-AML and suggests an addition pathogenic basis for the occurrence of chromothripsis.

P549

PHYSIOPATHOLOGICAL MECHANISM OF LEUKEMIC PREDISPOSITION IN ANKRD26-RD PATIENTS

A Donada[1,2,3,*], V Manchev[1], N Balayn[1,2,3], D Sliwa[1,2,3], I Plo[1,2,3], N Debili[1,2,3], R Favier[4], W Vainchenker[1,2,3], H Raslova[1,2,3]
[1]UMR1170, Equipe Labellisée Ligue Contre le Cancer, INSERM, [2]Gustave Roussy, [3]Université Paris Saclay, Villejuif, [4]Service d'Hématologie Biologique, Assistance Publique-Hôpitaux de Paris, Hôpital Trousseau, Paris, France

Background: Familial thrombocytopenia 2 (THC2) is a rare autosomal dominant platelet disorder, associated with a predisposition to develop haematological malignancies and is caused by different mutations in the *ANKRD26* 5' UTR. This gene is coding for a membrane-associated protein that is predicted to interact with signaling effectors including cytokine receptors, and that behaves as a scaffold between different protein partners.

In megakaryocytes (MKs), the mutations in the 5' UTR eliminates the DNA binding of two transcription factors, RUNX1 and FLI1, causing the loss of transcriptional repression of *ANKRD26* along differentiation; this results in an abnormal expression of the protein in mature megakaryocytes inducing an over-activation of the TPO/MPL/MAPK signaling pathway responsible for a defect in platelet formation and explaining the thrombocytopenia.

Aims: To study the mechanisms responsible of the pre-leukemic state, we generated iPSC lines from isolated CD34+ cells of three patients harbouring three different *ANKRD26* mutations; in addition, they were transduced with a short hairpin RNA (shRNA) targeting *ANKRD26* (shANKRD26).

Methods: The iPSCs were successfully differentiated toward an haematopoietic fate with a co-culture system (OP9 cells) and a feeder-free system: the derived MKs showed the same defects observed in patient primary cells, that were rescued by the shANKRD26, therefore validating the relevance of the iPSC model.

Results: Next, we used this model to study the granulo-monocytic (GM) compartment: we found an increased expression of *ANKRD26* in the GM progenitors derived from patients iPSC and primary cells, but also an increase in their number and proliferation. We observed an over-activation of the JAK/STAT, MAPK and AKT signalling pathways in presence of G-CSF, suggesting a possible interaction between ANKRD26 and the G-CSF receptor (CSFR3). Those results were confirmed in the cell line UT7/G-CSFR. This cell line constitutively overexpresses ANKRD26, and its knock down by the shRNA markedly decreased proliferation in the presence of G-CSF. In contrast we did not observe any difference in the proliferation rate in presence of GM-CSF, a feature that suggests a functional link between ANKRD26 and the G-CSFR, but not with the GM-CSF receptor. In addition, we observed a sensible reduction of the proliferation rate of patients and iPS-derived granulocytic precursors in presence of JAK1/2 inhibitor (ruxolitinib). We also detected an increase of PIM1 expression, a direct target of STAT3/5 and a possible mediator of this lineage over-proliferation (Figure 1).

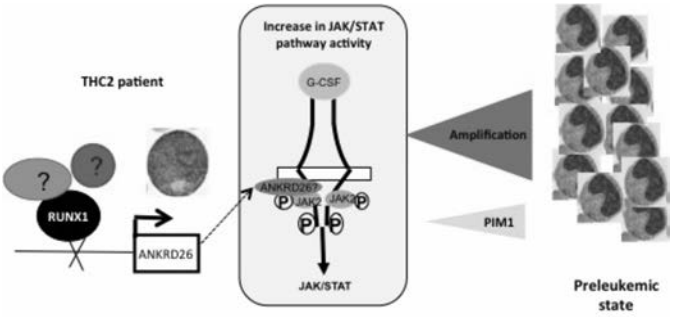

Figure 1.

Summary/Conclusions: In conclusion, this work shows an important role for ANKRD26 in two different signaling pathways, TPO/MPL and G-CSF/G-CSFR, the former responsible for the thrombocytopenia, the latter may be implicated in the pre-leukemic state.

NOTCH SIGNALLING INHIBITION AS A MULTI-TARGET THERAPY TO OVERCOME BONE MARROW MICROENVIRONMENT-MEDIATED DRUG RESISTANCE IN AML

P Takam Kamga*, G Bassi, A Cassaro, A Adamo, A Gatti, G Dal Collo, M Midolo, R Carusone, M Di Trapani, M Bonifacio, M Krampera
Medicine, University of Verona, Verona, Italy

Background: Several pro-survival proteins promoting resistance to chemotherapy, such as BCl-2, STAT3,NFκB and AKT,are over-expressed in AML cells, thus representing the basis for targeted therapies. However, only multi-target drug strategy may lead to the modulation of the pro-survival protein network, due to the simultaneous activation of alternative pathways.

Notch signalling is a master developmental pathway that controls tumour cell survival by interacting with pro-survival proteins, such as β-catenin, BCL-2, STAT3, NFκB, and AKT, thus representing an ideal target to interfere with all these pathways in different cancer systems.

We recently showed that Notch inhibition was capable of abrogating microenvironment-mediated AML cell chemo-resistance (P550, EHA20); however, little is known about the mechanism involved.

