Background: Lenalidomide has clinical activity in chronic lymphocytic leukemia (CLL) patients exerting pleiotropic activity on the immune system. The combination of lenalidomide with the anti-CD20 monoclonal antibody ofatumumab induces durable responses in patients with relapsed/refractory CLL. In addition to cell- and complement-mediated B-cell depletion induced by anti-CD20 antibodies and to immunomodulatory activity of lenalidomide, both drugs have been shown to directly inhibit survival and proliferation of malignant B cells. Signal transduction mediated by the B-cell receptor (BCR) promotes CLL survival and proliferation and is considered a key determinant of CLL clinical behavior and target for therapeutic interventions. However, the hypothesis that ofatumumab and lenalidomide could target BCR signal transduction has never been examined in CLL.
Aims: In this study, we used phospho-specific flow cytometry to investigate the direct effects of lenalidomide and ofatumumab on BCR signaling in CLL cells from different prognostic groups of treatment-naive patients.
Methods: The phosphorylation levels of four proteins downstream of the BCR signaling, namely SYK, ERK1/2, PLC-γ, and NF-κB p65, were analyzed at the single-cell level in 9 CLL cell samples treated *in vitro* with single-agent ofatumumab, single-agent lenalidomide or their combination, using phospho-specific flow cytometry. Phosphorylation was measured in the basal condition and following BCR stimulation with anti-IgM, resulting in overall 576 signal readouts. The repeated measures Anova with Dunnett's multiple comparison test was used to compare drug effects on protein phosphorylation.
Results: Ofatumumab and lenalidomide induced different effects in ex-vivo CLL cells with different prognostic features as defined by the *IGHV* mutational status. In the *IGHV*-mutated (M) subset, treatment with ofatumumab, alone or in combination with lenalidomide, induced a significant reduction of SYK and ERK1/2 basal phosphorylation. Remarkably, in the same CLL group, lenalidomide significantly inhibited ERK1/2 basal phosphorylation. On the contrary, in the patient group defined by unmutated *IGHV* status (UM), treatment with ofatumumab and lenalidomide induced no significant changes in basal phosphorylation of BCR proteins. As expected, BCR stimulation with anti-IgM antibodies induced a signaling response in CLL cells that was statistically significant for ERK1/2, PLC-γ, and NF-κB p65. In the M subset, treatment with ofatumumab, alone or in combination with lenalidomide, significantly inhibited the anti-IgM signaling response of SYK and ERK1/2. Interestingly, lenalidomide significantly reduced the anti-IgM-induced signaling response of SYK. In contrast, in the UM CLL subset, ofatumumab and lenalidomide induced no significant changes in anti-IgM responses of BCR proteins.
Summary/Conclusions: This study suggests that ofatumumab and lenalidomide can influence the BCR signaling in the basal state as well as under stimulation, with differential effects in distinct prognostic subsets of CLL. Although a study on a larger patient set is needed to extend and confirm these results, overall they indicate that ofatumumab and lenalidomide can inhibit BCR signaling in the M subset of CLL whilst have no significant effect in UM CLL, potentially contributing to the capacity of these drugs to differentially inhibit disease-progression in patients with CLL.
Funding. This study was funded by Fondazione Cassa di Risparmio di Verona, Vicenza, Belluno e Ancona and AIRC (grant #6599).
Acknowledgments. We thank GSK and Celgene for providing ofatumumab and lenalidomide.

DECREASED EXPRESSION OF WNT3, A CANONICAL WNT PATHWAY LIGAND, IS FREQUENT IN CHRONIC LYMPHOCYTIC LEUKEMIA PROGRESSION AND IDENTIFIES PATIENTS WITH SHORT TREATMENT-FREE SURVIVAL IN MUTATED IGHV SUBSET

L Poppova[1,2,*], P Janovska[3], K Plevova[1,2], L Radova[2], H Plesingerova[1,2], M Borsky[1], J Kotaskova[1,2], B Kantorova[1,2], M Hlozkova[1], J Figulova[1], Y Brychtova[1], M Doubek[1,2], A Kozubik[3,4], S Pospisilova[1,2], S Pavlova[1,2], V Bryja[3,4]

Background: Wnt ligands drive several distinct pathways-the best explored are Wnt/β-catenin (canonical) and Wnt/Planar Cell Polarity (PCP) pathways. We have shown recently that ROR-1 driven Wnt-5a-activated WNT/PCP pathway controls migratory properties of chronic lymphocytic leukemia (CLL) cells and *WNT5A* positivity correlates with aggressive CLL (Janovska *et al.*, Clin Cancer Res 2016). Several reports suggested that the canonical Wnt/β-catenin pathway, known to drive malignant transformation of multiple cell types, also participates on CLL pathogenesis. This was based on the high expression of canonical Wnt ligands and LEF1, and mutations in Wnt pathway genes. There is, however, a lack of direct evidence showing that CLL cells can respond to canonical Wnt ligands by activating β-catenin-dependent transcription. On the other hand, the observation that *WNT3*, encoding for the canonical Wnt ligand, is among the most up-regulated genes, supports the role of Wnt/β-catenin pathway in CLL.
Aims: To clarify the role of Wnt/β-catenin pathway in CLL by (1) detailed analysis of *WNT3* expression and (2) cell-line based study of the ligand-induced pathway activation.
Methods: B-cells from CLL patients and non-malignant controls were negatively separated with RosetteSep (StemCell) or MACS kits (Miltenyi Biotec). *WNT3* mRNA expression was analyzed with quantitative RT-PCR using TaqMan Gene Expression Assays (Applied Biosystems). The *WNT3* expression was correlated with clinical and biological parameters. Survival analyses were performed using Kaplan-Meier curves, Cox regression model and log-rank test; cut-off was assessed in CutOff Finder web application. Wnt/β-catenin pathway activity was analyzed by the SuperTopFlash reporter system (Promega).
Results: By analyzing 137 previously untreated patients we confirmed that *WNT3* gene is strongly overexpressed in CLL compared to normal B-cells (P=0.0001) and that its level is higher in patients with mutated IGHV (M-CLL; P=0.047). Further, we identified low *WNT3* level as a strong independent marker indicating shorter treatment-free survival (TFS) in M-CLL (P<0.0002). Time course analysis in 86 patients revealed that WNT3 declines with disease progression in a significant proportion of patients (decrease in 37%, increase in 4% of patients; P<0.0001), namely in a disease activity onset in untreated M-

CLL and in a disease recurrence after therapy in patients with unmutated IGHV (U-CLL). Functional tests showed that selected lymphoid cell lines (CLL-derived MEC1 and ROR1-positive REC1) failed to respond to the ligand-induced activation of the Wnt/β-catenin pathway while bone marrow stromal cells M210B4 were able to transduce a signal to TCF/LEF-dependent transcription.

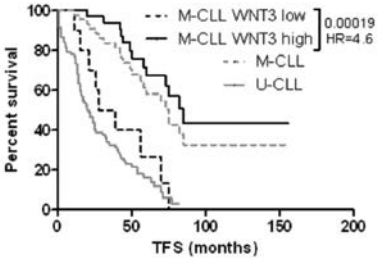

Figure 1.

Summary/Conclusions: Our results show that despite *WNT3* overexpression in CLL cells, its high levels are not associated to aggressive CLL. On the contrary, low *WNT3* independently identifies patients with short TFS in M-CLL and *WNT3* level decrease accompanies disease evolution in a significant proportion of patients. The data indicate that the Wnt/β-catenin pathway plays a more complex role in CLL pathogenesis than previously anticipated, opening a hypothesis that Wnt-3 ligand might be associated to early steps in CLL pathogenesis possibly via mediating interaction with the cells in the microenvironment.

INNATE LYMPHOID CELLS ARE EXPANDED AND FUNCTIONALLY ALTERED IN CHRONIC LYMPHOCYTIC LEUKEMIA

I De Weerdt[1,2,*], V van Hoeven[2], JM Munneke[2], S Terpstra[1,2], T Hofland[1,2], MD Hazenberg[2], AP Kater[2,3]
[1]Experimental Immunology, [2]Hematology, Academic Medical Center, [3]Lymphoma and Myeloma Center Amsterdam, Amsterdam, Netherlands

Background: Both innate and adaptive immune cells markedly affect CLL cells, yet recent findings also highlight reciprocal stimulation of immune cells by clonal B cells. Multi-directional signals derived from a triad formed by malignant cells, lymphocytes and innate immune cells could therefore critically contribute to shaping a supportive environment for the malignant clone. Elucidation of the immune disturbances and tumor microenvironment in CLL is essential for improving therapeutic possibilities and treatment of the CLL immunodeficiency. At the crossroad of innate and adaptive immunity, innate lymphoid cells (ILCs) have recently entered the stage as key players in the initial immune response and tumor surveillance. ILCs have lymphoid morphology but lack rearranged antigen receptors. In addition to NK cells, the ILC family consists of 3 non-cytotoxic groups, mirroring T helper subsets. Group 1 ILCs produce IFN-γ, whereas group 2 ILCs secrete IL-5 and IL-13. Group 3 ILCs produce IL-22 and IL-17, and are subdivided based on the expression of the natural cytotoxicity receptor NKp44. The role of ILC in CLL has not yet been clarified.
Aims: The aim of this study is to investigate the frequency and functionality of ILCs in CLL patients.
Methods: ILCs, defined as lineage$^-$CD127$^+$CD161$^+$ lymphocytes, were measured by flow cytometry in 21 untreated CLL patients and 8 age-matched healthy controls (HCs). We studied functionality of ILCs through measuring cytokine production by flow cytometry upon PMA/ionomycin stimulation in CLL patients (n=6) and HCs (n=6). To assess function after cytokine activation, proliferation and cytokine production was measured in ILC subgroups in 4 CLL patients and 3 HCs.
Results: The number of ILCs in the peripheral blood is significantly increased in CLL patients. Moreover, the ILC count correlates with the absolute leukocyte count in CLL patients, suggesting a rise in ILCs with disease progression. The absolute counts of both ILC1s and NKp44$^-$ ILC3s are significantly elevated in comparison to HCs. The activation status of ILCs, as measured by CD69 expression, is similar in CLL patients and HCs. Next, we compared the functionality of ILCs from CLL patients and HCs by measuring cytokine production. TNF-α production is significantly reduced in CLL patients, yet IFN-γ production is comparable between CLL patients and HCs. The production of type 2 (IL-13) and type 3 (IL-22) cytokine production by ILCs in CLL patients is similar to that in HCs. Finally, we investigated whether functional differences remained present upon cytokine activation. In parallel with direct cytokine measurements in the total ILC pool, cultured ILC1s from CLL patients produce less TNF-α, while IFN-γ production by cultured ILC1s was not affected. ILC1s from CLL patients tend to expand slower than their healthy equivalents, although the difference was not statistically significant. In contrast with ILC1s, the expansion and production of IL-17A and IL-22 of NKp44$^-$ ILC3s was not affected upon cytokine activation.
Summary/Conclusions: Taken together, we demonstrate that in patients with CLL, ILC homeostasis is disturbed. ILCs are expanded in CLL patients and their absolute numbers correlate with disease stage. In addition, ILC1 function is impaired which persists upon cytokine activation. These observations are in line with NK cell alterations and may represent a bystander effect, or reflect functional involvement of ILCs in CLL pathobiology. The extent to which ILCs affect disease progression and therapeutic response is yet to be identified.

IN VITRO EVALUATION OF BORTEZOMIB MOLECULAR EFFECTS IN LARGE GRANULAR LYMPHOCYTE LEUKEMIA

G Calabretto[1,2,*], A Teramo[1,2], G Barilà[1,2], C Ercolin[1,2], M Leoncin[1], A Cabrelle[2], E Boscaro[1], S Teolato[1], E Pagnin[1], M Facco[1,2], L Trentin[1,2], G Semenzato[1,2], R Zambello[1,2]
[1]Department of Medicine, Hematology and Clinical Immunology Branch, University School of Medicine, [2]Venetian Institute of Molecular Medicine, Padua, Italy

Background: Large Granular Lymphocyte Leukemia (LGLL) is a chronic lymphoproliferative disorder characterized by clonal expansion of Large Granular Lymphocytes (LGLs) with cytotoxic activity. LGLs proliferation is maintained through the activation of several survival signaling pathways. Among these, one of the most important deregulated pathway is the JAK/STAT axis. STAT3 activation, mediated by IL-6 signaling or activating STAT3 mutations, promotes LGLs survival by inducing several anti-apoptotic genes transcription and represents a hallmark of this disease. Nowadays, LGLL therapy is based on immunosuppressive drugs, such as Methotrexate (MTX), Cyclophosphamide (CTX) and Cyclosporine A (CyA), showing however only a partial efficacy with an Overall Response Rate (ORR) of about 50-60%. Bortezomib (Bz), the first FDA-approved proteasome inhibitor used in Multiple Myeloma (MM) therapy, is not an approved treatment opportunity for LGLL, but the rare co-association of LGLL with MM offered the opportunity to retrospectively investigate the effect of this drug on leukemic LGLs. The literature reports that patients diagnosed with both LGLL and MM showed a decrease in the LGLs count after Bz treatment, suggesting that this drug may have an effect on inhibiting the LGL clone.
Aims: The aim of this study is to investigate the *in vitro* effects of Bz on PBMCs from LGLL patients, in order to understand its molecular mechanism of action in reducing the LGL clone.
Methods: Peripheral blood mononuclear cells (PBMCs) of 20 LGLL patients (8 out of 20 characterized by STAT3 mutations), isolated through Ficoll density centrifugation, were cultured and treated with Bz (5.2 nM) for 24 or 48 hours. Real Time-PCR, western blot (WB) assays and immunofluorescence assay were performed to analyze mRNA and protein expression. Cell apoptosis was evaluated by Flow cytometry, using Annexin V staining.
Results: We analyzed *IL-6* mRNA expression levels in patients-derived PBMCs by Real Time-PCR. Our results demonstrated that *IL-6* gene expression significantly decreases in Bz-treated cells, as compared to a not treated condition ($p<0.01$). The transcriptional data were supported by immunofluorescence assay, showing that this cytokine is mainly produced by the monocyte/macrophage lineage and that its expression is reduced after Bz treatment. To investigate the Bz effect on *IL-6*-induced JAK/STAT pathway, we performed WB analysis to evaluate STAT3 activation by measuring pSTAT3 Tyr705. Our results showed that pSTAT3 Tyr705 levels strongly decrease in Bz-treated condition, irrespective to the presence of STAT3 mutations. This pattern strictly differs from untreated PBMCs, in which STAT3 remains over-activated. Then, by Real Time-PCR and WB assays, we analyzed the expression of STAT3 downstream targets, focusing on the anti-apoptotic *MCL-1* and *BCL-2* gene expression. Our results demonstrated a significant reduction of the expression levels of both these genes following Bz treatment ($p<0.01$). Finally, we evaluated Bz effect on cell survival by Annexin V staining. Our results showed a significant time-dependent increase in LGL apoptosis after Bz treatment, as compared to a not treated condition. Moreover, we observed that this drug is highly specific in inducing leukemic LGLs apoptosis, not affecting the other PBMCs.
Summary/Conclusions: Our results provide evidence that Bortezomib might represent a new intriguing therapeutic option to be added to the immunosuppressive drugs already used in LGLL therapy.

E1033

A SHARP CONTRAST IN FUNCTIONALITY BETWEEN EBV- AND CMV-SPECIFIC CD8+ T-CELLS IN CHRONIC LYMPHOCYTIC LEUKEMIA

T Hofland[1,2,*], I de Weerdt[1,2], S Endstra[1,2], EB Remmerswaal[2,3], IJ ten Berge[2,3], AP Kater[1,4], SH Tonino[1,4]
[1]Hematology, [2]Experimental Immunology, [3]Renal Transplant Unit, Academic Medical Center Amsterdam, [4]Lymphoma & Myeloma Center Amsterdam, Amsterdam, Netherlands

Background: Chronic lymphocytic leukemia (CLL) is characterized by a tumor induced T-cell dysfunction, which leads to impaired cytotoxicity, which is probably caused by an inability to form immune synapses and increased expression of exhaustion markers. However, we recently found that CMV-specific CD8$^+$ T-cells from CLL patients are functionally intact when compared to age-matched healthy

controls (HC). This finding challenges the concept of a global T-cell dysfunction in CLL. Whether intact functionality of CMV-specific T-cells is a rare exception or whether T-cell functionality is indeed more heterogeneous is currently unknown. Acquired T-cell dysfunction in CLL needs to be better understood in order to improve anti-tumor immunotherapies that rely on T-cell mediated effects.
Aims: To analyze T-cell function heterogeneity in CLL, we studied the immunophenotype and functionality of $CD8^+$ T-cells specific for Epstein-Barr-virus (EBV), another widely common chronic latent viral infection.
Methods: EBV-specific $CD8^+$ T-cells were analyzed using EBV tetramers and 14-color flow cytometry in 45 untreated CLL patients and 23 age-matched HC. We studied T-cell differentiation, expression of exhaustion markers (PD-1, CD244 and CD160), functional markers and homing markers. To study the functionality of EBV-specific $CD8^+$ T-cells, we determined cytokine production and polyfunctionality after stimulation with EBV-derived peptides. Furthermore, we analyzed *ex vivo* cytotoxicity of EBV-specific $CD8^+$ T-cells.
Results: We found that, when compared to HC, EBV-specific T-cells in CLL patients are further differentiated with a significantly smaller percentage of "early" effector memory cells (also called EM1; CLL=39.6% *vs* HC=57.68%). These results are mirrored by the expression pattern of the transcription factors T-bet and Eomes; 25.79% of EBV-specific T-cells of CLL patients display a $T\text{-}bet^{high}\text{-}Eomes^{high}$ phenotype *vs* 17.44% in HC, again pointing to an increased differentiation state. In comparison with HC, EBV-specific T-cells in CLL patients show higher expression of exhaustion markers CD244 and CD160, but not PD-1. However, there were no significant differences in granzyme B and K expression, suggesting an unaltered cytotoxic potential. On a functional level, no differences between CLL and HC were found with respect to production of the cytokines TNFα, IFNγ, IL-2 and MIP-1β and degranulation (measured as $CD107a^+$ cells) of EBV-specific T-cells after peptide stimulation. Polyfunctionality of EBV-specific T-cells of CLL patients was comparable with HC. Surprisingly, we found that EBV-specific T-cells of CLL patients display significantly less direct cytotoxic capacity compared to HC in an *ex vivo* killing assay (mean specific lysis of target cells CLL=6,83% *vs* HC=32,4%), indicating a functional impairment despite normal differentiation and cytokine production. We are currently performing experiments to study immune synapse formation of EBV-specific T-cells (which we will be able to present during the EHA meeting) to determine involvement of the immune synapse in this acquired defect.
Summary/Conclusions: Taken together, we conclude that EBV-specific T-cells show signs of functional impairment and are, in contrast to CMV-specific T-cells, not able to evade CLL induced T-cell dysfunction. In depth studies on differences in T-cell mediated viral responses in the context of CLL will yield important clues to develop strategies to overcome T-cell dysfunction in this disease.

E1034

IDENTIFICATION OF A STRUCTURALLY NOVEL BTK MUTATION THAT DRIVES IBRUTINIB RESISTANCE IN CLL BUT NOT RICHTER TRANSFORMATION

YL Wang[1,*], S Sharma[1], N Galanina[2]
[1]Pathology, [2]Medicine, University of Chicago, Chicago, United States

Background: Ibrutinib (ibr), a first-in-class Bruton tyrosine kinase (BTK) inhibitor, has demonstrated high response rates in both relapsed/refractory and treatment naïve chronic lymphocytic leukemia (CLL). However, about 25% of patients discontinue ibrutinib therapy at a median follow-up of 20 months and many patients discontinue the treatment due to leukemia progression or Richter transformation. Mutations affecting the C481 residue of BTK disrupt ibrutinib binding and have been characterized by us and others as the most common mechanism of ibrutinib resistance. In addition, *BTK* mutations have been found in several Richter-transformed patients treated with ibr. In these patients, it is not clear whether *BTK* mutations are related to Richter transformation or ibr treatment or both.
Aims: As the use of ibr becomes more prevalent in CLL and other types of non-Hodgkin lymphoma (NHL), more patients are expected to develop resistance. Thus, a complete understanding of the mechanisms of ibr resistance is important for the development of strategies to prevent and treat ibrutinib resistance.
Methods: Serial samples were collected from a Richter transformed CLL patient who were treated with ibrutinib, responded and then relapsed. The samples were analyzed using Onco1K, a 1,200-gene next-gen sequencing panel with an average sequencing depth of 420x. The uncovered novel mutation was then validated with Sanger sequencing and characterized with structural modeling. The role of the mutation was further functionally defined with cell transfection followed by assays for cell-proliferation, BrdU-incorporation, and intracellular B-cell receptor signaling.
Results: A structurally novel mutation of Bruton tyrosine kinase was identified which was associated with CLL relapse but not Richter transformation. Functionally, cells carrying the mutant *BTK* show resistance to ibrutinib at both cellular and molecular levels to a similar extent as BTK^{C481S}.
Summary/Conclusions: Our study lends further insight into the diverse mechanisms of ibrutinib resistance that has important implications for the development of next-generation BTK inhibitors as well as mutation detection in relapsed patients.

E1035

CHECKPOINT KINASE 1 INHIBITION POTENTIATES APOPTOSIS AND INFLICTS MITOTIC FAILURE IN CLL-DERIVED MEC-1 CELL LINE

J Zemanova[1,*], O Hylse[2], J Collakova[3], P Vesely[3], A Oltova[1], K Paruch[2], M Trbusek[1]
[1]Department of Internal Medicine-Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, [2]Center of Biomolecular and Cellular Engineering, International Clinical Research Center, St. Anne's University Hospital, [3]Central European Institute of Technology, Brno University of Technology, Brno, Czech Republic

Background: Treatment options for patients with TP53-mutated lymphoid tumors are very limited. In chronic lymphocytic leukemia (CLL), TP53 defects were not surmounted by chemoimmunotherapy regimens functioning in other patients, and also remain challenging for innovative small-molecule inhibitors of B-cell receptor signaling. Recently, the inhibition of ataxia-telangiectasia mutated and Rad-3 related (ATR) kinase operating in the DNA damage response (DDR) pathway has been identified as a potential alternative therapeutic strategy in CLL. ATR is a key molecule activating the DDR pathway through phosphorylation of checkpoint kinase 1 (Chk1) upon recognition of DNA damage.
Aims: (1) to test the Chk1 inhibition potential for sensitizing TP53-mutated CLL-derived MEC-1 and MEC-2 cell lines to nucleoside analogs (NAs) fludarabine, cytarabine and gemcitabine, and (2) to analyze appropriate cell death mechanisms in MEC-1 cells.
Methods: We used highly specific Chk1 inhibitor SCH900776 and measured (a) overall cell viability using a metabolic WST-1 assay, (b) DNA double strand breaks (DSBs) accumulation using pS139 detection on H2AX (γ-H2AX), and (c) apoptosis and cell cycle profile using annexin-V/PI and DNA content staining, respectively. In case of fludarabine, we also analyzed structure of mitotic chromosomes and employed a cell-live imaging for direct cell death monitoring.
Results: The MEC-1 cell line was significantly ($P<0.01$; two-way ANOVA) sensitized to all three NAs using 200 nM SCH900776, as evidenced by 72 h cell cultivation and concentration-dependent curves of viability. Interestingly, the serial sister cell line MEC-2 established from the same patient one year later completely lost the Chk1 inhibition-mediated sensitization to fludarabine. Analyzing further cell death mechanisms in MEC-1 cells, we observed that SCH900776 greatly facilitated γ-H2AX accumulation in the co-treatments with all three NAs and in all tested time intervals (4, 14, 24, and 48 h). Accordingly, apoptosis was clearly augmented in the co-treatments compared to single agent treatments with NAs. In the cell cycle analysis, an increase of sub-G1 (apoptotic) fraction in the co-treatments with Chk1 inhibitor resulted in all three NAs from diminished post-G1 populations (S and G2/M). The cytogenetic analysis for the co-treatment of SCH900776 with fludarabine disclosed a substantially reduced mitotic index (0.6% compared to 15.8% in control), and severe chromosome pulverization in cells undergoing mitosis (detected in 42% of analyzed mitotic cells). By contrast, this pulverization was only occasionally observed in single agent treatment with fludarabine (4%) and never present in control untreated MEC-1 cells. The cell-live imaging then disclosed several abnormal features during mitosis including (a) hardly recognizable metaphase plate, (b) inner cell mass asymmetric division between daughter cells, (c) accelerated time course of division process involving approximately 14 minutes (compared to 22 minutes in untreated cells), and (d) signs of apoptosis such as membrane blebbing.
Summary/Conclusions: The intrinsic resistance of TP53-mutated CLL cells to NAs can be significantly surmounted by Chk1 inhibition leading to cell cycle checkpoints abrogation and augmented DNA damage. Further testing of clinical candidate SCH900776 and other specific Chk1 inhibitors in CLL is justified and particularly appropriate among TP53 mutated patients.
Supported by grant 15-33999A (MH CR), project MUNI/A/1028/2015, grant CZ.1.05/1.1.00/02.0123 (MEYS CR), and project CEITEC 2020 (LQ1601).

PROGNOSTIC SIGNIFICANCE OF SIGNAL TRANSDUCER AND ACTIVATOR OF TRANSCRIPTION 5 AND 5B EXPRESSION IN EPSTEIN-BARR VIRUS POSITIVE PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

P Diamantopoulos[1,*], M Sofotasiou[1], Z Georgoussi[2], N Giannakopoulou[1], V Papadopoulou[1], A Galanopoulos[3], E Kodandreopoulou[1], P Zervakis[1], P Pallaki[2], F Kalala[1], MC Kyrtsonis[1], A Dimitrakopoulou[4], T Vassilakopoulos[1], M Angelopoulou[1], N Spanakis[1], NA Viniou[1]
[1]1st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, [2]Laboratory of Cellular Signaling and Molecular Pharmacology, Institute of Bioscience and Applications, National Center for Scientific Research "Demokritos", [3]Department of Clinical Hematology, G. Gennimatas District General Hospital, [4]Department of Immunology and Histocompatibility, Laikon General Hospital, Athens, Greece

Background: Signal Transducer and Activator of Transcription (STAT) proteins

are cytosolic transcription factors that, upon activation, dimerize and migrate to the nucleus to control gene expression. Among them, STAT5 consists of two isoforms (STAT5A and STAT5B) that are 90% identical and are encoded by two adjacent genes on 17q11.2. Aberrant STAT5 activity has been linked to tumorigenesis, and the implication of STAT5 in leukemias and lymphomas that are correlated to viruses has been long speculated. EBV-related lymphomagenesis has not been thoroughly studied in correlation to the JAK-STAT pathway, although there are in vitro data supporting a constitutive activation of STATs in EBV positive lymphoma cell lines.

Aims: We investigated the expression of total STAT5 and STAT5b in patients with Chronic Lymphocytic Leukemia (CLL) in correlation to the presence of Epstein-Barr Virus (EBV) and Latent Membrane Protein 1 (LMP1).

Methods: Peripheral blood samples from patients with CLL and healthy blood donors were obtained. EBV DNA quantification was performed by real time PCR using the EBV R-gene Quantification Complete kit (bioMérieux, Paris, France). A conventional Real time PCR was used for the detection of LMP1-mRNA and LMP1 expression was verified by ELISA (LMP1 detection kit, MYBiosource, San Diego, CA, USA). Western-blotting was performed for STAT5 and STAT5B in protein extracts. The secondary antibodies used were Affinity Purified Antibody Peroxidase Labeled Goat anti-Rabbit and anti-Mouse IgG (H-L) (Kirkegaard & Perry Laboratories, USA). Gel Pro Analyzer 4 was used to analyze the results. IBM SPSS statistics, v19.0 (IBM Corporation, NY, USA) was used for the statistical analysis of the results.

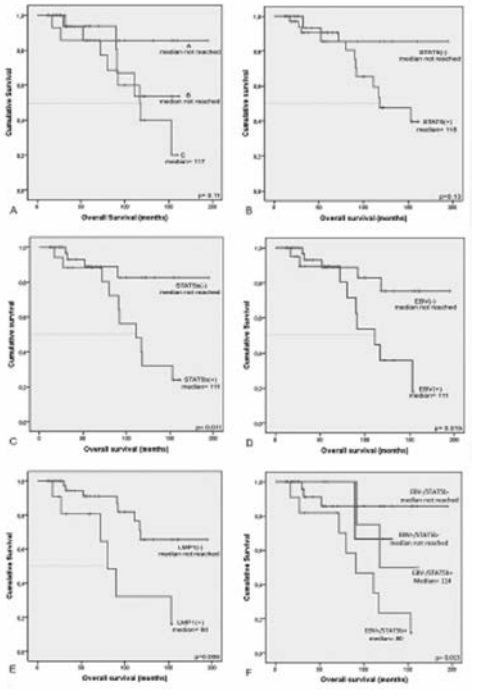

Figure 1.

Table 1. Correlation of EBV and LMP1 status with the expression of STAT5 and STAT5b.

Patients	EBV(+), N (%)	EBV(-), N (%)	P*
Expressing STAT5	17 (77.3)	21 (51.2)	0.044
Not expressing STAT5	5 (22.7)	20 (48.8)	
Expressing STAT5b	11 (50.0)	7 (17.1)	0.006
Not expressing STAT5b	11 (50.0)	34 (82.9)	
	LMP1(+)	LMP1 (-)	
Expressing STAT5	11 (91.7)	27 (52.9)	0.014
Not expressing STAT5	1 (8.3)	24 (47.1)	
Expressing STAT5b	7 (58.3)	11 (21.6)	0.011
Not expressing STAT5b	5 (41.7)	40 (78.4)	

**Pearson's chi-square test, 2-sided p*

Results: Sixty-three (63) patients with CLL and immunophenotypical comfirmed disease by peripheral blood at the time of sample collection were included in the study. The vast majority of the patients (81%) were treatment naïve, and the clinical stage according to the Binet staging system was: stage A 42.9%, B, 34.9%, and C 22.2%. Total STAT5 was expressed in 38 patients (60.3%) and STAT5b was expressed in patients only (18, 28.6%) but not in healthy subjects. Its expression was correlated to the detection of EBV (77.3% *versus* 51.2%, p=0.006) and the expression of LMP1 (58.3% *versus* 21.6%, p=0.011), (detailed results in Table 1). The expression of STAT5b and the presence of EBV and LMP1 were strongly negatively correlated to the overall survival (OS) of the patients (p=0.011, 0.015, 0.006 respectively). Double positive (for EBV and STAT5b) patients had the lowest OS (p=0.013), (Figure 1).

Summary/Conclusions: This is the first report of a survival disadvantage of EBV positivity in CLL, and the first correlation of STAT5b to OS. Moreover, double positivity (for EBV and STAT5b) was correlated to a worse prognosis, while double negative patients had the highest OS. The correlation of STAT5/5b expression with the presence of the virus and OS defines a subgroup of patients that may benefit from treatment with anti-STAT agents.

E1037

EX VIVO LYMPH NODE NATIVE MICROENVIRONMENT ASSAY SHOWS NOVEL ANTIPROLIFERATIVE ACTIVITY FOR IDELALISIB AND IBRUTINIB ON CLL CELLS

J Ballesteros[1,*], L Scarfo[2], M Mattsson[3], A Xochelli[4], P Ranghetti[2], D Primo[1], A Robles[1], J Gorrochategui[1], J Martinez Lopez[5], J de la Serna[5], M Gonzalez[6], V Munugalavadla[7], S Tannheimer[7], R Rosenquist[3], K Stamatopoulos[4], P Ghia[2]
[1]Vivia Biotech, Tres Cantos, Spain, [2]Universita Vita-Salute San Raffaele and Ospedale San Raffaele, Milan, Italy, [3]Uppsala University, Uppsala, Sweden, [4]Center for Research and Technology Hellas, Thessaloniki, Greece, [5]Hospital 12 de Octubre, Madrid, [6]Hospital Clinico Universitario de Salamanca, Salamanca, Spain, [7]Gilead Sciences, Foster City, CA, United States

Background: Survival and proliferation of chronic lymphocytic leukemia (CLL) cells is favored by the essential role of the tumor microenvironment (TME) that is similarly responsible at least in part for disease progression and drug resistance.

Aims: We planned to evaluate and predict the efficacy of therapeutic compounds *in vivo*, by reproducing in a co-culture system the different microenvironmental components that enable B cells to survive and proliferate, mimicking in particular the lymph node microenvironment where most of the crucial events of the pathogenesis of CLL occur.

Methods: To this purpose, cryopreserved peripheral blood (PB) mononuclear cells from CLL patients in need of treatment were tested with the Exvitech® proprietary automated flow cytometry-based platform. Different components have been evaluated to reproduce the ME and induce proliferation and survival of CLL cells: (i) 3 backbone stimulations: CD40L+CpG, CD40L+IL21, CpG+IL2; (ii) "Native Environment", defined as the plasma & erythrocyte/granulocyte fraction of a Ficoll gradient: (iii) the stroma cell line H5S, added at different ratios (1:10 or 1:100); (iv) both human and bovine fetal serum (at 10 or 20% total volume); (v) stimulatory B cell factors, including IL-21, soluble CD40L, BAFF, and B cell receptor stimulation (anti-IG).

Results: Of all the described combinations, the addition of CpG+IL2, HS5 (at 1:100 ratio), human serum 10%, and "native environment" from PB of CLL samples (pooled samples to prevent interpatient variability) were the best to promote CLL proliferation (30±3%) and viability (60±5%). We then tested dose responses of the novel BCR inhibitors, idelalisib (PI3kδ inhibitor) and ibrutininb (BTK inhibitor) in 29 and 25 cryopreserved progressive CLL samples, respectively (Figure) and showed that resting CLL cells were virtually unaffected by either drug (EC_{50} of 12,5μM and 28.3μM), suggesting a limited direct pro-apoptotic activity of the drugs. In contrast, marked inhibition of proliferation was observed (EC_{50} of 30 nM and 550 nM, respectively) in the presence of either inhibitor, leaving only a median of 5% CLL cells that continued proliferating even at the highest doses.

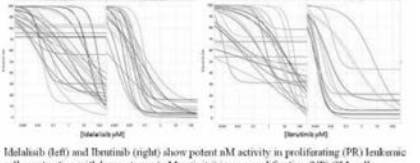

Figure 1.

Summary/Conclusions: We here report a novel *ex vivo* assay that incorporates TME stimuli thus more accurately simulating *in vivo* interactions and enabling high-throughput pharmacological characterization in more physiological conditions. This assay demonstrated a previously unreported anti-proliferative activity for both idelalisib and ibrutinib that may explain the efficacy of both drugs in patients.

E1038

THE RETINOID DRUG ACITRETIN UPREGULATES CD38 EXPRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA AND MEC-1 CELLS AND REDUCES CELL HOMING TOWARDS THE CHEMOKINE CXCL12: POTENTIAL FOR EXPLOITATION IN THERAPY

S Elsir Mohammed[1,*], J Quinn[2], P Thornton[1], B Hennessy[3], S Bergin[2], S Napolitano[2], P Murphy[1]

[1]Haematology, Royal College of Surgeons of Ireland, [2]Haematology, Beaumont Hospital, [3]Oncology, Royal College of Surgeons of Ireland, DUBLIN, Ireland

Background: CD38 expression is a robust prognostic indicator in Chronic Lymphocytic Leukemia(CLL) and has gained importance among the repertoire of markers utilised to aid management decisions in CLL. The CD38 molecule is also attracting interest as a mark for targeted therapies, namely anti-CD38 monoclonal antibody treatment. Retinoids modulate CD38 expression due to the presence of the Retinoic Acid Response Element (RARE) DNA sequence in intron 1 of the *CD38* gene. Several studies have investigated this effect in myeloid malignancies however little is known about retinoid effect on lymphoid malignancies.
Aims: In this study we demonstrate that the retinoic acid derivative, acitretin, upregulates the expression of CD38 on the MEC-1 cell line and on primary CLL cells from CD38 positive patients. We propose that by doing so, acitretin may render these cells more susceptible to the actions of anti CD38 monoclonal antibody drugs and thus have a potential role as an adjunct to such therapies. We also show that acitretin reduces CLL cell homing in response to the chemokine CXCL12, therefore potentially preventing cells from reaching the micro environment niche and may as a result, lead to shortened survival.
Methods: Ethical approval for the study was obtained from the ethical committee in Beaumont University Hospital. Peripheral blood samples were collected from 32 patients with a confirmed diagnosis of CLL and who had given written informed consent. MEC-1 cells were obtained from DSMZ, Germany. MEC-1 cells and cells from five CD38 negative and five CD38 positive patients were treated with 10μM acitretin for 24 and 72 hours. CD38 expression was measured by flow cytometric analysis at baseline and at the different time points. Results are expressed as fold difference in Mean Fluorescence Intensity (MFI) in treated *versus* untreated cells. Migration assays were performed using $2x10^6$ cells per well incubated with either 10μM acitretin or media, overnight in 1%FBS. Cells were subsequently transferred to chamber inserts overlying 10%FBS media containing 200ng/ml CXCL12 in all wells, except negative controls. Cells were allowed to migrate for 4hrs. Migration was calculated as percentage of cells in lower chamber to upper chamber.
Results: CD38 expression in MEC-1 cells was significantly upregulated in cells incubated with 10μM acitretin for 72 hours, (6.89 fold higher expression in acitretin treated cells compared to controls, n=3,**p=0.00075). In primary cells derived from patient samples that had CD38 expression ≥9% at baseline, acitretin produced an increase in CD38 expression that was 2.25 fold higher compared to untreated cells(n=5,* *p=.022*). However, in primary cells from patient samples with CD38 expression<9% at baseline, the effect of acitretin was only 1.53 higher CD38 expression in cells treated with 10μM acitretin at 72 hours. Significant modulation of CD38 expression in these cells was only achieved in the cells treated with 50μM acitretin for 72 hours (*p=.022). In cell migration, acitretin treatment resulted in a significant reduction in CLL cell homing toward CXCL12 in 14 out of 17 patient samples. Mean relative migration was reduced from 23.5% to 11.9% of input cells (11.6% reduction, ***p=.00018,* n=14, mean +/- SEM).These were cell samples from a varied group of patients that included 8(54%) from previously treated, relapsed patients and 6(43%) treatment naïve patient samples.
Summary/Conclusions: CD38 expression is significantly unregulated by acitretin in CLL cells expressing CD38 at baseline. We suggest this would prove advantageous in the setting of anti-CD38 monoclonal antibody therapy through improving efficacy of this drug, and should be studied further in CLL. Acitretin also reduced the homing ability of CLL cells towards the chemoattractant CXCL12, the mechanism and potential therapeutic implications of which needs to be further explored.

ARRAY CGH ANALYSIS REVEALS DELETION OF CHROMOSOME 22Q11 IN CLL WITH NORMAL KARYOTYPE AND NO FISH ALTERATIONS

F Mestichelli*, A Dalsass, S Ferretti, E Camaioni, M Angelini, S Mei, V Pezzoni, F Travaglini, E Troiani, S Angelini, P Galieni
U.O.C Ematologia, Ospedale Mazzoni, Ascoli Piceno, ASCOLI PICENO, Italy

Background: Genomic aberrations have increasingly gained importance as prognostic markers in B-cell chronic lymphocytic leukemia (CLL). Recently, a number of additional studies have been completed that clearly demonstrate the feasibility of using array comparative genomic Hybridization (a-CGH) as a clinical tool to identify genomic alterations of prognostic importance in CLL.
Aims: aCGH is able to identify a significant percentage of genomic abnormalities that escapes conventional cytogenetics and CLL FISH panel due to the limitations of these methods.
Methods: Using Oligonuckleotide-based array CGH (CytoChip 4x180K-Illumina) we detected copy number changes in the tumor genomes of 23 CLL cases at diagnosis, with normal karyotype e no FISH alterations. The cytogenetic study was performed on nuclei and metaphases after stimulation with a combination of CpG-oligonucleotide DSP30 and interleukin 2 (IL-2). In Chromosome Banding Analysis (CBA) we analyzed a minimum of 20 metaphases for each patient. Interphase FISH was performed using a comprehensive set of commercially available probes, as follows: P53 (TP53)Deletion (17p13), ATM Deletion (11q22), D13S25 Deletion (13q14.3), MYB Deletion (6q23)[Cytocell], CEP-12 (Chromosome 12) [Abbott], XL IGH plus Break Apart Probe [MetaSystems]. A minimum of 100–200 interphase nuclei were evaluated per probe for each patient.
Results: A total of 21 of the 23 (91%) cases were successfully analyzed by Oligonuckleotide-based array CGH. We observed a submicroscopic deletion of chromosome 22q11, as the sole anomaly in 4/21 cases (19%). Patients with loss 22q11 showed progression disease, and the median Time to Treatment (TT) was 64.2 months (range 24.6 - 83.1 months). Loss 22q11 ranged in size from 0.68Mb-0.28Mb. The minimally deleted region included the ZNF280A, ZNF280B, GGTLC2, and PRAME genes. Moreover this genomic change had not been detected by standard cytogenetic and/or FISH analyses. Gunn et al. suggest that the incidence of 22q11 deletions was second only to loss of the 13q14 region, found in approximately 50% of CLL cases; few and divergent data were reported in literature regarding prognostic impact of this genomic abnormality in CLL.
Summary/Conclusions: Our results showed that submicroscopic 22q11 deletion is potentially significant genomic aberration in CLL and this alteration is being missed by the current routine techniques. Moreover, increasing the number of cases to analyze we can confirm the data obtained and to correlate the alteration observed to the clinical course.

EXPRESSION OF FCGAMMARIIB PREDICTS TIME TO TREATMENT IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

R Bosch[1,2,*], EP Vicente[1,2], A Mora[1,2], G Ferrer[3], R Damle[3], S Gorlatov[4], K Rai[5], E Montserrat[6], J Nomdedeu[7], L Blanco[7], M Pratcorona[7], J Delgado[6], J Sierra[2], N Chiorazzi[3], C Moreno[2]
[1]Laboratory of Oncology/Hematology and Transplantation, Institute of Biomedical Research, IIB Sant Pau, [2]Department of Hematology, Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain, [3]Karches Center for Chronic Lymphocytic Leukemia Research, The Feinstein Institute for Medical Research, Manhasset, NY, [4]MacroGenics, Inc., Rockville, MD, [5]Hematology/Oncology, Oncology LIJ Medical Center, Lake Success, NY, United States, [6]Department of Hematology, Institute of Hematology and Oncology, Hospital Clínic, IDIBAPS, [7]Laboratory of Hematology, Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain

Background: The Fcγ receptor IIb (FcγRIIb) is a low-affinity Fcγ receptor that negatively regulates B-cell receptor (BCR) function in normal B-cells. In chronic lymphocytic leukemia (CLL) cells, FcγRIIb may exert this inhibitory effect when colligated with the BCR. Since CLL cells are activated *in vivo*, the clinical impact of FcγRIIb expression in this malignancy is worth of being investigated.
Aims: The aims of this study were to: (1) analyze the basal expression of FcγRIIb on CLL cells and normal B-cells; (2) investigate the relationship between FcγRIIb and well-known prognostic markers; and (3) explore the prognostic impact of FcγRIIb on clinical outcome of patients with CLL.
Methods: The study population included 174 patients with active CLL and 34 healthy donors. The median age at diagnosis was 66 years (34-88) and follow-up was 8.0 years (0-38.7). FcγRIIb expression was determined by flow cytometry using an Alexa488-conjugated mAb specific for human FcγRIIb within the following combinations: FcγRIIb/CD38/CD19/CD5 and FcγRIIb/CD49d/CD19/CD5. Results were expressed as the ratio between the MFI for FcγRIIb and the MFI for the corresponding isotype (MFIR). The Fisher's exact test and the Mann-Whitney U test were used for comparisons between groups. Kaplan–Meier survival and Cox regression analysis were performed to evaluate the correlation of FcγRIIb expression with clinical outcome. Best cut-offs for time to treatment (TTT) were determined by ROC curves.
Results: Both CD5+CD19+ leukemic cells and CD19+ normal B-cells expressed FcγRIIb, with no significant differences in MFIR between the populations [median MFIR: 46.4 (8.3-153.4) *vs* 49.4 (30.8-73.2), p=0.812]. FcγRIIb expression, however, was highly heterogeneous among CLL samples, with 4.5% showing very high expression (outliers). Within clones from the same patient, FcγRIIb MFIR was higher on CD38+ or CD49d+ cells than on CD38- or CD49d- cells, respectively (p<0.01). Eighty-one percent (142/174) of patients showed high (MFIR>30.8) and 19% had low FcγRIIb expression (MFIR<30.8). We did not find any association between FcγRIIb expression and well-known prognostic markers except CD49d (p=0.025). However, the correlation between FcγRIIb and CD49d expression was very weak (κ=0.085) showing concordance in only 39.7% of cases. At the time of analysis, 52 patients (29.9%) had required therapy. Patients with low FcγRIIb expression had a significantly shorter TTT than those with high FcγRIIb expression (median 46.07 *vs* 62.7 months; log-rank p<0.028). In univariate analysis, other prognostic parameters, such as clinical stage, serum B2M, elevated LDH, ZAP70, CD38 and CD49d expression, *IGHV* mutational status, cytogenetics, and mutations of *NOTCH1* and *SF3B1* significantly correlated with shorter TTT (p<0.01). In a multivariate analysis incorporating FcγRIIb expression, ZAP70, CD38 and CD49d expression, *IGHV* mutational status, cytogenetics, and mutations of *NOTCH1* and *SF3B1*, only low FcγRIIb expression (HR 2.66, 95%CI 1.22-5.80, p=0.014), unmutated *IGHV* (HR 3.02, 95%CI 1.30-7.02, p=0.010), and mutated *SF3B1* (HR 11.27, 95% CI 2.82-45.12, p=0.001) and *NOTCH1* (HR 4.79, 95%CI 1.31-17.48, p=0.018) retained prognostic significance for shorter TTT.

Summary/Conclusions: FcγRIIb expression can predict time to treatment in CLL, underlying a key role of the receptor in the progression of this malignancy. These results encourage further investigation to characterize the mechanisms by which FcγRIIb controls CLL cell activation and to uncover the relationship of FcγRIIb with other molecules, particularly CD49d.

FYN INHIBITOR INDUCES APOPTOSIS IN NK LEUKEMIA CELLS

I Laurenzana[1,*], A Caivano[1], L De Luca[1], S Trino[1], F La Rocca[1], V Simeon[1], C Tintori[2], F D'Alessio[3], A Traficante[4], M Maietti[4], A Teramo[5], R Zambello[5], G Semenzato[5], S Schenone[6], M Botta[2], P Musto[7], L Del Vecchio[3,8]
[1]Laboratory of Preclinical and Translational Research, IRCCS Referral Cancer Center of Basilicata, Rionero in Vulture (PZ), [2]Department of Biotechnology, Chemistry and Pharmacy, University of Siena, Siena (SI), [3]Biotecnologie Avanzate s.c.a.r.l., CEINGE, Napoli (NA), [4]Unit of Clinical Pathology, IRCCS Referral Cancer Center of Basilicata, Rionero in Vulture (PZ), [5]Department of Medicine Hematology and Clinical Immunology, Padua University School of Medicine, Padova, [6]Department of Pharmacy, University of Genoa, Genova, [7]Scientific Direction, IRCCS Referral Cancer Center of Basilicata, Rionero in Vulture (PZ), [8]Department of Molecular Medicine and Medical Biotechnologies, University of Naples, Napoli (NA), Italy

Background: Fyn protein, a member of Src-family kinase, has different biological functions including growth factor/cytokine receptor, T and B-cell receptor and integrin-mediated signaling, cell-cell adhesion, mitosis, differentiation of natural killer (NK) cells. Some studies show its involvement in hematologic malignancies. However, the tissue-specific pattern of Fyn mRNA expression indicate that it is more expressed in NK and T cells respect to other human tissues. NK cell neoplasms are a rare and heterogeneous group of disorders characterized by increased proliferation of cytotoxic NK cells. They include aggressive NK leukemia (ANKL) and chronic lymphoproliferative disorder of NK cells (NK-CLPD). ANKL has a fulminant clinical course frequently resulting in death within two months; NK-CLPD is typically indolent. Since no standard therapies for immature NK cell neoplasms have been established so far, new therapeutic options are needed. Tintori et al. found a new Fyn inhibitor by a structure-based drug design protocol followed by hit-to-lead optimization. The 4c pyrazolo[3,4-*d*]pyrimidine compound showed antiproliferative activity against different cancer cell lines.
Aims: The aim of this study was to determine the effect of 4c compound in NK leukemic cells.
Methods: Fyn mRNA level was evaluated in peripheral blood mononuclear cells (PBMC) from 10 healthy controls (HC) and 8 NK-CLPD patients by qRT-PCR; protein level was evaluated in PBMC from 3 HC and 3 NK-CLPD and in 2 ANKL cell lines (KHYG1 and NK92) by western blotting (WB). The 4c compound was tested in a time course MTS assay at increasing concentrations on HC-PBMC, KHYG1 and NK92. KHYG1 were treated with 4c at 4μM for 24h to evaluate apoptosis and cell cycle by cytometric analysis, as well as gene expression profile by Illumina HiScanSQ. Fyn immunoprecipitation and proteome profile arrays of apoptosis and phospho-kinase were also performed. Expression of procaspase3, active caspase3, P70 and Akt was validated by WB. 4c compound was tested also in 3 NK-CLPD e 1 ANKL patients. Cell viability was assessed by trypan blue dye count method and apoptosis was verified by cytometric analysis.
Results: qRT-PCR data showed a significant overexpression of *Fyn* level in PBMC of NK-CLPD patients compared to HC. Protein level was highest in NK-CLPD patients ($p<0.001$) and NK cell lines ($p<0.0001$) respect to HC. To verify the effect of 4c compound, we treated KHYG1 and NK92 with different concentrations, showing a reduction of cell viability (EC50= 4μM and 14μM respectively at 24h); on the contrary, there was no effect on HC-PBMC. Moreover, this treatment induced a significant caspase3 dependent apoptosis ($p<0.01$) and G2/M cell cycle arrest. Gene expression analysis of 4c treated or not KHYG1 identified 455 down-regulated and 326 up-regulated genes, most of which involved in cell death function, thus confirming the apoptosis data. To corroborate Fyn inhibition by 4c treatment, we detected a reduction of its phosphorylation and we also observed a decrease of phospho-Akt and phospho-P70, two proteins involved in apoptotic process and cell proliferation. Interestingly, 4c treatment reduced cell viability and activated caspase3 dependent apoptosis ($p<0.05$) in 3 NK-CLPD and 1 ANKL patients.
Summary/Conclusions: In this study we demonstrated a higher Fyn expression in NK leukemia patients compared to healthy controls. We also demonstrated an apoptotic effect of pyrazolo[3,4-*d*]pyrimidine 4c compound on NK leukemia cells and we provided *in vitro* preliminary evidences that Fyn is its possible cellular target.

E1042

RETROTRANSPOSONS SHAPED NON-REDUNDANT CLLU1 GENE MODULES

S Papamichos[1,*], D Margaritis[1], E Spanoudakis[1], A Christoforidou[1], Z Bezirgiannidou[1], G Koutra[2], E Lamprianidou[1], I Kotsianidis[1]
[1]Department of Haematology, Democritus University of Thrace Medical School, Alexandroupolis, [2]Cardiac Intensive Care Unit, General Hospital of Kavala, Kavala, Greece

Background: *CLLU1* was originally identified as a gene differentiating IgV_H-unmutated (IgV_H-UM) and IgV_H-mutated (IgV_H-M) chronic lymphocytic leukemia (CLL) and is now appreciated to represent a potent predictor of overall survival of CLL patients. Whilst *CLLU1* is located in a genomic region that is highly expressed in both germinal center B cells and CLL cells, indicating an open-chromatin structure, its transcription is highly restricted. *CLLU1* expression is markedly high in IgV_H-UM CLL, low in IgV_H-M CLL and negligible in normal B-cell subpopulations or any other hematological specimens tested. Alternative splicing of the *CLLU1* gene generates 7 transcript variants. Previous studies revealed a powerful linear relation between the expression levels of all the variants, signifying that transcription is orchestrated by a common promoter located upstream of exon 1. Accordingly, it was deduced that (epi)genetic aberrations, occurring during leukemogenesis, could trigger the inordinate activation of this promoter. DNA methylation microarray analysis identified *CLLU1* to present lower methylation levels in IgV_H-UM CLL cases compared to IgV_H-M CLL cases and to normal B-cells. It was shown that the larger proportion of methylated sites occupied *CLLU1* gene body, while a strong correlation between *CLLU1* body hypomethylation and gene expression was also established. Transposable elements (TEs) carry a markedly high density of CG dinucleotides and remain heavily methylated in normal cells. Aberrations in DNA methylation marks could allow for TEs to exert a significant impact on host gene expression. For example, long terminal repeats (LTRs) of endogenous retroviruses (ERVs) contain transcription regulatory elements that, in the sense orientation, are functional and could initiate transcription of adjacent human genes.
Aims: Document that non-redundant *CLLU1* gene modules were evolutionary provided by TEs. Provide a rationale for the intriguing transcriptional profile of the gene.
Methods: *CLLU1* genomic sequence was downloaded from the NCBI Gene database and scanned for the presence of integrated TEs by RepeatMasker. EMBOSS Cpgplot was used to identify genomic regions of unusual CG composition located within *CLLU1* body. PROMO Version 3.0.2 software, employing version 8.3 of TRANSFAC database, was used to evaluate transcription factor (TF) binding affinity of the region spanning 150 nucleotides (nts) upstream and downstream of *CLLU1* transcriptional start site (TSS), assumed to include important transcription regulatory elements. *CLLU1* locus syntenic alignments of numerous mammals were downloaded from the UCSC Genome Browser Database. Phylogenetic and molecular evolutionary analyses were conducted using MEGA version 6.
Results: *CLLU1* exon 1 is located within a region reported from RepeatMasker to match a sense orientation MLT2B1 LTR, of the ERV-L family. The LTR extends 109 nts upstream of *CLLU1* TSS. *CLLU1* start codon was evolutionarily provided by a MIR element. *CLLU1* polyadenylation signal was also provided by a MIR element. *CLLU1* body contains CG-rich genomic content. EMBOSS Cpgplot analysis identified a CpG island in the gene body, which, however, is an AluY element of unusually high CG composition than a bona fide CpG island. Of note is the high Observed/Expected CG ratio within and adjacent to *CLLU1* coding DNA sequence. The region spanning 150 nts upstream and downstream of *CLLU1* TSS includes a plethora of high-affinity TF binding sites. Analysis identified multiple binding sites for TFs known to play a major role in CLL pathogenesis, namely PAX5, the NF-κB subunit RELA, IRF1 and ELK1. Binding motifs for known oncoproteins (JUN, MYB) as well as for XBP1, a potent TF factor in B cells, were also detected. Of note, XBP1 is known to immensely enhance the transcription of HTLV-I exogenous retrovirus. Phylogenetic analysis revealed that a 4 bp genomic deletion allowed the generation of an ELK1 binding site exclusively in the Hominid genome. Because the DNA sequence adjacent to the site presents null variation between Hominids and also because this genomic region includes no common single nucleotide polymorphisms in human, we assume the occurrence of a selective sweep fostering the creation of the motif.
Summary/Conclusions: Non-redundant *CLLU1* gene modules were provided by TEs thereby remain heavily methylated in normal cells and become susceptible to increased hypomethylation during leukemogenesis. This finding provides a mechanistic link between high *CLLU1* expression and poor clinical outcome prognostication since *CLLU1* body hypomethylation occurs predominantly in IgV_H-UM CLL cases. - In the Eμ-TCL1 transgenic mouse model, whilst *TCL1* mice are expected to develop an IgV_H-UM CLL-like disease phenotype at around 11 month, hypomethylation of TEs occurs as early as in 7-months-old mice. In addition, DNA methylation levels remain relatively stable over time among IgV_H-UM CLL cases, not affected by treatment. The above, combined with our findings, provide a rationale for *CLLU1* expression representing an inherent and constant feature of a particular CLL clone.

E1043

AMONG CLL PATIENTS WITH MULTIPLE FISH ABNORMALITIES, 13Q AND 11Q DELETIONS ENTAIL THE COMMONEST COMBINATION IN CONTRAST TO 11Q AND 17P DELETIONS, BEING THE COMBINATION WITH WORSE OUTCOME

Background: Fluorescence *in-situ* hybridization (FISH) defines a hierarchy of genetic changes that predicts survival in CLL. However, multiple abnormalities (MA) may also occur and little is known about its distribution and clinical impact.
Aims: To assess the frequency and clinical outcome of 245 patients with CLL and MA detected by FISH in a database containing clinical and biological data.
Methods: Cases with more than one FISH abnormality were retrieved from the database. FISH abnormalities included in the routine CLL FISH panel (13q-, 11q-, 17p- and +12) were taken into account.
Results: MA were detected in 245 out of 1743 CLL cases (14%). FISH studies were performed at diagnosis (FISH-d) in 154 cases (61%), and during disease evolution (FISH-e) in 91 cases (38%). Among the 91 cases from the group of FISH-e, 26 cases (11%) had a prior FISH without MA, and 39 cases (16%) had received treatment for CLL before FISH. The most frequent associations in the group of FISH-d were the combinations of 13q- with 11q- observed in 52 cases (33.8%), followed by 13q- with 17p- (37 cases, 24%), and 13q- with +12 (28 cases, 18.8%). By contrast, in the group of FISH-e 13q- and 17p- were the most prevalent partners (28 cases, 31%) followed by 13q- and 11q- (25 cases, 27%) and +12 and 17p- (12 cases, 13%). More than 2 abnormalities were observed in a low proportion of cases: 17 (11%) in the group of FISH-d, and 7 (7.6%) in the group of FISH-e. Interestingly, most of them included 17p- (14/17 FISH-d; 6/7 FISH-e). The weirdest combination was 11q- and 17p-, only observed in 5 cases (3.2%) in the group FISH-d and 2 cases (2.1%) in the group FISH-e. Globally, 17p- was found in more cases during disease evolution (48 cases, 52%) than at the moment of diagnosis (66 cases, 42%). Moreover 17p- appeared as the major clone in a very low proportion of cases in both groups, whereas 13q- or +12 where observed more frequently as the major clone, suggesting 13q- or +12 as early events, in contrast with 17p-. Overall survival (OS) and time to first therapy (TTFT) were analyzed in the group of FISH-d, being respectively 68 months, and 25 months, for the whole series. The combination of 13q- and 11q- showed the larger OS (75 months), while CLL with 13q- and 17p- showed the shorter OS (37 months). Moreover the presence of 17p- was associated with a shorter OS (63 m *vs* 75 m, p=0.02). Regarding TTFT, CLL with 13q- and +12 showed a median TTFT of 53 months while the CLLs with 17p- and 11q- only had 4 months of TTFT (p=0.017) (Figure 1).

Figure 1. Overall Survival and time to first therapy in patients with multiple FISH aberrations at the time of diagnosis.

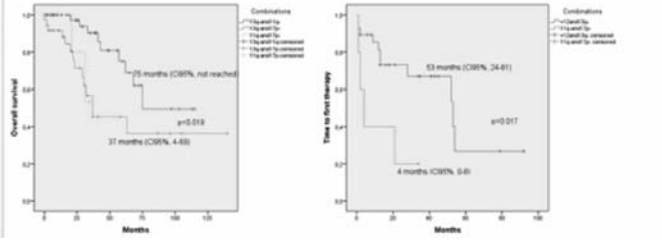

Figure 1.

Summary/Conclusions: MA were observed in 14% of CLL cases, representing a heterogeneous group. The distribution among combinations was unequal. The combinations of 13q- with 11q- and 17p- were the most frequent associations, in contrast to 11q- and 17p-, observed in a minority of the cases. 17p- often occurred during disease evolution involving minority clones. MA entailed poor prognosis when emerged at diagnosis, probably due to the high incidence of bad prognosis aberrations such as 17p- and 11q-. On behalf of Grupo Español de Leucemia Linfática Crónica (GELLC) and Grupo Cooperativo Español de Citogenética Hematológica (GCECGH).

FUNCTIONAL ROLE OF PI3K-DELTA IN MALIGNANT B CELLS

L Neumann*, E Göckeritz, M Hallek, G Krause
Dept. I of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Among catalytic PI3K subunit isoforms, p110-δ is highly and selectively expressed in malignant compared to other cell types and involved in B cell receptor (BCR) signaling. Idelalisib, which specifically targets p110-δ, shows clinical efficacy e.g. for the treatment of chronic lymphocytic leukemia (CLL), but only modest direct cytotoxicity against malignant B cells *in vitro*.
Aims: To elucidate the mechanism of action of idelalisib and to dissect the contributions of p110-δ to both cell autonomous functions as well as interactions with the tumor micro-environment, engineered inhibitor-resistant p110-δ mutants were employed as chemical genetic tools. In addition cell line models expressing such mutants might anticipate a potential type of clinically acquired resistance.
Methods: According to structural alignment with known inhibitor-resistant p110-α mutants, p110-δ-I777M and –I825V were generated by site-directed mutagenesis as potentially inhibitor-resistant mutants. Inhibitor resistance was assessed by comparing phospho-Akt levels after inhibitor treatment in retrovirally transduced cell lines expressing wild type or mutant p110-δ. Transductants of the murine fibroblast cell line NIH3T3 were assessed for anchorage-independent growth and saturation density as markers of oncogenic transformation. The emphasis of our chemical genetic evaluation was on malignant B cells and employed the human Burkitt lymphoma and murine pre-B cell lines Ramos and BaF/3. Chemokine levels in culture supernatants were determined by enzyme-linked immunosorbent assay, while chemotaxis to CXCL12 was examined in trans-well migration assays.
Results: The murine fibroblast cell line NIH 3T3, which lacks endogenous p110-δ expression and sensitivity to idelalisib, gained sensitivity to idelalisib concentrations above 1 µM upon over-expression of p110-δ with regard to phosphorylation of Akt at serine 473. According to pAkt levels, the I777M mutation in p110-δ partly reversed the sensitivity to idelalisib of NIH 3T3 cells expressing p110-δ. Moreover expression of p110-δ-I777M increased the anchorage-independent growth and the saturation density of NIH3T3 cells. In Ramos and Baf-3 cells, which endogenously express p110-δ, additional expression of p110-δ-I777M led to markedly increased Akt phosphorylation and to resistance against 10-100 nM idelalisib. Expression of p110-δ-I777M rescued the secretion of the chemokine CCL-3 by Ramos cells upon stimulation of the B-cell receptor from inhibition by idelalisib. Chemotaxis of Baf-3 cells to the chemokine CXCL-12 was reconstituted by expression of p110-δ-I777M in the presence of inhibitory concentrations of idelalisib.
Summary/Conclusions: The novel engineered p110-δ-I777M mutant showed an unexpected gain of function and mediated resistance against idelalisib that can be exploited for the chemical genetic evaluation of p110-δ function. In malignant B cell lines, p110-δ was less involved in cell autonomous functions than in their interactions with the micro-environment, exemplified by chemokine secretion and migration.

E1045

ACTIVATION INDUCED DEAMINASE SPLICE VARIANTS EXPRESSED IN B CELL LEUKEMIA AND LYMPHOMA DO NOT RETAIN THEIR CATALYTIC ACTIVITY

K Zápražná[1,*], J Malčíková[1,2], N Tom[1], L Radová[1], M Trbušek[2], M Atchison[3], Š Pospíšilová[1,2]
[1]Center of Molecular Medicine, Masaryk University CEITEC, [2]Department of Internal Medicine-Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Department of Biomedical Sciences, University of Pennsylvania School of Veterinary Medicine, Philadelphia, United States

Background: Activation induced deaminase (AID) is essential for enhancing antibody affinity and effector functions in B cells during secondary immune response. It induces somatic hypermutation (SHM) and class switch recombination (CSR) in the immunoglobulin (Ig) genes. AID is a potent mutator -SHM frequency in the Ig genes is a million times higher than the frequency of spontaneous mutagenesis (10^{-3} -10^{-4} mutations/ cell/ generation). AID studies performed in mouse models have shown a correlation between AID activity and genomic instability. AID is aberrantly expressed in various B lymphoid malignancies and also in some solid tumors.
Aims: In this project, we set out to investigate the function of four alternatively spliced AID variants that differ from the full-length protein in the C terminal domain. These variants are present in an increased proportion in chronic lymphocytic leukemia (CLL), Ph-positive acute lymphoblastic leukemia (Ph-positive ALL) and mantle cell lymphoma (MCL).
Methods: Individual AID splice variants were cloned from peripheral blood CLL cells into an HA-tagged retroviral vector. Mature B cells purified from AID knockout spleens were stimulated with lipopolysaccharide and interleukin-4 and subsequently infected with retroviruses carrying individual AID splice variants. Cells were cultured ex vivo for a total of 4 or 5 days and then assessed for CSR to IgG1 by flow-cytometry or sorted based on high GFP expression marking the

infected cells. The level of SHM in the Ig switch region Sm was assessed by ultra-deep next generation sequencing. The amount of double strand breaks in the Ig Sm was quantified by ligation-mediated PCR and hybridization with an Sm probe.
Results: While full-length AID induced CSR, SHM and double strand breaks in the Ig genes, alternatively spliced AID variants behaved as catalytically inactive in all performed functional assays. Immunoblotting with an anti-HA antibody revealed that AID splice variants had lower protein expression compared to full-length AID. It is a well-established fact in the AID field that in most situations, AID levels correlate with its activity. Therefore, lower expression of alternatively spliced AID variants might have contributed to their loss-of function in our model system.
Summary/Conclusions: Alternatively spliced AID transcripts were previously shown to be expressed in CLL, Ph-positive ALL and MCL. We hypothesized that alternative splicing might modulate their activity and consequently change AID deamination levels in the Ig genes or its targeting in the whole genome. Results of AID splice variant analysis done in AID knockout mouse B cells stimulated ex vivo indicated their loss of function. Therefore, the role of alternatively spliced AID expressed in B-lymphoid leukemia and lymphoma remains unclear, and their function is to be further analyzed using human cell lines derived from B-cell malignancies.

CHROMOSOMAL GAINS IN CHRONIC LYMPHOCYTIC LEUKEMIA: A RARE EVENT ASSOCIATED WITH A DISMAL PROGNOSIS

I González-Gascón Y Marín[1,2,*], AÁ Martín[3], M Hernández-Sanchez[4], C Robledo[4], ML Hermosín[5], N de las Heras[6], L Lacalle[7], J Galende[8], F de Arriba[9], AE Rodriguez-Vicente[4], JÁ Hernández[1,2], JM Hernández-Rivas[3,4]
[1]Hematology, Hospital Universitario Infanta Leonor, [2]Medicine, Universidad Complutense de Madrid, MADRID, [3]IBSAL-Hospital Universitario de Salamanca, [4]Hematology, Centro de Investigación del Cáncer-IBMCC, Universidad de Salamanca, Spain (USAL-CSIC), Salamanca, [5]Hematology, Hospital Jerez de la Frontera, Cádiz, [6]Hematology, Hospital Virgen Blanca, León, [7]Hematology, Hospital Miguel Servet, Zaragoza, [8]Hematology, Hospital el Bierzo, Ponferrada, León, [9]Hematology, Hospital Morales Meseguer, Murcia, Spain

Background: Hyperdiploidy is a common cytogenetic alteration in some hematological diseases such as B acute lymphoblastic leukemia or multiple myeloma, with prognostic value. However, the presence of chromosomal gains other tan trisomy 12 (+12) in chronic lymphocytic leukemia (CLL) has scarcely been reported before.
Aims: The aim of this study was to analyze, by FISH, the frequency and prognostic implications of chromosomal gains in CLL.
Methods: A retrospective review of 1,359 consecutive cases diagnosed with CLL referred for FISH analysis to a unique institution, between 2004 and 2012, was carried out. Chromosomal gains were considered when a gain of at least 3 out of the 5 FISH probes used (11q22/*ATM,* 12q13, 13q34, 14q34/*IGH*, and 17p13/*TP53)* was observed. In addition, Next Generation Sequencing analysis was carried out to investigate the mutational status of *TP53* (exons 4–11) gene.

Table 1.

Table I. Detailed fluorescence *in situ* hybridization (FISH) results for each case.

	Number of chromosomal gains (% of cells with the alteration)				
Probes	11q22/*ATM*	12q13	13q34	14q34/*IGH*	17p13/*TP53*
Case 1 (PB)	3n (23%); 4n (60%)	3n (23%); 4n (60%)	3n (23%); 4n (60%)	3n (23%); 4n (60%)	3n (23%); 4n (60%)
Case 2 (BM)	3n (6%)	3n (7%)	3n (5%)	3n (7%)	n (75%)
Case 3 (BM)	3-4n (25%)	3-4n (42%)	3-4n (37%)	3-4n (35%)	n (74%)
Case 4 (PB)	3n (14%)	3n (16%)	3n (13%)	3n (15%)	3n (12.5%)
Case 5 (PB)	n (36%)	3n (22%); 4n (14%)	3n (22%); 4n (14%)	Rearrangement (53%)	3n (22%); 4n (14%)
Case 6 (BM)	3n (12%)	3n (22%)	3n (23%); n (13%)	n (19%)	3n (13.5%)
Case 7 (PB)	3n (8%)	3n (12%)	3n (10%)	3n (10%)	3n (10%)

Abbreviations: PB= peripheral blood; BM= bone marrow; n= number of chromosomes

Results: 8 cases with chromosomal gains were identified out of the 1,359 CLL patients (0.59%), referred for FISH studies. One case was excluded from the analysis due to inadequate follow-up. Five cases (cases nº 3-7) presented chromosomal gains at diagnosis; the other two (case nº 1 and 2) during disease evolution and after having received treatment with chlorambucil. Four patients (57%) were female, and the median age at diagnosis was 74 years (range 63-86). The median white blood cell count at the time of diagnosis was 16 x 10^9/L (range, 7-67). No significant anemia or thrombocytopenia were detected in any case at diagnosis. It is noteworthy that the immunophenotype of three out of the seven cases suggested the diagnosis of atypical CLL. Serum LDH and $\beta_2$microglobulin levels at diagnosis were high in 57% (4/7) and 29% of the cases (2/7), respectively. Three out of seven (43%) patients presented with splenomegaly and hepatomegaly, and 29% with more than three enlarged lymph node regions. The presence of B symptoms was detected in 29% of the cases. Of note, at the time of diagnosis most cases were classified as early stages according to Binet classification (stage A 57%; stage B 29%; stage C 14%). *IGHV* mutation status was available in 57% of the cases being all of them classified as unmutated pattern. Besides chromosomal gains, additional chromosomal abnormalities were detected in 57% of the patients including: 17p- (2 cases), 11q- and *IGH* alteration (1 case), and 13q- and *IGH* deletion (1case). Detailed FISH results are shown in Table I. Only one patient (case nº 7) showed a missense *TP53* mutation (c.613T>G; p.Y205D) with a mutational burden of 95%. This variation was previously described as a mutation in the COSMIC database (COSM43844). This *TP53* mutated case did not show 17p deletion. Six patients (86%) required treatment during follow-up with a median TTFT of 1.4 months (CI95%, 0.8-1.9). Most treated patients (4/6, 66%) required two or more chemotherapy therapies (median 3, range: 1-4), due to refractoriness or relapse. Median duration of response to first line treatment was 7 months (0-36). With a median follow-up of 66 months (6-115), 5 patients have died due to: disease progression (3 cases), infection (1 case), and cardiovascular disease (1 case). Median OS from the time of diagnosis was 66 months (CI95%, 0-174), and from the time of chromosomal gains acquisition was 20 months (CI95%, 16-24).
Summary/Conclusions: Chromosomal gains are a rare event in CLL. Our results also suggest that the presence of chromosomal gains involves poor prognosis in these patients.

Martino-IST, Genova, [6]Centro di Ricerca per lo Studio delle Leucemie, Fondazione IRCCS, Universitàà di Milano, Milano, [7]University of Magna Graecia and Cancer Center, Catanzaro, [8]Hematology Unit, Department of Onco-hematology, Azienda Sanitaria Provinciale, Aprigliano and Hematology Unit, Department of Onco-hematology, Cosenza, Italy

Background: The proteomic approach is essential in the multi-disciplinary field of hematological research. Previously, using MALDI-TOF analysis we identified Tβ4, a G-actin sequestering protein involved in the regeneration of injured tissues and cell migration, as a downregulated protein in CLL patients, also confirmed by an independent GEP analysis comparing B-CLL cells and normal controls.
Aims: Here, using 2DE proteomic analysis we evaluated differential protein expression patterns after treatment with exogenous Tβ4 and/or Len, which has been shown to improve immune dysfunction in CLL by repairing actin polymerization and rapid signaling at the immunological synapse. We investigated whether purified B-CLL cells having high/low Tβ4 expression respond differently to migratory stimuli such as CXCL12/SDF1α.
Methods: Purified B-CLL lymphocytes were isolated from untreated Binet stage A CLL patients prospectively enrolled atdiagnosis (O-CLL1 clinicaltrial.gov identifier NCT00917540) and healthy controls. N=93 patients were evaluated for Tβ4 expression by Flow cytometry (FC, median^{RFI}=15.06, IQR:6.9–28.8).For migration assays, SDF1α (100nM) as chemoattractantwas used to determine the CLL migration index. B-CLL cells from two patient samples havinglow or highTβ4expression were pre-treated with Len (5mM) and then with Tβ4 (100nM)for 2DE analysis.
Results: CLL samples with the lowest Tβ4 expression (n=12) also had higher F-actin levels as evaluated by FC than normal controls (n=7) in a sample cohort (n=93). FC assessed Tβ4 expression in B-lymphocytes in CLL patients (n=93) *vs* controls (n=7). Tβ4^{RFI}values showed Tβ4 expression was heterogeneous (Tβ4^{RFI}=1.3–152.05;median^{RFI}=15.06) compared to controls (Tβ4^{RFI}=3.4–70.9;median^{RFI}=38.3). Baseline F-actin expression is also influenced by different levels of Tβ4 expression: CLL CD19$^+$CD5$^+$ samples with Tβ4^{high}also had higher G-actin expression, with a lower F/G-ratio, and conversely Tβ4^{low} samples, there wasa higher expression of F-actin, with a higher F/G-ratio (n=14), also confirmed by FC experiments. CD19+CD5+ CLL cells express high levels of functional CXCR4/CD184,which facilitates CLL cell migration beneath stromal cells. B-CLL strongly responded to the migratory stimulus SDF-1α. Furthermore, migration induced by SDF1α increased in CLL cells after Len (0.5 μM) treatment. Conversely, the CLL with Tβ4^{low} was more responsive to Len inhibition, resulting in a reduction in migratory potential towards SDF1α. Purified B-CLL lysates (n=2) were analyzed by 2DE analysis. Protein profile

analysis showed a number of protein spots ranging from 18 to 60kDa that were differentially expressed with respect to cells exhibiting Tβ4$^{low/high}$ expression. More importantly, treatment with Len or following Tβ4 replenishment also changed protein expression in function of the endogenous Tβ4
Summary/Conclusions: Our preliminary qualitative analysis suggests that the proteomic profile of CLL samples exhibiting higher or low Tβ4 levels also correspond to groups of proteins with a differential protein expression. Moreover, in the presence of Tβ4 or Len, or Tβ4/Len combination these proteins may respond with a strong inhibition or up-regulation of the expression of other proteins. Here,we show that 2DE evaluation of CLL profiles may be useful to identify changes in expression profiles of CLL proteins following treatment with different agents. These differences may translate into functional differences such as cell migration and cytoskeletal dynamics in the malignant clone.Special thanks to Celegene Corp and AIRC-CARICAL Regional Grant 16695.

A COMPARATIVE STUDY ON THE EFFECTS OF NUTLIN-3A IN B-CLL CHRONIC LYMPHOCYTIC LEUKEMIA CELLS WITH AND WITHOUT 17P DELETION

M Reiter, S Schnabl, M Hilgarth, E Ponath, R Hubmann, D Demirtas, C Zielinski, U Jäger, M Shehata*
Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria

Background: The p53-MDM2 interaction is emerging as a promising therapeutic target in chronic lymphocytic leukemia (CLL). It is well known that MDM2 oncoprotein inhibits the function of wild-type p53 by its degradation and that MDM2 inhibitors are mainly effective in CLL cases with wild type p53. However, there is no substantial data on the effect of MDM2 inhibitors on CLL cells with p53 mutation or 17p deletion (17p-).
Aims: The aim of this work is to have a deeper insight into the effect MDM2 inhibitor Nutlin-3a on CLL cells obtained from patients with or without 17p deletion under standard suspension culture conditions and in a microenvironment model using co-cultures of CLL cells with primary bone marrow stromal cells (BMSC). This includes evaluating the effect of Nutli-3a on cell viability, induction of apoptosis and the regulation of key p53 downstream targets.
Methods: Peripheral blood mononuclear cells (PBMC) were obtained from 25 B-CLL patients with (n=7) and without (n=18) 17p deletion and exposed to Nutlin-3a under suspension or co-culture conditions for 2-3 days. Dose and time kinetics were also performed and cell viability was evaluated by MTT assay. Induction of apoptosis was assessed by AnnexinV/propidium iodide (PI) staining and FACS analysis. In parallel, a selective effect of Nutlin-3a on CLL cells, T-cells and monocytes was investigated using specific markers for B cells (CD19), T-cells (CD3) and monocytes (CD14) in combination with PI. In addition, the effect of Nutlin-3a on the key p53 downstream targets involved in the regulation of apoptosis (MDM2, Bax, PUMA, Noxa and Mcl-1), cell cycle regulation (p21) or DNA repair (PARP) was assessed by Western blotting and RT-PCR.
Results: In vitro treatment with Nutlin-3a induced cell killing in CLL cells from patients with and without 17p deletion as demonstrated by MTT assays. The effect of the inhibitor was relatively higher on the samples from patients with wild-type 17p at low concentrations (0,5μM to 1μM) compared to patients with 17p deletion. However, at higher concentrations (1-10μM), Nutlin-3a showed a remarkable effect on both groups. A similar pro-apoptotic response to Nutlin-3a was detected by FACS analysis experiments where Nutlin-3a induced 2,5 fold increase in apoptosis rate in patients without 17p deletion compared to 1,6 fold increase in apoptosis in patients with 17p deletion. The pro-apoptotic effect of Nutlin-3a was comparable under suspension and co-culture conditions and was higher in CLL (CD19+) cells compared to T-cells and monocytes. Consistent with the increase in apoptosis rates, Nutlin-3a treatment induced the expression of p53 downstream target p21 mRNA and this was associated with PARP cleavage in both patient groups.
Summary/Conclusions: These data confirm the beneficial effect of Nutlin-3a in CLL and further suggest that MDM2 inhibitors might be effective in 17p wild-type and 17p deleted patients depending on the concentration of Nutlin-3a. Therefore, the clinical relevance of these data deserves further investigations.

DNA-DEPENDENT TRANSCRIPTIONAL REGULATORY GENES WERE HYPOMETHYLATED IN KOREAN CHRONIC LYMPHOCYTIC LEUKEMIA-A METHYLCPG BINDING DOMAIN NGS STUDY

YK Lee[1,*], M Kim[1], EJ Lee[1], HJ Kim[2], DY Zang[2], HY Kim[2], E Lee[1]
[1]Department of Laboratory Medicine, [2]Department of Internal Medicine, Hallym University College of Medicine & Hallym University Sacred Heart Hospital, Anyang-si, Korea, Republic Of

Background: Chronic Lymphocytic Leukemia (CLL) is the most common leukemia in Western countries, but it is very rare and shows relatively poor prognosis in Asian countries including Korea.
Aims: To investigate the differences in the pathobiology of Korean CLL, we analyzed the methylation profile and the expected affected pathways using the methylCpG binding domain NGS (MBD-seq).
Methods: Bone marrow aspirate of 9 CLLs and 5 control individuals were used for MBD-seq using MethylMiner Methylated DNA Enrichment Kit and Illumina Hi-Seq 2000. Differentially methylated regions (DMRs) were determined by filtering for each regions associated with |log2FC|≥1 and exact test p-values<0.05. Hierarchical clustering analysis, gene-enrichment and functional annotation analysis was performed.
Results: Pair-wise correlation coefficient matrix showed a high similarity was observed among either CLL group or control group, but not between the CLL group and the control group. Among 79,612 tested regions regarding to 18,434 genes with CpG islands, CLL group showed 2,078 DMRs (780 genes)-1,083 hypermethylated regions (350 genes) *vs* 995 hypomethylated regions (430 genes). In CpG islands analysis, the DMR profiling clearly separated CLL group from control group. The most frequently hypermethylated genes included *ANKRD20A2, CHERP, PRPF38A, C1orf123, FKTN, TRAFD1, SH3D21, MGAT1, NECAB3* and *UCKL1*. Gene ontology analysis showed genes related with protein localization, cellular macromolecule localization and protein transport were hypermethylated. The most frequently hypomethylated genes included *CBX4, OSR2, LMX1B TNRC18, ICAM5, GATA6, CDX2, NR3C2, STK3* and *HOXB8.* Gene ontology analysis showed genes related DNA dependent transcriptional regulation and RNA metabolic process regulation were hypomethylated. Pathway analysis showed genes related pathways in cancer or hedgehog signaling pathway were hypomethylated.
Summary/Conclusions: We performed the whole genome methylation profile analysis using NGS MBD-seq in Korean CLL for the first time. Our result demonstrated that Korean CLL has a distinct methylation profile. Genes related with protein localization, cellular macromolecule localization and protein transport were hypermethylated, and genes related DNA dependent transcriptional regulation and RNA metabolic process regulation were hypomethylated. Cancer pathway and hedgehog signaling pathway could be overexpressed due to hypomethylation in relevant genes.

INCREASED EXPRESSION OF PIM2 GENE IS ASSOCIATED WITH POOR PROGNOSIS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

K Kapelko-Slowik[1,*], D Urbaniak-Kujda[1], J Dybko[1], D Wolowiec[1], B Jazwiec[1], M Slowik[2], M Biernat[3], S Potoczek[1], K Kuliczkowski[1]
[1]Hematology,Blood Neoplasms and Bone Marrow Transplantation, [2]Ophthalmology, [3]Microbiology, Wroclaw Medical University, Wroclaw, Poland

Background: *PIM2* gene belongs to *PIM* family, which encodes serine/threonine kinases involved in cell survival and apoptosis. *PIM2* gene is implicated in many neoplasms including solid tumors and acute myeloid leukemia. The relation between expression of *PIM2* gene and course of chronic lymphocytic leukemia`s (CLL) as well as outcome has not been fully defined.
Aims: The aim of the study was to evaluate the role of *PIM2* gene as a marker for CLL malignancy and the importance of *PIM2* gene expression as a prognostic factor in CLL.
Methods: Sixty-seven patients, 35 females and 32 males, aged 49-90 years (median age was 66 years) with de novo CLL were enrolled in the study. Thirty-two patients reached complete remission (CR). Bone marrow samples were collected in all patients at the time of diagnosis, whereas only samples with monoclonal lymphoid cells for more than 80% of total cellularity were assessed. In 16 patients bone marrow in CR phase was examined. The control group consisted of 14 healthy individuals. The expression of *PIM2* gene was analyzed by Taq Man RQ-PCR assay and PIM2 protein was detected by Western blot. All statistical analyses were performed using Statistica software.
Results: Median *PIM2* gene expression in CLL patients was significantly higher than in control group. CLL patients with high expression levels of *PIM2* gene (above the median) had significantly shorter progression free survival (PFS) than patients with low *PIM2* expression (p=0.001). In addition, it was found that patients who achieved CR, had significantly lower expression of *PIM2* gene than patients with no CR (p=0.002). Importantly, elevated *PIM2* gene expression assessed initially, was restored to normal level in all patients in CR. Moreover, the overexpression of the PIM2 kinase was detected in CLL patients in contrast to controls. *PIM2* expression in correlation to CLL Rai stages was evaluated also and it was noted that *PIM2* expression in stages IV and III was higher than in both stages I and II (p=0.002). Moreover, CLL patients with rapid lymphocyte doubling time (LDT) (<12 months) shown higher PIM2 expression than patients with lower LDT (≥12 months), p=0.003. Positive correlation between *PIM2* gene expression and the percentage of malignant lymphocytes with ZAP70 expression was found (r^2=0.3214 p=0.01).
Summary/Conclusions: We showed that increased expression of *PIM2* gene in CLL cells is associated with poor prognosis and resistance to chemotherapy in CLL patients.

LB2251

RECOVERY OF TUMOUR SUPPRESSOR FUNCTION OF NOTCH3 BY AN ASPERGILLUM DERIVED MYCOTOXIN IN CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL)

R Hubmann*, S Schnabl, M Araghi, M Hilgarth, M Reiter, E Ponath, D Demirtas, C Zielinski, U Jäger, M Shehata

Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria

Background: Deregulation of NOTCH2 signalling is critically involved in CLL leukemogenesis. We have recently shown that CLL cells are less sensitive to γ-secretase inhibitors (GSI) indicative for the expression of constitutively active NOTCH2 forms which do not depend on γ-secretase for processing and function. In contrast, targeting CLL cells with the Aspergillum derived NOTCH2 transactivation inhibitor gliotoxin efficiently induced apoptosis in the leukemic cells by a mechanism which appeared to involve the induction of NOTCH3.
Aims: To gain deeper insight into the function of NOTCH3 in CLL cells, we analysed NOTCH3 expression in relation to spontaneous and gliotoxin induced apoptosis and tested the effect of *NOTCH3* inhibition on CLL cell viability.
Methods: The *NOTCH3* gene was inhibited by GSI (RO4929097) or by siRNA mediated gene silencing. Apoptosis was calculated as the sum of PI-/AnxV+ (early apoptosis) and PI+/AnxV+ (late apoptosis) cells. The expression of NOTCH and apoptosis related genes was monitored by RT-PCR and FACS analysis.
Results: Results showed that inhibition of NOTCH2 signaling by gliotoxin led to the concomitant induction of NOTCH3 signalling as indicated by the induced co-expression of *NOTCH3* and its ligands *JAG2* (in unstimulated CLL cells) or *DLL1* (in PMA activated CLL cells) at the mRNA level. Gliotoxin induced a tumour suppressive NOTCH3 signalling signature as demonstrated by the induction of the apoptosis regulating NOTCH3 target genes *HEY1*, *NR4A1*, and *CDKN1A* (p21) in the pre-apoptotic phase. In contrast, the anti-apoptotic genes *NOTCH2*, *FCER2* (CD23), and *AKT1* were inhibited by gliotoxin. We then tested the effect of gliotoxin and GSI on induction of apoptosis. Gliotoxin induced apoptosis in CLL cells (mean %±SD: 85±10% *versus* 13±5%), while GSI (RO4929097) mediated NOTCH3 inhibition was associated with a decrease in spontaneous (7±3% *versus* 13±5%) and gliotoxin induced apoptosis (51±7% *versus* 85±10%) in the leukemic cells. To directly confirm that NOTCH3 has a pro-apoptotic role in CLL, we silenced NOTCH3 by RNA interference. After 3 days in culture, *NOTCH3* siRNA decreased the apoptotic effect of gliotoxin leading to a 3.5-fold increase in the percentage of living CLL cells. Inhibition of NOTCH3 by siRNA was also associated with an increased surface expression of CD23, a downstream target of NOTCH2. These data show that the inhibition of NOTCH3 may lead to the upregulation of NOTCH2/CD23 axis and resistance to apoptosis. This reciprocal regulation of NOTCH2 and NOTCH3 together with their opposite effects on cell viability strongly suggests that these two NOTCH receptors have different roles in the regulation of the viability of CLL cells. Interestingly, NOTCH3 mRNA could be detected in patients with early stage of the disease (Rai 0-II) but not in Rai III-IV. Thus, in CLL cells, constitutive active NOTCH2 signalling might suppress pro-apoptotic NOTCH3 signalling enabling the expansion of the malignant clone particularly in advanced stages of the disease.
Summary/Conclusions: In summary, these novel data indicate that selective targeting oncogenic NOTCH2 might recover a pro-apoptotic NOTCH3 activity which should be considered in the design of therapies aimed to target the NOTCH pathway in CLL cells. Moreover, this data points for the first time to a tumour suppressive function for NOTCH3 in CLL.

Chronic lymphocytic leukemia and related disorders - Clinical

E1051

SURVIVAL IN CHRONIC LYMPHOCYTIC LEUKEMIA: A POPULATION-BASED STUDY INCLUDING 13,034 PATIENTS DIAGNOSED IN 1982-2013 IN SWEDEN

V Steingrímsson[1,*], SH Lund[2], PW Dickman[3], C Weibull[3], M Björkholm[4], O Landgren[5], SY Kristinsson[1,4]
[1]Medicine, [2]the University of Iceland, Reykjavik, Iceland, [3]Medical Epidemiology and Biostatistics, [4]Medicine, Karolinska University, Stockholm, Sweden, [5]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in Western countries with a median age between 65-74 years at diagnosis. In clinical trials on CLL treatment, elderly patients with comorbidities have been heavily underrepresented and therefore population-based studies on survival are important to estimate effects of newer treatment on survival. Few observational studies on survival in CLL have been conducted and they have not been consistent in showing improved survival.
Aims: To evaluate the effect of the introduction of new drugs on survival in CLL patients, we conducted a population-based study in CLL patients diagnosed in Sweden from 1982 until 2013, with follow-up through 2014.
Methods: Information on CLL patients diagnosed between January 1, 1982 and December 31, 2013 was retrieved from the well-established Swedish Cancer Registry. The registry has been validated with regards to CLL and has a diagnostic accuracy of more than 90%. Relative survival ratios (RSR) and excess hazard ratios (EHR) were used for estimating the impact on patient survival.
Results: Between January 1, 1982 and December 31, 2013, a total of 13,034 CLL patients were reported to the Swedish Cancer Registry. Age was a significant predictor of survival reflected in reflected in EHRs of 1.48 (95% confidence interval (CI) 1.21-1.81), 2.69 (2.22-3.27) and 5.37 (4.33-6.66) for age groups 51-65, 66-80, and >81 years, respectively, compared to the reference interval of<50 years. Similar results were obtained when comparing 1-, 5- and 10-year survival between age groups. Males had a significantly increased excess risk of death compared to females (EHR=2.12, 95%, CI 1.93-2.34) and worse 1-, 5-, 10- and 15-year RSR. A significantly increased excess risk of death was observed in CLL patients diagnosed in the calendar period 1993-2002 compared to 2003-2013 (EHR=1.36; 95% CI 1.22-1.51). Furthermore, a significantly improved 5- and 10-year RSR was observed comparing CLL patients diagnosed 2003-2013 (5-year RSR 0.81, 95% CI 0.79-0.82 and 10-year RSR 0.61, 0.58-0.65) to 1993-2002 (0.75, 0.73-0.77 and 0.54, 0.51-0.56, respectively. When stratified by age groups, the excess risk of death was significantly higher in 1993-2002 compared to 2003-2013 in age groups<50, 51-65 and 66-80 years old, with EHR 2.87 (95% CI 1.52-5.42), 1.56 (1.26-1.93) and 1.25 (1.08-2.13), respectively. However, it was non-significant in patients 81 years and older (EHR=1.23, 95% CI 0.96-1.58). In age groups<50 and 51-65 years the 5-year survival was significantly better when calendar period 1993-2002 was compared to 2003-2013 (Figure). The 5-year RSR in age group<50 years old was 0.84 (95% CI 0.79-0.90) in 1993-2002 *vs* 0.99 (95% CI 0.97-1.01) in 2003-2013 and in the age group 51-65 years the RSR was 0.84 (0.81-0.86) in 1993-2003 *vs* 0.91 (0.89-0.93) in 2003-2013. The difference in 5-year RSR was non-significant in older age groups.

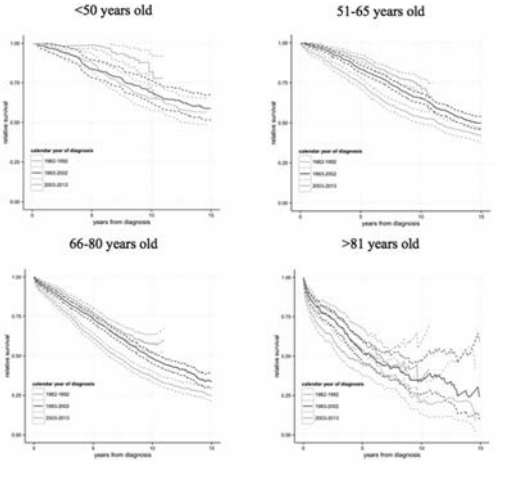

Figure 1.

Summary/Conclusions: We have in this large population-based study, including more than 13,000 patients with CLL, shown improvement in survival of CLL patients in the last decade and the difference is most apparent in younger

patients. Younger patients are in general healthier and less likely to have comorbidities. Based on our results we conclude that risk stratification is likely to benefit older patients for better selection of those patients that can receive intensive treatment. Furthermore, a more significant improvement in overall survival in elderly patients might be obtained with the introduction of a more targeted therapy with less side effects.

E1052

IDELALISIB IN COMBINATION WITH BENDAMUSTINE/RITUXIMAB IMPROVES OVERALL SURVIVAL IN PATIENTS WITH RELAPSED/REFRACTORY CLL: INTERIM RESULTS OF A PHASE 3 RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED STUDY

P Hillmen[1,*], C Ferrá[2], J García-Marco[3], A Jacob[4], W Jurczak[5], N Lamanna[6], D MacDonald[7], P Marlton[8], J Mayer[9], F Morchauser[10], A Nathwani[11], A Schuh[12], S Stilgenbauer[13], W Wierda[14], L Ysebaert[15], A Adewoye[16], Y Kim[16], A Zelenetz[17], J Delgado[18]

Background: Patients (pts) with relapsed/refractory CLL and adverse prognostic features (e.g., del17p/*TP53*mut) respond poorly to standard treatment. Here we present results of a pre-specified subgroup analysis of OS and ORR from an ongoing randomized double-blind placebo-controlled study (ClinicalTrials.gov ID: NCT01569295).

Aims: To demonstrate an improvement in OS and ORR in pts on idelalisib (IDELA) in combination with bendamustine/rituximab *vs* bendamustine/rituximab alone in pts with relapsed/refractory CLL and in a pre-specified pt population with adverse risk features.

Methods: Between June 2012 and August 2014, 416 pts with relapsed/refractory CLL from 180 centers in North America, Australia, New Zealand, and Europe were enrolled in this ongoing study. After informed consent, eligible pts were randomized 1:1 to idelalisib 150 mg BID (207 pts) or matching placebo (209 pts). All pts received bendamustine 70 mg/m^2 on days 1 & 2 and rituximab 375 mg/m^2 day 1 of cycle 1 and 500 mg/m^2 D1 cycles 2 to 6. A cycle of the regimen was Q28 days. Study treatment continued until disease progression, death, intolerable toxicity, or withdrawn consent. Stratification performed by an independent laboratory was by del17p, *TP53* mutations, or mutated *IGHV*, and clinically by refractory (progression<6 months from completion of prior therapy) or relapsed (progression at least 6 months from completion of prior therapy) disease. Median follow-up at the time of this report was 12 months. The primary endpoint of PFS defined by standard criteria was adjudicated by an IRC. Overall survival and ORR were secondary endpoints. Crossover was not permitted at the time of CLL disease progression.

Results: Median overall survival was not reached in either arm; there was a statistically significant improvement in overall survival, after the pre-specified multiplicity adjustment, in the idelalisib arm (HR=0.55; 95% CI: 0.36, 0.86; P=0.008 [stratified]). As of 15 June 2015, there were 34 deaths in the idelalisib arm and 51 deaths in the placebo arm. An improvement in ORR was observed on the idelalisib *vs* placebo arm in all adverse-risk categories evaluated (Table).

Table 1.

Prognostic Feature	IDELA + BR	Placebo + BR	IDELA + BR	Placebo + BR
All pts

HR (95% CI)	0.60 (0.34, 1.06)		0.50 (0.25, 1.00)	
ORR (%)	59	25	73	55

Summary/Conclusions: Idelalisib in combination with bendamustine and rituximab is superior to bendamustine and rituximab alone, reducing the risk of death and disease progression, and increasing progression-free and overall survival. Overall response rate was also increased on the idelalisib arm. These results were consistent across pts with adverse-risk features. The safety profile was consistent with prior reported studies. This trial provides further evidence for the improved outcomes for idelalisib-based therapy in pts with relapsed/refractory CLL. This regimen represents an important new treatment option for the management of relapsed/refractory CLL, further establishing the role of idelalisib in this setting.

E1053

PRELIMINARY RESULTS OF A PHASE I/IB STUDY OF IBRUTINIB IN COMBINATION WITH TGR-1202 IN PATIENTS WITH RELAPSED/REFRACTORY CLL OR MCL

MS Davids[1,*], HT Kim[1], A Nicotra[1], A Savell[1], K Francoeur[1], JM Hellman[1], H Miskin[2], P Sportelli[2], T Rado[3], A Bashey[4], L Stampleman[5], J Rueter[6], A Boruchov[7], JE Arnason[8], CA Jacobson[1], DC Fisher[1], JR Brown[1]

[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, [2]TG Therapeutics, New York, [3]Kadlec Clinic Hematology and Oncology, Kennewick, WA, [4]Bone Marrow Transplantation Group of Georgia, Atlanta, [5]Pacific Cancer Care, Salinas, CA, [6]Eastern Maine Medical Center, Bangor, [7]St. Francis Medical Center, Hartford, CT, [8]Medical Oncology, Beth Israel Deaconess Medical Center, Boston, United States

Background: The oral BTK inhibitor ibrutinib is effective and well-tolerated for patients (pts) with relapsed/refractory (R/R) CLL and MCL; however, the rate of complete remission (CR) is low, and response duration is limited in MCL and in CLL with del(17p) or complex cytogenetics. TGR-1202 is a 2nd generation oral PI3K-delta specific inhibitor with promising efficacy and tolerability. We hypothesized that dual BCR pathway blockade would be tolerable and efficacious.

Aims: The primary aim of this open-label, phase I/Ib investigator-initiated multicenter trial is to determine the RP2D (recommended phase 2 dose) and the safety/tolerability of TGR-1202 plus ibrutinib in pts with R/R CLL or MCL. Secondary aims are to assess efficacy including response rates, duration of response, and PFS/OS.

Methods: Pts received continuous simultaneous daily oral dosing of ibrutinib (420 mg CLL, 560 mg MCL) and TGR-1202, starting at 400 mg daily and escalating in a standard 3+3 design from 600 to 800 mg. The DLT observation period was the first 28 day cycle, with CLL and MCL pts evaluated in separate cohorts. Pts continue until progression or unacceptable toxicity. Eligibility criteria include: ≥1 prior therapy, requiring treatment by IW-CLL criteria, ECOG PS ≤2, and adequate hematologic and organ function. Prior BTK or PI3K inhibitors were allowed. CTCAE v4 and IW-CLL criteria were used to evaluate toxicity and efficacy, with response evaluations after 2 mo., every 3 mo. up to 1 year, and every 6 mo. thereafter.

Results: As of 25 Feb 2016, 20 pts were enrolled, 10 CLL, 10 MCL. The median age at enrollment was 66 yrs. (range 48-83). The median number of prior therapies was 2 for CLL (range 1-6, including 2 with prior ibrutinib and 2 with prior PI3Ki) and 3 for MCL (range 2-5, including 2 with prior ibrutinib). Two CLL pts had del(17p), 2 had del (11q), and 7/10 (70%) had unmutated *IGHV*. The phase I portion in both diseases is now complete. Hematologic toxicities in CLL: neutropenia (37.5%, all gr 3-4), thrombocytopenia (25%, all gr 1), and anemia (37.5%, all gr 1/2). All grade non-hematologic toxicities occurring in >25% of CLL pts: diarrhea and nausea (37.5% each, all gr 1). There were no DLTs, and SAEs included gr 3 atrial fibrillation, gr 3 lipase elevation, and gr 3 CNS infection. The RP2D of TGR-1202 was 800 mg. Hematologic toxicities in MCL: neutropenia (37.5%, 12.5% gr 4), thrombocytopenia (50%, 12.5% gr 3), and anemia (37.5%, 12.5% gr 3). All grade non-hematologic toxicities occurring in >25% of MCL pts: diarrhea (75% [62.5% gr 1, 12.5% gr 2]), fatigue (50%, all gr 1/2), and 37.5% each for nausea (all gr 1/2) and transaminitis, dizziness, hypocalcemia (all gr 1). There were no DLTs, and SAEs included gr 3 hypophosphatemia in 2 pts and 1 pt with gr 3 amylase / gr 4 lipase elevation. The RP2D of TGR-1202 was 800 mg. There were no gr 3/4 bleeding events in either cohort. 6/9 (68%) of CLL pts achieved response, including 1 CR and 5 PR or PR-L. 4/7 (57%) of MCL pts who have reached the first response evaluation achieved response (all PR).

Summary/Conclusions: We report to our knowledge the first clinical data on combined delta-PI3K and BTK inhibition in B cell malignancies. TGR-1202 plus ibrutinib is well-tolerated in pts with R/R CLL and MCL, with no DLTs observed to date. The RP2D of TGR-1202 for both CLL and MCL was 800 mg daily. Preliminary efficacy data suggest a high response rate in both diseases, and phase Ib expansion cohorts at 800mg are now accruing in this ongoing study (NCT 02268851).

E1054

CLINICAL EPIDEMIOLOGY OF CLL AND CYTOGENETIC ABNORMALITIES: ASSOCIATION OF UNIQUE EPIDEMIOLOGIC EXPOSURES WITH 17P OR 11Q DELETION IN NEWLY-DIAGNOSED CLL

JM Foran[1,*], MM O'Byrne[2], AA Chanan-Khan[1], JF Leis[3], NE Kay[4], DL Van Dyke[5], JR Cerhan[2], TD Shanafelt[4], SL Slager[2]

[1]Division of Hematology & Medical Oncology, Mayo Clinic Cancer Center, Jack-

sonville, [2]Department of Health Sciences Research, Mayo Clinic, Rochester, [3]Division of Hematology & Medical Oncology, Mayo Clinic Cancer Center, Phoenix, [4]Division of Hematology, [5]Cytogenetics Laboratory, Mayo Clinic, Rochester, United States

Background: Clinical epidemiologic exposures associated with risk of developing CLL have been described in large case-control studies, including allergy, some autoimmune diseases, obesity, medical and family history, and some occupational exposures including rural/farm habitat. However, it is not known whether specific exposures are associated with a unique disease phenotype, and specifically whether risk factors for development of CLL are themselves associated with adverse cytogenetic profile by FISH, namely del(11q) and del(17p).
Aims: Primary Aim: To determine whether common clinical epidemiologic exposures associated with development of CLL are associated with a unique cytogenetic profile as determined by FISH at the time of diagnosis, and specifically which CLL risk factors are associated with adverse FISH profile [del(11q) and del(17p), either alone or in combination with other abnormalities]
Methods: We used cases from the Mayo Clinic Case-Control Study of Lymphoma, annotated with molecular markers from the Mayo Clinic CLL database to evaluate associations of medical history, lifestyle, family history, and farming history in a case-only study of the risk 17p or 11q deletion in CLL patients. Newly diagnosed CLL patients were enrolled between 2002 and 2012, and weight was patient-reported from 2 years prior to diagnosis. Unconditional logistic regression was used to estimate Odds Ratios (ORs) and 95% Confidence Intervals (CI) for risk adverse FISH profile (11q or 17p deletion). A significance level of 5% was used to determine statistical significance.
Results: We included n=683 patients, of whom n=100 had 11q or 17p deletions. Results of the analysis are noted in the Table.
We observed a significant association of rheumatoid arthritis with adverse FISH profile (11q or 17p deletion) at diagnosis (OR=2.49, 95% CI 1.06-5.86, p=0.037). In contrast, we observed a significant inverse relationship of any Allergy (Food, Plant, Animal, Insect, Dust, Mold) (OR=0.59, 95% CI 0.36-0.96, p=0.035) and of Atopy (OR 0.63, 95% CI 0.40-0.99, p=0.045) with adverse FISH profile. Other common exposures including obesity, smoking, and farm exposures were not associated with high risk FISH profile. Similarly, family history was also not associated with an adverse FISH profile, consistent with earlier reports.

* Allergy: Food, Plant, Animal, Dust, Insect, Mold

Summary/Conclusions: Some clinical epidemiologic risk factors (allergy, atopy and rheumatoid arthritis) associated with the development of CLL are themselves significantly associated with specific disease-related cytogenetic abnormalities as determined by FISH profile at diagnosis. This suggests that some CLL risk factors may be associated with a unique clinical and genetic phenotype, which may influence disease biology and prognosis after diagnosis. Specific exposures that appear to mediate disease risk through alternate pathways of immune stimulation (i.e. allergy and atopy *vs* rheumatoid arthritis) are associated with a significantly different cytogenetic risk profile at diagnosis, suggesting that they likely have unique mechanisms of leukemogenesis. Further studies are ongoing to determine the impact of CLL epidemiologic risk factors on clinical outcome in association with other clinical and biological prognostic factors at diagnosis.

E1055

ASSESSING TIME TO FIRST TREATMENT IN EARLY CLL: A COMPARATIVE PERFORMANCE ANALYSIS OF FIVE PROGNOSTIC MODELS WITH INCLUSION OF CLL-IPI

S Molica[1,*], D Giannarelli[2], M Gentile[3], R Mirabelli[1], L Levato[1], F Morabito[3]
[1]Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, [2]Biostatistic Unit, IRCCS Regina Elena, Roma, [3]hematology-Oncology, Azienda Ospedaliera Annunziata, Cosenza, Italy

Background: Recent research in CLL focused on the development of prognostic scores which assemble in a same model different prognostic markers. However, analyses comparing the performances of these models are lacking.
Aims: In a prospective patient cohort we evaluated the capability of four recently proposed prognostic models in CLL (*i.e.*, 2007 MDACC score, GCLLSG score, 2011 MDACC score,O-CLL1 score) to predict time to first treatment (TTFT). Results were compared with those obtained using the CLL-IPI.
Methods: Newly diagnosed Binet stage A patients (n=337) from several Italian Institutions prospectively enrolled into the O-CLL1 protocol (clinicaltrial.gov identifier: 115 NCT00917540) form the basis of this analysis.
Results: The Harrell's c values which indicate the discriminatory power of the models (higher is better) were better for 2011 MDACC score (c-index, 0.71) and the O-CLL1 score (c-index,0.75) which were generated looking at TTFT as endpoint and combine clinical, biological and genetic markers. The same applied with GCLLSG (c-index,0.70) score and CLL-IPI (c-index, 0.70) even though they were originally developed with overall survival as main end pont. Finally, a c-statistic below 0.70 which is the threshold necessary to have value at the individual patient level was observed with 2007 MDACC score (c-index, 0.65) which was designed to assess overall survival as end point and did not incorporate major genetic factors. A global view of performances of different scores was also provided by the area under the receiver operating characteristic (ROC) curve figures considered an alternative measure of discrimination (Figure 1). Furthermore, the time-dependent ROC analysis which is an extension of ROC curves demonstrated that for early time points (<24 months) scores provided limited ability in distinguishing patients with different TTFT. In contrast, for late time points (≥24 months after diagnosis), the predictive accuracy of TTFT was higher for models including both clinical and genetic variables (i.e., O-CLL1, CLL-IPI,2011 MDACC score, GCLLSG score) in comparison with models which included only clinical variables (i.e., 2007 MDACC score). Finally, values of Aikaike information criterion (AIC) which indicates the goodness of the fit (lower is better) were better for the O-CLL1 score (AIC, 810) and worse for 2007 MDACC score (AIC, 851). In between there were the GCLLSG score (AIC, 837), the CLL-IPI (AIC, 841) and the 2011 MDACC score (AIC, 844), respectively.

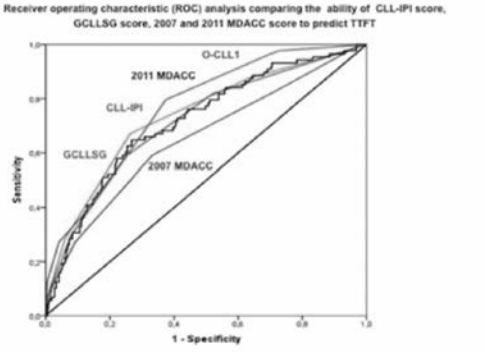

Figure 1.

Summary/Conclusions: Although different with respect to either the endpoints for which they were generated (*i.e.*, OS *versus* TTFT) or the prognostic factors considered (*i.e.*, only clinical *versus* clinical and genetic) all models used in this validation analysis worked in predicting TTFT. Results of AIC and Harrell's c value demonstrated that the predictive accuracy of TTFT was higher for models including both clinical and genetic variables (i.e., CLL-01, CLL-IPI,2011 MDACC score, GCLLSG score).

E1056

BCL6 ABNORMALITIES ON FLUORESCENCE IN SITU HYBRIDIZATION ARE ASSOCIATED WITH EARLY AGE AT DIAGNOSIS, KARYOTYPIC COMPLEXITY, AND AGGRESSIVE DISEASE IN CHRONIC LYMPHOCYTIC LEUKEMIA

P Eulitt*, Q Zhao, A Ruppert, L Abruzzo, C Coombes, A Gordon, J Jones, F Awan, J Blachly, L Andritsos, J Byrd, N Heerema, J Woyach

The Ohio State University Wexner Medical Center, Columbus, United States

Background: The clinical course of CLL is variable but can be predicted in part by recurrent cytogenetic abnormalities. BCL6 functions as a transcriptional repressor during germinal center formation, and alteration of 3q27 has been well characterized in some B cell malignancies. However, the incidence and significance of BCL6 abnormalities in CLL is unknown.
Aims: We aimed to determine the incidence and clinical significance of BCL6 abnormalities in CLL by analyzing a large database of CLL patients. We then aimed to analyze subsets of patients enrolled in clinical trials to determine the signficance of primary BCL6 abnormalities compared to acquired BCL6 abnormalities.
Methods: Between 10/2007 and 6/2014, 1811 patients (pts) with CLL at our institution underwent FISH which included a probe for 3q27. Clinical and molecular data were reviewed for pts with rearrangements or extra copies of BCL6. Data were also obtained from pts participating in 4 sequential clinical trials of ibrutinib, and characteristics of pts with and without pre-treatment BCL6 abnormalities were compared.
Results: 152 pts (8.4%) were found to have an abnormality of BCL6 at any time during their clinical course. Clinical and cytogenetic characteristics are summarized below. BCL6 abnormalities were present prior to first therapy in 28 pts, suggesting a primary abnormality. These pts had an early age at diagnosis (62.5 years), short time from diagnosis to first treatment (median 23.6 months), and relatively low 5-year survival (estimated at 62.9%). Pts with BCL6 abnormalities were likely to have complex karyotype and other high risk abnormalities including MYC rearrangement/copy gains and del(17p). Comparing pts with and without BCL6 abnormalities undergoing similar therapy, those with BCL6 abnormalities were more likely to have complex karyotype (p=0.0007), MYC abnormalities (p<0.0001), and del(17p) (p<0.0001).

Table 1.

	All BCL6+ pts (n = 152)	BCL6+ before first therapy (n = 28)
Median age at diagnosis	58.0 years	62.5 years
Median time from diagnosis to first therapy	15.5 months	23.6 months
Karyotype complexity (≥ 3)	71.3%	64.3%
Concurrent FISH abnormalities:		
MYC	49.0%	33.3%
Del(17p)	57.9%	42.9%

Summary/Conclusions: BCL6 abnormalities are associated with other high risk markers in CLL, and these pts have early age at diagnosis, short time to first therapy, and relatively short survival. These data suggest that BCL6 FISH abnormalities may be an important biomarker in CLL. Work to further characterize the biologic basis for these findings is ongoing.

E1057

VERY YOUNG PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA HAVE LOWER INCIDENCE OF ADVERSE CYTOGENETICS AND IMPROVED OVERALL SURVIVAL: 10-YEAR EXPERIENCE FROM MEMORIAL SLOAN KETTERING CANCER CENTER

B Getta[1,*], S Devlin[2], J Park[1], M Tallman[1], E Berman[1]
[1]Leukemia Service, [2]Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, United States

Background: Young pts, arbitrarily defined as ≤ age 40, comprise a very small fraction of patients with CLL. Risk factors and outcomes in this young age group are not well described.
Aims: To compare biologic disease factors and clinical outcomes between patients age ≤40 with those >40.
Methods: Young pts were arbitrarily defined as ≤40 at diagnosis. Pts from the MSKCC CLL database diagnosed between 1/1/2005 and12/31/2015 were included. Two control CLL pts age >40 were matched to each patient ≤40 and served as controls. Matching was based on diagnosis year (+/- 2 yrs) and the time from diagnosis to the first MSKCC visit (+/- 2 yrs). Patient and disease characteristics were compared using Fisher's exact test. Cox regression analysis accounting for the matched pairs was used to estimate overall survival, time-to-first and –second treatment, and duration of first response. Survivor curves were estimated using Kaplan-Meier methods. The National Cancer Institute Surveillance, Epidemiology and End Results (SEER) database was used to compare the overall survival of pts ≤40 years with those >40 diagnosed between 1990-2005. Statistical analysis was performed using the R statistical package. The project was approved by the MSKCC institutional review board.
Results: 71/3455 (2.1%) pts in the MSKCC database were < age 40. Characteristics of the two groups are shown in Table 1. Significant differences included: initial WBC, presence of B symptoms, B2M and adverse cytogenetics. Second malignancies occurred more frequently in pts >40. There were 6 cases of Richter's transformation (RT) to DLBCL in each group, one case of histologically 'accelerated CLL' in each group and two cases of transformation to Hodgkin lymphoma in the group >40. DLBCL with TP53 mutation/del17p was seen in 1/6 pts ≤40 and 3/6 in >40 group. DLBCL was the initial indication for CLL therapy in 5/6 young pts who had RT, 3 of whom presented concurrently with CLL and RT. No pt >age 40 presented with CLL and DLBCL. There was no difference in the incidence of autoimmune complications in the two groups and no difference in the incidence of hematologic or solid organ malignancy in 1st or 2nd degree family members. The median follow-up of the MSKCC pts ≤40 was 54 months (1-313) and those >40 was 48 months (0-271). 48% of pts in each group required treatment. The time to first therapy and duration of response following 1st and 2nd line therapy were similar (Table 1). Six pts ≤40 (8.5%) and 2 pts >40 (1.4%) underwent allo-BMT (p=0.018). There were 4 deaths in pts ≤40 (5.6%) and 18 deaths in pts >40 (12.7%). Seven of the 22 deaths were unrelated to CLL (Table 1); and 6 of these were due to secondary malignancies. The estimated OS at 8 years was 0.97% in the group<40 and 86% in the group >40 (p=0.053) (Fig 1A). Lastly, in order to compare our results with a larger database, we evaluated young pts in the SEER database. There were 29,822 CLL pts of whom 279 were ≤40 (0.94%). The median OS in SEER cohort for pts age ≤40 was not reached, and in those age>40 was 6.9 years (95% CI 6.8-7.0),(p<0.001) (Fig 1B).

Age at CLL diagnosis	≤40 years	>40 years	P-value
Total Patients/% men	71 / (55%)	142 / (50%)	
Median age (range)	38 (21-40)	61 (41-86)

Time to second therapy, months	138 (121-NR)	177 (87-NR)	0.86 (0.32-2.62), p=0.75
8-yr estimated OS, (%)	0.97 (0.79-0.94)	0.86(0.79-0.94)	0.34 (0.11-1.02), p=0.053
CLL related deaths/total deaths	3/4	12/18	

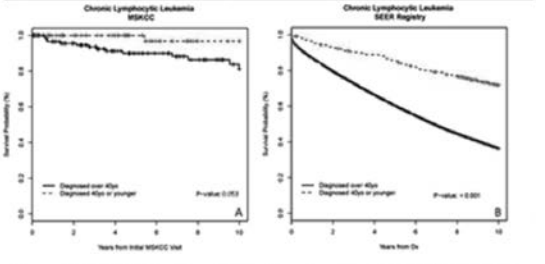

Figure 1 (A) OS of MSKCC cohort calculated from date of first MSKCC visit (2005-2015). (B) OS from date of CLL diagnosis in SEER registry cohort (1990-2005).

Figure 1.

Summary/Conclusions: A very small fraction of pts with CLL are diagnosed before the age of 40. These data suggest: a lower incidence of adverse cytogenetics at diagnosis, equivalent treatment response, and a higher incidence of RT that was not associated with del17p. MSKCC and SEER data suggest that young pts with CLL do not have an inferior survival compared pts >age 40.

CD49D EXPRESSION IS ASSOCIATED WITH DEVELOPMENT OF LYMPHADENOPATHY IN PATIENTS WITH MONOCLONAL B-CELL LYMPHOCYTOSIS (MBL) AND CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

P Strati[1,*], K Chaffee[1], S Achenbach[1], S Slager[1], T Call[1], N Kay[1], W Ding[1], S Parikh[1], D Jelinek[2], C Hanson[1], T Shanafelt[1]
[1]Mayo Clinic, ROCHESTER, [2]Mayo Clinic, Scottsdale, United States

Background: CLL clinical presentation is very heterogeneous, including lymphadenopathy, organomegaly, and cytopenias. The biologic factors which determine these differences in clinical manifestation are poorly understood. CD49d is a surface integrin expressed on CLL lymphocytes that facilitates interactions between CLL B-cells and stromal cells in the microenvironment. Although case series suggest high expression of CD49d in CLL patients may be associated with presentation with lymphadenopathy, these series are small and nearly all the information to date is cross-sectional.
Aims: We used the Mayo Clinic CLL database to prospectively evaluate the association between CD49d expression and subsequent development of lymphadenopathy in a cohort of patients with newly diagnosed MBL and CLL Rai stage 0.
Methods: All patients seen at our center between 08/2001 and 12/2015 and

who had pre-treatment CD49d testing available within 1 year of the date of diagnosis were included in the study. CD49d was considered positive if ≥30% of cells expressed CD49d (JCO 32:897). Time to development of lymphadenopathy was defined as time from diagnosis to appearance of palpable lymph nodes; in the absence of development of lymphadenopathy, patients were censored at date of first therapy or last follow-up. The Kaplan-Meier plots display time to development of lymphadenopathy.
Results: The study included 720 individuals, 333 with MBL and 387 with Rai stage 0 CLL. Among these patients, CD49d was positive in 34.5% of those with MBL and in 19.4% of patients with CLL Rai stage 0 (p<0.001). The median% of clonal B-cells expressing CD49d at diagnosis was 12% (interquartile range [IQR] 5%>59%) in individuals with MBL and 3.7% (IQR, 2%>14%) in patients with Rai stage 0 (p<0.001). Fourty-four (15%) patients with MBL and 82 (21%) patients with CLL Rai 0 subsequently developed palpable lymphadenopathy during the course of follow-up (median follow-up= 3.4 years). CD49d positivity at baseline was also associated with shorter time to development of lymphadenopathy both in patients with MBL (p=0.048) and CLL Rai 0 (p<0.001; Figure 1).

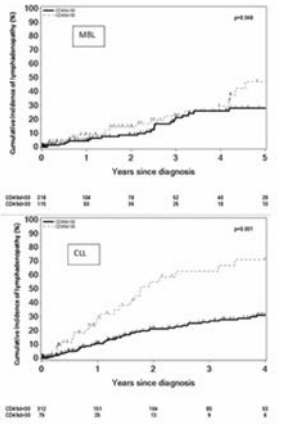

Figure 1.

Summary/Conclusions: CD49d expression identifies a cohort of MBL and Rai 0 CLL patients whose clinical course may be dominated by development of lymphadenopathy as opposed to bone marrow infiltration and cytopenias.

E1060

IMPACT OF THE APOPTOTIC REGULATOR DRAK2 IN CHRONIC LYMPHOCYTIC LEUKEMIA

C Ciardullo[1], E Willmore[2], P Zhou[2], V Rand[2], C Harrison[2], A Hall[2], J Eswaran[2], M Soundararajan[1,*]
[1]Faculty of Health and Life Sciences, Northumbria university, [2]NICR, Newcastle University, Newcastle upon Tyne, United Kingdom

Background: In chronic lymphocytic leukaemia (CLL), the impaired balance between the pro-apoptotic and anti-apoptotic stimuli is involved in chemorefractoriness and clinical outcome. The low proliferation rate indicates that one of the primary mechanisms during disease development may be apoptotic failure. The apoptotic pathways and CLL proliferation is controlled by a variety of regulator molecules including various protein kinases. DRAK2 belongs to the Death-associated protein kinase (DAPK) family sharing 52% homology with DAP kinase 1 (DAPK1), a heritable predisposing factor in CLL. DRAK2 is expressed exclusively in lymphoid tissue while *drak2*$^{-/-}$ mice showed five-fold decrease in spleen germinal center compared to their wild-type littermates resulting from increased B-cell apoptosis. Further according to recent studies DRAK2 has been shown to control cell proliferation through its interaction with TβR1 thereby downregulating the smad2/3 mediated signalling.
Aims: The aim of this investigation is to understand the impact of one of the major apoptotic regulators, Death-Associated Protein Kinase-Related 2 (DRAK2) in CLL and its relationship to two distinct cellular networks a) involving TGF-β and b) Zap70-RhoH mediated signalling pathway in CLL
Methods: In our study, we have analyzed 102 CLL samples using TaqMan quantitative real-time PCR (qPCR) and calculated the relative expression by the $2^{-\Delta\Delta Ct}$ method. A ROC curve was generated to identify the optimal diagnostic cut-off. *DRAK2* expression was then split at this cut-off and the resulting dichotomous variable was included in a survival analysis.
Results: The *DRAK2* mRNA expression ranges from 0.16 to 9.26. Interestingly, *DRAK2* low-expressing patients showed significantly shorter survival than *DRAK2* high-expressing patients (p=0.003). The low expression of *DRAK2* is also identified as an adverse prognostic factor within the 13q deleted CLL patients. When we studied the relationship between DRAK2 and critical prognostic factors such as ZAP70 and its interaction partner RhoH, an atypical GTPase which influences the development of CLL, mRNA level of RhoH had no impact on overall survival in our cohort but discovered positive correlation (Pearson's r=0.36, p=0.00002) between DRAK2 and RhoH mRNA expression levels. Further based on the recent literature, which suggests negative feedback loop regulation between DRAK2 and Transforming growth factor β Receptor I, controlling TGF-β/Smads signalling in solid tumours, we measured the *TGFBR1* mRNA expression and found a positive correlation between *DRAK2* and *TGFBR1* expression (Pearson's r=0.446, p=0.000003).
Summary/Conclusions: Together, our data show for the first time an association between *DRAK2* expression and CLL poor prognosis and suggest the possibility of novel TGF-β/DRAK2 apoptotic signalling regulation in CLL. Moreover Zap70-RhoH mediated regulatory mechanism of DRAK2 remains rather complex that needs to be further investigated.

E1061

THE PROGNOSTIC SIGNIFICANCE OF PROLYMPHOCYTES IN CLL AND CORRELATION WITH MOLECULAR MARKERS IN THE LRF CLL4 TRIAL

D Catovsky[1,*], M Else[1], E Matutes[1], R Morilla[1], J Strefford[2], D Oscier[3]
[1]Molecular Pathology, The Institute of Cancer Research, London, [2]Faculty of Medicine, University of Southampton, Southampton, [3]Molecular Pathology, Royal Bournemouth Hospital, Bournemouth, United Kingdom

Background: An increase in the percentage and number of circulating prolymphocytes in CLL has been associated with strong expression of surface immunoglobulin (SmIg), trisomy 12 and a poor outcome (Melo *et al*, Br J Haematol 1986;63:377 & 1987;65:23; Que *et al*, Blood 1993;82:571).
Aims: This study re-examines the biological and clinical significance of increased peripheral blood prolymphocytes in patients entered into the randomised UK LRF CLL4 trial. It also investigates the associations between increased prolymphocytes and a comprehensive array of biomarkers.
Methods: 777 previously untreated patients were randomised between 1999 and 2004 to receive either chlorambucil or fludarabine, alone or in combination with cyclophosphamide. Median follow-up for overall survival (OS) was 11.8 (range 10.2-15.9) years. The proportion of prolymphocytes was assessed at trial entry in 508 patients.
Results: 270 patients (53%) had <5% prolymphocytes, 167 (33%) had 5-9%, 60 (12%) had 10-14% and 11 (2%) had =>15% prolymphocytes. We confirmed the association of increased prolymphocytes (=>10%) with strong SmIg expression and trisomy 12. In multivariate analysis =>10% prolymphocytes was independently associated with *NOTCH1* mutations, absence of 13q deletion, high CD38 expression and unmutated *IGHV* genes:

Table 1.

Variable	Odds ratio	95% Confidence Limits		p
NOTCH1 mutation	3.88	1.46	10.30	0.006
Absence of 13q deletion	4.41	1.82	10.69	0.001
Positive CD38 expression	6.48	1.44	29.25	0.02
Unmutated *IGHV* genes	5.02	1.39	18.17	0.01

Increased prolymphocytes (=>10%) were associated with a shorter progression-free survival (HR 1.50 [95%CI: 1.16-1.93], p=0.002) and OS (HR 1.99 [95%CI 1.53-2.59], p<0.0001; Figure 1). An absolute prolymphocyte count >=15x10^9/L was also associated with longer OS (HR 1.53 [95%CI 1.15-2.04], p=0.004). =>10% prolymphocytes was an independent predictor of OS when the multivariate model included the significant variables age, disease stage, 11q and 13q deletion and *TP53* del/mut together with any one of the following, each included separately: *IGHV* mutational status, B2M, CD38, Zap70 or *CLLU1* expression, mutations on *NOTCH1* or *SF3B1,* or telomere length. When all the significant variables were included together,% prolymphocytes was not an independent predictor of OS. Deaths due to Richter's syndrome were more common amongst patients who had =>10% prolymphocytes at trial entry (9/71, 13%) *vs* those with<10% prolymphocytes (8/437, 2%; p<0.0001).

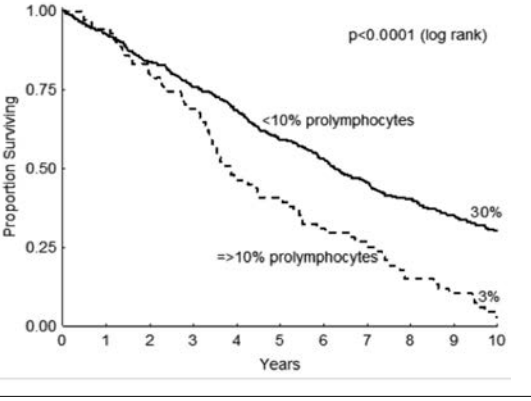

Figure 1. Overall survival by <10% *vs* =>10% prolymphocytes.

Summary/Conclusions: Our data support the routine examination of blood films in CLL and suggest that a finding of an increased proportion of prolymphocytes may be a trigger for a further evaluation of clinical and laboratory features of progressive disease.

E1062

ITALIAN VALIDATION OF THE INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS (CLL-IPI) AND COMPARISON WITH MDACC PROGNOSTIC INDEX: ANALYSIS OF 620 CASES

Martino-IST, Genova, [7]Consiglio Nazionale delle Ricerche, Istituto di Fisiologia Clinica, Reggio Calabria, [8]IFC-CNR, UOS di Roma, Rome, [9]Biotechnology Research Unit, AO/ASP di Cosenza, Aprigliano (CS), [10]Department of Clinical Sciences and Community Health, University of Milano and Hematology CTMO, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, [11]Direzione Scientifica IRCCS, San Martino IST, Genova, [12]Division of Hematology, Department of Translational Medicine, Amedeo Avogadro University of Eastern Piedmont, Novara, [13]Hematology Sapienza University, [14]UOC Ematologia di Cosenza, Rome, Italy

Background: In the last two decades, a plethora of clinical, serological and biological markers have been identified that are significantly associated with the prognosis of chronic lymphocytic leukemia (CLL) patients. Recent research has focused on the development of scoring systems capable of integrating the major prognostic parameters. A recent international collaboration proposed an international prognostic index (CLL-IPI) built on clinical, serological, and biological parameters (TP53 deletion and/or mutation, IGHV mutational status, β2M, clinical stage, and age) universally applicable to previously untreated CLL patients to predict overall survival (OS).
Aims: We performed a validation of the CLL-IPI in an independent series of Italian patients. Furthermore, we compared this tool with the prognostic index proposed by the MDACC CLL group in 2007.
Methods: Databases from 4 Italian centers including roughly 3000 newly diagnosed CLL patients were used to evaluate the validity and reproducibility of the CLL-IPI. Baseline data regarding age, Binet stage, *IGHV* mutational status, β2M and *TP53* status, using only del17p, were available for 620 cases. The parameters for the calculation of the MDACC score were also available in these patients. The CLL-IPI and the MDACC score were calculated using the methods proposed. The accuracy of the prognostic models was assessed by the Harrell C index (an index of discrimination), the explained variation in mortality (an index combining calibration and discrimination), and the Akaike information criterion (AIC, an index comparing two non-nested prognostic models). The lower the AIC, the higher the prognostic accuracy of a predictive model.
Results: The median age of the 620 patients was 65 years (range 27-92) with 55.1% males. The majority of patients had Binet stage A (81.9%) and 366 cases (58.7%) had Rai stage 0. All 5 parameters of the CLL-IPI were found to be independently associated with survival in this study cohort (age >65 years: HR 5.48, P<0.0001; Binet B/C stage: HR 2.17, P<0.0001; β2M>3.5 mg/L: HR 1.99, P=0.001; *IGHV* unmutated: HR 1.82, P=0.002; *TP53* deleted: HR 2.84, P<0.0001). According to the CLL-IPI, 57.1% of patients were classified as low-, 23.3% as intermediate-, 14.9% as high-, and 4.7% as very high-risk. The 5-year OS probabilities were: 93.5% for low-risk, 83.2% for intermediate-risk, 68.6% for high-risk, and 35.1% for very high-risk cases (P<0.0001; Harrell C index=73%; P<0.001). The prognostic index risk category remained a predictor of survival when analysis was limited to Rai stage 0 (P<0.0001). Subsequently, we compared the CLL-IPI with the MDACC prognostic index score in our cohort. The Harrell C index of the MDACC score was 70% (P<0.001), similar to the CLL-IPI (73%). The AIC showed the superiority of the CLL-IPI compared to the MDACC score in predicting OS (CLL-IPI, AIC=1372.007 *versus* MDACC score, AIC=1383.364). Accordingly, the explained variation in mortality provided by the CLL-IPI was 29% (P<0.001), a figure higher than that due to the MDACC score (26%, P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for mortality compared to that of MDACC score.
Summary/Conclusions: Our results confirm the validity of the CLL-IPI to predict survival among patients with previously untreated CLL. Moreover, we have demonstrated that the CLL-IPI which combines clinical and serological data with biological parameters has a higher accuracy for predicting prognosis of CLL patients than the MDACC score, a model built only on clinical and laboratory markers.

IDELALISIB PLUS AN ANTI-CD20 ANTIBODY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WHO ARE HBV CORE ANTIBODY POSITIVE: SIMILAR PATTERNS OF LIVER TEST ABNORMALITIES

T Robak[1,*], AD Zelenetz[2], A Mato[3], JA Jones[4], JM Pagel[5], JC Barrientos[6], JR Brown[7], M Montillo[8], R Dubowy[9], G Xing[9], JJ Li[9], TJ Kipps[10], P Hillmen[11]
[1]Medical University of Lodz, Lodz, Poland, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]Center for CLL, Hospital of the University of Pennsylvania, Philadelphia, PA, [4]Ohio State University, Columbus, [5]Fred Hutchinson Cancer Research Center, Seattle, WA, [6]Hofstra Northwell School of Medicine, Hempstead, NY, [7]Dana-Farber Cancer Institute, Boston, MA, United States, [8]Niguarda Ca' Granda Hospital, Milan, Italy, [9]Gilead Sciences, Inc., Foster City, CA, [10]University of California, San Diego/Moores Cancer Center, San Diego, CA, United States, [11]St James's University Hospital, Leeds, United Kingdom

Background: Increased hepatitis B virus (HBV) reactivation risk has been reported in patients (pts) undergoing treatment with anti-CD20 therapies, including rituximab (R) and ofatumumab (O).[1] Reactivation can also occur after HBV surface antigen (HBsAg) loss, especially in immuno-compromised pts.[2,3] A high rate of reactivation has been reported in such pts receiving an anti-CD20 antibody+chemotherapy.[4] The incidence of transaminase elevation in CLL pts who are core antibody positive (anti-HBc+)/ HBsAg-/HBV PCR- and receiving anti-CD20+kinase inhibitors including idelalisib (IDELA) has not been reported.
Aims: The objective of this analysis was to characterize the patterns of changes in liver tests in pts with CLL and anti-HBc+/ HBsAg-/HBV PCR- and receiving IDELA+anti-CD20.
Methods: The patterns of changes in liver tests were analyzed among 477 pts with relapsed/refractory (R/R) CLL treated with IDELA+R *vs* placebo+R (NCT01539512) or IDELA+O *vs* O (NCT01659021). Pts with anti-HBc+/HBsAg- were enrolled only if they were HBV PCR- by quantitative PCR (qPCR). Pts who were anti-HBc+/HBsAg- at screening were monitored for potential HBV reactivation (manifested as detectable HBV DNA by qPCR).
Results: During the study period beginning May 2012, 283 pts received IDELA+anti-CD20 therapy (110 IDELA+R; 173 IDELA+O) and 194 pts received anti-CD20 monotherapy (108 R; 86 O). Of 477 pts analyzed, 390 pts were anti-HBc-/HBsAg- (86 IDELA+R; 152 IDELA+O; 79 R; 73 O); 85 pts were anti-HBc+/HBsAg-/HBV PCR- (24 IDELA+R; 21 IDELA+O; 28 R; 12 O); 2 pts had missing data (1 R; 1 O). Of the 85 pts who were anti-HBc+, 3 had a prior history of HBV infection and 41 (22/45 on IDELA+anti-CD20 and 19/40 on anti-CD20) had received IV immunoglobulin (IVIG) before screening for treatment of hypogammaglobulinemia; 5 pts on IDELA+anti-CD20 and 3 on anti-CD20 received anti-HBV prophylaxis on-study. In the subgroup analysis, no significant difference in liver test abnormalities was detected between anti-HBc+/HBsAg- and anti-HBc-/HBsAg- subgroups in pts receiving IDELA+anti-CD20 or anti-CD20 monotherapy (table).

Table 1.

	IDELA+anti-CD20		anti-CD20	
	anti-HBc+ (n=45)	anti-HBc- (n=238)	anti-HBc+ (n=40)	anti-HBc- (n=152)
Grade ≥3 ALT/AST+-, n (%)	7 (15.6)	25 (10.5)	1 (2.5)	1 (0.7)
P value	0.449		0.379	
Med Time to Onset, wks	6.9	8.1	-	-
Grade ≥3 total bilirubin+-, n (%)	1 (2.2)	3 (1.3)	0 (0)	1 (0.7)
Grade ≥3 GGT+-, n (%)	1 (2.2)	13 (5.5)	3 (7.5)	1 (0.7)
Drug discontinuation due to hepatic-related TEAE, n (%)	0 (0)	8 (3.4)	0 (0)	0 (0)

Summary/Conclusions: Prior exposure to Hep B does not appear to be a risk factor associated with liver test abnormalities in pts treated with IDELA+anti-CD20.

E1064

SECONDARY CANCERS, MAJOR INFECTIONS AND AUTOIMMUNE DISEASES OCCUR IN DIFFERENT SUBSETS OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A Visentin[1,2,*], S Imbergamo[1], F Frezzato[1,2], C Gurrieri[1,2], V Martini[1,2], V Trimarco[1,2], F Severin[1,2], M Pizzi[3], E Scomazzon[1], R Zambello[1,2], F Piazza[1,2], M Facco[1,2], G Semenzato[1,2], L Trentin[1,2]
[1]Department of Medicine, University of Padova, Hematology and Clinical Immunology unit, [2]Venetian institute of Molecular Medicine, [3]Department of Medicine, University of Padova, Surgical Pathology and Cytopathology unit, Padova, Italy

Background: Chronic lymphocytic leukemia (CLL), the most common leukemia in western country, is still an incurable disease and the most relevant complications are major infections (MI), second cancers (SC) and autoimmune diseases (AD).
Aims: The aim of this study was to define the prevalence, risk factors and the evaluation of the impact of MI, SC and AD on the survival of CLL patients
Methods: We retrospectively analyzed clinical and biological data from 795 patients referred to Hematology and Clinical Immunology Unit of Padua University hospital. MI, were defined as those infective events that required in patients management or the use of intravenous antibiotics. SC comprised all other malignancies; while low and high-grade dysplasia were excluded. AD included all autoimmune and immune-mediate diseases. FISH analysis

(n=598), CD38 expression (n=656), IGHV mutations (n=507) and TP53 abnormalities (n=527, account for TP53 deletion and mutation) were evaluated according to international guidelines. Statistical analyses were performed with Fisher exact test, Chi-square test, Log-rank test, Kaplan-Meier method and Cox model. Overall survival was calculated from the date of diagnosis to death (event) or last available follow-up (censored).
Results: With a median follow-up of almost 100 months, thirty-four percent of patients developed at least one complication among MI, SC and AD with 95% of them being occurred after CLL diagnosis (Figure 1A). Ninety-eight patients experienced 138 MI, among which pneumonia (65%), septic shock (13%) and deep tissue abscess (10%) were the most common. 120 patients reported 187 SC; skin cancer (32%), colon cancer (16%) and other-hematological malignancies (14%) resulted to be the most common SC. Eighty patients were diagnosed with 103 AD, the most common of which resulted to be hematological (41%), rheumatologic (17%) and thyroid-related diseases (16%). We observed that only 0.9% of the cohort developed all the complications and that 1.4% experienced both SC and AD, 1.8% both MI and AD, and 3.9% both MI and SC during the follow-up period (Figure 1B). These data suggest a low probability to develop two or three complications and, as shown in Figure 1C, they seem to occur in a mutually exclusively manner. MI were found with a higher prevalence in males, in previously treated patients and in those with high-risk cytogenetic by FISH and TP53 abnormalities. SC resulted to be more common in male, in advance Rai and Binet stages at diagnosis, in previously treated patients, in high-risk FISH and TP53 abnormalities. AD were more common in female, in advance stage disease and in patients with 11q. No associations were found between specific treatments. The estimated median time to SC and MI development were 20 and 21 years, respectively; while it was not reached for AD. After 20 years from the diagnosis SC, MI and AD occurred in 48%, 42% and 29% of patients, respectively. *Kaplan-Meyer analysis* showed that patients who developed a MI had the worst prognosis whereas those with AD had the best; in fact medians overall survival were 14.14 and 17.16 years form MI and SC groups, while it was not reached for AD and all others patients not included in the three groups. These data were confirmed in multivariate analyses; MI and SC have a negative impact on the overall survival among with TP53 abnormalities and IGHV mutations (HR 2.04, 1.50, 2.25 and 3.70, respectively).

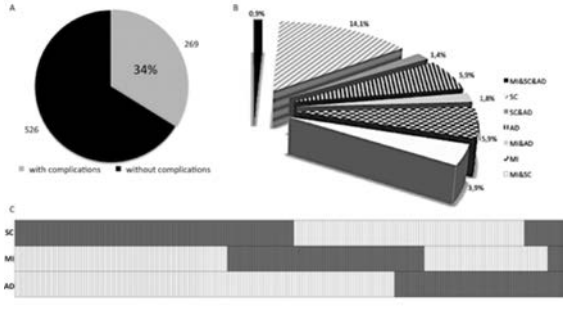

Figure 1.

Summary/Conclusions: We herein provide evidence for the existence of clinical subsets with different predispositions to develop major infections or secondary cancers or autoimmune diseases, with significant impact of the survival of CLL patients.

E1065

HYPOGAMMAGLOBULINEMIA IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICOBIOLOGICAL ASSOCIATIONS

[1]Department of Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala University, Uppsala, Sweden, [2]Hematology Department and HCT Unit, G. Papanicolaou Hospital, [3]Institute of Applied Biosciences, CERTH, Thessaloniki, [4]Hematology Department, General Hospital of Serres, Serres, [5]Department of Hematology, Papageorgiou Hospital, Thessaloniki, [6]Department of Hematology, Democritus University of Thrace, Alexandroupolis, [7]Department of Hematology, Aristotle University of Thessaloniki, "AHEPA" Hospital, Thessaloniki, [8]Hematology Department, Nikea General Hospital, Piraeus, Greece

Background: A frequent feature of chronic lymphocytic leukemia (CLL) is progressive hypogammaglobulinemia that can affect one or more immunoglobulin (IG) subclasses.
Aims: To report the incidence of hypogammaglobulinemia in a large series of patients with CLL and explore associations with various clinical and biological markers.
Methods: Study group included 502 CLL patients with the following characteristics: median age: 65 years; males/females: 326/176; Binet stage A: 330/417 (79%), unmutated IGHV genes (U-CLL): 177/502 cases (35.2%); CD38 expression: 68/390 cases (17.4%); clonotypic IG of the MD or G isotype: 295 (78%) and 53 (14%) cases, respectively; isolated del(13q): 73/208 (35%); trisomy 12: 21/207 (10.1%); del(11q): 21/210 (10%); del(17p): 13/216 (6%); *NOTCH1* del7544-45/p.P2514Rfs*4: 12/259 (4.6%).Within our cohort, we identified cases belonging to one of three different, major subsets with stereotyped B-cell receptor IG (BcR IG), namely: (1) subset #1 (clan I IGHV genes/IGKV1(D)-39): U-CLL, clinically aggressive, n=12; (2) subset #2 (IGHV3-21/IGLV3-21), mixed IGHV mutational status, noted clinical aggressiveness, n=6; and, (3) subset #4, mutated IGHV4-34/IGKV2-30 BcR IG, clinically indolent, n=14.
Results: At diagnosis, decreased IG serum levels in at least one subclass were identified in 283/502 patients (56.3%), as follows: (i) decreased IgM, 224/502 cases (44.6%); (ii) decreased IgG, 105/502 cases (21%); (iii) decreased IgA, 131/502 cases (26%). In 54/502 cases (10.7%), all serum IG subclasses were decreased. Among cases with hypogammaglobulinemia, 114 (40.2%) and 31 (11%) exhibited isolated IgM and IgA subclass deficiency, respectively; isolated IgG decrease, was relatively rare (13 cases, 4.6%). Isolated IgA deficiency was significantly ($p<0.05$) more frequent amongst females, patients with advanced clinical stage (Binet B/C, Rai III/IV) and those with *NOTCH1* mutations ($p=0.01$) compared to isolated IgM deficiency. Notably, all stereotyped subset #2 cases showed low levels of at least one serum subclass, while in 2/6 such cases, all three IG subclasses (IgA, IgM, IgG) were affected. No statistically significant differences were identified between patients with normal serum IG levels *versus* those with hypogammaglobulinemia regarding age, gender, disease burden at diagnosis, IGHV gene mutational status, CD38 expression, cytogenetic aberrations, *NOTCH1* mutations and the incidence of a second malignancy. With a median follow up of 5 years, 192/413 cases [46.5%] received treatment. Patients with hypogammaglobulinemia exhibited increased need for treatment compared to those with normal serum IGs (124/234 *vs* 68/179 respectively, $p=0.002$). IgG and IgA deficiency were correlated with shorter time-to-first-treatment (TTFT) while none of the decreased IG subclasses impacted on overall survival (OS). In multivariate analysis for TTFT, IgG and IgA deficiency did not retain independent significance, with advanced clinical stage, U-CLL, del(11q) and del(17p) remaining as independent adverse factors.
Summary/Conclusions: In conclusion, abnormalities of serum IGs at diagnosis are detected in CLL patients with heterogeneous clinicobiological profiles, including different disease burden at diagnosis, cytogenetic aberrations and IGHV gene mutational status. However, certain observations reported herein, in particular the high incidence of hypogammaglobulinemia in subset #2 and the association of *NOTCH1* mutations with IgA subclass deficiency, open novel possibilities for unraveling the implicated pathophysiological mechanisms.

E1066

THE ASSOCIATION OF DYSLIPIDEMIA WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A POPULATION-BASED STUDY

L Mozessohn[1,*], C Earle[2], D Spaner[1], S Cheng[2], M Kumar[2], R Buckstein[1]
[1]Sunnybrook Odette Cancer Centre, [2]Institute for Clinical Evaluative Sciences, Toronto, Canada

Background: Metabolic syndrome (MetS) is a risk factor for the development of cancer. In addition, pre-clinical data suggest that chronic lymphocytic leukemia (CLL) cells are dependent on adipocytes and fatty acids for growth and that aberrant lipid metabolism is an important pathogenic mechanism in CLL.
Aims: Our objective was to determine whether patients with CLL have a higher incidence of MetS prior to their CLL diagnosis compared to those without CLL and to determine the impact of lipid-lowering medications on survival.
Methods: We conducted a population-based retrospective cohort study in Ontario, Canada using administrative databases of adults ≥66 years old to compare the prevalence of MetS and its components (diabetes, dyslipidemia, hypertension) before a diagnosis of CLL compared to age and sex-matched controls without CLL. Logistic regression was used to study the association between MetS and its components to CLL. The Kaplan-Meier method and Cox Regression were used to investigate survival.
Results: We identified 2124 persons with CLL and 7935 controls from January 1, 2000 to December 31, 2005 with follow-up until death or March 31, 2014. The median follow-up was 10.7 years (95% CI, 10.5 to 10.9). Overall, the mean age was 75.6 years and 42.1% were female, 20.2% had diabetes, 35.8% had hypertension, 17.6% had dyslipidemia and 28.0% received lipid-lowering medications prior to a diagnosis of CLL. In multivariable analysis, dyslipidemia (OR 1.34, 95% CI 1.17 to 1.54) and hypertension (OR 1.20, 95% CI 1.07 to 1.34) were associated with the development of CLL, whereas MetS and diabetes alone were not. On univariable survival analysis, dyslipidemia in CLL patients was associated with a significantly worse overall survival, however, not on multivariable analysis (HR 1.06, 95% CI 0.91 to 1.23). In comparison, lipid-lowering medication use at any time was associated with a significantly improved overall survival on univariable (see Figure) and multivariable analysis (HR 0.55, 95% CI 0.49 to 0.63) as was female sex (HR 0.66, 95% CI 0.59 to 0.75) and fewer comorbidities (HR 0.72, 95% CI 0.59 to 0.89). Advanced age (HR 1.08, 95%

CI 1.06 to 1.09) and diabetes (HR 1.31, 95% CI 1.14 to 1.50) were associated with a significantly worse overall survival.

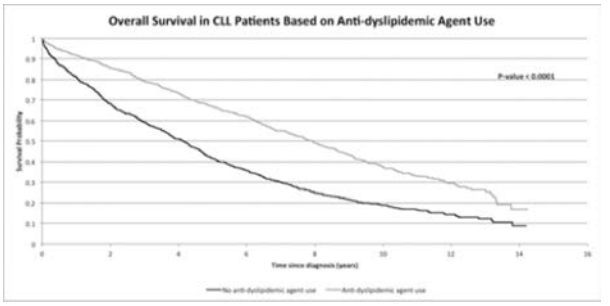

Figure 1.

Summary/Conclusions: We demonstrate an association between dyslipidemia and the development of CLL, supporting pre-clinical data. Furthermore, the relationship is independent of metabolic syndrome and diabetes. Lipid-lowering medications appear to confer a survival advantage in CLL. Prospective studies are needed to confirm these results and test their potential application to intervention strategies.

PATTERNS OF IDELALISIB TREATMENT-EMERGENT LYMPHOCYTOSIS IN PATIENTS WITH CLL OR SLL

P Ghia[1,*], BD Cheson[2], RR Furman[3], M Hallek[4], P Hillmen[5], SM O'Brien[6], JP Sharman[7], RL Dubowy[8], B Velasco[8], CC Waldapfel[8], AD Zelenetz[9], JR Brown[10]

[1]Universita' Vita-Salute San Raffaele and IRCCS Instituto Scientifico San Raffaele, Milano, Italy, [2]Georgetown University Hospital, Lombardi Comprehensive Cancer Center, Washington, DC, [3]New York-Presbyterian/Weill Cornell Medical Center, New York, NY, United States, [4]Department of Internal Medicine and Center of Integrated Oncology Cologne Bonn, University Hospital, Cologne, Germany, [5]Haematology, St. James's University Hospital, Leeds, United Kingdom, [6]University of California, Irvine/Chao Family Comprehensive Cancer Center, Orange, CA, [7]US Oncology Network/Willamette Valley Cancer Institute, Springfield, Oregon, [8]Gilead Sciences, Inc., Foster City, CA, [9]Memorial Sloan Kettering Cancer Center, New York, NY, [10]Dana-Farber Cancer Institute, Boston, United States

Background: Lymphocytosis is a known effect of B-cell receptor (BCR) targeted therapies used to treat CLL and SLL, including idelalisib (IDELA). IDELA is a selective oral PI3Kδ inhibitor which inhibits multiple signaling pathways, including those downstream of the B-cell receptor, CXCR4, and CXCR5. Per updated response criteria (Hallek M, el al. *Blood*. 2012;119:5348; Cheson B, et al. J *Clin Oncol*. 2012;30:2820-2822.), drug-induced lymphocytosis alone should not interfere with the time of designation of a partial response (PR) and is not considered progressive disease (PD) in the absence of other signs or symptoms of progression.
Aims: This post hoc analysis characterized the patterns of lymphocytosis observed in patients (pts) with CLL/SLL treated with IDELA-based regimens, and evaluated the effect of lymphocytosis on safety and efficacy.
Methods: Pts from 4 studies (2 phase 1, 1 phase 2 and 1 phase 3) who received IDELA dosed at 100 or 150 mg BID were included in this analysis. Pts were grouped by disease status (treatment-naïve *vs* relapsed/refractory) and treatment regimen (IDELA-monotherapy *vs* IDELA in combination with chemotherapy, an anti-CD20 mAb [anti-CD20], or both. Chemotherapeutic agents included chlorambucil, bendamustine, or fludarabine. Anti-CD20 mAbs included rituximab or ofatumumab. Absolute lymphocyte counts (ALC) were measured throughout each study to calculate peak ALC, time to peak ALC, and time to 50% reduction from baseline ALC. To evaluate the effect of lymphocytosis on safety, grade ≥3 treatment-emergent adverse events (TEAEs) and TEAEs of interest (leukostasis, blood viscosity abnormalities, central nervous system hemorrhage, and disseminated intravascular coagulation) were summarized in pts with ALC >200 K/μl at any time during IDELA treatment. To evaluate the effect of lymphocytosis on efficacy, median progression-free survival (PFS) was analyzed in pts receiving IDELA monotherapy for relapsed/refractory CLL (phase 1 study) and treatment-naive CLL/SLL (phase 2 study) stratified by ALC reduction from baseline (≥50% [yes or no]).
Results: The analysis population included 352 pts (105 treatment-naïve; 247 relapsed/refractory), 63 on IDELA monotherapy and 289 on IDELA combination regimens. 68% of pts experienced a post-baseline increase in ALC, including 83% of pts on IDELA monotherapy and 50% of pts on combinations. Time to peak was 2-4 weeks across groups. 73% of pts achieved a 50% reduction from baseline ALC, including 33% of pts on IDELA monotherapy and 82% of pts on combinations. Median time to 50% reduction from baseline ALC was longest for pts with relapsed/refractory CLL/SLL on IDELA monotherapy (15 wks) and shortest for pts with relapsed/refractory CLL on IDELA+chemotherapy+anti-CD20 (2 wks). The safety analysis included 31/352 pts (9%) with ALC >200 K/μl at any time on IDELA treatment, with a maximum reported ALC of 447 K/μl. Of these 31 pts, Grade 3/4 TEAEs were reported in 8 (26%) during the time when ALC >200 K/μl. No pt with signs or symptoms of hyperleukocytosis was identified. The efficacy analysis included 63 pts (41 treatment-naïve; 22 relapsed/refractory) on IDELA-monotherapy. The median PFS was similar for pts with or without a ≥50% reduction from baseline ALC (Table).

Table 1. PFS by achievement of ≥50% reduction from baseline ALC.

	≥50% reduction from Baseline ALC	<50% reduction from Baseline ALC	Log-rank P value
Treatment-naive CLL/SLL on IDELA-monotherapy (n=41)			
n (%)	17 (41)	24 (59)	
Median PFS (95% CI), mo	NR (8.3, NR)	NR (11.8, NR)	0.6326
Relapsed/refractory CLL/SLL on IDELA-monotherapy (n=22)			
n (%)	4 (18)	18 (82)	
Median PFS (95% CI), mo	9.7 (5.0, NR)	9.1 (2.6, NR)	0.9119

Summary/Conclusions: Addition of anti-CD20 and/or chemotherapy to IDELA abrogated the transient lymphocytosis seen with IDELA-monotherapy, regardless of disease status. Consistent with the updated response criteria, lymphocytosis does not appear to impact the efficacy of IDELA in this pt population. Lymphocytosis also did not predispose pts to severe or unexpected AEs.

E1068

RESULTS OF PROSPECTIVE OBSERVATIONAL TRIAL OF POLISH ADULT LEUKEMIA GROUP (PALG) ON IBRUTINIB COMPASSIONATE USE IN RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL) IN POLAND

Background: Ibrutinib is a selective and covalent inhibitor of Bruton's tyrosine kinase approved for chronic lymphocytic leukemia (CLL). Outcome and burden of adverse events of specific therapy reported in clinical trials may differ from routine clinical practice due to selection bias and different monitoring.
Aims: The aim of this observational study of Polish Adult Leukemia Study Group (PALG) was to prospectively assess the efficacy and toxicity of ibrutinib monotherapy in relapsed/refractory CLL patients treated within the ibrutinib compassionate use named patient program (NPP) in Poland.
Methods: Patients were eligible for ibrutinib compassionate use NPP if they met all following criteria a) relapsed or refractory CLL, b) active CLL/SLL requiring treatment, c) a minimum of 1 prior line of chemotherapy. Data on treatment outcome and complications were anonymously collected using electronic CRFs.
Results: This report is based on data obtained for 163 patients (158 with CLL and 5 with SLL) treated in 15 hematology centers participating in the observational study of PALG. There were 91 male and 72 female patients with median age 63 (range 40-84). Fifty-two patients (32.5%) had advanced disease (III or IV Rai stage) at diagnosis. Median number of chemotherapy lines prior to ibrutinib was 3 (range 1-10). FISH cytogenetics at inclusion to NPP was conducted in 96 (60%) patients, and it revealed del17p in 30 patients (19%). The median follow-up time was 9.2 months (range 0.4-22.2 months). Overall response rate (complete remissions, partial remissions or partial remissions with lymphocytosis) was 73%. Median progression free survival and overall survival (OS) had

not been reached with 24 deaths recorded during the time of observation. The estimated probability of 12-months OS was 0.83 (95%CI: 0.75-0.88) that appears inferior to 0.90 reported in RESONATE clinical trial (Byrd et al, NEJM 2014). Among parameters analyzed as potential prognostic factors, the advanced clinical stage (Rai III and IV) was associated with inferior OS, with estimated 12-months survival of 0.72 (95%CI: 0.577-0.826) (Fig 1A). Interestingly, no negative influence of del17p regarding OS was detected (Fig 1B). Regarding ibrutinib toxicity grade 3 or 4 side effects occurred in 43 patients (27%). Infections of any grade were diagnosed in 57 patients (36%), while atrial fibrillation of any grade was seen in 14 patients (8.8%). Thirty-three patients (20.2%) required ibrutinib dose reductions, mainly due to infections or hematological toxicity. Interestingly, in RESONATE trial with similar follow up time (median 9.4 months) ibrutinib dose reduction was reported only for 4% of patients.

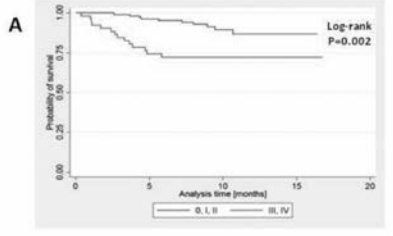

Figure 1. The Kaplan-Meyer plot for the estimated probability of 12-months survival.
A. The advanced clinical stages (Rai III and IV; red line) was associated with inferior estimated 12-month survival (compared to early clinical stages (Rai 0, I and II; blue line; 0.86).
B. No significant difference between patients with revealed del17p (blue line), patients without del17p (red line) and those without performed FISH analysis (green line).

Figure 1.

Summary/Conclusions: This large analysis of refractory/relapsed CLL patients treated with ibrutinib monotherapy in real-world clinical practice shows satisfactory treatment results, however, patients' outcome appears inferior as compared to that observed in the clinical trial. This difference could be partially due to relatively frequent ibrutinib dose reductions and treatment interruptions observed in this patient cohort. Furthermore, our report confirms efficacy of ibrutinib in relapsed/refractory CLL patients with del17p, but also shows that advanced CLL stage at diagnosis retains its prognostic value.

E1069

SF3B1 MUTATIONS, IGHV MUTATION STATUS AND ABNORMALITIES DETECTED BY GENOMIC ARRAYS DETERMINE PROGNOSIS IN CLL WITH NORMAL KARYOTYPE

C Vetro[1,2,*], S Jeromin[2], A Stengel[2], T Haferlach[2], W Kern[2], C Haferlach[2]
[1]University of Catania, Division of Haematology, Catania, Italy, [2]MLL, Munich Leukemia Laboratory, Munich, Germany

Background: Normal karyotype (NK) CLL accounts for 15-20% of all CLL cases and confers *per se* an intermediate risk. Our group reported a higher *SF3B1* mutation (mut) rate compared to other cytogenetic subgroups and only one third of patients showed unmutated *IGHV* status (*IGHV*u). Furthermore, we previously demonstrated that array-based comparative genomic hybridization (aCGH) technology could detect cryptic abnormalities in 19% of NK CLL.
Aims: To further characterize CLL with normal karyotype and identify prognostic parameters.
Methods: We selected 164 patients with NK and CLL cells percentage >15% (16% of total CLL cohort). Chromosome banding analysis yielded normal karyotypes. FISH analyses, performed with probes for 17p13 (*TP53*), 13q14 (D13S25, D13S319, *DLEU*), 11q22 (*ATM*), centromere region of chromosome 12, t(11;14)(q13;q32)(*IGH-CCND1*), 6q21 and *IGH* rearrangements, did not reveal any abnormalities. aCGH was performed with SurePrint G3 ISCA CGH+SNP Microarray (Agilent, Waldbronn, Germany). *IGHV* status, mutational analysis by DNA sequencing for *SF3B1*, *NOTCH1* and *TP53* and information on time to treatment (TTT) were available for all patients. White blood cell (WBC) count was available for 153/164 patients.

Results: Median follow-up was 5.6 years and 10-year OS was 75%. Median age was 63 years (range, 34 to 83) and 93/164 (54%) were male. Median WBC count was 36,500/mL (range, 3,300 to 463,000). Cases with CLL cells ≤5000/μL had nodal presentation. By flow cytometry, median% CLL cells was 52% (range, 16% to 94%). Cut-off for CD38 and ZAP70 positivity was 30% and 20%, respectively. 34 patients (20%) showed CD38 positivity and 61 (36%) ZAP70 positivity. By aCGH, we detected 68 copy number abnormalities (CNA) in 37 patients (22%). Majority (24/37; 65%) had 1 CNA, 9 patients (24%) showed 2 CNA and 4 (11%) more than 2 CNA. *IGHV*u was present in 52/164 (32%) cases. *SF3B1* was mutated in 26/164 (16%), *NOTCH1* in 12 (7%) and *TP53* in 7(4%). Univariate Cox analysis for TTT showed adverse impact for: WBC (HR:1.05 per 10,000/μL increase; 95%CI 1.02-1.09; p=0.001);% CLL cells (HR:1.3 per 10% increase; 95%CI 1.16-1.5; p<0.001); CD38 positivity (HR:2.7; 95%CI 1.5-5; p=0.001); ≥2 CNA (HR:3.6; 95%CI 1.6-8.1; p=0.002); *SF3B1mut* (HR:2.3; 95%CI 1.2-4.5 p=0.013); *IGHVu* (HR:4.8; 95%CI 2.6-8.7; p<0.001). Detection of any CNA, ZAP70 positivity, *TP53*mut and *NOTCH1*mut did not relate with TTT. In multivariate analysis,% CLL cells (HR:1.2 per 10% increase; 95%CI 1.04-1.4; p=0.015), ≥2 CNA (HR:2.9; 95%CI 1.2-7.012; p=0.015), *SF3B1*mut (HR:2.3; 95%CI 1.16-4.5; p=0.016) and *IGHV*u (HR:4.3; 95%CI 2.1-8.4; p<0.001) retained their prognostic value. Therefore, we clustered patients into 3 groups (figure 1; table 1). Patients without risk factors (#0) showed the best outcome (median TTT not reached); patients with 1 risk factor (#1) had a median TTT of 6.5 years; patients with at least two risk factors (#2) showed a median TTT of 6 months (p<0.001).

Table 1. Cluster groups according to prognostic factors.

Cluster	number of cases		Prognostic factors	median TTT
#0	92		no	Not reached
#1	55	15	*SF3B1*mut	6.6 yrs
		35	*IGHV*u	
		5	CNA≥2	
#2	17	9	*SF3B1*mut AND *IGHV*u	6 mo
		6	*IGHV*u AND CNA≥2	
		2	*IGHV*u AND *SF3B1*mut AND CNA≥2	

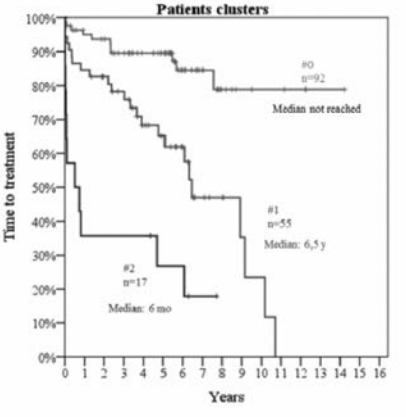

Figure 1.

Summary/Conclusions: Through the evaluation of *IGHV* mutational status, *SF3B1* and aCGH, we identified CLL patients with normal karyotype at the highest risk for need of treatment.

E1070

A SYSTEMATIC LITERATURE REVIEW OF RANDOMIZED CONTROLLED TRIALS FOR THE TREATMENT OF RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

J Thompson[1,*], M Bibby[2], A Gara[2], J Quigley[3], S Sciuto[4], R Perard[5], V Leblond[6]
[1]Epidemiology, ICON plc, Abingdon, United Kingdom, [2]Epidemiology, ICON plc, Vancouver, Canada, [3]Health Economics, ICON plc, Abingdon, [4]Gilead Sciences, UK Ltd., [5]Gilead Sciences, Europe Ltd., Uxbridge, United Kingdom, [6]Hematology, Hôpital Pitié-Salpêtrière, Paris, France

Background: Treatment of Chronic Lymphocytic Leukemia (CLL) by chemotherapy is not curative, and patients receive multiple chemotherapy lines in an attempt to manage their disease along the years. Due to cumulative toxicity or resistance, treatment options following first-line therapy quickly become limited and new treatment options are needed. Idelalisib is a novel oral inhibitor of PK13K delta for the treatment of relapsed/refractory (R/R) CLL. This study reviewed randomized controlled trials (RCTs) of idelalisib and treatment options in the management of R/R CLL.
Aims: To review the efficacy and safety of idelalisib relative to other commonly used treatments for R/R CLL.
Methods: A systematic literature review was conducted to identify articles evaluating idelalisib (Id), ibrutinib (Ib), alemtuzumab (A), fludarabine (F), rituximab (R),

ofatumumab (O), bendamustine (B), cyclophosphamide (C), methylprednisolone (Mp), chlorambucil (Ch), lenalidomide (L), doxorubicin (D), vincristine (V), prednisone (P), CHOP, and CVP as single agents or in combination, in adult patients with R/R CLL. Searches were conducted in the following literature databases: EMBASE, MEDLINE, MEDLINE In-Process and CENTRAL. Conference abstracts from ESMO, ASCO, EHA and ASH 2012–2015 were also searched. Screening was carried out independently by two reviewers. English language RCTs reporting overall, complete or partial response, stable or progressive disease, overall survival (OS), progression-free survival (PFS) or safety were included.

Results: Of 2222 potential studies, 29 full papers were screened, eight of which were included in the final review. Nineteen conference abstracts were also included. Overall, data from 14 unique RCTs were included in the final analysis (Table 1). Three RCTs included Id; in combination with R, or O, or BR. The other 11 studies identified are outlined in table 1. Only eight studies reported baseline genetic characteristics. The included studies were heterogeneous with regards to CLL stage, cytogenetics, and prior lines of therapy; all of which are recognised as treatment modifiers. The median duration of progression-free survival (PFS) between treatment arms was available for nine studies and ranged from 5.5 months (R) to 30.6 months (FCR). Across all studies, the greatest difference in the median duration of PFS between treatment arms was 13 months (IdR *vs* R; hazard ratio= 0.15; 95% CI 0.09-0.24). The Median duration of PFS in treatment arms that contained Id ranged from 16.3 months (IdO) to 23.1 months (IdBR). Median OS was reported in 11 studies and ranged from 16.7 months (O) to not reached.

Summary/Conclusions: This systematic literature review suggests that idelalisib (in combination with BR, O and R) is an acceptable alternative treatment compared to interventions currently used in clinical practice for R/R CLL patients.

E1071

PREVALENCE OF AGE-RELATED CLONAL HEMATOPOIESIS (ARCH) AND LOW FREQUENCY MUTATIONS IN CLL & MONOCLONAL B LYMPHOCYTOSIS: A MAYO CLINIC EXOME SEQUENCING COHORT STUDY

JM Foran[1,*], YW Asmann[2], SJ Achenbach[3], KG Chaffee[3], DR O'Brien[3], TG Call[4], NE Kay[4], JR Cerhan[3], TD Shanafelt[4], SL Slager[3]
[1]Division of Hematology & Medical Oncology, Mayo Clinic Cancer Center, [2]Health Sciences Research, Mayo Clinic Florida, Jacksonville, [3]Health Sciences Research, [4]Division of Hematology, Mayo Clinic, Rochester, United States

Background: ARCH refers to somatically acquired single-nucleotide variants (SNV's) and small indels in DNA involving hematologic (and non-hematologic) genes (most commonly *DNMT3A, TET2, ASXL1 & PPM1D*) detected by whole-exome sequencing (WES) in peripheral blood in unaffected individuals. The incidence of ARCH increases with age and is asociated with an 11-fold increase in the risk of hematologic malignancy including leukemia. However, the contribution of ARCH to the development of CLL, the hematologic malignancy with highest prevalence, is unknown. Furthermore, the frequency and clinical impact of ARCH-associated and other non-ARCH low frequency mutations is unknown in CLL. We therefore sought to understand the contibution and frequency of ARCH and other low frequency mutations in a cohort of patients with CLL and monoclonal B-lymphocytosis (MBL, an established precursor state with increased risk of CLL development) who have undergone WES.

Aims: To determine the prevalence of ARCH and non-ARCH low frequency mutations and their association with clinical risk factors in a cohort of unaffected (UA) and affected individuals with CLL & MBL using peripheral blood WES.

Methods: Bioinformatic analysis was performed using raw data (BAM and FASTQ files) from WES performed in a cohort of 445 patients, comprised of CLL (n=160), MBL (n=73), and unaffected individuals (UA, n=212). Samples were prepared using the Agilent V2 Exome Capture Kit, and in some cases prepared using the Agilent V4 Exome Capture Kit. WES alignment was performed with Novoalign within GGPS and recalibrated and realigned with GATK. Pileup files were obtained from the recalibrated and realigned BAM files, and identification of clonal and sub-clonal variants performed using DV-Boosting method and Q value of 0.05 as cut off. Consistent with previous evaluation of ARCH, "non-functional" variants were filtered out (synonymous, UTR, intron, etc.). In addition, variants with an Alternative Allele Frequeny (AAF) ≥0.05 in European or Caucasian populations of HapMap, 1000G, and ESP6500 were filtered out as "polymorphisms" and not included as mutations. Remaining variants were categorized as "disruptive" and "non-synonymous" (NS) variants in accordance with previous publications. Disruptive SNV's included those with Start/Stop codon and at splice sites. Because of the inclusion of "affected" individuals in this analysis who may have subclinical clonal disease variants, we defined the "non-inherited" variants more conservatively as those with<40% of the AAF.

Results: The frequency of detectable mutations is noted in Figure. In almost all cases the AAF was ≤10%. Based on previous population-based studies, we anticipated a rate of disruptive (Disrupt) and NS ARCH mutations for the cohort of 445 patients (noted in Table). We did not detect ARCH mutations in any CLL or UA patient, and in total detected *DNMT3A* and *ASXL1* mutations each in 2 MBL patients. We detected non-ARCH low AAF disruptive somatic mutations in other genes in 12 CLL and 11 MBL patients, respectively, including in 4 Tier 1 cancer genes (*JAK2, FGFR3, MLH1 & STK11*) occurring in 3 patients each with CLL and MBL. No mutations were detected in UA population in this analysis. To determine if low AAF mutations were associated with any unique CLL clinical characteristics, we compared frequencies among the subset of CLL patients. Among those with available Rai stage, CLL patients with a detectable low AAF mutation appeared to be more likely to have advanced (stage III/IV) disease at diagnosis (25%) compared with those without a mutations (2.3%) (p=0.03), but there was no difference in early stage disease (Stage 0: 75% *vs* 67.7%; and Stage I/II: 0% *vs* 31.1%, respectively) (p=0.13). There was no difference in age at diagnosis or gender.

Table 1.

	Anticipated Mutations		Observed Mutations					
Gene			CLL		MBL		UA	
	Disrupt	NS	Disrupt	NS	Disrupt	NS	Disrupt	NS
DNMT3A	1	2	0	4	2	8	0	9
TET2	0.8	0	0	12	0	10	0	9
ASXL1	0.6	0	0	12	2	3	0	15
PPM1D	0.4	0	0	0	0	0	0	0

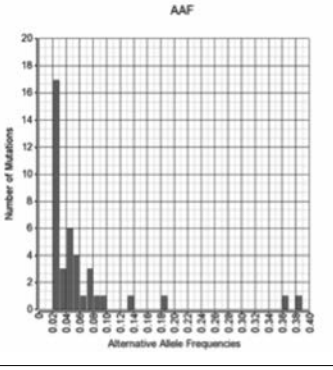

Figure 1.

Summary/Conclusions: ARCH appears to be a very infrequent event in CLL, and therefore is unlikely to constitute a major risk factor for CLL development. Low AAF non-ARCH mutations are detectable in some patients with CLL (7.5% in this analysis), including in some Tier 1 cancer genes, and may be associated with advanced stage disease at diagnosis, although this is based on a limited number of observations and will require prospective confirmation. These results suggest an important role for Deep Sequencing in advanced CLL focusing on Tier 1 cancer genes.

E1072

PERFORMANCE STATUS AND COMORBIDITY AFFECT SURVIVAL IN ELDERLY PATIENTS WITH CLL AFTER LOW DOSE ALEMTUZUMAB COMBINED WITH CHEMOTHERAPY: RESULTS FROM THE HOVON68 TRIAL

F Vojdeman[1,*], M van't Veer[2], G Tjønnfjord[3], M Itälä-Remes[4], E Kimby[5], A Polliack[6], KL Wu[7], J Doorduijn[8], W Alemayehu[9], S Wittebol[10], T Kozak[11], J Walewski[12], M Abrahamse-Testroote[9], M van Oers[13], C Geisler[1]

Background: In CLL, chemo-immunotherapy is the standard of care. Until recently fludarabine and cyclophosphamide (FC) has been considered the chemotherapy of choice in fit patients irrespective of age. However, ageing results in a decline in organ function and immune competence resulting in higher susceptibility to the toxicity of chemotherapy, while FC+Rituximab resulted in more infections when compared to Bendamustine+Rituximab, also in the elderly (Eichhorst et al. 2014). Furthermore, in the HOVON68 CLL trial, patients above 65 years of age had no survival benefit from the addition of low-dose alemtuzumab to FC in contrast to younger patients (Geisler et al. 2014).
Aims: Here we address the issue of why elderly patients with CLL did not benefit from the addition of low-dose alemtuzumab to FC, using a 5 year update of the HOVON68 trial.
Methods: 272 patients from the HOVON68 trial were included in this study. All data were collected from the HOVON database, updated as of February 2015, to reach a median follow-up period of 61 months. Baseline characteristics, causes of death, comorbidities, organ related adverse events, infections, and lymphocyte counts during treatment and the follow-up period were extracted as variables. The statistical analyses included survival- and competing risk analysis using univariate and multivariate cox regression performed in STATA version 13.1. P-values were two-sided and considered as statistically significant if below 0.05.

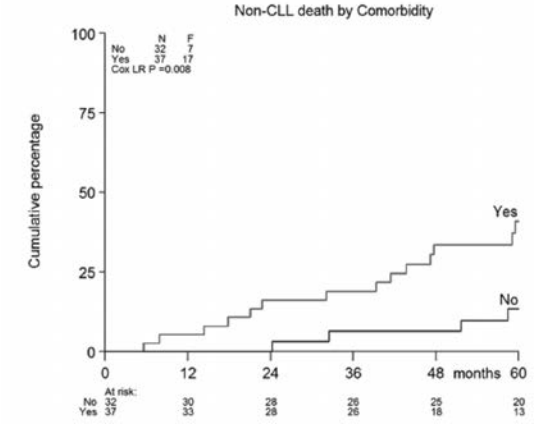

Figure 1.

Results: The addition of alemtuzumab to FC (FCA) improved overall survival from a median of 77 months to median not yet reached (log rank P=0.049) in the 5 year update of the HOVON68 trial. In addition, we confirmed that elderly patients aged 65 to 75 of age had no improvement in OS (p=0.38). Overall 40% (110/272) of patients died in the follow-up period. Excluding deaths related to allogeneic transplant (n=10), 44% (44/100) died from CLL-related causes. The elderly patients who received FCA had close to a significantly higher non-CLL related death rate compared to all others (p=0.05). Infections accounted for almost half (46.4%) of all non-CLL related causes of death. However, among FCA treated patients, non-CLL related deaths in the elderly were primarily due to secondary cancer or cardiovascular disease (10/14, 71%). At trial entry, most of the comorbidity in the elderly was cardiovascular (23/37, 62%) including hypertension, atrial fibrillation, history of transient cerebral ischemia, or ischemic heart disease. The comorbidities were balanced between the treatment arms.
In the elderly, performance status (PS)>0, del(17p), β2microglobulin≥3.5mg/dL, opportunistic infection, and comorbidity>0 (Figure 1) were significantly associated with non-CLL related mortality by univariate Cox regression using competing risk analysis. By multivariate analysis of factors found to be significant on univariate analysis, only PS>0 (HR 5.25 [1.88-14.63], p=0.002), del(17p) (HR 4.47 [1.35-14.81], p=0.014), and comorbidity (HR 5.4 [1.66-15.33], p=0.004) remained independently significant. No interactions were found between the three significant variables with treatment arm, or between PS and comorbidity.
Summary/Conclusions: FCA induced more non-CLL and non-infection related deaths in elderly patients compared to younger patients with biological high risk CLL in the HOVON68 trial. Both PS and comorbidity had a significant impact on non-CLL related mortality in the elderly after treatment with FC or FCA.

E1073

OUR APPROACH TO HAIRY CELL LEUKEMIA (HCL): 31 YEARS OF EXPERIENCE

P Ataca Atilla*, E Atilla, S Civriz Bozdag, M Kurt Yuksel, S Kocak Toprak, P Topcuoglu, O Arslan, M Ozcan, H Akan, M Beksac, O Ilhan, G Gurman
Ankara University School of Medicine Department of Hematology, Ankara, Turkey

Background: HCL is a rare chronic lymphoid malignancy generates from mature B cells. The frequency is 2% in all leukemia and diagnosed mostly in middle ages. Patients response to purine analogues treatment.
Aims: In this study our aim is to present our HCL patients with demographic features, treatment modalities and responses.
Methods: 38 HCL patients who were diagnosed and treated at Ankara University Department of Hematology between 1984 and 2015 were retrospectively evaluated. Ki-square test and student t test were used in comparison. P<0.05 was considered statistically significant.
Results: Median age of patients were 38 (range, 31-79). 29 of patients (76%) were male. The average leucocyte, hemoglobin, platelet, lactate dehydrogenase (LDH) levels and the spleen size at diagnosis were as follows: 5,1 x 10^9/L (range, 1,5-20), 12,4 g/dl (range, 9-17,5), 118x10^9/L (range,15-300), 179 IU (range,107-394), 155 mm (range,110-290). BRAF mutation could be evaluated in one patient and revealed as positive. 8 patients (21%) underwent splenectomy prior to chemotherapy. All patients received cladribine (0.1mg/kg, 7 days) as a first line treatment; 8 patients (21%) had two courses for remission. 11 patients (30%) had treatment related febrile neutropenia, 2 patients (0.05%) had transient skin rash after infusion. 7 patients (18%) had a relapse and 1 patients received pentostatin (4mg/m^2, 1 dose every 2 weeks, 6 months), 6 patients were retreated with the first line treatment and achieved complete response. The overall survival was 67 months, respectively. Leucocyte, hemoglobin, platelet levels were lower, LDH levels were higher and spleen size was increased in patients with relapse however no statistical difference were detected.The patients with splenectomy had improved survival compared to patients without splenectomy (107 *vs* 292 months, P=0.04) (Figure).

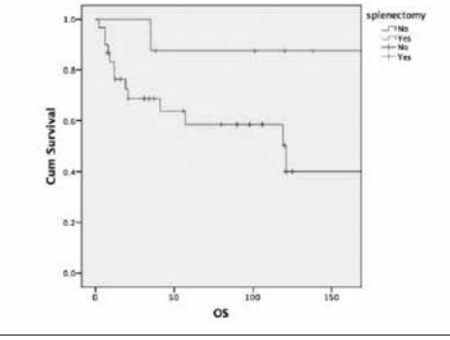

Figure 1. Splenectomy had increased overall survival.

Summary/Conclusions: We detected 18% relapse rate in our series and all patients were followed in remisson after second line purine analogue treatment. Splenectomy has improved overall survival and possibly still has a role to play in HCL therapy. Generally, HCL is a chronic disease with a favorable prognosis.

E1074

ARRAY COMPARATIVE GENOMIC HYBRIDIZATION HAS PROGNOSTIC VALUE IN CHRONIC LYMPHOCYTIC LEUKEMIA BEYOND STANDARD FLUORESCENCE IN SITU HYBRIDIZATION

B Beaton[1,*], J Howard-Reeves[2], D Brazma[2], K Mokretar[2], T Boneva[2], C Hockings[3], F Sillito[1], E Phillips[4], L Blake[5], C Grace[2], K Cwynarski[1], EP Nacheva[2]
[1]Hematology, Royal Free NHS Foundation Trust, [2]OncoCytogenetics Laboratory, Health Services Laboratories LLP Royal Free London site, [3]Hematology, Barnet and Chase Farm NHS Hospitals Trust, [4]Hematology, The Whittington Hospital NHS Trust, [5]Hematology, North Middlesex University Hospital NHS Trust, London, United Kingdom

Background: Chronic lymphocytic leukemia (CLL) has significant clinical heterogeneity. Fluorescence in situ hybridization (FISH) is an integral component

of current risk stratification models, with poor prognosis associated with deletions of 11q and 17p and good prognosis with deletions at 13q. In addition to identification of clinically significant clonal aberrations by FISH, array comparative genomic hybridization (aCGH) offers a high resolution assessment of genetic imbalance.
Aims: To demonstrate prognostically significant features using aCGH beyond that shown by FISH alone.
Methods: Consent for genomic investigation on excess material was given by 91 patients (67 diagnostic, 19 post-treatment, 5 relapse) from 5 referral centres. Diagnosis was confirmed by standard morphology, immunophenotype and FISH and/or karyotype. FISH was performed using commercial probes (Abbott Molecular, UK and Cytocell, UK). aCGH was performed on DNA extracted from either peripheral blood, bone marrow aspirate, stored frozen cells or post-culture fixed chromosome preparations using a standard 8 x 60K Agilent array platform (SurePrint G3 Human CGH Microarray Kit, G4450A). Additional FISH analysis was performed to address questions raised by the microarray results when necessary. Clinical data was collected retrospectively.
Results: Of 91 patients (males 73.4%, females 26.6%), data regarding treatment was available for 67 (73.6%). Of these, 54 (80.5%) required chemotherapy treatment. Of those treated, median time to treatment (TTT) was 34 months (range: 0-264 months). Median time from diagnosis to end of follow-up in the untreated group was 74 months (range: 30-432 months). The known prognostic markers assessed demonstrated: diagnostic lymphocyte count >30 x10^9/l (73.3%); CD38 positive (48.3%); ZAP70 positive (46.5%); IGHV unmutated (43.9%); β-2 microglobulin elevated (40%). Elevated lymphocyte count and ZAP70 positivity were statistically significant between treated and untreated groups with p values of 0.023 and 0.0043, respectively. The other markers showed trends towards a difference between treated and untreated groups, but did not have a p value<0.05. There was a strong inverse relationship (see Figure 1) between TTT and total genomic aberrations (TGA) observed in the treated group (p=0.0014). Using a cut-off of 2Mb, aCGH was able to delineate between small deletions (<2Mb) and large deletions (>2Mb) at chromosome 13q14.1. This difference cannot be delineated by standard FISH probes. Interestingly, of the untreated group, 7/13 (53.8%) had a small deletion, while 0/13 had a large deletion detected, compared with the treated group where 10/54 (18.5%) had a small deletion, while 16/54 (29.6%) had a large deletion. The difference here, where large deletions are seen in only the treated group, suggests the large deletions are associated with more aggressive disease. Another interesting observation was that by using aCGH, deletions involving Mitogen-Activated Protein Kinase Kinase 4 (MAP2K4) found at chromosome 17p, which has not yet been described in CLL, was observed in 5 patients, all in the treated group. Three of the 5 were associated with Tumor Protein P53 (TP53) found by FISH.

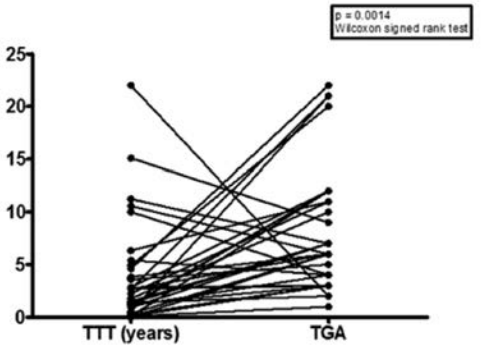

Figure 1. Relationship between Total Genomic Aberrations (TGA) and Time to Treatment (TTT).

Summary/Conclusions: The correlation between aCGH and clinical data demonstrates the utility of aCGH beyond that of standard FISH. Increased TGA is significantly associated with shorter TTT from diagnosis. Detecting the difference between a deletion of 13q14.1 involving >2Mb (large) compared with<2Mb (small) by aCGH, which cannot be differentiated by standard FISH probes, may be useful in predicting patients that will need to be treated. MAP2K4 may be an important marker in CLL in predicting patients that may need treatment, but will need further investigation.

E1075

RISK FACTORS AND PROFILE OF INFECTIONS ON IBRUTINIB THERAPY OUTSIDE CLINICAL TRIALS: A SINGLE CENTER EXPERIENCE OF 68 PATIENTS

C Protin[1,*], K Paricaud[2], F Despas[3], G Martin-Blondel[2], L Ysebaert[1]
[1]Hematology, IUC Toulouse-Oncopole, [2]Infectious diseases, CHU Purpan, [3]Pharmacology, Faculté de Médecine de Toulouse, Toulouse, France

Background: Ibrutinib is a first in class oral inhibitor of Bruton's Tyrosin Kinase, a protein critical for the B-cell receptor signaling cascade, but with significant activity also against NK, T cell, and macrophage signaling pathway downstream other receptors. High response rates in relapse/refractory chronic lymphoid leukemia (CLL), mantle cell lymphoma (MCL) and Waldenström's disease have granted ibrutinib a global market approval in these lymphomas. In the context of various clinical trials, investigators reported 24% of grade ≥3 infections, more frequently bacterial.
Aims: In this study, we aimed to assess in "real life" the profile of infections related to this targeted therapy, and identify risk factors.
Methods: Between March 01, 2014 and January 15, 2016, we included all patients starting ibrutinib (and exposed for >1 month), referred to the Toulouse University Hospital Cancer Center (IUC-Toulouse Oncopole).
Results: We enrolled 68 patients with a median age of 69.7 years, 76.5% of the patients with CLL and 23.5% with MCL. Forty-three infectious adverse events (IAE) occurred in 30/68 patients (44.1%), including 18/43 (41,9%) grade 1-2, 21/43 (48,8%) grade 3-4 and 4/43 (9,3%) grade 5. Median time to IAE onset was 2,9±1,7 months, 33/43 (76,7%) being observed the first 6 months of therapy, suggesting recovery of the normal immune system with CLL improvement. Among 43 IEA, 23 were of unknown origin (treated with wide spectrum antibiotics, most therefore of bacterial origin), and 20 IAE were documented: 13 bacterial (including 2 Campylobacter *jejunii* and 3 Pseudomonas *aeruginosa*), 5 fungal (2 invasive aspergillosis, 1 mucormycosis, 1 pneumocystosis and 1 disseminated cryptococcosis) and 2 viral (hepatitis E virus reactivations). In accordance with published results from clinical trials (Maddocks *et al.*, JAMA Oncol 2015), PFS was significantly shorter in those patients with onset of any grade IAE during the first 3 months of therapy (median PFS 8mo *vs* NR, p=0.02), or with onset of severe IAE grade ≥3 (median PFS 10mo *vs* NR, p=0.02). The baseline characteristics of the patients were well balanced between the two study groups (infected and non infected) regarding comorbidities, history of previous infections, number of previous lines of therapy (median of 3), or primary prophylaxis (cotrimoxazole+/-valaciclovir: 40% of patients with IAE *vs* 50% of patients without). There was no clinical or biological parameter before commencing ibrutinib correlated to IAE risk (median neutrophil and lymphocyte count, CD4/8 T lymphocyte count and gammaglobulin levels). However, peak lymphocytosis induced by ibrutinib at month 1 and 2 was correlated to IAE risk (median 126843/ml *vs* 69409/ml after 1 month, 100238/ml *vs* 63485/ml after 2 months, Mann-Whitney test p<0,05 for both).
Summary/Conclusions: In this real-life practice series, 44% of patients have developed IAE of which 50% were severe (grade ≥3) including 13% fungal infection. As compared to clinical trials, we confirmed the significant correlation of early-onset IAE with PFS, and that IEA risk decreases with time (even after 3 months), without disappearing over time (10% IAE occuring >6 months). Interestingly, and consistent with an improvement of normal immune responses linked to the desinfiltration of lymph nodes/spleen/bone marrow, ibrutinib-induced lymphocytosis was associated with a lower incidence of infection.

E1076

IMPACT OF ANTI-CD20 ANTIBODIES ON THE INCIDENCE OF SECONDARY CANCERS IN PATIENTS TREATED FOR CHRONIC LYMPHOCYTIC LEUKEMIA

S Guidez[1,*], H Demarquette[2], M Nudel[2], C Le Grand[2], C Herbaux[2], T Facon[2], B Cazin[2], F Morschhauser[2]
[1]Hématologie et thérapies cellulaires, CHU de Poitiers, POITIERS, [2]Service des maladies du sang, CHRU de Lille, LILLE, France

Background: An increased incidence of second primary malignancies (SPM) is described in chronic lymphocytic leukemia (CLL). Current hypothesis to explain this phenomenon mainly relies on immunosuppression conferred by both CLL itself and CLL treatment. The imputability of fludarabine has been long recognized but the risk associated with monoclonal antibodies, especially rituximab recently shown to improve overall survival in CLL when combined with fludarabine and cyclophosphamide (FC), remains unknown.
Aims: The objective of this study was to investigate the impact of anti-CD20 antibodies on the incidence of secondary cancers in patiens treated for chronic lymphocytic leukemia.
Methods: We conducted a retrospective study of the incidence of secondary cancers in 1255 CLL patients diagnosed since 1980 in the University Hospital of Lille to better characterize the possible risk of SPM associated with rituximab.
Results: Of 1255 patients, 651 (52%) received therapy including rituximab (38%), FC (26.7%), F alone (22.4%), chlorambucil (27.5%), alemtuzumab (15.5%) and bendamustine (9.3%). Rituximab was given either in combination with FC (27.5%), other chemotherapy (2.6%) or as a single-agent (3.5%). There was no significant difference in terms of age (58 *versus* 62 years), gender, Binet stage, cytogenetic abnormalities and number of regimen received between patients treated with or without rituximab. Median follow-up was 6 years for all patients (range 2-23), 4.8 years (range, 2-8) since initiation of therapy for patients treated without rituximab and 3.6 years (range, 0.2-11) for patients who received rituximab. Median overall survival (OS) was 18 years for patients treated with R-chemotherapy *versus* 11 years for patients treated with chemotherapy alone (p<0,001). Of 1255 patients, 21.5% were diagnosed with SPM. The incidence of SPM was 17.1% in patients who did not receive treatment compared to 10% in those treated. Among treated patients, the incidence

of SPM was significantly higher (19% v 2%) in patients who received rituximab (p<0.001). SPM incidence was increased after R-FC (24.4%), FC (10.5%) compared to other regimen (p<0,001). Most frequent SPM were skin (25%)-and urologic cancers (23%). Median onset of SPM was 5 years (range, 2-20) without rituximab and 2 years (range, 1-7) with rituximab.
Summary/Conclusions: In this large single center retrospective study, we found an earlier and significantly increased incidence of SPM, mainly skin cancers, in CLL patients treated with R-chemotherapy compared to those given chemotherapy alone. It remains to be determined whether this increased SPM incidence is a due to a direct toxicity of rituximab or merely a collateral consequence of improved OS observed after rituximab.

E1077

BACH2 AND BCL6 COOPERATIVELY FUNCTION AS TUMOUR SUPPRESSORS IN CLL

C Ciardullo[1], E Willmore[2], A Enshaei[2], P Zhou[2], V Rand[2], M Soundararajan[1], A Hall[2], C Harrison[2], J Eswaran[2,*]
[1]Applied Sciences, Northumbria University, [2]Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in adults in the Western World. Aberrant germinal center (GC) reactions could be a triggering factor in CLL, potentially contributing to its pathogenesis. The transcriptional repressors BCL6 (B-Cell CLL/Lymphoma 6) and BACH2 (BTB and CNC Homology 1, Basic Leucine Zipper Transcription Factor 2) are crucial regulators of GC B-cell fate. The double heterozygous $Bcl6^{-/+}$ $Bach2^{-/+}$ mice exhibit profound reduction in GC formation in response to T-cell dependent antigen immunization. In GC B cells, the stability of BACH2 protein is regulated by BCL6 and 30% of BACH2 DNA binding sites overlap with BCL6 binding sites. Both proteins are upregulated and interaction between BACH2 and BCL6 represses transcription of PRDM1 (PR Domain Containing 1, With ZNF Domain), a key driver of plasma cell differentiation.
Aims: The aim of the study is to determine the role of these two critical GC B-cells regulators, BCL6 and BACH2 in CLL and investigate whether there is a functional collaboration between them in CLL using a patient sample cohort comprising 102 patients.
Methods: We have analyzed 102 CLL samples using TaqMan quantitative real-time PCR (qPCR) and calculated the relative expression by the $2^{-\Delta\Delta Ct}$ method. A ROC curve was generated to identify the optimal diagnostic cut-off. The expression was then split at this cut-off and the resulting dichotomous variable was included in a survival analysis.
Results: We observed different levels of *BCL6* and *BACH2* expression throughout the CLL cases analysed. Median RQ (Relative Quantity) was 32.47 (range 4.04-153.29) for *BCL6* and 232.62 (range 16.50-1132.30) for *BACH2*. Interestingly, CLL cases expressing low levels of *BCL6* and *BACH2* mRNA had significantly shorter overall survival (OS) than high *BCL6* and *BACH2*-expressing samples. Moreover, the low expression of *BACH2* and *BCL6* specifically decreased OS of CLL patients with mutated IgV_H and 11q and 13q deletions. *BACH2* mRNA expression negatively correlates to the expression of CD38 (Pearson Correlation coefficient=-.418, p=.011), a poor prognostic factor in CLL. Finally, we identified a positive correlation between BCL6 and BACH2 expression (Pearson correlation coefficient =.335, p=.001), suggesting that these two factors could act synergistically in CLL. We also assessed the impact of *BACH2* expression in combination with other variables that are known to be relevant for CLL prognosis (age and 17p deletion) and we identified a prognostic index (PI=2.6). According to this model, patients with a PI<= 2.6 have a shorter OS compared to patients with a PI >2.6 (p=0.004).
Summary/Conclusions: Taken together, our study shows the prognostic role of BCL6 and BACH2 in CLL and the possibility of increased B cell receptor signalling due to the lack of Bcl6 and BACH2.

E1078

IMPORTANCE OF PHARMACIST CONSULTATION TO PREDICT EARLY TOXICITIES WITH IBRUTINIB AND IDELALISIB: A SURVEY FROM 119 PATIENTS TREATED IN A SINGLE INSTITUTION

C Vinson[1], E Degui[1], E Delmas[2], C Protin[2], V Pelagatti-Charrade[1], S Perriat[1], F Despas[3], G Laurent[2], L Ysebaert[2,*]
[1]Pharmacy, [2]Hematology, IUC Toulouse-Oncopole, [3]Pharmacology, Faculté de Médecine de Toulouse, Toulouse, France

Background: Ibrutinib (IB) and idelalisib (ID) have changed treatment paradigms in the management of R/R B-cell malignancies but their safety profile in the real-world setting is ill-defined.
Aims: Here, we report on the impact of drug-drug interactions (DDI) on early toxicity in a series of 119 patients (28 prospectively, 91 retrospectively evaluated) with CLL, mantle cell (MCL) and follicular lymphoma (FL), treated outside the context of clinical trials.
Methods: Consecutive IB/ID pts who initiated therapy off-protocol at Institut Universitaire du Cancer (IUC) Toulouse-Oncopole from Apr2014 to Dec2015 were included (given they had been exposed to drug at least 1mo). A medication review for potential DDI was performed by a clinical pharmacist on all files. Baseline characteristics, concomitant medications (COMED), and toxicities were recorded. Toxicity at month 1 (TOXM1) was defined by any grade 3-4, or grade 2 but leading to dose reductions due to impact on quality of life (always on patients' demand).
Results: 67 IB pts (52 CLL, 12 MCL) and 52 ID pts (39 CLL, 13 FL) were assessed (all with a median of 3 previous lines of therapy). *Ibrutinib*: median age was 68.6y, with a median number of 3.6 COMED (range 0-14, 30% with COMED>5, defining polypharmacy). Fifty-five% were taking substrates of CYP3A4/Pgp, 21% inhibitors of Pgp, 16% and 25% inhibitors of CYP2D6 and 3A4, respectively. No dose reduction was allowed at the initiation of therapy. TOXM1 was reported in 22/67 pts (32.8%), with only 5/22 grade 3-4 toxicities, and 17/22 grade 2 impacting QoL (mostly cramps, diarrhea, dyspepsia, rash). TOXM1 was not correlated to type of lymphoma, previous therapies, gender, age, COMED>5, but correlated statistically to Pgp inhibitors (52.4% *vs* 23.9%, p=0.02) or CYP3A4 inhibitors (57% *vs* 26.4%, p=0.03) concomitant drug intake, as could be expected from pharmacokinetics profile of ibrutinib. PFS was not impacted by dose reduction. *Idelalisib*: median age was 74y, with a median number of 4.2 COMED (range 0-12, 41% with COMED>5). Sixty-five% were taking substrates of CYP3A4/Pgp, 36% inhibitors of Pgp, 0% and 25% inhibitors of CYP2D6 and 3A4, respectively. TOXM1 was reported in 15/52 pts (28.8%), but due exclusively to grade 3-4 events: neutropenia (23%), mucositis (4%), diarrhea/transaminitis (2% each). TOXM1 was not correlated to type of lymphoma, age, number or type of COMED, but to female gender (50% *vs* 14%, p=0.01). Aldehyde oxydase activity (the main pathway of ID metabolism) is poorly defined in humans, but reduced in female rats. When looking at the first 3 mo of ID therapy, women had an increased frequency of neutropenic (39% *vs* 14.44%) and diarrhea (16.7% *vs* 2.9%) events of any grade, but less transaminitis events(5.5% *vs* 9%), as compared to men. TOXM1 led to dose reductions after a month of ID in 44.5% and 11.2% of female/male pts, respectively (impacting PFS). At 6mo follow-up, 38.5% of patients were still on therapy (most discontinuations due to grade 3-4 AE).
Summary/Conclusions: DDI were found to impact early toxicities with IB but not with ID, emphasizing the urgent need of better PK/toxicity evaluation for both drugs in real-life practice. Such prospective evaluation is just starting in our institution (protocol PK-E3i) to better monitor plasma levels (and adequately adapt drug dosage), and better support patients' compliance in the long-term.

E1079

IBRUTINIB FOR CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): IMPACT OF THE YOU&I™ PATIENT SUPPORT PROGRAM ON TREATMENT ADHERENCE

A Peters[1,*], J Wiernikowski[2], S Barker[3], M Mahler[4], S Luker[5], J Connors[6]
[1]University of Alberta, Edmonton, [2]Juravinski Hospital and Cancer Centre, Hamilton, [3]Janssen Inc., Toronto, Canada, [4]Janssen Research & Development, Raritan, [5]Human Care Systems Inc., Boston, United States, [6]BC Cancer Agency Centre for Lymphoid Cancer, Vancouver, Canada

Background: Oral therapies for cancer can present several advantages over intravenous drugs, including greater flexibility and convenience for the patient and reduced healthcare costs. However, for treatment to be effective, a high degree of adherence must be maintained. Prior studies have shown a range of non-adherence to long-term oral anticancer therapy, with adherence rates varying considerably with patient characteristics. Consequences of low adherence can include increased healthcare costs and inferior patient outcomes, including decreased time to relapse and decreased survival. The YOU&i™ Patient Support Program (PSP) supports patients with reimbursement services and provides patients and their physicians with a comprehensive nurse-coaching program in an effort to encourage treatment adherence.
Aims: To examine patient satisfaction and adherence to ibrutinib within the YOU&i™ PSP.
Methods: Using evidence-based literature reviews and global/local market research, barriers to treatment adherence were identified. These included a lack of disease/treatment education, high financial burden, negative psychosocial/motivational factors, poor medication routine-building, and suboptimal patient:physician communication. Each patient's risk for non-adherence was calculated using the Morisky Medication Adherence Scale© score and the total number of barriers identified at initial assessment, and the frequency of nurse-coaching calls was adjusted accordingly. Patients were categorized as "adherent" if they had ≥85% compliance (obtained refills within 4 days of expected refill date) and as "discontinued" if ibrutinib was not dispensed for ≥3 months, if the patient was confirmed as discontinued prior to ibrutinib not being dispensed for ≥3 months, or if the patient was confirmed as deceased. All other patients were categorized as "partially adherent". Patient questionnaires were used to gauge satisfaction with the YOU&i™ PSP.
Results: As of January 19, 2016, a total of 903 CLL patients were enrolled in the PSP; 87% of patients opted in for nurse coaching. Most patients (58%) had received 1-2 prior lines of therapy. At 9 months from treatment initiation, 81% of patients who received nurse coaching *vs* 59% of those who did not were categorized as "adherent" (excludes patients who discontinued due to disease progression or death). Similarly, only 7% of those who received nurse

coaching *vs* 23% of those who did not were discontinued from ibrutinib for reasons other than disease progression or death. In the overall PSP population, 17% discontinued the program; among the patients discontinuing, the most common reason was death (49%). Overall, 91% of patients reported that they were satisfied/very satisfied with the PSP, with 87% likely to recommend the program. Furthermore, 78% reported that the PSP was very helpful in supporting their adherence to ibrutinib.
Summary/Conclusions: Although there is an inherent potential for self-selection bias, these results from the YOU&i™ PSP suggest that nurse coaching may contribute to improved patient adherence to oral anticancer treatment. In the YOU&i™ PSP, nurse coaching appeared to also be associated with decreased treatment discontinuation. This program, or similar supportive programs, may be helpful in assisting patients in maintaining adherence to treatment with ibrutinib.

INCIDENCE OF AND RISK FACTORS FOR MAJOR HEMORRHAGE IN US VETERANS ADMINISTRATION PATIENTS WITH NEWLY DIAGNOSED CHRONIC LYMPHOCYTIC LEUKEMIA

P Georgantopolous[1,*], H Yang[2], M Cai[2], L Norris[3]
[1]The Southern Network on Adverse Reaction (SONAR) project, the South Carolina Center of Economic Excellence for Medication Safety, the South Carolina College of Pharmacy, University of South Carolina, Arnold School of Public Health, WJB Dorn VA Medical Ctr, Columbia, [2]Pharmacyclics LLC, an Abbvie Company, Sunnyvale, [3]The Southern Network on Adverse Reaction (SONAR) project, the South Carolina Center of Economic Excellence for Medication Safety, the South Carolina College of Pharmacy, University of South Carolina, Columbia, United States

Background: Patients with chronic lymphocytic leukemia (CLL) have an increased risk for major hemorrhage (MH) compared to the age- and gender-matched general population (Gifkins et al, Blood, 2015). However, the specific risk factors associated with bleeding among patients with CLL are not well established.
Aims: Our objective was to estimate the incidence of MH among patients newly diagnosed with CLL receiving care at US Veterans Administration (VA) healthcare facilities and to identify risk factors associated with MH in these patients.
Methods: Patients diagnosed with CLL from 1999 through 2013 were identified using ICD-9 codes from VA electronic medical records. Those with<6 months of VA care before CLL diagnosis were excluded from analysis to capture a newly diagnosed patient cohort. Follow-up was from initial CLL diagnosis until death, 12/31/2013, or MH onset, whichever occurred first. We defined an MH event as a diagnosis code of bleeding in a critical area or organ or bleeding that was treated with blood transfusion within 7 days. We calculated the incidence rate of MH after CLL diagnosis. Potential risk factors included demographic characteristics and selected medical history based on ICD-9 codes within 6 months before the first CLL diagnostic code. We performed univariate comparisons and a backward stepwise Cox proportional hazards regression analysis.
Results: Of the 24,581 veterans with newly diagnosed CLL, 24,166 (98.3%) were male, 20,464 (83.3%) were white; median age at diagnosis was 72.0 years; 2,013 (8.2%) experienced MH after CLL diagnosis, with a median time of 2.6 years between diagnosis and MH event. The incidence of MH was 16.4 per 1,000 person-years (95% CI, 15.7-17.1/1000). Statistically significant (P<0.05) risk factors for MH were (HR; 95% CI) history of MH (4.0; 3.4-4.7), anemia (2.6; 2.0-3.4), stroke (2.0; 1.2-3.5), male (2.0; 1.3-3.0), African American (1.7 *vs* white race; 1.5-2.0), uncontrolled hypertension (1.7; 1.3-2.2), atrial fibrillation (1.5; 1.2-1.7), CAD (1.3; 1.1-1.4), and age >75 years (1.1 *vs*<65 years; 1.0-1.3).
Summary/Conclusions: The incidence of MH in newly diagnosed CLL patients was 16.4 per 1,000 person-years. Risk factors most strongly associated with MH after CLL diagnosis are history of MH, anemia, stroke, and being male.

E1081

MALE GENDER IS ASSOCIATED WITH AN IMPAIRED OVERALL AND PROGRESSION FREE SURVIVAL IN PATIENTS WITH PROGNOSTIC LOW RISK CHRONIC LYMPHOCYTIC LEUKEMIA

C Da Cunha-Bang[1,*], C Geisler[2], L Enggaard[3], C Poulsen[4], P Brown[2], H Frederiksen[5], O Bergmann[6], E Pulczynski[7], R Schou Pedersen[8], L Nielsen[9], I Christiansen[10], C Niemann[2]
[1]Cardiology, Roskilde Hospital, Roskilde, [2]Hematology, Rigshospitalet, Copenhagen, [3]Hematology, Herlev Hospital, Herlev, [4]Hematology, Roskilde Hospital, Roskilde, [5]Hematology, Odense Hospital, Odense, [6]Hematology, Vejle Hospital, Vejle, [7]Hematology, Aarhus Hospital, Aarhus, [8]Hematology, Holstebro Hospital, Holstebro, [9]Hematology, Esbjerg Hospital, Esbjerg, [10]Hematology, Aalborg Hospital, Aalborg, Denmark

Background: Recently the new International Prognostic Index for Chronic Lymphocytic Leukemia (CLL) patients (CLL-IPI) was developed (Bahlo J, et al: The International Prognostic Index For Patients With Chronic Lymphocytic Leukaemia (CLL-IPI). ICML, Lugano, 2015). The index does not include gender as a weighted factor. However, previous analyses of Danish CLL patients indicate gender specific variations in Overall Survival (da Cunha-Bang C, et al: Improved Survival for Patients with CLL in the Era of Combination Chemoimmunotherapy - a Danish Population Based Study. Blood 126:1740-1740, 2015).
Aims: To analyze gender-specific outcome for patients following diagnosis with CLL for different CLL-IPI risk groups based on the Danish CLL-database.
Methods: All patients diagnosed with CLL in Denmark were registered and prospectively followed in the Danish National CLL database (2008-2015). The present analysis included all patients for whom all five factors included in the CLL-IPI score were registered (del(17p/TP53, IGHV mutation status, beta-2-microglobulin, Binet/Rai stage, age). Overall survival (OS), treatment free survival (TFS) and progression free survival (PFS) were calculated using Kaplan Meier and multivariate Cox regression models adjusted for relevant confounders.
Results: In total, 1541 patients were included. Analyzing the entire population, no difference in OS was found based on gender. However, analysis of the 1314 (778 (59%) male, 536 (41%) female) patients from the low and intermediate risk CLL-IPI score groups showed an impaired OS ((Hazard ratio (HR (95%CI)) for death; 1.7 (1.2-2.3) P=0.002)) for male *versus* female patients. No variation in TFS was found. However, following treatment male patients had a significantly impaired PFS (HR for progression; 3.0 (1.5-6.2) P=0.003)) *versus* female patients.
Summary/Conclusions: Male CLL patients in low and intermediate CLL-IPI risk groups have a higher risk of dying than their female counterparts. The increased risk of dying from non-CLL related causes for male patients may explain this difference, which is overruled by the increased risk of dying from CLL among high and very high CLL-IPI risk groups. Following CLL treatment the gender disadvantage is apparently accentuated. Focus on reducing pretreatment risk factors for male CLL patients may improve survival in this population. Further analyses of cause of death following treatment in male CLL patients are warranted.

U. 12 de Octubre, [8]Hematology, H. Infanta Leonor, Madrid, [9]Hematology, H. General de Castellon, Castellon, [10]Hematology, H. G. U. Gregorio Marañon, Madrid, [11]Hematology, H. U. La Fe, Valencia, [12]Inmunología Clinica, H. Clínico San Carlos, [13]Hematology, Hospital Fundacion Jimenez Diaz, [14]Traslational Medicine, Fundación MD Anderson, [15]Hematology, H. U. La Paz, Madrid, Spain

Background: Frontline Chemoimmunotherapy with Bendamustine and Rituximab (BR) in Previously Untreated and Physically Fit Patients (pts) with Advanced Chronic Lymphocytic Leukemia (CLL) has been compared against the standard Fludarabine, Cyclophosphamide, and Rituximab (FCR) and suggested as an option for elderly pts *(Eichhorst el al ASH 2014).* There is a lack of data regarding BR as CLL front line in routine clinical practice.
Aims: The aim of this study is to evaluate the toxic profile and effectiveness of BR as front line in 65 yr and above CLL patients in daily practice and to identify risk factors.
Methods: We performed the analysis of the 65yr and above patients included in the *MDA-LLC-2015-02* study, which consisted of a retrospective study CLL patients from 12 Spanish sites treated with BR as front line (B 90 mg/m2 days 1 and 2 every 28 days and R 375 mg/m2 on day 1 of the first cycle and 500 mg/m2 on day 1 of the other cycles). We evaluate effectives as IWCLL, toxicity as *CTCAE v4.0 of NCI,* overall survival *(OS)* and progression free survival *(PFS)* (Kaplan-Meier). This study has been approved by the Spanish Medicines Agency *AEMPS.*
Results: Sixty two (male 46 pt/female 16 pt) out of 85 pt included in MDA-LLC-2015-02 study were 65 or older, median age 72 (65-84). Risk factors as follows, ECOG≥2: 6 pt, high LDH: 25 pt, high β2 microglobulin: 50 pt, Binet C: 22 pt, Creatinine >1.3 mg/dL: 8 pt. Toxicity: A total of 316 cycles were administered, median 6 per patient, grade 4 neutropenia: 9pt, hospitalization do adverse events 13 pt, all febrile neutropenia. No cases of treatment related mortality. Efficacy: ORR 90.2%, with a median follow up 36 months 19 pt required second line therapy and 10 pt died, 2 because of progression. Median OS 56 months and median PFS 45 months (3 year OS 85.5%). ECOG≥2 (p0.002, p0.008) and grade 4 neutropenia (p0.017, p0.006) predict OS and PFS. High LDH, high β2 microglobulin, Binet C, Creatinine >1.3 mg/dL, trisomy 12, del11q, del13q did not predict OS neither PFS.
Summary/Conclusions: This results confirms BR as an effective (ORR 90.2% and PFS 45 months) and safe (no cases of treatment related mortality) as first lines for 65 year old and above CLL patients.

LB2252

PHASE 1 FINAL RESULTS AND PHASE 2A DOSE SELECTION FOR CERDULATINIB (PRT062070) A DUAL SYK/JAK INHIBITOR IN PATIENTS WITH RELAPSED/REFRACTORY B CELL MALIGNANCIES

P Hamlin[1,*], I Flinn[2], N Wagner-Johnston[3], J Burger[4], G Michelson, A Pandey[5], M Birrell[5], G Coffey[5], J Leeds[5], A Sabalvaro-Torres[5], Y Kim[5], J Curnutte[5], M Patel[6]
[1]Memorial Sloan Kettering Cancer Center, New York, [2]Sarah Cannon Research Institute, Nashville, [3]Johns Hopkins University, Baltimore, [4]MD Anderson Cancer Center, Houston, [5]Portola Pharmaceuticals Inc, South San Francisco, [6]Florida Cancer Specialists, Sarasota, United States

Background: Subsets of B cell lymphomas demonstrate a reliance on B-cell antigen receptor (BCR) and/or cytokine JAK/STAT signaling for survival. SYK is upstream of BTK, PI3Kδ, and PLCγ2 on the BCR pathway, making it a potential therapeutic target. Additional survival mechanisms are mediated by cytokine-induced JAK/STAT pathways, derived from the tumor or tumor infiltrating leukocytes, which leads to upregulation of BCL2 family members. In pre-clinical tumor models, cerdulatinib induces apoptosis in a genetically diverse panel of cell lines and primary B cell tumors in the 1 to 2 μM range.
Aims: The primary aim of the study was to establish the maximum tolerated dose of cerdulatinib.
Methods: This is a 3+3 dose escalation study with 28-day cycles. Once daily (QD; up to 100 mg) and twice daily (BID; up to 45 mg) dosing was evaluated. Pharmacokinetics (PK), pharmacodynamics (PD), and safety were monitored, as well as an initial assessment of efficacy. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL2, IL4, IL6, and GM-CSF. Serum markers of inflammation were also measured.
Results: 43 patients with CLL/SLL or B-cell NHL were enrolled on the completed phase 1. Median age is 67 years (range 23-85) and median prior therapies is 3 (range 1-8). Treatment related AEs ≥ grade 3 occurring in 2 or more patients with daily dosing were: fatigue (n=5), anemia and neutropenia (n=3 each), and abdominal pain, neutrophil count decrease, and pneumonia (n=2 each). A number of these events occurred in the setting of progressive disease. The highest overall exposure was achieved at the 45 mg BID dose, in which 2 DLTs occurred: grade 3 pancreatitis and grade 3 fatigue. Enrollment to this dose was discontinued, and the phase 2a dose was selected. In review of the 40-100 mg QD doses, the average SS C_{min} and C_{max} concentrations plateaued at 0.70±0.20 and 1.38±0.23 μM, respectively. QD dosing of 40-100 mg resulted in 50 to 100% (SS C_{min} to C_{max}) inhibition of SYK and JAK signaling in peripheral blood, and significant inhibition of serum markers of inflammation. The extent of inhibition of SYK and JAK signaling as well as inhibition of serum markers of inflammation significantly correlated with tumor response. While the PK is suitable for QD dosing with a $t_{1/2}$ of 12-16 hours and a 2:1 peak-trough ratio, the pH dependent low solubility of cerdulatinib limited dissolution, and physiologic modeling suggested that BID dosing would increase overall exposure. This was accomplished with the 45 mg BID dose, where complete inhibition of SYK and JAK at SS C_{min} (~1.5 μM) in peripheral blood assays was observed, consistent with an approximate doubling in exposure. Partial responses in phase 1 were observed in 5 heavily pretreated patients with CLL, FL, and transformed DLBCL at doses ranging from 30-65 mg QD. Two PRs were observed in the 45 mg BID dose group, one in a patient with FL and another with CLL. Responses typically occurred after 2 cycles of treatment. Multiple patients have demonstrated nodal reductions and maintained clinical benefit for over a year. Based on the PK/AE profile, there appeared to be higher grades of adverse events at SS C_{min} of 1.25 μM or greater. PK modeling indicated a dose of 35 mg BID would yield a SS C_{min} of 1.02 μM and a SS C_{ave} of 1.16 μM, which is predicted to be tolerable, efficacious, and achieve complete inhibition of SYK and JAK in peripheral blood. 35 mg BID was therefore selected as the phase 2a dose.
Summary/Conclusion: Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. BID dosing has overcome the previous plateau in exposure and has enhanced PD effects. A phase 2a study is now open for CLL/SLL, FL/other indolent NHL and aggressive B-cell NHL at a dose of 35 mg BID.

ABERRANT MECHANISMS OF TELOMERE MAINTENANCE IN CHRONIC MYELOID LEUKEMIA - THE POTENTIAL ROLE OF POT1

A Deregowska[1,2,*], K Pruszczyk[3], I Solarska[4], J Adamczyk[5], A Lewinska[6], M Machnicki[2,3], I Seferynska[4], M Wnuk[5], T Stoklosa[3]
[1]Department of Genetics, University of Rzeszow, Rzeszow, [2]Postgraduate School of Molecular Medicine, [3]Department of Immunology, Medical University of Warsaw, [4]Department of Hematology, Institute of Hematology and Blood Transfusion, Warsaw, [5]Deparment of Genetics, [6]Department of Biochemistry and Cell Biology, University of Rzeszow, Rzeszow, Poland

Background: As in most cancers, a reduction in the telomere length is one of the features of chronic myeloid leukaemia (CML) and telomere shortening is correlated with disease progression from the chronic phase (CML-CP) to the blastic phase (CML-BP). Targeted therapy in CML with tyrosine kinase inhibitors (TKIs), such as imatinib, gives long-lasting remission in the majority of patients. However, significant proportion of patients may develop resistance and progress to advanced phases with limited therapeutic options. Majority of studies are focused on monitoring the telomere length during the progression of the disease. However the precise role of telomere-associated proteins, including shelterin complex in *BCR/ABL1*-mediated genomic instability in CML progression and resistance to TKIs have not been fully elucidated.
Aims: The aim of our study was to determine the role of the members of the shelterin complex in aberrant telomere maintenance mechanisms in CML progression with special focus on *POT1*.
Methods: We employed human *BCR-ABL1*-positive cells (K562), and *BCR-ABL1*-negative cells (HL60), as well as CD34+ primary cells isolated from peripheral blood leukocytes of CML patients at various stages of the disease (chronic phase, chronic phase TKI-resistant and blastic phase). Blood samples were taken after informed consent. The components of telomere complex were studied at the mRNA level (RT-qPCR) and protein level (Western blotting). The activity of telomerase was measured using ELISA. The mean TRF length was measured using the TeloTAGGG telomere length assay and individual telomere length using primed in-situ labelling technique. Global DNA damage was assessed using comet assay. ROS and RNS were analysed using fluorogenic probes.
Results: Initially, we confirmed with Southern blotting that the telomere shortening was positively correlated with CML progression (CML-CP in comparison to CML-BP). However, in samples from CD34+ CML-CP TKI-resistant patients in comparison to CML-CP patients, an increase in telomere length was observed. Dynamic changes in telomere length were neither associated with expression of TERT/TERC nor with enzymatic activity of telomerase in the course of the disease. Therefore, we decided to examine the potential role of shelterin complex in telomere maintenance in disease progression looking at the expression pattern of selected members of telomeric complex. We found that the expression of *POT1* was significantly upregulated in CML-BP as compared to CML-CP (Fig.1). Moreover, expression of *POT1* was positively correlated with *BCR-ABL1* expression. To verify the hypothesis that telomeres are elongated in TKI-resistant cells, imatinib-resistant K562 cells were used. We showed that telomeres in the resistant cells were significantly longer which was associated with differential expression of shelterin complex members, including *POT1*. These findings suggest that actual telomere length in disease progression may change in biphasic mode and may include initial telomere lengthening (possibly by alternative telomere lengthening mechanisms) in TKI-resistant cells. We also found that the changes in telomere *length* in TKI-resistant cells were accompanied by the genomic changes at chromosome level and oxidative/nitrosative stress

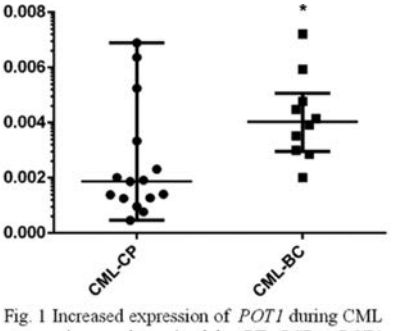

Fig. 1 Increased expression of *POT1* during CML progression as determined by RT-qPCR. *POT1* expression in samples from 15 CML-CP patients at diagnosis and 10 CML-BC patients. (*)P<0.05 (significance was tested using a non-parametric Mann-Whitney test).

Figure 1.

Summary/Conclusions: In conclusion, we postulate that abnormal expression of members of the shelterin complex, such as *POT1,* may be responsible for aberrant telomere maintenance mechanisms in CML cells and may play role in genomic instability associated with CML progression as well as the clonal selection and resistance to TKIs.

MONOCYTIC MYELOID DERIVED SUPPRESSOR CELLS (M-MDSC) AS PROGNOSTIC FACTOR IN DASATINIB TREATED PATIENTS WITH CHRONIC MYELOID LEUKEMIA

C Giallongo*, NL Parrinello, D Tibullo, P La Cava, A Romano, G Camiolo, G D'Amante, F Stagno, P Vigneri, GA Palumbo, F Di Raimondo
Division of Hematology, azienda ospedaliera universitaria policlinico vittorio emanuele, Catania, Italy

Background: Recently, we and another group demonstrated that Myeloid suppressor cells play an important role of immune escape in chronic myeloid leukemia (CML) patients.
Aims: Investigating the effect of the tyrosine kinase inhibitors (TKI) therapy on MDSC and possible correlation with clinical response.
Methods: CML patients at diagnosis (n=30) and during TKI treatment (n=43) were enrolled in this study. Eighteen patients were treated with imatinib (IM), 13 with nilotinib (NIL) and 12 with dasatinib (DAS). MDSCs were also analyzed in peripheral blood of 20 healthy donors (HD). Granulocytic MDSCs (G-MDSCs) were identified as CD11b+CD33+CD14-HLADR- cells while monocytic MDSCs (M-MDSCs) as CD14+HLADR by cytofluorimetric analysis. Their immunosuppressive activity was tested through incubation with autologous CFSE+T cells. Exosomes were isolated from CML serum at diagnosis (n=5) by sequential ultracentrifugation.
Results: G-MDSCs and M-MDSCs percentages in CML patients were greater than HD (respectively 82.5±9.6% *vs* 56.2±5.4% and 33.6±19% *vs* 5.9±4%, p<0.0001). Both isolated subpopulations showed expression of BCR/ABL and were able to inhibit T cells proliferation in comparison to positive control (from 48±7.6% to 25±5% for G-MDSC, p=0.0057 and 16.7±0.6% for M-MDSC, p<0.0001). No suppressive effect was observed in co-cultures with G-MDSC and M-MDSC obtained from HD. In addition, M-MDSC percentage correlated with BCR/ABL transcript levels in patients at diagnosis (r=0.579, p=0.0004). Evaluating the effect of TKI therapy on MDSC levels, we found that both IM, NIL and DAS induced a significant reduction of G-MDSC percentage at 6 months (from 82.5±9.6% to 55±17.3% after IM, to 60.9±9% after NIL and to 48.7±13% after DAS, p<0.0001) and 12 months (61.2±9.7% after IM, 61.4±6.7% after NIL and 33.4±14% after DAS, p<0.0001) of treatment. The levels of M-MDSCs significantly decreased only after DAS therapy (from 33.6±19% to 6.8±12.6% at 6 months, p=0.014 and 11.4±12.3% at 12 months, p=0.008). M-MDSC reduction was also present but did not reach statistical significance after IM treatment (22.2±24.5% and 22.3±21.7% respectively at 6 and 12 months) and after NIL therapy (21±19.9% and 17.4±16.3% at 6 and 12 months) with a great variability among patients. Subsequently, correlation of MDSC with clinical response to TKI therapy was investigated. We found that in DAS, but not in IM or NIL treated patients, a correlation between percentage of Major Molecular Response (MMR) and number of persistent M-MDSCs was found. A significant difference was calculated comparing M-MDSC levels in the MMR group (n=6) *versus* no MMR (n=6) at 12 months (p=0.008). To evaluate if leukemic cells are able to expand MDSC releasing soluble factors or exosomes, we incubated monocytes obtained from HD with sera or exosomes from CML patients at diagnosis or healthy subjects. M-MDSCs percentage significantly increased only in conditions with CML serum (29±13%; p=0.0006) or exosomes (8±2.8%; p=0.01). No effect was observed on G-MDSC percentage.
Summary/Conclusions: Therapy with TKI reduces the percentage of MDSCs and levels of the monocytic subset correlates with MMR value in patients treated with dasatinib, suggesting their importance in clinical investigation as prognostic factor. Moreover, our data suggest the possible development in CML patients of a circuit primed by tumor cells that, through the release of soluble factors and exosomes, are able to expand M-MDSCs, creating an immunotolerant environment that results in T cell anergy and facilitates tumor growth.

THE USE OF THE EAC PRIMERS IN DIGITAL PCR FOR MONITORING MINIMAL RESIDUAL DISEASE IN CML RESULTS IN A SHIFT BETWEEN MOLECULAR RESPONSE GROUPS.

J Maier [1], GN Franke [1], M Cross [1], K Wildenberger [1], F Giles [2], O Frank [3], A Hochhaus [4], C Dietz [5], MC Müller [6], D Niederwieser [7,*], T Lange [8]
[1]Abteilung Hämatologie, Internistische Onkologie, Universität Leipzig, Leipzig, Germany, [2]Robert H. Lurie Comprehensive Cancer Center, Chicago, IL, United States, [3]Novartis Pharma GmbH, Nürnberg, [4]Jena University Hospital, Jena, [5]Universität Heidelberg, [6]Institute for Hematology and Oncology (IHO GmbH), Mannheim, [7]Universität Leipzig, Leipzig, [8]Asklepios Klinikum Weißenfels, Weißenfels, Germany

Background: Digital PCR (dPCR) generates an absolute read out that is largely robust to variations in PCR efficiency and should reduce the requirement for standardisation by laboratory-specific conversion factors.
Aims: The aim of this study was to compare the results of dPCR to qPCR (quantitative PCR) in blinded samples from two independent laboratories with respect to the observed rates of molecular response (MR) in CML patients (pts) having undergone 18 months of nilotinib treatment in the ENEST1st trial (ClinicalTrials.gov:NCT01061177).
Methods: A total of 230 cDNA samples from CML pts with e13 or e14/a2 BCR-ABL fusion genes who were treated within the ENEST1st trial between 2012 and 2013 were analysed in Leipzig (L, n=75) or Mannheim (M, n=155) with qPCR. BCR-ABL levels were determined relative to those of ABL and standardization was achieved using plasmid DNA. Both labs are accredited by the European Treatment and Outcome Study (EUTOS) collaboration. The cDNA samples were blinded for the qPCR results and re-analysed in L with a duplex dPCR using a QX200 Droplet Digital PCR System (BIO-RAD). In line with the manufacturer's recommendations, duplicate samples yielding a minimum of 3 positive droplets from the 12-19.000 routinely analysed droplets were scored as positive. Depth of MR was scored using the EUTOS definitions used in the ENEST1st trial.
Results: A previous comparison between dPCR and qPCR showed significant differences in the distribution of the molecular response (MR) categories (p=0.02) with more residual disease (RD) measured by dPCR. In detail, significantly fewer patients achieved deep molecular responses (MR4 to MR5) by dPCR (p=0.035). Of the 230 samples analysed by the two methods, 58% (n=134) were classified in the same MR category, while 11% (n=25) skipped to classes with less RD and 31% (n=71) moved to classes with more RD by dPCR, mostly over a range of 1-2 classes. ABL copies in non-concordant samples were median 1.1 fold higher by dPCR than by qPCR, while BCR-ABL transcripts were 3 fold higher by dPCR in 56/71 samples analysed, resulting in significantly more patients having more RD by dPCR. Experimental tests of the sensitivity between 0.25 and 25 BCR-ABL copies showed a LOQ (limit of quantitation) of 3 positive droplets in duplicates (cut-off 3). Interestingly, application of the laboratory-specific qPCR conversion factor to the dPCR data (cut-off 3) independently reduced the difference in distribution categories between the qPCR and dPCR to below significance (Table 1).

Table 1. Distribution of MR classes.

MR class dPCR versus qPCR	dPCR with Cut-off 3 for positivity	dPCR multiplied by CF qPCR
Concordance [%]	58	61
Less RD [%]	11	16
More RD [%]	31	23
X-fold more RD/less RD	2.8	1.4

Summary/Conclusions: The use of M-BCR-ABL primers according to the EAC (Europe Against Cancer) protocol in dPCR with a cut-off of 3 droplets results in a shift of molecular response categories towards more minimal RD by dPCR than by qPCR. This difference is reduced to below significance by application of the laboratory specific qPCR conversion factor to the dPCR data.

PRE-EXISTING SOMATIC MUTATIONS IN GENES COMMONLY MUTATED IN MYELOID MALIGNANCIES (RUNX1, DNMT3A, ASXL1) MAY CONFER BAD PROGNOSIS IN CHRONIC MYELOID LEUKEMIA

M M Machnicki[1,2,*], I Solarska[1,3], M Zawada[4], P Stawinski[5], R Ploski[5], I Seferynska[3], T Sacha[6], T Skorski[7], T Stoklosa[1]
[1]Department of Immunology, Centre of Biostructure Research, [2]Postgraduate School of Molecular Medicine, Medical University of Warsaw, [3]Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, [4]Department of Hematology Diagnostics, The University Hospital, Krakow, [5]Department of Medical Genetics, Medical University of Warsaw, Warsaw, [6]Department of Hematology, Jagiellonian University, Krakow, Poland, [7]Department of Microbiology and Immunology, Fels Institute of Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, PA, United States

Background: Chronic Myeloid Leukemia is readily manageable disease for majority of patients. However, a subset of patients either never achieve or lose response to tyrosine kinase inhibitors (TKIs) and progress from chronic (CML-CP) to blastic phase (CML-BP). The genetic basis of this transition remains only partially understood, particularly when loss of TKI sensitivity cannot be attributed solely to *BCR-ABL1* mutations.
Aims: We sought to determine the genetic background of CML progression in patients who experienced TKI treatment failure not associated with *BCR-ABL1* mutations using targeted enrichment and next-generation sequencing strategy.
Methods: Sequential DNA samples were collected from 9 patients who were diagnosed in CML-CP and progressed to CML-BP (8 myeloid, 1 lymphoid). SeqCapEZ Choice (NimbleGen) enrichment was used to capture coding sequences of 952 genes (7Mb) implicated in human cancer (with focus on hematological malignancies), followed by high-throughput sequencing on Illumina HiSeq 1500 (>90% ge20, >100x mean coverage).
Results: In 7 patients we observed variants in *RUNX1*, *DNMT3A*, *ASLX1*, *PTPN11* and *IDH1* genes (table), all of which were considered as damaging and located in previously known hotspots (except for novel *DNMT3A* mutations).

Almost all variants could be detected at CML-CP at varying allele frequency, thus preceding diagnosis of CML progression.

Table 1.

Patient	Mutation(s)	NCBI Reference	Pre-existing in CML-CP?	Allele frequency CML-CP	Allele frequency CML-BP(s)	CML-BP type
1	**RUNX1** R230*	NM_001754.4	Yes	1%	39% | 46% | 18%	lymphoid
2	**IDH1** R132S	NM_005896.3	Yes	8%	52%	myeloid
3	**RUNX1** R166L	NM_001754.4	No	0%	34%	myeloid
	E202_P203ins	NM_001754.4	No	0%	18%	
4	**DNMT3A** Y481*	NM_175629.2	Yes	52%	54%	myeloid
	PTPN11 A72V	NM_002834.3	No	0%	45%	
5	**RUNX1** E316_L317fs	NM_001754.4	Yes	17%	18%	myeloid
6	**DNMT3A** L798F	NM_175629.2	Yes	50%	57%	myeloid
	ASXL1 G643_G644fs	NM_015338.5	Yes	21%	40%	
7	**ASXL1** G626_A627fs	NM_015338.5	Yes	39%	22%	myeloid

Summary/Conclusions: Our results suggest that in rare, refractory CML cases mutations in genes frequently mutated in myeloid neoplasms might cause or contribute to an aggressive CML phenotype. Early detection of such genetic lesions might be important for patients who will not achieve remission with currently available standard treatment regimens and who should be considered as high-risk patients.

E1087

EVOLUTION OF RUNX1 AND ASXL1 MUTATIONS DURING THE PROGRESSION OF CHRONIC MYELOID LEUKEMIA TO MYELOID BLAST PHASE: AN ANALYSIS OF 52 MATCHED PAIRED SAMPLES AT BOTH INITIAL DIAGNOSIS AND BLAST PHASE

HW Kao[1,2,*], MC Kuo[1,2], PN Wang[1], P Dunn[1,2], JH Wu[1], CL Lai[1], TH Lin[1], LY Shih[1,2]
[1]Chang Gung Memorial Hospital at Linkou, [2]Chang Gung University, Taoyuan, Taiwan, ROC

Background: Before imatinib era, most patients with Ph-positive chronic myeloid leukemia (CML) diagnosed at chronic phase (CP) or accelerated phase (AP) will transform to blast phase (BP) compared with a small number of patients receiving imatinib therapy. The biology of CML-BP is still largely unknown. Data from direct comparison of matched samples between both diagnosis and BP was limited.
Aims: We aimed to determine the role of *RUNX1* and *ASXL1* mutations in addition to *BCR-ABL1* kinase domain (*ABL1*-KD) mutations during the progression of CML in a larger cohort of matched paired samples in CP/AP and myeloid BP.
Methods: Bone marrow samples from 52 patients with CML at initial diagnosis (47 CP and 5 AP) and myeloid BP transformation were enrolled. Nineteen patients received imatinib therapy before BP transformation (group A) and the remaining 33 patients had not been treated with imatinib (group B). Semi-nested polymerase chain reaction (PCR) assay followed by denaturing high-performance liquid chromatography and/or direct sequencing was used to detect *ABL1*-KD mutations. *RUNX1* (exons 3-8) and *ASXL1* (exon 12) mutations were analyzed by PCR-based assays and direct sequencing. Patients with *ABL1*-KD, *RUNX1,* or *ASXL1* mutations in myeloid BP were subjected to the analyses of the corresponding genes in the matched diagnosis samples. Pyrosequencing was used to measure the mutant levels.
Results: The median age of patients at the time of CML diagnosis was 45 (16-84) years. The median time from CP/AP to myeloid BP was 26 (1.9-162.9) months. Eight (42.1%, 8/19) of group A patients had *ABL1*-KD mutations at BP compared with none in group B patients (*P*=0.0003). None of the 8 patients carrying *ABL1*-KD mutations at BP had *ABL1*-KD mutations detected in the diagnostic samples. Ten (19.2%, 10/52) patients in myeloid BP had *RUNX1* mutations, but none of them had *RUNX1* mutation in the corresponding diagnostic samples. Only one of the 10 patients with *RUNX1* mutations in myeloid BP had *ABL1*-KD mutations. Two patients (10.5%, 2/19) acquired *RUNX1* mutations at BP in group A compared with 24.2% (8/33) in group B (*P*=0.227). *ASXL1* mutation was detected in 6 (11.8%, 6/51) samples in myeloid BP, of which only one was positive for *ASXL1* mutation in the diagnostic sample which was in AP. All the 5 patients who acquired *ASXL1* mutations did not have *ABL1*-KD mutation in myeloid BP. Acquisition of *ASXL1* mutations in myeloid BP was 0% (0/18) and 18.2% (6/33) in group A and group B, respectively (*P*=0.054). Together, 3 patients had co-existence of *RUNX1* and *ASXL1* mutations at myeloid BP. Emergence of *ABL1*-KD mutations did not significantly affect the acquisition of *RUNX1* or *ASXL1* mutations during myeloid BP transformation.
Summary/Conclusions: *RUNX1, ASXL1 or ABL1*-KD mutations were not detected in CML patients at initial diagnosis except one who presented with AP. Acquisition of *RUNX1* and/or *ASXL1* mutations occurred in 25.5% (13/51) of patients during myeloid BP transformation. *ABL1*-KD mutations only occurred in patients treated with Imatinib, and *ASXL1* mutations were prone to develop in patients not treated with Imatinib. (Grant support: XMRPG360366 and OMRPG3C0021).

E1088

NEXT-GENERATION SEQUENCING OF AMPLIFIED DNA FRAGMENTS WITH LENGTH POLYMORPHISMS ASSOCIATED WITH CHRONIC MYELOID LEUKEMIA REVEALED POLYMORPHISMS IN REPETITIVE ELEMENTS AND CANCER RISK LOCI

J Koblihova[1,*], K Srutova[1,2], M Jaruskova[1,2], H Klamova[1], K Machova Polakova[1,2]
[1]Institute of Hematology and Blood Transfusion, [2]Institute of Clinical and Experimental Hematology, First Faculty of Medicine, Charles University, Prague, Czech Republic

Background: A genetic predisposition and molecular mechanisms of chronic myeloid leukemia development (CML) and of resistance to the treatment with tyrosine kinase inhibitors (TKI) is the matter of the research worldwide. High-throughput techniques such as next generation sequencing (NGS) enable whole-genome analysis per each individual, however, often with limitations in a large volume of obtained data requiring extensive bioinformatics analysis.
Aims: We created an approach to scan the individual CML genomes using the combination of highly reproducible amplified fragment length polymorphism (AFLP) analysis and of NGS in order to identify polymorphic loci associated with CML or response to imatinib (IM).
Methods: AFLP was performed on 65 CML patients treated with IM first line (39 pts with optimal response; 26 pts with IM failure) and 30 healthy donors; for confirmatory analysis next 30 controls were added. The median age of patients was 55 years (range 18-84). AFLP analyses were performed using MseI and EcoRI endonucleases and commercially available kits and protocols. Fragmentation was run on ABI PRISM 3130 sequencer. The lengths of DNA fragments were analyzed with GeneMapper. DNA fragment frequency among CML patients and controls were analyzed by the exact binomial test. Nine selected DNA fragments were further characterized by NGS and the obtained data were evaluated using NextGENe. Polymorphisms in identified DNA fragments were confirmed by Sanger sequencing.
Results: AFLP generated 3912 AFLP markers/DNA fragments with diverse distribution among CML patients and healthy controls. Among them 199 were significantly associated with CML and 5 with IM response. Using NGS, we characterized 7 loci associated with CML and 2 with response to IM. In CAC_ACC_25, we confirmed SNP rs113864098 (C/T) resulting in an introduction of EcoRI restriction site. The locus is on chromosome 1 and is a part of L1MC1 and AluSz repetition. The significantly higher frequency of rs113864098-T allele was found in the patient cohort (60%) in comparison to healthy donors (13%) (P=0.016). SNP rs7906704 (G/T) was confirmed in the CAT_ACC_54 fragment localized on chromosome 10 between NRAP and CASP7 genes resulting in the introduction of MseI restriction site in this locus. The frequency of minor rs7906704-T allele was significantly higher in CML patients (38%; P=0.04) in comparison to healthy controls. This SNP was found to be involved in apoptosis pathway in pancreatic tumorigenesis (Li et al., 2012). Further, we identified DNA fragment CTT_ACA_57, which was significantly frequently present in patients with optimal response to IM (65%) in comparison to patients with IM failure (19%) (P=0.03). The fragment is a part of satellite sequence ALR/Alpha occurring in centromeric regions with the highest frequency on chromosome 5. Wide evidence of small genomic aberrations of ALR/Alpha was found in chronic lymphocytic leukemia (Kim et al., 2010).
Summary/Conclusions: In this work, we applied whole-genome fragmentation analysis to identify DNA polymorphisms associated with CML and response to IM and subsequently confirmed these potential novel DNA markers by genotyping. Up to now, we identified and confirmed 2 SNPs significantly associated with CML and 1 repetitive element polymorphism associated with response to IM. We assume identification of more genomic markers associated with CML and suppose potential use of AFLP/NGS combinational approach as the alternative to whole-genome sequencing.
Supported by Ministry of Health of CZ grant IGA NT11555 and project 00023736.