Aims: We studied the mechanisms underlying microenvironmental, Notch-mediated AML chemo-resistance by investigating the contribution of BCl-2, STAT3, NFκB and AKT. Using *in silico* and *in vitro* approaches we analyzed the expression changes of these proteins in *ex-vivo* AML cell samples in condition of pharmacological or genetical Notch down-regulation, as well as in AML cells either cultured alone or co-cultured with human bone marrow mesenchymal stromal cells (hBM-MSCs) in presence of chemoterapeutic agents, such as cytarabine (Ara-C) and Idarabucin.

Methods: Cells were obtained from bone marrow (33) and peripheral blood (22) samples of AML patients. hBM-MSCs were expanded from bone marrow of 20 healthy donors (BM-MSCs) and 20 AML patients (BM-MSCs*). Gene set enrichment analysis (GSEA) were perform using GEOR tools on AML expression array of 304 patients previously deposited in Gene Expression Omnibus (GSE10358). Genetic inhibition of Notch signalling was achieved in AML cell lines (HL-60 and THP1) by infecting cells with lentiviral particles carrying shRNA for either RBP-jK or MALM1, two mediators of Notch signaling. Pharmacological Inhibition of Notch in AML was achieved by using Gamma secretase Inhibitors (GSIs), Notch transcription factors Inhibitor SAHM1, and combination of Notch blocking antibodies.Ara-C, and idarubicin were added to culture supernatants at different concentrations. Cell viability was evaluated by Annexin-V/Propidium Iodide (PI). Protein levels were analyzed by intracellular staining with corresponding fluorophore conjugated antibodies, followed by flow cytometry analysis.

Results: *In silico* Gene set enrichment analysis and flow cytometry analysis showed that AML samples highly expressed Notch1, Jagged1, STAT3, NFκ-B and AKT genes and proteins. Notably, higher levels of Notch1 were found in patients with poor cytogenetic prognosis, while STAT3, NF-κB and AKT were uniformly expressed by AML patients. Protein analysis revealed low levels of

pro-survival proteins AKT, STAT3 and NF-κB in RBP-jk and MALM1 knockdown cells, as compared to control cells infected with non specific shRNA. We then verified that genetic (shRNA) and pharmacological inhibition of Notch, by using either GSIs or Notch receptor blocking antibodies, was capable of sensitizing AML cells, either cultured alone or in presence of hBM-MSCs, to ARA-C or idarubucine. Additionally, we found that hBM-MSC-dependent induction of AML chemoresistance was associated to increase of AKT, NF-κB and STAT3 protein levels in AML cells. Similarly, Notch inhibition with GSIs prevented hBM-MSC-mediated increase of AKT, NF-κB and STAT3, thus restoring sensibility of AML cells to Idarubucin treatment.

Summary/Conclusions: These results suggest that inhibition of Notch signalling is sufficient to reduce protein levels of AKT, STAT3 and NF-κB proteins involved in AML chemoresistance, thus making the pro-survival core network controlled by Notch a potential target for specific Notch targeted therapies.

Background: Acute myeloid leukemia (AML) is a heterogeneous myeloid neoplasm that develops in hematopoietic stem and progenitor cells (HSPCs) with altered ability to self-renew, proliferate and differentiate. The karyotype and recurrent lesions in *NPM1*, *FLT3-ITD* and *CEBPA* are associated with patient remission, relapse and survival and have been integrated into AML prognostic indices such as those developed by the United Kingdom Medical Research Council (MRC) or the European Leukemia Net (ELN). However, the utility of these guidelines for clinical decision making has only been validated in the ~40% of patients younger than 60 years (SEER). The human genome consists of more than three billion nucleotides that encode a relatively small number of coding (~1.5%) and a larger number of non-coding (~75%) transcripts. The association between the coding genome and the biology and pathogenesis of AML and its utility for clinical decision making has been extensively studied. However, the contributions from the large pool of non-coding RNAs to these events is largly unknown.

Aims: Long intergenic non-coding RNAs (lincRNA) are emerging as key regulators of an increasing number of molecular processes and have been shown to regulate stem cell activity and function during myeloid and lymphoid differentiation, while their role in leukemia is poorly understood. Therefore, we aimed to: 1. Comprehensively describe and evaluate the expression of lincRNAs in leukemic cells from widely used, large, clinically annotated AML cohorts, AML cell lines and in normal hematopoietic stem and progenitor cell subsets. 2. Develop and validate lincRNA signatures that are robust predictors of patient survival, not limited to single patient cohorts but significant across multiple large cohorts, and do not require measurement of large numbers of genes.

Methods: Here we analysed expression profiles of 1664 lincRNAs measured using three technologies in 922 patients from three independent patient cohorts including those from the United States of America (The Cancer Genome Atlas), Netherlands (HOVON), Germany (CALGB) and we sourced a fourth independent Australian AML dataset to experimentally validate our findings. We also analysed datasets from the BLUEPRINT epigenome project and the Cancer Cell Line Encyclopedia to compare our findings to expression profiles in normal hematopoietic cells and AML cell lines.

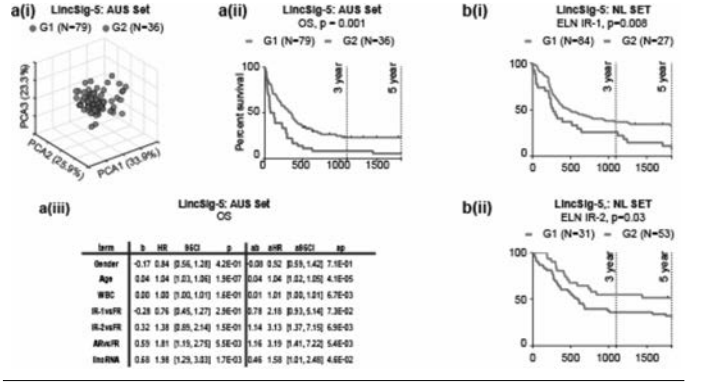

Figure 1.

Results: We developed and validated a novel approach to quantify the expression of 1664 lincRNAs in 736 AML patients from 3 well-characterized patient cohorts representing the largest resource of lincRNA expression profiles available in AML. Interrogation of this database (i) reconfirmed previously known regulatory relationships and uncovered lincRNAs in close proximity to key haematopoietic genes that showed strong expression correlations across AML

datasets, identified that distinct lincRNAs expression profiles are (ii) associated with recognized cytogenetic and mutational subgroups of AML and (iii) expressed in AML and normal HSPC subsets. We also (iv) identified 48 lincRNAs that were significantly correlated with patient outcomes and (v) expression signatures composed of 2-4 lincRNAs that have prognostic value in addtion to current clinical risk algorithms based on the assesment of karyotype and mutations in *CEBPA*, *FLT3* and *NPM1*, (vi) that these signatures can be measured by RT-PCR and used as a standalone tool or in conjunction with the ELN to predict survival across multiple AML cohorts, including patients older than 60 years (Figure 1a and b).
Summary/Conclusions: Taken together, this comprehensive analysis of lincRNA expression in multiple AML patient cohorts and in normal hematopoietic cell subsets not only highlights their value as prognostic markers but also provides a platform to selectively perturb lincRNAs in leukemic cells.

ENANTIOMER-SPECIFIC AND PARACRINE LEUKEMOGENICITY OF MUTANT IDH METABOLITE 2-HYDROXYGLUTARATE

A Chaturvedi[1,*], MM Araujo Cruz[1], N Jyotsana[1], A Sharma[1], R Goparaju[1], A Schwarzer[2], K Görlich[1], R Schottmann[1], EA Struys[3], EE Jansen[3], C Rohde[4], C Müller-Tidow[4], R Geffers[5], G Göhring[6], A Ganser[1], F Thol[1], M Heuser[1]
[1]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, [2]Institute of Experimental Hematology, Hannover Medical School, Hannover, Germany, [3]Department of Clinical Chemistry, VU University Medical Center, Amsterdam, Netherlands, [4]Department of Hematology and Oncology, University of Halle, Halle, [5]Genome Analytics Group, Helmholtz Centre for Infection Research, Braunschweig, [6]Institute of Human Genetics, Hannover Medical School, Hannover, Germany

Background: Canonical mutations in *IDH1* and *IDH2* produce high levels of the R-enantiomer of 2-hydroxyglutarate (R-2HG), which is a competitive inhibitor of αKG-dependent enzymes and a putative oncometabolite. Almost all patients with *IDH1/2* mutations express high levels of intracellular R-2HG, while an increase of the S-enantiomer of 2HG has never been described in AML, glioma, chondrosarcoma or intrahepatic cholangiocarcinoma patients.
Aims: To investigate whether oncometabolites R-2HG and/or S-2HG, have a causative function in leukemogenesis or instead are rather only biomarkers for oncogenic IDH.
Methods: We daily administered R-2HG and S-2HG at a dose of 1mg/mouse *in vivo* in three independent mouse models (HoxA9, MLL-AF9 and an AML patient derived xenotransplantation model) containing only wild-type IDH1 and compared the blood profile, survival, gene expression and differentially methylated regions between the groups.
Results: R-2HG treated mice had significantly higher engraftment levels in peripheral blood than S-2HG and PBS treated mice. R-2HG treated mice developed striking leucocytosis, and had declining hemoglobin and platelets compared to S-2HG or PBS treated mice. Peripheral blood from R-2HG treated mice revealed significantly more immature and less mature myeloid cells after treatment than S-2HG, αKG and PBS treated mice. Furthermore, the R-2HG treated mice died significantly earlier than mice treated with S2HG and PBS in all three models. A question of current investigation is whether R-2HG alone is responsible for the transforming effects of mutant IDH or if the mutant protein contributes additional oncogenic functions. Interestingly, both cohorts, HoxA9+IDH1mut and HoxA9 treated with R-2HG, developed leukemia, albeit with different kinetics. Next, we examined whether the faster disease kinetics of mutant IDH1 compared to R-2HG would be overcome if the R-2HG dose was increased from 1 to 5 mg R-2HG per day. We observed a dose dependent increase of R-2HG in bone marrow cells of treated mice, while the dose of 5 mg R-2HG per day even slightly exceeded R-2HG of cells expressing mutant IDH1. Mice treated with 1 or 5 mg of R-2HG had similar engraftment levels and died with an identical latency, while IDH1 mut mice died significantly earlier. In gene expression data R-2HG treated cells clustered with IDH1 mut cells, while IDH1 wt cells clustered with HoxA9 control cells. However, many genes that were exclusively upregulated in IDH1 mut cells but not in R-2HG treated cells showed that R-2HG treated cells were at an intermediate stage between control/IDH1 wt cells and IDH1 mut cells. The differentially methylated regions (DMRs) between R-2HG treated cells and IDH1 wt cells were well represented in IDH1 mut cells. However, DMRs between IDH1 mut and IDH1 wt cells were not well represented in R-2HG treated cells and these cells clustered with IDH1 wt and not IDH1 mut cells. The higher number of hyper- and hypomethylated regions in IDH1 mut cells compared to R-2HG treated cells, supports an additional function of the mutant protein on transcriptional regulation and DNA methylation beyond the function of the metabolite R-2HG and can explain the earlier disease onset of IDH1 mut cells compared to R-2HG treated cells.
Summary/Conclusions: We show that R-2HG, but not S-2HG, is an oncometabolite that does not require the mutant IDH1 protein to induce hyperleukocytosis and to accelerate disease onset *in vivo*. Thus, circulating R-2HG acts in a paracrine fashion and can drive the expansion of many different leukemic and preleukemic clones that may even express wildtype IDH1, and therefore can be a source of clonal evolution and diversity.