E1089

DROPLET DIGITAL PCR IMPROVE MINIMAL RESIDUAL DISEASE DETECTION IN >35% OF SAMPLES COMPARING TO RQ-PCR

M Andrade-Campos[1,*], P Alfonso[1], L Lopez de Frutos[2], G Soro[3], P Giraldo[1]
[1]Translational Research Unit, IIS-Aragon. CIBERER., [2]Translational Research Unit, IIS-Aragon., [3]Research Nurse, IIS-Aragon, Zaragoza, Spain

Background: The gold standard for BCR-ABL quantification in chronic myeloid leukemia patients (CML) is the real time quantitative polymerase chain reaction (RQ-PCR), this technique has a limited sensibility to MR4.0 or MR4.5 in the majority of laboratories. Several discontinuation studies in chronic phase CML (CP-CML) patients reveal that both, the achievement a deeper response and a long time in this response seem the main factors for good outcomes. The droplet digital PCR (ddPCR) had shows more sensitivity to detect minimal amounts of BCR-ABL transcripts in patients with undetectable BCR-ABL transcripts by RQ-PCR, leading an opportunity to investigation in this field.
Aims: To evaluate the usefulness of the ddPCR in detect the presence of BCR-ABL transcripts in CP-CML patients under TKI therapy, compared with RQ-PCR.
Methods: Between August-2013 to Mar 2015, a total of 112 samples from 34 CP-CML patients under TKI therapy were analyzed. The blood samples were obtained in EDTA for RQ-PCR and in Tempus™ tube for RNA isolation. The RQ-PCR was performed following the current recommendations. The RNA was obtained from peripheral blood using Tempus™ Spin RNA isolation kit according manufacturer recommendations. The analysis by ddPCR for each sample was done using 5 µg of RNA obtained using One-step kit and processed in

Qx100 Droplet Digital PCR, Biorad; using primers and probes described by Gabert et al., 2003, the results were analyzed using QuantaLife Biorad software and expressed in absolute number of BCR-ABL copies and positive droplets. Samples were processed per triplicate (3 wells). Positive samples: were considered when the sum of ≥3 positive droplets in minimum of 24,000 droplets.
Results: From the 112 samples analyzed by RQ-PCR, 69 (61.6%) were negative and 43 (38.4%) were positive. According molecular response the distribution by international scale (MR) and number of transcripts (NT). Table 1. The ddPCR analysis reveals that 65 (58.0%) of the samples were positive, median of positive droplets: 22.5 (3-35,529). Median BCR-ABL NT: 41.5 (5.5-11,129.3). For samples with a negative result by RQ-PCR (n=69), in 44 (63.7%) the analysis by ddPCR confirmed the negativity of the sample, however in 25 (36.2%) there were positivity in 3 or more droplets (median 4, 3-25), with a median NT 9.9 (5.5-44.7) copies. Table 1 exposed also the relation between the MR by RQ-PCR and the positivity by ddPCR. However if the threshold is settled in two positive droplets with a minimum of 3.5 NT, the number of positive samples increase to 38 (55.1%), with a median NT: 8.1 (3.6-44.7). There was a correlation in the number of copies between both techniques, but with a significant increase in the amount of NT copies.

Table 1.

Positive samples (43/112, 38.4%)					
RQ-PCR	No MR	MR3.0	MR4.0	MR4.5	MR5.0
MR	24 (55.8%)	13 (30.2%)	6 (14.%)	0	0
Median NT	118.5(68.9-291.4)	7.5 (4.8-59.1)	3.3 (3.0-1,371)	0	0
Ratio	1.18 (0.68 – 2.9)	0.075 (0.011-0.09)	0.008 (0.003 – 0.008)		
RQ-PCR negative samples (69/112, 61.6%)					
MR		5 (7.2%)	49 (71.1%)	14 (20.3%)	1 (1.4%)
ddPCR + (3 droplets) 36.2%		2 (40%)	17 (34.7%)	5 (35.7%)	0 (0%)
ddPCR – (3 droplets) 62.3%		3 (60%)	32 (65.3%)	8 (57.1%)	1 (100%)

Summary/Conclusions: The ddPCR offer a new way to assess CP-CML patients, in special for patients with MR4.0 or undetectable molecular response by RQ-PCR, and would offer a more secure alternative to select patient for discontinuation trials. In our cohort, at least an improving of 36% on identification of samples with presence of minimal residual disease has been founded. The use of this technique to monitoring and select patients for discontinuation trials is warranted.

Background: Treatment-free remission is a major goal in CML. Nowadays it is possible to safely discontinue imatinib but it is still not clear which patient (pt) will relapse. High sensitivity techniques like droplet digital (dd)PCR may help to discriminate pts who still present a significant amount of disease despite being in MR4 by standard real-time quantitative PCR (RQ-PCR).
Aims: To evaluate the capability of ddPCR to predict relapse after imatinib discontinuation in CML pts with stable MR4 by RQ-PCR.
Methods: Total RNA was extracted at different time-points from 19 pts in stable MR4 for two years before discontinuation of imatinib. ddPCR was carried out in triplicate using 200 ng of cDNA for each replicates and droplets were analyzed by QX100™ droplet reader (Bio-Rad) using the DigiDrop P210 Master Mix Kit (Bioclarma). All results were expressed according to the new recommendations [Cross, Leukemia 2015].The Wilcoxon test was used for the comparison of the total ABL medians; the Agreement Coefficient of the 2 methods was calculated with Cohen's K test; Logistic Regression was used to assess the relationship between the probability of relapse and disease level by RQ-PCR and ddPCR.
Results: A total of 48 samples were retrospectively analyzed by RQ-PCR and ddPCR. All pts discontinued imatinib; 8/19 pts had to restart treatment for loss of MMR/MR4 after a median of 5.3 mos (2.2-8.5). A difference between ddPCR and RQ-PCR median total ABL copies (p<0.001) was found with the following medians (ranges): 46290 (8420-124600) and 93060 (25440-210000) for RQ-PCR and ddPCR respectively. A difference between ddPCR and RQ-PCR median total BCR-ABL1/ABL1% (p<0.001) was found: 0 (0-0.09); and 0.0009 (0-0.015) for RQ-PCR and ddPCR respectively. Sixteen pts had >2 evaluations, 3 had an evaluation between 14 and 18.5 mos before discontinuation. 6 pts had an evaluation at -12 mos (+/-0.81), 10 at -9 mos(+/-1.3), 14 at -6 mos(+/-0.9), 15 at -3 mos(+/-1.2), considering as time "0" the date of discontinuation. At time -12, only 1pt resulted BCR-ABL1 positive by both methods, 1 by ddPCR only and 0 by RQ-PCR only (K0.6, moderate agreement, p 0.13). At time -9, 3 pts resulted BCR-ABL1 positive by both methods, 6 by ddPCR only and none by RQ-PCR only (K=0.1, slight agreement, p 0.34). At time -6, 3 pts resulted BCR-ABL1 positive by both methods, 5 pts by ddPCR only and none by RQ-PCR only, (K=0.3, fair agreement, p 0.08). At time -3, none resulted BCR-ABL1 positive by both methods, 4 pts were positive by ddPCR only and 1 by RQ-PCR only (K=-0.1, no agreement, p 0.62). Over one year of molecular follow-up before discontinuation, for negative values obtained measuring BCR-ABL1 by RQ-PCR the probability of relapse was equal to about 50% (45%, Figure 1), *i.e.* the capability of RQ-PCR of detecting relapse was basically same as random being almost constant for all the positive values of BCR-ABL1. On the contrary the probability of a relapse for negative values of BCR-ABL1 by ddPCR was about 30% and it grew up linearly at increasing level of transcript, achieving a probability of 69% when BCR-ABL1/ABL1% was equal to 0.008%. The difference between RQ-PCR and ddPCR in predicting the probability of relapse was statistically significant (p 0.02).

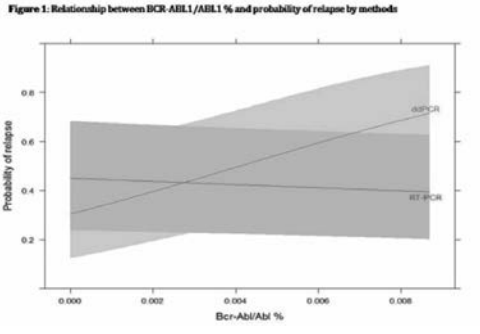

Figure 1.

Summary/Conclusions: Despite the small number of cases, our results confirm that the ddPCR is more sensitive than RQ-PCR for low levels of disease. Molecular follow-up by ddPCR at several time-points before discontinuation may have a prognostic value for predicting relapse, and this is worthy to be tested prospectively and in larger cohorts of pts.

PROGRAMMED CELL DEATH PROTEIN 1 (PD-1) DOWNREGULATION ON REGULATORY T CELLS DURING TYROSINE KINASE INHIBITOR THERAPY IN CHRONIC MYELOID LEUKEMIA

P Rodrigues Santos[1,2,*], J Almeida[1], P Couceiro[1], V Alves[2], L Ruzickova[3], P Freitas-Tavares[3], M Santos-Rosa[2]
[1]Lab Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, Universidade de Coimbra, [2]Instituto de Imunologia, Faculdade de Medicina da Universidade de Coimbra, [3]Serv Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Programmed death-1 (PD-1) receptor and its ligands (PD-L1 and PD-L2) are involved in attenuating tumor immunity and facilitating tumor progression. PD-1, PD-L1 and PD-L2 therapeutic blocking agents have been reported to have significant antitumor effects. In chronic myeloid leukemia (CML), the expression of this receptor and its ligands is not fully characterized for the different subsets of cells of the immune system in which their expression is found constitutively or post-induction.
Aims: In this study, we analyzed the expression of PD-1 and its ligands on regulatory T cells (Tregs) in chronic phase CML patients to understand the mechanisms underlying suppressor effects that inhibit the anti-leukemia immune response.
Methods: Peripheral blood samples from chronic phase CML patients (n=50) under Interferon-alpha 2b (IFN-α 2b), imatinib, dasatinb, nilotinib, bosutinib and ponatinib therapy were analyzed by multi-parametric flow cytometry for the characterization of regulatory T cells and surface expression of PD-1. Buffy coats (n=13) from healthy blood donors were used as control. Cytokines and chemokines were evaluated in a 34-plex panel by xMAP technology (Luminex®). Gene expression analysis and miRNA profiling were also performed for these samples.
Results: PD-1 Tregs were found significantly decreased (p<0.0001) in CML patients and down-regulation of this receptor was also observed (p<0.01). Naïve and memory Treg subsets were equally affected. No significant alterations were observed for PD-L1 and PD-L2 ligands. Although TGF-β and IL-10 production were not significantly altered by down-regulation of PD-1 in Tregs, the overall effect of tyrosine kinase inhibitor (TKI) therapy suggests a negative impact in these cells concerning the anti-leukemic immune response.

Summary/Conclusions: Regulatory T cells represent a major population of suppressors in the immune response against leukemia. Down-regulation of PD-1 receptor in Tregs during chronic phase CML reinforces the notion that discontinuation of treatment must be carefully evaluated beforehand, since these suppressor cells could permit the proliferation of existent residual leukemic cells.

SINGLE NUCLEOTIDE POLYMORPHISMS IN DRUG-RELATED GENES ARE ASSOCIATED WITH RESISTANCE OR TOXICITY TO IMATINIB IN CHRONIC MYELOID LEUKAEMIA

N Estrada[1,*], B Xicoy[1], P Velez[2], L Palomo[1], C Boque[2], I De la Fuente[3], M Sagües[3], O Garcia[1], M Cabezon[1], M Cortes[4], R Vallansot[5], J Buch[6], E Plensa[7], D Vela[8], JM Ribera[1], E Feliu[1], F Milla[1], A Sureda[2], D Gallardo[3], J Sarra[5], L Zamora[1]

[1]Hematology, ICO-Hospital Germans Trias i Pujol, Josep Carreras Leukaemia Research Institute, Badalona, [2]Hematology, ICO-Hospital Duran y Reynals, Barcelona, [3]Hematology, ICO-Hospital Josep Trueta, Girona, [4]Hematology, Hospital de Granollers, Granollers, [5]Hematology, ICO-Hospital Joan XXIII, Tarragona, [6]Hematology, Hospital Sant Jaume de Calella, Calella, [7]Hematology, Hospital de Mataro, Mataro, [8]Hematology, Hospital de Mollet, Mollet, Spain

Background: Imatinib (IM) induces apoptosis in *BCR-ABL1* positive cell lines and is extensively used to treat patients with newly diagnosed Philadelphia chromosome-positive Chronic Myeloid Leukaemia (Ph+CML). However, about 20% of Ph+CML patients fail to achieve optimal response, and a substantial proportion develop intolerance or toxicity. Amplification and overexpression of the *BCR-ABL1* gene, *BCR-ABL1* kinase domain point mutations and genetic variability (as genetic polymorphisms), among others, may explain IM resistance.
Aims: To assess the association between single-nucleotide polymorphisms (SNP) in drug-related genes and IM resistance or toxicity in CML patients.
Methods: In a pilot study with 45 Ph+CML patients treated with IM from three Spanish centers, we tested 1936 SNPs in 225 drug-related genes using the Affymetrix Drug Metabolism Enzymes and Transporters (DMET) microarray. Response criteria were assessed according to ELN2009 or ELN2013 guidelines. Relevant toxicity to IM was defined as the need for switching to another tyrosine kinase inhibitor (TKI). SNPs significantly associated with response or toxicity to IM treatment were validated in an independent group of 105 Ph+CML patients from 8 Spanish centers. Informed consent (according to the Declaration of Helsinki) was obtained from all patients. Validation genotyping was performed using Fluidigm 96.96 Dynamic Array with BioMark HD Systems (Fluidigm Corp., CA). Data were analysed by the BioMark SNP Genotyping Analysis software to obtain genotype calls. Candidate SNPs were primarily evaluated for adequacy of Hardy-Weinber Equilibrium (HWE) using the Chi-square test. For the association study, the SNPassoc package from R was used (PMID: 17267436, www.r-project.com).
Results: In this pilot study we found 76 SNPs to be significantly associated with response or toxicity to IM treatment. In the validation cohort, 5/76 SNPs and 2/76 SNPs were related to IM resistance or toxicity, respectively (*Table 1*). Patients carrying at least one variant allele for *CYP2C8* (C), *UGT2A2* (A), *CYP19A1* (T), *ABCC3* (A) and *CYP2C8* (A) were significantly associated with IM treatment failure. In the same way, AC-AA genotypes in *CYP19A1* and CT-TT genotypes in *CYP11B1* were significantly associated with lower risk of IM-toxicity.

Table 1. Significant SNPs related to IM resistance or toxicity (Log-Additive Model).

dbSNP ID (Gene)	Genotype	Controls N(%)	Cases N(%)	OD (CI95%)	p-value

[1] RESPONSE. Data available in 93 patients (29 failed to achieve IM response)
[2] TOXICITY. Data available in 105 patients (27 developed IM toxicity)

Summary/Conclusions: The SNPs found in the present study allow the identification of CML patients at risk to develop IM resistance or toxicity, suggesting that a second generation TKI should be offered to these patients as first line therapy. Furthermore, our results suggest that SNP analysis may be included in clinical practice as a predictive tool for response and toxicity at diagnosis of CML patients.
Acknowledgements: This study was supported by an unrestricted grant from Novartis.

Background: Chronic myeloid leukemia (CML) is a clonal myeloproliferative disorder and the biomolecular mechanisms of CML response to tyrosine kinase inhibitors are not fully defined.
Aims: Thirty chronic phase CML patients were investigated at diagnosis and at 3, 6 and 12 months of first-line nilotinib treatment and optimal response was achieved at 3, 6 and 12 months after nilotinib in all the 30 patients (figure 1). We established cut off values of molecular response (MR) to define groups of patients, and to explore differences of gene expression profiles (GEP) between patients at diagnosis based on the MR achieved after 3, 6 and 12 months of nilotinib, respectively.
Methods: Cut off values were: 1% IS at 3 months of nilotinib, 0.1% IS at 6 months of nilotinib, and 0.01% IS at 12 months of nilotinib. We divided patients into 2 groups based on MR values of each patient at 3 months of nilotinib: group A (n=24) with MR≤1.0% IS and group B (n=6) with MR>1% IS. At 6 months of nilotinib, patients were divided into: group C (n=22) with MR≤0.1% IS and group D (n=8) with MR>0.1% IS. At 12 months of nilotinib, patients were divided into: group E (n=18) with MR≤0.01% IS and group F (n=12) with MR>0.01% IS. GEP on the selected bone marrow (BM) CD34+/lin- cells of 30 patients at diagnosis was performed using Affymetrix-GeneChip-HTA 2.0. RMA was used for preprocessing data. SAMR and GSEA detected differentially expressed genes and pathways associated with the different groups, respectively. MTC was performed using the FDR with a threshold 0.05 for SAMR and 0.25 for GSEA.

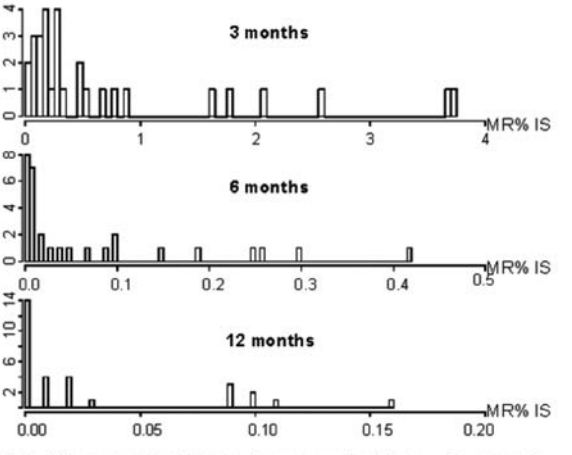

Fig.1 Histograms showing the frequency of patients with a certain Molecular Response (MR% IS) at 3, 6 and 12 months (upper, middle and lower panel, respectively)

Figure 1.

Results: GSEA identified significant differences in the transcriptional signature between group A and group B associated with the MR at 3 months as well as between group C and group D in respect to the MR at 6 months of nilotinib. Based on the MR at 3 months, Reactome-pathways-"P130-cascade" and "GRB2-SOS-linkage-to-MAPK-signaling-for-integrins" were significantly upregulated in group A. *FGA*, *FGB*, *FGG*, *APBB1IP*, I*TGA2B* and *CRK* genes contributed to call the pathways upregulated. From literature data, nilotinib inhibits BCR-ABL1 mediated phosphorilation of CKRL which acts in the CML hematopoietic stem cells in diverse signaling pathways playing an apoptotic role in CML. CRK was overexpressed in patients with a better MR≤1% IS at 3 months of nilotinib. Aminoacid-and-amine-transport-across-the-plasma-membrane-pathway was significantly overexpressed, whereas "lipid metabolism" was significantly downregulated (*AKR1C1*, *ANGPTL3*) in group A compared to group B, respectively. Based on the MR at 6 months, "positive-regulation-of-cytokine secretion" and "interleukin1-secretion" were significantly upregulated in group C compared to group D, involving *PYCARD8, NLRP2, NLRC4, NLRP3* and *CARD8* genes. *PYCARD* and *CARD8* promote caspase-mediated-apoptosis processes involving the recruitment of recognition receptors: *NLRP2, NLRP3* and *NLRC4.*
Summary/Conclusions: The study showed that MAPK-signaling-for-integrins and amine-transport-across-the-plasma-membrane were significantly overexpressed in CML patients with MR≤1.0% IS while lipid metabolism was significantly underexpressed in CML patients with MR≤1.0% IS after 3 months of nilotinib. Positive-regulation-of- cytokine-secretion-and-interleukin1-secretion was significantly overexpressed in CML patients who achieved MR≤0.1 IS after 6 months of nilotinib. In summary, distinct sets of genes involved in apoptosis were differentially expressed in 30 CML patients at diagnosis based on the MR at 3 and at 6 months of first-line nilotinib treatment.

MATE1 REGULATES CELLULAR UPTAKE AND SENSITIVITY TO IMATINIB IN CML PATIENTS

B Edemir[1,*], S Harrach[2], C Schmidt-Lauber[2], E Schmidt[3], WE Berdel[3], T Pap[4], U Schulze[2], S Jeromin[5], T Haferlach[5], G Ciarimboli[2], J Bertrand[4]
[1]Department of Internal Medicine IV Hematology and Oncology, University Hospital Halle, Halle (Saale), [2]Experimental Nephrology, Department of Internal Medicine D, [3]Department of Medicine A, [4]Institute of Experimental Musculoskeletal Medicine, University Hospital Muenster, Muenster, [5]MLL Munich Leukemia Laboratory, Munich, Germany

Background: Imatinib is highly effective in the treatment of chronic myeloid leukemia (CML). Up to 30% of CML patients treated with Imatinib as a first-line therapy experience treatment failure. The response rate varies within different stages of the disease. Besides other mechanisms of resistance such as mutations in the *Bcr-Abl1* fusion gene, the transport of Imatinib into its target cells has been proposed to be crucial for its effectiveness. As an organic cation, Imatinib has to be actively translocated across the cell membrane. Though some studies suggested a critical role of the organic cation transporter 1 (OCT1) in regulating Imatinib efficacy, other studies could not confirm these findings. Although OCT1 is generally capable to transport Imatinib, it might have minor relevance under clinical conditions. We recently demonstrated that the multidrug and toxin extrusion protein 1 (MATE1) accepts Imatinib as a substrate.
Aims: In this study, we focused on transporters, which are relevant for Imatinib uptake and investigated their expression pattern in PBMCs and if they contribute to Imatinib uptake and expression in samples from CML patients or CML cell lines.
Methods: We used PBMC from 6 healthy volunteers and transporter expression profile was analyzed by qPCR and intracellular Imatinib accumulation was quantified by HPLC-UV using stably transfected HEK cells. To assess Imatinib dependent biologic effects on MATE1 expression, activity of bcr-Abl1 protein was detected by Western blot analysis using anti-phospho ABL and GAPDH antibody. To address the clinical significance of MATE1 on the Imatinib therapy in CML, we evaluated the clonal growth of the immortalized CML cell line K562 cells stably transduced with shRNA against MATE1 in methylcellulose medium supplemented with Imatinib.
Results: The results showed that Imatinib uptake was significantly increased in OCT1, OCT2- and MATE1 expressing HEK-cells. We found that the transport via MATE1 is clinically highly relevant as represented by a remarkably high quotient for therapy regimes. This is supported by qPCR expression of MATE1 in 31 patients with Bcr-Abl1 major transcript (p210) positive CML.The mRNA expression of potential Imatinib transporters in PBMC of healthy volunteers as well as in K562 cells showed that in both cell types OCT1, OCT2 and MATE1 were detected at similar levels comparable to the Imatinib uptake rate into these cells. Inhibitor studies showed that MATE1 plays an important role in Imatinib accumulation. In patients, Imatinib non-responders showed a significantly lower MATE1 expression than Imatinib responders and we found a correlation between MATE1 transporter expression and clinical response to Imatinib treatment, suggesting that MATE1 might enable to predict whether CML patients are likely to respond to Imatinib therapy.
Summary/Conclusions: Thus, we identify MATE1 as the main transporter for the Imatinib dependent therapeutic response of CML patients.

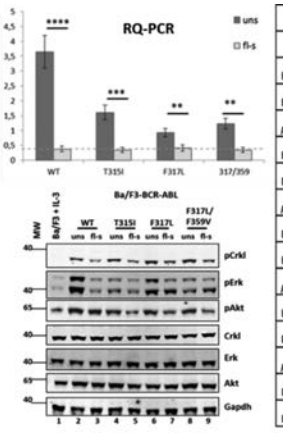
TRANSPOSON-MEDIATED GENERATION OF BCR-ABL1-EXPRESSING TRANSGENIC CELL LINES FOR FAST AND UNBIASED SENSITIVITY TESTING OF TYROSINE KINASE INHIBITORS

K Byrgazov[*], O Haas[1], G Hoermann[2], P Valent[2], T Lion[1]
[1]Children's Cancer Research Institute, [2]Medical University of Vienna, Vienna, Austria

Background: Point mutations in the ABL1 kinase domain are an important mechanism of resistance to tyrosine kinase inhibitors (TKI) in BCR-ABL1-positive and, as recently shown, BCR-ABL1-like leukemias. The cell line Ba/F3 lentivirally transduced with mutant BCR-ABL1 constructs is widely used for *in vitro* sensitivity testing and response prediction to tyrosine kinase inhibitors. The transposon-based *Sleeping Beauty* system presented offers several advantages over lentiviral transduction including the absence of biosafety issues, faster generation of transgenic cell lines, and greater efficacy in introducing large gene constructs. Nevertheless, both methods can mediate multiple insertions in the genome.
Aims: Establish a method for enrichment of virtually pure cell fractions carrying single insertions of the gene construct to permit unbiased *in vitro* testing of drug resistance.
Methods: Transposon-mediated gene transfer, flow soritng, FISH, RQ-PCR, qPCR, immunoblotting, survival assays
Results: We showed that multiple BCR-ABL1 insertions result in elevated IC_{50} levels for individual TKIs, thus overestimating the actual resistance of mutant subclones. The establishment of a flow-sorting-based fractionation of BCR-ABL1-transformed Ba/F3 cells has enabled us to enrich for cells carrying single-site insertions, as demonstrated by FISH analysis and real time PCR. Fractions of unselected Ba/F3 cells not only showed a greater number of BCR-ABL1 hybridization signals, higher expression levels of BCR-ABL1, and increased activation of BCR-ABL1 downstream signaling, but also revealed higher IC_{50} values for the TKIs tested.



IC_{50} values of unselected and flow-sorted Ba/F3-BCR-ABL1 (nM)

	Nilotinib	Dasatinib	Ponatinib
BCR-ABL1^{WT} unselected	25.0 ± 6.0	4.2 ± 1.3	10.0 ± 2.0

Figure 1.

Summary/Conclusions: The generation of multiple gene construct insertions in Ba/F3 cells by lentiviral- or transposon-mediated transfer has not been reported previously as a relevant problem in the context of *in vitro* drug sensitivity testing. Our data demonstrate that targeted flow-sorting of low-fluorescent Ba/F3-BCR-ABL1 cells facilitates enrichment of virtually pure cell fractions carrying single insertions of the gene construct. Employment of this selection step is highly recommended to permit unbiased *in vitro* testing of drug resistance. The clinical relevance of our observations has far reaching consequences beyond Ph+ neoplasia. The rapidly increasing number of reports on BCR-ABL1-like leukemias involving a variety of activated kinases highlights the relevance of TKI-based treatment and *in vitro* prediction of sensitivity to these agents. Appropriate modeling of mutant kinases inserted at single sites into Ba/F3 cells, as presented in this report, is therefore of paramount importance for reliable prediction of treatment responses to kinase inhibitors.

LB2254

THE PROLIFERATIVE ACTIVITY OF THE BONE MARROW CELLS INVESTIGATED *IN VITRO* CELL CULTURE OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TYROSINE KINASE INHIBITORS

T Perekhrestenko[*], I Sviezhentseva[1], D Bilko[1], N Tretiiak[2], I Dyagil
[1]Centre for Molecular and Cell Research , National University of "Kyiv-Mohyla Academy", [2]blood disease, State Institution «Institute of Hematology and Transfusiology of NAMS of Ukraine», Kyiv, Ukraine

Background: The mechanisms of CML progression were postulated based on *in vitro* modeling even before they were detected in the clinical practice. CML

progression can be driven by different mechanisms on tissue, cell, chromosomal and molecular level. Recent *in vitro* studies of CML bone marrow cells also suggest that disease progression can be caused by functional changes in pool of more matured hematopoietic progenitor cells rather than in population of HSCs. Such evolution of HPCs during CML progression can be identified by changes in their clonogenic potential during cultivation in semi-solid agar.
Aims: To analyze the changes in functional properties of HSCs and HPCs, such as ability to form cell aggregates during cultivation in CFU assay with further evaluation of cell composition of individually picked-up cell aggregates, with respect of correlation with CML progression in each individual patient.
Methods: Totally 51 samples of bone marrow were analyzed from patients with CML in chronic phase, who were treated with TKI, Imatinib. *CFU-assay:* Mononuclear fraction was separated from bone marrow aspirates by centrifugation over Ficoll-Hypaque gradient. All results were expressed as the mean number obtained from quadruplicate cultures. Clones of > 40 cells were counted as colony forming units granulocyte monocyte (CFU-GM) and those with 5 - 40 cells as cluster forming units (ClFU).
Results: CFU assay indicated that there was a significant ($p < 0.05$) difference in clonogenic potential (number of CFU-GM and ClFU) between groups of patients with different response to the therapy. CFU numbers were lower in group of patients with optimal response to the TKI therapy (mean value of 25.54±4.6) and for patients with TKI treatment failure (26.00±9.70) when compared to CFU numbers for groups of patients before TKI treatment (70.40±22.51) and patients with suboptimal response to TKI treatment (72.37±15.32). Significant decline ($p < 0.05$) was also indicated for mean numbers of ClFU for group of patients with optimal response for TKI (24.05±6.75) when compared to groups of patients with suboptimal response to TKI (49.94±7.89), but also for group of patients with TKI treatment failure (51.17±9.22). The mean number of ClFU for patients before TKI treatment was 41.80±9.78 and was not significantly different from other groups ($p > 0.05$). As to colony to cluster ratio our results showed, that there is a correlation ($\rho = 0.67$) between CCR index and number of bone marrow cells with Ph-chromosome. To have a possibility of identification of cells, composing aggregates obtained in CFU assay, a positive correlation was also found between numbers of colonies, formed during cultivation in CFU assay and level of CD34+ cells in bone marrow ($\rho = 0.46$) and between number of clusters and CD33+ cells of bone marrow ($\rho = 0.76$). To evaluate changes in the differentiation potential of HSCs and HPCs that can be related to pathologic process of CML, we picked-up individual cells aggregates, formed during in vitro CFU assay of bone marrow mononuclear cells of CML patients. Cells, composing those aggregates were analyzed with calculation of maturation index (MI) for each individual sample. It was indicated, that MI correlates with level of bone marrow cells, containing Ph-chromosome. CFU assay is one of the standard methods used to identify functional properties of HSCs and HPCs of bone marrow. Our data indicated alteration of clonogenic activity of bone marrow hemopoietic cells for patients with different response to TKI treatment. Thus, CFU and ClFU numbers were increased in case of examination of bone marrow of patients before TKI treatment, so as for patients with suboptimal response and TKI treatment failure.
Summary/Conclusions: In summary, obtained results suggest that different mechanisms (BCR-ABL dependent and independent) may be involved in CML progression process in the same time. Disease prognosis should be preferably carried out on an individual basis.

Background: Development of a quantitative BCR-ABL monitoring assay with sensitivity down to 4.5 logs below baseline ($MR^{4.5}$) is important for patients being considered for tyrosine kinase inhibitor (TKI) discontinuation, and it is essential to ensure that variability in testing methodologies across laboratories is tightly controlled. Through analytical and clinical evaluations, Xpert BCR-ABL Ultra, an automated cartridge-based real-time qPCR BCR-ABL monitoring assay, has demonstrated sensitivity reaching $MR^{4.5}$, and every production lot of cartridges is assigned a unique conversion factor assuring substantial alignment to the WHO International Scale (*IS*).
Aims: Here we describe the implementation of a certified plasmid reference material (IRMM_ERM-AD623 BCR-ABL Calibrator) for the standardization of BCR-ABL mRNA quantification through copy number calibration to ensure sufficient BCR-ABL and ABL copies are present to support the $MR^{4.5}$ sensitivity claim for Xpert BCR-ABL Ultra.
Methods: To establish the correlation between Cycle threshold (Ct) reporting and copy number for BCR-ABL and ABL, and to understand the assay sensitivity limit in terms of relative copy number, the IRMM plasmid was used in a titration study involving three independent BCR-ABL Ultra assay lots. Based on the titration study, a copy number calibration curve was derived and used to estimate the copy number for BCR-ABL and ABL in analytical studies previously performed for CE registration, including the Linearity/Dynamic range, Analytical LoD and Clinical LoD studies.
Results: The results demonstrate that a linear detection range between $1x10^6$ copies down to 3 copies was achieved with 5 copies being detected in 24 out of 24 replicates and determined as the Limit of Detection (LoD) for both BCR-ABL and ABL. The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of ≥32,000 to support a claim of $MR^{4.5}$ and ≥100,000 for $MR^{5.0}$. This is explained by the fact that 4ml whole blood is used to prepare the sample lysate and an aliquot of which equivalent to 0.6ml whole blood is then processed completely in a fully automated and integrated GeneXpert system for nucleic acid extraction, target amplification, and quantification, resulting in improved target recovery. The%ratio of the derived BCR-ABL and ABL copy numbers was further calculated and compared to the original assay lot-specific%reporting (*IS*) per WHO calibration, revealing an unbiased correlation between%BCR-ABL/ABL (Copy number) and%BCR-ABL/ABL (*IS*) across the range 100% to 0.001% (*IS*). To validate the assay performance, Xpert BCR-ABL Ultra was further evaluated in field studies compared to three independent laboratory developed tests (LDTs) previously calibrated with the IRMM plasmid using either ABL or GUSB as control genes, demonstrating a correlation of >0.91, covering samples in the range 100% - 0.001% (*IS*).
Summary/Conclusions: These studies, using two different calibration systems (WHO/*IS* and IRMM/Copy number) and two different control genes (ABL and GUSB), carried out in four independent research labs, demonstrate, for the first time, good reporting correlation between%BCR-ABL/ABL (*IS*) and%BCR-ABL and ABL (Copy number) in Xpert BCR-ABL Ultra. Furthermore, these data demonstrate that from a typical clinical specimen, the BCR-ABL Ultra assay captures more than enough ABL copies to support a sensitivity claim of $MR^{4.5}$.

META-ANALYSIS OF THE RISKS OF ARTERIAL AND VENOUS OCCLUSIVE EVENTS WITH NEW GENERATION BCR-ABL TKIS IN PATIENTS WITH CHRONIC MYELOID LEUKAEMIA

H Haguet[1,2,*], J Douxfils[1], F Mullier[2], C Chatelain[1], C Graux[3], JM Dogné[1]

[1]Department of pharmacy, University of Namur, Namur, [2]Hematology laboratory, [3]Department of hematology, CHU UcL Namur, Yvoir, Belgium

Background: A recent meta-analysis demonstrated that 3 of the new generation BCR-ABL tyrosine kinase inhibitors (TKIs) (i.e. dasatinib, nilotinib and ponatinib) are associated with an enhancement of major molecular response without improving the overall survival at one year in patients with PH+ chronic myeloid leukaemia (CML) compared with imatinib. This study also highlighted their association with an increased risk of vascular occlusive events compared with imatinib but distinction between arterial of venous events was not assessed.
Aims: To perform a meta-analysis on the risk of arterial and venous occlusive events in patients with Ph+ CML treated with new generation BCR-ABL TKIs in randomized clinical trials (RCTs).
Methods: The literature search (data lock point: November 26, 2015) was conducted according to a registered protocol (PROSPERO 2014:CRD420140 14147). All RCTs comparing a new generation BCR-ABL TKI *versus* imatinib in patients with Ph+ CML were included. Two independent investigators were responsible of the screening, the review and the extraction of the data using standard forms. The meta-analysis was performed using a random (REM) and a fixed (FEM) effect model according to the characteristics of the included studies. ORs with 95% CIs were computed using the Peto method. Statistical heterogeneity was quantified using the I^2 value, and publication bias was assessed by funnel plots.
Results: Among the 400 abstracts identified, 12 studies fulfilled the established criteria and were included in the statistical analysis. Overall, 4.47% (99/2,217) of patients developed arterial occlusive events with new generation BCR-ABL TKIs compared with 0.80% (15/1,884) with imatinib (REM OR_{PETO}: 3.46; 95%CI: 2.35 to 5.10). Ponatinib (REM OR_{PETO}: 3.26; 95%CI: 1.12 to 9.50), nilotinib (REM OR_{PETO}: 3.60; 95%CI: 2.21 to 5.86) and dasatinib (REM OR_{PETO}: 3.32; 95%CI: 1.37 to 8.01) are associated with higher risk of arterial occlusive events than imatinib. No significant difference was found with bosutinib. Venous occlusive events occur in only 0.86% (13/2,217) of patients treated with new generation TKIs and in 0.16% (3/1,884) of imatinib-treated patients. Overall, new generation TKIs increase the rate of venous occlusive events (REM OR_{PETO}: 2.85; 95%CI: 1.04 to 7.78) but stratifications by treatment provided nonsignificant results. Funnel plots demonstrate no evidences of publication bias, and the I^2 statistic specifies no heterogeneity among studies. Limitations of this meta-analysis include the absence of a time-to-event analysis and the inconsistent report of cardiovascular events in the literature. However, the use of a clinical trial register aimed to decrease this heterogeneity.
Summary/Conclusions: The increased risk of vascular occlusive events associated with new generation BCR-ABL TKIs is mainly driven by thrombotic events occurring at the arterial side. Additional investigations are required to assess the underlying pathophysiological mechanisms and provide appropriate risk minimization measures.

Sacco, [16]REL Scientific Coordinator, Lombardy Hematology Network, Milano, Italy

Background: CML is a clonal disorder characterized by the presence of the Philadelphia (Ph) chromosome which encodes for the bcr-abl tyrosine-kinase (TK). Target therapy with the TK inhibitor (TKI) imatinib (IM) has greatly improved outcome in CML; however, only a minority of responsive pts can discontinue treatment without relapsing in the short term and even less pts can be considered free of disease. This data probably relates to persistence of quiescent CD34+Ph+ stem cells (SC) whose persistence has been documented even among pts in optimal response (Bocchia et al, 2008). Compared to IM, faster and deeper responses in CP-CML pts can be achieved with the second generation TKI Nilotinib (NIL); however, only preliminary data are available on NIL potential to eradicate Ph+ SC. Moreover, in vitro studies (Corbin AS, et al 2011; Hamilton A, et al 2012) suggest that CD34+Ph+SC may not be sensitive to TKI-mediated Bcr/Abl inhibition. However, *in vivo* data (Defina et al, 2012) have shown that, compared to IM treated pts, residual leukemic SC are very rarely detected among NIL treated pts in CCyR even after short-term NIL therapy and even if duration of treatment is shorter for NIL compared to IM treated pts (median 39 *vs* 22 mos). At present, no clear evidence of TKI effect on the leukemic SC clearance is available.
Aims: On behalf of the Rete Ematologica Lombarda (REL), the PhilosoPhi34 protocol (EudraCT: 2012-005062-34), an open label, single arm, phase II study, was designed to investigate the efficacy of NIL 300 mg BID in BM CD34+/lin-Ph+cells clearance at 3, 6 (primary objective) and12 months of treatment in newly diagnosed CP-CML pts.
Methods: Enrolled pts' BM cells were collected and stored at diagnosis and at 3,6 and 12 mos of treatment. CD34+/lin- cells were purified using a Diamond CD34 Isolation Kit Miltenyi (97% of purity). FISH analysis of selected unstimulated CD34+/lin- cells was performed according to standard method; considering the low sensitivity of the test, at least 200 nuclei were examined in order to define the test as negative. This phase II study was designed according to the A'Hern single stage design, where, at 6 mos, we assumed a proportion defining a poor response as PP=0.10, and the proportion defining a good response as PG=0.30, PA being the proportion of responders.The study required 41 subjects to decide, with a power of 95%, whether PA ≤0.10 or PA ≥0.30. To have 41 evaluable, 87 pts had to be enrolled, considering 80% of them being fully analysed and 60% of these reaching CCyR (according to ENESTnd data).
Results: Enrolment of 87 pts was completed by June 2015; the database hasn't been locked yet. At present, FISH analysis on CD34+/lin- cells at 6 mos of treatment is evaluable for 68 of 75 pts with a documented CCyR; 7 negative tests were not evaluable since less than 200 nuclei were analysed. Only 5/68 (7,3%) evaluable FISH tested positive. Results at 3 and 12 mos are as follows: 8/58 (13,8%) and 0/46 (0%) evaluable FISH respectively tested positive (7 and 6 negative test excluded respectively). Sokal score did not predict for FISH positive results at any time point.
Summary/Conclusions: These results strongly point to a role for NIL 300 mg BID in fast clearance of BM CD34+/lin-Ph+ cells in a high proportion of treated pts. In view of the potential clinical relevance of our data, the protocol was amended in order to revise our FISH data using a test with higher sensibility and specificity, i.e.: the gDNA PCR. These results might give insight into a possible correlation with depth and stability of molecular response.
We acknowledge all REL Colleagues for their collaboration and Novartis SpA for the partial financial support to the study.

MEANING OF MOLECULAR RESPONSES FLUCTUATION IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH LONG-TERM IMATINIB

M Breccia[*], M Molica, G Colafigli, L Quattrocchi, R Saracino, R Latagliata, M Mancini, D Diverio, G Alimena
Dept Cellular Biotechnologies and Hematology-Sapienza University, Hematology, Rome, Italy

Background: Prognostic significance of molecular response fluctuation in the long-term outcome during imatinib treatment in chronic phase chronic myeloid leukemia (CP-CML) patients have not been so far reported in details.
Aims: Aim of our study was to correlate, over a median follow-up period of 7 years, how instability of molecular response can affect overall survival (OS) and failure-free survival (FFS).
Methods: A series of 208 patients treated with imatinib first-line was retrospectively analysed. There were 144 males and 94 females, median age was 57.7 years. According to the IS, we considered as MR3 a BCR-ABL/ABL ratio of ≤0.1%, as MR4 a ratio ≤0.01% and as MR4.5 a ratio ≤0.0032%; stable response was defined as a response that persisted over 3 consecutive RQ-PCR tests, whereas fluctuation, was defined as the alternation of a test that reached or was below the threshold ratio according to IS and the consecutive was above the threshold. We considered OS the time elapsed from diagnosis to death for any cause, and FFS the timespan that follows therapy without signs of recurrence (loss of hematologic and/or cytogenetic response, acquisition of clonal cytogenetic abnormalities or mutations).
Results: At a median follow-up of 7 years, overall incidence of MR3 was 64.4%: during the course of treatment, 17 patients (11.6%) had a fluctuation above and then below the cut-off of 0.1%. Of these 17 patients, 13 (76%) lost the response and 3 subsequently developed secondary resistance (17.6%) with an estimated FFS of 82.4% and an OS of 94.6% at 7 years. Considering the threshold of MR3, of the remaining 117 patients that never had a fluctuation and maintained a stable response over time, only 3 (2.5%) subsequently lost the response and developed secondary resistance with an estimated FFS of 93.2% (p=0.02) and OS of 94% (p=ns). All patients were analysed for mutational screening according to Sanger sequencing analysis: only two patients were found to develop a mutation of the ABL1 kinase domain, in particular 1 patient a E255K and 1 patient a M351T. Cumulative incidence of MR4 was 51% and of MR4.5 was 34.6%, obtained after a median time of 3.8 and 5.4 years, respectively. Overall, 7 patients (6.5%) showed a fluctuation of MR4 response and 4 subsequently lost the response. None of these patients showed secondary resistance or acquired mutations in the ABL kinase domain and main reason

for loss of response was confirmed to be low adherence to long-term treatment. Eighteen patients (25%) showed an unstable MR4.5, but none of them developed secondary resistance or progressed to blast phase. Considering the threshold of MR4, fluctuation of molecular burden was associated to FFS of 100% and to OS of 98.2% as compared to patients with stable response that had a FFS of 99.4% and OS of 97.8%, without any statistical significance.
Summary/Conclusions: Our results showed that unstable MR3 was indeed associated to an increased probability to develop resistance, whereas long-term fluctuation of deeper molecular response (MR4-4.5) did not influence the long-term outcome of CML patients treated with imatinib.

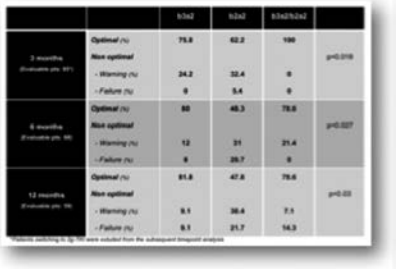
E1099

BCR-ABL FUSION TRANSCRIPT B2A2 IS ASSOCIATED WITH A HIGHER RISK OF NON-OPTIMAL EARLY RESPONSE IN CP-CML PATIENTS TREATED WITH STANDARD DOSE IMATINIB: A STUDY FROM GRUPPO TRIVENETO LMC

G Binotto[1,*], M Tiribelli[2], M Bonifacio[3], L Frison[1], M Narbergoj[1], F De Marchi[2], L Scaffidi[3], M Medeot[2], E Maino[4], E Calistri[5], A Bonalumi[3], M Krampera[3], A Ambrosetti[3], R Fanin[2], G Semenzato[1]
[1]Department of Medicine, Hematology and Clinical Immunology, Padua University School of Medicine, Padova, [2]Division of Hematology and Bone Marrow Transplantation, Department of Experimental and Clinical Medical Sciences, AOU Udine, University of Udine, Udine, [3]Department of Medicine, Section of Hematology, University of Verona, Verona, [4]Hematology Unit, Dell'Angelo Hospital, Venezia-Mestre, [5]Hematology Unit, Ca' Foncello Hospital, Treviso, Italy

Background: The clinical significance of BCR-ABL transcript type in the tyrosine kinase inhibitors (TKI) era has recently been debated. However, few data concerning the impact of different BCR-ABL transcripts on early response dynamics in chronic phase-chronic myeloid leukemia (CP-CML) patients treated with standard dose imatinib (IM) have been reported.
Aims: To evaluate the probability of optimal response at early timepoints, according to different p210 BCR-ABL1 transcripts, in a real life population of CML-CP patients treated with standard dose front-line imatinib.
Methods: 93 CP-CML patients treated with IM 400 mg daily, diagnosed from 2010 to 2015 were retrospectively analyzed. The type of BCR-ABL1 transcript was determined by multiplex RT-PCR at diagnosis. Molecular monitoring was performed with quantitative RT-PCR and results were expressed in International Scale (IS) values. Optimal, warning and failure categories were analyzed according to the 2013 ELN recommendations. Frequencies were compared by chi-squared test ($\chi 2$) or Fisher's exact test. Progression-free survival (PFS) was calculated from the start of IM to ABP or death. Overall survival (OS) was calculated from the start of IM to death.

Table 1. Response rates at 3, 6 and 12 months according to BCR-ABL trascript type.



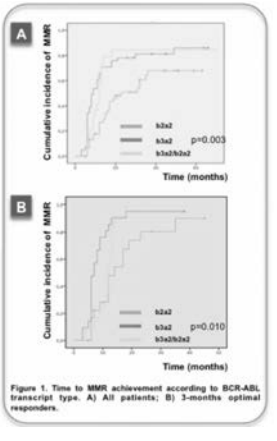


Figure 1. Time to MMR achievement according to BCR-ABL transcript type. A) All patients; B) 3-months optimal responders.

Figure 1.

Results: Patients with b3a2, b2a2, b3a2/b2a2 BCR-ABL transcript were 44.1%, 36.6% and 19.4%, respectively. The cohorts were comparable for age, sex and risk score (both Sokal and Eutos). Forty-three patients (46.2%) moved to second generation TKI (2GTKI), 24 (55.8%) due to primary or acquired cytogenetic or molecular resistance, 19 (44.2%) for intolerance. Rates of optimal *vs* non optimal response at 3 months were different between b3a2 *vs* b2a2 *vs* coexpressed transcript groups (75.8% *vs* 62.2% *vs* 100% respectively, p=0.018). Interestingly, all failures at 3 months were observed in the b2a2 group (Table 1). At 6 months, optimal responses were documented in 80% *vs* 48.3% *vs* 78.6% of b3a2, b2a2 and b3a2/b2a2 group, respectively (p=0.027); 60% of warnings and 75% of failures were associated to b2a2 transcript. At 12 months timepoint, major molecular response **(**MMR) rate was significantly different between transcripts (81.8% *vs* 47.8% *vs* 78.6% respectively, p=0.03). 52% of treatment changes within 12 months, either for resistance or intolerance, were observed in the b2a2 group. Differences in early response did not translate into inferior cumulative incidence of complete cytogenetic response (CCyR) (93.9% *vs* 82.1% *vs* 83.3% respectively, p=0.30) or different time to CCyR achievement. Patients with b3a2 and b3a2/b2a2 transcript had comparable rates of cumulative MMR (81.8% and 88.9%, respectively), superior to b2a2 patients (66.7%, p=0.12) with a significantly faster time to MMR achievement, either on IM treatment or with sequential IM+2GTKI approach (Figure 1A). Notably, among optimal responders at 3 months, MMR was obtained significantly later by patients with b2a2 transcript (Figure 1B). Long term outcomes (PFS, OS) were not affected by transcript type.
Summary/Conclusions: This retrospective analysis suggest a different kinetics of early optimal response achievement based on transcript type, with inferior rates in patients expressing b2a2. However, this difference did not translate into unfavourable clinical outcome. Longer time to MMR among optimal responders presenting with b2a2 could partially account for the negative impact of this transcript type on stable deep molecular response, previously observed by our group.

Maria alle Scotte Hospital, University of Siena, Siena, [15]Universita'" Sapienza", Rome, [16]IRCCS Ca' Granda - Maggiore Policlinico, Milano, [17]University of Bologna, Bologna, [18]Ucsc, Rome, Italy

Background: Chronic myeloid leukemia (CML) is the result of t(9;22) balanced translocation and/or presence of BCR-ABL1 fusion gene. Usually CML presents with marked leukocytosis and only in rare cases CML can present at the diagnosis with an isolated and marked thrombocytosis, defined as platelet count >1000x10^9/L. There are no data on the optimal treatment of these subcategories of "theoretically high risk" patients in the era of tyrosine kinase inhibitors (TKIs).
Aims: To identify a specific subset of CML chronic phase patients with extreme thrombocytosis (platelet count >1000x10^9/L) at diagnosis and to assess clinical outcomes: overall survival, progression free survival and cumulative response in terms of CCyR and/or MMR at 12 and 24 months
Methods: Data were collected and evaluated through the analysis of 1591 CML CP patients registered in 16 Italian Haematological Departments from January 2002 to December 2015
Results: The incidence of extreme thrombocytosis at diagnosis was 5,4% (87/1591). Median age was 59 years (range 18-87), F/M 63/24. Median spleen size below the costal margin was 0 cm (range 0-15), and liver size below the costal margin was 0 cm (range 0-3). Median white blood cell count was 31.600x10^6/microl(range 6.340-390.000), median haemoglobin level was 11,8 g/dl (range 7,7-16,3), and median platelet count was 1466x10^9/L. (range 1054-4720). Sokal score was low in 6 patients (6,8%), intermediate in 23 (26,4%) and high in 55 (63,2%). Hasford score was low in 17 patients (22%), intermediate in 22 (28,6%) and high in 38(49,42%) out of 77 evaluable cases. Coagulation tests were available in 59/87 (67,8%), and aPTT was abnormal in only three patients (5%). Bleeding time test was available only in 5 patients and was prolonged in all of them (median value 41 sec1"). Iron assessment was reported in 56 out of 87 patients and was consistent with iron deficiency in 7 patients (12,5%); assessment of the, JAK2V617F mutation was performed in 43 (49,4%) patients. At diagnosis, 9 out of 87 (10.3%) patients showed haemorragic or thrombotic complications, with only 3 of grade >2 according to the NCI-CTC.In order to reduce severe thrombocytosis, 73/87 patients (83%) received hydroxyurea before starting TKI and in two patients thrombocyta-

pheresis was reported[s1]. As first line TKI 63/87 (72,4%) patients received imatinib, 16 (18,4%) dasatinib and 8 (9,2%) nilotinib.Seventy-seven out of 87 patients were evaluable after 12 months of treatment, and 67 of 77 (87%) obtained cCyR or major molecular response (MMR). Sixty-seven patients were evaluable at 24 months of treatment and 51 out of 67 (76,1%) were in cCyR and/or MMR. After a median follow-up of 66 months (range 3-179), 81/87 (93,1%) patients are still alive. Six patients (6,9%) died: two from myocardial infarction, three from concomitant neoplasia, and one from GvHD.Nine (10,3%) patients developed primary resistance to imatinib and they were shifted to the second line. Eight additional patients developed secondary resistance, mainly after imatinib

Summary/Conclusions: The incidence of extreme thrombocytosis in CML chronic phase is rare;this subset of patients shows the following peculiarities: predominance of female sex, high or intermediate risk score with a favourable outcome in terms of both cumulative response rate and survival, low incidence of thrombotic/haemorragic risk[s1]. Due to the inclusion of patients prior to the acquisition of JAK2 V617F in the differential diagnosis of thrombocytosis, only half of the patients were assessed for this mutation

E1101

BCR-ABL1 TRANSCRIPT LEVEL HALVING TIME IS THE ULTIMATE PROGNOSTIC FACTOR FOR ACHIEVING MAJOR AND DEEP MOLECULAR RESPONSE IN CML PATIENTS

M Gniot*, K Lewandowsk, M Iwoła, M Lewandowska, A Lehmann-Kopydłowska, A Balcerzak, R Kroll-Balcerzak, M Joks, M Komarnicki
Hematology, Poznan University of Medical Sciences, Poznań, Poland

Background: Since 2012, the dynamics of early molecular response to tyrosine kinase inhibitor (TKI) treatment is being considered a very useful prognostic factor for further outcome of chronic myeloid leukemia (CML) patients. Two ways of determining dynamics of response are being used: *BCR-ABL1* transcript level at 3rd month of the therapy and individual transcript reduction rate, expressed as *BCR-ABL1* halving time (HT).
Aims: The goal of this analysis was to determine whether *BCR-ABL1* transcript level at third month or *BCR-ABL1* HT is more useful for predicting the molecular responses. Another aim was to perform the analysis using *GUSb* as a reference gene, which should provide more accurate results for high *BCR-ABL1* transcript level samples.
Methods: The analyzed group consisted of 96 patients diagnosed with CML in Faculty of Hematology and Bone Marrow Transplantation at Poznań Medical University, who were monitored and treated according to ELN recommendations. The *BCR-ABL1* transcript level assessment was performed using an in-house method with *GUSb* as a reference gene. The method is being validated on a regular basis in the reference laboratory in Adelaide, and in 2014 was positively validated for MR4.5 assesment (ELN/EUTOS performance evaluation). Statistical analysis was made using Statistica 10. All analyses were performed only in patients with full clinical documentation, non-degraded pre-treatment sample and at least 3 years of follow up. The Kaplan-Meier analyses of MMR, MR4 and MR4.5 were performed for groups divided by *BCR-ABL1* halving values (5-40 days interval). The frequencies of molecular responses in 12th, 24th and 36th month of therapy were aggregated in tables and the graphs showing MMR, MR4 and MR4.5 in selected time points depending on HT cut-off values were plotted.

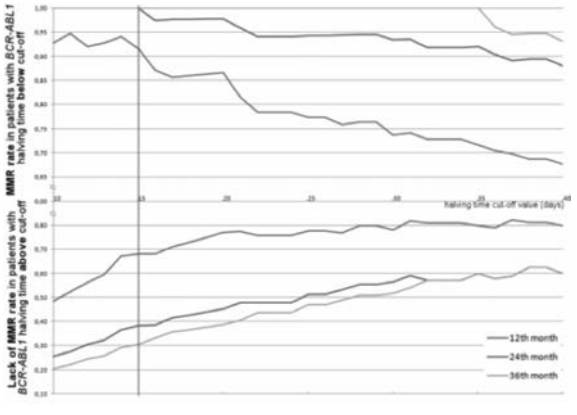

Figure 1.

Results: The *BCR-ABL1* transcript level at 3rd month was proven to have a limited prognostic value. The values greater than 10% and lower than 1% have significant prognostic implications; the interval between 1 and 10% (49% of our patients) does not predict any molecular outcome. On the other hand, the *BCR-ABL1* HT of 15 days was proven to be a great predictor of MMR, MR4 and MR4.5. 91,5% of patients with HT shorter than 15 days achieved MMR by 12th month of treatment (100% by 24th and 36th month). In case of deep molecular responses, 61,1% achieved MR4 after a year of treatment (83,3% by 24th and 94,4% by 36th month) and 33,3% MR4.5 after twelve months of TKI therapy (80,5% by 24th and 83,7% by 36th month). The molecular outcome of patients with *BCR-ABL1* HT greater than 15 days was significantly worse: 31,8%, 61,7% and 69,4% had MMR by 12th, 24th and 36th month of therapy, respectively. Moreover, the frequency of deep molecular responses was also significantly lower: 9,1%, 36,5% and 41,4% for MR4 and 4,5%, 16% and 28,8% for MR4.5, respectively.
Summary/Conclusions: Our results confirmed that the use of *GUSb* as a reference gene allows precise evaluation of transcript level at the beginning of the treatment and probably increases the prognostic value of *BCR-ABL1* HT. The *BCR-ABL1* HT below 15 days is an accurate predictor of molecular response for TKI treated CML patients. The response to the therapy is so good that the surrogate endpoint such as MMR is achieved by vast majority of them, regardless of the initial response dynamics. The *BCR-ABL1* HT greater than 15 days also predicts significantly lower molecular response rates, especially MR4 and MR4.5. It is worth pointing out that the proposed *BCR-ABL1* HT cut-off is applicable to the entire group of patients and allows for early identification of potential non-responders.

E1102

MEASUREMENT OF BCR-ABL1 BY RT-QPCR IN CHRONIC MYELOID LEUKAEMIA: FINDINGS FROM AN INTERNATIONAL EQA PROGRAMME

S Scott[1,*], D Travis[1], L Whitby[1], J Bainbridge[2], N Cross[3,4], D Barnett[1]
[1]UK NEQAS for Leucocyte Immunophenotyping, Sheffield Teaching Hospitals NHS Trust, Sheffield, United Kingdom, [2]Duke Human Vaccine Institute, Duke University Medical Center, Durham, United States, [3]Wessex Regional Genetics Laboratory, Salisbury District Hospital, Salisbury, [4]Faculty of Medicine, University of Southampton, Southampton, United Kingdom

Background: *BCR-ABL1* measurement by RT-qPCR is integral to both the diagnosis and monitoring of Chronic Myeloid Leukaemia (CML), and has been central to the remarkable improvement in patient outcomes seen in this disease. As an ISO 17043 accredited international provider of External Quality Assessment (EQA)/Proficiency Testing (PT) in this area, UK NEQAS for Leucocyte Immunophenotyping (UKNEQAS LI) has a unique perspective on the evolving field of *BCR-ABL1* testing in CML by having access to participants' technical data.
Aims: To assess the impact of technical standardisation and the development of the International Scale (IS) on the accuracy of *BCR-ABL1* testing, by reviewing our EQA trial data.
Methods: We analysed all trial data submitted to UKNEQAS LI that could be meaninfully compared between 2007 and 2015 (16 trial issues, 32 samples). In order to normalise the log normal EQA data, and allow the application of parametric statistics, a constant was applied to all participant data before log10 transformation. Robust statistics were used to assess variation, including the exclusion of outliers as per Algorithm A from ISO 5725-5. Whilst variation was calculated using log transformed data, where a meaningful data midpoint was required, medians were used because log transformed means (geometric means) are difficult to interpret and back transforming log transformed means is not recommended as it leads to underestimation.
Results: Comparison of participant results identified considerable variability at high and low levels of disease, including current and proposed therapeutically important levels. Despite rapid adoption of the IS by laboratories, and the fact that we have shown lower standard deviations in our IS data sets when compared to our unconverted data sets, suggestive of decreased variability, a statistically significant difference in variation between our unconverted and IS data sets could not be proven. We found that different methods of converting to the IS are producing consistently different median results within UKNEQAS LI IS data sets.

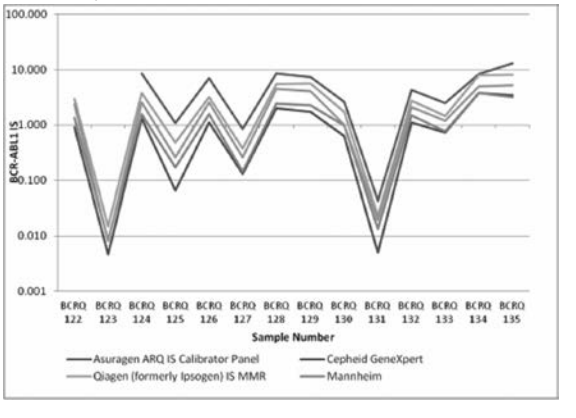

Figure 1.

Summary/Conclusions: To allow better quantification of 'Early' and 'Deep' Molecular Response to fully realise the benefits of improved treatment regimens our data suggests that further refinement of RT-qPCR protocols, or perhaps a

switch to new technologies such as droplet digital PCR, will be required. The finding that different methods of converting to the IS are producing consistently different median results suggests the need for a review of the process of converting to the IS.

E1103

VERY EARLY MOLECULAR RESPONSE AT 1 MONTH CAN PREDICT 12-MONTH MAJOR MOLECULAR RESPONSE IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA TREATED WITH TKIS

HY Song[1,*], SY Choi[1], SE Lee[1,2], SH Kim[1], HL Yoo[1], MY Lee[1], HJ Hwang[1], KH Kang[1], KM Kee[1], DW Kim[1,2]
[1]Catholic Leukemia Research Institute,The Catholic University of Korea, [2]Department Hematology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Imatinib (IM) has been the standard of care for chronic phase (CP) chronic myeloid leukemia (CML). Recent studies have demonstrated that BCR-ABL1 transcript levels at 3 and 6-month of front-line therapy is a useful predictor of long-term outcomes. Neelakantan *et al(Blood 2013; 121:2739-42).* found that the prognostic value of the 3-month early molecular response (EMR) could be improved by combining the 3- and 6-month results, but suggested that the 3-month EMR had superior prognostic value than the 6-month EMR so early interventions could be determined based on the 3-month result. However, prognostic value of very early molecular response (VEMR) have not been fully defined.
Aims: In this study, predictive value of BCR-ABL1^{IS} at 1 month after front-line therapy for an achieving MMR at 12 months was evaluated. In addition, the difference of prognostic role of VEMR in IM group and 2G TKI group were compared.
Methods: With a data cut-off date of 20 Feb 2016, among 223 newly diagnosed CP CML patients who received IM (N=127) and 2G TKI (N=96) treatment and had molecular data at 1 month, 98 patients in IM group and 65 patients in 2G TKI group with at least 1 year of follow-up and available RQ-PCR at 12 months were included. Based on receiver operating characteristic (ROC) curve analysis, the predictive cutoffs of BCL-ABL1 transcripts at 1 month for achieving MMR at 12 months in IM group and 2G TKI group were evaluated. All RQ-PCR were tested with at least 4.5-log sensitivity in the central laboratory (Catholic Leukemia Research Institute, The Catholic University of Korea, Seoul, Korea).
Results: A total of 163 patients (101 men and 62 women) were analyzed. With a median age of 44 years (range, 18-81 years), the distribution of low, intermediate, and high Sokal risk scores were 41%, 39%, 20%. 36 (37%) of 98 patients in IM group and 46 (71%) of 65 patients in 2G TKI group achieved MMR at 12 months of front-line treatment. The predictive cutoffs of BCR-ABL1^{IS} level at 1 month for achieving MMR at 12 months were 42.57% (sensitivity 66.67%, specificity 56.45%, AUC 0.585(0.481-0.684), P=0.1617)and 38.41% (sensitivity 84.78%, specificity 89.47%, AUC 0.846(0.734-0.923), P=0.0001)in IM group and 2G TKI group, respectively based on ROC curve analysis. In IM group, 24(47%) of 51 patients with ≤42% and 12(25%) of 47 patients with >42% achieved 12-month MMR respectively (P=0.027). In 2G TKI group, 39(95%) of 41 patients with ≤38% and 7(30%) of 24 patients with >38% achieved 12-month MMR respectively (P<0.001).
Summary/Conclusions: Our results demonstrated that VEMR is a predictor for an achieving 12-month MMR in both IM-group and 2G TKI group. Specially, 38.4% cutoff in 2G TKI group showed higher sensitivity and specificity, compared with those of IM group.

E1104

PONATINIB EVALUATION AND SAFETY IN REAL LIFE CHRONIC PHASE (CP) CML PATIENTS FAILING ≥2 TYROSINE KINASE INHIBITORS (TKI): UPDATE OF THE PEARL OBSERVATIONAL STUDY

FE Nicolini[1,*], M Heiblig[1], D Caillot[2], A Charbonnier[3], P Rousselot[4], V Coiteux[5], M Escoffre-Barbe[6], V Dubruille[7], F Huguet[8], F Guilhot[9], E Hermet[10], A Guerci-Bresler[11], S Amé[12], P Mouchel[13], L Roy[14], S Morisset[1], G Etienne[15], D Rea[16]

Background: Ponatinib (PON) induces high response rates in heavily pretreated CML patients (pts) failing TKIs. A substantial proportion of pts on PON [17% by 3 years, J. Cortes, Haematologica 2015] experience severe arterial thrombotic events (ATE). The impact in the real-life setting of this recently licensed agent is unknown yet.
Aims: We analyzed the French PON compassionate use program (19/04/2012-30/09/2013) to evaluate outcomes in the real-life setting.
Methods: Multicenter observational retrospective study to examine safety and efficacy of PON in CML failing TKIs, benefiting from the national PON compassionate use program. Data collection followed the regulations of observational studies in France. Pts were analyzed in intention-to-treat. Molecular biology tests were expressed as *BCR-ABL/ABL* (%IS) in all centers. Standard clinical data, cardiovascular risk factors (CVRF), onset of any CV events (before and during PON treatment) and metabolic biological parameters were captured.
Results: 48 patient records were collected in CP, 5 in AP and 6 in BC. We focused our analysis on CP pts only. There were 24 (50%) males, median age of 53 (18-76) years at CML diagnosis and 60 (20-82) years at PON initiation. Sokal scores were high in 15 (31%), intermediate in 17 (35%), low in 6 (12%) and unknown in 10 (22%) pts. Fifteen pts (31%) were treated for hypertension, 2 were diabetic, 11 (23%) had dyslipidemia (all on statins), tobacco abuse was present in 19 (39%) pts (1 unknown) and 21 (44%) pts had some pre-existing cardiovascular risk factors (CVRF) in total prior to PON. Median weight was 66 (50-107) kg, and BMI was 24 (17.85-43) kg/m^2. Fifteen (31%) pts (3 unknown) were on anti-aggregants or anti-coagulants (AAG/C) before PON. Two pts had nilotinib, 4 dasatinib and all other pts had imatinib first-line for a median of 22 (2-132) months, 25 (52%) dasatinib and 20 (42)% nilotinib for 14 (0.5-64) months, as second-line, 4 pts developed a T315I mutation after imatinib only; 29 (60%) had received all 3 TKIs prior to PON. At PON initiation, 11 (23%) harbored a T315I mutation, 9 (19%) other mutation(s), 24 (50%) none (3 not done). The trigger for PON was resistance in 34 (71%) pts, intolerance in 11 (23%) pts and both in 3 (6%) pts. Pts were initiated at a median of 45 (15-45) mg daily after a median of 73.5 (17-217) months of disease duration. The median follow-up was 26.5 (2-42) months since PON initiation, and 102.5 (27-230) months since diagnosis. Median time on PON was 19 (0.13-41.79) months. Eight pts died, 6 of disease progression, 1 of myocardial infarction and 1 of PAOD-related complications. The probability of OS was 81.5 (70.5-94)% at 36 months (Fig. 1a) with no influence of the presence of mutations or reason for PON prescription. Overall, the cumulative incidence of MMR was 55 (35-73)% at 18 months. Seven (14.5%) pts had hematologic AEs imposing transient PON withhold, and 19 (40%) diverse grade 1-2 non-hematologic, non-CV AEs (pancreatic, hepatic, skin toxicities, no grade 3-4). Significant CV AEs (including hypertension) occurred in 29 (60%) pts after a median of 5.8 (0.1-25.4) months of PON (Fig 1b), in 11 pts without CVRF. Eight thrombotic events occurred (3 heart strokes, 2 brain strokes, 1 PAOD, 2 DVT). Of note, 3 thrombotic AEs occurred on AAG/C. Lipids and HbA1c do not seem to be modified on PON. At last follow-up 22 (46%) pts are still on PON.

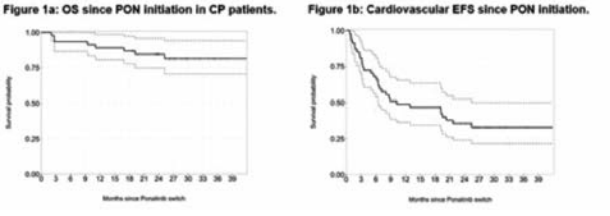

Figure 1.

Summary/Conclusions: In this real-life setting, CP-CML patients resistant or intolerant to previous TKIs, PON still displayed strong efficacy, ATEs represent the main adverse factor observed.

Elia, Caltanissetta, [19]Unit of Medical Oncology, A.O.U. University Hospital "Vittorio Emanuele", University of Catania, Catania, [20]Department of Hematology and Oncology "L. and A. Seràgnoli", University of Bologna, Bologna, Italy

Background: The main academic-and company-sponsored studies of the treatment of CML with TKIs focus on the results achieved with only one TKI, in single-arm trials or in randomized trials comparing two TKIs as first line treatment. After the discontinuation of the study drug, few data on further treatments are collected. In real life and in many countries, for several years imatinib has been used as first-line treatment, but nilotinib and dasatinib have been available and used as second-line therapy.
Aims: To investigate the response and the outcome on first-line imatinib, with switch to 2nd generation tyrosine kinase inhibitors (TKIs) in case of failure or toxicity, in BCR-ABL1+ chronic myeloid leukemia (CML) patients enrolled in a population-based registry (real-life setting).
Methods: From a cohort of 337 consecutive, unselected, newly diagnosed, adult, chronic phase, Ph+, BCR-ABL1+, CML patients who were registered according to population-based criteria in two Italian Regions (Emilia-Romagna and Sicily) between 2008 and 2012, we identified 236 patients who were treated with imatinib 400 mg once daily in first-line. The decision to switch to second-line treatment was up to the Local Investigator (no predefined criteria) Definitions: major molecular response (MMR): BCR-ABL1^{IS} ratio<0.1%; MR4.0: BCR-ABL1^{IS} ratio<0.01% with >10,000 ABL1 copies; failure and suboptimal response: according to 2009 European LeukemiaNet (ELN) criteria; progression: transformation to advanced phases according to ELN criteria; leukemia-related death (LRD): death after progression.
Results: Sokal risk distribution was 29% low, 47% intermediate, and 24% high. Median age was 60 years at diagnosis and 64 years at last analysis, with a median follow up of 4 years. 145 patients (61%) received only imatinib, 57 (24%) were switched to 2nd generation TKIs for failure, and 34 (14%) were switched to 2nd generation TKIs (n=31) or to Hydroxyurea (n=3) for toxicity. The median time to switch was 20 months for failure and 8 months for toxicity. After the switch, the molecular response improved of 1 to 3 logs in 57% of patients. Molecular responses and outcomes are shown in the Table. Eleven patients (5%) progressed to blast phase, and all of them died, but one. The 5-year leukemia-related survival was 95%. The 5-year overall survival was 89%, with 6% of patients dying in major molecular remission or in chronic phase, without any evidence of progression. Noticeably, 48% of living patients had achieved MR 4.0 (BCR-ABL 1 ≤0.01% IS) by 4 years (including first- and second-line treatment).

Table 1.

No. of patients	236
Early molecular response (BCR-ABL1 ≤ 10% at 3 months)	80%
Major molecular response (BCR-ABL 1 ≤ 0.1%) at 1 year	55%
Major molecular response (BCR-ABL 1 ≤ 0.1%) at 2 years	69%
Major molecular response (BCR-ABL 1 ≤ 0.1%) at 4 years	75%
MR 4.0 (BCR-ABL ≤ 0.01%) at 1 year	24%
MR 4.0 (BCR-ABL ≤ 0.01%) at 2 years	40%
MR 4.0 (BCR-ABL ≤ 0.01%) at 4 years	48%
Failure and suboptimal response$^{\Phi}$ (including progression)	23%
Progression to blast phase/death in blast phase$^{\Phi}$	5%
Death in remission or in chronic phase $^{\Phi}$	6%
$^{\Phi}$as defined by European LeukemiaNet 2009	

Summary/Conclusions: A policy of imatinib first-line with switch to 2nd generation TKIs for failure or toxicity, as recommended by European LeukemiaNet 2009, in an unselected (median age 60 years) cohort of patients registered according to population-based criteria showed a high efficacy.

E1106

THE ALTERATION OF IMMUNOPROFILE DURING DASATINIB TREATMENT IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA: A PROSPECTIVE OBSERVATIONAL STUDY

M Kuno*, H Nakamae, T Katayama, M Nishimoto, Y Hayashi, A Hirose, M Nakamae, Y Nakashima, H Koh, T Nakane, M Hino
Hematology, Graduate School of Medicine, Osaka City University, Osaka, Japan

Background: Some chronic myeloid leukemia (CML) patients treated with dasatinib develop lymphocytosis with an expansion of large granular lymphocytes (LGLs) and natural killer (NK) cells. The lymphocytosis is known to be related to a better response to dasatinib therapy and survival. However, it has been not elucidated whether increased lymphocytes harbor an effective immunological and/or anti-tumor activity.
Aims: The aims of this prospective study were 1) to evaluate changes of NK-cell reactivity and soluble factors and 2) immune cell counts by dasatinib therapy in treatment naive CML patients and those who were treated with dasatinib beyond the first line therapy.
Methods: Thirty patients with CML in chronic phase who started tyrosine kinase inhibitor (TKI) as the first-line treatment or switched to the other TKI were enrolled in this study between September 2010 and December 2013 at our institute. TKIs were; dasatinib (as first line n=7, beyond first line n=12), imatinib (as first line n=3), nilotinib (as first line n=2, beyond first line n=6). We analyzed peripheral blood samples collected from patients at enrollment, 1, 3, 6 and 12 months after the initiation of treatment to determine cell counts, lymphocyte subset (such as NK cells, NK-LGLs, T-LGLs and regulatory T cells) immunophenotyping by flow cytometry, NK cell activity and plasma levels of 27 soluble factors.
Results: The number of lymphocytes, NK cells, T-LGLs and NK-LGLs significantly increased in patients treated with dasatinib (all P<0.01). NK cell activity at effector to target (E: T) ratios of 10: 1 and 20: 1 significantly elevated in patients with dasatinib as the first-line treatment (P<0.01) and beyond first-line treatment (P<0.01). The levels of NK cell activity at diagnosis were below the normal level in all treatment naive CML patients and elevated above the normal level at 12 months after the dasatinib therapy in more than half of the patients. In addition, NK cell activity was significantly negatively correlated with BCR-ABL mRNA transcript levels in the dasatinib group (r= -0.304, P=0.011) but not in patients treated with imatinib or nilotinib. A significant association was found between the numbers of T-LGL before and 3 months (P<0.01), and before and 6 months after dasatinib therapy (P<0.01). There were no significant change in counts of any immune cell in patients receiving imatinib or nilotinib. Furthermore, we could not determine a type of chemokine or cytokine associated with lymphocytosis induced by the dasatinib treatment.
Summary/Conclusions: Dasatinib might increase the numbers of LGL and enhance NK-cell cytotoxicity *in vivo*. Dasatinib might restore the function of exhausted cytotoxic lymphocytes present already at the time of CML diagnosis. Increase in LGL counts was strongly correlated with the number of LGL before dasatinib therapy. We speculated that the number of LGL present before dasatinib therapy is potentially a prognostic factor.

E1107

PLA FLOW; A FLOW CYTOMETRY-BASED ASSAY FOR DETECTION OF BCR-ABL FUSION PROTEIN IN BLOOD CELLS FROM CML PATIENTS

L Löf[1,*], U Olsson-Strömberg[2], U Landegren[1], M Kamali-Moghaddam[1]
[1]Departement of Immunolgy, Genetics and Pathology, Uppsala University, [2]Department of Medical Science, Division of Hematology, Uppsala, Sweden

Background: Chronic myeloid leukemia (CML) is currently diagnosed using RT-PCR and/or FISH to reveal the presence of the fusion mRNA transcripts for BCR-ABL, or of the characteristic Philadelphia chromosome. RT-PCR is also used to monitor the effects of treatment by sensitively measuring transcripts representing minimal residual disease (MRD). It has not been possibly to use flow cytometry to identify the neoplastic cells but such a method would be helpful in the workflow of a hematopathology lab. The PLA flow could provide a strong complement to the powerful RT-PCR method used today, with the advantages of flow cytometry.

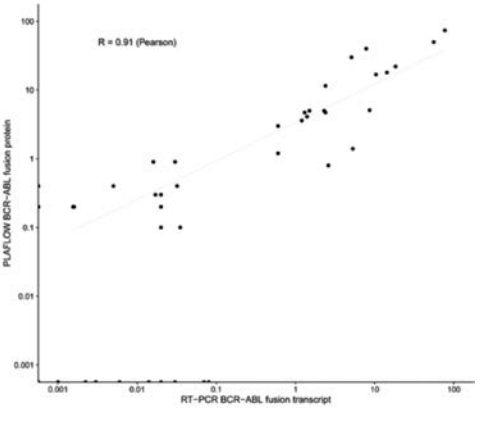

Figure 1. Blood samples from 47 CML patients analyzed for BCR-ABL positive cells, using FlowPLA (y-axis) and routine analysis of the BCR-ABL transcript using RT-PCR (x-axis) and compared. Pearson correlation coefficient was performed.

Aims: We have now developed a method that successfully detects and enumerates cells harboring the fusion protein BCR-ABL by flow cytometry in CML patients.
Methods: The method, PLAflow, uses the *in situ* proximity ligation assay (PLA)

(Söderberg et al 2006, Leuchowius et al 2009), where two antibodies target the BCR and the ABL part, respectively, of the fusion protein. The antibodies are equipped with DNA oligonucleotides that-when brought in proximity-guide the formation of a circular DNA molecule as a template for localized DNA amplification through rolling circle amplification (RCA). Each RCA-product is then labeled with around 1,500 fluorophore-coupled DNA oligonucleotides, allowing cells to be detected by flow cytometry. Using this method we analyzed blood samples from CML patients and compared it to the routine RT-PCR analysis.
Results: The method that was proven to be very sensitive, enable us to detect very low number of cells harboring BCR-ABL in patient samples.
Summary/Conclusions: The PLA flow is a senstive and robust method that could provide a strong complement to the powerful RT-PCR method used today, both at diagnosis and monitoring MRD. Since the PLA flow method is developed for flow cytometry, and now also adapted for CyTOF, all the advantages with multiparametric analysis can be achieved simultaneously. This allows monitoring of patients using their own cytogenetic signatures, both at diagnosis, and during the MRD monitoring. By investigating which cell populations are expressing the BCR-ABL fusion protein, the method may provide tools to identifying patients responding to a specific treatment.

E1108

COMPARISON OF PACE CLINICAL TRIAL *VS* REAL-WORLD PONATINIB PRESCRIBING AND DURATION OF THERAPY IN CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) PATIENTS

M Mauro[1,*], LJ McGarry[2], M Yang[2], S Lustgarten[2], H Huang[2]
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: Ponatinib demonstrated efficacy in patients with highly-resistant CP-CML in the pivotal phase 2 PACE trial (NCT01207440). Introduced to the US market in Dec'12, ponatinib was reintroduced in Jan'14 after an 11-week withdrawal to review data on vascular occlusive events and revise US prescribing information. In the US, ponatinib is available exclusively through a specialty pharmacy that maintains real-world prescribing data for all US patients treated with ponatinib since Jan'14.
Aims: Comparison of real-world pharmacy data to PACE trial data for patients with CP-CML, to identify any differences in duration of therapy due to potential noncompliance or availability of alternative therapies.
Methods: Data from patients with CP-CML enrolled Sep'10-Oct'11 into the PACE trial (all providing informed consent) were compared to real-world data for CP-CML patients starting ponatinib Jan'14-Dec'15. Real-world data source includes referring physicians, pharmacy intake forms and dispensing records. Patient characteristics and dosing were compared overall and by line of therapy using non-parametric tests; average dose was calculated, including therapy gaps as "zero" dose. Duration of therapy was assessed using Kaplan-Meier techniques and log-rank tests.
Results: PACE enrolled 270 CP-CML patients; 333 US real-world CP-CML patients started treatment over the 2-year period. PACE patients were older (median 60 *vs* 55 years; p=0.004). Comparing PACE to 258 real-world patients with known line of therapy, 7% PACE *vs* 16% real-world were in 2nd line, 36% *vs* 28% 3rd line and 57% *vs* 56% ≥4th line (p=0.084). All PACE patients received 45 mg/day as the initial dose of ponatinib; in real-world ponatinib use, 48% of patients initially received 45 mg/day, 30% 30 mg/day, and 22% 15 mg/day; however, average ponatinib dose was similar in PACE *vs* real-world (2nd line: 29.4 *vs* 29.0 mg/day; 3rd line: 26.0 *vs* 25.9 mg/day; ≥4th line: 26.4 *vs* 26.9 mg/day; all p>0.05.) Duration of therapy was similar in 2nd line and ≥4th line patients in PACE *vs* real-world, but longer in PACE *vs* real-world for 3rd line patients (Table).

Table 1.

Duration of Therapy in PACE vs Real-world CP-CML Patients by Line of Therapy

Line of therapy	Population (n)	6month	12month	18month	24month	P
		(%)				
2nd line	PACE (19)	95	89	84	68	0.077
	Real-world (42)	63	63	63	—	
3rd line	PACE (97)	79	69	68	64	0.047
	Real-world (72)	69	59	59	—	
≥4th line	PACE (154)	79	62	58	53	0.311
	Real-world (144)	67	57	56	—	
Total	PACE (270)	80	66	63	58	<0.001
	Real-world (333*)	66	54	52	—	

*Includes 75 patients with missing line of therapy

Summary/Conclusions: Real-world CP-CML ponatinib patients are younger but otherwise similar to PACE patients. Real-world data suggests an increase in earlier (second) line ponatinib use and >50% of initial ponatinb dosing is below 45 mg/day. As expected, the real-world duration of therapy is somewhat shorter than in PACE; however, the majority of real-world ponatinib patients across all lines of therapy were on therapy for >1.5 years.

E1109

PATIENT-REPORTED OUTCOMES FROM AN OPEN-LABEL SAFETY AND EFFICACY STUDY OF BOSUTINIB IN PHILADELPHIA CHROMOSOME POSITIVE CHRONIC MYELOID LEUKEMIA RESISTANT OR INTOLERANT TO PRIOR THERAPY

JE Cortes[1,*], C Mamolo[2], Y Su[3], A Reisman[3], M Shapiro[4], JH Lipton[5]
[1]University of Texas MD Anderson Cancer Center, Houston, TX, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, New York, NY, [4]Pfizer Inc, Cambridge, MA, United States, [5]Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Bosutinib (BOS) is a tyrosine kinase inhibitor indicated for the treatment of Philadelphia chromosome-positive (Ph+) chronic myeloid leukemia (CML) in adult patients with resistance or intolerance to prior therapy. A 5-year update of the safety and efficacy results from a phase 1/2 study of BOS for Ph+ leukemia resistant/intolerant to prior tyrosine kinase inhibitors (clinicaltrials.gov: NCT00261846) has recently been conducted.
Aims: To assess the long-term health-related quality of life (HRQoL), functioning, and symptoms in patients with chronic phase CML following imatinib resistance or intolerance (chronic phase second line; CP2L) or resistance or intolerance to imatinib plus dasatinib and/or nilotinib (chronic phase third line; CP3L), based on patient-reported outcomes (PROs) from this trial.
Methods: Patients received a starting dose of BOS 500 mg/day and completed the EuroQoL 5 Dimensions (EQ-5D) and the Functional Assessment of Cancer Therapy-Leukemia (FACT-Leu) questionnaires at screening; weeks 4, 8, and 12; every 12 weeks thereafter; and at the end of treatment visit. Mean and 95% CIs were reported. Informed consent was obtained from all patients. The PRO results at 5 years are presented.
Results: A total of 284 patients were enrolled in the CP2L population and 119 patients in the CP3L population. At treatment completion, EQ-5D completion rates were 67.6% and 65.5% in the CP2L and CP3L populations, respectively; FACT-Leu completion rates were 65.7% and 64.7% in the CP2L and CP3L populations, respectively. At baseline, the mean EQ-5D utility score was 0.83 in the CP2L population and 0.80 in the CP3L population. Mean (95% CI) changes from baseline in EQ-5D utility scores ranged from -0.04 (-0.13 to 0.06) to 0.12 (0.03-0.21) in the CP2L population and from -0.05 (-0.16 to 0.07) to 0.01 (-0.15 to 0.16) in the CP3L population. At baseline, the mean EQ-5D visual analog scale (VAS) score was 71.3 in the CP2L population and 72.6 in the CP3L population. Mean (95% CI) changes from baseline in EQ-5D VAS scores ranged from 0 (95% CI not available) to 30.17 (-86.96 to 147.29) in the CP2L population and from -2.64 (-6.14 to 0.85) to 19.69 (-5.30 to 44.68) in the CP3L population. At treatment completion, most patients reported "no problems" on all of the 5 dimensions of the EQ-5D health state profiles (Table 1). At baseline, the mean FACT-General (FACT-G) Total Score and FACT-Leu Total Score were 81.0 and 133.2, respectively, in the CP2L population and 80.8 and 132.5, respectively, in the CP3L population. In the CP2L population, mean (95% CI) changes from baseline in FACT-G Total Score (minimally important difference: 3-7 points) and FACT-Leu Total Score (minimally important difference: 6-12 points) ranged from -1.02 (-2.41 to 0.36) to 9.87 (0.94-18.80) and -4.66 (-14.81 to 5.48) to 17.34 (6.33−28.36), respectively. In the CP3L population, mean (95% CI) changes from baseline in FACT-G Total Score and FACT-Leu Total Score ranged from -2.74 (-5.09 to -0.39) to 9.50 (95% CI not available) and -3.05 (-6.84 to 0.73) to 7.22 (-3.40 to 17.85), respectively.

Table 1.

Table 1. Percentage of Patients on Bosutinib in the CP2L and CP3L Populations Who Reported No, Some, or Extreme Problems on the EQ-5D Health State Profiles

	No Problems			Some Problems			Extreme Problems		
	Baseline	Treatment Completion	Change From Baseline	Baseline	Treatment Completion	Change From Baseline	Baseline	Treatment Completion	Change From Baseline
Second-Line Population, %									
Mobility	75.6	78.0	2.4	24.4	21.5	−2.9	0	0.5	0.5
Self-care	97.6	91.6	−6.0	2.4	8.4	6.0	0	0	0
Usual activities	76.5	72.8	−3.7	23.1	25.1	2.0	0.4	2.1	1.7
Pain/discomfort	61.1	58.9	−2.2	35.2	36.3	1.1	3.6	4.7	1.1
Anxiety/depression	63.2	64.9	1.7	35.6	33.5	−2.1	1.2	1.6	0.4
Third-Line Population, %									
Mobility	77.7	75.3	−2.4	21.4	24.7	3.3	1.0	0	−1.0
Self-care	95.1	92.2	−2.9	4.9	6.5	1.6	0	1.3	1.3
Usual activities	67.0	66.2	−0.8	32.0	32.5	0.5	1.0	1.3	0.3
Pain/discomfort	59.2	55.8	−3.4	35.9	39.0	3.1	4.9	5.2	0.3
Anxiety/depression	56.9	55.3	−1.6	43.1	40.8	−2.3	0	3.9	3.9

Summary/Conclusions: These findings are of considerable importance to patients and physicians and indicate, for the patients who remained in the study, that HRQoL was largely maintained with BOS during the 5-year study duration in both second line and third line patients with Ph+ CML with resistance or intolerance to prior therapy.

E1110

PRELIMINARY FINDINGS FROM A CHART REVIEW OF LOWER DOSING OF PONATINIB IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS

M Mauro[1,*], L McGarry[2], A Inguilizian[2], R du Moulin[2], H Huang[2]
[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: Ponatinib is approved for adult patients with refractory CML or Ph+ ALL and those with the T315I mutation. Current prescribing information recommends a starting dose of 45 mg/day, with consideration of lower doses in patients with selected comorbidities, to manage adverse events, and for patients who achieve response. Post hoc dose-response analyses from the registrational PACE trial suggest lower doses of ponatinib may mitigate safety risk while maintaining response; however, outcomes of patients with lower doses have not been evaluated in clinical practice.
Aims: Characterize response and adverse events of special interest (AESI) in real-world CML patients treated with ponatinib doses ≤45mg/day.
Methods: We conducted a chart review of adult (aged ≥18 years) US CML patients receiving ponatinib. Patients were required to have ≥6 months of follow-up from first dose; however, no minimum ponatinib exposure was required. Data were abstracted from 6 months prior to first dose ("baseline") through date of chart review, death or loss to follow up. Baseline characteristics, treatment response and AESI (including arterial occlusive events [AOEs] and venous thromboembolic events) are reported overall and by average daily dose ≤30 mg ("low dose") and >30 mg ("standard dose"), calculated including therapy gaps as "zero" dose.
Results: Preliminary analysis of 35 patients from 9 US sites found patients did not differ significantly by dosage group in baseline age, CML phase, time since diagnosis or prior therapy lines; however, fewer low dose patients had no response at start of ponatinib therapy (Table). Significantly more low dose patients had hyperlipidemia at baseline (p=0.027), and there was a trend toward more history of myocardial infarction (MI), coronary artery disease and revascularization among low dose patients (all p=0.070). Low dose patients had nominally more baseline risk factors or prior events compared to standard dose patients (Table). Median time on therapy was 11 *vs* 12 months for low dose *vs* standard dose patients, respectively (p=0.336), and dose reduction was common (73% *vs* 60%; p=0.411). Best response of major molecular response (MMR) or better was reported in 40% of low dose patients and 25% of standard dose (p=0.344); major cytogenetic response (MCyR) or better in 53% *vs* 45% (p=0.625), and major hematologic response (MaHR) or better in 80% and 65% of low *vs* standard dose, respectively (p=0.331). AESIs reported in ≥2 patients were: venous recanalization (n=8), mesenteric artery stent insert (n=6), cerebral small vessel ischemic disease (n=6), MI (n=3), increased troponin (n=3), cardiac arrest (n=2), creatine phosphokinase (n=2). There was no statistically significant difference in AESIs between groups; however, a trend toward more AOEs in patients with lower average doses (p=0.076) was noted, perhaps due to patient selection or post-event dose reduction. Power to detect differences was limited by sample size; further analysis of correlation between baseline risk factors and outcomes is ongoing.

Table 1.

Baseline characteristics of patients with average ponatinib dose ≤ 30 mg ("low dose") and >30 mg ("standard dose")

Baseline Characteristics	≤30 mg n=15	>30 mg n=20	All n=35	p-value
Median average daily dose, (mg)	22.4	43.2	31.5	
Starting dose, n (%)				0.202
45 mg	9 (60)	16 (80)	25 (71)	
30 mg	4 (27)	4 (20)	8 (23)	
15 mg	2 (13)	0 (0)	2 (6)	
Median age at ponatinib start, years	43.5	48.3	47.5	0.995
Time since diagnosis, months	48.4	30.8	34.5	0.347
CML Phase at Study Entry, n (%)				0.401
CP	13 (87)	14 (70)	27 (77)	
AP/BP	1 (7)	5 (25)	6 (17)	
Unknown/Missing	1 (7)	1 (5)	2 (6)	
# of prior TKIS, n (%)				0.454
Missing or 0	1 (7)	0 (0)	1 (3)	
1	2 (13)	8 (40)	10 (29)	
2	6 (40)	8 (40)	14 (40)	
3+	6 (40)	4 (20)	10 (29)	
Response at baseline, prior to ponatinib initiation, n (%)				0.014
MCyR or better	0 (0)	2 (10)	2 (6)	
MaHR or better	5 (33)	6 (20)	11 (31)	
No response	5 (33)	10 (50)	15 (43)	
Unknown/Missing	5 (33)	2 (10)	7 (20)	
Any risk factor or history prior of events, n (%)	9 (60)	8 (40)	17 (49)	0.315

Summary/Conclusions: Preliminary data suggest that in clinical practice, response is similar among CML patients treated with low and standard dose ponatinib. Patients with selected risk factors or history of prior event received lower average doses, and the trend toward greater number of AOEs in the low dose group suggests that AOEs may be correlated more with risk than dose. Additional data are needed to fully characterize outcomes of patients treated with ponatinib at doses lower than the currently recommended 45 mg/day.

E1111

IMPACT OF IMATINIB PHARMACOKINETICS ON HEALTH RELATED QUALITY OF LIFE AND ADVERSE EVENTS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

J Cao[1,*], J Allen[1], B Chowbay[2], C Chuah[3]
[1]Duke-NUS Medical School, [2]National Cancer Centre Singapore, [3]Department of Haematology, Singapore General Hospital, Singapore, Singapore

Background: Imatinib has improved survival of chronic myeloid leukemia (CML) patients considerably. However, many patients suffer persistent, low-grade adverse events (AEs) and have relatively inferior health-related quality of life (HRQOL). This impairment is in part ascribed to low grade AEs, which is experienced by a large proportion of patients. Studies have demonstrated that imatinib pharmacokinetics may correlate with imatinib-related AEs but none investigated the impact on HRQOL.
Aims: To determine the correlation of imatinib pharmacokinetics with HRQOL, incidence and severity of AEs.
Methods: A prospective cross-sectional study of 70 chronic phase CML patients at Singapore General Hospital was performed. All patients were on imatinib for at least 6 months. Blood samples for imatinib pharmacokinetic analysis were taken at 0 (pre-dose, trough) and 2 hours (peak) after imatinib administration and analyzed via high performance liquid chromatography. Oral clearance was calculated using: $Cl_{oral}=(D/2t)/C_{ss}$, where D=dose (mg), t=dosing interval (hr), and C_{ss}=steady state imatinib concentration (ng/ml). AEs and HRQOL were measured using M.D. Anderson Symptom Inventory Chronic Myeloid Leukemia Module (MDASI-CML), which was filled up within 48 hours of imatinib pharmacokinetic sampling. MDASI-CML is a multi-symptom patient-reported outcome comprising of 20 symptom items (13 core MDASI items, 7 CML-specific symptom items) and 6 HRQOL interference items. Higher scores indicate more severe AEs and worse HRQOL. Clinical responses was determined based on European LeukemiaNet 2013 guidelines. The study was approved by the institutional review board and all participants were required to sign informed consent.
Results: Median daily dose of imatinib was 400mg and the median imatinib trough concentration, peak concentration and clearance were 1365 ng/ml, 2372 ng/ml and 5.74 L/hr respectively. Impairment in at least one of the six HRQOL life activities was experienced by 65.7% of patients while 91.4% of patients experienced at least one AE. Higher HRQOL scores significantly correlated with higher imatinib trough (r=0.274; p=0.021) and slower clearance (r=-0.331; p=0.005) but not with imatinib peak concentrations. Median HRQOL score was significantly higher in the trough Q4 group compared to the Q1 group (1.50 *vs* 0.17; p=0.034) and was significantly lower in the clearance Q4 group compared to the Q1 group (0.17 *vs* 1.50; p=0.010) (see Figure 1). Higher imatinib trough and slower clearance also correlated with increased patient-rated incidence of AEs (r=0.238; p=0.045 and r=-0.278; p=0.020 respectively) and increased severity of AEs (r=0.248; p=0.037 and r=-0.315; p=0.008 respectively), but not with clinical response.

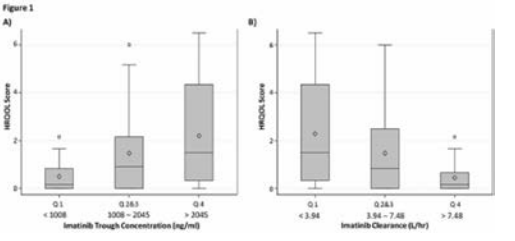

Figure 1.

Summary/Conclusions: Higher imatinib trough levels and slower clearance of imatinib are associated with poorer HRQOL, higher incidence and increased severity of AEs. Dose adjustment using imatinib trough levels may be beneficial in reducing AEs and improving HRQOL.

E1112

CMREGISTRY: AN OBSERVATIONAL, MULTI CENTER, PROSPECTIVE FOLLOW-UP REGISTRY OF PATIENTS WITH CHRONIC PHASE CML WITH A HIGH PROBABILITY OF OBTAINING A STABLE DEEP MOLECULAR RESPONSE >CMR4 (IS)

F Capdevila[1], E Olavarria[2,*], M Perez Encinas[3], R de Paz Arias[4], RM Ayala Diaz[5], N Garcia Omeña[6], F Ferrer Marin[7], G Bautista Carrascosa[8], V Conesa Garcia[9], JL Steegmann[10], OBOTGED Leucemia Mieloide Cronica (GELMC)[11]
[1]NavarraBiomed, Fundacion Miguel Servet, Pamplona, Spain, [2]Haematology, Hammersmith Hospital, London, United Kingdom, [3]Hospital Clínico Universitario, Santiago, [4]Hospital La Paz, [5]Hospital 12 de Octubre, Madrid, [6]Hospital Virgen de la Salud, Toledo, [7]Hospital Morales Meseguer, Murcia, [8]Hospital Universitario Puerta de Hierro, Madrid, [9]Hospital General Universitario de Elche, Elche, [10]Hematologia, Hospital de la Princesa, [11]GELMC, Madrid, Spain

Background: Since the advent of Tyrosine Kinase Inhibitors (TKI), many patients diagnosed with Chronic Myeloid Leukemia (CML) in chronic phase could achieve a deep molecular response, defined as at least a 4-log reduction in the bcr-abl transcripts when measured by a standardized PCR on the International Scale (IS). These patients are expected to maintain their molecular response even after discontinuation of their TKI treatment. Several on-going clinical trials are exploring the best way of stopping TKI therapy and evaluating the patient and disease characteristics that could predict long term disease control without treatment.
Aims: The aim of CMRegistry is to collect clinical data and molecular informa-

tion in the international scale for CML patients in Spain that have achieved a series of cytogenetic or molecular responses at different time points to any of the tyrosine kinase inhibitors currently available in Spain in order to monitor their progress and the achievement of a stable deep molecular response >MR^4 $^{(IS)}$. These data may be used to identify patients that would be candidates for inclusion in future discontinuation studies or combination studies with other compounds.

Methods: This is an observational, multi-center, prospective study open to all CML patients that are receiving treatment with any of the tyrosine kinase inhibitors currently available in Spain and are likely to achieve (or have already achieved) a deep molecular response (>$MR^{4\ (IS)}$). This likelihood of achieving >MR^4 is defined for the purposes of the study as a bcr-abl/abl ratio of: 1) ≤1% at 3 months from start of TKI therapy; 2) ≤0.1% at 6 months from start of TKI therapy; or 3) ≤0.01% any time point during treatment. Clinical data have been collected using a specific CRF created exclusively for this study. All data were registered in an anonymous manner. The BCR-ABL ratios in the IS have been provided by standardized labs in Spain.

Results: From June 2014 to January 2016 a total of 732 patients were registered in the study. Median age was 55 years (18-78) and 440 patients were male. The Sokal risk groups were as follows: 254 patients low risk, 230 intermediate risk and 97 high risk. Hasford (Euro) risk stratification showed 223 patients low risk, 225 intermediate and 136 high risk. Eutos classification yielded 341 patients in the low risk and 220 in the high risk categories. The majority of patients received treatment with Imatinib (409 patients), Dasatinib (82 patients) or Nilotinib (122 patients). Of note, 5 patients received Bosutinib, 1 patient Ponatinib and 4 patients were treated with Interferon. So far 722 patients remain alive. 10 patients have died, mostly of non-CML related conditions such as Carcinoma (3 patients), Cerebral Hemorrhage, Ischemic heart disease, respiratory failure and sepsis (1 patient each). Interestingly, 2 patients developed progression of their CML to Accelerated phase and blast crisis (1 patient each). At present, 104 patients (14%) have achieved a MR^4 and 70 (10%) patients a MR^5, while 176 patients (24%) have obtained a complete molecular remission (undetectable bcr-abl transcripts with a sensitivity of at least 10^{-5}).

Summary/Conclusions: In summary, a large number of CML patients have been identified in Spain in a prospective study as having a promising molecular response that would predict for a sustained deep molecular remission. A significant proportion of these patients has already achieved a complete molecular remission and would be potential candidates for discontinuation studies.

E1113

BCR-ABL1 MONITORING ON THE IS USING AN ANALYTICALY AND CLINICALLY VALIDATED MULTIPLEX ASSAY DIRECTLY ALIGNED TO THE WHO PRIMARY STANDARDS

J Brown*, I Beldorth, W Laosinchai-Wolf, M Fahey, J Hedges, A Ruskin, B Andruss
Asuragen, Austin, United States

Background: Detection of BCR-ABL1 e13a2/e14a2 fusion transcripts (major breakpoint, M-BCR) of t(9;22) is important in studying tumor burden in CML. The International Scale (IS) was established to standardize the reporting of these transcripts against a common baseline. As newer TKI therapies create deeper responses, analytical sensitivity has become a critical topic in investigations into TKI discontinuation, where researchers require an assay that confidently calls molecular responses of ≥4.5 logs below baseline (0.0032%IS or MR4.5). This has led to various reporting formats as a patient achieves deep response over time, creating a non-contiguous language of monitoring: baseline, 10%IS, 1%IS, MMR, MR4, and MR4.5.

Aims: We describe the analytical and clinical validation of a multiplex assay system reporting continuous MR values via automated software analysis, clinical accuracy at MR3, analytical sensitivity of MR4.7, and direct traceability to the WHO Primary BCR-ABL1 reference materials without requiring establishment and revalidation of a conversion factor.

Methods: We developed reagents for RT-qPCR, both steps performed on the ABI 7500 Fast Dx. Armored RNA Quant® (ARQ) technology was employed to generate a blend of nuclease-resistant BCR-ABL1 and ABL1 RNA transcripts to calibrate and control the system. A single four-point standard curve using ARQ blends mimics the WHO Primary BCR-ABL1 reference materials and accounts for the relative batch run-specific efficiency of the RT step. cDNA generation and qPCR were optimized, including allowance of high mass of nucleic acid without inhibition. Residual clinical RNAs were tested to estimate LOD at minimum RNA input. Software was developed, including a floating, traceable logic algorithm to ensure that sufficient ABL1 was detected to protect this LOD. A multi-center clinical outcome study was conducted at 3 clinical laboratories to validate clinical monitoring. Performance was assessed by event-free survival (EFS) at 32-40 months against test results at 12-18 months on TKI as estimated by the Kaplan Meier survival function. A total of 139 samples from 98 patients were enrolled at 2 clinical sites.

Results: We surpassed the desired analytical sensitivity: 1680 measurements were generated across 28 levels and yielded an LOD estimate of 95% positivity by probit analysis of MR4.74 (0.0018%IS). LOQ was similar. Despite deep analytical sensitivity, this system maintains analytical specificity (non-leukemic and non-CML leukemic specimens were true negative). Linearity was observed from at least MR0.3 (50%IS) to MR4.7 (0.002%IS). Single-site precision included lot, instrument, operator, and run, and was verified as SD ≤0.13 for MR values ≤3.7. Multi-site precision included site, instrument, operator, and day, and was verified as SD ≤0.10 for MR values ≤3.7. Traceability to the higher order WHO standards was demonstrated. In the clinical study, the difference in EFS between.

Summary/Conclusions: The BCR-ABL1 test improves workflow with its streamlined reagent formulation, multiplex assay format, and automated software analysis. It facilitates assessment on the IS without conversion (through integrated ARQ materials traceable to the WHO Primary), reports results on a continuous scale (as both MR and%IS values), and generates results sufficient for studies in deep molecular responses. Further, it is clinically validated to predict EFS outcomes at the MR3 level.

E1114

RESULTS OF OBSERVATION WITHOUT TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH DEEP MOLECULAR RESPONSE WHO STOPPED THERAPY DUE TO PREGNANCY, ADVERSE EVENTS OR BY OWN CONSIDERATION

E Chelysheva[1,*], A Turkina[1], V Shuvaev[2], G Gusarova[1], A Bykova[1], O Shukhov[1], M Vakhrusheva[1], A Abdullaev[1], M Fominykh[2], A Sudarikov[1], I Martynkevich[2], K Abdulkadyrov[2]
[1]Scientivic Advisory Department of Chemotherapy of Myeloproliferative disorders, Federal State Funded Institution National Research Center for Hematology of the Ministry of HealthCare of the Russian Federation, Moscow, [2]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: A possibility of observation without treatment in chronic myeloid leukemia (CML) patients is important as the long-term survival on tyrosine kinase inhibitors (TKI) therapy is excellent and a significant proportion of patients (pts) may achieve a deep molecular response (DMR).

Aims: To evaluate the results of observation without TKI treatment in CML patients with DMR who stopped therapy for different reasons.

Methods: Sixty-one CML pts with DMR were observed after TKI cessation. Fifty-nine pts had chronic phase, 2 pts had accelerated phase of CML at initial diagnosis. Sokal risk groups ratio low/intermediate/high was 65%/20%/15%. Male/female ratio was 15/46. Median (Me) age at TKI cessation was 37 years (range 22-76). The reasons for TKI discontinuation were: 1) adverse events (AE) of TKI (n=28), 2) self-made decisions of pts or TKI absence (n=15), 3) pregnancy (n=18). Imatinib and second generation TKI (TKI2) were used in 40(66%) and 21(34%) of pts respectively. Twenty-three (38%) pts were pretreated with interferon prior to TKI. Me treatment duration before TKI discontinuation was 72 months (range 6-159 months). BCR-ABL transcript level was assessed by quantitative Real-time polymerase chain reaction according to international scale (IS). DMR was considered for at least molecular response 4 log (MR4) or BCR-ABL≤0,01%. TKI were resumed after loss of major molecular response (MMR) or BCR-ABL>0,1%. For pregnant pts therapy was resumed at BCR-ABL level>1% if it happened during pregnancy and at *BCR-ABL* level>0,1% if it happened after delivery. MR4 duration >2 years was in 45 (74%) of pts. We evaluated survival probability without MMR loss, terms of MMR loss and BCR-ABL level at MMR loss.

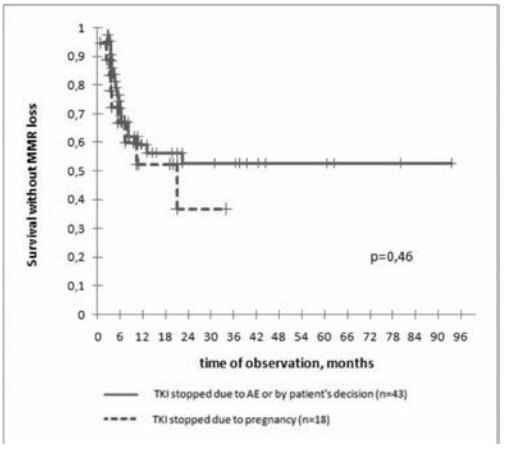

Figure 1. Survival without MMR loss after TKI discontinuation.

Results: Me follow-up after TKI discontinuation was 31 month (range 4-99 months). MMR was lost in 28 (46%) pts, TKI were restarted in all of them. Me time of MMR loss was 5 months (range 1-22 months). MMR loss happened within 6 and 12 months after TKI cessation in 20(33%) and in 5(8%) of pts respectively. In 3(5%) pts MMR loss was at 13,21 and 22 months. No hema-

tologic relapses were observed. At the time of MMR loss BCR-ABL level ranged from 0,11% to 13%. In 6 pts TKI were restarted without MMR loss by physician's decision at BCR-ABL level 0-0,082%. Two pts with DMR died due to concomitant diseases. Twenty-five (41%) pts continued to be treatment free under monitoring for Me 20 months (range 4-93 months), including 4 women without MMR loss after delivery. The probability of survival without MMR loss after TKI cessation at 6, 12 and 24 months was 67%, 57% and 49% respectively. For pregnancy group the probability of survival without MMR loss after TKI cessation at 6, 12 and 24 months was 67%, 32% and 37% respectively. No significant difference with pts in whom TKI were stopped for other reasons was found (p=0,46, figure 1). No MMR loss was observed after 24 months of TKI discontinuation neither in patients who stopped TKI due to pregnancy nor in those who stopped treatment for other reasons.

Summary/Conclusions: Approximately half of CML patients with DMR had a possibility to keep MMR within one year after TKI cessation. MMR loss mostly occurred within first 6 months after TKI discontinuation. No MMR loss was marked after 24 months of treatment free observation. Pregnancy in CML patients with DMR did not influence on the ability to maintain MMR after TKI cessation. A safe treatment free observation in CML patients who stop TKI may be warranted only with accompanying regular BCR-ABL level monitoring.

E1115

CONCURRENT OPTIMAL MOLECULAR AND CYTOGENETIC RESPONSES AT BOTH 3 AND 6 MONTHS PREDICT A HIGHER PROBABILITY OF MR4.5 ACHIEVEMENT IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB

YZ Qin[1,*], Q Jiang[1], YY Lai[1], H Jiang[1], XS Zhao[1], YR Liu[1], XJ Huang[1,2]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: Tyrosine kinase inhibitors (TKIs) have become the first line treatment of chronic myeloid leukemia (CML). Because early molecular and cytogenetic responses have been demonstrated to strongly predict long-term outcomes, the 2013 European LeukemiaNet (ELN) recommends that the patient early response should be defined by both molecular and cytogenetic tests to optimally direct the selection of subsequent treatments. The rapid achievement of a deep molecular response has become the treatment goal, therefore, the impact of the combination of early responses on it needs to be investigated.
Aims: We tried to evaluate the impact of the combined molecular and cytogenetic responses at 3 and 6 months on the achievement of molecular response of 4.5 (MR4.5) in imatinib treated CML patients.
Methods: A total of 228 newly diagnosed chronic phase CML patients treated with imatinib were included. At 3 and 6 months, they all were detected BCR-ABL transcript levels by real-time quantitative polymerase chain reaction (RQ-PCR) using peripheral blood samples, and performed karyotyping by standard G-banding techniques. Patients were grouped into 3-month and 6-month molecular optimal cytogenetic optimal (MOCO), molecular optimal cytogenetic warning (MOCW), molecular warning cytogenetic optimal (MWCO), molecular warning cytogenetic warning (MWCW) and failure groups according to the 2013 ELN recommendation. BCR-ABL^{IS} (BCR-ABL levels according to the international scale) was serial followed up for molecular response evaluation.

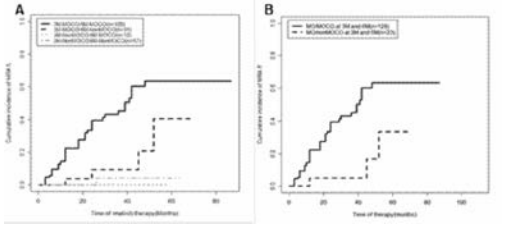

Figure 1.

Results: The median follow-up time was 27 months (range 8-94). For 3 months, both MOCW and MWCO patients had 3-year MR4.5 rates similar to those of MWCW and failure patients (8.3% [95% confidence interval (CI), 0-70.5%], 0, 0 and 0, all P>0.05), and they all were significantly lower than that of MOCO patients (35.5% [95% CI, 23.2-48.0%]; P=0.0047, 0.0057, 0.0089 and 0.0081, respectively). Similarly, for 6 months, both MOCW and MWCO patients had 3-year MR4.5 rates similar to those of MWCW and failure patients (5.6% [95% CI, 0-66.6%], 20.0% [95% CI, 0.2-67.0%], 0 and 0, all P>0.05), and they were all significantly lower than that of MOCO patients (41.6% [95% CI, 29.2-53.5%]; P=0.025, 0.021, 0.0005 and 0.0010, respectively). Next, responses at 3 and 6 months were combined. Three-month MOCO/6-month non-MOCO, 3-month non-MOCO/6-month MOCO and 3-month non-MOCO/6-month non-MOCO patients had similar 3-year MR4.5 rates (9.4% [95% CI, 0-56.5%], 0 and 4.2% [95% CI, 0-64.0%], P>0.05), and they were all significantly lower than that of 3-month MOCO/6-month MOCO patients (45.4% [95%CI, 32.9-57.1%]; P=0.0024, 0.0073 and<0.0001). This patient group also had significantly higher 3-year event-free survival (EFS) and progression-free survival rates (PFS) than those of patients with non-MOCO at 3 and/or 6 months (P<0.0001 and 0.0065) and had a significantly higher 3-year MR4.5 rate than that of patients with a 3-month/6-month molecularly optimal response but not a cytogenetically optimal response at 3 and/or 6 months (including 3-month MOCO/6-month MOCW, 3-month MOCW/6-month MOCO and 3-month MOCW/6-month MOCW, 5.0% [95%CI, 0-65.6%], P=0.0028).
Summary/Conclusions: The combination of early molecular and cytogenetic responses better predicts a deep molecular response in CML patients treated with imatinib. Concurrent optimal molecular and cytogenetic responses at both 3 and 6 months are associated with MR4.5 achievement.

Eugenio Hospital, University of Tor Vergata, Rome, [6]Department of Clinical and Experimental Medicine, Section of Hematology, University of Pisa, Pisa, [7]Department of Clinical and Experimental Medicine, University of Sassari, Sassari, [8]Department of Internal Medicine, University of Milano Bicocca, Monza, Italy

Background: Telomere biology has been more extensively studied in chronic myeloid leukemia (CML) than in any other blood cancer. Shorter telomeres have been associated to disease progression, poor prognosis, higher Hasford score and acquisition of further cytogenetic aberrations. So far, there are no studies investigating the possible influence of telomeres on treatment-free remission (TFR) after discontinuation of therapy with tyrosine kinase inhibitors (TKIs).
Aims: The aim of the present study was to investigate whether telomere length was associated with durable TFR in a cohort of CML patients after discontinuation of treatment with imatinib.
Methods: Thirty-two chronic-phase CML patients discontinued TKI treatment after achieving complete molecular remission (MR4). All patients were treated with imatinib. Two patients underwent second-line TKI (nilotinib) following molecular relapse. Telomere length analysis was performed as described by Cawthon (2002) using a quantitative PCR (q-PCR). The Relative Telomere Length (RTL) was determined as the Telomere (T) to Single copy gene (36B4) (S) ratio (T/S) normalized to a reference sample (K-562 DNA). Peripheral blood samples were also collected from 32 age- and sex-matched healthy controls. Age corrected RTL (acRTL) represented the difference in telomere length between patients and age- and sex-matched controls.

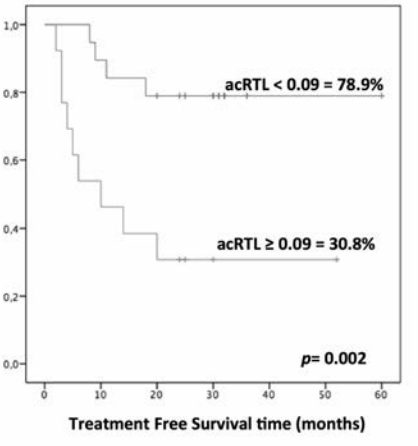

Figure 1.

Results: Complete molecular remission (CMR) was achieved after a mean of 26 months of imatinib (range 3-93). TKI treatment was discontinued after a mean of 84 months from the start of treatment (range 24-143). The median follow-up after discontinuation was 30 months (range 18-60). Thirteen patients (41%) showed loss of CMR. All relapsed patients regained CMR after restarting treatment with TKIs. The 36-month cumulative probability of TFR was 59.4%. RTL was assessed at a mean of 32 months from discontinuation in TFR patients and at a mean of 23 months after relapse in others. The median value of acRTL in the CML cohort was 0.09 (range -0.26, +0.86). The Mann-Whitney U test

showed shorter acRTL in TFR patients compared to patients with molecular relapse (mean±SD = 0.01±0.14 *vs* 0.20±0.21; p=0.01). Patients were stratified according to the median value of acRTL ≤0.09. TFR was significantly higher in CML patients with acRTL ≤0.09 in comparison to those with longer telomeres (78.9% *vs* 30.8%, p=0.002) (Figure 1).

Summary/Conclusions: Achievement of biological recovery through control or eradication of CML stem cells might depend on their proliferative potential in relation to telomere length. Age (a parameter directly proportional to telomere shortening and senescence) has recently been reported as a predictive factor for molecular relapse in CML patients who discontinue imatinib. CML cells would escape senescence through up-regulation of telomerase, restoring telomere length. In our study cohort, TFR patients showed significantly shorter acRTL than patients who presented molecular relapse. It can be postulated that quiescent CML stem cells harboring longer telomeres possibly escape senescence mechanisms and maintain a proliferative potential after discontinuation of imatinib treatment. To avoid such tumor escape mechanisms, anti-telomerase treatment strategies after TKI discontinuation would seem to be a reasonable proposal.

Gene therapy, cellular immunotherapy and vaccination

THE JAK1/2 INHIBITOR RUXOLITINIB MODULATES ANTIGEN PRESENTING FUNCTIONS OF ACTIVATED PRIMARY B CELLS ON A METABOLIC LEVEL

S Theurich[1,2,*], J Iltgen[2], K Wennhold[2], M Garcia Marquez[2], S Rothschild[2], B Schneider[1], U Holtick[1], M Thelen[2], C Scheid[1], HJ Becker[1,2], H Schlösser[2], S Reuter[2], A Shimabukuro Vornhagen[1,2], M von Bergwelt-Baildon[1,2]
[1]Department I of Internal Medicine, Hematology & Oncology, [2]Cologne Interventional Immunology (CII), University Hospital Cologne, Köln, Germany

Background: B lymphocytes not only balance the physiologic immune response but can also be involved in a variety of immune pathologies. Besides their traditional function as antibody producing plasma cells, it has been shown that B cells, upon activation, can develop into professional antigen-presenting cells (APCs) which mediate further cellular immune responses. Moreover, cytokines modulate B cell activation via the Janus kinase - signal transducer and activator of transcription (JAK-STAT) pathway. Inhibition of the JAK-STAT pathway has been introduced into clinical practice with the specific JAK1/2 inhibitor ruxolitinib. Approved for the treatment of JAK2 mutated myeloproliferative diseases, ruxolitinib has also shown to alleviate immune mediated symptoms such as fatigue and night sweat. Also in steroid-refractive graft-*versus*-host disease, ruxolitinib has shown activity.
Aims: Given the broad employment of JAK-STAT signaling in immune responses and the suggested clinical benefits of ruxolitinib mediated JAK1/2 inhibition in immune pathologies, we analyzed if such "off-target" effects can also mediate B cell activation.
Methods: Primary human B cells from healthy donors as well as from ruxolitinib treated patients were used for in vitro analyses. Here, CD40ligand mediated B-cell activation was applied as a well established model for T-cell dependent B-cell activation. Morphologic, phenotypic and functional changes were analyzed by 10-color flow cytometry. Cell metabolism was analyzed via extracellular flux changes (Seahorse Bio.).
Results: We found that ruxolitinib treatment significantly suppressed CD40L induced B-cell activation. These alterations became manifest in a reduced cell size and less homotypic cluster formation as well as in a reduced expression of co-stimulatory (CD80, CD86) and HLA-class-II molecules. On a functional level, JAK1/2 inhibition significantly reduced the ability of CD40L activated B cells to induce T-cell activation in a mixed allogeneic lymphocyte reaction. As a mechanism of action we found that ruxolitinib reduced glycolysis and the glycolytic capacity of activated B cells. Vice versa, inhibition of glycolysis via 2-deoxyglucose could recapitulate the ruxolitinib induced phenotype. Finally, data from ruxolitinib treated patients suggest that similar alterations of B cells also occur *in vivo*.
Summary/Conclusions: Taken together, our data suggest that ruxolitinib has important effects on B-cell activation which might contribute to its previously reported immunosuppressive features. Furthermore, we show that ruxolitinib can modulate APC-features of activated human B cells via glycolysis.

INTRA-BONE DONOR LYMPHOCYTE INFUSION IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES RELAPSING POST ALLOHSCT

A Lange[1,2,*], M Mordak-Domagala[2], J Bochenska[2], E Kocwin[2], H Pakos[2], M Krydel[2], A Borowik[2], E Jaskula[1,2]
[1]L. Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, [2]Lower Silesian Center for Cellular Transplantation with National Bone Marrow Donor Registry, Wroclaw, Poland

Background: Donor Lymphocyte Infusion (DLI) is effective in a proportion of patients with leukaemia relapsing post alloHSCT. This effect is over-paid by a high risk of severe aGvHD. Ikehara and Frassoni showed the efficacy of the intra-bone (IB) marrow hematopoietic stem cell transplantation associates with a prompt hematopoietic reconstitution and a low risk of aGvHD in animal experiments and in human setting, respectively. Recurrence and GvHD are major causes of treatment failure post alloHSCT.
Aims: In this study we evaluated a novel technique for relapse treatment in which donor lymphocytes are directly injected into the patient's bone marrow cavity. This study was approved by the local ethic committee.
Methods: Four patients: 3 with AML (2 alloSIB: 50 years old, female, normal karyotype; 22 years, male 7q31 del., CNS lesions post trauma; and one alloMUD: 25 years, male FLT3 ITD), and one with CLL, 64 years old male, *TP53* del, chronic EBV infection. FLT3 ITD AML case relapsed 9 months, other AML cases 2 and 3 yrs and CLL patient 7 years post alloHSCT. The salvage chemotherapy included FLAG for FLT3 ITD case, anti-CD20 MoAb for CLL case, two other AML cases received DLI upfront. All received IB DLI (according to the escalating dose regimen starting from 10E6 for the first and 10E7 for the second and usually 5 times 10E7 CD3+ lymphocytes for the third dose [cells/kg

body weight]). The intervals between IB DLI in 3 patients varied from 1 to 2 months being longer in one AML case in which between IB DLI 5' azacitidine was administrated. The cells for DLI were obtained from the primary PBPC transplant material in alloMUD AML case and from unstimulated PBPC in alloSIB and in two AML cases as well as in one CLL case. The cells were injected directly to the bone marrow cavity under local anaesthesia and a low molecular Heparin prophylaxis.
Results: 1) At 30 check points post IB DLI the marrow and blood lymphocyte profile was investigated in 4 patients. We found the prevalence of CD8+ cells proportions in the marrow over those in the blood (median: 24.3% *vs* 23.8%, p<0.004) but in particular the prevalence of CD279+ lymphocytes (16.3% *vs* 9.5%, p<0.001) and those CD8+CD279+ (6.5% *vs* 3.2%, p<0.001). 2) In CLL cases there was a drop in the count of blood lymphocytes, cellularity of the marrow also decreased and the patient was haematologically stable. The examination 8 months after the last DLI revealed 3300/µl CD5+CD19+ lymphocytes in the blood. The level which was also seen soon after the completion of the IB DLI treatment. 3) AML FLT3 ITD patients responding well to the FLAG salvage therapy followed by IB DLI is leukaemia free 3 months after the relapse, two other cases were stable haematologically (ECOG1) but an increase in the proportions of myeloblasts from 23% to 34% seen during 7 and 6 months of observation time which included IB DLI treatment prompted us to perform the second transplantation in one case (uncomplicated) and to schedule the second transplant in the other case.
Summary/Conclusions: 1) The observation of four patients they completed IB DLI suggests that it is safe procedure and GvHD was not observed. 2) The anti-leukemic effect was seen in CLL case and a stabilization of the haematopoiesis was seen in two patients receiving IB DLI being not in remission. AML FLT3 ITD positive case relapsing soon after transplant responded to the FLAG regimen followed by IB DLI. 3) The higher proportions of CD8+CD279+ lymphocytes in the marrow as compared to the blood suggest the presence in the marrow the cells actively involved in the surveillance of leukaemia.

INTERLEUKIN-2-PRIMED NAÏVE CD8 T CELLS AS A POTENTIAL REMEDY FOR OVERCOMING TUMOR-DERIVED IMMUNOSUPPRESSION IN TUMOR MICROENVIRONMENT

DH Yang[1,*], SS Lee[1], SY Song[2], JS Ahn[1], SH Jung[1], HJ Kim[1], JJ Lee[1], YR Do[3]
[1]Hematology, [2]Thoracic and Cardiovascular Surgery, CHONNAM NATIONAL UNIVERSITY HWASUN HOSPITAL, Jeollanam-do, [3]Hematology, Dongsan Medical Center, Daegu, Korea, Republic Of

Background: CD8 T cells have cytotoxic effector functions upon antigen stimulation and receive considerable attention for adoptive immunotherapy against cancer. Despite of their potential implication, however, conventional approaches using in vitro expanded CD8 T cells have not been successful so far, mostly due to lack of functionality with cellular exhaustion.
Aims: In this study, we therefore investigated the phenotypic and functional differences among in vitro activated CD8 T cells of three different sources, namely naïve, memory and tumor-infiltrating lymphocytes (TILs) of human and mice, for better understanding mechanisms behind potent effector functions and overcoming limitations of the current approaches.
Methods: Effector T cell populations were activated from $CD8^+$ naïve, memory T cells, and $CD8^+$ TILs obtained from cancer tissue (T_{eff} N, T_{eff} M, and re-stimulated TILs, respectively). Individual effectors were analyzed for functional difference and cytotoxicity. In murine model, we also checked the same methods for the phenotypes of T cell exhaustion and tumor challenging test using EG7-EL4 cell line (expressing the OVAp) in adoptively transferred OT-1, thy1.1 T_{eff} N, T_{eff} M and activated TILs T to C57BL6 mice.
Results: *In vitro* stimulation of human naïve, memory, and TIL CD8+ T cells using typical anti-CD3/CD28 antibodies were able to generate phenotypically homogenous populations of $CD62L^{lo}CD44^{hi}OX40^{hi}CD27^{hi}$ cells. Notably, proliferation and total yield after the in vitro expansion were far greater in NT_{eff} cells than for MT_{eff} and TIL_{eff} cells, which was well correlated with the enhanced telomere length of NT_{eff} cells compared to the latter two populations. In line with the longer telomere length, NT_{eff} cells exhibited significantly less amounts of T cell exhaustion markers, PD-1, CTLA-4 and KLRG-1, than those of MT_{eff} and TIL_{eff} cells, and moreover, acquired distinct expression patterns of memory-promoting transcription factors, with T-bet and Eomes being highly induced in a rapid, sustainable manner. With regard to tumor-induced immune-suppression, interestingly, NT_{eff} cells appeared to have lower expression of Foxp1, a transcription factor promoting T cell quiescence, and were refractory to apoptosis upon TGF-β conditioning, implying a better survival potential. As with *in vitro* stimulated human T cells, *in vitro* priming of murine naïve CD8 T cells using high doses of IL2 were also found to be effective for generating potent effector cells that can exert tumor-specific cytotoxic activity.
Summary/Conclusions: Of CD8 T cell pools that are different in their activation states, naïve cells other than pre-existing effector/memory and TIL cells were better poised to develop into potent effector cells after in vitro stimulation, which provide an implication for rational design of adoptive immunotherapy against cancer.

E1119

SYNERGISTIC KILLING EFFECT OF A NOVEL TRIPLE-REGULATED ONCOLYTIC ADENOVIRUS CARRYING PROGRAMMED CELL DEATH 5 GENE AND DAUNORUBICIN ON HUMAN LEUKEMIC CELLS

QM Yao[1], J Zhou[1], Y Chang[1], JL Li[1], YZ Wang[1], QJ Qian[2], HP Wu[2], LF Li[2], YH Chen[1], XJ Huang[1], GR Ruan[1,*]
[1]Institute of Hematology, Peking University People's Hospital, Beijing, [2]Laboratory of Viral and Gene Therapy, Second Military Medical University, Shanghai, China

Background: The expression levels of programmed cell death 5 (PDCD5) are down-regulated in many malignancies. A novel triple-regulated conditionally replicating adenoviruses (CRAd) carrying PDCD5 gene expression cassette, SG611-PDCD5, alone could inhibit tumor growth in vitro and *in vivo* and protect selectively the normal cells.
Aims: The purpose of this study was to investigate the synergistic killing effect of SG611-PDCD5 and low-dose daunorubicin (DNR) on human leukemic cells in vitro and *in vivo*.
Methods: The antitumor efficacy was characterized in several leukemic cell lines in vitro and in xenograft models of human leukemic cell line in nude mice. A panel of leukemic cells was treated with different concentrations of DNR alone or in combination with different multiplicities of infection (MOI) of SG611-PDCD5. The cell viability was determined by using CCK-8 assay. Apoptosis was detected in whole living cells using flow cytometry or in paraffin-embedded tumor tissues using the TUNEL kit.
Results: Combined SG611-PDCD5 and low-dose DNR showed synergetic effects in inhibiting the proliferation of human leukemic cell lines K562, MEG-01, KG-1a and TF-1. Synergistic effects in inducing apoptosis were observed both in K562 cells in vitro and in tumor tissues from xenograft models of K562 cells in nude mice. In K562 cells, the apoptotic percentages of SG611-PDCD5 at an MOI of 240 pfu/cell in combination with 0.12 ug/ml DNR were 72.5%, significant higher than that of SG611-PDCD5 alone (49.4%) or DNR alone (16.7%). TUNEL assay showed significantly more apoptotic cells in the SG611-PDCD5 plus DNR group than in SG611-PDCD5 group or in DNR group (25.0, 12.5 and 7.8 apoptotic cells/field, respectively, $P<0.05$). As shown *in vivo* experiment (Figure1), the tumor sizes were significantly decreased in combined treatment group on days 8 and 10 after treatment than those in DNR alone and SG611-PDCD5 alone (all $P<0.05$). Tumor sizes in the control, DNR, SG611-PDCD5 and DNR plus SG611-PDCD5 groups were 175.9±82.5, 80.9±42.8, 51.6±17.4, and 27.6±11.9 mm^3 on day 10, respectively.

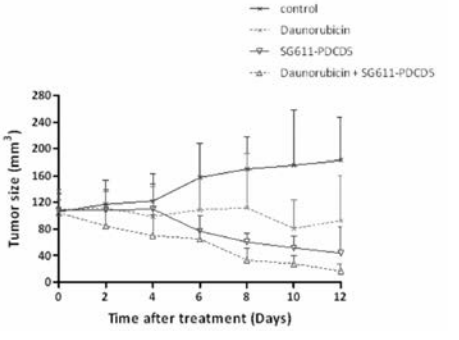

Figure 1.

Summary/Conclusions: Combined treatment of SG611-PDCD5 and DNR achieves synergistic effects in inhibiting human leukemic cell growth in vitro and *in vivo*. This study may lead to development of new strategies for effective leukemia treatment with a potential reduction in systemic toxicity.

E1120

TRIPLE-REGULATED ONCOLYTIC ADENOVIRUS-MEDIATED VSTM1 OVEREXPRESSION EXHIBITS POTENT ANTITUMOR ACTIVITY ON COMMON HUMAN LEUKEMIC CELL LINES

J Zhou[1], QM Yao[1], JL Li[1], Y Chang[1], T Li[2], WL Han[2], QJ Qian[3], HP Wu[3], LF Li[3], XJ Huang[1], GR Ruan[1,*]
[1]Institute of Hematology, Peking University People's Hospital, [2]Department of Immunology, Peking University Center for Human Disease Genomics, Beijing, [3]Laboratory of Viral and Gene Therapy, Second Military Medical University, Shanghai, China

Background: VSTM1 (V-set and transmembrane domain-containing 1), as a potential myeloid differentiation antigen gene, is downregulated in bone marrow cells from myeloid leukemia patients. Restoration of VSTM1 expression inhibited myeloid leukemia cells' growth. VSTM1 might provide a potential target for the diagnosis and treatment of leukemia.
Aims: The purpose of this study was to construct a triple-regulated oncolytic adenovirus carrying VSTM1 gene expression cassette, SG611-VSTM1, and to explore its antitumor efficacy on human leukemic cell lines.

Methods: In SG611-VSTM1, the E1a gene with a deletion of 24 nucleotides within CR2 region was controlled under the human telomerase reverse transcriptase promoter, the E1b gene expression was directed by the hypoxia response element, whereas the VSTM1 gene was controlled by the cytomegalovirus promoter. The insertion and orientation of all recombined plasmids were confirmed by restriction enzyme digestion and polymerase chain reaction (PCR). The relative VSTM1 expression level in human leukemic cell line K562 after infection with SG611-VSTM1 was detected by real-time quantitative PCR (RQ-PCR) and western blot. The tumor-selective replication of this virus and its antitumor efficacy were characterized in several leukemic cell lines with different multiplicities of infection (MOI) in vitro. Cell viability was detected by using Cell Counting Kit-8 (CCK-8). Cell apoptosis was analyzed by flow cytometry (FCM).
Results: A triple-regulated oncolytic adenovirus carrying VSTM1 gene expression assette, SG611-VSTM1, was completed and confirmed. VSTM1, hTERTp, HRE, skeleton and fiber 11 of recombinant adenovirus SG611-VSTM1 were successfully amplified. SG611-VSTM1 expressed VSTM1 with high efficiency in leukemic cells as compared with SG611 (P<0. 001). The expression level of VSTM1 increased gradually along with the increase of MOI. In CCK-8 assay, the cell viabilities were decreased gradually along with the increase of MOI in leukemic cells with SG611-VSTM1 in comparison with SG611, while the cell viabilities were maintained a relatively higher level in the normal cell lines BJ (about 50%) and L-02 (about 60%) with SG611-VSTM1. Similarly, the proapoptotic effect of SG611-VSTM1 on leukemic cells was superior to SG611. In K562 cells at 48 h after infection (Fig.1), the apoptotic percentage of SG611-VSTM1 at a MOI of 40 and 160 pfu/cell were 19.3% and 70.9%, significantly higher than that of SG611 (11.0% and 46.6%), respectively.

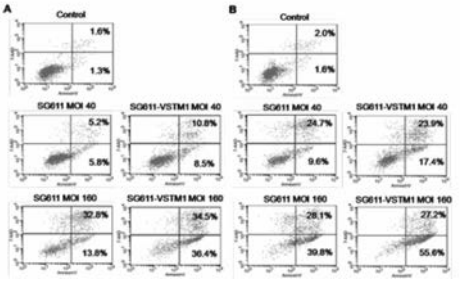

Figure 1. Apoptosis of K562 cells infected with SG611-VSTM1 or SG611. A: at 48 h after infection; B: at 72 h after infection. The apoptotic percentage was increased gradually along with the increase of MOI and infection time prolonging, especially in the group treated with SG611-VSTM1.

Summary/Conclusions: It is concluded that the triple-regulated adenovirus of SG611-VSTM1 containing the VSTM1 has been successfully established with high VSTM1 expression level in leukemic cells. SG611-VSTM1 holds an increase of anticancer efficacy and might be an improvement of the safety as a new anticancer agent.

E1121

COMBINED ISOLATION OF MULTI ANTIGEN SPECIFIC T CELL PRODUCTS CONTAINING NAÏVE AND/OR MEMORY VIRUS-SPECIFIC T CELLS AND T CELLS SPECIFIC FOR TUMOR ASSOCIATED AND MINOR HISTOCOMPATIBILITY ANTIGENS

M Roex[1], J Matamoros Luna[1], L Hageman[1], E van Egmond[1], S Veld[1], E van Liempt[1], C Hoogstraten[1], L Germeroth[2], P van Balen[1], S Halkes[1], JF Falkenburg[1], I Jedema[1,*]
[1]Hematology, LEIDEN UNIVERSITY MEDICAL CENTER, Leiden, Netherlands, [2]Juno Therapeutics, Goettingen, Germany

Background: T cell depleted allogeneic stem cell transplantation (aIloSCT) followed by a donor lymphocyte infusion (DLI) is a potential curative treatment for patients with hematological malignancies. However, between the aIloSCT and the DLI patients are vulnerable to viral infections and disease relapses. Within a clinical phase I/II study in the EU FP7 program T-control we isolate and adoptively transfer multi-antigen specific T-cell products to prevent these complications. Therefore, we isolate donor T-cells directed against HLA-A1, A2, A24, B7, and/or B8-restricted peptides of CMV, EBV and Adenovirus and HLA-A2-restricted peptides from the tumor-associated antigens (TAA) NY-eso, WT-1, RHAMM, PRAME and proteinase 3, and the minor histocompatibility antigen (MiHA) HA-1h. Due to the relatively high precursor frequency of virus-specific T cells in seropositive donors, memory virus-specific T cells can be easily isolated.
Aims: To investigate the presence and functional activity of the specificities with a very low precursor frequency, e.g. TAA and MiHA specific T cells, and virus specific T cells from seronegative donors.
Methods: HLA-A2, B7, and/or B8-positive CMV seronegative donors (n=5) and EBV seronegative donors (n=2) were selected for isolation of CMV, EBV and AdV-specific T cells. From 4 HLA-A2 positive donors TAA and MiHA specific T cells were isolated. The reversible HLA/peptide streptamer and magnetic nanobead technique (Juno) was used for the isolation out of 1-2*10^9 donor PBMC, using all relevant streptamers according to the HLA-type of the donor. The positive fractions were non-specifically expanded using PHA, IL-2 and allogeneic feeder cells. The presence of the different specificities was assessed 10-14 days after the isolation by tetramer staining. To confirm the presence of the invisible very low frequency T cell specificities, subsequent enrichment and expansion rounds were performed until populations were visible. Specificities that were present in a frequency >1% were clonally expanded and tested for their functional potential.
Results: After 2 or 3 enrichment and expansion rounds, we were able to demonstrate specific T cell populations for 6 CMV specificities from 4 seronegative donors (pp65 A2 NLV (3x), pp65 B7 TPR, 1E-1 A2 VLE, 1E-1 B8 QIK) and 4 EBV specificities from 2 seronegative donors (BMLF-1 A2 GLC, EBNA-3a B7 RPP (2x), BZLF-1 B8 RAK). The CD8/tetramer positive clones from two CMV specificities (pp65 A2 NLV and pp65 B7 TPR) and one EBV specificity (EBNA-3a B7 RPP) were tested for antigen specific reactivity measured by cytokine release (IFN-gamma and GM-CSF) after 24 hours of stimulation with TAP deficient T2 cells and/or allogeneic EBV-LCL exogenously loaded with the relevant peptide. This analysis revealed the presence of clones of high avidity recognizing up to 10^-9M peptide on T2 cells and 10^-8M peptide on allogeneic EBV-LCL. Besides this, all mentioned TAA and MiHA specificities could be isolated from all four HLA-A2 positive donors after 2 to 4 enrichment and expansion rounds, and comprised clones with a range of different functional avidities.
Summary/Conclusions: In conclusion, the HLA/peptide streptamer technology allows the simultaneous isolation of multi antigen specific T cell products containing not only highly frequent virus-specific memory T cells, but also EBV and/or CMV specific T cells from the naïve T cell repertoire of seronegative donors, as well as TAA and MiHA specific T cells with differential functional avidities.

E1122

THE IGE REPERTOIRE IN HEALTHY, NON-ALLERGIC INDIVIDUALS: IMPLICATIONS FOR EFFICIENT ALLERGEN DESENSITATION IMMUNOTHERAPY

M Koning*, I Trollmann, M Griffioen, H Veelken
Department of Hematology, Leiden University Medical Center, Leiden, Netherlands

Background: Type I allergic disease is a hypersensitivity reaction mediated by allergen-specific IgE. Allergen desensitation immunotherapy consists of serial injections of increasing doses of the allergen. A possible mechanism for the restriction of the severity of type I allergy by desensitation is the induction of allergen-specific neutralizing antibodies of non-IgE isotype. It is unclear whether allergen-specific IgG clones in desensitised individuals have been recruited form the naive repertoire or from pre-existing clones from which the IgE clones originated. The largest reported IgE repertoire from a single person comprises 32 immunoglobulin sequences.
Aims: To characterise the IgE repertoire in healthy donors in-depth by an unbiased approach.
Methods: Peripheral blood CD19+ cells from six healthy donors were isolated by magnetic bead separation and divided into aliquots of $2x10^6$ cells. For each donor, mRNA was amplified from 5 aliquots by ARTISAN PCR, an anchored RT-PCR primed on constant immunoglobulin regions and employing a template-switching reverse transcriptase. ARTISAN PCR was performed in parallel to obtain IgE, IgG, and IgM libraries. PacBio sequencing of the resulting 15 amplicon libraries per donor yielded a median of 284 (range: 100-743) full-length sequences/aliquot and 27500 sequences in total.
Results: A median of 261 (range: 175-358) unique IgE sequences were obtained per donor. 9.1-61.8% of individual IgE sequences were represented in ≥2 aliquots of the same donor. In contrast, 1.4-7.8% IgM and 5.7-16.3% IgG sequences, respectively, were represented in multiple aliquots. 29 unique VDJ sequences were identified in both IgM and IgG compartments. All IgE sequences were strictly restricted to their isotype. Somatic mutation loads per sequence differed significantly between IgE (median: 5.6%), IgM (0.3%), and IgG (8.3%). Intraclonal sequence diversity in IgE clones was predominantly due to silent framework region mutations. IGHV3-11, IGHV3-9, and the IGHV3 family were significantly overrepresented in IgE compared to IgM/IgG. IGHV3-30, IGHV3-33, IGHV4-59, and IGHV2, 4, 5, and 6 families were underrepresented.
Summary/Conclusions: These data provide a reference for investigations of the IgE repertoire in allergy and parasitology. In healthy donors, the peripheral IgE repertoire is less diverse than IgM/IgG, displays a strong IGHV bias, and carries an intermediate mutation load without evidence for ongoing affinity maturation. IgE and IgG/IgM repertoires apparently do not overlap. The lack of overlap between IgE sequences and expanded IgG clones, as well as the higher mutation load of the latter, suggest that most IgE sequences have undergone class switch recombination directly from IgM, rather than from class-switched expanded IgG clones as intermediates. These findings suggest that desensitisation strategies should focus on recruiting novel allergen-specific cells from the naïve B-cell compartment, rather than attempting to activate and expand existing IgG-expressing B cells that belong to the same B-cell clone and have the identical antigen specificity as the allergy-causing B-cells that have undergone alternative or subsequent class switching to IgE.

THE EFFECTS OF VARIOUS BLOOD PROTEINS ON THE ZETA POTENTIAL OF POLYMER NANOPARTICLES AND PROTEIN CORONA FORMATION: AN ANALYSIS BY TUNABLE RESISTIVE PULSE SENSING

E Blundell[1], M Healey[1], E Holton[1], M Sivakumaran[2], M Platt[1,*]
[1]Chemistry, Loughborough University, Loughborough, [2]Haematology, Peterborough City Hospital, Peterborough, United Kingdom

Background: Nanoparticles are increasingly used as delivery vehicles for targeted drug delivery, gene delivery, imaging and theranostics. Upon introduction of nanoparticles into biological fluids such as blood, the particles interact with the constituents of the environment, in particular with proteins. The interaction of nanoparticles with the proteins leads to formation of a protein-corona and change in the surface charge of the particles. These changes significantly affect the pharmacokinetic, pharmacodynamic and toxicological properties of the nanoparticles. Tunable Resistive Pulse Sensing (TRPS) technology, based on Coulter principle, enables particle-by-particle measurement of the size and zeta potential of nanoparticles during their passage through a tunable pore (Langmuir (2016) 32,1082-1090.
Aims: To ascertain the effects of three predominant proteins in blood, namely albumin, immunoglobulin and fibrinogen, in biologically relevant concentrations on the zeta potential of carboxylated polymer nanoparticles (CPNPs) in saline, serum and plasma at room temperature and 37ºC using TRPS
Methods: The particle size and zeta potential of carboxylated polymer nanoparticles were studied in phosphate buffered saline, albumin (40g/l), immunoglobulin (20g/l), fibrinogen (4g/l), normal human serum and normal human plasma at room temperature and 37ºC using TRPS (qNano, Izon Sciences, Oxford, UK). The kinetics of the protein corona reorientation for particles initially placed into serum and then adding 5%(V/V) plasma was then studied by monitoring changes in size and zeta potential of the particles using qNano.
Results: We observed a significant difference in distributions and zeta values between room temperature and 37ºC assay. The effect was protein dependent, and the largest difference between the two temperatures was recorded for the γ-globulin protein where the mean zeta potential changed from -16.7 mV to -9.0 mV for 25 and 37ºC, respectively. This method was further applied to monitor particles placed into serum and/or plasma. A temperature dependent change was again observed with serum showing a 4.9 mV difference in zeta potential between samples incubated at 25ºC and 37ºC, this shift was larger than that observed for samples in plasma (0.4 mV). Finally we monitored the kinetics of the corona reorientation for particles initially placed into serum and then adding 5%(V/V) plasma.
Summary/Conclusions: The technology presented offers an interesting insight into protein corona structure and kinetics of formation measured in biologically relevant solutions *i.e.* high protein, high salt levels and its particle-by-particle analysis gives a measure of the distribution of particle zeta potential that may offer a better understanding of the behaviour of nanoparticles used for drug/gene delivery in blood.

Hematopoiesis, stem cells and microenvironment

EXPANDING THE KNOWLEDGE OF BLOOD TRANSCRIPTOME: CIRCULAR RNAS IN HEMATOPOIESIS

A Bonizzato[1,*], E Gaffo[2], S Bortoluzzi[2], G te Kronnie[1]
[1]Women and Children's Health, [2]Molecular Medicine, University of Padova, Padova, Italy

Background: Circular RNAs (circRNAs) are a class of covalently closed RNA molecules generated by back-splicing joining exons in a non-collinear way. circRNAs have been found throughout the tree of life and are conserved in mammals. As reported circRNAs may decoy miRNAs thus de-repressing miRNA targets and regulating cellular processes and may interact with RNA-binding proteins and other RNAs. High stability and complex cell type- and differentiation-specific expression patterns make circRNAs promising disease biomarkers. In cancer circRNAs are highly relevant since they associate with cancer miRNAs and regulate cancer-related pathways. Moreover, specific circRNAs exhibit anti-cancer effects, whereas others discriminate malignant cells from healthy ones. Recent studies demonstrated that the circRNA number and expression level in normal blood is reproducible and higher than in other tissues and incipient observations detected circRNAs in B-ALL.
Aims: We aim to detect, discover and characterize circRNAs expressed during hematopoiesis in order to expand the knowledge of transcriptome complexity and variations in normal differentiation to set the basis for circRNA studies in hematologic malignancies.
Methods: CircRNA detection grounds on identification of RNA-seq reads that contain a back-splice junction. Different programs rely on slightly different approaches, such as using a pre-compiled dataset of all possible exons of each gene coupled in reverse order, or by *de novo* identifying the back-splice junction from signals in the alignment data coupled with signals of canonical splicing. Combining the output of at least two programs increases the accuracy of true circRNA detection, as suggested by recent literature. Poly-A enriched RNA-seq data of eight cell populations of the hematopoietic tree (Figure 1A) were collected (HSC, MPP, CMP, CLP, GMP, MEP, MK, EB cells; three biological replicates per cell type; ID: EGAS00001000284, by Chen L et al., 2014, Science).
Results: A bioinformatics pipeline for detection and analysis of cirRNAs from RNA-seq data was set up that brings together published circRNA detection tools (CIRI, find_circ and testrealign.x) and custom made scripts, with a modular design expandable to novel programs. Preliminary analyses performed with CIRI allowed us to detect 11,079 putative circRNAs expressed during hematopoiesis, of which 41% are exonic, 42% are intronic and 17% fall in regions annotated as intergenic (Figure 1B). Expressed circRNAs are associated to 4,317 known genes, 58% of which produce only one circRNA, whereas 837 (19%) genes produce two different circular isoforms each, and 959 (22%) even more than three isoforms. The large majority (87.5%) of circRNAs was detected only in one cell type, and in each cell population on average 15% of the total detected circRNAs is present. We identified 20 circRNAs expressed in all cell stages (Figure 1C) and defined several patterns of circRNAs that are up or down regulated in less differentiated cells compared to more mature stages (e.g. HSC *vs* CMP), specifically in the lymphoid compared with the myeloid branch of the tree (CMP *vs* CLP) and, through the myeloid lineage, from CMP to more and terminally differentiated cells.

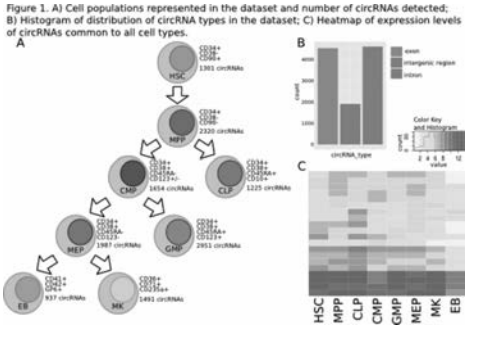

Figure 1.

Summary/Conclusions: Recent studies have unveiled a great potential of circRNAs in hematology. Our results, although preliminary, confirm that a high number of circRNAs are expressed during hematopoietic cell differentiation. We identified circRNAs expressed by all cell stages in the dataset, and several expression patterns that seem to be specific of stem cells, of differentiated cells, or of cellular lineages. We plan to conduct additional RNA-seq data analyses with different approaches to enrich the set of detected circRNAs in true positive hits, in order to validate them, to confirm some of the more striking expression variations observed and to predict functions and interactions of expressed circRNAs.

THE APC/C COACTIVATOR CDH1 CONTROLS MAINTENANCE OF THE HEMATOPOIETIC STEM CELL POOL *IN VIVO*

S Kreutmair*, D Ewerth, A Gengenbacher, J Duyster, R Waesch, AL Illert
Hematology, Oncology and Stem Cell Transplantation, University medical center Freiburg, Freiburg, Germany

Background: Cdh1 is a co-activator of the anaphase-promoting complex (APC/C) and highly active during G1 to target cell cycle proteins for proteasomal degradation thereby regulating cell proliferation. Recently, evidence accumulates, that Cdh1 may play a role in proliferation, self-renewal and multilineage differentiation of hematopoietic stem cells (HSCs).
Aims: Our objective was to examine the functional role of Cdh1 in the hematopoietic compartment in *vivo*.
Methods: We used a murine transplantation model in combination with targeted genetic RNAi approach for Cdh1 deletion in a competitive transplantation (TX) assay. Therefore, 5-FU enriched murine bone marrow cells (BMCs) were lineage depleted and retrovirally infected either with pLMPmiR^{Ctrl} or pLMPmiR^{CDH1}. Primary BMCs and equal proportions of stem and progenitor cells with significant Cdh1 knockdown were transplanted in competition with non-infected wildtype BMCs into lethally irradiated wildtype recipients.
Results: Peripheral blood (PB) chimerism of recipient mice revealed a significant higher ratio of EGFP+ leukocytes in recipients of pLMPmiR^{CDH1} BMCs compared to controls (p=0.009). Moreover, spleen and BM chimerism showed significantly enhanced repopulation of Cdh1 knockdown cells at week 3 compared to pLMPmiR^{Ctrl} BMC recipients (p=0.004). Furthermore, Cdh1 knockdown leads to a significant decrease of apoptotic cells compared to control BMCs. Additionally, a highly significant decrease in the Sub-G1 cell population in Cdh1 knockdown BMC recipients confirms enhanced viability of Cdh1 knockdown cells. In contrast to apoptosis alterations, no obvious difference in cell cycling could be monitored between sorted EGFP+ pLMPmiR^{Ctrl} or pLMPmiR^{CDH1} infected BMCs of recipient mice 3 and 8 weeks after TX by dynamic 2-dimensional EdU/FxCycle violet assays. Interestingly, the difference in chimerism vanished during the course of the TX assay. To evaluate differences in the repopulation capacity of Cdh1 knockdown and control BMCs in transplanted animals, FACS analysis were performed and showed a significant reduction of LK- (lineage-, cKit+, Sca1-) and LSK- (lineage-, cKit+, Sca1+) cell frequency within pLMPmiR^{CDH1} BMC recipient mice compared to controls at the end of TX indicating that Cdh1 knockdown leads to an initial increase in repopulation capacity followed by exhaustion of hematopoietic stem and progenitor cells in a competing situation. To examine whether Cdh1 modulates lineage differentiation of HSCs we performed FACS analyses and detected a significantly higher proportion of B-cells in recipient mice transplanted with pLMPmiR^{CDH1} BMCs compared to control animals. Analyses of the myeloid compartment displayed differences with reduced levels of granulocytes as well as monocytes in the PB of Cdh1 knockdown transplanted BMCs compared to the pLMPmiR^{Ctrl} group. T-cells were not affected significantly by Cdh1 knockdown, at least in this short transplantation setting.
Summary/Conclusions: Taken together, Cdh1 knockdown leads to enhanced viability as a consequence of less susceptibility to apoptosis *in vitro* and *in vivo*, suggesting that Cdh1 plays an important role in maintaining the stem cell numbers within the HSC pool. Furthermore, Cdh1 knockdown regulates lineage differentiation in favor to the B-cell differentiation, whereas the myeloid lineage is repressed in Cdh1 knockdown cells in competitive transplantation experiments.

E1126

THE TRANSCRIPTION FACTOR C/EBPG IS RESPONSIBLE FOR RAPID PRODUCTION OF NEUTROPHILS DURING EMERGENCY GRANULOPOIESIS

M Kardosova[1,*], P Zjablovskaja[1], T Brdicka[2], D G. Tenen[3,4], M Alberich-Jorda[1]
[1]Laboratory of Hematooncology, [2]Laboratory of Leukocyte Signalling, Institute of Molecular Genetics, Prague, Czech Republic, [3]Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore, [4]Harvard Stem Cell Institute, Harvard University, Boston, United States

Background: CCAAT/enhancer binding protein γ (C/EBPγ) is a member of the C/EBP family of myeloid transcription factors, which are known as master regulators of hematopoiesis. Recently, it has been shown that increased C/EBPγ levels contribute to the block of neutrophilic differentiation in acute myeloid leukemias characterized by C/EBPα hypermethylation. Hovewer, the function of C/EBPγ in normal and stress-induced hematopoiesis remains largely unknown.
Aims: In this study we investigate the role of C/EBPγ in hematopoiesis both in steady-state and under stress conditions.
Methods: We generated a C/EBPγ conditional knockout murine model, which allows tissue and time specific excision of C/EBPγ. These mice were crossed to Vav-1Cre deleter strain to excise C/EBPγ specifically in the hematopoietic system from early embryonic stages. We employed C/EBPγ f/f Vav-1Cre- and C/EBPγ f/f Vav-1Cre+ mice, refered here as wt and C/EBPγ ko respectively. First, frequency of distinct hematopoietic lineages in bone marrow, spleen, and blood of C/EBPγ ko mice was determined by flow cytometry. Next, to elucidate whether C/EBPγ is necessary for stress induced granulopoiesis, *in vivo* administration of different stimuli, including lipopolysacharide (LPS), granulocyte colony-stimulating factor (G-CSF) and *Candida albicans*, was used to model bacteria- or candidemia-induced emergency granulopoiesis. Mice were sacrified and examined 24 hours after infection since we focused on early phases of granulopoiesis. Differential cell counting and flow cytometric analysis were performed to assess whether C/EBPγ is involved in demand-accelerated neutrophilic production.
Results: Mice lacking C/EBPγ within the hematopoietic system presented partially reduced levels of blood neutrophils (wt 1.438x10^6/ml -/+ 0.114 *vs* CEBPγ ko 0.988x10^6/ml -/+ 0.078, p=0.0021), although this reduction did not result in any signs of sickness. Analysis of other cell populations, including progenitors and hematopoietic stem cells, did not reveal further differences between wt and C/EBPγ ko mice. These data suggest that hematopoietic-specific genetic ablation of C/EBPγ is not critical for steady-state hematopoiesis. Since C/EBPγ forms heterodimers with another C/EBP member, C/EBPβ, we determined whether C/EBPγ can modulate the function of this transcription factor. C/EBPβ is critical for emergency granulopoiesis, and therefore we investigated whether the absence of C/EBPγ would affect this process. Deletion of C/EBPγ did not compromise the ability of the hematopoietic system to respond to G-CSF or LPS, since flow cytometric analysis revealed similar hematopoietic response in C/EBPγ ko mice in comparison to wt control animals. Interestingly, C/EBPγ ko mice showed reduced numbers of blood neutrophils during early phases of candidemia (wt 2.44x10^6/ml +/- 0.78, *vs* CEBPγ ko 1.55x10^6/ml +/- 0.59, p=0.031). In addition, the distribution of different developmental stages within the neutrophilic compartment in bone marrow was perturbed, leading to the accumulation of more immature granulocytic populations and reduced percentage of mature neutrophils. Altogether, these results indicate that C/EBPγ promotes accelarated neutrophilic production during early phases of emergency granulopoiesis upon *Candida* stimulation.
Summary/Conclusions: Taken together, our data unravel C/EBPγ as a player in the expansion of granulocytes during early phases of candidemia-induced emergency granulopoiesis. On the other hand, C/EBPγ appears to be dispensable for the regulation of steady-state hematopoiesis and bacteria-induced granulopoiesis.

TELOMERASE MRNA IN T CELL LEUKEMIA CELL LINE (JURKAT) DERIVED EXOSOMES TRANSFORMS NONMALIGNANT FIBROBLASTS INTO TELOMERASE POSITIVE CELLS

O Uziel[1], A Gutkin[1], E Beery[1], J Nordenberg[1], M Pinchasi[1], H Goldvaser[2], S Henick[1], M Goldberg[3], M Lahav[4,*]
[1]FMRC, Beilinson Hospital and Tel Aviv University, [2]Institute of Oncology, Davidoff Cancer Center Beilinson Hospital, Petah-Tikva, [3]Department of Genetics, Institute of Life Sciences, Hebrew University of Jerusalem, Jerusalem, [4]FMRC, 5Institute of Hematology, Davidoff Cancer Center Beilinson Hospital and Tel Aviv University, Petah-Tikva, Israel

Background: Exosomes are small (30-100nm) vesicles secreted from all cell types serving as inter- cell communicators by affecting biological processes in "recipient" cells upon their uptake. Telomerase is transcriptionally repressed in non malignant somatic cells thus enabling cellular senescence caused by telomere shortening. Telomerase activation is a hallmark of cancer cells providing them with endless replicative potential. Telomerase activation is associated also with other major cellular changes such as resistance to DNA damage, protection from apoptosis and others. We demonstrate that hTERT mRNA is transferred via exosomes from Jurkat cells into telomerase negative primary fibroblasts. The mRNA is translated into active telomerase causing several major changes in those cells. These findings have potential implications for tumor cells-microenvironment interactions.
Aims: To assess the presence of hTERT mRNA, the transcript of the enzyme telomerase, in exosomes secreted from Jurkat cells; to study the possible effects of this transcript on the phenotype of fibroblasts cells upon exposure to exosomal hTERT mRNA.
Methods: Exosomes were isolated by exosome isolation kit (exoquick). Real time PCR was performed to assess the hTERT mRNA levels in exosomes and in the cells. Verification of exosome isolation and telomerase levels were estimated by Western blotting. Telomerase activity was assessed by Real time PCR based TRAP assay. Cellular proliferation and senescence status were assessed by Trypan blue exclusion and b-Galactosidase activity assays, respectively. Nuclear morphology was visualized after DAPI staining. DNA damage response was evaluated by counting gH2AX foci accumulation following phleomycin insult.
Results: The current study demonstrates for the first time that hTERT mRNA, the transcript of the enzyme telomerase, is shuttled from "donor" cancer cells via exosomes into "recipient" telomerase negative fibroblasts, where it is translated into a fully active enzyme. All tested cells secreted exosomal hTERT

mRNA in accordance with the endogenous levels of their hTERT mRNA and telomerase activity. A non-cancer fibroblasts cell line in which telomerase was ectopically expressed secreted relatively high levels of exosomal hTERT mRNA as well. A similar *ex-vivo* shuttle of exosomal hTERT mRNA isolated from the serum of a patient with pancreatic cancer into primary fibroblasts was demonstrated as well. Telomerase activity induced phenotypic changes in the recipient fibroblasts including extension of life span and postponing senescence. In addition, telomerase activity protected the fibroblasts from DNA damage induced by Phleomycin and also protected from apoptosis, indicating that telomerase extracurricular activities are also manifested in the recipient cells.
Summary/Conclusions: The shuttle of telomerase from cancer cells into fibroblasts and the induction of these changes may contribute to the formation of cancer associated fibroblasts representing a unique aspect of the cross talk between tumors and their microenvironment. These processes bear a therapeutic potential targets and as such serve as a promising research avenue.

E1129

PERIPHERAL BLOOD LEUKOCYTE TELOMERE LENGTH AND RISK OF INFECTIOUS DISEASE: A PROSPECTIVE STUDY OF 75,919 INDIVIDUALS FROM THE GENERAL POPULATION

J Helby[1,2,3,*], BG Nordestgaard[1,2,3,4], T Benfield[3,5], SE Bojesen[1,2,3,4]
[1]Department of Clinical Biochemistry, [2]The Copenhagen General Population Study, Herlev and Gentofte Hospital, Copenhagen University Hospital, Herlev, [3]Faculty of Health and Medical Sciences, University of Copenhagen, [4]The Copenhagen City Heart Study, Bispebjerg and Frederiksberg Hospital, Copenhagen, [5]Department of Infectious Diseases, Hvidovre Hospital, Copenhagen University Hospital, Hvidovre, Denmark

Background: In the general population, older age is associated with short leukocyte telomere length and with high risk of infections. In a recent study of allogeneic hematopoietic cell transplantation for severe aplastic anemia, long donor leukocyte telomere length was associated with improved long-term survival in the recipients. These findings suggest that leukocyte telomere length could possibly be a marker of overall immune competence. However, previous studies examining this hypothesis among individuals from the general population have produced conflicting results.
Aims: We tested the hypothesis that short telomere length in leukocytes is associated with high risk of infectious disease hospitalization.
Methods: Peripheral blood leukocyte telomere length was measured using quantitative polymerase chain reaction in 75,919 individuals from the general population. The participants were followed for up to 23 years.
Results: During follow-up, 9671 individuals were hospitalized due to infections. Short telomere length was associated with high risk of any infection (hazard ratio 1.05 per 1000 base pair shorter telomeres; 95% confidence interval 1.03-1.08), pneumonia (1.08;1.04-1.12) and endocarditis (1.32;1.06-1.66) after adjustment for other infectious disease risk factors. Telomere length was not associated with risk of skin infection, urinary tract infection, sepsis, diarrhoeal disease, meningitis or other infections.
Summary/Conclusions: Short leukocyte telomere length was associated with high risk of any infection, pneumonia and endocarditis. These findings indicate that leucocyte telomere length may be a marker of immune competence among individuals from the general population. Further studies are needed to determine whether risk of infections in allogeneic hematopoietic cell transplant recipients can be reduced by considering donor leukocyte telomere length when selecting donors.

E1130

ABNORMAL EXPRESSION OF PYRUVATE KINASE M2 IN MYELOID DENDRITIC CELLS OF THE PATIENTS WITH SEVERE APLASTIC ANEMIA

S Zonghong[*], C Liu, M Zheng, W Qi, R Fu, H Wang, Y Wu
Department of Hematology, General Hospital of Tianjin Medical University, Tianjin, China

Background: Severe aplastic anemia (SAA) is a hematologic disease characterized by pancytopenia with severe bone marrow failure. dendritic cells was found to be an antigen-presenting cell (APC) with a most powerful function.Our previous studies have demonstrated that activated myeloid dendritic cells (mDCs) increased in the bone marrow of SAA patients, which could accelerate the polarization of Th1 from Th0 cells, and then initiate the cellular immunity which played an important role in the primary stage of the immune response.
Aims: We further analyzed the protein components of mDC in SAA and explored the possible pathogen that activated mDC.
Methods: Basing on our previous research, we further analyzed the protein components of mDC in SAA as well as normal control, furtherly we applied both FACS western and qRT - PCR technology from a perspective of mRNA and protein to validate our discovery.to explored the possible reason that activated mDC.
Results: After 7 days of culture, the purity of mDC cells was more than 90% determined by flow cytometry. Results revealed that expression of pyruvate kinase M2(PKM2) were enhanced in mDCs from SAA patients at an early stage of the onset. Concurrently, the level of PKM2 in mDC of SAA patients (59.1±15.8)% was conspicuously higher than that in normal control (32.7±20.2)% at the protein level. We measured the levels of mRNA of *PKM2* genes in our patient samples and identified significantly higher expression of *PKM2* in the SAA untreated group (1.50±0.84) relative to the recovering group (0.81±0.24) and the control group (0.32±0.11, $p<0.05$). In addition, a similar phenomenon was seen by Western blot. As expected, the percentage of PKM2 in mDCs of SAA patients appeared to be strongly correlated with proliferous degree of bone marrow. The percentage of PKM2 in mDCs in patients with SAA was positively correlated with the proportion of reticulocytes absolute neutrophil counts and quantity of mDCs in peripheral blood. Additionally, the ratio of CD4+ T-helper lymphocytes to CD8+ T-suppressor lymphocytes ($T_{H/S}$) was correlated with the percentage of PKM2 in mDCs. However, no significant difference in platelet counts was detected in SAA patients.

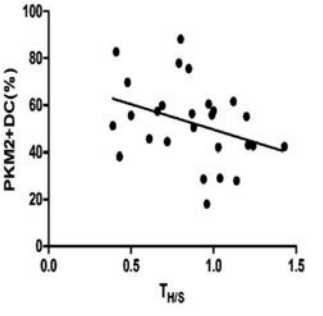

Figure 1. The purity of mDC cells was more than 90% determined by flow cytometry.

Summary/Conclusions: These findings demonstrated that dysregulation of PKM2 expression and activation in mDCs might exert an impact on the immune status of SAA patients by enhancing the cellular function of mDC.

E1131

ANALYSIS OF T CELL SUBSETS IN G-CSF PRIMED BONE MARROW FOR ALLOGENEIC STEM CELL TRANSPLANTATION AND ITS ASSOCIATION WITH CHRONIC GVHD INCIDENCE

MM Rivera Franco[1,*], D Gomez Martin[2], C Balderas Delgado[1], J Merayo Chalico[2], JC Alcocer Varela[2], E Leon Rodriguez[1]
[1]Hematology-Oncology, [2]Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, MEXICO CITY, Mexico

Background: There is a subset of T cells which modulate the immune system, maintain tolerance to self-antigens, and abrogate autoimmune disease, called regulatory T cells (Tregs). These cells generally suppress or downregulate induction and proliferation of effector T cells. Regulatory T cells come in many forms with the most well-understood being those that express CD4, CD25, and Foxp3 (CD4+CD25+ regulatory T cells). Mouse models of bone marrow transplantation as well as some clinical trials, have shown that the administration of Tregs in combination with the harvested bone marrow prevent and decrease graft-*versus*-host-disease (GVHD) and facilitate engraftment. At our institution the population transplanted with G-CSF primed bone marrow, has a lower incidence of chronic GVHD compared to those transplanted with peripheral blood and not primed bone marrow. Some microenvironment characteristics of this hematopoietic stem cells (HSC) source remain unknown, as well as the quantitative profile of different T cell subsets in patients who develop chronic GVHD and those who do not.

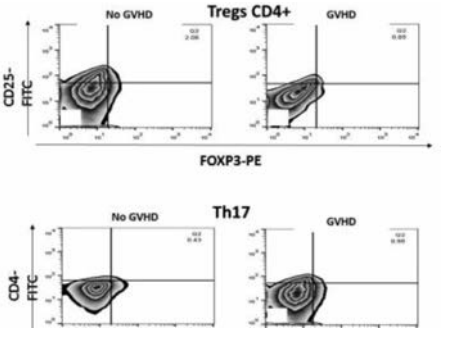

Figure 1.

Aims: To analyze the characteristics of G-CSF primed bone marrow, identifying different T cell subsets, such as Th1, Th2, Th17, and Tregs. in 29 donor samples, between patients who developed chronic GVHD and those who did not.
Methods: A prospective analysis was performed in 29 G-CSF primed bone marrow samples from donors from 1999 to 2012. Mononuclear cells were

defrosted, counted, and viability was assessed by trypan blue exclusion After a 24 hour resting time (RPMI), mononuclear cells were stimulated with PMA (50 ng/ml) for 48 hours and cells were harvested and stained for FACS analysis. Supernatants were collected and measured by Cytometric Bead Array. From each sample, one million mononuclear cells were permeabilized, fixed, and stained with CD4-FITC, IL17A-PE, *IFN*-γ APC, and IL-4 PECy7, and were analyzed by FACS. All samples were obtained in a BD LSR Fortessa cytometer and analyzed with the Flow-Jo software. Patients (recipients) demographic and clinical data were analyzed with support of the software SPSS v.21.
Results: GVHD incidence was reported as following: Ten patients (34.5%) developed chronic GVHD (10% extensive, and 90% limited), and 16 patients did not present either. There was no difference in TH1 and TH2 numbers between both groups, but mononuclear cells from donors of patients who developed chronic GVHD had a higher percentage of Th17 cells (0.99% *vs* 0.44%, p<0.001), as well as decreased Tregs (0.91% *vs* 2.00%, p<0.001), compared to those who did not developed GVHD. It was not possible to relate T cell subsets with chronic GVHD severity since only one patient developed extensive disease.
Summary/Conclusions: With the usage of G-CSF primed bone marrow as a source of HSC, the incidence of chronic GVHD at our institution was 34.5%. Patients who develop chronic GVHD are characterized by a pro inflammatory response with a higher percentage of Th17 cells, as well as a decreased suppressive response characterized by reduced Tregs levels. The low incidence of chronic GVHD show that G-CSF primed bone marrow is an excellent source for allogeneic HSC transplantations, and would be useful to compare its lymphocyte subset profile and cytokines levels with other HSC sources.

E1132

DYSFUNCTION OF BONE MARROW ENDOTHELIAL PROGENITOR CELLS FROM SUBJECTS WITH POOR GRAFT FUNCTION FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION CAN BE IMPROVED BY ATORVASTATIN

M Shi*, Y Kong, Y Song, X Huang
Peking University Institute of Hematology, Beijing, China

Background: Poor graft function (PGF) is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT) and the mechanisms are poorly understood. Murine studies suggest that endothelial progenitor cells (EPCs) are preferential supporting cells for hematopoietic stem cells (HSCs) in the bone marrow (BM) microenvironment. Our previous prospective nested case-control study suggested that a lower frequency of EPCs, which represent a key cellular component of the BM microenvironment, was an independent risk factor for the occurrence of poor graft function after allo-HSCT. However, the functional role of bone marrow EPCs in the subjects with poor graft function has never been reported. Moreover, approaches for improving the dysfunction of bone marrow EPCs in subjects with PGF are lacking. Atorvastatin has been reported to improve the mobilization and function of circulating EPCs in a number of diseases, such as heart disease, diabetes, ischemic stroke and others. Nevertheless, no previous studies have focused on the roles of atorvastatin on bone marrow-derived EPCs in subjects with poor graft function following allo-HSCT.
Aims: In this study, we evaluated the function of bone marrow EPCs in subjects with poor graft function post-allotransplant. Moreover, we investigated whether atorvastatin could enhance the number and function of bone marrow EPCs derived from subjects with poor graft function in vitro.
Methods: Three cohorts were included: subjects with poor graft function (N=15), subjects with good graft function (N=15), defined as persistent successful engraftment after allotransplant, and transplant donors as normal controls (N=15). Atorvastatin (0.5nM,5nM,500nM) was administrated to the bone marrow EPCs in subjects with poor graft function cultured for 7 days. The number and functions ofCD34(+)/CD133(+)/KDR(+)EPCs were evaluated by flow cytometry, cell counting, DiI-Ac-LDL and FITC-lectin-UEA-1 double staining, migration, tube formation test and apoptosis. Reactive Oxygen Species (ROS) level was evaluated by flow cytometry and DCFH-DA staining. Cell proliferation was determined by cell counting kit-8 assay. Protein expression for p-p38,p38, p-akt, akt was measured by flow cytometry and western blots.
Results: Dysfunctional bone marrow EPCs, which were characterized by decreased migration and angiogenesis and higher levels of reactive oxygen species and apoptosis, were found in subjects with poor graft function following allo-HSCT. The phospho-p38 expression was significantly elevated in subject with poor graft function but all groups showed similar intracellular levels of phospho-Akt. Furthermore, bone morrow EPCs derived from subjects with poor graft function were enhanced both quantitatively and functionally by 500nM atorvastatin treatment in culture on day 7 through down-regulation of the p38 MAPK pathway.
Summary/Conclusions: In summary, the current study is, to our knowledge, the first to demonstrate the dysfunctions of bone marrow EPCs in the bone marrow microenvironment of subjects with poor graft function following allo-HSCT. Moreover, atorvastatin treatment in vitro quantitatively and functionally improved the bone morrow EPCs derived from subjects with poor graft function through down-regulation of the p38 MAPK pathway. Our results indicate that atorvastatin represents a promising therapeutic approach for repairing the impaired EPCs in subjects with poor graft function post-allotransplant.

E1133

MULTIPOTENT PROGENITOR CELLS AND ACQUIREMENT OF HEMATOPOIETIC CAPACITY IN THE BONE MARROW OF XENOPUS LAEVIS

Y Tanizaki[1,*], Y Mochizuki[2], T Aiso[1], T Kato[1,2]
[1]Faculty of Education and Integrated Arts and Sciences, [2]Integrative Bioscience and Biomedical Engineering, Graduate School of Advanced Science and Engineering, Waseda University, Shinjuku, Japan

Background: Hematopoietic stem cells (HSCs) are characterized by their capacity for long-term repopulation and multilineage differentiation upon cytokine stimulation. Thrombopoietin (TPO) is one of the key regulators of HSC maintenance and platelet production. Previously, we cloned *Xenopus laevis* (*X. laevis*) TPO (*xl*TPO) and demonstrated that differentiation and proliferation in thrombocyte progenitors and hematopoietic progenitors are regulated by *xl*TPO. Unlike that of mammals, bone marrow (BM) of *X. laevis* is filled with adipose cells, and blood cells are mainly produced in the liver. However, functional contribution of fatty marrow for hematopoiesis is unclear, and multipotent hematopoietic progenitor is not yet identified in *X. laevis*.
Aims: In this study, we attempted to identify multipotent hematopoietic cells and evaluate the ability of hematopoiesis in fatty marrow in *X. laevis*.
Methods: The suspension cells in *X. laevis* were cultured in semi-solid culture system in the presence of *xl*TPO. Laparotomy was performed in *X. laevis* under anesthesia with MS222. The left liver was resected, and cultured with *xl*TPO for 24 days. The cultured cells were labeled by PKH26 and autologously transplanted by intracardiac injection. After 30 days, the *X. laevis* were killed and their right liver was analyzed by FACS. PKH26 labelled cultured cells were also injected into the blastocoels of *X. laevis* embryos at stage 8, which have no immune system. After 3 days, the labeled cells were analyzed by fluorescence microscope. For low-temperature exposure, cage containing *X. laevis* were transferred to an incubator set at 5°C for 12 days. For micro-computerized tomography (mCT) analysis, *X. laevis* were restrained in polystyrene foam restrainers, and the femurs were imaged by three-dimensional X-ray CT scan.
Results: Hepatic colonies stimulated by *xl*TPO could be cultured for more than 3 months, during which the cell number reached 1×10^6, indicating that the cells divided at least 20 times. These colonies expressed erythrocyte-, thrombocyte-, leukocyte-, and HSC-specific markers. Moreover, these cells differentiated to thrombocytes and leukocytes in the presence of splenic-conditioned media. Liver cells obtained by partial hepatic resection were cultured in the semi-solid culture system in presence of *xl*TPO, and cells labeled with PKH26 were autologously transplanted. After 30 days, PKH26-positive cells were detected in the sinusoids of liver and spleen. Flow cytometric analysis showed that the PKH26-positive cells displayed low forward (FSC) and side (SSC) scatter and had thin-layered cytoplasm and round nuclei, which are typical features of mammalian HSCs. These results indicated that *xl*TPO regulates proliferation of hematopoietic progenitors, which can be engrafted and differentiated to multiple lineages. To enrich multipotent hematopoietic cells, we generated anti-*xl*Mpl monoclonal antibodies and showed that anti-thrombocyte antibody $(T12)^-$/*xl*Mpl^+/FSC^{low} population was enriched in high nuclear/cytoplasm ratio-hematopoietic progenitors, and the ratio of these cells to all hepatic cells was 0.28%. Surprisingly, $T12^-$/*xl*Mpl^+/FSC^{low} cells were identified in the liver, spleen, and BM in normal state. Although BM in *X. laevis* comprises mostly of adipocytes, large colonies induced by *xl*TPO were identified in the BM. The protein expression patterns in these cells overlapped with those in colonies derived from the liver, demonstrating that multipotent hematopoietic progenitors were localized in the BM. To explore the hematopoietic capacity in the BM, *X. laevis* were exposed to 5°C, which led to pancytopenia. After exposure to low temperature for 12 days, the numbers of erythrocyte and multipotent progenitors were increased. mCT revealed that femoral bone density was higher than that before exposure to 5°C, indicating change in the BM microenvironment.
Summary/Conclusions: In conclusion, multipotent hematopoietic progenitors in *X. laevis* are enriched in $T12^-$/Mpl^+/FSC^{low} cells and these cells are mainly localized in the liver and BM. These findings suggested that $T12^-$/Mpl^+/FSC^{low} cells in BM is dormant, and changes in the BM microenvironment by low-temperature stimulation induced proliferation of hematopoietic progenitors.

E1134

BONE MARROW STROMAL CELLS FUNCTIONAL CHARACTERISTICS STUDY IN RECIPIENTS BEFORE ALLO-BMT

N Tcvetkov, I Barkhatov*, E Davydova, A Shakirova, D Romaniuk, O Smykova, A Borovkova, O Slesarchuk, L Zubarovskaya, B Afanasyev
R.M. Gorbacheva Memorial Institute of Children Oncology, Hematology and Transplantation, First Pavlov Saint Petersburg State Medical University, St.Petersburg, Russian Federation

Background: The role of the stromal microenvironment in hematopoietic stem cell transplantation (HSCT) is based on nonlineage-specific effects on proliferation and differentiation of HSCs. Deficient graft functioning observed in some cases necessitates development of functional tests for the stromal cells, in order to provide clinical indications for co-transplanting of hematopoietic and bone marrow stromal cells (BMSC), and evaluable introduction of alternative therapeutic approaches.

Aims: The aim of this study was to investigate the role of bone marrow stromal cells in the course of donor marrow cells engraftment and their significance in post-transplant complications.
Methods: The study included clinical observation of the post-transplant course in ten patients with acute myeloid leukemia (AML) and 7 healthy donors. Bone marrow nucleated cells were selectively harvested two weeks prior to BMT, followed by monolayer culture in alpha-MEM culture medium with 20% fetal bovine serum. Upon growth of fibroblast-like cell colonies (CFU-F), their hematopoiesis-supporting activity was determined in the agar-drop/liquid culture system, as well as their differentiating ability along adipogenic and osteogenic pathways. We have also analyzed the relative expression of *selectin* and *CXCR4* genes in these cells.
Results: When comparing functional characteristics of BMSC from healthy donors and AML patients, an increased hemostimulatory activity of the latter was noted, as reflected by an increase in large and small CFU-GM numbers ($p<0.02$). In addition, an increase in differentiation along adipogenic and osteogenic pathways was observed in AML patients ($p=0.03$). Moreover, the number of CFU-Fs, capable for adipogenic differentiation was inversely correlated with platelet recovery time ($p=0.05$). In contrast, higher numbers of osteogenic colonies in culture were associated with an increased time to leukocyte lineage recovery ($p=0.05$). When analyzing gene expression in BMSC population, a decreased expression of the *CXCR4* gene responsible for the homing effect, with age of the patient's ($p=0.05$) was noted. The *selectin* gene expression in BMSC was higher by AML patients as compared to healthy donors.
Summary/Conclusions: Stromal cells derived from the patients' bone marrow exhibit higher proliferative activity and marked expression of molecules mediating HSC homing, as compared with a group of healthy donors. That finding could be explained by affection of stromal cells by previous chemotherapy and myelosuppression. BMSC from AML patients taken before bone marrow transplantation are characterized by a more pronounced capacity to osteogenic and adipogenic differentiation than those from healthy donors. Increased adipogenic differentiation ability of the BMSCs is associated with a more rapid recovery of hematopoiesis.

G-CSF TREATMENT IN VIVO INDUCES BONE MARROW RELEASE OF PD-L1 POSITIVE MYELOID DERIVED SUPPRESSIVE CELLS

E Lereclus[1,*], X Lafarge[2], M Donnard[3], S vigouroux[4], P Turlure[5], A Assal[2], J Feuillard[1], Z Ivanovic[2], R Jeannet[1]
[1]UMR CNRS 7276, CBRS, Limoges, [2]EFSAL, Bordeaux, [3]CHU Limoges, Limoges, [4]Hematologie, CHU Bordeaux, Bordeaux, [5]Hematologie, CHU Limoges, Limoges, France

Background: For its two main adverse effects which engage the vital prognosis, graft *versus* host disease (GVHD) and graft *versus* leukemia (GVL), tuning the immune system is the major challenge for successful cure of the patient who benefits from Hematopoietic Stem Cell (HSC) transplantation. Myeloid derived suppressor cells (MDSCs) are supposed to be an immature leukocyte subset composed of granulocytic cells (GrMDSC) and monocytic cells (MoMDSC). They are well described in different pathologies such as cancer, burns and sepsis. Few publications suggest that G-CSF induces bone marrow release of myeloid derived suppressive cells (MDSCs). But, phenotypically, it is hardly possible to distinguish them from other myeloid precursors with the classical lineage markers. Recently, immunosuppressive action of MDSCs was reported to be due to the PD-L1 molecule that renders these cells able to kill T-cells through the PD-1/ PD-L1 axis.
Aims: Using PD-L1 as an additional marker, the aim of this study was to quantify MDSCs subsets (GrMDSC and MoMDSC) before and after G-CSF treatment as well as in bone marrow of donors prior Hematopoietic Stem Cell (HSC) transplantation.
Methods: Recruitment of donors was done in two hospitals university centers (Bordeaux and Limoges, France).We analyzed 10 samples of peripheral blood (PB) before and 17 after G-CSF treatment, 27 samples of cells collected after apheresis (PSC) and 5 samples of bone marrow (BM) as control. We measured the rate of GrMDSC ($CD45^+$ Lin^- $CD11b^+$ $CD14^-$ $CD33^+$ $CD16^-$ HLA-DR^- $PD\text{-}L1^+$) and MoMDSC ($CD45^+$ $CD11b^+$ $CD14^+$ $CD33^+$ $CD16^-$ HLA-DR^- $PD\text{-}L1^+$) in BM, PB and PSC sample by flow cytometry. Percentage and absolute counts CD34 and CD3 positive cells in G-CSF treated donors have been also collected. Differences between groups were tested for significance with the Student t-test.
Results: White blood cell count was 5.09 +/- 2.55 G/L and 45.77 +/- 25.5 G/L before and after G-CSF treatment. Levels of $PD\text{-}L1^+$ HLA DR^- MoMDSCs and $CD33^+$ Lin^- $PDL1^+$ GrMDSCs were 0.0013 +/- 0.0027 G/L (0.023% +/- 0.042%) and 0.058 +/-0.048 G/L (1.15% +/- 0.91%) in PB before and were 0.078 +/- 0.085 G/L (0.21% +/- 0.25%) and 12.31 +/- 6.52 G/L (28% +/- 13.3%) after G-CSF treatment ($p=0.002$ and $<10^{-4}$ respectively). Percentages of MoMDSCs and GrMDSCs with PDL1 expression in bone marrow were 0.0033% +/- 0.0071% and 0.84% +/- 1.21%. Apheresis treatment was associated with enrichment in $PDL1^+$ MoMDCs but with a loss of $PDL1^+$GrMDSCs. Nevertheless, when compared to bone marrow, percentages and total numbers of both PDL1+ MoMDSC and GrMDSC in apheresis products were still much higher than in bone marrow ($p<0.0001$ and $p=0.0006$). There was no correlation between levels of $CD34^+$ stem cells, $CD3^+$ or $CD19^+$ lymphocytes and MDSCs after G-CSF treatment.
Summary/Conclusions: In this study we have shown that $PDL1^+$ MDSCs were virtually absent in normal bone marrow and that G-CSF treatment induced a strong MDSC production. We have also demonstrated that, compared to PB, the product of apheresis was even more enriched in MoMDSC but was partially depleted in GrMDSC. These results point a major difference between bone marrow HSCs and PSCs in terms of immunomodulation capacities of the engraftment product.

E1136

ALTERATIONS OF BONE MARROW MICROENVIRONMENT IN PATIENTS WITH HEMATOLOGICAL DISORDERS AT THE DIAGNOSIS AND DURING THE TREATMENT

T Sorokina[1,*], I Shipounova[2], A Bigildeev[2], N Petinaty[2], N Drize[2], L Kuzmina[1], E Parovichnikova[1], V Savchenko[3]
[1]Bone Marrow Transplantation, [2]Physiology of Hematopoiesis Lab, [3]National Research Center for Hematology, Moscow, Russian Federation

Background: Bone marrow (BM) microenvironment is involved in the initiation and propagation of normal hematopoiesis and hematological diseases. Leukemia and chemotherapy affect hematopoietic and stromal precursor cells. Multipotent mesenchymal stromal cells (MMSCs) are the essential element of hematopoietic microenvironment.
Aims: The study aimed to characterize MMSCs and their more differentiated progeny CFU-F derived from the BM of the patients with hematological disorders at diagnosis and during the treatment.
Methods: 74 newly diagnosed cases (33 AML, 21 ALL, 20 CML) were involved in the study after informed consent. BM was aspirated prior to treatment (time-point 0) and at days 37, 100 and 180 since the beginning of treatment of acute leukemia and +3, +6 and +12 months for CML (time-points 1-3). MMSCs were cultured in aMEM with 10% fetal calf serum. Time to P0 and cumulative MMSC production after 3 passages were evaluated and CFU-F concentration was analyzed. The relative expression level (REL) of genes was measured by TaqMan RQ-PCR. As a control MMSCs and CFU-Fs from 88 healthy donors were used.

Table 1.

	Time-point	AML	ALL	CML
Time to P0, days	0	17.6 ± 0.6 *	19.8 ± 1.4 *	17.7 ± 0.8 *
	1	15.5 ± 0.9	14.1 ± 0.9	16.7 ± 0.8 *
	2	16.6 ± 0.6 *	16.0 ± 0.9	18.2 ± 1.0 *
	3	16.8 ± 0.5 *	16.2 ± 0.7 *	17.6 ± 0.7 *
Cumulative cell production for 3 passages, $x10^6$	0	4.8 ± 0.7 *	5.2 ± 1.4	7.5 ± 1.6
	1	7.9 ± 1.4	7.7 ± 1.5	7.1 ± 1.1
	2	10.1 ± 1.7	8.2 ± 1.4	6.7 ± 1.2
	3	9.8 ± 1.4	9.4 ± 2.3	6.5 ± 0.7
CFU concentration per 10^6 BM cells	0	11.5 ± 4.6 *	8.3 ± 3.6*	15.8 ± 4.2*
	1	27.7 ± 4.4	30.3 ± 8.2	21.2 ± 4.4
	2	16.3 ± 3.5	18.5 ± 6.5	12.6 ± 2.8 *
	3	21.2 ± 3.7	28.9 ± 7.8	4.9 ± 1.1 *

*statistically significant difference from control group($p<0.05$)

Results: Time needed to reach P0 reflects the quantity of MMSC in the BM sample. The time to P0 in control group was 13.7±0.3 days. Its elongation in acute leukemia cultures at the time of the diagnosis (table) suggested the reduction of MMSC number probably due to leukemic expansion, while the longer time to P0 at time-points 2 and 3 could be explained by the therapy influence. In CML cultures time to P0 was significantly longer during the whole observation period due to the continuous therapy and maintaining disease. Cumulative MMSC production in control group was 7.1±1 x 10^6 cells. In patients with AML it was 1/3 of the donor's at the disease manifestation with no difference at time-points 1-3, indicating the impaired proliferative abilities of MMSC at the AML manifestation. Cumulative MMSC production in patients with ALL and CML didn't differ from donor's. BM blast count did not correlate with MMSC production. CFU-F concentration in the BM of acute leukemia patients was significantly lower than donor's (25.4±3.1 per 10^6 cells) at the time-point 0 with no difference at time-points 1-3. CFU-F concentration in the BM of CML patients was also nearly 40% lower than in control group at the time-point 0 with its following restoration at time-point 1 and subsequent drop (up to 5 fold lower) at time-point 3, reflecting the long-lasting lesion of CFU-Fs during the course of the disease. Gene expression analysis of MMSC from all patients revealed significant decrease in REL of VEGF and SOX9 genes at the disease manifestation that did not restore after the treatment. The REL of LIF was significantly increased at the disease manifestation, reflecting the efforts of MMSCs to inhibit leukemic proliferation. REL of PDGFRB and IL6 increased during the treatment. The treatment lead to the downregulation of FGF2, TGFB1 and 2. As FGF2 and TGFB inhibit the differentiation of MMSCs, their downregulation may refer to the effectiveness of therapy. In MMSCs from acute leukemia patients the ICAM and SPP1 genes were downregulated at all points, reflecting the mechanism of the blocking of MMSCs migration and differentiation during the stress conditions. The influence of chemotherapy lead to decrease in REL of SDF1, IL8, VCAM, IL1b1R1, JAG1, IGF1, FGFR1 and 2.

Summary/Conclusions: The study supports the major influence of leukemic cells and chemotherapy on the BM microenvironment. The two types of studied precursors are affected differently. Future studies are needed to evaluate the role of MMSCs in leukemia pathogenesis.

COMPARISON OF MOLECULAR AND FUNCTIONAL PROFILES OF WHARTON'S JELLY AND BONE MARROW MESENCHYMAL STEM CELLS

A Batsali[1,2], C Pontikoglou[1,*], E Kouvidi[1], A Damianaki[1], F Papadogiannis[1], I Liapis[1], H Papadaki[1]
[1]Department of Hematology, [2]Graduate Program, University of Crete School of Medicine, Heraklion, Greece, Heraklion, Crete, Greece

Background: We have previously shown that *ex vivo* expanded human mesenchymal stem/stromal cells (MSCs) derived from the Wharton's jelly (WJ) of the umbilical cord exhibit increased proliferative capacity and reduced differentiation potential to adipocytes and osteocytes, compared to bone marrow (BM) derived-MSCs. This altered differentiation capacity has been attributed, at least in part due to reduced expression of Wnt antagonist sFRP4 (a promoter of adipogenesis) and WNT-induced secreted protein-1 (a regulator of osteogenesis in WJ-MSCs), thereby supporting the contribution of WNT-pathways in human MSC biology (Batsali A et al.,Blood 2014:124,21).
Aims: In order to extent the comparative study between BM and WJ-MSCs we seek to estimate the telomere length of cultured MSCs and analyze the cell-cycle signaling pathway. Moreover, we aim to investigate the capacity of WJ-MSCs to support the growth of hematopoietic stem cells (HSCs).
Methods: MSCs were isolated and expanded from healthy donors' BM aspirates (n=15) and from the WJ of full-term neonates (n=15) after written informed consent. MSCs were *in vitro* expanded and re-seeded for a total of 10 passages and were verified phenotypically by flow cytometry. The expression of 84 genes related to cell-cycle signaling pathway was assessed using a PCR array (Fold Change (FC) $=2^{-\Delta\Delta Ct}$). DNA was isolated from culture expanded MSCs (at P2, P6 and P10) and telomere length was measured by means of real-time-PCR using β-globin as control. Telomere length is proportional to the relative telomere/single-copy-gene ratio, $T/S= 2^{-\Delta Ct}$ ($\Delta Ct= Ct^{telomere} - Ct^{\beta\text{-globin}}$). Levels of human hematopoietic associated cytokines (Flt-3 ligand/G-CSF/GM-CSF/SDF-1a) were measured by means of enzyme-linked-immunosorbent assay, from supernatants of MSC cultures (from P2, P6 and P10). MSC hematopoietic supportive capacity was evaluated in two-week co-cultures with allogeneic BM or UC-blood CD34+ cells.
Results: Culture-expanded cells from both WJ and BM displayed typical morphological and immunophenotypic MSC characteristics and were able to differentiate into osteoblasts and adipocytes. Regarding the cell-cycle signaling pathway many genes essential for mitosis and genome stability were up-regulated in WJ-MSCs, such as ATM (FC=4.04), CCND2 (FC=4.55), AURKB (FC=3.15) and MKI67 (FC=2.86), while the anti-apoptotic gene BCL2 was down-regulated (FC=4.07). Moreover the relative telomere length of WJ-MSCs was higher comparing with BM-MSCs through all passages, with a significant difference in P2 ($p=0.032$). The expression of hematopoietic associated cytokine Flt-3 ligand, an important cytokine for development of several hematopoietic populations, was expressed in both MSC-sources. G-CSF and GM-CSF, growth factors of HSCs involved in the production of granulocytes, macrophages and dendritic cells, were significantly up-regulated in WJ-supernatants but were almost absent in BM-cultures ($p<0.001$). The regulator of migration, adherence and engraftment of HSCs, SDF-1a, was significantly overexpressed in BM-supernatants through cultivation ($p<0.05$). Nevertheless, WJ-MSCs seemed not to support CD34+ cell growth as evidenced by the numbers of total colony-forming units (CFUs), at least in the current experimental setting.
Summary/Conclusions: Collectively, our results suggest that WJ-MSC population exhibit greater proliferation potential and decreased apoptosis, longer telomeric length and higher genome stability. The observed differences of CFUs in the co-culture systems could be attributed to the differences in cytokines secreted by WJ and BM-MSCs. Our results point out that WJ- and BM-MSCs exhibit unique characteristics and therefore the appropriate source should be selected for a specific clinical application.

E1138

IMPACT OF LEUKEMIA STEM CELLS PHENOTYPE EXPRESSION ON RESPONSE TO INDUCTION THERAPY IN ACUTE MYELOID LEUKEMIA PATIENTS

F Albeldawi[1,*], S Al-Mudallal[2]
[1]Hematopathology, Iraqi Ministry of Health, Balad, [2]Hematopathology, Al-Nahrain University, Baghdad, Iraq

Background: Laboratory data suggest that acute myeloid leukemia AML originates from a rare population of cells, termed leukemic stem cells (LSCs) or leukemia-initiating cells, which are capable of self-renewal, proliferation and differentiation into malignant blasts. There's a universal agreement that LSCs lie within the CD34+ compartment of hemopoietic cells and most of leukemic stem cells express the interleukin-3 alpha chain receptor, CD123 and lack CD38. The standard model of leukemogenesis posits the stepwise acquisition of genetic mutations in a susceptible cell and its progeny, leading to the development of an autonomous clone that expands enough to cause a clinical syndrome. The genetic events occur in susceptible cells that are either hemopoietic stem cells or its progeny. The resultant leukemic cell has the properties of a stem cell in terms of self-renewal, but with persistent uncontrolled division and resistance to chemotherapy. This leukemia stem cell theory has been proved by proliferation of proposed leukemic stem cell after its injection into lethally irradiated mice. This finding inspired scientists and researchers to explore new fields for leukemia treatments because with the current regimes, the relapse rate is high and death frequently happens due to treatment failure or consequences of bone marrow blast invasion. In the same perspective, researchers began to assess the prognostic value of leukemic stem cells at diagnosis and to weigh its significance with other known prognostic factors of AML.
Aims: This study aimed to estimate the expression of LSC phenotype in AML patients and to correlate it with response to induction therapy.
Methods: A cohort of 41 patients older than 15 years with newly diagnosed de novo AML were enrolled in this study. They were obtained from the National center of hematology in Baghdad and Baghdad teaching hospital between February and July 2013. The expression of CD34, CD38 and CD123 was assessed by multi-color flow cytometry. LSC positive (LSC+) samples must express CD34 and CD123 and lack the expression of CD38 in >1% of cells. French American British (FAB) classification system was used in this study. After four weeks of induction therapy; three groups were found: those who reached the complete morphological remission (CR), those who failed to reach CR and those who died before assessment of morphological remission. The last two groups were merged for statistical purposes. All statistical operations were done by Microsoft excel 2010 and SPSS programs. The p-value for significance was calculated from Chi square test and Fisher Exact test for 2X2 contingency tables when the Chi square test was not applicable. The percentage of LSCs was calculated as the percentage of cells in CD34+CD123+ quadrant X the percentage of CD38- cells X the blast% of the individual patient
Results: The mean expression of CD34+CD38-CD123+ cells at diagnosis was 3.85 ± 7.14 (mean$\pm$SD), range=0% to 42.05%, median=2.15%. A cut off value of 1.0% was designed to separate two groups of patients; those with LSCs of less than or equal to 1.0% and those with more than 1.0%. In the first group (LSCs<1.0%), the CR rate was 53.33%, while it was 34.61% in the second group. Percentage of cases who sustained NR was 46.67% in the first group and 65.39% in the second age group. Regarding gender, LSC+ male patients were more (70.83%) than LSC+ females (52.94%). Patients with a low (<1%) percentage of CD123+CD34+ cells had a CR rate of 50% and an NR rate of 50%. On the other side, in patients who had a higher expression (>1%) of CD123+CD34+ cells, the CR rate was less (7 of 21, 33.33%) and NR was higher than the other group (14 of 21, 66.67%).
Summary/Conclusions: 1. LSCs were expressed in 63.41% of AML cases and were distributed among FAB subtypes without preference to any FAB subtype. 2. The expression of LSC phenotype was associated with poor response to induction therapy in AML patients.

E1139

VASCULAR ENDOTHELIAL CELL-RELATING MOLECULES EXPRESSED IN AN ADULT HUMAN DERMAL FIBROBLAST WHEN CULTURED WITH INTERLEUKIN-1-BETA

R Sumiyoshi[*], T Matsuo, T Yamamoto, K Matsumoto, J Ooi, N Shirafuji
[1]Department of Hematology/Oncology, Teikyo University School of Medicine, Tokyo, Japan

Background: We previously reported that when an adult human dermal fibroblast (HDF) was cultured with interleukin (IL)-1-beta (b), vascular endothelial growth factor (VEGF)-A, erythropoietin (EPO), anti-human VEGF-C antibody (Ab) and anti-human tumor necrosis factor (TNF)-alpha (a) Ab, hematopoiesis-related genes expressed; however, culturing cells were morphologically fibroblasts (56th ASH). We also reported that hemogenic endothelium-relating molecules expressed in HDF with poly (I:C) culture and an electrical stimulation (44th ISEH).
Aims: In this report we observed the biological effects of IL-1-b to HDF for up to one month-culture.
Methods: HDF was cultured with CELRENA medium, used for induced pluripotent stem (iPS) cell-culture, on 0.1% gelatin-coated plate (porcine skin). Cultures were added with recombinant human IL-1-b for up to four weeks with splitting each one week. Morphological changes and the expression of vascular endothelial cell-related genes, and hematopoiesis-related ones were observed.
Results: When HDF was cultured with IL-1-b, CD31, CD34, and CD41 molecules expressed for two weeks' culture, which are vascular endothelial cell-markers. Also, VEGF-receptor type-1, and -2, and VE-cadherin expressed significantly. Morphologically, HDF was changed to an endothelial cell. When HDF was further cultured, blast cells were attached to an endothelial cell, and SCL, and GATA-2 molecule expressed significantly.
Summary/Conclusions: Recent reports reveal that a kind of vascular endothelial cells, hemogenic endothelium, can be converted into a hematopoietic cell. We identified that IL-1-b worked an important role in vascular endothelial cell-formation.

LB2256

EXOSOMES SECRETED BY STROMAL CELLS CONTRIBUTE TO THE HEMATOPOIETIC STEM CELL NICHE

G Stik[1,*], S Crequit[2], J Durant[2], L Petit[3], P Charbord[3], T Jaffredo[1], C Durand[2]
[1]CNRS, [2]UPMC, [3]INSERM, Paris, France

Background: Hematopoietic stem cells (HSCs) are identified by their ability to self-renew and to differentiate into all blood cell lineages. *In vivo*, hematopoietic stem/progenitor cells (HSPCs) are in close association with stromal cells that constitute a supportive microenvironment also called niche. Recently, exosomes that are small microvesicles enclosed by a lipid bilayer and enriched in cytoplasmic proteins, mRNAs, microRNAs, have emerged as major communication mediators between cells. However, their implication in the cross-talk between HSCs and stromal cells is still largely unknown.
Aims: This study aims to assess the existence and the functionality of stromal cell-derived exosomes in the HSPC support.
Methods: To address this issue, we used two murine stromal cell lines derived from the fetal liver and with differing capacity to maintain HSPCs *ex vivo* as revealed by repopulation assay and long-term cultures. AFT024 (AFT) harbors a potent HSPC supporting capacity *in vitro* whereas BFC012 (BFC) is non supportive. For each cell line, the exosome fractions were isolated from culture supernatant by ultra-centrifugation. Electron microscopy, western blot, and flow cytometry were performed to characterize the exosomal fraction isolated. Using PKH67 staining we analyze the uptake of exosomes after co-culture with Lin-Sca1+ cKit+ (LSK) cells, total bone marrow or after *in vivo* injection. Clonogenic assay and FACS analysis were performed after co-culture of LSK cells with exosomes to assay their biological effect. High-throughput sequencing was realized to explore the molecular signature followed by several bioinformatic analyses. Finally, RNA transfer from exosomes to recipient cells was analyzed by qPCR.
Results: Electron microscopy performed on stromal cells showed multivesicular bodies containing exosomes. Additional electron microscopy, FACS and western blot analyses performed on the fraction isolated by ultracentrifugation revealed that both AFT and BFC stromal cells secrete exosomes. We then investigate if these exosomes could be taken up by HSPCs. Interestingly, using PKH67 stained exosomes, we demonstrated that bone marrow $Lin^{-}Sca\text{-}1^{+}c\text{-}kit^{+}$ (LSK) cells preferentially uptake AFT-derived exosomes. This observation might be related to the different tetraspanin compositions of AFT and BFC derived exosomes as observed by flow cytometry. Furthermore, *in vitro* and *in vivo* assays showed that AFT exosomes specifically target hematopoietic CD45+ cells. We then showed an increase in cell viability and clonogenic potential when LSK cells were exposed to AFT-derived exosomes for 96 hours in cytokine-free medium as compared to controls. Moreover, cultures with AFT-derived exosomes exhibited a 3.5 fold increase in the number of LSK cells as compared to untreated conditions. We then used high-throughput sequencing to explore the molecular signatures of AFT and BFC derived exosomes, as well as their cells of origin. We identified a list of 324 mRNAs and 23 microRNAs specifically expressed in exosomes and correlated to the HSPC support. Gene ontology analysis revealed that the apoptotic regulation, cell survival and proliferation pathways were significantly enriched in the AFT-derived exosomal signature. In addition, we showed the transfer of mRNAs involved in these pathways from the AFT-exosomes to the LSK recipient cells. Together with our observation of a decrease in the LSK apoptotic cells after co-culture with AFT-derived exosomes, these data suggest that exosomes released by AFT cells may protect HSPCs from apoptosis.
Summary/Conclusions: Collectively, our results revealed an important role for exosomes in the HSPC supporting capacity of stromal cells. This work provides new insights in our understanding of the molecular and cellular mechanisms involved in the cross-talk between HSPCs and their niches. It may also have interesting applications in regenerative medicine, regarding the *ex vivo* manipulation of HSCs in stromal-free conditions for cell therapy.

LB2257

HUMAN UMBILICAL CORD BLOOD STROMAL CELLS PROMOTE HEMATOPOIETIC RECONSTITUTION AND REDUCE GVHD BY AFFECTING THE TH CELL SUBSETS IN HAPLOIDENTICAL-HSCT

Y Liu, SJ Yang, C Zhang, Q Wen, X Zhang[*]
Department of Hematology, Xinqiao Hospital, The Third Military Medical University, Chongqing, China

Background: Microenviroment palys very important role in the regulation of graft-versus-host desease (GVHD).
Aims: To investigate the effect of human cord blood–derived stromal cells (hUCBDSCs) combined with haploidentical-hematopoietic stem cell transplantation (haplo-HSCT) on GVHD and hematopoietic reconstitution of severe bone marrow radiation disease.
Methods: The hybrids F1 generation mice were taken 8.0Gy of 60Coγ ray total body irradiation (TBI). Haploidentical-HSCT were taken after TBI. Grouping: mBMSC (mouse bone marrow-derived stromal cells) + HSC(Hematopoietic stem cells) group, hUCBDSCs + HSC group, HSC group and the control group (saline group). Peripheral blood were taken at 0,3,7,10,14,21,28d days respectively after transplantation to count WBC, RBC, Hb, PLT. Bone marrow, liver, spleen, intestine and skin were collected and paraffin-embedded after transplantation at each point to observe pathologic changes. The changes of body weight, postural, activity, hair, toilet and survival were observed after transplantation at each point. Cell colony culture were taken at 7,14,21d after transplantation. IL-2, IL-4, IL-10, IL-12, IL-17, IL-21, IL-22, IL- 23, IL-33, TGF-β, IFN-α and IFN-γ in serum were detected by ELISA at 0,7,14,21d after transplantation.
Results: All mice in control group died at 9d to 11d after TBI. The hemogram began to recover at 7d in hUCBDSCs + HSC group and mBMSC + HSC group after transplantation which was earlier than that in HSC group (10d). Cell colony of CFU-E, CFU-GM, CFU-GEMM and CFU-G in hUCBDSCs + HSC group was more than mBMSC + HSC group ($p < 0.05$). And mBMSC + HSC group was more than HSC group ($p < 0.05$). The death rate of hUCBDSCs + HSC group and mBMSC + HSC group were (20.00±5.00)% and (21.67±12.58)% which were lower than (38.33±7.64) % in HSC group ($p < 0.05$). The GVHD of hUCBDSCs + HSC group was not obviously which was better than HSC group. There were no significant differences of IL-12, IL-17 and IL-23 in each group. IL-2, IFN-γ expression were increased after transplantation, which is higher in HSC group than hUCBDSCs group($p < 0.05$); IL-10 expression in the peripheral blood were decreased in each group after transplantation. The recovery of IL-10 in hUCBDSCs + HSC group was faster than HSC group ($p < 0.05$). TGF-β expression were increased faster in hUCBDSCs + HSC group than the other two groups($p < 0.05$) which was the same as TNF -α.
Summary/Conclusions: HUCBDSCs promote hematopoietic reconstitution and reduce the incidence of GVHD in severe bone marrow radiation disease in vivo. The main mechanism of this may be associated with the decrease of Th1 cells and increase of Th2 cells expression.

Hodgkin lymphoma - Clinical

E1140

THYROID DISEASES IN LYMPHOMA SURVIVORS

MP Simula[1,*], AM Mamusa[1], S Usai[1], A Oppo[2], S Mariotti[2], E Angelucci[1]
[1]Struttura Complessa di Ematologia e Centro Trapianti. Ospedale Oncologico di Riferimento Regionale. Cagliari, Italia, AOB Cagliari, [2]UOC Endocrinologia e Diabetologia Centro Studio per la prevenzione e la terapia delle malattie della tiroide, Università di Cagliari, Cagliari, Italy

Background: Improvements in the treatment of both Hodgkin's (HL) and non Hodgkin's Lymphomas (nHL) have resulted in an increasing number of long term survivors. However this patient's population is at high risk of developing late therapy related complications that can negatively affect their survival and quality of life. In this report we focus on thyroid diseases.
Aims: In our institution the HL and aggressive nHL long term survivors are followed up in a dedicated clinic since September 2014. Here we report preliminary data on thyropathies.
Methods: We have reviewed our lymphoma survivors database
Results: We have analyzed data regarding 469 consecutive patients coming in our clinic from 15 September 2014 to 18 February 2016, 247 were affected by HL and 222 by nHL. Two hundred thirty three were females, 236 males; median age at diagnosis was 29 years for HL (range 13-84), 48 years for nHL (range 12-83); median age at last observation in the follow up clinic was 50 years for HL (range 21-89) and 62 years for nHL (range 24-88). The median duration of follow up was 18 years for HL (range 5-40) and 13 years for nHL (range 5-37). One hundred eight patients (23%) experienced thyroid disorders; they were 85 females (79%) and 23 males (11%), 77 have been treated for HL (71%) and 31(29%) for nHL. Thyroid diseases observed in our patients were: hypothyroidisms in 54, autoimmune thyroiditis in 24, nodules in 10, goiters in 10,carcinomas in 8, hyperthyroidism in 2 (table1). Thirteen of these patients had thyroid exeresis after thyroid disease diagnosis (table2). Regarding the previous therapies in thyroid disease patients: mediastinal and/or neck radiotherapy has been administered to 83 (77%) of patients and chemotherapy in 99 (92%). The median time between diagnosis of lymphoma and diagnosis of thyroid problems was 10 years (range 0-33). Thirty four of these disorders (31%), including one carcinoma, have been detected during planned controls (hormonal dosage and echotomography) in absence of symptoms.

Table 1. Type of thyroid disorders in our lymphoma survivor patients.

Type of thyropathies	Patients	%
Hypothyroidis	54	50
Autoimmune thyroiditis	24	22,2
Nodules	10	9,2
Goiters	10	9,2
Carcinomas	8	7,4
Hyperthyroidism	2	2

Table 2. Causes of thyroidectomy.

Causes	number	%
Carcinoma	8	62
At diagnosis of lymphoma	2	15
Goiter	2	15
Basedow disease	1	8

Summary/Conclusions: In our Department we described a high number of cases of thyroid disorders in the lymphoma survivors population. These were more common in females, as in general population, and in previous HL, probably because of higher rate of radiotherapy received in the treatment of HL compared to nHL. Almost a third of these disorders were found by tests done for early diagnosis of late complications in asymptomatic patients. These results outline the importance of screening of thyropaties in this setting of thisspecial population.

PROGNOSTIC RELEVANCE OF SERUM FERRITIN LEVELS IN HODGKIN LYMPHOMA (HL) UNDER TREATMENT WITH ABVD OR EQUIVALENT REGIMENS WITH OR WITHOUT RADIOTHERAPY (RT)

TP Vassilakopoulos[1,*], MN Dimopoulou[1], M Arapaki[1], MP Siakantaris[2], G Boutsikas[1], E Variami[2], JV Asimakopoulos[1], M Dimou[3], MC Kyrtsonis[3], X Yiakoumis[4], M Moschogiannis[4], G Dryllis[1], T Giannikos[1], M Efstathopoulou[1], E Konstantinou[1], I Stergiou[1], T Tzenou[3], T Iliakis[3], G Gainarou[1], V Telonis[1], KA Petevi[1], K Zervakis[2], E Pessach[3], P Tsirkinidis[5], NA Viniou[2], V Komninaka[1], P Tsaftaridis[1], E Plata[1], S Sachanas[4], GA Pangalis[4], P Panayiotidis[3], K Konstantopoulos[1], MK Angelopoulou[1]
[1]Department of Hematology, National and Kapodistrian University of Athens, [2]1st Department of Internal Medicine, National and Kapodistrian University of Athens, [3]1st Propedeutic Department of Internal Medicine, National and Kapodistrian University of Athens, Laikon General Hospital, [4]Department of Hematology, Athens Medical Center, [5]Department of Hematology, 401 Army General Hospital, Athens, Greece

Background: Cytokine-driven inflammatory processes dominate the clinical and laboratory expression of HL, especially in advanced stages. Serum ferritin (SF) levels increase in the context of "acute phase reaction" along with fibrinogen, ESR, cerulloplasmin, haptoglobins etc. Although SF elevations are a well known feature of HL, their prognostic significance has not been adequately evaluated. Recently, Fernandes-Alvarez et al reported that elevated SF levels (>350 μg/L) were an independent prognostic factor in 173 optimally treated patients with classical HL (Leuk Lymphoma 2015).
Aims: To evaluate the prognostic significance of SF levels in a large series of patients with HL treated with ABVD or similar chemotherapy with or without radiotherapy (ABVD±RT).
Methods: We evaluated 309 pts with HL, treated with ABVD or equivalents (±RT), who had available data for SF levels. Median age was 33 yrs (15-87), 54% of patients were male, 34% had B-symptoms, 17% had stage IV disease, 50% had advanced stage (IB,IIB,III,IV), 33% had IPS ≥3, 67% nodular sclerosis histology and 19% mixed cellularity. Failure-free survival (FFS) was defined as time between treatment initiation and toxic death, failure to achieve remission requiring switch to salvage therapy, relapse after remission or last follow-up; deaths in remission of unrelated causes were not counted as events.
Results: Median follow-up of currently alive patients was 41 months. The median SF levels were 149 μg/L (range 6.6-6709.0, interquartile range; IQR 63.9-316.5). As expected, SF levels were lower in females than males (medians 70.6 *vs* 240.2, p<0.001). Increased SF levels were highly correlated (p<0.001) with older age, advanced stage, increased IPS and markers of systemic disturbance (B-symptoms, anemia, ESR, CRP, low serum albumin), as well as with beta2-microglobulin, elevated serum LDH (p=0.01) and mixed cellularity (p=0.01 compared to nodular sclerosis). However, there was no correlation with leukocytosis or lymphocytopenia. At a cutoff of 150 μg/L (almost the median), the 5-year FFS was 85% *vs* 67% for patients with lower and higher SF levels (p=0.0005). If a gender-based median cutoff was adopted (high levels above the median of each gender), the results were similar (84% *vs* 68%, p=0.0006). At the published cutoff of 350 μg/L only 21% of patients had high SF levels and the difference in the outcome was less pronounced (79% *vs* 64%; p=0.01). In both early (IA/IIA) and advanced (IB, IIB-IV) stages, SF ≥150 μg/L provided an 8-9% absolute difference in 5-year FFS, which was not however statistically significant (p=0.18 and p=0.16). In multivariate analysis, SF ≥150 μg/L was an independent prognostic factor (p=0.04; HR=1.79) along with advanced stage (p<0.001; HR=2.66), when adjusted for B-symptoms, anemia, LDH and gender. Further adjustment for CRP or ESR did not result to any meaningful alteration of the magnitude of the HR. However, the significance of SF became marginal if stage IV was used instead of "advanced stage". In models containing SF levels, B-symptoms and IPS, SF displaced IPS.
Summary/Conclusions: Elevated SF levels may be an independent prognostic factor in HL treated with ABVD or equivalent regimens±RT after adjustment for other important variables, including B-symptoms, anemia, ESR and CRP. However, larger patient series are needed in order to extract safe conclusions and determine the optimal cutoff.

E1143

INFRADIAPHRAGMATIC HODGKIN LYMPHOMA: A LARGE SERIE OF PATIENTS AT THE ERA OF TEP-CT. A PARTICULAR SUBSET OF HL?

C Rossi[1,*], M mounier[2], P brice[3], H ghesquières[4], V safar[4], E nicolas-virelizier[5], C sebban[5], A stamatoullas-bastard[6], M alcantara[6], A chauchet[7], E reboursière[8], L filiattre-legras[9], A perrot[9], G salles[4], B Coiffier[4], O Casasnovas[1]
[1]Hematology, CHU Dijon, Dijon, [2]Registre des hémopathies malignes de côte d'or, Université de Bourgogne, Dijon Cedex, [3]Hematology, CHU Paris St louis LAriboisière F Widal, Paris, [4]Hematology, CHLS, Pierre Bénite, [5]hematology, CLB, Lyon, [6]hematology, Centre henri Becquerel, Rouen, [7]Hematology, CHU besançon, Besançon, [8]hematology, CHU caen, Caen, [9]hematology, CHU NANCY, NANCY, France

Background: Infradiaphragmatic Hodgkin Lymphoma (IDHL) accounts for 3-11% of adult cases of stage I-II Hodgkin Lymphoma. The strategy of treatment has been improved and standardized along the last decades in most clinical subsets of HL, while it remains heterogeneous in IDHL these patients being often excluded from clinical trial. Moreover, in previous studies focused on IDHL, the patients were not staged by PET-CT and the risk was considered localized stages as advanced.
Aims: Thus, this study aimed to include PET staged patients by comparing with PET non staged patients for demographic, clinical and biological data the outcome of these patients.
Methods: The clinical, biological data at baseline, the details of treatment and

outcome of patients with a first diagnosis of stage I-II of IDHL were retrospectively collected in 8 french departments of hematology. During the same period, patients with a positive HIV serology and those treated with radiotherapy alone were excluded. Also, we reported only the patients treated with ABVD regimen of chemotherapy.
Results: From 1986 to 2014, 100 patients were included whose 65 of them staged with PET. The characteristics between patients staged with or without PET-CT were significantly different for age (higher median for PET staged, 53 years *vs* 47 years, p=0.041), ESR (higher median for PET non staged; 27 *vs* 58mm, p= 0.044), haemoglobin (lower for PET non staged, 13.6 *vs* 12.8g/dL, p=0.0267) and frequence of central adenopathy involvement (60% *vs* 80%, p=0.042). Indeed, the following analyses were made in each group separately in univariate and after adjustment with these four parameters. In the PET-staged patients group, which were considered as real pure infra-diaphragmatic, the median of follow-up was 3.8 years. At five years, the PFS was 78% (IC95% 0.64-0.87) and OS was 88% (IC95% 0.73-0.95). Thirteen relapses occurred (20%) whose eleven (16%) in the five-years after diagnosis, and five died (8%), 3 from HL progression and 2 from toxicity of chemotherapy. In univariate ananalysis, bulky mass at baseline (p=0.03) and the chemo-radiotherapy combination (p=0.024) influenced the PFS and only bulky mass and the combination of treatment remained significant (p=0.008) and at the limit of statistical significativity (p=0.069) in the modelisation analysis, respectively.
Summary/Conclusions: This multicenter retrospective study including PET-staged patients, considered as pure IDHL, shows clinical and biological specific characteristics, which confirm that PET was very useful for management of these patients. Thus, IDHL could be identify as a subset of HL, in particular of elderly HL. The chemo-radiotherapy combination seemed be related to a better PFS in these patients.

E1144

RESULTS AND OUTCOME WITH ABVD-PLATINE PROTOCOL IN HODGKIN LYMPHOMA WITH BULKY MEDIASTINAL INVOLVEMENT
RM Hamladji*, F Belhadri, M Benakli, R Belhadj, N Abdennebi, F Tensaout, A Talbi, S Akhrouf, R Ahmed Nacer
Hematology-Bone Marrow Transplantation Department. Pierre and Marie Curie Center, Algiers, Algeria
Background: Mediastinal lymph node involvement can be large in 50-60% of Hodgkin lymphoma (HD) wich may be discovered on imaging in asymptomatic patients (pts) or pts with respiratory signs or chest pain. Bulky form is defined as a mediastinal mass exceeding one third of the maximum transverse thoracic diameter on standard chest X-Ray at the level of 5th and 6th thoracic vertebra=mediastinal tumor ratio (MDR) ≥35.
Aims: We report the results of 179 HD with bulky mediastinal treated by ABVD-Platine protocol.
Methods: Over a period of 9 years (2004-2012), 341 pts / 674 (50,6%) with HD had mediastinal involvement with bulky's one in 200 (58,6%), median MTR=0,43 (0 -35- 0,80) among them 179 were treated with ABVD-P: median age 25 years (11-64), sex ratio 1,03. The most frequent revealing symptom was lymphadenopathy (51%), fonctionnal respiratory signs (23%) and superior cava vein syndrome in 5 pts. The histopathologic patterns are nodular sclerosis (65%), mixed cellularity (28%) lymphocyte depleted 06 pts or predominant 1 pt and unclassified 5 pts. The clinical Ann Arbor staging was stage II: 53%, stage III 32% and stade IV 15%. According to prognostic score GHSG (German Hodgkin Lymphoma Study Group): 18 pts (10%) were in intermediate stage and 161 (90%) in advanced stage. The protocol treatment is ABVD with platine 30 mg/m^2 D2, D3 and D16, D17) monthly: 3 cycles for stage II, 4 for stage III and IV. After chemotherapy (CT), 122 pts received radiotherapy (RT), 24 pts high dose CT (HDC) with autologous stem cell transplantation(ASCT) and 25 pts were followed after CT alone. At december 2015, the median follow-up is 98 months (39-143).
Results: After CT, 177pts / 179 are evaluable, the overall response (OR) is 96,6% with 32,2% in complete remission (CR) and 64,4% partial remission (PR),6 pts are in failure treatment. At term follow-up 158 pts are alive, among them 155 CR, 3 relapse and 19 died. The overall (OS) and event free (EFS) actuarial survival are 90% and 83% respectively at 8 years. Among the 171 pts in response after CT: 122 pts with CT-RT, 24 pts with CT-ASCT and 25 pts followed after CT alone, the OS were 94,8%, 71,6%, 77,4% respectively and EFS 93,8%,46,8% and 49,7%.
Summary/Conclusions: The protocol ABVD-Platine in HD with bulky mediastinal involvement allowed good results in association with RT better than in association with CT-ASCT (p<0,001), but no with CT alone (p=0,08) on OS. Concerning EFS the association CT-RT is better than CT-ASCT and CT alone p<10^{-8}).

E1145

ADDITION OF ABSOLUTE LYMPHOCYTES/MONOCYTES RATIO IMPROVES THE STANDARD PROGNOSTIC SCORES FOR ADVANCED AND LOCALIZED HODGKIN LYMPHOMA PATIENTS TREATED WITH ABVD +/- RADIOTHERAPY
I Herráez Balanzat[1,*], L Bento de Miguel[1], L García Maño[1], J Martinez Serra[2], F Mestre Mestre[3], R Ramos Asensio[4], P López Perezagua[5], J Daumal Domenech[3], S Ruiz de Gracia[1], A Sampol Mayol[1], A Gutierrez Garcia[1]
[1]Hematology, [2]Molecular Biology, [3]Nuclear Medicine, [4]Pathology, [5]Radiology, Hospital Son Espases, Palma de Mallorca, Spain

Background: Hodgkin lymphoma (HL) is a lymphoproliferative malignancy constituted by a few malignant cells (Reed-Sternberg cells) surrounded by an inflammatory microenvironment. The amount of monocytes infiltrating HL is a known prognostic factor but its study implies immunohistochemistry. Lymphopenia is a recognized adverse prognostic factor included in the International Prognostic Score (IPS). In the last years the clinical value of the absolute lymphocytes/monocytes ratio (LMR) has been reported as an alternative way to consider previous prognostic factors.
Aims: We aim to evaluate the combination of the absolute lymphocytes/monocytes ratio with the standard prognostic scores for advanced (IPS) and localized (GHSG) HL in order to improve definition of prognosis.
Methods: We retrospectively selected from the Pathology and Pharmacy registries of Son Espases University Hospital those patients with HL homogenously treated with ABVD +/- radiotherapy (RT). All standard prognostic factors were obtained from the records included in IPS and GHSG prognostic scores, as well as the absolute value of lymphocytes and monocytes. COR curves were used to determine the cutoff value for the LMR. IPS and GHSG scores were combined with LMR as follows: IPS 0-2=0; IPS>2=1; GHSG 0=0; GHSG>0=1; LMR≤cutoff=1; LMR>cutoff=0. LMR-IPS and LMR-GHSG were the sum of IPS or GHSG with LMR previous values (ranging from 0 to 2). Survival analysis was performed using Kaplan-Meier curves with the Log-rank test.
Results: From January 1990 to June 2015, 124 patients fulfilled inclusion criteria. Median age was 37 years (15-75), 62% males, 48% Ann Arbor (AA) stage III-IV, 13% with ECOG performance status >1, 53% with IPS >2. Median LMR was 2.19 (0.2-7.7). Response was as follows: 105 (87%) achieved complete response (CR), 2 (2%) partial response (PR) and 17 (12%) stable disease or progression (SD/P). Using COR curves we set the cutoff for LMR in 1.56. Response rate, CR and SD/P were significantly better in patients with LMR >1.56: respectively 95% *vs* 72%, 94% *vs* 69% and 5% *vs* 29% (p=0.001); as well as patients younger than 45 (p=0.024) and 60 (p=0.003) years, with ECOG 0-1 (p=0.001), LMR-GHSG 0 (p=0.037) and LMR-IPS 0-1 (p=0.007). Univariate survival analysis showed several factors significantly influencing OS: age, ECOG PS, GHSG and IPS, ALC, AMC, LMR, LMR-IPS and LMR-GHSG (Figure 1). PFS was significantly influenced by age, AA stage, ECOG PS, IPS, LMR and LMR-IPS (Figure 1). In multivariate analysis for early HL age >45 (HR 13.1; p<0.001), ECOG PS>1 (HR 9.7; p=0.034) and LMR-GHSG>0 (HR 19.8; p=0.045) (Figure 1) where independent predictors of worse OS while in advanced HL only remained independent age>45 (HR 4.8; p=0.028) and LMR-IPS 2 (HR 14; p=0.041). In the PFS multivariate analysis only LMR-IPS showed to be an independent adverse prognostic factor both for the whole group (HR 4.5; p<0.001) and the advance HL patients (HR 3.5; p=0.013).

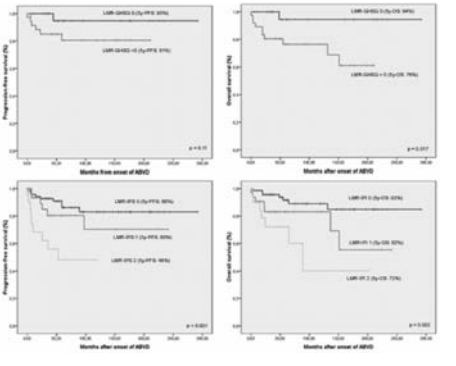

Figure 1.

Summary/Conclusions: Addition of absolute LMR improved the ability of IPS and GHSG scores in identifying HL patients with worse responses and survival after standard ABVD +/- RT. Particularly, LMR-IPS was able to identify a high risk subgroup of patients with a 5y-PFS of 48% inside the patients with IPS>2.

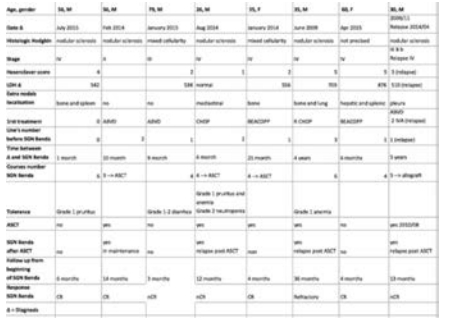
E1146

BRENTUXIMAB VEDOTIN-BENDAMUSTINE COMBINATION FOR HODGKIN LYMPHOMA: EXPERIMENT WITH 8 PATIENTS
C Carola[1,*], S Dennetiere[2], P Votte[1], JP Marolleau[1], B Royer[1]
[1]CHU Amiens, Amiens, [2]CH Compiegne, Compiegne, France

Background: Optimal treatment for patients (pts) with heavily pretreated Hodgkin lymphoma (HL) is controversial. Long term outcomes from autologous stem cell transplant (ASCT) in relapsed/refractory (R/R) HL are significantly better in pts achieving complete remission (CR) from salvage chemotherapy prior to ASCT. Brentuximab vedotin and bendamustine are highly active, as single agents, for pts with R/R HL and have manageable safety profile. Bren-

tuximab is an antiCD30 monoclonal antibody conjugated to monomethyl auristatin E. Patients in CR after Brentuximab, particularly young pts and low risk early stage disease, did not necessarily benefit additional consolidative therapy (ASCT or allograft). Elsewhere, Brentuximab consolidation following ASCT should be proposed for pts with primary refractory disease, early relapse, or extra nodal disease.
Aims: To point brentuximab-bendamustine combination efficiency and safety for R/R HL pts.
Methods: We retrospectively analyzed 8 HL pts in 2 centers, treated with 90mg/m^2 bendamustine on days 1 and 2, and 1.8mg/kg brentuximab on day 1, every 3 weeks. Six pts were R/R (including 1 post ASCT), 1 in partial response post chemotherapy and 1 in first line (contraindication to chemotherapy, heart and respiratory failures).

Table 1.



Results: Median follow-up was 12 months [3-36] from beginning of treatment. Median chemotherapy treatment was 4 courses [2-6]. Four pts were in CR, 3 in nearly CR, 1 refractory. Three pts underwent subsequently ASCT (2 where in CR and 1 in nCR): 1 of them had brentuximab maintenance and 1 relapsed post ASCT. One other pt in nCR beneficiated from reduced intensity-conditioning allograft. All pts remained alive at follow-up. This combination was well tolerated, without grade 3-4 toxicities: 2 pts had grade 1 anemia, 1 of them grade 2 neutropenia.
Summary/Conclusions: This regimen represents a promising approach to optimize response rate prior to ASCT or allograft in pts with R/R HL. It could also be proposed to frail pts as frontline treatment.

E1147

HODGKIN LYMPHOMA: A RETROSPECTIVE ANALYSIS OF SURVIVAL AND TREATMENT RELATED TOXICITIES OF A COHORT OF PATIENTS DIAGNOSED BETWEEN 2005-2015

G Bras[1,*], M Alpoim[1], P Soares[2], L Osório[2], R Pinto[1], F Príncipe[1], J Guimarães[1]
[1]Serviço de Hematologia Clínica, [2]Serviço de Radioterapia, Centro Hospitalar de São João, Porto, Portugal

Background: Hodgkin Lymphoma is highly sensitive to chemotherapy and radiotherapy. Treatment related toxicity is a major concern and have a negative impact on quality of life and overall survival of these patients.
Aims: To evaluate chemotherapy and radiotherapy attributable toxicity in a cohort of Hodgkin Lymphoma survivors.
Methods: We performed a retrospective analysis of a Hodgkin Lymphoma cohort diagnosed and treated in a Portuguese tertiary hospital centre, from 2005 to 2015. The toxicities assessed were: secondary neoplasia, infertility, thyroid, cardiac, pulmonary, cerebrovascular and neuropsychiatric disorders.
Results: From 2005 to 2015, 151 patients were diagnosed and received first treatment at our centre. 87 (56,7%) patients were male. At diagnosis, the median age was 34 (18-88) years. Prevalence of HIV infection was 9,9% (n=15). Among 151 patients, 138 (91,4%) were treated with a curative intention: 12 (8,6%) had early-stage favourable disease; 39 (28,2%) early-stage unfavourable; 87 (63%) advanced stage. As first line approach, 81 (58,7%) were treated with chemotherapy alone and 57 (37,7%) with combined chemotherapy and radiotherapy. The ABVD protocol was the chemotherapy regimen in 122 (88,4%) patients, followed by BEACOPP in 7 (5,1%). Radiotherapy was performed in 60 (41,7%) patients, with Involved Field protocol in 59. Overall Response Rate after first line treatment was 92% for early-stage favourable, 86% for early-stage unfavourable, 71% for advanced-stage. Autologous Transplantation was performed in 17 patients (12,3%), all in context of relapse or refractory disease. The 5-year Overall Survival was 86,3%. Among patients diagnosed throughout reproductive age, 10,4% (n=10) underwent gamete cryopreservation, while 24,4% (n=10) of females in fertile age underwent on GnRH agonists for ovarian protection. The overall incidence of reported treatment attributable toxicities was 57% (n=86). Pulmonary and neuropsychiatric disorders were the most commonly reported, 25,8% (n=39) and 29,8% (n=45), respectively. Pulmonary complications developed independently of previous thoracic radiotherapy exposure (p>0,05). Other reported toxicities were: infertility in 1% (n=1) of individuals in reproductive age; secondary neoplasia in 4,6% (n=7) with median presentation after diagnosis of 36 months; thyroid disorders in 7,9% (n=12), of which 75% (n=9) were exposed to cervical radiotherapy; cardiac complications in 4,6% (n=7), the majority (n=5) was not exposed to mediastinal radiotherapy; cerebrovascular disease developed in 3,3% (n=5).
Summary/Conclusions: In our cohort of Hodgkin Lymphoma survivors, chemotherapy and radiotherapy attributable toxicities had a significant prevalence. The short follow-up period and the lack of a fully applied surveillance protocol might be the reason for the lower prevalence of toxicities observed in this cohort, in comparison with the most relevant published studies. The development of surveillance protocols for detection of short and long-term toxicities are of major importance to understand their true impact in overall survival and quality of life of Hodgkin Lymphoma survivors.

LB2258

BENDAMUSTINE-BRENTUXIMAB COMBINATION IS EFFECTIVE AND HAS A FAVOURABLE TOXICITY PROFILE IN THE TREATMENT OF REFRACTORY AND RELAPSED HODGKIN LYMPHOMA

C Cerchione*, M Di Perna, N Pugliese, R Della Pepa, M Raimondo, F Pane, M Picardi
Hematology, Ematologia e Trapianto/AU Federico II, Napoli, Italy

Background: The management of patients with refractory or relapsed Hodkin lymphoma (HL), expecially if after autologous stem cell transplantation (ASCT) remains controversial. Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosage and the possibile combinations for a synergistic effect. Brentuximab Vedotin is a CD30-directed antibody-drug conjugate, currently approved for the treatment of relapsed or refractory Hodgkin lymphoma (HL), as single-agent at the dose of 1.8 mg/kg.
Aims: The objective of this phase II study was to evaluate efficacy and safety of salvage cytotoxic regimens in patients with refractory and/or relapsed HL. Three different schedules were evaluated.
Methods: From May 2011 to February 2016, 24 patients (13 M/11 F) (Table 1) with a median age of 32.5 years (range 16-73) received a salvage regimen after failure of ASCT. Patients were by chance assigned to one of these three arms : Standard dose Bendamustine (90 mg/sqm) days 1, 2 + DHAP x 3 cycles (Arm A), brentuximab single agent 1.8 mg/kg x 4-8 cycles (Arm B), High dose Bendamustine (120 mg/sqm, days 1, 2) + brentuximab 1.8 mg/kg (day 3) x 4-6 cycles (Arm C). Each cycle was repeated every 28 days and growth factor support was sistemically administered, in association with antimicrobial prophylaxis. The treatment efficacy in each group was evaluated according to Revised Response Criteria for Malignant Lymphoma. Any adverse event occurred was recorded and classified for type and grade using NCI-CTCAE criteria (v 4.0).
Results: In arm A, which included 10 patients, the overall response ratio was 40%, with 4 complete remission (CR) and 6 progressive disease (PD). Extra-hematological toxicities were grade 3 thrombocytopenia in 4 patients and bone marrow aplasia in 1 patient. In arm B, which included 6 patients, the overall response ratio was 66%, with 4 CR and 2 PR. Extra-hematological toxicities were grade 3 neuropathy in 1 patient, hematological toxicity was grade 2 neutropenia in 2 patients. In arm C, which included 8 patients, the overall response ratio was 100%, with 8 complete remission (CR) and then SCT (4 autologous and 4 haploidentical-SCT) with persistence of complete remission in all patients. Median overall survival was 32.2 months (r. 27-44) and median progression free survival 15.3 months (r. 9-18.4). Extra-hematological toxicities were increase of transaminase in 2 patients and CMV reactivation in 2 patients, treated successfully with valgangiclovir. Hematological toxicity was grade 3 thrombocytopenia in 2 patients.

Table 1.

	Arm A (High dose Benda + other agents)	Arm B (Brentuximab single agent)	Arm C (High dose Bendamustine)
Median age	31.5	25.3	35.3
Median number of previous treatments	3 (r. 2-6)	4 (r. 2-7)	6 (r. 2-8)
Median number of cycles of treatment	3 (r. 1-6)	8 (r. 1-16)	6 (r. 1-8)
ORR	40%	66%	100%
Response	4 CR 6 PD	4 CR 2 PD	8 CR
SCT + type	2 Auto-BMT 1 Haploidentical SCT	2 Haploidentical SCT	4 Auto-BMT 4 Haplo-SCT
Median overall survival	22.3 (r. 18-28)	28.1 (r. 23.9-34.5)	32.2 (r. 27-44)
Median progression free survival	10.2 (r. 8-19.1)	12.8 (r. 8.5-20.5)	15.3 (r. 9-18.4)
Extrahematological toxicities + grade	/	1 grade 3 Neuropatia	2 Increase AST/ALT 2 CMV reactivation
Hematological toxicities + grade	4 grade 3 Thrombocytopenia 1 bone marrow aplasia	2 grade 2 Neutropenia	2 grade 3 thrombocytopenia

Summary/Conclusions: High dose Bendamustine plus Brentuximab has shown significant efficacy in a particular severe setting of heavily pretreated patients, and it could be considered as a bridge to allogenic BMT.

LB2259

UPDATES ON EFFICACY AND SAFETY OF DOSE-DENSE AND DOSE-INTENSE (DD-DI) ABVD AS FRONTLINE THERAPY OF ADVANCED CLASSICAL HODGKIN LYMPHOMA (HL)

S De Lorenzo[1,*], M Barone[1], F Rivellini[1], V Belsito[1], M Langella[1], V Maglione[1], P De Prisco[1], AP Campana[1], C Ingenito[1], L Sparano[2], AM D'Arco[1]
[1]UOC Oncoematologia, [2]UO Anatomia Patologica, PO "A. Tortora", Pagani (SA), Italy

Background: The optimal therapeutic upfront strategy in advanced classic HL hasn't yet been standardized. In recent years, the scientific community has given greater attention to the concept of dose-intensity and several studies demonstrated that intensifying therapy through dose-escalation of drugs and shortening cycle intervals yields best results than standard ABVD. However, the best frontline approach is still debated and the dispute remains between 2 strategies: 1)The "first hit principle" followed by dose reduction in early responders, 2) The "standard dose" followed by the "second hit" in poor responders.
Aims: Based on the promising results of our recent experience (D'Arco et al, 2015) and of a phase II trial of DD-DI ABVD in advanced HL (Russo et al, 2014) we expanded our previous series and updated follow-up to confirm our findings.
Methods: We treated in frontline, 22 consecutive cases of advanced HL with the ABVD $_{DD-DI}$ protocol (Russo et al, 2014), between June 2011 and December 2015. The drugs were given on days 1 and 11, at the doses of standard ABVD except for doxorubicin (escalated to 35 mg/m2, in the first 4 of 6 cycles). Cycles were administered every 21 days plus granulocyte-colony stimulating growth factors. Patients received prophylaxis with cotrimoxazole and lamivudine (as required).
Results: 22 patients were treated in frontline. The median age was 43 years (range: 23-67) and unfavourable risk factors such as erytrocyte sedimentation rate>50 mm/h, ≥3 nodal areas, International Prognostic Score≥3 were present in 68%, 77%, 59% of patients, respectively. All patients completed the planned six courses of therapy without dose reductions or delay. Toxicities were: grade III-IV neutropenia and anemia (9%). Other relevant toxicities were: grade 2 mucocutaneous changes (23%) consisting of skin rash, skin hyperpigmentation and nail alterations, grade 2 transaminases elevation (14%), grade 2 and 3 vomiting (27%) and grade 2 fatigue (18%). We didn't observe severe or prolonged infections or acute/delayed cardiac or pulmonary toxicities. The overall response rate (ORR) was 100%, complete response (CR) were 91%, partial response (PR) were 9%. In patients with bulky disease, 83% achieved CR at the end of treatment. Positron emission tomography (PET) after 2 and 4 cycles was negative in 68% and 91% patients, respectively. Only 2 patients were in PR at the end of cycle 6 and underwent to consolidation treatment: 1) Radiotherapy (RT); 2) High-dose therapy followed by autologous stem cell transplantation (ASCT), improving PR, then salvage with brentuximab vedotin, reaching CR. At a median follow-up of 31.5 months (range: 4-53), all patients were alive and in continuous CR and the median progression free survival (mPFS) hasn't been reached.
Summary/Conclusions: On a larger series, we confirm the safety and feasibility of ABVD$_{DD-DI}$, in the context of "real life" clinical practice. This intensified schedule seems to be promising in increasing the efficacy of standard ABVD, in the subset of advanced, high risk HL, in frontline therapy. Our results reinforce the critical role of dose-intensity to achieve CR and probably to reduce the need for salvage therapy followed by ASCT. Probably, the role of RT may be limited to patients with positive PET disease sites, at the end of treatment, as already demonstrated for BEACOPPescalated in the same context (Engert et al, 2012). Finally, even with a longer median follow-up (31.5 months), mPFS hasn't yet been reached and relevant toxicities haven't been highlighted.