P553

INVOLVEMENT OF THE TRANSCRIPTION FACTOR ASCL2 IN NORMAL AND LEUKEMIC HEMATOPOIESIS

M Dépond[1,*], Y Zhang[1], L He[1], M Wittner[1], V Baral[1], R Tang[2], O Legrand[2], MC Béné[3], F Delhommeau[2], V Joulin[1], F Louache[1]
[1]IGR U1170 inserm, villejuif, [2]Service d'Hématologie et Thérapie cellulaire, Hôpital St Antoine, Paris, [3]Laboratoire d'Hématologie, Nantes, France

Background: The transcription factor ASCL2 (Achaete Scute-like 2) is involved in intestinal stem cell biology regulating their stem cell identity while its overexpression induces an intestinal hyperplasia. In addition, it is over-expressed in numerous tumor types. In cancer cells and T follicular cells, it regulates the expression of CXCR4, a chemokine receptor involved in cell migration, homing and proliferation. Conversely, CXCR4 and Wnt signaling regulates ASCL2 expression suggesting that CXCR4 and ASCL2 interact to regulate the metastasis formation. In acute myeloid leukemia (AML), CXCR4 has a predominant role in the regulation of interaction of cells with their environment and its expression is correlated with poor prognosis. However, ASCL2 contribution to AML in poorly understood.
Aims: The aim of this study is to elucidate the role of ASCL2 in normal and leukemic hematopoiesis by analyzing of its expression in AML and normal hematopoietic progenitors and using different cell line models for the overexpression and down regulation.
Methods: To study the function of ASCL2 transcription factor, 135 samples of AML patients were analyzed for the ASCL2 mRNA level. CXCR4+/+ and CXCR4-/- murine leukemic cells were generated by expression of MLL-ENL fusion protein in fetal liver cells for E15 embryos. To examine the effects of loss of function of ASCL2 on leukemic development, murine leukemic cells were transduced with shRNA targeting ASCL2 and engrafted to mice. Finally, we examined the consequences of ASCL2 overexpression by enforcing its expression using lentivirus transduction in CD34+ progenitor cells.
Results: We first observed that 32% (43/135) of AML samples displayed ASCL2 mRNA expression higher than normal progenitor CD34+ cells from bone marrow of control individuals. In addition, the level of ASCL2 mRNA correlates with poor prognosis AML (p<0,001). Normal hematopoietic cells and progenitors show a weak expression of ASCL2, except monocytes and NK cells. In murine leukemic models, we found a high expression of ASCL2 in leukemic stem cells that is dependent of CXCR4 and correlates with expression of the stem cell associated genes HOXB4 and HOXB13. Knocking-down ASCL2 by shRNA in murine leukemic cells induces a sharp decrease in the number of leukemic cells and delayed leukemic progression *in vivo* resulting *in* increased survival of leukemic mice. Enforced expression of ASCL2 in cord blood CD34+ progenitor cells induces a 4-fold decrease in the cloning efficiency in progenitor assays compared to cells transduced with GFP (p<0,02). Surprisingly, a subset of ASCL2 transduced cells were able to sustain colony formation in secondary, third and fourth serial colony assays suggesting that ASCL2 overexpression has differential effect depending on targeted cells.
Summary/Conclusions: Our results indicate that ASCL2 is overexpressed in AML. In AML murine models, ASCL2 down regulation delayed leukemic progression while it may maintains the self-renewal capacity of subsets of cells. Altogether, our results implicate ASCL2 as an important regulator in AML development and suggest that ASCL2 expression is associated with aggressiveness of leukemia.

P554

DIFFERENTIAL DNA METHYLATION IN CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA IS LINKED TO ALTERED GENE EXPRESSION OF ENHANCER TARGET GENES

Y Qu[1,*], L Siggens[2], L Cordeddu[2], K Ekwall[2], S Lehmann[1,3], A Lennartsson[2]
[1]Center for Hematology and Regenerative Medicine (HERM), [2]Department of Biosciences and Nutrition, Karolinska Institute, Stockholm, [3]Department of Medical Sciences, Hematology Unit,, Uppsala University, Uppsala, Sweden