Indolent Non-Hodgkin lymphoma – Clinical

HIGH THROUGHPUT TCR SEQUENCING PROVIDES ADDED VALUE IN THE DIAGNOSIS OF CUTANEOUS T-CELL LYMPHOMA

I Kirsch[1,*], R Watanabe[2], D Williamson[3], J O'Malley[4], LL Scott[2], C Elco[5], J Teague[2], A Gehad[2], E Lowry[2], N LeBoeuf[2], J Krueger[6], H Robins[7], T Kupper[2], R Clarke[2]
[1]Translational Medicine, Adaptive Biotechnologies, Seattle, [2]Dermatology, Brigham and Women's Hospital, Boston, [3]Client Services, Adaptive Biotechnologies, Seattle, [4]Pathology, Brigham and Women's Hospital, Boston, [5]Pathology, Brown University, Providence, [6]Dermatology, Rockefeller University, New York, [7]Adaptive Biotechnologies, Seattle, United States

Background: Diagnosis of early-stage CTCL can be challenging because skin lesions contain a mixture of both diverse benign and clonal malignant T cells. High throughput sequencing (HTS) of the TCR gamma (TCRG) and TCR beta (TCRB) CDR3 regions is a technique that provides comprehensive analysis of the total repertoire of T cell clones in a specimen, the breadth of repertoire diversity, and an exact quantitation of individual T cell clone
Aims: We investigated whether the Adaptive Biotechnologies multiplex PCR and high throughput sequencing assays of TCRB and TCRG could discriminate between benign and malignant T-cell skin dyscrasias
Methods: We analyzed skin biopsies from 46 patients with histopathologically and clinically (based on presentation, history, and course) labelled CTCL (over 80% Stage I or Stage II), 23 patients with psoriasis, 11 eczematous dermatitis, 10 allergic dermatitis, and 6 with normal skin findings.
Results: The TCRB and TCRG assays were able to define the dominant clonal sequences in every CTCL case and to distinguish likely gamma/delta from alpha/beta lymphoma. Using the fraction of the top two TCRG sequences as a fraction of the total nucleated cell population defined a cut off of approximately 1/1000 above which the biopsy was highly specific for malignant disease and below which the assay approached 100% specificity for non-malignant disease. The discrimination afforded by reference to the per cent comprised by the top two TCRG sequences of all TCRG sequences generated from the sample (most comparable to data generated by TCR PCR) was not nearly as robust. TCR PCR failed to provide relevant categorization in approximately 30% of the same CTCL cases. This approach also was able to identify low level presence of CTCL-correlated clones in systemic circulation and to distinguish subsequent inflammatory reactions from disease recurrence. Analysis of CTCL TCRG genes was consistent with CTCL being a malignancy derived from mature T cells.
Summary/Conclusions: Multiplex PCR and high throughput sequencing of TCRG and TCRB loci in suspect skin lesions was able to impact and add value to the diagnosis and monitoring of patients with early stage cutaneous T-cell lymphoma.

E1149

SENSITIVITY OF ULTRASOUND-GUIDED 16 G CORE-NEEDLE CUTTING BIOPSY AND EXCISIONAL BIOPSY FOR THE CHARACTERIZATION OF LYMPHADENOPATHIES IN PATIENTS WITH SUSPECTED LYMPHOMA: A RANDOMIZED SUPERIORITY TRIAL

N Pugliese[1,*], M Di Perna[1], I Cozzolino[2], G Ciancia[2], V Varone[2], R Della Pepa[1], C Cerchione[1], F Cacace[1], F Pane[1], M Picardi[1]
[1]Hematology, [2]University of Naples Federico II, Naples, Italy

Background: The performance of lymph node excisional biopsy requires validation. Although fine-needle aspiration under image guidance offers an alternative to open biopsies, its sensitivity in lymphoma diagnosis is still a matter of debate. New approaches to imaging-guided methods are needed. The introduction of new generation ultrasonographic devices (particularly effective in predicting the malignant status of lymphadenopathies), and progress in tissue sampling with needles with cutting edge of adequate diameter (particularly effective in providing architectural information of the core of nodal lesion) have enabled to obtain enough tissue for a definitive diagnosis (according to the WHO Classification) by mini-invasive procedures, without the need of excisional biopsy.
Aims: The primary endpoint was to demonstrate the superiority in terms of sensitivity in detecting malignancy of ultrasound (US)-guided core-needle cutting biopsy (CNCB) compared with standard excisional biopsy of lymphoadenopathies suspected for lymphoma. Secondary endpoints were: specificity, positive predictive value (PPV), negative predictive value (NPV), complication rate related to each diagnostic procedures and relative cost analysis.
Methods: From January 2009 to December 2015, in this single centre trial, patients having lymphoadenopathies with clinical suspicion of lymphoma were randomly assigned (1:1) to either US-guided CNCB or standard excisional biopsy. In the US-guided group, patients underwent baseline US exploration of all superficial lymph node areas and any abnormal lymph node underwent power-Doppler study to select the site of CNCB. The CNCB were all performed using a 16 gauge modified Menghini-type needle 150 mm in length with automatic aspiration (Biomol HS-Hospital). The selection of lymph node in the exci-

sional biopsy (standard) group was suggested by the physical examination (at surgeon's discretion).
Results: Overall, 372 patients were randomized into two well-matched arms. Histology showed a malignancies in 93% (172/185) of patients in the US-guided group (lymphoma, 151 patients; carcinoma, 21 patients) and in 80% (149/187) of patients in the standard group (lymphoma, 122 patients; carcinoma, 27 patients). During the follow-up of the patients with lymph nodes reported as being reactive, 19 of 38 patients in the standard group were rebiopsied and were found to have lymphoma or carcinoma at the subsequent lymph node histology, whereas three of the six patients in the US-guided group requiring a second biopsy were found to be positive for lymphoma diagnosis. Thus, sensitivity in detecting malignancy was higher in the US-guided group compared with the standard group (172/175 [98%] *vs* 149/168 [89%]; p=.0003), demonstrating the superiority of US-guided CNCB in reaching a definitive histopathological diagnosis for malignancies. Biopsy provided false-negative results for malignancy in 10.2% of patients affected by lymphoma in the standard group and 1.6% in the US-guided group (p=.0005). Furthermore, US-guided CNCB showed higher NPV than traditional biopsy, 80% (12/15) *vs* 50% (19/38; p=.04), respectively. No differences were found in terms of specificity and PPV between the two diagnostic techniques, by the time that no false positive were detected in both groups. Estimated cost per diagnosed with traditional biopsy was 11-fold higher compared with US-guided CNB group (p<.0001). Overall complication rate was significantly higher in patients who received excisional biopsy (78%) than in patients who underwent US-guided CNCB (15%), p<.0001.
Summary/Conclusions: US-guided CNCB has proven to be a quick, safe, and efficient technique and has radically altered the diagnostic strategy of enlarged lymph nodes at our institution, avoiding unnecessary lymph node excisions.

E1150

MCL-002: UPDATED EFFICACY AND SAFETY RESULTS FOR LENALIDOMIDE *VS* INVESTIGATOR'S CHOICE MONOTHERAPY IN RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA

L Arcaini[1,2,*], S Rule[3], T Lamy[4], J Walewski[5], D Belada[6], J Mayer[7], J Radford[8], W Jurczak[9], F Morschhauser[10], J Alexeeva[11], T Biyukov[12], M Patturajan[13], ML Casadebaig Bravo[12], M Trněný[14]
[1]Department of Molecular Medicine, University of Pavia, [2]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [3]Department of Hematology, Derriford Hospital, Plymouth, United Kingdom, [4]Department of Hematology, Hôpital Pontchaillou, Rennes, France, [5]Department of Lymphoid Malignancies, Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, Poland, [6]Fourth Department of Internal Medicine - Hematology, Charles University Hospital and Faculty of Medicine, Hradec Králové, [7]Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, [8]The University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom, [9]Department of Hematology, Jagiellonian University, Krakow, Poland, [10]Centre Hospitalier Universitaire Régional de Lille, Lille, France, [11]Federal Medical Research Center, Saint Petersburg, Russian Federation, [12]Celgene International Sarl, Boudry, Switzerland, [13]Celgene Corporation, Summit, United States, [14]Department of Hematology, Charles University Hospital, Prague, Czech Republic

Background: Although most patients with mantle cell lymphoma (MCL) respond to initial therapy, relapses are common and lead to increasingly shorter remissions. Lenalidomide, an IMiD® immunomodulatory agent with direct and immune-mediated mechanisms of action, has demonstrated efficacy and safety in relapsed/refractory (R/R) MCL in multiple studies, including heavily pretreated patients.
Aims: Evaluate results after an additional 1 year of follow-up after primary analysis for the randomized MCL-002 (SPRINT) study comparing lenalidomide *vs* investigator's choice (IC) monotherapy in R/R MCL patients.
Methods: MCL-002 is a multicenter, open-label study in MCL patients who had 1-3 relapses or failed prior therapy (including an alkylating agent and an anthracycline, and/or cytarabine, and/or fludarabine [± rituximab]) and were ineligible for intensified chemotherapy or stem cell transplantation (NCT00875667). Upon informed consent, oral lenalidomide was initiated at 25 mg/day on days 1-21 of 28-day cycles until disease progression or as tolerated. IC treatment included single-agent rituximab, gemcitabine, fludarabine, chlorambucil, or cytarabine. The primary endpoint was progression-free survival (PFS, central review per modified 1999 IWG criteria); secondary endpoints included ORR, time to response, OS, and safety. Post-primary analysis (07March2014) all subsequent analyses are based on investigator's assessment.
Results: 254 patients were randomized 2:1 to lenalidomide (n=170) or IC (n=84). As of the current data cut-off of March 7, 2015, 21 (12%) patients remain on lenalidomide and 2 (2%) patients on IC. With an additional 1 year of follow-up from the primary analysis (median 21.0 month follow-up [range, 0.02-69.6]), the median PFS by investigator assessment continues to show improvement for lenalidomide over IC (8.6 *vs* 5.4 months, respectively), with an HR=0.67 (95% CI, 0.48-0.89; sequential log-rank *P*=0.012). Response rates showed a similar trend with an ORR of 46% *vs* 23% (*P*<0.001) and CR/CRu of 12% *vs* 8% (*P*=0.336) for lenalidomide *vs* IC, respectively. Median time to best response was 5.9 *vs* 13.1 months and median OS was 27.8 *vs* 21.1 months. Among the safety population (250 patients receiving ≥1 dose of study drug), 68% of lenalidomide and 40% of IC patients with ≥1 adverse event (AE) had dose reductions/interruptions, in part due to a longer duration of lenalidomide treatment and strict dose modification requirements. At a median time of 2.9 months (range, 0.7-37.8) from randomization, 39 patients (46%) crossed over from IC to lenalidomide. The most common grade 3/4 AEs were neutropenia (45% for lenalidomide *vs* 34%% for IC, without increased risk of infection), thrombocytopenia (20% *vs* 28%), anemia (9% *vs* 7%), and leukopenia (8% *vs* 11%). Non-hematologic AEs with lenalidomide were primarily grade 1/2. Any-grade tumor flare reaction was observed in 10% of lenalidomide patients (2% grade ≥3), and 1 patient in each arm experienced tumor lysis syndrome. Invasive second primary malignancies were identified in 4% of lenalidomide and 5% of IC patients.
Summary/Conclusions: Lenalidomide continues to show significantly improved PFS and ORR by investigator assessment compared with IC in patients with R/R MCL, which was similar to previous central review. The consistent safety profile of lenalidomide partly reflected longer treatment exposure; AEs were manageable with dose modifications or supportive therapy. Overall, long-term follow-up of the MCL-002 trial confirms the improved efficacy of lenalidomide relative to IC monotherapy in patients with R/R MCL.

E1151

POSITIVE BENEFITS OF CHANGING FROM INTRAVENOUS RITUXIMAB ADMINISTRATION TO SUBCUTANEOUS ADMINISTRATION: A SINGLE UK CENTRE EXPERIENCE

S Irwin[*], C Rowntree, C Helen, C Bloodworth
Haematology, University Hospital of Wales, Cardiff, United Kingdom

Background: Addition of the anti CD20 monoclonal antibody, rituximab, to chemotherapy regimens for the treatment of B cell non Hodgkin lymphomas has been standard practice in the UK since 2003. The initial licence for rituximab was for intravenous (IV) administration. Subcutaneous (SC) rituximab was granted marketing authorisation in March 2014. Administration of IV rituximab takes between 90 and 270 minutes depending on a number of factors including the chemotherapy regimen used and the number of doses a patient has already received. SC rituximab takes 5-10 minutes to give. Prior to July 2014 80% of rituximab doses given at University Hospital of Wales (UHW) were prepared by our in house pharmacy staff and 20% of doses were bought in ready prepared bags, to allow flexibility in chemotherapy scheduling. SC rituximab is given as a standard dose for all patients and can be made up by nursing staff in the chemotherapy day unit.
Aims: To investigate cost savings and reduction in chair times for patients treated with chemotherapy regimens containing SC rituximab therapy compared to IV rituximab therapy in a single centre in the UK. Infusion related adverse events were also recorded for the study period.
Methods: Following local governance approval, the UHW department of haematology switched from IV to SC rituximab in July 2014. The policy change only applied to patients with a diagnosis of diffuse large B cell lymphoma (DLBCL) or follicular lymphoma (FL) receiving treatment with R-CHOP, R-CVP or R-bendamustine chemotherapy regimens plus any maintenance doses. All dispensed SC doses of rituximab were retrospectively identified from our pharmacy system in 2015. The actual cost of the SC doses was compared to projected drug costs and staff time for doses given IV with 20% pre prepared drug being bought in as prior to 2014. The chemotherapy day unit audited chair time for the same patient group receiving rituximab containing regimens during a 12 month period in 2013 prior to the change in practice and another 12 month period in 2015 post the changes. Patient notes were retrospectively audited for the same 2 time periods in 2013 and 2015 to record documented complications of rituximab administration.
Results: 92 patients with DLBCL or FL were treated in 2015, receiving a total of 372 doses of SC rituximab. The annual drug cost savings were estimated at £20K. The reduced time spent by pharmacy staff in the aseptic unit was estimated at 160 hours annually. The chemotherapy administration time audit showed that prior to the policy change, average administration times were as follows: R-CHOP 260 minutes (mins), R-CVP 135 mins, R-bendamustine 180 mins and maintenance rituximab 150 mins. Post July 2014 the average administration times were as follows: R-CHOP 130 mins, R-CVP 50 mins, R-Bendamustine 45 mins and maintenance rituximab 11 mins. This reduction in treatment administration translated into a saving of chair times of 842 hours in 12 months (approximately 72 hrs per month) (Fig 1). Retrospective review of patient notes did not show any increase in adverse events relating to SC rituximab administration.
Summary/Conclusions: The introduction of SC rituximab at the UHW resulted in reduced drug costs, reduced staff time in drug preparation and significant reductions in chemotherapy chair time for patients with no evidence of an increase in adverse events relating to drug administration. These savings have freed resources to allow for other therapies to be accommodated into the existing service.

IMPACT OF STABLE DISEASE OR BETTER RESPONSES TO LENALIDOMIDE ON SURVIVAL OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA: MCL-001 (EMERGE) AND MCL-002 (SPRINT) STUDIES

A Goy[1,*], L Arcaini[2,3], ME Williams[4], T Lamy[5], SK Besisik[6], J Drach[7], R Ramchandren[8], TE Witzig[9], T Fu[10], L Zhang[10], T Biyukov[11], E Barnett[10], ML Casadebaig Bravo[11], M Trněný[12]
[1]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, United States, [2]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, [3]Department of Molecular Medicine, University of Pavia, Pavia, Italy, [4]University of Virginia Health System, Charlottesville, United States, [5]Department of Hematology, Hôpital Pontchaillou, Rennes, France, [6]Istanbul University Faculty of Medicine, Istanbul, Turkey, [7]Oncology, Medical University of Vienna, Vienna, Austria, [8]Karmanos Cancer Institute, Detroit, [9]Mayo Clinic, Rochester, [10]Celgene Corporation, Summit, United States, [11]Celgene International Sarl, Boudry, Switzerland, [12]Department of Hematology, Charles University Hospital, Prague, Czech Republic

Background: Patients with relapsed/refractory mantle cell lymphoma (R/R MCL) show poor overall survival (OS) after experiencing failure to immunochemotherapy and other treatment regimens, including bortezomib. Lenalidomide is an IMiD® immunomodulatory agent with direct and immune-mediated mechanisms of action that has demonstrated safety and efficacy (including meaningful disease stabilization rates) in multiple studies of R/R MCL.
Aims: Post hoc analysis of lenalidomide-treated patients from the MCL-001 and MCL-002 studies to determine the survival benefit based on response status (focusing on patients with stable disease [SD]) at landmark points in time.
Methods: Patients receiving oral lenalidomide 25 mg/day on days 1-21 of each 28-day cycle until disease progression or as tolerated were evaluated from 2 phase II studies: MCL-001 (post-bortezomib failure) and MCL-002 (randomized *vs* investigator's choice monotherapy). Patients provided informed consent for each study. Kaplan-Meier methods and unadjusted Cox regression models were used to support the landmark analyses at the start of cycles 3, 5, and 7. Survival data for patients with SD were compared with those with progressive disease (PD) or those responding with at least a partial response (PR) for each time point. Data cutoff for MCL-001 was March 20, 2013 and for MCL-002 was March 7, 2015.
Results: 304 patients who received lenalidomide in MCL-001 (n=134) and MCL-002 (n=170) were included in the analysis. At baseline, patients had a median age of 68.0 years (66% were ≥65 years of age), 76% were male, 91% had stage III/IV MCL at diagnosis, and 52% had high tumor burden. Patients had received a median of 2 prior lines of antilymphoma therapy (range, 1-10); 48% were refractory (≤SD) to their last therapy. Baseline demographics and characteristics were similar for patients with ≥PR, SD, and PD. Response status at each cycle is shown in Table 1, with no response data for 24% of patients at cycle 3 due to early discontinuation, censoring or response being outside the time point window. Median OS in months by response group at cycle 3 was 28.5 for ≥PR, 34.0 for SD, and 11.3 for PD; at cycle 5: 45.3 for ≥PR, 34.7 for SD, and 13.4 for PD; and at cycle 7: not reached for ≥PR, 37.5 for SD, and 17.4 for PD. At all three time points, there was no significant difference in OS for patients with ≥PR *vs* SD, whereas the median OS for patients with SD was significantly prolonged *vs* PD. It is important to note that the SD and PD groups had a small number of patients at the later cycles.

Table 1. Response status and OS at cycles 3, 5 and 7.

Response status, n (%)	≥PR	SD	PD
Cycle 3	78 (26)	124 (41)	30 (10)
Cycle 5	78 (26)	69 (23)	18 (6)
Cycle 7	80 (26)	32 (11)	10 (3)
Median OS, months (95% CI)	**≥PR**	**SD**	**PD**
Cycle 3	**28.5 (21.3-40.4)**	**34.0 (27.8-42.0)**	**11.3 (6.7-18.7)**
≥PR vs. SD	HR=1.23 (95% CI, 0.83-1.81); *P*=0.2997		
PD vs. SD		HR=2.75 (95% CI, 1.73-4.38); *P*<0.0001	
Cycle 5	**45.3 (29.6-NR)**	**34.7 (28.4-44.1)**	**13.4 (8.8-29.8)**
≥PR vs. SD	HR=0.74 (95% CI, 0.45-1.20); *P*=0.2247		
PD vs. SD		HR=2.57 (95% CI, 1.38-4.78); *P*=0.0028	
Cycle 7	**NR (33.8-NR)**	**37.5 (30.0-NR)**	**17.4 (9.6-23.4)**
≥PR vs. SD	HR=0.66 (95% CI, 0.35-1.25); *P*=0.2036		
PD vs. SD		HR=4.24 (95% CI, 1.77-10.15); *P*=0.0012	

Summary/Conclusions: Landmark analyses for lenalidomide-treated R/R MCL patients with SD at cycles 3, 5, and 7 had OS comparable to patients who achieved ≥PR. Overall, these data show that R/R MCL patients with either SD or ≥PR at these time points have significantly improved long-term outcomes compared to those with PD.

Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin Lymphoma. Treatment of stage I disease is usually radiation monotherapy, but debate over the role of additional chemo-immunotherapy exists. Most of the data on treatment and prognosis are based on retrospective historical cohorts before PET-CT was introduced into routine staging procedures. In these previous cohorts, 5 year freedom from treatment failure (FFTF) was 60-80% and the 5 year overall survival (OS) was 80-93%.
Aims: The current study assessed the outcome of patients diagnosed with stage I FL who were treated with radiotherapy with or without rituximab, in the PET-CT era.
Methods: Patients diagnosed with stage I FL based on PET-CT and bone marrow biopsy (BMB), who were treated with involved field radiotherapy between 2002-2015, were retrospectively reviewed in this multi-center study. Patients were treated with either radiation monotherapy or radiotherapy and rituximab.
Results: Ninety one patients from 9 centers were identified. The median age at diagnosis was 60 years (range: 31-93) years. FLIPI score was compatible with a low risk disease (0 or 1) in 93% and with an intermediate risk (FLIPI =2) in 7% of the patients. Forty eight percent of the patients had FL Grade 1, 39%>Grade 2 and 13% -Grade 3a FL, with 30% presenting with an extra-nodal disease. Median radiation dose was 30.2 (18-50) Gy. Most patients were treated with radiation monotherapy (71 patients, 78%), additional rituximab was administered to 20 patients (22%). Within a median follow-up of 57 months, the 5 year FFTF and OS survival rates were 76% and 97% respectively (Figure 1). Twenty one percent of the patients (n=19) experienced relapse; most relapses (n=14) were outside the radiation field. An intermediate risk FLIPI score was the only independent significant factor for a shorter FFTF [HR=2.3, 95% CI= 1.096 - 4.89, p=0.028].Radiation dose or adjuvant rituximab therapy did not significantly affect outcome.

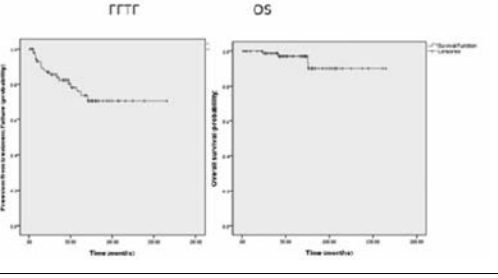

Figure 1. Outcome of patients with FL stage I, determined by PET.

Summary/Conclusions: Our findings show that staging with PET-CT and BMB of stage I FL may result in improved FFTF and OS in patients treated with radiotherapy compared to historical cohorts, possibly due to better identification of a true stage I disease. The distant nature of recurrences suggests that occult distant disease foci, not diagnosed even by PET-CT, are still possible.

PATTERNS OF HEMOGRAM CHANGES IN PATIENTS WITH RELAPSED/REFRACTORY INHL AND CLL TREATED WITH IDELALISIB

S Stilgenbauer[1,*], AJ Davies[2], IW Flinn[3], AK Gopal[4], TJ Kipps[5], T Newcomb[6], CC Waldapfel[6], Z Zhang[6], GA Salles[7], SM O'Brien[8]
[1]University of Ulm, Ulm, Germany, [2]Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, [3]Hematologic Malignancies Research Program, Sarah Cannon Research Institute, Nashville, TN, [4]Medical Oncology Division, University of Washington School of Medicine, Seattle, WA, [5]Moores Cancer Center, University of California, San Diego, San Diego, CA, [6]Gilead Sciences, Inc., Foster City, CA, United States, [7]Hematology Department, Hospices Civils de Lyon, University Claude Bernard, Pierre Benite, France, [8]University of California, Irvine/Chao Family Comprehensive Cancer Center, Orange, CA, United States

Background: Chronic lymphocytic leukemia (CLL) and indolent non-Hodgkin lymphoma (iNHL) are B-cell malignancies associated with neutropenia, anemia and thrombocytopenia. Although the etiology of cytopenia is not well understood, bone marrow leukemia/lymphoma cell infiltrates are thought to contribute. Idelalisib (IDELA) is a selective, first-in-class oral PI3Kδ inhibitor. In preclinical studies, IDELA selectively targeted malignant B cells with minimal toxicity to non-malignant B cells and other hematopoietic cell types. In clinical studies evaluating IDELA in B-cell malignancies, hematologic responses across all 3 lineages were observed in a majority of patients (pts) with baseline (BL) cytopenias.
Aims: The objective of this post hoc analysis was to evaluate hemogram changes in pts with relapsed or refractory (R/R) CLL or iNHL treated with IDELA in 2 pivotal studies.
Methods: In phase 3 Study 116, frail pts with CLL were randomized to receive rituximab (R) in combination with IDELA 150 mg BID or placebo (PBO). In phase 2 Study 101-09 (NCT01282424), pts with iNHL received IDELA monotherapy 150 mg BID. Trial inclusion criteria allowed enrollment of pts with BL cytopenias of any grade (CLL) or grade <3 (iNHL). Hematologic profiles for pts were categorized as normal or abnormal (any grade of cytopenia) at BL and assessed while on treatment. Supportive care utilization was assessed by use of blood product transfusions, hematopoietic growth factors, and immunosuppressant therapies. Treatment-emergent de novo autoimmune cytopenias (AIC) and/or worsening of pre-existing AIC were summarized. All analyses excluded pts from the iNHL study with PD at the first assessment to avoid confounding by underlying uncontrolled disease.
Results: A total of 345 pts participated in these trials. The overall response rates for IDELA-treated patients in the CLL and iNHL studies were 84% and 58%, respectively. For pts with CLL on IDL+R (n=110), BL cytopenias (grade ≥1) included anemia (76%), thrombocytopenia (62%), and neutropenia (34%). For pts with iNHL on IDELA-monotherapy (n=115), BL cytopenias included anemia (50%), thrombocytopenia (36%), and neutropenia (24%). In patients with a normal hemogram at BL, median hematologic values remained unchanged over time with IDELA treatment. In patients with BL cytopenia, IDELA treatment was associated with improved Hgb and platelet counts and a reduction in supportive care utilization for anemia, thrombocytopenia, and neutropenia. For pts with CLL, median peak values for Hgb (24% above BL) and platelets (120% above BL) were observed within 6 months of IDELA initiation. For pts with iNHL, median peak values for Hgb (20% above BL) and platelets (64% above BL) were observed within 3 months of IDELA initiation. ANC remained stable over time in IDELA-treated pts with CLL and increased in pts with iNHL; a reduction in G-CSF utilization was observed for pts with CLL or iNHL and BL cytopenias while on treatment with IDELA. A history of AIC was reported in 6.4% and 16.4% of pts with CLL on IDELA+R and PBO+R, respectively. As of the data cutoff, no pt had experienced treatment-emergent AIC and/or worsening of pre-existing AIC.

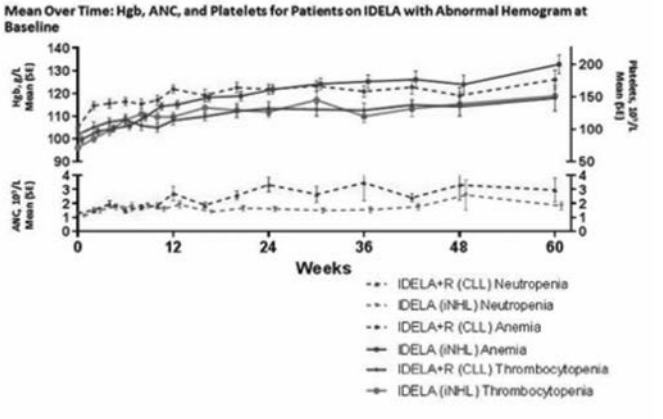

Figure 1.

Summary/Conclusions: This analysis indicates improved cytopenia in 2 lineages for pts with R/R CLL and iNHL treated with IDELA. Thus, pre-existing cytopenias, including those due to advanced disease, myelosuppression from prior chemotherapy, and AIC, do not by themselves preclude treatment with IDELA.
Studies included in this analysis: 101-09: NCT01282424; GS-US-312-0116: NCT01539512

E1155

A PHASE II STUDY OF THE COMBINATION OF OFATUMUMAB WITH FLUDARABINE AND CYCLOPHOSPHAMIDE IN PATIENTS WITH RELAPSED OR REFRACTORY WALDENSTRÖM'S MACROGLOBULINEMIA
M Gavriatopoulou[1], M Roussou[1], D Fotiou[1], D Ziogas[1], E Terpos[1], D Kalapanida[1], E Kafantari[1], A Papathoma[2], M Spyropoulou-Vlachou[3], MA Dimopoulos[1], E Kastritis[1,1,*]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens School of Medicine, [2]Immunology Lab, Alexandra Hospital, [3]Immunology Lab, Alexandra Hopsital, Athens, Greece

Background: Ofatumumab is a novel anti-CD20 monoclonal antibody which has been approved for the treatment of chronic lymphocytic leukemia, but limited data exist for patients with Waldenström's macroglobulinemia (WM). Ofatumumab targets CD20 in a different epitope than rituximab and may also have a more favorable profile regarding infusion related reactions since, in contrast to rituximab, it is a human and not chimeric antibody. Fludarabine with cyclophosphamide (FC) is a very effective treatment when combined with rituximab (FCR) in patients with relapsed or refractory WM.
Aims: to evaluate the combination of ofatumumab with FC (OFC) in symptomatic patients with relapsed or refractory WM requiring therapy
Methods: This is a phase 2 single center trial. Treatment consisted of four cycles of the OFC combination. A single dose of 100 mg of ofatumumab was given I.V. on day 1 of the first cycle followed by 1000 mg on day 8. Fludarabine 25 mg/m^2 and cyclophosphamide 250 mg/m^2 were given intravenously for 3 consecutive days every 28 days for 4 cycles, followed by ofatumumab (1000 mg) in cycles 2 to 4. Primary end point was overall response rate (complete (CR)+very good (VGPR)+partial (PR)+minor (MR) response) and secondary endpoints included safety and toxicity, occurrence of "IgM flare", duration of response, progression free and overall survival
Results: From 2013 until 2014, twelve patients were treated with OFC; 75% and 17% were high and intermediate risk per the International Prognostic Scoring System for WM. All patients had previously been exposed to rituximab and 4 (33%) were refractory to the last course of rituximab, while 4 (33%) had previously received bortezomib. On intent to treat, 11/12 (92%) patients responded (17% VGPR, 67% PR and 8% MR). Median time to first response (≥MR) was 2.2 months and median time to ≥PR was 8.5 months. In 11 (92%) patients a continuing decrease of IgM levels has been observed and at 6 months post OFC completion 6 (50%) patients have improved their response from MR to PR or VGPR. "IgM flare" was not observed. All patients completed the planned 4 cycles of treatment. Infusion related reactions occurred in only one patient (grade 2) who had a history of severe rituximab intolerance, during the day 8 dosing (1000 mg); the patient completed the full schedule without further reactions. After a median follow-up of 23 months, patients have progressed or died and the median progression-free survival is 21 months. The 2-year duration of response for patients with ≥PR is 70%, and 2-year survival is 83%. Neutropenia grade 3 occurred in 67% and grade 4 in 25% of patients. One patient experienced neutropenic fever and the dose of FC was reduced according to the protocol.
Summary/Conclusions: OFC is a rapidly acting combination, inducing high response rates, including deep and durable responses in heavily pretreated WM patients, even in those refractory to rituximab and/or bortezomib. Ofatumumab is well tolerated with low incidence of infusion related reactions, and although the combination has myelotoxicity, it is manageable.

MOLECULAR ACTIVITY IN FOLLICULAR LYMPHOMA MONITORED BY BCL2/IGH IN THE PERIPHERAL BLOOD. THE OLD STORY IN A NEW LIGHT?
A Janikova[1], E Miculkova[1,*], A Mareckova[1], N Kopalova[1], J Michalka[1], D Salek[1], D Dvorakova[1], L Kren[2], I Hanke[3], S Pospisilova[1], J Mayer[1]
[1]Dept of Hematology and Oncology, [2]Dept of Pathology, [3]Dept of Surgery, University Hospital Brno, Brno, Czech Republic

Background: Follicular lymphoma (FL) is highly associated with the molecular rearrangement BCL2/IGH. Although BCL2/IGH has been studied many times, its real clinical value remains still matter of debates.
Aims: In our work, we focused on the mutual relationship between molecular levels of BCL2/IGH measured in peripheral blood (PB) and clinical course of FL.
Methods: We performed qualitative and quantitative testing of BCL2/IGH by nested and real-time PCR in FL patients (grade 1-3B). PB samples were tested before the start of therapy (or watch and wait period, 12.8% cases), during treatment and during follow up at the time of routine clinical controls. According to mutual correlation of clinical course FL and molecular activity in PB, we divided patients into five groups (A, B, C, D, E): Group A included patients in a long-term molecular and clinical remission. Group B was defined by long-term remission with sporadic molecular activity. Group C included patients with concordant clinical and molecular remission and progression. Group D included patients with discordant clinical and molecular activity; there are two subgroups: 1) DM defined as evident molecular positivity in lasting clinical remission, and 2) DR defined by a clinically evident relapse in lasting molecular remission. Group E includes non-evaluable patients with the initial molecular negativity in PB, patients without treatment (watch and wait) and patients with lack of samples. Groups A and B with lasting molecular and clinical remissions brought no correlation information, the only informative population is represented by subgroups C and D.
Results: Totally, 187 patients with initial BCL2/IGH positivity were included, median of molecular follow up was 4.7 ys (range 1.1-14.8 ys) and median clinical follow up 5.3 ys (range 0.4-18.4ys); systemic treatment (chemotherapy or

immunochemotherapy) was administered in 173/187 (92.5%) cases. There were 83 men (44%) with median age of 57 ys (range 28-79 ys), clinical stage III-IV was determined in 144/187 (77%) patients. Median number of PCR samples per patient was 15 (range 3-67). There were 60 (32.2%) patients in group A, 16 (8.7%) pts in group B, 39 (20.8%) pts in group C, 26 pts (13.9%) in group D and 46 (24.6%) pts in group E. Groups C and D (65 pts) gave a relevant correlation information only; the proportion of discordant cases was 26/65 (40%) pts. As mentioned, group D was divided into two subgroups: DR group (clinical relapse in molecular remission) with 19 (10.2%) patients, 17/19 (89.5%) patients remain alive with median overall survival (OS) of 8.5 ys. DM subgroup (molecular activity in lasting clinical remission) consisting of 7 pts, all of them remain alive with median OS of 12.1 ys. Interestingly, 10/39 (25.6%) patients subscribed into group C died (median OS 4.5 ys; 7 cases with confirmed death due to FL progression), compared to 2/26 died patients from group D (7.7%, 1 died probably due to progression only) with median OS of 8.8 ys (p 0.067).
Summary/Conclusions: Based on our results, molecular activity of BCL2/IGH in blood does not correlate sufficiently with clinical activity of FL in about 40% cases. However, patients with correlating molecular activity in their clinical relapses seem to have a tendency to a worse prognosis with more deaths related to FL and shorter overall survival. We can speculate, that release bcl2/IGH+ cells into PB mirrors the real aggressiveness of FL.

E1157

THE IMPACT OF HISTOLOGIC GRADING ON THE OUTCOME OF FOLLICULAR LYMPHOMA: IS GRADE 3 FOR BETTER OR FOR WORSE?

M Angelopoulou[1,*], P Tsirkinidis[2], S Kokoris[1], M Siakantaris[3], P Tsaftaridis[1], F Kontopidou[4], MC Kyrtsonis[5], M Dimopoulou[1], E Plata[1], M Dimou[5], G Boutsikas[1], V Telonis[1], A Zannou[1], G Gainarou[1], JV Asimakopoulos[1], P Flevari[1], G Dryllis[1], M Arapaki[1], T Giannikos[1], E Konstantinou[1], I Stergiou[1], G Pangalis[6], K Christina[7], M Moschogiannis[6], S Sachanas[6], X Giakoumis[6], P Panayiotidis[5], K Konstantopoulos[1], T Vassilakopoulos[1]
[1]Department of Hematology and BMT Unit, National and Kapodistrian University of Athens, Laiko General Hospital, [2]Department of Hematology, 401 Military Hospital, [3]1st Department of Internal Medicine, National and Kapodistrian University of Athens, Laiko General Hospital, [4]2nd Department of Internal Medicine, National and Kapodistrian University of Athens, Hippokrateion Hospital, [5]1st Department of Propedeutics, National and Kapodistrian University of Athens, Laiko General Hospital, [6]Department of Hematology, Athens Medical Center-Psychikon Branch, Athens, [7]Department of Hematology, University Hospital, University of Crete, Heracleion, Crete, Greece

Background: Follicular lymphoma (FL) is an indolent lymphoma with an excellent prognosis. With the incorporation of chemoimmunotherapy, more than 70% of the patients survive at 10 years. The clinical significance of FL histologic grading according to the WHO Classification into grades 1/2 and grades 3A and 3B is still a matter of debate.
Aims: To study the clinical and laboratory characteristics of grade 3A and 3B FL compared to grades 1 and 2 and to explore whether higher grades are associated with a worse outcome.
Methods: We retrospectively studied all patients with FL diagnosed and treated in a single University Hematology Unit between 2001 and 2015.

Table 1. Patients' Characteristics (N=53)9 (103-556).

Characteristic	N (%)
Median age in years (range)	59 (25-83)
Male gender	27 (51)
Stage	
- I-II	25 (47)
- III-IV	28 (53)
FLIPI	
- Low	26 (49)
- Intermediate	13 (24)
- High	14 (26)
Median hemoglobin in g/dL (range)	13.5 (7.8-15.8)
Median lymphocyte counts –x10^9/L (range)	1.76 (0.64-45.8)
Median platelet counts - x10^9/L (range)	229 (103-556)
Elevated LDH	11 (21)
Bone marrow involvement	17 (32)
Bulky disease	9 (17)
Treatment	
- Watch and wait	1 (2)
- Radiotherapy/Surgery	5 (10)
- Rituximab plus radiotherapy	1 (2)
- Alkylators (chlorambucil/CVP)	2 (4)
- CHOP	1 (2)
- Rituximab monotherapy	1 (2)
- Rituximab-fludarabine based	1 (2)
- Rituximab-alkylators	9 (17)
- RCHOP	31 (60)

Results: Among 200 consecutive patients with FL with a median follow-up of 76 months (0.1-186), 53 patients with grade 3 FL were identified (47 with grade 3A and 6 with grade 3B). Patients' characteristics are shown in the table. The comparison between grade 3 and grades 1 and 2 patients revealed the following significant differences: Grade 3 cases had more frequently Ki-67>30% (p<0.0001), CD10 negativity (p=0.009), high LDH levels (p=0.009) and lymphocytopenia <0.8/μL (p=0.05). FLIPI score and bulky disease did not differ significantly. There was a trend that did not reach statistical significance for male gender, localized stage and absence of bone marrow involvement to be more frequent in grade 3 compared to grades 1/2. Treatment also differed significantly between the two groups (p<0.0001): 60% of grade 3 patients were treated with Rituximab (R)-CHOP, while 52% of grade 1/2 patients were treated with R-alkylators (chlorambucil or CVP). The outcome of grade 3 patients was not inferior: 10-year PFS was 64% *vs* 55.6% and 10-year OS was 83.7% *vs* 84.4% for grade 3 and grade 1/2 patients, respectively. Moreover, a plateau in the survival curves of grade 3 patients was observed in contrast to a constantly relapsing course of grades 1 and 2 cases. Among the 53 patients with grade 3, prognostic factor analysis revealed that Ki-67, age, gender, stage, LDH, bulk and FLIPI score did not have any significance for outcome, while there was a trend for superior PFS for R-CHOP treated patients (p=0.08) with a 10-year PFS of 67.3% *vs* 31.3% for patients treated with other modalities. However, overall survival did not differ between aggressive and low intensity treatment strategies. Of note, stage and FLIPI were well balanced between the two groups.
Summary/Conclusions: Grade 3 FL patients show more frequently high Ki-67 expression, CD10 negativity, elevated LDH and lymphocytopenia compared with lower grade FL patients. However, the long-term outcome of grade 3 FL is equally favorable with plateaus in the survival curves.

E1158

THE IMPROVING OUTCOME OF NON-HODGKIN LYMPHOMA (NHL) WITHIN 15 YEARS PERIOD-REAL WORLD DATA OF NATIONAL-WIDE LYMPHOMA PROJECT

M Trneny[1,*], V Campr[2], A Janikova[3], D Belada[4], V Prochazka[5], H Mocikova[6], J Pirnos[7], K Kubackova[2], J Duras[8], L Barsova[9], J Pukyova[10], M Brejcha[11], S Vokurka[12], D Adamova[13], R Bar[14], D Starostka[15], M Chodacka[16], P Kessler[17], R Pytlik[1], L Dusek[18], K Benesova[19], A Sykorova[19], J Dlouha[19], P Blahovcova[19], L Boudova[12]
[1]Charles University General Hospital, [2]University Hospital Motol, Praha, [3]University Hospital Brno, Brno, [4]University Hospital Hradec Kralove, Hradec Kralove, [5]University Hospital Olomouc, Olomouc, [6]University Hospital Kralovske Vinohrady, Praha, [7]Ceske Budejovice Hospital, Ceske Budejovice, [8]University Hopital Ostrava-Poruba, Ostrava-Poruba, [9]Liberec Hospital, Liberec, [10]Usti n/L Hospital, Usti n/L, [11]Novy Jicin Hospital, Novy Jicin, [12]University Hospital Plzen, Plzen, [13]Opava Hospital, Opava, [14]Tabor Hospital, Tabor, [15]Havirov Hospital, Havirov, [16]Chomutov Hospital, Chomutov, [17]Pelhrimov Hospital, Pelhrimov, [18]National Cancer Registry, [19]CLSG Data Centre, Praha, Czech Republic

Background: Non-Hodgkin's lymphomas (NHL) represent the most common hematologic cancer with increasing incidence over the years. Number of clinical trials demonstrated improved outcome of different NHL subtypes, the nationalwide studies describing real world data are however limited. Lymphoma Project established by Czech Lymphoma Study Group (LP-CLSG) in 1999 is focused on prospective collection of NHL patients data since that time.
Aims: The aim of this study is to analyze key data of patients diagnosed and entered into this project during the period 1999-2014.
Methods: The data National Cancer Registry (NCR) were used for incidence and mortality population based figures. Web based utility was developed for LP-CLSG, each center (17 with >50 pts.) is responsible for entering the data of consecutive newly diagnosed lymphoma patients, the central data office is responsible for validation of data. Pathology review were performed in dedicated reference centers. The project is approved by ECs.
Results: The NHL incidence and mortality resp. has been observed to increase from 6.1 and 3.6 resp. in 1981 to 10.8 and 6.0 resp. in 2001 and to 13.5 and 5.3 (decrease) per 100,000 resp. in 2011 (data from population based NCR). Altogether 11 828 patients were recorded in the specific Lymphoma Project in the period 1999-2014, 10 333 with B or T-cell NHL had the reference center pathology review and were included into the analysis. More than 2/3 of all newly diagnosed cases in Czech republic is covered by the project. There were 4187 (40.5%) DLBCL pts., 1969 (19.5%) FL, 885 (8.6%) MZL, 857 (8.3%) MCL, 393 (3.8%) SLL and 1252 (12.5%) other or unclassified B-NHL pts. T-NHL cohort consisted of 283 (2.7%) PTC NOS pts., 198 (1.9%) ALCL and 309 (3,0%) other T-NHL. There was no trend for increase or decrease of any NHL subtype during the observation period. The median age at the diagnosis was 62 (17-97) and there were similar proportion of men (51.2%) and women (48.8%). Altogether 9,718 had sufficient data for therapy and survival. The median OS for B-NHL and T-NHL was 13.0 and 3.4 y resp. The median OS for B-NHL patients treated with chemotherapy (CHT) and rituximab-chemotherapy (R-CHT) were 8.7 and not reached resp. with probability death risk reduction (DRR) of 36% (HR 0.64 p<0.0001). It was mainly due to DLBCL outcome improvement with median OS 5.9 years for CHT group *vs* unreached for R-CHT group, with DRR of 44% (HR 0.56, 95%CI; 0.44-0.57, p<0.0001). The OS was significantly improved by rituximab addition to chemotherapy in FL with HR 0.76 (95%CI; 0.59-0.92, p-0.012), MCL with HR 0.67 (95%CI; 0.49-0.82, p<0.001), SLL with HR 0.60 (95%CI;0.40-0.85, p<0.01), MZL did not show rituximab benefit in this analysis. The significant OS improvement in all NHL diagnosed in current period (2009-2014) was observed compared to period 15 years ago (1999-2002) with DRR by 14% (HR 0.86, 95%CI; 0.74-0.91, p<0.001) This is mainly due to the B-NHL outcome improvement with HR 0.87 (95%CI;0.75-0.92, p<0.005), there was

trend for T-NHL outcome improvement (HR 0.82) but it was not significant (p 0.20).
Summary/Conclusions: The analysis of the large national-wide population has revealed: 1. The lymphoma incidence is more than doubled during last 30 years whereas the mortality started decrease since 2001 after rituximab introduction. 2. The significant NHL outcome improvement in B-NHL mainly due to rituximab addition with HR 0.56 for DLBCL, 0.76 for FL, 0.67 for MCL and 0.60 for SLL. Other factors could however play the role since 3. There is insignificant trend for outcome improvement of T-NHL as well. 4. The lymphoma project allows the detailed subanalysis of different lymphoma subtypes and different therapeutic approaches, which will be presented.
Supported by grant: AZV CR 16-31092A.

E1159

THE IMPACT OF FDG PET-CT IN THE STAGING OF FOLLICULAR LYMPHOMA, A SINGLE CENTRE EXPERIENCE
R Fernandez-Alvarez[1,*], A Rubio-Castro[1], M Sorigue[2], A Fernandez-Rubio[1], E Gonzalez-Garcia[1], C Fernandez-Alvarez[1], JM Sancho[2]
[1]Hematology, Hospital Cabueñes, Gijon, [2]Hematology, Institut Català d'Oncologia, Hospital Germans Trias i Pujol, Badalona, Spain

Background: 18-F-fluorodeoxyglucose positron emission tomography-CT (FDG PET-CT) is now the recommended imaging technique for staging and response assessment in follicular lymphoma (FL) (Cheson et al. 2014). However, the relevance of FDG PET-CT in the staging of FL is not well established, apart from selected cases for specific purposes (accurate assessment of stage I and for guidance of biopsy when transformation is suspected). PET scanning is readily available at our centre and it is often included as part of standard staging procedures in FL patients (pts).
Aims: We aimed to investigate the value of FDG PET-CT scans in the staging of FL pts in routine clinical practice.
Methods: Retrospective study of pts with grade 1-3a FL who had undergone conventional staging workup (contrast-enhanced CT and bone marrow biopsy [BMB]) along with FDG PET-CT at our centre. Pts with concurrent diagnosis of diffuse large B cell lymphoma were excluded. We compared the disease extent based on conventional investigations with the incorporation of PET to staging.
Results: A total of 55 pts (female - 29, male - 26) were included, with a median age of 64 years (range, 33-82). Forty-eight pts (87%) were staged at the time of initial diagnosis, whereas 7 pts (13%) had received prior treatment and were staged at relapse. By conventional staging, 42 pts (76%) had advanced stage (III/IV) and 20 pts (36%) had high-risk FLIPI score. GELF criteria were met in 37 pts (67%). Following staging procedures, 49 pts (89%) received treatment with diverse regimens, while 6 pts (11%) were managed expectantly. Pathological uptake was detected for all FDG PET-CT scans. The median SUV_{max} of most FDG avid lesions was 9.04 (range, 2.8-37.5). However SUV_{max} was not correlated with the histological grade. PET identified a higher number of nodal areas than CT scan in 29 pts (53%). Furthermore, 25 pts (45%) showed "new" extranodal lesions not seen on CT. Overall, PET revealed 71 additional nodal areas (+31%) and 28 extranodal lesions not visualized by CT (+127%).. Bone marrow involvement was reported in 19 pts on PET, compared to only one case on CT. The uptake pattern was focal in 12 cases (9 multiple, 3 single) and diffuse in 7 cases. In 5 cases (4 focal, 1 diffuse) BMB showed no infiltration. No guided biopsies were performed to explore these discordant cases. However, focal lesions resolved after treatment in all pts, supporting the presence of disease pretherapy. The sensitivity, specificity, positive and negative preditive value of FDG PET-CT with respect to BMB was 50.0%, 81.5%, 73.7% and 61.1% respectively. PET also detected five splenic involvements not seen on CT. Among 13 pts initially classified as localized stage (I/II) by conventional staging, 5 pts (representing 38%) were found to have stage IV using FDG PET-CT, due to bone lesions on PET. Overall, the incorporation of PET led to a change in Ann Arbor stage in 8 pts (14%), all of them were up-staged. As anticipated, the FLIPI distribution was modified when PET was taken into account: five pts (9%) were re-classified as high risk group on the basis of higher number of nodal areas and/or more advanced stage on PET.
Summary/Conclusions: FDG PET-CT identifies a greater extent of nodal and extranodal disease in FL compared with conventional CT, accounting for an improved stage accuracy. The addition of PET leads to stage migration in a proportion of pts, where it has the potential to modify therapy decisions. Whether this additional information provided by PET improves prognostic stratification remains to be determined.

E1160

RITUXIMAB MAINTENANCE IMPROVED PROGRESSION-FREE SURVIVAL AND REDUCED THE INCIDENCE OF TRANSFORMATION IN PATIENTS WITH FOLLICULAR LYMPHOMA
Y Kusano[*], Y Terui, M Yokoyama, K Ueda, N Nishimura, Y Mishima, T Gunji, H Nitta, N Inoue, A Takahashi, N Tsuyama, K Takeuchi, K Hatake
Cancer Institute Hospital of Japanese Foundaton for Cancer Research, Tokyo, Japan

Background: Follicular lymphoma (FL) is incurable disease even in rituximab era. Continuous exposure by anti-CD20 antibody after the induction therapy was considered to improve prognosis of patients with FL. Several phase II and III trials demonstrated that progression-free survival (PFS) is upgraded by rituximab maintenance. Transformed FL is known as rare but has a negative impact on prognosis of FL patients. It has not been known the relationship between rituximab maintenance and the incident rate of transformation.
Aims: We analyzed our data to clarify the efficacy and safety of rituximab maintenance in FL patients and to verify whether rituximab maintenance is associated with the incidence of transformed FL.
Methods: We retrospectively analyzed patients aged over 18 who were diagnosed with previous untreated FL grade 1, 2, and 3a in single cancer institute hospital from 2005. Chemo-sensitive patients had given four weekly rituximab infusions every 6 months for two years if we had informed consent. Basically, R-CVP was used except when FL had a feature of (i) bulky disease (≥7 cm), (ii) maximum of standardized uptake value ≥10 measured by PET scan, and (iii) clinical aggressive manifestations. The primary efficacy endpoint is the incidence of transformation during rituximab maintenance phase. Secondary endpoints are the 5-year PFS, time to next treatment (TNT), and overall survival (OS) and adverse events (AEs) during maintenance phase. Estimates of survival were analyzed by using log rank test and by Cox hazard model. Analysis of contingency table was done by Fisher's exact test.
Results: A total of 217 patients achieved at least stable disease by R-CVP/R-CHOP. Overall 217, 162 received maintenance group and 49 were observed after induction therapy. Baseline characteristics of both groups were similar except R-CHOP ratio. At the median follow-up of 68.4 months, 5-year PFS was 78.4% (95%CI: 70.0-84.9) in the maintenance group and 38.8% (95%CI: 16.2-43.3) in the observation group (P<0.0001). Five-year TNT was 70.6% (95%CI: 71.2-86.0) in the maintenance group and 47.6% (95%CI: 22.9-50.9) in the observation group (P<0.0001). The 5-year OS was 95.3% (95%CI: 89.5-97.9) in the maintenance group and 94.8% (95%CI: 71.2-92.7) in the observation group (P=0.96). Backward stepwise selection method in Cox hazard model demonstrated four factors that had a positive impact on PFS independently: rituximab maintenance (HR: 0.34, 95%CI: 0.19-0.61; P<0.01); non-bulky disease (HR: 0.41, 95%CI: 0.22-0.76; P<0.01); no transformation (HR: 0.41, 95%CI: 0.22-0.65; P<0.01); and β_2 microglobulin<2 (HR: 0.33, 95%CI: 0.19-0.59; P<0.01). On the other hand, 27 patients experienced transformation after R-CVP/R-CHOP. Of 27, 7 (4.7%) in the maintenance group and 16 (28%) in the observation group were transformed (Figure, P<0.01), whereas 7 (3.4%) in the R-CVP group and 16 (6.6%) in the R-CHOP group were transformed (P<0.01). Additionally, rituximab maintenance reduced the incidence of transformed FL regardless of induction therapy. In the R-CVP group, the incidence of transformation was 0.67% in the maintenance arm *versus* 4% in the observation arm, (P<0.01), while in R-CHOP group, that was 10.7% in the maintenance arm *versus* 17.9% in the observation arm (P=0.23). The most common AE was infusion reaction (13%). One patient quit maintenance at the first cycles due to severe infusion reaction.

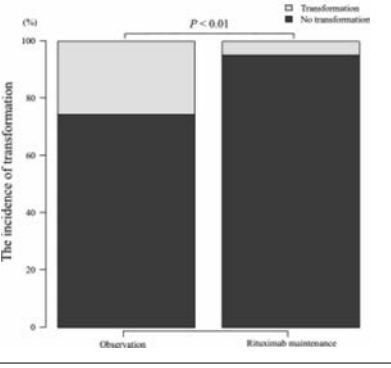

Figure 1. Rituximab maintenance reduced the incidence of transformed FL.

Summary/Conclusions: Rituximab maintenance was beneficial for only PFS at the median follow-up of 5 years. However, rituximab maintenance diminished the incidence of transformed FL significantly and tolerate.

E1161

CLONE-SPECIFIC IGH PLASMIDS AS AN ALTERNATIVE STANDARD FOR ASSESSMENT OF MINIMAL RESIDUAL DISEASE BY REAL-TIME QUANTITATIVE PCR IN FOLLICULAR LYMPHOMA
T Laubenstein[*], M Kneba, C Pott
Klinik für Innere Medizin II, Universitätsklinikum Schleswig-Holstein, Kiel, Kiel, Germany

Background: Development of novel treatment options, led to improved clinical outcome in follicular lymphoma (FL). Additionally sensitive diagnostic tools

have been established, able to detect low amounts of malignant cells, so-called minimal residual disease (MRD). Real-time quantitative pcr (RQ-PCR) using the t(14;18) as a molecular target is beeing broadly applied in FL. In cases with no PCR-detectable t(14;18), clonal rearrangements of the immunoglobulin genes (IGH) can be used, limited by the required information of lymphoma infiltration in the diagnostic sample, which is not regularly available due to nodal disease character. Cloned IGH-plasmids as an external standard for RQ-PCR could be a useful alternative.

Aims: This study investigated, whether RQ-PCR using clone-specific IGH-plasmids as standards for quantitative MRD-assessment in FL, is an accurate, reproducible and feasible alternative if no t(14;18) is available as a PCR-target.

Methods: IGH-rearrangements of a b-cell-lymphoma cell-line and 24 FL patients, amplified by FR1-IGH-PCR, were sequenced for identification of the clone-specific VDJ-region. Allel specific oligonucleotides were designed to the CDR3- and the FR3-region as reverse/ forward primers for RQ-PCR. Antisense consensus probes fitting to the FR3-region were used if possible, otherwise ASO-probes were designed. The IGH-rearrangements were cloned into plasmids and serial dilutions were performed for the cell-line and each patient to serve as external standards for RQ-PCR. Initially a serial dilution of cell-line DNA containing known IGH-copies was quantified by the plasmid-standard. Subsequently amplification characteristics of the IGH-plasmids of 24 FL patients were compared to each other and to relative genomic DNA (gDNA)-standards. Finally MRD-levels of follow-up samples, determined by using IGH-plasmid- and t(14;18)-cell-line- or IGH-gDNA-standards were compared.

Results: IGH-copies of a cell-line sample could be quantified accurately using IGH-plasmid-standards (*median deviation*: 6,9%, *SD*: 3,9%, *corr. coefficient*: 0,999). IGH-plasmid-standard-curves of the 24 patients indicated high conformity referring to slope (*median*: -3,39; *SD*: 0,08), correllation coefficient (*median*: 0,998; *SD*: 0,001), efficacy (*median*: 0,97; *SD*: 0,03), sensitivity (*median*: 10^{-5}) and specificity (*median*: $5x10^{-5}$). Compared to gDNA- plasmid-standards showed comparable sensitivity (*median*: 10^{-5} *vs* $1,25*x10^{-5}$; *SD*: $1,2x10^{-5}$ *vs* $2,69x10^{-5}$) and a superior specificity (*median*: $5x10^{-5}$ *vs* $1,41x10^{-4}$; *SD*: $2,5x10^{-5}$ *vs* $2,19x10^{-4}$). Moreover a significant superiority of the plasmid-standards was seen regarding to slope (*median*: -3,39 *vs* -3,67; *SD*: 0,08 *vs* 0,18; *p*: 0,008), correlation coefficient (*median*: 0,998 *vs* 0,990; *SD*: 0,001 *vs* 0,011; *p*: 0,009), and efficiency (*median*: 0,97 *vs* 0,87; *SD*: 0,03 *vs* 0,06; *p*: 0,008). In a final step patient follow-up samples were quantified by different strategies, using clone-specific IGH-plasmids *vs* IGH-gDNA or t(14;18)-cell-line-DNA respectively (total of 126 comparisons). In 92/126 (73,0%) of these comparisons Δmrd-level was<0,5 log-steps, in 21/126 (16,7%) within 0,5-1 log-steps, in 4/126 (3,2%) within 1-2 log-steps. Only in 9/126 (7,2%) cases Δmrd-level was >2 log-steps.

Summary/Conclusions: Quantitative MRD-assessment in FL using clone-/patient-specific IGH-plasmids as external standards for RQ-PCR, represents an accurate, reproducible and feasible strategy and can therefore be used in cases with no pcr-detectable t(14;18).

E1162

IS LIMITED STAGE FOLLICULAR LYMPHOMA (FL) A TRULY CURABLE DISEASE? A RETROSPECTIVE ANALYSIS ON 79 PATIENTS

M Angelopoulou[1,*], P Tsirkinidis[2], S Kokoris[1], M Dimopoulou[1], M Siakantaris[3], P Tsaftaridis[1], F Kontopidou[4], V Komninaka[1], MC Kyrtsonis[5], E Plata[1], M Dimou[5], G Boutsikas[1], V Telonis[1], A Zannou[1], G Gainarou[1], JV Asimakopoulos[1], P Flevari[1], G Dryllis[1], M Arapaki[1], T Giannikos[1], E Konstantinou[1], I Stergiou[1], G Pangalis[6], C Kalpadakis[7], M Moschogiannis[6], S Sachanas[6], X Giakoumis[6], P Panayiotidis[5], K Konstantopoulos[1], T Vassilakopoulos[1]

[1]Department of Hematology and BMT, National and Kapodistrian University of Athens, Laikon General Hospital, [2]Department of Hematology, 401 Military Hospital, [3]1st Department of Internal Medicine, National and Kapodistrian University of Athens, Laikon General Hospital, [4]2nd Department of Internal Medicine, National and Kapodistrian University of Athens, Hippokrateion Hospital, [5]1st Propedeutic Department of Internal Medicine, National and Kapodistrian University of Athens, Laikon General Hospital, [6]Department of Hematology, Athens Medical Center-Psychikon Branch, Athens, [7]Department of Hematology, University of Crete, University General Hospital of Heraklion, Heraklion, Greece

Background: Limited stage I/II FL is considered potentially curable in contrast to advanced stage (III/IV) disease. The most widely accepted treatment strategy is local radiotherapy (RT), occasionally followed by rituximab (R) monotherapy. However, studies specifically focusing on localized FL are limited.

Aims: To study the clinical and laboratory characteristics of limited stage FL and explore long-term outcomes.

Methods: We retrospectively studied all patients with FL diagnosed and treated in a single University Hematology Unit between 2001 and 2015 and stage I/II cases were recorded.

Results: Among 200 consecutive patients (median follow-up 76 months), 79 patients with limited stages were identified: 55 stage I and 24 stage II. Treatment differed according to histologic grade (p=0.002): RT±R was used in 53% of grade 1/2 histologies, whereas R-CHOP was administered in 54% of grade 3 cases. 5-and 10-year progression free survival (PFS) was 61% and 45%, respectively, while the corresponding values for overall survival (OS) were 94% and 90%. A plateau in the PFS curve was observed beyond 8 years. Disease bulk was identified as a borderline significant factor for PFS (p=0.09): Patients with bulky disease had a 5- and 10-year PFS of 43% and 29% *vs* 65% and 49% for those with non-bulky disease. The comparison of limited *vs* advanced disease stage revealed no significant differences regarding histologic grade, gender, age and bulk. FLIPI differed significantly, as expected (p<0.0001): 91% of limited stage patients had a low FLIPI score, whereas 78% of advanced stage ones had intermediate and high FLIPI scores. LDH was elevated in 5.3% of localized and 17.5% of advanced disease (p=0.01). There was a trend for higher Ki-67 in limited stages (p=0.07). Treatment also differed significantly, as expected (p<0.0001): 44% of limited stage patients were treated with RT±R *vs* 0.8% of advanced stage ones, whereas systemic chemotherapy was used in 53% and 92% of localized and advanced stage FL patients, respectively. Despite treatment heterogeneity, PFS and OS did not differ significantly between limited and advanced stage disease. However, there was a trend for superior OS in localized disease patients beyond 5 years (figure).

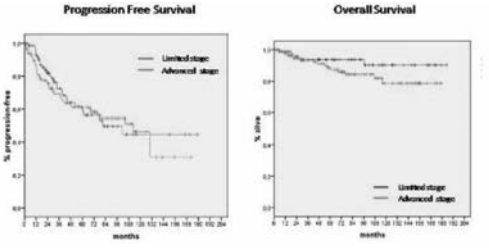

Figure 1.

Summary/Conclusions: Although limited stage FL is considered as a potentially curable disease, the present retrospective analysis revealed a relapsing pattern, similar to the one observed in advanced disease for the initial years of follow-up. However, beyond 8 years, survival curves are suggestive of a plateau, a finding that should be further confirmed. OS is excellent with 90% of the patients being alive at 10 years. The optimal treatment for this group of patients needs further investigation.

E1163

SINGLE CENTER EXPERIENCE OF 90Y-IBRITUMOMAB TIUXETAN IN THE OLDER POPULATION WITH NON-HODGKIN LYMPHOMA

V Agrawal[*], J Castillo, K Raup, T Girton, S Collins, J Brady, J Vadakara, S Khan

Geisinger Medical Center, Danville, United States

Background: ^{90}Y-Ibritumomab tiuxetan (^{90}Y-IT) as radioimmunotherapy in the treatment of B-cell non-Hodgkin lymphoma (NHL) has been approved for consolidation and salvage treatment of follicular and indolent lymphoma. It has also been studied in the treatment of diffuse large B-cell and mantle cell lymphoma. Toxicities primarily include myelosuppression with a risk of treatment-associated myelodysplastic syndrome (MDS).

Aims: To evaluate the toxicity and treatment benefit of ^{90}Y-IT administered to patients for consolidation and salvage treatment of non-Hodgkin lymphoma.

Methods: Retrospective cohort analysis of patients with B-cell NHL who received ^{90}Y-IT from 2010 to 2015 at Geisinger Medical Center. ^{90}Y-IT was administered according to recommended dosing guidelines and cytopenia was monitored at routine intervals.

Results: Sixty-five patients with NHL received ^{90}Y-IT at median age of 68 years (range 32-91), 32 (49.2%) patients were male, and 36 (55.8%) were older than 65 years of age. Thirty patients (46.1%) had aggressive NHL and 37 (56.9%) had stage III/IV disease. Twenty-nine (44.6%) patients received >1 line of treatment prior to ^{90}Y-IT therapy and 62 (97%) received Rituximab based regimens. No patient received fludarabine based therapy. Prior to administration of ^{90}Y-IT, the median bone marrow involvement was 0%, median platelet count was 183 x 10^9/L, median hemoglobin count was 12.7 g/dL, and median absolute neutrophil count was 3.8 x 10^9/L. The median follow-up period was 16 months (range 4-68). The overall response rate was 89.2% with a PR-to-CR conversion rate of 36%. The response rate was 54.5% in the salvage setting. The median PFS and OS were 12 and 15 months, respectively. There was no significant difference in PFS and OS between patients younger and older than 65 years of age or between patients in CR and not in CR at the time of ^{90}Y-IT. Patients on Rituximab maintenance after ^{90}Y-IT treatment (n=14, 21.5%) had PFS and OS improvement (p<0.0001), with median PFS and OS of 45.5 and 48 months, respectively. In the population without Rituximab maintenance (n=51, 78.4%), the median PFS and OS were 10 and 13 months respectively. Patients not in CR at the time of ^{90}Y-IT were found to be responsive to Rituximab maintenance: PFS improved from median 10.0 to 48.0 months (p<0.0001) and OS improved from median 14.0 to 53.0 months (p=0.0003). Among patients with grade 3/4 hematologic toxicities, 6 patients required blood transfusion, 4 needed platelet transfusion, and 17 (26.1%) received pegfilgastrim. One patient required hospitalization for febrile neutropenia. Seven patients relapsed after ^{90}Y-IT and one patient (1.5%) developed MDS (del 5q, del 20q) 54 months after treatment.

There were 9 deaths (six were secondary to progressive lymphoma or chemotherapy-related neutropenic sepsis).
Summary/Conclusions: This is one of the largest reported single-center experience of ^{90}Y-IT administered to a predominantly elderly population with B-NHL in the United States. This study demonstrates the safety and feasibility of ^{90}Y-IT in the elderly population with manageable toxicity and similar outcomes between patients younger and older than 65 years of age. Furthermore, treatment with ^{90}Y-IT did not negatively impact continued sensitivity and benefit from Rituximab maintenance.

E1164

DISEASE SURVEILLANCE AND LONG-TERM OUTCOME OF PATIENTS WITH MUCOSA-ASSOCIATED LYMPHOID TISSUE (MALT) LYMPHOMA INVOLVING THE STOMACH: A RETROSPECTIVE MULTICENTRE STUDY OF 49 PATIENTS IN FIRST REMISSION

SR Nielsen[1,*], LH Jakobsen[2], M Bøgsted[1,2], N Mannering[3], SD Schultz[4], G Mathiasen[5], AL Al-Mashadi[6], LS Lynggaard[7], P Jensen[1], TC El-Galaly[1,2]
[1]Hematology, [2]Department of Clinical Medicine, Aalborg University Hospital, Aalborg, [3]Odense University Hospital, Odense, [4]Vejle Hospital, Vejle, [5]Roskilde Hospital, Roskilde, [6]Holstebro Holspital, Holstebro, [7]Aarhus University Hospital, Aarhus, Denmark

Background: Gastric MALT lymphoma is a rare subtype of non-Hodgkin lymphoma with an indolent disease course. Treatment options span from simple eradication of Helicobacter Pylori with or without radiotherapy for patients with localized gastric MALT lymphoma to systemic, typically mild chemotherapy regimens and/or rituximab, for patients with non-localized disease. Complete remissions (CR) are often achieved, but relapses occur.
Aims: i) to analyze the relapse patterns and the efficacy of routine gastroscopy for patients with gastric MALT lymphoma in first remission, and ii) report the long-term outcomes of these patients relative to a matched background population.
Methods: We conducted a retrospective study of patients with localized and non-localized gastric MALT lymphoma from six Danish hematology centers between 2000 and 2012. Patients were identified from queries in the Danish Lymphoma registry (LYFO) and consecutive adult patients (>15 years) in CR or CRu were included in the study. Local investigators reviewed medical records and collected information regarding gastroscopic examinations, relapse (including relapse detection method and relapse histology), and cause of death. Gastroscopies were categorized as routine if prescribed to a patient in clinical remissions and clinical if prescribed to a patient with relapse suspicious symptoms/findings. Data collection was compliant with national regulations.
Results: In total, 49 patients with gastric MALT lymphomas stage I-IV and in CR or CRu following first line treatment were included. Median age was 64 years (range 25-87) and male:female ratio was 1.1. During a median FU of 88.8 months, seven patients relapsed and 14 patients died. The five-year PFS and OS estimates were 73% (95% CI 61-88) and 89% (95% CI 80-99), respectively (Figure 1). The OS of a matched background population was not different from the MALT lymphoma (P=0.94, standardized mortality ratio, Figure 1). During follow-up, the 49 patients received 100 routine endoscopies (mean 2 range 0-6) and 15 clinical endoscopies. In four patients (8%), routine gastroscopy detected preclinical MALT relapse or another cancer at an asymptomatic stage (adenocarcinoma). Thus, 4/100 routine endoscopies (4%, 95% CI 1-10%) contributed significantly to detection of relapse or other malignancy. These findings resulted in chemotherapy for 2/4, helicobacter eradication with antibiotics for 1/4 and surgery for 1/4 (adenocarcinoma). A single MALT lymphoma relapse was detected as a result of patient reported symptoms. Thus, 1/15 (7%, 95% CI 0-32%) of the gastroscopies performed in response to clinical symptoms/findings confirmed relapse. A case of adenocarcinoma localized in the stomach was found 28 months after first MALT lymphoma diagnosis, but transformation to high-grade lymphoma was not reported for any patients. Of note, no deaths were related to progressive MALT lymphoma in this cohort of 49 patients.

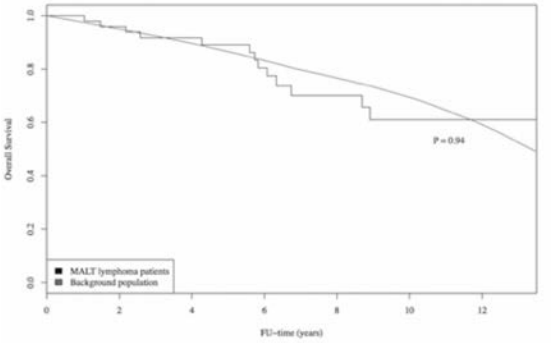

Figure 1.

Summary/Conclusions: This study confirms the very indolent nature of gastric MALT lymphoma with survival not statistically significantly different from the background population. Preclinical relapse detection has not been shown to improve outcome in gastric MALT lymphoma and asymptomatic relapse can be managed with a watch-and-wait strategy in selected patients. In this context, the yield of routine endoscopy is limited. However, one case of adenocarcinoma was detected at an early stage by routine endoscopy.

E1165

PRE-DOSING WITH UNLABELLED ANTIBODY SIGNIFICANTLY INCREASES THE PHARMACOKINETIC EXPOSURE BUT PROTECTS AGAINST MYELOSUPPRESSION OF 177LU-LILOTOMAB IN NON-HODGKIN B-CELL LYMPHOMA PATIENTS

A Kolstad[1,*], U Madsbu[1], C Stokke[2], T Bach-Gansmo[1], A Muftuler Løndalen[1], JE Holtedahl[2], ME Revheim[3], Ø Bruland[1], J Dahle[4], L Baylor Curtis[4], Å Åse Østengen[4], H Heyerdahl[4], S Turner[4], N Bolstad[3], R Hartvig Larsen[5], S Spetalen[3], M Erlanson[6], S Nygaard Rudå[1], H Holte[1]
[1]Oslo University Hospital, Radiumhospitalet, [2]The Intervention Centre, Oslo Univeristy Hospital, [3]Olso University Hospital, [4]Nordic Nanovector, [5]Sciencons, Oslo, Norway, [6]Norrland University Hospital, Umeå, Sweden

Background: ^{177}Lu-lilotomab (^{177}Lu-DOTA-HH1; Betalutin^{TM}) is a novel CD37-binding murine IgG_1 antibody (HH1) labelled with the beta-emitter lutetium-177, in a ready-to-use formulation currently in Phase 1/2 clinical development for the treatment of non-Hodgkin`s lymphoma (NHL). Pre-dosing with unlabelled antibody is routinely given with radio-immunotherapies for NHL.
Aims: This pharmacokinetic (PK) sub-study in NHL patients (pts) was designed to determine the PK profile of ^{177}Lu-lilotomab and to compare the PK profile with and without pre-dosing with unlabelled HH1.
Methods: Pts with relapsed incurable indolent NHL and with platelet counts ≥150 x10^9/L were eligible for inclusion in the study. Pts received rituximab (375 mg/m^2) on day 1 and 8 to deplete normal B cells. On day 29 pre-dosing with 50 mg HH1 was administered before the single dose of ^{177}Lu-lilotomab in 9 pts. The remaining 4 pts received ^{177}Lu-lilotomab without HH1 pre-dosing. Activity of ^{177}Lu-lilotomab administered after the pre-dose of HH1 were 10, 15 and 20 MBq/kg *vs* 10 and 15 MBq/kg without HH1. PK samples were collected at 0 and 5 minutes, then after 1, 2, and 20 hours and further 2, 3, 4, 7, 14 and 21 days post-^{177}Lu-lilotomab administration. Urine samples were also collected. Response was assessed by FDG PET/CT scans.
Results: A total of 13 pts, 12 with follicular lymphoma and 1 with mantle cell lymphoma, were enrolled into this sub-study and either received pre-dosing with HH1 (n=9) or without HH1 (n=4). The number of prior therapies ranged from 1 to 7, median body weight was 91.5kg (range: 67-118kg). A total of 153 blood samples were collected. As expected, the median $AUC_{0-\infty}$ increased with increasing activity of ^{177}Lu-lilotomab irrespective of pre-dosing (range: 3830.7 to 15226.48 h*kBq/mL). There was an increase in median activity-adjusted $AUC_{0-\infty}$ (675.51 *vs* 421.11 h*kBq/mL/(MBq/kg); p<0.001) in pts with pre-dosing compared to no HH1 pre-dosing and a decrease in the volume of distribution Vz (10.48L *vs* 17.56L) and clearance rate Cl (126 v 227 mL/h). The median activity-adjusted C_{max} (6.6 *vs* 6.9 kBq/mL/(MBq/kg)) and $T_{1/2}$ (53.3 *vs* 51.6 h) were similar with and without HH1 pre-dosing. The most common toxicities observed were haematological which were all reversible and manageable. With HH1 pre-dosing all Grade 4 thrombocytopenia and neutropenia were reported by pts with a ^{177}Lu-lilotomab $AUC_{0-\infty}$ >13415 h*kBq/mL (n=3), compared with >6147 h*kBq/mL (n=2) without pre-dosing. In addition grade 3 thrombocytopenia was reported by one pt with an AUC of 11730 h*kBq/mL with pre-dosing compared to one pt with an AUC of 4913 h*kBq/mL without HH1. The overall tumor response rate observed in the 12 evaluable pts in the PK sub-study was 67% (one pt had a transformed lesion at 3 months and is excluded from the efficacy analysis). Five pts with pre-dosing achieved CR or PR and had an AUC of >6976 h*kBq/mL. Without HH1 pre-dosing a PR was observed in 3 pts, with AUCs of 3830, 4913 and 6195 h*kBq/mL.
Summary/Conclusions: Pre-dosing with unlabelled antibody (HH1) increases the activity-adjusted AUC and decreases the volume of distribution and clearance rate of ^{177}Lu-lilotomab in NHL pts. Despite the increase in AUC resulting from pre-dosing with HH1 the incidence of haematological AEs was reduced compared with no HH1 pre-dosing, suggesting a protective effect of HH1 against the myelosuppression of ^{177}Lu-lilotomab. Further optimisation of the pre-dosing of ^{177}Lu-lilotomab may lead to greater increases in AUC, and/or improvement in the side-effect profile.

E1166

FOLLICULAR LYMPHOMAS ARE CURABLE DISEASES. DATA FROM A RETROSPECTIVE STUDY ON 133 PATIENTS WITH AT LEAST 10 YEARS OF OBSERVATION

S Kovalchuk*, L Rigacci, F Lancia, B Puccini, G Benelli, L Mannelli, M Novo, A Bosi
Haematology, AOU Careggi, Firenze, Italy

Background: Follicular lymphomas are usually defined as incurable diseases with a natural history characterized by continuous relapses. This study was launched to evaluate how many patients, after a long observation period, do not relapse or do not experience a new treatment.
Aims: The aim of the study was to identify which clinical characteristics or therapeutical approaches are associated with this cohort of favourable patients.
Methods: All patients with histologically confirmed diagnosis of follicular lymphomas grade I-II or IIIa were selected from our data base starting from January 2000 untill December 2004 in such a way to have at least 10 years of observation for alive patients. We considered patients obtaining at least a partial response and we divided patients in two cohorts, cohort 1 with patients relapsed or progressed and cohort 2 with patients never relapsed or progressed.
Results: One hundred and fourthy-six patients were diagnosed and treated at our Institution. Thirteen patients were excluded from the analysis, 8 lost to the follow-up and 5 did not obtained at least a partial remission. Finally 133 patients were analysed for the study. The median age at diagnosis was 61 years (range 30-87). Stage I-II in 47 patients, III-IV in 86. Bone marrow biopsy was positive in 87 patients, FLIPI 0-1 in 35, FLIPI 2 in 43, FLIPI 3 in 40 and FLIPI 4 in 15 patients. According to treatment 96 patients were treated with antracycline containing regimens, 24 with fludarabine containing regimens and 13 were observed or treated with radiotherapy. Rituximab was used in 92 patients, as sequential treatment in 70 or chemotherapy combined in 22; 41 patients did not use rituximab. We analysed cohort 1 (85 patients) and cohort 2 (48 patients) and the statistically significant differences between the two cohorts were: elderly patients (p 0.05), symptomatic patients (p 0.05), FLIPI and FLIPI2 high score (p 0.005), lack of complete remission (p 0.0000) all observed in cohort 1. The overall survival with a median period of observation of 127 months (range 2-196) was 71%, considering the two groups the overall survival in cohort 1 was 62% with a median of 142 months and it was 94% in cohort 2 with median not reached. In univariate analysis normal value of beta2 microglobulin (p 0.05) and the use of rituximab (p 0.01) were associated with a better overall survival; in multivariate analysis treatment with rituximab manteined a statistically significance.
Summary/Conclusions: In conclusion this retrospective monocentric study confirms that about one third of follicular lymphoma patients could be considered cured particularly if rituximab was used in the treatment. At the present time all patients with follicular lymphoma are treated with combined immuno-chemotherapy, moreover after induction therapy patients are started with manteinance. We can therefore hope for the future in an improvement of survival results.

Infectious diseases, supportive care

E1167

IMPACT OF AZACITIDINE TREATMENT ON INFECTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA, MYELODYSPLASTIC SYNDROMES AND MYELODYSPLASTIC/MYELOPROLIFERATIVE SYNDROMES

C Villegas*, S Ortiz, K Javier, S Costa, D Ivars, R Collado, M Lopez, L Irene, M Roig, M Sanchez, P Perez, M Orero
Hematologia, Hospital General Universitario, Valencia, Spain

Background: It has been described in previous studies a benefit on infection rate in azacitidine (AZA) treated patients. However, the characteristics of infectious episodes in patients with AZA or best supportive care (BSC) were not described in detail.
Aims: We decided to analyze the impact of AZA treatment on the risk of infection, the characteristics of the infectious episodes and outcome in our patients with acute myeloid leukemia (AML), myelodysplastic syndromes (MDS) and myelodysplastic/myeloproliferative syndromes (SMD/MPS).
Methods: Infections were assessed by reviewing medical records of our department´s database of patients treated with AZA from January 2006 to November 2015. A cohort of matched control patients treated with BSC (two controls for each patient) based on World Health Organization (WHO) subtype, neutrophil count and IPSS-R risk was selected. We took only on account infection´s episodes which required hospitalization.
Results: We included 138 patients, 92 received BSC and 46 treated with AZA at standard schedule (75mg/m^2/day 7 days every 28). The median follow up for both groups was 10 months. In the AZA group, 8/46 patients (17.4%) had<0.5x10^9/L neutrophils at diagnosis and 6/44 (13.6%) at four months, with no significant increase in neutropenia incidence (*p=0.773*). However, In the BSC group, 7/92 (7.6%) patients had<0,5x10^9/L neutrophils at diagnosis and 16/77 (20.8%) at four months, with a significant increase in the incidence of neutropenia. (*p=0.022*). The percentage of patients free of infection in AZA group was higher than BSC group. The median of infectious episodes per year was 1.17 in AZA group (CI 95% 0.44-1.90) and 3.08 in BSC group (CI 95% 1.56-4.60) (*p=0.004*).The days of hospitalization/year due to infection was 20.59 (CI95% 3.91-37.27) in the AZA group and 39.90 (CI 95% 21.63-58.18) in the BSC (*p=0.003*). The cumulative incidence of first infection, with death as competitive risk, was higher in BSC group than in AZA group; with a cumulative incidence at 12 months of 0.40 (CI 0.26-0.54) and 0.54 (CI 0.43-0.63) in the AZA and BSC group respectively (Grays´s test p=0.0195). In the AZA group 4 (18.2%) episodes were fatal and in the BSC group 24 (23.3%) (*P=0.78*). Multivariant logistical regression shows that only AZA treatment (HR 0.25 *p=0.001* CI 0.12-0.55) and absolute neutrophil count (ANC) >0.5X10^9/L (HR 0.28 *p=0.049* CI 0.08–1.03) showed an independent prognostic value. Age, comorbidities and WHO subtype were excluded by the test.

Table 1. Baseline characteristics of patients and number of infections.

	AZA N=46	BSC N=92	P-value
Age in years at diagnosis (median)	72,5	79	<0,001*
WHO subtype, *n*			
MDS/MPS	12	22	
AML	11	21	
MDS : Low / Intermediate / high	23: 5/5/13	49: 10 / 11 / 28	
ANC <1x10^9/L	11 (24)	22 (24)	1**
Hemoglobin (g/L)	92.2	97	0,192*
Platelets (x10^9/L)	67	97	0,157*
Diabetes mellitus (%)	26,1	26,4	1**
Chronic obstructive pulmonary disease (%)	19,6	16,3	0,63**
Number of infections (%)			
0	29 (63)	31 (33,7)	
1	14 (30,4)	41 (44,6)	0,0018***
=2	3 (6,5)	20 (21,7)	

* U-Mann Whitney test. ** Fisher´s test. *** Chi squared test.

Summary/Conclusions: Azacitidine treated patients had less risk of infection, showed with cumulative incidence, less infectious episodes per year and less days of hospitalization per year. However, the outcome of infection episodes was similar in both groups. The higher incidence of infections in BSC group could be explained by the mayor progression to severe neutropenia.

E1168

CLINIC RISK FACTORS OF REFRACTORY CMV REACTIVATION FOLLOWING ALLOGENEIC AHSCT: A SINGLE-CENTER STUDY IN CHINA

H Qiu*, X Bao, S Xue, Y Xu, X Ma, F Chen, X Hu, Z Zhu, S Chen, A Sun, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Cytomegalovirus (CMV) reactivation remains the main cause of viral complications after allogeneic hematopoietic stem cell transplantation

(aHSCT). Especially, CMV with gene mutations against antiviral drugs could lead to high mortality rate.
Aims: The purpose of this study is to explore the risk factors and outcome for CMV reactivation and CMV refractory to antiviral chemotherapy after aHSCT.
Methods: CMV reactivation occurred in 282 of 685 (41.2%) patients treated with myeloablative conditioning regimen. Among the patients with CMV reactivation, 84 of 282 (29.8%) cases developed refractory CMV reactivation (RCR), and 37 of 282 (13.1%) cases progressed into CMV diseases.
Results: Patients with RCR have a higher cumulative incidence of CMV diseases (26.2% *versus* 7.6%, *P*<0.001). Seventy nine of 84 cases (94.0%) developed RCR before 100 days after aHSCT (5 cases with PP65 detection only). The copy number of CMV-DNA more than doubled compared to its initial baseline in 42 of 74 (56.8%) cases after 2 weeks of antiviral therapy, whereas 32 cases did not have a double increase above baseline. CMV disease developed in 15 of 42 (35.7%) and 3 of 32 (9.4%) (*P*=0.011) cases in these two groups. The copy number of CMV-DNA increased at least 5 times above baseline in 24 of 74 (32.4%) patients, and among these 24 patients, 8 of 24 (33.3%) cases developed CMV disease. Among patients who do not have a 5-fold increase of CMV-DNA copy number, 10 of 50 (20.0%) patients developed CMV disease (*P*=0.232). Both univariate and multivariate analysis demonstrated that the risk of CMV reactivation and RCR increased in patients from HLA-haploidentical donor and matched unrelated donor, or without using peripheral blood (PB) as stem cell source. The multivariate analysis revealed that patients who developed acute graft-*versus*-host disease (aGVHD) ≥grade 2 have increased risk of developing CMV reactivation, whereas RCR occurred more frequently in those with total body irradiation-containing regimens and a high dosage methylprednisolone (MP) for aGVHD treatment. The prevalence of RCR is three and six times higher in patients who received MP 1-2mg/kg daily(*P*=0.024) and ≥2mg/kg daily(*P*=0.001), with an odds ratio (OR) of 2.74 and 6.03 respectively.
Summary/Conclusions: High dosage corticosteroids treatment is associated with incidence of RCR during the early phase after aHSCT.

E1169

INFECTIOUS CHARACTERISTICS AND LONG-TERM OUTCOME IN OBESE PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS

MJ Li[1,*], HH Chang[2], YL Yang[3], MY Lu[2], PL Shao[4], CM Fu[1], AK Chou[1], YL Liu[5], KH Lin[2], LM Huang[2], DT Lin[3], ST Jou[2]
[1]Pediatrics, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu, [2]Pediatrics, [3]Laboratory Medicine, National Taiwan University Hospital, Taipei, [4]Laboratory Medicine, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu, [5]Pediatrics, Taipei Medical University Hospital, Taipei, Taiwan, ROC

Background: Obese patients were reported to have poorer prognosis in pediatric acute lymphoblastic leukemia (ALL), however, the association with infection during chemotherapy was seldom reported.
Aims: To evaluate the difference of infectious characteristics and long-term outcome between obese and non-obese patients.
Methods: Total 252 newly diagnosed pediatric ALL patients from 1997 to 2012 at National Taiwan University Hospital treated by Taiwan Pediatric Oncology Group (TPOG) protocol were retrospectively reviewed. The fever event was classified into fever of unknown focus, clinically documented infection and microbiologically documented infection (MDI). Infectious sites were recorded by location: upper respiratory (EENT), lower respiratory (LRI), blood stream (BSI), genitourinary tract (GU), gastrointestinal tract, skin or soft tissue, central nervous system and others. Multivariate analysis for risk factors of infectious complications was evaluated by Poisson regression with incidence rate ratio (IRR) and 95% confidence interval (CI).

Table 1. Subgroup Univariate Poisson Regression Analysis in Obese *vs* Non-obese Patients.

		MDI			GU			LRI-MDI	
Variables	IRR	95% CI	*p*-value	IRR	95% CI	*p*-value	IRR	95% CI	*p*-value
Gender									
Male	0.846	0.594-1.206	0.355	1.947	0.958-3.956	0.066	0.790	0.242-2.581	0.696

HR	1.563	1.174-2.080	0.002	2.462	1.383-4.384	0.002	0.990	0.415-2.361	0.982
VHR	1.016	0.706-1.462	0.932	1.401	0.774-2.533	0.265	3.537	1.223-10.225	0.020

**No case in this subgroup. LRI-MDI, lower respiratory infection with pathogen; SR, standard risk; HR, high risk; VHR, very high risk.*

Results: Total 219 patients (86.9%) had fever with mean 2.74 episodes per person. Obese patients (n=38) harbored more MDI, GU and LRI with pathogen infections than non-obese patients (IRR=1.349, 2.228 and 2.014; 95% CI=1.109-1.642, 1.558-3.187 and 1.22-3.326; and *p*=0.003,<0.001 and 0.006, respectively). Subgroup analysis revealed the IRR in obese patients was higher in female and younger age patients (Table). The pathogen characteristics in obese patients included more Gram negative pathogen both in blood stream (29% *vs* 14%, *p*=0.029) and GU tract (32% *vs* 10%, *p*=0.001). *Klebsiella* spp. bacteremia was higher in obese patients (11% *vs* 3%, *p*=0.047). Overall prognosis analysis showed obese patients had more relapsed rate (42.1 *vs* 22.4%, *p*=0.012) but the mortality rate was not different (36.8 *vs* 23.4%, *p*=0.063). The 10-year event-free survival was also lower in obese patients (54±8% vs.72±3%, *p*=0.002, figure).

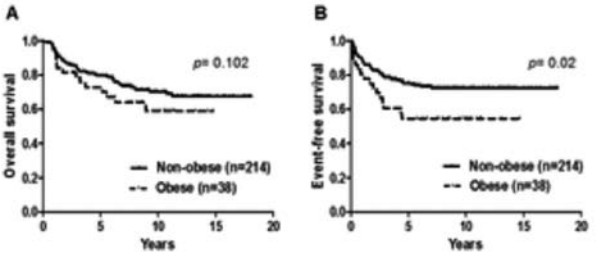

Figure 1.

Summary/Conclusions: Obesity was a potential risk factor in infectious complications in pediatric acute lymphoblastic leukemia patients, especially in microbiologically documented infection and genitourinary tract infection.

E1170

ANTIBIOTICS *VERSUS* G-CSFS *VERSUS* A COMBINATION OF BOTH TO PREVENT INFECTIOUS COMPLICATIONS AND DEATHS IN CANCER PATIENTS RECEIVING CHEMOTHERAPY: PRELIMINARY RESULTS OF A NETWORK META-ANALYSIS

N Skoetz[1,*], O Blank[1], L Buetikofer[2], I Monsef[3], A Engert[4], JJ Vehreschild[4]
[1]Department I of Internal Medicine, Cochrane Hematological Malignancies Group, University Hospital of Cologne, Cologne, Germany, [2]Department of Clinical Research, University of Bern, Bern, Switzerland, [3]Cochrane Haematological Malignancies; Department I Of Internal Medicine, [4]Department I Of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Cancer patients receiving chemotherapy are at an increased risk for infectious complications, which represent the most relevant treatment-related causes of death (2 to 21%). The risk of infection is dependent on the duration and intensity of treatment-induced neutropenia and often results in a reduction of the dose of chemotherapy. Uncertainty exists on the achievable degree of infection prevention and whether granulocyte colony stimulating factors (G-CSF), antibiotics or both should be administered.
Aims: The aims of this systematic review and network meta-analysis are to evaluate the benefits and risks of infection prophylaxis with antibiotics, G-CSF, or a combination of both in cancer patients receiving chemotherapy at risk for febrile neutropenia.
Methods: We developed sensitive search strategies for CENTRAL, MEDLINE, and conference proceedings (search date 12/2015). Study selection and data extraction:Randomized controlled trials evaluating infection prophylaxis with antibiotics, G-CSF or both in cancer patients at risk for febrile neutropenia. Only trials were included which clearly stated whether all patients received antibiotics or G-CSF in addition to the evaluated prophylaxis. Two authors independently assessed studies for eligibility, extracted data and assessed quality of trials. The primary outcome was mortality during the study. Secondary outcomes included infection related mortality, severe infection rate, rate of febrile neutropenia and adverse events. Data synthesis: Effect measures were odds ratios (OR). Direct comparisons within trials were combined with indirect evidence by using a Bayesian random-effects model. This project was funded by the Federal Ministry of Education and Research, grant number: 01KG1209.

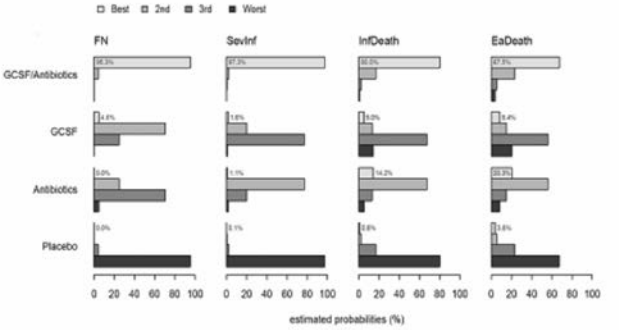

Figure 1.

Results: A total of 63 studies were identified, including 11838 patients. Only one study with 40 patients carried out a direct comparison of G-CSF *versus* antibiotics. Of all studies comparing antibiotics to no antibiotics, only 2 were from 2010 or later. The results of the direct comparisons found an advantage in terms of reduced rate of febrile neutropenia for those trials evaluating G-

CSF, both in the studies using G-CSF *versus* placebo (OR 0.37; 95% CI 0.12 to 0.86) and in those evaluating G-CSF plus antibiotics *versus* antibiotics alone (OR 0.45; 95% CI 0.24 to 0.74). However, there is no evidence for a difference for the outcomes mortality during the study, infection-related mortality and severe infection rate between the various preventive options. Network meta-analyses show that the combination of G-CSF and antibiotics has the highest probability to be the best for all the observed outcomes (see figure 1). Between-trial heterogeneity was considerable for the outcomes febrile neutropenia and severe infections, potentially due to various definitions (tau 1.08 and 0.97, respectively) and negligible for the other two outcomes (tau 0.42 and 0.18 respectively). The endpoint adverse events was very rarely and inconsistently reported, so no overall statement is possible.
Summary/Conclusions: The currently available direct evidence does not show any difference in terms of mortality for the various prophylactic options. The evidence from the network meta-analyses shows an advantage if G-CSF is administered in conjunction with antibiotics compared to placebo, antibiotics or G-CSF alone. Most evidence on antibiotic prophylaxis stems from studies older than 10 years, *i.e.* before the ongoing pandemic of multi-resistant gram-negatives and vancomycin-resistant enterococci. Further studies with clearly defined inclusion and exclusion criteria (risk of febrile neutropenia) and endpoints (e.g. definition of febrile neutropenia) are necessary in order to properly compare the various prophylactic options and to obtain valid results.

E1171

METRONOMIC FIRST-LINE ANTIBIOTICS FOR FEBRILE NEUTROPENIA-IMPACT ON ECOLOGY AND MORTALITY IN PATIENTS TREATED FOR HAEMATOLOGIC MALIGNANCIES

GC Wong[1,*], LKS Donato[1], AL Tan[2], S Kalimuddin[3], W Lee[4], MRT de Guzman[1], BH Tan[3]
[1]Department of Haematology, [2]Department of Pathology, [3]Department of Infectious Diseases, [4]Department of Pharmacy, Singapore General Hospital, Singapore, Singapore

Background: Rising antibiotic resistance threatens to limit our choices for empirical and definitive treatment of febrile neutropenia (FN). Reports suggest that increasing antibiotic heterogeneity might be associated with a decline in resistance. In our hospital's Haematology unit, cefepime (CEF) was recommended as the first-line empirical antibiotic in FN. Rising drug resistance and the potential usefulness of increasing antibiotic diversity led us to re-consider our approach.
Aims: To introduce antibiotic heterogeneity by alternating use of first-line antibiotics and to determine the impact of this on ecology and mortality of patients treated for haematological malignancies.
Methods: From mid-2013, a new FN guideline was implemented. Neutropenic patients who developed fever on odd dates of the month would be given Piperacillin Tazobactam (PTZ) and on even dates, a combination of Cefepime and Amikacin, post blood cultures. This is termed as "metronomic 1st line antibiotics". If fever persists after 48 hours, physicians could continue on the same antibiotics, or add vancomycin or switch to meropenem (MER). To assess the impact of this change, we collected the following data for the years 2012 and 2014: rates of bacteremia (including rates of bacteremia caused by carbapenem-resistant organisms), Methicillin Resistant Staphilococcus Aureus (MRSA) acquisition, Vancomycin Resistant Enterococcus (VRE) acquisition, mortality. We also calculated the defined daily doses (DDD) of CEF, PTZ, and MER for 2012 and 2014. This study was approved by the Institution Review Board.
Results: In 2012, 1183 patients were admitted 2012 times; in 2014, 1112 patients were admitted 1843 times. Males formed 54.5% and 55.7% of the patients in 2012 and 2014 respectively. The following were similar ($p>0.5$) in the 2 years: mean and median ages of the patients, number of new patients with acute myeloid leukemia (AML) and acute lymphocytic leukemia (ALL) who started on chemotherapy, spread of discharge diagnoses (AML, ALL, myeloma, lymphoma). Rate (DDD/1000 days) of CEF use fell ($p<0.001$) and rate of PTZ use rose ($p<0.001$) in 2014. Rate of MER use was unchanged. Bacteremia rates were unchanged. Rates of acquisition of MRSA and VRE were unchanged. Rates of CEF-resistant, and of PTZ-resistant E. coli, Klebsiella spp, and P. aeruginosa isolated from blood cultures were similar in the 2 years. The rate of carbapenem-resistant P. aeruginosa was 12.7% in 2012 and 17.5% in 2014 ($p=0.6$). Mortality among bacteremic patients was 24% in 2012, 14% in 2014 ($p=0.001$).
Summary/Conclusions: We conclude that "metronomic 1st line antibiotics" introduced an element of antibiotic heterogeneity. This was not associated with an increase in the rate of isolation of resistant organisms. It is possible that the increased use of PTZ was associated with a lower mortality.

E1172

ORAL GENTAMICIN THERAPY FOR CARBAPENEM-RESISTENT KLEBSIELLA PNEUMONIAE INFECTIONS IN HEMATOLOGIC PATIENTS: A SINGLE CENTER EXPERIENCE

F Simonetti[1,*], S Fortunato[2], M Rousseau[3], C Tascini[2], F Menichetti[2], A Stefanelli[1], E Baccelli[1], C Vettori[4], M Petrini[3]
[1]Hematology Unit, Versilia Hospital - Tuscany, Italy, Lido di Camaiore, [2]Infectious Disease Unit, [3]Hematology Unit, Pisa Hospital, Pisa, [4]Infectious Disease Unit, Versilia Hospital - Tuscany, Italy, Lido di Camaiore, Italy

Background: The worldwide spread of carbapenem-resistant *Klebsiella pneumoniae* (KPC-Kp) is nowadays a health threat worldwide. KPC-*Kp* mortality infections range from 18 to 48% and depend on the type of therapy administered; mono *vs* combo therapy. This result may be due to delayed time to active therapy, pharmacologic limitations of available treatment options, and the fact that patients with KPC-Kp infections tend to be critically ill. Patients with hematologic malignancies and hematopoietic stem cell transplant recipients are more vulnerable to Carbapenemase-resistant *Enterobacteriaceae* (CRE) because of chemotherapy-induced gastrointestinal mucositis, prolonged hospitalizations and neutropenia, and frequent use of broad-spectrum antibacterial agents. Mortality in these patients might be as high as 85%.
Aims: The aim of our study was to test he efficacy of oral gentamicin in gut decontamination from KPC-Kp in hematologic patients, in view of immunosuppressive therapy, stem cell transplantation or to prevent sepsis after chemotherapy.
Methods: We performed a prospective study in an Italian Hematology Unit to quantify the efficacy of gentamicin gut decontamination from KPC-Kp in hematologic patient with and without concomitant infection. We considered eligible all patient with rectal swab culture positive for KPC-Kp with hematologic disease and those patients were administered oral gentamicin (80 mg four times daily) for 7 to 25 days, having stopped the therapy three days after the proved decontamination. Rectal swab cultures were performed at the time of hospital admission and every 3 days thereafter.
Results: Fourteen patients with a hematologic disease and concomitant *KPC-Kp* positive rectal swab culture were enrolled in the study; only one was resistant to gentamycin. The patients were 5 female and 9 male, with a mean age of 68.5 years (range 39-80 years). Concomitant systemic associated therapy (CSAT) was administered to 4/14 patients due to systemic infections. The enrolled patients were treated with oral gentamicin for 7 to 25 days and the overall decontamination rate in the entire study population administered oral gentamicin was 71% (10/14). Only two patients took gentamicin for more than 15 days. Four patients were not decolonized by gentamicin oral therapy: one of these was the patient harbouring gentamicin-resistant strain and 3 patients have CSAT. One out of this 4 patients died for KPC-Kp sepsis. At 1 month of follow-up, no one KPC-Kp re-infection was documented. The decontamination rate was 90% (9/10) in patients receiving oral gentamicin only, *versus* 25% (1/4) in those also treated with CSAT. No new gentamicin-resistant KPC-Kp strain was isolated during oral gentamycin therapy.
Summary/Conclusions: The KPC-Kp infection are associated with high mortality and morbidity, especially in Intensive Care Units and hematologic patients; prevention of KPC-Kp infection is the first provision to implement, followed by the screening for gut colonization and eventually gut decolonization. In our experience the decontaminations rate in the entire population was 71% and 90% considering the patients receiving oral gentamicin only. Although the small number of patients analyzed in this study, our results were similar to others suggesting that the selective pressure of CSAT on gut microbiota may favor the persistent carriage of KPC-Kp, thereby contributing on the higher failure rates observed *versus* monotherapy. Therefore, the selective oral decontamination therapy of KPC-Kp with oral gentamicin is safe and possibly effective.

E1173

CLINICAL SIGNIFICANCE OF SERUM HEME OXYGENASE 1 IN PATIENTS WITH SECONDARY HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

D Wang[*], J Wang, L Duan, T Tian, H Qiu
Department of Hematology, First Affiliated Hospital of Nanjing Medical University (Jiangsu Province Hospital), Nanjing, China

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, threatening-life clinical syndrome, caused by cytokines storm due to provoked, uncontrolled proliferation and over activation of lymphocytes and macrophages. sHLH in adults is an etiologically heterogeneous entity that has been associated with infections, autoimmune disorders, and haematological malignancies, mainly with non-hodgkin lymphoma. Clinically, these disorders feature fever, hepatosplenomegaly, severe cytopenias, activated macrophages in hematopoietic organs. Biochemical abnormalities include hypofibrinogenemia, hypertriglyceridemia, and increased levels of soluble interleukin-2 receptor (sCD25), serum ferritin(SF), and a large number of inflammatory other cytokines. Heme oxygenase 1 (HO-1) is an inducible stress-response enzyme and it is also an rate-limitting enzyme that degrades heme to biliverdin, carbon monoxide (CO) and free iron in mammalian cells. Biliverdin and CO gain particular interest because of mediating most of anti-inflammatory, antioxidant and anti-apoptotic effects of HO-1. HO-1 can be induced by various stressors such as oxidative stress, inflammatory cytokine, heavy metals and ultraviolet irradiation. HO-1 is constitutively expressed in peripheral monocytes and organ-localized macrophages such as hepatic kupffer cells and splenic macrophages. These facts suggest that HO-1 plays a key role in regulation of the inflammatory response in physiological and pathological conditions. Recently, there are accumulating evidences that increased serum HO-1 level is related to macrophage activation. Herein, we measured serum HO-1 levels in sHLH patients and ana-

lyzed the relationship of serum HO-1 with other biological markers of sHLH. The results show that serum HO-1 is a novel marker to evaluating severity and activity of sHLH. In addition, serum HO-1 may be an indicator using in differentiating autoimmune-associated hemophagocytic lymphohistiocytosis (AHLH) from other underline etiologies of sHLH.
Aims: To investigate the levels and clinical significance of heme oxygenase 1 (HO-1) in patients with secondary hemophagocytic lymphohistiocytosis (sHLH).
Methods: Serum HO-1 levels were determined by using enzyme linked immunosorbent assays (ELISA) in 43 sHLH patients and 12 healthy contrlols. Clinically relevant laboratory values, including white blood cell (WBC), hemoglobin (HB), platelet (PLT), serum ferritin (SF), albuminin (ALB), alanine transaminase (ALT), aspartate aminotransferase (AST), lactate dehydrogenase (LDH), fibrinogen (FIB), blood sedimentation rate (ESR), triglyceride (TG), soluble interleukin-2 receptor (sCD25) and C reactive protein (CRP) were collected.
Results: (1) Serum HO-1 levels of the newly diagnosed group were found to be significantly higher than that of the healthy control group (P =0.001). (2) Serum HO-1 levels of the newly diagnosed AHLH (autoimmune-associated HLH) were significantly higher than those in patients with IHLH (infection-associated HLH), LHLH (lymphoma-associated HLH) and healthy controls (P<0.05); (3) The serum HO-1 levels of the clinical remission group were significantly lower than that of the newly diagnosed group (P<0.05);(4) Serum HO-1 levels in newly diagnosed sHLH patients positively correlated with SF (r=0.582, P<0.001), and negatively with ALB (r=-0.308, P=0.045); (5) The receiver operating characteristic curves (ROC) for serum HO-1 levels of patients with sHLH and healthy controls produced a cutoff value at 520.4ng/mL, with its sensitivity and specificity being 90.7% and 100%, respectively. In addition, an optimal cutoff value for HO-1 was 2922.3ng/mL, and Its sensitivity and specificity were 100% and 99.2%, in patients with AHLH and non-AHLH (LHLH+IHLH), separately. Another ROC for SF levels of patients with AHLH and non-AHLH(IHLH+LHLH) yielded an optimal cutoff value of 1189.0 ng/mL and its sensitivity and specificity were 85.7% and 55.5%, respectively.
Summary/Conclusions: Serum HO-1 levels are clinically significant in disease diagnosis, differential diagnosis, evaluating disease activity and treatment outcomes in patients with sHLH.

E1174

RESPIRATORY VIRAL INFECTIONS IN HEMATOLOGIC PATIENTS IN OUR ENVIRONMENT. A RETROSPECTIVE STUDY

R Cidre Lopez*, A Nieto Vazquez, A Santamaria Lopez, MDLA Fernandez Fernandez, MDC Albo Lopez
Hematology, Hospital Álvaro Cunqueiro, Vigo, Spain

Background: Respiratory viral infections are an important cause of morbidity and mortality in immunocompromised hosts. Hematology patients are especially susceptible due to their underlying disease and the treatments they receive. Rhinovirus, Influenza, Parainfluenza and RSV are some of the most frequent agents. Molecular diagnostic techniques have improved over time, providing fast and accurate results.
Aims: Analize the characteristics of viral respiratory infections in our patients.
Methods: A retrospective, descriptive study including 237 hematologic patients from the University Hospital Complex of Vigo with suspected respiratory viral infection for a period of two years (May 2013-May 2015). We collected 401 PCR samples of respiratory viruses in nasopharyngeal swab and BAL, focusing on the following data: demographic characteristics, underlying disease, comorbidities, symptoms, diagnostic tests, treatment and clinical evolution.
Results: 122 male patients and 115 female, with a median age of 64 years old (range 4-89). 88 underwent HSCT-46 autologous, 42 allogeneic (35 HLA identical, 6 haploidentical and 1 cord blood). 61'5% of the samples were positive for one or more respiratory viruses (63'9% in transplant patients *vs* 59'8% in non-transplant). 89'4% were positive in nasopharyngeal samples, 4'7% in BAL and 5'9% in both. Causal agents are shown in Table 2. 17% of samples were positive for more than one virus, and 15'4% had microbiologic evidence of infection by a different type of microorganism. 30'5% of the infections were considered nosocomial. Concerning those with an infection acquired in the community, 59'6% patients required hospitalization due to the respiratory illness. The symptoms referred by our patients are shown in table 1. 61'4% of the demonstrated viral infections were associated with lymphopenia. Hypogammaglobulinemia was observed in 57%. 30'3% presented comorbidities associated with an increased risk of respiratory infection (underlying heart or lung disease, smoking, HIV positivity, DM or other tumors). Radiologic findings: 50'8% showed a normal X-ray chest image or nonspecific findings, 11'4% pneumonic consolidation and 6'5% signs of atypical infection. 42 patients underwent a bronchoscopy. 12 obtained concordant results with nasopharyngeal samples. 10 patients with a negative nasopharyngeal swab had a viral identification in the BAL. We had an isolated case with different results in each sample (a RSV was found in the nasopharyngeal swab and a coronavirus in the BAL). In 8 patients we found other microorganisms (bacteria, fungus). Influenza virus infections were treated with oseltamivir. CMV infections in transplant recipients received immunoglobulins and ganciclovir. 28% of the RSV were treated with immunoglobulins and ribavirin. In most patients the outcome was good. 5 patients died, in 4 of them the respiratory infection was the main cause of death.

Table 1.

Fever	56%
Cough	71'5%
Rhinorrhea/nasal congestion	49%
Sore throat	13'4%
Dyspnea	8'5%
Pleuritic chest pain	2'4%

Table 2.

Non-transplant patients		Transplant patients	
Rhinovirus	33.1%	Rhinovirus	17%
Parainfluenza	13.9%	Parainfluenza	13.8%
Influenza A	11.9%	RSV	8.5%
RSV	8.6%	Influenza A	8.5%
Influenza B	6.6%	Coronavirus	6.4%
Bocavirus	4%	CMV	6.4%
Coronavirus	4%	Metapneumovirus	5.3%
Enterovirus	2.6%	Influenza B	4.3%
Metapneumovirus	2%	Bocavirus	2.1%
Adenovirus	1.3%	Adenovirus	1.1%
CMV	0.6%	Coinfection by two or more viruses	26.6%
Coinfection by two or more viruses	11.4%		

Summary/Conclusions: Our study confirms that viral respiratory infections are a common cause of morbidity in hematologic patients, even though related mortality was low. The most common symptoms were those of upper airway involvement. 44% of the patients remained afebrile during the course of infection. The presence of other comorbidities, lymphopenia and/or hypogammaglobulinemia seemed to be related with these infections. Although we didn't find an increased rate of infection in transplant recipient patients, it seems that several microorganisms coinfections are more common in this group. Molecular techniques like PCR have replaced previous diagnostic procedures (like virus cultures), demonstrating a higher sensibility. Given the high rate of nosocomial infections, we would like to highlight the importance of vaccinating staff and family, and isolation measures in patients with suspected respiratory infections transmitted by droplets or contact.

E1175

PHASE 1 SUMMARY OF ANF-RHO, A NOVEL PEG-MODIFIED FILGRASTIM INVESTIGATIONAL PRODUCT WITH SUPERIOR PK/PD PROPERTIES THAT MAY PROVIDE IMPROVED CONTROL OF NEUTROPENIA DURING DOSE-DENSE CHEMOTHERAPY

R Jubin*, A Abuchowski, D Byczkowski, H Misra, P Buontempo
Prolong Pharmaceuticals, South Plainfield, United States

Background: Anti-Neutropenia Factor - Rho (ANF-RHO) is a new longer acting granulocyte-colony stimulating factor (G-CSF) consisting of a novel pegylated version of recombinant human G-CSF protein. ANF-RHO has distinct biophysical and biological properties that produce an improved pharmacokinetic (PK) and pharmacodynamic (PD) profile as compared to either filgrastim (Neupogen®) or PEGfilgrastim (Neulasta®). *ANF-RHO is not a biosimilar drug product.*
Aims: A Phase 1 clinical study was conducted in healthy volunteers to assess safety and tolerability of ANF-RHO as well as its PK and PD profile.
Methods: The ANF-RHO cohort dosage levels ranged from 5 to50 µg/kg and were compared against both active (PEGfilgrastim) and placebo (saline) comparators. Subcutaneous, single dose treatment with ANF-RHO in ascending doses or PEGfilgrastim at the standard of care dosage (fixed, 6mg) were compared in a randomized, controlled, double-blind study that included peripheral blood absolute neutrophil counts (ANC) and CD34+ stem cell analytical assessments.
Results: Phase 1 clinical safety results were unremarkable, with no severe adverse events in any cohorts. The ANF-RHO PK/PD results in this Phase 1 study were similar to preclinical findings. PK and PD results (ANC and CD34+) were markedly prolonged in the ANF-RHO treatment groups even at the lowest dose. Mean ANC counts for all ANF-RHO treated subjects showed Cmax at 6-7 days, in contrast to 1-2 days for PEGfilgrastim treated subjects. The peak blood levels of ANF-RHO were significantly lower than PEGfilgrastim at all levels tested. Moreover, assessment of the ANC - AUC revealed that ANF-RHO at10 µg/kg was equivalent to PEGfilgrastim at 100 µg/kg, demonstrating an approximately 10-fold potency improvement over PEGfilgrastim in healthy volunteers, with a longer duration of effect of almost two weeks. Peripheral blood CD34+ levels also yielded similar results. ANF-RHO-induced neutrophil counts increased in a stable and prolonged manner following treatment, followed by a slow gradual decline, in contrast to PEGfilgrastim that showed a rapid ANC spike (2 days) and decrease to baseline within 7 days following administration.

Summary/Conclusions: The unique PK/PD of ANF-RHO suggests that a significantly lower dosage may achieve sustained neutrophil levels sufficient to mitigate neutropenia - specifically during the high-risk 7-day period following dose-dense myelosuppressive chemotherapy. Additionally, the sustained and elevated CD34+ counts suggest ANF-RHO may also have applications in stem cell mobilization. The lower effective dosages would be anticipated to reduce the incidence of leukocytosis. Collectively, the increased potency and prolonged pharmacodynamics of ANF-RHO should provide more effective management of hematological malignancies when treating patients at high risk for neutropenia and difficult to mobilize patients or when performing dose-intensification in advanced stage cancer patients.

E1176

INVASIVE PULMONARY ASPERGILLOSIS IN ALLOGENEIC BONE MARROW RECIPIENTS WITH B- THALASSAEMIA MAJOR OR SICKLE CELL DISEASE: INCIDENCE AND RISK FACTORS

K Paciaroni[1,*], G DeAngelis[1], C Gallucci[1], M Ribersani[1], M Marziali[1], A Isgrò[1], J Gaziev[1], L Sarmati[2], L Dori[2], P Sodani[1], G Lucarelli[1]
[1]International Centre for Transplantation in Thalassemia and Sickle Cell Anaemia, Mediterranean Institute of Haematology, [2]Clinical Infectious Disease, Tor Vergata University, Rome, Italy, Rome, Italy

Background: Invasive Pulmonary Aspergillosis (IPA) is a devastating opportunistic infection and remains a significant cause of morbidity and mortality in allogeneic Haematopoietic Stem Cell Transplantation (HSCT) recipients. IPA has been well characterized in adults and in the setting of oncological transplant. No data are available regarding IPA in patients with β- globin gene disorders undergoing bone marrow transplant (BMT).
Aims: To evaluate the incidence and the outcome of IPA among BMT recipients with β-Thalassaemia Major or Sicke cell Anaemia (SCA).
Methods: We evaluated the occurrence, the clinical setting and the clinical outcome of IPA in pediatric patients affected by Thalassaemia major or SCA transplanted at our institution.
Results: A total of 292 consecutive patients (median age 11,6, range 1,9-28 years) with β- globin gene disorders who underwent BMT (232 HLA-identical, related donor; 54 haplotype-identical donor and 4 matched, unrelated donor) were studied. Overall, the incidence of proven or probable IPA was 2.73% (8 out of 292 cases). The median time to onset IPA infection after transplantation was 68 days (range, 13-183 days). In particular, in 5 cases (50%) IPA were diagnosed in the late phase after transplant (day >60) and in 3 cases (50%) were diagnosed during the post-BMT neutropenic period before engraftment. All grade of Graft-*versus*-host-disease (GVHD) was present in 4 (50.0%) of 8 patients with IPA, compared with 97 (37,7%) of 284 patients without fungal infection (P=n.s.). Among 8 cases with IPA an alternative donor (matched unrelated or haplotype-identical) was used in 5 patients (62.5%) compared with 55 cases (19.3%) of 284 recipients without IPA (P=0.003). The infection remained confined in the lung in 7 (87.5%) of 8 IPA cases, in 2 cases surgical intervention was adopted in addition to the adequate systemic anti-fungal medical therapy; only in 1 case the infection was multifocal with CSN involvement. The overall mortality rate for IPA was 0.7% (2 of 292 patients) whereas the IPA attributable mortality rate observed in our population was 25% (2 of 8 cases).
Summary/Conclusions: Our data show that in a population affected by β- globin gene disorders who undergoing allogeneic BMT, the IPA rarely develop (2,7%) and the overall mortality (0.7%) and the IPA attributable mortality rate (25%) is markedly lower then the one observed in the setting of haematological malignancies. In our cohort, a significant risk factor for IPA was the alternative donor.

E1177

EARLY AND RAPID INCREMENT OF CRP AND IL-8 LEVELS TOGETHER WITH FASTER AND DEEPER DECLINING OF LEUKOCYTES PREDICT FOR TYPHLITIS DEVELOPMENT IN TREATED AML PATIENTS

L Span[1,*], G Dijkstra[2], E Vellenga[1], G Huls[1]
[1]Hematology, [2]Gastro-enterology, UMCG, Groningen, Netherlands

Background: Neutropenic enterocolitis (NE) or typhlitis is an important and severe complication in patients with acute myeloid leukemia (AML) receiving intensive chemotherapy.
Aims: In this study we evaluated serum C-reactive protein (CRP), interleukin (IL)-8, fecal calprotectin, and oral mucositis score as possible time-dependent predictors of developing NE.
Methods: Adult patients with AML treated with intensive chemotherapy (with cytarabine) were included. Serum IL-8 and CRP levels were measured daily during 14 days after cessation of chemotherapy, as well as calprotectin in the stool. Oral mucositis was also scored daily. Furthermore, CT scan of the abdomen at day 21 was performed to objectively define patients with NE.
Results: In total, 34 patients were included and 11 episodes of NE were diagnosed. All patients with NE received conservative treatment and only one patient with NE died because of refractory Enterococcus faecium sepsis. From day 5 onward (after cessation of chemotherapy), median IL-8 and CRP levels increased more rapidly to significantly higher levels in patients with NE, whereas white blood cell (WBC) counts decreased faster to significantly lower levels as compared to the non-NE patients. Oral mucositis score and fecal calprotectin levels failed to be different in both groups. Cytarabine dose was of no influence. As was corrected for bacteraemia, no differences were seen between both groups.
Summary/Conclusions: Pattern recognition of early and rapidly increasing IL-8 and CRP levels with significantly lower WBC counts after cessation of chemotherapy can identify AML patients developing NE. Early recognition of developing NE can potentially decrease the high mortality rate (25-50%) of this complication.

E1178

PRESEPSIN (SOLUBLE CD14 SUBTYPE) IS ELEVATED IN FEBRILE NEUTROPENIC PATIENTS WITH HEMATOLOGICAL MALIGNANCY: USEFULNESS AS ONE ANOTHER BIOMAKER

N Sugawara[1,*], T Oyake[1], T Masuda[2], M Asahi[1], Y Suzuki[1], Y Okano[1], Y Fujishima[1], Y Aoki[1], S Kowata[1], S Ito[3], Y Ishida[1]
[1]Hematology and Oncology, Internal Medicine, [2]Critical Care Medicine, [3]Medical Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Background: ebrile neutropenia (FN) is often observed in patients with hematological malignancy (HEM). Most of causes are bacterial infections in these FN, and many cases respond to empirical antibiotic therapy including an anti-pseudomonas b-lactam agent. Otherwise, it is often difficult to specify the focus and pathogen of infection in FN patients. Presepsin (Pre-SEP) is a subtype of soluble CD14, which is a receptor for lipopolysaccharide (LPS)/LPS-binding protein complexes and is expressed on the myelo-monocytic cell surface. Recently, it has been shown to be a useful biomarker for assessing the severity of sepsis and has come into use in the field of critical care medicine. However, little is known about the biological characteristics of Pre-SEP in FN patients.
Aims: To clarify the usefulness of new biomarker Pre-SEP in the setting of neutropenia, we performed analyses to determine the clinical relevance of Pre-SEP in the diagnosis of bacteremia or other infectious complications as a biomarker for FN patients after or during chemotherapy in HEM.
Methods: We measured the plasma concentration of Pre-SEP, procalcitonin (PCT) and C-reactive protein (CRP) at Day0, 2, 4, 7, 14 and 21 after the onset of FN, and compared them to those of non-febrile neutropenic patients. Furthermore we reviewed other clinical data including bacterial examination and clinical courses, and evaluated the utility of Pre-SEP as biomarker of FN.
Results: The 65 hospitalized FN patients with HEM (AML 16, ALL 12, MDS 14, NHL 13, MM 8, and ATL 2) were treated by IDSA guideline and administered antibacterial or antifungal agents, and the clinical data including Pre-SEP were evaluated. Pre-SEP (Day 0, 2, 4, 7, 14 and 21) was elevated (447 pg/ml (141-2204), 494 pg/ml (151-1975), 344 pg/ml (164-1264), 312 pg/ml (116-1512), 319 pg/ml (86-1512), 278 pg/ml (129-1425), p<0.05, respectively, cut off value: 314 pg/ml) compared to those in non-febrile neutropenic patients (196 pg/ml (97.5-453): median (range), respectively). Otherwise, PCT (Day 0, 2, 4, 7, 14 and 21) was also elevated (0.12 ng/ml (0.04-3.40), 0.13 ng/ml (0.05-1.60), 0.11 ng/ml (0.04-3.54), 0.08 ng/ml (0.03-8.21), 0.11 ng/ml (0.02-2.64), 0.36 ng/ml (0.10-7.75), p<0.05, respectively, cut off value: 0.05 ng/ml) compared to those in non-febrile neutropenic patients (0.175 ng/ml (0.06-1.91): median (range), respectively), and CRP (Day 0, 2, 4, 7, 14 and 21) was also elevated (5.07 mg/dl (0.19-27.83), 3.19 mg/dl (0.30-20.54), 2.26 mg/dl (0.15-34.01), 1.33 mg/dl (0.10-29.48), 0.28 mg/dl (0.10-22.49), 0.36 mg/dl (0.10-7.75), p<0.05, respectively, cut off value: 0.3 mg/dl) compared to those in non-febrile neutropenic patients (0.625 mg/dl (0.11-8.72): median (range), respectively). There was no relation between Pre-SEP value and bacterial examination data including blood cultures. Almost FN cases responded empirical antibacterial therapy, and elevated Pre-SEP, PCT and CRP values decreased again accompanied by defervescence. However, some cases of persistent remarkably elevated Pre-SEP cases ware observed, and these cases had very poor prognosis. The 5 of 9 cases with remarkably high Pre-SEP value (>1000 pg/ml) at both day7 and 14, or both day14 and 21 were dead by severe infection related events within 4 weeks, otherwise all other 56 cases than the above recovered from infection events and survived (p<0.05, respectively).
Summary/Conclusions: These data suggested that Pre-SEP is elevated due to active infection events in FN patients in spite of conditions being remarkably decreased neutrophil and monocyte. Pre-SEP is useful as a biomarker of infection in FN patients, as well as PCT or CRP.

E1179

INVASIVE ASPEGILLOSIS IN PATIENTS WITH ACUTE LEUKEMIAS: PROGNOSTIC VALUE OF LABORATORY BIOMARKERS DEFINING HIGH RISK PATIENTS

A Vidovic[1,*], V Arsic Arsenijevic[2], M Virijevic[3], D Tomin[1], N Suvajdzic Vukovic[1], I Djunic[1], M Mitrovic[1], P Tojic[4], D Marinkovic[4], B Mihaljevic[1]
[1]Clinical Center of Serbia, Medical Faculty of Belgrade, Clinic of Hematology, [2]Medical Faculty, University of Belgrade, Medical Mycology Reference Laboratory, Institute of Microbiology and Immunology, [3]Clinical Center of Serbia, Clinic of Hematology, [4]University of Belgrade, Medical Faculty, Belgrade, Serbia

Background: Invasive fungal diseases, especially invasive aspergillosis (IA) are the major cause of morbidity and mortality in patients with acute leukemias. Detection of early laboratory biomarkers: galactomannan (GM) and anti-Aspergillus antibodies IgM and IgG (Anti-A IgM, IgG) contributes to early recognition, as well as to the monitoring during aspergillosis treatment.
Aims: The aim of study was to evaluate clinical utility and prognostic value of "non- culture" methods: GM assay and anti-A (IgM and IgG) antibodies for early diagnosis of aspergillosis in patients with acute leukemias.
Methods: The study included 102 patients, 80 pts with AML and 22 pts with ALL (52 male/50 female, median age 51 years, range 19-73 years) hospitalized in the Clinic of Hematology during period of time from January 2012 until December 2015. All pts were treated with intensive chemotherapy according to the regimens recommended for the treatment AML and ALL, consequently developing febrile neutropenia, with median duration of 12 days (7-23days). Serum GM level were measured twice a weekly using the Platelia Aspergillus enzime immunoassay (EIA) kit (Biorad, France), applying the cutoff value of 0,5 as positivity. Anti-A IgM/anti-A IgG were measured using commercial tests (Serion ELISA classis, Virion/Serion, Germany). The concentration of antibodies above 12U/ml was considered as positive finding. In all patients routine radiological (high resolution CT scaning) was performed, as well as the biological monitoring consisted of hematological, biochemical and cytopathological tests. Median time of follow-up was 294 days (range 15-1300 days) and treatment outcome was assesed on the 100. day of follow-up. Statistical analysis was performed using IBM SPSS Statistics version 21.0.
Results: In analyzed group of 102 patients, there were 20 possible, 54 probable and 4 proven cases of IA, while in the last 24 pts were detected only positive GM or anti-A IgM/anti-A IgG. During 100 days of follow-up, 39 patients died while 63 patients had survival longer than 100 days. GM index, as well as the anti-A (IgM and IgG) antibodies, was defined as ratio of total number of positive findings and total number of performed tests. Predictive value of GM index was maintained after Cox regression adjustment. In multivariate analysis, GM index was an independent survival predictor (p=0.012). Anti-A IgM and anti – A IgG were not statisticaly significant predictor of survival (p=0,224 and p=0,987).
Summary/Conclusions: The GM assay is a useful tool for monitoring IA in patients with acute leukemias. Persistent GM positivity is associated with death and treatment failure, whereas a successful outcome is associated with GM negativity. Diagnostic and prognostic value of level of anti-Aspergillus antibodies is not documented and more studies, with more patients, are needed to define better the role of these biomarkers.

E1180

HEPATITIS B IMMUNE STATUS IN CHILDREN TREATED FOR ACUTE LYMPHOBLASTIC LEUKEMIA

Y El Chazli[1,*], H Hassab[1], M Salama[1], W El Gendy[2]
[1]Department of Pediatrics, [2]Department of Clinical Pathology, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: Hepatitis B virus (HBV) infection occurs worldwide, with the highest HBsAg carrier rates found in developing countries, where infection is expected to occur in infancy and childhood. Immunization with hepatitis B vaccine is the most effective way of preventing HBV infection and its consequences, especially in endemic areas. Hepatitis B vaccines are highly immunogenic, inducing a protective anti-HBs antibody titer (≥10 mIU/mL), in more than 95% of healthy children and young adult. Partial or complete loss of protective antibody titers against vaccine preventable diseases makes leukemic children more susceptible to infections. Hemato-oncological patients are considered at risk for either acute acquired HBV infection or HBV reactivation.
Aims: evaluate the immune status to HB vaccine in children treated for acute lymphoblastic leukemia (ALL) after completion of chemotherapy and determine factors affecting anti-HBs titer in those children.
Methods: We evaluated HBV immune status among 76 children who have been treated for ALL, 43 males and 33 females, their age ranged from 4.9 to 16.3 years with a mean of 11.19 years. They were consecutively recruited from the hematology oncology clinic at Alexandria University Children's Hospital. One hundred healthy children were also included as controls, 51 males and 49 females, age ranged from two to 12 years with a mean of 7 years. All have been previously vaccinated with 3 doses of hepatitis B vaccine at 2, 4 and 6 months of age. Anti-HBs titer was assessed in all leukemic children and controls by ELISA, and concentrations<10.0 mIU/mL were considered negative for anti-HBs (non-immune).
Results: Significantly more leukemic children were non-immune (51.3%) compared to only (15%) in the control group, (p<.0001). Moreover, mean anti-HBs titer in normal children was significantly higher than in leukemic children, (61.57 *vs* 42.79 mIU/mL, p=.038). When comparing immune and non-immune leukemic children according to age at diagnosis of leukemia, it was significantly higher in non-immune than in immune ones, (6±2.9 *vs* 4.6±1.9 respectively, p=.017). Using logistic regression analysis, both previous chemotherapy and age were identified as independent variables affecting immunity to HB vaccine, (p=.032, p=.001 respectively). An equation resulted from this analysis to predict the probability of non-immune status: Y=-3.589+[0.928×disease status]+[0.243×age (years)], where disease status is entered as "0" if normal child and as "1" if child has been previously treated for leukemia. The diagnostic performance of the new equation using Receiver Operating Characteristic (ROC) curve analysis was fair to good tool in discrimination between immune and non-immune children, (AUC=0.782, 95% CI 0.713-0.851, p<.0001). Children with value of ≤0.286 will be considered immune with negative predictive value of 86%. On the other hand, children having a value >0.656, are considered to be non-immune with a positive predictive value of 78.9%.
Summary/Conclusions: Several variables affect immunity of children to HB vaccine. Chemotherapy affects immunity to HB vaccine in children treated for ALL regardless the type of leukemia, the intensity of the protocol used for treatment, and the post chemotherapy interval. A novel equation was developed to predict non-immune state to HBV in children using both his age and his disease status thus help taking a decision concerning revaccination of these patients with minimal costs and time consumption.

E1181

IMPACT OF RESPIRATORY VIRUSES IN IMMUNOCOMPROMISED PEDIATRIC HEMATOLOGY PATIENTS

M Rompola[1,*], S Kinsey[1], F Azzuni[2], E Kane[3], E Roman[3], A Hale[4], B James[5]
[1]Leeds Institute of Cancer and Pathology, University of Leeds, [2]Pediatric Infectious Disease, Leeds General Infirmary, Leeds, [3]Department of Health Sciences, University of York, York, [4]Department of Virology, [5]Pediatric hematology, Leeds General Infirmary, Leeds, United Kingdom

Background: Respiratory viral infections are very common in children. Children immunocompromised (IC) by treatment for haematological malignancies or following stem cell transplant (SCT) are at increased risk, although the morbidity and mortality are not well understood.
Aims: To assess the impact of respiratory viruses in IC pediatric hematology patients aged 0-18 analysed by diagnosis, intensity of treatment, rates of admission, Pediatric Intensive Care Unit (PICU) and outcomes, including the effect of influenza H1N1 pandemic (swine flu).
Methods: Retrospective review of PCR positive viral isolates of respiratory secretions of children with hematological diseases or post SCT, sent between Jan 2009-Dec 2014. Review of patient records with regards to concurrent neutropenia, blood culture growth, admission, PICU and outcome.
Results: 952 specimens from respiratory secretions were sent, 465 were positive (48.8%), with total 528 viral isolates (63 specimens had multiple isolates) representing 171 patients. 232/465 (50%) were from nose swabs; 134/465 (29%) were nose and throat swabs; 71 /465 (15%) were throat swabs; 9/465 (1.9%) were from bronchio-alveolar lavage. Patients: 141 acute leukemias (AL), 27 SCT, 3 other haematological diseases. 96 boys, 75 girls. Mean age at diagnosis: 4.9 years. Mean age at sample: 6 years. Viral isolates overall: Of the total 528 viral isolates the majority, 52%, were rhinovirus, 14.2% Respiratory Syncitial Virus (RSV), 6.8% parainfluenza 3, 4.6% adenovirus, 4.6% parainfluenza 1, 4.2% metapneumovirus, 3.6% parainfluenza 4, 3.4% influenza B and 3.4% H1N1. 385/465 (83%) positive swabs were from AL patients (mean age at sample 6 years) 70/465 (15%) from SCT patients (mean age at sample 6.8 years) and 10/465 from patients with other disorders (mean age at sample 1.7 years). Treatment intensity: positive results in AL patients occurred at the following phases of treatment 10/385 induction; 164/385 at other phases of treatment; 211/385 in maintenance. In the UK males with ALL are treated for 3 years (compared with 2 years for girls). Of the total of 211 positive samples taken in maintenance, 42 (20%) were from boys in their 3rd year of treatment and resulted in 24 admissions. H1N1 was solated from 18 patients associated with 14 admissions. 1 PICU and subsequent death. Mean age at sample 8.18. 10 maintenance AL, 6 other phases AL and 2 SCT. (4 mixed isolates: 2 rhinovirus, 1 parainfluenza 1 and 1 RSV.) Overall, 301 admissions at the time of respiratory viral isolate. Of the 528 viral isolates, 64.7% during admission (mean age 5.7 years). 32.6% with concurrent neutropenia and only 1.9% with blood culture growth. 10 patients required PICU during their admission, 8 of which were all/partly attributed to the respiratory virus. 4 patients were in AL induction (1 died with RSV and parainfluenza 4). 1 in AL consolidation. 1 with relapsed ALL who died with rhinovirus and metapneumovirus. 2 were SCT patients (1 died with rhinovirus).
Summary/Conclusions: There was a surprisingly high (48.8%) positive rate in the respiratory secretion samples. 64.7% of positive viral isolates coincided with admission. Respiratory viruses are a cause of significant morbidity, including hospital admission and mortality. 38% of patients admitted to PICU all or partly as a consequence of a respiratory virus; 3 patients died. Rhinovirus, often dismissed as irrelevant, was present in 75% patients admitted to PICU and 33% PICU deaths. Although the data reflects a time of H1N1 outbreak: it was isolated in few patients, however 78% of patients with H1N1 isolate required admission and 1 patient died.

E1182

VORICONAZOLE AS PRIMARY PROPHYLAXIS OF FUNGAL INFECTIONS IN HIGH-RISK HEMATOLOGIC PATIENTS: NO NEED FOR EMPIRICAL ANTI-FUNGAL THERAPY

A Zabalza[1,2,*], C Mansilla[2], M Ciaurriz[2], L Beloki[2], M Lachen[2], E Perez-Valderrama[2], A Gorosquieta[1], M Rodriguez-Calvillo[1], N Ramirez[2], E Olavarria[3]

[1]Hematology, Complejo Hospitalario de Navarra, [2]Oncohematology Research Group, Navarrabiomed-Miguel Servet Foundation, Pamplona, Spain, [3]Hematology, Hammersmith Hospital-Imperial College Healthcare, London, United Kingdom

Background: Invasive fungal infections (IFI), predominantly aspergillosis and candidiasis, remain an important cause of morbidity and mortality following high-dose chemotherapy and allogeneic stem cell transplantation (alloSCT).
Aims: The primary endpoint of this study was to analysed the efficacy and safety of voriconazole primary antifungal prophylaxis in combination with a pre-emptive antifungal strategy in high-risk hematologic patients.
Methods: This is a retrospective, observational and non-interventional study conducted from March 2009 until February 2012 at the Complejo Hospitalario de Navarra. Patients could receive voriconazole prophylaxis at different periods of time in the course of their disease if they were at high-risk of IFI: following intensive chemotherapy (n=24), allogeneic stem cell transplantation (n=43) or receiving high-dose corticosteroids treatment for chronic graft *versus* host disease (n=11). If patients developed prolonged unresponsive fever after 5 days of broad-spectrum antibacterials and/or galactomannan antigen was positive, a high-resolution computed tomography (CT) was performed. If new pulmonary infiltrates were present, a bronchoscopy with BAL was performed. Only patients with abnormal CT findings, positive fungal isolates on BAL or positive GM antigen started on pre-emptive antifungal treatment and changed their anti-fungal treatment to liposomal amphotericin B or an equinocandin. Otherwise, patients remained on voriconazole prophylaxis despite continuing fever. The cumulative incidence (CI) of proven/probable IFI, pre-emptive antifungal treatment and adverse events were estimated by Kaplan-Meier survival curves.
Results: A total of 78 prophylactic voriconazole periods were analysed in a total of 44 hematologic patients. Only one patient developed a proven/probable IFI (a breakthrough candidemia) in the allogeneic stem cell transplantation group. No patient developed proven/probable IFI in the chemotherapy neither in the chronic graft *versus* host disease group. The cumulative incidence of pre-emptive antifungal treatment was 12.5% and 12.3% for the chemotherapy and the allogeneic stem cell transplantation respectively. The most frequent adverse event was hepatic toxicity with a cumulative incidence of 10.7%, 25.8% and 27.3% in the chemotherapy, the allogeneic stem cell transplantation and the chronic graft *versus* host disease respectively. No hepatic failure was registered and hepatic toxicity was reversible after drug discontinuation or transient interruption.
Summary/Conclusions: Voriconazole is a safe and an effective antifungal agent for prophylaxis of IFI in high-risk hematologic patients with a success rate of 97.4% provided that frequent liver monitoring and short intermittent interruptions are performed. Voriconazole prophylaxis allows for strategies with no empirical use of systemic anti-fungals.

E1183

RANDOMISED COMPARISON OF PALONOSETRON AND ONDANSETRON BOTH COMBINED WITH DEXAMETHASONE IN PREVENTION OF EMESIS IN LYMPHOMA PATIENTS RECEIVING MODERATELY EMETOGENIC REGIMEN BENDAMUSTINE AND RITUXIMAB

V Ptushkin[1,*], N Sharkunov[2], S Mayorova[2], M Pankrashkina[2], E Nikitin[2]
[1]Hematology Department, [2]Outpatient department for Hematology Oncology and Chemotherapy, S.P.Botkin's city hospital, Moscow, Russian Federation

Background: Palonosetron is a highly selective, second-generation 5-HT3 receptor antagonist with a prolonged half-life (40 hours) which makes it attractive in prevention of delayed nausea and vomiting. Bendamustine, a moderately emetogenic cytostatic drug is becoming increasingly used in treatment of lymphoid malignancies.
Aims: A randomized comparison of palonosetron and ondansetron both combined with dexamethasone in prevention of chemotherapy induced nausea and vomiting (CINV) in adult patients, receiving bendamustine and rituximab chemoimmunotherapy.
Methods: Data of 1st interim analysis are presented. The study included 23 patients with median age of 67 years (range 31 - 82 yrs), 13 males and 10 females. The patients did not received chemotherapy at least 6 months prior to inclusion. Ten patients had follicular lymphoma, 8-chronic lymphocytic leukemia, 6-marginal zone and other types of indolent lymphomas. The BR regimen consisted of rituximab 375 mg/m2 on day 1 and bendamustine 90 mg/m2 on days 1 and 2. Patients were randomly assigned to receive either a single intravenous bolus dose of palonosetron (0, 25 mg) on day 1 or ondansetron (8 mg on days 1 and 2 of each cycle) along with dexamethasone 30 min before administration of chemotherapy. CINV was assessed during 1st cycle of chemotherapy using MASCC Antiemesis Tool. Frequency and severity of acute (within 24 hours) and delayed (24-120 hours) emetogenic reactions were registered.
Results: Eleven patients received palonosetron and 12 ondansetron. Groups were comparable with regard to emetogenic risk factors including sex, age, kinetosis and alcohol use. Complete response (no emetic episodes and no rescue therapy) in acute phase was observed in 100% of patients receiving palonisetron and in 10/12 (83%) of patients receiving ondansetron. Complete response in delayed phase was achieved in all patients in palonosetron group and in 11/12 (92%) in ondansetron group. Complete protection (no emetic episodes, no rescue therapy, and no significant nausea [Likert scale 2 or less]) in acute phase was achieved in 10/11 (91%) patients in palonosetron group and in 5/12 (41%) in ondansetron group. In delayed phase complete protection of CINV was reported by 10/11 (91%) of patients receiving palonosetron and 6/12 (50%) of patients receiving ondansetron.
Summary/Conclusions: The frequency of delayed nausea in patients, receiving bendamustine is probably underestimated. Prevention of bendamustine induced nausea and vomiting with palonosetron merits further investigation.

E1184

EFFICACY AND SAFETY OF MICAFUNGIN ON THE MANAGEMENT OF INVASIVE FUNGAL INFECTIONS AMONG PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AT TERTIARY HOSPITALS IN GREECE- THE ASPIRE STUDY

M Kotsopoulou[1,*], G Vassilopoulos G[2], K Anargyrou[3], A Spyridonidis[4], I Baltadakis[5], HA Papadaki[6], M Angelopoulou[7], MC Kyrtsonis[7], V Pappa[8], K Liakou[9], M Tzanetakou[9], A Georgopali[9], N Anagnostopoulos[10]
[1]Metaxa Cancer Hospital, Pireus, [2]University General Hospital of Larissa, Larissa, [3]Hematology Clinic, 251 General Air Force Hospital, Athens, [4]University General Hospital of Patras, Patras, [5]General Hospital of Athens "Euaggelismos, Athens, [6]University General Hospital of Heraklion, Heraklion, [7]General Hospital of Athens "Laikon", [8]Second Department of Internal Medicine and Research Institute, "Attikon", University General Hospital, Athens, [9]Medical Affairs, Astellas Pharmaceuticals AEBE, Attica, [10]General Hospital of Athens "G. Gennimatas", Athens, Greece

Background: Immunocompromised patients, especially those with cancer or underling hematological malignancies and patients who undergo hematopoietic stem cell transplantation (HSCT), are at high risk for invasive fungal infections, which are often life threatening. Echinocandins are recommended as first -line treatment for the management of invasive candidiasis/candidemia from the recent ESCMID guidelines. However, there are relatively limited data for the daily clinical practice regarding the use of micafungin at hematological settings in Greece.
Aims: The aim of the study was to evaluate the efficacy and safety of micafungin administration in standard clinical practice among patients with hematological malignancies, including patients who underwent HSCT.
Methods: This was a multicenter, non interventional, prospective cohort study conducted in 10 research sites in Greece. Adult hospitalized patients with hematological malignancies, including recipients of HSCT, were enrolled in the study between 29 Jun 2013 and 31 Mar 2014. Eligible patients were intended to receive micafungin which was prescribed as per standard clinical practice according to its label, while their assignment to a particular therapeutic strategy was not decided in advance by the protocol. The observational study period lasted until clinical outcome was recorded. Patients were classified according to their clinical presentation at baseline using the revised EORTC criteria (2008).
Results: A total of 143 patients were enrolled. Of them, 122 patients had a hematological malignancy (85.3%), 4 underwent HSCT (2.8%) and 17 had hematological malignancy and HSCT (11.9%). Acute myelogenous leukemia (n=58, 40.6%) was the most common hematological disorder, while just over half of these patients were newly diagnosed (51%). Of the 21 patients in the HSCT group, 12 underwent autologous and 9 allogeneic HSCT. On treatment initiation, 78 patients had fever (54.5%) and 85 patients had neutropenia (59.4%) respectively, while 58 patients had previous febrile episodes(40.6%). In addition, 112 patients had received systemic antibiotics (78.3%), 64 patients had received corticosteroids (44.8%) and 69 patients other immunosuppressive agents (48.3%) as prior treatment. At baseline, 74 patients of the study received micafungin as prophylaxis while 69 received treatment for possible (52), probable (12) and proven (5) fungal infection. Micafungin was administered as monotherapy in 97.6% of patients and as first line treatment in 75.5% of patients, while the mean duration of micafungin administration was 14.2 days (14.1 days for prophylaxis and 14.3 days for treatment). The success rates of micafungin were comparable for prophylaxis, possible and proven treatment strategies (90.5% *vs* 96.2% *vs* 100% respectively), while for probable treatment strategy was 75%. It is worth noting that in the latest group, treatment was considered as success in 9 patients, as failure in one patient and in two patients treatment definition as success or failure was not available. Treatment success was defined by the Investigators based on the EORTC/MSG criteria and their judgment as applied for daily clinical decision-making. 26 patients (18.2%) discontinued micafungin mainly due to limited availability of therapy at study sites, patient discharge or safety events not related to the study treatment. In total, 30 adverse events were reported throughout the study, including 8 Serious Adverse Events (deaths) that were not related to micafungin and 22 cases of special situations. One case of lack of efficacy was reported.
Summary/Conclusions: Micafungin was effective and well tolerated in patients with hematological malignancies, including patients who underwent HSCT. To this end, micafungin appears to be a valuable treatment option for the management of fungal infections in hematological settings.

E1185

ANTIRETROVIRAL THERAPY AND CHEMOTHERAPY IN PATIENTS WITH HIV INFECTION AND HAEMATOLOGICAL DISEASE - TOXICITY ASSESSMENT

P Sousa e Santos[1,*], E Viegas[2], F Mousinho[1], T Baptista[3], A Reichert[1], AP Gomes[1], F Falcão[4], F Lima[1]
[1]Clinical Hematology, [2] Pharmacy Department, Hospital de São Francisco Xavier, [3]Infeciology and Tropical Medicine, Hospital de Egas Moniz, [4] Pharmacy Department, Faculty of Pharmacy, iMed.ULisboa Research Institute for Medicine, Universidade de Lisboa, Hospital de São Francisco Xavier, Lisboa, Portugal

Background: Haematological malignancies, especially lymphoproliferative diseases, are a common manifestation of infection with human immunodeficiency virus (HIV). With highly active antiretroviral therapy (HAART) the survival of infected patients with hematologic disease has increased, and in most cases, overlapping the general population. Concomitant use of HAART and chemotherapy (CT) has been advocated for enhancing the immune response.
Aims: Characterization of toxicity associated with the concomitant use of HAART and CT and its impact on prognosis.
Methods: Descriptive, observational, retrospective study to evaluate patients with haematological malignancies associated with HIV infection and under HAART during CT, admitted between January 2011 and August 2015. The data was analysed using SPSS V17.0 program.
Results: We evaluated 24 patients, 19 males. The median age was 45.5 years (27-61). 22 patients had HIV-1, 1 patient HIV-2 and 1 patient co-infected with HIV-1 and HIV-2. All patients were on ARVT, 47.8% with regimens based on two nucleoside reverse transcriptase inhibitors (NRTI) and boosted protease inhibitor (PI/ r) and 34.8% with 2 NRTI-based regimens and integrase inhibitor (II). The most common diagnosis was Burkitt's lymphoma (29.2%), followed by diffuse large B-cell lymphoma (25%) and Hodgkin Disease (16.7%). The CD4 cell count was below 250cells/ mcL in 10 patients and none had negative viral load at the start of CT. We documented 120 complications, most infectious (50.8%). Organ toxicity was revealed in 11 patients, of which 35% had renal and 20% liver toxicity. Of the 7 patients who experienced renal toxicity, 6 were treated with regimens containing tenofovir. Of the 4 patients who experienced liver toxicity, 2 were treated with PI/ r and 2 with II. It was necessary to suspend HAART in 5 patients. The scheme has been changed in two. The median of administered chemotherapy cycles was 4 (1-8) with an overall response rate of 77.8% (n=14), 50% (n=9) complete response, 27.8% (n=5) partial response, 4 patients were refractory, and the remaining (n=6) were not evaluated. The overall survival at 2 years was 36.4% (4/11).
Summary/Conclusions: The use of HAART associated with CT is not absent of toxicities, sometimes forcing its suspension. The new generation of antiretroviral drugs, with less pharmacokinetic interactions with antineoplastic drugs, seems to contribute to better compliance with HAART. The impact of this association should continue to be evaluated in further studies with larger samples.

E1186

RE-EVALUATING THE IMPACT OF INVASIVE ASPERGILLOSIS ON THE PROGNOSIS OF ACUTE MYELOID LEUKEMIA PATIENTS

MP Ledoux[1,*], N Baati[1], F Danion[1], E Toussaint[1], V Letscher-Bru[2], LM Fornecker[1], R Herbrecht[1]
[1]Hematology, [2]Mycology, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

Background: Invasive aspergillosis (IA) is a common complication of neutropenic and immunocompromised status occuring during acute myeloid leukemia (AML) management. Its prognosis has long been dismal, causing an important additional mortality in hematology patients. However, both diagnostic procedures and therapeutics have much improved, through galactomannan dosing, high resolution CT-scan and voriconazole avaibility.
Aims: We intended to assess frequency and prognostic impact of IA in a recent cohort of patients receiving high dose chemotherapy for AML.
Methods: We have therefore conducted a monocentric retrospective observational study on all consecutive patients diagnosed with an AML between 2008 and 2012 in Strasbourg University Hospital.
Results: Among 285 patients diagnosed with AML between 2008 and 2012 in our hospital, 154 received an intensive chemotherapy, with at least one induction course. Among them, 46 patients (29,9%) have been diagnosed with IA (2 proven IA, 25 probable IA, 19 possible IA). Twenty-eight (18,2%) of these infections occured following the first induction course (2 proven IA, 17 probable IA, 9 possible IA). Both groups of patients, whether they had an IA or not, had similar hematological prognosis as assessed by ELN scoring. Almost all IA patients (44, *i.e.* 96%) received voriconazole as a treatment. At the closing of our analysis, 17 patients diagnosed with an IA were still alive, with a follow-up ranging from 32 months to 93 months (median 64 months). The overall survival (OS) analysis of these patients showed no significant difference compared to patients without IA (p=0.94). Five-year survival of the two groups was respectively 40,6% and 41%.
Summary/Conclusions: With an incidence of IA close to recent data concerning patients treated for AML, our monocentric retrospective study on long-term survival of AML and IA patients shows no significant difference in terms of overall survival. These encouraging results shall now be confirmed on a larger cohort to conclude that the impact of IA on the prognosis of AML patients has been controlled in the era of diagnostic and therapeutic improvement.

E1187

PRIMARY ANTIFUNGAL PROPHYLAXIS (PAP) WITH MICAFUNGIN AT THE DOSE 50MG PER DAY IN ADULT PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA (ALL) DURING INDUCTION CHEMOTHERAPY: THE "REAL-LIFE" EVALUATION

T Kabut[1,*], F Folber[1], C Salek[2], J Prochazkova[1], M Rolencova[1], I Kocmanova[3], M Kouba[2], B Weinbergerova[1], P Cetkovsky[2], J Mayer[1], Z Racil[1]
[1]Dept. of Internal Medicine - Hematology and Oncology, Masaryk University and University Hospital Brno, Brno, [2]Institute of Hematology and Blood Transfusion, Prague, [3]Dept. of Clinical Microbiology, University Hospital Brno, Brno, Czech Republic

Background: Invasive fungal diseases (IFDs) during treatment of acute leukaemias are associated with a high morbidity and mortality. While in patients with acute myelogenous leukaemia PAP during induction treatment is well established (mainly with posaconazole), standardized PAP in patients with ALL is lacking. The major obstacle represents the risk of interactions of mould active azoles with chemotherapy agents during the intensive treatment of ALL. Thus the choice of PAP in these patients is difficult and they frequently remain without mould active PAP.
Aims: Evaluation of the efficacy and safety of micafungin PAP (dose 50mg/day) in adult patients with ALL during the induction chemotherapy.
Methods: A retrospective analysis of patients with ALL (or T-lymphoblastic lymphoma or Burkitt's leukaemia/lymphoma) treated with intensive ALL (or ALL-like) protocols in 2 tertiary care haematological centres in the Czech Republic receiving PAP with micafungin. Patients received micafungin (50 mg/day) from the start of induction chemotherapy till the neutrophils recovery. EORTC/MSG 2008 criteria for IFD diagnosis were used. CCTCAE v 4.0 criteria were used for evaluation of safety of PAP.
Results: Forty- nine patients received micafungin PAP 50 mg/day during induction chemotherapy of ALL between 2012 and 2015. ALL-CELL 2012 Junior protocol was used in 39 patients, GMALL B-ALL/NHL 2002 protocol in 3 patients and ALL-CELL 2012 elderly or EWALL Elderly protocol in 7 patients. The mean length of micafungin prophylaxis was 22 days (2-80 days). Antifungal prophylaxis failed in 2/49 (4.1%) patients, who developed IFD. Both patients developed proven IFD, no episode of probable IFD occurred. Both patients with proven IFD were successfully treated with combination of antifungal agents. One proven IFD had a form of invasive pulmonary aspergillosis (histologically proven and confirmed by PCR identification, culture negative) and occurred only early after the initiation of PAP (day 4). Second proven IFD represented disseminated *Geotrichum capitatum* infection (blood culture, liver and spleen) with MIC 32 µg/ml for echinocandins. Apart from the 2 IFD episodes, 10/49 (20.4%) patients developed pulmonary infiltrates-3/49 (6.1%) specific for IFD based on EORTC/MSG 2008 criteria (without any microbiological criteria and thus fulfilling criteria for possible IFD) and 7/49 (14.3%) non-specific pulmonary infiltrates.
Empirical antifungal therapy was initiated in 10/49 patients (20.4%). As an empirical therapy micafungin at dose 100mg/day was used in 8/10 patients, voriconazole in 1/10 patients and lipid based amphotericin B in 1/10 patient.
All 49/49 (100%) patients developed liver function test (LFT) elevation at least grade 1-2. However 63% patients had pre-existing liver test elevations. None of these LFT elevations were concluded as probably or definitely associated with micafungin and none required an interruption of micafungin prophylaxis.
Summary/Conclusions: Our real-life data proved efficacy of micafungin 50 mg/day as PAP in this population of patients at high risk of IFD, but also at high risk of drug-drug interactions. Only 2 (4.1%) patients developed breakthrough IFD, however in 1 case in a very early stage of PAP. The elevation of LFTs represented a major limitation of the prophylaxis, but was most likely associated with a therapy of ALL and did not require an interruption of micafungin PAP. Echinocandine-based PAP could represent a safe option for prophylaxis of this difficult to treat population of patients with ALL.

E1188

COMPARISON OF DE-ESCALATION AND NON-DE-ESCALATION EMPIRICAL THERAPY FOR CONTROLLING INFECTION IN PATIENTS WITH SEVERE APLASTIC ANEMIA TREATED WITH ANTITHYMOCYTE GLOBULIN

R Fu[*], T Chen, G Wang, J Song, L Li, H Liu, Z Shao
Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Aplastic anemia (AA) is a bone marrow failure syndrome, featuring pancytopenia, characterized by the reduction in hematopoietic stem and

progenitor cells.combined immunosuppressive therapy (IST) with antithymocyte globulin (ATG) and cyclosporine A (CsA) is a standard first-line treatment for SAA.However, neutropenia caused by SAA and the immunosuppressive effect of ATG could increase the risk of infections.
Aims: To compare De-escalation and Non-de-escalation Empirical Therapy for Controlling Infection in Patients with Severe Aplastic Anemia Treated with Antithymocyte Globulin.
Methods: We compared the efficacy of de-escalation and non-de-escalation empirical therapy for controlling microbiological culture-confirmed infections in 87 patients with severe aplastic anemia (SAA) treated with antithymocyte globulin (ATG) from 2006 to 2015 in our center.
Results: The response rate at 7 days and 30 days in de-escalation group was significantly higher than that in non-de-escalation group (60.32% *vs* 25.00%, p=0.003)(79.37% *vs* 58.33%, p=0.047). After anti-infection treatment, more patients' absolute neutrophil count(ANC) increased in de-escalation group than that in non-de-escalation (76.19% *vs* 45.83%, p=0.007), though no significant difference of ANC was found between two groups. Patients in de-escalation group had better survival outcome at 90 days (p=0.003). In de-escalation group, the response rate of patients with granulocyte transfusions at 7 days was higher than that of patients without granulocyte transfusions (78.26% *vs* 50%, p=0.027).
Summary/Conclusions: We concluded that early administration of broad-spectrum antibiotics pending the results of microbiological cultures combined with a commitment to change to narrow-spectrum antibiotics should be recommended for controlling infections in SAA patients treated with ATG and granulocyte transfusions might be an adjunctive therapy to improve the response rate.

E1189

A RETROSPECTIVE ANALYSIS ABOUT STENOTROPHOMONAS MALTOPHILIA SEPSIS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCY: A SINGLE CENTER STUDY FOR 12 YEARS

M Asahi[1,*], T Oyake[1], N Sugawara[1], Y Suzuki[1], Y Okano[1], Y Fujishima[1], Y Aoki[1], S Kowata[1], S Ito[2], Y Ishida[1]
[1]Hematology and Oncology, Internal Medicine, [2]Medical Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Background: Febrile neutropenia (FN) is often observed in hematological malignancy. Most of FN cases are infections by various causative agents rarely including antibiotic-resistant bacteria or low virulent bacilli. Stenotrophomonas maltophiria (SM) is a low virulent bacillus widely existing in the environment, a causative agent of opportunistic infection and a rare pathogenic bacteria in FN. Recently, some cases of sepsis by SM were reported in FN with hematological malignancy, and most of them had often very poor prognosis.
Aims: To clarify the prognosis of SM sepsis in FN patients of hematological malignancy, we should perform the surveillance of SM infections sufficiently.
Methods: We reviewed all blood culture data from our single institute from 2004 to 2015, and evaluated retrospectively clinical data of sepsis cases by SM in FN of hematological malignancy.
Results: Total 3490 events of blood cultures (BC) were performed just before the first line antibiotic agent administration was started for FN patients in the Hematology-Oncology unit of our institute from 2004 to 2015. In the 16.4% of these BC events, some kinds of bacteria or fungus were detected. The frequency of BC positive cases for SM were rarely observed in 2.3% of all BC events, and total 15 cases of SM sepsis were diagnosed. The primary diagnosis of hematological disease in those SM sepsis cases were NHL(N=5), AML(N=4), ALL(N=5) and CML(N=1), and almost all of these disease were relapse or refractory cases with many treatments for long duration. SMs detected in 15 cases were widely resistant to many antibiotic agents. Fourteen cases died of MOF, and 9 cases died within 7 days after the finding of BC in spite of intensive care including administration of sensitive antibiotic therapies.
Summary/Conclusions: The prognosis of SM sepsis in patients with hematological disease was extremely poor. Surveillance for SM infection in high-risk patients is essential, and rapid administrations of appropriate antibiotics should be considered.

Myelodysplastic syndromes - Biology

RIGOSERTIB (RIGO) COMBINED WITH AZACITIDINE (AZA) IN VITRO & CLINICAL: MODULATES EPIGENETIC EVENTS AND OVERCOMES CLINICAL RESISTANCE TO HYPOMETHYLATING AGENTS (HMA) IN MYELODYSPLASTIC SYNDROMES (MDS)

P Chaurasia, F Isoda, T Novy, J Ross, SC Navada, EP Demakos, R Odchimar-Reissig, EP Reddy, LR Silverman[*]
Cahn School of Medicine, Mount Sinai, New York, United States

Background: MDS is a challenging disease to treat due to intricate complexities at the genetic, molecular and epigenetic levels. Epigenetic based therapy with the HMA, AZA is the standard of care for patients (pts) with MDS with higher-risk disease. Treatment alters the natural history of MDS with increased survival, reduced risk of transformation to AML and improved hematopoiesis. However, all pts ultimately fail treatment due to either primary or secondary resistance. Initial results of an ongoing Phase I/II study of AZA combined with RIGO, an allosteric "ras mimetic" that binds to the Ras Binding Domain impacting pathways including ras, raf and PI3 Kinase, in pts with MDS demonstrated an overall response rate of 77%; and 64% in pts following HMA failure (Navada et al ASH 2015).
Aims: 1) To determine the in vitro effects of rigosertib alone and in combination with azacitidine on epigenetic signaling in MDS and AML cell lines and on patient samples treated with the combination *in vivo*.
Methods: We investigated the in vitro effects of RIGO alone or in combination on two cell lines: AML (BW90), MDS (MDS-L) and patient samples on global histone post-translational modifications (PTMs) including including methylation (H3K4me3, H3K4me2, H3K27me3, and H3K27me2) and acetylation (H3K9ac, & H3K18ac) levels.
Results: In vitro effects of RIGO alone or in combination on two cell lines: AML (BW90), MDS (MDS-L) altered global histone post-translational modifications (PTMs) including methylation (H3K4me3, H3K4me2, H3K27me3, and H3K27me2) and acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both cell lines, but effects were more pronounced in combination with AZA. Furthermore, Q-PCR studies demonstrated that individual treatment of BW90 and MDS-L with RIGO or sequential treatment with AZA (AZA/RIGO or RIGO/AZA) altered the class I, IIa, IIb, and IV histone deacetylases (HDACs), DNA methyl transferases (DNMT1, 3a and 3b) and chromatin remodeler (KDM2a, SET1, JMJD3 and LRWD1) transcript marks in cellular context suggesting that RIGO potentially acts as a chromatin modifying agent (CMA), in both cell lines. Treatment with RIGO either alone or combined with AZA differentially governed cellular proliferation, cell cycle arrest, apoptosis, histone PTMs, altered expression of cell cycle related proteins, and inactivation of the PI3/AKT signaling pathway in a cell specific manner. Similar effects were seen on patient samples. We further investigated the *in vivo* effects of RIGO combined with AZA on pt bone marrow samples obtained prior to and after one cycle of RIGO and AZA. Interestingly, the histone PTMs, HDACs and chromatin remodelers were significantly altered in the pts BM with increased apoptosis after AZA/RIGO treatment.
Summary/Conclusions: RIGO combined with AZA can govern epigenetic mechanisms and overcome clinical resistance to AZA in MDS pts. RIGO potentially functions as a CMA, in combination with AZA and significantly modifies global histone repression and activation marks suggesting that the combination may overcome AZA resistance through epigenetic remodeling of chromatin structure. Additional studies are underway.

PREVALENCE AND DYNAMICS OF LEUKEMIA-ASSOCIATED MUTATIONS IN ELDERLY INDIVIDUALS WITHOUT HEMATOLOGIC DISORDERS

T Ernst[1,*], J Rinke[1], V Müller[1], A Waldau[1], D Midic[1], F Pester[2], J Landschulze[2], L Rudolph[3], A Hochhaus[1]
[1]Abteilung Hämatologie und Internistische Onkologie, Klinik für Innere Medizin II, Universitätsklinikum Jena, Jena, [2]HausArztZentrum, Kahla, [3]Leibniz Institute for Age Research, Fritz Lipmann Institute e.V. (FLI), Jena, Germany

Background: Aging of the hematopoietic system is accompanied by an increased incidence of myeloid disorders such as myeloproliferative neoplasms (MPN), myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML). Recent data indicates that aberrations in the aged hematopoietic stem cell (HSC) compartment lead to maintenance or expansion of myeloid cells, while the number of lymphoid progenitors stagnates or declines. HSCs may be particularly predisposed to acquiring genetic aberrations since they are the only persistent cells of the blood system. Such mutations may provide enhanced survival, proliferation and self-renewal capabilities, and lead to the propagation of a cell clone.
Aims: Clonal hematopoiesis is frequently observed in elderly people and may represent a premalignant condition. Clonal HSCs acquiring additional mutations may then transform to cancer cells and give rise to a number of myeloid disor-

ders and leukemia. Evidence suggests that genetic alterations found in patients with myeloid malignancies may also be causative for induction of clonal hematopoiesis. Given these circumstances, discrimination between age-associated and leukemia-associated mutations is of major clinical importance, with potential applications in future prevention, therapy and prognosis.
Methods: In order to investigate the prevalence and dynamics of genetic alterations among elderly individuals without hematologic/oncologic disorders, genotyping of the 30 most commonly mutated leukemia-associated genes was performed. For this purpose peripheral blood DNA and buccal cells from a cohort of 50 elderly people (29 women; median age 84 years; range 80-90 years) were collected and analyzed by targeted deep next-generation sequencing (NGS). All mutations were validated in separate runs using genomic DNA isolated from leukocytes and buccal cells to confirm the somatic origin of mutations.
Results: A total of 16 somatic mutations in leukemia-associated genes were identified in 13 of 50 (26%) hematologically normal elderly individuals. One subject presented with two, another subject with three different mutations. Ten of 16 mutations (63%) affected epigenetic modifier genes (*DNMT3A*, n=8; *TET2*, n=1; *IDH2*, n=1). Four somatic mutations affected genes involved in the RNA splicing machinery (*SRSF2*, n=2; *SF3B1*, n=1; *U2AF1*, n=1). Mutations in *TP53* and *NRAS* were identified in two individuals. All but one mutation were missense mutations with cytosine to thymine transitions being the most common base pair change (n=7). Mutations occurred at low variant allele frequencies (VAF) with a median of 11.7% (range: 1.0% to 30.7%) indicating that mutations were presented in only a subset of blood cells. During a 2-year follow-up observation two subjects with mutations in splicing factor genes died, one subject with an *SF3B1* mutation developed pancreatic cancer, the other subject harbored a *U2AF1* mutation and died due to a stroke. All other individuals with mutations are alive without any evidence for a hematologic or oncologic disorder. Mutation kinetics remained virtually stable over two years as measured by targeted NGS (median VAF 13.1%, range 1.0% to 35.3%).
Summary/Conclusions: These findings indicate that the appearance of low-level clones with mutations in epigenetic regulator genes and the RNA splicing machinery is a common age-associated phenomenon which may represent a premalignant condition in the development of hematologic cancers and may also predispose to other aging associated disorders. The question why these subclones are selected in the elderly but apparently enter a stage of clonal size stability without further selection in healthy elderly in contrast to patients with myeloid disorders is of particular interest and needs further investigation.

Background: Recently, we have established a 5-parameter flow cytometry (FCM)-based score allowing for a precise prediction a deletion (5q) in therapy naïve MDS patients (pts.).
Aims: The aim of this prospective study was to test, whether this FCM-based profiling is at least equal to the cytogenetics/FISH-based del(5q) detection for monitoring response to treatment.
Methods: Overall, 164 FCM investigations were performed in 39 pts. with MDS and del(5q) (IPSS-R very low/low: n=17, int: n=9, high/very high n=13) including 27 pts. with isolated del(5q) or one additional cytogenetic abnormality. The majority of analyses were performed in pts. receiving lenalidomide or azacitidine (n=17 and n=15 pts.), or in pts. receiving chemotherapy and/or allogeneic transplantation (n=3), or growth factors (n=4). The del(5q)-FCM-score includes the following 5 parameters: myeloid progenitors (myPC >2%)=3 points, CD45 MFI ratio (lymphocytes: myPC ≤7.0)=10, SSC ratio (granulocytes: lymphocytes<6.0)=2, CD71 (≤20%) on granulocytes=1.5, and female gender=1.5; a score ≥15.0 indicates the presence of del(5q). A standardized FCM (lyse-stain-wash) and cytogenetics/FISH were performed according to ELN guidelines at the TU of Dresden and VUMC of Amsterdam.
Results: Before therapy, in 56 cytogenetic/FISH analyses in 39 MDS pts. a del(5q) was detectable. In 48/56 (86%) FCM measurements, performed in parallel, a del(5q) could be predicted using the del(5q)-FCM-score. A complete cytogenetic response (CCR) was detectable in 17 pts. (41 different evaluations). Remarkably, all determined del(5q)-FCM-scores matched the above mentioned CCR (sensitivity=100%). Otherwise, in 32 pts. (69 different evaluations) del(5q) was still detectable by cytogenetics/FISH, which was accompanied by a matching del(5q)-FCM-score in 58 measurements (specificity=84%). Next, we focused on those pts. who presented with a typical del(5q)-FCM-score before therapy (32 pts.; 49 measurements; median score=16.5). Again, all 31 cytogenetic evaluations, resulting in a CCR, showed a matching del(5q)-FCM-score (sensitivity=100%; median score=13.0). On the other side, 52 of the 54 analyses (96%) without CCR showed a properly high del(5q)-FCM-score (median score=16.5). Furthermore, we compared cytogenetics/FISH and del(5q)-FCM-score with additional methods for response monitoring as cytomorphology, two well established diagnostic FCM scores: FCSS (flow cytometry scoring system; Wells et al. Blood 2003) and the diagnostic score (Ogata et al. Haematologica 2012), as well as the assessment of hematological improvement (HI). Thus, cytomorphology and FCSS, analyzing dyspoiesis of multiple cell lineages, showed a CR or disappearance of a MDS typical FCSS in only around half of all investigations being in cytogenetic CR (sensitivity: 48% and 58%), but those two methods revealed a high specificity (100% and 96%). On the other side, the analysis of HI was highly sensitive (90%) but not specific (56%). Finally, the use of the 4-parameter Ogata score ended up with a nearly as high sensitivity (90%) and specificity (87%) as cytogenetics/FISH and the del(5q)-FCM-score.
Summary/Conclusions: Flow cytometry-based detection of a del(5q)-specific immunophenotype is feasible and can serve as a rapid tool for response monitoring during treatment with disease-modifying drugs. At the moment, we validate the FCM-scores in a larger multicentric study within the iMDS-Flow working group of the ELNet evaluating if response prediction by FCM might result in a better separation of the patients' survival.

ABT-199 EFFECTIVELY INDUCES APOPTOSIS IN HIGH-RISK MDS PROGENITOR CELLS IRRESPECTIVE OF PROGNOSTICALLY ADVERSE MUTATIONS OF TP53, EZH2, RUNX1, AND ASXL1

J Kauschinger[1,*], S Jilg[1], V Reidel[1], C Müller-Thomas[1], U Höckendorf[1], J Schauwecker[2], K Götze[1], C Peschel[1], P Jost[1]
[1]III. Medizinische Klinik für Hämatologie und Internistische Onkologie, Klinikum rechts der Isar, Technische Universität München, [2]Klinik für Orthopädie und Sportorthopädie, Klinikum rechts der Isar, Technische Universität München, Munich, Germany

Background: Myelodysplastic Syndromes (MDS) is a group of heterogeneous diseases with a broad spectrum of clinical outcomes. As we could recently show, the BCL-2 selective inhibitor ABT-199 effectively induces apoptosis in leukemic progenitors, as well as in blast cells of patients with high-risk MDS and secondary acute myeloid leukemia (sAML), while the healthy progenitor cell population was only marginally affected. As current therapeutic strategies such as Azacytidine have only a short response duration alternative regimes are urgently needed. Classification systems such as the International Prognostic Scoring System (IPSS) help to estimate the overall survival and the risk of developing a sAML. Disease-related molecular abnormalities are not incorporated in these scoring systems at the moment. However mutations of TP53, EZH2, RUNX1, and ASXL1 have been shown to identify patients with a shorter survival than predicted by the IPSS.
Aims: We were interested in analyzing whether ABT-199 could overcome resistance to apoptosis in high-risk MDS/sAML despite prognostically adverse mutations in TP53, EZH2, RUNX1, and ASXL1.
Methods: Purified bone marrow mononuclear cells (BMMNC) were treated with 1μM ABT-199 or a soluble control (DMSO) for 72h *in vitro*. Apoptosis was analyzed by flow cytometry after staining for 7-AAD, Annexin V, and CD34 as a progenitor marker. The long-term effect was investigated by colony formation assay. Mutational analysis was performed by Sanger sequencing at a certified laboratory (Munich Leukemia Laboratory). In total, seven healthy bone marrow samples and 38 MDS/sAML bone marrow samples (20 patients with proven wildtype alleles for TP53, EZH2, RUNX1, and ASXL1 as well as 18 patients with mutations in at least one of the indicated genes) were investigated.

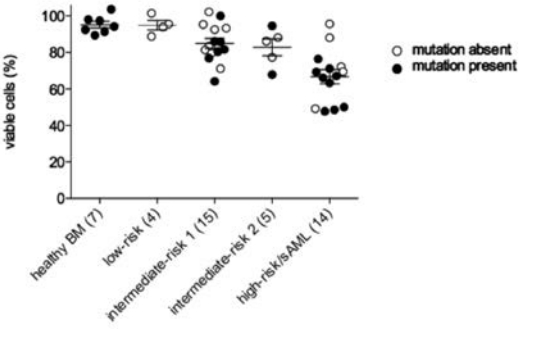

Figure 1. FICOLL-purified CD34+ BMMNC were treated for 72h with 1μM ABT-199 or a vehicle control (DMSO). Apoptosis was measured by flow cytometry. Each circle represents the ratio of viable cells after ABT-199 treatment to viable cells after sole vehicle treatment. Student's t-test showed no significant difference between mutated and not mutated samples within one risk group. When compared with healthy controls, we found that induction of apoptosis was significantly increased in the stem/progenitor population from IPSS-classified patients with intermediate-risk 1 and 2 MDS, high-risk MDS, and sAML.

Results: Prognostically bad molecular genetics including mutations of TP53, EZH2, RUNX1, and ASXL1 did not affect the response to ABT-199 treatment

in MDS progenitor cells. No difference in the induction of apoptosis was seen between mutated and not mutated samples. As expected, the effect of ABT-199 correlated with MDS disease progression to elevated clinical risk groups. In addition, the long-term effect of BCL-2 inhibition could be analyzed in three patients of the high-risk MDS/sAML group with proven mutations by colony formation assays. Here we show that ABT-199 effectively killed colony-forming stem/progenitor cells from patient samples of the high-risk MDS/sAML subgroup.
Summary/Conclusions: We conclude that ABT-199 is a promising drug for patients with high-risk MDS/sAML irrespective of prognostically adverse mutations of TP53, EZH2, RUNX1, and ASXL1.

Background: Myelodysplastic syndromes (MDS) are a group of hematopoietic stem cell disorders at high risk of developing acute myeloid leukemia (AML). Both disorders are characterized by the accumulation of a wide variety of genetic and epigenetic aberrations in hematopoietic progenitor cells, resulting in altered cell growth and differentiation. However, the molecular mechanisms underlying the evolution of MDS to more aggressive stages remain to be discerned.
Aims: To analyze common deregulated genes and gene pathways, which may potentially be associated with the progression of the disease.
Methods: A multi-platform genome-wide expression profiling was carried out in a series of 73 patients with normal cytogenetics and 17 controls with non-malignant disorders. Two platforms for gene expression analysis were used: the Human Exon 1.0 ST (test group) and the Human Genome U133 Plus 2.0 (validation group) (*Affymetrix*). The study was based on the analysis of gene expression changes occurring from non-malignant bone marrow conditions through different stages of MDS and towards AML. Two-steps analysis was carried out: (1) Identifying genes which expression levels evolved following an increasing/decreasing trend during the progression of the disease (Normal, Low-Risk MDS, High-Risk MDS and AML); (2) Identifying common expression patterns among the groups of genes with increasing/decreasing trends. At the end, only the genes that appeared deregulated in common with the two platforms were considered.
Results: This methodological approach allowed us to identify common genes and gene pathways that were progressively up-/down-regulated in the transition from non-malignant bone marrow conditions to early MDS stages (Low-Risk MDS), which also remained progressively deregulated during the progression towards advanced MDS (High-Risk MDS) and AML. These genes were classified in 4 major patterns: Pattern 1, MDS/AML-up, included a set of 83 genes that began to be up-regulated in Low-Risk MDS and remained progressively altered during the progression towards High-Risk MDS, with the maximum in AML (*NPM1*, *MYST1*, *RPL22*, *RPS6*); Pattern 3, AML-up, consisted of 26 progressively up-regulated genes showing the biggest change in their expression level in the transition from High-Risk MDS to AML (*HOXA9*, *MEIS1*, *FLT3*). By contrast, patterns 2 (70 genes) and 4 (32 genes), MDS/AML-down and AML-down, respectively, included those genes that were progressively down-regulated during the evolution of the disease, showing the minimum levels in AML (*CEACAM3*, *CRISP3*, *CAMP*, *MMP9*). These common and dynamically deregulated genes implicated in the progression of the disease were related to key cellular functions of known relevance in MDS. Thus, apoptosis, DNA damage response, ribosome and translation pathways, and chromatin assembly were progressively up-regulated as the disease progressed, since early MDS stages, while the immune response showed an increasing down-regulation. In addition, the transition from advanced MDS to AML would be characterized by a marked up-regulation of cell proliferation and a differentiation arrest.
Summary/Conclusions: The present study demonstrated the presence of a progressive deregulation of several cellular functions, with common deregulated genes, in the transition from non-malignant bone marrow conditions through early and advanced MDS to AML. This evolution seems to occur in an orchestrated way, involving common deregulated functional pathways.

BONE HOMEOSTASIS IS SIGNIFICANTLY ALTERED IN A MYELODYSPLASTIC SYNDROME MOUSE MODEL

H Weidner[1,*], M Rauner[2], E Bulycheva[1], C Khandanpour[3], M Bornhäuser[1], LC Hofbauer[2,4], U Platzbecker[1,4]
[1]Department of Medicine I, Technical University Dresden, [2]Division of Endocrinology, Diabetes, and Bone Diseases, Department of Medicine III, Technical University Dresden, Dresden, [3]Department of Hematology, West German Cancer Center, University Hospital Essen, University Duisburg-Essen, Essen, [4]German Cancer Consortium (DKTK), partner site Dresden and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: Myelodysplastic syndromes (MDS) are diseases of the elderly characterized by an ineffective hematopoiesis leading to cytopenias. Increasing evidence suggests a role of the bone microenvironment in influencing the development and progression of MDS. However, the underlying mechanisms are not fully understood. NUP98-HOXD13 (NHD13) mice develop MDS-like symptoms at an age of 6 months, including anemia and an increased number of blasts in the bone marrow. Thus, it is a suitable model to study bone homeostasis in the setting of MDS.
Aims: Here, we assessed bone homeostasis in NHD13 mice before (2 months of age) and after (6 months of age) the onset of MDS.
Methods: Micro-computed tomography was performed using the femurs of 2- and 6-month-old male NHD13 and wild-type mice. Bone samples were then histologically stained for the osteoclast marker tartrate-resistant acid phosphatase (TRAP). The bone formation rate was assessed using dual calcein labeling. In addition, serum was analyzed by ELISAs to assess the bone turnover markers C-terminal telopeptide of type I collagen (CTX-I) and procollagen type I propeptide (P1NP).
Results: At 2 months of age NHD13 mice had not yet developed any cytopenia. Nevertheless, there was already an apparent alteration of bone homeostasis. The trabecular bone volume (BV/TV) [-26%; $P<.05$] and trabecular number (Tb.N) [-20%; $P<.01$] were reduced in the femurs of NHD13 compared to wild-type mice. Serum markers indicated an increased bone turnover in NHD13 mice [P1NP 4-fold, $P<.01$; +17% CTX). At the age of 6 months the NHD13 mice had developed anemia indicated by a reduced hematocrit, -17%, $P<.001$. BV/TV in these mice was unchanged when compared with those of wild-type mice. Of interest, the number of trabeculae was reduced in the 6-month-old NHD13 mice [-15%; $P<.001$] whereas their thickness was increased [+18%; $P<.01$], suggesting increased osteoblast activity. In fact, histology indicated an increase in the osteoblast surface in the femurs from NHD13 by 10% [$P<.01$] and also the bone formation marker P1NP was elevated in the serum by 54% [$P<.05$] compared to wild-type mice. Although NHD13 mice had a lower osteoclast-covered surface on the bone [-78%; $P<.01$], the bone resorption marker CTX-I was increased by 32% [$P<.05$].
Summary/Conclusions: NHD13 mice show an altered bone homeostasis, which is characterized by a high bone turnover. This is in line with an abnormal interaction of dysplastic hematopoietic cells with the bone compartment.

Lee Moffitt Cancer Center and Research Institute, Tampa, FL, United States

Background: Chronic myelomonocytic leukemia (CMML) is a subset of myelodysplastic/myeloproliferative neoplasms (MDS/MPN), which are morphologically distinct from myelodysplastic syndromes (MDS). Nevertheless, CMML and MDS share several genetic defects and dysplastic features. Moreover, CMML can evolve from MDS, designated as secondary CMML (sCMML). The molecular characteristics of sCMML, which are distinct from those of primary CMML, remain to be elucidated.

Aims: By comparing the genetic/cytogenetic abnormalities between sCMML and other myeloid malignancies, we clarify the molecular pathogenesis of sCMML.
Methods: A total of 601 cases with different myeloid neoplasms, including *de novo* CMML (n=89), sCMML (n=26), MDS (n=348), and secondary AML (sAML) (n=138) were subjected to the analysis, combining the genotyping data from our cohort and publicly available datasets. Serial samples were available for 7 cases.
Results: In the *de novo* CMML cohort, the most frequently mutated genes included *TET2* (40%), *SRSF2* (30%), *ASXL1* (24%), *RUNX1* (16%), *CBL* (11%), *EZH2* (11%), *ZRSR2* (11%), and *KRAS* (10%), which, combined, accounted for 74% of the CMML cases. In the sCMML cohort, by contrast, *RUNX1* (32%), *TET2* (32%), *ASXL1* (24%), *SF3B1* (24%), and *SETBP1* (20%) represented common genetic alterations, together with -7/del(7q) (43%), complex karyotype (38%), and del(5q) (24%). In multivariate analysis comparing the spectrum of mutations between sCMML and *de novo* CMML, *SF3B1*, and *RUNX1* mutations were enriched in sCMML patients. In patients with sCMML, *SF3B1* mutations supposed to be acquired prior to *RUNX1* mutations based on the comparison of their variant allele frequencies. Most likely, *SF3B1* mutations were acquired as founder events in the MDS phase and *RUNX1* mutations occurred during sCMML evolution. However, *RUNX1* mutations were not always identified in patients with sCMML, suggesting that other causes are also related to sCMML evolution. To further identify genetic lesions specifically associated with CMML evolution, we compared the spectrum of mutations between sCMML and MDS. Multivariate analysis revealed that mutations in *SETBP1*, *RUNX1, TET2*, and *NRAS*, del(5q), and -7/del(7q) were significantly and independently associated with sCMML. Then we divided *de novo* CMML cases into 2 categories; Type-1 with ≥2 of these lesions (n=13) and Type-2 with<2 (n=54). Patients with Type-1 CMML had a significantly shorter overall survival compared to Type-2 disease (HR=3.73, 95%CI 1.78-7.79, P<0.001). Serial sample analysis revealed that mutations in *SETBP1*, *RUNX1*, and *NRAS*, and del(7q) tended to be newly acquired during evolution to sCMML. However, the lesions extracted in the comparison between sCMML and MDS were also detected in our cohort of sAML; -7/del(7q) (23%), del(5q) (20%), mutations in *SETBP1* (4%), *RUNX1* (19%), *TET2* (22%), and *NRAS* (7%). To investigate what lesions are really characteristic to sCMML evolution from MDS, we compared the frequencies of genetic lesions between sCMML and sAML. We found *SF3B1*, *SETBP1*, *NRAS*, and *RUNX1* mutations, as well as complex karyotype, and -7/del(7q) were significantly enriched in sCMML, which largely overlapped with the lesions associated with evolution from MDS to sCMML.

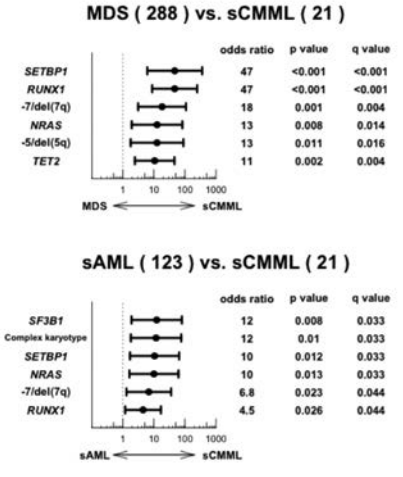

Figure 1.

Summary/Conclusions: In this study, a novel set of lesions associated with sCMML evolution (*SETBP1*, *RUNX1, TET2*, and *NRAS* mutations, del(5q), and -7/del(7q)) was identified and shown to be able to stratify *de novo* CMML into clinically distinct subgroups. By genotyping serial samples and comparing genetic lesions between sCMML and sAML, this set of lesions was thought to be characteristic to sCMML evolution. Our study demonstrated that specific genetic events might play an important role in sCMML evolution from MDS.

E1197

SCAPER AND RPRD1A: TWO NOVEL CANDIDATES IN THE PATHOGENESIS OF FAMILIAL PLATELET DISORDER WITH PROPENSITY TO DEVELOP MYELOID MALIGNANCIES (FPD/AML)

F Majidi[1,*], N Rahner[2], S Braunstein[3], S Martino[1], J Kaivers[1], M Wulfert[1], U Germing[1], R Haas[1], N Gattermann[1]
[1]Hematology/Oncology, [2]Human Genetics, [3]Pathology, Heinrich-Heine-University, Düsseldorf, Germany

Background: A patient with acute myeloid leukemia (AML) secondary to MDS and a strong family history of thrombocytopenia and myelodysplastic syndromes was referred to our clinic for evaluation of the possible hereditary nature of myeloid malignancies in the family.
Aims: To identify novel myeloid malignancy-predisposing mutations and contribute to a better understanding of biological processes involved in the development of myelodysplasia, also in cases of sporadic MDS.
Methods: Whole exome sequencing was performed on DNA from peripheral blood of 3 family members with myelodysplasia, one of whom developed AML. Sanger sequencing was used to determine the frequency of the identified mutations in 13 family members as well as 36 sporadic cases of MDS. Corresponding protein expression was evaluated by immunohistochemistry. Structural modelling using Pymol software was performed to estimate the probable impact of mutations on the three-dimensional structure of the corresponding proteins. Using site-directed mutagenesis we have recently created plasmids carrying the identified mutations, which will allow us to further evaluate their functional consequences.
Results: Two confirmed missense mutations were identified by whole exome sequencing. They affect SCAPER (S-phase cyclin A-associated protein in the endoplasmic reticulum) and RPRD1A (regulator of nuclear pre-mRNA domain-containing protein 1A). The SCAPER E342K and RPRD1A I143T mutations were detected by Sanger sequencing in 9 and 10 out of 13 family members, respectively. Molecular modelling showed that both mutations can significantly change the three-dimensional structures of the corresponding proteins. In one of the mutated cases where bone marrow biopsy material was available, both SCAPER and RPRD1A showed high protein expression in the cytoplasm and nucleus. We sequenced the SCAPER and RPRD1A mutation site in 36 patients with sporadic MDS, all of whom showed the wild type sequence. However, when protein expression of SCAPER and RPRD1A was evaluated immunehistochemically on a tissue microarray including core biopsies from 45 patients with MDS, both proteins showed marked heterogeneity of expression level among patients. Lack of RPRD1A expression was associated with significantly shorter overall survival (24 *vs* 50 months, p<0.03, HR=2.2), independent of the revised international prognostic scoring system (IPSS). Patients with high expression of SCAPER showed longer median survival than patients with low expression (50 *vs* 28 months) but the difference did not reach statistical significance. Interestingly, despite strong *inter*individual heterogeneity, there was strong *intra*individual correlation of protein expression between SCAPER and RPRD1A (r=0.818, p<0.0001).
Summary/Conclusions: Molecular modelling convinced us that these two non-conservative mutations cause significant changes in three-dimensional structure of both SCAPER and RPRD1A proteins, which may lead to altered affinity to their main binding partners, *i.e.* Cyclin A and RNA polymerase 2, respectively. Our findings suggest that SCAPER and RPRD1A should be included among the genes to be analysed in cases of familial thrombocytopenia with propensity for myeloid malignancies. Furthermore, strong heterogeneity of SCAPER and RPRD1A protein expression among patients with sporadic MDS, together with the prognostic impact of protein expression, suggests that both genes may play a role in MDS pathogenesis. Mutation analysis covering the full length of SCAPER and RPRD1A genes, as well as analysis of the epigenetic status of both genes may reveal further insight.

REAL-TIME DEFORMABILITY CYTOMETRY (RT-DC) AS NOVEL DIAGNOSTIC TOOL IN MYELODYSPLASTIC SYNDROMES

E Bulycheva[1,*], O Otto[2], M Herbig[2], H Weidner[1], U Baschant[3], S Herold[1], A Jacobi[2], M Kramer[1], M Stiehler[4], M Bornhäuser[1], C Thiede[1], L Hofbauer[3,5], J Guck [2], U Platzbecker [1 5]
[1]Medical Department I, University Hospital Carl Gustav Carus Dresden, [2]Biotechnology Center, Technical University Dresden, [3]Medical Department III, [4]University Center for Orthopaedics and Trauma Surgery, University Hospital Carl Gustav Carus Dresden, Dresden, [5]German Cancer Consortium (DKTK), partner site Dresden and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: Myelodysplastic syndromes (MDS) are a group of disorders, which are often difficult to differentiate from reactive and toxic conditions causing cytopenia. Contractility and cytoskeletal structure of hematopoietic stem cells in MDS are known to differ from the healthy counterparts. Thus, detection of the cells with abnormal mechanical properties could be a promising diagnostic procedure for patients with potential MDS.
Aims: Therefore we aimed to evaluate if real-time deformability cytometry (RT-DC) can be a reliable diagnostic and prognostic tool for MDS patients, as well as to clarify molecular factors, which are associated with differential cell deformability.
Methods: We analyzed MACS-separated CD34+ cells from 19 patients with MDS (median age at BM sampling 65 years [range, 44-87]; m/f=13/6) and 8 age-matched healthy donors (62 years [range, 43-83]; m/f=3/5). Mechanical characterization was carried out using RT-DC at three flow rates according to previously described protocol (Otto O. et al., *Nat Methods*, 2015). With this technology, single cells are flowed through a microfluidic channel constriction and deformed without contact by shear stress. Statistical significance was

assessed by 2-sided Kolmogorov-Smirnov test. Changes in cell cycle were evaluated by flow cytometry using propidium iodide staining. Molecular alterations were evaluated by targeted resequencing on a MiSEQ instrument using an amplicon assay (True Sight Myeloid Panel, Illumina) which covers 54 genes or gene hotspots related to myeloid neoplasms. Cytogenetic analysis was performed in all MDS patients. Overall survival (OS) was estimated using Cox proportionate regression models.
Results: Mean deformability for CD34+ cells of MDS patients was significantly lower than in control cells (0.0241 *vs* 0.0272, accordingly, p=0.018). MDS CD34+ cells underwent significantly less mitosis (2.4% *vs* 17.4%, p=0.002), arresting mostly in G1 phase (91.5% *vs* 66.7%, p<0.001). CD34+ cells from patients with mutations in *RAS*-pathway tended to be more deformable, whereas *RUNX1*-mutated cells appeared stiffer. Cytogenetics had no influence on mechanical properties. The deformability appears to be predictive for the OS starting from time of BM sampling, as 1-year OS in patients with more deformable cells (>median) was 72.9% *vs* 37.0% in patients with less deformable cells.
Summary/Conclusions: RT-DC provides a novel tool to reveal substantial differences in mechanical properties of CD34+ cells of MDS patients compared to healthy donors. This might allow incorporating this technique into diagnostic approaches of MDS patients.

E1199

SPATIAL INTERACTION OF CYTOGENETIC AND MOLECULAR MUTATIONS IN MYELODYSPLASTIC SYNDROMES
C Ganster[1], K Shirneshan[1], S Dierks[1], B Glass[2], R Stuhlmann[2], J Bäsecke[3], B Sievers[4], S Simon-Becker[5], J Flach[1], R Martin[1], U Bacher[1], D Haase[1,*]
[1]Clinics of Hematology and Medical Oncology, Specialized Diagnostic Laboratories INDIGHO, University Medicine Göttingen, Göttingen, [2]Asklepios Klinik St. Georg, Hamburg, [3]Department of Hematology and Oncology, St. Josefs-Hospital, Cloppenburg, [4]Onkologische Praxis, Hildesheim, [5]MVZ Alsfeld, Alsfeld, Germany

Background: In myelodysplastic syndromes (MDS), several frequent molecular mutations affect the same chromosomal regions as common cytogenetic mutations. These regions are potential targets of total loss of function of cancer-protective genes or could be involved in gain of function of oncogenes. Both alleles could be simultaneously affected by two different mutation types, one allele by a molecular mutation and the second allele by a cytogenetic mutation (deletion, copy number neutral loss of heterozygosity (CN-LOH) and others). Up to now the impact of biallelic mutations composed by a molecular and a cytogenetic mutation on leukemogenesis is unknown in MDS.
Aims: The aim of our study was to identify and to characterize such biallelic mutations (composed by a molecular and a cytogenetic mutation) to delineate the frequency and the potential clinical significance in MDS.
Methods: We included 209 patients in our analysis: 144 proven MDS, 27 suspected MDS with typical genetic aberrations, 9 myelodysplastic/myeloproliferative neoplasms (MSD/MPN), and 29 secondary acute myeloid leukemias (sAML) after MDS. Molecular analysis was done by Sanger sequencing including up to 17 of the most frequently mutated genes in MDS. The basis of cytogenetic analysis was conventional chromosome banding that was complemented by interphase fluorescence in situ hybridization (FISH), multicolor FISH and/or molecular karyotyping (SNP array analysis).
Results: Overall, genetic mutations were detected in 84.7% of patients. Cytogenetics identified mutations in 46.9% and sequencing revealed mutations in 70.8% of patients. In 20 patients (9.6%) a molecular mutation was located in a chromosomal region that was in addition affected by a cytogenetic aberration (assumed to affect the second allele). Such biallelic mutations were more frequent in MDS-RAEB (9/51, 18%), MDS/MPN (2/9, 22%), and sAML (5/29, 17%), but rarer in low-risk MDS (4/93, 4%). The highest frequency of such biallelic mutations was detected in patients with *CBL* mutations: 2/3 *CBL* mutations were located within a CN-LOH of 11q. Furthermore, 4/11 patients with *EZH2* mutations had a cytogenetic 7q aberration (2x deletion, 2x CN-LOH), 4/13 patients with *TP53* mutations additionally showed cytogenetic loss of 17p. We detected two patients with a *SRSF2* mutation and a simultaneous isochromosome iso(17q) that results in gain of 17q. Other molecular mutations involved in such biallelic mutations were: *SRSF2* (1x CN-LOH), *TET2* (2x loss, 1x CN-LOH), *DNMT3A* (2x CN-LOH), and *RUNX1* (2x CN-LOH).
Summary/Conclusions: Biallelic mutations composed by a molecular and a cytogenetic mutation affecting the same chromosomal region were recurrently identified in sAML and MDS/MPN in our study but were detected also in low-risk MDS albeit at lower frequency. Co-occurrence of molecular and cytogenetic lesions affecting e.g. *TP53*/7q, *EZH2*/7q or *CBL*/11q suggests individual pathomechanisms resulting in homozygous loss of function of potential tumor suppressor genes. The co-occurrence of activating *SRSF2* mutations and iso(17q) or CN-LOH of 17q might have an oncogenic effect. Biallelic mutations could be indicative for a regional genetic instability promoting disease progression. According to the two-hit hypothesis such "composed" biallelic mutations might arise stepwise. Therefore, they could refer to previous genetic evolution and consequently to advanced stages of the disease. Sixteen of the 20 biallelic mutations identified in our study affected patients with high-risk MDS or sAML. Thus, patients with biallelic mutations due to a molecular and a cytogenetic mutation in parallel could be at high risk for further progression of the disease.

MONUCLEAR MYELOID-DERIVED SUPPRESSOR CELLS (MO-MDSC) EXPANSION AND PROGRESSION IN MYELODYSPLASTIC SYNDROMES
F Hernández Mohedo*, P Montes Ramos, S Maroto Gallego, A Cruz Díaz, E Espinosa de los Monteros, M Jurado Chacón, F Ruiz Cabello, P Jiménez Gámiz
Hematology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: Myeloid Derived Suppressor Cells" (MDSC) are a heterogeneous population of inmature myeloid cells constituent of bone marrow microenvironment, whose expansion hampers the host anti-tumor immune response. They can play a pathogenetic role in the development of ineffective hematopoiesis in myelodysplastic síndromes (MDS), and contribute to progression to acute myeloid leukemia (AML), through inmunotolerance and as a cellular effectors that suppress hematopoiesis. The mechanisms that determine the evolution to AML are not entirely clarified although, a role of the immune response has been suggested. In this sense, the bone marrow microenvironment expansion of suppressor cells of monocytic origin (Mo-MDSC) and T cell inmunosupressive efector (T_{regs}) can contribute to tumor progression.
Aims: Our aim has been to investigate a possible role of the myeloid supressor cells of monocytic origin (CD14+HLA-DR$^{low/-}$) and T_{regs} in the development of ineffective hematopoiesis in myelodysplastic síndromes (MDS), that may contribute to the development and progression to acute myeloid leukemia (AML) of MDS.
Methods: We performed a prospective analysis of a group of 31 patients with MDS and AML evolved from MDS and a control group of 40 healthy subjects. It was analyzed by multiparametric flow cytometry techniques to study the presence of MDSC-Mo (CD14+HLA-DR$^{low/-}$) cells and CD34+blasts, in peripheral blood and bone marrow in both MDS patients and control cases. The monoclonal antibodies marked with their respective fluorochromes were: CD45-V_{500}, CD3-V_{450},. CD4-PER, CD8-APH- 7, CD19-PE-CY7, CD56-PE-CY7, CD127-APC, CD34-APC, CD64-FICT, DR- V_{450}, CD25-PE-CY7, CD14-PE and CD64-FICT and anti DR-V_{450}.The clinical and biological profile of MDS and control group has analyzed with statistical software IBM SPSS.19.
Results: In the 31 peripheral blood samples of patients with MDS and AML evolved from MDS, the WHO-2008 diagnostic classification was: RCUD(4), RCMD(8), RARS and RCMD-RS(2), RAEB-1(3), RAEB-2(6), MMCL-1(5) and AML evolved from MDS (3). We observed a positive correlation between MDSC cells with phenotype CD14$^+$ HLA-DR$^{low/-}$ and CD34+blasts in peripheral blood (p=0,001). In addition, the frequency of expression of CD14$^+$ HLA-DR$^{low/-}$ cells, was significantly elevated in MDS patients as compared to the control cases (26,52+/-5,47 *vs* 6,66+/-1,06; p=0,014). No significant results were obtained in bone marrow for the studied subpopulations. With regard to WHO classification, we observed a higher value of MDSC in RAEB-2 and AML *vs* other MDS, almost statisticaly significant (45,40+/-12,70 *vs* 18,80+/-5,04; p=0.055). The analysis of prognostic scoring system IPSS y IPSS-R shows higher incidence of Mo-MDSC in High risk IPSS (High+Int-2 *vs* Int-1 and Low risk) (59,55+/-14,14 *vs* 15,12+/-3,61; p=0.004) and High risk IPSS-R (Very High, High and Int *vs* Low and very low risk)(37,06+/-7,99 *vs* 9,49+/-4,05; p=0.006). Increase frequency of Mo- MDSCs was also linked to poor and intermediate cytogenetic risks (59,55+/-14,14 *vs* 15,10+/-3,94; Poor and Int *vs* Good and Very good; p=0.006).
Summary/Conclusions: The expansion of cells with MDSCs phenotype of monocytic origin can suppose a higher risk in myelodysplastic syndromes transformation, favouring the immune escape, which may be important for understand the pathogenesis of high-risk MDS and with poor cytogenetic risks. The good correlation between myeloid supressor cells of monocytic origin (CD14+HLA-DR$^{low/-}$) and CD34+blasts in peripheral blood, allows monitoring of patients with MDS.

E1201

ABERRANT METHYLATION OF PROMOTER REGIONS OF SOX7, P15INK4B AND WNT PATHWAY ANTAGONIST GENES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES
I Kostroma[1,*], S Gritsaev[1], Z Sidorova[2], S Kapustin[2], A Chechetkin[1]
[1]hematological clinic, [2]biochemical laboratory, Russian Institute of Hematology and Blood Transfusion, St.Petersburg, Russian Federation

Background: Epigenetic aberrations, including hypermethylation of CpG islands in tumor-suppressor genes, are supposed to be a key mechanism of myelodysplastic syndrome (MDS) development.
Aims: To find out the association between methylation status of *SOX7*, *p15^{INK4b}*, *SFRP1*, *SFRP4* and *SFRP5* genes and some hematological features and overall survival (OS).
Methods: The data of 46 MDS patients with median age of 67.5 years were analyzed. MDS was diagnosed according to WHO classification. Methylation-specific PCR was used to study the methylation status.
Results: Aberrant methylation of ≥1 genes was found in 43 patients (93.5%). The most frequently findings were *SOX7* (84.8%), *SFRP1* (71.7%) and *p15^{INK4b}*

(54.3%) genes methylation. Methylation of 1, 2, 3, 4 and 5 genes simultaneously was detected in 10.9%, 28.3%, 26.1%, 19.6% and 8.7% of patients, respectively. There was no any difference in the number of patients with *SFRP1*, *SFRP4*, *SOX7* and *p15^{INK4b}* methylation in the groups with different bone marrow blasts counts. Methylation of *SFRP5* gene was more frequently seen in patients with refractory anemia with excess of blasts (RAEB): 43.5% *vs* 13.0% in patients without excess of blasts; OR=5.1, 95%CI: 1.2-22.3, *p=0.047*. The patients without excess of blasts were characterized by methylation of 0-1 genes: 26.1% *vs* 8.7% of RAEB patients, although the difference was not significant. At the same time, there was the tendency to increase of the number of cases with 3-5 methylated genes in patients with 10-19% blasts compared to patients with 5-9% blasts. In the whole MDS group, there was no any correlation between the number of methylated genes and patient's age, number of bone marrow blasts or karyotype. Increased number of methylated genes did not influence on the OS.

Summary/Conclusions: MDS progression is associated with enhancement of epigenetic disturbances leading to increase of the number of methylated genes, in particular, *SFRP5*

E1202

IRON OVERLOAD-ASSOCIATED GENETIC INSTABILITY IN MYELODYSPLASTIC SYNDROME

G Westhofen[1,*], C Ganster[1], F Beier[2], T Rassaf[3], HK Al-Ali[4], R Stuhlmann[5], B Glass[5], U Bacher[1], TH Brümmendorf[2], U Germing[6], N Gattermann[7], D Haase[1]

[1]Clinics of Hematology and Medical Oncology, Specialized Diagnostic Laboratories INDIGHO, University Medicine Göttingen, Göttingen, [2]Department of Hematology, Oncology, Hemostaseology, and Stem Cell Transplantation, RWTH Aachen University Hospital, Aachen, [3]Department of Cardiology, Pneumology, Angiology, Heinrich-Heine-University Düsseldorf, Düsseldorf, [4]University Hospital of Leipzig, Leipzig, [5]Asklepios Klinik St. Georg, Hamburg, [6]Depatment of Hematology, Oncology, and clinical Immunology, [7]Department of Hematology, Oncology, and clinical Immunology, Heinrich-Heine University Düsseldorf, Düsseldorf, Germany

Background: Not only clinical experience, but also numerous experimental and animal-modell studies demonstrated that iron overload (IO) negatively impacts on survival outcomes in patients suffering from myelodysplastic syndromes (MDS). However, the molecular mechanisms of IO induced genetic damage have neither been sufficiently demonstrated nor been fully understood.
Aims: We aimed to investigate the association between IO, measured as serum ferritin (SF) as suitable surrogate marker, and genetic instability, considered to be a main factor responsible for MDS progression to secondary acute myeloid leukemia (sAML).
Methods: We included 55 patients (median age 74 years, 62% males). The majority (n=50) had different MDS subtypes, 5 patients had myelodysplastic/myeloproliferative neoplasms (MSD/MPN). The patients were divided into two subgroups with normal and elevated SF levels, using 275 µg/l as cut-off for elevated SF. 26 patients showed normal SF levels (median: 65 µg/l, range: 8-256 µg/l), while 29 patients showed elevated SF levels (median: 1150 µg/l, range: 283-3872 µg/l). Various parameters for genetic instability were analyzed and statistically compared between the two subgroups with normal and elevated SF: a) molecular karyotyping (SNP array analysis) to determine the total genomic alterations (TGA) size, b) immunofluorescent determination of γH2AX-foci for quantifying DNA double-strand breaks (DSB) in CD34+ peripheral blood (PB) cells, c) telomere length (TL) of PB granulocytes and lymphocytes, and d) plasma nitric oxide metabolites as markers for oxidative stress.
Results: Subsequent analyses revealed a positive correlation of SF levels and bone marrow blast counts. Thus, all further analyses were adjusted by a logistic regression model for unevenly distributed blast counts. PB nitric oxide metabolites did not correlate with SF level (N=33 patients with available data). Iron overload measured by SF showed a significant correlation with the number of γH2AX-foci per CD34+ PB cell (r=0.481, p=0.039). The median number of γH2AX-foci per CD34+ PB cells was significantly highlower in 8 patients with normal SF as compared to 10 patients with elevated SF level (1.9 *vs* 5.7 γH2AX-foci/CD34+ cell (adjusted p=0.050). TGA size was positively correlating with SF levels (r=0.397, p=0.026) and with marrow blast counts (r=0.381, p=0.077). TGA size was higher in 28 patients with elevated SF (median: 34 Mbp, range: 0-248 Mbp) as compared to 23 patients with normal SF (median: 0 Mbp, range: 0-155 Mbp, adjusted p>0.5). Telomere length and IO showed a significant negative correlation (r=-0.497, p=0.002). TL in granulocytes was significantly reduced in 13 patients with elevated SF (median: -1.61 kb, range: -4.06-1.31) as compared to 13 patients with normal SF levels (median: 0.48 kb, range: -3.13-5.32 kb, adjusted p=0.024). In contrast, lymphocyte TL was not influenced by the SF level.
Summary/Conclusions: In this study, IO was significantly associated with numerous markers of genetic instability. Elevated SF levels were promoting the TGA size, spontaneous nuclear damage assessed by γH2AX-foci and replicative stress (TL) in granulocytes representing the myeloid compartment, whereas the lymphocyte compartment remained uninfluenced by IO. These findings further support the assumption of IO being closely related to leukemic transformation in MDS. Our results contribute to explain the association of IO and disease progression found in several studies. Whether these results may have consequences for diagnostics and therapeutic decision-making in patients with MDS remains to be further investigated.

CONVENTIONAL CYTOGENETICS, ACGH, AND PCR AS INTEGRATED WORKUP FOR A CORRECT DIAGNOSIS OF MDS

S Galimberti[1,*], E Ciabatti[1], A Valetto[2], V Bertini[2], MI Ferreri[2], A Guazzelli[2], S Grassi[1], F Guerrini[1], MR Metelli[3], MA Caligo[2], M Petrini[1]

[1]Clinical and experimental Medicine, UO Hematology University of Pisa, [2]UO Cytogenetics AOUP, [3]UO Hematology University of Pisa, Pisa, Italy

Background: Conventional cytogenetics continues to have a fundamental role in the classification and risk scoring of myelodysplastic syndromes (MDS). Nevertheless, non-informative karyotypes represent up to 20% of cases. Some different molecular methods, such as FISH, aCGH or mutational analysis, could detect new abnormalities and improve the correct subtyping of MDS patients.
Aims: The aim of the study was to adopt an integrated diagnostic work-up for better characterizing MDS patients.
Methods: We analyzed 61 patients (71% male, with a median age of 74 years). According to the WHO classification, 33% were affected by multilineage refractory cytopenias, 12% by refractory anemia, 15% by refractory anemia with ring sideroblasts, 21% by refractory anemia with excess of blasts, 3% by 5q- syndrome, and 12% by chronic myelo-monocytic leukemia; 67% of patients were at low/intermediate-1 IPSS risk. All patients were assessed by conventional cytogenetics, FISH for chromosomes 5, 7, 8, PDGFRalpha and beta rearrangements, aCGH, and PCR for ASXL1, EZH2, TP53, and TET2 mutations. WT1 and RPS14 gene expression levels were also measured by quantitative PCR.
Results: In our series, conventional cytogenetics analysis failed in only 12% of cases: indeed, the sampling for this analysis was the first one during the bone marrow aspiration. Overall, 39% of patients showed at least one chromosomal aberration, with complex karyotypes in 7% of cases. FISH allowed to correctly classify two cases as affected by the 5q- syndrome and one as affected by deletion of chromosome 7; two patients carried PDGFRbeta rearrangement; these abnormalities had not been detected by the conventional cytogenetics.
The aGCH allowed to detect chromosomal aberrations in 38% of cases: aCGH detected 10 "new" mutated cases in respect of the conventional cytogenetics, including alterations of the ETV6 and GATA2 genes; After the mutational analyses, 28% of patients resulted mutated, with highest frequency for TP53 (mutated in the 16% of the overall series). Eight of these TP53-mutated patients showed normal karyotype, and resulted wild-type by FISH and aCGH. Four low/intermediate-1 risk patients (8%) showed the ASXL1 gene mutation. Two cases showed the TET2 mutation. The statistical analysis confirmed the prognostic role of poor cytogenetics either on overall survival (OS) or progression-free-survival (PFS). Also deletions detected by aCGH resulted to play a negative prognostic impact on OS. WT1 and RPS14 gene expression was assessed: over-expression of WT1 was found in one third of all patients, while 70% showed RPS14 values lower than those measured in healthy donors. Statistical analysis showed that the WT1 over-expression had statistical significance on survival, also in multivariate analysis.
Summary/Conclusions: Our study supports the feasibility and the utility of the introduction in the routinary workup of MDS of FISH and aCGH, in order to better stratify MDS patients and correctly design *ab initio* a patient-tailored treatment.

CLONAL DYNAMICS OF TWO DISTINCT CLONES IN LEUKEMIC TRANSFORMATION FROM MDS WITH ISOLATED DEL(5Q) HARBORING TP53 MUTATION

H Tsukamoto[1,2,*], Y Watatani[3], K Yoshida[3], Y Yamashita[2], H Tanaka[4], K Chiba[5], Y Shiraishi[5], Y Kawaguchi[1], S Fujiwara[1], N Kabasawa[1], N Hattori[1], H Makishima[3], S Miyano[5], S Ogawa[3], T Nakamaki[1], M Sanada[2]

[1]Division of Hematology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan, Tokyo, [2]Department of Advanced Diagnosis, Clinical Research Center, Nagoya Medical Center, Nagoya, Japan, Nagoya, [3]Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, Japan, Kyoto, [4]Laboratory of Sequence Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, Japan., [5]Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, University of Tokyo, Tokyo, Japan, Tokyo, Japan

Background: Although myelodysplastic syndromes (MDS) with isolated del(5q) represents a favorable prognosis, the presence of TP53 mutation has been associated with transformation to secondary AML (sAML) accompanied by the emergence of a complex karyotype (CK). The demethylating agent azacitidine (AZA) is currently the standard therapy for patients with high-risk MDS. However, some reports showed AZA treatment cannot improve survival in high-risk

MDS and sAML patients with TP53 mutations, in spite of response to AZA. The molecular mechanisms in the acquisition of resistance to AZA in TP53 mutated cases has not been completely understood.
Aims: To clarify the molecular mechanisms underlying disease progression and the acquisition of chemo-resistance in MDS, we delineated clonal evolution during disease course using high throughput sequencing of serial samples.
Methods: The 77-year-old female patient was diagnosed with MDS with isolated del(5q). She then received lenalidomide (LEN), but progressed to sAML with CK involving -7. She received AZA with LEN and then achieved temporarily marrow CR (blast<5%). Although she received same therapies, she relapsed and died of progressive leukemia. Genomic DNA was collected at four stages (RAEB-1, sAML, remission, and relapse) on informed consent. We performed whole exome sequencing (WES) and PCR amplicon based target deep sequencing by NGS (Illumina HiSeq 2500). Copy number alterations (CNA) were analyzed based on the read number and allelic imbalances were estimated from allele frequency of heterozygous SNPs.
Results: The mean coverage of WES and target deep sequencing was 209 times and 67073 times, respectively. We detected 15 somatic single nucleotide variants (SNV) and 2 frameshift/insertions in 17 genes. We identified the TP53 Y102C and NF1 T676fs as putative driver mutations. As the TP53 Y102C was the most abundant mutation identified in all stages, could represent the founding mutation. On the other hand, NF1 T676fs was rapidly enriched in the relapse. Next we delineated a model of clonal evolution using the proportion of SNV and CNA. Although CK with -7 was acquired during disease progression in this case, interestingly, deleted allele of chromosome 7 was different between sAML and relapse phase. In other words, two distinct clones characterized by deletion of different allele (-7A/-7B) existed after sAML, and clonal competition occurred during disease progression and having therapy.(Figure) The sAML stage was characterized by a founding clone harboring TP53 mutation and del(5q), major clone containing -7A and sub-clone with -7B. del(11p) was acquired in -7A clone and became dominant, but in remission the clone with del(11p) was extinct. On the other hand, clonal evolution took place on -7B clone, which acquired NF1 mutation, del(17p) encompassing TP53, and del(17q) including NF1. Finally, the evolved clone from -7B obtained chemo-resistance and contributed to relapse and also -7A clone flared up with deleted NF1.

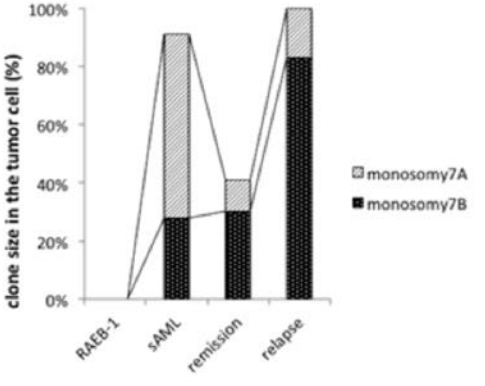

Figure 1. The proportion of -7 on each allele durng disease course.

Summary/Conclusions: To analysis serial samples during disease progression discloses that two distinct clone harboring chromosomal aberration on each allele competed with each other by selective pressure of therapy. These observations uncovered the complicated clonal architecture with the accumulations of genetic abnormality.

E1205

THE DNA METHYLATION INHIBITORS AZACITIDINE AND DECITABINE ACTIVATE UNIQUE AND COMMON TRANSCRIPTIONAL PATHWAYS THAT INCLUDE POTENTIAL NOVEL MARKERS OF RESPONSE

K Clarke*, C Young, A Thompson, K Mills
Blood Cancer Research Group, CCRCB, Queen's University Belfast, Belfast, United Kingdom

Background: Myelodysplastic syndrome (MDS) and acute myeloid leukaemia (AML) patients have poor tolerability of standard chemotherapies and an unmet need for novel therapeutic approaches. Epigenetic silencing of genes can occur via hypermethylation or the recruitment of histone deacetylases (HDACs), with these changes being reversible making them prime targets for therapy. Agents that inhibit DNA methylation have proven successful in the treatment of haematological malignancies and have shown promise by increasing the tolerability for MDS and AML patients, however the underlying mechanism of action remains to be fully elucidated.
Aims: In this report, we have studied the molecular and cellular consequences of treating AML and MDS derived cell lines with Azacitidine as a single agent as well as performing a small meta-analysis comparing Azacitidine an Decitabine gene expression with the intention of finding potential rational combination partners.
Methods: LINE-1 pyrosequencing was used to measure global methylation levels and western blotting used as a measure of protein expression. Cytospins were performed and slides were stained with Wright-Giemsa to assess the morphological effect on OCI-AML3 and SKM-1 cells. Gene expression profiling was performed using Affymetrix U133 plus 2.0 arrays and results were analysed using Partek Genomics Suite. CHI3L1 methylation was determined using pyrosequencing with primers designed against the promoter, intron and exon. Survival analysis examined TGCA dataset of 183 clinically annotated adult cases of *de novo* AML, whilst the local dataset consisted of 228 clinically annotated cases of MDS and AML.
Results: Azacitidine decreased viability and LINE-1 DNA methylation with a concomitant reduction in DNMT1 protein expression. Morphological assessment of treated OCI-AML3 and SKM-1 cells displayed an increase the proportion of macrophage cells-indicative of an induction of differentiation. Gene expression profiling using Affymetrix U133 plus 2.0 arrays identified 173 differentially expressed probesets following treatment with pathway analysis using DAVID identifying the immune system and an inflammatory response, which was also observed with network analysis using STRING. Overlap with Decitabine gene expression analysis highlighted 138 probesets that were common to both drugs and supported the role of the immune system in response to demethylating agents including S100A8/A9, HLA and CHI3L1. CHI3L1 was up-regulated with both agents and an increase in gene expression correlated to a loss of promoter, intron and exon DNA methylation. Survival analysis in locally and publically available datasets of stratified AML patients recognised that CHI3L1 could be used as a potential marker of response in patients with good cytogenetics (p=<0.02) compared to those in other subtypes (intermediate - ns; poor-ns).
Summary/Conclusions: These analyses give further insight into the mechanism of action of both Azacitidine and Decitabine in AML/MDS cell lines by identifying molecular gene and pathway targets that may be primed for novel therapeutic combinations for the treatment of elderly patients with AML or high risk MDS.

E1206

INTEGRATED ANALYSIS OF BOTH BIOLOGICAL AND MOLECULAR EFFECTS OF THE EPIGENETIC MODIFYING AGENT ROMIDEPSIN IN MDS/AML

K Clarke[1,*], F Liberante[1], S McDade[2], C Young[1], A Thompson[1], K Mills[1]
[1]Blood Cancer Research Group, CCRCB, [2]Functional Genomics Group, CCRCB, Queen's University Belfast, Belfast, United Kingdom

Background: Myelodysplastic syndrome (MDS) patients have poor tolerability of standard chemotherapies and an unmet need for novel therapeutic approaches. Epigenetic silencing of genes can occur via the recruitment of histone deacetylases (HDACs) with these changes being reversible, making them prime targets for therapy. Agents that inhibit HDACs (HDACi) have proven successful in certain malignancies and have shown promise by increasing the tolerability for MDS patients
Aims: In this report, we aimed to study the molecular and cellular consequences of treating AML and MDS derived cell lines with Romidepsin as a single agent, which could ultimately provide a rationale for combination therapy.
Methods: Cell Titre Glo® was used to measure viability, alongside HDAC Glo® assay to quantitate HDAC activity. Western blotting was performed to determine protein expression levels and flow cytometry using propidium iodide staining was used to measure cell cycle. Affymetrix U133 plus 2.0 arrays were used for gene expression analysis in conjunction with DAVID and STRING for pathway and network analysis. The Illumina Next-Seq 500 was used in-house to perform ChIP-Seq experiments.
Results: Preliminary analysis identified a candidate dose, time and cell line to be carried forward for gene expression profiling and ChIP-Seq analysis based on the ability of Romidepsin to affect proliferation, HDAC activity, acetylation and cell cycle. Microarray analysis indicated that 484 probesets were significantly (p<0.05) up-regulated compared to only 3 down-regulated after 24 hour treatment with 1.5 nM Romidepsin. Pathway and network analysis, using STRING and DAVID identified that ROS, inflammation and activation of mitochondrial stress pathways were associated with Romidepsin treatment. Matched samples from Romidepsin treated, and untreated SKM-1 cells were used for ChIP-Seq analysis of H3K9ac, H3K9me and H3K9me3 chromatin marks which provided information on positional enrichment and enabled an integrated transcriptomic-epigenetic mapping approach, thus identifying specific Romidepsin-induced gene-expression networks. Overlap of differential enrichment of each of the aforementioned marks with the microarray data has highlighted that increases in acetylation share the highest degree of overlap with gene expression.
Summary/Conclusions: These analyses give further insight into the mode of action of Romidepsin by identifying molecular gene and pathway targets that

may be primed for novel therapeutic combinations for the treatment of elderly patients with AML or high risk MDS.

THERAPY RELATED MYELOID NEOPLASM FOLLOWING RADIOTHERAPY HAS HIGHER INCIDENCE OF POOR RISK CYTOGENETICS AND ARE ASSOCIATED WITH POOR SURVIVAL COMPARED TO DE NOVO MDS CASES

D Singhal[1,2,3,*], S Moore[4], M Kutyna[2], R Chhetri[2], LA Wee[2], J Gray[5], S Nath[3,6], N Wickham[7], CH Hui[7], D Ross[8], P Bardy[1,2,3], LB To[1,2,3], I Lewis[1,2,3,9], D Hiwase[1]

[1]Haematology, The Royal Adelaide Hospital, [2]Haematology, SA Pathology, [3]Faculty of Medicine, University of Adelaide, [4]Genetics & Molecular Pathology, SA Pathology, Adelaide, [5]Haematology-Oncology, The Queen Elizabeth Hospital, Woodville South, [6]Haematology, Adelaide Haematology, Ashford, [7]Haematology, Adelaide Cancer Centre, Kurralta Park, [8]Flinders Medical Centre, Bedford Park, [9]Haematology, South Australian Health and Medical Research Institute, Adelaide, Australia

Background: Therapy-related myeloid neoplasms (T-MN) are well-known complication of prior cytotoxic/radiation therapy for malignancies and auto-immune diseases and are associated with poor survival compared to de novo MDS cases;most probably due to higher rate of poor cytogenetic in T-MN cases. Poor prognosis of T-MN cases following prior cytotoxic chemotherapy (CT) exposure is well established, however, there is ongoing debate about the prognosis of radiotherapy (RT) only associated T-MN cases.
Aims: This study compares the prognosis of T-MN cases following CT, RT and de novo MDS cases enrolled in the South Australian MDS (SA-MDS) Registry.
Methods: Demographic, clinical, cytogenetic and laboratory data on 744 de-novo and 148 T-MN patients were analysed. Survivals between the groups were compared by using log-rank test and were plotted using Kaplan Meier curve. Categorical variables were compared by using Chi-square test.

Table 1. Distribution of cytogenetic categories in de-novo &T-MN patients according to IPSS, R-IPSS and prior treatment type.

IPSS cytogenetic category	CT±RT N=112	RT N=34	De novo N=741	R-IPSS cytogenetic category	CT±RT N=112	RT N=34	De novo N=741
Good	28(25%)	15(44%)	498(67%)	Very Good	2(2%)	1(3%)	30(4%)
Intermediate	17(15%)	4(12%)	111(15%)	Good	26(23%)	14(41%)	474(64%)
Poor	58(52%)	12(35%)	95(13%)	Intermediate	22(20%)	4(12%)	103(14%)
Not available	9(8%)	3(9%)	37(5%)	Poor	25(22%)	3(9%)	31(4%)
				Very Poor	28(25%)	9(26%)	66(9%)
				Not available	9(8%)	3(9%)	37(5%)

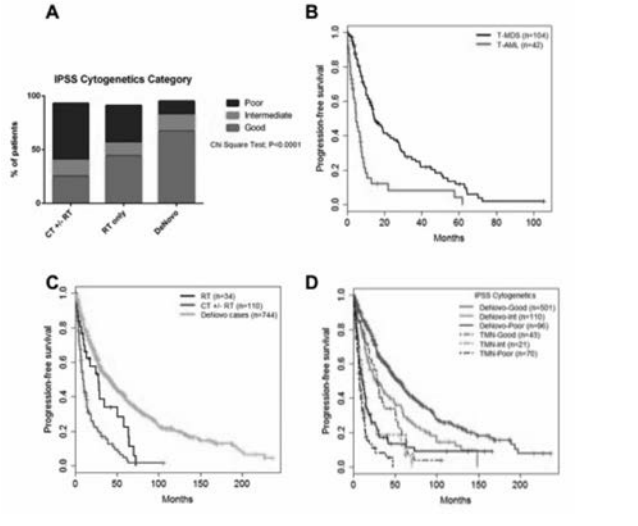

Figure 1.

Results: Median age of T-MN and de novo MDS was 71 (20-91) and 73 years (19-98). Most frequent primary diseases (PD) were lymphoproliferative diseases (n=56, 38%) and prostate cancer (n=22, 15%). Sixty-four (43%) patients had received CT only, 34 (23%) patients RT only, and 48 (32%) patients received both CT and RT for PD. 29(20%) patients received autologous stem cell transplant for their PD. During follow up, 42(28%) patients developed T-AML, while 104 (70%) developed T-MDS. The median time between cytotoxic treatment and t-MN diagnosis was 38.5months for RT only (range 0.9-123) and 31.9months (range 0.2-216.2) for CT(±RT) patients, respectively. As shown in table 1 and Fig1A, poor risk cytogenetic cases were significantly higher in T-MN cases treated with CT compared to cases treated with RT alone and de novo MDS cases (52% *vs* 25% *vs* 13% respectively; P<0.0001). Similarly, 47% CT(±RT)patients had R-IPSS defined poor and very poor cytogenetics compared to 35% of RT only and 13% of de-novo MDS/AML patients (P=<0.0001). Overall, 40(27%) of T-MN patients received disease modifying therapy (Induction CT, Hypomethylating agents, low dose Ara-C, and Allogeneic transplant). Within the T-MN group (144 patients), T-MDS patients had significantly better median survival than T-AML (14.7 *vs* 5.0 months, P<0.0001)(Fig 1B). T-MN patients who received prior RT only had worse median survival than de-novo patients but better than T-MN patients receiving prior CT (±RT) (9.7 *vs* 27.9 *vs* 41.3 months; p=0.001)(Fig 1C). Further, within the individual IPSS cytogenetic risk category, T-MN consistently had poor median survival than de-novo patients (Fig.1D) regardless of the type of prior therapy(p=0.001).
Summary/Conclusions: T-MN patients receiving prior CT(± RT) have poorer survival compared to RT only & de novo MDS patients. Contrary to the published literature (Nardi *et al* JCO 2012), our data suggest that the incidence of adverse cytogenetics is higher in T-MN patients who received prior RT compared to de-novo patients. T-MN patients have consistently poor survival than de-novo patients even when matched for IPSS cytogenetic categories.

E1208

POLY [ADP-RIBOSE] POLYMERASE 1 (PARP-1) EXPRESSION IS CORRELATED TO THE TYPE OF MYELODYSPLASTIC SYNDROME ACCORDING TO BOTH WHO CLASSIFICATION AND IPSS SCORE

P Diamantopoulos[1,*], P Zervakis[1], M Sofotasiou[1], K Zervakis[1], A Symeonidis[2], E Kodandreopoulou[1], A Galanopoulos[3], V Pappa[4], I Kotsianidis[5], G Christopoulou[2], V Papadopoulou [1], NA Viniou[1]

[1]1st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, [2]Department of Internal Medicine, University Hospital of Patras, Patras, [3]Department of Clinical Hematology, G. Gennimatas District General Hospital, [4]Hematology Division, Second Department of Internal Medicine, Attikon General Hospital, National and Kapodistrian University of Athens, Athens, [5]Department of Hematology, University Hospital of Alexandroupolis, Alexandroupolis, Greece

Background: Poly [ADP-ribose] polymerase 1 (PARP-1) has a central role in the repair of single-stranded DNA breaks, thus protecting the cell from genomic instability. Overexpression of PARP1 may lead a cell to apoptotic or necrotic death, thus defining the cell's fate. Genetic defects are important in the pathogenesis of myelodysplastic syndromes (MDS) and the role of PARP1 in the apoptotic pathways seems to be promising, since new agents targeting PARP1 are available. PARP1 expression has never been studied in MDS.
Aims: Our aim was to detect PARP1 mRNA in bone marrow samples of patients with MDS and investigate its correlations to the hematologic and prognostic characteristics of the patients.
Methods: Bone marrow samples were collected from patients with MDS. Quantification of PARP1 mRNA was performed by a SYBR-green based PCR, performed on BIORADCFX96 (BIORAD) and the results were expressed in correlation to those of the housekeeping gene of beta actin. Statistical correlations were carried out using IBM SPSS statistics, version 19.0.
Results: Fifty three (53) patients with MDS were included in the study. The basic demographic and hematologic characteristics of the patients are shown in the Table. The vast majority of the patients (92.5%) were treatment naïve. The median PARP1 mRNA levels were 0.0259 (range 0.0003-0.6410) and showed a statistically significant correlation to the type of MDS (according to the WHO classification) (p=0.016) and to the IPSS score (p=0.001) (detailed results in Table). The lowest levels were observed in patients with RA (0.0053 *vs* 0.1477 for non-RA patients, p= 0.016), as well as in patients with low and intermediate 1 IPSS score (0.0107 *vs* 0.1831, p=0.01) that had almost 20 times lower PARP1 mRNA levels than patients with intermediate 2 and high risk MDS.

Table 1. Patients' characteristics and results.

‡ based on only 2 samples

Summary/Conclusions: The correlation of higher levels of PARP1 mRNA with higher risk MDS has never been reported in the past. This correlation, if confirmed by larger studies, may render PARP1 a prognostic factor for patients with MDS. Moreover, this result can lay the basis for the design of clinical trials evaluating the use of PARP1 inhibitors in patients with higher risk MDS.

Campus ICO-Germans Trias i Pujol., Badalona, [4]Hospital Clínico de Valencia, Valencia, [5]Hospital Vall d'Hebrón, [6]Hospital del Mar, Barcelona, [7]ICO Girona- Hospital Josep Trueta, Girona, [8]Hospital de Sant Pau, Barcelona, [9]Hospital Mútua de Terrassa, Terrassa, [10]Hospital Arnau de Vilanova, Lleida, Spain

Background: Risk-adapted treatment strategy is currently used in myelodysplastic syndromes (MDS). Hypomethylating agents have introduced a new perspective in the therapeutic approach of higher risk MDS, azanucleosides being the standard of care for most patients with this disease. The application of next generation sequencing (NGS) technologies to study MDS has identified several recurrently mutated genes involved in RNA splicing, DNA methylation, chromatin modification, transcription, DNA repair control, cohesin function, RAS pathway and DNA replication. Even though there is a significant overlap between the commonly mutated genes in MDS with those found in AML, mutation status is not widely used to select MDS treatment.
Aims: The aim of this study is to identify the mutational status at diagnosis of MDS and secondary AML (sAML) patients treated with azacitidine to evaluate if it could help to discriminate which patients will respond from those who will not and its correlation with clinic-biological data.
Methods: A preliminary prospective study was performed on 39 patients with MDS and sAML (14 RAEB-2, 9 RAEB-1, 5 RCMD, 1 RCMD-RS, 1 RARS and 9 sAML). Genomic DNA was obtained from bone marrow at diagnosis. SeqCap EZ and KAPA Library Preparation Kit (Roche) reagents have been used to generate libraries and enrich DNA of 83 genes implicated in myeloid neoplasm. The customized panel has been analyzed in MiSeq Illumina platform with 150bp paired-end reads. NGS data were analyzed using Illumina MiSeq Reporter and Variant Studio softwares. In 21 patients a CD3+ matched control study was done, in order to distinguish between somatic and germline variants. Data from treatment response and overall survival (OS) has been collected from all patients.
Results: The mean depth of targeted resequencing per base was 779-fold. After filtering all the variations obtained for quality, biological consequence and discard the known SNPs, we obtained 116 variations with a mean of 3 variants per sample. The average of alterations detected in each cytological category can be observed in Table 1.

Table 1. Average of abnormalities according to cytological category.

	Nº patients	Average of alterations per patient (range)
sAML	9	3.56 (1-7)
RAEB-2	14	3 (0-6)
RAEB-1	9	2.78 (1-5)
RCMD	5	2.2 (1-4)
RCMD-RS	1	5
RARS	1	1

The most frequent altered genes have been *TP53* (48.7%), *TET2* (20.5%) and *DNMT3A* (20.5%). Statistical analysis confirmed that *TP53* alterations are associated with complex karyotype (p<0.001) and with the very high IPSS-R risk category (p=0.002). On the other hand, mutations of RNA splicing machinery (*SRSF2*, *U2AF1, SF3B1* or *ZRSR2*) and variations in cohesion complex (*STAG2, RAD21* or *SMC3*) are associated with non-complex karyotype (p=0.022 and p=0.02) and alterations in *SRSF2* are rarely detected in very high IPSS-R risk category (p=0.007). In our series we have not observed the impact of *TET2* mutations in treatment response. Survival analysis showed that the presence of variants in *TP53* correlated with shorter OS (9.2 *vs* 19.2; p=0.008). Alterations in *SRSF2* and mutations in cohesion complex are associated with longer OS (median not reached *vs* 10.4; p=0.025 and median not reached *vs* 10.4; p=0.048).
Summary/Conclusions: NGS technique is a good tool to study mutational profile in MDS and sAML. Patients with sAML and RAEB-2 present more variations than patients with RAEB-1 or RCMD. The most affected genes match with those described in the literature for high risk MDS. Alterations in *TP53* and *SRSF2* genes seem to be good markers to predict the outcome.

MOLECULAR ALTERATIONS ASSOCIATED WITH PROGRESSION OF MYELODYSPLASTIC SYNDROMES TO SECONDARY CHRONIC MYELOMONOCYTIC LEUKEMIA

A Valencia[1,*], A Sanna[1], E Masala[1], B Francesca[1], A Gozzini[1], E Contini[2], F Torricelli[2], B Przychodzen[3], J Maciejewski[3], A Bosi[1], V Santini[1]
[1]Experimental and Clinical Medicine, University of Florence, [2]AOU Careggi, Firenze, Italy, [3]Department of Translational Hematology & Oncology Research, Cleveland Clinic, Cleveland, United States

Background: Myelodysplastic syndromes (MDS) are heterogeneous disorders characterized by ineffective hematopoiesis and risk of progression to acute myeloid leukemia. However, MDS may progress to clearly myeloproliferative neoplasms. Some reports have demonstrated that *de novo* MDS patients can transform to secondary chronic myelomonocytic leukemia (CMML) independently of the presence of relative monocytosis (>10%) at initial diagnosis of MDS (Rigolin et al, Haematologica 1997; Wang et al, Am J Clin Pathol 2006). Clinical parameters and cytogenetic alterations failed to correlate with probability to develop this type of progression.
Aims: The knowledge of the mechanisms at the basis of proliferative-non leukemic progression could help define the prognosis of this group of MDS patients. We postulated that specific acquired somatic mutations could be associated with the transformation from MDS to secondary CMML.
Methods: Seven IPSS lower risk MDS patients (pts) that progressed to CMML were included in the study. The mutational profile was characterized using a TruSeq Custom Amplicon panel (Illumina) targeting the 57 recurrently mutated genes in myeloid malignancies. Around 250 ng of genomic DNA extracted from mononuclear cells obtained at diagnosis (MDS phase) and at progression (CMML phase) were used to prepare sequencing libraries following the Illumina standard protocol. Samples were run on an Illumina MiSeq and variants were annotated by ANNOVAR. Detected variants were distilled on the basis of their exonic function, allele frequency, the presence in variants databases, and several prediction scores.
Results: At diagnosis, 2 pts had RA and 6 pts had RCMD and at progression 5 pts presented a CMML-1 and 2 pts a CMML-2 (mean time to progression: 20 months). The total WBC count in the CMML phase was significantly higher than that of the MDS phase (mean, 24.4×10^9/L *vs* 4.04×10^9/L; *P*= 0.03). The mean hemoglobin level, platelet count, and blast count were not different between the MDS and CMML phases. In both phases, 3 pts presented a normal karyotype, 1 case a monosomy 7, 1 patient a trisomy 8 and 1 patient a trisomy 14. Only 1 patient presented a new trisomy 8 at progression. The most frequently mutated genes at MDS diagnosis were *TET2* and *ASXL1* (mutated in 7 and 6 pts, respectively). Only two pts presented new mutations in the progression CMML sample: one patient in the *SETBP1* gene and the other one in the *DNMT3A* gene. The mutational profiling of these 7 MDS pts at diagnosis (group 1) was compared with that of a second cohort of 40 low-intermediate1 MDS pts (group 2) that did not progress (mean follow up: 25 months) (Figure 1). The number of mutations was higher in group 1 (100% pts presented >3 mutations) than group 2 (80% of pts presented 0-2 mutations). The most commonly mutated genes differed between the two groups: *ASXL1* (100%) and *TET2* (86%) in group 1, while in group 2 were *SF3B1* (25%) and *TET2* (22%). In order to study the role of *ASXL1* and *TET2* mutations in the progression we compared variant allele frequency (VAF) data: VAF of *ASXL1* was significantly higher in CMML than in MDS phase (38 *vs* 21; *P*=0.02), while VAF of *TET2* did not shown differences.

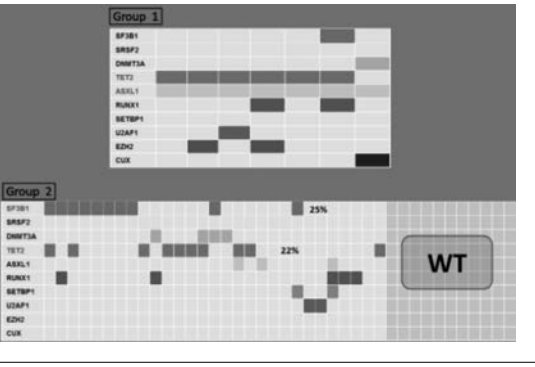

Figure 1.

Summary/Conclusions: This analysis of the rare type of progression from frank low risk MDS to MDS/MPN suggests that number of somatic mutations and presence of *ASXL1* mutations during the MDS phase is an important factor correlated with/predictive of proliferative-non leukemic progression. Increase in VAF of *ASXL1* seems also important in determining progression.

Myelodysplastic syndromes – Clinical

E1211

COST CHANGES ASSOCIATED WITH ACHIEVING TRANSFUSION INDEPENDENCE (TI) IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

AE DeZern[1,*], G Binder[2], S Rizvi[2], FA Corvino[3], SR Arikian[3], A Surinach[3], J Lee[3], BD Smith[1]
[1]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD, [2]Celgene Corporation, Summit, NJ, [3]Genesis Research, Hoboken, NJ, United States

Background: Given the bone marrow failure characteristic of the disease, patients with MDS are often dependent upon red blood cell (RBC) transfusions. Guidelines from the European Society of Medical Oncology note that chronic RBC transfusions are associated with chronic anemia, leading to excess morbidity, and cannot completely resolve impaired quality of life. This transfusion dependence (TD) has been shown to be a risk factor for progression, and achieving TI is an important treatment objective.
Aims: To evaluate MDS cost patterns associated with initial periods in which patients were TD, and subsequent periods of TI.
Methods: Patients were identified from a large US claims database (2008–2013) by ICD-9 codes for MDS; the index date was the earlier of ≥1 inpatient or ≥2 outpatient claims. Patients with medical and pharmacy (Rx) coverage for ≥12 months pre- and ≥6 months post-index were included. TD was defined as ≥2 consecutive 8-week periods with ≥1 transfusion each and no interim 56-day period without transfusion; TI was defined as 8 subsequent transfusion-free weeks. Patients with high-risk MDS or acute myeloid leukemia at diagnosis were excluded. TD patients were followed until they no longer met TD criteria or end of data. Patients who subsequently became TI were followed until they returned to TD or end of data. Total costs of care were based on paid claims and reported for 24 months post-onset of TD or TI.
Results: 13,741 MDS patients met the inclusion criteria regardless of transfusion needs; 2,645 (19%) were TD and 1,378 (52%) subsequently became TI. Median TD duration was 7.5 months. Age, prior treatment, baseline anemia, del(5q) mutation, and comorbidities were similar for TD patients who did and did not subsequently achieve TI. The average total cost of care (medical+Rx) was lower for TI than for TD patients ($8,138 *vs* $16,640 per patient-month) (Figure 1). TI patients had 54% lower monthly medical costs ($7,004 *vs* $15,289) largely due to differences in inpatient costs ($2,353 *vs* $7,056). Monthly Rx costs for TI patients were 16% lower than for TD patients ($1,134 *vs* $1,351). Over time, monthly costs for TI patients declined 50% from initial levels; TD patient costs declined 27%.

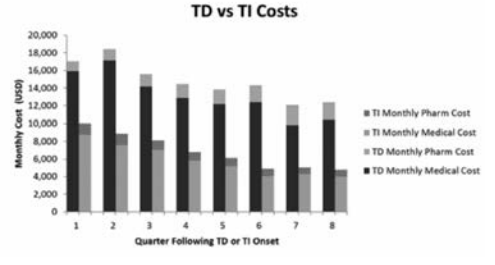

Figure 1.

Summary/Conclusions: Patients who are TD incur significant total costs of ≥$16,000/month. For patients who subsequently achieved TI, monthly costs were halved from TD costs and continued to decline over time. This suggests that treatment of TD patients offers the potential for a return to TI, resulting in economic benefit as well as clinical improvement.

E1212

FERRITINE LEVEL AND PERFORMANCE STATUS ARE SIGNIFICATIVE PROGNOSTIC FACTORS FOR OVERALL SURVIVAL IN LOWER-RISK MDS PATIENTS GRUPO ARGENTINO DE ESTUDIO DE LOS SINDROMES MIELODISPLASICOS

A Enrico[1,*], MG Flores[2], M Iastrebner[3], W Correa[1], G Alfonso[4], L Kornblihtt[5], MV Prates[1], M Narvaitz[6], V Novoa[7], M Rosenhein[8], I Santos[9], J Arbelbide[10]
[1]Hematologia, Hospital Italiano La Plata, La Plata, [2]Hematologia, Hospital Duran, [3]Hematologia, Osecac, Ciudad de Buenos Aires, [4]Hematologia, Hospital Nacional Posadas, El Palomar, [5]Hematologia, Hospital de Clinicas Jose San Martin, [6]Hematologia, Instituto de Investigaciones Hematologicas. Patologia. Academia Nacional de Medicina, [7]Hematologia, Laboratorio de Inmunologia Htal Carlos G Durand, [8]Hematologia, Hospital Tornu, [9]Hematologia, Sociedad Argentina de Hematologia, [10]Hematologia, Hospital Italiano de Buenos Aires, Ciudad de Buenos Aires, Argentina

Background: Myelodysplastic syndromes (MSD) are a heterogeneous group of clonal haematopoietic stem cell malignancies characterized by defects in haematopoietic cell maduration/differentiation. According to the original IPSS, the majority of patients are classified within low or intermediate-I (lower) risk with a survival of >3.5 years. However, a large diversity exists within these patients varying in several characteristics at diagnosis. Up to 10% evolve to AML and 50% succumb as a result of the severity of cytopenias. The WPSS, MD Anderson (MDA) and IPSS-R recognized some IPSS limitations. The use of these systems has improved survival prediction but their usefulness is not clear in lower risk patients. Also, the inclusion of non-classical variables, as ferritine level or performance status, is also in debate.
Aims: To analyze the usefulness of risk stratification to predict survival and evolution to AML in lower risk patients. And, to test whether non classical variables are independent prognostic variables in these patients.
Methods: This is a retrospective study of 566 patients from the *Registro Argentino de Enfermedades Hematologicas (RAEH)*, *Sociedad Argentina de Hematologia*, diagnosed between 2007 and 2015, last up-date Jan 2016. Out of the registry, 328 (57.9%) were selected and evaluated according to the IPSS criteria, excluding those with secondary MDS and with proliferative CMML. WPSS (both the one including transfusion dependence and with hemoglobin levels according to gender), MDA and the specific for Low Risk (MDA-LR), and IPSS-R systems were applied. Univariate (Kaplan-Meier and Long-rank) and multivariate (Cox regression) analysis were performed to evaluate survival and evolution to AML.
Results: The selected 328 lower risk patients showed a median age of 72.5 years, 54.6% were male and 17.7% showed a performance status ≥2. With a median follow-up of 25.4 months, 86 (26.2%) died and 38 (11.6%) evolved to AML. Gender, ferritine level (<170, 170-350, >350 mg/ML) and all variables grouped according to different evaluated systems were significant predictive variables for prognosis. Table 1 shows the distribution of patients according to all evaluated systems and their respective median survival and time to evolution to AML. It also depicts that all systems were useful to predict outcome. The IPSS-R sustained its independence for both survival [p<0.001, exp(B) 1.676] and evolution to AML [p<0.001, exp(B) 2.544]. Also the classic MDA was useful for survival [p<0.001, exp(B) 1.987] and both WPSS for evolution to AML [p<0.001 and 0.02, exp(B) 2.281 and 0.554, respectively including either trf or Hb]. As the IPSS-R was the only system that sustained its independence to predict both survival and evolution to AML, all variables not included were analyzed in a multivariate model. Performance status and ferritine level were significative predictive parameters in the model to predict survival [p<0.001 and p=0.012, exp(B) 1.807 and 1.455]. However, any variable showed an independent prognostic impact for evolution to AML besides the IPSS-R.

Table 1. Univariate analysis of variables of prognostic factors for survival and evolution to AML.

Variables	Patients (%)	Survival			Evolution to AML

NR: not reached; mo: months; all univariate p-values not explicitly stated are *p<0.001*, # group of risk with less of 10 patients were joined for statistic purpose IPSS: International Prognostic Scoring System according to P. Greenberg *et al.*, 1997. IPSS-R: revised IPSS according to P. Greenberg *et al.*, 2012.

Summary/Conclusions: WPSS, MDA, MDA-LR and IPSS-R systems allowed us to identify subgroups of patients (11.5%-26.2%) that shift to worse prognosis categories in lower risk-IPSS patients. IPSS-R sustained its independence to predict both survival and evolution to AML, while the MDA did it for survival and the WPSS for leukemic evolution. Performance status and ferritine level were significative independent prognostic factors to predict survival along with the IPSS-R in lower risk patients.

E1213

CHARACTERIZATION OF TREATMENT PATTERNS AND OUTCOMES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES: ANALYSIS OF UNITED STATES COMMERCIAL CLAIMS DATABASE

M Mehra[1,*], R Potluri[2], J He[1], J Fleischmann[3], J Bussolari[4], A Desai[1]
[1]Janssen Global Services, LLC, Raritan, [2]SmartAnalyst, New York, United

States, [3]Janssen-Cilag GmbH, Neuss, Germany, [4]Janssen Research & Development, LLC, Raritan, United States

Background: Myelodysplastic syndromes (MDS) constitute a heterogeneous form of blood cancer that primarily affects the elderly, and are characterized by anemia and other cytopenias as well as a high risk of transformation to acute myeloid leukemia (AML). Treatment, which is selected based on the International Prognostic Scoring System (IPSS), presence of cytopenia, and the presence of 5q deletion (del[5q] MDS), may include supportive care (eg, whole-blood and/or platelet transfusion), erythropoiesis-stimulating agents (ESA), hypomethylating agents, and lenalidomide for del(5q) MDS.
Aims: To characterize the burden of disease, treatment patterns, and outcomes of MDS patients using a large US database.
Methods: Optum's integrated claims and Electronic Medical Record database ("Optum Database") was retrospectively analyzed to identify adult patients with an index diagnosis of MDS between 2006 and 2014; to ensure index diagnosis, only patients with 365 days of retrospective data preceding the index diagnosis were included. Patients with baseline AML and patients younger than 18 years of age were excluded. MDS in patients was categorized as low-grade (ICD 9 code 238.72: Refractory anemia [RA], Refractory anemia with excess blasts-1 [RAEB-1], Refractory anemia with ringed sideroblasts [RARS], Refractory cytopenia with multilineage dysplasia [RCMD], Refractory cytopenia with multilineage dysplasia and ringed sideroblasts [RCMD-RS]), high-grade (ICD 9 code 238.73, which includes Refractory Anemia with Excess Blasts [RAEB] II), del(5q) (ICD 9 code: 238.74), or unspecified (ICD 9 code: 238.75) based on the earliest recorded ICD-9 diagnosis code based on French-American-British classification. Demographics and clinical outcomes were analyzed by descriptive summary. Treatment patterns were summarized by grouping treatments as "lenalidomide," "azacitidine," "decitabine," "imatinib," "chemotherapies," "ESA," and "others." Kaplan-Meier survival analysis was performed to define progression to AML.
Results: Of 10,465 MDS patients in the Optum Database, 8493 met the inclusion criteria and were evaluated over a median follow-up of 2.3 years; MDS was categorized as low-grade in 2136 (25.2%), high-grade in 367 (4.3%), del(5q) in 198 (2.3%), and unspecified in 5792 (68.2%) patients. Across all MDS categories, mean age at diagnosis was 70 to 72 years, 77% of patients were aged ≥65 years, roughly half were male, and the majority were white and non-Hispanic. In the overall cohort, 40% received ≥1 prescribed agent (46% in low-grade, 61% in high-grade, 42% in del[5q], and 36% in unspecified MDS). The most commonly used regimens were epoetin-alfa or darbepoetin in both low-grade and unspecified, hypomethylating agents (decitabine or azacitidine) in high-grade, and lenalidomide in del(5q) MDS (Table). In the overall cohort, 500 (5.9%) MDS patients progressed to AML, including 103 (4.8%) patients with low-grade and 78 (21.3%) with high-grade MDS. In the overall cohort, 38% of patients who received ≥1 regimen and 13% of patients without prescribed treatment went on to have a blood transfusion (Table).

Table 1. Demographics and treatment of patients with MDS in optum database.

Demographics	Low-grade MDS (ICD 9 code: 238.72) n = 2136	High-grade MDS (ICD 9 code: 238.73) n = 367	Del(5q) MDS (ICD 9 code: 238.74) n = 198	Unspecified MDS (ICD 9 code: 238.75) n = 5792
Age[a]				
≥ 65 years, %	75	76	75	77
Mean (SD)	71 (13)	71 (12)	70 (13)	72 (12)
Sex, %				
Male	51.7	58.0	48.0	53.1
Female	48.0	42.0	52.0	46.8
Distribution of regimens across all lines of treatment[b,c] %				
Lenalidomide	4.8	9.3	37.9	8.6
Azacitidine	10.8	35.2	10.2	12.8
Decitabine	3.8	15.0	2.3	4.5
ESA	73.4	24.9	41.2	61.7
RBC transfusion[c]				
Received RBC transfusion, %	23	39	27	22
Progression to AML				
Patients progressing to AML, %	4.8	21.3	6.1	5.3
Median days to progression from index MDS diagnosis	349.0	205.5	418.0	302.0

[a]Proportion of total number of patients within each risk category.
[b]Proportion of the total number of regimens within each risk category.
[c]Regimens containing listed agents (may reflect use as monotherapy or in combination regimens).
[d]Transfusion analysis for the interval of 30 days prior to index MDS diagnosis to end of follow-up.
ESA, erythropoiesis-stimulating agents darbopoietin or epoietin alfa; RBC, red blood cell; SD, standard deviation.

Summary/Conclusions: Despite the variety of agents available, a significant proportion of MDS patients across all categories did not receive any treatment, and many received only supportive care. Rates of transformation to AML and transfusion dependence are consistent with published estimates.

E1214

MINIMAL RESIDUAL DISEASE MONITORING AND PREEMPTIVE IMMUNOTHERAPY IN MYELODYSPLASTIC SYNDROME AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

XD Mo[1,*], YZ Qin[2], XH Zhang[2], LP Xu[2], Y Wang[2], CH Yan[2], H Chen[2], YH Chen[2], W Han[2], FR Wang[2], JZ Wang[2], KY Liu[2], XJ Huang[2]
[1]Peking University People's Hospital, [2]Institute of Hematology, Beijing, China

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is one of the most effective treatments for high-risk myelodysplastic syndromes (MDS). Although allogeneic HSCT has advanced significantly, post-transplant relapse remains an important cause of transplant failure. The presence of minimal residual disease (MRD) after HSCT can indicate impending relapse.
Aims: This study investigated the efficacy of MRD monitoring and MRD-directed preemptive immunotherapy in high-risk MDS patients who received allogeneic HSCT.
Methods: MRD assessment consisted of Wilms' tumor gene 1 (WT1) detection with PCR and leukemia-associated immunophenotypic pattern examination with multiparameter flow cytometry (FCM).
Results: Post-HSCT, 31 patients were positive for WT1, and 8, for FCM; positivity for WT1 (18.6% *vs* 6.1%, *P*=0.040) or FCM (62.5% *vs* 3.6%, *P*<0.001) indicated a higher 2-year relapse rate. Twenty-one patients met our combined criteria for MRD, and the presence of MRD was associated with a higher 2-year relapse rate (27.3% *vs* 4.5%, *P*=0.003). Thirty-one patients showed positive results for preferentially expressed antigen of melanoma (PRAME) after HSCT, which indicated a higher 2-year relapse rate (19.3% *vs* 6.2%, *P*=0.035). In patients positive for both PRAME and MRD, the relapse rate was 60% despite preemptive immunotherapy. Multivariate analysis confirmed the association between the increased relapse rate and positivity for both PRAME and MRD (hazard ratio=42.8, *P*=0.001).
Summary/Conclusions: MRD monitoring predicted relapse in high-risk MDS post-HSCT patients, and PRAME- and MRD-positive patients did not benefit from preemptive immunotherapy.

E1215

PROGNOSTIC SIGNIFICANT OF ASXL1 MUTATIONS IN MYELODYSPLASTIC SYNDROMES

SY Wang[1,*], Y Lin[2], Y Zheng[2], ZC Wang[2]
[1]Department of Hematology, Fujian Institute of Hematology, Fujian Medical University Union Hospital, [2]Union Clinical Medical College, Fujian Medical University, Fuzhou, China

Background: Although additional sex comb-like 1 (*ASXL1*) gene mutations have long been reported in Myelodyspastic Syndromes (MDS) and Chronic Myelomonocytic Leukemia (CMML), the prognostic significance has been controversial.
Aims: Perform a meta-analysis to study impact of ASXL1 mutations on patients with MDS and CMML.
Methods: The identified articles were retrieved from some common databases. We extracted hazard ratios (HRs) for overall survival (OS) and leukemic-free survival (LFS) and P value of some clinical parameters, which compared *AXSL1* mutations and those without from the available studies. Each individual HR and P value was used to calculate the pooled HR and P value.
Results: 6 studies covering 1689 patients were selected for this meta-analysis. The pooled HRs for OS and LFS were 1.45(95%CI, 1.24-1.70) and 2.20(95%CI, 1.53-3.17), respectively. When considering CMML patients alone the HR for OS was 1.50(95%CI, 1.18-1.90). Additional, *ASXL1* mutations were more frequently found in male (P=0.008), older (P=0.019) and patients with lower platelets (P=0.009) or hemoglobin level (P=0.0015) and associated with other mutations such as EZH2, IDH1/2, RUNX1 and TET2.
Summary/Conclusions: *ASXL1* mutations were associated with poor prognosis in MDS, which may contribute to risk stratification and prognostic assessment in the disease.

E1216

CIRCULATING CLONAL CELLS ARE PLENTYFUL IN PERIPHERAL BLOOD OF PATIENTS WITH MYELODYSPLASTIC SYNDROME: A COMPARISON OF THE PERCENTAGE OF CLONAL CELLS IN PB AND BM BY FLUORESCENT IN SITU HYBRIDIZATION

KO Im[1], DS Lee[2,*], SN Park[1], SM Hwang[3], JA Kim[2], SM Kim[4], Q Kim[1]
[1]department of tumor cell biology, [2]Dept of Laboratory Medicine, Seoul National University College of Medicine, Seoul, [3]Dept of Laboratory Medicine, [4]department of tumor cell biology, Seoul National University College of Medicine, Bundang, Korea, Republic Of

Background: Treatment response of MDS is determined by peripheral blood hemogram, bone marrow blast%, and cytogenetic results in BM. For the determination of treatment response, invasive BM study is required. We questioned whether the malignant cells are circulating or not in PB of patiens with MDS. We compared the percentage of clonal cells determined by fluorescent in situ hybridization (FISH) between PB and BM. If clonal cells are present in PB, monitoring of treatment response could be more easily accessible.
Aims: We aimed to investigate whether interphase fluorescence in situ hybridization (iFISH) clone size in peripheral blood correlate with bone marrow.
Methods: A tailored FISH panel (-5/5q-, -7/7q-, +8, -20/20q-, and +1/1q+) based on reported cytogenetic changes in Korean MDS patients, was performed in 98 patients with MDS at initial diagnosis. We performed corresponding FISH on peripheral blood in 28 patients in whom aberrant FISH results were observed in BM. The FISH probes used in the study were LSI EGR1 SpectrumOrange

(5q31)/D5S23, D5S721 SpectrumGreen (5p15.2), LSI D7S522 SpectrumOrange (7q31)/CEP7 SpectrumGreen, CEP8 SpectrumGreen, LSI D20S108 SpectrumOrange (20q12) and LSI Trisomy 1q (1q25) SpectrumGreen (Abbott,Downers Grove, IL, USA).
Results: Among 98 patients diagnosed with MDS at initial diagnosis, 56.1% (55/98 patients) showed positive result by 5 kinds of FISH probes. In 82.1% of patients (23/28 patients), clonal cells was detectable in PB and the mean percentage was 30.4% (range from 2.5% to 80.0%). The proportion of FISH-positive cells in PB was lower compared with the those in BM, and the mean percent difference between BM and PB was 30.5% (range from -11.2% to 45.0%). The proportion of FISH-positive cells in PB was lower compared with the those in BM, and the mean percent difference between BM and PB was 30.5% (range from -11.2% to 45.0%). However, the correlation of percentage value was high between PB and BM (r2=0.85); trisomy 8 (r2=0.85), 5q deletion (r2=0.85), 1q gain (r2=0.85) and 20q deletion (r2=0.85). In 3 patients with disease progression, percentage of clonal cells showed signficant interval change.
Summary/Conclusions: Our results suggest FISH monitoring of peripheral blood can be used as a potential candidate for monitoring tool of treatment response in MDS.

E1217

TREATMENT-EMERGENT ADVERSE EVENTS IN LENALIDOMIDE-TREATED LOW/INT-1-RISK MYELODYSPLASTIC SYNDROMES PATIENTS WITHOUT DEL(5Q) INELIGIBLE FOR OR REFRACTORY TO ERYTHROPOIESIS STIMULATING AGENTS

A Almeida[1,*], P Fenaux[2], G Garcia-Manero[3], A Giagounidis[4], S Goldberg[5], S Gröpper[4], A Jonasova[6], GJ Mufti[7], GF Sanz[8], N Vey[9], C Castaneda[10], J Zhong[10], C Beach[10], V Santini[11]
[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal, [2]Service d'Hématologie Séniors, Hôpital Saint-Louis, Université Paris 7, Paris, France, [3]MD Anderson Cancer Center, Houston, TX, United States, [4]Marien Hospital Düsseldorf, Düsseldorf, Germany, [5]John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NY, United States, [6]Charles University General Hospital, 1st Department of Medicine, Prague, Czech Republic, [7]King's College Hospital, London, United Kingdom, [8]Hospital Universitario y Politécnico La Fe, Valencia, Spain, [9]Institut Paoli-Calmettes, Centre Régional de Lutte Contre le Cancer, Marseille, France, [10]Celgene Corporation, Summit, NJ, United States, [11]AOU Careggi, University of Florence, Florence, Italy

Background: In the phase 3 MDS-005 study of lenalidomide (LEN) in RBC transfusion-dependent lower-risk non-del(5q) myelodysplastic syndromes (MDS) patients (pts) ineligible for or refractory to erythropoiesis-stimulating agents (ESAs), a significantly higher proportion of LEN-treated pts achieved RBC transfusion independence ≥8 weeks *vs* placebo (*P*<0.001).
Aims: To describe the frequency, timing, and management of treatment-emergent adverse events (TEAEs) in pts from MDS-005.
Methods: AEs of all 160 pts randomized to LEN who received ≥1 dose were reported per NCI-CTCAE v3.0.
Results: Median duration of LEN treatment was 164 days (range 7–1,158). Grade (G)1/2 and G3/4 TEAEs were reported in 96.9% and 86.3% of pts, respectively. The most common G3/4 TEAEs were neutropenia (61.9%), thrombocytopenia (35.6%), anemia (5.6%), pneumonia (5.6%); G3/4 deep vein thrombosis (DVT) occurred in 1.9%. G3/4 neutropenia and thrombocytopenia generally occurred in cycles 1–4. The most common G1/2 TEAEs were diarrhea (42.5%), constipation (22.5%), asthenia (21.9%), rash (21.3%), fatigue (20.6%), peripheral edema (20.6%). TEAEs led to 54.4% dose interruptions, 6.3% dose reductions, and 42.5% dose interruptions with subsequent reduction. Median time to first dose interruption or reduction was 57 days (range 6–504). The most common reasons for dose reduction following interruption were neutropenia (25.0%) and thrombocytopenia (16.3%); 1.9% of pts due to rash. TEAEs led to LEN discontinuation in 31.9% of pts; the most common reasons were thrombocytopenia (8.8%), neutropenia (4.4%), DVT (1.9%). In this short follow-up period, no increased incidence of AML or secondary primary malignancies was seen.
Summary/Conclusions: LEN has a predictable and manageable TEAE profile in this pt population. Diarrhea was the most common G1/2 TEAE; G1/2 TEAEs generally did not require dose reduction or discontinuation. The most common G3/4 TEAEs were neutropenia and thrombocytopenia; these occurred early and, in the majority of pts, reverted with dose reductions or interruptions, avoiding the need for discontinuation. The timing and characterization of TEAEs highlights the importance of frequent monitoring at the start of therapy.

E1218

IMPACT OF PREVIOUS TRANSFUSION AND COMORBIDITIES IN THE IPSS-R FOR OVERALL SURVIVAL

N Díaz Varela[1,*], G Teresa[2], A Manuel[3], G Lorena[4], A Olga[4], G Hermitas[5], S Sandra[6], F Angeles[7], R Rafael[8], L Inés[8], G Agustín[8], M Carmen[9], U Carlos[10], B Jose Luis[1]
[1]Haematology, Hospital Clínico Universitario. Santiago de Compostela, [2]Cytogenetics, Fundación Xenómica, Santiago de Compostela, [3]Haematology, Hospital Comarcal de Valdeorras, O Barco de Valdeorras, [4]Haematology, Hospital Xeral-Calde, Lugo, [5]Hospital Comarcal de Monforte, Monforte de Lemos, [6]Haematology, Hospital Meixoeiro, [7]CHUVI, Vigo, [8]Haematology, CHOP, Pontevedra, [9]Haematology, Hospital Arquitecto Marcide, Ferrol, [10]CHOU, Orense, Spain

Background: Myelodisplastic sindromes(MDS)are heterogeneus clonal hematological disorders, with different clinical outcome.The revised international prognostic score system(IPSS-R)showed improvement prognostic power as compared to IPSS. Disease and patient related factors not considered in IPSS-R are emerging as relevant for prognosis of individual patients with MDS.
Aims: This is a retropective cohort study to validate the IPSS-R and evaluate the impact of new variables in a MDS patients serie, wondering if adds any prognostic survival prediction at diagnosis.
Methods: Data from 339 patients diagnosed with MDS in 11 hospitals sited in Galicia, Spain from January 1,2007 to december 31,2011. End of the follow-up time was december 18,2012. The patients were registered in the central area citogenetic database and were reclassified according to 2008 WHO Criteria. Data of 30 patients with secondary MDS were included and CMML or AML diagnosys were excluded. Patients treatment was heterogeneous (conservative, supportive treatment, chemotherapy, IMIDs, hypometilant agents, BMT and others). The study was approved by the regional ethical committee.
Results: Population: 44% females and 56% males. Median age: 78 years (range 29-100). Median follow-up time: 1,7 years. Median survival time: 3,5 years. According to 2008 WHO classification: 14% CRDU, 11% RARS, 31% RCMD, 8% RCDMSA, 8% MDS(del5q), 12% RAEB-1, 12% RAEB-2,1% U-MDS. Included 1% fibrotic and 2% hipoplastic MDS. According IPSS, patients were classified as low risk: 43%, (median survival-MS-: 5 years), intermediate-1:37% (MS: 3,2 years), intermediate-2:16% and high risk: 4% (MS:5, 3.2, 1 and 0.3 years respectively). According IPSS-R: low IPSS risk patients were shifted to very low,low and intermediate risk (43%,53% and 4%. MS not reached, 4.4 and 3.6 years respectively).Intermediate-1 patients spread into very low(5%), low(54%),intermediate(31%), high, and very high risk (8% and 1%, MS:1 and 0.6 year). Intermediate-2 IPSS patients were classified into intermediate (26%), high (46%) and very high(28%) risk.High risk IPSS patients were staged in very high IPSS-R risk. The 3 and 5 year ROC survival curves and AUC was better for the IPSS-R than the IPSS(p<0.001)but not at 1 year. We studied 4 new variables at diagnosis to improve the survival prognostic IPSS-R prediction. Ferritin and LDH serum levels, comorbidities (measured by MDS-CI index)and previous RBC transfusión (at least two RBC in the 4 previous months).Univariate analisys not showed statistical significance for the serum LDH.The multivariate analisys didn´t it for serum ferritin levels.Data available for 327 patients for previous transfusion showed 46 individuals transfused (14%).Risk stratification according MDS-CI: 339 patients: 41% low risk,43% intermediate risk,16% high risk. The most frecuent observed comorbidities were: cardiac disease (35%), other tumour (15%) pulmonary (14%), renal (9%), hepatic (2%). ROC curves and AUC at 1,3 and 5 years showed better survival prediction power for IPSS-R if we added the two last variables individually and increase if we add the two variables simultaneously(p<0.001).

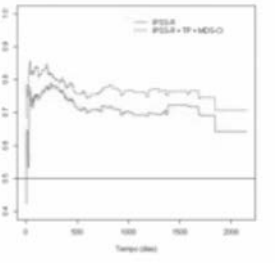

Figure 1.

Summary/Conclusions: IPSS-R provides pronostic power for OS compared to IPSS but not includes emerging relevant clinical events. Comorbidities exert a negative impact in life expectancy on MDS patients.Intrinsic MDS characterystics like anemia can worse patients sickness.Previous transfusion can reflect more aggressive disease or late diagnosis.Late iron develop has a negative impact in morbidity/mortality.Our study showed that adds the two variables improve the IPSS-R prognostic power for OS and helps in clinical decisión making.

E1219

ANALYSIS OF P53 EXPRESSION BY IMMUNOHISTOCHEMISTRY AS AN ADDITIONAL PROGNOSTIC TOOL IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

SW Maung[1,2,*], N Strahan[1], S O'Dowd[3], J O'Loughlin[3], R Desmond[1], J McHugh[1], M Jeffers[2,3], H Enright[1,2]
[1]Haematology, Tallaght Hospital, Dublin, Ireland, [2]School of Medicine, Trinity

College, University of Dublin, [3]Cellular Pathology, Tallaght Hospital, Dublin, Ireland, Dublin, Ireland

Background: Somatic mutations in *TP53* have been shown to be associated with aggressive disease, resistance to therapy and poor survival in many cancers including haematological neoplasms. The incidence of *TP53* mutations in Myelodysplastic Syndromes (MDS) is low (5-15%) compared to other malignancies but may be associated with adverse outcomes. Consistent correlations of up to 96% between *TP53* mutation by conventional sequencing and demonstration of p53 expression by immunohistochemistry (IHC) has been demonstrated by prior studies.
Aims: We assessed p53 expression by IHC on marrow trephine samples of 246 MDS patients to correlate the p53 expression with their clinical characteristics and outcomes.
Methods: IHC for p53 expression on marrow trephines of 246 MDS patients diagnosed between 2003 and 2014 in a single centre were analysed using DO-7 monoclonal antibody. Clinical information and overall survival including transformation to acute myeloid leukaemia (AML) were obtained from clinical notes and patient information systems. P53 expression was determined by assessing 1000 haematopoietic cells under high magnification and scored using a Modified Quick Scoring System.
Results: Thirty nine patients (16%) were positive for p53 expression and 207 patients (84%) were negative. P53 positive patients showed greater degree of peripheral cytopenias and higher marrow blasts. None of the patients with WHO subgroups of RARS, RCMD-RS or MDS 5q syndromes were p53 positive. P53 expression was positive in 5% of RA, 5% of RCMD, 18% of RAEB-1, 8% of RAEB-2 and 15% of MDS/MPN including CMML. P53 expression was significantly higher (51%) in patients with t-MDS (N=39). P53 positive patients showed a higher incidence of complex karyotype with ≥3 abnormalities (58%) and single/double abnormalities (40%). Only 7% of p53 positive patients had a normal karyotype. This is reflected by a higher proportion of patients with Int-2 and high risk IPSS (57% *vs* 14%) and with high and very high IPSS-R (53% *vs* 14%) in p53 positive patients compared to p53 negative patients. The median overall survival of p53 positive patients was 14 months compared to 33 months in p53 negative patients (p=0.000). The rate of AML transformation was 16% in p53 positive patients compared to 8% in p53 negative patients and the time to development of AML from MDS was shorter in p53 positive patients (9 months *vs* 20 months).

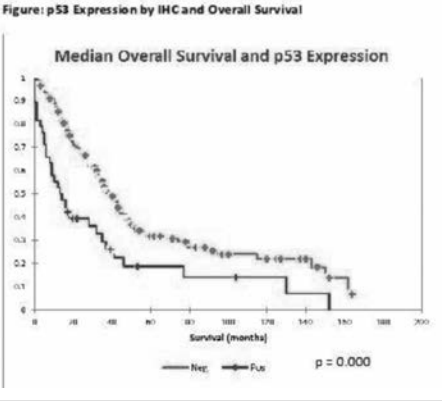

Figure 1.

Summary/Conclusions: Positive p53 expression of 16% in the MDS patients in this study reflected the incidence of p53 mutation published by prior studies. Positive p53 expression by IHC correlates with higher blast count, adverse WHO subgroup, complex karyotype, higher IPSS and IPSS-R, poor overall survival and increased risk of AML transformation. Analysis of p53 expression by IHC is a reproducible, rapid and inexpensive method and is a useful adjunctive prognostic tool in clinical practice.

E1220

A PROGNOSTIC SCORING MODEL FOR PATIENTS TREATED WITH AZACITIDINE FOR MYELODYSPLASTIC SYNDROMES/ACUTE MYELOID LEUKEMIAS

K Sato[1,*], J Inamura[1], N Tsukada[1], K Sato[2], T Hosoki[1]
[1]Department of Hematology/Oncology, [2]Department of Pathology, Asahikawa Kosei Hospital, Asahikawa, Japan

Background: Azacitidine (AZA) is widely used in clinical practice for patients with higher-risk myelodysplastic syndromes (MDS), as well as a proportion of patients with acute myeloid leukemia (AML). However, the predictive factors of a poor outcome in AZA-treated patients with MDS or AML have not been fully evaluated.
Aims: To clarify the risk factors (RFs) for patient survival, we retrospectively analyzed data of patients treated with AZA for MDS/AML.
Methods: We analyzed the clinical backgrounds, treatments, responses (hematological improvement: HI), survival, and prognostic factors of 31 patients with MDS/AML (MDS=24, AML with myelodysplasia-related changes=7) who were treated with AZA at our institute from 2011 to 2015. Expression of p53 protein in bone marrow cells (BMCs) was assessed immunohistochemically using a monoclonal mouse anti-human p53 protein antibody (Clone DO-7); p53 protein overexpression was defined as positivity in >50% of immunoreactive blasts. Overall survival (OS) was estimated from AZA treatment initiation via Kaplan-Meier analysis and compared with a log-rank test. RFs associated with OS were evaluated using a univariate (chi-squared test) or multivariate analysis (Cox proportional hazards model).
Results: The patients included 24 men and 7 women with a median age of 73 (range: 44-89) years. One, 10, 9, and 11 patients belonged to the low, intermediate (int)-1, int-2, and high-risk International Prognostic Scoring System (IPSS) groups, respectively; 2, 11, 6, and 12 belonged to the low, intermediate, high (H) or very high (VH) revised IPSS (IPSS-R) groups, respectively. Complex karyotypes (CKs) and p53 protein overexpression were observed in BMCs from 9 and 7 patients, respectively. Patients received a median of 6 (range: 1-43) AZA cycles at a median interval of 35 (range: 28-56) days. Eighteen (58%) patients exhibited HI, and 14 (45%) died from disease progression. The estimated 4-year OS of all patients was 36.4%. RFs associated with OS in a univariate analysis were CKs (p=0.0079), p53 protein overexpression in BMCs (p=0.0309), high C-reactive protein level (p=0.0018), serum ferritin >500 ng/ml (p=0.0291), no HI (p=0.0018), blood transfusion dependency (p=0.0039), and IPSS-R H/VH risk group (p=0.0484). Multivariate analysis identified p53 protein overexpression in BMCs (hazard ratio [HR]=10.2, p=0.0366) and serum ferritin >500 ng/ml (HR=10.1, p=0.0113) as independent RFs for OS. Two OS risk groups were defined according to scores from these risk factors: low risk (0) and high risk (1-2). The OS curves of AZA-treated patients with MDS/AML were significantly stratified into 2 risk groups using our scoring model (p<0.0001, Figure 1).

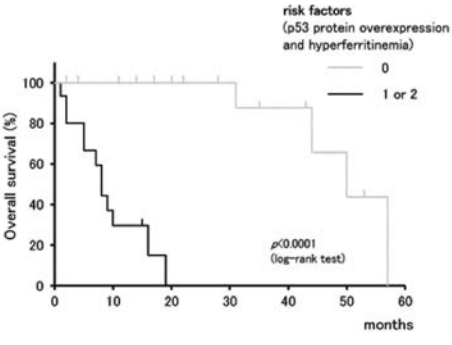

Figure 1. Overall survival for patients with MDS/AML treated with azacitidine according to our prognostic scoring model.

Summary/Conclusions: We demonstrated clear OS stratification of AZA-treated patients with MDS/AML into 2 risk groups according to our proposed scoring model using two risk factors, p53 protein overexpression and hyperferritinemia. Although further verification via prospective analysis is needed, these findings may provide valuable information for prognostic predictions of AZA-treated patients with MDS/AML.

E1221

THE IMPORTANCE OF IMMUNOPHENOTYPING OF HEMOPOIETIC PRECURSORS IN THE DIAGNOSIS OF CHILDHOOD MDS

I Lorand-Metze[1,*], AF Oliveira[2], A Tanzini[3], LF Lopes[2], K Metze[4]
[1]Internal Medicine, University of Campinas, Campinas, [2]Pediatrics, [3]Pathology, Cancer Hospital Barretos, Barretos, [4]Pathology, University of Campinas, Campinas, Brazil

Background: immunophenotyping of BM hemopoietic precursors has been recognized as useful ancillary technique to confirm the diagnosis of adult MDS. In children, few data about its utility are available.
Aims: to analyze retrospectively the immunophenotypic features of bone marrow (BM) cells at diagnosis of patients registered in the Brazilian Pediatric Cooperative Group of Myelodysplastic Syndromes (2012-2015).
Methods: diagnosis of the patients was based on clinical data, peripheral blood (PB) counts, BM cytology and histology and cytogenetics. Deficiency anemias, autoimmune diseases and viral infections were excluded, as well as patients with Down's syndrome. Classification was made by the WHO Pediatric Classification. Four pediatric deficiency anemias were used as controls. Immunophenotyping was made by an 8 color platform to evaluate myelomonocytic maturation and progenitor populations according to the recommendations of the European LeukemiaNet.
Results: 32 patients (RCC=6 cases; RAEB/-t=13 cases; JMML=13 cases) and 4 controls (deficiency anemias) were analyzed. Median age: controls=20 months, RCC=66 months, RAEB/-t=68 months and JMML=29 months. The

median number of abnormalities in myeloid maturation was 1.5 (0-4); 3 (0-6) and 3 (1-5) respectively. The median number of abnormalities in $CD34^+$ cells were 2 (1-3); 2.5 (1-6) and 3 (1-5) respectively. So, the total number of phenotypic alterations was 4 (1-6); 3 (2-11) and 6 (2-9) respectively. The percentage of $CD34^+/CD117^+/CD13^+$ cells was 0.5% (0.1-2.8); 3.7% (0.5-8.6) and 4.2% (0.3-10.1) respectively, compared to 1.1% (0.7-1.6) of the control cases. Aberrant cross-lineage antigen expressions in myeloid progenitors were found in 63% of the cases of JMML, in 45% of RAEB/RAEB-t but in none of the RCCs. Hematogones type I ($CD34^+/CD19^+/CD10^+$) were decreased in all groups: 0.28% (0-2.4); 0.5% (0-6.4) and 0.03% (0-0.6) respectively, compared with the controls: 2.1% (0.9-3.2). The same occurred in%$CD34^-/CD19^+/CD10^+$ cells: 1.6% (0-15.5); 0.8% (0-6.2) and 0.02% (0.-2.1) respectively, compared with the controls: 12.0 (3.9-12.9). T lymphocytes were markedly decreased only in patients with JMML. In a discriminant analysis, a model containing age of the patient, percentage of $CD34^+/CD117^+/CD13^+$ cells, hematogones type I, T lymphocytes and total number of phenotypic alterations were able to classify correctly 81% of the patients.

Summary/Conclusions: in childhood MDS, alterations in myeloid precursors and $CD34^+$ myeloid progenitors presented similar changes as in adult MDS. However, the alterations in B cell precursors and T lymphocytes were more pronounced, even in very young children. Phenotypic abnormalities in JMML were more similar to those of RAEB, regardless of the number of BM blasts counted in cytology or any feature of PB counts.

E1222

FAVORABLE OUTCOMES WITH TUMOR BURDEN REDUCTION WITH HYPOMETHYLATING AGENTS BEFORE ALLOGENEIC HEMATOPOIETIC CELL TRANSPLNATATION FOR PATIENTS WITH HIGHER RISK MYELODYSPLASTIC SYNDROME

SW Park[1,*], JY Kim[2], YJ Lee[2], SK Sohn[2], JS Ahn[3], HJ Kim[3], HJ Shin[4], WS Lee[5], SM Lee[5], YD Joo[6], H Kim[7], HS Lee[8], YS Kim[8], YY Cho[9], JH Moon[2]
[1]hemato-oncology, Busan National University Hospital, Busan, [2]Kyungbook University hospital, Daegu, [3]Chonnam National University Hwasun Hospital, Hwasun, [4]Busan National University Hospital, [5]Inje University Busan Baik Hospital, [6]Inje University Haewoondae Baik Hospital, Busan, [7]Ulsan University Hospital, Ulsan, [8]Kosin University Gosper Hospital, Busan, [9]Daegu Catholic University Medical Center, Daegu, Korea, Republic Of

Background: The use of hypomythylating agents (HMA) have improved the outcomes of myelodysplastic syndrome (MDS) in terms of hematologic improvement and long-term survival. HMA treatment while awaiting allogeneic hematopoietic cell transplantation (allo-HCT) or as a purpose of cytoreduction for higher risk MDS can be an attractive option with the hope of successful cytoreduction before allo-SCT. However, the role of induction response or cytoreduction for the patients with higher risk myelodysplastic syndrome (MDS) is not yet clearly defined.

Aims: In this sutdy, the clinical significance of tumor burden and transition of IPSS risk group for transplant eligible patients with higher risk MDS were evaluated.

Methods: The data of 79 transplant eligible patients (<65 years old) diagnosed with higher-risk MDS from Jan 1992 to Mar 2013 and received HMA as frontline therapy were retrospectively analyzed. To evaluate the effects of the tumor burden on treatment outcomes, treatment response (responder *vs* non-responder), IPSS risk group after HMA treatment, transition of IPSS risk group, and blast percentage in bone marrow after HMA treatment were evaluated.

Results: Among 79 patients, 30 patients (38.0%) performed allo-HCT (HCT group) and 49 patiens (62.0%) treated with HMA without allo-HCT (non-HCT group). Median follow-up duration was 778 days (range 143-2921 days) and 375 days (range 7-6561 days) in HCT group and non-HCT group, respectively (p=0.001). Three-year overall survival (OS) rate was significantly higher with HCT group (47.0±12.1%) than non-HCT group (19.6±7.0%, p<0.001), which confirmes the the role of allo-HCT for patients with higher risk MDS. For HCT group, the short duration until allo-HCT showed a better outcomes as regards OS (p=0.035). In the multivariage analysis, blast percentage ≥10% in bone marrow (HR 2.569, 95% CI 1.116-5.916, p=0.027) and IPSS higher risk prior to allo-HCT (HR 5.371, 95% CI 1.886-15.291, p=0.002) were found to be significantly correlated with the OS. However, IPSS transition did not affect the long-term outcomes (HR 0.703, 95% CI 0.079-6.285, p=0.752).

Summary/Conclusions: To predict the clinical outcomes of patients with higher risk MDS, the optimal time for tumor burden evaluation is prior to allo-HCT than at the time of initial diagnosis. For those with lower blasts in the BM or lower IPSS risk group were related with favorable OS. However, as early performance of allo-HCT was associated with favorable OS and IPSS transition did not affect the OS, it may not be resonable to delay allo-HCT to achieve better response to HMA for those who are planning to allo-HCT.

E1223

DISCONTINUATION OF HYPOMETHYLATING AGENT, DOES IT BRING REDUCED SURVIVAL IN PATIENTS WITH NEWLY DIAGNOSED MYELODYSPLASTIC SYNDROME?

HS Lee[1,*], YS Kim[1], JH Moon[2], HJ Kim[3], JW Cheong[4], DY Jo[5], H Kim[6], HS Eom[7], SM Bang[8], WS Lee[9], Y Park[10], MH Lee[11], JH Lee[12], MK Kim[13]
[1]Internal medicine, Kosin University College of Medicine, Kosin University Gospel Hospital, Busan, [2]Internal medicine, Kyungpook National University Hospital, Daegu, [3]Internal medicine, Chonnam National University Hwasun Hospital, Hwasun, [4]Internal medicine, Yonsei University College of Medicine, Seoul, [5]Internal medicine, Chungnam National University Hospital, Daejeon, [6]Internal medicine, University of Ulsan College of Medicine, Ulsan, [7]Internal medicine, National Cancer Center of Korea, Goyang, [8]Internal medicine, Seoul National University Bundang Hospital, Seoul, [9]Internal medicine, Busan Paik Hospital, Busan, [10]Internal medicine, Korea University College of Medicine, [11]Internal medicine, Konkuk University Medical Center, Seoul, [12]Internal medicine, Gachon University Gil Hospital, Incheon, [13]Internal medicine, Yeungnam University Medical Center, Daegu, Korea, Republic Of

Background: The myelodysplastic syndromes (MDSs) are a heterogeneous collection of clonal hematopoietic malignancies that primarily affect the elderly and are characterized by bone marrow failure, dysplasia. In previous study, prolonged treatment duration could have contributed to survival benefit. Although treatment with HMA undoubtedly prolongs survival in patients who have poor prognosis, there are still a significant proportion of patients with MDS who do not respond to therapy with HMA and patients who lose response or progress on therapy. However, in clinical practice, it is difficult to continue treatment of HMA because of problems such as toxicities, poor economics, comorbidities and compliance etc. For those reasons, discontinuation of HMA before disease progression often happen in clinical setting.

Aims: So there are some questions about survival in MDS patients treated with HMA in real clinical practice. Are there any differences of survival in patients with MDS received HMA between treatment failure and discontinuation of HMA ?. And what factors will be helpful to predict survival in both patients group ?.

Methods: The medical records of 246 patients were collected retrospectively from fourteen university hospitals in South Korea between January 2001 and October 2013. All included patients had been newly diagnosed to MDS and they were treated with HMA as front line therapy and they were treated continuously at least 4 cycles. Patients divided two groups into treatment failure group who discontinued HMA treatment due to disease progression and discontinuation of HMA group who stopped HMA treatment because of other cause without disease progression. The treatment free survival (TFS) was defined duration from the end date of HMA therapy to the date of disease progression, relapse, or death from any causes.

Results: The median age of the patients was 68 years. (range 24-92 years) and the male to female ratio was 1.9:1.0. The percentage of lower than 5% of bone marrow myeloblast was 37.9% in treatment failure group, 62.1% in discontinuation group (p=0.015). Patients who found lower risk IPSS or WPSS were documented in discontinuation group more than those in treatment failure group (p=0.050 or 0.005). The median TFS was 4.7 months (range 2.4-7.0) and the median OS was 34.8 months (range 28.4-41.2). In multivariate analysis, treatment failure of HMA is independent risk factor for shorter TFS (RR:5.996, 95% C.I. 3.684-9.757, p<0.001). Age of more than 65 years, bone marrow myeloblast of more than 5%, poor cytogenetics, platelet counts of less than 50 x 10^3/uL, higher risk of WPSS and IPSS-R, median number of HMA cycles of less than 7 cycles and treatment failure of HMA were independent risk factors for shorter OS. Especially, The 3-year TFS and OS were 0.0% *vs* 40.7%, (p<0.001) and 29.7% *vs* 60.2% (p<0.001) in treatment failure group *vs* discontinuation of HMA group, respectively. However, in univariate and multivariate analysis, higher risk of WPSS was independent risk factor for shorter TFS and higher risk of WPSS and median number of HMA of less than 7 cycles were independent risk factors for shorter OS in only discontinuation of HMA group.

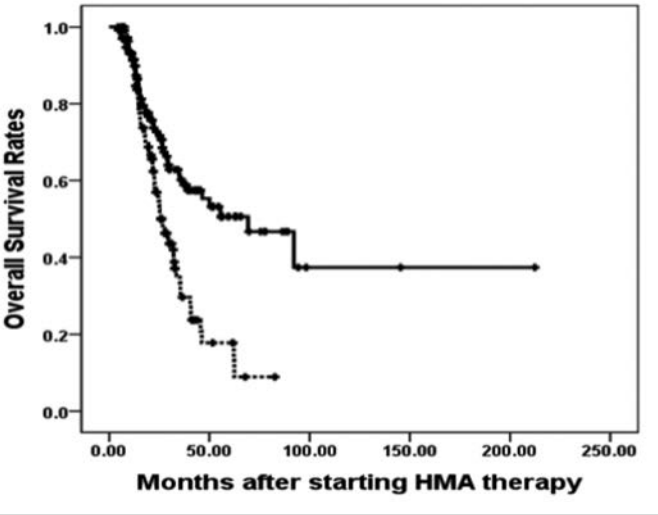

Figure 1.

Summary/Conclusions: Patients who discontinued HMA without disease progression showed prolonged survival than those who failed HMA treatment in real clinical practice. Especially, lower risk of WPSS and more number of performed cycles of HMA may be helpful to predict TFS and OS in patients who discontinued HMA because of other causes such as toxicities, economics or compliance etc.

E1224

HETEROGENEITY IN CYTOGENETIC AND CLINICAL FEATURES OF PATIENTS WITH MYELODYSPLASTIC SYNDROME AND DELETION 5Q

G Papaioannou, A Athanasiadou, E Gavriilaki*, Z Bousiou, M Iskas, M Papathanasiou, N Stavroyianni, I Sakellari, A Anagnostopoulos
Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: Deletion 5q [del(5q)] represents a distinct cytogenetic abnormality in patients with myelodysplastic syndrome (MDS). Although isolated del5q has been linked with favorable prognosis, the role of additional cytogenetic aberrations has not been clearly defined yet.
Aims: We aimed to study patients with MDS del (5q) in terms of cytogenetic and clinical features, as well as treatment outcomes.
Methods: We retrospectively analyzed data from 408 patients (pts) diagnosed with MDS and partial or complete deletion of the long arm of chromosome 5 in our centre from 2007 to 2014. All patients were studied by karyotyping and received standard of care by their treating physicians.
Results: Among 408 MDS pts, del(5q) was detected in 32 (7.8%). Isolated del5q was found in 7/32 (21%). Additional cytogenetic abnormalities were detected in 25/32 pts: chromosomal translocations of 1q, 11q and 20q and deletion of chromosomes 7, 17 and 18. Clinical data were available for 20/32 pts: 17 males: 3 females with a median age of 69.7 at diagnosis. MDS was de novo in 15 pts, post polycythemia vera in 2 pts and treatment-related in 3 pts (post chemotherapy±autologous transplant for Hogdkin lymphoma in 2 pts and for multiple myeloma in 1 pt). At diagnosis, median bone marrow blasts were 6% (range 0-19%). In the peripheral blood, median Hb levels were 8.7g/dl (8-11.7), white blood cell count 4.2K/μl (1.85-2.65) and platelets 131K/μL (26-330). No evidence of thrombocytocis was found. Cytogenetics revealed del(5q) as an isolated abnormality in 3/20 (15%) pts and additional abnormalities in the rest 17/20 (85%) pts. Patients with an isolated del (5q) presented no disease progression and 2/3 are alive in complete remission. One patient with isolated del (5q) succumbed from other causes. According to the IPSS (International Prognostic Scoring System), 6/20 (30%) pts were diagnosed as low and intermediate-1 risk; whereas, 6 pts were classified as intermediate -2 and 8 pts as high-risk. Lenalidomide treatment was initiated in 4 pts among which, 3 had additional cytogenetic abnormalities and classified as intermediate -1 (2 pts) and intermediate -2 (1 pt) risk. Median overall survival in pts treated with lenalidomide was 28 months (3-32) compared to 10 months (1-2) in pts not treated with lenalidomide. Other treatment options were: azacytidine (5 pts classified as high and 2 as intermediate -2 risk), erythropoietin (2 pts classified as intermediate -1 risk), low dose cytarabine (2 pts classified as intermediate -2 and high risk int-2) and hydroxyurea (1 pt classified as high risk). Allogeneic hematopoietic cell transplantation was performed in two pts with intermediate -2 risk according to IPSS.
Summary/Conclusions: Our study confirms that del(5q) as an isolated cytogenetic abnormality is rather rare in patients with MDS compared to del(5q) additional cytogenetic aberrations. Although the majority of additional cytogenetic abnormalities have been traditionally considered non high-risk, our findings link additional cytogenetic abnormalities with higher risk stratification and worse clinical outcomes.

E1225

VALUE OF THE MULTIPARAMETRIC FLOW CYTOMETRY IN LOW RISK MYELODYSPLASTIC SYNDROMES AND TYPE I CHRONIC MYELOMONOCYTIC LEUKEMIA

M Iastrebner[1,*], J Arbelbide[2], E Nucifora[2], D Fantl[2], S Viñuales[2], D Penchasky[2], H Garcia Rivello[2], M Tamashiro[1], V Barcala[3], AMG[4]
[1]Hematology, Sanatorio Sagrado Corazón, [2]Hematology, Hospital Italiano de Buenos Aires, [3]Laboratory - Flow Cytometry, Citomlab, [4]SAH, Ciudad Autónoma de Buenos Aires, Argentina

Background: Heterogeneity in Low Risk Myelodysplastic Syndromes (MDS) and Type I Chronic Myelomonocytic Leukemia (CMML) is very remarkable and demands a maximum expertise to establish the diagnosis and prognosis. Multiparametric Flow Cytometry (MFC) should allow physicians to systematize and standardize this assessment.
Aims: To analyze, by using MFC, the value of the immunophenotypic changes in Low Risk MDS and type I CMML patients.
Methods: This retrospective study included low risk MDS and type I CMML adult patients (pts) at diagnosis, and used FAB, WHO, and IPSS classifications. An eight-color MFC and a specific MDS panel validated by Euroflow with Infinicyt® program were applied. Granulocytic maturation is classified into 3 groups according to precise stops or blocking maturation observed in myeloblasts (Mbl) (stage 1), in promyelocytes (Pro) and metamyelocytes (MT) (stage 2), and without any blocking or Neutrophil (N) (stage 3):

Stage 1 (Mbl)	Stage 2 (Pro+MT)	Stage 3 (N)
>3,5% or >2,8% + >Stage 2	>48% with < stage I	>58,5% with < stage 2

Blasts (CD34), erythroid, monocyte (Mo), and mast cells count (≥0,04), aberrance and blocking maturation were taken into account. Peripheral cytopenia, cytogenetic, AML progression, and mortality rate were also studied. Informed consent was obtained.
Results: Sixty-six pts with low risk primary MDS (n=49) and CMML (n=17) were assessed. Median age 71 (R 21-89), male/female gender: 37/29, WHO classification: RCMDRS (1), RCMD (37), 5q- (2), RARS (1), RA (4), RAEB-1 (5) and type I CMML (17). AML progression: 15%; mortality rate: 30%, and causes of death: infections (35%), AML (40%), comorbidities (20%) and second tumor (5%). Sixty-two pts were evaluable for blocking granulocytic maturation and were divided into 3 groups: stage 1 (20), stage 2 (16) and stage 3 (26). Stage 1: (20 pts), 31.3% (CD34+ 1.92; range: 0.14-6.59), overall survival: 34 months (median), p=0,001 and, stage 2 and 3 were p=ns. Progression to AML was similar among all groups (p=ns). CMML patients had an increased blocking maturation in promonocyte stage (p=0,05), but not showed difference in mature monocytes (p=ns). Excluding CMML pts, we found that immature monocyte group (<56%) was significantly associated with thrombocytopenia (p=0,038), without any incidence over other cytopenia and cytogenetic abnormalities (p=ns). The overall survival was decreased with mast cells count ≥0.04 (with a median of 34 months; p=0.04), independently of the staging maturation group. Erythroid Aberrancies did not show higher transfusion requirement rate (p=0,5).
Summary/Conclusions: MFC in low risk MDS and type I CMML proved to be objective and reproducible by standards. Immature monocyte in MDS group correlated with thrombocytopenia (p=0,038). Short overall survival was associated with high mast cells count (p=0.04) and early granulocyte stages blocking maturation (p=0,001).

E1226

CLINICAL AND HEMATOLOGICAL FEATURES OF PRIMARY MYELODYSPLASTIC SYNDROMES IN ADULTS AND CHILDREN

N Klimkovich[1,*], O Krasko[2]
[1]Department of Pediatric Oncology and Hematology, Byelorussian Medical Academy of Post-Graduate Education, [2]Laboratory of Bioinformatics, United Institute of Informatics Problems of the National Academy of Sciences, Minsk, Belarus

Background: Myelodysplastic syndromes (MDS) are included into a heterogeneous group of clonal blood diseases characterized by peripheral cytopenias, dysplastic features of hematopoietic precursors, progressive deterioration and a high risk of transformation into leukemia. MDS occur in several versions that differ in frequency of appearance, the duration of the course and the probability of transformation into acute leukemia. There are differences in the structure of MDS variants in patients of different age. This is the basis for the discussion of clinical and hematological characteristics of primary MDS and systematization of the results.
Aims: Analysis of the clinical and laboratory characteristics of patients with primary MDS, depending on age.
Methods: The study included 162 (144 adults and 18 children) with primary MDS patients aged from 1.5 to 60 years (median age 49 years, adults, children - 8 years). The material of the study were clinical and medical history, peripheral blood (PC) and bone marrow (BM). Clinical criteria for inclusion of patients in the study: a verified diagnosis of MDS, setting variant of the disease in accordance with the criteria of the WHO classification of myeloid neoplasms (2008), written informed consent for inclusion in the study. The calculations are performed in the R version 3.1.3 statistical package.
Results: Primary MDS have a features of clinical - hematological manifestations in the age groups under 18 years, 18-39 years and 40-60 years, with the result that appears different variants of structure (p=0.028) and by IPSS risk categories (p=0.001). IPSS demonstrates a high prognostic significance in adult patients (p<0.001), in contrast to pediatric MDS (p=0.110). Most cases of MDS in children have been the normocytic anemia (MCV 86,5 (73... 103) fl). While MDS for adults, irrespective of age, a feature of dysplasia is macrocytosis (MCV 101,5 (83.. 123) fl), p<0.001. In children occur the hypocellularity BM in 22.2%. Adult patients have this characteristic in 2.8% of the age group of 18-39 years and there is no group in the 40-60 years of age (p<0.001). Erythroid hyperplasia BM and availability of microforms megakaryocytes BM are frequent signs of MDS in adults (72.2% and 94.4% in the age group 18-39 years, 62% and 92.6% in the age group 40-60 years, respectively). In children occur this feature only 22.2% and 66.7% of cases (p<0,001 and p= 0.002, respectively). Many young granulocytes in BM biopsy (p=0.022) and BM stroma fibrosis (p=0.036) more common in MDS in the age group 40-60 years compared to patients under 18 years and 18-39 years. A normal karyotype was detected in 71.8% of adults and 77.8% of children with MDS. In adult patients with MDS with increasing age decreases the frequency of normal karyotype with an increase in the num-

ber of unbalanced and complex aberrations. Children with MDS were observed with the same frequency the isolated and complex cytogenetic damage.
Summary/Conclusions: Patients with MDS of different age groups (children 18-40 years and 40-60 years) have variable manifestations of MDS, which is determined by the structure of variants, frequency of cytogenetic and dysplastic abnormalities BM cells, the intensity of the progression. Childhood MDS is a separate group of disease with features of clinical and hematological manifestations different from adults, which makes the feasibility of its version in the classification.

E1227

IS IT POSSIBLE TO DIAGNOSE LOW RISK MYELODYSPLASTIC SYNDROME (MDS) BY FLOW CYTOMETRY?
E Atilla[1,*], P Ataca Atilla[1], O Turedi[2], S Civriz Bozdag[1], S Kocak Toprak[1], H Akan[1], M Beksac[1], O Arslan[1], P Topcuoglu[1], M Ozcan[1], O Ilhan[1], HI Ruhi[2], G Gurman[1], K Dalva[1]
[1]Ankara University School of Medicine Department of Hematology, [2]Ankara University School of Medicine Department of Genetics, Ankara, Turkey

Background: World Health Organization (WHO) classifies myelodysplastic syndromes due to patolological hallmark of marrow dysplasia. Flow cytometry immunophenotyping has a crucial role in diagnosis and management of hematological malignancies. Ogata et al. demostrated a simple flow cytometry (FCM) score which helped to establish the diagnosis of MDS in patients without specific markers of marrow dysplasia.
Aims: Our aim in this study is to evaluate the patients who had biopsied for diagnosis of MDS in 2015, confirm with pathology and restage them with FCM-score at Ankara University School of Medicine Department of Hematology.
Methods:: From 386 patients presented with cytopenias, 78 (20%) was morphologically diagnosed with MDS. Four parameters were combined in a regression model in FCM score; increased myeloblast-related cluster size, decreased B-progenitor related cluster size, aberrant CD45 expression and reduced granulocyte side scatter. All MDS diagnosed patients were reevaluated with FCM score. The diagnosis of MDS was formulated in the case that the value of the FCM-score was 2 or more. Chi-squared test was used for categorical variables.
Results: Median age of 78 patients was 62 (range, 18-90), 49 (62%) of them was male. Patient characteristics were shown in table. Totally 44 patients (56%) from 78 patients had FCM-score 2 or more. Patients with MDS without specific markers of marrow dysplasia (such as ring sideroblasts and/or clonal chromosomal abnormalities) were 34% of FCM score positive population. In MDS patients high FCM score (3 or 4) was found to be significantly associated with transfusion dependency (P=0.021) and resulting in higher WPSS risk (P=0.002).

Table 1.

Karyotype, n (%)		Treatments, n (%)	
Very good	2 (3%)	None	34 (44%)
Good	48 (62%)	ESA and/or Filgrastim	15 (19%)
Intermediate	13 (17%)	Tabelomid/Danazol	6 (8%)
Poor	8 (10%)	Azacytidine	23 (29%)
Very poor	7 (9%)		
WHO diagnosis classification, n (%)		Response to treatments, n(%)	
RA	26 (33%)	Remission	38(49%)
RARS	7 (9%)	Stable	4 (5%)
RCMD	18 (24%)	Progression	6 (8%)
RAEB-1	7 (9%)		
RAEB-2	20 (26%)		
R-IPSS, (%)		WPSS, (%)	
very low/low/intermediate /high/very high	18%/27%/23%/28% /14%	very low/low/intermediate/high /very high	28%/32%/12%/28%/17%

Summary/Conclusions: FCM score can be a new tool for low risk MDS patients without specific markers of marrow dysplasia.

E1228

CLINICAL CHARACTERISTICS OF PATIENTS WITH MYELOID NEOPLASMS FROM REGIONS CONTAMINATED BY DEPLETED URANIUM: 20 YEAR ANALYSIS
A Kozaric[1,*], L Mehinovic[1], S Kurtovic[2], A Dizdarevic[2]
[1]Pathology, Cytology and Human Genetics, [2]Hematology, Clinical Center of The University of Sarajevo, Sarajevo, Bosnia and Herzegovina

Background: Depleted uranium (DU), a radioactive heavy metal, is used in military ammunition. It emits alpha particles and has the half life of 4.5 billion years. Studies have shown the potential health risks of contamination by DU by wounding, ingestion, and inhalation. *In vivo* and *in vitro* experiments showed the carcinogenic potential of DU by neoplastic transformation of human and mouse cells, leading to the development of myeloid neoplasms. It is assumed that the DU exposure induces genomic stability leading to carcinogenesis. During the war in Bosnia, DU ammunition was used in several towns, including the town of Hadzici. United Nations have measured the concentrations of depleted uranium and showed a significant increase in the municipality of Hadzici.
Aims: Increased numbers of patients with blood cancers was observed by hematologists in DU-stricken area, so we systematically analyzed hematological patients from this region in the last 20 years, from 01.01.1996.-31.12.2015.
Methods: Two regions were analyzed: DU stricken and a control region. As a control region, patients from a town with the same population number were used. Patient data from 01.01.1996.-31.12.2015 was collected including age at diagnosis, sex, address, blood parameters, cytogenetics, therapy, and survival.
Results: In the 20 year analyzed period from 01.01.1996–31.12.2015, we found 717 patients with hematological conditions (437 from DU-stricken town *vs* 280 from control town). There were 74 patients with myeloid malignancies (54 *vs* 20), 55 patients with non Hodgkin lymphoma (26 *vs* 29), 21 patients with Hodgkin lymphoma (9 *vs* 12), and 6 patients with ALL (4 *vs* 2). Among the myeloid neoplasms, MDS showed a 6 fold change. The median age at diagnosis for MDS patients was 50 *vs* 65. Male to female ratio was MDS 0.5 *vs* 1. Median age at diagnosis was 50 in DU-stricken area *vs* 65 in control region. Patients from the DU area showed the trends towards higher IPSS-R score (50% of patients had intermediate and 17% had very high score) compared to the control and international data.
Summary/Conclusions: Clinical parameters showed more severe course of myeloid malignancies in DU stricken area compared to the control and internatinal data. Further investigation is needed to elucidate the possible causes of stark increase in myeloid neoplasms in DU stricken area.

E1229

CLINICAL AND LABORATORIAL CHARACTERISTICS OF A COHORT OF PATIENTS WITH MYELODYSPLASTIC SYNDROME AND ERYTHROID HYPERPLASIA
Y Yu, A Sun[*], S Chen, Q Wang, T Zhang, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Myelodysplastic syndrome (MDS) is a clonal disease of hematopoietic stem cells, which is a clinically and biologically heterogeneous group of disorders associated with ineffective hematopoiesis, abnormal differentiation, and cytopenias. Approximately one third of MDS patients progress to secondary acute myeloid leukemia (sAML). Erythroid hyperplasia is very common in MDS patients, the proportion of erythroid was frequently more than thirty percent,even fifty percent, compared to ten percent to forty percent in normal bone marrow. The Erythroid hyperplasia is characterized with relatively or absolutely increase in the number of erythroid precursor cells, erythroid maturity curve shifts to the left, increase in early/late erythrocyte ratio, propagation of erythroid blasts and erythroid precursor cells. Erythroid hyperplasia is an important characteristic of MDS, however, there is still a lack of a related study of erythroid hyperplasia's significance in MDS.
Aims: To investigate the clinical and laboratorial characteristics of patients with myelodysplastic Syndrome (MDS) and erythroid hyperplasia.
Methods: We defined MDS patients whose bone marrow was hypercellular, the proportion of erythroid was more than fifty percent, and the ratio of mature erythrocytes and nucleated erythrocytes was no more than 20 as MDS patients with erythroid hyperplasia.(MDS-E). The retrospective analysis comprised 102 patients with MDS-E from the first affiliated hospital of Suzhou university. We analyzed their clinical characteristics, karyotype, and the effect of erythroid hyperplasia on their prognosis.
Results: 48 of 102(47%)MDS-E patients had a variety of cytogenetic abnormalities. The most frequent involved chromosomes were chromosomes 8(39.5% of all abnormal karyotypes), chromosomes 7(23%), followed by chromosomes 1(16.7%) and 20(16.7%). Survival analysis showed that the level of hemoglobin make a influence on prognosis. The overall survival(OS) of MDS-E patients with the level of hemoglobin more than 70 g/L was longer than that of patients whose hemoglobin concentration was less than 70 g/L(*P*<0.001). Hematopoietic stem cell transplantation (HSCT) could improve OS of MDS-E patients(*P*<0.001). In the chemotherapy group, MDS-E patients receiving chemotherapy including Decitabine had superior OS over those who were not treated with Decitabine.(*P*=0.014).
Summary/Conclusions: MDS-E patients have their own unique biological features compared with other MDS patients. The level of hemoglobin concentration and erythroid hyperplasia in bone marrow can affect MDS-E patients' prognosis. The using of Decitabine in chemotherapy and HSCT can improve OS of MDS-E patients.

E1230

TP53 GENE MUTATIONS IMPACT ON OVERALL SURVIVAL OF PATIENTS TREATED WITH LOW-DOSE CLOFARABINE AS A SECOND LINE THERAPY DUE TO THEIR RESISTANCE TO AZACITIDINE

T Braun[1,*], B Papoular[1], A Renneville[2], E Raffoux[3], T Prebet[4], S Brechignac[1], A Stamatoullas[5], F Dreyfus[6], B Samey[7], L Ades[7], N Vey[4], H Dombret[3], C Preudhomme[2], P Fenaux[7], C Gardin[1]
[1]Hematology, Avicenne Hospital Paris XIII University, Bobigny, [2]Molecular Biology, CHRU Lille, Lille, [3]Hematology, Saint Louis Hospital University Paris VII, Paris, [4]Hematology, Institut Paoli Calmettes, Marseille, [5]Hematology, Centre Henri Becquerel, Rouen, [6]Cochin Hospital University Paris V, [7]Hematology Seniors, Saint Louis Hospital University Paris VII, Paris, France

Background: Patients with higher risk Myelodysplastic Syndromes (IPSS-INT2 and High; HR-MDS) failing treatment with hypomethylating agents (azacitidine and decitabine; HMA) have a very poor outcome with a median survival of 5 months. No standard treatment is defined in this setting. We have recently conducted a dose escalation trial of clofarabine, at a starting daily dose of 5 mg/m2, among patients with HR-MDS or AML evolving from MDS if failing prior azacitidine therapy (NCT01063257; Braun et al., ASH 2011). Among MDS/AML associated mutations, TP53 gene mutations confer a poor patients overall survival and a short response duration to HMA (Takahashi et al., Oncotarget 2016).
Aims: We analyzed these MDS/AML mutations in respect to drug response and overall survival in this second line therapy trial.
Methods: Twenty-seven patients with a median age of 71 years (62-90) were included after informed consent from December 2009 to July 2012. All were due to receive clofarabine at a dose ranging from 5 to 10/m2 either for 5 consecutive days or 5 doses over 10 days, for a maximum of 8 cycles. All study patients were analyzed by next generation sequencing for evidence of mutations in the following genes: TET2, ASXL1, RUNX1, DNMT3a, TP53, IDH1/2, NRAS/KRAS, CBL, ETV6, EZH2, FLT3-ITD, NPM, JAK2, MPL515, PTPN11, SETBP1, SF3B1, SRSF2, U2AF1 and ZRSR2. Gene mutations identified by NGS were checked by Sanger sequencing if necessary.
Results: Twenty patients (74%) had HR-MDS including 1 patient with Chronic Myelomonocytic Leukemia-2 and 7 (26%) patients had AML evolving from MDS (16F/11M). Fifteen (56%) patients had adverse karyotype including 9 patients with complex cytogenetics. Among 8 (29%) patients, a TP53 mutation could be detected, which was isolated in 4 cases and associated with a complex karyotype in 7/8 cases. Distribution of the other gene mutations detected in this cohort were as follows: ASXL1 (26%), DNMT3a (22%), RUNX1 (15%), TET2 (15%), SRSF2 (15%), U2AF1 (11%), SF3B1 (11%), EZH2 (7%), IDH2 (7%), ETV6 (7%), NRAS (3.5%), ZRSR2 (3.5%), FLT3-ITD (3.5%), PTPN11 (3.5%) and SETBP1 (3.5%). Four (15%) patients had no gene mutation detected, 8 (29%) patients had 2 and 6 (22%) patients had at least 3 or more mutations detected. Only the detection of TP53 mutations had a significant impact on overall survival with a median survival of 4.7 *versus* 8.4 months of TP53 mutated patients and unmutated patients respectively (p=0.0022). The two other most frequent mutations of the ASXL1 and DNMT3a genes in this population, did no impact overall survival even among patients unmutated for TP53. As expected, adverse karyotype was significantly associated with shorter overall survival (8 months *versus* 4.4 months; p=0.017). When excluding patiens with TP53 mutations, survival of patients with unfavorable cytogenetics was not significantly shorter when compared to patients with intermediate or favorable cytogenetics (7.2 months *versus* 10.9 months; p=0.31). Eight (32%) of 25 patients evaluable for response achieved response according to IWG 2006 criteria after 1 or 2 cycles of clofarabine (1 CR, 4 mCR+HI, 2 mCR and 1 HI) and 10 (40%) patients had stable disease. Overall survival was 11.1 months (CI 0.68-3.9) *versus* 6.7 months (CI 0.25-1.46) in responders and non-responders to clofarabine respectively (p=0.18). In this phase I low-dose clofarabine trial, TP53 mutations were detected among 7/19 non-responders and 1/8 responding patients (p=0.36) to clofarabine. Interestingly, 6 of the 8 patients mutated for TP53 had obtained a prior response to azacitidine before relapse. Mutations of ASXL1 (p=0.63) and DNMT3a (p=1) had no impact on response to clofarabine.
Summary/Conclusions: Presence of TP53 mutations, detected here in about 50% of patients with an unfavorable karyotype, appears to be the most powerful adverse prognostic factor for overall survival in this MDS/AML population selected by its resistance to azacitidine.

E1231

REPORT ON OUTCOME OF HYPOMETHYLATING THERAPY WITH ANALYSIS ON PROGNOSTIC VALUE OF REVISED-INTERNATIONAL PROGNOSTIC SCORING SYSTEM IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES OF LOWER-RISK BASED ON IPSS

Y Lee[1], J Moon[2], J Yoon[1], J Kim[1,*], S Sohn[1]
[1]Hematology, Kyungpook National University Hospital, [2]Hematology, Kyungpook national university of hospital, Daegu, Korea, Republic Of

Background: The outcome of patients with lower risk myelodysplastic syndromes (LR-MDS) by International Prognostic Scoring System (IPSS) is very various and sometimes poorer than expected.
Aims: We retrospectively evaluated the prognostic value of revised-International Prognostic Scoring System (IPSS-R) in accordance with Hypomethylating therapy (HMT) response for precise prognostication.
Methods: The treatment outcome of 236 patients with IPSS LR-MDS who received HMT in the Korean MDS Working Party was retrospectively evaluated. The patients were reclassified to very low/low (VL/L), intermediate (INT), and high (H) risk groups by IPSS-R.
Results: According to the HMT response, 3 year overall survival (OS) did not differ between response group (43.4±0.8%) and stable group (Fig 1. 53.6±0.6%, p=0. 672). Although 25 patients (38.4%) out of 65 responders had a benefit to continued HMT with a median 14 cycles, H risk group was only 2 patients. Among 27 patients (41.5%) progressed to secondary failure, H risk group was most common. Indeed, 42 patients (20.8%) out of 236 patients with LR-MDS had changed to H risk group based on IPSS-R. Median OS was 63.8 months (range, 32.6-95 months) in VL/L, 35 months (range, 24.2-45.9 months) in INT, and 22.3 months (range, 16.6-27.9 months) in H risk group, respectively (Fig-2. p<0.001). Transformation to AML was 8 patients (8.8%) in VL/L, 12 (12.7%) in INT, and 10 (23.8%) in H risk group (p=0.049). On multivariate analysis, the following factors were associated with survival: age ≥65 (HR= 1.731, p=0.023), ECOG ≥2 (HR= 4.997, p<0.001), H risk group by IPSS-R (HR=3.054, 95% CI=1.714-5.441, p<0.001), blast ≥5% (HR= 2.070, p=0.035), P/VP cytogenetic risk by IPSS-R (HR= 4.501, p=0.006) and transformation to AML (HR=2.208, p=0.007).

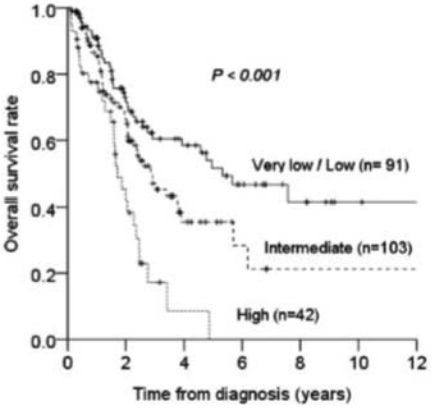

Figure 1.

Summary/Conclusions: If patients with LR-MDS are included in the H risk by IPSS-R, they should be considered early allo-HCT regardless of current benefits from HMT. Prospective study will be needed to establish the therapeutic strategies in MDS patients with Low-risk by IPSS including optimal timing of allogeneic transplantation and the continuing HMT.

E1232

SPRESAS (SPANISH REGISTRY OF ERYTHROPOIETIC STIMULATING AGENTS STUDY) SUBANALYSIS: IMPACT OF COMORBIDITIES AND CENTER LEVEL ON RESPONSE TO ESAS IN LOWER RISK MDS

J Davila Valls[1,*], M Sanchez Barba[2], M Lopez Pavia[1], E Such[1], T Bernal[1], E Luño[1], F Ramos[1], M Calabuig[1], H Pomares[1], B Gonzalez[1], B Merchan[1], E Barranco[1], R Sancho Tello[1], M Callejas[1], MJ Requena[1], MJ Jimenez[1], M Pedreño[1], A Medina[1], AI Vicente[1], A Campeny[1], M Cortes Sansa[1], C Pedro[1], JF Falantes[1], MJ Arilla[1], A Barez[1], R Garcia[1], MJ Arcos[1], V Gomez[1], C Muñoz[1], C Cervero[1], J Casaño[1], R de Paz[1], L Amigo[1], A Insunza[1], JA Muñoz[1], MT Cedena[1], M Gomez[1], P Font[1], R del Campo[1], C Fernandez Lago[1], JA Gonzalez Hurtado[1], MD Linares Latorre[1], A Mora Casado[1], M Vahi[1], L Benlloch[3], GF Sanz[1], MC Del Cañizo Fernandez-Roldan[1], M Diez Campelo[1]
[1]GESMD, Valencia, [2]Departamento de Estadística, Universidad de Salamanca, Salamanca, [3]Hospital Universitario de La Fe, Valencia, Spain

Background: Myelodisplastic syndromes (MDS) are heterogeneous diseases in old patients. These patients show very often comorbidities that could decrease the overall survival and the quality of life. Erythropoietic-stimulating agents (ESAs) are the most used treatment for low risk MDS with anemia and are available in almost all centers from the smallest ones to the big reference centers. The impact of the presence of comorbidities and the size of center where the treatment is administered on treatment response has not been still analyzed.
Aims: The main endpoint was to evaluate the impact of comorbidities on the response to ESAs treatment. The secondary endpoint was to evaluate if the size of the hospital where this treatment is administered influences on it.
Methods: Data from 530 patients with low or intermediate-1 risk MDS (according to FAB and WHO criteria) who received treatments with ESAs were recorded in SPRESAS. 458 of these patients had data available at diagnosis of MDS regarding comorbidities. These were classified as relevant (diabetes mellitus, atrial fibrillation, thromboembolic disease and renal impairement) and less rel-

evant (arterial hypertension, others). Data from the size of the center where the treatment was administered were available in all the patients. Centers were distributed in levels according to the number of beds available: centers above 1000 beds were considered "level 1" centers, between 500 and 1000 as "level 2" and below 500 beds as "level 3". Response was evaluated according IWG 2006 criteria.

Results: 370 patients (80.8%) had at least one comorbidity, but when only relevant comorbidities were analyzed, only 252 patients (55.0%) presented at least one comorbidity (table 1). The presence of one comorbidity relevant or not did not show any impact on the overall response to ESAs (HR=1.441; p= 0.138 for one comorbidity; HR=1.278; p=0.223 for one relevant comorbidity). However, curiously, the presence of two or more comorbidities was associated with statistically significant better response to ESAs (68.9% response in patients with two or more comorbidities *vs* 64.2% in patients with less than two comorbidities; HR=3.014; p=0.004), the only difference between both groups was ferritine level while other variables with impact on response were similar in both groups (PB and BM blasts, Hb level, cytogenetics, transfusion dependency, IPSS and EPO level). Additionally, the presence of two or more relevant comorbidities was also associated with a better response (75.2% response in patients with two or more relevant comorbidities *vs* 64.0% in patients with less than two relevant comorbidities; HR= 4.126; p=0.001). These 2 groups were different regarding ferritine and EPO level. When the impact of the different comorbidities was studied, only hypertension showed influence on the overall response rate: patients with hypertension had statistically significant better response to ESAs (72.7%) than those who did not have hypertension (61.5%); p=0.015, both groups had similar characteristics regarding variables with impact on response. Regarding center size, 213 patients (40.2%) were treated in "level 1"; 174 (32.8%) in "level 2" and 143 (27.0%) in "level 3" centers. When the center level was analyzed we could verify that patients who were treated in the smallest "level 3" centers had a statistically significant higher overall response rate to ESAs (81.7%) when compared with "level 2" patients (66.0%) and "level 1" patients (52.8%), HR=3.995; p<0.001; there were less patients in transfusion dependence in "level 3" centers than in the others while other characteristics were similar in the 3 groups. No differences were observed regarding duration of ESAs response (p=0.098).

Table 1. Comorbidities distribution.

COMORBIDITIES	YES	NO
Any comorbidity	370 (80.8%)	88 (19.2%)
Any relevant comorbidity	252 (55.0%)	206 (45.0%)
Two or more comorbidities	228 (49.8%)	230 (50.2%)
Two or more relevant comorbidities	106 (23.1%)	352 (76.9%)
Hypertension	204 (44.5%)	254 (55.6%)
Diabetes mellitus	109 (23.8%)	349 (76.2%)
Thromboembolic disease	26 (5.7%)	432 (94.3%)
Atrial fibrillation	65 (14.2%)	393 (85.8%)
Renal impairment	82 (17.9%)	376 (82.1%)
Concomitant hematologic disease	35 (7.6%)	423 (92.4%)
Other less relevant comorbidities	119 (26.0%)	339 (74.0%)
Other relevant comorbidities	128 (27.9%)	330 (72.1%)

Summary/Conclusions: The present study shows that ESA treatment should not be avoided in patients with lower risk MDS with comorbidities, as response rates are similar to those of patients without. Patients treated in the smallest centers had the best response rates to ESA.

LB2260

IMPACT OF PREVIOUS TRANSFUSION AND COMORBIDITIES IN THE IPSS-R FOR OVERALL SURVIVAL

DV Nicolás[1,*], G Teresa[2], G Francisco[3], A Manuel[4], G Lorena[5], A Olga[5], G Hermitas[6], S Sandra[7], F Angeles[8], R Rafael[9], L Inés[9], G Agustín[9], M Carmen[10], U Carlos[11], B Jose Luis[1]

Santiago de Compostela, [2]Citogenetics, Fundación Xenómica, Santiago de Compostela, [3]Statistics, Hospital Clínico Universitario, Santiago de Compostela, [4]Haematology, Hospital Comarcal de Valdeorras, O Barco de Valdeorras, [5]Haematology, Hospital Xeral-Calde, Lugo, [6]Haematology, Hospital Comarcal de Monforte, Monforte de Lemos, [7]Haematology, Hospital Meixoeiro, Vigo, [8]Haematology, CHUVI, Vigo, [9]Haematology, CHOP, Pontevedra, [10]Haematology, Hospital Arquitecto Marcide, Ferrol, [11]Haematology, CHOU, Orense, Spain

Background: Myelodisplastic sindromes(MDS) are heterogeneus clonal hematological disorders, with different clinical outcome. The revised international prognostic score system (IPSS-R) showed improvement prognostic power as compared to IPSS. Disease and patient related factors not considered in IPSS-R are emerging as relevant for prognosis of individual patients with MDS.

Aims: This is a retropective cohort study to validate the IPSS-R and evaluate the impact of new variables in a MDS patients serie, wondering if adds any prognostic survival prediction at diagnosis.

Methods: Data from 339 patients diagnosed with MDS in 11 hospitals located in Galicia, Spain from January 1,2007 to december 31,2011. End of the follow-up time was december 18,2012. The patients were registered in the central area citogenetic database and were reclassified according to 2008 WHO Criteria. Data of 30 patients with secondary MDS were included and CMML or AML diagnosys were excluded. Patients treatment was heterogeneous (conservative,supportive treatment, chemotherapy, IMIDs, hypometilant agents, BMT and others). The study was approved by the regional ethical committee.

Results: Population: 44% females and 56% males. Median age: 78 years (range 29-100). Median follow-up time: 1,7 years. Median survival time: 3,5 years. According to 2008 WHO classification: 14%CRDU, 11%RARS, 31% RCMD, 8% RCDMSA, 8% MDS (del5q), 12% RAEB-1, 12% RAEB-2,1% U-MDS. Included 1% fibrotic and 2% hipoplastic MDS. According IPSS, patients were classified as low risk: 43%,(median survival-MS-: 5 years), intermediate-1:37% (MS:3,2 years), intermediate-2:16% and high risk: 4%(MS:5, 3.2, 1 and 0.3 years respectively). According IPSS-R: low IPSS risk patients were shifted to very low, low and intermediate risk (43%, 53% and 4%. MS not reached, 4.4 and 3.6 years respectively). Intermediate-1 patients spread into very low (5%), low(54%), intermediate(31%), high, and very high risk(8% and 1%, MS:1 and 0.6 year). Intermediate-2 IPSS patients were classified into intermediate (26%), high (46%) and very high(28%)risk. High risk IPSS patients were staged in very high IPSS-R risk. The 3 and 5 year ROC survival curves and AUC was better for the IPSS-R than the IPSS(p<0.001)but not at 1 year. We studied 4 new variables at diagnosis to improve the survival prognostic IPSS-R prediction. Ferritin and LDH serum levels, comorbidities (measured by MDS-CI index)and previous RBC transfusión (at least two RBC in the 4 previous months).Univariate analisys not showed statistical significance for the serum LDH.The multivariate analisys didn´t it for serum ferritin levels.Data available for 327 patients for previous transfusion showed 46 individuals transfused (14%).Risk stratification according MDS-CI: 339 patients:41%low risk,43% intermediate risk,16% high risk. The most frecuent observed comorbidities were: cardiac disease (35%), other tumour (15%) pulmonary (14%), renal (9%), hepatic (2%). ROC curves and AUC at 1,3 and 5 years showed better survival prediction power for IPSS-R if we added the two last variables individually and increase if we add the two variables simultaneously(p<0.001).

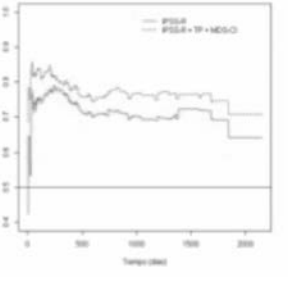

Figure 1.

Summary/Conclusions: IPSS-R provides pronostic power for OS compared to IPSS but not includes emerging relevant clinical events. Comorbidities exert a negative impact in life expectancy on MDS patients.Intrinsic MDS characterystics like anemia can worse patients sickness.Previous transfusion can reflect more aggressive disease or late diagnosis.Late iron develop has a negative impact in morbidity/mortality.Our study showed that adds the two variables improve the IPSS-R prognostic power for OS and helps in clinical decisión making.

LB2261

THE EFFECT OF MESENCHYMAL STEM CELLS DERIVED FROM DIFFERENT SOURCES IN COMBINATION WITH HAPLOIDENTICAL HSCT IN THE TREATMENT OF BONE MARROW TYPE RADIATION SICKNESS

YH Jia, SJ Yang, X Zhang*

Department of Hematology, Xinqiao Hospital, The Third Military Medical University, Chongqing, China

Background: Mesenchymal stem cells (MSCs) in the microenvironment can come from different origins and exhibit a diversity of properties. However, source-dependent and donor-dependent differences in MSCs properties, including their clinical application are still largely disputed.

Aims: To investigate the effect of the transplantation of mesenchymal stem cells (MSC) derived from different sources in combination with hematopoietic stem cells (HSC) in the treatment of bone marrow type radiation sickness.

Methods: 100 mice (CB6F1(H-2b×d)) were hybrids of C57BL/6 (H-2b) and BABL/C (H-2d), 8 weeks old, weight 18g-22g ,and were divided into 5 groups after 8.5Gy total body irradiation (TBI) of ^{60}Coγray, according to a completely randomized design, irradiation group (n=20), HSC transplantation group (n=20), human umbilical cord blood MSCs (HucbMSCs) and HSC cotransplantation group (n=20), bone marrow MSCs (BMMSCs) and HSC cotransplantation group (n=20), dermal MSCs (DMSCs) and HSC cotransplantation group (n=20). The clinical manifestation of mice were observed after trans-

plantation. The survival rate, pathological changes of BM, and other indicators were tested.
Results: Hair back , decreased activity, diarrhea and weight loss appeared at three days after irradiation. At the 11th day, all mice in irradiation group died while the amount of eating and drinking increased and body weight began to recover in the transplantation group. The clinical manifestation score of GVHD in cotransplantation group was lower than that in single transplantation. At 28th day after irradiation, the survival rate of mice in HucbMSCs group was 95%,which were 85%, 80% and 70% in BMMSCs group, DMSC group and transplantation group respectively. The hematopoietic reconstitution taperoffed in cotransplantation group, transplantation group, HucbMSCs group, BMMSCs group, and DMSCs group. The lowest value of hemogram were appear at 3-7d of WBC, 7-10d of PLT, and 10-14d of RBC after transplantation. The pathological change and the colony formation ability of BM were consistent with the change in hemogram.
Summary/Conclusions: MSCs could promote hematopoietic reconstitution and reduce GVHD effect in bone marrow type radiation sickness. HucbMSCs has better application prospect than others in bone marrow type radiation sickness.

Myeloma and other monoclonal gammopathies - Biology

E1233

IN MULTIPLE MYELOMA THERE ARE TWO SUBSETS OF IMMUNOSUPPRESSIVE POLYMORPHONUCLEAR NEUTROPHILS WITH INCREASED LEVELS OF ARGINASE

A Romano[1,*], V Simeon[2], NL Parrinello[1], C Giallongo[1], P La Cava[1], C Conticello[1], ML Consoli[3], M Parisi[1], D Tibullo[1], P Musto[2], F Di Raimondo[1]
[1]Division of Hematology, University of Catania, Catania, [2]Laboratory of Preclinical and Translational Research, CROB Referral Cancer Center of Basilicata, Rionero in Vulture, [3]Division of Hematology, Ospedale Ferrarotto, Catania, Italy

Background: Multiple Myeloma (MM) is a plasma cell malignancy with a well documented immune dysfunction. Development of MM is associated with accumulation of Myeloid-Derived suppressor cells (MDSC), mostly represented by pathologically activated relatively immature polymorphonuclear neutrophils (G-MDSC). Our previous work showed that also mature polymorphonuclear neutrophils (PMN) are activated and immunosuppressive in MM.
Aims: We hypothesized that two populations of polymorphonuclear neutrophils are present in MM, with differential distribution after a Ficoll separation and differential immunosuppressive activity
Methods: Using oligonucleotide microarrays we first evaluated the gene expression profile (GEP) of PMN at the steady state in 10 MM, 5 MGUS and 8 healthy subjects matched for sex and age, identifying Arg-1 as the first gene differentially expressed in MM *versus* healthy PMN. Thus, we validated Arg-1 by RT-PCR, immunohistochemistry and circulating levels in serum by ELISA in a series of 60 newly-diagnosed MM patients, 30 MGUS and 30 healthy subjects in both G-MDSC and PMN. Finally, we tested the immunosuppressive properties of G-MDSC (isolated by CD66b+ immunomagnetic beads in the upper Ficoll layer) and PMN (sorted from the lower Ficoll layer) isolated from the same MGUS or MM patients, through functional assays, based on in vitro co-culture with T-lymphocytes from healthy subjects.
Results: MM-PMN exhibit an increased expression of ARG-1 compared to MGUS and healthy subjects (25.5 *vs* 6.2 *vs* 1 fold changes in gene expression, p=0.003), confirmed by functional assay of enzymatic activity of ARG-1, positively correlated with advanced disease. In MM patients, increased levels of ARG-1 were positively associated with advanced bone disease and unfavourable cytogenetics. Circulating Arg-1 in serum was higher in MM than MGUS and healthy subjects (183.6±21.9 *versus* 88.3±15.6 *versus* 98.8±11.4 ng/ml, p=0.0022). In MM patients there was a progressive increase from ISS stage I through III (p=0.003). Immunostaining showed that Arg-1 was increased in MM *versus* healthy subjects, but higher levels were evident in G-MDSC than PMN. Moreover, only in MM-G-MDSC Arg-1 was evident at the nuclear level, while in PMN Arg-1 had an exclusive cytoplasmic localization. This differential distribution of Arg-1 was functionally evident, since G-MDSC were more immunosuppressive than PMN. Indeed, after 72 hours of co-culture with T-cells obtained from healthy donors in presence of mitogen stimulation (PHA), MM-PMN were able to reduce T-cell proliferation at both tested 1:2 and 1:8 ratios (respectively 38.3±2.6% and 14.3±0.6%, p<0.0001), while MGUS-PMN induced a partial inhibition only at the 1:8 (25.4±4.3%, p=0.002). This effect was partially reverted with the treatment of 200 μM nor-NOHA, an Arg-1 inhibitor, since within first 24 hours T-cell proliferation increased in presence of MM-PMN (14.3±0.6 *versus* 24.5±1.3%, p<0.0001) and MGUS-PMN (25.4±4.3 *versus* 31.6±2.3%, p<0.0001). MM-G-MDSC were more immunosuppressive than their MM-PMN counterpart, since at 72 hours T-cell proliferation was 22.3±1.6% and 8.4±0.5% (p<0.0001) at 1:2 and 1.8 ratio respectively.
Summary/Conclusions: Polymorphonuclear neutrophils in MM are immunosuppressive, but distinguished in two main subpopulations, at different stages of maturation, based on the expression of Arg-1 and grains distribution, to target in order to improve the effects of the immunochemotherapy.

E1234

RESISTANCE TO PROTEASOME INHIBITORS IS MEDIATED BY A OVER ACTIVATION OF THE UPR AND THE DNA DAMAGE RESPONSE IN A PRECLINICAL MODEL OF MM

S Hernández García, L González Méndez, D Quwaider, N Puig, EM Algarín, AA López Iglesias, L San Segundo, M Martín Sánchez, T Paíno, AB Herrero, I Misiewicz-Krzeminska, MV Mateos, NC Gutiérrez, M Garayoa, EM Ocio[*]
Complejo Asistencial Universitario de Salamanca (IBSAL) y Centro de Investigación del Cáncer (IBMCC-CSIC). Universidad de Salamanca, Salamanca, Spain

Background: MM is still considered incurable partly due to the development of resistance.
Aims: We have developed a cellular model of resistance to proteasome inhibitors to investigate the underlying mechanisms.
Methods: Cells sensitive to proteasome inhibitors (MM1S, MM1R, RPMI-8226) were continuously exposed to increasing concentrations of bortezomib until

development of resistance. Viability was analyzed by MTT. Activity of different subunits of the proteasome was analyzed with Proteasome-Glo™ Assay Kit and presence of unfolded proteins with ProteoStat® Aggresome Detection Kit. Western-Blot, flow cytometry and qRT-PCR were also used.
Results: The development of acquired resistance to bortezomib in three cell lines was assessed by MTT assay with IC50 (nM) of 2.5 *vs* >100; 6.7 *vs* 78.5 and 21.2 *vs* >100 for the sensitive *vs* the resistant counterpart in MM1S, MM1R and RPMI at 24 hours. Interestingly, cells were also resistant to other proteasome inhibitors such as carfilzomib, oprozomib or ixazomib, indicating a class-effect resistance. In absence of bortezomib treatment, resistant cells presented a lower activity of the different subunits of the proteasome compared to the sensitive counterpart by 52% for caspase-like (C-L); 54% for trypsin-like (T-L) and 42% for chemotrypsin-like (CT-L) activities. This was even lower in case of MM1R (26%, 25% and 12%) and RPMI-8226 (21%, 40% and 23%) resistant cells. This inhibition led to an accumulation of unfolded proteins in the resistant MM1S cells as compared with their sensitive counterpart (96% *vs* 45%). Moreover, the concentration of bortezomib required to inhibit the proteasome was around 20-fold higher in the resistant than in the sensitive MM1S cells (x23; x21 and x27 for the C-L, T-L and CT-L activities). Finally, and most importantly, even with doses of bortezomib achieving a complete inhibition of the three subunits, resistant cells were viable, indicating they were not dependent on the proteasome and had developed alternative mechanisms of survival. In this context, resistant cells significantly upregulated the pro-survival chaperone BIP/GRP78, a critical sensor of the ER stress. This upregulation activated the three main arms of the unfolded protein response (UPR): increased levels of p-IRE1, ATF-6 and activation of PERK as observed through phosphorylation of its downstream substrate EIFα. A sequelae of the activation of the UPR is the transcriptional activation of chaperones, and, accordingly, there was increased expression of HSP-40 and, particularly, HSP-70 (but not HSP-90) in resistant cells. The ER stress also induced a DNA damage response with an increase in pH2Ax in resistant cells and a subsequent upregulation of p53 protein levels. Moreover, the increase in p-IRE-1 induced the nuclear translocation of NFkB, where it could exert its pro-survival and transcriptional function. In fact, we also observed an increase in the anti-apoptotic proteins Bcl-2, Bcl-xL, Mcl-1 and XIAP, some of them known substrates of NFkB. Interestingly, these resistant cells had an increased sensitivity to Pifithrin, a Hsp-70 and p53 inhibitor (6 hours Pifithrin treatment induced 69% *vs* 26% apoptosis in resistant *vs* sensitive cells).
Summary/Conclusions: We have demonstrated some of the mechanisms associated with resistance to proteasome inhibitors: activation of the UPR (with subsequent upregulation of the chaperone system), DNA damage response and NFkB signaling with increased levels of antiapoptotic Bcl-2 family members.

E1235

DEREGULATION OF A-TO-I RNA EDITING IS FUNCTIONALLY AND CLINICALLY RELEVANT IN MULTIPLE MYELOMA

PJ Teoh[1,*], TH Chung[1], H Yang[1], L Chen[1,2], WJ Chng[1,3,4]
[1]Cancer Science Institute of Singapore, [2]Department of Anatomy, Yong Loo Lin School of Medicine, [3]Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, [4]Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore

Background: Multiple myeloma (MM) is a plasma cell neoplasm that remains high risk and incurable despite its therapeutic advancement. Adenosine-to-Inosine (A-to-I) RNA editing is a highly conserved post-transcriptional mechanism involving sequence alterations at the RNA but not the DNA level, mediated by ADAR family proteins (ADAR1, ADAR2 and ADAR3). RNA editing can result in recoding of the proteome, modification of mRNA stability and alteration in the miRNA biogenesis. In line with its physiological importance, an aberrant RNA editing activity has been implicated in various human cancers. However, the relationship between dysregulated RNA editing and the pathogenesis of MM remains elusive. Importantly, chromosome 1q21 which harbours the ADAR1 locus is amplified in more than 35% of MM, and this chromosomal abnormality is a poor prognostic marker. Considering the co-occupancy of other genes in 1q21, it is unknown if ADAR1 is an important driver gene.
Aims: We aim to define the RNA editome landscape of MM and to characterize the critical function of a disrupted editome in driving myelomagenesis. We would also like to delineate if ADAR1 is a critical gene in 1q21.
Methods: To establish the clinical significance of ADARs in MM, we analysed the publicly available myeloma datasets. Primary patient samples and human myeloma cell lines (HMCLs) were used as our study models. The level of ADARs was modulated through the highly-efficient lentivirus system. Systematic high-throughput RNA-sequencing is employed to investigate the genome-wide RNA editing status before and after ADAR1 knockdown and overexpression. The functional effects of differential ADARs expression were examined through cell viability (CTG), cell cycle (PI staining) and colony formation (Methocult semi-solid medium) assays.
Results: Comparing with normal plasma cells, MM samples showed a severely disrupted ADAR1:ADAR2 expression ratio, in which an overexpression of ADAR1 and downregulation of ADAR2 were observed. In correlation, we identified that there was a close association between 1q21 amplification and ADAR1 expression level, which consistently increases along the disease progression route, *i.e.* from normal plasma to MGUS, SMM and finally MM. Furthermore, analysis based on the disease subtypes revealed that the 4p16 and MAF subtypes (high-risk prognostic groups) displayed significantly higher ADAR1 expression than other groups, signifying its role in conferring an aggressive disease nature. More importantly, patients with high ADAR1 and low ADAR2 expression demonstrated a poorer overall survival. At the physiological level, knocking down and overexpressing ADAR1 in HMCLs affects the global editing events, as detected by RNA-sequencing. Gene specific validation demonstrated a differential degree of A-to-I conversion of bona fide ADAR targets, depending on the ADAR1 expression level. *In vitro* analysis implicated that both ADAR1 and ADAR2 can functionally affect MM growth and survival, whereby, ADAR1 behaves like an oncogene and ADAR2 displayed tumor suppressor properties. When the stable cell lines were treated with velcade, ADAR1-knockdown cells showed increased sensitivity while ADAR2-silenced cells were more resistant to the drug.
Summary/Conclusions: Considering that RNA editing is a widespread occurence in the human genome (85%), its biological significance in MM cannot be undermined. Our study unveils a potential novel role of ADAR-mediated-A-to-I-editing in conferring myelomagenesis. The functional relevance of ADAR1 and ADAR2 denotes that the RNA editing activity is clinically important and may represent an important therapeutic target for MM. Further characterization of the direct mechanisms of A-to-I editing will provide critical knowledge on whether this event would provide an extra layer of epigenetic deregulation to MM, leading to a worse disease prognosis.

TARGETING PROTEIN KINASE CK1A IN THE BONE MARROW MICROENVIRONMENT: A NEW POSSIBLE THERAPEUTIC APPROACH FOR MULTIPLE MYELOMA THERAPY?

M Carrino[1,2,*], S Manni[1,2], S Canovas Nunes[1,2], P Macaccaro[1,2], K Gianesin[1,2], L Quotti Tubi[1,2], A Cabrelle[1], G Semenzato[1,2], F Piazza[1,2]
[1]Venetian Institute of Molecular Medicine, [2]Department of Medicine (DIMED), Hematology and Clinical Immunology Branch, University of Padova, Padova, Italy

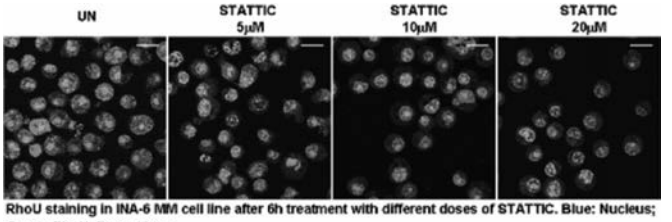
Background: Multiple myeloma (MM) is an incurable blood tumor arising from plasma cells. This malignancy is characterized by a multistep pathogenesis during which plasma cells progressively accumulate in the bone marrow (BM) and in the late stages of the disease spread to the peripheral blood and other tissues. Contacts between MM cells and the surrounding hematopoietic and non-hematopoietic (stromal) cells activate paracrine and autocrine intercellular loops, which support tumor cell growth and provide a protective *niche* against cytotoxic agents. Despite significant improvements in the overall survival over the last years, patients frequently develop resistance to many chemotherapeutic agents, therefore new curative strategies are urgently needed. Protein Kinase CK1α (CK1α) is a Ser/Thr kinase that we found overexpressed in a fraction of MM patients and cell lines. It is essential for the regulation of BM microenvironment dependent pathways (such as WNT/β-catenin and PI3K/AKT) important for plasma cell survival, suggesting a possible function of CK1α in the microenvironment dependent progression of this disease.
Aims: We aimed at evaluating whether or not CK1α inactivation in MM plasma cells could overcome the BM microenvironment protection, affecting cells growth and proliferation by impinging on survival signaling pathways associated to chemotherapeutic resistance. We also aimed to outline whether CK1α inactivation in the BM microenvironment context, could potentiate the therapeutic effect of drugs approved for the treatment of MM, such as Bortezomib.
Methods: Patient derived plasma cells and the BM microenvironment dependent MM cell lines INA-6 and SaMMi (a patient derived MM cell line, newly generated in our laboratory) were used. A model of BM microenvironment was established colturing MM cells with HS-5 stromal cells or with BM stromal cells (BMSC) from MM patients. RNA interference for CK1α was obtained through the generation of IPTG inducible MM clones. CK1 inhibition was obtained with D4476. Apoptosis was investigated with AnnexinV/PI staining and FACS analysis. CK1α downstream pathways were analyzed by WB.
Results: We found that CK1 inhibition caused apoptosis of MM cell lines and patient derived plasma cells. The presence of a defensive BM microenvironment did not protect MM cells from D4476-induced cell death. These results were confirmed also by RNA interference using siRNAs targeting the α isoform of CK1. We investigated also the effects of CK1α inactivation on the microenvironment-dependent prosurvival pathways WNT/β-catenin and PI3K/AKT and found a proteasome independent reduction of both β-catenin and AKT proteins expression. Furthermore CK1α inhibition enhanced Bortezomib induced cytotoxicity not only on plasma cells grown alone, but also on cells co-cultured with protective stromal cells.
Summary/Conclusions: Our results indicate that by impinging on critical microenvironment dependent survival pathways, CK1α inactivation leads to MM cell apoptosis and empowers Bortezomib induced cytotoxicity, overcoming stromal cell dependent protection and resistance to chemotherapeutic agents. These results might predict a possible use of CK1α inhibitors in the clinical setting as a new therapeutic approach for MM therapy.

E1237

RHOU GTPASE: A NOVEL POTENTIAL TARGET TO DISRUPT MULTIPLE MYELOMA PLASMA CELL INTERACTION WITH PROTECTIVE BONE MARROW NICHES

S Canovas Nunes[1,2,*], M Carrino[1,2], E Mandato[1,2], L Quotti Tubi[1,2], F Zaffino[1,2], S Manni[1,2], G Semenzato[1,2], F Piazza[1,2]
[1]Department of Medicine (DIMED), Hematology and Clinical Immunology Branch, University of Padua, [2]Venetian Institute of Molecular Medicine, Padua, Italy

Background: Bone marrow stromal cell (BMSC)-produced soluble factors, like the IL-6 cytokine, may impinge on Multiple Myeloma (MM) intracellular signaling and cytoskeletal properties, protecting it from cytotoxic agents. Rho GTPases, in their active GTP-bound state, interact with effector proteins in order to control cytoskeleton remodeling, cell adhesion and polarization, and other essential processes for cell-cell interaction. The atypical Rho protein Wrch-1/RhoU displays spontaneous activation and is normally expressed at low levels in various tissues and organs. This protein might mediate the effects of the IL6R/STAT3 signaling in inducing filopodium formation and stress fiber dissolution, both critical steps in promoting cell motility. While typical Rho proteins (that share significant sequence homology with RhoU) as Cdc42 and Rac-1 have an established role in cancer, very little is known on RhoU in tumorigenesis, in particular in hematologic malignancies.
Aims: Since the IL6R/STAT3 signaling is of great importance in MM malignancy, we have endeavored to study RhoU expression in normal *versus* MM plasma cells. We also focused on understanding its localization and cellular function in these cells. Lastly, we aimed at unraveling the mechanisms through which RhoU expression is regulated in MM cells in the context of bone marrow (BM) microenvironment.
Methods: Malignant plasma cells were isolated from BM extracts or peripheral blood of MM patients using a magnetic CD138 positive selection kit. Normal B cells were purified using a magnetic human B cell isolation kit. mRNA expression was analyzed by qRT-PCR for MM cell lines, MM patients and normal B cells from healthy donors. Fluorescence microscopy was performed using Zeiss LSM 700 microscope and the following antibodies were used for staining: Phalloidin 594, rabbit anti-RhoU, goat anti nucleolin, anti-rabbit Alexa fluor 488, anti-goat Alexa fluor 594 and DAPI. STATTIC was used for STAT3 inhibition and the IL-6 cytokine was used to stimulate the IL-6R. Migration assays were set-up using 5mm transwells with standard controls, cell count was done by 3 minutes reads in FACS Canto.
Results: Here we provide data showing that RhoU is overexpressed in BMSC-dependent MM cells, but not in malignant plasma cells from the peripheral blood of Plasma Cell Leukemia (PCL) patients. We also demonstrate that its expression was positively modulated to the same extent by BMSC conditioned media and by IL-6, a major growth factor for MM cells. In MM cell lines, a blockade in STAT3 activation inhibited RhoU mRNA transcription in a dose dependent manner, and caused a clear impairment in migration/motility capacity of these cells. Interestingly, we observed an unexpected subcellular localization for this protein in the nucleolus of BMSC-dependent MM cells, which could be independent from STAT3 regulation.



RhoU staining in INA-6 MM cell line after 6h treatment with different doses of STATTIC. Blue: Nucleus; Green: RhoU; Bars: 10μm

Figure 1.

Summary/Conclusions: RhoU GTPase is widely overexpressed in malignant plasma cells from BM extracts of MM patients but not in cells purified from the peripheral blood of PCL patients. Its expression is positively modulated by IL-6 stimulus through the activation of STAT3 transcription factor. We describe for the first time a localization of this G protein in the nucleolus of MM cells. These results put to light the pleiotropic features that RhoU could display in this malignancy. We firmly believe that RhoU might be important in MM pathogenesis and could become a suitable target to disrupt the MM plasma cell interaction with protective BM niches.

E1238

DEREGULATION OF MAJOR DNA REPAIR MECHANISMS CORRELATES WITH CLINICAL OUTCOME OF ANTI-MYELOMA THERAPY. THE BENEFICIAL EFFECT OF DNA REPAIR INHIBITION

M Gkotzamanidou[1,*], E Terpos[2], NC Munshi[1], MA Dimopoulos[2], VL Souliotis[3]
[1]Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [2]Department of Clinical Therapeutics, University of Athens School of Medicine, University of Athens School of Medicine, [3]3Institute of Biology, Medicinal Chemistry and Biotechnology, National Hellenic Research Foundation, Athens, Greece

Background: Deregulation of DNA repair pathways in malignant plasma cells mediates onset of disease and survival. The precise nature of dysregulated DNA repair and how it improves multiple myeloma (MM) cells survival or is co-opted during antitumor therapy is as yet unexplored and requires extensive study. If fully understood, DNA repair dysregulations could be exploited to selectively kill MM cells by targeting the remaining repair pathways that are critical for their survival.
Aims: We investigated the mechanistic basis for the link between DNA repair efficiency and response to anti-myeloma therapy.
Methods: We evaluated major DNA repair mechanisms [nucleotide excision repair (NER), interstrand cross-links repair (ICL/R), double-strand breaks repair (DSB/R)] in MM cell lines (melphalan-sensitive, RPMI8226; melphalan-resistant, LR5), peripheral blood mononuclear cells (PBMCs) from 25 healthy controls (HC; 14M/11F, median age 58 years), as well as bone marrow plasma cells (BMPCs) and PBMCs from 15 newly diagnosed MM patients (8M/7F; median age 61 years), responders (≥PR, n=9) and non-responders (
Results: Following ex vivo melphalan treatment, responders' primary cells (both BMPCs and PBMCs) showed significantly slower rates of NER and DSB/R compared to non-responders (P=0.0015). Similar rates of ICL/R were found in primary cells from all individuals. Moreover, apoptotic rates of the primary cells were inversely correlated with individual DNA repair efficiencies, being significantly higher in responders' cells compared to non-responders ones (P=0.0015). In line with these data, RPMI8226 cells showed slower rates of NER and DSB/R, but not ICL/R, and higher apoptotic rates than LR5 cells. Interestingly, co-treatment of all types of cells with DSB/R inhibitors significantly reduced the rates of DSB/R and increased melphalan sensitivity of the cells. Moreover, in untreated PBMCs from MM patients, we found an inverse correlation between the local chromatin condensation and the repair capacity of the cells. Particularly, we observed a progressive, significant increase in the looseness of the local chromatin structure, from HC to MM patients, with responders showing more condensed chromatin structure compared to non-responders (all P<0.05). Finally, microarray analyses of untreated PBMCs from MM patients consistently point to an altered expression of several DNA damage response-related genes in MM patients compared to HC. Particularly, responders' PBMCs showed upregulation of ATR, CHEK2, XPA, XRCC1 and CHEK2 genes and downregulation of ATM, MPG, UNG, CDKN1A and CDC25C compared to non-responders (in all cases, fold changes between groups were >2, P<0.001), suggesting that perturbation in the molecular components of DDR/R pathways also plays an important role in the therapeutic action of genotoxic drugs.
Summary/Conclusions: Responders to melphalan therapy are characterized by lower efficiencies of NER and DSB/R mechanisms resulting in higher accumulation of the extremely cytotoxic ICLs and DSBs lesions which in turn, triggers the induction of the apoptotic pathway. Moreover, the potentiation of melphalan cytotoxicity by DSB/R inhibition offers a promising strategy toward improvement of existing regimens.

E1239

BAX ACTIVATION IS A POTENTIAL BIOMARKER OF RESPONSE TO FILANESIB (ARRY-520) ALONE AND IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE

S Hernández García[1], L González Méndez[1], L San Segundo[1], M Martín Sánchez[1], I Misiewicz-Krzeminska[1], AA López Iglesias[1], EM Algarín[1], T Paíno[1], M Garayoa[1], BJ Tunquist[2], NC Gutiérrez[1], MV Mateos[1], EM Ocio[1,*]
[1]Complejo Asistencial Universitario de Salamanca (IBSAL) y Centro de Investigación del Cáncer (IBMCC-CSIC). Universidad de Salamanca, Salamanca, Spain, [2]Array Biopharma, Boulder, Colorado, United States

Background: Pomalidomide in combination with dexamethasone (PD) has demonstrated activity in refractory MM patients, but novel combinations are needed to improve its efficacy. In this context, the kinesin spindle protein (KSP) inhibitor, filanesib (Arry-520), has demonstrated clinical anti-myeloma effect and previous data from our group and others have demonstrated the preclinical synergy of pomalidomide with dexamethasone and filanesib (PDF) what set the stage for the recently activated clinical trial POMDEFIL being run by the Spanish MM group investigating this combination in relapsed MM patients.
Aims: In this abstract, we gained insights into the mechanism of the combination and aimed at identifying potential biomarkers that could predict response.
Methods: MM cells were transiently transfected with non-targeting control short interfering RNA (NT-SiRNA), Bax siRNA ON TARGET plus SMART pool siRNA using the cell line Nucleofector Kit V. *In vitro* action was evaluated in MM cells by Annexin V staining using flow cytometry. The mechanism of action was analyzed by Western Blot, immunohistochemistry and immunofluorescence techniques.
Results: All 11 MM cell lines tested were sensitive to filanesib and sensitivity to this agent correlated with basal levels of Bax and Bax/Mcl-1 protein ratio. Subcellular fractionation of MM1S cells indicated that filanesib triggered translocation of Bax from the cytoplasm to the mitochondria after 24 and 48 hours, and its subsequent cleavage into the very potent proapoptotic 18 kDa fragment. A simultaneous decrease in the levels of Mcl-1 was observed. Knock-down of Bax in MM1S

by using small interfering RNA decreased the sensitivity of these cells to filanesib, as treatment with 10 nM for 24 hours induced apoptosis in only 26% of the siRNA-Bax cells as compared with 50% in the non-targeted cells (as compared with 58% *vs* 61% for bortezomib, used as a control for this experiment). Next, we evaluated changes of Bax protein levels in comparison with others in MM1S cells after treatment with vehicle, F, PD and PDF treatments. The levels of the proapoptotic protein, Bax, were significantly increased in both cytosolic and mitochondrial fractions with PDF treatment, as assessed by Western blotting after 12 or 48 hours of treatment. Of note, this event preceded the initiation of the apoptosis process as evaluated by cleavage of PARP and annexin V staining. Moreover, total cellular antiapoptotic protein Mcl-1 levels declined with the combination, although less than with F treatment and no significant changes occurred in the mitochondrial and cytosolic compartments by western blot. These results were confirmed *in vivo* in a model of subcutaneous plasmacytoma in tumors with big plasmacytomas, that after two days of treatment with vehicle, PD, F or PDF were sacrificed and tumors were fixed, paraffin-embedded and stained with anti-Bax and counterstained with haematoxilin for analyses. *In vivo* treatment with PDF also induced a clear increase in Bax that was mainly present in cells with aberrant monopolar spindles (a hallmark of the KSP inhibition induced by filanesib) and with an increase of apoptosis evaluated by TUNEL ($p<0.001$).

Summary/Conclusions: Bax protein is specific involved in the response to filanesib in monotherapy and plays a significant role in the synergy of its combination with pomalidomide and dexamethasone, being one of the earlier events observed. Therefore, Bax protein could be a potential biomarker of response to filanesib and also this synergistic combination.

This work was funded in part by the company Array BioPharma.

E1240

COMBINATION DRUG THERAPIES WITH THE NOVEL RNA POLYMERASE I INHIBITOR CX-5461 IMPROVE EFFICACY IN THE TREATMENT OF MULTIPLE MYELOMA

K Maclachlan[1,2,*], A Cuddihy[1], N Hein[3], S Harrison[2], R Hannan[1,2,3,4,5,6,7]
[1]Research Division, Peter MacCallum Cancer Centre, [2]Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, [3]Department of Cancer Biology and Therapeutics, Australian National University, Canberra, [4]Department of Biochemistry and Molecular Biology, Monash University, [5]Department of Biochemistry and Molecular Biology, University of Melbourne, [6]Division of Cancer Medicine, Peter MacCallum Cancer Centre, Melbourne, [7]School of Biomedical Sciences, University of Queensland, Brisbane, Australia

Background: Ribosome biogenesis is dysregulated in malignancy, which is thought to contribute to cellular transformation and proliferation. Selective targeting of RNA polymerase I (Pol I), the enzyme responsible for transcribing the ribosomal RNA genes, with the novel small molecule inhibitor CX-5461 (Drygin *et al*., Cancer Res 2011) induces cell death using both p53-dependent and -independent pathways in both haematological and solid tumours. In a murine model of B-cell lymphoma, treatment with CX-5461 significantly increased survival (Bywater *et al*., Cancer Cell) and the drug is now in early stage clinical trials.

Aims: To determine the efficacy of CX-5461 in the treatment of multiple myeloma (MM), both alone and in combination with standard and emerging MM therapies.

Methods: A panel of human myeloma cell lines (HMCLs) were treated with CX-5461 prior to measuring proliferation, cell death and cell cycle distribution. Western blots were performed at serial time points for markers of DNA damage signalling and cell cycle control. CX-5461 was tested in combination with a variety of therapeutic agents that have demonstrated clinical or preclinical efficacy against MM.

Results: Testing CX-5461 against our panel of HMCLs reveals a wide range of sensitivity to Pol I inhibition. Our data show that sensitivity to CX-5461 is not solely dependent on proliferation rate or p53 status. Treatment of HMCLs with CX-5461 leads to a rapid increase in total and serine-15-phosphorylated p53 protein levels, in line with published data in other malignancies. Interestingly, CX-5461 induced phosphorylation of the checkpoint proteins Chk1 and Chk2, even in mutant p53 expressing cell lines, suggesting activation of p53-independent cell cycle checkpoints. The combination of CX-5461 with drugs having differing mechanisms of action shows increased inhibition of proliferation and induction of cell death compared to single agents alone. Increased efficacy is seen in combination with dexamethasone, everolimus, JQ1, ABT-199 and dinaciclib, with the most dramatic results being seen when CX-5461 is combined with bortezomib, carfilzomib or panobinostat.

Summary/Conclusions: Combination drug therapy is necessary to delay acquired drug resistance to single therapeutic agents and increase overall survival. Our data suggest that the novel Pol I inhibitor CX-5461 can be combined with a broad spectrum of agents, with bortezomib, carfilzomib and panobinostat showing the most promise.

E1241

CHARACTERIZATION OF A PERK KINASE INHIBITOR WITH ANTI-MYELOMA ACTIVITY

T Bagratuni[*], E Kastritis, N Mavrianou, C Liacos, E Terpos, M Dimopoulos
National And Kapodistrian University of Athens, Athens, Greece

Background: Due to the immunoglobulin production, multiple myeloma (MM) plasma cells are dependent on the unfolded protein response process (UPR), which controls protein production and ensures its proper translation and folding. A study by Michallet et al (2011) showed that knockdown of one of the three well-known arms of the UPR, PERK (protein kinase R (PKR)-like ER kinase) in MM cells resulted in autophagic cell death. This outcome indicated the important role of PERK activation for the metabolic shift of plasma cell to myeloma cell but also its ability to impede the apoptotic effect.

Aims: In this study we used a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding region, while displaying ≥385 fold selectivity over c-kit, Aurora B, BRK and many other kinases.

Methods: mRNA expression of PERK, CHOP and ATF4 in MM patients and cell lines was determined by real-time PCR. To deterine the effects of GSK2606414 on MM cell proliferation and apoptosis WST1 proliferation assay Annexin-PI staining was used respectively. To determine the effects of GSK2606414 in key genes of the UPR, UPR RT2 profiler PCR array was used.

Results: We initially screened 25 CD138+ MM patients and 6 human myeloma cell lines (HMCLs) for PERK mRNA expression. Our results showed that PERK mRNA is highly expressed in almost all patients (5-10 fold higher than the mean PERK expression of HMCLs). To test the effect of GSK2606414 on the proliferation of MM cells, 4 HMCLs were treated with different doses of GSK2606414 at two time points (24 and 48 hours). Treatment of cells with 3-30μM GSK2606414 resulted in a dose-dependent inhibition of cell proliferation in all HMCLs ranging for 20-95% reduction of proliferative activity, thus, indicating the dependency of these cells on PERK activity. Treatment with GSK2606414 at 20μM in H929 and L363 HMCLs for 24 hours resulted 25% and 15% increase in apoptotic cells by Annexin-PI staining respectively compared to the untreated cells. However, the most important finding was a significant synergistic effect of GSK2606414 with bortezomib in these cells. Specifically when H929 and L363 cells were treated with 5nM bortezomib in combination with 20μM GSK2606414, synergistic effect was seen where apoptotic cells reached 99% and 77% respectively, compared to bortezomib-treated cells (87% and 42% respectively). To determine the gene target effects of GSK2606414, ATF4 and CHOP mRNA expression levels were determined in H929 cell line after 24 hour of treatment. Treatment with GSK2606414 alone did not alter the expression levels of CHOP but reduced more than 50% the expression levels of ATF4. When combined with bortezomib CHOP and ATF4 levels were reduced 20% and 60% respectively while treatment with bortezomib alone increased the levels of CHOP and ATF4 by 50-100%. H929 and L363, were pre-treated with GSK2606414 and then subjected to ER stress conditions by treatment with tunicamycin (TM). In the presence of exogeneous UPR inducers, such as TM, GSK2656157 had a significant effect on the expression of the above genes at much lower IC_{50} range (≤100 nM) suggesting the in a more active UPR (sustained ER stress) the effects are more pronounced. Thus, the combination of GSK2606414 with bortezomib may inhibit one of the mechanisms of MM cells to escape ER stress induced by bortezomib. To determine the effects of the GSK2606414 on myeloma cells, a UPR RT^2 Profiler PCR array containing 84 key genes for the UPR pathway, was used in order to screen for differentially expressed genes between treated and non-treated cells. Results of this array will be presented at the meeting.

Summary/Conclusions: In conclusion, given the on-target pharmacological effects of PERK inhibitor on MM, development of PERK inhibitors may offer a therapeutic advantage that would affect MM pathogenesis and treatment.

E1242

EXPLORING THE BONE MARROW NICHE IN MULTIPLE MYELOMA USING AN ADHESION-INDEPENDENT THREE-DIMENSIONAL CO-CULTURE MODEL

JM Waldschmidt[1,*], D Wider[1], S Müller[1], C Klein[1], AR Thomsen[2], M Follo[1], G Herget[3], N Südkamp[3], J Duyster[1], R Wäsch[1], M Engelhardt[1]
[1]Department of Hematology and Oncology, [2]Department of Radiation Oncology, [3]Department of Orthopedics and Trauma Surgery, University Medical Center Freiburg, Freiburg i. Brsg., Germany

Background: The interaction between malignant plasma cells and their bone marrow (BM) niche is crucial for MM pathogenesis. The BM niche provides a specific tumor microenvironment which leads to quiescence, drug resistance and ultimately progression of myeloma. We and others have previously observed that reduced sensitivity to bortezomib, pomalidomide or vorinostat in the presence of BM stromal cells (BMSCs) can be restored by adding the adhesion inhibitors AMD3100 and NOX-A12. However, little is known about the mechanisms of how the MM niche mediates protection.

Aims: Our focus was to develop a novel bone-derived *in vitro* 3D co-culture platform and assess the cellular composition and function of the BM niche by studying the effects of niche cell subfractions on MM growth.

Methods: An adhesion-independent three-dimensional co-culture model was used to mimic the BM niche. This model consisted of an agarose matrix interlayer containing 100 microwells/cm² (Fig.1A). Each microwell was 1.5mm in depth and permeable for oxygen and cytokines, but not for BMSCs (Fig.1B). U266, RPMI-8226, OPM-2 and primary BM patient (pt) cells were utilized with

and without (w/o) HS-5 *vs* M210B4 stroma support (Fig.1C.a+b: stroma-support effect and pt characteristics). Analyses included trypan blue, Annexin/PI, MTT, FACS, cell cycle analyses and H2B-mCherry/cytochrome c-GFP assays (Udi, BJH 2013). To examine the effect of distinct BM niche cell populations on MM growth, niche cell subsets from C57BL6J mice were acquired, digested and FACS-sorted to collect cell subfractions of mesenchymal stem and progenitor cells (MSPC), endothelial cells, osteoblasts, premature CD146+ MSPCs (PαS) and CXCL12-abundant reticular cells (CaRs; Fig.1C.d).

Results: Human MM cell lines (MMCLs) and pt samples were cultured with 1, 10 or 100 cells/microwell, showing a growth advantage with *vs* w/o stroma support. Pt samples after 7 days (d) of culture benefitted from both murine M210-B4 and human HS-5 co-culture (Fig.1C.a). Expression of the chemokine CXCL12 and its corresponding receptor CXCR4 in U266 cells decreased after 7d with stroma support, thereby reflecting the dynamic regulation of the CXCL12-CXCR4 axis *in vitro* (Fig.1C.c). FACS-sorting of murine bone and BM cells led to valid subset separation, illustrated by a multipolar morphology of CD31+ endothelial cells and CD31-, CD45-, Sca1+ MSPCs with fibroblast-like bipolar appearance (Fig.1C.e), whereas PαS cells remained undifferentiated and positive for CD146. We observed that C57BL6J-derived murine cells differed in terms of their growth support for OPM-2 cells after 6d of co-culture: MSPCs from murine BM were more beneficial than those derived from murine bone (Fig.1C.f). BM-MSPCs also induced stronger support than premature MSPCs and CXCL12-abundant reticular cells, commonly considered as crucial mediators of adhesion in the murine niche. Current analyses focus on the generation of BM cell subsets from both MM pts and non-MM pts, thus overcoming the limitation of using C57BL6J mice.

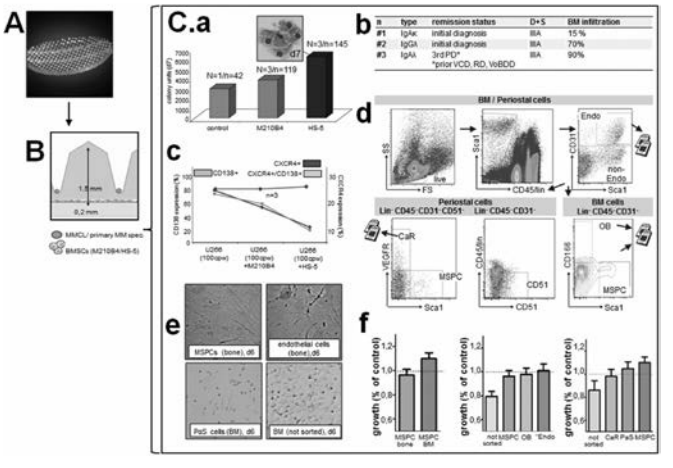


Figure 1.

Summary/Conclusions: We present a 3D culture model which reflects stromal protection for MM cells and may prove more reliable for *ex-vivo* drug screening and longitudinal studies. Assessment of the cellular composition of the MM niche in comparison to the normal BM microenvironment will help to better understand and selectively target stroma-mediated protection in MM.

E1243

ACTIVATION OF TOLL-LIKE RECEPTOR 4 PROMOTES MULTIPLE MYELOMA CELL GROWTH AND SURVIVAL THROUGH UPR PATHWAY AND IN A CASPASE-DEPENDENT MANNER

T Bagratuni*, E Kastritis, C Liacos, E Eleutherakis-Papaiakovou, N Kanellias, E Terpos, M Dimopoulos
National And Kapodistrian University Of Athens, Athens, Greece

Background: Toll-like receptor family (TLR) of receptors is an essential part of innate immunity. Expression and function of TLRs in Multiple Myeloma (MM) has recently become the focus of several studies and although the regulatory role of TLRs in MM plasma cells has been reported, the molecular mechanism remains unclear. During infection, human immune cells sense the presence of invading pathogens through TLRs which then activate transcriptional programs that orchestrate adaptive responses and induce the endoplasmic reticulum (ER) unfolded protein response (UPR) to accommodate essential protein translation. Studies have shown that prolonged ER stress occurs in response to microbes and specifically when cells are exposed to lipopolysaccharide (LPS), a TLR4 activator. The prolonged stress, possibly arising from a massive increase in protein synthesis, has shown to suppress CHOP, an apoptosis biomarker, in ER-stressed macrophages, while low levels of CHOP expression promote B cell survival.

Aims: The aim of our study was to investigate TLR4 signaling in myeloma cells and to explore possible implications with endoplasmic reticulum unfolded protein response as a potential mechanism of drug resistance.

Methods: mRNA expression of TLR4 and CHOP a in MM patients and cell lines was determined by real-time PCR. To deterine the effects of LPS on MM cell proliferation and apoptosis WST1 proliferation assay and Annexin-PI staining was used respectively. Protein expression of CHOP, ATF4, peIF2a, NFkB and caspases was assesed by immunoblotting analysis.Bottom of Form

Results: We found that TLR4 mRNA is expressed at increased levels (2-10 fold) both in human myeloma cell lines (HMCL) and primary cells. To investigate whether TLR4 signaling may suppress CHOP expression during sustained UPR response JJN3 and U266 cells, were pre-treated with LPS (5 ug/mL) and then subjected to ER stress conditions with a typical ER stressor, tunicamycin (TM). We found that ER stress-induced CHOP expression was suppressed by prior engagement of TLR4, by LPS pre-treatment. To test the relevance of these results, pre-treated LPS and TM samples were also subjected to Annexin-PI staining to determine the amount of apoptosis. As expected, pre-treated LPS HMCLs exposed to TM had almost 30% lower Annexin-FITC stained cells compared to the TM-stressed cells only. Thus, downregulation of CHOP by TLR4 ligands may confer resistance to apoptotic stimuli and promote the growth and survival of MM cells. To determine the potential therapeutic impact of TLR4 signaling in myeloma, we evaluated the activity of bortezomib in LPS pre-treated above cell lines.LPS pre-treatment partially abrogated the efficacy of bortezomib in these cell lines by decreasing its anti-proliferative effects compared to the non-LPS-pretreated cell lines as tested by the WST1 assay. In addition extract of cells were immunoblotted for CHOP protein expression. Pre-treatment of MM cells with low dose LPS selectively suppressed CHOP in bortezomib treated cells compared to the non-LPS treated cells. CHOP suppression was also accompanied with suppression of PERK, ATF4 and peiF2a, protein expression. In order to determine whether the escape from the apoptotic pathway which was achieved by LPS was preceded in caspase-dependent manner, the protein expression of caspase-8 and caspase-9 was explored upon treatment with LPS. Indeed, LPS stimulation was able to partially inhibit caspase-8 and caspase-9 expression in bortezomib-induced JJN3 cells. Furthemore pretreatment of LPS was able to completely abort NFκB inhibition induced by bortezomib. Then, we examined the impact bortezomib therapy on TLR4 and CHOP mRNA expression in primary tumors cells, collected before and at day 7 after bortezomib-based therapy from 6 myeloma patients. In 5 out of 6 cases TLR4 expression was significantly up-regulated and was accompanied with a coupled down-regulation of CHOP mRNA expression.

Summary/Conclusions: In conclusion, our data suggest that the TLR4 signaling pathway might provide a translational control pathway which disables cells to undergo the programmed cell death by apoptosis via CHOP branch. Further exploration of this pathway is needed to establish its role as a potential mechanism of drug resistance of MM cells which may direct future development of novel therapeutic targets.

E1244

LONG NON-CODING RNA MALAT1 WAS ASSOCIATED WITH PROGRESSION OF MULTIPLE MYELOMA AND INDUCED BY CELLULAR STRESS

H Handa[1,*], Y Kuroda[2], K Kimura[2], A Yamane[1], Y Masuda[2], T Kasamatsu[2], T Saitoh[2], K Tahara[1], N Kobayashi[1], H Shimizu[3], N Tsukamoto[3], A Yokohama[4], T Mitsui[1], T Ishizaki[1], H Koiso[1], M Takizawa[1], H Murakami[2]
[1]Department of Medicine and Clinical Science, [2]Graduate School of Health Science, [3]Oncology Center, [4]Blood Transfusion Service, Gunma University, Maebashi, Japan

Background: Recent transcriptome-wide analyses have revealed an overwhelming amount of transcribed but not translated non-coding RNAs capable of influencing diverse cellular processes such as proliferation, apoptosis, and motility. Long non-coding RNA (lnc RNAs), which are commonly defined as transcripts >200 nt in length, have emerged as a class of key regulatory RNA. LncRNAs are deregulated in diverse human cancers and associated with disease progression; however little is available in multiple myeloma (MM).

Aims: To elucidate the role of lnc RNA in MM, we studied expression pattern of several well-known lnc RNAs in plasma cells of MM, MGUS and plasmacytoma, and function in MM cell lines in vitro. Moreover, to reveal the distinct lnc RNA signature more comprehensively, we performed next generation sequencing based RNA sequencing, which is potentially able to discover novel lnc RNAs.

Methods: Purified CD138+ plasma cells from bone marrow (BM) mononuclear cells obtained from 110 of MM patients, 48 of MGUS patients, 19 of control BM and 5 of extramedullary disease (EMD) are subjected to the study after obtaining informed consent. The expression levels of lnc RNAs were determined by RQ-PCR. RNase H-activating LNA™ GapmeR antisense oligonucleotides were used to knockdown lnc RNA in vitro in MM cell lines. The cell lines were treated with bortezomib, MG132, doxorubicin to evaluate the effects of cytotoxic stress for the lnc RNA expression. RNA sequencing was performed with Illumina NextSeq 500. This study was approved by IRB of Gunma University Hospital under Declaration of Helsinki.

Results: We found significant higher level of MALAT1 expression in BM plasma cells of MM compared to MGUS and control (control *vs* MM, p<0.001; control *vs* MGUS, p=0.01; MGUS *vs* MM, p<0.001). MALAT1 expression in EMD was higher by 140 fold than BM MM cells. MALAT1 expression was higher in MM with t(4;14) and del 17p (p=0.049, p=0.03), but was not different among ISS (p=0.87). Higher MALAT1 expression is associated shorter progression free survival (p<0.05), and tendency of shorter overall survival (p=0.09). MM cell

lines KMS12PE, OPM2, KMS11 treated with bortezomib showed elevated MALAT1 expression by 4.3 -21.8 fold and ANRIL by 2.2-4.7 fold. Cytotoxic drug doxorubicin also elevated both lnc RNAs in the cell lines. MALAT1 knockdown by GapmeR did not affect cell proliferation. The reported cell motility genes HMMR, CTHRC1 and ROD1 did not alter in MALAT1 knockdown MM cell lines, but RNA sequencing revealed the changes of many gene expressions. Finally, RNA sequencing of MM, MGUS and EMD samples revealed distinct lnc RNA expression signature as well as protein coding genes.
Summary/Conclusions: Significant upregulations of lnc RNAs MALAT1 might be associated with MM progression. Given that MALAT1 is associated with lung cancer metastasis, MALAT1 might be strongly associated with EMD formation. Genotoxic and ER stress induced by therapeutic drugs might upregulate MALAT1 leading extramedullary extension. Revealing distinct lnc RNA signature of MM is current important issue to clarify molecular mechanisms underlying MM progression and to development novel therapies.

COMBINATION OF T(4;14), DEL(17P13), DEL(1P32) AND 1Q21 GAIN FISH PROBES IDENTIFIES CLONAL HETEROGENEITY AND ENHANCES DETECTION OF ADVERSE CYTOGENETIC PROFILES IN 233 NEWLY DIAGNOSED MULTIPLE MYELOMA

T Smol[1,*], A Dufour[2], S Tricot[3], M Wemeau[4], L Stalnikiewicz[5], F Bernardi[6], T Christine[2], A Daudignon[1]
[1]Service d'Hématologie-Immunologie-Cytogénétique, CH Valenciennes, Valenciennes, [2]Laboratoire de Cytogénétique Hématologique, CH Versailles, Le Chesnay, [3]Service d'Hématologie Clinique, CH Valenciennes, Valenciennes, [4]Service d'Hématologie Clinique, CH Arras, Arras, [5]Service d'Hématologie Clinique, CH Lens, Lens, [6]Laboratoire de Biologie, CH Douai, Douai, France

Background: Cytogenetic analyses play a leading part in the risk stratification of MM due to the prognostic and therapeutic impacts of cytogenetic abnormalities. However, with a metaphase cytogenetic approach only 35% of patients present abnormal karyotypes, often associated with an advanced stage of the disease. Practice guidelines now recommend interphase fluorescence in-situ hybridization (FISH) on isolated CD138-expressing plasma cells (PC) as the initial cytogenetic analysis for MM. The most pertinent markers target the deletion of 17p13 (*TP53* deletion) and the t(4;14)(p16;q32) *FGFR3-IGH* translocation, and partial aneuploidies of chromosome 1 (1q21 gain and 1p32 deletion) are retained as more relevant additional markers.
Aims: Our aim was to fix the FISH combination of del(17p13), t(4;14), 1q21 gain and del(1p32) in a prospective study of 233 newly diagnosed MM with an analysis of the association between abnormalities and the number of clones.
Methods: Between January 2013 and August 2015, 233 BM samples were collected from 233 patients during diagnostic at the Cytogenetic Laboratories in Valenciennes General Hospital, and Versailles General Hospital. The institutional ethics committee approved the study. PC were enriched from BM mononuclear cells, using a magnetic cell sorting CD138 MicroBeads kit (Miltenyi Biotec; BergischGlabach, Germany). The FISH panel included *TP53/CEP17* probe (Amplitech, Compiègne, France), *1p32/CDKN2C-FAF1-1q21/CKS1B* probe (Amplitech), t(4;14)(p16;q32) probe (MetaSystems, Altlussheim, Germany), and *IGH* break-apart probe (MetaSystems). Technical thresholds were determined for each probe using isolated CD138-expressing PC from patients without MM, on the basis of the same method as patients with MM. Thresholds were assessed after counting 200 cells for each negative sample, and established by "mean+3 DS" calculation.
Results: Cytogenetic abnormalities were identified in 79.0% of cases, with one or more adverse abnormalities in 51.9%. We observed a del(17p13) in 15.0%, a t(4;14) translocation in 11.5%, a 1q21 gain in 37.8%, and a del(1p32) in 8.7% of patients with statistically significant associations between 1q21 gain and t(4;14) ($p=0.001$), and del(1p32) and del(17p13) ($p=0.01$). Adding 1p32/1q21 FISH probe has enabled us to identify one or more adverse abnormalities in 39.0% of patients with absence of *TP53* deletion or t(4;14). Clonal heterogeneity was observed in 51.1% of cases. Adverse abnormalities were significantly more frequent when the number of clones was greater than or equal to 2, with a frequency of 85.1% against 45.6% when 1 single clone was identified ($p<0.0001$). We observed a greater number of MM with 1q21 gain when clonal heterogeneity was present (≥2 clones): 81.6% *versus* 18.4% when 1 single clone was identified ($p<0.0001$). In the case of marked clonal heterogeneity (≥3 clones), a higher involvement of del(1p32) was found with a frequency of 28.0% against 5.8% when only 2 related clones were present ($p=0.002$). In the subgroup $t(4;14)^+/1q21^+$ with 2 or more identified clones (n=14), 1q21 gain was found to be significantly more often present in the minor clone compared to the clone with t(4;14) (10/14) ($p=0.01$).
Summary/Conclusions: We were able to identify adverse abnormalities or derivative anomalies, and related clones or clonal evolution by FISH analysis. We confirm the presence of clonal heterogeneity and accumulation of adverse abnormalities in the first diagnostic analysis. The prognostic impact of these parameters should be evaluated, and could be included in cytogenetic classifications.

E1246

EXPRESSION OF HUMAN CRBN SENSITIZES MOUSE MULTIPLE MYELOMA CELLS TO LENALIDOMIDE

D Serdar[1,*], S Köpff[1], E Fink[2], BL Ebert[2], J Krönke[1]
[1]University Hospital of Ulm, Ulm, Germany, [2]Brigham and Women's Hospital, Boston, United States

Background: The immunomodulatory drugs (IMiDs) lenalidomide, thalidomide, and pomalidomide are highly active in the treatment of multiple myeloma. We and others have shown that IMiDs inhibit growth of multiple myeloma cells by inducing ubiquitination and degradation of the lymphoid transcription factors Ikaros (IKZF1) and Aiolos (IKZF3) by the cereblon (CRBN) E3 ubiquitin ligase. Recently, we identified another lenalidomide-induced substrate of the CRBN E3 ligase, Casein Kinase 1A1 (CK1α), the degradation of which is responsible for lenalidomide's activity in del(5q) myelodysplastic syndrome. However, in contrast to human cells, mouse cells are resistant to lenalidomide-induced degradation of CK1α due to a single amino acid change in the mouse CRBN (mCRBN) protein at position 391 (valine in human CRBN (hCRBN)), isoleucine in mCRBN) that can be overcome by expression of the human variant.
Aims: To determine whether expression of *hCRBN* and $mCrbn^{I391V}$ sensitizes mouse multiple myeloma cells to lenalidomide.
Methods: We studied the mouse multiple myeloma cell line MOPC-315.BM that has been previously shown to induce multiple myeloma in BALB/c mice after transplantation. The different *CRBN* forms were expressed by retroviral vectors.
Results: Western blot analyses showed that MOPC-315.BM multiple myeloma cells had high protein levels of IKZF1 and IKZF3 as compared to non-myeloma mouse cells such as Ba/F3 pro-B cells and myeloblast-like 32D cells. However, lenalidomide treatment of MOPC-315.BM neither induced degradation of IKZF1 and IKZF3 nor had an impact on proliferation. Using retroviral transduction we expressed *mCrbn, hCRBN,* and $mCrbn^{I391V}$ in MOPC-315.BM cells. After lenalidomide treatment, we observed effective degradation of IKZF1 and IKZF3 proteins by western blot analysis in *hCRBN* and $mCrbn^{I391V}$ expressing MOPC-315.BM cells but not in those expressing *mCrbn* or empty vector. Immunoprecipitation analysis revealed that in the presence of lenalidomide IKZF3 bound to hCRBN and $mCrbn^{I391V}$ but not mCRBN, indicating that the isoleucine present in mCRBN at position 391 prevents direct interaction with IKZF3. Next, we examined the effect of expressing different CRBN forms on drug sensitivity of MOPC315.BM cells. As in the parental cells, *mCrbn*-expressing cells were insensitive to lenalidomide. In contrast, lenalidomide inhibited proliferation of *hCRBN* and $mCrbn^{I391V}$ expressing cells in a dose-dependent fashion. Similar results were obtained for pomalidomide and thalidomide. Expression of a dominant negative *IKZF3* isoform that inactivates IKZF3 and IKZF1 inhibited proliferation of MOPC315.BM cells, demonstrating that these cells depend on both transcription factors as their human counterparts. Expression of *hCRBN* and $mCrbn^{I391V}$ did not sensitize Ba/F3 or 32D cells to lenalidomide, demonstrating the multiple myeloma-specific effect of IMiDs. In MOPC315.BM cells, expression of *hCRBN* or $mCrbn^{I391V}$ had no effect on the sensitivity of other potent anti-multiple myeloma drugs including bortezomib and dexamethasone, confirming the specific role of CRBN as a drug target for IMiDs.
Summary/Conclusions: These results demonstrate that mouse multiple myeloma cells can be specifically sensitized to IMiDs by expression of *hCRBN* or $mCrbn^{I391V}$ and provide a basis for further development of *in vivo* models for IMiDs.

E1247

INFLUENCE OF HISTONE DEACETYLASE INHIBITORS (HDACIS) ON THE EXPRESSION OF ADHESION MOLECULES AND MODERN TARGET STRUCTURES IN MULTIPLE MYELOMA (MM)

S Müller[1,*], J Senger[2], J Waldschmidt[1], D Wider[1], A Thomsen[3], G Ihorst[4], J Duyster[1], M Hug[5], M Jung[2], R Wäsch[1], M Engelhardt[1]
[1]Hematology & Oncology, Medical Center University of Freiburg, [2]Pharmaceutical Science, Albert-Ludwigs-University, [3]Radiation Oncology, [4]Clinical Trials Unit, [5]Pharmacy, Medical Center University of Freiburg, Freiburg, Germany

Background: During the last decades the vital role of the bone marrow (BM) niche was increasingly explored to elucidate the progression and drug resistance in multiple myeloma (MM), this leading to advances of treatment strategies to modulate the interaction between malignant plasma cells (PCs) and the microenvironment. Small molecules (IMiDs, plerixafor, NOX-A12) and biologicals (elotuzumab, daratumumab, indatuximab) have been developed and are in pre- and clinical use.
Aims: We assessed the influence of histone deacetylase inhibitors (HDACis) on the BM niche. For this purpose various HDACis were assessed alone and in combination with antimyeloma agents in a novel 3-dimensional (3D) co-culture, to predict most rational combination use targeting both PCs and BM niche.
Methods: To best mimic the microenvironment, whilst ensuring easy handling, we have established an agarose matrix-based 3D coculture model, suitable for high-throughput screening. The cells are seeded in conical microwells and their proliferation, viability and apoptosis are assessed. These properties are compared both in presence or absence of stroma and to 2D cultures. Cells are incubated with HDACis, their synergisms with established antimyeloma drugs and

stroma effects upon the treatment can be visualized via flow-cytometry and viability assays. The expression profile of relevant surface molecules (CXCR4, CD38, SLAM-F7, CD138) in primary MM cells and MM cell lines (MMCLs) are determined using fluorescent labeled antibodies and flow-cytometry.
Results: Inside the microcavities of the agarose matrices, PCs indeed formed 3D cell clusters and showed a similar cell proliferation rate compared to 2D cultures. Cell growth and expression pattern of surface proteins were influenced by the presence of BM stroma cells (BMSCs), leading to a decrease in CXCR4 but persistence of CD138 expression. Our current results suggest evident differences concerning growth and treatment response in our 3D *versus* 2D culture systems, which we currently further validate using HDACi as a novel substance class in MM within this easy to use culture system. Therein, the novel selective HDAC-6 inhibitor JS28 was selected from more than 20 hydroxamic acid derivates due to trypsin-dependent *in vitro* HDAC-inhibition assay results, with an IC_{50} of 59nM and a both 200-fold selectivity for HDAC 6 and HDAC 8 as compared to HDAC 1, respectively. The effect on target could be demonstrated in 2 different cell lines (HeLa and HL30) via western blot, quantifying a higher amount of acetylated tubulin, which is mainly degraded via HDAC 6 and consequently an evident marker for HDAC 6 activity. The phenotypic HDACi effect was determined with assessment in 2 MMCLs U266 and RPMI 8226: treatment of U266 and RPMI cells were performed with use of panobinostat or JS28 for 48 hours, either alone or combined with bortezomib, to test synergism. 2, 4 and 6nM bortezomib were combined with same ratios of both HDACi panobinostat with 2, 4 and 6nM or JS28 with 20, 40 and 60µM. The calculated combination indices (CI) in both MMCLs were <1 (=synergistic) within a range of approximately EC_{40} to EC_{55} for both combined panobinostat/bortezomib and JS28/bortezomib treatment schedules.

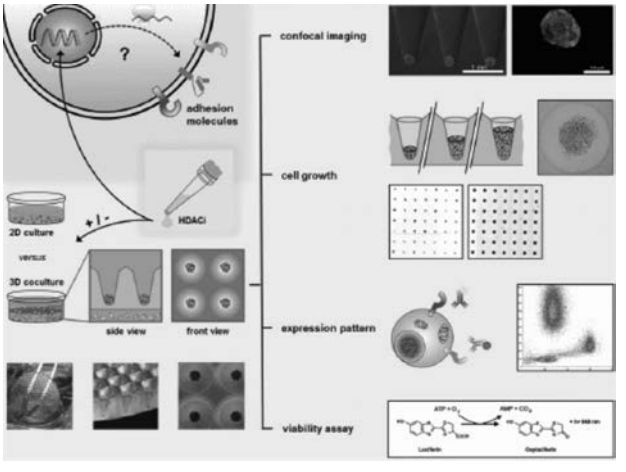

Figure 1.

Summary/Conclusions: Our current data underline the importance of accurate 3D co-culture models to mimic *in vivo* proliferation and drug resistance and to predict later clinical treatment success more effectively. So far, there is insufficient data that conclusively unravel the complex interactions between HDACis, their different subtype selectivity and the rapidly increasing number of treatment options in MM. In this context, our ongoing investigations will focus on cytokine secretion patterns, expression of adhesion molecules, their targeting and their alteration by HDACis.

HEME OXYGENASE 1 (HO-1) PROTECTS MYELOMA CELLS AGAINST BORTEZOMIB THROUGH NUCLEAR TRANSLOCATION AND REGULATION OF ER STRESS AND AUTOPHAGY PROTEINS

D Tibullo[1,*], I Barbagallo[2], C Giallongo[1], G Camiolo[1], G D'Amante[1], P La Cava[1], NL Parrinello[1], A Romano[1], C Conticello[1], S Saccone[3], MV Brundo[3], L Vanella[2], G Li Volti[4], F Di Raimondo[1]
[1]Division of Hematology, azienda ospedaliera universitaria policlinico vittorio emanuele, [2]Department of Drug Science, Biochemistry Section, [3]Department of Biological, Geological and Environmental Sciences, [4]Department of Biomedicine and Biotechnologies, University of Catania, Catania, Italy

Background: Despite recent advances in proteasome inhibitor and immunomodulatory drug-based therapies, MM remains largely incurable, primarily owing to acquired resistance. HO-1 is a cytoprotective microsomal enzyme that catalyzes the degradation of heme. We have recently shown that the protective effect of HO-1 on drug-induced cytotoxicity in leukemic cells does not involve its enzymatic byproducts, but rather its nuclear translocation following proteolytic cleavage. It has been recently described that Bortezomib (BTZ) is able to increase HO-1 expression.
Aims: We investigated about the role of BTZ-induced HO-1 in MM cell lines (U266, SKM-M1).
Methods: Cell Proliferation was performed by ATPlite one step assay (Perkinelmer) and using flow cytometry Annexin V/ iodure propidio. ROS formation was evaluated by flow cytometry. Endoplasmic reticulum (ER) associated proteins, autophagy-related proteins and HO-1 protein were evaluated by western blot assay. The fluorescent images were obtained using a Confocal Laser Scanning Microscopy (CLSM, Zeiss LSM700, Milan, Italy).
Results: As expected, we observed that Btz (15 nM) induced apoptosis after 24h ($p<0.001$). Flow cytometric analysis revealed increased levels of ROS after 1h ($p<0.0001$) of treatment with a peak after 3h ($p<0.001$). Btz was able to induce a significant increase in HO-1 mRNA levels after 3h ($p<0.0001$) of treatment with a maximum peak after 6h ($p<0.0001$). Since HO-1 is one of the major endoplasmic reticulum (ER) associated heme protein, we analyzed the ability of BTZ to induce ER stress. BTZ was able to induce the expression of ER stress proteins (Bip, IRE1α, Ero1, PERK and CHOP) in MM cells after 6h ($p<0.001$) with a peak after 24h ($p<0.0001$). Moreover, we observed that BTZ was able to induce autophagy-related genes such as ATFG5 and BENC1 in U266 cell lines. Silencing HO-1 using siRNA, we observed reduction of proteins described above indicating that induction of ER stress and then autophagy pathways by BTZ is HO-1 mediated. Furthermore, by confocal microscope we observed that HO-1 localized both in the cytoplasm and in the nucleus of MM cells. Interestingly, blockage of nuclear translocation by E64, a selective inhibitor of the protein cleavage, induced MM cells to become more sensitive to BTZ ($p<0.001$). No change in cell viability was observed inhibiting HO-1 enzymatic activity by using TIN (zync protoporphirin, 10 uM). Since nuclear HO-1 it has been reported to be a regulator of DNA repair activities, we also explored its role in genomic instability of MM cells. Using the cytochinesis-block micronucleus (CBMN) assay, we observed that pre-treatment of U266 with E64 for 24h led to a significant reduction of the percentage of micronuclei ($p<0.01$) and nucleolasmic bridges ($p<0.05$) observed in binucleated cells. Next, we evaluated U266 ability to activate G2/M checkpoint after UV damage using CBPI (cytochinesis block proliferation index) assay. The percentage of monucleated cells (G2/M checkpoint activated) was higher in cells pre-treated with E64 than control ($p<0.05$).
Summary/Conclusions: Our data suggest that BTZ-induction of HO-1 is probably linked to the activation ER stress and autophagy pathway by BTZ through HO-1 activation. HO-1 nuclear translocation may be involved in MM BTZ resistance. In addition, nuclear HO-1 may be involved in genomic instability of MM cells.

E1249

ANTI-MYELOMA EFFECT OF CANNABINOIDS

V Barbado[1], M Medrano[1], T Caballero-Velazquez[2], I Alvarez-Laderas[1], LI Sanchez-Abarca[1], E Garcia-Guerreo[1], J Martin-Sanchez[1], IV Rosado[1], P Gonzalez-Naranjo[3], N Campillo[3], JI Piruat[1], JA Paez[3], JA Perez-Simon[2,*]
[1]Department of Hematology, Institute of Biomedicine of Seville, [2]Department of Hematology, Hospital Virgen del Rocio, Seville, [3]Department Medicinal Chemistry, Medicinal Chemistry Institute, Madrid, Spain

Background: It is well studied the antiproliferative and proapoptotic effects of cannabinoids in neoplasias of the central nervous system, where the cannabinoid receptor type 1 (CB1) exhibits the highest levels of expression. In contrast, the cannabinoid receptor type 2 (CB) is found also exclusively in the hematopoietic and immune system. Despite this, the potential effect of cannabinoids on hematologic malignancies has been poorly determined.
Aims: Our purpose is to investigate the anti-tumor effect, both in vitro and *in vivo*, of different cannabinoids in multiple myeloma (MM) and know the main signaling pathways implicated in the effect of cannabinoids.
Methods: We evaluated the effect of five cannabinoid compounds in cell viability of six different human multiple myeloma cell lines, primary myeloma plasma cells and healthy primary cells from patients and donors. We studied the involvement of the main signaling pathways in the effect of cannabinoid as well as the expression of capases and some proteins of family Bcl-2 and also of the SPT enzyme by Western-blot. We used selective antagonists of cannabinoid receptors to know if the effect antiproliferative of tested cannabinoids is mediated by CB2. The role of ceramide was examined by immunohistochemistry and by pharmacological inhibition of the synthesis route. In addition we evaluated the synergism of the combination of cannabinoids with antimyeloma agents, such as dexamethasone and melphalan. Finally, we evaluated the effect of cannabinoids in MM xenograft models.
Results: We demonstrate that cannabinoids induce a selective apoptosis in myeloma cell lines and in primary malignant plasma cells from MM patients, without affecting the viability of normal cells from healthy donors, including hematopoietic stem cells. This antiproliferative effect is mediated by activation of caspases, mainly caspase 2, and is partially prevented by a pan-caspase inhibitor. Cannabinoid-induced apoptosis was correlated with an increased expression of Bax and Bak and a decrease of Bcl-xL and Mcl-1. In addition, cannabinoid treatment induced a biphasic response of Akt/PKB and significantly increased the levels of ceramide in MM cells. Remarkably, the blockade of ceramide synthesis prevented cannabinoid-induced apoptosis, indicating that ceramides play a key role in the pro-apoptotic effect of cannabinoids in MM cells. Furthermore, blockage of the cannabinoid receptor CB2 also inhibited cannabinoid induced apoptosis. Cannabinoid WIN-55 enhanced the antimyelo-

ma activity of dexamethasone and melphalan overcoming resistance to melphalan in vitro. Finally, administration of cannabinoid WIN-55 to plasmacytoma-bearing mice significantly suppressed tumor growth *in vivo*.
Summary/Conclusions: Our findings suggest that cannabinoids induce a selective apoptosis in tumor cells without adverse effects and thus they may be considered as potential therapeutic agents in the treatment of multiple myeloma.

E1250

BONE MARROW ADIPOCYTES PROMOTE MYELOMA CELL PROLIFERATION THROUGH INTERLEUKIN-6 SIGNALLING

AM Katumba[1,*], MS Shafat[1], KM Bowles[1,2], SA Rushworth[1]
[1]Department of Molecular Haematology, Norwich Medical School, University of East Anglia, [2]Department of Haematology, Norfolk and Norwich University Hospitals NHS Trust, Norwich, United Kingdom

Background: Multiple myeloma (MM) is a malignancy characterised by the proliferation of monoclonal plasma cells within the bone marrow (BM) and its progression crucially involves support from the BM microenvironment. The BM microenvironment consists of many cell types not directly involved in haematopoiesis including the adipocyte, which accounts for over 50% of the older adults BM by volume. Adipocytes are known to promote the growth and survival of breast, ovarian and prostate cancers. Subsequently, we hypothesised that BM adipocytes could play a role in mediating MM cell survival and proliferation.
Aims: To investigate the role of BM adipocytes in regulating the survival and proliferation of MM cells.
Methods: Primary myeloma cells and MM cell lines were cultured on patient derived adipocytes which were obtained following informed consent under approval from the UK National Research Ethics Service (LRCEref07/H0310/146). MM cell proliferation was determined using flow cytometry cell count and BrdU uptake while cell survival was determined by annexin V/PI staining. Immunocytochemistry using a lipid specific dye and nuclear staining was performed to determine free fatty acid (FFA) transfer between adipocytes and MM cells with and without the inhibitor acipimox. ß-oxidation rates in MM cells were determined by Seahorse XF analysis using palmitate and etomoxir. PCR and cytokine analysis was used to determine the levels of interleukin-6 (IL-6) and other factors.
Results: We report that BM adipocytes promote MM cell survival and proliferation. BrdU analysis and annexin V/PI staining revealed that adipocyte/MM cell co-culture led to increased MM cell proliferation and decreased MM cell apoptosis compared to MM cells cultured alone. Furthermore, MM cells cultured on adipocytes induced adipocyte lipolysis and initiated lipid transfer from adipocytes to MM cells. This process was inhibited by acipimox. In addition, MM cell/adipocyte co-culture also led to increased MM cell β-oxidation rates indicating that MM cells use BM adipocyte derived FFAs to produce ATP. Furthermore, pharmacological inhibition of ß-oxidation using etomoxir led to a significant decrease in survival and proliferation of MM cells. PCR and cytokine analysis identified an increased expression of IL-6 in MM cells co-cultured with adipocytes. Further analysis revealed that IL-6 derived from myeloma cells induced the breakdown of triglycerides into FFAs (lipolysis) in BM adipocytes.
Summary/Conclusions: Results indicate that adipocytes provide energy to MM cells in the form of FFAs for survival and growth in vitro. Moreover, we found that the signal which induces adipocyte lipolysis is myeloma derived IL-6.

E1251

RETROSPECTIVE STUDY OF PARAPROTEINEMIA PREVALENCE AND DEVELOPMENT OF HEMATOLOGICAL MALIGNANCIES IN HBSAG POSITIVE *VERSUS* HBSAG NEGATIVE PATIENTS

E Jou[1], CK Cheung[2], RC HO[2], KY Lam[3], D Mohan[4], U Felsen[5], HH Billett[1], EP Hui[3], AT Chan[3], R Raghupathy[3,*]
[1]Department of Oncology, Division of Hematology, Montefiore Medical Center, Bronx, United States, [2]Department of Medicine, [3]Department of Clinical Oncology, Chinese University of Hong Kong, Shatin, Hong Kong, [4]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, [5]Department of Medicine,Division of Infectious Diseases, Montefiore Medical Center, Bronx, United States

Background: Hepatitis B virus is lymphotropic and persists in peripheral blood mononuclear cells for years after active infection. In chronic infection, persistent antigenic stimulation of lymphocytes occurs. Whether these effects of the virus on B cells increase the risk of paraproteinemia and its progression is unknown.
Aims: We proposed to compare HBsAg+ *versus* HBsAg negative patients identified in the same time frame for prevalence of paraproteins and risk of development of hematological malignancy (HM).
Methods: Adults in Montefiore Medical Center with a HBsAg test between Jan 1st 2001 and Dec 31st 2011 were identified. Those with a positive serum protein electrophoresis (SPEP) test were included. SPEP results were classified into faint (F-SPEP) and discrete (D-SPEP). Demographics, results of Hepatitis C and HIV serology were obtained. Cancer registry data were reviewed for a diagnosis of biopsy confirmed HM.
Results: 216,522 patients were tested for HBsAg. 3,177 were positive. 346 of 3,177 HBsAg+ (10.9%) had an SPEP test. 66 of 346 (19%) had a +SPEP. 15 (4.5%) had a D-SPEP and 51 (14.5%) had a F-SPEP. Of the 213,345 HBsAg-, 21,291 (9.9%) had a SPEP. 2,226 of 21,291 (10.5%) were SPEP+. 739 (3.3%) had a D-SPEP and 1487 (7.2%) had a F-SPEP. HBsAg+ patients were more likely to be SPEP+ than HBsAg-. (19% *vs* 10.5%, p<0.0001). Patients with +SPEP among HBsAg+ and HBsAg- were compared. (Table 1) HBsAg+ SPEP+ patients were more likely to be male (69.7% *vs* 47.9%, p<0.001), more likely tested for HIV (OR:3.7, 95% CI: 2.1-6.4) and to be HIV positive (OR:2.3, 95% CI: 1.3-4.1). HBsAg+ SPEP+ patients were 6.7 times more likely to have a HM compared to HBsAg- SPEP+ patients. (OR: 6.7, 95% CI 3.5-12.7) The types of HM identified in the groups is described in Table 2.

Table 1. HBsAg- SPEP+ *versus* HBsAg+ SPEP+ patients.

Characteristic	HBsAg- SPEP+ (n=2226)	HBsAg+ SPEP+ (n=66)	p value
Male (n, %)	1067 (47.9%)	46 (69.7%)	<0.0001
HCV serology tested	2047 (92%)	65 (98.5%)	0.052
HCV positive/ tested for HCV	370 /2047 (18.1%)	12/65 (18.5%)	0.937
HIV serology tested	974 (43.8%)	49 (74.2%)	<0.0001
HIV positive / tested for HIV	319/974 (32.8%)	26/49 (53.1%)	0.003
D-SPEP positive	739 (33.2%)	15 (22.7%)	0.074
F-SPEP positive	1487 (66.8%)	51 (77.3%)	0.074
HM positive	79 (3.5%)	13 (19.7%)	<0.001

Table 2. Malignancies in HBsAg+ and HBsAg- patients with +SPEP.

Type of HM	HBsAg- SPEP+ HM+ (n=79)	HBsAg+ SPEP+ HM+ (n=13)
Plasma cell neoplasm	18 (21.4%)	8 (44.4%)
High grade B cell lymphoma/ Acute lymphoblastic leukemia	14 (16.7%)	1 (5.6%)
Low grade B cell lymphoma	26 (31%)	2 (11.1%)
T cell or NK cell lymphoma	8 (9.5%)	0
Acute myeloid leukemia or myelodysplasia	9 (10.7%)	1 (5.6%)
Myeloproiliferative syndromes	4 (4.8%)	1 (5.6%)

Summary/Conclusions: Our study shows that paraproteinemia is more prevalent in HBsAg+ patients, and HBsAg+SPEP+ patients are at a greater risk of developing HM compared to HBsAg- SPEP- Virus dependent B cell proliferation may be involved in Hepatitis B lymphomagenesis and paraproteins may be a marker. Modest frequency of HIV testing in our retrospective cohort is a significant limitation.

E1252

PROTEOMIC SIGNATURE PREDICTING COMPLETE RESPONSE TO PAD IN REFRACTORY MULTIPLE MYELOMA PATIENTS QUALIFIED FOR AUTOPBSCT AND VD CONSOLIDATION-MULTICENTER, POLISH MYELOMA CONSORTIUM 001 STUDY

D Dytfeld[1,2,*], L Usnarska-Zubkiewicz[3], K Brzeźniakiewicz[2,4], K Jamroziak[2,5], K Giannopoulos[2,6,7], N Grząśko[2,6,7], M Morawska[2,6,7], A Przybyłowicz-Chalecka[1], B Ratajczak[1], J Czerwińska- Rybak[1], A Nowicki[1,2], M Joks[2,8], E Czechowska[2,9], M Zawartko[10], T Szczepaniak[1,2], M Komarnicki[1], M Łuczak[11], T Wróbel[3]

Background: Despite the new drugs introduced to multiple myeloma (MM) treatment the disease remains incurable due to increasing resistance to therapy. Understanding biology of disease and identification of biomarkers of resistance is a key research challenge and may enable the individualization of treatment.
Aims: We aimed to identify biomarkers and signaling pathways differing plasma cells (PCs) of patients (pts) with refractory/relapsed MM (RRMM) who achieved complete response (CR) after PAD (bortezomib, adriamycin, dexamethasone) from those with lower response. All the patients were qualified to undergo a high dose melphalan and a VD (bortezomib, dexamethasone) consolidation afterwards.
Methods: Comparative proteome analysis was performed on purified by positive selection (EasySep), pretreatment PCs from pts, who were refractory to the first line (CTD) and qualified for PAD chemotherapy followed by high dose melphalan and 2 cycles of VD consolidation according to standard recommendations of Polish Myeloma Group. Treatment response was assessed using IMWG criteria. PCs acquired from pre-treatment bone marrow after obtaining informed consent from pts (IRB# 434/14 UMP) were lysed and protein was isolated. Proteins from each patient were analyzed using two different, independent proteomic methods: Isobaric Tag for Relative and Absolute Quantitation iTRAQ (4-plex) and Label Free-based (LF) proteomic approach. Peptides were analyzed using Q-Exactive hybrid quadrupole-Orbitrap mass spectrom-

eter coupled to the chromatograph Dionex 3000 Ultimate nanoLC (Thermo Scientific). Proteins which accumulation in the analyzed subgroups differed by at least 50% in both methods (iTRAQ and LF) were considered to differentiate. The dysregulated proteins were subjected to REACTOME and PANTHER bioinformatic tools for identifying enriched signaling pathways and networks.
Results: As of January 31th 2016 30/45 (66%) pts (median age: 60 (38-74)) received 6 planned PAD. Treatment was interrupted due to toxicity for 8 pts (G3 neuropathy, G2 infection) and disease progression (PD) (7 pts - 15%). After PAD 8 pts achieved CR (17%), 14 VGPR (30%), 14 PR (30%) and 9 - PD (20%). 4 pts died due to PD during PAD. Transplantation was so far performed in 12 pts and consolidation planned 3 months after autoPBSCT in - 7. Proteomic analysis was performed on PCs from 28 pts. Out of 499 proteins identified (FDR<1%), 56 showed significant differences in accumulation between patients, who, after treatment with PAD, achieved CR and patients with worse response. Accumulation of 13 proteins was up-regulated in resistant patients, among them thioredoxin domain-containing protein 5 (TXNDC5), proteasome activator complex subunit 2 (PSMA2) and peroxiredoxin-5 whereas relative abundance of 42 proteins were down-regulated in resistant patients. Among the latter were vimentin, annexin A1. Based on the log of p-value from Fisher's test and number of identified differential proteins, the most affected pathways constitute: proteasome pathway, apoptosis and programmed cell death, signalling by Rho GTPases, detoxification of ROS and activation of DNA fragmentation factor and apoptosis induced DNA fragmentation.
Summary/Conclusions: We indicated pathways involved in resistance to investigated regimen in RRMM and confirmed our previous finding in newly diagnosed MM and RRMM (Dytfeld BJH 2015, ASH 2015). We pointed significant biomarkers of resistance and potential therapeutic targets as basis for individualized MM therapy.

E1253

NOTCH PATHWAY AND INTELEUKIN-6 COOPERATE TO SUPPORT MULTIPLE MYELOMA CELL PROLIFERATION

S Galletti[1,*], M Colombo[2], G Bulfamante[3,4], M Falleni[2,4], D Tosi[2,4], K Todoerti[5], E Lazzari[2,6]
[1]Department of Oncology and Hemato-oncology, [2]Department of Health Sciences, [3]Università degli Studi di Milano, [4]Unit of Pathology A.O. San Paolo, Milano, [5]Laboratory of Pre-Clinical and Translational Research, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture, Italy, [6]Division of Regenerative Medicine, Department of Medicine, Moores Cancer Center at University of California, San Diego, United States

Background: Multiple myeloma (MM) is a malignant plasma cells (PC) disorder characterized by PCs accumulation in the bone marrow (BM) and a close interaction between PCs and the surrounding microenvironment. Infact, BM stromal cells (BMSCs) sustain the survival and proliferation of tumor cells through adhesion molecules and the production of several cytokines, especially interleukin-6 (IL6). At the initial stage, MM cells strictly depend on IL6 produced by BMSCs and during disease progression may acquire independence and/or the ability to produce autonomously this cytokine. The Notch pathway is highly conserved and plays a crucial role in cell-fate decision, tissue patterning and morphogenesis. Recent evidences suggest a key role of Notch pathway in MM progression, by its ability to positive regulate cell proliferation, drug resistance and BM infiltration through the overexpression of both receptors (Notch1 and 2) and ligands (Jag1 and 2).
Aims: We investigated the cooperation between the Notch pathway and IL6 signaling in the promotion of MM cells proliferation. Particularly, we analyzed how Notch upregulation during MM progression may support tumor cells growth. Moreover, we evaluate if it could promote the activation of an IL6 autocrine loop in MM and favor IL6 paracrine production by the surrounding BMSCs.
Methods: Notch signaling modulation was induced in MM cell lines and primary MM cells as follows: upregulation by 5µg/mL soluble Jag1; down-regulation by 50µM DAPT or Jag1-2 RNA interference. qPCR was performed using SYBR Green. Absolute cells count and evaluation of IL6 protein expression was achieved by flow cytometry. Immunohistochemistry (IHC) for Hes6, IL6 and Ig light chain was performed on BM biopsies at different stages of MM.
Results: Gene expression profiling (GEP) analysis evidenced the upregulation of Jag1 and Hes5 (Notch transcriptional target) in MM and pPCL (primary plasma cell leukemia) cases compared to normal controls, and the overexpression of Notch2, Hes5 and Hes6 in the worst prognosis, MAF-traslocated MM patients. These data support the hypothesis that over-expression of Notch pathway members correlate with progression or high-risk MM. Notch activity was modulated in MM cell lines, allowing us to demonstrate that the dysregulation of Notch signal can substitute IL6 stimulation. Infact, Notch activation in IL6-dependent cells may stimulate their proliferation in the absence of the cytokine. On the opposite, upon Notch blockade, IL6-indipendent cells became dependent on IL6 for their growth. Notch pathway is also able to support MM cells proliferation through the promotion of an IL6 autonomous production. Indeed, IL6 expression in U266 cells depends upon Notch signaling and IHC study confirmed an association between Notch activation and IL6 immunoreactivity in MM cells. Since the most important source of IL6 are BMSCs, we focused our attention on the interaction between MM cells and the surrounding niche. We showed, by IHC staining, that MM cells induced IL6 expression in the nearby BMSCs. By co-culture systems, we demonstrated that MM cell-derived Jag ligands are able to activate Notch pathway in BMSCs, promoting IL6 secretion and MM cell proliferation, whereas Notch inhibition reverts this effect. Our results were further confirmed in *ex-vivo* co-cultures of MM cells and BMSCs, collected from patients.
Summary/Conclusions: Notch signaling in MM cells and in surrounding BMSCs promotes MM cell growth by boosting IL6 production. These results support the rationale for a Notch-directed approach in MM and suggest that Jag ligands may be promising molecular targets in MM therapy.

INTEGRATIVE ANALYSIS OF DNA COPY NUMBER, DNA METHYLATION AND GENE EXPRESSION IN MULTIPLE MYELOMA REVEALS ALTERATIONS RELATED TO RELAPSE

P Krzeminski[1,*], L Corchete[1], A Martín[1], LLC López-Corral[1], E Fermiñán[2], E García[2], JL García[3], J Hernández-Rivas[1], R García-Sanz[1], J San Miguel[4], N Gutiérrez[1]
[1]Hematologia, Hospital Universitario. IBSAL, IBMCC (USAL-CSIC), [2]Genomica y Proteomica, [3]Hematology, Centro de Investigación del Cáncer-IBMCC (USAL-CSIC), Salamanca, [4]Clínica Universidad de Navarra, Centro de Investigaciones Medicas Aplicadas (CIMA), Pamplona, Spain

Background: Multiple myeloma (MM) remains incurable despite the introduction of novel agents and a relapsing course is observed in the majority of patients. Although the development of genomic technologies has greatly improved our understanding of MM pathogenesis, the mechanisms underlying relapse have been less investigated.
Aims: To investigate the genomic changes generated in the transition of myeloma cells from diagnosis to relapse, analyzing DNA imbalances, methylation, and transcriptomic modifications.
Methods: Twenty patients with symptomatic newly diagnosed MM were included in the study. Paired bone marrow (BM) samples were obtained at diagnosis and relapse in all the patients. A CD138 positive PC isolation using the AutoMACs automated separation system was carried out in all the BM samples (purity was above 90%). Genome-wide detection of CNA was carried out using the standard Affymetrix CytoScan 750k assay protocol (Affymetrix); DNA methylation was assessed using the "Human DNA Methylation 3x720K CpG Island Plus RefSeq Promoter Array" according to standard procedures by NimbleGen Systems, and gene expression profiling was performed by means of the Human Gene 1.0 ST Array (Affymetrix).
Results: Overall, the acquisition of abnormalities at relapse was much more frequent than the lost of lesions present at diagnosis, and DNA losses were significantly more frequent at relapse than in diagnosis samples. Interestingly, copy number abnormalities involving more than 100 Mb of DNA at relapse significantly impact the gene expression of these samples, provoking a particular deregulation of IL-8 pathway. On the contrary, no relevant modifications of gene expression were observed in those samples with less than 100 Mb affected by chromosomal changes. Although different statistical approaches were used to uncover genes whose abnormal expression at relapse was regulated by DNA methylation, only two genes significantly deregulated in relapse samples (*SORL1* and *GLT1D1*) showed a negative methylation-expression correlation. A deeper analysis demonstrated that DNA methylation was involved in regulation of *SORL1* expression in MM. Finally, relevant changes in gene expression observed in relapse samples, such us downregulation of *CD27* and *P2RY8*, were not apparently preceded by alterations in corresponding DNA.
Summary/Conclusions: Cross-platform integration of three different microarrays data revealed that genomic heterogeneity of MM already described at diagnosis is subject to change at relapse, both at the DNA and RNA level. This study, also, showed a limited effect of DNA methylation changes observed at relapse on the transcriptome of myeloma cells.

E1255

DETAILED FISH PROFILING OF MULTIPLE MYELOMA PATIENTS IDENTIFIES A GROUP OF PATIENTS WITH ONLY SECONDARY CHROMOSOMAL ABERRATIONS

M Pantic[*], I Bartsch, A Heumüller, R Claus, J Waldschmidt, A Zober, SM Dold, D Pfeifer, J Rawluk, J Duyster, R Wäsch, M Engelhardt
Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, Germany

Background: Using targeted fluorescence in situ hybridization (FISH) analyses of plasma cells, chromosomal aberrations are identified in more than 90% of patients (pts) with multiple myeloma (MM). It is postulated that early oncogenesis in MM is driven by two different (almost) exclusive genetic events: hyperdiploidy (HYP) and IGH translocations (IGH-R), and that clonal evolution occurs with acquisition of secondary aberrations (SA). Recent studies showed that some pts have both types of aberrations (IGH-R+HYP) and that myeloma relapses are sometimes related to clones quite different to those at diagnosis. However, the characteristics of MM pts with secondary aberrations only (SA) have not being extensively studied.
Aims: Our aim was to detect MM pts with SA and to analyze if these pts show dif-

ferent biological and clinical characteristics than MM pts with primary aberrations.
Methods: We performed FISH on CD138+ plasma cells of 163 MM pts consecutively diagnosed in our department since 2012. We used an extensive FISH panel to analyze five IGH-translocations, five different trisomies and five probes labeling recurrent secondary aberrations. Ten patients were analyzed by targeted next-generation sequencing (NGS) technology using the Agilent HaloPlex library preparation approach. Genes bearing hotspots for mutations in hematological malignancies were included in the sequencing panel.
Results: Chromosomal (chr) aberrations were detected in 98% (160/163) and hyperdiploidy was the most frequent primary aberration in 59% (94/160), IGH-R occurred in 29% (47/160) and SA in 12% (19/160) of MM pts. Overlapping IGH-R and HYP was found in three pts with HYP proceeding the developing of t(4;14), in line with recent publications (1,2). In comparison to all MM pts those with SA showed higher frequencies of IgA MM isotypes (6/19) and light chain-only MM (6/19). Moreover, they showed more aggressive MM with ISS3 in 74% (14/19) of pts at the time of analysis. 13q14 was the most frequent chromosomal locus involved in almost all pts (18/19) with equally distribution of deletion 13q14 (9/18) and monosomy 13 (9/18). Gain 1q21 was the second most frequent aberration present in even 68% (13/19) of SA pts. Deletion 1p32, cMYC and 14q32 (IGH)-abnormalities were discovered in 21% (4/19), 21% (4/19) and 26% (5/19), respectively. A total of 53 chr aberrations were detected in 19 MM pts with SA showing a high level of chr complexity compared to all MM pts. Interestingly, two of the analyzed pts, one with three SA and one with six, did not show additional mutations via NGS technology.
Summary/Conclusions: Our results reveal a progressive MM cell type with as yet unknown initiating oncogenetic events, but highly activated mechanisms of clonal proliferation. Moreover they raise two questions, 1. whether pts without detectable primary genetic events, but with occurrence of unfavorable and high-risk secondary cytogenetic lesions represent a distinct MM subgroup and 2. how these pts should be best assessed and treated. Using NGS technology in a large MM pt cohort should allow to gain more insight in the pathogenesis of this subgroup of MM pts.

LONG NON-CODING RNAS IN MULTIPLE MYELOMA
L Sedlaříková[1,*], B Gromesová[1], V Kubaczková[1], L Radová[2], M Almáši[3], M Penka[3], Z Adam[4], L Pour[4], M Krejčí[4], S Ševčíková[1,3], R Hájek[1,3,5]
[1]Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, [2]Central European Institute of Technology, Masaryk University, [3]Department of Clinical Hematology, [4]Department of Internal Medicine - Hematooncology, University Hospital Brno, Brno, [5]Department of Hematooncology, University Hospital Ostrava, Ostrava, Czech Republic

Background: Multiple myeloma (MM) is the second most common hematological malignancy in the world. It is characterized by increasing rate of various genetic mutations and dysregulated pathways. This work aims to find out if this observed dysregulation may be partly caused by a subgroup of non-coding RNAs, the so-called long non-coding RNA molecules (lncRNA). These molecules are over 200 nt long, primarily localized in the nucleus, and it seems increasingly obvious that lncRNAs play a crucial role in human diseases including cancer.
Aims: The goal of this study was to identify a disease-specific cellular lncRNA signature using a cohort of MM patients in comparison to healthy donors.
Methods: Fifty CD138+ samples obtained from newly diagnosed MM patients and healthy donors (HD) were evaluated for this study. Screening analysis of 83 lncRNA was performed on 6 MM patients and 6 HD using RT2 lncRNA PCR Array-Human lncRNA Finder (Qiagen). Significantly deregulated lncRNAs between MM *vs* HD were validated by qPCR using relative quantification approach $2^{-\Delta Ct}$ on a larger cohort of patients and HD. Receiver Operating Characteristic (ROC) analysis was used to calculate specificity and sensitivity of each lncRNA. P values<0.05 were considered significant.
Results: RT2 lncRNA PCR Array profiling revealed 27 deregulated lncRNAs (all p<0.01) between MM patients and HD. ZFAS1, UCA1, BDNF-AS, NEAT1 and FAS-AS1 expression levels were further verified on a bigger cohort of MM and HD samples. UCA1 was significantly down-regulated (p<0.0001), NEAT1 and BDNF-AS were up-regulated in MM samples when compared with HD (both p<0.00000001). To discriminate MM from HD, receiver operating characteristic (ROC) curve was calculated. It revealed sensitivity of 100% and specificity of 100%, and area under curve (AUC)=1.000 for NEAT1 and BDNF-AS lncRNA expression and sensitivity of 95.24% and specificity of 75%, and area under curve (AUC)=0.905 for UCA1 expression levels. We suppose that these dysregulated lncRNAs could have a biological relevance in MM since BDNF-AS is an antisense RNA for BDNF, a significant stimulating factor of osteoclasts in MM, NEAT1 and UCA1 were described as dysregulated in several types of cancer, including hematological malignancies.
Summary/Conclusions: Altogether, our first observations demonstrate that cellular lncRNA UCA1, NEAT1 and BDNF-AS may be involved in pathophysiological processes occurring in MM cells and prompt further studies in this field.
Grant support: AZV 15-29508A

E1257

NEXT GENERATION FLOW CYTOMETRY IS A RELIABLE TECHNIQUE FOR DETECTING MINIMAL RESIDUAL DISEASE IN MULTIPLE MYELOMA PATIENTS IN COMPLETE REMISSION: A STUDY COMPARING SHORT *VS* LONG TERM REMISSION
A Gozzetti[*], D Raspadori, S Sirianni, V Candi, D Tocci, R Crupi, G Papini, S Parigi, M Bocchia
Hematology, Siena, Italy

Background: 4-6 colours flow cytometry has been validated in the past years as a powerful and feasible technique able to detect MRD in multiple myeloma patients thus furnishing a clinical and prognostic tool to the physician. Although its applicability and specificity can be high, it requires good quality bone marrow aspirate and expert and trained personnel for the analysis. However, recent results have confirmed that 4-6 colours flow-MRD has a lower sensitivity than molecular techniques such as allele-specific oligonucleotyde (ASO)-PCR and next generation sequencing (NGS). Recently, two 8 colours tubes panel developed by the EuroFlow Consortium showed to be able to detect MRD with an increased sensitivity and to be applicable as standardized method.
Aims: Complete remission (CR) is a prerequisite for long term responses, progression free survivals, and ultimately overall survivals and cure, but while many studies have looked at MRD status soon after autologous or allogeneic stem cell transplantation with flow or molecular techniques, little is known about long term remission patients (>5-10 years) and in particular if more sensitive techniques such as NGF or NGS can still detect minimal disease in those patients.
Methods: We tested the feasibility of NGF-MRD to CR MM patients with a lyse-wash-and-stain sample preparation protocol, staining an high numbers of bone marrow (BM) cells ($\geq 2x10^6$ cells/tube) with 2-tubes optimized 8-colours antibody panel, (OneFlow PCST e PCD BD Biosciences) for accurate identification of BM plasma cells (PCs) and discrimination between phenotypically aberrant (aPC) and normal PC (nPC). Patients with a CR/stringent CR were tested for MRD in BM and peripheral blood samples. Patients with 5-10 years of remission duration were analysed as well as patients with 2 to 4 years of remission. Clinical characteristics will be reported as well as treatment received.
Results: Applicability was 100% of patients studied. A preliminary result on the first 20 patients analysed showed an MRD+status in 12/20 patients predefined as CR. In particular, 2/20 patients did show residual disease also in the PB. Interestingly when studying patients with >5 years CR status, 1/5 did show an MRD+. A plan to analyse patients in CR is ongoing within the Tuscan Group of Multiple Myeloma (GTMM). The target is to test NGF-MRD in >100 CR patients comparing different treatments (auto *vs* chemo, *vs* new agents), age (<65 years *vs* >65 years), CR duration (<5 ys *vs* >5 ys).
Summary/Conclusions: Next generation flow is able to detect minimal residual disease in approximately 60% of predefined CR patients. The sensitivity can be quite comparable to the molecular techniques, but with an applicability largely superior. Patients with long term CR seem to have more chances to be MRD negative, although these findings nee to be demonstrated in a large cohort of patients. To confirm these data a study is currently ongoing of the GTMM and results will be presented.

E1258

BONE DISEASE IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE: RESULTS FROM A SCREENED POPULATION-BASED STUDY
S Thorsteinsdottir[1,2,*], SH Lund[2], E Lindqvist[3], G Sigurdsson[4], R Costello[5], D Burton[5], H Steingrimsdottir[1], LJ Launer[6], V Gudnason[2,4], G Eiriksdottir[4], K Siggeirsdottir[4], TB Harris[6], O Landgren[7], SY Kristinsson[1,2]
[1]Department of Internal Medicine, Landspitali - The National University Hospital of Iceland, [2]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [3]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [4]Icelandic Heart Association, Kopavogur, Iceland, [5]Center for Cancer Research, National Cancer Institute, National Institutes of Health, [6]National Institute on Aging, National Institutes of Health, Bethesda, [7]Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Monoclonal gammopathy of unknown significance (MGUS) is a precursor condition that precedes multiple myeloma (MM). Bone disease is a major manifestation of MM, and includes osteolytic lesions, fractures, and osteoporosis. Previous population-based studies have shown that individuals with MGUS have an increased risk of fractures, although the mechanism behind this increased risk remains unknown. Furthermore, these studies have been performed on clinically established cohorts with a risk of bias due to underlying comorbidity.
Aims: Our aim was to analyze bone mineral density (BMD), bone volume, and risk of fractures among individuals with MGUS in a screened population.
Methods: We performed a screening for MGUS in the Age Gene/Environment Susceptibility Reykjavik study (AGES-Reykjavik) cohort, consisting of 5,764 elderly Icelandic men and women. Through serum protein electrophoresis and free light chain analyses, 300 individuals with MGUS (159 men and 141 women) and 52 individuals with light chain MGUS (LC-MGUS; 35 men and 18

women) were identified. Quantitative computerized tomography (QCT) was performed in the lumbar spine (L1/L2), hip and mid-femoral shaft to evaluate cortical, trabecular and integral BMD as well as bone geometry in all individuals. Analysis of variance and Tukey's honest significance test were used to compare individuals with MGUS and LC-MGUS with others. Hospital records with International Classification of Diseases were used to record fractures from the individuals' enrollment into the study with a mean follow up time of 6.9 years. Cox proportional hazard models were used to compare risk of fractures in MGUS and others. Results were adjusted for age and sex.

Results: No difference was found in BMD between subjects with MGUS and others at the spine (Table 1; mean for MGUS (M_{MGUS})=0.197 mg/cm^3, mean for others (M_{others})=0.194 mg/cm^3, p=0.21) or total hip (M_{MGUS}=0.239 mg/cm^3, M_{others}=0.237 mg/cm^3, p=0.22). Volumetric measurements showed that individuals with MGUS had a statistically significant increase in bone volume compared to others in the lumbar spine (M_{MGUS}=41.5 cm^3, M_{others}=39.7 cm^3, p<0.001) and total hip (M_{MGUS}=106.3 cm^3, M_{others}=100.1 cm^3, p<0.001). A significant difference was found in bone volume in total hip in MGUS men, compared to other men (M_{MGUS}=123.6 cm^3, M_{others}=119.3 cm^3, p=0.04). Overall, the risk of fractures was not increased in individuals with MGUS as compared to others (hazard ratio (HR): 1.19; 95% confidence interval (CI): 0.94-1.50). Men with MGUS had a significantly increased risk of fractures, compared to other men (HR: 1.49; 95% CI: 1.05-2.12).

Table 1.

TABLE 1

	Mean measurements				ANOVA	Tukey's HSD
SPINE		**No MGUS**	**MGUS**	**LC-MGUS**		
Average L1 and L2 integral BMD (mg/cm^3)	Men	0.206	0.206	0.191	P=0.179	NS
	Women	0.185	0.186	0.181	P=0.850	NS
	All	0.194	0.197	0.188	P=0.207	NS
Mean volume of L1 and L2 (cm^3)	Men	45.96	46.37	46.13	P=0.741	NS
	Women	35.16	35.43	34.91	P=0.842	NS
	All	**39.70**	**41.45**	**42.13**	**P<0.001**	**P_{MGUS}<0.001 $P_{LC-MGUS}$=0.017**
TOTAL HIP						
Integral BMD (mg/cm^3)	Men	0.249	0.250	0.230	P=0.143	NS
	Women	0.228	0.226	0.216	P=0.536	NS
	All	0.237	0.239	0.225	P=0.221	NS
Integral volume of total hip (cm^3)	**Men**	**119.31**	**123.59**	**125.29**	**P=0.020**	**P_{MGUS}=0.043 $P_{LC-MGUS}$=0.287**
	Women	85.63	84.65	84.98	P=0.760	NS
	All	**100.12**	**106.28**	**111.50**	**P<0.001**	**P_{MGUS}<0.001 $P_{LC-MGUS}$<0.001**

Summary/Conclusions: Our results from a screened population show that individuals with MGUS do not have a decreased BMD at the lumbar spine or hip. Surprisingly, however, we find that bone volume is increased in individuals with MGUS, especially in men, who also have an increased risk of fractures. This suggests an effect of MGUS on bone metabolism in men that is not noted in women, probably as a result of other stronger risk factors in women. Further reaserch is needed to explain the increased bone volume in men with MGUS.

E1259

COMPENSATORY STRESS PATHWAYS IN MODULATING ER STRESS IN BORTEZOMIB RESISTANT MULTIPLE MYELOMA

N Nikesitch[1,2,*], C Tao[2,3], K Lai[4,5], M Killingsworth[1,4], S Bae[2], CS Lee[1,5], S Ling[1,2,3]
[1]School of Medicine, Western Sydney University, Campbelltown, [2]Haematology Research Group, Ingham Institute for Applied Medical Research, [3]Department of Haematology, [4]Electron Microscopy Laboratory, Liverpool Hospital, [5]Cancer Pathology and Cell Biology, Ingham Institute for Applied Medical Research, Liverpool, Australia

Background: Multiple myeloma (MM) remains a predominantly incurable malignancy despite high-dose chemotherapy, autologous stem cell transplants and novel agents. Nonetheless, proteasome inhibitors (PI) such Bortezomib (Bz) have been effective in treating the disease to date. The 26S proteasome inhibitor indirectly targets the unfolded protein response (UPR) by inhibiting proteasomal degradation of ubiquitinated paraprotein, subsequently leading to the lethal accumulation of paraprotein within the cell. Initial treatment is effective, however most patients eventually develop resistance to the drug. The mechanism of resistance is still unknown, though one possible mechanism contributing to Bz resistance could be chaperone-mediated autophagy (CMA). Upregulated in a number of tumours, CMA specifically targets and degrades soluble cytosolic proteins. It is therefore likely that this pathway could be an alternative stress management pathway in Bz resistance.

Aims: We aimed to assess CMA in sensitive and resistant MM, and its role in alleviating ER stress in bortezomib resistance.

Methods: QPCR, western blotting, cell viability assays, ER imaging and shRNA assays were performed to assess the role and importance of UPR and autophagy in Bz resistant MM, and was correlated to Bz sensitivity.

Results: Molecularly and morphologically, we identified reduced UPR activity as a result of increasing Bz resistance in both resistant MM patients and in resistant KMS11 cells. We further identified that the chaperone-mediated autophagy (CMA) marker, LAMP2A, was highly expressed in resistant cells compared to sensitive cells in cell lines and patients. CMA activity was also seen to increase in 4 different MM cell lines under various levels of ER induced stress, strongly suggesting the pathways importance in ER stress management. Upon further investigation, preliminary data has also shown that macroautophagy may provide as a compensatory mechanism in cells with impaired CMA.

Summary/Conclusions: CMA is upregulated in Bz resistant MM and functions as a compensatory stress mechanism in alleviating ER stress in cells with reduced UPR activity. Partial inhibition of the pathway subsequently results in the activation of macroautophagy. To effectively treat MM and potentially overcome Bz resistance, new therapies targeting autophagy are required.

CARFILZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE (KCYD) IN ELDERLY NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM) PATIENTS: INITIAL RESULTS OF A PHASE 1 STUDY

S Bringhen[1,*], P Musto[2], F Gay[1], N Giuliani[2], AM Liberati[2], C Pautasso[1], E Ponticelli[1], L De Paoli[2], R Zambello[2], G Ciccone[3], AM Carella[2], M Boccadoro[1], P Sonneveld[4], A Palumbo[1]

[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, [3]Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy, [4]Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands

Background: The combination of carfilzomib at the dose 20/36 mg/m^2, cyclophosphamide and dexamethasone has been demonstrated to be well tolerated and highly effective (Bringhen S. et al, Blood 2014; 124:63-9). A further dose escalation could improve clinical efficacy. Herein we present initial results of the dose-escalation phase 1 portion of a multicenter, phase 1/2 study evaluating the safety and the efficacy of the combination KCyd in elderly NDMM patients (pts).
Aims: The primary objective was to determine the maximum tolerated dose. The secondary objectives were to determine the safety and the efficacy of KCyd, including response rate, time to progression, progression free survival, time to next therapy and overall survival. ated results will be presented.
Methods: Newly diagnosed pts not eligible for autologous stem cell transplantation due to age or co-morbidities were eligible. Carfilzomib was administered intravenously on days 1,2,8,9,15,16, cyclophosphamide was administered orally on days 1,8,15 and dexamethasone was administered orally once weekly. Dose-escalation used a standard 3+3 schema with dose-limiting toxicities (DLTs) assessed during cycle 1. All pts received carfilzomib at 20 mg/m^2 on days 1 and 2 of cycle 1. Beginning on day 8 of cycle 1, carfilzomib was escalated in 3 successive dose levels from 45 to 70 mg/m^2 in combination with the standard doses of cyclophosphamide 300 mg/m^2 and dexamethasone 40 mg. KCyd induction was administered for 9 28-day cycles. Adverse events (AEs) were graded by NCI-CTCAE v4. Response was assessed according to the modified International Uniform Response Criteria.
Results: Between June 2014 and March 2015, 9 pts were enrolled in the completed phase 1 dose-escalation portion of the study. Median age was 74 years (range 67-82), 44% had ISS stage III, 67% had unfavorable FISH profile [t(4;14) or t (14;16) or del17p or amp1]. No DLTs were observed in the 3 pts of cohort 1, with carfilzomib at 45 mg/m^2. In cohort 2 carfilzomib was escalated to 56 mg/m^2 and 1/6 pt had a DLT with acute kidney injury. Therefore, the MTD of carfilzomib was established at 56 mg/m^2. Drug-related AEs occurring in >20% of pts included anaemia (56%), fever (44%), thrombocytopenia (33%), diarrhoea (33%), vomiting (33%), infections (33%), hypertension (33%), heart failure (22%), acute kidney injury (22%). Grade 3 AEs occurring in >10% of pts included anaemia (22%), infections (22%), acute kidney injury (22%) and heart failure (11%). Only 1 grade 4 AE was reported (thrombocytopenia). Six pts completed induction treatment, 2 pts discontinued treatment due to AEs and 1 pt due to pt decision. After a median follow-up of 14.2 months, 2 pts achieved a complete response (CR), 4 pts a very good partial response (VGPR) and 3 pts a partial response (PR), for an overall response rate of 100%, at least VGPR of 66% and at least CR of 22%. No progressive disease or death occurred during induction.
Summary/Conclusions: The MTD of carfilzomib was established at 56 mg/m^2. KCyd combination given to untreated, symptomatic, elderly pts with myeloma is well tolerated and highly effective with an overall response rate of 100%, including a CR rate of 22%. Enrollment in the phase 2 portion of the study is ongoing and updated results will be presented.

E1261

AN ONGOING MULTINATIONAL OBSERVATIONAL STUDY IN MULTIPLE MYELOMA (PREAMBLE): PRELIMINARY REPORT ON PROGRESSION-FREE SURVIVAL

D Kuter[1], G Cook[2], H Goldschmidt[3], D Cella[4], T Zyczynski[5,*], C Davis[5], S Popov[6], R Vij[7]

[1]Hematology Division, Massachusetts General Hospital Cancer Center, Boston, United States, [2]Section of Experimental Haematology, University of Leeds, Leeds, United Kingdom, [3]Hematology and Oncology, Heidelberg University Hospital, Heidelberg, Germany, [4]Department of Medical Social Sciences, Northwestern University, Evanston, [5]Worldwide Health Economics & Outcomes Research, Bristol-Myers Squibb, Princeton, United States, [6]Biostatistics, Parexel, St Petersburg, Russian Federation, [7]Division of Medical Oncology, Washington University School of Medicine, St Louis, United States

Background: Multiple myeloma (MM) is associated with significant disease burden, and long-term prognosis is poor, with relapse almost inevitable. Immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) have improved patient outcomes; however, data on real-world clinical effectiveness of these available treatments are limited.
Aims: PREAMBLE (Prospective REsearch Assessment in multiple Myeloma: an oBservationaL Evaluation; NCT01838512) is an ongoing, international, prospective, observational cohort study to improve understanding of the real-world outcomes of IMiDs, PIs, and combination therapy in relapsed/refractory MM (RRMM). Here we report preliminary progression-free survival (PFS) data.
Methods: Patients with RRMM (≥1 prior therapy) who initiated treatment with an IMiD, PI, or IMiD+PI within 90 days before or 30 days after study enrollment were eligible. Data were analyzed using a Cox proportional hazard regression model that included patient demographics, baseline disease characteristics, and MM treatment-related variables as covariates.
Results: At the time of data cut-off (December 7, 2015), data were available for 764 patients and median duration of follow-up was 15 months. The median age of patients was 68 years and 55% were male. Of the 764 patients, 368 (48%) were receiving an IMiD (81% of whom were receiving lenalidomide, n=297), 347 (45%) were receiving a PI (80% of whom were receiving bortezomib, n=278), and 49 (6%) were receiving an IMiD+PI (59% of whom were receiving lenalidomide/bortezomib, n=29). Most patients (n=325; 43%) had 1 prior line of therapy, 203 (27%) had 2 prior lines, 111 (15%) had 3 prior lines, and 123 (16%) had >3. The majority of patients had relapsed MM (n=599, 78%). 161 (21%) patients were refractory to their last line of treatment; 260 (34%) patients discontinued 1 prior line of therapy due to progression, 61 (8%) discontinued 2 prior lines due to progression, and 25 (3%) discontinued >2 prior lines. 40% of patients had International Staging System (ISS) stage III disease. Median PFS was 9.26 months (95% CI 8.21–10.12); 1-year PFS rate was 40.9% and 2-year PFS rate was 19.7%. Approximately half of the patients (50.7%) were estimated to respond to treatment before then progressing. At 2 years, all patients in this analysis had either responded to treatment or progressed without response. Median (95% CI) duration of response was 14.2 (10.87–16.39) months and was longer for patients receiving an IMiD *versus* a PI (16.4 [11.73–not estimable] months *vs* 10.9 [7.13–14.69] months). Number of lines of therapy discontinued due to progression was most strongly associated with higher rates of progression/death (Figure; HR p<0.001 for all comparisons). Other factors associated with higher rates of progression or death were number of prior lines of therapy (2 *vs* 1, HR 1.38, p=0.016; 3 *vs* 1, HR 1.48, p=0.012; >3 *vs* 1, HR 1.63, p<0.001) and ISS stage at study entry (III *vs* I, HR 1.45, p=0.032).

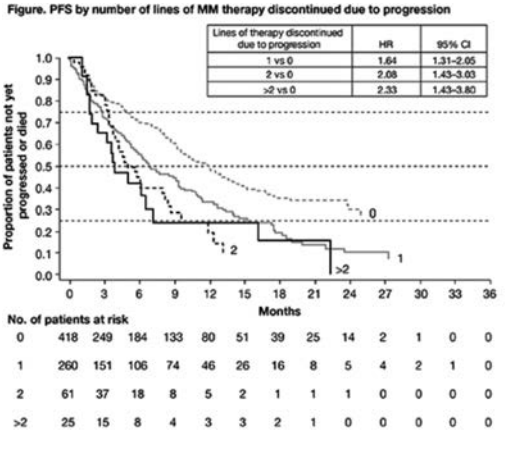

Figure 1.

Summary/Conclusions: Preliminary analysis of real-world data from PREAMBLE suggests that the number of lines of therapy discontinued due to progression, lines of therapy overall, and disease stage are key risk factors associated with the rate of progression/death in patients with MM, demonstrating an unmet need.

ROBUSTNESS OF THE PROGNOSTIC VALUE OF THE SKY92 MARKER *VERSUS* FISH MARKERS ACROSS NINE MULTIPLE MYELOMA COHORTS

M Van Vliet[1,*], R Kuiper[1], J Ubels[1], L Bosman[1], B Dumee[1], E van Beers[1], L de Best[1], A Waage[2], S Zweegman[3], G Morgan[4], J Levy[5], D Auclair[5], R Fonseca[6], H Goldschmidt[7], P Sonneveld[8]

[1]SkylineDx BV, Rotterdam, Netherlands, [2]Norwegian University of Science and Technology, Trondheim, Norway, [3]VU University Medical Center, Amsterdam, Netherlands, [4]Myeloma Institute for Research and Therapy, University

of Arkansas for Medical Sciences, Little Rock AR, [5]MMRF, Norwalk CT, [6]Mayo Clinic, Scottsdale AZ, United States, [7]GMMG and Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany, [8]Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background: Multiple Myeloma (MM) is recognized as a heterogeneous group of patients with varying response and outcome of their disease, associated with various risk factors including genetic aberrations. With increasing availability of genetic data, ever more reliable conclusions can be drawn about the relevance of individual and combined biomarkers. Here we compare multiple stratifications of MM to evaluate their value in relation to overall survival (OS). All available biomarkers were used and included interphase FISH (iFISH), virtual FISH (vFISH), SKY92, ISS and some combinations thereof. The other combination is SKY92+ISS recently identified to be superior to all other combinations of one or two biomarkers for identification of both high risk and low risk patients.
Aims: To demonstrate and compare the robustness of the prognostic value of the SKY92, ISS, SKY92+ISS and various FISH marker risk classification methods across a wide variety of clinical datasets including NDMM and RRMM, young/elderly patients and a wide diversity of treatments.
Methods: Nine GEP datasets publicly available or obtained by analysis of the CE IVD MMprofiler assay were used (Table 1, rows) and evaluated for 17 biomarkers (Table 1, columns). In each analysis the Cox proportional hazard ratio (HR) and its *p*-value are calculated. Interphase FISH (iFISH) data was not available for all datasets, therefore, the so-called Virtual FISH markers (as classified by GEP signatures with high accuracy) were determined using the MMprofiler assay algorithms. Note that there is no virtual FISH signature for del(17p). We combined the subtypes [t(14;16)+t(14;20)] since they are rare but both predictors of poor outcome.
Results: All available data was used to compare prognostic HR and *p*-values for overall survival in nine MM cohorts, see Table 1. Note that HOVON-65/GMMG-HD4 was the training set for SKY92. iFISH data was only available for a limited set of studies. Therefore, additionally, vFISH results are shown (HR in white). For some of the datasets, the microarray platform was not HG-U133Plus2 - for which the MMprofiler vFISH software was developed - such that no vFISH call was available. There was also missing ISS data for 4 study cohorts. SKY92 could be determined in all datasets and was always prognostic (Table 1, white across the column). ISS and the combination of ISS+SKY92 could be determined in 5 datasets and were significant in all 5 of the studies. The FISH markers did not show robust prognostic values across the evaluated datasets. Only gain(1q) showed prognostic value in 4 out of 6 datasets. Hazard ratios are given in Table 1 and cell-shading is white where *p*-values were significant (<0.05).

Table 1. Prognostic value (hazard ratios for OS) of ISS and genetic biomarkers in nine clinical datasets including NDMM and RRMM. White=significant (p<0.05); grey=n.s.; dark grey=NA / not available. 1) HOVON-65/GMMG-HD4 |n=329|, 2) HOVON-87/NMSG-18 |n=143|, 3) MRC-IX |n=246|, 4) MMGI |n=91|, 5) TT3 |n=139|, 6) TT6 |n=55|, 7) Czech E-MTAB-1038 |n=66|, 8) TT2 |n=351|, 9) APEX |n=264|. FISH column HR with underscores are based on vFISH, others on iFISH. Inf=infinitely large.

	SKY92	SKY92 + ISS	ISS	iV FISH t(4;14)	iV FISH t(11;14)	iV FISH t(14;16)/t(14;20)	iV FISH del(13q)	iV FISH gain(1q)	iV FISH gain(9q)	i FISH del(17p)
HOVON-65/GMMG-HD4	4,7	12,2	4,6	1,5	0,8	2,8	1,7	1,3	0,7	3,4
HOVON-87/NMSG-18	2,9	3,8	2,2	1,3	0,8	2,5	1,6	2,0	0,6	2,5
MRC-IX	2,2	5,7	2,9	1,4	0,7	1,1	1,3	1,6	1,0	1,7
MMGI	6,2	10,1	3,4	0,0	2,5	13,4	1,2	3,9	0,9	NA
TT3	5,2	NA	NA	1,6	0,3	1,2	1,5	1,6	0,7	NA
TT6	10,3	NA	NA	4,3	0,2	62,7	4,2	9,6	0,8	NA
Czech E-MTAB-1038	2,6	inf	inf	0,3	NA	NA	NA	1,4	NA	1,7
TT2	3,4	NA	NA	NA	NA	NA	NA	NA	NA	NA
APEX	3,0	NA	NA	NA	NA	NA	NA	NA	NA	NA

Summary/Conclusions: SKY92, and its combination with ISS, have demonstrated to be robust prognostic markers in MM while the evaluated FISH markers do not show robustness for prognostic purposes.

E1263

DARATUMUMAB MONOTHERAPY COMPARED WITH REAL-WORLD HISTORICAL CONTROL DATA IN HEAVILY PRETREATED PATIENTS WITH HIGHLY REFRACTORY MULTIPLE MYELOMA: AN ADJUSTED TREATMENT COMPARISON

J Diels[1,*], A Lam[2], T Ito[3], M Mehra[2], I Khan[4]
[1]Janssen Health Economics & Market Access EMEA Statistics & Modeling, Beerse, Belgium, [2]Janssen Global Services, LLC, Raritan, NJ, United States, [3]Janssen Health Economics & Market Access EMEA, High Wycombe, United Kingdom, [4]Janssen Research & Development, LLC, Raritan, NJ, United States

Background: Daratumumab (DARA) received FDA approval in November 2015 based on data from single-arm phase 2 studies, following fast track/breakthrough therapy designation based on preliminary clinical evidence showing substantial improvements over available therapy for the treatment of heavily pretreated/refractory patients with multiple myeloma (MM). Recent analyses of pooled DARA studies and real-world US data revealed median overall survival (OS) of 19.9 (95% confidence interval [CI], 15.1-not evaluable) months and 7.9 (95% CI, 6.9-8.9) months in heavily pretreated and refractory patients with MM, respectively (Usmani S, et al. *Blood*. 2015;126(23): Abstract 4498 and Usmani S, et al. *Blood*. 2015;126(23): Abstract 29). In the absence of randomized head-to-head trials, evidence on the relative treatment efficacy of DARA *versus* physician's choice (PC) based on an adjusted comparison of data from a single arm trial *versus* a historical control group of comparable patients can inform the decisions of both clinicians and payers.
Aims: To estimate the comparative efficacy of DARA, as measured by overall survival, *versus* real-world historical control (PC) based on a comparison of data from DARA monotherapy clinical studies *versus* real-world US data, adjusted for confounding factors between patient cohorts.
Methods: Patient-level data were pooled from DARA monotherapy clinical studies (patients treated with DARA 16 mg/kg in the SIRIUS and GEN501 studies) and from two independent US databases (IMS-LifeLink and OPTUM), which reflect treatments utilized in a real-world cohort of patients with MM who received at least 3 prior therapy lines or were double refractory to a proteasome inhibitor and immunomodulatory drug. Using a multivariate proportional hazards regression model, the relative treatment effect of DARA compared with PC was estimated, adjusting for imbalances in patient characteristics between patient cohorts; co-variates included gender, age, albumin, hemoglobin, number of prior therapies, prior pomalidomide/carfilzomib-exposure, and refractory status.
Results: Baseline characteristics that differed between patients treated with DARA (N=148) and the real-world US historical control (N=658) included median age (64 *vs* 69 y), median lines of prior therapy (5 *vs* 4), prior treatment with pomalidomide (55% *vs* 15%) and carfilzomib (41% *vs* 28%), and triple/quadruple refractory status (64% *vs* 14%). The adjusted OS-hazard ratio (HR) for DARA *versus* PC was 0.32 (95% CI, 0.22-0.46) compared with 0.44 (95% CI, 0.33-0.58) for unadjusted HR. The impact of adjustment was mainly driven by differences in refractory status and prior exposure to pomalidomide/carfilzomib.
Summary/Conclusions: This adjusted treatment comparison suggests that DARA demonstrates improved OS compared with real-world historical control data in heavily pretreated and refractory MM patients. Such comparisons allow evaluation of novel agents in the absence of head-to-head comparison studies.

E1264

IMPACT OF FAMILY HISTORY ON RISK OF PROGRESSION OF MGUS TO MULTIPLE MYELOMA: A POPULATION-BASED STUDY

K Aradóttir[1,*], SH Lund[1], O Landgren[2], M Björkholm[3], I Turesson[4], SY Kristinsson[1,3]
[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [2]Myeloma Service, Memorial Sloan Kettering Cancer Center, New York, United States, [3]Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, [4]Department of Hematology and Coagulation Disorders, Skåne University Hospital, Malmö, Sweden

Background: Multiple myeloma (MM) is characterized by a neoplastic proliferation of plasma cells in the bone marrow and overproduction of monoclonal immunoglobulins in serum or urine. MM is always preceded by a premalignant condition called monoclonal gammopathy of undetermined significance (MGUS). Individuals with MGUS have a 1-1.5% annual risk of developing MM or a related disease. Furthermore, familial aggregation of MM and MGUS has been described, and first-degree relatives of MGUS and MM patients have a 2-3 fold increased risk of a lymphoproliferative disorder (LP). We have previously shown that survival among MM patients with a family history of a LP have a significantly superior survival compared to sporadic MM. However, the effect of family history of LP on risk of progression among MGUS is unknown.
Aims: The aim of our study was to compare the risk of progression of MGUS to MM or other LPs in MGUS individuals with a family history of LPs compared to sporadic MGUS.
Methods: Individuals with MGUS and their first-degree relatives were identified using nationwide Swedish Registries. Information on malignancies in relatives of MGUS patients was obtained by record-linkages to the Swedish Cancer Registry. A positive family history of LP was defined as MGUS patients having at least one first-degree relative diagnosed with MM, chronic lymphocytic leukemia, non-Hodgkin's lymphoma, Waldenström's macroglobulinemia, or Hodgkin's lymphoma. Cox proportional hazard model was used to obtain hazard ratios (HR) and 95% confidence intervals (95% CIs). In statistical analysis all data were adjusted for age, sex, and year at diagnosis.
Results: A total of 24,126 individuals diagnosed with MGUS in 1958-2013 were included in the study of whom 12,504 were male. Median age at diagnosis was 69.7 and 64.6 years in the sporadic and familial groups, respectively. In a total of 1666 MGUS individuals, the disorder progressed to MM. When compared to patients with sporadic MGUS, patients with MGUS and family history of any LP had similar risk of progression to MM (HR 1.17, 95% CI 0.90-1.53, p=0.23). The same was true when compared only to individuals with family history of

MM (HR 0.79, 95% CI 0.52-1.20, p=0.26). Subgroup analyses, stratified by gender and different age groups gave similar results (data not shown).
Summary/Conclusions: In this large population-based study we have shown that family history of LPs is not a risk factor for progression among MGUS individuals. Our findings are of importance for counseling MGUS individuals with family history and provide information regarding the biology of hereditary LPs.

E1265

THE SWEDISH MULTIPLE MYELOMA REGISTER: MEDIAN 5-YEAR SURVIVAL OF 7.3 YEARS IN PATIENTS 65 YEARS AND YOUNGER, POPULATION-BASED DATA ON 3,876 MULTIPLE MYELOMA PATIENTS DIAGNOSED 2008-2013

CH Blimark[1,*], A genell[2], G Juliusson[3], H Nahi[4], K Forsberg[5], I Turesson[6], L Ahlberg[7], O Linder[8], K Carlsson[9], B Björkstrand[10], SY Kristinsson[10]

Background: The Swedish Multiple Myeloma Register (SMMR) is a prospective observational register designed to document real-world management and outcomes in newly diagnosed multiple myeloma (MM), and was designed to improve the quality of the management of MM patients in Sweden
Aims: With high representation and good data quality we can present survival data on a whole MM population.
Methods: SMMR, initiated in 2008, comprises data on all patients diagnosed with MM, plasmocytoma, and plasma cell leukemia treated in Sweden. Report sheet are sent to all clinicians diagnosing MM. Another request is sent to the clinician one year after diagnosis, requesting information on initial treatment and complications. Through linkage with the Register of Total Population, we collected information on vital status until August 6, 2015. This report contains data on patients reported to SMMR between 2008 and 2013 and follow-up data from the first year on patients with symptomatic MM 2008-2012, with a follow-up till August 6, 2015, with focus on survival at 1, 3 and 5 years. Analyses of incidence, characteristics at baseline, proportion of patients given intensive treatment, obtaining very good partial remission rate (VGPR) and overall survival (OS) were estimated. Survival data was analysed with respect to age and ISS stage at diagnosis.

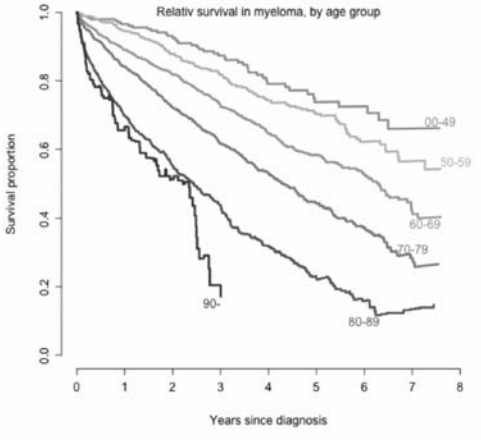

Figure 1.

Results: The SMMR has a current coverage of 98% compared to the Swedish Cancer Register on patients 2008-2013, to which reporting is obliged by law. Clinical data at baseline was available for 3876 patients and one year follow-up data was available on 2284 symptomatic MM patients (92% of all symptomatic MM cases initially reported to the register), from 70 different centers in Sweden. The median time of follow-up was 4.6 years. The age adjusted incidence was 6.2 MM cases per 100 000 inhabitants and year. The median age was 71 years, 70 years for men, and 73 years for women. Two third of patients were 65 years or older. Of the reported patients, 29% were in ISS stage I, 42% in stage II, and 29% in stage III. Overall, 80% of patients 65 years or younger received ASCT and 4% of patients above 65 years. In patients 66-70 years, ASCT was performed in 19%. In the year 2012, 67% of patients received one of the new drugs (thalidomide, bortezomib, or lenalidomide) as induction, (87% of patients<66 and 60% >65), an improvement compared to earlier years. The response grade >VGPR increased from 36% to 46% in the study period. The 1-, 3- and 5-year relative survival was 92%, 79%, and 66% for patients 65 years and younger and 79%, 56%, and 39% for the patients >65 years, respectively. The median relative survival was 7.3 and 3.7 years for patients<66 years and >65 years, respectively. Early death (<1year after diagnosis) was observed in 19% of patients. The relative median survival according to ISS stage was 3.2 years and 6.0 years for stages III and II, while not reached for stage I. Patients with no reported stage had the same survival as stage III patients.
Summary/Conclusions: The SMMR is an instrument for increased quality in the management of MM in Sweden. This report shows encouraging survival data on the MM population of Sweden. There was a significant difference in survival for younger and older patients that cannot be explained by age alone. The 19% early death rate (<1 year survival) can be compared to 48% in the period 1964 - 1968 (Swedish Cancer register data) and illustrates the enormous development in the care of MM patients in Sweden during the last 50 years.

E1266

CARFILZOMIB AND DEXAMETHASONE *VERSUS* BORTEZOMIB AND DEXAMETHASONE: SUBGROUP ANALYSIS OF THE PHASE 3 ENDEAVOR STUDY TO EVALUATE THE IMPACT OF PRIOR TREATMENT ON PATIENTS WITH RELAPSED MULTIPLE MYELOMA

Background: In a randomized phase 3 study (ENDEAVOR; NCT01568866), carfilzomib and dexamethasone (Cd) significantly improved median progression-free survival (PFS) *versus* bortezomib (BTZ) and dexamethasone (Bd) (18.7 *vs* 9.4 months; hazard ratio [HR] 0.53; 95% confidence interval [CI]: 0.44, 0.65; p<0.0001) in 929 patients with relapsed multiple myeloma (RMM).
Aims: This subgroup analysis evaluated treatment with Cd *versus* Bd in patients after first relapse *versus* ≥2 prior lines of therapy as well as the effect of previous exposure to BTZ or lenalidomide (LEN).
Methods: Adult patients with RMM who had received 1-3 prior lines of therapy were randomized 1:1 to Cd or Bd. Patients in the Cd arm received carfilzomib (30-min intravenous [IV] infusion) on days 1, 2, 8, 9, 15, and 16 (20mg/m^2 on days 1 and 2 of cycle 1; 56mg/m^2 thereafter) and dexamethasone 20mg on days 1, 2, 8, 9, 15, 16, 22, and 23 of a 28-day cycle. Patients in the Bd arm received BTZ 1.3mg/m^2 (IV or subcutaneous) on days 1, 4, 8, and 11 and dexamethasone 20mg on days 1, 2, 4, 5, 8, 9, 11, and 12 of a 21-day cycle. Treatment was continued until disease progression or unacceptable toxicity. Primary end point was PFS, secondary end points included overall survival, overall response rate (ORR; ≥partial response), duration of response (DOR), rate of grade ≥2 peripheral neuropathy (PN) and safety.
Results: Efficacy outcomes by prior lines of therapy are shown in the Table. Median PFS for Cd *vs* Bd was 15.6 months *vs* 8.1 months, respectively (HR: 0.56; 95% CI: 0.44, 0.73) for patients with prior BTZ exposure and NE *vs* 11.2 months, respectively (HR: 0.48; 95% CI: 0.36, 0.66) for patients without prior BTZ exposure. Median PFS for Cd *vs* Bd was 12.9 months *vs* 7.3 months, respectively (HR: 0.69; 95% CI: 0.52, 0.92) for patients with prior LEN exposure and 22.2 months *vs* 10.2 months, respectively (HR: 0.43; 95% CI: 0.32, 0.56) for patients without prior LEN exposure. ORRs for Cd *vs* Bd were 71.2% *vs* 60.3% (OR: 1.63; 95% CI: 1.12, 2.36) in patients with prior BTZ exposure, 83.6% *vs* 65.3% (OR: 2.72; 95% CI: 1.72, 4.31) in patients without prior BTZ exposure, 70.1% *vs* 59.3% (OR: 1.60; 95% CI: 1.03, 2.49) in patients with prior LEN exposure and 81.2% *vs* 64.6% (OR: 2.37; 95% CI: 1.62, 3.47) in patients without prior LEN exposure. Grade ≥3 adverse events (AEs) were reported in 69.8% (Cd) and 63.9% (Bd) of patients with 1 prior line and 76.6% (Cd) and 69.9%

(Bd) of patients with ≥2 prior lines. Grade ≥3 hypertension, dyspnea, and cardiac failure were more common with Cd *vs* Bd. The rate of grade ≥2 PN was lower with Cd *vs* Bd in patients with 1 prior line (6.5% *vs* 30.0%; OR: 0.16; 95% CI: 0.09, 0.29) and ≥2 prior lines (5.6% *vs* 34.1%; OR: 0.12; 95% CI: 0.06, 0.22).

Table 1. Efficacy outcomes and AEs of interest by prior lines of therapy.

Outcome	1 prior line		≥2 prior lines	
	Kd (n=232)	Vd (n=233)	Kd (n=232)	Vd (n=232)
Median PFS, months	22.2	10.1	14.9	8.4
HR for Kd vs Vd (95% CI)	0.447 (0.330–0.606)		0.604 (0.466–0.783)	
Best overall response, n (%)				
Stringent complete response	6 (2.6)	6 (2.6)	2 (0.9)	3 (1.3)
Complete response	21 (9.1)	12 (5.2)	29 (12.5)	8 (3.4)
Very good partial response	117 (50.4)	53 (22.8)	77 (33.2)	51 (21.9)
Partial response	46 (19.8)	80 (34.5)	58 (25.0)	77 (33.0)
Minimal response	11 (4.7)	21 (9.1)	13 (5.6)	32 (13.7)
Stable disease	16 (6.9)	24 (10.3)	24 (10.3)	29 (12.4)
Progressive disease	6 (2.6)	15 (6.5)	19 (8.2)	16 (6.9)
Not evaluable	9 (3.9)	21 (9.1)	10 (4.3)	17 (7.3)
ORR, % (95% CI)	81.9 (76.3–86.6)	65.5 (59.0–71.6)	72.0 (65.7–77.7)	59.7 (53.1–66.0)
Median DOR, months	21.3	14.1	NE	10.3
Grade ≥3 AEs of interest, n (%)[a]				
Hypertension[b]	24 (10.3)	8 (3.5)	17 (7.4)	4 (1.7)
Dyspnea[b]	12 (5.2)	5 (2.2)	13 (5.6)	5 (2.2)
Cardiac failure[b]	5 (2.2)	2 (0.9)	5 (2.2)	1 (0.4)
Acute renal failure[b]	2 (0.9)	3 (1.3)	7 (3.0)	2 (0.9)

[a]In the 1 prior line group, 232 (Kd) and 227 (Vd) patients were evaluable for safety; in the ≥2 prior lines group, 231 (Kd) and 229 (Vd) patients were evaluable for safety.

[b]Preferred term.

AE, adverse event; CI, confidence interval; DOR, duration of response; HR, hazard ratio; Kd, carfilzomib and dexamethasone; NE, not estimable; ORR, overall response rate; PFS, progression-free survival; Vd, bortezomib and dexamethasone.

Summary/Conclusions: A clinically meaningful improvement in PFS was seen for patients with RMM who were treated with Cd compared with Bd, regardless of the number of prior lines of treatment. The improvement was greatest for those who had received 1 prior line, where median PFS was over 1 year longer in patients treated with Cd *vs* Bd. PFS benefit with Cd *vs* Bd was also maintained regardless of prior exposure to BTZ and LEN. A higher ORR was also observed with Cd *vs* Bd across all subgroups. Cd had an acceptable benefit-risk profile in this study.

E1267

CARFILZOMIB AND DEXAMETHASONE *VS* BORTEZOMIB AND DEXAMETHASONE: SUBGROUP ANALYSIS OF PATIENTS WITH RELAPSED MULTIPLE MYELOMA BY BASELINE CYTOGENETIC RISK STATUS (PHASE 3 ENDEAVOR STUDY)

Background: In a previous study, single-agent carfilzomib demonstrated activity in patients with relapsed and refractory multiple myeloma with high-risk cytogenetic abnormalities. In the phase 3 study (NCT01568866; N=929 patients) carfilzomib plus dexamethasone (Cd) significantly improved progression-free survival (PFS) by 2-fold compared with bortezomib/dexamethasone (Bd) in patients with relapsed multiple myeloma (RMM) (18.7 months *versus* 9.4 months; hazard ratio [HR]: 0.53; 95% confidence interval [CI]: 0.44–0.65; P<.0001).
Aims: A pre-planned subgroup analysis of efficacy and safety outcomes in patients treated with Cd *vs* Bd according to patients' baseline cytogenetic risk status.
Methods: Adults with RMM who had received 1–3 prior lines of therapy received either carfilzomib (30-minute intravenous [IV] infusion on days 1, 2, 8, 9, 15, and 16 [20mg/m^2 on days 1 and 2 of cycle 1; 56 mg/m^2 thereafter]) and dexamethasone (20mg on days 1, 2, 8, 9, 15, 16, 22, and 23 of a 28-day cycle) (Cd) or bortezomib (1.3mg/m^2 IV bolus or subcutaneous injection on days 1, 4, 8, and 11) and dexamethasone (20mg on days 1, 2, 4, 5, 8, 9, 11, and 12 of a 21-day cycle) (Bd). Treatment continued until disease progression, withdrawal of consent or unacceptable toxicity. Primary end point was PFS, secondary end points included overall survival, overall response rate (ORR), duration of response (DOR), rate of grade ≥2 peripheral neuropathy (PN) and safety. The high-risk group was defined (using fluorescence in situ hybridization analysis of baseline bone marrow samples) as those patients with the genetic subtypes t(4;14) or t(14;16) in ≥10% of screened plasma cells or deletion 17p in ≥20% of screened plasma cells; the standard-risk group consisted of patients without these genetic subtypes.
Results: Of the 929 patients, 464 were randomized to receive Cd and 465 to receive Bd. Baseline cytogenetic risk status was balanced between the treatment arms (high-risk: Cd, 20.9%; Bd, 24.3%; standard-risk: Cd, 61.2%; Bd, 62.6%; unknown: Cd, 17.9%; Bd, 13.1%). Efficacy and safety end points by baseline cytogenetic risk status are presented in the Table. In the high-risk group, median PFS was 8.8 months (95% CI: 6.9, 11.3) for Cd *vs* 6.0 months (95% CI: 4.9, 8.1) for Bd (HR: 0.646; 95% CI: 0.453, 0.921). In the standard-risk group, median PFS was not estimable (NE) for Cd (95% CI: 18.7, NE) *vs* 10.2 months (95% CI: 9.3, 12.2) for Bd (HR: 0.439; 95% CI: 0.333, 0.578). ORRs (≥partial response) in the high-risk group were 72.2% (Cd) *vs* 58.4% (Bd) and 79.2% (Cd) *vs* 66.0% (Bd) in the standard-risk group. Median DOR in the high-risk group was 10.2 months for Cd *vs* 8.3 months for Bd. Median DOR in the standard-risk group was NE for Cd *vs* 11.7 months for Bd. Grade ≥3 adverse events (AEs) were reported at higher rates with Cd *vs* Bd in both the high- and standard-risk groups (70.1% *vs* 63.1% and 73.9% *vs* 68.3%). Grade ≥2 PN occurred less frequently with Cd *vs* Bd regardless of cytogenetic risk status (high-risk group: 3.1% *vs* 35.1%; odds ratio: 0.059; 95% CI: 0.018, 0.198 and standard-risk group: 6.4% *vs* 33.4%; odds ratio: 0.135; 95% CI: 0.079, 0.231).

Table 1. Efficacy outcomes and AEs of interest by baseline cytogenetic risk status.

Outcome	High-Risk		Standard-Risk	
	Kd (n=97)	Vd (n=113)	Kd (n=284)	Vd (n=291)
Median PFS, months	8.8	6.0	NE	10.2
HR for Kd vs Vd (95% CI)	0.646 (0.453–0.921)		0.439 (0.333–0.578)	
Best overall response, n (%)				
Stringent complete response	2 (2.1)	3 (2.7)	6 (2.1)	6 (2.1)
Complete response	13 (13.4)	2 (1.8)	31 (10.9)	17 (5.8)
Very good partial response	30 (30.9)	29 (25.7)	130 (45.8)	63 (21.6)
Partial response	25 (25.8)	32 (28.3)	57 (20.1)	105 (36.1)
Minimal response	8 (8.2)	11 (9.7)	12 (4.2)	36 (12.4)
Stable disease	9 (9.3)	17 (15.0)	21 (7.4)	28 (9.6)
Progressive disease	6 (6.2)	10 (8.8)	15 (5.3)	16 (5.5)
Not evaluable	4 (4.1)	9 (8.0)	12 (4.2)	20 (6.9)
ORR, % (95% CI)	72.2 (62.1–80.8)	58.4 (48.8–67.6)	79.2 (74.0–83.8)	66.0 (60.2–71.4)
Median DOR, months	10.2	8.3	NE	11.7
Select grade ≥3 AEs of interest, n (%)[a]				
Hypertension[b]	6 (6.2)	4 (3.6)	30 (10.6)	8 (2.8)
Dyspnea[b]	5 (5.2)	1 (0.9)	16 (5.7)	6 (2.1)
Cardiac failure[b]	3 (3.1)	2 (1.8)	7 (2.5)	1 (0.3)
Acute renal failure[b]	3 (3.1)	0	6 (2.1)	3 (1.0)
Peripheral neuropathy[c]	1 (1.0)	8 (7.2)	7 (2.5)	29 (10.1)
Treatment discontinuations due to an AE, n (%)[a]	18 (18.6)	22 (19.8)	56 (19.8)	62 (21.6)

[a]In the high-risk group, 97 (Kd) and 111 (Vd) patients were evaluable for safety; in the standard-risk group, 283 (Kd) and 287 (Vd) patients were evaluable for safety.

[b]Preferred term.

[c]Grouped term.

AE, adverse event; CI, confidence interval; DOR, duration of response; HR, hazard ratio; Kd, carfilzomib and dexamethasone; NE, not estimable; ORR, overall response rate; PFS, progression-free survival; Vd, bortezomib and dexamethasone.

Summary/Conclusions: Patients treated with Cd had a clinically meaningful improvement in PFS compared with Bd regardless of baseline cytogenetic risk status. Higher response rates, greater depth of response and longer DOR were also reported with Cd *vs* Bd. Cd had a favorable benefit–risk profile in patients with high-risk relapsed MM.

E1268

INCREASED LEVELS OF SOLUBLE SYNDECAN-1 AND LDH ARE MAJOR PROGNOSTIC FACTORS FOR SUBSEQUENT OVERALL SURVIVAL AND PROGRESSION FREE SURVIVAL AFTER A RELAPSE IN MULTIPLE MYELOMA

X Papanikolaou[1,*], D Maltezas[2], E Nikolaou[2], T Tzenou[2], P Pappaioannou[2], S Kotsanti[2], M Dimou[2], T Iliakis[2], V[2], P[2], MC Kyrtsonis[2]

[1]Athens Medical School Laikon University Hospital, Marousi, Athens, [2]Athens Medical School Laikon University Hospital, Athens, Greece

Background: Despite the recent advances in the therapy of Multiple Myeloma (MM), a relapse is almost a universal phenomenon in the clinical course of the disease. Nevertheless only few are known about the prognostic factors that characterize the relapses in MM, since robust and easily accessible prognostic factors as the levels of soluble Syndecan-1 (sS-1) or the ratio of involved to uninvolved free light chains in the serum (FLCR) have been verified only in newly diagnosed cases of MM.

Aims: A series of 245 MM patients with at least one relapse in their disease course, was studied to identify the prognostic factors that govern the prognosis of relapse in MM.
Methods: sS-1 levels in the serum were measured through the commercially available Diaclone™ ELISA kits. Survival statistical analysis was performed using the SPSS v22 statistical software. The running log rank method was used for the establishment of the optimal threshold of numerical variables. Clinical and laboratory values used were the ones closest to an established relapse and prior to the salvage treatment.
Results: From 01/01/2000 till 20/06/2014, 245 patients with symptomatic MM and at least one relapse were recorded for a total of 803 relapses.56 patients had 1 relapse, 51 patients 2 relapses, 48 patients 3 relapses and 90 patients more than 3. The clinical and laboratory characteristics of the relapses are presented in Table 1. The median Overall Survival (OS) and median Progression Free Survival (PFS) after a relapse were 1.7 and 0.9 years (yr) respectively. For the first relapse OS and PFS were 3.3 and 1.3 years, for the second relapse OS and PFS were 2.1 and 1 yr, for the third relapse OS and PFS were 1.2 and 0.8 yr, while for the fourth and above OS and PFS were 0.8 and 0.4 yr respectively. Statistically significant variables for the prediction of subsequent OS after a relapse in univariate analysis were: ISS stage III (HR:1.26, P<0.001), male sex (HR:1.39, P<0.001), sS-1>245 ng/mL (HR:2.56, P<0.001), LDH>480 IU/L (HR:1.99, P<0.001), number of prior relapses (HR:1.02, P=0.002) and response to treatment (HR:1.16, P<0.001). For the prognostication of subsequent PFS, the following factors were significant in univariate analysis: age≥65 years (HR:1.07, P=0.02), sS-1>245 ng/mL (HR:2.29, P=0.001), LDH>480 IU/L (HR:1.53, P=0.003), number of prior relapses (HR:1.14, P<0.001) and response to treatment (HR:1.12, P<0.001). Multivariate analysis revealed sS-1>245 ng/mL and LDH>480 IU/L as the only statistically significant factors for both OS and PFS. sS-1>245 ng/mL and LDH>480 IU/L retained their statistical significance both for univariate and multivariate analysis even when the subgroup of relapses treated with novel agents was independently studied.

Table 1. Characteristics of MM relapses.

Variable	n/N (%)
Age ≥ 65 yr	340/803 (42%)
Male Sex	452/803 (57%)
Albumin < 3.5g/dL	72/318 (23%)
B2M ≥ 3.5mg/L	461/732 (63%)
FLCR>100	345/524 (66%)
Monoclonal Immunoglobulin > 6000 mg/dl	80/614 (13%)
Creatinine ≥ 2.0 mg/dL	51/433 (11%)
Abnormal LDH	107/437 (24%)
sS-1> 245 ng/ml	22/74 (30%)
ISS stage I	184/732 (25%)
ISS stage II	216/732 (30%)
ISS stage III	332/732 (45%)
Salvage treatment novel agents	425/802 (53%)
Salvage treatment autologous transplant	55/802 (7%)

Summary/Conclusions: In conclusion both OS and PFS are gradually declining after each relapse. While both the number of prior relapses and the response to salvage treatment are important prognostic factors, subsequent OSand PFS are mainly dictated by the levels of sS-1 and LDH that characterize the MM relapse.

E1269

11C- METHIONINE PET SCAN FOR THE DETECTION OF MULTIPLE MYELOMA LESIONS

R Figueroa[1,*], M Marcos[1], B García-García[2], N Martínez[1], S Villar[1], S Franco[1], P Rodríguez[1], F Prósper[1], MJ García-Velloso[2], JÁ Richter[2], J San Miguel[1]
[1]Hematology, [2]Nuclear Medicine, Clínica universidad de Navarra, Pamplona (Navarra), Spain

Background: Multiple Myeloma (MM) is a plasma cell neoplasia that represents the 10-15% of hematological malignancies. The myeloma diagnostic criteria have recently changed based on the availability of more sensitive tools for early detection of the disease. This particularly apply to imaging techniques such as CT, MRI and PET. ^{11}C-methionine is a radiolabeled amino acid that has proven to have higher avidity for protein synthesis. Some recently published works show that ^{11}C-MET PET/TAC is useful for detecting bone and extramedullary lesions in MM and might be a promising tool in the diagnosis and follow up of this disease.
Aims: The purpose of this study is first to evaluate the performance of ^{11}C-MET PET/CT in MM as a diagnostic method compared to ^{18}FDG-PET/CT, and second to analyze the correlation between the metabolic activity and biological parameters of the disease.
Methods: We have reviewed retrospectively the results of 14 patients (50% women, ranged 31-79 years) with MM (12 cases), Smoldering Multiple Myeloma (one case) and solitary plasmacytoma (one case), who simultaneously underwent ^{11}C-MET and ^{18}FDG- PET/CT at our institution. We have analyzed the number and the uptake value (SUV_{max}) of the lesions observed with both techniques and we have correlated these findings with the biological parameters of the disease (M component, plasma cell percentage in bone marrow, free light chains, immunoglobulins, calcium, renal function). The concordance and correlation between both techniques were analyzed using Cohen's kappa coefficient and Pearson coefficient (SPPS version 19).
Results: A total of 54 lesions were studied (mean 3.8 lesions/patient). The number of lesions observed with ^{11}C-MET was higher than with ^{18}FDG in 57% of the patients. Only in two cases ^{18}FDG -PET/CT revealed lesions that were not seen with ^{11}C-MET, but interestingly in one of them a biopsy confirmed the non-malignant nature of the lesion. In most cases the SUV_{max} was higher in ^{11}C-MET for the same lesion compared to ^{18}FDG. Cohen's kappa coefficient between both tests was calculated with a result of 0.29 that means a fair agreement between ^{18}FDG and ^{11}C-MET. This coefficient also reflects a 35% of false negative lesions seen in ^{18}FDG-PET. The following biological parameters were correlated with a significant increase in the uptake value in ^{11}C-MET PET/CT: M-component (r=0.28; p=0.02), serum IgG (r=0.58; p=0.002), involved free light chain (r=0.28; p=0.04) and percentage of plasma cells in the bone marrow (r=0.32; p=0.03). These correlations were not significant with the ^{18}FDG PET/CT.

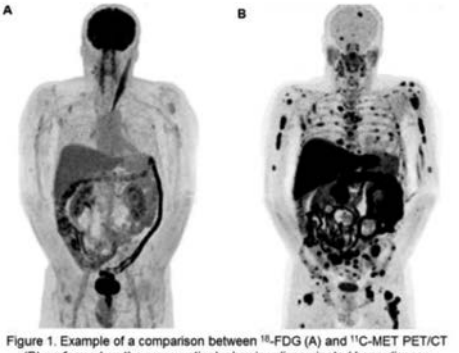

Figure 1. Example of a comparison between ^{18}-FDG (A) and ^{11}C-MET PET/CT (B) performed on the same patient, showing disseminated bone disease evident only with ^{11}C-MET.

Figure 1.

Summary/Conclusions: In our experience, PET with ^{11}C- MET could be a highly sensitive tool to evaluate MM lesions. Our data, despite the small number of patients, suggest that it may be superior to conventional ^{18}FDG-PET. Furthermore, there seems to be a significant correlation between some biological parameters, such as FLC, MC or immunoglobulins levels and the avidity of uptake. Larger series are needed to confirm the present findings.

E1270

ACY-241, A NOVEL, ORAL TABLET HDAC6 SELECTIVE INHIBITOR COMBINES SAFELY WITH POMALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA (ACE-MM-200 STUDY)

[1]Weill Cornell Medical College, New York City, [2]Dana Farber Cancer Institute, Boston, [3]Gabrail Cancer Center, Canton, [4]Cancer Therapy & Research Center, San Antonio, [5]Massachusetts General Hospital, Boston, [6]H. Lee Moffit Cancer Center, Tampa, [7]University of Miami Cancer Center, Miami, [8]Swedish Cancer Institute, Seattle, [9]Emory University, Atlanta, [10]University of Arizona Cancer Center, Tucson, [11]Colorado Blood Cancer Institute, Denver, United States, [12]University of Heidelberg, Heidelberg, Germany, [13]University of Athens, Athens, Greece, [14]Acetylon Pharmaceuticals Inc., Boston, United States

Background: Histone deacetylase (HDAC) enzymes are attractive therapeutic targets, but non-selective HDAC inhibitors have toxicities limiting exposure in patients (pts), particularly in combination with other agents. Ricolinostat (ACY-1215), is a first-in-class liquid orally available HDAC inhibitor 11-fold more selective for HDAC6, that synergizes *in vitro* and *in vivo* in models of multiple myeloma (MM) with bortezomib (Santo, *Blood*, 2012) and with carfilzomib (Mishima, *Br J Haematol*, 2015) and with lenalidomide (Len) and pomalidomide (Pom) (Quayle *Blood* 2013;122:1952). Ricolinostat, an oral liquid, has an excellent safety profile. (Raje, *Haematologica*, 2014, Suppl 1). We now identify ACY-241 as a structurally related, selective inhibitor of HDAC6 in tablet form.
Aims: Determine the safety, tolerability and preliminary efficacy of ACY-241 monotherapy and combination with pom and dexamethasone (dex).
Methods: Based on clinical experience with ricolinostat and non-clinical pharmacokinetics of ACY-241, we designed a first-in-human phase 1a/1b clinical

trial of a single-cycle of ACY-241 monotherapy followed by ACY-241 in combination with Pom and dexamethasone (Dex) in MM pts. A monotherapy/combination trial (mono/combo) design was chosen to grant pts access to combo therapy with an active regimen while exploring the safety, pharmacokinetics (PK) and pharmacodynamics (PD) of ACY-241 monotherapy. Pts with relapsed or relapsed-and-refractory MM (RRMM) previously treated with ≥2 cycles of Len and a proteasome inhibitor were eligible. Cohorts of 3 pts had ACY-241 PO QD as monotherapy (180, 360 and 480 mg) on days 1-21 of a 28 day cycle. If no mono DLT was noted, pts continued to cycle 2 of combo therapy with ACY-241/Pom/Dex. Safety review committee meetings for mono and combo therapy were separate. PK of ACY-241, Pom and Dex were analyzed. PD assessment were acetylated tubulin (HDAC6) and histones (HDAC 1, 2 and 3) in peripheral blood mononuclear cells.
Results: Since June 2015, 13 safety-evaluable pts have enrolled. Median age was 62 (46-82) years and median number of prior regimens 2 (1-7). All pts had RRMM. 62% were refractory to len and 46% to both Btz and Len. Fifty percent of pts had high risk cytogenetics. No dose relationship of the number or severity of AEs in either monotherapy or combination therapy were noted. Common toxicities in the safety population included grade 1/2 fatigue (38%), cough, back pain and dizziness (23% each), diarrhea, constipation and nausea (20% each). Grade 3/4 toxicities included neutropenia (4 pts, 31%), thrombocytopenia (23%) and anemia (8%). No MTD was identified up to the highest dose of ACY-241 at 480 mg QD monotherapy and 180 and 360 mg po QD in combo with Pom/Dex. 360 mg QD was recommended for further clinical exploration of ACY-241 based on safety and PD data. PK results show dose-linear increase in exposure with no accumulation, drug-drug interaction with Pom and Dex, or exposure plateau (previously observed with ricolinostat.) Selective increase in acetylated tubulin was seen at 180 mg with increasing levels of acetylated tubulin and histones at higher doses. Confirmed efficacy data (minimum follow-up 3 months) for combo treatment in this refractory pt population (8 efficacy evaluable pts) shows 4 PR, 2 MR and 2 PD. Three pts had only one efficacy cycle reported and 2 are early.
Summary/Conclusions: ACY-241 is well-tolerated in combination with Pom/Dex with at least dose proportional PK. Early response data to combo treatment parallel those observed with ricolinostat/Pom/Dex and compare favorably to historic controls of Pom/Dex. Cohort expansion at biologically relevant combination doses is ongoing. Updated data will be presented.

E1271

TREATMENT OF PRE-MYELOMA STATES: A CLINICAL DECISION ANALYSIS
D Liu[1,2,3,*], S Manier[2], J Laubach[2], EM Van Allen[2,3], I Ghobrial[2]
[1]Medical Oncology, Massachusetts General Hospital, [2]Medical Oncology, Dana Farber Cancer Institute, Boston, [3]Broad Institute, Cambridge, United States

Background: Recent studies suggest that treatment of pts with pre-myeloma disease may result in reduced progression to myeloma and improvement in overall survival. However, there is a lack of data to determine which patients would benefit and what type of treatments are optimal. A decision analysis to synthesize available data and quantify the benefits and risks of different treatments in different at-risk populations can help clarify both individual and policy decision-making.
Aims: To quantify the benefit and risks of different treatments in different at-risk populations. To develop a decision framework that informs both individual and policy decision-making for treatment of pre-myeloma states.
Methods: Monte Carlo simulations using a Markov Model were used to simulate the life course of patients diagnosed with pre-myeloma states in the modern era, either treated pre-emptively or monitored per standard of care. The primary outcome was number needed to treat (NNT) to save one life from myeloma, along with life expectancy (LE) and number needed to harm (NNH) given treatment risks. Pre-myeloma risk states modeled included standard risk MGUS (21% 20-yr progression), high risk MGUS (58% 20-yr progression), and smoldering myeloma (78% 20-yr risk of progression). Three interventions were modeled: (1) "high-intensity" treatment (e.g. lenalidomide+dexamethasone) with a conservatively modeled 50% reduction in risk of progression but also an increased risk of developing a secondary hematologic malignancy; (2) "low-intensity" treatment with a 10% reduction in risk of progression; and (3) observation until progression. Rates of progression, increased risk of hematologic malignancy, and death rates from myeloma and secondary malignancies were estimated by literature review. The life course of 500,000 patients for every combination of pre-myeloma state, treatment, and ages ranging from 35 to 75 was simulated. The model was validated against existing cohort data. Probabilistic sensitivity analyses were conducted to generate 95% "confidence intervals" [95% CI] given uncertainty in model parameters.
Results: NNT and NNH varied substantially by age, pre-myeloma state, and type of treatment (Figure). For 65 year old patients with high risk MGUS, the high and low-intensity treatments yielded NNTs of 8.3 [6.8-9.8] and 47.6 [33.6-90.9] respectively, an increase in LE of +0.9 [0.3-1.5] and +0.2 [+0.1-0.4] yrs respectively, and an NNH of 29.4 [95% CI 18.2-47.1] for the high-intensity treatment. For 75 yr old patients with MGUS, the high-intensity regimen yielded a lower NNH (27.8 [17.6-58.7]) than NNT (38.5 [27.2-58.1]), suggesting that more patients would be harmed by secondary malignancies than be benefited with treatment, with a non-statistically significant decrease in LE of -0.1 [-0.3-0.1]. In the same cohort, the low-intensity treatment had an NNT of 200 [105.6-887.5] and no benefit in LE (mean=0 [0-0.1]). In general, younger patients with higher-risk disease benefitted more from treatment. In 35 yr old patients with smoldering myeloma, the high and low intensity treatments had NNT of 5.3 [4.8-6.5] and 41.7 [30.3-121.9] respectively, with estimated LE increase of +6.5 [5.5-7.7] and +1.0 [0.4-1.3] yrs, respectively, and a NNH for the high-intensity regimen of 71.4 [37.7-154.2].