Background: During normal hematopoiesis, DNA methylation is tightly controlled at regulatory elements. Enhancer methylation patterns can distinguish both between different cell identities and maturation stages. In our previous work, we found aberrant DNA methylation in low CpG density regions and in transcription factor genes in AML patients and that dynamic enhancer methylation during normal granulopoiesis correlate with gene expression pattern. However, changes of DNA methylation in enhancer regions occur in leukemia are remaining largely unknown.
Aims: To study the aberrant DNA methylation of enhancers in AML patients in correlations to altered chromatin status and putative target gene expressions.
Methods: In this study a total of 57 cytogenetically normal AML (CN-AML) patients and 12 FACS sorted bone marrow myeloid samples with four differentiation stages from 3 healthy individuals were used to profile DNA methylation changes in AML and granulopoiesis using the Illumina 450k array. H3K27ac ChIP sequencing was performed on 6 CN-AML patients' mononuclear cell samples and analyzed together by integrating data of hypersensitivity sites sequencing (DHSseq) of normal bone marrow CD34+, NB4 and HL60 from ENCODE project and 5 CN-AML patients from recent published paper. Total enhancers were obtained from FANTOM5 project and used for analyzing correlation to putative target genes. Moreover, selected enhancers were edited by CRISPR/Cas9 system in order to test the expression change of target genes.
Results: We found a number of hypermethylated and hypomethylated sites in

AML patients compared to NBM, some of which are specific to AML while others correspond to changes observed during granulopoesis. In addition a core set of the changes observed were independent of specific mutations. Strikingly, the majority of these changes occurred in regulatory regions of the human genome defined as DNA hypersensitivity (DHS) sites. Hypermethylated sites show reduced chromatin accessibility and histone acetylation (H3K27ac) at transcription start sites (TSS) proximal and distal regions from TSS suggesting active promoters and enhancers that are hypermethylated are silenced. Hypomethylated sites occurred more frequently outside of TSS regions with only a subset of hypomethylated sites in distal regions from TSS correlated to increased chromatin accessibility and H3K27ac. To examine if the changes in DNA methylation at enhancer regions are correlated to altered gene expression of target genes in AML we focused on differential methylation of enhancers defined by the FANTOM consortium, which have high confident target gene predictions. An adverse correlation between enhancer methylation changes and putative target gene expression levels was found by integrating transcriptome data from RNA sequencing in the AML patients. Moreover, by using CRISPR/Cas9 system, targeted editing of selected active enhancer elements in AML cell lines HL60 and KG1a lead to decreased expression of target genes.
Summary/Conclusions: This study demonstrates the relationship between abnormal DNA methylation and enhancer activation, which correlates with target gene expression in CN-AML. This suggests that there are unique regulatory events that occur in CN-AML at enhancer regions, which distinguish AML patients from NBM and granulopoietic progenitors. Our results suggest that aberrant DNA hypomethylation at distal regulatory regions in AML can cause opening up of the chromatin, resulting in abnormal transcriptomic alternation of the target genes that potentially contribute to leukemogenesis.

P555

IN VIVO SHRNA SCREEN IDENTIFIES SPLICING FACTOR RBM25 AS A TUMOR SUPPRESSOR IN ACUTE MYELOID LEUKEMIA

Y Ge*, M Schuster, S Pundhir, F Bagger, N Rapin, B Porse
Finsen Laboratory & Danstem center & BRIC – Biotech Research and Innovation Center, University of Copenhagen, Copenhagen N, Denmark

Background: Acute Myeloid Leukemia (AML) is a heterogeneous collection of hematological malignancies, which are maintained by a population of so-called leukemic stem cells (LSCs). LSCs accumulate various genetic and epigenetic abnormalities, including aberrations in mRNA splicing. Recent progress suggests that dysregulation of splicing factors contributes to pathogenesis of AML, but little is known about the AML-specific dependency on splicing factors for leukemic cells survival and proliferation.
Aims: The current study uses *in vivo* shRNA screen approach to identify novel splicing factors required for leukemia progression.
Methods: We used a mouse model of human CEBPA mutant AML and a splicing factor shRNA library to screen for novel splicing factor genes essential for AML. Functional study of the best candidate gene RBM25 included *in vivo* competitive bone marrow transplantation assay, survival assay and *in vitro* colony forming unit assay. In the human leukemic cell line U937, RBM25 knockdown cells were assessed proliferation, cell cycle and apoptosis by flow cytometry. Splicing events were detected by SpliceR tool based on RNA-sequencing data on U937 cells carrying RBM25-shRNA or not.
Results: By *in vivo* shRNA screen in CEBPA mutant AML mouse model, we found that splicing factor Rbm25 was important for murine leukemic cells *in vivo* and for human leukemic cells in liquid culture. Rbm25 knockdown accelerated the growth of leukemic cell after transplantation, and shortened the lifespan of leukemic mice. RBM25 knockdown accelerated proliferation and colony formation of human leukemic cells U937 by increasing cell cycle progression and decreasing apoptosis. Using RNA-seq profiling in U937 cells, we identified 368 transcripts that were regulated by RBM25. Particularly, RBM25 knockdown promoted alternative splicing of BIN1 to produce inactive form that block its interaction with MYC, thus the oncogenic MYC pathway was activated. Moreover, by accurate RT-qPCR method, we showed RBM25 regulated Bcl-x splicing to affect apoptosis. RBM25 knockdown caused the accumulation of anti-apoptotic isoform Bcl-xL, and ABT-263 inhibition of Bcl-xL partially reversed the RBM25-mediated tumor progression.
Summary/Conclusions: This study showed that splicing factor Rbm25 knockdown can promote proliferation of both murine and human leukemic cells, and provides detailed mechanistic insights into RBM25-regulated splicing dysregulation in AML. The newly identified tumor suppressor gene RBM25 has great therapeutic potential and clinical values as a prognostic factor.