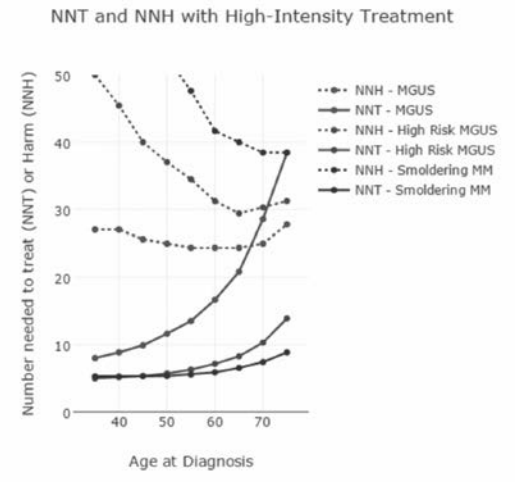

Figure 1.

Summary/Conclusions: The benefit/risk ratio of treatment for pre-myeloma patients varies considerably depending on age, risk of myeloma progression, and intensity/risk of treatment. For younger higher-risk pre-myeloma patients, the benefit/risk ratio of high-intensity pre-myeloma intervention is increased, whereas for older patients with lower-risk disease a lower-intensity or no treatment is preferred. Though cost and quality of life under these treatments also need to be considered, our results suggest there are substantial subgroups of patients with pre-myeloma disease who would benefit from treatment. As we develop improved therapies and risk-stratification, using such a quantitative framework will help inform decision-making.

E1272

PHASE I/IIA CLINICAL STUDY OF AUTOLOGOUS DENDRITIC CELL THERAPY IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA
SH Jung[1], HJ Lee[2], MC Vo[2], YK Lee[3], SS Lee[1], DH Yang[1], HJ Kim[1], JJ Lee[1,3,*]
[1]Department of Hematology-Oncology, [2]Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, [3]Research Institute, Vaxcell-Bio Terapeutics, Hwasun-Eup, Korea, Republic Of

Background: Cellular immunotherapy using dendritic cells is emerging as a useful immunotherapeutic modality to treat multiple myeloma (MM). We have developed potent immunotherapeutic agent (VAX-DC/MM) generated by dendritic cells loaded with the ultraviolet B-irradiated autologous myeloma cells.
Aims: In this study, we evaluated the safety and efficacy of VAX-DC/MM in patients with relapsed or refractory MM.
Methods: This trial enrolled relapsed or refractory MM patients who had received thalidomide- and bortezomib-containing regimen. Patients received the intradermal VAX-DC/MM injection every week for four weeks. Before the first injection of VAX-DC/MM, low-dose cyclophosphamide (375 mg/m^2, i. v) was administered to stimulate immune response at D-3. In a phase I trial, each three patients were treated with 5 x 10^6, and 10 x 10^6 cell, respectively. After higher dose was established as the tolerable dose, an additional 6 patients were enrolled at 10 x 10^6 cell doses.
Results: Median time to VAX-DC/MM therapy from diagnosis was 56.6 months (28.5-130.5). Patients had received a median of five prior treatments, and 75% had received autologous stem cell transplantation. VAX-DC/MM therapy was well tolerated, and most frequent adverse event was grade 1-2 myalgia (33.3%). In 8 of 9 patients who received 10 □ 10^6 cell, immunologic response (88.9%) was observed by interferon-gamma ELISPOT assay or mixed lymphocyte reaction assay for T-cell proliferation. Clinical benefit rate was 66.7% including 1 minor response (11.1%) and 5 stable disease (55.6%), and 3 patients (33.3%) showed a progression disease. The median progression free survival was 3.1 months (95% CI, 2.8-3.5 months), and all patients are alive.
Summary/Conclusions: In conclusion, VAX-DC/MM therapy was well-tolerated, and has activity in heavily pretreated MM. Further studies are needed to increase the efficacy of VAX-DC/MM in patients with MM.

E1273

ECONOMIC EVALUATION OF CARFILZOMIB+LENALIDOMIDE+DEXAMETHASONE (KRD) *VS* LENALIDOMIDE+DEXAMETHASONE (RD) IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA (R/RMM)

R Fonseca[1], S Panjabi[2,*], M Campioni[3], A Giannopoulou[3], A Benedict[4], I Houisse[4], S Aggarwal[5], A Jakubowiak[6]
[1]Department of Medicine, Mayo Clinic in Arizona, Arizona, [2]Global Health Economics, Amgen Inc, South San Francisco, United States, [3]Global Health Economics, Amgen, Zug, Switzerland, [4]Health Economics, Evidera, Budapest, Hungary, [5]Clinical Development, Amgen, Thousand Oaks, [6]Myeloma Program, University of Chicago, Chicago, United States

Background: In ASPIRE, KRd achieved superior progression free survival (PFS) (HR=0.69; p=0.0001) and improved quality of life (QoL) (p<0.001) over Rd in patients (pts) with R/RMM.
Aims: We assessed the cost-effectiveness (CE) of KRd *vs* Rd from a US payer perspective with data from ASPIRE and long-term overall survival (OS) data from the Surveillance, Epidemiology, and End Results Program (SEER).
Methods: A partitioned-survival model with progression-free (PF), post-progression (PP) and death states was built with a 30 year horizon. Treatment (Tx) effect for PFS and OS was estimated with parametric regression models and applied over the time horizon. Since 60% of pre-specified OS events were observed, post-trial OS transition probabilities were estimated by matching SEER data to ASPIRE pts. Grade ≥3 adverse events (AEs) with >2% incidence in any ASPIRE arm were included. Utilities were derived from literature and adjusted for the relative improvement in QoL increase observed when pts were PF in ASPIRE. Costs related to drug (WAC prices) as well as wastage (30% for carfilzomib), administration, monitoring, AE management, and subsequent Tx were considered. Tx duration was derived fitting ASPIRE data and carfilzomib was dosed up to 18 cycles. The base case assessed the CE of adding carfilzomib to Rd, and considered only additional costs of carfilzomib, *i.e.* neglecting Rd drug costs in both arms. A scenario including Rd costs in both arms was conducted. A 3% discount rate was applied to costs and outcomes.
Results: KRd was more effective compared to Rd, providing 1.134 PF life year, 1.927 life year, and 1.616 quality-adjusted life year (QALY) gains over the modelled horizon. KRd incurred $123,524 in total additional costs. Incremental CE ratio (ICER) was $76,416/QALY. With the inclusion of Rd costs, KRd incurred $179,863 additional costs with an ICER of $111,270/QALY.
Summary/Conclusions: The model predicts that KRd delivers nearly 2.86 additional undiscounted life year's over the standard of care (Rd), and is cost-effective *vs* Rd at a willingness-to-pay threshold of $120,000/QALY. Therefore, carfilzomib when added to Rd delivers considerable incremental value to patients and payers.

Background: The selective proteasome inhibitor carfilzomib is approved in the United States (US) as a single agent for the treatment of relapsed and refractory multiple myeloma (MM) and in combination with dexamethasone for relapsed MM. It is also approved in the US and Europe in combination with lenalidomide and dexamethasone for the treatment of patients with relapsed MM (RMM). In the phase 3 study (ENDEAVOR; NCT01568866) carfilzomib and dexamethasone (Cd) doubled progression-free survival (PFS) compared with bortezomib and dexamethasone (Bd) in patients with RMM (median 18.7 *vs* 9.4 months; hazard ratio [HR], 0.53; 95% confidence interval [CI], 0.44, 0.65; 1-sided p<0.0001).
Aims: A pre-planned subgroup analysis of the ENDEAVOR study according to patients' age (<65, 65–74, and ≥75 years of age).
Methods: Adults with RMM (1–3 prior regimens) were randomized to either the Cd arm (carfilzomib 30-min intravenous [IV] infusion on days [D] 1, 2, 8, 9, 15, and 16 [20mg/m^2 on D1, 2 in cycle 1; 56mg/m^2 thereafter]) and dexamethasone (20mg on D1, 2, 8, 9, 15, 16, 22 and 23 of 28-day cycles) or the Bd arm (bortezomib 1.3mg/m^2 IV or subcutaneous on D1, 4, 8, and 11) and dexamethasone (20mg on D1, 2, 4, 5, 8, 9, 11, and 12 of 21-day cycles). Treatment continued until disease progression, withdrawal of consent or unacceptable toxicity. Primary end point was PFS and secondary end points included overall survival, overall response rate (ORR), duration of response (DOR), safety, and rate of peripheral neuropathy (PN).
Results: Of the 929 patients enrolled, in the<65 years subgroup: 223 patients received Cd and 210 received Bd; in the 65–74 years subgroup: Cd, n=164; Bd, n=189; and the ≥75 years subgroup: Cd, n=77; Bd, n=66. Patient and disease characteristics were balanced across treatment arms within each age subgroup. For all age subgroups, median PFS was improved with Cd *vs* Bd (<65 years: not estimable *vs* 9.5 months [HR, 0.58; 95% CI, 0.44, 0.77]; 65–74 years: 15.6 months *vs* 9.5 months [HR, 0.53; 95% CI, 0.38, 0.73]; ≥75 years: 18.7 months *vs* 8.9 months [HR, 0.38; 95% CI, 0.23, 0.65]) (Table). ORRs in each age group were also consistently higher in the Cd arm *versus* the Bd arm (<65 years: 74% *vs* 61% [odds ratio, 1.82; 95% CI, 1.21, 2.74]; 65–74 years: 77% *vs* 66% [odds ratio, 1.80; 95% CI, 1.12, 2.89]; ≥75 years: 84% *vs* 59% [odds ratio, 3.75; 95% CI, 1.71, 8.24]). Grade ≥3 hypertension, dyspnea, cardiac failure, renal failure were more common with Cd *vs* Bd. However, rates of grade ≥2 PN were lower in the Cd arm compared with the Bd arm (<65 years: 6% *vs* 27% [odds ratio, 0.17; 95% CI, 0.09, 0.32]; 65–74 years: 8% *vs* 34% [odds ratio, 0.17; 95% CI, 0.09, 0.32]; ≥75 years: 3% *vs* 43% [odds ratio, 0.04; 95% CI, 0.01, 0.16]). Deaths within 30 days post-study drug due to adverse events occurred at a similar frequency in the Cd and Bd arms (<65 years: 3% *vs* 3%; 65–74 years: 5% *vs* 3%; ≥75 years: 4% *vs* 5%).

Table 1. Efficacy outcomes and grade ≥3 adverse events of interest.

Outcome	<65 years		65–74 years		≥75 years	
	Kd (n=223)	Vd (n=210)	Kd (n=164)	Vd (n=189)	Kd (n=77)	Vd (n=66)
Median PFS, months	NE	9.5	15.8	9.5	18.7	8.9
HR for Kd vs Vd (95% CI)	0.58 (0.44–0.77)		0.53 (0.38–0.73)		0.38 (0.23–0.65)	
Best overall response, n (%)						
Complete response or better	35 (16)	16 (8)	19 (12)	11(6)	4 (5)	2 (3)
Very good partial response or better	118 (53)	64 (30)	88 (54)	54 (29)	46 (60)	15 (23)
ORR, % (95% CI)	74 (68–80)	61 (54–68)	77 (70–84)	66 (58–72)	84 (74–92)	59 (46–71)
Median DOR, months	NE	11.1	NE	10.3	21.3	10.2
Select grade ≥3 AEs of interest, n (%)[a]						
Hypertension[b]	20 (9)	6 (3)	12 (7)	4 (2)	9 (12)	2 (3)
Dyspnea[b]	8 (4)	3 (1)	11 (7)	6 (3)	6 (8)	1 (2)
Cardiac failure[b]	2 (1)	1 (1)	5 (3)	1 (1)	3 (4)	1 (2)
Renal failure[b]	3 (1)	0	3 (2)	2 (1)	1 (1)	0
Treatment discontinuations due to an AE, n (%)[a]	37 (17)	31 (15)	35 (21)	41 (22)	20 (26)	23 (35)

[a]In the <65 year subgroup, 223 (Kd) and 208 (Vd) patients were evaluable for safety; in the 65–74 year subgroup, 163 (Kd) and 183 (Vd) patients were evaluable for safety; in the ≥75 year subgroup, 77 (Kd) and 65 (Vd) patients were evaluable for safety.

[b]Preferred term

AE, adverse event; CI, confidence interval; DOR, duration of response; HR, hazard ratio; Kd, carfilzomib and dexamethasone; NE, not estimable; ORR, overall response rate; PFS, progression-free survival; Vd, bortezomib and dexamethasone.

Summary/Conclusions: Cd significantly improved PFS and ORR compared with Bd across all age subgroups. A trend toward a greater improvement was observed in the eldest-age subgroup (≥75 years) *versus* the two younger-age subgroups (<65 and 65-74 years). In the eldest-age subgroup treatment with Cd was associated with an increased incidence of select grade ≥3 adverse events of interest, including cardiac failure and hypertension, compared with treatment with Cd in the younger-age subgroups. Hypertension is a common and manageable complication in elderly patients and should be monitored. Cd has a favorable benefit-risk profile in patients with RMM, irrespective of age.

E1275

TREATMENT AND OUTCOME PATTERNS IN PATIENTS WITH RELAPSED WALDENSTRÖM'S MACROGLOBULINEMIA: DEVELOPMENT OF A LARGE OBSERVATIONAL PAN-EUROPEAN DATA PLATFORM

C Buske[1,*], S Sadullah[2], E Kastritis[3], A Tedeschi[4], R Garcia-Sanz[5], L Bolkun[6], X Leleu[7], W Willenbacher[8], R Hajek[9], MC Minnema[10], M Cheng[11], T Graef[11], MA Dimopoulos[3], OBOTEC for Waldenström's Macroglobulinemia (ECWM)[1]
[1]University of Ulm, Ulm, Germany, [2]James Paget University Hospital, Norfolk, United Kingdom, [3]National and Kapodistrian University of Athens, Athens, Greece, [4]Niguarda Ca' Granda Hospital, Milan, Italy, [5]Complejo Asistencial Universitario de Salamanca, Salamanca, Spain, [6]Medical University Hospital of Bialystok, Bialystok, Poland, [7]Hopital Claude Huriez, CHRU Lille, Lille, France, [8]Innsbruck Medical University, Innsbruck, Austria, [9]University Hospital of Ostrava, Ostrava, Czech Republic, [10]University Medical Center Utrecht,

Utrecht, Netherlands, [11]Pharmacyclics LLC, an AbbVie Company, Sunnyvale, United States

Background: There are few randomized trials and no well-established treatment standards for Waldenström's Macroglobulinemia (WM). Data on treatment choices and their outcome in patients (pts) outside clinical trials are lacking.
Aims: The goal of this observational chart review was to generate real-world data on diagnosis, treatment patterns, and outcomes for WM over a decade in a large effort involving several European countries.
Methods: Physicians completed retrospective electronic records for pts who fit the following criteria: confirmed WM, symptomatic disease at treatment initiation, frontline treatment initiated between Jan 2000-Dec 2010, treatment with at least one salvage regimen (excluding maintenance therapy), and availability of clinical/biologic evaluation at diagnosis or initial therapy. Study endpoints included initial/subsequent lines of treatment, progression-free survival (PFS), and overall survival (OS). The number of pt records per country was prespecified to balance distribution between countries.
Results: Electronic records were reviewed for 368 pts from France (n=85), United Kingdom (n=62), Germany (n=51), Spain (n=45), Italy (n=40), Greece (n=25), Netherlands (n=21), Poland (n=14), Czech Republic (n=13), and Austria (n=12). Data were summarized across 2nd/3rd-lines for 368/155 pts. Median age at initiation of frontline treatment was 63 yr (range, 29-89); 61% were male. Reasons for initiating treatment were cytopenias (77%; anemia [75%]), constitutional symptoms (56%), IgM-related symptoms (55%), and organomegaly (26%). Choice of therapy varied with line of treatment and age; monotherapy fell from 35% in frontline to 21%/22% in 2nd/3rd-lines (Table 1) and age ≥70 was associated with greater use of monotherapy (40%) *vs* combination therapy (29%) in the frontline. Combination therapy with rituximab increased from 36% in frontline to 63%/56% in 2nd/3rd-lines. Across all lines, rituximab and cyclophosphamide were the most common agents, excluding steroids, used as monotherapy or in any combination. Median PFS decreased with successive lines of treatment from 31 mo for frontline to 24/16 mo for 2nd/3rd-lines. Median PFS varied by country and choice of agents (Table 1), but was similar for pts<50 and ≥50 y. Improved median PFS was observed for pts who received rituximab in 2nd-line *vs* pts who did not (26 *vs* 19 mo, *P*=0.014). Treatment outcomes were similar in 3rd-line with regards to rituximab use (15 *vs* 16 mo, *P*=0.69). The use of rituximab in the frontline did not affect median PFS of subsequent lines of therapy (2nd-line: 24 *vs* 23 mo, *P*=0.87; 3rd-line: 13 *vs* 16 mo, *P*=0.12). Median OS for the overall population was not reached, but was significantly lower in pts ≥75 yr (70 mo; *P*<0.0001) or in pts with high-risk IPSSWM risk score (91 mo; *P*=0.0014). The current data does not indicate a difference in OS with frontline rituximab use. Other malignancies were reported in 14% after receipt of at least one line of treatment for WM.

Table 1. Use of monotherapy or combination regimens and PFS in 2nd- and 3rd-Line settings overall and by country.

	Cases, n		Monotherapy, %		Combination Therapy With Antibody†, %		Combination Therapy Without Antibody†, %		Median PFS, Months (95% CI)	
Country	2nd line	3rd line	2nd line	3rd line	2nd line	3rd line	2nd line	3rd line	2nd line	3rd line
Overall	368	155	21	22	63	56	14	20	24.0 (20-27)	16.0 (10-18)
France	85	43	26	16	66	70	8	14	30.0 (20-37)	16.0 (9-32)
United Kingdom	62	19	23	21	55	42	23	37	25.0 (11-36)	13.0 (9-33)
Germany	51	17	8	24	80	53	8	12	24.0 (16-35)	8.0 (3-16)
Spain	45	19	36	42	49	53	13	0	17.0 (12-28)	11.0 (9-24)
Italy	40	19	18	16	75	68	3	16	30.0 (18-50)	17.0 (4-21)
Eastern European*	27	11	11	9	41	0	48	91	20.0 (16-26)	20.5 (4-38)
Smaller European**	58	27	21	26	67	63	12	11	16.0 (13-25)	16.0 (7-26)

*Includes Czech Republic and Poland, **Includes Austria, Greece, and Netherlands
† Antibodies other than rituximab, <1%

Summary/Conclusions: For WM pts treated in Europe, the most common reasons for initiating therapy are anemia and constitutional symptoms. Rituximab was the most commonly used agent across all lines of treatment and use of rituximab was associated with improvement in median PFS in the 2nd-line. Outside clinical trials, monotherapy is widely used even at first relapse with notable differences between countries. This large observational dataset will be an important tool to promote understanding of treatment practices and survival of WM pts outside of a clinical trial setting.

E1276

EFFICACY AND SAFETY OF ORAL IXAZOMIB-LENALIDOMIDE-DEXAMETHASONE (IRD) *VS* PLACEBO-RD IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS: IMPACT OF PRIOR THERAPY IN THE PHASE 3 TOURMALINE-MM1 STUDY

MV Mateos[1,*], T Masszi[2], N Grzasko[3], M Hansson[4], I Sandhu[5], L Pour[6], L Viterbo[7], S Jackson[8], AM Stoppa[9], P Gimsing[10], M Hamadani[11], G Borsaru[12], D Berg[13], J Lin[13], H van de Velde[13], P Richardson[14], P Moreau[15]

[1]Servicio de Hematología, Hospital Universitario de Salamanca, Instituto Biosanitario de Salamanca (IBSAL), Salamanca, Spain, [2]3rd Dept of Medicine, St. István and St. László Hospital, Budapest, Hungary, [3]Medical University of Lublin, and St John's Cancer Center, Lublin, Poland, [4]Skåne University Hospital, Lund University, Lund, Sweden, [5]University of Alberta, Edmonton, Canada, [6]University Hospital Brno, Brno, Czech Republic, [7]Instituto Português de Oncologia do Porto Francisco Gentil, Entidade Pública Empresarial (IPOPFG, EPE), Porto, Portugal, [8]Middlemore Hospital, Auckland, New Zealand, [9]Institut Paoli-Calmettes, Marseille, France, [10]University Hospital Rigshospitalet, Copenhagen, Denmark, [11]Medical College of Wisconsin, Milwaukee, United States, [12]Spitalul Clinic Coltea, Bucarest, Romania, [13]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [14]Dana-Farber Cancer Institute, Boston, United States, [15]University Hospital Hôtel Dieu, Nantes, France

Background: The TOURMALINE-MM1 study (NCT01564537) demonstrated improved progression-free survival (PFS) with the all-oral combination of IRd *vs* placebo-Rd (median 20.6 *vs* 14.7 months; HR 0.74) in patients (pts) with relapsed/refractory multiple myeloma (RRMM)(Moreau et al, ASH 2015). Based on this study ixazomib was approved by the US FDA in combination with Rd for the treatment of pts with MM who have received at least one prior therapy.
Aims: To analyze the efficacy and safety of IRd *vs* placebo-Rd according to prior proteasome inhibitor (PI) and prior thalidomide (thal)/lenalidomide (R) exposure.
Methods: Pts with RRMM were randomized 1:1 to receive IRd or placebo-Rd (ixazomib 4 mg or matching placebo on days 1, 8, and 15, plus lenalidomide 25 mg on days 1–21 and dexamethasone 40 mg on days 1, 8, 15, and 22, in 28-day cycles) until disease progression or unacceptable toxicity. Pts were stratified by number of prior therapies (1 *vs* 2 or 3), PI-exposed *vs* PI-naïve status, and International Staging System (ISS) stage I or II *vs* III. Pts who had received prior therapy with PI- and thal/R-based regimens, and pts who were refractory to thal, were eligible for inclusion. However, pts who were refractory to PI- or R-based prior therapy were not included.
Results: Of 722 pts, 69% had prior PI therapy (<1% prior carfilzomib) and 55% had prior thal/R therapy, including 45% prior thal (12% thal-refractory) and 12% prior R. Prior therapies were balanced between arms. At the primary analysis (median follow-up ~15 months), consistent PFS benefit was seen with IRd regardless of prior PI or thal/R exposure (Table). Overall response rate (ORR) with IRd *vs* placebo-Rd appeared generally similar across subgroups (PI-naïve: 81% *vs* 74%; PI-exposed: 77% *vs* 70%; thal/R-naïve: 80% *vs* 77%; R-naïve: 78% *vs* 73%) but slightly lower in thal-refractory pts (70% *vs* 57%), while ORR in the placebo-Rd arm appeared somewhat lower in thal/R-exposed (77% *vs* 67%) and R-exposed pts (77% *vs* 59%). Complete response plus very good partial response (CR+VGPR) rates with IRd *vs* placebo-Rd appeared generally similar in PI-naïve (54% *vs* 37%), PI-exposed (46% *vs* 40%), thal/R-naïve (51% *vs* 44%), thal/R-exposed (45% *vs* 35%), R-naïve (48% *vs* 39%), and R-exposed (45% *vs* 36%) pts, but lower in thal-refractory (30% *vs* 27%) pts. At a 23-month analysis, IRd safety profile was generally consistent regardless of prior PI or thal/R exposure. Rates of grade ≥3 AEs with IRd *vs* placebo-Rd were 76% *vs* 66% in PI-naïve, 73% *vs* 70% in PI-exposed, 75% *vs* 71% in thal/R-naïve, and 73% *vs* 67% in thal/R-exposed pts. Rates of individual AEs (all-grade and grade ≥3) with IRd *vs* placebo-Rd were similar and consistent with those reported for the overall patient population regardless of prior PI or thal/R exposure, including common AEs such as GI and hematologic toxicities, rash, and neuropathy, with the exception of neutropenia in the PI-naïve population; overall rates were 29% *vs* 20%, including 21% *vs* 15% grade ≥3, whereas IRd and placebo-Rd rates were similar in the overall population and other subgroups. Rates of serious AEs with IRd *vs* placebo-Rd were 47% *vs* 40% in PI-naïve, 46% *vs* 53% in PI-exposed, 48% *vs* 51% in thal/R-naïve, and 45% *vs* 48% in thal/R-exposed pts.

Table 1.

Median PFS, months	IRd, N=360	Placebo-Rd, N=362	HR
PI naïve (n=110 vs 109)	NE	15.7	0.75
Bortezomib (Btz) naïve (n=112 vs 112)	NE	15.9	0.75
PI exposed (n=250 vs 253)	18.4	13.6	0.74
Btz exposed (n=248 vs 250)	18.5	13.6	0.75
Thal/R naive (n=167 vs 158)	20.6	13.6	0.70
R (n=316 vs 318) / Thal naive (n=203 vs 192)	20.6 / 20.6	13.6 / 13.6	0.77 / 0.69
Thal/R exposed (n=193 vs 204)	NE	17.5	0.74
R exposed (n=44 vs 44)	NE	17.5	0.58
Thal exposed (n=157 vs 170) / refractory (n=40 vs 49)	NE / 16.6	15.7 / 13.0	0.75 / 0.73

NE, not estimable

Summary/Conclusions: The benefit of IRd *vs* placebo-Rd appeared consistent across subgroups defined by prior PI and thal/R exposure; IRd safety profile was also broadly consistent across subgroups.

E1277

PRACTICE PATTERNS AND OUTCOMES IN U.S. PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) AND COMORBID RENAL DYSFUNCTION (RD) AND/OR CARDIOVASCULAR DISEASE (CVD)

C Yong[1,*], B Seal[1], E Farrelly[2], D Romanus[1], M Jhaveri[1], S Noga[3], A Raju[2], M Blazer[4], R Labotka[5], H Parameswaran[6]

[1]Global Outcomes Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Real-World Evidence, Xcenda, Palm Harbor, [3]US Medical Affairs, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [4]Global Health Economics and Outcomes Research, Xcenda, Palm Harbor, [5]Oncology Clinical Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [6]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI, United States

Background: Multiple myeloma (MM) is a disease of the elderly, many of whom often present with comorbidities including RD and CVD (Gupta 2015; Dimopoulus 2015). While the presence of RD and/or CVD may influence RRMM treatment choices, there is limited real-world data on prescribing patterns and outcomes in these patient populations (Castelli 2014; Larocca 2015).
Aims: To describe the prevalence of RD and CVD over time, and the variation in prescribing patterns and clinical outcomes (progression-free survival (PFS) and overall survival (OS)) by comorbidity profile in RRMM pts initiating second line therapy (2LT).
Methods: This was a retrospective cohort study using a large national EMR database in the U.S. Newly diagnosed adult MM patients initiating first line therapy (1LT) between 1/2008 and 12/2014 were followed until death/loss to follow up or the end of study period (6/30/2015). 2LT was identified by: 1) retreatment after a treatment gap of >3 months after 1LT discontinuation, or 2) a switch to another drug combination after starting 1LT. Comorbid RD was based on presence of a diagnosis (dx) code or a lab value (creatinine clearance<40ml/min or serum creatinine >2 mg/dL) in the 12 months prior to start of 1LT through the start of 2LT; and comorbid CVD was based on dx codes in the same timeframe. Time to new treatment (TTNT) or death was used as a surrogate for PFS. Kaplan-Meier analyses were performed for TTNT/OS from start of 2LT.

Table 1.

Presence of Comorbid Condition prior to 1LT	No RD or CVD N=329	RD only N=172	CVD only N=48	RD and CVD N=79
Type of Therapy in the First Line, %				
PI-based	35.9	55.2	18.8	49.4
Bortezomib ± non-IMID	35.6	55.2	18.8	49.4
Carfilzomib ± non-IMID	0.3	0.0	0.0	0.0
IMID-based	37.4	23.3	50.0	31.7
Lenalidomide ± non-PI	31.3	21.5	43.8	29.1
IMID (other than lenalidomide) ± non-PI	6.1	1.7	6.3	2.5
PI + IMID-based	19.8	17.4	14.6	11.4
Lenalidomide + bortezomib ± other	16.7	14.0	10.4	11.4
Bortezomib + IMID (other than lenalidomide) ± other	2.7	2.9	4.2	0.0
Carfilzomib + IMID ± other	0.3	0.6	0.0	0.0
Other, not categorized elsewhere	7.01	7.0	4.1	16.7
Presence of Comorbid Condition prior to 2LT	**No RD or CVD N=202**	**RD only N=197**	**CVD only N=55**	**RD and CVD N=174**
Type of Therapy in the Second Line, %				
PI-based	32.2	34.0	34.6	33.3
Bortezomib ± non-IMID	29.2	27.4	30.9	26.4
Carfilzomib ± non-IMID	3.0	6.6	3.6	6.9
IMID-based	48.0	43.2	32.7	44.3
Lenalidomide ± non-PI	39.6	37.1	20.0	36.2
IMID (other than lenalidomide) ± non-PI	8.4	6.1	12.7	8.1
PI + IMID-based	8.4	9.6	10.9	8.1
Lenalidomide + bortezomib ± other	4.5	6.1	5.5	5.2
Bortezomib + IMID (other than lenalidomide) ± other	0.5	0.5	0.0	1.2
Carfilzomib + IMID ± other	3.5	3.1	5.5	1.7
Other, not categorized elsewhere	11.4	13.2	21.8	14.4

Key: IMID – immunomodulator; PI – proteasome inhibitor; Other – includes: cyclophosphomide, melphalan, vincristine, (liposomal) doxorubicin, interferon, pomalidomide, thalidomide, panobinostat bendamustine, vorinostat, single agent steroid

Results: Among 628 RRMM pts (mean age 69 years), 27.4% had comorbid RD, 7.6% had comorbid CVD, and 12.6% had both RD and CVD prior to 1LT; this increased to 31.4%, 8.8%, and 27.7%, respectively, prior to 2LT. The distribution of treatments across 1LT and 2LT is shown in Table 1. In 1LT, pts with RD±CVD were most likely to receive proteasome inhibitor (PI)-based therapies; in contrast, pts with CVD only were most likely to receive immunomodulatory drug (IMID)-based therapies. In 2LT, the use of IMID-based therapies was most common, except among pts with CVD only where a similar proportion used IMID-based or PI-based therapies (approx. one-third). Additionally, intensive regimens (PI+IMID) were more common for all pts regardless of comorbidity in 1LT compared to 2LT. Median TTNT from 2LT initiation was 14.3 months (95% CI: 9.2, 19.1) for pts with CVD only, 13.7 months (95% CI: 11.4, 17.8) for pts with RD only, 12.3 months (95% CI: 8.4, 16.6) for pts with RD and CVD, and 20.1 months (95% CI: 16.6, 24.4) for pts without CVD or RD. OS at 1 yr and 2 yrs from 2LT initiation were 77.8% and 64.1% for those with CVD only, 77.4% and 58.5% for those with RD only, 72.7% and 51.6% for those with CVD and RD, and 88.2% and 78.4% for pts without CVD or RD (log-rank test, $P<0.05$).
Summary/Conclusions: Among pts receiving 2LT for RRMM, prevalence of RD and/or CVD increased from 48% to 68% during the MM clinical course. The type of therapy varied by presence of comorbidity for 1LT but to a lesser extent for 2LT. Pts with RD and/or CVD had a shorter TTNT and a lower 1- and 2-yr OS probability relative to those without these comorbidities.

BORTEZOMIB-BASED TREATMENT MAY OVERCOME THE ADVERSE EFFECT OF FOPNL GENOMIC VARIANT ON THE PROGNOSIS OF MULTIPLE MYELOMA

KP Kiss[1,*], G Varga[2], G Mikala[3], A Bors[1], K Balassa[1], A Tordai[4], P Remenyi[3], T Masszi[2], H Andrikovics[1]

[1]Laboratory of Molecular Diagnostic, Hungarian National Blood Transfusion Service, [2]3rd Department of Internal Medicine, Semmelweis University, [3]Department of Haematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, [4]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary

Background: In a recent genome-wide association study (GWAS), the *FOPNL* (fibroblast growth factor receptor 1 oncogen partner N terminal like gene) single nucleotide polymorphism rs72773978 was identified as a novel adverse prognostic factor in multiple myeloma (MM).
Aims: The aim of our study was to investigate the associations of *FOPNL* polymorphism with clinical characteristics (sex, age, ISS, cytogenetic abnormalities) as well as treatment outcome (progression free survival, [PFS] and overall survival, [OS]) in a cohort of Hungarian MM patients.
Methods: Data of 373 MM patients (188 male/185 female; mean age: 60.5±11.2 year) diagnosed from 2005 to 2013 were retrospectively analysed. As a first line treatment, older regimens (containing no proteasome inhibitor) were administered in 132 cases, while PI based therapy was applied in 241 cases. The minimal follow up was 24 month. LightCycler melting analysis was applied to identify rs72773978 polymorphism.
Results: In the whole cohort applying a dominant model, the distribution of rs72773978 polymorphism was as follows: AA:328/373 (87.9%) *vs* AT&TT: 45/373, (12.1%). We found no significant difference in sex, age, ISS stage or citogenetics stratified subgroups. In our cohort *FOPNL* polymorphism showed difference in the prognostic effect depending on the treatment applied. In line with the previous GWAS study, carriership of the minor allele was significantly associated with adverse PFS among patients treated with non-PI based therapy (p=0.042). PFS at 24 months was 43.5±4.5% for AA patients (n=124) compared to 12.5±11.7% for AT&TT patients (n=8). Suprisingly in the PI treatment group, PFS at 24 months was 51.7±3.5% for AA (n=204) compared to 62.2±8% for AT&TT (n=37) patients (p=0.082). As significant interaction between *FOPNL* and PI treatment was observed (p=0.003), we performed multivariate analyses (Cox regression considering considering sex, age and ISS as covariates) in both treatment groups separately. The difference did not remain significant in either groups (non PI group: p=0.22; HR: 1.78, 95% CI: 0.7-4.5, PI group: p=0.094; HR: 0.7, 95% CI: 0.47-1.06). Similar comparisons for OS revealed a similar effect of *FOPNL* variant in both treatment groups. In the non-PI treated group adverse prognosis was observed in minor allele carriers: OS at 72 months for AA patients was 49±4.6% compared to AT&TT with 18.8±15.8% (p=0.022). In the PI-based group, OS at 72 months for AA patients was 40.9±4.5% compared to AT&TT 67.3±8.5% (p=0.048). The test for interaction between FOPNL and treatment was significant (p<0.001). Separate multivariate analyses revealed the independent adverse effect of rs72773978 on survival in the non PI group (p=0.029; HR: 2.9, 95% CI: 1.1-7.6); but not in PI treatment group: p=0.155; HR: 0.63, 95% CI: 0.34-1.19).
Summary/Conclusions: In the present study, we confirmed the adverse prognostic effect of *FOPNL* rs72773978 polymorphism in case of non-PI based treatment regimens. On contrary this adverse effect was overcome by the application of newer, proteasome inhibitor containing treatment protocols.

E1279

HIGH RESPONSE RATES BUT INEFFECTIVE PRE-SELECTION STRATEGIES FOR TREATMENT WITH HDM AND AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA BETWEEN 65-70 YEARS IN THE NETHERLANDS

M Brink[1,*], AG Dinmohamed[1,2,3], O Visser[1], MC Minnema[4]

[1]Department of Research, Netherlands Comprehensive Cancer Organisation,

Utrecht, [2]Department of Hematology, Erasmus MC Cancer Institute, [3]Department of Public Health, Erasmus University Medical Center, Rotterdam, [4]Department of Hematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: The Dutch national clinical guideline recommends bortezomib-based induction chemotherapy (inductionCT) followed by high dose melfalan (HDM) and autologous stem cell transplantation (ASCT) for patients with symptomatic multiple myeloma (symMM) aged ≤65 years. In addition, ASCT should also be considered for patients with symMM aged 66-70 years.
Aims: To evaluate how these recommendations were applied in daily practice in the Netherlands for patients with symMM aged ≤70 years and, secondly, what percentage of patients aged 66-70 years was offered ASCT as their first line treatment.
Methods: From the nationwide population-based Netherlands Cancer Registry, we identified 476 patients aged ≤70 years diagnosed with symMM in 2014 (60% male). Of these patients, 318 (67%) were ≤65 years and 158 (33%) were 66-70 years. InductionCT was defined as bortezomib-based chemotherapy regimens (i.e. BD, PAD, VCD or VTD) with or without (+/-) subsequent HDM and ASCT. Overall response rate (ORR) was defined as achieving complete or partial response *i.e.* CR, VGPR and PR as best achieved response outcome. Data were analyzed for the total cohort, as well as stratified by age at diagnosis.
Results: Overall, of patients ≤65 years, 283 (89%) were treated with inductionCT, of which VCD was most frequently used (N=231/283;82%), followed by PAD (N=30/283;11%) and BD (N=22/283;8%). The remaining patients received other types of chemotherapeutic regimens (2%) or no chemotherapy at all (9%). Of patients who received inductionCT, 217 of 283 (77%) received the planned HDM+ASCT. Of patients aged 66-70 years, 61 (39%) received inductionCT consisting of either VCD (N=38/61;62%), BD (N=19/61;31%) or PAD (N=4/61;7%). The remaining patients were mostly treated with VMP (N=77/158;49%), while 8% (N=13/158) did not receive any treatment. In contrast to patients aged ≤65 years, only 29 of 61 (48%) patients underwent ASCT after inductionCT. The ORRs were 86% (242/283) and 72% (44/61) for patients ≤65 and 66-70 years who received inductionCT +/- ASCT, respectively. The ORR for patients aged 66-70 years who received VMP was 34% (26/77), which is markedly lower than previously reported in the VISTA trial (ORR, 71%). The ORR for patients who received inductionCT, but did not proceed to ASCT was lower as compared to patients who did proceed to ASCT (51% *vs* 96%) irrespective of age group. Moreover, the ORR of patients aged 66-70 years who received inductionCT (+/- ASCT) was higher than the ORR of patients in the same age group who received VMP (72% *vs* 34%).
Summary/Conclusions: Our results show that most patients aged ≤65 years start with inductionCT and 77% of these are able to proceed to HDM+ASCT. In addition, among patients aged 66-70 years, 39% start with inductionCT of whom only 48% received subsequent ASCT. Although based on modest patient numbers, the ORR of inductionCT +/- ASCT in patients between 66-70 years was lower as compared to the ORR in the younger patient group, while higher than the ORR in the VMP group. This population-based analysis demonstrates that inductionCT is frequently offered to older patients with similar efficacy as in younger patients. However, pre-selection strategies for intensive treatment are insufficient since only half of the older patients subsequently receive their planned ASCT.

E1280

SURVIVAL AND TREATMENT PATTERNS IN PATIENTS WITH SYMPTOMATIC MULTIPLE MYELOMA (MM) IN A REAL-WORLD SETTING

Background: Survival rates for patients (pts) with MM have improved with the advent of new therapies, however data on real-world survival outcomes are limited.
Aims: Retrospective analysis using the Registry of Monoclonal Gammopathies database of the Czech Myeloma Group.
Methods: Pts diagnosed with symptomatic MM (May 2007–June 2014), were followed from diagnosis until death, loss to follow-up or June 2015. The primary analysis was to estimate overall survival (OS) from diagnosis; secondary analyses included treatment-line-specific OS and progression-free survival (PFS), treatment patterns and response. Exploratory analyses included OS and PFS from treatment initiation by International Staging System (ISS) stage, International Myeloma Working Group (IMWG) risk and therapy type (lenalidomide plus dexamethasone [Ld] or bortezomib [bor]-based regimens).
Results: 2513 pts were included. Median age at diagnosis was 67.0 years. Similar proportions of pts had ISS stage I, II or III disease. Median OS (months, 95% confidence interval [CI]) from diagnosis was 50.3 (46.1–54.5) and decreased from 47.5 (43.1–52.0) at 1st line to 13.2 (11.3–15.2) at 3rd (Figure). Median PFS (months, 95% CI) decreased from 16.3 (15.4–17.2) at 1st line to 6.0 (5.4–6.6) at 3rd. Main treatments at 1st line (n=2446) were bor- (46%) or thalidomide-based (40%). At subsequent lines, pts frequently received bor - or lenalidomide-based regimens (2nd line [n=1118], 49% and 31%; 3rd line [n=547], 26% and 47%, respectively). Overall response rates decreased across lines: 58% at 1st line, decreasing to 44% and 28% at 2nd and 3rd lines. Differences in median OS and PFS by treatment line were observed according to ISS stage and IMWG risk (Table). An analysis of pts (excluding those in clinical trials) receiving Ld 2nd to 4th line, showed median OS decreased at each subsequent line (2nd line 26.2 [21.7-30.8] and 3rd line 12.6 [11.4-13.7]), comparable to median OS in all patients. Median PFS was 7.5 (6.3-8.8); values at 2nd and 3rd lines were 8.7 (7.3-10.1) and 6.6 (5.3-8.0). Similar trends were seen in pts (excluding those in clinical trials) receiving bor in 2nd to 4th lines. At 2nd and 3rd lines, median OS values were 27.3 (22.7-31.8) and 16.2 (12.1-20.3); median PFS values were 11.3 (9.9-12.6) and 5.7 (4.7-6.8).

Table 1.

Line	ISS Stage I	ISS Stage II	ISS Stage III	IMWG Risk Low	IMWG Risk standard	IMWG Risk High
Median OS, months (95% CI)						
First	82.1 (Not Estimable)	46.9 (40.3–53.5)	29.9 (26.9–32.9)	Not reached	50.6 (40.6-60.6)	31.8 (27.1-36.5)
Second	46.7 (31.4–62.0)	28.6 (24.7–32.5)	19.3 (16.5–22.1)	57.3 (19.3-95.3)	35.5 (26.9-44.1)	14.9 (5.6-24.2)
Third	19.6 (14.2–25.0)	13.7 (10.9–16.4)	10.0 (7.6–12.4)	24.8 (14.7-35.0)	19.8 (14.5-25.2)	7.6 (3.3-11.9)
Median PFS, months (95% CI)						
First	23.2 (21.1–25.3)	17.2 (15.9–18.6)	11.6 (10.2–12.9)	37.5 (20.6-54.4)	17.3 (14.7-19.9)	14.2 (11.5-16.9)
Second	13.3 (12.2–14.5)	11.0 (9.6–12.4)	8.6 (7.4–9.9)	21.6 (5.9-37.3)	12.0 (9.7-14.2)	7.0 (5.0-9.0)
Third	7.3 (6.1–8.6)	5.7 (4.9–6.6)	5.5 (4.5–6.4)	5.9 (5.6-6.1)	7.1 (4.8-9.4)	4.4 (3.2-5.5)

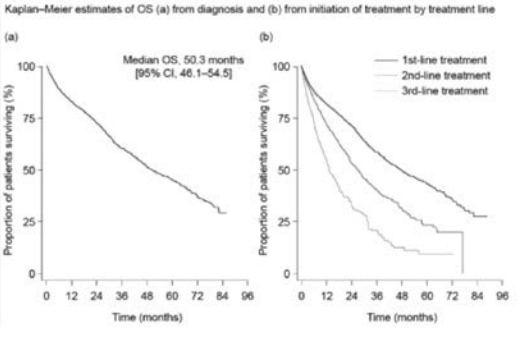

Figure 1.

Summary/Conclusions: Real-world outcomes in pts with symptomatic MM are considerably lower than those reported in clinical trials. OS and PFS decreased significantly with each successive treatment line. Despite availability of novel agents, MM remains a disease with high unmet need.

E1281

FC-GAMMA RECEPTOR POLYMORPHISMS AND PROGRESSION-FREE SURVIVAL: ANALYSIS OF THREE CLINICAL TRIALS OF ELOTUZUMAB IN MULTIPLE MYELOMA

V Poulart*, YM Jou, T Delmonte, M Robbins
Bristol-Myers Squibb, Princeton, United States

Background: Elotuzumab is a humanized IgG1 immunostimulatory monoclonal antibody that targets SLAMF7, a glycoprotein highly expressed by myeloma and natural killer (NK) cells. Elotuzumab works via a dual mechanism of action, both by directly activating NK cells and by facilitating antibody-dependent cell-mediated cytotoxicity (ADCC) to cause targeted myeloma cell death. Fcγ receptors, including CD16a (FcγRIIIa) and CD32a (FcγRIIa), bind the Fc portion of IgG1 antibodies to facilitate ADCC.[1] Multiple alleles exist for CD16a and CD32a

that confer affinity for Fc binding; therefore, differences in Fcγ receptor genotypes could affect responses to elotuzumab.[1] The high-affinity allele for CD16a is determined by a valine (V) residue at amino acid position 158, while a phenylalanine (F) residue determines the low-affinity variant. For CD32a, the high-affinity allele is a histidine (H) residue at position 131; arginine (R) determines the low-affinity variant.

Aims: To assess whether CD16a and CD32a polymorphisms affect progression-free survival (PFS) in patients receiving elotuzumab as monotherapy or as part of a combination therapy.

Methods: In ELOQUENT-2 (NCT01239797), patients with relapsed/refractory multiple myeloma (RRMM) and 1–3 prior therapies were randomized to elotuzumab (10 mg/kg IV) in combination with lenalidomide (Len) and dexamethasone (dex; ELd) or Len/dex alone (Ld). In Study 009 (NCT01478048), patients with RRMM and 1–3 prior therapies were randomized to elotuzumab (10 mg/kg IV) in combination with bortezomib (Btz) and dex (EBd) or Btz/dex alone (Bd). In Study 011 (NCT01441973), patients with high-risk (Mayo Clinic criteria) smouldering MM were treated with elotuzumab (10 mg/kg IV twice monthly or 20 mg/kg IV once monthly). Patients from ELOQUENT-2 and Study 009 were categorized by CD16a (VV *vs* FF) and CD32a (HH *vs* RR) genotype. Patients from Study 011 were categorized by the presence of ≥1 *vs* 0 high-affinity CD16a (VV/VF *vs* FF) or CD32a (HH/HR *vs* RR) alleles. PFS by genotype was assessed in the elotuzumab and control groups of ELOQUENT-2 and Study 009, and for all patients in Study 011 (combined-dose cohort).

Results: Genotyping was performed in 339/646 randomized patients in ELOQUENT-2, in all 152 patients in Study 009, and in 28/31 patients in Study 011. In ELOQUENT-2, neither CD16a genotype (VV *vs* FF) nor CD32a genotype (HH *vs* RR) was associated with a difference in PFS distribution in the ELd or Ld group (Table). In Study 009, CD16a VV *vs* FF status was associated with longer median PFS in the EBd arm, but not in the control arm. Given the available data for each estimate (n=15–19), CD32a genotype did not appear to be associated with a meaningful difference in median PFS in either the EBd or Bd group. In Study 011, median PFS was >20 months or non-estimable for all CD16a and CD32a genotypes. PFS was numerically higher for patients with ≥1 *vs* 0 CD16a V alleles; however, interpretation is limited by the small numbers of patients with each genotype.

Table 1. Median PFS (ITT definition) in ELOQUENT-2, study 009, and study 011, by FcγR genotype and treatment group.

Treatment arm	Median PFS (95% CI), months			
	ELOQUENT-2 (n=339)*			
	CD16aVV	CD16aFF	CD32aHH	CD32aRR
ELd group	n=29 22.3 (12.5–31.3)	n=60 22.2 (14.8–29.9)	n=59 18.5 (11.1–24.0)	n=40 19.5 (14.8–30.1)
Control (Ld)	n=18 18.4 (8.5–19.4)	n=69 19.4 (13.0–23.9)	n=62 18.4 (12.6–22.2)	n=33 14.4 (11.1–20.3)
	Study 009 (n=152)			
	CD16aVV	CD16aFF	CD32aHH	CD32aRR
EBd group	n=13 22.3 (3.8–33.2)	n=24 9.8 (5.7–14.3)	n=15 10.7 (4.5–17.0)	n=19 7.4 (3.7–18.2)
Control (Bd)	n=16 8.2 (1.7–10.2)	n=22 6.9 (3.8–10.6)	n=18 5.6 (2.8–13.1)	n=16 8.3 (3.5–15.2)
	Study 011 (n=28)			
	CD16aVV/VF	CD16aFF	CD32aHH/HR	CD32aRR
Dose cohorts combined	n=16 31.3 (12.3–NE)	n=12 22.1 (8.3–NE)	n=21 31.3 (12.9–NE)	n=7 NE (8.3–NE)

*PFS assessed by independent review committee and censored for subsequent therapy.

NE, not estimable.

Summary/Conclusions: The effect of Fcγ receptor polymorphisms on PFS may depend on elotuzumab treatment combinations, as CD16a genotype correlated with PFS in patients treated with EBd but not ELd. ELd benefits all patients, irrespective of genotype, as there is no evidence that high-affinity Fcγ alleles are associated with a differential benefit.

HIGH EXPRESSION OF AF1Q IS AN ADVERSE PROGNOSTIC FACTOR AND A PREDICTION MARKER OF EXTRAMEDULLARY DISEASE IN MULTIPLE MYELOMA

S Hagiwara[1,*], S Mine[1], AI Schiefer[2], L Kenner[3,4], W Tse[5]

[1]Division of Hematology, Internal Medicine, National Center for Global Health and Medicine, Shinjuku, Japan, [2]Clinical Institute of Pathology, [3]Department of Experimental Pathology and Pathology of Laboratory Animals, Medical University Vienna, [4]Ludwig Boltzmann Institute for Cancer Research Vienna, University of Veterinary Medicine Vienna, Vienna, Austria, [5]James Graham Brown Cancer Center, University of Louisville School of Medicine, Louisville, United States

Background: Multiple myeloma is an intractable hematological malignancy with various clinical manifestations, especially extramedullary disease (EMD). The prognosis of patients with EMD is extremely poor due to limited treatment options and aggressive nature of EMD, however the mechanism of the progression of EMD is not well known. AF1q is an oncogene which expressed in leukemia cells, located in 1q21. The gene is well known as one of the fusion partners of MLL, and as a poor prognostic factor in acute myeloid leukemia and myelodysplastic syndrome. Recently, we reported that high expression of AF1q results in an autonomous Wnt activity that promotes distant metastasis of breast cancer.

Aims: We hypothesized that high expression of AF1q is a poor prognostic factor of multiple myeloma and associated with EMD. To evaluate our hypothesis, we analyzed the expression of AF1q in patients with multiple myeloma and investigated the impact on the prognosis and the progression of EMD.

Methods: Newly diagnosed multiple myeloma patients in National Center for Global Health and Medicine hospital from January 2001 to March 2013 were studied. Patients were treated with vincristine-adriamycin-dexamethason or bortezomib-dexamethason induction therapy followed by autologous stem cell transplantation using high dose melphalan. The expression of AF1q was evaluated using the immunostaining of bone marrow clot samples at the diagnosis of multiple myeloma. The expression of AF1q was graded from "-" to "+++". EMD was diagnosed by pathological examination and/or CT/MRI/PET. The clinical response, progression free survival (PFS), and overall survival (OS) were analyzed using Kaplan Meier method with Log-rank test. Correlation between EMD and AF1q expression was tested by Chi-square test.

Results: Clinical data and bone marrow clot samples of 117 patients were analyzed. Mean age was 54.9 years old, and 51.9% was male. The grades of AF1q expression were 7 of "-", 33 of "+", 35 of "++", and 42 of "+++". We defined the cases with "-" and "+" as low expression, "++" and "+++" as high expression. Very good partial response or better was obtained after completion of autologous stem cell transplantation in 42.5% of patients with low AF1q expression and 37.7% of high expression. There was no statistically significant difference. Survival analysis using Log Rank method showed that high expression of AF1q was associated with significantly shorter progression free survival (3 year PFS was 56.2% in low AF1q expression *vs* 30.5% in high AF1q expression, p=0.009), but not overall survival (3 year OS was 89.6% in low AF1q expression *vs* 73.3% in high AF1q expression, ns.). EMD was found in 25.0% of patients with low AF1q expression and 44.7% of high expression. Chi-square test showed that the incidence of EMD was significantly higher in patients with high AF1q expression than low expression (p=0.045)

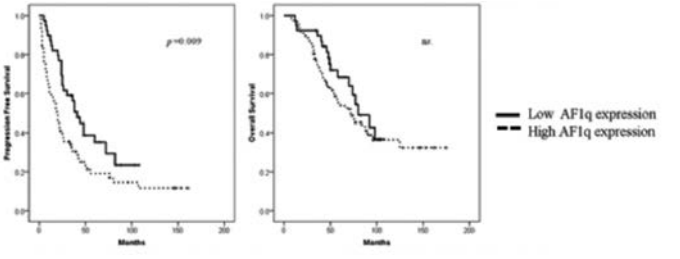

Figure 1.

Summary/Conclusions: To our knowledge, this is the first study that demonstrates a molecular marker associated with myeloma with EMD. We found that the high expression of AF1q was an adverse prognostic factor in multiple myeloma.

E1283

PHASE 1/2 TRIAL OF LENALIDOMIDE IN COMBINATION WITH CYCLOPHOSPHAMIDE AND PREDNISONE (REP) IN PATIENTS WITH LENALIDOMIDE-REFRACTORY MULTIPLE MYELOMA (REPEAT-STUDY)

Background: The outcome of lenalidomide- and bortezomib-refractory multiple myeloma (MM) patients is very poor, with a median event-free survival of 5 months and median overall survival (OS) of 9 months. Therefore new treatment modalities are urgently needed. In this respect, several new drugs have recently

been approved for the treatment of double refractory MM (such as pomalidomide, carfilzomib, and daratumumab). However, next to the development of new drugs, also the strategy of combining drugs with synergistic activity may result in significant clinical benefit for patients with advanced myeloma. Lenalidomide has well-described immunomodulatory effects, even in the setting of lenalidomide-refractory disease. Similarly, administration of continuous low-dose cyclophosphamide (metronomically dosed) has direct anti-tumor activity, as well as several well-characterized immunomodulatory effects. We have previously shown in a retrospective study that lenalidomide combined with continuous low-dose oral cyclophosphamide (endoxan) and prednisone (REP) had remarkable activity in heavily pretreated, lenalidomide-refractory MM patients.
Aims: To further evaluate this combination, we initiated a prospective phase I/II study to determine the optimal dosing schedule of lenalidomide, low-dose oral cyclophosphamide and prednisone, and to assess its efficacy and safety in lenalidomide-refractory MM patients.
Methods: 82 lenalidomide-refractory MM patients were included in this trial; 21 were included in the phase 1 dose-finding part with a classic 3+3 dose-escalation design (5 dose-levels) and 61 patients were included in the phase II part of this trial in which all patients were treated at the maximum tolerated dose (MTD).
Results: The median age of the 82 patients in this phase I/II trial was 66 years (range 41-82); 71% were male. The median duration from diagnosis was 48 months (range 5-169), median number of prior therapies was 3 (range 1-6), and 50 patients (61%) had previously received autologous SCT. All patients were lenalidomide-refractory, 71 (87%) had prior bortezomib treatment, and 54 (66%) had both lenalidomide- and bortezomib-refractory MM. 41% of the patients had high-risk cytogenetic abnormalities as determined by FISH. The MTD was defined as 25 mg lenalidomide (days 1-21/28 days), combined with continuous oral cyclophosphamide (50 mg/day) and prednisone (20 mg/day). Sixty-seven patients were treated at the MTD (6 in dose-level 4 of phase I and 61 in phase II part of the study). Forty-four of these patients (67%) achieved a partial response or better, including 12 patients (18.2%) with a very good partial response and 3 (4.5%) with a complete remission. Eleven patients (16%) achieved a minimal response, translating to an overall 83% clinical benefit rate. After a median follow-up of 24.5 months median PFS and OS were 12.1 and 29.0 months respectively. Similar results were achieved in the subset of patients with lenalidomide- and bortezomib-refractory disease as well as in patients with high-risk cytogenetic abnormalities. At the MTD, neutropenia (22%) and thrombocytopenia (22%) were the most common grade ≥3 hematological adverse events. Infections (21%) were the most common grade ≥3 non-hematological adverse events.
Summary/Conclusions: REP is a well-tolerated regimen and induces a high response rate with prolonged PFS and OS in lenalidomide-refractory MM patients. REP should be considered a valuable salvage option for lenalidomide-refractory MM patients.
This trial was registered at www.clinicaltrials.gov as #NCT01352338.

E1284

MANAGEMENT OF ADVERSE EVENTS IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA TREATED WITH POMALIDOMIDE PLUS LOW-DOSE DEXAMETHASONE: A POOLED SAFETY ANALYSIS OF 3 CLINICAL TRIALS

P Moreau[1,*], MA Dimopoulos[2], PG Richardson[3], D Siegel[4], A Palumbo[5], M Cavo[6], P Corradini[7], K Weisel[8], M Delforge[9], P O'Gorman[10], K Song[11], L Sternas[12], T Biyukov[13], K Hong[12], J Herring[12], X Yu[12], MH Zaki[12], J San Miguel[14]
[1]University Hospital Hôtel-Dieu, Nantes, France, [2]National and Kapodistrian University of Athens, Athens, Greece, [3]Jerome Lipper Multiple Myeloma Center, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, [4]John Theurer Cancer Center, Hackensack, NJ, United States, [5]University of Torino, Torino, [6]Seràgnoli Institute of Hematology, Bologna University School of Medicine, Bologna, [7]University of Milano, Fondazione IRCCS Istituto Nazionale de Tumori, Milano, Italy, [8]University Hospital of Tubingen, Tubingen, Germany, [9]University Hospital Leuven, Leuven, Belgium, [10]Mater Misericordiae University Hospital, University College Dublin, Dublin, Ireland, [11]Vancouver General Hospital, Vancouver, British Columbia, Canada, [12]Celgene Corporation, Summit, NJ, United States, [13]Celgene International Sàrl, Boudry, Switzerland, [14]Clinica Universidad de Navarra, CIMA, IDISNA, Pamplona, Spain

Background: Patients with relapsed and refractory multiple myeloma (RRMM) who are heavily pretreated often have advanced disease and comorbidities, increasing their susceptibility to adverse events (AEs). The management of AEs is important to ensure that patients remain on the therapy for as long as needed to receive a clinical benefit.
Aims: To further characterize the safety profile of pomalidomide (POM)+low-dose dexamethasone (LoDEX) and management of AEs using pooled safety data from 3 clinical trials of POM+LoDEX (Richardson et al, *Blood,* 2014; San Miguel et al, *Lancet Oncol,* 2013; Dimopoulos et al, ASH 2015).
Methods: The 3 trials enrolled patients who provided informed consent and had ≥2 prior therapies, including lenalidomide and bortezomib, and had progressed on or within 60 days of their last therapy. Patients received POM 4 mg/day on days 1-21 of each 28-day cycle and LoDEX 40 mg (20 mg for those >75 years of age) weekly until disease progression or unacceptable toxicity. Thromboprophylaxis was required. Grouped AE terms were used for analysis.
Results: A total of 1088 patients from the 3 trials were included in the safety population; median age was 66 years (range, 34-88 years). Most patients were male (57%), had an Eastern Cooperative Oncology Group performance status of ≤1 (88%), were refractory to both lenalidomide and bortezomib (77%), and had prior stem cell transplant (68%). The most common grade 3/4 AEs were neutropenia (56%), infections (34%), anemia (32%), and thrombocytopenia (26%). The median time to onset was 20 days (range, 1-591 days) in the 693 patients with neutropenia, 15 days (range, 1-498 days) in the 393 patients with thrombocytopenia, and 41.5 days (range, 1-493 days) in the 748 patients with infections. AEs were managed by dose modifications and/or supportive care, including anti-infectives (88%), red blood cell transfusion (45%), granulocyte colony-stimulating factor (17%), and platelet transfusion (14%). The rate of grade 3/4 venous thromboembolic events was low (2%). Peripheral neuropathy (PN) of any grade occurred in 17% of patients; 1% experienced grade 3/4 PN. The median average POM dose was 4 mg (range, 1.6-4.2 mg). AEs leading to POM dose interruptions occurred in 66% of patients. AEs leading to dose reductions occurred in 24% of patients; the most common were neutropenia (8%), thrombocytopenia (5%), and infections (4%). AEs leading to discontinuation of POM were infrequent (7%).
Summary/Conclusions: In this large pooled safety analysis, POM+LoDEX showed an acceptable safety profile in patients with RRMM. AEs were manageable, and discontinuations due to AEs were uncommon.

E1285

MP0250, A BISPECIFIC VEGF- AND HGF-BLOCKING MULTI-DARPIN*, IN COMBINATION WITH BORTEZOMIB IN MULTIPLE MYELOMA: PRECLINICAL RATIONALE AND PHASE 2 STUDY OUTLINE

U Fiedler[1], K Dawson[1], P Gilboy[2], M Stumpp[1,*], K Tadjalli-Mehr[1], A Harstrick[1]
[1]Molecular Partners AG, Zürich, Switzerland, [2]Horizon Pharma, Dublin, Ireland

Background: Despite advances in the treatment of multiple myeloma (MM), there is no cure. Patients eventually relapse, requiring multiple lines of treatment. Upregulation of both the vascular endothelial growth factor (VEGF) and hepatocyte growth factor (HGF) pathways has been implicated in loss of response to therapy. VEGF and HGF are increasingly overexpressed with MM progression and have been linked to poor prognosis: they are known to be able to stimulate neovascularization, bone destruction, and myeloma proliferation, migration, and adhesion in the bone marrow. Preclinical studies have shown that refractory, high HGF-expressing MM cell lines can be re-sensitized to treatment by inhibiting HGF/cMET signaling. MP0250 is a bispecific VEGF / HGF blocking multi-DARPin which is currently in a phase 1 study in solid tumors.
Aims: We are presenting the preclinical rationale for using MP0250 in combination with bortezomib (BTZ) in a planned phase 2 study in MM patients.
Methods: MP0250 and BTZ, alone and in combination, were tested in an orthotopic murine xenograft model in which human MM cells were implanted in murine tibial bone marrow. Tumor growth and muscle invasion was monitored by caliper measurements and CT scans, and bone destruction was analyzed by X-ray and microCT. Ex vivo analysis included the determination of M protein levels.
Results: MP0250 significantly inhibited bone lysis (total and cortical bone volumes) and tumor invasion in a dose-dependent manner. In both the MP0250 and MP0250+BTZ groups, tumor infiltration into the tibial muscle was significantly reduced while BTZ alone had no effect. M protein was reduced and inhibition of bone lysis was increased when the combination of BTZ and MP0250 was compared to BTZ alone. The results show that blockade of HGF and VEGF by MP0250 on its own has a beneficial effect and that enhanced effects can be achieved in combination with BTZ.
Summary/Conclusions: MP0250, a multi-DARPin specifically blocking HGF and VEGF, improves the efficacy of BTZ in a preclinical MM model. Consequent to this and a favorable phase 1 study, MP0250 will be evaluated in a phase 2 study in MM in combination with BTZ+DEX.
**DARPins are small repeat proteins, designed to bind targets with high specificity and potency, and which can be combined in a modular fashion.*

E1286

CAN CAPILLARY ZONE ELECTROPHORESIS MONITOR DARWINIAN EVOLUTION OF MULTIPLE MYELOMA CLONES?

PP Kotoucek[1,*], D Midda[2], R Wenban[3], S Peggler[3], A Reche[3], P Manghat[3], R Lock[4]
[1]Haematology, [2]Pharmacy, [3]Pathology, Darent Valley Hospital, Kent, UK, Dartford, [4]Severn Pathology, North Bristol NHS Trust, Bristol, United Kingdom

Background: At the time of diagnosis of multiple myeloma (MM) and similar disorders there are multiple clones in bone marrow or in extramedullary sites. Usually only a dominant clone is diagnosed and monitored in daily clinical practice before, during or after chemotherapy. Non dominant clones are not measured routinely nor their evolution under pressure of chemotherapy.We present identification and monitoring of multiple clones of multiple myeloma and similar

disorders by capillary zone electrophoresis (CZE) in routine clinical settings and evolution of these clones during a 5 year follow up and during third line chemotherapy by lenalidomide
Aims: Multiple myeloma is heterogenous disease with multiple clones. There is no techique available in routine clinical practice to monitor dominant and non-dominant clones in the same time. Chemotherapy bears a risk of supressing less aggressive dominant clone and enhancing evolution process of very aggressive and chemotherapy resistant clones. Our aim was to monitor all clones simultaneously during natural course of disease and during chemotherapy to understand evolution process in routine practice.
Methods: 1/CZE results captured from 1.1.2009 till 31.12.2009 in a single hospital pathology centre with a 5 year follow up correlated with clinical outcomes of patients. 2/Results of patients with mutliple myeloma on third line chemotherapy with lenalidomide in single centre from 1.1.2010 till 31.12.2015 monitored by CZE.
Results: 1/ All consecutive patients with any paraprotein visible in CZE within year 2009 in our centre: N=314. Break down these patients to a number of all patients with only one paraprotein on CZE is n= 277, a number of patients with two or three paraproteins is n= 37.Evolution of clones within one year (2009): from one paraprotein to two visible in CZE was in n=8 patients. One patient has experienced evolution from one clone to thee clones within one year. 5 year follow up data of all patients with more than 1 paraprotein are available only in 11 patients from original 37 patients.Their diagnoses were: MGUS n=2 with further increasing number of clones from 2 to 3 within 5 years; CLL n= 2, one patient with increasing number of paraproteins from 2 to 3, Waldenstroam Macroglobulinaemia n= 3, one patient with increasing number of paraproteins from 2 to 3. 2/ Patients on third line chemotherapy n=56 based on lenalidomide were monitored by CZE. Evolution of multiple clones is demonstrated by CZE
Summary/Conclusions: CZE is a very sensitive and unique method capable capturing even non-dominant minor clones and monitoring them during observation or chemotherapy and to assess response to chemotherapy in a deeper level in routine practice. CZE can describe selection of clones during chemotherapy. A high sensitivity of CZE can reveal paraprotein in patients with lymphopoliferative disorders. For better understanding of CZE in monitoring of non-dominant clones further correlation with flowcytometry and even with cytogenetic and genomic assays are needed.

E1287

THE CLINICAL COURSE OF RELAPSED OR REFRACTORY U.S. MULTIPLE MYELOMA (RRMM) PATIENTS RECEIVING TWO OR MORE LINES OF THERAPY

D Romanus[1,*], A Raju[2], B Seal[1], E Farrelly[2], C Yong[1], S Noga[3], M Jhaveri[1], R Labotka[4], M Blazer[5], H Parameswaran[6]
[1]Global Outcomes Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Real-World Evidence, Xcenda, Palm Harbor, [3]US Medical Affairs, [4]Oncology Clinical Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [5]Global Health Economics and Outcomes Research, Xcenda, Palm Harbor, [6]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI, United States

Background: The introduction of novel agents, proteasome inhibitors (PIs) and immunomodulatory drugs (IMIDs), has led to an improvement in prognosis in multiple myeloma (MM). However, over the course of the disease, less durable remissions with each successive therapy have been noted in MM. In a retrospective single-institution, chart review study, patients experienced shorter overall survival (OS) as they progressed through each line of therapy, first-line (1LT) and second-line (2LT), OS of 28.4 and 17.1 months, respectively (Kumar 2004). Other evidence from a multi-center observational analysis of 383 MM patients (treated between 2007 and 2010) reported a median progression free (PFS) and OS from start of salvage therapy after first relapse of 13 and 35 months, respectively (Durie 2012); however, the clinical course of RRMM in the era of novel agents among pts treated in the real-world remains to be elucidated.
Aims: This study aims to describe the PFS and OS of RRMM patients receiving two or more lines of therapy in the era of novel agents in a large national database in the U.S.
Methods: In this retrospective cohort study using an electronic medical records (EMR) database from 38 states in the U.S, newly diagnosed, adult MM patients initiating 1LT between 1/2008 and 12/2014 were followed to identify 2LT accordingly: 1) retreatment after a treatment gap of >3 months of a prior LT, or 2) a switch to another drug combination after 1LT initiation. Subsequent lines of therapy, 3LT and 4LT, began with a switch in regimen compared to the previous line. Pts with salvage stem cell transplants (SCT) were excluded. Time to new treatment or death (TTNT) was used as a surrogate for PFS. Kaplan-Meier analyses were performed for OS/TTNT from start of each line of therapy. Observations were censored at time of loss to follow up or end of study period (6/30/2015).
Results: Among 628 patients initiating both 1LT and 2LT, mean age was 69.2 years (SD: 10.3) at start of 2LT; 51% were male; 9.6% had known high cytogenetic risk MM (del[17p] and/or t[4:14] and/or t[14:16]); 19.6% had a frontline SCT; 46.7% had a Charlson Comorbidity Index (CCI) score ≥2. PI-based regimens predominated in 1LT (44.2%), 3LT (43.1%) and in 4LT (41.2%) (Table 1). The most common regimen in 2LT was IMID-based (44.2%). PI+IMID-based combination therapy increased from 17.7% in 1LT to 40.2% in 4LT. As patients progressed through lines of therapy, median TTNT decreased from 15.1 months (95% CI: 13.4, 17.3) in 2LT to 7.8 months (95% CI: 6.1, 9.7) in 3LT and 6.9 months (95% CI: 5.1, 11.8) in 4LT. Median OS decreased from 41.0 months (95% CI: 32.1, 59.5) in 2LT to 30.3 months (95% CI: 20.1, 46.0) in 3LT and 24.8 months (95% CI: 12.8, 43.0) in 4LT.

Table 1. Treatment patterns by line of therapy among MM patients initiating 1st and 2nd line therapy.

Line of Therapy	1st Line N=628	2nd Line N=628	3rd Line N=218	4th Line N=102
Type of Therapy, %				
PI-based	41.6	33.3	43.1	41.2
Bortezomib ± non-IMID	41.4	28.0	30.7	11.8
Carfilzomib ± non-IMID	0.2	5.3	12.4	29.4
IMID-based	33.8	44.2	30.7	35.3
Lenalidomide ± non-PI	29.3	36.2	17.9	11.8
IMID (other than lenalidomide) ± non-PI	4.5	8.0	12.8	23.5
PI + IMID-based	17.7	8.9	22.5	40.2
Lenalidomide + bortezomib ± other	14.8	5.3	12.4	29.4
Bortezomib + IMID (other than lenalidomide) ± other	2.6	0.6	3.7	2.0
Carfilzomib + IMID ± other	0.3	3.0	6.4	8.8
Other, not categorized elsewhere	7.0	13.7	11.0	8.8

*measured from the index date which is the start date of each line of therapy.

Key: IMID – immunomodulator (lenalidomide, thalidomide, pomalidomide); OS – overall survival; PI – proteasome inhibitor (bortezomib, carfilzomib); Other – includes: cyclophosphomide, melphalan, vincristine, (liposomal) doxorubicin, interferon, panobinostat, bendamustine, vorinostat, single agent steroid; TTNT – time to next treatment

Summary/Conclusions: Median OS and time to progression from 2LT was longer than previously reported (Durie 2012; Kumar 2004). However, successive treatment regimens yielded progressively shorter TTNT and OS durations. These data may support treatment decision making by informing the trade-offs between prognosis, treatment effectiveness and toxicity.

E1288

PRACTICE PATTERNS AND OUTCOMES IN ELDERLY U.S. PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

D Romanus[1,*], A Raju[2], C Yong[1], B Seal[1], E Farrelly[2], R Labotka[3], M Jhaveri[1], S Noga[4], M Blazer[5], H Parameswaran[6]
[1]Global Outcomes Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Real-World Evidence, Xcenda, Palm Harbor, [3]Oncology Clinical Research, [4]US Medical Affairs, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [5]Global Health Economics and Outcomes Research, Xcenda, Palm Harbor, [6]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI, United States

Background: Multiple myeloma (MM) is a disease of the elderly; median age at diagnosis is 70 yrs (Larocca 2015). The advent of novel therapies has improved survival (OS) among newly diagnosed MM (NDMM) patients (pts) (Kumar 2014). But, the link between therapeutic regimens and OS benefit in elderly pts is not clearly established (Kumar 2014; Verlest 2012). Real-world information regarding prescribing patterns and clinical outcomes in elderly pts with RRMM is limited.
Aims: To describe the prescribing patterns and clinical outcomes, and to evaluate the impact of age on progression-free survival (PFS) and OS in elderly RRMM pts initiating second line therapy (2LT) in a large, national database in the U.S.
Methods: In this retrospective cohort study of an electronic medical records (EMR) database, NDMM adult pts initiating first-line therapy (1LT) between 1/2008 and 12/2014 were included and 2LT was identified accordingly: 1) retreatment after a treatment gap of >3 months of 1LT, or 2) a switch to another drug combination after starting 1LT. Third-line therapy (3LT) began with a switch in regimen post 2LT. Pts with salvage stem cell transplants (SCT) were excluded. Time to new line of therapy (TTNT) or death was used as a surrogate for PFS. Cox proportional hazard models for TTNT and OS were conducted from start of 2LT. Pts were censored at loss to follow up or the end of study period (6/30/2015).
Results: Among 628 pts with 1LT and 2LT, 37.1% were ≥75 yrs of age (yo) at start of 2LT, 51% male; 2% of those ≥75 yr *vs* 30% of those <75 yr underwent frontline SCT. Pts ≥75 yo had a higher comorbidity burden (mean Charlson Comorbidity score [CCI]: 2.1 *vs* 1.6), and a higher proportion had cardiovascular disease (CVD [38.6% *vs* 27.3%]) than those <75 yo at start of SLT. Median follow-up from start of 2LT was 13.0 mos (IQR: 5.2, 23.3).Younger pts were 2-fold more likely to receive more intensive therapy with a proteasome inhibitor+immunomodulatory drug (PI+IMID)-based combination both in 1LT

(21.8% *vs* 10.8%) and in 2LT (11.1% *vs* 5.2%) compared to ≥75 yo (Table). In 1LT, older age was associated with an increased use of IMID-based therapies (42.1% *vs* 28.9% among ≥75 *vs*<75 yo). In 2LT, older age was associated with a higher frequency of PI-based therapies, 39.5% *vs* 29.6% in the younger cohort. OS probabilities at 1 yr and 2 yrs were 84.6% and 68.0% for those<75 yrs and 72.3% and 57.4% for those ≥75 yrs. Adjusting for observed confounders (gender, race, cytogenetic risk, CCI, CVD, yr of diagnosis, 1LT and 2LT regimen type), older age was associated with a significantly higher mortality risk after initiation of 2LT (HR: 1.57 [95% CI: 1.2, 2.1], *P*<0.01, for age ≥75 *vs*<75 yrs) (Figure). Median TTNT was 16.6 mos (95%CI: 13.5, 19.1) for pts<75 yrs and 13.8 mos (95% CI: 11.7, 17.8) for pts ≥75 yo. Age was not significantly associated with TTNT in 2LT in multivariate analyses.

Table 1. Drug therapy by age among MM patients (n=628).

Age Cohort, years	<75 N=395		≥75 N=233	
Line of Therapy	1st Line	2nd Line	1st Line	2nd Line
≤Doublet vs ≥Triplet therapy, %				
≤2 drug combination	55.4	75.7	75.1	85.0
≥3 drug combination	44.6	24.3	24.9	15.0
PI-based	43.0	29.6	39.1	39.5
Bortezomib ± non-IMID	42.8	24.3	39.1	34.3
Carfilzomib ± non-IMID	0.3	5.3	0	5.2
IMID-based	28.9	44.8	42.1	42.9
Lenalidomide ± non-PI	25.3	36.5	36.1	35.6
Other IMID[a] ± non-PI	3.5	8.4	6.0	7.3
PI + IMID-based	21.8	11.1	10.8	5.2
Lenalidomide + bortezomib ± other[b]	17.7	6.1	9.9	3.9
Bortezomib + other IMID[a] ± other[b]	3.5	1.0	0.9	0
Carfilzomib + IMID ± other[b]	0.5	4.0	0	1.3
Other[b], not categorized elsewhere	6.3	14.4	8.2	12.5

[a]IMID other than lenalidomide (ie, thalidomide or pomalidomide); [b]Other includes cyclophosphomide, melphalan, vincristine, (liposomal) doxorubicin, interferon, panobinostat, bendamustine, vorinostat, single agent steroid.

Key: IMID – immunomodulator (lenalidomide, thalidomide, or pomalidomide); OS – overall survival; PI – proteasome inhibitor (bortezomib or carfilzomib); TTNT – time to next treatment

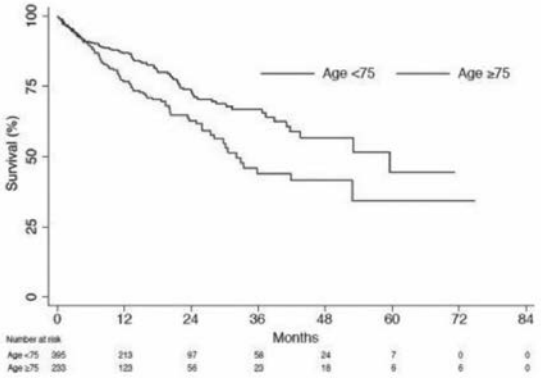

Figure 1. Adjusted overall survival by age from 2LT initiation.

Summary/Conclusions: In 1LT and 2LT in MM, older age appeared to impact treatment choice with less intensive therapy. The majority of patients received ≥1 novel agent irrespective of age; however, elderly pts were more likely to initiate IMID-based therapy in 1LT and PI-based therapy in 2LT compared to younger pts. Older age was associated with significantly worse OS outcomes after start of 2LT in the real-world.

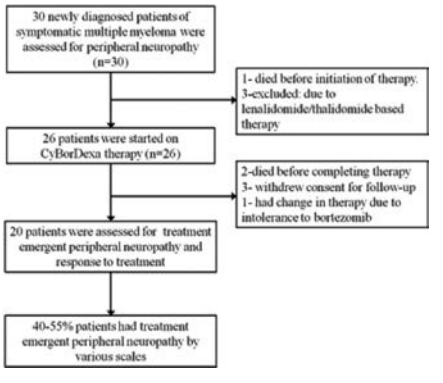
COMPARISON OF FOUR NEUROPATHY ASSESSMENT SCALES IN EVALUATION OF TREATMENT EMERGENT NEUROPATHY IN NEWLY DIAGNOSED PATIENTS OF MULTIPLE MYELOMA TREATED WITH BORTEZOMIB BASED REGIMEN

A Lakshman[1,*], G Prakash[2], M Modi[3], P Malhotra[2], R Nampoothiri[1], A Khadwal[2], V Suri[2], S Jain[2], S Kumari[2], N Varma[4], S Varma[2]
[1]Internal Medicine, [2]Clinical Hematology and Bone-marrow Transplant, Department of Internal Medicine, [3]Neurology, [4]Haematology, Postgraduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India

Background: Treatment emergent peripheral neuropathy (TEPN) is a distressing and potentially dose limiting side-effect of bortezomib containing regimen for multiple myeloma (MM). The reporting of extent and severity of TEPN is variable due to use of different neuropathy scales. Presently, most investigators use National Cancer Institute Common Toxicity Criteria for Adverse Events (NCI CTCAE) for reporting of TEPN.
Aims: We aimed to compare the utility of different neuropathy scoring scales for detection of TEPN and to evaluate the incidence, severity and electrophysiological characteristics of TEPN after bortezomib based regimen in newly diagnosed patients of MM.
Methods: We prospectively evaluated the incidence of TEPN in treatment naïve patients of MM receiving cyclophosphamide, bortezomib and dexamethasone (CyBorD) on days 1, 8, 15 and 22 of each 28-day cycle, by clinical evaluation, nerve conduction study (NCS) and four different neuropathy scores- NCI CTC v4.0, Total neuropathy score reduced (TNSr) and clinical (TNSc) and Numerical Response Scale (NRS) for neuropathic pain. TNSr includes results of nerve conduction study in addition to the clinical parameters used in TNSc. Post-treatment increment by one grade for NCI-CTC, by score of ≥2 for TNSr and TNSc, and by score of ≥1 for NRS defined TEPN. Informed consent was obtained from each patient and the study was approved by institutional review board.
Results: A total of twenty six patients received CyBorD regimen. Twenty patients completed follow-up. After a median of 7 (range: 3.5-11) months, the rates of occurrence of TEPN differed when the four scales were used; viz. NCI CTC=45% (n=9), TNSr=55% (n=11), TNSc=40% (n=8) and NRS=40% (n=8). All four scales showed worsening following treatment with CyBorD, especially with regard to sensory symptoms (p<0.01 for all scales). TNSr could pick up higher number of cases with TEPN in comparison to any other score, most notably in comparison to NCI CTCAE. Among 12 patients who did not have TEPN by NCI CTC scale, 41.7% (n=5), 16.7% (n=2) and 8.3% (n=1) patients satisfied the criteria for TEPN by TNSr, TNSc and, NRS, respectively. When compared against TNSr, sensitivity for detecting TEPN by NCI CTCAE, TNSc and NRS were 77.8%, 88.9%, and 77.8%, respectively. NCI CTCAE and TNSc, both showed specificity of 63.3% for detection of TEPN. Specificity with NRS was found to be 54.5%. The higher detection rate of neuropathy by TNSr is probably due to wider range of scores given for graded sensorymotor impairment and incorporation of electrophysiological parameters which increases its sensitivity. On NCS, three patients (42.9%) had sensorimotor and four (57.1%) patients had motor nerve conduction abnormalities. Five patients (71.4%) had axonal neuropathy while 2 (28.6%) patients had evidence of demyelination on NCS.

Table 1.



Summary/Conclusions: We suggest that, NCI-CTCAE may be suboptimal in comparison to TNSr in assessment of TEPN in patients with MM on bortezomib based therapy. It is desirable to use better scoring systems like TNSr as they may be more sensitive and they improve our understanding of bortezomib induced neuropathy. NRS is a simple screening tool that can be used in routine clinical practice for detecting bortezomib induced neuropathy. Further studies with large sample size including intraepidermal nerve fiber density testing on skin biopsy are required to better define TEPN in patients receiving bortezomib.

E1290

SERUM B-CELL MATURATION ANTIGEN IS A BIOMARKER FOR PATIENTS WITH B-CELL DISORDERS

J Berenson[1,*], K Udd[1], TM Spektor[2], J Wang[1], E Sanchez[1], G Tang[1], C Wang[1], M Li[1], H Chen[1], PJ Maglione[3], C Cunningham-Rundles[3]
[1]Institute for Myeloma & Bone Cancer Research, [2]Oncotherapeutics Inc., WEST HOLLYWOOD, [3]Mt. Sinai School of Medicine, New York City, United States

Background: Serum B-cell maturation antigen (sBCMA) is a tumor necrosis factor receptor family member that is expressed on normal and malignant B-cells including plasma cells.
Aims: We determined sBCMA levels in large cohorts of patients (pts) with multiple myeloma (MM), chronic lymphocytic leukemia (CLL) and Waldenström's macroglobulinemia (WM) and immune deficiency (ID) including common variable immune deficiency (CVID) and X-linked agammaglobulinemia (XLA).
Methods: Serum was obtained on healthy individuals and pts with B-cell disorders following informed consent. Enzyme-linked immunosorbent assay (ELISA) was used to determine sBCMA levels (R&D Systems, Minneapolis, MN). Kaplan-Meier survival analysis and log-rank comparison tests were used to determine the association between sBCMA levels and time to first treatment

(TTFT), overall survival (OS) and progression-free survival (PFS). Similarly, sBCMA levels were correlated with bone marrow (BM) and PET scan findings for non-secretory disease (NSD) MM pts. Proportional Hazard Regression Analysis and a multivariate analysis were utilized to determine the predictive ability of sBCMA on OS and other prognostic factors including: age, serum creatinine, serum hemoglobin, and ISS staging. One-way univariate analysis of variance was performed to study the relationship of sBCMA with bone disease status, based on presence of osteopenia, osteolytic lesions and fractures as well as the clinical status. All of the statistical analysis was performed using JMP Pro for Windows by SAS and P values<0.05 are reported as statistically significant.

Results: Compared to healthy donors (n=43), pts with untreated active MM (n=44) showed increased levels of sBCMA (*P*<0.0001). sBCMA levels correlated with changes in BM plasma cell involvement (Pearson r=0.609; p<0.0001) and current clinical status (n=164, *P*-values: 0.0045 CR *vs* PR;<0.0001 CR *vs* NR) for MM pts. Those with other untreated B-cell malignancies showed increased levels (CLL: n=94, WM: n=29, both *P*<0.0001). sBCMA correlated with changes in M-protein levels for MM and WM pts and changes in clinical status among both MM and CLL pts. Furthermore, sBCMA also correlated with PET scan and BM findings among MM pts with NSD. Kaplan-Meier analysis demonstrated that sBCMA levels predict PFS (*P*=0.0004) and OS (*P*=0.0043) among pts with MM (n=242). sBCMA levels correlated with depth of response (*P*-values: 0.05 CR *vs* PR, 0.03 CR *vs* SD, and 0.004 CR *vs* PD). Among CLL pts (n=171), sBCMA levels predicted TTFT (*P*<0.0001) and OS (*P*=0.02), and correlated with WBC count, serum ß2-microglobulin level, IgVH mutational status, ZAP-70 scores, and chromosome 13 deletion. Additionally, sBCMA did not correlate with renal function or presence of the bone disease or other prognostic factors and maintained independent significance when tested in cohorts of MM (n=188, Pairwise R=0.18) or CLL (n=155, Pairwise R=0.001) pts. Compared to healthy donors (n=104), pts with an ID showed lower levels of sBCMA (CVID: n=46; XLA: n=8; both *P*<0.0001). Among pts with CVID, sBCMA correlated with complications from the disease (*P*=0.01).

Summary/Conclusions: We have identified sBCMA as a novel independent diagnostic and prognostic biomarker that can monitor and predict outcomes for pts with MM, CLL and WM which show elevated levels whereas those with ID including CVID and XLA show decreased levels. Levels of this marker among pts with B-cell malignancies also correlate with clinical status, predict TTFT, PFS and OS, and provide MM pts with NSD a way to follow their disease course.

E1291

IMPACT OF IMMUNOPARESIS AND ALTERED SERUM FREE LIGHT CHAIN RATIO ON THE PROGRESSION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (MGUS) IN A DISTRICT GENERAL HOSPITAL IN UNITED KINGDOM

B Badugama*
Haematology, Royal Stoke University Hospital, Stoke on Trent, United Kingdom

Background: Monoclonal gammopathy of undetermined significance (MGUS) occurs in 3% of people >50 y and up to 10% in those >70 years.The risk of progression is heterogenous.The numbers are expanding and the existing risk stratification models needs to be dynamically improved to ensure the clinical monitoring to be more cost effective.The impact of altered serum free light chain ratio (ASFLCR) and immunoparesis (IP) as tools on MGUS progression been analyzed in the current study, in addition to the already known prognostic factors: type of M protein and the amount of monoclonal component.

Aims: In general, we aimed to identify the impact of immunoparesis and skewed SFLCR as prognostic factors for progression of MGUS to multiple myeloma in a district general hospital in UK.The specific objectives were to determine the socio-demographic characteristics of study population;to identify proportion of de novo myeloma at presentation and MGUS progressing to myeloma; to determine the impact of immunoparesis at presentation on progression of MGUS;to identify any association between abnormal SFLCR and progression of MGUS.;to find any association between the type of light chains with the risk of progression.

Methods: A Retrospective cohort. All patients with MGUS and Myeloma from 2000 to 2013 included in the study population. Baseline immunoglobulin, paraprotein and light chain levels are the main parameters. Data sources are medical records of hematology out patients' clinic department & electronic hematology data base. All patients with monoclonal proteins referred to Department of Hematology recruited. Other disorders contributing to immunodeficiency: hypogammaglobulinaemia, lymph proliferative disorders, autoimmune disorders, stage 4 CKD, nephrotic syndrome, and generalized hypoproteinaemic conditions, Patients on disease modifying drugs and immunosuppressive medications systemic steroids, chemoimmunotherapy within previous 1 year of diagnosis, Patients having paraproteins together with polyclonal increase in immunoglobulines on presentation were excluded from the study.

Results: Here, we have assessed the incidence of immunoparesis (IP) and abnormal serum free light chain ratio (ASFLCR) in a cohort of 653 patients with MGUS.They were 323 (49.2%) males and 333 (50.8%) females, with their ages ranging from 34 to 94y, having the median age of 71y. The median time from the diagnosis to the time of observation was 35 months. The paraproteins: IgG in 57.8%, IgM in 23.3% and IgA in 17.3%. About 1.2% of were light chain (LC) MGUS.Approximately, 10% of the myelomas were LC secreting. Kappa LC identified in 60% and Lambda in 37.6%.SFLCA was not available for the hospital before 2005. Even later, subjected to selection bias, as it is not an in house facility.Out of, 437 patients who had the assay 255 were having ASFLCR. Immunoparesis is seen in 254 (38.7%) and 402 (61.3%) have normal immunoglobulin levels. There is a significantly positive correlation with the incidence densities of myeloma in the group with >/=2 immunoparesis. The relative risk is 4.662 (95% CI 1.847-11.772) and the (p 0.001). We have identified positive correlation of relative risk of MGUS progression to Myeloma in the presence of abnormal SFLCR.(Rate ratio 2.531).

Summary/Conclusions: It is apparent that immunoparesis and altered SFLC ratio play a pivotal role in accelerating the MGUS progression to myeloma. Our current study shows that there a statistically significant evidences that immunoparesis and serum free light chain ratio correlates positively with MGUS progression.

E1292

OVERALL SURVIVAL IN PATIENTS WITH SYMPTOMATIC MULTIPLE MYELOMA IN THE REAL-WORLD SETTING: A RETROSPECTIVE ANALYSIS OF THE PHAROS REGISTRY IN THE NETHERLANDS

S Verelst[1,*], H Blommestein[2,3,4], S Gonzalez-McQuire[5], L DeCosta[6], J de Raad[7,8], P Sonneveld[1], C Uyl-de Groot[2,3,4]
[1]Department of Hematology, Erasmus University Medical Center, [2]Institute of Health Policy & Management, Erasmus University Rotterdam, Rotterdam, [3]Comprehensive Cancer Organisation, Utrecht, [4]Institute for Medical Technology Assessment, Erasmus University Rotterdam, Rotterdam, Netherlands, [5]Amgen (Europe) GmbH, Zug, Switzerland, [6]Amgen Ltd., Uxbridge, United Kingdom, [7]Amgen B.V., Breda, [8]Department of Pharmaceutical Sciences, University of Utrecht, Utrecht, Netherlands

Background: Survival rates have improved for patients with multiple myeloma (MM), yet relapse remains common. Data on real-world outcomes in these patients in Europe is limited.

Aims: To provide insights into the survival of patients with symptomatic MM in the Netherlands through a retrospective analysis of data from the PHAROS registry, a Dutch population-based database.

Methods: The PHAROS registry included patients with MM diagnosed between 2004 and 2012 (aged ≥18 years). The study population consisted of 1522 patients starting first-, second- or third-line therapy in 2008 or later (not all patients in the analysis on second- and third-line therapy were included in the analysis of previous lines). The primary endpoint was overall survival (OS); secondary endpoints included progression-free survival (PFS) and healthcare resource utilisation (HRU).

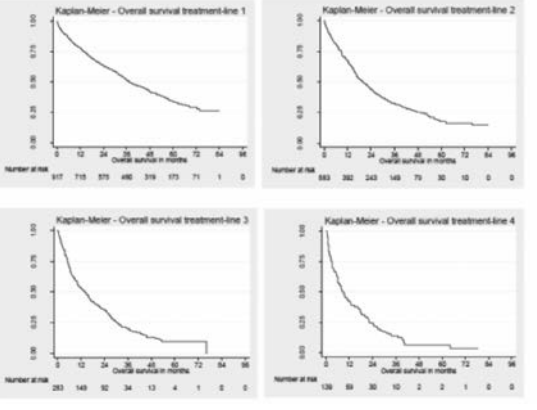


Figure 1. Kaplan-Meier curves of OS from first-, second-, third- and fourth-line therapy.

Results: Median patient age was 70, 71, 71 and 72 at the initiation of first-, second-, third- and fourth-line therapies, respectively. Median follow-up for the primary endpoint (OS from first-line therapy) was 62.4 months (95% confidence interval [CI]: 60.6, 64.3). First-line thalidomide-based regimens were prescribed to 66% of patients (n=608) and bortezomib-based regimens to 15% (n=139). In the second-line setting (n=583), the majority of patients received bortezomib- (41%, n=239) or lenalidomide- (27%, n=159) based regimens. Median OS (95% confidence interval [CI]) in first- (n=917), second- (n=583) and third-line (n=283) were 37.5 (34.8-41.8), 19.7 (17.2-22.9) and 13.9 (10.5-16.6) months, respectively. Median PFS (95% CI) were 18.0 (16.3-18.9), 8.9 (7.9-9.7) and 6.4 (5.5-7.2) months, respectively. Large differences were seen between subgroups in all treatment-lines, e.g. median OS from first-line therapy was 31.9 (29.1-35.4) and 64.6 (53.2-not reached) months for patients >65 years old and patients ≤65 years old, respectively, and was 32.2 (29.2-35.5) for patients without prior stem cell transplantation (SCT) (median OS not reached for patients

with prior SCT). Similarly, median PFS from first-line therapy was 16.2 (14.5-17.9) and 22.6 (19.8-26.5) months for patients >65 years old and patients ≤65 years old, respectively and 15.2 (13.6-17.0) and 32.0 (26.2-36.5) months for patients without or with prior SCT, respectively. Mean (standard deviation [SD]) number of inpatient days per month (excluding intensive care unit) were 1.7 (3.4), 1.4 (3.2) and 2.3 (4.6) in first, second and third-line, respectively.
Summary/Conclusions: In patients receiving first-line therapy for MM between 2008 and 2012 in The Netherlands, median OS was approximately three years. A difference in OS was observed for SCT *versus* non-SCT patients and resource use (inpatient stays) increased with later lines. Large differences in OS were also observed depending on a patient's age.

E1293

COMPARISON BETWEEN 8-COLOR MULTIPARAMETER FLOW CYTOMETRY AND NEXT-GENERATION SEQUENCING TO DETECT MINIMAL RESIDUAL DISEASE IN MULTIPLE MYELOMA PATIENTS WHO UNDERWENT AUTO-SCT

H Takamatsu[1,*], R Wee[1], N Takezako[2], J Zheng[3], V Carlton[3], M Moorhead[3], T Yoshida[4], M Faham[3], S Nakao[1]
[1]Cellular Transplantation Biology (Hematology/Respirology), Kanazawa University Graduate School of Medical Science, Kanazawa, [2]Department of Hematology, National Hospital Organization Disaster Medical Center of Japan, Tachikawa, Japan, [3]Adaptive Biotechnologies, South San Francisco, United States, [4]Department of Hematology, Shizuoka City Shimizu Hospital, Shizuoka, Japan

Background: Autologous stem cell transplantation (ASCT) in conjunction with novel therapeutic drugs can dramatically improve response rates and the prognosis of patients with multiple myeloma (MM). However, most patients with MM are considered to be incurable, and relapse owing to minimal residual disease (MRD) is the main cause of death among these patients. Therefore, new technologies to assess deeper responses are required. Next-generation sequencing (NGS) and multiparameter flow cytometry (MFC) methods have been used to assess MRD. However, the lack of standardization of conventional MFC approaches has had a negative impact on its reproducibility. Recently, a next-generation MFC method (EuroFlow) has been developed by the EuroFlow Consortium and the International Myeloma Foundation (IMF) for a highly sensitive and standardized detection of MRD in MM.
Aims: To compare the prognostic value of MRD detection in autografts in MM between NGS and EuroFlow.
Methods: A total of 22 newly diagnosed MM patients who underwent ASCT were included in this study. Median age 60 (range 41-65); males 14, females 8; ISS 1 (n=4), 2 (n=12), 3 (n=6). 6 patients showed high-risk chromosomal abnormalities (t(4;14) (n=6), del17p (n=1)). The induction regimen was bortezomib-based chemotherapy. All patients received melphalan 200 mg/sqm conditioning regimen before ASCT. 18 of 22 (82%) patients received maintenance therapy using lenalidomide or thalidomide. The best response post-ASCT was as follows: 10sCR, 1CR, 9VGPR, 2PR. 22 autografts, one from each MM patient, were analyzed using EuroFlow and NGS methods. The EuroFlow method was based on a standardized lyse-wash-and-stain sample preparation protocol, the measurement of high numbers of cells (≥5x10^6 cells/tube) and an optimized 8-color, 2-tubes, antibody panel, for accurate identification of plasma cells (PCs) and discrimination between phenotypically aberrant (aPC) and normal PC (nPC): tube 1: $CD138_{BV421}$ /$CD27_{BV510}$ /$CD38_{FITC}$ /$CD56_{PE}$ /$CD45_{PerCP-Cy5.5}$ /$CD19_{PE-Cy7}$ /$CD117_{APC}$ /$CD81_{APC-C750}$; and tube 2: $CD138_{BV421}$ /$CD27_{BV510}$ /$CD38_{FITC}$ /$CD56_{PE}$ /$CD45_{PerCP-Cy5.5}$ /$CD19_{PE-Cy7}$ /cytoplasmic (Cy) Immunoglobulin (Ig) κ_{APC} /Cyl$\lambda_{APC-C750}$. NGS-based MRD assessment was performed using the immunosequencing platform (Adaptive Biotechnologies, South San Francisco, CA) (Martinez-Lopez et al Blood 2014).

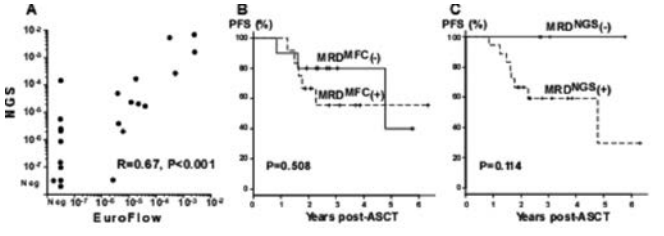

Figure 1.

Results: We identified abnormal plasma cells (aPC) in autografts based on multivariate analysis of individual cells from each patient (e.g. CD56+, CD19-, Cylgκ+, CD117+). For the MM MRD in autografts, the events from tube 1 and tube 2 were combined and a median of 5.6×10^6 (range: 1.3×10^6-11.7×10^6) events was acquired. 12 of 22 (55%) cases were MRD positive by 8-color MFC while 18 of 22 (82%) cases were MRD positive by NGS. The correlation of MRD level between 8-color MFC and NGS was relatively high (Fig. A). There was no significant difference in PFS between MRD negative cases by EuroFlow (MRD^{MFC} (-)) and MRD^{MFC} (+) cases (Fig. B) (P=0.508). However, MRD negative cases by NGS (MRD^{NGS} (-)) tended to show better PFS than MRD^{NGS} (+) (P=0.114) (Fig. C). There was no significant difference in overall survival between the MRD positive and negative groups.
Summary/Conclusions: In this comparison study of MRD assessment in autografts using Euroflow and NGS approaches, the NGS platform showed higher sensitivity and prognostic value than EuroFlow.

E1294

RENAL AND HEMATOLOGIC OUTCOMES OF BORTEZOMIB-BASED TREATMENT IN PATIENTS WITH LIGHT CHAIN DEPOSITION DISEASE

D Ziogas[1], M Roussou[1], D Fotiou[1], E Terpos[1], M Gavriatopoulou[1], E Eleutherakis-Papaiakovou[1], E Psimenou[1], I Boletis[2], M Spyropoulou-Vlachou[3], C Gakiopoulou[4], MA Dimopoulos[1], E Kastritis[1,1,*]
[1]Department of Clinical Therapeutics, [2]National and Kapodistrian University of Athens School of Medicine, [3]Immunology Lab, Alexandra Hospital, [4]Department of Pathology, National and Kapodistrian University of Athens School of Medicine, Athens, Greece

Background: Light chain deposition disease (LCDD) is characterized by amorphous deposits of monotypic immunoglobulin light chains in the kidneys leading inevitably to end-stage renal disease (ESRD) if untreated. LCDD is one of the recently defined monoglonal gammopathies of renal significance (MGRS) and less often is associated with an underlying symptomatic myeloma. However, no optimal treatment or response criteria for the evaluation of treatment outcomes have been established although bortezomib-based regimens have been recommended based on small patient series.
Aims: to evaluate the outcomes of LCDD after bortezomib-based treatment, the prognostic effect of clinicopathological characteristics and the impact of hematologic response to renal survival.
Methods: 18 consecutive patients with renal biopsy-proven LCDD who received primary therapy with bortezomib were included in the analysis.
Results: by IF all biopsies had linear staining exclusively for κ or λ chains along the TBM and/or GBM; other findings included interstitial fibrosis (78%), mesangial expansion/proliferation (72%), tubular atrophy (67%) and nodular mesangial sclerosis (56%). Median age was 65.5 (range: 46-85) years and 10(55%) patients were >65 years; 89% presented with hypertension, median 24h proteinuria was 3.3 gr (range 0.4-10.2), 13/18 patients had eGFR<60 ml/min and 9/18 (50%) had eGFR<30ml/min. Fourteen patients (78%) had measurable FLCs (dFLC≥50mg/l and abnormal ratio). Median bone marrow infiltration was 15% but no patient had symptomatic MM by the CRAB criteria. Bortezomib with dexamethasone (VD) was given in 12/18(67%) and VD plus cyclophosphamide (VCD) in 6/18 (33%) patients for a median of 4 cycles; 10/18(56%) received bortezomib SC. Among evaluable patients 11/14(79%) had a hematologic response (PR, VGPR or CR), including 5(36%) with CR, 1(7%) with VGPR and 5(36%) with PR. At the time of diagnosis or during follow-up, 6/18 (33%) patients progressed to ESRD. Three of the 9 patients improved their eGFR from<15 to 15-29ml/min and 3 patients from 15-29 to 30-59ml/min while 9/18 patients achieved a 50% reduction of proteinuria. Improvement in eGFR was observed only in patients (6 /14) who achieved a hematologic CR or VGPR, and no patient who achieved a VGPR or CR developed ESRD. In contrast, 5/8 patients who achieved a PR or less progressed to ESRD (P=0.031). Improvement of proteinuria was observed in all patients who achieved a CR and in 2/9 patients who achieved a hematologic PR. In univariate analysis baseline eGFR<30ml/min was associated with increased risk for ESRD (OR=8.75, p=0.086); no pathology feature was associated with renal response or risk of ESRD. Median follow-up is 39 months and 13/18 patients remain alive; only 3 (17%) had a hematologic relapse/progression. Two patients died on dialysis and median survival from initiation of dialysis was 5 (range:1-13) months. Three patients received ASCT as consolidation after bortezomib induction. Bortezomib-related peripheral neuropathy occurred in 67% (grade 2 in 7 and grade 3 in 2 patients); in 9/18 patients a dose reduction of bortezomib was required but no patient discontinued bortezomib due to neuropathy. Neuropathy grade ≥2 occurred in 7/8(87.5%) *vs* 2/10(20%) patients who received IV *vs* SC bortezomib (P=0.041).
Summary/Conclusions: bortezomib-based treatment is active and safe for patients with LCDD but at least a hematologic VGPR is required in order to improve renal prognosis. Prospective studies are needed to determine the optimal management for LCDD and identify further predictors for renal prognosis.

E1295

A POOLED ANALYSIS OF THE IMPACT OF AGE ON OUTCOMES IN PATIENTS WITH REFRACTORY OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA TREATED WITH POMALIDOMIDE+LOW-DOSE DEXAMETHASONE

Background: The survival duration of patients with multiple myeloma is inversely proportional to their age (Pulte et al, *Oncologist*, 2011). Pomalidomide (POM), a distinct immunomodulatory agent with tumoricidal and immunoregulatory effects, plus low-dose dexamethasone (LoDEX) is approved in the United States and European Union for the treatment of patients with relapsed and refractory multiple myeloma (RRMM) who have had ≥2 prior therapies, including lenalidomide and a proteasome inhibitor (bortezomib in the European Union). Approval was based on 2 phase 3 studies (Richardson, *Blood,* 2014; San Miguel, *Lancet Oncol,* 2013), and the regimen has been further evaluated in a large confirmatory study (Dimopoulos ASH 2015).
Aims: To conduct a pooled analysis of the impact of age on outcomes in patients treated with POM+LoDEX in 3 large trials.
Methods: Patients who provided informed consent, had ≥2 prior therapies, including lenalidomide and bortezomib, and progressed on or within 60 days of their last therapy were enrolled in the 3 trials. Patients received POM 4 mg/day on days 1-21 of each 28-day cycle and LoDEX 40 mg (20 mg for those >75 years of age) weekly until disease progression or unacceptable toxicity. Thromboprophylaxis was required. Outcomes analysis was conducted based on patient age subgroup (≤65, >65, ≤75, and >75 years).
Results: In total, 1097 patients were assigned to receive POM+LoDEX in the 3 trials and were included in the intent-to-treat population. Baseline demographic and disease characteristics were similar regardless of age (Table). Overall response rate (range, 32%-34%) and median progression-free survival (range, 4.2-4.6 months) were also similar across the age groups. Median overall survival was slightly longer in the ≤65 *vs* >65 subgroups (13.4 *vs* 11.9 months) but was similar in the ≤75 and >75 subgroups (12.3 months). The median duration of response was slightly longer in the >65 and >75 subgroups (7.7 and 9.0 months, respectively) compared with the ≤65 and ≤75 subgroups (7.0 and 7.1 months, respectively). In the 1088 patients who received at least 1 dose of POM+LoDEX (safety population), the median relative dose intensity was 0.9, and the median treatment duration was 4.8 months in each age subgroup. Grade 3/4 treatment-emergent adverse events (TEAEs), including neutropenia (range, 47%-50%), anemia (range, 29%-32%), thrombocytopenia (range, 17%-25%), and infections (range, 32%-35%) were similar across the age groups. Additionally, similar rates of TEAEs leading to dose reduction (range, 23%-26%) and interruption (range, 64%-69%) were observed in the four subgroups. POM discontinuation due to TEAEs was infrequent (range, 5%-8%).

Table 1.

	≤ 65 years	> 65 years	≤ 75 years	> 75 years
Intent-to-treat population	n = 542	n = 555	n = 971	n = 126
Median age, years	58	72	64	78

DVT/PE[b]	9 (2)	9 (2)	18 (2)	0
Peripheral neuropathy[b]	5 (1)	6 (1)	11 (1)	0
≥ 1 TEAE leading to dose reduction, n (%)	124 (23)	134 (24)	225 (23)	33 (26)
≥ 1 TEAE leading to dose interruption, n (%)	342 (64)	380 (69)	636 (66)	86 (68)
≥ 1 TEAE leading to discontinuation, n (%)	28 (5)	46 (8)	64 (7)	10 (8)

[a] ECOG status of 2 patients (> 65 and ≤ 75 years) is missing.
[b] Grouped term.
BORT, bortezomib; DOR, duration of response; DVT, deep vein thrombosis; ECOG, Eastern Cooperative Oncology Group; ISS, International Staging System; LEN, lenalidomide; MM, multiple myeloma; ORR, overall response rate; OS, overall survival; PE, pulmonary embolism; PFS, progression-free survival; TEAE, treatment-emergent adverse event; Tx, treatment.

Summary/Conclusions: POM+LoDEX demonstrated efficacy in patients with RRMM, with similar progression-free survival and response rates regardless of age; safety and efficacy in patients >75 years was comparable to that in patients<75 years. Similarly, the exposure and safety profile were similar across the age groups. These results support POM 4 mg as an effective starting dose and use of POM+LoDEX, regardless of age, in patients with RRMM.

E1296

PROSPECTIVE FUNCTIONAL GERIATRIC ASSESSMENT (CF-GA) IN MULTIPLE MYELOMA (MM) PATIENTS (PTS): CHANGES FROM BASELINE (T0) TO FOLLOW UP ASSESSMENT (T1)

A Zober[1,*], SM Dold[1], G Ihorst[2], M Pantic[1], S Knop[3], C Langer[4], J Duyster[1], M Schumacher[5], R Wäsch[1], M Engelhardt[1]
[1]Hematology & Oncology, [2]Clinical Trials Unit, University of Freiburg Medical Center, Freiburg, [3]Hematology & Oncology, University of Würzburg Medical Center, Würzburg, [4]Hematology & Oncology, University of Ulm Medical Center, Ulm, [5]Institute of Medical Biometry and Medical Informatics, University of Freiburg Medical Center, Freiburg, Germany

Background: Multiple myeloma (MM) is a hematologic malignancy, its incidence increasing with age. MM patients (pts) present with heterogeneous health status, whereby defined tests help to objectively define biological fitness, rather than considering pts' chronological age. This is specifically relevant, since treatment options are numerous today. For the discrimination of current therapies, a variety of MM- and patient-related risk factors, such as comorbidities (CM) and frailty can be considered. Therefore, the careful assessment of individual conditions before treatment and with subsequent, defined follow-up seems relevant. Therapy-related complications and early mortality may substantially increase in pts with CM, but may also change during treatment.
Aims: Our aim is to establish a prospective comorbidity and functional geriatric assesment (CF-GA) for MM pts and to show whether the GA shows substantial changes from baseline (T0) to follow-up (T1 and subsequently T2) and which tests are most indicative. This has - to the best of our knowledge - never been assessed in MM.
Methods: This prospective intervention trial performed a simple, defined GA in consecutive MM pts prior to initiation of antimyeloma treatment and during subsequent follow-up (6-12 [T1] and 24 months [T2]). The GA included the Karnofsky Performance Status (KPS), pain scale, rating of fitness, IADL, ADL, malnutrition, geriatric depression scale (GDS), mini-mental status (MMS) and established comorbidity (CM) scores: Charlson Comorbidity Index (CCI), Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), Myeloma Comorbidity Index (initial-MCI [I-MCI] and revised-MCI [R-MCI]; http://www.myelomacomorbidityindex.org) and Kaplan Feinstein (KF). The trial was approved by the ethics committees of the Freiburg University. All patients provided written informed consent and all procedures were conducted in accordance with the Declaration of Helsinki, the International Conference on Harmonization, and Guidelines for Good Clinical Practice.
Results: Currently a total of 97 consecutive pts have been included in this GA, all receiving both T0- and T1-assessment (median 12 months after treatment initiation). The median pt age was 60.3 years (27-83). Between T0 and T1, 54 pts had received stem cell transplants (n=49: ASCT, n=1: allo-SCT, n=4 auto-allo-SCT); and the other half of pts novel agent-containing, standard chemotherapy and/or regular surveillance. Significant changes between T0- to T1-assessments were observed for various GA tests as summarized in Table 1. Of note, all mean test and score results improved, most notably the I-MCI, R-MCI-, IMWG- and CCI-scores, whereas the Kaplan Feinstein and HCT-CI remained almost those of baseline levels. Moreover, the KPS, ADL, IADL, fitness as rated both by physicians and patients as well as MMS improved. Of interest, the fitness rating by physicians seemed to improve more substantially than that given by pts, demonstrating again that a brief GA assessment with simple tests is more objective than clinical judgement alone. Pain, depression and malnutrition also improved, albeit to lesser and non-significant extends.

Table 1. Ga via CM tests and scores: changes from baseline (T0) to follow-up (T1) (n=97 MM pts).

Comorbidity Tests / Scores	Mean T0 values	Mean T1 values	Mean changes from T0 -> T1	p-values
Functional comorbidity tests				
Karnofsky Performance Status (0%-100%)	73.9	87.7	13.8	**<0.0001**
Activity of Daily Living (0-6)	4.6	5.7	1.1	**<0.0001**
Instrumental Activity of Daily Living (0-8)	7.2	7.5	0.3	**0.0094**
Fitness by Physician (1-6)	3.5	3.0	-0.5	**<0.0001**
Fitness by Patient (1-6)	3.4	3.0	-0.4	**0.0040**
Mini Mental Status (0-30)	27.5	28.0	0.5	**0.0483**
Pain Scale Visual analogue Scale (0-10)	2.5	2.2	-0.3	0.22
Geriatric Depression Scale (0-15)	3.3	2.9	-0.4	0.1669
Comorbidity scores				
Revised Myeloma Comorbidity Index (0-9)	4.6	3.3	-1.3	**<0.0001**
Inital Myeloma Comorbidity Index (0-3)	0.6	0.3	-0.3	**<0.0001**
International Myeloma Working Group Score (0-5)	1.3	0.7	-0.6	**<0.0001**
Charlson Comorbidity Index (0-33)	2.0	1.5	-0.5	**<0.0001**
Kaplan Feinstein (0-3)	1.4	1.3	-0.1	0.1222
Hematopoietic Cell Transplant Comorbidity Index (0-26)	1.9	1.9	0.0	0.9756

Summary/Conclusions: Our CF-GA contains simple, reliable tests, which consistently and objectively test MM pts' fitness before and after treatment. Our results impressively demonstrate that MM pts' general and specific fitness

- as measured via defined GA tests - may improve during follow-up. This was induced by the implemented antimyeloma treatment, best supportive care measures and lower disease-specific symptoms after therapy. We continue this GA in an even larger prospective multicenter cohort to determine each test's predictive power for survival and treatment toxicity.

IMPROVEMENT OF OVERALL SURVIVAL IN DANISH MULTIPLE MYELOMA PATIENTS AFTER 2008; A POPULATION-BASED STUDY FROM THE DANISH NATIONAL MULTIPLE MYELOMA REGISTRY

N Abildgaard[1,*], A Vangsted[2], H Gregersen[3], N Frost Andersen[4], R Schou Pedersen[5], T Plesner[6], P Troellund Pedersen[7], M Frederiksen[8], U Froelund[9], C Helleberg[10], M Salamo[11], M Holmstroem[11], T Wirenfeldt Klausen[10], P Gimsing[11]
[1]Hematology, University Hospital Odense, Odense, [2]Hematology, University Hospital Copenhagen, Copenhagen, [3]Hematology, University Hospital Aalborg, Aalborg, [4]Hematology, University Hospital Aarhus, Aarhus, [5]Internal Medicine, Holstebro Hospital, Holstebro, [6]Internal Medicine, Vejle Hospital, Vejle, [7]Internal Medicine, Hospital of Southwestern Jutland, Esbjerg, [8]Internal Medicine, Hospital of Southern Jutland, Aabenraa, [9]Hematology, Roskilde Hospital, Roskilde, [10]Hematology, Herlev Hospital, Herlev, [11]Hematology, Rigshospitalet, Copenhagen, Denmark

Background: Improvement of overall survival in multiple myeloma (MM) after 2000 has been reported and it has been associated with introduction of new therapeutics (Kumar, *Blood* 2008,111,2516-20 & Kumar, *Leukemia* 2014,28,1122-28). The Danish National Multiple Myeloma Registry (DMMR) was established in 2005 and has registered all patients with newly diagnosed multiple myeloma in Denmark since 1 January 2005. The Danish Myeloma Study Group (DMSG) published in 2009 the first National evidence-based guideline for treatment of MM in Denmark. The guideline recommended bortezomib based induction treatment for younger MM patients prior to HDT and for elderly patients with aggressive disease presentation and adverse cytogenetics. Moreover, lenalidomide was included in the algorithm for treatment of relapsed/progressive disease.
Aims: We aimed to analyse population-based overall survival in Danish MM patients in relation to shift in National treatment guidelines in 2009.
Methods: At 30 June 2015, the database had registered a total of 2907 patients, 991 patients<65 years and 1916 patients >65 years, with newly diagnosed treatment-demanding MM. Age-adjusted survival analyses were done per 1 September 2015.
Results: Comparing OS for patients diagnosed in the two time periods 2005-2008 and 2009-2015, we found a highly significant improved age-corrected OS in patients >65 years, increasing from median 24.7 months (2005-08) to median 32.9 months (2009-15) (p=0.003). For patients<65 years at diagnosis the overall survival also improved from median 67 months (2005-2008) to above 74 months (median OS not yet reached) (2009-2015) (p=0.02). In patients >80 years at diagnosis the survival is poor and has not improved significantly between the 2 time periods (median 11.4 *vs* 14.9 months), and the early mortality rate in these very elderly is high (about 30% die within 6 months). The prognosis has particularly improved for MM patients that present with renal insufficiency. The database documents a shift in chosen therapies according to the National guidelines. Only, novel agents seem to have been less chosen for the most elderly patients.
Summary/Conclusions: Our "real life data" documents improved survival of MM patients in Denmark after 2008 and demonstrates a significant impact of National DMSG guidelines on treatment of multiple myeloma.

E1298

ASSESSING MYELOMA BONE DISEASE WITH WHOLE-BODY DIFFUSION-WEIGHTED MRI: COMPARISON WITH FDG PET-CT AND ASSESSMENT OF ADC VALUE

K Narita[1,*], Y Usui[1], Y Suehara[1], M Fujisawa[1], K Fukumoto[1], M Takeuchi[1], E Ouchi[2], Y Kikuchi[2], T Ouchi[2], K Matsue[1]
[1]Hematology/Oncology Kameda Medical Center, [2]Department of Radiology Kameda Medical Center, Kamogawa, Japan

Background: The recent International Myeloma Working Group (IMWG) consensus statement recommends whole-body magnetic resonance imaging (MRI) for patients with suspected smoldering multiple myeloma (SMM) and solitary plasmacytoma (Dimopoulos et al. 2015). Whole-body diffusion-weighted MRI (WB-DWI) is a promising technique with higher sensitivity for bone lesions and lower cost. However, little is known about its sensitivity compared to ^{18}F-fluorodeoxyglucose positron emission tomography (FDG PET-CT).
Aims: The aim of this study is to compare the sensitivity of myeloma-related bone disease by WB-DWI and FDG PET-CT, and to compare the apparent diffusion coefficients (ADC) of myelomatous lesions with normal healthy controls.
Methods: We identified patients with monoclonal plasma cell disorders that underwent WB-DWI between July 2015 and February 2016 at Kameda Medical Center, Kamogawa-shi, Japan. We compared disease burden by matched simultaneous assessments of WB-DWI and FDG PET-CT using a previously described scoring system based on the number and pattern (focal/diffuse) of disease in each body region (C-spine, T-spine, L-spine, pelvis, ribs/other, long bones). Whole-body score was calculated as the sum of each body lesion (Sharon et al. 2014). Scans performed in patients in different clinical status were excluded. We also analyzed ADC values of WB-DWI in comparison to eight healthy volunteers. Minimal ADC values were measured in each body region (C-spine, T-spine, L-spine, pelvis, ribs/other) and whole-body ADC value was defined as the mean ADC value of each body region. Inversion grayscale maximum intensity projection images of whole-body diffusion-weighted and ACD maps with *b* value=900s/mm^2 were assessed in this study. All statistical analyses were performed with EZR, which is a graphical user interface for R ver. 3.2.1.
Results: We identified 64 patients that underwent WB-DWI during the study period. Fifty patients underwent FDG PET-CT in the same disease status. Median age of the patients was 71 years (range: 53-89) and 23 (44.8%) were male. Three patients had monoclonal gammopathy of undetermined significance (MGUS), five patients had SMM, and 42 patients had symptomatic MM, including five with plasmacytoma. Diffuse lesions were found in 15 (30%) patients by WB-DWI, while FDG PET-CT detected two (4%) diffuse lesions. The detection ratio of focal lesions was the same for both procedures. The whole-body score was significantly higher in WB-DWI than FDG PET-CT (WB-DWI: mean 5.61±8.56 *vs* FDG PET-CT: mean 1.08, *P<0.001*). In each body region, scores for WB-DWI were significantly higher than those for FDG PET-CT. ADC values were analyzed in 64 patients that underwent diffusion-weighted WB-MRI and compared with eight healthy volunteers. Median age and number of male patients was 71 years (range 47-89) and 25 (39.6%), respectively. Four patients were diagnosed as MGUS, eight patients had SMM, and 51 patients had MM, including five with plasmacytoma. The median ADC value of the whole body was significantly lower in patients with monoclonal plasma cell disorders than in the healthy volunteers (680mm^2/s x10^{-6} *vs* 765.5 mm^2/s x10^{-6}, *P*=0.02). In each body region except C-spine and ribs/other, the ADC value was significantly lower in patients with monoclonal plasma cell disorders than in the healthy volunteers.

Table 1.

Score of WB-DWI vs FDG PET-CT

N=50	Score Mean (±SD)		P-value
	FDG PET-CT	WB-DWI	
WholeBody	1.08(±3.29)	5.61(±8.56)	<0.001
Region			
C spine	0.10(±0.59)	0.83(±1.49)	<0.001
T spine	0.24(±0.66)	1.02(±1.60)	0.001
L spine	0.10(±0.59)	0.73(±1.41)	0.002
Pelvis	0.26(±0.84)	0.91(±1.45)	<0.001
Long bones	0.10(±0.59)	0.65(±1.40)	0.005
Ribs/other	0.20(±0.41)	1.10(±1.66)	<0.001

Wilcoxon matched-pairs signed rank test

Summary/Conclusions: In patients with monoclonal plasma cell disorders, WB-DWI is more sensitive than FDG PET-CT for detection of bone lesions. Assessment of ADC value is an effective method for detecting bone lesions of monoclonal plasma cell disorders.

E1299

IMPROTANCE CD138 IMMUNOSTAINING FOR ASSESSMENT OF BONE MARROW PLASMA CELL INFILTRATION IN PATIENTS WITH MULTIPLE MYELOMA

Y Usui[1,*], Y Matsue[2], K Kumada[3], K Narita[1], M Takeuchi[1], K Matsue[1]
[1]Hematology/Oncology, [2]Cardiology, [3]Clinical Pathology, Kameda Medical Center, Kamogawa-shi, Japan

Background: Estimation of plasma cell (PC) infiltrates in bone marrow (BM) is integral to the diagnosis and monitoring of patients with multiple myeloma (MM). Traditionally, quantification of BM PCs has been performed by differential counting of May-Giemsa-stained aspirate smears. Although previous studies consistently showed a higher % of PCs in BM biopsy sections compared to BM aspirate smears, BM biopsy with CD138 immunostaining has not been widely adopted in clinical practice.
Aims: This study was performed to clarify the importance of CD138 immnostainig for quantification of BM PC by comparing the different methods [BM aspirate clot, BM aspirate smear, and multicolor flow cytometry (FCM)] in patients with MM and monoclonal gammmopathy of undetermined significance (MGUS). In addition, to clarify the clinical relevance of quantifying BM PCs by CD138 immunostaining, 116 patients with monoclonal gammopathy who did not fulfill the criteria of smoldering MM (sMM) based on aspirate smears were reexamined for its diagnosis by BM clots stained with anti-CD138 monoclonal antibody.
Methods: A total of 150 samples of BM biopsy and smears from 100 patients with MGUS and MM, at diagnosis or following therapy were selected. Percentages of PC of aspirated marrow was quantified by May–Giemsa staining, multicolor flowcytometry (MFC), and CD138 immunostianing of BM clot section and biopsy section. PC identification by FCM required at least two markers, *i.e.*, CD38 and either CD45 or CD138. The percentages of PC were calculated relative to the total nucleated cell population. We also investigated the clinical relevance of CD138 immunostaining in the differentiation of MGUS and MM. BM slide sets from 116 untreated patients with M-protein level <3000mg/dL in

serum or 500mg/day in urine and without organ damage were re-assessed with based on the % of BM PCs by CD138 immunostaining.
Results: Median % of PC measured by BM biopsy, BM clot, BM smear, and FCM were 13.3%, 12.8%, 3.7%, and 2.4%, respectively. There were significant correlations between BM biopsy and the three other measurement methods, and BM clot showed the strongest correlation with BM biopsy (r=0.94). In correlation analysis, BM biopsy and BM clot showed significant and very strong correlations in both NCC ≥40×10^3/μL and NCC<40×10^3/μL (r=0.95 and r=0.91, respectively). Bland-Altman plots showed that BM biopsy agreed well with BM clot but not with BM smear or FCM. There was a significant fixed bias between BM biopsy *vs* BM smear and BM FCM with mean difference of 15.0% and 16.4%, respectively, indicating that both of these measurements significantly underestimated PCs compared to BM biopsy. However, no significant fixed bias between BM biopsy and BM clot was observed (mean difference: 1.1%). Proportional bias by regressing the differences in values on means of values with linear regression analysis showed significant proportional bias between BM biopsy and BM smear and FCM, but not between BM biopsy and BM clot. As CD138 immunostaining consistently yielded a higher percentage of BM PCs than aspirate smear, it is possible that a considerable portion of patients diagnosed as MGUS by aspirate smear alone could be reclassified as sMM by CD138 immunostaining of BM clot or biopsy. We retrospectively reanalyzed the 116 consecutive patients with monoclonal gammopathy and <3000 mg/dL or 500 mg/dL M-protein in serum or urine at our hospital. Among the 116 patients that met the above criteria, 13 patients (11%) were classified as sMM as PCs exceeded 10% on aspirate smears. Among the remaining 103 patients, 59 patients (51%) showed >10% PCs by CD138 immunostaining and was reclassified as sMM and the remaining 44 patients (38%) were still classified as MGUS.

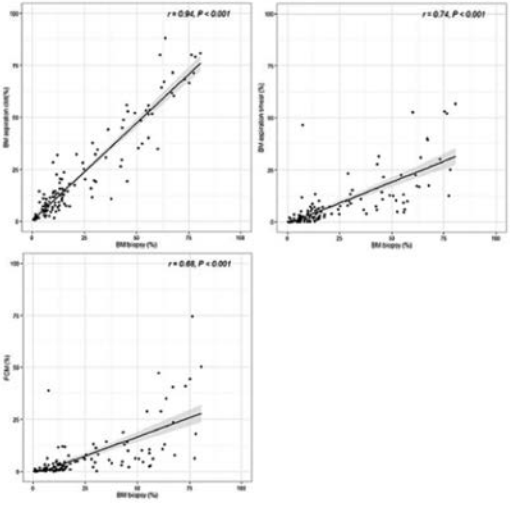

Figure 1.

Summary/Conclusions: Our data showed that considerable portion of sMM patients could be misclassified as MGUS by bone marrow smear alone and highlight the necessity of CD138 immunostaining of BM biopsy/clot specimens for correct diagnosis.

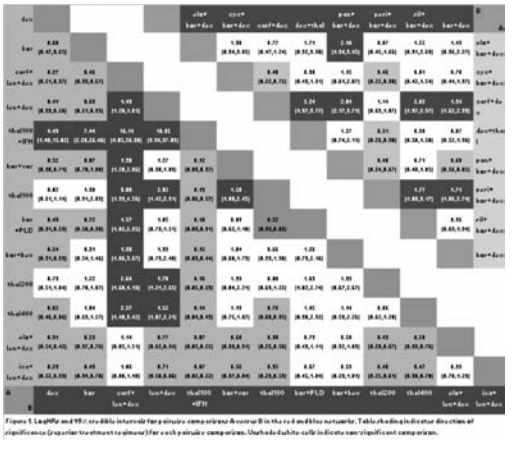
E1300

UPDATED RESULTS OF A SYSTEMATIC REVIEW OF THE RELATIVE EFFECTIVENESS OF TREATMENTS IN RELAPSED/REFRACTORY MULTIPLE MYELOMA

Á Maguire[1,*], S Schmitz[2], I Kuhn[3], E Haller[4], A Khan[5], G Cook[6], M O'Dwyer[7], C Walsh[8], K Ruggeri[1]
[1]Department of Psychology, University of Cambridge, Cambridge, United Kingdom, [2]Trinity College Dublin, Dublin, Ireland, [3]School of Clinical Medicine, University of Cambridge, Cambridge, United Kingdom, [4]Department of Psychology, University of Zurich, Zurich, Switzerland, [5]Institute for NanoBioTechnology, Johns Hopkins University, Baltimore, United States, [6]University of Leeds, Leeds, United Kingdom, [7]Department of Haematology, University Hospital Galway, Galway, [8]Department of Mathematics & Statistics, University of Limerick, Limerick, Ireland

Background: Outcomes for multiple myeloma (MM) have improved with the introduction of novel therapies, and ongoing trials suggest positive outlooks for those with relapsed/refractory MM (rrMM). However, head-to-head clinical trials across treatment options are limited, and as such the evidence on relative effectiveness to inform best practice is lacking. A recent systematic review[1] attempted to address this via a mixed treatment comparison using data from randomised control trials (RCTs) published before 2015. A network meta-analysis (NMA) was developed to estimate relative treatment effectiveness in this review, and two evidence networks were compiled, but no comparisons could be drawn across networks.
Aims: This systematic review is an update to a previously published study and aims to estimate the relative effectiveness of treatments for rrMM using the most up to date information available.
Methods: The literature search for the previous analysis was conducted in August and repeated again in December 2014. The search was then repeated January 2016 to identify further RCTs which might have been published in the interim. Data was extracted from all RCTs that reported median duration of progression-free survival (PFS), overall survival (OS) or time to progression (TTP) as a primary or secondary treatment outcome. A Bayesian NMA using non-informative prior distributions and assuming fixed effects was fitted due to scarcity of data in the networks. The number of prior treatment lines among patients recruited into trials in rrMM varied (1-5) and trials conducted in heavily pre-treated and refractory patient populations (a median of 3 or more prior lines of therapy) were excluded from the presented analysis in an attempt to reduce some heterogeneity.
Results: 14 RCTs were included in the initial analysis[1]. These 14 trials assessed 16 different treatment regimens. From the updated review, 5 new RCTs which presented PFS or TTP data for 5 additional treatment regimens were identified to be included into the existing NMA. The combined trials form two separate evidence networks; all pairwise comparisons in each network were estimated in the analysis (figure 1). No relative effects between the two networks could be estimated. In the larger evidence network, novel agents combined with len+dex had superior outcomes with carf+len+dex being the most effective treatment, followed by ixa+len+dex, and then elo+len+dex. In the other, smaller evidence network, bort+dex+pan was the most effective treatment, followed by bort+dex+cyc.

Table 1.



Summary/Conclusions: The availability of treatments for rrMM is rapidly increasing. Within a year of conducting an initial systematic review the PFS and TTP outcomes of five additional RCTs of treatments for rrMM were released. Results of the larger network suggest that novel agents combined with len+dex have superior outcomes compared to other treatment options in the network. Less inferences can be drawn from the smaller network; of the newly included RCTs bort+dex+cyc ranked second in the network, whilst new treatment regimens elo+bor+dex and carf+dex ranked lower, and demonstrated no significant superiority relative to all other treatments in the network. The networks are not connected and as such it is impossible to make comparisons between the two regarding overall effectiveness of treatments. More RCTs comparing existing treatment regimens would greatly supplement these comparisons and allow for greater certainty. Nonetheless, the presented analysis is a significant step in evidence-based assessment for treatment in rrMM which indicates that novel agents combined with len+dex substantially improve treatment outcomes.

DURATION OF THERAPY IN U.S. PATIENTS TREATED FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM) IN THE REAL-WORLD

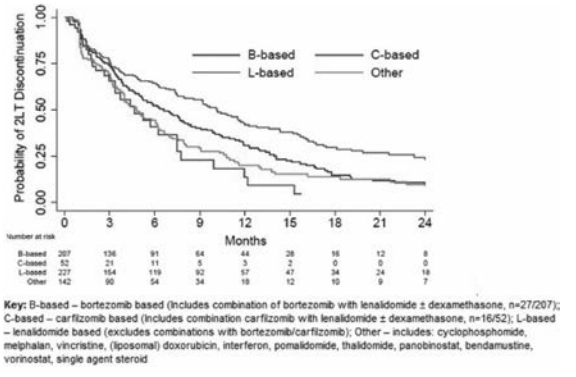
D Romanus[1,*], A Raju[2], C Yong[1], B Seal[1], E Farrelly[2], S Noga[3], M Jhaveri[1], R Labotka[4], M Blazer[5], H Parameswaran[6]
[1]Global Outcomes Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Real-World Evidence, Xcenda, Palm Harbor, [3]US medical Affairs, [4]Oncology Clinical Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [5]Global Health Economics and Outcomes Research, Xcenda, Palm Harbor, [6]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI, United States
Background: Extended duration of therapy (DOT) is associated with better clinical outcomes in clinical trials in patients (pts) with multiple myeloma (MM)

(Palumbo 2015; Mateos 2015). Many of the factors that influence DOT are more prevalent outside of clinical trials, including older age, and concomitant comorbidities. Real-world data related to DOT among RRMM pts are limited.
Aims: This study aims to 1) describe DOT of second line (2LT) and third line (3LT) therapy in RRMM, and 2) evaluate the associations between 2LT DOT and age; comorbidities; and regimen type.
Methods: In this retrospective cohort study, newly diagnosed adult MM pts initiating first-line therapy (1LT) between 1/2008 and 12/2014 were followed in a large U.S. national electronic medical records (EMR) database to identify 2LT accordingly: 1) retreatment after a treatment gap of >3 months of 1LT, or 2) a switch to another drug combination after starting 1LT. 3LT began with a switch to another regimen after 2LT. Pts with salvage stem cell transplants were excluded. Kaplan-Meier analyses were performed to calculate DOT from start of both 2LT and 3LT. Observations were censored at time of loss to follow up/end of study period (6/30/2015). A two-tailed log-rank test was used to test for statistical significance between groups.
Results: Among 628 pts, 37.1% were ≥75 years of age; 51.0% were male; 66.4% had ≥1 of the following comorbidities of interest at initiation of 2LT: diabetes, renal insufficiency, thromboembolic disease, cardiovascular disease, peripheral neuropathy. In 2LT, pts were most commonly treated with lenalidomide (L)-based regimens (36.2%) without bortezomib (B), followed by B-based therapies (33.0%, with/without L). Carfilzomib (C)-based treatments were least common (8.3%, with/without L). The remaining regimens (Other) comprised of MM-therapies without L, B, or C (22.6%). Overall, the median DOT in 2LT and 3LT was 6.9 months (mos) (95% CI: 5.9, 7.7) and 5.5 mos (95% CI: 4.0, 6.2), respectively. DOT in 2LT was similar for those <75 *vs* ≥75 years, median: 6.3 mos (95% CI: 5.2, 7.6) and 7.4 mos (95% CI: 5.9, 9.2), *P*>0.05, respectively (Table). Pts with baseline comorbidities of interest were significantly more likely to have a shorter DOT in 2LT, median: 6.2 mos (95% CI: 5.0, 7.4) compared to pts without, median: 9.2 mos (95% CI: 7.0, 11.9), *P*=0.02. In 2LT, the drug composition of the regimen was significantly associated with DOT (*P*<0.0001). L-based therapies had the longest DOT (median: 10.1 mos; 95% CI: 7.9, 11.9) compared to B-based (median: 6.6 mos; 95% CI: 5.1, 8.0), C-based (median: 4.6 mos; 95% CI: 3.0, 7.5) and Other regimens (median: 4.8 mos; 95% CI: 3.9, 6.2) (Figure).

Table 1. DOT of 2LT by age and comorbidity.

		Treatment Duration (in months)				
		Mean	SE	Median	Lower 95% CI	Upper 95% CI
2nd Line	*Overall*	11.71	0.68	6.90	5.90	7.67
By Age	*Age <75*	11.68	0.81	6.27	5.17	7.57
	Age ≥75	11.22	0.99	7.43	5.90	9.20
By Comorbidity	*Present*	11.07	0.83	6.17	4.97	7.40
	Absent	12.82	1.07	9.23	6.97	11.90

Key: CI – confidence interval; SE – standard error



Key: B-based – bortezomib based (includes combination of bortezomib with lenalidomide ± dexamethasone, n=27/207); C-based – carfilzomib based (includes combination carfilzomib with lenalidomide ± dexamethasone, n=16/52); L-based – lenalidomide based (excludes combinations with bortezomib/carfilzomib); Other – includes: cyclophosphomide, melphalan, vincristine, (liposomal) doxorubicin, interferon, pomalidomide, thalidomide, panobinostat, bendamustine, vorinostat, single agent steroid

Figure 1. Treatment duration by regimen type in 2LT.

Summary/Conclusions: DOT wanes with subsequent lines of therapy. Baseline comorbidities and regimen type in 2LT are significantly associated with DOT. The longest median DOT was observed with L-based therapies and the shortest DOT with C-based therapies. Tailored therapy choices that account for pts' baseline comorbidities may mitigate the observed variation in DOT.

THE SERUM HEAVY/LIGHT CHAIN IMMUNOASSAY SERVES AS AN ADDITIONAL VALUABLE TOOL FOR SENSITIVE PARAPROTEIN ASSESSMENT, RISK STRATIFICATION AND DISEASE MONITORING IN PATIENTS WITH MONOCLONAL GAMMOPATHY

C Greil*, FG, G Ihorst, E Bisse, R Wäsch, M Engelhardt
University hospital Freiburg, Freiburg, Germany

Background: A novel polyclonal immunoassay specific for the different light chain types of intact immunoglobulins (Ig) enables measurement of changes in the production of clone specific Ig and of the non-involved polyclonal Ig of the same isotype. This serum heavy/light chain immunoassay (HLC) was developed to recognize and separately quantify light chain types of each intact Ig class. Prior studies have demonstrated that immunofixation (IFE) and HLC-assay are complementary methods, and that HLC-values and -ratios serve as additional parameters for evaluation of response and early relapse recognition in patients with monoclonal gammopathies.
Aims: We aimed to a) investigate the HLC-assay compared to standard Multiple Myeloma (MM)-diagnostics in consecutive MM, smoldering MM (SMM) and Monoclonal gammopathy of undetermined significance (MGUS) patients, b) assess HLC results in MM *vs* MGUS and SMM patients, c) define a possible HLC cut-off for high-risk SMM patients and d) decipher the role of the HLC-assay for response, stage groups, progression free (PFS) and overall survival (OS) in MM.
Methods: We investigated the HLC [Hevylite™]-assay and compared its results to standard diagnostics, such as the capillary zone electrophoresis (CZE) and serum free light chain (SFLC)-assay: SFLC and HLC (IgGκ/IgGλ, IgAκ/IgAλ, IgMκ/IgMλ) measurements were performed using polyclonal antisera Freelite™ and Hevylite™ assays. Standard diagnostics for MGUS, MM and Waldenström's Macroglobulinemia (WM) patients also included IFE and bone marrow aspiration/biopsies as well as stage (Durie and Salmon and International Staging System [ISS]) and EBMT response assessment.
Results: We assessed 146 consecutive patients with abnormal M-spike via CZE: 57 had IgGκ-MM, 24 IgGλ-MM, 8 IgAκ-MM, 7 IgAλ-MM, 5 SMM, 5 light-chain-only MM, 28 MGUS and 12 had IgM WM. HLC-values and -ratios significantly correlated with the respective Ig values, isotype-matched SFLCs, M-gradient, ISS and remission status. Of note, with measurement of HLCs, up to 33% more pathological serum values were detected than via SFLC-assay alone. Moreover, due to pathological HLC-values, 57% of patients with MGUS were reclassified as SMM or MM, suggesting that the assay may assist in recognition of true MGUS, SMM *vs* symptomatic MM patients. Furthermore, patients with WM-M-spikes - the latter often difficult to quantify - revealed a clearly abnormal median IgMκ/λ ratio of 231 (normal range: 1.0-2.4). PFS in patients with extreme (<0.5/>50) HLC-values *vs* those without (0.5-50) was significantly impaired.
Summary/Conclusions: The HLC-assay is of particular value to monitor slow or indolent disease progression. Moreover, in WM, it can be a helpful additional technique to quantify the amount of monoclonal Ig clone and to more reliably decipher MGUS from SMM/MM patients.

ASSESSMENT OF FRAILTY IN A MULTIPLE MYELOMA (MM) SERIES

E Nikolaou*, D Maltezas, T Tzenou, T Iliakis, E Koulieris, M Dimou, A Bitsani, S Kotsanti, P Papaioannou, P Petsa, P Panayiotidis, MC Kyrtsonis
University of Athens-Medical School, Laikon General Hospital of Athens, Athens, Greece

Background: An increasing number of articles overflow literature concerning the importance of frailty assessment in elderly MM patients in treatment decisions making. Nevertheless, little is known about frailty assessment influence/importance in younger MM patients.
Aims: To assess frailty and investigate its impact in MM patients of any age.
Methods: We studied 409 MM patients, diagnosed and followed –up in our department. Median age was 69 years (31-90) while 55% were males. Twenty-eight percent, 25% and 47% were Durie-Salmon staged 1, 2 and 3 respectively, while 32%, 26% and 42% were ISS staged I, II and III respectively. Twenty-seven percent were asymptomatic (Smoldering MM). MM type was IgG in 66%, IgA in 22% and light-chain in 11% of the population, while 4 patients (1%) were biclonal. Frailty score was estimated following the Geriatric Assessment formula that involves Renal score, Katz andAkpom's basic activities of daily living (BADL) scale, Lawton and Brody's instrumental scale (IADL), and the Charlson Comorbidity Index (CCI). Statistical analysis was performed conventionally with SPSS v22.0 software.
Results: Of the 409 patients 24% were fit (frailty score 0), 39% were unfit (frailty score 1) and the rest were frail (14%, 19%, 3% ans 1% with frailty scores 2, 3,4,5 respectively). Frailty score was correlated to OS in the whole cohort (p<0,0001), being more significant in the symptomatic (p<0, 0001) than in the asymptomatic group (p=0,01). In the symptomatic patients, all the parameters examined were significantly correlated to OS [IADL (p<0,0001), BADL (p<0,0001), Renal score (p<0,0001), Performance status (PS) (p<0,0001), ISS (p=0,01), abnormal Ca (p=0,006) and abnormal LDH (p=0,007)]. In the Multiple regression analysis, only ISS (p=0,009), PS (p<0,0001) and level of fitness (p=0,018) preserved their prognostic value. However, in the patient group >70 years, parameters proven statistically important were GFR (p<0,0001) and CCI (p=0,04), while, in the age group >75 years, only CCI was correlated to OS (p=0,002). Finally frailty parameters proved to be more powerful in younger patients (<65 years), for whom GFR (p<0,0001), CCI (p=0,001), IADL (p=0,009) and level of fitness (p=0,002) were correlated to OS.
Summary/Conclusions: Intriguingly, frailty score better predicted OS in young MM patients than in elderly ones.

E1304

OVERALL RESPONSE RATE OF PATIENTS WITH REFRACTORY MULTIPLE MYELOMA TREATED WITH POMALIDOMIDE AND LOW DOSE DEXAMETHASONE AFTER LENALIDOMIDE FAILURE: INTERIM RESULTS OF THE POSEIDON STUDY

T Dechow[1,*], A Aldaoud[2], HJ Hurtz[3], W Knauf[4], M Groschek[5], R Hansen[6], J Mittermüller[7], S Grebhardt[8], E Boller[8], K Potthoff [8]
[1]Onkologie Ravensburg, Ravensburg, [2]Gemeinschaftspraxis für Hämatologie & Onkologie, Leipzig, [3]Onkologische Gemeinschaftspraxis, Halle (Saale), [4]Onkologische Gemeinschaftspraxis, Frankfurt a.M., [5]Hämatologie - Onkologie - Stolberg, Stolberg, [6]Onkologische Schwerpunktpraxis, Kaiserslautern, [7]Praxis für Innere Medizin, Hämatologie & Onkologie, Germering, [8]iOMEDICO AG, Freiburg, Germany

Background: The management of patients with primary refractory or relapsed and refractory multiple myeloma (RRMM) who failed lenalidomide and bortezomib treatment poses a clinical challenge. Prognosis for these patients is poor. The pivotal MM-003 trial demonstrated a benefit of the oral regimen pomalidomide (POM) in combination with low dose dexamethasone (LoDEX) for RRMM patients who had failed lenalidomide and bortezomib treatment. With a median follow-up of 10 months, POM+LoDEX showed an overall response rate (ORR; ≥partial response [PR]) of 31% *vs* 10% (p<0.001), a significantly longer progression-free survival (PFS) and a significant improvement in overall survival (OS) compared to high-dose DEX. Efficacy of POM+LoDEX was consistent across various age groups and tolerability was unaffected by age.
Aims: POSEIDON is a non-interventional, prospective, multicenter study designed to further evaluate effectiveness (ORR, PFS, OS) and safety of POM+LoDEX in routine clinical practice. It is carried out in 55 private practices and outpatient clinics in Germany.
Methods: Transplant-ineligible patients with RRMM who have received at least two prior lines of therapy including both lenalidomide and bortezomib, and who have demonstrated disease progression or were refractory to their last line of treatment could be enrolled. Patients received POM+LoDEX according to SmPC and were treated until disease progression or the development of unacceptable toxicity. At enrollment, patients were prospectively assigned to two subgroups with regard to lenalidomide in the preceding treatment line (subgroup A) or no lenalidomide in the preceding treatment line (subgroup B). The interim analysis was based on the modified intention-to-treat population including all patients who received at least one dose of POM.
Results: At data cut-off for this interim analysis (December 1st, 2015), 138 patients have been enrolled; 126 patients were evaluable with a median follow-up of 6.9 months. 66 and 60 patients were assigned to subgroup A and subgroup B, respectively. Median age was 74 years (range 46-87) with 49% and 43% of patients >75 years of age in subgroups A and B, respectively. 59% were male. The median time from diagnosis was 4.8 years (range 0.4-18.2). Median number of prior treatment lines was n=3 (range 2-9), with n=2 in subgroup A (range 2-9), and n=4 in subgroup B, respectively (range 2-9). For the 99 patients (55 patients in subgroup A, 44 patients in subgroup B) who received POM+LoDEX and had at least one response evaluation documented at data cut-off, the ORR was 26% in subgroup A and 52% in subgroup B, respectively. Additionally, 13% (subgroup A) and 9% (subgroup B) of these patients achieved a minor response. The most common ≥grade 3 adverse events were leukopenia (10%) and anemia (7%), respiratory tract infections (10%) and vascular disorders (3%).
Summary/Conclusions: The results of this interim analysis confirm the beneficial effectiveness and safety of POM+LoDEX in heavily pretreated RRMM patients in a real-life setting. Even lenalidomide and bortezomib refractory patients with lenalidomide in the preceding treatment line and heavily pretreated patients >75 years of age do benefit from POM+LoDEX treatment. The interim data of the non-interventional POSEIDON study are encouraging and highlight the potential clinical value of POM+LoDEX in these poor prognosis patients.

E1305

IXAZOMIB PLUS LENALIDOMIDE-DEXAMETHASONE (IRD) *VS* PLACEBO-RD IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM): CHINA CONTINUATION OF TOURMALINE-MM1

J Hou[1,*], J Jin[2], Y Xu[3], D Wu[4], X Ke[5], Z Daobin[6], J Lu[7], X Du[8], X Chen[9], J Li[10], J Liu[11], B Wang[12], X Zhang[12], H Wang[12], H van de Velde[12], P Richardson[13], P Moreau[14]
[1]Department of Hematology, ChangZheng Hospital, The Second Military Medical University, Shanghai, [2]First Hospital Affiliated Zhe Jiang Medical University, Zhejiang, [3]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Tianjin, [4]The First Affiliated Hospital of SooChow University, Suzhou, [5]The Third Affiliated Hospital of Beijing Medical University, [6]Peking Union Medical College Hospital, [7]Peking University People's Hospital, Beijing, [8]Guangdong General Hospital/ Guangdong Academy of Medical Sciences, Guangzhou Guangdong, [9]Xijing Hospital, The Fourth Military Medical University, Xi'an, [10]Ruijin Hospital, Shanghai Jiao Tong University, Shanghai, [11]The Third Hospital Xiang Ya Medical University, Hunan, China, [12]Millennium Pharmaceuticals Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, [13]Dana-Farber Cancer Institute, Boston, United States, [14]University Hospital Hôtel Dieu, Nantes, France

Background: The global, randomized, double-blind, placebo-controlled, phase 3 TOURMALINE-MM1 study (NCT01564537) demonstrated 35% improvement in PFS (HR 0.74, p=0.012) with IRd *vs* placebo-Rd in pts with RRMM (Moreau et al, ASH 2015).
Aims: This continuation study assessed the efficacy and safety of IRd *vs* placebo-Rd in pts with RRMM in China as a separate regional expansion of the global study.
Methods: Eligibility criteria and study design were per the global study, except high-risk cytogenetic and patient-reported outcome endpoints were not assessed. The primary endpoint was PFS, assessed by the same independent review committee (IRC) used in the global study. Pts were analyzed separately from the global study. Sample size was not based on a formal statistical hypothesis.
Results: 115 pts were randomized and treated (57 IRd, 58 placebo-Rd). Compared to the global study, pts had more advanced disease (63% ISS stage II/III *vs* 46% in the global study), were more heavily pretreated (60% *vs* 41% had 2 or 3 prior therapies), had more frequently received prior thalidomide (84% *vs* 45%), and more frequently had refractory MM (43% *vs* 11%). At data cut-off (12 July 2015; median follow-up 8.0 *vs* 7.8 mos for IRd *vs* placebo-Rd), PFS was significantly improved with IRd *vs* placebo-Rd: median PFS 6.7 *vs* 4.0 mos; HR 0.598; 95% CI 0.367–0.972; p=0.035. This benefit was seen across most prespecified subgroups including those with ISS stage I/II at screening, pts who had received 2–3 prior therapies, or prior proteasome inhibitor/IMiD compound therapy. A prespecified sensitivity analysis of PFS according to the EMA censoring rules was consistent with the primary analysis: median PFS 5.8 mos *vs* 4.0 mos; HR 0.543; 95% CI, 0.340–0.869; p=0.009. TTP was also significantly improved with IRd *vs* placebo-Rd: median TTP 7.3 *vs* 4.1 mos; HR=0.583; p=0.032. OS data were not yet mature; 6 (11%) IRd and 16 (28%) placebo-Rd pts have died. The study remains blinded and is ongoing with a final analysis for mature OS data planned. Overall response rate was 56% *vs* 31% (odds ratio=2.84, p=0.007); the ≥VGPR rate was 25% *vs* 12%. Among responders, the median duration of response was 7.4 mos with IRd *vs* 5.6 mos with placebo-Rd. Pts had received a median of 7 and 5 cycles of IRd and placebo-Rd, and 59% and 41% of pts remained on treatment. The median relative dose intensities of all drugs were high (>95%), similar between arms, and consistent with the global study. The overall safety profile was similar in both treatment groups: 56% *vs* 62% had grade ≥3 AEs, 23% *vs* 26% had SAEs, 5% *vs* 12% discontinued treatment due to AEs, and 4% *vs* 5% died on treatment. Common grade ≥3 AEs with IRd *vs* placebo-Rd included thrombocytopenia (23% *vs* 13%), neutropenia (23% *vs* 19%), anemia (12% *vs* 26%), and pneumonia (16% *vs* 10%). Rash was seen in 18% *vs* 19% of pts (no grade ≥3 events); 7% of pts in each group had peripheral neuropathy (no grade ≥3 events). There was no evidence of cardiac or renal toxicity with the addition of ixazomib, and no new primary malignancies. Based on an observed higher incidence of herpes zoster reactivation in the IRd treatment group (18%) *vs* placebo-Rd (0%), the IDMC recommended an antiviral prophylaxis requirement for the entire study population still on treatment; the China continuation protocol was amended accordingly.
Summary/Conclusions: In Chinese pts with RRMM, IRd was associated with a significant improvement in PFS, with limited additional toxicity, demonstrating the consistent relative benefit of IRd *vs* placebo-Rd in this distinct Chinese population and the global study.

E1306

PROSPECTIVE EVALUATION OF PROGNOSTIC AND PATHOPHYSIOLOGIC IMPLICATIONS OF BLOOD PRESSURE MONITORING AND BARORECEPTOR REFLEX SENSITIVITY (BRS) IN PATIENTS WITH AL AMYLOIDOSIS

E Kastritis[1,*], M Roussou[1], M Gavriatopoulou[1], D Fotiou[1], D Ziogas[1], M Gavriatopoulou[1], K Stamatelopoulos[1], C Pamboucas[1], E Papadopoulou[1], F Michas[1], A Lykka[1], E Terpos[1], S Giannouli[2], MA Dimopoulos[1], E Manios[1]
[1]Department of Clinical Therapeutics, [2]National and Kapodistrian University of Athens School of Medicine, Athens, Greece

Background: cardiac dysfunction is the major determinant of prognosis in patients with AL amyloidosis. Elevated levels of cardiac biomarkers (troponin and of NTproBNP) identify patients at high risk (stage 3 per Mayo stage) but low blood pressure (BP) is independently associated with poor prognosis especially in patients with Mayo stage-3 disease (Wechalekar et al Blood 2013). Cardiac output and autonomic nervous system (ANS) are major regulators of BP and both are affected in AL amyloidosis.
Aims: to prospectively evaluate the prognostic role of BP by using standard and 24 hour BP measurements and evaluate the importance of the deregulation of ANS in AL amyloidosis by assessing Baroreceptor reflex sensitivity (BRS).
Methods: Newly diagnosed patients, with biopsy confirmed AL amyloidosis, were prospectively evaluated. All patients underwent standard office BP office BP measurements (three BP measurements taken at a 1-min intervals, at sitting position, averaged to obtain a single systolic and diastolic office BP value), 24h ambulatory BP monitoring and a simultaneously electrocardiographic and

non-invasive BP monitoring (Finometer), under standardized conditions for 15 min. Ambulatory BP monitoring was performed on a usual working day. BP recordings were obtained automatically at 15-min intervals throughout the 24h period. BRS was expressed as the alpha-index (a-index), which was estimated by means of power spectral analysis.
Results: we evaluated 68 consecutive patients (median age 65, range 40-84 years, 50% males). Heart was involved in 65%, kidneys in 70% and nervous system in 23%, while 10% were Mayo stage-1, 60% stage-2 and 30% stage-3 and 14% had NTproBNP≥8500 ng/L. Median eGFR was 63 ml/min/1.73 m2. Primary treatment was bortezomib-based (VD, VCD or BMDex) in 80% and MDex in 20%. Median office systolic BP (SBP) was 118 mmHg and median diastolic BP (DBP) was 72 mmHg. SBP was lower in stage 2 *vs* stage 1 and stage 3 *vs* either stage 2 or stage 1 patients (p=0.026) but there was no difference in the DBP between groups. The median of mean 24h ambulatory SBP was 112.5 mmHg and for DBP was 69.5 mmHg. Advanced Mayo stage was associated with lower mean 24h SBP (p=0.048). None of the patients with Mayo stage 1, 13% of those with stage-2 and 33% of those with stage-3 had office SBP<100 mmHg. For 24h mean SBP, none with stage 1, 23% with stage 2 and 42% with stage 3 had mean ambulatory SBP<100 mmHg. Lower levels of SBP were associated with inferior survival: either office SBP<100 mmHg (6 months *vs* not reached) (p<0.001) or mean 24h SBP<90 mmHg (2 months *vs* not reached) (p<0.001) were associated with poor survival and early death. Further analysis of 24h ambulatory BP recordings indicated higher BP fluctuations among patients with less severe or no heart involvement, while more often patients with Mayo stage 3 had higher nighttime *vs* daytime SBP values than stage 2 or stage 1 patients. Median a-index was 2.85 (range 0.4-5.85) but it was lower in patients with advanced cardiac involvement and was also lower in patients who had nerve involvement (median 1.6 *vs* 3.3, p=0.016), reflecting both cardiac and nerve involvement by AL amyloidosis. In addition, low a-index was associated with early death.
Summary/Conclusions: Low BP, either measured in a sitting position as in standard office visits or by means of 24h ambulatory measurement, is associated with poor prognosis in patients with AL amyloidosis. Impaired BRS is associated with advanced cardiac and nerve involvement and risk of early death.

PREVALENCE AND PROGNOSTIC IMPACT OF OLIGOCLONAL BANDS IN PATIENTS WITH AL AMYLOIDOSIS

LG Rodríguez-Lobato[1,*], C Fernández de Larrea[1], MT Cibeira[1], N Tovar[1], JI Aróstegui[2], L Rosiñol[1], M Elena[3], J Yagüe[2], J Bladé[1]
[1]Amyloidosis and Myeloma Unit. Department of Haematology, [2]Department of Immunology, [3]Department of Biochemistry, Hospital Clínic, Barcelona, Spain

Background: The emergence of oligoclonal bands (OB) in patients with multiple myeloma (MM) achieving a complete response (CR) is a well-recognized event after autologous stem-cell transplantation (ASCT) and the use of novel agents. The presence of OB is considered a benign phenomenon, associated with favorable outcome due to a deeper humoral immune reconstitution. However, the frequency of clinical impact and outcomes of the emergence OB in patients with AL amyloidosis have never been described.
Aims: The objective of this study is to determine the prevalence, natural history and prognostic impact of OB in patients with AL amyloidosis who achieved at least a partial response (PR) either after upfront ASCT or after conventional treatment in patients ineligible for transplant at Hospital Clínic of Barcelona.
Methods: We reviewed the clinical records of patients with AL amyloidosis from January 1996 to September 2015. Fifty-six patients (27F/29M; median age at diagnosis 59 years; range 39 to 82) with PR or better after different induction regimens and/or ASCT were found. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up was 3.6 years. An OB was defined by the presence of a serum and/or urine immunofixation monoclonal spike different either in heavy and/or light chain component from the original amyloid protein.
Results: Fifty-three percent (30) of the patients were transplant ineligible while 46.4% (26) that had received an ASCT. The distribution of the immunoglobulin isotypes at diagnosis was as follows: light chains only (53.6%), IgG (35.7%), IgA (5.4%), IgM (3.6%), and one patient biclonal (1.8%). The light chain type was lambda in 43 patients (76.8%). Response achieved was: CR in 50% of patients, very good partial response (VGPR) 48.2% and PR in one patient. Three-year survival rate was 84%. We observed OB in 59% of the patients. The median number of bands per patient was 2 (range 1 to 5). The most frequents isotypes were IgG-kappa (31%) and IgG-lambda (22%). The oligoclonal phenomenon was more prevalent in patients in CR compared to the other degrees of response (82.1% *vs.* 35.7%; p=0.0001). There were no statistical differences between the emergence of OB and type of treatment received (50% chemotherapy alone *vs.* 69.2% ASCT; p=0.145) or isotype of involved light chains (46.2% for kappa *vs.* 62.8% for lambda; p=0.29). However, the presence of OB was more frequent in the group of patients who received induction chemotherapy (mainly bortezomib-based; 75%) before ASCT as compared to those who received upfront ASCT (91.7% *vs.* 50%; p=0.02). Duration of oligoclonality for more than one year was more prevalent in patients who underwent ASCT than in those ineligible for transplant (42.3% *vs.* 16.7%; p=0.034). Regarding its prognostic value, the presence of oligoclonality lasting for more than one year resulted in a significantly longer overall survival (OS) as compared to patients without OB or with only a transient phenomena (p=0.012), (Figure 1).

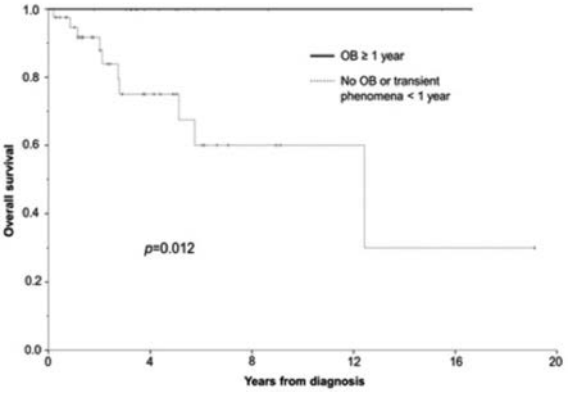

Figure 1. Overall survival according to the presence of oligoclonality lasting for more than one year compared with those without oligoclonal bands (OB) or with only a transient phenomena.

Summary/Conclusions: This is the first report describing the prevalence of OB in patients with AL amyloidosis after first-line therapy, which is even higher than that observed in patients with MM. The oligoclonal humoral phenomenon was more prevalent in patients who achieved CR as well as in those who received induction therapy prior to ASCT. Patients with oligoclonal humoral response lasting for more than one year had a significantly longer OS than those with shorter duration, likely reflecting a more robust humoral immune response.

COMPARISON OF PERIPHERAL BLOOD STEM CELL (PBSC) MOBILIZATION WITH G-CSF ALONE *VS* G-CSF WITH CYCLOPHOSPHAMIDE POST VCD INDUCTION IN MULTIPLE MYELOMA

CC Chua[1,*], HY Lim[1], KL Chai[2], J Ong[3], S Sim[3], M Dickinson[3], P Campbell[4], J Hempton[4], H King[5], C Dowsing[5], K Bergin[6], S Muir[7], S Gibbs[7], A Grigg[1]
[1]Clinical Haematology, Austin Health, [2]Clinical Haematology, St Vincent's Health Australia, Melbourne, [3]Clinical Haematology, Peter MacCallum Cancer Centre, East Melbourne, [4]Clinical Haematology, Barwon Health - University Hospital Geelong, Geelong, [5]Clinical Haematology, Royal Melbourne Hospital, [6]Clinical Haematology, Alfred Health, [7]Clinical Haematology, Eastern Health, Melbourne, Australia

Background: Bortezomib, cyclophosphamide and dexamethasone (VCD) combination is often used as induction therapy in transplant eligible patients with multiple myeloma (MM). However, the optimal PBSC mobilization strategy in this context is not established.
Aims: To review the efficacy of G-CSF alone (G-alone) *versus* G-CSF and cyclophosphamide (G-cyclo) PBSC mobilization strategies in MM patients who had only received VCD induction prior to autograft.
Methods: Retrospective review of PBSC mobilization strategies in patients from six apheresis centres from November 2012 to March 2015 after receiving VCD induction. Extended data were collected from a single centre to January 2016. Prior radiotherapy was not an exclusion criterion. Successful mobilization was defined as achieving physician-determined target PBSC yield, which in some older patients was ≥2x10^6/kg but in most patients was ≥4x10^6/kg to allow for two autografts (≥90% of both groups). Plerixafor was used in some centres as a rescue strategy if PB CD34 ≤10x10^6/L on the day of planned collection or PBSC yield was <1x10^6/kg after first apheresis. Univariate analysis was performed using chi-squared test for categorical data and Mann-Whitney-U test for continuous variables.
Results: Table 1 summarizes the results of 192 patients. Baseline characteristics and cumulative exposure to bortezomib and cyclophosphamide were similar in both groups. G-alone strategy consisted of G-CSF at 10μg/kg/day (n=120) or 20μg/kg /day (n=16), administered for a median of 5 days. G-cyclo comprised of intravenous cyclophosphamide (1g/m^2 (n=1), 1.5g/m^2 (n=14), 2g/m^2 (n=25), 3g/m^2 (n=4), 4g/m^2 (n=12)) with either G-CSF 5-10μg/kg/day for a median of 4 days (n=35) or single-dose 6mg pegfilgrastim (n=21). Overall, the rates of successful mobilization and the proportion of patients achieving a total PBSC yield of ≥4x10^6/kg were comparable between G-alone and G-cyclo with no significant difference in the median number of aphereses to reach this target. However the G-cyclo group had a significantly higher median PBSC yield per apheresis and a higher proportion of patients attaining a PBSC yield of ≥4x10^6/kg with ≤2 apheresis without rescue plerixafor. Ten (18%) G-cyclo patients had unplanned hospitalization, of which 8 had febrile neutropenia. In the G-alone group, age ≤60 and G-CSF doses of 20μg/d were significantly

associated with a higher median PBSC yield. In the G-cyclo group, higher cyclophosphamide doses for mobilization (3-4g/m^2 *vs* 1-2g/m^2) resulted in a significantly higher PBSC yield. Cumulative bortezomib doses, pre-mobilization platelet count and prior radiotherapy did not significantly impact on PBSC yield in either group.

Table 1. PBSC mobilization outcomes with G-alone *vs* G-cyclo.

	G-alone (n=136)	G-cyclo (n=56)	P-value
Median age (years; range)	61 (36-72)	59 (35-75)	0.28
Male	80(59%)	35(63%)	0.63
Median cumulative bortezomib dose (g/m^2)	21 (14-31)	21 (14-29)	0.19
Median cumulative cyclophosphamide dose (g/m^2)	3.6 (0.9-7.2) (116 patients evaluable)	3.7 (1.6-5.5) (48 patients evaluable)	0.88
Prior radiotherapy exposure	20 (15%)	8 (14%)	0.94
Target yield ≥2x10^6/kg ≥4x10^6/kg	 11 (8%) 125 (92%)	 3 (6%) 53 (94%)	0.51
Outcomes of collection Successful • required plerixafor rescue Target yield not reached but deemed sufficient* Failed	 118 (87%) 9 (6%) 8 (6%) 10 (7%)	 51 (91%) 1 (2%) 2 (4%) 3 (5%)	0.70
No. of patients who achieved PB CD34+ of ≥18x10^6/L**	114 (84%)	50 (89%)	0.33
Median total PBSC yield (10^6/kg; range)	5.4 (1-18)	8.4 (1-41)	<0.01
Median D1 apheresis PBSC yield	3.6 (0.6-13)	4.3 (0.8-28)	<0.01
No. of patients who achieved PBSC yield ≥4x10^6/kg with ≤2 apheresis, without plerixafor use***	89/125 (71%)	45/53 (85%)	0.03
No. of apheresis required to achieve CD34+ ≥4x10^6/kg***			
1	60 (48%)	34 (64%)	0.25
2	37 (30%)	12 (23%)	
3	12 (10%)	3 (6%)	
Failed to achieve PBSC yield ≥4x10^6/kg	16 (13%)	4 (8%)	0.07

*Deemed sufficient by clinician to proceed to transplant without further collections (median CD34+ yield: 3.5x10^6/kg; range: 1.4-3.9)
**The threshold above which apheresis were generally performed
***Excluding 11 and 3 patients respectively with target yield <4x10^6/kg

Summary/Conclusions: Despite a significantly higher PBSC yield with G-cyclo mobilization, the G-alone strategy is a reasonable first approach to mobilizing stem cells in the majority of patients receiving VCD induction.

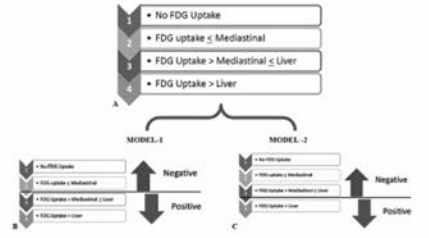
ROLE OF PET/CT IN PROGNOSTICATING POST-TRANSPLANT OUTCOMES BASED ON A NEW SCORING SYSTEM: RESULTS OF PIPET-M TRIAL

U Yanamandra[1,*], M BR[2], A Reddy[2], K Agarwal[2], K Kant Sahu[1], N Varma[1], V subhash[1], P Malhotra[1]
[1]Clinical Hematology, [2]Nuclear Medicine, PGIMER, Chandigarh, India

Background: Multiple myeloma (MM) is a heterogeneous disorder with varied responses to transplantation. ^{18}F-FDG-PET/CT has a role in prognosticating post-transplant outcomes, but the PET positivity has been reported in non-homogenous fashion leading to difficulty in interpretation and inter-trial comparisons. We defined a new staging system for PET/CT reporting in MM and validated it for predicting post-transplant outcomes, first in the world literature.
Aims: Aim: To assess the role of 18 FDG-PET/CT scan in prognostication of MM autologous stem cell transplantation (ASCT) candidates.
Objectives: To correlate pre-transplant FDG-PET/CT avidity with (a) Post transplant outcomes (b) Biochemical Markers (c) MRD as assessed by the flow cytometry (FCM).
Methods: It is a prospective systematic protocol based single centre observational study. As part of CTRI registered PIPET-M Trial, all autologous transplant MM patients underwent 18F-FDG-PET/CT during pre-transplant workup. The conditioning and treatment protocols were not modified based on PET/CT findings. PET positivity was defined as per a newly defined PIPET-M staging in lines with modified Deauville's staging based on target lesion SUVmax (Fig 1A). This staging was further classified into two models for defining PET positivity based on background physiological FDG uptake as an internal control (In model 1 - mediastinal SUVmax and in model 2 - Liver SUVmax was taken as physiological SUVmax) (Fig 1B, C). Progression was defined using revised IMWG criteria. Using SPSS ver.16.0, OS/PFS was assessed by Kaplan-Meier/Cox-regression survival analysis.
Results: A total of 43 patients underwent pre-transplant PET/CT evaluation. The staging was validated in this cohort. Further using model-1, PET negative patients had better PFS (88.2 *vs* 69.2%, p-0.65) and better OS (94.1 *vs* 65.4%, p-0.01). The hazard of all-cause mortality was 22.445 times higher for PET positive individuals (p-0.02). Using model-2, only statistically significant result was delayed neutrophil engraftment in PET-positive patients (11.69 *vs* 10.5d, p-0.02). There was good agreement between two models, but model-1 had significantly higher sensitivity and slightly lower specificity as compared to model-2 for predicting survival. Inter-observer variability was 0.02 for PIPET staging. Also, there was good agreement between the PIPET model -1 and MRD by FCM with Cohen's Kappa - 0.599,(p<0.0005). Levels of β2M and LDH were higher in the patients with PET positivity defined based on PIPET model 1, (Abnormal β2M-χ2 (1, 42)-0.842, p-0.017, Abnormal LDH - χ2 (1, 42)-0.762, p-0.037). There was no correlation of PET positivity with pre-transplant SPEP/UPEP/SIFE/SFLCA total of 43 patients underwent pre-transplant PET/CT evaluation. The staging was validated in this cohort. Further using model-1, PET negative patients had better PFS (88.2 *vs* 69.2%, p-0.65) and better OS (94.1 *vs* 65.4%, p-0.01). The hazard of all-cause mortality was 22.445 times higher for PET positive individuals (p-0.02). Using model-2, only statistically significant result was delayed neutrophil engraftment in PET-positive patients (11.69 *vs* 10.5d, p-0.02). There was good agreement between two models, but model-1 had significantly higher sensitivity and slightly lower specificity as compared to model-2 for predicting survival. Inter-observer variability was 0.02 for PIPET staging. Also, there was good agreement between the PIPET model -1 and MRD by FCM with Cohen's Kappa - 0.599, (p<0.0005). Levels of β2M and LDH were higher in the patients with PET positivity defined based on PIPET model 1, (p-0.017 and 0.037 respectively). There was no correlation of PET positivity with pre-transplant SPEP/UPEP/SIFE/SFLC.

Table 1.



Summary/Conclusions: Utilizing PET stages based on this newly proposed staging model is clinically relevant to predict post-transplant OS.

E1310

THE EFFECT OF LEVEL OF RESPONSE TO TREATMENT ON ASSOCIATED COSTS AND HEALTHCARE RESOURCE UTILIZATION: A RETROSPECTIVE CHART REVIEW STUDY IN PATIENTS WITH SYMPTOMATIC MULTIPLE MYELOMA

H Leleu[1,*], K Yong[2], S Gonzalez-McQuire[3], A Flinois[4], P Schoen[3], M Campioni[3], F Saverio Mennini[5], L DeCosta[6], L Fink[4], C Gazzola[4]
[1]Public Health Expertise, Paris, France, [2]Department of Haematology, University College London, London, United Kingdom, [3]Amgen (Europe) GmbH, Zug, Switzerland, [4]Kantar Health, Paris, France, [5]Faculty of Economics, University of Rome 'Tor Vergata', Rome, Italy, [6]Amgen Ltd., Uxbridge, United Kingdom

Background: An increase in incidence rates, treatment lines and use of novel agents, with improved efficacy, has impacted costs associated with treating multiple myeloma (MM). Real-world data are needed to accurately assess resource use and costs.
Aims: To evaluate how response to treatment affects associated costs and healthcare resource utilization (HRU) in the UK, Italy and France.
Methods: Physicians (n=189) retrospectively completed case report forms for patients (pts) with symptomatic MM who, in the 3 months before study start, had experienced disease progression after receiving specific treatment regimens (those most commonly prescribed) or received best supportive care (BSC) and died. Pt characteristics, treatment outcomes, costs and HRU were documented from beginning of last completed treatment line onwards. Pts had received: 2nd-line bortezomib (bor) or lenalidomide (len); 3rd-line bor, len, pomalidomide (pom) or bendamustine (ben); 4th-line bor, len, pom or ben; any regimen at 5th line or above; or BSC only. Costs of medication and resources were estimated based on standardized schedules and national databases.
Results: Data were collected for 1156 pts on active treatment and 126 pts receiving BSC. In all countries, mean monthly costs were lower in pts achieving deeper responses. In the UK, mean monthly costs from start of treatment line until progression were significantly lower (p≤0.05) for pts achieving a very good partial response or complete response (≥VGPR) than for pts achieving a partial response (PR) and for pts with stable or progressive disease (SD+PD) (Table 1). These costs were also numerically lower in Italy. In France, costs for pts with ≥VGPR were lower than for pts with PR and significantly lower (p≤0.05) than for pts with SD+PD (Table 1). Medications accounted for 92% of mean monthly costs in the UK, 88% in Italy and 83% in France. In all countries, when excluding cost of medication on a monthly basis, achievement of ≥VGPR was still associated with lower costs. In terms of healthcare resource use, the proportion of pts hospitalized increased with lesser response to treatment: in the UK, 11%, 16% and 28% of pts with ≥VGPR, PR and SD+PD, respectively, were hospitalized, and similar trends were observed in Italy (13%, 26% and 28%) and France (16%, 24% and 27%). In terms of overall costs for each country, the achievement of ≥VGPR was associated with higher mean total costs than the achievement of ≤PR. Total costs were significantly higher for ≥VGPR compared with costs for all pts combined (UK €71 414 *vs* €57 717; Italy €51 359 *vs* €34 496; France €45 831 *vs* €37 009; all p≤0.05). When medication cost was excluded, there was still a trend for pts with ≥VGPR to incur higher costs. These findings are linked to duration of treatment (DoT) and length of treatment-free interval (TFI). Mean DoT for pts with ≥VGPR was 10 months in the UK and 12 months in Italy and France. In all countries this was significantly longer than for pts with PR and twice as long as that for pts with SD+PD. Sim-

ilarly, in all countries, TFI until progression for pts with ≥VGPR was significantly longer than for pts with other response levels.

Table 1.

Multiple myeloma treatment costs by level of response in France, Italy and the UK

			Costs from beginning of line to progression* (€)		Costs from beginning of line to progression* excluding medication costs (€)	
Country	Level of response	N	Total Mean (SD)	Per month Mean (SD)	Total Mean (SD)	Per month Mean (SD)
France	Total	502	37 009 (31 530)	3904 (3272)	5193 (6006)	653 (1088)
	≥VGPR	163	45 831 (28 687)	3131 (2383)	5923 (6622)	405 (615)
	PR	153	41 758 (36 398)	3975 (3261)	5620 (6234)	627 (1003)
	SD+PD	177	25 855 (25 883)	4586 (3818)	4029 (4969)	886 (1380)
Italy	Total	393	34 496 (40 305)	2963 (2239)	3203 (3230)	349 (544)
	≥VGPR	140	51 359 (53 015)	2814 (1996)	3503 (3464)	205 (234)
	PR	120	32 437 (33 108)	2910 (2369)	3180 (3175)	310 (355)
	SD+PD	118	18 847 (18 320)	3007 (2247)	3058 (3073)	556 (837)
UK	Total	387	57 717 (52 432)	5504 (5189)	3467 (4378)	461 (720)
	≥VGPR	114	71 414 (67 140)	4342 (4466)	4082 (3605)	271 (310)
	PR	124	64 404 (49 374)	6031 (5735)	2931 (3984)	410 (469)
	SD+PD	138	32 518 (26 518)	5924 (5004)	3521 (5232)	736 (1108)

*BSC patients who did not progress before death were not included in analysis

BSC, best supportive care; PR, partial response; SD, standard deviation; SD+PD, stable disease and progressive disease; ≥VGPR, very good partial response or complete response.

Summary/Conclusions: Most of the cost of managing pts with relapsed MM is medication-related. Although overall costs are higher due to longer treatment duration, mean monthly costs for pts achieving a deeper response to treatment were lower compared with those pts who had a lesser response. These findings may be explained by hospitalization rates, as pts who exhibited deeper and better responses to treatment were hospitalized less frequently than those with a lesser response.

E1311

SEVERE DECREASE OF BONE MATERIAL STRENGTH IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE PATIENTS DETECTED BY OSTEOPROBE® MICROINDENTATION METHOD

A Gonzalez[1,*], E Abella[2], S Montesdeoca[3], X Nogués[4], F Mellibovsky[5], R Güerri[6], A Díez-Pérez[6], L Mellibovsky[6]

URFOA.IMIM.RETICEF. Uniiversitat autónoma Barcelona, [5]Escola d'Enginyeria de Telecomunicacions i Aerospacial de Castelldefels, Universitat Politécnica de Catalunya, [6]Servei de Medicina Interna, URFOA.IMIM.Hospital del Mar RETICEF. Universitat Autónoma de Barcelona, Barcelona, Spain

Background: Monoclonal gammopathy of undetermined significance (MGUS) affects over 3% of adults over 50 years old. Previous studies show that MGUS patients experience a significant bone fracture risk increase and that MGUS prevalence is higher in osteoporotic patients (1). The microindentation for *in vivo* measurement of bone tissue method (2,3) has shown to detect decrease in Bone Material Strength (BMS) even at early stages. These findings correlate with bone fragility and risk of fracture independently of bone mineral density (BMD) (4) measured by bone densitometry (DXA).
Aims: To analyze the BMS by Osteoprobe® microindentation method and the BMD by densitometry in MGUS patients and compare with an age control matched group.
Methods: We have included 22 patients diagnosed with MGUS. An informed consent was obtained and a general laboratory workup was undertaken. BMD measurement at the lumbar spine and hip using DXA (Hologic QDR 4500 SR™, Hologic, Bedford, MA) was performed. BMS determination by inserting a probe assembly through the skin covering the anterior midtibia and applying 20 indentations with an Osteoprobe® (Active Life Scientific Sta Barbara CA) device (3) was done. The results were compared with controls adjusted by sex and age.
Results: MGUS patients present low values of BMS (68.3±5) compared with control group values (83±4, p<0.001). No significant difference was observed in BMD between controls and patients (0.977 *vs* 0.929 p :0,288 at lumbar spine; 0.783 *vs* 0.730 p: 0,179 at femoral neck; 0.902 *vs* 0.898 p: 0,157at total femur).
Summary/Conclusions: These results suggest that microindentation method directly measures bone mechanical properties at the tissue level and can detect significant decrease of BMS in MGUS patients, which correlates with a greater risk of fracture. This could be useful to identify MGUS patients that would benefit from early antiresorptive treatment despite a normal DXA.

REAL-WORLD PRESCRIBING PATTERNS IN U.S. MULTIPLE MYELOMA (MM) PATIENTS REFRACTORY TO LENALIDOMIDE IN THE FRONT-LINE

M Jhaveri[1,*], D Romanus[1], A Raju[2], B Seal[1], E Farrelly[2], C Yong[1], S Noga[3], R Labotka[4], M Blazer[5], H Parameswaran[6]

[1]Global Outcomes Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [2]Real-World Evidence, Xcenda, Palm Harbor, [3]US medical Affairs, [4]Oncology Clinical Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [5]Global Health Economics and Outcomes Research, Xcenda, Palm Harbor, [6]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI, United States

Background: The introduction of novel agents into the treatment paradigm of MM has improved outcomes; however, MM remains incurable with patients requiring subsequent lines of therapy post-relapse. Patients with relapsed MM who are refractory to bortezomib and refractory to or ineligible for lenalidomide have a median overall and event-free survival of 9 and 5 months, respectively (Kumar 2012). There is a scarcity of data regarding real-world treatment patterns and clinical outcomes in previous lenalidomide-exposed patients with relapsed / refractory MM (RRMM).
Aims: This study aims to describe the patient characteristics and treatment patterns among MM patients treated in the real-world who relapsed or were refractory to lenalidomide in first-line treatment (1LT) within the U.S.
Methods: This was a retrospective cohort study using a large national EMR database. Newly diagnosed MM patients initiating a lenalidomide-based 1LT between 1/2008 and 12/2014 were followed 1 year prior to and up to 7 years after diagnosis. Maintenance therapy, if given, was included within 1LT. Patients were required to be ≥18 years of age with evidence of starting second-line therapy (2LT), which was identified accordingly: 1) retreatment after a treatment gap of >3 months of 1LT, or 2) a switch to another drug combination after starting 1LT. All patients were followed until death/loss to follow up or the end of study period (6/30/2015). Based on the International Myeloma Workshop Consensus Panel 1 and using initiation of 2LT as a surrogate marker for non-response or progressive disease, lenalidomide-refractory patients, for the purpose of this study, were defined as those who initiated 2LT within 60 days of 1LT discontinuation (Rajkumar 2011). Relapsed patients were those with a >60 day gap between end of 1LT and 2LT initiation.
Results: There were 279 RRMM patients who received lenalidomide in 1LT (n=89 (31.9%) refractory; n=190 (68.1%) relapsed); overall, mean age was 69.9 years (standard deviation (SD): 9.9) and 49.5% were male. More patients in the refractory population had known high cytogenetic risk disease (presence of any: del[17p], t[4:14], t[14:16]) than in the relapsed population (16.9% *vs* 3.2%), and refractory patients were more likely to have renal impairment (52.8% *vs* 37.9%), anemia (65.2% *vs* 45.3%), hypercalcemia (15.7% *vs* 3.7%) and bone disease (30.3% *vs* 23.7%) at initiation of 2LT than relapsed patients. Refractory patients were more likely than relapsed patients to receive only PI-based therapy (57.3% *vs* 19.5%) and less likely to receive only immunomodulatory drug (immunomod)-based therapy (16.9% *vs* 62.6%) in 2LT (*P*<0.001 for both; chi-square test). In addition, use of ≥3 drug-therapy in 2LT was higher in the refractory population than in the relapsed population (40.5% *vs* 8.4%) (*P*<0.001; chi-square test).

Table 1. 2LT by Lenalidomide refractory *vs* relapsed status.

Type of Regimen Utilized for 2LT, %	Lenalidomide Refractory N=89	Lenalidomide Relapsed N=190
PI-based	57.3	19.5
Bortezomib + steroid	27.0	13.2
Bortezomib + cytotoxic ± steroid	21.3	3.2
Carfilzomib ± steroid	7.9	2.6
Carfilzomib + cytotoxic ± steroid	1.1	0.5
Immunomod-based	16.9	62.6
Other immunomod (other than lenalidomide) + steroid	11.2	5.3
Lenalidomide + panobinostat or cytotoxic ± steroid	4.5	0.5
Lenalidomide ± steroid	1.1	56.3
Other immunomod (other than lenalidomide) + cytotoxic + steroid	0	0.5
PI + Immunomodulatory Drug-based	14.6	3.7
Bortezomib + lenalidomide ± steroid	6.7	2.1
Carfilzomib + lenalidomide ± steroid	4.5	0.5
Carfilzomib + other immunomod ± steroid	2.2	0
Bortezomib + other immunomod + steroid	1.1	1.1
Cytotoxic ± steroid	11.2	5.3
Steroid monotherapy	0	8.9

Key: Cytotoxic – includes any of the following: cyclophosphamide, melphalan, (liposomal) doxorubicin, and bendamustine; Immunomod – immunomodulator (lenalidomide, thalidomide, or pomalidomide); PI – proteasome inhibitor (bortezomib or carfilzomib)

Summary/Conclusions: RRMM patients refractory to lenalidomide in 1LT presented with a higher disease-related symptom burden at start of 2LT, were treated more aggressively in 2LT, and were more likely to switch to PI-based therapy than those defined as relapsed. One limitation to this real-world study is that patients may have stopped 1LT due to factors other than nonresponse or progressive disease.

DETERMINATION OF PROTHROMBOTIC PHENOTYPE IN PATIENTS WITH MULTIPLE MYELOMA ON IMMUNOMODULATORY THERAPY BY THE CALIBRATED AUTOMATED THROMBOGRAM

V Shmeleva[1,*], S Voloshin[2], S Karpich[1], L Papayan[1], O Smirnova[1]
[1]Laboratory of blood coagulation, [2]Haematology department, Russian Research Institute of Haematology And Transfusion, St-Petersburg, Russian Federation

Background: Patients with multiple myeloma (MM) have an increased risk of venous thromboembolism (VTE), particularly when immunomodulatory therapy is used. It is of great importance to choose proper thrombosis prophylaxis in these patients. Resistance to activated protein C (APCR) is proposed to be one of the pathogenic mechanism underlying thrombotic complications in MM patients. The Calibrated Automated Thrombography (CAT) determines the action of both procoagulant and anticoagulant factors and is now considered to reflect patient's phenotype better than traditional coagulation tests. When thrombomodulin (TM) is used CAT becomes sensitive to all disorders of the protein C (PC) system. Clinical utility of CAT in MM patients needs further elucidation.
Aims: Aim of our study was to evaluate the prevalence of APCR and determine prothrombotic phenotype in MM patients by an integrated approach with CAT made in parallel with and without TM.
Methods: The study involved 63 patients (M/F 23/40, mean age 62,0±14,0 yr) with MM and 30 age and sex matched controls. Patients and controls gave informed consent. We divided patients in 3 groups: 30 patients with IgA associated MM, 20 patients with IgG associated MM and 13 patients with MM associated with IgG on lenalidomide treatment with prophylaxis of VTE by aspirin. CAT was done according to Hemker et al. at 5 pM TF and 4 μM phospholipids in platelet poor plasma (PPP) with PPP plasma+/-TM reagent. The procedure was carried out on an automated fluorometer (Fluoroscan Ascent, Thermolab system, Finland). Thrombin generation curves were calculated using the Thrombinoscope software (Thrombinoscope BV, The Netherlands). Lupus anticoagulants (LA), activities of FVIII, protein C and S and antithrombin were also measured. STATISTICA 6.1 was used.
Results: Importantly endogenous thrombin potential (ETP) and peak thrombin (PT) in MM patients on lenalidomide were within the normal range. Increased ETP were defined as values above 95th percentile measured in controls (i.e. >2114 nMmin in the absence of TM and >1433 nMmin in the presence of TM). Normal ranges of ETP and PT inhibition calculated in controls were 22-62% and 15-51% respectively, means values of ETP and PT inhibition were 45% and 33% respectively. Abnormalities of inhibition were more pronounced in IgA associated MM compared to IgG group without lenalidomide (41% *vs* 64% for ETP and 25% *vs* 53% for PT). The most significant changes in the protein C system activities were found in IgG group on lenalidomide (mean inhibition of ETP 36% and 24% of PT). Values below 22% for ETP inhibition and/or 15% for PT inhibition (i.e. APRC) were found in 3 (23%) of patients on lenalidomide. Though ETP and PT inhibition showed significant correlation with PC activity (R=0,51 and R=0,63 respectively), all these patients had protein C and S activities as well as FVIII activity within the normal range and no one demonstrated LA.
Summary/Conclusions: An integrated approach defining an individual's phenotype could help in identifying patients with higher risk for thrombotic event. We suggest APCR detected by CAT to be important marker of thrombotic risk in MM patients. Whether these patients would benefit from more active primary thromboprophylaxis need further elucidation.

E1314

IN MULTIPLE MYELOMA, T REGULATORY CELLS ARE SIGNIFICANTLY REDUCED AFTER TREATMENT WITH LENALIDOMIDE BUT NOT BORTEZOMIB AND CORRELATE WITH THE ACHIEVEMENT OF AT LEAST VERY GOOD PARTIAL RESPONSE

C Hadjiaggelidou[1,*], E Mandala[2], E Terpos[3], D Markala[1], E Yiannaki[1], A Papatheodorou[4], G Ilonidis[2], S Vakalopoulou[5], E Katodritou[1]
[1]Hematology Department, Theagenion Cancer Hospital, Thessaloniki, Greece, [2]Fourth Department of Internal Medicine, Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece, Thessaloniki, [3]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, [4]Department of Medical Research, 251 General Air Force Hospital, Athens, Greece, Athens, [5]Second Propedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, School of Medicine, Thessaloniki, Greece

Background: Immune dysfunction is an important feature of Multiple Myeloma (MM) and has been associated with reduced survival. Studies have shown that T-regulatory cells (Tregs) implicated in immune surveillance are expanded in tumors, including MM. Data regarding alterations of Tregs during therapy with novel agents (NA) *i.e.* bortezomib and lenalidomide, are limited.
Aims: Our aim was to explore possible alterations of Tregs and lymphocyte subpopulations (T4, T8, B, NK, NK-like), as well as changes in the levels of cytokines related to Tregs function and MM biology (IL-6, IL-2, IL-17, TGF-β) during treatment with NA and to seek for correlations with disease characteristics and response parameters.
Methods: We evaluated 29 patients with symptomatic MM at diagnosis or relapse (M/F: 15/14, median age: 61 years, range: 39-77) and 20 healthy volunteers (HV). Eleven patients received bortezomib-dexamethasone (BD) (group A) and 18 patients received lenalidomide-dexamethasone (Rd) (group B). The median number of previous treatment lines was 2(0-3). The detection of Tregs and lymphocyte subpopulations was performed in peripheral blood samples using flow cytometry analysis. The cytokines were measured in serum samples using the enzyme-linked immunosorbent assay ELISA. The statistical analysis was performed with the appropriate methods; $p<0.05$ was considered statistically significant.
Results: In group A, no significant alterations of Tregs%, lymphocyte subpopulations or cytokines were observed during treatment. In group B, there was a significant reduction of Tregs% ($p<0.001$) and this was more profound in those who achieved ≥vgPR ($p=0.04$). No alterations regarding T subpopulations or cytokines were observed during treatment with NA in either group of patients. Patients had significantly higher median Tregs% compared to HV ($p<0.001$). There were no significant correlations between disease characteristics and Tregs in either group of patients. In the cox regression analysis, Tregs% did not correlate with progression-free survival (PFS).
Summary/Conclusions: Herein, we have demonstrated that Tregs% were significantly reduced after treatment with Rd especially in patients with ≥vgPR, suggesting a possible relation of immune surveillance with quality of response. However, PFS was not affected in the current study. Bortezomib-based treatment had no impact on Tregs number or function. Patients with myeloma had higher Tregs% compared to HV, confirming the implication of immune impairment in the biology of this disease. No relation between Tregs and disease characteristics was observed in this study nor between Tregs and relative cytokines, indicating that immune mechanisms underlying MM remain unexplored.

E1315

THE IMPACT OF THE TYPE OF MYELOMA-DEFINING EVENT ON EARLY MORTALITY AND SURVIVAL

R Ríos-Tamayo[1,*], J Sáinz[1], ÁM Alba[1], AJ Cruz[1], JA Pérez[1], E Morente[1], E Cornejo[1], JL García de Veas[2], T Rodríguez[2], M Jurado[1], J Martínez-López[3], JJ Lahuerta [3]
[1]Hematology, [2]Immunology, University Hospital Virgen de las Nieves, Granada, [3]Hematology, University Hospital12 de Octubre, Madrid, Spain

Background: Multiple myeloma (MM) is a complex disease with several levels of heterogeneity. The impact of the clinical presentation of MM is probably underestimated in daily clinical practice. The relationship between the initial clinical presentation in MM and the outcome in terms of overall survival (OS) has been recently highlighted (Greenberg et al, 2014). In this study, patients were divided into four groups: renal failure, anemia, lytic bone disease and a mixed group. They showed that patients with isolated RF as myeloma-defining event (MDE) had the worst OS, whereas patients with bone disease had the best outcome. However, there are many other well-established MDE that can be further analyzed in this regard. On the other hand, little is known about the impact of MDE on early mortality.
Aims: The aim of this study is to assess the impact of the key MDE on the outcome of MM patients, in terms of early mortality and OS.
Methods: All newly diagnosed MM patients recorded in our population-based registry for which the MDE is known were analyzed. Patients were divided into nine groups according with the key MDE: bone pain, pathological fracture, anemia, constitutional syndrome (weight loss, decreased appetite, malaise), infection, other, tumor, renal failure and mixed group (a combination of pain, renal failure, anemia and other). Median OS was estimated in months by the Kaplan-Meier method. Log-rank test was used to compare OS curves. Early mortality was analyzed at two, six, and twelve months.
Results: The MDE was available in 398 patients. Bone disease is the most frequent MDE (49% isolated bone pain, 8% pathological fracture), followed by anemia (9.5%). A constitutional syndrome was present in 7.5%, the same percentage as the mixed group. Isolated renal failure was detected in 6.3%, infection in 5.3%, other in 4.5% and a tumor in 2.3%. Median OS for the whole cohort was 32.7 months (IC 95%, 25-40.4). There were statistically significant differences in OS between subgroups (p=0.004). The subgroup with the best OS was anemia (77.6 months) and the worst was constitutional syndrome (8.9 months). The mixed group and the renal failure group had 20.4 and 21.8 months,

respectively. In patients with bone disease, OS of those with isolated bone pain reach 40.4, but falls to 18 months for those with pathological fracture. Early mortality at two months was observed in 53 patients (13.5%), whereas 87 patients (22.7%), and 116 (31.9%) had mortality at six and twelve months, respectively. In relation to the group constitutional syndrome, 24.1, 40.7, and 60% died at 2, 6, and 12 months. For those with pathological fracture, the percentages were 12.9, 25.8 and 45.2%, respectively. The mixed group had 13.3, 28.6 and 44.4%. Patients with renal failure had 21.7, 34.8 and 36.4% mortality, respectively.
Summary/Conclusions: The importance of clinical evaluation at diagnosis in MM should be emphasized. Patients presenting with isolated anemia as the MDE have the best survival, whereas those with constitutional syndrome have the worst prognosis. Patients having constitutional syndrome, pathological fracture, renal failure or those in the mixed group as the key MDE have a poor outcome in terms of early mortality and OS. The potential association between the MDE and other prognostic factors should be analyzed in depth.

REVLIMID, BENDAMUSTINE AND PREDNISOLONE (RBP) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: FINAL RESULTS OF A PHASE II CLINICAL TRIAL; OSHO-#077

J Beck[1,*], S Heyn[1], D Gläser[2], A Schwarzer[3], LO Mügge[4], J Uhlig[5], B Kragl[6], M Mohren[7], FA Hoffmann[8], T Lange[9], T Schliwa[1], T Zehrfeld[10], K Ute[11], C Winkelmann[12], T Edelmann[13], M Andrea[1], M Jentzsch[1], S Schwind[1], C Becker[8], D Niederwieser[1], W Poenisch[1]
[1]Hematology, University Hospital Leipzig, Leipzig, [2]Hematology, Südstadt Hospital Rostock, Rostock, [3]Hematology, Hematology Practice Park-Krankenhaus Leipzig, Leipzig-Probstheida, [4]Hematology, University Hospital Jena, Jena, [5]Hematology, Private Practice, Naunhof, [6]Hematology, University Hospital Rostock, Rostock, [7]Hematology, Hospital Stendal, Stendal, [8]Hematology, Private Practice, Leipzig, [9]Hematology, Hospital Weissenfels, Weissenfels, [10]Hematology, Hospital Torgau, Torgau, [11]Hematology, Heinrich Braun Hospital Zwickau, Zwickau, [12]Hematology, Hospital Wittenberg, Wittenberg, [13]Hematology, Private Practice, Schkeuditz, Germany

Background: While the role of lenalidomide monotherapy in the treatment of relapsed/refractory patients with multiple myeloma (MM) is well established, combination therapies with lenalidomide are still under investigation in many phase 2/3 studies.
Aims: In the current study, a combination therapy of lenalinomide (Revlimid®), bendamustine and prednisolone (RBP) was tested in patients with relapsed or refractory MM.
Methods: In the previously completed phase 1 study RPB with a dose of 25 mg lenalidomide d 1-21 and 75 mg/m² bendamustine d 1-2 was well tolerated in patients with relapsed/refractory MM (Pönisch et al. 2013). The treatment was repeated every 28 days for a maximum of eight cycles. Thereafter, patients received a maintenance therapy with 10 mg lenalidomide over 10 cycles.
Results: 25 patients (19 patients of the phase 2 study and additional 6 patients from the highest dose level of the phase 1 study) were included in this analysis. Twenty two patients (88%) responded after at least two cycles of RBP with 1 sCR, 5 nCR, 8 VGPR and 8 PR. Due to increased haematological toxicity a dose reduction was required in subsequent therapy cycles in the most of all patients. 19 patients discontinued the treatment prematurely due to a stem cell transplantation (n=7), hematological toxicity (n=7), non hematological toxicity (n=3) or progress (n=2). The median progression-free and overall survival was 22 and 38 months, respectively.
Summary/Conclusions: RBP is a highly effective therapy for patients with relapsed or refractory MM. However, dose reduction is necessary in many patients because an increased haematological toxicity rate.

E1317

BETTER OUTCOME IN AL AMYLOIDOSIS (ALA) TREATED WITH MULTIPLE MYELOMA-ORIENTED REGIMENS COMPARED WITH CYCLOPHOSPHAMIDE/BORTEZOMIB/DEXAMETHASONE (CYBORD) IN A SINGLE CENTER EXPERIENCE

A Belotti[*], R Ribolla, C Crippa, V Orlando, M D'Adda, A Re, E Morello, C Cattaneo, G Rossi
Division of Hematology, Spedali Civili, Brescia, Italy, BRESCIA, Italy

Background: Treatment of AL amyloidosis (ALA) is based on anti-myeloma therapy but there is no standard. Treatment-related toxicity is deemed to be higher in pts with ALA compared with patients with multiple myeloma (MM). Recently, the combination of cyclophosphamide-bortezomib-dexamethasone (CyBorD) showed high rates of haematologic response, although the outcome of high risk patients remained poor.
Aims: We compared the outcome of patients treated at our center with CyBorD with patients receiving more intensive therapy, including MM-type chemotherapy regimens followed or not by high doses of melphalan (HD-Mel) and autologous stem cell transplantation (ASCT) or upfront HD-Mel with ASCT.
Methods: Of 50 ALA patients (median age 62 years) referred to our center, 48 of whom newly diagnosed between 2007 and 2015, 25 patients received CyBorD, and 5 of them (20%) subsequently underwent ASCT. By intention to treat, 18 patients (control group) received more intensive treatment (upfront ASCT: 6 (33%); conventional myeloma induction therapy (VAD, VTD, VMP): 12 (67%), followed by ASCT in 5 of them, 42%). Seven patients receiving less intensive therapy were excluded from analysis. Risk groups were identified as follows: cTnI >0.1ng/ml and/or ECOG PS ≥3: high risk; age ≤65 years with normal cTnI levels, ECOG PS<3 and eGFR >50ml/min: low risk. Intermediate risk patients were defined if not meeting criteria for high or low risk. MM diagnosis was made according to IMWG criteria. Haematological and organ response, overall survival (OS) and event free survival (EFS: time to 2nd line therapy or death) were analyzed.
Results: The proportion of high risk patients was 32% in the CyBorD and 28% in the control group. Median age was 62 and 61 years in the CyBorD group and in the control group, respectively. Concomitant MM was present in 52% CyBorD and in 94% control patients. Treatment results of CyBorD patients were in line with those recently reported (Palladini et al, Blood 2015). Compared to the control group, no difference was observed in terms of haematologic response. Overall response rate (ORR) and complete remission (CR) were 72% and 20% in the CyBorD group and 89% and 39% in the control group, respectively. However, organ response rate was significantly lower in the CyBorD group (32% *vs* 75%, p 0.01). Toxicity was manageable in both groups. After a median follow up of 33 months no significant difference was seen between CyBorD and control group in terms of EFS (48% *vs* 61% at 2 years, respectively; HR 1.5, 95% CI 0.66-3.41), whereas OS was significantly inferior in the CyBorD group (47.6% *vs* 80% at 4 years, p 0.027, HR 3.45, 95% CI 1.15-10.36, see Figure 1). Excluding high risk patients in both groups, OS resulted similar, although a trend toward better long term survival was seen in the control group.

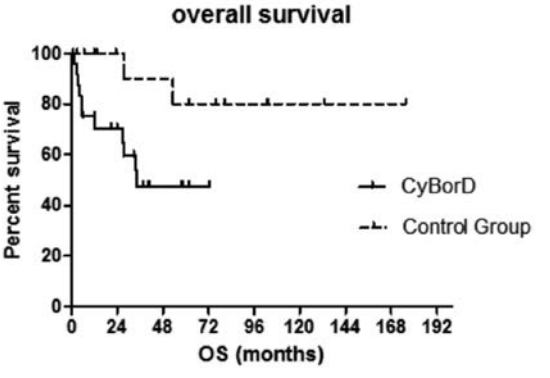

Figure 1. Overall Survival according to treatment: CyBorD *vs* MM-type chemotherapy (control group).

Summary/Conclusions: despite the high haematologic response rates, CyBorD regimen seems not to overcome the long term poor prognosis associated with organ damage in ALA. of high risk patients. Selected patients, even in the high-risk group may have a survival advantage with MM conventional treatment, including ASCT whenever possible.

E1318

PROGNOSTIC SIGNIFICANCE OF THE REVISED INTERNATIONAL STAGING SYSTEM IN MULTIPLE MYELOMA

A Sretenovic[1,*], J Bila[2], J Jelicic[1], M Dencic Fekete[1], V Djurasinovic[1], M Smiljanic[1], V Vukovic[1], D Antic[2], B Andjelic[2], M Todorovic[2], B Mihaljevic[2]
[1]Clinical Center of Serbia, [2]Clinical Center of Serbia, Medical Faculty of Belgrade, Clinic of Hematology, Belgrade, Serbia

Background: New prognostic markers are currently in the focus of investigation in order to personalize treatment approach in multiple myeloma (MM).
Aims: The aim of this study was to analyze the prognostic significance of the newest Revised International Staging System (R-ISS) in MM patients ineligible for autologous stem cell transplantation (ASCT).
Methods: A total of 92 newly diagnosed MM patients (median age 67 years, range 35-80 years; 44 male/48 female) were analyzed in the study, with following distribution: IgG myeloma had 55 patients (59.8%), IgA 18 (19.6%), light chains 16 (17.4%), and IgD 2 patients (2.2%). According to the clinical stage (CS, Durie&Salmon), advanced III CS was found in 68 patients (73.9%), II in 18 (19.6%), and symptomatic I CS in 6 (6.5%) patients. The ISS score 1 had 24 (26.1%) patients, 28 (30.4%) ISS 2, and 40 patients (43.5%) had ISS 3. Elevated LDH level was present in 18/92 patients (19.6%). High risk chromosomal abnormalities (CA, iFISH): t(4; 14), del(17p), or t(14;16) were detected in 14 patients (15.2%). Renal impairment existed in 16 patients (17.4%). New R-ISS scoring system based on LDH level, ISS and CA defines three risk categories with the following distribution: RSS I 21 patients (22.8%), II 63 (68.5%), and III 8 patients (8.7%). Renal impairment existed in 16 patients (17.4%).

Thalidomide based combinations were applied in 77 patients (83.7%) while 15 patients (16.3%) were treated with bortezomib based combinations. The patients were ASCT ineligible due to the age, high comorbidity index, progressive disease or personal attitude.
Results: Overall treatment response (CR/VGPR/PR/MR, IMWG criteria) was achieved in 77 patients (83.7%). In the group treated with thalidomide based combinations, 65 patients (84.5%) achieved favourable treatment response, in comparison to the 12/15 patients treated with bortezomib based combinations. According to the R-ISS score, overall treatment response was achieved in 20/21 patients (95.2%) with R-ISS I; in 54/63 (85.7%) with R-ISS II; and in 3/8 (37.5%) with R-ISS III. There wasn't observed correlation between R-ISS and therapy response neither in the thalidomide treated group (p=0.47) nor in the bortezomib treated group (p=0.149). The median follow up of analyzed group was 27 months (range 4-42 months). The components of R-ISS score as: ISS, elevated LDH and the presence of high risk CA, was found to be the factors of prognostic significance on PFS (Log Rank=4.19, p=0.041; Log Rank=12.23, p=0.001; Log Rank=4.94, p=0.026, respectively) and OS (Log Rank=4.34, p=0.04; Log Rank=13.34, p=0.001; Log Rank=5.08, p=0.024, respectively). In analyzed group, age didn't have impact on the PFS or OS (p>0.05). The R-ISS was highly statistically relevant regarding PFS (Log Rank=10.79, p=0.005) and OS (Log Rank=14.41, p= 0.001). Similarly, in the group treated with thalidomide based combinations, the R-ISS retained prognostic significance on OS (Log Rank=17.54, p=0.0001) and PFS (Log Rank=12.56, p=0.002). Cox regression analysis confirmed that R-ISS was the most important prognostic parameter that influenced PFS in thalidomide treated patients (HR, 5.1; 95% CI, 2.02-12.85; p=0.001).
Summary/Conclusions: Incorporating the findings of molecular genetics along with parameters of disease activity, the R-ISS score represents currently most sensitive prognostic tool in multiple myeloma with consequent implications to personalized treatment approach.

E1319

SHORT SYSTEMIC TREATMENT CONCURRENT WITH INTENSITY-MODULATED RADIOTHERAPY BY TOMOTHERAPY (IMRT) SHOWS IMPROVEMENT OF PROGRESSION-FREE SURVIVAL IN SOLITARY PLASMACYTOMA OF THE BONE (SPB)

E Le Ray[1,*], L Belin[2], C Plancher[2], D Bouscary[1], Y Kirova[3]
[1]Hematologie Clinique, Hopital Cochin, [2]Biostatistics, [3]Radiotherapy, Institut Curie, Paris, France

Background: SPB is a rare plasma cell dyscrasia characterized by a single bone tumor without evidence of multiple myeloma. Standard treatment is currently local 40Gy radiotherapy. Local control is achieved in more than 90% of patients. However, approximately half of the patients develop further disease progression, be it a new plasmacytoma or multiple myeloma.
Aims: To determine the impact and tolerance of short-term treatment with Immunomodulatory Drugs (ImIDs) or proteasome inhibitors (PI) in association with 40 Gy IMRT on the progression-free survival of SPB patients.
Methods: We retrospectively reviewed the medical and dosimetric records of all patients treated for solitary plasmacytoma of the bone at a single institution between 2004 and 2013. All patients had histologically proven plasmacytoma of the bone, without bone marrow involvement. Initial evaluation included clinical examination, biological tests and radiological exams. The absence of additional lesions was assessed by standard radiographies associated with a more sensitive technique such as total body MRI, CT-scan and/or PET-CT. Radiotherapy modalities were reviewed. Additional treatment was assessed. Toxicity was evaluated weekly during radiotherapy, then at 6 weeks, 4 months and 1 year using CTCAEv3.0. Local control of the lesion was defined as negativation of PET-CT. Progression was defined as the incidence of a new plasmacytoma or a multiple myeloma. Statistical analysis: Progression-Free Survival (PFS) was defined as the period from the beginning of radiotherapy to the first documentation of progression or death. Patients alive without progression were censored at the date of last known contact. PFS was estimated using the Kaplan Meier method and compared with the log-rank test.
Results: 28 patients were analyzed. Median age was 53.5y. Median follow-up was 52.2 months (7-99). 15 patients received the standard treatment, a local 40Gy radiotherapy (group 1); 13 patients (46%) received treatment with IMiDs or PIs, in addition to the 40 Gy local radiotherapy delivered by IMRT (group 2). In group 2, 9 patients (69%) received 4 cycles of lenalidomide+dexamethasone, of whom 2 also received bortezomib (15%); 3 received bortezomib+dex for 4 cycles (23%); and 1 received thalidomide for 12 months (7.5%) There was no significant difference between subgroups by conventional prognostic factors such as age, localization, M-Spike and ECOG. Toxicity was mostly hematological and manageable with standard approaches. 1 patient developed profound venous thrombosis on lenalidomide treatment in spite of aspirin prophylaxis. All patients achieved local control. Overall survival was more than 95% at 4 years. 1 patient died of disease progression (MM) in group 1. In group 1, 5 patients (33%) developed SPB and 5 patients developed multiple myeloma (33%) during follow-up, *versus* 1 SPB (7.5%) and 1 MM (7.5%) in group 2. PFS rates at 48 months were 50.3% CI95% [29.8 ;84.6] in group 1 and 80.0% CI95% [58.7 ;100] in group 2. PFS was significantly different between groups (p=0.032).
Summary/Conclusions: An additional treatment with IMiDs or PI to 40 Gy IMRT is well tolerated and allows prolonged progression-free survival for solitary plasmacytoma of the bone patients. These results need to be confirmed in a larger, standardized clinical trial.

E1320

POLYCLONAL SERUM IGM AS A PROGNOSTIC MARKER IN NEWLY DIAGNOSED MULTIPLE MYELOMA

M Napolitano[1,*], C Montante[1], G Saccullo[2], S Mancuso[3], MR Lanza Cariccio[3], A malato[4], F Fabbiano[4], A lucchesi[5], F pagan[6], C Conticello[7], D Mannina[8], F Di Raimondo[9], S Siragusa[3]
[1]Haematology Department, Università di Palermo, [2]Haematology Unit, Policlinico "P.Giaccone", [3]Haematology Unit, Università di Palermo, [4]Haematology Unit, Ospedale "Cervello", Palermo, [5]Oncologia Medica, [6]Unità di Biostatistica e Sperimentazioni Cliniche, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, [7]Haematology Unit, Ospedale "Ferrarotto", Catania, [8]Haematology Unit, "Papardo" General Hospital, Messina, [9]Haematology Unit, University of Catania, Catania, Italy

Background: Normal serum IgM plasma levels have been reported as an independent marker of good prognosis in patients with multiple myeloma (MM) but their role has been poorly investigated
Aims: We aimed to evaluate the role of polyclonal serum IgM levels as a surrogate marker of normal residual bone marrow function in newly diagnosed patients with multiple myeloma (NDMM).
Methods: Data were collected from the enrolling Hematology Centers. Patients with NDMM were evaluated for polyclonal IgM levels and their correlation with clinical and laboratory parameters of MM, at diagnosis and up to one year after standard treatment. Baseline data were retrospectively analyzed between January 2012 and June 2015; analyzed parameters were taken at the following time-points: diagnosis, after standard treatment and 1 year after diagnosis. The one-year evaluation was performed at least 3 months after the last autologous stem cell transplant (ASCT) and at least 2 months after the end of a first-line treatment in patients not eligible for ASCT. A dedicated database was created. Statistical analysis was performed with Medcalc 12.5.00. Wilcoxon test for paired samples was applied when indicated Patients were divided into two groups based on the serum IgM levels at diagnosis (IgM<0.3 g/L and IgM ≥0.3 g/L,respectively).

Table 1.

Characteristics at diagnosis	IgM<0,3 g/L (n=120)	IgM≥0,3 g/L (n=50)	p-Value
Male (%)	59,1%	40,9%	0,4901[ns]
Age (yr)	65,3 (38,8-83,8)	64,4 (47,3-91,2)	0,9681[ns]
Subtype of myeloma (%)			0,2009[ns]

Creatinine (mg/dL)	1,09 (0,35-11,07)	0,90 (0,50-7,81)	0,0209[*]
ClCr (mL/min)	69,90 (3,0-152,0)	84,0 (3,20-143,0)	0,0906[ns]
IgM suppression	at diagnosis (n=83)	at first revaluation (n=83)	
IgM (g/L)	0,16 (0,0-1,81)	0,29 (0,0-1,90	0,0023[**]

*Results are expressed as mean and SD.

Results: At diagnosis, we evaluated 170 NDMM (not IgM myeloma) patients and divided them into two groups based on polyclonal serum IgM levels (Table). M protein type frequency was similar between both groups. We found that patients with polyclonal serum IgM level higher than 0,3g/L had higher hemoglobin levels (median 12,0 *vs* 9,90g/dL; p<0,0001) and platelet count (252x10^9L^{-1} *vs* 193x10^9L^{-1}; p=0,0001), lower β2-microglobulin (3,6 *vs* 5,3mg/L; p=0,0012), lower creatinine levels (0,90mg/dl *vs* 1,09mg/dl; p=0,0209), higher creatinine clearance (ClCr, 84mL/min *vs* 69,90ml/min; p=0,0906), lower frequency of ISS stage III (42% *vs* 51%; p=0,0024). No significant statistical correlation was found between IgM plasma levels and LDH, serum calcium and albumin. At regression analysis, a strong correlation between polyclonal serum IgM level and serum beta-2 microglobulin (negative; p=0,034) and hemoglobin (positive; p<0,001) was observed.At the first revaluation, data on 98 patients were available. When comparing serum IgM polyclonal levels between diagnosis and first re-evaluation, IgM at diagnosis resulted lower (0,16g/L *vs* 0,29g/L; p=0,0023).Overall

survival was similar between both groups (82,8 *vs* 82 months; p=0,9118) and it was unrelated to the type of treatment administered.
Summary/Conclusions: In newly diagnosed MM, normal IgM levels can be evaluated as a surrogate marker of good bone marrow residual function in NDMM. After treatment, IgM do not statistically correlate with any of the clinical and laboratory prognostic markers examined.

E1321

NEW IMWG COMPARED TO CRAB CRITERIA TO PROPERLY DEFINE START-TIME THERAPY IN MULTIPLE MYELOMA: A RETROSPECTIVE SINGLE-CENTER ANALYSIS OF 180 PATIENTS

L Torti[1,*], S Pulini[1], AM Morelli[1], F Bacci[2], A Spadano[1], P Di Bartolomeo[1]
[1]Department of Hematology, Transfusion Medicine and Biotechnology, "Spirito Santo" Civic Hospital, Clinical Hematology, Pescara, [2]Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Section of Hematopathology, Bologna, Italy

Background: The diagnosis of Multiple Myeloma (MM) traditionally requires the evidence of signs of end-organ damage like hypercalcemia, renal failure, anemia and osteolytic bone lesions,usually referred by the acronym "CRAB". The International Myeloma Working Group (IMWG) recently updated the criteria for the diagnosis of MM,including biomarkers that are considered myeloma defining events (MDEs).They are: clonal bone marrow plasma cells >60%,serum free light chain (FLC) ratio >100 and the presence of more than one focal lesion on magnetic resonance imaging (MRI).
Aims: In this paper we'd like to share our experience regarding the recent IMWG criteria in a group of 180 newly diagnosed MM patients, to discuss strengths as well as caveats and uncertainties. Ninety were young and treated with transplant procedure and ninety were old (more than 65-year-old)and were treated with different regimens,including new drugs.
Methods: We performed a retrospective analysis of these MM cases with MDEs diagnosed from 1999 to 2014 in our Department, comparing traditional CRAB *versus* recent IMWG criteria. We retrospectively looked for the new defining characteristics published by Rajkumar (Lancet Oncol 2014) during the disease course before both the development of CRAB events and beginning of treatment.

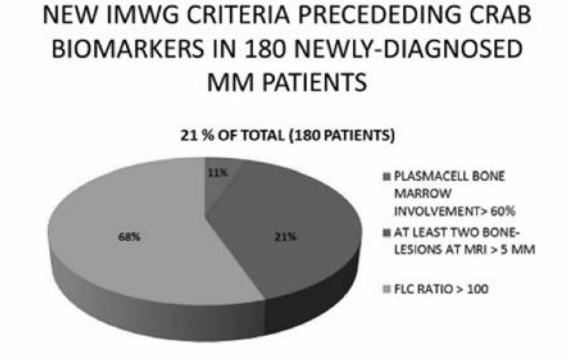

Figure 1.

Results: We found the occurrence of IMWG new criteria before clear manifestation of the CRAB markers in thirty-eight patients (21% of total). In particular the majority of this group has shown a FLC ratio>100 (14% of total),5% presented injuries detected by MRI and only 2% had a bone marrow plasma cells involvement >60%. Most of them (92%) were followed by development of CRAB features after a medium time of seven months (range 3-15) and progressed to active MM requiring therapy in less than one year. In the category of patients carrying the new criteria 71% were old (median age 70 years, range 53-89), 29% were young. Of them 56% had IgG MM, 26% IgA MM, 18% micromolecular MM; prevalent light chain was kappa (65%). The majority of these cases (76%) had a previous history of MGUS and smouldering MM. Only two patients among 180 started therapy not according to classic criteria, but on new IMWG biomarkers, associated with deterioration of clinical condition and increase in monoclonal component. However three young patients presented new IMWG events associated with a stable monoclonal protein, good clinical status. Clinical judgement was most important in this setting, as we decided not to start therapy and to maintain close follow-up. In our view it is likely that earlier treatment of these patients would not be beneficial,but might instead result in greater toxicity. On the other hand patients without IMWG 2014 preceding CRAB criteria,often identify a high-risk subgroup with a severe and faster biological behavior. The largest part of them indeed (57%) presented markers of aggressive biological profile like IgD paraprotein, extramedullary involvement or unfavorable cytogenetic abnormalities such as deletion of chromosome 17. Probably a well defined temporal difference between development of new IMWG and the old CRAB characteristics could be present only for intermediate-risk MM patients with a slower kinetics of disease. In most high-risk patients probably new IMWG and CRAB markers present all together simultaneously.
Summary/Conclusions: Our single-center study confirms the pivotal role of new IMWG criteria to optimize management of patients with smouldering MM and to antedate start-time of effective treatment before end-organ damage, expecially for elderly patients.In our experience the most powerful biomarker of progression is FLC ratio>100. Neverthless particular caution should be used in youth patients to avoid too much toxicity of a earlier intervention,that can also lead to selection of fitter clone and accelerated progression.Finally these new biomarkers should be critically validated prospectively in future clinical trials to allow an early treatment in patients without CRAB features with high-risk markers.

E1322

SPECIAL IMMUNE SIGNATURE OF MM PATIENTS IN LONG TERM COMPLETE RESPONSE (LTCR) WITH NEGATIVE MINIMAL RESIDUAL DISEASE (MRD) AFTER AUTOLOGOUS TRANSPLANT (ASCT): A SINGLE CENTRE EXPERIENCE

A Arteche[1], C Muñoz Calleja[2], B Aguado Bueno[3,*], A Kreutzman[3], G Miriam[4], Á Arriero[4], I Vicuña Andrés[4], A Alegre Amor[4]
[1]Imnunology, [2]Inmunology, [3]H. La Princesa, Madrid, Spain, [4]Hematology, H. La Princesa, Madrid, Spain

Background: The immune profile in MM patients in long term complete remission (LTCR) could be relevant in MM control and minimal residual disease (MRD) monitoring.
Aims: To evaluate this hypothesis, we have analyzed the immune profile and the MRD status of a group of LTCR-MM patients after autologous transplant (ASCT) and we have compared the results with a healthy control group.
Methods: 13 MM patients, median 60 y (46-71) in LTCR for >7 years, median 9 y (7-19) after ASCT were included. Only 2 patients had received thalidomide as induction. The rest only chemotherapy schemes. No other patient had received new drugs neither maintenance. 7 patients received conditioning with HD Melphalan and 6 with Busulphan+Melphalan. Only 2 patient showed high hisk iFISH, one with del(17p) and other with t(4;14). Control arm included 15 age-matched healthy blood donors (HD). Peripheral blood was immunophenotyped by multiparametric flow cytometry with 8 colours and $CD4^+$ and $CD8^+$ T-cells, B lymphocytes and NK cells were quantified. Serum immunoglobulins, free light chains and heavy/light chains (HLC) were quantified. MRD was evaluate with bone marrow multiparametric cytometry study (8 colours). Response was evaluated by IMWG Criteria.
Results: The percentage of $CD4^+$ T-cells in the LTCR group was significantly lower than in HD (p=0.0002), whereas no differences were observed in the proportion of total $CD8^+$ T-cells (p=0.3046). Conversely, the relative values of NK-cells (CD3-CD56+CD16+) were increased in the LTCR group (p=0,0514). The percentage of total B-cells ($CD19^+CD20^+$) in the patients was within normal range and no significant differences were found when compared to HD. Remarkably, the normalization of HLC measurements confirmed a complete reconstitution of the immune paresis in these patients, and a negative MRD by multiparametric flow cytometry ratified its usefulness at demonstrating a sustained complete response.
Summary/Conclusions: LTCR-MM MRD neg patients could express a particular immune signature which could reflect a "high quality" immune reconstitution in terms of anti-tumor immunological surveillance and the recovery of the humoral immunity. More studies are needed to confirm these results, with patients treated with new drugs combinations including immunomodulatory ones.

E1323

DURATION OF SECOND LINE TREATMENT AND SURVIVAL IN MULTIPLE MYELOMA

H Parameswaran[1,*], LM Tran[2], C Yong[3], S Noga[4], E Farrelly[5], A Raju[5], B Seal[3], R Labotka[6], M Blazer[7], M Jhaveri[3], D Romanus[3]
[1]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI, [2]University of California, Berkeley, CA, [3]Global Outcomes Research, [4]US medical Affairs, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [5]Real-World Evidence, Xcenda, Palm Harbor, [6]Oncology Clinical Research, Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, [7]Global Health Economics and Outcomes Research, Xcenda, Palm Harbor, United States

Background: Evidence from post-hoc analyses of clinical trials supports the paradigm of extended treatment leading to an overall survival (OS) benefit in relapsed/refractory multiple myeloma (RRMM).
Aims: This observational study evaluated whether longer 2nd line treatment (SLT) duration is associated with improved OS among patients with RRMM.
Methods: In this retrospective cohort study of a US national EMR database, newly diagnosed adults with MM initiating 1st line therapy (FLT) and SLT between 1/2008 and 12/2014 were followed through earliest of either 1 year or death/loss to follow up/end of study period (12/31/2014) after start of SLT. FLT began with the first claim for MM-directed therapy following diagnosis (dx). SLT was identified by: 1) retreatment with follow-up regimen with gap of >3 months

after end of FLT, or 2) switch to another drug combination after FLT. A logistic marginal structural model was used to estimate the causal effect of SLT duration on 1-year OS probability, adjusting for time-dependent confounders and baseline covariates. Immortal time bias was addressed by estimating the effect of SLT duration on outcome within each monthly interval from start of SLT.
Results: Among 340 patients, mean age was 70 years (standard deviation (SD), 10); 51% were male; 9% had known high risk MM; 46% received immunomodulatory (IMID-), 35% received proteasome inhibitor (PI-), and 6% received PI+IMID-based SLT. Median duration of SLT was 6.87 months (95% CI: 6.17, 8.40). The odds of 1-year OS were 1.17 times higher for each additional month of SLT (OR: 1.17 [95% CI: 1.10, 1.25] *P*<0.001), controlling for age, gender, cytogenetic risk, comorbidities, race, ethnicity, region, insurance type, treatment-free interval prior to SLT, FLT/SLT regimen type, year of diagnosis (dx), time since initial dx, time-dependent treatment- and MM-related symptoms, and post SLT regimens (Table 1).

Table 1. Adjusted predicted 1-year OS probability based on DOT in SLT.

Duration of SLT (months)	1-yr OS
1	0.61
3	0.68
4	0.72
6	0.78
7	0.81
8	0.83
9	0.85
10	0.87
12	0.90

Key: OS – overall survival; SLT – second-line therapy; yr – year

Summary/Conclusions: Longer duration of SLT was significantly associated with longer OS. Despite substantial heterogeneity in patient/disease characteristics and treatment patterns, the clinical benefit of continued longer term therapy at relapse appears to be generalizable to patients receiving care in the real-world setting.

E1324

AGE-RELATED HEALTHCARE DISPARITIES IN MULTIPLE MYELOMA
M Puyade[1,2,*], G Defossez[2], F Guilhot[1], X Leleu[1], P Ingrand[1,2]
[1]INSERM CIC 1402, CHU, [2]Registre des Cancers Poitou-Charentes, Faculté de Médecine et Pharmacie, Poitiers, France

Background: Age is a well-known factor in solid tumor linked to a lower adherence to guidelines. Scarce data exist for hematologic malignancies like Multiple Myeloma (MM), a disease that affects primarily elderly patients.
Aims: The aim of the study was to investigate the relationships between age, adherence to guidelines in MM and overall survival.

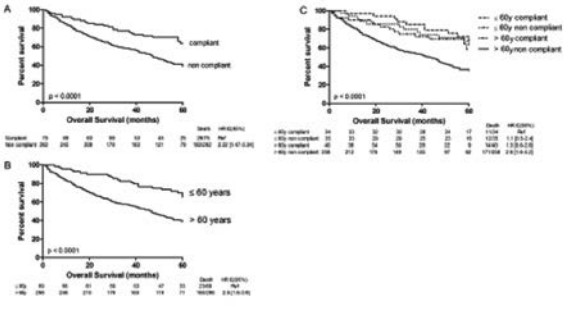

Figure 1.

Methods: The Poitou-Charentes cancer registry has exhaustively registered the incident cases of MM from 2008 to 2010. Provided care (diagnosis, staging, prognosis and first-line treatment) was compared to international guidelines.
Results: Three hundred and sixty seven patients aged 36 to 93y were included. Compliance to diagnostic procedure was 98%, staging 62%, prognosis 30% and first-line treatment 89%. Cytogenetic analysis was compliant in 37% (74%<66y, 31% between 66-74y and 13% for the oldest, *P*<0.001). Age was the strongest factor associated to compliant provision of care (OR 14.4 [6.1-33.8] for<66y, and 2.3 [0.9-6.1] for 66-74y; *P*<0.0001). The second independent factor was the diagnosis of multiple myeloma (OR 3.5 [1.6-7.3]; *P* =0.0009). Adherence to guidelines increased overall survival after adjustment on age HR: 1.8 [1.2-2.7], *P*=0.008.

Summary/Conclusions: Age is linked with inadequate provision of care in MM, particularly prognosis and first-line treatment. Compliance to guidelines improves OS. Future guidelines should stress that age and frailty should be taken into account at Myeloma care, eventually with specific guidelines for this population.

[1]Peking University People's Hospital, Beijing, China, [2]Gachon University Gil Hospital, Incheon, Korea, Republic Of, [3]National Taiwan University Hospital, Taipei, Taiwan, ROC, [4]Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China, [5]Chonnam National University Hwasun Hospital, Hwasun-gun, Jeonnam, Korea, Republic Of, [6]West China Hospital of Sichuan University, Chengdu, China, [7]Seoul National University Hospital, [8]Sungkyunkwan University, Samsung Medical Center, Seoul, Korea, Republic Of, [9]Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China, [10]National Cancer Center, Gyeonggi-do, Korea, Republic Of, [11]Beijing Chao-Yang Hospital, Beijing, China, [12]The Catholic University of Korea, Seoul, [13]Hallym University Sacred Heart Hospital, Anyang, [14]Seoul National University Bundang Hospital, Seongnam, [15]Chonbuk National University Hospital 42, Jeonju, Korea, Republic Of, [16]Celgene Corporation, Summit, NJ, United States, [17]Hospital University Center (CHU), Bordeaux, [18]Service des Maladies du Sang, Hôpital Claude Huriez, Lille, France

Background: The incidence of multiple myeloma (MM) in Asian countries is increasing; therefore, effective treatment options for these patient (pt) populations are needed (Kim et al, *Am J Hematol,* 2014). The pivotal phase 3 FIRST trial investigated continuous treatment with lenalidomide plus low-dose dexamethasone until disease progression (Rd continuous) in pts with newly diagnosed MM (NDMM) who were ineligible for autologous stem cell transplant (ASCT) from 18 countries, including China, South Korea, and Taiwan. Treatment with Rd continuous in the FIRST trial improved progression-free survival (PFS; hazard ratio [HR]=0.72; *P*<.001) and overall survival (OS; HR=0.78; *P* =.02) compared with melphalan-prednisone-thalidomide (MPT) (Benboubker et al, *N Engl J Med,* 2014).
Aims: To examine the efficacy and safety of Rd continuous in the Asian population of the FIRST trial.
Methods: Pts with NDMM aged ≥65 years or ineligible for transplant were randomized to 3 treatment arms: Rd continuous, Rd for 18 cycles (Rd18; 72 weeks), or MPT for 12 cycles (72 weeks). The primary endpoint was PFS in pts treated with Rd continuous *vs* those treated with MPT (primary comparators). Data cutoff was May 24, 2013; response and progression were assessed by an independent response adjudication committee. Data cutoff for OS was extended to March 3, 2014. All pts provided informed written consent.

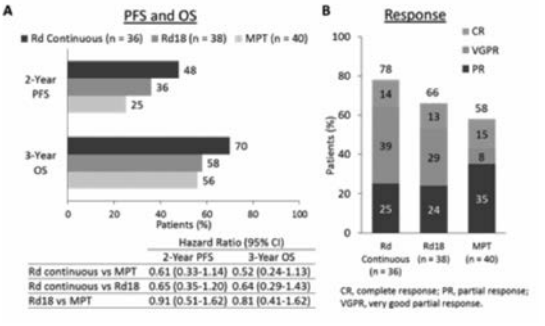

Figure 1.

Results: In the 114 pts enrolled in Asia, median age (68 yrs [range, 43-86 yrs]) was similar across the Rd continuous (n=36), Rd18 (n=38), and MPT (n=40) arms but lower than that of the overall study population (73 yrs [range, 40-92 yrs]). Pts in Asia also had a higher rate of Eastern Cooperative Oncology Group performance status ≥2 (28% *vs* 22% overall), a higher rate of International Staging System stage III disease (45% *vs* 41% overall), and double the rate of severe renal insufficiency (creatinine clearance<30 mL/min; 18% *vs* 9% overall), the latter of which was more frequent in the MPT (23%) and Rd18 (24%) arms *vs* the Rd continuous arm (8%). Median treatment duration was 18.4 mos (range, 0.5-35.9 mos) for Rd continuous, 11.0 mos (range, 0.6-19.6 mos) for Rd18, and 11.1 mos (range, 0.3-19.1 mos) for MPT. Treatment with Rd continuous *vs* MPT resulted in a 39% reduction in the risk of progression or death (Figure A). Rates of 2-year PFS were nearly doubled with Rd continuous (48%)

vs MPT (25%). Rd continuous also resulted in a 48% reduced risk of death *vs* MPT. Overall response rate was greater in the Rd continuous arm (78%) *vs* the Rd18 (66%) and MPT (58%) arms (Figure B). Median duration of response was not reached for Rd continuous and was 17.2 and 13.8 mos for Rd18 and MPT, respectively. The most frequent grade 3/4 adverse events with Rd continuous, Rd18, and MPT were neutropenia (25%, 34%, 44%), anemia (19%, 5%, 15%), pneumonia (6%, 24%, 15%), and thrombocytopenia (14%, 5%, 5%). Deep vein thrombosis was reported in 1 pt in the MPT arm, and pulmonary embolism was reported in 1 pt in each treatment arm. There were no reports of second primary malignancies in the Asian population.
Summary/Conclusions: Rd continuous treatment resulted in numerically larger PFS and OS benefits and higher response rates compared with MPT in the Asian subgroup of the FIRST trial, although pt numbers were small. Results were consistent with those in the overall population, with no unexpected safety signals, a low rate of thromboembolic events, and no second primary malignancies as of data cutoff. These findings support Rd continuous as a standard treatment for pts with NDMM who are ineligible for ASCT, including Asian populations.

E1326

DIAGNOSTICS AND PROGNOSTIC STRATIFICATION OF PATIENTS WITH WALDENSTRÖM'S MACROGLOBULINEMIA-SINGLE CENTRE EXPERIENCE
L Krupkova*, T Pika, M Divoka, M Orviska, J Minarik, T Papajik
Department of Hemato-oncology, University Hospital and Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

Background: Waldenström's macroglobulinemia (WM) is a rare B-cell neoplasm defined as lymphoplasmacytic lymphoma with bone marrow infiltration and monoclonal IgM in the serum. More than 90% of WM patients carry a point mutation L265P in the MYD88 gene and concurrently, almost one third of MYD88^{L265P}-positive patients harbor frameshift (WHIM-FS) or non-sense (WHIM-NS) mutation in gene CXCR4. The mutations in CXCR4 result in premature stop codons and in shortening of CXCR4 protein product. Incomplete C-terminal domain of CXCR4 chemokine receptor is known to hyperactivate CXCR4-mediated signalization. The presence and type of mutation in genes MYD88 and CXCR4 appears to be significant in diagnostics and prognostic stratification of WM patients and it also influences the clinical manifestation of the disease.
Aims: To analyze mutational status of MYD88 and CXCR4 genes in patients with WM, to compare our results with laboratory parameters and to evaluate the prognostic stratification of the patients according to MYD88 and CXCR4 mutational status.
Methods: Analyzed DNA was isolated from mononuclear fraction of bone marrow cells at the time of diagnosis. Mutational status of analyzed genes was determined using allele-specific PCR (in the case of MYD88) and using direct Sanger sequencing (in the case of CXCR4). All found mutations were confirmed by specific cleavage with restriction endonucleases at defined conditions.
Results: We analyzed a group of patients with WM (*n=16*). We identified 15 MYD88^{L265P}-positive patients (93.8%), and 4 of them (25%) were also CXCR4 mutants (1 patient harbored WHIM-FS mutation and 3 harbored WHIM-NS mutation). CXCR4 mutations were associated with more aggressive disease (higher IPSS score, pancytopenia, higher levels of paraprotein and free light chains in serum, higher bone marrow infiltration; Table 1), and CXCR4$^{WHIM-WT}$ patients were often asymptomatic. CXCR4 mutations were also associated with worse treatment response (2 CXCR4$^{WHIM-MUT}$ patients were resistant and 2 patients had a partial response to first-line therapy).

Table 1. The medians of laboratory parameters of the WM patients with and without CXCR4 mutation.

	MYD88^{MUT} CXCR4$^{WHIM-WT}$	MYD88^{MUT} CXCR4$^{WHIM-MUT}$
Paraprotein level [g/l]	14.3 (3.7-32.2)	25.4 (10.6-30.9)
Bone marrow infiltration [%]	25 (10-72.4)	64 (10-96)
Involved free light chain level [mg/l]	103.5 (26-633)	341 (317-507)
IPSS	1 (n=6); 2 (n=5);3 (n=1)	2 (n=1); 3 (n=3)
Hemoglobin [g/l]	112.5 (89-149)	111.0 (90-117)
Thrombocytes [x10^9/l]	258 (37-585)	189 (15-281)

Summary/Conclusions: The mutational analysis of MYD88 and CXCR4 genes is essential for the diagnostics and prognostic stratification of patients with WM and it allows a deeper understanding of the molecular pathogenesis of the disease. In accordance with published data, we confirmed that CXCR4 mutations are associated with more aggressive disease presentation and thus affect treatment outcome.

E1327

DESCRIPTION OF PATIENT CHARACTERISTICS, TREATMENT PATTERNS AND RESOURCE USE FOR PATIENTS WITH MULTIPLE MYELOMA TREATED IN THREE LOCAL HEALTH UNITS (LHUS) IN ITALY
S Panjabi[1,*], D Lambrelli[2], S Gonzalez-McQuire[3], L Degli Esposti[4], S Buda[4], S Saragoni[4], V Blini[4], E Merinopoulou[2], S Ramagopalan[2]
[1]Amgen Inc., Thousand Oaks, CA, United States, [2]Evidera, London, United Kingdom, [3]Amgen (Europe) GmbH, Zug, Switzerland, [4]CliCon S.r.L., Ravenna, Italy

Background: Recent data on resource utilization and treatment patterns in multiple myeloma (MM) in Italy are limited.
Aims: The objective of this study was to examine the resource utilization and treatment patterns of newly-diagnosed patients with MM in Italy.
Methods: Retrospective claims data from the administrative databases of three LHUs in Lazio, Sicily, and Lombardy in Italy were used. Patients with a hospitalization discharge diagnosis of MM between 1 January 2008 and 1 September 2013 were included. To identify newly-diagnosed cases, patients with a prior MM diagnosis or a prior prescription for bortezomib (Bor), thalidomide (Thal), melphalan (Mel), lenalidomide (Len) or cyclophosphamide (Cyc) 12 months prior to entry into the study cohort were excluded. Index date was defined as the earliest of: date of first MM diagnosis or first prescription of Bor, Thal, Mel, Len, Cyc, prednisone or dexamethasone in patients with a diagnosis of MM within six months following prescription date; or the visit date to an oncologist or hematologist in patients with a diagnosis of MM within six months following the visit date. The baseline period was defined as 12 months prior to index date and the follow-up period ranged from the index date (inclusive) until date of last data collection or patient's death. Data on patients' demographics and clinical characteristics were collected at baseline. Healthcare resource use and treatment patterns were explored during the entire study period. The identification of treatment lines was based on assumptions given the sequencing of treatments based on key literature and treatment guidelines in Italy.
Results: Overall, 938 patients with MM entered the study cohort; average follow-up was 1.7 years. A total of 157 patients underwent a stem-cell transplantation (SCT) during the study period. The mean age at diagnosis was 69.7 years (standard deviation [SD]: 12.3). A slight majority of patients were female (52%). The most common comorbidities at baseline were renal disease (5.9%), other malignancies (5.8%) and congestive heart failure (4.4%). Among 814 patients with at least three months of follow-up, 76.4% of patients received at least one treatment line and 40.8% and 18.3% received at least two and three lines, respectively. Mel (27.7%) and Bor (21.5%) were the most frequently administered first- and second-line treatments, while Len showed an increased uptake in third line and beyond. Bor was the most commonly used first-line treatment in SCT patients (31.3%), while Mel was the most commonly used first-line treatment for non-SCT patients (36.5%). During the entire follow-up period, 80% of patients had at least one hospitalization for MM, 74% of patients had at least one laboratory test and 63% at least one diagnostic test, with the most common procedure being biopsy of bone marrow (53%). The mean annual cost of hospitalizations and medications per patient was €13,558 (SD: 17,559) and €2,401 (5,532), respectively. The average annual cost of medication per patient increased from €2,590 (5,566) for patients in first-line to €3,253 (8,767) and €4,330 (11,439) for patients in second- and third-line, respectively.
Summary/Conclusions: MM poses a significant economic burden on the national health system in Italy with hospitalizations being the main cost driver. Treatment patterns data indicate an unmet need for more effective therapies in Italy.

E1328

OUTCOMES FOR ASIAN PATIENTS WITH RELAPSED MULTIPLE MYELOMA TREATED WITH CARFILZOMIB AND DEXAMETHASONE *VS* BORTEZOMIB AND DEXAMETHASONE: A SUBGROUP ANALYSIS OF THE PHASE 3 ENDEAVOR STUDY (NCT01568866)
JH Lee[1,*], SY Huang[2], JH Liu[3], TY Chen[4], P Lawasut[5], S Iida[6], S Feng[7], S Aggarwal[7], WJ Chng[8], D Joshua[9]
[1]Gachon University Gil Medical Center, Korea, Namdong-Gu, Korea, Republic Of, [2]National Taiwan University Hospital, [3]Taipei Veterans General Hospital, Taipei, [4]National Cheng Kung University Hospital, Tainan, Taiwan, ROC, [5]King Chulalongkorn Memorial Hospital, Bangkok, Thailand, [6]Nagoya City University Hospital, Nagoya, Japan, [7]Amgen Inc., Thousand Oaks, United States, [8]National University Cancer Institute, National University Health System, Singapore and Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore, [9]Royal Prince Alfred Hospital, Camperdown, Australia

Background: Carfilzomib is a selective proteasome inhibitor that is approved as a single agent and in combination with dexamethasone or lenalidomide/dexamethasone for relapsed or refractory multiple myeloma (RRMM). The ENDEAVOR study (NCT01568866) demonstrated statistically and clinically significant improvements in progression-free survival (PFS) for carfilzomib and dexamethasone therapy (Kd) compared with bortezomib and dexamethasone therapy (Vd; median 18.7 *vs* 9.4 months [mo]; hazard ratio [HR], 0.53; 95% confidence interval [CI]:0.44-0.65; 1-sided *P*<0.001) (Dimopoulos et al, *Lancet Oncol* 2016).
Aims: This preplanned subgroup analysis evaluated the efficacy and safety outcomes in Asian patients (pts) with relapsed MM from the ENDEAVOR study.
Methods: Adult Asian pts with RRMM (1-3 prior regimens) were included. Patients in the Kd arm received carfilzomib at 20/56 mg/m^2 IV of a 28-D cycle. The Vd arm received bortezomib 1.3 mg/m^2 IV or SC of a 21-D cycle. Cycles were repeated until disease progression or unacceptable toxicity. The primary end point was PFS; secondary end points included overall survival (immature at the time), overall response rate (ORR), incidence of grade ≥2 peripheral neuropathy, and safety.
Results: Of 929 pts randomized, 109 (11.7%) were of Asian ethnicity (Kd=54,Vd=55) from the JAPAC countries and received study treatment. The

majority were from Japan (n=44; 40.4%) followed by Taiwan (n=24; 22.0%), Singapore (n=20; 18.3%), Republic of Korea (n=16; 14.7%), and Thailand (n=5; 4.6%). Median PFS follow-up was 8.4 mo (Kd) and 7.6 mo (Vd). Median PFS was 14.9 mo (Kd; 95% CI:13.1–17.7) *vs* 8.8 mo (Vd; 95% CI:6.6–NE [not estimable]) (HR=0.57, [95% CI:0.29–1.14]; Figure 1A), representing a greater than 6 mo improvement. The ORR was 79.6% (Kd; 95% CI:66.5–89.4) *vs* 70.9% (Vd; 95% CI:57.1–82.4) (odds ratio=1.604 [95% CI:0.664–3.872]). The proportion of pts who achieved a best overall response (OR) of ≥complete response (CR) was higher in the Kd arm (9.3%) *vs* the Vd arm (1.8%). Also, the rate of ≥very good partial response (VGPR) in the Kd arm (63.0%) was more than twice of that in the Vd arm (23.6%). Grade ≥2 peripheral neuropathy occurred in 0% of pts in the Kd arm and 29% in the Vd arm. Rates of serious treatment-emergent adverse events (TEAE), significant AEs of interest, and AEs leading to treatment reduction or discontinuation (Kd or Vd) are shown in Figure 1B. Similar pt incidence rates of AEs, ≥Grade 3 AEs, and ≥Grade 3 treatment-related AEs were observed between the Kd and Vd arms except for higher cardiovascular events and hypertension being observed in Kd arm.

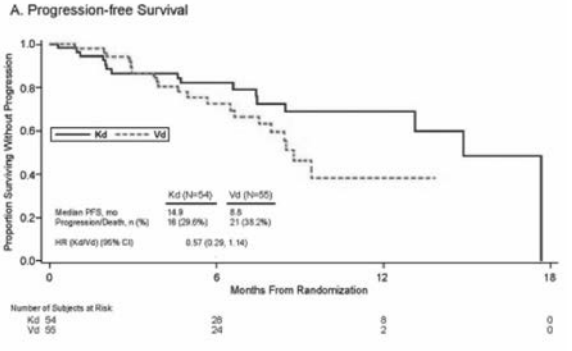

Figure 1.

Table 1.

B. Safety Results

	Asian Population (Safety Population)	
	Vd (bortezomib and dexamethasone) N=55, n (%)	Kd (carfilzomib and dexamethasone) N=53, n (%)
Number of Patients Reporting Serious TEAE	20 (36.4)	23 (43.4)
Significant AEs		
Cardiac failure	0	2 (3.8)
Dyspnea	2 (3.6)	9 (17.0)
Hypertension	4 (7.3)	14 (26.4)
Renal failure	0	0
Dose Reduction Due to an AE	34 (61.8)	13 (24.5)
Treatment Discontinuation due to an AE	7 (12.7)	8 (15.1)

Summary/Conclusions: In general, the efficacy and safety results from the Asian population analyses paralleled and are consistent with the results from the overall population of the ENDEAVOR study although the small sample size limits definitive conclusions regarding rates of AEs. For pts of Asian ethnicity, Kd therapy lead to clinically meaningful improvements in PFS, ORR, and CR/VGPR compared with the Vd arm.

E1329

THE PROGNOSTIC SIGNIFICANCE OF DEL1P IN MULTIPLE MYELOMA PATIENTS

A Nedeva[1,*], V Goranova-Marinova[2], E Naseva[3], T Boneva[4], A Assenova[4], L Mitev[4], E Hadjiev[5], R Petrova[6], T Popova[6], A Yordanov[6], D Todorieva[7], J Raynov[1], I Kindekov[1], N Petkova[1], I Nikolov[1]
[1]Department of Hematology, Military Medical Academy, Sofia, [2]Department of Hematology, St George University Hospital, Plovdiv, [3]Faculty of Public Health, Medical University, [4]Cytogenetic Laboratory, Military Medical Academy, [5]Department of Hematology, Alexandrovska University Hospital, [6]Department of Hematology, St Ivan Rilski University Hospital, Sofia, [7]Department of Hematology, G.Stransky University Hospital, Pleven, Bulgaria

Background: The genomic characteristics of the malignant clone are an important aspect of multiple myeloma pathogenesis. It is well known that the disease is associated with certain cytogenetic abnormalities, some of which confer poor prognosis. The detection of these abnormalities with fluorescence in situ hybridization (FISH) can identify a group of patients with high risk who should be treated differently compared to those with standard risk.
Aims: Identification of genetic markers as independent prognostic factors for survival in multiple myeloma patients and assessment of their significance in the era of novel agents.
Methods: 92 newly-diagnosed multiple myeloma patients with performed FISH and/or conventional cytogenetics were evaluated. FISH analysis was performed in 76 patients, using specific probes for the most frequent high-risk genetic markers, including t(4;14), del17p, del13, amp1q and del1p. Prognostic factors for progression-free survival (PFS) and overall survival (OS) were identified by means of the Cox proportional hazard model for covariate analysis. As possible prognostic factors the following parameters were included in the regression model: age, β2-microglobulin levels, hemoglobin levels, platelet counts, creatinine, calcium, percentage of bone-marrow infiltration, extramedullary disease, plasmablast morphology and presence or absence of the above mentioned genomic aberrations. Median survival times were calculated and compared according to the presence or absence of a particular high-risk aberration and the type of induction therapy (bortezomib-based or conventional). Kaplan-Meier curves were plotted and compared using the log-rank test. Statistical analyses were performed with the program SPSS v21.
Results: The prevalence of high-risk genomic aberrations in our patient cohort was as follows: del13 in 39 (42.4%) patients; amp1q - in 22 (23.9%); del1p and del17p each in 15 (16.3%), and t(4;14) in 8 (8.7%) patients. In our analyses only high β2-microglobulin levels (p=0,035) and del1p (p=0,000) were independent prognostic factors for PFS, while high β2-microglobulin (p=0.002), thrombocytopenia (p=0.037) and del17p (p=0.006) were independent predictors of poor OS. Among the high-risk genetic abnormalities del1p and del17p had the greatest negative influence on patients' outcome, regardless of the induction therapy performed (conventional or bortezomib-based). Patients with del1p and 17p had a significantly shorter median survival, compared with patients without these aberrations, even after induction with a novel agent: 16 months *vs* 79 months for del1p (p=0.014) and 12 months *vs* 79 months for del17p (p=0.001).
Summary/Conclusions: Del17p is a well-known adverse prognostic factor in multiple myeloma which is included in the risk stratification models. Presence of this aberration predicts short survival and such patients are candidates for clinical trials. Only few data however are present on the prognostic significance of del1p in the era of novel agents. According to our results patients with del1p should be considered high-risk, similarly to patients with del17p, and may be candidates for more aggressive induction therapy.

E1330

PEGFILGRASTIM *VERSUS* FILGRASTIM IN THE MANAGEMENT OF POST-CHEMOTHERAPY NEUTROPENIA IN RELAPSED AND REFRACTORY MULTIPLE MYELOMA IN TREATMENT WITH BVD (BENDAMUSTINE BORTEZOMIB-DEXAMETHASONE)

C Cerchione*, D Nappi, D Salvatore, I Migliaccio, F Pane, L Catalano
Hematology, Ematologia e trapianto/au federico ii, Napoli, Italy

Background: Patients receiving cancer chemotherapy are at increased risk of neutropenia, leading to increased risk of infections and delay in subsequent chemotherapy treatments. Recombinant granulocyte colony stimulating factors (G-CSFs) have been developed to stimulate proliferation and differentiation of neutrophils in patients receiving chemotherapy. Pegfilgrastim is a pegylated long-acting recombinant form of G-CSF that extends the half-life and allows for once-per-cycle dosing, requiring less frequent dosing than nonpegylated G-CSF. Multiple Myeloma (MM) in advanced phases of disease may be managed by regimens combining agents not frequently employed in early phases of treatment (e.g. Anthracyclines, Alkylating agents, etc), but myelotoxicity is the main expected side effect. In this context, G-CSFs are often necessary to counteract the risks of febrile neutropenia: their use is bound to frequent evaluation of neutrophil counts that may not be easy for patients in home-care. Avoiding severe neutropenia by prophylactic pegfilgrastim seems particularly useful in these cases.
Aims: The objective of this study was to compare the efficacy and safety of pegfilgrastim in patients affected by Multiple Myeloma in advanced phase of disease. treated with BVD (Bendamustine, Bortezomib, Dexamethasone), in order to determine whether a single subcutaneous injection of pegfilgrastim is as effective as daily injections of standard filgrastim, in terms of haematological toxicity, febrile neutropenic episodes, antibiotic usage and hospedalization duration.
Methods: 47 patients (25 male and 22 female) with a median age of 58.4 years (range 36-82) affected by multiple myeloma, all relapsed and refractory to a median of 6 lines of therapy (range 2-11), all previously exposed to Bortezomib, Lenalidomide, Melphalan and all relapsed after at least one autologous bone marrow transplantation, had been enrolled.
Results: Since first course, received in our out-patient department, patients performed blood counts twice weekly and received, from day +8 to day +19 (considering "day+1" the day in which the chemotherapy protocol starts), prophylactic oral chinolonic antibiotics and anti-fungal drugs. During neutropenia after first cycle of chemotherapy, Filgrastim (5μgr/kg/day for 3 days) was given if neutrophils count was <1500x10^9cells/L. Median number of filgrastim administrations was 4.1 (r. 3-6); nadir neutropenia was registered after a median of 11.6 days (r. 8-14); median of nadir neutrophil count was 1.22x10^9cells/L (range 0.4-1.5x10^9cells/L), with maximum duration of 13 days. From the second course of chemotherapy, all patients switched to prophylactic therapy with pegfilgrastim (6 mg), injected subcutaneously with a single administration on

day +3 independently from the neutrophil count at that time. Primary endpoint of this study was the duration of neutropenia (neutrophil count <1.5x10^9 cells/L), comparing pegfilgrastim and filgrastim. During pegfilgrastim, neutropenia was never longer than 8 days, with a consequent reduction of neutropenia-related infections. Median nadir neutrophil count, evaluated for every patients for at least three courses of therapy (r. 3-6) registered at day +11, was 1.484 (range 1.04-2.33x10^9cells/L); only six patients (12.7%) needed, one week after pegfilgrastim administration, a supplement of 3 administrations of filgrastim. During pegfilgrastim prophylaxis, neutropenia was shorter than during Filgrastim treatment. Besides the mono-administration, pegfilgrastim was well tolerated in all patients: main side effects in our patients were mild fever and bone pain, (9/47 patients,19.1%).
Summary/Conclusions: In conclusions, in patients affected by MM exposed to myelosuppressive agents in advanced phases of myeloma disease, pegfilgrastim seems to reduce the incidence of neutropenia and may increase the possibility to maintain the scheduled time of treatment.

LB2262

PREDICTIVE VALUE OF AUTOANTIBODIES AGAINST M2-MUSCARINIC ACETYLCHOLINE RECEPTOR FOR THE ONSET OF CARDIAC AMYLOIDOSIS IN MULTIPLE MYELOMA
L Li*

Background: Multiple myeloma (MM) is a clonal late B-cell disorder in which malignant plasma cells (PCs) expand and accumulate in the bone marrow, leading to anemia, lytic or osteopenic bone disease and renal failure. Nowadays MM has accounted for the second most common hematological malignancy after non-Hodgkin lymphoma with its incidence of 1% in neoplastic diseases and 13% in hematological malignance[1,2]. According to the data[3], approximately 10% of multiple myeloma tends to be complicated by cardiac amyloidosis, mainly AL amyloidosis, in which the amyloidosis protein is consisted of monoclonal immunoglobulin light chains produced excessively by plasma cell malignancy. Moreover, up to 50% of patients with AL amyloidosis would progressively develop restrictive heart failure[4]. Unfortunately the prognosis is still poor. M_2 muscarinic receptor is attached to the family of cardiac G-protein-coupled receptors. Previously the auto-antibodies against the second extracellular loop of M_2-muscarinic acetylcholine receptor (anti-M_2-R) have been verified to involve in the development of various heart diseases characterized by heart failure, such as idiopathic dilated cardiomyopathy, Chagas's heart disease and peripartum cardiomyopathy[5-7]. Furthermore, the level of anti-M_2-R is positively associated with the increased risk of onset of peripartum cardiomyopathy[7]. Consequently, our study aims to explore whether the level of anti-M_2-R would rise in MM patients with or without cardiac amyloidosis and whether anti-M_2-R would increase the risk of cardiac amyloidosis in MM patients.
Aims: 1. Anti-M_2-R might participate in the phathophysiologic mechanism of cardiac impairment complicated by MM;
2. Anti-M_2-R can be an earlier predictor to estimate the risk of cardiac amyloidosis in MM patients than NT-proBNP.
Methods: Totally 78 subjects were recruited, including23 MM with cardiac amyloidosis, 25 MM without amyloidosis (MM) and 30 normal control (NC). The frequency and titer of anti-M_2-R were compared in the three groups. All MM were under detection of serum anti-M_2-R by ELISA before chemotherapy. The risk of cardiac amyloidosis was estimated using the univariate and multivariate logistic regression.
Results: The positive rates of anti-M_2-R in the three groups are 69.6% (16/23) in MM with cardiac amyloidosis, 40.0% (10/25) in MM and 10.0% (3/30) in NC respectively (p=0.040,69.6% *vs* 40% and p=0.003, 40.0% vs.10%).Moreover, multivariate logistic regression indicates that the presence of anti-M_2-R is associated with an increased risk of complicated cardiac amyloidosis in MM patients (OR, 5.5; 95% CI, 1.4-21.4; p=0.013).
Summary/Conclusions: This study demonstrates that the elevated level of anti-M_2-R is an earlier independent predictor for the risk of cardiac amyloidosis in MM patients.

Myeloproliferative neoplasms - Biology

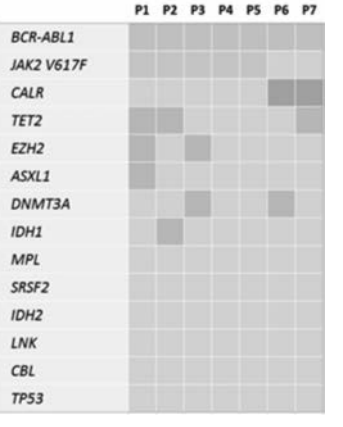
MOLECULAR CHARACTERIZATION OF MYELOPROLIFERATIVE NEOPLASMS WITH CONCOMITANT BCR-ABL1 AND JAK2 V617F OR CALRETICULIN MUTATIONS
C Bödör[1,*], P Király[1], T Krahling[2], A Gángó[1], D Marosvári[1], T Masszi[3], S Fekete[4], G Ujj[5], M Egyed[6], P Farkas[3], J Csomor[7], B Kajtár[8], A Bors[2], A Tordai[9], H Andrikovics[2]
[1]MTA-SE Lendulet Molecular Oncohematology Research Group, 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, [2]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, [3]3rd Department Of Internal Medicine, Semmelweis University, [4]Department of Haematology and Stem Cell Transplantation, St. Istvan and St. László Hospital, Budapest, [5]Department of Hematology, Hetenyi Hospital, Szolnok, [6]Department of Hematology, Kaposi Mor Hospital, Kaposvar, [7]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, [8]Department of Pathology, University of Pécs, Pécs, [9]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary

Background: Myeloproliferative neoplasms (MPN) are classified based on the presence of the *BCR-ABL1*, *JAK2* and *CALRETICULIN* mutations. These are considered to be mutually exclusive, however rare cases with concomitant occurrence of these driver mutations have been reported, representing an ideal model to chronicle the molecular alterations and to investigate the clonal architecture in these cases. We report a comprehensive clinical and genetic analysis of sequential samples obtained from 7 patients with concurrent *BCR-ABL1* and *JAK2* V617F or *CALR* mutations diagnosed at our centers between 1998 and 2015.
Aims: To perform a detailed clinical, morphological and quantitative genetic analysis of sequential samples obtained from 7 patients with MPN with concomitant *BCR-ABL1* and *JAK2* V617F (n=5) or *CALR* mutations (n=2) to gain further insight into clonal architecture and pathogenesis of these rare double-mutated cases.
Methods: DNAs and RNAs extracted from peripheral blood or bone marrow samples were used to perform quantitative analysis of the *BCR-ABL1* fusion transcript and *JAK2* V617F/*CALR* mutations as part of the routine molecular diagnostic workup. The mutation status of 13 genes (*JAK2, CALR, MPL, ASXL1, EZH2, SRSF2, IDH1, IDH2, LNK, CBL, TET2, DNMT3A, TP53*) frequently mutated in MPNs was analyzed using next generation sequencing (NGS). The NGS analysis for performed using the AmpliSeq technology with an IonTorrent instrument at an average depth of 1000x on 15 sequential samples from 7 patients.
Results: The quantitative analyses of the *BCR-ABL1* fusion transcript and *JAK2* V617F or *CALR* mutations suggested that these driver mutations occurred in different clones in 5 out the 7 cases analyzed. The next generation sequencing analysis of the 13 target genes identified additional mutations in 5 of the 7 cases with concurrent driver mutations (summarized in the heat map in *Figure 1*). The most frequently mutated gene was *TET2* with mutations identified in 3 cases (2 cases with *BCR-ABL1* and *JAK2* mutation and one case with *BCR-ABL1* and *CALR* mutation). Both *EZH2* and *DNMT3A* mutations were detected 2 cases. *ASXL1* and *IDH1* were found to carry mutations in single cases with BCR-ABL1 and *JAK2* mutation. The 5 patients harboring additional mutations carried 1-3 mutation per sample with one of the cases presenting with 3 additional mutations affecting the *TET2, EZH2* and *ASXL1* genes.

Table 1.



Summary/Conclusions: Our analysis of the 7 patients with concurrent MPN driver mutations suggested that the *BCR-ABL1* and *JAK2* or *CALR* mutations occur in different clones in majority of cases with frequent acquisition of additional phenotype modifying genes including *TET2, EZH2, ASXL1* and *DNMT3A*.

E1332

ABNORMAL EXPRESSION OF LCN2 (NEUTROPHIL GELATINASE ASSOCIATED LIPOCALIN) IN MYELOPROLIFERATIVE NEOPLASMS

T Fanelli[1,2,*], P Guglielmelli[1], F Gesullo[1], G Corbizi Fattori[1,2], G Rotunno[1], A Pancrazzi[1], AM Vannucchi[1]
[1]Department of Experimental and Clinical Medicine,University of Florence, CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Florence, [2]University of Siena, Siena, Italy

Background: Myeloproliferative neoplasms (MPNs), including polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF), are clonal hematopoietic stem cells' disorders. Clonal proliferation in MF is accompanied by a secondary inflammatory reaction characterized by bone marrow (BM) stromal changes and abnormal cytokine expression. We recently reported *LCN2/NGAL* upregulated mRNA expression in CD34+ cells of MF patients (Norfo et al. Blood 2014;124:e21-e32); increased BM expression of LCN2 might facilitate clonal predominance and contribute to a dysfunctional BM microenvironment (Lu M at al. Blood.2015;126:972-982).
Aims: We aimed to investigate the clinical significance of LCN2 levels and its correlation with clinical and molecular aspects in patients with MPNs.
Methods: One hundred well characterized MPN patients (20 PV, 20 ET, 30 PMF, 30 PPV-MF and PET-MF) were included in this study, and 20 health subjects. *LCN2* mRNA expression was performed in granulocytes by RTQ-PCR. Measurements of NGAL plasma protein (PP) were performed by ELISA (Bioporto Diagnostics). Mutational status of *JAK2, MPL, EZH2, ASXL1, IDH1/2, CBL, TP53, TET2, DNMT3A, SRSF2* was evaluated as previously reported. Statistical analyses were conducted with SPSS and Origin software.
Results: Significantly higher levels of *LCN2* mRNA and PP were found in PMF pts (mRNA: median RQ 9.70; PP: median 6.03ng/ml) in comparison with controls (mRNA:median RQ 1.09, P=.02; PP: median 1.19ng/ml; P=.005). mRNA LCN2 expression in PMF was also significantly higher compared with PV and ET (median RQ 1.89; P=.01 and median RQ 3.55; P=.02, respectively). Higher levels of PP were also observed in PPV-MF (median 4.82ng/ml) compared to controls (P=.003). LCN2 PP levels comparison among MPN sub-types is reported in Figure1. In particular LCN2 PP levels in PET-MF (median 2.86 ng/ml) were two-fold greater than in ET (median 1.395 ng/ml; P=.01), suggesting a link between increased LCN2 levels and progression to MF. mRNA expression inversely correlated with hemoglobin levels (P=.03, r=-0.29). LCN2 mRNA levels were positively correlated with IPSS scores (P=.01), and were higher in ASXL1+ pts (n=23) compared with WT (3.2 *vs* 10.4, P=.02). CALR+ pts showed lower levels compared with JAK2+ or Triple Negative (2.60 *vs* 4.85 *vs* 8.71 ng/ml respectively, P=.04), while PP levels were significantly higher in SRSF2+ pts (n=4) compared to WT (17.35 *vs* 4.04, P=.02). PP levels were linearly correlated with CD34+ count (P=.01, r=0.28). In 17 of 33 MF pts, reduction of PP LCN2 levels was observed after treatment with ruxolitinib; of these 6 (54.5%) achieved a spleen volume reduction and in 7 (63.6%) constitutional symptoms resolved.

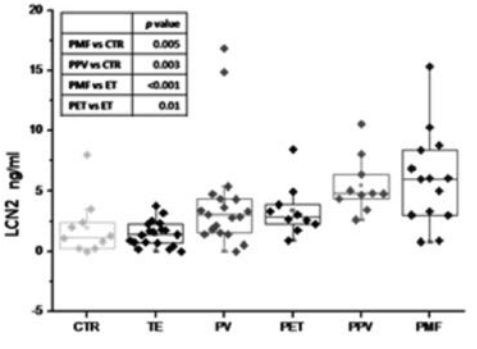


Figure 1.

Summary/Conclusions: Lipocalin might represent a novel diagnostic and/or prognostic marker and could also provide a new therapeutic target in MPNs, particularly myelofibrosis. Further studies are required to fully clarify the clinical significance of Lipocalin overexpression in myelofibrosis.

E1333

FACS SORTED PERIPHERAL BLOOD CELLS IDENTIFY CALR MUTATIONS IN B-AND T CELLS

L Kjær[1,*], MO Holmström[1], S Cordua[1], M Thomassen[2], TA Kruse[2], MH Andersen[3], IM Svane[3], N Pallisgaard[4], V Skov[1], HC Hasselbalch[1]
[1]Department of Hematology, Roskilde Hospital, Roskilde, [2]Department of Clinical Genetics, Odense University Hospital, Odense, [3]Department of Hematology, Center for Cancer Immune Therapy (CCIT), Copenhagen University Hospital, Herlev, Herlev, [4]Department of Pathology, Roskilde Hospital, Roskilde, Denmark

Background: Somatic mutations in exon 9 of the calreticulin gene (*CALR)* are found in the majority of the *JAK2V617F* negative Philadelphia-negative myeloproliferative neoplasms (MPNs) essential thrombocythemia (ET) and primary myelofibrosis (PMF). A hallmark of the mutated CALR protein is its preferential expression in megakaryocytes, and so far, mutations in CALR have only been found in cells of myeloid lineage. However, mutations in the *CALR* gene are considered an early event and thus expected to be present in cells of the lymphoid compartment as well. The mutant allele burden has been suggested to have an impact on the disease phenotype, but patients with high mutant allele burden appear to be rare and it is unknown if homozygous sub-clones is common in patients.
Aims: Here we wish to determine if the *CALR* mutations are present in B- and T- lymphocytes and investigate if homozygous clones are present in the patients.
Methods: In this study, we separated the myeloid and lymphoid cell fractions from 11 *CALR* mutated patients (4 ET, 1 pre-fibrotic primary myelofibrosis (pre-PMF), 5 PMF, and 1 post-ET MF) using fluorescent activated cell sorting (FACS). The mutations included the type 1 and type 2 subtypes, and two different 34 base-pair deletions. The allele burden was quantified for type 1 and 2 mutations using allele specific qPCR and the 34 base-pair deletions quantified by fragment analysis. Granulocytic and erythroid cell colonies from 15 patients (4 ET, 3 pre-PMF, 7 PMF, and 1 post-ET MF) were cultured in the presence of erythropoietin and after expansion individual colonies was isolated and analyzed for the *CALR* mutant allele burden.
Results: The mutant allele burden was determined in whole-blood (median: 41%, range: 3-47%), granulocytes (CD16+ median: 51%, range: 4.8-63%), and monocytes (CD14+; median: 47%, range: 5.6-61%). In 3 of 11 patients (27%), the type 1 mutation was found in T-lymphocytes (CD3+; median: 6.4%, range: 5-7.8%), and in 2 of 11 patients (11%) in B-lymphocytes (CD19+; median: 25%, range: 18-31%). One patient had the type 1 mutation in both cell types. The type 2 mutation was found in T-lymphocytes of a single patient (16%). Isolated granulocytes and erythroid cells from cultured cell colonies revealed the *CALR* positive clones from all patients to be heterozygous for the mutations.
Summary/Conclusions: The presence of the *CALR* mutations in both myeloid and lymphoid lineages indicates the *CALR* mutation to be an early event in a multipotent hematopoietic stem cell expanding as a heterozygous mutated clone of the myeloid lineage to become dominant in the majority of *CALR* mutated MPN patients.

E1334

FAILURE OF MEGAKARYOCYTE APOPTOSIS IN MYELOPROLIFERATIVE NEOPLASMS

J Malherbe[1,*], K Fuller[1,2], CC So[3], B Guo[1], R Howman[2], W Erber[1,2]
[1]Translational Cancer Pathology Laboratory, School of Pathology & Laboratory Medicine, University of Western Australia, Crawley, [2]Department of Haematology, PathWest Laboratory Medicine, Nedlands, Australia, [3]Department of Pathology, Faculty of Medicine, University of Hong Kong, Hong Kong SAR, China

Background: Megakaryocytic hyperplasia and morphological atypia are characteristic features of the myeloproliferative neoplasms (MPN) and its entities: polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (MF). Data from murine and *ex vivo* models suggest that multiple molecular abnormalities (*e.g. JAK2*^{V617F}, *CALR* mutations) underpin megakaryocyte expansion in the MPN. Limited studies also show that megakaryocytes utilize apoptotic caspases to shed platelets and in the MPN, they may have apoptotic disturbances. Despite these claims, there is little data demonstrating the precise apoptotic defects and pathways affected in megakaryocytes of human MPN.
Aims: We investigated the apoptotic pathobiology of megakaryocytes in human MPN. We determined whether these disturbances targeted the intrinsic and/or extrinsic apoptotic pathways and examined their differential associations between MPN disease entities and the *JAK2*^{V617F} and *CALR* driver mutations.
Methods: Bone marrow trephines of MPN (PV=20, ET=72, MF=53) and controls (n=15) were studied. These included *JAK2*^{V617F}, *CALR*-mutated (*CALR*-^{Mut}) and double negative (JAK2^{V617F}-/*CALR*^{WT}) cases. Sections were stained with antibodies to pro-apoptotic (BNIP-3, caspase-8, caspase-9, Diablo, p53) and anti-apoptotic (Bcl-XL, survivin) effectors involved in the intrinsic and extrinsic apoptotic pathways using an immuno-alkaline phosphatase and Fast Red chromogen detection system. Megakaryocyte positivity was assessed by light microscopy and the percent positive determined per case. Mean differences (MD) in megakaryocyte positivity between MPN entities and *JAK2*^{V617F}/*CALR* mutation states were statistically evaluated. Megakaryocyte positivity was also correlated with platelet count.
Results: Megakaryocytes in MPN showed significantly greater positivity for anti-apoptotic Bcl-XL and survivin, and pro-apoptotic Diablo, caspase-8 and p53 than controls. However, MPN had significantly fewer pro-death BNIP-3 positive megakaryocytes (MD=42.8%, p<0.0001). Caspase-9 was only marginally increased in MPN (MD=4.3%, p=0.02). The apoptotic dysregulation was most marked in MF. Significantly fewer BNIP-3 positive megakaryocytes were seen in MF than ET (MD=14.7%, p=0.008). MF also had fewer caspase-9 positive megakaryocytes compared with both PV (MD=33.8%, p=0.003) and ET

(MD=19.8%, p=0.02). However, p53 was increased ~2.7-fold in MF *versus* PV (p=0.007). *CALR*^{Mut} megakaryocytes typically had pyknotic chromatin and lower pro-apoptotic BNIP-3 levels relative to *JAK2*^{V617F} (MD=24.2%, p=0.0008). Platelet counts correlated positively with caspase-9 megakaryocyte positivity in MPN (r=0.28, p=0.002), and strengthened among MF (r=0.34, p=0.03) and *CALR*^{Mut} cases (r=0.50, p=0.03).
Summary/Conclusions: Megakaryocytic hyperplasia in the MPN is assisted by disruptions of the intrinsic apoptotic pathway. Our data shows overexpression of anti-apoptotic Bcl-XL and survivin to be the key apoptotic inhibitors mediating megakaryocyte survival. In MF, apoptotic failure is exacerbated by reductions in pro-death BNIP-3 and caspase-9; this may relate to the marked formation of cohesive megakaryocyte sheets and abnormal nuclear morphology common in MF. *CALR* mutations also showed greater reductions in pro-apoptotic BNIP-3 compared with *JAK2*^{V617F}. Finally, the upregulation of caspase-9 seen in megakaryocytes of *CALR*-mutated cases may account for the thrombocytosis associated with this molecular subgroup.

E1335

INCREASED PLASMA NICOTINAMIDE PHOSPHORIBOSYLTRANSFERASE (NAMPT) IS ASSOCIATED WITH A HYPERPROLIFERATIVE PHENOTYPE AND RESTRAINS DISEASE PROGRESSION IN MPN-ASSOCIATED MYELOFIBROSIS

V Rosti[1,*], R Campanelli[1], M Massa[2], G Viarengo[3], L Villani[1], V Poletto[1], E Bonetti[1], P Catarsi[1], G Fois[1], U Magrini[1], A Grolla[4], C Travelli[4], A Genazzani[4], G Barosi[1]
[1]Centro per lo Studio e la Cura della Mielofibrosi - L.S.R. Area Biotecnologie, [2]L.S.R. Area Biotecnologie, [3]Servizio Immunoematologia e Trasfusione, Fondazione IRCCS Policlinico San Matteo, Pavia, [4]Dipartimento di Scienze Farmaceutiche, Universita' del Piemonte Orientale, Novara, Italy

Background: Myeloproliferative neoplasm (MPN)-associated myelofibrosis is a clonal, neoplastic disorder of the hematopoietic stem cells, in which inflammation and immune dysregulation play an important role. Somatic mutations of JAK2 (JAK2V617F), CALR or MPL genes ar pathogenetically linked to the disorder. JAK-STAT pathway activation is the main mechanism of myeloproliferation; however, available evidence indicates that inflammatory/immune mechanisms play an important role in the phenotype of MPN-associated myelofibrosis by increased production of inflammatory cytokines and reduced number of regulatory T-cells. Nicotinamide phosphoribosyltransferase (NAMPT), intracellularly, is an enzyme that converts nicotinamide into nicotinamide mononucleotide, precursor of nicotinamide adenine dinucleotide (NAD^+), which is essential for cellular metabolism, energy production, DNA repair, and survival. NAMPT exists also as an extracellular protein defined in literature as Pre-B cell colony-enhancing factor (PBEF) or as an adipokine called visfatin. Different type of cells are able to release this protein, but its role as a cytokine is still unknown. Emerging data implicate eNAMPT in the pathogenesis of a number of different human diseases that share an inflammatory basis, such as rheumatoid arthritis, type 2 diabetes, acute life-threatening processes such as acute lung injury, sepsis, and tumorigenesis. In the tumour microenvironment, eNAMPT induces monocyte polarization to M2 macrophages secreting tumor-promoting cytokines and inhibiting T-cell responses rendering this pleiotropic molecule a novel player in tumor/host cross-talk. The function of NAMPT in MPN-associated myelofibrosis biology is completely unknown
Aims: Here we examined plasma levels of eNAMPT in patients with MPN-associated myelofibrosis and their effects on disease phenotype and outcomes. We also studied the concordance of eNAMPT levels with the marker of general inflammation high-sensitivity C-reactive protein (hs-CRP).
Methods: A total of 333 MPN-associated myelofibrosis patients (187 males and 146 females) and 31 age- and gender-matched normal-weight controls were enrolled in the study. The control group was selected among the general population excluding individuals with a body mass index greater than 25. At study entrance, all participants gave their informed consent, and study protocol was approved by the Ethics Committee of our Hospital before implementation. Since there is no accepted definition of disease severity, we evaluated a "severity score" by indexing leukocytosis, thrombocytosis, and splenomegaly (myeloproliferation index), and anemia, leukopenia, and thrombocytopenia (myelodepletion index) Levels of eNAMPT and hs-CRP were simultaneously assayed in 209 MPN-associated myelofibrosis patients. Twenty-four polycythemia vera or essential thrombocythemia patients were used as controls. eNAMPT levels were measured using a commercial immunoassay kit (BioPlex, BioRad Hercules, CA, USA) according to manufacturer instructions. All samples were assayed in duplicate.
Results: In the 333 MPN-associated myelofibrosis patients enrolled in the study main body, risk stratification according to the IPSS/DIPSS prognostic scoring system showed a predominance of low and intermediate I risk classes (74% of the patients). The severity score of the disease based on spleen size and hematological parameters measured at the time of eNAMPT analysis ranged from 0 to 6 with a median value of 3. The "myeloproliferation index" (range 0 to 4) had a median value of 3 and was equal to or lower than 1 in 39 patients (46.4%), while the "myelodepletion index" (range 0 to 4) had a median value of 2 and was equal to or lower than 1 in 34 patients (40.5%). eNAMPT was over expressed in MPN-associated myelofibrosis (n=333, median 1,487 ng/L, range 81-96,031) compared to healthy subjects (n=31, median 268 ng/L, range 81-4,981; P=0.001). There was no difference in the median eNAMPT level between patients with PMF and post-PV or post-ET myelofibrosis. eNAMPT expression was correlated with higher white blood cell count (R=0.13;P=0.029), higher hemoglobin (R=0.20;P<0.001) and higher platelet count (R=0.25;P=<0.001), suggesting that eNAMPT is an indispensable permissive agent for myeloproliferation of MPN-associated myelofibrosis. In 209 patients with MPN-associated myelofibrosis we simultaneously assayed eNAMPT and hs-CRP. Patients with MPN-associated myelofibrosis had higher levels of hs-CRP than healthy controls (median, 0.15 ng/µl, range, 0.02 to 11.4). However, the individual values of eNAMPT were not correlated with those of hs-CRP level, suggesting that eNAMPT in MPN-associated myelofibrosis does not behave as a canonical inflammatory cytokine. In addition, higher levels of eNAMPT predicted longer time to blast transformation, and protected against progression towards thrombocytopenia and large splenomegaly.
Summary/Conclusions: In conclusion, in MPN-associated myelofibrosis high levels of eNAMPT mark the myeloproliferative potential and, at variance with a high number of cancers, are protective against disease progression.

DOES THE MUTATIONAL STATUS AFFECT THE BONE MARROW MORPHOLOGICAL DATA IN PATIENTS WITH CLASSICAL PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS?

L Medina-Vega, L Hernández-Nieto, H Álvarez-Argüelles, B Soria, L Gutiérrez-Murillo, T Martín-Santos, A Martín-Martín, C De Bonis, S Martín-Batista, S Lakhwani, G González-Brito, MT Hernández-García, E Salido, JM Raya[*]
Hospital Universitario de Canarias, La Laguna, Spain

Background: It is known that there may be a correlation between a genetic or molecular alteration and the presence of characteristic histomorphological changes in the bone marrow (for example, 5q- syndrome). In recent years, molecular alterations described in chronic Philadelphia-negative myeloproliferative neoplasms, mainly *JAK2* V617F, calreticulin (*CALR*) and *MPL*, have gained great diagnostic and prognostic interest.
Aims: Our objective was to analyze the possible influence of the mutational status of these diseases on the histomorphological appearance of the bone marrow.
Methods: We have retrospectively studied 140 patients atended at our center between 1998 and 2013, with a diagnosis of Philadelphia-negative myeloproliferative neoplasm. The series included 44 patients with polycythemia vera (PV, male 61%, mean age 61, range 28-82), 78 with essential thrombocythemia (ET, female 62%, mean age 54, range 16-81) and 18 with primary myelofibrosis (PMF, male 61%, mean age 63, range 46-95). We determined the presence or not of the mutations for *JAK2*, *CALR* and *MPL* by standard methods. All patients had performed a bone marrow trephine biopsy at diagnosis, and samples were examined by two hematologists and a pathologist with proven experience on these entities. A total of 18 histopathological characteristics were analyzed: overall and differential (erythroid, myeloid and megakaryocytic) cellularity, megakaryocytes features (size, disposition in dense or loose clusters, nuclei morphology, presence of "naked" nuclei, intrasinusoidal and paratrabecular location), anormal location of immature precursors, emperipolesis, presence of lymph nodes, microvasculature density, vascular ectasia, iron stain, osteoclerosis, collagen fibers, CD34+ precursors, and intrasinusoidal hematopoiesis. Arrangement was considered when the degree of consensus included at least two observers. Statistical analysis was performed using the SPSS 17.0 version.
Results: The frequency and distribution of mutations were as follows: 1) PV: *JAK2* V617F mutation in 88.4% of cases and *JAK2* exon 12 mutation in 4.7%; 2) ET: *JAK2* V617F mutation in 43.4% of analyzed patients, *CALR* mutation in 26.4% and none was carrier of *MPL* mutation; 3) PMF: *JAK2* V617F mutation in 37.5%, *CALR* mutation in 31.2% and none with *MPL* mutation. No morphological differences were found in the bone marrow of patients diagnosed with PV or ET according to their mutational status (carriers or not of mutations in *JAK2* in PV cases, and carriers or not of *JAK2* or *CALR* mutation in patients with ET). However, some significant changes were observed in patients with PMF. In the latter group of patients, the *JAK2* V617F mutation is associated with a significantly increased overall marrow cellularity when compared with *CALR* mutation (predominantly normocellular) (p=0.025). Meanwhile, carriers of *CALR* mutation, compared to those with *JAK2*, show significant changes in nuclear lobulation of megakaryocytes (mostly hyperlobulated *versus* normo- or hypolobulated in *JAK2* mutated) (p=0.019). The emperipolesis phenomenon was significantly more frequent in PMF patients carrying the *JAK2* V617F mutation when compared with JAK2 non-mutated (p=0.024), and a substantially higher frequency of "naked" nuclei of megakaryocytes was observed in PMF *CALR* mutated cases in comparison with *CALR* non-mutated (p=0.035).
Summary/Conclusions: In our experience, the mutational status appears to influence the histopathological changes observed in the bone marrow of patients with primary myelofibrosis, but not in polycythemia vera or essential thrombocythemia. Further studies including a larger volume of patients are necessary to confirm these findings.

HDAC INHIBITION SYNERGIZES WITH ANTIOXIDANT THERAPY TO TARGET MYELOPROLIFERATIVE NEOPLASMS

BA Cardoso[1,2], TL Ramos[1,3,4], H Belo[1,2], F Vilas-Boas[5], C Real[5], AM Almeida[1,2,*]
[1]Unidade de Investigação em Patobiologia Molecular, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E., [2]Centro de Estudos de Doenças Crónicas, CEDOC, NOVA Medical School/Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal, [3]Instituto de Investigación Biomédica de Salamanca (IBSAL), [4]Servicio de Hematología, Hospital Universitario de Salamanca, Salamanca, Spain, [5]Centro de Química e Bioquímica, Faculdade de Ciências, Universidade de Lisboa, Lisbon, Portugal

Background: The BCR-ABL-negative myeloproliferative neoplasms (MPN) are a group of heterogeneous hematological diseases with constitutive JAK-STAT pathway activation. However, despite the recent advances in unravelling disease etiology (JAK2 activating mutations), there is still no curative treatment outside bone marrow transplantation. Epigenetic alterations, like histone acetylation, play pivotal roles in the pathogenesis of several hematological malignancies, including MPN. Preliminary data showed that histone deacetylase inhibitors (HDACis) promoted in cell death and growth arrest of myeloid neoplastic cells *in vitro*. Importantly, HDACis have proven efficacy in clinical practice, producing remissions and increasing the overall survival in hematological malignancies. HDAC inhibition has also produced results in MPN patients, an effect severely limited by toxicity.
Aims: In order to explore the mechanism of action of HDACis in MPN, we analyzed the impact of HDACi in the cellular biology of MPN cell lines and primary bone marrow cells.
Methods: Primary MPN cells were obtained from bone marrow samples at diagnosis following informed consent. SET2, HEL and UKE-1 MPN cell lines were used. Both primary cells and cell lines were incubated with the different pharmacological reagents and at different time points, the cells were stained for Apoptosis and Reactive Oxygen Species (ROS) for detection by Flow Cytometry.
Results: Vorinostat decreased cellular viability in primary MPN cells, particularly affecting the monocytic lineage, and this was associated with a concomitant decrease in ROS levels. In MPN cell lines we showed that a wide range of HDACi (Vorinostat, Trichostatin A, Butyric Acid and Depsipeptide) produced these effects. Interestingly, HDACi-induced apoptosis was dependent on decreased ROS levels suggesting that both events are connected and necessary for MPN cell death induced by HDACi to occur. By combining both HDACi and ROS reducing drugs (ROS production inhibitors; ROS scavengers and AntiOxidants) we were able to increase MPN cell death in a synergistic manner.
Summary/Conclusions: These results point to a promising synergistic effect of HDACi with ROS depleting drugs in the context of MPN, which must be confirmed *in vivo* and in the clinical setting. These combinations could improve efficacy a tolerability of these agents in MPN, opening the door to a new therapeutic alternative.

REDUCED FREQUENCY OF CIRCULATING CD4+CD25+CD127LOWFOXP3+ REGULATORY T CELLS IN PRIMARY MYELOFIBROSIS

R Campanelli[1], G Fois[1], L Villani[1], P Catarsi[1], E Bonetti[1], V Poletto[1], G Viarengo[2], V Rosti[1], RP Gale[3], G Barosi[1,*], M Massa[4]
[1]Centro per lo Studio e la Cura della Mielofibrosi - L.S.R. Area Biotecnologie, [2]Servizio Immunoematologia e Trasfusioni, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [3]Department of Medicine, Section of Hematology, Imperial College, London, United Kingdom, [4]L.S.R. Area Biotecnologie, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: A systemic dysregulation of immune system, represented by increased plasma levels of several inflammatory cytokines, and clinical and laboratory findings of autoimmunity, has been documented in primary myelofibrosis (PMF). Regulatory T cells (Tregs), currently identified as CD4+T cells with high expression of CD25 (interleukin-2 receptor), low expression of CD127 (IL-7 receptor), and high expression of FOXP3, are known to play a crucial role in the maintenance of T cell homeostasis and immunologic tolerance. Moreover, Treg cell defects have been associated with different autoimmune diseases, and a Treg cell deficit due to a mutation in the FoxP3 gene has been shown to cause aggressive autoimmunity and early death. Although a clinical study has indicated decreased number of Treg cells in the active status of PMF, conflicting results have been reported up to now.
Aims: In this study we investigated the frequency of Tregs, identified as CD4+CD25+CD127lowFoxP3+ cells, to clarify whether or not Treg cell number is reduced in PMF, and to investigate the associations between Tregs frequency and disease phenotype
Methods: Tregs frequency was assessed by flow cytometry in 202 patients with PMF, all out of therapy at time of sampling, and in 24 healthy subjects (HS), comparable for sex and age. Spleen-derived Tregs were evaluated in 17 different patients undergoing splenectomy for symptomatic splenomegaly and in 8 HS splenectomized for abdominal trauma. At study entrance, all participants gave their informed consent, and study protocol was approved by the Ethics Committee of our Hospital before implementation. A single cell suspension was obtained from splenic samples by means of mechanical dissociation followed by density gradient centrifugation. The frequency of $CD4+CD25+CD127^{low}FoxP3+$ cells was calculated as a percentage of positive cells in the total CD4 gate. For the Treg suppression assay circulating $CD4^{+}CD25^{+}$ T cells were immunoselected and cultured in triplicate with soluble anti-CD3/anti-CD28 and autologous irradiated cells. At day 4, ^{3}H thymidine (2Ci/well) was added to cultures for 16 hours and proliferation measured by the amount of incorporated ^{3}H.
Results: Compared with HS who had a median Treg frequency of 1.99% (range, 0.48% to 6.51%), patients with PMF had a median frequency of Tregs of 0.80% (range 0% to 10.2%; P<0.001). A similar trend was observed in the spleen were HS had a median Treg frequency of 1.20% (range 0.36% to 3.97%) and patients with PMF a median of 0.35% (range 0.04% to 1.26%; P<0.001). This result secures that the reduced frequency of circulating Tregs was not due to cell recruitment to sites of active malignancy, like spleen. To support that blood and spleen Tregs were independently regulated among total CD3+CD4+ cells, we measured the percentages of CD3+CD4+ in blood and in total spleen lymphocytes. They resulted non different from healthy individuals (data not reported). The percentage of suppression of Tregs on the proliferation of effector T-cells was comparable in patients with PMF (38.7%) and HS (36.5%) indicating that Tregs isolated from patients were functionally active. In patients bearing *JAK2*V617F mutation (N=126) we observed a higher frequency of circulating Tregs than those non mutated (N= 74; median, 1.00 *vs* 0.70; P= 0.002), and patients with high *JAK2*V617F allele burden (≥50%) had higher frequency of circulating Tregs than those with low allele burden (P= 0.07). In *CALR* mutants, the reduction of circulating Tregs was statistically associated with older age, longer disease duration, and higher IPSS/DIPSS prognostic score, and a strict direct correlation between Treg frequency and haemoglobin was documented.
Summary/Conclusions: Our findings showed that a large fraction of PMF patients had reduced frequency of Tregs, a non clonal component of bone marrow and spleen microenvironment. Blood Treg cell defect was particularly evident in patients lacking *JAK2*V617F mutation: in *CALR* mutated patients the defective Treg percentage was associated with an advanced and prognostically unfavourable disease, and strongly correlated with severity of anemia. These results open new research perspectives and support new therapeutic strategies aimed at increasing the number of Tregs in PMF.

Matteo Foundation, Pavia, [24]Ospedale di Circolo, Varese, [25]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [26]NU Hospital Organization, Uddavalla, [27]Stockholm South Hospital, Stockholm, [28]University Hospital, Uppsala, Sweden, [29]Chinese Academy of Medical Sciences and Peking Union Medical College, [30]Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China, [31]Ospedali Riuniti di Bergamo, Bergamo, Italy, [32]MPN Forum, Ashville, North Carolina, United States, [33]Johannes Wesling Klinikum, Minden, Germany, [34]University Hospital Basel, Basel, Switzerland

Background: Splenomegaly (SM) is frequently observed in Myeloproliferative Neoplasms (MPNs). Many MPN symptoms have been attributed to splenomegaly but studies exploring these associations are lacking.
Aims: We sought to evaluate how the presence of severe splenomegaly (>10cm below costal margin [BCM]) impacts patient symptomatology and relates to other clinical features.
Methods: Data was collected among an international cohort of MPN patients including polycythemia vera (PV), essential thrombocythemia (ET) and myelofibrosis (MF) without splenectomy as reported previously (Emanuel et al., JCO 2013). Subjects completed BFI and MPN-SAF instruments. Items were scored on a 0 (absent) to 10 (worst imaginable) scale. For individuals completing at least 6 of the 10 MPN-SAF TSS items, the survey was scored by multiplying the average score across items by 10 to achieve a 0 to 100 scaled score. Demographics, clinical features and symptom scores were compared between splenomegaly subgroups using ANOVA F-tests or chi-squared tests. Splenomegaly was assessed by clinicians based on physical examination and reported as an estimated value BCM. Patients were categorized into 'No-SM' (non-palpable), 'Mild-SM' (1-10cm) and 'Severe-SM' (>10cm).
Results: *Demographics*: A total of 2043 patients were included in the analysis (No-SM, n=1462; Mild-SM, n=404; Severe-SM, n=177) with a mean spleen size of 2.6 cm BCM (range 10.1-31.0 cm). Patients were of expected age (59.7 years) and similar gender distribution (54.6% female). MPN subtypes included ET (41.9%), PV (35.2%) and MF (22.9%). The most prevalent prognostic risk group for each subtype was as follows: ET, intermediate (46.1%); MF, Int.-1 (54.9%); PV, High (49.2%). Compared to a history of prior thrombosis (20.3%), anemia (8.7%), leukopenia (9.9%), thrombocytopenia (11.0%), red blood cell transfusions (5.8%) and prior hemorrhage (5.0%) were relatively uncommon. *Clinical Correlations*: When compared to No-SM populations, patients with Severe-SM were most likely to be >60 years (54.5% *vs* 45.5%, p=0.015) and have MF (62.7% *vs* 10.8%, [p<0.001]). Severe-SM patients were also most likely to suffer from anemia (29.3% *vs* 4.0%), leukopenia (16.4% *vs* 7.5%) and thrombocytopenia (34.2% *vs* 7.1%, all p<0.001), along with prior hemorrhages (8% *vs* 4.2%, p=0.029) and have the highest transfusion requirements (15.3% *vs* 2.8%, p<0.001). In contrast, No-SM patients were most likely to have a history of prior thrombosis (20.1% *vs* 14.3%, p=0.046). SM did not correlate with gender or individual prognostic risk categories. *Symptoms*: Severe-SM was associated with the highest Total Symptom Scores (TSS, 28.5 *vs* 16.3 in No-SM, p<0.001) and individual symptom scores for all items assessed, with the exception of fever and bone pain (both p>0.05; Figure 1). Highest scores were noted for fatigue (4.9 *vs* 4.1, p=0.006), early satiety (3.6 *vs* 2.3, p<0.001), inactivity (3.4 *vs* 2.2, p<0.001), and impact on overall quality of life (3.8 *vs* 2.7, p<0.001). Abdominal discomfort (2.9 *vs* 1.7, p<0.001) and weight loss (1.9 *vs* 1.1, p<0.001) scores were of relatively low severity in comparison to other complaints.

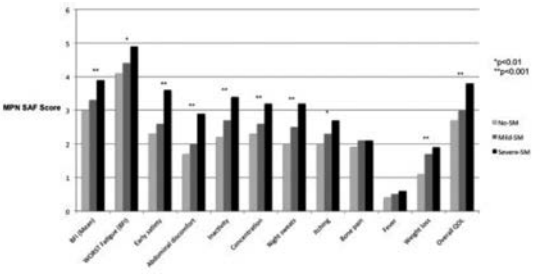

Figure 1.

Summary/Conclusions: Spleen size directly correlates with symptoms unrelated to the abdominal cavity and overall MPN disease burden. The lack of association between spleen size and prognostic risk scores suggests low risk patients may still suffer from significant, undermanaged symptomatology.

E1340

ANALYSIS OF CLINICAL PHENOTYPE AND OUTCOME IN CALR *VERSUS* JAK2 MUTATED OR TRIPLE-NEGATIVE ESSENTIAL THROMBOCYTEMIA

A Aroldi[1,*], F Mottadelli[2], A Carrer[1], F Colnaghi[2], PE Pioltelli[1], C Gambacorti-Passerini[1], EM Elli[1]

[1]Hematology Division, San Gerardo Hospital, [2]Centro di Ricerca Tettamanti, Fondazione MBBM, Monza, Italy

Background: About 85% of patients (pts) with Essential Thrombocythemia (ET) harbors one of three driver mutations: JAK2, calreticulin (CALR) and MPL; the remaining are defined "triple-negative". Recent studies have analyzed the clinical and hematological features of ET or primary myelofibrosis (MF) according to mutational genotype. However the clinical impact of these mutations seems to differ between cases of ET and MF. In particular controversial data were reported regarding the risk of MF progression in triple-negative and CALR mutated ET.
Aims: We retrospectively analyzed a cohort of 350 ET pts, diagnosed between 1990 and 2015 according to WHO classification, and we compared the clinical phenotypes and outcome of CALR mutant cases with the group of JAK2V617F positive and triple-negative pts.
Methods: Hematological parameters, cardiovascular factors, IPSET score, microvascular symptoms and thrombotic complications were reported for each cohorts of ET pts, as well as cytoreductive treatment. During follow-up, progression to MF and leukemic evolution were also recorded. Mann-Whitney test was used for numerical comparisons while Chi-square test was used for nominal ones. Overall survival (OS) and myelofibrosis-free-survival (MFS) and Leukemia-free-survival (LFS) were estimated by Kaplan–Meier analysis and compared with the Log-rank test.

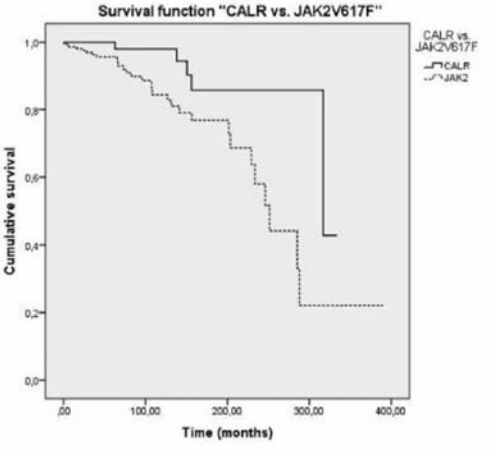

Figure 1.

Results: Among 350 ET pts, CALR mutations were detected in 69 (19.7%), JAK2V617F mutations in 216 (61,7%) and MPL mutations in 13 (3.7%). 52 (15%) pts were triple-negative. The median follow-up was 77,5 months, with a longer time of observation for CALR mutants (median 125 months). JAK2-mutated ET had a higher risk of thrombosis at onset, which was about three times higher than CALR mutated pts or triple-negative ET (20,4% *vs* 7,2% *vs* 17,3% respectively, p=0,05). No difference between JAK2, CALR mutated and triple-negative ET was identified in terms of incidence of recurrent thrombosis during follow-up. Compared to those with JAK2 mutation, CALR-mutated ET

pts were characterized by younger age (p=0,012), lower leukocyte count (p<0,0001) and hematocrit (p<0,002) and higher platelet count (p<0,0001) and presented a lower IPSET score (p<0,0001). Triple-negative pts showed a low IPSET score, similar to CALR-mutated pts; they had a lower incidence of microvascular symptoms (13.5%) in respect to JAK2 (39,8%) and CALR-mutated (34,8%) pts (p<0,0006 and p=0,014, respectively), with a low intensity of cytoreductive treatment. Interestingly, CALR-mutated ET presented an increased risk of progression to MF (24,6%) in comparison with JAK2V617F positive (5,6%) and triple-negative (7,7%) ET (p<0,0001). CALR type 1 deletion seemed to be strongly associated with MF evolution (15/17 pts). Median MFS seemed shorter in JAK2 positive pts (79,77 months) compared to CALR-mutated (106,44 months) and triple-negative ET pts (96,04 months). As shown in Figure 1, we finally documented a better OS in CALR pts than in JAK2 positive group (median OS 317 *vs* 251 months respectively; p=0,007). No difference in LFS according to different genotypes was demonstrated.

Summary/Conclusions: This study in a large cohort of ET supports and extends the growing body of evidence showing that different mutational genotypes in ET present significant differences with regards to clinical and hematologic presentation as well as risk of MF progression. Even though OS was higher, *CALR* mutation-positive patients appear to have a higher risk of evolution to MF compared to the *JAK2* V617F-positive and triple-negative pts.

E1341

A MULTICENTER EVALUATION OF THE REVISED 2015 WHO MINOR CRITERIA FOR PREFIBROTIC PRIMARY MYELOFIBROSIS

G Jeryczynski[1,*], W Albert[2], B Gisslinger[1], M Schalling[1], S Burgstaller[3], V Buxhofer-Ausch[4], MT Krauth[1], K Geissler[5], E Schlögl[6], T Sliwa[6], AI Schiefer[7], L Müllauer[7], I Simonitsch-Klupp[7], C Beham-Schmid[8], J Thiele[9], H Gisslinger[1]
[1]Department of Hematology and Hemostaseology, Medical University of Vienna, Wien, [2]Department for Hematology, Medical University of Graz, Graz, [3]Department for Internal Medicine IV, Klinikum Wels-Grieskirchen, Wels, [4]Krankenhaus der Elisabethinen, Linz, [5]Krankenhaus Hietzing Wien, [6]Hanisch Krankenhaus Wien, [7]Clinical Institute for Pathology, Medical University of Vienna, Wien, [8]Institute for Pathology, Medical University of Graz, Graz, Austria, [9]Institute for Pathology, University of Cologne, Köln, Germany

Background: The gold standard for the diagnosis of prefibrotic primary myelofibrosis (prePMF) remains the histomorphologic assessment of bone marrow (BM) biopsy samples. Clinically, especially early cases are difficult to distinguish from other myeloproliferative neoplasm (MPN), in particular essential thrombocythemia (ET). Most prominently, thrombocyte counts are not different in those two entities. However, several clinical features are frequently encountered in prePMF, that are not routinely found in ET. The revised 2015 WHO diagnostic criteria recognize four of these features as minor criteria for prePMF, at least one of which must be present to establish the diagnosis: anemia, leukocyte counts ≥11 G/L, elevated lactate dehydrogenase levels (LDH) as well as palpable splenomegaly.

Aims: The aim was to evaluate the new WHO minor criteria for prefibrotic primary myelofibrosis on a cohort of histomorphologically characterized patients.

Methods: From a multicenter database, 161 cases of prePMF in which the diagnosis had been established through BM biopsy, were selected. The presence of the minor criteria was then assessed at diagnosis. The results were compared to 186 patients diagnosed with ET from the same database. A fiber grade of 1 was present In 54 of prePMF patients, while no ET patients showed increased fibrosis in the BM.

Results: One or more minor criteria could be found in 90.7% (146/161) patients with prePMF, while this was true for only 52.7% (98/186) of ET cases. In both entities elevated LDH levels were the most prevalent feature (77.0% *vs* 29.0%, p<0.001), followed by high white blood cell counts. There were no significant differences between patients with fiber grade 0 or 1, except in splenomegaly (37.4% *vs* 42.9%, p=0.030). The number of minor criteria increased with age. While prePMF patients with one criterion were aged 60 years, patients that displayed all four symptoms were aged 74 years. Accordingly, overall survival was shorter in patients with a higher disease burden.

Table 1.

Parameter	prePMF		ET		p-value
	%	n	%	n	
Anemia (Hemoglobin m/f ≤ 13/12 g/dl)	26.7	43	8.6	16	<0.001
Splenomegaly (palpable or increased length diameter by imaging analysis ≥13 cm)	43.5	70	11.3	21	<0.001
LDH (above upper institutional limit)	77.0	124	29.0	54	<0.001
WBC ≥ 11 x 10^9/L	47.2	76	25.8	48	<0.001

Summary/Conclusions: The revised minor criteria for prePMF could be well reproduced in this population. In combination with the histomorphologic assessment, they are suitable to correctly establish the diagnosis of prePMF. However, there is a small subgroup of prePMF patients that show no minor criteria at time of diagnosis. These patients should be monitored closely and their diagnosis should be re-evaluated if they should present with one of the features. The proportion of ET patients that also display one or more minor clinical symptoms underlines the central role of histomorphologic differentiation of MPN patients.

E1342

THE MEGAKARYOCYTIC INDEX: A NEW TOOL FOR THE DIAGNOSIS OF ESSENTIAL THROMBOCYTHEMIA

M Pizzi, I Bertozzi, M Rugge, ML Randi*
Dept of Medicine - DIMED, University of Padua, Padova, Italy

Background: The 2008 WHO diagnostic criteria of Essential Thrombocythemia (ET) require the integration of clinical, molecular and histological parameters. Megakaryocytes (Mk) are the mainstay of bone marrow (BM) histological assessment, as they are present at increased numbers and display peculiar cytological features. While the morphology of ET-associated Mk has been widely studied, their objective quantification may prove challenging (e.g. biased count due to variable BM cellularity in patients of different age).

Aims: This study aimed to: (i) identify a quantitative parameter to define the number of Mk, irrespective of BM cellularity; (ii) define a Mk threshold to objectively discriminate between ET from non-neoplastic BM samples.

Methods: The present study considered BM biopsies from: (i) 89 patients with WHO-defined ET; (ii) 6 patients with secondary/reactive thrombocytosis (ST); and (iii) 22 controls with normal platelet counts and no evidence of BM disease. For the aims of this study, each biopsy was assessed for the following histological parameters: (i) BM cellularity; (ii) total number of Mk; (iii) BM biopsy area (as measured by digital imaging techniques). These parameters were used to calculate Mk density (ratio between total number of Mk and BM biopsy area) and its cellularity-normalized value (here referred to as "megakaryocytic index"), calculated as: Total number of Mk/(BM biopsy area) x (BM cellularity). Statistical analysis was performed using one-way ANOVA and ROC curve analysis.

Results: Differences in BM cellularity among ET and control cases were not statistically significant. ET patients had higher values of Mk density and Mk index compared to both ST and normal controls (Table 1) (p<0.01). At ROC curve analysis, Mk density had limited efficacy in distinguishing ET from non-neoplastic BM samples (threshold value: 10.5/mm^2; sensitivity: 89.9%; specificity: 90.9%). Better results were obtained with the Mk index (threshold value: 25.5/mm^2; sensitivity: 94.4%; specificity: 95.5%).

Table 1. Histological parameters (mean±SD) of ET, ST and control marrow biopsy samples.

	ET	ST	Controls
Cellularity (%)	42.6 ± 17.3	61.7 ± 13.3	34.3 ± 18.8
Mk density (n°/mm^2)	20.7 ± 9.4	9.6 ± 3.3	6.1 ± 2.9
Mk index	52.3 ± 24	15.3 ± 2.9	18.9 ± 5

Summary/Conclusions: BM cellularity can greatly vary among patients, mainly as a result of the age-related decrease of hematopoietic elements. This may impair the evaluation of the Mk number (a key feature for the diagnosis of ET and other myeloproliferative neoplasms). Our model allows the quantification of Mk, irrespective of BM cellularity. In particular, a megakaryocytic index ≥25.5/mm^2 can sensitively and specifically discriminate between ET and non-neoplastic controls. Poorer results have been obtained by Mk density. In conclusion, the megakaryocytic index may represent a valuable tool for the histological diagnosis of ET.

E1343

MOLECULAR CHARACTERIZATION OF ESSENTIAL THROMBOCYTHEMIA PATIENTS EVOLVED TO POLYCYTHEMIA VERA

C Besses[1,2,*], A Angona[1,2,3], C Fernández-Rodriguez[1,4], A Alvarez-Larrán[1,2,3], R Longarón[1,4], L Camacho[1,4], S Pairet[1,4], B Bellosillo[1,4,5]
[1]Grup de Recerca Clínica Aplicada en Neoplasies Hematològiques, IMIM, [2]Hematology, Hospital del Mar, [3]Universitat Autonoma de Barcelona, [4]Pathology, Hospital del Mar, [5]Universitat Pompeu Fabra, Barcelona, Spain

Background: *JAK2*V617F-mutated essential thrombocythemia (ET) and polycythemia vera (PV) represent a biological spectrum of the same *JAK2*V617F disease modulated by several acquired and constitutional factors. In this sense, the phenotypic transformation of ET to PV occurs in 3-10% of patients. There is scarce information comparing the clinical and molecular profile of this group of patients, at baseline and at the time of transformation.

Aims: To characterize the clinical and molecular profile of a group of 10 ET patients who evolved to post-ET PV, before and after transformation.

Methods: From a whole cohort of 262 ET patients, 10 cases that evolved to post-ET PV (3.8%) were included in the study. In all patients, PV diagnosis was established according to the demonstration of an increased red cell mass (>125%). *JAK2*V617F was analyzed by quantitative allele specific PCR in granulocytes at ET and post-ET PV diagnosis. To determine acquisition of 9p loss of heterozygosity (LOH), breakpoints for chromosome 9p were mapped using fluorescence microsatellite PCR. Targeted next generation sequencing (NGS) was used to detect additional non-driver somatic mutations. Clonality based on X-chromosome inactivation pattern by *HUMARA* and *JAK2* 46/1 haplotype were also analyzed. The study was approved by the local Ethics Committee and informed consent was obtained according to the Declaration of Helsinki.

Results: All 10 patients (male/female: 2/8) initially diagnosed with ET according to WHO criteria fulfilled the criteria for PV after a median of 75 months (range:

13-305). One patient started cytoreductive treatment prior to the transformation. The main clinical and hematological data at the time of ET and post-ET PV are summarized in Table 1. *JAK2*V617F evolutionary pattern was available in 8 patients. In all instances, a progressive increase in the *JAK2*V617F allele burden was documented. Mitotic recombination of 9p was observed in 4/10 patients (40%) and 3 of them corresponded to the patients with higher *JAK2*V617F increase. Mutations in *ASXL1* (n=1), *DNMT3A* (n=1) and *TP53* (n=1) were detected at the time of transformation. Clonal hematopoiesis could not be demonstrated in any case. The *JAK2* 46/1 haplotype was present in 7 out of 8 available patients (87.5%), 4 in heterozygosis and 3 in homozygosis.

Table 1. Main clinical and hematological features at the ET and Post-ET PV diagnosis.

	ET	Post-ET PV	*p*
Age (years)	42 (32-63)	56 (40-75)	0.003
Hemoglobin (g/l)*	147 (123-166)	171 (140-192)	0.001
Hematocrit (%)*	45.1 (38-49)	52.7 (45.6-58.9)	<0.001
Platelet count (x10^9/l)*	615 (513-1064)	916 (533-1347)	0.097
Leukocyte count (x10^9/l)*	9.86 (6-15)	12.9 (8.7-18.2)	0.042
***JAK2*V617F allele burden, (%)**	30.5 (16.9-42.3)#	47.4 (25.5-84.9)	0.006

**Median (range). # Available in 8 patients. M: male. F: female. ET: Essential thrombocythemia. Post-ET PV: polycythemia vera post essential thrombocythemia.*

Summary/Conclusions: An increase in *JAK2*V617F allele burden is observed in all ET patients transforming to PV and may be accompanied by other mechanisms such as acquisition of 9p LOH or additional somatic mutations.
Funding. This study was supported by grants from the Ministry of Education and Science of Spain and Instituto de Salud Carlos III FEDER (FIS PI10/018087, PI13/00557, PI13/00393, RD12/0036/0010) and SGR 2014-567.

E1344

PALPITATIONS AND ARRHYTHMIA IN 3649 HIGH-RISK PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA: RESULTS FROM THE PROSPECTIVE LONG-TERM OBSERVATIONAL EXELS STUDY

L Gugliotta[1,*], G Tortorella[2], C Besses[3], M Griesshammer[4], C Harrison[5], JJ Kiladjian[6], J Wu[7], H Achenbach[8], C Marelli[8], G Birgegård[9]
[1]Department of Haematology, 'L e A Seragnoli', St Orsola-Malpighi Hospital, Bologna, [2]Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy, [3]Department of Haematology, Hospital del Mar-IMIM, Barcelona, Spain, [4]Hematology and Oncology, Johannes Wesling Medical Center, Minden, Germany, [5]Department of Haematology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [6]APHP, Hôpital Saint-Louis, Centre d'Investigations Cliniques, Paris, France, [7]Global Biometrics, Shire Pharmaceuticals, Lexington, MA, United States, [8]Research & Development, Shire GmbH, Zug, Switzerland, [9]Department of Haematology, Uppsala University, Uppsala, Sweden

Background: The Evaluation of Xagrid Efficacy and Long-term Safety (EXELS) study (NCT00567502) is the largest prospective observational cohort of high-risk patients with essential thrombocythemia (ET) reported to date. Although anagrelide (ANA) is typically well tolerated, as patients with ET often have cardiac risk factors, it is important to analyze ANA's cardiac safety in these patients.
Aims: The primary objective of EXELS was safety and pregnancy outcomes of ANA compared with other cytoreductive therapies (CRT). Here we assess palpitations and arrhythmia events as reported in EXELS.
Methods: High-risk patients (≥1 of age >60 years, previous thrombotic event, platelet count >1000x10^9/L) with ET were enrolled across 13 countries in Europe from 2005-2009. Patients were required to be receiving CRT. Data, including events predefined in the protocol (PDEs), were collected every 6 months for 5 years for all patients.
Results: 3649 patients were categorized according to treatment at registration as follows: ANA (n=804), ANA+other CRT (n=141), other CRT (n=2666). Over 80% of patients received either hydroxycarbamide (HC) or ANA, and 69.8% of patients received anti-aggregatory therapy. At registration, median age was lower in the ANA (55.5 years) and ANA+other CRT (59.0 years) groups *vs* the other CRT group (70.0 years). Due to the non-interventional nature of the study, patients were able to switch treatments and did not necessarily remain in the same group over the entire observation period. As such, the analysis of palpitations and arrhythmia events were performed according to the treatment group patients were on for at least one day during the study. Higher rates of palpitations were observed in patients receiving ANA alone (1.69%, n=19) *vs* other CRT alone (0.21%, n=6; Table). Similar differences were observed for tachycardia# events; 2.04% of patients (n=23) receiving ANA experienced tachycardia compared to 0.24% (n=7) of those receiving other CRT. There did not appear to be a clear difference in rates of supraventricular arrhythmia* events observed between patients receiving ANA (1.06%, n=12) or other CRT (1.34%, n=39). This was also observed with ventricular arrhythmias** with no apparent difference between the ANA only group (0.09%, n=1) *vs* other CRT (0.10%, n=3). Very low rates of other arrhythmias*** were observed across all groups. Similar rates of palpitations, tachycardia and arrhythmias (supraventricular, ventricular and other) were seen in patients receiving ANA+other CRT compared with ANA alone.

Table 1.

	ANA only (n=1127)		Other (n=2909)		ANA + other (n=451)		No treatment (n=645)	
	Patients n (%)	Events (n)	Patients n (%)	Events (n)	Patients n (%)	Events (n)	Patients n (%)	Events (n)
Palpitations	19 (1.69)	21	6 (0.21)	6	8 (1.77)	8	1 (0.16)	1
Tachycardia#	23 (2.04)	26	7 (0.24)	8	6 (1.33)	6	2 (0.31)	2
Supraventricular arrhythmia*	12 (1.06)	13	39 (1.34)	51	4 (0.89)	4	5 (0.78)	6
Ventricular arrhythmia**	1 (0.09)	1	3 (0.10)	3	0	0	0	0
Other arrhythmia***	3 (0.27)	3	3 (0.10)	4	1 (0.22)	1	1 (0.16)	1

#Tachycardia comprises tachycardia, tachycardia paroxysmal and tachyarrhythmia (not otherwise defined).
**Supraventricular arrhythmia comprises atrial fibrillation/atrial flutter, arrhythmia supraventricular, supraventricular extrasystoles, supraventricular tachycardia and sinus tachycardia.*
***Ventricular arrhythmia comprises ventricular fibrillation/ventricular tachycardia/ventricular extrasystoles.*
****Other arrhythmia comprises arrhythmia (not otherwise defined), bradycardia, extrasystoles, sinus bradycardia.*

Summary/Conclusions: Of the most commonly reported cardiac PDEs, palpitations and tachycardia were more frequently observed with ANA *vs* other CRT. Arrhythmia events (supraventricular, ventricular and other) were observed at similar rates in the ANA and other CRT groups. Palpitations, tachycardia and arrhythmia events were reported at a similar rate in the ANA+other CRT group compared with the ANA group. While there may be an increase in specific cardiac events with ANA, these are mostly mild and reversible with appropriate treatment.

E1345

SYMPTOMS, RISK CLASSIFICATION, AND SPLEEN SIZE IN JAK2 INHIBITOR-NAÏVE MYELOFIBROSIS: IMPLICATIONS FOR JAK2 INHIBITOR TREATMENT

R Scherber[1,2,*], A Dueck[3], H Geyer[3,4], H Kosiorek[3], JJ Kiladjian[5], S Slot[6], S Zweegman[6], P Boekhorst[7], H Schouten[8], F Sackmann[9], A Fuentes[10], D Hernandez-Maraver[10], H Pahl[11], F Stegelmann[12], K Doehner[12], K Bonatz[13], A Reiter[13], F Boyer[14], G Etienne[14], JC Ianotto[15], D Ranta[16], L Roy[17], JY Cahn[18], C Harrison[19], D Radia[19], P Muxi[20], N Maldonado[21], C Besses[22], F Cervantes[23], P Johansson[24], G Barosi[25], A Vannucchi[26], F Passamonti[27], B Andreasson[28], J Samuelsson[29], G Birgegard[30], X Sun[31], J Xu[31], P Zhang[32], Z Xu[31], T Barbui[33], T Barbui[33], Z Senyak[34], M Grieshammer[35], A Rambaldi[33], M Ferrari[33], T Lehmann[36], R Mesa[3]

Matteo Foundation, Pavia, [26]Ospedale di Circolo, Varese, [27]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [28]NU Hospital Organization, Uddavalla, [29]Stockholm South Hospital, Stockholm, [30]University Hospital, Uppsala, Sweden, [31]Chinese Academy of Medical Sciences and Peking Union Medical College, [32]Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China, [33]Ospedali Riuniti di Bergamo, Bergamo, Italy, [34]MPN Forum, Ashville, North Carolina, United States, [35]Johannes Wesling Klinikum, Minden, Germany, [36]University Hospital Basel, Basel, Switzerland

Background: Symptom burden in myelofibrosis (MF) is severe and a risk factor for mortality (Blood 2010;115(9):1703-8). In trials comparing JAK2 treatment to best available therapy, patients receiving JAK2 therapy had significant alleviation in disease related symptom burden and decreased spleen size (N Engl J Med 2012;366:787-798).
Aims: To date no studies have evaluated which cutoffs are most associated with Dynamic International Prognostic Scoring System (DIPSS) risk score and thus may identify patients for further symptom-directed treatment.
Methods: Patient demographics, symptom burden, DIPSS risk classification, and spleen size were collected from MF patients at an office visit. Symptoms were assessed via the MPN-10 total symptom score (TSS, JCO 2012;30(33)4098-103). The TSS was calculated as the summated 10-item score, reported in a range of 0-100 for patients completing at least 6/10 symp-

tom items. Associations of symptoms (worst single symptom score and TSS utilizing various cutoffs) with DIPSS risk and spleen size (categorized as >10cm and separately as >15cm) were investigated using ANOVA F-tests and ordinal logistic regression. Lowest Akaike Information Criteria (AIC) was used to select an optimal model among all a priori models.

Results: Demographics and symptom burden: 851 MF patients with known DIPSS risk score or spleen size were selected, of which 695 were JAK2 inhibitor-naïve (420 with DIPSS risk, 425 with known spleen size). Among participants, 58% had a TSS >20. The worst single symptom (or multiple worst if tied) was most often fatigue (50%) followed by night sweats (19%) and satiety (19%). The worst single symptom score was >5 for 57% patients, and 50% had both a TSS >20 and worst single symptom score >5. Associations of symptoms with DIPSS risk and spleen size: Similar to prior published data, increased TSS was significantly associated with higher DIPSS risk score (p<0.001) with mean TSS of 15.8, 24.5, 30.1, and 37.7 for low, int-1, int-2, and high risk groups, respectively. Increased TSS was also significantly associated with spleen size (>10cm: mean TSS 25.2 *vs* 30.0, p=0.02; >15cm: 25.5 *vs* 32.9, p=0.004). Increased worst single symptom severity was associated with higher DIPSS risk score (mean worst single symptom score 5.0 *vs* 6.3 *vs* 7.0 *vs* 7.5, p<0.001) as well as the largest spleen size (>10cm: 6.3 *vs* 6.8, p=0.11; >15cm: 6.3 *vs* 7.3, p=0.02). Ordinal logistic regression modeling of DIPSS risk: When comparing models, worst single symptom score >5 had the lowest AIC (Table 1), suggesting this as an optimal model predicting increased risk. In this model, worst single symptom score >5 was associated with 14.1%, 49.3%, 32.3%, and 4.3% probabilities of being low, int-1, int-2, and high risk, compared to 20.8%, 52.8%, 23.7%, and 2.7% for single score ≤5. The next best model was based on a TSS score >20 alone (AIC 936.657). Among combined TSS and single item models, a combined TSS >20 and single item >5 had the relative lowest AIC (938.51).

Table 1. Ordinal logistic regression models of DIPSS risk score (N=420) by symptoms in JAK2-naïve myelofibrosis patients.

Model	DIPSS Risk AIC
TSS >20	936.657*
Worst single symptom score >5	935.281*
Worst single symptom score >6	942.198
Worst single symptom score >7	942.684
TSS >20 & single score >5	938.510
TSS >20 & single score >6	943.335
TSS >20 & single score >7	944.867

*Optimal models based on lowest AIC.

Summary/Conclusions: Alleviation of MPN symptoms, now measurable through standardized instruments such as the TSS, are an integral part of assessing therapeutic impact in both clinical practice and trials. In our modeling, a cutoff criteria of the worst single symptom being >5/10 is optimal for predicting increased DIPSS risk score suggesting that this criterion may differentiate between which patients will most benefit from symptom-based treatment. We propose that JAK2 inhibitor treatment be strongly considered in any JAK2-inhibitor naïve MF patient with an individual symptom score >5.

OSTEOPROTEGERIN (OPG) AND INTERLEUKIN-8 (IL-8) IMMUNOSTAINING IN BONE MARROW (BM) BIOPSIES OF PATIENTS WITH PH-NEGATIVE MYELOPROLIFERATIVE DISORDERS (MPD) AT DIAGNOSIS: CLINICAL CORRELATIONS

D Triantafyllopoulou[1,*], D Maltezas[1], EA Trigka[2], T Tzenou[1], T Iliakis[1], M Dimou[1], P Petsa[1], K Spanou[2], P Ntailiani[2], E Patsouris[2], P Korkolopoulou[2], P Panayiotidis[1], MC Kyrtsonis[1]

[1]Department of Haematology, First Propedeutical Clinic for Internal Medicine,Laikon Hospital,National and Kapodistrian University of Athens, [2]First Laboratory of Pathology, Medical School,National and Kapodistrian University of Athens, Athens, Greece

Background: Both IL-8 and OPG have been implicated in the pathogenesis and clinical manifestations of myelofibrosis (MF), the most severe Ph(-) MPD. IL-8 and its receptors were reported to promote altered megakaryocyte (MGK) growth (Emadi et al), a typical MF finding, while OPG was found upregulated in endothelial cells (Bock et al).

Aims: To evaluate the expression and intensity of IL-8 and OPG immunostaining in BM biopsy of MPD patients at diagnosis and to study any eventual correlations between them and clinical characteristics or outcome.

Methods: 78 patients were studied, diagnosed with MPN from 1984 to 2012 with a median follow up period of 55 months. Median age was 65 years, 49 were males. 22% were diagnosed with polycythemia vera (PV), 42% with essential thrombocytosis (ET) and 36% with MF. Of those, 58% had splenomegaly, 8% had bone pain, 81% presented with fatigue, 9% had sweating, 11.5% experienced a thrombotic event, 5% lost weight and 77% were JAK2 positive. Karyotype was abnormal in 32% while 7% presented unfavourable karyotype findings. Immunostaining for IL-8 and OPG was performed on paraffin-embedded 4μm sections of formalin fixed BM biopsies, carried out at the time of diagnosis, using the two-step peroxidase conjugated polymer technique. Grade of positivity and intensity of IL-8 and OPG expression was scored according to a 0 to 3 scale. Statistical analysis was performed conventionally, using the SPSS version 22.0 package, and p values<0.05 were considered significant.

Results: There was no significant difference observed concerning the grade of expression of both stainings among the different MPN-groups. High intensity of IL-8 expression in MGK correlated, in the whole cohort, with a high neutrophil count (p=0.029), low lymphocyte count (p=0.026), and increased haemoglobin (p=0.02). OPG was also expressed in cells of myeloid lineage (MLC) and its high intensity in MLC was observed in patients with high platelet counts (p=0.015). High intensity of OPG expression in MGK correlated with high neutrophil counts (p=0.045), high hemoglobin (p=0.045), high platelet counts (p=0.02), and a favourable karyotype (p=0.006). Most importantly, OPG low intensity in MGK correlated with poor survival (p=0.012). There was no correlation found between OPG and bone pain.

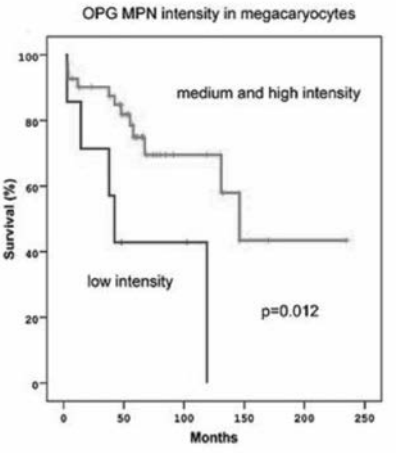

Figure 1.

Summary/Conclusions: Our most important finding is that high intensity of OPG expression in MGK correlated with increased survival and a favourable karyotype in patients with MPDs (PV, ET and MF). To the best of our knowledge, this finding has not been reported yet. It should indeed be further validated.

MYELOPROLIFERATIVE NEOPLASMS AND THROMBOSIS: A DANISH COHORT STUDY

IL Gade[1,2,*], H Højmark Eriksen[1,3], K Overvad[4], S Risom Kristensen[1,5], M Tang Severinsen[1,2]

[1]Department of Clinical Medicine, Aalborg University, [2]Department of Hematology, Aalborg University Hospital, [3]Unit of Clinical Biostatistics and Bioinformatics, Aalborg University, Aalborg, [4]Department of Public Health, Section for Epidemiology, Aarhus University, Aarhus, [5]Department of Clinical Biochemestry, Aalborg University Hospital, Aalborg, Denmark

Background: Arterial (AT) as well as venous thromboembolism (VTE) are causes of morbidity and mortality in patients with myeloproliferative neoplasms (MPN). Despite cytoreductive therapy and antiplatelet drugs MPN patients seem more prone to develop both AT and VTE than the background population. The influence of known cardiovascular risk factors on the risk of thrombosis in MPN patients is debated.

Aims: To investigate the absolute and relative risks of AT and VTE in MPN patients compared to matched controls in a prospective population based cohort study, adjusting for cardiovascular risk factors.

Methods: The Diet, Cancer and Health (DCH) Study is a Danish prospective population based cohort study enrolling 57.053 subjects between 1993-1997. Follow-up for this study was until 2008. Subjects were excluded if they had pre-baseline history of AT, VTE or cancer. Diagnosis of MPN was identified by linking to the Danish National Patient Registry, which provides information on date of diagnosis coded in the ICD-8 or ICD-10 system. All identified cases of

VTE and AT, which in this study was either myocardial infarction (MI) or stroke, have been objectively confirmed by trained personnel looking through medical records or discharge letters, biochemical investigations and diagnostic images. Information on cardiovascular risk factors was obtained by self-administered questionnaires at baseline. Biometric measures were obtained by trained technicians at enrolment. For each MPN patients five participants matched on age and sex were identified in the DCH cohort. We used Cox regression models to estimate the relative risk of AT and VTE in MPN patients.
Results: During follow-up 72 women and 71 men were diagnosed with MPN, mean age was 56.8 years. Among MPN exposed subjects 10 MI's, 6 cases of stroke and 3 VTE events were observed after MPN diagnosis, corresponding to incidence rates of 15.4 events per 1000 person years (10^{-3} p-y), $9.3*10^{-3}$ p-y and $4.4*10^{-3}$ p-y. In the Cox regression analysis MPN was associated with a significantly higher risk of MI, Hazard Ratio (HR) 5.7, 95% confidence interval (95%CI) 2.4-13.7. The HR for stroke among MPN exposed was 2.2, 95%CI 0.8-5.7. The observed VTE events resulted in a HR of 5.6, 95%CI 1.1-27.8 in the regression analysis. Our study was underpowered regarding the adjusted regression analysis.

Table 1. Absolute and relative risks of thrombosis.

	MI	Stroke	VTE
MPN exposed (N= 143)			
n	10	6	3
Incidence ($*10^{-3}$ p-y), (95% CI)	15.4 (8.3-28.6)	9.3 (4.2-20.7)	4.4 (1.4-13.7)
Matched controls (N= 715)			
n	10	15	3
Incidence ($*10^{-3}$ p-y), (95% CI)	2.6 (1.4-4.8)	4.0 (2.4-6.7)	0.8 (0.3-2.4)
Relative risk of thrombosis			
HR, (95% CI)	5.7 (2.4-13.7)	2.2 (0.8-5.7)	5.6 (1.1-27.8)
p value	< 0.001	0.11	0.035

Summary/Conclusions: In our prospective cohort study a 6-fold increased risk of MI was observed among MPN patients. The risk of stroke was increased by 2-fold, however not statistically significant. The risk of VTE was increased by 6-fold in MPN patients, however the number of events in this study was too few for adjusted analysis.

E1348

PROCOAGULANT MICROPARTICLE IS A NEW SURROGATE BIOMARKER FOR THROMBOTIC EVENTS IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

Y Taniguchi*, H Tanaka, T Kumode, S Rai, I Matsumura
Department of Hematology and Rheumatology, Kindai University Faculty of Medicine, Osaka-sayama, Japan

Background: Previous studies have identified several clinical and genetic markers for thrombosis in myeloproliferative neoplasm (MPN) patients, such as age >60 years, thrombosis history, cardiovascular risk factors, and the presence of JAK2 mutation. Microparticles (MPs) are circulating small vesicles released from the membranes of activated or apoptotic cells, which contribute to thrombosis with their procoagulant activities. However, to date, there have been a very few reports evaluating the relationship between the levels of MPs and procoagulable state in MPN patients.
Aims: In this study, we characterized MPs in MPN patients and assess their relationship with the thrombotic events in MPN patients in comparison with previously reported risk factors in the practical setting.
Methods: We analyzed 52 patients with MPNs: 17 with PV, 31 with ET, 1 with Primary myelofibrosis (PMF), and 3 with secondary MF, according to the revised WHO criteria and 12 healthy controls. The patient group consisted of 35 men and 17 women with a median age of 68 years ranging from 30 to 87 (at analyses). Thrombotic events were observed in 16 cases (30.8%). To assess the levels of MPs, we extracted platelet free plasma (PFP), in which MPs were enriched from sodium citrate-anticoagulated blood by centrifugations. Quantification and phenotypic characterization of MPs were performed by Flow cytometry. This study was approved by the ethics committee at Kindai University, and patients provided written informed consent.
Results: There was no difference in the total amount of MPs between MPN patients and controls (MPNs *vs* controls: median 2240 *vs* 3110/μL PFP; p=0.058), whereas MPN patients had more AnnexinV$^+$ or tissue factor (TF)$^+$procoagulant MPs (PCMPs) than controls (median±SD 15.1±6.2% *vs* 11.5±7.4%, p<0.05; 2.5±1.6% *vs* 0.89±0.52%, p<0.05, respectively). The majority of PCMPs derived from platelets and endothelial cells in MPN patients, which was confirmed by positivity for CD41a and CD146, respectively. The levels of AnnexinV$^+$ and TF$^+$ MPs tended to decrease in response to cytoreductive treatment in MPN patients but with no significant difference (n=35: p=0.143, p=0.084, respectively). Also, there was no statistically significant association between PCMP levels and common hematopoietic parameters (e.g. Hb, WBC, and PLT counts), suggesting that PCMPs were elevated independently of excessive hematopoiesis in MPN patients. In addition, none of age, cardiovascular risk factors, and JAK2 mutation showed a statistically significant relationship with thrombosis history in untreated MPN patients (n=17) by univariate analysis. In this setting, only high levels of TF$^+$ MPs showed a strong association with thrombosis history (p<0.01). The ROC analysis revealed that the best cut-off value of TF$^+$ MPs in accordance with thrombosis history was >52.0/μL PFP with 100% sensitivity and 75.0% specificity (AUC: 0.88, 95% CI: 0.71-1.0; p=0.102). These data indicate that elevated levels of TF$^+$ MPs will be a new surrogate biomarker to predict thrombotic events in MPN patients.
Summary/Conclusions: The current study shows the presence of elevated PCMPs in the peripheral circulation of MPN patients, which was supposed to contribute to the thrombotic events in these patients. Moreover, measuring PCMPs, especially TF$^+$ MP levels, seems to be a promising strategy to predict thrombosis in MPN patients. Further studies to analyze their pathologic roles in thrombosis may provide us with a new approach to prevent thrombotic events in MPN patients.

E1349

SPLENOMEGALY AND ELEVATED ALKALINE PHOSPHATASE ARE STRONG AND INDEPENDENT ADVERSE PROGNOSTIC MARKERS IN PATIENTS WITH SYSTEMIC MASTOCYTOSIS

M Jawhar[1,*], J Schwaab[1], D Hausmann[2], J Clemens[1], N Naumann[1], T Henzler[2], HP Horny[3], K Sotlar[3], SO Schoenberg[2], NC Cross[4], A Fabarius[1], WK Hofmann[1], P Valent[5], G Metzgeroth[1], A Reiter[1]
[1]Hematology and Oncology, [2]Institute of Clinical Radiology and Nuclear Medicine, University Medical Centre, Mannheim, [3]Institute of Pathology, Ludwig-Maximilians-University, Munich, Germany, [4]Wessex Regional Genetics Laboratory, Salisbury, United Kingdom, [5]Department of Internal Medicine I, Division of Hematology and Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, Vienna, Austria

Background: Systemic mastocytosis (SM) comprises a group of rare myeloid neoplasms characterized by accumulation of mast cells (MC) in various tissues, predominantly skin, bone marrow (BM), and visceral organs. Depending on the affected organ(s), SM-related organ damage, and involvement of other hematopoietic lineages, SM can be divided into indolent SM (ISM) and advanced SM (advSM). The *KIT* D816V mutation is a primary driver of disease manifestations while the presence and number of additional mutations, e.g. in *SRSF2*, *ASXL*, or *RUNX1* (S/A/R gene panel), have a strong adverse impact on disease phenotype and prognosis. However, only little is yet known about the prognostic impact of aberrant clinical, laboratory or hematological parameters.
Aims: We sought to evaluate the influence of organomegaly, as measured by magnetic resonance imaging (MRI)-based volumetry of liver and spleen as well as other known clinical and hematological characteristics, on disease evolution and overall survival (OS) in SM.
Methods: We retrospectively analyzed 108 patients (median age 64 years, range 27-82; male 57%) with ISM (n=41) or advSM (n=67) (aggressive SM/mast cell leukemia [ASM/MCL], n=12 or SM/ASM/MCL with associated hematologic non-mast cell lineage disease [AHNMD], n=55). Median observation time from the date of MRI was 26 months (range 1-79); 33/108 (31%) patients have died in the observation period. The 2-year OS probability of all patients was 77%, with a median OS of 5.4 years.
Results: The median volumes of liver and spleen were 2035 mL (range 1034-4265) and 540 mL (range 92-3193), respectively. Overall, MRI-documented hepatomegaly (>2400 mL) was observed in 31/108 (29%) patients, and splenomegaly in 67/108 (62%) patients (ISM 12%, advSM 88%). Splenomegaly was mild (≥450 mL) in 43/67 (64%) patients and marked (≥1200 mL) in 24/67 (36%) patients. High disease burden, presence of an AHNMD and organ damage (C-findings) were strongly associated with mildly or markedly increased spleen volume (P<0.05). In multivariate analysis, however, only an increased spleen volume ≥450 mL (hazard ratio [HR], 9.4; 95% confidence interval [CI], [2.2-39.9]; P=0.0002) and an elevated alkaline phosphatase (AP; HR 8.4 [3.2-22.1]; P<0.0001) remained independent predictive adverse prognostic markers for OS. The 2-year OS was 100%, 76%, and 56%, respectively (P<0.001), for patients with 0 (low-risk, n=37), 1 (intermediate-risk, n=32) or 2 (high-risk, n=39) parameters. If available (n=74), the relative frequency of mutations in the S/A/R gene panel was significantly different in the various risk groups (low: 0/15, intermediate: 12/24 [50%], high: 28/35 [80%], P<0.01).
Summary/Conclusions: Splenomegaly and elevated AP provide relevant prognostic information in SM patients that is independent of other clinical, laboratory or hematological parameters. In addition to the recently identified adverse prognostic impact of mutations in the S/A/R gene panel, this data will have major implications for the implementation and validation of novel prognostic scoring systems on the basis of larger patient cohorts, such as the dataset of the ECNM registry, with the long-term objective to develop an IPSS for patients with SM.

E1350

DEFERASIROX IN THE TREATMENT OF IRON OVERLOAD DURING MYELOPROLIFERATIVE NEOPLASMS (MPN)

R Porrini[1,*], M De Muro[2], M Trawinska[3], A Di Veroli[4], S Crescenzi Leonetti[5], L Petriccione[6], A Spadea[7], A D'Addosio[8], A Rago[9], M Montanaro[10], A Andriani[11], P Niscola[3], E Montefusco[1], M Breccia[12], G Alimena[12], R Latagliata[13]
[1]Hematology, Sant'Andrea Hospital, [2]Hematology, University Campus Biomedico, [3]Hematology, Sant'Eugenio Hospital, [4]Hematology, University Tor Vergata, [5]Hematology, Sandro Pertini Hospital, Rome, [6]Hematology, Fabrizio

Spaziani Hospital, Frosinone, [7]Hematology, Regina Elena Cancer Institute, [8]Hematology, Villa San Pietro Hospital, Rome, [9]Hematology, Polo Universitario Pontino, Latina, [10]Hematology, Belcolle Hospital, Viterbo, [11]Hematology, Nuovo Regina Margherita Hospital, [12]Department of Cellular Biotechnologies and Hematology, University Sapienza, [13]Cellular Biotechnologies and Hematology, Policlinico Umberto I, Rome, Italy

Background: Deferasirox (DFX) is an oral iron chelator widely employed in the treatment of iron overload during thalassemic syndromes and myelodysplastic syndromes.
Aims: At present, very few data are available on the treatment with DFX in patients with Ph- Myeloproliferative Neoplasms(MPN) and transfusional requirement.
Methods: To address this issue, we report here on 37 patients (M 29; F 8) with MPN and iron overload secondary to transfusional requirement enrolled in the database of our regional cooperative group who received a treatment with DFX. Of them, 33 had a primary Myelofibrosis, 3 a post Essential Thrombocythemia myelofibrotic phase and 1 a post Polycythemia Vera myelofibrotic phase.
Results: According to IPSS classification, 7 patients (18.9%) resulted low/intermediate-1 risk, 13 (35.1%) intermediate-2 risk and 17 (46.0%) high-risk. The main features of the patients at diagnosis and at baseline of DFX treatment are reported in the Table 1.Treatment with DFX was started after a median interval from diagnosis of 12.3 months [interquartile range (IR) 7.6-37.6] and from start of transfusion dependence of 11.0 months (IR 6.0-17.4), with a median of 27 packed red cells units received (IR 17-39). The starting DFX dose was 20 mg/Kg in 21 patients (56.7%), 15 mg/Kg in 11 patients (29.7%) and 10 mg/Kg in 5 patient (13.5%). All patients were evaluable for toxicity: extra-hematological toxicity of all WHO grades was reported in 20/37 patients (54.1%) and consisted of gastro-intestinal symptoms in 7 patients, transient renal impairment in 10 patients and skin reactions in 3 patients: however, only 3 patients (8.1%) needed a permanent discontinuation for toxicity. As to chelation efficacy, after a median treatment period of 15.4 months (IR 8.1-22.3), 4 patients achieved ferritin levels<500 ng/ml, 9 patients ferritin levels<1,000 ng/ml and 3 patients presented a reduction >50% of basal ferritin but with levels >1,000 ng/ml, with a global response rate of 16 out 37 patients (43.2%): among the remaining 21 patients, 2 discontinued for early toxicity, 18 did not have any ferritin reduction and 1 had an early unrelated death (<6 months of treatment). As to hematological improvement, 7/37 patients (18.9%) showed an unexpected and persistent rise of Hb levels >1.5 g/dl, with disappearance of transfusional requirement in 5 cases. The median overall survival of the whole cohort from DFX initiation was 20.7 months (95% CI 16.1-25.1): the median overall survival from DFX initiation in patients with chelation response was 46.9 months (95% CI 23.6-70.1) compared to 15.8 months (95% CI 2.9-28.7) in patients without chelation efficacy (p=0.007).

Table 1.

	DIAGNOSIS	BASELINE
Median age, years [interquartile range (IR)]	69.8 (63.8 – 74.7)	71.1 (67.2 – 76.2)
Median Hb, g/dl (IR)	8.3 (7.2 – 9.7)	7.9 (7.3 – 8.4)
Median ferritin, ng/ml (IR)	439 (150 – 1086)	1486 (1177 – 2209)
Median creatinine level, mg/ml (IR)	NR	1.0 (0.8 – 1.1)

Summary/Conclusions: Treatment with DFX is feasible and effective in MPN with iron overload. Moreover, also in this setting an hematological improvement can occur in a sizeable rate of patients.

E1351

CLINICAL FEATURES OF DIFFERENT GENOTYPES IN A COHORT OF 172 PATIENTS WITH CALRETICULIN-MUTATED ESSENTIAL THROMBOCYTHEMIA

V De Stefano[1,*], E Rossi[1], M Ruggeri[2], S Betti[1], C Nervi[3], T Za[1], A Ciminello[1], F Bartolomei[1], G Carli[2], I Nichele[2], E Albiero[2], DG De Ritis[1], G Cimino[4], P Chiusolo[1]
[1]Institute of Hematology, Catholic University, Rome, [2]Department of Hematology, San Bortolo Hospital, Vicenza, [3]Department of Medical and Surgical Sciences and Biotechnology, University of Rome Sapienza, [4]Department of Cellular Biotechnology and Hematology, University of Rome Sapienza, Rome, Italy

Background: Calreticulin (CALR) mutations occur in 15-24% of patients with essential thrombocythemia. The 52-bp deletion (mutation type 1) and the 5-bp insertion (mutation type 2) are the most frequent alterations, being 45-53% and 32-39% of all mutations; the remaining types are described in very few patients each. CARL-mutated ET has a higher platelet count, a lower leukocyte count, a lower haemoglobin level, and a lower thrombotic risk in respect to the JAK2 V617F-ET. However, the differences between types 1 and 2 have been rarely investigated (Tefferi A et al, Am J Hematol 2014; 89: E121).
Aims: To assess in a retrospective multicenter cohort of CALR-mutated ET patients the clinical and laboratory features of type 1, type 2, and types non-1/non-2.
Methods: We analysed a retrospective cohort of 172 patients with CALR-mutated ET diagnosed according to the updated WHO 2014 criteria. CALR mutation was type 1 in 91 patients (52.9%) (M/F 46/45, median age at diagnosis 59 yrs, range 18-84), type 2 in 55 patients (32.0%) (M/F 17/38, median age at diagnosis 43 yrs, range 17-85), and type non-1/non-2 in 26 patients (15.1%) (M/F 11/15, median age at diagnosis 46 yrs, range 20-83). Laboratory and clinical features were compared among the groups. The relative risk of thrombosis between groups was estimated by a Cox proportional hazards model.
Results: The total observation time was 1586 pt-years (median 7.5, range 0.1-34 years). As previously reported, male sex and younger age were more present in type 1 mutation than in type 2 (p=0.02 and p=0.002, respectively). On the other hand, no significant difference in sex and age distribution was found between patients with type non-1/non-2 mutation and those with type 1 and type 2. Patients with type 1, type 2, and type non-1/non-2 mutations did not significantly differ in the rate of splenomegaly (10.9% vs.14.5% *vs* 0%), Hb gr/dL (median 13.4, range 9.4-16.5 *vs* median 13.6, range 11-16 *vs* median 13.6, range 10.9-13.4), Hct (median 0.40, range 0.28-0.49 *vs* median 0.41, range 0.33-0.43 *vs* median 0.40, range 0.32-0.48), leukocyte count $x10^9$/L (median 8.43, range 4.63-17.15 *vs* median 8.05, range 3.56-13.40 *vs* median 7.82, range 4.55-15.30), and platelet count $x10^9$/L (median 787, range 454-2000 *vs* median 920, range 465-1743 *vs* median 887, range 453-2042). As for clinical phenotype, patients with type 1, type 2, and type non-1/non-2 mutations did not significantly differ in the rate of microvascular disturbances (17.5% *vs* 16.3% *vs* 15.3%), need of cytoreduction (71.4% *vs* 72.7% *vs* 73.0%), major bleeding (19.7% *vs* 27.2% *vs* 23.0%), transformation to myelofibrosis (9.8% *vs* 12.7% *vs* 11.5%), occurrence of solid neoplasia (14.2% *vs* 9.0% *vs* 7.6%). No patient evolved to acute leukemia. Thrombosis occurred in type 1 in 26.3% of cases (arterial thrombosis in 14 cases, venous in 8, both sites in 2), in type 2 in 21.8% of cases (arterial thrombosis in 6 cases, venous in 6), and in type non-1/non-2 in 7.6% of cases (arterial thrombosis in 2 cases). In patients with type 1 the risk of thrombosis was increased over time with a borderline statistical significance in comparison with type 2 (hazard ratio, HR, 1.77, 95%CI 0.91-3.64) and type non-1/non-2 (HR 3.31, 95%CI 0.91-6.29).
Summary/Conclusions: Male sex and younger age are confirmed to be more present in type 1 than in type 2. In this cohort of ET patients the type of CALR mutation did not influence significantly other laboratory and clinical features. However, a trend towards a higher thrombotic risk was displayed in type 1, deserving further studies.

E1352

GERMLINE VARIATIONS AT JAK2 AND TERT ARE ASSOCIATED WITH MYELOPROLIFERATIVE NEOPLASMS IN TAIWANESE POPULATION

YH Chiang[1,*], KH Lim[1], YC Chang[1], HC Lin[1], L Huang[2], YF Chang[1], CGS Chen[1], J Lin[1], MC Chang[1], RK Hsieh[1], NW Su[1], YW Su[1], HI Cheng[1], YY Kuo[3], WC Chou[4]
[1]Hematology/Oncology, [2]Department of Medical Research, MacKay Memorial Hospital, [3]Graduate Institute of Oncology, National Taiwan University College of Medicine, [4]Division of Hematology, Department of Internal Medicine, and Department of Laboratory Medicine, National Taiwan University Hospital, Taipei City, Taiwan, ROC

Background: In addition to the *JAK2* 46/1 haplotype, a recent study reported that germline variations at *JAK2* rs12339666, *TERT* rs2736100, *HBS1L-MYB* rs9376092 and *MECOM* rs2201862 are associated with myeloproliferative neoplasms (MPNs) in European populations.
Aims: In this study, we sought to evaluate the association of these five germline variations (*JAK2* 46/1 haplotype is tagged by rs12343867) with MPNs in Taiwanese population.
Methods: A total of 178 MPN patients (111 ET, 53 PV and 14 PMF) seen at Mackay Memorial Hospital were enrolled into this study. Genetic testing in MPN patients has been approved by the institutional review board. All patients were screened for $JAK2^{V617F}$, *CALR* and *MPL* mutations. All the above 5 germline variations were genotyped by high-resolution melting analysis and/or Sanger sequencing. Data of healthy controls were obtained from 118 local controls, published papers, and Taiwan Biobank database (https://taiwanview.twbiobank.org.tw). Chi-square or Fisher's exact test were used to analyze difference between patients and healthy controls, and to calculate odds ratios and 95% confidence intervals. Population attributable risks (PAR) were calculated as previously described. The SPSS software (version 22.0) was used for statistical analysis, and a two-side *p* value<0.05 was defined as significant.
Results: The *JAK2* 46/1 haplotype, *JAK2* rs12339666 and *TERT* rs2736100 were significantly associated with MPN cases (*p* value, $7.5x10^{-8}$, $3.2x10^{-8}$ and $3.0x10^{-6}$, respectively), and $JAK2^{V617F}$-positive cases (n=121) (*p*=$7.0x10^{-10}$, $2.7x10^{-9}$ and $5.9x10^{-7}$, respectively). For the whole cohort, the PAR for *JAK2* 46/1 haplotype, *JAK2* rs12339666 and *TERT* rs2736100 were 43.6, 42.1 and 28.5, respectively. In $JAK2^{V617F}$-negative cases (n=55), only the *JAK2* 46/1 haplotype remained statistically significant (*p*=0.044). When stratified by disease subtypes, the *JAK2* 46/1 haplotype, *JAK2* rs12339666 and *TERT* rs2736100 were significantly associated with both polycythemia vera (*p*=$7.9x10^{-10}$, $6.8x10^{-10}$ and $6.1x10^{-4}$, respectively) and essential thrombocythemia (*p*=$1.5x10^{-4}$, $1.8x10^{-3}$ and $4.9x10^{-4}$, respectively). The *JAK2* 46/1 haplotype, *JAK2* rs12339666 and *MECOM* rs2201862 were significantly associated with primary myelofibrosis (*p*=0.021, 0.01 and 0.007, respectively).
Summary/Conclusions: In this cohort, germline variations at *JAK2* (both the 46/1 haplotype and rs12339666) and *TERT* rs2736100 were significantly associated with MPNs in Taiwanese population.

E1353

MORPHOLOGIC DYSPLASIA IS ASSOCIATED WITH A MORE AGGRESSIVE DISEASE PHENOTYPE IN MYELOFIBROSIS

M Byrne[1,*], A Shaver[1], S Mohan[1], S Strickland[1], PB Ferrell[1], C Vnencak-Jones[1], C Belludi[1], D Head[1], R Daber[2], M Zutter[1], A Seegmiller[1], C Mosse[1], M Savona[1]
[1]Vanderbilt University, Nashville, [2]BioReference Laboratories, Elmwood Park, United States

Background: Primary myelofibrosis (PMF), post-essential thrombocytemia-MF (PET-MF) and post-polycythemia vera-MF (PPV-MF) are Philadelphia-chromosome negative myeloproliferative neoplasms (MPNs). These diseases are frequently associated with driver mutations within the JAK-STAT signaling cascade. However, additional mutations may be acquired during disease progression. MDS/MPNs are distinct myeloid diseases with similar genetic and morphologic characteristics of myelodysplasia and MPNs. To better understand the significance of these mutations, we correlated DNA mutation profiles with bone marrow (BM) dysplasia and clinical outcomes.
Aims: Evaluate the impact of non-driver mutations and BM dysplasia on clinical outcomes in patients with PET-MF, PPV-MF, and PMF.
Methods: We identified 19 patients diagnosed with PMF and 18 patients with PET- or PPV-MF, reviewed their BM biopsies and aspirates, and performed NGS with a 37 gene myeloid panel. At least 2 hematopathologists, blinded to original diagnosis and genetic results, classified the BM biopsies according to WHO guidelines and morphologic dysplasia. A committee of hematologists and hematopathologists reviewed all data and rendered a consensus diagnosis. Statistical comparisons between groups relied on the two-sided student's t-test; the log-rank test was utilized for survival assessments. This study was approved by our IRB
Results: The mean age at diagnosis was 57.1 years and NGS occurred at a median of 2.2 months from diagnosis; the mean length of follow-up is 8.2 years. Fourteen patients (39%) had an abnormal karyotype. *JAK2* mutation V617F was identified in 25 (68%) patients, *CALR or MPL* mutations were present in 8 (22%), and 4 had no identifiable driver mutation. Patients had a mean of 2 mutations; *TET2*, *EZH2*, *IDH1*, *IDH2*, *DNMT3A*, and *ASXL1* represent the most common mutations. For analysis, patients were divided according to the dynamic international prognostic scoring system plus risk: high (7), int-2 (17), and low/int-1 risk (13) disease. Those with high-risk disease were significantly more likely to have BM dysplasia relative to those with low/int-1 disease (77% *vs* 33%, *P:*<0.05) and twice as likely to be re-categorized as MDS/MPN overlap syndrome (67% *vs* 35% and 23%) during consensus review. These patients had a trend toward a higher mutational burden (3* *vs* 2.2 and 1.7* mutations, **P:* 0.09), and were twice as likely to have an unfavorable karyotype (*67% *vs* 41% and *8%, **P:*<0.05). Clinically, these patients experienced a more aggressive disease phenotype with a shortened overall survival (OS) compared to patients with non-dysplastic MF. Five patients in this analysis had *TET2* mutations. *TET2* mutated patients were more likely to have BM dysplasia compared to wild type (WT) (80% *vs* 50%). These patients were younger at diagnosis (mean: 49.3 *vs* 60.4 years, *P*:<0.05), had a higher number of non-driver mutations (3.8 *vs* 1.2, *P*: 0.001), were more likely to have an unfavorable karyotype (80% *vs* 42%) and circulating blasts (40% *vs* 14%). Six year OS was significantly shorter in the *TET2* mutated group *vs* WT (*P:*<0.05).

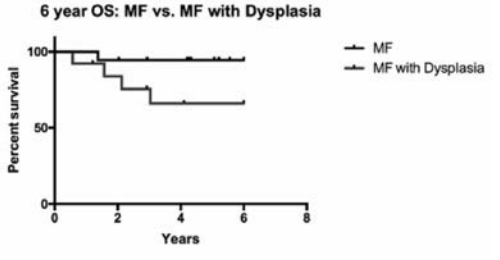

Figure 1.

Summary/Conclusions: Distinguishing between 'MF with dysplasia' and MDS/MPN is a diagnostic challenge because the significance and natural history of MPN dysplasia is poorly understood. Our data demonstrate that this dysplasia is associated with established clinical and genetic markers of aggressive disease, including mutations of *TET2.* Taken together, this suggests that MPN with dysplasia represents a MPN with aggressive disease biology and shortened survival.

E1354

PROPOSAL FOR A REVISED PROGNOSTIC MODEL IN PRIMARY MYELOFIBROSIS THAT ACCOUNTS FOR JAK2, MPL AND CALR MUTATIONS: AN EXPERIENCE OF A SINGLE CENTER IN CHINA

B Li[1,*], Z Xu[1], Y Li[1], T Qin[1], Y Zhang[1], P Zhang[2], Z Xiao[1]
[1]MDS and MPN Centre, [2]Department of Pathology, Institute of Hematology and Blood Diseases Hospital Chinese Academy of Medical Sciences, Tianjin, China

Background: Primary myelofibrosis (PMF) is a Philadelphia-chromosome-negative myeloproliferative neoplasm (MPN) in which JAK2V617F, CALR and MPLW515 mutations are the most frequent driver mutations. PMF appears to have different clinical features in different population. For example, Chinese patients have different clinical and laboratory features compared with PMF in patients of predominately European descent. These differences may affect prognostic scoring systems which might require revision based on the population being evaluated.
Aims: In current study, we focus on the contribution of driver mutations (JAK2, MPL and CALR) to survival and propose a clinical-molecular prognostic model based on the data from a single center in China.
Methods: 402 consecutive subjects with PMF had a bone marrow sample collected at diagnosis or referral, February 1990 to February, 2015 at the Institute of Hematology and Blood Disease Hospital, Chinese Academy of Medical Sciences were enrolled. Follow-up data were available for 361 subjects. Median follow-up of survivors was 36 months (range, 1-385) months. Patients were divided randomly into a study group (n=279) and a test group (n=123). The impact of JAK2, MPL or CALR mutations on prognosis was analyzed by univariate- and multivariate survival analyses.
Results: JAK2V617F mutations were detected in 189 subjects (47%), MPLW515 mutations in 13 (3.2%) and CALR mutations in 81 (20.1%). 119 subjects (29.6%) had no detectable mutation in JAK2, MPL or CALR. There were 30 (37%) type-1 and 48 (59.3%) type-2 CALR mutations. In the study group, patients with CALR type-2 mutations or no detectable mutation had briefer survival compared to those with JAK2, MPL or CALR type-1 or other less common CALR mutations (HR 2.99, 95% CI 1.935-4.619, P<0.001). Therefore, patients were categorized into the high-risk with CALR type-2 mutations or no detectable driver mutation and the low-risk without aforementioned mutations status. A multivariate analysis of prognostic factors in the study group identified the following independent factors (P<0.05): Dynamic International Prognostic Scoring System (DIPSS) risk group, palpable spleen and the status of JAK2, MPL or CALR mutations. We assigned each factor a weight: (1) 3 for DIPSS high-risk; (2) 2 for DIPSS intermediate-2 risk; (3) 1 for DIPSS intermediate-1 risk; (4) 0.5 for no splenomegaly, (5) 1 for CALR type-2 mutation or non-mutated JAK2, MPL and CALR. Subjects were categorized into 4 risk cohorts: (1) low (score 0-1; 39.5% of patients); (2) intermediate-1 (score 1.5-2; 34% of patients); intermediate-2 (score 2.5-3; 19% of patients); and high (score ≥3.5; 7.5% of patients; Fig. 2A).The revised clinical-molecular prognostic model divided patients into 4 prognostic groups with significantly different outcomes (Figure 1) and had a significantly higher predictive power for survival than the DIPSS. The model was validated in the test group.

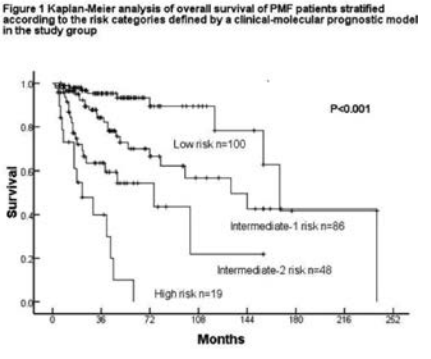

Figure 1.

Summary/Conclusions: This study indicates that the prognostic system including driver mutations (JAK2, MPL and CALR) status could more accurately evaluate survival for patients with PMF.

E1355

INCREASED RISK OF AGE-RELATED MACULAR DEGENERATION IN PATIENTS WITH PHILADELPHIA-NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASMS

M Bak[1,*], TL Sørensen[2], E Meulengracht Flachs[3], ADO Zwisler[4], K Juel[5], H Frederiksen[6], HC Hasselbalch[7]
[1]Department of Hematology, [2]Department of Ophthalmology, Copenhagen University Hospital Roskilde, Roskilde, [3]Center for Prevention and Health, Glostrup University Hospital, Copenhagen, [4]National Center for Rehabilitation and Palliation, University of Southern Denmark and Odense University Hospital, Odense, [5]National Institute of Public Health, University of Southern Denmark, Copenhagen, [6]Department of Hematology, Odense University Hospital, Odense, [7]Department of Hematology, Roskilde Hospital, Roskilde, Denmark, Roskilde, Denmark

Background: Patients with Philadelphia (Ph) -negative chronic myeloprolifer-

ative neoplasms (MPNs) can experience visual symptoms which are caused by microcirculatory disturbances, but the risk of other ophthalmic manifestations such as age-related macular degeneration (AMD) is unknown. AMD causes progressive loss of the central vision and it is the most common cause of blindness in elderly in western countries. Chronic inflammation is involved in the development and progression of both AMD and MPNs, and similar inflammatory pathways are dysregulated. Our previous findings suggest that patients with Ph-negative MPNs have increased prevalence of AMD at time of diagnosis. The potential link between the diseases is possibly explained by the degree of systemic inflammation in patients with MPNs, which may predispose some individuals to develop AMD.
Aims: To determine the risk of AMD in patients with essential thrombocythemia (ET), polycythemia vera (PV), myelofibrosis (MF) and unclassifiable MPN (MPN-U) compared to the general population.
Methods: We undertook an observational matched cohort study and included patients diagnosed with Ph-negative MPNs in Denmark between 1994 and 2013. We included nationwide cohorts of patients with ET, PV, MF and MPN-U by using population-based registries. To compare the risk of AMD, we identified 10 individually sex-and-age matched comparisons from the general population for each patient. We excluded patients and comparisons who had a prior AMD diagnosis or a follow-up time of less than 30 days after the MPN was diagnosed. Everyone was followed until death, December 31, 2013, or until they were diagnosed with any AMD diagnosis at a hospital. Cox proportional hazards models were used to estimate the hazard ratio (HR) of AMD in patients with Ph-negative MPNs (ET, PV, MF, MPN-U) as well as separately for each MPN subgroup. We adjusted for smoking (proxy measure used by including smoking related diagnoses from the Danish National Patient Registry) as smoking is a risk factor for developing AMD. Additionally, we also adjusted for risk-time (1994-2001, 2002-2006, 2007-2013), since new AMD treatments were introduced in Danish hospitals in 2002 and 2007. This could imply that individuals were more likely to be diagnosed with AMD at hospitals after these treatments had been introduced.
Results: We included 7 958 patients with Ph-negative MPNs and 77 445 sex-and-age matched comparisons in the study, after 365 patients and 2 619 comparisons had been excluded. Of the excluded individuals, 222 patients (1 907 comparisons) had a prior AMD diagnosis and 143 patients (712 comparisons) had a follow-up time of less than 30 days. In total, we included: ET=2 628; PV=3 063; MF=547 and MPN-U=1 720 patients. Significant more patients with ET, PV and MPN-U had smoking-related diagnoses compared to comparisons ($p<0.05$), but no difference was seen for patients with MF. Smoking was associated with an increased risk of AMD in both patients and comparisons. We found an increased risk of AMD in patients with Ph-negative MPNs (ET, PV, MF, MPN-U), adjusted hazard ratio (HR) [95% confidence interval] =1.28 [1.10-1.48]. Subset analyses of the HR in each MPN subgroup revealed an increased risk of AMD in each group, but the risk was only significantly increased in patients with PV. The smoking and risk-time adjusted HR (95% CI) was 1.15 [0.88-1.49] for ET; 1.42 [1.15-1.76] for PV; 1.54 [0.67-3.53] for MF and 1.33 [0.93-1.88] for MPN-U.
Summary/Conclusions: Our study indicates that patients with Ph-negative MPNs have increased risk of AMD compared to the general population. We speculate that the increased risk is caused by chronic inflammation, but further studies are needed to investigate the potential causal relationship.

E1356

IMPACT OF JAK2 AND CALR MUTATIONS ON THE DISEASE FEATURES AND OUTCOME AMONG PATIENTS WITH PRIMARY MYELOFIBROSIS OR ESSENTIAL THROMBOCYTHEMIA TREATED WITH STANDARD OF CARE (INCLUDING RUXOLITINIB)

V Hupfer[1,*], J Wehrle[1], C Niemöller[1], S Bleul[1], C Kirchner[1], D Pfeifer[1], T Haferlach[2], M Werner[3], J Duyster[1], N von Bubnoff[1], C Waller[1], HL Pahl[1], H Becker[1]
[1]Department of Internal Medicine I, Medical Center - University Freiburg, Freiburg, [2]MLL Munich Leukemia Laboratory, Munich, [3]Department of Pathology, Medical Center - University Freiburg, Freiburg, Germany

Background: Primary myelofibrosis (PMF) and essential thrombocythemia (ET) share the same mutations in *JAK2* and *CALR* but differ in their clinical features and outcomes.
Aims: Here, we assessed the impact of *JAK2* and *CALR* mutations on the clinical features at diagnosis and on the outcome of patients with PMF or ET treated with standard of care including the JAK2 inhibitor ruxolitinib.
Methods: We studied the clinical and genetic features of 212 patients (median age at diagnosis, 60 years [y]; range, 22-93 y) with PMF (n=93), ET (n=84) or PMF/ET (n=35). Diagnosis was made applying the WHO 2008 criteria, with no clear assignment to PMF or ET possible for patients with PMF/ET. *CALR* mutations were primarily assessed in patients without *JAK2* V617F. Median follow-up time was 5.9 y. Associations were assessed using the Mann-Whitney U-Test for continuous and Fisher's exact test for categorical variables. Overall survival (OS) and leukemia-free-survival (LFS) were estimated using the Kaplan-Meier-method and compared using the log-rank-test.
Results: In the entire cohort of 212 patients, 58.6% carried a *JAK2* V617F and, of the *JAK2* V617F negative patients tested for *CALR* mutations, 38.3% had a *CALR* type 1/type 1-like and 25.5% a type 2/type 2-like mutation. Patients with *CALR* mutations were of younger age at diagnosis (p=0.003) and of predominantly male gender in comparison to *JAK2* V617F positive patients (58.8% *vs* 48.8%). Patients with *CALR* mutations tended to present more often with splenomegaly at diagnosis than patients with *JAK2* V617F (p=0.19). Considering ET patients only, patients with *JAK2* V617F presented with higher white blood counts compared to those with *CALR* mutation (p=0.0006). Among the PMF patients, those with *CALR* mutations had higher platelet counts at diagnosis than those with *JAK2* V617F (p=0.043). Of the 212 patients, 77.4% received treatment specific for PMF or ET (excluding aspirin); 58% had hydroxyurea, 12.8% received an allogeneic blood stem cell transplantation. Regarding the outcomes, patients with *JAK2* V617F had slightly higher rates of thromboembolic events compared to those with *CALR* mutations (35.8% *vs* 23.5%, p=0.21). There were significant differences in OS and LFS in the PMF cohort with patients with *CALR* mutations having better OS (p=0.047; 10y rates 88.9% *vs* 65.1%) and LFS (p=0.049) than patients with *JAK2* V617F; the difference in the OS remained significant among patients aged >60y (p=0.02). Among the ET patients, we did not observe differences in OS or LFS according to the *JAK2* V617F or *CALR* mutation status. Importantly, PMF patients with *CALR* mutations had a similar risk profile in terms of OS as ET patients (p=0.71), implicating that *CALR* mutations attenuate the generally accepted adverse prognosis associated with the diagnosis of PMF as opposed to that of ET. Among the 24 PMF patients treated with ruxolitinib, there were no significant differences in the reduction of spleen size, changes in blood counts or OS between patients with *JAK2* V617F or *CALR* mutations, suggesting that response to ruxolitinib is independent of the *JAK2* and *CALR* mutation status.
Summary/Conclusions: *JAK2* V617F and *CALR* mutations are associated with distinct clinical features in ET and PMF. Patients with PMF and *CALR* mutation have an OS better than that of PMF patients with *JAK2* V617F and similar to that of patients with ET. The treatment response to ruxolitinib is similar among PMF patients with *JAK2* V617F or *CALR* mutations, which refers to the role of JAK-STAT signaling in both mutation types.

E1357

JAK2 AND CALR MUTATION STATUS DEFINES SUBTYPES OF ESSENCIAL THROMBOCYTHEMIA WITH SUBSTANTIALLY DIFFERENT CLINICAL COURSE

M Alpoim*, ML Amorim, G Brás, M Lopes, P Gomes, R Pinto, F Príncipe, JE Guimarães
Hematology Department, Centro Hospitalar de São João, Porto, Portugal

Background: The JAK2V617F mutation is found in about 50 to 60% of cases of essential thrombocythemia (ET) while 5% to 10% of JAK2V16F negative ET patients carry MPL mutations at codon 515. Recently, mutations at exon 9 of CALR, were identified in 50% to 70% of ET patients with nonmutated JAK2 and MPL (double-negative).
Aims: To analyze the prevalence of JAK2V617, CALR and MPL mutations in a population of patients with WHO-defined ET and their association with clinical and laboratory features.
Methods: We retrospectively analyzed a cohort of ET patients in a single center, between 2010 and 2014. The JAK2V616F mutation was detected by allele-specific polymerase chain reaction (PCR) testing. For the detection of MPL exon 10 and CALR exon 9 mutations, we applied PCR amplification and Sanger sequencing.
Results: Of the 172 patients studied, 111 (64.5%) carried JAK2V617F mutation (JAK2+), 35 (20.3%) CALR mutation (CALR+), 6 (3.5%) MPLW515K/L mutation (MPL+) and 20 (11.6%) patients had nonmutated JAK2, MPL and CALR (triple-negative). These mutations were mutually exclusive and therefore, CALR-positive cases represented 63.5% of double-negative ET cases. Within the 35 CALR+ patients, 21 (60%) carried the type 1 mutation, 10 (28.6%) the type 2 mutation and 4 (11.4%) carried other less frequent indels. Compared to JAK2+ patients, CALR+ patients had a younger age at diagnosis (<60 years) (57.1% *vs* 31.5%; p=0.006) and a higher platelet count (≥900x10^9/L) (51.4% *vs* 26.1%; p=0.005). On the other hand, the JAK2+ patients presented a higher hemoglobin level (≥15g/dL) compared to CALR+ patients (45.9% *vs* 20%; p= 0.006). No differences were found between type 1 and type 2 CALR+ subgroups. The distribution according to thrombotic risk classification was statistically different (p=0.003) among the two groups: the percentage of low/intermediate risk patients was 48.6% (n=17/35) in the CALR+ group *vs* 22.5% (n=25/111) in the JAK2+ group. The distribution of International Prognostic Score for Essential Thrombocythemia (IPSET) categories was also statistically different (p=0.002) among the three groups analyzed: the percentage of high risk patients was 38.7% (n=43/111) in the JAK2+ group, 20% (n=7/35) in the CALR+ group and 10% (n=2/20) in the triple-negative group. The IPSET-thrombosis model also stratified patients with significant difference (p<0.001) among the three groups: the percentage of high risk patients was 82.9% (n=92/111) in the JAK2+ group, 17.1% (n=6/35) in the CALR+ group and 5% (n=1/20) in the triple-negative group. When comparing the two groups, CALR+ patients belonged more frequently to the low-risk group than those with JAK2+ (48.5% *vs* 5.4%; p<0.001). The incidence of thrombotic events was 25% (n=43/172) and most occurred prior to the diagnosis of ET (74.4%; n=32/43). The group

of triple-negative patients had the lower incidence of thrombotic events (5%) *vs* the CALR+ group (17.1%) and *vs* the JAK2+ group with the highest incidence of thrombotic events (32.4%) (p=0.015). Transformation to post-ET myelofibrosis occurred in 7 patients (3 CALR+, 2 triple-negative, 1 MPL+ and 1 JAK2+; p=0.093). The median overall survival (OS) was not reached in any group and no differences were identified in OS by univariate analysis according to mutational status (CALR+ *vs* JAK2+ *vs* MPL+ *vs* triple-negative; p=0.3).
Summary/Conclusions: Our study confirms that CALR-mutated ET is phenotypically and biological distinct from JAK2-mutated ET with regard to clinical presentation and thrombotic risk.

E1358

THROMBOSIS IN MYELOPROLIFERATIVE NEOPLASIA ASSOCIATED WITH DIFFERENT COAGULATION FACTOR POLYMORPHISMS

R Dambrauskiene*, R Gerbutavičius, M Rudžianskienė, R Ugenskienė, R Jankauskaitė, A Savukaitytė, R Šimoliūnienė, E Juozaitytė
Lithuanian University of Health Sciences, Department of Oncology and Hematology, Institute of Oncology, Kaunas, Lithuania

Background: The group of myeloproliferative neoplasms (MPNs) are known for their different phenotypes but similar vascular events complications. Blood cells, interaction between them, and the activation of coagulation factors play a role in the pathogenesis of thrombosis in MPNs. Platelet-specific polymorphisms, FVII as well as β-fibrinogen single nucleotide polymorphisms (SNP's) have been never analyzed together in patients with MPNs.
Aims: To evaluate the effects of coagulation factor VII, β-fibrinogen and TT genotype of GP c.807C>T single nucleotide polymorphisms, and the risk of thrombosis in patients with PV, ET, and PMF at the Department of Oncology and Hematology of the Institute of Oncology, the Lithuanian University of Health Sciences.
Methods: We included 108 patients in this survey. Findings of clinical and hematological analyses were collected. Genotyping was done using PCR and PCR-RFLP analysis
Results: TT genotype of GP c.807C>T polymorphism was more frequently found in the group of MPN patients with arterial thrombosis compared to the MPN patients who were thrombosis-free (26.5% *vs* 11.5%, p=0.049). CT genotype of β-fibrinogen c.-148C>T polymorphism occurred significantly more frequently in MPN patients with arterial and total thrombosis compared to the wild type or homozygous genotype (respectively, 57.7% *vs* 40.0 *vs* 12.5%; p=0.027), (64.7% *vs* 44.4% *vs* 25% p=0.032). The carrier state for 323P10 variant of FVII SNP (summation of P10/10 and P0/10) was significantly more frequent in MPN patients with total thrombosis compared to the wild-type genotype carriers (71.4% *vs* 43.4%, p=0.049). The coexistence of both genotypes - heterozygous β-fibrinogen c.-148C>T and FVII -323P0/10 SNP - statistically significantly increased the odds of arterial thrombosis in MNP patients (21.1% *vs* 3.7%, p=0.008).
Summary/Conclusions: We found that 323P10 variant of FVII, TT genotype of GP c.807C>T and CT genotype of β-fibrinogen c.-148C>T SNP polymorphism may be associated with risk of thrombosis in patients with MPNs.

E1359

A PHASE 1 OPEN LABEL STUDY TO DETERMINE THE PHARMACOKINETICS OF PACRITINIB IN PATIENTS WITH MILD TO SEVERE RENAL IMPAIRMENT AND END STAGE RENAL DISEASE (ESRD) COMPARED WITH HEALTHY SUBJECTS

S Al-Fayoumi*, S Amberg, H Zhou, L Millard, JW Singer, M Campbell
CTI BioPharma Corp., Seattle, United States

Background: Treatment and management of patients with hematologic malignancies and co-morbid renal impairment (RI) is challenging as the kidneys are a major route of excretion for many therapeutic agents. The conduct of a RI study is an important regulatory requirement to support appropriate dosage recommendation in patients with RI. Patients with myelofibrosis (MF) and moderate to severe RI treated with the JAK1/JAK2 inhibitor ruxolitinib require dosage reductions. Pacritinib is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R being evaluated for patients with primary or secondary MF.
Aims: Evaluate the pharmacokinetics (PK) and safety of pacritinib and its major metabolite in patients with RI (mild, moderate, severe, and ESRD requiring hemodialysis) compared with healthy age-, sex-, and weight-matched control participants.
Methods: Study participants (N=39) who provided written informed consent included healthy volunteers and subjects with RI (mild, moderate, severe based on estimated glomerular filtration rate and ESRD on hemodialysis). All participants except those with ESRD received a single dose of pacritinib 400 mg, with PK and urine assessments conducted for up to 168 h post-dose. Subjects with ESRD received 1 dose of pacritinib 400 mg in each of 2 periods (dialysis and inter-dialysis) separated by a 14-day washout. Pacritinib was administered immediately before and after hemodialysis in the dialysis and inter-dialysis periods, respectively, followed by PK assessments for 72 h post-dose.
Results: Time to maximum plasma concentration (t_{max}) was reached at 8, 6, and 5.5 h post-dose in patients with mild, moderate, and severe RI, respectively; t_{max} was 7 h in patients with ESRD. In healthy controls, t_{max} was 8 h post-dose. Pacritinib plasma concentrations demonstrated comparable elimination phases across RI groups. Excretion of pacritinib in urine was minimal (1.0-1.4% of dose over 72 h interval) and RI did not decrease urinary excretion. PK analysis revealed slightly higher maximum plasma concentration (C_{max}) and total exposure (area under the plasma concentration-time curve [AUC]) in patients with RI *vs* healthy controls, which are unlikely to be of clinical relevance (Table). C_{max} and AUC were similar for patients with ESRD during dialysis and inter-dialysis periods. Apparent total clearance (CL/F) was comparable across RI groups. All adverse events (AEs) were grade 1-2; diarrhea was the most frequent AE.

Table 1.

PK Parameter (unit)	Group 1: Mild RI	Group 2: Moderate RI	Group 3: Severe RI	Group 4: Subjects With ESRD N=8		Group 5: Matched Healthy Subjects
	N=8	N=8	N=8	Dialysis	Inter-Dialysis	N=7
C_{max} (µg/mL)	5.00 ±2.22	4.75 ±0.896	5.83 ±2.86	6.01 ±2.45	5.97 ±2.27	4.26 ± 0.596
t_{max} (h)	8.00 (4.00-12.00)	6.00 (5.00-24.00)	5.50 (3.00-8.00)	6.96 (4.08-12.00)	7.00 (5.00-8.00)	8.00 (3.00-24.00)
AUC_{0-t} (µg.h/mL)	274 ±106	334 ±103	430 ±287	243 ±149	267 ±136	268 ±75.5
$t_{1/2}$ (h)	39.4 ±9.11	58.0 ±13.3	55.6 ±17.2	44.0 ±23.3	54.1 ±37.6	44.7 ±11.4
CL/F (L/h)	1.57 ±0.622	1.32 ±0.622[a]	1.41±1.11[b]	2.96 ±1.15[c]	NC[d]	1.58 ±0.862
Vz/F (L)	86.1 ±28.8	98.1 ±49.2[a]	90.9 ±43.8[b]	87.8 ±6.20[c]	NC[d]	99.3 ±48.9

Values are arithmetic mean ±SD, except median (range) for tmax.
[a] n=6; [b] n=7; [c] n=3; [d] n=2
AUC_{0-t}, area under the plasma concentration time curve from time of dosing to last measurable concentration; NC, not calculated; $t_{1/2}$, half-life; Vz/F, apparent total volume of distribution.

Summary/Conclusions: PK parameters and renal excretion of pacritinib were not significantly affected by RI. Administration of 400 mg single doses of pacritinib to patients with RI was well tolerated. Dosage adjustment for pacritinib is not warranted in patients with RI.

E1360

RUXOLITINIB TREATMENT FOLLOWING INTERFERON IN PATIENTS WITH POLYCYTHEMIA VERA: AN ANALYSIS FROM THE RESPONSE TRIAL

JJ Kiladjian[1,*], P Guglielmelli[2], M Griesshammer[3], T Masszi[4], S Durrant[5], F Passamonti[6], MM Jones[7], H Zhen[7], J Li[8], B Gadbaw[8], D Habr[8], S Verstovsek[9]
[1]Hôpital Saint-Louis et Université Paris Diderot, Paris, France, [2]CRIMM, Center for Research and Innovation of Myeloproliferative Neoplasms, AOU Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy, [3]Johannes Wesling Academic Medical Center, University of Hannover Teaching Hospital, Minden, Germany, [4]St. István and St. László Hospital, Semmelweis University, Budapest, Hungary, [5]Royal Brisbane Hospital, Herston, Australia, [6]Ospedale di Circolo e Fondazione Macchi, Varese, Italy, [7]Incyte Corporation, Wilmington, Delaware, [8]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, [9]The University of Texas MD Anderson Cancer Center, Houston, Texas, United States

Background: Polycythemia vera (PV) is characterized by excessive proliferation of erythroid, myeloid, and megakaryocytic components in the bone resulting in an increased risk of thromboembolic events, cardiovascular complications, and disease progression. Both hydroxyurea (HU) and interferon-alpha (IFN) are used as first-line treatment for high-risk pts with PV but pts may become resistant/intolerant (Barbui. *JCO* 2011; 29(6):761-770). The recent phase 3 RESPONSE study showed that ruxolitinib (RUX) was superior to best available therapy (BAT) following HU resistance/intolerance; however, little information has been presented on the sub-group of pts treated with IFN in BAT arm.
Aims: This subgroup analysis of RESPONSE study evaluates the safety and efficacy of pts treated with IFN in the randomized BAT arm before and after crossover to RUX.
Methods: RESPONSE, an open-label, phase 3 study enrolled pts with PV, who were resistant to or intolerant of HU per modified European LeukemiaNet criteria, had splenomegaly and required phlebotomy (PBT) to control hematocrit (HCT). Pts were randomized 1:1 to RUX (110 pts) 10 mg bid or BAT (112 pts), of which 13 pts received at least one dose of IFN during the randomized treatment phase. Pts were evaluated for HCT control (<45%) without PBT; spleen response (≥35% reduction in spleen volume from baseline by magnetic resonance imaging); and complete hematologic response [CHR: HCT<45%, white blood cell (WBC) ≤10×10^9/L, platelet (PLT) count ≤400×10^9/L]. JAK2V617F allele burden, adverse events (AEs) and hematologic abnormalities were assessed for randomized and crossover treatment.
Results: Baseline demographics were comparable among RUX (N=110) and IFN-treated pts of the BAT arm (N=13). Three pts (23%) received IFN at some time prior to inclusion in the RESPONSE trial. On trial, 9 pts were treated with PEG-IFN and 4 pts were treated with non-PEG-IFN at varying doses. All IFN pts discontinued and crossed over to RUX due to lack of efficacy (11 pts crossed

over prior to wk 48 and 2 pts after wk 48). No pt treated with IFN achieved spleen response and only 23% of pts achieved HCT control without PBT from wk 8 to 32 (40% and 60% while on RUX therapy, respectively). Thirty-eight percent, 31%, and 31% of pts required no PBT, 1 PBT, and ≥2 PBT, respectively, from wk 8 to 32 of randomized treatment and only 15% of pts achieved CHR at wk 32. Following crossover to RUX, 62% of pts achieved spleen response and PBT requirements decreased (64% of pts did not require any PBT and no pt required ≥2 PBT from wk 32 to 80 after switching to RUX). A majority of pts randomized to IFN had modest reductions in WBC, PLTs, and JAK2V617F allele burden over the course of treatment (figure), with most pts showing further reduction after crossover to RUX. The rates and incidence of hematologic abnormalities (WBC, PLT, and neutrophils) reduced after crossover to RUX with the exception of hemoglobin (prior to crossover: grade 1 [N=2] and grade 2 [N=1]; after crossover: grade 1 [N=5] and grade 2 [N=2]). Similarly, rates and incidence of nonhematologic AEs (systemic, metabolic, gout, pruritus, and fatigue) reduced after crossover to RUX with the exception of infections (primarily grade 1 or 2). Four pts discontinued crossover treatment due to AE (N=3) or pt decision (N=1). One death due to CNS hemorrhage occurred after crossover to RUX (not related to study drug).

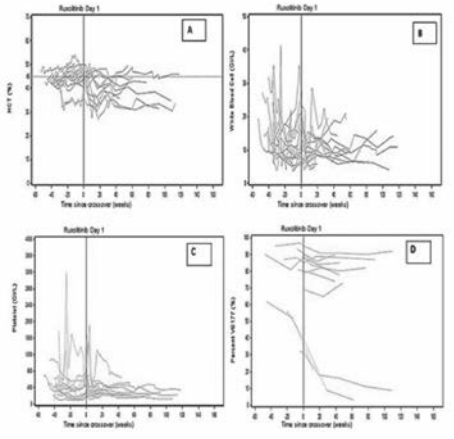

Figure 1. Spaghetti plot of hematocrit (A), WBC (B), platelet counts (C) and JAK2V617F allele burden (D) over time in interferon patients.

Summary/Conclusions: In the HU-resistant/intolerant PV population of the RESPONSE study, no pt treated with IFN achieved spleen response and a limited number of pts achieved HCT control. However, following crossover to RUX, pts showed improvement in hematologic and spleen response with an overall reduction in PBT procedures and a majority of pts being able to achieve spleen response.

Background: Myelofibrosis (MF) is recognized for its debilitating constitutional symptoms, splenomegaly, profound cytopenias and inflammatory state. Current MPN PROs (MF-SAF, MPN-SAF and MPN-10) have proven sensitive for symptom detection. Formal FDA qualification requires that these tools integrate a comprehensive literature search of previously reported symptoms as well as complete physician cognitive debriefing.
Aims: In this investigation, we aimed to complete these required steps to ascertain the most prevalent and pertinent MPN symptoms for PRO inclusion.
Methods: *Literature Search:* An initial review of the published literature was performed using OVID Medline®. The Medical Subject Headings (MeSH) terms included 'primary myelofibrosis' or 'MF', 'Myeloid metaplasia' and 'agnogenic myeloid metaplasia' which were meshed with 'symptom' or 'signs and symptoms' and limited from 1980 to 2011. Articles that were not original research or in the English language were excluded. Articles were then individually reviewed for content with further exclusion of case reports where search terms occurred concurrently with other medical conditions, articles presenting in-vitro data and articles with a primary focus on pharmacotherapy that utilized the MPN-SAF, MPN-SAF TSS or MF-SAF. Articles were then evaluated for all symptoms and recorded by the number of publications they were reported in. *Cognitive Debriefing:* International MPN specialists were contacted via email to complete the Physician Cognitive Debriefing Evaluation via a REDCAP® survey. Implied consent was provided through survey completion and demographic data was recorded. Responders were asked a series of questions on each symptom acquired through the literature search, along with three free-standing questions on MF PRO development. Thirteen responders were also contacted to complete an in-person interview and respond to eight questions on MF-PRO development. Descriptive statistics were used for data analysis.
Results: The OVID Medline search yielded 166 articles for MF which were then individually reviewed. A total of 30 symptoms were extracted from the literature and recorded for incorporation into the REDCAP survey. The survey was distributed to 48 MPN specialists and 17 (35.4%) agreed to participate. Most responders were Caucasian (94.1%) and male (76.5%) with >5 years experience (94.1%) as physicians. Providers saw between 1-5 (58.8%), 6-10 (23.5%) or >10 (11.8) MF patients per week and most held primary practices in Europe (70.6%). Survey responses to symptom questions are provided in Figure 1. During in-person interviews, some providers felt that a different list of symptoms should be provided to patients with: early *vs* late MF (61.5%), primary *vs* secondary MF (7.7%) and clinical trial settings *vs* office environments (23.1%). Most providers felt that 'inactivity' (100%), 'fever' (92.3%) and 'weight loss' (92.3%) were signs as opposed to symptoms of the disease, though should still be included in the PRO (92.3% for each). Most providers believed that the ideal survey length should be between 10-20 questions. Two providers believed that 'health economics' and 'activities of daily living' should be integrated into a final PRO.

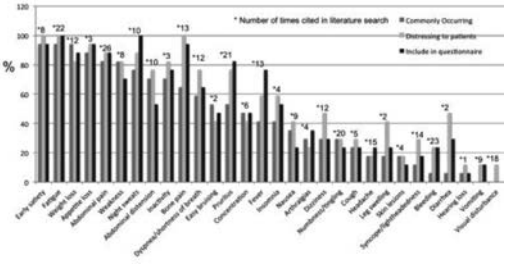

Figure 1.

Summary/Conclusions: Results of the literature search and Physician Cognitive Debriefing support that the MPN-SAF currently addresses the most frequent and symptomatic MF symptoms, with the exception of four items (dyspnea, easy bruising, arthralgias, nausea). Addition Patient Cognitive Debriefing is required to ensure that the final PRO is comprehensive of the most important symptoms to patients.

STUDY OF ADHERENCE RATES AND SIDE EFFECTS OF ORAL TREATMENTS IN POLYCYTHEMIA VERA OR ESSENTIAL THROMBOCYTEMIA (OUEST STUDY)

R Le Calloch[1,*], M Abiven[2], C Le Gall-Ianotto[3], K Lacut[4], E Nowak[2], A Tempescul[5], JR Eveillard[5], G Guillerm[5], V Ugo[6], C Berthou[5], JC Ianotto[5]

[1]Service d'hématologie, CHIC Quimper, Quimper, [2]CIC GETBO, CHRU Brest, [3]Laboratoire de neuroscience, Faculté de médecine, [4]Médecine Interne, [5]Service d'hématologie, CHRU Brest, Brest, [6]Laboratoire d'hématologie, CHU Angers, Angers, France

Background: Polycythemia vera (PV) and essential thrombocythemia (ET) are two chronic hematological malignancies with no curative project. Interna-

tional consensus recommends combining long-term low dose antiplatelet drug and a cytoreductive therapy to reduce hyperviscosity (thrombosis) and phenotypic evolutions (myelofibrosis and acute leukemia). There is actually no study in the literature which evaluates the level of adherence in this population.
Aims: The aim of our study was to evaluate patient adherence rate to physicians prescriptions, explore the reasons and identify the occurrence of side effects.
Methods: A total of 134 patients treated for PV or ET with a median follow-up of 6.8 years were asked for about their adherence using a one-shot questionnaire designed by investigators. Data on complications (thrombosis and industrial) were collected from diagnosis to the time of consultation. All the patients signed inform consent before completing the form.
Results: Twenty-eight percent (37 patients) of the patients reported non-adherence to their cytoreductive drug. Patients who forgot their anti-platelet or anticoagulant drugs (22 patients=X%) are mostly those who belong to the first non-adherent group (15/22; *p<0.0001*). In total, 44 patients (32.8%) were declared as non-adherent. A typical profile of these patients could be described: patient who lives alone (*p=0.007*), rather young (p=0.06) and male (p=0.09). The main cause of non-compliance was oblivion (23/37, 69.7%). Polymedicated patients were significantly more adherent (*p=0.001*). Thrombotic history were recorded in 21.7% of patients (21/97) members against 24.3% of non-adherent patients (9/37) (*p=0.74*). On the other hand, myelofibrotic evolutions were more seen in adherent group (14.4% *vs* 5.4%, *p=0.233*). Side effects related to anti-proliferative treatments were reported by 101 patients (75.4%), and were most frequently cutaneous (53/101, 52.5%) or mucosal toxicity (16/101, 15.8%) likely due to the high prevalence of hydroxycarbamide (94/134, 70%).
Summary/Conclusions: For patients treated for PV or ET, non-adherence to anti-proliferative treatment and anti-agregant therapy seems to be frequent. We did not found any correlation with history of thrombosis and myelofibrotic evolution. The patients will be followed for five years to assume the occurrence of new events instead to correlate them with adherence in a prospective way. An analysis of data on a total population of 286 patients will be presented at the conference.

E1363

ERYTHROPOIESIS-STIMULATING AGENTS (ESA) FOR ANEMIA IN MYELOFIBROSIS (MF): A REAL LIFE EXPERIENCE ON 31 UNSELECTED PATIENTS

M Cerrano[1,*], E Crisà[1], G Benevolo[2], C Aguzzi[1], V Giai[1], E Beggiato[1], A Borchiellini[1], U Vitolo[2], M Boccadoro[1], D Ferrero[1]
[1]Hematology department, Università degli studi di Torino, [2]Hematology department, A.O.U. Città della Salute e della Scienza di Torino, Turin, Italy

Background: Anemia in MF is common but few therapeutic options are available. ESA are safe and widely used but the experience in MF is limited and only a few reports are available.
Aims: We evaluated the safety and efficacy of ESA in MF in a real life context.
Methods: We retrospectively analyzed all the MF patients treated with ESA in our institutions. ESA was started in transfusion-dependent patients or if hemoglobin (Hb) was <10g/dL. According to IWG-MRT and ELN 2013 revised response criteria, anemia response (AR) was defined as a 2 g/dL increase in Hb level for transfusion-independent patients or becoming transfusion-independent for transfusion-dependent patients. The possibility of pretreatment variables to predict a AR to ESA was analyzed using Chi-squared test and Student's t-test. The duration of response was estimated using the Kaplan-Meier method.
Results: Thirty-one MF patients were treated for anemia with ESA (median age at diagnosis 68 years, range 38-85). MF was primary in 42% of the patients while 26% and 32% of the cases were secondary to polycythemia vera or essential thrombocythemia, respectively. JAK2 mutation was detected in 62% of the patients. Seven patients were transfusion-dependent while in the other group median Hb value was 9.1 g/dL (range 7.9-9.9) at the beginning of ESA treatment. Median time from MF diagnosis to ESA start was 3 months (range 0-89). Fourteen patients received epoetin-alpha (originator product) while 11 cases were treated with epoetin-zeta and 5 with other biosimilar ESA. Median ESA starting dose was 40000 U/weekly (range 8000-40000). One patient received low-dose darbopetin-alpha. Median follow up of living patients after ESA start was 27 months (range 3-80). Globally the AR rate was 52%. Most response occurred in the first 3 months, with a median time to AR of 2 months (range 1-7). Nine patients not responsive to standard-dose ESA increased dose to 80000 U/weekly and 2 of them responded. Two of the 5 patients treated with low-dose ESA (i.e.<20000 U/weekly) responded. Median duration of response was 29 months and the probability of maintaining AR at 12 months was 75%. The elapsed time from MF diagnosis to ESA treatment start was predictive of response to ESA: AR rate among patients who started ESA within 3 months from MF diagnosis was 87% *vs* 14% in the others, p<0.01. Transfusion-dependent patients showed a trend towards a reduced probability of AR (29% *vs* 67%, p=0.08). No other predictive factors of response could be found. Among patients with an available baseline serum erythropoietin level (13/31), only 3 showed a value above 125U/L and 1 of them achieved AR after ESA dose increase. Considering the most frequently used types of ESA in our patients, both originator epoetin-alpha and epoetin-zeta obtained favorable results (43% *vs* 70%, p>0.1).The treatment was well tolerated and no significant adverse events related to ESA were reported. In 5 patients an increase in splenomegaly was recorded during ESA therapy.
Summary/Conclusions: Our report confirms the safety and efficacy of ESA for anemia in MF with a fair response duration and it suggests that an early initiation of ESA treatment could yield better results. Besides, we confirm the negative predictive value of transfusion dependence. Epoetin-zeta achieved result at least equal to originator epoetin-alpha, an observation that need to be confirmed but could be important when treatment costs are taken into account.

E1364

A RETROSPECTIVE COHORT STUDY REPORTING ON THE DISEASE CHARACTERISTICS AND OUTCOMES OF PATIENTS DIAGNOSED UNDER THE AGE OF 50 YEARS WITH PRIMARY OR SECONDARY MYELOFIBROSIS

S Alimam[*], Y Beauverd, D Radia, D McLornan, C Harrison
Haematology, Guy's and St Thomas' Foundation Trust, London, United Kingdom

Background: Myelofibrosis (MF), a rare clonal haematopoietic disorder is commonly diagnosed in the 6th or 7th decade of life. The clinical and molecular profile of younger patients remains poorly defined.
Aims: In this retrospective study we evaluated patients who were ≤50 years of age at diagnosis with WHO-defined primary MF (PMF), post-essential thrombocythaemia MF (PET-MF) or post-polycythaemia vera MF (PPV-MF) managed at our centre.
Methods: Forty three patients with a median age of 43 years (range 19-50 years) at diagnosis were included; 24/43 (55.8%) were male. Median follow-up was 44 months (range 0-208 months). Twenty (47%) had a diagnosis of PMF, 14/43 (33%) PET-MF and 9/43 (21%) PPV-MF.
Results: Concerning mutations 22/43 (51%) had *JAK2*V617F, 18/43 (42%) *CALR*, 0/43 (0%) *MPL* mutations and 3/43 (7%) were 'triple negative' (TN). The IPSS and DIPSS scores were low risk in 26/39 (67%) and 26/39 (67%), intermediate-1 in 8/39 (21%) and 11/39 (28%), intermediate-2 in 3/39 (8%) and 2/39 (5%) and high risk in 2/39 (5%) and 7/39 (18%), respectively. Univariate analysis did not demonstrate any significant impact of mutational status upon haemoglobin, leukocytes, platelet count, circulating blasts, red blood cell transfusion need, splenomegaly or constitutional symptoms at diagnosis. Additionally, we did not observe any influence of driver mutation on age at diagnosis, gender, IPSS or DIPSS scores. Comparing *JAK2*V617F and *CALR* mutated subjects, there was a significant increase in the presence of palpable splenomegaly in the *JAK2*V617F mutated patients (p<0.05). TN patients were more like to have a platelet count<100x109/L (p=0.073), adverse karyotype (p=0.06), a high DIPSS-plus score (p=0.076), and the only transformation to acute myeloid leukaemia (AML) occurred in a TN patient. Two thrombotic events occurred: a deep vein thrombosis in a *JAK2*V617F mutated patient, and a myocardial infarction in *CALR* mutated patient, giving an overall calculated incidence rate of 1% patient-year. No major bleeding events were identified. Only one patient progressed to AML with an overall calculated incidence rate of 0.5% patient-year. No deaths were recorded during the follow-up period.
Summary/Conclusions: The distribution of driver mutations in our cohort of patients with MF diagnosed age less than 50 years differs from that of the overall MF patient population; we report that 51% of patients had *JAK2*V617F mutation *vs* 58-64.7% for the broader patient population, 42% *CALR* mutated *vs* 22.7-25%, 0% *MPL* mutated *vs* 4-8.3% (1,2). The frequency of TN patients mirrors that of the wider MF population, 7% in our cohort *vs* 8.6-8.7% in the literature (1,2). Although we were not able to demonstrate any significant impact of driver mutation status on age, gender or laboratory parameters, we recorded a higher incidence of splenomegaly in *JAK2*V617F mutated patients compared to *CALR* mutated patients, (P=0.047). We found that TN status appeared to be associated with higher risk profile and transformation to AML.
Our findings suggest that younger MF subjects may have a higher frequency of *CALR* mutations and a more indolent disease course *i.e.* low IPSS and DIPPS score, lower incidences of thromboembolic events and with less evidence of negative prognostic variables and disease progression compared to the general MF population.

USEFULNESS OF PERFORMING JAK2 MUTATIONAL ANALYSIS IN PATIENTS WITH MODERATE ABSOLUTE ERYTHROCYTOSIS

E Roncoroni[1,*], E Rumi[1,2], D Pietra[1], VV Ferretti[1], IC Casetti[2], C Cavalloni[2], M Bellini[2], C Milanesi[1], C Astori[1], M Cazzola[1,2]
[1]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [2]Department of Molecular Medicine, University of Pavia, Pavia, Italy

Background: The diagnosis of polycythemia vera (PV) is based on clinical and biological criteria defined by the World Health Organization (WHO 2008).

The proposed revised version (WHO 2016) has lowered the threshold hemoglobin (Hb) level for the diagnosis of PV from 18.5 g/dl in men and 16.5 g/dl in women to an hemoglobin level of 16.5 g/dl in men and 16 g/dl for women. The importance to lower hemoglobin threshold in the evaluation of patients with absolute erythrocytosis has not been validated yet.

Aims: To evaluate the importance of the new hemoglobin threshold we retrospectively assessed the frequency of polycythemia vera *versus* secondary erythrocytosis in patients with absolute erythrocytosis categorized according to hemoglobin value at diagnosis.

Methods: We included in the current study all patients recorded in our database with a diagnosis of polycythemia vera or secondary erythrocytosis who showed isolated absolute erythrocytosis at diagnosis according to the new proposed WHO criteria (Hb >16.5g/dl in men and >16g/dl in women, leukocyte count <10x10^9/L, platelet count <450x10^9/L). We stratified these patients according to their hemoglobin level at diagnosis (<17g/dl, 17-19g/dl, 19-21g/dl, 21-23g/dl, >/=23g/dl) and calculated the percentage of PV cases in each subgroup. Only patients assessed for both V617F and exon 12 *JAK2* mutations were included in the study.

Results: Patients who satisfied the above criteria were 236 patients, including 82 PV and 154 secondary erythrocytosis. Diagnosis of PV was made according to WHO 2008 criteria (Hb >16,5g/dl (female) or 18,5g/dl (male) or >15g/dl (female) or 17g/dl with a sustained increase of >2g/dl from baseline, *JAK2* V617F or exon 12 mutation, low erythropoietin level and/or panmyelosis at bone marrow analysis). As shown in table 1, around one third of patients stratified in the subgroup with the lowest hemoglobin (Hb below 17 g/dl) had a final diagnosis of PV, thus reinforcing the importance to perform *JAK2* analysis also in patients with moderate erythrocytosis. This was particularly important in female patients. Namely, when we repeated the same stratification taking into account sex distribution, we observed that half (52.6%) of female patients with Hb level <17g/dl received a final diagnosis of PV. According to our data set, instead, no male patient with Hb lower than 17 g/dl was diagnosed with polycythemia vera. Patients who satisfied the above criteria were 236 patients, including 82 PV and 154 secondary erythrocytosis. Diagnosis of PV was made according to WHO 2008 criteria (Hb >16,5g/dl (female) or 18,5g/dl (male) or >15g/dl (female) or 17g/dl with a sustained increase of >2g/dl from baseline, *JAK2* V617F or exon 12 mutation, low erythropoietin level and/or panmyelosis at bone marrow analysis). As shown in table 1, around one third of patients stratified in the subgroup with the lowest hemoglobin (Hb below 17g/dl) had a final diagnosis of PV, thus reinforcing the importance to perform *JAK2* analysis also in patients with moderate erythrocytosis. This was particularly important in female patients. Namely, when we repeated the same stratification taking into account sex distribution, we observed that half (52.6%) of female patients with Hb level <17g/dl received a final diagnosis of PV. According to our data set, instead, no male patient with Hb lower than 17g/dl was diagnosed with polycythemia vera.

Table 1.

Hb range (g/dl)	Whole cohort		Female patients		Male patients	
	PV n°(%)	SE n°(%)	PV n°(%)	SE n°(%)	PV n°(%)	SE n°(%)
<17	10 (29.4)	24 (70.6)	10 (52,6)	9 (47,3)	0 (0)	15 (100)
17-19	36 (24.7)	110 (75.3)	16 (66,7)	8 (33,3)	20 (16,4)	102 (83,6)
19-21	28 (59.6)	19 (40.4)	10 (83,3)	2 (16,7)	18 (51,4)	17 (48,6)
21-23	6 (85.7)	1 (14.3)	3 (100)	0 (0)	3 (75)	1 (25)
≥23	2 (100)	0 (0)	0 (0)	0 (0)	2 (100)	0 (0)

Table 1. Frequency of polycythemia vera (PV) versus secondary erythrocytosis (SE) according to hemoglobin value at diagnosis in the whole cohort and divided by gender

Summary/Conclusions: In patients with isolate erythrocytosis it is important to perform screening for *JAK2* mutations also when hemoglobin level is slightly increased (>16,5 in men and >16 in women) as a significative proportion of patients with polycythemia vera show at diagnosis only mild erythrocytosis. This result reinforces the importance to lower the hemoglobin threshold required for PV diagnosis as proposed by the new WHO criteria, especially as far as female patients are concerned.

E1367

PROGNOSIS FACTORS CONDITIONING THE RISK OF MIELOFIBROTIC TRANSFORMATION IN ESSENTIAL THROMBOCYTHEMIA: SIGNIFICANCE OF ALLELIC BURDEN AND THE NUMBER OF LEUCOCYTES AT DIAGNOSIS IN YOUNG PATIENTS

M Montero[1,*], T Knight[2], MA Domínguez[2], F Márquez[2], E Carrillo[2], F de la Cruz[2], FJ Falantes[2], J González[2], M Martino[2], JA Pérez- Simón[2]
[1]Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocío, [2]Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background: Even though there are predictive prognostic scores of thrombotic risk in patients with Essential Thrombocythemia (ET), there is no agreement established on the factors influencing the evolution of myelofibrosis in these patients, this is a factor that adversely affects their life expectancy, which is initially similar to that of the healthy population of the same age.

Aims: To analyse in a group of patients with ET the impact of parameters such as age, platelet count at diagnosis, number of leucocytes, time until cytoreductive therapy was needed, time under observation, presence of JAK2 V617F mutation and allelic burden on the risk of myelofibrotic transformation.

Methods: We analysed a total of 100 patients diagnosed in our centre between 1996 and 2013 based on bone marrow study. All patients received anti- platelet agregation and began cytoreductive therapy with hydroxyurea and / or anagrelide according to IPSET criteria. JAK2 V617F mutation was detected by allele - specific real- time quantitative in peripheral blood samples. Homozygous patients for the mutation occurred when the load allelic was >50%, being the rest considered heterozygous. Statistical analysis was performed using SPSS version 15.0 software, considering a statistical significant difference if p<0.05.

Results: Average age of the study population was 63 years. 73% of patients had JAK2 V617F mutation, being homozygous for the same 7% of patients. 11% of patients progressed to myelofibrosis, with a median follow-up of 5 years from diagnosis to transformation. The transformed and untransformed groups were similar in platelet count at diagnosis, time under observation, time to need for cytoreductive treatment and presence of the mutation JAK2 V617F, although there is a tendency to older (74 *vs* 63) and more number of leukocytes (15,1x10e9 /L *vs* 9,6x10e9 /L) in the transformed *versus* non-transformed group. Patients with JAK2 V617F mutation and allelic burden above 40% had a higher risk of myelofibrotic transformation in the multivariate analysis, with an accumulated incidence at 5 years of 57.1% (Figure 1), p=0.04.

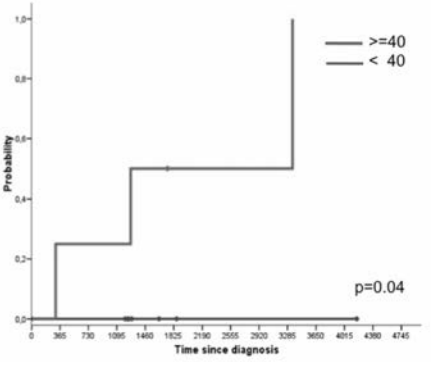

Figure 1. Probability of evolution to positive JAK2 myelofibrosis.

Summary/Conclusions: Patients with ET and JAK2 V617F mutation have an increased risk of myelofibrotic transformation when allelic burden is above 40%, which is why specific therapeutic strategies will be needed aimed at reducing allelic burden to maintain an adequate life expectancy in young patients with this condition. Leucocytes cell count at diagnosis would be a variant to be considered in the prognostic stratification, although specific studies are required to examine this in more detail.

ACTIVATED STAT5 DRIVES PERIPHERAL T CELL LYMPHOMAS

B Maurer[1,2,*], H Nivarthi[3], M Prchal-Murphy[4], B Wingelhofer[1,2], D Chen[3], S Winkler[1], M Schlederer[1,5], HTT Pham[1,2], L Kenner[1,5], V Sexl[4], T Kolbe[6,7], R Kralovics[3], M Müller[2], T Rülicke[8], R Moriggl[1,2,9]
[1]Ludwig Boltzmann Institute for Cancer Research, [2]Institute of Animal Breeding and Genetics, University of Veterinary Medicine Vienna, [3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, [4]Institute of Pharmacology and Toxicology, University of Veterinary Medicine Vienna, [5]Department of Clinical Pathology, Medical University of Vienna, [6]Biomodels Austria, University of Veterinary Medicine Vienna, Vienna, [7]IFA-Tulln, University of Natural Resources and Applied Life Sciences, Tulln, [8]Institute of Laboratory Animal Science, University of Veterinary Medicine Vienna, [9]Medical University of Vienna, Vienna, Austria

Background: STAT5 transcription factors are essential regulators of differentiation, survival and proliferation during hematopoiesis. Hyperactive STAT5 signaling requires enhanced tyrosine phosphorylation (pYSTAT5), which is frequently found in hematopoietic cancers and is associated with negative prognosis. Importantly, recurrent gain-of-function STAT5 variants have been reported in Peripheral T Cell Lymphoma (PTCL) patients, who suffer from aggressive diseases with no targeted therapy options.
Aims: We aim to analyze STAT5-dosage dependent effects on hematopoiesis. Here, we investigated whether constitutive activation of STAT5 suffices to drive PTCL and whether inhibition of the JAK/STAT pathway offers a novel therapeutic opportunity in this disease.
Methods: We used $cS5^{F}$, a hyperactive point mutant of STAT5A (S710F), to generate mouse models expressing the transgene under the vav-promoter at low ($vcS5^{lo}$) or high ($vcS5^{hi}$) levels from hematopoietic stem cells (HSC) on. The phenotypes were characterized by regular blood sampling, flow cytometric analysis of hematopoietic cells and HE, anti-CD3e and -Ki67 stainings on organ sections. RNA-seq and gene-set enrichment analysis was done to confirm the PTCL-like disease of $vcS5^{hi}$ mice. We quantified STAT5 expression levels in PTCL patient tissues by immunohistochemistry and qPCR. Effects on viability and pYSTAT5 levels of murine and human PTCL cell lines after JAK-STAT5 signalling inhibitor treatment were determined.
Results: High pYSTAT5 levels in $vcS5^{hi}$ mice led to an aggressive expansion of $CD8^{+}$ T cells being lethal between 25 and 45 weeks of age. In contrast, $vcS5^{lo}$ mice developed only a mild expansion of $CD8^{+}$ T cells with no effect on life expectancy. The $vcS5^{hi}$ PTCL-like disease was associated with lymphadenopathy, splenomegaly and T cell infiltrations into various organs. The $CD8^{+}$ T cells were transplantable and expressed T cell activation markers. Furthermore, the number of active cycling HSCs increased. The expression profile determined by RNA-seq correlated closely with human PTCL forms. STAT5 expression and activation levels were found to be elevated in PTCL patients. Treatment with Ruxolitinib, Tofacitinib and a novel STAT5 SH_2-domain inhibitor decreased murine and human PTCL cell line viability in response to pYSTAT5 decline.
Summary/Conclusions: Our results obtained from mouse models and patients support the concept that enhanced STAT5 signaling drives PTCL and that STAT5 represents a target in these life-threatening malignancies.

Background: Cutaneous T-cell lymphoma (CTCL) is a type of non-Hodgkin's lymphoma of skin-homing T-cells. It represents about 70-80% of all cutaneous lymphoma with unknown pathogenic mechanisms and no cures. There is good evidence to support a divisive role of interleukin-15 (IL-15) in controlling oncogenic processes in CTCL, since it serves to increase T-cell survival, proliferation, migration and invasion in CTCL cell lines.
Aims: While the malignant CD4+ T-cells from CTCL patients appear to produce and be activated by IL-15, the role of this cytokine in the pathogenesis of CTCL remains unresolved. With the intent of gaining insight into mechanisms of IL-15 overexpression and its role in CTCL pathogenesis, we first confirmed the relevance of IL-15 by showing stage-dependent overexpression in lesional skin and peripheral blood CD4+ T-cells from CTCL patients. We elucidated at least one mechanism by which IL-15 can be overexpressed *in vivo,* and then investigated the biological and clinical aspects of a spontaneous epidermotropic CTCL that develops in mice that constitutively overexpressing IL-15.
Methods: We explored shared molecular aberrations between the CTCL in IL-15 transgenic mice and human CTCL, which could be replicated in normal human T-cells exposed to IL-15. We also interrogated the IL-15 animal model with the purpose of identifying mechanisms and pathways amenable to selective pharmacological targeting for preclinical validation using isotype specific HDAC inhibitor.
Results: Here we report that CTCL patients show increased IL-15 in a clinical stage-dependent manner. Mechanistically, we show that Zeb1 is a transcriptional repressor of IL-15 in T-cells and that hypermethylation of the Zeb1 binding region within the IL-15 promoter, as seen in CTCL patients, prevents Zeb1 binding and causes increased transcription of IL-15. Using a transgenic mouse model of IL-15, we provide evidence that overexpression of IL-15 induces a spontaneous CTCL that mimics the human neoplasm. Excessive autocrine production of IL-15 in T-cells inhibits an HDAC1-mediated negative autoregulatory loop, resulting in the upregulation of HDAC1 and HDAC6, and transcriptional induction of the onco-miR-21. Interruption of IL-15 downstream signaling with isotype-specific HDAC inhibitors halts (HDAC1) or significantly delays (HDAC6) the progression of CTCL *in vivo* and provides pre-clinical evidence supporting a hierarchical model of oncogenic signaling in CTCL.
Summary/Conclusions: In summary, we provide *in vivo* evidence that IL-15 likely can have a causal role in the pathogenesis of at least some cases of CTCL, in part via the epigenetic inhibition of the transcriptional repressor, Zeb1, that in turn leads to overexpression of IL-15 and activation of specific HDACs. IL-15 transgenic CTCL mice provide a novel model for studying the development of CTCL and evaluating potential therapies. Selective inhibition of HDAC1/2 produces a comparable halt in the progression of experimental CTCL as that seen with the pan-HDAC inhibitors, and thus may provide an equally potent yet less toxic alternative in the clinic. Our findings not only demonstrate a critical role for IL-15-mediated inflammation in cutaneous T-cell lymphomagenesis, but also uncover a new oncogenic regulatory loop in CTCL involving IL-15, HDAC1, HDAC6 and miR-21 that show differential sensitivity to isotype-specific HDAC inhibitors.

EXOME SEQUENCING REVEALS RECURRENT GERMLINE VARIANTS IN PATIENTS WITH FAMILIAL LYMPHOPLASMACYTIC LYMPHOMA

A Roccaro[1,*], A Sacco[2], J Shi[2], M Chiarini[3], A Perilla-Glen[2], S Manier[2], S Glavey[2], Y Aljaway[2], Y Mishima[2], Y Kawano[2], M Moschetta[2], M Correll[2], L Imberti[4], G Rossi[1], M Freedman[2], MR Improgo[2], JJ Castillo[2], S Treon[2], J Brown[2], E Van Allen[2], W Hide[2], E Hiller[2], I Rainville[2], I Ghobrial[2]
[1]Hematology - CREA Laboratory, Spedali Civili di Brescia, Brescia, Italy, [2]Medical Oncology, Dana-Farber Cancer Institute, Boston, [3]CREA Laboratory, Spedali Civili di Brescia, Brescia, United States, [4]CREA Laboratory, Spedali Civili di Brescia, Brescia, Italy

Background: Waldenström's Macroglobulinemia (WM) represents a B-cell lymphoproliferative disorder, classified as a lymphoplasmacytic lymphoma, according to the WHO classification. Previous studies have identified familial aggregation of WM cases, and the clustering of B-cell lymphoproliferative disorders among first degree relatives of patients with WM, including chronic lymphocytic leukemia, non-Hodgkin lymphoma, multiple myeloma, IgM-MGUS and IgG/IgA-MGUS, thus suggesting a possible contribution of inherited susceptibility to familial WM. Nevertheless, whether relatively common germline variants may contribute specifically to familial WM cases, remains unexplored.
Aims: To identify the potential contribution for inherited susceptibility to familial WM. To define the functional relevance of the most recurrent observed variant.
Methods: Whole exome sequencing was performed on germline DNA obtained from four members of a single family with documented coinheritance of WM (three affected; 1 unaffected) and applied bioinformatic tools to identify candidate germline variants likely to have a biological role in WM. Additional 246 independent, unrelated WM cases (50 probands from familial cases; 196 from non-familial cases) were screened for the identified variants. The DNA was size-selected to exonic hybrid capture using SureSelect v2 Exome bait (Agilent). Samples were multiplexed and sequenced on Illumina HiSeq flow cells with the goal of an average depth of coverage of 100x. Allele frequencies (AF) in 1000G, as well as PolyPhen-2 prediction, were used to quantify the deleteriousness of SNVs. Variants with AF >0.05 in 1000G were filtered out, and the remaining SNVs were defined as potential familial WM-associated variants. Gene prioritization was obtained by using GRAIL and global coexpression network COXPRESdb. Functional validation was performed by engineering WM cells for the most recurrent variant, by using site-directed mutagenesis and LentiORF.
Results: LAPTM5(c403t) and HCLS1(g496a) represented the most recurrent variants, present in 3/3 affected members of the index family. Each of these variants was present in 8% of the unrelated familial cases, in 0.5% of the non-familial cases and in <0.05 of a control population. To interrogate a possible involvement of LAPTM5 and HCLS1 in WM biology, we used the HEFalMp

database to construct a combined LAPTM5/HCLS1 module and interrogated whether this module is disrupted in WM patients compared to healthy donors (HDs), using an independent gene expression profile dataset (GSE6691). We demonstrated a statistically significant high gene-to-gene connectivity in HDs, while the sub-network was disrupted in WM. Importantly, the change in mean connectivity was significantly different in the WM- *versus* the HD-modules ($P<0.0001$). Together, these findings suggest a conserved high interactivity between LAPTM5 and HCLS1 in normal B cells, while WM cells present a disrupted pattern of connectivity, which likely impacts disease biology. Previous studies have reported on LAPTM5 over-expression in patients with B-cell lymphomas. LAPTM5c403t was the most significantly predicted variant to be functionally related to the WM mRNA signature, and therefore dissected its functional relevance, by using site-directed mutagenesis in WM cells. LAPTM5c403t mutated cells presented with enhanced cell growth, NF-kBp65 activation and phospho- NF-kBp65 nuclear translocation, compared to the non-mutated cells, thus suggesting the role of the LAPTM5(c403t) variant in enhancing WM cell proliferation through modulation of NF-kB activation.
Summary/Conclusions: LAPTM5(c403t) and HCLS1(g496a) may represent predisposition alleles in patients with familial WM. Future studies will be needed to clarify the penetrance of specific alleles as well as possible combinatorial effects.

COMBINATION OF THE GLYCOENGINEERED TYPE II CD20 ANTIBODY OBINUTUZUMAB WITH THE NOVEL BCL-2 SELECTIVE INHIBITOR VENETOCLAX INDUCES ROBUST CELL DEATH IN NHL MODELS AND CLL PATIENT SAMPLES

D Sampath[1,*], S Herter[2], E Ingalla[1], F Herting[3], T Friess[4], M Bacac[5], P Umana[6], W Fairbrother[7], L Ysebaert[8], M Anne-Quillet[8], C Klein[6]
[1]Translational Oncology, Genentech, South San Francisco, United States, [2]Roche Innovation Center Zurich, Roche Pharma Research and Early Development Center, Zurich, Switzerland, [3]Roche Innovation Center Penzberg, Roche Pharma and Early Development, [4]Roche Innovation Center Penzberg, Roche Pharma Research and Early Development, Penzberg, Germany, [5]Roche Innovation Center Zurich, Roche Pharma Reserach and Early Development, [6]Roche Innovation Center Zurich, Roche Pharma Research and Early Development, Zurich, Switzerland, [7]Early Discovery Biochemistry, Genentech, South San Francisco, United States, [8]Cancer Research Center of Toulouse, Université Toulouse III Paul Sabatier, Toulouse, France

Background: Obinutuzumab (GA101) is a novel glycoengineered type II anti-CD20 monoclonal antibody that induces a high level of non-apoptotic direct cell death and, due to increased affinity for FcγRIII on effector cells, results in enhanced antibody-dependent cellular cytotoxicity (ADCC) and phagocytosis (ADCP). Venetoclax (ABT-199/GDC-0199) is a novel, orally bioavailable, selective BCL-2 inhibitor that induces intrinsic apoptosis in preclinical models of hematological malignancies (NHL, AML, MM) and primary CLL patient samples.
Aims: Based on their complementary mechanisms of action involving increased apoptosis (venetoclax) or direct cell death (obinutuzumab) we aimed to determine if the combination of both agents has the potential for greater efficacy in treating B lymphoid malignancies such as NHL and CLL when compared to monotherapy and co-treatment with other anti-CD20 antibodies such as rituximab.
Methods: In vitro studies primarily utilized fluorescence activated cell sorting (FACS) to measure direct cell death induction/apoptosis on NHL cell lines (WSU-DLCL2, SU-DHL4 and Z138) and primary CLL patient samples (n=27) as well as the impact of BCL-2 inhibition on ADCC induction. ADCC assays utilized peripheral blood mononuclear cells (PBMCs) isolated from healthy donors as effector (E) cells and SU-DHL4 as target (T) cells and measured by Lactate dehydrogenase (LDH) release using the LDH Cytotoxicity Detection Kit (Roche Applied Science). *in vivo* efficacy of venetoclax monotherapy or in combination with anti-CD20 antibodies was evaluated in WSU-DLCL2, SU-DHL4 and Z138 sub-cutaneous xenograft models. Venetoclax (100 mg/kg) was administered daily by oral gavage for 21 days and anti-CD20 antibodies (1 mg/kg) were delivered intrapertioneally once during the treatment period.
Results: Venetoclax enhanced induction of cell death when combined with obinutuzumab or rituximab in SU-DHL4, WSU-DLCL2 and Z138 cell lines. However, a greater degree of cell death was observed when venetoclax was combined with obinutuzumab *versus* rituxumab at lower drug concentrations. Importantly, venetoclax did not antagonize natural killer (NK)-cell mediated ADCC or B cell depletion induced by obinutuzumab or rituximab treatment. Treatment of SU-DHL4, WSU-DLCL2 and Z138 xenografts with venetoclax plus obinutuzumab resulted in complete regressions, increased overall response rates or greater tumor growth inhibition *in vivo*. Moreover, monotherapy with venetoclax following combination treatment with obinutuzumab resulted in sustained *in vivo* efficacy and increased duration of response in SU-DHL4 and WSU-DLCL2 xenograft models suggesting a potential benefit of utilizing venetoclax as maintenance therapy. In primary CLL samples (from untreated or relapsed patients), venetoclax plus anti-CD20 antibody drug combination treatment significantly increased B cell depletion (based on direct cell death/ADCC) after 7 days in culture ex vivo. Under these conditions, venetoclax in combination with obinutuzumab was more effective than the combination with rituximab or venetoclax alone. Moreover, co-culture with nurse-like cells that increases B-cell survival did not protect primary CLL cells from venetoclax demonstrating that drug efficacy is maintained in a protective tumor microenvironment such as lymph node.
Summary/Conclusions: Collectively, our data demonstrate that combination of obinutuzumab with venetoclax results in greater cell death and robust anti-tumor efficacy in xenograft models representing NHL sub-types and primary CLL patient samples that is superior when compared to co-treatment with rituximab. The preclinical data presented supports clinical investigation of obinutuzumab and venetoclax combination therapy, which is currently in phase Ib clinical trials for relapsed/refractory CLL (clinical trial.gov identifier NCT01685892), and warrants further investigation in other B-cell malignancies such as NHL.

THE CD47-BLOCKING CANCER IMMUNOTHERAPEUTIC TTI-621 HAS ANTI-TUMOR EFFECTS ACROSS A BROAD RANGE OF HEMATOLOGICAL MALIGNANCIES

NN Viller[1,2], H Chen[1], V Lee[1], K Dodge[1], V Chai[1], M Wong[1], X Pang[1], SM Vareki[2,3], R Figueredo[2,3], M Pampillo[2], J Koropatnick[2,3], S Trudel[4], O Galkin[4], L Jin[4], J McLeod[4], JCY Wang[4,5], PS Petrova[1], RA Uger[1,*]
[1]Trillium Therapeutics Inc., Toronto, [2]London Regional Cancer Program, London Health Sciences Centre, Lawson Health Research Institute, [3]Department of Oncology, University of Western Ontario, London, [4]Princess Margaret Cancer Centre, University Health Network (UHN), [5]Division of Medical Oncology and Hematology, Department of Medicine, UHN, Toronto, Canada

Background: CD47 binds to signal-regulatory protein α (SIRPα) on the surface of macrophages and delivers a "do not eat" signal that suppresses phagocytosis. There is strong evidence that many hematological and solid tumors upregulate cell surface expression of CD47 as a means to exploit the CD47-SIRPα pathway and escape macrophage-mediated immune surveillance. Blockade of CD47 using TTI-621, a soluble SIRPα-Fc fusion protein (SIRPαFc), is a promising therapeutic strategy to neutralize the suppressive effects of CD47 and promote the eradication of tumor cells by host macrophages.
Aims: Here we have examined the effect of TTI-621 on human hematological tumor cells in vitro and *in vivo*.
Methods: Human macrophages were derived from peripheral monocytes of healthy donors. For the in vitro phagocytosis assay, tumor cells were co-cultured with macrophages for two hours in the presence of TTI-621 or control Fc protein. Phagocytosis was assessed by confocal microscopy or flow cytometry. Acute myeloid leukemia (AML) xenografts were performed in NOD.SCID mice. Cells from AML patients were transplanted intra-femorally, and following a three week engraftment period, mice were dosed with 5 mg/kg mouse SIRPαFc or 3.3 mg/kg control Fc protein three times/week for four weeks. AML engraftment was determined by%$CD45^+CD33^+$ human cells. Lymphoma xenografts were performed in SHrN mice. Namalwa cells were injected subcutaneously into each flank. Toledo cells were injected in 50% Matrigel. Three days (Nawalma) or 10 days (Toledo) after tumor cell implantation, animals received 10 mg/kg mouse SIRPαFc or 6.75 mg/kg control Fc protein, daily five times/week, for three weeks. Tumor volumes were monitored until they reached the maximum volume of $1500mm^3$.
Results: We first assessed the ability of TTI-621 to trigger macrophage-mediated phagocytosis of cancer cells. In cultures left untreated or treated with a control Fc fragment, macrophages exhibited a low level of phagocytosis, consistent with CD47-mediated suppression. Blockade of CD47 by TTI-621 led to a dramatic increase in the phagocytosis of human tumor cell lines of both myeloid and lymphoid origin, including non-Hodgkin lymphoma lines. Furthermore, TTI-621 enhanced macrophage-mediated phagocytosis of primary tumor samples from patients with AML, myelodysplastic syndrome, multiple myeloma and B- and T-cell acute lymphoblastic leukemia. In total, 77% (23/30) of cell lines and 97% (32/33) of primary patient samples were readily phagocytosed following treatment with TTI-621. We next evaluated the *in vivo* efficacy of a mouse surrogate of TTI-621 in an AML xenograft model. Treatment of mice with mouse SIRPαFc for four weeks significantly reduced the tumor burden in the injected femur of 7/10 patient samples compared to a control Fc protein, while dramatically reducing the tumor burden in non-injected bone marrow in all 10 AML patient samples. Finally, we assessed the *in vivo* activity of mouse SIRPαFc in xenograft models of Burkitt lymphoma (Namalwa) and diffuse large B cell lymphoma (Toledo). Treatment with SIRPαFc ablated the growth of Namalwa and Toledo tumors and was superior to rituximab therapy in both models.
Summary/Conclusions: Collectively, these data indicate that TTI-621 is active across a broad range of human hematological tumors. A Phase I clinical trial of TTI-621 in patients with advanced hematological malignancies is currently underway (ClinicalTrials.gov #NCT02663518).

E1374

ACTIVATION OF MTORC2 COMPLEX CONTRIBUTES TO CELL CYCLE PROGRESSION AND SURVIVAL IN ALK+ ANAPLASTIC LARGE CELL LYMPHOMA

G Rassidakis[1,*], N Tsesmetzis[1], D Chioureas[1], G Baltatzis[2], V Atsaves[1], V Leventaki[3], T Panaretakis[1], E Drakos[4]

[1]Oncology and Pathology, Karolinska Institutet, Stockholm, Sweden, [2]Pathology, University of Athens, Athens, Greece, [3]Pathology, St Jude Children's Research Hospital, Memphis, TN, United States, [4]Pathology, University of Crete Medical School, Heraklion Crete, Greece

Background: ALK+ anaplastic large cell lymphoma (ALK+ ALCL) is characterized by chromosomal translocations of ALK gene locus, the most frequent being the t(2;5)(p23;q35) resulting in aberrrant expression and activation of the NPM-ALK oncoprotein. The NPM-ALK activates multiple oncogenic pathways including the mTOR-Raptor (mTORC1) pathway, however, the potential role of mTOR-Rictor (mTORC2) complex in ALCL pathogenesis is yet unknown.
Aims: To investigate the potential role of Sin1, a critical component of the mTORC2 complex required for its integrity and activation, in ALK+ ALCL pathogenesis.
Methods: Expression, phosphorylation, and localization of Sin1 protein were assessed by Western blot after subcellular fractionation, immunofluorescence and confocal microscopy in 3 ALK+ and 2 ALK- ALCL cell lines. Physical interaction between various proteins was assessed by co-immunoprecipitation assays. Real-time RT PCR was used to assess Sin1 gene products at the RNA level. Transfection experiments were performed in BaF3 cells and in ALK+ and ALK- ALCL cells using NPM-ALK and Sin1 expressing plasmids and Sin1-shRNA constructs (gene silencing). Standard cell viability, proliferation and colony formation assays as well as flow cytometry were utilized to assess cell growth and survival following forced expression or gene silencing of Sin1 gene, as well as after treatment with ALK and STAT3 inhibitors. In a cohort of 32 previously untreated patients with ALK+ ALCL, Sin1 protein expression was assessed by immunohistochemistry performed on a tissue microarray.
Results: Sin1.1 and Sin1.5 were the main isoforms detected in immunoblots and they were differentially expressed among ALK+ and ALK- ALCL cell lines. Sin1 protein was co-localized with activated (Ser473-phosphorylated) AKT kinase in ALCL cells. Treatment of ALK+ ALCL cells with Crizotinib led to reduced expression and de-phosphorylation of Sin1 protein. Forced expression of Sin1.1 and Sin1.5 isoforms resulted in increased cell proliferation in ALK+ ALCL cells with downregulation of the CDK inhibitor p21. Inversely, knocking down Sin1 gene by two specific Sin1-shRNA constructs resulted in dramatic decrease of cell viability and colony formation (by 80%) of ALK+ ALCL cells, which was associated with AKT de-activation and downregulation of the anti-apoptotic BCL-XL and MCL-1 proteins. Using our in vitro system and ex vivo (xenografts) mouse model, Sin1 gene expression was, at least in part, regulated by STAT3 transcription factor. In the cohort of ALK+ ALCL patients, Sin1 protein was expressed in all 32 tumors studied with cytoplasmic and nuclear pattern.
Summary/Conclusions: Taken together, these novel findings suggest that mTORC2 complex, through Sin1-dependent activation of AKT and possibly other AKT-independent functions, may contribute to cell cycle and apoptosis deregulation and oncogenesis in ALCL. Thus, modulation of mTORC2 activity might represent a novel target for investigational therapy in patients with ALCL.

E1375

SEARCHING FOR NOVEL PROGNOSTIC BIOMARKERS IN DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) BY CIBERSORT-BASED ANALYSIS OF TUMOR MICROENVIRONMENT

S Ciavarella[1,*], MC Vegliante[2], G Graziano[1], S Serrati[1], G Loseto[1], A Rana[1], A Iacobazzi[1], C Minoia[1], V De Fazio[1], A Scattone[3], G Nardelli[1], G De Tullio[1], A Negri[1], A Guarini[1]
[1]Onco-Hematology, IRCCS - National Cancer Institute "G. Paolo II", [2]Interdisciplinary Medicine, University of Bari "A. Moro", [3]Pathology, IRCCS - National Cancer Institute "G. Paolo II", Bari, Italy

Background: Diffuse large B cell lymphoma (DLBCL) comprises a large group of disease entities with high molecular heterogeneity and variable treatment responsiveness. Results from gene expression profiling (GEP) studies highlighted the role of cell of origin, namely activated B cell-like cells (ABC) and germinal center B cells (GCB), and stromal gene signatures for predicting clinical outcome and stratifying patient risk. However, translation of GEP information in easily applicable prognostic biomarkers remains a challenge.
Aims: We applied an innovative GEP-based computational method, namely CIBERSORT, to determine the cellular composition of DLBCL microenvironment and investigate associations between abundance of certain tumor-infiltrating non-malignant cell types and molecular/clinical traits of the disease.
Methods: We generated a gene signature matrix including a total number of 1028 genes that distinguish 17 different immune and non-immune cell types, the latter including adipocytes, endothelial cells (EC), pericytes and myofibroblasts (MF). This matrix was used to perform CIBERSORT analysis (on-line access to the webserver http://cibersort.stanford.edu/) of GEP data from 3 publicly datasets (GSE10846, GSE19246 and GSE34171) of overall 604 DLBCL cases. The relative percentage of each tumor-infiltrating cell fraction was estimated and a global heatmap of tumor microenvironment composition was generated. Results were also stratified according to either cell of origin or clinical outcome data and significant differences in each subgroup calculated by a two-sided Mann-Whitney test.
Results: By applying CIBERSORT, we found that, among immune cells, memory B cells, plasma cells, NK cells, dendritic cells, CD4 T cells and macrophages mainly infiltrate DLBCL tissues. In particular, plasma cells, NK and dendritic cells showed significant higher proportion in ABC than GCB tumors, whereas CD4 T-cells and dendritic cells were prevalent in patients with better outcome. Notably, among stromal cells, MF was the most represented population and exhibited a significant predominance in patients with more favorable outcome and a strong positive correlation with overall survival (Figure 1). Consistently, the fraction of MF was significantly larger in GCB tumors compared with ABC subtypes. These latter resulted more enriched in EC.

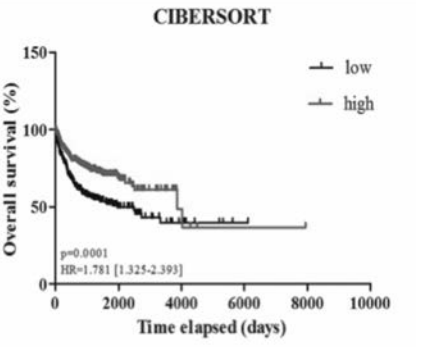

Figure 1 - Publicly available DLBCL GEP datasets (GSE10846 and GSE34171) were analyzed by CIBERSORT (cases=488) to estimate the percentages of myofibroblast infiltration. Kaplan-Meier curve shows patients stratified into the two groups 'high' or 'low', according to the median value of myofibroblast fraction (p=0.0001,log-rank test; n=238 low and 241 high patients).

Figure 1.

Summary/Conclusions: By estimating relative fractions of DLBCL-infiltrating cells using CIBERSORT, we studied unknown aspects of tumor microenvironment with potential prognostic implications. Our data suggest that the composition of DLBCL with diverse molecular and clinical features also differ in term of immune and, particularly, stromal cell infiltration. These findings are in line with previous reports highlighting the prognostic value of specific stromal gene signatures and support further studies aimed at uncover novel prognostic/predictive biomarkers correlated with non-malignant tumor-associated cell subsets.

E1376

MOLECULAR AND FUNCTIONAL CHARACTERIZATION OF ALK+ AND ALK- ANAPLASTIC LARGE CELL LYMPHOMA (ALCL)-DERIVED EXOSOMES AND THEIR INTERACTIONS WITH TUMOR MICROENVIRONMENT

G Rassidakis[1,*], D Chioureas[1], N Tsesmetzis[1], E Drakos[2], T Panaretakis[1]
[1]Oncology and Pathology, Karolinska Institutet, Stockholm, Sweden, [2]Pathology, University of Crete Medical School, Heraklion Crete, Greece

Background: Anaplastic large cell lymphoma (ALCL) is an aggressive type of T-cell non-Hodgkin lymphoma with high frequency in childhood. The current WHO classification recognizes two distinct types of ALCL based on the expression of the anaplastic lymphoma kinase (ALK), the ALK+ and the ALK- ALCL. The ALK+ ALCL is characterized by chromosomal translocations involving the *alk* gene locus, the most frequent being the t(2;5) leading to aberrant expression and activation of NPM.ALK oncoprotein. The latter is known to activate multiple oncogenic pathways including the Ras/ERK, JAK/STAT3, PI3K/AKT/MTOR, JNK/Jun, Sonic Hedgehog and others, resulting in cell cycle and apoptosis deregulation. However, the potential role of bi-directional crosstalk between the microenvironment (TME) and ALCL cells is not yet known. Exosomes are endosome-derived vesicles that contain DNA, RNA, proteins, lipids and other factors that have been reported to play significant role in intercellular signaling. Their role in the ALCL-TME interactions has not been investigated to date.
Aims: To characterize the ALCL-derived exosomes and investigate their possible functional interactions with microenvironment using an in vitro system as well as an ex vivo mouse model of ALK+ and ALK- ALCL.
Methods: Exosomes derived from ALK+ and ALK- ALCL cell lines were isolated using well established ultracentrifugation protocols. The exosomes were subsequently characterized by nanoparticle tracking analysis (NanoSight) and transmission electron microscopy for their size and shape. The molecular composition of exosomes at the RNA and protein level was assessed by real time RT-PCR and Western blotting, respectively. Stromal cells including bone marrow-derived fibroblasts and mesenchymal stem cells were co-cultured with ALK+ and ALK- ALCL cells or they were educated with exosomes and the biologic effects were investigated. Uptake levels of exosomes by recipient lymphoma or stromal cells were assessed by DIR labeling and flow cytometry. Expression of proteins associated with the Cancer-Associated Fibroblasts (CAF) was evaluated by immunofluorescence and confocal microscopy. The biologic effects of co-cultured lymphoma and stromal cells after ALK (Crizotinib) and STAT3 (Stattic, XIII) inhibition were analyzed with standard cell viability and proliferation assays and flow cytometry in our in vitro ALCL system. In addition, an ex vivo mouse model for ALK+ and ALK- ALCL (xenografts) was used in this study.

Results: We characterized for first time the ALK+ and ALK- ALCL-derived exosomes. Transmission electron microscopy and nanoparticle tracking analysis showed significant differences in exosome size among various ALCL cell lines. Western blot analysis performed on both, whole cellular and exosomal lysates, confirmed the expression of various exosomal markers including Rab5, Alix, and CD82. Lack of AIF in the exosomal lysates served as a quality control. More importantly, Western blot analysis revealed the presence of critical components of the ALK signaling in NPM-ALK positive ALCL-derived exosomes including pALK, pSTAT3, AP-1 transcription factors, pAKT and mTOR pathway kinases. ALCL-derived exosomes were uptaken by ALK+ and ALK- ALCL cells at a high level ranging from 30% to 80% at 6 hours, and similarly, they were uptaken by bone marrow-derived fibroblasts and mesenchymal stem cells at a high level as well. Co-culture of the ALCL cells with stromal cells resulted in activation of stromal fibroblasts that acquired a CAF phenotype (aSMA+) as shown by immunofluorescence and confocal microscopy. Furthermore, co-culturing of ALK+ ALCL and stromal cells altered response (sensitivity) of ALK+ ALCL cells to Crizotinib treatment at a moderate level.
Summary/Conclusions: This is the first study to characterize the ALK+ and ALK- ALCL-derived exosomes and demonstrate potential exosome-associated interactions between the ALCL and stromal cells. Ongoing functional studies will enrich our understanding for the involvement of the microenvironment in the mechanisms of resistance to targeted therapy that would lead to more efficient therapeutic approaches for the ALCL patients.

Background: The aggressive clinical behavior of mantle cell lymphoma (MCL) is mainly attributed to the t(11;14)(q13;q32) traslocation and cyclin D1 (CCND1) overexpression. Nevertheless, a certain degree of clinical/biological heterogeneity has been reported.
Aims: To identify MCL subsets with peculiar clinical/biological features in the context of a cohort of homogeneously treated MCL patients.
Methods: The study used gene expression profiling (GEP) and quantitative real-time PCR (qRT-PCR) validations in peripheral blood (PB, n=46) and formalin fixed paraffin embedded (FFPE, n=42) samples from 82 MCL cases enrolled in the Fondazione Italiana Linfomi (FIL)-MCL-0208 randomized clinical trial (high-dose therapy followed by autologous transplantation).
Results: i) Unsupervised and supervised analyses. GEP from 27 PB samples were analyzed by principal component analysis (PCA) and divided in two subgroups named PCA1 (14 cases) and PCA2 (13 cases). Supervised analysis, according to PCA classification, identified a gene expression signature of 902 probes (700 up-regulated). Gene Set Enrichment Analysis (GSEA) demonstrated a significant enrichment of five B Cell Receptor (BCR)-related gene sets, these genes being constitutively over-expressed in PCA2 samples. ii) Identification of a "PCA2-type" gene signature. By merging the lists of differentially expressed genes and the BCR signaling related genes according to GSEA, a group of 14 genes, all overexpressed in PCA2 cases, was obtained. Among these genes, 6 genes, *AKT3*, *BCL2*, *BTK*, *CD79B*, *PIK3CD*, and *SYK*, were selected for further validations. iii) Generation of a 6-gene prediction model. These 6 genes were analyzed by qRT-PCR and utilized to generate a prediction model by using 17 cases as training cohort and 10 cases as validation cohort (all from PB samples). By this approach, 10/10 cases of the validation cohort were correctly assigned according to the PCA2/PCA1 classification. qRT-PCR was then utilized to classify 19 additional cases (10 PCA2 cases) not employed in GEP. Overall, in the 46 cases, 23 cases were classified as PCA2 by the GEP/qRT-PCR approach. iv) Clinical/biological correlations. No association was found between the 6-gene signature and *IGHV* status (33/41 unmutated *IGHV* cases) and the overexpression of *SOX11* (15/27 cases over the median value). Moreover, no association was found with the presence of the main recurrent mutations of the *ATM*, *BIRC3*, *CCND1*, *KMTD2*, *NOTCH1*, *TP53*, *TRAF2*, *WHSC1* genes. Finally, an "ad-interim" analysis of progression free survivals (PFS) suggested a shorter PFS (2-years PFS 76% *vs* 44%, p=0.04) for PCA2 cases. v) Application of the 6-gene signature to FFPE samples. By testing the 6-gene signature, by qRT-PCR in FFPE samples, 22 and 20 cases were classified PCA1 or PCA2, respectively. Again, in this independent series, PCA2 group demonstrated a trend for shorter PFS (2-years PFS 95% *vs* 80%, p=0.15). Merging together cases analyzed using PB and FFPE material, PCA2 patients had a shorter PFS (2-years PFS 85% *vs* 61%, p=0.02). vi) 6-gene signature and sensitivity to the BCR inhibitor ibrutinib. We investigated the proliferation rate of the MCL cell lines Rec-1, Jeko-1, Mino, JVM-2, JVM-13, and Z-138 in presence or in absence of ibrutinib 10 nM for 7 days. By qRT-PCR sensitive cell lines showed higher expression levels of the selected six genes than the resistant counterpart, and were classified as PCA2.
Summary/Conclusions: A novel 6-gene expression signature related to the BCR pathway has been found to characterize MCL cells with peculiar clinical/biological features and sensitivity to BCR inhibitors.

BONE MARROW MESENCHYMAL STEM/STROMAL CELLS FROM SPLENIC MARGINAL ZONE LYMPHOMA PATIENTS SHOW DISTINCT INTRINSIC CHARACTERISTICS AND EFFECTS ON B-LYMPHOCYTE CHEMOTAXIS AND APOPTOSIS

A Kalyva[1], C Pontikoglou[2,*], C Kalpadakis[2], E Stagakis[2], L Kalaitzaki[1], G Pangalis[3], HA Papadaki[2]
[1]Hemopoiesis Research Laboratory, [2]Department of Hematology, University of Crete School of Medicine, Heraklion, Crete, [3]Department of Hematology, Iatriko Athinon Psychiko Branch, Athens, Greece

Background: Splenic marginal zone lymphoma (SMZL) originates from the neoplastic transformation of mature B-lymphocytes. In most cases, B-lymphocytes infiltrate bone marrow (BM), suggesting a potential involvement of BM microenvironment in disease pathology.
Aims: To examine BM-derived mesenchymal stem/stromal cells (MSCs), since they comprise key components of the BM hematopoietic stroma, in order to investigate if they exhibit altered intrinsic properties *in vitro* or if they stimulate altered B- and T-cell immunomodulatory properties in SMZL patients compared to healthy controls.
Methods: BM MSCs were isolated and expanded *in vitro* from 12 SMZL patients and 11 healthy controls. MSCs were cultured for a total of 5 passages (P) and were phenotypically characterized by flow cytometry (FC). The colony forming unit-fibroblast (CFU-F) assay was used to estimate MSC frequency within the BM mononuclear cell (BMMC) fraction in P0 and their clonogenic capacity in P2. MSCs differentiation to adipocytes and osteoblasts was assessed by cytochemical stains. Their proliferative potential was evaluated by Methyl Triazolyl Tetrazolium assay. To assess the effect of SMZL MSCs on lymphocyte proliferation, B- and T-cells were immunomagnetically isolated (Miltenyi Biotec) from peripheral blood (PB) of normal individuals, labeled with carboxyfluorescein succinimidyl ester (Gibco) and subsequently cultured in the absence or presence of confluent layers of SMZL or normal MSCs, in the presence of activating factors. B cell apoptosis was evaluated via FC using 7-AAD staining, after co-culturing with SMZL or normal MSCs. Finally, B-cell chemotaxis was evaluated by monitoring the migration of isolated B-cells through a 5μm pore membrane in a transwell plate towards the confluent layers of either SMZL or normal MSCs.
Results: In vitro expanded MSCs from both groups were adherent cells with a spindle-shape morphology, which expressed CD29, CD73, CD90 and CD105 and were negative for the CD14, CD34 and CD45 cell surface markers. SMZL and Normal MSCs were similar in their differentiation to adipocytes and osteocytes as evidenced by Oil Red O and Alizarin Red staining, respectively. The frequency of MSCs within the BMMC compartment was significantly lower in patients as compared to healthy individuals (2.51 *vs* 7.95 colonies per 10^5 BMMCs respectively; p=0.04) apparently due to the predominance of the lymphoma cells within patient BMMCs. SMZL MSCs in comparison to Normal MSCs at P2, displayed defective clonogenic potential (3.36 *vs* 6.23 colonies respectively, p=0.03) and reduced proliferative potential (p<0.03). In co-culture experiments, SMZL and Normal MSCs showed no difference in their effect on normal B-cell or T-cell proliferation. However, SMZL MSCs produced a statistically significant advantage on B-cell survival as measured in B-cell apoptosis experiments. More specifically, 50±1.46% of B cells cultured in medium alone were apoptotic, while only 23±2.63% and 17±0.77% of B cells co-cultured with either Normal MSCs or SMZL MSCs were apoptotic (p=0.009 when comparing SMZL *vs* Normal MSCs). Finally the transwell migration assays showed that SMZL MSCs displayed a stronger chemotactic activity on isolated normal B-cells, in comparison to Normal MSCs, with the percentages of migrated B-cells being 34% and 22% respectively, (p=0.009).

Summary/Conclusions: Our data suggest that SMZL MSCs are intrinsically defective in terms of proliferative and clonogenic potential and moreover they exert distint anti-apoptotic and chemotactic effects on healthy-donor derived B cells. The impact of SMZL MSCs on the properties of patient derived peripheral B cells is currently under investigation.

E1379

INTERRUPTION OF CCL20-CCR6 INTERACTION INHIBITS METASTASIS OF ADVANCED CUTANEOUS T-CELL LYMPHOMA

H Tagawa[1,*], S Ikeda[1], A Kitadate[1], N Takahashi[1], M Sugaya[2]
[1]Hematology, Akita University, Akita, [2]Dermatology, University of Tokyo, Bunkyo-Ku, Japan

Background: The expression of interleukin-22 (IL-22), chemokine receptor CCR6, and its ligand CCL20 is upregulated in advanced Cutaneous T-cell lymphoma (CTCL) (Miyagaki et al., Clin Cancer Res 2011). We have also shown that a non-coding RNA, microRNA-150 (miR-150), is silenced in advanced CTCL, and that the miR-150 downregulates CCR6 directly and CCL20 indirectly. Based on these data, we hypothesized that continuous CCR6 and CCL20 upregulation might lead to continuous CCL20-CCR6 interaction in CTCL cells and in turn, lead to metastasis to distal organs in a nutrition-dependent manner. We further found that IL22RA1, one of the IL-22 receptor subunits, was aberrantly overexpressed in CTCL, and that its knockdown decreased CCL20 production. These results suggested that the IL-22 produced by the CTCL cells might activate the IL-22 receptor in these cells, leading to the activation of downstream targets and subsequently increasing the transcription of CCL20 (Ito et al., Blood 2014). However, we could not determine the downstream cascade of IL-22 that mediates CCL20 transcription activation.
Aims: Aim of this study is to determine whether 1) CCR6-CCL20 interaction is actually functional in advanced CTCL cells representing metastatic capability, and 2) which transcriptional factor(s) might activate CCL20 activation.
Methods: Immunohistochemistry of p-STAT3 and CCR6 were performed for five patients with Mycosis Fungoides patients of early and advanced phase of the same individual. CTCL cell lines such as My-La, HH MJ and HUT78 were used for in vitro experiment. Transient knockdown of IL22RA1, CCR6, and CCL20 was conducted for detecting functional analysis of CTCL cells. To determine whether the transient knockdown of STAT3, CCL20, or CCR6 or treatment with neutralizing CCL20 antibody could reduce the migration ability of CTCL cells, we conducted an in vitro migration assay. To examine the *in vivo* effect of neutralizing CCL20 antibody, we used NOD/Shi-scid IL-2γnul mice inoculated with CTCL cells (namely CTCL mice). Written informed consent was obtained from all patients prior to collection of specimens, in keeping with all institutional policies and according to the Declaration of Helsinki. Samples were collected under a protocol approved by the Institutional Review Boards of Akita University and University of Tokyo.
Results: We demonstrated increased STAT3 expression during the progression of primary CTCL. STAT3 was spontaneously activated and mediated the transcription of CCL20 in CTCL cell lines. However STAT3 was not spontaneously activated in mantle cell lymphoma cell lines because these cell lines required upstream stimulation of IL-22 for activation of CCL20. In vitro migration assay demonstrated that all treatments reduced the nutrition-dependent migration activity of CTCL cells. Notably, treatment with neutralizing CCL20 antibody reduced the migration ability of the cells without decreasing the expression of CCL20 and CCR6. This demonstrates that the CCL20-CCR6 interaction is actually functional in metastatic CTCL cells. *in vivo* administration of neutralizing CCL20 antibody significantly prolonged the survival of the CTCL mice.

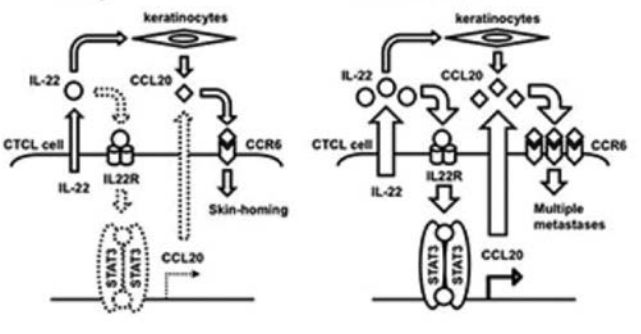

Figure 1.

Summary/Conclusions: These findings suggested that automatic activation of the STAT3/CCL20/CCR6 cascade was actually involved in advanced CTCL lymphomagenesis. On the other hand, activation of STAT3 might require upstream stimulation of IL-22 in early CTCL (see image Figure). Thus, disruption of CCL20-CCR6 interaction could be a key therapeutic strategy against advanced CTCL.

E1380

TUMOR GENE EXPRESSION PROFILES ASSOCIATED WITH SINGLE-AGENT COPANLISIB ACTIVITY IN HEAVILY PRETREATED PATIENTS WITH INDOLENT AND AGGRESSIVE NON-HODGKIN LYMPHOMA (NHL)

L Liu[1,*], K Koechert[2], J Cheng[1], J Garcia-Vargas[1], BH Childs[1], M Dreyling[3], C Peña[1]
[1]Bayer HealthCare Pharmaceuticals, Whippany, United States, [2]Bayer AG, Berlin, [3]Klinikum der Universität München LMU, Munich, Germany

Background: Copanlisib, a novel pan-class I PI3K inhibitor with predominant activity against α and δ isoforms, has shown promising single agent anti-tumor activity in a phase 2 study (NCT01660451, part A) in heavily pretreated patients with indolent and aggressive lymphoma.
Aims: Tumor gene expression profiling was used as a discovery tool to identify genes or pathways associated with copanlisib treatment outcomes and provide potential predictive markers and rationale for novel combinations.
Methods: Single gene multivariate approach and gene set enrichment analysis (GSEA) using RNA expression array data from archival tumors from patients enrolled in the phase 2 trial were performed to identify genes and pathways associated with copanlisib efficacy. A weighted gene expression score (WGS) reflecting overall expression level for each pathway was generated from logistic regression and Cox proportional hazards models to assess association with response status and progression-free survival (PFS), respectively.
Results: A total of 24 patients including both indolent and aggressive lymphoma were available for analysis. Patients had either complete response (n=3), partial response (n=5), stable disease (n=11), or progressive disease (n=5) as best clinical response; follicular lymphoma (FL, n=10), marginal zone lymphoma (n=2), mantle cell lymphoma (n=2), diffuse large B-cell lymphoma (DLBCL, n=5), transformed indolent lymphoma (n=2) or chronic lymphocytic leukemia (n=3). The GSEA gene sets ranked highest for correlation with response were those reflecting upregulated B-cell receptor (BCR) signaling and a PI3K signature (including both α and δ isoforms), with normalized enrichment scores of 1.92 and 1.62 and false discovery rates of 0.014 and 0.087, respectively. Response rates were increased in patients with high BCR and PI3K WGS compared to low (nominal p=0.06 and 0.07, AUC=0.81 and 0.75, respectively). PFS was longer in copanlisib-treated patients with high (above the median) BCR WGS (377 *vs* 62 days, HR=0.035, nominal p<0.0001) and in patients with high PI3K WGS (288 *vs* 104 days, HR=0.24, nominal p=0.02) compared to those with low. In contrast, upregulation of NFκB, IL6/JAK/STAT3, stromal and inflammatory process gene sets and the individual genes NOP10, MT2A, and CSTB were potentially associated with lower likelihood of response to copanlisib.
Summary/Conclusions: Durable response to single-agent copanlisib is associated with tumors with PI3K pathway activation and/or strong BCR signaling. A strong NFκB expression profile is associated with lower likelihood of response to single-agent copanlisib. The higher response rate in FL as compared to DLBCL is consistent with a predominant BCR/PI3K expression profile in FL, with low NFκB activation. These results suggest that FL even in advanced stage and prior extensive treatment can respond to single-agent copanlisib. Efficacy in DLBCL may require combination therapy, adding agents that target NFκB pathway to copanlisib.

E1381

PROGNOSTIC IMPACT, PHENOTYPIC AND MOLECULAR CHARACTERIZATION OF CONCORDANT AND DISCORDANT BONE MARROW INVOLVEMENT IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

S Alonso[1,*], M Alcoceba[1], M García-Alvarez[1], JC Caballero[1], J Davila[1], O Blanco[2], MD Caballero[1], M González[1], N Gutiérrez[1], A Martín[1]
[1]Hematologia, [2]Pathology, Hospital Universitario de Salamanca, Salamanca, Spain

Background: In the rituximab era, the biology and prognostic influence of bone marrow (BM) infiltration in patients with diffuse large B-cell lymphoma (DLBCL) has been hardly studied.
Aims: In this retrospective study, we aimed to investigate: i) the prognostic influence of concordant (DLBCL histology) and discordant (low-grade lymphoma) BM infiltration in patients with DLBCL; ii) the correlation of cell of origin (COO) of the DLBCL and the type of BM infiltration; iii) the clonal relationship between BM and lymph node (LN) tumor cells in the discordant cases; and iiii) the incidence of *TP53*, *CMYC*, *BCL2*, *BCL6* genetic alterations in the cases with BM infiltration.
Methods: All patients with histological diagnosis of DLBCL in our center from January 1, 1999 were included. Survival analysis was performed only in the patients treated with rituximab (R) plus curative chemotherapy. All BM samples were reviewed and classified as concordant or discordant infiltration according to histological criteria. COO was assessed by Hans method. Phenotypic description of discordant marrows was performed by flow cytometry (FCM). Clonal relationship between BM and lymph node (LN) was performed by VDJ sequencing according to BIOMED-2 protocol. *TP53*, *CMYC*, *BCL2*, *BCL6* were analyzed using fluorescence in situ hybridation (FISH).
Results: From 232 patients included in the study, 36 (15%) had concordant histological BM infiltration and 22 (9%) discordant. Phenotypic characterization of the discordant cases, including those detected only by FCM, was heteroge-

neous, representing different types of indolent B-cell lymphomas:CLL (7), FL (8), MZL (4) LPL (2), DLBCL (23), Composite (2), Not specified (8). Clonality studies from the 15 evaluable discordant cases, confirmed the same clone in both BM and lymphadenopathy in 12 patients (80%); we observed that the most frequent VH segment was VH4.34, only seen in patients with non-germinal center (non-GCB) COO phenotype. FISH analysis revealed a high rate of genetic aberrations, particularly in the concordant group of patients, as shown in table 2. *BCL2* translocations stood out in the GC phenotype group, while CMYC gains concentrated among those with discordant BM infiltration. *TP53* deletions, were mostly seen in the concordant non-GC group of patients. Survival analysis were conducted in the 189 patients treated with R plus curative chemotherapy. With a median follow up of 58 months, 5-year PFS was significantly worse in patients with concordant BM infiltration (30,4%) compared with those with discordant (64.8%, p=0.004) or without infiltration (67.8%, p=0.001). This negative influence of concordant BM involvement on PFS was independent of IPI in the multivariate analysis (HR=2.25, 95% CI 1.2 to 4.3, p=0.01). IPI was the only variable with independent influence on OS. By combining COO and type of BM infiltration, we observed that patients with discordant BM and non-GC COO were a group not previously described with decreased PFS (41.9% at 5 years) as compared with the non-infiltrated GCB group (78.3%, p=0.007) and the non-infiltrated non-GCB group (73%, p=0.05) (Figure 1).

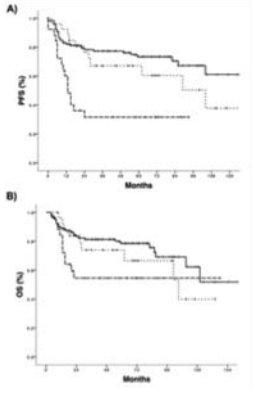

Figure 1. A) PFS of patients without BM infiltration (continuos line), discordant infiltration, dotted line (p=0.2) and concordant infiltration, discontinuous line (p<0.001). B) OS of the concordant BM infiltration group is significantly decreased (p=0.005) while there are no differences between the non-infiltrated group and those with discordant infiltration (p=ns).

Figure 1.

Summary/Conclusions: Our results confirm the adverse prognosis of concordant BM infiltration but reveal that the type of BM infiltration could be more informative when combined with DLBCL COO and FISH analysis, allowing better prognostic stratification of patients. Among discordant cases we find a high rate of clonal relationship between the two different histologies, which suggest that most cases are histologic transformations from a low-grade lymphoma. Larger prospective studies are needed to confirm these results.

E1382

MULTIPLE NF-KB INDUCERS PROMOTE C-MYC-DEPENDENT B-CELL LYMPHOMAGENESIS

N Arnaud[1,*], A David[1], M Fradet[1], H Lascaux[1], U Zimber-Strobl[2], C Ouk-Martin[1], N Gachard[1], J Feuillard[1], N Faumont[1]
[1]UMR 7276, Limoges, France, [2]Department of Gene Vectors, Research Center for Environmental Health GmbH, Munich, Germany

Background: Not only Burkitt lymphoma (BL) with the translocation of MYC, but also diffuse large B-cell lymphoma (DLBCL) by other mechanisms (mutation, amplification, promoter dysregulation…) are associated with dysregulation of c-Myc, the master transcription factor for proliferation. DLBCL's are classified in two subgroups: "Germinal center B-cell" (GCB) without and "activated B-cell" (ABC) with constitutive NF-kappa B activation. This constitutive activation of NF-kappa B can be the result of genetic alterations (MYD88, A20, TRAF2, and TRAF5) or the activation of B-cell receptor or CD40. These features raise the question of the synergy between NF-kappa B and c-Myc in ABC DLBCL. By inducing c-Myc and NF-kappa B, *via* in particular, the viral oncogene LMP1 (Latent Membrane Protein 1), Epstein-Barr virus (EBV) immortalized B cells are another example of the coexistence of these two transcription factors in continuous proliferating B-cells. Although BL are described without NF-kappa B activation, frequent association with EBV raises the question of the role of NF-kappa B activation during the early phase of the oncogenic process.
Aims: To study the synergy between NF-kappa B and c-Myc using the effect of several NF-kappa B drivers in the context of a continuous activation of c-Myc.
Methods: *In vitro*, study of an EBV and c-Myc double inducible human B-cell model and Burkitt lymphoma cell lines. *Ex vivo* and *in vivo,* study of TLR9 activation of B cells from the λ-c-Myc transgenic mouse model. *In vivo,* study of double transgenic mouse model with constitutive activation of CD40 and c-Myc (mouse CD40 / Myc). Techniques used are those for studying functional proliferation, apoptosis, B-cel-differentiation, expression of protein and regulation of genes.
Results: Our results show that induction of NF-kappa B in the context of overexpression of c-Myc, i) by EBV latency III program, provides a selective advantage to those cells (gene expression in favor of a high metabolism, intense proliferation and protection against apoptosis), ii) by TLR9 (*in vivo* and *in vitro* model) increases the survival and proliferation of B lymphocytes of λ-c-Myc mice (increase of activated B cells, splenomegaly, increased B cells proliferation), and iii) by CD40 in the double transgenic CD40/Myc mice have a very aggressive B lymphomagenesis with *in vivo* increased proliferation and tumorigenesis.
Summary/Conclusions: We concluded that, whatever the tested model, NF-kappa B and c-Myc are functionally synergistic for transformation B cells.

E1383

PROGRAMMED CELL DEATH 1 EXPRESSION IS ASSOCIATED WITH INFERIOR SURVIVAL IN PATIENTS WITH PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA

SY Hyun[1,*], H Cho[2], SJ Kim[2], YR Kim[3], JY Lee[2], H Park[2], JE Jang[2], Y Kim[2], JW Cheong[2], YH Min[2], JS Kim[2]
[1]Wonju Christian Hospital, Wonju, [2]Severance Hospital, [3]Gangnam Severance Hospital, Seoul, Korea, Republic Of

Background: Programmed cell death 1 (PD-1) and its ligands PD-L1/PD-L2 have been shown to mediate immune evasion in various cancers, but their prognostic roles have not been studied in patients with primary central nervous system lymphoma (PCNSL).
Aims: To evaluate the prognostic role of immunohistochemical PD-1, PD-L1, and PD-L2 expression in immunocompetent patients with PCNSL.
Methods: We performed a retrospective, immunohistochemical study on 76 PCNSL patients at initial diagnosis initially treated homogenously with high-dose methotrexate (HD-MTX)-based chemotherapy, and evaluated the prognostic roles of high PD-1, PD-L1, and PD-L2 expression. The cut-off values for high PD-1 (≥70 cells/high power field [HPF]), PD-L1 (≥100 cells/HPF), and PD-L2 (≥100 cells/HPF) were determined by the area under the receiver operating characteristic curve.
Results: The median follow-up duration for surviving patients was 31.9 (range, 2.4–128.5) months. Sixteen (21.1%) patients received consolidative upfront ASCT after a median of 4 cycles (range 2–4) of HD-MTX-based chemotherapy. Expression of PD-1, PD-L1, and PD-L2 was high in 7.9%, 13.2%, and 42.1% patients, respectively. High PD-1 (HR: 4.95, 95% CI: 1.54–15.86, P=0.007) and MSKCC prognostic scoring (HR: 2.56, 95% CI: 1.17-5.64, P=0.019) were independently associated with inferior overall survival on multivariate analysis. High PD-1 also remained an independent prognostic factor for inferior progression-free survival (HR 2.73, 95% CI: 1.12-6.69, P=0.028), as did MSKCC prognostic scoring (HR: 1.56, 95% CI: 1.09-2.45, P=0.041) on multivariate analysis. However, there were no differences in survival according to the expression levels of PD-L1/PD-L2. Patients with high expression of PD-1 showed significantly shorter survival compared to those with low expression of PD-1 (P=0.008 for OS, and P=0.037 for PFS) (Figure A, B). In a subgroup analysis of 60 patients who did not receive upfront ASCT, high PD-1 expression tended to associate with inferior OS (P=0.145) and PFS (P=0.197) (Figure C, D). However, among 16 patients who received upfront ASCT, high PD-1 expression was significantly associated with inferior OS (P<0.001) and PFS (P=0.008) (Figure E, F).

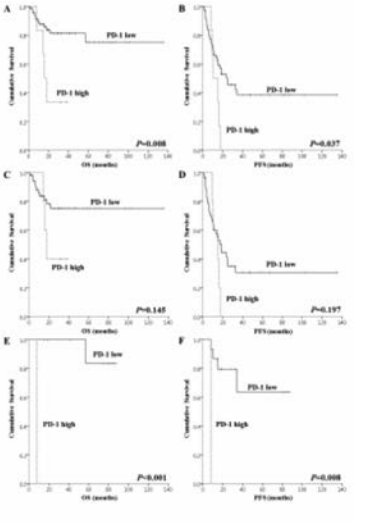

Figure 1.

Summary/Conclusions: We found that high PD-1 expression was associated with inferior survival in patients with PCNSL. PD-1 may be considered a biomarker and potential therapeutic target in PCNSL.

ARGINASE 1 IS A MARKER OF MYELOID-MEDIATED IMMUNOSUPPRESSION WITH PROGNOSTIC MEANING IN CLASSIC HODGKIN'S LYMPHOMA

A Romano[1,*], NL Parrinello[1], D Tibullo[1], C Vetro[1], C Giallongo[1], P La Cava[1], A Chiarenza[1], G Motta[1], V Simeon[2], L Caruso[3], S Cosentino[4], M Ippolito[4], U Consoli[5], P Musto[2], F Di Raimondo[1]
[1]Division of Hematology, University of Catania, Catania, [2]Laboratory of Preclinical and Translational Research, CROB Referral Cancer Center of Basilicata, Rionero in Vulture, [3]Division of Hematology, Ospedale Ferrarotto, [4]Nuclear Medicine Center, Azienda Ospedaliera Cannizzaro, [5]Division of Hematology, ARNAS Garibaldi, Catania, Italy

Background: The role of microenvironment in the pathogenesis of classic Hodgkin`s Lymphoma (HL) is well recognized. Our previous work showed that myeloid-derived suppressor cells have prognostic meaning, but their detection in peripheral blood is controversial due to lack of specific surface markers that could help to distinguish from mature polymorphonuclear neutrophils (PMN).
Aims: Evaluate if mature PMN in HL are different from healthy and in particular if they are immunosuppressive
Methods: Using oligonucleotide microarrays, we first evaluated the gene expression profile (GEP) of PMN at the steady state in 5 HL and 5 healthy subjects matched for sex and age, identifying arginase (Arg-1) among the first 10 genes differentially expressed in HL *versus* healthy PMN. Secondly, we investigated if HL-PMN could suppress T-cell activation. Thirdly, since we found that N-HL immunosuppression was due to the increased amount of Arginase-1, we prospectively measured Arginase (s-Arg-1) in sera collected from 118 HL patients, distinguished in a training set (N=40) and a validation set (N=78), and 35 healthy participants.
Results: Arg-1 was increased in HL-PMN (at both m-RNA and protein level), with an increased activity up to 15 times compared to healthy subjects matched for age and sex. In lymphocytes isolated from healthy subjects and PHA-activated, T-cell proliferation and expression of activation markers were down-regulated by co-culture of with HL-N at ratio 1:2, 1:4, and 1:8. s-Arg-1 was increased in HL patients compared to healthy subjects, and reduced after therapy. At diagnosis, s-Arg-1 was higher in patients with advanced stage (p=0.045), carrying B-symptoms (p=0.0048) and with a positive PET-2 scan after two cycles of chemotherapy (p=0.012). In the validation set, baseline levels of s-Arg-1 >200 ng/mL resulted in 92% sensitivity and 56% specificity to identify patients with positive PET-2 scan. Patients carrying s-Arg-1 more than 200 ng/mL had a shorter progression free survival. In multivariate analysis, PET-2 and s-Arg-1 at diagnosis were the only significant prognostic variables (respectively p=0.0004 and p=0.012). With these two prognostic variables, we were able to define three distinct groups based on PET-2 status after two cycles of chemotherapy and s-Arg-1 level at diagnosis. Patients with low s-Arg-1 and negative PET-2 scan (score 0, N=63) had 89.5% PFS at 36 months *versus* 67.6% of patients with at least one unfavourable prognostic factors (score 1, N=46) *versus* 37% of those patients with high s-Arg-1 and positive PET-2 (score 2, N=9, p=0.0004).
Summary/Conclusions: In HL, neutrophils are dysfunctional and immunosuppressive. They also produce Arg-1 that can be easily measured and represents a promising prognostic tool, to validate in larger prospective series.

E1385

A NOVEL DIGITAL PCR ASSAY FOR MYD88 L265P MUTATION DETECTION IN WALDENSTRÖM MACROGLOBULINEMIA: MINIMAL RESIDUAL DISEASE MONITORING AND CHARACTERIZATION ON CIRCULATING FREE DNA

D Drandi[1,*], E Genuardi[1], I Dogliotti[1], I Sciascia[1], F Guerrini[2], B Mantoan[1], M Gilestro[3], V Muccio[1], P Ghione[1], P Omedè[3], S Galimberti[2], L Orsucci[4], F Cavallo[1], M Boccadoro[1,3], M Ladetto[5], S Ferrero[1]
[1]Molecular Biotechnology and Health sciences, University of Torino, Torino, [2]Clinical and Experimental Medicine, University of Pisa, Pisa, [3]Hematology, [4]Hematology 2, Città della Salute e della Scienza, Torino, [5]Hematology, AON SS. Antonio e Biagio e Cesare Arrigo, Alessandria, Italy

Background: MYD88^{L265P} mutation is the earmark of Waldenström Macroglobulinemia (WM) and might represent an ideal marker for minimal residual disease (MRD) monitoring. However, current diagnostic tools, as allele-specific quantitative PCR (ASqPCR), are not sensitive enough for MRD monitoring on peripheral blood (PB), harboring low concentrations of circulating tumor cells. Besides, cell-free DNA (cfDNA) analysis has been shown to be highly promising for mutational studies. However, more sensitive approaches are needed and droplet digital PCR (ddPCR) might thus represent a powerful tool in this setting.
Aims: Here we describe the applications of a new, highly sensitive, ddPCR assay for MYD88^{L265P} detection to assess: 1) its feasibility for MYD88^{L265P} mutation screening and MRD monitoring in bone marrow (BM) and PB; 2) its potential application for mutational studies on cfDNA isolated from plasma.
Methods: BM, PB and plasma samples from a local series of WM and IgG-lymphoplasmacytic lymphomas (LPL) and IgM-MGUS patients (pts) were collected at baseline and during follow-up. 20 healthy subjects were used as negative controls. Genomic DNA (gDNA) and plasma derived cfDNA were extracted, according to the blood or body fluid protocols, by Maxwell RSC automatic system (Promega). MYD88^{L265P} was assessed on gDNA (100ng) and cfDNA (5µl) by a custom ddPCR assay on a QX100 System (Bio-Rad). For comparison ASqPCR was assessed on gDNA (100ng), as described [Xu L, 2013]. MYD88^{L265P} cut-off was settled based on the healthy samples background level. IGH-based MRD analysis was performed as described [Ladetto M, 2000; Drandi D, 2015].
Results: Once optimized, MYD88^{L265P} ddPCR assay sensitivity was compared to ASqPCR on a ten-fold serial dilution standard curves. Whereas ASqPCR confirmed the reported sensitivity of 1.00E−03, ddPCR reached a sensitivity of 5.00E−05. Overall, 137 samples from 77 pts (68 WM, 6 LPL, 3 IgM-MGUS), 86 baseline (64 BM, 22 PB) and 51 follow-up (23 BM and 28 PB), were analyzed. Median values at baseline were: age 67 years (range: 38-88), IgM 2.2 g/l (0.3-10.8), IgG for LPL 1.9 g/l (0.8-3.4), B2M 2.6 mg/l (0.14-7.9), infiltration at BM biopsy 45% (0-90%), BM infiltration by flow cytometry 10% (range: 0-87%). 12 pts had splenomegaly and 15 adenopathies. 63/64 (98.4%) diagnostic BM samples and 19/22 (86.4%) diagnostic PB samples scored positive for MYD88^{L265P} (BM median 4.5%, range: 0.02-72.6%: PB median 0.15%, range: 0.01-27.8%) (all 3 negative PB had a positive BM match). To investigate the concordance between methods, 100 samples (60 BM, 40 PB) were tested by both ASqPCR and ddPCR. Overall a good concordance was observed (p=0.0005) with the majority of discordances found in the follow-up samples (13/60 ddPCR positive-ASqPCR negative, 11/60 ddPCR negative-ASqPCR positive). However, ddPCR was able to detect a higher number of mutated cases in diagnostic samples (38 *vs* 36). Moreover, to investigate whether MYD88^{L265P} ddPCR could be used for MRD monitoring we compared it to the gold standard IGH-based MRD assay. Preliminary results on baseline and follow-up samples (18 BM, 5 PB) from 5 pts, selected from 33/57 (57.9%) displaying an IGH rearrangement, showed highly superimposable results between methods. Finally, pivotal results on cfDNA from 33 pts showed 1 log higher median levels of MYD88^{L265P} mutation in cfDNA from plasma (0.7%, range 0-25,7%) compared to PB (0.037%, range: 0.01-20.0%).
Summary/Conclusions: MYD88^{L265P} ddPCR is a feasible and highly sensitive assay for mutational screening and MRD monitoring in WM, particularly in samples harboring low concentrations of circulating tumor cells (e.g. PB after immunochemotherapy). Moreover, cfDNA from plasma samples represents a promising tissue source and might be an attractive, less invasive, alternative to PB or BM for MYD88^{L265P} detection. Methodological validation against IGH-based MRD detection and flow cytometry, as well as correlations with clinical data, are currently ongoing.

E1386

THE ROLE OF PREGNANCY IN PROMOTING NON-HODGKIN LYMPHOMA GROWTH AND AGGRESSIVENESS

T Katz[1,*], A Abd El Wahed[2], N Bettman[1], M Hayun[1], I Avivi[3], NA Horowitz[1]
[1]Rambam Health Care Campus, [2]Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, [3]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background: Lymphoma is the most common hematological cancer reported during pregnancy. Recent data suggest that unlike lymphoma occurring outside of pregnancy, pregnancy-associated non-Hodgkin lymphoma is characterized by an excessive involvement of reproductive organs, advanced disease stage at diagnosis and an aggressive course, potentially leading to a high death rate of mothers. However, the mechanisms facilitating this clinical phenomenon are not fully defined.
Aims: The current study aimed to explore the hypothesis that pregnancy-induced hormonal milieu could be an important mediator in the interaction between lymphoma cells and their associated microenvironment, which may potentially contribute to the growth and progress of lymphoma developing during pregnancy.
Methods: BALB/c pregnant and non-pregnant mice were subcutaneously (s.c.) inoculated with murine B cell lymphoma cells (A20). Primary tumor growth was measured biweekly in both groups. Several human lymphoma cell lines (Ramos, Raji and Bl2) and the human lymph node (LN) stromal cell line (HK) were assessed using flow cytometry, Western blot and qPCR analysis, for the expression of estrogen and progesterone receptors (ER α&β and PR, respectively). The direct effect of estradiol (E2) or progesterone on lymphoma cell proliferation was analyzed by trypan blue exclusion. The effect of E2 on the expression of growth factors VEGF-C and VEGF-D and their receptor VEGFR3 in lymphoma and stromal cells was analyzed by qPCR. Similarly, the expression of metalloproteinases MMP-2 and MMP-9 was evaluated.
Results: Pregnant mice showed a significantly accelerated tumor growth, as demonstrated by its increased volume and weight, following lymphoma cell inoculation compared to non-pregnant mice (Fig. 1). All the three lymphoma cell lines, as well as LN stromal cells were found to express ER α&β, but not PR. The Ramos lymphoma cell line treated with E2 demonstrated an increased proliferation rate. This effect was found to be mediated by ERα. In contrast, progesterone appeared to have no effect on lymphoma cell proliferation or viability. Furthermore, E2 induced the expression of VEGF-C and VEGF-D mRNA in lymphoma and LN stromal cells. Notably, the expression of their receptor VEGFR-3 was elevated in lymphoma cells. Likewise, E2 treatment resulted in

increased expression of MMP-2 and MMP-9 mRNA in lymphoma and LN stromal cells, respectively.

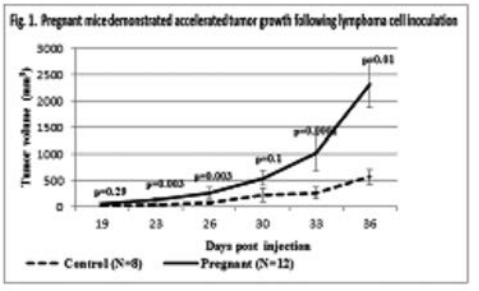

Figure 1.

Summary/Conclusions: The results of the current study have demonstrated for the first time that pregnancy significantly enhances lymphoma growth *in vivo*. This finding could be partially explained by a direct impact of pregnancy-induced estrogen on lymphoma cell proliferation through its effect on the expression of growth factors and metalloproteinases on lymphoma and LN stromal cells. These potential mechanisms need to be be further explored and validated.

ALK-POSITIVE ANAPLASTIC LARGE CELL LYMPHOMA WITH THE VARIANT EEF1G-, RNF213- AND ATIC-ALK FUSIONS IS FEATURED BY COPY NUMBER GAIN OF THE REARRANGED ALK GENE

I Wlodarska[1,*], JA van der Krogt[1], J Finalet Ferreiro[1], K Jacobs[2], E Geerdens[2], A Uyttebroeck[3], P Vandenberghe[1], T Tousseyn[4], J Cools[2]
[1]Center for Human Genetics, KU Leuven, [2]Center for the Biology of Disease, VIB, [3]Department of Pediatrics, UZ, Leuven, [4]Department of Pathology, UZ Leuven, Leuven, Belgium

Background: Molecular pathogenesis of ALK-positive Anaplastic Large Cell Lymphoma (ALK+ ALCL) is not completely understood. Approximately 80% of ALK+ ALCL cases harbor the t(2;5)(p23;q35)-associated *NPM1-ALK* rearrangement, while variant 2p23/*ALK* translocations involving at least nine partner genes have been identified in the remaining cases. The 5'*ALK* partners play a key role in the constitutive activation of the chimeric protein by mediating its oligomerization and its subcellular localization. In addition, they impact a range of biological activities of ALK chimeras, including proliferation, transformation and metastatic capacities. Comparative analysis of biological properties of ALK oncoproteins, however, is hampered by the relative low frequency of different variant ALK fusions.
Aims: The aim of the present study was to identify novel ALK-related fusions in ALK+ ALCL and to gain more insight into the molecular pathogenesis of this tumor.
Methods: Six cases of ALK+ ALCL with a cytoplasmic expression of ALK recently diagnosed in our institution were selected. The ALK fusions were characterized using 5'RACE PCR, low coverage full genome sequencing (LCFGS), FISH, array CGH and QRT-PCR. Functional studies were performed on the IL3-dependent Ba/F3 cell line transformation model.
Results: The ALK partner genes identified in the present cases included *EEF1G* (Eukaryotic translation elongation factor 1 gamma), a novel *ALK* partner located at 11q12.3 (one case), and the already known genes, *RNF213/ALO17* (17q25) (one case) and *ATIC* (2q35) (four cases). Notably, all six cases displayed a similar LSI ALK break-apart FISH pattern showing copy number gain of the rearranged *ALK* gene. The LSI 3'ALK/red signal was duplicated on der(11)t(2;11)(p23;q12.3) in the case with *EEF1G-ALK* and amplified in cases with the *RNF213-ALK* (5-7 extra red signals) and *ATIC-ALK* (2-4 extra red signals) rearrangements. FISH pattern in the ATIC-ALK cases suggests the presence of underlying inv(2)(p23q35) associated with one or two copies of the derivative i(2)(q10) carrying two additional *ATIC-ALK* loci each, as previously reported (PMID: 10706887). FISH findings were confirmed by array CGH in two available cases. These data provide a strong evidence that ALCL driven by at least three variant ALK fusions (EEF1G-, RFN213- and ATIC-ALK), but not by the classic NPM1-ALK, requires an increased gene dosage of the rearranged *ALK*. To assess whether this need is caused by the weaker promoter of *EEF1G, RFN213* and *ATIC*, compared to the *NPM1* promoter, we determined at first the relative mRNA expression level of the four *ALK* partner genes. The study revealed a significantly lower expression of *EEF1G, RNF213* and *ATIC* in nonmalignant lymph nodes when compared to *NPM1*. In the next step, we compared oncogenic potential of all four fusions in the murine hematopoietic IL-3 dependent Ba/F3 cell line. We found that *EEF1G-ALK, RNF213-ALK* and *ATIC-ALK* are less potent to transform BaF3 cells than *NPM1-ALK,* which showed the highest oncogenic potential.
Summary/Conclusions: ALK+ ALCL driven by three variant ALK fusions, EEF1G-ALK (novel), RNF213-ALK and ATIC-ALK, are characterized by copy number gain of the rearranged ALK. These lymphomas, but not the NPM1-ALK-positive ALCL, likely require an increased gene dosage of the rearranged *ALK* to compensate the relatively low and insufficient expression of the chimeric gene driven by the partner genes. Occurrence of the *ATIC-ALK* rearrangement in four out of six cases analyzed confirms that *ATIC-ALK* is the most prevalent variant fusion in ALK+ ALCL.

E1388

THE IMMUNE SURVEILLANCE CONSTRAINTS B CELL LYMPHOMAS WITH CONTINUOUS CD40 SIGNALING TO AN INDOLENT PHENOTYPE

C Vincent-Fabert[1,*], N Arnaud[1], U Zimber-Strobl[2], J Feuillard[1], N Faumont[1]
[1]Contrôle de la Réponse Immune B et des Lymphoprolifératıons (CRIBL) UMR CNRS 7276, Centre de Biologie et de Recherche en Santé, Limoges, France, [2]Research Unit Gene Vectors, Helmholtz Center Munich, German Research Center for Environment and Health, Munich, Germany

Background: LMP1/CD40 transgenic mice, with specific expression of the chimeric protein composed of the transmembrane domain of LMP1, the main Epstein Barr Virus oncoprotein, and intracellular signaling domain of CD40 in B cells, develop indolent lymphomas after one year in 60% cases. LMP1/CD40 expressing B cells are characterized by constitutive activation of the MAPK JNK and ERK as well as the non-canonical NF-kappa B signaling pathway (Hömig-Hölzel et al., 2008). Since (i) NF-kappa B can induce a strong immune surveillance of the tumor when activated by LMP1, such as in transgenic LMP1 mice (Zhang et al., 2012) or in EBV immortalized human B cells (Le Clorennec et al., 2006, 2008) and (ii) not all LMP1/CD40 transgenic mice will develop a tumor, we supposed that the LMP1/CD40 activation signal could also favor some immuno-surveillance of B cells.
Aims: We asked the question of the control by the immune system on B-cell lymphoproliferation related to the constitutive activation of CD40 since the activation signal is very similar to that of the EBV protein LMP1.
Methods: In order to test the effect of immunosuppression on the kinetics of tumor emergence, we injected every day for 3 months the immunosuppressive Cyclosporin A molecule (CsA) at a dose of 10 mg/kg to 8 months-old wild type (WT) or LMP1/CD40 mice.
Results: While cyclosporin A was toxic *in vitro* on B cells, *in vivo* lymphomagenesis B was accelerated with a greater splenomegaly and increased number of tumor cells in the blood in LMP1/CD40 mice treated with CsA in comparison to untreated mice. Morphologically, tumor B cells of mice treated with CsA were larger with a more immunoblastic phenotype, both on blood smears and spleen tissue sections. Proliferation was increased both ex vivo and *in vivo* (Ki67 and BrdU labeling). Similarly, the number of cells with an activated phenotype was increased in CsA treated LMP1/CD40 mice. Finally, we noted that the injection of CsA increases the expression of PDL -1/B7 -H1 and decreases the expression of CD95.
Summary/Conclusions: Despite direct toxic effect on B-cells in vitro, immunosuppressive treatment with CsA accelerates CD40 signal dependent B-cell lymphomagenesis *in vivo* by inducing the transformation of an indolent tumor into a tumor morphologically and phenotypically resembling to a Richter syndrome. This suggests that B-cell lymphomagenesis related to constitutive CD40 signaling is under partial control of the immune microenvironment, which may influence tumor morphology. This may give some clues explaining why indolent B-cells lymphomas may transform in aggressive form.