Background: Acute Myeloid Leukemia (AML) are heterogeneous haematological diseases characterized by a clonal expansion of immature progenitors and associated with overall poor prognosis. Many aberrant activation of signalling pathways are found in AML which enhances the proliferation and survival of leukemic cells. Among them, mTORC1 signalling, which controls protein translation, autophagy and metabolism, is activated in almost all AML samples. Metabolic reprogramming is a common phenotype in cancer cells and mainly occurs through the well-known "Warburg effect» which consists in enhanced glucose catabolism even in the presence of oxygen. High rate glycolysis provides tumor cells advantages through rapid production of ATP and intermediates for the synthesis of nucleotides, amino acids, and lipids.
Aims: We investigated in our present study whether mTORC1 signaling could drive the metabolic reprogramming of AML cells, especially toward glucose utilization, and if high mTORC1 activity could lead to the sensitivity of leukemic cells to metabolic targeted therapy.
Methods: We performed analysis in 6 AML cell lines, in primary AML cells obtained from bone marrow or blood samples of 18 patients at diagnosis and in normal CD34+ hematopoietic progenitor cells (HPCs). mTOR signalling was down-regulated with either rapamycin or ShRNAs targeting RAPTOR, mTOR or RICTOR and mTORC1 activity was up-regulated through TSC2 deletion by CRISPR/Cas9. Glucose flux was analyzed using ^{13}C nuclear magnetic resonance.
Results: Using a transcriptomic profiling, we first identified an mTORC1-dependant glucose metabolic signature in AML cells. We also showed that high mTORC1 activity promoted glycolysis and led to glucose addiction in AML cells. Indeed, the level of mTORC1 activity determines the sensitivity of AML cells to glycolysis inhibition: whereas AML cell survival with high mTORC1 activity is dependent on glucose availability, switch-off mTORC1 activity by pharmacological (rapamycin) or genetic invalidation (mTOR or RAPTOR knockdown) leads to glucose-independent cell survival that is mainly sustained by a compensatory increase in mitochondrial oxidative phosphorylation (OXPHOS). Finally, we observed a high flux of glucose through the pentose phosphate pathway (PPP) which supports AML cell growth. Indeed, 6-aminonicotinamide (6-AN), which blocks the activity of the glucose-6-phosphate dehydrogenase (G6PD), the key limiting enzyme of PPP, induced cytotoxicity against AML cells *in vitro* – including in primary samples from AML patients – and *in vivo*, without impact on normal hematopoietic progenitor cells.
Summary/Conclusions: Overall, our results demonstrate that high mTORC1 activity creates a specific vulnerability to G6PD inhibition that may work as a new AML therapy. Given that mTORC1 signaling is deregulated in almost all AML samples, targeted therapy against G6PD may be beneficial for a broad range of patients with AML.

ALVOCIDIB POTENTIATES THE ACTIVITY OF ABT-199 IN NONCLINICAL MODELS OF ACUTE MYELOID LEUKEMIA

C Whatcott[1,*], J Bogenberger[2], W Kim[1], K Soh[1], YS Lee[1], P Peterson[1], K Maughan[1], A Siddiqui-Jain[1], S Weitman[1], D Bearss[1], S Warner[1], R Tibes[2]
[1]Tolero Pharmaceuticals, Inc., Lehi, [2]Mayo Clinic, Scottsdale, United States

Background: The BCL-2 inhibitor ABT-199 (or venetoclax) has recently received FDA breakthrough therapy designation for use in combination with hypomethylating agents (HMAs) in patients with acute myeloid leukemia (AML). Early stage trials have demonstrated clinical response rates over 70% in combination with HMAs (azacitidine or decitabine) in previously untreated elderly patients with AML. Single-agent activity of ABT-199 was modest in AML, and resistance is developing in combination regimens. One proposed mechanism of resistance is compensatory up-regulation of other BCL-2 family proteins such as MCL-1, which plays a general role in resistance to BCL-2 inhibitors. The CDK9 inhibitor, alvocidib, as a component of a sequential regimen with chemotherapy, demonstrated a superior rate of complete remission in newly diagnosed intermediate and high-risk AML patients over standard induction chemotherapy in a randomized multicenter Phase 2 trial. We and others have demonstrated that alvocidib inhibition of CDK9 can mediate transcriptional repression of anti-apoptotic MCL-1. Further, we and others have shown that alvocidib can increase pro-apoptotic BIM (a pan BH3-only protein) in some cells. BIM is known to neutralize all anti-apoptotic BCL-2 family proteins such as MCL-1 and BCL-2, thus having a similar net effect on mitochondrial outer membrane permeabilization (MOMP)-induced apoptosis as MCL-1 down-regulation. Therefore, we hypothesize that alvocidib and ABT-199 synergize in the treatment of AML by shifting the balance/activity of pro- *versus* anti-apoptotic BCL-2 family members in favor of apoptosis induction.
Aims: These studies sought to investigate the nonclinical activity of the combination of alvocidib with ABT-199 in the context of (drug-resistant) AML.
Methods: CellTiter-Glo was used for all cell viability assays interrogating alvocidib and ABT-199 activity in cell lines, following manufacturer's protocol. RT-PCR was used to measure mRNA expression of MCL-1 and other markers in