E1389

EXPLOITING OXIDATIVE PHOSPHORYLATION TO IMPROVE ANTIBODY THERAPY OF LYMPHOMA

E Vilventhraraja[*], J Gribben, A Ivanov
Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Background: Diffuse Large B Cell Lymphoma (DLBCL) is the most prevalent non-Hodgkin's lymphoma (NHL) in adults. Since the addition of the Type I anti-CD20 antibody Rituximab to chemotherapy, overall survival of patients has improved dramatically compared to the pre-Rituximab era. However DLBCL has the worst survival rates out of all NHLs with an average 5-year survival of 55%. Unfortunately 40% of all DLBCL patients relapse within 2 years, and those that relapse or have refractory disease tend not to respond well to antibody-based salvage therapies. This has prompted many to try and enhance the efficacy of anti-CD20 antibodies in order to improve first-line treatment of DLBCL, resulting in the evolution of Type II humanised anti-CD20 antibodies. Metabolism has been reported to be involved in Type II anti-CD20 antibody-mediated cell death, however the mechanism and extent of metabolic involvement remains unknown.
Aims: The aim of this investigation is to see whether oxidative phosphorylation can be exploited to improve the efficacy of Type II anti-CD20 therapy of DLBCL.
Methods: Here, we established a panel of DLBCL cells that consisted of two groups of cell lines; one group harbouring a gene expression profile (GEP) with an enrichment of genes associated with an oxidative phosphorylation (OxPhos) phenotype, and the other group without this gene signature. We used the XF Seahorse Mito Stress Test to reveal bioenergetic profiles of the

cell lines before and after treatment with a panel of anti-CD20 antibodies that included Type I and Type II anti-CD20 antibodies. This assay utilises the differential activity of four mitochondrial inhibitors to calculate basal respiration, ATP production, and maximal and spare respiratory capacity of the cell. Using the same method we then assessed whether chemically manipulating oxidative phosphorylation added to the effect on the bioenergetic profile observed following treatment with anti-CD20 antibodies. Finally, we performed clonogenic survival assays to assess whether cytotoxicity of anti-CD20 antibodies was enhanced by simultaneous treatment with Metformin, a well-established inhibitor of oxidative phosphorylation.
Results: We have observed that treatment with anti-CD20 antibodies has a significant effect on the bioenergetic profile of all DLBCL cells in our panel. Each of the antibodies in our panel had a differential ability to increase or decrease bioenergetic activity, in a cell-line specific manner. Further, we have shown that treatment with Metformin causes a significant reduction in the amount of energy produced by oxidative phosphorylation in both groups of cells in our panel. Finally, when analysing the clonogenic survival of cell lines we have found that the cytotoxicity of Type II anti-CD20 antibodies, was enhanced by simultaneously treating cell lines with an oxidative phosphorylation inhibitors.
Summary/Conclusions: With regard to clonogenicity of DLBCL cells, our data suggests that compounds that inhibit oxidative phosphorylation enhance the cytotoxicity of Type II CD20 antibodies. We believe that understanding the mechanism of loss of clonogenic survival will allow us to establish effective treatment combinations to significantly improve the efficacy of anti-CD20 antibody therapy in DLBCL.

CORRELATION OF PRE-TREATMENT SERUM CYTOKINE ABNORMALITIES AND BLOOD MARKERS OF IMMUNOSUPPRESSION IN PATIENTS WITH LYMPHOMA

M Binder[1,*], MM O'Byrne[2], MJ Maurer[2], SM Ansell[3], AL Feldman[4], JR Cerhan[2], AJ Novak[3], LF Porrata[3], BK Link[5], TE Witzig[3]
[1]Department of Internal Medicine, [2]Department of Health Sciences Research, [3]Division of Hematology, [4]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, [5]Department of Internal Medicine, University of Iowa Hospitals and Clinics, Iowa City, United States

Background: Multiple studies have demonstrated that higher ratios of pre-treatment absolute lymphocyte counts (ALC) and absolute monocyte counts (AMC) are associated with improved outcomes in non-Hodgkin (NHL) and Hodgkin lymphoma (HL). Conversely, elevated serum cytokines at diagnosis are associated with inferior outcomes. Lymphocytes and monocytes have been implicated in immune surveillance, suppression of host anti-tumor immunity, and alterations of the tumor microenvironment supporting growth and survival of lymphoma cells. The relationship between pre-treatment serum cytokines and ALC and AMC remains unknown. We hypothesized that patients with elevated serum cytokines would be more likely to have suppressed ALC/AMC ratios.
Aims: To evaluate the relationship between pre-treatment serum cytokines and ALC/AMC ratios in patients with newly diagnosed diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), mantle cell lymphoma (MCL), T-cell lymphoma (TCL), and HL.
Methods: We studied pre-treatment samples from 725 patients with lymphoma (DLBCL=202, FL=216, MCL=88, TCL=69, HL=150) who enrolled in the University of Iowa / Mayo Clinic Lymphoma SPORE between 2002 and 2011 and were part of previous studies on cytokine secretion in lymphoma. Three-hundred seventy-six of these patients also had ALC/AMC ratios available, obtained from pre-treatment complete blood counts. Serum cytokine concentrations in patients and controls were measured using a standard ELISA (Invitrogen, Camarillo, CA) and analyzed using the Luminex-200 system. Data were acquired using STarStation software (Applied Cytometry, Dinnington, UK). Twelve cytokines passed quality control and were determined to have adequate measurements within the dynamic ranges of the assays: IL-1Ra, IL-2R, IL-8, IL-12p40p70 (IL-12), EGF, HGF, FGF-β, EOTAXIN, MIP-1β, MCP-1, IP-10, and MIG. The cytokines used for analysis were median-normalized to correct for plate effects. To assess the relationship between pre-treatment serum cytokines and ALC/AMC ratios, Spearman's rank correlation coefficients were calculated. P-values below 0.001 were considered statistically significant.

Table 1. Correlations between blood cytokines and ALC/AMC ratios by disease.

	All	DLBCL	FL	MCL	TCL	HL
	(n=376)	(n = 128)	(n = 101)	(n = 37)	(n = 37)	(n = 73)
IL-2R	**-0.37 ***	**-0.43 ***	**-0.33 ***	-0.24	-0.24	**-0.38 ***
IP-10	**-0.21 ***	**-0.43 ***	-0.17	0.10	0.01	-0.18
MIG	**-0.30 ***	**-0.38 ***	-0.22	0.03	-0.41	-0.38
IL-12	-0.16	-0.17	-0.23	0.06	**-0.53 ***	-0.03

Values denote Spearman's rank correlation coefficients (for p<0.001)*

Results: The median age at enrollment was 60 years (18 - 93), 407 patients (56%) were male. Ann Arbor stages were I-II (35%), III-IV (64%), or unknown (1%). Nineteen percent were experiencing B symptoms and 30% had bone marrow involvement. International prognostic index scores were 0-1 (49%), 2 (28%), 3 (16%), or 4-5 (6%). Table 1 shows the statistically significant correlations by lymphoma type.
Summary/Conclusions: Patients with NHL or HL with high pre-treatment serum cytokines tended to have lower ALC and higher AMC. Similar results were observed in all subsets except MCL. These data support the notion that high levels of serum cytokines are immunosuppressive and add to our understanding why the ALC/AMC ratio is of prognostic significance in lymphoma. It also provides further rationale to target immunosuppressive monocytes and the tumor microenvironment for therapeutic benefit.

E1391

KPT-8602, A SECOND GENERATION CLINICAL STAGE SELECTIVE INHIBITOR OF NUCLEAR EXPORT (SINE) COMPOUND SHOWS ENHANCED ANTI-TUMOR ACTIVITY WHEN COMBINED WITH VENETOCLAX OR BENDAMUSTINE IN DLBCL

E Baloglu[*], H Chang, W Senapedis, T Kashyap, S Elloul, S Shacham, S Friedlander
Karyopharm Therapeutics, Newton, MA, United States

Background: Selinexor, the first-in-class oral selective inhibitor of nuclear export (SINE) compound, is currently in Phase 1/2 clinical trials for the treatment of solid and hematological malignancies, including relapsed/refractory diffuse large B-cell lymphoma (DLBCL; NCT02227251). XPO1, the target of selinexor, has been shown to export >200 cargo proteins from the nucleus including major tumor suppressors (TSPs). SINE compounds prevent the nuclear export of many of TSPs facilitating suppressor reactivation. KPT-8602 is a second generation clinical stage oral SINE compound currently undergoing a Phase 1/2 open label study in patients with relapsed/refractory multiple myeloma (NCT02649790).
Aims: In preclinical studies KPT-8602 demonstrated improved tolerability over selinexor, possibly due to its reduced brain penetration. The goal of this study was to test whether single agent or combination of KPT-8602, with either venetoclax (selective BCL2 inhibitor) or bendamustine (DNA damaging agent) can further enhance the anti-tumor effect of KPT-8602 in DLBCL.
Methods: The effects of KPT-8602, bendamustine and venetoclax as single agents and KPT-8602 in combination with either bendamustine or venetoclax on cell viability were tested on a panel of DLBCL cell lines (i.e. RL, DB, SUDHL4, SUDHL10, Pfeiffer, U937, and Farage including the double hit lymphomas Toledo, DoHH2, and SUDHL6) using MTT assays. Total RNA and whole protein cell lysates from DLBCL cells were extracted and analyzed by qPCR and immunoblots. DoHH2 sub-cutaneous xenograft in mice were treated with KPT-8602, venetoclax or bendamustine alone or in combinations of KPT-8602-bendamustine or -venetoclax. Percent tumor growth inhibition (%TGI) and overall survival were determined for each treatment condition. Tumors were collected and analyzed using standard immunohistochemistry (IHC) methods.
Results: Combinations of KPT-8602 with bendamustine or venetoclax were highly effective both *in vitro* and *in vivo*. Using an MTT assay, we showed KPT-8602 was potent against a panel of DLBCL cells (median IC_{50}: ~100 nM) and was synergistic/additive when combined with bendamustine or venetoclax. In the KPT-8602-bendamustine combination DoHH2 xenograft, treatment with each drug showed a%TGI of 52% (KPT-8602) and 76% (bendamustine) while the combination%TGI was 107%. Western and IHC analyses showed that KPT-8602 reduced the expression of key DNA Damage Response (DDR) proteins preventing treated cells from repairing the damage induced by bendamustine. In the KPT-8602-venetoclax *in vivo* study, the individual drugs had similar%TGI (52%; KPT-8602 and 56%; venetoclax). However, when the two drugs were combined, the treatment showed an additive effect (98%). Although, the anti-BCL2 proteins, Bax and Bim, were upregulated in KPT-8602 treated xenograft tumors, these pro-apoptotic pathway proteins were elevated to a greater extent in the combination-treated tumors suggesting the two drugs induced non-redundant mechanism of apoptosis activation.
Summary/Conclusions: KPT-8602 shows single agent activity as well as enhanced antitumor activity in combination with bendamustine or venetoclax through modulation of the DDR and BCL2 pathways in models of DLBCL (including double hits). These data provide rational support for the study of single agent KPT-8602 and in combinations with bendamustine or venetoclax in future DLBCL clinical trials.

E1392

ANALYSIS OF DIFFERENT BIOLOGICAL FACTORS IN PATIENTS AFFECTED BY PERIPHERAL T-CELL LYMPHOMAS NOT OTHERWISE SPECIFIED: GATA-3 EXPRESSION IS ASSOCIATED TO REFRACTORY DISEASE AND POOR OUTCOME

A Dodero[1,*], F Maura[1], A Pellegrinelli[2], A Chiappella[3], A Cabras[4], P Zinzani[5], D Novero[6], F Zaja[7], E Sabbatini[8], S Pizzolitto[9], C Carniti[10], U Vitolo[3], N Bolli[10], P Corradini[10]
[1]Hematology, [2]Pathology, Fondazione IRCCS Istituto Nazionale dei Tumori Milano, Milano, [3]Hematology, AOU Citta' della Salute e della Scienza, Torino, [4] Pathology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, [5]Hema-

tology, Policlinico Sant'Orsola, Bologna, [6]Pathology, AOU Citta' della Salute e della Scienza, Torino, [7]Hematology, AOU Santa Maria della Misericordia, Udine, [8]Emalinfopatologia, Policlinico Sant'Orsola, Bologna, [9]Pathology, AOU Santa Maria della Misericordia, Udine, [10]Hematology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy

Background: Peripheral T-cell lymphomas (PTCL) have an aggressive clinical course with a poor 5-year overall survival with conventional therapy. Autologous stem cell transplantation (autoSCT) and allogeneic stem cell transplantation (alloSCT) can improve long-term disease control in first and second remission, respectively. Prognostic factors are not able to discriminate patients with chemorefractory disease. Preliminary evidence from gene expression profiling (GEP) and immunoistochemical studies have suggested that the majority of PTCL-not otherwise specified (PTCL-NOS) can be subdivided in two different groups based on GATA3 and Tbet (transcription regulators of T-helper 2 and T-helper 1 lymphocytes) expression with a poorer prognosis in the former group.
Aims: Because GEP studies are not feasible in routine clinical practice, we investigated whether expression changes of those proteins could be evaluated by immunohistochemistry (ICH) and used to predict prognosis
Methods: We collected paraffin tissues from 47 consecutive patients (pts) with a diagnosis of PTCL-NOS treated at different Italian Institutions, and 38 were available for analysis. Histology was centrally reviewed. Sections were analyzed for Ki-67, GATA3, T-bet expression by IHC. Results were expressed as mean percentages of positive tumor cells. Cases were regarded as immunoreactive for GATA-3 and T-bet if at least 27% and 25% of neoplastic cells exhibited positive staining, respectively. In case of GATA-3, we performed a quantitative analysis [from score 0 (<1%) to score 4 (>80%)] combined with staining intensity [score 1 (weak) to score 3 (strong)] and we defined high score for a summary value of 6-7. Median age was 57 years (range,18-79 years); 13 (38%) pts were characterized by IPI>2; 29 pts (76%) were candidated to transplantation whereas 9 (24%) were not due to age >65 years (n=8) or limited stage/IPI (n=1). All the pts received an anthracycline-based induction chemotherapy followed by autoSCT in 9 patients (7 in first remission); 16 pts (42%) underwent alloSCT in first remission (n=3) or at relapse (n=13). The median follow-up of alive pts was 33 months.
Results: The mean value of Ki67 expression was 60% (range, 10%>95%). Only 5 of 38 (13%) pts were immuno-reactive for T-bet whereas 17 of 38 (45%) were positive for GATA-3. Only two (5%) pts were characterized by double expression of GATA-3 and T-bet. 5 pts (31%) had a high GATA3 score that was associated with a median PFS of only 6 months. We did not observe differences baseline clinical characteristics between pts with positive (n=17) and negative (n=21) immunostaining for GATA-3. Pts immunoreactive for GATA3 were characterized by poor response to anthracycline therapy: 10 of 17 PD (58%) as compared to 4 of 21 (19%) in the negative cohort (p=0.01). Cases with positive GATA3 expression were significantly associated with a reduced 5-year PFS as compared to those with no expression [PFS: 6% (95%CI:0%>22%) *versus* 39% (95%CI:18%>59%), (p=0,03); OS: 38% (95%CI:13%>63%) *versus* 58% (95%CI:30%>78%),(p=ns), respectively]. By multivariable analysis, GATA-3 and Ki67 retained prognostic value on PFS whereas both GATA-3 and IPI influenced significantly the OS.
Summary/Conclusions: Our analysis identifies GATA3 ICH expression as a strong prognostic and predictive biomarker among PTCL-NOS. Pts with positive GATA3 expression values were characterized by chemorefractory disease and poorer outcome even with transplantation strategies. Validation of this biomarker in a larger series of patients is ongoing.

E1393

IN MANTLE CELL LYMPHOMA, BCR SIGNALING AND WNT PATHWAY INDUCE B-CATENIN STABILIZATION AND CELLULAR RE-LOCALIZATION BY DIFFERENT MECHANISMS

G Lazarian[1,*], E Dondi[2], N Varin-Blank[2], F Cymbalista[1], L Gardano[2], F Baran-Marszak[1]
[1]Laboratoire d'hématologie, Hopital Avicenne, APHP, [2]U978, INSERM, Université Paris 13, Bobigny, France

Background: Mantle cell lymphoma (MCL) cells survival relies on the B-cell receptor (BCR) signaling pathway that also facilitates the interactions with the microenvironment. In more than 50% of MCL cases, the Wnt/β-catenin pathway is activated and contributes to cyclin D1 and c-myc expression. As both pathways are important for cell survival as well as tumor cell adhesion, we hypothesized that a cross talk between BCR signaling and β-catenin could affect the cell homeostasis and could be targeted by specific inhibitors.
Aims: The aim of the project is to identify the role of β-catenin in MCL and how it is activated. In parallel, the inhibition of a cross talk between the BCR signaling and the Wnt pathway by ibrutinib is analysed.
Methods: Peripheral blood B cells from MCL patients (n=8) were pretreated with Wnt/ β-catenin inhibitors: XAV-939 (25 μM), promoting degradation of β-catenin through the Axin dependent destruction complex or PKF118-310 (500 nM) blocking the interaction of β-catenin with the transcription factor TCF4. Cells were pre-treated with quercetine (20μM) a PI3K inhibitor, or Ibrutinib (5μM) a BTK inhibitor. BCR signaling pathway was then stimulated with soluble anti-IgM (10 mg/ml). As a control, Wnt/β-catenin pathway was activated by the conditioned media from human bone marrow stromal cells secreting large amount of Wnts. Apoptosis, β-catenin -dependent genes expression and β-catenin subcellular localization were analyzed by flow cytometry, RT-qPCR and cell fractionation respectively.
Results: β-catenin expression is detected in all leukemic MCL samples in variable amount. The inhibition of β-catenin/TCF transcriptional complex by PKF118-330 induces tumor cells apoptosis, suggesting an important contribution of β-catenin to MCL cell survival. In parallel, β-catenin level increases rapidly in response to BCR stimulation and this stabilization is inhibited by a pretreatment with Ibrutinib showing the existence of a cross talk between these two survival pathways. Wnt stimulation stabilizes β-catenin and its translocation into the nucleus leads to an increase of the target genes *i.e.* axin2, cyclin D1 and LEF1. After BCR stimulation, even though β-catenin rapidly translocates into the nucleus it does not induce the same transcriptional response, suggesting a different role of β-catenin when activated by BCR or Wnt. Moreover, stabilization of β-catenin degradation complex by a pretreatment with XAV939 does not induce its degradation after BCR stimulation suggesting that BCR signaling interferes with the β-catenin degradation process. Thus, the impact on β-catenin by BCR signaling is likely independent from Wnt.
Summary/Conclusions: The BCR signaling pathway leads to β-catenin stabilization and nuclear translocation. However, this nuclear translocation translates into a different transcriptional response than the one induced by Wnt. Most likely, β-catenin associates with different nuclear partners driving the expression or repression of BCR specific genes. Since β-catenin can stabilize cell adhesion structures, β-catenin likely represents another player through which the BCR signaling impacts on the interaction of MCL cells with the microenvironment. Importantly, this cross talk can be efficiently interrupted by Ibrutinib, currently used in mantle cell lymphoma treatment.

METHOTREXATE ELIMINATION AND TOXICITY: THE ROLE OF MTHFR 677C>T POLYMORPHISM IN PRIMARY CNS LYMPHOMA PATIENTS TREATED WITH HIGH DOSE METHOTREXATE MONOTHERAPY

YJ Choi[1], JS Lee[2], JY Lee[3], TW Kim[4], JS Park[4], JE Kim[4], DH Yoon[4,*], C Suh[4]
[1]Clinical Trial Center, [2]Clinical Research Center, Asan Medical Center, Seoul, [3]College of Pharmacy and Institute of Pharmaceutical Science and Technology, Hanyang University, Gyeonggi, [4]Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Methylenetetrahydrofolate reductase (MTHFR) plays a key role in metabolism and homeostasis of intracellular folate, and substitution of C >T is reported to be associated with decreased MTHFR enzyme activity, contributing to low folate level. The genetic association of MTHFR 677C>T in methotrexate (MTX) toxicity was evaluated in a number of studies, however the results were conflicting. The substantial heterogeneity within the study population could compromise the effect of MTHFR 677C>T polymorphism on MTX toxicity, and conflicting published results may have attributed to this.
Aims: The aim of this study was to evaluate the role of MTHFR 677C>T polymorphism in MTX toxicity within a homogenous study population by limiting cancer type to primary central nervous system lymphoma (PCNSL) and chemotherapy protocol to the first four cycles of high dose methotrexate monotherapy and fixed leucovorin rescue regimen (HD-MTX & HD-ARA regimen).
Methods: Data of patients diagnosed with PCNSL treated with HD-MTX & HD-ARA regimen were retrieved. The effect of MTHFR 677C>T polymorphism on the incidence of MTX toxicity was evaluated using a generalized estimating equation analysis.
Results: A total of 111 patients (402 cycles) was included in the analysis. The hematologic toxicity and nephrotoxicity were most frequently presented in patient with heterozygous variant genotype, with an incidence of 57 (29.1%) and 7 (3.6%). The incidence rate of hepatotoxicity and oral mucositis requiring treatment was highest in patient with wild genotype (hepatotoxicity: 7.3%, oral mucositis: 4.1%). None of the patients with homozygous variant genotype experienced the oral mucositis. Twenty eight point six percent of nephrotoxicity occurred in cycles with delayed elimination, and delayed elimination was most frequently seen in patients with homozygous variant genotype (3.6%). The risk for developing clinically meaningful hematologic toxicity was higher in patients with heterozygous variant genotype than wild genotype (odds ratio; OR: 2.60, 95% confidence interval; CI: 1.32-5.09, *P*-value=0.0055). No valid difference was observed between patients with homozygous variant and wild genotype in terms of hematologic toxicity. Other explanatory variables shown to increase the risk of hematologic toxicity were the presence of delayed elimination (OR: 10.06, 95% CI:2.87-35.31, *P*-value=0.0003), high serum lactate dehydrogenase level exceeding the upper range of normal at the time of diagnosis (OR: 2.04, 95% CI:1.09-3.81, *P*-value=0.0257) and concomitant administration of penicillin antibiotics with MTX (OR: 2.88, 95% CI:1.17-7.07, *P*-value=0.0213). No correlation between age, sex, Eastern Cooperative Oncology Group performance status, concomitant administration of proton pump inhibitor and hematologic toxicity was demonstrated. For hepatotoxicity, MTHFR 677C>T polymorphism was the only explanatory variable included in the model. The MTHFR 677C>T polymorphism was not shown to be correlated with risk of

hepatotoxicity (heterozygous variant genotype; OR: 0.75, 95% CI: 0.29-1.96, *P*-value=0.5575, homozygous variant genotype; OR: 0.80, 95% CI: 0.24-2.69, *P*-value=0.7176).
Summary/Conclusions: The MTHFR 677C>T polymorphism is shown to be a valid marker in predicting MTX associated hematologic toxicity. Clinically significant nephrotoxicity might occur in patients without delayed elimination, suggesting that factors other than serum MTX level could play a role. MTX induced hepatotoxicity and oral mucositis occur independently of the serum MTX level.

E1395

IMPACT OF TREATMENT ON RNA EXPRESSION OF IMMUNE PROFILE IN PATIENTS WITH CLASSICAL HODGKIN LYMPHOMA

P Silva[1,*], J Monte Real[1], L Ferreira[2], G Esteves[3], J Garibaldi Jr[1], F Brito[1], A Penna[1], E Cavalcante[1], O Baiocchi[1]
[1]Clinical Oncology and Experimental, Federal University of São Paulo, [2]Lab. Immunology, Heart Institute, University of São Paulo School of Medicine, Sao Paulo, [3]Estatistic, University of Paraiba State, Campina Grande, Brazil

Background: Although immunosuppression has long been recognized in classical Hodgkin lymphoma (cHL), the underlying basis for the lack of an effective immune response against tumor remains unclear. Recently, our group showed increased frequencies of pro and anti-inflammatory cytokines, such as interleukins (IL)-6, IL-10, TNF-alpha and sCD25, in cHL patients and the impact of treatment on these cytokines. These cytokines participate in the Hodgkin and Reed-Sternberg (HRS) cells survival and immunological escape.
Aims: In this study we aimed to evaluate the immune gene expression profile in cHL patients at diagnosis and the impact of treatment on this profile.
Methods: Twenty consecutively diagnosed cHL patients, with whole blood RNA extracted at diagnosis and after treatment, were recruited for this study and prospectively evaluated. The general expression of 96 messengers RNAs present in the peripheral blood and involved in immune response was performed by a customized quantitative real-time PCR array (TaqMan® Low Density Array). We also included 7 healthy controls. The data was normalized with B2M mRNAs levels and relative gene expression was calculated by the 2^DDCt method, considering Wilcoxon test and Benjamini-Hochberg adjustment to correct p-values.
Results: At diagnosis we observed that blood of cHL patients presents higher expression of IL-10 (2.4 fold, p=0.013) and decreased expression of CCL2 (-5 fold, p=0.028), CD40 (-2 fold, p=0.013) and HLA-DRA (-2 fold, p=0.028) compared with healthy controls. On the other hand, after treatment, the mRNAs levels returned to normal and no immune-related gene studied was found in different amounts when compared to control subjects. Considering patients after treatment, an important reduced expression of BCL2 (1.5 fold, p= 0.043), CCL2 (3,7 fold, p= 0.003); CCL22 (1.9 fold, p=0.025); CCL5 (1.7 fold, p=0.025), CD40 (2.2 fold, p=0.007), CD80 (2 fold, p=0.015), CSF2(2,5 fold, p=0.007), HLA-DRA (1.7 fold, p=0.025), IL-2RA (1.7 fold, p=0.025), IL-4 (2.5 fold, p=0.007), IL-6 (3.7 fold, p=0.007), LTA(1.7 fold, p=0.038), RORC (1.6 fold, p=0.025) in comparison with cHL patients before treatment. Epidemiologic and clinical correlation are currently being done.

Table 1.

Pre X Control

Gene	Pre	Control	^^Ct mean	Fold Change	p adjusted
IL-10	↑	↓	-1,241	2,4	p=0.013
CCL2	↓	↑	2,445	-5	p=0.028
CD40	↓	↑	1,418	-2	p=0.013
HLA-DRA	↓	↑	1,050	-2	p=0.028

Pre X Post

Gene	Pre	Post	^^Ct mean	Fold Change	p adjusted
BCL2	↑	↓	-0,636	1,5	p=0.043
CCL2	↑	↓	-1,884	3,7	p=0.003
CCL22	↑	↓	-0,924	1,9	p=0.025
CCL5	↑	↓	-0,738	1,7	p=0.025
CD40	↑	↓	-1,144	2,2	p=0.007
CD80	↑	↓	-0,973	2	p=0.015
CSF2	↑	↓	-1,342	2,5	p=0.007
HLA-DRA	↑	↓	-0,744	1,7	p=0.025
IL-2RA	↑	↓	-0,739	1,7	p=0.025
IL-4	↑	↓	-1,342	2,5	p=0.007
IL-6	↑	↓	-1,885	3,7	p=0.007
LTA	↑	↓	-0,761	1,7	p=0.038
RORC	↑	↓	-0,699	1,6	p=0.025

*↑ (High), ↓ (Low)

Summary/Conclusions: In this study, we showed that, at diagnosis, cHL patients presented with more inflammatory gene expression and, after treatment, a more effector immunological profile is found. Interestingly, posttreatment immunological profile is similar to healthy controls. Understanding cHL associated immunosuppression and the immune reconstitution after treatment maybe the key to develop new prognostic factors and treatment strategies.

MIR-181C REGULATES BRK1, PART OF THE WAVE COMPLEX, AND IS INVOLVED IN T CELL FUNCTION

SP Lim*, G Mufti, J Gaken
King's College London, London, United Kingdom

Background: miRNAs are short endogenous non-coding RNAs of 18-25 nucleotides in length which play an important role as negative regulators of gene expression either through mRNA degradation or translational repression. miRNAs have been shown to be involved in many cell functions such as angiogenesis, cell adhesion, cell differentiation, cell proliferation and cell survival. Thus, their aberrant expression implicated in various types of cancer including haematological malignancies. In this project, we studied miR-181 family which has been reported to play a crucial role in haematopoiesis, including megakaryocytic, erythroid and myeloid differentiation as well as B and T cell development and differentiation. Most of the available methodologies for miRNA target identification are based on computational algorithms. Therefore, there is a relatively high incidence of false positive target identification. To enable the identification of biologically relevant miRNA targets, a novel functional assay was developed in our lab, which is based on positive/negative selection (Gaken et al, 2012). By using this assay, we identified two functional targets of miR-181c which are *BRK1* and *DHTKD1*. Due to the well-known role of WAVE protein (BRK1 is a component of the WAVE complex) in actin polymerisation in T cells, and the published studies on the function of *BRK1* in cell migration in neuroblastoma, squamous cell lung carcinoma, renal carcinoma and osteosarcoma, we focused on studying the biological roles of BRK1 in T cells. As a model system, we used Jurkat T cells and investigated the role of *BRK1* in actin polymerisation.
Aims: The aims of this project are to identify the potential targets of miR-181 family by using a dual selection functional assay and to study the roles of *BRK1* (identified target of miR-181c) in actin polymerisation and T cell functions, in association with WAVE2 complex.
Methods: Using a functional assay, we identified *BRK1* and *DHTKD1* as novel targets of miR-181c/d and validated these targets by quantitative RT-PCR and western blot analysis of cells transfected with miR-181c/d as well as miR-181c and d inhibitors. We focused on ascertaining the roles of *BRK1* in T cell functions. We demonstrated a targeted reduction of *BRK1* in Jurkat T cells through shRNA (lentiviral strategy) or siRNA knockdown. The effects of *BRK1* knockdown on actin polymerisation and Jurkat T cells functions including changes in total cellular F-actin content, T cell proliferation, T cell activation, lamellipodia formation and T cell spreading as well as cell migration were assessed.
Results: By using the novel functional assay, two targets of miR-181c/d have been identified which are *BRK1* and *DHTKD1*. Both of the genes were validated as targets for miR-181c at protein level. To study the roles of *BRK1* in Jurkat T cell functions, we first showed that knockdown of *BRK1* in Jurkat T cells reduced the expression of other proteins (WAVE2, Abi1, Sra1 and Hem1) that are part of the WAVE2 complex and this indicated that any effects on T cell functions due to *BRK1* knockdown is indeed a result of dissociation of WAVE2 complex. Stable knockdown of *BRK1* in Jurkat T cells showed changes in total cellular F-actin content prior and after T cell activation by F-actin staining using Rhodamine phalloidin. Next, we showed that stable *BRK1* knockdown decreased cell proliferation by trypan blue staining. Also, *BRK1* knockdown showed reduced CD69 expression, indicating defects in T cell activation. Besides that, we also demonstrated that knockdown of *BRK1* caused defects in lamellipodia formation and cell spreading upon Jurkat T cell activation. Knockdown of *BRK1* also resulted in defects in cell migration in Jurkat T cells.

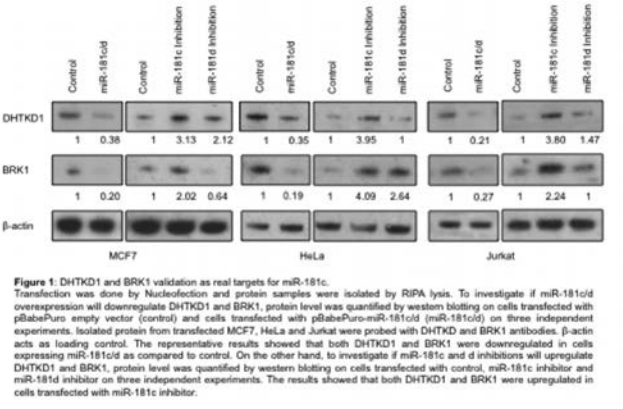

Figure 1: DHTKD1 and BRK1 validation as real targets for miR-181c.
Transfection was done by Nucleofection and protein samples were isolated by RIPA lysis. To investigate if miR-181c/d overexpression will downregulate DHTKD1 and BRK1, protein level was quantified by western blotting on cells transfected with pBabePuro empty vector (control) and cells transfected with pBabePuro-miR-181c/d (miR-181c/d) on three independent experiments. Isolated protein from transfected MCF7, HeLa and Jurkat were probed with DHTKD and BRK1 antibodies. β-actin acts as loading control. The representative results showed that both DHTKD1 and BRK1 were downregulated in cells expressing miR-181c/d as compared to control. On the other hand, to investigate if miR-181c and d inhibitions will upregulate DHTKD1 and BRK1, protein level was quantified by western blotting on cells transfected with control, miR-181c inhibitor and miR-181d inhibitor on three independent experiments. The results showed that both DHTKD1 and BRK1 were upregulated in cells transfected with miR-181c inhibitor.

Figure 1.

Summary/Conclusions: This study showed that miR-181c regulates *BRK1* by translational repression and *BRK1* plays a crucial role in Jurkat T cell functions including cell proliferation, T cell activation, cell spreading and cell migration mediated via actin polymerisation.

E1397

BIOMARKERS IN RELAPSED/REFRACTORY DLBCL AND FL PATIENTS TREATED WITH POLATUZUMAB VEDOTIN: RESULTS FROM THE PHASE II CLINICAL TRIAL (ROMULUS)

E Penuel[1,*], K Mundt[1], R Bourgon[1], T Sumiyoshi[1], I Flinn[2], O Press[3], M Patel[4], R Advani[5], JM Venstrom[1], YW Chu[1], J Hirata[1]
[1]Genentech, Inc., South San Francisco, [2]Sarah Cannon Research Institute Tennessee Oncology, Nashville, [3]Fred Hutchinson Cancer Research Center, Seattle, [4]Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, [5]Stanford Cancer Institute, Palo Alto, United States

Background: Polatuzumab vedotin (PoV) is an antibody drug conjugate (ADC) comprised of a monoclonal antibody targeting the B-cell marker, CD79b, linked to the microtubule-disrupting agent, monomethyl auristatin E (MMAE). PoV has shown clinical activity in patients with relapsed/refractory (R/R) non-Hodgkin lymphoma. Target expression, CD79b, and expression of anti-apoptotic factors, such as BCL-2, have the potential to mediate sensitivity and/or resistance to ADCs. Moreover, diffuse large B-cell lymphoma (DLBCL) is a heterogeneous disease in which distinct subtypes defined by gene expression profiles and, in some cases, prevalence of genetic variants, have been defined.
Aims: Perform a retrospective biomarker analysis on tumor samples at baseline (archival biopsies) from patients in the phase II trial (ROMULUS) who received PoV with rituximab, to correlate the activity of PoV with biomarkers in R/R DLBCL and follicular lymphoma (FL).
Methods: We evaluated target expression (CD79b) and potential for PoV resistance driven by BCL-2 expression by immunohistochemistry (IHC) and quantitative reverse transcription polymerase chain reaction (qRT-PCR) in 34 DLBCL and 19 FL patients with sufficient tissue for analysis. In DLBCL, cell of origin (COO) was evaluated by signature gene expression and a linear predictor score method described previously.[1] Additionally, mutations (i.e., *CD79b*, *CARD11*, *MYD88* and *EZH2*) enriched in COO DLBCL subtypes, and that may confer resistance to anti-lymphoma therapies, were evaluated using a multiplexed gene panel by next-generation sequencing.
Results: CD79b expression was comparable in DLBCL and FL by qRT-PCR and IHC. Consistent with the role of CD79b as a B-cell lineage marker, expression was seen in all samples. There was a range of CD79b expression, but ~90% of patients had expression at higher levels (IHC2/3+). Response to PoV was independent of CD79b expression, as responses were seen in patients with both high and lower levels. For BCL-2, there was no significant difference in expression across indications by qRT-PCR. However, while high BCL-2 expression (IHC 2/3+) was observed in ~90% of FL patients, expression was more distributed across levels in DLBCL. Importantly, there was no relationship between BCL-2 expression and response to PoV by IHC or qRT-PCR. PoV showed activity in both GCB and the more aggressive ABC DLBCL subtypes. Moreover, we observed mutations associated with COO, including *EZH2* (n=2) in GCB patients and dual *CD79b*/*MYD88* (n=2) in ABC patients. Tumor shrinkage and clinical response to PoV were observed in these patients. Similarly, mutations, such as *MYD88* (n=2), associated with resistance to ABC targeting agents were also observed but clinical response was variable.
Summary/Conclusions: These analyses demonstrate broad activity of PoV in R/R DLBCL and FL. CD79b was expressed across B-cell malignancies; while a majority of samples expressed high levels of CD79b, even minimal expression was sufficient for PoV activity. Though anti-apoptotic regulators, like BCL-2, have potential to drive resistance to microtubule-disrupting agents, this was not observed with PoV. While the DLBCL treatment landscape is evolving to account for biologic subtypes, PoV showed activity independent of subtype, in contrast to other targeted therapies. Overall, the robust and expansive activity observed with PoV may position it as an effective component of therapy across DLBCL subtypes and FL. Studies of PoV combined with other anti-lymphoma agents in multiple indications, including in newly diagnosed DLBCL patients, are ongoing.

ROLE OF BORTEZOMIB IN COMBINATION WITH AEROBIC OXIDATION INHIBITOR ON BURKITT LYMPHOMA CELLS

T Wang[*], X Shao, J Cai, B Xu, J Zhong, F Chen
Division of Hematology, Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China

Background: Caner and non-malignant cells vary vitally with respect to their metabolic pathway. Consuming elevated levels of glucose from a frequently nutrient-poor environment in order to satiate anabolic respiratory reactions, is a sufficiently prevalent phenomenon of cancer cell metabolic adaptions, which has been conceptualized as the "Warburg effect". However, the molecular mechanism underlying this metabolic reprogramming is obscure. Recent investigations propose that the oncogene-directed metabolic reprogramming, rather than the permanent malfunction of mitochondrial oxidative phosphorylation (OXPHOS), may have profound effects on aerobic glycolysis. The biochemical aspects of the Warburg effect outline a strong explanation for the cause of cancer cell proliferation. However, the more reliant of malignant cells manifest on glycolysis, the more vulnerable to drugs targeting this pathway they will be. Prognosis of Burkitt lymphoma, the most aggressive B-cell lymphoma, is poor even in the Rituximab era. Therefore, targeting the aberrant metabolic pathway rather than illimitably increase the dose of chemotherapy prompts a highly desirable strategy for treating this aggressive lymphoma. Bortezomib is the first proteasome inhibitor approved for treating multiple myeloma and mantel cell lymphoma. In addition to the well-known mechanism on proteasome inhibition, bortezomib is supposed to have effects on the phosphoinositide 3-kinase/protein kinase B/mammalian target of rapamycin (PI3K/Akt/mTOR) pathway, which is deemed crucial to underpin the glycolysis of malignant cells. Given the central role of glycolysis in cancer metabolism, we sought to explore the effect of bortezomib on tumor cell metabolism in Burkitt lymphoma. Considering the fact that even counteracting glycolysis, cancer cells shows low-glucose resistance, which may associate with an increased compensatory upregulation of mitochondrial OXPHOS, the present study was undertaken to investigate the potential of using Bortezomib in combination with OXPHOS inhibitor as a novel therapy for Burkitt lymphoma.
Aims: To investigate the effect of bortezomib (BTZ) in combination with aerobic oxidation inhibitor oligomycin (OM) on proliferation and apoptosis of Burkitt lymphoma cell line Raji, and to explore its possible molecular mechanism.
Methods: Raji cells were treated with different concentrations of BTZ (0, 5, 10, 15, 20, 25 and 30 nmol/L) alone or in combination with OM (0.05 μg/mL). Cell proliferation was detected by CCK-8 method. The mRNA and protein expression levels of oncogene C-myc, hypoxia inducible factor-1α (HIF-1α) and its target genes vascular endothelial growth factor (VEGF) and glucose transporter 1 (GLUT1), as well as key enzymes and proteins related to glycolysis pathway including hexokinase II (HKII), lactic dehydrogenase (LDHA) and succinate dehydrogenase (SDHA) were detected by real-time fluorescent quantitative PCR and Western blotting, respectively. Glucose consumption and lactic acid generation were examined by Glucose (hexokinase, HK) Assay Kit and Lactate Assay Kit, respectively. Apoptosis and cell cycle distribution were analyzed by FCM.
Results: The result of CCK-8 method showed that treatment with different concentrations of BTZ could inhibit the proliferation of Raji cells in a dose-dependent manner (all $P<0.01$), the inhibition effect was significantly enhanced at lower initial concentrations of BTZ (5, 10, 15 and 20 nmol/L) in combination with OM (all $P<0.01$). The expression levels of C-myc, HIF-1α, VEGF, GLUT1, HKII, LDHA and SDHA mRNAs and proteins were suppressed by BTZ, and the expression levels were further down-regulated due to treatment with BTZ in combination with OM (all $P<0.05$). The inhibition of glucose consumption and lactic acid generation induced by BTZ in combination with OM was significantly enhanced as compared with those induced by BTZ alone (both $P<0.05$). The result of FCM showed that BTZ could induce apoptosis of Raji cells in a dose-dependent manner, and the cell cycle was arrested in G2/M phase under a relatively high concentration of BTZ (25 nmol/L). Furthermore, when BTZ was used in combination with aerobic oxidation inhibitor OM, significant synergistic effect was observed; besides, the cell cycle was arrested at G0/G1phase instead.

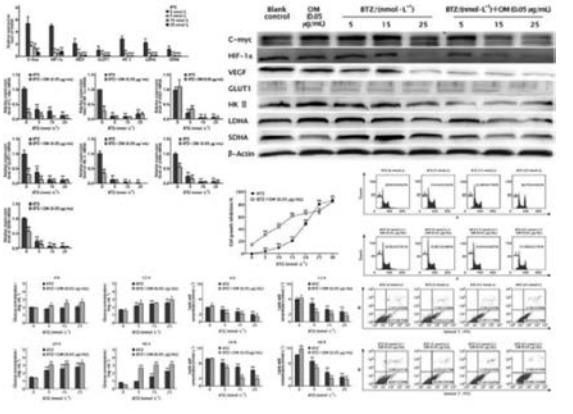

Figure 1.

Summary/Conclusions: BTZ can hinder the glycolysis pathway in Burkitt lymphoma cell line Raji, which can also be enhanced by the involvement of aerobic oxidation inhibitor OM, acting as a synergistic inhibition. The mechanism of this synergy may be interpreted as inhibiting the dual metabolic pathway, namely glycolysis and aerobic oxidation. This inhibition of dual metabolic pathway may imply a novel approach to the treatment of Burkitt lymphoma.

CONSTITUTIVE GSK-3B ACTIVATION INDUCED B-CATENIN DEREGULATION IN CLASSICAL HODGKIN LYMPHOMA PATIENTS

S De Matteis[1,*], S Carloni[1], F Limarzi[2], R Napolitano[1], C Agostinelli[2]
[1]Bioscience Laboratory, IRCCS Istituto Scientifico Romagnolo per lo studio e la cura dei tumori (IRST), Meldola, [2]Experimental, Hematopathology and Hematology Sections, Diagnostic and Specialty Medicine, S. Orsola-Malpighi Hospital, Bologna, Italy

Background: Glycogen synthase kinase-3 beta (GSK-3β) is a serine/threonine kinase involved in glycogen metabolism, in cell cycle progression, differentiation and embryogenesis. One of the major biological functions of GSK-3β is to inhibit β-catenin by sequestration and promotion of its proteasomal degradation in the Wnt canonical pathway. Aberrant GSK-3β has been implicated in the pathogenesis of many disorders such as diabetes, Alzheimer's and Parkinson's disease and cancer. The biological role of GSK-3β in classical Hodgkin lymphoma (cHL) has not yet been clarified.
Aims: The aim of this study is to clarify the biological relevance of GSK-3β in the regulation of the β-catenin in cHL.
Methods: Three tissue microarrays (TMA) for immunohistochemical studies were obtained from formalin-fixed paraffin-embedded samples collected at diagnosis from 100 cHL patients. TMA sections were investigated by antibodies reactive with pY216 and pS9 GSK-3β and β-catenin. Three samples of hyperplastic lymph nodes were added to investigate the expression of the same markers in the reactive lymphoid tissue. Immunohistochemical preparations were visualized and images were captured using Olympus Dot-slide microscope digital system equipped with the VS110 image analysis software.
Results: Our results showed that the pY216 GSK3β, which is the stimulatory form of the kinase, was observed in 100% of cHL cases with a range of positivity in the neoplastic population from 8% to 100% and a mean expression of 56%. In 78/100 cases, we noticed that the kinase was predominantly relocated in the nucleus of the Hodgkin and Reed-Sternberg cells (Figure A), in which it is expected to be highly active. Conversely, the germinal centres of the reactive follicles showed a weak cytoplasmic positivity of the stimulatory pGSK-3β. Moreover, 20 samples were assessed positive for the inhibitory form pS9 GSK-3β with a range of positivity from 1% to 58% and a mean expression of 8%. β-catenin was detected only in 12% of the cases with a nuclear localization (Figure B). Interestingly, a statistically significant association between the presence of β-catenin in the nucleus and the inhibitory pGSK-3β expression was observed (P=0.013).

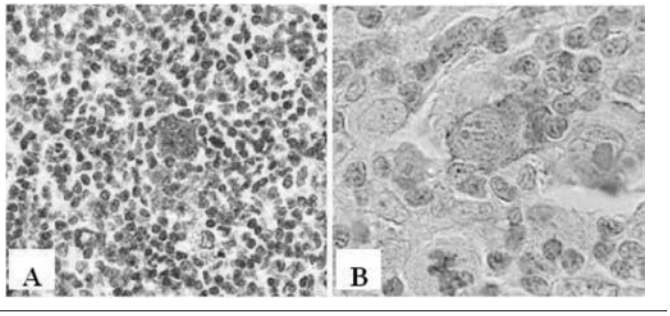

Figure 1.

Summary/Conclusions: Our results reported the constitutive activation of the stimulatory pGSK-3β that plays a previously unrecognized important role in the negative regulation of β-catenin transcription activity in cHL cells, by affecting its binding to the promoters of a subset of related-target genes. GSK-3β is an intriguing protein that seems to be involved in the pathogenesis of cHL, but many questions remain unanswered and the role of GSK-3β and its potential application in this disease become an interesting aspect to clarify. These data suggest GSK-3β as a promising novel target for therapeutic intervention in cHL.

E1400

AUTOLOGOUS STEM CELL TRANSPLANTATION MODULATES T-CELL RECEPTOR PROFILES IN HIV-INFECTED AND -UNINFECTED PATIENTS WITH NON-HODGKIN LYMPHOMA

D Bertoli[1,*], M Chiarini[1], F Serana[1], C Ghidini[1], A Sottini[1], V Giustini[1], M Vaglio Tessitore[1], A Roccaro[1], C Cattaneo[2], C Lamorgese[2], A Re[2], G Rossi[2], L Imberti[1]
[1]Centro di Ricerca Emato-oncologica AIL (CREA), [2]Hematology, ASST Spedali Civili, Brescia, Italy

Background: Treatment of HIV$^+$ lymphoma patients has been greatly improved by the combination of highly active antiretroviral therapy with high-dose chemotherapy and autologous stem cell transplantation (ASCT). It has been demonstrated that the T-cell recovery after ASCT does not differ between HIV$^+$ and HIV$^-$ patients with non-Hodgkin lymphoma (NHL), because the two groups present with a similar thymic output, as measured by means of T-cell receptor excision circles (TRECs) quantification. Nevertheless, whether T-cell repertoire (TCR) modifications may occur at the same extent in the two group of patients receiving ASCT has not been described yet.
Aims: To better elucidate the extent of T-cell recovery and its effects on the TCR repertoire in HIV$^+$ and HIV$^-$ patients with NHL who underwent ASCT.
Methods: Eleven ASCT-treated HIV$^+$ and nine HIV$^-$ NHL patients were followed for 2 years (T0: pre-ASCT; T6, T12 and T24: 6, 12 and 24 months from ASCT, respectively). The number of TRECs was measured by quantitative real-time PCR. Recent T emigrants (RTE), the cells that were recently produced in the thymus, were identified as CD4$^+$CD45RA$^+$CCR7$^+$ lymphocytes expressing the CD31 molecule. The analysis of TCR beta variable (TCRBV) families was performed by complementarity determining region 3 (CDR3) spectratyping. The deviation of CDR3 size distributions from a theoretical Gaussian curve in each TCRBV family was analysed both qualitatively and quantitatively using the generalized Hamming distance method. Results were compared to that of age matched healthy controls (HC).
Results: Starting at T6, both HIV$^+$ and HIV$^-$ patients presented with a gradual but significant increase in naïve CD4 lymphocytes (difference between means: T12 − T6=27 cells/ml, p=0.011), RTE (T12 − T6=23 cells/ml, p=0.003) and TRECs$^+$ cells (T12 − T0=1355 TRECs/ml, p<0.001) that reached the top at T24. TCR repertoire analysis showed that, compared to HC, the mean proportion of TCRBV families with shifted, restricted and mono/oligoclonal profiles of TCRBV families was significantly higher in samples obtained pre-ASCT (HIV$^+$ − HC=32.3%, p<0.001; HIV$^-$ − HC=39.8%, p<0.001) and post-ASCT (HIV$^+$ − HC=29.8%, p=0.002; HIV$^-$ − HC=24.2%, p=0.012) in both groups of patients. Quantitative analysis showed that the mean perturbation of CDR3 distributions was higher compared to HC in infected and uninfected patients both pre-ASCT (HIV$^+$ − HC=10.5%, p<0.001; HIV$^-$ − HC=12.8%, p=0.001) and post-ASCT (HIV$^+$ − HC=13.1%, p<0.001; HIV$^-$ − HC=12.6%, p<0.001). However, in both HIV$^+$ and HIV$^-$ patients, the pattern of TCR repertoire distortions changed 24 months after ASCT, as supported by modifications in the number of perturbed TCRBV and within the CDR3 distribution profiles, leading to either enlargement or restriction of the TCR heterogeneity.
Summary/Conclusions: Using different approaches, we confirmed that new CD4$^+$ cell production is similarly increased in HIV$^+$ and HIV$^-$ patients with NHL that received ASCT. The production of new lymphocytes was not sufficient to induce a general enlargement of the TCR repertoire but, nevertheless, led to relevant modifications of TCRBV family profiles, not related to HIV infection. Because TCR repertoire is usually extremely stable in HC, these modifications cannot be merely due to a physiologic repertoire "drift" over time, but are likely due to a repertoire re-assortment occurring after ASCT. Modulation of TCR repertoire may have important implications for immune system-mediated anti-infective and anti-tumor activities.

Background: Biological variation may arise from ethnic diversity or environment which may influence disease or host response. The International Atomic Energy Agency sponsored a prospective cohort study of diffuse large B-cell lymphoma (DLBCL) in countries from 5 United Nations-defined geographical regions to test this hypothesis.
Aims: The molecular analysis of DLBCL was conducted aiming to use the pre-

viously reported 6-gene score (*LMO2, BCL6, FN1, CCND2, SCYA3* and *BCL2)* (Lossos *N Engl J Med* 2004; 350: 1828–37) as a predictor of prognosis in DLBCL and validation of the utility of this scoring system in an international cohort.
Methods: Consented patients with DLBCL (n=162) in Hungary (n=28), Chile (n=27), India (n=27), Thailand (n=27), Brazil (n=18), Turkey (n=15), Philippines (n=13) and S Korea (n=7) were treated with R-CHOP between 2008 and 2013. RNA from formalin fixed paraffin embedded (FFPE) diagnostic tissue was shipped to a central laboratory. Expression of the 6 genes were assayed, using either high volume or low volume (Brazil) cDNA, by Taqman QPCR and relative quantification assigned based on expression ratio to normalised copy number. In a multivariate analysis, as described in the following equation: mortality-predictor score=(-0.0273x*LMO2*)+(-0.2103x*BCL6*)+(-0.1878x*FN1*)+(0.0346x*CCND2*)+(0.1888x*SCYA3*)+(0.5527x*BCL2*), variation in gene expression by country was investigated using analysis of variance, while variation in event-free (EFS) and overall survival (OS) for the whole cohort was investigated using Cox proportional-hazards regression models.
Results: There was significant inter-country variation for all 6 genes individually ($p<0.0001$), and when combined in the 6-gene model ($p<0.0001$). The variation in 2y EFS between countries ranged from 56% (Turkey) to 85% (Chile) With the analysis of the cohort as a whole the 6-gene score returned a hazard ratio of 0.35 (95% CI 0.17–0.74) for OS, demonstrating the score can stratify relative survival risk. To further develop the prognostic value, patient mortality-predictor scores were ranked into 2 groups with lower or higher risk of death. In a univariate Kaplan–Meier model of these 2 groups [low (n=81), and high (n=81)], defined by the prediction model based on the weighted expression of the 6 genes (Malumbres *Blood* 2008; 111:5509-5514), there was no significant difference in EFS between low and high risk groups (p=0.18); however, a significant difference in OS between low and high risk ($p<0.01$) was observed (Figure 1A). When patients with a high international prognostic indicator (IPI) (3-5), n=51, and low IPI (0-2), n=111 were analysed separately, the 6-gene score did not add prognostic value to the low IPI cases (p=0.08), but did add additional predictive value for OS, though not EFS, in high IPI cases (Figure 1B, $p<0.05$). There was no significant difference between patients treated with CHOP (n=28) or R-CHOP (n=132) for EFS or OS. *Conclusion:* The analysis of this cohort showed that the 6-gene model added prognostic information for overall survival in high IPI cases, thereby validating its utility for predicting outcome in an international setting.

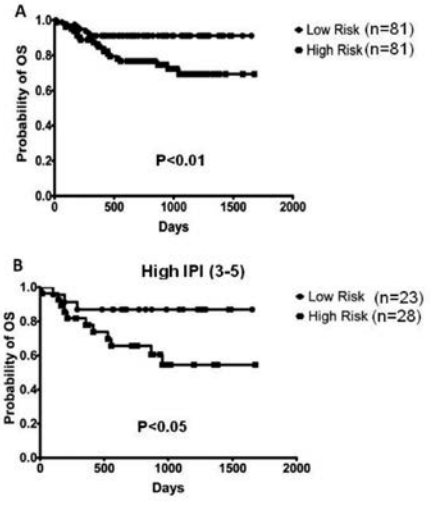

Figure 1. Kaplan-Meier curves showing 6-gene predictor score correlating with overall survival (OS) and adding a prognostic value to a high International Prognostic Index (IPI).

Summary/Conclusions: The analysis of this cohort showed that the 6-gene model added prognostic information for overall survival in high IPI cases, thereby validating its utility for predicting outcome in an international setting.

Non-malignant hematopoietic disorders

EVALUATION OF IRON OVERLOAD IN THE HEART AND LIVER TISSUE BY MAGNETIC RESONANCE IMAGING AND ITS RELATION TO SERUM FERRITIN AND HEPCIDIN CONCENTRATIONS IN PATIENTS WITH THALASSEMIA SYNDROMES

V Karakus[1,*], A Uğur Kurtoğlu[2], DE Soysal[3], E Kurtoğlu[4]
[1]Department of Hematology, Muğla Sitki Kocman University Research and Training Hospital, Muğla, [2]Department of Biochemistry, Antalya Research and Training Hospital, Antalya, [3]Department of Internal Medicine, Katip Celebi University, Ataturk Research and Training Hospital, izmir, [4]Department of Hematology, Antalya Research and Training Hospital, Antalya, Turkey

Background: Thalassemias are inherited disorders characterized by the presence of hypochromic microcytic anemia due to the reduced or absent production of one or more globin chains in hemoglobin. Individuals with thalassemia are classified according to genotype and the severity of anemia as thalassemia major, intermedia, or minor. Life expectancy is dependent on lifelong blood transfusions and iron-binding therapies. Iron overload (IOL) and associated tissue damage are the most important factors that determine mortality and morbidity.
Aims: We aimed to evaluate iron accumulation in the heart and liver by MRI in thalassemia major, thalassemia intermedia, and S-ß thalassemia patients and to examine its association with ferritin and hepcidin levels.
Methods: Serum ferritin and hepcidin levels were recorded. Iron overload (IOL) in the liver and heart parenchyma was determined based on the standardized R2 and T2* values calculated on MRI. The results were evaluated considering the tissue iron overload, serum ferritin and hepcidin levels.
Results: Comparing the 109 patients with the 30 healthy controls showed the mean age: 24.4±11 *vs* 31.2±5 years, and, median levels of serum ferritin and hepcidin: 1693 *vs* 40 ng/mL and 1.94 *vs* 0.355 ng/mL; (p=0.0001), respectively. In order of the disease diagnosis, the median cardiac T2* and hepatic R2 values were: 25.3 msec, 31.4 msec, 28.2 msec, and, 4.49 msec, 8.14 msec, and 10.35 msec on MRI, respectively. Comparing age, serum ferritin and hepcidin levels in the patients with or without iron overload, only ferritin was significantly higher (p=0.004) in the patients with IOL by means of cardiac tissue, and, age and ferritin were significantly higher (p=0.036 and $p<0.001$) in the patients with IOL by means of liver tissue. Positive correlations between serum ferritin levels and the severity of IOL were found (p=0.002 and $p<0.001$).
Summary/Conclusions: In the present study, enhanced intestinal iron absorption in the intervals between successive transfusions characterized by decreased serum hepcidin levels were considered to result in iron accumulation in our patients.

E1403

HYPERFERRITINEMIA AND SERUM INFLAMMATORY CYTOKINES IN ADULTS WITH GAUCHER DISEASE TYPE 1

F Lorenz[1], E Pawlowicz[2], C Kämpe Björkvall[3], A Bulanda Brustad[2], M Machaczka[2,*]
[1]Department of Radiation Sciences, Section of Hematology, Umea University, Umea, [2]Hematology Center Karolinska, Karolinska University Hospital Huddinge, Stockholm, [3]Department of Medicine, Sunderby Regional Hospital of Norrbotten County, Lulea, Sweden

Background: Gaucher disease type 1 (GD1, OMIM #230800) is a rare multisystem lysosomal storage disorder (autosomal recessive). The storage of glucosylceramide in macrophages produces an inflammatory response with iron recycling dysregulation and a release of cytokines. Patients with GD1 suffer from an increased susceptibility to malignancies (*e.g.*, multiple myeloma), and while the underlying mechanisms are not known, it is postulated to be associated with macrophage dysfunction and immune dysregulation.
Aims: This study was undertaken to evaluate ferritinemia, iron metabolism profiles and inflammatory cytokine concentrations in Swedish patients with GD1.
Methods: The study included 16 adults with GD1 aged 20–86 years. All but one patient (94%) carried at least one allele with c.1226A>G (N370S) mutation in the *GBA1* gene. Zimran's severity score index (SSI) was calculated for all patients at the time of their inclusion in the study. The following laboratory variables were collected from fresh blood for analysis: iron profile (s-ferritin, p-iron, p-TSAT); *HFE* gene mutations; s-hepcidin; LFTs; CRP; serum IL-1β, IL-6, IL-8, IL-10, TNF-α; serum sIL-2Rα. Assessment of the aforementioned variables was performed at baseline (the first blood sampling at Karolinska) and at follow-up (every 6–12 months).
Results: Hyperferritinemia >500 µg/L was present in all but 3 patients (81%). Values of P-transferrin, P-Fe, and P-TSAT were within normal limits for all but one patient. There was no correlation between hyperferritinemia and patient's sex, spleen status, and clinical status as defined by the Zimran's SSI. *HFE* gene mutations were analyzed in 11 patients: 4 pts were heterozygous for

His63Asp mutation, one pt was heterozygous for both His63Asp and Cys282Tyr mutations, and 6 patients had no mutation in the *HFE* gene. No obvious correlation between ferritinemia and *HFE* genotype was detected in the studied group. Serum hepcidin concentrations were analyzed in 10 patients; 7 pts had normal hepcidin results; one pt with a normal ferritinemia (75 µg/L) had a low hepcidin concentration at 4 µg/L and 2 pts with a hyperferritinemia of 1910 and 833 µg/L had elevated hepcidin at 50 and 55 µg/L, respectively. *Cytokine and inflammatory marker analysis* The serum concentrations of IL-1β, IL-8, IL-10 were normal in all studied GD1 patients. The mean and median serum concentrations of TNF-α, IL-6, sIL-2Rα, and CRP were within normal limits in all studied patients. However, in 5 of 11 patients (45%) TNF-α was moderately increased. Additionally, 2 patients with the highest TNF-α concentrations (28.4, and 30.4 ng/L) showed mildly elevated IL-6 concentrations (5.9 and 10.7 ng/L, respectively). In the first aforementioned patient, CRP was increased to 12 mg/L but was normal in the second patient. Of note, the first patient was diagnosed with concomitant chronic lung infection (*Mycobacterium avium* and *Aspergillus fumigatus*). Serum levels of IL-6 were within normal limits in the remaining 14 patients (87%). Serum sIL-2Rα concentrations were within normal range in 62% of patients (10/16). *Longitudinal assessment of hyperferritinemia and inflammatory cytokines in treated patients with GD1* Eight patients with at least 36 months' follow-up data were eligible for a longitudinal assessment of ferritinemia, TNF-α, IL-6, IL-8, and sIL-2Rα. Four patients were untreated when their baseline sampling was performed and began GD1 therapy. All remained on unchanged therapy throughout follow-up. Longitudinal assessments of the studied variables for the treated patients are presented in the figure.

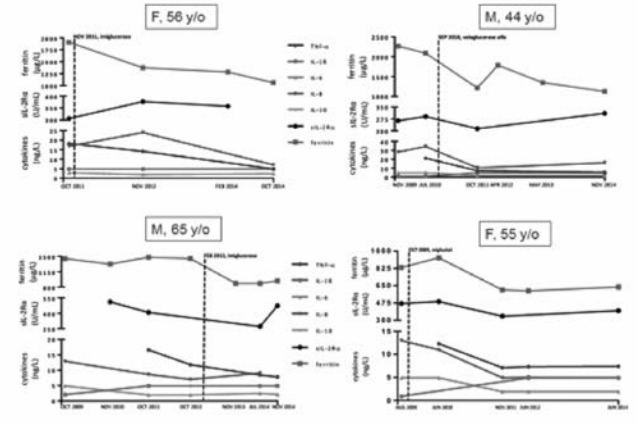

Figure 1.

Summary/Conclusions: The study revealed that hyperferritinemia is common in Swedish GD1 patients. Unlike hemophagocytic lymphohistiocytosis, hyperferritinemia in GD1 is not associated with high serum levels of sIL-2Rα. In some, but not all patients TNF-α and IL-6 levels could be mildly elevated. GD1 therapy has a potential to improve ferritinemia and cytokine levels.

E1404

PEG-HBCO MEDIATED CARBON MONOXIDE AND OXYGEN TRANSFER TO HYPOXIC RED BLOOD CELLS PREVENT, SLOW, AND/OR REVERSE SICKLING IN VITRO

R Jubin*, P Buontempo, R Yglesias, C Buontempo, A Abuchowski
Prolong Pharmaceuticals, South Plainfield, United States

Background: In Sickle Cell disease (SCD), a mutation promotes HbS polymerization causing abnormal cell morphology that results in occlusion of small blood vessels and increased circulatory inflammation. PEGylated-carboxyhemoglobin (PEG-HbCO; SANGUINATE) is a novel therapeutic agent designed to release carbon monoxide (CO) and then transfer oxygen (O_2) to hypoxic tissue and cells. PEG-HbCO was shown to mediate transfer of either a CO or O_2 and restore normal morphology to hypoxic, sickled RBCs *in vitro*. Studies are now focused on the potential therapeutic implications of delaying sickling, which should maintain normal blood flow through hypoxic microvasculature.
Aims: Current *in vitro* studies examined the effects of time and dose of PEG-HbCO to not only reverse, but also prevent or delay sickling by transferring CO and expedite atmospheric O_2 transfer to the sickled RBCs.
Methods: Reversal of sickling were conducted by deoxygenating RBCs from healthy and SCD volunteers followed by treatment with either PEG-HbCO, fully oxygenated PEG-Hb (PEG-HbO_2) or PEG-BSA. For prevention of sickling studies, fully oxygenated RBC suspensions were treated with increasing amounts of PEG-HbCO and then subjected to hypoxia for 3 hours. Time-dose effects were quantified by area under the curve (AUC) analysis. O_2 transfer studies were conducted by treating hypoxic, sickled RBCs to increasing concentrations of PEG-HbCO and raising the pO_2 from 3.8mm to 40mm. In all studies, the fractions of CO-Hb, O_2-Hb and reduced Hb were determined by co-oximetry and sickled RBCs were quantified by imaging flow cytometry of fixed RBC specimens.
Results: PEG-HbCO -mediated delivery of either CO or O_2 unsickles SCD RBCs. The sickle reversion time-course studies showed differential kinetics between the CO and O_2 capacity to cause unsickling. AUC analysis at 20 minutes demonstrated that both CO and O_2 reversed sickling by 41% and 42%, respectively. PEG-HbO_2 was able to exert substantial unsickling by 5 minutes, where PEG-HbCO showed a delayed, more pronounced effect, peaking approximately 20 to 40 minutes post-treatment. When fully oxygenated SCD RBCs were pretreated with PEG-HbCO prior to oxygenation, sickling was inhibited with an IC_{50} of 2.5±0.6 mg per mL in deoxygenated saline. In addition, treatment concentrations below IC_{50} values had increased time-dose AUC values indicating that sickling was delayed. Oxygen transfer facilitation studies indicated that PEG-HbCO increased the rate of unsickling as measured by AUC by 50% and 15% at 4 and 2 mg per mL, respectively. These levels are within the expected therapeutic dosage of PEG-HbCO.
Summary/Conclusions: RBCs from patients with SCD undergo morphological changes. It is only when the fraction of oxygenated HbS reaches a sufficient level that reversion to normal morphology occurs which promotes vascular perfusion. These experiments showed a concentration and time-dependent effect of PEG-HbCO ability to deliver both O_2 and CO to sickled RBC. Additionally since ASH 2016, PEG-HbCO was shown to improve rheology and down-regulate inflammation in a hemorrhagic shock model; these pathologies also exist in SCD. These data suggest that PEG-HbCO is a promising gas transfer agent that has the potential to improve sickle cell morphology by reversing sickling; the underlying pathology of sickle cell disease co-morbidities as well as decrease hypoxia-induced inflammation. SCD patients with hyperhemolysis and acute chest syndrome have been treated with PEG-HbCO under eINDs. Phase 2 trials with PEG-HbCO are underway in SCD vaso-occlusive crisis.

E1405

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: RETROSPECTIVE ANALYSIS FOR PROGNOSTIC FACTORS

B Dholaria*, W Hammond, A Shreders, T sher
Hematology- Oncology, Mayo Clinic, Jacksonville, United States

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life- threatening systemic inflammatory condition. Due to rarity of the cases, it presents difficulties in diagnosis and management. Survival remains poor despite aggressive chemotherapy. Patients with fever of unknown origin, lymphadenopathy, deteriorating performance status, encephalopathy and elevated systemic inflammatory parameters frequently show no clear cut diagnostic criteria specific for HLH. Among adults, late onset of inherited HLH is possible, but acquired HLH triggered by infection, malignancy or autoimmune disease is more frequent than in pediatrics.
Aims: Patient outcomes varied markedly despite standardize therapy. Reliable prognostic disease markers may help to tailor intensity of therapy and predict long term outcomes. We attempt to look for variables associated with difference in mortality within 30 days of diagnosis.
Methods: We performed a retrospective search on mayo clinic patient database for the patients with the diagnosis of HLH from 2005 to 2015. HLH-04 criteria were used to select the study population.[1] Patients were divided in two groups based on survival after the diagnosis. We analyzed different clinical and laboratory parameters to detect significant difference between patients expired within 30 days of diagnosis or survived longer than 30 days. Chi-square analysis was performed between two groups of patients: 1- Time to death from diagnosis<30 days. 2- Time to death from diagnosis >30 days. We assessed difference in various clinical and laboratory parameters.

Table 1.

Clinical variables	Survival < 30 days	Survival > 30 days	P value
Age (years)	62	40	0.0004
Median time to start treatment (weeks)	40.7	8.6	0.23
Baseline ferritin (mcg/L)	32866	10667	0.01
Peak ferritin (mcg/L)	45870	29894	0.26
Albumin (g/dL)	2.3	2.6	0.41
LDH (U/L)	1271	720	0.51
Bilirubin (mg/dL)	8.9	4.5	0.14
Triglyceride (mg/dl)	260	276	0.70

Results: Demographics: 40 patients were included in the analysis who met HLH- 04 criteria. Mean age was 49 years, 40% (16/40) were female and 60% (24/40) were male. Underlying HLH etiology was malignancy 37% (15/40), infection 20% (8/40), rheumatological 17% (7/40), idiopathic 20% (8/40). Two patients were peripartum and one with Kikuchi syndrome. Fever was present in 90% (36/40) and splenomegaly was found in 75% (30/40) of the patients.
Labs: Average ferritin at diagnosis 19546 mcg/L, ferritin peak 36284 mcg/L, ALP 226U/L, AST 274U/L, T. bilirubin 6.3mg/dL, LDH 937 U/L, triglyceride 269

mg/dL, albumin 2.4g/dL and EBV DNA PCR were positive in 32% (13/40) of the patients. **Treatment:** Median time from onset of symptoms to start the treatment was 8.1 weeks. Steroids were used in 92% (37/40), etoposide was used in 55% (22/40), and HLH 04 protocol (Etoposide/dexamethasone/cyclosporine) was used in 40% (16/40) of the patients. IVIG was used in 13% with underlying rheumatological process. Mean follow up was 57 weeks (0.1 to 336 weeks) for the whole group. Total 40% (16/40) died within 30 days of diagnosis.
Outcomes: Risk of 30- days mortality was significantly higher in the patients with ferritin >5000 mcg/L at the time of diagnosis and age >55 years. Out of total 40 patients, 54% (12/22) died in ferritin >5000mcg/L group and 22% (4/18) died in ferritin<5000 mcg/L group within 30 days. (p- 0.03) Death rate within 30 days was 65% (11/17) with age >55 years and 22% (5/23) with age<55 years at the time of diagnosis of HLH. (p-0.05). We did not find any significant difference in the following factors: 30 day mortality was 31% (4/13) in EBV positive group and 44% (12/27) in EBV negative group (P-0.40); 50% (8/16) in malignant group and 33% (8/24) in non- malignant. (P-0.29). No difference between the groups in terms of gender, etoposide use, and time to start treatment was found in 30 days mortality. Table 1 summarizes the findings.
Summary/Conclusions: Elevated ferritin at the time of diagnosis and older age are associated with significant risk of 30 day mortality from HLH. In combination with other prognostic factors age and ferritin can be used to risk stratification at the time of diagnosis. These factors can be incorporated in future clinical trials to choose different treatment pathways.

E1406

CLINICAL RELEVANCE OF LOW PERCENTAGE OF GLYCOSYLATED FERRITIN IN MANAGEMENT OF ACQUIRED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS: A SINGLE CENTER EXPERIENCE

M Nabergoj[1,*], M Marinova[2], L Astolfi[3], G Binotto[1], M Zaninotto[2], M Plebani[2], F Vianello[1], G Semenzato[1]
[1]Hematology and Clinical Immunology, [2]Department of Laboratory Medicine, [3]Department of Neuroscience, Padova University School of Medicine, Padova, Italy

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare and life-threatening condition characterized by excessive chaotic and uncontrolled inflammation leading to multiorgan failure and death. HLH can be either primary (familial), when caused by a genetic mutations affecting cytotoxic function, or secondary (acquired), when due to infectious, malignant, rheumatologic or metabolic conditions. Although diagnostic scores have been proposed such as HLH-04 criteria, which were validated only in pediatric patients, and the HScore, HLH diagnosis is still challenging owe to lack of solid criteria allowing differential diagnosis with other multisystem illnesses characterized by fever, hepatic failure, and neurologic symptoms. Recently, a percentage of glycosylated ferritin (GF)<20% has been proposed as highly specific of HLH and useful in the differential diagnosis from other hyperinflammatory syndromes, such severe sepsis and flare of a secondary underlying disease.
Aims: To validate the usefulness of glycosylated ferritin levels in identification of patients with HLH and to evaluate its potential role in predicting treatment outcome.
Methods: Over a 2-year period, nineteen adult (>18 years) patients with a clinical and laboratory pattern consistent with HLH were included in the study. HLH-04 criteria and HScore were applied for HLH diagnosis. The percentage of glycosylated ferritin was measured by an in-house assay (Marinova et al, in press). Specificity and sensitivity for each approach was then calculated.
Results: Ten out of 19 (53%) subjects had clinical and laboratory findings consistent with HLH. In all cases an underlying disorder was identified: infection (n=1), autoimmune disease (n=1), malignancy (n=1), Hodgkin or non Hodgkin lymphoma (n=1 and n=6, respectively). All but one patient (90%) fulfilled the HLH-04 criteria, whereas a high probability HScore (>90%) was present in 7 out of 10 subjects (70%). Nine out of 19 patients (47%) in whom HLH was ruled out, underlying disorders were autoimmune disease (n=1), infection (n=1), AML (n=1), non-Hodgkin lymphoma (n=5). Among these 9 patients, 2 (22%) met at least five HLH-04 criteria and no one had a HScore probability >90%. Ferritin levels failed to differentiate patients with HLH (11565±95161 *vs* 4669±3541 µg/L, HLH *vs* non-HLH, p=0,18). When GF was measured in our cohort, a percentage of GF level<20% was observed in 9/10 patients with HLH, whereas all unaffected patients had GF level >20%. We found a negative linear correlation between HScore and GF percentage (p<0,05, r=-0,54) and between HLH-04 criteria and GF percentage (p<0,05, r=-0,47). All three methods were able to significantly discriminate affected patients from unaffected (all p<0,05), but GF level<20% showed higher sensitivity against HScore (90% *vs* 70%) and better specificity against HLH-04 (100% *vs* 78%). Moreover, GF shows higher negative predictive value compared to the other diagnostic methods (GF: 90%). Five patients had GF levels measured over the course of the disease. Although the very limited number of patients does not allow to draw any conclusion, two patients who did not show recovery of GF levels >20% within one week after treatment initiation died within one month, while 3 patients who experienced a rise in GF >20% showed a resolution of HLH-related clinical picture and longer survival (median 6 months).
Summary/Conclusions: In our study a fraction of glycosylated ferritin<20% showed high concordance between HLH-04 criteria and HScore and it seemed of help in identifying patients affected by HLH when scores are contradictory as well as in excluding false positive cases. Monitoring GF levels over the course of HLH may also allow to predict response to therapy.

PROSPECTIVE STUDY OF SPLENECTOMY IN AUTO-IMMUNE CYTOPENIA OF CHILDREN

N Aladjidi[1,*], Y Bertrand[2], H Fernandes[1], B Nelken[3], M Pasquet[4], N Cheikh[5], S Bayart[6], C Armari-Alla[7], H Chambost[8], Y Perel[1], T Leblanc[9], G Leverger[10]
[1]pediatric oncohematology unit/CEREVANCE/CIC1401, Inserm CICP, University Hospital of Bordeaux, Bordeaux, [2]Pediatrics, Institut d'Hématologie et d'Oncologie Pédiatrique, Lyon, [3]Pediatric Hematology Unit, University Hospital of Lille, Lille, [4]Pediatric Hematology Unit, University Hospital of Toulouse, Toulouse, [5]Pediatric Hematology Oncology Unit, University Hospital of Besançon, Besançon, [6]Pediatric Immuno-Hematology Oncology Unit, University Hospital of Rennes, Rennes, [7]Pediatrics Unit, University Hospital of Grenoble, Grenoble, [8]Pediatric Hematology Unit, University hospital of Marseille - Timone Enfants, Marseille, [9]Hemato-Immunology Unit, Robert Debré Hospital, APHP, [10]Pediatric Hematology Unit, Armand Trousseau Hospital, APHP, Paris, France

Background: Chronic immune thrombocytopenic purpura (cITP), autoimmune hemolytic anemia (AIHA) and Evans syndrome (ES) are rare autoimmune diseases in children, characterized in 20-70% of cases by recurrent outbreaks and treatment dependence. In AIHA and ES, the effectiveness of splenectomy has never been clearly established, as it was in ITP. Since 2004, the OBS'CEREVANCE cohort has been recording all the cases of auto-immune cytopenias in children treated in the 30 French pediatric hematology units.
Aims: This prospective observational national study reports the practice, efficacy and safety of splenectomy performed for all the patients of this cohort.
Methods: On 1st January 2016, patients recorded in this cohort who underwent splenectomy in second-line after immunoglobulin and/or steroid failure, before the age of 18, were analyzed in 3 homogeneous groups according to the target: isolated cITP, isolated AIHA, and ES.
Results: Among the 1094 children included in the cohort, diagnosed between 1986 and 2014 (556 isolated cITP, 356 isolated AIHA and 172 ES), 181 underwent a splenectomy. 86 of those splenectomies were performed in third or more line in heterogeneous patients. 95 splenectomies were carried out on second-line, 80 for isolated cITP, 8 for isolated AIHA and 7 for ES. Laparoscopy was realized in 79% of cases. The median age at splenectomy was respectively 11.5, 5.9 and 8.4 years. The median delay from diagnosis to splenectomy was respectively 2.3, 0.7 and 1.8 years. The complete response achievement rate was similar in the 3 groups. With a median follow-up of 5 years post splenectomy, there was no need for further immunosuppressive treatment for 64/80 cITP (80%), 4/8 AIHA (50%) and 1/7 SE (15%). Of these 69 patients, 84% were still in continuous complete remission at the last follow-up (54 cITP, 4 AIHA, 0 ES). Comparative relapse-free survival curves are presented. Three of the four deaths are possibly related to the weight of the treatments. Infections and thrombosis were more frequent in AIHA and ES than in cITP.
Summary/Conclusions: This prospective national study provides the first evidence-based comparative data on children with early splenectomy for those rare diseases. The benefit-risk ratio of splenectomy seems lower in AIHA and SE than in cITP. Some underlying immune deficiencies as autoimmune lymphoproliferative syndrome are formal contraindications. Prospective pediatric studies will refine alternative immunomodulatory strategies aiming to delay splenectomy as late as possible in children with AIHA or ES.

E1408

A RETROSPECTIVE REVIEW OF BACTEREMIA AND OSTEOMYELITIS IN SICKLE CELL PATIENTS PRESENTING WITH FEVER IN LEBANON

S Khalife[1,*], R Ahmad[1], R Haidar[2], N Khoury[3], G Dbaibo[1], MR Abboud[1]
[1]Pediatrics and Adolescent Medicine, [2]Surgery, [3]Diagnostic Radiology, American University of Beirut Medical Center, Beirut, Lebanon

Background: Patients with sickle cell disease have higher risk of infections with encapsulated bacteria due to immature immune response and functional asplenia manifested by impaired complement activity. This has led historically to serious bacterial infections which include bacteremia with *Streptococcal pneumonia* and osteomyelitis mainly caused by *Salmonella* species.
Aims: In this study we aim to review the bacteremia rates in sickle cell patients in the era of vaccination against *Streptococcus pneumonia* and osteomyelitis rates with the causative organisms. The purpose is to prove an emergence of gram negative organisms, other than *Salmonella*, as the cause of osteomyelitis; and the vast decrease in *Streptococcal pneumonia* bacteremia rates after vaccination.
Methods: We conducted a retrospective chart review of 158 sickle cell patients registered at our database. Every patient presenting to ER with fever had his chart reviewed for blood cultures, pus cultures and MRI results for osteomyelitis over a period of 13 years. 16s ribosomal DNA was also performed to detect organisms not recovered by regular cultures.

Results: Sickle cell patients reviewed included 117 patients with SS type (74%), 36 patients with SB thalassemia type (23%), 2 patients with SC type (1%), 2 patients with SD type (1%), 1 patients with SO Arab type (1%). Patient ages ranged between 3 years and 40 years, with mean of 16 and median of 15. In the time period of the study, 105 patients (66%) presented to ER with fever leading to 581 febrile episodes. 341 episodes were in males (59%) and 240 in females (41%); 384 patients had SS type (66%), 171 had SB thalassemia type (29%), 26 had SD(5%). A total of 912 blood cultures were obtained. None of those grew *Streptococcus pneumonia* (0%), 14 cultures grew *Staphlococci* coagulase negative (1.5%), 1 culture grew *Salmonella paratyphi B*, and 3 cultures grew *Salmonella group C* (in same patient). There was a total of 9 episodes of osteomyelitis documented by imaging among patients who presented with fever (1.5%). 4 of the patients were females (44%), 5 were males (56%), 7 patients had sickle type SS (78%) and 2 had SB thalassemia type (22%). Ages ranged from 6 years to 28 years, with mean of 14 years. 4 patients (44%) had positive cultures and 5 patients (56%) had negative cultures. Cultures (puss/tissue) obtained included 1 with *Enterobacter cloacae*, 1 with *Bacteroides*, 1 with *Pseudomonas aeruginosa* (by 16s rDNA) and the fourth was a blood culture growing *Salmonella* group C. 16s rDNA was performed on tissue samples of 4 patients with osteomyelitis. Two of those patients had negative 16s rDNA and cultures. The remaining patients had *Bacteroides* detected by both modalities in one patient, and *Pseudomonas aeruginosa* detected only by 16s rDNA, not by culture, in the other. Osteomyelitis occurred in the spine in 3 patients (33%), in lower extremities in 3 patients (33%) and in upper extremity in 3 patients(33%). All our patients received pneumococcal vaccination, 104 patients (63%) were on hydroxyurea, and 86 patients (47%) were on oral penicillin prophylaxis.
Summary/Conclusions: Immunization against *Streptococcus pneumonia* has virtually eliminated pneumococcal bacteremia as was evident in our patient population. However, there was emergence of gram negative organisms, other than *Salmonella* as the cause of osteomyelitis. This has important implications for the empiric antibiotic coverage in sickle cell patients with osteomyelitis. Molecular testing by 16s rDNA is to be considered to detect causative organisms of osteomyelitis on tissue/ pus cultures when cultures fail to grow any.

FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN OMAN: AN UPDATE ON UNIQUE CLINICAL AND MOLECULAR FEATURES

M Elshinawy[1,*], A Al Rawas[2], Y Wali[2]
[1]Pediatric Hematology, SQUH & Faculty of Medicine, Alexandria University, Muscat & Alexandria, [2]Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman

Background: Familial hemophagocytic lymphohistiocytosis (FHLH) is a rare life-threatening autosomal recessive disorder. Due to high rate of *consanguineous* marriage in Oman, the incidence of HLH is relatively higher in this part of the world. Clinically, HLH is characterized by unexplained high-grade fever and splenomegaly associated with bi/pancytopenia, hyperferrtinemia, hypofibrinogenemia and hypertriglyceridemia.
Aims: To review the clinical features, laboratory findings, molecular characteristics, course and outcome of all cases of FHLH in Oman.
Methods: A retrospective/prospective data analysis of all patients diagnosed with FHLH in Oman during the period from January 1997 to February 2016 was done. Flowcytometry has been used as a fast method to detect perforin expression at diagnosis. Direct DNA sequencing was done to specify mutations in patients and their families. Our results have been initially confirmed and validated by Karolinska Institute, Sweden.
Results: Forty-eight patients (26 males & 22 females) with FHLH were identified. Their median age was 88 days with a range of (3 days– 13 months). Thirty-seven patients (77%) had positive consanguinity, while 25 (52%) had positive family history. Forty-one patients (85.4%) presented with fever and 44 (91.6%) had splenomegaly. Twenty-seven cases (56.25%) had evidence of central nervous system involvement detected either at diagnosis or during the course of therapy. Atypical rare clinical presentations included capillary leak syndrome in 5 cases (10.5%), severe hypertrophic obstructive cardiomyopathy in 2 siblings after receiving high dose dexamethasone, and bilateral renal infiltration as a unique clinical feature in a 2 month-old male infant (Figure 1). Of note, renal involvement in this patient was completely reversed after 4 weeks of chemotherapy. Bicytopenia was found in 39 (81.3%) infants, hypertriglyceridemia in 28 (58.3%) and hypofibrinogenemia in 45 (93.8%). All patients had serum ferritin>500 ng/ml. At molecular level, the most commonly detected genetic abnormality was perforin gene mutation (FHLH2), identified in 14 out of 17 studied families (82.4%). Syntaxin 11 mutation (FHL4) was detected in only one patient, while MUNC 13-4 mutation was not found. Two families did not show any mutations. The high incidence of perforin gene mutations may denote a common genetic pool of FHLH cases in Oman. Twenty-three (47.9%) cases passed away. Fifteen infants were referred late after being treated with antibiotics in peripheral hospitals as presumed cases of sepsis. Our standard of care is HLH-2004 protocol, followed by hematopoietic stem cell transplant (HSCT). Twenty-one patients were successfully transplanted in our center. It is noteworthy that three of them have received haploidentical HSCT.

Figure 1.

Summary/Conclusions: We report an updated registry of FHLH cases in Oman, including typical and atypical unique clinical presentations, characteristic molecular features, course of the disease and treatment outcome. Taken into consideration the relatively higher incidence of FHLH in this part of the world, we recommend premarital screening, implementation of pre-implantation genetic diagnosis (PGD) for high risk families and raising the awareness of health care professionals in order to suspect and refer new cases as early as possible.

E1410

CLINICAL PRESENTATION AND OUTCOME OF BENIGN HISTIOCYTIC DISORDERS IN CHILDREN

AA Tantawy[1,*], IA Ragab[1], NH Elsherif[1], SM Elsayed[2], HG Ali[1], SM Makkeya[1], HI Elsantiel[1]
[1]Pediatric Hematology&oncology, [2]medical genetics, children hospital, Ain Shams University, Cairo, Egypt

Background: Langerhans cell histiocytosis (LCH)& Hemophagocytic lymphohistiocytosis (HLH) are the most common benign histiocytic disorders. The clinical picture of LCH varies from single-system to multisystem disease which carries a potentially poor prognosis. HLH is referred to as either a"primary" form which is hereditary, or a "secondary" form associated with an underlying illness. The disease is invariably fatal if untreated.
Aims: Our goal was to evaluate the different clinical presentations of histiocytic disorders, mainly LCH and HLH. and to determine their outcome and survival in relation to the predisposing factors and the current treatment protocols
Methods: Demographic, clinical, laboratory and radiographic data of patients diagnosed with LCH and HLH over a period of 10 years was retrosecpectively collected. Protocol of treatment was evaluated including the 1 and 3 year event free and overall survival rates
Results: This study included 19 LCH patients (median age 2.3 years) with a males to female ratio of 1:1.7. All LCH patients had multisystem affection, 16 (84.2%) had risk organs involvement. Seven patients(36.8%) had Bone marrow infiltration; 13 (68.4%) patients had hepatosplenomegaly and 14 (73.7%) had lung infiltrations in their CT. In our study 19(94.7%) of LCH patients received LCH III protocol, while only one (5.3%) patient received LCHII protocol of treatment. Six (31.6%) had received salvage line, half of them (3 patients) needed only one treatment protocol, 1patient needed 3 salvage and the last 2 patients received 2 salvage treatment. Six patients died, the median duration from diagnosis till death duration was 1.9 year. Their 1,3 years overall survival was 78.9% and 46.1%. Twenty six patients with HLH were registered; their median age was 3.4 yrs with a male to female ratio of 2:1. Ten patients had HLH secondary to another disease (2 patients (7.7%) had ALL, 2 (7.7%) had Chediak Hegashi, 3(11.5%) had LCH, one had Wolman, one with myelodyplasia and one with ALPS). Sixteen (61.5%) patients did not have an underlying disease, 4 of them(15.4%) had MUNC13-4 gene mutation, 1(3.8%) had RAB27A gene mutation and 1(3.8%) patient had LYST gene mutation, and 2 patients had no common HlH mutations. Thrombosis was reported in 2(7.7%) of the patients and (19.3%) of them presented initially with skin lesions, moreover five (19.3%) patients had CNS manifestations but only 2 of them had positive findings in their MRI and CT brain. Most of the patients were treated according to HLH 2004 protocol, while only 2 received HLH 94 protocol. twelve patients (46.2%) had reactivations, 6 needed only one reinduction, 4 had 2 rein-

ductions and 2 had 3 reinductions. We report the death of 18 patients, with a median duration since the diagnosis till death of 3.36months.
Summary/Conclusions: All our LCH patients had multisystem (MS) risk organ affection, hence the high reactivation and the low overall survival rate. The increased awareness of the HLH criteria for diagnosis, allowed early and accurate detection of cases, yet the death rate is still high.

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: CLINICAL FEATURES AND OUTCOME IN 124 PATIENTS EVALUATED IN A SINGLE CENTER

M Zanichelli[1,*], D moromizato[2], G fonseca[2], L suganuma[2], S gualandro[3]
[1]Bone marrow transplantation, Itaci - HC FMUSP, [2]Hematology, Hematology - HCFMUSP, [3]Hematology, Hematology-FMUSP, São Paulo, Brazil

Background: The Paroxysmal Nocturnal Hemoglobinuria (PNH) is a rare acquired disorder of hematopoietic stem cells characterized by intravascular hemolytic anemia, thrombotic phenomena and marrow failure. It is caused by a somatic mutation in the phosphatidylinositol glycan class A (PIG-A) X-linked gene, responsible for a deficiency in GPI-anchored proteins (GPI-AP). The lack of the GPI-AP complement regulatory proteins (CD55 and CD59) leads to the main manifestations of the disease. The Paroxysmal Nocturnal Hemoglobinuria (PNH) is a rare acquired disorder of hematopoietic stem cells characterized by intravascular hemolytic anemia, thrombotic phenomena and marrow failure. It is caused by a somatic mutation in the phosphatidylinositol glycan class A (PIG-A) X-linked gene, responsible for a deficiency in GPI-anchored proteins (GPI-AP). The lack of the GPI-AP complement regulatory proteins (CD55 and CD59) leads to the main manifestations of the disease.
Aims: The objective of this study was to describe the clinical features at diagnosis and outcome of PNH patients followed-up at a single institution.
Methods: Demographic, clinical, haematological and biochemical data were collected from patients followed-up at the our centre. The diagnosis of PNH was established using flow cytometry.
Results: 880 patients were tested for PNH. A hundred forty patients had PNH clone. Of these, 124 had complete records and were included in this study (61 male and 63 female). The median age at diagnosis was 29.5 years (range 10-72). Ninety one patients (74%) had a previous diagnosis of Aplastic Anemia, 5 patients had MDS (4%) and 28 (22.5%) patients had classical PNH. The most common symptom at diagnosis was fatigue present in 109 patients (88%). 63/124 (51%) had bleeding and / or hemorrhagic suffusion, 18 (14%) jaundice, 23 (18%) hemoglobinuria, 13 (10%) abdominal pain, 11 (9%) thrombosis, 4 (3%) renal failure and 34 (27%) fever / infection. Median hemoglobin at diagnosis was 7.9 (2.6 to 14.0), median neutrophils / mm3 was 1.050 (100-8400) and median platelet 21,500 / mm3 (1000-494000). 55/124 (44%) had LDH>1.5 times or more the upper limit of normal. Fifty one (41%) patients had PNH clone>50% in granulocytes. During evolution 31/124 (25%) patients had thrombosis, 33/124 (27%) had hemoglobinuria and 15/124 (12%) had renal failure. Patients with classical PNH received supportive treatment with red blood cell transfusions, folic acid, prophylactic anticoagulant (14 patients with PNH clone>50%) and long-term anticoagulation (31 patients with thrombosis). Two patients have been treated with eculizumab. 23/80 (28.6%) patients with AA/PNH have undergone bone marrow transplantation and the others (n=57) were immunosuppressed with cyclosporine and antithymocitic globulin. 15/57 patients after immunosuppressive treatment, developed in a median period of 3.4 years (2-11 years), large clones (>50%) behaving like classical PNH. In this period 8 patients with classical PNH died. The causes of death were thrombosis in 4 patients and infection in the others.
Summary/Conclusions: This study has a limitation because it was retrospective. Despite of that our results are similar to those found in the literature except in the occurrence of abdominal pain (less than expected). Eculizumab is not available for all patients in our centre. Because of that we have prophylactically anticoagulated patients with PNH clone above 50% and no contraindications for the procedure.

LB2263

EPSTEIN-BARR VIRUS-ASSOCIATED T-LYMPHOPROLIFERATIVE DISORDERS IN ADULTS: A CASE SERIES OF 13 PATIENTS IN A SINGLE INSTITUTION AND REVIEW OF LITERATURE

P Shi[*], S qian, Y xie
Department of hematology, Hangzhou first people's hospital, Hangzhou, China

Background: Epstein-Barr virus (EBV) usually infected B lymphocytes, sometimes also infected T- or natural killer (NK)-cells. EBV-associated T/NK cell lymphoproliferative disease (EBV-T/NK-LPD) represents a continuous spectrum of diseases, ranging from benign hyperplasia of reactivity to clonal and malignant lymphoproliferations. Epstein-Barr virus-associated T/NK-cell lymphoproliferative disorder in children and young adults is a systemic disease, and features with EBV infection of T or NK cells cloned proliferation.
Aims: To understand the clinical features of EBV-associated T/NK cell lymphoproliferative disease and its poor prognosis, recognize the importance of early diagnosis and timely treatment.
Methods: Retrospective analysis of 13 patients with clinical features, EB virus spectrum, treatment and prognosis
Results: we report 13 adult cases of systemic Epstein-Barr virus-positive T-cell lymphoproliferative disorder including 9 males and 4 females with a median age of 41 years old (range,24-75). the most common clinical symoptoms were fever 92.3% (12/13), splenomegaly 100% (13/13), hepatomegaly 30.8% (4/13), lymph node enlargement 38.5% (5 /13), blood cells decrease 92.3% (12/13), abnormal liver function 76.9% (10/13), elevated lactate dehydrogenase 76.9% (10/13), coagulant function abnormality 61.5% (8/13). All patients had significantly increased serum EBV-DNA levels (3.41×10^4-6.61×10^6 copy/ml). EBER were positive by Fluorescence in situ hybridization (FISH) (5 cases lymph node and 8 cases bone marrow). T lymphocytes were involved in this group, 7 cases were diagnosed as chronic active EB virus infection (CAEBV), and 6 cases were diagnosed as EBV-associated hemophagocytic lymphohistiocytosis (HLH).One paient with CAEBV had no fever and blood cells decreases, keeping stable disease with prednisone treatment; and another one patient with CAEBV progress for aggressive NK cell leukemia after 4 months diagnosis, with EPOCH regimen combined L-asparaginase chemotherapy. The remaining 11 patients were treated with immunochemotherapy containing etoposide, but the effect is not good. In a median follow-up time of 18 months, one patient was free of disease, one was alive with disease, and eleven died of disease in 5 months, respectively.
Summary/Conclusions: Adult systemic EBV + T/NK-LPDs was relatively rare disease and the prognosis is poor. Our report adds to the understanding of these rare disease with early diagnosis and intervention.

LB2264

MICROVASCULAR NETWORK IN BONE MARROWS OF TREATMENT-NAÏVE PATIENTS WITH TYPE 1 GAUCHER DISEASE: SKEWED ANGIOGENIC SIGNALS IN AN INFLAMMATORY MILIEU

M Klimkowska[*], M Machaczka[1], I Vedin[2], J Palmblad[3]
[1]Hematology Center, Karolinska University Hospital, [2]Department of Medicine and Hematology, Karolinska Institute, [3]Department of Medicine and Hematology, Karolinska Insitute, Stockholm, Sweden

Background: Gaucher disease (GD) is characterized by accumulation of glucocerebroside-storing macrophages, called Gaucher cells (GC) in various organs, including bone marrow (BM). Since macrophages play a major role in chronic inflammation, it can be assumed that macrophage proliferation in GD can elicit or modify local inflammation-associated phenomena, including angiogenesis.
Aims: The study was aim to evaluate microvascular network in BM samples from untreated patients with GD type 1, and compare them to samples from healthy adults.
Methods: Bone marrow core biopsies from 11 treatment-naïve patients with GD type 1 (3 women, 8 men, median age 68.5 years), followed at the Hematology Center, Karolinska University Hospital, were analyzed retrospectively. Biopsies from 36 subjects (18 women, 18 men, median age 63.6 yrs) with no hematological diseases, were used as controls. In the immunohistochemically

and immunofluorescent stained samples, the following parameters were analyzed: cellularity, vessel morphology, microvascular density (MVD), vessel wall pericyte coverage and expression of proangiogenic growth factors (VEGF, ANGPT1 and 2). In GD biopsies, analyzes were performed separately in areas with greater and lower percentage of infiltrating GC (≥50% and <50% in a high power field).

Results: In GD patients, hematopoietic tissue was hypercellular for age, and MVD was 2.6-fold higher than in controls (p<0.001). In GC rich areas, MVD was 1.4-fold higher (p=0.026) and vessel architecture was abnormal as compared to GC poor areas. Moreover, 30±17% of GD BM vessels were pericyte-coated, significantly fewer than in controls (48±16%; p<0.001). Expression of ANGPT1 and 2 was significantly higher in BM vessel walls in GD samples than in controls (7.2 and 13.2 fold higher, respectively), whereas VEGF expression was 20-fold lower in GD (p<0.05 for all parameters). MVD values correlated with BM cellularity, particularly in GC rich areas. Gaucher cells stain moderately for ANGPT1 and 2, and variably for VEGF.

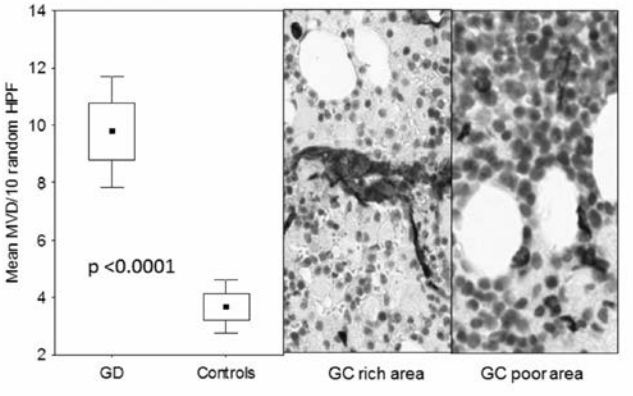

Figure 1.

Summary/Conclusions: Bone marrow in patients with GD type 1 demonstrates abnormal angiogenesis, with defective pericyte coating, and skewed VEGF/angiopoietin balance, which is presumably related to local accumulation of Gaucher cells.

Platelets disorders

E1412

POINT OF CARE PLATELET REACTIVITY TESTING AND DOSE-TITRATION IN A DOUBLE-BLIND STUDY OF PRASUGREL IN CHILDREN WITH SICKLE CELL ANAEMIA

JA Jakubowski[1,*], CC Hoppe[2], C Zhou[1], BE Smith[1], PB Brown[1], LE Heath[1], B Inusa[3], DC Rees[4], MM Heeney[5], J Kanter[6]
[1]Eli Lilly and Company, Indianapolis, [2]Children's Hospital Oakland Research Institute, Oakland, United States, [3]Paediatric Haematology, Evelina Children Hospital, [4]Paediatric Hematology, King's College Hospital, London, United Kingdom, [5]Dana-Farber / Boston Children's Cancer and Blood Disorders Center, Boston, [6]Sickle Cell Research, Medical University of South Carolina, South Carolina, United States

Background: Platelet activation and aggregation induced by release of ADP from haemolysed sickle erythrocytes may contribute to vaso-occlusion and ischaemic pain, a hallmark of sickle cell anaemia (SCA). Anti-platelet agents such as prasugrel (Pras) that target the P2Y12 ADP receptor may thus provide benefit. However, the potential increase in haemorrhagic stroke risk with high levels of platelet inhibition in SCA makes dose titration imperative. Previous studies suggested that a PRU (P2Y12 reaction unit, a measure of ADP-induced platelet aggregation) range of 231-136 would be appropriate to determine the risk / benefit ratio of prasugrel in SCA, and could be achieved by individual dose adjustment based on platelet testing - a challenge in a double blind study.
Aims: Attenuation of platelet reactivity to a pre-defined target range in patients with SCA, by dose titration using point-of-care platelet testing.
Methods: The DOVE study was a Phase 3 double-blind, placebo (Pbo) controlled study of Pras in pediatric patients with SCA. Treatment assignment was balanced according to hydroxyurea (HU) use, age group and country. Baseline PRU values were determined by Verify*Now*® P2Y12 (VN-P2Y12), a point-of-care platelet aggregation test which reports both PRU and% platelet inhibition (% inhibition) values. Over the subsequent 6 weeks patients returned for repeat VN-P2Y12 assessment and, if necessary doses were adjusted to titrate patients into a PRU range of 231-136, with a lower PRU value indicating greater platelet inhibition. The final dose was fixed for the remainder of the study, adjusted only if deemed necessary by changes in body weight. The majority of patients returned after 9 months for a final VN-P2Y12 measurement. All VN-P2Y12 data were encrypted and entered into an interactive voice response system which instructed the investigator to maintain or adjust the current dose for patients in both the Pras and Pbo (mock titration) arms, thus maintaining the blinding of the study.

Table 1.

	PRU LS Mean (SE)			% Inhibition LS Mean (SE)		
	Prasugrel	Placebo	p-value	Prasugrel	Placebo	p-value
Baseline	276.3 (3.8)	276.1 (3.8)	0.97	2.8 (0.4)	2.0 (0.4)	0.17
On final dose	203.1 (4.2)	275.5 (4.2)	<0.001	21.9 (1.0)	2.1 (1.0)	<0.001
9 Months	214.3 (5.3)	281.2 (5.4)	<0.001	19.4 (1.3)	1.3 (1.3)	<0.001

LS=least square; LS mean and p-values from ANOVA analysis with treatment, HU and age group as factors.

Results: 170 patients were assigned to the treatment arm and received Pras; of these, 160 were titrated to a final dose. Baseline (predose) PRU values were similar for both Pras and Pbo groups (Table). After titration to the final Pras dose, PRU values dropped to 203 (from 276 at baseline) and remained low through 9 months. In contrast and as expected, PRU values in the Pbo group did not change after mock titration or at 9 months. Baseline VNP2Y12-reported% inhibition levels were low in both Pras (2.8%) and Pbo (2%) groups. Mean% inhibition in the Pras group increased to approximately 22% after titration to the final dose and was maintained at this approximate level (19.4%) through 9 months of treatment. In the Pbo group, there was no change from baseline in% inhibition at either timepoint.
Summary/Conclusions: Although primary efficacy endpoints were not met in the DOVE study, the results of platelet function studies indicate that in the majority of patients, Pras at the final dose administered effectively reduced ADP-mediated platelet reactivity with a corresponding increase in platelet inhibition. This was achieved using encrypted point-of-care testing. Additionally, results demonstrated that safety was not compromised on the treatment arm, raising the question as to whether higher levels of platelet inhibition might provide a more optimal benefit/risk ratio.

E1413

THE STUDY OF GENETIC MUTATIONS THAT INFLUENCES THROMBOPOIESIS IN PATIENTS WITH NEOPLASMS: THE ROLES OF ANKRD26, RUNX-1 AND ETV6

S Ferrari*, F Vianello, AM Lombardi, I Cortella, I Barzon, F Fabris
Department of Medicine, University of Padua, Padua, Italy

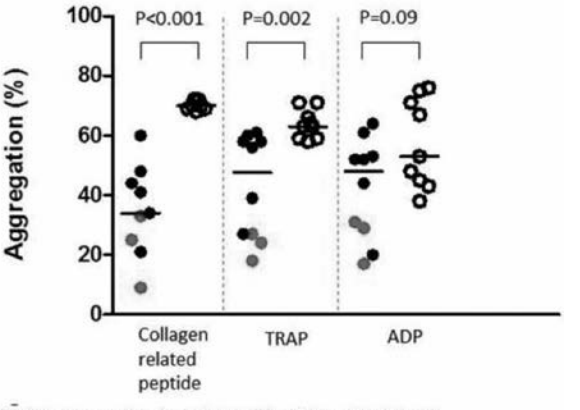
Background: The phenotype of inherited thrombocytopenia is characterized by different sizes of platelets, different degrees of thrombocytopenia, the presence or absence of platelet function defects, and an association with syndromes involving other cell lines or other organ functions. In particular, some forms of inherited thrombocytopenia secondary to 5' UTR of *ANKRD26, RUNX-1*, and *ETV6* mutations are associated with neoplasms of haematological or non-haematological type.
Aims: Study of genetic mutations in *ANKRD26*, *RUNX*-1 and *ETV6* that influences thrombopoiesis in patients with myelodysplasia (MDS).
Methods: We study the presence of mutations in the 5'UTR of the *ANKRD26, RUNX-1*, and *ETV6* gene in the following cohorts of patients: a) 27 patients affected by sporadic and familial thrombocytopenia and normal platelet volumes, b) 12 patients with myelodysplasia and normal platelet count, c) 9 patients with myelodysplasia with prevalent thrombocytopenia.
Results: In the cohort of the studied patients we found mutations in the 5'UTR of the *ANKRD26*, *RUNX-1* and *ETV6* genes only in 6 patients with thrombocytopenia and MDS of the group c. The mutations found are 5. One deletion in exon 1 of the *ANKRD26* gene (c.60_62del AGA), three mutations in the *RUNX-1* gene: a missense mutation with a modification in the amino acid polarity in exon 4 (c.76C>G), a deletion (c.934del A) and an insertion (c.1214_1215insTG), respectively, in exon 8 and 9. Finally, a deletion in intron 1 of the *ETV6* gene (c.28+192delC). All the mutations found were not present in public databases.
Summary/Conclusions: The preliminary data demonstrated that mutations in the *ANKRD26*, *RUNX-1* and *ETV6* genes were present in patients with MDS and prevalent thrombocytopenia. Even if the involvement of these genes in megacaryopoiesis is well known, the exact mechanism responsible for thrombocytopenia is not yet clear. As the pathology is extremely rare, it is difficult to find data for genotype-phenotype analyses. However we hypothesized that these mutations are responsible for the low platelet counts in patients with myelodysplasia. Greater knowledge about the pathogenesis of these forms of thrombocytopenia will facilitate finding new therapies for them. This will have important clinical implications since platelet transfusion is the only therapeutic option for these patients. Defining the molecular mechanism of thrombocytopenia in these patients could constitute the first step on the path leading to new therapeutic possibilities with TPO mimetics as has been demonstrated in hereditary form of thrombocytopenia.

E1414

DECREASED PLATELET FUNCTION IN ACUTE MYELOID LEUKAEMIA AND MYELODYSPLASIA DETECTED BY A NEW TEST OF PLATELET AGGREGATION OF VIABLE CELLS USING FLOW CYTOMETRY

PJ Vinholt[1,*], H Frederiksen[2], C Nielsen[3]
[1]Department of Clinical Biochemistry and Pharmacology, [2]Department of Haematology, [3]Department of Clinical Immunology, Odense University Hospital, Odense, Denmark

Background: It is unknown why only some thrombocytopenic patients bleed despite equally low platelet counts. Platelet function is likely to be of importance, but is difficult to access as results from existing platelet aggregation methods have major methodological limitations at low platelet count.
Aims: The aim was to establish a method for measuring platelet aggregation of viable platelets in thrombocytopenic patients. Secondly, we investigated platelet function in thrombocytopenic patients with acute myeloid leukaemia (AML) or myelodysplasia (MDS).
Methods: Washed platelets were split in two and differently labelled with fluorescent dye (Calcein AM and Calcein Violet) and added to AB-positive donor plasma in a 1.5 mL tube. Agonist was added (collagen-related peptide, adenosine diphosphate (ADP) or thrombin-receptor activator peptide-6 (TRAP)), samples were shaken for 5 min and subsequently analyzed using flow cytometry. Double-colored events in stimulated samples were defined as platelet aggregates. Effect of addition of platelet inhibitors (abciximab, ticagrelor or vorapaxar) was determined. Using flow cytometry, platelet activation after addition of agonist to whole blood was evaluated by fl ow cytometry using antibodies to detect alpha-granule release (P-selectin(CD62p)), dense-granule release (CD63) and activated fibrinogen receptor (PAC1 binding), respectively. Surface receptor levels were quantified using antibodies against GPIIb/IIIa (CD41/CD61), GPIb(CD42b)/GPIX(CD42a)), and CD49b. Participants were ≥18 years, healthy individuals or patients with AML or MDS. Participants who received platelet inhibitors within two weeks, platelet transfusions, or major surgery within one week were excluded. Informed consent was obtained. Comparisons were made with Wilcoxon ranksum test.
Results: Presence of aggregates in unstimulated samples was low (≤4%). The intra-assay coefficient of variation was 1-3%. Increasing inhibition of platelet aggregation at increasing dose of platelet inhibitors was observed. Enrolled were ten patients (n=8 AML/n=2 MDS) and nine healthy controls with platelet count ranging 6-47 x 10^9/L *versus* 145-337 x 10^9/L, respectively. The inter-individual variation among healthy persons were low (Figure 1). Collagen-related peptide and TRAP-induced aggregation were lower for patients compared with controls, while no difference in ADP-induced aggregation was found. Three patients reported bleeding episodes within the past one month and comprised three out of four persons with platelet aggregation below 34% for any agonist. No difference was observed in platelet count in patients with *versus* without bleeding episodes: 23 x10^9/L (12-24 x10^9/L) *versus* 25 x10^9/L (6-47 x10^9/L), p=0.51. Platelet activation was lower for patients *versus* controls for all agonists. There was a strong correlation between results from the platelet activation method and platelet aggregation method e.g. for PAC1-binding *versus* collagen-related peptide induced aggregation, r=0.96, p<0.001. No difference in expression of platelet surface receptor levels was found.



Platelet aggregation in patients with AML or MDS and platelet count <10 x10^9/L (full circles) compared with healthy individuals (open circles). Red circles represent patients with a history of bleeding within the past month. Horizontal lines indicate the median aggregation in each group.

Figure 1.

Summary/Conclusions: Based on the presented method for testing platelet aggregation of viable cells, our study shows that low platelet aggregation by the method identifies thrombocytopenic patients with bleeding problems among AML/MDS patients with thrombocytopenia. This platelet aggregation method may be useful for providing indications for prophylactic platelet transfusions or for evaluating indication of platelet inhibitor therapy in thrombocytopenic individuals. Further, it may facilitate the important distinction between inherited thrombocytopenia from immune thrombocytopenia.

E1415

SEASONAL VARIATIONS OF PRIMARY IMMUNE THROMBOCYTOPENIA INCIDENCE IN ADULTS

G Moulis[1,2,3,*], S Guénin[4], N Limal[4], M Michel[4], P Bierling[5], B Godeau[4], M Mahévas[4]
[1]Internal Medicine, Toulouse University Hospital, [2]UMR 1027, INSERM, [3]CIC 1436, Toulouse University Hospital, Toulouse, [4]Internal Medicine, [5]EFS, CHU Henri Mondor, Créteil, France

Background: Seasonal variations of primary immune thrombocytopenia (ITP) incidence have been suggested in cohorts of childhood ITP. The existence of such variations is not well known in adult ITP.
Aims: The aims of this study were to assess the variations of primary ITP incidence in a clinical cohort of adult patients and to detect differences in seasonal patterns about the outcome of patients, differentiating ITPs lasting less than 3 months (defined by complete remission before 3 months: stable normal platelet count without any bleeding, without any exposure to treatment active on ITP) and ITPs lasting more than 3 months (*i.e.* persistent and chronic ITPs).
Methods: We conducted a retrospective study in the patient database of the French National Referral Center for Adult Autoimmune Cytopenias in Créteil, France. ITP was defined in accordance with international guidelines. We restricted the population to adult patients (aged ≥15 years) with primary ITP whose onset occurred between 1990 and 2014. ITP onset was defined by the date of first abnormal platelet count (<100 x 10^9/L) in patients with previous normal platelet count. Demographics data (age and gender), platelet count at ITP onset, bleeding score excluding the age at ITP onset, first line treatment and ITP activity at 3 months were also extracted from the database. We, then, calculated the proportion of patients with ITP symptoms onset by calendar month, with their 95% confidence intervals.
Results: Out of 663 primary ITP patients included in the study, 127 (19.1%) were excluded due to missing record of calendar month of first abnormal

platelet count. Median age was 40.9 years (range: 15.0-94.2), and 358 (66.8%) were females. Median platelet count at ITP onset was 14.0x10^9/L and 131 (26.2%) patients had bleeding signs. Median Khellaf's bleeding score excluding the age was 3 (range: 0-36). Out of these 536 patients, 321 (59.9%) became persistent or chronic (lasted more than 3 months) and 184 (34.3%) lasted less than 3 months (31 patients with missing value for this data). In regards to first-line treatment, 452 (84.3%) were treated by corticosteroids and 193 (36.0%) were exposed to with IVIg. Overall, there was a significantly higher proportion of patients with ITP onset in January/February than in August (nadir). Variations were marked in ITPs lasting less than 3 months. In this population, two smaller peaks of incidence were also observed: in June and in October. By contrast, there was no significant difference of ITP incidence by calendar month in ITPs that became persistent or chronic.

Summary/Conclusions: This study tends to confirm seasonal variations of ITP incidence with peak in winter and nadir in August in adults, as suggested by a previous population-based study in France. This pattern corresponds to influenza outbreak in France. The two smaller peaks (in June and in October) observed in ITP lasting less than 3 months are superimposable to enterovirus outbreaks in France. Both influenza and enterovirus have been associated with ITP occurrence in children. Moreover, vaccine against influenza tended to be protective against ITP onset in adults in a recent case-control study in France. In conclusion, this study suggests that ITP lasting less than 3 months in adults may be timely linked with major viral outbreaks in France, unlike persistent and chronic ITP. Further prospective epidemiological and microbiological studies are needed to confirm this observation.

E1416

SAFETY AND EFFICACY OF LONG-TERM OPEN-LABEL DOSING OF SUBCUTANEOUS (SC) ROMIPLOSTIM IN CHILDREN WITH IMMUNE THROMBOCYTOPENIA (ITP)

M Tarantino[1,*], J Bussel[2], V Blanchette[3], J Despotovic[4], C Bennett[5], A Raj[6], B Williams[7], D Beam[8], J Morales[9], M Rose[10], X Wang[11], M Eisen[11]
[1]The Bleeding and Clotting Disorders Institute, Peoria, [2]Department of Pediatrics, Division of Hematology, Weill Medical College of Cornell University, New York, United States, [3]Hospital for Sick Children, Toronto, Canada, [4]Texas Children's Hematology Center, Houston, [5]Emory University, Atlanta, [6]Pediatric Blood and Cancer Disorders Clinic, Louisville, United States, [7]Lady Cilento Children's Hospital, South Brisbane, Australia, [8]Cook Childrens Medical Center, Forth Worth, [9]Louisiana State University Health Sciences Center, New Orleans, [10]Nationwide Children's Hospital and The Ohio State University College of Medicine, Columbus, [11]Amgen Inc., Thousand Oaks, United States

Background: Pediatric patients with chronic immune thrombocytopenia (ITP) that completed the romiplostim phase 1/2 or phase 3 study could enroll in this open-label long-term extension study.
Aims: To examine the long-term effects of romiplostim in children with chronic ITP.
Methods: All patients received subcutaneous romiplostim once weekly. The initial dose was the final dose from the parent study or 1 µg/kg (for patients previously receiving placebo or that had not received romiplostim for >24 weeks), adjusted weekly from 1-10 µg/kg to target platelet counts of 50-200×10^9/L.
Results: A total of 66 patients (parent study: phase 1/2, n=12; phase 3, n=54) entered the extension study; 1 patient withdrew consent before treatment. At baseline, median (min-max) age was 11 (3–18) years; 56% were female; 61% were white, 14% African American, and 14% Hispanic/Latino; 9.1% had prior splenectomy. Median (min-max) treatment duration was 57.9 (1–269) weeks. Median (range) average weekly romiplostim dose was 5.5 (0.1–10.0) µg/kg. Thirteen patients discontinued treatment: consent withdrawn (n=6), noncompliance (n=2), administrative decision (n=2), nonresponse (n=2), and per protocol (n=1). For 15 patients (23%), the first study week was the first week they were receiving romiplostim (ie, they received placebo in the parent study). Fifty-six (86%) patients (or caregivers) self-administered romiplostim. Twenty-one (32%) patients received rescue medications on 63 occasions (for low platelet counts [n=35], bleeding/bruising [17], pre- or post-procedure [9], and other [2]); treatments included IVIg (n=10), prednisone (9), aminocaproic acid (3), tranexamic acid (2), methylprednisolone (2), and platelet transfusion (1). Patients required rescue treatment during the first 3 months (27/63 instances), >3–6 months (9), >6–9 months (6), >9–12 months (7), and after 1 year (14) in the extension study. Five patients who previously received placebo received rescue medication in this extension, mostly during the first 3 months (10/14 instances). Three patients achieved remission (platelet counts ≥50×10^9/L for 24 weeks with no ITP treatments): 1) A 9-year-old boy with ITP for 8 years; after 4 years of romiplostim, he entered remission for the last 2 years as of this datacut; 2) An 11-year-old boy with ITP for 6 years; after 3 years of romiplostim, he entered remission for the last year; and 3) A 17-year-old girl with ITP for 8 years; after 6 years of romiplostim, she entered remission for the last 44 weeks of the study. Thirty-nine serious AEs occurred in 14 patients, including pyrexia (n=3), epistaxis (n=2), and thrombocytopenia (n=2); 3 were deemed treatment-related (anemia, epistaxis, and thrombocytopenia), and none led to discontinuation of romiplostim. Five patients had life-threatening AEs, including thrombocytopenia (n=2) and infection, decreased platelet counts, and subcutaneous abscess (n=1 each); none were fatal or deemed treatment-related. Bleeding AEs occurred in 47 patients; 3 were deemed treatment-related by the investigator (gingival bleeding, petechiae, and epistaxis). No thrombotic events were reported. There were no peripheral blood abnormalities suggestive of malignancy to warrant a bone marrow examination in any patient. Anti-romiplostim neutralizing antibodies were found in one patient at end of study after 50 weeks. This patient received rescue medications for much of the study.

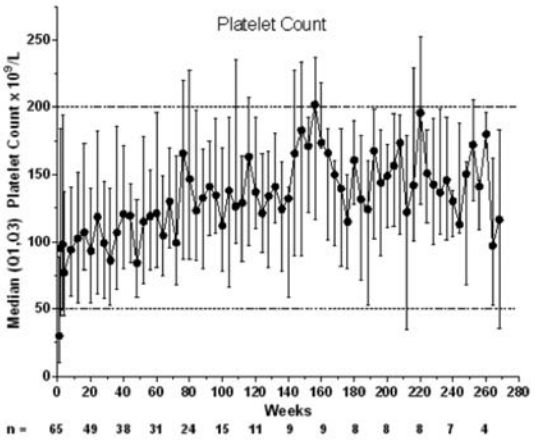


Figure 1.

Summary/Conclusions: In this ongoing open-label extension study of children with chronic ITP, romiplostim for ≤5.2 years maintained platelet counts with a safety profile similar to that seen in past studies.

E1417

SAFETY AND EFFICACY/EFFECTIVENESS OF SECOND-LINE TREATMENTS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA: A SYSTEMATIC REVIEW OF THE LITERATURE

K Cetin[1], F Callaghan[2], J Fryzek[3], L Bylsma[3], C Bezold[3], B Mehta[4,*]
[1]Center for Observational Research, Amgen Inc, Cambridge, [2]Center for Observational Research, Amgen Inc, San Francisco, [3]EpidStat Institute, Ann Arbor, [4]Development, Amgen Inc, Thousand Oaks, United States

Background: Immune thrombocytopenia (ITP) is a rare disorder characterized by low platelet counts and an increased tendency to bleed. Typical first-line therapies include corticosteroids, intravenous immunoglobulin, and anti-D. Patients who fail initial treatment or relapse may require second-line treatment, yet definitive guidelines in this setting are lacking, presumably because of a paucity of relevant rigorous clinical research.
Aims: To systematically review studies evaluating the safety and efficacy/effectiveness of therapies used to treat ITP in the 2nd-line setting (splenectomy, azathioprine, cyclophosphamide, cyclosporine A, danazol, dapsone, eltrombopag, mycophenolate mofetil, rituximab, romiplostim, and vinca alkaloids), with a focus on randomized controlled trials (RCTs).
Methods: Using comprehensive search strings, Cochrane Central Register of Controlled Trials, the Cochrane Database of Systematic Reviews, PubMed, EMBASE, and clinicaltrials.gov were searched with no time or geographic constraints. Studies in which these agents were used as first-line therapy; with<20 patients; in populations of children, pregnant women, or patients with secondary thrombocytopenia; or not published in English were excluded. Studies were reviewed for several safety and efficacy endpoints. Twelve prospective, randomized, placebo- or standard-of-care (SOC)-controlled studies were further evaluated given their comparable study designs and levels of evidence provided. Outcomes common to multiple studies (bleeding, overall and complete platelet response, and use of rescue therapies) were summarized and indirectly compared using forest plots of calculated risk or response ratios for each outcome from each study.
Results: Final abstraction was performed on 165 articles meeting inclusion criteria. The majority of studies were observational in nature and none represented interventional studies providing head-to-head comparisons of the second-line therapies. Twelve prospective, randomized, placebo- or SOC-controlled studies evaluated the efficacy and safety of either one of two thrombopoietin-receptor (TPO-R) agonists (romiplostim [n=5] and eltrombopag [n=5]) or rituximab (n=2). Although aspects of study design, outcome definitions, and specific subject inclusion/exclusion criteria varied across the studies, patients receiving romiplostim, eltrombopag, or rituximab tended to demonstrate a reduced risk of bleeding and use of rescue therapy and an increased likelihood of platelet response compared with patients receiving either placebo or SOC almost without exception. These risk/response differences tended to be greatest in trials involving a TPO-R agonist (e.g., the range of response ratios for overall platelet response was 1.81-34.28 for romiplostim *versus* placebo/SOC; 1.40-14.00 for eltrombopag *versus* placebo; and 0.86-1.09 for rituximab *versus* placebo).

Summary/Conclusions: Data from rigorous RCTs are still currently limited for most second-line ITP treatment options. Twelve prospective, randomized placebo- or SOC-controlled studies were identified but covered only three (eltrombopag, rituximab, and romiplostim) of the several second-line medical treatment options available. These studies provide high-quality evidence regarding the efficacy and safety of these three therapies and, in the absence of head-to-head data, offer insights regarding how they compare to one another in terms of clinical outcomes.

E1418

THYROID DYSFUNCTION AND ITS RESPONSES TO TREATMENT ARE ASSOCIATED WITH THROMBOCYTOPENIA IN CHRONIC HEPATITIS B-INFECTED SUBJECTS WITH COMPENSATORY CIRRHOSIS

J Xue, JM Zhang, XL Zhu, LP Xu, Q Jiang, J Lu, H Jiang, HX Fu, KY Liu, XJ Huang, XH Zhang*
Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Many reports have demonstrated a significant relationship between thrombocytopenia and thyroid dysfunction and its treatment. However, the pathogenetic link between these conditions has not been clarified. Autoimmune theory has been well-supported hypothesis. Our previous studies have demonstrated that chronic hepatitis B (CHB) withcompensatory cirrhosis accompanied by thrombocytopenia is an important research subject. Additionally, we have observed many casesof hypothyroidism in CHBpatients with thrombocytopenia in our clinicalstudies. However, no information is available regarding the association between thyroiddysfunction and thrombocytopenia in CHBpatients with compensatory cirrhosis.
Aims: We investigated whether thrombocytopenia in patients diagnosed with CHB withcompensatory cirrhosis is related to thyroid dysfunction, and further explored the treatment and the platelet response to treatment.
Methods: Thrombocytopenia was defined as a platelet count of $<100\times10^9$/L. We divided all patients into two groups based onplatelet counts of $<50\times10^9$/L and $>50\times10^9$/L. The prevalence of thyroid dysfunction, including normal thyroid function, overt or subclinical hyperthyroidism, and overt or subclinical hypothyroidismwas determined in each group. Thyroid function and liver function were detected periodically. During treatment, platelet counts were assessed weekly during the first month and then every 4 weeks for one year. Treatment of thyroid dysfunction and treatment responses were also recorded.
Results: A total of 261 patients were enrolled in this observational study. Among the 30(11.49%) patients with abnormal serum TSH levels, there were 6 (2.29%) with hyperthyroidism, and 24 (9.20%)with hypothyroidism, and 60% were female. Patients with a platelet count $<50\times10^9$/L had a higher incidence of hypothyroidism, which developed in 11% of patients in group A (platelet count $<50\times10^9$/L) compared with 8.07% in group B (platelet count $>50\times10^9$/L) ($P<0.05$). Serum TSH was significantly higher but serum FT3,FT4,TT3, and TT4 were significantly lower in group A ($P<0.05$). We identified risk factors associated with platelet count before therapy. Logistic regression analysis showed that serum TSH, FT3, FT4,TT3 and TT4 levels were positively associated with the platelet count. We calculated the difference in platelet count from baseline for each time pointduring treatment. A greater change was exploredin group A than group B ($P<0.05$). In each group, the change in platelet count was higher in patients who received treatment for their thyroid condition ($P<0.05$).We further assessed factors influencing patients who had a platelet response compared with those who had no reponse. Highly significant variables associated with a platelet response, even in the multivariate analysis, included serum TSH, FT3, FT4, TT3 and TT4 levels.
Summary/Conclusions: This is the first studyto demonstratethat thyroid dysfunction, especially hypothyroidism, is common in patients with CHB accompanied by thrombocytopenia.Females are more likely to develop thyroid dysfunction. Thyroid function is associated with platelet counts. Additionally, a more dramaticplateletcountresponse was observed with administration of thyroid hormone therapy in patients with hypothyroidism, even in the multivariate analysis.It may provide a novel approach for thetreatment of thrombocytopenia in CHB patients with compensatory cirrhosis.

E1419

RITUXIMAB THERAPY AS PROPHYLAXIS AGAINST THROMBOTIC THROMBOCYTOPENIC PURPURA: COMPARISON OF STANDARD AND REDUCED DOSE REGIMENS

JP Westwood[1,*], D Ellis[1], S Mc Guckin[1], K Langley[2], V McDonald[3], M Thomas[1], M Scully[1]
[1]Department of Haematology, University College Hospital, [2]Haemostasis Research Unit, University College London, [3]Centre for Haemostasis and Thrombosis, St Thomas' Hospital, London, United Kingdom

Background: Acute antibody-mediated thrombotic thrombocytopenic purpura (TTP) is a thrombotic microangiopathy with high morbidity and mortality. Rituximab is highly effective when given as prophylaxis in patients at high risk of acute TTP relapse, but the ideal dosing regimen is unknown.
Aims: A retrospective cohort study across two centres was performed to compare outcomes between TTP patients given rituximab prophylaxis at standard dose ($375mg/m^2$) *vs* reduced dose (200mg), weekly for 4 weeks.
Methods: Patients had all previously had at least one acute TTP episode, and were deemed at high risk of TTP relapse based on ADAMTS13 activity dropping to ≤15%, having previously been documented in the normal range. Outcome measures included normalisation of ADAMTS13, subsequent relapse rate. Comparison was made of time to re-treatment for patients given standard dose *vs* reduced dose rituximab.
Results: Rituximab was given in 51 patient episodes, to 32 patients (24F, 8M); in 19 episodes (14 patients) this was re-treatment where patients had received rituximab prophylaxis on at least one prior occasion. In 47/51 (92%) episodes, patients had a median pre-prophylaxis reduction in ADAMTS13 level of ≤15%. Patients received standard dose rituximab in 24 episodes and reduced dose in 27 episodes. Normalisation of ADAMTS13 occurred in 48/51 (94%) patients. Over a median follow up of 14.5 months (range 9-133 months), there were only 2 subacute relapses, both occurring in the reduced dose group. Of the 29 patients requiring re-treatment, 12/29 (41.4%) had received standard dose, and 17/29 (58.6%) reduced dose, at a median 22.5 months (range 10-112 months) in the standard dose group, and 12 months (range 9-33 months) in the reduced dose group, p=0.1351.
Summary/Conclusions: Rituximab therapy is effective as prophylaxis normalising ADAMTS13 and preventing acute TTP relapses in patients with immune TTP. Standard dose rituximab prophylaxis may be associated with longer treatment free survival than reduced dose.

E1420

MODELING AND SIMULATION (M&S) SUPPORT ELTROMBOPAG (EPAG) DOSAGE ESCALATION BASED ON PLATELET COUNT FOR PEDIATRIC PATIENTS WITH PERSISTENT OR CHRONIC IMMUNE THROMBOCYTOPENIA (CITP)

J Grainger[1,*], N Sirachainan[2], MB Wire[3], V Aslanis[4], W Sallas[5], J Zhang[6], J Bussel[7]
[1]Royal Manchester Children's Hospital, Manchester, United Kingdom, [2]Ramathibodi Hospital, Bangkok, Thailand, [3]Chimerix, Durham, United States, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharmaceuticals Corporation, East Hanover, [6]PAREXEL International, Research Triangle Park, [7]Weill Cornell Medicine, New York, United States

Background: EPAG is approved for use in patients with persistent or cITP, chronic hepatitis C, and severe aplastic anemia. M&S supported EPAG dosing in adult populations (Gibiansky E et al. *J Clin Pharmacol* 2011; Hayes S et al. *J Clin Pharmacol* 2011; Wu K et al. *J Clin Ther* 2015; Zhang J et al. *Pharm Res* 2015).
Aims: To support initial EPAG doses and dose titration based on platelet count response in pediatric patients with cITP.
Methods: Plasma EPAG concentration and platelet count (PLTC) data collected in pediatric cITP patients in the PETIT & PETIT2 studies (Bussel JB et al. *Lancet Haematol* 2015; Grainger JD et al. *Lancet* 2015) were analyzed by nonlinear mixed-effects modeling. Patients received EPAG for ≥24 weeks. Doses were increased at 2-week intervals for PLTC<50 Gi/L, decreased for >200 Gi/L, and interrupted for >400 Gi/L. Serial pharmacokinetic (PK) samples were collected at Week 6 in PETIT. A single PK sample and PLTC were collected at all visits in both studies. A population PK (PPK) model was developed with PETIT data. Following successful external validation with data from PETIT2, data from both studies were combined to obtain final model parameter estimates. PLTC data were fitted alone using individual post-hoc PK parameter estimates. Simulations of PLTC for various starting doses and dose titration schedules were completed.
Results: The analyses included 168 patients (mean age 9.5 [1–17] years; weight 42.1 [11–135] kg; baseline PLTC 14 [1–38] Gi/L; 51% female; 20% East Asian; 6% splenectomized); 98% received prior ITP medication. Concurrent ITP medications were used at 17% of the PLTC assessments. PK was described by a 2-compartment model. Inter-individual variation (IIV) was included on apparent clearance (CL/F), intercompartmental exchange/clearance rate (Q/F), distribution volume of central compartment (Vc/F), and inter-occasion variability (IOV) on CL/F. Typical values were CL/F=0.612 L/h, Vc/F=2.74 L, Q/F=0.716 L, distribution volume of peripheral compartment (Vp/F)=21.5 L, and Ka=0.189/h. The final PPK/pharmacodynamics (PD) model was a 7-compartment life-span model, including 3 PK and 4 PD compartments. Zero-order production rate of platelet precursors (KIN) was fixed to the value from adult healthy volunteers (KIN=1.43 Gi/L/h). The increase in KIN due to EPAG was linearly related to plasma EPAG concentrations by the parameter SLOP (ie, linear coefficient of drug effect on KIN). SLOP, first-order maturation rate of platelet precursors (KOUT), and proportion of patients identified as responders (P1) were estimated; IIV was included on SLOP and KOUT. Typical PD parameter values were P1=0.96, SLOP=0.651 mL/μg in responders, and KOUT=0.0126/h, and increased with age. The average platelet half-life was 7 h. A majority of patients, as also seen in PETIT/PETIT2, required dose escalation to achieve target platelet response.
Summary/Conclusions: M&S supports eltrombopag starting doses and dose adjustments based on platelet counts in children with cITP. A majority of children

require dose escalation from eltrombopag starting doses to achieve platelet thresholds ≥50 Gi/L. Higher starting doses may need to be considered when clinically indicated such as in cases of severe bleeding or pending surgery. Studies NCT00908037/NCT01520909 were sponsored by GlaxoSmithKline; EPAG became an asset of Novartis AG as of March 2, 2015.

E1421

EXPRESSION OF GLUCOCORTICOID RECEPTOR ISOFORMS (A, B, Γ, AND P) IN ADULT EGYPTIAN PRIMARY IMMUNE THROMBOCYTOPENIA PATIENTS

M Eldefrawy[1,*], N A. M. Hamed[1], D Elneely[2], O Gallab[1], B Jepngetich[3]
[1]Hematology, [2]Clinical Pathology, Faculty of Medicine Alexandria, Alexandria, Egypt, [3]Hematology, Moi Teaching and Referral Hospital, Moi, Kenya

Background: Glucocorticoid (GC) resistance has been demonstrated in nearly 30% of primary immune thrombocytopenia (ITP) patients even managed with high dosages GC. The biological effects of GC are mainly mediated through activation of glucocorticoid receptors (GR). An insight into the molecular mechanisms underlying GC resistance is important to avoid GC treatment in patients contraindicated from steroid use.
Aims: We aimed at determining glucocorticoid receptor (GR) isoforms expression in adult ITP and its relation to glucocorticoid resistance.
Methods: Thirty three ITP patients from the Hematology unit, Alexandria Main University Hospital were the subject of the study. They were subdivided into two groups (sensitive and resistant) according to their response to 4 weeks GC treatment. 15 healthy volunteers of matched age were also included. Glucocorticoid Receptor α, β, γ and p gene expression were measured in cases and controls by real time Polymerase Chain Reaction. (QIAamp® RNA blood mini kit (cat no. 52304). Informed written consent was obtained from allpatients and the study was approved by theMedical Ethical Committee.
Results: The mean age value of glucocorticoids sensitive (GCS), glucocorticoid resistant (GCR) and control group was 33.4±11.6, 38.1±12.3 and 31.7±5.8 years respectively (F=1.496, p=0.235). Half of our female patients (n=14) were GC resistant while all the males (n=5) were GC sensitive. Statistically significant difference between GR alpha mRNA isoform and GRa/ GRβ ratio was detected between GC resistant and GC responsive group while GRp, GRγ and GRβ were insignificantly differed between groups. GRα is expressed in most human tissues and cell line. It functions as ligand-dependent transcription factors. There is a wide variability in median value of GRα between our GCS and GCR patients. The ratio of GRα/GRβ expression is critical to the glucocorticoid responsiveness of various cells. Higher ratios correlate with glucocorticoid sensitivity, while lower ratios correlate with glucocorticoid resistance. There was non-statistically significant correlation between GR α and age (r=-0.302, p= 0.087). GRα had a strong inverse correlation with GRβ and a significant direct correlation with GRγ and p. Fig. 1 shows ROC curve of different GR isoforms in predicting GC resistance in ITP. GRα/β ratio had the highest sensitivity (81.8%) and is the most accurate predictor of GC resistance (79.2%). GRγ had the highest specificity (86.7%). GRβ had the lowest sensitivity (9.1%) and the lowest specificity (26.7%).

GR isoform	Cases (n=33)		Test of significance
	Sensitive (n=19)	Resistant (n=14)	(p value)

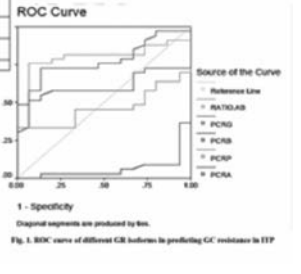

Fig. 1. ROC curve of different GR isoforms in predicting GC resistance in ITP

Figure 1.

Summary/Conclusions: In this study, we noted a statistical significant difference between GR alpha mRNA isoform and GRa/ GRβ ratio within ITP patients. GRa and GRa/ GRβ were higher among GC sensitive compared to GC resistant groups. GRα/β ratio had the highest sensitivity (81.8%) and is the most accurate predictor of GC resistance (79.2%). We concluded that the study of GRa and GRa/ GRβ ratio is recommended early in ITP assessment to avoid unnecessary glucocorticoids side effects during treatment.

E1422

ABNORMALITY OF CD8+ CD28- SUPPRESSOR T CELLS IN PRIMARY IMMUNE THROMBOCYTOPENIA

H Li[*], D Zhang, R Yang
Institute of Haematology and Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Primary immune thrombocytopenia (ITP) is an acquired disorder characterized by autoantibody-mediated platelet destruction and insufficient platelet production. Multiple factors have been implicated in ITP pathogenesis, including loss of immune tolerance. CD8+CD28- suppressor cells (Ts), which have been identified in recent years, play important roles in maintenance of peripheral immune tolerance. Thus Ts cells are involved in immune escape of tumor and pathogenesis of several autoimmune diseases. Ma et. al. found steroid treatment selectively increased Ts proportion in both the passive and active mice models of ITP, suggesting Ts may be involved in ITP. However, until now, the role of Ts cells in ITP etiology was not clear yet.
Aims: To evaluate whether the number and the regulatory functions of Ts were abnormal in ITP patients, and found the reasons for these defects.
Methods: A total of 90 active ITP patients, 21 ITP patients in remission and 93 age- and sex-matched healthy donors (HCs) were enrolled in this study. And (1) the proportion of CD8+CD28- Ts cell was detected by flow cytometric analysis (FACS). (2) The CD8+CD28-Ts, CD8+CD28+/CD4+ effector cells and CD4-CD8- cells (as antigen presenting cells, APCs) were sorted by MACS, and then mixed lymphocyte reaction and BrdU method were used for evaluating the inhibitory rate of Ts cells. Here, Transwell (TW) experiments were also performed to identify soluble cytokines or direct cell-contact was involved in immune regulation of Ts cells. (3) The sorted Ts and APC were co-cultured with PHA and IL-2, then after 48 hours, CD80, CD86, ILT3 and ILT4 expressions on CD14+ monocyte were analyzed by FACS. And the proliferation of APC were detected by BrdU corporation after 72 hours. (4) Peripheral blood mononuclear cells were activated by PHA and IL-2 for 24 hous, following ICOS, PD-1 expression on Ts cells surface and IL-10 expression in Ts cells (were reactivated by PMA, BFA and Ionomycin for final 4 hours) were examined by FACS.
Results: (1) The percent of Ts cells in peripheral blood from active ITP patients were lower than those of HCs, although Ts proportion seems elevated in patients with remission, there was no difference between ITP patients in remission and active ITP patients or HCs. (2) Ts cells both from HCs and ITP patients inhibited CD8+CD28+/CD4+ effector cells proliferation in quantity dependent manner. The inhibition effect of Ts on CD4+ effector cells at ratio 1:2 and inhibition effect of Ts on CD8+CD28+ effector cells at ratio 1:4 were significantly lower in ITP patients than that in the HCs. (3) Ts cells from HCs and ITP patients suppressed effector cells proliferation both in the presence and absence of a TW; In addition, the suppressive degree of Ts cell from HCs is greater in the absence of TW, while no difference was found between presence and absence of TW groups in ITP patients. Thus, the results suggested that both the soluble mediators and direct cell-contact were involved in suppressive function of Ts cells, and the cell-contact regulated ability of Ts cells form ITP patients may be have defect. (4) The ICOS expressions on Ts cell surface with or without activation were both decreased in ITP patients than that in HCs. However, the PD-1 and IL-10 expressions of Ts cells were not different between ITP patients and HCs. (5) Ts cell inhibited proliferation of APCs both in HCs and ITPs. However, inhibition rate will decreased in ITPs than that of HCs. Moreover, Ts from HCs could down-regulated CD80, up-regulated of ILT3 and ILT4 expressions on CD14+ monocytes, but these abilities were disappeared in Ts cells from ITP patients.
Summary/Conclusions: The down-regulation of number and inhibitory function of Ts cells in active patients indicated that Ts defect was involved in pathogenesis of ITP. In addition, decreased ICOS expression on Ts cell surface and loss the ability of regulating co-stimulator expression on APCs were partly illustrated the reasons for defect s of Ts.

E1423

FIRST OBSERVATION OF TUBB1 GENE MUTATIONS IN TURKISH PATIENTS WITH MACROTHROMBOCYTOPENIA

D Özkan[1,*], AA Waheed[2], A Kandilci[2], N Akar[3]
[1]Okan University, Vocational School of Health Service, Istanbul, [2]Gebze Technical University, Moleculer Biology and Genetic Department, Kocaeli, [3]Tobbetu Hospital, Pediatrics Department, Ankara, Turkey

Background: Frequency of the rare bleeding disorders (RBDs) in the general population ranges from 1:500.000 to 1:2 millions. In countries with a high rate of consanguineous marriages RBDs occur more frequently, representing a significant clinical and social problem. Macrothrombocytopenia (giant platelet syndrome) is an autosomal dominant disorder and previous studies have demonstrated that Myosin Heavy Chain 9 (MYH9) mutations lead to this disorder. The pathogenesis of almost the half of diseases related to MYH9 gene is unknown. So its diagnosis is not possible. The membrane skeleton and the link between actin filaments of skeleton and microtubules contain the normal platelet morphology. The defects occurred on these systems results with macrothrombocytopenia. The relation between macrothrombocytopenia and the defect occurred on microtubules that consisted by alpha and beta tubulin heterodimers can be explained by the defect occurred on Tubulin Beta 1 (TUBB1) gene. According to HGMD (Human Gene Mutation Database) data; 52 mutations are defined in MYH9 gene between 2004-2014. 17 of these mutations are defined in patients with giant thrombocyte syndrome(macrothrombocytopenia). Only 2

mutations are defined related to TUBB1 gene, so the researches done on relation between TUBB1 and macrothrombocytopenia is limited. The guiding indicators on the treatment of this disease can be achieved in case of defining the effects of TUBB1 mutations on megakaryocytes-microtubule organization, proplatelet formation and platelet morphology

Aims: In this study, we aimed to analyze TUBB1 gene at Turkish population with clinically diagnosed macrothrombocytopenia.

Methods: A written informed consent for genetic analysis was obtained from the patients. The patient blood was collected from various hematology clinics in Turkey. In this study, TUBB1 gene mutation analysis was performed by using the blood of patients diagnosed with macrothrombocytopenia following the DNA isolation. Then samples were sequenced using a DNA sequencer (Beckman Coulter, USA). Sequencing are evaluated using with FinchTV program.

Results: TUBB1 gene analysis of Turkish patients with macrothrombocytopenia revealed a novel heterozygous Cytosine to Timin nucleotide change at 821 at exon4 (p.T274M/ Threonin to Methionine), at a child and his father in the same family, 99 nucleotide ahead which is at nucleotid 920, there is a novel heterozygous Guanine to Adenin nucleotide change, this situation caused to change of Arginine aminoacid to Histidine aminoacid at 307 position (p.R307H) in protein. These changes are conserved at evolutionary process, so we can say that these transitions are novel mutations. We also identified a double base pair substitution at nucleotide positions 130-131 at exon 2,this transition encodes the Q43P (p.Gly43Pro, p.Gly43His) mutant form of the protein. (nucleotide and aminoacid numbering as per m RNA GenBank entry NM_758664).

Summary/Conclusions: In this study, we identified the first TUBB1 mutation; combined 821C>T and 920 G>A mutations in a family and these mutations are not defined previously in Human Gene Mutation Database (HGMD). And Q43P single nucleotide polymorphism is defined firstly at Turkish population, so they are very important findings in terms of explaining the relationship of macrothrombocytopenia and TUBB1 gene.

Funding: This research is financially supported by Starting R&D Projects Funding Program (3001) of The Scientific and Technological Research Council of Turkey (TUBITAK)

E1424

PLATELET INCREASING STRATEGIES IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA REQUIRING LONG-TERM ANTITHROMBOTIC PROPHYLAXIS

V De Stefano*, A Ciminello, T Za, S Betti, F Bartolomei, E Rossi
Institute of Hematology, Catholic University, Rome, Italy

Background: As in the general population, patients with immune thrombocytopenic purpura (ITP) can develop pathologies requiring long-term treatment with anticoagulant or antiplatelet agents. Challenging situations in this setting are antithrombotic prophylaxis in patients with atrial fibrillation (AF), artery stenosis, previous cardiac or vascular surgery, percutaneous transluminal coronary angioplasty (PTCA) with or without stenting, arterial or venous thrombosis. Concomitant use of platelet increasing treatment is mandatory for acceptable safety.

Aims: To summarize a monocenter experience in the management of ITP patients requiring long-term antithrombotic treatment and concomitant platelet increasing treatment.

Methods: We analysed the medical records of 108 ITP patients referred to our Center since 2000 to 2015; we identified 18 patients with risk situations making necessary platelet increasing treatments (M/F 11/7, median age at the treatment 52 yrs, range 47-90). Antithrombotic treatments were categorized as vitamin K-antagonists (VKA), direct oral anticoagulants (DOACs), low molecular weight heparin (LMWH), antiplatelet agents (aspirin, clopidogrel, indobufene). Platelet increasing treatments were categorized as prednisone (PDN), high-dose dexamethasone (DEX), high-dose immunoglobulins (HD-IG), thrombopoietin receptor agonists (TPO-RA: eltrombopag ETP, romiplostim RPL). A platelet count >100 x10^9/L or >30 x10^9/L in at least 4 consecutive weeks defined complete response (CR) or partial response (PR). Antithrombotic treatments were started at a platelet count higher than 50 x10^9/L.

Results: All patients had previously received at least one line of treatment (one line=4, two lines=7, three lines=4, >three lines=3); five patients had had splenectomy. Four patients had AF and received AVK (n=2), DOACs (n=1), LMWH (n=1); two had carotid stenosis and received aspirin; one underwent aortic valve replacement and received after surgery AVK and then aspirin; one underwent angioplasty of popliteal aspirin plus clopidogrel; one patient had coronary bypass and received indobufene; three patients had coronary stenting and received AVK (n=1) and aspirin plus clopidogrel (n=2); four patients had deep venous thrombosis of the legs and received LMWH for 6 to12 months; two patients had caval vein and portal vein thrombosis, respectively, and received VKA; one patient had retinal vein thrombosis and received LMWH. The median platelet count before the platelet increasing treatment was 46 x10^9/L (range 13-67). Twelve patients received TPO-RA (ETP=10; RPL=2), 3 patients received PDN, 2 patients received DEX, and one received HD-IG and PDN. Nine patients receiving TPO-RA achieved CR, and three PR (62, 91, and 99 x10^9/L); on the other hand four patients receiving steroids achieved CR, and one PR (88 x10^9/L). The remaining patient with caval vein thrombosis had no response after HD-IG and PDN and a caval filter was placed. All the other patients received antithrombotic treatment at therapeutic doses. No thrombotic or bleeding event was recorded after starting antithrombotic treatment together with a platelet increasing treatment.

Summary/Conclusions: Antithrombotic treatments can be given safely in patients with ITP after having obtained an increased platelet count. TPO-RA and steroids are both effective as platelet increasing strategies, but possible long-term side effects due to prolonged steroid treatment should induce caution.

E1425

THE ROLE OF ROMIPLOSTIM IN CHEMOTHERAPY-INDUCED THROMBOCYTOPENIA TREATMENT

L Entrena Ureña*, D Fernandez Jimenez, Z Mesa Morales, F Hernandez Mohedo, M Jurado Chacon
Haematology, Virgen de la Nieves Hospital, Granada, Spain

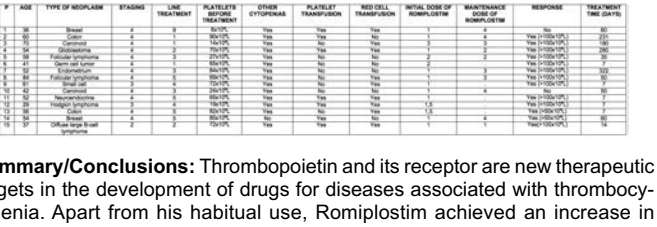
Background: The thrombocytopenia due to chemotherapy and/or marrow infiltration is a common complication in cancer patients. When it is moderate or severe, it can cause difficulties in the clinical management and the continuity of full-dose treatment. Romiplostim stimulates the thrombopoietin receptor inducing proliferation and differentiation of megakaryiocites, so administered at the right time, it could lead to a faster recovery or maintenance of platelet counts, avoiding delays and dose adjustments which may cause poor response to chemotherapy.

Aims: To evaluate safety and efficacy from Romiplostim in post-chemotherapy thrombocytopenia.

Methods: 15 patients with malignancies, 11 non-hematologic (2 breast cancer, 2 colon cancer, 2 carcinoid tumors, 1 glioblastoma multiforme, 1 neuroendocrine tumor, 1 endometrial cancer, 1 germ cell tumor and 1 small cell lung cancer) and 4 lymphomas (2 follicular lymphomas, 1 diffuse large B-cell lymphoma and 1 Hodgkin lymphoma) were treated with Romiplostim. The median age was 54 years (29-84) and the median baseline platelet counts was 69 x 10^9 L (8-90). All were receiving chemotherapy, 3 in first-line and the rest in second-line or later and 53% had marrow invasion. 14 patients develop cytopenia, requiring red cells transfusion (60%), platelet transfusion (47%) and the use of granulocyte-colony stimulating factor (G-CSF) (66%). The median starting dose of Romiplostim was 1 mcg/kg (1-3) and the median maintenance dose was 3 mcg/kg (1-4), for a median time of 50 days (7-322).

Results: 2 patients achieved no response, one of them requiring continued platelet transfusion support to carry on with chemotherapy. 87% of patients achieved response, in 11 cases with platelet counts of >100 x 10^9L. This allowed the use of full-dose chemotherapy and according to the initial scheme, except for dose adjustment in 2 cases due to platelet counts of<50 x 10^9L. Romiplostim treatment was well tolerated, with no treatment-related toxicities observed. No haemorrhagic events were reported over this period.

Table 1.



Summary/Conclusions: Thrombopoietin and its receptor are new therapeutic targets in the development of drugs for diseases associated with thrombocytopenia. Apart from his habitual use, Romiplostim achieved an increase in platelet counts in cancer patients, even after several treatment lines, making possible the use of full-dose chemotherapy and without delays, which could result in a therapeutic benefit. Despite the good results achieved, it would be necessary a larger number of patients to prove the thrombopoietin receptors agonists as equivalents to G-CSF and erythropoietin in post-chemotherapy cytopenias.

E1426

PRIMARY IMMUNE THROMBOCYTOPENIA TREATED WITH ROMIPLOSTIM IN ROUTINE CLINICAL PRACTICE: A RETROSPECTIVE STUDY FROM THE UNITED KINGDOM IMMUNE THROMBOCYTOPENIA REGISTRY

IU Doobaree[1], R Nandigam[1], L Mensah[2], A Seesaghur[2,*], H Patel[3], S Wetten[2], D Provan[1]
[1]Barts and The London School of Medicine and Dentistry, [2]Amgen Limited, London, [3]Amgen Limited, Cambridge, United Kingdom

Background: Immune Thrombocytopenia (ITP) is a rare disorder characterized by low platelet counts, leading to an increased tendency to bleed. Adult chronic ITP patients (pts) in Europe who are refractory to other treatments (e.g. corticosteroids, immunoglobulins) are eligible for treatment with romiplostim, a thrombopoietin-mimetic peptibody. Since ITP treatment-related decisions are principally dependent on clinical expertise or pt preference, observational studies can provide a better understanding of ITP treatment in routine practice.

Aims: To describe the demographic and clinical characteristics of patients with ITP receiving romiplostim in the UK, and to provide details on platelet counts, and the use and pattern of administration of romiplostim in routine clinical practice.
Methods: The United Kingdom Immune Thrombocytopenia (UKITP) Registry retrospectively and prospectively collects demographic and ITP-related clinical data on primary ITP pts enrolled by consent through a network of 68 centres throughout the UK. All adults (≥18yrs) within the UKITP registry who received at least one dose of romiplostim in routine clinical practice from October 2009 until 31st January 2015 were included in the analysis. Data described included demographic and clinical characteristics and ITP medications in patients since ITP diagnosis until end of follow-up and platelet counts before and after romiplostim initiation.
Results: At the time of data extraction from the registry (31st January 2015), a total of 1440 ITP pts were registered and 118 patients were treated with romiplostim. The median age at ITP diagnosis of the romiplostim cohort was 59 years (IQR: 36, 73). Members of the cohort had been diagnosed since 1980, with 50% diagnosed between 2010-14. The median time from ITP diagnosis to romiplostim initiation for those diagnosed between 2010-14 was 0.9 years (IQR: 0.3, 1.9). Almost three-quarters (73%) of patients initiated romiplostim ≥1 year from ITP diagnosis, and 12% of patients initiated romiplostim within 3 months of ITP diagnosis. There were some differences in baseline demographics between splenectomised and non-splenectomised patients (Table). Most patients (77%) had received at least three different ITP medications before romiplostim. The most common prior ITP treatments were corticosteroids (90%), intravenous immunoglobulin (IVIg) (77%), and rituximab (57%). The median maximum weekly dose of romiplostim was 3.1 mcg/kg (IQR: 2.0, 6.0). 82% of patients had 2 or fewer ITP medications after romiplostim initiation. The median platelet count within 2 weeks before romiplostim initiation was 17 x 10^9/L (IQR: 8, 41), which rose to 81 x 10^9/L (IQR: 31,155) within 1 month of romiplostim treatment and remained >50 x 10^9/L thereafter.

Table 1. Demographic and clinical characteristics of the romiplostim cohort overall, and by splenectomy status at romiplostim initiation.

	Total (N=118)		Splenectomised (N=26)		Non-Splenectomised (N=92)	
	N	%	N	%	N	%
Female	58	49.2%	15	57.7%	43	46.7%
Caucasian	96	81.4%	18	69.2%	78	84.8%
Age group at diagnosis						
18 to < 30	20	17.0%	4	15.4%	16	17.4%
30 to < 45	20	17.0%	5	19.2%	15	16.3%
45 to < 65	32	27.0%	11	42.3%	21	22.8%
≥ 65	46	39.0%	6	23.1%	40	43.5%
Time period of ITP diagnosis						
< 2010	59	50.0%	21	80.8%	38	41.3%
2010-14	59	50.0%	5	19.2%	54	58.7%
Year of romiplostim initiation						
<2011	6	5.1%	4	15.4%	2	2.2%
≥2011	112	94.9%	22	84.6%	90	97.8%
Disease phase (from ITP diagnosis to romiplostim initiation)						
Newly diagnosed ITP (< 3 months)	14	11.9%	1	3.8%	13	14.1%
Persistent ITP (3 months to < 1 year)	18	15.3%	1	3.8%	17	18.5%
Chronic ITP (≥ 1 year)	86	72.9%	24	92.3%	62	67.4%
< 3 prior therapies	27	22.9%	0	0%	27	29.3%
≥3 prior ITP therapies	91	77.1%	26	100.0%	65	70.7%

Summary/Conclusions: Limitations include potential selection bias into the registry and the small sample size and heterogeneous nature of the selected cohort. This retrospective analysis of secondary and tertiary care data from the UKITP registry provides a valuable insight in the real-world ITP pt population prescribed with romiplostim in the UK.

E1427

VARIATIONS IN CYTOKINE GENE POLYMORPHISM AMONG EGYPTIAN CHILDREN WITH PRIMARY IMMUNE THROMBOCYTOPENIA

G Mokhtar[1], N El-beblawy[1], A Adly[1], N Elbarbary[1,*], T Kamal[2], E Hasan[1]
[1]Hematology and Oncology Unit, Department of Pediatrics,Ain shams University, [2]Human Genetics Unit, Department of Pediatrics,Ain shams University, Cairo, Egypt

Background: Childhood immune thrombocytopenia (ITP) is a common pediatric hematologic disorder with an association between the cytokine gene polymorphisms affecting the cytokine production and autoimmune diseases at the stage of formation of disease and in the course of disease and their responses to treatment.
Aims: To evaluate the possible role of cytokine genes as well as of their polymorphisms in Childhood ITP, we analyzed the allelic and genotypic frequencies of different cytokine gene polymorphisms known to be related to autoimmunity and inflammation (IL-6−174, IL-10−1082, IL-17F, TNF- α−308, 1RaVNTR) in Egyptian patients with ITP and healthy control subjects. In addition we assessed the potential role of these polymorphisms in relation to phases of ITP, disease progression and response to different treatment modalities.
Methods: A total of 50 (22 males, 28 females) pediatric patients with primary ITP (20 newly diagnosed, 30 chronic) and 50 healthy controls age and sex matched were investigated via polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) analysis for cytokine gene polymorphism. Information on demographic characteristics, duration of disease, bleeding symptoms, life threatening bleeding, severity of bleeding, disease phases, type and response to different types of treatment were assessed.
Results: Compared to controls, all patients showed a higher frequency of IL-6−174 CC (P= 0.0001, OR=7.048, 95% CI=2.18-22.7), higher GA genotype of TNF-α(−308) (P= 0.001, OR=6.469, 95% CI=2.0-20.9), higher CC genotype of IL-17F (P= 0.0001,OR=55.545, 95% CI=14.4-213.2), higher GG of IL-10−1082 (P= 0.029, OR=3.6, 95% CI=1.08-12.18) and A1A2 genotype of IL- $1Ra^{VNTR}$ (P=0.039, OR=2.374, 95% CI=1.03-5.4). The frequency of IL-6 (-174) C allele (66% *vs* 49%, P=0.015), A allele of TNF-α−308 (24% *vs* 6%, P=0.001), A2 allele of IL-1RaVNTR (30% *vs* 14%, P=0.007), IL-17F C allele (89% vs.53%, P=0.0001) were significantly higher in all patients with ITP compared to controls. However, there was no significant difference revealed in allele distribution of IL-10(-1082) (p=0.67). IL-10 GA and IL-1Ra A1A1genotypes were higher among chronic patients (P=0.042, P=0.001 respectively) compared to newly diagnosed. There were no significant differences between different cytokine genotypes and the various clinical features including gender, age,disease duration, bleeding score, wet purpura, life threatening bleeding among newly diagnosed ITP patients (P>0.05). On the other hand, among chronic patients with ITP, 30% presented with mucosal bleeding (wet purpura) with highest prevalence among CC genotype (50%) followed by GC genotype (15.4%)and lastly GG genotype (0%) of IL-6 (P=0.048). Of note, the age of diagnosis of chronic patients was significantly higher than the newly diagnosed patients with ITP (2.84 *versus* 5.75 years(P=0.011). Best platelet response to steroid treatment was found among GC genotype of IL-6 (-174) and GG genotype of IL-10(-1082) in all patients with ITP with P value of (P=0.001 and P=0.002 respectively).
Summary/Conclusions: This suggests that previously mentioned cytokine gene polymorphisms possibly contribute to the susceptibility of acquisition of childhood ITP. Furthermore, GA genotype of IL-10 and A1A1 genotype of IL-1Ra polymorphisms are associated with increased risk of chronic ITP. IL-6 (-174) and IL-10 (-1082) genes might play a role in the effectiveness of steroid therapy among patients with ITP. However, the role of other genetic and environmental factors cannot be entirely ruled out.

E1428

LOW-DOSE RITUXIMAB AS PRE-EMPTIVE THERAPY IN MULTI-RELAPSING AND PRIMARY REFRACTORY PATIENTS WITH ACQUIRED IDIOPATHIC THROMBOTIC THROMBOCYTOPENIC PURPURA: A MONOCENTRIC RETROSPECTIVE STUDY

L Fianchi[1,*], M Criscuolo[1], S Lancellotti[2], MT Voso[3], A Giordano[1], N Piccirillo[1], R De Cristofaro[2], L Laurenti[1], G Zini[1], S Sica[1], G Leone[1], V De Stefano[1], L Pagano[1]
[1]Hematology, [2]Hemostasis Research Center, Fondazione Policlinico Universitario A.Gemelli/Catholic University, [3]Biomedicine and Prevention, Tor Vergata University, Rome, Italy

Background: Acquired idiopathic thrombotic thrombocytopenic purpura (TTP) is a life-threatening microangiopathic disorder for which therapeutic plasma exchange (TPE) and steroids represent the primary standard of care. However, a significant proportion of patients still experiences refractory disease, with exacerbations shortly after a perceived remission, or relapse.
Aims: The aim of this retrospective study was to evaluate the long-term efficacy of rituximab in preventing early death in refractory/exacerbated TTP and avoid relapse in "relapsing" patients.
Methods: We collected retrospectively clinical data on all patients with acquired TTP, admitted to our Hematology Department between January 2005 and December 2015. Forty-eight patients [37 female and 11 male; median age: 42.5 years (range 17-80)] were registered and treated for TTP in this period.
Results: Thirty-six patients were included at their first episode of TTP, while 12 patients had a history of multiple relapses [median 2 (range 2-4)], in the previous 10 years (1995-2004). Nine of 48 patients (19%) were diagnosed with TTP during pregnancy. Median platelet and hemoglobin values at diagnosis were 13x10^9/l (range 5-49) and 7,9 g/dl (4,2-10.1),respectively. ADAMTS-13 concentration was measured at diagnosis or at relapse in all patients and was<10% in all cases [median 0% (range 0-6)]. Anti-ADAMTS13 autoantibodies were present in all 23 patients tested. All 48 patients received TPE associated to 1mg/kg methyl-prednisolone as frontline therapy. After a median of 10 TPE (range 8-18), 32 patients (67%) (20/36 naïve, 12/12 at relapse) achieved disease remission [normal platelet counts, increase of ADAMTS-13 activity [median 78% (range 50-215)] and disappearance of inhibitors), while 16 (33%) resulted refractory or experienced exacerbation. Rituximab (RTX), at the dose of 375 mg/m^2 weekly for 4 weeks, was then added to TPE in 27 patients (56%), including 15/36 patients at their first TTP episode, who resulted refractory to TPE or showed exacerbation, and in the 12 relapsing patients, to prevent subsequent relapse. One patient with TTP exacerbation died early, prior to RTX start. Complete response to RTX was documented in 12 of 15 refractory patients, and in all 12 relapsing patients. Three patients died early, before the

second RTX dose, resulting into 8% overall 30-day mortality rate (4 patients). Mainteinance treatment with low dose RTX (100 mg every three months for 2 years) was then administered to 23 patients (12 relapsing and 11 refractory), while 1 patient refractory to TPE refused maintenance. At a median follow up of 34 months (range 1-87) from the first dose of maintenance none of the patients relapsed, and we did not observe any infectious complications. This resulted into a significant reduction in the incidence of relapses after RTX treatment (HR 4.26, 95% CI 1.511-12.05, p 0.0089). ADAMTS-13 activity was stable at >50% and inhibitors were not detected during follow-up visits, performed every three months in all 23 patients.
Summary/Conclusions: Our results suggest that pre-emptive treatment with low dose rituximab, is safe and effective to maintain remission also in patients with primary refractory TTP or with a history of multiple relapse.

E1429

THE INTERLEUKIN-17F (7488T/C) GENE POLYMORPHISM AND THE RISK OF CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA IN EGYPTIAN PATIENTS

S Yousry[1,*], G H.Shaheen[1], N Diaa[1], H N.Ellithy[2]
[1]Clinical Pathology, [2]Internal Medicine, Cairo University, Giza, Egypt

Background: Chronic primary immune thrombocytopenia (ITP) is an acquired autoimmune disease characterized by both reduced platelet counts and suppression of megakaryocyte and platelet development.IL-17F is a novel inflammatory cytokine and plays an important role in some autoimmune diseases by inducing the expression of multiple chemokines, cytokines, and adhesion molecules. IL-17F (7488T/C) polymorphism influence IL-17 expression and activity. Thus, considering the abnormal percentage of T helper 17 cells and the reported high levels of circulating IL-17F in patients with primary immune thrombocytopenia suggests a possible role of IL-17F (7488T/C) polymorphism in development of chronic ITP.
Aims: We investigated the role of IL17F polymorphism (7488T/C) on the susceptibility and clinical features of chronic ITP in Egyptian patients and if it may be linked to response to treatment with glucocorticoides.
Methods: A cohort of 107 patients with chronic ITP and 100 healthy control were enrolled in this case control study.Genotyping of IL17F (7488T/C) gene polymorphism was determined by the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique
Results: Chronic ITP patients had a significantly higher frequency of the IL-17F 7488-TT genotype compared to controls (84.1% *vs* 70.0%; Odd ratio= 2.269; P-Value=0.015).Furthermore the IL17F 7488 TT genotype was significantly associated with poor response to corticosteroid therapy; 11.1% were steroid responsive *vs* 88.9% were not responsive (P value= 0.001)
Summary/Conclusions: These findings suggest that the IL-17F 7488 T allele is significantly associated with the development of chronic ITP, suggesting a role for IL-17F polymorphism in the pathogenesis of chronic ITP.

Background: Eltrombopag is a a thrombopoietin receptor agonist (TPO-RA) approved for chronic primary immune thrombocytopenia (ITP) patients. However, ITP clinical practice in more than 65 years old patients could not reflect efficacy and safety of clinical trials results.
Aims: To evaluate the safety and efficacy results of eltrombopag in older than 65 years old patients in a real world setting
Methods: 81 equal or more than 65 years old primary ITP patients from 23 Spanish centers who had been treated with eltrombopag and included in the Spanish Eltrombopag ITP Registry were retrospectively evaluated.
Results: -The median age of the whole cohort was 75 (IQR, 69-79) years. Our case series included 16 newly-diagnosed, 16 persistent and 49 chronic primary ITP patients [78 (IQR, 73-81), 78 (IQR, 74-85) and 73 (IQR, 68-76) median years, respectively]. There were 51 women and 30 men. 23% of patients had a Charlson Comorbidity Index score of 2 or more at diagnosis. The median time from ITP diagnosis to eltrombopag initiation was 36 (IQR, 4-47) months [1(IQR,0-1.25), 4(IQR,6-8) and 57(IQR, 22-73) months, for each of the groups]. The median number of therapies before starting eltrombopag was 2 (IQR, 1-3), including rituximab (18%), romiplostim (17%) and splenectomy (10%). At the time of treatment start, 22 of 81 patients (27%) patients were receiving concomitant medication for primary ITP, mainly including corticosteroids (20%) or immunoglobulins (11%). 24 of 81 (30%) patients had bleeding symptomatology during the month preceding the starting eltrombopag. At eltrombopag initiation the median platelet count was 27 x 10^9/L (IQR, 7-26 x 10^9/L). 68 of 81 (84%) patients had a response (R) to eltrombopag treatment whilst 62 patients (76%) achieved a complete response (CR; platelet count >100 x 10^9/L). [R and CR rates were 94% and 87% in newly-diagnosed ITP; 75% and 68% in persistent ITP; 84% and 75% in chronic ITP]. Women reached 86% and 78% of R/CR while 80% and 73% of men. Responses were 91% in patients who received concomitant ITP medication at baseline and 64% in patients without other added treatments. The proportion of patients achieving a platelet response was quite similar regardless bleeding at starting eltrombopag (79% and 86% for patients with and without bleeding, respectively). Of the 82 patients, 20 (24.4%) experienced one or more adverse events during treatment with eltrombopag. Adverse events were mainly grade 1–2 in severity. The commonest adverse effects reported during eltrombopag treatment were diarrhea and headache. Eight percent of patients (7 of 82) had hepatobiliary laboratory abnormalities (HBLAs). On the other hand, we observed seven deaths: three of them were caused by ITP severity (cerebral bleedings), two were due to progression of COPD (chronic obstructive pulmonary disease), one was a gram-negative sepsis and one patient suffered an arrhythmia related sudden death. A subanalysis of primary ITP patients with more than 80 years (6 male and 14 female), revealed as high efficacy rates as younger patients (85% of CR with 75% of responses). This kind of patients are expected to be a very frail patients. Nevertheless, only 7 (35%) patients of this population reported adverse events.
Summary/Conclusions: Our case series describe the great efficacy and safety results observed with the use of eltrombopag in our more than 65 years old ITP patients. However more studies are needed to confirm the possible usefulness of TPO-RAs in this variety of primary ITP cases.

E1431

WERE THE MEASUREMENTS STANDARDIZED SUFFICIENTLY IN PUBLISHED PAPERS ABOUT MEAN PLATELET VOLUME?

C Beyan[1,*], E Beyan[2]
[1]Department of Hematology, Gulhane Military Medical Academy, [2]Department of Internal Medicine, Kecioren Training and Research Hospital, Ankara, Turkey

Background: Recently, mean platelet volume (MPV) aroused interest of the researchers and several studies about MPV changes in various pathological conditions were published.
Aims: The aim of this study was to evaluate the data accuracy of MPV measurements in these studies.
Methods: The study was performed using the data of 181 studies contain healthy control subjects within 1181 paper about mean platelet volume indexed by PubMed database since 2012.
Results: 81 studies (%44.7) were performed retrospectively. Healthy control groups included 80.52±70.51 subjects (mean±standard deviation). The distributions of gender in 16 (8.8%) and age in 12 studies (6.6%), and platelet counts in 28 studies (15.5%) were not reported. The gender and age groups were not differing significantly by the means of platelet counts (r= -0.40; p >0.05). EDTA, low (1:9) and high concentrate (1:4) citrate were used as an anticoagulant in 112, 7 and 2 studies, respectively and type of anticoagulant was not noted in 60 studies (33.1%). There was no study to compare the different anticoagulants. The instruments of Beckman Coulter, Sysmex, Abbott Cell-Dyn, Siemens ADVIA, Mindray BC-6800, HORIBA ABX Micros 60 and Diatron Abacus Junior B were used for the measurements of MPV in 53, 46, 32, 9, 2, 2, and 1 studies, respectively and the used technology in automated blood cell counting was not specified in 36 studies (19.9%). The MPV values measured with Sysmex was higher significantly than the MPV values measured with Beckman Coulter, Abbott Cell-Dyn and Siemens ADVIA. The MPV measurements varied up to 17.8% by the instruments. The measurement times between 15 minutes-2

hours was significantly different from the measurement times<15 minutes and >2 hours. The MPV measurement times from venipuncture were not indicated in 86 studies (47.5%). The MPV measurements by the MPV measurement times and plus the used instruments varied up to 17.8% and 27.7%, respectively. Both the MPV measurement times and used instruments were not stated in 29 studies (16.0%). Only 47 prospective studies (26.0%) enlightened about type of anticoagulant, used instruments for MPV measurement, MPV measurement time, platelet counts and MPV values.
Summary/Conclusions: As a result, the measurements were not standardized sufficiently in published papers about MPV. It may be explained the differences between the results of studies made same pathological conditions.

E1432

COMPARISON OF MEAN PLATELET MASS AND MEAN PLATELET COMPONENT IN IMMUNE THROMBOCYTOPENIA, HYPOPROLIFERATIVE THROMBOCYTOPENIAS, AND HEALTHY INDIVIDUALS
H Melinscak[1,*], T Mirzoyev[1], YT Hong[2], M Varma[1]
[1]Hematology-Oncology, [2]Pathology, Mount Sinai St. Luke's-Roosevelt, New York, United States

Background: Immune thrombocytopenia (ITP) remains a diagnosis of exclusion. The Siemens ADVIA 120 has the capacity to calculate the mean platelet (PLT) component (MPC), a measure of PLT density, and the mean platelet mass (MPM), neither of which are currently employed in clinical decision making.
Aims: To determine if the MPC and MPM are significantly higher in ITP (reflecting increased PLT granules) than in hypoproliferative thrombocytopenia (HT) and in the healthy population.
Methods: Institutional review board approval was obtained. A prospective study was initiated in September 2013. This trial is registered at ClinicalTrials.gov. Patients at Mount Sinai Roosevelt Hospital with ITP, as defined by the ASH 2011 practice guidelines, and HT's (delineated in Results section) were included. A reference population was established. Patients with human immunodeficiency virus, hepatitis C, cirrhosis, pregnancy, and disseminated intravascular coagulation were excluded. Enrollment of 20 patients in each arm and 10 healthy individuals in the control arm was planned. Lavender tri-potassium EDTA tubes were filled and analyzed on the Siemens ADVIA 120 within a period not exceeding 2 hours from their collection. MPC and MPM values were compared for all 3 groups using one-way analysis of variance. The student's t-test was used to compare these parameters in the patient groups.
Results: Twenty patients with ITP, 20 patients with HT (4 aplastic anemia, 8 chemotherapy-induced thrombocytopenia, 3 myelodysplasia, 1 acute myelogenous leukemia, 1 hairy cell leukemia, 1 multiple myeloma, and 2 drug-induced thrombocytopenia (valproic acid, imatinib)), and 10 controls were enrolled. Baseline characteristics of the patient groups were similar. Median age, M:F ratio, and mean PLT count were 54 years, 0.67:1, and 62,500/µL (ITP) and 60.5 years, 1:1, and 53,900/µL (HT), p>0.05. MPC (g/dL, mean +/- SD) for each group was 26.7 +/- 1.89 (ITP), 24.2 +/- 1.89 (HT), and 28.09 +/- 0.74 (controls), p<0.01. MPM (pg, mean +/- SD) for each group was 2.43 +/- 0.451 (ITP), 1.95 +/- 0.210 (HT), and 1.91 +/- 0.10 (controls), p<0.01. Comparison of these parameters for the 2 patient groups showed statistical significance (p<0.01).
Summary/Conclusions: MPM is significantly higher in ITP than in HT and in controls, likely reflecting increased granular content. While MPC is significantly higher in ITP than in HT, it is highest in controls, etiology unclear. Future studies should further evaluate these parameters for distinguishing ITP from other thrombocytopenias.

E1433

ELTROMBOPAG LOW DOSES AS PROPHILAXIS OF CHEMOTHERAPY INDUCED THROMBOCYTOPENIA (CIT) IN CANCER PATIENTS TREATED WITH PLATINUM BASED CHEMOTHERAPY
F Iuliano[1,*], S Blotta[2], E Iuliano[3], MA Santoro[1], P Alessia[1], M Luci[1], A Pomillo[1]
[1]Internal Medicine, UO di Onco-Ematologia PO "N.Giannettasio", Rossano, [2]ASST Bergamo Est, UOC Oncologia, Seriate (BG), [3]Magna Graecia University, UO di Oncologia, Catanzaro, Italy

Background: Chemotherapy-induced thrombocytopenia (CIT) can cause delay or reduction in subsequent courses of chemotherapy. As reported in literature, thrombocytopenia occurred in 82% of those receiving only carboplatin, and in 58%, 64%, and 59% of those receiving combination therapies with carboplatin, gemcitabine or paclitaxel, respectively. Eltrombopag is an oral, non-peptide thrombopoietin receptor agonist that has been shown efficacy and safety in chronic immune thrombocytopenia (ITP) patients not responding to previous therapy by raising the platelets count in both continued long-term administration and in a repeated short-term administration. Eltrombopag bound the thrombopoietin receptor in the transmembrane region, an area different from where thrombopoietin or romiplostim bound, and activated the thrombopoietin receptor in a different fashion. Here, we report on a series of 18 patients at high risk of CIT because of platinum chemotherapy schedules who received low doses eltrombopag as prophilaxis
Aims: To prevent CIT in patients who cannot be supported by platelet transfusions and for whom the maintenance of dose intensity is crucial for remission or survival.
Methods: A total of 18 consecutive adult patients, female (60%), median age 47 years (range 28 - 65) were enrolled in the study.The reason of chemotherapy has been ovary cancer in 4 patients, colon cancer in 6 patients, relapsed DLBC lymhoma in 4 patients, TNBC in 2 patients, pancreatic cancer in 2 pts. All patients received eltrombopag 25 mg by mouth twice a weekly as soon as the platelet count falls below 80000 mmc, and continued on treatment until completion of cycles of chemotherapy.
Results: The mean platelet count nadir was 60000 mmc; the number of days with platelet count<80000/µL was 4 days; The maximum value reached was 270,000 mmc. No treatment-related toxicity was observe. The principal endpoints of the study: avoid nadir platelet counts<50,000/µL,platelet transfusions,bleeding events, chemotherapy dose reductions chemotherapy delays. were achieved in all patients.
Summary/Conclusions: In our opinion low dose eltrombopag prophilaxis can be an effective and safe strategy for preventing the CIT.

E1434

THERAPEUTIC APPROACH TOWARDS SYMPTOMATIC THROMBOCYTOPENIA IN DENGUE HEMORRHAGIC FEVER
T Jameel[1,*], I saleem[2]
[1]Department of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia, [2]Iffefaq Hospital, Lahore, Pakistan

Background: Introduction: Immune-mediated destruction of platelets is thought to be the mechanism of thrombocytopenia seen after the viremic phase of dengue hemorrhagic fever (DHF). Immuno-suppressants such as steroids, immune globulin and Anti D immunoglobulin are effective in the treatment of this type of immune thrombocytopenic purpura.
Aims: To evaluate the efficacy of oral Prednisolone in the rate of resolution of thrombocytopenia and monitoring of complications in patients recovering from Dengue hemorrhagic fever.
Methods: A controlled study was carried out on diagnosed cases Dengue hemorrhagic patients presenting with sever thrombocytopenia and symptoms like confluent ecchymosis, epistaxis and purpuric rashes. This study was conducted in Ittefaq hospital (trust) in collaboration with KAU Jeddah, during the period of October to December 2013. Treatment group received steroids in two forms *i.e.* 1st line therapy prednisolone orally or as 2nd line therapy of initial I/V high dose (prednisolone) in pulse doses *i.e.* 40 mg bid for four days and later oral prednisolone as in 1st line therapy with omeprazole 20 mg bid in addition to standard treatment. Control group received standard supportive care only.
Results: A total of 341 suspected patients were admitted in hospital. Serological diagnosis was confirmed in 166 patients. CBC revealed platelet count ≤100x10^9/l in 106 patients. A group of symptomatic febrile patients have platelet count<20x10^9/l was selected for therapeutic intervention. 1st line therapy (oral prednisolone was stated in 43 patients. In Fourteen patients 2nd line therapy (high dose dexamethasone pulse) therapy was instituted. Seven of them attained complete response whereas two patients achieved partial response. Four patients were shifted to Anti D therapy. Three deaths occurred during our study. Rest of all the patients improved and were discharged in due course of time.
Summary/Conclusions: This small scale preliminary study shows promising results in reducing the morbidity of patients in a relatively serious stage but large scale double blinded randomized controlled studies are needed before making recommendations on use of steroids in symptomatic thrombocytopenic patients with dengue hemorrhagic fever.

E1435

WISCOTT ALDRICH SYNDROME IN A GIRL! WHAT IS THE MYSTERY?
A Akdemir[1,2], M Witzel[3], T Patiroglu[4], Ma Ozdemir[4], M Karakukcu[4], C Klein[5], E Unal[4,*]
[1]Department of Pediatrics, Erciyes University, Faculty of Medicine, Kayseri, Turkey, [2]Division of Hematology-Oncology, Department of Pediatrics, Dr von Hauner Children's Hospital, Ludwig Maximilians University, [3]Department of Pediatrics, Division of Pediatric Hematology Oncology, Dr. von Hauner Children's Hospital, Munich, Germany, [4]Department of Pediatrics, Division of Pediatric Hematology Oncology, Erciyes University, Faculty of Medicine, Kayseri, Turkey, [5]Department of Pediatrics, Division of Pediatric Hematology Oncology, Dr von Hauner Children's Hospital, Munih, Germany

Background: Wiscott-Aldrich Syndrome (WAS) is an X-linked recessive inherited immunodeficiency; which is presented with micro-trombocytopenia, eczema, recurrent infections, and increased incidence of autoimmune diseases, and malignencies. WAS gene is located on the short arm of X chromosome, and encodes WAS protein (WASP). WASP is expressed in hematopoietic stem cell-lineages and responsible for cytoskeleton reorganization affecting the functions of T, B, NK- cell, granulocytes, dendritic cells and platelets. Mutation in the WAS gene ends up with X-linked thrombocytopenia (XLT) or classical WAS. The prevalence of WAS is, 1 in 100 thousand live births.
Aims: In this presentation we would like to share our experience about a girl diagnosed with WAS.
Methods: A 7 year old female patient was followed with trombocytopenia since she was born. She had been hospitalized for recurrent infections, gastrointesti-

nal bleedings, and CMV pneumonia. Bilateral ventilation tube regarding to persistent otitis media was also performed. Serum immunoglobulin levels were checked, Ig A and Ig E levels were increased, Ig M level was decreased and Ig G level was normal. Western blot studies confirmed the reduced WAS protein expression in peripheral mononuclear blood cells. The complete WAS gene was sequenced, one heterozygous mutation in Exon 7, leading to a premature stop codon p.G219*, c.655G>T was found.
Results: WAS is an X-linked recessive disorder, which is seen in male patients due to the transition. But, in case of X gene inactivation, it can also be presented in female patients.
Summary/Conclusions: The clinicians must be vigilant about the possibility of X linked diseases such as WAS in females.

Quality of life, palliative care, ethics and health economics

E1436

EFFECT OF EXERCISE AND COUNSELING INTEGRATED IN THE CLINICAL MANAGEMENT OF ACUTE LEUKEMIA ON PHYSICAL FUNCTION AND QUALITY OF LIFE DURING CONSOLIDATION CHEMOTHERAPY: A MULTICENTER RANDOMIZED TRIAL

M Jarden[1,*], T Møller[2], L Kjeldsen[2], H Birgens[3], K Birgens[4], L Adamsen[2]
[1]UniversityHospitals Center for Health Research, [2]Copenhagen University Hospital, Copenhagen University, [3]Department of Hematology, Herlev Hospital - Copenhagen Universiy, [4]Institute of Public Health, Department of Biostatistics, University of Copenhagen, Copenhagen, Denmark

Background: Exercise and counseling interventions, widely used as rehabilitation strategies in cancer patients to remedy disease and treatment-related sequelae is novel in patients with acute leukemia due to the life threatening nature of the disease, the intensive treatment and safety monitoring requirements.
Aims: We assessed whether an exercise and counseling intervention could prevent and modulate physical and functional debilitation and improve health-related quality of life (HRQoL) in a two-center, randomized controlled trial of patients with acute leukemia during outpatient consolidation chemotherapy.
Methods: Patients were randomized to usual care or a twelve-week supervised exercise and counseling intervention. The primary outcome was 6 minute walk distance (6MWD), and secondary outcomes included submaximal VO_2 max, sit-to-stand test, biceps arm curl, and patient-reported HRQoL questionnaires. 70 patients were randomly assigned to the intervention (n=32) or control group (n=34), and 62 completed study requirements (88.6%).
Results: Changes in the primary outcome 6MWD differed significantly across randomization groups (85.5 m [51.2-119.8], $p<0.0001$) and physical capacity and functional outcomes were substantial (effect sizes 1 or above). Self-rated leisure-time physical activity levels, health-related quality of life (FACT-An) and levels of depression and anxiety differed significantly between groups, in favor of the intervention group. Eight patients experienced non-serious adverse events.
Summary/Conclusions: Exercise and counseling in patients with acute leukemia undergoing outpatient consolidation chemotherapy improved physical and functional capacity, physical activity levels, HRQoL and psychological well-being. The role of exercise and counseling integrated in the clinical setting has the potential of optimizing the management of acute leukemia and may facilitate resumption of everyday activities.

E1437

COST-EFFECTIVENESS ANALYSIS OF A DIRECTLY SELECTED CMV-SPECIFIC T CELL THERAPY FOR MANAGEMENT OF CMV DISEASE IN PATIENTS POST ALLOGENEIC STEM CELL TRANSPLANTATION: A UK ANALYSIS

M Nuijten[1,*], C Kielar[2], K Peggs[3]
[1]Health Economics, A2M, Amsterdam, Netherlands, [2]Cell Medica Ltd, [3]Stem Cell Transplantation and Immunotherapy, University College Hospital, London, United Kingdom

Background: Hematopoietic stem cell transplantation (HSCT) is a curative treatment option for a variety of malignant and non-malignant hematological diseases. However, cytomegalovirus (CMV) infection, an acknowledged complication after HSCT, is associated with significant morbidity, decreased patient survival, and considerable cost to health-care systems. Two randomized clinical studies, CMV~ACE/ASPECT and CMV~IMPACT (NCT01220895 and NCT01077908), assessed the efficacy and safety of a CMV-specific T cell therapy for prevention or treatment of CMV reactivation post allogeneic HSCT.
Aims: We assessed the cost-effectiveness of a CMV-specific T cell therapy for the management of CMV disease in patients after allogeneic HSCT in the UK.
Methods: A Markov model, reflecting current clinical guidelines, was developed to estimate cost-effectiveness of a CMV-specific T cell therapy for the management of CMV infections and CMV disease in patients after allogeneic HSCT in the UK from the perspective of the NHS in 2015. Here we report the results of this economic analysis in the CMV disease setting. Data sources, in the model, included the two randomized clinical trials for the CMV-specific T cell therapy, published literature, national costs, tariff lists, and a Delphi panel of 7 English hematologists. The model simulated clinical and economic outcomes associated with the a CMV-specific T cell therapy and standard treatment. The main comparators in the analysis depended on the positioning of the CMV-specific T cell therapy and were foscarnet in 2-line and cidofovir in 3-line. Clinical probabilities included response probabilities, mortality and recurrence. Inpatient costs included daily hospital stay, laboratory analyses, microbiological culture, specialists' visits, therapy acquisition and administration costs. Utilities were included for the Quality Adjusted Life Years (QALY).

Results: The use of the CMV-specific T cell therapy as 2-line CMV disease treatment increases costs from £27,882 to £30,656, which results in additional costs of £2,774, but leads to a gain in QALYs of 0.215 from 3.179 to 3.394. Consequently, the incremental cost-effectiveness ratio (ICER) is £12,902/QALY. The probabilistic sensitivity analysis (PSA) shows a probability of 79% that the ICER remains below £30,000/QALY. The use of the CMV-specific T cell therapy as 3-line CMV treatment increases total costs from £27,882 to £28,648 leading to additional costs of £766, but to a gain in QALYs of 0.031 from 3.179 to 3.210. Consequently, the resulting ICER is £24,710/QALY. The PSA shows the probability is 53% that the ICER remains below £30,000/QALY. The impact of risk adjustment for the clinical benefits of the CMV-specific T cell therapy *versus* standard therapy on the ICER was explored. The health economic outcomes were sensitive to a risk adjustment for mortality, but not for response and recurrence in the 2-line setting. In the 3-line setting, the ICER was sensitive to risk adjustment for mortality and response, but not to recurrence. The analyses also show that the health economic outcomes were quite robust for both 2-line and 3-line positioning of the CMV-specific T cell therapy for other variables. The favourable cost-effectiveness of the CMV-specific T cell therapy results mainly from the prevention of treatment failure and as a consequence the avoidance of mortality and the cost of salvage therapy.
Summary/Conclusions: CMV-specific T cell therapy is a cost-effective treatment for patients with CMV disease after allogeneic HSCT in 2-line and 3-line therapeutic treatment in the UK setting.

E1438

CLINICAL CHARACTERISTICS, TREATMENT PATTERNS AND HEALTH CARE RESOURCE UTILIZATION AMONG ITALIAN PATIENTS WITH RELAPSED REFRACTORY MULTIPLE MYELOMA: RESULTS FROM A PROSPECTIVE OBSERVATIONAL STUDY

A Palumbo[1], A Zagorska[2,*], S Popov[3], T Zyczynski[2], C Davis[2], P Di Rienzo[2]
[1]University of Torino, Torino, Italy, [2]BMS, Princeton, United States, [3]Parexel International, Moscow, Russian Federation

Background: Knowledge of clinical practice and healthcare resource utilization (HCRU) in relapsed refractory multiple myeloma (RRMM) can inform and improve national treatment strategies.
Aims: To describe clinical and treatment characteristics, HCRU and associated costs in patients (pts) with RRMM in Italy compared to a general European cohort.
Methods: PREAMBLE (NCT01838512) is a prospective, multi-region (US, Canada, EU: Italy, France, UK, Germany), observational study with up to 3 years of follow up per pt. Eligible pts have ≥1 prior therapy for MM with disease progression from the most recent therapy, and have initiated index therapy with immunomodulatory drugs (IMiDs) and/or proteasome inhibitors (PIs) within 90 days prior to or 30 days after study consent. Demographics, treatment and HCRU data were collected, including hospitalizations, visits to healthcare professionals due to MM, diagnostic tests, MM treatments and concomitant medications. Costs were calculated by assigning standardized specific costs from Italy and other EU countries. Descriptive statistics from an interim analysis are reported.
Results: At the cutoff date (December 7th 2015), 764 of 815 enrolled pts had received treatment (509 in Europe, including 197 in Italy), with a median follow-up of 15.1 (Q1–Q3: 8–24) months. Pts were mostly male with mean age 68 years, both in Italy and the EU. At study entry the majority of pts were relapsed (Italy 76%; EU 80%) or refractory (Italy 23%; EU 20%). In Italy most pts were ISS stage I (44%) or II (33%); EU pts were equally spread across severity stages. In both cohorts 44% of pts had prior transplantation. 72% of pts in Italy had comorbidities, commonly one (25%) or two (21%). Cardiovascular (40%) and metabolic (16%) disorders were most frequent. 39% of pts receiving PIs and 19% of pts receiving IMiDs had no comorbidities. In Italy for index therapy, 101 pts received IMiDs, 92 PIs and 4 IMiDs+PIs. The most common scheme amongst IMiDs was lenalidomide and amongst PIs bortezomib, both in combination with dexamethasone. Duration of index therapy varied between treatment types: median 8.8 (Q1–Q3: 3.9–14.2) months for IMiDs; 4.6 (2.8–6.2) for PIs; 4.4 (2.2–7.5) months for IMiD+PIs, with a similar pattern observed in the EU cohort. 52% of pts in Italy had received 1 prior line of therapy; most commonly bortezomib-based schemes. Average HCRU for RR MM patients during the first year of follow-up was lower in Italy compared to European cohort (Italy: mean 1.1 visit/year [max 27]; EU: 13.8 visits/year [max 112]). In both cohorts the number of visits decreased in subsequent years. In Italy HCRU differed by treatment: mean number of visits/year for pts treated with IMiD: 0.76, PI: 1.2, IMiD+PI: 7; the majority being hospital outpatient visits (68%) and all-cause hospitalization (17.5%). In the EU cohort, after outpatient visits (63%), most common were clinic/physician office visits (18%). The main reason for hospitalization was management of MM (Italy 78%; EU 67%). Cost distribution was heterogeneous among pts in both cohorts (median overall costs during index treatment: 116,000 (Q1–Q3: 78–152) euros in Italy; 88,000 (44–149) euros in the EU). Main cost drivers were MM treatments, concomitant medications (in Italy only for PI-treated pts) and hospitalizations.
Summary/Conclusions: Preliminary data from the PREAMBLE prospective observational study show variation in the management of RRMM pts in Italy having lower HCRU compared with the EU cohort. Routine management and disease progression continues to drive HCRU in MM.

E1439

EVALUATION OF PSYCHOMETRIC PROPERTIES OF EUROPEAN ORGANISATION FOR RESEARCH AND TREATMENT OF CANCER QUALITY OF LIFE QUESTIONNAIRE CORE 15 PALLIATIVE (EORTC QLQ-C15-PAL) IN MULTIPLE MYELOMA PATIENTS

XH Hu[1,*], AM Rodriguez[2], B Katic[2], L Purnomo[1], CJ Gibson[1]
[1]Celgene Corporation, Summit, NJ, [2]PatientsLikeMe, Boston, MA, United States

Background: The EORTC QLQ-C15-PAL was developed by shortening the QLQ-C30 from 30 to 15 items for easier administration to patients receiving palliative care. Its performance in measuring health-related quality of life (HRQoL) in relation to its parent version in patients with multiple myeloma (MM) has not been previously evaluated.
Aims: To assess the psychometric properties of the EORTC QLQ-C15-PAL in relation to the QLQ-C30 in patients with MM at different disease stages.
Methods: US patients with self-reported MM were recruited through an online patient-powered network, PatientsLikeMe. Upon completion of informed consent, study participants were asked to provide a brief MM treatment history and complete the EORTC QLC-C30. Domain scores for QLQ-C30 and QLQ-C15-PAL were calculated. Item-scale correlations, and floor and ceiling effects for all items on the QLQ-C30 were stratified by disease progression and palliative care status separately. To measure equivalent-form reliability, regression analysis was used to determine the proportion of variance (R-squared) using QLQ-C30 as the response variable and QLQ-C15-PAL as the explanatory variable for those domains shortened in the QLQ-C15-PAL. Intraclass correlation coefficients (ICCs) were calculated between the subscales shortened in QLQ-C15-PAL. The internal consistency of domains with 2 or more items was assessed using Cronbach α coefficients.
Results: A total of 199 patients completed the online survey, and 10 patients were excluded from the analysis because they had not received any MM treatment. Of the remaining 189 patients, the median age was 61 years (range, 37-82 years) and 57.6% were women. 51 patients (27.0%) received palliative care currently or previously and 65 patients (34.4%) switched treatment regimens at least once due to disease progression. With few exceptions, item-scale correlation, and floor and ceiling effects were in similar ranges for all items regardless of disease progression status or palliative care status. R-squared values ranged from 0.72 to 0.92 and ICCs varied from 0.87 to 0.96. Cronbach α coefficients for Physical Functioning, Emotional Functioning, and Fatigue were 0.64, 0.76, and 0.76, respectively.
Summary/Conclusions: The EORTC QLQ-C15-PAL appears to be a reasonable substitute to measure HRQoL in patients with MM at different disease stages.

E1440

CRYOPRESERVATION OF MATURE OOCYTES TO PRESERVE FERTILITY IS FEASIBLE WITHOUT TREATMENT DELAY IN YOUNG ADULT LYMPHOMA PATIENTS

S Viviani[1,*], E Somigliana[2], G Mangili[3], M Soldarini[1], A Paffoni[2], E Papaleo[3], L Devizzi[1], A Dodero[1], L Farina[1], F Filippi[2], C Sigismondi[3], F Raspagliesi[4], P Corradini[1]
[1]Hematology and Pediatric Onco-Hematology, Fondazione IRCCS Istituto Nazionale dei Tumori, [2]Obstetrics and Gynecology; Infertility Unit, Fondazione Ca' Granda Ospedale Maggiore Policlinico, [3]Obstetrics and Gynecology, San Raffaele Hospital, [4]Gynecologic Oncology Surgery, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Background: Advances in the treatment of lymphomas have led to a substantial decline in the mortality rate and a remarkable improvement in the long-term outcomes, that has raised patients' expectations of a better quality of life, among which fertility preservation represents an imminent wish. However the majority of treatment protocols consist of combination chemotherapy (CT) which may lead to infertility due to severe injury to ovarian reserve, when alkylating agents –containing regimens, CT combined with radiotherapy (RT) on the pelvis, high-dose CT and autologous hematopoietic stem cell reinfusion and/or allogeneic bone marrow transplantation have to be given in the course of the disease. Attempts to prevent ovarian damage during CT±RT include a) the concomitant administration of Gonadotropin Releasing Hormone (GnRH) agonists, but results of randomized trials have led to controversial results, b) ovarian tissue cryopreservation, which requires two subsequent laparoscopic sessions, carries the possibility of malignant cells reimplantation and has produced only a limited number of published live births c) mature oocyte cryopreservation, d) embryo cryopreservation, which is not admitted by italian rules and requires the availability of a male partner.
Aims: To evaluate in a prospective observational study the acceptability and feasibility of the procedure of ovarian hyper-stimulation and mature oocyte retrieval and cryopreservation, in female patients with newly diagnosed Hodgkin (HL) and non Hodgkin lymphoma (NHL).
Methods: Female patients aged ≥18 years and ≤38 years with histologically proven untreated HL or NHL at any stage, diagnosed at Istituto Nazionale Tumori of Milan, without contraindications to ovarian stimulation, *i.e.* symptomatic rapid progressive disease, and/or superior vena cava syndrome, active

viral infectious disease and ovarian failure, were eligible for the study. After having addressed expected gonadal toxicity of CT±RT during their first haematological evaluation, they were referred to gynecological counseling. Ovarian reserve was assessed by antral follicle count regardless of the menstrual cycle. If the woman consented, she underwent ovarian hyper-stimulation according to a random start protocol. Briefly, gonadotropins were started the same day regardless of the menstrual cycle and the cycle was monitored through serial ultrasounds to tailor the initiation of GnRH antagonists and to identify the most proper time for ovulation trigger

Results: From July 2013 to December 2015 20 patients were enrolled into the study, median age was 27 years (range, 19-35), 16 patients were diagnosed with HL, 4 with NHL (2 DLBCL, 1 PMBCL, 1 follicular). Median time from first hematological visit and gynecological counselling was 2 days (range, 0-10), median time from diagnostic biopsy and gynecological counselling was 14 days (range, 0-29). 11 out of 20 (55%) patients were considered eligible and/or accepted to undergo ovarian stimulation; 6 patients refused due to personal reasons, 1 due to gynecological reasons (ovarian cysts), 1 due to symptomatic progressive disease after the first gynecological visit and in 1 DLBCL NHL patient stimulation was suspended due to initial superior vena cava syndrome. Median time from first gynecological visit and oocyte retrieval was 13 days (range, 12-16); median number of retrieved oocytes was 16 (range, 11-32) and median number of cryopreserved oocytes was 14 (range, 9-23). Median time from oocyte retrieval and CT start was 4 days (2-14).

Summary/Conclusions: Preliminary results of this study document that ovarian hyper-stimulation and oocyte retrieval using a random start protocol is feasibile in young females diagnosed with HL or NHL without a significant delay in CT start. The number of mature oocyte cryopreserved is adequate and comparable to non-cancer patients. Oocyte cryopreservation should be systematically considered in lymphoma patients of childbearing age before starting gonadoxic therapy and should be preferably performed during staging procedures.

E1441

PSYCHOMETRIC VALIDATION OF THE SF-36V2® HEALTH SURVEY IN AN AL AMYLOIDOSIS POPULATION

MK White[1], M Bayliss[1], KL McCausland[1], S Guthrie[2,*]
[1]Optum, Lincoln, RI, [2]Prothena Biosciences Inc, South San Francisco, CA, United States

Background: Light chain (AL) amyloidosis, a rare protein misfolding disease, leads to deficits in health-related quality of life (HRQoL). Patients with AL amyloidosis present with a wide variety of non-specific symptoms, organ involvement, and functional impairment. The SF-36v2® Health Survey (SF-36v2), a general HRQoL survey, has been used to quantify the impact of AL amyloidosis on HRQoL, though to-date there is no evidence of its psychometric validity for use with AL amyloidosis patients.

Aims: To document the psychometric properties of the SF-36v2 among AL amyloidosis patients, including tests of data quality, scaling success, reliability, and validity.

Methods: Adults (≥18 years old) with self-reported AL amyloidosis completed baseline (n=341) and one-month follow-up (n=252) surveys online to assess HRQoL, clinical and socio-demographic characteristics. Data quality evaluation (DQE) checks included item and scale distributions and a response consistency index (RCI). The online system did not allow out of range values or missing data. Scaling success was evaluated against assumptions of summated rating scales. Internal consistency reliability used Cronbach's α. Test-retest reliability used intra-class correlations (ICC) between baseline and one-month follow-up scores among a stable disease subgroup (n=180). Scale convergent and discriminant validity was tested and used correlations between scores from the SF-36v2, the Kansas City Cardiomyopathy Questionnaire (KCCQ-12), Patient Global Assessment of Functioning (GAF), and other surveys. Known-groups validity tests used ANOVA of scores across patient groups varying in disease severity (self-reported hematologic response status, and Patient Global Impression-Severity (PGI-S)).

Results: DQE showed excellent response distribution and RCI (94.1%). Scale reliability (Cronbach's α ≥ 0.780 across all 8 domains) and test-retest reliability (ICC ≥ 0.731) were acceptable. Tests of summated rating scale assumptions were satisfactory. Scale convergent and discriminant validity showed strong correlations with conceptually related measures. Tests for known-groups validity showed that the mean scores for respondents with self-reported complete hematologic response or remission were significantly greater than scores for respondents with no response to treatment (p<0.05 for all scores). Similarly, mean scores were also significantly associated with responses to the PGI-S (p<0.0001 for all scores).

Summary/Conclusions: This study provided robust evidence of the psychometric properties of the SF-36v2 in a diverse sample of patients with AL amyloidosis. Planned future analyses will assess responsiveness and confirm psychometric properties of the SF-36v2 in clinic-based samples of AL amyloidosis patients.

E1442

MONOCENTRIC ASSESSMENT OF THE PROFESSIONAL PRACTICES IN THE MANAGEMENT OF PAIN DURING BONE MARROW ASPIRATION

G Poenou[1,2,*], S Zia Chahabi[1,2], N Gendron[1,2,3], N Rivet[1,2], T Belleville-Rolland[1,2,3], M Ciaudo[1,2], V Siguret[2,3,4], P Gaussem[1,2,3], L Darnige[1,2]
[1]Hématologie, AP-HP, European Hospital Georges Pompidou, [2]Université Paris Descartes, Sorbonne Paris Cité, [3]Inserm UMR-S1140, Paris, France, [4]Hématologie, AP-HP, Lariboisère, Paris, France

Background: Bone marrow aspiration performed for the diagnosis of hematologic malignancies is known for being painful. However, pain management is a current concern in the follow-up of patients with chronic diseases.

Aims: Within this overall dynamic of improvement of the analgesic gesture support, an evaluation of the professional practices was initiated by the Hematology Department of the European Georges Pompidou Hospital (Paris, France). The aim of this study was to evaluate the factors involved in the feeling of pain during bone marrow aspiration.

Methods: This monocentric cohort study included 480 patients from 2010 to 2015. They underwent bone marrow aspiration and filled out a standardized questionnaire-based survey including: demographic characteristics (patient's sex and age, medical department), clinical data (bone hardness, puncture site, diagnosis assumptions and final diagnosis), analgesia methods (lidocaine patch, infiltration with lidocaine, inhalation sedation and premedication) and processing (patient anxiety; intensity of pain evaluated after bone marrow aspiration quoted by the patient and the operator, using a visual analog scale (VAS) from 0 to 10; awareness of the gesture by the patient).

Results: Among the 480 patients, 58% were men. Patients' average age was 68.7 years. Most patients were from Nephrology (16%), Hematology (16%) and Internal medicine (30%) departments. The main indication of bone marrow aspiration was the diagnosis assessment of monoclonal gammapathies (30%). The most used puncture site was sternal site (88%) and in most cases the bone hardness was described as medium (64%). Bone marrow examination allowed us excluding a central origin for the hematologic anomaly in 43% patients. The foremost analgesia method was the use of lidocaine patch (80%) with an average exposure of 68 minutes. Half of patients declared not to be anxious before bone marrow aspiration. Pain was generally rated between 3 and 4 on a scale of 10 (43%), and lower than they had expected (58%). Overall, 97% of bone marrow aspirations were performed under analgesia.(Table 1.Pain's management). Analgesic treatment was found significantly effective compared with no analgesia? (p<0.001). Patients experienced less pain when they considered that they were well-informed (p<0.001).Women were significantly more sensitive than men (p<0.05). In our study, sternal site was more painful than superior iliac bone site (p<0.001). There were no relationships between pain intensity and patients' age, medical department, bone hardness, diagnosis assumptions, final diagnosis, a particular analgesia method and patient anxiety (p>0.05).

Table 1.

Puncture site	Sternal (n=421)	Iliac (n=58)
	n patients (visual analog scale mean)	
Lidocaine patch	345 (4.0)	2 (2.7)
Infiltration with lidocaine	17 (3.7)	48 (2.9)
Lidocaine patch + Infiltration with lidocaine	27 (2.9)	3 (1,9)
Premedication + Infiltration with lidocaine	1 (4.0)	2 (1.2)
Premedication+ Lidocaine patch	2 (/)	0
Inhalation sedation	1 (4.0)	1(2.0)
Inhalation sedation + Infiltration with lidocaine	1 (4.0)	0
Inhalation sedation+ Lidocaine patch	1 (1.0)	0
Inhalation sedation+ Lidocaine patch + Premedication	1 (3.5)	0
Premedication + Lidocaine patch + Infiltration with lidocaine	1(9.0)	
No analgesia	15 (5.1)	2 (3.8)

For 10 patients there was no available information

Summary/Conclusions: The perception of and reaction to pain are influenced by the psychological state of the patient. This is an undisputed fact that medical staff should provide information on the steps taken in daily practice and our study on bone marrow aspiration is consistent with this behavior. The prevention and management of pain require an integrated approach between its sen-

sori-discriminative component and its psychological dimension. In our study, we show the benefit of analgesia together with intelligible information in the management of pain during bone aspiration.

E1443

BURDEN OF ILLNESS ASSOCIATED WITH MULTIPLE MYELOMA

M Singh[1,*], G Kay[1], J O'Rourke[1], J Eaton[1], D Berg[2], T Skacel[2], M Jhaveri[2], B Seal[2], HM Lin[2]
[1]ICON Health Economics, ICON, Abingdon, United Kingdom, [2]Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, United States

Background: Multiple myeloma (MM) is a cancer of plasma cells originating in bone marrow and affecting multiple organs. It accounts for 0.8% of all new cancers and is the 2nd most common haematological cancer in the US. It is an incurable disease with an average survival of 4-5 years. Median age at diagnosis is approximately 70 years. MM poses humanistic and economic burden by affecting the health related quality of life (HRQoL) of the patients and/or carers and by impacting healthcare budgets, respectively.
Aims: To review the humanistic and economic burden of MM.
Methods: Two targeted literature reviews were performed; one each for humanistic and economic burden. MEDLINE®, Embase and PubMed (for e-publications ahead of print) were searched to identify relevant publications from 2005 to date. EconLit and NHS Economic Evaluations Database (EED) were searched to identify articles specific to the economic burden. Search terms included disease, QoL and economic terms.
Results: A total of 1029 abstracts for the humanistic burden review and 629 abstracts for economic burden review were identified and screened. Twenty articles were included in the humanistic burden and 18 in the economic burden review. MM is associated with substantial burden of illness. Patients experience a high symptom burden that adversely affects their HRQoL. Bone pain and fatigue are the most common symptoms of the disease. Patients exhibit impaired physical, role, cognitive, emotional and social functioning. Coping with the disease and managing its consequences including loss of independence and being vigilant to prevent incidences of fracture emerge as the predominant factors of the disease. The causes of disease burden are similar in newly diagnosed and/or RRMM patients, with both populations experiencing significant symptom burden which adversely affects their HRQoL. However, the burden in RRMM patients worsens with disease progression such as increased bone pain, fractures and fatigue. Additionally, there is considerable burden on caregivers who report restricted social, leisure, professional/work activities. MM also imposes significant economic burden. The total cost varies depending on whether the disease presents as asymptomatic or symptomatic and by line of treatment. Non-drug costs, which include hospitalisation, autologous stem cell transplant (ASCT), adverse events and ambulatory costs account for approximately 54% of the total cost. Patients treated with novel agents or ASCT and patients who experience skeletal-related events incurred the highest spend for hospitalisation. Some adverse events associated with novel agent treatment required hospitalisation; anaemia and neuropathy were most common. These were associated with a mean length of stay of 9 to 14 days in R/R patients depending on the novel agent received. Costs of productivity loss due to MM were evaluated in one study. Patients who undergo ASCT incurred the highest costs of productivity loss based on working days and hours lost by the patients and caregivers, respectively. Improved outcomes associated with ASCT were not assessed in this study.
Summary/Conclusions: MM poses significant humanistic and economic burden; which increases with disease progression and subsequent lines of therapy. HRQoL in these patients diminishes with symptom severity and disease progression. The total cost of illness is driven by treatment line and choice. These findings warrant the need for more effective therapy with better safety profile delaying disease progression, reducing symptoms and improving patient's outcome.

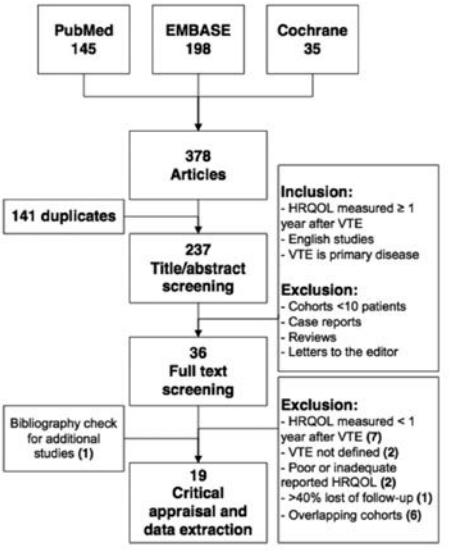
E1444

WHAT IS THE EFFECT OF VENOUS THROMBOEMBOLISM AND POST-THROMBOTIC SYNDROME ON HEALTH-RELATED QUALITY OF LIFE? A SYSTEMATIC REVIEW AND META-ANALYSIS

B Lubberts[1,*], NR Paulino Pereira[1], C Kabrhel[2], D Kuter[3], C DiGiovanni[1]
[1]Orthopaedic Surgery, [2]Emergency Medicine, [3]Clinical Hematology, Massachusetts General Hospital, Boston, United States

Background: There is limited insight for patients, their families, and their providers into the mid and long-term effects of pulmonary embolism (PE), deep vein thrombosis (DVT), and post thrombotic syndrome (PTS) on health related quality of life (HRQOL).
Aims: We conducted a systematic review and meta-analysis of the literature to (1) assess the HRQOL for patients with a minimum follow-up of one year after an episode of PE or DVT, and (2) to assess the HRQOL for patients with DVT who develop PTS.
Methods: PubMed, EMBASE, and the Cochrane Library were search from inception to October 12th, 2015. All studies measuring HRQOL at least one year after an episode of PE or DVT, with or without development of PTS, were selected. Data were extracted by two of the authors and pooled using random-effects meta-analysis. Heterogeneity was assessed with I^2 and Tau^2 tests. SF-12, SF-36, and VEINES-QOL were evaluated with pooled standardized mean difference (SMD) and 95% confidence intervals (CI).
Results: Fourteen studies were included for meta-analyses. In patients with PE physical health was impaired (SMD:-0.30, 95% CI: -0.46 to -0.15, Tau^2: 0.0, I^2:0%, 2 studies) and mental health was similar to population norms (SMD: 0.14, 95% CI: -0.01 to 0.30, Tau^2: 0.0, I^2: 0%, 2 studies). In patients with DVT physical health (SMD:-0.22, 95% CI: -0.53 to 0.10, Tau^2: 0.21, I^2: 94%, 9 studies), mental health (SMD: 0.03, 95% CI: -0.12 to 0.19, Tau^2: 0.03, I^2: 73%, 9 studies), and disease specific quality of life (SMD: 0.04, 95% CI: -0.10 to 0.18, I^2: 2.5%, Tau^2: 0.0, 8 studies) were similar to population norms. Patients who develop PTS reported worse physical health (SMD:-0.89, 95% CI: -1.21 to -0.57, Tau^2: 0.14, I^2: 82%, 7 studies), mental health (SMD:-0.27, 95% CI: -0.43 to -0.11, Tau^2: 0.01, I^2: 31%, 7 studies), and disease specific quality of life (SMD:-0.97, 95% CI: -1.35 to -0.59, Tau^2: 0.30, I^2: 84%, 10 studies) than population norms.

Table 1.



Summary/Conclusions: Patients who had a PE event report worse physical health. Quality of life after a DVT event is comparable to population norms, although those who develop a PTS have worse overall quality of life. These data can be used to inform patients in the rehabilitation process.

E1445

TREATMENT HISTORY, TOLERABILITY AND IMPACT ON HEALTH-RELATED QUALITY OF LIFE IN AL AMYLOIDOSIS

M Bayliss[1], MK White[1], KL McCausland[1], S Guthrie[2,*]
[1]Optum, Lincoln, RI, [2]Prothena Biosciences Inc, South San Francisco, CA, United States

Background: Light-chain (AL) amyloidosis is a rare disease characterized by misfolded amyloid protein deposits in tissues and vital organs. There are currently no FDA- or EMA-approved medications indicated for AL amyloidosis; however, chemotherapy, stem cell transplants (SCT), and immunomodulary drugs can reduce the production of amyloid-forming light chains. All existing regimens have tolerability problems due to treatment-related symptoms (TRSs). The SF-36v2® Health Survey (SF-36v2) is a widely-used general health-related quality of life (HRQoL) survey that can be used to describe and quantify the impact of many diseases and treatments.
Aims: To describe the history of treatments, past and current TRSs, and impact on HRQoL among a diverse sample of individuals with AL amyloidosis.
Methods: We report baseline data from an online non-interventional study was initiated in 2015 among patients with self-reported AL amyloidosis (n=341). Patients reported their current and prior treatment for AL amyloidosis. Aspects of TRSs were captured based on the following: 1) lifetime history of TRSs (dichotomous variable); 2) consequence of TRSs (discontinuation of a treatment; reduction of a treatment; or maintenance of treatment despite TRSs); and 3) ability to *tolerate the current AL amyloidosis treatment* (based on a 4 point scale from "extremely poorly" to "very well", higher scores indicate better tolerability). The prevalence of each treatment type and TRSs were estimated. The patients' ability to *tolerate the current treatment* was evaluated in relation to specific medications and HRQoL (as measured by the SF-36v2® Health Survey Physical [PCS] and Mental [MCS] Component Summary scores) using chi square tests for categorical variables and *t*-tests and ANOVA for continuous measures.

Results: The most commonly reported treatments were dexamethasone (81% reported ever being treated, 52% reported as the current treatment), bortezomib (72% ever, 36% current), SCT (53% ever, 24% current), melphalan (47% ever, 15% current), cyclophosphamide (46% ever, 20% current), and lenalidomide (28% ever, 15% current). Many patients reported combination treatments, including cyclophosphamide+bortezomib+dexamethasone (CyBorD, 17% current). Half of the patients (51%) had received three or more different treatments. Nearly three-quarters (71%, n=226) reported ever having problems tolerating AL amyloidosis treatment, of which nearly half (47%, n=107) had discontinued at least one treatment. Nearly half (46%) of those currently being treated reported some tolerability issue (less than very good tolerability). Tolerability varied across the common treatments from a low of 3.22 (SD=0.90) for cyclophosphamide to a high of 3.61 (SD=0.52) for SCT. Problems with tolerating current medications corresponded with decrements in HRQoL (both MCS and PCS, $p<0.001$).
Summary/Conclusions: Lifetime history of TRSs was high. Discontinuation of life-saving AL amyloidosis treatments was fairly common, though most patients were able to tolerate their current regimen. The high prevalence of treatment discontinuation and history of multiple AL amyloidosis treatments suggests that physicians and patients try a variety of treatments to balance tolerability and efficacy. TRSs are associated with decrements in HRQoL, over and above the burden of AL amyloidosis. These findings highlight the importance of assessing HRQoL during treatment for AL amyloidosis to better understand tolerability, and the need for more treatment options for AL amyloidosis, particularly those with favorable tolerability.

ICU AND LONG-TERM MORTALITY ANALISIS OF HEMATOLOGOGICAL MALIGNANCIES ADMITTED IN ICU. A UNICENTRIC SEVEN YEARS REVIEW IN A SPANISH HOSPITAL

A Jiménez-Ubieto[1,*], R Garcia-Gigorro[2], P Martinez- Sánchez[1], A Rodriguez[1], L Montejano[1], C Grande[1]
[1]Hematología, Hospital 12 de Octubre, [2]Intensive care, Hospital 12 de ocutbre, Madrid, Spain

Background: Improvements in survival in patients with haematological malignancies (HM) admitted to the intensive care unit (ICU) has largely been reported in uncontrolled cohorts. Newly diagnosed patients should be admitted, since their prognosis is still to be defined. Nevertheless the admission of the remaining patients remains a matter of substantial controversy.
Aims: To analyse the survival of HM patients admitted to ICU over a 7-year period (from 2008 to 2014) in a single high complexity Spanish hospital
Methods: We conducted a detailed retrospective study of sequential adult ICU admissions with HM in a single centre, considering numerous variables with regard to their influence on ICU and mortality. Overall survival (OS) was defined as the time from ICU admission to death from any cause, and surviving patients were censored at last follow-up. OS were calculated using the Kaplan–Meier method estimates and the differences assessed by the log-rank test. All *P*-value less than 0.05 were considered significant.

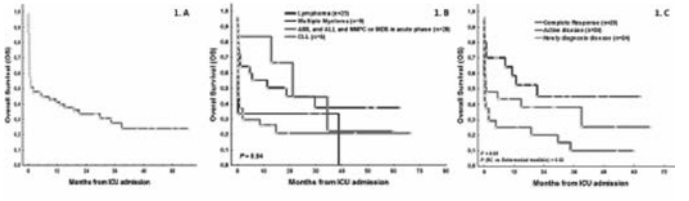

Figure 1.

Results: Overall, 67 HM patients were included, 62% were male, with a median age of 59 years (IQR: 19–82). The median APACHE II was 22 (IQR: 12-49). The hematologic diagnosis was as follow: 25 lymphomas (37%), 9 Multiple Myeloma (MM) (13%), 6 chronic lymphocytic leukaemia (CLL) (9%) and 28 acute leukaemia or myeloproliferative or myelodisplasic syndromes in acute phase (41%). Disease status at the moment of UCI admission was: 19 (28%) in complete response (CR), 24 (36%) with a newly diagnosis disease and 24 (36%) whit active disease (of those, 18 patients were refractory to disease specific treatment and 6 patients were chemosensitive). 67% of patients were on active oncologic treatment at the moment of UCI admission. Principal ICU diagnosis was sepsis (68%). Median number of organ failures was 2 (IQR: 0-4); 71% presented a respiratory and 70% a hemodynamic failure.70% accurate vasoactive drugs, 64% invasive mechanical ventilation and 34% dialysis. More than one third of patients (36%) presented neutropenia at the moment of UCI admission. Median ICU length of stay was 7 days (IQR: 1-48) and median hospital length of stay was 38 days (IQR: 8-109). ICU mortality was 46% (25% of the deaths occurred the first day of ICU admission, and 75% within the first week). The rates for ICU, 1-month, 6-month and 12 month mortality were 48%, 55% and 66%, respectively. With a median follow-up from the day of UCI admission of 18.5 months (IQR: 8-66), estimated OS at 1, 6 and 12 months were 51%, 44% and 41%, respectively (fig. 1a).Hematologic diagnosis (fig. 1b) status of the disease at the moment of ICU admission (fig. 1c) and the number of organ failure (≤2: 67% *vs* ≥3: 28%, *P*=.009) were the most powerful predictor variables associated with an increased OS.
Summary/Conclusions: OS of our HM patients is not worse than that recently reported from other specialist units.The decision for or against ICU admission of patients with HM should become dependent of the underlying malignant disease and especially with the status of the disease at the moment of admission. Almost 50% of survivors are still alive one year after ICU admission, suggesting that an important subgroup of HM patients benefit from ICU admission. In addition, only 25% of patients died beyond the 1st week of admission, not consuming resources without benefit. A multidisciplinary approach between intensivists and hematologists is essential in these patients.

E1447

THE IMPACT OF HAEMATOLOGICAL MALIGNANCY ON PATIENTS' HEALTH-RELATED QUALITY OF LIFE AND SYMPTOMS: A QUALITATIVE STUDY

S Salek[1,*], P Goswami[1], A Fielding[2], J Kell[3], R Else[4], E Oliva[5], T Ionova[6]
[1]School of Life and Medical Sciences, University of Hertfordshire, Hatfield, [2]University College London, Cancer Institute, London, [3]Cardiff and Vale University Health Board, Cardiff, [4]Patient Research Partner, Milton Keynes, United Kingdom, [5]Haematology Unit, Azienda Ospedaliera, Reggio Calabria, Italy, [6]National Medical Surgical Centre and Multinational Centre for Quality of Life Research, St Petersburg, Russian Federation

Background: The impact of haematological malignancies (HM) in patients' lives is not well understood. For some there is a possibility of cure, for others treatment aims at prolonging survival or containing symptoms and complications. We present interim results of a cross-sectional qualitative study in patients with HM.
Aims: The aim of this study was to investigate the impact of a wide range of haematological malignancies and their treatments on patients' health-related quality of life (HRQoL) and Symptoms.
Methods: Multicentre Ethics approval was obtained from the NRES South West Bristols, UK. Adult patients with HM as per 2008 WHO classification, capable of reading English and able to give the written informed consent were recruited from inpatient/outpatient clinics of two secondary care hospitals in England and Wales. This qualitative study employed semi-structured face-to-face interviews with open-ended questions related to HRQoL and symptoms. All the interviews were audio recorded and transcribed verbatim and content analysis was carried out using the NVivo 11 qualitative analysis software.

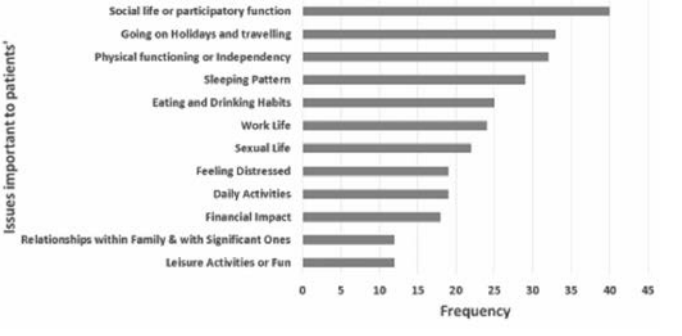

Figure 1. Prevalence of quality of life issues (n=55).

Results: Fifty-five patients (male=27; mean age=60 years; SD=15.2; median age 63 years; and age range =21-83 years) with mean duration of the HM of 3.8 years (SD=4.7; median=2.1 years; and range= 19 days-23 years) were recruited into the study. Diagnoses were Acute Myeloid Leukaemia (11), Acute Lymphoid Leukaemia (3), Chronic Myeloid Leukaemia (6), Chronic Lymphoid Leukaemia (4), Aggressive Non-Hodgkin's Lymphoma (3), Indolent Non-Hodgkin's Lymphoma (7), Hodgkin's Lymphoma (3), Multiple Myeloma (12), Myeloproliferative Neoplasm (3) and Myelodysplastic Syndrome (3). There were overall 44 categories of issues identified which were important from the patient perspective. These issues were then divided into two broad categories: QoL and symptoms. The QoL issues which had the highest impact on patients' lives (Figure1) were: 'social life and participatory function; going on holidays and travelling; physical functioning or independency; sleeping patterns; eating and drinking habits; work life; and sexual life' from high to low prevalence, respectively. Forty-four percent of the patients experienced impairment in different aspects of their work life with the prevalence of sixty-two percent (4 job role function; 2 made redundant; 3 relationship with co-workers; and 24 overall work life). Most of the patients who suffered from financial difficulties because of their HM were from 35-65 age group. With respect to disease related symptoms, 62 issues were identified, the most prevalent being 'tiredness (35%),

feeling unwell (24%), breathlessness (23%), lack of energy (16%), back pain (15%) and weight loss (13%)", from high to low prevalence respectively. Out of 78 treatment related symptoms identified, the most prevalent symptoms were 'tiredness (36%), feeling sick (17%), breathlessness (14%), loss of appetite (9%), neutropenia related symptoms such as infections & slowed healing (8%), nausea (8%) and lack of energy (8%)', from high to low prevalence, respectively.

Summary/Conclusions: The findings of this study clearly indicate that haematological patients' lives are greatly affected by their disease and treatment. This highlights the need for development of a new measure of HRQoL and symptoms, specific for the assessment of patients with HM to evaluate individual intervention strategies in daily clinical practice. This could lead to greater patient engagement in the process of clinical decision-making.

E1448

USE OF PRE-RECORDED AUDIO-VISUAL INFORMATION FOR PATIENTS DIAGNOSED WITH SIX COMMON MALIGNANT HAEMATOLOGICAL DISORDERS WITH AN AIM TO IMPROVE PATIENT EXPERIENCE AND FACILITATE BREAKING BAD NEWS

H Ahmad*, B Van Staden
Haematology, Burton Hospitals NHS Foundation Trust, Burton on Trent, United Kingdom

Background: The diagnosis of a haematological malignancy can be overwhelming for patients. Shock and fright are common initial patient responses to bad news and may prevent patients from fully understanding important information given to them during the consultation. Use of printed information can be helpful but often these may be too detailed for patients to extract the key information from these in a timely manner. The plan for treatment requires shared decision making with the patient which in turn depends on patient understanding the key facts about the diagnosis and the treatment approaches. Although this key information is provided during consultation, the patient may have difficulty remembering these facts due to reasons noted above. This hurdle can potentially be overcome with the use of pre-recorded audio-visual patient information materials which can help patients to recall and also share key information with their loved ones. We report here on our innovative project to produce pre-recorded audio-visual information for patients about six common haematological malignancies.
Aims: We applied for and secured a grant from a charity for a two year project to develop and produce professionally recorded short films for patient information about six common haematological malignancies. The conditions chosen were: Chronic Lymphocytic Leukaemia, Chronic Myeloid Leukaemia, High grade Lymphoma, Low grade Lymphoma, Myeloma and Hodgkin's disease.
Methods: We started by consulting and seeking guidance from numerous patients with these conditions. We also spoke and took advice from experienced health professionals working with haemato-oncology patients. Based on the wisdom gathered we compiled the key evidence based facts about each of these diseases and their management. Details on specific treatment regimen were not included and the importance of building a partnership with the treating team was emphasized as the source of specific detail about planned therapy. These key evidence based facts were then converted into lay language which became the written scripts for each short film. A 10-15 minute short film was recorded for each of six diseases with the help of a professional team specialising in creating educational films. A clip about the role of specialist nurses was also recorded. We also included additional voice recordings of real patients talking about their experience with the same diagnosis / disease.
Results: The result of this two year project was a professionally produced DVD for each of the six diseases. The patient information films have been recorded in English language with possibility of translation /transliteration as sub-titles. As a proof of concepts each DVD short film has been translated to Polish language subtitles using this method. The copies of the DVDs can be produced at fairly low cost to be given out to patients. However, keeping with current trends, most patients are able to use web based information technology quite easily. In view of this we have expanded the project by developing a dedicated website (www.patientmedianetwork.com) to make these audio-visual materials available online to make it easy to access them without the need for DVD players etc. Also by making it freely available on the web, it shall serve patients beyond our geographic boundaries as anyone can access this patient information resource online now.
Summary/Conclusions: Pre-recorded, purposeful and specific audio-visual information can not only provide key facts about the diagnosis and its management but can also be used to create hope. It can be a resource to improve recall of important information as the patient and family can listen to it again and again after the initial visit to the clinic. And better understanding of their disease helps with patient participation in shared decision making which enhances their subsequent adaptation to the illness and its experience. Most importantly aim of this work is to reduces human suffering associated with diagnosis of these haematological malignancies and help optimize patient adjustment to the journey ahead. Our work also illustrates the importance of informatics and technology to improve patient-centeredness and we are keen to share our innovative work and ideas with the wider professional community.

E1449

SEXUAL DYSFUNCTION AMONG FEMALE LYMPHOMA PATIENTS IN MALAYSIA

DLC Ng[1,*], GG Gan[2], L Yeh Chwan[2]
[1]Medicine, University Malaysia Sarawak, Samarahan, [2]Medicine, University Malaya, Kuala Lumpur, Malaysia

Background: Sexual dysfunction is a recognized long-term consequence among cancer patients who had received cytotoxic chemotherapy. Previous studies on female dysfunction were mainly on patients with breast cancer or gynecological malignancies. This is the first study of sexual dysfunction among lymphoma patients in this region.
Aims: To study the prevalence of sexual dysfunction among lymphoma patients and its association factors.
Methods: This is a cross sectional survey which was conducted among female lymphoma patients who attend haematology clinic at University Malaya Medical Centre, Kuala Lumpur, Malaysia. Patients age 18 years and above were recruited and patients with previous gynecological surgery, other previous malignancy and those who are newly diagnosed were excluded. Demographic data and medical history were obtained from patients and medical notes. Patients were interviewed using the validated Female Sexual Function Index (FSFI), European Organization for Research and Treatment of Cancer (EORTC QLQ C30) and Hospital Anxiety and Depression Scale (HADS). Presence of anxiety and/or depression symptoms were identified with cut off score of 8/21 for each subset. Data were analyzed using SPSS version 21.0. Total sum of FSFI scores were dichotomized into 2 categories; presence and absence of sexual dysfunction based on cut off value of 26.55. Associations between the demographic / clinical factors, HADS groups, and quality of life scores with sexual dysfunction were tested using Pearson Chi-Square or Fischer Exact Test where applicable.
Results: A total of 107 women aged 51.71±17.48 years (18-89) participated, of which 72% (n=77) were not sexually active for more than 4 weeks. The main reasons for non-sexually active were 1) no partner, 63.6% (n=49), followed by 2) problems suffered by partners, 24.7% (n=19) and 3) physical problem suffered by patients, 18.2% (n=14). Among those with partners, 70% (n=21) had sexual dysfunction despite being sexually active. Mean score of FSFI for patients with partner was 16.27 (± 10.28). All of these patients had lack of sexual desire. The sexual dysfunction was not significantly associated with demographic characteristics (age group, ethnicity, religion, education levels) or clinical characteristics (presence of comorbidity, remission status, treatment received, progress of treatment). However it was associated with menopausal state $X^2(1)=7.366$, p=0.007. Presence of anxiety (22.4%) and depression (8.2%) symptoms was not significantly associated with sexual dysfunction. There was no significant association between sexual dysfunction and quality of life.

Table 1.

Table 1. Association of clinical characteristics with sexual dysfunction (FSFI score < 26.55)

Clinical characteristics		Sexual dysfunction,N (%)	p value
Age group	< 56	22 (47.8)	0.301
	≥ 56	24 (52.2)	
Ethnicity	Malay	15 (32.6)	0.604
	Chinese	24 (52.2)	
	Indian	6 (13)	
	Others	1 (2.2)	
Religion	Muslim	15 (32.6)	0.18
	Christian	8 (17.4)	
	Buddhist	18 (39.1)	
	Hindu	5 (10.9)	
Education level	None/ Primary	12 (26.1)	0.243
	Secondary	25 (54.3)	
	College/ University	9 (19.6)	
Menopause status	No	10 (21.7)	0.007*
	Yes	36 (78.3)	
Comorbidity	None	20 (43.5)	0.506
	Yes	26 (56.5)	
Remission status	No	5 (10.9)	0.35
	Yes	41 (89.1)	
Treatment received	Treatment naive	0 (0)	0.742
	Chemotherapy/ immunotherapy	36 (78.3)	
	Chemotherapy + Radiotherapy	9 (19.6)	
	Transplant	1 (2.2)	
Treatment progress	Ongoing treatment	4 (8.7)	0.456
	Completed treatment	41 (89.1)	
	Pretreatment	1 (2.2)	
Current therapy	Nil	42 (91.3)	0.234
	Chemotherapy	4 (8.7)	
Duration from treatment completion	< 1 year	5 (12.2)	0.664
	1 - 5 year	18 (43.9)	
	≥ 5 year	18 (43.9)	
HADA ≥ 8	No	36 (78.3)	0.466
	Yes	10 (21.7)	
HADD ≥ 8	No	42 (91.3)	0.358
	Yes	4 (8.7)	

*p≤ 0.05 is statistically significant: HADA (Anxiety), HADD (Depression)

Summary/Conclusions: The prevalence of sexual dysfunction among lymphoma patients were higher than in general populations and unreported by most of our patients. Further study on association of sexual dysfunction and quality of life is needed. Partners' problem should not be neglected in assessment of female patients with sexual dysfunction.

E1450

FATIGUE, QUALITY OF LIFE AND PHYSICAL FITNESS IN PATIENTS WITH MYELOMA

O McCourt[1,*], M Heinrich[2], A Fisher[2], B Paton[3], R Beeken[2], A Hackshaw[4], A Rismani[5], S D'Sa[5], K Yong[6]

[1]Acute Therapy Services - Cancer Therapy Team, University College London Hospitals NHS Foundation Trust, [2]Health Behaviour Research Centre, Department of Public Health & Epidemiology, University College London, [3]Institute of Sport, Exercise & Health, [4]Cancer Research UK Clinical Trials Centre, Cancer Institute, University College London, [5]Department of Haematology, University College London Hospitals NHS Foundation Trust, [6]Research Department of Haematology, Cancer Institute, University College London, London, United Kingdom

Background: Myeloma is a haematological malignancy characterised by periods of active, symptomatic disease that require intensive treatment, followed by periods of stable disease of 'plateau phase'. Complications include anaemia, hypercalcaemia, infections, renal failure, neuropathy and bone destruction which can lead to significant physical disability and impaired quality of life (QOL). Additionally, cancer-related fatigue is a common, chronic and often-debilitating side-effect of treatment. Combined, these factors could potentially lead to very low levels of physical fitness, further accelerating the decline in QOL of patients with myeloma. There are, however, limited data on objectively measured fitness in patients with myeloma, and it is unclear to what extent fitness is related to fatigue and QOL.
Aims: To evaluate levels of physical fitness, cancer-related fatigue and QOL in a myeloma survivorship population, and examine how these variables are related to one another.
Methods: Patients with myeloma were recruited to a survivorship lifestyle cohort study from hospital outpatient clinics. Participants were included if they had stable disease for at least 6 weeks, off treatment or on maintenance treatment, with ECOG 0-2, and were clinically able to carry out exercise testing. Fatigue was measured using the fatigue sub-scale of the Functional Assessment of Chronic Illness Therapy Fatigue Score (FACIT-F). A high score on the FACIT-F represents less fatigue, ranging from 0-52. QOL was assessed using the emotional well-being and functional well-being sub-scales of the Functional Assessment of Cancer Therapy (FACT-G) score. Higher scores in the FACT-G indicate better QOL, ranging between 0-52. VO_2^{peak} was measured during cardiopulmonary exercise testing (CPET) with a cycle ergometer.
Results: 51 patients in plateau phase were included in these analyses. Median age was 64 years (range 42-78), and 59% were male. 5 patients were older than 70. Median time from last treatment was 19 months (range3-139). Mean fatigue (FACIT-F) score was 40.94 (median 45, range 8-52), and 20 patients had a score below the mean reference range of 40.1.Mean quality of life (FACT-G) score was 40.58 (median 42, range 19.4-52), and 21 patients had a score below the mean reference value of 38.4. Mean VO_2^{peak} was 17.59ml/kg/min (SD ±4.94, range 10-28ml/kg/min). FACIT-F scores and VO_2^{peak} were positively correlated r=0.30 p<0.04. FACT-G scores and VO_2^{peak} were positive correlated r=0.31 p<0.03. FACIT-F and FACT-G scores were positively correlated r= 0.60 p<0.001.
Summary/Conclusions: Patients with higher levels of cardiopulmonary fitness scored higher on FACIT-F fatigue and FACT-G QOL measures. This indicates that patients with higher levels of fitness were less fatigued and had higher levels of emotional and functional well-being. A significant proportion of patients had scores below normative means for both fatigue and QOL. This analysis of baseline data in a post treatment myeloma survivorship group provides support for further investigation into the use of PA interventions delivered during and post cancer treatment to improve physical fitness and reduce fatigue so as to enhance QOL in this population.

E1451

PALLIATIVE CHEMOTHERAPY PEPC (PREDNISOLONE, ETOPOSIDE, PROCARBAZINE AND CYCLOPHOSPHAMIDE) IS EFFECTIVE AND TOLERABLE IN PATIENTS WITH RELAPSED/REFRACTORY LYMPHOMAS

I Kryachok*, I Titorenko, T Kadnikova, K Filonenko, T Skrypets, Y Kushchevyy, I Pastushenko, O Aleksik, K Ulianchenko, O Novosad [1], A Martynchyk, I Stepanishyna, A Novdah
Oncohematology, National Cancer Institute, Kiev, Ukraine

Background: Nowadays there are no universally accepted protocols and specific criteria for carrying out palliative chemotherapy in patients with lymphoproliferative diseases. The main problem of palliative chemotherapy is to choose an optimal treatment strategy for conducting effective therapy with minimization of adverse events. Therefore, there are a lot of needs to organize studies to improve palliative chemotherapy protocols in patients with lymphomas.
Aims: In the department of oncohematology the present trial was aimed to study the efficacy and toxicity of PEPC chemotherapy in research period from August 2011 to November 2015.
Methods: A total of 70 patients were included in study who received PEPC chemotherapy with palliation aim. Indications for palliative treatment were: relapsed or refractory Hodgkin or Non-Hodgkin lymphomas after 2nd and 3rd line treatment without efficacy and contraindications of further treatment, with the aim of nonradical treatment. Patients received therapy every day till leukocytes level <3x10 9/L: prednisone 20mg, cyclophosphamide 50mg, etoposide 50 mg, procarbazine 50 mg. When leukocytes level decreased below (<3 x 10 9/L) therapy was stopped and then renewed when leukocytes were recovered >3x10 9/L in every day regimen or every other day or fractional regimen (5 times a week, then 2 day break). The daily dose was always the same, perhaps it was only a change in the number of days in a week in which to take the drugs. Another goal was to investigate subjective improvement in general condition.
Results: A total of 70 patients were enrolled. Median age of patients was 46,85±4,3 years (from 19 to 74 years old), 38 man, 32 woman. There were included 25 patients with Hodgkin's lymphoma and 45-Non-Hodgkin lymphoma (large B-cell lymphoma-35 pts, MZL-35, CLL/SLL-2, T-lymphoblastic-3, peripheral T-cell lymphoma-1, anaplastic-1). Relapsed lymphoma was diagnosed in 37 patients. The number of relapses ranged from 1 to 5 (median 1,69±0.90). Refractory lymphoma was observed in 43 patients. As a second and third line treatment patients received DHAP, GVP, GEMOX, ICE, MINE chemotherapy. Prior to palliative course they received an average of 2.03+0.62 - treatment lines (from 1 to 5 salvage-regimens). Response rate to therapy was assessed in 46 patients. OR was achieved in 36,95% (n=17), CR - 6,52% (n=3), PR - 30,43% (n=14), SD - 39,13% (n=18). All patients had subjective improvement in general condition. PD on therapy with no apparent positive response was observed in 23.91% patients (n=11). Duration on PEPC therapy ranged from 1 to 15 months, average duration of therapy was 5,15±2,01 months (from 3 to 20 months). Nonhematologic toxicities (II / III grade CTC NCI v.4.02) are seen in 19 patients (27,14%). Infectious complications were observed in 3 patients (8,1%), febrile neutropenia (grade III-IV) - 27 (29,7%) and grade I-II - 12 (17,14%). Grade III anemia occurred in 5 patients (7,14%), grade II anemia-in 23 (32,85%). Thrombocytopenia (grade III) registered in 3 patients (4,28%) without hemorrhagic syndrome.Currently, 22 (31.4%) patients continue treatment. Because of disease progression 48 patients died.
Summary/Conclusions: PEPC chemotherapy is an effective treatment for extremely unfavorable group of patients with relapsed/refractory non-Hodgkin's lymphoma and Hodgkin's lymphoma and has an acceptable toxicity profile.