response to drug treatment. Protein expression was assessed using standard western blotting techniques. To determine the efficacy of an alvocidib/ABT-199 combination on tumor growth in an *in vivo* model, multiple xenograft mouse models, and *ex vivo* studies with AML patient samples were performed.
Results: In this report, we demonstrate that alvocidib inhibits both mRNA and protein expression of MCL-1 in a time and concentration-dependent fashion in a majority of AML cell lines analyzed. Additionally, in a cell line for which alvocidib did not reduce MCL-1 protein levels (MOLM-13), we observe a potent, dose-dependent increase in BIM protein after 24 hours of alvocidib treatment. Concurrent treatment of alvocidib with ABT-199 in standard 96-hour assays resulted in potent, dose-dependent, synergistic reductions of cell viability in ABT-199-sensitive and resistant cells. ABT-199-sensitive lines, MV4-11 and MOLM-13, exhibited 5- to 10-fold reduction of ABT-199 EC50 values in the low nM range when combined with 80 nM alvocidib. Importantly, ABT-199-resistant lines, OCI-AML3 and THP-1, exhibited at least a 20-fold reduction of ABT-199 EC50 values from near 1 μM to 10-50 nM, when combined with 80 nM alvocidib. Xenografts models, as well as *ex vivo* drug synergy studies with AML patient samples, are currently under way to interrogate the efficacy of this combination.
Summary/Conclusions: Taken together, our data suggest that the combination of alvocidib with ABT-199 could be a novel therapeutic regimen in both ABT-199-sensitive and -resistant AML across a heterogeneous genomic background. Although reduction of MCL-1 by alvocidib may be associated with synergy in some cells, other mechanism(s) are operating as well. We conclude that a CDK9 inhibitor/ABT-199 combination may be a novel approach for the treatment of AML and warrants further pre-clinical and clinical validation. To this effect, animal models are underway, as are plans for clinical trials.

FIRST-IN-CLASS CDK7 INHIBITOR, INDUCES ROBUST APOPTOSIS IN ACUTE MYELOID LEUKEMIA AND DEMONSTRATES DURABLE *IN VIVO* EFFICACY

YJ Choi[1,*], S Hu[1], N Ke[1], Y Ren[1], J Lopez[1], S Milijovska[2], D Orlando[2], D Schmidt[3], M Bradley[1], K Sprott[3], C Fritz[1], E Olson[1]
[1]Biology, [2]Computational Biology, [3]Chemistry, Syros Pharmaceuticals, Cambridge, United States

Background: CDK7 acts bi-functionally as a CDK-activating kinase (CAK) controlling proliferation and as a transcriptional kinase phosphorylating the P-CTD-RNAPol II, thereby driving efficient transcriptional processes. CDK7 has recently emerged as an attractive gene control target in cancers driven by transcriptional dependencies and regulated by Super-enhancers (SEs) (Kwiatkowski *et al.*, 2014; Chipumuro *et al.*, 2014; Christensen 2014; Wang 2015). Acute Myeloid Leukemias (AML) harbor mutations in genes controlling gene expression, and as a consequence, are exquisitely sensitive to CDK7 inhibition. Employing our SE-platform technology we reveal mechanistic insights underlying the vulnerability of AML to gene control modulation via selective CDK7 inhibition.
Aims: Evaluate CDK7 as an anti-cancer target in AML, using our covalent, potent and highly selective CDK7 inhibitor. Investigate the cellular and mechanistic consequences of targeting CDK7 in AML underlying their susceptibility to CDK7-dependent transcriptional control.
Methods: Characterize CDK7 inhibition *in vitro* and *in vivo* to evaluate potency and efficacy in AML cell lines and xenografts (cell line derived xenografts, CDXs and patient derived xenografts, PDXs). We employ our SE-platform technology and next-generation sequencing to identify key mechanisms targeted in AML with our selective CDK7 inhibitor.
Results: Here we report a first-in-class CDK7 inhibitor that covalently targets a cysteine outside the kinase domain, resulting in sustained, highly selective inhibition. Syros compound, SY-1365, exhibits significant biochemical potency (K_i=17±7nM) and selectivity when profiled against >450 other kinases. In a cancer cell line panel, acute leukemias emerged among the most sensitive to CDK7 inhibition. Moreover, AML cell lines undergo rapid and robust apoptosis within 24 hours. This is preceded by >90% CDK7 target engagement and concomitant loss of P-CTD-RNAPol II suggesting the primary consequence of targeting CDK7 is the impaired transcriptional activity dependent on CDK7. Further investigation of the transcriptional consequences of CDK7 inhibition point to a reliance on key disease relevant transcriptional aberrations including translocations and SE-genes (*e.g. MLL* fusions, *MYB, HOX10A* and *MYC*). Given the covalent mechanism of SY-1365 and PK profile, we evaluated intermittent treatments *in vitro* with subsequent washout of free drug to model dosing regimens *in vivo*. We demonstrate that brief drug exposures maintain a robust irreversible apoptotic response in leukemia cells. In contrast, treated non-transformed cells recover from a transient G2/M arrest followed by re-synthesis of free CDK7 and no apoptosis/cell death. We have extended these findings to *in vivo* experiments whereby intermittent dosing in AML patient derived xenograft models (PDX, AM7577) maintains efficacy (reducing human CD45+ leukemia cells to <1%) with a significant survival advantage. We have established a PD assay by measuring target engagement of CDK7 both in mouse xenografts and human PBMCs to support: 1) establishing a PK-PD-efficacy relationship 2) quantifying target engagement during dose escalation in a Ph1 clinical trial.
Summary/Conclusions: In summary, we describe our first-in-class CDK7 inhibitor, SY-1365 that is potent, highly selective and leads to durable, complete responses in xenograft models of AML. These data support the rationale for advancing compounds with this profile toward clinical development.

Background: Among STAT family members, STAT5 has been described to be the most frequently hyper-activated in a variety of hematopoietic cancers and solid tumors as a result of deregulated tyrosine kinase signaling. To date, various tyrosine kinase inhibitors (TKIs) are in the clinic or in clinical trials for treatment of hematopoietic diseases. However, TKI treatment is often accompanied by resistance development, cytotoxicity as a result of poor kinase selectivity, as well as cardiovascular toxicity. Bypassing tyrosine kinases through direct inhibition of STAT5 phosphorylation would be advantageous for therapy development especially in the case of STAT5 regulated cancers. Despite essential roles of STAT5 in solid and hematopoietic cancers, only first generation pharmacologic STAT5 inhibitors are currently available for clinical development.
Aims: The tight association of STAT5 activation with transformation and tumor progression has made STAT5 an attractive molecular target for the development of novel cancer therapeutics. We therefore aim to identify a selective and specific inhibitory compound to interfere with STAT5 signaling in hematopoietic cancers to contribute to the development of a new generation of targeted drugs. On top, we will support functional studies into the mechanistic details of STAT gene activation, which holds the potential to develop even more specific and less toxic compounds for clinical application.
Methods: In collaboration with Prof. Patrick Gunning, University of Toronto, Canada, a library of lead STAT5 inhibitors targeting the SH_2 domain has been established, which was extensively validated *in vitro* on AML model cell lines and primary AML patient samples in regard to their mechanism of binding and action. Therefore, standard techniques, such as Western Blotting, immunoprecipitation, Electrophoretic Mobility Shift Assay (EMSA), qRT-PCR, as well as AnnexinV/PI and PI staining were used. Furthermore, combinatorial effects of the selected STAT5 inhibitor with a library of >1800 experimental or FDA approved drugs, especially TKIs, were evaluated using a luminescent cell viability assay.
Results: We identified a small inhibitory molecule, called AC-4-130, which binds to the SH_2 domain of STAT5, subsequently resulting in the disruption of the reciprocal STAT5-phosphopeptide interactions. The selected compound efficiently blocked kinase-mediated phosphorylation, dimer formation, nuclear translocation, DNA binding and STAT5 mediated target gene expression. Furthermore, AC-4-130 led to a cell cycle blockade in G_0/G_1 and the induction of apoptosis in the model cell lines used. Studies with human AML patient-derived samples similarly showed the induction of apoptotic cell death and an encouragingly low IC_{50} of about 1 μM after efficient blockade of STAT5 activation. A combinatorial drug screen revealed a synergistic effect of AC-4-130 with TKIs, such as Dasatinib and Sunitinib, as well as with drugs standardly used in the clinical treatment of AML patients *e.g.* with the JAK2 inhibitor Ruxolitinib or the chemotherapeutic agent Clofarabine.
Summary/Conclusions: In summary, our findings indicate that AC-4-130 is a potent and selective inhibitor of STAT5. This compound provides a lead structure for further chemical modifications and clinical development, especially in combination with standard treatment, to improve existing therapies and overcome resistance development in hematopoietic malignancies.

IMPAIRED BASE EXCISION REPAIR GLYCOSYLASE/AP ENDONUCLEASE ACTIVITY CONTRIBUTES TO CYTARABINE RESISTANCE IN ACUTE MYELOID LEUKEMIA

W Olipitz[1,2,*], K Lind[2], N Monsberger[2], A Katschnig[2], A Mangerich[3], J Rankl[2], S Hofer[2], M Mueller[2], E Schulz[2], F Quehenberger[4], D Schlembach[5], C Robier[2], A Woelfler[2], A Zebisch[2], H Sill[2]
[1]Department of Medicine III, LMU Munich, Munich, Germany, [2]Division of Hematology, Medical University of Graz, Graz, Austria, [3]Molecular Toxicology, Department of Biology, University of Konstanz, Konstanz, Germany, [4]Institute of Medical Informatics, Statistics and Documentation, [5]Department of Gynecology and Obstetrics, Medical University of Graz, Graz, Austria

Background: Base excision repair (BER) is the primary DNA repair mechanism dealing with DNA base lesions representing the predominant type of DNA dam-

age in mammalian cells. Deficiencies in BER initiating enzymes - glycosylases and AP endonuclease - have been associated with increased genomic instability and cancer.
Aims: Here we investigated the role of BER in acute myeloid leukemia (AML).
Methods: We determined BER activity in 99 primary AML samples, 34 CD34+ umbilical cord blood cell samples and 27 AML cell lines using the alkaline comet assay and H_2O_2 treatment. Oxidative base lesion levels were determined in 10 AML cell lines using a modified version of the Comet assay with bacterial enzymes Fpg and Endo III as well as using liquid chromatography-coupled tandem mass spectrometry (LC-MS/MS). Using nuclear protein extracts in an oligonucleotide incision assay, we tested the enzymatic activity of glycosylases and AP endonuclease. Nuclear protein levels were determined by western blot. Mutational analysis of BER genes was performed using Sanger sequencing and sensitivity of AML cells to cytarabine treatment was tested using an MTS assay.