E1452

OUT-OF-POCKET ECONOMIC BURDEN AMONG COMMERCIALLY INSURED PATIENTS NEWLY DIAGNOSED WITH MULTIPLE MYELOMA IN THE U.S.

B Seal[1,*], S Schwartz[2], M Jhaveri[1], M Lingohr-Smith[3], J Lin[3], D Romanus[1]
[1]Millennium Pharmaceuticals, Inc., Cambridge, [2]Wharton School of the University of Pennsylvania, Philadelphia, [3]Novosys Health, Green Brook, United States

Background: Patient (pt) outcomes have markedly improved with the introduction of novel agents for multiple myeloma (MM), but the economic burden of MM management in the U.S. is high. The increasing burden of out-of-pocket (OOP) costs on cancer pts is of concern especially with a shift in insurance coverage towards more cost-sharing. Annual OOP expenditures have been estimated as $5,054 for lung cancer (2015 US $, Romanus 2008) and $5,472 for solid tumors (Zafar 2013). Data on OOP costs in MM in the era of novel treatments are limited.
Aims: This retrospective cohort study estimated overall healthcare costs (OHC) of MM management and OOP burden among commercially insured U.S. pts newly diagnosed with MM (NDMM) in the U.S.
Methods: Pts<65 years of age with NDMM were identified, based on ICD-9-CM codes, in the MarketScan claims database from 1/1/2008 to 9/30/2013. Pts initiating MM treatments were followed from the date of initial MM treatment (index date). All pts had continuous medical and prescription (Rx) commercial insurance coverage 12 months (mos) before (baseline period) and at least 12 mos after (follow-up) the index date. Pts with claims for transplants or Medicare insurance were excluded. Pt socio-demographic characteristics were evaluated during the 12-mo baseline period. Cumulative OHC (sum of payments to the provider paid by the insurance, the patient and other payers) and OOP payments (sum of copayments, co-insurance and deductibles paid by pts) were determined at 1-, 2-, and 3-years post-index date among pts who had continuous commercial insurance coverage through each corresponding year.
Results: Among 628 commercially insured pts with NDMM, mean age was 56.2 years (SD:6.3); 54.6% were male, 32.8%, 33.4% and 33.8% had a Charlson Comorbidity Index (CCI) score of 0, 1-2, 3+, respectively; 57.2% were enrolled in a preferred provider organization (PPO) plan, 17.7% in a healthcare managed organization (HMO) plan; 38.2% resided in the South, 24.8% in the West, 22.5% in the North Central, and 13.9% in the Northeast regions of the U.S. Mean total healthcare payments per patient in year 1 were $202,593, with $76,595 for outpt medical services, excluding drug and drug administration, $42,681 for inpt services, $35,491 for outpt MM drug and drug administration services, $40,414 for MM drug prescriptions, and $930 for the emergency room (Table). Over time the relative proportions of OHC by service type were consistent. Over the 3 year study period, OOP payments ranged from 2.2% to 2.7% of the total healthcare payments (Table). Total cumulative OOP costs increased from $4,363 in year 1 to $9,909 over the first 3 years after the index date. MM drug related OOP (those administered in outpatient clinics or filled as an Rx) ranged from 1.6% in year 1 and 2 to 1.7% in year 3 of total MM drug treatment expenditures. The main contributor to OOP costs was related to outpatient medical services, $2,200, $3,704 and $5,099 through years 1, 2 and 3, respectively.

Table 1.

Table. Cumulative Payments over 1-, 2-, 3-year Follow-up Time Periods in NDMM.

Service Type	Mean Total Payment ($) (% of total payment)	Mean OOP Payment ($) (% of total OOP)	% OOP of Total Payment by Service Type
Within First Year (n=628)			
Outpatient Medical Services	76,595 (37.8)	2,200 (50.4)	2.9%
Inpatient	42,681 (21.1)	286 (6.6)	0.7%
Emergency Room	930 (0.5)	50 (1.1)	5.4%
Outpatient MM Drug and Administration Services[a]	35,491 (17.5)	622 (14.3)	1.8%
MM Drug Prescriptions[b]	40,414 (19.9)	581 (13.3)	1.4%
Non-MM Drug Prescriptions	6,483 (3.2)	624 (14.3)	9.6%
Total (Inpatient + Outpatient, including Drug Costs)	**202,593 (100)**	**4,363 (100)**	**2.2%**
Within First Two Years (n=310)			
Outpatient Medical Services	107,516 (37.3)	3,704 (49.7)	3.4%
Inpatient	45,391 (15.7)	570 (7.6)	1.3%
Emergency Room	2,246 (0.8)	96 (1.2)	4.3%
Outpatient MM Drug and Administration Services	39,164 (13.6)	731 (9.8)	1.9%
MM Drug Prescriptions	83,590 (29.0)	1,231 (16.5)	1.5%
Non-MM Drug Prescriptions	10,381 (3.6)	1,120 (15.0)	10.8%
Total (Inpatient + Outpatient, including Drug Costs)	**288,289 (100)**	**7,451 (100)**	**2.6%**
Within First Three Years (n=133)			
Outpatient Medical Services	131,736 (36.4)	5,099 (51.5)	3.9%
Inpatient	50,413 (13.9)	408 (4.1)	0.8%
Emergency Room	1,503 (0.4)	108 (1.1)	7.2%
Outpatient MM Drug and Administration Services	47,952 (13.2)	919 (9.3)	1.9%
MM Drug Prescriptions	116,271 (32.1)	1,808 (18.2)	1.6%
Non-MM Drug Prescriptions	14,053 (3.9)	1,567 (15.8)	11.2%
Total (Inpatient + Outpatient, including Drug Costs)	**361,928 (100)**	**9,909 (100)**	**2.7%**

[a]MM drug therapy administered in outpatient clinics; [b]MM drug therapy filled as a prescription in a pharmacy; MM drugs include: immunomodulators (lenalidomide, thalidomide, pomalidomide); proteasome inhibitors (bortezomib, carfilzomib); other: cyclophosphomide, melphalan, vincristine, (liposomal) doxorubicin, interferon, panobinostat, bendamustine, vorinostat

Summary/Conclusions: In this study based claims data from 2009 to 2013, the main cost driver of OHC and OOP among U.S. NDMM pts receiving treatment was accounted for by non-MM drug therapy related services. Mean MM drug therapy and drug administration related OOP costs were less than $100 per month. These results are based on commercial claims and do not reflect reimbursements from copayment assistance programs.

Città della salute e della scienza di Torino, Hematology, Turin, [22]Ospedali Riuniti B.M.M, Hematology, Reggio Calabria, [23]Ospedale Santa Maria delle Croci, Hematology, Ravenna, [24]Dipartimento salute, GFK Eurisko, Milan, [25]Sapienza University, Health Psychology, Rome, [26]Ospedale Sant'Orsola Malpighi, Hematology, Bologna, [27]Ospedale S. Eugenio, Hematology, Rome, Italy

Background: Despite impactful result achieved with imatinib, about 40% of patients experience treatment failure and more than 15% the persistence of long-term side effects that impaired quality of life.
Aims: To investigate how a change in TKI therapy has an impact on familiar, social and working setting of CML patients' daily life.
Methods: A structured questionnaire was administered to patients switched to nilotinib second-line after imatinib resistance or intolerance for not less than 6 months and not more than 36 months, regardless type of response. Twenty-five Italian centers participated collecting 142 patients.
Results: There were 61% males and 39% females, median age was 57 years (range 29-91). 65% with superior scholar degree. Median time from diagnosis for the overall cohort was 8 years, with 9% diagnosed less than 4 years, 66% from >4 to<10 years and 25% for ≥10 years. Sixty-one% of patients changed because of loss of efficacy with imatinib, whereas 39% for persistence of intolerance. Median time in imatinib treatment was 5 years, whereas median time with nilotinib after switch was 2 years. Overall, the level of satisfaction was requested to nilotinib and imatinib, respectively, and 93% of nilotinib-treated patients reported high level as compared to 52% of imatinib-treated patients. Dissecting this data, nilotinib-treated population reported in particular high satisfaction for achieved response (64%), for the level of daily quality of life (33%) and for tolerability (32%). Comparing imatinib and nilotinib, the majority of patients reported an impact of therapy on daily activities: 64% with imatinib reported low productivity at work (as compared to 33% with nilotinib) with 57% of them required absences from work (as compared to 35% with nilotinib). Analysing psychological perceptions, 64% of patients treated with imatinib reported the sensation of no longer feel themselves (as compared to 33% with nilotinib), and 36% to feel uncomfortable with their families (as compared to 18% with nilotinib). Overall, after switch, more patients referred a strong improvement of approach in daily living towards disease and therapy. More common emotions requested to patients to represent actual therapy with nilotinib were "trust" (65% *vs* 24% with imatinib), "joy" (52% *vs* 4% with imatinib) and "serenity" (29% *vs* 10% with imatinib); indeed, referred to previous therapy with imatinib, the more common emotions reported were "worry" (52% *vs* 22% with nilotinib), sadness" (30% *vs* 6% with nilotinib). "fear" (27% *vs* 15% with nilotinib), "frustration" (22% *vs* 4% with nilotinib). After switching to nilotinib, it has been asked perceptions about a possible discontinuation: 50% of patients would discontinue due to trust in personal physician, 26% to no longer feel sick and only 18% of patients would not stop for fear to losing all benefits achieved.
Summary/Conclusions: The results of this patient-centered analysis indicating high level of satisfaction in CML patients who switch to nilotinib after previous imatinib therapy, with improvements toward social, working and familiar daily life.

E1454

PSYCHOMETRIC PROPERTIES OF THE GREEK TRANQOL QUESTIONNAIRE FOR MEASURING QUALITY OF LIFE IN GREEK ADULT PATIENTS WITH THALASSEMIA MAJOR

P Klonizakis[1,*], R Klaassen[2], S Nikolaos[1], L Aris[3], A Tsapas[3], E Vlachaki[1]
[1]2nd Department of Internal Medicine, Thalassemia Unit, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]Department of Pediatrics, Division of Hematology/Oncology, University of Ottawa, Children's Hospital of Eastern Ontario, Ottawa, Canada, [3]2nd Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Greece is a country with a large population of thalassemia patients. To date, there only a few studies measuring quality of life in Greek thalassemia major patients, with the available data mainly derived from generic QoL questionnaires. TranQoL is a novel disease-specific QoL instrument that has been specifically developed to assess QoL in thalassemia major patients.
Aims: This study aimed to evaluate the construct validity, reliability and responsiveness of the Greek translated version of the TranQoL questionnaire.
Methods:
The novel Greek TranQoL and the valid generic Greek SF-36v2 questionnaires were administered in 94 consecutive thalassemia major patients that were followed up at the Adult Thalassemia Unit of "Hippokration" general hospital of Thessaloniki, Greece, one of the largest thalassemia centres in Greece. Both questionnaires were completed anonymously during two subsequent transfusion visits, 2-3 weeks apart. A week after the transfusion visit the participants were asked to complete the TranQol at home, a third time, and describe any change in their quality of life using a 7-point Likert-type scale. Construct validity was assessed using Pearson's correlation between the TranQoL scores and the SF-36v2 scores at the first visit. In addition, the t-test or analyses of variance were used to compare TranQoL scores between patient groups that have known differences in quality of life. Assessment of reliability involved the determination of internal consistency by calculating the Cronbach's α-coefficient. Accordingly, the intra - class correlation coefficient (ICC) between the TranQol scores of the baseline visit and the subsequent visit was calculated in order to assess test-retest reliability. In order evaluate responsiveness, we used the paired t-test method to compare TranQoL scores between the transfusion visit and the home visit, in the group of patients who reported to be at least "a little better" after their last blood transfusion.
Results: There was a moderately strong correlation between the TranQoL summary and both the SF-36 Physical and Mental Component Summaries ($r=0.43$, $p<0.001$ and $r=0.520$, $p<0.001$ respectively). There was also a moderately strong correlation between the Physical Health scale of TranQoL and the relevant SF 36 scales, including Physical Functioning ($r=0.4$, $p<0.001$), role - physical ($r=0.6$, $p<0.001$) and bodily pain ($r=0.5$, $p<0.001$). In terms of reliability, TranQoL exhibited good internal consistency, with a Cronbach alpha coefficient reported of 0.89. Test-retest reliability was excellent (intra-class correlation coefficient, 0.9). Regarding know groups validity, patients with hypothyroidism had significantly lower TranQoL summary scores compared to patients without hypothyroidism (65%, range: 57-83 *vs* 75%, range: 42-98, $p<0.05$). There was also a significant difference in the score of the domain "school and career functioning" for oral (81±17%) *vs* subcutaneous iron chelation (70±29%). In terms of responsiveness, in the patients subgroup that rated their QoL as better in the Likert-type scale, there was a 4.2 point (SD 5.0) improvement in TranQol scores, from their transfusion visit (73.9%) to one week later at the home visit (78.1%), ($p<0.005$).

Summary/Conclusions: In conclusion, the psychometric properties of the Greek version of TranQoL confirmed that it is valid, reliable and responsive to change. The TranQoL can be incorporated into future studies of thalassemia major in Greek patients.

E1455

BIG DATA ANALYTICS & PATHOLOGY SERVICES IN NHS: ACHIEVING STEP CHANGES IN CAPACITY

M Laffan[1], S Douglas[2], R Littlewood[2,*]
[1]Haematology, imperial college london, [2]Applied, Applied Strategic, London, United Kingdom

Background: A major hospital Trust in London provides healthcare for a large population across Medicine, Surgery, Obstetrics and other specialties. Three laboratories are on sites using automated, high capacity analysers to provide pathology services much of which requires rapid turnaround. The major challenge for laboratories in this situation is centred on the high throughput tests comprising full blood count, assessment of renal/ liver function, and coagulation. To date these services have not been subjected to detailed analysis of demand, efficiency of use of analyser capacity and efficiency of physician requesting.
Aims: First to determine the factors limiting the turnaround times for routine testing throughout periods of varying demand and those factors limiting the optimum use of existing analyser resources. Second, to identify requesting practices that are inefficient or which drive the changes in demand.
Methods: A database consisting 20M data points from 1M pathology test requests, recorded over 1 year was provided including details of requester and site of request with way points defining the passage of the sample from request time through to test reporting. This allowed a map of volume and activity over time and test turnaround times identifying bottlenecks and changes in efficiency. Parameters showing healthcare professional ordering of tests, location of patient and laboratory site were also provided and analysed.
Results: Initial descriptive analysis showed 1 particular laboratory had difficulties achieving its potential capacity utilization rate and target turnaround times. Bottlenecks were clearly identified at sample entry into the laboratory and at validation of results. These resulted in build-up of samples and delays in reporting that were staggered in time: thus although the peak in TAT occurs at 4pm the extra capacity was required prior to this, revealing a negative, delayed impact of test arrival on test turnaround time. This has obvious implications for laboratory management. The fastest 10% of FBC tests were reported in 0.2hr and 80% in 1.5 hrs but the slowest 10% varied from 2-120 hours. Of 200,000 tests processed per year at one lab, 47% were ordered by clinical division Medicine, 34% Surgery & Cancer / Clinical Haematology, 15% Women and Children. Medicine was the leading requester at all 3 sites. Of 2,000 physicians, 87% order fewer than 500 tests per year. Some intensive requesting practices are probably masked by the use of common requesting codes. 61% of patients have only 1 to 2 tests per year, the proportion of patients having 100 tests per year being less than 1%. However at one site >1% of patients had >50 tests per year, identifying an intensively monitored population. Measurement of true machine capacity highlighted a large gap between current performance and maximum potential indicating that better sample profiling and management could produce savings. The maximum capacity for FBC was 420 tests per hour but the average performance was 60/hr and the peak rate of reporting only 95/hr.
Summary/Conclusions: Big data analytics and process mapping identified 2 rate-limiting steps to performance inherent in current test system: test received at lab and validation of results. Close analysis of such a large dataset indicates how we can optimise the laboratory processes and improve utilisation of current installed capacity in NHS pathology services.

E1456

THE EFFECTIVENESS OF CLINICAL TRIAGE: CLOSING THE AUDIT LOOP

L Vanhinsbergh*, F Chowdhury
Haematology, NHS, London, United Kingdom

Background: In 2014-2015 there were 85 million outpatient clinic attendances in NHS hospitals across the UK with a cost to secondary care exceeding £15 billion. 25.9 million (30 percent) of these were first appointments. In 2014 we audited a 6 month period of haematology outpatient clinic referrals and established the effectiveness of clinical triage in filtering inappropriate referrals. We established that 74% of all new patient referrals were from primary care in 2014. Of the rejected referrals 96% were from primary care.
Aims: In 2015, we implemented audit guided interventions, consisting of structured consultant led primary care teaching sessions across the North West London region. These sessions were specifically designed to educate and guide primary care physicians regarding haematological symptoms and blood parameters requiring secondary care input. The intervention was made with the aim of both capturing potential haematological malignancies at an early stage and also reducing inappropriate referrals. The proposed secondary outcome of this intervention was cost efficiency saving and improvement in regional haematology care.
Methods: Data was collected retrospectively from a local clinic referral database containing information on all new patient referrals including demographics, referral reason and triage outcome. We compared data from a four month period (June to September) in 2014 with the same four month period a year later in 2015.
Results: Our data shows a 31 percent increase in monthly referrals in 2015. The mean monthly referral number increased from 169 in 2014 to 244 in 2015. Despite this we saw a reduction in the percentage of inappropriate referrals to the service. In 2014 a monthly mean of 22 percent of referrals were rejected with feedback provided to the referring clinician. In 2015 the rejected referral rate was reduced by 6 percent to a monthly mean of just 16 percent for the same time of year period. 37% of referrals were for clotting/ thrombosis, 23% potential haematological malignancy including 2 week waits and the remaining 40% general haematology.
Summary/Conclusions: Our data support the ongoing use of consultant led clinical triage and primary care education in order to reduce the significant cost burden of new patient clinics whilst remaining safe for patient care.

E1457

USE OF COMBINED ORAL ADMINISTRATION OF ANALGESIA AND ANXIOLYSIS FOR PAIN ASSOCIATED WITH BONE MARROW ASPIRATION AND BIOPSY

A Gravetti, C Cerchione*, A Casoria, N Pugliese, L Marano, F De Gregorio, M Di Perna, M Picardi, V Martinelli, F Pane
Hematology, Ematologia e Trapianto/AU Federico II, Napoli, Italy

Background: Bone marrow aspiration and biopsy (BMB) is central to the diagnosis and management of many haematological disorders and is a safe procedure associated with low morbidity and mortality. For adults, the infiltration of local anesthesia at the biopsy site has been used as the principal form of analgesia for BMBA. Unfortunately pain relief is often incomplete especially during aspiration of the bone marrow. In addition, pain is likely to contribute to the anxiety the patient may already be experiencing.
Aims: In this study we assessed an oral administration of analgesia (fentanil-ACTIQ) and anxiolysis (midazolam). 107 consecutive ambulatory adult patients referred for bone marrow examination were enrolled. Informed consent for the procedure was obtained from all patients.
Methods: All patients received local anaesthesia (LA) with 10 mL of injected 2% lignocaine, but 52 patients received LA alone (group A) and 55 patients LA plus 5 mg midazolam (oral administration) and 200 mcg of Fentanyl transmucoso (group B), 30 min before the procedure. The pain level was assessed with the Numeric Rating Scale which distinguishes ten levels of pain, from 0 to 10 in five times of procedure (baseline, start LA T1, aspiration T2a, biopsy T2b, five minutes after the end of the procedure T3). At the end, all were given a questionnaire about efficacy, satisfaction, comfort with three levels (1/low-2/medium-3/high).
Results: This medium values were found: at time T1 the medium level of pain was 0.87 for the group A *vs* 0.88 of group B, at time T2a 3,63 group A *vs* 3,54 group B, at time T2b 4,63 group A *vs* 4 group B ($p<0,05$), time T3 0,41 group A *vs* 0,16 group B ($p<0.05$). In addition 21 Patients, who have already undergone the procedure without sedoanalgesia, saw to prefer the new medication.
Summary/Conclusions: Our preliminary results seem interesting because underline the different subjective perception of pain in the two groups and especially show a main level of satisfaction and comfortable in our patients undergone medication with sedoanalgesia and a lower level of anxiety in view of a possible repeat of examination.

E1458

THE IMPACT OF AL AMYLOIDOSIS ON ABSENTEEISM, REDUCED PRODUCTIVITY, AND JOB LOSS

S Guthrie[1,*], MK White[2], KL Mccausland[2], M Bayliss[2]
[1]Prothena Biosciences Inc, South San Francisco, CA, [2]Optum, Lincoln, RI, United States

Background: Debilitating chronic conditions and their treatments often negatively impact patient's ability to work, resulting in absenteeism, reduced productivity, and job loss. Light-chain (AL) amyloidosis is a rare disease in which misfolded light chains are deposited in tissues, which may lead to organ failure, disability, and death. Current treatments are known to affect patients' functioning and well-being, but there is little evidence to date on the impact of AL amyloidosis on patients' ability to work.
Aims: To describe the impact of AL amyloidosis on patients' work using data from qualitative and quantitative research.
Methods: Data for these analyses were collected from two phases of a broad research program on the experience of patients with AL amyloidosis. First, qualitative in-depth individual telephone interviews were conducted with 10 patients. Results are presented from coded interview transcripts that were analyzed using a grounded theory approach to identify themes. Second, a quantitative online survey including a battery of patient-reported outcome measures

was conducted in a separate sample of patients (n=341). The data presented are based on the Work Productivity and Activity Impairment (WPAI) questionnaire for the subset of employed patients, including a single-item measure of the number of hours absent from work due to AL amyloidosis and a multi-item scale assessing overall lost productivity. Wilcoxon-Mann-Whitney tests were used to compare mean WPAI scores by time since diagnosis (<12 months ago *vs* ≥12 months ago) among those with cardiac involvement.
Results: In qualitative interviews, 7 of 10 patients reported that AL amyloidosis impacted their ability to work, manifesting as loss of focus or productivity, absenteeism including extended leaves of absence, and job loss. Patients reported underperforming at work and attributed this to symptoms, treatment side effects, and time required for doctor visits. Most felt their employers were supportive of their health needs; however, in some cases, job loss led to financial difficulties for families and frustration at subsequent changes in household roles. In the quantitative study, 115 patients (38.3%) were currently employed. Of these, the mean age was 56.1, 56% were female, and 10% were non-Caucasian. On average, employed patients reported being absent from work 5 hours per week and a 27.6% reduction in overall work productivity due to AL amyloidosis. Patients with cardiac involvement reported significantly higher absenteeism compared to those without cardiac involvement (mean hours absent per week: 15 *vs* 2.5 hours, respectively, $p<0.02$). Within the subgroup with cardiac involvement, overall lost work productivity for those diagnosed within the past year was twice that of patients with cardiac involvement who were diagnosed more than a year ago (54.4% *vs* 25.4%, respectively, $p<0.04$).
Summary/Conclusions: These results indicate that AL amyloidosis has a significant impact on patients' work, causing absenteeism, impaired productivity, and job loss. These results highlight additional costs of AL amyloidosis that are not related to medications or procedures, but are borne by patients, their employers, and their families. Advancements in treatment options for patients with AL amyloidosis and increased attention to patients' functioning and well-being could potentially minimize these hidden costs.
Study supported by: Prothena Biosciences Inc.

HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH MULTIPLE MYELOMA IN RELATION TO LINE OF TREATMENT AND RESPONSE

XH Hu[1,*], K Bozena[2], M Lowe[2], L Purnomo[1], C Gibson[1], AM Rodriguez[2]
[1]Celgene Corporation, Summit, NJ, [2]PatientsLikeMe, Boston, MA, United States

Background: Health-related quality of life (HRQoL) in patients with multiple myeloma (MM) has mostly been evaluated in controlled trials composed of largely homogeneous patient populations. There is a paucity of literature examining HRQoL in patients with MM at different treatment stages in a real-world setting.
Aims: To document and compare self-reported HRQoL outcomes in patients with MM across different lines of treatment and response status.
Methods: US patients with self-reported MM were recruited through an online patient-powered network, PatientsLikeMe. Upon completion of informed consent, study participants were asked to provide their MM treatment history and complete the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30). HRQoL scores were compared using the Kruskal-Wallis test across the following subgroups: patients who had received stem cell transplant (SCT); patients who had not switched their drug regimens as a result of disease progression; patients who had 1-3 drug regimen switches because of disease progression; and patients who had ≥4 switches because of disease progression. HRQoL domain scores were also compared across subgroups based on response status reported to patients at their last provider visit (complete response, partial response/under control/stable, relapse/recurred or not responsive/progressive disease) irrespective of treatment lines.
Results: A total of 199 patients completed the online survey. Of these, 10 patients were excluded from this analysis because they had not received any MM treatment. Of the remaining 189 patients, the median age was 61 years (range, 37-82 years) and 57.6% were women. 58 patients reported receiving SCT, 66 patients reported not switching treatment regimens because of disease progression, 43 patients reported 1-3 switches because of disease progression, and 22 reported ≥4 switches because of disease progression. Global HRQoL domain scores varied from 58.3 to 68.7 ($P=.279$) as measured by the EORTC QLQ-C30. Comparable HRQoL in other domains were also reported across different treatment lines. Patients reporting their most recent response status as "complete response" had the highest Global HRQoL score (71.7) relative to patients reporting their most recent status as "partial response/under control or stable" (63.0) or "relapsed/recurred or not responsive/progressive disease" (55.6; $P=.012$). Similarly, statistically significant higher HRQoL scores were reported in the Physical Functioning, Social Functioning, and Pain domains in patients who experienced complete responses.
Summary/Conclusions: Domains of Global HRQoL, Physical Functioning, Social Functioning, and Pain in patients with MM treated in usual care settings were associated with their response status.

E1460

POMALIDOMIDE OR CARFILZOMIB USE IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA: REAL-WORLD TREATMENT PATTERNS, TIME TO NEXT TREATMENT, AND ECONOMIC OUTCOMES

K Parikh[1,*], L Purnomo[1], S Abouzaid[1], CC Chen[2], C McGuiness[2], M Hussein[1], R Wade[2]
[1]Celgene Corporation, Summit, NJ, [2]IMS Real-World Evidence Solutions and Health Economics & Outcomes Research, Plymouth Meeting, PA, United States

Background: Pomalidomide (POM) is an immunomodulatory agent first approved in the United States in February 2013 in combination with dexamethasone (DEX). Carfilzomib (CAR) is a proteasome inhibitor first approved in the United States in July 2012. Both POM and CAR were approved for patients with relapsed multiple myeloma (MM). Real-world data on the use of these agents in the United States are limited.
Aims: The aim of this study was to fill in gaps in real-world data on treatment patterns and outcomes with POM or CAR in patients with relapsed MM.
Methods: Patients with ≥2 MM diagnoses (ICD-9 203.0x) and a POM or CAR claim (index date) from 2/1/2013 to 2/28/2015, assumed to be relapse therapy, were identified in the PharMetrics Plus™ US claims database. Treatment regimens were defined as all MM therapies observed within 60 days of index. Patients with both POM and CAR within 60 days of index were excluded. Time to next treatment (TTNT), a proxy for disease progression, was defined as the addition of a new agent >60 days from index or treatment restart following a >90-day gap in therapy. Plan-paid median monthly apportioned costs were reported for total follow-up time, and Wilcoxon rank-sum tests were used to compare the cohorts.
Results: A total of 454 patients indexed to POM (n=264) or CAR (n=190) were identified. The mean age was 61.6 years (SD=9.3 years), 60.1% were men, and these characteristics were similar between groups. Pre-index stem cell transplant occurred at any time in 34.5% of POM patients and 26.3% of CAR patients ($P=.064$). POM+DEX (47.0%) and POM alone (33.0%) were the most common indexed POM treatments; and CAR alone (45.3%) and CAR+DEX (14.7%) were common indexed CAR treatments. The most frequently observed next-line treatment for POM-indexed patients was addition of or switch to CAR±DEX (29.0%), and for CAR-indexed patients it was switch to POM+DEX (9.3%), and CAR alone (6.7%) or CAR+DEX+cyclophosphamide (6.7%). For patients followed-up to disease progression (POM, n=100; CAR, n=75) the mean TTNT was longer for POM-indexed patients compared with CAR-indexed patients (6.9 *vs* 5.3 months; $P=.0164$). With a mean follow-up time of 8.9 months across both groups, 22.0% were still on index treatment, 17.0% were on subsequent treatment (POM, 17.8%; CAR, 15.8%), 9.7% were not on treatment, 25.3% had died (POM, 25.0%; CAR, 25.8%), and 26.0% had lost eligibility prior to classification. Median monthly costs were lower for POM *vs* CAR patients ($18,298 *vs* $24,734; $P=.001$).
Summary/Conclusions: This retrospective study of POM or CAR treatment in patients with relapsed MM found a significantly longer TTNT with POM-based regimens *vs* CAR-based regimens. POM-based regimens were observed to have lower monthly costs through the end of follow-up compared with CAR-based regimens.

INFLUENCE OF EXTENDED CARE ON LIVING QUALITY OF PATIENTS AFTER ALLOGENEIC HEMATOPOIETIC STEM TRANSPLANTATION

X Du[1], C Zhang, AH Sun[1], X Zhang[2,*], PY Kong[1], L Gao[1]
[1]Department of Hematology, Xinqiao Hospital, Third Military Medical University, [2]Department of Hematology, Xinqiao Hospital,Third Military Medical University, Chongqing, China

Background: Patient satisfaction with health care has become a widely recognised patient reported outcome of the quality and clinical effectiveness of health services. Assessment of patient satisfaction is essential to ensure that care and services meet the needs of patients because the expectation of quality care can vary between patients and practitioners.
Aims: To evaluate the influence of extended care on living quality of patients after allogeneic hematopoietic stem transplantation.
Methods: A total of 80 patients after allogeneic hematopoietic stem transplantation were enrolled in this study. They were randomly divided into intervention group and control group according to hospital number ending(odd and even numbers).The intervention group cases were given the extended care after discharging from hospital, but no intervention for the control group,and the quality of life was evaluated by using cancer patients quality of life measure scale developed by European Organization for research and treatment of cancer(EORTC) in the two groups at 1 month and 3 months after discharged.
Results: At 1 month after discharge,the cognitive function score and emotion function score in intervention group were better than that of control group; at 3 months after discharge,the scores of physical function,role function,cognitive function,social function,general health status and fatigued,insomnia symptoms in intervention group were better than that of control group.
Summary/Conclusion: Extended care for patients after allogeneic hematopoietic stem transplantation can effectively improve the quality of life of them.

SAFETY IN PROCEDURE OF EVALUATION FOR PRESCRIPTION OF ENDURANCE EXERCISES IN PATIENTS WITH SICKLE CELL DISEASE: A PILOT STUDY

LA Messonnier[1,2], B Gellen[3,4], S Peyrot[4], R Lacroix[1], T Rupp[1,5], F Galactéros[5,6,7], P Bartolucci[5,6,7,*], L Féasson[5,8,9]
[1]Laboratoire Interuniversitaire de Biologie de la Motricité, Université Savoie Mont Blanc, Chambéry, [2]Laboratoire d'Excellence GR-Ex, PRES Sorbonne Paris Cité, Paris, [3]Faculté de Médecine et de Pharmacie, Université de Poitiers, Poitiers, [4]Service de Cardiologie, APHP - GHU Henri Mondor-Albert Chenevier, Créteil, [5]Laboratoire d'Excellence GR-Ex, PRES Sorbonne Paris Cité, Paris, [6]IMRB équipe 2, Université Paris-Est Créteil, [7]Centre de Référence des Syndromes Drépanocytaires Majeurs, GHU Henri Mondor-Albert Chenevier, Créteil, [8]Unité de Myologie, Centre Référent Maladies Neuromusculaires Rares Rhône-Alpes, CHU de Saint-Etienne, [9]Laboratoire Interuniversitaire de Biologie de la Motricité, Université de Lyon, Saint-Etienne, France

Background: Physical activity is considered as potentially harmful in patients with sickle cell disease (SCD) and is therefore usually discouraged. Literature reports that during exercise, SCD patients may display gas exchange abnormalities, dyspnea, elevated pulmonary artery systolic pressure, left ventricular diastolic dysfunction, arterial hypoxemia. Vigorous exercise can also induce acidosis, hemorheological alterations, endothelial dysfunction and oxidative stress, which may trigger vaso-occlusive crisis in those patients. However, moderate and regular physical activity seems to be not only safe but also potentially beneficial for SCD patients (Barbeau et al. 2001, Faës et al. 2014, Martin et al. 2015).
Aims: The aim of the present study was i) to propose a submaximal incremental exercise test sufficiently intense to evaluate the physical ability of the patients but not intense enough to induce severe adverse events, and ii) to test the safety of moderate-intensity endurance exercise sessions individualized on basis of data obtained in i).
Methods: Twenty adult patients with homozygous SCD (12 men and 8 women, aged 21-53 years, 78.2±2.0% and 9.8±1.9% of HbS and HbF, respectively) participated in this study approved by the ethics committee (ClinicalTrials.gov NCT02571088). All patients underwent a submaximal incremental exercise (SIE). SIE started at 20 W and 30 W for women and men, respectively. After 2 minutes at this load, and every 2 minutes thereafter, workload increased by 10 W and 15 W for women and men, respectively. During exercise, twelve-lead EKG, heart rate (HR), pulmonary ventilation (VE), oxygen uptake (VO_2), systolic (SBP) and diastolic (DBP) blood pressure, peripheral capillary oxygen saturation (SpO_2), blood lactate concentrations ([Lac^-]) and rate of perceived exertion (RPE) were measured. Exercise was stopped (exercise completion) when a [Lac^-] of 4 mmol·L^{-1} was reached in order to limit acidosis. The first lactate threshold (LT1) was determined as the first inflection point of the [Lac^-] *vs* work rate curve. Besides, eight men and seven women of the group took part in three constant-load submaximal endurance exercise sessions. Each session lasted 40 min and consisted in a 5-min warm-up, 30 min of cycling at the workload corresponding to LT1, and 5 min of active recovery. HR, SpO_2 and [Lac^-] were checked regularly and values at the end of exercise were recorded. Work rate was adjusted between sessions to target a [Lac^-] of ~2.5 mmol·L^{-1}, which is usually used for endurance exercise in healthy sedentary and trained subjects. Descriptive statistics are expressed as mean±standard error (SE).

Table 1.

Table 1: data obtained during incremental and constant load exercises

	Men (n = 12)			Women (n = 8)		
	Rest	LT1	Completion	Rest	LT1	Completion

Results: Results are presented in table 1. Although submaximal, the incremental exercise was physiologically stressful since exercise completion intervened at ~85% of maximal theoretical heart rate ($HR_{max-theor}$). SIE allowed estimation of LT1 and related parameters (e.g., workload) for prescription of endurance exercise in SCD patients. HR, SpO_2, [Lac^-] and RPE observed during the constant load exercises were close to the expected values based on SIE. None of the studied patients experienced severe adverse events during or after SIE and endurance exercises.
Summary/Conclusions: We concluded that this procedure of SIE allowed evaluation of physical ability of SCD patients without inducing severe adverse events. Besides, SIE provided useful data (i.e., LT1 and related parameters) allowing prescription of apparently safe endurance exercises in patients with SCD. Armed of this experience, an individualized endurance training program might be proposed to patients with SCD.

E1462

ANXA2 GENE POLYMORPHISM (RS7170178) IS ASSOCIATED WITH OSTEONCROSIS DEVELOPMENT IN SICKLE CELL ANEMIA

DA Pereira-Martins[1,*], JL Coelho-Silva[1], A Ferreira da Cunha[2], J Cabral-Peres[3], F Ferreira Costa[4], A da Silva Araújo[3], AR Lucena-Araujo[1], MA Bezerra[1]
[1]Departament of genetics, Federal University of Pernambuco, Recife, [2]Department of Genetics and Evolution, Federal University of São Carlos, São Carlos, [3]Hematology Hospital, Hematology and Hemotherapy Foundation of Pernambuco, Recife, [4]Haematology and Hemotherapy Centre, University of Campinas, Campinas, Brazil

Background: The occurrence of vaso-occlusive crisis (VOC) and chronic hemolysis are clinical complications frequently observed in patients with sickle cell anemia (SCA). Nevertheless, these complications may vary in intensity and frequency within of the disease and several studies support the idea of a genetic component involved in the clinical modulation of these complications. With this in mind, two previously published genetic variants in *ANXA2* gene (*ANXA2**5681 G>A and IVS-14-1046 C>T) were associated with the development of specific clinical complications in SCA. Initially described as an important modulator of the bone mineralization and co-activator of the fibrinolysis process, the imbalance of the *ANXA2* expression may constitute a promising molecular marker for clinical heterogeneity in SCA.
Aims: Here, we evaluated the clinical impact of A*NXA2**5681 G>A and IVS-14-1046 C>T polymorphisms in patients with SCA, diagnosed and followed by a single reference center from northeast Brazil.
Methods: Seven hundred fourteen SS-genotyped patients were enrolled. The median age was 25 years (range: 3-61 years), with 347 males (49%). One hundred ninety four (27%) were younger than 18 years. The main clinical complications described in patients with SCA (osteonecrosis, stroke, acute chest syndrome, priapism, leg ulcer) were obtained from medical records. The last update occurred in January 2016. The A*NXA2**5681 G>A (rs7170178) and IVS-14-1046 C>T (rs7163836) polymorphisms were detected by real-time PCR. For test if both selected polymorphisms could influence the *ANXA2* gene expression, 70 patients with SCA were selected at random and the total RNA was isolated from peripheral blood. The *ANXA2* transcript levels (Hs_00743063_s1) were analyzed by real-time quantitative PCR quantified using the *GAPDH* as endogenous control.
Results: Overall, 144 patients (20%) developed leg ulcer, followed by priapism (97 patients, 14%), osteonecrosis (84 patients, 12%), acute chest syndrome (82 patients, 11%), and stroke (70 patients, 10%). One hundred and thirty-four patients (19%) had none of the main clinical complications aforementioned. According to *ANXA2**5681 genotype, 105/714 patients (15%) carried the GG genotype, while 285/714 (40%), and 314/714 (45%) presented the GA and AA genotypes, respectively. *ANXA2**5681 polymorphism was associated a higher frequency of osteonecrosis (P<0.0001). In fact, univariate analysis demonstrated that AA-genotyped patients had a 3-fold higher risk to develop osteonecrosis (OR: 3.3, 95%CI: 1.9-5.9; P<0.0001). These data were consistent with multivariate analysis (OR: 3.08, 95%CI: 1.6-5.8; P=0.001), considering fetal hemoglobin levels, number of VOC/year, sex, and age as confounders. In addition, the cumulative probability of osteonecrosis was significantly higher in AA-genotyped patients (88%) compared to non AA-genotyped patients (GG+GA patients, 43%; P=0.001). The AA genotype retained its prognostic value in multivariate proportional hazards regression analysis (HR: 2.4, 95%CI: 1.4-3.8; P<0.001). Finally, AA-genotyped patients with osteonecrosis had a lower *ANXA2* transcript levels compared to GG- and GA-genotyped patients (P<0.05). We could find no impact for the IVS-14-1046 polymorphism with none of the variable analyzed.
Summary/Conclusions: *ANXA2**5681 polymorphism in homozygosis may be an independently predictor of osteonecrosis and may impact the *ANXA2* transcript levels, with possible decrease of the encoded protein, in SCA.

E1463

ATP11C IS DOWNREGULATED IN LEUKOCYTES AND RETICULOCYTES IN SICKLE CELL ANEMIA

D Martins[1,*], J Coelho-Silva[1], A da Silva Araújo[2], J Cabral-Peres[2], A Ferreira da Cunha[3], MA Bezerra[1], AR Lucena-Araujo[1]

[1]Departament of genetics, Federal University of Pernambuco, [2]Hematology and Hemotherapy Foundation of Pernambuco, Hematology Hospital, Recife, [3]Department of genetics and evolution, Federal University of São Carlos, São Carlos, Brazil

Background: In general, the phosphatidylserine (PS) exposure represents the major cause of blood cells adhesion to the vascular endothelium, and may contribute for vaso-occlusive crisis and extravascular hemolysis in beta-hemoglobinopathies, including sickle cell anemia (SCA). Such process may be potentiated by the SS-hemoglobin polymerization and significantly worsened in the absence of physiologic mechanism involved in PS internalization. In this context, members of the P4-type ATPase family constitute an important class of enzymes responsible for phospholipids translocation in plasma membrane, and several evidence suggests that the low expression of the *ATP11C* gene (a specific member of the P4-type ATPase family) is associated with higher rate of PS exposure in peripheral blood cells. Corroborating these data, the evaluation of erythropoiesis in *ATP11C*-deficient mice showed an abnormal shape of erythrocytes, lower rate of PS translocation, and shortened life span of mature erythrocytes, with consequent anemia. Therefore, it is conceivable that lower *ATP11C* transcripts levels may act as an important genetic modifier, increasing the PS exposure and, consequently, enhancing the adhesion of leukocytes, platelets, erythrocytes and vascular endothelial cells in SCA.
Aims: Here, we evaluated the gene expression profile of the *ATP11C* in granulocytes, mononuclear cells and reticulocytes from patients with SCA, beta-thalassemia and healthy donors. We also correlated these findings with the main chronic clinical complications in SCA.
Methods: Sixty-four patients with SCA (median age: 31 years, range, 15-61 years), with 35 male (55%), and fully characterized for β^S-globin gene haplotype (bantu/bantu), and co-inheritance alpha-thalassemia (absence of -3.7kb deletion) were included. Total RNA from granulocytes, mononuclear cells, and reticulocytes was isolated. In addition, 14 patients with beta-thalassemia and 16 healthy donors (hemoglobin profile AA) were enrolled. *ATP11C* transcripts levels (Hs_00937051_m1) were analyzed by real-time quantitative PCR using the median value of *GAPDH* and 18S as endogenous control.
Results: First, we analyzed the *ATP11C* transcript levels in granulocytes, mononuclear cells and reticulocytes from patients with SCA. Reticulocytes presented lower levels of *ATP11C* transcripts ($P<0.05$). We next showed that the SCA reticulocytes had a lower *ATP11C* transcripts levels compared to beta-thalassemia and healthy donors reticulocytes ($P<0.05$). Of interest, *ATP11C* transcript levels were lower in both leukocytes (granulocytes and mononuclear) and reticulocytes from patients with SCA compared to healthy donors ($P=0.023$). According to the chronic clinical complications frequently reported in patients with SCA, 13 patients (20%) had leg ulcer solely, followed by cerebrovascular disease (7 patients; 11%). Twenty-one patients (33%) had more than one clinical complication (including osteonecrosis along with acute chest syndrome, and priapism), and 23 patients (36%) had no documented clinical complication. Patients who presented more than one clinical complication exhibited lower *ATP11C* transcripts levels ($P<0.05$).
Summary/Conclusions: Although limited number of patients and no validation data in an independent cohort constitute the main limitations of our study, our results showed that *ATP11C* transcript levels is decreased in SS-genotyped cells, in particular reticulocytes, and such decrease may be associated with higher rate of clinical complications in SCA.

E1464

A 6 NUCLEOTIDE IN FRAME DUPLICATION IN PIEZO1 GENE IN TWO FAMILIES WITH DEHYDRATED HEREDITARY STOMATOCYTOSIS

I Andolfo[1,*], R Russo[1], F Manna[1], G De Rosa[1], A Gambale[1], L De Franceschi[2], A Iolascon[1]
[1]Dept. of Molecular Medicine and Medical Biotechnologies, University Federico II of Naples, Ceinge, biotecnologie avanzate, Naples, [2]Department of Medicine, University of Verona, Piazzale Lo Scuro 10, Verona, Italy, Verona, Italy

Background: Dehydrated hereditary stomatocytosis (DHSt), also known as hereditary xerocytosis, is an autosomal dominant congenital hemolytic anemia associated with a monovalent cation leak. DHSt consists of an usually compensated hemolysis, associated with moderate splenomegaly. Blood smears show variable numbers of stomatocytes, elevated reticulocyte count and a slightly increased red cell mean corpuscular volume (MCV). DHSt red blood cells (RBCs) exhibit decreased intraerythrocytic K+ content and increased intraerythrocytic Na+ content. The causative gene of this condition was recently identified in the FAM38A gene encoding the mechanosensitive cation channel, PIEZO1 (Andolfo I., et al, 2013; Zarychanski R., et al, 2012). Several functional characterizations of identified PIEZO1 mutations in DHSt families have uniformly demonstrated gain-of-function properties consistent with the increased net ion fluxes leading to DHSt (Andolfo I., et al, 2013; Albuisson J, et al, 2013; Bae C., et al, 2013). Recently, a new causative gene of DHSt was identified in the KCNN4 gene encoding the Gardos channel (Andolfo I., et al, 2015; Raphael R-M, et al, 2015; Glogowska E., et al, 2015). The Gardos channel/KCNN4 is a widely expressed Ca2+-dependent K+ channel that mediates the major K+ conductance of erythrocytes (Begenisich T, et al, 2004).
Aims: In this study we performed osmotic gradient ektacytometry and DNA sequence analysis of PIEZO1/KCNN4 genes in seven patients with clinical suspicion of DHSt from two unrelated families (family 1 and family 2) to assess the clinical diagnosis.
Methods: Deformability of the RBCs of the patients and relative control subjects were evaluated by osmotic gradient ektacytometry using the Laser-assisted Optical Rotational Cell Analyzer (LORCA). Genomic mutational screening was performed by direct sequencing analysis, as previously described (Andolfo I., et al, 2013).
Results: Ektacytometric analyses showed a leftward shift of the bell-shaped curve for all the patients in respect to the healthy controls indicating dehydration of the RBCs. Subsequently, DNA analysis of the patients revealed no mutations in KCNN4 gene and the mutation c.7473_7478dupGGAGCT, p.Glu2492_Leu 2493dup in PIEZO1 gene that cosegregated with the disease phenotypes in both the families. Both Glu2492 and Leu2493 residues are highly conserved in PIEZO1 (http://genome.ucsc.edu/). Interestingly, the duplication is localized in the C-terminal domain of the protein that was recently identified as the pore of the mechanosensitive cation channel. Moreover, the proband of the family 1 showed another de novo PIEZO1 mutation c.5591G>A, p.Arg1864His in cis with the duplication p.Glu2492_Leu2493dup. Of note, the proband presents a more severe clinical phenotype when compared to that observed in his affected father.
Summary/Conclusions: Molecular characterization of seven DHSt patients from two unrelated families revealed a novel in frame duplication and a novel missense mutation in PIEZO1 gene. We are currently performing a functional study to evaluate the causative role of both novel mutations here described. Particularly, we are characterizing the possible modifier role of the de novo mutation, p.Arg1864His, in cis with the inherited duplication on the occurrence of severe phenotype observed in the proband of family 1.

E1465

NON DELETIONAL ALPHA THALASSAEMIA AND STRUCTURAL HAEMOGLOBINOPATHIES OF ALFA CHAIN MOLECULAR CHARACTERIZATION IN SPAIN IN A COHORT OF 1623 PATIENTS

F De La Fuente Gonzalo[*], JM Nieto, M Guijorro Gonzalez-Conde, RB Martinez Martinez, FA Gonzalez Fernandez, A Villegas Martinez, P Ropero Gradilla
Hematology, Hospital Clínico San Carlos, Madrid, Spain

Background: Thalassaemias are a heterogeneous group of inherited anaemias that are characterized by the reduction or total absence of the synthesis of one or more globin chains. Structural haemoglobinopathies are inherited disorders in which the sequence of one of the globin chains, which form the haemoglobin, is altered.
Aims: To analyze the distribution of demographic variables of patients with α-thalassaemia and structural haemoglobinopathies in our region and to describe the molecular heterogeneity of both diseases and to examine the incidence of non-deletional α-thalassaemia within all cases of α-thalassaemia.
Methods: Studied Subjects: From January 2009 to December 2014, 1,623 individuals were studied from different Spanish regions (both native and immigrant populations). It was an study comprising 1,470 patients with hypochromic and microcytic anaemia, 176 subjects with a peak of abnormal haemoglobin and 23 patients who were studied for both diagnosis. Diagnostic techniques: α-thalassaemia required a conventional haemocytometer study, the reticulocyte count, the determination of Hb A_2 and Hb F by ion exchange HPLC and quantification of the Hb H inclusion bodies. The diagnosis of structural haemoglobinopathies required capillary electrophoresis of haemoglobins and reversed phase or globin chain HPLC. Molecular biology techniques: automatic extraction of the DNA, discarding the most frequent large deletions and point mutations using the α-globin StripAssay®, discarding other large deletions by MLPA, and Sanger sequencing for other point mutations.

Table 1.

Age (Years)	N	Ethnicity	N	Autonomous community	N
0-10	317	Caucasian	642	Madrid	806
10-20	177	Asian	61	Castilla La Mancha	240
20-30	150	Sub-Saharan African	44	Castilla y León	154
30-40	201	Maghrebi	40	Andalusia	128
40-50	155	Latin American	22	Basque Country	91
50-60	104	Hindu	10	Cantabria	71
60-70	79	Gipsy	8	Navarre	37
70-80	57	Jewish	1	Canary Islands	35
80-90	18	Unknown	795	Extremadura	26
90-100	3	Total	1623	Balearic Islands	8
Unknown	362			Murcia	8
Total	1623			Catalonia	7
				Valencia	6
				Asturias	6
				Total	1623

Results: The demographics results are summarised in table 1 (Table 1: Demographics data including age, ethnicity and Autonomous community of residence of the patients). Gender balance was found in this study. Clinical diagnosis: 1

hydrops fetalis, 18 Hb H disease, 1,200 thalassaemias traits and 160 thalassaemia silent carriers were recorded within the α-thalassaemia clinical diagnostics. Regarding structural haemoglobinopathies, there were only 2 cases of haemoglobinopathies with low oxygen affinity and 1 case of haemoglobin M, which represented the only symptomatic patients. Genetic diagnosis: 1,298 carriers of the α-thalassaemia deletion were identified (905 heterozygous, 366 homozygous and 27 double heterozygous). A total of 188 patients with non-deletional α-thalassaemia were found (185 heterozygous and 3 homozygous). A total of 176 patients had structural haemoglobinopathies of the α chain (173 heterozygous and 3 homozygous). Finally, it is important to note that this study described 9 and 5 new alterations responsible for non-deletional α-thalassaemia and structural haemoglobinopathies of the α chain, respectively.
Summary/Conclusions: 1)Most individuals were diagnosed with α-thalassaemia at an early age, particularly in severe cases. Further, the disease occurred predominantly in Caucasians and, to a lesser extent, in Asians. 2)Non-deletional α-thalassaemia represented 12% of all α-thalassaemias in our region, representing a higher value than described to date. 3)The most common deletion in our region was the 3.7Kb deletion that is common in Mediterranean populations, followed by Asian -SEA and -FIL. The alterations responsible for non-deletional α-thalassaemia are most represented by the Hph and Hb Groene Hart and, in the case of structural haemoglobinopathies, Hb Le Lamentin and Hb J-Paris. However, there is a high heterogeneity in the population analysed with the discovery of 36 and 35 different alterations responsible for non-deletional α-thalassaemia and structural haemoglobinopathies of the α chain, respectively.

E1466

OXIDATIVE STRESS IN COMPLEMENT-MEDIATED HEMOLYSIS: THE AMELIORATING EFFECT OF FERMENTED PAPAYA PREPARATION

E Fibach[1,*], E Rechmilewitz[2]
[1]Hematology, Hadassah University Hospital, Jerusalem, [2]Hematology, The E. Wolfson Medical Center, Holon, Israel

Background: The complement (C') and the redox systems play important roles in the physiological functioning of the body, such as the defense system, but they are also involved in various pathological conditions, including hemolytic anemia. Antioxidants ameliorate oxidative stress by preventing generation of free radicals, by scavenging and preventing their accumulation and by correcting their cellular damage.
Aims: Using experimental model systems, we studied the interaction between the C' and the redox systems in C'-mediated hemolysis in Paroxysmal Nocturnal Hemoglobinuria (PNH) and in Auto-Immune Hemolytic Anemia (AIHA), and the ameliorating effect of fermented papaya preparation (FPP), an antioxidant-containing product of yeast fermentation of Carica papaya Linn.
Methods: PNH-like cells were generated by treating normal human red blood cells (RBC) with the sulphydryl compound 2-aminoethyl isothiouronium bromide. AIHA was simulated by treating group-A RBC with anti-blood group A antibodies. Both treated RBC were incubated with fresh (C'-containing) autologous or O-type serum. Reactive oxygen species (ROS), as a parameter of oxidative stress, and the surface C'-protecting CD55 and CD59 antigens were measured by flow cytometry.
Results: The sulphydryl-treated RBC demonstrated a PNH-like phenotype manifested by reduced surface expression of CD55 and CD59. In both systems, treated RBC underwent hemolysis about 40 min following interaction with activated C'. Hemolysis was preceded by an abrupt increase in ROS generation. Inactivation of the C', either by heat (56ºC for 30 min) or by the addition of an anti-C' antibody, effectively reduced the ROS generation and hemolysis, indicating both are mediated by active C'. Addition of FPP (20 mg/ml) during the exposure to activated C' significantly reduced ROS generation and hemolysis.
Summary/Conclusions: The present results suggest that oxidative stress, in conjunction with activated C', may be involved the underlying symptoms of PNH and AIHA such as intra- and extra-vascular hemolysis. Currently, a humanized monoclonal antibody that specifically targets the C' protein C5 is the main treatment modality for PNH and some other hemolytic anemias. The present results raise the possibility that treatment with antioxidants might be considered as a potential therapeutic modality for C'-mediated hemolytic anemias. Since FPP is well tolerated and relatively inexpensive compared to the humanized anti-C' monoclonal antibodies, its use may be considered as an alternative or an adjuvant therapeutic modality in PNH and other C'-mediated hemolytic anemias.

E1467

INEFFECTIVE ERYTHROPOESIS DUE TO AN ALPHA SPECTRIN GENE DEFECT

B Clark[1,2,*], F Smith[2], D Brawand[2], P Rushton[2], M Oakley[2], D Rees[1,3]
[1]Dept Molecular Haematology, Kings College London, [2]Molecular Pathology, Viapath LLP at Kings College Hospital, [3]Dept Haematological Medicine, Kings College Hospital, London, United Kingdom

Background: Inherited red cell membrane disorders result from genetic changes within membrane and cytoskeletal proteins. When altered these proteins affect the deformability of the red cell and the stability of the membrane, which affects red cell function and results in a reduced red cell life span. Hereditary spherocytosis and elliptocytosis are relatively common with 1 in 2000 North Europeans being affected. Specific alpha spectrin gene variants, such as the low expression allele (LELY) have carrier frequencies of 20%, contributing to the high frequency that hereditary elliptocytosis is seen. The severity of the haemolytic anaemia is variable with some individuals unaware they are affected while others are lethal requiring in-utero transfusion for survival. We have identified two cases of particular interest. Both have a have a thalassaemia like syndrome with marked ineffective erythropoiesis due to mutations in the SPTA1 gene, coding for alpha spectrin. Case 1 presented with neonatal anaemia and liver failure, and is transfusion dependent. Case two presented with fetal anaemia and was treated with intrauterine transfusions; neonatally case two presented with hepatitis, anaemia and relative reticulocytopenia, and is also transfusion dependent.
Aims: To identify pathogenic variants in red cell membrane genes which account for ineffective erythropoiesis observed in the two patients.
Methods: Case 1 used whole exome sequencing of a nuclear family to identify the causative mutation while targeted sequencing using a focused red cell gene panel identified the pathogenic variant in the second case. Bespoke bioinformatics was used to analyse the data and call the variants.
Results: Case 1: Identified to be homozygous for the c. 7132C>T; p.Gln2378 * pathogenic variant in SPTA1 gene. Both parents were carriers and unaffected which is consistent with a recessive inheritance model. Case2. Identified to be homozygous for the c.2659C>T; p.Arg887* pathogenic variant in the SPTA1 gene. The individual was also homozygous for the SPTA1 c.[5572C>G; 6531-12C>T]; p.Leu1858Val low expression allele (Alpha Spectrin LELY). The parents were carriers of the pathogenic variant and also homozygous for the low expression allele. They did not have a clinically significant condition.
Summary/Conclusions: In both cases the affected individual was homozygous for a truncating mutation within SPTA1. The individual in case 1 was also homozygous for alpha spectin LELY and this may have contributed to the more severe phenotype, requiring intrauterine transfusion. We suggest, due to this novel mutation the red cells are too fragile to be released from the marrow, resulting in the phenotype of ineffective erythropoiesis (low reticulocytes) rather than haemolytic anemia, which is typically associated with alpha spectrin mutations.

Background: Iron deficiency (ID) is considered as the most frequent micronutrient deficiency in the world including in well-resourced countries. Iron depletion, the first stage of ID, corresponds to a reduction of body iron stores and is usually diagnosed by serum ferritin (SF) measurement. ID in early years is associated with impaired neurodevelopment both at the short and long terms. Several strategies have been proposed to prevent and/or to screen ID in children. The effectiveness of these strategies can be evaluated by the prevalence of ID. Estimated prevalences of ID in Europe are highly variable, probably because population-based studies are lacking.
Aims: Our objectives were to estimate ID prevalence and to assess ID risk factors among French children younger than 6 years-old in a population-based study.
Methods: We conducted a secondary analysis on the biobank constituted during the national survey "SaturnInf", carried out by the InVS-French Institute for Public Health Surveillance [Etchevers, 2014]. The Saturninf study recruited 3831 French children younger than 6 years-old between 2008 and 2009 according to a two stages probability sample design. For the present ancillary study, we measured SF (electro-chemiluminescence immunoassay) and CRP (immunoturbidimetric assay) on the sera kept frozen at -80°C for children with

the following criteria: parents' written consent, sera aliquot in sufficient quantity, lack of inflammatory syndrome (CRP<10 mg/l), and available socio-demographic data. ID was defined by a SF level<10 or<12 µg/l. Uni- and multivariate analyses were performed to identify ID risk factors and correlations with SF.
Results: The 657 included children (17% of the children included in the Saturninf study) had an average age of 3.1 years (SD 1.6), 58% were boys, 12% had a mother born outside France, and 22% a family with a healthcare coverage type linked to poverty ("CMU"). SF median was 45 µg/l (IQR: 29-75). ID prevalence was 3% (95%CI: 2-5) and 4% (95%CI: 3-6) for a SF threshold of 10 and 12 µg/l, respectively. At a 10 µg/l threshold, ID prevalence was higher (p<0.05) when the mother was born outside France (8%) and when the healthcare expenses were covered by CMU (7%). Significantly (p<0.05) lower SF levels were observed among males (median 42 µg/l *vs* 52), when the mother was born outside France (34 *vs* 46), was unemployed (38 *vs* 46) or had a low educational level (38 *vs* 47), when the father had a low educational level (38 *vs* 48) and when the healthcare expenses of the family were covered by CMU (39 *vs* 47), but not (p>0.4) among youngest children (47 before 2 years-old, 41 between 2 and 3, 46 after 3 years-old) nor when the father was unemployed (39 *vs* 47). After adjustment, a lower SF level was significantly (p<0.01) associated with a male gender and a lower mother's educational level.
Summary/Conclusions: In this first population-based study in France, ID prevalence was much lower (3 to 4% depending on SF threshold) than prevalences retrieved in other French and European studies performed in precarious populations but close to the lower values observed in other population-based studies in Europe. Male gender and low mother's educational level were independent risk factors for ID, as in other studies. Further studies are needed to explore the relation between this low ID prevalence and the national French preventive strategy of ID in children that is mainly based on the recommendation of a universal use of fortified cow's milk formula between 1 and 3 years of age.

E1469

IGG MEDIATED OPSONIZATION MECHANISM ACCORDING TO THE UNDERLYING PROTEIN DEFICIENCY IN HEREDITARY SPHEROCYTOSIS: TESTING A HYPOTHESIS

S Rocha[1,*], E Cleto[2], J Barbot[2], F Ferreira[3], A Quintanilha[4], L Belo[1], M Lima[5], E Bronze-da-Rocha[1], A Santos-Silva[1]
[1]UCIBIO, REQUIMTE, Laboratório de Bioquímica, Departamento de Ciências Biológicas, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, [2]Sector de Hematologia Pediátrica, Centro Hospitalar do Porto - Hospital Santo António, [3]Serviço de Hematologia Clínica, Hospital São João, [4]Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, [5]Sector de Hematologia, Centro Hospitalar do Porto - Hospital Santo António, Porto, Portugal

Background: Hereditary Spherocytosis (HS) is the most common non-immune congenital hemolytic anemia in individuals of northern European ancestry, ranging from an asymptomatic condition to a severe life-threatening anemia which results from an erythrocyte membrane protein defect. Splenectomy corrects anemia, though the intrinsic erythrocyte membrane defect persists. Reliene *et al*. (1) proposed that the type of protein deficiency underlying HS determines erythrocyte *in vivo* survival since, after splenectomy, the opsonization mechanism mediated by IgG (which involves the binding of natural occurring antibodies to erythrocyte membrane band 3) is distinct for spectrin/ankyrin- and band 3-deficient HS.
Aims: Our study aimed to evaluate the levels of membrane bound IgG and band 3 aggregates, according to the protein deficiency underlying HS, in order to ascertain how our HS population fitted this hypothesis.
Methods: We studied 35 healthy individuals and 125 HS patients [(82 unsplenectomized (unspl) and 43 splenectomized (spl)] previously studied for membrane protein deficiency identification (2). Membrane bound IgG and the high molecular weight aggregates (HMWAg) of band 3 (as percentage of total band 3) were determined by western-blot.
Results: We analyzed our data according to spectrin, ankyrin- and band 3-deficient HS (Figure 1).

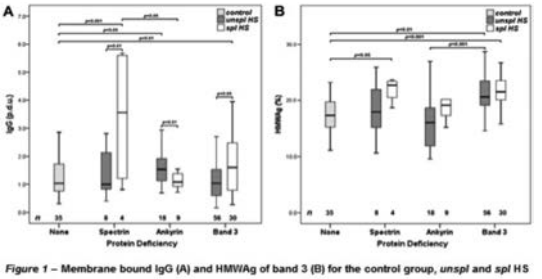

Figure 1 – Membrane bound IgG (A) and HMWAg of band 3 (B) for the control group, *unspl* and *spl* HS patients according to erythrocyte membrane protein deficiency underlying HS. Data presented as median (inter-quartile range). The differences between groups were evaluated using the Mann-Whitney *U* test. The co-variance adjustment test (univariate ANCOVA) was used as these variables were affected by the subject's age. A *p*<0.05 value was considered as statistically significant.

Figure 1.

Summary/Conclusions: For spl band 3-deficient HS, our results were in agreement with the work from Reliene *et al*. (1), since IgG levels were increased, as well as the amount of band 3 aggregates (to which IgG binds), in comparison with either the control or ankyrin deficiency groups, confirming that in these individuals membrane loss through vesiculation does not include band 3 loss, leaving these cells susceptible to IgG mediated opsonization. Since they found that the amount of IgG was not increased in relation to controls, these same authors (1) proposed that for spl spectrin- and ankyrin-deficient HS, the vesiculation of the membrane leads to the loss of band 3 clusters and, consequently, less opsonization occurred, thus explaining the higher deformability of these patients' cells. Our results were slightly different because we analyzed spectrin- and ankyrin-deficient HS separately. For spl ankyrin-deficient HS, our findings corroborate those from Reliene *et al*. (1), as we found lower membrane bound IgG and HMWAg than in band 3 deficiency, and no difference to the control group, meaning that band 3 was lost through vesiculation (hypothesis that is strengthened by HMWAg in unspl ankyrin-deficient being lower than in band 3-deficient HS). However, for spectrin-deficient HS, our results were comparable to those found for band 3 deficiency. This might imply that in spectrin-deficient HS the membrane structural modifications are such that membrane loss does not include band 3, leaving these patients' cells prone to increased IgG linkage. As cell deformability has not been evaluated, we cannot say if the mechanism of opsonization in spl spectrin-deficient HS is comparable to band 3-deficient or to ankyrin-deficient HS, which is an issue that requires further studies.

GROWTH DIFFERENTIATION FACTOR-15 IS ELEVATED IN PATIENTS WITH COMPOUND HETEROZYGOUS SICKLE CELL AND BETA-THALASSEMIA AND CORRELATES WITH HEMOLYSIS, ENDOTHELIAL DYSFUNCTION AND ANGIOGENESIS

E Voskaridou[1,*], K Larrisi[2], E Terpos[3], A Margeli[2], D Christoulas[4], M Dimopoulou[1], I Papassotiriou[2], M Politou[5]
[1]Thalassemia and Sickle Cell Disease Center, "Laikon" University General Hospital, [2]Department of Clinical Biochemistry, "Aghia Sophia" Children's Hospital, [3]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, [4]Hematology Department, 251 General AirForce Hospital, [5]Laboratory of Hematology and Blood Bank Unit, "Aretaieio" Hospital, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece

Background: The clinical manifestations of Sickle Cell Disease (SCD) include episodes of vascular occlusion, chronic hemolytic anemia and frequent infections. SCD is also characterized by the presence of a chronic inflammatory state manifested by leukocytosis and monocytosis and increased circulating levels of pro-inflammatory cyto- and chemokines. Growth Differentiation Factor-15 (GDF-15), also known as macrophage inhibitory cytokine 1 (MIC-1) and non-steroidal anti-inflammatory drug-activated gene (NAG-1) is a member of the transforming growth factor-□ superfamily. Expression of the GDF-15 gene in cardiomyocytes, vascular smooth muscle cells, and endothelial cells is strongly upregulated in response to oxidative stress, inflammation and tissue injury. Increased GDF-15 concentrations have been associated with an adverse prognosis in patients with acute coronary syndromes and chronic heart failure.
Aims: The aim of this study was to evaluate the GDF-15 levels in patients with compound heterozygous SCD and beta-thalassemia (HbS/β^{thal}) and to explore possible associations with disease features, such as hemolysis, inflammation, endothelial dysfunction and angiogenesis.
Methods: Seventy-five adult Caucasian patients with HbS/b^{thal} were included in the study, while 20 healthy individuals served as controls. Patients with HbS/β^{thal} divided in two groups: group A included 36 patients under hydroxycarbamide (HC+) treatment and group B included 39 patients without hydroxycarbamide (HC-) treatment. Along with hematology and blood chemistry parameters determination, measurements of circulating levels of GDF-15, hs-CRP, vWF-antigen, hs-TnT and Placental Growth Factor (PlGF) were measured in patients with HbS/β^{thal} and controls using immunoenzymatic techniques.
Results: The main results of the study showed that: GDF-15 were elevated in patients with HbS/β^{thal} compared to controls (1,980.7±159.8 *vs* 665.4±50.9 pg/mL, p<0.0001). Regarding hydroxycarbamide treatment, GDF-15 levels were elevated in (HC+) patients compared to (HC-) patients (2,478±222.6 *vs* 1,520±204.7 pg/mL, p=0.002), or 30/36 *vs* 21/39 patients with elevated GDF-15 levels (c^2=0.002). GDF-15 levels correlated significantly with markers of erythropoiesis, such as Hb, HbF, ferritin and reticulocytes (r=-0.424, p<0.01; r=0.562, p<0.001; r=0.423, p<0.001 and r=0.510, p<0.001, respectively), with markers of hemolysis, such as LDH and uric acid (r=0.412, p<0.001 and

r=0.321, p=0.005, respectively), and with markers of endothelial dysfunction and angiogenesis such as vWF-antigen and PlGF (r=0.238, p<0.05 and r=0.461, p<0.001, respectively). Surprisingly, no correlation was found between GDF-15 and hs-CRP levels (p>0.65).
Summary/Conclusions: These findings suggest a multifactorial role of GDF-15 in patients with HbS/β^{thal} as it correlates with hemolysis, endothelial dysfunction and angiogenesis. The higher GDF-15 levels measured in patients treated with hydroxycarbamide may reflect a possible drug reaction. More studies are needed to clarify the exact role of GDF-15 in HbS/β^{thal}.

E1471

MOLECULAR CHARACTERISATION OF 85 INDIVIDUALS WITH PYRUVATE KINASE DEFICIENCY
C Laas[1,*], T Jaques[2], T Senior McKenzie[2], E Cooper[1], D Rees[3,4], B Clark[2,4]
[1]Red Cell Centre, [2]Dept of Molecular Pathology, Viapath, [3]Dept of Haematological Medicine, King's College Hospital, [4]Molecular Haematology, Division of Cancer Studies, King's College London, London, United Kingdom

Background: Pyruvate kinase (PK) deficiency is the most common glycolytic cause of non-spherocytic haemolytic anaemia. It is inherited as an autosomal recessive condition with 50 individuals per million being affected in the Caucasian population. The *PKLR* gene codes for Pyruvate Kinase, a red cell specific isoenzyme that converts phosphoenolpyruvate to pyruvate which releases ATP. ATP is essential for red cell function and without it the half-life of the red cell is reduced, being cleared by the spleen and liver. There are 200 known mutations which can cause PK deficiency, which is diagnosed using an enzyme assay. KLF1 is a transcription factor known to bind to the promoter of the *PKLR* gene and drives expression. Variants in the *KLF1* gene have previously been shown to produce a PK deficient phenotype.
Aims: We screened for genetic variants in individuals with PK enzyme activity<11 IU/g Hb to determine if a genetic cause could be identified in every case.
Methods: Individuals with reduced PK enzyme activity underwent *PKLR* gene sequencing. Cases without an affected genotype were screened for indels in the *PKLR* gene followed by sequencing of the *KLF1* gene.
Results: Of the 85 cases, 21 were identified with genotypes consistent with PK deficiency with 27 cases left having identified only a single pathogenic variant. 35 Cases were left without a pathogenic variant (although 38% of samples were heterozygous for the c.-248delT polymorphism), all falling within the range of 8-11 IU/g Hb. This is consistent with other labs that use lower normal range. The sequencing analysis identified ten variants not previously described (c.319 A>G, c.508-57 G>A, c.508-2 A>G, c.602 G>T, c.627 G>C, c.822 C>G, c.959 T>C, c.965+2 T>C, c.1063 A>G, c.1299 C>A) of which seven are likely to be highly pathogenic. One individual had a deletion encompassing exon 11 in combination with a missense variant. One unknown variant (c.881 C>A) was identified in the *KLF1* gene and in silico tools predicted this to be damaging. There were no *PKLR* variants found in this patient, yet they had a PK activity of 3.5 IU/g Hb.
Summary/Conclusions: Genetic investigations into the PKLR gene is not diagnostically informative in individuals with a PK enzyme activity of >8 IU/g Hb. Of the 39 individuals with an enzyme activity of<8 IU/g Hb, 46% had two affected alleles, 44% had one affected allele, and in 10% of the cases no pathogenic variants were identified. The enzyme activity range of the 10% group (n=3) was 7-7.9 IU/g Hb excluding the individual with a variant in *KLF1*. This indicates that the more severe the PK enzyme deficiency the more likely the assay is to identify a genetic cause. In those cases with a genetic cause most are non-synonymous base changes probably resulting in protein instability. Two splice site variants were identified affecting the core consensus motif and also a single case with a deletion, all predicted to be severe alleles. It is unknown if the KLF1 gene variant is influencing PKLR gene expression, and further work is necessary to understand this.

STRUCTURAL HAEMOGLOBINOPATHY CARRIERS CAN BE IDENTIFIED BY LABORATORY PARAMETERS PROVIDED BY ADVIA 2120 ANALYSER
D Velasco-Rodríguez[1,*], JM Alonso-Domínguez[2], FA González-Fernández[3], A Muriel[4], L Abalo[5], M Sopeña[5], J Villarrubia[1], M Tenorio[1], P Ropero-Gradilla[3], F de la Fuente-Gonzalo[3], J Martínez-Nieto[3], A Jiménez-Martín[1], G Moreno[1], FJ López-Jiménez[1], F Cava[5]
[1]Hematology, Hospital Ramón y Cajal, [2]Hematology, Fundación Jiménez Díaz, [3]Hematology, Hospital Clínico San Carlos, [4]Statistics, Hospital Ramón y Cajal, [5]Hematology, Laboratorio Central de la Comunidad de Madrid BR Salud, Madrid, Spain

Background: Hemoglobinopathies have spread owing to human migrations, and the number of people needing diagnosis and management of these conditions is increasing. More than 1500 variant Hb have been described to date. In more than 95% of variant Hb, the structural alteration is a point mutation that produces a single amino acid substitution in a globin chain. Carriers are asymptomatic, and clinicians need to accurately identify them and provide adequate genetic counselling to them in order to prevent the occurrence of homozygous or compound heterozygous offspring.
Aims: The aim of our study was to identify red blood cell (RBC) laboratory parameters that discriminate between structural hemoglobinopathy carriers and healthy subjects
Methods: Samples of 500 variant Hb carriers (355 HbAS, 104 HbAC, 19 HbAD, 7 HbAE, 7 HbAO-Arab, 4 alpha-chain variants and 4 Hb Lepore) and 251 normal controls were run on an Advia 2120 analyser (Siemens Medical Solutions Diagnostics, Tarrytown, New York, USA). Hb variants were detected by HPLC in the HA-8160 analyzer (Menarini Diagnostics, Florence, Italy) and further characterised according to their alkaline and acid electrophoretic pattern using cellulose acetate electrophoresis. Classic hematological parameters and RBC populations of the complete blood count (CBC) were assessed in all subjects. A multivariable binary logistic regression model was created to predict the probability of a subject carrying any structural hemoglobinopathy.
Results: Variant Hb carriers presented significantly higher RBC count (4.96×1012/L *vs* 4.84×1012/L, p=0.031), lower MCV (85.39 fL *vs* 92.81 fL, p<0.001), lower MCH (28.97 pg *vs* 30.18 pg, p<0.001), higher MCHC (34.29 g/dL *vs* 32.71 g/dL, p<0.001), higher RDW (14.10% *vs* 12.94%, p<0.001), lower%MACRO (0.67% *vs* 1.63%, p<0.001), higher%MICRO (2.31% *vs* 0.42%, p<0.001), higher%HYPER (1.99% *vs* 0.45%, p<0.001), lower%HYPO (1.51% *vs* 2.47%, p<0.001) and higher M/H (9.31% *vs* 0.67%, p<0.001). A clinical prediction rule was developed by assigning one point to each of the most efficient variables: mean corpuscular volume (MCV)<88.4 fL, RBC distribution width >13.4%, percentage of microcytic RBCs (%MICRO) >0.7% and the ratio of microcytic RBCs to hypochromic RBCs >0.8. A score of 0, 1, 2, 3 or 4, resulted in a probability of 9.6%, 36.3%, 66.7%, 85.2% or 98.3%, respectively.
Summary/Conclusions: Although molecular analysis (gold standard) or another laboratory technique such as electrophoresis and/or HPLC is mandatory for the diagnosis of structural hemoglobinopathies, a CBC is a quick, cheap and handy test that provides useful information for a presumptive diagnosis of these entities. RBCs of variant Hb carriers are smaller, denser and show a higher degree of anisocytosis in comparison to RBcs of normal controls. Structural hemoglobinopathy investigation should be performed if a score of 3 or 4 is seen in subjects belonging to ethnic groups with a high prevalence of variant Hb. Our model is not structured as a complex mathematical formula, and in our opinion, this facilitates its clinical use. Although differences in haematological parameters have been reported by many authors, none evaluated the value of the CBC as a screening tool to identify variant Hb carriers.

E1473

HEMOGLOBINOPATHIES WITH LEVELS HBA2 DECREASED. DELTA GENE MUTATIONS FOUND IN A SPANISH CENTER
P Ropero[*], FA González, JM Nieto, F de la Fuente-Gonzalo, M Guijorro, A Villegas, R Martínez
Hematology, Hospital Clínico San Carlos, Madrid, Spain

Background: HbA_2 reaches its final value (2.5% -3.5%) in the first year of life. Due to this low expression and the lack of significant pathology, HbA_2 is not considered relevant, but mutations in the δ gene can cause δ-thalassemia and Hb variants of δ chain are interesting because they interfere in HbA_2 quantification. HbA_2 consists of chains of α globin and δ; therefore, alterations in any of these genes may influence HbA_2 levels.
Aims: We present structural hemoglobinopathies and thalassemias that present with decreased levels of HbA_2, as well as the first compilation of mutations in the gene δ globin, found in Spain.
Methods: The 208 patients that were analyzed presented HbA_2 values below 2.5% and microcytic and hypochromic or normocytic and normochromic without iron deficiency anemia. HbA_2 and HbF levels, as well as the different hemoglobins, were measured and analyzed by ion-exchange HPLC (VARIANT™ II). Hemoglobins were studied by capillary zone electrophoresis (CE) (Sebia) and globin chains by reverse-phase HPLC. Genetic analysis of the α and δ genes was carried out by automatic sequencing and, in the case of α genes, by multiplex PCR.
Results: In α-thalassemia (n=94), HbA_2 levels ranged from 1.39 to 2.43%; in δ-thalassemia (n=5), HbA_2 levels researched in δ^+-thalassemia 1.77% and for δ^0-thalassemiain 1.70%; in δβ-thalassemia (n=13), homozygosity resulted in undetectable HbA_2 levels. Structural hemoglobinopathies (n=96), all heterozygous, in the α chain (n=84) and δ chain (n=12) had HbA_2 rates of 1.76% and 1.75%, respectively.
Summary/Conclusions: 208 samples, with HbA_2<2.5%, showed α gene or δ globin anomalies of quantitative (thalassemia) or qualitative (structural hemoglobinopathies). In the α-thalassemia, the greatest loss of genes corresponds to the lowest levels of HbA_2, since α genes are preferably combined to form the β HbA. The heterozygous δ^+-thalassemia had higher levels than δ^0-thalassemia. It should be suspected of a δ-thalassemia when, in normal and without iron deficiency, HbA_2 levels are lower than the 2%., in these cases the direct sequencing of the gene δ, it will reveal a point mutation in homozygous or heterozygous state. In the δβ-thalassemia, homozygosity no levels of HbA2. The decrease in levels of HbA_2 in α chain hemoglobinopathies is owing to a new α globin chain (α^X) because its variant corresponding HbA_2 ($\alpha_2{}^X\delta_2$) is formed. The greater decrease corresponds to homozygosity, because there is less α^A globin chain synthesis, regardless of the mutated gene (α1 or α2). In

this work we have identified five variants of δ chain because they are relatively common and generally easy to detect not only because halved the HbA_2 value, but because they often show a second fraction of HbA_2 almost the same expression, whether prior or after normal HbA_2. The variant HbA_2-Madrid was first described in the literature. HbA_2 is an essential parameter in the differential diagnosis of thalassemia. Using the HPLC and EC provide not only the quantification of HbA2 but also information other hemoglobins, so the same analysis helps identify hemoglobin variants of either strand and detect thalassemias not otherwise It has been possible diagnosis, avoiding that risk couples may be advised incorrectly.

LB2266

ACTIVIN B PRODUCED BY SINUSOIDAL ENDOTHELIAL/KUPFFER CELLS IN RESPONSE TO INFLAMMATORY STIMULI INDUCES HEPCIDIN EXPRESSION THROUGH UNCANONICAL SIGNALING IN HEPATOCYTES

Y Kanamori[1,*], M Sugiyama[2], O Hashimoto[3], M Murakami[4], T Matsui[1], M Funaba[1]
[1]Division of Applied Biosciences, Graduate School of Agriculture, Kyoto University, Kyoto, [2]Laboratory of Veterinary Anatomy, [3]Laboratory of Experimental Animal Science, Kitasato University School of Veterinary Medicine, Towada, [4]Laboratory of Molecular Biology, Azabu University School of Veterinary Medicine, Sagamihara, Japan

Background: Hepcidin, a liver-derived peptide hormone, is involved in the pathogenesis of anemia under inflammation. Activins and BMPs bind to corresponding type I and type II receptors and phosphorylate Smad2/3 and Smad1/5/8, respectively, as canonical signaling pathway. BMPs are well known to up-regulate hepcidin expression through the canonical signaling pathway when hepatocytes accumulate excess iron. On the other hand, activin B is suggested as a key molecule responsible for the up-regulation of hepcidin in inflammation based on the following two evidences: (1) the elevation of activin B mRNA level in the livers of LPS-injected mice, and (2) the stimulation of hepcidin expression by activin B in hepatocytes. Furthermore, activin B has been shown to activate uncanonical Smad1/5/8 signaling as well as canonical Smad2/3 signaling in hepatocytes.
Aims: We examine the following three points in the present study: (1) which cell-types in the liver are responsible for the up-regulation of activin B by inflammatory stimuli, (2) which receptor combination is responsible for the induction of Smad1/5/8 phosphorylation and hepcidin expression by activin B, and (3) whether activin B induces uncanonical Smad1/5/8 signaling in extrahepatic cells.
Methods: A male Sprague-Dawley rat was intraperitoneally injected with LPS (5 mg/kg). After 2.5 h of injection, hepatocytes and non-parenchymal cells were collected from the liver by collagenase-perfusion. Sinusoidal endothelial and Kupffer cell-rich fraction was isolated from non-parenchymal cells by a two-step density gradient centrifugation. The expression of activin B was measured by RT-qPCR. Rat primary hepatocytes, HepG2 human hepatoma cells, C2C12 myoblasts, 3T3-L1 pre-adipocytes, and RAW264.7 murine macrophage-like cells were stimulated with 2 nM of activin B. Phosphorylation of Smad1/5/8 and mRNA level of hepcidin or Id1 were examined. HepG2 cells were transfected with siRNAs of type I or type II receptors and luciferase reporter of murine hepcidin promoter. After transfection, cells were treated with activin B. Transcriptional activity of hepcidin was assayed.
Results: Significant expression of activin B was detected in sinusoidal endothelial and Kupffer cell-enriched fraction isolated from the liver of a rat injected with LPS, while expression of activin B in hepatocyte-enriched fraction was almost negligible, suggesting that sinusoidal endothelial cells or Kupffer cells are the major sources of hepatic activin B under inflammation. Knockdown of the BMP type I receptor, ALK2 or ALK3, indicated that ALK2, but not ALK3, is involved in the responsiveness of the hepcidin promoter to activin B through the activation of Smad1/5/8 signaling in HepG2 cells. Knockdown of the type II receptor ActRIIA inhibited activin B-mediated Smad1/5/8 phosphorylation and hepcidin transcription. These results suggest that upon the binding of activin B, the receptor complex, ALK2 and ActRIIA, stimulates Smad1/5/8 signaling, followed by induction of hepcidin. Unexpectedly, the induction of Smad1/5/8 phosphorylation and hepcidin expression by activin B was resistant to LDN-193189, an inhibitor of ALK2 and ALK3, whereas those actions of BMP2 was sensitive to the inhibitor. These results implicate that unknown mechanisms distinct from BMP signaling are involved in the modulation of Smad1/5/8 signaling by activin B. We also showed that activin B increased phosphorylation of Smad1/5/8 and mRNA level of Id1, a representative BMP response gene, in C2C12 cells, 3T3-L1 cells and RAW264.7 cells, implicating that activin B-induced uncanonical Smad1/5/8 signaling is independent of cell-type.
Summary/Conclusion: Upon inflammatory stimuli, sinusoidal endothelial cells and/or Kupffer cells up-regulate activin B expression in the liver, followed by induction of Smad1/5/8 phosphorylation and hepcidin expression in hepatocytes via the receptor complex of ALK2 and ActRIIA. In addition, activin B-induced Smad1/5/8 signaling is not limited to hepatocytes. The present study provide novel insights into the molecular mechanisms underlying induction of hepcidin by inflammation and the possible roles of activin B-mediated Smad1/5/8 signaling in several tissues.

TREATMENT WITH CYCLOSPORIN IN AUTO-IMMUNE CYTOPENIAS IN CHILDREN: THE EXPERIENCE FROM THE FRENCH COHORT OBS' CEREVANCE

M Penel Page[1], Y Bertrand[2], D Kherfellah[3], H Fernandes[3], Y Perel[3], G Leverger[4], G Michel[5], N Sirvent[6], T Leblanc[7], N Aladjidi[3,*]
[1]Pediatrics, Institut d'Hematologie et d'Oncologie Pédiatrique, [2]Pediatrics, Institut d'Hématologie et d'Oncologie Pédiatrique, Lyon, [3]Pediatrics, Universitary Hospital, Bordeaux, [4]Pediatrics, Trousseau Hospital, Paris, [5]Pediatrics, Timone Hospital, Marseille, [6]Pediatrics, Universitary Hospital, Montpellier, [7]Pediatrics, Robert Debré Hospital, Paris, France

Background: Auto-immune cytopenias are rare in children, and there is no recommendation about treatments in case of resistance or dependence to steroids.
Aims: Since 2004, the cohort OBS'CEREVANCE has been recording the cases of auto-immune cytopenias in children treated in the 30 French pediatric hematology units. This study reports the treatment with cyclosporin for all the patients of the cohort treated with cyclosporin for auto-immune hemolytic anemia (AIHA), Immune throbopenic Purpura (ITP) and Evans Syndrome (ES).
Methods: We analyzed the data of 15 AIHA, 7 ITP and 12 ES. Median age was 4.5 years for AIHA and ES, 7.2 for ITP. Ten patients had underlying immunodeficiency and 5 had auto-immune disease.
Results: The best response was a complete remission (CR) for 7 AIHA, 1 ITP and 6 ES, maintained in median 8.6 months for AIHA and 25.5 months for ES. The treatment allowed steroids decrease in 9 cases of AIHA and 9 ES. Three patients treated for AIHA maintained CR after discontinuation of treatment, whereas all the patients with ES relapsed during or after treatment. Toxicity was acceptable. Median residual level was 96.5 mg/L (31-369) for patients achieving CR or PR and 117 mg/L (23-956) for patients with no response.

Table 1.

		AIHA (N=15)	ITP (N=7)	ES (N=12)
Median duration of treatment (months)		15 (2-76,8)	3,3 (1-8,1)	20 (0,9-86,5)
Best response	CR	7	1	6
	PR	1		1
	NR	7	6	5
	Decrease/stop steroids	9	3	9
Delay initiation of treatment-CR (months)		1,5 (0,4-12,9)	3	2,3 (0,5-4,8)
Overall response	6 months CR+PR	7	1	6
	12 months CR under treatment	5	0	4
	2 years CR (in which under treatment)	4 (3)	0	3 (2)
	3 years CR (in which under treatment)	4 (1)	0	1 (0)
Duration of response (months, median)		**8,6** (4,4-51)	3	**25,5** (3-52)
Need for subsequent treatment		12	7	12
Subsequent relapse (after CR)		3	7	12
Reason of discontinuation	CR	4	0	2
	Failure	11	7	6
	Adverse effect	0	1	3
	death	0	0	2
Median follow-up time (months)		86,5 (0,5-151)	9 (1-12,9)	81 (22-168)
Status at last follow-up	SCR (in which after cyclosporin alone)	13 (3)	3 (0)	5 (0)
	NR	1	2	3
	Dead of toxicity of other treatments	0	1	1
	Dead of disease	1	0	3

Summary/Conclusions: Given our results, we propose to use cyclosporin for AIHA (excluding in context of immunodeficiency) and ES, after failure of corticosteroids, or in case of dependence to steroids. We propose to base the prescription on aplastic anemia treatment recommendations with a blood level residual target between 50 and 100 mg/L: treatment at least three months before concluding to failure, treatment at least a year at full dose in case of response, very slow decrease over several months, return to previous dose in case of relapse during the decrease, or to full doses in case of relapse at treatment discontinuation, monitoring of residuel level, in case of success (CR), toxicity or failure.

Background: Long-term iron chelation therapy (ICT) is required in regularly transfused patients (pts) to reduce the chronic iron overload (IOL) which is a

major complication causing morbidity and mortality. The oral iron chelator deferasirox (DFX) is indicated for the treatment of chronic IOL due to blood transfusions in adult and pediatric pts aged ≥2 years (yrs). Multiple clinical studies have established the efficacy and safety of DFX in transfusion-dependent pts with IOL. The present study reports the results of a postmarketing active surveillance program for DFX.

Aims: To evaluate the long-term safety and clinical management of DFX in adult and pediatric pts aged ≥2 yrs with chronic transfusional IOL in the actual practice setting.

Methods: Pts aged ≥2 yrs treated with DFX for transfusional hemosiderosis according to the local prescription information were enrolled in this non-interventional study. Data were collected for 3 yrs from initiation of treatment with DFX, and retrospective data were collected in pts who had treatment with DFX for up to 1 yr prior enrollment. The primary endpoints were as follows: (a) the proportion of pts with at least 1 notable increase in serum creatinine (SrCr), defined as >33% above baseline (BL) and the age adjusted upper limit of normal (ULN) in at least 2 consecutive measurements (≥7 days apart), and (b) notable increase in alanine aminotransferase (ALT), defined as >5×ULN in at least 2 consecutive measurements (≥7 days apart).

Results: Of the 120 pts enrolled, majority were diagnosed with β thalassemia (n=49), sickle cell disease (SCD, n=31), and myelodysplastic syndrome (MDS, n=21) (Table 1). The mean age (±SD) was 7.5±4.2 yrs in pts with<18 yrs (n=69) and 57.9±22.1 yrs in pts with ≥18 yrs (n=51) of age. Median duration of DFX exposure was 29.9 months and average actual dose was 23.2±8.2 mg/kg/d. Overall, 42.5% (<18 yrs, n=45; ≥18 yrs, n=6) of pts completed the study. The most common reasons for study discontinuation (>10%) were subjects who no longer required study drug (19.2%), adverse events (AEs, 12.5%), and consent withdrawal (10.8%). Dose reductions and interruptions occurred in 39.3% and 23.9% of pts, respectively. Of the 46 pts who had dose reductions, 5 pts reported increase in SrCr (n=3) and ALT (n=2). Of the 28 pts who had dose interruptions, 3 pts reported increase in SrCr (n=2) and ALT (n=1). Notable increase in SrCr was observed in 12% (14 of 117; 95% CI, 7.1-19.2) of pts with MDS (n=3), SCD (n=7) and other anemias (n=4). Notable increase in ALT was observed in 1 pt (0.9%; 95% CI, 0.0-5.2) with β thalassemia (BL ALT missing). Overall, 34.2% (40 of 117) of pts had AEs suspected to be related to DFX, including AEs (>5%) such as diarrhea (9.4%), increase in SrCr (7.7%), and vomiting (6.0%). A total of 4.3% (5 of 117) of pts had serious AEs (SAEs), suspected to be related to DFX, and SAE >1% was gastrointestinal hemorrhage (1.7%). The AEs leading to the discontinuation of DFX occurred in 18.8% of pts (MDS, n=11; β-thalassemia, n=2; SCD, n=2; other anemias, n=7) regardless of the relationship with DFX, including AEs (>2%) such as increase in SrCr (3.4%) and diarrhea (2.6%). None of the pts discontinued DFX due to the increase in ALT. Eight (6.8%; MDS, n=4, other anemias, n=4) on-treatment deaths were reported, all in pts ≥18 yrs of age, majorly due to gastrointestinal disorders (n=2) and neoplasms (n=2). Of these 8 deaths, 7 were not suspected to be related to DFX (data unknown, n=1).

Table 1.

Characteristics	<18 years (n=69)	≥18 years (n=51)	All Patients (N=120)
Mean age±SD, years	7.5±4.2	57.9±22.1	28.9±29.0
Female:Male, n	35:34	21:30	56:64
Race, n (%)			
Caucasian	37 (53.6)	44 (86.3)	81 (67.5)
Black	21 (30.4)	6 (11.8)	27 (22.5)
Asian	7 (10.1)	0 (0.0)	7 (5.8)
Native American	0 (0.0)	1 (2.0)	1 (0.8)
Other	4 (5.8)	0 (0.0)	4 (3.3)
Disease, n (%)			
β thalassemia major	34 (49.3)	7 (13.7)	41 (34.2)
β thalassemia intermedia	7 (10.1)	1 (2.0)	8 (6.7)
Refractory anemia	0 (0.0)	2 (3.9)	2 (1.7)
Sideroblastic anemia	0 (0.0)	3 (5.9)	3 (2.5)
Myelodysplastic syndrome	0 (0.0)	21 (41.2)	21 (17.5)
Diamond-Blackfan anemia	2 (2.9)	0 (0.0)	2 (1.7)
Hemolytic anemia	0 (0.0)	1 (2.0)	1 (0.8)
Sickle cell disease	24 (34.8)	7 (13.7)	31 (25.8)
Other	2 (2.9)	9 (17.6)	11 (9.2)

Summary/Conclusions: The results demonstrated a safety profile for DFX which is consistent with previously published data. The data demonstrates that changes in SrCr can be managed with dose adjustments or interruptions and occasionally led to permanent discontinuation. DFX has been associated with rare hepatic toxicity. Only 1 pt had a notable increase in ALT. The overall incidence of AEs that lead to DFX discontinuation was higher in pts with MDS during the study.

E1476

EVALUATION OF THE FOOD INTAKE, NUTRITIONAL STATUS AND NUTRITIONAL DEFICIENCY IN CHILDREN WITH SICKLE CELL DISEASE: PRELIMINARY RESULTS OF A CROSS - SECTIONAL STUDY

F Menzato[1,*], F Piras[2], A Battistin[2], G Verlato[2], M Montanaro[1], S Zaccaria[1], C Marin[1], G Basso[1], R Colombatti[1], L Sainati[1]
[1]Clinic of Pediatric Hematology-Oncology, [2]Dietetics and Clinical Nutrition, Università degli Studi di Padova, Padova, Italy

Background: Children with Sickle Cell Disease (SCD) have poor growth compared to their peers; they also present a higher percentage of cognitive impairment compared to age matched controls. Clinical practice shows that the presence of nutritional deficiencies with important clinical implications (anemia, abnormal bone metabolism..) is frequent in these patients and that it can have an adverse impact on disease severity. Currently there are no European studies that correlate specific nutritional deficiency to the nutritional intake; demonstrating the correlation between reduced or inappropriate dietary intake and selective nutritional deficiencies could lead to targeted nutritional interventions aimed at improving the nutritional status and the altered hematological parameters.

Aims: 1) To identify any nutritional deficiencies in patients with SCD and correct them promptly. 2) To identify, if possible, the correlations between nutritional status, dietary intakes and deficiency states, and between states of deficiency and clinical expression of the disease, including patient's performance assessed through ad hoc questionnaires.

Methods: Children with SCD of the clinic of Pediatric Hematology-Oncology in Padua were included in this prospective study. An ad hoc questionnaire (on food frequency, quantity and eating habits) was administered; the data were processed with GEDIP 4 software to derive the minimum, average amounts, maximum and standard deviations of various nutrients and to compare them with the recommended requirements in the Recommended intake levels (RDAs, 2014 edition). Nutritional status was assessed by weight, height, Body Mass Index and arm circumference that were used for drawing the percentiles using CDC growth curves. The following hematochemical parameters were evaluated at Time 0: Complete Blood Count, PTH, Vitamins A, D, E, ferritin, serum iron, zinc, copper, calcium, phosphate, folic acid, methylmalonic acid, homocysteine, blood gas analysis. These parameters will be re-assessed at Time 1 (6 months) and 2 (12 months) to evaluate the effectiveness of any additional therapy.

Results: 72 consecutive pediatric patients with SCD were included in our study (SS 62/72, 8/72 SC, 2/72 Sß), 31 F and 41 M, mean age 9.6 years (range: 8 months-23 years), from 1st March 2015 to 31st August 2015. The main nutritional deficiencies were: folic acid (9/72); Vitamin D (62/72) correlated with increased PTH (27/72); Vitamin A (43/72); Vitamin E (0/72); serum iron (23/72); zinc (18/72). In some cases high levels of methylmalonic acid (10/72) and homocysteine (4/71) have been reported, showing lack of Vitamin B12. The following supplementations were given: folic acid (55/72), vitamin D (57/72), iron (15/72), zinc (1/72); in the remaining cases with slight deficits were provided appropriate dietary advices. At the moment 37/72 patients underwent the nutritional assessment questionnaire, which shows a nutritional intake of 69% of energy intake established by the RDAs, and values between 25° and 50°P for weight, height, BMI and arm circumference for age. Their protein intake is on average 150% from the RDAs, while recording contributions of about 50% for calcium, iron and folic acid and 8% for Vitamin D. Even if most of the patients are African first generation immigrants with a specific but balanced dietary habits; a significant part of them belongs to low-income families and feeds with "junk food", which could be the cause of their nutritional deficits.

Summary/Conclusions: Preliminary data of our study does not show an adequate intake of macro and micro nutrients for SCD children; calcium, iron, folic acid and especially Vitamin D are the most deficient nutrients and determine suboptimal growth state. The continuation of the study, with a larger number of subjects, will help us to highlight the possible correlation of nutritional status with the progress and severity of the disease.

E1477

CLINICAL SAFETY AND EFFICACY OF FERRIC CARBOXYMALTOSE IN THE TREATMENT OF IRON DEFICIENCY: META-ANALYSIS EVALUATING INDIVIDUAL PATIENT DATA OF 18 RANDOMIZED TRIALS

Y Beguin[1,*], A de Francisco[2], H Brunner-La Rocca[3], B Roubert[4], L Southall[4]
[1]Department of Hematology, University Hospital of Liège, Liège, Belgium, [2]Dialysis Unit and Nephrology Section, Hospital Universitario Valdecilla, Santander, Spain, [3]Department of Cardiology, Maastricht University, Maastricht, Netherlands, [4]Vifor Pharma Ltd., Glattbrugg, Switzerland

Background: Iron deficiency and iron deficiency anemia are highly prevalent in both industrialized and developing countries. Patients and special populations with a wide variety of underlying conditions are affected and may experience debilitating symptoms. Intravenous iron therapy is indicated when oral iron supplementation is not tolerated or iron absorption is ineffective. Ferric carboxymaltose (FCM) is an intravenous iron formulation for administration of single doses up to 1000 mg iron during a short administration time (≥15 minutes).

Aims: The aim of this analysis was to describe the safety and efficacy of FCM across studies with different patient populations.

Methods: Individual patient data collected at European trial sites of 18 randomized controlled clinical trials performed by Vifor Pharma were analyzed. Study populations included patients with chronic kidney disease, inflammatory bowel disease, chronic heart failure, cancer, and women of childbearing age. FCM treated patients were compared to a pooled comparator group, including other intravenous iron formulations, oral iron, placebo or standard medical care. All treatment emergent adverse events (TEAEs) and related TEAEs were

investigated, with focus on special adverse events of interest, including changes in serum phosphorus levels. Furthermore, therapeutic efficacy parameters (hemoglobin, ferritin and transferrin saturation) were analyzed over time. Changes from baseline in laboratory parameters are statistically presented as least-squares means (LS means) and standard errors (SE).
Results: Data from 3,331 patients with iron deficiency were analyzed. Of these, 1,969 patients had received FCM. The mean cumulative dose of FCM over the first 6 weeks was 1,124±417 mg iron, with single doses of 1,000 mg iron in 36% of the patients. Overall, the most frequent related TEAEs in the FCM group were serum ferritin increased (1.4%), headache (1.4%), and nausea (1.0%). In the pooled comparator group, the most frequent related TEAEs were constipation (2.5%), diarrhea (1.8%) and nausea (1.0%). Among patients with available serum phosphorus values over time (FCM n=1,370; comparator n=1,194), 27.4% of subjects in the FCM group and 2.0% in the comparator group had a value below 2.0 mg/dL at any time during the first 8 weeks of follow-up. Signs and symptoms that could possibly be related to transient decrease in phosphate level (using the broad SMQ-definition) were reported in 9.6% of FCM-treated subjects and in 11.3% in the comparator group. In the FCM group, hemoglobin steadily increased from the first post-treatment assessment at week 1 or 2 (n=1,404; mean changes from baseline: 0.411 [0.098] g/dL) to week 4 (n=1,619; 1.176 [0.168] g/dL) and week 8 (n=1,398; 1.466 [0.190] g/dL). Ferritin and transferrin saturation were significantly increased in the FCM group compared with comparator pool, at all time points (p<.0001; week 1 or 2, 4, 8), and remained stable throughout the 8-week period (mean change from baseline at week 8: +227.7 [53.7] *vs* 105.7 [53.8] ng/mL and +13.4 [1.2] *vs* 8.5 [1.2]%, respectively; p<.0001), reflecting repletion of iron stores.

Table 1.

Table 1. Incidence of treatment emergent adverse events.

	FCM <1,000 mg n=1,267	FCM ≥1,000 mg n=702	FCM total n=1,969	Control n=1,463
Any TEAE	54.9%	61.8%	57.4%	55.0%
Treatment-related	12.5%	17.7%	14.3%	13.0%
Severe TEAE	6.4%	5.6%	6.1%	7.1%
Treatment-related	0.5%	1.0%	0.7%	0.8%
Any serious TEAE	9.7%	11.3%	10.3%	11.8%
Treatment-related	0.2%	0.3%	0.2%	0.1%
TEAE leading to study drug withdrawal	3.3%	2.7%	3.1%	6.1%
Treatment-related	1.3%	1.0%	1.2%	2.3%
TEAE with outcome of death	1.0%	2.1%	1.4%	1.8%
Treatment-related	0.0%	0.0%	0.0%	0.0%

FCM = ferric carboxymaltose, TEAE = treatment emergent adverse event.

Summary/Conclusions: This large-scale analysis is based on individual patient data and includes a broad variety of different patient populations. The results confirm that FCM is effective and has a similar tolerability to the pooled comparator. FCM causes a transient decrease in phosphate levels but this does not appear to increase the reported frequency of associated signs and symptoms.

E1478

CHANGES IN GAMMA GLOBIN MRNA LEVELS DO NOT CORRELATE WITH TOTAL HEMOGLOBIN OR FETAL HEMOGLOBIN LEVELS IN BETA THALASSEMIA INTERMEDIA PATIENTS ON HYDROXYUREA

GK Viswanathan[1,*], A Aggarwal[1], P Sharma[1], S Chhabra[1], J Kaur Hira[1], A Trehan[2], P Malhotra[3], R Das[1]
[1]Hematology, [2]Pediatrics, [3]Internal Medicine, Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: Hydroxyurea is a hemoglobin-F inducing drug used to increase hemoglobin levels in sickle cell disease and β-thalassemia intermedia. The response to hydroxyurea is variable among individuals and its mechanism of action is less well understood. This prospective study on β-thalassemia intermedia patients aimed at analysing the effects of hydroxyurea on γ-globin mRNA levels and correlate its dynamics with changes in total hemoglobin and fetal hemoglobin levels to better understand its mechanism of action. The underlying β thalassemia mutations, α thalassemia deletions and *Xmn-1^{G}*γ (C-T) polymorphism were characterised and correlated with changes in γ-globin mRNA levels.
Aims: To study the changes in γ-globin mRNA levels in β-thalassemia intermedia patients on hydroxyurea compared to baseline levels and correlate them with changes in total hemoglobin and fetal hemoglobin levels.
Methods: Eleven newly diagnosed individuals with β-thalassemia intermedia were included in the study. Changes in γ-globin mRNA levels were compared at baseline and after 6 months of hydroxyurea therapy. These were correlated with changes in hemoglobin, hemoglobin-F, hemoglobin-A2 levels and red cell parameters. The quantitation of γ-globin mRNA levels was done by real time PCR (Roche Lightcycler 480®). ARMS-PCR was used to study the β thalassemia mutations and GAP-PCR was employed to study the α globin gene deletions. *Xmn-1^{G}*γ (C-T) polymorphism was studied by PCR-RFLP.
Results: The study group included nine pediatric cases and two adult patients with age at enrolment ranging from 2 to 30 years. The male to female ratio was 1.2: 1. Four mild, five moderate and two severe β-thalassemia intermedia cases were enrolled. Milder β-thalassemia mutations were responsible in majority of cases for the thalassemia intermedia phenotype. The most frequent β-thalassemia mutation in our study group was -88 (C-T) followed by Cap+1 (A-C). All the eleven patients were negative for the 8 α-globin gene deletions tested by GAP-PCR. Seven patients were *Xmn-1^{G}γ* (-/-), two patients *Xmn-1-^{G}γ* (+/+) and two were of *Xmn-1^{G}*γ (+/-) genotype. Seven patients (63.6%) were good responders, two (18.2%) were partial and two (18.2%) were non-responders to hydroxyurea therapy. The mean increase in Hb post-HU therapy was 1 g/dl. The mean HbF increased by 1.5 g/dl in the post-HU group. Six (54.5%) patients had increased relative expression of γ-globin mRNA after HU therapy, 4 (36.4%) patients had decreased relative expression and one patient (9%) did not show any change measured by qRT-PCR. Four patients who had a decrease in relative expression of γ-globin mRNA after hydroxyurea therapy did not show a drop in Hb; rather all had a rise in Hb ranging from 0.8 to 2.6 g/dl. The relative expression of γ-globin mRNA levels did not correlate with rise in hemoglobin. *Xmn-1^{G}γ* (C-T) polymorphism was associated with high fetal hemoglobin levels at baseline and also post hydroxyurea. Hydroxyurea showed good response in majority of the patients. These results indicate that the actions of hydroxyurea might extend beyond γ-globin gene regulation. The mean hemoglobin A2 levels were decreased post hydroxyurea compared to baseline. This indicates hydroxyurea might affect regulation of other globin genes apart from the γ-globin gene. In addition there was improvement in red cell parameters (red cell indices, nucleated red cell count and reticulocyte count), bilirubin and lactate dehydrogenase levels indicating that hydroxyurea has a role in improving red cell rheology and survival.

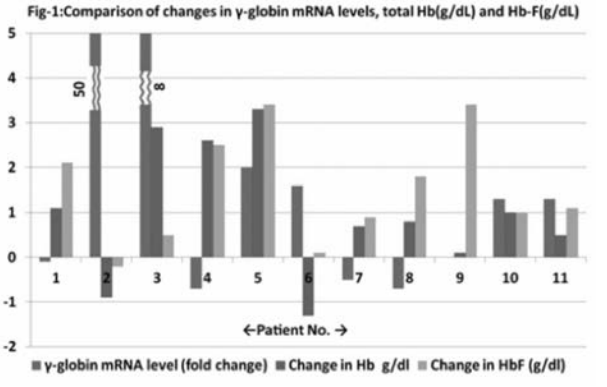

Figure 1.

Summary/Conclusions: In our study, the changes in relative expression of γ-globin mRNA levels (both increased and decreased levels) as measured by qRT-PCR did not directly correlate with changes in either of total hemoglobin or fetal hemoglobin levels. The increase in hemoglobin levels even in patients with decreased relative expression of γ-globin mRNA levels suggests that alternate mechanisms of action of hydroxyurea exist to increase the fetal hemoglobin and total hemoglobin in β-thalassemia intermedia patients. *Xmn-1^{G}γ* (C-T) polymorphism is associated with better response to hydroxyurea.

E1479

FERROPORTIN DISEASE: A CASE SERIES AT THE REGIONAL REFERRAL CENTER FOR IRON DISORDERS IN VERONA

C Piubelli[1], P Bozzini[2], A Castagna[1], G Marchi[2], M Rizzi[2], F Busti[1], R Pozzi-Mucelli[3], L Xumerle[4], M Delledonne[4], O Olivieri[1], D Girelli[1,2,*]
[1]Department of Medicine, University of Verona, [2]Veneto Region Referral Center for Iron Disorders, Azienda Ospedaliera Universitaria Integrata, [3]Department of Diagnostics and Public Health, Section of Radiology, [4]Department of Biotechnology, University of Verona, Verona, Italy

Background: Ferroportin Disease (FD), due to mutations in the *SLC40A1* gene encoding for the hepcidin receptor and cell membrane iron exporter ferroportin, is deemed as the most frequent form of "atypical" or "non-HFE" Hereditary Hemochromatosis (HH) (Wallace DF, Genet Med 2015). To date, knowledge on FD is mainly based on individual case reports, with heterogeneous clinical and biochemical features.
Aims: The aim of the work is to describe our experience as Regional Referral Center for Iron Disorders, after the recent implementation of a next generation sequencing (NGS)-based 2nd level genetic test for the molecular diagnosis of non-HFE HH.
Methods: We used our recently validated molecular test (Badar S, Am J Hematol 2016) combining capture and enrichment of the five HH genes (HFE, HFE2, TFR2, SLC40A1/ferroportin, and HAMP/hepcidin) through HaloPlex™ Technology and NGS using the IlluminaHiSeq 1000 platform (Illumina, San Diego CA).
Results: New cases of FD have been detected, so that we are now following 9 FD patients from 7 families. The 3bp-deletion p.Val162del, the most frequent FD-associated variant reported in literature was found in 3 families. We recently detected a new variant (p.Leu233Gln) in a patient showing mixed biochemical/pathological features between Type 4A/4B HH, *i.e.* marked hyper-

ferritinemia (6,923 ng/ml), elevated transferrin saturation (85% at diagnosis), iron deposition in both liver and spleen at MRI, and iron overload in both Kupffer cells and hepatocytes at liver biopsy. Noteworthy, the mutation affected the same residue involving a different mutation (p.Leu233Pro) previously described in a patient with a quite similar phenotype (Girelli D, J Hepatol 2008). All 4 patients with p.Val162del (all females, age range 30-69) had marked hyperferritinemia (range 1,101-3,020 ug/L) and normal transferrin saturation. Despite in some cases hyperferritinemia dated back several years without treatment before the correct diagnosis, all patients were clinically asymptomatic, with no overt biochemical signs of liver disease. Hepcidin levels in FD patients were high-normal at diagnosis, but tended to decrease with iron depletion through phlebotomies.
Summary/Conclusions: Our single center experience confirm FD disease as the most frequent atypical HH, and call for multicentre registries to better define the clinical features of this heterogeneous condition.

E1480

LONG-TERM SAFETY AND EFFICACY OF DEFERASIROX IN PEDIATRIC PATIENTS WITH TRANSFUSIONAL HEMOSIDEROSIS: RESULTS FROM A 5-YEAR OBSERVATIONAL STUDY (ENTRUST)

E Vichinsky[1,*], A El Beshlawy[2], A Alzoebie[3], A Kamdem[4], S Koussa[5], T Chotsampancharoen[6], A Bruederle[7], G Gilotti[8], J Han[8], M Elalfy[9]
[1]Children's Hospital & Research Center, Oakland, United States, [2]Cairo University, Cairo, Egypt, [3]Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates, [4]Centre Hospitalier Intercommunal, Créteil, France, [5]Chronic Care Center, Hazmieh, Lebanon, [6]Songklanagarind Hospital, Songkhla, Thailand, [7]Novartis Pharma AG, Basel, Switzerland, [8]Novartis Pharmaceuticals, East Hanover, United States, [9]Ain Shams University, Cairo, Egypt

Background: Young patients with red blood cell disorders, such as β thalassemia major (βTM), sickle-cell disease (SCD) and Diamond–Blackfan anemia (DBA), receive regular transfusions from an early age and consequently accumulate iron. Complications of iron overload include organ damage and delayed growth/development, therefore optimal management of iron is required. Deferasirox, a once-daily oral iron chelator, has demonstrated safety and efficacy in adult and pediatric patients with transfusional hemosiderosis. As requirements for therapy may be lifelong, continual assessment of long-term outcomes is valuable, as conducted in the 5-year multinational, observational ENTRUST study.
Aims: Evaluate the long-term safety and efficacy of deferasirox in younger transfusion-dependent children with chronic iron overload in clinical practice.
Methods: Patients aged 2–<6 years at enrolment were prescribed deferasirox according to local labels, with dose adjusted based on serum ferritin, therapeutic goals, tolerability and changes in patient weight. Parents/guardians provided written, informed consent. The primary objective was to evaluate safety, specifically renal and hepatic function, assessed by ≥2 consecutive post-baseline measurements ≥7 days apart of serum creatinine (SCr) >age-adjusted upper limit of normal (ULN) and >33% from baseline and alanine aminotransferase (ALT) >5xULN. Secondary objectives included analysis of serum ferritin, investigator-reported adverse events (AEs) and growth.

Table 1.

Table. Most common investigator-assessed drug-related AEs (occurring in ≥4 patients)

	All patients (Safety set* N=261)
Patients with any drug-related AE, n (%)	102 (39.1)
AE by preferred term, n (%)	
Investigations	
Alanine aminotransferase increased	55 (21.1)
Aspartate aminotransferase increased	31 (11.9)
Serum creatinine increased	10 (3.8)
Serum bilirubin increased	4 (1.5)
Gastrointestinal disorders	
Vomiting	14 (5.4)
Abdominal pain	8 (3.1)
Diarrhea	5 (1.9)
Skin and subcutaneous tissue disorders	
Rash	13 (5.0)
Hepatobiliary disorders	
Hepatocellular injury	4 (1.5)
Infections and Infestations	
Gastroenteritis	4 (1.5)
Renal and urinary disorders	
Proteinuria	4 (1.5)

*All patients who received ≥1 dose of deferasirox over the analyzed period and ≥1 post-baseline safety assessment; AE, adverse event

Results: In total, 267 patients (mean age 3.2 years: 61.4%<4 years, 38.6% ≥4 years) with βTM (n=176, 65.9%), SCD (n=52, 19.5%), DBA (n=12, 4.5%) and other anemias (n=27, 10.1%) were enrolled and received ≥1 deferasirox dose. 122 (45.7%) patients discontinued, most commonly (>5% of patients) due to 'Other' reasons (n=55; 20.6%), loss to follow-up (n=19, 7.1%) and AEs (n=18, 6.7%; most commonly increased ALT and increased AST, n=7 each). Mean±SD deferasirox exposure and dose were 44.1±21.2 (range 1.2–65.6) months and 25.8±6.5 mg/kg/day, respectively. Most patients (n=172; 64.4%) received an average blood intake >7 mL/kg/month. Median serum ferritin decreased from 1702 (range 334–9577) ng/mL at baseline (n=243) to 1127 (range 38–6428) ng/mL at 5 years (n=84). Eight (3.1%) patients had two consecutive SCr increases >age-adjusted ULN and >33% from baseline; two received deferasirox dose adjustments to resolve the observed SCr increase. Overall, 11 (4.2%) patients had two consecutive ALT increases >5 or >10xULN, three of whom received deferasirox dose interruptions. There were no unexpected adverse events (AEs) or laboratory abnormalities. The most frequently observed AEs with suspected relationship to study drug (Table) were increased ALT (21.1%), increased AST (11.9%), vomiting (5.4%) and rash (5.0%). A steady increase in weight was observed.
Summary/Conclusions: This long-term, observational study of deferasirox in pediatric patients supports previous trials indicating favorable safety and efficacy. Over half the patients completed the 5-year study, with limited discontinuations due to AEs. Few patients experienced notable increases in renal or hepatic assessments and continued deferasirox therapy at the same or reduced dose. In this pre-pubertal study population, growth was normal. Thus, with regular monitoring and dose adjustments, effective long-term chelation therapy with deferasirox is manageable in the majority of pediatric patients in clinical practice.

E1481

CONCURRENT TREATMENT OF APLASTIC ANEMIA (AA) WITH IMMUNOSUPPRESSIVE THERAPY AND PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) WITH ECULIZUMAB

M Griffin[*], P Hillmen, T Munir, S Richards, L Arnold, K Riley, C Pelton, A Hill
Hematology, Leeds teaching hospitals, Leeds, United Kingdom

Background: At least 50% of aplastic anaemia (AA) patients have a PNH clone. Many have a small proportion of PNH cells requiring monitoring alone whereas others may present with both significant aplasia as well as PNH. Concurrent treatment for AA and PNH may therefore be required.
Aims: This retrospective analysis assess's the outcome of patients with concurrent PNH and aplastic anaemia who require complement blockade with eculizumab alongside immunosuppressive therapy (IST) for AA
Methods: The PNH National Service database (Leeds) was reviewed retrospectively. Patients who commenced eculizumab within a year of their aplastic anaemia treatment, or those treated for aplasia who were already established on eculizumab were selected.
Results: Fourteen patients were treated with eculizumab and immunosuppressive therapy concurrently. Median age was 38.5 years (range 7-76). AA treatment varied as per national guidelines dependant on the patient's age, patient choice and co-morbidities. Seven out of fourteen received ATG and ciclosporin (median follow-up 20 months post ATG), six received ciclosporin monotherapy (median follow-up from commencement of ciclosporin 97 months). 6 of the 7 patients receiving ATG+Ciclosporin responded, two achieved complete response (CR) and four a partial response (PR), one of whom required tacrolimus and subsequently achieved a CR with androgen therapy and one who achieved PR with oxymetholone. One did not respond and achieved a CR with a bone marrow transplant (BMT). Median granulocyte count reduced from 88% to 50% post ATG treatment however there was no change in the monocyte PNH clone. Of the six patients treated with ciclosporin monotherapy, one had a CR with concurrent androgen therapy, two had a PR, one had a CR then relapsed and is now in PR on recommencement of ciclosporin, two had no response. There was no change in the granulocyte PNH clone following ciclosporin treatment. One patient proceeded to first line bone marrow transplantation (mean follow-up from presentation 7 months). Both BMT recipients stopped eculizumab post transplant due to resolution of PNH. Two patients died, one from infection following a PR with ATG and ciclosporin, and one from unknown causes who had not responded to treatment. One patient had spontaneous remission of their PNH and stopped eculizumab; the remaining nine patients continue on eculizumab. Fourteen age matched controls not on eculizumab received similar therapies, nine of whom received ATG and ciclosporin (median follow-up from ATG commencement 37 months). Four had a CR, one had a CR then relapsed with no response to re-introduction of ciclosporin, one had a PR and two had no response, one of whom had a BMT with CR and one achieved CR with oxymetholone. One ATG patient is awaiting response (four months post ATG). Five patients were treated with ciclosporin monotherapy (median follow-up from ciclosporin commencement 115 months). Two had a CR, one had a PR then relapsed, one had no response and achieved a PR with oxymetholone and one is awaiting response (three months post ciclosporin commencement).
Summary/Conclusions: Concurrent treatment of AA with IST and PNH with eculizumab has not previously been reported. The response rates for IST in patients on eculizumab compared with age matched controls were similar, with similar numbers of patients achieving CR or PR with IST. Eculizumab therapy does not appear to affect response to IST for aplastic anaemia patients.
This strategy may be required especially with improved life expectancy for PNH patients receiving complement inhibition therapy. The patients in this study were treated in accordance with current aplastic anaemia guidelines and the presence PNH should not influence this.

E1482

4 YEAR COST-ANALYSIS OF AUTOMATED RED CELL EXCHANGE TRANSFUSION FOR MANAGEMENT OF RECURRENT PAINFUL CRISES IN ADULT PATIENTS WITH SICKLE CELL DISEASE

DA Tsitsikas [1,*], A Ekong [1], L Berg [1], B Sirigireddy [1], N Lewis [1], RJ Amos [1]
[1]Haematology, Homerton University Hospital NHS Foundation Trust, London, United Kingdom

Background: Automated red cell exchange transfusion (ARCET) is a promising modality in treating chronic complications in sickle cell disease (SCD). However, concerns around the cost of the procedure may limit its adoption in some institutions.
Aims: To assess the cost implications / financial gains of regular ARCET for SCD patients who have been on the programme for 4 years for recurrent pain in our institution.
Methods: We adopted ARCET in our institution in June 2011 and 8 patients have been on the programme for 4 consecutive years for management of recurrent painful crises. Data were collected retrospectively and the hospital attendance of these patients one year prior to the intervention (as a comparator) and every year after starting ARCET were analysed. Prices for different aspects of the service were provided by the divisional operational manager of the department and the haematology laboratory manager and were as follows: Haematology day unit unplanned attendance: £1022, emergency department (ED) attendance: £235, in-patient stay up to 8 days: £1540 and in-patient stays in excess of 8 days: £1540+£294 / every day in excess of 8. The total cost of blood over these 4 years was £309,200, the cost of using the day unit for the procedures £218,400 and the cost of the consumables used £36,839 giving a total cost of £564,439 for the 4 years. Cost of hospital attendance without the intervention was projected over 4 years based on the hospital attendance the year prior to commencing the intervention.
Results: 1) Total day unit unplanned attendance (without admission): 222 days one year prior to intervention, projected 888 over 4 years with projected cost £907,536. Attendance after intervention was 103, 142, 78 and 37 days 1, 2, 3 and 4 years post intervention respectively with a total of 360 days in 4 years and an actual cost of £367,920 and a 4 yr projected cost reduction of £539,616. 2) Total ED attendance (without admission): 173 days one year prior to intervention, projected 692 over 4 years with projected cost £162,620. Attendance after intervention was 130, 86, 72 and 53 days 1, 2, 3 and 4 years post intervention respectively with a total of 341 days in 4 years and an actual cost of £80,135 and a 4 yr projected cost reduction of £82,485. 3) Total in-patient episodes up to 8 days: 42 one year prior to intervention, projected 168 over 4 years with projected cost £258,720. Episodes after intervention were 48, 31, 37 and 32 1, 2, 3 and 4 years post intervention respectively with a total of 148 episodes in 4 years and an actual cost of £227,920 and a 4 yr projected cost reduction of £30,800. 4) Total in-patient episodes in excess of 8 days: 26 one year prior to intervention, projected 104 over 4 years with projected cost £160,160. Episodes after intervention were 11, 13, 10 and 11 1, 2, 3 and 4 years post intervention respectively with a total of 45 episodes in 4 years and an actual cost of £69,300 and a 4 yr projected cost reduction of £90,860. 5) In-patients days in excess of 8: 485 days one year prior to intervention, projected 1940 over 4 years with projected cost £570,360. In-patient days in excess of 8 after intervention were 73, 138, 57 and 86 days 1, 2, 3 and 4 years post intervention respectively with a total of 354 days in 4 years and an actual cost of £104,076 and a 4 yr projected cost reduction of £466,284. Overall, cost was £564,439 with projected savings of 1,210,045 and a 4y projected cost benefit of £645,606.
Summary/Conclusions: ARCET appears cost-effective for management of recurrent pain in SCD in the medium-long term.

E1483

PREDICTIVE ROLE OF MYOCARDIAL FIBROSIS IN THALASSEMIA INTERMEDIA PATIENTS

A Meloni[1,*], M Cinquetti[2], N Giunta[3], P Giuliano[3], V Positano[1], A Carrà[4], N Dello Iacono[5], A Massa[6], G Sinagra[2], A Pepe[1]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Dipartimento Cardiovascolare, Azienda Ospedaliero-Universitaria "Ospedali Riuniti", Trieste, [3]Unità Operativa Complessa di Radiologia, ARNAS Civico "Benfratelli-Di Cristina", Palermo, [4]Unità Operativa di Pediatria, Ospedale "G. Da Saliceto", Piacenza, [5]Centro Microcitemia-Day Hospital Thalassemia Poliambulatorio "Giovanni Paolo II", Ospedale Casa Sollievo della Sofferenza IRCCS, San Giovanni Rotondo (FG), [6]Servizio trasfusionale, Ospedale "Giovanni Paolo II", Olbia, Italy

Background: Myocardial fibrosis detected by late gadolinium enhancement (LGE) cardiac magnetic resonance (CMR) is currently used to predict adverse cardiovascular events in different cardiomyopathies. However, its clinical implications in thalassemia intermedia (TI) have not been studied.
Aims: The aim of this study was to assess the distribution and the predictive value of myocardial fibrosis for future events in TI.
Methods: We considered 218 white TI patients (37.82±11.00 years, 113 females) consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network and free of cardiac complications concomitant to CMR. LGE images were acquired to detect myocardial fibrosis and the extent of LGE areas was quantified using a semiautomatic, previously validated software.
Results: Myocardial fibrosis was detected in 46 patients (21.1%). LGE followed a subendocardial ischemic pattern typical of coronary artery disease in two patients. One patient showed both an ischemic and non ischemic pattern. Thirty-two patients had a single focus while 14 had at least two foci. The mean number of LGE segments per patient was 2.70±1.52. LGE involved the septal region in 76.1% of patients. The extent of LGE areas was 2.09±1.77% of the total left myocardial mass. Twenthy-two (47.8%) patients showed fibrosis in the infero- or anteroseptal junction, 18 (39.1%) had a non ischemic no-junctional pattern (intra or subepicardial) and 6 (13.0) had both a junctional and no-junctional pattern. Mean follow-up was 56.76±23.17 months. We recorded 13 cardiac complications: 1 heart failure, 7 arrhythmias and 5 pulmonary hypertension (PH). Myocardial fibrosis was a significant prognosticator for arrhythmias, PH and cardiac complications globally considered (see Table). Number of segments with LGE and extent of myocardial fibrosis were comparable in patients who developed cardiac complications *versus* the patients who did not.

Table 1.

	N(%) in Group	N(%) with Arrhythmias	Univariate analysis HR (95%CI)	P

Summary/Conclusions: In TI patients, myocardial fibrosis is a predictor of adverse outcome.

E1484

ORAL HIGH DOSE LIPOSOMIAL IRON *VS* INTRAVENOUS IRON IN SIDEROPENIC ANEMIA PATIENTS INTOLERANT/REFRACTORY TO IRON SULPHATE. MULTICENTRIC RANDOMIZED STUDY

G Giordano[1,*], A parente[2], R gigli[3], M magri[1], G berardi[4], B carabellese[5], F d'amico[2], L luciano[2], R fratangelo[2], G niro[3], A licianci[6], L di marzio[6]
[1]medicine, Regional Hospital "A. Cardarelli", [2]molise university, [3]laboratory medicine, Regional Hospital "A. Cardarelli", [4]general medicine, asrem molise, [5]nuclear medicine, [6]hospital management, Regional Hospital "A. Cardarelli", Campobasso, Italy

Background: In iron deficiency anemia support with intravenous iron allows a faster anaemia correction and a faster ferritin increase than iron sulfate. Frequently iron sulfate and intravenous iron generate adverse events as hypotension, urticarioyd reactions, shock, epygastralgia, constipation or diarrhea. High doses of oral iron frequently are poorly tolerated because of adverse events.
Aims: Aim of this study is to verify if high doses of oral liposomial iron are safe, cost-effective and well tolerated as standard doses of intravenous ferrigluconate in patients with iron deficiency anemia intolerant/refractory to iron sulphate.
Methods: We considered two group of patients(RANDOMIZED 1:1) with iron deficiency anemia without other relevant comorbidities. In group A M/F was 2/3, 15 patients had haemorragic gastritis, 8 hemorragic enteric bleeding angiodysplasia, 22 hypermenorrhaea, median level of hemoglobin (Hb) was 8.5 g/dl(R 6.5-10), median ferritin level was 5 ng/ml (R 3-21), with a normal level of CRP or ESR, and received liposomial iron 30 mg 4 tablet/day. In group B M/F was 2/3, 18 patients had haemorragic gastritis, 6 hemorragic enteric bleeding angiodysplasia, 21 hypermenorrhaea, median level of Hb was 8.2 g/dl(R 7.5-9.5), median ferritin level was 7 ng/ml (R 2-19), with a normal level of CRP or ESR, and received iv sodium ferrigluconate 62.5 mg iv in NS 100 ml in 3 h/day. The median treatment costs in each group were calculated considering the monthly global treatment cost for each patients in the treatment period. This provided an estimate of the costs, independent of the precise cost of the drug, but tied to the final outcome (efficacy) of the therapeutic strategy used during the observation period.
Results: In group A,1g Hb increase was observed after a median of 9 days (R 7-15), a target Hb level of 12g/dl was achieved in a median time of 4 weeks (R 2-5) with a median cost of € 120/months (R 95-180), 12(26%) patients showed adverse events (7 epigastralgia, 5 diarrhoea). In group B,1 g Hb increase was observed after a median of 7 days (R 6-11), a target Hb level of 12g/dl was achieved in a median time of 3 weeks (R 1.5-4) with a median cost of €300/months (R 250-380), 10(22%) patients showed adverse events (2 hypotension, 2urticaria and headhace).
Summary/Conclusions: Oral high dose liposomial iron support is safe, fast, well tolerated and cost-effective as intravenous iron in sideropenic anemia. This study needs confirmation on a larger cohort of patients.

E1485

NEXT GENERATION OSMOTIC GRADIENT EKTACYTOMETRY FOR THE DIAGNOSIS OF HEREDITARY SPHEROCYTOSIS: METHOD VALIDATION AND FIRST DIAGNOSTIC EXPERIENCE OF TWO CENTERS

E Lazarova[1,*], B Gulbis[1], B van Oirschot[2], R van Wijk[2]

[1]Department of Clinical Chemistry, Hôpital Erasme, Université Libre de Bruxelles, Brussels, Belgium, [2]Department of Clinical Chemistry and Hematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Osmotic gradient ektacytometry (Osmoscan) is part of the laboratory diagnosis process of hereditary spherocytosis (HS) and other red blood cell membrane disorders. A new generation ektacytometer, the LoRRca MaxSis, has recently become commercially available. We here present for the first time the experience of two independent institutions with this analyzer in HS diagnostic settings.
Aims: The objectives were (a) to validate the LoRRca MaxSis analytically independently in two centers, (b) to estimate the diagnostic accuracy of the various parameters available from the Osmoscan curve and their clinical application for HS diagnosis, (c) to establish a standardization of result reporting and cut-off values of Osmoscan parameters for HS diagnosis, and (d) to introduce the next generation osmotic gradient ektacytometry in the diagnostic work-flow of RBC membrane disorders.
Methods: Inter- and intra-assay variability and sample stability for different storage (4°C and 20°C) and anticoagulant conditions (*K2*-EDTA, *Li*-Heparin and acid-citrate-dextrose) were studied. In addition, we performed Osmoscan on samples from patients with HS (N=40), probable HS (N=21), auto-immune hemolytic anemia, AIHA (7), and patients with other pathologies (N=37). Daily control samples (n=54 in Erasme Hospital and n=80 in University Medical Center Utrecht) were run in parallel with patient samples. Laser-assisted measurements of RBC deformability under changing osmotic gradient and constant sheer stress were expressed and recorded as elongation index (EI). An Osmoscan curve was created with the following parameters: EI *min* (minimal elongation index), O *min* (the osmolality at EI *min*), EI *max* (the maximal elongation index), O *max* (the osmolality at EI *max*), O *hyper* (the osmolality in the hypertonic region at 50% of the EI *max*), EI *hyper* (the EI at O *hyper*), and *area under the curve* (AUC). Patient results for the various Osmoscan parameters were expressed as percent of change (increase or decrease) compared to the mean of controls.
Results: Analytical performance of the LoRRca MaxSis ektacytometer showed an inter-assay variability between 0.2% and 3%. Samples were stable for 48-72 hours depending on temperature storage and anticoagulant used. No difference was observed for any of the Osmoscan parameters between the "HS" group, "probable HS" and "AIHA" group. However, a significant difference was observed between the "HS" group and the "other pathologies" group for O *min*, EI *max*, EI *hyper*, and the AUC. The following diagnostic cut-offs were established for HS: an increase of more than 21.5% for the osmolality point at the minimal elongation index (O *min*), a decrease of more than 8.5% for the maximal elongation index (EI *max*), and a decreased area under the curve (AUC) of more than 18.5% compared to the mean of controls.
Summary/Conclusions: The next generation ektacytometer is an efficient tool for the laboratory diagnosis of HS. Samples are stable, thereby enabling long-distance shipping to specialized laboratories. Additionally, the proposed standardized reporting of results allows inter-laboratory exchange and comparison. Different parameters of the Osmoscan curve were found useful for HS diagnosis but particularly the AUC, the O *min* and the EI *max* parameters. Finally, we considered the introduction of the next generation ektacytometry Osmoscan in the diagnostic work-flow of RBC membrane disorders at two levels: (1) as a potent screening method in a general laboratory, and (2) as an effective intermediate step between the screening laboratory methods and the confirmatory protein deficiency tests or DNA-based methods in a reference laboratory.

E1486

NEURO-PSYCHIATRIC INVOLVEMENT IN PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH)

W Barcellini[1,*], E Scola[2], S Lanfranconi[3], M Grottaroli[4], F Binda[1], B Fattizzo[1], P Bianchi[1], C Boschetti[1], M Buoli[4], CA Altamura[4], N Bresolin[5], F Triulzi[2], A Cortelezzi[6]
[1]Oncohematology Unit, [2]Neuroradiology Unit, [3]Neurology Unit, IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, [4]Department of Psychiatry, University of Milan, IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, [5]Neurology Unit; Dino Ferrari Centre, Neuroscience Section, IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, [6]Oncohematology Unit, IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Milan, Italy

Background: PNH is a rare disorder due to a deficiency in GPI–anchored proteins, characterized by haemolytic anaemia, marrow failure and thrombosis. Thrombotic events in PNH generally occur in unusual sites, such as hepatic, portal, mesenteric, splenic, and renal veins. Case reports of cerebral venous sinus thrombosis and arterial ischemic strokes are described in PNH. However, no systematic studies have been reported in asymptomatic patients
Aims: to investigate neuro-psychiatric involvement and neuroradiological findings in PNH patients
Methods: 17 PNH patients underwent non-enhanced cerebral magnetic resonance imaging (MRI), and intracranial arterial and venous angio-MRI. The following variables were evaluated: chronic ischemic small vessel disease, quantified according to ARWMC scale (Wahlund LO, Stroke 2001); focal alterations consistent with silent ischemic strokes; active or previous bleeding or micro-haemorrhages; atrophy. Moreover, abnormalities of the circle of Willis and its branches, and of cerebral venous sinus were evaluated. Psychiatric evaluation included the Brief Psychiatric Rating Scale, the Structured Clinical Interview 1 for DSM IV Axis Disorders (SCID-1), the Short Form (36) Health Survey, and the Trail making test
Results: Clinical and haematological parameters of patients are shown in table; 15/17 patients were classic haemolytic (60% transfusion dependent), and 2 PNH in the context of aplastic anemia (both transfusion-dependent until treatment with ATG-Cya). Abdominal pain was present in 41% (N. 1, 2, 4, 10, 11, 14, 15), and abdominal thrombosis in 18% (N. 2, 7, 10). Eculizumab was administered in 53% of cases for transfusion dependence, abdominal pain and/or thrombosis. On MRI, 10 subjects showed white matter (WM) abnormalities related to chronic ischemic small vessel disease. In particular, 5 subjects displayed periventricular WM vascular degeneration, and 6 deep WM focal chronic ischemic lesions. In one subject (N.10) a focal abnormality >5 mm was detected. The evaluation of WM and basal ganglia lesions (ARWMC scale) gave a score of 2 in 2 subjects (N.7, 17), a score of 4 in 3 subjects (N. 2, 10, 11), and a score of 5 in 1 subject (N. 9). No subject displayed active or previous bleeding. Two patients (80 and 81 yrs) showed atrophy of the cerebral hemispheres. Regarding vascular abnormalities, one subject (N.1) had hypoplastic left transverse sinus with irregularities in the sinus wall, suspected for prior partial venous thrombosis. Intracranial artery stenosis or aneurysm, and Moya–Moya like alterations were not observed. Finally, cerebral MRI was unremarkable in 7/17 subjects. Neurological clinical examination was normal in all patients. Psychiatric evaluation did not reveal any psychotic behaviour (except a doubt case in which emerged ideas of delusional thoughts), and test scores for visual attention and task switching resulted appropriate to age. SCID-1 highlighted the presence of a case of generalized anxiety disorder and the suspect of a case of bipolar disorder type 2. The SF36 results evidenced a better health perception than the norm, and even a perception of increased quality of life.

Table 1.

Patient N.	Year of diagnosis	PNH type	Data at diagnosis				Therapy with eculizumab, starting date	Data at last follow-up (2015/2016)			
			Age (yrs)	Hb (g/dL)	LDH (t>ULN)	PMN (% GPI neg)		Age (yrs)	Hb (g/dL)	LDH (t> ULN)	PMN (% GPI neg)
1	1996	haemolytic	48	12,0	9,5	48	yes, 2005	68	11,9	1,2	33

4	1999	haemolytic	24	9,9	1,5	33	no	41	8,6	6,7	80
5	2002	haemolytic	20	8,4	6,8	80	yes, 2008	34	8,4	0,9	97
6	2004	haemolytic	68	9,2	9,1	60	no	80	13,1	5,2	6
7	2005	haemolytic	43	6,7	5,4	42	no	54	11,1	2,2	76
8	2006	haemolytic	25	11,5	2,5	75	yes, 2007	35	12,7	1,6	nd
9	2006	haemolytic	63	8,1	4,0	67	yes, 2009	73	9	1	99
10	2006	haemolytic	50	10,8	7,8	20	no	60	13,9	1	13
11	2007	haemolytic	46	8,7	16,3	90	yes, 2008	55	11,2	1	92
12	2007	aplastic	31	9,6	1,2	14	no	40	10,6	4,4	75
13	2007	aplastic	49	7,9	1,9	56	no	58	12,1	4,7	89
14	2011	haemolytic	31	10,5	8,6	81	yes, 2011	36	10,5	1	94
15	2013	haemolytic	17	9,8	3,4	69	yes, 2014	20	12,5	1,1	66
16	2014	haemolytic	50	10,9	2,6	64	no	52	11,1	4,9	74
17	2014	haemolytic	80	8,1	3,1	93	no	82	11,1	4,0	nd

t>ULN: times over the upper limit of normal, nd: not done, na: not available

Summary/Conclusions: Although largely related to age, unexpected chronic ischemic white matter involvement was present in PNH, and particularly important in two subjects with severe haemolytic disease (N. 9 and 10), of whom one not in eculizumab. White matter lesion burden in asymptomatic patients may help the decision to start therapy, which is not always easy on the clinical/haematological basis.

E1487

SLEEP OBSTRUCTIVE APNEA SYNDROME (SOAS) IS NOT ASSOCIATED WITH MARKED ERYTHROCYTOSIS. A STUDY ON 337 PATIENTS

P Morel[1,*], S Lecerf[2], O Florea[2], H Vandeputte[2], A Duhamel[3], JP Marolleau[1], L Garcon[1]
[1]CHU d'Amiens, Amiens, [2]Centre Hospitalier de Lens, Lens, [3]CHRU de Lille, Lille, France

Background: Normal values of hemoglobin concentration (Hb) and hematocrit (Ht) depend on gender only.
Aims: To check the role of age and frequent disorders that may influence erythropoiesis (renal function, iron metabolism and oxygenation abnormality).
Methods: This prospective study enrolled 337 patients (pts) aged 16 to 88 years (median 61, M/F=1.51) referred to the sleep unit of Hospital of Lens. All patients had arterial blood gas, blood cell count and routine chemistry. Apnea hypopnea index (AHI) was available in 250 pts.
Results: Severe SOAS (AHI>30/hour) was found in 121 pts (48% of evaluated pts). Median HB and HT was 13.3 g/dL (range from 8.5 to 17.2 g/dL) and 40.7% (range 18,1 to 51,4%) respectively. Only 5 pts presented with increased HB (>17.5 g/dL in male, >15.5 g/dL in female) and HT (>50% in male and >47% in female). Conversely, anemia (HB<13.5 g/dL in male,<12.5 g/dL in female or HT<40% in male,<37% in female) was present in 118 pts (35%): Renal failure (MDRD creatinine clearance<60 ml/min), iron deficiency (ferritin<30 µg/L) or

features of anemia of chronic disease (CRP>10 mg/L or ferritin >400 µg/L) were observed in 84 (25%), 58 (17%) and 72 (21%) pts respectively. Finally, 173 pts presented none of these disorders (no cause of anemia) and 219 pts presented without anemia according to HB and HT criteria (non-anemic pts). Female pts had lower HB and HT than male pts (median 12.6 g/dL and 38.5% *vs* 13.9 g/dL and 42.4%,respectively, p<0.0001). HB and HT were mainly influenced by age and also MDRD creatinine clearance (that takes age and gender into account) (table 1). The relationships between age and HB and HT were confirmed in linear models (R2=0.133 and 0.118, respectively, p<0.0001) and these inverse relationships were validated in an independent seris of 3892 patients referred in the medicine units of the Centre Hospitalier Universitaire of Amiens. Testing the lack of fit showed that the linear model was inadequate in the subgroup of male pts, and smoothing spline analysis showed an increase in the inverse relationship between HB and age in elderly male pts older than 60 years. AHI was the only respiratory parameter that influenced only HB (r=0.13085, p=0.047). There was no significant correlation between AHI and age, no significant difference in the distribution of AHI in male and female. Nevertheless, significant correlations were observed between AHI and HB and HT when the analyses were performed in the non anemic pts (r=0.20676, p=0.0067 and r=0.18340, p=0.0163 respectively) and in pts without cause of anemia (r=0.20092, p=0.0224 and r=0.16335 p=0.0644 respectively).

Table 1.

Characteristics	HB		HT	
Age	r= -0.34650	p<.0001	r= -0.32086	p <.0001
Creatinine clearance (MDRD)	r=0.23686	p<.0001	r=0.21106	p=0.0003
Ferritin	r=0.30928	p<.0001	r=0.13743	p=0.016
CRP	r=-0.12961	p=0.0227	r=-0.10795	p=0.058
AHI	r=0.13085	p=0.047	r=0.11799	p=0.0735

Summary/Conclusions: This prospective study showed an inverse relationship between age and HB and HT. We confirmed the rarity of marked erythrocytosis in pts with SOAS and the weak correlation between AHI and HB and HT. Our data suggested that SOAS pts also frequently present with characteristics that may play a part in reducing HB and HT. Thus, checking the presence or the absence of associated comorbidity should be considered in SOAS pts with erythrocytosis.

"SEPARATING THE WHEAT FROM THE CHAFF" CONGENITAL HEMOLYTIC ANEMIA STUDY WITH A TARGETED NEXT GENERATION SEQUENCING PANEL

C Bento, T Magalhães Maia*, AC Oliveira, L Relvas, H Almeida, J Pereira, E Cunha, L Manco, L Ribeiro
Clinical Hematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Diagnosing a Coombs negative hemolytic anemia (HA) can be a true challenge, specially in the absence of family history or when the peripheral blood smear is not very informative. A few years ago, we had to sequence gene by gene by Sanger methodology, which was time costly. Nowadays, with Next Generation Sequencing (NGS) panels it is much faster, nevertheless we may be drowned in a large number of putative pathological mutations. The concept of one mutation (or two for the autossomal recessive disorders) one disease, have changed and now we have to deal with pathological variations or not, or modulating factors. As a reference laboratory dedicated to the study of benign red blood cell disorders (RBC) we have many of HAs with an identified molecular lesion, but also several cases, that even though thoroughly screened for hemoglobinopathies, enzymes and membrane defects remained without identification of the pathological mutations. This has implications at prognostic and therapeutic level, and makes the correct genetic counseling impossible.
Aims: Identify the molecular causes in a group of 14 patients with congenital HA, after screening for the most common hemoglobinopathies, enzymopathies and membranopathies.
Methods: Informed consent was signed for all the individuals in the study. We have used a targeted NGS panel encompassing the exonic regions of 24 genes (del Orbe et al, 2015) and sequenced 14 samples from patients with a congenital HA. In all the samples the common screening tests for RBC disorders were preformed, like high performance liquid chromatography (HPLC) for Hb variants, enzymatic quantification and membrane disorders screening tests as cryohemolysis test and eosin-5'-maleimide. The variants found were classified using *in sillico* analysis and the presence of pathological and likely pathogenic variants were confirmed by Sanger sequencing and, when available, familial studies were performed.
Results: All the samples showed a great number of variants, the majority were benign or likely benign (a media of 320/sample) or of unknown significance or likely pathogenic (media of 25/sample). Only 8 samples showed pathologic variants that can justify the clinical presentation. Most of them are associated with membrane disorders (Table). In 5 of the samples no pathological mutations were found, in one sample (sample 11) we found a *NT5C3A* missense mutation but in the heterozygous state (Sanger sequencing of all gene also didn't reveal any other mutation). Three samples are compound heterozygous for mutations in the *SPTA1* gene, three have a combination of mutations in different genes affecting membrane structure, one is a compound heterozygous for two missense *CDAN1* mutations not described before. Sample 5 is form a sickle cell disease patient with an uncommon presentation in the newborn period, a *PIEZO1* mutation inherited from the mother and a *EPB41* mutation inherited from the father are likely to be the causes of the aggravated phenotype.

Table 1. Results of the NGS sequencing-pathological variants.

Sample ID	Gene	Mutation
Sample 1	*SPTA1*	p.Gln2146Arg / p.Tyr653Cys
Sample 2	*SPTA1*	p.Ala1945Pro / p.Glu671Stop/ p.Leu1485Phe
Sample 3	no mutations	
Sample 4	*SPTA1*	p.Ser1163Ala;
	ANK1	p.Gly460Glu
	SPTB	p.Asn1151Asp
	CDAN1	p.Ala448Gly
Sample 5	*HBB*	HbS/ HBD
	PIEZO1	p.Arg2476Cys
	EPB41	p.Arg409His
Sample 6	no mutations	
Sample 7	*SPTA1*	p.Gln2146Arg / p.Tyr653Cys
	ANK1	p.Val1318Met
Sample 8	no mutations	
Sample 9	*SPTA1*	p. Leu1485Phe / p. Leu1858Val
Sample 10	*SPTA1*	p. Leu1858Val/ p. Leu1858Val / p.Ala970Asp
	ANK1	p.Asn251Lys
Sample 11	*NT5C3A*	p.Asp283His
Sample 12	no mutations	
Sample 13	no mutations	
Sample 14	CDAN1	p.Trp1184Ter / p.Tyr713Ser

Summary/Conclusions: After *in sillico* analysis of the variants found by NGS (almost 350 per sample) and confirmation by Sanger sequencing of the pathological variants, we have identified a molecular cause for the HA in 8 of the 14 samples studied. This study confirms that target NGS is the most complete and cheaper method for sequencing the genes associated with AH but, for the cases that remain without mutations, whole exome sequencing or whole genome sequencing need to be done, in order to identify new genes that can later be added to the AH panel.

E1489

SERUM HEPCIDIN-25 IN COMPARISON WITH BIOCHEMICAL MARKERS AND HAEMATOLOGICAL INDICES FOR THE DIFFERENTIATION OF ANAEMIA STATES AND CORRELATION WITH RESPONSE TO ORAL IRON

A Cowley[1,*], A Cooper[2], S Lewis[3], W Thomas[1]
[1]Haematology, [2]Biochemistry, [3]Gastroenterology, Plymouth Hospitals NHS Trust, Plymouth, United Kingdom

Background: Hepcidin is a key regulator of iron metabolism and may be a useful analyte in the differentiation of iron states in anaemia. Hepcidin is down regulated in the presence of iron deficiency to promote iron absorption and is up regulated when iron stores are in excess or in the setting of inflammation via IL-6. In combination with hypochromia indices and other markers of iron deficiency such as reticulocyte haemoglobin (Ret-He), a raised hepcidin level may provide evidence of both reduced iron absorption and iron restricted erythropoiesis. Conversely, a low or normal hepcidin level may be suggestive of true iron deficiency. In recent years immunoassays have become more readily available, allowing hepcidin to complement existing routine biochemical indices to differentiate anaemia states.
Aims: The primary aim of this study was to assess whether there was a correlation between hepcidin and markers of iron status in patients referred via the iron deficiency clinic at Plymouth Hospitals NHS Trust. The second objective was to investigate the association of baseline hepcidin-25 with response to oral iron.
Methods: Patients referred to the iron deficiency anaemia clinic by their GP were prospectively recruited. A clinical history, examination, blood tests including haematological indices and biochemical markers, appropriate investigations and oral iron supplementation were prescribed where appropriate. To determine the response to oral iron, the full blood count was repeated at 1 and 3 months. For the measurement of hepcidin-25, serum was frozen at -70C and then determined by batch analysis using a commercial ELISA kit (DRG Instruments, Marburg, Germany). Patients were classified as having iron deficiency anaemia (IDA), anaemia of chronic disease (ACD) or the combined state of iron restricted erythropoiesis (IRE) with ACD (ACD/IRE) using clinical findings and standard biochemical markers and haematological indices.
Results: The Hepcidin-25 immunoassay performed well, with a low within- and between- assay coefficient of variation. The table shows the numbers and characteristics of the patients allocated to the 3 types of anaemia. Numbers given

as median and interquartile range. Hepcidin concentrations correlated significantly with ferritin concentrations. Serum hepcidin was less than 1 ng/mL in 80 of 85 patients with IDA. This is consistent with previous data. There were no linear associations seen between hepcidin and other indices of anaemia (Total Hb, MCV, MCH, Ret-He, Transferrin, Transferrin saturation, Iron and CRP). 96 patients had a trial of oral iron, with 65 responding (increase of >10g/l by 12 weeks) and 31 failing to achieve an adequate rise in haemoglobin. There was no correlation between response to oral iron and hepcidin.

Table 1.

Variables	IDA	ACD	ACD/IRE
Number	85	30	15
Age	72 (61-80)	76 (65-79)	79 (64-79)
Haemoglobin (g/L)	109 (99-120)	112 (98-121)	111 (106-117)
MCV (fL)	80.4 (76.2-84.9)	86.7 (83.8-90.7)	82.5 (77.5-83.8)
MCH (pg)	25.1 (23.6-27.1)	28.1 (26.6-29.8)	26.1 (24.7-27.7)
Ferritin (ug/L)	12 (9-16)	119 (63-256)	40 (34-72)
CRP (mg/L)	2 (1-5)	9 (2-56)	4 (2-14)
Transferrin saturation (%)	7.29 (5.67-11.13)	16.45 (9.87-21.93)	13.72 (11.41-18.51)
Ret-He (pg)	27.6 (24.9-30.5)	31.9 (28.5- 35.6)	31.6 (30.1-32.9)
Hepcidin (ng/mL)	0 (0 - 0)	5.4 (0 - 75.4)	0 (0 - 1.268)

Summary/Conclusions: A positive correlation exists between Hepcidin-25 and serum ferritin. The majority of patients in this study had iron deficiency anaemia and correspondingly low hepcidin concentrations. A low hepcidin did not correlate with subsequent response to oral iron therapy. Further investigation, however, of hepcidin in anaemic patients with normal to high ferritin levels is warranted to further evaluate the role of this hormone in the management of these patients.

E1490

EFFECT OF ZINC SUPPLEMENTATION ON GLUCOSE METABOLISM, OXIDATIVE STRESS AND IRON TRAFFICKING PROTEINS IN TRANSFUSION DEPENDENT PATIENTS WITH THALASSEMIA

P Walter[1,2,*], C Curtis[1], M Hodge[1], M Razavi[3], M Minkley[1], A Lal[2], A Higa[2], D Killilea[2], T Pearson[3], E Fung[2]
[1]Biology, University of Victoria, Victoria, Canada, [2]Hematology, UCSF Benioff Children's Hospital, Oakland, United States, [3]Biochemistry, University of Victoria, Victoria, Canada

Background: Thalassemia (Thal) is a genetic anemia of incomplete erythropoiesis causing iron overload and roughly 25% of patients to be marginally zinc (Zn) deficient. Nearly 30% of adult subjects with Thal will develop diabetes, thought to be related to transfusional iron overload, but the diabetogenic effects of altered Zn status are not well known. It is hypothesized that a functional Zn deficiency in Thal may affect insulin secretion, glucose homeostasis and/or oxidative stress. Oxidative stress can be manifested by labile plasma iron (LPI), a component of non-transferrin bound iron that is often found in Thal suffering from iron overload. LPI is both redox-active and chelatable, and is the likely culprit of distributing iron to peripheral tissues inducing tissue iron overload. LPI can catalyze lipid peroxidation and release malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE) from cells, which are lipid peroxide damage-associated molecular patterns that indicate tissue damage and induce inflammation. To monitor the proteins that may traffic this free iron we used an advanced proteomics technique, measuring soluble transferrin receptor (sTfR), transferrin, haptoglobin, hemopexin and inflammatory proteins C-reactive protein (CRP) and Immunoglobulin G (TgG).
Aims: The purpose of this pilot project is to determine Zn supplementation effects on 1) circulating levels of oxidative stress and iron trafficking proteins and 2) glucose homeostasis and insulin secretion in Thal.
Methods: 39 subjects with informed consent were enrolled (9 Thal with diabetes (DM), 20 Thal without DM, 10 controls). Thal on intervention (60% Female, 28.4±11.0y) had a 2 hr OGTT at 3 time points (0, 3 and 6 mos) and took 25 mg Zn/d between 3 and 6 mos. 30% of Thal and 44% of DM had low serum Zn at baseline. LPI was measured using fluorogenic dihydrorhodamine 123 (measures reactive radicals) with desferrioxamine as a chelator. Both MDA and MDA+4-HNE was measured using N-methyl-2-phenylindole. Iron trafficking proteins were measured by MRM mass spectrometry.
Results: C-peptide levels were significantly reduced in DM compared to controls (p=0.002) as were lipase levels compared to controls (33 *vs* 21 IU/L, p=0.04). Serum Zn was related to beta cell function by the Homeostatic Model Assessment (HOMA) (r=0.45, p=0.049) and in subjects with low serum Zn supplementation improved insulin response to the glucose challenge (p=0.04). LPI, MDA, and 4-HNE were significantly elevated in Thal *vs* Control (4.95µM±3.12 *vs* -1.81±2.45 p=0.0004; 4.8 *vs* 3.0 µM, p=0.005; 9.37±2.94 *vs* 13.9±5.84 µM, p=0.024). MDA patients with low iron levels at baseline were found to have an increase in MDA over time *vs* those with high iron (p=0.005). LPI, MDA, and 4-HNE comparisons between all three time points of Zn therapy in Thal patients–with results of both Control and DM patients–did not show significant differences. However, significant differences were noted in Thal patients *vs* Controls for the following iron trafficking related proteins: sTfR, transferrin, haptoglobin, hemopexin and TgG (p<0.05).
Summary/Conclusions: These preliminary data suggest that in patients with Thal, Zn status is related to insulin resistance and beta cell function, possibly related to circulating LPI, oxidative stress and some iron trafficking proteins such as sTfR or hemopexin. More results are needed to explore how non-invasive therapy may improve glucose tolerance in Thal patients.

AN SPECKLE TRACKING IMAGING REVEAL MYOCARDIAL IRON OVERLOAD IN THALASSEMIA MAJOR? A COMBINED ECHOCARDIOGRAPHY AND CARDIAC MAGNETIC RESONANCE STUDY

A Meloni[1,*], F Pizzino[2], A Terrizzi[2], M Allò[3], S Macchi[4], G Giuffrida[5], C Paci[6], V Positano[1], M Missere[7], P Keilberg[1], G Di Bella[2], C Zito[2], A Pepe[1]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, [2]Azienda Ospedaliera Universitaria "Policlinico G. Martino", Messina, [3]Servizio Microcitemia, Presidio Ospedaliero ASL 5, Crotone, [4]Servizio Trasfusionale, Ospedale "Santa Maria delle Croci", Ravenna, [5]Divisione Clinicizzata di Ematologia, Ospedale "Ferrarotto", Catania, [6]Centro Trasfusionale, Ospedale "S Maria alla Gruccia", Montevarchi (AR), [7]Dipartimento di Immagini, Fondazione di Ricerca e Cura "Giovanni Paolo II", Campobasso, Italy

Background: Cardiac complications related to myocardial iron overload (MIO) remain the main cause of morbidity and mortality in thalassemia major (TM). Cardiac magnetic resonance (CMR) is a unique non-invasive technique to quantify MIO and the multislice T2* technique allows the identification of different patterns of MIO. Unfortunately, the availability for CMR scans in validated centers is still limited in many countries. On the other hand, echocardiography is a widely diffused, non-expensive and feasible technique, with elevated accuracy in the evaluation of cardiac function and morphology. Nevertheless, standard echocardiographic examination fails in detecting MIO until a substantial reduction of the left ventricular ejection fraction (LVEF) occurs. The evaluation of myocardial deformation by two-dimensional speckle tracking imaging (2DSTI) demonstrated a great accuracy in detecting subtle myocardial dysfunction in many different pathologic conditions.
Aims: We aimed to investigate the role of 2DSTI in the detection of MIO in patients affected by TM, comparing the data of myocardial deformation with T2* values derived by CMR.
Methods: We recruited 31 TM patients [15 males (48,4%); mean age: 37.87±9.64 years] consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. All patients underwent to CMR and to echocardiography in the same day. CMR was performed with a 1.5-T scanner and segmental and global T2* values were measured with a previously validated software (HIPPO MIOT®). Values of GLS were derived from the three apical views, while radial and circumferential strain were obtained from the three parasternal short axis views. All the echocardiographic examinations were performed with a commercial ultrasound system (Mylab-alpha, Esaote) equipped with a 1-4 Mhz phased array probe.
Results: Mean global heart T2* was 35.91±12.69 ms (range:5.63-47.13 ms). Six patients (19.4%) showed pathologic T2* values (<20 ms) indicative of MIO. GLS showed a significant correlation with T2* values (R=-0.401; P=0.025), moreover, the percentage of patients with altered GLS (lower or equal -19) was significantly higher in the group with a significant MIO than in the group with no significant MIO (global heart T2* ≥20 ms) (83% *vs* 28%, P<0.05). Logistic regression demonstrated that patients with impaired GLS had a significant higher risk of showing pathological T2* values (Odds-ratio-OR=12.86, 95%CI=1.27-130.54; P=0.031). No relation was observed between GLS, age and sex, and between T2* values, LVEF, radial strain and circumferential strain.
Summary/Conclusions: Left ventricular GLS can be useful in detecting subtle myocardial dysfunction due to MIO in TM patients, demonstrating a significant correlation with MIO detected by CMR.

E1492

THE IMPACT OF CARDIAC AND HEPATIC MRI ASSESSMENT ON THE CLINICAL MANAGEMENT OF AUSTRALIAN PATIENTS WITH TRANSFUSION DEPENDENT ANEMIAS OR NON-TRANSFUSION-DEPENDENT THALASSEMIA IN THE TIMES STUDY

PJ Ho[1,*], D Hiwase[2], R Ramakrishna[3], N Viiala[4], D Ross[5], E Zor[6], O Gervasio[7], DK Bowden[8]
[1]Royal Prince Alfred Hospital, Sydney Medical School, Sydney, [2]Royal Adelaide Hospital, Adelaide, [3]Southern Sydney Haematology, [4]Liverpool Hospital, Sydney, [5]Flinders Medical Centre, Adelaide, [6]Novartis Pharmaceuticals Australia Pty Limited, North Ryde, [7]Novartis Pharmaceuticals, Sydney, [8]Monash Medical Centre, Melbourne, Australia

Background: Iron overload can lead to impaired organ function and is associated with significant morbidity and mortality, the risks of which can be reduced by effective long-term iron chelation therapy (ICT) and control of iron loading. Magnetic resonance imaging (MRI) allows accurate, reproducible assessment of iron load and its use may affect clinical management decisions, leading to improved patient care. The epidemiological TIMES study used MRI to assess prevalence and severity of cardiac and hepatic siderosis in a large population of Australian patients with transfusion-dependent anemia or non-transfusion-

dependent thalassemia (NTDT). In this analysis of the TIMES study, we report the impact of MRI results on investigator treatment decisions.
Aims: To determine the prevalence of iron overload by MRI and its impact on the clinical management of iron overload in a population of patients with transfusion-dependent anemia or NTDT.
Methods: Patients with thalassemia major (TM), NTDT (β thalassemia intermedia, β thalassemia/Hb E, Hb H disease), myelodysplastic syndromes (MDS) or other chronic anemias were enrolled. Patients with NTDT had serum ferritin (SF) >300 ng/mL; others had a lifetime history of ≥20 units red blood cell (RBC) transfusions and SF >500 ng/mL. Past medical history was collected (including red blood cell (RBC) transfusion, ICT and hematologic data). Prospective MRI (FerriScan) was used to determine R2 liver iron concentration (LIC) and myocardial T2* (mT2*). Treatment decisions were assessed and recorded using an investigator questionnaire after evaluation of patient MRI results.
Results: Of the 243 enrolled patients, 10 and 48% had cardiac and hepatic siderosis, respectively. In all disease groups, mean LIC was above the target range (3-7mg Fe/g dw), while mean mT2* was normal (≥20ms). 65.8% of patients received ICT for ≥1 month before or during the study. During the 12-month period prior to the study, 55.9% received deferasirox, 11.9% received deferoxamine and 2.5% received deferiprone. All patients with TM had received ICT; among patients with MDS, NTDT or other anemia types, some patients were chelation naïve (CN)/minimally chelated (MC, chelation<1 month in lifetime; Table). MRI assessment led to a change in management in 105 (45.9) of all evaluable patients (n=229) and in ~60% of CN/MC patients with MDS (17/27 [63.0%]) and other anemias (22/37 [59.5%]; Table). Across all diseases, the predominant changes were increasing chelator dose (43/75 [57.3%]) and starting chelation (27/75 [36.0%]; Table). In patients who had received ICT for >1 month, the most frequent change was increasing chelator dose (TM, 20/23 [87.0%]; MDS, 11/16 [68.8%]; NTDT, 4/7 [57.1%]; other anemias, 5/6 [83.3%]). In CN/MC patients, starting ICT was the predominant change (MDS, 10/13 [76.9%]; NTDT, 2/2 [100.0%]; other anemias, 8/8 [100.0%]). Cardiac MRI assessment (mT2*) was the key driver for ICT decisions in patients with TM (63.8%; ranked as the most important factor in the treatment decision); however, LIC was the key determinant in patients with MDS (42.0), NTDT (44.4%) and other anemias (56.3%).

Table 1.

Table. Summary of MRI-based treatment decisions

Change to ICT	Overall	TM	MDS		NTDT		Other anemias	
Any change, n (%)	n=229	ICT n=77	CN/MC n=27	ICT n=42	CN/MC n=11	ICT n=7	CN/MC n=37	ICT n=28
Yes	105 (45.9)	26 (33.8)	17 (63.0)	19 (45.2)	3 (27.3)	7 (100.0)	22 (59.5)	11 (39.3)
No	124 (54.1)	51 (66.2)	10 (37.0)	23 (54.8)	8 (72.7)	0 (0.0)	15 (40.5)	17 (60.7)
Type of change, n (%)	**n=75**	**ICT n=23**	**CN/MC n=13**	**ICT n=16**	**CN/MC n=2**	**ICT n=7**	**CN/MC n=8**	**ICT n=6**
Start ICT therapy	27 (36.0)	0 (0.0)	10 (76.9)	4 (25.0)	2 (100.0)	3 (42.9)	8 (100.0)	0 (0.0)
Stop ICT therapy	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)
Increase ICT dose	43 (57.3)	20 (87.0)	3 (23.1)	11 (68.8)	0 (0.0)	4 (57.1)	0 (0.0)	5 (83.3)
Decrease ICT dose	2 (2.7)	1 (4.3)	0 (0.0)	1 (6.3)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)
Switch to other ICT	2 (2.7)	1 (4.3)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	1 (16.7)
Change ICT delivery	1 (1.3)	1 (4.3)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)

Patient numbers based on evaluable patients. CN, chelation naïve; ICT, iron chelation therapy; MDS, myelodysplastic syndromes; MC, minimally chelated; MRI, magnetic resonance imaging; NTDT, non-transfusion dependent thalassemia; TM, thalassemia major

Summary/Conclusions: These data provide real-life insight into the impact of MRI on treatment decisions in a large population of patients with heterogeneous causes of chronic anemia receiving RBC transfusions. A change in ICT management due to MRI analysis occurred in nearly half of all patients. This emphasizes the importance of accurate monitoring of iron load in patients with transfusion-dependent anemias or NTDT to allow for informed clinical decision making.

E1493

HOME-BASED CONTINUOUS 24-HOUR DEFEROXAMINE VIA A PERIPHERALLY INSERTED CENTRAL CATHETER IN SEVERE AND REFRACTORY IRON OVERLOAD: A CONVINIENT AND EFFECTIVE APPROACH IN THALASSEMIA MAJOR PATIENTS

K Belhoul, H Dewedar*, F Alkhaja, A Farag, N Susan
Thalassemia centre, Dubai Health Authority, Dubai, United Arab Emirates

Background: Severe iron overload leads to significant morbidity and mortality in β-thalassemia major (TM) patients. Intensive chelation is required in these patients to reduce iron to lower risk thresholds and avoid the development or worsening of end-organ dysfunction. Continuous intravenous deferoxamine (DFO) infusion in the inpatient setting remains the only management option in patients who fail to respond to high chelator doses, combination therapy, or those with symptomatic dysfunction requiring rescue therapy. The approach, however, may be associated with inconvenience and time lost in prolonged hospital admissions.
Aims: To evaluate the efficacy and safety of home-based continuous 24-hour DFO infusion via a peripherally inserted central catheter (PICC) in TM patients with severe and refractory iron overload.
Methods: This was a retrospective cohort study of TM patients attending our center between October 2013 and August 2015 who had received home-based continuous 24-hour DFO infusion via PICC. To receive such therapy, patients had to have no contraindication to PICC line insertion of DFO. They also had to have severe iron overload with evidence of no response to mono or combined therapy with subcutaneous DFO, defeiprone, or deferasirox. Severe iron overload was defined as a liver iron concentration (LIC) >15 mg/g, cardiac T2*<8 msec, or cardiac T2* 8-15 msec with any of the following: a left-ventricular ejection fraction (LVEF)<45% per echocardiogarphy, cardiac arrhythmia, compensated or decompensated clinical heart failure, or two or more endocrinopathies. The dose of DFO was 40 mg/kg titrated based on the index (<0.025) by Porter el al, administered with or without concomitant oral chelation.
Results: A total of 41 patients received home-based continuous 24-hour DFO infusion via PICC during the observation period (mean age 28.4±5.6 years, 51% male). Among these, 9 (22.0%) discontinued therapy, 7 (17.1%) only had<6 months follow up, while 25 (61.0%) patients had >6 months follow up and were included in efficacy analysis. Seventeen (42%) received concomitant deferasirox and 21 (51%) received deferiprone. Reported adverse events in the 41 patients included: local reaction (n=17), renal tubular acidosis (n=6), arthritis (n=4), line thrombosis (n=4), line displacement (n=4), local infection (n=4), systemic infection (n=2), retinopathy (n-1). None of the patients required hospitalization, developed new endocrine complications or progressed to advanced cardiac disease and no treatment related mortality was observed.
In the efficacy cohort (n=25, mean age 28.2±5.0 years, 36% male), patients had receive treatment for an average of 431±137 days. There was a significant and remarkable decrease in mean serum ferritin level (10848±5872 to 4095±4116 ng/mL, p=0.0001) and LIC (37.5±9.9 to 12.6±11.0, p=0.001) and a significant increase in cardiac T2* (8.1±3.5 msec to 12.4±6.3 msec, p=0.002). Heart failure was reversed in 2 out of 3 patients and LVEF improved from a mean of 40% to 60%. Eight out of 9 insulin-dependent diabetic patients had insulin dose reduction (mean reduction 34.3±0.2 Units), while one patient shifted to an oral hypoglycemic. All of the eight patients on oral hypoglycemic agents prior to treatment manged to stop it successfully.
Summary/Conclusions: Home-based continuous 24-hour DFO infusion via PICC is an effective treatment option in TM patients with severe iron overload that could not be controlled otherwise by other chelation regimens. The convenience of home-based therapy further promotes the role of this therapy in such high risk patients, although data from prospective clinical trials remain of merit.

E1494

A STUDY OF BONE AND JOINT INVOLVEMENT IN THALASSEMIA MAJOR

A Nayyar[1], S Kakkar[2,*], P Sobti[3], H Selhi[4]
[1]Pediatrics, Dayanand Medical College & Hospital, [2]Pediatrics, Dayanand Medical College &Hospital, [3]Pediatric Hemato-oncology, Christian Medical College & Hospital, [4]Orthopaedics, Dayanand Medical College & Hospital, Ludhiana, India

Background: Thalassemia major is an inherited hemoglobinopathy causing imbalance in globin chain synthesis, ineffective erythropoiesis and increased peripheral haemolysis. Thalassemia patients have a variety of bone and joint disorders like bone pain, deformity, growth failure, rickets, scoliosis, spinal deformity, nerve compression, pathological fractures, osteopenia and osteoporosis. There is a paucity of data about the extent of bone and joint disorders in thalassemia in developing countries.
Aims: 1. To determine bone and joint involvement in thalassemia major. 2. To evaluate serum biochemical parameters of bone formation and resorption and their relation with bone and joint formation. 3. To evaluate DEXA scan scores of Thalassemia patients and find a correlation, if any, with daily physical activity.
Methods: The study was carried out on 40 thalassemia patients between 5-18 years of age under regular follow up at our centre. All patients were interviewed as per a well-structured proforma for symptoms relating to bone and joint disease as described by the patient/parents in past one year and physical activity by QAPACE questionnaire. Venous blood samples were drawn under aseptic conditions and used for estimation of biochemical parameters (calcium, phosphorus, alkaline phosphatase, vitamin D, parathyroid hormone, thyroid hormone and serum ferritin). Enrolled subjects were scanned for bone mineral density (BMD) at femur neck, trochanter and Ward's angle using dual energy X ray absorptiometry.
Results: A total of 40 patients were enrolled in the study (M:F=80:20). Half the patients (n=20) had symptoms pertaining to bone and joint disease. The most common symptom was leg pain (42.50%), followed by backache (22.50%), generalized weakness (20%) and joint pains (20%). Asymptomatic patients had greater mean serum vitamin D as compared to the symptomatic patients (22.2 *vs* 15.08 ng/ml)(p= 0.225). Five patients were detected to have osteopenia, all above 10 years of age. The mean BMD in symptomatic patients at femur neck, trochanter and ward's angle was 0.781, 0.639 and 0.735 g/cm^2 respectively as compared to 0.754, 0.635 and 0.722 g/cm^2 in asymptomatic patients. The difference was not statistically significant. Patients with low BMD had lower mean pretransfusion Hb (<9 g/dl) (p= 0.01).Eighty percent of osteopenic patients had sedentary lifestyle as compared to 44% of patients with normal BMD. Bone mineral density did not have any correlation with vitamin D levels, serum ferritin and type of chelation therapy.

Summary/Conclusions: Pre transfusion hemoglobin of more than 9 g/dL has a protective role in maintaining good bone health and bone mineral density and helps to prevent osteopenia. Engaging thalassemia patients in physical activity has a positive effect on bone mineral density. Low vitamin D levels contribute to symptoms of bone and joint involvement in thalassemia and the same needs to be determined and supplemented.

E1495

EVALUATION OF WHILE MATTER INTEGRITY BY DIFFUSION TENSOR MRI AND NEUROCOGNITIVE FUNCTIONS IN NON-STROKE CHILDREN WITH SICKLE CELL DISEASE

M El-Tawil[1], I Ragab[1,*], K Ahmed[2], E Abdel-Kader[1], S Abdel-Sattar[2], M Abdel-Maguid[3]
[1]Pediatrics, [2]Radiodiagnosis, [3]neuropsychiatry, Ain Shams University, Cairo, Egypt

Background: Cerebral vasoocclusion may result in overt or silent infarctions, whether in absence of infarction, it may induce subtle ischemic changes need to be determined. Conventional brain MRI cannot precisely delineate microstructural changes and the white matter tracts of the brain. Diffusion-tensor imaging (DTI) can detect and quantify microstructural brain changes.
Aims: We aimed to evaluate the ability of multiple diffusion measures to detect subtle changes in the white matter integrity in patients with SCD compared with age and sex matched healthy control subjects; and to correlate the MRI findings with neurocognitive functions.
Methods: We performed a cross-sectional case control study including twenty one patients with SS and Sβ0 with age between 5-15 years. All patients were free from any neurological symptoms with no history of stroke. They were subjected to history taking and revision of hospital records for details of diagnosis including age, hemoglobin electrophoresis, transfusion, hydroxyurea, hospital admission and SCD complications. Diffusion tensor MRI (DTI) were done for all patients and ten age matched healthy control subject. Fractional anisotropy (FA) and apparent diffusion coefficients (ADCs) were calculated in regions of interest selected in various brain areas (superior and inferior frontal, parietal, occipital, and temporal white matter areas), centrum semiovale, basal ganglia (lentiform nucleus), pons, cerebellar white matter areas. Transcranial doppler was done for the patients with assessment of flow velocities in different brain regions. Cognitive assessment was done using the following tests, Wechsler intelligence scale for children for measuring IQ, the Benton visual retention test for visual memory and Wisconsin card sorting test is used as a measure of 'executive' or higher-order cognitive functions.
Results: Patients group included 7females (33.3%) and 14 males (66.7%), with mean age of 11.2±3.2 years, weight for age SDS was (-0.029±1.6), height for age SDS (-0.243±1.4) and median age at diagnosis was 18 months. As regards admission etiologies over the last year, 19 patients had vaso-occlusive crises (90.5%), 3 patients had acute chest syndrome(14.3%). Twelve patients were receiving frequent transfusions (57.1%). Patients with SCD had mean full scale IQ, verbal and performance IQ below 90 and there is no significant difference between patients and control group in full scale IQ (P= 0.892), verbal IQ (P= 0.759) and performance IQ (P =1). Concerning executive functions tested by WCST there was no significant difference in all parameters of the tests between patients and control group except for (non preservative errors) (P= 0.045). Regarding MRI DTI there was no significant difference between patients and control group in both FA and ADC in superior and inferior frontal, temporal, parietal, occipital, basal ganglia and cerebellum.No significant difference in FA and ADC results in patients with CBF velocity less and above 70cm/sec. There was positive correlation between difference in errors in BVRT and ADC of right frontal lobe (r=0.458) and parietal lobe (r=0.455). While there was negative correlation between ADC of right temporal lobe and FSIQ (r=-0.452), VIQ (r=- 0.518) and positive correlation between FSIQ and FA of left temporal lobe (r=0.475).
Summary/Conclusions: In absence of clinical evidence of cerebral infarction, white matter integrity by MRI DTI and neurocognitive functions in children and adolescents with SCD were preserved compared with healthy control group.

E1496

PROHEPCIDIN CONCENTRATIONS IN GAUCHER DISEASE AND FABRY DISEASE: INVESTIGATING THE ROLE OF HEPCIDIN IN ABNORMAL IRON HOMEOSTASIS AND ANAEMIA

A Creamer*, A Li, D Hughes
Haematology Department, Royal Free Hospital, London, United Kingdom

Background: Hepcidin is a 25-amino acid peptide first identified in 2001. It is recognised to have a key role in the regulation of iron stores, acting on duodenal enterocytes, macrophages and hepatocytes. Hepcidin levels have been found to respond to inflammatory cytokines (IL-6), iron status, erythropoetic activity and oxygen tension. Its precursor, prohepcidin, is synthesised by the liver and can be measured by a commercially available ELISA. Gaucher disease (GD) and Anderson-Fabry disease (AFD) are lysosomal storage disorders, a heterogenous group of diseases resulting from an inherited defect in a specific lysosomal enzyme or associated proteins. Haematological abnormalities including anaemia and disordered iron homestasis are recognised in GD. AFD is more commonly associated with organ dysfunction, but anaemia has also been described.
Aims: The Lysosomal Storage Disorders Unit at the Royal Free Hospital, London, has a unique cohort of patients with GD and AFD. By measuring serum prohepcidin levels, along with haematological indices and levels of circulating inflammatory cytokines, we sought to investigate the role of hepcidin/prohepcidin in GD and AFD. We looked specifically at whether it may have a role in the pathophysiology of the disordered iron profile and anaemia associated with GD.
Methods: Consecutive samples from patients with GD (n=33) or AFD (n=41) and normal control subjects (n=10) were obtained. All patients gave informed consent. Commercial ELISA kits were used to measure soluble transferrin receptor (Biovendor Medicine Inc) and IL-6 (BD Biosciences). A commercial ELISA for prohepcidin (DRG International Inc) was used.
Results: A total of 33 patients with GD were included, with 27 receiving enzyme replacement therapy (ERT). A total of N= 41 patients with AFD were included, of which 26 were receiving ERT. All groups had mean haemoglobin (Hb) within normal reference ranges. Mean soluble transferrin receptor (sTfR) levels were below lab reference ranges (1.8-4.6mg/L) for both ERT and non-ERT receiving patients in GD and AFD groups (GD on ERT mean 1.51mg/L, no ERT 1.47mg.L, AFD on ERT mean 1.04 mg/L, no ERT 0.93mg/L). GD patients had mean ferritin levels elevated above the upper limit of normal reference range (Non-ERT group mean=453 µg/L, ERT group mean 398 µg/L). For AFD patients, mean ferritin was within in the normal range for both ERT (88 µg/L) and non-ERT (54 µg/L) receiving groups. In all groups, there was a wide range of serum prohepcidin levels (figure 1). Mean prohepcidin was lower in both AFD and GD groups *vs* controls, but this did not reach statistical significance in any group. There was no correlation between prohepcidin and Hb, serum IL-6 or serum sTfR in any group.

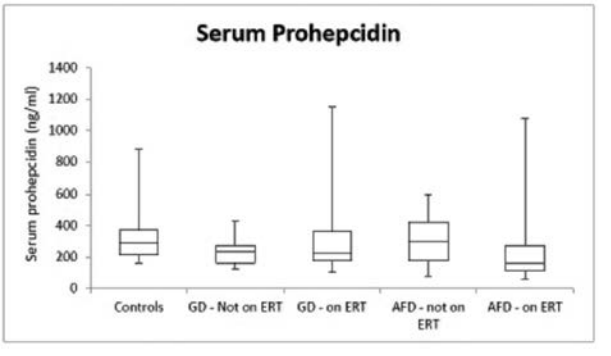

Figure 1.

Summary/Conclusions: Our study confirms previous results that GD is associated with a hyperferritinaemic state which is not found in AFD. As sTfR levels in GD and AFD patients were low, this appears to be secondary to inflammation rather than iron status. As in previous studies, we found IL-6 levels to be higher in GD patients then controls. Anaemia was not prevalent in any patient groups, although this may be masked by treatment and appropriate transfusion in a carefully monitored patient group. There was no significant difference between prohepcidin levels in AFD or GD patients and controls, and no correlation between Hb, IL-6, or iron status with prohepcidin in any group. The extent to which prohepcidin reflects hepcidin itself is controversial, but there is a growing body of evidence that prohepcidin levels are affected by inflammatory conditions, iron deficiency anaemia and changes in EPO levels, amongst other things. Further studies, with a higher number of patients, and using an ELISA targeted against hepcidin itself are required to further explore what role it may play in AFD/GD patients.

LB2267

L-ARGININE SUPPLEMENTATION DECREASES HEMOLYSIS AND PULMONARY ARTERIAL HYPERTENSION IN SICKLE CELL DISEASE PATIENTS: A RANDOMIZED, DOUBLE-BLINDED, PLACEBO-CONTROLLED TRIAL

JR Friedrisch[1,*], CM Bittar[2], CM Bittar[1], MCG Meirelles[1], LE Daudt[1], AA Paz[1], LM Fogliatto[1], BK Friedrisch[3], SSM Barreto[4], LMDR Silla[1]
[1]Service of Hematology and Bone Marrow Transplantation, Hospital de Clínicas de Porto Alegre, [2] Service of Hematology and Bone Marrow Transplantation, Hospital de Clínicas de Porto Alegre, HCPA, Porto Alegre, [3]UNISC, Santa Cruz Do Sul, [4]Division of Pulmonary Medicine, HCPA, Porto Alegre, Brazil

Background: Low nitric oxide (NO) bioavailability contributes to vasculopathy in sickle cell disease (SCD), and is associated with increased morbimortality. Since the obligate substrate for NO production is arginine and enhanced NO bioavailability markedly decreased hemolysis and oxidative stress in SCD, we

hypothesized that oral L-arginine (LA) supplementation could be beneficial for SCD outcomes and a reduction the in degree of hemolysis.
Aims: We assessed the impact of 6 months of LA supplementation on SCD clinical outcomes: leg ulcers, priapism, pulmonary arterial hypertension (PAH), and vaso-occlusive pain episodes, and the degree of hemolysis rate.
Methods: Sixty-eight patients with SCD were randomized for this double-blinded placebo-controlled trial. Patients received LA (0.1g/kg/day) or placebo for 6 months.
Results: The LA group presented more pronounced decrease in lactate dehydrogenase (DHL) (1065±495 U/L to 784±267 U/L vs. 952±383 U/L to 907±395 U/L; p=0.03) and a tendency of PAH reduction. Ten patients of the study group had PAH (6 in the LA group and 4 in the placebo group). The tricuspid regurgitant jet velocity (TRV) in the 6 patients receiving LA decreased from 2.83±0.36 m/s to 2.46±0.36 m/s, while the TRV in the 4 patients receiving placebo increased from 2.75±0.35 m/s to 2.80±0.18 m/s (p=0.13), representing a tendency of PAH reduction in the LA group. Non drug-related severe adverse events were perceived.
Summary/Conclusion: In conclusion, supplementation of LA was associated with a significant reduction in hemolytic activity with and a tendency towards reduced PAH. Weighing outlays and benefits, these preliminary results provide a strong rationale for therapeutic use of LA in SCD disease and other chronic hemolytic diseases, although an extended multi-center trial with larger number of SCD individuals is warranted to confirm these findings.

LB2268

HOW SHOULD WE SELECT THE MOST VULNERABLE THALASSEMIC PATIENTS FOR IRON OVERLOAD EVALUATION BY MRI IN A RESOURCE LIMITED COUNTRY?

S Ekwattanakit[1,*], P Saivirooporn[2], K Sanpakit[3], N Siritanaratkul[1], J Buaboonnam[3], A Khuhapinant[1], B Rerkudom [2], S Erberich[4], J Wood[5], R Krittayaphong[6], V Viprakasit[3]
[1]Division of Hematology, Department of Medicine, [2]Department of Radiology, [3]Division of Hematology/Oncology, Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, [4]Department of Radiology , [5]Division of Pediatric Cardiology, Department of Pediatrics, Childrens Hospital of Los Angeles, Keck School of Medicine, University of Southern California,, Los Angeles, CA, United States, [6]Division of Cardiology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Serum ferritin (SF) can be used for determination of iron overload (IO), however, it does not perfectly correlate with tissue iron status in transfusion-dependent thalassemia (TDT) and even worst in non-transfusion-dependent thalassemia (NTDT). The magnetic resonance imaging (MRI) for cardiac T2* and liver iron concentration (LIC) is now considered as a gold standard for IO evaluation in thalassemia worldwide. Nevertheless, this tool was not widely available and expensive in Thailand.
Aims: To evaluate the SF cut-off level for diagnosis of severe IO in real-life situation and determine the utility of SF in predicting IO in thalassemic patients and select the most vulnerable patients for further MRI evaluation.
Methods: In this retrospective cross-sectional study, total 1,034 standard MRI (LIC and cardiac T2*) evaluations performed at Siriraj hospital during 2009-2014 and paired clinical data including SF were collected. Regardless of globin genotypes, all 350 thalassemia patients were divided into NTDT (N=108, 162 LIC and 89 cardiac T2* results) and TDT (N=242, 696 LIC and 692 cardiac T2* results). Different SF cut-off values were tested at 100 or 250 ug/l intervals and receiver operating characteristic (ROC) analysis was performed.
Results: Using SF >800 ug/l to predict LIC ≥5 mgFe/g dw, 86.4% of NTDT would be correctly started on iron chelation. However, 42% of patients (42/100) with LIC ≥5 mgFe/g dw had SF between 301-800 ug/l and 62.7% (42/67) of those with SF 301-800 ug/l had LIC ≥5 mgFe/g dw. Using threshold of SF >300ug/l, we could detect IO in 92% (92/100) of those with LIC ≥5 mgFe/g dw. When α-NTDT patients were excluded, ROC analysis found that SF >400 ug/l correctly predict LIC ≥5 mgFe/g dw in 90% of β-NTDT with lower risk of delayed treatment than using SF threshold >800 ug/l (40.6% vs. 61.9%, according to NPV). Of 89 cardiac T2* results in NTDT (SF range of 24-11,668), none had T2* <20ms. For TDT, ROC analysis suggested SF >3,500 ug/l was the best predictive threshold for T2* <20ms (AUC=0.785), while SF >2,500 ug/l was an appropriate cut-off level for LIC ≥15mgFe/g dw (AUC=0.861).
Summary/Conclusion: In a resource limited setting for MRI, SF could be used as a predictive marker for selecting severe IO in both TDT and NTDT. In NTDT, MRI for cardiac T2* could be omitted and, once for diagnosis, MRI for LIC should be done in those with SF >300 ug/l. For TDT, the SF cut off of >2,500 and >3,500 ug/l are useful to predict patients with severe LIC and cardiac siderosis, respectively.

Stem cell transplantation - Clinical

ASSESSING NPM1 MUTATIONS TYPE A AS MINIMAL RESIDUAL DISEASE MARKER BY DIGITAL DROPLET PCR BEFORE STEM CELL TRANSPLANTATION IS A STRONG PROGNOSTIC FACTOR IN PATIENTS WITH AML

M Bill*, L Kloss, M Jentzsch, J Grimm, K Schubert, J Schulz, M Knyrim, M Cross, V Vucinic, G Behre, W Poenisch, GN Franke, D Niederwieser, S Schwind
Hematology and Oncology, University of Leipzig, Leipzig, Germany

Background: Acute myeloid leukemia (AML) patients (pts) who relapse after hematopoietic stem cell transplantation (HCT) have a dismal prognosis. Identifying AML pts with high risk of hematological relapse after HCT is crucial for treatment guidance. Mutations in the *NPM1* gene (*NPM1*mut) occur early in leukemogenesis & are relatively stable during disease course, representing suitable Minimal residual disease (MRD) markers. Recently, MRD assessment, based *e.g.* on the quantitative detection of *NPM1*mut, has been shown to be of clinical relevance. However, data in pts receiving HCT is limited.
Aims: We tested the feasibility of *NPM1*mut type A (*NPM1*mutA) - representing up to 80% of all *NPM1*mut-as pre-HCT MRD marker using digital droplet PCR (ddPCR) for sensitive & specific absolute quantification without the use of standard curves.
Methods: We identified 46 AML pts with available bone marrow (BM) pre-HCT (within 30 days before HCT) & *NPM1*mutA who were in complete remission with (CR; n=42; 91.3%) or without complete hematological recovery (CRi; n=4; 8.7%). Median age was 64.5 (range 33.1-74.1) years (y). Pts received HCT after myeloablative (Cyclophosphamide 2x60mg/kg+12Gy total body irradiation [TBI], n=11) or non-myeloablative (Fludarabine 3x30mg/m²+2Gy TBI, n=35) conditioning at our institution between 2000 & 2015. Median follow-up was 2.1y. *NPM1*mutA & *CEBPA* mutation status were assessed by Sanger sequencing & presence of an internal tandem duplication in *FLT3* by fragment analysis in diagnostic BM. *NPM1*mutA copy numbers were assessed by ddPCR in pre-HCT BM. Results were normalized to *ABL1* copy numbers. Samples were measured in triplicates & those with mutation burden ≤0.01% or<3 positive droplets were defined as negative according to the manufacturer's recommendations.
Results: At diagnosis 40 pts (87.0%) had a normal karyotype. According to European LeukemiaNet (ELN) classification 26 (56.5%) had favorable, 14 (30.4%) intermediate-I, 5 (10.9%) intermediate-II & 1 (2.2%) adverse genetic risk. 18 pts harbored a *FLT3*-ITD & 4 were *CEBPA* mut. We found 13 (28.3%) of the 46 pts to be MRD+ pre-HCT (*NPM1*mutA/*ABL1* range 0.014% - 612.88%). Except for a trend for lower peripheral blast count at diagnosis ($_{dx}$) in the MRD+ group (*P*=.07) no differences were detected between MRD+ & MRD- pts in other clinical or molecular characteristics (i.e. age_{dx}, sex, ELN group distribution, Hb_{dx}, $Platelets_{dx}$, white blood $count_{dx}$, BM $blasts_{dx}$, CR1 *vs* CR2 *vs* CRi, *CEBPA*mut, *FLT3*-ITD). The number of chemotherapy cycles pre-HCT was not different between the MRD+ & MRD- group. Eleven pts relapsed of which 9 (81.8%) were MRD+ pre-HCT. Four patients did not experience relapse but were MRD+, 2 of them died within 100 days after HCT due to treatment-related complications. With respect to the remission status, only 2 (50%) of the 4 pts transplanted in CRi suffered relapse & both were MRD+. MRD+ pre-HCT was associated with a significantly higher cumulative incidence of relapse (*P*<0.001, Figure 1A) & shorter overall survival (OS, *P*=0.004, Figure 1B).

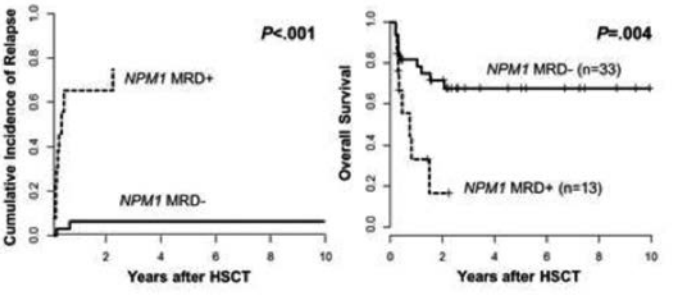

Figure 1.

Summary/Conclusions: Our study demonstrated that the novel ddPCR is a feasible method to determine *NPM1*mutA MRD burden by absolute quantification. Pre-HCT MRD+ identified pts with a significantly higher relapse rate & subsequently shorter OS independently of the clinical, cytogenetical & molecular context. MRD monitoring by *NPM1*mut detection before HCT should be incorporated in clinical trials to validate these data & guide therapeutic decisions for AML pts.

E1498

HLA-DRB1*04 CONFERS BETTER OVERALL SURVIVAL TO MALE PATIENTS WITH LYMPHOID MALIGNANCIES FOLLOWING ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

K Balassa[1,*], H Andrikovics[1], P Remenyi[2], A Batai[2], A Bors[1], KP Kiss[1], A Szilvasi[3], K Rajczy[4], D Inotai[3], E Torbagyi[2], L Lengyel[2], A Barta[2], L Gopcsa[2], A Tordai[5], T Masszi[6]

[1]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, [2]Department of Haematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, [3]Transplantation Immunogenetics Laboratory, [4]Hungarian Stem Cell Donor Registry, Hungarian National Blood Transfusion Service, [5]Department of Pathophysiology, [6]3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary

Background: Several studies reported associations of individual human leukocyte antigen (HLA) genes and outcome of allogeneic haematopoietic stem cell transplantation (allo-HSCT). Similarly, HLA genes were found to predispose to certain lymphoid malignancies. HLA-DRB1*04 is among the documented genetic risk factors for lymphoid malignancies, and in some studies the risk was identified to be male-restricted.
Aims: In this study we looked into the effect of HLA-A, -B and -DRB1 allele groups on overall survival (OS) following allo-HSCT in patients with lymphoid malignancies.
Methods: Data of 186 consecutive adult patients, who underwent first allo-HSCT for a lymphoid malignancy at our single centre in Hungary between 2007 and 2013, were retrospectively analysed. The median follow-up time for surviving patients was 44 months. In the cohort five patients (3%) received a graft, mismatched for HLA-A, and none for HLA-B or HLA-DRB1 at the antigen level. There were slightly more patients undergoing transplantation from a sibling donor (106/186, 57%).
Results: Examining the role of HLA status on survival, analyses showed that carriers and non-carriers displayed no survival difference for any of the HLA-A or -B allele groups. However, OS of HLA-DRB1*04 carriers was significantly better compared with non-carriers (24-month OS 66±8% [n= 36] *vs* 50±4% [n=150], p=0.01). As baseline transplantation characteristics were uneven in the two groups, we conducted multivariate analyses, which showed that the association remained independent (p=0.05, odds ratio [OR] 0.55, 95% confidence interval [CI]: 0.3-1). In view of previous reports of sex-specific features of HLA-DRB1*04, we performed separate analyses for male (n=114) and female (n=72) patients. Interestingly, the survival benefit was confined to males (p=0.01), whereas in female individuals no difference was detected (p=0.41). The baseline transplantation characteristics were comparable in female and male patients. Furthermore, we found that the donor gender also affected the outcome. The survival of male patients varied significantly according to recipient/donor gender pairs and HLA-DRB1*04 carriership (p=0.04). Surprisingly, in male recipients the best survival was achieved in HLA-DRB1*04 carriers who received a graft from a female donor, followed by those HLA-DRB1*04 carriers for whom the donor was male. HLA-DRB1*04 negative patients displayed worse survival compared with carriers, and among them the survival was worse for those whose donor was female. No clear explanation was found to explain the survival benefit, although there was a tendency for less CMV reactivation/disease among HLA-DRB1*04 carriers (3/36, 8% *vs* 31/150, 21%, p=0.097).
Summary/Conclusions: In summary, we observed in a cohort of 186 patients with lymphoid malignancies that HLA-DRB1*04 male carriers had significantly better overall survival following allo-HSCT compared to non-carriers. Our findings support that HLA-DRB1*04 carriership might result in male-specific consequences in the lymphoid malignancy patient group. Our results suggest that the prognosis of patients with sex-specific disease risks might be modified by transplantation from the opposite sex. Our findings should be confirmed in larger patient populations, and similar data could affect donor selection preferences for HLA-DRB1*04 carrier patients in the future.

IMPACT OF T CELL DOSE ON OUTCOMES OF NON-MYELOABLATIVE ALLOGENEIC TRANSPLANTS IN MULTIPLE MYELOMA

A Nair[1,*], T Das[1], T Walker[1], A Kalff[1,2], K Bergin[1,2], J Hocking[1,2], S Avery[1], D Curtis[1,2], S Patil [1], D Klarica[1], J Muirhead[1], J Reynolds[2], A Spencer[1,2]

[1]Haematology, Alfred Health, Melbourne, [2]Monash University, Melbourne, Australia

Background: Donor T cells are responsible for graft *versus* host disease (GVHD) following allogeneic stem cell transplantation (alloSCT). Studies have shown a reduced incidence of GVHD but increased relapse risk with T cell depleted transplants. T cell replete stem cells are generally used for non-myeloablative (NMA) alloSCT to prevent graft failure and to avail the benefit of a potential graft *versus* tumor effect which is considered the major tool for disease control in this type of transplant. T cell doses in individual T cell replete transplants vary and to the best of our knowledge no previous studies have looked at the impact of T cell dose on the outcome of NMA alloSCT. We routinely perform tandem autologous (ASCT)-NMA alloSCT for high risk as well as relapsed multiple myeloma (MM) patients at our centre. High risk MM patients are defined by the presence of at least 2 out of 5 risk features including International Staging System score 3, adverse cytogenetics [t(4;14),17p- on FISH and/or complex karyotype], elevated lactate dehydrogenase, plasma cell leukemia (all at diagnosis) and induction failure (<PR) with bortezomib or IMID-based induction therapy. These patients receive 'upfront' tandem ASCT-NMA SCT and the patients relapsing following conventional treatment receive 'deferred' tandem ASCT-NMA SCT. All patients receive high dose Melphalan conditioned ASCT and within 2-3 months, receive an outpatient-based Fludarabine (48mg/m2 X 3days) and TBI (2Gy X1day) conditioned NMA SCT from matched sibling or unrelated donors. We use Cyclosporine and Mycophenolate mofetil as GVHD prophylaxis.
Aims: To find out whether the outcomes after NMA SCT for MM were influenced by the T cell dose received.
Methods: After obtaining informed consent, we undertook a retrospective analysis of patients who underwent tandem ASCT-NMA SCT from May 2008 to June 2015 for MM. Primary end points were progression free survival (PFS) and overall survival (OS). Secondary end points were cumulative incidences of acute GVHD, chronic GVHD and relapse, treatment related mortality and achievement of donor chimerism.
Results: Out of 59, 19 patients had received T cell dose of ≥3x10^8/kg. This high dose cohort (Hi-T) was compared to 40 patients who got <3x10^8/kg T cells (Lo-T). Median age was 59yrs (range 22-66yrs) for Hi-T and 54yrs (range 38-67yrs) for Lo-T (p=0.43). 52.5% of patients received upfront transplants in Hi-T against 42% in Lo-T (p=0.23). 68% of patients had unrelated donors in Hi-T *versus* 57.5% in Lo-T (p=0.22). After a median follow up of 45.7 months, PFS and OS were significantly inferior in Hi-T group (median PFS 366 days *vs* 1067 days, p=0.05, median OS 752 days *vs* not reached, p=0.002). Cumulative incidences of grade 2-4 acute GVHD and extensive chronic GVHD were higher in Hi-T (47% *vs* 17.5%; p=0.03 and 80% *vs* 50%; p=0.04 respectively). There were 5 treatment related deaths (26.3%) in Hi-T (all due to GVHD) against 2 (5%) in Lo-T (both due to infections); (p=0.009). Cumulative incidence of relapse was not different between the arms (48% *vs* 49% respectively at 4yrs.). Achievement of donor CD3 chimerism at different time points (days 30, 60, 90 and 180) was not different between the arms. All patients who were alive at 1yr achieved full donor chimerism. On multivariate analysis, Hi-T was independently associated with inferior OS.

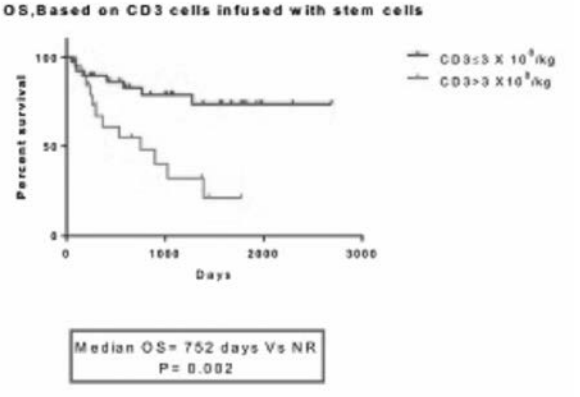

Figure 1.

Summary/Conclusions: To conclude, in NMA alloSCT for MM, the T cell dose infused has a significant influence on outcomes. Limiting the T cell dose to <3x108/kg can improve the OS and reduce TRM and GVHD. Larger randomised trials are required to confirm this observation.

E1500

LOW DOSE TOTAL MARROW/TOTAL LYMPHOID IRRADIATION (TMI/TLI) INSTEAD OF TOTAL BODY IRRADIATION (TBI) INDUCE FULL DONOR CHIMERISM BEFORE T-REPLETE HAPLOIDENTICAL TRANSPLANTATION

B Sarina[1,*], A Rimondo[1], P Mancosu[2], L Morabito[1], S Bramanti[1], R Crocchiolo[1], P Navarria[3], J Mariotti[1], L Castagna[1]

[1]Hematology Unit, Humanitas Cancer Center, [2]Physics Service of Radiation Oncology Department, [3]Radiotherapy and Radiosurgery Department, Istituto Clinico Humanitas, Rozzano, Italy

Background: T cell replete haploidentical stem cell transplantation (haploSCT) with post-transplantation cyclophosphamide (Cy) (PT-Cy) has been increasingly applied in high-risk hematologic patients. In the original, nonmyeloablative conditioning regimen (NMAC) included low dose total body irradiation (TBI).
Aims: The aims of the study were to evaluate the engraftment, chimerism, and tolerance of NMAC regimen with low dose total marrow and lymphoid irradiation (TMI/TLI) instead of TBI, in patients with advanced disease.

Methods: Between April 2009 and August 2015, 98 patients received a haploSCT at our institution. NMAC was used in 60 patients. For 20 patients (33%), TMI/TLI (2 Gy) was used instead of TBI. 12 of 20 (60%) had bone and/or bone marrow involvement. The median age was 49 years (range 20-68). NMAC consisted of fludarabine (30mg/m^2/day) on day -6 to -2, Cy (14.5mg/kg/day) on days -6 and -5, TMI/TLI (200 cGy in a single fraction) on day -1, followed by bone marrow or peripheral blood stem cell graft. Graft *versus* host disease/host *versus* graft prophylaxis consisted of Cy (50mg/kg/day) on days +3 and +4, and from day +5 mycophenolate mofetil until day +35 days, and tacrolimus or cyclosporine A.
Results: Patient characteristics are shown in Table 1. The median follow-up time was 15 months (range 6-48). Immediate tolerance was good and no patients developed nausea or vomiting nor parotid hyperplasia. The median time to ANC >500/μL, and platelet recovery >20,000/μL was 22 days (range 16-28) and 27 days (range 12-41), respectively. At day +30, full donor chimerism was obtained in all evaluable patients (19/20). The cumulative incidence of acute grade ≥2 was 20% (95% CI: 6.0-39.9). No severe/moderate cGVHD was observed. The 1-yr cumulative incidence of relapse, overall survival and non-relapse mortality were 23% (95% CI: 6.1-45.8), 60% (95% CI: 38.4-81.6) and 30% (95% CI: 11.8-50.8), respectively. Causes of death were: disease progression (n=2), septic shock (n=2), fungal pneumonia (n=2), renal failure (n=1) and JCV encephalopathy (n=1). Engraftment, chimerism, aGVHD incidence were not different to patients receiving conventional TBI.

Table 1. Patient characteristics.

	n=20
Median age (range), yr	49 (20-68)
Gender	
Male	14 (70%)
Female	6 (30%)
Diagnosis	
Hodgkin lymphoma	10 (50%)
Non-Hodgkin lymphoma	6 (30%)
Chronic Lymphoid Leukemia	3 (15%)
Multiple Myeloma	1 (5%)
Disease status at haploSCT	
Complete remission	9 (45%)
Partial remission	6 (30%)
Stable/progressive disease	5 (25%)
Graft source	
Bone marrow	11 (55%)
Peripheral blood stem cell	9 (45%)
Median CD34+ infused cell dose (range)	4.8 x10^6/kg (2.1-8.0)

Summary/Conclusions: This retrospective analysis suggests that TMI/TLI could substitute conventional low dose TBI, with a sufficient degree of immunosuppression of recipient, allowing engraftment and full donor chimerism. Moreover, the 100 days TRM, the relapse incidence, aGVHD and cGVHD were comparable to that observed in the TBI group.

E1501

POSITIVITY OF WHOLE BODY POSITRON EMISSION TOMOGRAPHY (PET) BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION HAS NEGATIVE PROGNOSTIC IMPACT BUT IT DIFFERS ACCORDING TO LYMPHOMA SUBTYPE AND LINE OF ASCT

D Pohlreich[1,*], B Vackova[1], M Trnkova[1], R Pytlik[1], M Trneny[2]
[1]BMT unit, [2]Dept of hematooncology, General Teaching Hospital Charles University, Prague, Czech Republic

Background: Pre-transplant PET is considered as an important prognostic variable. Positive PET is usually linked with worse prognosis. There is however limited information if there are any differences in PET impact according to line in which is ASCT performed as well as different lymphoma subtypes.
Aims: To analyze the impact of the pre-transplant PET on post-transplant outcome of patients with lymphoma according to lymphoma subtypes and the line of treatment.
Methods: Retrospective analyzes of patients who underwent ASCT between 2010 and 2014. Only pts. with pre-transplant PET were eligible for the analysis. PET had to be performed after the last cycle of chemotherapy before ASCT in interval less than 60 days. Patients who were PET negative and received one more cycle of chemotherapy due to logistic reasons were eligible. Visual PET evaluation was used in comparison to mediastinum and liver accumullation. All pts. signed the informed consent and agreed with data analysis.
Results: There were 350 pts. transplanted for lymphoma between 2005 and 2014. Pre-transplant PET was performed in 253 pts. Patients who were PET positive (PET+), but received additional chemotherapy before ASCT without PET reevaluation (n=20) were excluded from the study. In two patients PET findings were inconclusive and were excluded as well. Altogether 231 patients were evaluated, age at ASCT 53y (21-71), male/female 134/97, DLBCL 108/43% (68 in 1. line, 40 at relapse) FL 33/14% (2 in 1. line, 31 at relapse), MCL 43/19% (41 in 1. line, 2 at relapse), HL 21/9% (1 primary progressive in 1. line, 20 at relapse) and others 26/11% (13 in 1. line, 13 at relapse). Altogether 79 (34.2%) patients were PET positive (PET+) and 152 were PET negative (PET-). PET+ pts. had significantly higher death or relaps risk (HR 1.75, p 0.04). There was however only borderline impact of PET in 1st line ASCT (p 0.06) and significant in at relapse ASCT (p 0.002). It was mainly due to DLBCL, where was found significant risk for PET+ in the whole group (HR 2.35, p 0.02). No difference was observed in the 1st line ASCT (p ns) with PET negative predictive value (NPV)=0.91 and PET positive predictive value (PPV)=0.13. Patients with DLBCL and ASCT at relapse had significantly worse outcome (HR 2.42, p 0.037) with NPV 0.63 and PPV 0.47. The majority of MCL pts (41) underwent 1st line ASCT. There was significanty worse outcome for PET+(HR 157.3, p<0,0001) with NPV 0.88 and PPV 0.43. There was limited number of FL (31) and HL (20) patients resp. transplanted for relapse and there was found only trend for worse outcome of PET+ pts for HL (HR 3.7, p 0.11, NPV 0.76, PPV 0.42) and no difference in FL subgroup (HR 0.64, p 0.49, NPV 0.75, PPV 0.14).
Summary/Conclusions: We have confirmed prognostic value of pretransplant PET. We have however found that there are differences in lymphoma subtypes (1st line ASCT for DLBCL *vs* MCL), and differences according to the line of ASCT (1st line ASCT *vs* at relapse ASCT DLBCL) with differences in NPV (high in 1s line ASCT DLBCL and MCL *vs* low at relapse ASCT for all subtypes) and PPV (low in 1st line ASCT for DLBCL). Lymphoma subtype as well as line of treatment should be considered in the PET finding interpretation before possible treatment change based on pretransplant PET.

E1502

WHAT IS THE OUTCOME OF PATIENTS WITH ACUTE LEUKEMIA WHO SURVIVE SEVERE ACUTE GRAFT-VERSUS-HOST DISEASE?

O Ringdén[1], M Labopin[2], A Maihol[2], D Beelen[3], Y Fløisand[4], A Ghavamzadeh[5], J Finke[6], G Ehninger[7], L Volin[8], A Ganser[9], S Giebel[10], A Nagler[11,*]
[1]BMT Unit, Stockolm, Sweden, [2]Hôpital Saint Antoine, Paris, France, [3]BMT Unit, Essen, Germany, [4]BMT Unit, Oslo, Norway, [5]BMT Unit, Teheran, Iran, [6]BMT Unit, Freiburg, [7]BMT Unit, Dresden, Germany, [8]BMT Unit, Helsinki, Finland, [9]BMT Unit, Hannover, Germany, [10]BMT Unit, Gliwice, Poland, [11]BMT Unit, Tel Hashomer, Israel

Background: Acute graft-*versus*-host disease (GVHD) is a major complication of allogeneic hematopoietic stem cell transplantation (HSCT). With new promising therapies, survival may improve in patients with severe acute GVHD.
Aims: We wanted to analyze the long-term outcome among patients who survive severe acute GVHD.
Methods: This is a landmark analysis of 23,567 patients with acute leukemia who survived >6 months after HSCT during 2002-2014. Patients with severe acute GVHD (n=1,738) were compared to controls.
Results: Patients with severe acute GVHD had a higher non-relapse mortality (NRM) and chronic GVHD compared to controls ($p<10^{-5}$). Extensive chronic GVHD was 26.9% before 6 months and 27.2% after 6 months in the severe acute GVHD group ($p<10^{-5}$). The probability of relapse was significantly lower in the severe acute GVHD group, and leukemia-free survival (LFS) and survival was significantly lower than for the controls ($p<10^{-5}$). Five-year LFS in patients who survived severe acute GVHD was 49% as opposed to 61% in controls with no or mild, and 59% in patients with moderate GVHD.
Summary/Conclusions: HSCT patients who survive severe acute GVHD have a high risk of extensive chronic GVHD, a higher NRM, a lower relapse probability and lower LFS, compared to other HSCT patients.

E1503

SCLERO-CORNEAL LENSES SAFE AND EFFICIENT FOR THE TREATMENT OF KERATOCONJUNCTIVITIS SICCA IN PATIENTS WITH REFRACTORY OCULAR GVHD: A STUDY ON BEHALF OF THE SFGM-TC

L Magro[1,*], A delcampe[2], M robin[3], S n'gyen[4], A huynh[5], MT rubio[6], F suarez[7], S vigouroux[8], I yakoub-agha[9]
[1]CHRU Lille (France), Hôpital Claude Huriez, Lille Cedex, [2]hôpital Charles Nicolle, CHU Rouen, Rouen, [3]hôpital saint louis, assistance puplique hîpitaux de paris, [4]hôpital la pitié salpétrière, assistance puplique hôpitaux de paris, paris, [5]hematologie, oncopole, toulouse, [6]hôpital saint antoine, [7]hôpital Necker, assistance puplique hôpitaux de paris, paris, [8]hematologie, CHU Bordeaux, bordeaux, [9]hôpital claude Huriez, CHRU Lille, Lille Cedex, France

Background: Keratoconjunctivitis sicca syndrome (KCS) due to chronic GvHD (cGvHD) is responsible for major alteration in quality of life of patients undergoing allogeneic stem cell transplantation (allo-CST). The conjunctival fibrosis secondary to inflammation is often slow and subtle and is responsible for impaired corneal and conjunctival epithelial surfaces potentiated by tear quantitative and qualitative deficiency. Treatment of KCS remains disappointing; variable success in the correction of the conjunctival dryness has been obtained with variety of topical treatments with or without systemic immunosuppressive agents. These treatments, though, do not seem to have any effect on sicca symptoms and patients' quality of life. Sclero-corneal lenses bring a valid therapeutic option by creating a pre-corneal reservoir of tears allowing permanent lubrication of the epithelium, the protection of the corneal surface against the eyelid and ciliary mechanical friction and against environmental stresses and the creation of a uniform refractive surface to be taken into optimum optical load and stable visual acuity.

Aims: Scleral lenses bring a valid therapeutic option by creating a pre-corneal reservoir of tears allowing permanent lubrication of the epithelium, the protection of the corneal surface against the eyelid and ciliary mechanical friction and against environmental stresses and the creation of a uniform refractive surface to be taken into optimum optical load and stable visual acuity. In this multicenter retrospective study we wanted to assess the incidence of scleral lenses on sixty one patients concerning by refractory ocular GVHD.
Methods: We describe the safety and efficacy of Sclero-corneal lenses in a retrospective analysis of 62 patients with KCS due to cGvHD following allo-CST. All patients had superficial punctate keratitis refractory to standard treatments. Evaluation of patients was carried out by two ophthalmologists. cGVHD was recorded according standard criteria. Ocular surface disease index (OSDI) and Oxford score were used to evaluate ocular symptoms. The scale of "Monoyer" was used and converted into visual acuity "LOG MAR" for comparative purposes of the study.
Results: All patients but two agreed to hold the lenses. The 62 patients were equipped with sclero-corneal lenses. With a median follow-up of 22 months (IQR 8-43) from the treatment with lenses, all patients have experienced an improvement in their quality of life with a clear improvement of dry-eye symptoms. This quality of life is also improved by decreasing the frequency of eye-drop instillation and the attenuation of the discomfort and post-instillation visual fluctuation. At two months, all patients but one experienced improvement in OSDI score with a median of 92 points (range, 40-100) before lenses to a median of 25 points (range, 3-90). We also observed improvement or stability of visual acuity with median gain of -0.2 (range, -1 to +0.1) LOG MAR acuity and improvement or stability of the Oxford score score with a median of 3 points (range, 0-5) before lenses to a median of 1 points (range, 0-4) after lenses. with a median gain of 2 points in almost all patients.
Summary/Conclusions: Treatment of KCS with sclero-corneal lenses is promising. Whenever possible, this approach should be considered in patients experiencing KCS due to cGVHD.

E1504

UNMANIPULATED HAPLOIDENTICAL STEM CELL TRANSPLANTATION FOLLOWING BUSULFAN BASED REDUCED INTENSITY CONDITIONING AND POST-TRANSPLANTATION CYCLOPHOSPHAMIDE FOR ADVANCED HODGKIN´S LYMPHOMA

MJ Pascual, M Ortiz, J Díez*, S Lorente, I Sánchez, I Vidales, A Contento, MA Cuesta, L Baeza, G Navarro, M Espeso, AI Heiniger
Department of Hematology, Regional Hospital, Málaga, Spain

Background: Hodgkin´s Lymphoma (HL) is a potentially "curable malignant disease" with chemotherapy, radiotherapy or, eventually, high-dose chemotherapy followed by autologous stem cell transplantation (SCT). For patients relapsing after auto-SCT or those with advance refractory lymphoma, allogeneic SCT is a valid option. In this setting, our institution has opted for haploidentical donors as source of stem cells for allo-SCT in advanced HL patients.
Aims: Patients with advanced HL who received haploidentical SCT (haplo-SCT) were retrospectively analyzed in terms of overall survival (OS), progression-free survival (PFS) and graft *versus* host disease (GVHD).
Methods: From May 2012 to September 2015 eighteen haplo-SCT were performed at our hospital on patients with HL who had relapsed after auto-SCT or had needed more than three lines of chemotherapy to reach any kind of response. The conditioning regimen consisted of cyclophosphamide (Cy) 14.5 mg/Kg on days -6 and -5, fludarabine 30 mg/m2 on days -6 to -2 and busulfan (Bu) on days -3 and -2. GVHD prophylaxis consisted of Cy 50 mg/Kg on days +3 and +4, followed by tacrolimus plus mycophenolate mofetil from day +5.
Results: The median age of the cohort was 31 years (19-58). The HCT-CI >2, EBMT score >3 and high DR index were 28%, 67% and 11%, respectively. Thirty-nine percent of all patients were not in complete remission and eleven percent were in progression at the time of transplantation. The median number of treatment lines before SCT was five (4-11) and brentuximab-vedotin was employed as bridge to the allo-SCT in 44% of cases. Thirty-nine of the patients had received a previous autograft and one patient both, auto-SCT and allo-SCT. Median time to haplo-SCT from diagnosis was 42 months. The stem cell sources were bone marrow (22%) and peripheral blood (78%). All the patients engrafted and full donor chimerism was reached in 100% of the entire cohort at day +30. The median times to neutrophil (>0.5 x 10e9/L) and platelet recovery (>20 x10e 9/L) were 18 (13-30) and 26 (10-44) days from SCT. Extramedullary toxicity grade 3-4 occurred in 2 cases. One of them developed severe hepatic veno-occlusive disease which was resolved with defibrotide. Seventeen patients were evaluable for acute and chronic GVHD. The 100-day cumulative incidence (CI) of grade II-IV acute GVHD was 35% (7% grade III-IV) with a median time of 33 days (23-80). The cumulative 3-year incidence of moderate chronic GVHD was 13%. With a median follow-up of 14 months (range 2-44), the CI of non-relapse mortality (NRM) and of relapse were 5% (1/18) and 42% (6/18), respectively. The actuarial OS and PFS at 45 months was 77% and 57%, respectively. Fifteen patients are alive, 12 disease free. The causes of death were relapse (n=2) and BK virus encephalitis (n=1). Relapses are being treated with brentuximab-vedotin followed by donor lymphocyte infusions (DLI), with no cases of GVHD.
Summary/Conclusions: Haplo-SCT with Bu based RIC and high-dose post-transplantation Cy offers high rates of remission in advanced HL, with low incidence of GVHD and NRM. In our experience, retreatment with brentuximab-vedotin combined with DLI is well tolerated and a good option to manage relapses after haplo-SCT.

E1505

UNRELATED TRANSPLANT FOR SEVERE APLASTIC ANEMIA (SAA): LONG TERM RESULTS AND RISK FACTOR ANALYSIS FOR OVERALL SURVIVAL

V Funke*, C Bernardi, M Oliveira, M Bitencourt, C Bonfim, S Nabhan, C Bonamin, D Setubal, L Ribeiro, G Loth, S Michelle, R Pasquini
Hematology, Federal University of Parana, Curitiba, Brazil

Background: For patients with SAA, Transplantation from an unrelated donor (UD) is usually considered after failure of at least one course of immunessupression. This strategy is based on a relatively high risk of complications for UD transplant recipients, such as graft rejection, graft-*versus*-host disease (GvHD) and infections. However, the outcome of unrelated donor transplants has significantly improved in recent years, due to better donor selection, conditioning regimen otimization and better supportive care.
Aims: The authors aim to describe results from 51 patients with SAA who have received unrelated allogeneic transplants in a single reference institution from 1997 to 2014 and identify risk factors for survival.
Methods: Data of 51 patients were retrieved from the center databasis. Fisher exact test was used for categoric variables and Kaplan Meier for survival estimates. P level of significance was<0,05. Primary endpoint was overall survival. Secondary endpoints were engraftment, acute and chronic gvhd and identification of risk factors for survival.
Results: There were 30 females and 21 males. Median age was 15 years old (0-47). Median total number of cells infused was 3,4 x 108/kg.61% of the patients have received more than 50 transfusions previously. Conditioning regimen were: CY 120+TBI 1320 +/- ATG in 16 (31%) patients, Bu 12 mg/kg+ Cy 120+ ATG in 18 (35%), and Fludarabine+Cy+ATG in 8 (16%), Fludarabine, Cy+TBI 200 in 9 (18%) patients. Stem cell source was marrow in 84%, cord blood in 13% and peripheral blood in 3% of patients. Transplants were full matched in 32 (62%) patients, had one mismatch (out of 12) in 12 (24%) and 2 mismatches in 7 (14%) patients. Engraftment was complete as evaluated by donor chimerism at day 30 and 100 post transplant in 36 patients (71%), partial in 4 (8%) and graft failure was observed in 9 (18%) patients. Acute GVHD grade II-IV was seen in 9 patients (18%) and NIH moderate to severe chronic GVHD was seen in 8 (16%) patients. Median overall survival was 328 days (4-4287) and estimated 5 years overall survival was 55%. Risk factors for survival identified were: HLA mismatch and stem cell sources other than marrow.
Summary/Conclusions: Unrelated transplants are a feasible salvage therapy for patients with SAA refractory to immunessupression, being HLA compatibility and marrow stem cell source factors with a positive impact on survival.

E1506

DIFFERENT CLUSTERS OF IMMUNOLOGIC VARIABLES ARE ASSOCIATED WITH CHRONIC GVHD AND RELAPSE IN A DYNAMICAL MODEL

C Skert[1,*], S Perucca[1,2], L Imberti[2], M Chiarini[2], V Giustini[2], C Ghidini[2], M Malagola[1], F Cattina[1], V Cancelli[1], B Rambaldi[1], S Bernardi[1,2], N Polverelli[1], D Russo[1]
[1]Usd Tmo Adulti, [2]CREA Diagnostics Department, Brescia, Italy

Background: The long-term efficacy of allogeneic haematopoietic stem cell transplantation (SCT) relies primarily on the Graft-*versus*-tumor (GVT) effect, which partially overlaps with Graft *versus* Host disease (GvHD), the most common cause of morbidity and mortality in HSCT. Immune parameters that univocally associate with GVHD or GVT have not been identified yet.
Aims: In this study, lymphocyte subsets together with TCR-repertoire analysis, and index of thymic and bone marrow output were evaluated at different time points, in order to identify possible predictors of chronic GVHD and ineffective GVT.
Methods: Prospective evaluations of lymphocyte subsets, thymic and bone marrow output were performed in 40 patients before SCT, at 30, 90, 180 days and 1 year after SCT. CD4+/CD8+ naïve, central memory, effector memory, terminally differentiated effector memory (TEMRA) cells, subsets of regulatory T-lymphocytes, immature B cells, naïve, switched and unswitched memory B cells, memory double negative (IgD-CD27-) B cells were analysed by flow cytometry. Analysis of thymic and bone marrow output was performed by detection of T cell receptor excision circles (TRECs) and kappa-deleting recombination circles (KRECs). TRECs and KRECs were simultaneously quantified by a duplex quantitative Real-Time PCR. Heteroduplex assay was used to perform TCR-repertoire analysis. A 2-step multivariate analysis was performed using principal component analysis (PCA) and Cox regression analysis, to solve the problem of the high number of variables (immunological, patients- and trans-

plant related) in comparison with the relatively limited and heterogeneous pool of patients.
Results: Chronic GVHD was observed in 9 patients (median time: 7 months, range 4-10). In 2-step multivariate analysis, lower values of regulatory effector memory lymphocytes at day +30 and lower percentage of CD8+TEMRA cells at +90, together with lower values of immature B cells and KRECs at +180 were inversely correlated with chronic GVHD (HR 0,4; p=0,002). The relapse rate (30%; median time: 9 months, range 3-48) was used as clinical index of ineffective GVT. The following clusters (C) of immunological parameters were associated with relapse: C1(pre-transplant lower values of CD4+central memory, all regulatory, and regulatory central memory cells; HR 4,0 p=0,02); C2(pre-transplant higher percentage of mature B cells, lower values of switched memory B cells and KRECs at day+90; HR 0,1 p=0,008).
Summary/Conclusions: Different clusters of immunological parameters at different time points were evidenced as predictors of cGVHD and ineffective GVT, allowing a clear-cut distinction between these immunological reactions. Changes in pre- and post-transplant B-lymphopoietic microenvironment and imbalances in the subsets of B-cells may influence GVHD and GVT. The atypical association of regulatory T-cells with GVHD may be explained by the relative efficiency of different subsets of regulatory T-cells (naïve>memory), as shown in some experimental models. The correlation of CD8+TEMRA at +90 with chronic GVHD may early indicate a persistently activated and dysregulated immune system. The validation of these clusters of immunological parameters as specific early predictors of GVHD or GVT, even before SCT, could potentially allow the development of pre-emptive and targeted therapies.

E1507

THE JAK2 46/1 HAPLOTYPE IS ASSOCIATED WITH ACUTE GRAFT-VERSUS-HOST DISEASE IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

N Meggyesi[1,*], K Balassa[1], T Krahling[1], P Remenyi[2], A Batai[2], A Bors[1], KP Kiss[1], E Torbagyi[2], L Gopcsa[2], L Lengyel[2], A Barta[2], G Varga[3], A Tordai[4], H Andrikovics[1], T Masszi[2]
[1]Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, [2]Department of Haematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, [3]3rd Department of Internal Medicine, [4]Department of Pathophysiology, Semmelweis University, Budapest, Hungary

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) has proven to be the most effective treatment option for certain hematological malignancies, however the favorable outcome of the procedure could be jeopardized by graft-*versus*-host disease (GvHD). Cytokines play a well established role in the mechanism of acute GvHD (aGvHD) and many of the involved cytokines relay their signal through the Janus kinase/signal transducer and activator of transcription (JAK/STAT) pathway.
Aims: In the present work, we investigated whether recipient and donor JAK2 46/1 haplotype could affect allo-HSCT outcomes, such as aGvHD, relapse rate and mortality in AML patients.
Methods: We examined the association of recipient and donor JAK2 46/1 haplotypes and allo-HSCT outcome in a cohort of 124 adult patients diagnosed with AML, who received first allo-HSCT in complete remission (CR) between January 2007 and December 2013 at our single center. For identification of JAK2 rs12343867 from genomic DNA LightCycler melting curve analysis (LightCycler 480II, Roche Diagnostics) was performed.
Results: Presence of JAK2 46/1 haplotype was associated with higher frequency of aGvHD grades II-IV (carrier *vs* non-carrier recipients 42% vs.19% p=0.008 and carrier *vs* non-carrier donors 40% *vs* 21%, p=0.038). We confirmed significantly higher risk if both, recipient and donor were 46/1 haplotype carriers compared to those where recipient and donor were non-carriers (OR=5.242, 95% CI=1.784-15.404, p=0.003). Relapse free survival (RFS) did not differ between 46/1 haplotype carrier and non-carrier recipients (2-year RFS 69.1±6.1% *vs* 54.2±6.9%, respectively, p=0.25), but we found significant alterations in the cause of death between the subgroups. In the 46/1 haplotype group the major causes of death were transplantation related complications, including aGvHD (18/21, 86%), while 3 deaths (14%) were attributed to relapse. In the non-46/1 haplotype subgroup 48% died of relapsing leukemia, while non-relapse mortality accounted for 52% (p=0.024). If donors were 46/1 carriers, patients more often died of transplantation related complications (81% *vs* 50%, p=0.049). The relapse rate was comparable in patients transplanted from a carrier or a non-carrier donor. Survival analysis according to the donor haplotype showed a favorable RFS in the non-46/1 haplotype group (2-year RFS 71±6 *vs* 53±7%, p=0.033). The difference in 2-year RFS rates remained significant in the four recipient-donor groups [64±8% (non-carrier recipient, non-carrier donor), 82±8% (carrier recipient, non-carrier donor), 36±11% (non-carrier recipient, carrier donor) and 61±8% (carrier recipient, carrier donor); p=0.038).
Summary/Conclusions: Although the exact pathomechanism is yet to be explored, our findings suggest that recipient and donor JAK2 46/1 haplotypes might be involved in the regulation of aGvHD.

E1508

IN THE ERA OF TKIS, WHICH PH+ ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS ARE SUITABLE FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION?

X Liu[*], E Jiang, Y Huang, D Yang, Y He, J Wei, L Qiu, S Feng, M Han
Institute of Hematology & Blood Disease Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China

Background: Outcome of Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL) improved significantly with the introduction of tyrosine kinase inhibitors(TKIs).The role of autologous stem cell transplantation(auto-SCT) in this setting has gradually received increasing attention.
Aims: The aim of our study was to determine which Ph+ ALL patients are suitable for auto-SCT in the era of TKIs.
Methods: Fifty-nine Ph+ ALL patients received SCT and TKIs therapy were enrolled in this study,the auto-SCT group has 23 patients and the matched sibing donor(MSD-SCT) group has 36 patients.We analysized retrospectively the data according SCT type and the statue of molecular response.
Results: The 3-year overall survival(OS) rates of patients in the auto-HSCT group and MSD-SCT group were 67.1±10.3%, and 67.0±8.3% (*P*=0.701); the 3-year leukemia-free survival (LFS) rates were 53.9±10.9% and 61.3±10.5% (*P*=0.918); the incidence of replase(IR) were 46.3±11% and 25.5±7.9% (*P*=0.31); the transplantation-related mortality(TRM) were 0 and 14.7±6.1% (*P*=0.058). Twenty-seven patients reached molecular remission within 3 months after induction therapy and could stably maintain this response before transplantation(CMR3). The patients received the second generation TKIs(nilotinib or dasatinib) seemed to have a higher possibility to reach CCR3 than those received imatinib(70% *vs* 40.8% *P*=0.18). For these patients who reached CCR3, The 3-year OS of patients in the auto-HSCT group and MSD-SCT group were 90.9±8.7% and 78.7±11% (*P*=0.503); the 3-year LFS were 80.8±12.2% and 75.0±10.8% (*P*=0.661); the IR were 19.2±12.2% and 19.6±10.2% (*P*=0.909); the TRM were 0 and 6.2±6.1% (*P*=0.407).

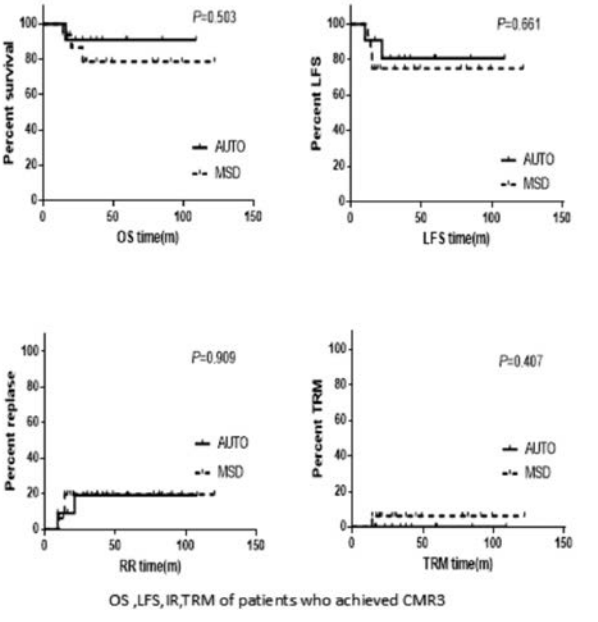

Figure 1.

Summary/Conclusions: Those patients who reached CMR3 were suitable for auto-SCT.The second generation TKIs could help more patiens benefit from auto-SCT.

E1509

COULD GRAFT *VERSUS* TUMOR EFFECT IMPROVE OUTCOMES IN MYELOID MALIGNANCIES WITH ACTIVE DISEASE UNDERGOING REDUCE INTENSITY ALLOGENEIC TRANSPLANT?

O Lopez Godino[*], E Pérez López, S Alonso, M Cabrero, JM Bastida Bermejo, O Ferré, F López Cadenas, L Vázquez, MD Caballero, L López Corral
Hematology department, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Allo-transplant (allo-HSCT) has become a significant treatment for refractory and relapsed haematological malignances; however, relapse remains a mayor cause of treatment failure. Reduce intensity conditioning (RIC) regimens have shown to be safe and effective in older patients or with comorbidities, but patients with chemorefractory disease still have high relapse rates and poor out-

comes. Although graft *versus* tumor effect (GVT) has been demonstrated in some malignancies, the benefit for relapsed acute myeloid leukaemia (AML) and myelodisplastic syndrome (MDS) is often limited because of its rapid growth.
Aims: Analysis of patients with myeloid malignancies (including AML, MDS and secondary myelofibrosis) receiving RIC allo-HSCT with or without complete response (CR) in terms of transplant related mortality (TRM), event free survival (EFS) and overall survival (OS) in order to investigate the GVT in both groups.
Methods: We analysed 169 patients who underwent to allo-HSCT in our centre between 1995-2015. Characteristics of both groups are described on table 1. Although cytogenetic abnormalities are not available at this moment, the data is been recording and this variable will be included in the final analysis.
Results: In the overall series and with a median follow-up of 36 months for patients alive, the estimated OS and EFS at one year, two years and five years was 71%, 64% and 58% and 61%, 51% and 45% respectively. The mainly cause of death was relapse in 32 patients (19%) and 25 (15%) due to TRM. In the Kaplan-Meier analysis the variables associated with OS (p<0,05) were: CR status, III-IV acute graft *versus* host disease (GVHD), development of cGVHD, fungal infection, thrombotic microangiopathy and veno-occlussive disease while just the development of cGVHD (p=0,001) with differences between grades: limited (p=0,046, HR 0,37, 0,14-0,98) and extensive (p=0,00, HR 0,24, 0,11- 0,52) and development of thrombotic microangiopathy (p=0,004, HR 4,6, 1,6-12,8), but not CR status at the moment of allo-HSCT (p=0,49), maintained significance in multivariate analysis. Regarding the outcomes on the basis of disease status at transplant, there were differences between CR and not CR patients in terms of OS (p=0,02, not achieved *vs* 32 months) and EFS (p=0,012; 71 *vs* 9 months) but there where no differences in PFS (p=0,6); attending the TRM (p=0,05, estimated 8% *vs* 22% at 1 year), there were differences manly due to the GVHD related mortality (p=0,05; 2% *vs* 17% at 1 year). Exploring the GVT in both groups separately: in the group of patients with CR, there were differences between patients without cGVHD compared with patients with limited or extensive cGVHD (p=0,00) with median OS not achieved in all groups; but in those patients without CR, just extensive cGVHD seems to be effective (p=0,00) with a median OS not achieved *vs* 10 and 28 months in those patients without and with limited cGVHD respectively.

Table 1.

Status at allo-HSCT (n = 169)	p	CR (n/%) (n = 93)	No CR (n/%) (n = 76)
Diagnosis			
• AML	p = 0,00	79 (84%)	31 (41%)
• MDS		14 (15%)	39 (51%)
• Secondary MF		1 (1%)	6 (8%)
Time from diagnosis	p = 0,014	5 months (2-123)	9 months (1-200)
Age	p = 0,18	56 years (18-69)	58 years (24-69)
Male	p = 0,8	51 (54%)	43 (57%)
Previous Auto-HSCT	p = 0,9	15 (16%)	10 (13%)
Donnor	p = 0,4		
• Sibling		63 (68%)	48 (63%)
• Unrelated [mismatch]		26 [11] (28%)	21 [5](28%)
• Haploidentical		4 (4%)	7 (9%)
Source peripheral blood	p = 0,04	83 (88%)	73 (97%)
FluBu Conditioning regimen (Vs others)	p = 0,3	80 (85%)	64 (85%)
GVHD prophylaxis	p = 0,06		
• TCR/Sirolimus		34 (36%)	38 (51%)
• Calcineurin inhibitor/MTX		48 (52%)	28 (37%)
• Others		11 (12%)	10 (12%)
In vivo T cell deplection	p = 0,68	4 (4%)	2 (3%)
Median CD34	p = 0,9	5,5 (2,2-11,2)	5,7 (2,3-12,2)
Acute GVHD			
• Grade II- IV	p = 0,34	42 (46%)	39 (54%)
• Grade III-IV	**p = 0,008**	**4 (4%)**	**13 (18%)**
Induced by early withdrawal IS treatment and/or DLI	**p = 0,03**	**7 (8%)**	**14 (21%)**
Median day aGVHD	p = 0,3	29 (5-196)	38 (15-252)
Chronic GVHD	**p = 0,03**		
• No cGVHD		**23 (27%)**	**27 (45%)**
• Limited		**22 (26%)**	**7 (12%)**
• Extensive		**40 (47%)**	**26 (43%)**
Induced by early withdrawal IS treatment and/or DLI	p = 0,18	21 (25%)	12 (17%)
Median day cGVHD	p = 0,06	182 (84-708)	207 (62-1258)
CMV reactivation	p = 0,24	24 (26%)	27 (36%)
Fungal infection	p = 0,08	21 (25%)	12 (17%)
Thrombotic microangiopathy	p = 0,5	5 (5%)	6 (8%)
Veno-occlusive disease	p = 0,6	3 (3%)	1 (1%)
Relapse		30 (32%)	23 (31%)
Death		28 (30%)	36 (48%)

Summary/Conclusions: In our series, the PFS of patients without CR at the moment of transplant was similar to those with CR, but the first group had worse OS, EFS and higher TRM due to a larger rate of severe acute GVHD with a high proportion of induced GVHD because the early withdrawal of the immunosuppressive treatment. On the other hand, patients without CR and development of extensive cGVHD had long term survival rates, similar to those patients with CR, reflecting the GVT. Efforts should be focus on avoid severe aGVHD maintaining the GVT in order to improve the TRM rates with new immunosuppressive strategies and improve the management of minimal residual disease.

PROTECTIVE EFFECT ON CHRONIC GRAFT-VERSUS-HOST DISEASE OCCURRENCE IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION PATIENTS WITH EPSTEIN BARR VIRUS VIREMIA TREATED BY RITUXIMAB

S Xue*, S Ji, X Bao, T Tao, X Ma, D Wu

Background: Chronic graft-*versus*-host disease (cGVHD) is an important cause of late morbidity, mortality and impaired quality of life in patients after allogeneic hematopoietic stem cell transplantation (allo-HSCT). It has been demonstrated that B cells are involved in cGVHD pathogenesis, which is evidenced by the presence of antibodies reactive to the host tissue in allo-HSCT patients with active cGVHD. It has also been proven that Rituximab could have a distinctly therapeutic effect on cGVHD in allo-HSCT patients. And now the prophylactic effect of Rituximab on cGVHD is being focused on. However, until now, no related studies have been conducted in Chinese patients.
Aims: To assess the prophylactic effect of Rituximab on cGVHD, a group of Chinese allo-HSCT patients receiving Rituximab to eliminate EBV viremia within 100 days following transplant is retrospectively evaluated.
Methods: Between January 2012 and August 2014, a total of 102 allo-HSCT patients from the First Affiliated Hospital of Soochow University, who underwent a myeloablative conditioning regimen and suffered EBV viremia within post-transplantation 100 days with a median time of 54 days (range 14-99), were included in this study. Among them, 50 (49%) patients (Rituximab group) received Rituximab treatment by 375mg/m2 weekly to deal with EBV viremia, while other 52 cases (control group) were treated by other anti-EBV agents. A competing risk model was adopted to compare the cumulative incidence of cGVHD, relapse rate and transplantation related mortality (TRM) between Rituximab group and control group. Death and relapse were treated as competing events in the analysis of cGVHD. Overall survival (OS) and progression-free survival (PFS) were estimated by the Kaplan-Meier method.
Results: All patients either in Rituximab group or in control group achieved viral load negativity except 3 patients who died before achieving viral negativity. In the Rituximab group, the median start time of Rituximab administration is post-transplantation 64 days (range 23-101) and the median count number of Rituximab administrations was 1 (range 1-4). The overall cumulative incidence of cGVHD in the cohort at 6-, 12-, 24-month were 23.5%, 42.2% and 46.1%, respectively. Retrospectively, the cumulative incidence of cGVHD in Rituximab group was lower at each time point (14.0% *vs* 32.7%, 34.0% *vs* 50%, 36.1% *vs* 54.1% at 6-, 12-, 24-month, respectively, P=0.059) when compared with controls. Moreover, there was no significant difference regarding cumulative relapse rate (P=0.48) and TRM (P=0.39) between two groups. Multivariable analyses corrected by other factors showed that Rituximab was one of the independent factors for the reduction of cumulative incidence of cGVHD (Hazard ratio (HR)=0.37, 95%CI=0.178-0.767, P=0.0075). Additionally, survival analyses showed that there was no significant difference between two groups regarding overall survival (OS) (P=0.667) or progression free survival (PFS) (P=0.571).
Summary/Conclusions: Rituximab administrated in post-transplantation early phase could reduce the cumulative incidence of cGVHD and play a protective role in cGVHD occurrence among allo-HSCT patients but without increasing relapse rate and TRM.

CHANGES OF PLASMA COMPLEMENT C3B, C5B AND VWF, ADAMTS13 IN PATIENTS WITH THROMBOTIC MICROANGIOPATHY AFTER HEMATOPOIETIC STEM-CELL TRANSPLANTATION

Y Han*, J Qi, J Wang, J Chen, J Su, Z Ma, Y Tang, X Wu, H Qiu, Z Wang, C Ruan, D Wu
The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, Suzhou, China

Background: Transplant-associated microangiopathy (TMA) is an uncommon but devastating complication in patients undergoing hematopoietic stem-cell transplantation (HSCT). It may be confused with severe graft-*versus*-host disease (GVHD), infection, and other transplant related thrombotic diseases. Limited studies have shown the changes in plasma VWF/ADAMTS13 or complement activation markers in patients after HSCT. However, the role of VWF/ADAMTS13 and complement activation in patients with TMA and GVHD is not fully understood.
Aims: Current study is to investigate the alterations of plasma levels of C3b, C5b and VWF/ADAMTS13 in patients with TMA and to explore their roles in the pathogenesis and early diagnosis of transplant-associated TMA.
Methods: From 2011 to 2014, 14 patients with TMA were enrolled into the study in a single medical center. 71 other patients following HSCT were recruited as control subjects including 11 cases of hepatic vein occlusion disease (VOD), 20 cases of severe infections, 20 cases of severe II-IV° GVHD and 20 cases without complications. Blood sample was collected before transplantation and at the onset of transplantation related complication. Fluorescence resonance energy transfer substrate (FRETS)-VWF73 assay detected plasma ADAMTS13 activity. Collagen-binding assay and latex immunoassay determined VWF activity and VWF antigen, respectively. Plasma VWF multimer was determined by agarose gel electrophoresis and Western blot. Plasma levels of complement C3b and C5b were measured with ELISA.
Results: Compared with the levels before transplantation, plasma ADAMTS13
